Guest access (Azure AD B2B Collaboration)	Yes	Yes	No
Federated access (Azure AD Direct Connect)	No	No	Yes
Automatic access to all team members	Yes	No	No
Join channel without team membership	No	No	Yes
Share channel with other teams	No	No	Yes
Share channel with the parent team	No	No	Yes
Channel moderation	Yes	No	No
Breakout rooms	Yes	No	No
Email support for channel	Yes	Yes	Yes
Dedicated SharePoint site	No	Yes	Yes
Support for channel meetings	Yes	No	Yes
Support for channel tabs	Yes	Limited	Limited
Support for bots and apps	Yes	Limited	Limited
Tag members in channel conversations	Yes	No	No
Channel analytics	Yes	No	No

Table 12-3: Capability comparison for Teams channel types

Guest members enjoy full access to everything in a team except private and shared channels. They can access a private channel, but only after a channel owner adds their account to the membership of that channel. Shared channels don't support guest accounts as members. However, a guest member with a Microsoft 365 account can join a shared channel if the channel owner sends an invitation to their account in their home tenant. In this scenario, the user joins the shared channel using their account rather than the guest account.

## Channel Type and Controlling Creation

You cannot convert a channel from one type to another. Once you assign a channel type at creation, a channel retains that type until its deletion. If you make a mistake and create a channel with the wrong type, you must delete the channel created in error and create a new channel of the correct type. The teams policy assigned to an account controls its ability to create:

- Org-wide teams (*AllowOrgWideTeamCreation*)
- Private channels (*AllowPrivateChannelCreation*)
- Shared channels (*AllowSharedChannelCreation*)

In addition, policy settings are available to control if a user can share channels with external users or participate in shared channels hosted by other tenants. These settings are available through the Teams admin center or PowerShell. For example:

```
[PS] C:\> Get-CsTeamsChannelsPolicy | Format-List Identity, AllowPrivateChannelCreation,
AllowSharedChannelCreation, AllowChannelSharingToExternalUser,
AllowUserToParticipateInExternalSharedChannel
```

```
Identity : Global
AllowPrivateChannelCreation : False
AllowSharedChannelCreation : True
AllowChannelSharingToExternalUser : True
AllowUserToParticipateInExternalSharedChannel : True
```

## Channel Purpose

Each channel should have a clear purpose. For instance, a team might have a channel for their weekly update calls and others for specific topics, like ideas for a marketing campaign or plans for a trade show. Although the ability to split conversations over many channels gives a wide degree of latitude in the topics supported by a team, the trick is to create just the right number of channels. Creating too many channels runs the risk of confusing users (the “where do I start this conversation” syndrome). Take the example shown in Figure 12-4 (taken from a real-life deployment). How do you think the average user will respond when they see that a team has 114 hidden channels to explore? How will the average person decide what channel is the best destination for their topic? The other side of the coin is that too few channels can result in a mixture of wildly different topics in channels and lead to people losing sight of important conversations. It’s important to achieve a balance, with the preference to go slowly when creating new channels.

114 hidden channels **New**

Figure 12-4: Too much choice in too many channels?

When users find channels with content that interests them, they can follow those channels so that notifications for items posted to the channel appear in their activity feed. Unless you like dealing with hundreds of notifications daily, it can be a bad idea to do this for a busy channel. Instead, users should only choose channels where they want to see notifications of new activity.

## Naming Channels

A channel should have a name and description to inform members what they should expect to discuss in the channel. When composing the name of a channel, you cannot use the special characters (~#%&\*{}+/\:;<>?|'"), but you can include the @ sign. You can include a full stop in a channel name if it is not at the end. You can also include emojis in channel names.

Although you don’t need to enter a description for a channel, it is good practice to do so. Teams displays the name given to a channel no matter what language someone uses. For this reason, in multinational organizations, it is wise to seek channel names that make sense in as many languages as possible. This isn’t

needed for the General channel because Teams displays a translated value for “General” based on the language chosen for the client. For instance, the channel is *Général* in French and *Allgemein* in German.

Except for the General channel, you can edit channel settings to rename a channel if necessary. Until September 2021, Teams didn’t synchronize the new name assigned to a channel with SharePoint Online, meaning that the channel name shown in Teams could differ from what appeared in SharePoint Online. Microsoft then deployed an update to make sure that Teams renames the folder created for the channel in SharePoint Online when it renames a channel. Channels renamed before September 2021 do not synchronize their name with SharePoint Online, so if you want the same name to appear in both places, you need to rename the channel again.

## Showing Channels and Notifications

Some teams have more channels than others and the discussions in some channels are more interesting than others. Users can organize the channels that they find most interesting by making sure that these channels are visible while putting the less interesting channels into the background. For instance, you might want to keep channels where active discussions about your current projects happen in the foreground while pushing channels used to track posts about code updates or similar developments into the background. Use the **Show** option (in the ellipsis menu) to mark a channel to appear in the visible list while the **Hide** option puts it on the hidden list. You can decide to access a channel at any time (with or without putting it back into the visible list). Note that if you create a channel, Teams assumes that you want the channel to be visible and makes it visible.

To help new members get to know the ebb and flow of what happens inside a team when someone joins a team, the application automatically adds the five most popular channels from the team to the visible list, meaning that the channels appear under the team name when you open it. Popular means the busiest channel in terms of conversations. The user can accept the recommended set of channels or organize a custom list by hiding and revealing available channels. If a team has fewer than five channels, Teams automatically adds all existing channels to the shown list for new members. When they create a new channel, owners can mark the channel to show up automatically in the list visible to team members, which is a good way to make members aware of the existence of an important new channel. If an owner forgets to highlight an important channel, they can do this later through the Channels section of team settings by checking the auto-show box. Users can always hide the channel if they decide that they don’t consider the content to be important.

Some channels are inevitably more important than others. For these channels, use the **Channel notifications** option in the channel menu to enable notifications for new posts and replies in the channel. You can choose to have notifications for:

- All new posts.
- All new posts and replies.
- Channel mentions.

Notifications come in two types: banners and the activity feed (you can choose both). A banner is a notification message that pops up to tell the user that someone has posted in the channel. Banner notifications can become quite distracting, especially in busy channels, so it is usually better to have Teams update the activity feed with notifications for these channels. If the notification settings are not set for a channel, Teams uses the user’s **All teams and channels** notification setting (controlled in **Settings** under the user avatar).

## Pinned Channels

Over time, the number of teams and associated channels available to users will inevitably grow. This can create a challenge for users to keep track of the channels where the most important discussions occur as their

activity feed becomes cluttered and they receive too many notifications. The solution is to use the **Pin** option (in the channel menu) to mark selected channels as important.

Teams places the set of pinned channels on top of the teams list in the sidebar. Teams lists the set of pinned channels in the order the user pins them to the list and the user can reorder the list by dragging and dropping channels into their preferred order. The name of the team a pinned channel belongs to appears under the channel name, and if the channel has unread messages, Teams highlights this fact by bolding the channel name. The user can remove a channel from the pinned list at any time with the **Unpin** option.

## Removing Obsolete Channels

Channels can become underused or obsolete over time. Team owners can delete a channel at any time. This action removes the channel from the list of active channels displayed to users. Deleted channels enter a holding pattern for 30 days. During this period, team owners can restore the channel through the Channels section of the Manage team dashboard. After 30 days, Teams removes deleted channels and they become irrecoverable. The content in the channel folder in the team's SharePoint Online document library remains unaffected by the channel deletion. There's no way to force the removal of a deleted channel before the 30-day retention period lapses.

If a channel becomes obsolete, there's no way to archive it (set the channel to be read-only). Instead, you can delete it to clean up the team. Before deleting a channel, it's a good idea to mark it as obsolete and pending deletion. This allows users to look through the messages in the channel to see if any valuable information exists that team members should extract and keep (you can't copy or move channel messages to another channel in the same or another team). It's also a good idea to check the contents of apps reached through channel tabs. Then, when you're ready to mark the channel as obsolete, a team owner can:

- Use the Edit this channel option to change the channel name. For instance, you could insert a Windows emoji (accessed using the Windows logo key and period) as a prefix as a visual marker for the channel's status, and then add a suffix to indicate that it is obsolete. For example:

Also, make sure that the *Automatically show this channel in everyone's channel list* checkbox is not set.

- Post an announcement to the channel to tell team members the deletion date for the channel.

When the deletion date comes around, a team owner can delete the channel and begin the 30-day deleted channel recovery period.

**No Way to Reuse Channels:** If a channel becomes disused, you can remove it to clean up the team. However, you cannot then reuse the same name for a new channel in that team. Once a channel name exists within a team, Teams does not allow you to reuse it. Microsoft says that the restriction exists "for information protection scenarios."

## Private Channels

Private channels have a small lock shown against their name to mark them in a team's channel list. You can't convert a regular channel to become a private channel or vice versa. In a multi-geo environment, private channels and their dependent sites are in the same geography as the parent team. Teams administrators can manage the membership of private channels through the Teams admin center. However, Teams administrators cannot access the content of private channels unless they are a member of the channel.

Private channels handle scenarios such as the need to limit access to information to a subset of a team. For example, if you create a team to work on a project, there might be financial or other sensitive aspects of the project restricted to people directly involved with that data. To address the need, you can create a private channel in the team and add those people, including guest users, to the membership of the channel. Only the

channel members can then access the conversations in the private channel and the files in the SharePoint site belonging to the channel.

Channel owners can add members to a private channel using the Teams client. Team owners and administrators can update channel membership with PowerShell. However, team owners can't access the contents of a private channel unless they become a member. Although they can see private channels listed in the Channels tab of the Manage team option in the Teams client, if they're not a member, the only sign of activity in a private channel available to a team owner is through administrative interfaces. For instance, if they use the *Get-SPOSite* cmdlet to examine the properties of a private channel, the *LastContentModifiedDate* property might indicate recent activity in the site belonging to the channel. Audit records for file activities in the channel are available in the audit log.

Because the channel owners manage the membership of a private channel, these channels need at least one owner. If the last channel owner leaves a tenant (for instance, an administrator deletes their account), the Microsoft Teams AadSync background process detects that the channel is now ownerless and selects a channel member at random, and promotes that member to be the channel owner. The user receives a notification of their new status and can then decide if they wish to hand over the responsibility to another channel member by promoting them to be an owner.

The SharePoint Online sites used by private channels inherit their properties and membership from the parent team. A synchronization process updates the site properties when necessary. If an administrator updates the site properties using a SharePoint admin interface, the synchronization process will reverse the change within six hours.

## Limiting Creation of Private Channels

By default, any tenant user can create a private channel. If you want to limit the creation of private channels, go to the Teams section of the Teams admin center, and edit the Global (org-wide default) Teams policy to change the **Create private channels** settings to **Off**. Then create a new Teams policy with Create private channels set to On and assign this policy to the accounts you want to be able to create private channels. The PowerShell *Get-CsTeamsChannelsPolicy* cmdlet returns details of the Teams policies in a tenant (the *AllowPrivateChannelCreation* property is the one you're interested in), while the *Grant-CsTeamsChannelsPolicy* cmdlet assigns an appropriate policy to accounts.

## Shared Channels

Shared channels are part of the Microsoft Teams Connect initiative. Shared channels depend on a new federation mechanism called Azure B2B Direct Connect. External users can present credentials gained by signing into their home organization and have another Microsoft 365 tenant accept their credentials to authenticate access to resources in that tenant. This mechanism eliminates the need for guest accounts as used for team membership. This does not mean that guest accounts are bad or that Microsoft will remove them. Direct Connect is a different way to grant access to tenant resources that comes with its foibles and concerns.

Users do not need to switch tenants to access shared channels hosted by other tenants. Teams clients use the authentication granted through Azure AD Direct Connect to open and display shared channels alongside standard and private channels from the user's home tenant. Figure 12-5 shows the manage channel screen for a shared channel. In the teams list, the set of channels for the selected team includes standard, shared, and private channels. As a further visual indicator to users, when browsing the teams list, teams from other tenants with shared channels display the name of the home tenant under the team name, as in "@Tenant Name."

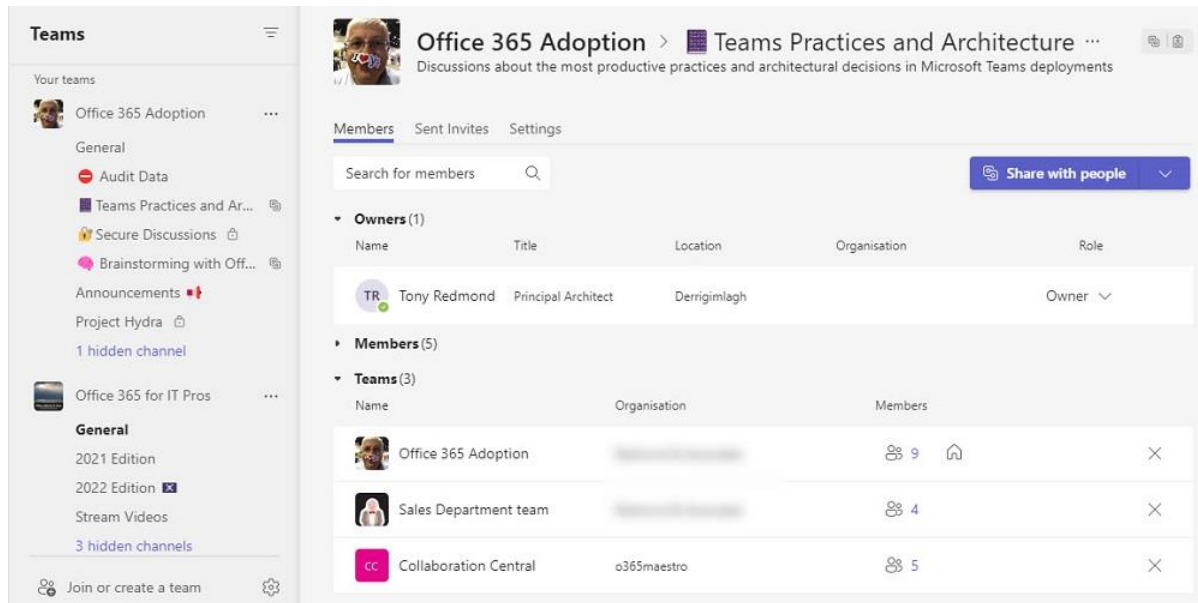

Figure 12-5: Three types of channels are visible in the Office 365 Adoption team

Azure AD cross-tenant access settings control Direct Connect sharing with other organizations. Cross-tenant access works on a mutual trust basis. In other words, the tenant sharing channels must be happy to allow inbound access for external users while their home tenants must allow outbound access (to allow the users to access resources in your tenant). If you allow inbound access to a tenant and that tenant doesn't allow outbound access to your tenant, mutual trust doesn't exist, and adding external users to shared channels isn't possible.

The simplest policy allows inbound access and outbound access from any other Microsoft 365 tenants. However, cross-tenant access settings can limit sharing to a granular level. For instance, only members of a specific group can join shared channels in a specific tenant, or only specific external users or groups (identified by the GUIDs for the objects in the Azure AD of the external organization) can join shared channels in your tenant. Applying granular control to cross-tenant settings is an Azure AD Premium feature. It's usually best to start with a policy that allows flexible sharing and then amend the policy over time as necessary. See the identity chapter for more information about Azure AD cross-tenant access settings.

Like private channels, shared channels have owners who manage the channel membership. Owners, who can only be accounts from the host tenant but do not have to be a member of the host team, can share a channel with:

- People (individual users from inside or outside the tenant). There's no need to add users from the home tenant to the host team. The first time an external user accesses a shared channel in a host tenant, they must give consent to allow the host tenant to access details of their profile like their picture, display name, and email address. This information is available to other channel members in the channel roster and profile cards.
- A team (invited using the email address of an owner of the team). Only tenant members from the team will join the shared channel.
- A team from the home tenant that's owned by the channel owner. Teams lists the available teams, and the channel owner selects which one to add.

To share, a channel owner selects the appropriate action from the Share dropdown menu. In Figure 12-5, the *Share with people* option is visible, this shares with individual users. We can see that the current membership of the shared channel includes three teams, including a team from an external tenant. The membership of a shared channel can contain individual users and teams from multiple tenants.

In the case of team memberships, an individual's access to the shared channel is available only while they remain a member of a team in the shared channel's membership. Channel owners must invite users or teams to share a channel: users or teams cannot browse for shared channels and decide to join on their initiative. You cannot invite a guest account to share a channel. Invitations are only valid when extended to full member accounts in the home tenant or other Microsoft 365 tenants.

When a channel owner extends a sharing invitation to the owner of a team, that person sees the invitation in their activity feed and must respond within 14 days. During this period, the channel owner can see the status of the invitation and how long remains before the invitation becomes void. Once extended, a channel owner cannot revoke an invitation. However, they can reject the acceptance when it comes back from the team owner. Part of the response is the selection of the team whose members will gain access to the channel (this cannot be an org-wide team). When the channel owners receive the response, they can review the team selected by the team owner and decide if they wish to share the channel with the nominated team. A channel owner can see the number of members in the chosen team, but they cannot see any details of the individual members. If necessary, the channel owner who processes the response can reject it. If accepted, Teams validates the membership of the chosen team to ensure that none of the members conflict with the cross-tenant access policy. Teams drops these members, as also happens for any guest members of the team. After Teams completes its check, the team shows up in the membership of the shared channel. A member of a shared channel can leave it at any time, and the owner of a team that shares a channel can remove the entire team from the sharing roster when they wish.

Teams limits members of a shared channel to whatever resources are available to the channel, including a SharePoint team site associated with the channel like a private channel. External members can only see limited directory information for other channel members, but they can chat or call anyone in the channel. Teams adds an External suffix to the display names of external members to indicate their status. In addition, if a shared channel has external members, Teams flags this with a banner saying *This channel is shared with members in other orgs*.

Unlike private channels, which only support Meet Now meetings, shared channels support both Meet Now and scheduled meetings, but only tenant users can schedule meetings. The person who schedules the meeting becomes the meeting organizer, but the meeting is a channel meeting, not a personal meeting. The Teams channel meeting app does not currently support shared channels. Microsoft stores the calendar data for a shared channel in the cloud-only mailbox created to store compliance data for the channel.

## Channel Information Pane

The channel information pane is available by clicking the **(i)** icon. The information pane displays some basic information about the channel (display name and description) plus:

- **Recent contributors:** Members who have recently participated in the channel by posting or replying to the last twenty topics in the channel.
- **All members:** If you select *See all members*, you're brought to the Manage team screen to view the full list of owners, members, and guests.
- **Updates:** This is where Teams posts system messages covering team membership changes and channel updates (Figure 12-6).

When you see *Unknown User* in a system message, it means that Teams can't find the user in Azure AD. Usually, this is because the user's account is deleted. A note that *Microsoft Teams AadSync* has added or removed someone from a team means that the action happened through some other administrative interface, like an update to a Microsoft 365 group using the Exchange Online PowerShell module. Teams learns about changes made to group membership by monitoring a pipeline within Azure AD. Once a change is detected, the *Microsoft Teams AadSync* process replicates the information to Teams to update the team roster.

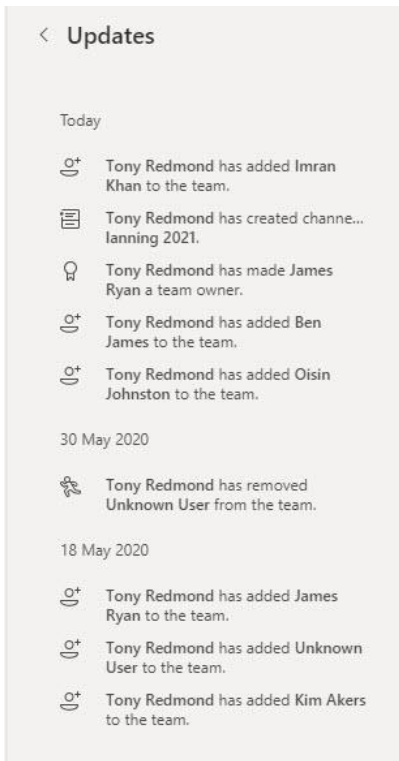

Figure 12-6: Teams system messages in the channel information pane

Any team member, including guests, can pin or unpin a channel topic or reply. No limit exists for the number of pinned messages in a channel. However, only the latest two pinned messages appear in the About section of the information pane.

## Channel Tabs

Users access the content owned by a channel through a set of tabs. A tab is analogous to a browser tab and acts as a link to a resource available within the channel. Some channel tabs are available only to regular channels while others can be used in shared and private channels too. Conversations, Files, and Wiki are default tabs that appear in all channels. Unlike the Files and Conversations tabs, you can remove the Wiki tab from a channel. Examples of other tabs that you can add to a channel include:

- **Planner:** Link to a Microsoft Planner plan owned by the underlying group.
- **SharePoint:** Link to a SharePoint site or folder to which team members have the necessary access rights.
- **OneNote:** Link to sections of the shared OneNote notebook for the underlying group.
- **Power BI:** Link to a Power BI report or workspace.
- **Office documents:** Link to specific Excel, Word, or PowerPoint documents in the SharePoint document library for the team. You can also add a link to a **PDF** document in the same manner.
- **Stream:** Link (URL) to a video file or channel stored in Microsoft Stream.
- **Website:** Link to the URL for any website. For example, you can create a very easy integration with Yammer by creating a link to a Yammer group.
- **Visual Studio:** Link to a Visual Studio Team Services board to allow the team to work on code projects.
- **Third-party apps** such as YouTube, HootSuite, Smartsheet, Polyscribe, Trello, Intercom, Polly, Zendesk, and Asana. You can browse the complete set of available apps through the Teams Store.

Where it makes sense (as in the case of links to individual documents or websites), you can assign your chosen name to the tab. When someone adds a new tab to a channel, Teams highlights the tab with a “New”

icon. The icon stays for seven days after the creation of the tab and then disappears. It also disappears after you access the tab for the first time.

**Access to Office and other Web Apps:** Because of the way it integrates different functionality into a single client, some people compare Teams to Outlook. You can make Teams a launching point for many Office applications by creating website tabs to link to those apps. For example, you could create a tab for OWA by pointing it to <https://outlook.office365.com>, for the user's OneDrive for Business site by linking a tab to <https://tenant-my.sharepoint.com/>, or for To-Do by linking to <https://to-do.microsoft.com/?app>. The general rule is that if users can authenticate themselves with a website, they can access that site through Teams. This approach allows users to work in Teams while having access to all the applications they need to use.

## The Teams Wiki and OneNote

Microsoft's [definition for the Teams wiki](#) is that it is "a smart text editor that doubles as a communication machine, because you can draft, edit, and chat all in one place." The provisioning process for channels creates a tab for the wiki when it creates a channel, but you can rename or remove the tab as needed. Wiki content is in a document library called *Teams Wiki Data* in the SharePoint team site belonging to the team. The first time someone accesses the wiki in a channel, Teams creates a folder in the document library named after the channel and stores MHT (web archive file) files for the wiki pages and sections there. It is possible to create multiple wiki tabs for a channel. In this case, the pages for all the wikis go into the channel folder. The MHT files don't hold any real data. Instead, they are pointers to information stored in hidden SharePoint lists. When you edit the wiki, Teams extracts the data from the list and presents it in the editor.

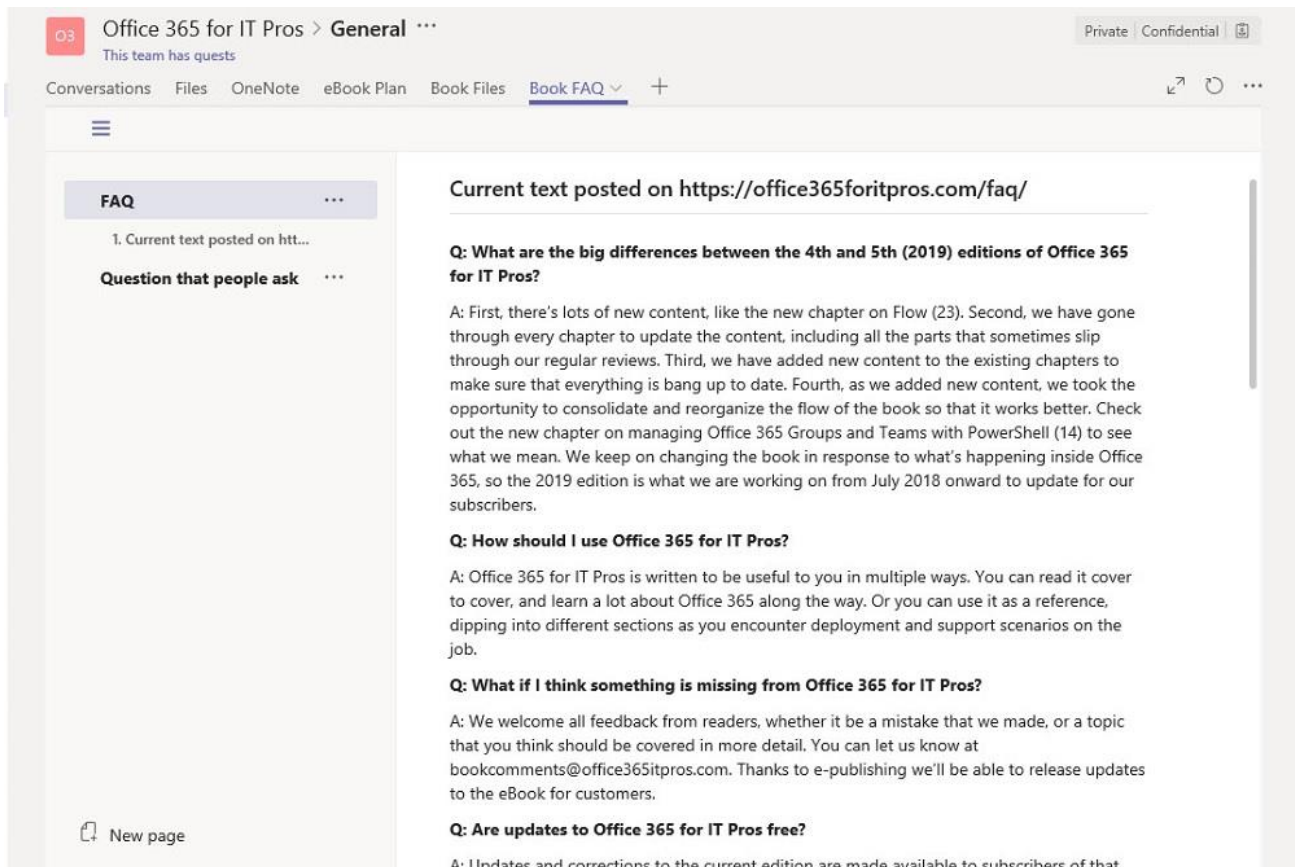

Figure 12-7: Editing content in a Teams wiki (the channel tab is renamed)

The wiki editor (Figure 12-7) is available in the desktop and browser clients and is like the editor used to compose Teams messages. The editor includes the ability to insert formatted text using a small number of predefined styles (paragraph, heading 1, and so on), hyperlinks, graphics, pages, and tables. One obvious

deficiency is the lack of support for search as you can't use Teams search (command box) or SharePoint search to find content stored in wiki pages. Meeting Notes are stored as a Teams wiki file and use the same editor.

## Wiki versus OneNote

The way that the Teams wiki works, especially in terms of notetaking and the page/section structure, often causes customers to ask why Teams includes a component that seems to compete with OneNote. OneNote is Microsoft's flagship notetaking application which supports many high-end features such as inking. You can integrate OneNote into Teams by creating a tab to point to a new or existing notebook. Many experienced deployment consultants recommend that if a tenant has invested heavily in OneNote, it should not try to force the use of yet another notetaking application on users as this approach forces users to change the way they work. It's also the case that people will lose functionality if they change from OneNote as the Teams wiki misses some of the features supported by OneNote. In these circumstances, it is best to remove the wiki tab from channels after creation and replace it with a tab linking to the most appropriate OneNote notebook.

Compared to OneNote, the Teams wiki is not as good for dynamic notetaking; it is better suited for capturing and sharing relatively static text, such as the rules of engagement about the topics discussed in a channel. One way of thinking about the two tools is that a small team working in a channel might use the wiki to sketch out some ideas that they later publish to a wider audience. A shared OneNote notebook might be the final publication vehicle, but it is more likely that a Word document or web page will be.

Because it is part of Teams, the wiki is more integrated with Teams than OneNote is. For example, you can start a conversation within a wiki page and use @ mentions to refer to the team, channel, or team members within wiki content if you need to draw their attention to something. Microsoft says that the wiki will pick up other features over time, such as the ability to send information directly from a channel conversation into the wiki. Whether tight integration is enough to prefer Wiki to OneNote remains an open question.

If you don't want to use the Teams wiki, you can remove it manually or programmatically. An example of how to remove the wiki tab from all channels in a tenant is outlined in [this blog post](#).

# Maintaining Team Membership

Teams does not maintain a central directory of teams (like the Exchange Online Global Address List) to allow end-users to browse to find teams to join. People can find teams to join through suggestions or owners can add them to team memberships, but there's no notion of browsing to find interesting teams. In some way, the lack of a directory is understandable because not all teams are public and some host very sensitive discussions, so no desire exists to make their existence known to all users. Some tenants create and publish a Teams directory. Different approaches to the task are [explored in this article](#).

The usual ways that people join teams include:

- Tenant or Teams administrators add users to team memberships via **admin portals**.
- Administrators can also update team memberships **programmatically** using PowerShell or the Microsoft Graph.
- Team owners can **manage the membership** of their teams, including being able to add guest users if allowed by policy settings.
- **Members of a team** (except guests) can add another tenant user to the membership from the team's [...] menu. If the team is private, an email request to add the new member goes to the team owners for their approval.
- Tenant accounts can **discover and join teams** suggested by Teams based on their membership of other teams and other signals gathered in the Microsoft Graph.
- Tenant accounts can also receive a **code or deeplink** to join a team.

In all cases, when someone joins the membership of a team, they also join the underlying group and can access all the resources available to both the team and the group.

## Suggested Teams

To find new and interesting teams to join, tenant users can browse the set of suggestions that Teams creates for them to join by selecting **Teams** in the navigation bar and then **Join or create a team** in the bottom left-hand corner (guests do not see this choice). Teams uses signals collected in the Microsoft Graph to display a list of suggested teams the user might like to join. The list can contain both public and private teams.

Many suggestions are based on “common interests” shared by the existing membership and the potential new member. In other words, if a public team exists with a membership composed of people who are also members of other teams with the user, a reasonable chance exists that the user will be interested in the topics discussed in that team. Groups perform similar calculations when users browse for groups to join. The computations to suggest teams to users occur behind the scenes and it takes up to a day after its creation or after a team’s access changes from private to public before Teams suggests a team to users.

To join one of the suggested teams, move over the icon for the team and a **Join team** button appears. Click the button and the team appears in the navigation bar for the user to access its resources. Once someone is a team member of a public team, they can add new members by selecting **Manage team** from the ellipsis menu for the team, followed by **Add Member**. If the team is private, requests to add members to the team are routed to team owners for approval.

**Limited Directory Searches:** If a tenant uses Exchange address book policies to set the scope for users to see items in the directory (enabled by the Search by name setting under Teams settings), Teams is no longer able to suggest public teams for people to join. This is because the query against the Microsoft Graph to find teams to suggest doesn’t take any notice of directory scoping, so Teams disables the functionality for everyone in a tenant when address book policies are in use. In addition, the /Join command, which also lists the teams available for someone to join, is disabled. If you deploy information barrier policies (see Chapter 21), scoped directory searches are used with the same effect.

## Joining a Team with a Code

To make things easier for owners to manage teams with hundreds of users, Teams supports the ability of users to join a team with a system-generated code. The idea is that it is easier to supply potential members with a code that they can input to join a team than it is for a team owner to manually add them to the membership. Using a code is also a good way for someone to know that they are joining the right team in a situation where many teams with similar names exist in an organization, such as classes in a school. Team codes work for both public and private teams. The process is as follows:

- A team owner goes to the **Team code** section under team **Settings** and clicks the **Generate** button to have Teams generate a unique seven-character code for the team. The code is a value something like “jny9ota.”
- The team owner publishes the code to potential team members. For example, if the team is open to anyone in the organization, you could publish the code on a website for all to see. On the other hand, if the potential membership comes from a more limited population, you could email the code using a distribution list.
- When someone receives a team code, they can join the team using the normal **Join or create a team** process and input the code into the **Join a team with a code** box, or by typing the /Join command in the command box. For example, /Join jny9ota.
- Teams checks the supplied code and flags an error if it is invalid. If valid, Teams adds the user to the membership and opens the team.

- Team codes are only valid for tenant members. Guest users cannot use codes to join teams.
- The team owner also can remove a code at any time or reset the code. You can't use a removed or reset code to join a team.

Apart from the way that they join a team, members who join with codes are like any other member.

## Joining a Team with a Deeplink

A [deeplink](#) is a hyperlink (URL) used to navigate to some item within Teams. Examples of deeplinks are the URLs generated by Teams when someone fetches a link to a team, channel, tab, or message. For instance, if you go to the ellipsis menu for a message and select **Copy Link**, Teams creates and copies a deeplink to the message to the clipboard. You can paste the link into another message or use it to open Teams at the linked message. The same happens if you use **Get link to team**, **Get link to channel**, or **Copy link to tab** to create a link to these elements.

The format of a deeplink varies depending on its purpose. When you link to something in Teams, the link includes several important elements to allow Teams to find the right data. If we look at the link below, three pieces of information are highlighted:

```
https://teams.microsoft.com/l/message/19:45ac50d1afa2425a80362e94f381b1e7@thread.skype/1523005757318?tenantId=c662313f-14fc-43a2-9a7a-d2e27f4f3478&groupId=ce23aef8-c551-40d4-bdb6-2bcc1eb64626&parentMessageId=1523005757318&teamName=The%20New%20Hydra%20Project%20Team&channelName=General&createdTime=1523005757318
```

These important parts of the deeplink are:

- The reply chain identifier, which identifies the message thread (**1523005757318**). This identifier appears in several places within the link. The identifier is a Unix timestamp (epoch), based on the number of seconds since 1 January 1970. The timestamp is calculated to the millisecond. You can convert the identifier to human readable time with converters such as [the Epoch Converter](#), which reveals that the identifier shown above is Friday, April 6, 2018, at 9:09:17.318AM.
- The tenant identifier, which tells Teams what tenant to access (**c662313f-14fc-43a2-9a7a-d2e27f4f3478**).
- The group identifier, which tells Teams the team that the message belongs to (**ce23aef8-c551-40d4-bdb6-2bcc1eb64626**). The identifier points to the Azure AD group underpinning the team.

The team name and channel name are also included in the link.

If you send a deeplink pointing to an item in a team to another person and they are not a member of that team, they can use it to join the team. The link opens a dialog to ask the person if they want to join the team. If the team is public and the user accepts, they become a member of the team. If the team is private, Teams sends a request to join by email to the team owners, who can then accept or deny the request. In addition to receiving email notifications about requests to join their team, owners can go to the Manage team page to view requests waiting to be processed under the **Pending Requests** tab.

## Starting a Chat with a Deeplink

Applications usually generate and consume deeplinks. However, anyone can create and use a deeplink if they know the format of the hyperlink needed by Teams. For example, let's assume that you want to allow other people in the tenant to start a personal chat to follow up with you after receiving some email. To automate the process, you can include a deeplink in your email signature. When someone reads an email from you and clicks the deeplink, Teams navigates to personal chat and starts a new chat (if they have never chatted with you before) or continues an existing chat.

The form of deeplink that you need to include in the email signature is:

<https://teams.microsoft.com/l/chat/0/0?users=Kim.Akers@office365itpros.com&topicname=Chat>

Anyone clicking this link will start a chat with Kim Akers. Deeplinks to personal chats only work for people inside the same tenant. They don't work for guest users or external (federated) access to users in another tenant.

## Leaving a Team

A user can leave a team at any time by selecting the **Leave the team** option from the ellipsis menu available for the team and any channel in the team. Alternatively, a team owner can remove a member by selecting **Manage team**, moving to the entry for the member, and then clicking the "X" to the far right of the entry.

Guests can also leave teams. However, this action does not remove their Azure AD account because the guest account might be in active use for other purposes, such as membership of a group, another team, or access to some SharePoint or OneDrive for Business documents. If you want to remove the account, you must do this through the Azure or Microsoft 365 portals, or by running the *Remove-MgUser* cmdlet.

## Maintaining Team Membership

Normally, team owners handle membership. If the team is private, the team owners take care of membership by adding and removing users, promoting members to become owners, or demoting owners to become members, which is a necessary first step before you can remove an owner from a team. If the team is public, users can join the team without owner intervention, so owners only need to add or remove guests and decide who are owners. It is also sensible for team owners to check team membership periodically in case someone joins that should not be there.

Tenant administrators and other users assigned with user management permissions can update team membership even if they are not a team owner. A variety of methods is available to do the job:

- **The Teams admin center.** Update the membership of teams.
- **The Azure AD portal.** Update the membership of the Azure Active Directory groups used by Teams.
- **The Microsoft 365 admin center.** Apart from tenant administrators, accounts assigned the User Management Administrator role can update the membership of groups, including those enabled for Teams.
- **The Exchange admin center.** Accounts assigned the Exchange administrator or User Management Administrator role can update the membership of Groups through the EAC.
- **PowerShell.** You can run the *Add-TeamUser* or *Add-UnifiedGroupLinks* cmdlets to update team membership. Given the choice, use the *Add-TeamUser* cmdlet because this mimics what happens when you add a user through a Teams client. See the discussion in Chapter 23 explaining how to use PowerShell to manage Teams. For now, this example shows how to add a user to a team:

```
[PS] C:\> Add-TeamUser -GroupId (Get-UnifiedGroup -Identity "My Microsoft 365 Group").ExternalDirectoryObjectId -User Donald.Vickers@Office365itpros.com
```

Because of the need to synchronize directories, users might experience a short delay before Teams picks up the new membership data and they can access a team.

**Unknown Users:** If you see an "unknown user" listed in team membership, it refers to someone whose account has been removed from the tenant directory or whose account cannot be resolved against the directory, or a glitch in the local Teams cache. Because the Teams client cannot resolve the member against the directory, they are deemed to be unknown.

## Stale Teams

Over time, people usually accumulate membership in multiple teams. They might end up being a member of so many teams that it's difficult to find a specific team in their list of teams (or "teams gallery"). Teams divides the teams a user belongs to into a section called *Your teams*, meaning the teams the user has opted to highlight because they are important to them, and *Hidden teams*. Teams in the hidden section might be as important to the user because of the information they contain, but the user might not want to access them as regularly. By hiding teams and placing them in the *Hidden teams* list, the user focuses on the teams they work with most often.

To help users manage the set of teams they belong to, Teams periodically checks the set of teams available to each user (but not for guest users) to detect those that might be "stale" and could be moved out of view to allow the user to focus on the teams most important to the user. Several tests are used to decide whether a team has become stale. The basic test is that the user has not accessed the team in the last 45 days, but there are some qualifiers. For instance, a team with an unread @mention for the user is never regarded as stale, the team the user last moved from the more list is never regarded as stale, and the same is true for any team marked as a favorite in the last 45 days.

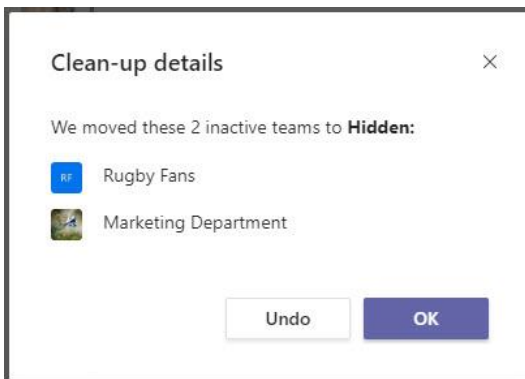

Figure 12-8: Teams shows that it has hidden some teams

When Teams decides that some teams are stale, it notifies the user that these teams have been moved to the *Hidden teams* section (Figure 12-8). The user can undo the move if they wish, which moves the team back into their *Your teams* list.

Users always have access to every team they belong to, but they must navigate to the *Hidden teams* section to find hidden teams when they need to access their contents (alternatively, they can go to the Manage teams section and search for the team name). For ease of finding a team in what can be a very large list, Teams organizes the *Hidden teams* section alphabetically, and users cannot move teams up or down within the list. Users can move a team from the hidden list by selecting the team and choosing the Show option from the ellipsis menu. Likewise, they can move a team into the hidden list by selecting the Hide option from the menu.

## List All My Teams

To see the set of teams that they belong to, a user can click the cogwheel icon at the bottom of the Teams list to expose the **Manage teams** screen. The splits into active and archived teams and lists:

- Team Name. Click on the name to access the General channel for the team.
- Description.
- Membership (Owner or Member).
- People: The number of members of the team.
- Type: Org-wide, Public, or Private.
- Show or hide the team to put it in the *My Teams* (Show) or *Hidden teams* (Hide) lists.

- More options: Manage team, add channel, add members, leave the team, **edit team**, get link to team, **archive team**, or **delete the team**. The bolded options are only available to team owners.

The Analytics option available in this section gives users a view of how active the teams they belong to are. Statistics available for active teams include the number of members, guests, posts, and replies over the last 7, 30, or 90 days.

## Arranging the Teams List

After you join a team, you can move the team within the list of teams to which you belong (*Your teams*). Teams does not display the list alphabetically but in the order that you joined the teams. To reorder the list, simply drag and drop a team into the position that you want. In most cases, people place their most important teams at the top. You can also use the **CTRL+Shift+Up** and **CTRL+Shift+Down** key combinations to move a team up or down within the list (on a Mac, use the Command key).

You cannot change the channel order within a team. The General channel is always first, with the other channels following in alphabetical order.

## Members and the Manage Team Option

The **Manage team** option displays information about a team and is available to members (including guests) and owners. The ability to take management actions, like changing a team setting or adding a channel, is restricted to team owners, tenant administrators, and teams service administrators. Members can see:

- The **membership** list, including their title, location, and role. Users can add a member here. If the team is private, the membership request must be approved by a team owner.
- The **channels** in the team, including the channel name, description, and date of last activity. The ellipsis menu is available to allow the member to get the email address for the channel (if enabled), get a link to the channel, or follow/unfollow the channel. If team settings allow members to add, remove, or restore channels, they can take those actions here.
- The **apps** that are available to the team. If team settings allow members to add or remove apps, they can do so here.
- **Analytics** for the team are available to give an overview of how active the team is.
- **Tags** defined for use in the team. Some tags are available in all teams, but most are specific to a team.

## Teams Messaging

For many organizations, the central focus and purpose of Teams is the ability to connect team members through short, interactive conversations. Or as Microsoft puts it "*communicate in the moment and keep everyone in the know.*" The individual messages that make up conversations are persistent, meaning that they continue to exist unless the author or a team owner decides to remove them. Teams conversations are complete with all the modern ways to brighten discussions (reactions with icons such as "Like" and "Angry", emoji, and memes). Reactions (like, laugh, angry, and so on) are important signals to chat participants (and recorded in the Microsoft Graph) to show the view someone has about a message in a conversation. If desired, you can disable the ability to add images to conversations through Teams messaging policies managed in the Teams admin center.

Conversations in channels are public because they are available to any member of the team. Those in chats are private to chat participants. You can't change a private conversation to be public or vice versa or move a chat from one channel to another, either within a team or between teams. People control the participants in private chats by adding others to or removing them from chats. The mechanics of contribution are identical for public and private teams, but people indeed tend to be more chatty or informal in personal chats and

more formal and perhaps verbose in channel conversations. In either case, participants type their thoughts into the compose box and then post them to the chat or channel. Or just use the thumbs-up reaction to indicate that you've seen and approved of a message without the need to post a more complex response.

Chats are persistent, and people can leave and rejoin the conversation as they wish. Persistent means that conversations are enduring and can be resumed at any time. For performance reasons, Teams caches recent messages in memory. Clients might have to page older messages back from storage before being able to display details of a conversation. Normally, it takes a client just a few seconds to retrieve and show old chats.

If you find that you want to develop a personal chat into a more general discussion, you can either expand the chat up to the participant limit or start a new conversation in an appropriate channel.

## Starting Conversations

Channels divide into topics or conversations. Each conversation has a base note to set the context for the conversation followed by a set of replies. In technical terms, a conversation is a set of messages connected by a common thread identifier, which is how Teams knows what messages belong to a conversation. Replies are ordered within a conversation using the message timestamp. To start a new conversation, click **New conversation** and enter the text for the initial post. Although effective, this isn't a great way to start a conversation. It's much better to give the new topic a subject to inform team members about what you want to discuss. Entering a subject also makes it easier for people to scan a busy channel and find conversations important to them.

To start a new topic and give it a subject, click the Format icon under the Start a new conversation box (the icon looks like a capital A with a pen at its bottom right). This exposes several options to give much more control over how and what is posted. The important options here are:

- **Add a subject:** Give your topic a meaningful subject to clearly show what's going to be discussed here. A good subject is brief, to the point, and clear about the intent of the post.
- **Post as a conversation or announcement:** The default is to start a regular conversation, but you can choose to post an announcement to give your topic more impact (see below).
- **Restrict who can reply:** The default is that all members of the channel can reply, but you can restrict replies to just you and channel moderators. People often do this for announcement posts when organizations want to convey information to team members when the need to debate a matter no longer exists. As explained in the Managing Teams chapter, individual teams can have moderators to restrict who can add topics to channels, but you don't need to enable channel moderation to restrict replies. If specific moderators aren't defined for the channel, team owners serve in their place.
- **Post in multiple channels:** Normally you only want to post a conversation in the channel you're working in, but you can post in up to 49 other channels if you want. Naturally, you can only post in channels that you are a member of. You can't post in channels where posting is restricted to moderators (and you're not a moderator). Teams treats each message separately and, apart from visiting each of the target channels, there's no way to see all the replies for the same message from all the channels where the message is posted. You can include attachments in multi-channel posts. If you upload a document from your workstation, Teams stores it in the channel folder of the SharePoint document library belonging to the current team and shares it from that folder with the teams for the target channels.
- **Use an advanced editor:** Instead of a single line editor, you can use an editor like WordPad. The editor includes the ability to insert tables, code snippets, weblinks, bulleted and numbered lists, and highlight text in different ways (see *Making Your Point* below).

**A use case for multi-channel posts:** A good example of where it's very useful to post in multiple channels is when a company wants to spread the news of an announcement as widely as possible. Create an

announcement post and limit replies to the author and channel moderators to eliminate the need to deal with responses to the individual posts. You still want to encourage communication and responses to the announcement, and a good way to do this is to include a link in the announcement to redirect users to a topic in a channel in an org-wide team where they can post replies.

## Editing Posts

If you make a mistake, you can edit a post (message) to correct the error, but only if the Teams messaging policy applied to your account allows you to edit sent messages and the team settings allow members to edit their messages. In most cases, it's reasonable to allow people to edit their messages. All of us make mistakes and there's nothing as annoying as sending a message and then discovering a spelling or grammatical error.

If you post to multiple channels, you can edit the original post and the edited text will appear in all the channels where the original message was posted. However, you won't be able to update the post in channels owned by teams whose settings don't allow members to edit posts. You can also edit a conversation that is only posted in a single channel to add extra channels and make it a multi-channel post. When this happens, the original topic message is posted to the new channels but any existing replies for that topic are not.

The author of a message can recall a multi-channel post from a channel by editing the post to remove that channel. You can even edit a post and remove the channel the message originated from and the message will disappear from that channel. Replies to recalled messages are not removed from channels. If you delete a multi-channel post, Teams removes it from all channels but leaves any replies intact.

Unlike regular posts, Team owners can't edit or delete multi-channel posts.

## Finishing Conversations

Starting a conversation is easy (but please make sure you start it with a subject), but finishing is more difficult. Structured conversations about a well-defined topic usually conclude, but how many of them are summarized? If a conversation finishes, consider posting an "end of debate" note to let everyone know what was decided and what the next steps will be. Another advantage is that people will then be able to see what happened without having to look through all the messages in the thread.

## Announcements

Many channel conversations begin with someone asking a question or sharing a piece of information they have learned. Announcements are a more formal kind of post where people highlight something important. Teams supports the announcement post type for this purpose. When you compose a new conversation, you can select the post to be an announcement. To mark announcements in the message stream, they have a large heading with a background composed of a graphic or a solid color (Figure 12-9). If you decide to use a graphic, you upload a JPEG or PNG file and then select the area of the file to fit the oblong shape used for the heading. The ideal proportions for the graphic are 914 x 120 pixels, but if your graphic is a different shape, Teams allows you to select part of the graphic. The title of the announcement can be up to 40 characters long.

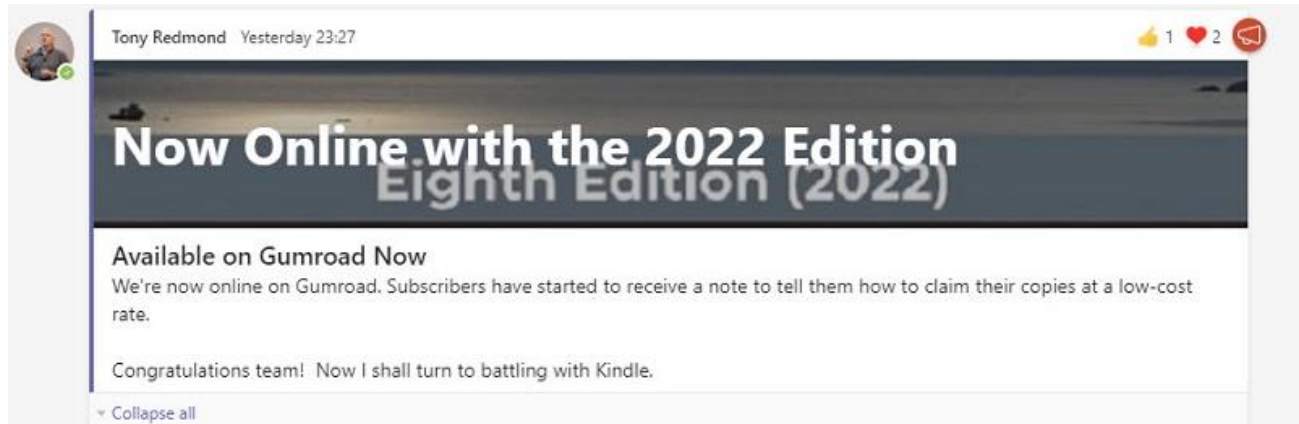

Figure 12-9: An announcement post as seen by readers

The heading attracts the attention of readers, so announcements are a good way to make people aware of important company events or news. Anyone can compose an announcement and if everyone begins to post announcements to a channel, the headings lose their uniqueness. With that in mind, it's a good idea to coach people to post announcements only when they need to highlight something important.

## Keeping Conversations Focused

Team conversations tend to be “high velocity,” meaning that contributions flow quick and fast. Typical interactions are often brief and use simple formatting, just like text messaging. Like any conversation, people are most productive and achieve the best results when everyone obeys some simple guidelines to structure communications.

A common mistake is to create new conversations instead of replying to an existing conversation. This quickly creates a confusing mass of posts that make it difficult for anyone to understand what happens in a conversation. People sometimes assume that Teams is like email and that it does not matter where they post. This is untrue. Email can preserve the context of a conversation by including the text of earlier replies, meaning that a recipient can see how a conversation unfolds by reading those replies. However, Teams conversations do not include earlier replies, so readers can only see the full context of a discussion if people reply to the conversation and do not split off into new conversations.

**Teams Conversation Etiquette:** Left to their own devices, it is easy for users to reduce a channel to a confused mass of incoherent conversations. Just like any other communications medium, it is sensible to advise people so that they understand how to extract full advantage from their contribution. Here are some simple rules to help keep Teams conversations civil and focused:

- **Always create a subject for new conversations:** Teams doesn't force users to create a subject for new conversations. However, you should always add a subject to highlight the commencement of a new thread and tell team members what you want to discuss.
- **Leverage existing threads when possible:** The temptation exists for users to start new conversations to express their ideas when existing conversations are better locations for their thoughts. Ask people to check if their contribution should be a reply to an existing thread instead of a new topic as this will help the channel avoid degenerating into many split and duplicated conversations. Using the search feature to check if a team previously discussed something takes only a few seconds. In addition, when you keep all the posts relating to a topic in a single thread, it maintains the full context of the discussion and makes it easier for people to find the information later.
- **Don't hijack conversations:** Keep conversations to a single topic and resist the temptation to introduce new topics in the middle of a conversation. It doesn't make sense to mix topics in a thread and it makes it harder to search and find information. If a topic is important enough, it deserves a dedicated conversation.

- **Mark important messages.** You can mark a message as being especially important by clicking the exclamation mark when composing the message or using the CTRL+Shift+1 key sequence. Teams then includes the text "Important!" (highlighted in red bolded and uppercased text) in the message and highlights the message with a red and white exclamation tab as a visual indicator that this is a "must-read" message.
- **Use Announcement posts for important news:** Another way to highlight important messages is to post them as announcements, which allows you to add an attractive graphic and titles to grab the attention of team members. Make sure that the graphic you choose is appropriate to the topic. It's just more professional that way.
- **Don't post private information.** Everything in a channel is available to its members. Never post anything in a channel you are unhappy to share with everyone in the membership. If you're unsure, check the membership before posting anything sensitive.
- **Use reactions instead of short replies.** If you receive a question in an email, you might respond with a one-line answer like "OK" or "Go ahead." You can do the same in Teams, but it's usually better to respond with a reaction (for instance, "Like" or "Laugh") to let the author know that you've seen and approved of its contents. Apart from anything else, this also reduces the number of messages in a thread and makes the conversation easier to read. If you don't like the content, the "Sad", "Surprised", or even "Angry" might be a good response. It's sometimes appropriate to react to one of your messages, such as when someone has liked a message to acknowledge what it's saying, and you want to react in turn to show that you've seen their response.
- **Use @mentions and tags intelligently.** Channels can be busy places where it's easy for people to overlook a question to which you want them to respond. Highlight the need for specific individuals to respond by using an @mention or a tag (if a suitable tag is available). And if you expect everyone in a team to respond, use an @Team mention, or even an @channel mention (only those who have the channel visible in their channel lists receive these notifications). Don't use these "reply-all" mentions unless you need to as you don't want to clutter up the activity feed of team members. It's also true that you cannot assume that someone has seen something in a channel conversation unless you @mention them to force the conversation into their activity feed.
- **Be Friendly.** If you @mention someone, Teams automatically inserts their full display name into the text. You can use the backspace key to remove everything but their first name, which seems a little friendlier than something like "Kim Akers (Operations)."
- **Use styles to highlight text.** The in-built styles exist to help users highlight important parts of their conversations. You can add headings, quotations, or code examples.
- **Summarize conversations:** If a conversation comes to a decision, conclude the conversion by writing an end of debate message that summarizes what the decision was and what the next steps will be.
- **Use private chats for personal conversations:** Teams allows people to share their ideas and viewpoints with anyone who can access a team, but sometimes it is best to take a conversation somewhere more private. Personal chats exist for this purpose. Use these chats when small groups need to thrash something out before making a topic public.
- **Don't just say Hello in Chats:** It's polite to let people know why you're contacting them in personal chats. Follow the [guidelines described here](#) and avoid starting a chat with Hello, Are you there, or something similar. Apart from anything else, starting with a meaningful message gives the recipient some context and allows them to respond with something useful immediately instead of waiting for you to describe what you want in other messages.

Users can use the save option in the [...] menu for a conversation to mark a complete conversation as something they wish to bookmark. The set of saved conversations (or bookmarked) is available by selecting **Saved** in the options revealed through the user photo or by typing /Saved in the command box. To remove a conversation from the saved set of conversations, select it and use the Unsave option from the [...] menu.

## Making Your Point

When you need to compose more than a simple sentence or two, click the Format icon (it looks like a capital A with an attached pen) under the compose box. This exposes a more capable editor that supports highlighting, font size and color, bulleted and numbered lists, bolding, italics, underlining, and a small set of styles. A primitive table formatter is also available to insert and populate tables. You can apply basic formatting to text, such as different headings or marking some text as a quote from a source (you can also use the markdown convention and highlight text as a quote by prefixing it with the ">" character). There is also a code style to include code examples in a code box (click the `</>` icon) to help programmers share ideas. As shown in Figure 12-10, you can name a code example and choose the language (in this case, PowerShell) from a list including C++, CSS, HTML, JSON, Markdown (GitHub), Python, Ruby, and TypeScript.

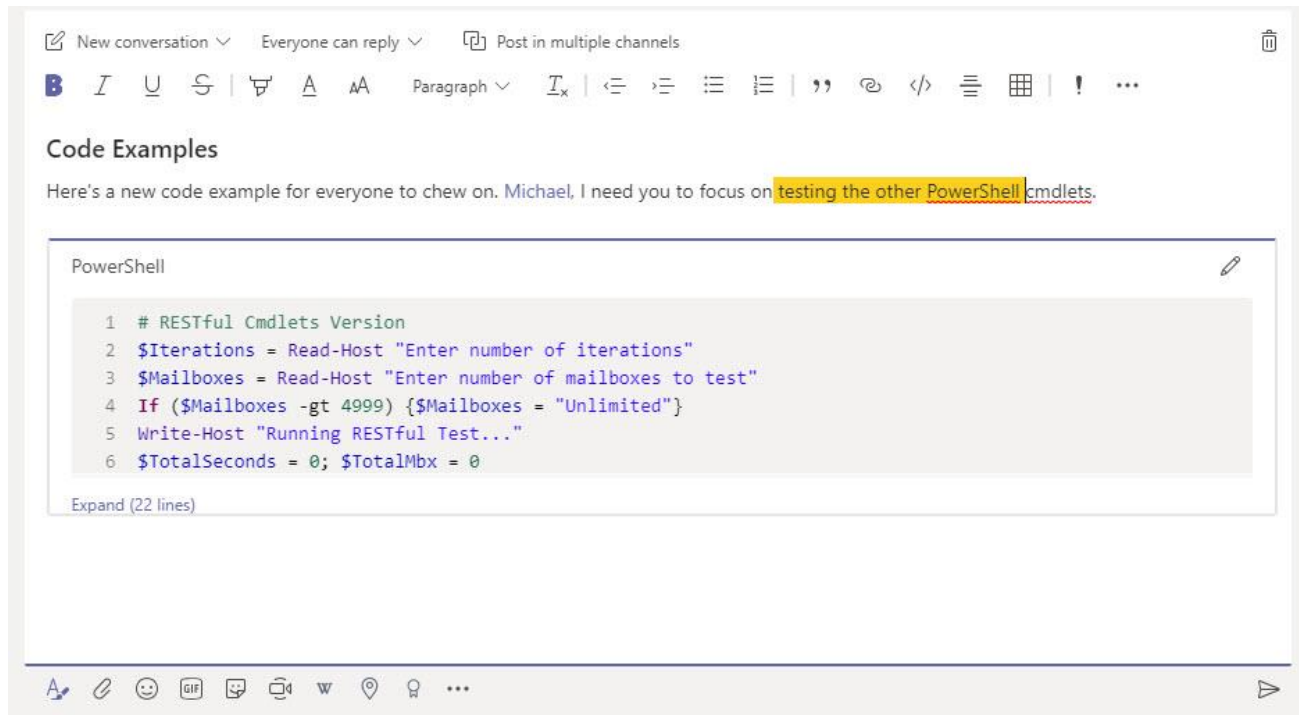

Figure 12-10: Sharing code snippets in a conversation

If you make a mistake in something you write, you can edit the content to fix the error or remove the item if it is no longer valid. Team owners can also exercise editorial control by removing messages from conversations if the need arises, but they cannot edit someone else's message.

The Teams editor does not offer as much control over formatting as a full-featured editor like Word, but if you need to compose something like a complex announcement, you can write it in your preferred editor and cut and paste the text into Teams. Text and basic formatting, including hyperlinks, survive the transition. Specific styles and embedded graphics do not. You cannot copy and paste graphics from other applications directly into a Teams conversation. If you want to include a graphic, copy it to the clipboard and then paste it into Teams. If you have a complex document that you want to share and discuss with others, upload it to the channel where you want to discuss the content. Teams stores these documents under Files, but members can review and discuss the content in the channel.

## Quoting Someone

Often you might want to highlight something another person says in a channel conversation. You can use a quoted reply in a chat, but not in channel conversations. To include someone's text in a reply, do the following:

- Select the text you want to quote and copy it (CTRL + C).

- Start a new reply and make sure that you use the full editor (click the Format button).
- Insert a line. Go back to the top of the text and type Shift and > (right arrow) together. Teams creates a highlighted area into the reply. Position the cursor in the area and paste the text you copied (CTRL + V). Teams inserts the copied text into the highlighted area.
- To insert your comment about the quoted text, move the cursor to the unhighlighted area and start typing.

## Pasting Text into a Conversation

If you compose text outside Teams and then want to include that text in a conversation, you can paste up to the maximum supported message size of 25 KB of text (roughly 2,000 words in English or approximately 12,000 characters) into a conversation. Including tables and other complex structures affects the amount of text you can paste. The maximum size of a message is approximately 28 KB, but this size includes reactions, @ mentions, and other elements. If the message is too long, Teams generates a preview of the message and tells you to shorten the text before it can be posted. You cannot drag and drop a message from one channel to another or from one team to another. If you make a mistake and post to the wrong channel, you must copy the message and repost it in the correct place.

**Spell Checking:** Teams has its own spell-checking dictionary, which it downloads to `%AppData%\Roaming\Microsoft\Teams\ictionaries` (you might find several language files there, one for each language you use Teams with). This dictionary is separate from any other used by Office applications, and you can't add new words (like technical terms) to it.

## Translating Messages

Teams uses the Microsoft Translator service for inline translation of messages in channel conversations and personal chats in the desktop and browser clients (the mobile clients can translate channel messages). In many cases, the members of a team can communicate quite happily in a common language. For larger teams, such as those used to share ideas across an entire company, being able to express a thought in a person's native language might reduce the barrier to collaboration, and that's why Teams supports inline translation for chat and channel messages in the ellipsis menu. The Translate option is available if Teams detects that a message is in a different language to the user's chosen language in Teams settings. To translate text, Teams calls Microsoft Translator to detect the language of the message and then translate it into the user's chosen language. Guest users don't have a preferred language, so the option to translate doesn't appear for them.

Languages are complex and regional accents, local sayings, idioms, jargon, argots, and technical terms often cause problems in translation. Some glitches might still happen even with simple text, but the translated output is usually good enough to convey the sense of a message. At the time of writing, Microsoft Translator supports [90 languages and dialects](#).

Translation can handle large messages, but a limit does exist. Teams supports posts of up to 25 KB. However, the buffer allowed for translations is smaller than this. In practical terms, you can expect to be able to translate messages of up to 1,000 words. The exact number depends on the language and size of the words. If you try to translate a larger post, Teams will tell you that the message is too long to translate.

The ability of a user to translate messages is controlled by the `AllowUserTranslation` setting in the Teams messaging policy assigned to their account. If the setting is `$True` (the default), translation is available. To check the translation setting across all policies, connect to Teams with PowerShell and run this command:

```
[PS] C:\> Get-CsTeamsMessagingPolicy | Format-Table Identity, AllowUserTranslation
```

Identity	AllowUserTranslation
-----	-----
Global	True
Tag:Advanced	True

**Tag:Advanced Users**  
**Tag:Restricted - No Chat**

**True**  
**False**

You can also update the allow translation setting in messaging policies through the Teams admin center, where the setting is called *Allow users to translate messages*. Remember that disabling translation in a messaging policy affects all users covered by that policy.

## Other Multilingual Features

Teams supports localized translations for the @Team and @Channel mentions. For instance, where English users type @Channel to draw attention to a topic in the channel, French users can type either @Channel or @Canal, while German users can type @Kanal. Teams recognizes the English and local language version of the term.

Normally Teams uses the default language configured on a device to know what language to use for spell check. The Teams desktop client for Windows can detect when users switch languages in chats and channel conversations. If a user sends several messages in a different language than their norm, Teams will switch spell checking to that language and prompt the user to confirm that this is OK. Unlike message translation, no data goes to the server. There's no administrative control over this feature.

## The Activity Feed

The Teams Activity Feed (Figure 12-11), is an app accessed through **Activity** in the top left-hand corner of the desktop and browser client. The role of the app is to highlight important items for the attention of a user. As people respond to chats and channel conversations with replies and reactions, notifications appear as banners in the activity feed. Notifications for messages posted by bots or connectors, including email sent to channels, do not show up in the activity feed. Apps can use the [notifications API for the activity feed](#) to post notifications too. For example, the Viva Insights app posts reminders to notify users to begin their virtual commute or note their current state of feeling.

The default view in the activity feed is *Feed*, which reveals all notifications related to the user. For example, someone uses an @mention to ask you a question or to bring something to your attention, or it's time to renew a team that you own. Along with a text snippet for each event, Teams uses different icons as visual clues of why the event appears in the feed. The clues include @mentions, channel mentions, team mentions, replies, and reactions. The number in the red circle beside the Activity Feed "bell" shows how many conversations have recent unseen activity.

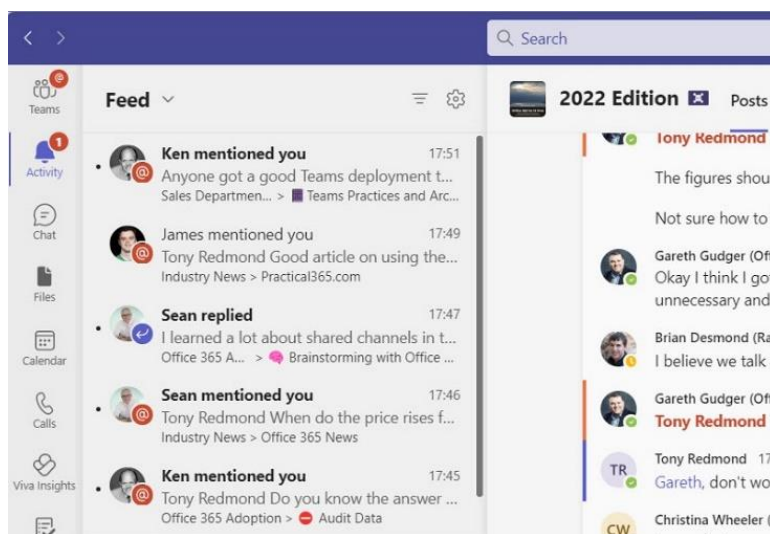

Figure 12-11: The Teams Activity feed

If you are a member of some busy teams, your activity feed is also likely busy. To help find messages in specific categories, you can filter by:

- **Unread:** Show unread notifications. You can also type /unread in the command box to see the unread items in the activity feed.
- **Mentions:** Show notifications where someone @mentions you in a conversation. Typing /mentions in the command box has the same effect.
- **Replies:** Show notifications for replies to your messages.
- **Reactions:** Show notifications for reactions to your messages.
- **Apps:** Show notifications posted by apps.
- **Missed call:** Show notifications for missed calls.
- **Voicemail:** Show notifications for voicemail messages.
- **Trending:** Show notifications for messages considered by Teams to be trending. In other words, messages with large amounts of activity (reads, responses).
- **Suggested:** Show notifications for messages that Teams believes will interest you. Teams derives both Trending and Suggested notifications from signals about user activity gathered in the Microsoft Graph with the idea being to encourage greater user involvement with these messages. An administrator can disable these notifications for the tenant in the Teams settings section of the Teams admin center.

If someone responds to one of your messages or mentions you in a conversation, Teams generates a notification in your activity feed. However, if its author or a team owner later removes a message, you might see an entry in the activity feed that doesn't point to anything. This doesn't happen very often, but it can.

## Refining the Activity Feed

After you've worked with Teams for a little while, you'll probably have a lot of items showing up in the activity feed. In email terms, an overloaded activity feed is like an overloaded inbox – it's hard to know where to start processing items, especially if you've been away from Teams for a while. One strategy often used to impose order on an activity feed is:

- Be very careful about what channels you follow. Unfollow channels that host discussions of lower importance and try to keep the channels you follow to the bare minimum. This will reduce the number of notifications you see.
- Process direct questions first. If someone uses an @mention to refer to you, it means that they want to bring something to your attention, so you should scan these entries and decide which ones need attention.
- Check replies to conversations you participate in next. You've joined these conversations, so you probably want to find out how they end.
- After you've cleared items from important channels, questions, and replies, you can leave other channel conversations until you have time.

The notifications section of the Teams settings app allows users to control notifications for personal and team @ mentions, replies, and likes and reactions. A user can turn these settings off to reduce the volume of notifications posted to the activity feed. They can also use the [...] menu for a notification for a reaction (thumbs-up, heart, etc.) or generated by an app to turn these types of notifications off. Notifications for an app are dealt with separately. In other words, if you want to disable notifications generated by ten different apps, you must find a notification from each app and use the menu option to instruct Teams to turn the notifications off for that app.

## The Importance of @Mentions

To make sure that an item shows up in a user's activity feed, you can address them with an @mention. Four options are available.

- **Direct @mention:** To bring something to the attention of a specific team member, input the @ sign followed by the name of the team member in a personal or group chat or channel conversation. For example, **@Kim Akers**. You can include a list of people, each prefixed by @. Teams checks mentions against a cached set of member and channel names (for channel conversations) and people you communicate with often (for personal chats). If you're in a channel conversation, you can't mention someone who doesn't belong to the team. If in a personal or group chat, you can't mention someone who isn't participating in the chat. Teams is intelligent enough to detect the names of team members as you type text into messages. If Teams finds a match against one or more members is detected, it displays a list of suggested names for you to select and add as a mention in the text.
- Teams also supports **@-less mentions**, which means that you don't need to prefix a name with the @ character. Instead, the client scans text as you write messages to check text against its cache. The initial letter of the member's first name (as in *Kim* for *Kim Akers*) must be capitalized otherwise Teams treats it as just another word. If it detects a match against the membership list, Teams displays a list of matching names. You can then select a name to make it into a mention.
- **@Channel mention:** Instead of the member's name, input the name of the channel. For example, @Budgets. Use a channel mention when you want to highlight something to the team members who include the channel in their channel list. You can also use @Channel (or its local language equivalent, like @Canale in Italian) and Teams will insert the channel name. The @Channel mention is particularly useful for private channels when only a subset of team members have access to content.
- **@Team mention:** Use the team name. For example, @Engineering. Use a team mention when you want to bring something to the attention of everyone in the team. You can also use @Team (or its local language equivalent) and Teams will insert the name of the team.

You can also use the tags defined in a team to refer to subsets of team members. See the section below.

Team owners can control whether members can use channel and team @mentions through team settings. By default, team settings allow users to use mentions in conversations.

**Toast Replies:** When someone sends you a message or replies to you in a personal or group chat (or meeting), Teams sends a "toast" notification to tell you what's happening. You can then respond to that user by entering your reply in the toast, but only with the Windows and Mac clients. This is a great way to send a quick response, but the reply cannot exceed 1,000 characters and can only include text.

When someone involves you in a conversation with a mention, a notification appears in your activity feed. You can click the notification to go to the conversation and pick up the thread. Figure 12-12 shows how Teams uses different icons to highlight conversation threads, including a team mention, personal mention, and an item marked as important.

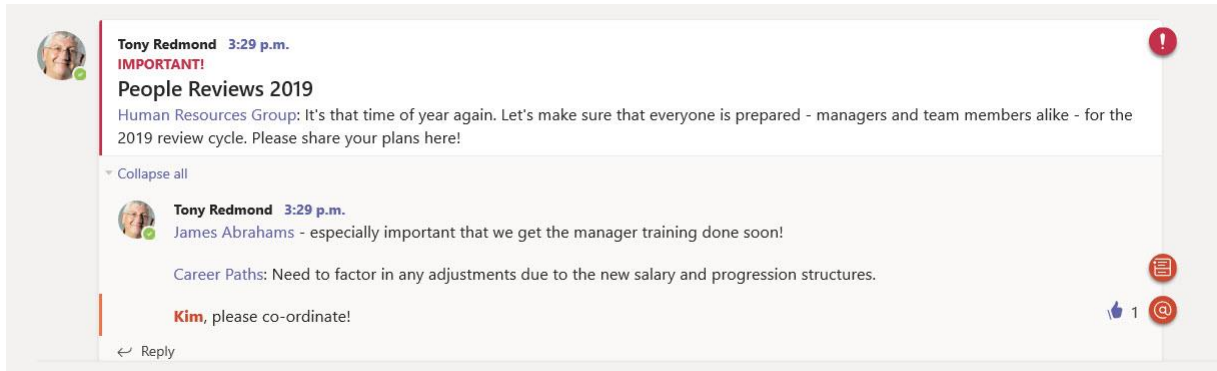

Figure 12-12: Visual indicators in conversations

Unlike most email systems, there is no equivalent of an “all users” distribution list that people can use to notify every account in the organization. If company-wide announcements are important to you, the closest equivalent is to create a team that has everyone as a member and use that team for general announcements. If you use dynamic groups, this is an easy way to keep the membership updated and ensure that new people automatically join the team when an administrator creates their account.

## Tags and Tagging

@Mentions allow users to address messages to an individual member, a channel, or the complete team. Team and channel mentions aren’t very precise because they flag a message to everyone in a team or channel. Heavy use of these mentions can clutter the activity feed of people who don’t need to know about something. Tags fill the gap between individual mentions and channel/team mentions by giving people a way to address a subset of members in a team. A tag has a descriptive name like “Managers” or “Individual Contributors” that team owners can assign to members to allow Teams to know who should receive notifications when someone uses the tag to address a message. Tags are different from hashtags because tags refer to a collection of team members while hashtags refer to a topic, place, or thing.

When you access a team, Teams builds a list of the team members and channel names in memory to allow personal and channel @ mentions. Tags are added to the roster of team members, which means that you can address the members of a tag by prefixing the tag name with an @. Because dynamic teams have non-fixed membership, you can’t use tags with these teams.

### Tag Management

Tag management is available in the Teams admin center in the Tagging section of Teams settings. There you can choose to use the following options to create tags:

- Team owners.
- Team owners and members.
- Not enabled (tagging is unavailable).

You can also allow team owners to override the organization settings (for instance, you might allow team members to create tags across the organization, but some team owners might not want this to happen in their teams). Owners control who can define tags in a team through the **Manage team** option (select Settings, then Tags).

Organizations can define a set of default tags that then become available for use in all teams. For example, you could create a default tag called *Owners* to allow members to address the team owners using @Owners. Or you could have a default tag for *Guests* to address guest members in a team. Other ideas include role-based tags like Programmers, Managers, Support, or other jobs that people commonly have, tweaked for your organization. Defining a default tag isn’t enough to make it useful; members must be assigned to tags (default or team-specific) in a team before the tags can be used to address messages within a team.

Other points to remember about tags include:

- Except for default tags defined at the organization level, tags are specific to a team and not shared between teams.
- A team can define up to 100 tags and each tag can have up to 100 members.
- The name of a tag can be up to 25 characters.
- An individual team member can have up to 100 tags.
- You cannot use tags in messages posted to multiple channels or in personal or group chats.
- Because the membership of private channels is a subset of the main team, tags cannot be used to address messages in private channels.
- Tags cannot be used to address messages in personal, group, or meeting chats.
- You can't use tags as a search filter.

By default, Teams enables Tags to allow team owners to create and assign tags using the **Manage tags** option in the [...] menu (Figure 12-13). Click on a tag to edit the people with the tag (you can also launch a chat with the tagged people from here). The tags defined by the organization are suggested at the bottom of the list. After someone is added to a default tag, it joins the set of tags for the team.

The screenshot shows the 'Tags' management page for a team. At the top, there's a search bar and a 'Create tag' button. Below that, there are two main sections: 'Tags assigned to you (4)' and 'Other tags (3)'. Each section contains a table of tags with columns for Name, Members, Description, and Imported from.

Name	Members	Description	Imported from
Admin	1		...
Editors	2		...
Managers	1		...
Writers	6		...

Name	Members	Description	Imported from
Guest Contributors	2		...
Guests	6		...
Technical Editor	2		...

Figure 12-13: A set of tags defined for a team

Another way of managing tags is through the **Manage team** option. You can view the list of team owners and members and see their assigned tags. You can then assign tags to people and see the set assigned to each tag. If a suitable tag doesn't exist, you can create a new tag and assign it to appropriate members.

Apart from the settings to control tags in the Teams admin center, there's no other management interface to deploy tags or have any insight into how team members use tags. The Microsoft Graph supports APIs to find

the set of tags in a team and return the members of a tag. See [this article](#) for an example of how to create a report using these APIs about tag usage in a tenant.

**Automatic grouping:** Teams generates an automatic grouping (tag) for team owners to allow people to address team owners in channel conversations using *@Team Owners*. You don't need to do anything to maintain this tag and it is available for use in all the regular channels of a team.

## Praising Others

The Praise app allows users to highlight the work of co-workers with a message composed of a badge and some celebratory text. People can praise others in personal chats or channel conversations or using the Viva Insights app. Both tenant and guest users can give and receive praise. The flow of the application is simple:

- Click the Praise icon below the compose box for a new message or reply.
- If using Viva Insights, choose to post the praise in a chat or channel conversation.
- Select the badge from a set provided by Teams. Each badge expresses a tribute to give to a recipient like "Thank You" or "Problem Solver."
- Select the recipients. For personal chats, the recipients must be members of the chat. For channel conversations, the recipients must be members of the team hosting the channel.
- Add some words to show why you're praising the recipients.
- Review and send the message when you're happy with the content.

Teams treats praise messages as a graphical form of an @mention, so the message shows up in the activity feed of the recipients.

## Searching Teams Content

Teams uses Microsoft Search to help users find messages, people, and files. To run a search, type something into the Search box and press return. Because this form of search looks through all the content in chats and channels available to the user, many matches likely result, divided into messages, people, and files. If you do not see what you are looking for, click the Filter icon to reduce the set of results to a more manageable number. Filtering supports preset date ranges like "Last month" or "Yesterday" and can restrict search to a specific team or channel or look for items with attachments. If you look for Files, you can restrict the search to a certain file type (for instance, PowerPoint).

When searching Files, as you enter characters into the search box, Microsoft Search scans for the most relevant hits based on multiple criteria such as the files you recently worked on or shared. These files are suggested as soon as Search finds them. Often, one of the suggested files is the file you're looking for and there's no need to progress to a full-scale search.

### Refining Search Queries

Applying filters to search results can help to find the right information, but it's even better to use precise search queries to find information, which isn't always the case. Most people mimic what they do with Google or another general-purpose search engine and search based on a word or phrase. Teams search is keyword-based and supports some (but not all) of the [KQL \(search\) syntax](#) for Exchange (email) items and used by Office 365 content searches. This means that precise queries can be constructed. For example, by adding a date range.

Let's start with a query to look for chats and channel conversations containing the phrase "Office 365 book" posted in the current month (the uppercased words in these examples are search operators):

*"Office 365 book" AND Sent = "this month"*

We could also use a specific date range:

*"Office 365 book" AND Sent >= "1 June 2020" AND Sent <= "15 June 2020"*

And limit the search further by including the name of the user who posted the message:

*"Office 365 book" AND Sent >= "1 June 2020" AND Sent <= "15 June 2020" AND From:"Tony Redmond"*

We could even refine the original search keywords ("Office 365 book") to say that two further phrases must be within ten words of each other:

*"Office 365 book" AND "book" NEAR(10) "planet" AND Sent >= "1 June 2020" AND Sent <= "15 June 2020" AND From:"Tony Redmond"*

Precise search queries work with the Teams mobile client too.

## Contextual Searches

Teams refers to searches confined to a single chat or channel as "contextual." The CTRL + F (Command + F for macOS) command tells Teams to launch a contextual search within the currently selected chat or channel. The query entered in the command box is used for the search, including precise queries as described above, so the number of items returned by a search is likely much fewer than with a more general search.

Using a contextual search effectively applies a filter, and you can't apply other filters on the results of a contextual search as are available for normal searches (which is a good reason to use precise searches). Also, CTRL + F only searches messages in channels and chats, so the **People** and **Files** results returned by normal searches aren't available.

## Search Suggestions

When a user inputs a term into the command box, Teams looks for the presence of a "/" to see if the user wants to execute a command. If none is found, Teams uses the term to generate suggestions matching the search term and displays them in a drop-down list known as the "suggestions well." The suggestions are organized into Top Hits (which include teams and documents stored in OneDrive for Business or SharePoint Online), People, Group chats, teams, and files. Selecting an item either brings the user to the location (chat or channel) or opens a file. Alternatively, the user can view full search results generated using the search term by pressing enter.

## Removing Messages

Some organizations hate the idea of anyone being able to remove anything they posted electronically (to email, SharePoint, or Teams) and some think this is sensible. After all, you can always have second thoughts and want to remove something written in error. Teams controls the ability of users and team owners to remove messages from conversations at a tenant level and within individual teams.

The **Messaging Policies** section of the Teams admin center includes the tenant-wide controls for message deletion.

- **Allow owners to delete all messages** controls whether team owners can remove messages in any channel in the teams they own.
- **Allow users to delete their messages** controls whether people (including guests) can delete messages that they post.

The intention behind owner control is to allow them to police conversations within a team and be able to remove anything posted that is inappropriate, insulting, or otherwise objectionable. Within a specific team, an owner can select **Manage Team** from the ellipsis menu, and then **Settings** to access the settings for that team. Navigate to **Member Permissions** to select whether:

- Everyone can edit their messages.
- Everyone can delete their messages.

- Owners can delete all messages.

The settings apply to all channels within the team. If the tenant-wide settings do not allow users to remove or edit messages, Teams hides these settings at the team level.

When someone removes a message, Teams flags it with *"This message has been deleted."* Contributions to the conversation before or after the deleted item are unaffected. If someone removes a message from a channel, they can restore it by clicking Undo. Teams does not remove the compliance records for deleted messages. These items persist as evidence that a conversation occurred.

Although you can remove individual messages from personal chats or channel conversations, you cannot remove a complete thread (all the messages that compose a conversation). Attachments pose another issue. When someone includes an attachment in a message, Teams uploads the file to that user's personal OneDrive for Business site (for personal chats) or the channel folder in the SharePoint document library belonging to the team. If the team owner or author later removes a message that has an attachment, Teams removes the message but leaves the attachment intact. I can understand the logic of leaving the file in place, but it might be the case that the attachment holds the objectionable content that you want to eliminate. If so, checking and cleaning up SharePoint and OneDrive content are extra steps in the removal process.

Searching for and removing content from multiple teams is another issue. This might happen if someone posts something inappropriate to one or more teams or people copy content posted to one team into others. To purge the content, you then must find and remove each post individually. Unlike the purge action for content searches, Teams does not have a method to scan all teams in a tenant to find and remove specific content.

## When Members Leave

Team conversations are persistent, so they exist even when people involved in conversations leave the organization. The contributions of removed users to private chats and channel conversations remain in place. The user no longer exists in the membership list (or the tenant directory), which means that other members can no longer @mention the user. Because their account is no longer in the tenant directory, the removed user shows up as an "unknown user" as a participant in private chats. However, Teams keeps their display name for their contributions in the conversation history.

If you restore a user account within 30 days of deletion, they regain their membership in groups and teams and can function as they did before the deletion of their account.

## Personal (1:1) and Group Chats

To this point, we have focused on using team channels as the basis for conversations. Channel conversations are under the control of the organization because channels only exist inside teams. By comparison, personal chats occur when two or more people converse on an ad-hoc or persistent basis. Chats are under the control of the participants, who decide when to start the conversation and who should take part. You cannot "promote" a personal chat to move the conversation to a channel in a team.

Like channel conversations, personal chats are persistent and are always available. The content of personal chats is always confidential to the participants. In other words, no one outside the chat can see what's happening unless they join the chat. Even then, a newly added participant can be restricted to just seeing chats after they join.

Personal chats are either one-to-one (1:1), meaning that two people take part, or group chats, meaning that between three and 250 people participate, including federated and guest participants. Both kinds of chats are accessed through the **Chat** section of the Teams client, which lists the set of active conversations for the last month. This doesn't mean that older chats are dropped. They're merely hidden and ready to be shown if you

restart a conversation. Although you cannot drag and drop chats to arrange them into a preferred order, fast access to important conversations can be achieved by using the **Pin** option in the ellipsis menu. Up to fifteen chats can be pinned at the top of the chats list and you can drag and drop the pinned chats to arrange them in whatever order is best. Within a chat, any participant can choose to pin an individual message to appear at the top of the chat. This is a useful way to highlight important information about a chat such as its purpose. On the downside, any chat participant can unpin the pinned message. Because no one in a chat has more rights over chat contents than other participants, there's no way to lock a pinned message.

Table 12-4 lists the most important differences between channel conversations and personal chats.

	<b>Channel Conversations</b>	<b>Personal/Group Chats</b>
<i>Participants</i>	Open to anyone in the team owning the channel. Shared and private channel conversations are open to channel members.	Open to those invited to join the chat, from 1:1 or group chats with 3 to 250 participants. Teams also supports chat with self.
<i>Purpose</i>	Discussion of ideas, concepts, and announcements.	More detailed discussion (often preliminary) about topics that might later be shared in channels.
<i>Structure</i>	Each conversation is a separate thread.	The conversation in a chat is a single thread.
<i>Notifications</i>	Based on @mentions and channel favorites.	Messages in a chat generate pop-up notifications for the participants.
<i>History</i>	Full history of channel conversations available to all team members.	Previous conversations can be shared with new members, but don't have to be.
<i>Sharing</i>	Files shared in the team's SharePoint site.	Files shared in sharer's OneDrive for Business account or by uploading to the sharer's account.
<i>Calendar</i>	Scheduled and "Meet now" ad-hoc meetings.	On-demand audio and video calls (with screen sharing). Can schedule meetings with chat participants.
<i>Pinning</i>	Pinned channels appear at the top of the channel list. Team members can pin individual messages which appear in the channel information pane.	Users can pin up to 15 chats to appear at the top of their chat list. Anyone in a chat can pin a message to appear at the top of the chat. Anyone can unpin the pinned message.
<i>Apps</i>	Channels can deploy apps in tabs and menus and as bots.	Chats can include apps from the Teams app store and add tabs to invoke other apps.
<i>Search</i>	Use Teams search to find messages in channel conversations.	Use Teams search to find messages in chats or use the Filter function to find specific conversations. A specific filter is available to find chats from meetings.
<i>Read Receipts</i>	Unavailable in channel conversations.	Available for 1:1 chats and group chats with up to 20 participants.
<i>Quoted Replies</i>	Unavailable unless the user cuts and pastes a reply into a new response.	Supported through the reply option in the [...] menu. Teams inserts approximately 200 characters from the chosen message into the reply.
<i>Smart Replies</i>	Not available.	Supported for 1:1 chats with other tenant members.
<i>Loop components</i>	Not supported in channel conversations.	Fully supported in chats with internal and guest users.

Table 12-4: Differences between channel and personal conversations

Tenant participants can record a 1:1 meeting if both use Teams clients and the Teams calling policy assigned to the account of the person who wishes to start the recording permits this action. Recordings don't work when calls involve PSTN lines or federated connections to Skype consumer users. After a recorded chat finishes, the recording is available in the meeting chat.

**Limitations of Large Chats:** Although Teams supports large group chats, to save system resources, some limitations apply to group chats of more than 20 participants:

- Outlook out-of-office replies and Teams status messages are not displayed for participants.
- The indicator showing that someone is typing a message is disabled.
- Video and audio calls can't be started in the chat.
- Sharing of documents (using OneDrive for Business) isn't allowed.
- Read receipts for messages don't work.

Teams disables these features to reduce the strain on the service. Fetching out-of-office information for many participants requires a lot of interaction with Exchange Online mailboxes while tracking who's read a message for the same number consumes many processing cycles.

## Starting Chats

To start a new chat, click **Chat**, right-click, and then **New Chat** (or click the New Chat icon in the menu bar). Teams invites you to start typing a name of an individual or existing group chat in the To: line. You can add the following as chat participants:

- Tenant accounts.
- Guest accounts.
- People in other tenants by entering their User Principal Names (as explained below, these people can only participate in 1:1 chats).
- The name of an existing group. In this context, "group" means the name of an existing group chat rather than a Microsoft 365 group or a distribution list. If you want to chat with a team, you do so within a channel in that team.

If you restart a new chat with a set of people with whom you have already chatted, Teams recognizes that a chat with those people exists and displays the messages from the earlier discussion to allow you to continue from that point.

You can also start a chat or continue a conversation with someone by typing @ and their name in the command box, followed by the message you want to send. This approach works well when you want to send a quick note without switching context away from something else, like a meeting or discussion in a channel. You can't address more than one person through the command box.

## Read Receipts

Read receipts are a well-known concept in email. When someone reads a message marked with a read receipt, the email service creates a notification for the original sender to tell them that the recipient has read the message. Teams uses a different concept. In personal chats and group chats involving up to 20 participants, Teams tracks who has seen a message and marks its status with a small icon to the right of the message. The icon is either a checkmark (the message is *Sent*) or an eye (the message is *Seen*). In group chats, you can see a list of who has read a message by selecting the Read by option in the [...] menu for a message. When everyone in the chat has read the message, the icon changes to Seen.

Read receipts only work if they are enabled for all participants in a chat. Read receipts can be blocked by the messaging policy assigned to user accounts. If enabled by policy, users can turn off read receipts through the Privacy settings for their account. Read receipts don't work for federated chats and they are not supported in channel conversations.

## Tabs in a Personal Chat

In the desktop and browser clients, personal chats have three default tabs:

- **Chat:** shows the messages in the conversation.
- **Files:** access to files shared with chat participants. As explained below, these files are in the OneDrive for Business accounts of the people who share them. Federated participants don't see the Files tab.
- **Activity:** shows recent messages posted by the person to team channels. Both tenant users and guests can see messages through the activity tab.
- **LinkedIn** is a tab to access LinkedIn profile information for the other user in a 1:1 chat. This tab isn't available in group chats.

The **Organization** tab is also visible to tenant users if it is enabled by the Show Organization tab in chats setting. The information exposed through the organization tab is explained later. Group chats do not display the activity tab, nor is the activity tab available for federated chats.

The idea of the activity tab is that it gives you an insight into what the person you're chatting with has been doing recently in teams where you share common membership. The lookback period is approximately two weeks. If you see something interesting in the list of messages, you can click it to go to the channel to see the full conversation. There's no risk that you'll see something you shouldn't because the messages that show up here are from teams that you both belong to.

Any tenant user in a chat can add a tab. For instance, you might decide that you want to discuss a website or a PDF file on a website with the other participants in a chat. To add a tab, click the plus sign in the menu bar to add tabs for:

- Documents that you have shared in the conversation (Word, Excel, PDF, PowerPoint).
- Link to videos stored in Stream.
- Link to a website page.
- Link to Power BI report (such as usage analytics for the tenant).
- Apps authorized by the tenant.

The intention behind adding tabs to a conversation is to give fast access to information being discussed or needed for the conversation. Participants can quickly move from the conversation to a tab and back again without pause. Teams opens objects as soon as the tab is accessed to make it even easier to access the content.

## Sharing Files in Chats with OneDrive for Business

Sharing a file to a personal or group chat is like posting to a channel. If you include a file in a conversation that's stored on your PC, Teams uploads the file to a folder called *Microsoft Teams Chat Files* in your personal OneDrive for Business account and shares the file with the other users in the conversation. On the other hand, if you share a file that's already in OneDrive for Business, the file is left where it is and its access is amended to include chat participants.

Files are shared with chat participants on a direct basis. In other words, each chat participant receives explicit access to the file being shared. If you make a mistake and share the wrong file or share a file with the wrong set of people, you must remove the access permissions from the file in OneDrive for Business as Teams does not support removing a file from a conversation. If Teams detects that the permissions on a shared file do not allow chat participants to access the file, the sharer is asked to adjust the sharing link for the file to include them.

Retrospective sharing isn't currently supported, so if someone joins the conversation after you share a file, they will be able to see that a file was shared with the chat (in the chat history or in its Files view), but you must share the file with the newly-added participant before they can access its content.

## Expanding a 1:1 Personal Chat to be a Group Chat

Group chats involve three or more people. Conversely, 1:1 or personal chats occur between two people. The two participants in a personal chat can be accounts belonging to the tenant, between a tenant account and a guest account, between two guest accounts, or between a tenant account and a Teams user in another tenant. Guest users can also create new personal chats and include other users and guests in the conversation. In fact, a guest can create a chat that only guest users join. However, guests can only communicate with the members of the teams they belong to. A guest can't chat with a tenant user who doesn't share membership of a team with the guest.

Anyone taking part in a group chat can add someone else to the conversation by clicking the **Add people** icon in the top right-hand corner, which you might do to include an expert to answer a question that has come up in the conversation.

When you start a group chat, you can give it a name (Figure 12-14) to let people know what topic you want to discuss. You can also edit a chat name after the conversation starts. It is always good to assign a name to group chats as it makes it easier to find the right chat in the list the next time you want to share a thought. If necessary, anyone taking part in a chat can rename it at any time to reflect the current scope and focus of the conversation. One-to-one chats use the name of the person with whom you chat.

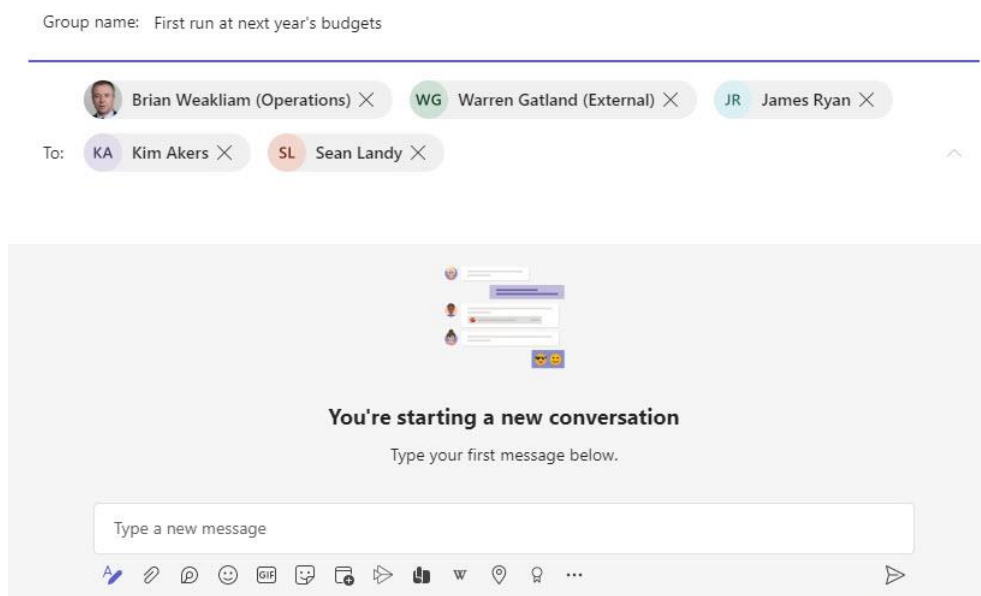

Figure 12-14: Creating a new group chat

You cannot add a guest to a chat unless their account exists in the tenant directory, meaning that they must have previously joined a team. When you add someone to a group chat, you decide whether they can see all or some of the prior message history. For instance, if you bring someone into a conversation to answer a specific question, you might allow them to see messages from the last five days so that they understand the context.

Personal chats behave differently from group chats in that you cannot reveal previous messages with someone you add to a 1:1 chat. The reason is simple. Whatever's discussed in a 1:1 chat is available only to the other person in the conversation. Chats are persistent and so if you could reveal prior messages to someone joining a conversation, you might impinge on the other person's privacy by revealing something that they prefer to keep confidential. An argument can be made that people should control their data and

decide how to share conversations, but in this case, Microsoft decided that it was best to limit the sharing of prior messages in a conversation to group chats. When a 1:1 chat evolves to become a group chat, Teams creates a brand-new chat and those participating in the chat then have full access to anything discussed thereafter.

## Leaving and Muting Chats

If you make a mistake and discover that the wrong set of people are in a group chat, any of the tenant accounts participating in the chat can remove the person who should not be in the conversation. The option to remove users from group chats is controlled by the Teams messaging policy assigned to accounts, so it is possible that some participants can remove people while others cannot. Guest accounts cannot remove other participants from group chats.

To remove someone from a group chat, click on the list of participants, find the person you want to remove, and click the **X** beside their name. Someone removed from a group chat can see the messages sent in the chat up to the point they are removed but once removed, they cannot send or receive any further messages. If you remove someone in error, you can add them back to the chat and they can pick up from where they left off. Remember to allow them to see the full chat history to ensure that they don't miss anything that happened during their removal from the chat.

Participants who do not want to be in a group can leave it at any time by selecting it from the list of personal chats and then **Leave** from the right-click menu (you can't leave a chat when only two people are in the chat). When you leave a chat, you no longer see new messages posted to the chat, but you can still see any message posted up to the time you left. Alternatively, if you simply want to remove a chat from the list of active chats, you can **Mute** the chat (another choice in the right-click menu). The chat is still there, and you can take it up again at any time, but notifications for new content in the chat do not show up in your activity feed.

If you don't want people to be able to remove other participants from group chats, change the **Allow a user to remove users from a group chat** setting to *Off* in the Teams messaging policy assigned to the user accounts you want to restrict.

## Chat with Self

Chat with Self means that a user starts a chat by entering their own name as the chat participant. It is a similar capability to the functionality found in other messaging platforms that allow people to send themselves messages as a form of aide memoire.

There have always been situations where someone ended up as the only person in a chat, such as when everyone else left a group chat either voluntarily or following the deletion of their account, but Teams did not allow users to start a chat with only themselves until June 2022. Unlike the other instances that created a single-person chat, each user can only have one chat with self and they cannot transform the chat into a regular chat by adding other participants.

If someone needs to share information in their chat with self, they can create a Loop component in the chat and make it available by sharing the link to the loop file in OneDrive for Business to allow others to open and interact with the component.

## External Access: Federated Chat Outside the Tenant

External Access or federated chat is the ability to have 1:1 and group chats with Teams users in other tenants, Skype consumer users, or [Teams consumer users](#). This is not the same as guest user access because federated chat makes a restricted set of features available to chat participants. If you make an external user a guest in your tenant, they enjoy extensive access to resources (personal chats, channel conversations, documents,

apps, and so on) in your tenant, including access to private channels. External participants can access whatever's in the chat.

The [following conditions](#) govern external access:

- External access must be enabled for the tenant (managed through Users section of the Teams admin center.)
- Your tenant does not block access to the remote user's domain. Each tenant can construct allow or blocklists to limit the connections users can make. On the other hand, if you don't use these lists, you allow inbound connections (or federation) from any other tenant.
- The remote user's tenant also allows external access.
- The remote tenant does not block your tenant. They might have blocked your tenant or limited the connections the tenant will accept to an allow list.

The [Microsoft 365 admin center includes diagnostics](#) to help resolve difficulties in Teams federation which might give you some hints about why external access to a specific address does not work.

Once everything is set up, users can enter the user principal name (or email or SIP address) for external users into the search box to have Teams search their tenant's directory to find their account. Teams first checks if federation is available between the tenants, and if so, uses the domain name in the address to connect to the other tenant to look up the user. If it finds a match, Teams adds the external user to the chat. For 1:1 or group chats involving an external user, Teams flags that you're using federated chat by including the **External** label at the top of the chat. Teams also flags external participants in the participant list of group chats.

External chat participants use rich native federated chat. In other words, they can compose and send messages like normal chats containing formatted text, links, emojis, stickers, and so on. They can also call or participate in meetings with other chat participants.

## Chats and Calls with Skype Consumer Users

External access also includes communication with Skype consumer users. This connection is natural because Teams and Skype consumer share the same media stack. The feature is disabled for tenants by default, so the first step is to enable the *Users can communicate with Skype users* setting in the **External access** section of the Users settings in the Teams admin center. Once enabled, it takes an hour or so before Teams is ready to connect to Skype.

Teams and Skype consumer users can use chats and VOIP calls to communicate. Because Skype consumer users don't belong to a verifiable organization, when a Skype consumer user reaches out to connect with a Teams user for the first time, the Teams user has the option to accept or block the connection. The Teams user is also able to view the message sent from Skype as an aid to decide whether they want to connect. Both Skype and Teams users find each other using their email addresses (you can't use a Skype ID or phone number to find a consumer user). In the case of Teams, the connection is like finding a Teams user in another tenant. You input the email address into a new chat, Teams won't find the address in the local directory, and you must instruct Teams to search externally to find the user.

Chats between Teams and Skype consumer accounts support only plain-text messages. Unlike federated chat between tenants, you can't use text formatting and emojis. The two platforms do not share presence information, so you can't find out if a Skype consumer user is free or busy.

## Urgent Messages and Priority Notifications

Urgent messages cause Teams to prompt the recipient with priority notifications every two minutes for twenty minutes (or until the message is read) to grab their attention and hopefully respond to the message. The idea is that you can use these messages to signal critical events to recipients, like the arrival of a high-priority

patient at a hospital emergency department. The ability to send urgent messages is controlled by the *AllowPriorityMessages* setting in Teams messaging policies. By default, the setting is **On**, so all users can send urgent messages. If you have people who abuse priority notifications and make all their messages urgent, you can create a new messaging policy with *AllowPriorityMessages* set to **Off** and assign that policy to their accounts.

To create an urgent message, open the Chat window, select the recipient, create a new message (Figure 12-15), and click the exclamation icon to reveal the option to mark the message as urgent. Compose and send the message as normal.

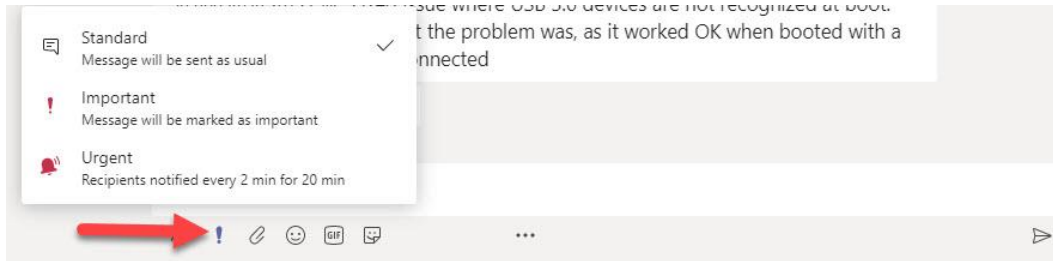

Figure 12-15: Creating an urgent message

Unlike notifications for normal Teams messages, you cannot use a priority notification to create an inline reply. Teams wants you to read the urgent message, so clicking Reply opens the chat with the sender to see the urgent message and complete the priority notification cycle.

Urgent messages are intended for direct communication with an intended recipient and are not supported for channel conversations. However, you can send an urgent message to a group chat so that everyone else in the chat receives a priority notification.

## Loop Components and Teams Chat

Loop (previously live or fluid) components are based on [Microsoft's Fluid Framework](#). Announced at the Ignite conference in November 2021, a new Microsoft 365 app called Microsoft Loop is built with loop components. In addition, loop components are available in apps, with [Teams chat](#) (not channel conversations) being the first. The Teams Windows, macOS, and Linux desktop clients and browser and mobile clients support the following loop components:

- Agenda. Build an agenda for a meeting (we'll see more use of this component when it shows up in Teams meetings).
- Table. Just like a table in Word.
- Bulleted list and Numbered list. Work like any other bulleted and numbered list in a Microsoft word processor.
- Checklist. Write down all the things people need to do. Like a task list, but with no assigned task owners and target dates.
- Paragraph. Free text component that's good for capturing ideas and sharing information like web links.
- Task list. Build a set of tasks or follow-up items and assign tasks and expected completion dates to chat participants.

The major advantage of a loop component is that once sent in a chat message, updates to the content of the component synchronize and appear for chat participants in almost real-time. It's like the way updates appear in Office documents using co-authoring with the notable difference that the updates appear much faster than in Office. According to Microsoft, using a loop component for dynamic collaboration avoids the need for back-and-forward debate in chat because those involved can work out details within the component. All participants see what's happening and it's easier to follow what develops. Figure 12-16 shows a bulleted list loop component with three active users. The component includes an embedded table, and one of the table

cells has a comment. This is a good example of how to use a loop component to have an active discussion in chat.

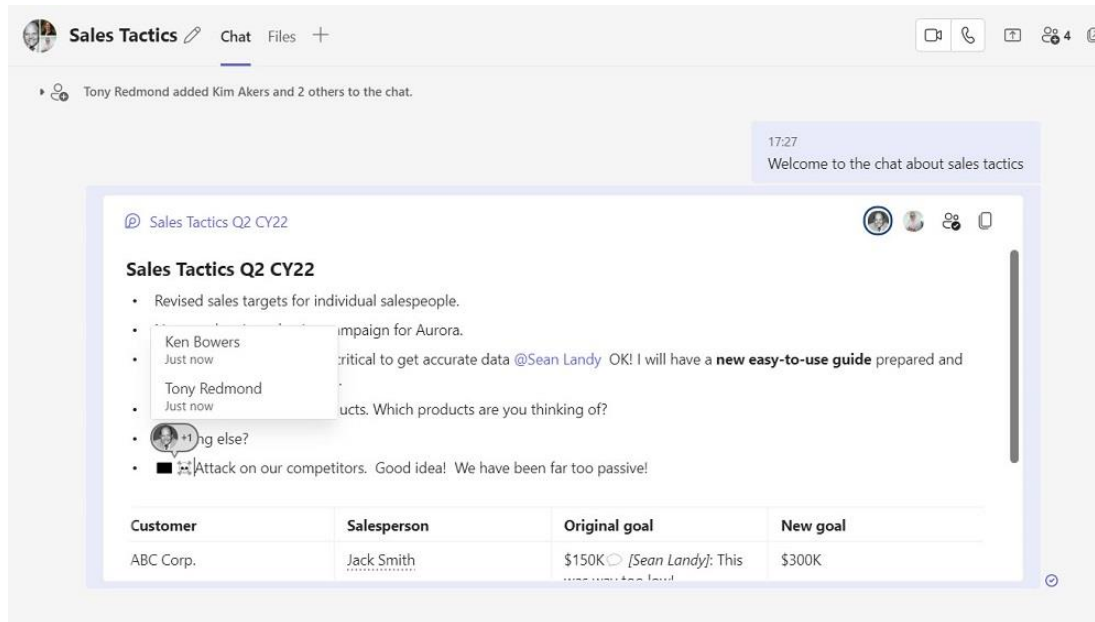

Figure 12-16: A loop component in active use in a Teams chat

Points to note about the use of loop components in Teams chat include:

- A loop component must be the only item in a message (a component can store other loop components). Teams stores the files for loop components in the *Microsoft Teams Chats Files* folder in the sender's OneDrive for Business account (so only those with OneDrive accounts can send loop components). These files have a fluid extension. To make a loop component available to chat participants, Teams shares the file. If necessary, the owner can share the file with others.
- Because of the dependency on OneDrive for Business, guest users can't create new chat messages with loop components. However, they can edit loop components sent in chat by tenant users.
- You can paste text from other applications into loop components. However, the resulting formatting might not be perfect.
- Unlike normal chat messages, translation of content in a loop component is not available.
- Share to Outlook doesn't work for chat messages with loop components.
- DLP for Teams doesn't detect policy violations in loop components.
- Loop components cannot be used in chats with external (federated) participants.
- Microsoft search processes the content of fluid files, meaning that you can include loop components in content searches. However, the copies of the files retrieved by a search can't be opened.
- Compliance records captured for chats containing loop components reference the file stored in OneDrive for Business and don't contain any of the content. As such, these records are useless to features like communications compliance policies which rely on compliance records.

Microsoft will likely resolve some or all these issues over time. We will track progress here.

## Teams Meetings

Teams meetings are a very popular part of the application. In April 2020, Microsoft said that Teams users consumed [2.7 billion meeting minutes on March 31, 2020](#), with 43% of calls involving video. Three months later, [Teams handled 5 billion meeting minutes in a single day](#). Given the growing interest in working from home, Microsoft expects Teams calling to continue to have strong growth in the future.

A Teams meeting is a virtual workspace with an identity (a unique URI) in the Teams meeting service. Although meetings have start and end times, participants can join a meeting immediately after creation, even if the scheduled time is many days away. A participant can join a meeting multiple times with different devices. A meeting has associated objects, like the participant list, including those nominated in different roles (organizer, presenters, and attendees), optional recording, and a chat thread. Collectively, these form the complete meeting. A Teams meeting can last a maximum of 24 hours. Broadly speaking, the meeting (and calling) experience available in the Teams desktop and browser (Chrome and Edge) clients support equivalent features. Other browsers, like Safari, use a simplified meeting experience.

Users create and manage Teams meetings with the Teams **Calendar app** or via an Outlook client. Control over the ability for users to create Teams meetings is set via the meeting policy assigned to accounts. Guest users can't create meetings. Four settings in the general section of the meeting policy assigned to accounts exert control over the kind of meetings users can create:

- Allow the **Outlook** add-in: If the setting is on, Outlook (Windows and Mac desktop clients, Mobile, or OWA) can schedule online Teams meetings (you can [configure settings to make Teams online meetings the default](#)) and Outlook automatically loads the [Teams meeting add-in](#) when the client starts. Modern authentication must be used for the connection between Outlook and Exchange. If these conditions don't exist, Outlook won't load the add-in. Outlook desktop and mobile clients can support several mail accounts in a profile, with one account assigned as the default (used to send outbound email). Outlook add-ins run in the context of the default account, so it's important that the account chosen as the default is the one used to create Teams meetings. Outlook can only create private meetings, so the Teams meeting policy assigned to their account must allow the user to create private meetings (any meeting not published in a channel is private).

The Teams meeting add-in uses the Edge WebView2 component, and it receives updates during the automatic update cycle for the Teams desktop client. It also depends on the .Net framework. The workstation should run the latest version (4.8 at the time of writing). On Windows PCs, you can check the version of the .Net framework with PowerShell. This command returns *True* if 4.8 or above is installed.

```
[PS] C:\> (Get-ItemProperty "HKLM:\SOFTWARE\Microsoft\NET Framework Setup\NDP\v4\Fu11").Release -ge 528040
```

Apart from creating new Teams private meetings, the add-in also allows users to update meeting settings (like who can join without going through the lobby, who can present during the meeting, etc.). The add-in includes a *Meet Now* button to allow users to create impromptu personal meetings. The user must be signed into their home tenant to allow the Meet Now option to work, so if they're connected to a different tenant, they must switch back to use Meet Now. See this post for [more information about the Teams meeting add-in for Outlook for Windows](#). A version of the add-in is available to [allow Google Calendar and Google Workspace users schedule and manage Teams meetings](#).

- Allow **channel meeting** scheduling: If on, the user can create a meeting in any standard or shared channel in teams they belong to by:
  - Selecting a channel when creating the meeting in the Teams calendar app.
  - Using the *Schedule a meeting* button in the compose reply options.
  - Using the *Meet Now* option in the channel header.
  - Creating a new meeting in the channel calendar.

Channel meetings appear as a new topic within the channel to make the meeting available to team members. Chat messages from the meeting also appear in the topic and are visible to all members, including those who do not take part in the meeting. You can add participants to a channel meeting

who don't belong to the team. These attendees can join the meeting but cannot access resources shared through the channel. One advantage of channel meetings is that meeting resources like documents and recordings are in the channel folder of the document library in the team's SharePoint site instead of an individual user's OneDrive for Business account, as is the case for private meetings. This can be important when people leave the organization along with their OneDrive for Business accounts, which might contain documents relating to important meetings. Although it's possible to give someone else access to a user's OneDrive for Business account when they leave to review and recover information, this is a step easy to overlook.

- Allow scheduling **private meetings**: If set, the user can create a private (or personal) meeting. As noted above, a private meeting is a meeting not scheduled in a channel. Like personal chats, you dictate who receives invitations to join the meeting. If a participant cannot join the video or audio part of a meeting, they can still contribute to the conversation. Invitations for private meetings come from the meeting organizer's mailbox. Teams considers meetings created with the Teams add-in for Outlook as private, even if you add a team as an attendee for a meeting. You can invite people outside your organization to a meeting, even if they do not have a guest account in the tenant, by adding their email address as a participant. This is known as an *anonymous join* and generates an invitation to the email address to allow the recipient to join the meeting.
- Allow **Meet Now** in channels: If on, the user can create an ad-hoc meeting. These meetings are like channel meetings in that they occur in a channel. To start an ad-hoc meeting, click the *Meet Now* icon under the compose message box. Team members can join the meeting if they wish. Another policy setting (Meet Now in private meetings) controls whether users can create unscheduled meetings outside channels.

**Exploiting the Virtual Lobby:** The *automatically admit people* setting in the meeting policy assigned to a meeting organizer's account dictates who can join a meeting. Depending on the setting, some participants can join direct by bypassing the virtual lobby while others must remain until the meeting organizer, a co-organizer, or a presenter admits them. Available options include the ability to admit everyone in the organization automatically (this includes guest users) or everyone in the organization and other federated Office 365 tenants. Organizers can update the settings of an individual meeting to fine-tune who waits in the lobby. Options such as "Only me" or "People I invite" allow organizers to exert more precise control over the lobby. For instance, for confidential meetings it's a good idea to update meeting options so that only the organizer or those invited explicitly can join automatically. All other participants must wait in the lobby for admittance, which removes the risk that someone else might be able to join the meeting without being noticed and gain access to confidential information.

Teams meetings support desktop sharing (including the ability to only share a specific window rather than the entire screen), recordings, muting noisy attendees, and transfer control to other participants so that they can run a meeting. Participants can use [Whiteboard as a collaborative space](#) to share and develop ideas during meetings.

If you record a meeting, a Teams bot joins the meeting to capture the audio, video, and screen sharing activity in a feed sent to Azure Media Services. When the recording is turned off (or the meeting ends), the video file is stored in Stream or OneDrive for Business. Any of the meeting participants can play the recording. The owner of the recording can share it to allow others access to the content. The Videos chapter has more information about the management of Teams meeting recordings.

Up to 1,000 participants with full access to all resources can join a Teams personal or channel meeting. This means that attendees can use video and access meeting resources such as the whiteboard, and chat. After the meeting reaches its capacity, Teams can switch automatically to admit view-only attendees. See the later section covering meeting overflows and view-only attendees.

## Sharing Files in Teams Meetings

People accustomed to Outlook often notice a difference in the way files are handled when scheduling meetings with Outlook and Teams. Outlook allows the attachment of files to meeting invitations while Teams does not. The Teams calendar app doesn't display attachments added by Outlook. If you want to share files with meeting participants, the organizer can include links to the files in the meeting invitation or participants can upload them to the Files section of the meeting. If the text isn't too long, the organizer can include it in the body of the meeting invitation.

Any tenant user can share a file before, during, or even after a meeting. If the attachment is a text file and isn't too long, you can also cut and paste the text into the body of the message invitation. Guest users who have OneDrive for Business accounts can also share files once the meeting starts (permissions might need adjustment to allow access to these files). Other participants can share links to files in the meeting chat during the meeting.

Files shared in meetings are in the *Microsoft Teams Chat Files* folder of the sharer's OneDrive for Business account. Teams uses sharing links to control access to files by meeting participants. One thing to note is that the sharing link applied to a file shared in a meeting doesn't give access to people who subsequently join the meeting. If new attendees join, file sharers must update the permissions to allow them access.

## Streaming Meetings and View-Only Attendees

Organizations can update Teams meeting policies to enable the use of Teams Live Events streaming services for overflow attendance at large meetings. When enabled, Teams will allow people to join a meeting after the meeting reaches its capacity. These people are view-only participants and have limited access to meeting content. Up to 20,000 view-only attendees can join a meeting. Microsoft will reduce this limit to 10,000 from July 1, 2022.

View-only attendees can:

- See the video feed for the current presenter or content they share from their desktop.
- Hear the audio feed for other full participants.

They cannot:

- Use the gallery, large gallery, or together mode views to see other participants.
- Interact with other participants through meeting chat, polls, or file sharing.

View-only attendees can join using any Teams client. They cannot join using a Teams Room system or Cloud Video Interop (CVI) services. View-only attendees don't appear in the participant list, which means that the meeting organizer can't remove them from the meeting. They don't appear in the attendance report. Because Teams uses streaming services to deliver the video and audio content to view-only attendees, the content is approximately 30 seconds behind the live meeting.

Control for view-only attendance for meetings is through the *StreamingAttendeeMode* setting in the Teams meeting policy assigned to the organizer. By default, this is False. To enable view-only attendees, update the policy to True. For example:

```
[PS] C:\> Set-CsTeamsMeetingPolicy -Identity "Allow Meeting Recording" -StreamingAttendeeMode Enabled
```

As always, it can take several hours before a policy change becomes effective.

## Using Teams Meeting Policies to Control Features

Teams meeting policies include settings to control aspects like meeting and call recording, transcription, screen sharing, PowerPoint sharing, and use of the whiteboard. The settings of the default meeting policy enable users to create all supported types of meetings within Teams. If necessary, you can create new meeting policies to disable access to some meeting features and assign the policies on a per-user basis. For example, you might decide that only specific users can record meetings. To do this, you would:

- Set *Allow cloud recording* to *Off* in the default Teams meeting policy. This setting blocks the ability of users to record meetings. To enable meeting recordings, assign users a meeting policy with the setting turned to *On*.
- Create a new Teams meeting policy where the *Allow cloud recording* and *Allow transcription* settings are enabled (set to *\$True*). This will allow meeting organizers assigned the policy to record meetings and generate automatic transcripts. The transcription setting is only available in PowerShell, so you will need to run a command like:

```
[PS] C:\> Set-CsTeamsMeetingPolicy -Identity Global -AllowTranscription $True -AllowCloudRecording $True
```

- Assign the new Teams meeting policy to selected accounts.

Although you can assign the new meeting policy to accounts through the Teams admin center, PowerShell is usually the best way to assign a policy if a large set of accounts is involved. This example shows how to fetch a set of mailboxes based on a filter against one of the custom attributes and then use the *Grant-CsTeamsMeetingPolicy* cmdlet to assign a custom Teams meeting policy to each account.

```
[PS] C:\> $Mbx = Get-Mailbox -RecipientTypeDetails UserMailbox -Filter {CustomAttribute1 -eq "Meetings"}
ForEach ($M in $Mbx) {
    Try {
        Grant-CsTeamsMeetingPolicy -PolicyName "Allow meeting recording" -Identity
    $M.UserPrincipalName
        Write-Host $M.DisplayName "is allowed to record Teams meetings" }
    Catch {
        Write-Host "Problem occurred when assigning the Allow meeting recording policy to"
    $M.DisplayName } }
```

By default, Teams meeting policies disable recordings for 1:1 calls. If you want to change this, use the *Set-CsTeamsCallingPolicy* to update the *AllowCloudRecordingForCalls* setting to *\$True*. More information about the settings in Teams meeting policies is discussed in the Managing Teams chapter.

**Teams Meeting Etiquette:** Like any other business activity, some preparation on the part of meeting attendees and a sense of how people should behave in meetings make online gatherings run smoother. Here are some basic points about Teams meeting etiquette:

- **Be on time:** There's nothing worse than people showing up late for meetings, even if the meetings are online.
- **Start the meeting muted and stay muted unless you need to talk:** There's no need to share background noise and other distractions that might be happening around you, like a jet passing overhead. Keep your microphone muted until you have something to say and make sure that your microphone is unmuted a second or so before you speak. Always mute if you need to cough, sneeze, burp, or otherwise do something that others might find unpleasant.
- **Use a camera if your PC has one:** People are more connected and involved in meetings when everyone is visible. If your network connection supports the video load, turn on your PC's camera when you join meetings, after positioning the camera so that your face is visible and head-on. Once the meeting starts, it's acceptable to turn your camera off when listening to a presentation or need to step out to do something. No one needs to see a video feed of an empty seat. Well-lit

rooms are better than dark rooms for video calls as the lighting helps camera performance. Use lighting above or to the side, never behind you. Above all, you'll look better when people can see you.

- **Blur your background:** No one needs to see just how messy your office is. Remove the distraction by blurring your background. Alternatively, you can choose to use a custom background image. If you do, make sure that your chosen image is professional and appropriate.
- **Understand Q&A protocol:** Some presenters like taking questions during a meeting. Others hate the idea because they believe questions are distracting and spoil the flow of their presentation. These presenters prefer to take questions in a structured manner when they're finished. It's good to set ground rules before presentations begin. When asking questions, make sure they're directed to someone as open-ended questions often result in a cacophony of competing voices.
- **Use meeting chat intelligently:** Every meeting includes a group chat. You can use the chat to capture questions to make sure that they are noted and either addressed during the meeting or followed up afterward. Making notes in the meeting chat is also a great way to make attendees aware of resources, such as posting links to supporting material.
- **Raise your hand:** Teams has a virtual raised hand feature that you can use to indicate to other participants that you want to speak. Use it. And presenters should keep an eye on the meeting roster to see if anyone raises their hand.
- **Use reactions to communicate with the presenter:** Reactions like the thumbs-up or like emoticon are good ways to inform a presenter what you think of their material and delivery. They are also excellent ways to avoid a barrage of responses in chats to common presenter queries like "Can you hear me" or "Can you see my screen."
- **Restrain multitasking:** You can multitask during a meeting, but if your video is on people might know that you're not concentrating on the meeting. Is that an impression you want to give?
- **Silence your phone:** If you're in a meeting, you should be involved. Don't disturb the flow of discussions by having your mobile or landline ring during the meeting. And if you do need to take another call, make sure to mute your microphone as it's highly unlikely that the other meeting participants want to listen to your call.
- **Ask before recording:** Teams is good at capturing the audio and video content for a meeting in a recording. Before you record a meeting, make sure that all participants are happy with the idea. And let them know that the recording will be available in OneDrive for Business soon after the meeting ends. The recording and transcript allow participants to check what happened during the meeting. Remember that only tenant users have access to these meeting resources.
- **Add color to the call:** Sharing app content to make your point is good, unless you have some boring PowerPoint to share (or boring Excel). If you're going to share content, make sure it's relevant, accurate, and restrained to just what people need to know.
- **Invest in a good headset:** There's nothing worse when someone in a meeting uses poor audio equipment that forces participants to strain to hear what they're saying. Do everyone a favor and invest in a good headset to use for Teams calls, preferably one that the manufacturer attests will work well with Teams.

A good way to remind people about the etiquette for online Teams meetings is to include some text in calendar invitation messages. As [explained in this post](#), a mail flow rule can insert a disclaimer in calendar messages. The disclaimer text can point to a website or contain some basic rules like those explained above.

## Creating Teams Meetings with Outlook and the Calendar App

If Teams is enabled for an account, the Teams meeting add-in is automatically loaded when Outlook starts. The add-in is available for Outlook desktop (Windows and Mac), OWA, and Outlook mobile to allow users to create and manage private Teams meetings. Each meeting has a link to the online location or thread which is included in meeting notifications and reminders. The link is a [Globally Routable User Agent URI \(GRUU\)](#), a URI formatted to allow Session Initiation Protocol (SIP) clients to connect to an online event. In the case of Teams,

the URI is a deeplink to the location in the Teams infrastructure where the meeting is hosted. Meetings created through the calendar app insert the same kind of URI.

You can think of the online location as the workspace where audio and video feeds come together to instantiate the meeting. It's one of the resources belonging to the meeting along with the participant list, recording, notes, whiteboard, and so on. Once created, the online space is available for any participant to join, even if the starting time for the meeting is long in the future. This facility exists to allow people to prepopulate a meeting with resources, like notes or shared files, before it begins. Likewise, a meeting persists after its formal end time to allow participants to access its resources after the meeting finishes.

To allow meeting participants to navigate to the online workspace, Outlook populates several properties of the calendar event such as *OnlineMeetingConfLink* and *SkypeTeamsMeetingURI* with joining information. Outlook and the Teams calendar app use these properties to recognize the event as an online event and to show the Join button in meeting reminders and other places in the client UI. Clicking the Join button (or the *Join Microsoft Teams Meeting* link in the body of the meeting item) starts the process of joining the meeting, which might involve navigating through a web page to choose how to join and waiting in the meeting lobby for admittance. An example deeplink for a Teams meeting looks like this:

```
https://teams.microsoft.com/l/meetup-join/19%3ameeting_ZjcxMDVhNjYtOTE4OS00ZTFmLTlkOWQtMzQ1MjZjNjc4M2Ni%40thread.v2/0?context=%7b%22id%22%3a%22b662313f-14fc-43a2-9a7a-d2e27f4f3478%22%2c%22oid%22%3a%22eff4cd58-1bb8-4899-94de-795f656b4a18%22%7d
```

All instances of a recurring meeting use the same joining information. In other words, the same online workspace hosts all instances of a recurring meeting.

Users can copy the deeplink for a meeting from the body of the invitation or the Teams calendar app (it's available in several places, including if you right-click on a meeting). People often retrieve the deeplink to send it to other people who might want to join the call. Any client can use the deeplink to join the meeting.

Apart from using the deeplink to connect to a Teams meeting, people can use a combination of meeting identifier and passcode to join. The Teams meeting invitation includes the necessary details, which can be entered into a Teams client or the or the special webpage <https://www.microsoft.com/microsoft-teams/joinmeeting>.

**Tip:** If you edit an Outlook meeting and update the Join Microsoft Teams Meeting link, you can add the string *&webjoin=true* to the end of the link to force users to join the meeting with the browser client instead of getting the option to choose between joining with the browser or desktop client.

## Private Meetings

A private (or personal) meeting is one scheduled by an individual user with other tenant accounts, external users, distribution lists, and Microsoft 365 Groups (for the groups included in the GAL). After entering the invitees, Exchange Online sends a copy of the meeting invitation to each participant, who can accept or decline the invitation. Like Outlook, the Teams calendar app has a scheduling assistant to help find the right time for a call.

When you add a distribution list to an invitation, Exchange Online expands the membership and sends notifications to the individual recipients. Distribution lists can contain recipients like other groups, mail contacts, mail users, and even public folders, so you might not know the full set of users who receive invitations to a meeting. Microsoft 365 groups don't support nested groups and are composed of mailboxes and guests.

Teams meetings appear along with other events in the personal calendars in the mailboxes of participants. The Teams calendar app synchronizes data from the personal calendar. If reminders are set for meetings,

Outlook notifies users when meetings are about to happen. Except for an icon posted alongside a channel name when a meeting is in progress, Teams does not have an external notification mechanism of its own to let people know about active meetings, but they can join a meeting from an Outlook reminder or the events in the Outlook or Teams calendars.

You can also schedule recurring meetings by selecting a value such as Daily, Monthly, or Yearly from the Repeat drop-down list.

## Meeting Recap

A notable feature available to private meetings is “meeting recap,” which is how Teams highlights important resources under the Details tab for the meeting. After a meeting is over, participants can access the meeting recording and transcript, and the organizer can access the attendance report here. Channel meetings and Meet Now meetings support recordings, but don’t generate a transcript.

## Transcription and Recording

Meeting organizers have the option to capture a recording or transcript as records of what occurred during the meeting. Meeting recording is available for all forms of meetings. Organizers, co-organizers, and presenters can initiate recording from the desktop, browser, and mobile clients. Teams stores meeting recordings as MP4 files in OneDrive for Business (personal meetings) or SharePoint Online (channel meetings).

Enterprise Teams licenses include support for live captions, CART captions, captions in other languages, and automatic transcription. This functionality includes access to captions for anonymous meeting participants. If permitted by the meeting policy assigned to the meeting organizer, participants with the organizer, co-organizer, or presenter roles can initiate transcription for private meetings using the Teams desktop client. Microsoft says that they will introduce the feature for channel and Meet Now meetings in the future. To generate live captions and create the transcript, Teams uses an AI-based learning model to listen to the audio feeds of participants and analyze what they say. Originally only available in English, live captions and transcription now support multiple languages including Arabic, Chinese, German, French, Italian, Russian, Spanish, and Dutch with more languages becoming available over time. Support means that the AI can recognize and parse the spoken contributions of people in those languages. The AI can capture but cannot understand participant contributions in other languages, so the output won’t make much sense.

Transcription includes speaker attribution, meaning that Teams includes the name of the speaker alongside their contributions. Attribution makes it easier for people to know who said what during a meeting. If users prefer, they can disable attribution in the *Captions and transcripts* section of Teams client settings. When this happens, Teams inserts generic speaker identifications (like “Speaker 1”) instead of their real names.

After the meeting finishes, Teams generates the final copy of the transcript and makes it available in the meeting recap and through the Recordings & Transcript tab for the meeting. Users can then download the transcript in Word (DOCX) or Video Text Track (VTT) format. Guest users don’t have access to the Teams calendar app, so they can’t access the transcript. Only the meeting organizer or a Teams administrator can remove a transcript.

Pointers to transcript data are in the meeting organizer’s mailbox. However, the transcript texts are not in the mailbox and are therefore not indexed and discoverable. In many cases, organizers download the transcript to a Word document and fix any errors created by the AI to produce a final record of the meeting. If this document is stored in OneDrive for Business or SharePoint Online, or attached to an Exchange Online message, it will be indexed and discoverable.

## Attendance Report

After private meetings finish, Teams generates an attendance report for the meeting organizer. The Teams back end generates the meeting data from the information gathered in the Graph as people join and leave

the call. Teams stores the data for these reports in [a hidden folder of the meeting organizer's Exchange Online mailbox](#). The meeting organizer can view the information through Teams by opening the meeting and going to the attendance tab. Alternatively, they can download the data to a CSV file (a sample attendance CSV file is shown below).

#### Meeting Summary

Total Number of Participants	8
Meeting Title	High Performer Review
Meeting Start Time	15/1/2021, 11:13:08
Meeting End Time	15/1/2021, 12:45:48

Full Name	Join Time	Leave Time	Duration	Email	Role
Sarah James	15/1/2021, 11:22:59	15/1/2021, 12:45:48	1h 22m	Sarah.James@Office365itpros.com	Attendee
James Ryan	15/1/2021, 12:02:24	15/1/2021, 12:37:15	34m 51s	James.Ryan@office365itpros.com	Attendee
Michael Conroy	15/1/2021, 11:22:59	15/1/2021, 12:45:48	1h 22m	Michael.Conroy@Office365itpros.com	Attendee
Tony Redmond	15/1/2021, 11:13:08	15/1/2021, 12:45:48	1h 32m	Tony.Redmond@office365itpros.com	Organizer

Meeting attendees cannot access the attendance report. However, the organizer can download the data and share the CSV file with attendees if they wish.

It's possible that the meeting organizer will restart a meeting several times with each instance having a different attendance. Teams generates a separate version of the attendance report each time a meeting restarts. The organizer can choose which version to view using a drop-down menu in the attendance tab. Downloading the CSV file uses the data for the latest instance of the meeting. However, if the organizer goes to the meeting chat, they can select whichever instance they wish to download that data.

## Lobby Bypass

The lobby is a virtual area where participants wait for admittance to a meeting. The lobby bypass setting for a meeting dictates who can join a meeting without waiting. The default value for lobby bypass is set by the Teams meeting policy assigned to the meeting organizer. The organizer can amend the lobby bypass setting for a meeting afterward by updating the meeting options. The following values are available:

- **Everyone:** All users, including anonymous users, can join the meeting without waiting.
- **People in my organization, trusted organizations, and guests:** Everyone with a tenant or guest account, or those with accounts in federated (trusted) organizations, can join without waiting.
- **People in my organization and guests:** Only people with accounts in the tenant directory can join without waiting.
- **People in my organization:** Only tenant users can join without waiting.
- **Invited people only:** Only those who receive an invitation to the meeting (they are on the attendee list) can join without waiting. It's a good idea to amend meeting settings to disable the ability for users to forward invitations to other people for meetings with restricted attendance. The flag prevents [email clients which can block forwarding of meeting invitations](#) from showing the forward option. However, those who receive invitations via forwarding can still join automatically, which is why it's a good idea to check the participant roster during confidential meetings.
- **Only me:** Only the meeting organizer can join automatically. Everyone else must wait for admittance.

The more sensitive a meeting, the tighter control should apply to lobby bypass.

## Channel Meetings

Channel meetings differ from personal meetings because they are scheduled by someone on behalf of the channel using the calendar app or the channel calendar app. Because it's designed to create personal

meetings, the Teams meeting add-in for Outlook doesn't support the scheduling of channel meetings. When a channel meeting is created, the team owning the channel becomes the meeting owner and the meeting is created in the group calendar of the team's group mailbox instead of the organizer's calendar. The group calendar stores meetings for all channels in a team, and the channel calendar app applies a filter to display only the events belonging to the channel into which the app is installed.

Because they act as the meeting organizer, the original creator of a channel meeting can change its details, such as adding extra attendees, altering the time, or deleting the event. Channel meetings are open to any member of the team the channel belongs to and therefore members don't need specific invitations to attend these meetings. Another way of looking at this is that people don't need to attend the meeting unless they are interested in the topic. It's there for them to attend, but there's no compulsion to be there.

If you don't add team members to the participant (invitation) list for channel meetings, they learn about the meeting by seeing it in the channel. When the meeting is active, Teams posts a new topic in the channel with a join button for members to participate. A camera icon is also shown beside the channel name in the team list. Unless they are added to the attendee list, only members receive invitations to channel meetings if they are subscribed to the group for calendar events. Users can update their subscription settings for a Microsoft 365 group by opening it in OWA and editing the **Manage group mail** settings from the [...] menu. The group is only available in OWA if it is not hidden from Exchange clients. However, most of the groups used by Teams are hidden, so some administrator intervention is often necessary to update group subscriber lists. See this [article for more information](#) about how to use PowerShell to update group subscriptions so that team members receive invitations for channel meetings.

Any member of a team can attend a channel meeting. The organizer can invite people from outside a team to join a channel meeting. These participants can attend the meeting, but they won't be able to participate in the meeting chat, or access shared documents, or the transcript because they don't have access to resources stored in the channel.

Private channels can't host channel meetings. Although they belong to a team, private channels don't have access to its group mailbox, so they can't schedule the meeting in its calendar. Another restriction to remember is that after you schedule a meeting in a channel, you can't edit the meeting to move it to another channel. If you create a meeting in the wrong channel, you must remove the original meeting and reschedule it in the correct location.

**Don't Use Channel Meetings for Sensitive Subjects:** Because any member of a team can attend a channel meeting, it's a bad idea to use channel meetings to discuss sensitive or confidential topics. Doing so creates the risk of inadvertent information disclosure. For instance, any member of the team can view the recording of a channel meeting or access files shared in the meeting. Use personal meetings instead as this gives you the ability to control who attends the meeting and who can access content shared in the meeting.

## Channel Meetings App

The channel meetings app is one of the Microsoft apps automatically available to a tenant. The app can be installed as a tab to allow team members to access meetings scheduled for the channel. Events for all channels are in the group calendar, so the app filters and displays the meetings for the channel into which it is installed. The interaction between users and meetings is like that available in the Teams calendar app. Because guests don't have permission to access the group calendar, the channel meetings tab isn't available to them. Any other member can use the app to schedule or view channel meetings. As with channel meetings scheduled through the Teams calendar app, the person who creates a meeting is its organizer and is the only one who can update meeting settings.

## Meet Now Unscheduled Meetings

The Meet Now feature is a way for users to launch impromptu or unplanned meetings without having to schedule a formal event. *Meet Now* events are launched by clicking  the Teams calendar app (to create a private meeting) or a channel (to create a channel meeting) on the  desktop, browser, and mobile clients. The Teams meeting add-in for Outlook for Windows also includes a Meet Now button to create a private meeting. As with other Teams meetings of the same type, participants must be invited to private meetings while channel meetings are available to the members of the team which owns the channel.

The ability to use Meet Now is controlled by two settings in the Teams meeting policy assigned to user accounts:

- **Allow Meet Now in channels:** Controls if the user can use Meet Now to create a new channel meeting. Applies to all channels in all teams the user belongs to.
- **Allow Meet Now in private meetings:** Controls if the user can use Meet Now to create private meetings.

When using PowerShell to manage policy settings, run the `Set-CsTeamsMeetingPolicy` cmdlet and set `AllowMeetNow` and `AllowPrivateMeetNow` to True (allowed – the default) or False (blocked). In most cases, being able to create meetings on demand is a welcome capability and organizations are happy to let the feature be used. The usual situation where Meet Now is disabled is in education scenarios where organizations often block students from organizing online events.

## Planning Meetings

Teams currently doesn't support a way for a user or administrator to create a specific type of meeting, such as starting with everyone's video turned on to display a corporate background image. Meetings are treated separately, meaning that when you create a meeting, you can configure some meeting settings (like who can present in the meeting), and when you join a meeting, you need to configure your video and audio settings for that meeting.

Some aspects of meeting functionality are controlled by the Teams meeting policy assigned to the organizer's account. For example, the screen sharing mode control in the meeting policy assigned to the organizer determines if desktop and/or window sharing is allowed in a meeting while the allow chat setting controls if participants can chat during the meeting. Other important controls are those that allow anonymous people (dial-in users) to start a meeting (without an authenticated user being present) and which participants can join a meeting automatically (without being forced to wait in the meeting lobby). This is an important control if your tenant commonly organizes meetings with external people because you might want to force organizers to be sure that a meeting is ready to begin before admitting certain types of participants. The available options to restrict the ability to join meetings automatically are described above under "Lobby bypass."

The last option is useful in a policy assigned to organizers who often create meetings where confidential or sensitive information is discussed. Remember that a meeting policy sets the default for meetings created by people; organizers can change settings for created meetings through the Teams meeting add-in for Outlook or the Teams Calendar app to adjust the lobby bypass settings if necessary. For instance, the organizer can decide that only people who receive direct invitations to the meeting (their email address is in the invitee list) can bypass the meeting lobby. Another interesting control available to the organizer is how meeting chat works. They can enable chat (the default), disable chat, or enable it only while the meeting is active.

**Guard the Meeting Link:** As described earlier, clients use the deeplink pointing to the online meeting space to join the meeting and access meeting resources. Anyone with a deeplink for a meeting can join it and might gain automatic admittance if allowed by the meeting policy assigned to the organizer or the lobby bypass settings for the meeting. Uninvited attendees will be able to access the video and audio

feeds, including any information shared during the meeting. In private meetings, they can access the meeting chat. This isn't possible in channel meetings because access is restricted to members of the team owning the channel. Because possession of a deeplink makes this access possible, it's important that the organization considers who can join a meeting automatically and organizers tune lobby bypass settings for confidential meetings to restrict access to those invited.

## Meeting Roles

When planning larger or more structured Teams meetings, it is usually important to define specific roles for some participants. For regular meetings, including webinars, the roles are:

- **Organizer:** The organizer is the person who creates the meeting. The organizer has full control over the meeting, its participants, and meeting settings.
- **Co-organizer:** Optionally, a meeting can have up to ten co-organizers chosen from the tenant users invited to the meeting. Guest accounts can't be co-organizers. Apart from managing breakout rooms, users with this role can manage the other aspects of meeting while it is active. However, they cannot edit the meeting invitation or access the attendance report.
- **Presenter:** This is also an optional role. By making a tenant user or guest user from another tenant a presenter, the meeting organizer allows them to share content like presentations during the meeting. Presenters can also start and stop the meeting recording and manage participants (mute and remove participants, admit people from the lobby).
- **Attendee:** All other invited participants are attendees. These are full participants in the meeting (they can speak and chat). However, they can't share content, present, or manage the meeting in any way.

For Teams Live Events, the roles are:

- The **Producer** is responsible for making sure the presentation works. The producer is also responsible for managing the feeds in the event and monitoring the quality and stability of the event. This role serves the same purpose as the organizer of a regular meeting.
- **Presenters** focus on content delivery.
- The **Moderator** follows questions asked by attendees to answer questions or to ask the speaker when they finish presenting. The moderator can be a person assigned the producer or presenter role.

The big difference between live events and regular meetings is that attendees are more restricted in live events as their role is essentially passive. By comparison, participants in regular team meetings can usually interact with each other unless meeting settings prohibit chat or a meeting organizer, co-organizer, or presenter mutes them.

[This article](#) describes what presenters and attendees can do during meetings. The short version is that presenters have all capabilities, but attendees can only join in the meeting chat (unless this feature is disabled), speak and share videos, and view PowerPoint presentations shared privately.

## Updating Meeting Options

The *Roles that have presenter rights* setting in the Teams meeting policy assigned to the meeting organizer sets the default presenter right for meetings created by that person. The options are:

- Everyone can present.
- Everyone in the organization (including guests) can present.
- Specific people can present.
- Only the organizer and co-organizers can present.

When the meeting is created, Teams sets the presenters for the meeting according to policy. Later, you can modify the roles assigned to meeting participants. For structured meetings, it's common to find that you need to nominate some people to be presenters before the meeting starts. To preassign the presenter role, you:

- Add the people you want to be presenters to the meeting participant list.
- After the meeting is created, you can update meeting options through the calendar app or the Teams meeting add-in.
- Select specific people to be presenters (the other option to nominate presenters are Everyone, people in the organization, and only me).

Once you limit who can present in a meeting, you also restrict people outside your organization from presenting because you can't preassign the presenter role to external participants (including guests). However, once the meeting starts, you can update the role of these participants to allow them to present.

For larger meetings, it's best to restrict the set of presenters to those you expect to speak and use the (virtual) raise hand feature to allow other attendees indicate if they wish to contribute. Presenters can see who's got their hands raised (if multiple people raise their hands, they are listed in chronological order based on when they raised their hands). If people are muted, the presenter can unmute them to allow them to speak and lower their hand in the list.

When a meeting is active, you can change a person's role. For instance, you can make an attendee a presenter and vice versa. Do this by viewing the meeting participants in and selecting *More options* for an individual participant. These controls are not available in channel meetings.

## Galleries and Together Mode

The view of participants displayed in Teams meetings is known as a gallery. Teams creates a tile for each participant to display their video feed. If the user disables their video feed, Teams uses the photo from the user's account or their initials if no photo is available. Galleries have three view options:

- The **default gallery view** shows nine tiles in a 3x3 arrangement. If more than nine participants are in a call, Teams prioritizes those with video turned on and highlights the current speaker. If more than nine video-enabled participants are in a call, Teams shows the most active speakers in the tiles. The default gallery view is available to all clients. Teams meeting recordings use the 3x3 view.
- The **large gallery view** accommodates up to 98 tiles in a 7x7 view (organized in pages) with navigation controls to move between the pages. The standard 3x3 view also supports paging. The desktop and Chromium-based browser clients support the large gallery view.
- **Together mode** is available in meetings with more than five participants. The difference between Together mode and the gallery view is that the gallery shows tiles for participants while Together mode uses artificial intelligence to isolate the head and shoulders from the video feed for each participant before combining the feeds in a background scene. According to Microsoft, active participation increases when large meetings use together mode. Meeting organizers and presenters can select a background to place people into from a set provided by Microsoft, including some suitable for large meetings (like an amphitheater) and others suitable for smaller gatherings (like a boardroom). When they enable together mode, meeting organizers and presenters can choose to *Select Together Mode for Everyone*. This option applies together mode with the selected scene for all participants. New participants join in together mode with the selected scene. Participants can switch to the regular gallery mode if they prefer.

Teams dynamically adjusts the view available to meeting participants based on factors such as the number of attendees, who enables their video and who uses audio only, active speakers during meetings, and when people share content during the meeting. Here's how dynamic view affects what attendees see:

- Tiles for attendees with video feed enabled appear differently to those who only use an audio feed, Audio participants appear in smaller tiles (a reasonable call because a set of initials or a static photo in a circle isn't very visually compelling).

- Content shared in a meeting, like a presentation, app, or whiteboard, is given more space. Depending on how many people are in a meeting, dynamic view resizes attendee tiles to make them more visible.
- Users can pin or spotlight selected attendees to make their cards larger than other participants.
- The together mode view can appear alongside content.
- Users can “dock” the gallery of attendee cards on the top of their screen.

Dynamic view aims to make meetings more visually interesting than the flat gallery views used in the past. The hope is that user attention and engagement will be higher because Teams adjusts the view to concentrate on the most important content in the meeting.

**Customizing Together Mode:** Tenants can [create and package new background scenes for Together Mode in the developer portal](#) (here's a [description of how to build a new scene](#)). This capability requires a Teams advanced communications license.

## Background Effects: Images and Blurring

No one likes distracting other meeting participants with a video feed of a messy office. To help people disguise messy surroundings, they can use a background filter in personal and channel meetings. Background filters work by isolating the image of a user from their video feed and replacing the background with either:

- **Background blur:** The user's surroundings are blurred.
- **Custom background image:** The user's image is merged with a background image. The image can be selected from a standard set provided by Microsoft, or a custom image obtained from another source and uploaded to a workstation or mobile device. In effect, the mechanism works like a video green screen.

If their camera is on, users can select a background filter through the pre-join screen or by using the **Apply background effects** option during a meeting. CTRL + Shift + P is the Windows keyboard combination to invoke this option.

To apply the chosen filter, Teams uses artificial intelligence to work out what part of the image is the user and what forms the background, and then applies the filter to the background. On Windows PCs, the ability to apply background filters depends on the workstation having a post-Haswell chipset with AVX (Advanced Vector Extensions); all recent PCs should have the necessary hardware.

### Background Filters Policy Setting

The ability for users to choose background filters is controlled by the *VideoFiltersMode* setting in the Teams meeting policy assigned to an account. The available values for the *VideoFiltersMode* setting are:

- **NoFilters:** No filters are available.
- **BlurOnly:** Background blur is available (but only if certain hardware conditions are met).
- **BlurAndDefaultBackgrounds:** Background blur and the set of curated background images selected by Microsoft can be used.
- **AllFilters:** All filters are available, and the user can upload and remove custom images. This is the default value for meeting policies.

You can change the background filter setting by updating a Teams meeting policy in the Teams admin center. Alternatively, you can update the *VideoFiltersMode* setting for a meeting policy by running the PowerShell *Set-CsTeamsMeetingPolicy* cmdlet. For example, this command removes the ability to use background filters from any user assigned the *RestrictedFunctionality* meeting policy.

```
[PS] C:\> Set-CsTeamsMeetingPolicy -Identity RestrictedFunctionality -VideoFiltersMode NoFilters
```

Two standard filters designed to improve the appearance of users in video meetings are unaffected by the policy setting. The brightness filter lightens a participant's image in the video feed to make it clearer when the

lighting in the area where they sit is dark. The effect is much like using a ring light. The soft-focus filter smoothens facial wrinkles and lines to make them less distinct. The filter works better for some people than it does for others. These filters are supported on the Teams desktop client for Windows and can be enabled before joining a meeting or while the meeting is in progress.

## Standard and Custom Background Images

The basic Teams license allows the use of two types of background images:

- **Standard images.** A set of curated background images chosen by Microsoft. These images are stored on a content delivery network (CDN) to make them available to all users. If you choose one of the standard images, Teams downloads a copy of the image to the device. On a PC, downloaded images are stored in the %AppData%\Microsoft\Teams\Backgrounds folder. Sometimes users can't reach the CDN to access the standard images. Usually, this is because of a VPN or other network restriction. To test, try and access one of the standard Teams background images, like [the contemporary office scene](#).
- **Custom images.** You can upload your JPEG or PNG images using the Teams client or by copying the files to the following folders.
  - PC: %AppData%\Microsoft\Teams\Backgrounds\Uploads.
  - Mac: /users/<username>/Library/Application Support/Microsoft/Teams/Backgrounds/Uploads (you may need to hold down the Option key before you choose Go from the Finder Menu to get the Library to appear).
  - Mobile clients: The iOS and Android clients allow users to upload their images to local storage.

When you browse the set of available images, Teams shows the standard images first followed by custom images (blur is included as a standard image). The images are ordered alphabetically within their respective folders. Users can remove images they upload by hovering over the image and selecting the Remove option. Standard images cannot be removed. After a user selects a background filter (blurring or image), Teams displays that effect for every meeting they join with video-enabled until the user selects a new filter.

Microsoft publishes suitable images for use with Teams in a [public custom backgrounds gallery](#). Other companies create their custom background images for use with Teams and other conferencing software, and some release the images for public use (images released for Zoom can also be used by Teams). Two examples are the images [made available by IKEA](#) (a major Teams customer) and [Star Wars](#). A collection of free-to-use background images intended for use as [PC wallpapers is available online](#). You can also download and use the images used on the Bing home page using [this PowerShell script](#).

Microsoft's guidelines for custom background images are that images should be a minimum of 360 x 360 pixels and a maximum of 2048 x 2048 pixels. Images at the minimum size will look horrible. Best results are gained when you use images with a 16:9 ratio sized at 1920 x 1080 pixels (the default size used by Microsoft and other sites) with the resolution scaled to produce files of around 1 MB. Files can be larger in both pixels and size as the uploading process will downscale them to fit. Best results are always obtained when you control the sizing process and generate images yourself. When displayed in a video feed, the operating system will adjust the image to fit the screen display. Depending on the shape of the screen, some of the images might not be visible at the edge. To avoid problems, make sure that the important part of an image is in the center.

If you use Teams on several workstations and want to use the same custom background images everywhere, you must load the images onto each workstation. Although they can control the level of access users have to background filters, tenants cannot mandate the use of a standard image.

## Organization Images

Organization or corporate images are a feature of the Teams Advanced Communications add-on. Tenant administrators can upload images in the meeting policies section of the Teams admin center. The images then become available to users with the Teams Advanced Communications add-on and are shown before the Microsoft-curated set of standard images. If a user selects an image, Teams downloads it from the cloud to the same folder used to store custom images and uses it as the meeting background. Teams desktop and mobile clients support organization images. See [this article](#) for more information.

## Noise Suppression

Device settings in user profiles have settings to control how Teams suppresses background noise during a meeting. Available for the Teams Windows and macOS desktop clients and the iOS mobile client, noise suppression uses the CPU to process background noise around the meeting participant using the workstation to eliminate sounds like paper rustling or fans. The higher the level of suppression, the more computer resources are used. You can choose from:

- **Auto:** Teams manages background suppression and tune it up or down depending on the level of ambient noise.
- **Low:** Use this level when music or a low consistent level of noise is present in the background.
- **High:** The maximum level of noise suppression is used. This might be chosen by someone working in a very noisy environment.
- **Off:** No background noise suppression is used.

The setting in a user profile becomes the default for all meetings. If needed, you can select a different setting during a meeting from the Devices option in the meeting menu.

Noise suppression is done on the audio feed from the workstation to the meeting. It does nothing to improve the sound received by headsets or phones. To ensure the best quality sound in meetings, use a Teams-certified device. Teams does not apply noise suppression when a meeting is recorded (suppression is applied to the recording as a whole) or when live captions are used.

## Maintaining Focus During Meetings

A busy Teams user can receive multiple notifications during a meeting to inform them of @mentions, replies posted in chats, and so on. These notifications can become disruptive and distracting during meetings. Two controls are available to help. First, a user can opt to mute notifications during all meetings by selecting this option in the Meetings and Calls section under Notifications in Teams client settings. Second, if they prefer to control notifications on a meeting-by-meeting basis, they can use the *Mute notifications* option (in the [...] menu) during a meeting. This option disables notifications for the current meeting. An *Allow notifications* option restores notifications for the current meeting.

Teams displays the video feeds from individual users on cards in a gallery during meetings. User feedback revealed that the presence of a user's video feed in the set of cards shown in the gallery can distract and become a source of anxiety for some users. To resolve the issue, meeting participants can select their card and then use the Hide for me option from the [...] menu to transform their card into a chevron. Everyone else in the meeting sees the user's video feed as normal. By clicking the chevron, the user can restore their video feed and display it in their gallery.

## Music Mode

Teams music mode leverages [the Satin codec](#) to transmit high-fidelity sound in meetings and calls. When music mode is used, Teams adjusts the sampling rate automatically up to 32 kHz at 128 kbps using the available bandwidth to deliver the best possible sound quality (the transmission of acceptable human voices

requires a much lower bitrate). The lowest bitrate for good quality sound is 48 kbps. Because sound quality is linked to available bandwidth, Microsoft recommends that you use music mode only when connected to wired networks.

In environments like a studio with low background noise and microphone control, users (including guests joining calls in other tenants) can control the audio stream further by turning off noise cancellation and disabling echo cancellation if using closed-back headphones. If using professional microphones with external gain adjustment, you can disable the auto-adjust microphone sensitivity setting. Microsoft recommends that you don't use Bluetooth headsets with music mode.

The important thing to realize about using music mode is that you must enable the feature in Teams settings before you join a call or meeting. You can also decide to enable echo cancellation, noise cancellation, or auto-adjust microphone sensitivity. If you forget to enable music mode before starting a call, you'll have to leave the call, enable music mode, and restart. With music mode enabled, you'll see a music note symbol in the control bar to toggle music mode on and off. You can leave music mode enabled for the entire meeting or turn it off once the music finishes reducing the demand for bandwidth and codec processing. In addition, music mode doesn't suppress background noise as well as regular mode does.

## Using Whiteboard in Teams Meetings

Whiteboard is an application intended to allow people to collaborate by drawing and refining ideas on a digital canvas (a board), or as Microsoft says an *"infinite canvas where imagination has room to grow."*

Whiteboard runs as an Azure service and is enabled by default for all Office 365 enterprise tenants. If you want, you can disable Whiteboard through tenant settings in the Microsoft 365 admin center.

Users can access Whiteboard through the Office menu, which launches the [browser version](#), signing in with their Azure AD credentials to create, update, or remove boards. Versions of Whiteboard are also available in the Microsoft Store and [for iOS](#) and [Android](#).

Whiteboard in Teams can be installed as [an app in a channel tab](#). It is also available in the share tray for Teams meetings. When invoked in a channel tab or meeting, you can choose to open Whiteboard in Teams or use the app (if installed on a Windows PC). If your PC supports digital inking, you can draw with your finger or a digital pen on a board, which works surprisingly well. Whiteboard includes support for note grids, an wide range of colors for sticky notes, ink, and highlighting, along with templates designed to get ideas flowing. The same capabilities are available in the Teams, Windows, or browser clients.

When you create a board for a meeting, it is associated with the meeting and all meeting participants can access the board during the meeting and afterward (the whiteboard is listed as a meeting resource). Because a board is a common resource that everyone connects to, changes made to the board are seen everywhere in real-time. Guest members can interact with boards during a Teams meeting, but full guest access to the Whiteboard service isn't currently available.

Often a discussion centered around a board will conclude that you want to share with other people who weren't in the discussion. A Post to Teams option is available in the Windows app to post a link to the board as a message in a selected channel. The link can be copied from Teams and used to share the board with other people via email or in a personal chat. Clicking the link opens the board in the app (if installed) or the browser. You can only share boards with other tenant users. It's also possible to invite other users to collaborate in Whiteboard through sharing invitations sent via email. The link can be read-only or allow full write access. When the recipient accepts the invitation, Whiteboard adds the board to their list of available boards and opens the board to allow them to contribute immediately. Invited users aren't allowed to delete boards.

If you don't want to send a link to allow access to a board, you can save a static view of a board as a graphic file (PNG format) and include the file in an email, document, or web page.

All boards created in Teams meetings are stored in OneDrive for Business and have the same “Whiteboard meeting” name. To avoid confusion, you can use the app to select a board in the list of boards and edit it to assign a more meaningful name. For now, Whiteboard content is not captured by Teams compliance records, nor is the content indexed and available to content searches and eDiscovery cases.

Teams isn't limited to Whiteboard when it comes to discussing ideas on a digital canvas as [other brainstorming applications](#) are available in the Teams app store.

## Meeting Reactions

Teams meetings allow attendees to react to whatever's happening in the meeting with a set of four emoticons. Like how the virtual hands-up feature works, the attendee selects the emoticon they wish to use (like a laugh or thumbs-up) and sends it. The reaction is visible to others on their attendee card or, if someone is presenting or sharing information at the time, reactions float up from the bottom of the screen.

Some organizations don't like meeting reactions. You can disable the ability of users to send reactions through the *AllowMeetingReaction* setting in the Teams meeting policy assigned to meeting organizers. In this example, we disable reactions for meetings organized by anyone assigned the default meeting policy.

```
Set-CsTeamsMeetingPolicy -Identity "Global" -AllowMeetingReactions $False
```

Note that meeting organizers can override the meeting policy by editing the settings of a meeting to allow reactions.

## Meeting Polls

Meeting organizers and presenters of personal meetings can create simple single-question polls with up to six answers and make them available to attendees before and during meetings. Polls aren't supported for channel meetings or live events. The Microsoft Forms app for Teams is used to create and manage polls and the app must be added to a meeting before polls are available.

Polls can be published to attendees before and during meetings. When published during a meeting, users of Teams desktop and browser clients see the poll questions in a pop-up notification in the middle of the meeting window and can respond there. Teams publishes the poll as a card within the meeting chat, where it can be accessed by Teams mobile clients. Polls can be opened and closed as needed during a meeting and the results are displayed to users as responses come in unless the poll is marked as anonymous. Once complete, poll results can be exported and downloaded in an Excel worksheet.

Meeting polls are stored as a personal form in the user's account and can be accessed to view results through the Forms app (the forms used by Teams polls are read-only in the Forms app). See Chapter 9 of the companion volume to learn more about Forms.

## Teams Webinars

A Teams webinar is a special form of meeting created when a user selects *webinar* from the drop-down *New meeting* menu or if they choose a value for the *Require registration* setting for a meeting. Along with the normal meeting functionality, a webinar has a sign-up page created by the organizer to allow potential internal or external participants to register for the event. The organizer can customize the sign-up page to collect information about attendees such as their name, company, and custom fields that can be used to collect data relevant to the webinar topic. Presenters and other interested parties are invited to the meeting. Those who register through the sign-up page attend the meeting at the regular time using event details (including an .ics file) emailed to them by Teams. Teams keeps registration and attendance reports to allow webinar organizers to compare those who signed up with the eventual attendance.

Settings in the Teams meeting policy assigned to user accounts control who can schedule webinar meetings and if webinars are internal-only or accessible by both internal and external attendees. The settings are configurable by PowerShell and are:

- **AllowMeetingRegistration:** Controls if a user can create a webinar meeting. The default is *True*.
- **WhoCanRegister:** Controls the attendees who can attend a webinar meeting. The default is *EveryoneInCompany*, meaning that internal accounts and guest accounts can attend. If you want to organize public webinars, set the value to *Everyone*. If anonymous join is disabled in the meeting settings for the tenant, anonymous users will be unable to join webinars even if the *WhoCanRegister* setting is *Everyone*.
- **AllowEngagementReport:** Controls if the user can download the [meeting's attendance report](#) and the registration report. Make sure this value is *Enabled* as a big part of running a webinar is knowing about audience acquisition and participation.
- **StreamingAttendeeMode:** Controls if Teams uses overflow capability once a meeting reaches its capacity (1,000 users with full functionality). Set this to *Enabled* to allow up to 20,000 extra view-only attendees to join.

For example, this command enables the necessary settings in a Teams meeting policy:

```
[PS] C:\> Set-CsTeamsMeetingPolicy -Identity "Allow Meeting Recording" -AllowMeetingRegistration $True -WhoCanRegister Everyone -AllowEngagementReport Enabled -StreamingAttendeeMode Enabled
```

Teams generates attendance reports for meetings when the *AllowEngagementReport* setting of the meeting policy assigned to the organizer is *True*. Webinars also have a registration report, controlled by the same settings. The attendance data can also be downloaded as a CSV file, which is especially useful if a meeting organizer wants to do some analysis of meeting attendance.

## Breakout Rooms

Teams breakout rooms allow a Teams meeting to be split into several subordinate meetings (the breakout rooms) linked to the main meeting. The feature is designed to support scenarios like brainstorming sessions, online classes, and corporate events which often start by assembling all the participants to set the goals before dividing into smaller groups to work on specific issues, and then come back together to report findings and make decisions. The basic flow for breakout rooms is:

- A meeting starts as normal. The meeting organizer chooses the breakout rooms option in the meeting control bar to create the number of breakout rooms needed for sub-groups. Additional breakout rooms can be added or removed later, up to the maximum of 50 rooms. To make their purpose clear, breakout rooms can be renamed. For example, a group working on a corporate merger might have breakout rooms for Finance, HR, and Legal. Microsoft says that in the future you'll be able to predefine breakout rooms including room assignments before a meeting starts.
- The meeting organizer assigns meeting participants to the different rooms. This can be done manually or automatically (participants are evenly divided at random among the available rooms). Users can be moved between breakout rooms.
- After assigning participants to breakout rooms, the organizer uses the Start rooms command to allow the participants assigned to each room to begin work. It's possible to open rooms individually if you don't want them all to begin at the same time. A setting controls whether people are moved automatically into their assigned rooms (the default) or receive a prompt to join. Those assigned to a breakout room cannot add other people – this can only be done by the meeting organizer.
- The organizer can set a countdown timer for the rooms. When the timer expires, participants rejoin the main meeting or leave the meeting.

- Participants meet in the breakout rooms and use normal meeting functionality such as chat, app sharing, turn on together mode, and collaborate with a whiteboard. To encourage people to participate, everyone in a breakout room is assigned the presenter role.
- The meeting organizer can visit the breakout rooms to help keep everything on track. When they join a breakout room, the organizer can work with the other participants.
- The meeting organizer can also make announcements to all breakout rooms. For instance, they might send a note to remind people that the breakout rooms will close in five minutes and that someone should be nominated to present findings. Announcements are posted to the meeting chat in each open breakout room. If participants in a room need to contact the meeting organizer, they can send an @mention message in the chat.
- To bring the meeting back together again, the organizer closes the breakout rooms (or the countdown timer expires). After a short delay, the participants from the breakout rooms rejoin the main meeting. If necessary, the organizer can reopen a breakout room to allow people to restart discussions. Attendees cannot close breakout rooms.
- After wrapping everything up with the complete set of participants, the organizer ends the meeting.
- Separate meeting chats and notes are kept for each room and the main meeting. Separate recordings and transcripts can be captured for each breakout. Access to the information shared or generated in a breakout room is limited to the participants in that room. For instance, if a file is shared in the Finance breakout room, the permissions on the file uploaded to the sharer's OneDrive account are restricted to the people in the breakout room at that time. In the future, Microsoft says that it will be possible to share information more easily from a breakout room with the main meeting.

Managing breakout rooms depends on the pop-out meeting and chat experience, so the desktop client must be used by meeting organizers. Participants can use the desktop, browser, or mobile client. The ability to use breakout rooms in meetings depends on several settings in the Teams meeting policy assigned to the meeting organizer. See [this article](#) for more information.

It's not always the case that those who schedule meetings are the people who run the meetings, and it's also possible that a meeting creator might not be available when the meeting happens. To avoid the obvious issue that the meeting organizer is the only person initially allowed to manage breakout rooms, Microsoft says that it will be possible to assign multiple organizers in the future.

## Real-Time Streaming from Teams Meetings

Teams personal (not channel) meetings support real-time streaming of content to streaming platforms like YouTube via the Real-Time Media Protocol (RTMP). The essential steps are:

- Create a suitable video feed within a meeting, using background images and other effects (like the brightening filter).
- Load the Custom Streaming app into the meeting.
- Get an RTMP URI and an RTMP key from the target streaming platform to identify the content coming from Teams.
- Connect Teams to the target streaming platform.
- Deliver the content and terminate it from Teams or the streaming platform when it's complete.
- Perform any post-production you want on the video before making it available long-term on the streaming platform.

The process is quick and easy and can be accomplished using regular PC hardware. Naturally, you can increase the quality of the video output by adding a better camera, lights, and microphones. It's a great way of making events like webinars and product announcements available from Teams to a public audience. See [this article](#) for more information.

## Teams Live Events

A live event is a structured form of meeting intended for large-scale information dissemination such as company announcements, product launches, training, and so on. The ability to present is limited to those assigned the presenter role; attendees are limited to listening and interacting through moderated Q&A. Organizers can create events with live captions and subtitles, including [the ability to translate spoken words into captions shown in multiple languages](#). Live events support recordings. Those invited to events can play back recordings for up to 180 days after the event finishes. Recordings are not stored in Stream, but they can be [downloaded by event producers](#) and then uploaded to Stream.

A tenant can run up to fifteen concurrent live events, each of which can last up to four hours (sixteen hours until December 31, 2022). Stream and Yammer can also host Live events.

**Large Events:** Normally, Live Events support up to 20,000 attendees. However, with the support of the [Microsoft 365 Live Events Assistance](#) team, an event can extend to support up to 100,000 attendees.

Two types of Teams Live Events are available: quick start and external encoder. Anyone equipped with a PC and webcam can create and run a quick start live event with audio, video, screen sharing, application sharing, and QA. These events, also called “produced with Teams,” are limited in terms of the video quality and the type of information presented during the broadcast (for example, no overlaid graphics), but the output is more than good enough for many topics.

Teams Live Events are created in the Teams calendar app in a similar way to a personal or channel meeting. Instead of *Schedule meeting* (the default), select *Live event* from the **New meeting** drop-down menu. The person who creates a live event is called the organizer or producer. Event organizers must meet the following criteria:

- Their account is assigned an enterprise license (E3 or E5 or academic/government equivalent).
- The assigned license must include Teams and Stream. The need for a Teams license is obvious. Behind the scenes, Teams uses Stream for all the necessary video processing including storage, caption and transcript generation, and delivery of content in formats suitable for different devices.
- Their mailbox must be hosted in Exchange Online.

Setting up a Teams live event is straightforward. You can limit event attendance to:

- Specific people and groups.
- Organization-wide (anyone who can sign into your tenant can attend, including guest accounts).
- Public. Anyone can attend and no sign-in is required. These events are designed for public briefings and presentations.

When creating a live event, the organizer decides to produce the event using Teams, meaning that the content for the event comes from presenter workstations, or using an external app or device. The former option is sufficient for internal meetings while the latter uses an external encoder (see below) to create more of a TV studio-like event, complete with special effects. The event recording is automatically available to the organizer and presenters. It is then up to the organizer to make the recording available to attendees via a website or another repository. You can choose to add captions in the spoken language translated in up to six other languages. Other options control the generation of an attendee report and if attendees can ask questions during the event. Q&A is not like the interaction chat used in other Teams meetings; attendee questions go through a moderation process before they become public (visible to event attendees).

### Notifying Event Participants

Presenters automatically receive calendar invitations generated when the event is created. These links contain the special links to enable the presenter role during the event. Sometimes event organizers forget to send out notifications to their intended audience to tell them how to join the event. To do this, copy the deeplink for

the event and paste the link into an email (use a standard non-Teams meeting invitation to have the event inserted into recipient calendars). The deeplink looks something like this:

```
https://teams.microsoft.com/l/meetup-join/19%3ameeting_Mzc4M2E0MzgtM2ZINS00M2UwLTlkMmQtYTBhYjk5NjMzMzMzNmMy%40thread.v2/0?context=%7b%22Tid%22%3a%22b662313f-14fc-43a2-9a7a-d2e27f4f3478%22%2c%22Oid%22%3a%22eff4cd58-1bb8-4899-94de-795f656b4a18%22%2c%22IsBroadcastMeeting%22%3atrue%7d
```

The reason for sending the deeplink generated for the live event via email or a calendar invitation is simple: distributing the deeplink like this avoids the possibility of including two sets of join information in the invitation (one for the live event, the other for a regular Teams meeting).

## Creating Pass-through Deeplinks

When a deeplink is used by an external participant to join a live event, they see a screen to allow them to sign in or join anonymously. If you organize many public events, you can [edit the deeplink to bring participants directly into the event](#). The edit must be accurate to generate a working link and involves scanning and replacing the following strings:

- "%3a" with ":" (colon – four times).
- "%40" with "@" (at sign – once).
- "%2c" with "," (comma – twice).

In addition, add the string `"setting=enableDirectPublicBroadcastJoin:true"` to the end of the link. The result is a link that works well on mobile devices. If you want it to work with desktop and browser clients, you must also replace "l" in the original link with "/\_#/l/". Taking the deeplink shown above as an example, when the edits are made, the output for desktop and browser clients is:

```
https://teams.microsoft.com/_#/l/meetup-join/19:meeting_Mzc4M2E0MzgtM2ZINS00M2UwLTlkMmQtYTBhYjk5NjMzMzMzNmMy@thread.v2/0?context=%7B%22Tid%22:%22b662313f-14fc-43a2-9a7a-d2e27f4f3478%22,%22Oid%22:%22eff4cd58-1bb8-4899-94de-795f656b4a18%22,%22IsBroadcastMeeting%22:true%7d&anon=true&anon=true&setting=enableDirectPublicBroadcastJoin:true
```

## Live Events Policy Settings

Teams supports anonymous access to live events, but only if this is allowed by the live events policy assigned to the person who organizes the event. If the event permissions allow, anonymous attendees can access the event recording. Live events policies are managed in the Teams admin center.

The settings controlling public access and disable recording for download are both off by default. To enable these settings, go into Live events policies in the Teams Admin Center and change the global policy or create a new policy with these settings enabled and assign them to specific users. You can also control these settings in PowerShell using the `Set-CsTeamsMeetingBroadcastPolicy` cmdlet. For example:

```
[PS] C:\> Set-CsTeamsMeetingBroadcastPolicy -Identity Global -BroadcastAttendeeVisibility Everyone -BroadcastRecordingMode UserOverride
```

## Live Event Presenters

Unlike regular meetings, where everyone can speak, share their video feed, and chat, only people assigned the organizer and presenter roles can speak, present information, and be visible during live events. Presenters can be:

- Tenant accounts.
- Guest and federated users.

- Anonymous external accounts. These are accounts without an Azure AD or Microsoft (MSA) account. If you want to use anonymous presenters for an event, you must set the [Allow external presenters](#) toggle when creating the event.

Attendees can ask questions, but only through a moderated Q&A facility. Because attendees have limited functionality in live events, the number of participants is much higher than for normal Teams meetings. The structured nature of Live Events means that some preparation is necessary to ensure the delivery of the best possible event. Steps to ensure a smooth event include:

- Having a dress rehearsal to make sure presenters understand the flow of the event and how they transition to speak. Presenters must join the event by signing into the host tenant. If they are a guest in that tenant, the presenter must switch to the host tenant before they join; if not, they will join as an attendee.
- Projecting an “Event will start soon” slide complete with information about the event and some music from five minutes before the event is scheduled to begin. This will reassure attendees that they’ve connected to the right event and will be able to hear the proceedings.
- Beginning the event with “house rules” to let attendees know how to ask questions and how presenters will respond to questions. During the event, someone should monitor incoming questions and note those that a presenter should answer. Moderators can reply to other questions straightway while other topics might need later follow-up.

**Note:** Microsoft has temporarily increased the [limit for attendees at a live event](#) to 20,000 with up to 50 simultaneous events per tenant. Each event can last up to 16 hours. The increased limits will expire on December 31, 2022, after which a Teams advanced communications license will be required to host live events with more than 10,000 participants or events lasting longer than four hours.

## Recordings

Organizers can record live events for later playback. The recording is stored in Stream and accessible for up to 180 days after the event, which makes it convenient for people to replay an event later and listen to specific parts of the discussion. Event organizers can download the recording and upload it to Stream if they want to keep it for a longer period. Live events can also be live-streamed to platforms like YouTube and Facebook using an encoder like [OBS Studio](#) (an open-source encoder).

## Teams Live Events External Encoder

Largescale live events which need output of the highest quality are usually carefully-planned productions created with studio-quality recording, camera, and broadcast facilities. These events often involve external encoder software to connect to studio production equipment.

The hardware or software-based encoder must support streaming to a Real-time Messaging Protocol (RTMP) service. Supported encoders include Haivision KB, OBS Studio, Wirecast, and XSplit Broadcaster (here is a [link to the encoders](#) tested by Microsoft and a [write-up](#) by MVP Luca Vitali on how to set up external encoder integration with OBS Studio).

To schedule a live event with an external encoder, create the meeting the same way as for a quick event. On the settings page, you select external encoder. Note that external encoder events are only consumed via Microsoft Stream, which is why public viewing will be unavailable for external encoder meetings. Users can view the streamed content in Stream or via the meeting invite in Teams.

# Teams Calling

Teams is the preferred communications solution for Microsoft 365 and supports two methods to enable users to make, receive, and transfer calls to landline and mobile phones connected to public networks (PSTN). You

can buy Phone system licenses with a [calling plan](#) (various plans are available in different countries for national and international calls), in which case the phone numbers assigned to users come from a pool assigned and managed by Microsoft. Alternatively, you can use [Direct Routing](#) (or direct connect) to link Teams to your existing connection to the PSTN network via a Session Border Controller (SBC). The technology for Teams calling comes from the Microsoft Phone System (originally called Cloud PBX).

Users must have a Microsoft calling plan to place calls to PSTN numbers. Accounts without a calling plan can call other Teams users using VOIP, including those in other tenants. The Teams Calling and Devices chapter contains detailed information about how to deploy and manage the foundational elements for voice and audio meetings, including calling inside and outside the organization.

Teams Devices and Calling are covered in a separate chapter.

## End to End Encryption for Teams Calls

Teams secures VOIP traffic with Transport Layer Security (TLS) and Secure Real-time Transport Protocol (SRTP). The combination is sufficient to secure most voice traffic, but if users need an extra degree of protection for ultra-confidential calls, the Teams Windows and Mac desktop clients can use end-to-end encryption (E2EE). In this scenario, the workstations at both sides of the conversation agree on an encryption key that they use to secure the call. Because of the additional layer of encryption, some Teams calling features don't work, including call transfer, recordings, and live captions. However, E2EE calls support chat.

By default, the Teams enhanced encryption policy for the tenant disables E2EE calling. To enable E2EE, an administrator must:

- Update the default policy to allow users to make E2EE calls, or:
- Define a new Teams enhanced encryption policy that allows E2EE calls and assign the policy to specific users.

In this example, we update the default Teams enhanced encryption policy to allow users to make E2EE calls.

```
[PS] C:\> Set-CsTeamsEnhancedEncryptionPolicy -Identity Global -CallingEndToEndEncryptionEnabledType DisabledUserOverride
```

Setting the policy to *DisabledUserOverride* allows Teams to display an option to use E2EE calls in the Privacy section of client settings.

End-to-end encrypted calls 

One-on-one Teams calls are end-to-end encrypted if both participants turn on this setting. Some features won't be available, including recording and transcription. [Learn more](#)

Directory self both users in a call enable E2EE, their call will be in E2EE mode, they'll know that this is happening by checking the shield icon at the top left-hand corner of the call screen. If it has a lock, E2EE is in force. Clicking the shield icon reveals a set of five 4-digit codes which should be the same for both users.

## Viewing Organizational Information

If the **Show organization tab for users** (in the Teams settings section in the Teams admin center) is **On**, users can view the organizational information about tenant users by:

- Searching for their name, and then selecting the organization view.
- Typing /org followed by their name in the command box.
- Hovering over their people card.

Like other Microsoft 365 applications, the people card reveals some personal information about the user such as their title, phone number, and if set, their email out of office message and their Teams status message. The people card also has links to a set of tasks:

- Switch to a personal (1:1) chat.
- Send a quick message to the person (the message is listed in your personal chat).
- Email the person. In this case, Teams launches the default email program configured for the workstation (for example, Outlook) with a new message addressed to the person using their email address defined in their Microsoft 365 account.
- Start an audio call with the person.
- Start a video chat with the person.
- View their organization information.

The organizational information about a person (Figure 12-17) comes from the reporting relationships, job title, and other information held in Azure AD. The information is only as good and as accurate or complete as it is in the directory, so it's a good idea to invest effort in populating and maintaining the directory.

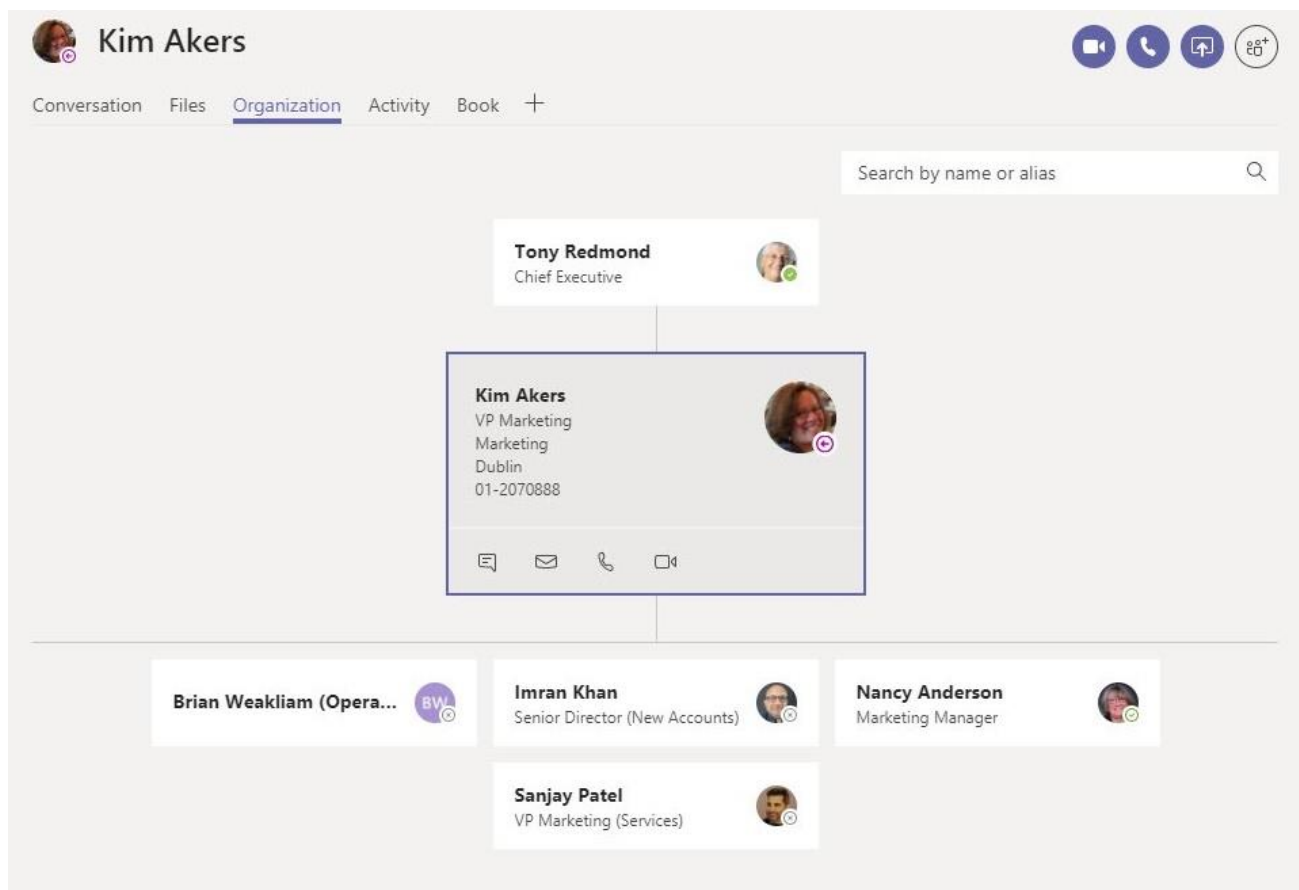

Figure 12-17: Viewing organizational information about a user

If incorrect or incomplete information about management relationships exists in Azure AD, it is impossible to get much insight into the organization through Teams. An inconsistent directory also makes it much harder to use features like dynamic Teams which depend on queries run against the directory. To ensure that up-to-date information is available to end-users, some companies use their HR system as the directory of record and have a direct feed between it and Azure AD, with updates in reporting relationships, job titles, phone numbers, and so on being transmitted periodically, while others use third-party products like [Hyperfish](#) to find and fix problems in Azure AD. For instance, you might find inconsistent use of account properties like city or state, and province. Another frequent problem is missing values for properties like department or office.

You can edit the contact information section of a user's account through the Microsoft 365 admin center to update properties like their job title, department, office, phone number, address, including a user's reporting relationship. You can also update this information through the:

- **Azure AD portal:** Select the user's account and update the job title and manager properties in the *Job Info* section. Update contact information (phone number, address) in the *Contact Info* section.
- **Exchange admin center:** Select the user's mailbox, then Organization, and update their manager in the *Manage Organization Information* section. You can also update their contact information in the *Manage Contact Information* section.

Changes made in EAC synchronize to Azure AD and are then available to Teams. Guests do not have access to organizational information. They can see someone's title, work address, and phone number, but the org chart icon does not appear on the people card.

When you view information about a person, you can also see details of personal chats you have had with them (Conversation), if you share files from your OneDrive for Business site with them in a 1:1 chat (Files – documents shared in group chats do not show up here), and recent posts from them to channels in teams to which you belong (Activity). Guests can only see the Conversation and Activity tabs. Another way of navigating the organization structure is to use the WhoBot, discussed in the section on bots later. WhoBot can track connections between users in a tenant, but it still depends on an accurately populated Azure AD to understand the organizational structure.

## Presence and Status

Teams keeps two indicators about someone to help users understand the current situation for that person.

**User presence** shows their availability to connect and appears in the user's people card and avatar in places like the activity feed. **User status** is a free-text message configurable by the user for Teams to display to others.

### User Presence

User presence is set in two ways:

- **User-configured:** The user picks a status and sets it in the Teams client. The presence values are Available, Busy, Do Not Disturb, Be Right Back, Appear Away, and Appear Offline. Users set their presence status by entering a command in the command bar (for instance, **/dnd** is the shorthand code used to set your status to *Do Not Disturb*) or by clicking their picture in the top right-hand corner and setting their presence there. Federation allows guest users to see user presence. If Teams cannot determine someone's online presence, Teams shows their presence status as "Offline." Users can also set their presence to Offline if they want to appear unavailable and uncontactable to other people. Teams supports the ability to set a duration for a presence, meaning that you configure a presence to last for a period from 30 minutes to a future custom date (for instance, after you return from an extended vacation). When the presence duration lapses, Teams reverts to an app-configured presence. You can't use the Available status when you set a duration.
- **App-configured:** A presence status chosen by a user always has priority and Teams uses this status whenever possible. If the user doesn't set their presence status, Teams tries to determine a presence based on their activity. For example, if someone is in a meeting or a call, Teams knows this and can change their presence status to reflect this activity. Teams synchronizes out-of-office information and calendar data with the user's Exchange mailbox and uses this information to figure out their status and current presence. For instance, if the user blocks some time in their calendar for an appointment or meeting and marks the time as busy, Teams knows that they are unavailable during their period. Time blocks booked by Viva Insights for "focus time" cause Teams to automatically set a user's

presence to Do Not Disturb. In addition to synchronizing calendar data, when a Teams client is signed in, it uses the [Graph presence subscription API](#) to detect calendar updates to take new events into account when calculating the user's presence.

Teams publishes presence changes immediately (or very soon afterward) following an update. When someone's presence is set to Do Not Disturb, Teams does not deliver notifications for normal messages and @mentions, while continuing to deliver notifications for urgent messages or those from people on the user's priority access list (managed in the **Privacy** section of **Settings**).

See [this page for more information](#) about the icons displayed by Teams to reflect a user's presence status. Of course, just because Teams reports someone as being available doesn't mean that they are. They might just be asleep!

## User Status Message and the Profile Card

Teams shows a user's profile card (Figure 12-18) when users hover over their photo or avatar in chats and conversations. The profile card contains:

- User information: Name, job title, department.
- Current presence status as calculated by Teams.
- User status (see below).
- Local time for the user and the time difference between the user and the person viewing the profile card. This information comes from the user's calendar time zone setting. Local time information is available for guest accounts if a federated organization sharing policy to share free/busy calendar information exists with their home tenant. Users can update their calendar time zone through Outlook settings, or administrators can run the *Set-MailboxCalendarConfiguration* cmdlet. See [this article](#) for more information.
- Primary SMTP email address.
- Fixed and mobile phone numbers.
- Office.
- Direct reports and manager.

This information will not be accurate if the data held for user accounts in Azure AD is inaccurate.

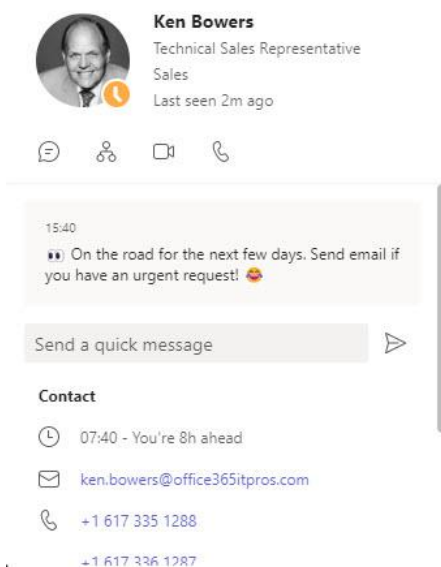

Figure 12-18: The user profile card holds lots of information

In addition to the information extracted from Azure AD, users can publish their personal status message. This is a free-form 280-character value status message intended to give other people a more descriptive insight

into their status. To update the status message in the desktop and browser clients, click the user photo in the top right-hand corner and select **Set status message**. Plain text and emojis are usable in a status message. Mobile clients support setting the status message through the user menu (top left-hand corner). When a status message is available, Teams displays it under the user's photo.

Like the presence status, a user status has a lifetime, which can be Today (until midnight), 1 hour, 4 hours, This week, Custom, or Never (the status never expires). After its lifetime expires, Teams removes the status message. Users can choose for Teams to display their status when someone sends them a message or @mentions them in a message. In these cases, Teams displays the status message over the compose message box. It also displays a reminder about the status message and its lifetime in chat.

In Figure 12-18, the user's presence is set to *Appear Away*, and their status gives some information about their ability to respond to messages. The people card also shows when the user was last active in Teams.

If an Exchange out of office notification is set for a mailbox, Teams includes this information in the people card unless the user has already explicitly set a status. If the user sets an out of office notification first, it takes precedence until the user clears the notification in Exchange. On the other hand, if the user sets their status in Teams first, subsequently setting an out of office notification in Exchange won't overwrite the status. Guest users can see the status message for other users in host tenants, so it's not a good idea to include anything confidential in a status message. Users can set the Exchange out of office notification from the Teams desktop and browser clients and Teams will update the auto-reply configuration for their mailbox to make sure that all clients use the same settings.

Guests can also set a status message, and they can set a different message in each tenant where they have an account. The status message set by federated contacts in other tenants aren't available during chats.

## Files: Linking Teams and SharePoint Online

The process to create a new team includes provisioning a new SharePoint Online team site containing a document library with a folder for the General channel. The purpose of the folder is to hold documents posted to the General channel. The creation of a new channel also creates a new folder of the same name in the document library. Users access the contents of the document library through the **Files** channel tab. This is one of two default tabs created for every channel that team owners or administrators cannot remove or rename.

Accessing the Files tab opens the folder holding channel files. Team members can upload documents to the folder or drag and drop files from File Explorer or the Mac Finder to move items into the folder. Naturally, any files created in the folder through the SharePoint browser interface or using Office apps are also available. Users can edit Word, Excel, and PowerPoint documents within Teams or open the file with the Online version of the app. The editing experience is similar but opening the file with Office Online or the desktop application allows the user to continue to do something else with Teams during the edit.

The Files tab supports navigation to sub-folders belonging to the channel, but if users want to move to another folder in the document library, they can click **Open in SharePoint** (available in the Files tab or the [...] menu for Posts) to open the site with SharePoint's browser interface. They can then access other folders in the document library, such as the folders belonging to other channels, or, if you team-enable an existing group, folders previously created in the default document library. It's important to understand that Teams does not integrate other document libraries in its navigation. If a site spans multiple document libraries that you'd like to access from Teams, you need to create individual channel tabs pointing to the root folder of those libraries (see below).

Another example of where you might create a channel tab pointing to a SharePoint resource is where you want to expose the site Recycle Bin to users to allow them to recover items deleted in error.

## Using Tabs to Access SharePoint Resources

To enable access to other SharePoint resources from within Teams, you can add tabs to bring users directly to a specific folder in a document library, a list, or a page in the SharePoint site belonging to the team. Here's how:

- Select the channel you want to make SharePoint resources available to team members, and then click the plus sign (+) to invoke the **Add a tab** dialog. Now select the **Document library** tab to add a link to a document library or the **SharePoint** tab to link to a published page or list in the site.
- If you select the Document library tab, you can now select one of the **Relevant sites** (essentially, a list of the sites that you accessed recently) and then a document library from that site; or select **Use a SharePoint link** and input the URL to the library you want to make available through the tab. The easiest way to get the URL is to open the target location in a browser and copy the URL from there to Teams. Make sure that team members have the necessary permissions to open the target.
- Give a name to the tab to help users understand its purpose (you can rename the tab later if necessary) and then **Save**.
- If you select the SharePoint tab, Teams retrieves a set of available pages to choose from. Select the page in the team site to display (for example, Home or News) and **Save** the setting. The tab will take the name of the chosen page (you can rename the tab if you want to).

An example of linking to a specific page is when you want to publish news articles to Teams. You can bring news articles into Teams as cards created by the News connector, but if you link to the News page for the site, you see all the news items posted, including the web parts (images, etc.) used for each item, and can comment on an item. In other words, you can interact with the page instead of just seeing a static snapshot of the content.

### Linking to Resources in Another Site

As noted above, the SharePoint tab is a good way to bring people to the News page for the site. However, what happens if you want a tab to open resources in another SharePoint site that doesn't belong to the team? Teams does not have an out-of-the-box way to do this, but a workaround exists through the website tab. This tab accepts and displays any valid URL, so it is possible to input a URL to take users to any SharePoint resource that they can access. All you need to do is format the URL to tell Teams what to do. For example, let's say that you have a URL pointing to an important news item:

*<https://office365itpros.com.sharepoint.com/sites/BlogsAndProjects/SitePages/Microsoft-Launches-New-Teams-Exploratory-Experience.aspx>*

The format of the URL to input into the website tab is:

*[https://office365itpros.sharepoint.com/sites/BlogsAndProjects/\\_layouts/15/teamslogon.aspx?spfx=true&dest=/sites/BlogsAndProjects/SitePages/Microsoft-Launches-New-Teams-Exploratory-Experience.aspx](https://office365itpros.sharepoint.com/sites/BlogsAndProjects/_layouts/15/teamslogon.aspx?spfx=true&dest=/sites/BlogsAndProjects/SitePages/Microsoft-Launches-New-Teams-Exploratory-Experience.aspx)*

This URL construct takes care of any authentication necessary to access the site hosting the content (assuming the user has access to that site). This is a workaround and it's not guaranteed to work every time (the best solution would be if Microsoft delivered a tab that could access any SharePoint page in the tenant). If you encounter problems, consider the [solution proposed here](#). It takes more work, but it might be just the trick for you.

## The Files Channel Tab

The Files Channel tab is a standard tab available for all channels to enable access to the files stored in the folder belonging to a channel in the team's SharePoint Online document library. Figure 12-19 shows the source Word documents for this book. The original version of the Files channel tab presented a simplified

view of documents when compared to the view available in the SharePoint browser interface. Microsoft has made steady progress towards the goal of giving the Files tab parity with the browser interface, and the two are much closer now, with support included for features such as column formatting and customization. By default, Teams uses the OneDrive file viewers to open and work with files. These viewers support over 300 file formats. For Office documents, users can configure clients to open files as follows:

- Desktop: Use Teams (the viewers), Office Online, or desktop apps. Only Office 16 or later is supported.
- Browser: Use Teams or Office Online.

The Files channel tab lets users open, move, copy, rename, download, and delete files to work with documents without the need to open the SharePoint browser client. You can also check out documents. Co-authoring is supported because Teams supports both the [WOPI](#) and [FSSHTTP](#) protocols.

Some limitations exist in the Files tab compared to the SharePoint interface. For example, you can't access the version history for a document, so you can't restore a previous version. You can't add a Flow or an alert to a document, and you can't apply retention labels to documents or access other custom properties. Finally, you can't share a document. In these cases, you're forced to open the library in SharePoint to perform these actions. The lack of label support in the Files tab might mean that some documents do not get the labels they need for retention or compliance purposes. If this is a concern, make sure that users receive advice about how to apply retention labels (see Chapter 17) to individual files. Alternatively, if the organization has Office 365 E5 licenses, it can deploy auto-label policies to detect and label files containing sensitive information.

Tenant users can synchronize files in the SharePoint document libraries used by Teams just like any other SharePoint site. The situation is different for guest users, where a OneDrive for Business feature called [B2B Sync](#) must be used to allow guest accounts to synchronize documents.

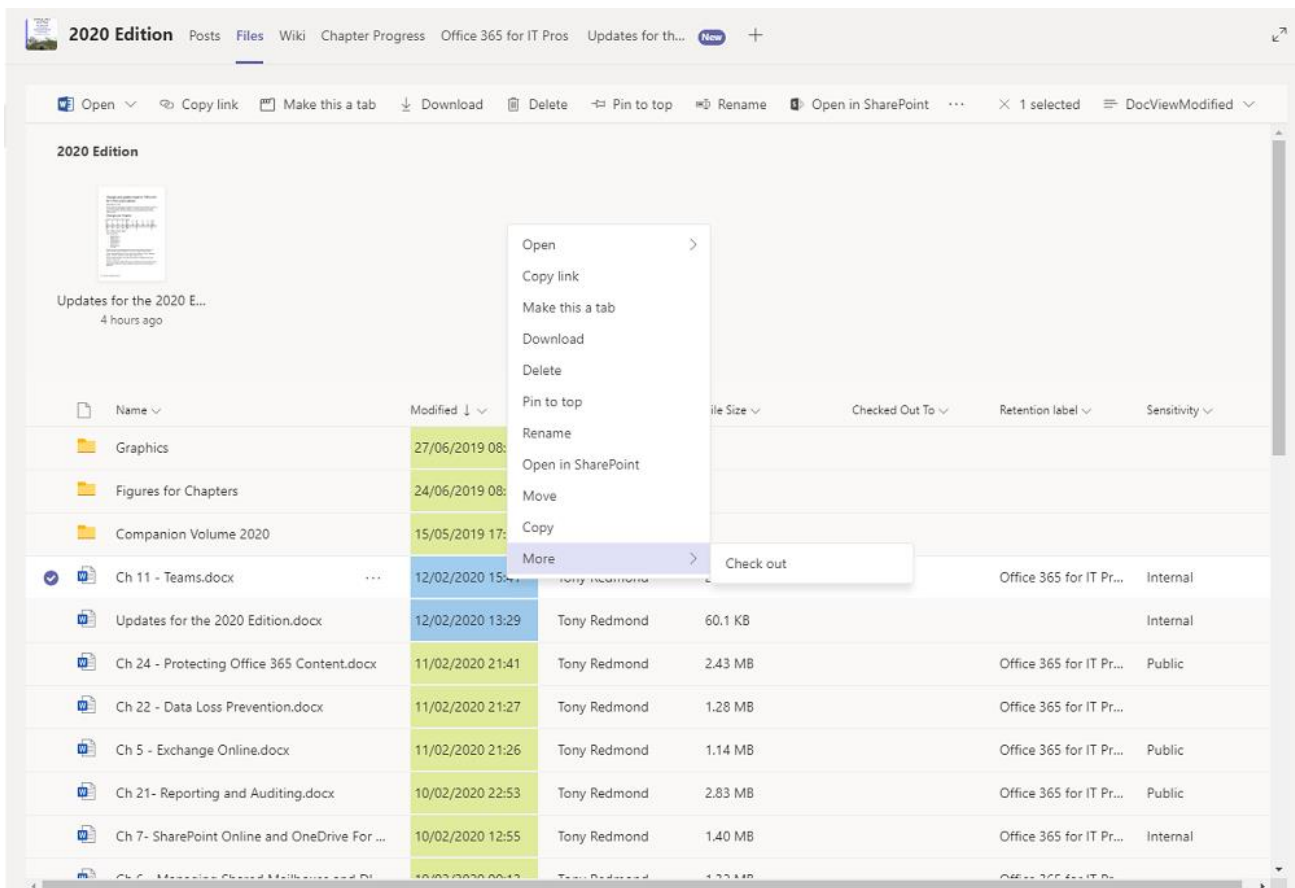

Figure 12-19: The Files channel tab displays files in a folder in a SharePoint document library

## SharePoint Site Membership

You should let Teams manage the membership of the SharePoint sites connected to teams. If you are a SharePoint expert and understand the consequences of making changes to site membership, feel free to do so. However, remember that if something doesn't work afterward, you will have to support what you've done.

Another thing to consider is that Microsoft might synchronize site membership between Teams and SharePoint in the future. This happens for private channels today where every four hours (approximately) Teams synchronizes membership of the private channel to SharePoint and overwrites the existing site membership. In other words, if you change the site membership in between synchronizations, Teams will reset the membership the next time synchronization occurs.

## Sharing Links

The **Copy link** option creates a sharing link to the folder belonging to a channel or a selected document. The organization's sharing policy for SharePoint Online dictates which types of sharing links are available for use. See Chapter 8 for more information about sharing links.

To use a link, click **Copy Link** and then adjust the link settings to control who can use the link, if they can edit the file, and so on. When the link is ready, click **Copy**. The sharing link is then available in the clipboard. You can then paste the link into a chat or email and send it to the intended recipients.

## Tabs to Link to Specific Documents

Apart from tabs connected to SharePoint sites, team owners can add tabs for fast access to a selected document. Open the SharePoint library with Teams, select the document, and then use the **Make this a tab** option. Teams creates the tab to point to the document. Alternatively, add a tab and then select the file type (Word, PowerPoint, etc.), and then select the document you want from the document library belonging to the team (you cannot select a file from another document library). When you create a tab for a file, selecting the tab invokes an Office viewer to display the content of the file. You can also edit the file in either the online app or by launching the desktop app if it is available on the workstation.

## Files in the Navigation Rail

The **Files** link in the left-hand navigation rail exposes a different set of files to the Files tab for a channel. Instead, the default (Recent) view for this link lists the recent files worked on by the user stored in SharePoint sites and their OneDrive for Business site. Some other shortcuts appear under Files:

- **Recent** is a list of files in SharePoint document libraries belonging to teams that the user recently accessed. Guests do not see this link.
- **Microsoft Teams** shows a list of files, including email messages, recently loaded into teams to which the user belongs.
- The **OneDrive** link exposes a list of folders and files stored in the user's OneDrive for Business site. Guests do not see this link because they do not have a OneDrive site in the tenant.
- **Downloads** shows the files in the Downloads folder on the device.
- If you connect a **cloud storage service** to Teams, like Google Drive, a shortcut to that service appears here.

## OneNote

When you create a tab in a channel to access OneNote, you have the choice to create a new notebook, browse to find existing notebooks to link to the tab, or paste [a notebook link](#) to bring users to a specific notebook, or a section, page, or paragraph within a notebook.

## Sharing Files

When someone shares files in a public conversation, Teams captures copies of the files in the folder of the group document library for the channel. However, when someone shares files in a private chat, Teams first uploads the file to a folder called “Microsoft Teams Chat Files” (under the Files folder) in the owner’s OneDrive for Business site and then shares it with the other chat participants.

## SharePoint News Connector

SharePoint news items are a special form of web page created in a SharePoint site. The SharePoint News Connector creates notifications about news items in a channel after they are posted. You can only create notifications for news items posted to the SharePoint site belonging to a team. News items posted to other sites are ignored. After the notification messages appear in the channel, users can click on a message to go to the full news item in the SharePoint site or use the item to begin a conversation.

To create a connector, select **Connectors** in the ellipsis menu for the channel where you want the notifications for news items to appear, search for **SharePoint News**, and then click **Configure**. Teams then creates the webhook to check for news items posted to the site. Click **Save** to set up the link.

## Email Folders

If people send an email to a channel, the email travels through a connector. SharePoint Online captures copies of the messages sent through the connector in sub-folders of the channel folder, created as needed on a month-by-month basis. For instance, messages sent to a channel in July 2022 are in the *EmailMessages\_7\_2022* sub-folder of the channel folder.

## Cloud Storage

If allowed by the Teams settings for the tenant, the Files tab supports access to different cloud services such as Dropbox, Box, Egnyte, Citrix ShareFile, and Google Drive (including personal drives) that the tenant might use instead of OneDrive for Business or SharePoint. The process of connecting to a cloud service means that you provide credentials to connect to an account in the service and use that account to select a folder in the storage accessible to the account. Once configured, a link to the cloud service appears in the list of files. Users must be able to authenticate with the service and access the files in the chosen storage location. Once connected, you can view, edit, upload, and remove files stored in the cloud storage. You can also start a new conversation about a file in cloud storage, just like you can discuss files stored in SharePoint.

## Teams for Frontline Workers

Teams for Frontline Workers is a Teams-based app built by Microsoft to replace the old StaffHub app. Designed around the premise that frontline staff such as sales associates and construction workers are often organized into scheduled periods of work activity, the app is also known as Shifts. In addition to the app, the [Shifts Graph API](#) is available for organizations to integrate Shifts into existing workforce management tools. Neither the app nor the API is available in the free version of Teams.

All Teams clients support the Shifts app. To access the app, click the More apps (...) button in the Teams navigation menu and look for the app in the Teams app store. It is also possible to assign a [Teams app policy](#) to selected users so that Shifts shows up in the app bar (along the side in the desktop and browser clients, at the bottom for mobile clients).

Inside Shifts, team owners can select a team to host a schedule and begin creating shifts (periods of work) and worker categories (called groups) to organize the shifts. Like a calendar, you can view shifts by day, week, or

month and see which of the members are already scheduled and those who are still available. Because the schedule is built around the people defined by team membership, a team can only support a single schedule. If you need to maintain several schedules, you must create a team for each schedule.

After creating a schedule, team owners and members permitted to manage schedules can assign members of the team to shifts and note absences such as scheduled vacations (Figure 12-20). To make things easier to build a schedule, you can copy the data for an existing shift from a previous period. If you add someone to a shift who isn't already a member of the team, the app adds them to the underlying group. Although Shifts allows you to create a schedule for a dynamic team, you shouldn't use these teams with Shifts. Two problems are apparent. First, if the query against Azure AD changes the team membership, some shift assignments might be affected. Second, if you try to add a new user to the team and assign them some time slots, Shifts accepts the assignments, but the person is not added to the membership and so can never see the schedule.

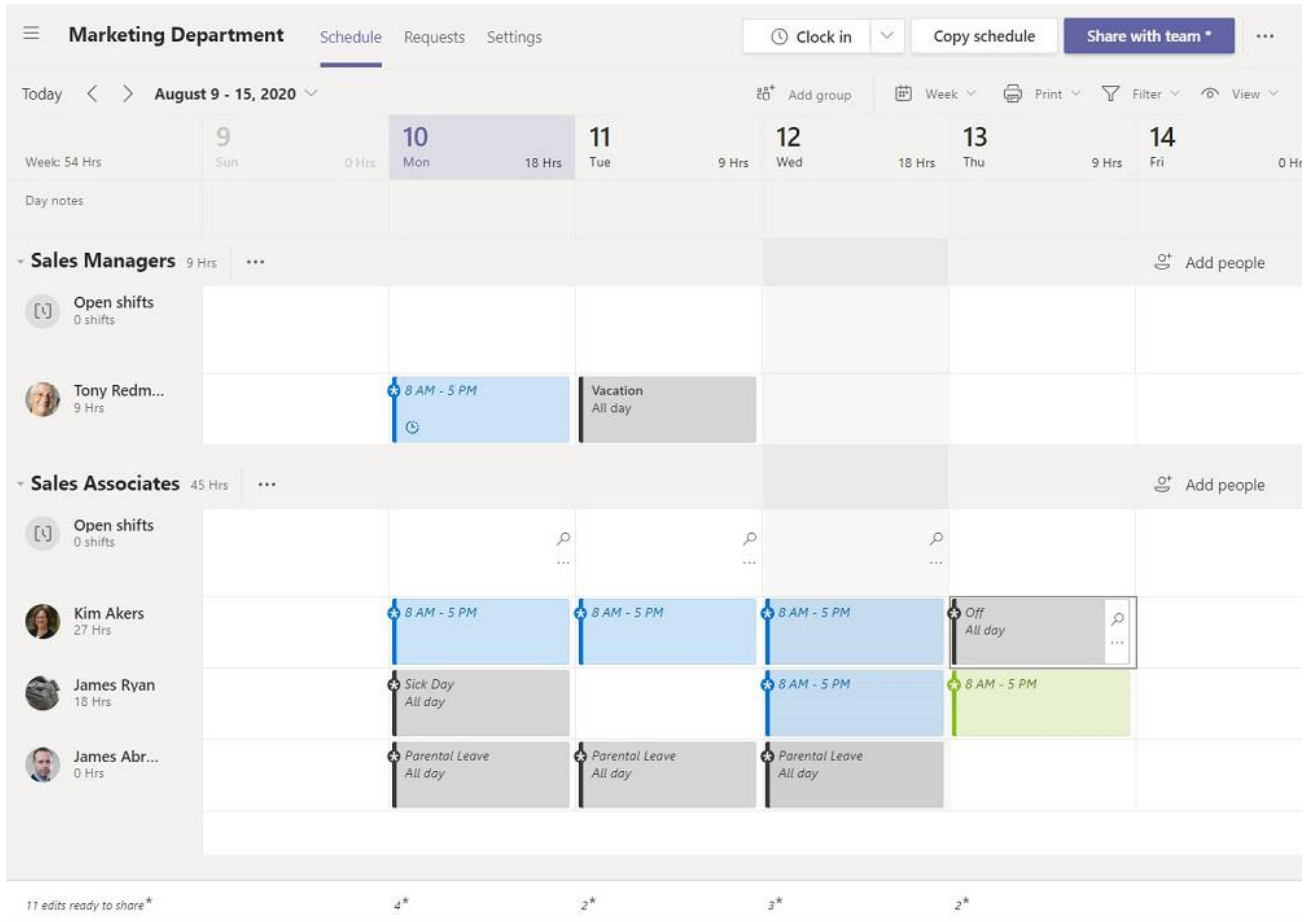

Figure 12-20: Building out a shift with the Shifts app

Once the shift is populated with assignments, you use the **Share with team** button to publish the information to the team. Publication can be to the complete team or just those who are affected by any changes made to the schedule since it was last shared. Sharing notifies team members that details of a new schedule are available. Members then open the Shifts app to review their schedule and request any adjustments they might want to make. For example, someone might want to ask for time off, or swap one of their scheduled shifts with someone else. These requests go to the team owner, who can approve or deny the requests.

## Can Teams Replace Email?

Although messaging is an important part of Teams, it's obvious that other parts of the app are equally if not more important to different people. Meetings and calls, for instance, became the most important part of

Teams for many organizations during the Covid-19 pandemic, while the development of Teams as an app platform has been remarkable. Nevertheless, some proponents of Teams focus on messaging and believe that you can reduce the use of email within an organization by replacing email with chat and channel conversations. Among the advantages cited for this approach are:

- Conversations and documents exist in the team rather than in multiple mailboxes. Thus, users have just one place to find information. Conversations are in channels while documents (including attachments in emails sent to the channel) exist in Files (a SharePoint document library).
- Conversations do not fork. It is easy for a small subset of recipients to begin a separate conversation after receiving email. This does not usually happen inside a channel because the conversation stays there and is visible to all team members.
- The volume of email declines when some traffic moves to Teams and email evolves to serve different purposes. Internal conversations stay in Teams while email handles external communications that Teams cannot handle (because no way exists to send outbound email from Teams). If necessary, people can initiate internal conversations by sending emails to a channel and continue the discussion in the channel from that point.
- Group chats are a good way to get together small teams of people to dissect and understand a problem before bringing a decision to a wider audience.

The advantages its supporters envisage for Teams are aspirational, and no guarantee exists that everyone is willing to change the habits of a lifetime and move from their preferred email client to Teams overnight, even as Teams adopts some of the characteristics of email in features such as message moderation and auto-replies. It's also fair to say that it is as easy to create a chaotic mess of Teams conversations spread across a sprawl of channels as it is to create an unordered messy inbox. Much of the success in any transition to a new technology comes from the effort put into user training and support. Left alone, users will find their bad habits for Teams.

It's also important to consider how different email clients affect the transition. People often refer to their client and how they use it instead of the email application. Their view of email comes from how they use their client(s). Outlook desktop is a great case in point as many people have built their working habits around how Outlook functions. People who use simpler email clients, like the Windows Mail client or a POP3 client, are perhaps less likely to be quite so attached to their client.

## Teams Messaging Can Work Better than Email

There's no doubt that Teams messaging (chat or channel conversations) can be a better tool to drive issues forward and get things done than email is. Take the situation shown in Figure 12-21 where a channel conversation has 269 replies and there are 207 members in the team. If the communication happened over email and every one replied as they did to the conversation, 55,890 (1 topic + 269 replies x 207 recipients) messages would circulate among the team. Not only would people have to spend a lot of time deleting some of the thread messages unread, but they also must cope with out-of-office notifications. Finally, consider the length of the final message and the impossibility of navigating through all the appended replies, auto-signatures, and other junk to get to the gist of the conversation. A well-organized threaded conversation in one place is a much better host for fast-paced to-and-fro communications.

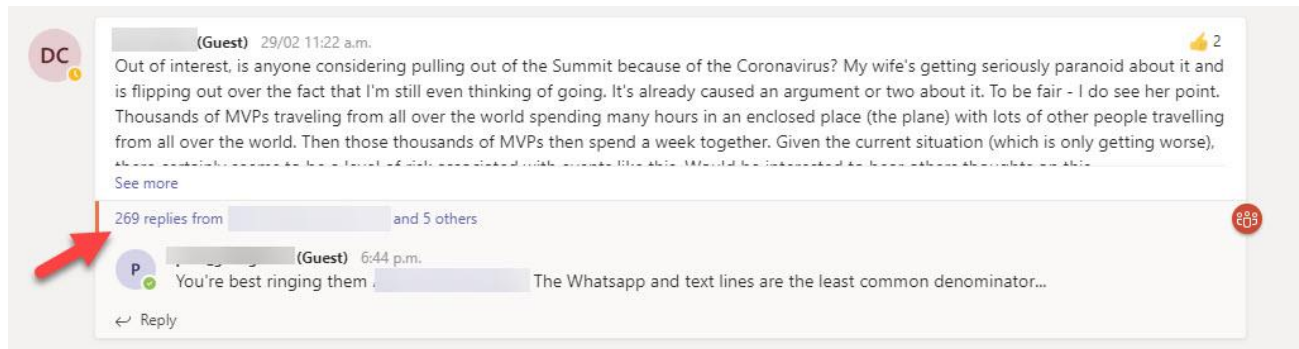

Figure 12-21: A Teams channel conversation with many replies

Channel conversations can be as chaotic as a cluttered inbox, especially when multiple team members contribute to different conversations over a short period. It can be very easy to lose sight of something important in a flurry of messages. It is also important to understand that Teams is very much an internal-facing collaboration mechanism. Even with guest users joining in, the data associated with Teams always remains in the home tenant. Compare this to the way that email serves as the lingua franca for the internet where anyone with an email server can use it to communicate and collaborate with anyone else. Another important factor to consider is the added functionality available in email, such as the ability to protect messages and attachments with rights management and encryption, not to mention features to make it easier for users to organize messages, like rules, categories, flagging items for follow-up, and so on. These features take years to develop and deploy, and Teams is still very much a young application.

Those who champion Teams should consider that all applications have their flaws. Among those seen in Teams are:

- Chaotic, badly organized conversations composed of short, incomplete, and shallow sentences that fail to form fully thought-out ideas. A conversation might have many replies from many individuals and be devoid of analysis and insight.
- Conversations that veer away from the subject at hand because they are hijacked by people who fail to understand the topic.
- Conversations can be dominated by the speedy, the quick-witted, those who have a point of view that they want (and need) to express, and those who suffer from verbal diarrhea. Some members of a team might choose not to contribute to a fast-paced conversation that, although open to them, is taking place between others.
- Conversations about anything that comes into peoples' heads that mask the real work.
- Conversations about topics driven by people who have no authority to speak on a subject or no accountability for an outcome. It is truly amazing how easy it is to waste time in such discussions.
- A rush to decision based on a feeling that chats should develop quickly.
- The fear of losing out if you fail to keep pace with all the conversations that happen in all the channels in all the teams you belong to. Apart from flagging a conversation as important and favoring and following channels, it's hard to prioritize the firehouse of chats daily, let alone sort out what might have occurred when you return from a vacation.

Email can suffer from some of the same problems, but because your inbox is under your control, it can be easier to sort, ignore, prioritize, and respond to what flows into the inbox.

Some organizations will find the transition from inward-circulating email to Teams easy and some will decide that they are best off staying with email and favor Outlook Groups as their collaboration platform instead, especially when regulations or legal requirements dictate the use of some of the compliance functionality presently missing in Teams. Interestingly, it can be easier for users of other collaboration platforms, like Lotus Notes, to move to Teams than to break habits formed around Outlook.

Usage reports, such as those available in the Microsoft 365 admin center or the Teams admin center, can help you understand if any email traffic moves to Teams. However, when you examine usage data, remember that some traffic handled by Teams might replace conversations previously carried in other apps. It is also important to measure after the first burst of activity subsides and people start to use Teams consistently. You will then know whether overall traffic is static or growing and what modality is most popular with users.

## Delegation of Access

Unlike many email systems, Teams does not support the concept of delegation of access for messaging, a feature that underpins common email functionality such as the ability for someone to:

- Send messages on behalf of or as (impersonate) another user.
- Schedule meetings on behalf of another user.
- Manage another user's workspace (their mailbox).

Teams is very different from email, so there's no reason why Teams should slavishly copy functionality from email systems across to its methods of messaging and collaboration. Nevertheless, the desire to move some volume of communications from email to personal chat and channel conversations plus the growth in Teams online meetings creates some need to support the manager-assistant scenario.

There's no good answer for delegation of access in Teams today, only workarounds. For more information, see [this article](#). Teams Calling does support delegation for call handling.

## Other Email Strengths

Other areas of functionality where email is ahead of Teams include:

- Printing. Teams doesn't include the ability to print messages or the calendar.
- Single focus: If someone has guest accounts in multiple tenants, they must switch to each tenant to check chats, channels, and apps. Compare this to the single inbox for all new emails, no matter where they originate.
- Secure communications: Chats and channel conversations are excellent methods for internal communications that extend to some external communication through guests and federated chat. Teams messaging does not include the secure (protected) functionality commonly found in emails such as S/MIME or other encryption (like sensitivity labels).
- Complex messages: Email is better suited to composing longer and more complex messages of the type used for formal business communications.
- Calendar: Outlook's calendar is more functional than the version available in Teams.
- History: Email allows users to keep all messages if desired in online or offline locations.

Different people will assign different levels of importance to each of the points listed above. The important thing is to help users decide when it is best to use Teams and when to use email. Although messaging might seem to be a common thread, they are very different tools.

## Can an Organization Cope Without Email?

Overall, it is hard to see Teams replacing email anytime soon. Teams is a great vehicle for communication, but if it wasn't available, organizations could continue to work with people inside and outside the company because other communication media exist, including email. If an organization decided to remove email, it could continue to communicate internally using Teams, Yammer, and other applications, but its ability to communicate externally with partners, clients, and other companies would be significantly and fundamentally reduced (in some cases, eliminated). With [over 3.9 billion users worldwide](#), email is ubiquitous, secure, and backed by a range of well-understood and widely-deployed standards. Moving on from such a foundation will be difficult.

# Teams and Email Interaction

Because email isn't going away anytime soon, Teams includes several methods for the two modalities to interact:

- **Share to Teams** uses an Outlook add-in to send a message to a Teams channel or chat (including the ability to create a new chat. Share to Teams works with Outlook for Windows (Microsoft 365 apps for Enterprise), Outlook for Mac, and OWA. It isn't available on Outlook mobile.
- **Share to Outlook** is a Teams client option that calls OWA to create and send a message containing a copy of a channel or chat conversation. The message can go to any email recipient, including distribution lists and external recipients.
- **Chat with Teams** and **Reply with IM** are Outlook desktop options available when Teams is the registered chat application for Windows. Teams launches a pop-out chat window connected to the author of the selected message. Chat participants can include Teams users from other domains.
- **Reply to Teams Missed Activity Mail** gives users who receive missed activity notifications the ability to respond to conversations in Teams using [Outlook actionable messages](#).
- **Email-enabled channels** have special email addresses to allow the delivery of messages through a connector to become channel conversations. Organizations can restrict who can send email to an email-enabled channel. See the Managing Teams chapter for more information.
- **Drag and Drop from Outlook desktop** allows users to drag and drop a message (and any attachments) into a Teams channel conversation. The feature doesn't work with chat.

The Share to Teams and Share to Outlook features depend on cloud mailboxes, so users with on-premises Exchange server mailboxes or guest users cannot use the feature.

## Share to Teams

The Outlook desktop client installs the Share to Teams add-in automatically when a user signs into the Teams desktop or Teams browser client. The add-in uses single sign-in to allow Outlook or OWA to post messages into target Teams channels, personal chats, or group chats. To share a message, click the Share to Teams icon in the Outlook menu bar. Outlook checks the connection to the user's home tenant (if the user switches to be a guest to another tenant, they need to switch back to use Share to Teams) and for the presence of the Teams desktop client. If the Teams desktop client is available, Outlook opens a window in the Teams client and loads the current message into a form to allow the user to add addressees (Figure 12-22). After someone uses the feature a few times, Teams learns about the people and locations commonly used for sharing and suggests these as potential sharing targets.

Valid sharing targets are:

- Individual users: Outlook posts the message to a private chat.
- Several users: Outlook posts the message to a group chat.
- Channels in Teams: This includes private channels the user belongs to. Posting to multiple channels is not possible.

To add context to the post in Teams, the user can insert some cover text to explain the message to the channel members. If the message has attachments, you can choose to include or omit these files. When the message is ready for posting, click **Share**.

Behind the scenes, Outlook shares messages through the same mechanism as used to post a message to a channel via email. Depending on the recipients, sharing creates a new topic in the target channel or a new message in a personal or group chat and posts the message. When Outlook posts a message to a channel, Teams saves the message and any attachments in the *Email Messages* folder for the channel in the SharePoint document library belonging to the team. Messages posted to a private or group chat are in the Microsoft

Teams Chat Files folder of the sender's OneDrive for Business account. Teams shares these messages with the group participants to allow them access.

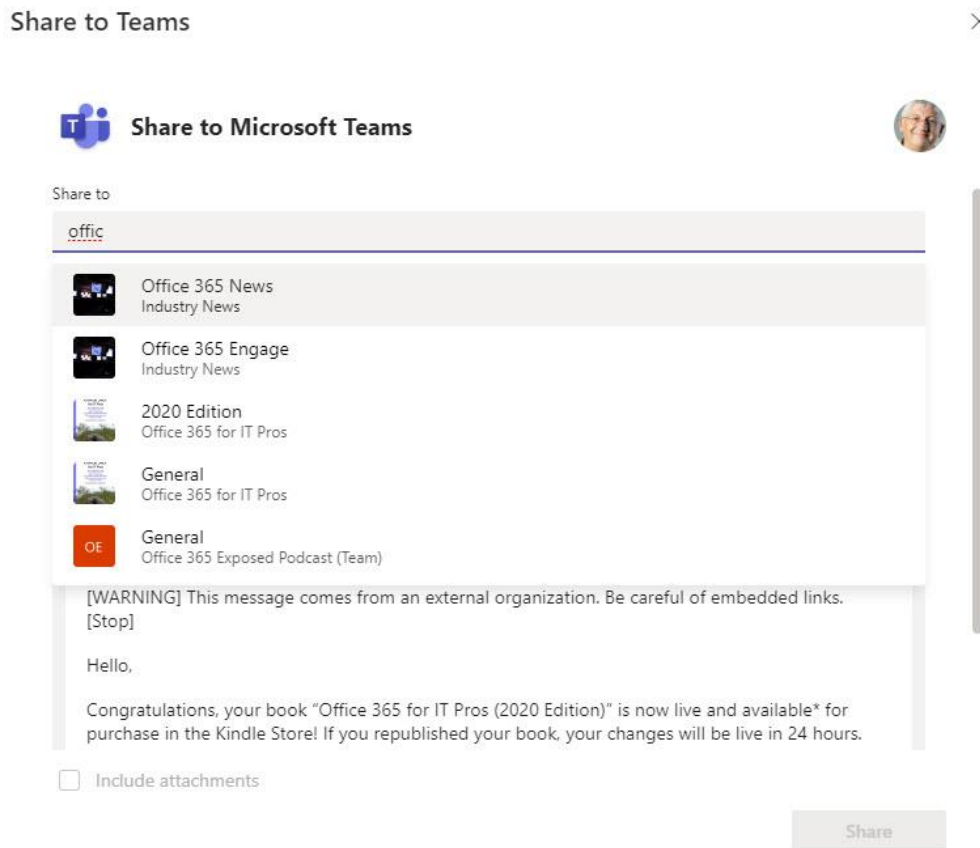

Figure 12-22: Selecting recipients to share an Outlook message with Teams

Share to Teams does not support messages encrypted with Microsoft Information Protection sensitivity labels, Office 365 message encryption, or S/MIME.

If you don't want users to use the add-in, you can disable it using PowerShell by running the *Disable-App* cmdlet. This code finds the identifier for the Share to Teams add-in and uses it to disable the add-in for a mailbox. If necessary, to disable the add-in for multiple accounts, use an input array of mailboxes and pipe the objects to the *Disable-App* cmdlet:

```
[PS] C:\> $ShareToTeamsApp = (Get-App | ? {$_.DisplayName -eq "Share to Teams"}).AppId
Disable-App -Identity $ShareToTeamsApp -Mailbox Chris.Bishop@office365itpros.com -Confirm:$False
```

## Share to Outlook

Sharing to Outlook means *"forward a conversation from a Teams conversation or personal chat to one or more email recipients."* To share, select **Share to Outlook** from the [...] menu, which only appears if the user mailbox is in Exchange Online. Guest accounts can't use Share to Outlook because they don't have a mailbox that they can sign into.

When you forward a personal chat, Teams shares the selected message rather than the entire chat. For a channel conversation, Teams extracts a copy of the complete conversation (this can be slow for a conversation with many replies). Teams loads the HTML content into an OWA message compose form for the user to add address information and make any changes necessary to the message body. If a user's mailbox is not enabled for OWA, Teams won't be able to call the OWA message compose form.

You can add any valid email address, and you can choose to send the message from any mailbox for which you have permission, including shared mailboxes and Microsoft 365 Groups. Because an OWA component creates and sends the message (unsent messages are in the Drafts folder), OWA features like support for sensitivity labels are available. And of course, email clients can print the messages sent from Teams, thus solving the lack of printing support in Teams clients.

Messages forwarded from Teams travel through the Exchange Online transport pipeline and are subject to any mail flow rules enforced there.

## Reply to Teams Missed Activity Mail

Depending on a user's missed activity email settings, Teams sends periodic email reminders to make sure that users know what's happening in a chat or channel conversation, like being @mentioned. Teams missed activity notifications are actionable messages which include two action buttons:

- The **Go to conversation** button uses an embedded deeplink to open Teams positioned ready to reply to the message, much like users can join a Teams meeting from an Outlook calendar event.
- The **Reply** button opens a dialog to allow the user to reply to the Teams conversation without leaving Outlook. Being able to compose and send an inline reply to a conversation without having to switch context from email is especially valuable in terms of helping users to maintain focus. Actionable messages support only simple text replies (no attachments, emoticons, reactions, or text formatting). One of the nice things about this feature is that you can reply from email even when you have not signed into Teams in the tenant that hosts the conversation.

Outlook desktop, OWA, and Outlook mobile support actionable messages for Teams responses. Email clients that can't process the JSON content within the message which defines the actions and the transactions with Teams to perform responses replace the two action buttons with a **Reply in Teams** button. This button works like the **Go to conversation** button in that it uses the deeplink in the message to open the Teams client. In addition, if someone is using Outlook desktop and is not signed into their home tenant with the Teams desktop client, Outlook offers only the Reply in Teams option. To restore full functionality, the user must switch back to their home tenant and then restart Outlook desktop.

A tenant can block actionable messages by setting *SmtplibActionableMessagesEnabled* in the Exchange Online organization configuration to False. By default, this value is True, meaning that applications like Outlook can interact with actionable messages. To block this capability, run the *Set-OrganizationConfig* cmdlet:

```
[PS] C:\> Set-OrganizationConfig -SmtplibActionableMessagesEnabled $False
```

The block affects messages generated by all Microsoft 365 workloads, including Teams and Yammer.

## Reply with IM

The idea behind the Reply with IM feature is simple. You receive an email in Outlook and instead of having endless rounds of to-and-fro replies, you continue the conversation in an instant messaging platform that's more suitable for an interactive debate. The Reply with IM option is in the [...] menu of Outlook's read message window or in the Respond section of the Outlook menu bar (Microsoft has a habit of moving these options around). Reply with IM launches a conversation with the sender while Reply All with IM includes all the recipients in the conversation.

To use the feature with Teams, a user must be:

- Configured in [TeamsOnly mode](#). The value of the registry key *HKCU\Software\IM Providers\DefaultIMApp* should be "Teams." This value is set when you choose to register Teams as the chat app for Office in Teams settings. You can [update the registry using this script](#).

- Signed into the Teams tenant hosting the users you want to chat. In other words, if you want to chat with people from your home tenant, make sure that you sign in there.

There are some details to remember when using Reply with IM:

- If an existing chat with the recipients exists, Teams will use that. Otherwise, Teams creates a new chat.
- Teams doesn't take the message subject and use it to name the chat, even when it creates a new chat. Apart from the recipients, Teams copies nothing from the message into the chat, so you must cut and paste information from the message body into the chat if you want to provide context for the conversation.
- Reply with IM supports federated (external access) chat with Teams users from other Microsoft 365 domains. However, it does not support chat with Teams consumer users.
- If one of the message recipients is blocked for chats by Teams, you won't be able to send messages to the chat.
- If you are signed in as a guest to a Teams tenant where an external recipient is homed, Reply with IM can launch a conversation with that person.
- Rather bizarrely, if a shared mailbox is in message recipients, Teams includes the shared mailbox in the chat (you can clean things up by removing the shared mailbox from the chat).
- If the message recipients contain a group, Teams drops the group when it starts the chat.

Despite some oddities, Reply with IM works well and is a useful feature to have when a chat is a more appropriate host for a conversation than keeping it in email.

## Drag and Drop from Outlook Desktop

Outlook for Windows supports drag and drop of a message and any attachments from any folder to a Teams channel conversation. You can't drag and drop a message to a personal or group chat and the feature isn't available in OWA or Outlook for Mac.

To get the message into Teams, Outlook uploads a copy of the message (as a .msg file) into the channel folder in the SharePoint site belonging to the target team and creates a link to the email in the Teams message. The user can then add extra context for the message, just like they would for any other attachment shared in a channel before posting. Users can also drag and drop messages from Outlook to the Files channel tab. This action uploads the message to SharePoint without creating a message in the channel.

SharePoint Online stores messages as .msg files. These are copies that preserve the structure of the messages. The viewers included in Teams and SharePoint Online only display the text of the message and don't support access to any attachments. If users want to see the attachments, they must download a copy of the .msg file and open it with Outlook.

Although Outlook can upload messages protected with sensitivity labels (or S/MIME or another protection mechanism) to Teams, users can't read the content unless they download the message and open it with Outlook. When this happens, Outlook can call the protection mechanism applied to the message to access its content. For example, if a sensitivity label with encryption protected the message, Outlook can obtain the necessary use license, check if the user has the necessary rights to view the content, and if so, decrypt and display the message.

Another way of handling protected email is to copy the decrypted text from Outlook and paste it into a Teams message. If you want to include the message header to show recipients, forward the message to someone (but don't send it) and copy the text inserted into the forwarded copy. Any attachments (which will also be protected) must be downloaded and posted to Teams separately.

# Chapter 13: Managing Teams

*Tony Redmond*

## Keeping Teams in Good Shape

Applications require management if they are not to fall into a state of utter chaos over time. Teams is no different. Here we discuss the tools available to manage Teams from the policies managed through the Teams admin center to day-to-day management tasks like creating and removing teams. We also cover guest user access to Teams and the compliance and auditing infrastructure that helps to manage the content stored in Teams.

## Creating a Deployment Plan for Teams

Before describing different aspects of Teams management, it's worth listing the areas to consider in a deployment plan. Here are some things to consider:

- What **training** will you deliver to users? How will you keep that training updated to match what users see in the Teams clients?
- What training is available for administrators and team owners? How will you keep the training up-to-date with new developments in Teams and Microsoft 365?
- Are the default settings for messaging, calling, and meeting **policies** appropriate, and if not, what changes are necessary? What method will the organization use to assign policies and what policies will different sets of users receive?
- Will you allow all users to **create new teams**, or will the organization impose control over team creation? If so, how can users request the creation of new teams, and who will approve their creation?
- Will you impose a **naming convention** for Teams? If so, what is an appropriate and useful naming structure?
- Are **org-wide** or similar large-scale Teams needed? If yes, who will manage these teams, and what is their purpose?
- Will you use the **Groups expiration policy** to control the retention of inactive Teams? This feature requires Azure AD Premium licenses, but it can be very helpful when managing large numbers of teams. Another policy to consider is the ownerless groups policy.
- Will Teams **affect how you use other applications** like SharePoint Online or Exchange Online? For instance, if you use a hybrid Exchange organization, do you need to upgrade on-premises servers or should you move some mailboxes to Exchange Online?
- Will you allow **external access** to Teams? If yes, will you use the Azure B2B Collaboration (guest accounts) or Azure AD B2B Direct Connect (for shared channels)? How will you manage external access to confidential information held in teams? Will you require owners to validate the need for continued external access to their teams periodically?
- Do you need to migrate **meetings and voice applications** from other platforms? Will this affect the devices you use in meeting rooms or on user desktops? Do you need to invest in calling plans to allow users to make PSTN calls with Teams?
- How does Teams affect the **data governance framework** for the company? Will Teams be within the scope of data lifecycle policies like Data Loss Prevention, Retention, and communications compliance?
- What **first-party apps** will be used with Teams (Tasks, SharePoint, Insights, OneNote, etc.) and how will users be trained to use these apps effectively?

- What **third-party apps** will be used alongside Teams and by whom? How is access controlled to these apps and how do they feature in the data governance framework?
- Will **bots and connectors** be used with Teams? If yes, what purpose will these components serve?
- Will the organization invest in the development of apps, bots, and channel tabs for Teams? If yes, who will receive training and what training will they receive?

It's a long list that you should tailor to meet the needs of your organization. It's also important to realize that some of the defaults Microsoft chooses for Teams (such as allowing everyone to create new Teams) are there to accelerate the adoption of Teams instead of making long-term management easier. This is especially true for larger organizations where the number of Teams is more than a single administrator can remember. With that thought in mind, let's consider the details of how to approach the management of Teams.

## Teams Management

The [Teams admin center](#) (Figure 13-1) is the focus of team and policy management. Because the admin center is under active development, some of the settings described here might not be the same as presented in your tenant. The next chapter covers the settings for Teams Voice and the Phone system, including aspects such as calling plans, resource accounts, and holidays.

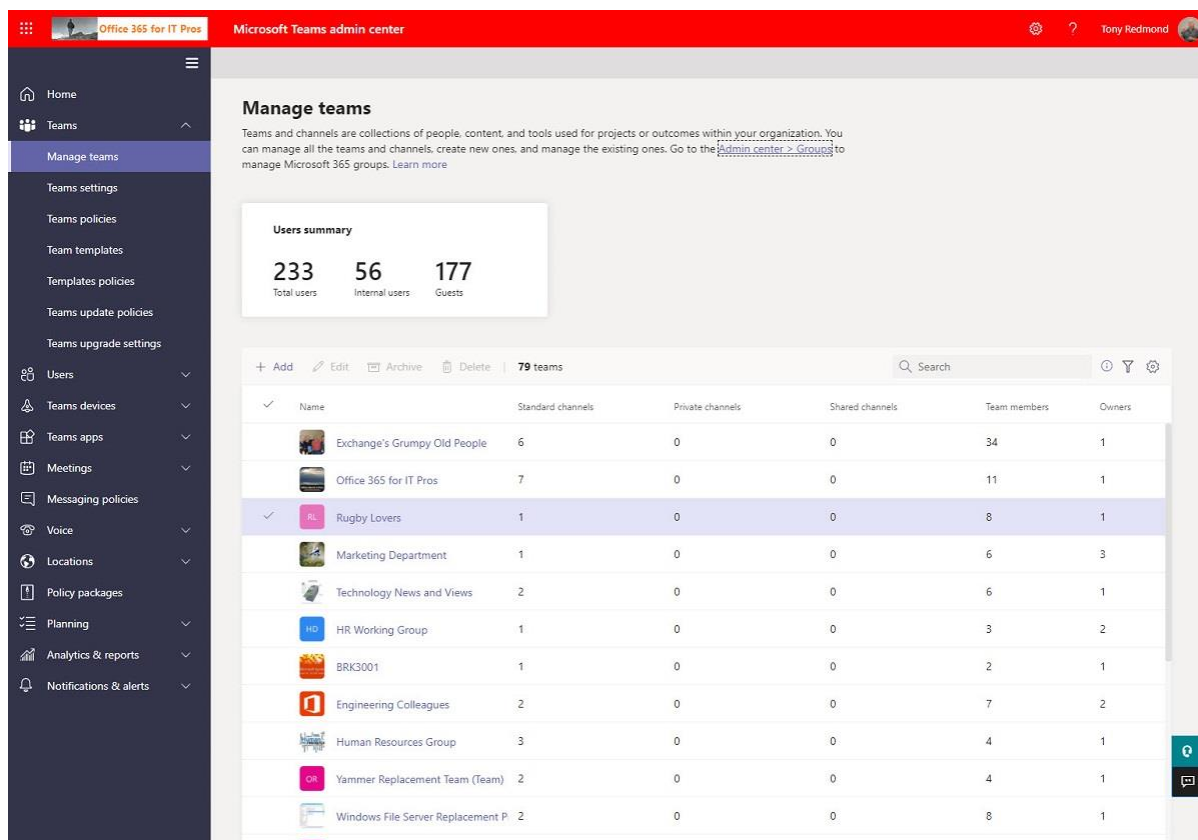

Figure 13-1: The Teams admin center

Not only does the admin center allow tenants to manage the creation and maintenance of individual teams, but it also supports the management of a wide range of user and organization policies to control how different aspects of Teams work, such as messaging, meetings, and guest access. As explained later, while tenant administrators have full access to all the settings and policies, a set of Teams administrative roles is available for assignment to users to grant them the ability to manage specific parts of Teams. See Chapter 4 for more information on these roles.

**Teams in the Microsoft 365 admin center:** If you look at the Groups section of the Microsoft 365 admin center, you can apply the *Groups with Teams* filter to see the list of Groups in the tenant that are teams-enabled (a small Teams icon also appears in the Teams status column). You can edit details of teams such as description, or membership through the Microsoft 365 admin center, but you need to use the Teams admin center or PowerShell to update team-specific settings.

The **Admin** app is available in the Teams app store. Microsoft created the app to help administrators of small to medium Microsoft 365 tenants manage Teams more easily. In these tenants, administrators often take care of Microsoft 365 as a whole, whereas in larger enterprises administrators might be more specialized. Also, in large enterprises, it's common to see the principle of account separation at work, where people use permissioned administrative accounts to manage Microsoft 365 and personal accounts to interact with Exchange Online, SharePoint Online, OneDrive for Business, and Teams. The app allows administrators to manage user accounts, teams, licenses, and some organization-wide settings for Teams. Although the Admin app is convenient for a limited set of tasks, management through the Microsoft 365 admin center and Teams admin center is often more effective.

## How Teams Global Policies Work

Microsoft creates a default policy called *Global (org-wide default)* for most of the policies used to manage teams. The purpose of a default policy is to dictate how a certain aspect of Teams works, like messaging, meetings, or app setup.

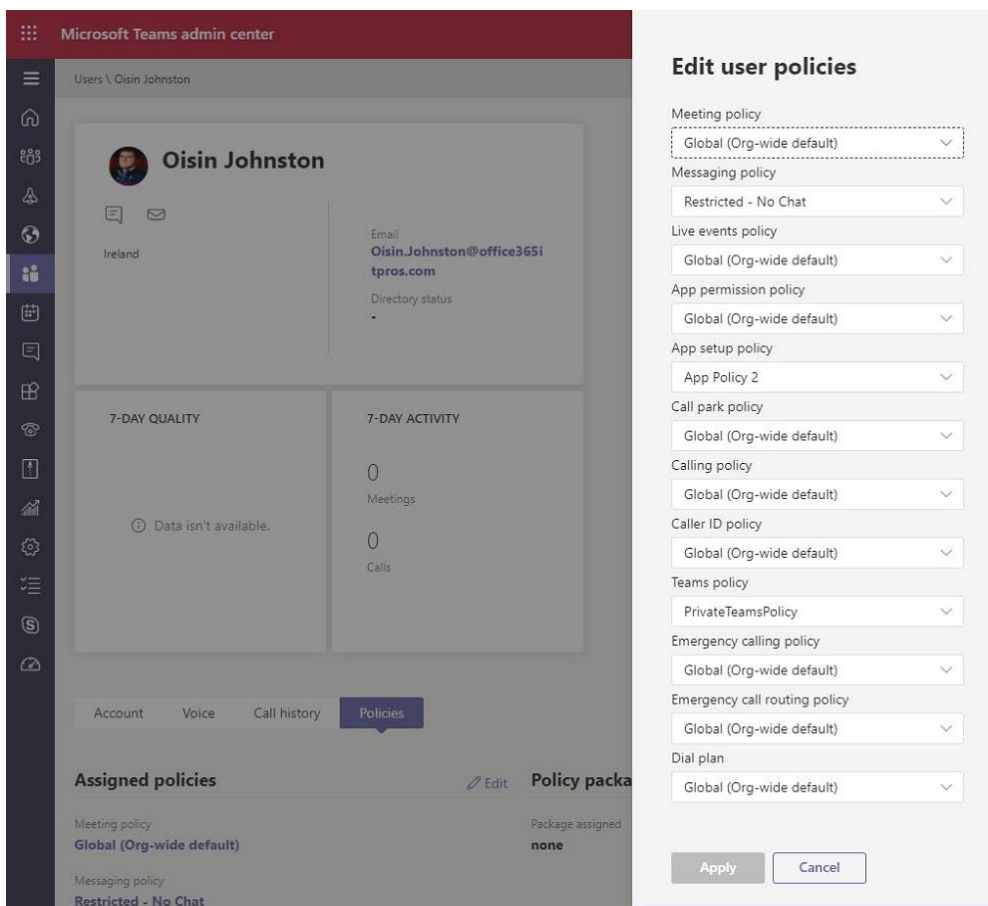

Figure 13-2: Editing the policies assigned to a Teams user

The default policies apply to all users until the organization creates a custom version of the policy and assigns that policy to some or all accounts. This mechanism allows a tenant to manage functionality on a user-by-user basis. Although you can edit the default policies to reflect the way that you want Teams to work for your organization, some administrators prefer to leave the default policies intact and create custom versions of

Teams policies instead. They take this approach because they believe this gives them more control and avoids problems if Microsoft changes something in a default policy in the future. However, if you use custom policies, remember that you must apply those policies to new accounts after creation. This is one reason to depend on the default policies whenever possible.

You can manage Teams with default policies applicable to all users or create policies with different settings and assign them to specific users using the Teams admin center or PowerShell, including batch policy assignments to process large sets of users. Individual accounts have a mixture of default and custom policies. In Figure 13-2 we see a user account assigned nine default policies and three custom policies.

Changes made to user policies need to synchronize with Teams clients before they are effective. Normally, this process takes an hour or so, but it can take longer.

## Microsoft Management of Default Policies

Microsoft manages default versions of Teams policies to allow them to easily change policy settings to reflect to support the introduction of new functionality. A tenant uses the Microsoft versions of default policies until the first time an admin views or updates a default policy through the Teams admin center or PowerShell.

When this happens, Teams copies that default policy to the tenant to allow the tenant to use a custom version of the default policy. From that point forward, any change Microsoft makes to the global policy will not affect the tenant because the custom version of the policy takes precedence.

As an example, Microsoft updated the default meeting policy to force external users to wait in the lobby before admittance to Teams meetings. They did this by changing the *AutoAdmittedUsers* setting to "EveryoneInCompany" and the *AllowPSTNUsersToBypassLobby* setting to False. The net effect was to allow only tenant users to join meetings without going through the lobby. Microsoft updated its copy of the default meeting policy, and the change was picked up by tenants that had never accessed the default meeting policy. A tenant-specific version of a default policy always takes precedence over Microsoft's version. Therefore, Microsoft's update did not affect tenants who had their copy of the default meeting policy and any customizations applied by a tenant remained in force.

## Teams Policies

Teams policies (which sound much more comprehensive than they are) control the enabling or disabling of complete features such as private and shared channels. The default policy enables all features to make functionality available to users immediately after Microsoft releases updated software. If you prefer a more phased approach that takes training and help desk preparation into account, you can disable features in the Teams policy until the organization is prepared for their introduction. Microsoft often exposes the setting to control a new feature sometime before releasing the feature to users, which means that administrators have the time to assess if they want to make the feature available.

To assign a policy to an account, choose the account, and then select the Policies tab. You can then edit the set of assigned policies. If the organization uses policy packages for policy assignment, you can select a policy package to apply to the account.

## Messaging Policies

New users automatically receive the tenant's default messaging policy. The messaging policy controls the actions a user can take when working with Teams chat and channel messages and can override team-specific settings. If you don't want to use the settings in the global policy, you can change them or can create new messaging policies through the *Messaging policies* section of the Teams admin center, which also includes the ability to assign different policies to specific users. For example, you might want to restrict the ability of some users to send voice messages. To achieve the goal, define a new messaging policy that disables voice memos and assign it to accounts you want to restrict.

A messaging policy includes the following settings:

- **Owners can delete sent messages:** Allow team owners to remove all messages from channel conversations.
- **Delete sent messages:** Allow users to delete messages that they sent in channel conversations.
- **Edit sent messages:** Allow users to edit the text of messages they sent to channel conversations.
- **Chat:** If you disable this feature, Teams hides the Chat app from the navigation bar and limits users to channel conversations. Removing chat takes a big piece of functionality from Teams (see below) and is not recommended.
- **Read Receipts:** This setting is enabled for everyone, turned off for everyone, or user-controlled. If user-controlled, users can choose to use read receipts in 1:1 and group chats (read receipts are limited to group chats with up to 20 participants).
- **Translate messages:** Controls if users can translate messages from their entered language to the language of the user.
- **Use Giphy in conversations:** Allow users to add [animated GIF files](#) to conversations. Clients make connections to the Giphy service to fetch available files. The choice to use GIFs links to the content rating, which can be set to "Strict" (nothing offensive to young audiences), "Moderate" (parental guidance needed), and "Allow all content" (all bets are off).
- **Use Memes in conversations:** Allow users to add the [memes](#) available to Teams to personal or channel conversations.
- **Use Stickers in conversations:** Allow users to add the stickers available to Teams to channel or private conversations.
- **Voice message creation:** Controls if users can create voice messages in chats, and channel conversations.
- **Allow URL preview:** By default, clients create previews of the content pointed to by URLs. Turn this setting to *Off* if you don't want Teams to do this.
- **Allow immersive reader for viewing messages:** By default, people can view messages in Microsoft Immersive Reader. When the tool is used, Teams displays message text in a full-screen window. The text is enlarged to make it easier to read and the reader can also choose to have the text read for them in a male or female voice.
- **Remove users from a group chat:** Controls if users can remove another person from a group chat.
- **Send urgent messages using priority notifications:** Controls if users can send priority messages. The number of these messages that a user can send is limited by the license assigned to their account.
- **Create voice messages:** Controls if users can post voice messages to chats and channels, chats only, or not at all.
- **On mobile devices, display favorite channels above recent chats:** If set, this setting forces the iOS and Android clients to display favorite channels on the top of the screen.
- **Suggested replies:** Teams can use AI to analyze the context of a message and generate up to three appropriate responses. This feature is available only in 1:1 chats.
- **Chat permission role:** This setting applies when the organization is configured for supervised chat, usually in an educational environment.

Organizations will communications compliance policies can use the **Report a concern** setting (for PowerShell, this is the `AllowCommunicationComplianceEndUserReporting` setting) to allow users to report messages they believe to violate corporate policies. See Chapter 21 for details about communications compliance policies. By default, the setting is True.

No control is available over the ability of users to insert emojis into channel conversations or personal chats.

## Disabling Chat

Disabling Chat through a messaging policy removes access to the Chat app throughout Teams, but this approach is not recommended. Disabling the Chat app means that users won't be able to:

- Collaborate with other Teams users on an ad-hoc basis, including both personal (1:1) and group chats. Losing the ability to use group chats means that people won't be able to discuss issues and resolve points among a small number of people before bringing the issues for a wider general review in a channel conversation.
- Use federated connections to Teams users in other tenants or Skype consumer users.

Guest users don't have accounts, so they cannot be assigned Teams policies, so if you want to stop guests from using chat between themselves or with tenant users, you must disable Chat in the Guest access section in the Users settings.

Although some feel that it is a good thing to remove chat to force users to conduct conversations in channels, the experience of Teams deployments indicates that users are more likely to seek other options for personal conversations outside Teams, such as WhatsApp. Moving these conversations outside Teams impacts the effectiveness of the organization's compliance policy because chats are then not captured and available for eDiscovery.

## Disabling Meeting Chat

Meeting chats are different from personal chats. A meeting chat is associated with a Teams meeting and is governed by the meeting policy assigned to the participants. The *Allow chat in meetings* setting is usually enabled to permit users to join the meeting chat. If disabled, users cannot chat with other participants during the meeting. This is a big loss because chat is an excellent way for participants to post questions and responses during presentations, or for meeting presenters to share additional information (such as the URL to a web page) with participants.

## Meeting Policies

The meeting policy assigned to a user account controls what that user can do in meetings. The General policy is the default, but you can create as many other policies as you like in the *Meeting policies* section under *Meetings*. Some settings apply to meeting organizers (like who can present in a meeting) and allow organizers to change how meetings work through meeting options. Other settings apply on a per-user basis to control the functionality available to individual accounts when they join meetings.

The settings in a meeting policy are in the following groups:

- **General:**
  - **Allow Meet Now:** Users can create ad-hoc private meetings within a channel.
  - **Allow the Outlook add-in:** Allow users to schedule Teams meetings via the Outlook add-in for Teams.
  - **Allowing channel meeting scheduling:** A channel meeting is available to anyone who can access the channel. For public teams, this means that anyone in the tenant can join the meeting.
  - **Allow scheduling private meetings:** Users can create private meetings, meaning that only invited attendees can access the meeting.
- **Audio and Video:**
  - **Allow transcription:** Allow users to turn on automatic transcription generation for a meeting.
  - **Allow cloud recording:** Allow Teams to record meetings. Teams stores MP4 files for meeting recordings in OneDrive for Business and makes the recordings available to meeting attendees after meetings finish. A separate setting in calling policies controls if users can record 1:1 calls.

The *AllowCloudRecordingForCalls* setting is Off (*\$False*) by default and can only be enabled (set to *\$True*) in PowerShell by running the *Set-CsTeamsCallingPolicy* cmdlet.

- **Allow IP video:** The default is to allow video meetings. If you want to restrict meetings to audio, move this switch to off. Individual users have the choice to restrict their participation to audio when they join a meeting and might choose to do so if the network connection is poor, or they simply don't want other participants to see them in all their glory.
- **Allow NDI streaming:** Allow the user to employ NDI technology where the video for each participant becomes a discrete video source processible by video production software to create an output.
- **Media bit rate:** The default is 50000 (50 MB). Do not change this value unless you have good reason to do so.
- **Content Sharing:**
  - **Screen sharing mode:** Teams allows users to share content from their PC to meeting attendees on the entire screen or as a single application. If you want to prevent this, disable the setting. The default is "Entire Screen."
  - **Allow participant to give or request control:** Allow a meeting participant to give control of a meeting to another participant, or request control if they don't already have control.
  - **Allow an external participant to give or request control:** An external participant is a guest user or an anonymous user who joins a meeting. The setting is *On* for the default policy, but *Off* for other meeting policies that you create.
  - **Allow PowerPoint sharing:** Allow meeting participants to share PowerPoint presentations. Sharing a PowerPoint presentation is an alternative to sharing a complete desktop and consumes less bandwidth when network resources are scarce. See [this page](#) for more information.
  - **Allow whiteboard:** Allow meeting participants to use the whiteboard app.
  - **Allow shared notes:** Allow meeting participants to share notes during the meeting.
  - **Select video filters:** Allow users to select from no filters, background blur, curated background images, or custom images they upload.
- **Participants and Guests:**
  - **Let anonymous users start a meeting:** This setting allows anonymous users (people unknown to the organization) to start a meeting if they are the first to join. The default is *Off*.
  - **Roles that have presenter rights in meetings:** This setting controls who can act in the presenter role during a meeting. The usual value is *Everyone, but user can override*, which means that meeting organizers decide who can present.
  - **Automatically admit people:** This setting controls whether people can join meetings automatically. The default is *Everyone in your organization*, which means that tenant users can join meetings without going through the meeting lobby. You can also set it to *Everyone*, which then allows external users to join without having to wait for admittance in the lobby.
  - **Allow dial-in users to bypass the lobby:** Allow meeting participants who join via phone to enter the meeting without pausing for admittance in the lobby.
  - **Allow meet now in private meetings:** Allow users in personal chats to meet now and create a video or audio meeting.
  - **Enable live captions:** If enabled, Teams generates captions for the conversation.
  - **Allow chat in meetings:** If enabled, meeting participants can chat during the meeting. You can enable or disable chat for all participants or allow all participants to send messages except those who join anonymously. Blocking the ability of anonymous participants to send messages doesn't prevent them from reading the meeting chat.
  - **Meeting reactions:** Set the toggle on to allow participants and guests to use reactions (like applause) during meetings.

## Updating Meeting Policies with PowerShell

In some cases, Microsoft introduces meeting policy settings to support new functionality that is managed through PowerShell. This is usually an interim situation while Microsoft updates the Teams admin center UI. The `Set-CsTeamsMeetingPolicy` cmdlet updates meeting policy settings. This example enables settings in the default policy to:

- Allow meeting chat for everyone except anonymous participants.
- Allow the download of meeting engagement reports.
- Sets the languages used to generate meeting invitations to US English and German (user language preferences cannot override this setting because it's applied on the server when [Teams generates the joining instructions for meetings](#)).

The Global policy applies to Teams users unless their accounts are assigned other meeting policies:

```
[PS] C:\> Set-CsTeamsMeetingPolicy -Identity Global -MeetingChatEnabledType EnabledExceptAnonymous -AllowEngagementReport "Enabled" -MeetingInviteLanguages "en-US,de-DE"
```

## Meeting Customization Policies

Meeting customization policies control features that require users to have the [Teams advanced communications add-on](#). A customization policy allows an organization to define one or more lobby images for meeting organizers to choose from when they set up a meeting. People in the lobby then see the selected image, which is often a corporate logo. The other feature controlled by a meeting customization policy is the ability to upload corporate images for people to use as backgrounds during meetings. Corporate images appear before Microsoft's default set of meeting backgrounds and the custom images uploaded by a user.

## Custom Teams Meeting Invitations

Organizations can customize the emails generated for Teams meeting invitations. Open the Meetings section of the Teams admin center and navigate to *Meeting settings*. You can now customize four components used by Teams to create email invitations for meetings:

- **Logo URL** points to a network-accessible JPEG or PNG file that Teams inserts into meeting details. [Microsoft's documentation](#) recommends using an image that's no more than 188 pixels wide by 30 pixels tall. I have used considerably larger images, but it's best to stay somewhat close to the recommended size to avoid bloating Teams meeting invitations with unnecessary graphic content.
- **Legal URL** points to a web page containing information users need to know about Teams meetings. For instance, the page might explain why Teams displays reminders when an organizer records a meeting.
- **Help URL** points to a web page containing information about Teams meetings. For example, the page could explain that Teams meeting recordings are subject to an automatic expiration policy.
- The **footer** is free-form text containing whatever words of wisdom seem appropriate.

After completing the meeting settings, you can test what the customized body of a Teams meeting invitation looks like by clicking the *Preview invite* button. The view presented is only an approximation of what users see. The actual format depends on the client in use, but it's close enough to understand what people might see.

If meeting organizers update the details of a meeting (like setting a new time), the meeting invitation sent by Teams does not include the organization logo.

## Feedback Policy

By default, users can submit feedback to Microsoft using the **Give feedback** option under Help. Microsoft can also prompt users to take periodic surveys to tell Microsoft how they're getting on with Teams. Many

organizations dislike the idea of users providing direct feedback as they consider this to be a function of the organization after gathering opinions across the entire user base. In these circumstances, you can disable the ability of users to give feedback or participate in surveys by:

- Amend the default (global) feedback policy. This approach has the advantage that it covers every user, including new accounts. If you decide to allow some users to submit feedback, you can create and assign a feedback policy that allows these options.
- Assign the Disabled feedback policy provided by Teams.
- Create and assign a new custom feedback policy to disable the options. The advantage of this approach is that the tenant controls the policy settings. The downside is that you must remember to assign the custom policy to new accounts after their addition.

These actions must be performed with PowerShell because the Teams admin center doesn't include the ability to manage feedback policies. To create a new feedback policy, run the *New-CsTeamsFeedbackPolicy* cmdlet:

```
[PS] C:\> New-CsTeamsFeedbackPolicy -Identity "Tenant Disabled Feedback" -UserInitiatedMode Disabled -ReceiveSurveysMode Disabled
```

*UserInitiatedMode* controls the visibility of the **Give feedback** option while *ReceiveSurveysMode* controls if users see the Microsoft surveys. Unfortunately, bulk policy assignment (which we will cover soon) does not support feedback policies, so you must assign the new policy individually using the *Grant-CsTeamsFeedbackPolicy* cmdlet. These commands read in a set of user principal names stored in a CSV file, assign a policy to each user, and check that the target accounts have the expected feedback policy.

```
[PS] C:\> Users = Import-CSV c:\temp\Users.csv
# Assign the Disabled feedback policy to all users loaded from the CSV file
ForEach ($User in $Users) { Grant-CsTeamsFeedbackPolicy -Identity $User.UserPrincipalName -Policy "Tenant Disabled Feedback" }
# Check that the assignment works
Get-CsOnlineUser | ? {$_.TeamsFeedbackPolicy -eq "Tenant Disabled Feedback"} | Format-Table DisplayName, TeamsFeedbackPolicy
```

## Assigning Policies

Several methods exist to assign Teams policies to user accounts, including:

- Individual assignment by updating the policies section of user accounts in the Teams admin center.
- Bulk editing by selecting a set of users in the Teams admin center and assigning the same policies to the selected accounts.
- Running PowerShell cmdlets like *Grant-CsTeamsMeetingPolicy* to update individual or multiple accounts. Companies often configure Teams policies for users as part of their account provisioning process.
- Using a bulk policy assignment to assign a policy to up to 5,000 accounts. This is a good method to assign the same policy to many accounts at one time and works by defining a set of accounts to receive a policy and submitting a batch job to perform the assignments using the *New-CsBatchPolicyAssignmentOperation* cmdlet.
- Group policy assignment. This is an effective way to assign a set of policies to a large population of target accounts. The membership of a distribution list, security group, or Microsoft 365 group defines the target accounts. Through the Policy packages section of the Teams admin center, the group is associated with a policy package, a set of up to ten different Teams policies including meeting, message, app setup, voice routing, and calling. The association of the policy package with the group causes Teams to assign the individual policies specified in the package to the user accounts defined in the group. Microsoft includes a set of predefined policy packages with Teams. The predefined policy packages are unchangeable, but the details of the policies contained in the predefined packages are editable. Organizations can define custom policy packages using tenant-specific policies if they have

Teams advanced communications add-on licenses for every account assigned policies through these packages.

Direct policy assignment occurs when an administrator assigns a policy to an account by editing the account properties. Direct assignments take precedence over assignments inherited through group membership. In addition, an account might inherit policies through multiple groups. When this happens, the priority order for the policy package dictates which policy becomes effective.

Given the range of options available to manage Teams policies, most companies should be able to find suitable methods to assign policies to individuals or sets of users.

## Bulk Policy Assignment

Although it's easy to write PowerShell scripts to process policy assignments for users, using bulk assignment jobs is the most efficient way to assign policies to large groups of users. Here's an example of the bulk application of a policy (in this case, a meeting policy) to a set of users. First, we find a set of mailboxes based on a value in a custom attribute and extract the user principal name for each account. The data is stored in an array variable.

```
[PS] C:\> $Users = Get-ExoMailbox -RecipientTypeDetails UserMailbox -Filter {CustomAttribute14 -eq "Code22"} -ResultSize Unlimited | Select -ExpandProperty UserPrincipalName
```

Although a maximum of 5,000 accounts can be included in a single operation, it's wise to divide processing up across smaller batches and run a single batch at a time. This approach allows you to take corrective action if errors are encountered for some reason. Another way of managing the set of users for a bulk assignment is to use a CSV to collect the account information. If you do, make sure that the CSV file only contains user principal names. When you're ready to import the data, create an array and populate it with the user principal names from the CSV. For instance, this snippet creates a suitable variable and populates it with the imported data:

```
[PS] C:\> $TargetUsers = Import-CSV c:\temp\UsersToProcess.CSV
$Users = [System.Collections.Generic.List[Object]]::new()
ForEach ($U in $TargetUsers) { $Users.Add($U.UserPrincipalName) }
```

Next, create a policy assignment operation linking the policy to apply and the set of users to process:

```
[PS] C:\> New-CsBatchPolicyAssignmentOperation -PolicyType TeamsMeetingPolicy -PolicyName
RestrictedFunctionality -Identity $Users -OperationName "Teams Meeting Policy Assignment"
2d5c6c07-bc19-4c6c-a359-2f6530b3a652
```

As you can see, Teams responds with an operation identifier (a GUID). This can be used to find the status of the operation:

```
[PS] C:\> Get-CsBatchPolicyAssignmentOperation -OperationId 2d5c6c07-bc19-4c6c-a359-2f6530b3a652 |
Format-List

OperationId      : 2d5c6c07-bc19-4c6c-a359-2f6530b3a652
OperationName    : Teams Meeting Policy Assignment
OverallStatus    : NotStarted
CreatedTime      : 3 Jun 2020 17:13:46
CreatedBy        : 53f08764-07d4-418c-8403-a737a8fac7b3
CompletedTime    :
CompletedCount   : 0
ErrorCount       : 0
PendingCount     : 4
```

We can see that the background processor has not yet started to process the operation. It can take up to an hour before processing starts. We can determine which account submitted the operation by fetching its object identifier from the operation properties and running the Get-MgUser cmdlet to return the display name of the account:

```
[PS] C:\> Get-MgUser -UserId (Get-CsBatchPolicyAssignmentOperation -OperationId 2d5c6c07-bc19-4c6c-a359-2f6530b3a652).CreatedBy | Select DisplayName
```

```
DisplayName
```

```
-----
```

```
Global Tenant Administrator
```

Eventually, the operation will finish, and its status will change to *Completed*. If the *ErrorCount* is non-zero, we can check the state of each account processed with:

```
[PS] C:\> Get-CsBatchPolicyAssignmentOperation -OperationId 2d5c6c07-bc19-4c6c-a359-2f6530b3a652 | Select -ExpandProperty UserState
```

Id	Result	State
--	-----	-----
Ben.James@Office365itpros.com	Success	Completed
Imran.Khan@office365itpros.com	Success	Completed
John.Adams@office365itpros.com	Unknown error occurred.	Completed
Rene.Artois@office365itpros.com	Success	Completed

In this instance, a problem happened with the John Adams account. You'll need to check the account to see what might have caused the problem. It might just be a temporary glitch (or the account was already assigned the policy) and you can go ahead and make the change to the account manually through the Teams admin center. The "user not found" error is common and usually happens when a mistake is made with a property like a user principal name and the batch processor cannot find the account to update.

To discover who has been assigned a policy, you can use the *Get-CsOnlineUser* cmdlet. For example, this command reports the accounts assigned a Teams meeting policy called 'RestrictedFunctionality':

```
[PS] C:\> Get-CsOnlineUser -Filter {TeamsMeetingPolicy -eq 'RestrictedFunctionality'} | Select UserPrincipalName
```

To report users assigned a default policy, check for a null value in the meeting policy:

```
[PS] C:\> Get-CsOnlineUser -Filter {TeamsMeetingPolicy -eq $Null} | Select UserPrincipalName
```

**Reporting Teams Policy Assignments:** After you're finished assigning policies to Teams users, you might like to generate a report showing what policies apply to what accounts. Teams doesn't include a report of this nature, but it's easy to generate with PowerShell. [This article](#) explains how to write a script to create a Teams policy report output in both HTML and CSV formats.

## User Settings

User settings cover the management of users, settings for guest access, and controls for external access (federation). User management deals with the assignment of Teams policies to user accounts.

### External Access

**External access** defines how users communicate with people outside the tenant. The settings are:

- **Teams and Skype for Business users in external organizations** – This setting needs to be *Allow all external domains* (open federation – the default) or *Allow only specific external domains* (limited federation) before people can communicate with users in other organizations. See the later section covering how external access works.
- **Skype users** – Turn *On* to allow Teams to communicate with Skype users.

In addition, you can define a list of domains to block or allow for external communication. If you only want users to communicate with people in specific domains, define those domains here, or block the domains that you don't want people to communicate with. Leave the list blank if you are happy for people to communicate with users in any other Teams organization.

## Guest Access Settings

**Guest access** settings control what a guest user can do within Teams. The settings include enabling or disabling guest access for the tenant, allowing guests to use personal chat, and settings to control the interaction guests have with messages like the ability to edit or delete sent messages. Settings are available to control aspects of guest participation in meetings, such as allowing guests to use the Meet Now feature to create impromptu meetings. Microsoft enables guest access for Teams for new tenants.

## Teams Settings

**Teams settings** are organization-wide settings to control how users interact with Teams for aspects not covered by messaging and meeting policies. These settings include:

- **Notification and Feeds:** Define if you want Teams to add suggested items in users' activity feeds.
- **Tagging:** Define who can manage tags, suggested tags that appear in all teams, and whether users can create custom tags.
- **Email integration:** Settings to control if people can send email to channels (see later section later) using special email addresses generated by Teams for channels. If you enable email integration, you can also confine the ability of people to send email to channels to an allowed list of SMTP domains.
- **Files:** Settings to control how users can share files, including whether they can share files using third-party cloud storage solutions (ShareFile, Box, DropBox, and Google Drive).
- **Organization:** Turn the organization tab on or off. If enabled, the tab allows Teams users (but not guests) to see details of the organizational hierarchy represented by the manager-employee connections stored in Azure AD.
- The **Devices** settings control how Room Systems (like a Surface Hub) and IP phones work in meetings. The settings are:
  - Require a secondary form of authentication (the default is no access).
  - Set content PIN. The default is that a PIN is needed for outside scheduled meetings.
  - Surface hub accounts can send messages. Some devices such as Surface Hub use device accounts to interact with real users through email, IM, and calls. By default, this setting is True, which allows devices to send IM messages.
- **Search by Name** defines whether directory searches performed by Teams users are limited by Exchange address book policies (ABPs). An address book policy limits the visibility of a user to specific sections of the overall corporate address book, such as only the users in a certain department or country. Policies are often used to limit communications between different groups like students and teachers or traders and financial advisors. The default for the directory search setting is Off, meaning that no restrictions are placed on users. If set to On, the user is limited to whatever address book policy is defined for their mailbox (if no policy is defined, they can see and communicate with everyone in the directory). For example, they can only start a personal chat with another user who is visible to them according to the address book policy. In addition, if you use address book policies to limit the directory search for users, Teams is no longer able to suggest teams for them to join (and disables the /Join command). Limiting directory searches for Teams is a prerequisite for Information Barriers (discussed later). See Chapter 3 in the Companion Volume for more information about creating and using address book policies.
- **Safety and Communications:** This setting controls if supervised chat is enabled for the organization. The most common use of supervised chat is in education settings where a teacher or responsible adult oversees chats between students.

## Planning

The Planning section of the admin center covers:

- Teams advisor: This is a wizard-based guide to help organizations who do not currently use Teams roll out different areas of functionality. See [this page](#) for more information. Among the topics covered by the advisor are:
  - Chat, messaging, and apps.
  - Meetings and conferencing.
- Network planner: See the Calling and Devices chapter for more information about planning your network for Teams and the Microsoft Phone system (cloud voice).

## Licensing Teams

The license necessary to access Teams is bundled in many Microsoft 365 offerings, with the notable exception being standalone subscriptions, like Exchange Online Plan 2. These users can't even join teams as guest users because Microsoft 365 considers them to be part of the same organization that hosts the teams and therefore aren't guests.

You can selectively enable or disable Teams on a per-user basis by editing a user's account in the Microsoft 365 admin center and switching their Teams license on or off. If you need to enable or disable Teams for many accounts, it's easier to do this with PowerShell (see the license management section in the PowerShell chapter). To ensure that the widest range of functionality is available to users, make sure that you enable Exchange Online and SharePoint Online for anyone using Teams. Users who do not have a license for SharePoint Online cannot use OneDrive for Business to share files with users in personal or group chats.

### Teams Licenses for Guest Users

Guest users for Teams are licensed based on five guest users per licensed tenant user. In other words, if your tenant has 100 licensed users, it can support up to 500 guest users.

If you don't want a guest user to access Teams in your tenant any longer, you should remove their account from Azure AD. Removing the account has the side-effect of removing their access from any other application that depends on Azure B2B Collaboration, such as Planner. It also removes any sharing access the account has been granted to documents in SharePoint Online or OneDrive for Business libraries.

## Access for On-Premises Users

If a tenant uses AAD Connect to synchronize accounts with an on-premises deployment, users can create and access Teams even if their mailboxes are on Exchange on-premises servers. These users can take part in conversations, group chats, and calls and set up new tabs. However, they cannot create or change the connectors associated with a tab, nor can they create or access meetings or even change their profile picture.

## Creating Teams

Before anyone can create a new team, they must be able to create a new group. Some tenants allow any user to create a group while others control group creation to a limited set of authorized users. The settings to control who can create new groups (and teams) are in the Azure AD policy for Groups. Chapter 11 includes a full discussion of how to manage policy settings using PowerShell. If the policy restricts the ability of users to create new groups, it should also include a pointer to a group holding a list of people who can create new groups. If your account is on that list, you can go ahead and create a new team. If not, you will see an error informing you that *"Your IT department has disabled this Microsoft Teams feature for you"* together with a suggestion to contact the IT department for help.

The recommended methods to create new teams are:

- Teams app (desktop, web, or mobile).

- Teams admin center.
- *New-Team* cmdlet in the Teams PowerShell module.
- Teams Graph API. This includes methods such as “teamifying” a SharePoint Online site (create a new team for an existing site using the SharePoint browser UI).

The advantage of these methods is that they explicitly mark a group as intended for use by Teams. In technical terms, this means that several properties of the group are set for Teams. These include:

- The group is hidden from Exchange clients like Outlook and OWA (*HiddenFromExchangeClientsEnabled* is *\$True*).
- The group is hidden from Exchange address lists like the GAL and OAB (*HiddenFromAddressListsEnabled* is *\$True*).
- New members receive a welcome message for Teams instead of Microsoft 365 Groups.
- Members are not subscribed to receive calendar updates for the group. This means that team members do not receive invitations to meetings scheduled in the group calendar (channel meetings). Some organizations prefer that team members receive invitations. If this is the case, you can update the *AlwaysSubscribeMembersToCalendarEvents* property for the group to *\$True*.

You can also create a new group and add members to it through the Azure AD admin center, OWA, the *New-UnifiedGroup* cmdlet, or any of the other methods available for group creation, and then team-enable the group. If you take this approach, consider updating the group settings listed above to make the group work like those created by Teams.

## Automate Teams Creation

Many organizations restrict the creation of teams and require users to go through a process to seek approval for a new team and use methods like a Power Automate flow or PowerShell script to automate the collection of details for the new team, gaining approval, and creating the team if approved. Microsoft has a sample Power Apps application (called [request-a-team](#)) to automate the provisioning of new teams. You can [download its source code from GitHub](#). Whatever method you use, remember to:

- Update team properties like hidden from address lists, and hidden from Exchange clients, just like a team created by Teams would be.
- Add a description so that people will remember why the team exists.
- Set the privacy of the new team to Public or Private.
- Assign a classification or sensitivity label to the team (assigning the label will set the privacy).
- Ensure that the new team has at least one owner.
- Populate the initial membership.

## Creating a Team in the Teams Client

To create a new team in the desktop or browser client, click **Teams** in the navigation bar and then **Join or Create a Team** at the bottom of the screen. You can now choose to create a new team or join one of the teams suggested by Teams. To create a new team, you can:

- Create a new team from scratch.
- Use an existing group or team as a template.
- Use a template created by Microsoft.

You can also team-enable an existing modern SharePoint Online site (one with a Microsoft 365 group) from the SharePoint browser interface.

The Teams mobile client only allows you to create a new team from scratch. You can't create an org-wide team or team-enable an existing group using the Teams mobile client.

## Creating a New Team from Scratch

Creating a team from scratch means that you have maximum control over its characteristics. The first step is to choose what kind of team to create. A team can be:

- **Private:** The team owners and tenant administrators control membership and decide who can join the team. This kind of team isn't discoverable by users.
- **Public:** Anyone in the organization can join the team.
- **Org-wide:** Every licensed account in the organization automatically becomes a member of the team. Like other teams, org-wide teams can support up to 10,000 members. If your tenant exceeds the membership threshold or five org-wide teams already exist, you won't have the choice to create org-wide teams and should consider an alternative for org-wide communications (Yammer, SharePoint, etc.). Only tenant global administrators can create org-wide teams.

The basic details for the new team are:

- **Team Name:** This is the display name for the team (and the underlying group) and it is what appears in the list of teams in the Teams client and the Exchange GAL (if you decide to reveal Teams to Exchange). It is always best when you give a team a meaningful name that conveys its purpose. If your organization uses a group naming policy, Teams shows the effect of the policy by displaying the name of the team after it applies the policy when it creates the new team. The group naming policy does not affect tenant administrators, so teams created by administrators keep the display name as entered.
- **Description:** This is a free-form text description of why the team exists and what the members of the team use it to do. Users see the team description when they browse teams, so it is important to put some thought into the description to make it accurate, interesting, and easily digestible. Get right to the point and put the essential information like the purpose of the group at the start and make sure that the first 80 characters convey the essence of the group because this is the amount of text displayed in search interfaces. Put less essential information at the end of the description, such as who created the team, the contact name for the team, and so on.

To indicate the level of confidentiality of the information contained in a team, it has a classification. This can be set by assigning a:

- **Sensitivity label:** if the tenant uses sensitivity labels for container management (see below), the team inherits the privacy level (public or private) and guest access (on or off) from the settings in the chosen label.
- **Classification:** Classifications are simple text description strings defined in the Azure AD policy for Groups. Classifications do not affect team settings.

Teams clients do not check that a group, distribution list, or team of the same display name already exists in the tenant, so it is quite possible to create multiple teams with the same name. This is one of the good reasons why some tenants restrict team creation to a small set of people, who have the responsibility to check that the display name does not clash before they create a team.

After entering the properties, click **Next** to continue. Teams creates the group object in Azure AD and Microsoft 365 provisions the resources used by the team, such as the SharePoint team site.

## Sensitivity Labels and Teams

If the tenant enables sensitivity labels for container management, Teams retrieves settings from sensitivity labels when creating new teams or when editing the properties of existing teams. When a team has a sensitivity label, the team uses the name of the label as its classification and applies the settings in the label

for privacy and guest access. If the team has any private or shared channels, the channels and the SharePoint sites belonging to those channels inherit the label assigned to the parent team.

If an administrator or group owner updates the sensitivity label assigned to a group or SharePoint site linked to a team, the updated label assignment synchronizes to Teams to apply the settings from the new label. The synchronization of label assignments from other workloads can take up to 24 hours.

Currently, the only way to assign a sensitivity label to a team is via a client. The Teams PowerShell module does not support sensitivity labels (cmdlets in the Groups and SharePoint modules can assign labels, which then synchronize with Teams) and you can't assign a sensitivity label to a team using the Graph API or when creating a team from a template.

Assigning a sensitivity label to a team does not affect the information stored in the team. See the Information Protection chapter for more information about sensitivity labels and container management.

## Create a Team from an Existing Team or Group

If you don't want to create a team from scratch, you can choose to create a new team based on the settings of an existing team (a template) or you can team-enable a group.

### Using an Existing Team as a Template

The idea behind creating a team using an existing team as a template is that if you are in the position where you need to create multiple teams with approximately the same structure, it's easier to create one team to use as a template and set the team up in a form that you want to replicate to other teams. You can only use a team as a template when you have access to that team (you're a member).

When you create a new team based on a template, you can replicate the membership (including guests), settings, channels, apps, and tabs from the template team. No content is copied across in terms of conversations or files, and some tabs will need to complete a setup process before they can be used. For instance, if the template team includes a tab pointing to Planner in a channel, the channel and the tab are copied to the new team, but because the plan doesn't exist for the channel, you must start Planner and create the plan.

### Enabling Existing Groups for Teams

In many ways, team-enabling a group is an interesting decision because it switches the focus for conversations in the group away from email to channel conversations. There is no way to migrate existing conversations from a group into channels, so the switch is a one-time all-in operation. However, the files stored in the group document library remain available to the team.

Whether you create a team from scratch or team-enable an existing group, you end up in the same place with a team-enabled group. The difference between the two methods is that team-enabling an existing group automatically makes the team available to the current group members because Teams and Groups share the same membership.

Groups can only be team-enabled by their owners. To begin, a group owner goes through the normal process to create a new team, but instead of creating a new team, they select **Create from an existing Microsoft 365 group or team** and then choose **Microsoft 365 group**. This option only appears when the user is an owner of one or more Outlook-based groups that are not yet team-enabled (Yammer-based groups are unsupported). Click the link to expose the set of groups owned by the user that are not team-enabled. (Figure 13-3). As the UI only shows only a small number of groups at a time, it might be necessary to scroll through the list to find the group that you want to upgrade. Among the list, you will find groups that are hidden from Exchange address lists (because Teams does not use address lists). However, groups with hidden membership do not appear. Select the group that you want to enable for Teams and click Choose team to begin the

process to populate the team resources and properties for the group. You cannot team-enable several groups at one time.

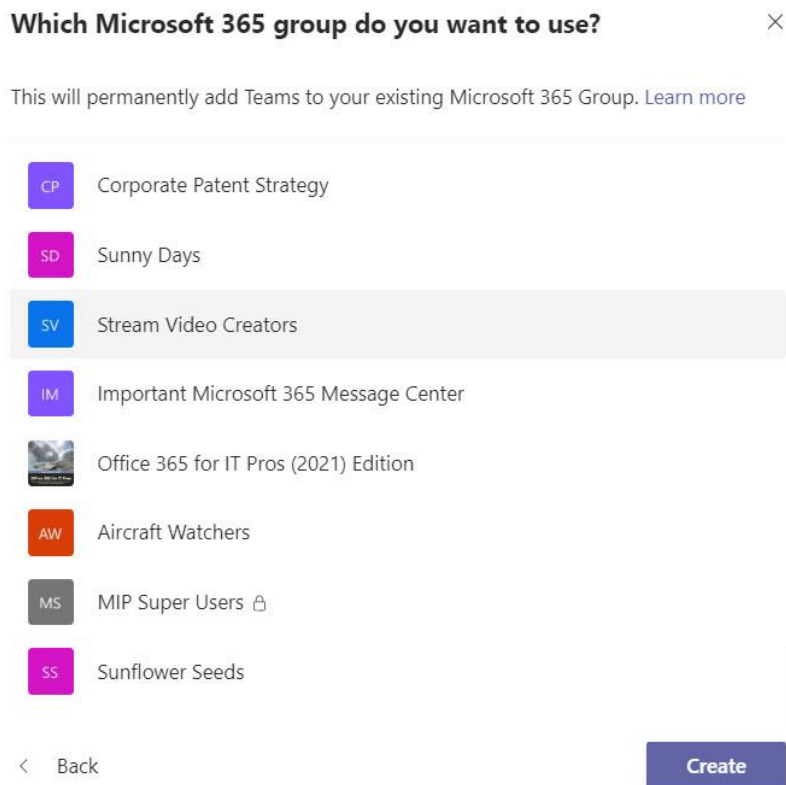

Figure 13-3: Selecting an existing group to create a new team

A group owner must decide to enable the group for Teams. There is no way for a user to search for a group that is not team-enabled and ask its owner to upgrade it. A group owner does not have to be permitted to create new groups to be able to team-enable an existing group. After you team-enable a group, you should consider hiding it from Exchange clients to force users to use Teams for conversations (see below).

## Creating Teams from Templates

Team templates are prepopulated structures created by Microsoft or the organization to make it easy to create teams to do a specific job. Each template consists of a set of channels, tabs, and apps automatically added to teams created using the template. Some of the 13 out-of-the-box templates are for general use (like project management); others (like Organize a Store) are for a particular industry. Among the templates published by Microsoft are:

- Adopt Office 365.
- Manage a project.
- Manage an event.
- Onboard employees.
- Organize help desk.
- Coordinate incident response.

Read [this documentation](#) for more information about creating teams from templates.

As an example of what happens when you create a team using a template, if you use the Manage a Project template, Teams adds four channels and two apps to the new team. The channels are General, Announcements, Resources, and Planning while the apps are OneNote and Wiki. During the creation process, you can rename the channels to make them more appropriate for the new team and add a sensitivity label to

reflect the importance of the information you expect the new team to contain. After creating the team, you still need to add team members, add other apps and channels (including private channels), post a welcome note, and take whatever other actions are necessary to build out the complete team.

Template management is in the Teams section of the Teams admin center. You can add, edit, or remove templates to meet the needs of the organization, including the ability to copy (duplicate) one of Microsoft's policies to create a customized version more suitable for your organization. Custom templates created by a tenant appear before the standard templates from Microsoft when shown to people creating new teams.

[PowerShell cmdlets to manage team templates](#) are also available.

## Template Policies

Template policies control the set of templates visible to users when they create new teams. The default global policy makes all templates visible. It's a good idea to consider creating custom team templates to deliver a more refined view to users. For instance, you could create a template that shows only custom templates and omits all the standard templates created by Microsoft. Template policies are managed in the Teams section of the Teams admin center. No PowerShell cmdlets are available to manage these policies.

Creating a new template policy is simple. Navigate to the Teams section in the Teams admin center and select Teams templates. Create the policy and give it a name and description. Then select the set of templates you want to hide from the available set. Click the *Hide* button to make the choice effective and then save the policy. The next step is to assign the policy to users individually or by using a bulk policy assignment job (the policy type is *TeamsTemplatePermissionPolicy*). Give the policy a couple of hours to become effective and then test it by asking one of the users assigned the policy to create a new team. They should then see the set of templates dictated by the policy.

## Adding Team Members

### Add members to Infrastructure and Technology Plans 2020 (Team)

Start typing a name, distribution list, or mail enabled security group to add to your team.

Figure 13-4: Adding members to a team

After Teams creates the new team, you can add members (Figure 13-4) and specify whether the new member is an owner or just a normal member. You can add individual users or use a distribution list, mail-enabled security group, or group (or another team) as a source, in which case Teams expands the membership of the selected group and adds each user individually to the team. Teams excludes unsupported recipient types found in these groups (such as a mail-enabled public folder) and will not try to add them as members. If you

use any form of a group to add members to a team, remember that any later changes to the membership of the source group will not replicate to update the membership of the team.

As described later, if the tenant supports guest accounts, you can add external people as guest members. If team settings block guest membership, Teams won't show you guest accounts that already exist in the tenant directory or allow you to input the email address of an external user to create a new guest account. Finally, if your tenant uses information barrier policies to stop different sets of users from communicating with each other, you won't be able to add someone to a team if their presence causes a policy violation. To automate processing, any of the supported member types can be added to (or removed from) a team with PowerShell.

## Updating Team Rosters

Internally, Teams refers to the membership of a team as its "roster." If you add someone to a team through a Teams client, the roster is refreshed immediately in that client. Changes to membership can be made elsewhere by another Microsoft 365 application and synchronized to Teams. For example:

- A team membership is updated with a Teams client. The update is synchronized across Teams and to Azure AD.
- A team membership is updated using PowerShell, the Graph API, or another administrative interface. Usually, the change is written to the underlying Microsoft 365 group.
- A team membership is updated with a non-Teams client like OWA. The change is made available to Teams by synchronization between the workload and Azure AD.

Behind the scenes, Teams uses a background process called *Roster sync* to implement changes made in Azure AD in clients. When a user connects to a team with the desktop client, a check is made to see if any changes are waiting in Azure AD. If some are, the Roster sync process downloads the changes and updates the local cache.

The internal SLA for synchronization between Teams and Azure AD is 24 hours, and at worst it can take this long before a change made to group membership by another workload is effective across Teams. Usually, changes are available much sooner than the SLA limit.

**Teams with Duplicate Names:** As noted above, Teams will let you create a team with a display name that duplicates another team. This will confuse users who belong to those teams as they will never be quite sure which team they should use. From a technical perspective, Teams is quite happy to have duplicate display names because behind the scenes the teams have different aliases and names. If you get into this unhappy circumstance, you can change the display name of one of the affected teams by editing the team properties (Edit team) or by running the *Set-UnifiedGroup* cmdlet to update the *DisplayName* property for the underlying group. For example:

```
[PS] C:\> Set-UnifiedGroup -Identity BudgetPlanning -DisplayName "Budget Planning Group"
```

Renaming the team fixes the immediate issue of the duplicate display name. It will not rename the SharePoint team site. If you want to rename the SharePoint site, do so in the SharePoint Admin Center or use the *Start-SPOSiteRename* cmdlet.

## Creating an Org-Wide Team

If your tenant has fewer than 10,000 accounts (the limits are smaller for GCC and GCC/High tenants), you can create an org-wide team. A tenant can have up to five org-wide teams. Org-wide teams are intended for tenant-wide communications without the need for an administrator or team owner to manually add all the employees to the team membership, including the need to check for new employees and add them periodically with PowerShell. The advantage of using PowerShell to manage the membership of an org-wide team is that you have more flexibility in managing the membership; the downside is that you must check and

update the membership with new users and remove those who leave the organization periodically. Using an org-wide team avoids this work.

Larger tenants can consider using:

- **Dynamic Teams** to support discussions for different sections of the organization. For example, you might have a team for each department or each country.
- **Yammer** for company-wide communications and collaboration. Yammer can easily scale up to handle very large organizations with hundreds of thousands of users.

To create an org-wide team, choose **Join or create a team** as usual, then **Build a team from scratch**, and then select **Org-wide** from the list of options. The choice to create an org-wide team is only exposed to tenant (global) administrators and when you create an org-wide team, Teams adds all the global admins as team owners. It then adds all “active users” as members. You know the membership is managed by Teams because the Manage team screen has a banner saying, “*Team members will be automatically added and removed to reflect your Active Directory*”.

Automatic membership should exclude accounts without valid Teams licenses as well as guest users. However, sometimes accounts that should not be included in an org-wide team turn up in the automatically generated membership. Among accounts that should be checked against the team membership are:

- Service accounts (if they are assigned a license).
- Mailboxes used for purposes such as DLP incident reports.
- Accounts that don’t have a valid license where the Teams license is disabled.

Although Microsoft has fixed the bugs at the root of automatic membership, it is still good practice to check the membership after creating an org-wide team to remove anything that doesn’t belong. Once you remove someone from an org-wide team, the service remembers the deletion and won’t try to add that account back to the membership. Likewise, if you find that an account that should be in the membership has been omitted for some reason, you can add them manually. As with any team with a large membership, after you create an org-wide team, consider imposing some order on discussions from the start by updating team settings to restrict channel creation, the ability to post to the General channel, and to use @team mentions (because these generate notifications to everyone).

On an ongoing basis, employees leave and join the company and people lose or gain Teams licenses. When someone leaves the company and their account is removed, their membership in the team is also removed. To handle new joiners and people who gain or lose Teams licenses, a background process running on Teams clients scans the accounts in the tenant periodically (expect new users to appear within a few minutes) and adds or removes the user as needed.

Unlike normal teams, members can’t choose to leave an org-wide team. This limitation is the same as exists for dynamic teams, but unlike dynamic teams, an org-wide team doesn’t use an Azure AD query to calculate its membership. Instead, the background process manages membership and the Azure AD group for the team has an “assigned” membership, so you don’t need to buy Azure AD P1 licenses for all the members.

## Adding New Employees to Org-Wide Teams

Soon after you create an account for a new employee, if the account has a license for Teams, the account is added to the membership of org-wide teams. If your company provisions Microsoft 365 accounts for new employees in advance of their joining date as part of an onboarding process, you might not want this to happen because you don’t want other employees to know that someone is joining the company. In this case, you can either:

- Wait for the employee to join the company and create their account at that point.
- Create the account for the new employee but assign dummy information for the display name and primary SMTP address. For example, you could assign “New Employee” as the display name so that

other employees see that “New Employee.” has joined. The reason why to assign a dummy SMTP address is that users can click on “New Employee” to see more information from their people card. The SMTP address usually contains the first and last name of a person, so you don’t want to expose that information on the people card.

You then update the mailbox display name, name, and SMTP address after the new employee comes on board. If you use a dummy email address, you also need to update the account’s User Principal Name to be the user’s real sign-in address. These updates are easily done using PowerShell. For example:

```
[PS] C:\> Set-Mailbox -Identity NewEmployeexxx20 -DisplayName "Jake Adams" -WindowsEmailAddress "Jake.Adams@Office365itpros.com" -Alias "Jake.Adams" -Name "Jake Adams"
[PS] C:\> Update-MgUser -UserId (Get-Mailbox -Identity Jake.Adams).ExternalDirectoryObjectId -UserPrincipalName Jake.Adams@office365itpros.com
```

You don’t need to worry about keeping the dummy email address assigned to the account because it will never have been used to send an email. Any messages delivered to the mailbox will be waiting for the new employee.

If this arrangement doesn’t work, consider using all-employee teams whose membership is updated manually. It is easy to script additions and removals of employees from membership as part of the HR onboarding or leaving processes. Another workaround is to create accounts for new users in a disabled state and only enable the accounts when people join the organization. Teams ignores disabled accounts when it builds the membership of org-wide teams.

## Updating an Existing Team to be an Org-wide Team

Any existing team with private or public access can be converted by a tenant administrator to be an org-wide team to gain the benefit of automatic membership management. To make a team into an org-wide team, use the **Edit team** feature to change the privacy setting to be org-wide. When you save the setting, Teams updates the membership with all valid accounts. Any users not included in the automatic membership remain in place, including guest users. You can also change an org-wide team to be a private or public team using the same approach, and in this case, the existing membership stays in place, but the automatic background refresh of membership is disabled.

# Dynamic Teams

 This team has membership settings that prevent you from adding or removing members.

You cannot create a team with dynamic membership using a Teams client. Instead, you create a new dynamic Microsoft 365 group through the Azure AD admin center or PowerShell, together with the query to populate the membership. Dynamic groups can have membership rules based on account attributes (such as “everyone in New York City”) or use the membership of other groups, including other Microsoft 365 groups and distribution lists.

When you’re happy that the membership rule for the Azure AD group results in the expected membership, you can go ahead and select the group when creating a new team as described earlier. Teams respects the membership calculated by Azure AD and if you examine the membership (using **Manage team**), you see the same membership there as you see in the Azure AD admin center. However, if you view team membership you see a banner saying that you cannot add or remove members. In addition, the normal **Add Member** button is not shown.

Team owners are static and not computed automatically. You can add team owners to the dynamic group through the Teams client, the Azure AD admin center, or with PowerShell. You can change a member in the

dynamic set to be an owner. However, if you demote an owner to become a member and they are not in the set computed by the query, they lose their membership of the team.

You can also use a dynamic group as the source to add members to another team. In this case, just like a regular distribution list or group, Teams reads the present membership and adds them to the team. And just like when you use other types of groups to populate membership for a team, this is a one-time operation and anyone who joins the original team thereafter does not automatically join the other team.

Dynamic teams depend on the dynamic groups feature in Azure AD. Microsoft considers this to be a premium feature. Every member who comes within the scope of a query used for a dynamic team must have an Azure AD Premium license.

## Hiding Teams from Exchange Online

Teams uses the Microsoft 365 Groups membership service. And because each team has all the resources of a Microsoft 365 group, it has a group mailbox that can function as an Outlook group with email-based conversations. Users therefore could use email or Teams for their conversations. To remove any potential for confusion, Microsoft hides the existence of groups created by Teams from Exchange-based clients (OWA, Outlook desktop, and Outlook mobile).

Following the creation of a new team, Exchange Online sets the *HiddenFromExchangeClientsEnabled* and *HiddenFromAddressListsEnabled* properties of the underlying Microsoft 365 group to *\$True*. The new group is perfect for Teams but remains invisible to Exchange clients and does not appear in address lists like the GAL. In addition, because the focus of communication for the group is Teams communications, the group's subscriber list is not populated with tenant users (guest members are added). Any email sent to the group is delivered to the group inbox, but copies are not distributed to local tenant members (as explained in the Groups chapter, you can set an auto-reply for team-enabled groups to inform email senders that the group doesn't use email). Email from external senders is blocked.

Unfortunately, the flags to hide teams from Exchange Online are not set when an administrator creates a new team-enabled group using an administrative interface like the Teams admin center, Microsoft 365 admin center, Azure AD admin center, SharePoint admin center, or APIs like *New-UnifiedGroup* and the Microsoft Graph API. Administrators have full control over group settings and can update the settings as they wish. The net result is that team-enabled groups can be visible to Exchange Online clients. In addition, older team-enabled groups might not have *HiddenFromExchangeClientsEnabled* set to *\$True* because Microsoft did not update groups retrospectively following the introduction of the setting.

To check if any team-enabled groups are visible to Exchange, fetch the set of team-enabled groups and filter out the hidden groups. For example:

```
[PS] C:\> [array]$Groups = Get-UnifiedGroup -Filter {ResourceProvisioningOptions -eq "Team"}  
-ResultSize Unlimited  
[array]$Groups = $Groups | ? {$_.HiddenFromExchangeClientsEnabled -eq $False}  
$Groups | Format-Table DisplayName
```

To hide a team-enabled group from Exchange clients, update the properties with the *Set-UnifiedGroup* cmdlet. For example:

```
[PS] C:\> Set-UnifiedGroup -Identity Team1 -HiddenFromExchangeClientsEnabled:$True  
-HiddenFromAddressListsEnabled:$True
```

Setting *HiddenFromExchangeClientsEnabled* to *\$True* should also set *HiddenFromAddressListsEnabled* to *\$True*, but it's good to be specific. You can [download a script to find and set the flags for team-enabled groups from our GitHub repository](#).

Exchange clients periodically refresh their list of groups from the server, so it might take between 15 minutes and an hour before a hidden group disappears from a client. When you hide a group from Exchange, you also remove the group from users' Favorites lists for Outlook clients. Another side effect is that because Teams has no user-accessible directory, once a group disappears from address lists, users won't be able to browse groups in the GAL and so won't know of the existence of public teams that they might want to join (or private teams, for that matter). Also, remember that most Outlook desktop clients depend on the OAB and that it takes some time for Exchange to publish the removal of groups in OAB updates that must then be downloaded and applied by clients. See Chapter 3 in the companion volume for information about OAB updates.

## Using a Team-Enabled Group as a Distribution List

Before rushing to hide the groups used by Teams from Exchange clients, remember that Teams uses the Groups service to manage team members. A group is a mail-enabled object, meaning that people can send emails to the group. A group also functions as a distribution list and it can be useful to use the group for that purpose, even when you conduct most discussions inside Teams. For example, you can't send an encrypted message to Teams, but you can send a protected email to the group and the members will receive and be able to read the content in the message (if they subscribe to the group).

It's easier to decide to hide a team when its communications are exclusively internal. Making the call for a team with guest members is harder. When you have a team with many guest members and want to send something important and time-critical to those members, you could post a message in Teams, but each guest then needs to switch to your tenant to read the message. An email to the group might be quicker and more effective if you need fast action.

Even when a team is hidden from Exchange clients, you can send messages to the group by using its SMTP address fetched through the Microsoft 365 admin center or PowerShell. For example:

```
[PS] C:\> Get-UnifiedGroup -Identity MyOffice365Group | Select PrimarySmtpAddress
```

Administrators can find this address relatively easily, but users might not be so lucky.

If you create a team and decide that you want to keep its ability to act as a distribution list, you can reveal it to Exchange by setting the property to `$False`:

```
[PS] C:\> Set-UnifiedGroup -Identity MyTeam -HiddenFromExchangeClientsEnabled:$False
```

Exchange Online delivers messages sent to a group to the Inbox folder of the group mailbox. Local team members do not receive copies of messages because they are not part of the group's subscriber list. This is by design because Teams uses a different type of conversation. For this reason, when you create a new team, Groups sets the `AutoSubscribeNewMembers` property for the group to `False` and does not populate the subscriber list.

Normally, no issue arises because the group's subscriber list is empty. That is, unless you want to be able to use the team to distribute email to all or some of the members by using the team in the same way as a distribution list. To do this, you must add the members who you want to receive emails (or calendar requests) sent to the team to the group subscriber list. You can only do this through PowerShell. For example, this code adds two users (who must already be members of the group) to the subscriber list.

```
[PS] C:\> Add-UnifiedGroupLinks -Identity SeniorLeaders -LinkType Subscribers -Links Jack.Healy@Office365itpros.com, Marc.Vigneau@office365itpros.com
```

# Deleting (and Restoring) Channels and Teams

By default, any member can remove a channel or restore a deleted channel, but you can restrict this ability to team owners by updating team settings and unchecking the “allow members to delete and restore channels” setting under **Member Permissions**. Not only will this prevent accidents (unless a team owner makes a mistake), but it also stops disaffected employees who might be on the way out of the company doing something silly on the way to the exit (they might not know that the channel can be recovered). Like channel creation, Teams generates an audit record whenever someone removes a channel and writes a notification into the General channel. Teams also generates an audit record for the deletion. This information tells you who removed the channel, which might be cold comfort when you consider how much information might be lost in a deleted channel.

## Removing a Channel

You cannot delete the General channel for a team, but you can remove any of the other channels using the desktop, browser, or mobile client. When someone deletes a channel, Teams puts the channel into a soft-deleted state and starts a 30-day countdown, after which the messages and metadata for the channel become irrecoverable. During the 30-day grace period, you can recover the channel by selecting **Manage Team** and then **Channels**. Any deleted channels are listed under the set of active channels. To recover a deleted channel, select it and then click **Restore**. Teams then restores the channel to its original configuration to make its conversations available to users. One point to note is that the restored channel does not regain its previous status in the list of channels visible to the user, so users must mark the channel if they want it to show in their activity feed.

If the 30-day retention period for a deleted channel lapses, you can still recover messages from a deleted channel if the team is subject to a retention hold. To do this, run a content search to find the copies of the items held for compliance purposes in the group mailbox and export the found items to a PST, ZIP file, or individual messages. Although you cannot reassemble the recovered items into the threads they had in the channel, you will be able to email them to a channel or cut and paste content from the recovered items into Teams.

Teams does not remove the folder and files belonging to a deleted channel from the SharePoint document library, including the OneNote sections associated with the deleted channel. If you want to remove the folder and files, you must do so through SharePoint. One good reason why Teams does not remove the SharePoint content is that some or all the content in the folder associated with the channel might come under the scope of a retention policy applied to the site or that individual documents might be assigned retention labels that prevent their removal.

It's also possible that other channel tabs might be associated with content like a plan or form that will remain after the channel deletion. For this reason, it's a good idea to note what tabs exist for a channel and investigate what content is accessed via the tabs to build up a full picture of what's associated with the channel so that you can decide what to remove and what should be left before you go ahead with a channel deletion.

Remember that a team can have a maximum of 200 channels. If a team is at the limit and you remove some channels, the 30-day period must lapse before a Teams background process removes the channels permanently. When this process completes, new channels can be created for the team.

## Removing a Team

A team owner (using the Teams client) or a tenant administrator (using an administrative interface, like PowerShell) can remove a team. When this happens, Azure AD removes the underlying group and all its

resources including its SharePoint team site. For this reason, the owner must confirm that the deletion of the team should go ahead before Azure AD executes the command. This is important because once Azure AD removes the group object all the team data become inaccessible.

Generally, if you want to remove a team, do this from a Teams client as this action makes the team unavailable to all members at once. After removing the team, Teams synchronizes the deletion of the group object to Azure AD. In turn, the deletion command ripples across workloads through the normal directory synchronization process to instruct applications to remove any resources they manage for the group. It can take up to 30 minutes before all the resources belonging to a team are completely removed.

In most cases, unless you need to remove a team, it is better to leave it in place as a disused team. To do this, remove all members from the team except a single owner and update its display name to include a sign that the group is not in active use. This approach keeps the team in a state where you can revive it if needed by simply assigning new owners and members to its membership.

If you remove a team accidentally, you can recover its group (and the team) using the Microsoft 365 admin center or PowerShell, providing you do so within the 30-day retention period for deleted groups. When Azure AD recovers a team belonging to a soft-deleted group, the recovery process puts all content back in place into channels and personal chats and restores any connectors. Any email addresses belonging to channels in the deleted team are reactivated. Although the object for a recovered team is in the directory soon after a recovery begins, it often takes up to 24 hours before all the resources for a team are reconnected. At this point, Teams makes the recovered team available to users.

Although you can team-enable an existing group, no method exists to remove a team from a group, which you might want to do to “reset” a team by removing all channels, including the default channel, removing any tabs, bots, and connectors, and reducing the membership to a single owner. The only way to reset a team is to remove the group (and all its resources) and recreate it from scratch.

## Channel Moderation

You might want to reserve a channel for specific posts such as group announcements. The General channel has a setting to limit new posts to group owners. Moderation serves much the same purpose for channels other than General by controlling who can post new topics and replies to the channel.

Moderation is supported for both public and private teams. To enable moderation, select the channel you want to control and then **Manage channel** from the [...] menu. You can then turn moderation on or off for the channel (the default is Off). Even if moderation is disabled, you still have the option to restrict the creation of new topics (posts) to any member of the team or everyone except guests. After enabling moderation for a channel, the next step is to decide who the moderators should be (Figure 13-5). By default, all team owners are moderators, but you can select a different set of owners and members to act as moderators. Click **Manage** to change the set of moderators. Up to 100 moderators can be defined for a channel.

After moderation is enabled, members who aren't moderators cannot create new conversations in the channel and will see an informational banner saying, “only channel moderators can post in this channel.” In channels where moderation is enabled, it's a good idea to create an “Anything Goes” topic where people can discuss anything they like, including appealing to the channel moderators to create a new topic to discuss something specific.

You can also control if members can reply to posts and if automated processes (bots and connectors) can submit messages to the channel. For example, you could use this setting in situations where the channel hosts automated notifications about builds performed by Visual Studio.

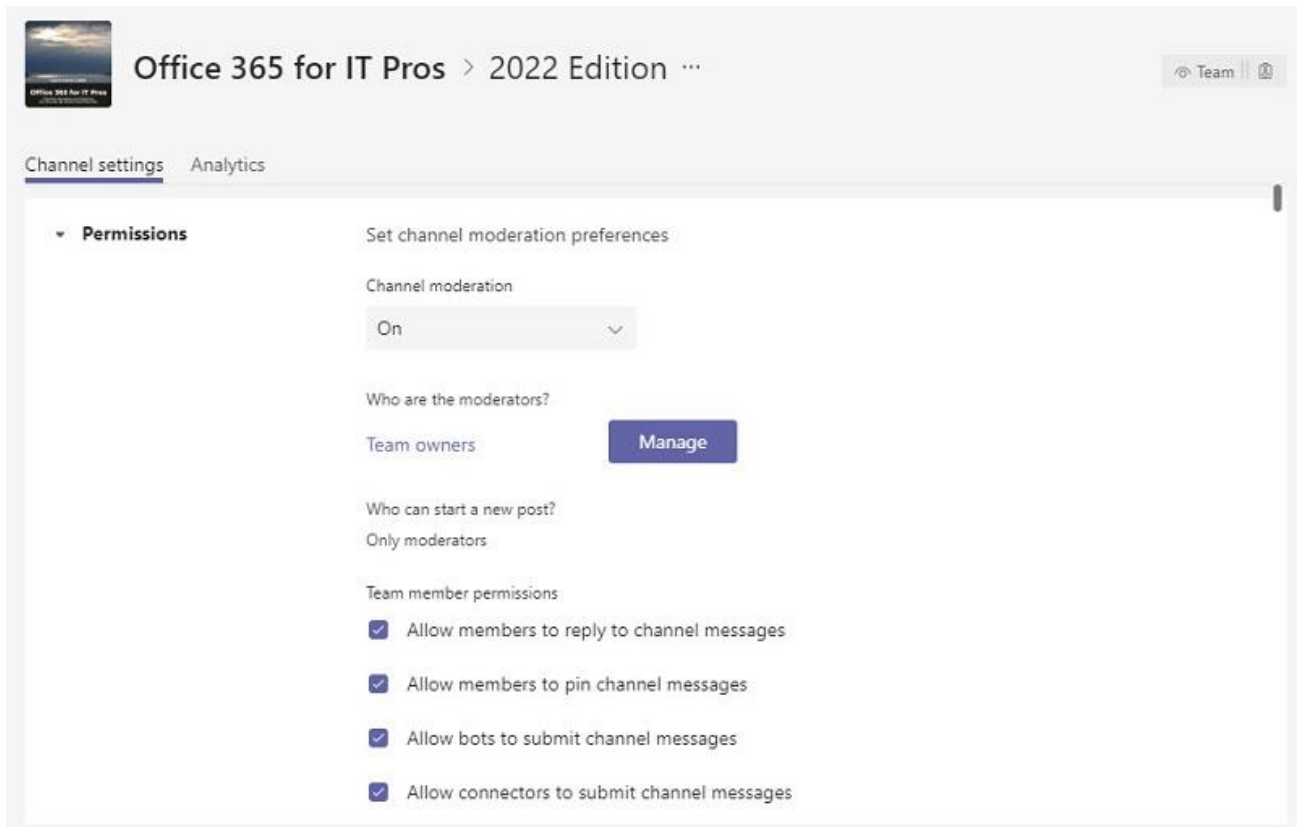

Figure 13-5: Setting up moderation for a channel

You can't update moderation settings for a channel with PowerShell, but you can [with the Graph API](#).

## Managing Settings for a Team

Team owners can manage team settings through the ellipsis [...] menu found beside the team name. Select **Manage Team** from the menu to access the available settings:

- **Members:** List existing team members (including guests), change roles (from Member to Owner and vice versa), remove members from the team, or add new members. When you add or remove members to a team, Teams updates the group membership.
- **Pending Requests.** Process any waiting requests to join the team. This tab is only visible for private teams.
- **Channels:** Manage channels for the team. You can also gain insight into the level of activity for the channels as you can see the number of members who have accessed each channel and the date of the last activity (Figure 13-6). As mentioned earlier, if a channel is important and should be brought to the attention of team members, a team owner can check the auto-show box to force the inclusion of the channel in each member's *Your teams* list.
- **Settings:** Settings to control the team picture; change the discoverability for a private team; assign permissions to users and guests; allow team members to use @mentions to reference other members, teams, and channels; and use stickers and memes (including the uploading of new memes). You can also upload a graphic file (of up to 4 MB) to add a team picture. A file measuring 640 x 420 pixels works well. Under **Member permissions**, you control the actions users can take within a team, such as whether they can add or remove channels, tabs, apps, or connectors; restore deleted channels; whether owners and members can delete messages; and restrict who can post messages to the General channel to team owners instead of anyone. For large teams, you can allow anyone to post but warn them that all members will see the message. If your tenant deploys a group expiration policy,

you'll see the expiry date for the team and be able to renew it here. Settings also include the ability to define **Tags**, a way to address subsets of members (see Chapter 12).

- **Analytics:** View usage information for the team and individual channels. See the later section about reporting usage of teams.
- **Apps:** Add or remove an app for the team. Apps include first-party apps like Forms, Planner, OneNote, SharePoint, and Stream as well as third-party apps like the Hipmunk bot installed in the team.

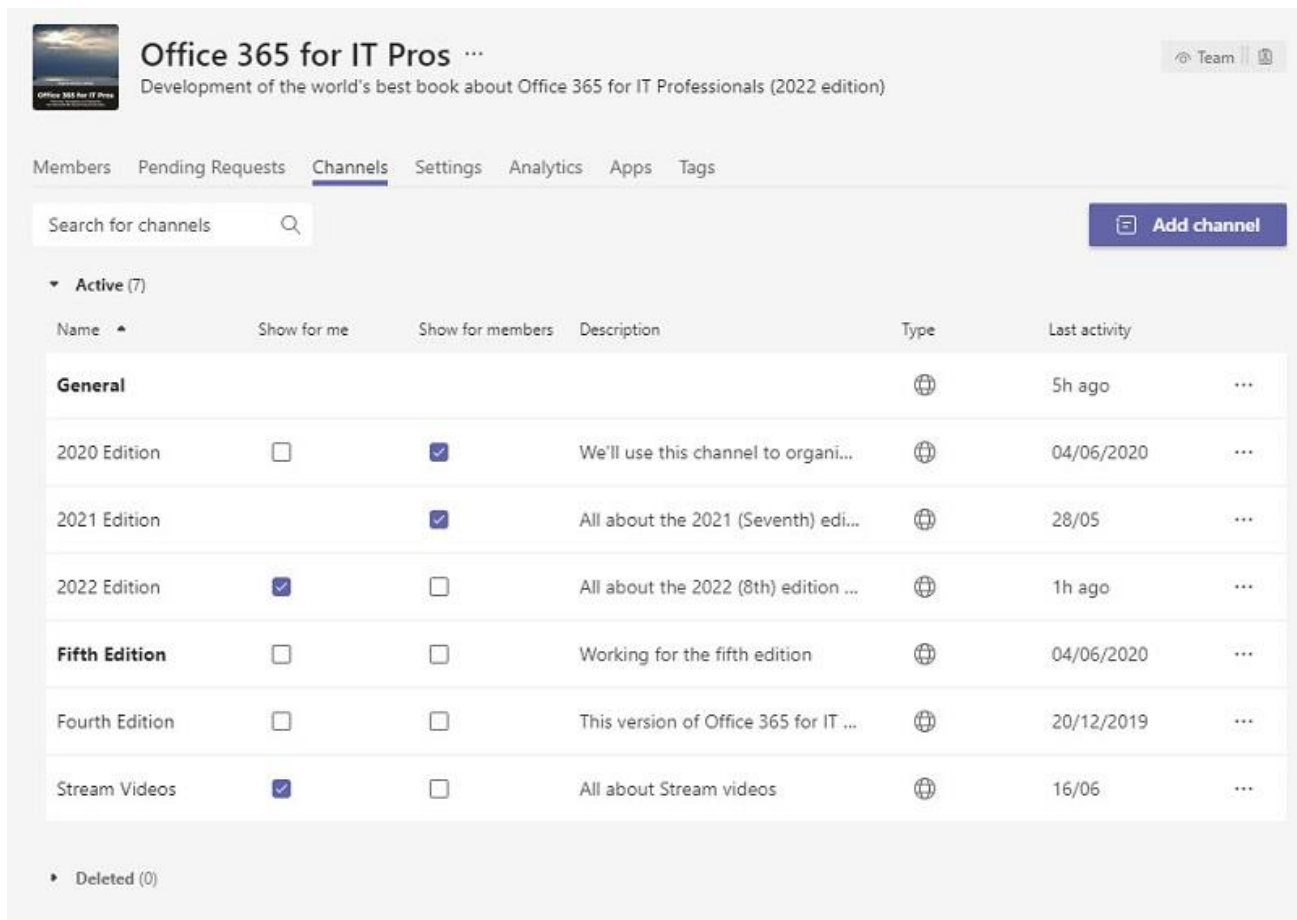

Figure 13-6: Managing the set of channels in a team

The ellipsis menu has choices to **Delete the team**, which also removes the underlying group and any other resources belonging to the group, and **Edit team**, which you can use to amend:

- The team name (display name). When you rename a team, you change the display name for the group. The change, therefore, affects applications like Groups and Planner. Because of the need to synchronize directories and clients, the name change might take some time before it is fully effective.
- Team description.
- Privacy (change the team from Public or Private or vice versa).
- Sensitivity (or classification).

These settings are group-wide and apply to all workloads using the group. Updating the settings is the equivalent of running the *Set-UnifiedGroup* cmdlet to change group properties. For example:

```
[PS] C:\> Set-UnifiedGroup -Identity HydraProjectTeam -DisplayName "The New Hydra Project Team"
-Notes "A very nice group of people that is team-enabled to get stuff done" -AccessType Public
-Classification Confidential
```

As explained in the Information Protection chapter, if you use sensitivity labels to control group settings for privacy and classification, those settings come from the label assigned to the group. The only way to update the settings is to change the sensitivity label to one which imports the settings you want to use.

## System Messages for Membership Changes

Teams posts system messages about updates to team settings, including those made with PowerShell, in the information pane. If you add or delete members for a team, system messages tell team members about the change. If someone uses a Graph API call (including the Teams clients and the *Add-TeamUser* cmdlet) to add or remove a member, the system message includes the display names of the member and the person (owner or administrator) who took the action. Changes made through the other administrative interfaces, such as the *Add-UnifiedGroupLinks* and *Remove-UnifiedGroupLinks* cmdlets (Exchange Online module) or *Add-MgGroupMember* and *Remove-MgGroupMember* cmdlets (Microsoft Graph PowerShell SDK), don't include the name of the person who took the action. It takes some time before Teams posts the system messages to inform members about changes. Changes that occur through other workloads, like Exchange Online or SharePoint Online, update Azure AD first. Subsequently, a background process called Microsoft Teams Aad Sync, synchronizes the changes to Teams. If you want membership changes to be effective immediately, you should manage team membership through the Teams admin center or Teams client rather than using other administrative interfaces.

## Guest Access for Teams

The mechanics of guest user access for Teams function like those for Microsoft 365 Groups. Team owners add guests to teams, joining invitations go to the email address identifying the guests, who then redeem the invitation to complete the process and join the team. As part of the Azure B2B collaboration process, Teams creates Azure AD guest accounts to allow guests to authenticate their access to resources. The Microsoft Invitations service generates the invitations and Teams manages the redemption process, including the verification of the guest account. You can invite anyone to be a guest if they have a valid email address.

Users can accept invitations to join other organizations as a guest from any client. The desktop and browser clients support other features through the Accounts section of Teams settings, including the ability to:

- Decline an invitation received to join a team in another organization.
- Leave an organization by removing their guest account. This option takes the user to the Azure AD [Organizations page](#) to choose the tenant to leave.
- Mute notifications from another organization.
- Hide or show organizations where the user has a guest account from the drop-down list displayed by Teams when the user selects a target organization for switching.

After a guest joins a team in a tenant, they don't have to accept invitations to join other teams through the links contained in the emailed notifications. Instead, the Teams apps detect that the guest is now part of other teams and perform an in-app redemption to add those teams to the list available to the guest.

A user of the free Teams version can be a guest in a tenant that uses the enterprise version and can switch between free and enterprise tenants. The same is true for users belonging to enterprise tenants, who can switch to guest accounts in free tenants.

## Enabling Guest Access for Teams

Because Teams consumes multiple Microsoft cloud services, different settings in the services combine to control guest access. In order of priority, these are:

1. **Azure AD.** The first hurdle is to make sure that Azure AD allows group owners and members to invite guests. In the **External Identities** section of [the Azure AD admin center](#), the **External collaboration settings** control external access to Azure AD. Under Guest invite settings, the default setting is *"member users and users assigned to specific admin roles can invite guest users including guests with member permissions."* If the setting is more restrictive, for instance, the control is set to *"only users assigned to specific admin roles can invite guest users,"* any attempt by users who don't hold an Azure AD administrative role such as Groups administrator fails.
2. **Groups.** In the Settings-section of the Microsoft 365 Admin Center, select Org Settings, then Microsoft 365 Groups, and make sure that *Let group members outside the organization access group content* and *Let group owners add people outside the organization to groups* are both On. When set, you can invite guests to join Teams. If you have specific teams that discuss sensitive information, you can block the ability of the owner to add guests to those teams by either editing the properties of the teams or by assigning a sensitivity label to the teams which prohibit guest membership. For more information, see the discussion about how to block guests for specific groups in Chapter 11.
3. **Teams.** Go to the Teams admin center and then the **Guest access** setting under the **Users** section to make sure that the **Allow guest access in Teams** slider is set to *On* (the default for this setting). Other settings in this policy control the functionality available to guests, such as if they can edit their sent messages. Guest users don't need a license to access Teams. You can also enable guest access to Teams with PowerShell by running the [Set-CsTeamsClientConfiguration](#) cmdlet and setting the *AllowGuestUser* setting to *\$True*.
4. **SharePoint.** In the SharePoint Admin Center, under External Sharing, set *Let users share SharePoint Online and OneDrive for Business content with people outside the organization* to On. This enables guest access to the Files in SharePoint document libraries used by Teams and to files in users' OneDrive sites shared in personal chats.

With all settings turned on, the full spectrum for guest access is supported for all teams in the tenant.

Teams shared channels do not use guest accounts. Instead, users connect to shared channels in other tenants using Azure AD B2B Direct Connect. See the Identities chapter for more information on this topic.

## Adding Guests to Teams

With all the correct settings in place, team owners can add guests. It is important to understand that the group and its associated team share a common membership list, including guests. Therefore, if you add a guest to the group, the guest gains access to the team and vice versa. Sometimes a small delay happens between adding or removing a guest from the membership and that action showing up when viewing membership, but background synchronization processes make sure that any addition or removal of guests applies across both Teams and Groups.

To add a guest member, select **Manage team** and then **Add Member**, or use **Add members** from the ellipsis menu. You then input the email address of the new member (Figure 13-7). In this case, the email address entered for the guest was John.Smith@contoso.com. Left as is, Teams uses John.Smith (Guest) as the display name seen by other team members. The (Guest) suffix is a language-specific string added by Teams to mark someone as external. The string is translated when displayed by Teams clients and notifications – for example, if a guest user runs Teams in Spanish and you receive an email notification for something they post, you'll see (Invitado) after their name. You cannot change the guest suffix because that is a visual reminder to other members that a guest is an external person, but you can amend the other part of the display name by clicking the pencil mark beside the name to edit guest information (Figure 13-7). You can now update the display name to whatever you want. For instance, by adding a company name so that the display name is "John Smith (Contoso)" to inform other members what organization the guest is from.

### Add members to "Corporate Business Development"

Start typing a name, distribution list or security group to add to your team. You can also add people outside your organisation as guests by typing their email addresses. Note: Guests need a work or school account in Office 365. [Learn more about who can join as a guest](#)

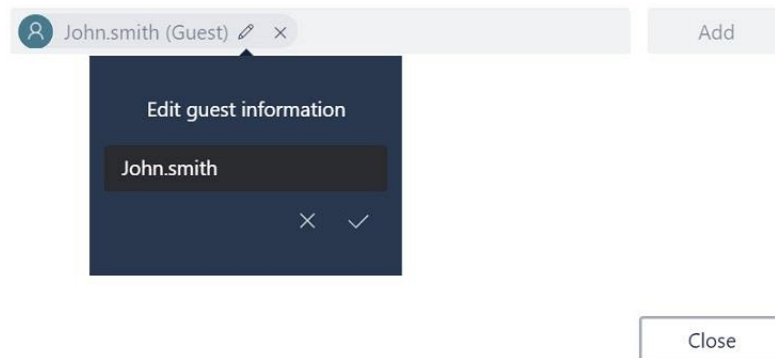

Figure 13-7: Adding a guest to a team

When the information for the guest member is complete, press **Add**. Teams checks whether a guest account for this address already exists in the tenant directory and adds it to the membership if found. If not, Azure AD creates a new guest account. Teams then adds the account to the team membership and generates an invitation for the user to redeem. The invitation has all the information necessary for the recipient to know about the team they are joining, including a GUID to find the right tenant, another GUID for the team, and a token request to redeem the invitation to join the team. The recipient redeems the invitation by clicking the **Open Microsoft Teams** link in the message, which then invokes the necessary flow to confirm the user's details, update the Azure AD guest account for the user with credentials to allow them to connect to the tenant, and access the team. Azure AD logs the redemption in a "redeem external user invite" audit record.

To give a visual clue to tenant users that they should be careful about the information shared externally, once you add a guest to a team, Teams displays the number of guests in the team in the top right-hand corner of the conversations pane.

**Updating Guest Information:** Do not worry if you forget to update the display name for a guest when you add them as you can always update it afterward. You can edit the contact information for the guest through the Microsoft 365 admin center, update the guest account properties in the Azure AD admin center, or run the *Update-MgUser* cmdlet. For example, this code updates the display name for the guest account created for John.Smith@contoso.com bypassing the user principal name as the object identifier. It also updates the user's job title and city as Teams displays these properties when you view a team. Finally, we update the telephone and mobile numbers for the user so that they appear when someone looks at their contact card.

```
[PS] C:\> Update-MgUser -User John.Smith_contoso.com#EXT#office365itpros.onmicrosoft.com
-DisplayName "John Smith (Contoso)" -JobTitle "Account Manager" -City "NY" -BusinessPhones "+1
617 551 6531" -MobilePhone "+1 650 561 4136"
```

It's also a good idea to upload photos for guest accounts. You can either upload an actual photo (the nice approach) or use a default photo to mark the guest as an external person. In either case, uploading a photo for a guest is done by editing their account in the Azure AD admin center or by running the *Set-MgUserPhotoContent* cmdlet. See the Groups chapter for more information. Teams must synchronize with Azure AD before the updated account information shows up in the Teams clients.

Every guest has an Azure AD account. An administrator can amend settings for the guest user account (like their photo), but because guests don't have mailboxes in the tenant, they can't set an out of office notification or any other feature which depends on a mailbox.

## Multi-Factor Authentication for Guests

Like the other Microsoft 365 applications, Teams supports multi-factor authentication (MFA). If your tenant implements an Azure conditional access policy to require MFA, you can include guest members in the scope of the policy to force them to use MFA to connect to Teams, even if their home tenant does not require MFA for connection to services. The logic here is that a tenant always controls its resources and can therefore dictate the level of authentication required to access those resources.

To ensure that a conditional access policy applies to guest users, choose *All Guests and External Users* as the target group for the policy to apply to.

## Blocking Guests from Specific Domains

If you do not want team owners to add guests from specific domains, you can create a block list using the Azure B2B Collaboration policy. The same policy can also create an allow list to restrict guest user access to specific domains, but a tenant can only support either an allow or a block list. When a policy is in place, team owners cannot add guests from blocked domains. However, any guests from blocked domains who are already members of teams continue as before and that guest can be added to other teams because Teams only uses the deny list when adding new guest accounts. It could be the case that the account was added by another application (to share a SharePoint document, for instance) that has nothing to do with Teams.

If you want to revoke membership for guests belonging to blocked domains, you must use PowerShell to search the membership lists for all Microsoft 365 Groups and remove any guest members found that belong to those domains. An example of how to remove a user whom you wish to block is in Chapter 11. If you want to ensure that no guest users are added to specific teams, disable the ability for team owners to add guests to those teams with a sensitivity label or by updating the policy setting for the group as described in Chapter 11.

## Switching Between Tenants

When a user with a guest account wants to access teams in your domain, they must “switch” Teams client by signing into your tenant using their guest account. Switching to work as a guest into another tenant means that an account has a limited view of the Teams environment within that tenant when compared to what they can do in their home tenant. Guests can only see teams to which they belong and cannot browse to join other public teams; they cannot see organizational information about other members, nor can they create new teams or add apps to channels. Because guests cannot access the directory, they cannot update the picture for their account, or any other setting related to their account such as the display name. In addition, they cannot browse the directory to find people to chat with. Instead, guests enter the email address of the person they are looking for and Teams checks the directory and creates a chat if that person exists.

On the other hand, guests can join in private and public conversations, take part in video and audio chats and access files from the team SharePoint site (or the sites used by private channels, if their account is added to the membership of private channels). Another point to note is that guests can only access applications available to the team if they have the right credentials and the application supports guest user access. It is as if they signed into your tenant with more restricted access than a normal tenant user has, which is exactly what you want.

Assuming you have an account in at least one other tenant where Teams is active, switching to an account in a different tenant is simple. In the desktop and browser clients, click the name of the tenant you’re currently connected to in the title bar to reveal the set of known tenants in your Teams profile. A tenant is listed only if your account is added to at least one team in that tenant. If your access expires for a tenant, you’ll be asked to reauthenticate before you can connect. For mobile clients, click the hamburger menu in the top left-hand corner and select the target tenant from the list shown at the bottom of the screen. In Figure 13-8, the

desktop client shows that eight host tenants (and the home tenant) are available for switching. One tenant has a warning sign, showing that I need to reauthenticate before I can connect.

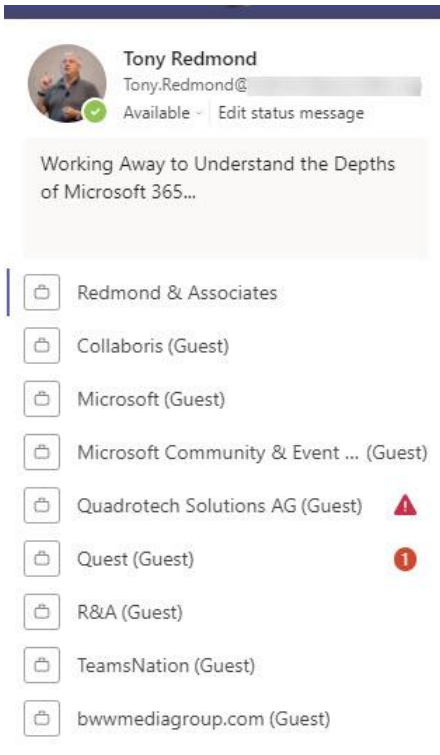

Figure 13-8: Selecting a host tenant to switch to

When you select a different tenant, Teams signs out of the active tenant, signs into the target tenant, and then displays the teams that the user belongs to in that tenant. The sign-in process ensures that the user picks up the rights and permissions they enjoy within the tenant; when they are a guest, they have those rights in that tenant. When they return their host tenant, they can interact with Teams with all the rights of that tenant account.

Generally, users do not see events for other tenants in their activity feed (the exception is when you participate in a call hosted by another tenant – chat notifications for the meeting do appear in the activity feed). Although Teams flags activity with indicators in your avatar, the lack of notifications can be a problem if you need to keep an eye on an active conversation about an evolving situation as you must then sign into the tenant hosting the relevant team to check what’s happening. Teams does not have a good solution for concurrent access to multiple tenants, but you can consider using the [approach described in this article](#) to create “wrappers” for each tenant where you use Teams. You can then move from one tenant to another while keeping access to Teams in the other tenants.

## Personal Account

Users can add a personal account to their Teams profile. A personal account is a Microsoft Services account with a valid email address. When someone uses Teams with a personal account, they switch away from Teams enterprise to Teams personal. Teams personal has different functionality to Teams enterprise and two separate clients (windows) are active after the user signs into Teams personal. The user can move from one client to the other as they like.

## Removing Guests

You remove guests from a team in the same way as you remove a tenant user. Select **Manage team** from the menu and then **Remove** for the user in the member list. Alternatively, you can run the *Remove-TeamUser*

cmdlet to remove the user from the group. For example, this command removes the guest Joan.Smith@contoso.com from the Industry News team.

```
[PS] C:\> $TeamId = (Get-UnifiedGroup -Identity "Industry News").ExternalDirectoryObjectId
[PS] C:\> Remove-TeamUser -GroupId $TeamId -User "Joan.Smith@contoso.com"
```

Removing an external member from a team does not remove the guest account from Azure AD. If you want to remove an external user from all teams in a tenant, you can remove their guest account from Azure AD using the Azure portal, the Microsoft 365 admin center, or by running the *Remove-MgUser* cmdlet. Removing the account removes membership from all teams and groups and removes any sharing permission the user has for SharePoint and OneDrive for Business files in the tenant.

## Email Integration for Teams Channels

The Teams architecture chapter discusses the various methods available to bridge the gap between email and Teams. The *Email Integration* settings for the tenant (managed through Teams settings in the Teams settings section of the Teams admin center) control if channels can receive SMTP addresses to allow them to accept emails. This is a useful way for people to introduce a new topic into a channel using information contained in emails. To retrieve the email address of a channel, use the desktop or web client to click the ellipsis menu for the channel, select **Get email address**, and then **Copy** (Figure 13-9) to copy the address to the clipboard. If an email address does not already exist for the channel, Teams creates one. You can then use the address to send a message to the channel. Any team member can retrieve the email address for a channel, but guest members can't force Teams to create an email address for a channel that doesn't already have one.

 Remove email address

Close

Copy

Figure 13-9: Retrieving the email address for a channel

By default, anyone inside or outside the tenant can use the email address to send a message to the channel. Two levels of restrictions are available.

- On an organization level, tenant administrators can block all channels from receiving email or define a **list of domains allowed** to send email to channels. Any user from these domains can send an email to a channel in the tenant, including private channels. If you create an accepted domains list, make sure to include all the domains you wish to allow to communicate with Teams via email. Note that you cannot specify a wildcard domain like \*.onmicrosoft.com.
- On a channel level, a team owner can use the **Advanced Settings** option to restrict the acceptance of messages to **only members of the team**.

You can also use PowerShell to update the set of accepted domains for the tenant. In this example, we pass the set of accepted domains as a string with each domain separated by a semi-colon (don't leave any spaces). The *Set-CsTeamsClientConfiguration* updates the configuration, which we can then check with *Get-CsTeamsClientConfiguration*.

```
[PS] C:\> [string]$SenderDomains = "Microsoft.com;Office365itpros.com;contoso.com"
Set-CsTeamsClientConfiguration -RestrictedSenderList $SenderDomains -AllowEmailIntoChannel $True
```

It can take a couple of hours before the updated list of accepted domains becomes active. When delivery restrictions are in place, Teams rejects emails sent to a channel from senders not on the allowed list, and the sender receives a message from Teams. The text of the notification is something like this:

**Delivery has failed to these recipients or groups:**

*1e2d0eb3.office365itpros.com@emea.teams.ms*

*The administrator has restricted permissions to send emails to this channel.*

Team members don't receive copies of emails delivered to a channel. If you want people to receive a copy of a message sent to a channel, add their email addresses to the message.

## Managing Channel Email Addresses

When Teams creates an email address for a channel, it also creates a mailbox in a special tenant dedicated to Teams email processing and assigns the email address to the mailbox. The channel's email address is in the form `<unique-identifier>.tenant-domain@region.teams.ms`. Tenants cannot change the format of the address or the domain it uses to make it more human-friendly.

For example, the email address `b400aa20.tenant-smtpaddress@emea.teams.ms` belongs to a tenant in the EMEA region. The SMTP domain included in the email address generated for the channel uses the domain defined in the email address policy for the tenant. If a separate email address policy exists for Microsoft 365 groups, Teams uses that domain.

After creating a mailbox to handle inbound email for the channel, Teams creates a connector (see below) to link the mailbox to the channel so that any email arriving in the mailbox flows through to the channel. Dedicated infrastructure exists to host Teams mailboxes in every Microsoft data center region supported by Teams. It's worth noting here that because Teams uses a connector to bring messages into a channel, any information barrier policies used by the organization don't apply. This means that someone otherwise blocked from communicating with team members can send emails to them via the channel.

Any team member (except guests) can use the **Remove email address** option to nullify the email address for a channel. Allowing users to remove the email address used for inbound communications is in line with the general rule that everyone shares equal access to team resources, but it is easy to see how this could lead to problems if people rely on the address to communicate with the channel. It is easy to reconnect email access for a channel by using the **Get email address** option again, but Teams does not restore the old address to the channel and generates a new address instead.

Teams captures audit records when team members generate or remove channel email addresses. Here's an example of [how to interrogate the audit log to find the relevant records](#). Teams doesn't expose email addresses in the properties reported for a channel in the `Get-TeamChannel` PowerShell cmdlet. You can't generate a report of Teams channels with email addresses using pure PowerShell, but you can with [a combination of PowerShell and Graph API calls](#).

## Posting to a Channel from Exchange Online

To make it easier for people to post emails to a channel, you can create an Exchange Online mail contact with the channel's email address and give the mail contact a suitable display name. The mail contact will appear in the Exchange GAL and users can add it to messages as easily as any other email address, including [using the mail contact in a distribution list](#). If someone changes the email address for the channel, you'll have to update the mail contact because no synchronization exists for these objects between Exchange and Teams.

Messages sent to the email address of the Microsoft 365 group used by a team go to the group mailbox. Members who subscribe to the group receive copies, but Exchange will not deliver a copy of the message to a

channel in the team unless you add the channel's email address as an external member of the team. For example, let's assume that you want any email sent to the Corporate Business Development group to show up in Teams and you create a channel called Email Communications for this purpose. You can then get the email address for the channel and add it to the group as a new guest member with OWA. Exchange Online delivers a copy of any messages sent to the group thereafter to the channel. Guest user accounts do not appear in the Exchange GAL.

**Use BCC to Stop Mail Storms:** The email address for a Teams channel functions in the same way as any other email address in that you can use it as a message recipient. However, there's a very good reason for always using BCC when sending emails to Teams. The purpose of a Teams email address is to allow users to start new discussions in a channel with content that already exists in emails. You do not want the channel to take part in a lively back-and-forth email conversation because every interaction shows up as a new thread in the channel and can confuse team members. Use BCC to address email for a channel and then develop the conversation forward in the channel.

## Message Hygiene for Inbound Email to Teams

Because the mailboxes used by Teams are part of the Microsoft 365 infrastructure, inbound messages go through Exchange Online Protection (EOP). Although EOP will stop the delivery of malware to Teams, the special nature of the configuration used by Teams means that inbound mail does not go through the same processing as the email stream for a regular customer tenant. For example, if you license Office 365 E5 and configure the Microsoft Defender for Office 365 policy to enable Safe Attachments and Dynamic Delivery, you expect that EOP processes all attachments in this manner. However, this will not happen for messages routed through Teams. On the other hand, if you configure Microsoft Defender for SharePoint, when Teams captures the message files in the SharePoint document library (see below), Microsoft Defender processes any attachments at that point.

Teams will not deliver a message to a channel if the message has more than 20 file attachments or more than 50 inline images. Exchange Online sends a non-delivery-notification to the sender whenever Teams rejects a message.

## SharePoint Captures Email Sent to Teams Channels

When a channel receives an email, the text of the message appears as a new topic in the channel. If the text exceeds the limit for a contribution to a chat (25 KB, or roughly 20,000 characters including spaces), you see some text but need to download the "original email" to view the full content. You cannot reply to an inbound message because Teams has no other access to email except its ability to receive inbound messages. Any attempt to reply to an inbound email generates the response that your reply will only be visible in Teams.

When Teams receives a message via email, it strips any attachment and stores the file in the channel folder created in the SharePoint Online document library for the team (a separate folder exists for each channel in the team). Originally, Teams held copies of received messages in a single *Email Messages* folder. To improve performance, Teams creates a separate folder per month named after the month. For instance, the folder used for February 2021 is **EmailMessages\_2\_2021**.

In addition to attachments, Teams captures a copy of the message as an *.eml* file and keeps the file in the same location. Keeping copies of messages and attachments received by Teams in SharePoint means that Microsoft Search can index the information to make it available for eDiscovery. Users can download a copy of the original message from email conversations posted to the channel.

Because copies of messages sent to channels end up in SharePoint Online, each delivery of a message to a channel creates an *Uploaded File* audit record. You'll see that the user noted in the audit record is

*app@sharepoint*, a background process that performs many management operations for SharePoint. This process copies the message from Teams to SharePoint.

# Teams and Compliance

Teams stores chat and channel messages in a data store hosted by Azure Cosmos DB. The information in the Teams data store is not directly accessible to the data governance framework. It is obvious that many interesting conversations occur in Teams and that the information discussed in these conversations might be of interest to eDiscovery investigations. The same fear that eDiscovery investigations might not have access to all relevant information exists when employees use third-party chat networks like Slack.

Despite the lack of access to the native Teams data stores, Teams has other mechanisms to support many of the data governance technologies available in Microsoft 365, including:

- **eDiscovery:** The Microsoft 365 substrate captures and indexes compliance records so that content searches can find, preview, and export these items. The substrate captures compliance records for Teams chats and conversations, meetings, adaptive card content, and call data records.
- **Retention:** Teams supports the application of retention policies against messages sent to Teams channels and private/group chats.
- **Communications Compliance:** Teams supports the capture of messages matched against classifiers identifying offensive, threatening, or other problematic interactions. Administrators can remove messages that violate policies to make them inaccessible to anyone but the sender.
- **Data Loss Prevention:** Teams supports the checking of personal chats and channel messages to detect the presence of sensitive information types.
- **High-value audit events:** If your tenant has the necessary licenses (Office 365 E5 is one example), Teams generates audit events for meetings to capture details of the meetings and their participants. See [this article](#) for more information.

Retention policies govern the preservation or removal of data as required by the organization. By default, Teams does not remove any conversation or other information belonging to a channel or chat. This data remains in the Teams data stores or the underlying application (for example, Planner) unless a user or team owner takes action to remove the data. If you want to ensure the retention of Teams data for a defined period or removed after a certain period, you must deploy retention policies to cover Teams messages (chat and channel conversations) and any other repository used by Teams, such as SharePoint Online. We'll discuss how to use retention policies to manage Teams data later. A more general discussion of retention policies to cover other Microsoft 365 data is in Chapter 17.

## Capturing Teams Compliance Data

To ensure that Teams conversations are available for eDiscovery, the Microsoft 365 substrate captures copies of the messages sent in personal chats and channel conversations as items in Exchange Online mailboxes, including messages emailed to channels. These mail items are compliance records. They are imperfect copies of the complete Teams message data as they contain the information needed for eDiscovery and other compliance functionality, such as communications compliance policy checks. The substrate stores the compliance records in the **TeamsMessagesData** folder in the non-IPM part of user and group mailboxes. You can see how many compliance records exist in these mailboxes with PowerShell (see [this article](#)). Because the compliance messages exist in Exchange Online mailboxes, Microsoft Search indexes their content and metadata to make the items available for eDiscovery.

As people communicate in chats and channel conversations, the Microsoft 365 substrate captures each message as a separate compliance record. A complete conversation between multiple people might involve thirty or more contributions, each of which exists as a separate compliance record. The compliance records

are mail items, so they have a sender (the author), a recipient (the group mailbox for channel conversations or user mailboxes for personal chats), and a timestamp for when Teams created the item. Like other mail items, you can examine the properties and content of Teams compliance items using the MFCMAPI program. If the author or a team owner edits a message, the substrate captures compliance records for the original message and every edited version of the message.

The Microsoft 365 substrate captures compliance records as follows:

- **Personal and group chats:** The substrate creates compliance records in the *TeamsMessagesData* folder of the mailboxes of the participating users. For example, if John and Pat have a chat, the substrate creates compliance records for the chat in both their mailboxes. If a group chat involves ten people, compliance records for every message in the chat exist in all ten mailboxes. Compliance records for chats in private meetings are also in user mailboxes.
- **Regular channel conversations:** The substrate captures compliance for messages posted to channels in the group mailbox belonging to the team. Compliance records for conversations in all channels in a team are intermingled.
- **Private channel conversations:** The substrate captures compliance records for these messages in the user mailboxes of the channel members.
- **Shared channel conversations:** The substrate captures compliance records for these messages in a special cloud-only mailbox created for the shared channel. This mailbox is inaccessible to regular email clients and is also known as a *SubstrateGroup* mailbox.
- **Meetings and Calls.** The substrate generates compliance records as the calling infrastructure creates records of meetings and calls. Meetings include scheduled private meetings and ad-hoc meetings associated with a channel. Group chats that include more than two people are also in this category. Calls cover one-to-one calls. The substrate captures compliance records when users from your tenant participate in meeting chats hosted by another tenant.
- **Meeting artifacts:** These artifacts include meeting attendance reports, transcripts, whiteboards shared during meetings, and recordings. As described below, Teams captures meeting and webinar information in Microsoft Lists stored in the meeting organizer's OneDrive for Business account. This data is available for eDiscovery. Transcripts generated from Teams meeting recordings are in the OneDrive for Business account of the person (usually the organizer) who initiates the recording. OneDrive hides this data from users. A background process indexes the spoken words from the transcripts against meeting recordings to allow concurrent playback of video and text. The text (spoken words) is available to SharePoint Search but is not yet available for eDiscovery. See the Managing Video chapter for more information about Teams meeting recordings.
- **Adaptive card data:** First-party and third-party apps integrated with Teams can use adaptive cards as part of their user interface. Another category is cards representing data from network sources created in channels using the inbound webhook connector. The substrate captures compliance items for adaptive cards. If an app creates a card in a personal or group chat, the substrate creates compliance records in the mailboxes of all those involved in the chat. Compliance records for cards created in channel conversations are in the group mailbox of the team which owns the channel.

Compliance records are available very soon after users or apps create messages in Teams (usually a matter of seconds, never more than a few minutes). The substrate does not capture records for draft messages. These messages remain in the local client cache until the user eventually sends the times, at which point the substrate creates a compliance record.

**Warning:** The compliance records created for voice memos generated in personal chats by Teams mobile clients do not contain any metadata or other information necessary for inclusion in content indexes. No attempt is made to transcribe the voice message into a form that can be indexed, so these memos cannot

be found by content searches. Because some Microsoft 365 workloads do not support eDiscovery, other challenges for Teams compliance capture include:

- Planner tasks.
- Whiteboards in meetings.
- Meeting transcripts (available for Microsoft Search, but not yet for eDiscovery).
- Data belonging to third-party apps stored outside Microsoft 365.
- Loop components in Teams chat. Compliance records exist, but they don't contain any of the content for the loop component.

## Capture of Webinar Event Data

The Microsoft 365 substrate captures attendance information for Teams meetings as items in the hidden `93c8660e-1330-4e40-8fda-fd27f9eafe10AttendanceReportV3Collection` folder in the non-IPM part of the meeting organizer's mailbox. The data in these items is sufficient to display the attendance report for a regular meeting.

Special processing occurs to make information about meetings configured as webinars available for eDiscovery. For a webinar, Teams creates three lists in the meeting organizer's OneDrive for Business account. These lists are:

- **Event:** Stores event information such as its start and end time and webinar description and title. The *ThreadId* for the webinar is stored in this list. The webinar title and description can be edited in the list but the information created by Teams for the meeting cannot.
- **Questionnaire:** Stores the attendance records for individual webinar attendees. The information about attendee details (like name and email address) can be edited in the list but information relating to the Teams meeting (like its URI) cannot.
- **Speakers:** Stores details of the speakers such as their names and bios. This information can be edited in the list.

The lists used to hold webinar data are not usually visible to users unless they navigate to the lists section of their OneDrive account (Site Settings, then Site Libraries and Lists). They can then retrieve the URL to a list and use the URL to access the data in a browser.

Information held in webinar lists (including any updates) is available for searching through SharePoint Search or Microsoft 365 eDiscovery. See [this article](#) for more information.

If your organization has Office 365 E5 or Microsoft 365 E5 compliance licenses, Teams generates audit events for meetings (*MeetingDetail*) and participants (*MeetingParticipantDetail*). See the section on advanced auditing in the reporting and audit chapter.

## Compliance and Communications Compliance Policies

Teams supports communications compliance policies. When a user or team comes within the scope of a policy, copies of their messages which violate communications policies are captured in a special mailbox and kept there until reviewed. The messages generated for review are like those captured for compliance purposes, but they go through a different process. During the review process, messages identified as violations can be blocked so that recipients can no longer see these messages. The sender can still see the message, but it is highlighted as being blocked due to a policy violation. See Chapter 21 for more information about communication compliance policies.

## Compliance Records for Private Channels

Two challenges exist for compliance records collected for private channels:

- *Compliance records for private channel messages are in member mailboxes:* Private channels don't have a group mailbox. For this reason, Exchange Online stores the compliance records captured for

conversations in the private channel in the personal mailboxes of channel members like the way that it stores records for group chats. From a content search perspective, it means that the substrate captures more copies of compliance records (up to 250 copies of each message posted to a private channel). Another way of looking at this is that you'll find a record if you add a single member of a private channel to a content search. The compliance records in private mailboxes contain a mixture of records for private chats, group chats, and private channel conversations. The items for private channel messages have different MAPI property values to chat messages. For instance, property 0x0DE001F is *MicrosoftTeams* for chat messages but *MicrosoftTeamsChannelMessages* for private channel messages.

Because compliance records for private channel conversations are in user mailboxes, retention policies must apply special processing to find and deal with compliance records created for private channels. For this reason, retention policies to process private channel messages are separate from other retention policies. By contrast, the substrate stores compliance records captured for Teams shared channels in cloud-only mailboxes (like those used for hybrid and guest users), meaning that regular retention processing for Teams channel messages covers these items.

- *eDiscovery searches might not include some SharePoint sites*: Private and shared channels use special hidden SharePoint sites to store their documents. If you include teams in content searches, the search only includes documents in the standard SharePoint sites used by the teams. To ensure searches process documents stored in the special sites used by private and shared channels, you must add the URLs for the channel sites to the content search locations.

This code returns the URLs for sites belonging to Teams private channels. If you exclude the filter against the set of sites returned by the *Get-SPOSite* cmdlet, the set includes both private and shared channels.

```
[PS] C:\> [array]$Sites = Get-SPOSite -Template "TeamChannel#1" -Limit All | ? {$_.TeamsChannelType -eq "PrivateChannel"}

ForEach ($Site in $Sites) {
    $SPOSite = Get-SPOSite -Identity $Site.url -Detailed
    $Group = Get-UnifiedGroup -Identity $SPOSite.RelatedGroupID.Guid
    Write-Host "Team" $Group.DisplayName "owns private channel site" $Site.URL}
```

Earlier iterations of private channels used the *TeamChannel#0* template. Microsoft switched the template in mid-2021. However, it's possible that you might find some sites with the old template.

## Teams Compliance Record Structure

Like other mail items stored in an Exchange Online mailbox, a Teams compliance record is composed of a set of MAPI properties that can be viewed using a MAPI editor like [MFCMAPI](#). The properties include:

- *SkypeInternalIds*: a list of GUIDs for each of the participants (other than the sender) in the conversation. Teams uses GUIDs internally to avoid problems with user display and principal names, both of which can change over time due to marriage, divorce, or other circumstances. Teams resolves the GUIDs for display and stores the display names in the *PR\_DISPLAY\_TO* property.
- *ParentMessageId*: The reply identifier for the message thread (also in the *LinkId* property).
- *CreatedDateTime*: Date and time of the message.
- *PR\_BODY*: Text of the message (also captured in HTML format in *PR\_HTML*).
- *PR\_SUBJECT*: The subject of the message (also contains the channel name).
- *PR\_SENDER\_NAME*: The display name of the sender. The GUID for the sender is found in the *FromSkypeInternalId* property.

Compliance records don't currently capture the channel name for channel conversations, which makes it more difficult to track down the original message within its host channel.

Compliance records captured for meetings hosted by other tenants contain slightly different information. To resolve the GUIDs used to record participants in the compliance records, remove the “&orgid:” prefix from the value and run the *Get-MgUser* cmdlet. For example:

```
[PS] C:\> Get-MgUser -UserId c7745bc8-6f5c-4d45-82c7-fee55f384985

DisplayName  UserPrincipalName
-----
Ståle Hansen stale.hansen_cloudway.no#EXT#@office365itpros.onmicrosoft.com
```

## What Teams Compliance Records Capture

It is important to understand that the compliance records captured by the Microsoft 365 substrate in user and group mailboxes are only copies of Teams messages. They are not the real messages (which remain stored in Azure Cosmos DB), nor are compliance records perfect replicas of those messages. Instead, the copies captured by the substrate are mail items that Microsoft Search indexes to make discoverable. If investigators find some issues in an eDiscovery case, they can access the real content in Teams to understand the full context of messages (the investigators will need access to the teams where the content exists to allow this to happen).

When the substrate captures copies of Teams messages, some transformation happens to create the compliance records. Not everything found in a Teams message ends up in the mail item. Because the copies created in Exchange Online are incomplete versions of the original data in Teams, you can't compare the copies generated by this process to email journaling. Elements copied to the mail item include:

- Links to any embedded emojis, stickers, inline images, and GIFs.
- Tables.
- Embedded deeplinks to other Teams messages.
- Sharing links to files in SharePoint Online document libraries.
- For channel messages, the compliance item records the subject of the message (if available) as is the name of the team holding the message. For personal chats, the compliance item captures the names of the people involved in the conversation.
- Code snippets in the body of messages. People can use code snippets to disguise conversations that they want to hide. Compliance records capture code snippets in Teams messages as .DAT attachments. The attachments store the HTML-formatted text for the code snippet.

However, Teams compliance records do not capture:

- Reactions (for example, a like, heart, or smile) to messages. In an eDiscovery context, reactions can be important signs that certain individuals have seen a conversation in the same way that changing the read status of an email from “unread” tells you that someone opened the message. According to [Microsoft 365 roadmap item 65130](#), Microsoft Purview Advanced eDiscovery will support the discovery of message reactions from August 2022.
- Recordings of audio messages sent from mobile clients.

Compliance records created for adaptive cards are in the form of mail items with one or more attachments. The attachments hold the adaptive card content. In addition, compliance records captured for *praise* messages only have the text of the praise and don't include the graphic, and compliance messages for messages with quoted text include the text but not the formatting marking the text as a quote.

## Versions of Compliance Records

If a retention policy is in place for Teams, the substrate captures changes made by a user to a message in the *Versions* sub-folder of Recoverable Items in the target mailbox. Thus, a content search might uncover several different versions of the same message, with the last version stored in the *TeamsMessagesData* folder being the content of the last update applied to the message (the earlier versions are in Recoverable Items).

## Compliance Records for Hybrid and Guest Users

Not every person who interacts with Teams has an Exchange Online mailbox in which the Microsoft 365 substrate can create and store compliance records. To get around the problem, the substrate creates special cloud-only Exchange Online mailboxes to store compliance records for:

- Hybrid users with Exchange on-premises mailboxes.
- Federated connections, such as external access to chat with Teams users in other domains or Skype consumer users.
- Guest accounts.

The substrate provisions a cloud-only mailbox (otherwise known as a “phantom” or “shard” mailbox) the first time it needs to create a compliance record for an external user. Cloud-based mailboxes are in the same data center region as the host tenant. The substrate uses the same approach to store compliance records for Yammer and Planner. Users cannot sign into these mailboxes, nor are they used for sending or receiving emails. They exist purely for storage purposes.

For example, if a Teams user starts a federated (external access) chat with a Skype consumer user, the substrate creates a mailbox called *Skypeld@teams.microsoft.com* (where *Skypeld* is the user’s Skype identifier) to store the compliance records.

On-premises users must be part of a hybrid organization that synchronizes their accounts with Azure AD using AAD Connect. The mail user accounts created for hybrid mailboxes must have both Teams licenses and Exchange Online P1 licenses. If a hybrid mailbox moves from on-premises to Exchange Online, the transfer process moves the compliance records from the phantom mailbox into the user’s new cloud mailbox.

Although Teams supports retention policies, those policies do not apply to cloud-based mailboxes. Likewise, you cannot apply retention holds to these mailboxes.

## Teams Compliance Outside the Tenant

When people collaborate in Teams, they can work with external users from outside their tenant. In this scenario, the rule is that the home tenant has all the compliance data. In other words, if an external user posts a message to a channel in your tenant, the substrate captures the compliance record in your tenant and no trace exists of their contribution within their home tenant. The reverse is also true: a tenant administrator has no oversight into what users from their tenant do inside other tenants.

Usually, this isn’t an issue unless compliance administrators need to access information about what users do in other tenants. For example, an investigation needs to know if someone discussed a confidential issue with people they should not have. A search can scan the Microsoft 365 repositories in the user’s home tenant, but any communications with the relevant individual in a channel (regular or private as a guest, or in a shared channel using their home account) remains invisible to eDiscovery performed in the home tenant. To find evidence, an arrangement must be made with the administrators of the tenant where the conversation occurred.

Administrators usually want to know when people are accessing data outside the tenant. To see signs of cross-tenant activity, you can check the Azure AD sign-in logs. This code uses the Microsoft Graph PowerShell SDK to find the sign-in log entries not related to your tenant. A filter extracts the records for shared channels.

```
[PS] C:\> Connect-MgGraph -Scopes "AuditLog.Read.All, Directory.Read.All"
Select-MgProfile -Name "beta"
$TenantId = (Get-MgOrganization).Id
Get-MgAuditLogSignIn -Filter "ResourceTenantId ne '$TenantID'" -All | ? {$_.CrossTenantAccessType -
eq "b2bDirectConnect" -and $_.AppDisplayName -eq "Microsoft Teams"} | Format-List CreatedDateTime,
UserDisplayName, ResourceDisplayName, AppDisplayName, ResourceTenantId

CreatedDateTime      : 20/03/2022 00:04:51
UserDisplayName      : Tony Redmond
```

```
ResourceDisplayName : Office 365 SharePoint Online
AppDisplayName      : Microsoft Teams
ResourceTenantId   : 22e90715-3da6-4a78-9ec6-b3282389492b
```

You can download a script to [find and analyze Azure AD sign-in records from GitHub](#). A similar approach is possible to find records for guest access (the filter used is `CrossTenantAccessType -eq "b2bCollaboration"`). See the PowerShell chapter for more information about using the Microsoft Graph PowerShell SDK.

The [Get-MSIDCrossTenantAccessActivity](#) function from the [MS Identity tools PowerShell module](#) is a good way of monitoring inbound and outbound cross-tenant connections for an organization.

## Call Records

Compliance records captured for meetings and calls depend on the Call Record Processing service. In telephony terms, the compliance records captured for calls and meetings are known as call detail records or CDRs. The substrate creates CDRs in the mailboxes of all call participants in the same hidden folder used to store the compliance records for messages. It can take up to eight hours before CDRs are available for searching. This usually is not a problem because eDiscovery searches normally happen after an event occurs.

CDRs do not include audio or video events in meetings. If you want this, record the meeting, and Teams will store the audio and video feeds for the meeting in an MP4 file in OneDrive for Business. CDRs capture textual details of a meeting or call such as:

- The start and end time of the meeting or call, and its overall duration.
- Notes of when each participant joined and left the meeting. Participants can join through VOIP or PSTN, and as anonymous, federated, and guest users. Teams assigns an identifier for anonymous joiners in the form `teamsvisitor:13c3a4132a584b918b9c6528b6dabef9`. It isn't possible to translate these identifiers into email addresses or other more identifiable addresses.
- Calls to voicemail.
- Missed or unanswered calls.
- Call transfers (which are represented as two separate calls).

An example of a CDR is:

```
Start Time (UTC): 6/20/2020 3:54:56 PM
End Time (UTC): 6/20/2020 5:05:28 PM
Duration: 01:10:31.9773921
```

```
[6/20/2020 4:21:17 PM (UTC)] teamsvisitor:d1cce625a5ee4a29911a7a954a89f1ee joined.
[6/20/2020 4:23:29 PM (UTC)] teamsvisitor:d1cce625a5ee4a29911a7a954a89f1ee left.
[6/20/2020 3:59:38 PM (UTC)] John.Hubbard@office365itpros.com joined.
[6/20/2020 5:05:27 PM (UTC)] John.Hubbard@office365itpros.com left.
```

Because CDRs are captured as email items, the person who starts a call or schedules a meeting is recorded as the sender, and participants are recorded as message recipients. The first part of the item's subject captures the kind of call or meeting while the remainder is a unique identifier for the event in the Teams media stack.

For example:

- Meeting (ScheduledMeeting).
- Meeting (RecurringMeeting).
- Call (Completed).

Microsoft plans to capture more details for calls such as screen and app sharing in the future.

## Storage of Teams Compliance Records

For both group and personal mailboxes, the substrate stores compliance records captured for Teams conversations in a special hidden folder called `TeamsMessagesData` in the non-IPM (system) part of user and group mailboxes. Because the folder holds compliance data that users should not be able to interfere with,

clients like OWA and Outlook desktop do not expose the folder in their GUI. If you need to examine compliance records, you can open the folder in a personal mailbox (but not a group mailbox) to examine individual items with a program like MFCMAPI. Exchange Online doesn't charge the storage used by Teams compliance records against user mailbox quotas.

Depending on load, the delay before a compliance record appears in the mailbox varies from a few seconds to a few minutes. Once captured in a mailbox, Exchange Online automatically indexes the compliance records to make them discoverable by content searches. To see how many Teams compliance records are in a user or group or user mailbox, run the *Get-ExoMailboxFolderStatistics* cmdlet to report the items held in the *TeamsMessagesData* folder:

```
[PS] C:\> Get-ExoMailboxFolderStatistics -Identity "Office 365 Adoption" -FolderScope NonIPMRoot
-IncludeOldestAndNewestItems | ? {$_.FolderType -eq "TeamsMessagesData"} | Format-Table Name,
ItemsInFolder, NewestItemReceivedDate, OldestItemReceivedDate
```

Name	ItemsInFolder	NewestItemReceivedDate	OldestItemReceivedDate
TeamsMessagesData	4227	02/02/2022 16:10:41	11/03/2017 15:41:34

The reason why we use the *IncludeOldestAndNewestItems* switch with the command is to force Exchange Online to return information about the oldest and newest items found in the folder. This is interesting information if you want to know if retention policies are removing items as their retention period expires.

In addition to compliance records captured for chats and conversations, Teams captures copies of email messages sent to a channel in a sub-folder called "Email Messages" of the channel folder in the SharePoint document library belonging to the underlying group. The messages are individual indexed files discoverable by content searches. Any files uploaded to the SharePoint document libraries used by Teams or to users' OneDrive for Business sites come under the usual compliance controls deployed to those workloads.

## Searching Teams Compliance Records

Content searches for Teams messages do not process Teams data stored in its Azure-based data services. Instead, searches depend on the Teams compliance records held in Exchange as those records are the data indexed and available for search. You do not have to do anything special to include compliance records in content searches because these items are searched whenever you include the mailboxes (group or user) or sites used by Teams in content searches. The sole exception is for users who have their mailboxes on on-premises Exchange servers. The content of these mailboxes is unavailable to content searches, so they cannot be included. In addition, you cannot apply a hold to content stored in on-premises mailboxes.

Figure 13-10 shows how Teams compliance records appear in the preview of items found by a content search. In this case, the compliance record captures details of a message posted to a channel. We know this by examining the item properties, where we can find:

- **From:** The display name and email address of the user who posted the message.
- **To:** The name of the team and the email address of the group mailbox used by the team or the names and email addresses of the participants in a personal chat.
- **Send date:** The date and time in UTC format when the sender posted the item.

As noted above, Teams compliance records for channel and personal conversations use the message item type of IM rather than the normal "Email" used for mailbox items. Note that messages created in channels by Office connectors also use the IM message type. Compliance records for meetings have the "Meeting" message type while personal calls use the "Call" message type.

We can't do much if we don't know how well Contoso is doing in terms of their results. Does anyone have a snapshot to share?

Figure 13-10: Teams compliance records in a preview sample generated by a content search

**No Team or Channel Names Displayed for Compliance Items:** In the past, content searches displayed the names of the team and channel in the Subject field of items returned by searches. This information was useful in terms of finding the exact location of an item, but it's no longer displayed. The team name and email address are now the only clues as to the team where an item is found.

## Refine Searches for Specific Teams Items

The parameters for the content search shown in Figure 13-10 scans Exchange Online mailboxes to find any Teams compliance record matching the keyword. However, if it asked to search mailboxes without further qualification, the search will also find other non-Teams messages. To restrict search results to Teams content, we add the IM message kind condition to the search. This will find chat and channel conversations. Other search refinements are:

- Message kind set to *MicrosoftTeams* to find chat and channel conversations and call detail records.
- Keyword: *Itemclass:IPM.AppointmentSnapshot.SkypeTeams.Meeting* to find call detail records for meetings.
- Keyword: *Itemclass:IPM.AppointmentSnapshot.SkypeTeams.Call* to find call detail records for calls.
- Keyword: *Itemclass:IPM.AppointmentSnapshot.SkypeTeams.Meeting OR Itemclass:IPM.AppointmentSnapshot.SkypeTeams.Call* to find all call detail records.

Note: when you create a content search, make sure to set the "add app content for on-premises" checkbox to allow the search to include compliance records generated by hybrid and guest users.

## Searching Other Microsoft 365 Workloads for Teams Content

Remember that Teams content exists in many other places than channel conversations and chats. To do a complete search, you might need to include:

- OneDrive for Business accounts to find files shared in personal and group chats.
- SharePoint Online sites for files shared in channel conversations.

Some information used by Teams will remain unavailable to content searches until applications support indexing. Whiteboards shared during meetings are a good example of information unavailable to content searches.

## Reassembling Conversations

The way that the Microsoft 365 substrate captures individual compliance records for each message posted to a chat or channel conversation makes it more difficult to reconstruct a full conversation from start to finish. Normally, when eDiscovery investigators review information, they want to see the full context to understand who said what to whom and how a conversation developed. A full message thread gives context by recording the different interactions of participants in a conversation. Email can do this too by including the text of prior replies in a message.

The Microsoft 365 Advanced eDiscovery and Communications Compliance services are both able to reconstruct a Teams conversation from discovered messages and present the conversation in the same manner as it appears in a Teams client. This isn't possible with Core eDiscovery or simple content searches as these operations return individual compliance records instead of complete conversations. However, it is possible to use a manual process to construct a complete conversation from the compliance records captured by Teams. To do this, you must:

- Search for and find the compliance records for all contributions to the conversation. You won't find all the compliance records belonging to a conversation unless you use its reply chain identifier as a search keyword. For example, you could search for 1529919175913 to find all items in the conversation with that reply chain identifier.
- Because items from all channels are in the same mailbox, be careful not to mix items from different channels together.
- Arrange the items in date order using the timestamp. Some commercial products combine compliance records to form threads when they present search results.

You can export the information found in Teams by a content search to PST files or as individual items, and then give the PST or items to external investigators for their review. See Chapter 18 for more information about how to build and run content searches and export items found by the searches.

If a Teams meeting is recorded and a transcript is produced, Microsoft Search can look for information in the transcript. Content searches can also find videos based on transcript text, but the content search UI doesn't display the transcript. The found items are the recordings (MP4 files) rather than the transcript. If you download an item, the compliance center creates a file without an extension. You can rename the file to give it an MP4 extension and it will then play as normal. Microsoft expects to correct these issues and deliver full capability to search transcript text via Microsoft 365 eDiscovery in 2022.

## Searching Hybrid and Guest for Teams Compliance Records

If a guest user sends a message to a tenant user in a chat, the substrate captures two copies of the message: one in the cloud-only mailbox created for the guest, the other in the tenant user's mailbox. Searches executed through the Microsoft 365 Compliance Center automatically include Teams messages sent by hybrid and guest users using the copies kept in user or group mailboxes but do not scan the mailboxes belonging to these users.

Two ways exist to search compliance items stored in guest mailboxes. You can:

1. Amend search settings to set the checkbox to include *"Add app content for on-premises users."* The checkbox covers the cloud-based mailboxes created for hybrid, federated, and guest users. This is the default setting for new content searches.
2. Use PowerShell to update the search criteria to include app mailboxes.

Content searches find Teams compliance records in cloud-based mailboxes when two parameters are set to *\$True*:

- **AllowNotFoundExchangeLocationsEnabled** controls if the search covers Exchange Online mailboxes that cannot be verified. These are the cloud-only mailboxes used by hybrid and guest accounts.
- **IncludeUserAppContent** controls if app content is searched. App content means the cloud-based mailboxes used by guest and hybrid users.

You can set these parameters for a new content search with the *New-ComplianceSearch* cmdlet or apply them to an existing search with the *Set-ComplianceSearch* cmdlet.

For example, these commands create a search including cloud-only mailboxes and then start the search.

```
[PS] C:\> New-ComplianceSearch -Name "Teams Chat Scan" -Description "Search for Teams Chat Information about Finance" -IncludeUserAppContent $True -AllowNotFoundExchangeLocationsEnabled $True -ExchangeLocation All -ContentMatchQuery "Finance AND Kind:MicrosoftTeams"
```

```
Start-ComplianceSearch -Identity "Teams Chat Scan"
```

After the search completes, you can use the content search GUI in the Microsoft 365 Compliance Center to preview search results, refine the search keywords and qualifiers, and export results for further investigation.

## Teams and Retention Policies

Teams messages are persistent and remain in the Azure Cosmos DB data store until removed by user action or through retention processing. Channel messages belong to the channel and don't disappear following the removal of the authors from Microsoft 365 (if Teams can't resolve the user who posted a message because their account no longer exists in Azure AD, it displays the message as posted by an "unknown user"). Chat participants collectively own the messages in the chat. A participant can delete their link to a chat message, but the message will remain available to the other participants.

Retention policies can remove messages from Teams. An organization can create retention policies to process Teams chats and/or channel conversations. These policies are separate from the retention policies used to control other Office 365 data such as documents and email and instead operate against the compliance records stored in user and group mailboxes. Retention policies for email do not process the contents of the *TeamsMessagesData* folder.

A background retention assistant job processes retention policies for non-Exchange workloads, including the compliance records created by Teams activity and subject to Teams retention policies. The assistant uses the settings in Teams retention policies to remove compliance records when the items expire. When the assistant removes compliance records, the Microsoft 365 substrate synchronizes the deletions back to the Teams chat service, which then removes the relevant messages from its store. Later, Teams clients connect to the Teams service and synchronize their local cache to complete the removal cycle.

If an in-place hold or litigation hold applies to some group or personal mailboxes which include compliance records, those items come under the scope of the hold. The substrate captures any attempt to remove or edit a compliance record by keeping the copies of the removed or edited item in the *\Purges* or *\DiscoveryHolds* sub-folders under Recoverable Items in the mailbox. However, Teams removes the items from its message store in Azure Cosmos DB.

When you create a retention policy for Teams, you can choose to keep messages for the chosen retention period (a minimum of one day) or remove items after the retention period elapses. What you cannot do is give users the ability to mark specific messages to force retention policies to remove those items sooner or keep them longer. SharePoint and Exchange support this kind of flexibility through retention labels or mailbox personal tags.

# Auditing Teams

In addition to capturing compliance records for individual and channel conversations, Teams generates audit records for many user and administrative operations. The most common audit record is to record each time a user, including guests, signs in. Teams captures an audit record for a user sign-in for every hour in a session. This is because the access token expires after an hour. After Azure AD renews the access token, the user signs in again. The user does not notice the sign-in happening as token renewal and reconnection happens in the background. The audit record tells you when the user signed into Teams and some information about what client they used, but it does not capture details of which team or channel they accessed.

Among the administrative activities that Teams captures audit records for are:

- Team creation and deletion.
- Channel creation and deletion.
- Users added or removed from teams.
- Settings changed for the organization, team, or channel.
- Tab addition and deletion (for a channel).
- Connector addition, deletion, and updates.

For example, audit events are captured for the creation and removal of teams and the creation of channels within teams. For instance, when you use a Teams client to create a new team, the audit log receives an *"add group"* event when Azure AD creates the new group followed by some *"update group"* events when it populates the properties of the new group. Finally, you see a *"TeamCreated"* event for the new team. Audit events are also recorded for any alteration of team settings. However, a *"TeamCreated"* audit event is not captured when you enable an existing group for Teams.

The audit records for the creation of teams and channels capture the names given to the new teams and channels and who created the object. However, the records for tab creation only tell you that someone created a tab. No information is captured about the content the tab links to. For example, if you create a tab to link to a YouTube video, the audit record tells you that the tab type is *"extension"* but not that it links to a video or what the video is (apart from third-party apps like YouTube, the extension tab type covers Microsoft applications like Planner and Stream too). No information is recorded about the content either when someone updates a tab. The lack of data is sometimes explained by the need to protect user privacy, and sometimes because tenants and Microsoft need to define what information Teams should capture (and why) for audit purposes.

Teams periodically uploads its audit data to the audit log. You can interrogate audit records using the audit log search in the Microsoft Purview compliance portal, by running the *Search-UnifiedAuditLog* cmdlet, or with third-party security products. Techniques for using these tools are explained in Chapter 21.

## Teams and the Groups Expiration Policy

Removing old Teams when their period of usefulness expires is part of compliance planning. If your tenant uses an Azure AD group expiration policy (Chapter 11) and the group used by a team comes within the scope of the policy, an extra section called **Team Expiration** (Figure 13-11) is visible to team owners under the Settings tab to inform owners about when the team needs renewal. A team owner can click the **Renew Now** button to extend the lifetime of the team for whatever period is set in the policy (normally a year or two). Renewal can happen at any time.

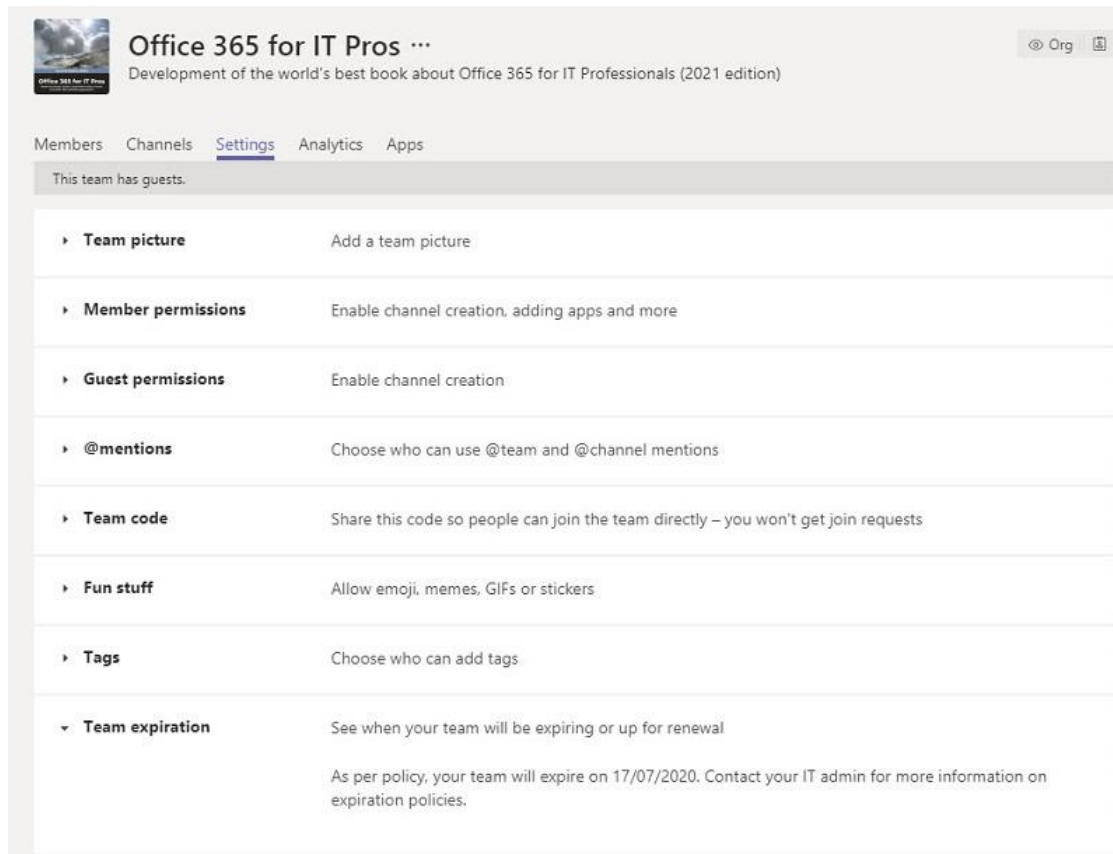

Figure 13-11: Showing the expiry date for a team

When a team is within a month of its expiry date, Teams highlights its potential expiration with a warning posted to the activity feed of the team owners. In addition, a warning triangle appears beside the team name in the navigation pane (but only to team owners). Hovering over the warning triangle reveals the expiry date and the choice to **Renew team** appears in the ellipsis menu. Because the Groups expiration policy auto-renews groups if they are active (and posting topics and replies in team channels is good evidence of activity), you shouldn't see warnings unless the assessment against the policy settings considers the team to be inactive. This can happen for teams used to host connectors where the number of human posts is low. If you see a warning, go to the Manage team options for the team and renew it there.

If a team reaches its expiry date and isn't renewed, Azure AD soft-deletes the group and all associated resources, including the team, and removes the ability of users to access those resources. An administrator can restore the team at any time within 30 days of its being soft-deleted. Once the 30-day period elapses, Azure AD permanently removes the group and all its associated resources, and the group becomes irrecoverable.

## Archiving Teams

Expiring a team removes it from the tenant. Archiving a team is another way of dealing with teams that are no longer active. When you archive a team, you make the elements controlled by Teams (like channel conversations and the wiki) read-only. Users can access messages in an archived team, but they cannot post new messages, edit messages, or remove messages from a channel. In addition, members can access files in the document library belonging to the team, but they cannot upload new documents or remove files from the library, and the link to open the document library in the SharePoint browser interface is not available. When users open an archived team, they see notices to tell them that they can no longer post to the team. Teams also displays an icon (a closed drawer) alongside the names of archived teams in the team list). The idea is

that the team remains available to its membership to allow users to continue accessing information while not being able to add to that information. You can update the membership of an archived team to add or remove members, including guests, or promote members to be owners.

Three methods are available to archive a team:

- In the desktop or browser client, select Teams, then the **Manage** cogwheel icon at the bottom of the list of teams to display the set of teams you belong to, divided into active teams and archived teams. This option is available to all team members, including guest accounts. However, only team owners, tenant administrators, and Teams service administrators see the option to **Archive team** in the ellipsis menu for the team (Figure 13-12). To restore an archived team and make it read-write again, select it in the list of archived teams and then choose **Restore team** from the ellipsis menu.
- In the Teams admin center, find the team in the **Manage teams** section and then select the **Archive** option. Only those assigned a Teams administration role can archive a team using this method.
- Use the Teams PowerShell module to archive a team. For example, to see the set of archived teams:

```
[PS] C:\> Get-Team -Archived $True
```

To archive a team, run the *Set-TeamArchivedState* cmdlet and pass the identifier to the team to archive. The *SetSPOSiteReadOnlyForMembers* setting controls if the SharePoint site belonging to the team is set to read-only.

```
[PS] C:\> Set-TeamArchivedState -GroupId $GroupId -Archived $True  
-SetSPOSiteReadOnlyForMembers $True
```

To reverse the process, set the *Archived* switch to *False*. You can only update the *SetSPOSiteReadOnlyForMembers* setting if it was set when archiving the team:

```
[PS] C:\> Set-TeamArchivedState -GroupId $GroupId -Archived $False  
-SetSPOSiteReadOnlyForMembers $False
```

Before archiving a team, it's important to check the status of any private or shared channels in the team. Administrators or team owners don't have access to the content of these channels unless they are channel members. A private or shared channel can be very active without the knowledge of the team owner, and if the team is archived at this point, team members (including external and guest members) won't be able to post new content. The Teams desktop client doesn't display any details about private and shared channels in a team. This information is available in the Teams admin center and can be retrieved by querying the team channel configuration with PowerShell using the *Get-TeamChannel* cmdlet.

After archiving a team, Teams moves it into the set of hidden teams displayed at the bottom of the teams list. Removing a team from the active set effectively makes the archived team invisible to users unless they go looking for it by opening the hidden set or by using the *Manage teams* option to find the team in the archived section. If you restore an archived team, Teams makes it writeable again but leaves the restored team in the set of hidden teams.

When archiving a team, you can choose to make its SharePoint site read-only for team members (this also sets the wiki to be read-only). Team owners can continue to upload and update content, but team members who access the site after the team is archived have restricted options because Teams adjusts the site permissions for team members to remove their write access. For example, members cannot upload files to the library, rename or remove files, update document details, assign retention or sensitivity labels, and so on. They can still synchronize the library and download files. The sites belonging to private and shared channels also become read-only (even for channel owners), and in these instances, SharePoint displays a banner to inform channel members of the site's read-only state.

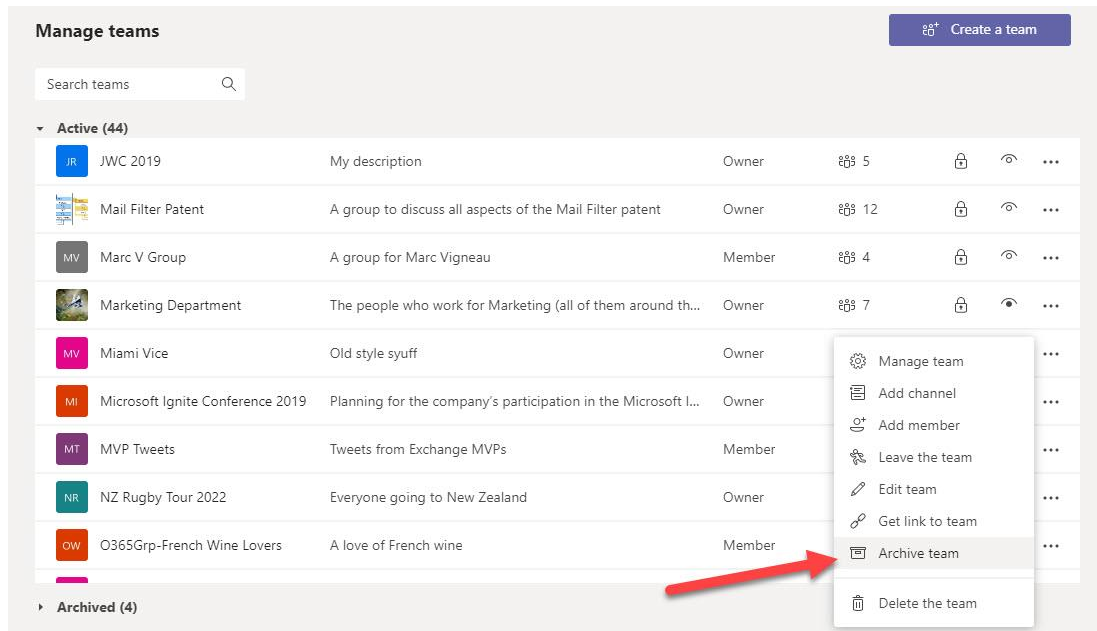

Figure 13-12: The option to archive a team

Setting read-only access to the conversations and files belonging to a team is an effective way of putting it into an archive status, but a big selling point for Teams is its ability to be an integration point for other third-party applications. To make archive status fully effective, every application connected to Teams must understand when a team is archived. SharePoint does this, but the other connected apps don't, which means that team members can continue to have read-write access to other apps like Planner, OneNote, and apps added to the team as tabs, and bots. This makes sense for third-party apps as they might be shared across multiple teams.

Archiving a team does not stop it from expiring if it is within the scope of the group expiration policy. The team still exists, albeit in a read-only state; expiration kicks in once the renewal time of the underlying group is reached and if the group is not renewed, Azure AD soft-deletes the archived team.

The mechanism used to archive teams is reasonable. Its biggest advantage is that members continue to enjoy access to channel conversations. A different approach is outlined in the PowerShell chapter showing how to archive teams by removing everyone but a single owner from group membership. The advantage of this approach is that access to all team resources is removed from previous members, which is what you might want to achieve.

## Reporting Teams Usage

Microsoft 365 includes several methods to gain an insight into the activity levels of Teams:

- The standard usage reports available in the Microsoft 365 admin center include a Teams usage report. The data can be viewed in 7-day, 30-day, 90-day, or 180-day snapshots. The data is available for the overall tenant, per-team, and per-user level (in a sortable table) and is exportable to a CSV file.
- The **Analytics and Reports** section of the Teams admin center includes a set of usage reports. The Teams admin center doesn't support sorting of the report detail, but you can export the information to a CSV file to analyze and report the data as you wish. Reports are available for the last 7, 30, or 90 days, except the PSTN data, which is available for up to 28 days. The same data is available for device usage and user activity in the Microsoft 365 admin center. The reports include:
  - Teams user activity (number of channel messages, chat messages, 1:1 calls, video and audit minutes, and date of last activity).
  - Teams device usage (Windows, Mac, iOS, Android).

- Teams usage (active users, guest members, active channels, number of messages, team privacy setting).
- Teams Live Event usage (event, start time, organizer, presenter, producer, and views).
- PSTN blocked users.
- PSTN minute and SMS pools.
- PSTN and SMS usage.
- Information protection license report. This has nothing to do with Microsoft 365 Information Protection and instead deals with if users have the [necessary license for apps to receive subscriptions](#) to the endpoints tracking changes to messages and chats.
- Apps usage (number of active users per app, number of teams where the apps are used).
- Analytics for individual teams are available through the Manage team option in the Teams desktop and browser clients (Figure 13-13). The data reveals activity for the selected team over a 7, 30, or 90-day period. The information is available to any member of a team, including guests, and is intended to give an overall view of the activity within a team together with some other information such as the breakdown of membership into active and inactive members and tenant users and guests. You can view data for all channels or select the data for an individual channel (including private channels). The data available for a channel covers the number of topics and replies posted. Team analytics track active users over time, the split between tenant users and guests and members and owners, the number of apps installed in the team, and meeting activity. The data doesn't include messages posted to channels by Office connectors (like an RSS feed) or those that come in through email. Analytics for an individual channel is also available through the Manage channel menu. Teams doesn't include a facility to export analytics data from a client, but a Graph API is [available and can be used to generate downloadable data](#). The report also lists the top five inactive channels in the team. Typically, the channels listed have had no activity in over a month, but this depends on the number of channels in the team.
- The [Microsoft 365 usage analytics content pack](#) for Power BI includes a Teams usage report. Like the usage data for all workloads available in the content pack, the Teams data can be up to a month or so behind, depending on when Microsoft 365 last refreshed the data. The content pack exists to track usage over a sustained period and that is how to use it.

Usage data is collected and collated by background processes and stored in the [Microsoft Graph](#), so the information available for analysis through any of these options is at least two days old. The analytics and reports available in the Teams client and the admin centers present data in different ways, so you might observe some minor inconsistencies when comparing the data viewed in one interface against another. Remember that third-party reporting alternatives are available (see Chapter 21) that usually offer more powerful and flexible analysis and reporting functionality than is available in Microsoft 365.

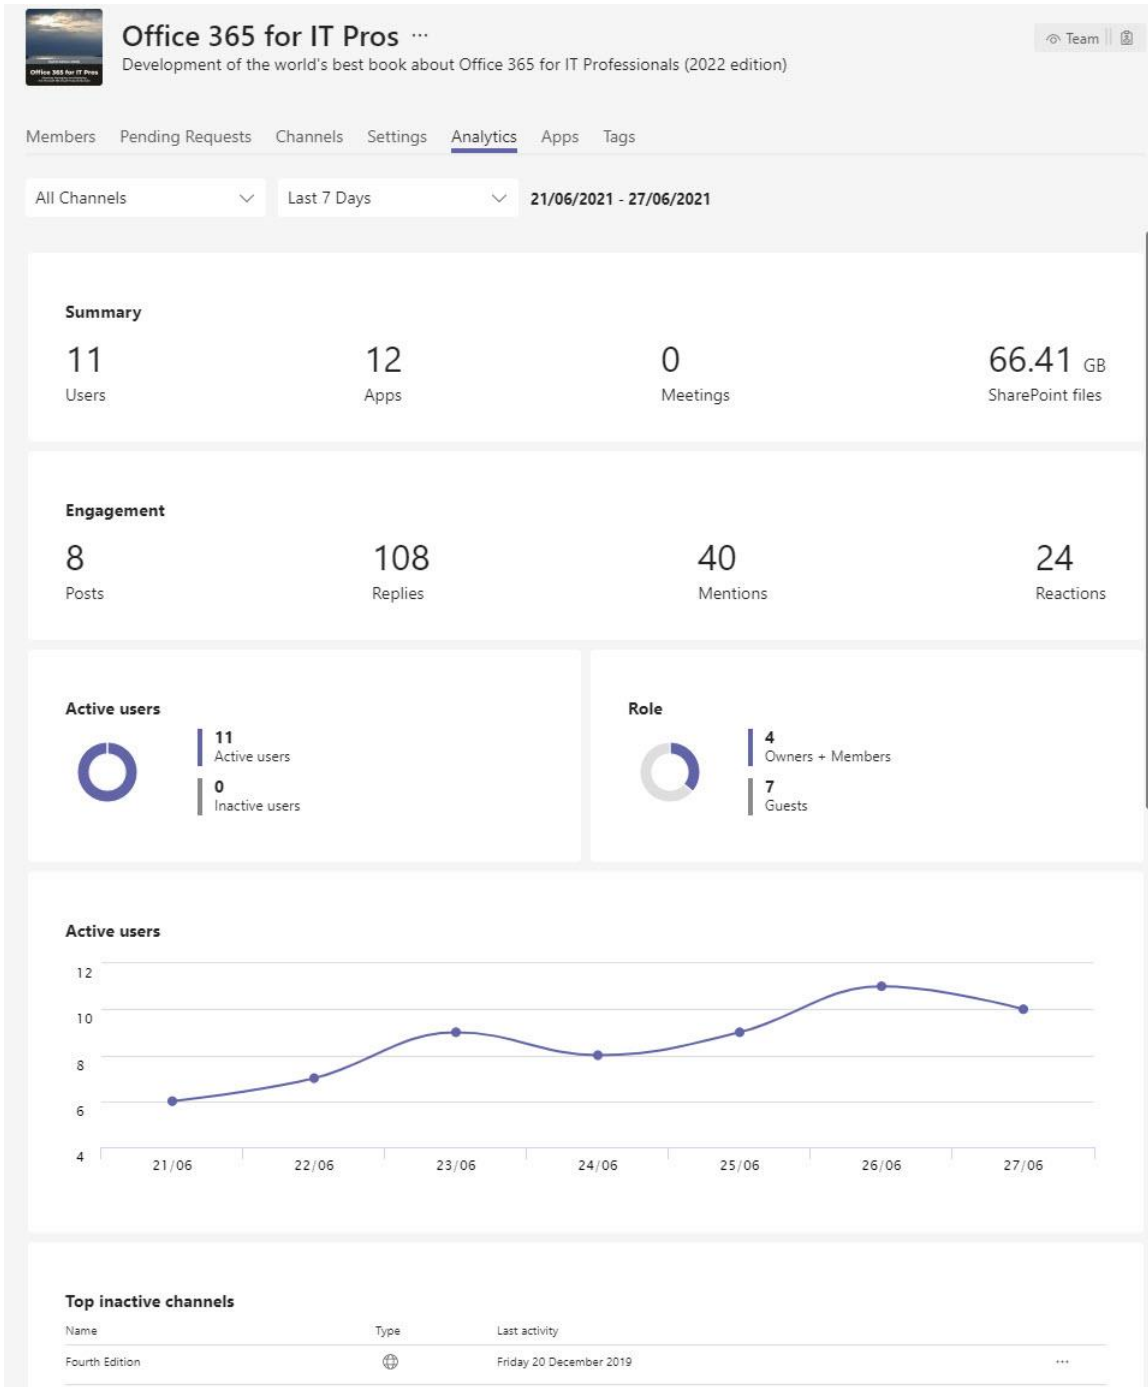

Figure 13-13: Analytics for an individual team (all channels)

## Extending Teams

Out-of-the-box, you can extend Teams by adding tabs, apps, bots, and connectors to channels. Bots fit into conversations to allow users to interact via chat with software assistants, usually to answer questions about specific topics. Connectors set up links between channels and network data sources so that information flows from the data source and appears in the channel like user contributions.

Microsoft has a [developer program for Teams](#) focusing on different aspects of integration like:

- Extending the tabs available for a channel to incorporate access to an application.
- Adding a new bot to answer questions posed by team members.

- Creating a connector to a network data source.

MVP Tom Morgan publishes [Building and Development Apps and Bots for Microsoft Teams](#). It's a good starting point for app developers who want to build apps using the Teams platform. Given the attractiveness of the platform and the hundreds of millions of active Teams users, it is no surprise that the number of Teams apps increases over time. As of mid-June 2022, over 1,600 apps are available in the Teams app store, and the number of apps increases by approximately 80 per month.

The [Microsoft 365 app certification program](#) helps customers to understand what apps they might like to run in Teams by publishing developer-provided information about the apps. Three levels are available:

- **Publisher verification:** The app developer has a Microsoft developer network identity. The app supports modern authentication and is capable of multi-tenant activity. This is the entry-level participation in certification.
- **Publisher attestation:** The app developer completes a questionnaire covering security, data handling, and compliance.
- **Microsoft 365 certification:** Instead of the app developer reporting details of their app, third-party assessors audit the assertions to validate that the app meets Microsoft standards for security and compliance. The process occurs annually, and details gathered during the audit are available online. The audit information is available through the Microsoft 365 certification link for the app. Abode Sign is an example of a Microsoft 365 certified app.

Regretfully, many apps (including some created by Microsoft) are uncertified and few app developers go through the full Microsoft 365 certification process. This might be a question of resources or a lack of perceived value in achieving certification. However, the audit information gathered by the attestation procedure is valuable and worthwhile knowledge for customers interested in the data accessed by apps.

## Managing Teams Apps

Not every organization is willing to allow users free rein over the apps they can install and use with Teams. To exert control over the apps available to users, three mechanisms are available in the **Teams Apps** section of the Teams admin center:

- **Manage apps:** Define which apps are available in the tenant. By default, any app published in the Teams app store is available to a tenant. Some apps might be inappropriate or not very useful for an organization, so tenant administrators can block individual apps here. Blocked apps can't be installed by users and won't be displayed in the app navigation bar if included in an app setup policy. To decide whether to allow an app, you can check its properties:
  - *Publisher:* The organization responsible for creating and maintaining the app.
  - *Version:* The current version of the software.
  - *Categories:* For example, Productivity or Business Management. The publisher chooses these categories as general guidance for the type of solution an app is.
  - *Certification:* The highest level of certification is [Microsoft 365 certified app](#), which means that Microsoft has reviewed and approved the app against a set of security, compliance, and data handling standards.
  - *Licenses:* ISVs can generate Teams apps that support per-user licensing (monthly or annually) or in-app purchases. The Plans and Pricing tab for the app tells administrators what licensing is available. Some apps offer free versions that users can upgrade to a premium version with a license.
  - *Capabilities:* Where in Teams the app can be used. If *Team*, the app can be installed into a team channel. Other categories include *Personal*, meaning that a user can install the app for

their personal use, and *Group chats*, meaning that the app can be installed to be shared by participants in a group chat.

- *App Id*: Each app gets a unique identifier (GUID) during the publication process to make the app available in the Teams app store. The identifier is the same for all tenants.

To block an app, select it from the app inventory and move the App status slider from *On* to *Off*.

If an app is scoped for installation into a team (normally as a channel tab), the administrator can install it into selected teams.

- **App Setup policies**: Controls the set of apps displayed in the Teams app navigation bar. Setup policies also control if users can pin apps or upload custom apps. See the section below.
- **App Permission policies**: Apps come from multiple sources and not every app is suitable for every user. App permission policies allow tenants to control the set of allowed apps that individual users can install in Teams.

The Manage apps page also includes **org-wide app settings** for apps. These settings are tenant settings to:

- **Allow third-party apps**: If *On*, third-party apps can be installed by users. Turning this setting to *Off* prevents users from installing third-party apps and limits them to apps provided by Microsoft.
- **Allow new third-party apps published to the store by default**: If *On*, any new third-party apps published to the Teams app store are visible in the tenant's Teams app store and are available to users if the app permission policy assigned to their account allows third-party apps. If *Off*, new third-party apps do not appear in the app store.
- **Allow interaction with custom apps**: Custom apps are those developed for your organization. If this control is *On*, users can install and access custom apps. If *Off*, they cannot (this setting also disables [outgoing webhooks](#)). This setting is *Off* by default for GCC tenants.

Microsoft creates default app setup and app permission policies (both called Global (Org-wide default)). These policies are assigned automatically to Teams users and stay in place unless an administrator updates the policy assignment for an account. You can amend the default policies or create new policies to assign to individual users or sets of users to match organizational requirements.

## Customizable Apps

Depending on the manifest settings published by an app's developers, the settings of an app can be customized for an organization. For instance, you can replace the app's icons with versions that include corporate branding. When an app is customizable, it is marked as such in the Teams admin center and an administrator can update the following settings:

- **Short name**: a 30-character app name.
- **Short description**: an 80-character description of what the app does. You can also add a full description. I've used descriptions of over a thousand words.
- **Privacy policy URL**: You can use this link to point to an appropriate page on the organization's website where users can find information about the company's privacy policy.
- **Website URL**: This is usually the URL for the main landing page of your company's website.
- **Terms of use URL**: Typically points to a web page where users find information about the terms of use for the application. Normally provided by the app developer.
- **Color and outline icons**: The color image must be smaller than 1,000 KB and must be a PNG file and should be 192 x 192 pixels. The outline icon is 32 x 32 pixels. The color app shows up in the Teams app store. Teams uses the outline app to display in the app navigation bar.
- **Accent color**: A hex code defining the background upon which Teams displays the app's color icon. Here's a [website](#) to help find the code for the background color.

Some experimentation might be needed to identify the best icons and colors.

## Applications and Permissions

Administrators (or users, if access is only needed to that user's information) must grant consent to applications based on the Graph API to use the required permissions before they can access data such as teams, channels, and messages. Although some apps do not need to access tenant data, many third-party and LOB apps interact with data from Teams or other workloads which they access using the Microsoft Graph APIs. Before they can access any tenant data, an app must be granted consent by a tenant administrator. Consent is managed through the Permissions tab of app properties, divided into two sections:

- **Org-wide permissions:** Allow access to org-wide data, such as all sites, users, or teams in the tenant.
- **Teams Resource-specific-consent (RSC) permissions:** These are permissions granted to access [certain types of Teams data](#) (like channel settings or the tabs available in a team) scoped only to the team in which an app is installed. Some [Azure AD configuration](#) is necessary to allow RSC to work. Trello, Zoho CRM, and Template Chooser are examples of apps that support RSC. Not all Graph-based applications support resource-specific consent permissions. The ability to use resource-specific consent permissions is enabled by default at the tenant level. A tenant can enable or disable the feature by blocking team owners from granting consent to apps. To do this, go to the Enterprise application section of the Azure AD admin center and set **Group owner consent for apps accessing data to Off under User consent settings**.

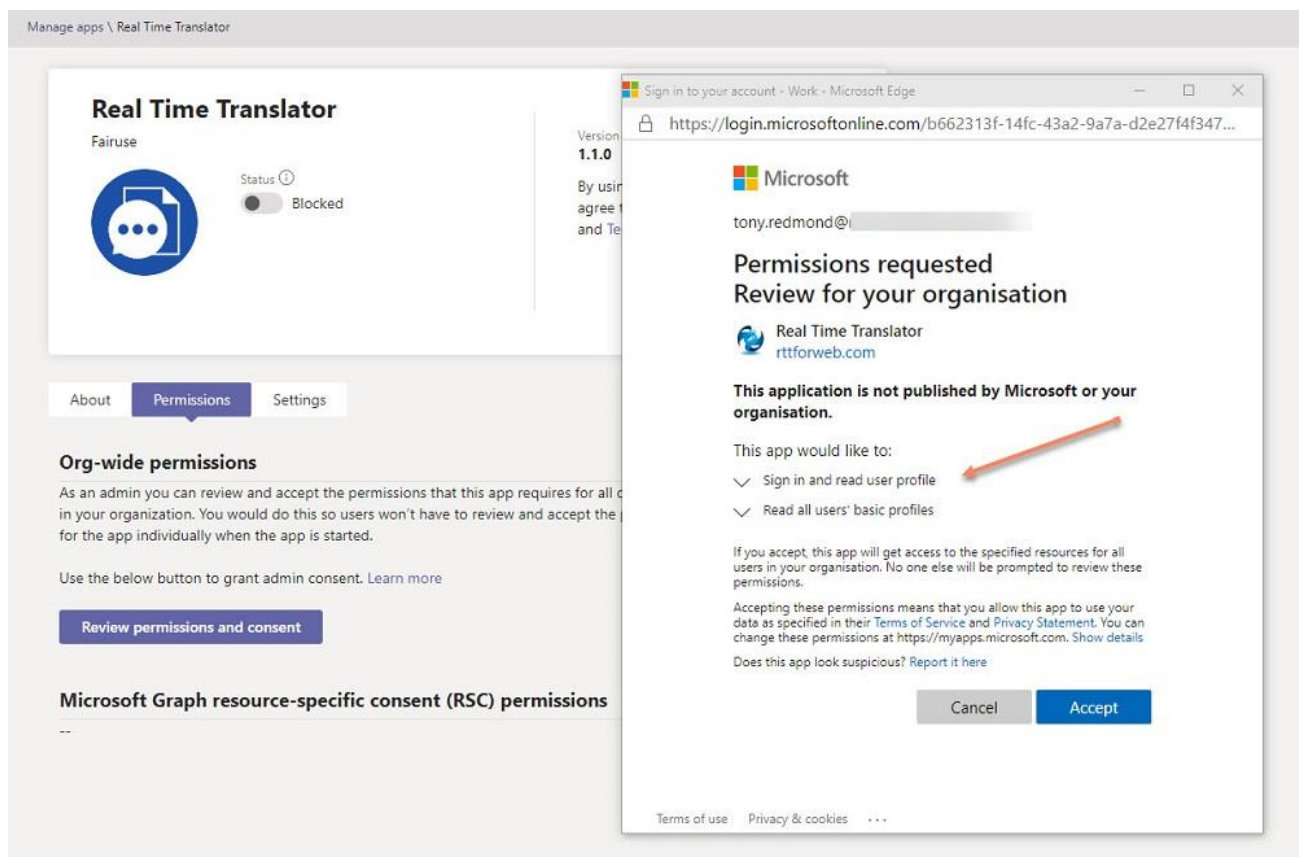

Figure 13-14: Granting consent to permissions requested by an app

When an administrator grants consent to the permissions requested by an app, they do so on behalf of the tenant. This has the advantage that individual team owners won't be asked to grant consent when they install an app into their team. Often, team owners don't have the necessary administrative rights to grant the necessary permission, which causes a delay in making the app available to users. It's also the case that team

owners might be unaware of the danger of granting consent, especially org-wide permissions, to an app published by a company they don't know.

Figure 13-14 shows the screen used to display the permissions requested by an app during an administrator review. In this case, the app is requesting two org-wide permissions needed to read user profiles. To grant consent, the administrator clicks **Accept**. Teams then updates the app's service principal in Azure AD. App consent can be withdrawn at any time by editing the app details through the [Enterprise applications blade](#) in the Azure AD admin center.

Upon receiving consent, the permissions granted to the app are registered in Azure AD and Microsoft Graph allows the app to access data within the scope of the permissions. See [this article](#) for more information about app permissions.

## App Templates

To illustrate the capabilities of the platform, Microsoft has created a set of production-ready apps for Teams. This is both a learning tool and a way to accelerate app development for Teams. The idea is that organizations can browse [the available set](#) to find an app that's similar in concept (or an exact match) for what they want to do and then download the code base and deployment scripts for the chosen app from GitHub before tailoring the code to meet their requirements. The GitHub repository for each app template also includes documentation. Among the available templates are:

- Ask Away: A bot to conduct question and answer sessions within Teams.
- Building Access: Administration of access to buildings.
- Company Communicator: Create and send messages to multiple teams or large numbers of users over chat.
- Employee Ideas: Allow employees to submit ideas.
- Expert Finder: A bot to find someone in the organization based on their skill set (depends on data registered in Azure AD).

## Teams App Setup Policies

The Teams app navigation bar contains a set of pinned apps and an ellipsis [...] menu to allow quick access to other apps. The apps in the navigation bar are controlled by the Teams app setup policy assigned to the user account. [App setup policies](#) are managed through the **Teams Apps** section of the Teams admin center. An app setup policy describes the set of apps to show in the app navigation rail (left-hand side in desktop and browser clients, bottom of the mobile client) and the order in which the apps appear. An app setup policy also controls if the users assigned the policy can pin apps or upload custom apps.

A typical app setup policy includes all or some of the default Teams apps (like Chat and Teams) together with other apps from the Teams app store or the organization's app catalog. The idea is that you can build sets of apps appropriate for different kinds of users and assign them via policy. The default Teams app setup policy (called Global) is used unless another policy is assigned. Teams also installs an out-of-the-box policy for front-line workers in each tenant.

In Figure 13-15, we see that the set of core Teams apps are rearranged so that Teams is at the top of the list in the app bar. Planner is a non-standard app that has been pinned to the bottom of the list. The user can select additional apps to pin to the app navigation rail from the Apps menu. Any of the core Teams apps unpinned from the navigation bar remain accessible in the Apps menu.

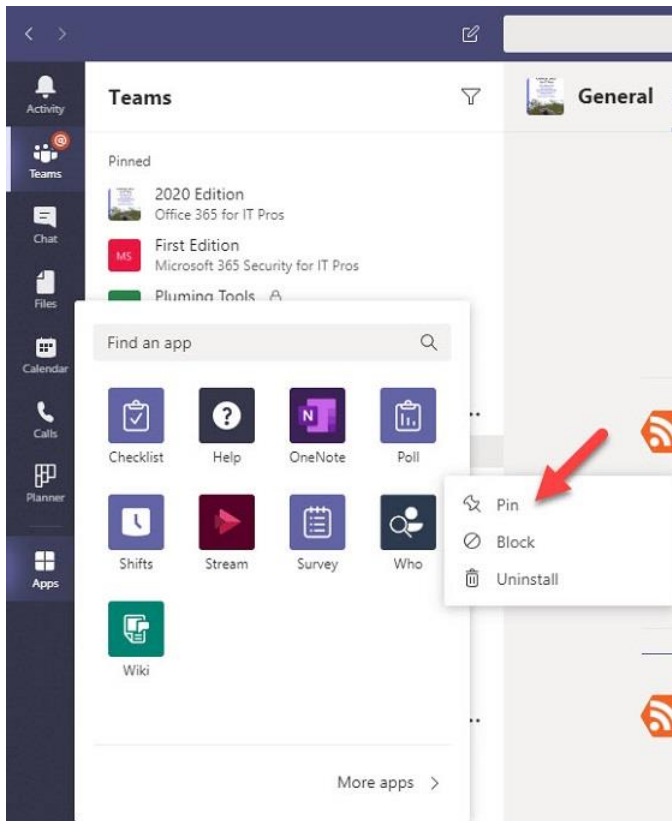

Figure 13-15: Selecting an app to pin to the app bar in the left rail of the Teams client

The *Allow user pinning* setting in an app setup policy controls if users can add (pin) or remove (unpin) apps to the app bar. By default, the setting is On. Update the policy setting to Off if you don't want users to be able to select apps for the app bar. Clients won't implement the new settings until they refresh their copies of policies, which can take an hour or so. Guest users don't have app setup policies and are limited to the apps they can access (Teams, Chat, Activity, and Files).

If an administrator changes the app setup policy assigned to an account, Teams notifies the user that their settings have been updated and that some of their pinned apps might have been moved.

## Analyzing App Usage

The Apps usage report in the Reports section of the Teams admin center helps administrators to understand the effectiveness of Teams app setup policies. For instance, if you see that an app displayed in the navigation pane isn't being used, it's a prompt to either make people aware of the app or to consider replacing the app in the pane. Likewise, if you see an app in heavy use that isn't shown in the navigation pane, perhaps it's time to include it there. The most effective way of analyzing app usage is to download the data to Excel and review it there. The apps with the heaviest usage are likely to be Teams (channels and conversations), Activity (the feed), Files (SharePoint Online), and other standard Microsoft apps found in all Teams installations.

## Assigning App Setup Policies

App setup policies can be assigned individually to accounts in the Teams admin center or via PowerShell. It's usually more convenient to use PowerShell to assign a new policy to multiple accounts. In this example, the set of users for the marketing department is selected and an app policy designed for that department is assigned to each account.

```
[PS] C:\> $Users = (Get-CSOnlineUser -Filter {Department -eq 'Marketing'})
Foreach ($U in $Users) {
    Write-Host "Assigning Teams App Setup Policy for the Marketing department to" $U.DisplayName
```

```
Grant-CsTeamsAppSetupPolicy -PolicyName "Marketing" -Identity $U.UserPrincipalName }
```

# Teams App Permission Policies

App permission policies control the set of apps available to users. Each policy can give access to a separate set of apps. After you assign an app permission policy to a user, they can install any of the apps covered by the policy. An app permission policy can't override a block set in the org-wide app settings. Management of app permission policies is through the Teams apps section of the Teams admin center.

If you want to allow access to different apps, you can customize the set of apps defined in the global app permission policy or create a new app permission policy and assign it to selected accounts. An app permission policy covers three types of apps:

- Microsoft apps.
- Third-party apps. Some of these apps support the purchase of applicable licenses through the Teams admin center.
- Custom or tenant apps (apps published and owned by the organization).

For each category, you can decide to:

- **Allow all apps.** Users can install and use any app of the type published in the Teams app store.
- **Allow specific apps and block all others:** The administrator selects the apps that users can install and use. Teams doesn't allow users to install blocked apps in the Teams app store.
- **Block specific apps and allow all others:** The administrator blocks selected apps available in the Teams app store and makes them unavailable to users.
- **Block all apps:** Users cannot install apps of this type.

When you restrict the set of apps with an app permission policy, Teams filters the set of apps, bots, and connectors it displays to users assigned that policy. Due to caching, it can take up to a day before Teams clients respond to a change in the set of apps allowed to users or a change in the policy assigned to an account.

Users can request administrators to allow them to install blocked apps. Administrators don't receive notifications of these requests. Instead, they must check for waiting requests in the Teams admin center by looking for apps with open requests from users. After finding a request, the administrator can unblock the application and add it to the relevant app permission policy to allow the user to install the app. After clients download the updated policy, users can install the unblocked app.

Once a user installs an app in a chat, the app becomes available for use in any other chat without the need to reinstall the app from scratch.

## Assigning App Permission Policies with PowerShell

The *Get-CsTeamsAppPermissionPolicy* cmdlet lists the Teams app permission policies available in the tenant. Use the *Grant-CsTeamsAppPermissionPolicy* to assign a policy to a user. For example:

```
[PS] C:\> Grant-CsTeamsAppPermissionPolicy -PolicyName "Unrestricted App Access" -Identity Kim.Akers@office365itpros.com
```

To assign an app permission policy to the members of a team, we need to retrieve the members of the team and then assign the policy. Here's how to do it using the *Get-Team* and *Get-TeamUser* cmdlets from the Teams PowerShell module followed by a call to *Grant-CsTeamsAppPermissionPolicy* to assign the policy to the individual members:

```
[PS] C:\> $HRGroup = Get-Team -DisplayName "Human Resources Group"
$TeamUsers = Get-TeamUser -GroupId $HRGroup.GroupId -Role Member
```

```
$TeamUsers | ForEach-Object { Grant-CsTeamsAppPermissionPolicy -PolicyName "HR App Policy" -Identity $_.User }
```

# Teams App Store

The Teams app store is the place where users go to discover the set of apps available to them. Apps blocked by the tenant (in Manage apps) are not shown. Users reach the app store by opening the app selection panel from the app (left-hand) rail and then selecting the [...] option. The More apps link leads to the app store (Figure 13-16) where they can browse the set of available apps permitted for installation by the organization. Depending on the app type, it might be installable in various places. The target varies with app type. For instance, a connector usually installs into a channel while other apps might show up in a channel tab. See [this link](#) for more information.

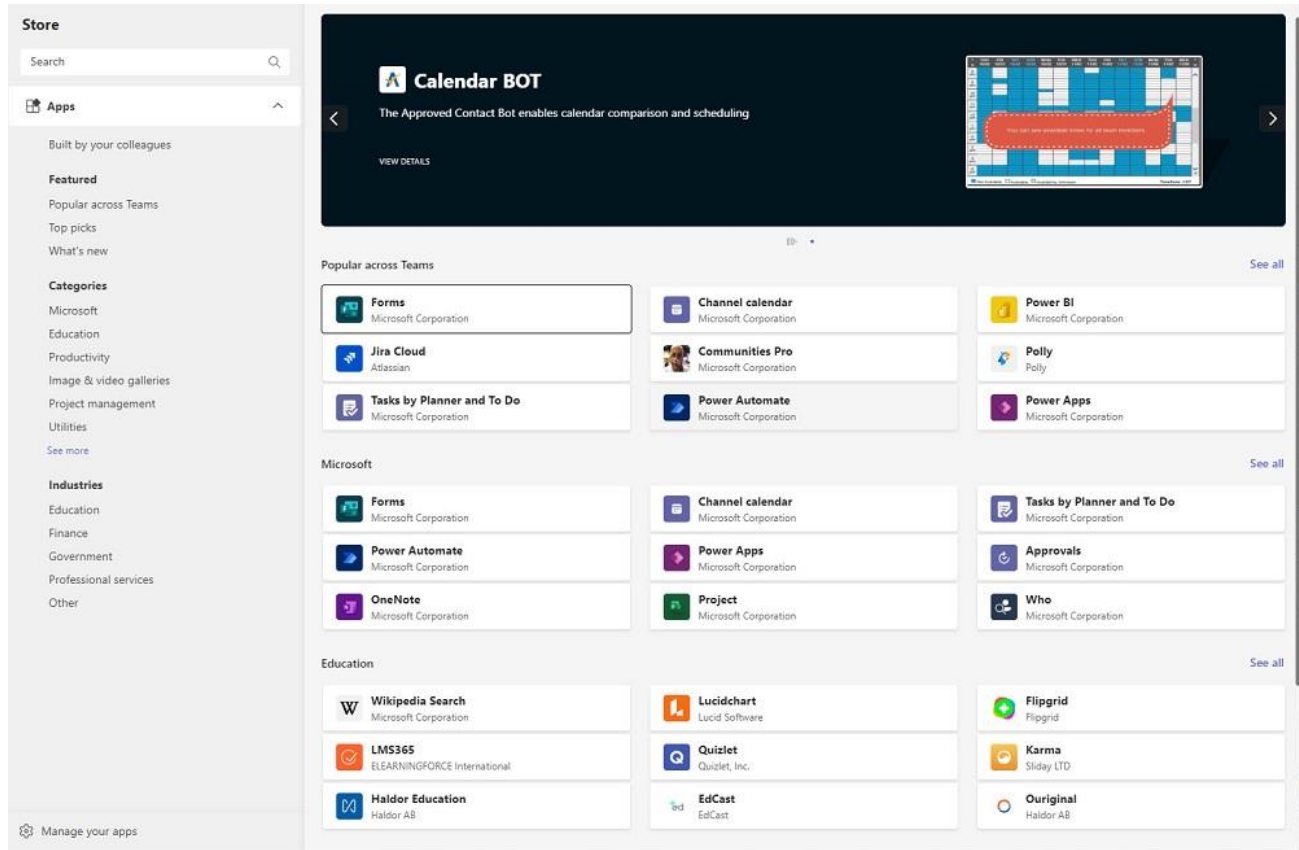

Figure 13-16: The Teams App Store

Organizations can [customize the Teams app store](#) by adding their logo and corporate colors.

## Teams and Bots

Another way of extending the usefulness of a team is to connect it to one or more bots. A bot is a virtual software assistant. In the context of Teams, a bot is an application that accepts questions about specific topics from team members and responds, all within a conversation like those conducted with humans. The Microsoft [Bot Framework](#) assists developers to build their bots for use with Teams. A sample [Teams application written in C#](#) is available too. Another example of how to create a bot for use with Teams based on an [Azure knowledge base](#) is also available. After creating a bot, to enable it for a team, go to the Teams Apps Store and click **Bots**. You can then browse the set of available bots and decide which bot to install into a channel within a team.

The Who bot is one of the standard bots included with Teams. Before you can use the bot, you must install it from the Apps Store. Once installed, the Who bot uses the organizational information included from Azure AD and signals gathered in the Microsoft Graph to answer questions such as “Who is Kim Akers” or “Who knows about collaboration.” The answer to the first question comes from the manager-employee data in Azure AD; the answer to the second is from information in Teams chats. In both cases, to find answers, the Who bot executes searches on behalf of the user. To find experts, the bot scans all the teams to which the user belongs to find messages relating to the topic. The bot then performs some post-processing to score the results, using @mentions as important signals. The bot ranks each user by the number of messages about the topic they post, with their ranking increased for each @mention they receive. The idea here is that if someone mentions another person in a message about a topic, they do so because they think that person is an expert and might know the answer. Messages that include multiple @mentions receive a lower scoring boost because these mentions are often used as notify people of something they should know about.

If you do not want users to interact with bots, you can disable access to bots on a user-specific basis by configuring and assigning an app permission policy.

## Office Connectors and Teams

Office connectors create a link between a network data source and an Office application. In Teams, the destination is a channel within a team. Connectors work much the same way with Teams as they do with Groups. The results fetched through the connector show up as “cards” created as conversations within the target channel. The cards do not hold the full content of an item fetched from a source like an RSS feed or the Office 365 Service Management API. Instead, they hold enough text to let users decide whether they want to discuss the content – or click the link to explore the full content. Note that only users with an Exchange Online license can create a connector for a channel.

You can use connectors with teams in many ways. For instance, you could have a marketing team that needs to keep an eye on information posted for corporate communications. This would be easy to configure within a channel called “Corporate External Communications” inside the “Marketing Group” team. Another example is [how to use Google Analytics](#) to track basic usage patterns for visits of the web client to Teams. Many other different out-of-the-box connectors are available, including the Incoming Webhook connector, which you can use to bring data from custom data sources into a team or group. The PowerShell chapter includes an example of how to use the Incoming Webhook connector for this purpose. The example code explained there also supports Teams.

Because the cards created by connectors appear as messages in channels, it is logical that you add connectors to specific channels. To add a connector, click the ellipsis menu to the right of the channel name you want to use and select “Connectors.” You can then browse through the gallery of available connectors and select which one you want to use to bring network data into the channel. Some of the connectors need credentials before they can fetch content, so you might need to have a username and password to configure the connector.

When someone creates or removes a connector for a channel, Teams notifies members of the fact by posting a system message with details about the connector in that channel. After the connector downloads content and creates messages in the channel, users can comment on them like any other conversation.

## Disabling Connectors

Connectors are part of the default and external apps supported by Teams. As mentioned above, you can enable or disable individual apps through tenant-wide settings. If the app is a connector, it then becomes available or unavailable for inclusion in a channel.

If you want to disable the ability to add any connector to a team, you must disable the feature for the underlying group by running a command like:

```
[PS] C:\> Set-UnifiedGroup -Identity "Marketing Team" -ConnectorsEnabled:$False
```

Setting the *ConnectorsEnabled* property for a group disables the ability to add new connectors in any channel in the team. Any attempt to add a connector results in the error:

```
Connectors have been turned off for this mailbox by the admin.
```

Because of the need to synchronize between Teams and Azure AD, it might take a little time to apply or remove a block. Unfortunately, the implementation of the block within Teams is not particularly graceful as the choice to add Connectors persists in the menu even when a block is in place for the group (or the organization). To block the creation of connectors for all Teams in the tenant, run the following PowerShell command to update the organization configuration:

```
[PS] C:\> Set-OrganizationConfig -ConnectorsEnabled:$False
```

Existing connectors in use before the implementation of a block continue to run as before. If you want to remove connectors, you must do so manually. Teams captures audit records for the addition or removal of connectors in the audit log. The audit records hold details of the type of connector (for example, RSS) but not the source.

## Teams Approvals

The Teams Approvals app delivers easy-to-use and simple workflow processing. The app has links to Power Automate, but Teams hides the details of that connection from users. Users can:

- Use the basic approval form to seek approval from reviewers for a variety of requests from time off to trips.
- Use a variation of the [basic form connected to an eSignature package](#) like Adobe Sign or DocuSign to seek approval for a document. In this case, Teams gathers information about the document for approval and the reviewers and passes the details to the eSignature provider for processing. As the document goes through the approval process, the eSignature provider sends status information back to Teams for the user to track.
- Use approval templates created by the organization. An approval template deals with a specific form of approval, such as a form to request authority to discount a customer order. Administrators create custom approval templates from scratch or use sample templates as a base. Approval templates have a scope defining who can use them. The scope can be org-wide, confined to a named set of people, or a team (in which case, any team member can create approval requests using the template). Figure 13-17 shows the creation of a Teams approval request based on a custom template.

An approver can view and approve requests generated by the Teams Approvals app in the Power Automate admin center.

Initially, approvals with e-signatures could only be processed on the Teams desktop client. From August 2022, the capability is available on the Teams mobile clients too.

The screenshot shows a mobile-style interface for creating a Teams approval request. At the top, there's a header 'Technical or Copy Edit Request' with a sub-header 'This approval template is used by an author to request a technical or copy ...'. Below this is a text input field for 'Name of request' containing 'Copy Edit Teams Architecture'. The 'Approvers' section lists two people: Kim Akers and Vasil Michev (Technical Guru). There's a toggle for 'Require a response from all approvers' which is currently turned off. Under 'Edit type', 'Copy edit (grammar, layout, house style)' is selected. The 'Editing requirements' field contains the text 'Please copy edit the attached chapter'. At the bottom, there are 'Back' and 'Send' buttons.

Figure 13-17: Creating a Teams approval request using a custom template

## Power Platform and Teams

Microsoft is keen that people use the Power Platform to build Teams apps on a low-code or no-code basis. To help people start, several resources are available:

- [Dataverse](#) for data storage. Dataverse organizes data into tables of columns and rows. A set of standard tables are available, and apps can create custom tables if needed. The idea is to have a cloud-based, easy-to-access data service that apps can use without building custom data stores.
- Sample applications such as [Milestones](#) and [Bulletins](#). Milestones is an app to keep track of projects. Bulletins are a way to publish information to people within an organization. Source code is included to enable customization of the apps to meet the needs of organizations. Although off-the-shelf alternatives exist within Microsoft 365 like Project, Planner, and Communications sites, it still might be interesting to use custom versions of these apps to meet specific needs within the business.
- Documentation for [integrating Power Apps and Teams](#).

See Chapter 22 for more information about the Power Platform.

## Debugging Teams Clients

If something goes wrong and you experience a problem with the Teams desktop client, the approach to get started again usually follows these steps:

1. For desktop and mobile clients, sign out of Teams and then sign in again. This removes any lurking problems with authentication and credentials and solves many connectivity and cache synchronization issues. For browser clients, use a private session to connect to Teams. If this works, clear any browser cookies associated with Teams and office.com and try with a normal session again.
2. If the desktop client is still failing, stop all the Teams processes. On Windows, use Task Manager to find the processes and end them. Restart the client to see if the problem disappears.
3. If that doesn't work and the desktop client continues to have problems, clear the Teams cache. On Windows workstations, to speed up performance, Teams caches copies of server data in

`%UserProfile\AppData\Roaming\Microsoft\Teams` folder. Occasionally, the cached data is out of sync with the server or holds some corrupted data. Both conditions cause problems for the client. Before removing the cache, stop the Teams client (all processes). Then remove the complete Teams folder. When you restart Teams, the client rebuilds the cache so that its content is fresh. Although it's not recommended to blow away the Teams cache as the first step in troubleshooting, it can solve problems where other steps fail.

4. If you cannot resolve the problem, you should file a service request and give the diagnostics and client logs (see below) to Microsoft to help them understand where the root cause might lie.

If you find that you can't switch to another tenant, you may have expired credentials. To solve the problem, sign out of Teams and sign back in again. After you sign in, if you then try to switch to another tenant, Teams will prompt for credentials to allow the client to connect to that tenant.

## Teams Client and Diagnostic Logs

As summarized in Table 13-1, Teams can generate several diagnostic logs.

<b>Type</b>	<b>Clients</b>	<b>Contains</b>
Debug	Browser, Windows, Mac, Linux	Text file read from the bottom up to capture client activity such as login, connection, call, and conversation events. Also includes information about the environment such as the client version.
Desktop	Windows, Mac, Linux	Also known as the bootstrapper log. This text file notes details of communications between Teams and the underlying platform.
Media	Windows, Mac, Linux	Contains information about audio, video, and screen sharing in Teams meetings.

Table 13-1: Teams diagnostic logs

To generate the debug log, use the CTRL-Shift-Alt-1 key combination on Windows and Linux, and Command-Option-Shift 1 on a Mac. On all platforms, Teams creates the diagnostics log in the Downloads folder on the workstation and creates a name by combining *MSTeams Diagnostics Log* with the current timestamp.

Use the following commands to get the desktop log:

- Windows and Linux: click the system tray and find the Teams icon. Click the icon and select **Get Logs** from the right-click menu.
- macOS: Choose **Get Logs** from the Help pull-down menu.

By default, Teams turns off media logging. When needed, enable media logging through the General section of the Settings app and restart Teams. The locations of the various files created by media logging are noted in [this support article](#).

Utilities such as [Fiddler](#) and [Charles Proxy](#) are useful tools to collect a browser trace recording the communications between a Teams client and the back-end services. Make sure that you install the root certificate for the utility in the Trusted Root Certificate Store of your computer and enable HTTPS decryption before collecting anything. You can also use the [native functionality built into browsers like Edge](#) to capture logs (replace the references in the article to the Azure portal with Teams).

If asked to provide diagnostic information to Microsoft support, the easiest method to collect diagnostic information is to click the Teams icon in the system tray and select the **Collect support files** option. This command captures information used by Microsoft (like the debug log) and stores the data in a folder in Downloads. The folder is called *MSTeams Diagnostics Log* together with the date and time of its creation.

# Migration to Teams

Microsoft has no migration tools to import existing content into Teams in such a way that the migrated information is usable within Teams. Instead, if you want to import content into Teams, you must do so manually. For example, you can email content to a channel from any application that supports SMTP, or you can move documents into the folders in the SharePoint document libraries belonging to Teams. Several ISV products are available from companies such as AvePoint, Quest, and ShareGate to import documents from SharePoint on-premises servers, file servers, and other sources, or you can use Microsoft's free [SharePoint Migration Tool](#).

If you want to move content from another chat platform like HipChat or Slack to Teams, you can export data from these platforms. The difficulty then arises in how to import that data into Teams in the form of conversations and associated documents. The availability of [a Graph API to import third-party messages into Teams](#) has encouraged ISVs to investigate the area of Teams migration, so it's worth doing an internet search to discover what migration products are currently available.

All trans-platform migrations involve some form of data manipulation to ensure that the data imported into the target platform is usable. The migration code must parse the information taken from the source platform and update it to fit the data requirements of Teams. For instance, when the items forming a conversation go into a channel, the items must be in the correct order. The migration must apply permissions to attachments, and so on. Usernames are probably different, so some process of fixing these is necessary as otherwise, permissions might not work.

# Chapter 14: Managing Teams Calling and Devices

**Ben Lee**

Previous chapters covered the structure and management of Teams. Here, we expand on that by looking at how to use Teams to make good quality calls and explore the different devices available, from phones to full-blown meeting room systems.

## Teams Calling Fundamentals

Traditionally, IT administrators might have viewed PSTN (Public Switched Telephone Network) calling from Teams as a black art. Microsoft has put great effort into making Teams calling as straightforward to use as they can, but things still need to be configured to ensure everything is working optimally.

### Teams Calls, Teams Meetings, and Teams Phone

When we talk about calling in Teams this is a “catch-all” term and could refer to a few different things. Essentially it means making a voice, or video, call from your device to another endpoint but let’s go a bit deeper by breaking those calls up into some specific definitions:

- **Teams Calls** is where users call from one Teams endpoint to another Teams endpoint. This could be between two internal users, or an internal user and an external user. The important thing is that Teams is used on either end of the call. Media for a Teams call can either pass directly between the Teams clients or be relayed through components of the Teams service.
- **Teams Meetings** are when more than two people are in a call together. All communications occur between the Teams endpoint and the Teams meeting service. Teams automatically converts any call with more than two participants into a meeting regardless of whether it was a scheduled or ad-hoc call.
- **Teams Phone** (PSTN – public switched telephone network) is when a call is between a Teams endpoint and a phone number. This could be a local number, an international number, a premium rate number, a mobile phone number, or even a call that terminates in another tenant. At some point in its journey, the call passes over the PSTN network. This is the global interconnection of phone carriers that provide telephony services to customers.

The first two types of Teams calls are similar in terms of their path over the network and the codecs used. They are also the types of calling included “out of the box” as part of the standard Teams product. To make calls with Teams Phone you need to have some extra licenses, which may be included in your licensing plan, and the traffic paths and codecs used can be very different from the other call types. The three main technologies that you can use to access the PSTN with Teams Phone are; Calling Plans, Direct Routing, and Operator Connect. We will cover all these technologies and their differences over the next few sections. But first, let’s look at how to prepare your network to best support calling in Teams.

## Networking Preparation

Almost everything you do inside Teams sends traffic backward and forwards from your endpoint to the Microsoft service. In non-calling workloads, we usually aren’t too concerned about what path that traffic takes

or how fast the connection is (unless things have gotten really bad). However, any of the calling workloads described above are very sensitive to bad network conditions as the voice and video are being processed in near real-time. If we end up on a network connection where, for example, there is very high latency, our calls have a lot of delay in them or garbled voice or video. Teams does an excellent job at optimizing itself for any network it is using, but we need to give it a helping hand to ensure that things are operating as smoothly as possible.

There are two basic design principles that we should apply when working with network optimization for Teams, summarized as follows:

1. Ensure you move traffic onto the Microsoft network as quickly as possible:
  - a. Use local internet breakout.
  - b. Use local or regional DNS resolution. Microsoft 365 and Teams use GEO DNS for name resolution, meaning that you need to resolve the Teams services using local DNS to get the IP addresses of services closest to you.
  - c. Avoid sending traffic over internal or multiple WAN links unless they are very low latency.
2. Interfere with the network traffic as little as possible:
  - a. Open all the correct IP and port ranges that Teams needs found in this [link](#). The most important ones for Teams Calling are ID 11 (required), 12, and 13 (recommended).
  - b. Disable any deep packet inspection on the traffic.
  - c. Disable any WAN optimization technologies.
  - d. Avoid using VPNs with Teams traffic.

Following these two basic principles helps you get the traffic from the client and over to Microsoft where it becomes their problem as quickly and cleanly as possible.

**Note:** Teams meetings and calls route to local media relay services and are independent of which region hosts your tenant. For example, If your tenant is in Europe and a team of four people in the US meet, the media flows through US media relay services to ensure the best possible quality for the call

Microsoft has documented [the range of IP addresses, ports, and FQDNs used by Teams](#) and other Microsoft 365 workloads accessed when consuming services. They break these up into three categories:

- **Optimize:** this traffic is extra sensitive to network performance, latency, and availability. The IP addresses listed are guaranteed to come from Microsoft-hosted IP ranges. This category covers the endpoints used to process Teams media.
- **Allow:** is not as sensitive to network performance and latency but still provides connectivity to Microsoft 365 services and features. This category includes the main teams.microsoft.com URL.
- **Default:** should be handled as regular internet traffic, no optimization required. Non-Microsoft data centers could host these IP address ranges. The traffic could be icons inside SharePoint or other supporting types of data.

We cannot stress how important optimizing these categories is for Teams call quality as audio, video, and desktop sharing are all consumed in real-time, so any issues are very noticeable. If traffic is not optimized you may get random connectivity issues, call drops, or poor audio, video, and desktop sharing quality. The Optimize and Allow ranges should be treated as trusted data center locations by your network and be allowed and bypass any advanced network security features. Teams encrypt all traffic that goes to these IP ranges.

Is ExpressRoute a requirement for optimizing Teams traffic? The short answer is no, you still connect to the same IP addresses and services regardless of using ExpressRoute or the internet. ExpressRoute is an option when you want the bandwidth to be reserved and guaranteed to the Microsoft 365 services, have an SLA on connectivity, and need to preserve DSCP tagging for QoS to the Microsoft Network. If you have constraints on existing internet connectivity, setting up an additional connection using ExpressRoute for Microsoft 365 traffic may be an option. However, keep in mind that the recommendation is to have local internet breakout per site,

which could mean multiple ExpressRoute connections would be needed. However, keep in mind the recommendation to have local internet breakout per site, which could mean multiple ExpressRoute connections would be needed. Read more about [ExpressRoute and Teams](#).

The IP ranges may change at any point in time. Microsoft has published a [web service](#) where you can always get up-to-date IP ranges and ports. To stay abreast of changes, you can set up a routine to fetch this feed and send it to a suitable team, and some network vendors support auto-updating of rules using this service.

## Documenting Internal Networks and Subnets

Documenting your network topology can be time-consuming. However, the networking data is usable in a range of Microsoft tools to help plan, review, and monitor the performance of your calling deployment. The tools where you can reuse this information are:

- Teams Network Planner.
- Network Topology in the Teams admin center.
- Microsoft 365 Network connectivity, part of the Productivity Score.
- [Microsoft 365 Network connectivity test](#).
- Call Quality Dashboard.
- Reporting Labels in the Teams admin center.

The sooner you start gathering information, the better. Not all the tools need the same information, but if you create a complete data set in, for example, an Excel spreadsheet, you can reuse the information for each tool by creating the necessary csv files. Here is the information you need for each subnet:

- Site name.
- Internal network subnet range.
- Network Mask.
- Public IP(s) the client will present themselves with.
- Physical location address.
- Physical location City.
- Physical location State.
- Physical location Region.
- Physical location Country.
- Building name(s).
- The approximate number of users.
- Expected number of Meeting Room Devices.
- Internet breakout with bandwidth if local.
- If ExpressRoute is being used for connectivity to Microsoft.
- If branch site, which site is it connected to for internet breakout.
- If branch site, WAN link bandwidth.
- If using Teams Phone, how will it be delivered (Calling Plans, Operator Connect, or Direct Routing).
- The FQDN of the local Session Border Controller (SBC) if you are going to use Direct Routing.
- The proxy SBC FQDN, if you plan to use this with Direct Routing.

After gathering the data, you are ready to populate the tools.

## The Network Planner

The Network Planner tool (available under **Planning** in the Teams admin center) helps to estimate the network capacity required to support Teams based on the number of users, links between sites, and internet breakouts. The inputs to the Network Planner are personas that model the type of users you have, and subnet sites that describe the network topology and how they connect to Teams. You can even add Microsoft Teams Rooms (MTR) as personas per site, which is important as they may require more bandwidth than a normal

user as they are usually used for video first meetings which can consume more bandwidth. The output is a report listing estimated constraints in your network. Use this tool to get an overview of your environment and a starting point for a network assessment for Teams. Read more about how to get started [here](#).

**Note:** To save some time, a [PowerShell script is available](#) to automate the population of the Network Planner.

When you have populated the Network Planner, you can use the tool to identify any expected network constraints. A good result is when the tool finds no expected constraints but remember this is only based on anticipated usage with the inputs you have supplied. You should still then refer to tools such as Call Quality Dashboard (CQD) to monitor actual usage and user experiences after deployment.

The planner measures the centralized internet breakout with the number of sites connected to it so that you can capture your total expected bandwidth usage. If you experience bandwidth issues for sites that Network Planner does not flag, you should look for other issues outside Teams to investigate why this is the case. If you find sites with network constraints, then you can either improve the sites for better connectivity or use the Teams Network Roaming policy to limit bandwidth usage for those sites.

## Teams Network Roaming Policy

A challenge for branch sites with network constraints is that calls and meetings can consume too much bandwidth for video and screen sharing. The Network Roaming policy is a per-site policy that ensures that branch offices with low bandwidth do not get overloaded when users are using Teams, regardless of their Meeting Policies. You can then avoid having to rely on users remembering that they shouldn't be using video in a particular location and just inform them that video does not work in this location because of network restrictions.

There are two settings we can control with the Teams Network Roaming policy: *MediaBitRateKb* and *AllowIPVideo*. You can also find these settings in the Teams admin center under **Meetings**, then **Meeting policy**, these values are used if there is no site-specific Teams Network Roaming policy applied. You can create multiple meeting policies in an organization, each with different values, and assign the policies to different sets of users as appropriate.

Before you can create a Network Roaming policy you need to define the following:

- The public IP address that a client will present to the Teams service, so that Microsoft knows that this client is internal.
- A region (can span multiple sites).
- A site (can span multiple subnets).
- One or more subnets assigned to the corresponding site.

These configuration items are used by the Network Roaming policy and for Direct Routing if using Local Media Optimization or Survivable Branch Appliances (SBA). These concepts are described later.

External trusted IPs are the Internet external IPs of the enterprise network used to determine if the user's endpoint is inside the corporate network. This must be properly defined since the Network Roaming policy will only apply if the client has been identified as "internal" in the first place.

Use the Teams PowerShell module with the following cmdlets to configure the required policies:

```
[PS] C:\> New-CsTenantTrustedIPAddress -IPAddress 172.16.240.110 -MaskBits 32 -Description "Site1 or Region1 Public IP"
```

After adding the public IP addresses, you can create a region. You don't need to connect a region to the public IP addresses:

```
[PS] C:\> New-CsTenantNetworkRegion -NetworkRegionID "Region1"
```

Now you can create a site and connect it to a region, a region can have multiple sites:

```
[PS] C:\> New-CsTenantNetworkSite -NetworkSiteID "Site1" -NetworkRegionID "Region1"
```

Before you create the Network Roaming policy, create a subnet for the site. You can assign multiple subnets to a site:

```
[PS] C:\> New-CsTenantNetworkSubnet -SubnetID 192.168.1.0 -MaskBits 24 -NetworkSiteID "Site1"
```

After documenting the network topology, you can create the policy and define if video is available and the maximum amount of bandwidth Teams can use in that location:

```
[PS] C:\> New-CsTeamsNetworkRoamingPolicy -Identity "Site1RoamingPolicy" -AllowIPVideo $false -MediaBitRateKb 2000 -Description "Site1 roaming policy"
```

This creates a roaming policy that prevents video and limits the total bandwidth used within that site to 2000 kbps. The default limit in a Teams Meeting policy is 50000 kbps per user.

To finalize the setup, modify the site you created representing the location and add the new Network Roaming policy:

```
[PS] C:\> Set-CsTenantNetworkSite -Identity "Site1" -NetworkRoamingPolicy "Site1RoamingPolicy"
```

You can validate the site configuration with this command:

```
[PS] C:\> Get-CsTenantNetworkSite
```

Users configured for Teams Phone who visit the location now cannot consume more bandwidth than you have assigned. To include non-telephony users, configure the *AllowNetworkConfigurationSettingsLookup* in your meeting policies. For example, this command updates the global Teams Meeting policy:

```
[PS] C:\> Set-CsTeamsMeetingPolicy -identity Global -AllowNetworkConfigurationSettingsLookup $True
```

You have now created the necessary regions and sites, added the subnets for the location, assigned a roaming policy to the site, and made sure it covers most users. T's.

## Network Topology in the Teams admin center

Network information is in the Teams admin center under **Locations > Network Topology** and **Network & Locations**. You will see a tab for trusted IPs related to your tenant, and you can update the addresses through the admin center. When setting up Call Analytics, we will populate the **Reporting Labels**, which you will also find under **Locations** in the Teams admin center.

## Microsoft 365 Network Connectivity

The Microsoft 365 Network Connectivity report is under Health in the Microsoft 365 admin center. It is an important part of the tenant's Productivity Score discussed in Chapter 4. This tool can validate site performance as part of the planning process and monitor performance as part of the operational process. Network performance for Exchange Online, SharePoint Online and Teams is highlighted by drilling into the Network Connectivity under Technology experiences in the Productivity Score. In the Points breakdown on the right side, you see your Productivity Score rating for Teams performance. The performance is based on the same network metrics (packet loss, jitter, and latency) highlighted by the Call Analytics and Call Quality Dashboard. Administrators use these same metrics to validate if a tenant is ready to deploy Teams, and the Locations tab also shows how your sites are performing.

At first, you may see some locations which do not make sense. The information is a mix of locations where you have offices, and it also includes home offices and places where users connect to Office 365 on the road. Here we can use the information you gathered to add your sites, subnets, and associated public IP addresses. By clicking Add location, you can add details of the name, physical office location, LAN subnets, and the

public IP addresses presented from that location. When you have added your locations, you can filter the view to show only locations you have added and get a more controlled view. It can take up to 72 hours before data is available for a location after creation.

## Microsoft 365 Network Connectivity Tests

As part of planning for Teams calling and meetings, you can manually capture and report network data using the Microsoft 365 Network Connectivity tool. Selecting Network connectivity tests in the top right corner of the Microsoft 365 Network Connectivity page leads you to <https://connectivity.office.com/>. From there, you can run local connectivity tests from your current location. When the test finishes, you can upload the results to the Microsoft 365 Network Connectivity report. You can use the overview to see the network readiness for real-time communications. Over time, this report is a great way to validate Microsoft 365 performance because it uses actual traffic and tells you if you are following the two principles for network connectivity.

When running the tool, you see how you connect to the Microsoft network, the public DNS used, and the connectivity performance for Exchange Online, SharePoint Online, and Teams. It will also perform a traceroute to some Microsoft services to measure the number of hops and show you if you are spending unnecessary time routing traffic over the internet before you hit the Microsoft network. The number of traceroute hops should be between 6-20; anything over 20 could result in increased latency.

You should run connectivity tests in two places: close to your network edge and where users are. By comparing the results, you can see if there are any differences in quality between your network edge and user locations that might indicate bottlenecks in your network. Remember that a single result may not be a good enough measurement to launch a network investigation. By running many tests at different times of the day over a sustained period, you will gather sufficient data to highlight trends within your network. By understanding the trends, you'll know if a more thorough investigation of internal network quality is necessary.

When running the tool, the admin center prompts you to download a file. After downloading, this executable file runs connectivity tests from your computer and sends the results back to the service. You will see that the test almost seems to stop towards the end. This is because the test makes some sample calls that are 17 seconds long to measure audio, video, and desktop sharing performance. The captured metrics then become the basis for measurement. By clicking details, you see data for the performance and see if any of the expected metrics are below expectations. Figure 14-1 shows a capture, and you also see the expected values for the metrics.

### Microsoft Teams

Test	Result
✔ Media connectivity (audio, video, and application sharing)	No errors
✔ Packet loss	0.00% (target < 1% during 15 s)
✔ Latency	23 ms (target < 100 ms)
✔ Jitter	3 ms (target < 30 ms)

Figure 14-1: Microsoft 365 Connectivity test results for Teams

If you are signed into Microsoft 365 when you run the test, the test automatically uploads the data to the Microsoft 365 Network Connectivity report. The data is available under the office location you have already

added, and an administrator can see the results and view trends for that location. The uploaded data should be available on the site within minutes, but delays might occur if the service is busy.

The [Teams Network Assessment Tool](#) is a manual method to gather network insights for a location. This tool can measure Teams performance but does not upload its results to the Microsoft 365 admin center. It is a command-line tool downloadable from the Microsoft Download Center. If you run the tool with no command-line switches, it will test whether the ports and protocols that Teams needs are open outbound from the client. If you run the tool with the `/qualitycheck` switch, it generates sample 17-second calls and measures the key quality metrics for those calls. This tool can run without having any Teams components installed on the machine, so it can be run from servers in datacenters to help map out your network paths. You may recognize that the results are the same metrics that Microsoft 365 Network Connectivity highlights for Teams. Here is an example:

```
PS C:\Program Files (x86)\Microsoft Teams Network Assessment Tool> .\NetworkAssessmentTool.exe
/qualitycheck
Microsoft Teams - Network Assessment Tool

Initializing media flow.

*****
Starting new call

Media flow will start after allocating with relay VIP FQDN: worldaz.tr.teams.microsoft.com
If user wants to allocate with a particular relay VIP IP address, please specify in
NetworkAssessment.exe.config.

Waiting for call to end after 300 seconds, displaying call quality metrics every ~5 seconds.
Change the 'MediaDuration' field in the NetworkAssessmentTool.exe.config file to change the media
flow duration.

TIMESTAMP is in UTC. LOSS RATE is in percentage, out of 100.
LATENCY and JITTER are in milliseconds, and are calculated as averages in ~5-second windows.
PROTOCOL displays whether UDP, TCP (PseudoTLS/FullTLS), or HTTPS protocol was used to allocate with
the relay server.
Note that for PROTOCOL, UDP protocol is attempted first to connect to the relay, by default.
LOCAL ADDRESS is the local client IP and port that media is flowing from.
REMOTE ADDRESS is the peer (relay server) destination IP and port that media is flowing to.
IS PROXIED PATH shows whether a proxy server is used to connect to the relay, only applies to
TCP/HTTPS connections
LAST KNOWN REFLEXIVE IP shows what your latest public (NAT translated) IP and port is that the relay
sees during media flow.

[If LOSS RATE is 100%, the output lines here will be in red]

Quality check source port range: 50000 - 50019

Call Quality Metrics:

2022-06-15 05:46:35          Loss Rate: 0          Latency: 25.63          Jitter: 13
Protocol: UDP
Local IP: 192.168.1.53:50016          Remote IP: 52.114.231.164:3478
Is Proxied Path: False          Last Known Reflexive IP: 212.159.102.162:14846
```

The tool runs for 300 seconds by default and saves the output to `c:\Users\<username>\AppData\Local\Microsoft Teams Network Assessment Tool\<date_timestamp>_quality_check_results.csv`. You can open the results file to calculate your average for that run. Read the Usage.docx file found at the tool install location for information on how to configure longer iterations.

You can also measure the number of hops to the same IP address as shown in the Network Assessment Tool to check that you have an optimal path over the internet to the Microsoft data centers. Using `tracert` in the example below gives us the following result:

```
C:\>tracert 13.107.8.20
```

```
Tracing route to 13.107.8.20 over a maximum of 30 hops
```

```
  1    8 ms    8 ms    8 ms  192.168.10.1
  2   16 ms   14 ms   19 ms  1.51-175-128.customer.lyse.net [51.175.128.1]
  3   21 ms   18 ms   18 ms  111.81-166-123.customer.lyse.net [81.166.123.111]
  4   13 ms   29 ms   18 ms  microsoft.dix.dk [192.38.7.76]
  5   24 ms   29 ms   18 ms  tor3.ber30.msedge.net [104.44.80.170]
  6    *      *      *      Request timed out.
  7   29 ms   18 ms   18 ms  13.107.8.20
```

We entered the Microsoft network at hop 5 and reached our destination after seven hops. You would normally see between seven and twelve hops before reaching the Microsoft network. More than twelve hops are not bad, but if you see more than twenty hops you should work with your ISP to get a more optimal path. More hops can introduce latency and jitter and may be suboptimal in terms of the media path. Depending on what the IP is that you are tracing against you may end up with a string of "Request timed out" messages. This is normal as not all devices inside the MS network will respond to pings.

**Note:** It is possible to use Resource Monitor on your PC to monitor Teams client network traffic. You get an overview of how much bandwidth Teams is using at any given time. You can use the same metrics to upload information to Azure Monitor. This could be useful for organizations that want to validate Teams performance in different locations by for instance using support personnel computers. This [blog post](#) goes into more detail.

## Adding Network Information to the Call Quality Dashboard (CQD)

The CQD portal shows you call quality trends in your environment. The same information you initially gathered about your network is useful with the CQD portal. The portal can be accessed from the Teams admin center. When opening the dashboard for the first time, you may feel that it does not give you much feedback. Only when you upload your subnets to the portal will the dashboard become useful because that is when you can differentiate on-call quality per location. You will also see the difference between outside traffic (typically unmanaged networks) and inside traffic (typically internal networks). When uploading subnets to the portal, you should also specify the IP range for VPN traffic by creating a region for that. The source of an unexpectedly high volume of VPN traffic should be investigated. VPN traffic is not optimal since it is better when the media flows directly from the external client to the conference bridge.

To import subnets to CQD you need to fill out a CSV file and upload it to the portal by navigating to <https://cqd.teams.microsoft.com/spd/#/TenantDataUpload> and using these steps:

1. The CSV file you are must only contain only the actual data, headers are not needed.
2. To upload the file, go to the cogwheel in the CQD portal and choose tenant data upload.
3. Specify your file and upload the data, unless you want a specific start and end date for your new upload, just leave the default options.
4. When imported successfully you will see "Successfully uploaded file."
5. It may take up to 24 hours before the reports reflect the new subnets.

The headers used are in the file are:

```
Network,NetworkName,NetworkRange,BuildingName,OwnershipType,BuildingType,BuildingOfficeType,City,ZipCode,Country,State,Region,InsideCorp,ExpressRoute
```

Here is an example showing how to populate the csv, using some of the information we gathered at the beginning of this chapter:

192.168.1.0,US/Seattle/SEATTLE-SEA-1,24,SEATTLE-SEA-1,Contoso,IT Termination,Engineering,Seattle,98001,US,WA,MSUS,1,0

## Reporting Labels for Call Analytics

In the Teams admin center under Analytics & reports, you will find the Reporting labels used by Call Analytics to make the reports easier to read by adding network names to internal sites. Here you can upload the same csv file that was used with the CQD portal. Call Analytics shows the same metrics information you found when running the Microsoft 365 Connectivity tests. You can use it to investigate individuals to see how their clients performed in calls and meetings, we will cover it more when we discuss troubleshooting.

Now that you understand the importance of documenting your network, make sure that you periodically update the information in Network Planner, Microsoft 365 Connectivity, CQD and Call Analytics to keep it current

## Licensing for Teams Calling

Teams products are available in three (possibly four or even five depending on your choices) licensing types. The core Teams license covers you for all the Teams collaboration workloads and Teams Calls, but there are more license types when you want to do something with the PSTN (this can be referred to as telephony). This could be the Audio Conference license to add PSTN capabilities for meetings or Teams Phone license to let you make and receive PSTN calls. There are also licenses aimed at some specific device use cases.

**Note:** When considering the overall benefits of migrating your telephony workload to Teams it is important to consider more than just the price point. In January 2020 Forrester Consulting conducted a [Total Economic Impact™ \(TEI\)](#) study for Microsoft that helps provide a framework for organizations to evaluate the potential financial impact of Microsoft 365 Cloud Voice.

### Audio Conferencing

The Audio Conferencing license lets users dial-in and dial-out of meetings (subject to the appropriate configuration) using a normal phone. This can be helpful when you do not have suitable internet connectivity to sustain a full Teams call, or it can be a quick and easy way to allow external users to join a meeting. Remember that a dial-in participant can only hear the audio portion of the meeting.

By default, when a user is enabled for Audio Conferencing they have access to a set of Microsoft-provided shared numbers in over 180 Countries. You can also add more numbers to the service if you have particular numbers that you want to bring with you from a legacy platform. It is also possible to use toll-free numbers with the dial-in service, however you need a license called Communication Credits where the cost of the incoming call costs can be taken.

The Audio Conferencing license is standard in the Office 365 E5 plan but needs to be added for users with an Office 365 E3. Alternatively, a pay-per-minute version is available for companies with a volume licensing agreement.

### Teams Phone

Teams Phone is the basic license required for an account to have a PSTN number. This license covers the ability to make and receive calls via your Teams account. You still need to provide the means of actually placing calls which could be through one of several different delivery methods which we will talk about soon.

The Teams Phone license is included as standard in Office 365 E5 but must be added to Office 365 E3 accounts.

## Calling Plans

Once you have a Teams Phone license you still need to provide numbers and dial-tone. Calling Plans is a way to use Microsoft as your carrier and have them provide numbers for you. The numbers come from a pool owned by Microsoft and this service does not integrate with existing telecommunications services but you can port numbers to and from Microsoft in supported regions.

Calling plans are subject to geographical restrictions where Microsoft has been licensed to provide telephony services which currently includes thirty-one countries. You can view a full list of the telephony services available [here](#).

As well as letting you take a number from Microsoft, a Calling Plan acts as a pool of credit that can be spent on calls. Several different types of Calling Plans are available to provide some flexibility depending on your calling requirements. Typically, plans include per-user domestic calling minutes (3,000 in the US and 1,200 in EU countries) and 600 tenant-wide international calling minutes.

The minutes in plans combine across all users with the same type of Calling Plan and in the same geography. For example, if you have two Calling Plans subscriptions for US users, you would have 6,000 domestic calling minutes each month and this would stay the same even if you added more Calling Plan users in say the UK. Unused calling minutes do not carry over to the next month.

Calling Plans have two categories of licenses:

- **Domestic Calling Plan** allows calls to the country/region where users are assigned. These are also available in either small, medium, or large variations.
- **Domestic and International Calling Plan** allows calls to a users home country/region and to international numbers in 196 countries/regions.

When you buy a Calling Plans license, you can order user numbers for that country. User Numbers are numbers you assign directly to user accounts and for use by individuals. To order User Numbers, you must have at least one Calling Plan subscription assigned to your tenant.

When you assign a Calling Plans license to a user account, the following happens:

- The user's Voice policy is set to *BusinessVoice*.
- You can assign a user number to the account using either PowerShell or Teams admin center.
- After assigning a Calling Plans license, it may take up to 48 hours until the dial-pad appears in the calling tab in the user's Teams client. Also, the user may need to sign out and back in to clear Teams client cache.
- The ability to assign a Calling Plan license to a user requires that the *UsageLocation* attribute is set to a country where Calling Plans are available.

**Note:** Calling plans are not your only option when adding numbers and dial-tone to your Teams service. You still need to have a Teams Phone license but you can bring your own numbers through Direct Routing (more on that later), or you use a partner/provider using either their hosted Direct Routing platform or something called Operator connect.

## Communications Credits

Communications Credits are used as a "pot" of money that is then used to pay for telephony-related functionality that isn't covered elsewhere. Funds added apply across the tenant, but only the users assigned the license can access it if needed. The Communication Credits are used to:

- Add toll-free numbers to Audio Conferencing meetings, auto attendants, and call queues. Toll-free calls are billed per minute.
- Cover costs for dial-out in a meeting when not covered by another license type.

- Dial-out from a Teams meeting to your mobile.
- Pay for any call-back features not covered by another license type.
- Cover international calls when a user is assigned a Domestic Calling Plans license.
- Covering telephony calls for a user where their pot of Calling Plan minutes has been used.

Communications Credits are available in the same countries where Audio Conferencing is available. You can buy and assign the license once you have either an Audio Conferencing license or a Phone System license in your tenant. The amount of funds you want to allocate varies greatly depending on expected usage so you should keep a close eye on it for the first few months. The funding can be auto-recharged to avoid any service disruption.

**Note:** Funds are used for Communications Credits at Microsoft published rates only when the services are used. Any funds not used within 12 months of the purchase date expire and are lost. You can monitor Communication Credits under **Billing > Your products** in the Microsoft 365 admin center.

It can take a bit of time to set up Communications Credits so you may want to add a small amount to the tenant so that you have it available at short notice if required.

## Number types

Numbers in Teams are split into two main categories depending on their intended use:

- **User Numbers** are allocated to users for use with Teams Phone and are used to route calls in and out. User Numbers only apply if you are consuming Teams Phone via Calling Plans or Operator Connect.
- **Service Numbers** are used in several different places, such as dial-in conferencing numbers or for VoiceApps (telephony-enabled workflows) with Attendants and call Queues.

**Note:** All number management in Teams is done using E.164 format where numbers start with a + symbol, followed by a country code. Teams converts user-entered numbers from their local country format into E.164 for you (you can modify this to some degree as we will cover later).

## User Numbers

To be able to order user numbers (from Microsoft) you must first buy and assign Calling Plans to all users you want numbers for. The amount of user numbers you can order is calculated as follows:

$\langle \text{Number of Calling Plan Licenses} \rangle \times 1.1 + 10$

In other words, if you have 50 Calling Plan licenses, you can order 65 numbers. Because they come from a pool of available numbers it is improbable that you will get consecutive numbers. However, these days when most calling is done via contact cards having consecutive number ranges is less important. If you do need specific ranges of numbers for your tenant, you can raise a ticket to Microsoft, and they will see what can be done.

Ordering user numbers from Microsoft is done through the Voice section of the Teams admin portal, where you specify the type (user) and quantity of numbers you need. If you have not added a location for your users, you must provide a location during the ordering process. The location describes where you are in case of an emergency and defines the area code you get for your numbers.

After finding a suitable block of numbers, you have 10 minutes to claim the numbers before the system releases them back to the available pool. After claiming the numbers, you can assign numbers to users through the Teams admin center (**Voice** and then **Phone numbers**) or using the `Set-CsPhoneNumberAssignment` cmdlet. For example:

```
[PS] C:\> Set-CsPhoneNumberAssignment -Identity Ben.Lee@office365itpros.com -PhoneNumber +44191375xxx -PhoneNumberType CallingPlan
```

**Note:** If you need to port existing numbers, you can read about the process [here](#).

## Service Numbers

Service Numbers are numbers available in a limited supply per tenant when necessary to handle a large call volume. As with user numbers, you can either take them from the Microsoft pool or port them from your existing provider (see note in previous section).

There are two types of Service Number: toll numbers and toll-free numbers. The most common type of service number is a toll number. All that you need to order toll numbers is a Phone System license in your tenant. Toll-free numbers can only be ordered if Communications Credits are configured (see above).

When assigning toll-free numbers to an auto attendant, the call is free for the customer dialing into the service and the company pays that cost as a charge against the Communications Credits prepaid amount. When using toll numbers, the user dialing into the service pays the regular fee. Service numbers are available in ~80 countries today, and the markets will grow over time.

To get new service numbers, go to the Teams admin center, navigate to **Voice, Phone numbers**, and click **Add**. From there you define the country, type, and region to find suitable numbers. The amount of service numbers a tenant can get is also based on the number of Phone System and Audio Conferencing. A sample of the table is shown here, for the complete list [see here](#):

- If there are 1-25 licenses, 5 service numbers can be requested.
- If there are 100-149 licenses, 30 service numbers can be requested.
- If there are 500-749 licenses, 90 service numbers can be requested.
- If there are 1000-1,249 licenses, 125 service numbers can be requested.
- If there are 7,000-9,999 licenses, 500 service numbers can be requested.
- If there are 50,000+ license, 1500 service numbers can be requested.

## Teams Administrator Roles

In larger organizations, you may have different people looking after communication platforms such as telephony and video conferencing and collaboration platforms such as SharePoint, Yammer, and the intranet. Office 365 supports a set of RBAC roles to allow people to have the necessary permissions to manage different services, including Teams.

Because the Teams Calling workloads are pretty specialized in their own right, Microsoft provides the following Admin roles specifically for managing them:

- **Teams Service Administrator:** can manage everything Teams-related without needing Global Admin rights, including all Teams Calling configuration.
- **Teams Communications Administrator:** can manage calling and meeting features within Teams.
- **Teams Communications Support Engineer:** can troubleshoot communications issues with access to advanced tools.
- **Teams Communications Support Specialist:** can troubleshoot communications issues within Teams by using basic tools, is not allowed to see user identifying information such as SIP addresses or phone numbers.
- **Teams Device Administrator:** can manage Teams certified devices from the Teams admin center.

The RBAC role best suited for working with calling and meetings is the Teams Communications Administrator. With this role you will be able to configure everything related to voice, even create resource accounts, and you will get full access to Call Analytics and CQD.

If you have AV partner deploying shared devices for you, they will usually only need the Teams Devices Administrator role which grants them the ability to manage the devices in the tenant. They do not have access to Call Analytics or CQD, but If that is a requirement, you can combine the role with the Teams Communications Support Engineer. Read more about Teams Administrator roles [here](#). You can also use Administrative units in Azure to define the scope of which devices they can manage, see [here](#) for more details.

## Teams Meeting Enhancements

Chapters 12 and 13 cover Teams meeting configuration and policies. Here we consider some improvements we can make to the calling capabilities discussed in the previous section.

In recent years, working from home for many became the new normal, and conducting meetings through Teams became common. As offices embrace hybrid work models, there is a new expectation that people can be first-class participants in a meeting no matter how they choose to join.

There have also been steps towards better interoperability between the key players in the UC space to allow some elements of cross-platform interoperability. The goal should be a universal invitation that works if you want to call in with a conference phone while driving home from work or even a video system from a vendor such as Cisco or Zoom. We should remove any technology barriers to joining meetings and make them as universal as possible.

How do we do that? First, we ensure users have a Teams Audio Conferencing license that enables dial-in scenarios from any phone. We can also add a Cloud Video Interop integration that supports joining from legacy conferencing systems.

Figure 14-2, shows a meeting invite broken down to show what is being provided by which license and also where you can customize it with your own information.

### Microsoft Teams meeting

Join on your computer or mobile app  
[Click here to join the meeting](#)

Or call in (audio) [Click or tap to follow link.](#)

+47 21 40 22 21,,362187906# Norway, Oslo

Phone Conference ID: 362 187 906#

[Find a local number](#) | [Reset PIN](#)

<Add your logo or a descriptive picture here>

If you are using Skype for Business, you can join the meeting by calling [teams@contoso.com](mailto:teams@contoso.com) and use the VTC Conference ID

[Learn More](#) | [Meeting options](#)

Teams meetings can be joined from the clients on PC, Mac, Mobile and as guest users via Edge or Chrome

Cloud Video Interop, which is part the of the Phone System license and via the three providers enables users to join from any system into the teams meeting. This is the service that helps your Teams invite transcend all technology barriers

The Audio Conferencing license enabled dial-in number in the meeting. You can find a local number from more than 70 countries, gives the ability to join the meeting on the go, notice that conference ID is part of the dial in link!

Add a custom text, disclaimer and logo to the meeting, here we describe that you can call in to the meeting using Skype for Business client via the interoperability service

Figure 14-2: The anatomy of a Teams meeting invite

To change the custom text and disclaimer shown in Figure 14-2, go to Meetings in the Teams admin center and open Meeting Settings. You can add a logo or an explanatory picture, a link to a support site, and maybe a disclaimer that meetings can be recorded.

## Audio Conferencing for Teams Meetings

Assigning an Audio Conferencing license lets users create Teams meetings with a dial-in telephone number, but why might you want to do this Teams supports many different clients and devices? The main reason is that the telephony network is one of the few services that is (mostly) global and doesn't need an internet connection.

The dial-in option increases the usability of Teams meetings. It is a popular feature in organizations that use conference rooms where attendees want to use existing phones in the room to join meetings. Audio Conferencing also allows external users to dial into meetings from a mobile phone, which can be beneficial for joining from locations with poor internet coverage.

## Licensing Audio Conferencing

The Audio Conferencing license operates independently of Teams Phone, it does not require the user to have a Teams Phone license and covers any meeting they create.

You assign Audio Conferencing licenses to user accounts via the Microsoft 365 admin center or as part of your license lifecycle management via PowerShell or Azure AD Group-Based Licensing (see Chapter 5). Teams automatically assign users a primary Audio Conferencing number based on their configured location (as specified in the Microsoft 365 admin center). You can change the assigned Audio Conferencing number by editing the user in the Teams admin center.

It is recommended that you enable Audio Conferencing for all users so that all their generated meetings include dial-in details. If you do not have a suite such as Office 365 E5 where this license is already included, this could be an expensive outlay however, there are two ways to purchase it:

- Audio Conferencing service plan add-on to Office 365 E3 (included in Office 365 E5).
- A pay-per-minute license acquired through a volume license agreement.

The difference between the two is that the regular add-on has a cost per user, as well as enabling dial-in, it also includes 60 dial-out minutes per licensed user per month pooled on a tenant level to [zone A countries](#). When considering this option you should focus on the expected volume of minutes dialing into meetings as this is the main use case for Audio Conferencing.

The pay-per-minute license type is a free license you can assign to all users, but then you need to use Communication Credits to pay for both dial-in and dial-out capabilities. Therefore, you should calculate how many dial-in minutes you might expect to use to help determine which license type is a good fit. Most volume licensing customers find the pay-per-minute model works out best, sometimes with a 90% cost reduction if covering all users. To help calculate costs for Audio Conferencing minutes, you can find a form near the bottom of this [link](#) that lets you view the rates used.

After deploying Audio Conferencing, you can monitor how many minutes are available and the current usage from inside the Teams admin center. The report can be found under: **Analytics & Reports > Usage reports**, and run the **PSTN minute & SMS (preview) pools** report.

## Configuring Audio Conferencing

If you do go ahead and deploy Audio Conferencing, there are some things to consider about how it operates.

Firstly, the default setting is that all participants in the meeting hear a tone when someone joins a meeting using the Audio Conferencing bridge. Some companies consider this a must-have requirement so that no one can join a meeting without everyone being aware. You can even force dial-in users to record their name that is played into the meeting. However, suppose you plan to have large meetings with many dial-in participants. In that case, these announcements can soon distract from the audio in the meeting itself with a constant stream of join/disconnect notices, so configure accordingly.

The setting is in the Teams admin center under **Meetings, Conference Bridges, and Bridge Settings**.

Secondly, when you assign the Audio Conferencing license as part of an onboarding process Teams sends a “welcome” email to the configured user. This email gives the user some information about what Audio Conferencing is and their PIN (used to authenticate them if they were to dial-in to a meeting). However, this is not a commonly used scenario so it can cause more confusion than benefit.

If you want to disable the notification email, this can be done before configuring users with the `Set-CsOnlineDialInConferencingTenantSettings` cmdlet in the Teams PowerShell module:

```
[PS] C:\> Set-CsOnlineDialInConferencingTenantSettings -AutomaticallySendEmailsToUsers $false
```

Thirdly, if you have Direct Routing deployed you could use On-network Conferencing for Audio Conferencing that allows PBX users to dial-in to the meeting via the Direct Routing. This is designed to allow users who have not been migrated to Teams to dial-in to Teams meetings from their legacy PBX phone without incurring any billable calls. It is not intended to let you bring your own conferencing numbers to the Teams platform. You can read up further about On-network Conferencing [here](#).

And finally, you can control how the phone numbers of external participants are displayed in the Teams meeting. By default, internal users can see the full phone numbers of those who join Teams meetings via audio conferencing. For external users Teams applies a mask so that the numbers show up like +35\*\*\*\*\*85.

The `MaskPstnNumbersType` setting managed with the `Set-CsOnlineDialInConferencingTenantSettings` cmdlet controls how Teams deals with participant numbers. The setting can be:

- **MaskedForExternalUsers:** This is the default value and means that external users see masked numbers.
- **MaskedForAllUsers:** Teams masks the number for any user joining a meeting with audio conferencing.
- **NoMasking:** Teams doesn't apply masking to participant numbers.

As an example, here's how to enable masking for participant numbers:

```
[PS] C:\> Set-CsOnlineDialInConferencingTenantSettings -MaskPstnNumbersType "MaskedForAllUsers"
```

The cmdlet is only available to tenants with the Audio Conferencing license.

## Teams Meetings and Cloud Video Interoperability (CVI)

To complete our mission of building a universal meeting, the last barrier to overcome is the ability to join a Teams meeting from VTC (Video Teleconferencing) endpoints (sometimes referred to as legacy video conferencing devices). Even though Microsoft Teams Rooms and Surface Hubs offer a great meeting room experience, it may still be too expensive for an organization to replace fully functional VTC's in meeting rooms with Certified for Teams devices. CVI helps by allowing any legacy VTC device to connect to a Teams meeting. VTCs must always join the meeting with the details provided in the CVI enabled meeting invite, a Teams client cannot dial out to them through the CVI service.

Four CVI providers are available today and are all pre-configured by Microsoft, so you just need to select which ones you want to purchase and then enable it. You can access details of the providers via PowerShell:

```
[PS] C:\> Get-CsTeamsVideoInteropServicePolicy | Format-Table Identity, ProviderName
```

Each provider has its flavor to CVI:

- **Poly** is the only provider where the licenses integrate into the Microsoft 365 admin portal. It is a shared service and all VTCs join either via the lobby or directly into a meeting as Internal and external endpoints cannot be differentiated.
- **BlueJeans** is also a shared service but licenses are bought directly from BlueJeans.
- **Pexip** is the most flexible of the solutions. You can choose to host the service yourself, use dedicated hosting from a suitable service provider, or access a shared service delivered by a service provider. Licenses are purchased through a Pexip partner. Pexip is the only solution that can differentiate

between your own internal VTCs and external ones, allowing yours to join directly while making external VTCs enter the meeting via the lobby.

- **Cisco** is the latest addition to the CVI platform, and their offering is run as part of their Webex cloud.

The quickest to configure is Poly, as the management of their licenses happens in the Microsoft 365 admin center, which suits those wanting a simple solution to enable CVI. You need one license per user who needs to include the CVI data in their meeting invitations.

Pexip differentiate themselves with the ability to choose a flexible deployment method which suits the enterprise market where there is a higher demand for integration with existing video infrastructure, customization, and control over media traffic. Additionally, with Pexip you pay for the capacity you need based on concurrency rather than per enabled user, so you can assign the capability to all users without extra licensing costs.

After choosing your preferred provider, you must run the *New-CsVideoInteropServiceProvider* command to configure the provider and its settings. You can set the provider up with false info in advance just to see how it looks in your tenant. You can create the provider and grant the policy tenant wide or on a per-user basis:

```
[PS] C:\> New-CsVideoInteropServiceProvider -Name CVI -TenantKey "teams@yourdomain.com"
```

You can then grant the policy at a tenant wide level or per user. For example:

```
[PS] C:\> Grant-CsTeamsVideoInteropServicePolicy -PolicyName PexipServiceProviderEnabled -Global
[PS] C:\> Grant-CsTeamsVideoInteropServicePolicy -PolicyName PexipServiceProviderEnabled -Identity ben.lee@office365itpros.com
```

Granting the policy formats your meeting with info from the correct predefined provider.

**Note:** To integrate with a CVI partner, you need to give the partner access to meetings in your tenant. This may pose some security concerns. Pexip has a good writeup of what the consent gives access to [here](#).

## Content Delivery Networks for Live Events

Live events are a special meeting type designed to cover a broadcast-style scenario where a few presenters send content to many watching users. From a Teams point of view the same principles of networking optimization apply, however we also have the option to integrate third-party Enterprise Content Delivery Network (eCDN) solutions to minimize the streaming footprint on your internet connection.

eCDNs work as local caching repositories so that the required media is streamed once from the internet to a local destination. Clients nearby access that copy instead of downloading their own version. For Teams where all traffic is encrypted deploying your own eCDN solutions would not be possible. This is why Microsoft has partnered with some vendors to bring an integrated solution to the Teams service (similar to how we just discussed using third-party CVI solutions for meeting interop). Using eCDNs can help reduce your internet bandwidth by as much as 98% when viewing Live Events.

Hive Streaming and Kollektive are examples of eCDNs that are already integrated with the live event service. You still need to install and configure the third-party software on each client to set up a peer-to-peer streaming network inside your organization per the vendors instructions, but once installed you can configure the selected solution for your tenant. This configuration enables an eCDN provider and redirects media streams to use their service.

In the following PowerShell command, we enable Hive Streaming for the tenant by amending the broadcast configuration.

```
[PS] C:\> Set-CsTeamsMeetingBroadcastConfiguration -AllowSdnProviderForBroadcastMeeting $True -SdnProviderName hive -SdnLicenseId {license ID GUID provided by Hive} -SdnApiTemplateUrl "{API template URL provided by Hive}"
```

If you run large Teams meetings with more than 1000 attendees, then eCDN is used for all users in the overflow experience for user number 1001 and up joining the meeting. Here's where [to read more about eCDN](#).

# Teams Phone

Teams Phone is used for making and receiving calls over the telephony or PSTN network from inside Teams. Teams Phone is a very mature solution with many organizations worldwide relying on it as their only phone system. Many have undergone projects to remove costly legacy phone system solutions that require lots of support and upkeep.

## Teams Phone delivery methods

To make and receive PSTN calls in Teams, besides having a Phone System license, you need to have some way of bringing dial-tone to your Teams environment. There are three broad categories of how you can manage this:

- **Calling Plans** with numbers from Microsoft if they are available in your region. Call charges and numbers are provided by Microsoft
- **Operator Connect** lets certified voice carriers/partners bring their telephony services directly to your tenant. Call charges and numbers provided by the carrier
- **Direct Routing** provides a BYO approach where you (or a partner) provide SBCs and PSTN connectivity. Call charges and numbers provided by you or the chosen hosted DR provider

Calling Plans were covered in detail in the previous section as little other configuration is needed.

### Operator Connect

Operator Connect bridges the gap between the management simplicity of Calling Plans (where no tenant configuration is required) and the freedom of Direct Routing (selecting your providers, negotiating minutes outside of what Microsoft can provide). It is a certification program where voice carriers or Partners (operators) must meet minimum requirements for connectivity into Microsoft 365 and maintain certain levels of calling quality. Once a partner has been certified, they are available for selection via the Teams admin center.

Operator Connect settings are shown under **Voice** and **Operator Connect**. Here you can send a request to one of the operators offering services in your required countries. A notification goes to the operator, who will contact you for further steps to enable their service. Microsoft is not involved in the billing aspects of Operator Connect services. The certification program only covers the technical aspects of the carrier to Teams integration, all billing for PSTN services is handled directly between you and the provider.

The advantage of using Operator Connect is that the operators have large-scale direct SIP trunks connected to the Microsoft backend with end-to-end QoS. As an administrator, you must assign users the Phone System license and a number. No additional configuration is necessary, much like Calling Plans. Operator Connect is a great way to add local connectivity to the Teams offering, with next to no configuration, and might allow you to reuse existing telco agreements.

As part of Operator Connect, you can also get Operator Conferencing, letting the operator provide local dial-in conferencing numbers. It may be beneficial if you expect large numbers of employees to dial into meetings, and you want to cover that traffic with your existing telco agreement.

The testing process behind Operator Connect is very rigorous and lengthy. To help rapidly onboard more carriers, Microsoft introduced a program called the Operator Connect Accelerator (OCA). OCA allows smaller partners to bring their PSTN offerings to Teams through several pre-certified providers. This shows that

Microsoft has the ambition to quickly onboard a broad set of operators. As a result, you may find your favorite operator on the list soon if they are not already there.

**Operator Connect Mobile:** Microsoft announced Operator Connect Mobile in March 2022. This enables the assignment of mobile numbers to Teams users. Inbound calls ring on Teams or a mobile device as a cellular call. Operator Connect Mobile requires a special eSIM solution from carriers supporting the program in your mobile device. The intended use case is to help Frontline Workers stay connected with a single number. OCM is not a simple call forking scenario but deeper integration where the same number is accessed across a user's mobile phone and their Teams client. Read more about Operator Connect Mobile [here](#).

## Direct Routing Architectures

Direct Routing is the fully flexible way to bring existing PSTN connections into Teams. Teams does not care what the actual PSTN connections are, they could be legacy Integrated Services Digital Network (ISDN), analog connections or SIP trunks to either another PBX or your carrier. What Teams does care about is that you have:

- Have a [compatible SBC](#).
- Provide internet access to the SBC.
- Have an internet resolvable DNS name for the SBC.
- Provide a public certificate for the SBC.
- Configure your firewall to allow Teams traffic to the SBC.

This SBC can be hosted in many different ways, and you may not even need your own SBC but can simply pay to use a service provider/partner's hosted SBC with whatever PSTN connectivity they provide.

Three main scenarios exist for deploying Direct Routing:

- Installed in your data center.
- Installed in Azure.
- Hosted by a Service Provider.

**Note:** Some SBCs are also certified for connecting analog devices and make them reachable from Teams read more about it in the [Microsoft documentation](#). Read more about it in the [Microsoft documentation](#).

### Installed in Your Datacenter or Offices

You may install your own SBCs in a datacenter or local office depending on what needs to connect into the SBC. This option is for companies that need to manage and maintain their own SBCs and have full control of call paths. This could be for a number of reasons such as; providing coverage in countries where neither carriers nor Microsoft can deliver Teams numbers (commonly countries such as Russia, China or Brazil); or wanting media to stay on their network as much as possible.

### Installed in Azure

You could install virtual SBCs in Azure to still have full control over them and include them as part of your managed infrastructure but do not have to maintain any hardware. If you have a strategy of removing on-premises equipment and are reducing your datacenter infrastructure this is a good choice. The leading SBC vendors (Ribbon and AudioCodes) have software-only versions of their SBCs and AudioCodes have a [whitepaper on how to set up their virtual SBC in Azure](#).

The requirements from Microsoft's side are still the same regardless of where the SBC is running and if it is a physical or virtual device.

**Note:** When you have set up your Direct Routing solution and want to validate and test it, you can use the SIP Tester client script found [here](#). This tool requires that you authenticate with licensed users who have numbers assigned. The script does not support modern authentication, so the account must bypass any conditional access policies if implemented.

### Hosted by a Service Provider

Since the integration with Teams using Direct Routing is just a SIP trunk connection, service providers can easily connect to multiple tenants from a centralized SBC deployment. Microsoft supports a specific variation of Direct Routing designed for just such a scenario. The service provider simply registers a subdomain per customer from their infrastructure and uses this to connect to the customer tenant.

You might wonder how this can operate when the domain used by the SBC is different from the tenant domain? Remember that from Teams point of view the Direct Routing connection is just a SIP trunk; all it needs to see is an FQDN registered in Microsoft 365 for connectivity. You can read up further on supported multi-tenant Direct Routing scenarios [here](#).

Consuming Teams Phone from a service provider is a good choice for organizations that do not want to manage any SBCs with their upstream connections and do not need to keep close control of the calling traffic.

### [When to Use Calling Plans, Operator Connect or Direct Routing](#)

From an end-user perspective, all of these delivery methods look the same. The differences are in what is happening behind the scenes to make calls work. The good news is that you can mix and match at will, depending on your requirements. For example, Calling Plans can be a quick and easy way to test out Teams Phone, but for a wider deployment, you might find Operator Connect a better deal, or you may want the flexibility to manage your own SBCs and migrate your current numbers and contracts.

**Note:** Emergency calling is available for Calling Plans, Operator Connect and Direct Routing. For example, you can configure policy settings to automatically notify your organization's security desk and have them included in the call, you can also define an in-client notification message that your users must acknowledge. Read more on emergency calling configuration [here](#).

## Direct Routing Configurations

When dialing from a Teams client, the following are all configuration elements used to determine where Teams will send the call:

- **Online PSTN Gateway:** contains the DNS name for an SBC, and any configuration to be used when sending calls to it, such as forward P-Asserted-Identity (PAI) or Preferred Codecs.
- **Voice Routes:** matches the pattern of the number dialed against Online PSTN Gateway entries.
- **PSTN Usages:** hold one or more Voice Routes. They can be shared across different Voice Routing Policies
- **Voice Routing Policy:** contain one or more PSTN Usages. These are assigned against users.

The configuration can be found in Teams admin center under **Voice** and is split between the **Voice Routing Policy** and **Direct Routing** sections.

This call routing can be confusing to set up initially and can become very complex when you have multiple SBC gateways and routes. This [docs article](#) provides a good reference for how to handle failover and other scenarios.

**Note:** You can find an in-depth overview of how routing works in Teams in [this Microsoft diagram](#).

By default, the traffic path taken by media is from your Teams client, to the Media Processes (in the Teams service) and then to the SBC before being placed onto the downstream PSTN connection. However, this may

not be ideal in scenarios where the user is already inside the firewall with the SBC, or if we want to reduce the volume of internet traffic generated.

With Direct Routing, three techniques can help with optimizing the media paths:

- Media Bypass for Direct Routing.
- Local Media Optimization for Direct Routing.
- Survivable Branch Appliance (SBA) for Direct Routing.

These scenarios do not apply to Operator Connect and are unlikely to be helpful when using Direct Routing hosted in Azure or Direct Routing hosted by a service provider as the SBCs are outside your core company networks.

### Media Bypass for Direct Routing

Media Bypass shortens the path of media traffic and reduces the number of hops in transit for better performance. This is a great option if you host an SBC in your data center or in Azure using Express Route. With media bypass, media is kept between the Session Border Controller (SBC) and the client instead of sending it via the Microsoft Phone System relay service. By enabling Media bypass, media traffic can negotiate to travel between the Teams clients and the external public leg of the SBC.

You must ensure that the SBC and firewall are configured to allow the correct ports through (even if it is just from inside your network). Internal clients also need to resolve the public leg of the SBC and send media traffic to that IP address on the port range of 50 000 – 59 999. On some firewalls, this can cause hairpinning issues where internal traffic goes to an IP on the outside edge of the firewall. It is only the media that goes to the SBC, signaling still goes through the Teams services.

When Media Bypass is enabled, you can restrict access to the SBC from non-Microsoft [IP ranges](#), forcing internet clients to still relay via the Teams services and reducing your external attack surface area.

To support Media Bypass the SBC must have ICE light negotiation configured, the SBC vendors have instructions specific to their devices with how to configure this. You then must enable it in Teams against the SBC object, with the following PowerShell cmdlet:

```
[PS] C:\> Set-CSOnlinePSTNGateway -Identity "SBCSite1.office365itpros.com" -MediaBypass $true
```

### Local Media Optimization for Direct Routing

Local Media Optimization is very similar to Media Bypass but takes things a step further by allowing the internal clients to send media directly to an internal IP address on the SBC (rather than relaying to the external interface). The advantage is that you can avoid firewall hair pinning and apply end-to-end QoS on the media traffic when making and receiving PSTN calls. It can also be used to have multiple internal SBCs (for example at branch sites) that can be accessible to Teams via one master SBC (in the datacenter) so that you do not have to publish multiple gateways to the internet.

Earlier, we talked about Teams Network Roaming policy and defined Public External IP addresses, regions, sites, and subnets. Local Media Optimization uses the same configuration data, and the clients needs to be identified as one of the defined local networks. If, for example, the public IP range does not match, then the client is deemed external and Local Media Optimization is not used. When using Local Media Optimization, you have two configuration choices:

- **Always** will send media to the internal leg of SBC regardless of where the user is located if they are classified as inside. This would require the SBC internal leg to be available from all internal networks.
- **Only for local users** means that the user subnet needs to match one of the subnets added to the *GatewaySiteID*. This applies if you have Direct Routing deployments with multiple SBCs in different countries. If that is the case, you also need to create a region, a site and assign the internal subnets for the site where the SBC should be accessed. You can re-use the configuration described for *Teams*

*Network Roaming Policy*, the *GatewaySiteID* is the same as the *SiteID* we created as part of that process.

To enable Local Media Optimization, connect to the Teams PowerShell module and use the following cmdlet:

```
[PS] C:\> Set-CSOnlinePSTNGateway -Identity "SBCSite1.office365itpros.com" -GatewaySiteID "Site1" -MediaBypass $true -BypassMode "OnlyForLocalUsers" -ProxySBC $Null
```

In the above cmdlet you also see that the *ProxySBC* attribute is set to *\$Null* as this setting is required. This attribute is used when you have a branch site SBC without internet connectivity. The branch SBC routes its calls to a centralized SBC and then to Teams, using the central SBC as a proxy. You can still use Local Media Optimization in this scenario, but clients need to be able to send media traffic to the internal leg of the branch SBC. To enable the *ProxySBC* functionality, the SBC is registered in Teams and a relay SBC configured. Here is an example PowerShell command to run to create a branch SBC using our existing SBC as the proxy.

```
[PS] C:\> New-CSOnlinePSTNGateway -Identity "SBCBranchSite2.office365itpros.com" -GatewaySiteID "BranchSite2" -MediaBypass $true -BypassMode "OnlyForLocalUsers" -ProxySBC "SBCSite1.office365itpros.com"
```

To complete the configuration, you would need to have a site called Branchsite2 with the correct local network subnets defined. Read more about configuring Local Media Optimization for Direct Routing [here](#).

### Survivable Branch Appliance for Direct Routing

Teams Phone relies heavily on an internet connection to make calls so you are stuck if a site's internet link goes down. Survivable Branch Appliances (SBA) are designed to help solve this issue.

An SBA is an SBC running a Windows Server based appliance which enables limited call routing to be maintained even if there is an internet outage. More precisely, it handles signaling for setting up the call, and directs the Teams client to route media to the local SBC. For this to work, Local Media Optimization needs to be set up and validated before the SBA is configured for that branch site. Setting up and configuring the SBA is well documented by the SBC vendors and usually requires an extra license from the SBC vendor.

The configuration in Teams is simple, and clients need to have signed in once for the configuration to be picked up before the internet link is unavailable. Run the *New-CsTeamsSurvivableBranchAppliance* cmdlet to create the SBA in Teams.

```
[PS] C:\> New-CsTeamsSurvivableBranchAppliance -FQDN "SBABranchSite2.office365itpros.com" -Description "SBA Branch Site 2"
```

After creating the SBA, you need to create an SBA policy and assign it to users using the *Grant-CsTeamsSurvivableBranchAppliancePolicy* cmdlet or you can use the *New-CsBatchPolicyAssignmentOperation* cmdlet for multiple users.

```
[PS] C:\> New-CsTeamsSurvivableBranchAppliancePolicy -Identity "Branch Site 2" -BranchApplianceFqdns "SBABranchSite2.office365itpros.com"
[PS] C:\> Grant-CsTeamsSurvivableBranchAppliancePolicy -PolicyName "Branch Site 2" -Identity "ben.lee@office365itpros.com"
```

Read more about configuring Survivable Branch Appliance [here](#).

**Note:** An SBA seems like a great solution to maintaining calling during an internet outage. In reality, most customers choose to improve resiliency in their internet connections (such as providing backup lines). This saves spending on hardware appliances that need to be maintained, and improving WAN connectivity helps sustain other services, such as access to documents and email.

## Calling Configuration

After you have decided on how to consume telephony in Teams with Calling Plans, Operator Connect or Direct Routing, it is time to assign the Phone System license to users to enable calling capabilities. One account setting that is easy to overlook is the *UsageLocation* attribute. The location is assigned at account creation and influences the services available to accounts, especially phone services.

When Teams makes a call the number format needs to be in the [E.164 format](#), a universal format that includes '+', country code, and subscriber number. Before the call is routed the number is normalized into the E.164 format by dial plans. All users with a Phone System license are assigned a dial plan by default. This is a basic dial plan provided by Microsoft that covers simple country based number conversions.

The *UsageLocation* attribute of a Microsoft 365 account controls the default dial plan and Audio Conferencing number. For Phone System, it defines how users normalize numbers and if they configured with a location where Calling Plans are not available you cannot assign that license. To check *UsageLocation* and the location based *DialPlan* assigned, use the *Get-CsOnlineUser* cmdlet:

```
[PS] C:\> Get-CsOnlineUser ben.lee@office365itpros.com | Select-Object DisplayName, UsageLocation, DialPlan, TenantDialPlan
```

To change the *UsageLocation*, use the *Update-MgUser* cmdlet:

```
[PS] C:\> Update-MgUser -ObjectId ben.lee@office365itpros.com -UsageLocation US
```

**Note:** Typically, adding the country code and a plus is not enough for localized country specific normalization of local or special numbers. <https://UCDialplans.com> has a comprehensive set of scripts to implement proper normalization rules. The site generates the necessary code to create *TenantDialPlans* that you can assign on a user level for the correct normalization of numbers. *TenantDialPlans* works together with the default dial plan. When dialing out, the normalization process looks at *TenantDialPlans* first and then at the default *DialPlan*.

## Calling Policies

Calling Policies control the calling features available to users, these do not apply to Meetings. A default global calling policy is available within a tenant found under **Voice** then **Calling policies** in the Teams admin center, but admins can also create and assign custom calling policies. The settings controlled in a policy are:

- **Make private calls:** Acts as a control switch for all calling functionality in Teams.
- **Cloud recording:** Allows calls to be recorded
- **Transcription:** Allows calls to be automatically transcribed by Azure voice services
- **Call forwarding and simultaneous ringing settings:** Controls if incoming calls can be passed on to either other internal users, or external PSTN numbers.
- **Voicemail is available for routing inbound calls:** If inbound calls can be sent to voicemail. It can be either enabled, disabled or left to the end-user to decide
- **Inbound calls can be routed to call groups:** Controls if call groups can be configured to receive incoming calls
- **Prevent toll bypass and send calls through the PSTN:** Helps meet any legal requirements if international calling cannot pass over an IP network and must use the PSTN.
- **Music on hold:** If system music should be played when a call is on hold.
- **Busy on busy when in a call:** What should happen if a user is already on a call and a second one comes in. Setting this to unanswered lets users decide in their client.
- **Web PSTN calling:** Allows PSTN calls to be made from the Teams web client.
- **Real-time captions in Teams calls:** Allows in-call captioning to be enabled

- **Automatically answer incoming meeting invites:** Useful to configure against a meeting room account where you want the room to join if invited automatically.
- **Spam filtering:** Options to include SPAM notifications as part of the incoming call toast if Microsoft identifies the number as suspect.
- **SIP devices can be used for calls:** Ability to place calls from SIP registered devices.

Some of these settings can have an impact on the traffic path, for example, if a user enables services that are cloud-powered like recording, transcription or captioning then the media must go through the Teams service for processing to enable the feature. Other features you may want to control at a more granular, country or regional level (with corresponding policies), busy on busy being a good example where different countries naturally expect this to behave a certain way.

## Cloud Voicemail

Another setting controlled by the **Calling policies** is Cloud Voicemail, which is available by default in the Teams client, even without the Phone System license. The voicemail capability replaces the old voicemail hosted by Exchange Online and Exchange on-premises servers. Microsoft hosts the voicemail service in Azure, and you control the availability of voicemail for users through the Teams calling policy assigned to their accounts. You can decide if users can enable voicemail manually, make it mandatory or disabled. If it is set to user-controlled, users can decide if unanswered calls go to voicemail by configuring it in the Teams client under settings. Sending a call to voicemail in Teams does not mean someone has to leave you a message, you can customize the behavior from the Teams client by clicking **Configure voicemail** in the **Settings** menu.

Integrating cloud Voicemail with a hybrid Exchange solution is possible, but the user's mailbox must be in Exchange Online for voicemail to work with Teams. Voicemail supports depositing voicemail messages only in an Exchange Online mailbox and doesn't support any third-party email systems. As a fallback mechanism, Cloud Voicemail can resend messages using SMTP, which means third-party email system could receive voicemail messages, but this has no guaranteed availability or support for features, such as changing their greeting so is not recommended.

Transcription of voicemails is enabled by default for all users enabled for Cloud Voicemail and can be turned off using the `Set-CsOnlineVoicemailPolicy` command. Twenty-seven languages are available for greetings, and transcription is available for ten of those languages. Read more about the set of supported languages [here](#).

**Note:** Some countries have language laws requiring that callers must have the option to choose which of the country's official languages they wish to be served in. Voicemail has Dual Language support to meet this need, read more about the capability [here](#).

## Toll Bypass Restrictions

Over 50 countries including India, China, Brazil, Algeria, Bahrain, and UAE have some form of toll bypass restrictions in their local law or telephony regulations. Essentially, they mandate that all international PSTN calls should go through a local endpoint so that the (usually state owned) telecommunications provider handles the call. For instance, if an organization has a support center in India, calls to international numbers must dial out from India. Modern routing methods such as least cost routing are therefore unhelpful in these scenarios as essentially for users in those countries we need to apply most cost routing.

Microsoft has introduced Location-Based Routing (LBR) to support this in Direct Routing based scenarios, LBR does not apply to Calling Plans as Microsoft does not offer services in these locations, and with Operator Connect your provider needs to manage it via their network. LBR is assigned on a site level and ensures that all international calls break out from the local SBC, enforcing international toll on international calls. Here is an example:

If you have users in India dialing a UK number and have SBCs in both India and the UK, ideally, you would route that call to the UK SBC and only pay the cost of a UK local call. However, as India has toll bypass restrictions this is not legally allowed. LBR would be configured to route these calls to the India SBC where it would be at full international cost. If one of those Indian users travels to the UK, LBR will match the new user and route calls to the UK SBC for the duration of their trip. If a UK user travels to India for a short period, they can still have their calls routed via the UK gateway.

LBR re-uses the same External IP, region, site, and subnets described at the beginning of this chapter. To use LBR, we need to enable the capability against the site we configured and assign a pre-defined Calling policy using the Teams PowerShell module.

```
[PS] C:\> Set-CsTenantNetworkSite -Identity "Site1" -EnableLocationBasedRouting $true
[PS] C:\> Set-CsOnlinePSTNGateway -Identity "SBCSite1.office365itpros.com" -GatewaySiteLbrEnabled $true -GatewaySiteID "Site1"
[PS] C:\> Grant-CsTeamsCallingPolicy -PolicyName "AllowCallingPreventTollBypass" -Identity "ben.lee@office365itpros.com"
```

The last command grants the built-in Calling policy called *AllowCallingPreventTollBypass* (where *PreventTollBypass* is set to *\$true*) to a user. If you have a list of all users in a site, you can use the *New-CsBatchPolicyAssignmentOperation* to assign it to multiple users at once. Read more about planning and configuring LBR [here](#).

## Number Management

There are three ways to consume phone numbers in Teams:

- Ordering them via Microsoft for Calling Plans
- Getting them from carriers via Operator Connect
- Acquiring them from carriers via sip trunks for Direct Routing

Service numbers, Calling Plan numbers and Operator Connect numbers can be found in the Teams admin center by going to **Voice** and **Phone numbers**. However, Direct Routing numbers are not shown in the Teams admin center as Teams does not hold a record of what your ranges are. You will see the location they belong to, if they are available and details of how they can be assigned (available usage).

To manually assign a number to a user, use the filter in the top right to search by Unassigned status and match the location to your user. After finding a number you want to use, select it and use edit to assign it. Using these filters is a good way to investigate how many available numbers you have at any given time for a location. This page also gives you access to your Microsoft number order history and you can get support using the link under the Actions menu for number-related issues, such as porting queries or changing number assignment types.

## Automating Phone Numbers

The Phone number portal in the Teams admin center is a great start, but the information found there is not available via Graph API yet, so you cannot use the same information in your automation routine. If you have numbers via Direct Routing or want to classify numbers by desirability, such as gold or silver, then you need to create your own routine. If you open PowerShell and connect to the Teams module, you can run one simple command to get all users with numbers in your deployment:

```
[PS] C:\> Get-CsOnlineUser -Filter {LineURI -ne $Null} | Format-Table DisplayName,LineURI
```

The command lists all numbers used in your Teams environment, including numbers assigned to CAP, MTR, auto attendant and call queue users. With this, if you also know your full number ranges, you could easily and programmatically find the next available number. There is a script available to get you started with this routine, and it can output all available numbers in your company as a CSV, grid view, and variable. You could integrate the script into an existing identity management procedure or use it as part of a standalone number

management process. For a larger environment, you might want to store this information in a database to keep additional information with the numbers. For example, if you need to mark the numbers of recent leavers so that Teams does not automatically assign the numbers to new users. You can add your own numbers for retention, and it will not offer numbers classified as gold or silver. Read more about this script [here](#).

## Unassigned Numbers

Organizations often have vanity phone numbers, which have a specific meaning to your organization, such as a previous sales queue number or an old main number. These are numbers not assigned to any auto attendant, call queue, or user, but you need them to be answered. Unassigned numbers in Teams can catch numbers that are not associated with a specific user or account and then redirect them to another user, resource account or play an announcement. An additional scenario is when people leave your organization, and you may want to route the calls to reception for a few months. You can configure unassigned number ranges that cover large portions of your full range, numbers assigned to users, resource accounts, or conference bridges are ignored and are routed to their correct destination.

Today, administrators can create unassigned numbers only using PowerShell with the *New-CsTeamsUnassignedNumberTreatment* cmdlet, and you can only assign a number or number range using regex. You can route the call to a number on Operator Connect or Direct Routing but be aware that if you send it to a Calling Plan user, Communications Credits must be available in the tenant to pay for it.

There are some good examples provided in the [Microsoft docs](#).

**Note:** [This](#) site builds a nice visual from your regex code so you can see at a glance if it looks correct.

## Blocking Numbers

Like the regular phone system, your users might receive calls from spammers or others offering dubious services. Users can block callers in the calling app in the Teams client, but it can be more effective to put an organization-wide block in place. This is configured using PowerShell by creating a block rule with the *New-CsInboundBlockedNumberPattern* cmdlet. As the name suggests, the block works by defining a number pattern for Teams to recognize inbound calls to block. The pattern can block a single number, a sequential range, or multiple separate numbers. For example, here's how to block a single number:

```
[PS] C:\> New-CsInboundBlockedNumberPattern -Name "Spam Block" -Enabled $True -Description "Blocks spammer from Tunisia offering Microsoft support services" -Pattern "\+21690373633"
```

After setting up a rule, you can test it using the *Test-CsInboundBlockedNumberPattern* cmdlet.

## Managing Users Calls

One of the primary benefits of deploying Teams Phone for users is that it gives them a lot of flexibility to choose how to manage their phone calls. The availability of these features is controlled through Teams calling policies covered in earlier.

Users can choose to forward their calls to other users or numbers in several different ways:

- **Call forwarding** sends the call straight to the destination number.
- **Simultaneous ring** forks the call and rings both Teams and the destination number, whoever answers first takes the call.
- **Call Groups** allow users to create a mini group of users they are working closely with who will receive the call on their behalf.
- **Delegation** for calling lets another user make or receive (subject to configuration) calls on the original users behalf.

**Note:** When a call is forwarded to another Teams user the incoming call notification will include a visual indicator to tell the user that it has been forwarded from another source. Teams also will not apply any call forwarding settings from the destination user to avoid a calls looping and forwarding forever.

## Configuring Call Forwarding for Users

These settings can be updated through Teams admin center under **Manage Users**, select the user then in the **Voice** tab, or via the `Get-CsUserCallingSettings` cmdlet. As well as seeing the current configuration, you will be able to update the timeouts before actions happen, for example allowing calls to route to the users Call Group after 20 seconds of trying the original user first. The documentation for the cmdlet is [available online](#).

## Call Delegation

Call delegation is when a user delegates the ability to make and receive calls on their behalf to someone else. This setting can be controlled through PowerShell, the Teams admin center or by end-users directly. It is best practice to try and get users to take responsibility for defining their call behavior and delegates are a part of that. When configuring a delegate, users can decide what a delegate can do. Options include; make calls, receive calls, or change call and delegate settings. If a delegate can change the call and delegate settings, they can add and remove other delegates on behalf of the original user.

A typical delegation scenario is when executives want personal assistants to be able to handle incoming and outgoing calls on their behalf. The executive can configure their first delegate through their Teams client, if allowed in their calling policy, by going to **Settings, General, and Delegation**. Once the first delegate has been assigned, they can configure any other delegates that are required. Alternatively, as executives do not usually want to handle setup tasks, you could use the Teams admin center to find the executive under **Users, Manage users** then configure the first delegate in the **voice tab**.

You can add up to 25 delegates for a user, and delegates can have up to 25 managers. There is no limit to the number of delegation relationships created in a tenant. Read more on how to configure it as an end-user [here](#) or as an administrator using PowerShell [here](#).

## Group Call Pickup

Group call pickup is configured in the Teams desktop client under **Settings, Calls** and then choosing a forwarding scenario that uses it. Here you can add users to your **Call group** as well as choosing the order to call them. When you have defined your call group, you can choose call groups under call answering rules and it rings to your group of users if you choose the call group if your call is unanswered.

As an administrator, you can manage users call groups in the Teams admin center under the voice tab in user administration, as for delegates. There you can define members of the personal call group and define the notifications the members get such as ring, muted, or in client banner. A tenant can contain a maximum of 32,768 call groups. [This documentation explains](#) how users can configure group call pickup.

## Call Park

Call Park (CP) is not strictly a user-calling action as you cannot park calls automatically. However, it is important to know about it as it is used in some niche, but important scenarios. It is used by companies where employees are hard to contact when they are working. Users (such as reception) can assist the caller and help connect them to the at-large employee. When the call comes in, reception (or any user) can park the call by using the "more actions" icon after answering it. A unique code will be given to the person who parks the call. An intercom, pager, or even texting can be used to send the code to the target employee. The target employee can then retrieve the call from a Teams client using the code provided. The code is entered in the Teams client on the calling page by clicking on **Unpark** button and entering the code. Call Park is available to users with a Teams Phone license.

Call Park is controlled via the call park policy assigned to user accounts. New call park policies are created using the *New-CsTeamsCallParkPolicy* cmdlet, or in the Teams admin center under **Voice, Call Park Policies**. Administrators assign policies to specific users using *Grant-CsTeamsCallParkPolicy*. If you want to remove the policy from a user, you still use the grant command but set the policy name to *\$Null*. Here is how you create the policy and grant it to a user:

```
[PS] C:\> New-CsTeamsCallParkPolicy -Identity "SalesPolicy" -AllowCallPark $false
[PS] C:\> Grant-CsTeamsCallParkPolicy -PolicyName SalesPolicy -Identity
"ben.lee@office365itpros.com"
[PS] C:\> Grant-CsTeamsCallParkPolicy -PolicyName $Null -Identity "ben.lee@office365itpros.com"
```

## Voice Apps

So far, we have covered scenarios for “individual calling” where calls are to/from specific users. However, it is very common for businesses to need to direct calls to groups of users, or have workflows associated with PSTN calls. For example, to route calls among a support team or to handle incoming calls to a main office number where you might also need to take a message after business hours. Fortunately, Teams allows for these scenarios with two types of Voice Apps:

- **Auto attendants** let you define welcome messages, interactive menu choices, and program different behavior based on opening hours.
- **Call queues** determine how calls are sent to different users (agents). You can define the group of agents, type of call distribution, and overflow options for calls in the queue. call queues can be mandatory, where users are always in a queue when online, or you can allow opt in and out so users can control their availability for receiving the incoming calls.

All the features discussed under group-based calling require that users and agents have a Phone System license and have a number assigned, either through Calling Plans, Operator Connect or Direct Routing.

**Note:** APIs to build customized switchboards and call centers are available inside the Teams service, allowing integrated switchboards that can deliver better reporting, wallboards, and more advanced IVRs than is available with the standard auto attendant and call queue functionality in Teams. The APIs are [Cloud Communications APIs](#) and [Presence API](#). Now that the *UpdateRecordingStatus* API is available, third parties can incorporate recordings of audio, video, screen share, and chat. Read more about [supported contact centers](#) and the recording API [supported vendors](#). To use [Policy Based Recording](#) Graph API Access and Contact Center solution, Graph API Access users need Microsoft 365 E3, E5, A3 or A5 licenses. Microsoft has announced a voice and Teams integration for their Dynamics 365 Customer Service which integrates with Power Virtual Agent. This integration can be used as an interactive voice response (IVR) for the voice channel, chatbot for SMS, live chat, and social messaging channels, all landing in Dynamics 365 and Teams. Read more in this [announcement](#).

## Resource Accounts

Behind each voice app lies a resource account. The resource account is a disabled user account configured with the number used so Teams knows where to route calls to. The settings for resource accounts are located under **Voice** in the Teams admin center. Resource accounts must have a special kind of license called the Teams Phone Resource Account. This is a free license, and you can get 25 licenses with the first Phone System license in your tenant, together with one new virtual license per ten Phone System licenses acquired. You can get the licenses from the Microsoft 365 admin center, from your CSP provider or as part of your Enterprise license Agreement.

After creating the resource account in the Microsoft 365 admin center, you can license the resource account and assign numbers. You can assign service numbers directly through the Teams admin portal, but you need to assign Direct Routing numbers via PowerShell.

Here is a summary of the process to create a resource account:

1. Obtain two or more service numbers as described earlier.
2. Obtain some free *Teams Phone Resource Account* license by going to the add-on licenses section in the Microsoft 365 Admin portal, under **Billing**, then **Purchase services**. You can have as many as you want but must provide valid billing details.
3. Create at least two Resource accounts under **Voice** in the Teams admin center and specify one as call queue and the other as auto attendant.
4. Assign the Virtual user license to the resource accounts, preferably using Group Based licensing in the Azure portal.
5. Assign a service phone number to the Resource accounts by going to the Teams admin center > **Voice** > **Resource account**. Select the resource account you are working on and click **Assign/unassign**. Next, select the number you want to assign and click **Save**.
6. Create a call queue, assign a Resource account, assign agents, and choose the routing method.
7. Create an auto attendant with a welcome message and open hours. Assign a Resource account and route the auto attendant calls to the call queue that contains the agents.

The example below shows how to create a resource account using the Teams PowerShell module. Give it a name and define the type of service by setting the *ApplicationID* which defines which service (AA or CQ) the resource account is to be used for. These IDs are the same across tenants as they reference the global M365 IDs:

- Auto attendant: ce933385-9390-45d1-9512-c8d228074e07
- Call queue: 11cd3e2e-fccb-42ad-ad00-878b93575e07

```
[PS] C:\> New-CsOnlineApplicationInstance -UserPrincipalName
"_service_TeamsRouting_GSDDR@office365itpros.com" -DisplayName "Service Desk" -ApplicationId
"11cd3e2e-fccb-42ad-ad00-878b93575e07"
```

After assigning the account a Phone System Virtual User license, we can assign it a Service Number by using the *Set-CsPhoneNumberAssignment*. The *PhoneNumberType* defines the source as *CallingPlan*, *OperatorConnect* or *DirectRouting*:

```
[PS] C:\> Set-CsPhoneNumberAssignment -Identity "_service_TeamsRouting_GSDDR@office365itpros.com" -
PhoneNumber +4714073200 -PhoneNumberType CallingPlan
```

Remember that you can mix and match calling delivery so even if your users numbers come via Direct Routing, you can still take Service Numbers directly from Microsoft. This can be a good idea for some queues, like an internal support queue where you would want that to be operational even if you have a fault with your infrastructure. After assigning a number to the resource account, you can then associate it to an auto attendant or call queue in the Teams admin center.

## Call Queues

Call queues are simple hunt groups configured in Teams admin center under **Voice** and **Call queues**. You would typically have an auto attendant in front of a call queue to enable opening hours and interactive routing. Call queues are used to distribute many calls (up 200 calls per instance) and use the first-in, first-out principle by default, there can be up to 50 agents per call queue. Users can opt in and out of the queue from the Teams client under **Settings** and **Calls** if allowed by the queue.

Microsoft introduced conference mode to speed up the time it takes to answer a call as an agent. The inbound call is held in a conference with audio established, so when an agent joins, they only need to add

their audio instead of negotiating a media path end-to-end. Without conference mode it can take longer before the agent can hear the audio of the inbound call.

The following routing methods are available for distributing incoming calls:

- **Attendant** – sends the call to all agents at the same time.
- **Serial** – sends the calls in the published order each time.
- **Round-robin** – distributes the calls at random between the agents.
- **Longest idle** – sends the call to the agent who has had no call for the longest.

If you turn on presence-based routing, calls will only be presented to agents who have Available as their presence status and is only applicable for users in Teams only mode.

Microsoft supports the mobile clients for the auto attendant and Call queues features so users on the move can still take calls. However, you should ensure they are fully aware of how to update their presence to avoid calls coming in at inappropriate times.

Another big customer request is the ability to redirect calls to a voicemail or external phone number as part of a call workflow. While an external number cannot be part of the group of agents called first, you can achieve this using queue timeouts and overflow configuration.

**Note:** Microsoft has released Power BI reports to report on auto attendants and call queues. These are not real-time reports as the data is delayed by at least 30 minutes. Even so, the data lets you review the past performance of queues. Read more [here](#).

Auto attendants and call queues are covered by the Phone System license and do not need additional licenses. Both services need service numbers to be assigned to your tenant for setup. You can assign multiple numbers to a single auto attendant or call queue using resource accounts.

Three ways exist to add agents to call queues. You can:

- Add users one by one.
- Add sets of users using a distribution list or Microsoft 365 Group.
- Enable collaborative calling by selecting a channel within a team.

Agents must have a Phone System license and have a phone number assigned to become call queue agents. Collaborative Calling adds a visual experience of the call queue as a tab in the channel named Calls. Users can see an overview of all calls and see active agents for the queue. They can see the call history, who answered calls, and what calls have been sent to voicemail. Via the call history, agents can listen to voicemails and choose to call back. Keep in mind that it may take 24 hours for the Calls tab to show in your chosen channel.

When agents call back or use the built-in dial pad, agents can display their personal number or choose to display a number assigned to any resource account. Numbers available are specified in the call queue configuration in the Teams admin center under **Assign calling ID**. This is separate from Caller ID policies and is configured per call queue. If you have a setup with Auto Attendants in front of call queues, you may wish for the agents to show the auto attendant number when dialing out. This can be done by adding the resource account for the auto attendant to the Assign calling ID configuration on the agent's call queue.

## Auto Attendants

The auto attendant is an automated interactive system for incoming calls that can generate welcome messages, give opening hours, provide interactive menu choices, and route calls to other auto attendants, call queues, and users directly. It also includes a voice-driven Directory Search to reach a person by name. Directory Search is a niche feature, but if you need it, be aware that the default configuration allows searching across the entire directory. To configure an auto attendant, go to the Teams admin center under **Voice** and

find **Auto attendant**. To give the auto attendant a number, you need to configure a Resource account as detailed earlier.

It is common practice for organizations to combine auto attendants (to allow time based routing and providing users a menu of call options) with call queues into a single voice workflow. This is a fully supported scenario.

A common requirement is to route calls to voicemail after hours, during holidays, or whenever the business is closed. The voicemail receiver is a Microsoft 365 Group; all members of that group will be able to see and play the message in any Outlook client. Auto attendants can also route calls to an external phone number, if you want the call to go to on-duty person for example.

Holidays are managed in the Teams admin center under **Voice** settings and **Holidays**. Here you can define a set of holidays and assign them to multiple auto attendants. It is possible to add holidays for a country programmatically as described in this [blog](#).

## Teams Devices

Teams supports a rich ecosystem of third-party devices where manufacturers have produced devices that are compatible with and certified for use with Teams. We spent a lot of time earlier this chapter talking about how to prepare your network and making sure you have a suitable connection to handle your traffic going to Teams, but a significant, but often underestimated contributing factor to call quality is the device you are using. If you put bad audio or video into Teams, you will only ever get poor quality out the other side. Audio quality can significantly impact the overall perception of the quality of experience.

It is not uncommon to get support cases where users complain about poor call quality in a meeting, only to find that their call streams were all good, but it was someone else broadcasting bad audio into the call (or picking up the conversations of everyone else nearby!).

The certification program not only guarantees a minimum level of quality for the key components of the device, but it also means that all the expected functionality works. This includes proper mute/unmute synchronisation between the device and your Teams client or answering a call directly from the device by pressing a button if your PC is locked.

## Device Types

Traditionally devices were split into two broad categories:

- **Personal Devices** are devices designed to be used by one user and typically refer to headsets, webcams or individual phones.
- **Shared Devices** on the other hand refers to equipment that more than one person uses, such as hardware in a meeting room or a phone in a communal workspace.

In the last few years Microsoft has been introducing several newer categories of devices such as Teams Displays and Teams Panels, as well as broadening their cross-device compatibility with the introduction of services like the SIP gateway. For this reason, I think that in this chapter it is helpful to move Phones and their specific nuances into their own category of Phone Devices as you. You can choose to either jump straight to, or skip over, that section depending on where you are in your Teams Journey.

You can find a full list of the current certified device & device categories in the [Teams Enabled Devices catalogue](#).

## Personal Devices

Personal devices typically refer to devices owned by, or signed in as, one user. It is an important device category as the chances are these devices will be the ones used most frequently by your users, and while there is a temptation to allow users to bring their own headsets, such as AirPods, while these headsets work, they might not provide the best experience for either the user in question, or the others in the call.

## Headsets and Webcams

The Teams client will accept the video feed from any USB camera that the underlying Operating System can access. The main consideration with webcams should be whether you want to give laptop users an external camera. If you want to drive the use of “video first” meetings, you may find that relying on the webcam in laptop lids doesn’t provide the best quality video (or the most flattering up-nose shots).

For headsets, it is a different story, because there are some specific benefits to having a certified device:

- Dedicated Teams button and LED indicator light. The Teams button provides context-sensitive actions; for example, press it when a call is ringing and it will answer, when a meeting starts and it will join the meeting, or long hold and it will raise your virtual hand in the meeting.
- User notification of events and alerts from the Teams client (e.g., meeting starting, voicemail or missed call).
- Ability to activate the Teams client or respond to notification with a button press (e.g., to join a meeting).
- Certification designed for extensibility (new device/client features to be delivered via firmware update).
- Automatic selection as the default audio device in Teams because they are USB based.
- Basic call control means that you are muted in Teams when you click mute on your headset.
- Audio quality such as no echo or excessive glitches, echo cancellation across devices, wideband audio support, comfort noise support.

Microsoft lists some benefits of using certified Teams devices [here](#), and you can also find the full specification for certification for all Teams devices [here](#).

Recently the Teams desktop client has been gaining many capabilities around audio processing where it can apply noise suppression to outbound audio generated during online meetings. Does this replace the need to deploy certified headsets? Not at all, it will simply complement the already good capabilities of your headset and further improve things.

**Note:** If you use headsets for both Teams calls and to listen to music, keep in mind that you have a secondary ringer option. You can define the device where you want to hear incoming calls. This setting is found in the Teams desktop client under **Settings**, and then **Devices**.

Most vendors have management tools you can use to centrally manage firmware upgrades and push configuration to their devices, [Jabra Direct](#) and [EPOS Manager](#) are examples such tools.

To know which headsets are used in your organization, you can create a custom Power BI report. The Call Quality Dashboard (CQD) database has this information, and you can create a view by looking at two fields, Audio Call Count and Second Capture Dev. To connect to the CQD and read this data, you must have at least the Teams Support Engineer admin role. At the end of this chapter, you will find all you need to know on how to implement the Power BI report and show it in Teams through a channel tab.

If you had previously invested in certified headsets for Skype for Business, those devices are still acceptable to use with Teams today. Anything Optimized for Lync 2013 or above works with Teams but may not support all of the correct button press actions.

For headsets certified for Teams with Bluetooth capabilities, you will find that you get a Bluetooth dongle with the headset. The built-in Bluetooth in laptops today is meant for keyboard and mice peripherals, not for Teams codec support or advanced HID functionality which enables the headset to control the Teams client. Bluetooth support without a dongle was recently improved allowing button press support but does not yet support the SILK codec.

## Teams Displays

Teams displays are a new category of device designed to act as a sort of “companion” alongside your primary computer. They are Android-based devices with a touch screen and speakerphone built-in. The offering from Lenovo is based on the same hardware platform as their Google smart assistant device.

They are personal devices intended to offload your computer and be an always-on, always-available Teams device, allowing users to join meetings without needing to disturb whatever’s happening on their workstation. The functionality available in Teams displays includes chat, channel conversations, switching tenant, meetings, and making and receiving calls. You can connect a Teams display to your computer, making the device part of the joining experience when you connect to a meeting. This means that the Teams display acts as an extension of a desktop client to deliver video and audio while shared content (as necessary) comes from your computer. These devices can also be used with multiple account logins, so they support hot desking scenarios.

While these devices may not seem like they have an obvious use case, they can prove popular for small offices or spaces where an executive spends a lot of time in Teams meetings. However, they are unlikely to go down well in open office type scenarios as they are intended for hands free use and can generate a lot of noise when used as a speakerphone.

From a management perspective, they benefit from the same management capabilities as the other dedicated Teams hardware devices we will cover next. In Teams admin center you can find them listed under the **Teams displays** tab under **Devices**. You can create and assign the same type of configuration profiles as you do with IP phones and control settings such as time zone and language. A list of all certified Teams displays is available [here](#) with a list of latest features available [here](#).

## Meeting Room Devices

Meeting room devices are the collective term given to hardware found in a shared space where people need to work together. These can vary in size and type from very large board room type spaces to smaller fluid huddle rooms or pods. When looking at what hardware to put in your meeting room you should consider its primary purpose, if it is mainly used for voice & video or if there is a requirement to also have some form of collaboration via whiteboards or some other medium.

The meeting room is one of the areas that is seeing the fastest evolution and growth with new features being added rapidly and a strong ecosystem of hardware partners producing devices.

### Phones

We will cover phones in more detail in the next section, but it is worth mentioning here that the most basic type of meeting room device is a phone or speaker phone. Teams phones come in many shapes and sizes, even one that matches the traditional “spider phone” device that you may have seen in many standard meeting room layouts. Teams phones have a special sign in mode for phones better suited for use in a meeting room. More on this and their modes later.

### Teams Panels

Teams Panels are Microsoft’s solution to the growing requirement to have status displays outside of meeting rooms. They display the current status of a room and show future meetings and availability. In addition, the panels allow users to search for an available meeting room and make an ad-hoc booking via the panel.

The panels support advanced scenarios such as meeting room check-in where a user taps on the panel as they enter the room to acknowledge that they are using the room for the booked meeting. If the room is not used after a predetermined length, the booking can be removed from the room and made available for someone else to use without worrying about clashes. Also, if a room is currently free, you can use the panel to book an ad-hoc meeting to claim the space as your own.

Teams panels are Android-based devices that can be managed in the Teams admin center under **Devices**. No extra user account or license is necessary for Teams panels as they are normally logged in with the same user as the Teams Room or Surface Hub devices already in the room. A list of all certified Teams panels is available [here](#) and more info on how to prepare for Teams panels can be found [here](#).

### Teams Rooms on Windows

Microsoft Teams Rooms on Windows (MTRoW – yes, it’s a mouthful), are designed to be a premium in-room solution for joining Teams meetings. Several vendors produce these devices. Sitting at the heart of each room setup is a Windows 10 PC connected to the other devices in the room (cameras, screens, microphones, etc.). This runs a special version of the Teams client designed to be operated full screen and via touch.

There are many kinds of MTRoW devices from vendors and many different possible configurations of cameras and microphones to suit different scenarios. Some vendors, such as Crestron, also bring their own customizations or integrations. For Crestron this allows managing the in-room devices (like raising or lowering projector screens, or diming lighting) but they all have to have a touch panel in the room to control the Teams application.

Teams Rooms can also join meetings hosted natively in Cisco Webex or Zoom using WebRTC. This can be a very useful feature to help maximize the use of your meeting rooms, because your users might be invited to meetings at other companies who use a different technology stack.

### Teams Rooms on Android

Microsoft Teams Rooms on Android (MTRoA) started out life as Collaboration Bars. They were intended to be lower specification meeting room hardware for smaller spaces where an investment in MTRoW wasn’t worthwhile. As time has passed, the hardware and software capabilities of the MTRoA devices have caught up somewhat with their larger MTRoW siblings. For some companies, they are becoming the preferred hardware choice as Android-based devices can be easier to manage and have (in theory) a smaller attack surface area. For example, if an MTRoA device develops a fault and needs to be factory reset these appliance-like devices are easier to restore than something running a full Windows 10 OS. There are some features that MTRoA do not have, however if you look at the latest [comparison list](#), you will see that there is not many. The main things missing from MTRoA are currently:

- Lack of support for content cameras. These are cameras pointed at traditional whiteboards to support better collaboration scenarios in a meeting
- Coordinated meeting join, where separate meeting room devices can be combined into the same meeting, usually with a Surface Hub
- Peripheral health management reporting

For most companies looking to deploy meeting room devices, the MTRoA appliance approach outweighs the slightly feature-rich MTRoW experience.

### Surface Hub

The Surface Hub is Microsoft’s own variant of meeting room hardware. It is a 55” or 84” touch and pen-enabled screen that can be used as a giant digital whiteboard. The Surface Hub can also run other Windows “modern applications” such as maps or a browser, so it operates almost like a large tablet at the front of the room. Some models of the Surface Hub can be mounted on a wheeled stand with a battery allowing them to be moved about freely, although your mileage may vary depending on your office layout.

The Surface Hub used to have a different meeting interface to the Teams Room devices as it allows more usage outside of just Teams, however with recent [updates](#) a new Teams application was installed which makes the room interactions align more closely with the Teams Rooms experience.

You can also configure a Surface Hub and a MTRoW to work in tandem with each other. For example, the Surface Hub provides digital whiteboarding for meetings and an MTRoW device provides the voice and video streams.

### Teams Meeting Room Licenses

The MTRoW/MTRoA/Surface Hub devices have their own license SKU for Teams which comes in a standard or Premium version. This license includes:

- Teams license
- Phone System
- Audio Conferencing
- Intune (for management)
- Azure AD P1

The premium license includes a managed service license from Microsoft where the devices are monitored and proactively kept up to date by Microsoft. Of course, you need onsite support available, but Microsoft can provide 24x7 escalation for issues relating to the meeting rooms. You can read more about the licensing for Teams Rooms [here](#), or about this unique managed service offering in the premium tier [here](#).

### Phone Devices

Teams supports several different types of phones but only one category offers full native support, the others operate through compatibility gateways. If you have legacy devices that are supported by one of the compatibility services, then analyse what functionality you need from your phones and test that they work how you need. If you have no existing phones that are compatible with Teams, then you should only consider deploying native Phones for Teams as they provide the fullest user experience.

### Phones for Teams

Microsoft has had hardware phones that are compatible with their platform for many years. How those devices have been built and operated has changed over the years. For Teams, Microsoft reset the phone delivery model and now allows manufacturers to produce their own hardware, but they must run a version of the Android OS. Microsoft then provides a version of the Teams client to run on them. This way hardware manufacturers can keep up with current specifications, but Microsoft has control over the application and the UI, providing users with a clear and consistent interface across different device types.

Features found on Teams IP Phones include:

- Native Teams experience with hardware button integration and LED notifications
- Calendar integration and one-touch meeting join
- Support for touchscreens

As mentioned in the previous section, these devices can run in three modes depending on your requirements:

- User mode, with a focus on contacts, calendar, and voicemail
- Meeting mode, with a focus on the calendar
- Common Area phone mode provides quick access to just a dial pad

It is easy to get started as an end-user with IP Phones, just enter your email address, type your password, and answer the two-factor authentication challenge, and you are in! The IP Phone inherits the same capabilities you have as a user, so if you have the Phone System license, you get the same capability when you are signed in with the device.

## Skype for Business phones (3PIP)

For businesses that have previously invested heavily in Skype for Business 3PIP (3rd Party IP Phone) certified phones, there is a special interoperability gateway that Microsoft runs as part of the Microsoft 365 service. This gateway allows these devices to be registered against a Skype for Business service (transparent to the user and administrator), allowing them to make/receive calls in Teams.

This gateway service will be retired in July 2023, so it is not something you should be considering using unless you already have a significant estate of these type of devices. You can read more about the gateway and the functionality available [here](#). While this gateway does provide a suitable method for connecting older devices, depending on the models, you might find that using the SIP gateway (see below) is a better solution with improved management capabilities.

## SIP Gateway

The SIP gateway is another service provided by Microsoft out of the Microsoft 365 cloud where certain compatible devices can be SIP registered against the Teams service. These phones will download a specific firmware version and then log on using the SIP protocol against the gateway and will have capabilities such as make and receive calls, hold, resume, mute, unmute and call transfers. A presence indicator is not available on the device itself, but the presence will update for other users in the Teams client.

You can see a list of compatible devices on this [page](#) from Microsoft.

## Common Area Phone License

You will need to provide an account with basic licensing when you need to use phones in shared areas (but not meeting rooms) such as canteens, reception waiting areas or factory floors. Microsoft has a specific license for this shared usage scenario.

Instead of giving these shared devices a full Office 365 E5 or Office 365 E3 license with a Phone System add-on, the Common Area Phone license provides just a Teams and Phone System license, so it is cheaper to purchase.

The Common Area Phone license, however, does not include an Intune license, which means that these devices cannot enroll into Intune. Therefore, depending on the volume of devices you have and your approach to device management, you may find it preferable to use a Teams Meeting Room Standard license.

# Device Management and Security

Teams device management is evolving quickly, more options are becoming available directly in the Teams admin center, making common tasks much simpler. For example, you can now remotely provision Common Area IP Phones, check the health status of MTRs and receive alerts about status issues. However, a downside to these improved admin capabilities is that some features are only available via the Teams admin center and not via PowerShell or Graph API where they could be automated.

Most of the devices we have talked about run either Windows or a variant of Android and are capable of being included in any Intune management of your estate (subject to the right licensing). However, you would not normally want to apply the same policies as you do for standard user devices. The challenge is that they are Android based but not a phone, or Windows based but not a PC. Policies in Intune or conditional access can block access, rendering the devices useless. Here are the steps you should take to cater for these devices.

## Managing Meeting Room Devices

Meeting room devices (or other shared hardware) such as Conference Phones, MTRoA, MTRoW and Surface Hubs are typically used in open shared areas, so we need to ensure they are properly configured.

For example, you might consider not allowing these devices to make calls to international numbers. If using Calling Plans, this is easy, just assign them a Domestic only Calling Plan and do not assign communication

credits. However, if you are using Direct Routing, you must create an *OnlineVoiceRouting* policy per country for CAPs and MTRs. Below is an example from Netherlands which enables dialing only to numbers starting with the correct country code.

```
[PS] C:\> New-CsOnlineVoiceRoute -Identity "NL-Amsterdam-NationalOnly" -NumberPattern
"^+\d{3,14}$" -OnlinePstnGatewayList @{{Add="SBCSite1.office365itpros.com"}} -Priority 1
-OnlinePstnUsages @{{Add="NL-Amsterdam-NationalOnly"}} -Description "For CAP and MTR will be able to
call Netherlands numbers except premium numbers and international numbers"
```

You might also consider blocking premium numbers for these shared devices. <https://www.ucdialplans.com/> has information on premium numbers for more than 200 countries. You can use this information to create PSTN Usages and Voice Routes which restricts the use of premium numbers for shared devices.

### Configuring Resource Accounts MTRs

Configuring accounts for devices can be complicated, as there are many different elements to check, especially if you are running hybrid identity or hybrid Exchange. Microsoft has a good starter article [here](#). Typically, when introducing a Teams component to a meeting room, you want to enable the existing Exchange meeting room resource account for Teams. Here is a checklist when configuring meeting room accounts:

- Make sure the network is ready with proxy exceptions and firewall configuration. These are the same as the Teams client on a PC.
- Create Intune enrollment token, so that all MTRs are enrolled in Intune as discussed earlier.
- Create conditional access rules for MTR accounts to avoid requiring MFA as discussed earlier.
- Assign Teams Rooms license to the synced user.
- Change UPN to have a common prefix, such as MTR.
- Enable the Exchange meeting room account for sign in and give it a unique password that never expires. Do this from Active Directory in a hybrid deployment or through Azure Active Directory if it is a cloud-only account. Migrate user to exchange online if part of a hybrid environment.
- It is usually enough to assign the Teams license to enable the room for Teams. If you have a hybrid SfB deployment, then you must migrate the account to Teams. If the resource account was not originally enabled for SfB and hosted on-premises in Exchange, consider enabling it as an online meeting room in the SfB deployment so that all attributes are configured correctly since this is a synced account. Run the below cmdlet from the SfB PowerShell module from one of the SfB Front Ends:

```
[PS] C:\> Enable-CsMeetingRoom -Identity "username@domain.com" -SipAddressType "EmailAddress"
-HostingProviderProxyFqdn "sipfed.online.lync.com"
```

- After the MTR is set up and Intune enrolled, evaluate changing the admin account password after deployment, as this password is the same for all MTRs by default. This [YouTube video](#) shows how to change the password.

When reusing an existing Exchange room resource account, you need to ensure calendar processing is configured correctly to work for MTR meeting invitations. It is important that the settings *DeleteComments* and *DeleteSubject* are set to *\$False*, otherwise the join button for the meeting may not show up on the MTR. By using Exchange Online PowerShell, you can check this with the following cmdlet:

```
[PS] C:\> Get-CalendarProcessing -Identity mtr-room1@office365itpros.com | Format-List
AutomateProcessing, AddOrganizerToSubject, AllowConflicts, RemovePrivateProperty, DeleteComments,
DeleteSubject, AddAdditionalResponse, AdditionalResponse
```

```
AutomateProcessing      : AutoAccept
AddOrganizerToSubject   : False
AllowConflicts          : True
RemovePrivateProperty   : False
DeleteComments         : False
```

```

DeleteSubject           : False
AddAdditionalResponse   : True
AdditionalResponse      : This room has Teams enabled room equipment for up to 10 people

```

You can use a string stored in the *AddAdditionalResponse* property to tell users that this meeting room has Teams Room equipment installed. A common misconception is that it should be possible to forward external Teams meetings to the Teams Room account. This does not work by default and the reason is that *ProcessExternalMeetingMessages* is set to false. To fix this, *ProcessExternalMeetingMessages* needs to be set to true, which enables anyone to send meeting invitations to the room. To enable the feature, run the following cmdlet:

```

[PS] C:\> Set-CalendarProcessing -Identity mtr-room1@office365itpros.com
-ProcessExternalMeetingMessages $True

```

In addition, you may see that the forwarded meeting invitation arrives at the MTR, but there is no join button. This could be because of the way that Microsoft Defender for Office 365 safe link processing works. You need to create an exception for your mtr-\* devices and not rewrite [https://teams.microsoft.com/\\*](https://teams.microsoft.com/*) links. When this exception is in place, you should see a forwarded meeting arrive at the MTR with a meeting join link. If you are using guest join with the MTRoW, you should also add Zoom and Webex meeting links to the allow list.

**Note:** A Microsoft article is available about [MTR security](#), covering hardware, software, account, and network security. The text is updated regularly.

## Intune and Conditional Access for MTRoW and Surface Hubs

The recommendation for MTRoW and Surface Hub devices is that they are not enrolled in Active Directory, but as cloud native devices. Teams is a cloud-only service, so it does not make sense to administer them with on-premises legacy techniques such as Group Policy. Here are the planning considerations for MTRoW:

- **The account:** should have a UPN prefix such as MTR-xxxx to let you create an Azure AD dynamic group for all room accounts. It is acceptable to rename the UPN of existing meeting rooms since users search for the room using display name, and email clients like Outlook use email proxy addresses to find accounts, which will not change.
- **Conditional access policy:** Exclude the group you made from the need to use MFA but require that it logs on from a trusted public IP address.
- **Compliance policy:** Create a Windows based compliance policy for Teams Rooms that includes BitLocker, secure boot and MS Defender.
- **Intune Bulk enrollment for Windows devices:** It is recommended to use bulk enrollment for Windows for both MTRoW and Surface Hub. The advantage with this is that the person setting up the device does not require Intune enrollment rights in your environment. This can happen after the first time setup for MTRoW but must be done as part of the initial bootup for Surface Hubs. Read more about bulk enrollment [here](#).
- **Bulk deployment of MTRoW:** Autopilot will soon be supported for MTRoW which will be the preferred way over using Endpoint Manager Configuration Manager. Using the autopilot approach may be able to automatically enroll the device to Intune as well.

## Managing Teams Rooms

MTRoW shows up under **Teams devices, Teams Rooms on Windows** in the Teams admin center, while MTRoA show up under **Teams Rooms on Android**. From there, you will be able to see the health of the devices, peripherals connected, call activity, and management history of your MTRs. A typical scenario is to discover when a peripheral is disconnected or what software version the device uses.

You can interact with the device by gathering device logs and restarting the MTR, be careful though as it will restart even if in a call. You can also control most of the settings you find in *SkypeSettings.xml* (a file used during manual deployment of the devices) such as **Account, Meetings, Device, Peripherals, and Theming**.

For instance, you can enable modern authentication under **Account**, turn on proximity join via Bluetooth beaconing under **Device** (beaconing is also required to let screen casting to the device work), and set the current theme under **Theming**. The custom theme still requires an upload of the image file to the device as a separate process.

The Teams admin center shows the MTRoW status under **Teams Devices, Teams Rooms on Windows** where administrators can view the health of their devices. If you click on a device, as shown in Figure 14-3, you can see the status of individual components that make up the MTRoW. You can use the [...] menu for each device and mark it as non-urgent, no-impact, critical or reset to default. In this example, you see that the Microphone and Conference speaker have been set to “No impact.” The room is configured to perform coordinated meeting joins with a Surface Hub, so they are not needed. Read more about the management options [here](#).

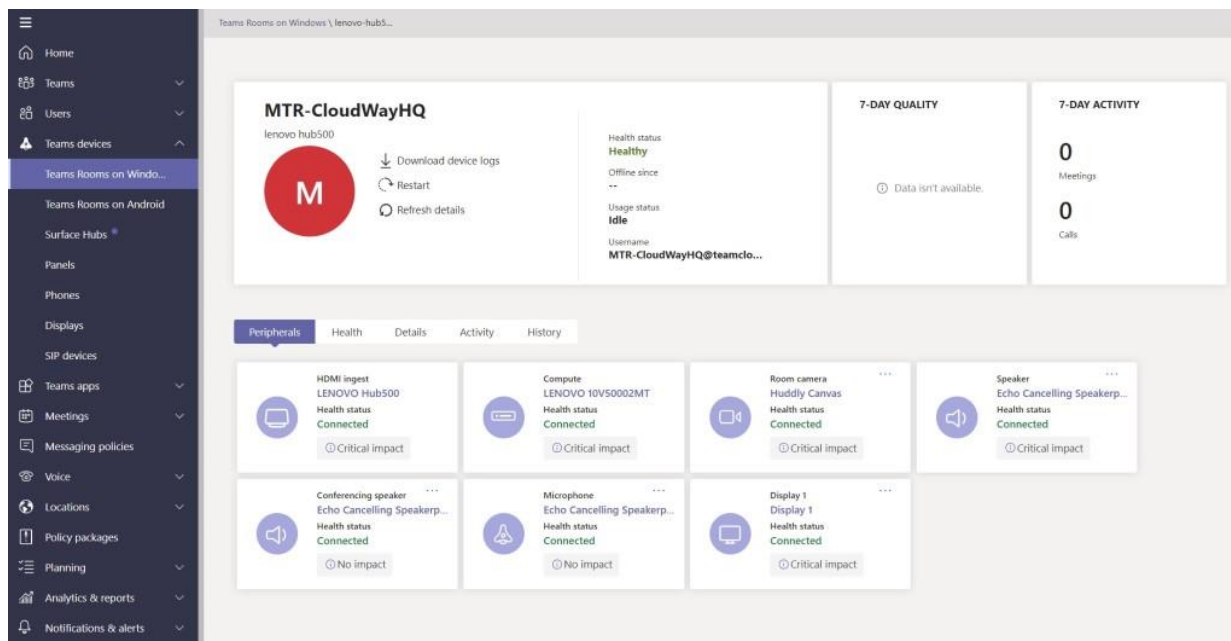

Figure 14-3: MTR management in the Teams admin center

**Note:** MTRoW devices are rebooted every night at 2am local time. During that reboot the device checks for updates, installs any if available and does necessary maintenance. This is a feature to make sure the device functions at peak efficiency. Microsoft wrote a [detailed article](#) about the difference between the quarterly updated Teams Room UWP application, which gets pushed via Windows store, and the Teams web app component which updates at a higher interval with new features.

## Managing Surface Hubs

Surface Hubs are discoverable and available the Teams admin center, but this is a preview feature so subject to change. By going to **Teams devices > Surface Hubs**, you can see the inventory of hubs that have signed into your tenant. You can see the software version and network connectivity and if the devices run the latest software version. If a device is connected correctly, it is marked as healthy. Unfortunately, you cannot publish any settings to the devices, but you can restart them and collect device logs for troubleshooting. Hopefully, more capabilities will be available in the future.

## Remote Provisioning for Teams Android Devices

Remote provisioning lets you safely sign in devices without having to give anyone access to account credentials. To remotely provision a Teams Phone, Teams Panel or MTRoA as a shared device, the MAC address must be added to the Teams admin center. Do this by selecting **Teams devices**, choose the sub-section for the device type you want to add, then in the top right corner click **Actions** and select **Provision devices**. Either add MAC addresses manually or upload a .csv file containing MAC address and location. The menu here contains a CSV template you can download. After adding the MAC address(es), select the phone or

phones and click on **generate verification code**. This will generate a verification code that is used at the initial stage of signing in. Distribute the list of MAC addresses and verification codes to the on-site technicians for deployment.

When the onsite personnel signs into the phone, click on the cog icon in the top right of the device screen. From there they select provision phone and enter the provided verification code. If the operation was successful a welcome screen will then appear. When a Teams phone is successfully provisioned it can be remotely signed in to using Teams admin center.

Go to the same section you just used to add the MAC address, except this time move to the **Waiting for sign in** tab. Select a Teams Android device to which you want to sign in and click Sign in a user. Follow the instructions on the pop-up screen, navigate to <https://microsoft.com/devicelogin> and paste the code. Select which account should sign into this specific phone and please note that it is only possible to sign in using a shared account. This is a great approach as it ensures that no need exists to share the password for the shared account with the onsite personnel. The list of supported devices [is available online](#).

### MTR Notification and Alerts

A default alert rule is available to get notification on changes to MTR health status which can be found in the Teams admin center > **Notifications & alerts** > **Rules**. These rules are near real-time, but you may have up to a 30-minute delay before you get a notification of an MTR being offline or unhealthy. It isn't ideal but does allow you to respond more or less proactively to an incident.

You need to manually add the MTR user accounts to the rule, and there is no PowerShell or Graph API approach to automate this. The monitoring rule looks at all devices the account is signed in to. You can receive the alerts in a Teams channel and/or via a webhook. To configure the JSON for the webhook, check out the docs article [here](#).

### Managing Phone Devices

Traditionally phone devices used to be placed in segregated sections of the network (who remembers the Voice VLAN) where they had direct access to the PBX onsite. While you can still use this technique to separate your phones from user traffic, it can be less helpful as the devices connect over the internet to the Teams service, and generate more than just voice traffic. Therefore, you need to make sure any QoS rules you have for user networks also apply for these devices. Removing this type of VLAN separation can help simplify your overall network topology.

### Networking Considerations

If you use 802.x authentication on your network, the recommendation is to pre-register the MAC addresses for Teams devices so that they can access the network. Most of the devices can be configured with Wi-Fi enabled, but keep in mind that while this might work, it is not technically supported, so you should plan to have ethernet connectivity available to ensure good quality calls. Most of these devices also support Power over Ethernet which helps to reduce cabling requirements.

### Managing IP Phones and Teams Displays

Management of IP Phones is performed in the Teams admin center, under **Teams devices** then **Phones**. There you can differentiate the view on All phones, User phones, Common area phones, and Conference phones. From here you can download device logs, update software and firmware and restart the devices. You can get the details on each device, including MAC address and call history. If you have people who specialize in device management and setup, then the Teams Devices Administrator role gives them access to just this part of the Teams admin center. Be aware that holders of this role do not get access to call history, so combining this role with the Teams Communications Support Engineer could be beneficial.

You can create configuration profiles to make sure all phones have the correct time zone, language, and time format. You can configure device settings such as display screensaver timeout, backlight timeout, and office hours. The recommended network setup on these devices is DHCP, but you can also manually configure network settings.

To assign a configuration policy for multiple devices mark all the devices you want and then assign a configuration policy to them. Sorting by IP address, for example, can help show all devices in one location. Make sure to name the configuration policy to reflect the location you want the devices assigned to, as you need to search for them when assigning. Unfortunately, there is no way to automate this procedure, so you should make this process part of a device onboarding routine.

### Intune and Conditional Access for Teams Phones and MTRoA

As stated earlier, MTRoA devices run Android but are not phones. This means that we need to make exceptions for these devices if Intune and Conditional Access are in use. There are two perspectives to look at when making sure these devices can sign in:

- For IP Phones that are for personal use, administrators should create an Intune enrollment restriction policy to require the preregistration of the serial number in Intune before the devices can enroll. This is how IT can stay in control of which devices can access corporate resources.
- For IP Phones or MTRoA that are for shared use such as Common Area Phones, we need to look at the account signing in to the device in addition to the above enrollment restriction:
  - **Account prefix:** Add a prefix, for example CAP-xxxx so that we can identify them with a dynamic group. We discuss account setup in the configuration part later.
  - **Compliance policy:** Exclude the dynamic group from other policies and require that the device is not rooted.
  - **Enrollment restriction policy:** Target the dynamic group and allow for “legacy” Device Admin management as IP Phones do not yet support Enterprise Admin Device management. It is also recommended that you use a corporate device identifier by pre-registering the serial numbers of the devices to control access to the environment.
  - **Conditional access:** Exclude the dynamic group from all other Conditional Access policies and create a dedicated policy that blocks all platforms except Android and requires a compliant device to bypass MFA. In addition, you can also require that the device logs on from a trusted public IP address so that users cannot take a common area phone home and continue using it.

### Intune and Conditional Access for SIP Gateway

Devices connecting via the SIP Gateway need to bypass conditional access policies because the actual sign in does not happen from the phone but rather from a Microsoft trusted IP addresses (that of the SIP Gateway). You should create a separate conditional access policy and add the accounts you expect to sign in on these devices, be it regular users or common area phone accounts. In this rule you should add the six IP addresses used to sign in the accounts. There are two IP addresses for EMEA, two for North America, and two for APAC. Your organization might only need to sign in from one or two regions, which means you can limit the authorized set. Review the current IP addresses [here](#).

### SIP Gateway Registration

You can get a full list of all SIP devices logged in to your environment through the Teams admin center by going to **Teams devices** and **SIP devices**. From here you can provision new devices by adding the MAC addresses to make sure that only devices approved by administrators can sign in. Limited capabilities are available to manage these devices: you can restart the device and see if the device is signed in. No configuration policies are available. You cannot define the device’s language as this is done by appending a

code string at the end of the registrar URL (read about supported languages and find the code [here](#)). To sign into a device the following conditions must be met:

- The user must have a Teams and Phone System license (or Common Area Phone license).
- The user must be assigned a phone number through Direct Routing, Operator Connect or Calling Plan.
- SIP devices used for calls must be enabled in the Teams Calling policy assigned to the users.
- MAC address must be pre-registered in the Teams admin center under **SIP devices**.
- URLs and IP ranges must be opened in the network where the phone is located (documented [here](#)).

The PowerShell code below is an example of creating an appropriate Calling policy. Note that these phones depend on call redirect, which must be set to enabled.

```
[PS] C:\> New-CsTeamsCallingPolicy -Identity "SIPPhones" -AllowSIPDevicesCalling $true
-AllowCallRedirect Enabled
```

After registering the MAC address of the devices, assigning the correct licenses and calling policy to user accounts they are ready to sign in. The device must be set up with the correct registrar address, either through DHCP or manually. The registrar addresses for each region are documented [here](#). When the user signs in, a pairing code appears and the user must navigate to the URL shown, type in the pairing code, and sign in using their credentials. For Common Area Phones, the process is the same, except that an administrator can perform the final sign in steps from the Teams admin center as these are special accounts.

### Configuring Common Area Phones

The Teams IP Phone policy, *CsTeamsIPPhonePolicy*, applies configuration settings specific to Teams common area phones. Available policy settings are:

- **AllowHomeScreen** – A Teams phone home screen displays a summary of contacts and future meetings.
- **AllowBetterTogether** – When connected to a computer it will sync the users' settings and experience.
- **AllowHotDesking** - Allows for any user in the organization to temporarily sign into the phone enabled with this feature.
- **HotDeskingIdleTimeoutInMinutes** – How long before a temporary logged in user will be logged out.
- **SignInMode** - Determines the sign in mode/experience for the phone: User, CAP, or Meeting room.
- **SearchOnCommonAreaPhoneMode** - Determines whether it is possible to search the Global Address List when CAP sign in mode is set.

You may not want to enable hot desking on CAP devices since there is a long timeout. By default, the timeout is 120 minutes. If the user goes to lunch and the phone remains signed in as that user, then anyone can answer calls or make calls on behalf of this user. Therefore, you might want to consider any risks of enabling hotdesking for CAPs.

To disable it, use this command:

```
PS C:\> New-CsTeamsIPPhonePolicy -Identity "CAPNoHotDesking" -SignInMode CommonAreaPhoneSignIn
-AllowHotDesking $false -SearchOnCommonAreaPhoneMode Disabled -AllowHomeScreen Disabled
-AllowBetterTogether Disabled
```

As you see, we disable *SearchOnCommonAreaPhoneMode* so that those using the phone do not have access to search in the Teams global address list. To apply an IP Phone policy to a CAP account, use the *Grant-CsTeamsIPPhonePolicy*:

```
PS C:\> Grant-CsTeamsIPPhonePolicy -Identity CAP-MainOffice@office365itpros.com -PolicyName
CAPNoHotDesking
```

# Troubleshooting and Monitoring Calls

So far, we have covered a lot of technical details about calling configuration, devices types and setup, as well as how to prepare your environment to support calling. Lastly, we will talk about how to keep on top of all these things, looking at what tools are available to help pro-actively monitor and troubleshoot any issues as and when they occur.

## Validating functionality for Teams Phone

When implementing Teams Phone it is important to test all features you are expecting to use before making it widely available. The goal is to find niche scenarios that do not work as intended as it can be difficult to troubleshoot when the system is fully live.

You should develop a structured testing process to document what is tested, how it was tested, what the result was. Then you will have a good overview of what was working when telephony was implemented. If it should stop working at some point, you know how it was working initially. Typical scenarios you want to verify when testing include:

- Normalization of numbers per country and region when dialing out.
- Forwarding and transferring of calls to mobile phones or Teams users.
- That your PSTN usages are working as expected, for instance, restricting calls to premium numbers.
- Verify that you can have calls longer than 30 minutes when using Direct Routing, sometimes, firewall filtering can interfere with the call and disconnect long calls.

Having a structured test to verify call handling may save you a lot of time further down the road. For example, when you know it was working initially but has stopped working, you know something may have changed to break the feature. You can find a very basic sample test schema [here](#), which focuses mainly on Direct Routing testing, but can be adapted to Calling Plans.

## Troubleshooting Teams Phone for Users

There are a lot of settings that need to be in place for telephony to function. Users must have the correct policies, the right set of licenses, and the correct settings in Azure Active Directory. This PowerShell one-liner will help you gather the key information you need for an account so that you can evaluate a user's settings all in one go:

```
[PS] C:\> $user="stale.hansen@office365itpros.com"

[PS] C:\> Get-CsOnlineUser $user | Format-List UserPrincipalName, DisplayName, SipAddress,
OnlineVoiceRoutingPolicy, TenantDialPlan, DialPlan, TeamsVideoInteropServicePolicy,
TeamsUpgradeEffectiveMode, EnterpriseVoiceEnabled, AccountEnabled, LineURI, OnPremLineURI,
FeatureTypes, TeamsCallingPolicy, UsageLocation, City, HostingProvider, InterpretedUserType

UserPrincipalName           : stale.hansen@office365itpros.com
DisplayName                 : Stale Hansen
SipAddress                  : sip:stale.hansen@office365itpros.com
OnlineVoiceRoutingPolicy    : AzureSBC1
TenantDialPlan              : US-NY-NewYorkCityZone01
DialPlan                    : US
TeamsVideoInteropServicePolicy : PexipServiceProviderEnabled
TeamsUpgradeEffectiveMode   : TeamsOnly
EnterpriseVoiceEnabled       : True
AccountEnabled              : True
LineURI                     : tel:+19175428xxx
OnPremLineURI               : tel:+19175428xxx
FeatureTypes                 : {CallingPlan, AudioConferencing, Teams, PhoneSystem}
TeamsCallingPolicy          :
UsageLocation                : US
```

```
City : New York
HostingProvider : sipfed.online.lync.com
InterpretedUserType : PureOnlineTeamsOnlyUser
```

Let's go through each attribute and discuss how to validate them:

- **UserPrincipalName:** This is the UPN of the user as found in Azure AD.
- **DisplayName:** Not much can go wrong here, it is based on *DisplayName* as set in the Azure AD account.
- **SipAddress:** The SIP address is based on UPN. If you see that the SIP address is not populated, then it may be that another user is configured with the same SIP address. Use the following cmdlet to locate the user:

```
[PS] C:\> Get-CsOnlineUser | Where-Object {$_.SipAddress -match "stale.hansen@office365itpros.com"}
| Format-List UserPrincipalName, DisplayName, SipAddress
```

You can manually overwrite the SIP address by populating the *SIP:ProxyAddresses* value in Exchange or the *msRTCSIP-PrimaryUserAddress* in AD.

- **OnlineVoiceRoutingPolicy:** To be able to dial out via Direct Routing, this attribute must be populated with the correct policy. To assign the correct value, use the following cmdlet:

```
[PS] C:\> Grant-CsOnlineVoiceRoutingPolicy -Identity $user -PolicyName "AzureSBC2" -Verbose
```

- **TenantDialPlan:** Make sure the correct *TenantDialPlan* is set on the user. This setting is configured manually. A good attribute to match with is the *UsageLocation* or *City*, depending on if you have multiple locations in the same country:

```
[PS] C:\> Grant-CsTenantDialPlan -PolicyName "US-NY-NewYorkCityZone01" -Identity $user -Verbose
```

- **DialPlan:** This is the default dial plan assigned to the user based on the *UsageLocation* attribute. If it is blank and *UsageLocation* is set correctly, make sure the user has a Phone System license assigned.
- **TeamsVideoInteropServicePolicy:** To make sure users get the correct CVI settings in their meeting invite if it is configured in the tenant. Set one of the three correct policies if you need to:

```
[PS] C:\> Grant-CsTeamsVideoInteropServicePolicy -PolicyName PexipServiceProviderEnabled -Identity $user -Verbose
```

- **TeamsUpgradeEffectiveMode:** This shows the mode the user is in, all the modes are documented [here](#), and to use Teams Phone should be set to TeamsOnly. To set the correct mode, run the following command:

```
[PS] C:\> Grant-CsTeamsUpgradePolicy -PolicyName UpgradeToTeams -Identity $user
```

- **EnterpriseVoiceEnabled:** If it is set to false, ensure the user has a Phone System license. If you migrate from SfBS and the user was disabled for enterprise voice, but should be enabled online, this attribute is still set to false. To enable the user, run the following command:

```
[PS] C:\> Set-CsPhoneNumberAssignment $user -EnterpriseVoiceEnabled $true
```

- **AccountEnabled:** indicates if the account is enabled for login in Azure AD. If the account is disabled, you can enable the user with the following command (after connecting with *ReadWrite* Graph API permissions):

```
[PS] C:\> Update-MgUser -UserID $user -AccountEnabled:$true
```

- **LineURI:** Defines the actual telephone number a user has and shows when dialing out from Teams. If you use Direct Routing, this attribute is synced with *OnPremLineURI*. If the *LineURI* attribute does not

sync, validate that the user is not also assigned a Calling Plan in addition to using Direct Routing. If Calling Plan is used, use this cmdlet to set the correct phone number:

```
[PS] C:\> Set-CsPhoneNumberAssignment -Identity $user -PhoneNumber +15555428572 -PhoneNumberType CallingPlan
```

- **OnPremLineURI:** Is the phone number provided to the user through Direct Routing. If you have migrated from SfBS to Teams, you need to clear out the *msRTCSIP-Line* attribute in Active Directory.

```
[PS] C:\> Get-ADUser -Filter "UserPrincipalName -eq '$user'" -property * | Set-ADUser -clear 'msRTCSIP-Line'
```

Wait until Azure AD Connect has synced the setting to Azure AD and then set the phone number using *Set-CsPhoneNumberAssignment*, which almost instantly populates the number. After the attribute is cleared, you can use the *Set-CsPhoneNumberAssignment* cmdlet to manage phone numbers. The *PhoneNumberType* option defines the source of the assigned number, this can be either *CallingPlan*, *OperatorConnect* or *DirectRouting*.

```
[PS] C:\> Set-CsPhoneNumberAssignment -Identity $user -PhoneNumber +15555428572 -PhoneNumberType DirectRouting
```

- **FeatureTypes:** Shows an array of values depending on what features are enabled. Values you may expect to see here include; Teams, AudioConferencing, PhoneSystem and CallingPlan. This tells you what features Teams thinks a user has activated.
- **TeamsCallingPolicy:** Defines the calling policy assigned to the user which defines calling features such as voicemail.
- **UsageLocation:** Based on *UsageLocation* in Azure AD. This attribute affects Calling Plan availability and the default dial plan that is assigned to the user. Use the *Update-MgUser* cmdlet to update the *UsageLocation* attribute:

```
[PS] C:\> Update-MgUser -UserID $user -UsageLocation GB
```

- **City:** A typical location defining attribute. A great way to determine which *UsageLocation* to assign to the user account.
- **HostingProvider:** If a different value than sipfed.online.lync.com is found here, the user is considered an on-premises user. If you have migrated all users online and decommissioned your on-premises environment, use this Active Directory PowerShell cmdlet to clean up the attributes for SfBS. First, to check the current value of the attributes:

```
[PS] C:\> Get-ADUser -Filter "UserPrincipalName -eq '$user'" -property * | Format-Table 'msRTCSIP*'
```

Clean up at least the *DeploymentLocator* attribute. The *PrimarySIPAddress* should remain as it helps the SfB client with SSO the first time a PC logs on. *LineURI* should remain as it is the user phone number when using Direct Routing:

```
[PS] C:\> Get-ADUser -Filter "UserPrincipalName -eq '$user'" -property * | Set-ADUser -clear 'msRTCSIP-DeploymentLocator'
```

- **InterpretedUserType:** This is a great source of information on the state of your user in a hybrid environment and pure online environment. Microsoft has added more states to this attribute, and it is possible to show its value in the Teams admin center in the user view. This [GitHub article](#) has descriptions of the different states for this attribute. For instance, it may show that the user is a disabled user in the local Active Directory, configured as an on-premises user when it should be an online user. It will also show if you are missing the correct licenses. If the user shows as *HybridOnpremSfBUser* when it should be a *DirSyncSfBUser* user, it may be an indicator of residual SfBS

attributes. To see the SfBS attributes for a user, run this command on a server that has the Active Directory PowerShell module installed:

```
[PS] C:\> Get-ADUser -Filter "UserPrincipalName -eq '$user'" -property * | ft 'msRTCSIP*'
```

It is a best practice that all attributes, except *msRTCSIP-PrimaryUserAddress*, should be cleared out. *msRTCSIP-PrimaryUserAddress* is used by the SfB client to discover the user's SIP address and populates the Sign-In address for newly deployed PC's. If *Disable-CsUser* was not run as part of decommissioning SfBS when moving online, these attributes are still populated. Here is how to clear out the common msRTCSIP attributes, make sure you capture all *msRTCSIP-Line* values if they are configured, so that you can configure users online with the same number:

```
#Get all msRTCSIP properties for a user that has a value
[PS] C:\> $Properties = Get-ADUser -Filter {UserPrincipalName -eq
"stale.hansen@office365itpros.com"} -Properties * | Select-Object -Property 'msRTCSIP*'

#Clear all properties for a user
[PS] C:\> Get-ADUser -Filter {UserPrincipalName -eq "stale.hansen@office365itpros.com"} -Properties
* | Set-ADUser -clear ($Properties | Get-Member -MemberType "NoteProperty" | % { $_.Name })
```

**Note:** Sometimes, users might complain about not seeing a dial pad for Teams Calling in their client. There could be multiple reasons for the problem. After enabling calling for a user, it can take up to 72 hours before all the settings synchronize across Microsoft 365 and another 24 hours before the desktop clients receive the new policies. If your users are in a hurry, ask them to check if a dial pad appears in the web client. If it is not there, refer to [the documentation](#) to make sure all necessary settings are present. There is even an administrator test button available to run a self-diagnostic test in the Microsoft 365 admin center.

## Call Quality

To succeed with a Teams voice deployment, you need to make sure calls are properly connected and that call quality is good. What constitutes good call quality? This is highly subjective, but packet loss, jitter, and latency are key network metrics you can measure. At the start of this chapter, we covered basic best practices for approaching your networking setup, but here we are going to go deeper into how Teams actually uses the network. This is where Teams gets challenging to understand and master, but luckily there are several tools available that we can work with, such as the Network Assessment tool, Call Quality Dashboard, and Call Analytics, that can help. These are all covered in the final section of this chapter.

### Understand Signaling and Media

Every call has two parts, signaling and media. Signaling is the part that manages your call such as establishing, maintaining, and terminating it. The concept used in Teams for signaling is the same as SfB, even if the protocol differs. SfB uses the Session Initiated Protocol (SIP) while Teams uses HTTPS REST signaling. Media communication is still based on UDP and travels as directly as possible between endpoints in all scenarios.

In 1-to-1 calls, media will try to go directly between the clients after signaling is established. For clients on the same corporate network, or subnet, this is likely to succeed as shown in Figure 14-4. Voice and video here will have a higher chance of being good quality with fewer packet drops than when passing through the internet.

Figure 14-4: Signaling goes via the Call Control and media goes directly between the clients

In 1-to-1 calls where media cannot go directly, because a firewall is between subnets or one user is external, the media will be relayed as shown in Figure 14-5.

Figure 14-5: Signaling goes via the Call Control and media goes via the relay service in Azure

In an ad-hoc multiparty call with more than two participants or a scheduled meeting, the media will go to the conferencing service as shown in Figure 14-6. Regardless of who is invited to the scheduled meeting, the first participant to join the call dictates where the conference is hosted. For instance, if you have three participants in the US and 10 participants in the EU and a US participant joins first, the conference will be hosted in a US data center, and all 10 EU participants must join the call hosted in the US.

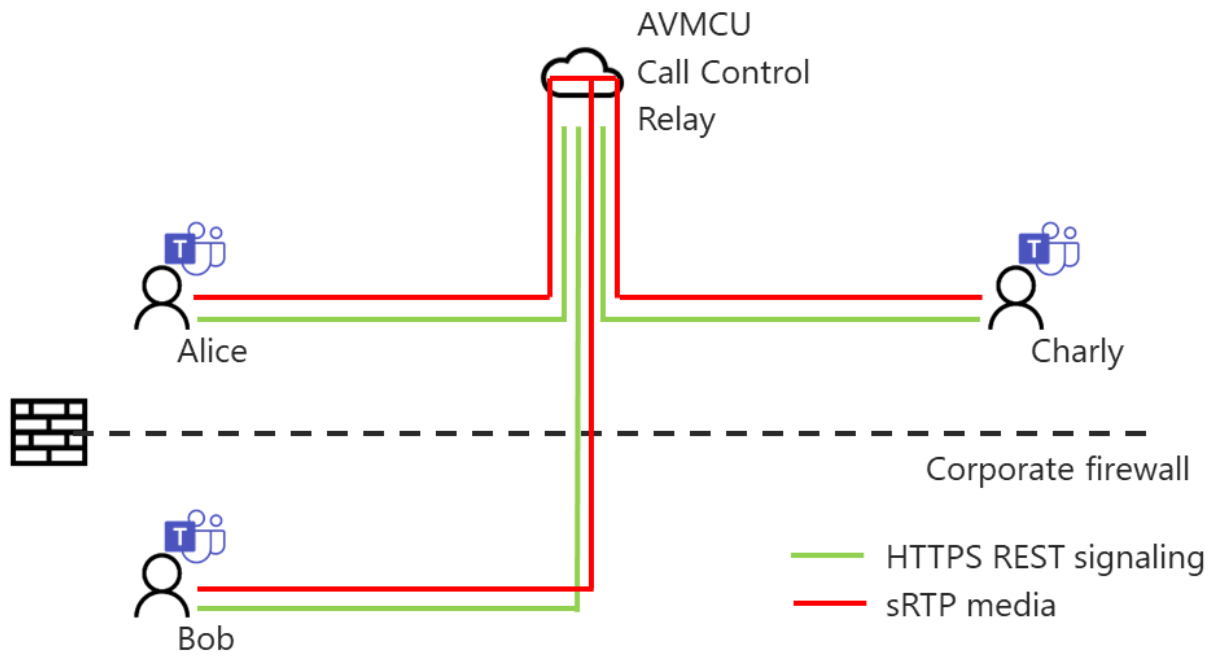

Figure 14-6: Signaling goes via the Call Control and media goes to the AVMCU where the first joiner is homed

If you have a VPN configured, you could see what effect this would have on the traffic. For example, in Figure 14-6, Alice's media traffic must first come inside the firewall before going to the AVMCU. The best practice for Teams is to separate the Teams media traffic to go outside the VPN tunnel wherever possible. The traffic that Teams puts out on the network is always encrypted and so does not need the additional protection of a VPN tunnel as this just adds overhead to the packets (for processing and hops).

If you must use a VPN try to at least allow the Teams Optimize media ranges to go outside the VPN tunnel and keep in mind, those are just IP ranges and do not have URLs associated.

### Codecs and their impact

There are four codecs used for Teams depending on the scenario and devices used on either end of the connection:

- **Satin** is the primary codec for 1-to-1 calls and soon for meetings. It uses AI to optimize for high quality under high packet loss and starts at a bit rate for wideband voice at 6 kbps. At 17 kbps it can produce full-band stereo music. Check this [article](#) for some audio samples.
- **SILK** is the primary codec in meetings and is both wideband and narrowband across clients except for Edge and Chrome.
- **G.722** is the secondary codec that is available in all scenarios across clients.
- **G.711** is the secondary codec in PSTN calls.

Table 14-1 shows the typical bandwidth usage of Teams codecs, however Microsoft has not released data statistics for Satin yet.

**Note:** Forward Error Correction is when you start having packet loss in the network and Teams compensates by sending overlapping information per packet over the network so that we lose less information per packet lost.

<b>Audio codec</b>	<b>Scenarios</b>	<b>Audio payload bitrate</b>	<b>Bandwidth Payload, IP header UDP, RTP</b>	<b>Bandwidth payload, IP header, UDP, RTP, SRTP</b>	<b>Bandwidth Payload, IP header, UDP, RTP, SRTP, Forward Error Correction</b>
SILK Wideband	Meetings	36.0	52.0	64.0	100.0
SILK Narrowband	Meetings	13.0	29.0	41.0	54.0
G.722	Secondary in all	64.0	80.0	95.6	159.6
G.711	PSTN	64.0	80.0	92.0	156.0

Table 14-1: Teams and codec bandwidth in kbps for audio

Video is based on X.264 and hasn't changed much in recent years, Teams can scale video by resolution and framerate. Resolution may vary based on the screen the participants use in the meeting and the resolution they request. Each client sending video will send a stream to the Teams service at the best quality that can be supported (or is needed). The participating clients in the meeting then request different quality streams from the server depending on what layout is being shown to the user, for example there is no point in the client requesting a full 30FPS 1080p video feed from all users when they are only being shown as thumbnails alongside a screen share. Usually, the more participants there are in the meeting, the smaller the requested video gets as the more thumbnails are being displayed.

You only see an option for Large Gallery view when more than 10 people are in a meeting. In gallery view the meeting service stitches together the video streams from participants and then sending one video stream of this combined image to the users client.

Screensharing is done by Teams using Video Based Screen Sharing (VbSS), which means that the share is another video stream in the meeting that is handled differently when displayed by the client.

PowerPoint decks can still be presented through the Office Online Server and are not video based, so PowerPoint content is not recorded when using Cloud Recording.

Table 14-2 shows some video scenarios and potential bandwidth when using a 1080p resolution. Be aware of the equipment your users are using and where most of them may run video meetings and make sure you scale available bandwidth to anticipate the estimated load. This is where the network planner will help.

<b>Participants/Activity</b>	<b>Max resolution</b>	<b>Total max download bit rate</b>	<b>Total max upload bit rate</b>
2 Participants	1 * 1920x1080	4	4
3 Participants	2 * 1920x1080 (Full Bleed) 2 * 1280x720	8 5	6.5
4 Participants	1 * 1280x720 + 2 * 960x540	5.5	4
5+ Participants	4 * 960x540	6	1.5
Video Based Screen Sharing (Only)	1 * 1920x1080	4	4
N Participant + VBSS [N=0-4]	1 * 1920x1080 + N * 424x240	4 + (N*350 Kbps)	~4.34

Table 14-2: Teams and bandwidth for video (bit rate in Mbps)

Keep in mind that when Teams uses the large gallery and together mode in meetings, it is one video stream.

## Network Factors Affecting Voice Quality

Network metrics such as packet loss, jitter, and latency affect voice quality. These network metrics affect real-time media and are experienced in different ways.

Users experience packet loss in two ways. If you hear metallic and variable sound quality, it can be caused by random packets being dropped. Sometimes you may hear the person talking go silent for several seconds, which is caused by burst loss of packets, where contiguous packets are lost.

**Packet loss** is typically caused by transmission errors and router congestion. If contiguous packet loss exceeds 10 seconds, the call may be disconnected. This is typically a problem over Wi-Fi that is designed for access and not throughput. Especially if you walk around with an active call and need to switch access point, the handover time may be too long, and the call gets disconnected.

**Jitter** is caused by packets arriving in a different order than the order they were put on the network and with longer intervals. It is typically caused by packet taking different routes due to load balancers or re-direction due to router congestion. You experience jitter when you hear a short silence and then hearing the person talking faster than normal. That is the Teams client buffering packets and playing them back when enough packets have arrived. If there are more than 20 ms between packets the audio healer will start dropping packets and the experience will be the same as packet loss.

**Latency** is the time it takes for a packet to travel from the sender to the receiver. When measuring latency, it is important to put the result in context. Latency higher than 100 ms within the same country is not good. A latency of 150 ms across continents is very good. Latency is typically caused by distance, queuing, and buffer overflow on the network. You experience latency when people you talk to on a call seem to take a long time to answer. A call with a lot of latency can be quite difficult to manage and those on the call may end up talking at the same time.

Table 14-3 shows the target network metrics in an unmanaged network, which include all the locations the network administrator has no control over such as the internet, home office, or favorite coffee shop. Table 14-4 shows the target network metrics in a managed network, typically inside corporate offices. Meeting these network metrics is important to meet user expectations of good voice quality and dependent stability of calls. We look at managed networks in two scenarios, where the users are and the corporate network edge. The goal is to know when it is an internet problem or where it is a local network problem.

<b>Unmanaged Network Voice</b>	<b>Optimal</b>	<b>Acceptable</b>	<b>Poor</b>
Inter arrival packet jitter (average)	≤ 5ms	≤ 10ms	> 10ms
Inter arrival packet jitter (maximum)	≤ 40ms	≤ 80ms	> 80ms
Packet loss rate (average)	≤ 1.0%	≤ 5.0%	> 5.0%
Network latency one-way	< 100ms	≤ 100ms	> 100ms

Table 14-3: Unmanaged network targets

<b>Managed Network Voice</b>	<b>Teams client to Microsoft network edge</b>	<b>Corporate edge to Microsoft network edge</b>
Latency (one-way)	<50 ms	<30 ms
Latency (round-trip)	<100 ms	<60 ms
Burst packet loss	<10% during any 200 ms interval	<1%
Packet loss	<1% during any 15s interval	<0.1% during any 15s interval
Packet inter-arrival jitter	<30ms during any 15s interval	<15ms during any 15s interval
Packet reorder	<0.05% out-of-order packets	<0.01% out-of-order packets

Table 14-4: Networking requirements for Teams media in managed networks (source: Microsoft)

## Teams and QoS Tagging

Two QoS port ranges are used for Teams, 1-to-1 port ranges and meeting port ranges. 1-to-1 calls use the port range of:

- Audio using TCP/UDP: 50,000-50,019
- Video using TCP/UDP: 50,020-50,039
- Screen Share using TCP/UDP: 50,040–50,059

As well as using network based tagging, for your windows clients you can create a GPO to make Windows apply DSCP tags against the Teams.exe client. You can add different markings for audio, video, and screen sharing. Audio is typically DSCP value 46 which is the highest priority.

If you use Direct Routing with Media Optimization, the audio port range is UDP 50,000 to 59,999 and the traffic goes directly to the SBC. In the future, media bypass ports may change to 3478 and 3479.

Conference media traffic goes via the Teams media relay services in Office 365. Some of that transport is over the internet, but you are still able to add QoS tagging and prioritize the traffic while it is in the internal network. All media that goes via the Teams media relay use port UDP 3478 by default. To separate audio, video, and screen sharing traffic you need to go to the Teams admin center, **Meetings**, and **Meeting settings**, and turn on **Insert Quality of Service (QoS) markers for real-time media traffic**.

When this is done, port 3479 will be used for Audio, 3480 for video, and 3481 for screen sharing. The QoS markings will be persistent if used with ExpressRoute and traffic from Android, iOS, and Mac clients will have DSCP tagging on these ports. Read more about QoS for Teams [here](#).

**Note:** The [Media in Teams - Media Flow YouTube video](#) does a great job of explaining Teams and network impact and routing in detail.

## Monitoring and Validating Call Quality

Teams includes two ways to monitor and troubleshoot call quality problems: Call Analytics and Call Quality Dashboard (CQD). Call Analytics is meant for reviewing call quality for individual calls and you can see and explain why a call was experienced as poor. You get information about what equipment was used, if it was a wired or wireless call, and information on network metrics. CQD is meant to look at trending quality within your environment. CQD has a separate portal, found in the Teams admin center, but the CQD reports are best consumed via Power BI reports as described at the end of this chapter.

### Reporting Teams Phone Activity

When an organization uses Teams Phone, you will want to report on how people are calling, by understanding your usage you can make sure you are not paying too much for your PSTN services. A usage report of PSTN calls for Calling Plans and Direct Routing is available in the Teams admin center. The report is good, but you can also access the data programmatically to create custom reports. You can do this using the *callRecord: getPstnCalls* API (documented [here](#)). The information retrieved includes who called, duration, dial plan used, and destination, amongst other attributes. You might be unfamiliar with the Graph API, but the Teams community is here to help you out. You can find a PowerShell script to get this data [here](#) and a PowerShell module to simplify access to the data [here](#).

### Call Analytics

Call analytics, which can be accessed from the Teams admin center by going into **Users, Manage users** and then in a users details picking **Meetings & calls**, shows the users most recent calls and meetings. Call analytics focuses on single calls and meetings, providing a detailed analysis of the selected call or meeting for issue resolution by the helpdesk and requires one of the Teams Administrator, Teams Communications Support Specialist, or a Teams Communications Support Engineer roles.

You can analyze four core areas:

- **Device** shows you specific information about the capture and renders device the user was using during this call, and you can determine if it was a Teams certified device.
- **System** shows you system statistics such as OS and client patch level.
- **Connectivity** tells you how the system is connected, for example, via Wi-Fi.
- **Network** shows you networking statistics such as packet loss, jitter, and delay.

Figure 14-7 shows an example of the report where we see a good call where network performance is acceptable. The report shows you real actionable statistics in each category described above. You can use what you have learned here to analyze the metrics collected.

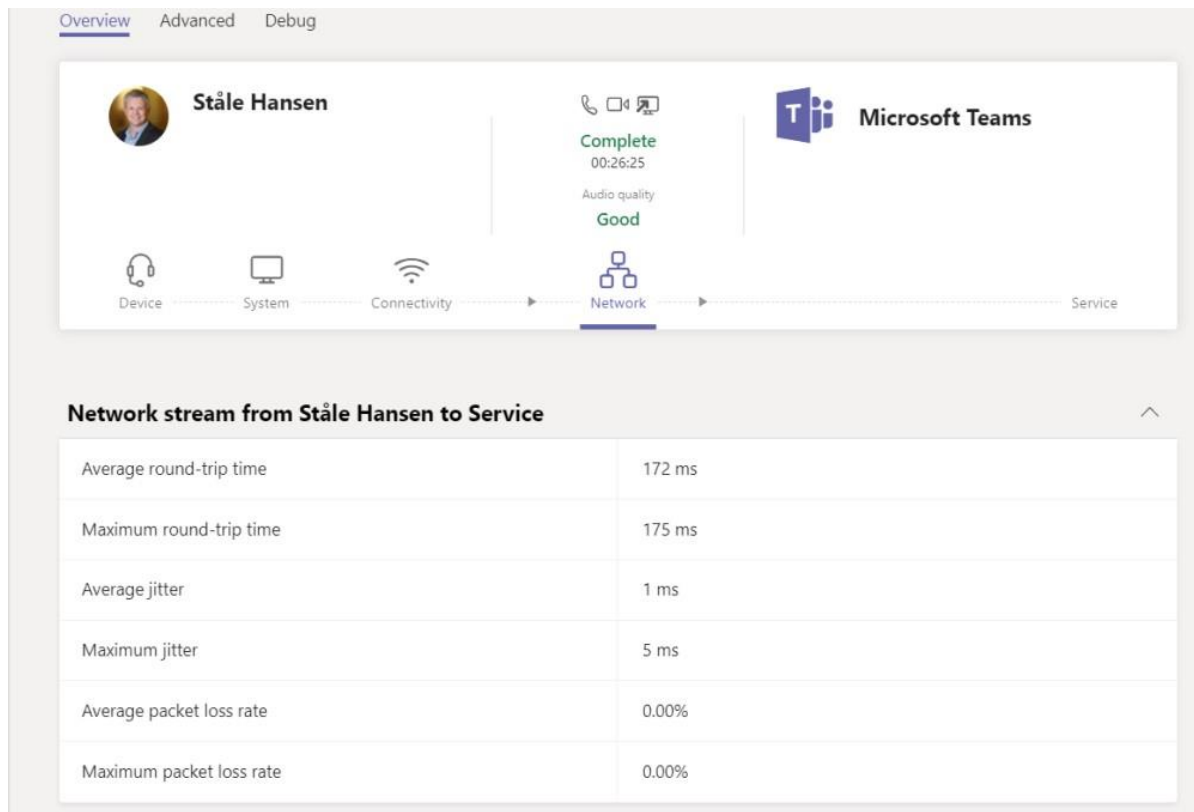

Figure 14-7: Call Analytics example of a conference call

Analyzing the metrics, you can tell the user why the call failed, whether it was because of packet loss on a Wi-Fi connection or if they used an unsupported audio device. You can also use the data to investigate further trending on the network location or the user's driver version. The report highlights poor calls for individuals and is only good for investigating individual calls. If you want to review further trends in your subnets, you should use the Call Quality Dashboard.

You can also see near real-time statistics for meetings when a user is in them. From the same part of Teams admin center with a user selected under **Meetings & calls**, any active meeting is highlighted as **In progress** and from there you can see user network metrics using the **Real-Time Analytics** capability. Having access to real-time information about calls allows the IT/Helpdesk to deliver live support during high stakes meetings. The data you will see is jitter, latency, packet loss, and frames per second for audio, video, and screen sharing. Based on this insight it is possible to take immediate action during meetings or use it as an active troubleshooting tool. There are some known real-time limitations which you can read more about [here](#).

You can also find a **Call Health** feature in the Teams client when in a call. This is accessed via the **More** menu. Here you can verify what codec is used, compare the network metrics to the guidelines in Table 14-4 and dive into details broken into four categories: Network, Audio, Video and Screen Share. Be aware that this

information is only what your client sends and receives and is not a total overview of all participants in the call.

**Note:** Users should be encouraged to use the **Make a test call** feature in the Teams client under **Devices** in the client **Settings** menu before meetings or important calls to verify that your sound is working properly.

## Call Quality Dashboard

Call Quality Dashboard (CQD) is a tool that helps you identify and troubleshoot trends in your organizations calling usage. It is there to capture symptoms and help you get a feel of the solution and where to focus your improvement efforts. As such, you should try and build a habit of exploring CQD at least once a month as part of your maintenance processes. If you have only recently deployed Teams or added a new workload such as telephony then you should be doing more regular weekly reviews to ensure things are working smoothly.

CQD is accessed via its own [URL](#) and is also found under **Analytics & reports** inside Teams admin center. All Teams admin roles can access CQD, which updates on average every 30 minutes. Due to compliance reasons, Personally Identifiable Information (PII) data is kept for only 30 days, and all other CQD data is available for up to 90 days.

CQD is all about streams. A stream is a one-way direction of a media modality in a call. You can have multiple streams within a call, so the number of streams in a location is much higher than the number of calls. It is dependent on how many users were in the call and how many streams there were per user. The streams are classified into three categories which are Good, Poor, and Unclassified. The percentage of poor streams indicates how many of the total streams were graded as poor. However, make sure the total stream count is significant, or this can throw out the average. Unclassified streams are too short to collect data or calls with federated parties. Data from federated parties is not visible inside your tenant. Figure 14-8 shows a summary report from the CQD portal, showing the overall number of streams for any given month.

Figure 14-8: All Audio Streams default report in CQD

A good place to start is looking at the Quality of Experience Reports. Here you can follow a breakdown of calls split by those with quality issues or reliability problems. Each section lets you dig into calls by type, such as conference, 2-party or PSTN calling. From the previous section on Call Quality, you should now be able to help identify where issues may be on the network. One sub-report here that can be particularly useful is TCP Usage. If you see a high volume of TCP traffic in your media calls, this indicates something is blocking Teams traffic. Teams always tries to use UDP for media first.

While you should be aiming to drive down the overall percentage of poor calls, it is unlikely that you will get it close to zero. Quite simply, too many factors can influence call quality and too many scenarios where users

are making calls. An administrator's job is to optimize as many of these factors as possible. Having a poor percentage figure below 4% means you are doing a good job.

**Note:** When working with CQD you will see two sets of most metrics. Anything generated by the server (so Teams) is always referenced as "first" and the client as "second" so when working with filters make sure you use the "Second" value, for example, *Second Building Name*.

### What classifies as a poor stream?

Five factors are evaluated to determine if a stream is considered poor, these are slightly different to the metrics we used previously for call troubleshooting. The stream is classified poor if one or all metrics are above the threshold shown in Table 14-5. These metrics are higher than what is considered bad, this way you know that a poor stream was terrible. Degradation average is when the network gets worse during a call, if the degradation average is above 1 you have an unstable or constrained network, look for routers or switches that are underperforming or overloaded Wi-Fi. Ratio Concealed Average is a technique used to compensate for dropped network packets, and the Ratio (%) is the percentage of packets concealed in a call.

<b>Network Metrics</b>	<b>Poor Stream</b>
Packet Loss Rate	> 10%
Round Trip Time	> 500 ms
Jitter	> 30 ms
Degradation Average	> 1
Ratio Concealed Average	> 0,07 (7%)

Table 14-5: Network metrics and poor streams

**Note:** If you want to learn more about CQD customization, the SOF CQD training videos found on the [Skype for Business YouTube channel](#) are highly recommended and are still relevant in a Teams setting.

### Implement Power BI reports to view CQD Data

Microsoft has released a set of Power BI reports to view CQD data. These reports are better and more usable than the native CQD reports to look at trending data and give the helpdesk a better tool to look at call quality. The Power BI reports connect directly to the CQD dataset and may be a bit slow because of that, but they give valuable information, so it is worth the wait. To view the CQD data in Teams via the Power BI reports, you need to have one of the below admin roles assigned.

- Global Administrator
- Global Reader
- Teams Service Administrator
- Teams Communications Administrator
- Teams Communications Support Engineer
- Teams Communications Support Specialist
- Reports Reader

Note that the Teams Support Specialist and Reports Reader roles do not have access to see PII data such as SIP address and telephone numbers. The available reports are:

- CQD Helpdesk Report
- CQD Location Enhanced Report
- CQD Mobile Device Report
- CQD PSTN Direct Routing Report
- CQD Summary Report
- CQD Teams Utilization Report

- CQD User Feedback (Rate My Call) Report

The helpdesk report as shown in Figure 14-9 is especially useful for day-to-day support. To get started with the reports you can download them [here](#). There is a detailed instructions in the zip file which you can follow, you can also follow the instructions in this [blog post](#).

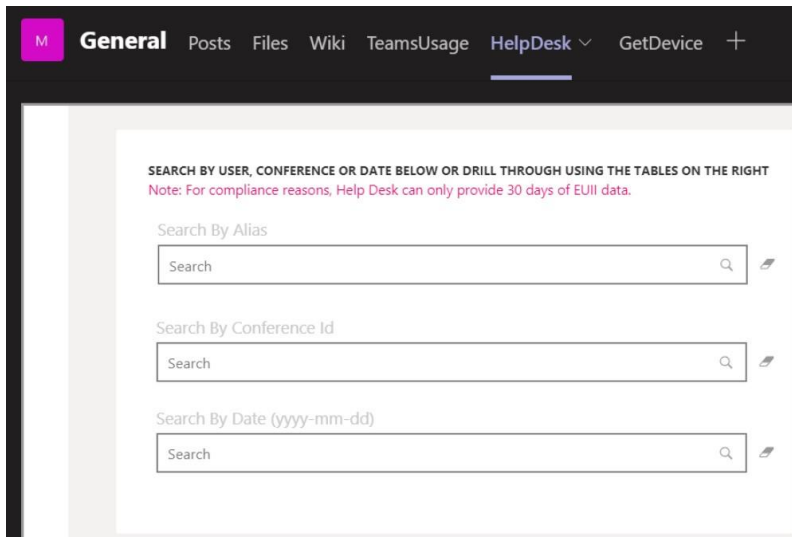

Figure 14-9: The CQD Helpdesk Power BI report in Teams

One important report is missing. This is an overview of all audio devices used in your environment as shown in Figure 14-10. As we mentioned earlier, Teams certified headsets should not be considered optional! We have created a report that shows all devices used in Teams and you can even drill down on specific users and see what devices they are using. We are looking at Audio Call Count and Second Capture Dev to accomplish this. You can download the CQD Get Device report [here](#). Follow the same procedure as for the CQD reports to publish this report to Teams. The report is provided as-is and you may see duplicate device entries in the report. When you have an overview of which devices are being used, you can see if it worth creating more user training to increase awareness around using certified for Teams devices.

Audio Call Count	Second Capture Dev
506	Sennheiser BTD 800 USB for Lync
471	Sennheiser SDW 5 BS - EU
365	Sennheiser SDW 3 BS - EU
297	Headset Microphone (Sennheiser BTD 800 USB for Lync)
290	Default input device
244	Headset Microphone (Sennheiser SDW 5 BS - EU)
220	Jabra Link 370
165	Headset Microphone (Plantronics BT600)
160	Headset Microphone (2- Plantronics BT600)
157	Audio
155	Realtek High Definition Audio(SST)
121	Headset Microphone (Sennheiser SDW 3 BS - EU)
95	Headset Microphone (Jabra Link 370)
91	Headset Microphone (Sennheiser MB 660 MS)

Figure 14-10: Reporting the devices used in your environment

**Note:** No centralized way exists to gather Teams Live Meeting reports. There is a manual way to import Live Event data into Power BI based on the post-meeting Q&A and attendee reports. Find out more [here](#).

# Chapter 15: Managing Clients

**Paul Robichaux**

## Many Clients, One Service

In the same way that users say things like “My Outlook is down” when they mean that their Exchange Server mailbox is broken, many of us think of cloud systems through the lens of the clients we use. Microsoft has a sometimes-confusing mix of clients for its cloud services, including desktop clients for macOS and Windows; mobile applications for iOS and Android; web applications; and embedded clients built into desktop phones, Surface Hub devices, and so on.

It makes sense to consider these applications as individuals for two reasons. First, the same application (say, Outlook) may have different features on different platforms. As an example, Outlook for Windows has several features, including voting buttons, that still haven’t made it to Outlook for macOS. Second, different applications on the *same* platform (say, Windows) may have significant differences too—you may remember how long it took for all of Microsoft’s desktop applications to fully support modern authentication.

With that in mind, we can put Microsoft 365 clients into three basic categories:

- *Browser-based clients* run in a compatible web browser and communicate directly with the service. Their supported features depend much more on the browser you choose than on the underlying host OS. Every workload in Office 365 has some level of browser-based client support.
- *Rich applications* run on macOS or Windows and provide, usually, more functionality than their browser-based counterparts. For example, the macOS and Windows versions of Outlook both support accessing multiple Exchange Online accounts in the same client, whereas Outlook on the web does not.
- *Mobile applications* run on Android or iOS and provide on-the-go access from tablets and phones to some, but not necessarily all, of the service workloads and their features.

Within these categories, you’ll notice some interesting differences. For example, Exchange Online, Teams, and To Do all have clients in all three categories, while Planner and Stream don’t have desktop clients. It’s important to keep in mind that Microsoft thinks of these clients as ways for users to interact with the data maintained in the “intelligent substrate,” the collection of all the data and services that Microsoft 365 delivers. If you think of Microsoft 365 as a single unified service powered by the substrate instead of a collection of standalone services, this blurring of client boundaries makes sense. As you’ll see in Chapter 9, a task is a task, no matter whether you access it through To Do, Planner, or Exchange Online, and no matter where it’s stored. As Microsoft adds new services to their cloud platform, they introduce clients for those services but the feature set and supported platforms for each service’s clients may differ.

## The Browser: The Base Microsoft 365 Client Platform

All Microsoft 365 workloads support web browsers. Most new services initially appear as web-only applications; some gain desktop applications later, but some do not. Some services launch on multiple platforms simultaneously. Teams is the best example as it launched into preview with web, desktop, and mobile clients from day 1.

For some time, Microsoft has stuck to a simple broad theme: the [Microsoft 365 system requirements page](#) recommends that you use the *latest* versions of the supported browsers. Right now, the “supported” list includes Edge, Apple Safari, and Google Chrome. Mozilla Firefox is labeled as supporting “most Microsoft 365 apps.” Other browsers, such as Opera or Brave, or older versions of supported browsers, may work, but Microsoft doesn’t guarantee that every app feature will work.

Notice what’s *not* on this list: Internet Explorer. Support for IE 11 formally ended June 15, 2022. If you’re still using IE11, shame on you. To help customers move away from it, Microsoft provides a feature in the **Setup** pivot in the Microsoft 365 admin center that allows you to customize a template to tell your users “hey, start using Edge,” including giving them instructions on how to reload their legacy web apps in Edge’s IE11 compatibility mode.

There are still a few edge cases to the broad outline of browser support. For example, [Teams audio/video calls won’t work](#) in Firefox just yet (see MC352622), and you may occasionally notice odd UI behavior or display problems in browsers not made by Microsoft. This situation is complicated by the fact that sometimes browser developers make changes that break things that worked properly before their intervention.

One more key thing you should know about browser-based clients: there are no special licensing requirements to use them (as there are for some of the desktop and mobile clients). There is also a specific license type, the kiosk or frontline worker license, which gives access mainly via web browser and not via desktop applications. Kiosk users can also access mailboxes using ActiveSync clients, as well as POP3 and IMAP4.

## Rich Office Clients

Microsoft 365 supports any version of Microsoft Office desktop software that is still in [mainstream support](#). The Microsoft 365 Business Basic and Standard plans, and Enterprise plans from E3 upward, include the right to install and run the Microsoft 365 Apps suite of enterprise applications (Word, Excel, PowerPoint, Outlook, and so on). Companies can also license the Office desktop applications separately, without any of the other cloud services such as Exchange Online or SharePoint Online included in the plan, and gain the benefits discussed below. But because you are reading this book, we’ll assume that you are doing more with Microsoft 365 than just using the desktop applications.

The desktop Office applications have historically been available in two forms. First is the familiar “perpetual license” version: you buy it once and keep it forever. Perpetual versions of Office for Windows have long been built on the Microsoft installer (MSI) format. The second, newer, form delivers Office as a subscription-based service. When you license Office this way, you only have the right to use it while you keep paying. In exchange for this ongoing fee, you get more rapid product updates. You will sometimes hear people refer to subscription-based Office as “click-to-run” or “C2R” because the Office apps themselves are built on an application virtualization technology (known as App-V) that allows application updates to be streamed on-demand. It is challenging to mix C2R and MSI versions of Office on the same machine, and Microsoft recommends that you not do it.

**Real World:** The Microsoft Teams desktop client doesn’t use either the MSI or C2R mechanisms even though it is officially now part of the Microsoft 365 Apps suite. You can download a platform-specific executable installer that streams the Teams installation bits to the machine using App-V, but after that initial installation, the Teams client will automatically update itself. Bowing to user requests, Microsoft also offers an [MSI-based installer for bootstrapping Windows Teams installations](#) through Microsoft Endpoint Configuration Manager or Group Policy, but once the product is installed that’s the end of your control over its updates.

In February 2021, Microsoft introduced a new perpetual version of Office, the [Long Term Servicing Channel](#) (LTSC) version, which was released in September 2021. As with the [LTSC branch of Windows 10](#), Microsoft targets Office LTSC at devices that cannot or should not be updated frequently. Microsoft cites examples such as process control systems on a factory floor or devices used in regulated industries such as healthcare or financial services. Office LTSC is intended for limited use on a subset of any organization's devices, not as the primary Office version in use. Instead of including the Skype for Business client, Office LTSC will include the Teams client, which raises some interesting questions about how Microsoft will balance the high frequency of Teams client and service updates with the concept of a stable, slow-changing LTSC version. In exchange for getting less functionality and less frequent updates, Microsoft is also raising the price of the LTSC version of Office Professional and Office Standard by "up to 10%." There's also a macOS version, known as "Office 2021 for Mac." Alongside these LTSC versions, there's also a perpetually-licensed consumer version known as "Office 2021."

Why would anyone ever be willing to pay an ongoing license fee for Office? That's a fair question, but this approach offers some concrete benefits. First is that Microsoft updates subscription-based applications regularly, and much more frequently than the perpetual versions. Secondly, and probably more importantly, getting Office apps as part of a Microsoft 365 subscription can be surprisingly cost-effective. Buying a subscription to Office apps offers a fixed, predictable monthly cost tied to the number of users you have. This has historically been true even though Microsoft in August 2021 announced a price increase for many Office 365 and Microsoft 365 plans—the additional US\$36/year for Office 365 E3 represents a 15% increase, but given that there have been no similar price increases in the past, it's not unwarranted.

Some people argue that the cost of a subscription is higher over the long term than the traditional model of buying licenses at a one-time cost. There are many variables to consider in that equation, including the upfront cost, the cost of buying new versions to remain in mainstream support, and the cost of deploying and maintaining the software with updates. It's important to make a fair comparison, and not try to compare prices for Home, Family, or Personal editions of Office with the full Microsoft 365 Apps suite, as the non-business versions are not licensed to connect to cloud services like Exchange Online. The Microsoft 365 Apps versions allow customers to install on up to 5 machines, which may further reduce your overall cost of deployment. For customers using Microsoft 365 cloud services, the additional requirement to stay fully within mainstream support will come into effect in the year 2023, requiring standalone Office users to upgrade to newer versions, whereas right now it's possible to stretch out the lifespan of an Office install and connect to Microsoft 365 services with versions of Office that are in extended support.

The third reason can be a bitter pill to swallow. Microsoft mostly releases new features, such as Focused Inbox in Exchange Online and integrated support for streamed language translations in PowerPoint, only in the subscription-based applications. This irritates many people who have purchased the perpetually-licensed versions, but there is no reason to expect Microsoft to add new features to a previously shipped version of a product for free. It's quite clear that the bulk of Microsoft's attention and focus going forward will be on the cloud, and that on-premises software, while still important, is no longer the most important thing to them. When you consider the likely future for Microsoft's perpetually-licensed desktop and server software, moving to cloud-based licensing seems much more attractive.

As a rule, the subscription-based client applications deliver the most up-to-date, feature-complete, and compatible version of Office for your users, and that will often outweigh any comparison based on price alone. The introduction of the LTSC version means that organizations that need a stable, slowly-changing version of Office can still get it, but Microsoft's positioning of LTSC as the solution for small, select deployments reinforces their argument.

**Real World:** Many client applications, such as browsers, Teams, and the C2R version of the Office desktop applications automatically update themselves when new versions are released. Some enterprises prefer to disable automatic updates and control the deployment of updates. That is fine... as long as you don't prevent the updates from *ever* being deployed. Your update strategy should be either automatic or manual. Not updating at all isn't a valid strategy for Microsoft 365. For smaller organizations that are content to allow automatic updates, the IT administrators should at least maintain awareness of the vendor releases by subscribing to RSS or email notifications from those vendors.

## Mobile Clients

Apple, Google, and Microsoft desktop and mobile operating systems all include basic applications for email and calendar access; they may also include apps for simple office productivity tasks, chat, and so on. Interestingly, Apple and Google also compete directly with Microsoft for productivity and cloud services dollars. That limits their willingness to put first-class support for Microsoft 365 into their native applications. That's perfectly OK, though, because Microsoft is doing that on their own.

Microsoft produces a wide array of Microsoft 365 client apps for iOS and Android, including:

- Authenticator (used for passwordless authentication, multi-factor authentication, and more).
- LinkedIn.
- Microsoft 365 Admin.
- Microsoft Lists.
- Microsoft Teams.
- Microsoft To Do.
- Microsoft Lens (formerly known as Office Lens).
- Office (collection of different capabilities including Word, Excel, and PowerPoint).
- OneDrive (the same app can connect to both OneDrive for Business and OneDrive consumer).
- OneNote.
- Outlook (described in more detail later in the chapter).
- Planner.
- SharePoint Online.
- Sway.
- Whiteboard.
- Word, Excel, and PowerPoint, although these apps have largely been superseded by the single Office app mentioned earlier.
- Yammer.

Companion mobile apps typically appear soon after an application reaches General Availability. For example, Microsoft Lists became generally available starting in July 2020, and later in the year Microsoft announced released the Lists mobile client for iOS, with the Android version following in late 2021. Some differences might exist between the iOS and Android versions of mobile apps due to the different capabilities available to developers on the two platforms. More details about how to manage mobile devices and application access are in Chapter 16.

## Managing the Microsoft 365 Apps Suite

The pace of innovation and development in Microsoft 365 makes it impossible to maintain support for older versions of client software without incurring high development and support costs that Microsoft would then need to pass on to customers. When you consider moving to the cloud, one factor in your decision must be

an implicit commitment to keep your clients up to date. If you allow your client applications to become outdated, you can expect the quality of the user experience to degrade over time. Eventually, users might be unable to use some advanced features because their client software is unsupported or obsolete. For that reason, in this book, we've chosen to focus on Microsoft 365 Apps, the "service" version of the Office desktop applications. There are other versions; the full list of supported versions of Office includes:

- Microsoft 365 Apps: The Microsoft 365 Apps for enterprise suite of desktop Office applications is available both for Windows and macOS.
- The Office LTSC version, described earlier in the chapter.
- Office 365 Professional Plus ("Pro Plus"): desktop applications before version 2004 retain the Pro Plus branding
- Office Professional 2019: Office 2019 is essentially a perpetually licensed snapshot of features previously introduced in Office 365 Pro Plus. It's also available for both macOS and Windows, but we won't discuss it further.
- Office Professional Plus 2016: the 2016 standalone version of the Office client apps.
- Office Professional Plus 2013: the 2013 standalone version of Office, and predecessor to Office 2016; this version is supported for use with Microsoft 365 until October 2023. (Note that this is not the same as "the 2013 versions of Office 365 Pro Plus," support for which ended in 2017).

These are just the product names. In terms of specific versions, Microsoft doesn't usually emphasize specific version numbers, and instead recommends that you apply the latest updates. There's no minimum update level specified at any given time, and if you are experiencing client problems with Microsoft 365 services the first step should always be to check for available updates and, if there are new updates available, apply them to your client installations to see if your problem is resolved.

Once a version of an Office suite or application enters extended support, it is no longer supported for use with the service. Microsoft says that it won't deliberately seek to block or prevent you from connecting with unsupported versions of Office applications, but no bug fixes or other updates will ever be applied to make them compatible with the service, and they always have the option to block specific older client versions from communicating. They also can, and have, deprecated protocols required for older clients, rendering them unable to connect.

## Understanding Office Update Channels

Microsoft 365 Apps updates are distributed in what Microsoft now calls *channels*. The channel model has evolved, with the most recent changes happening in May 2020 as part of the Microsoft 365 Apps rebranding. The [Microsoft website](#) now describes three channels, as shown in Table 15-1, and the support lifecycle for feature updates now varies between channels. To summarize, the new channels are:

- **Current Channel** releases features and bug fixes as soon as they're ready (but at least once per month), with security fixes released on the second Tuesday of each month ("Patch Tuesday") to conform with Microsoft's existing security release schedule.
- **Monthly Enterprise Channel** releases monthly updates on Patch Tuesday, along with bug and security fixes. Microsoft expects most enterprises to use this as the default.
- **Semi-Annual Enterprise Channel** releases updates twice a year (in January and July). Bug and security fixes are released monthly on Patch Tuesday.

This is a pretty dramatic change from the old model. In the new model, each channel releases fixes and security updates on the same day of the month, each month. The primary difference in the channels is how often feature updates appear.

<b>Channel</b>	<b>Feature Updates</b>	<b>Security Updates</b>	<b>Non-Security Updates and Fixes</b>	<b>Products that default to this channel</b>
Current Channel	When they're ready	Monthly (Patch Tuesday)	Monthly	Visio Pro Project Microsoft 365 Apps
Monthly Enterprise Channel	Monthly, on Patch Tuesday	Monthly (Patch Tuesday)	Monthly	Microsoft 365 Apps
Semi-Annual Enterprise Channel	Every six months, on Patch Tuesday in January and July	Monthly	Monthly	None

Table 15-1: Microsoft 365 Apps Branches and Channels

Whether you use the Office Deployment Tool, the Office Customization Tool, or install from the Microsoft 365 admin center, when you install the apps, they will default to the Current Channel unless you have chosen another default as described below. The Current Channel is suitable for businesses that are willing to have their clients updated to the newest features rapidly (but at least once per month). Typically, these are customers who do not have special macros or Office add-ins that are critical to their business processes. Historically, these automatic updates have not caused major, widespread issues, and can be considered safe to use if you don't have the type of customizations or integrations in your environment that might break after an update.

There are also preview versions of the Current and Semi-Annual Enterprise channels. The intent of these preview channels is to let you test upcoming releases before they hit the corresponding channels and go into wider distribution. For example, a new feature is first released to Current Channel (Preview), then to Current Channel. Once it meets Microsoft's criteria for a wider release, it will be pushed to the Monthly Enterprise Channel. At some point before the next Semi-Annual Enterprise Channel release, the feature may appear in Semi-Annual Enterprise Preview, so that organizations using the semi-annual channel can test it against their release processes. However, the progress of a feature through these channels may be slowed or interrupted if it fails to meet Microsoft's criteria for usability, functionality, or quality—so just because a feature appears in (say) the Monthly Enterprise Channel in May, there's no guarantee that it will appear in the July Semi-annual Enterprise Channel.

If you have devices configured to use the Monthly Enterprise channel, Microsoft allows you to roll them back to a previous build in the channel. You might want to do this if you find that a Monthly Enterprise change breaks some part of a line of business application, for example. You can also skip an upcoming release. You access both these options from the **Office installation options** page in the Microsoft 365 admin center.

To control which channel a Microsoft 365 Apps installation uses, you can set the channel during installation, or by using Group Policy. The Group Policy administrative templates for Office include an Update Channel setting in Computer Configuration. Setting the update channel using Group Policy has the advantage of allowing you to change clients to a different update channel than was used during the initial setup or allowing you to target different channels to different parts of your user population without designing a different installation configuration file for each of them.

**Note:** The update channel Group Policy setting is not available for Office 2013 clients. It also does not apply to Office 2016 or Office 2019 clients that were installed using the MSI package, only those installed using C2R.

Each update channel has a different period of support. For the Current Channel, support for a build (or release) is only applicable until the next build is released. If a security bug is found in the latest build of the

Current Channel, a patch will be released for the latest build, but no patches will be released for any previous builds in the Current Channel. This means that the Current Channel builds are normally supported for one month.

The Semi-Annual Enterprise Channel versions are released every six months, and each build is supported for 14 months. Semi-Annual Enterprise releases that ship in January are supported until March of the next year; the July releases are supported until September of the next year. This [list shows all the build numbers and release dates](#) for Microsoft 365 Apps going back to 2015.

Because Microsoft supports both the current and previous Semi-Annual Enterprise Channel versions, there is no immediate pressure to update when a new version is released to that channel as there is with the other channels. Microsoft recommends this channel only for “those select devices in your organization where extensive testing is needed before rolling out new Office features.” If a security bug is found in today's version of the Semi-Annual Enterprise Channel, a patch will be released for the latest version and the previous version, but no older builds.

In mid-April 2022, Microsoft reinforced this belief by announcing (in a little-noticed Message Center post, MC362760) that they were going to move clients from Semi-Annual Enterprise to monthly. If you didn't see this post, it may be because you didn't have any devices currently enrolled in that channel.

This update cadence and support period for Microsoft 365 Apps are important to keep in mind when you're planning your update strategy. If you decide to manually control updates, you need to ensure that you deploy new versions promptly and do not let your clients fall into an unsupported state that could put them at risk of a security vulnerability.

With multiple update channels to choose from, you also need to strike a balance between providing a stable version of the desktop applications for the bulk of your user population, while also ensuring that new builds are being tested on a sample of your user population before all users receive the updates. Microsoft recommends splitting up devices into two broad categories: one (which some Microsoft folks call “general purpose”) that doesn't normally have or use any applications, macros, add-ins, or other business-critical tools that cannot be allowed to break, and another (“business essential”) set of devices that run line of business applications, belong to key employees, or otherwise need to be protected. You should assign the general-purpose devices to update directly from Microsoft or Endpoint Configuration Manager using the Monthly Enterprise Channel, then keep the “business essential” devices on the Semi-Annual Enterprise Channel to reduce the number and scope of changes you need to adjust to at any given point in time.

**Other update channels you should know about:** Other teams at Microsoft, including the Windows, Exchange, and Teams product groups, have their release strategies which are broadly similar to how Office does releases... but there are enough differences that you should carefully examine them to ensure that you're getting the desired mix of update frequency and stability. In particular, understanding how the Windows Long-Term Servicing Branch (LTSB) works is critical for organizations that have strict change control requirements.

## Operating System and CPU Support

For the most part, Microsoft seems to believe that customers update their computers to the latest operating systems whenever a new version is released, and they act accordingly. In practice, there are [specific requirements](#) for the underlying OS for the full Office clients.

Windows 11, Windows 10, Windows 8.1, Windows Server 2022, Windows Server 2019, and Windows Server 2016 are all officially supported. There is no blanket requirement for a particular version of Windows 11 or

Windows 10, although at any time Microsoft might add dependencies that require a certain OS level for specific features.

For macOS, the three most recent major versions are supported. When a new major version of macOS is released, that major version of macOS and its two immediate predecessors remain supported. For example, now that Apple has released macOS 12.0 (“Monterey”), version 10.14 (“Mojave”) is no longer supported. Apple does not have the same predictable release schedule for its OS families that Microsoft does, so the gaps between major releases may be shorter or longer than you expect. Microsoft provides plenty of advance notice of their support requirements, though.

As a further complication, occasionally Microsoft will draw a new support boundary between a version of the host OS and the applications. For example, in January 2021, Microsoft announced that version 16.43 of the macOS apps would be the last supported version on macOS 10.13 and earlier. That is if you have an older Mac that can’t run 10.14 or later, you won’t be able to update the Office apps themselves past version 16.43. In the same vein, in August 2021 they announced the forthcoming end of support for iOS 13 and earlier in the Teams Mobile client. Apple in general does a superb job of supporting older hardware (for example, my 2011 MacBook Pro shipped with macOS 10.6 and was supported until the release of macOS 10.14) but all good things must eventually end.

Microsoft has released versions of Word, Outlook, PowerPoint, OneDrive, and Excel for macOS that are recompiled for the [Apple Silicon](#) CPU architecture. Although no timeline has been announced for Apple Silicon-native versions of most other macOS applications (including Teams and To-Do), reports are that these applications run quite well using the M1 Rosetta translator included in macOS 11.0 and later. Microsoft hasn’t said anything publicly about native versions of other applications yet.

## Faster Updates Through the Office Insider Program

Microsoft has three programs for those who like to add excitement to their lives by running early, and possibly unstable, versions of software. You’ve probably run beta versions of software for test purposes in the past; the Windows Insider and [Office Insider](#) programs offer a very similar experience. When you join one of these programs, you’ll have access to builds of Windows or Microsoft 365 Apps before they are generally released. When you enroll in the Office Insider program, you’ll get builds in one of two additional channels: Beta (formerly known as “Insider Fast”) and Current Channel (Preview) (formerly “Monthly Channel (Targeted)”). These channels [generate releases](#) roughly weekly, which means you’ll get earlier access to new features but also that you may run into problems with features that don’t quite work properly. In exchange for granting early access to Insider members, Microsoft wants to collect user feedback and bug reports, and they maintain a set of Insider forums for that purpose.

Interestingly, Office Insider exists both for macOS and Windows desktops; there isn’t an equivalent for the mobile or web-based Office applications, although Microsoft does occasionally conduct open beta testing for the Office, Word, Excel, PowerPoint, Outlook mobile, Whiteboard, and Microsoft To Do client on iOS and Android.

What about the third program? Microsoft runs a [separate preview program and channel set for Teams](#). As with Office Insider, the Teams Public Preview program features three channels: Beta, Private Preview, and Public Preview. The details of these channels, how to join them, and how to manage your Teams Insider membership are covered later in this chapter.

## Installing Microsoft 365 Apps

Microsoft 365 Apps is packaged as a “Click-to-Run” application, using application streaming and virtualization technologies to reduce the amount of time between beginning the installation of the software and being able to start using the applications. Microsoft 365 Apps is included in the Microsoft 365 Business Standard, Office 365 Enterprise E3 and E5 licenses, as well as a standalone Microsoft 365 Apps license (this used to be called Office ProPlus).

### Users May Self-Install the Apps

Microsoft 365 users who have a license for Microsoft 365 Apps can install the desktop applications by logging into the Microsoft 365 portal, navigating to their user profile, and using the **Manage** link in the **Office apps** section.

For macOS users, Microsoft 365 Apps are also available from Apple’s Mac App Store. This might seem like a pointless offering, given that licensed users can download the apps from the portal, but it allows organizations using [Apple Business Manager](#) to centralize and manage Office deployments. Just downloading the apps from the Mac App Store gives you read-only access to documents and email; if you want to create or modify documents, or send or receive emails with Outlook, you’ll have to activate the apps by signing into the service using an account that has an appropriate license.

On both Windows and macOS, installing or updating the Microsoft 365 Apps package will get you the Teams client too. Microsoft considers Teams to be a full-fledged peer of the other desktop applications and treats it accordingly. If you don’t want the Teams client installed, your options are limited. You can block that installation by building a custom configuration using the Office Deployment Tool (as [described here](#)), or you can use Group Policy, or you can allow the installation but use Group Policy to [stop the client from starting](#) when the user signs in. There’s no obvious way to stop this behavior in the user interface, but you can control it via a registry or [Group Policy setting](#).

### Controlling User Software Installs

You can disable software downloads from the portal for users, which is often preferred by organizations who are using existing software licensing for Office clients, or who want to fully manage the installation process and not allow users to install the software at all.

1. Log into the [Microsoft 365 admin center](#) with your administrator account.
2. Navigate to **Settings**, then **Org settings**, then click the **Services** pivot.
3. Select **Office installation options**.
4. On the **Installation** pivot, choose the user software options you want.
5. Click **Save** to apply the changes.

When users log into the Office portal with their normal user accounts, they’ll see installation options based on your selections above. Users must hold local administrator rights on the computer where they install the applications, which is not likely to be an issue in a BYOD environment but may present a challenge for organizations that do not grant local administrator rights to end-users.

**Real World:** Although your corporate-owned computers may prevent users from installing Microsoft 365 Apps themselves, each license entitles the user to install on up to 5 computers, so if they are allowed to download the software at all, they will be able to log into the admin center from home and install the Microsoft 365 Apps software there.

## Managing Updates for Click-to-Run Builds of Microsoft 365 Apps

Updates to Microsoft 365 Apps can be managed in different ways to suit the needs of the organization. However, Microsoft recommends that you let them do the management by allowing all clients to individually download updates from the [Office 365 content distribution network](#) (CDN). Microsoft maintains multiple CDNs (including one that's used purely for caching web libraries used in Microsoft web applications), but the Office 365 CDN is unique in that it is used only to push application updates for the Microsoft 365 Apps suite and other Office 365 components. Using the Office 365 CDN allows the network and client to intelligently negotiate exactly which updates are required and transmit them as efficiently as possible, as described in [this Microsoft article](#).

Users who install Microsoft 365 Apps from the Office portal will find that their clients' updates are automatically downloaded from the internet and installed as they are released by Microsoft, and no other action is required by the end-user other than restarting applications when prompted that an update is ready.

If you've deployed the applications using ODT, then the XML configuration file you used will determine how updates are applied by enabling updates and configuring an update path. If you want your clients to automatically update themselves using the Microsoft 365 Apps update behavior, you'll have to re-run the Office Deployment Tool for Click-to-Run to download the latest build of Microsoft 365 Apps to the appropriate location on the network. Once the updated build is available in the update path your clients were originally configured with, the computers will automatically apply the updates.

Many enterprises prefer to use Microsoft Endpoint Configuration Manager, System Center Configuration Manager, [Quest KACE](#), or other similar tools to provide them better control over the operating system and application updates. When Microsoft releases updates to the Microsoft 365 Apps suite, they also release installer packages that can be deployed using these types of tools. Keep in mind that if you're using the Current Channel, Microsoft will be releasing updates at least once per month... and they only support the current version of each application against the service, meaning that if you're managing updates yourself you may wish to force your clients to use the Monthly or Semi-Annual Enterprise channels.

If you need to disable automatic updates completely, the ODT XML configuration file you use must specify the exact build number of Microsoft 365 Apps that you want to install. If automatic updates are disabled in your XML file, any new builds that you download using the Office Deployment Tool for Click-to-Run will need to be manually deployed to end-user computers.

### Using Delivery Optimization with Click-To-Run

Peer-to-peer update delivery can reduce the amount of time required to deploy updates throughout a large organization. Apple and Microsoft have used this technology for some time for operating system updates. The basic idea is that one client on a network downloads the updates, then caches and redistributes them to other nearby computers on the same network. Compared to having every computer download updates from a CDN over the internet, peer-to-peer delivery (which Microsoft calls *Delivery Optimization*) promises to speed deployment significantly when implemented properly.

The good news is that, by default, Windows 10 computers automatically use Delivery Optimization for OS updates, and when you install Microsoft 365 Apps, so will those applications *if* the prerequisite requirements are met:

- The client device must be running build 1709 or later of Windows 10 Enterprise or Windows 10 Education to enable Delivery Optimization updates for Microsoft 365 Apps when they're pushed by Microsoft.

- If you want users to be able to request updates (by going to the application backstage and using **Account > Update Options > Update Now**), the client device must be running build 1908 or later of Windows 10.
- You must have version 1912 or later of Microsoft 365 Apps. That version was released in January 2020, so you should certainly already have it.

Keep in mind that Delivery Optimization only works with computers that are configured to download their application updates. If you're using Microsoft Endpoint Configuration Manager or another distribution-management tool, the client applications won't use it.

If you want to check whether an individual Windows 10 device is using Delivery Optimization, you can use the *Get-DeliveryOptimizationStatus* and *Get-DeliveryOptimizationLog* PowerShell cmdlets. Microsoft has lots more [documentation of the Delivery Optimization feature](#) available if you're interested but, in general, most Microsoft 365 administrators can ignore the feature and let it work silently in the background.

## Managing Updates for MSI Builds of Microsoft 365 Apps

The update mechanisms and Channels described so far apply only to the C2R versions of Office. Licensed Microsoft 365 customers also get access to the traditional MSI packages for Office client deployment. If you use these MSI packages, you'll need to manage updates yourself using tools such as Microsoft Update, Windows Server Update Service (WSUS), System Center Configuration Manager (SCCM), Quest KACE, or the Microsoft Endpoint Configuration Manager.

For C2R clients, all update types are released at the same time on the second Tuesday of each month, also known as "Patch Tuesday" among IT pros. The MSI clients are handled differently. Non-security updates are released on the first Tuesday of each month, while security updates remain on the second Tuesday of each month.

MSI deployments are still widely used by customers for a variety of reasons, but update management is more complex and time-consuming because you must do it all yourself with whatever deployment tool you're using. As with so many other aspects of cloud services, if you want a higher degree of control, you can get it, but at the cost of increased overhead and inconvenience. For your client deployments, consider the C2R service as your first choice, and only revert to the MSI package if you have a good reason to. It will save you time and effort overall that can be better spent elsewhere.

## Managing Updates for macOS Versions of Microsoft 365 Apps

You can get the macOS versions of the Microsoft 365 Apps suite by downloading them from the Office 365 portal, or Apple's Mac App Store. In both cases, you'll find that Microsoft has an app update mechanism. The Microsoft AutoUpdate (MAU) app is automatically installed when you install any of the Microsoft 365 Apps family; it runs periodically to download and install updates to the component applications, or you can trigger it manually by choosing **Help > Check for Updates** from the apps. The MAU app uses the same Office 365 CDN that Windows does, just with a different set of update bits. Interestingly, Teams client updates are now delivered through MAU.

## Edge WebView2 and Office Apps

Many parts of the desktop Office applications create or display web-compatible content. Some of the features you use in Outlook, for example, aren't built into the Outlook desktop client, but are instead loaded from a different Microsoft service and rendered inside Outlook. Examples include the Meeting Insights view and the

room finder view. These components are called OWA experiences (OCX) and use an Edge component called WebView2. The One Outlook “Monarch” client also uses WebView2, as will the Teams 2.0 client.

Microsoft loads the WebView2 component onto PCs through:

- The Edge browser.
- The Microsoft 365 enterprise apps.
- Windows 11 updates.
- Windows 10 updates (starting June 2022).

After deployment, a program called Microsoft Edge WebView2 Runtime (`msedgeview2runtime.exe`) is available on a PC. You can manually install the runtime in advance if you want to, or you can prevent it from being installed by changing a setting in the Apps admin center (both operations are [described here](#)).

## Troubleshooting Office Clients with SaRA

Although Microsoft 365 is a very reliable service, there will naturally be problems that occur from time to time. Part of that is due to the scale and complexity of the service; it is impossible to keep that much software and hardware in 100% healthy condition all the time. Part of it is also due to factors outside of Microsoft’s direct control. A large proportion of the support calls that Microsoft receives are client issues that are due to the software on the computer, network issues, DNS issues, or other factors that can be difficult to identify quickly. The more time Microsoft spends supporting these types of issues, the costlier it is to run the service.

That’s why Microsoft has released the [Support and Recovery Assistant](#) (SaRA). This downloadable troubleshooting tool has a wizard-driven interface to allow users to identify the issue they are experiencing, and then allow SaRA to perform diagnostic tests and suggest solutions to the most common client-side issues. SaRA can check for issues around mail flow, access to shared mailboxes and calendars, Outlook freezes, and repeated authentication prompts. Although it doesn’t exhaustively test for every possible cause, it’s still a useful tool. In May 2021, Microsoft added a [new command-line version of SaRA](#), which is useful for enterprises that want to allow technicians to remotely diagnose Office problems.

SaRA requires administrative rights on the computer to be able to install the software and run the tests. For BYOD users or environments where local admin rights are given to end-users, this won’t be a problem. However, you can also imagine that the existence of SaRA may not be known to end-users who do not have an IT focus. They’re likely to call Microsoft for support anyway, but if they were to try to raise a support ticket using the admin center SaRA can be suggested to them automatically as part of that process. For customers with IT support staff, it is a simple matter of the IT personnel installing the tool on client computers and running the diagnostic tests.

It’s easy to think that Microsoft should just provide working support tools like this to customers. And indeed, with all the data they have from telemetry and from analyzing support trends, Microsoft can make reasonable guesses about the most useful diagnostics to develop for SaRA. That said, it’s important that customers and IT professionals provide feedback to drive the development of tools like SaRA, by letting Microsoft know when the tools don’t have any information about our problems, or when they fail to detect and suggest fixes for issues. To that end, SaRA has multiple places where feedback can be submitted to Microsoft.

## Controlling “What’s New” Content Displayed to Users

The Microsoft 365 desktop apps can display pop-up notifications to users to tell them what’s new in the product. To see what this content looks like, go to the Help item on the Office ribbon and choose the “What’s New” icon; you’ll see the content appear as a pop-up navigation bar on the right edge of the window. There are two ways to look at this. One is that it’s a useful and user-friendly way to notify users of valuable new

features. Another is that it's an unwanted intrusion. Since individual end-users could turn this feature off, which view you took was a matter of individual preference.

However, since mid-2019, Microsoft has been much more aggressive about connecting directly with enterprise users—not the admins and other IT people involved in managing and supporting tenants, but the end-users who are using the service to get their work done. While the impulse behind it may be commendable, Microsoft's continual insistence that they should be able to talk to (or, more properly, *talk at*) these end-users has ruffled a lot of feathers among their proper customers. However, they are trying to strike the right balance between making sure users are aware of new features and respecting the rights of companies and their employees. One of the latest changes in this balancing act is a new set of controls that allow administrators to control what users see in the "What's new" sections of the desktop clients. In early 2020, Microsoft introduced a feature in the Microsoft 365 admin center that allows you to hide specific cards for new features. To control which items users see, go to the admin center and select **Settings** -> **Org settings** tab, then select **What's new in Office** and then you can hide or show specific feature cards for individual features in individual releases. Each Office release has its section; most sections have only two or three new feature cards.

## Using the Microsoft Apps Admin Center

Traditionally, there have been several ways of enforcing Office client configurations: you could build a custom installation of the MSI version, you could use the Office Configuration Tool to specify a configuration applied with the installer, or you could specify a configuration template and push it to clients using Group Policy or another similar configuration management tool. This latter method is probably the most common approach, but it has a significant limitation: the target machines must be able to apply Group Policy settings. For devices that are only joined to Azure Active Directory, or for BYOD-style devices that aren't joined to any directory, there was no good way to enforce or change client policy settings. As an alternative, Microsoft offers a suite of cloud-based tools for managing Microsoft 365 Apps clients, the Microsoft Apps Admin Center (<https://config.office.com>). You can use this admin center to manage several aspects of the Microsoft 365 Apps deployed to your end-users without MEM, Office 365 MDM, or Group Policy objects. Currently the Apps Admin Center is available worldwide, except for Office 365 GCC, GCC High, Office 365 DoD, and Office 365 operated by 21Vianet.

The combination of desktop applications delivered by a cloud-based content delivery network and then managed by a cloud-based service is interesting and offers several potential benefits to customers. For now, the Apps Admin Center contains six items in its left navigation bar (note that some of these services are marked as being in preview):

- **Servicing** allows you to create and manage servicing profiles. Earlier in the chapter, I mentioned Microsoft's recommendation for creating "business essential" and "general purpose" device sets—you can follow this recommendation by creating servicing profiles, assigning devices to them, and then assigning update channels to them. You can define profiles that exclude devices based on the amount of free disk space they have, whether Office application macros have been used in the preceding 28 days, what channel they're currently in, and whether they have Office add-ins installed. Each profile can have exclusion dates, during which devices in the profile won't receive any updates.
- **Customization** contains tools that allow you to define and deploy custom configurations and policies for the Office apps.
- **Health** and **Inventory** allow you to monitor which applications are installed, whether they are healthy, and whether they are receiving updates as you expect—read on to learn more.

- **Learn More** is a collection of links to documentation, videos, and so on that may be useful as you learn to manage your Microsoft 365 apps using the Apps Admin Center.
- **Settings** has very little in it; it contains a control for generating what Microsoft calls a tenant association key (a base-64-encoded key that lets you tie devices in a specific tenant to your portal) and a slider that allows you to adjust how long the tool will remember devices that haven't updated their inventory data (the default is 30 days).

## Customizing Microsoft 365 App Configurations

Some organizations are happy to allow users to install local copies of the Microsoft 365 Apps packages. Others want or need centralized control or have constraints that make it impossible or impractical to install using the normal process of launching the small bootstrap installer and letting it download the required software over the Internet. Fortunately, the setup files can be downloaded in advance and then distributed through a network share or other means to avoid a dependency on the Internet connection. In addition, you can customize exactly what parts of the Microsoft 365 Apps suite are downloaded, where they are installed, how they're configured, and several other settings. To do this, you'll use two tools:

- The [Office Deployment Tool](#) (ODT) is a command-line tool that you run to apply a configuration file (formerly known as a transform) to the installation files. The result: the settings specified in the *configuration.xml* file drive the installation.
- The [Office Customization Tool](#) (OCT) is now part of the Apps Admin Center, under the **Customization** section in the left nav bar. The OCT provides a web-based tool for creating and modifying configuration files to be used with the ODT. You can also create a configuration file and then apply it to existing installations (as you might wish to do if you don't want the Teams client to auto-start).

You can find a full reference for how to customize the XML configuration file on the [Microsoft Support website](#). However, Microsoft recommends that you use the OCT to avoid making mistakes in XML formatting that will cause your installation to fail. In addition, OCT allows you to upload and store configuration files in the cloud, making it easier to keep track of them.

Normally you'll use these tools by following a process like this:

1. Install the ODT. That will give you two files: *setup.exe* and a sample *configuration.xml* file.
2. Navigate to <https://config.office.com> and either create a new device configuration from scratch or modify an existing configuration. It's a good idea to create a new configuration every so often to verify that you are taking advantage of all available settings in the OCT; Microsoft occasionally adds new features that may not be included in your older configuration files.
3. Test the configuration file to verify that it does what you expect, and that the resulting installation is set up the way you want it.
4. Use OCT to adjust the configuration file as required.
5. Once you're happy with the results from your configuration file, use the ODT to complete the installation.

You can run the ODT to complete the installation using any tool that can execute a command-line program. This includes almost every endpoint-management tool out there, plus Group Policy, plus even having users run the command themselves from a desktop shortcut you've previously deployed.

**Real-world:** If your environment doesn't provide good Internet connectivity, you might want to host the installation files on your internal network. You can do so using a conventional network share, a DFS share, or even removable media. To install in this manner, you'll need to run the ODT with the */download* switch to download the files. To do this, after customizing the XML configuration file, copy it to the same folder

that you placed the Setup.exe file in. Open a cmd.exe prompt on a computer on the network and run *Setup.exe* with the */download* switch to download the Microsoft 365 Apps source files.

```
C:\> start /wait \\obcdc1\installs\Office365ProPlus\setup.exe /download \\obcdc1\installs\Office365ProPlus\configuration.xml
```

The source files will be downloaded and placed in a folder structure automatically. Do not change or rename the folder structure created by Setup. After the download is completed you can deploy the apps from the install point by running *Setup.exe* with the */configure* switch. You can also run this command line using software deployment tools such as Group Policy or Microsoft Endpoint Configuration Manager.

Pay close attention to the “Product ID” that you configure in your XML file. The correct product ID must be used for the Microsoft 365 license assigned to the user. If the wrong product ID is installed on the computer, the user will not be able to activate it with their Microsoft 365 credentials and will need to reinstall the correct version. You will normally use a value of O365ProPlusRetail for most product SKUs (except Visio and Project, which have unique product IDs). Microsoft publishes a complete list [of product IDs matched to license types](#).

If you do not specify an update channel in your configuration file, and none is specified via Group Policy, the default branch or channel will be used (refer to the earlier section about Update Channels).

[A tutorial and sample PowerShell script](#) are available to help in deploying Microsoft 365 Apps using GPOs.

**Real World:** If you’ve already purchased licenses and provisioned Microsoft 365 accounts, you can begin your client deployments before you start moving mailboxes and other data to the cloud. The client applications can connect to on-premises servers such as Exchange, within the limits of the normal client system requirements for those on-premises products. Outlook is generally smart enough to automatically deal with mailboxes that have been moved from on-premises servers to the cloud without user intervention.

## Creating and Managing Application Policies

The Apps Admin Center allows you to create policies that are applied from the cloud to desktop Office applications (**Customization > Policy Management**). In its current release, it doesn’t support all the policy settings available through Group Policy templates, although it does have a *lot* of settings (as of July 2022, for example, there are 287 individual policy settings just for Microsoft Word and 2,182 policy settings in total)! Perhaps more importantly, the Apps Admin Center only allows you to set up user-based policies, whereas with GPOs you can apply Office policies to machines.

**Note:** The only Teams-related policies currently implemented in the Apps Admin Center allow you to prevent the Teams client from starting automatically on Windows machines or to restrict which domains Teams may sign into. If you want to control other aspects of Teams client behavior, you’ll have to use the Teams policies described in Chapter 13.

Policies are applied to the applications in a way very similar to how Group Policy settings are applied. When a user signs into Office 365 on a device, the application she signs into immediately checks the policy service for any applicable policies. If no applicable policies are found, the application checks again every 24 hours; any time a policy is found and applied, the application will recheck for policy changes every 90 minutes while the app is open. Each time a Microsoft 365 App is launched, it will check for policies (this includes Visio and Project, but not Power BI or To Do). It is important to understand that policy changes are not applied until the app is *next* restarted though—so if a user launches Outlook at 8 am, and you update the policy at noon, the new policy will be downloaded but not applied to that user until the next time she launches an Office application.

As one concrete example of a policy that you can manage with the Apps Admin Center, consider the user feedback mechanism described in Chapter 5. There are “feedback” and “survey” policy categories ([described here](#)) that let you control whether users can submit feedback, including free-text comments and surveys, to Microsoft, and (separately) whether Microsoft is allowed to follow up with individual users on their feedback.

The Policy configurations page in the Apps Admin Center shows which policies you have defined, their relative priority, and their health. Microsoft is deprecating the policy health status feature starting in mid-March 2022; per MC335282, they will eventually replace it with “advanced health reporting and compliance monitoring features” but there is no date associated with this.

To use the service, you need version 1808 or later of the Microsoft 365 Apps suite, and the users you want to target must all have accounts that are either homed in or synchronized with Azure AD. You assign policies to users based on their group memberships, so you’ll need to create groups for whichever sets of users you want to assign policies to. You can also create a policy that applies to anonymous users who read or edit documents using sharing links sent by users in your tenant.

## Monitoring Application Health

The **Health** section of the Apps Admin Center contains four sections:

- The **Apps Health** section is meant to show you data about individual machines’ applications and how healthy they are. You’ll only see data for users who have an E3, E5, or equivalent license, and only if they are running version 2008 or later of Microsoft 365 Apps for Windows. The **Add-in Health** pivot shows the health of COM and VSTO add-ins for Office, whether those are internally developed by your organization or obtained from public sources. Note that this pivot will only appear if you’ve enabled inventory collection.
- **Security Update Status** (currently in preview) shows you which machines are behind on security updates for the Microsoft 365 apps (not general Windows Update updates, sadly). This is based on the release date of the most recent Microsoft 365 apps security update; as of this writing, the most recent update was June 14, 2022, so any device that doesn’t have that update will be marked as “not up to date”. You can set goals for the percentage of devices you want to be up to date or the average time between patch release and deployment; these are useful to track.
- **OneDrive Sync** (currently in preview) shows reports and data about the sync health of OneDrive for Business clients, including how (or whether) the [known folders sync feature](#) is enabled, and how many clients have reported sync errors, and an aggregated view of issues by type.
- **Service Health** shows you whether the Microsoft 365 Apps portion of the Apps Admin Center is itself healthy.

There’s a lot of potential for Microsoft to improve and extend the features of this section of the Apps Admin Center, including linking “who’s not up to date” lists with the policy tools, or a notification mechanism, to help automatically notify users and/or bring their machines into compliance.

## Inventorying Your Application Estate

Keeping track of which devices have which versions of the Microsoft 365 apps on them is an enduring hassle for many Microsoft 365 customers. This hassle is magnified if you don’t have a solution such as Microsoft Endpoint Configuration Manager running; as individual machines can freely self-update, you can quickly end up with a confusing mess of different versions spread across your tenant. The **Inventory** section of the Apps Admin Center is intended to help address this by summarizing which devices, which builds, and which add-ins are present in your tenant. There’s a new client-side component of Office known as the Serviceability Manager (SM) that gathers this data and provides it to the service. SM only starts collecting this data after you do two

things. First, you must sign into the Apps admin center, and second, you must accept the onboarding prompt. Once you've completed both of those tasks, SM will start gathering data and passing it to the service and you'll see it appear.

Each of the sections in the inventory report (Figure 15-1) has links that allow you to see more detailed data. For example, the "Show all devices" link in the Devices section will show whether each device has macros or add-ins, what Office version and build it's running, what update channel it is on, and so on.

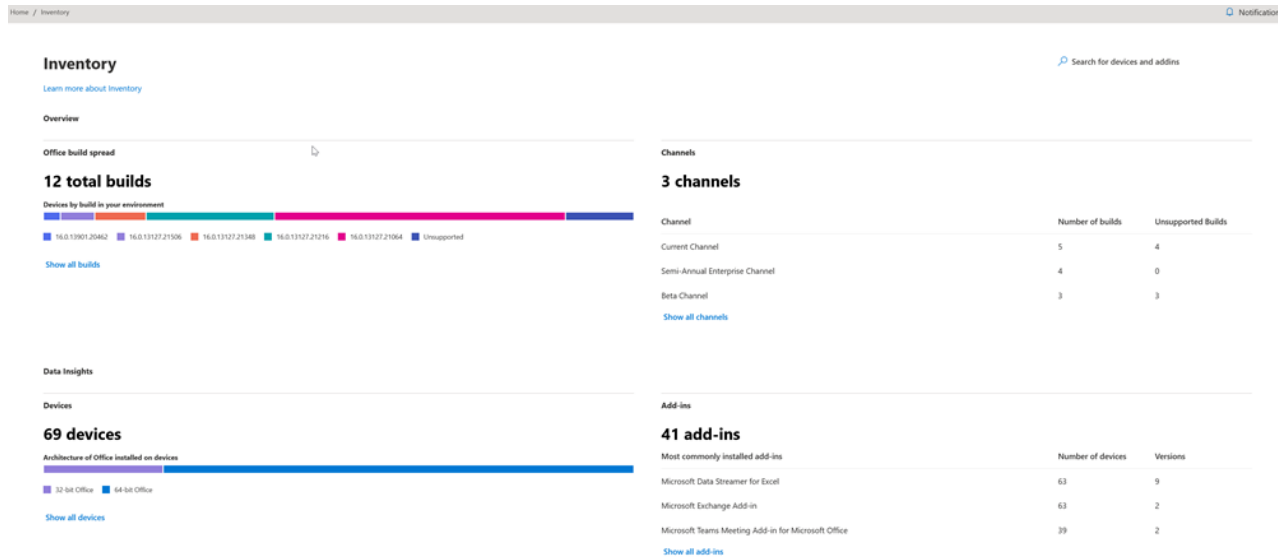

Figure 15-1: An example application inventory

## Managing the Outlook Client Family

Outlook is still the most common desktop email client used to access both on-premises and cloud Exchange mailboxes. It's also arguably the most important of the clients, and it's fair to say it has the broadest set of management features (in part because those management features are spread across several parts of the service). Microsoft is trying to create a unified user experience and identity for Outlook across multiple platforms, which can lead to some confusion when discussing "Outlook" in books like this. (In fact, they go so far as to [say that](#) "One of the Outlook design principles is to make Outlook feel native to your preferred operating environment"). Despite that confusion, we'll tackle managing the Outlook client family as a single topic. The family currently includes several members:

- Desktop Outlook, available for both macOS and Windows. There are [some differences in the functionality](#) between the two clients, and of course, there are differences between different versions, but in general, you can consider the two as equivalent. Both versions support multiple Exchange Online accounts in a single client session; both can work online or offline, and both offer extensive caching features.
- The new "One Outlook" client (codenamed "Monarch") is an ambitious effort to replace the Windows, web, and macOS clients with a single unified codebase.
- Outlook Web App (OWA) is the webmail interface for Exchange Online, providing users access to their mailbox, calendar, contacts, and tasks, as well as a launch pad for other services such as the Office Online apps, OneDrive for Business, SharePoint sites, Delve, and Stream. Although Microsoft officially refers to "Outlook on the web," this is a clunky name, so we won't use it, especially as most documentation for the product still refers to "OWA".

- Outlook mobile for iOS and Android is Microsoft's first-party mobile client for Exchange Online. It adapts the Outlook user experience to the smaller screens and touch-based interface of mobile phones and tablets, and it includes some mobile-only features such as Play My Emails (a voice-based system that will read your emails to you and let you respond via a connected Bluetooth or wired headset). As with the macOS-vs-Windows split, you'll find that features come to the Android and iOS versions of Outlook at different speeds.
- An [Outlook extension for the Edge browser](#). This extension shows up in your browser toolbar when installed and lets you do some simple tasks without having to open a separate window or tab to load OWA. Reviews are mixed on both the utility and stability of the extension so far, and Microsoft had to back away from its initial plans to advertise it to users (at least users who have enterprise licenses for Microsoft 365 apps).

**Real-world:** Outlook for Windows performs best when you configure it to use cached mode to connect to Exchange Online. In this configuration, you can decide how much of the server copy of the mailbox Outlook should keep locally on the user's computer for faster access. The local cache is known as the OST file and is on the hard drive of the user's computer in a default folder path within their local profile. You can use a slider control in the Outlook account settings to manage how much of the mailbox Outlook synchronizes to the OST file so that you can balance the availability of data and storage consumption. For instance, many users find that keeping the last year's email in the OST is the right balance. Outlook for Mac uses a similar approach to cache mailbox contents on the local drive; it uses a file very similar in concept to the OST file, but with a different structure. Unfortunately, there's no equivalent of the Outlook for Windows slider control, so you can't regulate how much email is synchronized with the client. This is a long-standing, and popular, feature request that Microsoft will hopefully get to sometime soon.

Features come to the three main flavors of Outlook at different times and in an unpredictable order. For example, Microsoft first developed and released "dark mode" for OWA, then rolled it out to macOS users, then to Outlook for Windows customers who were on Monthly Channel (Targeted)... after which the Outlook mobile team released their dark mode implementation. While there are certainly exceptions, in this case, it's fair to say that *most* new features come to OWA first. The individual versions of Outlook have a pretty high degree of independence for feature releases; in general, it seems that new features that require changes to the back-end services in the substrate usually appear first in OWA but that the mobile and desktop versions freely introduce UI-only changes on a more frequent schedule. Overall, the principle Microsoft's trying to apply is that the user experience for its multiplatform applications should be as consistent as possible whilst still fitting into the design language of the host platform—but those underlying implementation choices are to be minimized in favor of giving users a consistent *Microsoft-centric* experience on whatever device they're using. Common UI elements, affordances, color schemes, and so on are the vehicle Microsoft uses to deliver this consistency—if you look at the UI of OWA on Edge, Outlook for Windows, Outlook for macOS, and Outlook on iOS side-by-side, you'll notice the consistency.

Of course, there are always exceptions to this feature flow—starting in October 2021, Microsoft added a toggle labeled "Coming Soon" to Outlook for Windows that allows users to opt into seeing some prominent changes to the Outlook UI, including moving modules to a small left-side navigation rail instead of the bottom of the folder pane. If you want to turn this specific feature off, you can but it [requires a registry change](#).

When it comes to managing Outlook, it's important to differentiate between managing settings on the client (such as whether certain features are enabled or disabled on the client) versus managing them at the tenant level versus managing them at the mailbox or protocol level. For example, you might (and probably should) disable IMAP4 and POP3 in your tenant but that wouldn't necessarily stop an individual user from connecting Outlook using those protocols to another mailbox in another tenant (or another service). Several of the

newest features added to Outlook in late 2020, for example, are integrations with Cortana-powered services for things such as word suggestions. You may be able to control those features at the tenant level but there is no separate policy or setting that allows you to control the features' availability in Outlook itself.

## Outlook for Windows

The C2R version of Outlook for Windows is almost always delivered as part of a Microsoft 365 Apps installation. There are several ways to manage its behavior:

- Policies defined in an Office administrative template and distributed via Group Policy to domain-joined clients.
- Policies defined by the Office Client Policy Service and distributed when the client connects to the service.
- Local customizations made through the Windows registry.
- Local customizations made directly through the Outlook settings interface. These changes typically apply to the user's profile and thus only impact the specific user for whom the customizations are applied.

For the most part, the first three of these management techniques have an identical effect. Which one you use will depend on the infrastructure you deploy. User-specific customizations are a bit tricky, though, because they are usually chosen by the user herself, and users can be *very* protective of their customizations.

## Using Outlook for Windows in a Virtualized Desktop Environment

In virtual desktop environments, such as Citrix XenApp or XenDesktop, where multiple users log onto published applications or desktops hosted on a farm of servers, some issues exist with Outlook when it runs in cached mode:

- The OST files for multiple users accumulate on the hard drive of the server and can quickly consume all the available disk space.
- If a user logs on to a new session on a different server than their last session, the OST file may need to go through a major resynchronization, or even recreate its copy of the mailbox from scratch, which causes both a poor user experience as well as a server performance issue that can affect all other users on the same server.

Similarly, in virtual desktop environments that use non-persistent storage, Outlook needs to rebuild the OST file from scratch each time a user opens Outlook to start a new session.

Microsoft has somewhat belatedly realized that customers want to use Office 365 in environments that are built around virtualized desktops, and they have been making steady improvements to support those environments. For example, in 2019 they modified the default sync behavior for Outlook cached mode to sync the Inbox folder before the Calendar folder, and to reduce the number of folders that were synced (or resynced) by default. As an administrator, you also can tweak Outlook sync settings using the [Office 2019 Group Policy administrative templates](#) (ADMX files) to improve the sync experience in these environments:

- **Sync Settings** – this setting allows you to specify the amount of data (by age) that Outlook should cache in the OST file. For example, you could set this to 1 month for users logging on to the virtual desktop environment and then set it to 12 months for users who typically work from the same desktop or laptop each day. Users who frequently work offline in remote locations may even prefer *all* their email to be cached always.

- **Fast Access** – this setting allows Outlook to connect to Exchange Online in online mode while building the OST file at the same time, and then switches to cached mode when there is enough data available.
- **Cache File** – this setting can be used to specify a network location for storing the OST file so that it can be stored on persistent storage and accessed from any virtual desktop that the user is logging on to. Microsoft has [published guidance](#) and some specific requirements covering this configuration scenario.

There are also third-party solutions, such as [Liquidware's ProfileUnity](#) or [FsLogix Office Container](#), that can help Outlook cached mode perform well in VDI environments. (Technically, FsLogix isn't a third-party solution since it comes from Microsoft but, as it must be deployed separately from Office, I'll call it that).

**Real World:** Microsoft offers several interfaces that developers can use to extend the various Outlook clients. For the most part, there are three categories of plugins: those which work only in Windows Outlook, those which work only in Mac Outlook, and those which are written using the Office extension APIs and can be loaded in both versions of desktop Outlook, OWA, and even Outlook Mobile. For example, the familiar button that allows you to make a meeting into a Teams or Skype meeting with a single click is an "add-in" (the preferred term for desktop-native extensions to Outlook), while the FindTime tool is written with the Office APIs and can thus be used in multiple clients once it's enabled for the user.

## One Outlook/Monarch

We already have a single Outlook client for macOS, Linux, and Windows—it's called OWA. But, for a variety of reasons, not every user wants to, or can, use a web-based client for their everyday work. Microsoft has recognized this, but at the same time they have the quite reasonable desire to consolidate on the smallest possible number of unique client versions. Announced at Ignite 2020, "One Outlook" promises to satisfy both users who want a desktop client and Microsoft's desire for consolidation. For now, the Monarch client is only [available for Windows](#), and even then only to users who are in the Office Insider Beta channel. The current version is missing lots of features that both OWA and the desktop clients have. For example, there's no unified inbox, no support for PST files, and only limited support for offline access. Over time, Microsoft's goal is to reach feature parity with the existing versions, but they aren't quite there yet.

The earlier discussion in this chapter about WebView2 is important for Monarch because some parts of its functionality are enabled by a technology known as OPX ("OWA Powered Experiences"). Just as desktop Outlook embeds the OWA room finder in a separate subpane instead of duplicating its functionality, OPX allows Monarch to consume features originally developed for OWA. That's one big reason for the list of things that Monarch supports or doesn't—it's easier for Microsoft to plug in OWA features using OPX, so those features, in general, were the first ones delivered.

## Outlook for iOS and Android

For many years, Microsoft pursued a terrifically successful strategy of licensing Exchange ActiveSync (EAS) as widely as possible to third parties to enable their devices to connect to Exchange. EAS proved stable and both the cloud and on-premises versions of Exchange include basic security and management capabilities for mobile devices. The strategy of licensing ActiveSync to all and sundry worked in terms of making EAS the de facto protocol for Exchange mobile connectivity. The downside was that Microsoft ceded control over the user experience to the device vendors. Companies like Apple and Samsung incorporate EAS into the mail apps running on their devices while exerting absolute control over which features the clients expose to end-users. Even Microsoft's clients do not use the entire EAS protocol. Exchange ActiveSync was always intended to do

two different things: synchronize mail items between the device and a mailbox and provide mobile device management (including remote device wipe, PIN enforcement, and so on). Despite the popularity of EAS, there was never a real advantage for device vendors to implement all the functionality in the EAS protocol, instead of just whatever subset they felt was useful. A good-enough job allows a user to connect to Exchange and access their mailbox. No added value exists for Apple or Samsung or any other EAS licensee to extend their mail apps to offer more functionality to Exchange users than they do when the apps connect to Gmail or another email server, although some vendors grudgingly added support for a subset of EAS device management features. The native mail app is “good enough” if you can use it to process messages, meetings, tasks, and contacts. This attitude has existed for years and has resulted in situations like the famous series of bugs in the Apple iOS mail and calendar apps that caused excessive transaction log growth on Exchange servers or calendar appointment “hijacking”. The net result is that EAS is now the lowest common denominator protocol for mobile devices to connect to Exchange. The need to do better and to have control over functionality available through mobile clients drove Microsoft to come up with a new two-pronged strategy: first, they bought a company called Accompli and rebranded their clients as Outlook Mobile for iOS and Android, then they invested in improving device management by building mobile device management tools into Microsoft 365 and then releasing Microsoft Intune.

**Licensing Outlook for iOS and Android:** Not all plans include a license for the Outlook mobile clients. [Microsoft's FAQ](#) makes it clear that you need a suitable commercial license. “Suitable” really means that the license grants access to a desktop version of Outlook; Business Basic, Business Standard, and Enterprise E3 or E5 all count, as do or the corresponding versions of those plans for Education or Government. Exchange Online plans or the kiosk (front-line worker) plans may not include a license; these lower license tiers allow the use of Outlook on devices with screens smaller than 10.1”. Users who only have on-premises Exchange mailboxes with no service licenses aren't permitted to use the client at all. However, Microsoft does not enforce these licensing restrictions, so users can violate the license terms without realizing it.

Microsoft has kept up a rather astonishing cadence for feature improvements in the mobile versions of Outlook. The client is regularly updated every two weeks, with minor features and bug fixes appearing in each release and larger, more complex features arriving as soon as they're ready. It's always safe to assume that major Microsoft events will bring out a clutch of feature changes; for example, Ignite 2020 brought better separation between personal and corporate email and contacts, the ability to automate S/MIME certificate distribution, and policies for automatic signing and encrypting, along with several changes to “Play My Emails,” support for the Surface Duo, and more. However, Microsoft regularly releases features as a matter of course, too.

Feature support varies between platform and license. For example, dark mode is available on Android and iOS for both commercial and consumer customers. Support for sensitivity labels and shared mailboxes, on the other hand, are only available to commercial customers, and delegate access is available only to commercial customers whose mailboxes are in the service. As it's impossible to roll out new features to more than 100 million clients worldwide simultaneously, Microsoft uses a random selection process to decide who picks up new features first. Features for both commercial and consumer users go to a random selection of people, which means that it's possible to have some people within a tenant see a feature and some not. Microsoft releases commercial-only features on a tenant-wide basis. Successive waves of releases move the roll-out to 100% status over a period that can take some weeks to complete.

Another unique point about the Android and iOS Outlook clients: their support lifecycle is necessarily quite different from their desktop cousins. Microsoft typically supports two versions of iOS: whatever the latest major release is, and its immediate predecessor. For example, when iOS 14 was released, Microsoft stopped supporting Outlook on iOS 12. In September 2021, Apple released iOS 15, which triggered Microsoft's August

2021 announcement that they'd drop support for Outlook mobile on iOS 13. The rapid adoption of iOS versions means that this n-1 support policy won't generally be a problem for most enterprises, as users will self-update their devices to get the latest shiny goodness, but you should remain aware of it.

## Supporting Outlook Cloud Settings

As part of its steady output of new features, Microsoft occasionally delivers something from the long backlog of features that have been requested for years and years. One example: the ability to synchronize signatures between different machines, something that people have been requesting for nearly two decades! Signature synchronization was the first element of the plan to synchronize most Outlook settings through the cloud, a worthy goal. However, signature sync has been delayed multiple times (see MC305463 for the latest). For now, sync covers a subset of Outlook settings (the settings found in the Advanced, Calendar, Ease of Access, General, Groups, Mail, People, Search, and Tasks tabs), and settings are only synchronized for Outlook on Windows.

By default, this feature is enabled in your tenant, and you can't turn it off at the tenant level; you'll need to use a Group Policy template to disable it. Users can [control the setting themselves](#), though.

## Managing Outlook Web App

When Microsoft first shipped Outlook Web Access, it was primitive compared to desktop Outlook, and yet still revolutionary. It was the first mass-market enterprise product to use the technologies we now call AJAX (asynchronous JavaScript and XML). For several releases, OWA's feature set lagged Windows Outlook, but as time passed, we eventually reached a turning point where new features started to be delivered first into on-premises OWA before reaching the desktop rich clients, and now that trend has accelerated so that on-premises Exchange is basically in maintenance mode with very few new features being released. New client features are more likely to appear first in Outlook Web App in Exchange Online than in desktop Outlook, and it's become very clear that we will see few if any new features in the on-prem version of OWA.

The modern OWA user experience rivals that of the full Outlook client. In fact, for many users, OWA provides all the functionality they need, with the convenience that it can be used from anywhere that has an Internet connection without having to first install client software. A good way to start an argument is to ask a room full of heavy email users whether they prefer OWA or desktop Outlook—you'll probably hear some vigorous opinions pros and cons.

## OWA Browser Compatibility

Outlook Web App works with all the browsers Microsoft 365 supports: the latest versions of Microsoft Edge (including both the original version, officially deprecated in May 2020, and the newer version based on the Chromium browser engine), Firefox, and Chrome on Windows, Safari on macOS, and Firefox or Chrome on Linux. You may see some minor differences in your client as the OWA interface evolves rapidly.

OWA supports a "light" mode that is automatically used for older versions of web browsers or operating systems such as Linux that are not fully supported by Microsoft 365. Being HTML-based, OWA light is used as the accessibility version because it can work better with screen readers. The OWA light user experience is degraded when compared to the full version of OWA, with some features not working or simply not available in the interface.

With the pace of changes and new features appearing across the service, maintaining updates to web browser clients is important for customers. If you experience some unexpected behavior of OWA when running a

supported combination of web browser and operating system, you should check for recent updates to the browser. You can find the latest guidance on [OWA web browser compatibility](#) on the Office Support website.

## Managing Mailbox Settings

Over time, Outlook and Exchange have accumulated a large number of mailbox-level settings to provide fine control over things like whether week numbers are displayed in the calendar view or whether read receipts should be sent. Normally, users will configure these settings themselves, but in some cases, you may want to standardize them; for example, as part of user onboarding, you might want to preload a signature into every newly created mailbox. [Set-MailboxMessageConfiguration](#) controls mailbox settings such as signatures and the use of read receipts; [Set-MailboxCalendarConfiguration](#) covers how the calendar looks and how reminders are managed; [Set-MailboxRegionalConfiguration](#) controls regional settings such as the date and time formats, and [Set-MailboxSpellingConfiguration](#) governs the default spelling checker configuration and language. These cmdlets are covered in more detail in Chapter 6.

## Managing Features with Outlook Web App Mailbox Policies

Outlook Web App mailbox policies provide administrators with control over which OWA features are available to individual mailboxes. Examples of the features controlled by OWA mailbox policies include inbox rules, calendar access, mobile device controls, and social network integration. Although an OWA mailbox policy controls access to these features for OWA, it does not disable them on the mailbox itself. For example, a mailbox user prevented from accessing their calendar due to an OWA mailbox policy can still access their calendar using Outlook or a mobile device.

In the on-premises version of Exchange, the OWA virtual directories also provide a point of control for client functionality. You don't have the option of messing about with vdirs within Exchange Online, so you must work with OWA mailbox policies if you wish to disable specific OWA features. A default OWA mailbox policy is created for each tenant. You'll find OWA mailbox policies, including this default, in the **permissions** section of the classic Exchange admin center. The default policy enables all features for OWA.

The OWA mailbox policy that is assigned to a mailbox user can be viewed and changed in the classic EAC by selecting a mailbox and clicking **View details** under **Email Connectivity**. (The modern EAC shows any assigned OWA mailbox policies on the **Mailbox** pivot of the user details but you can't change policy assignments there yet.) You can also retrieve the OWA mailbox policy that is assigned to a mailbox user by running the `Get-CASMailbox` cmdlet.

```
[PS] C:\> Get-CASMailbox Kim.Akers | Format-List OwaMailboxPolicy
```

```
OwaMailboxPolicy : OwaMailboxPolicy-Default
```

The set of OWA mailbox policies defined in a tenant is accessible through the **Permissions** section of the classic EAC. After opening a policy, you can disable or enable features like autosignatures, the premium client interface, and inbox rules by checking or unchecking boxes. Although convenient to manage the set of features published to users through the EAC, it's important to realize that the EAC surfaces some, but not all, of the possible configuration options for OWA mailbox policies. In this example, the `Get-OWAMailboxPolicy` cmdlet is used to display the name of the OWA mailbox policy, as well as a setting that controls whether the LinkedIn contact sync is enabled within OWA.

```
[PS] C:\> Get-OwaMailboxPolicy | Select Name, LinkedIn*
```

```
Name                : OwaMailboxPolicy-Default
LinkedInEnabled     : True
```

Most organizations only need a single, default OWA mailbox policy to which they make one or two changes to suit organizational needs. Alternatively, you can create multiple OWA mailbox policies and assign them to different mailbox users to limit access to some features. For example, you might want to create an OWA mailbox policy that turns off Calendar access for temporary employees or people working on an assembly line, along with another OWA mailbox policy that allows Calendar access for other users. After configuring a new OWA mailbox policy it needs to be assigned to mailbox users by running the *Set-CASMailbox* cmdlet.

```
[PS] C:\> Get-OwaMailboxPolicy | Format-List name  
  
Name: Limited Access OWA Users  
Name: OwaMailboxPolicy-Default  
  
[PS] C:\> Set-CASMailbox Kim.Akers -OwaMailboxPolicy "Limited Access OWA Users"
```

The next time the user refreshes their session or logs on to OWA the new policy is applied. To revert the mailbox user to the default OWA mailbox policy, run the *Set-CASMailbox* cmdlet again.

```
[PS] C:\> Set-CASMailbox Kim.Akers -OwaMailboxPolicy (Get-OwaMailboxPolicy |  
Where {$_.IsDefault}).Name
```

An OWA mailbox policy is not mandatory for mailboxes (the default policy is applied if one is not specified), so you can also remove policies entirely from the mailbox using *Set-CASMailbox*.

```
[PS] C:\> Set-CASMailbox Kim.Akers -OwaMailboxPolicy $Null
```

## Customizing the OWA URL

The OWA URL for all Exchange Online customers is the same, <https://outlook.office.com>. There are some variations of that URL that will also work thanks to redirections that Microsoft has in place. For example, <http://outlook.office365.com> will redirect from HTTP to HTTPS and from the root of the domain to the /OWA virtual directory.

Although this is a simple URL some organizations would prefer a custom URL that includes their domain name, which may be easier for their end-users to remember. This can be achieved with a simple DNS CNAME record in the organization's public DNS zone. For example, a CNAME of *webmail* in the DNS zone for *office365itpros.com* with a target of *outlook.office365.com*, will redirect anyone browsing to <http://webmail.office365itpros.com> to <http://outlook.office365.com>, where Microsoft's redirection to /owa takes care of the rest.

Aside from the branding and ease of remembering, this is also a good strategy for retaining the same OWA URL that you may have previously used for on-premises Exchange, by simply changing it to a CNAME that resolves to the Exchange Online OWA URL instead. This avoids issues with your end-users still having web browser bookmarks for the on-premises OWA URL. However, this technique should not be used for Hybrid deployments.

## Using Microsoft 365 Groups with Desktop Outlook

Originally, Microsoft intended Microsoft 365 Groups to be used for email-based collaboration as "Outlook Groups." The focus for collaboration has since moved to Teams, but organizations can still use email-based collaboration with Groups through all Outlook clients. Group owners can also manage membership and other group settings through Outlook.

Both Outlook for Windows and Outlook for Mac support Microsoft 365 Groups. Apart from having a suitable client, there are two major prerequisites. First, the Autodiscover service must deliver information to clients about what groups are available in the tenant. This is a straightforward matter (you should not have to do

anything) for a cloud-only tenant but can be more complicated for a hybrid environment. Second, your clients must be capable of using Outlook cached mode.

Groups appear in two places in Outlook. First, Outlook includes any groups marked by a user as a favorite (with either OWA or Outlook) alongside other favorites such as folders and shared mailboxes. The mailbox holds details of favorite groups to make them available across all clients. Second, if the user clicks the **Groups** root in Outlook's navigation pane, Outlook expands the set of Outlook groups to which the user belongs with recently-access groups shown first. Groups do not have a hierarchy, but the full list is sorted in order of use, with the most-recent items at the top. You can browse the set of groups, but it can be easy to "lose" sight of an important group if it is at the end of the list. It's best to highlight important groups by marking them as favorites so that they show up in Outlook's list of favorite folders. The interface used to display the contents of group conversations is like the interface used to display the content of mailbox folders.

When you contribute to a conversation, Outlook posts the message to the group mailbox. Because you're emailing the group, copies of your messages are in the Sent Items folder of your mailbox. Given the way that people use Outlook, it is almost inevitable that many of the interactions with Groups are via normal email rather than opening a group to browse its content. If users have opted to do so, they will receive messages sent to groups in their inboxes and can then respond as they do to any other message.

## Groups Toolbar

After opening a group, Outlook switches its normal ribbon to a special group toolbar. Options available are to start a new conversation, switch to the group calendar, or open the shared group document library or notebook. Selecting **Files** or **Notebook** opens web pages to access the documents in the library or the contents of the shared notebook. Outlook calls the desktop version of OneNote if available on the PC. Otherwise, Outlook invokes the browser version to access the group notebook. The **Group Settings** button allows the user to choose what updates they receive for messages posted to the group (for example, all messages or just replies to your messages).

## Group Calendars

Group calendars appear under Outlook's "All Group Calendars" calendar group. To view items in a group calendar, click its checkbox to display it on-screen. Two ways exist to add an event to a group calendar. You can create an event in your calendar (in which case, you are the organizer) and add the group to the list of attendees. The event invitation goes to the group calendar as well as all members of the group. However, if you create the event in the group calendar, the group is the organizer. Email notifications for the new event will only go to group members who subscribe to the group. The difference in behavior is because a group member creates the item in the calendar instead of the group receiving a meeting request via email. In this case, the mail transport service expands the group membership and subscribers receive copies of the event.

## Groups in the GAL

Like all mail-enabled objects, Groups are in the Address Book, where they appear in the Global Address List (GAL) and the All Groups address list. Users can browse the GAL to find groups and examine their properties. After selecting a group, the user will see the group's properties. If the group is public, they can use the **Join group** button to join the group. If private, the **Request to Join** button emails a request to the group owners to add the person as a member. The group owners can then decide to accept or reject the request to join. There's also a **Send email** button that the user can use to send mail directly to the group, whether or not she has previously joined it.

Navigating through a large directory and scattering groups here and there between all the other objects that make up the GAL can create a search challenge for users. It is helpful when a tenant deploys a naming policy

for groups so that they are all gathered in a single place in the GAL. Once a user has found and joined a group, they can add it to their folder favorites.

## Discovering Groups

The prospect of reviewing hundreds of groups to find just the right one to join can be an intimidating task. To make things easier, users can find groups to join with **Browse Groups** (accessed in the Outlook ribbon or by right-clicking the **Groups** resource in the navigation pane). Like OWA's **Discover** feature, Browse Groups displays a set of suggested groups that the user might be interested in joining (Figure 15-2). Outlook uses the Microsoft Graph Insights API to calculate the set of suggested groups based on interactions between users. Simply put, if three other people often use a group and you interact with them often, a high chance exists that the group will show up as a suggestion.

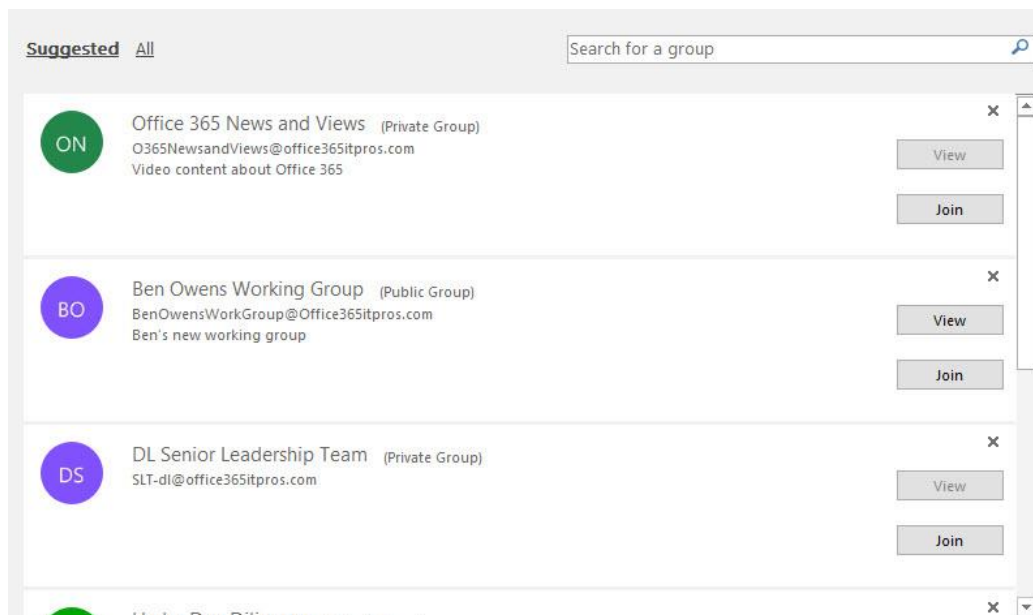

Figure 15-2: Browsing suggested groups from Outlook

Users can see what is happening in a public group by clicking **View**. This opens the group and shows the user the most recent conversations. Clicking **All** reveals a full alphabetic listing of available groups, including those that the user has already joined. It is the equivalent of viewing the *All Groups* address list.

## Offline Access for Groups

One of the biggest advantages of Outlook is its ability to enable users to continue working when a network connection is unavailable. Outlook stores offline group content in the GST (group storage table file). The GST is analogous to the OST used for offline mailbox content and is in the same folder as the OST with a .nst extension.

For performance reasons, Outlook synchronizes conversations and calendar data for groups accessed by the user into the GST. Outlook must run in cached Exchange mode for synchronization to occur, which means that Groups are not available when the client runs in online mode. Groups do not even appear in Outlook's resource list when the client works in online mode. This is an issue for deployments where Outlook runs on thin clients and local files are undesirable. A partial workaround exists by configuring Outlook to synchronize a minimal amount of data. However, given that much of the information shared by groups is only available online, OWA might be the better client choice as people in these situations don't need one of Outlook's strongest selling points (offline access).

Offline access to data in the group document library and shared notebook is not dependent on Outlook. You can synchronize the group document library with the OneDrive for Business sync client to have copies of those files offline, but you cannot get to this cache directly from Outlook. Instead, you can access the synchronized files through File Explorer and make changes there. The group notebook is also accessible offline if you have used it with the OneNote desktop application. OneNote synchronizes any change made in the desktop copy of the notebook back to the online version when the network is available again.

Like mailbox folders, Outlook synchronizes any updates for group conversations created when working offline to the server once a network connection is available.

## How Autodiscover tells Outlook About Groups

Outlook learns about new mailbox resources such as a new shared mailbox through the XML manifest returned by Autodiscover. Although they show some of the same characteristics as shared mailboxes, Autodiscover does not process group mailboxes in the same way. After it returns information about the user's mailbox and any other mailboxes that a user can access, Autodiscover issues a call to list all the Groups that the user belongs to. Details of each group are put in a set of XML files in the `C:\Users\<username>\AppData\Local\Microsoft\Outlook\16` folder (for Outlook 2016). Autodiscover generates a separate XML file, prefixed with "AutoD", for each group, and refreshes the data hourly.

## Group Visibility

Not all Microsoft 365 Groups appear in Exchange Online clients like Outlook. Since mid-2018, Microsoft hides the groups used by Teams from Exchange Online. The rule is:

- New Groups created by Teams set the *HiddenFromExchangeClientsEnabled* property to *\$True*. This stops Exchange clients like Outlook from listing team-enabled groups. Teams also sets the *HiddenFromAddressListsEnabled* property for its groups to *\$True* to prevent the groups from appearing in the GAL and other address lists.
- New Groups created by Outlook and Microsoft 365 administrative interfaces set the *HiddenFromExchangeClientsEnabled* property to *\$False*.

These are the default settings. As described in Chapter 11, you can set their values to control whether users can find team-enabled groups in the GAL.

## Using Microsoft 365 Groups with OWA

OWA was the first client to support Groups and is usually the first client to surface new functionality. If you expand the **Groups** section in OWA's left-hand navigation pane a list of the most used Groups appears. You can click **More** to expand the full list. In this case, OWA lists the groups that you have added to your Favorites list, followed by all groups of which you are a member. You can use the right-click menu to view information about a group or to add or remove it from your favorites list. An option to copy the email address of the group is also available in the right-click menu.

Click on the name of a group to access its contents. The first thing you see are the conversations in the group mailbox (Figure 15-3). A list of conversations in chronological order (last in, first out) appears to the left, and the items that make up the selected conversation appear in the viewing pane to the right. You can set the read status for individual conversations as read or unread, just like you can for messages in your mailbox.

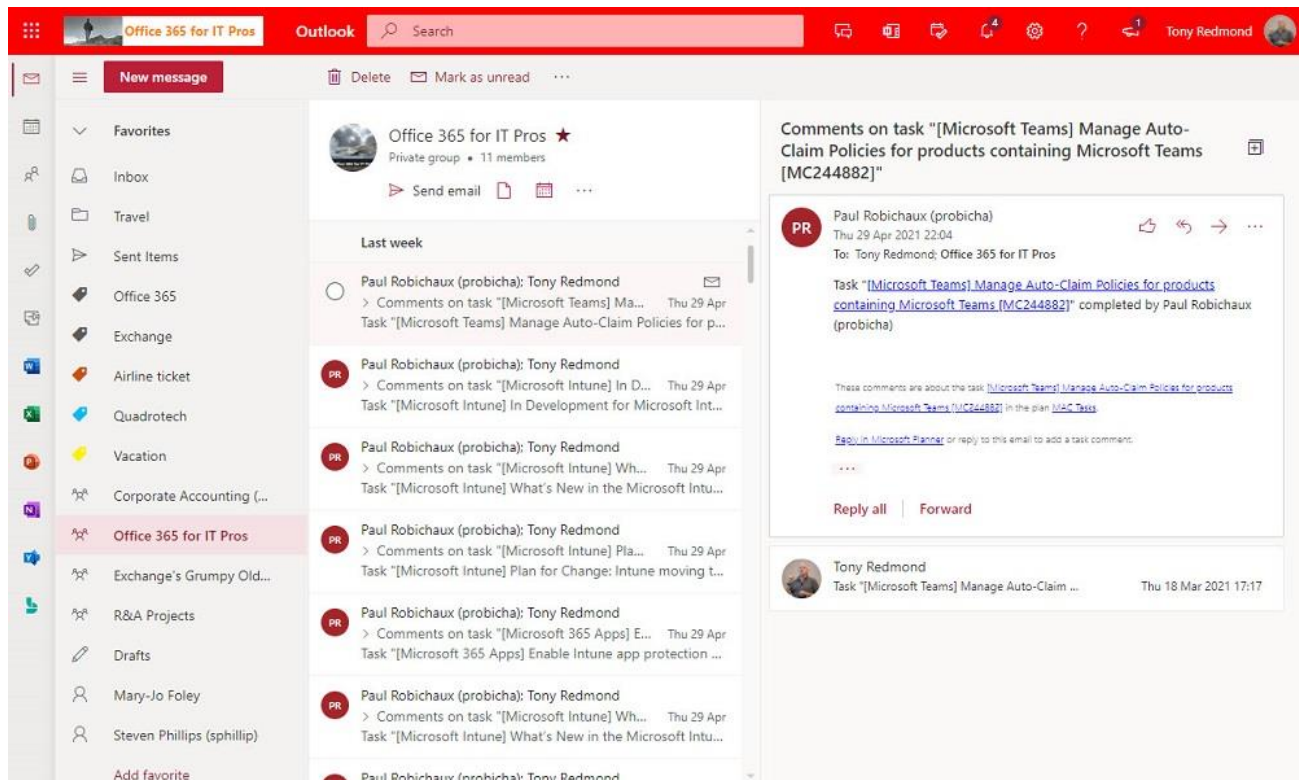

Figure 15-3: The OWA interface for group conversations

Users can reply to the selected conversation by hitting the corresponding button at the bottom of the list of contributions, which invokes the OWA editor. You can use the @ sign to address individual people (including those who are not members of the group). If you add someone outside the list to a conversation, they receive a copy of all earlier items in the conversation and Groups adds their email address to the conversation to ensure that they receive later contributions. When the reply is complete, click send. OWA submits the message for processing through the messaging system to allow Exchange Online to apply transport rules before delivering the item to the group mailbox. Once delivered, the item appears in the conversation.

In the menu bar under the group name, we see icons to switch between:

- **Group Files:** The group document library in SharePoint Online. This view shows the files and email attachments available to the group.
- **Group Calendar:** The group calendar. By default, the group calendar displays alongside the user's calendar using the normal OWA calendar interface.

The [...] menu reveals:

- **Planner:** Access the default plan for the group – if one does not exist, it will be created.
- **Notebook:** The group shared notebook. Other OneNote notebooks can be stored in the document library.
- **Site:** Open a new tab to access the home page of the SharePoint team site for the group.
- **Settings:** You can:
  - **Manage group email:** Decide what messages you receive from the group.
  - **Edit Group** (for group owners): Edit group settings, like whether it is public or private.
  - **Connectors:** Connect the group to various network data sources. We explore how to use Connectors with Groups in Chapter 13.

The settings menu includes the option to **Leave** the group. The menu bar also shows whether the group is private or public.

**Deleting conversation items:** Sometimes people post content to groups that should not appear. Perhaps a conversation includes some inaccurate information or maybe it is just a matter of formatting, spelling, or the choice of words that makes someone want to retract a conversation or a reply to a conversation. OWA allows a user to remove a complete conversation if they start that conversation. Group owners can remove conversations started by any user. OWA also allows users and group owners to remove individual items from a conversation and user who starts a conversation can remove an individual reply from that conversation, even if they are not its author. Removing items during a conversation is not something that should happen without thought as someone else might be replying only to discover that their reply does not make sense when posted. Users and group owners can also remove conversation items with Outlook, but Outlook does not support the deletion of individual items within a conversation. Deletion affects all replies, including those from other users. Unlike personal mailboxes, when a user removes a reply or conversation from a group mailbox, the deleted items do not move into the Recoverable Items folder. Instead, Exchange Online moves the deleted items into the Deletions sub-folder of Recoverable Items in the group mailbox. The deleted items stay in Deletions for 14 days after which the Managed Folder Assistant permanently removes them from the database. The exception is when the group is under the control of a hold, such as those placed by an eDiscovery case, or must be kept because a retention label exists for an item. In this case, the deleted items stay in Deletions for 14 days as normal and then move to the Purges sub-folder, where they stay until an administrator releases the hold or the hold expires.

## Discovering Groups

Naturally, you might want to find some more groups to join. To see what is available, click **Discover Groups** under the Groups section in OWA's resource list and OWA lists a set of cards displaying information about groups that you might want to join (Figure 15-4). Queries against the Microsoft Graph Insights API calculate the set of groups to display, based on the people with whom the user interacts inside the tenant and other signals. Frequent interaction with someone is a strong sign that you might like to be part of a group that the person already belongs to. You can click the X in the top right-hand corner of a card (exposed when you hover the cursor over the card) to hide it from view and show that you are not interested in the group.

Clicking a card displays more information about the group. The name and description are critical to conveying the intent and purpose of the group to a potential member. For example, "HR Working Group" is a reasonable title for a group as it is easy to understand that this group is probably associated with the Human Resources department and is to do with some item of work that the department needs to do.

The search box allows you to look for a group based on its name and the results include groups that you have yet to join as well as those you already belong to. One immediate shortcoming is obvious in that no facility is available for users to narrow their search. For example, you cannot look only for public groups that have a certain word in their title or use other search criteria to find the right group to join.

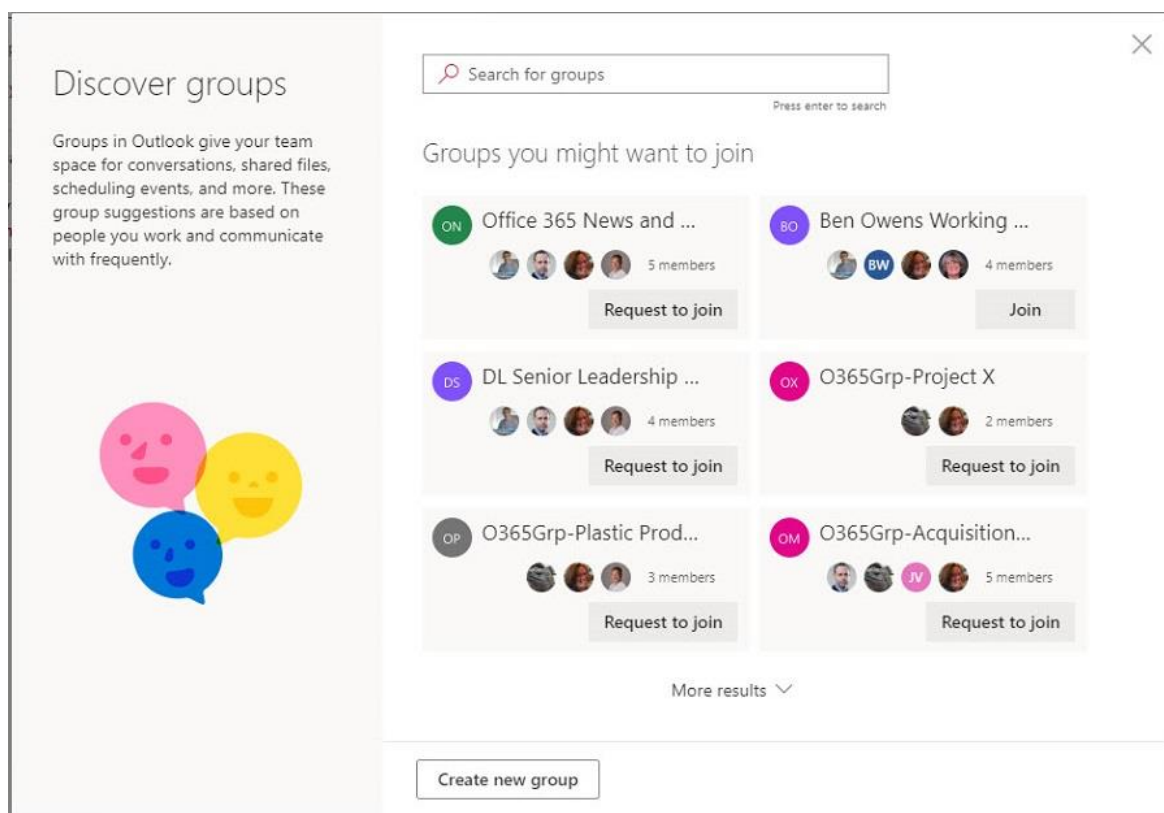

Figure 15-4: Viewing Groups a user might want to join

## Managing Client Access and Protocols

Managing which clients can use mailboxes, and what protocols they can use to do so, is not so common a task as it was in the days before the cloud, but you may still find that you need to apply some restrictions to block old clients, protocols you don't want on your network, and generally tailor connections to meet your security needs. Microsoft 365 can do this in multiple ways, including applying conditional access settings (as described in Chapter 3), using mobile application management (MAM) to control what mobile applications can do (Chapter 16), or controlling the protocols and client access on the service side.

### Managing Application Idle Timeout Periods

Since its introduction as part of Exchange 5.5, OWA has had an idle timeout feature that allows administrators to sign out users after a specified period of inactivity. SharePoint Online has a similar feature, and of course, Azure AD token expiration and revocation may force users to log in again at any time even if they've been active. In late June 2022, Microsoft made a [new idle session timeout feature](#) generally available for a selected set of Microsoft 365 web apps. For now, idle session timeout covers OWA, OneDrive for Business, SharePoint, Office.com, the Office web apps, and the Microsoft 365 admin center, but it should cover more apps in the future. Once you configure the idle session timeout feature in the **Security & privacy** tab of the **Org settings** item in the Microsoft 365 Admin center, the timeout you specify will take effect in all supported apps and supersedes the timeout values set for OWA and SharePoint Online.

### Managing Mailbox Client Protocols

A set of connectivity protocols is available to allow clients to connect to Exchange Online. By default, Exchange Online mailboxes can use all protocols and features, which include:

- **Mail Application Programming Interface (MAPI)** - Outlook clients use MAPI to connect to mailboxes. Older Outlook clients are still able to connect using RPC over HTTP, but Outlook 2010 and newer clients running the latest service packs and updates connect using MAPI over HTTP. RPC over HTTP is an unsupported protocol from October 31, 2017.
- **HTTPS:** the OWA webmail client for Exchange Online connects via the HTTPS protocol.
- **Exchange ActiveSync** - Most mobile devices and applications that connect to Exchange Online do so via the Exchange ActiveSync (EAS) protocol. Note that Microsoft has no control over how a vendor implements the EAS protocol in their email client, a fact that accounts for some "interesting" problems that have occurred with mobile devices over the years. Of course, because the Windows 10 Mail client uses Exchange ActiveSync, Microsoft does have control over its behavior!
- **POP3/IMAP4** - although these are now outdated protocols that do not support the advanced features found in most email clients, some users still use POP or IMAP to connect to mailboxes, and IMAP is also commonly used by external applications that need to ingest email items from mailboxes. POP and IMAP are covered in Chapter 9 of the companion volume to this book.
- **Exchange Web Services (EWS)** - EWS is the API for application access to Exchange mailbox resources, commonly used for integrating external applications. EWS is also used by Outlook to retrieve free/busy, out-of-office, and calendar sharing information.
- **SMTP** - Outlook can perform all its functions using MAPI, but POP and IMAP are access-only protocols. IMAP and POP clients need to use SMTP to send emails. SMTP is also used by external applications to send emails.
- **Microsoft Graph/REST API** - The Microsoft 365 APIs allow applications to access data such as email messages, contacts, calendars, and files. There are separate APIs for the various services (like Outlook and Teams), as well as the Microsoft Graph API.

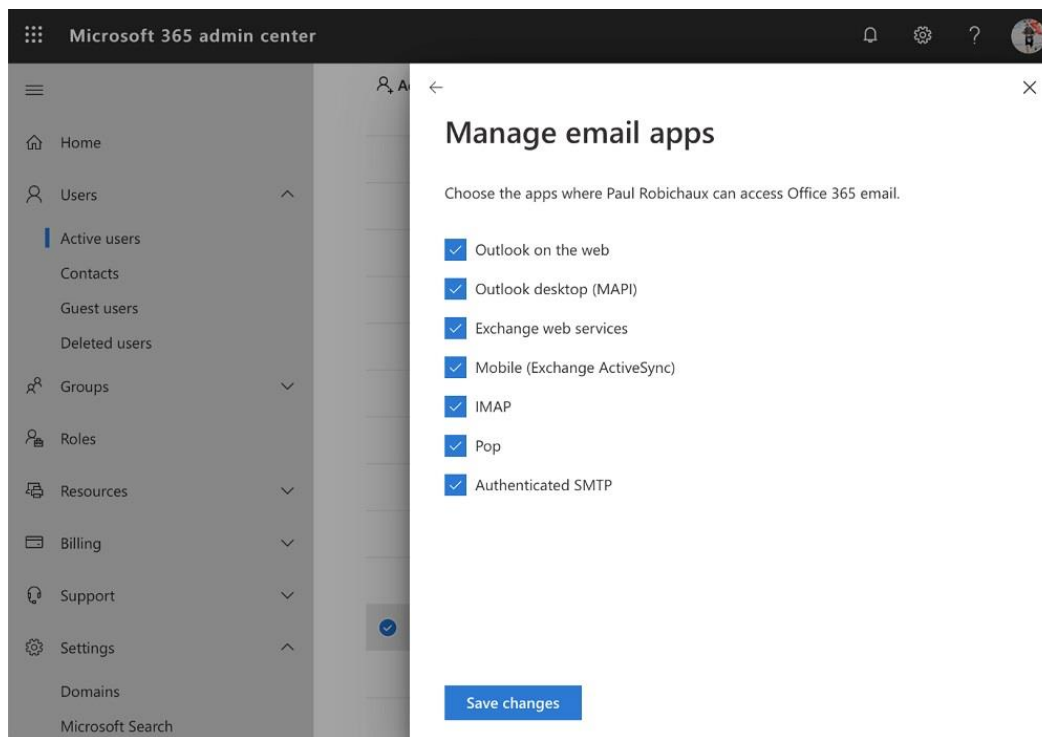

Figure 15-5: Accessing email apps settings in the Microsoft 365 admin center

You can manage mailbox client protocols through the Microsoft 365 admin center, the classic EAC, or PowerShell. Different capabilities exist through each interface, which we will explore in this section. First, the Microsoft 365 admin center includes an "Email Apps" section for user properties. Select a user, and then click

the **Manage email apps** link in the **Mail** pivot and you'll see a list of available protocols (Figure 15-5). Enabling or disabling access to a client protocol is merely a matter of checking the boxes accordingly.

To change the client protocols available to a user through the classic EAC, go to the **mailboxes** section under **Recipients**, open the properties of any mailbox, then **mailbox features**, and then scroll down the controls for the different protocols. The modern EAC doesn't support this feature yet.

You can disable a protocol by clicking the **disable** link. To enable the protocol for the mailbox user again click the **enable** link. Most protocols can be managed in the classic EAC, however, access to Exchange Web Services (EWS) can only be managed using PowerShell. Managing EWS is described in more detail later.

To view the status of each client protocol for a mailbox user via PowerShell, use the *Get-CASMailbox* cmdlet.

```
[PS] C:\> Get-CASMailbox -Identity Kim.Akers | Select *enabled
```

```
ActiveSyncEnabled      : True
OWAEnabled              : True
OWAforDevicesEnabled   : True
ECPEnabled              : True
PopEnabled              : False
PopMessageDeleteEnabled : False
ImapEnabled             : False
MAPIEnabled             : True
MapiHttpEnabled         : True
UniversalOutlookEnabled : True
OutlookMobileEnabled   : True
MacOutlookEnabled      : True
EwsEnabled              : True
OneWinNativeOutlookEnabled : False
```

To disable a client protocol in PowerShell, you could use the *Set-CASMailbox* cmdlet. For example, to disable access to the Monarch client for a mailbox, run the following command:

```
[PS] C:\> Set-CASMailbox -Identity Kim.Akers - OneWinNativeOutlookEnabled $False
```

You can repeat the same steps for each protocol. If you have a combination of enabled/disabled protocols you want to apply to mailboxes by default, then you will need to develop a custom script to apply those changes as part of your mailbox provisioning process. You may be able to avoid some of this tedium now that Microsoft has given us the [Set-CASMailboxPlan cmdlet](#). This cmdlet allows you to set up a template for protocol access, then apply the template automatically to newly created mailboxes. By default, you get four CAS mailbox plans in the service; you cannot create, rename, or remove them. The plan applied when a mailbox is created depends on the license assigned to the mailbox: Exchange Online Kiosk plans get the ExchangeOnlineDeskless plan, Exchange Online P1 gets ExchangeOnline, and Exchange Online P2 gets ExchangeOnlineEnterprise (which means that E3 and E5 subscribers get it too). Microsoft 365 Business Basic subscriptions get ExchangeOnlineEssentials. Suppose you wanted newly created mailboxes for your enterprise users to have IMAP and POP disabled—you could easily do this by running the following cmdlet:

```
[PS] C:\> Set-CASMailboxPlan -Identity ExchangeOnlineEnterprise -POP3Enabled $False -IMAPEnabled $false
```

**Note:** There are two protocols in the *Get/Set-CASMailbox* cmdlets that you can probably ignore for now. *MapiHttpEnabled* is only applicable to on-premises Exchange organizations, so changing it in a cloud environment will do nothing. The second, *UniversalOutlookEnabled*, controls whether the Mail app for Windows 10 (sometimes called "Universal Outlook" in news articles and blog posts) is enabled.

## Managing Exchange Web Services

The Exchange Web Services (EWS) API was originally introduced with Exchange 2007 as a replacement for WebDAV and, at the time, the planned successor to MAPI. MAPI lives on, but so does EWS. Applications can use EWS to retrieve information from Exchange Online services or to interact with data in Exchange Online mailboxes. For example, an EWS application can retrieve information about calendar items for room mailboxes to determine which items might have an organizer who no longer works for the company.

Since 2018, Microsoft has steadily been [moving away from EWS](#) as the preferred API for programmatic access to Exchange Online data, in favor of Microsoft Graph. This change has no impact on on-premises Exchange servers. However, for those who are using EWS to talk to Exchange Online, this change means that:

- EWS will not receive future feature updates.
- Microsoft will decommission basic authentication for EWS and exclusively use [OAuth 2.0](#). Originally planned for October 13, 2020, due to the worldwide COVID-19 pandemic, Microsoft temporarily paused its plan to block basic authentication for connectivity protocols where tenants actively use these connections. However, the plan is now back to full strength: Microsoft will decommission basic authentication fully in October 2022 and is already being turned off for select tenants when Microsoft detects that the protocol is unused in the tenant.
- EWS will remain supported in production for Exchange Online environments if you use OAuth 2.0.
- Microsoft deprecated 25 EWS APIs ([listed here](#)) on March 31, 2022.
- Beginning in September 2022, Microsoft will block the registration of new EWS applications. That means that migration vendors, as well as vendors that create client applications that leverage EWS, won't be able to register new instances of their applications—which will pose a problem for vendors whose applications depend on capabilities that aren't yet available in Graph.

If you create (or use) applications that use EWS features not yet present in Graph, you'll be stuck with using EWS unless and until Microsoft delivers feature parity between the two.

Despite Microsoft's plans to eventually deprecate it, there are lots of clients that still use EWS today. For example, the Windows Outlook client uses EWS for calendar free/busy information, Out of Office settings, calendar sharing, and other features such as MailTips. Other applications (including the macOS Mail application) use it for access to mailbox data as well. As with the other protocols used to access Exchange Online, there are controls available for administrators to use for a variety of scenarios. EWS controls can be managed at the mailbox level or the organization level. The EWS settings for a mailbox are retrieved by running the *Get-CASMailbox* cmdlet, and the organization level settings are retrieved by running the *Get-OrganizationConfig* cmdlet.

### Using the EWS Application Allow or Block List

Because EWS was the preferred protocol for mailbox access, naturally an ecosystem of third-party tools sprung up that used EWS to access mailbox data. For example, the Fantastical calendaring application for macOS and iOS uses EWS to access your calendar when you install it, and LinkedIn for years had an option to synchronize your mail contacts to their service using EWS. Thankfully, Microsoft has provided tools for controlling these applications without having to block *all* EWS traffic.

Disabling the entire EWS protocol because of one unapproved example of application access would deny your organization the many good things that EWS allows. Fortunately, we can be selective in what we block or allow for EWS by configuring an EWS application access policy. The EWS application access policy can be configured on a per-mailbox basis or configured for the entire organization. It's important to know that this

blocking mechanism depends on the User-Agent header sent by the client to the service, which is easily spoofed. Don't rely on this mechanism alone to protect critical data.

**Real World:** If your tenant has "K" (Kiosk) or Office 365 F3 licenses, the EWS allow/block controls for your tenant will not work at the organization level. For non-Kiosk mailboxes, apply the allow/block controls on a per-mailbox basis. For the mailboxes themselves, direct EWS application access to the mailboxes is not permitted anyway.

Suppose you wanted to block access to an application whose User-Agent string had a value of "LinkedInEWS." This would require two separate calls to the *Set-OrganizationConfig* cmdlet. First, set the *EWSApplicationAccessPolicy* to enforce the block list.

```
[PS] C:\> Set-OrganizationConfig -EwsApplicationAccessPolicy EnforceBlockList
```

Unless and until you do this, the EWS block list won't be used at all. Next, add the target user agent to the EWS block list.

```
[PS] C:\> Set-OrganizationConfig -EwsBlockList @{add='LinkedInEWS'}
```

The EWS block list is a multi-value attribute so it should be managed using add/remove methods to avoid overwriting existing values when you are making modifications. For example, to add the Outlook mobile user agent to the block list you'd run this command.

```
[PS] C:\> Set-OrganizationConfig -EwsBlockList @{add='Outlook-iOS/*',"Outlook-Android/*"}
Get-OrganizationConfig | Format-List ewsblocklist
EwsBlockList: {Outlook-iOS/*, Outlook-Android/*, LinkedInEWS*}
```

Similarly, to remove an entry you run this command.

```
[PS] C:\> Set-OrganizationConfig -EwsBlockList @{remove="LinkedInEWS*"}
Get-OrganizationConfig | Format-List ewsblocklist
EwsBlockList: {Outlook-iOS/*, Outlook-Android/* }
```

Unlike ActiveSync device access rules, the strings used for EWS block and allow lists can use wildcards for partial matches. However, unlike ActiveSync controls there is no quarantine action available, only allow or block.

If you only wanted to block access for an application on a single mailbox, you'd follow the same process, except that you'd use the *Set-CASMailbox* cmdlet instead of *Set-OrganizationConfig*. Enforcing a block list will permit any EWS application that is not in the block list to connect. A more restrictive approach is to enforce an allow list instead, which requires that any EWS applications be listed in the allow list before they can connect.

```
[PS] C:\> Set-OrganizationConfig -EwsApplicationAccessPolicy EnforceAllowList
```

Enforcing a block or allow list for EWS has no impact on the Entourage, Outlook for Mac, or Microsoft Outlook applications. These applications are controlled with different EWS settings which are discussed next.

## Blocking/Allowing Mac Clients

Organizations that standardize on Windows may want to block Mac clients from various parts of their network. In addition, organizations that allow Macs may still want to control how clients connect. For example,

an organization that supports BYOD may wish to require users to connect only through Outlook Web App or Outlook Mobile.

Even though some versions of the Mac Outlook client use EWS, Microsoft provides a separate way to prevent only Microsoft's Mac clients from connecting to the service. The Mac clients are allowed by default and can be blocked using *Set-CASMailbox* or *Set-OrganizationConfig*. For example, to block Mac Outlook for a mailbox user you would run the following command.

```
[PS] C:\> Set-CASMailbox Kim.Akers -MacOutlookEnabled $False
```

Apple's Mail and Calendar clients use EWS, and you can block their access by specifying their user agent strings using the EWS block list described in the preceding section. Note that the *EwsAllowEntourage* flag to these cmdlets only affects the ancient, and long-deprecated, Microsoft Entourage client for macOS. It doesn't affect any other client.

## Blocking/Allowing Outlook EWS Access

You can also block Windows Outlook's access to EWS. This will break free/busy information, Out of Office, and calendar sharing. Blocking Outlook is a rare requirement and typically only applies to organizations that want to limit specific users from being able to share calendars or see the availability of other users.

The *Set-CASMailbox* or *Set-OrganizationConfig* cmdlets are used to apply the block. For example, to block EWS access by Outlook for a mailbox user you would run the following command.

```
[PS] C:\> Set-CASMailbox Kim.Akers -EwsAllowOutlook $False
```

## Other Uses for EWS

Exchange Web Services is used by many organizations for custom application development, such as creating integrations between Exchange Online and their in-house line of business applications. It was also the API used for integration between Exchange Online and other Microsoft services such as Skype for Business and SharePoint Online. EWS applications can send and receive email messages, manage calendar items, and a whole lot more.

Many third-party migration tools use EWS to access Exchange Online mailboxes. In addition, an ecosystem of "cloud backup" products uses EWS as the access protocol to extract mailbox data from Exchange Online to copy to cloud storage and so meet the needs of many organizations who would like to make use of cloud systems but are concerned about backup and recovery.

Starting on September 30, 2022, Microsoft will block tenants from registering new EWS applications in Azure Active Directory. This will effectively prevent new deployments of any applications that use EWS, whether from commercial vendors or internal applications.

## Client Access Rules

Exchange Online supports the ability for a tenant to create and apply client access rules, which let you block or allow specific protocols, authentication types, and IP address ranges. The *New-ClientAccessRule* cmdlet creates [client access rules](#); as you would expect, *Get-ClientAccessRule*, *Set-ClientAccessRule*, and *Remove-ClientAccessRule* cmdlets are also available. You must use PowerShell to create and manage client access rules, as there is no support for them in the Exchange admin center.

To be more specific, you can use these rules to selectively block or allow access through the Exchange ActiveSync, IMAP, EWS, Outlook Anywhere, OWA, POP3, PowerShell, and REST API access, as well as controlling access to the Exchange Admin Center and PowerShell Web Services. You can also restrict or allow

connections using AD FS, basic, certificate-based, or OAuth authentication types. These selectors can be combined so that, for example, you can do things like block all OWA access that's not authenticated via AD FS.

By default, a tenant has no client access rules, so anyone with a valid mailbox can access Exchange Online from any IP address using any protocol not blocked at the tenant or mailbox level. A tenant can define up to 20 rules to control what protocols clients can use over what connections. You can even create a filter based on some Azure Active Directory account properties to control the scope of a rule (for instance, only apply this rule to users in Dublin). This example creates a new rule to block ActiveSync connections such as those from Apple iOS mail app clients unless they come from a specific IP address range corresponding to the corporate network.

```
[PS] C:\> New-ClientAccessRule -Name "Block ActiveSync" -Action DenyAccess -AnyOfProtocols ExchangeActiveSync -ExceptAnyOfClientIPAddressesOrRanges 203.0.113.0/24
```

Each rule must contain an action (specifying whether the rule should allow or block access when its conditions are met) and then a set of conditions. These conditions may either be positive or negative; that is, for a positive condition, the rule matches if the specified parameter *does* match the rule, and for a negative condition the rule matches if the specified parameter *doesn't* match. The rule above is an example of a negative condition: it matches any IP that is not in the specified range. You could get the same effect using this command:

```
[PS] C:\> New-ClientAccessRule -Name "Block ActiveSync" -Action AllowAccess -AnyOfProtocols ExchangeActiveSync -AnyOfClientIPAddressesOrRanges 203.0.113.0/24
```

However, this example wouldn't do anything unless you created other rules, because by default all clients can connect using all protocols from all addresses. To make this rule work, you'd need another rule that blocks everything else... so it's simpler just to use the first form unless you need a more complex set of rules to enforce your requirements.

Exchange evaluates client access rules in priority order, which you can alter to promote or demote rules. As soon as the conditions of a rule match, the rule is applied, and rule processing stops. When you create a rule, you can explicitly apply a priority (0 is the highest priority value). If you don't specify a priority, the first rule you add becomes priority 0, the second priority 1, and so on. Changing the priority of an existing rule bumps down the priority of all the rules after it; if you create a new rule with priority 5, the former priority-5 rule becomes priority 6, and all rules after it follow suit.

**Creating Client Access Rules Programmatically:** PowerShell is one of the protocols you can control with client access rules. Microsoft strongly recommends that the first rule you create is this:

```
[PS] C:\> New-ClientAccessRule -Name AllowPS -Action Allow -AnyOfProtocols RemotePowerShell -Priority 0
```

This rule guarantees that you'll be able to use Remote PowerShell even if you later create a rule that might block it. If you do manage to create a rule that prevents you from using PowerShell against your tenant, you'll have to contact Microsoft support to ask them to fix it.

You can create rules that apply to users instead of only to protocols and IP ranges, too. The *UserNameMatchesAnyOfPatterns*, *UserRecipientFilter*, and *ExceptUserNameMatchesAnyOfPatterns* conditions are useful for meeting requirements such as "Allow any users in the sales department to use Exchange ActiveSync but block it for everyone else." In that case, using *UserRecipientFilter {Department -eq "Sales"}* as a filter condition would do the trick.

You can also scope rules to control whether they apply to users only or all applications and clients. If you scope a rule using `-Scope All`, connections from services and applications (such as EWS connections from an on-premises hybrid Skype for Business server) will be affected by the rule.

Because you can create complex chains of rules, it is very important to validate the effect of the rules you build using a test tenant. Even with the [Test-ClientAccessRule](#) cmdlet, there's no substitute for a thorough test before you unleash these rules on your environment.

## Managing OneDrive for Business Clients

The OneDrive for Business client has come a long way since its 2016 debut. The first version of the client was based on the legacy Groove.exe client, then Microsoft introduced the Next Generation Sync Client (NGSC). NGSC morphed into what is now known as OneDrive and has by now replaced the legacy client. The current client offers full sync functionality for personal OneDrive folders, OneDrive for Business libraries, and SharePoint Online document libraries (including those associated with Microsoft 365 Groups). Sync works across tenants and Active Directory domains; for example, the files used to produce this book are hosted in the Office 365 for IT Pros tenant, but I synchronize them to several Mac and Windows PCs that are joined to various (or no) other Azure AD tenants.

### Deploying the OneDrive Sync Client

If you've already deployed a reasonably modern version of the desktop applications to your computers (say, Office 2016 or later), then the latest OneDrive client is installed. Note that the OneDrive client has its separate update mechanism and doesn't get updates through the same channel as either Office or the host OS.

If you have domain-joined computers, you should probably also download and configure the [OneDrive Group Policy template](#) for your organization. If you plan to use Group Policy to control sync settings for end-users, you will need to modify the copy of the Group Policy ADMX file that you place in your Central Store. You can edit the file using any text editor such as Notepad or Visual Studio Code. Within the ADMX file replace any instances of the placeholder text for the tenant ID with your real tenant ID, discovered by running the `Get-MgOrganization` cmdlet. The tenant ID is the GUID string displayed after a successful connection.

```
PS C:\> Connect-MgGraph
Get-MgOrganization | Select Id

Id
--
2b9bca49-687e-4e5f-8a52-21350b719b06
```

The Group Policy template also contains a [wealth of other settings](#), including controls that allow you to restrict what tenants users may synchronize with, control what the client should do on laptops when they're on battery power, apply default bandwidth limits for upload and download, block sync traffic when the computer is idle and no one is signed into it, and block or allow the client from synchronizing personal OneDrive accounts.

Besides these Group Policy-based settings, Microsoft supports [silently configuring OneDrive using the user's credentials](#) to provide single sign-on, but this requires you to configure the `SilentAccountConfig` registry key. If you don't do that, plan on communicating to your users how to sign into their OneDrive client manually.

## Managing OneDrive Sync Client Updates

Whether you install the OneDrive sync client with Microsoft 365 Apps or by using the OneDrive standalone installer, the sync client application files are installed in the `%localappdata%\Microsoft\OneDrive` folder. This means that OneDrive is installed by default as a per-user application, not as a per-computer application. It also means that OneDrive can be installed and updated by users who do not have local administrative rights on the computer. If you want to install the OneDrive client per machine, you can do so [with these instructions](#).

Microsoft releases OneDrive sync client updates through [three deployment rings](#):

- **Insiders** – this ring is an opt-in distribution channel for early adopters; releases into this ring go only to users who have enrolled in the Windows or Office Insider programs. Complete deployment of a new version into this ring takes about 3 days.
- **Production** – Once Microsoft releases a new update for this ring, updates are released to a small percentage of clients in this ring first, and the remaining clients receive the update within approximately two weeks. This is the default deployment ring for OneDrive installs, and there are no controls available for including or excluding your computers from that initial small percentage of clients that receive updates first. During the release of updates to the production ring, Microsoft uses its telemetry to measure the success of the initial rollout. If a problem is discovered, updates will be stopped while a fix is developed. The clients that received the problematic update will then be the first to receive the next update to fix the issues, and then updating will continue through the rest of the production ring.
- **Deferred** - Updates are released to the deferred ring only after they have been successfully deployed to the production ring without any major issues. The deferred ring receives updates over a 60-day window that starts after the production ring deployment window has ended. Critical updates might be released to clients early in that 60-day window, but otherwise, you can expect your clients to update any time within that period. You can use [Group Policy objects](#) to control this behavior.

The OneDrive sync client checks for newly available updates every 24 hours while it is running. To check for or apply sync updates, the client must be able to reach the `oneclient.sfx.ms` and `g.live.com` domains. If OneDrive has not been running within the last 24 hours, it will check for updates immediately the next time it starts. Windows 10 clients also have a scheduled task that will check for OneDrive updates every 24 hours regardless of whether the sync client has been running. These mechanisms are all designed to keep OneDrive updated with the latest bug fixes and feature enhancements. If you're tempted to block OneDrive from checking online for updates then you'll need to periodically check for an updated OneDrive standalone installer, download the updated application files, package them for deployment, and then manage the rollout using your enterprise software deployment tool. That's an unnecessary overhead for most organizations though. If you prefer to take a conservative approach to OneDrive updates then you can configure clients to use the enterprise ring, but you should be aware that this will slow the release of new features as well.

You can configure the update ring for OneDrive by using the [OneDrive Group Policy template](#). In **User Configuration, Administrative Templates, OneDrive**, there is a setting to *Delay updating OneDrive.exe until the second release wave*. Enabling that setting places the client in the deferred deployment ring.

## Managing Teams Clients

The Teams desktop app is available for:

- **Windows:** 32-bit versions are available for Windows 8.1 or later; a native 64-bit ARM version is available for ARM on Windows 10. You can also install Teams on Windows Server 2012 R2 or later. Teams requires .NET Framework 4.5 or later.
- **macOS:** running OS X 10.11.0 or later. There is no officially released Apple Silicon-native Teams client, although the Intel version runs fine on Apple Silicon machines.
- **Linux:** .deb and .rpm formats.

If you prefer to use MSI packages to control the roll-out of Windows desktop clients, you can [download 32-bit and 64-bit versions](#). A special Teams app is available for [Microsoft Surface Hub](#) devices. The [Teams client downloads page](#) has pointers for the supported platforms while the [Teams features by platform page](#) describes the features supported on the different platforms, including the mobile clients.

Microsoft uses a portable framework known as [Electron](#) to write the desktop clients. As part of the Windows 11 announcement, Microsoft said that they are drastically changing the Teams client architecture, moving away from Electron and the Angular user interface library. The new version, which is informally being called “Teams 2.0”, should dramatically improve the Teams client’s performance, as well as making it easier for developers to take full advantage of OS-native features such as notifications and external audio and video devices. Microsoft has not made any public statements about the exact schedule for when the Windows 11 integrated client will be usable with the Teams workload in Office 365 (as opposed to the “Teams for Life” consumer version), nor when the improved client will be available on macOS or Linux.

In most cases, the browser client is functionally equivalent to the desktop client, but as evident in the hints dropped when you use Teams with a browser, Microsoft prefers the desktop client. As with other Office Online applications, Teams supports modern browsers like Chrome, Edge, and Brave. The Safari 14 browser (and later) on macOS supports most features of the Teams browser app, including using video cameras and sharing in calls and meetings.

Mobile Teams apps are available for [Apple iOS](#) and [Android](#). Platform-specific technology is used (Swift for iOS and Java for Android) to create the user interfaces. Underneath, the mobile clients share the same basic functionality as their browser and desktop counterparts, including the ability to create and manage teams (membership and channels). As you’d expect, mobile clients are easier to use and more responsive than the other clients in some areas and less functional in others. For example, the mobile client often switches to a different tenant faster than the desktop or browser client do, but it is easier to compose a complex post with the desktop or browser client.

As detailed in Table 15-2, the Teams desktop and browser clients support limited offline capability to read and send personal chats and channel conversations. Almost every other piece of functionality needs an internet connection to work unless an app is designed to work offline. In some cases, like the calendar or documents, other tools are available to maintain local copies of data that permit offline activity.

<b>Feature</b>	<b>Offline capability</b>
Personal and group chat messages	Cached copies of messages are available offline for pinned and recent chats. Messages can be composed and queued for delivery locally when the network connection resumes. Messages are sent if a connection becomes available within 24 hours. If the delay is longer, the attempt to send the message will fail and Teams prompts the user to retry.
Channel messages	Cached copies of messages are available offline for pinned channels and channels recently accessed by the user, going back about 90 days. Messages for hidden channels are unavailable. Sending channel messages when offline works similarly to chat messages.

Calendar app	Cached copies of calendar events can be viewed. You can't schedule, initiate, or join meetings using Teams when offline. You can use Outlook to work with your calendar when offline.
Files	Both channel folders (SharePoint Online) and personal files in (OneDrive for Business) are unavailable offline. Files can be synchronized to the local drive with the OneDrive for sync client and accessed offline.
Tasks	None. You can use Outlook or the To Do app to work with personal tasks (but not tasks in Planner) when offline.
Wiki	None.
Lists	None.
Whiteboard	None. This may change now that Microsoft has moved Whiteboard storage to OneDrive for Business.
Yammer communities	None.
People card	None.
Third-party apps	Depends on the offline capability of the app.
Switch tenant	Not possible—when you go offline, you're stuck in the tenant you're currently in until you regain network access.
Manage team	None.
Calls	None unless the location deploys a <a href="#">Survivable Branch Appliance</a> (SBA).

Table 15-2: Teams offline capabilities

From a practical perspective, no matter what client you're using, the internet connection must be reasonably capable in terms of both latency and bandwidth. Even though Teams clients cache data for faster access, the high latency, and low bandwidth often available in airplane Wi-Fi services can make using Teams an excruciating experience. To help assess the impact of Teams usage on a network, the Teams admin center includes a network planner to help figure out what network capacity is needed. Your mileage will vary depending on how people use Teams and the clients used. Remember that although Teams usage increases over time, the usage of other applications like email might decrease to offset the extra network demand. In terms of security, Teams supports the same multi-factor authentication methods as other Microsoft 365 applications do.

## Teams Insider and Pre-Release Channels

Like Windows and the rest of Office, Teams supports pre-release channels for the Enterprise version to allow customers early access to pre-production features. Three channels are available:

- **Beta Preview Channel:** The earliest that non-Microsoft users can access new Teams features. Microsoft uses rings to describe the release of new functionality from the development group (ring 1) to general availability (ring 4). This channel was Ring 1.5.
- **Private Preview Channel:** Access to more developed forms of new Teams features. Microsoft previously called this Ring 3.
- **Public Preview Channel:** Tenants can enable public preview for selected users via an update policy (see later section) to allow those users to have early access to new features. This channel layers pre-release functionality on top of the general availability build (Ring 4).

Collectively, the three pre-release channels are known as Teams Insider. Restricted access to the Beta Preview and Private Preview channels is available to companies participating in Microsoft's Technology Adoption Program (TAP). Features released to the TAP are under Non-Disclosure Agreements (NDA).

Clients configured to use the Current Channel (Preview) release of Microsoft 365 Apps for enterprise automatically use the Teams Public Preview channel unless the Teams update management policy assigned to their account disables the link between Office preview and Teams (the link is on by default). To disable the link, update the policy in the Teams admin center or use the `Set-CsTeamsUpdateManagementPolicy` cmdlet (in the Teams module). For example, this command disables the link for any account assigned the default update management policy:

```
[PS] C:\> Set-CsTeamsUpdateManagementPolicy -Identity Global -AllowPublicPreview Disabled
```

The value of the `AllowPublicPreview` setting can be either Enabled or Disabled. Enabled allows users to switch the Teams desktop client into preview mode manually. Disabled hides the option to switch to preview mode. When a client runs in preview mode, the Teams desktop client signals this status by displaying a **P** beside the upper right-hand quadrant of the user profile photo in the menu bar.

## Teams Client Release Notes

Like most of Microsoft 365, Teams is developing rapidly. Microsoft publishes [release notes for Teams](#) online to give formal guidance about the introduction of new features. The release notes don't cover every new feature released for Teams, but they are a useful resource.

## Teams and Memory

The Teams desktop client has a reputation for being a performance hog on Windows which loves to grab lots of memory from the operating system. This well-earned reputation came about because Teams is an Electron application, and both the desktop and browser clients use the Chromium memory management model. This model uses free available memory to cache data and releases memory when it's needed by other applications (much as on-prem Exchange used to), so it's expected to see the set of Teams processes use what appears to be a large amount of memory, even when idle. As memory demand from other applications grows, the amount used by Teams should reduce, or at least not grow. For more information, see [this Microsoft article](#).

The Teams processes include:

- Main window: This process caches chat and channel data and uses the most memory.
- Experience renderer: This process drives the pop-out window for meetings and chats.
- GPU process: This is the Electron GPU process responsible for GPU interaction.
- Plugin Host: The Teams media processor (video and audio).
- Notification Manager: Handles notifications.

You can see the names of the processes by running the Windows process explorer and hovering over a process listed under Teams.exe. Note that on macOS these process names will of course be different.

## Teams Desktop Client Updates

For Windows computers, the Teams desktop client can be deployed automatically [using group policy or other distribution mechanisms](#). Microsoft automatically deploys the Teams client as part of the Microsoft 365 Apps installation for users who have Microsoft 365 Business or Enterprise subscriptions.

The Teams Windows client is self-updating and the mechanism used (Squirrel, an open-source component that is the default auto-update method for Electron-based apps) works differently from the other Office click-to-run desktop applications as users do not have to exit the client before an update proceeds. The combination of using this approach plus installing into a folder in the user area (`%LocalAppData%\Microsoft\Teams\`) rather than the program files structure (which requires administrative

permission) makes it simpler to ensure that Teams runs the latest software if you allow Teams to auto-update. Among the contents of the Teams directory, you'll find:

- **Current:** The files for the currently installed version of Teams.
- **Previous:** Files for the previously installed version of Teams. If the update process fails, the Squirrel utility can roll back using these files.
- **Packages:** Files downloaded by the Squirrel utility to update Teams.

Note that Teams user data is in `%LocalAppData%\Roaming\Microsoft\Teams\`. Here you'll find folders like `IndexedDB`, which store cached copies of Teams data for local (and offline) access. More information about the use of this file [is available here](#).

On macOS, the Teams client also installs its updates using Squirrel. The other Office apps use a macOS-native app called Microsoft AutoUpdate to download feature updates for both production and Insider rings, except for versions of the apps downloaded through the Mac App Store. Teams updates for old versions are delivered through Microsoft AutoUpdate, presuming it's installed. This covers the case where a previously installed version didn't receive updates and is now too old to be directly updated through Squirrel—the updates will be downloaded through AutoUpdate and applied, and, once the Teams client is up to date, the normal Squirrel-based mechanism will be used for future updates.

Microsoft usually releases Teams update packages on a two-week schedule. This schedule could vary if a problem discovered in a build is important enough to warrant an immediate fix, in which case Microsoft will release a new package. When signed into their home tenant, Teams desktop clients perform a check every few hours to detect new updates, and, if found, the client downloads and applies the update in the background when the workstation is idle.

Users can also update the client through the **Check for updates** option in the profile menu. This does no more than accelerate the process of finding and applying available updates, but it might be necessary if Microsoft releases an urgent update. Depending on the type and scale of the update, Teams might prompt the user to refresh the client (reload) to complete the procedure.

Several reasons can affect the ability of the Teams client to download updates, including:

- Antivirus software blocks the Teams update executable or the download of the update packages.
- Network infrastructure to specific locations is not capable of supporting software downloads.
- People only use Teams desktop client for calls and/or meetings. To ensure performance, Teams does not check for updates during these activities, and if the user closes Teams after their meeting finishes, the client will never download and apply updates.
- The files for the Teams client are in a non-standard path (not `%LocalAppData%\Microsoft\Teams\`). In this situation, users must update the client manually.

The fact that the Teams client self-updates is challenging for some organizations who like to control the software users have on their workstations. However, Teams is more aligned with the app model found on mobile devices than traditional software distribution channels and the aim is to deliver the best and most functional experience to users. For this reason, if you want to know what Teams delivers in client updates, you need to keep a close eye on the [release notes published by Microsoft](#). The release notes are also available by typing `/whatsnew` into the command box.

## New Features and Enablement Flags

When Teams ships a new feature, it uses a two-phase process to enable the functionality. First, updated software rolls out to backend services and for download to desktop, browser, and mobile clients (as

appropriate). To allow Microsoft to enable features separately from software updates, they use configuration flags to turn features on or off. Features don't become available to users until Microsoft sets the relevant flags.

Clients can receive software updates with the feature flags set off. When Microsoft testing and validation with early adaptors show that the feature is stable, Microsoft enables the flag to "light up" the feature. This process happens progressively as tranches of clients are enabled. Given the distributed nature of Office 365, the process of enabling a new feature can take some time. To ensure continual validation against a cross-section of workstation configurations and usage patterns, Microsoft does not organize users into tenants. Instead, tranches include users selected from multiple tenants and multiple countries. All of this means that some users within an organization may see a new feature before others.

## Mandatory Updates

Teams supports [Microsoft's Modern Lifecycle Policy](#), which requires users to run a recent version of software to maintain access to services. Once the Teams desktop client is more than a month behind the current release, the client displays a banner to advise that a software update is necessary. The banner includes a link to start an update. If the user doesn't perform a software update, Teams continues to prompt the user to update until the software is more than three months behind the released version. At this point, Teams displays a blocking page to give the user the choice to update the software now, looking for help from their IT administrator (to help with the update or apply a manual update), or to continue accessing Teams via the browser client.

New installations of the Teams client can deploy software more than three months old. In this situation, a 28-day grace period begins during which the user can continue to use the old software while Teams attempts to update the client in the background. At the end of the grace period, the user cannot use Teams, and an IT administrator must update the device.

## What Version of the Desktop Client is on a Workstation?

To learn what version of Teams is running on a workstation, select **About** and then **Version** from the profile menu. The client lists the current version number and the date of the last software update in a banner at the top of the screen.

You have Microsoft Teams Version 1.4.00.34266 (64-bit). It was last updated on 09/12/2021.

Sometimes it is useful to programmatically fetch information about the version of the Teams client running on a workstation. If you need to retrieve the information programmatically, on Windows, you can use PowerShell to report details about the Teams executable and updates from and the log file that records updates. With an eye on the requirement to keep the client software up to date, here is a script to report about the last update and age of the Teams executable on a Windows workstation.

```
[PS] C:\> $TeamsExecutable = Get-Item("${Env:LocalAppData}" + "\Microsoft\Teams\Current\Teams.exe")
$TeamsInstallFile = $Env:AppData+"\Microsoft\Teams\InstallTime.txt"
$TeamsLogFile = $Env:AppData + "\Microsoft\Teams\Logs.txt"
[datetime]$TeamsInstallDate = Get-Content $TeamsInstallFile
$TeamsVersion = [System.Diagnostics.FileVersionInfo]::GetVersionInfo($TeamsExecutable)
$R = Get-Content $TeamsLogFile | ? {$_.Contains("ring=") }
$LastRec = $R[-1]
$SplitRec = $($LastRec) -split "<"
$TeamsLastUpdated = (Get-Date($SplitRec[0].Split("+")[0]) -format d)
Write-Host "Teams Executable:" $TeamsExecutable
Write-Host "Teams Version:" $TeamsVersion.ProductVersion
Write-Host "Installed on:" (Get-Date($TeamsInstallDate) -format d)
Write-Host "Last Updated:" $TeamsLastUpdated
$DaysSinceUpdate = ($TeamsLastUpdated | New-TimeSpan).Days
If ($DaysSinceUpdate -le 30) { Write-Host "Congratulations. It is" $DaysSinceUpdate "days since
Teams was updated. It's nice to have updated software" }
```

```
Else {Write-Host "Your Teams software is" $DaysSinceUpdate "old. Time for an update!"}
```

To see details of the environment a Teams desktop client runs in, use the command:

```
[PS] C:\> Get-Content $env:UserProfile\AppData\Roaming\Microsoft\Teams\settings.json |
ConvertFrom-Json | Select-Object Version, Ring, Environment, CloudEnvironment
```

```
version      ring      environment cloudEnvironment
-----
1.5.00.17271 ring3_6 Production
```

Apart from the version number, the important information here is the ring. *Ring3\_6* means that the client runs the preview version of Teams attached to the production service.

## Teams and VDI

VDI, or Virtual Desktop Infrastructure, is a virtualization technology that allows desktop systems to be hosted on centralized servers. If you wish to run the Teams desktop client on VDI, make sure that [you read Microsoft's guidance](#), including advice about caching of Teams content, client installation, and VDI performance. If you use Azure Virtual desktop, [separate guidance is available here](#).

## Teams Phone Application

The Teams Phone application is a special version of the Android mobile client built for device manufacturers to build [Teams-enabled devices](#). These devices allow users to call other Teams users or PSTN numbers, join a Teams meeting, and retrieve voicemail. In effect, the phone application delivers the same functionality as other mobile clients with the chat (personal and channel), files, and extensibility features removed. Only devices specifically designed to work with Teams can support the Teams Phone application.

## A Few Teams Application Tips

Unlike, say, Outlook or Word, which have been around a very long time, Teams has lots of little features that aren't well understood by many users or admins. Here are a couple of things you might want to delve into within the app to help you, and your users, get the best experience.

### Notifications

Teams can notify users when different events occur in chats and channels, such as being @mentioned in a conversation. These are global settings that apply across all teams and channels that appear in your teams list. Teams doesn't notify you of events in hidden teams or channels or when you mute a channel or conversation. You can choose default settings such as notifications for all activity or just mentions and replies or customize each source of notifications.

A user can choose to receive missed activity emails. These messages are for events that happen when the user does not sign into Teams. The available intervals range from "as soon as possible" to "once a day." You can disable notifications by setting the interval to "Off." Teams can also monitor the status of priority users and flag when they appear online or sign in.

In terms of the type of notifications, you can choose:

- **Banner and feed:** Teams signals events in both the activity feed and a desktop notification. You can choose between Teams built-in notifications or native operating system notifications (Windows and macOS). For example, if you opt for native notifications on Windows, Teams posts its notifications to the Windows notification center.
- **Only show in feed:** Show events in the activity feed.

- **Off:** Don't show these kinds of events (for example, don't show reactions to messages).

Both the Windows and macOS clients allow you to choose between the Teams notification style and notifications that use the underlying host OS notifications. This is largely a matter of personal preference.

## Switching Between Organizations

Users might have accounts in multiple tenants. The desktop and browser clients show the current tenant as a clickable link in the title bar. To switch tenants, click the link and select the target organization from the list of available tenants to which the signed-in user has access. The list includes:

- Their home tenant.
- Other Microsoft 365 tenants where the signed-in user has a guest account.
- The consumer version of Teams accessed using a Microsoft Service account (MSA).

Each tenant in the list includes the number of unread items in the user's activity feed in that organization. If the user's credentials for a tenant have expired, you see a warning sign. Unread item counts are not available for these organizations until the user reauthenticates to gain new credentials. Switching from one tenant to another terminates any open calls and closes chat windows. Teams caches credentials for each tenant to make switching easy if the credentials are still valid. Settings are specific to an account in a tenant. If someone is a guest in another tenant, they must configure settings for Teams in that tenant if they want to see the same behavior everywhere.

On mobile devices which support multiple profiles, if you have notifications enabled, you will see notifications from all the organizations you're signed into. This can cause some confusion if you tap on a notification from tenant B whilst you're logged into tenant A, because tapping the notification will cause the client to load the item of interest, which means now you're seeing something from tenant B. It's easy to switch back to the desired tenant at any time.

You should also be aware that there are many subtle (and not-so-subtle) bugs still lurking around tenant switching. For example, while writing this book I often found that switching to the Office 365 for IT Pros tenant to work, then switching back to my primary work tenant would cause some chat participants in my work tenant to be labeled "Unknown User" until I signed out and signed back in.

## Switching to Preview Versions of Teams

Teams desktop and browser clients support two preview versions. If the policies assigned to user accounts allow switching to these versions, the options appear in the **About** menu.

- The **Public preview** allows users to test new features released in public preview. The idea is that early exposure to new features assist organizations to prepare (training, help desk support, documentation) for their general availability. Control over switching to [public preview](#) is through the Teams update policy assigned to an account, which must allow the user to select public preview. Using the public preview version of Teams is broadly equivalent to running the preview channel version for Microsoft 365 apps.
- The **Developer preview** allows app developers to test their code against beta versions of Teams. Control over switching to [developer preview](#) is through the App setup policy assigned to an account, which must allow the user to upload apps to Teams.

When a user switches to a preview version, they are asked to confirm the action. If confirmation is given, Teams terminates the current client and loads the preview version. The user might be asked to reauthenticate at this point. To switch back to the current client, the user opens the About menu and unticks the selected preview. Switching between tenants will usually switch back to the release version (that is, if you've enabled the preview in tenant A and switch to tenant B, you will normally see the release version in tenants A and B

until you switch back to a preview version). Microsoft does not support the use of preview versions, but users can provide feedback to the development group if they encounter problems. Bugs are expected in preview code.

To manage the set of users allowed to select public preview, it's a good idea to use some method to mark the accounts. For example, you could use:

- A value in a mailbox custom attribute.
- Membership in a Microsoft 365 group.
- Membership in a distribution list.

Once the preview members are marked, it's easy to use a Teams bulk policy assignment job to assign the necessary update policy to their accounts. See [this post](#) for details.

From a support perspective, it's important to know that the version number reported by the desktop client does not change when the preview or developer preview is enabled. The only trace that a preview is enabled is a tick against the chosen preview shown in the About menu.

## Managing Quiet Times

Teams has multiple ways to let users know when new information has arrived from banner notifications to the activity feed to email digests. If you belong to busy teams, you might like to have some quiet time when notifications aren't delivered unless they are urgent. Desktop and browser clients obey operating system settings for notifications. For instance, on Windows 10 clients, the Focus Assist setting controls when applications can send notifications. One of the automatic Focus Assist rules stops notifications between 23:00 and 07:00, and if the rule is enabled, you won't see notifications for channel or personal messages during that period. Even when notifications are suppressed, they still accumulate in the activity feed.

The Teams mobile clients take a different approach and have their own Quiet Hours settings to control when during each day notifications are allowed and Quiet Days to control on what days notifications are accepted. For example, you can disable notifications entirely at the weekend and define that you only want to see notifications between 09:00 and 17:00 during the working week. These settings are specific to each tenant—so if you've signed into multiple tenants on mobile, you will have to set quiet hours in *each* tenant or you may still receive notifications from any tenant where you haven't done so.

Incoming calls are not governed by the notification settings. If you are signed in and available when a call arrives, you'll have to decide if you want to answer or ignore it.

## Understanding the Teams User Profile

The settings chosen by a user are in their profile. Because Teams works across platforms, Teams stores the profile online and caches some information locally. For instance, on Windows, the *desktop-config.json* file in the *%appdata%/Microsoft/Teams* folder holds information like the user principal name, tenant GUID, user account GUID, and the list of tenants where the user is a registered guest. The source of this information is a table managed by the Teams Chat service called *users/ME/properties* (a Fiddler trace will expose the interaction between a Teams client and the table). Unfortunately, no management interface is available to allow tenants to control user settings for Teams clients and it's up to each user to choose whatever settings they like.

Another file called *settings.json* stores additional configurational information for the desktop client. Teams doesn't support updates of the information held in these files in the same way as you can update the system registry to affect how other desktop clients like Outlook work.

## Using the Command Box

The command box at the top of the Teams window gives users fast access to common Teams operations. For instance, to call someone, type `/call` in the command box and then select the person you want to talk to while the `/chat` command switches to a personal chat with the selected person. Unfortunately, the command box limits user lookup to tenant accounts so you can't select a federated or guest user in the command. The command box is also a great way to update your presence with commands like `/dnd` (Do not disturb) or `/busy`.

In addition to Teams commands, if you install apps into Teams, they can become available in the command box. For example, if you install the weather app, you can type `@weather` to find out the current weather in a location, or `@news` to use the News app to look for breaking stories about a topic, or `@YouTube` to look for a video. Once you find what you need, you can copy it to the clipboard and then paste it into a conversation.

# Managing Microsoft Authenticator

You can make a good argument that reusable passwords are bad. Giving users individual passwords for access control can lessen security—if you require long complex passwords, users will reuse them or write them down, but if you don't, users will pick short, simple passwords that can easily be brute-forced. In the same vein, passwords that expire are bad (because users will just recycle old ones) but passwords that *don't* expire are bad too (because once compromised a non-expiring password might be used for a long time). However, for many years, reusable user-specific passwords were less bad than the alternatives. Thankfully, we live in a world where the widespread availability of smartphones and hardware tokens has led to the increasingly broad deployment of multi-factor authentication (a topic discussed at some length in Chapter 3). Microsoft 365 and Azure MFA support several authentication factors, including phone-based authentication, one-time codes sent via SMS, and push notifications or codes generated by a mobile application. Although Google, LastPass, and other companies make mobile authentication apps that are compatible with Microsoft MFA, Microsoft's Authenticator app is best matched with Azure and Microsoft 365 MFA.

You can use Authenticator to set up MFA for both your Microsoft account and other accounts homed in Azure Active Directory, including accounts that are federated or synchronized from on-premises Active Directory. The MFA challenge/response process occurs after, and only if, the user presents valid credentials. Authenticator can operate in two modes: it can display a code (which changes every 60 seconds) that serves as the authentication challenge, or it can display a push notification prompt that allows you to accept or reject the authentication request. Push notifications only work with Microsoft and Azure Active Directory accounts, but you can use the Authenticator app to generate codes for other apps, including Google's mobile apps and the LastPass and 1Password mobile password managers.

One interesting thing to note about the Authenticator app: just as new features tend to be delivered in the service first, with on-prem versions coming later if at all, new Authenticator features tend to accrue to the consumer Microsoft account side first, before (or if) they are rolled out to Azure Active Directory. For example, code matching for passwordless login (which I'll discuss below) was first introduced for consumer Microsoft accounts before making its way to Azure AD. Some features (such as the ability for [Authenticator to show you alerts](#) when your Microsoft account password is changed) haven't made it to the Azure AD world yet, and they may never.

## Basic MFA with Authenticator

There are several steps required to use Authenticator as an MFA client with Microsoft 365, all well-covered in the [Authenticator app documentation](#). First, of course, you must license (if necessary) and enable MFA for your tenant. Once that's done, you can enable individual users for MFA. The app is one of the available

authentication methods to enable or block individual users, but the app is available to MFA-enabled users by default. To configure it for the user, here's what to do:

1. Download the Authenticator app itself from the Apple App Store or Google Play. If you have Microsoft Intune or another similar MDM solution deployed, you can use that solution to push the app to devices as well.
2. Visit <https://myprofile.microsoft.com> and make sure that "Microsoft Authenticator - notification" is selected as the default method. Until you set up the Authenticator app on one or more devices, you'll see an error message telling you that you need to set the app up.
3. Click the **+ Add method** link, then choose "Authenticator app" and click **Add** (Figure 15-6).
4. When prompted, set up the app as directed on your mobile device. As you follow the dialogs, the web page will eventually display a QR code.
5. In the mobile app, use the **+** icon to add an account by using the device camera to take a picture of the on-screen QR code displayed in step 4.
6. You might be asked to enter a code from the app to verify that you've got it set up properly.

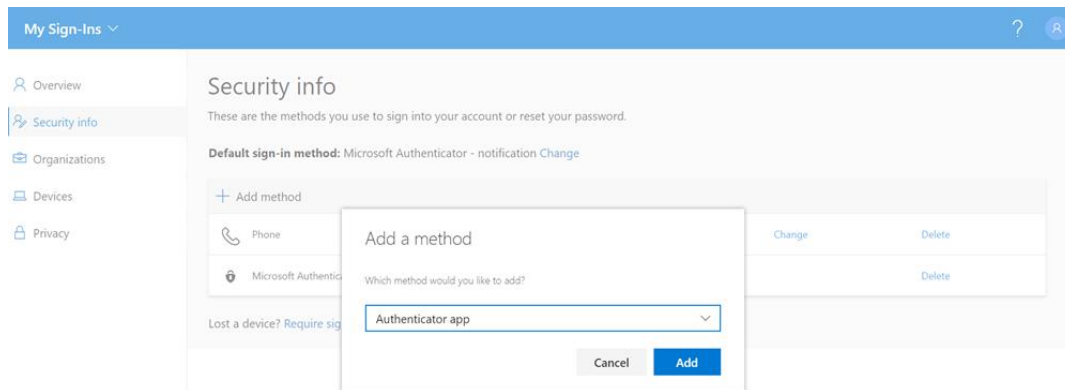

Figure 15-6: Setting up a user for MFA using the Authenticator app

Once the app is set up, when you log on to a service that requires MFA, you'll see a screen on your device like the one shown in Figure 15-7. (This version shows the authentication context features added to the service in late 2021, including the app name and rough IP-based geolocation of the authentication request.)

Authentication requests are presented on the phone as modal dialogs, so you must respond to them before doing anything else on the phone. If you've been using Authenticator for a while, you may have noticed a change made in late 2020; Microsoft used to display and allow action on, requests on the lock screen of iOS and Android devices. Now the App Lock feature of Authenticator is enabled by default, meaning that you must be logged into the Authenticator app, and have it active, before it accepts an authentication request.

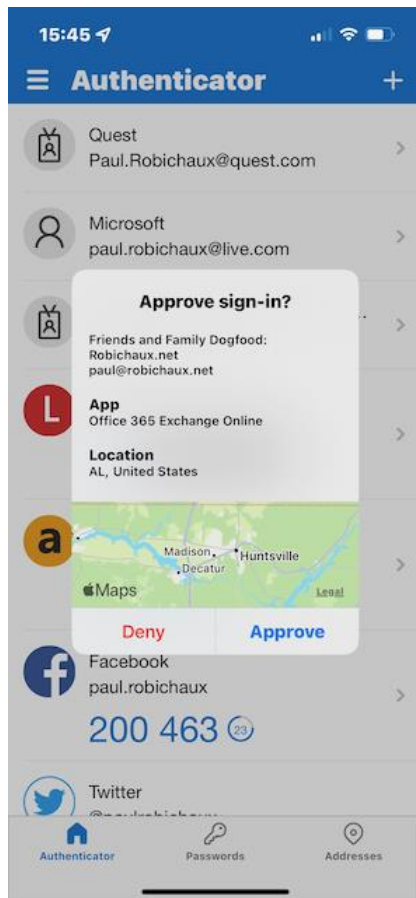

Figure 15-7: The iOS Authenticator app displays an MFA request

## Using Authenticator for Passwordless Authentication

In Chapter 3, we describe how passwordless authentication works in Azure AD. If you've enabled passwordless authentication in your tenant, you can optionally enable individual users to sign in without using a password. The way the process works is simple: when the user requests access to an app, the Microsoft authentication library will generate a two-digit challenge code and display it on screen. At the same time, the Authenticator app will prompt the user to select the matching code from a list of 3 choices. After properly selecting the matching code, she'll be prompted to use a PIN or biometric to authenticate to the device. This approach means that no user passwords are exposed at any point, nor do they need to be stored—with no password in use, there's no way for a user to accidentally compromise it, nor for an attacker to steal it.

The [instructions to set up passwordless](#) authentication for Authenticator are reasonably detailed, but the basic steps are as follows:

1. Enable the [combined security information registration](#) process in Azure AD. You do this once per tenant; note that tenants created after August 15, 2020, already have this done. In September 2022, the rest of us will have this change applied to our tenants automatically.
2. Configure Azure AD to allow passwordless sign-in with the Authenticator app. This setting applies at the tenant level.
3. Each user who wants to use passwordless authentication must add the Authenticator app as an authentication method for their account.

As of July 2022, Microsoft is rolling out the ability to have multiple accounts with passwordless authentication within Authenticator. Until this change hits your tenants, you'll only be able to add one passwordless account

to your device. The change is coming first to iOS; Microsoft promises it for Android but hasn't released a timeline.

As with all other Authenticator-based sign-in methods, if notifications don't make it to the Authenticator app the user won't be able to sign in unless they choose an alternate authentication method such as SMS.

## Authenticating from Your Wrist

If you have an Apple Watch, you can use the companion app included with the iOS Authenticator app to approve or deny authentication requests without using your phone. While this might seem like useless frippery, it's surprisingly useful because it allows you to respond to an MFA prompt without having to find and unlock your phone if it isn't already in your hand.

# Optimizing Microsoft 365 Client Network Access

Microsoft has published extensive guidance on [designing your enterprise network to work optimally](#) with Office 365. The primary principle they push is that you should design your network to minimize round-trip latency between the client endpoint (that is, the machine or device that the user's working on) and the "front door" service connection point that the client connects to. Traffic that reaches the front door will be carried over [Microsoft's internal network](#), which they manage with a ruthless focus on lowering round-trip latency.

To be more specific, Microsoft recommends that you consider the following when designing your network. First, you should know that Microsoft has separated Microsoft 365 service endpoints into [three categories](#): Optimize, Allow, and Default:

- **Optimize** endpoints represent roughly 75% of traffic to the service and include the *outlook.office365.com* and *sharepoint.com* name spaces. Microsoft says you should prioritize traffic to these endpoints by bypassing network inspection and proxies and ensuring the fastest possible DNS resolution for these namespaces.
- **Allow** endpoints, such as *protection.outlook.com*, are still important but are less sensitive to network latency. There are roughly 100 of these endpoints; because of this large number, many customers will choose not to do anything special with these endpoints to reduce the need for change management and control.
- **Default** endpoints have no special requirements for performance and can be treated as ordinary Internet traffic.

Second, Microsoft has some specific recommendations that you should apply to the design of your enterprise network:

- Don't use proxies, WAN accelerators, or other devices that sit between the client and the front door. Since you may very well need to do so anyway, see the section "Proxies and Network Devices" below for additional guidance.
- [Allow each office \(or client\) to connect directly to the Internet](#) instead of backhauling traffic from a remote office to a centralized data center and thence to the Internet.
- [Avoid network hairpins](#), or connections where a client's traffic exits your corporate network and then comes right back in again. Instead, you should always try to route all client traffic for Microsoft 365 endpoints directly to the Internet.

## Proxies and Network Devices

Client applications and servers within your corporate network that will be connecting to Microsoft 365 will need to have access to all the appropriate endpoints. The general recommendation from Microsoft is to bypass any web proxies or other network devices that shape or rewrite traffic such as WAN accelerators, for connections to the service. That recommendation is counter to the security policies of many organizations, with the adoption of cloud services making them more likely to want to push all their internet traffic through a security or performance device.

There are good reasons for customers to want to secure their internet traffic. These days, clients on their network will be connecting to more services over HTTPS, making the traffic invisible to traditional security measures. In response, organizations implement security devices that can intercept, decrypt, and inspect HTTPS traffic to detect viruses, data leakage, and ransomware. Similarly, with so much traffic now running over internet connections, organizations try to reduce the impact on their bandwidth with WAN accelerators and traffic caching devices.

Unfortunately, such measures often result in degraded performance for clients, and in some cases, they completely break connectivity to application endpoints, causing problems such as Offline Address Book download errors, OneDrive for Business sync failure, and poor audio or video performance in Teams calls. The specifics will vary depending on the vendors involved and their ability to provide guidance and templates for properly implementing their devices into your network without impacting client traffic. If you're going to attempt to implement such measures, approach it with caution and do ample testing to ensure you don't cause problems for end-users, particularly those on BYOD devices that will require special considerations for any SSL traffic inspection you plan on doing.

There may be a happy middle ground if your chosen security devices are not fit for use with Microsoft 365, but you want to continue using them to manage other internet traffic. Bypassing security devices for clients connecting to the service is a reasonable approach but can be poorly implemented if you're not careful. The natural inclination of firewall administrators is to apply controls based on IP addresses. But as Microsoft [explains in their guidance](#), Microsoft 365 IP address ranges are a constantly moving target. To keep up, you might be making changes to firewall configurations as often as every 14 days, which is a heavy burden to carry for very little real benefit. If your device supports it, Microsoft [publishes a web service](#) that your perimeter devices can query to get updates on IP address ranges and URLs for the service. Endpoint definitions are published at the start of each calendar month and take effect 30 days after their publication.

No matter the security devices at play, NATing of outbound connections to Microsoft 365 services is also a concern. Simply put, if too many clients are being NATed to the same public IP address, port exhaustion can occur which results in degraded performance for the clients. NATing is fully supported, but Microsoft recommends limiting the number of clients on one public IP to around 2000. This is mainly due to the number of connections a single client can have open. Outlook alone has 2-4 connections open for a basic user scenario, and more if they are also connecting to shared mailboxes, Microsoft 365 Groups, or are performing an OAB download. Once you add in other applications such as Teams or a web browser, the number of connections per client can easily be 10 or more. With a maximum of 64000 ports per public IP address, limiting NATing to 2000 clients per IP is a safe place to start. A pool of public IP addresses will be needed for NATing outbound connections if you are running a very large organization.

**Real World:** If you use a proxy, security, or performance device for client traffic, and you notice problems, bypassing the device is a good troubleshooting step. The goal is not to point the finger of blame at the network devices, rather it is to narrow down the likely cause of the issue. Ultimately if you choose to

implement such network devices in your environment, you are better off identifying issues and working to resolve them rather than pretending they do not exist.

## Split Tunnelling and VPNs

Some users may be required to connect to their corporate network through a virtual private network (VPN). This is especially common after the huge surge in telework brought on by the COVID-19 pandemic. For a lucky portion of the workforce, all the services they need are accessible directly through the Internet, but users who must use remote desktop solutions or access internal line-of-business systems are probably stuck with VPNs. The problem with combining VPN access and Office 365 is that the default VPN configuration will probably send all the user's network traffic from her computer over the VPN to the VPN endpoint on the corporate network, where it will be routed onwards. Traffic that's bound for the Internet (whether that's Office 365, Netflix, or something else) will thus have to traverse the VPN and then be sent onwards, with return traffic taking the same path. Microsoft calls this behavior "forced tunneling."

The solution to the performance problems caused by forced tunneling is to allow Microsoft 365 traffic to go straight to the Internet, a configuration known as *split tunneling*. When you [enable split tunneling on the VPN connection](#), traffic to select destinations is allowed to go directly to the Internet. Microsoft's guidance on how to enable split tunneling lists a set of "Optimize" endpoints that you should allow traffic interchange with over the Internet. The specifics of how you implement this are up to the specific VPN solution you use.

## Checking Office Client Network Connectivity

As described in Chapter 2, Microsoft now offers basic network connectivity monitoring in the Microsoft 365 admin center. This monitoring uses telemetry sent by the OneDrive for Business client on Windows computers to assess several aspects of your connectivity, including whether user traffic from a particular location is going to the optimal service front door location and whether there are excessive backhauls. As an example of the real-world problems this testing can catch, an early version of the connectivity tester identified that some traffic from a facility in Slovakia was being (incorrectly!) routed to Macomb, Michigan, more than 7,200 kilometers away. The unnecessary extra routing caused some additional delay for some types of traffic, but not enough delay to be routinely noticeable.

# Chapter 16: Managing Devices

## **Brian Desmond**

As workers become more mobile and security risks for corporate data increase, the management of mobile devices becomes an increasingly important factor in daily operations. Organizations have a choice of solutions for mobile device management (MDM) and mobile application management (MAM). Each of these solutions offers different features, strengths, and weaknesses.

Let's start with a quick definition to separate MDM and MAM. MDM refers to controlling the entire device, whereas MAM is concerned only with controlling the behavior of specific applications and the associated data on the device. This may seem like an obvious distinction, but there are some subtle points to it. For example, is it better to enforce a requirement to use a PIN on the entire device, or just on applications that contain corporate data? Your security team might prefer the former, but your users might prefer the latter.

Some of the considerations that come into play when planning for a mobility strategy include

- The devices and operating systems within scope.
- Who owns the target devices (BYOD versus corporate).
- The applications running on the devices (Microsoft, other vendor, and custom apps).

Some organizations can take a unified approach to mobility management, while others need to apply different policies and configurations to deal with different sets of use cases. Specific compliance requirements are also important, as some organizations fall under strict government or industry regulations.

At a high level, there are three solutions that you can choose from in Microsoft 365:

- Exchange ActiveSync (covered in the companion volume).
- Microsoft 365 Basic Mobility and Security (BMS).
- Microsoft Endpoint Manager (MEM), which includes Microsoft Intune.

In addition to the Microsoft solutions, there is an extensive range of third-party mobility solutions provided by other vendors. Here, we focus on MEM, and more specifically, Microsoft Intune.

## Comparing the Three Solutions

Before we dig into the details of Intune, let us take a quick look at the three options Microsoft offers. Consider this section somewhat of an executive summary to help you understand the basic capabilities and tradeoffs of each.

Exchange ActiveSync costs you nothing. It works on a very broad range of devices, and it offers basic device management functionality. It is only loosely integrated with the rest of Microsoft 365; it is very much Exchange-centric. It is not undergoing active development and it is increasingly being replaced by Microsoft's other solutions. We have coverage of Exchange ActiveSync in the Companion Volume.

Microsoft 365 Basic Mobility and Security (BMS) offers a [broader set of functions](#) than Exchange ActiveSync, including the ability to secure access to documents stored in OneDrive for Business and SharePoint Online. It also gives you more control over which devices you want to allow to connect, and what they can do when they do connect. There is no additional cost for BMS if you have an enterprise or business subscription. Since BMS offers, as the name implies, very basic functionality, we also have coverage in the Companion Volume.

Microsoft Endpoint Manager (MEM) is a full-fledged MDM and MAM solution. It does everything ActiveSync and BMS do, plus much more. For example, Endpoint Manager can also manage Windows PCs and macOS devices, and you can manage access to individual applications and their features even for devices that are not enrolled in Endpoint Manager for MDM. This is extremely useful in environments that have BYOD policies. MEM requires you to buy licenses, through Microsoft 365, the Enterprise Mobility + Security suite, or as a standalone license. Table 16-1 summarizes the differences between the three options.

<b>Feature</b>	<b>Licensing requirements</b>	<b>Manages data</b>	<b>Manages apps</b>	<b>Manages devices</b>
Exchange ActiveSync	Included with Exchange Online	Exchange only (online and on-premises)	No	Limited (PIN, device encryption)
Microsoft 365 Basic Mobility and Security	Requires Office 365 enterprise or business	Yes, for most Microsoft 365 workloads	Limited	More than Exchange ActiveSync
Microsoft Endpoint Manager/Intune	Requires EMS, Microsoft 365, or standalone license	Yes, including conditional access	Extensive	Extensive

Table 16-1: Choices for mobile device management

With that bit of perspective, let's dig into how you can use Microsoft Intune to manage mobile devices and apps.

## Getting Started with Intune

In this chapter, we will discuss how to use Microsoft Intune. More specifically, we will focus on managing Apple iOS/iPadOS and Android devices. Intune also supports Windows devices and macOS too, but we will not discuss those capabilities. If you are just getting started with Intune, there are a few tasks you will need to do to configure your tenant to work with Apple and Google services. You may also wish to configure branding to make the end-user experience more familiar to your users.

Unless we note otherwise, all the tasks discussed here are performed in the Microsoft Endpoint Manager admin center. You can access the admin center at <https://endpoint.microsoft.com>. You will need to be a member of the Global Administrator or Intune Administrator role in Azure AD.

### Company Portal

The Company Portal application is how you enroll most devices into Intune. If you will be doing MDM on iOS or Android devices, or MAM on Android devices, your users will need to install the Company Portal app from their device's app store. The Company Portal app is responsible for brokering Intune's MDM capabilities as well as providing a private app store, and a place to manage your device on iOS and Android. On Android, even if you choose not to use MDM, the Company Portal serves as an authentication broker. As an authentication broker, the Company Portal is responsible for enabling an integrated single sign-on experience across Microsoft's mobile apps. On iOS, Microsoft's Authenticator serves as the authentication broker.

You can customize the Company Portal to show your organization's name, logo, colors, and other branding elements. While these items are not mandatory, they do provide a familiar look and feel to end users. To customize the app, browse to **Tenant administration > Customization** in the admin center. Microsoft documents the specific requirements for branding elements, as well as certain best practices [in their documentation](#). We recommend that you work with stakeholders in your organization such as marketing

and/or internal communications teams to select branding elements that best represent your organization. Sometimes this process can take a while, so do not leave it until the last minute.

## Apple Device Enrollment

Before you can enroll your first Apple device, you must configure an important certificate in Intune. This certificate is used with the Apple Push Notification Service (APNs). The APNs does exactly what the name suggests: it lets Intune send push notifications to your devices. You can request this certificate for free from an Apple website with a few minutes of work. Once a year, you must renew the certificate. It is **extremely** important that you do not forget to renew the certificate. If you do, you must re-enroll your devices.

To setup your Apple MDM push certificate, browse to **Devices > iOS/iPadOS > iOS/iPadOS enrollment** in the admin center and click on **Apple MDM Push certificate**. The next screen takes you through the process step-by-step. Intune will provide you with a certificate signing request (CSR) in step 2 that you upload to the Apple Push Certificates Portal [linked](#) in step 3. If you have never used this portal, you must register for an Apple account first. It is very important that you do not use a personal email address for this account. Your organization's APNs certificate is permanently linked to the account you use. Instead, you should use a shared email address such as a distribution list or shared mailbox to complete the registration.

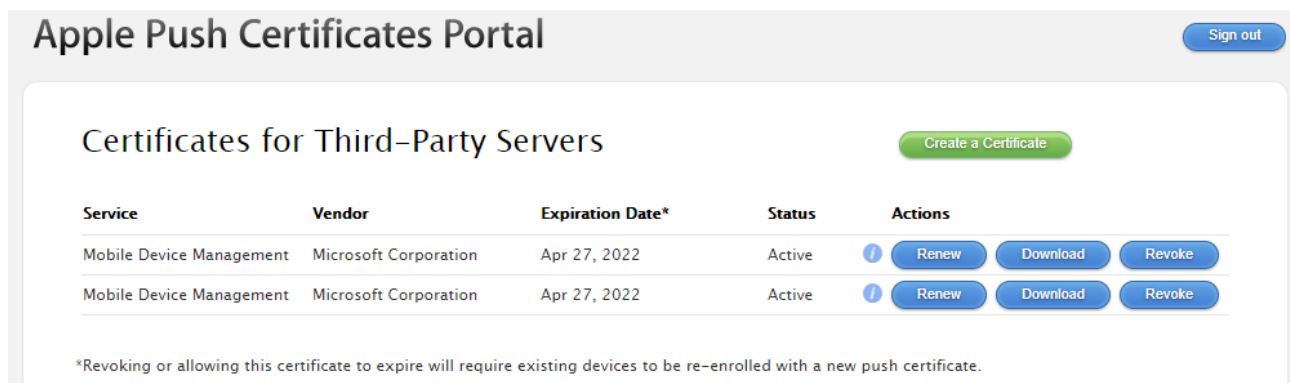

Figure 16-1 Apple Push Certificates Portal

Click **Create a Certificate** (Figure 16-1) and upload the CSR Intune generated. You will then be able to download the APNs certificate and upload it to Intune in Step 5. In Step 4, you must enter the email address of the Apple account you registered. Click **Upload** and you will be ready to enroll iOS devices using the Company Portal app.

You can also use the Apple Configuration application or Apple's Device Enrollment Program (DEP) to enroll iOS devices. However, we do not cover these topics here.

## Android Device Enrollment

While Apple makes device enrollment a universal process, Android offers a plethora of options for enrolling your devices. Android's enrollment options primarily revolve around Android Enterprise. With Android Enterprise, you have a choice of five MDM enrollment options:

1. **Android Enterprise personally-owned with a work profile** – use this option for BYOD devices that also need to access and store corporate data. Android separates corporate data and does not let the MDM system control personal data.
2. **Android Enterprise corporate-owned with a work profile** – use this option for devices your organization owns that you also allow end users to store/access personal data and apps from.

3. **Android Enterprise fully managed** – use this option for devices your organization owns that should be 100% controlled by Intune. Do not use this option if users are storing personal data on the device.
4. **Android Enterprise dedicated** – use this for devices that serve a singular purpose such as for a walk-up kiosk. Dedicated devices are restricted to a specific set of apps that can be used on the device.
5. **Android Open-Source Project (AOSP)** – use this for devices that do not interact with Google Mobile services. This feature is currently in public preview.

Regardless of the enrollment option(s) you choose, you will need to connect Intune to the Google Play store. To do this, browse to **Devices > Android > Android enrollment** in the admin center, and click on **Managed Google Play**. Click **Launch Google to connect now**. You will need to create a Google account or sign-in with an existing one. Much like Apple, you should not use a user-specific email address for this account. Use a distribution list or shared mailbox. Once you sign-in, supply your organization's name and agree to the terms and conditions and click **Confirm**. Once this is complete, you are ready to begin enrolling Android devices.

You can also enroll device using Android's legacy "device administrator" management model. While this may be necessary with certain older devices, Google is no longer investing in device administrator, and we do not recommend you use this model if it can be avoided. Microsoft has begun removing support for certain features in device administrator mode as well.

## Enrollment Restrictions

If you plan to use MDM to manage some (or all) of your devices, you may also be concerned with what devices are allowed to enroll. By default, any user in your Azure AD tenant that has been assigned an Intune license is permitted to enroll up-to five devices. You can alter the maximum number of enrolled devices per-user (up-to 15) or restrict users to only enroll certain operating systems (iOS or Android) or operating system versions, Android enrollment type (Enterprise or device administrator), Android device manufacturer, and/or block personally owned devices from enrolling.

To create or manage any of these restrictions, browse to **Devices > Enroll devices > Enrollment device limit restrictions** or **Enrollment device platform restrictions** in the admin center. The default profiles cannot be deleted, and they apply to everyone in your tenant. You can assign alternative restrictions that take precedence by clicking **Create restriction** on the toolbar. These alternatives can either be assigned to all users in your tenant, or to specific users or groups. If, for example, you need to permit certain users to participate in a BYOD program while other users can only use corporate devices, you can create two device type restriction profiles and assign them to separate groups.

## Device Categories

If you need to classify the types of devices used in the organization, device categories may be helpful. Device categories provide a list of options end users must choose from in the Company Portal when they enroll a mobile device. These can be anything you want. For example, you might create categories for departments like *Manufacturing* and *Sales* or you might categorize devices by purpose, e.g., *Point-of-Sale* and *Quality Control*. The options you choose are persisted on the device's record in Azure AD. This is helpful because you can create dynamic groups in Azure AD based on a device's category (amongst other options).

Azure AD will keep the group's membership up-to-date as the devices in your tenant change. You can then deploy Intune configuration items like apps, profiles, and policies to these groups. If you have a set of apps that are only used by Manufacturing devices, for example, you can see how this capability can be useful. To configure device categories, browse to **Devices > Device categories** in the admin center and then click **Create device category** on the toolbar.

## Device Updates and Intune

As Apple and Google evolve the iOS and Android operating systems (OS), Microsoft also evolves their minimum supported OS versions. Generally, this does not present an issue since devices typically update automatically or make an ongoing effort to ask the end-user to perform the update. However, as devices age, they may no longer be compatible with the latest OS versions.

When you have a BYOD program, and older devices are no longer supported by Intune, it can be difficult to inform end users that they must purchase a new device to continue accessing your organization's resources. Microsoft begins communicating planned OS support changes well in advance in the [Notices](#) section of the Intune docs.

For Apple devices, Microsoft supports for iOS 13 and better. For Android devices, Microsoft supports for Android 9 and better. For up-to-date support information, refer to the [supported operating systems](#) documentation. Microsoft supports the three most recent version of iOS and Android. As new versions are released, Microsoft will begin planning to deprecate support for earlier versions. While these supportability limits apply to device enrollment, individual applications (e.g., Microsoft Teams) may have different support lifecycles for iOS and Android.

## Managing Apps

Regardless of whether you choose MDM, MAM, or both, chances are you will need to manage some aspect of the apps on a device. For many organizations, Intune's MAM capabilities combined with the Microsoft Office apps (and select third-party apps) provides a good balance of control over corporate data while not putting controls on a BYOD device. If you use MDM, you will likely also use MAM to manage the apps on the device, but you might also want to use Intune to install apps on the device, or provide a curated app store in the Company Portal app.

### App Deployment

Intune has two app deployment options: "required" and "available". Depending on whether you are working in the context of MDM or MAM, the options you must install apps on mobile devices varies. If a device is MDM enrolled, you can use either option. When an app is deployed as "required", it will automatically be installed on the device. You can also choose to require uninstallation of an app you have previously deployed as "required". On the other hand, "available" publishes the app in the Company Portal. End users can click on "available" apps in the Company Portal, and they will be installed on their device.

Whether you choose required or available, you need to target your app deployment to a group of users or devices. Intune uses Azure AD groups so you can either use an existing group, or you can create a new one. If you simply want to target an app deployment to everyone, you can choose "all devices" or "all users". Be careful if you try to mix groups containing users and devices. Intune does not try to resolve the relationship between users and their devices so you may not get the results you want. As a best practice, we recommend that you stick with assigning to users *or* devices, but not at the same time.

To deploy an app, browse to **Apps > All apps** in the admin center. Click **Add** on the toolbar and choose **Android store app** or **iOS store app**. In this example, we will create a deployment for a Microsoft Outlook for Android. The process is very similar for iOS. You will need the URL of the application from the Google Play store which you can find by searching the store at <https://play.google.com/store/apps/>. Fill in the details for the application as shown in Figure 16-2. You can copy and paste all the details from the app's store listing.

While you do not need to provide optional details like the category or logo, they greatly enhance the user experience in the Company Portal. You can obtain the logo by saving the image in the app store listing as a PNG file and then uploading it to Intune. The category is used to help end users find apps that are available for installation in the Company Portal. There are nine built-in categories that come with Intune. You can add your own categories by browsing to **Apps > App categories** in the admin center.

Figure 16-2 App deployment for Microsoft Outlook for Android

Once you configure the app information, you can assign the app to users or devices. When you create an app assignment, you have several options to choose from. The assignment options are very similar across everything you will do in Intune. Fundamentally, you can assign apps to groups of users and/or devices by setting the **Group mode to Included**. If you need to exclude certain users or devices, you can change the **Group mode to Excluded**. Make sure you do not combine groups of users and devices, or you might see unexpected results. If, for example, you include a group of users and exclude a group of devices, Intune will not filter those devices as you would expect. If you need to only include or exclude certain devices in combination with users, use a Filter. We discuss Filters later.

For apps, you have a choice of assigning the app as **Required**, **Available for enrolled devices**, or **Available with or without enrollment**. Apps assigned as required will be automatically installed on devices. Apps assigned as available will be displayed in the Company Portal app for end users to install. The choice of whether to make apps available only to enrolled devices (MDM) or with or without enrollment (MDM or MAM) gives you additional control over when users can select the app for installation.

If you are not ready to deploy the app, this step is optional. If you do list one or more groups, the deployment will begin as soon as you click **Create** and complete the wizard. Find your app under **Apps > All apps** and click the app to monitor deployment status, change the properties of the app, or modify what users or devices the app is deployed to.

You can use the **App install status** report under **Apps > Monitor** to keep an eye on your app deployments. From here you can investigate the progress of a specific app deployment and see installation failures at-a-glance. To investigate a specific app, click on the row to go to the status dashboard for that app.

### Bulk Purchased and Private Apps

Apple and Google support managed app procurement as well as the ability for app publishers to advertise private apps to select customers. Apple manages this process through the Apple Business (or School) Manager, while Google uses the managed Google Play store. With both Apple and Google, once you approve or make a bulk purchase of an app, Intune will allow you to synchronize your app library and the apps will become available for deployment using the same process as we described earlier in this section.

The process with Android is straight forward. Browse to **Tenant administration > Connectors and tokens > Managed Google Play**. Click the **Open the managed Google Play store** link and approve the app(s) you want to deploy with Intune. Next, click the **Sync** button in the admin center. The apps you approved in the managed Google Play store will appear under **Apps > Android**. You can assign these apps the same way you assign any other app.

With Apple, you must enrol for an account in Apple Business Manager. This process requires several steps and data about your organization. Apple documents this process [here](#). Once you have obtained an Apple Business Manager account, you can browse to <https://business.apple.com> to login. Next, you must connect Intune to Apple Business Manager. To do this, go to **Settings > Apps and Books**. Click the **Download** link under *My Server Tokens*.

Next, in the Microsoft Endpoint Manager admin center, browse to **Tenant administration > Connectors and tokens > Apple VPP Tokens** and click **Create** on the toolbar. Give the token a name, provide the Apple ID you used to login to Apple Business Manager, and upload the file you downloaded in the previous step. Intune will automatically synchronize with Apple Business Manager the first time, but you can manually synchronize by selecting the token clicking the ellipsis (...) and clicking **Sync**.

To make apps available for Intune in Apple Business Manager, you must buy licenses (even if they are free) for the app in the **Apps and Books** area of Apple Business Manager. When you buy the license, you must be sure to assign it to the location that you downloaded the server token for in the previous step. If you have multiple locations configured, you must add a token for each location to Intune. If you are attempting to work with a private app and you do not see a Custom Apps area, go to **Settings > Enrollment Information** in Apple Business Manager and configure **Custom Apps** to **Enabled**.

Once you have bought licenses for an app, synchronize the token in Intune, and you will find the apps under **Apps > iOS/iPadOS**. You can assign these apps the same way you assign any other app. Occasionally Apple updates their terms and conditions. When this happens, the sync between Intune and Apple Business

Manager will stop working until you sign-in to Apple Business Manager and accept the updated terms and conditions.

## App Protection Policies

MAM is a core component of managing your organization's data on mobile devices. With MAM and Intune's app protection policies, you can apply controls to your data in apps that support MAM while leaving personal data untouched. This often creates a good balance of control versus autonomy in a BYOD program. MAM is primarily supported by Microsoft's Office applications on iOS and Android, but Microsoft publishes an SDK and an app wrapping tool that let third parties and in-house developers support MAM too., Zoom, Adobe Acrobat Reader, and Box are three examples of third-party apps that support MAM.

To implement MAM, you use app protection policies. These policies define what users and the supported mobile apps can do with your organization's data. For example, you can allow copy and paste between managed apps, but, if a user tries to copy managed data from Microsoft Word to Gmail, you can block this. You can also protect access to your data in managed apps by requiring a PIN to access the app rather than requiring a device PIN. The settings and capabilities are slightly different between iOS and Android, but fundamentally, the concepts are the same.

To create an app protection policy, browse to **Apps > App protection policies** in the admin center, click **Create policy** and select **iOS/iPadOS** or **Android**. For this example, we will create an iOS policy. Once you give the policy a name, you will need to select the devices and apps that the policy applies to. On the **Apps** tab, you can either select specific apps to apply the policy to, or use curated collections maintained by Microsoft. In the Target Policy to menu, you can choose from the following options:

- **All Apps** – automatically apply the policy to all publicly available apps that support app protection. Microsoft maintains [a list in the documentation](#).
- **All Microsoft Apps** – automatically apply the policy to any Microsoft-published app that supports app protection.
- **Core Microsoft Apps** – automatically apply the policy to a small set of "core" Microsoft-published apps including the Office apps, Microsoft Teams, and Edge.
- **Selected apps** – allows you choose the specific apps the policy applies to.

If you use any of the curated collections, Microsoft will update them from time-to-time as new apps become available that support app protection.

If you want to select specific apps, configure **Target Policy to** **Selected apps** and use the **Select public apps** link to target your policy to apps available in the app store. If there is an app that is available in the app store but not listed, or you develop an app that integrates with Intune, use the **Select custom apps** link to target the policy to the app.

Unlike app deployments, app protection policies can only be targeted to users. If you have a mixture of MAM and MDM devices, you might want to have one app protection policy for MAM-only devices that requires a PIN to access managed apps, while on MDM devices, you might require a PIN to access the device, rendering a second PIN to access managed apps unnecessary. If you need this level of control, change **Target to apps on all device types** to **No** and select **managed** (MDM) or **unmanaged** (MAM) from the **Device types** menu.

Next, select the apps you want to deploy the policy to. For traditional store apps, click **Select public apps** and select the apps you want to manage. If you have in-house developed apps that you want to manage, or MAM-capable apps that are not listed under **Select public apps**, click **Select custom apps**.

The bulk of the MAM controls are configured on the **Data protection** screen:

- **Backup org data to iTunes and iCloud backups** – controls whether your organization’s data can be backed up to Apple’s iTunes/iCloud services. We generally recommend selecting **Block**.
- **Send org data to other apps** – what apps on the device can the end user transfer data between using iOS’ sharing tools. We generally recommend selecting **Policy managed apps** or **Policy managed apps with Open-In/Share filtering**. These controls allow the end user to move organizational data between other MAM-managed apps, but not to unmanaged apps. If you have a special case that isn’t MAM-managed, you can use **Select apps to exempt** to enable sharing.
- **Save copies of org data** – can the user “save as” to an alternate location. The user interface (UI) for this control is confusing. You probably will want to select **Block** and then modify the **Allow user to save copies to selected services** and enable locations like OneDrive and SharePoint, Local Storage, or Box.
- **Transfer telecommunications data to** – controls whether the user can click on a phone number in an email, for example, to dial the number. By default, **Any dialer app** lets the user use any calling application (whether the native Phone app or otherwise), but, you can restrict this if you need to.
- **Receive data from other apps** – indicates whether managed apps can receive data from other apps. If you select the default, **All apps**, a user can transfer data from their personal email to their corporate email (for example). Like the **Save copies of org data** setting, if you want to choose specific data sources, you must select **Block**.
- **Restrict cut, copy, and paste between other apps** – this is an important data sharing control that determines whether an end user can copy organizational data and paste it into an unmanaged app, or vice-versa. We generally recommend selecting **Policy managed apps with paste in**. This enables full cut/copy/paste between managed apps, but also enables an end user to copy *from* an unmanaged app and paste it into a managed app.
- **Third party keyboards** – iOS supports alternative keyboards that can be installed from the iTunes Store. These keyboard apps can present a security risk since they have access to every keystroke.
- **Encryption** – enforces encryption of organizational data on the device. The downside of this is that it requires the user to have a device PIN which you may not wish to enforce.
- **Sync policy managed app data with native apps** – this is a roundabout way of saying if Outlook Mobile, for example, can add contacts to the native contacts app. There are more elaborate controls specific to Outlook Mobile that you should use if this setting is of interest.
- **Printing org data** – as the name implies, can an end-user use the native iOS printing functionality inside a managed app?
- **Restrict web content transfer with other apps** – if you want to require Microsoft Edge for browsing or to bring data into managed apps, you can use this control.
- **Org data notifications** – controls whether managed apps can create notifications on the device (or a companion device like an Apple Watch). These notifications can potentially disclose sensitive data such as in the subject of a meeting invitation.

Next, you can further restrict access to managed apps in the **Access requirements** tab by requiring the user to enter a PIN or biometric (e.g., TouchID) and/or login with their corporate credentials (the **Work or school account credentials for access** setting). Typically we find that these settings are useful if you are not using MDM. Without MDM, you cannot guarantee that users have setup security to unlock their device. By using the settings on the Access requirements tab, you can implement equivalent security controls to launch apps protected by the policy.

You may also wish to apply additional security precautions on the **Conditional launch** screen. These controls are divided into two sections: **App conditions** and **Device conditions**. App conditions control the behavior of managed apps (e.g., has the device been offline for too long, has the user entered too many invalid PINs, or

what to do if their account disabled in Azure AD) and what happens (e.g., restricting access or wiping data). Device conditions inspect the status and health of the device (e.g., is the device jailbroken, is it running a minimum OS version, and/or is it at an acceptable risk level as reported by a [mobile threat defense \(MTD\) solution](#)). Like app conditions, device conditions can take access such as blocking access to data or wiping the data entirely.

Finally, you must assign the policy to one or more groups of users on the **Assignments** tab. Once this is complete, click **Create** and complete the wizard. You can come back to the Apps > App protection policies screen later to monitor the status of the policy or make changes. New apps that support MAM periodically become available so you should occasionally check that you are including all the desired apps in the policy.

Once you deploy your policy, use the **App protection status** report under **Apps > Monitor** to keep track of your policy as shown in Figure 16-3. The dashboard in this report gives you an at-a-glance view of how many users are protected by the policy, the top apps, and any errors that you should investigate. To get more detail, you can use the download links on the toolbar, such as **App protection report: iOS, Android** to export the data to a CSV file.

Figure 16-3 App protection status report

## Email Client Configuration

Generally, we recommend choosing Outlook Mobile as the mobile email client for Exchange Online whenever possible. It provides the most complete combination of Microsoft 365 integration and administrative control. However, you may need to support the native email client on mobile devices as well. iOS in particular supports complete configuration of a profile in the native email client for MDM enrolled devices. Android devices support relatively limited pre-configuration of the Gmail and Nine for Work email apps. Outlook Mobile for iOS and Android can be pre-configured regardless of whether you use MDM or MAM.

### iOS Native Mail Client

To deploy settings for the native mail client to MDM enrolled iOS devices, you will need to create an email configuration profile. To begin, browse to **Devices > Configuration profiles** in the admin center and click **Create profile**. Select **iOS/iPadOS** for the **Platform** and **Templates** for the **Profile type**, and **Email** for the **Template name** and then click **Create**. You will need to complete the following fields to configure the profile:

- **Email server** – the ActiveSync endpoint to connect to. For Office 365 in the commercial cloud, use **outlook.office365.com**.
- **Account name** – this is shown in the iOS mail app as the name of the email account. You could use the name of your organization, for example.
- **Username attribute from AAD** – Select the user's username as represented in Azure AD. Generally this is the User Principal Name (UPN), but if you are connecting to an on-premises Exchange server, you might need to pick sAMAccountName, for example.
- **Email address attribute from AAD** – Select the user's primary email address as represented in Azure AD. If your UPN does not match the primary email address, then you will need to select Primary SMTP Address.
- **Authentication method** – select Username and password unless you are using client certificate authentication.
- **SSL** – select Enable.
- **OAuth** – this enables modern authentication. For Office 365, and any on-premises Exchange organization using modern authentication, select Enable.

**Note:** Microsoft will remove support for Basic Authentication in Exchange Online. You should only deploy profiles with modern authentication to prepare for this change. If you are using Basic Mobility and Security, discussed in the Companion Volume, Microsoft will automatically update your email profiles to use modern authentication.

- **Exchange data to sync** – generally you will select All data, however you can filter this to a subset. You might want to combine the **Calendar only** option with Outlook Mobile to provide access to the native Calendar app while using Outlook mobile for email and contacts, for example.

The remaining choices control behavior of the native mail app and are not critical for deploying an email profile. Like deploying an app, you must target one or more Azure AD groups of users or devices on the **Assignments** screen. Once this is complete, you can click **Create** to complete the wizard. You can monitor the status of your email profile deployment as well as modify settings and assignments by browsing to the profile under **Devices > Configuration profiles**.

One important thing to note is what will happen if you deploy an email profile to a device that already has a matching profile as determined by the Email server and Account name fields. Intune will not allow the profile to be installed. Instead, the end user will receive a notification that they must delete the profile that is already installed on their device. Intune will subsequently install the profile you have configured.

## Outlook Mobile

You can configure Outlook Mobile much more granularly than the native email client apps. In conjunction with an app protection policy, Outlook Mobile gives you a great deal of control over how the app behaves and what end users can do with your data. To configure Outlook Mobile, browse to **Apps > App configuration policies** in the admin center and click **Add > Managed apps**. Give your policy a name and click **Select public apps**. Select **Microsoft Outlook** for iOS and/or Android and then click to go to the **Settings** screen.

Microsoft documents all the Outlook Mobile configuration settings [here](#). Most of these settings are listed in Intune under **Outlook configuration settings** and are self-explanatory. Sometimes, though, Outlook Mobile introduces new settings before Intune catches up. You can use the **General configuration settings** in Intune to set these settings. For example, if you want to prevent end-users from adding a personal email account to Outlook Mobile, add a row under General configuration settings that looks like Table 16-2.

<b>Name</b>	<b>Value</b>
IntuneMAMAllowedAccountsOnly	Enabled

Table 16-2 Outlook Mobile custom configuration settings

All the settings for Outlook Mobile are documented and can be configured like the example in Table 16-2. Outlook Mobile custom configuration settings, however most are also listed in a much more friendly manner under **Outlook configuration settings**. Before you use General configuration settings, take a minute to confirm that is the only way. The raw settings are also useful if you are using a third-party MDM solution.

## App Selective Wipe

One of the benefits of MAM is the ability for Intune administrators to wipe organizational data without touching a user's personal data. This is useful when a user leaves the organization, for example. You can target a selective wipe to a specific device or all the user's devices. Once a selective wipe request is created for a user, it will remain until you delete the request.

To create a selective wipe request, browse to **Apps > App selective wipe** in the admin center. To selectively wipe organizational data on specific device, click **Create wipe request** on the toolbar. To selectively wipe organizational data on *all* a user's devices, open the **User-Level Wipe** tab and then click the **Add** hyperlink at the bottom of the list.

Select a user and/or their devices to create the request. You can open the request and monitor the progress of the wipe request for each managed app on each of their devices.

## App Configuration

Some applications support managing how the application works through Intune. For example, Outlook Mobile provides this capability as discussed above. Microsoft Edge is another example. These capabilities are not specific to Microsoft, however. You might need to specify a server for a line-of-business application to connect to, or you might need to change how the application behaves so that it can correctly interact with conditional access policies.

The availability of settings you can configure is completely up to the application developer. One common example is Salesforce. Salesforce [documents](#) a variety of settings that you can apply to their app through an MDM service like Intune. To do this, you must create an app configuration policy for each platform that you will deploy the app to.

To create an app configuration policy, browse to **Apps > App configuration policies** in the admin center and then click **Add > Managed devices** on the toolbar. Select the platform you are targeting (iOS or Android), and the app you will configure settings for. You must select an app that you have previously deployed in Intune. Next, you can choose how you enter the settings. In the **Configuration settings format** menu, **Use configuration designer** gives you a simple GUI for data entry, while **Enter XML data** is useful if the app developer has provided pre-configured settings that you can paste into Intune.

Finally, you must assign the app configuration policy to users or devices. The settings will be applied to the targeted app on any device that has the app installed.

## Managing Devices

Now that we have discussed managing apps on devices, what if you want to also manage the device itself? To do this, you will use the MDM capabilities of Intune. With MDM, you have substantial control of every facet of the device, limited only by what iOS and Android let you do. There are countless scenarios for how you deploy MDM, and thousands of settings that you can control on devices. We will not dive into all these settings or scenarios, but we will show you how to get started.

### Configuration Profiles

You use configuration profiles to control the behavior of devices, as well as install organizational settings such as wireless networks, virtual private networks (VPNs) or PKI certificates. Configuration profiles are specific to device platforms (iOS or Android) and must be configured individually for each. To create a configuration profile, browse to **Devices > Configuration profiles** in the admin center and click **Create profile** on the toolbar. You will need to select a **Platform** (e.g. iOS/iPadOS), **Template**, and **Profile type**. Most of the time, we expect you will use the **Device features** and/or **Device restrictions** template.

As you explore the configuration settings available in your profile, pay attention to the notes and information tips that Intune displays. Many settings are very specific about when and how they apply. For example, some iOS settings apply to any MDM enrolled device, while others only apply to *supervised* devices that are enrolled through Apple's automated device enrollment program.

Once you have configured the profile as you desire, assign it to one or more groups of users and/or devices. You can combine groups of users and devices and even exclude certain groups. As a reminder, be very careful if you decide to combine user and device groups in your profile assignment! You may find that it does not work the way you expect. If you need to only include or exclude certain devices in combination with users, use a Filter. Like other assignments, you can come back to your configuration profile later to monitor the status of the deployment or make changes.

### Device Inventory and Actions

Intune collects many data points about enrolled devices and makes it available to you in the properties of the device. You can learn about device hardware and installed apps, explore the status of configuration profile deployments, and check on app deployments. All this information is available by browsing to **Devices > All devices** in the admin center and clicking on a specific device. You can also use Intune's reporting features, which we will discuss later, to learn about this information for many devices at once.

In the same screen, you can also remotely take a limited number of useful actions on MDM enrolled devices. These actions are all accessible by. Actions you can take include:

- **Retire** – wipes managed app data and settings and removes the device from Intune. The user's personal data is retained.
- **Wipe** – removes all data from the device, resets the operating system settings, and unenrolls the device from Intune. Optionally, you can select to preserve user data on the device.
- **Remote Lock** – returns the device to the PIN lock screen.
- **Remove Passcode** – removes the device passcode, such as in scenarios where the user has forgotten their PIN.

These actions are primarily useful when someone leaves the organization or if a device is lost or stolen. From the **Devices > All devices** screen you can also perform these actions in bulk on many devices by clicking **Bulk device actions** on the toolbar. Be very careful using this tool! You could accidentally wipe many devices at once.

## Storing Custom Device Properties

Intune and Azure AD track various properties of devices such as their model, operating system version, etc. You might want to keep track of information that is specific to your organization too. For example, what department does a device belong to, or is the device approved for specific uses? To do this, you can use device extension attributes. You can use device extension attributes to populate dynamic groups or in device filters that are applied to a conditional access policy.

To populate device extension attributes, you must use the Graph API. Microsoft does not currently make an editor available in the admin center. You can use the Microsoft Graph [PowerShell module](#), the [Graph Explorer](#), or a custom script or program. In the example below, we will use the Graph Explorer to populate extensionAttribute1 with the value 'Finance Department'.

1. Obtain the Object ID of the device you want to update by logging in to the Azure Portal and navigating to **Azure Active Directory**. From there, select **Devices**, find the device you are planning to update, and click **Properties**.
2. Browse to the Graph Explorer at <https://developer.microsoft.com/en-us/graph/graph-explorer>.
3. Click **Sign in to Graph Explorer** on the left side of the screen.
4. Click **Modify permissions (preview)** and then click **Consent** for the *Device.ReadWrite.All* permission.
5. Configure your query with the following parameters:
  - a. **Method** – Patch
  - b. **Version** – v1.0
  - c. **URL** - `https://graph.microsoft.com/v1.0/devices/<device Object ID>` **URL** - `https://graph.microsoft.com/v1.0/devices/<device Object ID>`

6. Configure the body of the query with the following JSON:

```
{
  "extensionAttributes": {
    "extensionAttribute1": "Finance Department"
  }
}
```

7. Click **Run query**. A response of "No Content – 204" indicates success. You can modify Step 5 to use the Get Method to confirm the results of your update.

For more information on using Device Filters or dynamic groups, refer to Chapter 3.

## Custom Push Notifications

Intune can send push notifications with custom text to all the iOS and Android devices enrolled by a user. This can be useful for sending emergency alerts, such as for a weather event or a security situation. Custom notifications are shown on the lock screen of the phone or tablet so you should be careful not to include sensitive information. You can send notifications to individual users or to groups of users. Microsoft restricts you to sending up to 25 messages per-hour to groups, and up-to 10 messages per-hour to a specific user's devices.

To send a custom push notification, browse to **Tenant administration > Custom notifications** in the admin center. Give your notification a title (up-to 50 characters in length) and a body (up-to 500 characters in length). The title and body appear on the lock screen of the device when the notification is received. On the Assignments tab, select individual users or groups of users to send the notification to. Note that if the group includes devices, those devices will only receive the notification if the device's owner is *also included* in the group. Once you complete the wizard, Intune will immediately send the custom notification to the targeted users. It is not possible to cancel the notification or track its status.

## Security by Compliance

The configuration profiles and policies you deploy with Intune can be used as signals for access control decisions in Azure AD. This integration makes Intune even more powerful and an important part of your toolkit if you are implementing a zero-trust architecture. Whether you decide to use MAM, MDM, or both, you can make powerful decisions about whether a user and their device have access to applications or data using signals from Intune.

## Compliance Policies

If you use MDM, you can define policies that declare devices as compliant or non-compliant. Device compliance is determined by measuring certain settings on the device as well as risk indicators from MTD solutions. Based on the results of this evaluation, Intune sets a flag on the device's object in Azure AD that indicates if the device is compliant (or not). Subsequently, Azure AD can use this compliance flag to influence access control.

Like configuration profiles, compliance policies are created on a per-platform basis. To create a compliance policy, browse to **Devices > Compliance policies** in the admin center and click **Create Policy** on the toolbar. Select a **Platform** and give your policy a name. In this example, we will create a compliance policy for iOS. You'll find the settings you can choose from are relatively limited in comparison to a configuration profile, but the settings you can choose from are typically the most important indicators of a device's security posture:

- **Email > Unable to set up email on the device** – if you set this to require, the device must have an iOS Email configuration profile deployed to it that is successfully installed. If you are not using the native email app, this setting is not useful.
- **Device Health > Jailbroken devices** – this setting lets you mark jailbroken devices as non-compliant. We typically recommend that you select **Block**.
- **Device Health > Require the device to be at or under the Device Threat Level** – if you are using a mobile threat defense solution, this integrates the risk score from the MTD into the compliance indicator.
- **Device Properties > Operating System Version** – use these settings to require minimum (or maximum) versions of the device OS for the device to be considered compliant.

- **Microsoft Defender for Endpoint** – if you are deploying Defender for Endpoint to your mobile devices, this integrates the device’s risk score from Defender for Endpoint into the compliance indicator.
- **System Security > Password** – use this setting to require the device to have a PIN or passcode. We generally recommend you set this to Require. You can subsequently configure more specific details of the PIN such as its length or how often it must be changed.
- **System Security > Device Security** – list apps here that you want to block from mobile devices. If a listed app is installed, the device will be considered non-compliant.

When a device is considered non-compliant you can configure what Intune should do. By default, Intune will immediately mark the device as non-compliant which may have adverse consequences for the end-user’s access to organizational apps and data. You can take a more measured approach on the **Actions for noncompliance screen**:

- **Mark device noncompliant** – after how many days should Intune mark the device as noncompliant in Azure AD?
- **Send email to end user** – after how many days should Intune send an email to the end user (and optionally to others such as your helpdesk) informing them about their device?
- **Send push notification to end user** – after how many days should Intune send a push notification to the end user informing them about their device?
- **Remotely lock the noncompliant device** – after how many days should Intune lock the device, requiring the device’s PIN/passcode to be entered?
- **Retire the noncompliant device** – after how many days of noncompliance should Intune take the device retirement action, discussed earlier.

You might decide to first send the user an email immediately, wait three days to mark the device as non-compliant in Intune, and then retire the device if it is still non-compliant after 90 days. On the other hand, your security requirements might not allow a non-compliant device for any period so you might decide to both send an email and mark the device as non-compliant immediately (after 0 days).

Once you have configured the policy, you must assign it to groups of users or devices in the same way as you have assigned other profiles or apps. It is important to remember that compliance policies only *test* settings. They never configure settings on a device.

## Conditional Access

Conditional access policies are a feature of Azure AD Premium that let you make decisions about the who, what, when, where, and how of access to apps and data. We discuss the conditional access feature of Azure AD in detail in Chapter 3, including various examples of how to configure policies that integrate information from Intune. A classic example is organizations that want to make sure email is only accessed from devices that are either enrolled in Intune and policy compliant, or from end-users that are using a managed app like Outlook Mobile.

You can use two indicators from Intune to achieve these goals (and we show you how in Chapter 3). Since the compliance status of a device is reflected in Azure AD based on the results of your compliance policies, you can require a device to be compliant in your conditional access policy. Likewise, conditional access policies can determine if a user is using a managed app (e.g., Outlook Mobile) and if an app protection policy manages the app. If these factors are met, Azure AD will permit access. Otherwise, it can be configured to deny access.

## Terms of Use

Some organizations require end users to accept terms and conditions before they can enroll a device in Intune. Common examples are acceptable use policies for organization-owned devices and agreements for how personal mobile devices can be used to access organization data. There are two ways you can accomplish this with Intune:

1. Intune terms and conditions
2. Azure AD conditional access terms of use

We recommend using Azure AD's terms of use if you have Azure AD Premium. Azure AD terms of use support a much broader set of features including uploading PDFs that can have formatting and hyperlinks, multiple languages, requiring users to scroll through the entire terms document, and more.

You must first create a terms of use document in Azure AD. To do this, login to the Azure Portal and navigate to **Azure Active Directory**. From there, select **Security > Conditional Access > Terms of use** and click **New terms** on the toolbar. Configure the terms with the following settings:

- **Name** – a name for the terms that is useful to administrators. This value is not shown to end users.
- **Terms of use document** – upload a PDF that will be shown to end users for acceptance. You can upload additional PDFs in alternate languages. You must specify the **default language** for the first PDF you upload and provide a **Display name** that will be displayed to end users.
- **Require users to expand the terms of use** – if you select **On**, users must view the contents of the PDF before they can accept the terms.
- **Require users to consent on every device** – if you select **On**, users will be prompted to accept these terms on every device rather than just once.
- **Expire consents** – if you select **On**, users will be forced to re-accept the terms after the number of days specified in the **Duration before re-acceptance required** field.
- **Enforce with conditional access policy templates** – choose **Create conditional access policy later**.

Next, you will need to create a conditional access policy to apply the terms you created to Intune device enrollment. We cover conditional access policies in depth in Chapter 3. The policy that you create must be configured with the following minimum settings:

- **Cloud apps or actions** – choose **Select apps** and then select the **Microsoft Intune** and **Microsoft Intune Enrollment** apps.
- **Grant** – check the box next to the name of the terms of use you created previously.

Auditing information for when users accept terms of use is accessible from the **Audit logs** area of the Azure AD portal. Click the **Activity** filter below the toolbar and select **Accept Terms of Use** to filter the audit data.

## Intune Management

As you plan to use Intune in your organization, you will need to determine how to operationalize management of the service. In a small organization, this may be simple, but in larger organizations, you will probably need to grant access to different teams such as your service desk or endpoint management team to manage different parts of your Intune configuration. You may also need to give management insight into how the service is being used and what your mobile device and application footprint looks like. In this section we will explore some of these requirements and how you can accomplish them with Intune.

## Privileged Access and Role Based Access Control

Members of the Global administrators and Intune administrator roles in Azure AD are automatically granted full access to Intune. While these roles grant broad access, you probably will want to delegate more granular access to administrators in your IT organization. There are several [built-in roles](#) that you can start with by browsing to **Tenant administration > Roles > All roles** in the admin center.

If your organization is more complex, you can define custom roles to meet your specific needs. Custom roles define two components: the permissions the grant and the objects (e.g., devices, policies, apps, profiles, etc.) the permission are applicable to. There are hundreds of individual permissions that you can explore as you create a role. The objects that the role grants access to use a capability called scope tags. We have not discussed scope tags thus far, but you may have noticed that you can set them anytime you created a policy, profile, or app.

If you do not need to segment access to individual devices or policies/profiles/apps, you can use the built-in Default scope tag. If you do need to segment access, scope tags are for you. You might want to create individual scope tags for different departments, regions or geographies, or categories of users (e.g., executives). Scope tags are assigned to devices based on group membership. You can either put devices in a group manually, or you can use Azure AD dynamic groups to automatically place devices in certain groups. All other objects in Intune (e.g., configuration profiles, apps, etc.) are manually assigned one or more scope tags.

To create a scope tag, browse to **Tenant administration > Roles > Scope (tags)** in the admin center. Click **Create** on the toolbar and give your new scope tag a name and description. You can choose anything you want – for example “Headquarters Devices” or “Executives”. If the tag will apply only to certain devices, select a group that meets your needs.

Next, when you create a custom role by browsing to **Tenant administration > Roles > All roles** in the admin center and clicking **Create**, you can choose one or more scope tags in the wizard. The permissions you select will *only* be granted to items that are tagged with the scope tag(s) you select. To apply a scope tag to almost anything in Intune, go to the Properties of that item and click **Edit** in the **Scope tags** section of what you are editing.

## Complex Assignments with Filters

One of the limitations of traditional assignments in Intune is the inability to combine inclusion and exclusion groups that mix users and devices. For example, you cannot include a group of users in a specific department but then exclude a group of devices that are personally owned. Filters allow you to create reusable rules for when an assignment should (or should not) apply to certain devices.

Filters can be used with most types of assignments, but there are a [few exceptions](#). To create a filter, browse to **Tenant administration > Filters** in the admin center and then click **Create** on the toolbar. Give your filter a name and select the **Platform** that it will apply to. You can either manually specify the filter in the **Rule syntax** editor or use the expression builder. For example, if you wanted to create a filter that targets only devices that are personally owned, configure the following expression:

- **Property** – deviceOwnership
- **Operator** – Equals
- **Value** – Personal

Under the **Rule syntax** editor, there is a **Preview devices** link. Clicking this link allows you to test the results of the filter in real time before you deploy it.

After creating the filter, you can apply it to an assignment for an App, Configuration Profile, Enrollment Restriction, or Compliance Policy. You will configure the **Filter mode** to **Include** or **Exclude** in the assignment and select the filter you previously created.

## Simplifying Assignments

Throughout the examples described here, we assign various policies, apps, and profiles to groups. As your Intune deployment grows in scale and complexity, this can become difficult to accurately manage. To address this, Intune has a feature called *Policy Sets*. You can use policy sets to create a single assignment for any combination of apps, app configuration policies, app protection policies, configuration profiles, compliance policies, device type restrictions, and more. For example, you might create a policy set for all of your users in North America and assign everything they need at once.

To create a policy set, browse to **Devices > Policy sets > Policy sets** (or **Apps > Policy sets > Policy sets**) in the admin center and click **Create** on the toolbar. Give your policy set a name and then click through the **Application management** (apps, app configuration policies, and app protection policies) and **Device management** (configuration profiles and compliance policies) tabs. Add the relevant items that you want to deploy on each tab. Finally, on the assignments tab, add the groups of users or devices that you want to include (and, optionally, exclude) from the deployment. Note, again, that you cannot combine inclusions and exclusions of users and devices in the same assignment.

Once you create the policy, all the items you selected will be deployed according to the assignment. In the future, if you need to deploy a new item such as an app or profile to the same set of users or devices, you can simply add it to the policy set without recreating potentially complicated assignment logic in yet another location.

## Maintaining a Clean Admin Center

Over time, your Intune console will probably become cluttered with old devices. People get new phones all the time, but they do not call you to ask for their old device to be removed from Intune. You might remember that you can configure a compliance policy to retire non-compliant devices from Intune which will remove them from the console next time they check-in. This does not solve all the clutter, though.

Fortunately, you can configure Intune to automatically delete devices that have not checked-in for some time. To do this, browse to **Devices > Device clean-up rules** in the admin center. Set **Delete devices based on last check-in date** to **Yes**, and then set **Delete devices that haven't checked in for this many days** to a number of days ranging from 30 to 270 days. This configuration applies to every device in Intune (except Macs managed by Jamf), and it is not possible to choose different settings for different types of devices. You will need to choose a value that makes the most sense for your organization. For example, if you have a set of tablets that are only used for special events that happen quarterly, you might configure this feature to 120 days to allow time for those tablets to be used periodically.

## Reporting

The **Reports** section of the admin center contains a [set of reports](#) that highlight specific aspects of your Intune deployment. One thing you may notice when you click on a report is that it does not show any data. You must manually refresh the Intune reports before you can see any data in them. From time to time, Microsoft makes changes to the reports available here, or the contents of existing reports. The list of reports in this section is short, but, in the individual areas of the admin center, you will find a **Monitor** section with more reports. For example, if you browse to **Devices > Monitor**, you will find twenty additional reports that you can generate.

While the built-in reports are useful, the most powerful way to take advantage of the data in Intune is to access Intune’s data warehouse. The data warehouse is available as an OData feed that you can integrate into any tool you want. Microsoft supplies a [sample app](#) for Power BI, shown in Figure 16-4, that is a very useful getting started tool if you have access to Power BI.

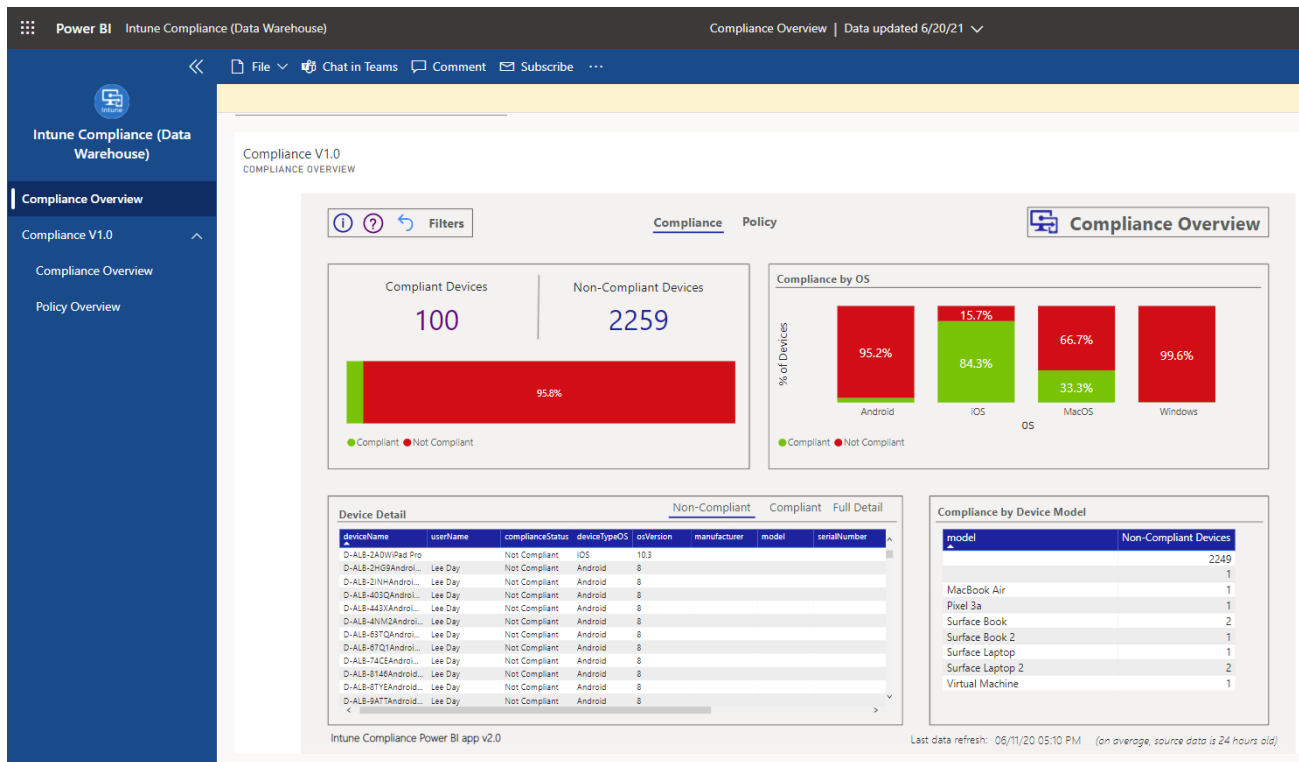

Figure 16-4 Power BI Intune data warehouse dashboard

# Chapter 17: Managing Data Governance and Compliance

## **Tony Redmond**

The Microsoft Purview suite covers a range of risk and compliance and data governance solutions available to Microsoft 365 tenants. For Information Technology, compliance is how organizations comply with established guidelines, regulations, and legislation. It can also refer to the practical measures taken by an organization to ensure compliance. Legislation varies from country to country. Well-known examples in the United States include the Sarbanes-Oxley Act (SOX 2002) and the Health Insurance Portability and Accountability Act (HIPAA – 1996). Companies working in these industries must ensure that their IT systems store and keep data in compliance with the regulations laid down in legislation. The [General Data Protection Regulation](#) (GDPR) and the California Consumer Privacy Act (CCPA) are good examples of how regulations exist to compel companies to protect personal data properly.

Microsoft began its journey to deliver compliance features in Exchange 2010. Since then, Microsoft has delivered an array of features. Although not every workload currently supports every aspect of compliance functionality, coverage is steadily spreading. The aim is to cover all workloads where users generate information that organizations might need to keep for business or regulatory purposes. Collectively, these categories give organizations a framework for “data governance.”

A data governance framework helps organizations satisfy regulations and applicable standards. Technology helps users to be compliant, but only if that technology is easy to use and unobtrusive. Experience proves that trying to implement difficult-to-use or complex compliance technology is not a recipe for success. Building compliance into applications like SharePoint Online or Teams intuitively and unobtrusively is challenging, especially as the volume, complexity, and sources of data requiring governance increase. Without good governance, organizations cannot meet compliance and regulatory requirements and expose themselves to the consequences of data leakage or external threat.

## Data Governance

Originally, workloads implemented different compliance capabilities limited to the extent of the workload’s functionality. Because each took a different approach to compliance, bringing the on-premises functionality to the cloud resulted in a fragmented and disjointed situation. Some data have protection, and some do not. Some data are subject to retention policies, and some are ignorant of policies. Some data come within the scope of eDiscovery, and some are invisible to searches. And so on.

A complication is that some applications have been slow to support the compliance framework. Another arises through the introduction of new applications like Teams and Planner, which create new sets of data that might be of interest from a compliance perspective. In short, the old approach of depending on workload-specific compliance functionality was obsolete. A new cross-service architecture was necessary to handle compliance for cloud applications running inside Microsoft 365. Microsoft rolled out the new Data Governance framework in April 2017. Over the next five years, many add-on solutions joined the framework, renamed the Microsoft Purview suite in April 2022.

Depending on the business requirements that exist within an organization to preserve and protect its information, the individual compliance solutions in the Purview suite are less or more important. Fitting them together into a coherent plan is a major task that needs input from Information Technology, Human Resources, and Legal personnel in addition to overall direction and support from senior management. As the

regulatory and legal frameworks that govern compliance vary extensively from country to country and industry to industry, the treatment of the topic here is by necessity at a reasonably high level. However, it should be enough to give guidance as to what is and what is not possible.

## Licensing Data Governance and Compliance Services

Many of the data governance and compliance services require premium or advanced licenses. This isn't a problem if you have the necessary licenses, but if you don't, you should remember that:

- Microsoft might enable a service for every account in the tenant. This can incur a potential licensing liability if you are not careful to restrict access to functionality to the accounts that need to use the service.
- Microsoft does not enforce licensing for many services. This might change in the future and if the accounts do not possess the correct licenses, they will lose access to a service once "targeted capabilities" are available.

Among the Purview solutions you might want to use are:

- Microsoft Purview Information Protection and Sensitivity Labels.
- Microsoft Purview eDiscovery (Premium).
- Microsoft Purview Customer Lockbox.
- Microsoft Purview Data Loss Prevention.
- Microsoft Purview Data Lifecycle Management.
- Microsoft Purview Information Barriers.
- Microsoft Purview Insider Risk Management.
- Microsoft Purview Communications Compliance.
- Microsoft Purview Records Management.
- Microsoft Purview Audit (Premium).

Other Microsoft Entra and Microsoft 365 components assist with data governance, including:

- Privileged Access Management.
- Azure AD Conditional Access Policies.
- Microsoft Defender for Cloud.
- Office 365 Message Encryption.
- Office 365 Advanced Message Encryption.
- Microsoft Priva.

These lists are not complete and will change over time as Microsoft introduces new services and capabilities.

Some inconsistencies in Microsoft licensing deserve mention. For example, Data Loss Prevention policies for Exchange Online, SharePoint Online, and OneDrive for Business require Office 365 E3 while DLP and retention policies for Teams need Office 365 E5. Finally, make sure you know the rules for which accounts need additional licenses. For instance, anyone who is a custodian in a premium eDiscovery case because they "control" documents or messages needed by the case must have an Office 365 E5 or Microsoft 365 E5 Compliance license.

Because detail is important, before deciding to invest in any functionality, you should first consult [Microsoft's licensing guidance](#) and review the feature chart available on that page in both PDF and spreadsheet format.

With that information in hand, you can work with the organization from which you purchase licenses (Microsoft or partner) to clarify exactly what licenses you need for the features you want to use.

## Keeping Content in Place

Traditionally, when a company needed to preserve email or documents for compliance purposes, they move copies of the items to a separate archiving system. Veritas Enterprise Vault is a classic example of such an archival system. When necessary, administrators run eDiscovery or retrieval activities to find content held in the archival system. This approach was acceptable when products like Exchange and SharePoint did not have archiving capabilities. Today, the focus is on leaving data in place within its native repository and integrating compliance technology inside applications. Advantages of this approach include:

- No need exists to transfer copies of messages, documents, and other content to external systems for searching, analysis, or otherwise interrogation for legal reasons.
- Avoidance of additional cost for software and hardware by not having to use external systems. In addition, the IT infrastructure is simplified because the extra systems are unnecessary.
- It is easier to prove the “chain of custody” and show that no one can tamper with emails and documents before these items become evidence in legal cases.
- Keeping content in its native repository means that no opportunity exists to compromise content during transfer to a new repository.

Removing the need for copying files from one system to another makes it easier to meet chain of custody requirements and prove that no one could have interfered with an item to compromise its contents. Guaranteeing the chain of custody is important when data proves facts during litigation. In-place archiving means that information stays in its original location and is protected against interference for as long as the hold persists. The data retained in place is immutable as neither administrators nor users can interfere with it after a hold is in place.

Keeping everything in place inevitably means that repositories become larger. The software therefore must be more intelligent and more capable to deal with higher volumes of data. Searches must be able to find information quickly and accurately when needed for compliance purposes. The work done by Microsoft Research to improve and make search technology smarter together with the acquisitions of FAST (otherwise known as the Search Foundation) and Equivio are examples of how Microsoft responded to the need to have better search technology. Today, Microsoft Search indexes information as soon as documents, files, messages, chats, and other items are added to repositories via user activity or bulk imports while Equivio has evolved to become Microsoft 365 Advanced eDiscovery and is capable of processing millions of messages or documents to find the desired results very quickly. Another advantage is that when you have a unified view of data such as the Microsoft 365 substrate, it is much easier to build the necessary infrastructure around that data to secure and audit its use. For instance, the audit log captures details of user activity from multiple workloads which administrators can then search using the audit log search in the Microsoft Purview Compliance portal, Office 365 Cloud App Security, or third-party tools such as [Quest On Demand Audit](#).

## Principles of Data Governance

Microsoft 365 takes a cross-service approach to data governance based on common policies that apply across multiple workloads. This approach is obvious in the way that content searches, eDiscovery, and Data Loss Prevention work, and is rolling out for data governance in the form of retention labels, retention policies, and associated features. The Microsoft Defender and Microsoft Purview Compliance portals are important parts of that strategy because they bring together functionality designed to work across applications rather than just a single workload.

Data Governance is a policy-driven framework to control the retention and removal of content across all applications. We can break the framework down into four parts:

- **Import:** Bring information from multiple sources, including from non-Microsoft sources like Facebook and Bloomberg messaging, into Exchange Online through the Import Service or third-party products. The aim is to allow customers to gather all the information they need to manage in repositories such as archive mailboxes or SharePoint sites to replace older methods like PSTs and file servers. Once the service holds the data, it becomes possible to manage the data through the application of policies.
- **Retain:** Provide customers with the ability to state what data they need to retain for compliance purposes, for whatever period is necessary. The policies used to enforce retention must apply across all workloads (or as many as possible).
- **Delete:** It is equally important for customers to be able to remove data that they no longer need. Methods need to exist to remove information from all repositories according to policy.
- **Classify:** Some data is more important or secret than others. The framework must allow users to classify information as they work. Applications should highlight information classified by users to raise awareness of the importance of the information. The system should recognize the sensitivity of the information and potentially restrict what users can do with that content.

Of course, when a company retains data for data governance, the data should be immutable. The Office 365 Import Service is the cornerstone for “Import.” Retention policies and retention labels make sure that tenants can keep or remove information as they need and classify items to mark important data for retention. Other functionality, like Data Loss Prevention, handle the need to protect against the misuse or inadvertent disclosure of data, while sensitivity labels (applied manually or automatically) restrict access to confidential information to authorized users.

## The Influence of Privacy Laws

Companies with business operations inside the European Union must follow the [General Data Protection Regulation](#) (GDPR) to safeguard how they process personal data while companies operating in California must follow the California consumer privacy act (CCPA). In both cases, heavy penalties for breaches ensure that companies must take this and similar legislation seriously. According to Microsoft, over 90% of an organization’s data stored in Exchange Online, SharePoint Online, and OneDrive for Business is in Word, Excel, PowerPoint, OneNote, and Outlook (Exchange). It is easy to imagine examples of where applications hold personal information, including:

- Annual employee reviews that are stored in a SharePoint or OneDrive for Business site.
- A list of applicants for a position is in an Excel worksheet attached to an email message.
- Lists holding data (names, employee numbers, hire dates, social security numbers, salaries) about employees in files in SharePoint Online sites.
- Discussions about potential new hires in a Teams chat.
- Word documents holding applications for employee work visas.

Given that personal information can be found in almost any application, the work to locate the 10% of personal information stored outside Office documents is likely to take the most effort (for example, see this [guide](#)). Organizations must know what applications hold personal data and how they process personal data in compliance with legislation. Knowing where to look is only the start of the process and it might not be possible to automate many of the steps involved in responding to data subject requests.

Fortunately, the compliance features available in Microsoft 365 assist tenants to satisfy legislative requirements. These features include:

- Sensitivity labels and policies to mark and potentially protect (encrypt) documents, messages, and other objects, like Power BI reports.
- Auto-label policies to find and classify documents holding personal data. Microsoft 365 includes sensitive information definitions for many country-specific personal identity cards and passports. You can create an auto-label policy to find and label documents holding these sensitive information types.

Retention processing can remove items stamped with a suitable label after a defined period, perhaps after including a manual disposition review.

- Data Loss Prevention (DLP) policies can use the same sensitive information types to stop people from sharing confidential data outside the tenant. A General Data Protection Regulation DLP template makes it easy to deploy protection for all the defined European Union sensitive information types.
- Content searches to find personal data stamped with retention labels used to mark items holding personal data.
- Alert (or advanced alert) policies to detect actions that might be privacy violations. For example, multiple downloads of documents from a SharePoint site holding HR information. You can also search the audit log to discover and report potential issues.
- The Microsoft Privacy Subject Rights Request solution makes it easy to retrieve information stored in Microsoft 365 when necessary to satisfy a request to provide information held about an individual.

Microsoft publishes information about how various aspects of Microsoft 365 align with GDPR (as an example, see this post covering [SharePoint Online and OneDrive for Business](#)). Having technology available to help satisfy the regulatory requirements is helpful. However, it is only one step to achieving full compliance. Tenants still need to protect data through a mixture of user education and technology. See [this paper](#) for information comparing the terms used in GDPR with those used in U.S. eDiscovery contexts.

This chapter covers retention labels and retention label policies. Other relevant chapters are:

- Chapter 18: Managing eDiscovery.
- Chapter 21: Managing auditing.
- Chapter 19: Managing Data Loss Prevention.
- Chapter 20: Managing Information Protection.

## Compliance Manager

Microsoft Purview [Compliance Manager](#) is a tool to guide compliance managers through the often-confusing array of rules involved in privacy frameworks. Compliance Manager is a static tool in that it does not have the necessary features to organize the work needed to achieve compliance with complex regulations like GDPR. However, many tools are available to help tenants to organize and manage the work set down in Compliance Manager. For example, Planner tasks can track progress to completion for responsibilities assigned to those working on ensuring compliance with regulations. To gain some collaboration capabilities, including document management, the tasks in plans are accessible on SharePoint Online sites, Teams, and Groups.

# Compliance Permissions

Microsoft 365 Purview compliance functionality uses role-based access control to allow or deny access to individual features. When users access the compliance portal, Purview evaluates the permissions held by their account to decide what they can do. Microsoft Purview uses a separate set of permissions to control access to compliance functionality than those used for general administrative purposes or in Exchange Online.

Compliance permissions are grouped into roles to reflect the access needed to perform specific tasks, like Data Investigator or Compliance Data Administrator. Roles also make it easier to assign relevant permissions to users. Only members of the Compliance Administrator role group can create or manage retention policies.

Compliance roles are managed through the **Permissions** section of the Microsoft Purview Compliance portal, where users holding the Organization Management role can manage the set of permissions assigned to a role or who holds a role. Some compliance roles can also be assigned by editing user accounts in the Microsoft 365 admin center. After you assign the necessary role to a user, they must sign out and back into Microsoft 365 to ensure that the new permissions are respected. Sometimes it takes a little while before the new role assignments are acknowledged. If this happens, just wait for a few minutes, and then retry.

# Retention Policies and Publishing Label Policies

The retention strategy for an organization usually contains a mixture of removal and retention. Organizations want to remove items after their useful lifetime or to stop the ongoing accumulation of data that has no value. On the other hand, keeping high-value content is important because these items form the collective recorded memory of the company. Documents and emails relating to policies and procedures, strategy discussions, board minutes, reports, research papers, and so on must remain available for as long as the organization needs them. Sometimes laws or regulations define the retention period, and sometimes the organization sets the period. Within Microsoft 365, retention processing operates by applying retention labels to items and retention policies to locations (mailboxes, sites, or groups). The settings in retention policies and retention labels can do the following:

- **Retain-only:** Microsoft 365 retains items in their home locations for a specified period (or forever), called the retention period. When the retention period expires, users decide how to dispose of items. The retention period can be forever.
- **Delete-only:** Microsoft 365 permanently deletes items after their age reaches a specific period (set by the creation or last modified date). Because retention is not enforced, users can delete the items beforehand.
- **Retain and Delete:** Microsoft 365 keeps items for a specified period and then deletes the items permanently after the retention period expires.

Other settings exist to enable more granular processing, but the basics of retention boil down to defining a retention period and action.

A retention label is more precise because it applies to a single item instead of to every item found in a location. For instance, a user who works on a new corporate policy will know what retention label is most appropriate for that kind of content. Retention policies apply to all the items in containers coming within the scope of the policy, such as all the documents stored on a site. A retention label always takes precedence over a policy because of its specificity. Two types of retention policies exist to satisfy the specific requirements of a tenant. A tenant can deploy both types of policies.

- **Publishing Label policies** make retention labels available to users by publishing the labels to workloads. Settings within the retention labels control what happens to content marked with the labels. Multiple publishing policies can make labels available to a user. Workloads are responsible for combining all the labels available to a user and presenting the complete set through client interfaces.
- Assigning individual retention labels to items is more precise than container-based assignment through **Retention policies** because users select and apply the labels to specific items. Retention policies allow organizations to achieve broader coverage by applying retention settings to all items stored in selected containers or locations (such as mailboxes, sites, or groups). Background processes such as the Exchange Managed Folder Assistant (MFA) process the retention settings defined in policies against the items stored in the target locations. Tenants can use retention policies to preserve or remove content for the entire organization or specific groups of up to 1,000 accounts. Typically, tenants use retention policies to ensure that a company meets the compliance requirements set out in legislation such as the Sarbanes-Oxley Act. Management of retention labels and policies is in the **Data lifecycle management** section of the Microsoft Purview Compliance portal.

It can be confusing to understand the scenarios where it's best to use retention policies and where retention labels are a better choice. Usually, tenants end up using a mixture of both to ensure broad coverage through policies and precise retention of specific items through labels. For instance, you might apply a retention policy

to a mailbox or SharePoint site that mandates the removal of items after six months and then provide some retention labels for users to assign to items they wish to keep for longer periods.

Table 17-1 lists several features that you should consider when planning how and when to use retention policies and retention labels.

<b>Feature</b>	<b>Retention Policy</b>	<b>Retention Label</b>
<i>Workloads:</i>		
<i>Exchange Online</i>	Yes	Yes (except for items in public folders)
<i>SharePoint Online</i>	Yes	Yes
<i>OneDrive for Business</i>	Yes	Yes
<i>Yammer</i>	Yes	No
<i>Planner</i>	No	No
<i>Teams</i>	Yes (chats and channel messages)	No
<i>Microsoft 365 Groups</i>	Yes (group mailbox)	Yes (items in group mailbox)
<i>Skype for Business</i>	Yes (conversation history)	No
<i>Automatic application</i>	Yes	Yes (by auto-label policy, DLP, etc.)
<i>Manual application by a user</i>	No (policies can only be set and applied by administrators)	Depends on the client's UI
<i>Labels displayed in client UI</i>	Partially (by Outlook clients for email)	Depends on the client's UI
<i>Persistence</i>	Policies are location-dependent, so items move out of scope if moved out of location	Persistent within supported Microsoft 365 locations. For instance, if you move a message from one folder to another, it keeps its assigned label
<i>Mark item as a record</i>	No	Yes
<i>Event-based retention</i>	No	Yes
<i>Require manual disposition review</i>	No	Yes
<i>Office 365 audit</i>	Audit records not generated for application of policies to locations	Audit records are generated when labels are applied, changed, or removed to/from items
<i>Find items subject to retention</i>	No	Via content searches (select retention label as a search condition), content explorer, and activity explorer

Table 17-1: Comparing retention policies and retention labels

Over the remainder of this chapter, we explore the details of how to create and manage retention labels, the policies used to publish retention labels and to auto-apply, and general retention policies. We will also

examine how Exchange Online mailbox retention policies work because of the ongoing need to support hybrid environments.

# Rules or Principles of Retention

The many workloads and types of data in use across Microsoft 365 create a complex environment for retention management. Multiple ways exist to mark content for retention or deletion. Therefore, a need exists for a mechanism to resolve the conflict that can occur when several policies apply to a mailbox or site, especially when Microsoft 365 retention policies remove items after retention periods expire. Microsoft applies the following four rules of retention (sometimes called the *principles of retention*) to decide how to process content. The rules work from top to bottom. Workloads use the rules as tie-breakers to set precedence when processing items if multiple policies apply.

1. **Retention wins over deletion:** You could call this the “keep safe” principle. In practical terms, it means that when multiple retention policies apply to content, retention wins over deletion. Take the example of where a mailbox comes under the scope of two retention policies. The first removes all messages after they are four years old. The second, perhaps applied to a subset of mailboxes belonging to senior managers, retains all messages for seven years. The solution is to move messages into the Recoverable Items structure after four years and to keep them there for three more years. Both policies are respected because items seem to be deleted after four years (users do not realize that the messages are still available) while keeping the items in the background ensures that the messages stay indexed and discoverable for the full seven years.
2. **Longest retention period wins:** If multiple policies specify different retention periods, items are always kept for the longest period. This principle ensures that content is kept for as long as it might be needed. If you want to deliberately remove content after a certain period, deploy a policy that explicitly removes the content after that period elapses and make sure that the location holding the content does not come within the scope of any other policy (Exchange mailbox retention policy or retention policy). Note that an item will be kept for longer if a user applies a label with a longer retention period to it.
3. **Explicit wins over implicit:** Explicit means that a user or administrator has selected specific content for special retention. This can happen when a user applies a label with a retention action to an item in a mailbox or site, or when a location is within the scope of a “non-org wide” policy (one that only applies to some content within the tenant). The logic here is that the user or administrator has made an explicit decision about retention for a specific item (a label applied manually) or location (non-org wide policy created by the administrator). Manual application of a retention label always takes precedence over a catch-all retention policy that applies across all locations, including when an auto-label policy applies retention labels automatically. This principle has long existed in Exchange retention policies where a personal retention tag applied manually by a user always has precedence over a tag applied to a folder or a default tag applied to a mailbox.
4. **Shortest deletion wins:** Retention policies allow administrators to actively remove content after a certain period (still called the retention period). If multiple deletion policies apply with different retention periods, Microsoft 365 applies the shortest retention period and removes the content when that period expires. The logic here is that an administrator decided to remove content after a certain period. The presumption is that good reason guided this decision. It would therefore not make sense if another policy, perhaps created by another administrator, interfered with the decision to remove content after that period. Again, this is a reason to consider how the retention policies in a tenant interact with content.

Remember that holds always take precedence over deletion. If an eDiscovery case places a hold on content for a set period, Microsoft 365 cannot remove items within the scope of the hold until the hold period expires or an administrator releases the hold, even if the retention periods of policies applied to the content expire.

It often takes time and some experience in working with retention policies across different workloads to understand the effect of the retention principles and how to best deploy these principles to support the data governance strategy for the organization. Microsoft [publishes a helpful flowchart](#) to explain how retention decides to keep or remove items (Figure 17-1). It's much easier to follow and understand the steps in the flowchart after gaining some experience working with retention policies and labels.

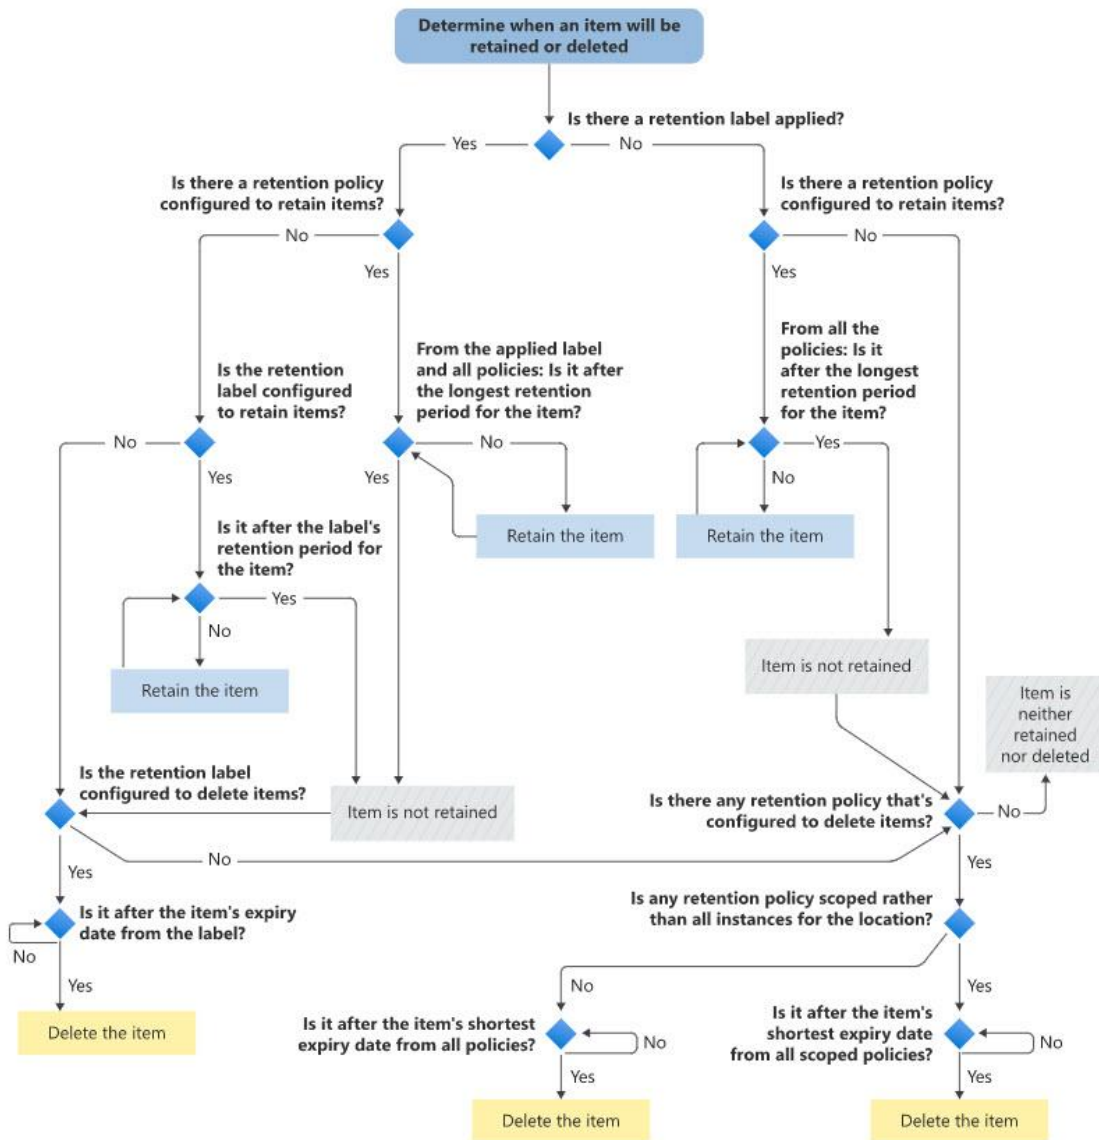

Figure 17-1: Microsoft's flowchart to determine how retention removes or keeps items

## Retention Policies

Retention policies apply retention rules to target containers (locations). The supported containers include:

- Exchange (mailboxes and cloud-based public folders).
- SharePoint Online (including files owned by Yammer, Teams, and Groups).
- OneDrive for Business.
- Teams compliance records for chats and regular and shared channel conversations. Compliance records for chats are in personal mailboxes, while regular and shared channel compliance records for

conversations in group mailboxes. Because shared channels aren't associated with a group mailbox, Microsoft 365 creates a special version called a *SubstrateGroup* mailbox to hold their compliance records.

- Teams private channel conversations.
- Yammer (when configured in Microsoft 365 network mode, user messages and community conversations can be subject to retention).
- Groups (Outlook conversations in the group mailbox).

Retention labels contain settings to tell Microsoft 365 how the organization wishes to retain or remove items in a location. The basic settings are a retention action or rule, defining what should happen when a retention period expires, and a retention period, which defines when the action should occur.

The Managed Folder Assistant processes retention policies for Exchange locations:

- User and shared mailboxes (primary and archive, if enabled).
- Public folders (you can't select specific sections of the public folder hierarchy for processing).
- Group mailboxes.

A separate Microsoft 365 retention assistant processes all the other workloads, including the compliance records stored in Exchange Online.

## Broad and Narrow Retention

Retention policies can be broad or narrow in scope. A broad retention policy applies the same retention settings to a set of containers. Each workload has its locations: Exchange has mailboxes (user, shared, and group), SharePoint has sites, OneDrive for Business has accounts, and Teams has chats and conversations. The broadest retention policy is one that applies the same retention settings to all the locations managed by all workloads in a tenant. As described below, this is an example of an org-wide policy.

Narrow retention policies make retention labels available to workloads. Each retention label has its retention settings and a retention policy for labels can have just one label or include many labels. Publication means the process of making workloads like Exchange and SharePoint aware of the existence of the labels in a retention policy. Following publication, the workloads expose the retention labels in client interfaces so that users can then apply the labels to the selected content. The application of a retention label to a message or document is a much more precise way to keep information. As such, retention labels trump the settings applied by broad retention policies. For instance, the organization uses a broad retention policy to assign a five-year retention period to all SharePoint sites. All documents stored in a document library inherit the policy and SharePoint will keep documents until they are five years old. If a user then assigns a retention label with a ten-year retention period to a set of documents, SharePoint will keep those documents for that period.

## Org-Wide and Scoped Retention Policies

Two types of retention policies exist:

- **Org wide:** The purpose of an org-wide policy is to apply a single retention policy to all supported workloads. The scope of an org-wide policy is the tenant, but the scope can be amended to exclude or include specific workloads. Currently, org-wide policies can apply to Exchange mailboxes, Exchange public folders, Groups, Yammer private and community messages, and documents stored in SharePoint Online sites and OneDrive for Business accounts. Separate policies handle the retention of Teams chats and channel messages (use of these policies requires E5 licenses). There can be up to 10 org-wide policies in a tenant. You should use org-wide policies sparingly as it is easy to create a policy that has unintended consequences. For instance, if you create a policy to keep all content for two years and then remove the content afterward, the policy will remove everything from the tenant that is more than two years old and does not come under the control of another policy. That could

lead to the removal of most content across workloads, which might not be what you want to do. Org-wide policies are “entire location” policies because they cover all the locations within the selected workloads (for example, all Exchange Online mailboxes).

- **Non-org wide:** These policies apply retention to a subset of the locations available within a tenant. The scope of these policies is set by picking specific mailboxes, sites, or groups to include in the policy or by applying a query based on keywords or sensitive information types to find the content to which the policy applies. Each workload has its restrictions for the number of locations in a non-org-wide policy. For example:
  - Exchange Online and Teams: 1,000 mailboxes (accounts).
  - Microsoft 365 Groups: 1,000 groups.
  - SharePoint Online sites and OneDrive for Business accounts: 100 of each.
  - Teams chat or channel messages: 1,000 accounts.
  - Yammer community or private messages: 1,000 accounts.

[This article](#) details the current limits for Microsoft 365 retention policies.

The number of org-wide and non-org-wide policies available for deployment means that organizations can get very creative with their retention strategy. In general, it is best to simplify retention processing by limiting the number of active policies as this will help to avoid situations where the actions and retention periods of policies clash. See the *Rules of Retention* section to understand what happens when several policies apply to an item.

**Getting Round Policy Limits:** The limits for the target locations processed by retention label policies divide into SharePoint locations (sites and accounts) and Exchange locations (mailboxes and groups). SharePoint locations have a 100 limit while Exchange can deal with 1,000 locations. In either case, these limits are often too small for large tenants. To get around the limits, you can create multiple policies that have the same settings but different target locations. For example, if you need to apply retention settings to 500 SharePoint sites, create five examples of the same policy and include a different set of 100 target sites in each policy. With the necessary licenses, adaptive scopes (see below) allow organizations to solve the problem by creating scopes to find target locations and using the scopes in retention policies. Adaptive scopes don't have the same numeric limitations as static policies do.

## Adaptive Scopes

Adaptive scopes are a way to find target locations by applying a filter (query) against the set of available locations in a tenant. In some respects, adaptive scopes work like dynamic Azure AD groups or dynamic distribution lists, both of which use a query to find a set of objects. Adaptive scopes must be created first before they can be used in a retention policy.

Three kinds of adaptive scope are available:

- **Users:** Filter applied against selected account properties like job title, city, state or province, department, and the Exchange custom properties. For example, an adaptive scope can find all the users located in France whose job title starts with “Manager.” Mailbox states and types are also usable in filters, meaning that you can create scopes to look for inactive mailboxes (a state) or shared mailboxes (a type). Figure 17-2 shows the query builder in use to build the scope for an adaptive scope for users. You can also see the set of properties available to build the query. Adaptive scopes of this type apply retention to mailboxes and OneDrive for Business accounts.
- **Sites:** Filter against the site URL, name, or the 100 refinable string properties (refinablestring00 to 99) available to customize the SharePoint Online search schema. For example, find all sites where the value of a custom property (represented by the RefinableString99 refiner) is “Secret.” To update custom properties for a site, its administrator must write values into the site property bag. [This article](#)

explains how to update the site property bag using PowerShell. Another example is to use an adaptive scope with a query to find sites with URLs starting with a certain value to find all OneDrive for Business accounts in a tenant.

- **Microsoft 365 groups:** Filter against group properties like name, description, and Exchange custom properties.

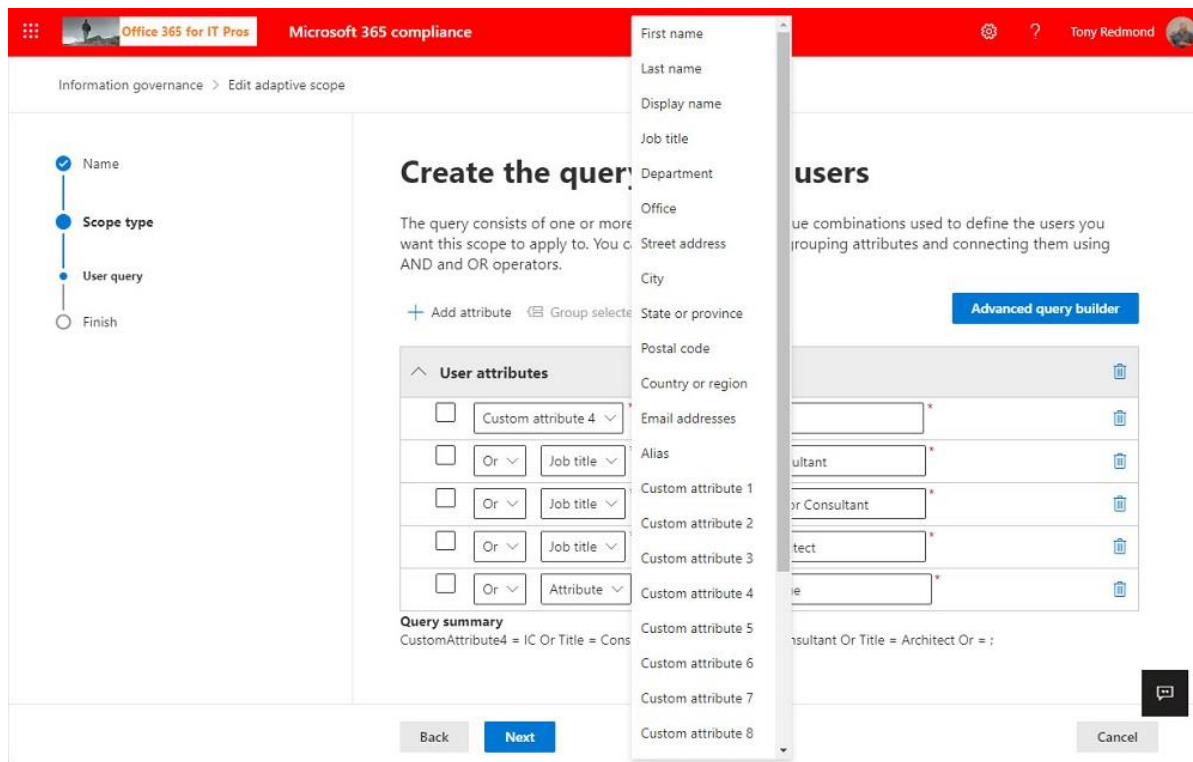

Figure 17-2: Defining an adaptive scope

The operators available to build an adaptive scope query are:

- is equal to.
- is not equal to.
- starts with.
- not starts with.

You can combine *And* or *Or* checks against properties. For instance, the query shown in Figure 17-2 contains several *Or* tests for different values in the Job title property. If the query builder can't construct the query you need, you might be able to build an advanced query in OPATH syntax (users and groups) or KQL (sites). For instance, an adaptive scope to find inactive mailboxes uses the OPATH query:

```
IsInactiveMailbox -eq 'True'
```

While the query to find shared mailboxes is:

```
IsShared -eq 'True'
```

However, although advanced queries can build user adaptive scopes using mailbox types and states and employ access to more operators (such as *like* or *notlike*) than available in the query builder, advanced queries can only use the same set of Azure AD account properties presented by the query builder.

The results of adaptive scope queries are not available immediately. Instead, a background process that runs daily uses the queries in adaptive scopes to identify the set of target locations identified by the scope query. You can view the current set of locations by accessing the scope details (Figure 17-3). If you see *No data*

*available*, it means that either the background process has not yet resolved the query, or the query doesn't find any objects.

Figure 17-3: Viewing the set of locations calculated using an adaptive scope query

A retention policy can use one or more adaptive scopes to find the locations to which it applies. Figure 17-4 shows that a retention policy uses two user adaptive scopes. Because these are user adaptive scopes, the set of workloads that the retention policy can cover doesn't include SharePoint Online. However, it does include OneDrive for Business because these accounts are personal and linked to individual users. When a workload processes a retention policy with adaptive scopes, it resolves the queries from all scopes to find the up-to-date set of locations and applies the settings in the retention policy to those locations.

Adaptive scopes are only available to tenants with Office 365 E5 or Microsoft 365 E5 compliance licenses. Office 365 E3 tenants are limited to retention policies with static scopes. These policies process a defined set of locations. To change the set of locations, an administrator must amend the policy. This approach is satisfactory when an organization doesn't need to change its retention framework very often. It is less good when an organization wishes to apply retention policies based on some criteria, such as the people who work in a certain country or department, or SharePoint sites containing a certain kind of information.

Because adaptive scopes depend on settings such as Azure AD account properties or custom site properties, it's easy to add new locations to policies by updating the account, mailbox, or site settings. Workloads then pick up new locations or remove locations no longer within the scope the next time they process locations to enforce retention policies.

Retention policies with adaptive scopes require an Office 365 E5 or Microsoft 365 E5 compliance license for every account coming within their scope. Administrators can manage adaptive scopes through the Data lifecycle management or Records management sections of the Microsoft Purview Compliance portal.

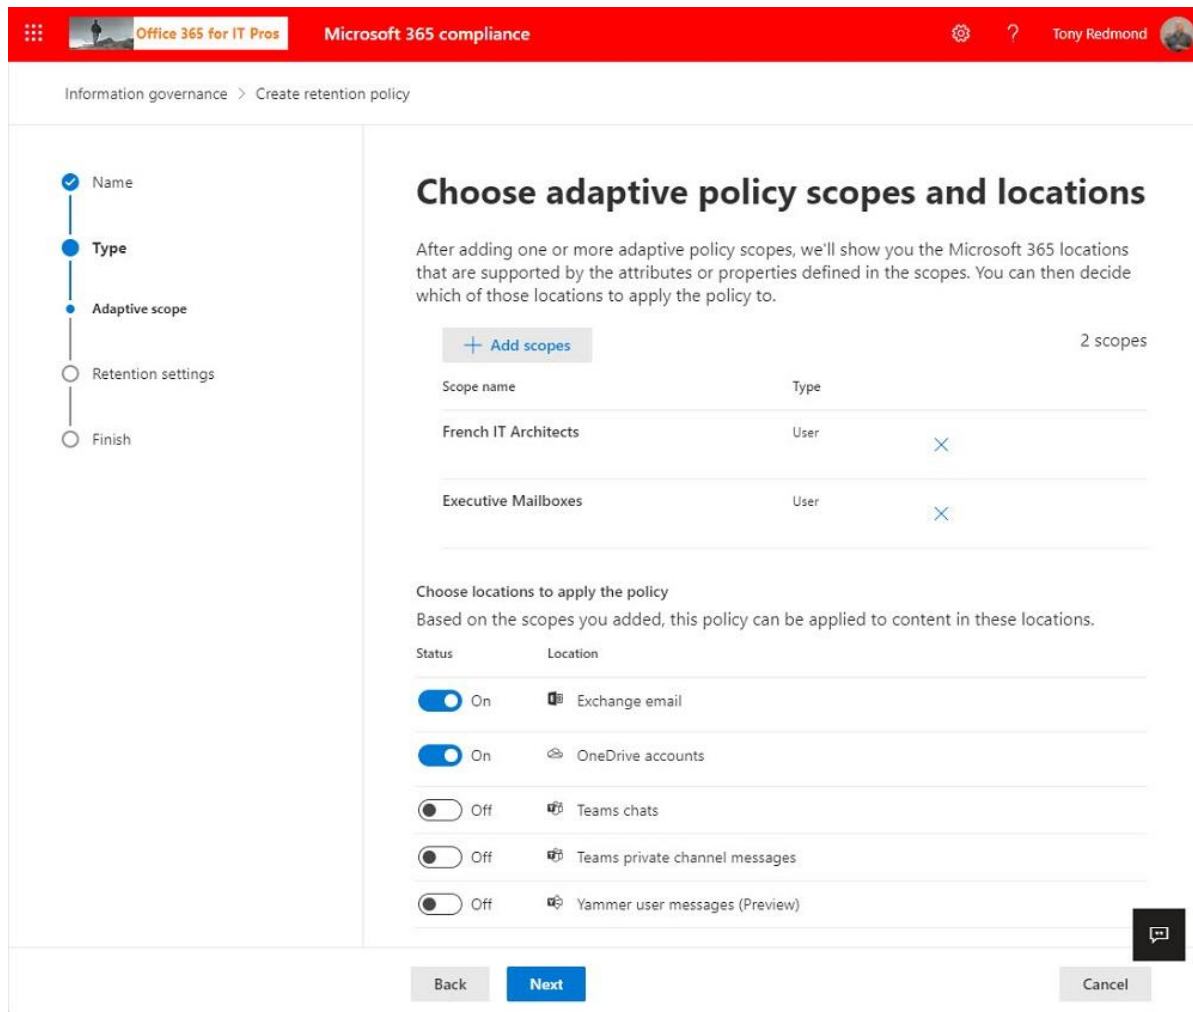

Figure 17-4: Using an adaptive scope in a retention policy

## The Effects of Retention Policies

It's important to understand how content might come under the influence of retention settings through broad policies or the more precise application of retention labels:

- Broad retention publishing policies that define retention settings for locations (selected or org-wide defined through static or adaptive means) are invisible to users. These policies run in the background and users are unaware that retention is in force. This assignment is implicit because an item inherits the retention policy because of its location instead of having a retention label assigned by a user.
- Narrow retention publishing policies make labels available to users when they work with content in the covered locations. After publication, a user can assign one of the published retention labels to a document or mail message. This assignment is explicit because it takes a deliberate action by a user to assign the label.

Organizations can apply retention to an item in these ways:

- A user assigns a retention label to an item. This explicit assignment has the highest priority. Remember that a label used purely as a visual marker does not have a retention action or period.
- A location comes within the scope of a broad org-wide or non-org-wide policy, including policies that use advanced processing to find content. The items take the retention settings from the policy unless someone assigns a retention label to the item.
- The owner of a SharePoint site defines a default retention label for a document library. New items created in the library inherit the label. Library settings can also dictate if existing items receive the

same label. A label inherited from a document library overrides any org-wide or non-org-wide retention policy assigned to the location.

- An auto-label policy assigns the label contained in the policy to items. An auto-label policy never replaces a label if a user has already assigned a label.

If their account has the appropriate permissions, users can change the retention label assigned to an item (unless the label is a regulatory record). They do not see or cannot affect the retention policy assigned to a location.

If multiple retention policies apply to an item, an explicit assignment always takes precedence over an implicit assignment. It is worth emphasizing that the presence of any type of retention affects the ability to remove a mailbox, site (including OneDrive for Business accounts), or group. Mailboxes holding retained items or under the scope of a retention policy become inactive when deleted until the retention expires. Sites and accounts cannot be removed until retention on individual documents, lists, and files lapses, and no retention policies are in effect for these locations.

## Planning a Retention Policy

Before beginning the process to create a new retention policy, it is sensible to write down the basic structure of the policy, broken down into several headings:

- **Broad or Narrow:** Do we need to apply default retention settings to some or all locations, or publish retention labels to allow users to dictate how to retain content? If the policy uses retention labels, what are those labels? Organizations often implement org-wide (broad-scope) policies to cover all workloads and all users with selective deployment of non org-wide (narrow-scope) policies to target specific workloads, users, or sensitive information types.
- **Scope:** What locations will this policy cover? If the policy targets a subset of locations within a workload (for instance, ten mailboxes or five SharePoint sites), write down those locations. If you want to exclude a subset of locations from the policy's scope, you should also note those locations. If the policy covers inactive mailboxes, this fact should be noted. If an adaptive scope will be used, some thought must be given to how the set of target locations can be found.
- **Purpose:** Will the policy keep or remove content? If so, how long will the retention period be?
- **Records:** Is the content that comes under the scope of the policy considered to be a formal record for the company and if so, must the content be immutable? (See the sections on Preservation Locks and Records).

For the example used here, the conditions listed in Table 17-2 apply.

<b>Heading</b>	<b>Policy setting</b>
Scope	The policy applies to mailboxes and OneDrive for Business sites belonging to senior managers defined as members of the Senior Leadership Team (SLT) distribution list. It also covers the content held in the SLT group and team.
Purpose	The policy keeps all information in the targeted locations for ten years and then removes the content.
Type	This is a "non-org wide" policy. The group membership dictates the accounts to which the policy applies.
Lock	A preservation lock is not required.

Table 17-2: Planning a retention policy

It is bad to find yourself in a situation where you create and deploy a retention policy only to discover that the policy removes needed information. For example, it is very easy to apply an aggressive retention policy to “All Exchange mailboxes” that removes items after 30 days. This is the equivalent of a default delete tag in an Exchange retention policy to remove content after 30 days. When stamped on a mailbox, the Exchange Managed Folder Assistant (MFA) applies the “Delete and Allow Recovery” retention action to all items in the mailbox that do not have a more explicit tag. After items reach 30 days old, the MFA moves them to the Recoverable Items folder and preserves them for a further period (the deleted items retention period). When that period expires (usually 14 days), MFA permanently removes the items from the database. Exchange Online does not use backups, so you cannot recover the items at this point. Because retention policies affect the content stored in user mailboxes, it is only sensible to consider and understand exactly what will happen when a retention policy is active.

It is also possible that a retention policy will clash with an Exchange mailbox policy or another retention policy. It is a good idea to take some of the target locations and work out what policies have those locations within their scope to figure out if a clash occurs.

### No Change for Retention Action or Period

A crucial factor to consider when planning the implementation of retention policies and labels is that you cannot change some of the important settings that control how the policy functions after creation. For example, you can alter the retention period for a policy, add new locations to its scope, and alter the KQL query to find content for the policy to apply. However, you cannot change its basic operation. For instance, you cannot change a policy that keeps content into one that simply removes content.

The logic is that users expect consistency in the processing of their data. If you can change the fundamental operation of how retention works inside a tenant, users will not know whether their data will be kept or removed or when this will happen. For this reason, it is wise to take time to chart out how retention will work across the tenant for all workloads before you create any policies. Fools rush to implement retention without thought!

### Naming a Retention Policy

With our structure in mind, we can go to the **Data lifecycle management** section of the Microsoft Purview Compliance portal, select **Retention policies**, and then **New retention policy**. The first step is to assign a name and description (only visible to administrators) to the new policy. Some tenants insist that administrators include their name and a pointer to supporting documentation in the description of a new policy. It's more useful to include notes about what the policy does. For example:

*“This is a retention label policy to publish a set of general-purpose labels to every location in the tenant.”*

*“This policy publishes the Highly Confidential label to the Senior Leadership Team locations.”*

*“This policy searches for content with the “Kazaa” keyword and applies the Ten Year retention label.”*

### Setting the Scope for a Static Retention Policy

The simplest form of a retention policy is one that includes every available location, but quite often the need exists to focus on a select group of individuals and the data with which they work. Retention policies allow you to include or exclude subsets of locations. When you enable a retention policy for a location, you can choose the scope to be:

- **Org-wide:** Cover Exchange mailboxes, public folders, Groups, SharePoint Sites, and OneDrive for Business accounts. The policy applies to all content in all locations. As the tenant adds new locations, they come under the control of the policy.
- **Non org-wide** (choose specific locations): You can select individual mailboxes, sites, and so on. You can select everything from a workload, like all Exchange mailboxes, or you can select a subset of the

locations available within a workload, such as only a few SharePoint sites. You can also exclude a selected subset from the policy. This means that the policy will not apply to the mailboxes or sites that you select.

Two special processing cases exist for retention policies. First, you can't exclude or include specific public folders, all of which are either processed by the retention policy or not. Second, you cannot mix inclusions and exclusions for a location in a policy. If you exclude some sites or mailboxes from a policy, it means that the policy applies to all other sites or mailboxes but not to those selected for exclusion.

A retention policy for Teams can only cover Teams content (chats, channel messages, or private channel messages). The same is true for Yammer policies, which can only process messages posted to Yammer communities in networks configured in Microsoft 365 mode. You cannot include another workload in a retention policy for Teams. However, you can have multiple retention policies for Teams that cover different subsets of users, or separate policies for channel messages and personal chats. Table 17-3 explains the various location types and how you input the selected locations.

<b>Location type</b>	<b>Identified by</b>
Exchange email	Select <b>All recipients</b> to include all items stored in Exchange user mailboxes, otherwise, select the mailboxes to apply the policy. You can also input the name or alias of a distribution list or mail-enabled security group.
SharePoint site	Select <b>All sites</b> to include all the sites in the tenant or input the URLs for selected sites. Example: <i>https://tenant.sharepoint.com/Projects/</i> .
OneDrive for Business accounts	Select <b>All accounts</b> to include all OneDrive accounts in the tenant or input the URLs for selected accounts. Example: <i>https://tenant-my.sharepoint.com/personal/kim_akers_office365itpros_com/</i> .
Microsoft 365 Groups	Select <b>All groups</b> to cover the mailboxes used by all Microsoft 365 groups in the tenant (but not the compliance items stored in mailboxes for Teams and Yammer) or the names of the selected groups.
Exchange public folders	Select <b>All</b> to extend the policy to cover every public folder in the hierarchy. The default is "None." You cannot select a subset of public folders.
Teams channel messages	Select <b>All teams</b> to cover messages posted to all channels in every team in the tenant or select the individual teams to come within the scope of the policy.
Teams chats	Select <b>All users</b> to include all personal chats sent by users in the tenant or select the users to come within the scope of the policy.
Teams private channel messages	Select <b>All users</b> to include the messages sent to private channels in all user mailboxes or select the users to come within the scope of the policy.
Yammer community messages	Select <b>All communities</b> to include all messages sent to Yammer communities or select the communities the policy will apply to. This option is only available when the Yammer network runs in Microsoft 365 mode.
Yammer user messages	Choose <b>All users</b> to include all private messages sent between Yammer users or select the users to which the policy will apply. This option is only available when the Yammer network runs in Microsoft 365 mode.

Table 17-3: Microsoft 365 workloads and locations supported by retention policies

## Choosing Specific Locations

Figure 17-5 shows the user interface to add locations to a policy. If your policy covers a subset of workloads and locations, some up-front work is necessary to list the locations and gather the information to input each location. The easiest way to add a set of mailboxes to a retention policy with a static scope is to use a distribution list or a mail-enabled security group. Each mailbox counts against the 1,000 location limit for the policy. In addition, Microsoft 365 includes the owners of the distribution list in the mailboxes added to the set of locations (some consider the inclusion of distribution list owners as a feature; I believe it to be a bug). The population of the Exchange locations in the policy is a one-time operation and any future additions or removals to the membership of the distribution list do not synchronize with the locations in the retention policy. You must edit the policy to ensure that it continues to cover the correct individuals.

### Choose locations to apply the policy

The policy will apply to content that's stored in the locations you choose.

Status	Location	Included	Excluded
<input checked="" type="checkbox"/> On	Exchange email	All recipients <a href="#">Edit</a>	None <a href="#">Edit</a>
<input checked="" type="checkbox"/> On	SharePoint sites	All sites <a href="#">Edit</a>	None <a href="#">Edit</a>
<input checked="" type="checkbox"/> On	OneDrive accounts	All accounts <a href="#">Edit</a>	None <a href="#">Edit</a>
<input checked="" type="checkbox"/> On	Microsoft 365 Groups	All groups <a href="#">Edit</a>	None <a href="#">Edit</a>
<input type="checkbox"/> Off	Skype for Business		
<input type="checkbox"/> Off	Exchange public folders		
<input type="checkbox"/> Off	Teams channel messages		
<input type="checkbox"/> Off	Teams chats

Figure 17-5: Choosing a set of target locations for a retention policy

While mailboxes are relatively simple to add to policies with static scopes, the same is not true for SharePoint Online and OneDrive for Business locations. This is because you must input the URLs for each location that you want to add to the policy. It can sometimes be difficult to know what the URL is for a location, so it's a good idea to collect the URLs beforehand in a text file and cut and paste the URLs from the file into the policy. For example, you can use the *Get-SPOSite* cmdlet to output the URLs and export the information to a CSV file. It's relatively easy to automate adding SharePoint Online and OneDrive for Business locations to a retention policy with PowerShell. You can add up to a hundred individual sites in a non-org wide policy.

The processing of Teams chat and channel messages and Yammer messages rely on compliance records stored in personal and group mailboxes. The rules are:

- Retention policies for chats and channel conversations cannot include any other non-Teams locations.
- Retention policies for Teams private channel conversations cannot include any other location (even other Teams locations). It's important to note that retention policies for private channels operate

based on individual accounts rather than teams. This is because the compliance records for private channel conversations are in user mailboxes and it's not necessarily true that all the members of a team are members of a private channel. To be sure of processing all messages for a private channel, add the mailboxes of all the members of the channel to the policy. Also, make sure that the SharePoint content for the channel comes within the scope of a separate SharePoint Online retention policy as the Teams private channel policies process only channel conversations.

- Retention policies for Yammer content can process only Yammer locations.

After adding the target locations to the policy, click **Next** to continue.

**Be Careful with Inclusions and Exclusions:** Retention policies allow you to include or exclude specific locations. For example, you might create a policy to process a single mailbox or SharePoint site. If you edit the policy and remove the exclusion or inclusion, the target locations revert to All. This might be what you want (for example, you've tested the effect of the policy and are now happy to apply it to all locations in a chosen workload), but if it's not, it's easy to end up applying a retention policy inadvertently to all locations, which might remove items that the organization wants to keep.

## Keeping or Removing Content

The final step is to define what the policy does to keep or remove content (Figure 17-6). When a retention policy removes items, it uses a "delete and allow recovery" action, to allow users to recover items later if needed from Exchange's Recoverable Items structure or the SharePoint recycle bin. In either case, we must know the length of the retention period and how to calculate the age of an item. You can keep content forever, but it is more common to set a period like seven or ten years. For mail messages, the creation date is used, but when a policy spans both documents and other items, it is best to choose the last modification date as shown here as this accommodates the fact that documents are often changed well after their creation date.

## Decide if you want to retain content, delete it, or both

Retain items for a specific period  
Items will be retained for the period you choose.

Retain items for a specific period

7 years

Start the retention period based on

When items were created

At the end of the retention period

Delete items automatically

Do nothing

Retain items forever  
Items will be retained forever, even if users delete them.

Only delete items when they reach a certain age  
Items won't be retained, but when they reach the age you choose, we'll delete them from where they're stored.

Figure 17-6: Defining the actions a retention policy takes to process content

Administrators accustomed to working with Exchange mailbox retention policies see an immediate difference here. Exchange retention policies let you remove or archive items after the retention period lapses. While retention policies do not support an archive action, they let you say that you want to keep information for a set period. When the retention period lapses, you can choose to leave the content alone (in which case

another policy could apply) or remove it. Alternatively, if you are more concerned about cleaning out locations to remove information that the organization no longer needs, you can instruct retention policies to remove items after they reach a certain age.

**Immediate Evaluation:** After you publish a retention policy, workloads make it active. This means that the workload processes that evaluate items know about the new policy. If you're not careful, the introduction of a new policy can have a significant effect on users. For example, let's say that you create a policy to remove items after three years and set the scope of the policy to be all OneDrive for Business accounts. After publication, the retention policy begins to evaluate items in all accounts and will remove anything more than three years old. If users aren't prepared for this clean-up to happen, the sudden removal of many items could come as a nasty surprise.

## Reviewing Policy Settings

The last step is to review its settings. If all looks to be in order, click **Submit** to begin the publication process to the locations covered by the policy. You can opt to save the policy for later, meaning that the policy is in a draft state that you can update later (perhaps to add some extra locations) before making the policy live.

It can take some time before a retention policy becomes fully effective across all locations. The assistants must process each location coming under the scope of a policy, including the compliance records stored for Teams and Yammer. You can check the distribution status of the policy by selecting the policy and viewing its properties. The following values are available:

- **Enabled (Success):** All locations know about the policy and are processing content as per the policy. However, the policy might still not be effective everywhere because background jobs might not have completed their processing to enable all locations.
- **Enabled (Pending):** The policy is being enabled in the target locations.
- **Enabled (Errors):** The policy is active, but some errors have occurred in its distribution.
- **Disabled (Success):** The policy is disabled and is not being applied to content. You can reenable the policy at any time.
- **Disabled (Pending):** Microsoft 365 is in the process of disabling the policy. All locations are stopping the processing of content. However, the process is incomplete.
- **Disabled (Errors):** The policy is off, but due to some errors, it might still be active in some locations. You can click the error to get more information. In many cases, the fault will disappear if you leave it alone for an hour or so.

Note that you can't disable a policy that applies a preservation lock.

## The Actions Taken to Deploy Our Retention Policy

In terms of what you might have done previously with Exchange retention policies or SharePoint document delete policies, the retention policy we just created has the following effects:

- The policy imposes a seven-year retention period on every item in the target mailboxes that do not already have an explicit mailbox retention tag (directly assigned on items or inherited from folders) or retention label. In addition, Exchange places an in-place hold on the mailboxes (both primary and archive) for seven years. During this period, Exchange preserves any item that a user removes from the mailbox in the Recoverable Items structure. The preserved items are indexed and discoverable. When an item's retention period elapses (in this case, seven years after creation), the Managed Folder Assistant applies a "Delete and Allow Recovery" action and moves the now-expired item into the Recoverable Items folder. The user can recover the item until the deleted items retention period set for the mailbox expires (usually 14 days).

- An equivalent seven-year in-place hold applies for documents and lists stored in SharePoint or OneDrive for Business sites. When users delete or remove items, SharePoint Online captures copies in the preservation hold library for the site.
- The Exchange Online Managed Folder Assistant processes the contents of group mailboxes to apply retention policies. SharePoint Online treats the sites belonging to groups (teams) like other non-group connected sites.
- Although our policy does not cover public folders, if they were, any copies kept by policy stay in the public folder mailboxes to which they belong until the retention period expires. A process like that used to assess content removed from user mailboxes ensures that any attempt to remove held content from a public folder cannot succeed.

## SharePoint Online's Preservation Hold Library

To preserve copies of information required for retention purposes, SharePoint Online uses a special retention destination called the **Preservation Hold Library**. SharePoint Online creates the preservation hold library automatically when first needed by a site to retain information about changes and deletions to files and lists. Once a site comes within the scope of a retention policy or individual items receive retention labels, user actions to remove or change content cause SharePoint to copy items to the preservation hold library. A single preservation hold library handles retention for the complete site, no matter how many document libraries and lists exist on the site.

User actions that cause SharePoint Online to capture information in the preservation hold library include:

- **Update or deletion of a document under a retention policy:** SharePoint Online captures a copy of the document. If versioning is enabled for the site (the default), SharePoint Online retains copies of all changes made to the document.
- **Deletion of labeled files (with unexpired retention periods):** Until a change deployed in November 2021, SharePoint Online stopped users from deleting labeled files and displayed a message saying that the label applied to the file blocked its removal. This behavior differed from OneDrive for Business and exposed a weakness in that members of a group could remove the label and then delete the file. With the change, both SharePoint Online and OneDrive for Business allow users to delete labeled files and capture the deletion in the preservation hold library. Users cannot remove files assigned a record label from either SharePoint Online or OneDrive for Business.
- **Unlocking of a retention label (record) on a file:** Users must unlock files assigned retention labels marked as a record before editing. SharePoint Online captures a copy of the file when it is unlocked.
- **Deletion of a OneNote section:** A copy of the section is captured.
- **Deletion of a OneNote notebook:** A copy of the notebook is captured.
- **Update of document metadata:** A copy of the update is captured.
- **Update or deletion of a list item:** A copy is captured in an Excel XLS. If the list item has an attachment, SharePoint Online captures the list and the attachment separately. The same happens if an attachment is removed from a list item.

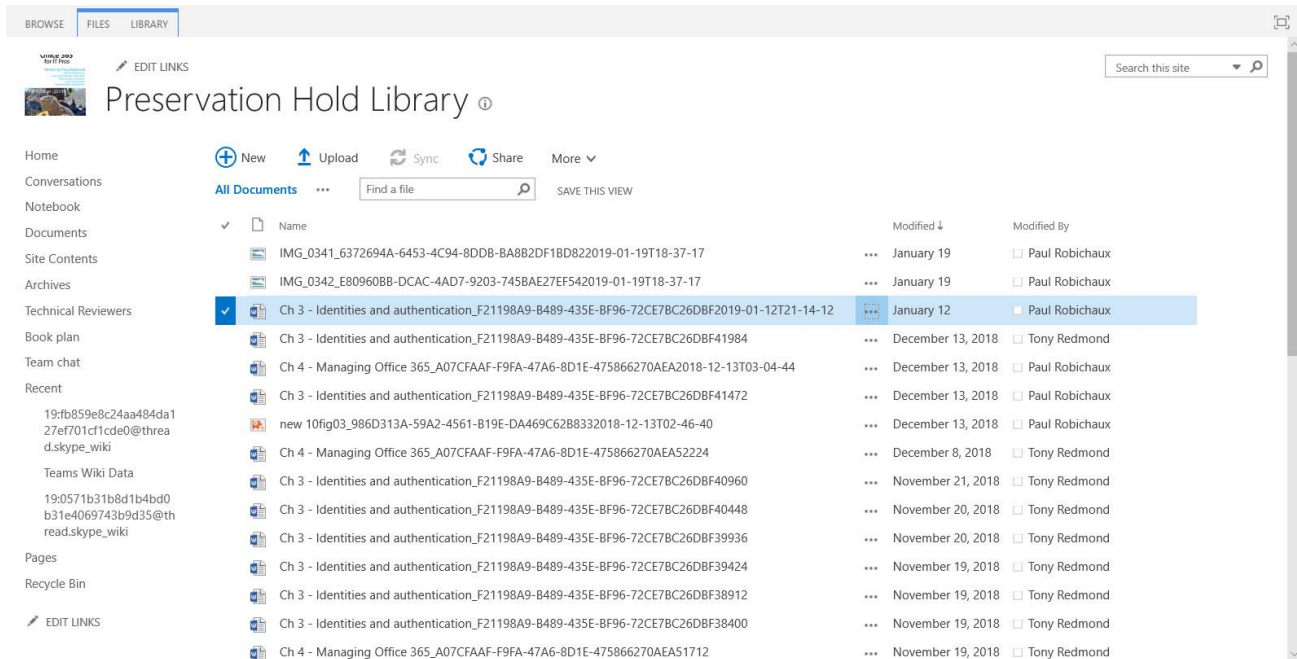

Not every change generates an update to the preservation hold library. The aim is to retain the original content before the imposition of retention controls plus the current content. When a user attempts to update or delete an item, SharePoint Online checks if this is the first action since retention for the item became active (or the policy changed). If it is, SharePoint Online captures the original content and allows the user to update it. Any subsequent updates to the content are available in the versions that SharePoint Online captures automatically, meaning that the original content plus the complete change history are available through the data in the preservation hold library plus the online content. If a user deletes an item coming within the scope of a retention policy, SharePoint Online removes the item from the library or list and stores it in the preservation hold library until its retention period expires.

Users are unaware of the preservation hold library because it is only visible to site administrators, who can access the preservation hold library by going to Site Contents and then selecting the library, or they can append */PreservationHoldLibrary* to the site URL (because users administer their own OneDrive for Business account, they can access the preservation hold library for their account). Site administrators cannot remove or change items kept in the preservation hold library, but they can copy items from the library to retrieve a file for a user.

## Using the Preservation Hold Library

When users add new documents to a library, several operations happen to create the document, apply updates, add metadata, and so on. SharePoint Online captures none of these actions in the preservation hold library. However, once the initial creation is complete, SharePoint Online monitors and captures subsequent file updates.

Every week, a background job runs to clean out old items from the preservation hold library. The job looks for items in the library for more than 30 days and compares them against the retention settings applicable to the site to find and remove items with expired retention periods. If the file or list item is still present in its original location, the background job removes it too. Items removed from the preservation hold library go into the second stage recycle bin from where SharePoint Online removes them permanently after the normal 93-day period in the recycle bin expires. Figure 17-7 shows items in a preservation hold library. SharePoint Online generates the names of the retained items by combining the original name with a GUID (and sometimes the date and time of the change) to create a unique value.

The screenshot shows the SharePoint interface for a Preservation Hold Library. The top navigation bar includes 'BROWSE', 'FILES', and 'LIBRARY'. Below the navigation bar, there are options for 'EDIT LINKS' and a search box. The main content area displays a list of documents with the following columns: Name, Modified, and Modified By. The list contains several items, including images and documents, with their names containing GUIDs and dates. The item 'Ch 3 - Identities and authentication\_F21198A9-B489-435E-BF96-72CE7BC26DBF2019-01-12T21-14-12' is highlighted in blue.

Figure 17-7: Items in the Preservation Hold library for a SharePoint site

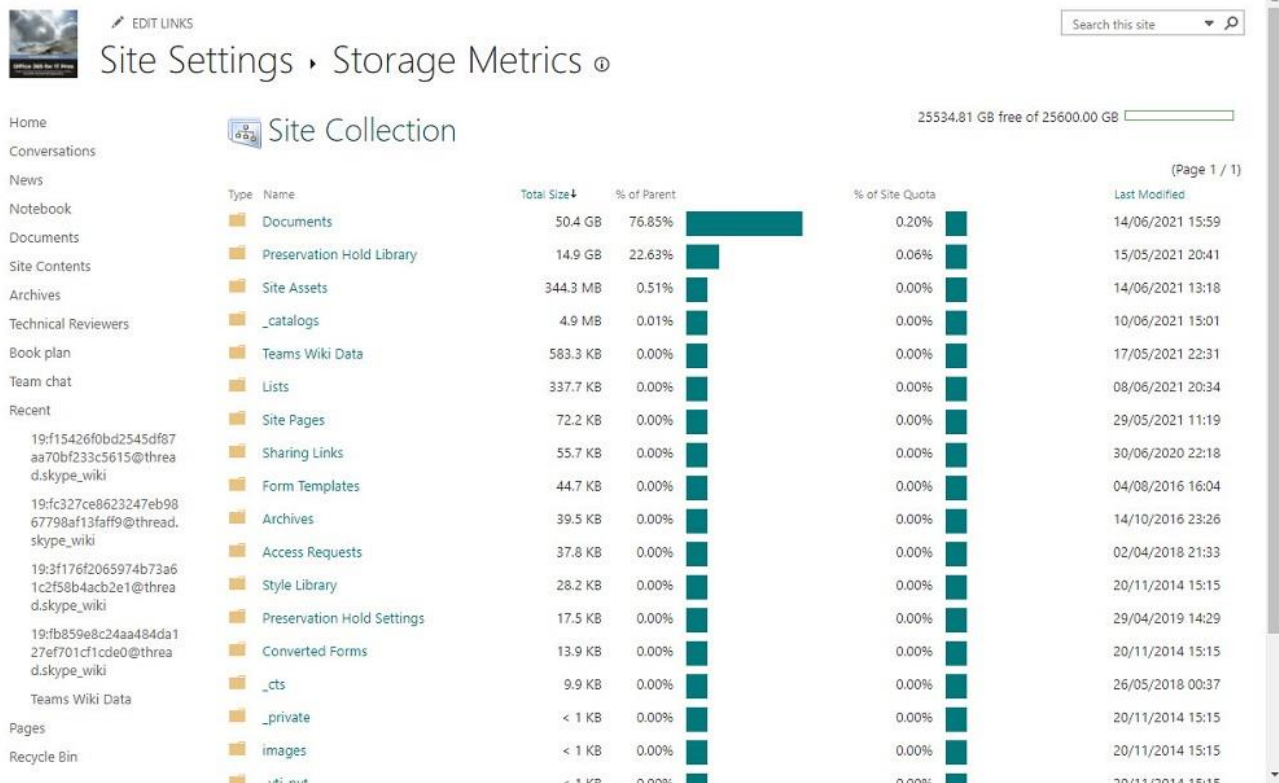

Figure 17-8: Site Settings include storage metrics

Files in the site recycle bin and those retained in SharePoint Online because of a retention policy count against the overall storage quota for the tenant. When a retention policy is in place, the SharePoint admin center can help you understand the effect of retention through the storage metrics available through site settings (Figure 17-8). The fact that retained files occupy 22.63% of the total storage for the site underlines how much tenant quota retention can consume.

Your mileage might vary in terms of storage consumption for retained files. The number of files retained by policy differs from site to site and is highly dependent on user activity and the size of the files. If people create and save files and never edit them again, no extra versions exist and no deletions happen, so few files end up in the preservation hold library. On the other hand, if you constantly edit files stored in a library, the versions accumulate (especially through Office's Autosave feature) to consume storage. This is especially evident in libraries that store large files with frequent updates, such as the Word documents for the chapters for this book.

### Purging the Preservation Hold Library After Removing a Retention Policy

When an administrator removes a retention policy from a site, a 30-day grace period starts to stop the release of the hold on the site. During the grace period, SharePoint Online preserves the items in the preservation hold library because the hold is still in place. Once the 30-day grace period elapses, the hold lapses and SharePoint Online proceeds to delete the items. Items deleted from the preservation hold library go into the second-stage recycle bin instead of an immediate purge. Items stay in the second-stage recycle bin for up to 93 days after their deletion before permanent removal. During this time, site administrators can recover items.

This mechanism gives administrators the ability to recover from the consequences of an error in removing a retention policy that results in data loss. Instead of having background processes purging content soon after the removal of a retention policy, administrators can access the preservation hold library and second-stage recycle bin to recover data during the grace period. Recovering data from these locations is a manual process that will take time and effort, but at least it's better than losing valuable documents.

## Knowing That a Retention Policy Works

It can be difficult for a user to know that a retention policy is in force. It can also be difficult for an administrator to know when retention policies work as expected. Here are some ways to verify that all is well:

- For **user mailboxes**, you can check to see whether the retention tag assigned by a policy is stamped on folders and messages as expected. Clients display these tags like older Exchange Online retention tags, so if Outlook or OWA displays the tag, you know that the policy is working. Another method is to check the Purges sub-folder of Recoverable Items to see if retained items accumulate there.
- Conversations in **group mailboxes** do not display retention tags. You must check that the items in the Inbox folder are what you expect based on the retention policy in force. You can also check that the Managed Folder Assistant is processing the group mailbox and removing items.
- **Teams** and Yammer compliance records are in special hidden folders in group and user mailboxes. You can use the MFCMAPI utility to check these folders to ensure the expected retention of compliance data. Another (easier) method is to use the `Get-ExoMailboxFolderStatistics` cmdlet to check the number of items in the folder before the retention assistant processes it and compare it to the number of items reported afterward. For example, the command below shows that the oldest item in the folder used to hold Teams compliance items (for group mailboxes, items from all channels are in the same folder) is from 7 October 2020. You know the retention period set in the policy, so it is easy to calculate what the date of the oldest item should be if the retention policy is working.

```
[PS] C:\> Get-ExoMailboxFolderStatistics -Identity O365ITPros -FolderScope NonIPMRoot -
IncludeOldestAndNewestItems | ? {$_.FolderType -eq "TeamsMessagesData"} | Format-Table Name,
ItemsInFolder, NewestItemReceivedDate, OldestItemReceivedDate
```

Name	ItemsInFolder	NewestItemReceivedDate	OldestItemReceivedDate
TeamsMessagesData	513	02/02/2022 16:10:41	7/10/2020 08:17:09

- Documents stored in **SharePoint Online** and **OneDrive for Business** sites, including the sites used by Groups, show no trace of retention because everything remains in place until user actions trigger the need for SharePoint to capture copies of documents. If a policy dictates that an item should be kept, and an attempt is made to remove it, a copy of the item will be in the special Perseveration Hold library for the site. The capture happens even if a retention label stops the user from removing an item. The site collection administrator can access the Preservation Hold Library through Site Contents to verify the capture of changes or deletions for files under the control of retention policies are there.
- Check the audit log to look for *FileDeleted* events logged for deletions of SharePoint and OneDrive items because their retention period expired, and the retention action forces a deletion. *FileDeleted* events capture information about what account removes an item. In the normal course of events, the data captured in the user property is the User Principal Name of the account. When a retention policy or label causes a deletion, the audit event captures the name of the policy or label. For example, this command searches for all *FileDeleted* events logged during a month:

```
[PS] C:\> Search-UnifiedAuditLog -Operations FileDeleted -StartDate 4-Nov-2018 -EndDate 5-Dec-2018 -
ResultSize 2000
```

After retrieving the audit events, you can use the techniques explained in Chapter 21 to interpret them and generate data for analysis. A review of the information reveals if retention processing deleted files. In this example, a user deleted two files and a retention policy deleted the next three files.

## Retention Policy Lookup

Sometimes many different retention policies affect an individual location (user, site, or group) and it's difficult to understand what influence these policies have on the location. For example, the SharePoint admin center might inform you that a retention policy is blocking a site from deletion, and you want to find out what policies might be the block. To help understand the set of policies that apply to a location, use the Policy Lookup option under Data lifecycle management in the compliance portal. To lookup the policies for a location, enter the:

- Primary email address of a user.
- URL for a SharePoint Online site or OneDrive for Business account.
- Primary email address of a Microsoft 365 group.

The response is the full set of retention policies for the selected location. These can be:

- Label publishing policies for which the location is a target. In other words, policies that make labels available for use by the user or in the site or group.
- Auto-label retention policies that process the location.
- Retention policies that include the location in their scope.

Figure 17-9 shows a typical result where a user account is subject to seven policies, one of which has an adaptive scope. The others are all org-wide policies created for different reasons, including to process messages in Teams channels and Yammer communities. Two of the policies are label publishing policies (for example, the manual disposition label policy publishes labels used for manual disposition), but the only way to know this is to recognize the policy name. Disabled policies are included in the list, so the need exists to check policies to understand the full coverage of retention,

Figure 17-9: Looking up the retention policies applying to a user

The results of a retention policy lookup only include Microsoft 365 retention policies. They do not include Exchange Online mailbox retention policies or litigation holds.

## Retention Policies and Inactive Mailboxes

An inactive mailbox is a mailbox kept for compliance or some other reason that belonged to a now-removed Microsoft 365 user account within the scope of a hold placed before deletion. Including a mailbox in the locations processed by a retention policy ensures that a mailbox becomes inactive if its account is removed, but only if the policy settings keep content. A policy configured to remove content does not transform a mailbox into inactive status upon deletion. This is logical because if you deploy a policy to remove content from mailboxes, it doesn't follow that you want to keep mailboxes after their accounts are deleted.

It is a good idea to have a retention policy to hold the complete contents of user mailboxes for a period after deletion. To make this work, you must add the mailboxes to the policy (up to 1,000 mailboxes can be included in a single policy) before removing the account. Alternatively, you can use an org-wide policy that covers the content in all mailboxes. In either case, when the account is deleted, Exchange Online recognizes that one or more holds exist on the mailbox and makes the mailbox inactive. See [this page](#) for more information on how retention policies process inactive mailboxes.

## Hybrid Governance

Retention policies do not apply to on-premises locations such as Exchange mailboxes, public folders, or SharePoint sites. The same issue occurs for content searches and eDiscovery cases. If you have a hybrid environment, it's a good idea to try to have the same retention policies (or as close as possible) apply in both on-premises and cloud locations and be prepared to perform eDiscovery processing on both platforms to capture all information necessary to satisfy eDiscovery searches. Unfortunately, synchronizing retention policies across on-premises and cloud environments is a manual process.

## Groups, Teams, and Retention

When a group is deleted, it enters a 30-day soft-deleted state. Following this period, Azure AD permanently removes the group, and it becomes irrecoverable. Deletion of the group also removes all the linked resources associated with the group. However, if content in the group mailbox or the SharePoint site belonging to the group (or team) comes within the scope of a retention policy or retention label, the group mailbox and/or site is retained until the retention period expires. The group mailbox becomes an inactive mailbox while the SharePoint site becomes a deleted but retained site.

### Retention Processing for Teams Compliance Records

When we discuss retention for Teams content, it is important to understand that retention policies process the compliance records that the Microsoft 365 substrate creates to record messages posted in channel conversations and chats. The substrate also creates compliance records for messages posted in channels by Office connectors. The compliance records are in a folder called *TeamsMessagesData* in the system part of user, group, and cloud-only mailboxes that are invisible to email clients. Retention policies do not directly process any data in the Teams message store in Azure Cosmos DB. Synchronization with Exchange apply the effects of retention to that store.

Retention policies can process all Teams accounts with a valid Office 365 license. However, a difference exists between accounts with enterprise licenses (Office 365 E3 and E5) and other licenses. Accounts with enterprise licenses can use retention periods as low as one day while the other accounts have a minimum retention period of 30 days.

When a Teams retention policy is in place, the substrate ensures the retention of changes made to Teams messages. If a user modifies or deletes a message in a personal chat or channel conversation that comes within the scope of a retention policy, the substrate moves (for deletions) or copies the message to the

*SubstrateHolds* subfolder of the Recoverable Items folder. Messages remain in *SubstrateHolds* until their retention period expires.

The retention assistant processes mailboxes covered by Teams retention policies to remove compliance records according to the criteria set in those policies. Different policy settings cover chat and channel messages. Messages in chats are “owned” by all the chat participants, so each participant has a copy of each message in their mailbox. As chats are removed from mailboxes by retention processing, the number of references to a message drop until it eventually reaches zero. At that point, Teams removes the message from its data store in Azure Cosmos DB. Only one copy of channel messages is kept in the group mailbox belonging to the team. When this copy is removed by retention processing, the resulting synchronization removes the message from the Teams data store.

MFA processes Teams compliance records in the same way that it deals with other mailbox items (for example, a mailbox holding compliance records is not processed if the mailbox size is under 10 MB). The date used to determine whether items exceed their retention period are the creation dates of compliance records in the *TeamsMessagesData* folder.

When MFA removes Teams compliance records, it first moves the messages from the *TeamsMessagesData* folder to the *SubstrateHolds* folder. Messages remain in *SubstrateHolds* for a day before they are permanently removed from the mailbox. During this period, a background job removes the source items in the Teams data store in Azure Cosmos DB and later, through server-to-client synchronization, from client-side caches. Depending on the load on different components across the service and how often clients connect to the Teams service, the end-to-end removal process usually takes a couple of days to complete and can take up to a week. The minimum period for Teams compliance policies is one day. Great care should be taken when setting such policies as any error might lead to an irrecoverable data loss like [that suffered by KPMG](#).

System messages posted to channels (for example, the addition or removal of a member) are not removed by retention policies. In addition, some older messages posted by guest or hybrid users might not be removed.

If you want retention policies to apply to the content posted in the SharePoint document libraries used by Teams, you must include those sites in the **SharePoint** section of the retention policy. A retention policy cannot process data stored in other locations used by Teams such as third-party applications accessed through tabs or bots.

Retention policies for Teams messages cannot use the advanced features to search for content based on keyword queries or sensitive information types. The minimum retention period for Teams is one day.

**Be Careful with Short Retention Periods:** The reason why Teams supports a 1-day minimum retention period is that some organizations don't like the idea of keeping chats around for any longer. Although there can be good business reasons for such a stance, it's important to understand the downside. If you configure a very short retention period for items, the intended recipient might never see some messages. For instance, a message sent on Friday might be removed before the recipient checks for new messages on Monday. Short retention periods are really to cover scenarios where messages do not need to be persistent. In most Teams scenarios, removing chats and conversations quickly can mar business effectiveness if you're not careful and users understand just how quickly items are removed.

## Org-wide Policies and SharePoint Online Sites

When an org-wide retention policy covering SharePoint sites is deployed, SharePoint Online keeps deleted sites until their retention period expires. The policy spans all SharePoint sites in the tenant, including the team sites belonging to Groups and Teams as well as the hidden sites used by Teams private channels. This is expected behavior: SharePoint is told to retain deleted sites for a period and that's what it does.

If you want to permanently remove a deleted SharePoint site before the retention period expires, you must:

- Use the SharePoint Admin Center to restore the site from the Deleted sites list. If the site was connected to a group and more than 30 days have elapsed since the group was deleted, you won't be able to restore the group and reconnect the site.
- Wait a few minutes after the site restore finishes and then edit the retention policy to exclude the now-restored site from the locations covered by the policy (you can't exclude a deleted site from a retention policy because it's already deleted). The delay allows the Microsoft Purview Compliance portal to recognize that the site exists.
- Wait another little while for the amended retention policy to be effective and then delete the site from the Active sites list in the SharePoint Admin Center.
- Finally, permanently remove the site from the Deleted sites list.

## Applying Retention Policies to Microsoft 365 Groups

By default, when retention policies cover Microsoft 365 groups, the same retention settings apply to content in both the mailboxes and the SharePoint team sites owned by the groups. You cannot, for instance, remove conversations after a month and keep documents for a year. If you want retention policies to process either mailboxes or sites, you can update the policy with PowerShell by running the *Set-RetentionCompliancePolicy* cmdlet. For example:

To process only the contents of group mailboxes covered by the policy:

```
[PS] C:\> Set-RetentionCompliancePolicy -Identity "General Retention Policy" -Applications "Group:Exchange"
```

To process only the contents of the SharePoint team sites for groups covered by the policy:

```
[PS] C:\> Set-RetentionCompliancePolicy -Identity "General Retention Policy" -Applications "Group:SharePoint"
```

To reset the policy so that it covers both mailboxes and team sites:

```
[PS] C:\> Set-RetentionCompliancePolicy -Identity "General Retention Policy" -Applications $Null
```

The Managed Folder Assistant (MFA) processes the group mailbox to remove or keep items based on the settings in a retention policy. MFA will not process mailboxes unless they hold more than 10 MB of data, so MFA might never process some groups, even if their mailboxes hold several hundred conversation items. The information in the group team site does not count against the 10 MB threshold. You can use the *Get-ExoMailboxStatistics* cmdlet to check the current storage for a group mailbox:

```
[PS] C:\> Get-ExoMailboxStatistics -Identity Office365TenantServiceHealth | Format-Table DisplayName, TotalItemSize, ItemCount
```

DisplayName	TotalItemSize	ItemCount
Tenant Service Health	11.29 MB (11,836,393 bytes)	154

In this case, MFA will process the group mailbox. See the section about Logging the Managed Folder Assistant later to understand how to see a summary of the actions taken by the MFA to remove items from a mailbox per the settings of a retention policy.

## Removing Retention Policies

To remove a retention policy, select it in the Microsoft Purview Compliance portal and take the **Delete policy** action. When you remove a retention policy, Purview notifies the affected workloads that the policy no longer exists so that they cease to implement it. Retention labels applied by automatic label policies stay in place after the removal of that policy.

The next time a background process reviews content, it might apply a new retention policy to items. The time taken to switch retention policies depends on how quickly workloads cease processing the original policy and how soon afterward the content covered by the original policy is reevaluated.

If you delete a label publishing policy, the labels published by the policy are no longer available in the locations covered by the policy. However, any labels applied when the policy remain assigned to items.

## Preservation Locks

Some regulatory regimes require that after an organization implements a retention policy, administrators cannot turn the policy off or make it less restrictive. To meet this need, you can apply a preservation lock to a retention policy. After applying a preservation lock to a policy, an administrator cannot disable the policy or remove locations from the policy. The lock remains in force and active for all locations under the scope of the policy until the retention period expires. Users cannot remove or update content within the scope of the policy during this period either. The only option open to an administrator is to add locations to the policy or extend its duration.

To lock a retention policy, set its *RestrictiveRetention* property through PowerShell. For example:

```
[PS] C:\> Set-RetentionCompliancePolicy -RestrictiveRetention $True -Identity "Management Preservation Policy"
```

Microsoft can remove the preservation lock from a retention policy. If you get into a situation where you need this to happen, the tenant administrator must open a support incident and supply Microsoft will the information to justify unlocking. If Microsoft concurs, they will remove the preservation lock from the policy. Because the potential exists that Microsoft might not agree to unlock a policy, it is wise to pause and think before enabling preservation lock on a retention policy. You might need to implement such a policy to satisfy a legal or regulatory need, but in most cases, tenants do not need to lock down content in this way. In short, make sure that you need a preservation lock before turning it on for a policy. Apart from waiting for the policy to expire, there is no way back if you make a mistake and enable the lock-in error.

To discover if any policies include preservation locks and the workloads they cover, view its details through the Microsoft Purview Compliance portal or run this command:

```
[PS] C:\> Get-RetentionCompliancePolicy | ? {$_.RestrictiveRetention -eq $True} | Format-Table Name, Workload
```

Note that if you move a mailbox that is subject to a preservation lock back to an on-premises Exchange server, Exchange Online keeps a copy of the mailbox to satisfy the lock. The copy held in Exchange Online is a point-in-time copy and no mechanism exists to synchronize the two copies after the mailbox moves.

## Auto-Label Retention Policies

Publishing labels for people to apply to documents and messages is certainly one way to solve the need for data governance. The problem with this approach is that it depends on human beings to be very precise, consistent, and persistent in how they classify material. As noted in this book, we know that humans are very inventive, but they also tend to lose interest in boring technicalities after a while. On the other hand, computer systems are all about processing the same steps time after time until told to stop. Auto-label policies help organizations meet their data governance needs by finding content to retain and applying the right label to that content. Auto-label policies work alongside standard label policies. People apply the labels published to their accounts to explicitly label important or specific items while most items that need labels receive them automatically. Auto-label policies require Office 365 E5 or Microsoft 365 E5 compliance licenses for any account coming within the scope of the policies.

Take the “Business Critical” label for example. We know that we want users to use the label to classify any content that the organization needs to keep for audit purposes. We have reasonable confidence that people will classify new documents and messages, but tens of thousands of pertinent documents exist in SharePoint Online and OneDrive for Business that the business should retain. If we can build rules to tell Microsoft 365 how to find the content, an auto-label policy is the right tool for this job.

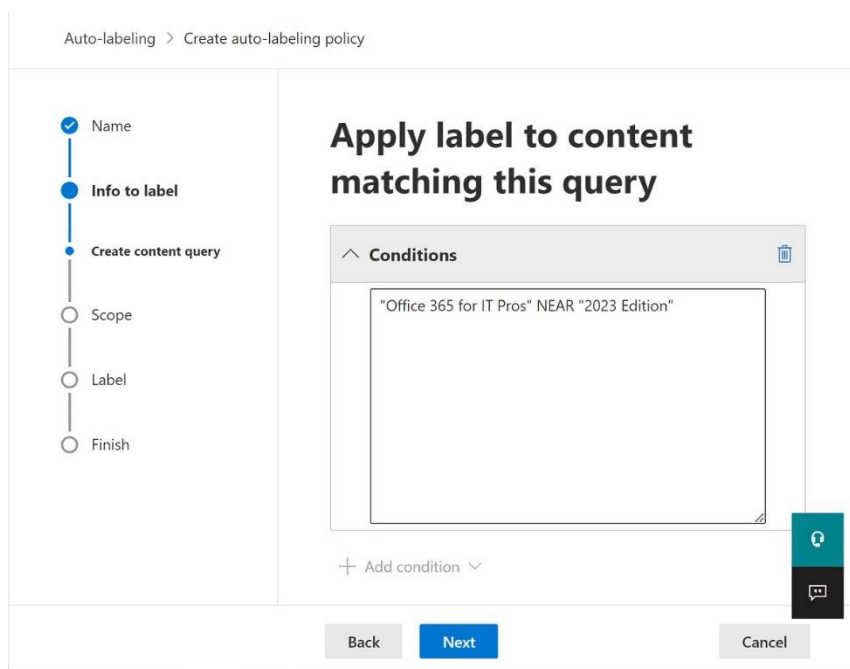

Figure 17-10: Using keyword queries to find content to keep through a retention policy

Auto-label policies use conditions to find matching items in the locations covered by the policy and assign a retention label to those items. For instance, you might want to use an auto-label policy to protect items identified with matching criteria. Three options exist to find content for an auto-label policy:

- **Sensitive Information:** Find items containing sensitive information types such as credit cards, bank account numbers, taxpayer identification numbers, and social security numbers. Any sensitive information type known within a tenant is usable, including custom types defined by the tenant or created using digital fingerprinting.
- **Content (KQL) Queries:** Find items using a content query containing keywords or search terms. Good examples of this kind of policy inaction are those used to [find and label Teams meeting recordings](#) and [apply retention labels to documents marked with sensitivity labels](#). Like content searches, the query is expressed in KQL syntax (this [page is helpful](#) to understand how to construct KQL queries). A good way of testing a query before using it in an auto-label policy is to use it with SharePoint search or a content search. Either way, by checking the items returned by the search, you’ll know if the content query finds the correct items for the auto-label policy. See Chapter 18 for more information about running content searches.
- **Trainable classifier:** Find items matching a classifier created by Microsoft or created by the tenant. Auto-label policies that use trainable classifiers can’t process content that’s more than six months old.

To create a new auto-label policy, go to Label policies and then select auto-apply a label. After naming the new policy, you select the kind of criteria to match items against. In Figure 17-10, we see a simple query to look for one phrase close to another. You can specify as many keywords as necessary to create the best chance of matching items for retention using the same approach as for eDiscovery searches.

Content queries can filter out certain kinds of files for retention processing. For example, let’s assume that you only want to assign retention labels to Word documents and PowerPoint presentations stored on specific sites. The keyword query to find documents of these types must include a reference to their file extensions.

Some search experts recommend adding a term to have SharePoint Online only search items it considers documents (*isDocument* is true). However, an argument also exists that it's sufficient to pass the desired file extensions. This content query uses both file extensions and an explicit term to limit the search to documents:

```
filetype:doc* filetype:ppt* isDocument:1
```

If you change a policy to update the keywords used in the content query, the target locations evaluate the updated content query to decide whether to keep or remove content.

Microsoft 365 publishes auto-label policies to the target workloads in a similar manner to label publishing policies. Auto-label policies work against data at rest for both SharePoint and Exchange locations. Policies detect matches against conditions when the indexer processes items, leading to the assignment of labels to matched items. When an Exchange mailbox comes within the scope of an auto-label policy, the locations include both the primary and archive mailboxes.

Figure 17-11 shows how to include a sensitive information type in a retention policy. When you choose to use sensitive information types, you select a template like the way you create a new DLP policy. In this case, we chose the U.S. Financial Data template, which imports three sensitive information types into the policy. You don't have to use all the imported sensitive information types and can remove the unneeded types.

Auto-labeling > Create auto-labeling policy

**Define content that contains sensitive info**

Choose a category of industry regulations to see the classification groups you can use to classify that information or create a custom group.

Figure 17-11: Using sensitive information types in a retention policy

Figure 17-12 shows how to use a custom trainable classifier as the basis for an auto-label policy. You can use either the set of classifiers created and published by Microsoft or build a tenant-specific classifier. Classifiers are “trainable” because their creation involves a training process where artificial intelligence technology processes sets of sample documents to recognize their essential characteristics and create the classifier. In this instance, the trainable classifier is *Customer Billing* constructed by analyzing a set of 400 customer invoices. When the auto-label policy is active, each time the indexer meets a matching document (one with the same characters as learned from the sample set), Microsoft 365 applies the label to the matched item.

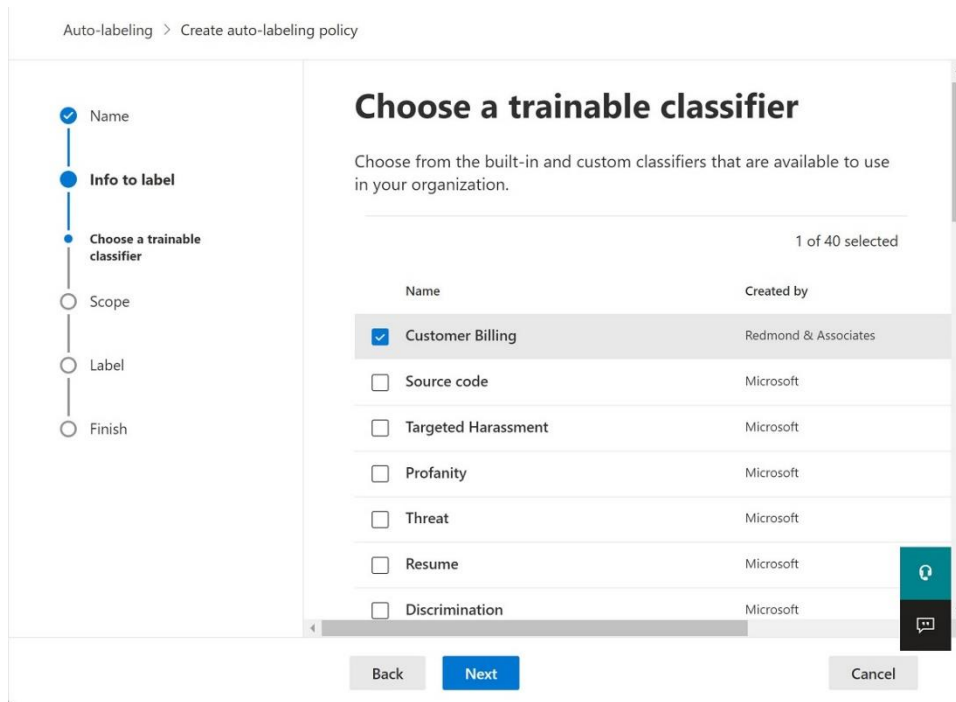

Figure 17-12: Choosing a trainable classifier for an auto-label policy

After choosing the criteria to find matching items, you select an adaptive scope or select static target locations from:

- Exchange mailboxes. Note that when using sensitive data as the criterion for auto-labeling, the policy applies to all mailboxes. You cannot include or exclude individual mailboxes.
- SharePoint sites.
- OneDrive for Business accounts.
- Microsoft 365 Groups. These locations include the group-connected SharePoint Online sites, including those used by Teams. When using sensitive data, you cannot include or exclude individual groups. Also, you must include Exchange mailboxes in the policy to ensure that the policy processes the complete content for the groups.

Finally, you choose the retention label to apply. After a last check of the policy settings, submit the policy for publication to the target workloads. The Compliance portal validates the settings and if everything is OK, go ahead and publish.

Auto-applying labels are an effective way to achieve broad coverage of content that a query can find using a keyword or because the content holds some sensitive data. Later, users can review items with the label and decide whether the label is correct, or if another label is a better fit. Unlike other labels, the labels included in auto-apply policies do not show up in SharePoint, OneDrive, or Exchange as labels that users can apply manually.

## Validating the Progress of Auto-Labeling

It can take up to a week before an auto-label policy becomes fully effective. Unfortunately, there's no easy way to measure the effectiveness of auto-labeling without some degree of manual checking. You can:

- Check the properties of individual items that you expect to receive labels to see if the auto-label policy has assigned a label to those items.
- Use the Activity explorer in the compliance portal to see what items have received the label applied by an auto-label policy.

- Analyze the *TagApplied* events from the Office 365 audit log to track the application of the label applied by an auto-label policy. An example [script in the Office 365 for IT Pros GitHub repository](#) shows how to approach the task.

If you deploy several auto-label policies, documents can end up with labels that you think are incorrect. Apart from using bad search queries to find the items, the problem might be because more than one policy applies to documents. When this happens, the oldest policy (by creation date) wins and once a policy applies a label to an item, other policies will ignore that item because it already has a label. Because auto-labeling works in this manner, you need to be careful with the queries used to find content and with the order in which you deploy policies.

## Replacing Labels Assigned by Auto-Label Policies

Auto-label policies are an effective way of applying retention labels to large quantities of items. Microsoft 365 won't process matching items in the target locations if they already have labels assigned manually (by users) or automatically (by policy). Auto-label policies ignore labeled items to avoid the potential that overwriting the existing label with another might cause data loss.

Good as this logic is, it does create a problem if an organization's retention strategy changes. You can update a retention label to change its retention period, but you cannot change its retention action. For instance, if a label's retention action is to delete items when the retention period expires, you can't change the action to leave items in place. Microsoft is aware that this lack of flexibility can cause problems for organizations forced to change their retention strategy due to government or other regulations. In the future, you might be able to alter an auto-label policy to instruct it to replace one label with another but for now, you should remember that once you apply retention labels through policy, those labels will stay assigned to items unless replaced by a label explicitly assigned by a user.

## Other Methods to Automatically Assign Retention Labels

Although auto-label retention policies are a good way to find and label items automatically, several other methods exist to apply retention labels to content. These include applying labels by:

- Defining a default retention label for a SharePoint Online or OneDrive for Business document library. This method requires Office 365 E5 or Microsoft 365 Compliance E5 licenses.
- Using Power Automate to assign a label to a document (here's [an example](#)).
- Applying a retention label to a SharePoint Syntex document understanding model.
- Programmatically using the [SetComplianceTag method](#).

Automatic assignment of retention labels usually requires a specific license. For example, if you define a default retention label for a document library, users accessing that library need Office 365 E5 or Microsoft 365 Compliance licenses. Applying retention labels using mail flow rules doesn't require any additional licenses.

## Retention and Sensitivity Labels

Two forms of compliance labels exist within Office 365:

- **Retention labels:** Mark content like documents and messages that the organization wants to retain, like keeping certain documents because they hold valuable information, such as accounting records, sales records, and so on. Users apply labels to messages or documents to mark the items as a visual marker of the importance of the content or to make sure that Microsoft 365 keeps the item for a set period. Two types of retention labels exist: standard and record. Standard labels are the more common type while the major use of record labels is in the Records management solution, covered later.

- **Sensitivity labels.** Apply marking with optional protection to content. [Sensitivity labels](#) are how Microsoft has extended the functionality of the original Azure Information Protection labels as part of their Microsoft Information Protection initiative. They refer to these labels as “unified” because they bring together the work done by Azure Information Protection to make it easy for users to self-classify content by applying labels in the Office applications with the data governance framework. Applying a sensitivity label to an item can protect it through encryption or add visual indicators such as watermarks to show users the importance or sensitivity of the information. See Chapter 20 for more information about how to define sensitivity labels and deploy them to users through sensitivity label policies.

When we refer to the two types of labels in general, we say “labels” or “Office 365 labels.” Otherwise, we refer to the specific type. The information presented here covers retention labels.

## Retention Label Concepts

A retention label can be passive, meaning that it serves as a marker for a certain type of content but takes no further action because it doesn’t have any retention settings. Passive labels are useful to mark content that someone will need to process in the future or to find items belonging to a project. Mostly, retention labels are active, meaning that the label has a defined retention action and period. The action tells the owning workload to keep content for the period or to remove content after that period. For instance, the organization might decide to retain all documents marked with the “Confidential” label for five years and removed afterward. Auto-label policies remove the need for users to apply labels manually. The combination of manual (explicit) and auto-applied (implicit) classification gives tenants great flexibility in how they manage important content.

Items such as a document or message can only ever have one retention label (it can also have a sensitivity label). Apart from the precedence of manually-applied retention labels, the other rules are:

- Anyone with write access to content can change the label assigned to that content whether the item receives a label manually or automatically. For example, if an email has the “Confidential” label, the user can go ahead and change that label to any other available label. The exception is retention labels that mark items as formal company records. Once a user applies a record label to an item, the item can’t be edited, updated, or removed until its retention period lapses (for instance, Exchange Online keeps deleted records in the Recoverable Items structure).
- Retention labels applied automatically can never overwrite labels manually applied by users.
- If multiple auto-label policies match an item, the workload uses the label belonging to the oldest policy. On the creation of a label policy, the policy receives a priority number incremented from 0 (zero) as more policies are created. Thus, the policy with the lowest number is the oldest. You can discover the priority order for policies by running the *Get-RetentionCompliancePolicy* cmdlet as shown below:

```
[PS] C:\> Get-RetentionCompliancePolicy | Format-Table Name, Priority, WhenChanged
```

Name	Priority	WhenChanged
Management Preservation Policy	0	13 Apr 2018 13:02:36
Company Confidential Policy	1	29 Apr 2017 03:07:38
Clean up Groups with Connectors	9	29 Apr 2017 03:07:40
Formal Company Records	13	29 Apr 2017 03:07:39

You cannot change the priority order of retention policies.

## Retention Label Publishing Policies

Broad retention policies assign retention settings to locations. Retention label policies make one or more retention labels available to end-users through a publication process to inform workloads about the labels and their settings. It is then up to the workload to decide how best to reveal the labels through the different

clients supported by the workload. A label policy is composed of one or more retention labels. A retention label can be in multiple label publishing policies. For instance, the “Confidential” label referred to above to keep content for five years could be in the policies assigned to different departments along with other labels that meet the specific needs of each department. The members of the legal department might have a policy that includes labels called “Case Review”, “External Counsel”, and so on while people working in Accounts might have labels for “Collections”, “Audit Records”, and “Tax.” Being able to create label publishing policies with a mixture of generic labels and work-specific labels supports flexibility in data governance. After all, not everyone who works in a company needs to deal with information in the same way.

When complete, administrators publish the policy to make the labels available to end-users. After a period, the labels included in the policy become available to clients and users can then apply the labels to email, documents, and other content to mark those items as being of interest for business reasons. Behind the scenes, background processes make sure that workloads respect the instructions contained in the label settings. For instance, items stamped with the “Archive Retention” label might be kept for 10 years before being removed.

## Planning Retention Labels

The first thing to decide is what labels the organization needs to build out the retention strategy. Broadly speaking, you can divide retention labels into the following categories:

- **Targeted:** Retention labels needed by certain departments and used for specific purposes. For example, “Project Documentation,” “Board Minutes,” or “Patent Material.” These labels usually keep information that is of high importance to the organization and might be published to a select group of locations.
- **Generic:** Retention labels used anywhere in the business. Often, these labels are named after the length of the retention period, as in “Keep Five Years.” They might also have names that describe the business purpose, like “Commercially Sensitive” or “Required for Audit.” These labels are usually published to all locations in an org-wide policy.
- **Special-Purpose.** Retention labels that the organization creates for a specific well-defined purpose. For example, to mark and keep a set of information needed for a merger and acquisition project.

After consulting with business units (including the IT department) to gather suggestions for retention labels, you can rationalize the set to a manageable number. Each label should serve a distinct and obvious purpose definable in clear and easily understandable terms. In addition, you should be able to say where the records marked by labels are stored. For example:

*“We are required to preserve financial records for five years because we can be audited during this period. We need a label to mark these records and ensure that they are retained for at least five years. Items needed for audits include messages and documents across all mailboxes and sites.”*

It is sensible to write down each of the retention labels that you plan to use before creating anything. It is much easier to delay the release of a label and the training of users to use the label properly than it is to launch a label into general circulation only to discover that you later need to withdraw it. Another thing to consider is how easy it is for users to decide between different retention labels when the time comes for them to apply a label. Too many labels, misleading names, or too many choices can lead to frustration and bad decisions.

Other points to consider include:

- An item can only ever have a single retention label. To change a label, you must remove the first label and replace it with another. Sometimes, you might have to remove a label from an item before you can remove the file.

- A retention label applied by a user always has the highest priority. A workload never applies a retention label to content if a label applied by a user already exists. On the other hand, a user can always replace a label applied by an automatic policy with one that they choose. The logic here is that the user understands the full import of the content and can therefore make the best decision about its importance.
- If you use automatic label policies to apply labels to content found using a keyword query or because the content has sensitive data, you might find yourself in a situation where some documents come within the scope of multiple policies. a tiebreaker decides which policy to apply. The tiebreaker is the age of the policy, and the workload always complies with the oldest policy. The logic here is that companies usually create their most important policies first, so it makes sense to apply those policies first. This is a key factor in the planning process as you must decide what your most important policy is and make sure to create it first. No way exists to reorder the priority of automatic label policies as the only factor is a policy's creation date. Therefore, if you make a mistake with your priority, you must remove policies and recreate them in the correct order.
- Although auto-label policies cannot replace labels assigned by users, they can replace labels previously automatically assigned to items by other policies.

In summary:

- Make sure that every retention label has an obvious purpose.
- Try to have a small number of retention labels so that it is easier for users to make good choices about for how long they should keep content.
- Create retention labels and policies in priority order.
- Deploy auto-label policies after users have had a chance to apply retention labels manually.

**Removing a Site:** Before you can remove a SharePoint Online site, you must remove any documents that have retention labels from the site. Normally, this means that you must remove the label from the documents and then delete them.

## Creating New Retention Labels

After understanding the labels necessary to implement the data governance policy, we can create them through the Data lifecycle management section of the Microsoft Purview Compliance portal. Click **Labels** and then **Create a label**. You can then start by entering the name of the label and some text to describe the purpose of the label for administrators and a separate description that is visible to users when they browse labels as they classify material.

### Naming a Retention Label

The name given to a retention label is important because this is what users see when they use the label to classify a message or document. One issue for multilingual tenants is that no facility exists to translate labels. Whatever name you give to a label shows up in clients, no matter what language they use. For this reason, it is best to give labels names that are simple to understand and unambiguous in their intent as this will make it easier to communicate how to use the labels to classify information.

### Create retention label

**Name**

Retention settings

Finish

#### Name your retention label

This is the name of the label your users will see in the apps where it's published (like Outlook, SharePoint, and OneDrive). So be sure to come up with a name that helps them understand what it's used for.

Figure 17-14: Selecting a retention label to apply to a SharePoint document

For example, if we publish the label shown in Figure 17-13 to OneDrive for Business and SharePoint Online, people can use the label to classify a document stored on a site by amending the document properties and selecting the label. As you can see in Figure 17-14, the user gets two visual hints about the meaning of the label: its name and the descriptive text that appears when they hover over the label. You can also see that it's

possible to include Windows emojis in the display name of retention labels to deliver another visual hint to users about a label's purpose.

## Retention Actions and Periods

The next step is to define how workloads will process items with a retention label. You must choose what action the label will apply and when the action occurs. A retention label can:

- **Retain** items for a **specific period**. The retention period is the number of days that elapse before workloads process the retention action.
- **Retain** items **forever**. If users attempt to delete a labeled item, the workload will keep a copy of the item in a safe location where the user cannot access it. For example, Exchange Online moves the copy to the Recoverable Items folder.
- **Enforce actions** after a specific period. Once the item reaches the set age (retention period), it is removed.
- **Just label** items. These labels act as visual markers for the type of information in an item (sensitivity labels with no encryption that apply watermarks, headers, and footers might be a better choice). For instance, you could create a "Draft" label to allow users to mark items that have not yet reached the point where the content is interesting or valuable enough to justify its retention. Another way of using labels without actions is as a convenient way to find information with content searches (for instance, find all documents for "Project X"). Labels that do not have a retention action show up with a "Never" expiration date when viewed through Outlook or OWA.

If you choose to keep items for a specific period, you can choose between date-based retention or event-based retention as the baseline for the retention period. For date-based retention, you select one of the three predefined periods (5, 7, or 10 years) or a custom period in years, months, and days. The GUI allows the selection of a retention period of over 100 years, but a shorter period is best. You then choose the basis for the retention period:

- The **creation date** for items: This is the default and works well for most items.
- The **last modification date** for items: This is a better retention base for documents that go through multiple review cycles before finalization.
- The date when a user or policy applies a **label** to an item.

If you use event-based retention instead of date-based retention, the retention period starts when the event occurs. Some of the standard event types are listed below. You can create additional event types to meet business needs. We cover event-based disposition in the Records Management section.

- Employee activity.
- Expiration or termination of contracts and agreements.
- Product lifetime.

The user interface presented to create a retention label depends on its settings. Figure 17-15 shows the how to configure a label that the label sets a seven-year retention period based on the creation date for items. When the retention period for an item expires, Microsoft 365 deletes the items. This means that the next time that the item goes through retention processing, its expired status causes the workload to apply its normal deletion process. For instance, a document removed from a SharePoint Online site goes into the recycle bin.

**Create retention label**

Define the period

Choose how long the period is and when it begins.

How long is the period?  
7 years

Delete items automatically  
We'll permanently remove labeled items from wherever they're stored.

Change the label  
You can extend the period by choosing an existing label to replace this one with. [Learn more about relabeling items](#)

Figure 17-15: Defining retention periods and actions for a new label

You can also choose to trigger a disposition review (change the label). When this happens, the item stays in place until a designated person reviews it to decide to keep or remove the item, or do nothing (deactivate retention settings).. The item remains in place and it's up to its owner to decide what to do with it.

When all the details are complete for the new label, click **Next** to review the settings and then take the **Create label** option.

**One chance to get label settings right:** Be careful with the settings you specify when creating a new label as you can only change the retention duration afterward. The logic is that allowing other changes after label creation will disrupt how the label behaves when applied to content. For example, if you change a label that keeps content for ten years and does not remove it afterward to now remove the items, users might lose information that they expect to have.

## Publishing Retention Labels Through a Label Policy

To make the new label available to users, you must publish it in a label policy. You can publish the new label in a separate policy, but it's usually better to create policies to publish sets of labels to users. For instance, you might have a label policy called "Finance Department Labels" that includes all the labels needed by workflow processes in the finance department. The department users can apply the labels when an administrator publishes the policy to them.

Start the publication process by going to the **Labels policies** section under **Data lifecycle management** to view the set of label policies defined in the tenant. You can then select an existing policy and edit it to add or remove labels from the policy or use the **Publish labels** or **Auto-apply a label** option to create a new label policy. The first type of policy makes the label available to workloads, the second sets the conditions for the automatic application of a label. You can select several labels and take the action to publish the set of selected labels in a single policy (bulk publish). We will explain how to create an auto-applied policy in the next section.

After deciding on the set of labels to include, you select the locations where the labels are available to users. The options for static policies are:

- **All locations:** This means that the labels in the policy are available to all users in the following workloads. This is an org-wide policy.
  - **Exchange Online mailboxes.** Labels appear in clients in the same way as Exchange retention tags and behave like retention tags. For example, you can create a rule in Outlook desktop to apply a label to messages, such as all those that come from a specific address.
  - **SharePoint sites.** Users assign labels to classify individual documents or items inherit a label because it is the default for a document library. When a default label is present, new items created or uploaded in the library inherit the label.
  - **OneDrive for Business accounts.** Users assign labels to classify individual documents stored in OneDrive folders.

- **Microsoft 365 Groups.** Users apply labels to conversation items in Outlook Groups. Yammer communities don't support the labeling of conversations. Because SharePoint supports retention labels, they can classify information in the document libraries belonging to Outlook Groups or Yammer communities.
- **Let me choose specific locations:** For each of the supported workloads, you can opt to include or exclude certain mailboxes, sites, OneDrive for Business accounts, or groups. For mailboxes and groups, you enter the names of individual mailboxes or distribution lists you want to include or exclude. For site collections, you enter the URL in the form `https://mytenant.sharepoint.com/`. For OneDrive for Business accounts, enter the URL for the site. Figure 17-16 shows the locations available for label publication. We can see that a single Exchange recipient is selected together with all SharePoint sites and OneDrive accounts, and five groups.

## Edit retention policy

**Choose locations**

We'll publish the labels to the locations you choose.

All locations. Includes content in Exchange email, Office 365 groups, OneDrive and SharePoint documents.

Let me choose specific locations.

Status	Location	Included
<input checked="" type="checkbox"/> On	Exchange email	1 recipient <a href="#">Edit</a>
<input checked="" type="checkbox"/> On	SharePoint sites	All sites <a href="#">Edit</a>
<input checked="" type="checkbox"/> On	OneDrive accounts	All accounts <a href="#">Edit</a>
<input checked="" type="checkbox"/> On	Office 365 groups	5 groups <a href="#">Edit</a>

Figure 17-16: Selecting locations to publish labels in a retention label policy

## Scoping with Non Org-Wide Policies

Label policies with excluded or included locations are known as non-org wide policies. You can have up to 1,000 non-org wide policies in a tenant. This figure includes both retention and label policies.

When you exclude or include locations in a label policy, certain limits exist in the picker used to select target locations:

- For **Exchange**, if you don't enter anything in the search box, the picker shows the first 50 mailboxes and distribution lists in the directory. Enter a search phrase to find the mailboxes to include or exclude. The easiest way to add many mailboxes at one time to a policy is to use distribution lists. The membership of the list is expanded, and the mailboxes are added to the policy.
- For **SharePoint**, you can include or exclude up to 100 sites. These are sites, not libraries within sites. Use this location to publish labels to traditional SharePoint sites that are not connected to Groups.
- For **OneDrive for Business**, you can include or exclude up to 100 accounts by specifying the URLs for the target accounts.

- For **Groups**, the picker shows the first 100 groups in the tenant, including those hidden from Exchange clients (used by Teams). You can add up to 1,000 groups to a label policy. Labels published to Groups apply to the chosen group mailboxes and the group team sites. Use this location type to publish labels to modern team sites connected to Groups.

Workloads like Teams and Planner do not currently support retention labels, so there is no need to include them in the publication process. Teams does support retention policies.

Click **Next** after selecting all the target locations. You now name the policy and give some optional information to explain its purpose. Click **Next** to review the settings for the policy. If any issues are detected at this point (for instance, you enter a SharePoint site instead of a site collection), the policy cannot be published, and you must fix the problem before you can continue and save the policy.

When everything is ready, click **Publish labels** to begin the provisioning process that makes the policy available to the target locations. You know when the provisioning process is complete when the policy status changes from "Pending" to "Success." Once published, the new label is available to the target workloads defined in the policy. This process can take up to one day to complete as, in some cases, clients must find out about the new labels. For example, the XML data used to inform Outlook desktop clients about retention policy settings must receive an update with details of the new label. The clients then need to download the label information before the new label appears in Outlook's user interface. Web clients typically pick up new labels faster, but it is reasonable to expect that the entire end-to-end publication and provisioning process might take one or two days before a new or updated label is available throughout the tenant.

## Comparing Retention Labels and Retention Policies

A retention policy (not a label publishing policy) applies a single retention setting to everything in a container or location (mailbox, site, group, or team). A retention label applies retention settings at the item level. Together, the combination of retention policies and retention labels gives administrators a lot of flexibility in planning a retention strategy for content. However, policies and labels support different settings, and this can be confusing at times.

Let's summarize what retention labels and retention policies can do:

- You can apply retention actions and periods through both policies and labels. Some workloads (Teams and Yammer) only support the application of the same settings to everything in the targeted containers. Others (Exchange, SharePoint, and OneDrive) support label assignment to individual items and targeted containers.
- A retention label can act purely as a visual marker. In this case, the label has no retention settings. Because it can add visual markings to documents and messages, a sensitivity label might be a better choice for this purpose.
- Both policies and labels support the ability to retain content for a set period, remove content after a set period, or retain for a period and then delete it. Both can use the created date or the last modified date as the date when the retention period begins.
- A retention label assigned explicitly to an item can override the retention period imposed by the policy assigned to a container. For instance, if a site has a retention policy that removes items after three years and an individual document in the site is assigned a retention label with a retention period of five years, SharePoint will remove all the unlabeled items on the site after three years and keep the labeled document for five years.
- After the retention period lapses, both policies and labels allow items to remain in place for the user to decide what to do with them. An analogy is government papers that have restricted access for ten years after creation. When the ten-year period expires, the papers are not dumped. Instead, they become available for public access. This subtle differentiation is important for records management.

- Because they are more explicit, retention labels offer extra control over what happens when a retention period is over. A retention label can invoke manual disposition or use event-based retention. We'll get to these topics later.
- A retention label can classify an item as a formal record or regulatory record. Labels created for this purpose are managed through Records management – see later section.
- Labels assigned by auto-apply policies can be replaced by explicitly (user-assigned) labels. Explicitly-assigned labels can never be replaced by automatic assignments.
- Labels inherited from a container (like the default label for a SharePoint site) can be replaced by labels assigned by auto-apply policies.
- Unlike Exchange Online retention tags, neither retention policies nor retention labels support a “move to archive” action. If moving mailbox items to the archive is important, you can continue to use mailbox retention policies in conjunction with retention policies.

Figure 17-17 shows the retention settings for a retention policy (right) and retention label (left). These are old UI screens (2021), but they show the extra flexibility available in retention labels better than the current GUI. The ability to set a label to mark items as records (label classification) is only available when editing retention labels through the File Plan section of Record Management in the Microsoft Purview Compliance portal.

### Define retention settings

When this label is applied to items, the content is retained and/or deleted based on the settings you choose here.

Retain items for a specific period  
Labeled items will be retained for the period you choose. During the retention period, Users will be able to edit items and change or remove the label. If they delete items, we'll keep copies in a secure location. [Learn more](#)

Retention period of  years  months  days

Retention period

At the end of the retention period

Delete items automatically

Do nothing

Retain items forever  
Items will be retained forever, even if users delete them.

Only delete items when they reach a certain age  
Items won't be retained, but when they reach the age you choose, we'll delete them from where they're stored.

**Policy**

Figure 17-17: Retention settings in a retention policy (right) and retention label (left)

In summary, retention labels offer more flexibility, but they must be assigned manually or through auto-label policies. The retention settings in policies are simpler, but they are easier to apply because you can deploy retention across the entire organization or for a selected set of locations with just a few policies.

## Using Retention Labels

We now know how to set up, publish, and manage labels and understand the basic principles that only one label can exist on an item at any time, whether a user assigns the label to an item manually or a background process assigns the label automatically. With those thoughts in mind, we can now go ahead to discuss how to use labels within the different locations.

## Using Retention Labels with Exchange Online

Publication of a label means that workload-specific mechanisms make the new label available to users of an application. For Exchange Online, that mechanism is to insert the label into the set of retention tags available to a mailbox through its assigned mailbox retention policy. The Managed Folder Assistant (MFA) creates a unified set of retention tags and retention labels and publishes the set to user and group mailboxes (group mailboxes only see retention labels and not tags). MFA includes only labels with a retention action in its published set.

MFA operates a workcycle to process mailboxes at least once every seven days. Therefore, it might take up to a week before new retention labels become available to mailboxes. See the “Logging the Managed Folder Assistant” section later to understand how to extract and interpret MFA diagnostic logs for a mailbox to know when MFA last processed the mailbox.

Mailboxes must hold more than 10 MB of content before the MFA processes the mailbox to make retention labels available. This restriction exists to ensure that MFA does not waste processing cycles on unused mailboxes. When it opens a mailbox for processing, MFA makes sure that the current set of labels is known to the mailbox before it begins to check items against their retention status.

Integrating retention labels with retention tags allows OWA and Outlook desktop to handle the two kinds of tags consistently. In effect, OWA and Outlook treat labels in the same way as personal retention tags and make the labels available to users to tag individual messages or folders. Figure 17-18 shows how Outlook presents a mixture of retention tags and retention labels to the user when they want to apply a policy to a folder.

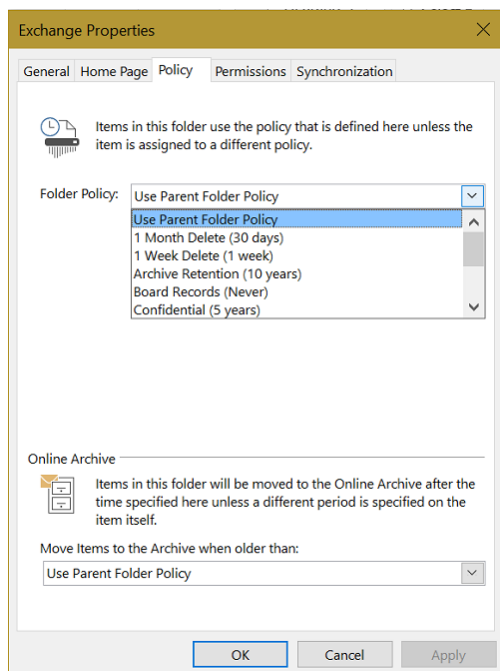

Figure 17-18: Outlook lists retention tags and labels

Because Outlook clients display retention labels alongside personal retention tags, users should not see any difference between the two types. If a user assigns a label to a folder, all items in the folder inherit that label, unless the item already has a personal tag or another retention label. Likewise, if you change a label at the folder level, the next time MFA processes the mailbox, it updates the items in the folder with the new label unless they already have an explicit label or tag.

Because Exchange public folders do not support retention policies, they also do not support retention labels.

## Integration with Exchange Retention Policies

Although OWA and Outlook present retention labels to users in the same way as they see personal retention tags from mailbox retention policies, we already know that labels function differently from retention tags.

Table 17-4 lists some of the differences between the two methods used to mark mailbox items for retention processing.

<b>Feature</b>	<b>Mailbox Retention Tag</b>	<b>Retention Label</b>
Remove content from mailboxes	Yes, when the retention period expires.	Yes, when the retention period expires.
Archive content from mailboxes	Yes, when the retention period expires.	No. Labels do not support an archival action.
Expiration of control	No. A retention tag stays with an item until it is removed from the mailbox.	Yes. The effect of a label ceases when it expires.
Policy-driven tagging of default folders	Yes. Retention policies can include folder tags for any of the Exchange default folders (like Inbox).	No. A retention label functions as a personal retention tag and can be applied to any other folder except default folders.
User-driven tagging of items and folders	Yes. Retention policies can include personal tags for users to stamp on non-default folders and individual items.	Yes. A label can be used in the same way as a personal tag to mark items or folders.
Policy-driven default retention	Yes. Retention policies can include default tags that apply to all items in the mailbox that are not stamped with a more explicit tag. A policy can include default tags to define removal and archival actions and you can have a specific default tag for voicemail.	No. It is possible to create an auto-label policy that applies to all items in the mailbox, but that is different from a default tag.
User-selectable tags	Yes. Users can select personal tags (through OWA options) that are not in the assigned retention policy and use them to tag items and folders.	No. Users do not have access to labels not published to their mailbox.
Target	Limited to Exchange mailbox folders, items within a conversation, individual items, or complete mailboxes.	As for retention tags, with the addition that labels can be used in other workloads.

Table 17-4: Differences between Exchange retention tags and retention labels

The last point is the most important. Retention policies and tags only cover Exchange content. OWA and Outlook desktop clients combine retention labels with the tags published through Exchange mailbox policies.

Meaning users can apply labels to email items in the same way as they use retention tags. Of course, the big difference between labels and tags is that labels are available in other workloads.

## Using Retention Labels with Groups

When you publish retention labels to a group, they become available in both the group mailbox and the group document library. At the time of writing, OWA is the only client that supports the application of labels to conversations in Groups. Only group owners can use labels to classify conversations as OWA hides the labels from ordinary group members.

However, all group members can assign retention labels to files and folders in the group document library and any group member can overwrite a label previously assigned by another group member, except if that label is a formal record (in which case only the site collection administrator can update the item). The reasons why labels behave differently in a group's mailbox and document library are because of the different ways that Exchange retention tags and SharePoint permissions work. An Exchange mailbox is typically under the sole control of its owner while a SharePoint site is designed to support multiple levels of shared access.

## Using Retention Labels with SharePoint and OneDrive for Business

Any user in the default members group for a SharePoint site (with the Contribute permission level) can apply labels to documents, folders, or items in a list within the site. If the site belongs to a group, any of the members can apply labels because they all have equal access to the site. The owner of a OneDrive for Business account can apply labels to content within their account. When you apply a retention label to a folder, all items in the folder inherit the same label, unless some of the items in the folder already have labels. Applying a retention label to a folder holding thousands of files can take a little time to complete. A retention label inherited from a folder stays with a document even when the document moves to another folder or another site. Also, if you upload a file to replace an existing document that has a retention label, the uploaded file inherits that label.

To apply a label to an item in OneDrive for Business or SharePoint, select the document or folder and then open the Details pane. Go to the **Apply Label** section and select a label from the set published to the location. Placing a label with a retention action on an item has some consequences:

- Depending on the Retention labels settings (available in the Records management section of the Microsoft Purview Compliance portal), users might be unable to remove a labeled item. See the section covering Record management settings.
- Users cannot edit documents marked with a label that classifies items as a formal record. They can update documents marked with labels not classified as formal records. Site administrators can remove the label or replace it with another if users need to edit the item.
- SharePoint records updates and deletions for documents in the site's Preservation Hold library.
- If a document is subject to a retention policy, users can remove it from the library, but because the document comes within the scope of a retention policy, SharePoint must keep a copy. In these instances, SharePoint Online moves the deleted document into the Preservation Hold library and keeps it there until the retention period expires.

The behavior is different for files held in OneDrive for Business because these sites are personal rather than shared and the owner of the site has the right to remove files from the site. When a user removes a file from their OneDrive for Business site, the file goes into the site recycle bin. Thereafter, when the retention period for the recycle bin expires (93 days), a timer job examines expired items and moves copies of any item with a label into the site's Preservation Hold library.

A label is a managed property that SharePoint indexes along with other document attributes. Indexing occurs when the crawler accesses new or updated documents. It can take up to an hour before a newly-assigned

label is in the index. When indexed, you can search for documents tagged with a retention label by using the *complianceTag* property. For example, you can input *complianceTag:"GDPR Personal Data"* in the SharePoint search box or a content search to find documents stamped with the *GDPR Personal Data* label.

## Displaying Retention Labels Used in a Document Library

The Outlook clients include the necessary user interface to make retention tags available to users, including those published by retention policies. This is valuable because users get a clear visual understanding of for how long Exchange will keep an item. Retention labels are not one of the default fields shown for SharePoint document libraries or lists. You can make the labels more obvious by customizing the view of items in the library or list to include the “Labels” and (if necessary), “Item is a record” fields. Figure 17-19 shows how information about assigned labels appears in a document library. Note that the column only displays the label name and doesn’t show anything else such as the outstanding retention period. This points to the need to either include the retention period in label names or to coach users about what each retention label does.

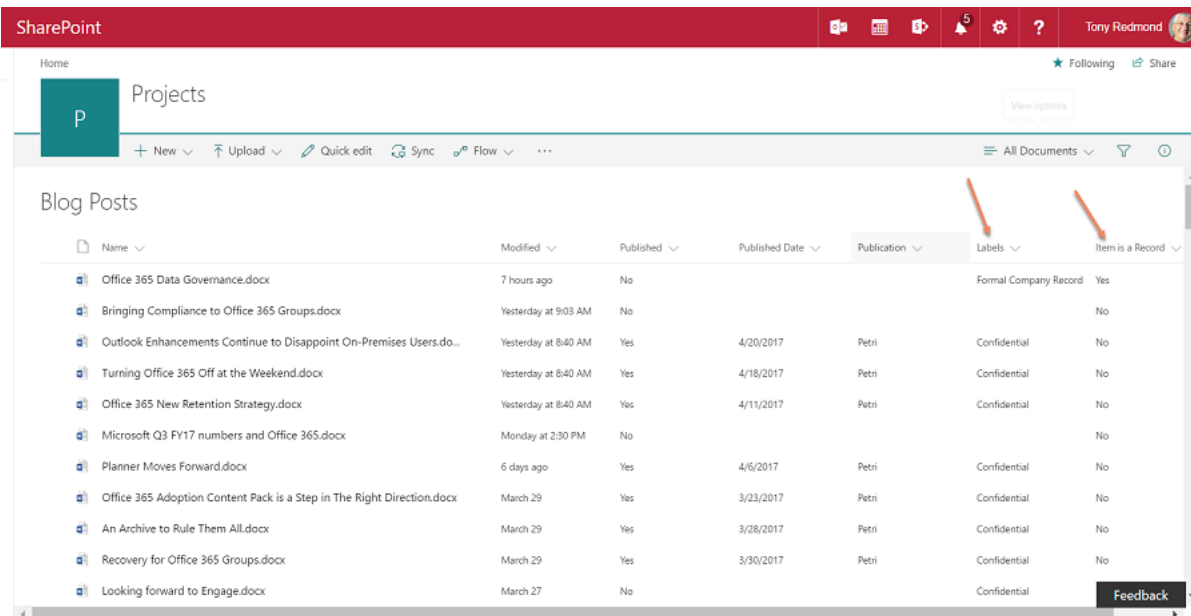

Figure 17-19: Viewing label information in a SharePoint document library

Unlike when you update properties like a document’s name or title, SharePoint does not treat applying a label as a modification. Instead, it is more of an administrative event. SharePoint, therefore, does not update the “Modified By” property with the name of the person who applies the label.

An organization might have many retention labels in active use at any time. It can be confusing for users to have to choose between multiple labels when they classify documents. In addition, some labels might be inappropriate for the content of certain sites. With these points in mind, it is sensible to consider what sites should receive a label when you publish it. Some labels are general purpose and are useful across all sites while others are better if restricted to specific sites.

## Finding Items Marked with Labels in Content Searches

You can create content searches (either standalone or part of an eDiscovery case) to find content marked with specific labels. You do this by using the “ComplianceTag” keyword in searches. For example, this search finds any items stamped with the “Draft” or “Approved” labels.

*(ComplianceTag:Draft) OR (ComplianceTag:Approved)*

If the label name contains spaces, enclose the name in quotation marks. See Chapter 18 for more information about eDiscovery searches.

## Audit Records Generated for Retention Label Actions

When someone assigns, changes, or removes a retention label from a document or folder in a SharePoint Online or OneDrive for Business library or an item in a list (including a list created in the Lists app), a *ComplianceSettingChanged* audit record captures the event.

- For retention labels applied by a user or retention labels assigned because a default label exists for a document library, the *UserIds* property holds the user principal name of the account that executed the action.
- For retention labels applied by the background job for auto-label policies, the *UserIds* property holds the GUID of the background job. You will see a value like *1b1c17be-a6f8-4691-9fca-9b6ac128c9e1*.
- SharePoint Online does not generate audit events for retention labels inherited by new documents because a site has a default label. This is an acknowledged gap in Microsoft's compliance story.

If a user removes a retention label from a document or list item, SharePoint Online captures the *TagUnApplied* audit event.

Audit records captured for retention label actions in a library include the site, the document name, the user, and the name of the label. If a label previously existed for a document, the audit record captures both the original (*SourceLabel*) and new (*DestinationLabel*) classifications. For label actions involving list items, SharePoint Online writes the item number into the audit event, so you see values like:

[https://office365itpros.sharepoint.com/sites/GDPRPlanningMarkII/Lists/Things to do/2\\_000/2](https://office365itpros.sharepoint.com/sites/GDPRPlanningMarkII/Lists/Things%20to%20do/2_000/2)

Exchange Online does not capture audit events when messages receive retention labels. This is because Exchange treats retention labels in the same way as mailbox retention tags. Exchange does not capture the assignment of mailbox retention tags as mailbox audit events.

### Analyzing Retention Policy Updates

Retention policies exercise control over user information, so it's wise to keep an eye on changes made to policy settings to ensure that administrators don't make mistakes that result in inadvertent loss of data. Microsoft 365 captures audit records for additions, updates, and removals of retention policies and retention label policies. [This article](#) explains how to analyze audit events for retention policy changes to report change details. The situation is more complicated than it first appears due to the information captured in audit events for different types of retention policies.

## Default Assignment of Retention Labels

If you have Office 365 E5 licenses, one solution is to classify items by using an automatic label policy to find documents using searches based on keywords or sensitive information types. This is a good way to make sure that documents with certain characteristics (like HR personnel files) are classified no matter where they are stored within SharePoint.

Another method to ensure that all items in a SharePoint or OneDrive for Business list or library are assigned a retention label is to assign a default label. Microsoft considers this to be an advanced feature, so it also requires an Office E5 license. To assign a default retention label, go to a library and select **Apply label to items in this list or library**, and then choose the default label from the set of available retention labels (Figure 17-20). In addition to assigning a default label to new items, you can choose to have SharePoint or OneDrive for Business apply the selected label to existing items. If you need to add default retention labels to multiple libraries, it's possible to [use PowerShell to script the assignment of a default label](#) to a SharePoint library.

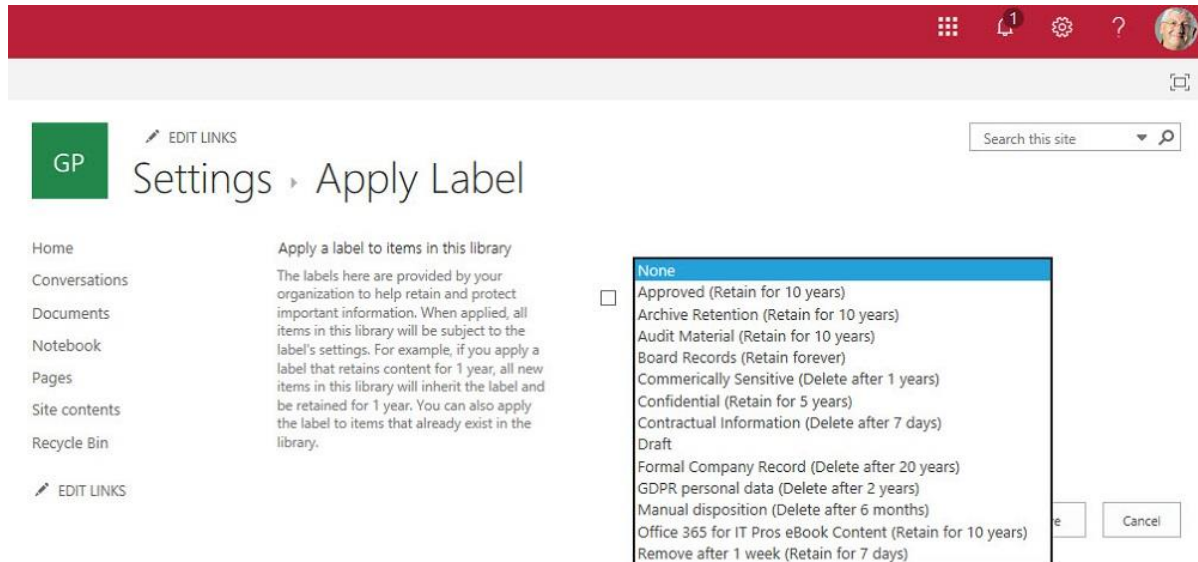

Figure 17-20: Applying a default retention label to a SharePoint library

**OneDrive for Business Library Settings:** If you want to set a default retention label for a OneDrive for Business account, you must either enter the URL for the library settings (it's the settings.aspx page) or use the old-style interface. Library settings are available when you expose the ribbon, select the library tab, and then library settings. You can then select a retention label as described for SharePoint above.

## Applying Retention Based on Sensitivity Labels

Given that files with sensitivity labels often hold confidential information that the organization wishes to keep (or wants to remove after a set period), it makes sense to use auto-label policies to find documents with certain sensitivity labels to make sure that they have appropriate retention labels. In this example, we'll create an auto-label retention policy to assign a retention label to documents and messages protected by the Highly Confidential sensitivity label. To do this, you:

- Connect to the compliance endpoint with PowerShell by connecting to Exchange Online and then running the *Connect-IPPSSession* cmdlet.
- Find the unique identifier (GUID) for the selected sensitivity label by running the *Get-Label* cmdlet. The *ImmutableId* property contains the GUID.

```
[PS] C:\> Get-Label | ? {$_.DisplayName -eq "Highly Confidential"} | Select-Object
-ExpandProperty ImmutableId
```

Guid

```
-----
9ec4cb17-1374-4016-a356-25a7de5e411d
```

- Use SharePoint search to test the KQL query for the auto-label policy. The search term is in the form *InformationProtectionLabelId:9ec4cb17-1374-4016-a356-25a7de5e411d* where the managed SharePoint property that holds the GUIDs of sensitivity labels (*InformationProtectionLabelId*) is combined with the GUID identifying the sensitivity label you want to search for. Run the search and open one of the documents returned by the search to check that it has the correct sensitivity label. If no documents are found, it might indicate that the GUID is incorrect or that your account has access to no documents that have this sensitivity label.

- If the search term finds the correct documents, create an auto-label retention policy that uses the same search term as the content query to find the target documents and apply a suitable retention label to keep the documents for the desired period.
- Configure the policy to find documents in the desired target locations. Remember to use Microsoft 365 Groups to cover SharePoint sites owned by groups and teams. Publish the policy when everything is complete.
- After ten days or so, check that documents with the sensitivity label have the correct retention label, remembering that if a user assigns a retention label to a document, an auto-label policy won't replace it.

The ten days mentioned above are an estimate rather than a guarantee. It can take SharePoint Online anything from seven days to two weeks for a new auto-label retention policy to become operational and start to apply retention labels.

## Records Management

Microsoft Purview Records management is a solution managed through the section of the same name in the Microsoft Purview Compliance portal. Records management makes management of retention labels and policies easier in large organizations and includes these features:

- **File plan:** Enterprises typically use more retention labels than smaller organizations and often have retention labels created for specific purposes. A file plan gives extra flexibility in grouping and managing retention labels based on different properties, such as labels used for manual disposition. Administrators can assign a set of file plan descriptors to retention labels, such as the *authority* for the label (the intended business category requiring the use of the retention label – default values are business, legal, or regulatory). In addition, the file plan allows tenants to mark retention labels as formal company records and regulatory records.
- **Retention label policies:** The same functionality is available to create and publish labels as exists under Data lifecycle management.
- **Events:** Create the events used for event-driven disposition, such as the termination of a project.
- **Disposition:** Process items that have reached the end of their retention period and require a manual check to decide what should happen to the item (deletion, further retention, and so on).

These features all require Office 365 E5 or Microsoft 365 Compliance E5 licenses.

## Records Management Settings

Three important controls for retention labels are in the Settings section of Records management:

- **Deleting content labeled for retention:** Until early 2022, SharePoint Online blocked users from deleting labeled items while OneDrive for Business allowed them to do so. To achieve consistency across the two applications, Microsoft changed SharePoint Online to behave like OneDrive for Business, meaning that users can delete labeled items and SharePoint Online will store the items in the site's preservation hold library until their retention period expires. Some organizations prefer the previous behavior because they believe that users should not remove labeled items. If this option is set, users see an error if they attempt to remove a labeled item. To proceed, a site administrator or user with permission must remove the label to allow deletion to happen or replace the label with one that does not have a delete action.
- **Configure record versioning:** By default, record versioning is on, meaning that users can unlock items assigned a record label and edit their content. If off, items assigned a record label remain locked and updates are not possible after the creation of these items. In effect, record labels then act like regulatory record labels.

- **Allow editing of record properties:** Apart from its content, an item has metadata like its title and other attributes. By default, users can edit items assigned a record label to update metadata. If this control is off, users cannot update item metadata after creation.

Although the Records management solution requires Office 365 E5 or Microsoft 365 Compliance licenses, administrators can set these controls without those licenses. The controls apply to all sites in a tenant.

## Record Labels

Retention policies and labels play a key role in the ability of Microsoft 365 to meet the requirements of Rule 17A-4 of the U.S. Security and Exchange Commission (SEC), stating that companies that employ brokers, dealers, and other workers in the financial industry must keep records of their electronic communications for between three and six years, depending on the type of communication. Among the requirements set out are that the records should not be amendable or erasable by an administrator.

Microsoft 365 supports two forms of record retention labels to help organizations satisfy regulatory requirements. Unlike regular retention labels, you cannot create or edit record labels through the Data lifecycle management section of the Microsoft Purview Compliance portal. Instead, these special forms of retention labels are managed in Records management. The two types of record label are:

- **Record:** After a user applies a record label to an item, only administrators can remove the label or change it for another label. Anyone with write access to an Exchange mailbox can apply a record label to an item in the mailbox. Any member of a SharePoint Online site can apply a record label to a file or list item. Once applied, a record label stops any attempt to delete the item. Items with record labels stored in SharePoint Online and OneDrive for Business can have a locked or unlocked status. Users cannot update the content of a locked item, but they can update its metadata (like the title) subject to the tenant Record management settings for updating items marked as records. Any site member can unlock an item to permit editing.
- **Regulatory record:** This is a stricter form of record label. Not even a tenant administrator can remove a regulatory record label after its creation, and the only changes allowed to the label settings are an increase in the retention period or publishing the label to additional locations. After applying a regulatory record label to an item, no one can remove the label or delete the item until its retention period expires. Site administrators cannot change the locked status of an item, so no one can edit an item's content. However, users can open documents in review mode and save their content as a new file.

Not every organization needs to implement the strict retention regime implied by regulatory records. For this reason, before you can create new regulatory record labels, you must expose the UI to allow the compliance portal to manage regulatory record labels. Do this by connecting a PowerShell session to the compliance endpoint and running the *Set-RegulatoryComplianceUI* cmdlet.

```
[PS] C:\> Set-RegulatoryComplianceUI -Enabled $True
```

The command is effective immediately. To disable the UI to manage record labels, run:

```
[PS] C:\> Set-RegulatoryComplianceUI -Enabled $False
```

When you create a new retention label through Records management, you can choose to make the label act as a:

- Regular retention label.
- Record label.
- Regulatory record label.

The latter two options depend on enabling the necessary GUI. You can't select an existing retention label and transform it into a record label. Just like normal retention labels, the tenant must publish record labels

through a label policy to make the labels available to users. If you want to withdraw a record label from active use, you should disable the policy used to publish the label.

After assigning a record label to a document, folder, or list item, users cannot delete the item until the retention period specified in the label expires. Any site member can lock or unlock records. SharePoint indicates the locked status of records with a small padlock on the item or folder icon. You can also see the locked status in the item properties (Figure 17-21). Assuming the record management settings for the tenant allow, after unlocking a record, users can edit its content. If someone subsequently updates a record after the last unlock action, SharePoint Online captures a copy of the item (before editing) in the *Records* folder of the site Preservation Hold Library. SharePoint Online highlights the version it captures by writing **Record** into the *Comment* field in the version history. You can't unlock an item assigned a regulatory record label, meaning that you shouldn't assign these labels until after you are sure that the record contains the final content.

Someone might lock a record while another member is editing the file. When this happens, the file contains anything saved (by autosave or the last explicit save) up to the point the user executes the lock action. To generate a complete copy including the changes made since locking, the person editing the file will have to save it under a different name and then exit the edit session. After a short period, SharePoint frees the file to allow an unlock to proceed. It will then be possible to merge any differences between the versions into the file.

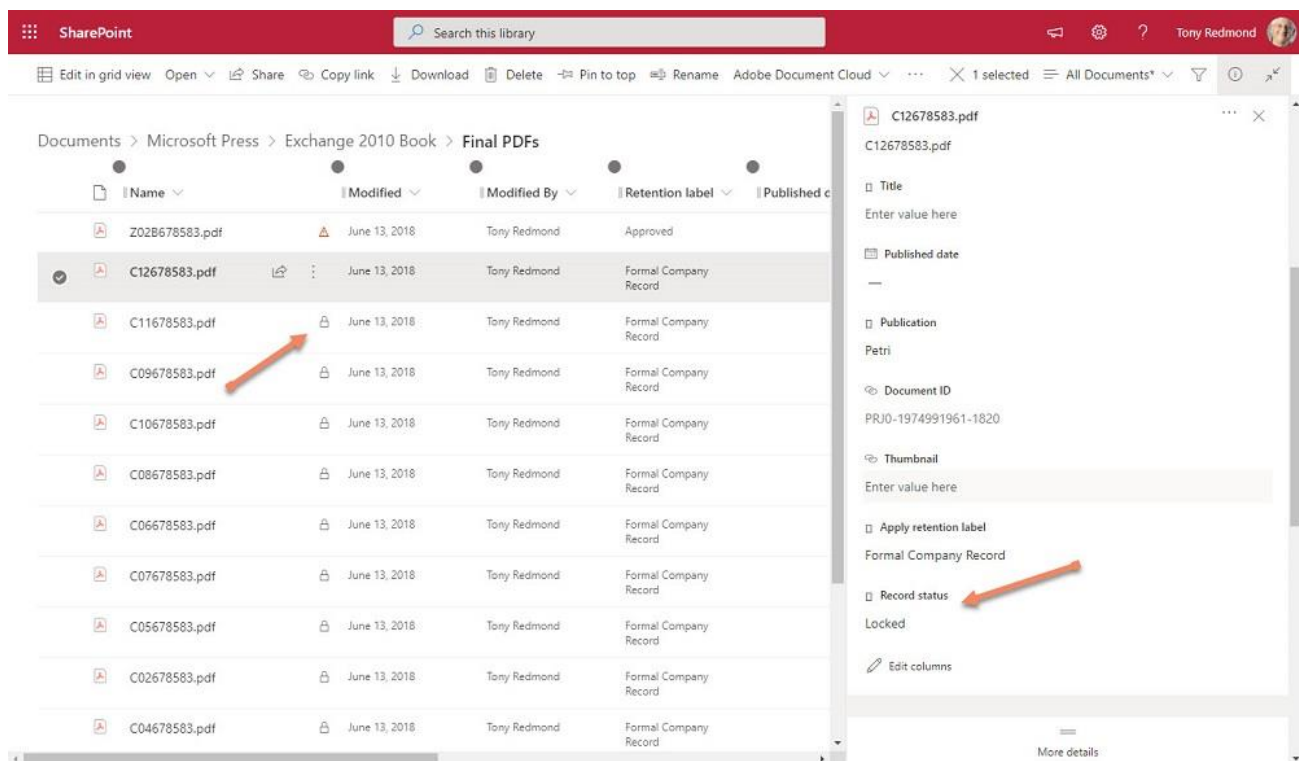

Figure 17-21: Documents in a SharePoint library marked as records

Although users need Office 365 E5 or Microsoft 365 E5 licenses to access the Records Management section in the compliance portal, any SharePoint Online or Exchange Online plan allows users to apply record labels to items. From a user perspective, after an item has a record label, it cannot:

- Permanently remove the item. If you try to remove an Exchange item labeled as a record, Exchange copies the item to the Recoverable Items structure and keeps it there until its retention period expires. If you try to remove an item marked as a record in SharePoint, an error is flagged, and the item is unchanged. If someone tries to remove a record from a OneDrive for Business account, OneDrive for Business moves the item into the preservation hold library where it remains until its retention period expires.

- Edit a locked item. Users can unlock an item assigned a record label and edit its content, but those assigned a regulatory record label cannot.
- If the assigned label is a regulatory record label, item metadata cannot be updated.
- Change or delete the label. A site administrator can remove a record label, but no one can remove a regulatory record label.

Only users can assign record labels to items. You cannot use an auto-label policy to apply regulatory record labels to items.

Owners of OneDrive for Business sites can apply and remove record labels to any item under their control. They can also remove items marked as records. However, for SharePoint content, while site members can apply a record label to an item, only the site administrator or a global administrator can change the label or update the properties of the item when it has a record label.

The implementation of regulatory record labels within Exchange differs from that used by SharePoint Online and OneDrive for Business. Browser interfaces interact directly with the server while Exchange must support the synchronization model that enables Outlook desktop clients to work offline for extended periods. After applying a regulatory record label to a message, a certain window of time is available to change the label. The window accommodates Outlook's synchronization model and the need to update the new label status across multiple clients. After a few minutes, the window closes, and no further change is possible. Also, when you apply a record label to an Exchange folder, all the items stored in the folder automatically become records, even if the user later moves some or all the items out of the folder. When an Exchange item is tagged as a regulatory record, Outlook clients block deletion of the item. However, users can move messages tagged as records between folders in the mailbox.

See this [white paper](#) for more information about the ability of Microsoft 365 to meet various regulations applicable to financial bodies through the use of record labels and other mechanisms.

**Audit records for Records Management:** When you apply a record label or a regulatory record label to an Exchange item, Exchange writes an *ApplyRecord* event into the audit log. This event comes from mailbox auditing, so it's not captured for the application of labels to SharePoint or OneDrive content using the browser interface. In these situations, SharePoint Online captures a *TagApplied* event, as it does for the application of any retention label. Note that SharePoint Online does not generate *TagApplied* events when new documents receive the default label assigned to a library. To find events for the assignment of record labels and regulatory record labels to documents and list items, you must search the audit log for *TagApplied* events and then examine the *AuditData* property of the events to look for those associated with record labels. See Chapter 21 for more information about how to find data in the audit log. As [explained in this blog](#), it's also possible to use Microsoft Search to find items tagged as records in both a locked and unlocked state.

## Processing Manual Dispositions

Retention labels are good for marking content for retention or removal, however, sometimes you do not want an automated process to function without supervision. For instance, you might have a label to mark documentation for customer projects. Usually, projects finish in a few months, and it is certainly safe to remove the associated documentation after five years. However, in some more complex or extended projects, you need to keep files for longer. A label that removes all documents classified as project documentation after five years would not work. The same might be true for items that the company might need for litigation or audit purposes.

As described in this [SharePoint blog from 2006](#), manual disposition is not a new idea. Microsoft 365 manual disposition allows retention labels to mark content for manual disposition from all workloads covered by data

governance instead of just SharePoint. For now, Microsoft has enabled “Disposition Review” for items in SharePoint Online, OneDrive for Business, Exchange Online, and Microsoft 365 Groups. Support for other workloads might come in the future.

Manual disposition means that human intervention is necessary to check expired content to decide if the business still needs the items or if the deletion (disposition) can happen. A workflow notifies one or more expert reviewers, nominated because they have the skills needed to recognize content that the organization should retain for longer when they examine items with expired retention periods. The expert then decides to approve the removal of items or to extend their retention. Disposition can happen through a single review, or items can progress through up to five review stages with different reviewers processing items at each stage. The reviewers defined for each stage are individual accounts or mail-enabled security groups.

Background processes for each workload scan to detect expired items for manual disposition. When items await disposition, the compliance portal sends mail notifications to the reviewers defined in the retention label settings to tell them that content awaits their decision. Items remain in the awaiting disposition stage until a reviewer decides about their future. Reviewers also receive weekly reminders about items waiting for disposition. If a retention label uses multi-stage disposition, items processed in one stage pass to the next stage and so on until the last stage is complete.

Reviewers must have accounts with cloud mailboxes in the tenant. They should also be members of two compliance role groups:

- **Records management:** Members of this role group (containing the Disposition management role) have access to the disposition section of records management within the compliance portal.
- **Content explorer content viewer:** Members of this role group (containing the Data classification content viewer role) can view the content of items awaiting disposition. Members of the record management role group can see the details and history of items, but not the content.

If you wish, you can create a new role group and assign the necessary roles and members to that group. For instance, you might decide that it's a good idea not to grant access to the other features enabled for members of the Records management role group, like being able to customize the messages sent to reviewers. In this situation, you create a new role group and include only Disposition management and (optionally) the Data classification content viewer roles.

In addition to making decisions about keeping or removing items, the review process helps organizations understand whether people apply labels correctly. For instance, if you see documents stamped with inappropriate retention labels, you might ask why people use labels in error and then take steps to update procedures or change behavior.

## How to Dispose of Items

When items marked with a label that triggers the manual disposition process reach the end of their retention period, background processes mark the items as being available for manual disposition. For example, when the Managed Folder Assistant processes mailboxes, it detects messages that need manual disposition and copies these items to a special hidden mailbox. Reviewers then process the items in this mailbox. When a reviewer decides how to dispose of an item, Exchange replicates the action taken for the item in the hidden mailbox and back to the source mailbox. The need for workloads to process items before the compliance portal recognizes them as being ready for manual disposition means that it can take a little time between the retention period for an item elapsing and that item showing up in the list of items awaiting disposition.

Those specified as reviewers in the label settings receive email notifications about items waiting for disposition. The reviewers can go to the **Disposition** section under **Records management** in the Microsoft Purview Compliance portal to see the items they should review, grouped into the items tagged with each label. Reviewers only see the items they can review while compliance administrators can see all items waiting

for review. To process the items, select a retention label and then the *Open in new window* icon to see the waiting items. In the review window, the compliance portal selects *SharePoint and OneDrive* as the source and loads the items awaiting disposition. If necessary, you can apply a filter (like a date range for item expiration) to refine the set of items shown. If email messages are awaiting disposition, you can see the messages by choosing *Exchange* in the Source filter. Figure 17-22 shows a set of messages waiting for disposition. Note that you can see messages shown in a set of SharePoint and OneDrive items. For instance, this can happen when messages are in SharePoint document libraries because someone sent them via email to a Teams channel.

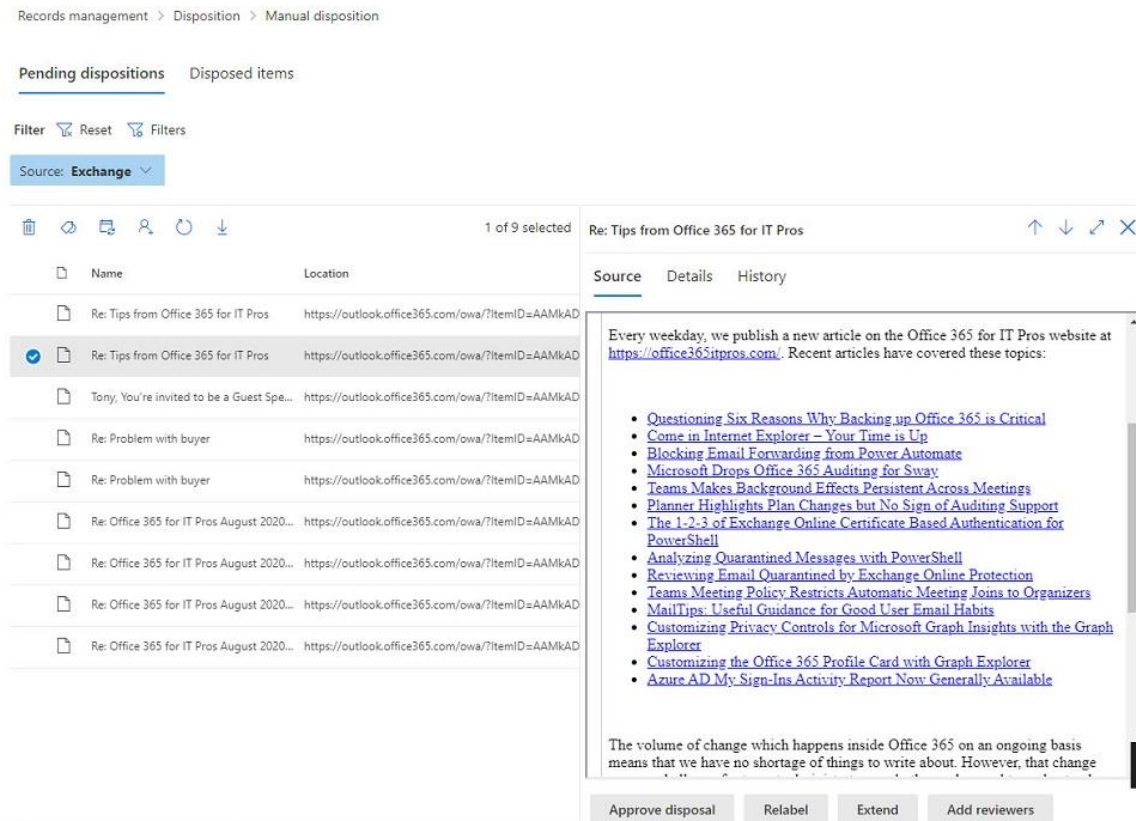

Figure 17-22: A set of messages marked for manual disposition

After selecting an item waiting for disposition, you can:

- **Approve disposal (Delete permanently):** The organization no longer needs this content. When a reviewer approves an item for final deletion, the compliance portal releases the block on the deletion and logs the action in an *ApproveForDelete* audit record. The workload-specific jobs that remove expired items delete the items the next time they process the host location. If the item is in a document library when its retention period expires, marking it for deletion means that the item goes into the first stage Recycle Bin within 7 days of the disposition decision. On the other hand, if the item was already deleted and is in a site's Preservation Hold library, it is eligible for immediate deletion and will be removed following the normal disposal cycle. The audit log captures the actual file deletion in a *Deleted file* or *Deleted file from the second-stage recycle bin* audit record. The delay in deletion is because of the need to run background jobs to process the disposition decisions.
- **Relabel:** The organization should keep this content by applying another retention label to the item. The other label might not have a retention action or a longer retention period.
- **Extend:** Leave the original label on the item but extend the retention period to a specific date (a one-year extension is the default period) after which the item goes through the review process again. This action overwrites the computed retention date for the item with the retention date selected by the

reviewer. The compliance portal captures details of the extension in an *ExtendRetention* audit record. The audit record does not include the new retention date.

- **Add Reviewers:** Add other people who need to review the content to decide on its disposition. These people must have the necessary permissions to access record management.

You can also export the set of items waiting for disposition to a CSV file.

If the reviewer has access to a document's location, they can use the link to view the content. The compliance portal creates the link when the item becomes eligible for manual disposition, and if the item is subsequently deleted or moved the link is invalid. A document might be in a different folder or a preservation hold library, while a message might be in Deleted Items, Recoverable Items, or another folder. A reviewer might want to understand the full context of an item before authorizing its deletion, and if they don't have access to its location (or the link doesn't work), they must consult with the location's owners to decide on its disposition.

Items that a reviewer extends or relabels remain in their original location, or if they were moved into the Recoverable Items folder or preservation hold library, they are moved from there back to their original location.

A busy tenant can generate a heavy workload of review items if disposition review is the norm rather than an exception. For this reason, users should receive training about when they should apply labels that trigger reviews. Reviewers also need the training to understand how to deal with items awaiting their attention so that they know when they can authorize deletion or when they need to seek further guidance from the business about how to handle items.

## Disposed Items and Proof of Disposal

Reviewers can see details of Items that they or other reviewers previously authorized for deletion by selecting the **Disposed items** tab. This view only shows items that reviewers approved for deletion. It does not show items where the reviewer decided to apply a different label or extend the retention period. Items don't show up disposed until the underlying workload has processed the deletion. Because of the reliance on background processes, it might take a couple of days between a decision to delete an item and its appearance in the dispositions list.

Sometimes organizations need to show evidence of the removal of items. To meet this need, Office 365 retains details of all delete dispositions. You can download a CSV file containing details of these operations using the Export option under Disposed Items, using the filters to decide to download documents or messages and the time range for the download. Each line in the file notes the deletion of an item, including:

- Location.
- Title or Subject.
- Retention Label.
- The user principal name of the user who authorized the deletion.
- The timestamp when the deletion occurred.

According to Microsoft, the compliance portal can log up to one million disposal operations.

## Records Management Settings for Disposition

The settings on the Record management page allow members of the records management role group to:

- Define a mail-enabled security group for record managers allowed to see awaiting dispositions for all retention labels. Normally, a member of the records management role group sees only the dispositions assigned to them.
- Define additional text to include in the email notifications reviewers receive to let them know when items await their attention. You can't change the default text and can only add text that appears after

the default text. For instance, you could add text to inform reviewers how to find company guidelines for disposition reviews.

You can also define the mail-enabled security group for record managers to see all disposition reviews using the *Enable-ComplianceTagStorage* cmdlet. Connect to the compliance endpoint and pass the email address of the security group as the parameter:

```
[PS] C:\> Enable-ComplianceTagStorage -RecordsManagementSecurityGroupName Compliance.Records.Managers@office365itpros.com
```

Allowing people to see all items waiting for disposition review is a highly permissioned capability. As such, the compliance portal doesn't support changing it through the GUI. Instead, if you need to make a change, run the *Enable-ComplianceTagStorage* cmdlet again to update the setting with the email address of a different mail-enabled security group.

The *Get-ComplianceTagStorage* cmdlet returns details of retention label (aka compliance tag) management settings. To see the email address of the group defining record managers with full access to disposition reviews, type:

```
[PS] C:\> (Get-ComplianceTagStorage).RecordsManagementSecurityGroupName
```

## Event-based Retention

Labels normally use age-based retention periods and invoke retention actions based on the creation or last modified date of the content. Event-based retention takes a different approach and waits until a specific event occurs before starting the retention countdown for items. For instance, let's assume that you want to preserve all project documents for seven years after a project completes. The event is the project completion, which the project manager might have to sign off. The retention period begins as soon as the event occurs.

Because it depends on something happening rather than just the passing of time, event-based retention is more complex than date-based retention. Here is the general flow of what happens:

1. The administrator creates a new label and selects "an event" as the decision point for the retention period rather than the usual "date created" or "date modified" as used with other labels.
2. The administrator selects an event type (which must already exist) to associate with the label. An event is something like, the expiration of a contract or the departure of an employee, or any other common occurrence in the life of a business. A set of pre-packaged event types are available, but you can create new event types if needed.
3. After saving the label, the administrator includes it in a label policy and publishes the policy to make it available to end-users. After an hour or so, the label is available to SharePoint and OneDrive for Business. It takes a little longer for the label to appear in Exchange.
4. Users apply the label to content that they want to link with the event. For example, they might look for the set of documents belonging to a contract and apply the label to those documents.
5. When they apply the label, users also give a value to a field called "Asset ID," which is part of the standard SharePoint Online schema. A label for an event type is reusable across many different events, so a mechanism is necessary to isolate the content belonging to a specific event. The Asset ID is used to identify individual projects, tasks, or other entities. For instance, if the event deals with the departure of an employee, the Asset ID might hold the employee's number. The Asset ID must be populated correctly because this is the value used to find content associated with an event. You can find out what items are stamped for a specific event by using SharePoint search or content searches to look for the *complianceassetid* tag. For example, find items with *complianceassetid:PK1*.
6. When an event occurs, like an employee leaving or a contract reaching its end, the administrator goes to **Events** under **Records Management** in the Microsoft Purview Compliance portal and creates a

new event to trigger compliance processing. They select the event type to use or choose an existing label configured for event-based retention used to classify items. To find the items for the event, they input the associated Asset ID (for SharePoint and OneDrive items in the form *complianceassetid:<value>*) and/or keywords to locate Exchange items. If other keywords are necessary to find the relevant items, they can be added at this stage (for instance, a tenant might already have assigned a different form of asset identifiers to project documentation). Finally, they select the date the event happened and save the event.

7. Background processes now start looking for content matching the event in SharePoint, OneDrive for Business, and Exchange (in effect, a content search is run). As the search finds matching items, the retention action and period specified in the label are applied to the items. Once the items are stamped, normal retention processing begins. For instance, if the label states that items should be kept for five years, the items are kept for five years after the event date. It can take up to a week before the background processes find all matching content across workloads.

Once created, you cannot update an event, so you should be sure that everything is ready to find the items relating to an event when you create it. In addition, once you associate a label with an event, you cannot change the label to associate it with a different event. For these reasons, it is important to have a good understanding of the business events that occur within the tenant and how people working in the business can use labels to aid the processing of content associated with using event-based labels. For more information about event-based retention, see the [Microsoft documentation](#).

## Removing Retention Labels

Four scenarios occur for removing retention labels from a tenant:

- **A label is created, but not published.** Because the label is not in use, you can edit the label in the Microsoft Purview Compliance portal and remove it with the **Delete label** option. Alternatively, run the *Remove-ComplianceTag* cmdlet.

```
[PS] C:\> Remove-ComplianceTag -Identity "Bad Label"
```

- **A label is published in one or more policies but has never been assigned to items.** If you try and remove the label, you'll see an error that the label is in use. This is technically correct because the label is in a policy even a user or policy never assigned the label to any items. To remove the label, you first remove it from all the policies it is included in (or remove a complete policy if the label is the only one in that policy). After removing the label from all policies, you can remove the label as described above.
- **A label is in active use and applied to content.** You can run a content search to find all the items that have the label (find a compliance tag equal to the label name) and remove the label from the items. This works when a label is recent and only applied to a small number of items but is unreasonable in a tenant of any size. Instead, you can follow the procedure as if the label was never assigned to any items by removing it from all policies and then removing the label in the Microsoft Purview Compliance portal or using PowerShell. The label then goes into a pending deletion state, meaning that some background processes in the different workloads must run to remove the label from items. A background timer job removes labels from SharePoint Online and OneDrive for Business documents and the process can take several hours to complete. For Exchange, the Managed Folder Assistant removes labels from mailbox items; it might take up to a week before the assistant processes a mailbox. Once the Managed Folder Assistant removes a label from an item, the item becomes a potential target for the assignment of another label by any other retention policy applying to the mailbox.

- **A label is a record.** As noted above, an item assigned a record label cannot be changed. You cannot remove any label marked as a record (even if the label has never been assigned to an item), but you can stop people from using it again by removing the label from any policies that it is in.

Removing labels is not something to do at a whim. The complexities involved in removing labels that are applied to content underline the need for planning and preparation for the deployment of labels as part of your data governance strategy. Removing labels from items can result in their deletion by background processes because their retention period has expired, so if you remove a label from content, you might need to replace those labels with different labels to ensure the retention of the items.

## Data Classification Dashboard

Retention labels have existed for several years. Sensitivity labels were the next step. Over time organizations are likely to accumulate a reasonable amount of labeled material. But how does a compliance administrator know that their data governance strategy is effective, that users apply labels as intended, and that the right information is protected? Microsoft's response is the Data classification dashboard (Figure 17-23) in the Microsoft Purview Compliance portal. The dashboard contains some useful statistics about where and what labels are in active use and has the following sections:

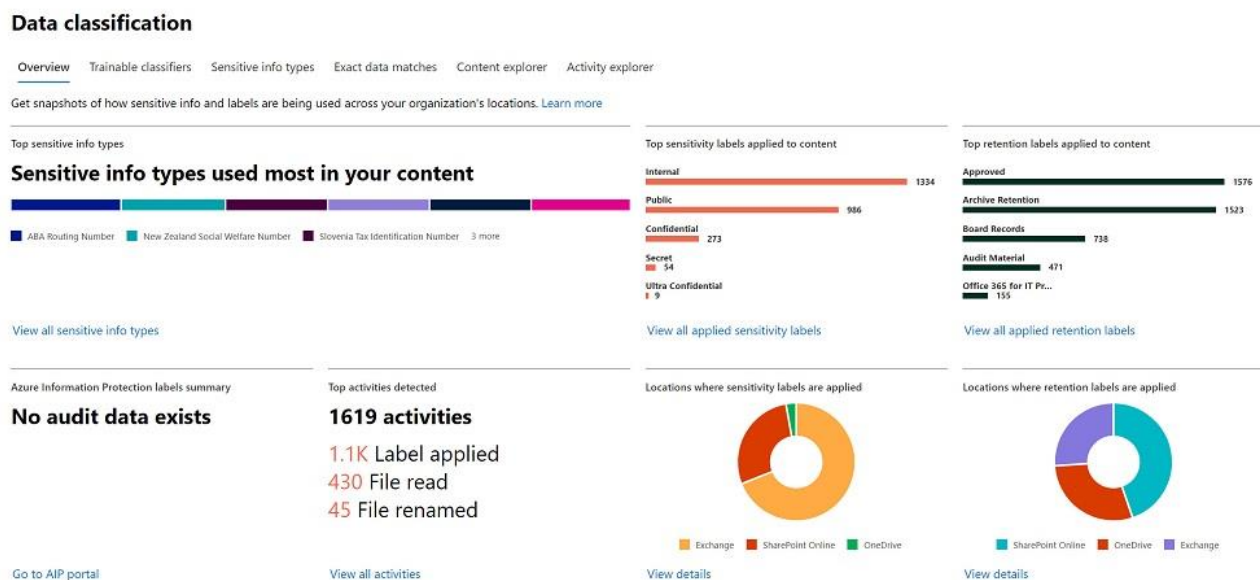

Figure 17-23: Data classification dashboard

- **Overview:** Displays the sensitivity and retention labels are in use and in what workload use the labels. The dashboard also highlights sensitive information types found in documents and messages.
- **Trainable classifiers:** This feature allows tenants to build custom sensitive information types by [using AI training based on a set of examples](#). Microsoft's default classifiers include document types like resumes and source code and classifiers used to detect objectionable behavior like profanity and threat.
- **Sensitive Info types:** Lists the sensitive information types known in the tenant, including the default set (over 200) created by Microsoft and those created by the tenant through digital fingerprinting, dictionaries, or simple rule matching.
- **Exact data matches:** The regular sensitive information types used in Microsoft 365 match items using generic patterns, an approach that works well for document-centric information. As the name implies, [exact data matches \(EDM\)](#) use more precise matching and are more suitable for structured data. This

option allows administrators to define EDM schemas and use those schemas to build custom sensitive information types.

- **Content Explorer:** Allows compliance administrators to see where retention and sensitivity labels are applied in Exchange Online, SharePoint Online, and OneDrive for Business. To view the locations where labels are applied, the user must hold the *Content Explorer List Viewer* permission; to view the source content of items in those locations, their account must hold the *Content Explorer Content Viewer* permission.
- **Activity explorer.** Shows usage data for both sensitivity and retention labels.

The overview is available with an Office 365 E3 license. Organizations need to have Office 365 E5 or Microsoft 365 E5 compliance licenses to use the content explorer, activity explorer, and trainable classifiers.

## Content Explorer

The content explorer is especially useful in validating the effectiveness of label usage. The explorer allows administrators to see how users and policies apply retention and sensitivity labels and the type of content users apply labels to. For example, let's assume that you define a retention label for formal company records with a ten-year retention period. You probably don't want this label applied to run-of-the-mill documents and messages, and the content explorer allows you to see what's in the labeled items to check if the content is as valuable as the label implies.

The downside of the content explorer is its access to any user information in a SharePoint Online site, OneDrive for Business account, or Exchange Online mailbox. Although compliance administrators can use other features to access user data (a content search, for instance), because the content explorer organizes items by label, it's easy to find information labeled as being the most confidential or valuable to the organization and then peruse the content (items protected with sensitivity labels with encryption can't be opened by content explorer). For this reason, it's wise to make sure that the only people with the permissions needed to use content explorer are those who must have it to perform specific operations, and then remove those permissions once the need passes.

## Activity Explorer

The Activity Explorer displays information about the application of retention and sensitivity labels to content in Exchange Online, SharePoint Online, and OneDrive for Business to help compliance administrators understand the use of labels within the organization. Data flows through to the Activity Explorer when sensitivity and retention labels are applied using Office Online, desktop (Microsoft 365 apps for enterprise), and mobile apps. Using a 30-day sliding window, the explorer gives an insight into:

- How labels were applied (manually by a user or by policy).
- Who applied, changed, or removed a label, including labels applied by an auto-labeling policy. If a user or policy changed a label on an item, you see details of the old and new labels. Details of labels applied by endpoint monitoring are also available.
- The location (Exchange Online, SharePoint Online, including OneDrive for Business).
- The target document or folder (the data does not show labels inherited by files from a label assigned to a folder).

You can filter by date range, label activity (all actions or just label changes, removals, or applications), user, workload, or specific label to focus on a specific activity. To see added information, click on an individual record to open the details pane. Sometimes it's good to create your view on this data. Chapter 21 includes an example of using PowerShell to extract and interpret audit records logging how users assign retention labels. Chapter 20 covers the capture of audit records for sensitivity labels.

## Trainable Classifiers

A [trainable classifier](#) is a digital map of a defined category of documents such as a customer invoice, order form, or personnel review. Microsoft 365 includes a set of built-in classifiers (created by Microsoft) such as HR, Healthcare, Legal Affairs, and Threat for use out-of-the-box. The pre-trained classifiers are available in English, Spanish, Japanese, French, German, Portuguese, Italian, and Chinese (simplified).

Organizations can create custom trainable classifiers by going through a training process. The major steps in the process are:

- Define the kind of information you want the trainable classifier to recognize. For example, you might want to create a trainable classifier that recognizes financial reports in a specific format.
- Assemble a set of sample documents for the training process to scan and build a digital picture using machine learning. The set acts as seed content for the classifier and should include between 50 and 500 “positive” samples available on a SharePoint Online site. Leave the content on the site for a day or so to allow indexing to happen before creating the classifier. By analyzing the seed content, the classifier builds a prediction model (the digital picture) to allow it to recognize documents of the same type when it processes them in the future. The more representative the seed content is of real-life documents, the more accurate the prediction model is likely to be.
- Test the classifier to see how it performs when it processes real content and tweak it if necessary. The seed set might require a refresh to introduce new examples to help the classifier refine its prediction model. During this phase, compliance administrators help the refining process by marking files identified by the classifier as good or bad matches. The aim is to increase the percentage of good matches to as close to 100% as possible.
- Publish the classifier to make it available for use with Microsoft Purview compliance solutions. If you discover that the classifier does not work well in production and retraining the prediction model with feedback does not improve its accuracy, you might need to withdraw (delete) the classifier and restart the training process with a new set of sample documents, including samples not detected by the previous iteration of the classifier. For this reason, use new trainable classifiers in limited policies (for instance, against a small number of SharePoint sites) and monitor its results closely until the classifier works as expected.
- Over time, monitor the items matched by the classifier and mark them as good or bad matches. The prediction model incorporates received feedback from administrators into new, hopefully, more accurate, versions. The caveat here is that feedback is only valuable when compliance policies use a trainable classifier to detect content. If this is not the case, retraining to take account of feedback is useless.

Machine learning takes time, and you cannot rush the creation of the prediction model for a trainable classifier. The entire end-to-end process from assembling the sample document set to publication might take several weeks before the classifier is accurate enough for production use (98% or better). After publishing the classifier, it becomes available to find items in:

- Communications compliance policies.
- Data Loss Prevention policies.
- Auto-label policies for sensitivity labels and retention labels.
- The Content explorer.

Trainable classifiers require Office 365 E5 or Microsoft 365 E5 Compliance licenses. See [this page](#) for more information.

# Ingesting Items for Review from External Sources

Companies that need to supervise employee communications need coverage over more than just email. Employees can conduct business using a variety of consumer and business services including Twitter, Facebook, Bloomberg, HipChat, Thomson Reuters, and BlackBerry messaging. To cater to the problem, Microsoft has signed deals with [third parties](#) who specialize in the extraction of data from different communication systems to create connectors to extract data from those systems and ingest the data into Microsoft 365. The basic approach is:

- A connector from a selected partner (like Actiance or ArchiveSocial) connects to the source data using whatever API is available. The connection runs on a scheduled or ongoing basis to find and extract data of interest.
- The connector uses Exchange Web Services to connect to an Azure endpoint for the ingestion of data into Exchange Online.
- Data flows across the connector to either:
  - User mailboxes, if a match exists between the identifier used by Exchange Online (usually the User Principal Name) and the identifier used by the source service. For instance, if the corporate Twitter account logs in as TwitterService@tenant.com and an Azure AD account exists with the same identifier, a match exists, and the data extracted from Twitter goes to that mailbox. Because you do not want someone to be able to access the information brought in via the connector, the items go into the Purges folder within Recoverable Items. The items are indexed and discoverable but invisible to anyone who logs into the mailbox.
  - Connector mailboxes are set up explicitly as a target for data ingested into Exchange Online through a connector. In this case, the items go into the Inbox folder because someone usually needs to check the items and decide where to keep the items over the long term.
- As items flow into Exchange Online through the connector, a separate set of agents watch the Exchange Web Services traffic to apply communications compliance policies.

When the data reaches Exchange Online, the imported items are indexed as normal and the content they hold is discoverable and usable by other data governance features. You can apply the data governance policies that exist within the tenant. In other words, you can assign retention policies to the mailboxes used by the connectors to ensure that you keep the ingested content for the desired retention period, including the mailboxes in content searches and eDiscovery cases, and so on.

## Microsoft Connectors for Third-Party Data

Microsoft supports methods to import information from third-party sources into Exchange Online where the third-party information is then subject to data governance functionality. Many connectors are currently available including popular social media feeds like:

- **LinkedIn:** Import information from a [company's LinkedIn page](#).
- **Facebook:** Import information from a [Facebook business page](#).
- **Twitter:** Import tweets sent and received from a [company's Twitter account](#).

Preview versions of other connectors are also available. In general, connectors work by extracting information from the target source and creating items in an Exchange Online mailbox as described above.

# Using PowerShell with Retention Labels and Policies

A set of cmdlets is available to manage labels and retention policies. To access the cmdlets, you must connect a PowerShell session to the compliance endpoint after connecting to the Exchange Online endpoint:

```
[PS] C:\> Connect-ExchangeOnline
Connect-IPPSSession
```

It is not the intention to have a detailed and in-depth discussion of all the cmdlets here as it would occupy too much space. In any case, given the complexity of some of the operations involving compliance, it is usually best to create and update policies and labels through the GUI.

## Working with Retention Labels

The *\*-ComplianceTag* cmdlets manage retention labels. In this example, we extract the set of retention labels defined in a tenant and list the most important properties of each tag to understand the purpose of the tag: to mark an item as a record, has a retention action, the retention duration (in days), the retention action, and if it is in use.

```
[PS] C:\> Get-ComplianceTag | Format-Table Name, IsRecordLabel, HasRetentionAction,
RetentionDuration, RetentionAction, Mode -AutoSize
```

Name	IsRecordLabel	HasRetentionAction	RetentionDuration	RetentionAction	Mode
Confidential	False	True	1825	Keep	Enforce
Remove after 1 week	False	True	7	Delete	Enforce
Patent Materials	False	True	7300	Keep	Enforce
Board Records	False	True	Unlimited	Keep	Enforce
Formal Company Record	True	True	7300	KeepAndDelete	Enforce

Labels marked as regulatory records can be found by examining the *Regulatory* property.

```
[PS] C:\> Get-ComplianceTag | ?{$_.Regulatory -eq $True} | Format-Table Identity, Notes
```

Identity	Notes
Regulatory Record (Legal)	A legal regulatory record

The *New-ComplianceTag* cmdlet creates a new retention label. In this example, we create a retention label to keep content for ten years. This retention label does not mark content as a formal record.

```
[PS] C:\> New-ComplianceTag -Name "Patent Information" -IsRecordLabel $False -RetentionDuration 3650
-RetentionAction Keep -Comment "Items marked with this classification are associated with patents"
-RetentionType ModificationAgeInDays
```

The *Set-ComplianceTag* cmdlet updates the properties of a retention label while the *Remove-ComplianceTag* cmdlet removes a label from a tenant. For example, this command sets the retention duration for the "Patent Materials" label to 15,000 days (the maximum is 24,855):

```
[PS] C:\> Set-ComplianceTag -Identity "Patent Materials" -RetentionDuration 15000
```

The audit log captures changes made to retention tags with the *SetComplianceTag* event. Updates to retention policies generate *SetRetentionCompliancePolicy* events for updates to policy settings and *SetRetentionComplianceRule* events for changes to rules belonging to policy rules, like updating the retention period.

## Working with Retention Policies

Retention policies use a parent/child structure. The parent is the policy itself and the child is the set of rules that implement the policy settings. Another way of thinking about this is that the parent for a policy defines the overall data to which the policy applies while the rules govern the application of a policy. It is a little simpler than it seems because a 1-to-1 relationship usually exists between retention policies and retention rules (including label policies). The Compliance portal hides the links between retention policies and rules, but the connection needs to be understood when we manage retention policies through PowerShell. Two cmdlet sets are used:

- The *\*-RetentionCompliancePolicy* cmdlet set manipulates retention policies. Use these cmdlets to manipulate the workload locations to which a policy applies or to enable or disable a policy.
- The *\*-RetentionComplianceRule* cmdlet manipulates the rules for retention policies. Use these cmdlets to work with properties such as the retention duration of a policy.

When you fetch details of retention policies with the *Get-RetentionCompliancePolicy* cmdlet, the set returned includes policies used to:

- Apply retention settings to workloads and policies.
- Publish retention labels to workloads.
- Publish sensitivity labels to workloads.

Not all the retention policies in a tenant publish retention labels to workloads. The *Get-RetentionCompliancePolicy* cmdlet returns all the policies used for retention labels. Here is some code to find the set of retention policies used to publish retention labels and then tell us what retention labels are in each policy:

```
[PS] C:\> $Policies = (Get-RetentionCompliancePolicy -RetentionRuleTypes | ? {$_.RetentionRuleTypes
-eq "Publish"})
ForEach ($P in $Policies) {
    Write-Host "Processing" $P.Name
    $Tag = $Null
    $Rules = (Get-RetentionComplianceRule -Policy $P.Guid)
    ForEach ($R in $Rules) {
        If (-Not [string]::IsNullOrEmpty($R.PublishComplianceTag)) {
            $Tag = $R.ComplianceTagProperty -Split(",")
            $TagValues = Get-ComplianceTag -Identity $Tag[0]
            Write-Host $P.Name "includes the retention label" $TagValues.Name }
    }
}
Processing Company Confidential Policy
Company Confidential Policy includes the retention label eBook Content
Company Confidential Policy includes the retention label Contractual Information
Company Confidential Policy includes the retention label Confidential...
```

*Get-RetentionCompliancePolicy* does not return all retention policies. Microsoft regards the retention policies for Teams private channels and Yammer conversations as “app specific” policies and the cmdlet does not return details of these policies (compliance records for conversations from Teams shared channels are in the mailboxes of channel members). Instead, you must fetch details of app specific policies using the *Get-AppRetentionCompliancePolicy* cmdlet, which behaves in the same way as *Get-RetentionCompliancePolicy* does. There’s some obvious inconsistency here because Microsoft doesn’t treat the retention policies for Teams (regular) channels and chats as app specific.

### Retention Rule Types

The *RetentionRuleTypes* property of a policy tells us what kind of policy an individual retention policy is. To see this information, you must return the policy type by including the *RetentionRuleTypes* parameter in the call to *Get-RetentionCompliancePolicy*. For example:

```
[PS] C:\> Get-RetentionCompliancePolicy -RetentionRuleTypes | Sort RetentionRuleTypes | Format-Table
Name, RetentionRuleTypes
```

Three values report the types of retention policies:

- **Apply:** The policy uses advanced settings (like a keyword search) to find the content to which it applies labels. These are also known as auto-label policies.
- **Default:** The policy publishes retention settings to workloads (static or adaptive policies).
- **Publish:** The policy publishes labels to workloads.

## Fetching Retention Policies

To fetch the properties of an individual retention policy, run the *Get-RetentionCompliancePolicy* cmdlet:

```
[PS] C:\> Get-RetentionCompliancePolicy -Identity 'GDPR Personal Data' -DistributionDetail | Format-List
ExchangeLocation, SharePointLocation, OneDriveLocation, ModernGroupLocation, TeamChatLocation, TeamChannelLocation, Workload, Enabled, Mode, RestrictiveRetention, DistributionStatus
```

```
ExchangeLocation      : {All}
SharePointLocation    : {All}
OneDriveLocation      : {}
ModernGroupLocation    : {}
TeamChatLocation      : {}
TeamChannelLocation   : {}
Workload               : Exchange, SharePoint, OneDriveForBusiness, ModernGroup
Enabled                : True
Mode                  : Enforce
RestrictiveRetention  : False
DistributionStatus     : Success
```

We can interpret the output as follows:

- **ExchangeLocation:** Lists the names of the mailboxes covered by the policy. If All, it means that all mailboxes are covered (the same is true for the other locations).
- **SharePointLocation:** Lists the SharePoint Online sites covered by the policy.
- **ModernGroupLocation:** Lists the aliases for the Groups covered by the policy.
- **OneDriveLocation:** Lists the OneDrive for Business locations covered by the policy.
- **TeamChatLocation:** Lists the locations for personal and group chats covered by the policy.
- **TeamChannelLocation:** Lists the Teams (all channels) covered by the policy.
- **Workload:** Lists the workloads where the policy is active. In this case, Exchange Online, SharePoint Online, OneDrive for Business, and Microsoft 365 Groups.
- **Enabled:** Tells you whether the policy is active or not. The default is *\$True*, but if a policy has been disabled for some reason, this value is *\$False*.
- **Mode:** If "Enforce", the policy is active.
- **RestrictiveRetention:** The default is False, meaning that the policy can be changed. If True, a preservation lock exists on the policy, meaning that administrators can only make limited changes to the policy.
- **DistributionStatus:** *Success* means that the different workloads have the information needed to enforce the policy settings. *Pending* means that Microsoft 365 is distributing details of a policy change to workloads. Any other value shows that a problem has occurred in the policy distribution. Sometimes this happens for good reason, such as a change occurring in a data center. If you see problems when distributing labels to certain locations, it might be possible to figure out where the problem lies by examining the *DistributionResults* property for the policy. You won't see the current distribution status or any errors unless you include the *DistributionDetail* parameter (see example below).

If you see "All" listed as a value for a workload, it means that the policy covers every location supported by that workload. For example, "All" listed in *ExchangeLocation* means that the policy covers every Exchange

mailbox in the tenant. You can exclude specific mailboxes or sites in a workload from the policy. If this is the case, you will find a list of those locations in the properties *ExchangeLocationException*, *SharePointLocationException*, and so on.

To find retention policies using adaptive scopes, check the value of the *IsAdaptivePolicy* property:

```
[PS] C:\> Get-RetentionCompliancePolicy -Identity "Retention Policy for French IT Architects"
-DistributionDetail | ? {$_.IsAdaptivePolicy -eq $True} | Format-List Name, IsAdaptivePolicy,
AdaptiveScopeLocation
```

```
Name                : Retention Policy for French IT Architects
IsAdaptivePolicy     : True
AdaptiveScopeLocation : {French IT Architects, Executive Mailboxes}
```

Retention policies for Teams private channel messages use the *ExchangeLocation* property to indicate the set of locations (compliance records for these messages are in Exchange mailboxes). The *Applications* property is set to **User:MicrosoftTeamsChannelMessages** to indicate the type of information the policy covers. The same approach is used for retention policies for Yammer messages. In this case, the *Applications* property holds **Group:Yammer** to indicate that the policy processes community messages and **User:Yammer** for user messages.

### Including Distribution Details

When you look at retention policies with the *Get-RetentionCompliancePolicy* cmdlet, you won't see details of the individual mailboxes or sites specified for locations, the up-to-date distribution status, or any error information unless you include the *DistributionDetail* parameter. To see details of locations or errors, you need to expand the relevant property for the location you want to examine. For example, here's how to examine details of the mailboxes to which a policy applies.

```
[PS] C:\> Get-RetentionCompliancePolicy -Identity "Senior Leadership Team" -DistributionDetail |
Select -ExpandProperty ExchangeLocation
```

```
DisplayName        : Kim Akers
Name               : Kim.Akers@Office365itpros.com
ImmutableIdentity  : f120e18f-8305-41e3-abd4-de93d4a2a493
Type               : IndividualResource
Workload           : Exchange
SchemaVersion      : 2
```

```
DisplayName        : Brian Weakliam
Name               : Brian.Weakliam@office365itpros.com
ImmutableIdentity  : aae8332a-6832-4c00-b873-6ec443c36395
Type               : IndividualResource
Workload           : Exchange
SchemaVersion      : 2
```

Here's an example of looking at retention policies that have encountered problems when distributed to workloads. Often the issue is a transient problem caused by a recipient selected for the policy being unavailable for some reason that you can fix by editing the policy to remove the recipient and then add them back again.

```
[PS] C:\> $Errors = (Get-RetentionCompliancePolicy -DistributionDetail | ? {$_.DistributionStatus -
eq "Error"})
ForEach ($E in $Errors) {
    $Results = ($E | Select -ExpandProperty DistributionResults)
    Write-Host "Policy:" $E.Name "Issue:" $Results }
Policy: Company Confidential Policy Issue: [Exchange]SMO-

```

## Retention Policy Rules

Returning to our discussion about rules, when you create a new retention policy, Microsoft 365 creates the underlying rule for the policy is created to instruct workloads on how to process content. We can see the rule for a retention policy by using the *Get-RetentionComplianceRule* cmdlet. Because policies can have similar names, passing the GUID identifying the policy makes sure that the correct information is returned. To discover the identifiers for retention policies, run the command:

```
[PS] C:\> Get-RetentionCompliancePolicy | Format-Table Name, Guid
```

If you don't want to use a GUID, pass the policy name and hope it's unique:

```
[PS] C:\> Get-RetentionComplianceRule -Policy 'Patent Materials' | Format-List ContentMatchQuery, RetentionDuration, RetentionComplianceAction, ExpirationDateOption, Workload
```

```
ContentMatchQuery      : Patent NEAR(10) claim
                        : Patent NEAR(10) prosecution
                        : Patent NEAR (10) application
RetentionDuration      : 3650
RetentionComplianceAction: KeepAndDelete
ExpirationDateOption   : ModificationAgeInDays
Workload                : Exchange, SharePoint, OneDriveForBusiness, ModernGroup
```

Some of the output (Workload in this case) matches what you see when examining the policy. The interesting pieces here are:

- **ContentMatchQuery:** The Keyword Query Language (KQL) query to determine whether items come under the scope of the retention policy. In this case, three separate tests are used.
- **RetentionDuration:** The length of time in days to retain items. You can also use "unlimited". In this case, the items remain held indefinitely until the hold set by the policy lapses or the policy is removed from the tenant. The hold duration is calculated using the created date for email items and the date last modified for files in SharePoint Online or OneDrive for Business sites.

Rule settings can be changed using the *Set-RetentionComplianceRule* cmdlet. For example, this command sets the retention duration for a rule to 3,600 days (the maximum duration is 24,855 days):

```
[PS] C:\> Set-RetentionComplianceRule -id 86f67249-74b9-48bf-8fe6-9e0c58416dfb -RetentionDuration 3600
```

Changes made to a rule will not be effective until the publication of the policy update becomes known to all the workloads. This might take a few hours.

To publish labels and make them available to workloads, we create a retention label policy and associate a rule for each label with that policy. In other words, every label published by the policy has a separate rule. Labels can be in multiple label policies and the connection between label and rule is through the label GUID. If you run the *Get-RetentionComplianceRule* cmdlet to find all the rules belonging to a policy, you can find the different labels by looking at the *PublishComplianceTag* property, which holds the GUID pointing back to the label. The rule for an auto-label policies specifies its label in the *ApplyComplianceTag* property.

## Setting Retention Policies

You can force the republication of a policy to the workloads by running the *Set-RetentionCompliancePolicy* cmdlet. For example:

```
[PS] C:\> Set-RetentionCompliancePolicy -Identity 'Patent Materials' -RetryDistribution
```

Republishing a policy to workloads only works if an error previously prevented a policy from reaching a workload. If a policy cannot be published to workloads for some reason, you should file a support incident with Microsoft.

The *Set-RetentionCompliancePolicy* cmdlet can also add or remove workload locations to the policy. In this example, we remove a mailbox and add a mailbox to the set of Exchange locations. The same approach is taken remove and add some SharePoint sites. Note that you must give the URL for each site.

```
[PS] C:\> Set-RetentionCompliancePolicy -Identity 'Patent Lock-down'
-AddExchangeLocation 'Frank Clonan' -RemoveExchangeLocation 'Rob Young'
-RemoveSharePointLocation 'https://office365itpros.sharepoint.com/Projects/'
-AddSharePointLocation 'https://office365itpros.sharepoint.com/Exchange Connections'
```

## Reporting Retention Policies Applied to SharePoint

As an example of using information about distribution detail and retention rule type to analyze or report on retention policies, let's say that you want to know what retention policies apply to SharePoint sites. The code in [this GitHub script](#) fetches information about the retention policies including their distribution detail, excluding retention policies for Teams, those that don't process SharePoint, and policies used to publish retention labels. We then examine each policy to extract the locations within the policy scope and figure out whether the retention settings are simple or advanced (using a keyword query or sensitive information type). Some policies apply to every SharePoint site, so the location is "All." Others have specific SharePoint sites defined, and some policies process everything except a set of excluded sites. The output is an ordered array. We can look at the data in different ways with PowerShell (see below) or export it to a CSV file to load into Excel or Power BI.

Policy	Site	Duration	Action
SharePoint Online Retention Policy	*Exclude* Interesting Patent		
SharePoint Online Retention Policy	*Exclude* Frank's Italian Job		
Label Customer Invoices	All SharePoint Sites	2555	Keep
SharePoint Online Retention Policy	All SharePoint Sites	2555	Keep
Preserve Office 365 for IT Pros Files	Company Communications	Unlimited	Keep
Preserve Office 365 for IT Pros Files	GDPR Planning Mark II	Unlimited	Keep
Senior Leadership Team (SLT) Retention Policy	Office 365 2020 Speakers	3600	KeepAndDelete
Office 365 for IT Pros eBook Content	Office 365 for IT Pros	3650	Keep
Preserve Office 365 for IT Pros Files	Office 365 for IT Pros	Unlimited	Keep
Preservation Lock - Mailboxes and Sites	PL Test Group	3650	KeepAndDelete
Management Presevation Policy	Projects	Unlimited	Retain

## Viewing Teams Retention Policies

Remember that a Teams retention policy can only cover Teams personal chats and channel conversations and a general retention policy applied to other locations cannot cover Teams. If you only want to work with retention policies that affect Teams, use the *TeamsPolicyOnly* parameter when fetching retention policies:

```
[PS] C:\> Get-RetentionCompliancePolicy -TeamsPolicyOnly
```

Likewise, to exclude the Teams policies, use the *ExcludeTeamsPolicy* parameter:

```
[PS] C:\> Get-RetentionCompliancePolicy -ExcludeTeamsPolicy
```

## Remove a Retention Policy

To remove a retention policy, run the *Remove-RetentionCompliancePolicy* cmdlet. Remember that you will not be able to remove a policy if a preservation lock is in place.

## Tracking Retention Holds for Mailboxes

When a non-org-wide retention policy applies an in-place hold to a mailbox, Exchange Online notes the fact by updating the *InPlaceHolds* property of the mailbox with the GUID for the hold. Thus, you can get a quick

view of what mailboxes are on hold by checking the mailbox properties for *InPlaceHolds* using PowerShell. For instance:

```
[PS] C:\> Get-ExoMailbox -RecipientTypeDetails UserMailbox -Properties InPlaceHolds | ?
{$_ .InPlaceHolds -ne $Null} | Format-Table DisplayName, InPlaceHolds
```

DisplayName	InPlaceHolds
Tony Redmond	{skp748f77b020124e6e8304e66021fb297b:3, mbx748f77b020124e6e8304e66021fb297b:3}
Kevin A. Laahs	{UniH26c5d797-0fd3-496d-92ac-4f405700c917}
Kim Akers	{mbx748f77b020124e6e8304e66021fb297b:3, skp748f77b020124e6e8304e66021fb297b:3, UniHec6...}

One reason why you might want to check the holds set on mailboxes is to find out what holds are keeping inactive mailboxes alive.

```
[PS] C:\> Get-Mailbox -RecipientTypeDetails UserMailbox -InactiveMailboxOnly -Properties
InPlaceHolds | Format-Table DisplayName, InPlaceHolds
```

DisplayName	InPlaceHolds
Holly Holt	{}
James Gangley	{mbx29550d04cffd42109bdd94cc56c65041:2}
Jodie Smith (Program Manager)	{}
Rob Young	{d9eb7052cc0f4200b6a1ad0d6f2171ed...}
Mary Smith (Customer Support)	{}
Ed Banti	{skp748f77b020124e6e8304e66021fb297b:3}

When you see an inactive mailbox shown with a null value in *InPlaceHolds*, you know that the hold on the mailbox comes from an org-wide retention policy (or an Exchange Online litigation hold) instead of a non-org-wide policy. More on this topic in a little while.

To get a full view of the holds that apply to an individual mailbox, use the *Get-ExoMailbox* cmdlet, and expand *InPlaceHolds*:

```
[PS] C:\> Get-ExoMailbox -Identity "Ben Owens" -Properties InPlaceHolds | Select -ExpandProperty
InPlaceHolds
```

```
mbx748f77b020124e6e8304e66021fb297b:3
skp748f77b020124e6e8304e66021fb297b:3
UniH47f67751-1036-4621-80d6-d25837adf813
UniHec6163be-6ed6-4b16-afe8-1b2165b9359f
UniH84dea76f-c845-4101-b066-a8b10c13c210
```

One of the holds listed applies to Skype for Business conversions (skp). Another is for mailbox contents (mbx). If you see a minus sign before an "mbx" hold, it means that a retention policy explicitly excludes the mailbox. The numeric notation following the hold identifier tells you the kind of hold it is:

- 1: The retention policy deletes items. Microsoft also uses this value for label publishing policies for retention labels and sensitivity labels.
- 2: The retention policy holds items. Microsoft 365 doesn't remove the items after the hold lapses.
- 3: The retention policy holds items and then deletes them after the retention period expires.

The holds with a "UniH" prefix are "unified holds" and belong to:

- A hold placed by an eDiscovery case created through the Microsoft Purview Compliance portal.
- A hold placed by an old preservation policy now upgraded to a retention policy.

If a hold shows up as a GUID without a prefix or it has a "cld" prefix, it belongs to an Exchange in-place hold managed from the EAC. These include holds created for mailboxes included in eDiscovery cases managed in the SharePoint eDiscovery Center. While you might come across these GUIDs, they should begin to disappear over time as workload-specific holds expire.

The GUID for a hold placed by a retention policy can be used to find which policy the hold belongs to. Take the value stored in the *InPlaceHolds* property, remove the prefix (like "mbx") and suffix (like :3), and use the value to check against the set of retention policies for the organization.

```
[PS] C:\> Get-RetentionCompliancePolicy 748f77b020124e6e8304e66021fb297b
```

Name	Workload	Enabled	Mode
Senior Leadership Team (SLT) Retention Policy	Exchange, ModernGroup	True	Enforce

We now know that the mailbox comes under the scope of the Senior Leadership Team (SLT) Retention Policy. This is a non-org wide policy that applies to selected Exchange locations (mailboxes). If we look at the *ExchangeLocation* property, we see a list of the mailboxes the policy applies to, or "All" if the policy applies to all mailboxes. For example, here's a typical entry for a mailbox.

```
[PS] C:\> Get-RetentionCompliancePolicy 748f77b020124e6e8304e66021fb297b -DistributionDetail |
Select -ExpandProperty ExchangeLocation
```

```
DisplayName      : Tony Redmond
Name             : Tony.Redmond@office365itpros.com
ImmutableIdentity : d446f6d7-5728-44f8-9eac-71adb354fc89
Type            : IndividualResource
Workload         : Exchange
SchemaVersion    : 2
```

The *ImmutableIdentity* property reported for each mailbox on hold equates to the GUID identifying the user account in Azure AD and is the same value that you see if you run the *Get-ExoMailbox* cmdlet and examine the *ExternalDirectoryObjectID* property.

## Group Mailboxes and Holds

To discover if any holds apply to a group mailbox, run the *Get-UnifiedGroup* cmdlet and examine the contents of the *InPlaceHolds* property:

```
[PS] C:\> Get-UnifiedGroup -Identity "Office 365 for IT Pros" | select InPlaceHolds
```

```
InPlaceHolds
-----
{grp6a9f7bf0507b4a4983c301a701958d11:2, UniH26c5d797-0fd3-496d-92ac-4f405700c917}
```

To find what groups a hold applies to, specify the *DistributionDetail* parameter when calling *Get-RetentionCompliancePolicy* to return details of the locations covered by the policy. For example:

```
[PS] C:\> Get-RetentionCompliancePolicy -DistributionDetail | ? {$_.ModernGroupLocation -ne $Null
-and $_.ModernGroupLocation -notlike "*All" } | Format-List Name, ModernGroupLocation
```

```
Name                : Clean up Groups with Connectors
ModernGroupLocation : {office365tenantervicehealth, office365roadmapupdates, askhr}

Name                : Senior Leadership Team (SLT) Retention Policy
ModernGroupLocation : {Senior Leadership Team}
```

This technique only works to report details of the holds placed by retention policies. We need to process the other types of holds differently to uncover their secrets. More on this topic soon.

## Org-wide Retention Policies

Org-wide retention policies applying to all mailboxes do not stamp hold information on individual mailboxes. Instead, the Exchange Online organizational configuration for the tenant stores details of the holds belonging to retention policies applicable to all mailboxes. This approach avoids the need to write the hold information into every mailbox and then check for individual holds when evaluating items for deletion. Here is how to retrieve information about the holds for org-wide retention policies.

```
[PS] C:\> Get-OrganizationConfig | Select -ExpandProperty InPlaceHolds
```

```
mbx15382841af9f497c83f9efe73e51888d:1
mbx9696959111f74ecda8a40aef97edd2c2:1
mbx703105e3b8804a1093bb5cb777638ea8:1
mbxf6a1654abdba4712a43c354e28a4d56c:2
grp6a1654abdba4712a43c354e28a4d56c:2
```

“mbx” refers to policies applied to user mailboxes and “grp” means policies applied to group mailboxes.

## Phantom Holds for Sensitivity Labels

If your tenant uses sensitivity labels, sensitivity label policies exist to publish the labels to workloads. As explained earlier, sensitivity policies appear like retention policies and must be excluded if you want to focus solely on retention policies. Even though the policies only publish labels, the policies insert entries into the set of org-wide retention holds held in the Exchange organization configuration. These holds can be ignored.

## Discovering Holds in Force for a Mailbox

Taking all that we know about the different forms of holds into account, we can come up with a PowerShell script ([downloadable from GitHub](#)) to report the set of holds that are in force for a mailbox. The script accepts the name of a mailbox and reports any organization-wide holds followed by holds where the mailbox is in scope.

```
Enter User to check: Ben Owens
```

```
The following organization-wide mailbox holds are in force...
```

Name	Workload
GDPR Personal Data	Exchange, SharePoint, OneDriveForBusiness, ModernGroup
General sensitivity policy	Exchange, SharePoint, OneDriveForBusiness, ModernGroup
Office 365 for IT Pros ...	Exchange, SharePoint, OneDriveForBusiness, ModernGroup
Formal Company Records	Exchange, SharePoint, OneDriveForBusiness, ModernGroup
Company Confidential Po...	Exchange, SharePoint, OneDriveForBusiness, ModernGroup

```
The following specific holds are in place on the Ben Owens (Business Director) mailbox...
```

```
Exchange In-Place Hold: New EAC Search
```

```
Hold Applied by: Senior Leadership Team (SLT) Retention Policy on Exchange, SharePoint, OneDriveForBusiness, ModernGroup
```

```
Hold Applied by: Management Preservation Policy
```

```
Litigation hold is enabled on the mailbox Ben Owens (Business Director)
```

If your tenant uses sensitivity labels, you need to amend the code to exclude the holds set by sensitivity label policies in the Exchange organization configuration. See the earlier discussion.

## The ComplianceTagHoldApplied and DelayHoldApplied Properties

If a user applies a retention label that’s configured to retain content to an item or folder in their mailbox, Exchange Online updates the *ComplianceTagHoldApplied* property for the mailbox. Because a specific hold is in place for one or more items, Exchange regards the mailbox as being in the same state as if an administrator assigned it a retention policy or placed the mailbox on litigation hold. For this reason, if the account for the mailbox is removed, Exchange puts the mailbox into an inactive state and keeps it there until the longest retention period for any label assigned to the mailbox expires. To see a list of mailboxes with applied retention labels, use the command:

```
[PS] C:\> Get-Mailbox -Filter {ComplianceTagHoldApplied -eq $True} | Select DisplayName
```

If a mailbox is not listed, it does not mean that its contents are not on hold due to a retention policy, in-place hold, or litigation hold. It simply means that the mailbox owner has never applied a retention label to an item or folder.

## Delayed Holds

After any type of hold is removed from a mailbox, Exchange puts the mailbox into a delayed hold state and keeps it there for 30 days. The extra retention step exists to give administrators the chance to recover information released by the hold after the hold is removed. In effect, this is a backstop to stop Exchange purging data in case a mistake is made in releasing a hold. While the mailbox is on delay hold, Exchange treats it as if it were on litigation hold and everything is kept. To mark the mailbox as being on delayed hold, Exchange updates the *DelayHoldApplied* property to *\$True*, so we can check to see what mailboxes are in this situation:

```
[PS] C:\> Get-Mailbox -RecipientTypeDetails UserMailbox -Filter {DelayHoldApplied -eq $true} |  
Select DisplayName
```

It takes about an hour after releasing a hold before the delay hold status shows up for a mailbox. Exchange does not expose any information about when the delayed hold status starts or ends, nor does Exchange give any information about the removed holds. When the 30-day delay hold period elapses, Exchange sets the property back to *\$False* to tell the Managed Folder Assistant that it can now purge the items that were on hold.

If the need exists to release the delayed hold, you can do so by running the *Set-Mailbox* cmdlet to set the *RemoveDelayHoldApplied* switch. For example, this command clears the delay hold for any mailbox where it is set.

```
[PS] C:\> Get-Mailbox -RecipientTypeDetails UserMailbox -Filter {DelayHoldApplied -eq $true}  
| Set-Mailbox -RemoveDelayHoldApplied
```

You can remove a delayed hold for an inactive mailbox to speed its removal:

```
[PS] C:\> Set-Mailbox -Identity Peter.Jenkins -InactiveMailbox -RemoveDelayHoldApplied
```

## Exchange Retention Holds

Apart from in-place holds, Exchange Online supports retention holds. This is not a hold of the type generally referred to as Exchange in-place or litigation holds, holds due to retention policies, or eDiscovery case holds, all of which stop the removal of information by a user or a system process (except retention processing). An Exchange retention hold stops the Managed Folder Assistant from processing the retention policy for a mailbox for a period and is usually applied when a mailbox owner cannot manage their mailbox because they are ill, on vacation, or absent for some other reason.

Exchange retention holds are still in use. Because they affect how MFA processes mailboxes, they influence the retention policies applied to mailboxes. In other words, if a retention hold stops MFA from processing a mailbox, MFA will not process either Exchange mailbox retention policies or retention policies for that mailbox while the retention hold exists. To set a retention hold, set the *RetentionHoldEnabled* property for a mailbox as follows:

```
[PS] C:\> Set-Mailbox -Identity "Kim Akers" -RetentionHoldEnabled $True
```

When the user can resume working with their mailbox, it is usual to give them a week or so to allow them to process new messages awaiting their attention. You can then disable the retention hold by setting the *RetentionHoldEnabled* property to *\$False*. MFA will then restart applying retention policies to the mailbox.

## Moving Data Between Tenants

Content can have multiple policies controlling how it is retained or disposed of. These policies exist within a tenant but have no application elsewhere. Therefore, if you move content from a tenant, even to another

tenant, the effect of retention policies and labels disappear. This problem already exists when users move from on-premises environments to the cloud and the situation is similar in merger/acquisition scenarios when tenants join or split. The migration technology available from Microsoft does not take retention policies into account because the focus is on extracting information from one tenant to bring it to another. It is unlikely that Microsoft will change its approach due to the complexities of reconciling retention demands as content moves from one organization to another. Instead, they'll leave the problem to ISVs to solve in third-party migration products, some of which do a better job in this respect.

Some basic steps can be taken to help:

- Understand how data governance functions within the source tenant (or tenants, in the case of amalgamations). Know what retention policies exist and how those policies treat content.
- Prepare for the migration by understanding where data is stored after the move.
- Create a new data governance strategy for the target tenant.
- Execute the strategy as data is moved from source tenants so that it is managed from day 1. In other words, have the retention policies in place in the target tenant so that newly arriving content is preserved as soon as it is transferred. This task might take some PowerShell scripting.

Data subject to holds remains in the source tenant until its retention period expires. That is, the data is kept if the owning tenant is funded (licensed). In the case of tenant mergers, the source tenants will likely eventually close. At this point, any data kept due to retention policies will be removed from workloads.

# Understanding the Exchange Mailbox Lifecycle

Items held in Exchange Online mailboxes follow a lifecycle from their creation by the user (calendar, posts, tasks, contacts, and so on) or when delivered as new messages. The major points in the lifecycle of Exchange Online items are:

- **Mailboxes** store and process incoming and outbound emails. Mailboxes can be archive-enabled to enable long-term retention of less-frequently accessed items for extended periods.
- The **Deleted Items** folder is the equivalent of the Trash or Wastebasket folder used by other email systems. The Deleted Items folder holds items that the user removes from other folders. Items stay in the Deleted Items folder until the user empties the folder or a retention policy dictates the removal of the items.
- Items removed from the Deleted Items folder move into **Recoverable Items**, a set of sub-folders used to preserve deleted items. The Recoverable Items folder also holds system items, such as audit entries to record actions taken within the mailbox. The Recoverable Items structure is not part of the normal IPM\_SUBTREE folder tree exposed by clients. It is in the hidden part of the mailbox that clients never synchronized to local copies. The Recoverable Items folder structure is also known as the "dumpster". This term goes back to its first implementation allowing users to recover deleted items without the need for administrator intervention.
- The **Managed Folder Assistant** (MFA) is a background assistant that processes mailboxes regularly to remove items no longer needed from the Recoverable Items structure, remove items from other folders, and move items into folders in archive mailboxes. Retention policies applied to mailboxes control MFA's processing. Holds that might exist for those mailboxes constrain the removal of items until their retention period lapses.
- Administrators create **Retention policies and tags** to define how the MFA automatically manages mailbox items on behalf of users. A mailbox can have a single retention policy, consisting of a set of tags that apply to default folders (such as the Inbox and Sent Items folders), other folders and items

as dictated by the user, and every other item in the mailbox (including the archive if available) that is not under the control of another tag.

- Administrators can apply different forms of **holds** (retention hold, legal or litigation hold, or in-place hold) to mailboxes to control whether users can remove information. Holds usually come about through a legal or other authorized action that forces a company to keep data for some purpose. When a mailbox is on hold, MFA will not permanently remove items from the mailbox, and Exchange Online copies any item that the user attempts to remove or update.

Collectively, these components interact with each other to form the lifecycle of Exchange Online mailbox items. Let's discuss what happens during the deletion of items to gain a better understanding of how the different parts of the lifecycle fit together.

## Cleaning Mailboxes

Over time, users remove items from various mailbox folders. Some remove messages immediately after reading, and some keep everything and leave items to accumulate. Exchange uses a two-stage removal process. First, the item is "soft-deleted" and moves to the Deleted Items folder, a default mailbox folder that acts as a convenient collection point for any item removed from another folder. Then, if the user empties the Deleted Items, the items are "hard deleted" (sometimes called "purged") and moved to the Recoverable Items\Deletions folder. You can also assign a folder retention tag to the Deleted Items folder to govern how long items stay in the folder.

A user can force a "hard delete" for an item by using the *Shift+Delete* key combination in either Outlook or OWA. This command instructs Exchange to ignore the Deleted Items folder and move the item directly to the Recoverable Items\Deletions folder. Exchange also moves items into the Deletions folder when a user moves an item from a mailbox folder to a PST. The reason here is that the move is a combination of an item deletion from the mailbox folder and an item creation in the PST.

When a user soft- or hard-deletes an item, Exchange writes a pointer to the original folder into the item's Last Active Parent Folder Identifier property (the MAPI property is *LastActiveParentEntryID* or LAPFID). Knowing which folder an item originally came from allows OWA to restore the item into that folder using the **Recover Deleted Items** feature, even if the mailbox owner renames or moves the folder. Exchange Online has recorded LAPFID information since 2016, but some older items might not have a value stored in this property. If this is the case, OWA uses a scheme called "folder type origin" to figure out where to recover items. Calendar items go back to the Calendar folder, Task items into Tasks, Contacts into Contacts, and mail and any other items go into the Inbox. It can be a little strange to find recovered items in the Inbox, especially if they are not mail items. For instance, if you recover a Word document or Excel spreadsheet (many people store these files in their mailbox), it shows up in the Inbox.

Outlook clients use a different mechanism to recover items. First, Outlook does not use the LAPFID to restore items. Second, Outlook recovers all items into the Deleted Items folder, the idea being that users can then decide where to move the items to as a permanent location. Microsoft might upgrade Outlook to support LAPFID in the future. Table 17-5 summarizes the target recovery location used by Outlook and OWA for different types of items.

	<b>Outlook</b>	<b>OWA</b>
Mail item (message)	Deleted Items	Original folder or Inbox
Contact item	Deleted Items	Original folder or Contacts
Calendar item	Deleted Items	Original folder or Calendar
Task item	Deleted Items	Original folder or Tasks

Any other non-mail item	Deleted Items	Original folder or Inbox
-------------------------	---------------	--------------------------

Table 17-5: The recovery destination for various Exchange item types

If you remove a complete folder, you can recover the individual items within the folder, but you cannot recover the complete folder as a single entity.

## Deletions, Purges, and Versions

The Recoverable Items structure uses sub-folders to organize items that it needs to keep. Some items stay until their deleted items retention period elapses. Others stay in the structure for a lot longer because one or more holds exist on the mailbox.

Items reach the Recoverable Items\Deletions folder when:

- They are hard-deleted.
- They are deleted from the Deleted Items folder.
- The Deleted Items folder is emptied.

Items stay in the Deletions folder for the period set in the deleted items retention period for the mailbox. In Exchange Online, the default period is usually 14 days. You can increase the deleted items retention period to a maximum of 30 days by running the *Set-Mailbox* cmdlet (and while you will probably use whole days, you can specify a retention time down to the second). For example:

```
[PS] C:\> Set-Mailbox -Identity 'Sanjay Patel' -RetainDeletedItemsFor 29.23.57.03
```

An exception exists for calendar items, which Exchange keeps for 120 days.

**Recoverable Items Only Online.** Because the Recoverable Items folder is only present on the server, you can only use Recover Deleted Items when Outlook can make a network connection to Exchange Online. In addition, if you ever need to use [the MFCMAPI utility](#) to see the items in the various sub-folders under Recoverable Items, you must configure MFCMAPI to open the message store online. Do this by going to the **Tools** menu, selecting **Options**, then setting the checkbox "Use the *MDB\_ONLINE* flag when calling *OpenMsgStore*".

When the deleted item retention period expires for an item, MFA removes it from the database and the user can no longer recover the item. The exception to the rule is when a mailbox is on hold or has single item recovery enabled as Exchange then moves items into the Recoverable Items\Purges folder and keeps the items there until the hold or the single item recovery period lapses. During this period, administrators can recover items with a content search.

A user can try to remove an item permanently by using the Recover Deleted Items feature to select the item and then select **Purge**. What happens next depends on the *SingleItemRecoveryEnabled* setting for the mailbox. Exchange uses the Single Item Recovery (SIR) feature to ensure that a deleted item can be recovered during the longest possible time set by the deleted item retention period:

- If *SingleItemRecoveryEnabled* is *False* and the mailbox is not subject to a hold, Exchange removes the item from the database at once and it is irrecoverable.
- If *SingleItemRecoveryEnabled* is *True* (the default value) and the mailbox is not subject to a hold, MFA moves the item to the Recoverable Items\Purges folder. The item stays there until its deleted item retention period (between 14 and 30 days as defined for the mailbox) expires. At that point, MFA removes the item from the database and the item is irrecoverable. However, as discussed below, while this description is true, a retention policy might cause something different to happen.
- If *SingleItemRecoveryEnabled* is *True* and the mailbox is subject to a legal hold, Exchange moves the item into the Recoverable Items\Purges folder and keeps it there while the hold applies.

- If *SingleItemRecoveryEnabled* is *True* and the mailbox is subject to an in-place hold, part of MFA known as the Email Lifecycle Assistant (ELC) determines whether a copy needs to be retained to satisfy the hold criteria (query and date range). If this is the case, MFA moves the item to the Recoverable Items\DiscoveryHolds folder, where the item stays until the hold lapses. ELC examines items that have exceeded the deleted items retention period in mailboxes at least once a day.

See Chapter 18 for more information on how to apply in-place holds to mailboxes.

**Nothing moves to DiscoveryHolds:** If you review items in the Recoverable Items structure, you might see that nothing ever moves into the DiscoveryHolds (or Purges) folder in the primary mailbox, even if those items are subject to an in-place hold. This can happen when the mailbox is under the control of the Default MRM Policy and is archive-enabled. Here is why.

When the Deleted Items folder is emptied, or items are hard-deleted by users, they end up in the Deletions sub-folder. Items in any folder under Recoverable Items are subject to the folder tag contained in the MRM policy, which instructs the Managed Folder Assistant to move the items to the archive after 14 days. If the mailbox is archive-enabled, the items are moved. If not, they stay in the primary mailbox.

ELC processes items when they reach the deleted items retention period. By default, this is between 14 and 30 days. ELC moves items subject to a hold to the DiscoveryHolds folder when their deleted items retention period expires. However, no items reach the 30-day deleted item retention period in the primary mailbox because they have already been moved to the archive. ELC processes the archive and will move the held items to the DiscoveryHolds folder in the archive, but no trace is seen of an item in the DiscoveryHolds folder in the primary mailbox. This can be confusing at first, but it is quite logical when you consider the age limits that control where items stay for different periods in a mailbox.

No client can permanently remove items under hold, including low-level utilities such as MFCMAPI. Exchange integrates checks for holds into how it manages data in its databases, and no one can circumvent the effect of a hold. Preventing the unauthorized removal of data from mailboxes allows Exchange to preserve items in an immutable fashion when needed by an organization.

Exchange monitors mailbox items that are subject to an in-place hold to detect if the user or any other process changes the item. If this happens, a copy of the original item is moved into the Recoverable Items\Versions folder to ensure that everything that happens to an item is fully recorded. This action is called a "copy on write". When the hold elapses, MFA removes the items from the Versions folder along with items held in the DiscoveryHolds and Purges folders.

**The SearchDiscoveryHoldsFolder folder:** This is a sub-folder of the DiscoveryHolds folder that is used by ELC when it processes the DiscoveryHolds folder to decide if any items can be removed. If such an item is found, it is moved to *SearchDiscoveryHoldsFolder* and kept there until it is eventually removed by the Managed Folder Assistant.

## Recoverable Items Quota

The Recoverable Items structure has a separate storage quota from that given to the primary mailbox. If a mailbox is archive-enabled, a separate quota is available to a similar Recoverable Items structure in the archive mailbox. The default quota for recoverable items is 30 GB, and Exchange Online increases the quota to 100 GB automatically when the first hold is applied to a mailbox. If a mailbox is created when org-wide holds exist in the organization, its recoverable items quota is set to 100 GB. Between the primary and archive mailbox, Exchange can keep up to 200 GB of recoverable data for a user. Items stored in the Recoverable Items folder in the archive behave in the same manner as if they were in the primary mailbox and are discoverable by eDiscovery searches.

You cannot change the *RecoverableItemsQuota* for a mailbox with the EAC or PowerShell, but you can log a support case with Microsoft Support if a mailbox is likely to exhaust its recoverable items quota. To find out how much data exists in Recoverable Items for a mailbox, use either of the *Get-MailboxStatistics* or *Get-MailboxFolderStatistics* cmdlets:

```
[PS] C:\> Get-ExoMailboxFolderStatistics -Identity Kim.Akers -FolderScope RecoverableItems | Format-Table Name, FolderSize, ItemsInFolder, FolderAndSubFolderSize -AutoSize
```

Name	FolderSize	ItemsInFolder	FolderAndSubFolderSize
Recoverable Items	0 B (0 bytes)	0	563.3 MB (590,650,854 bytes)
Audits	523.1 MB (548,504,424 bytes)	149324	523.1 MB (548,504,424 bytes)
Calendar Logging	18.37 MB (19,261,189 bytes)	734	18.37 MB (19,261,189 bytes)
Deletions	10.72 MB (11,236,121 bytes)	115	10.72 MB (11,236,121 bytes)
DiscoveryHolds	0 B (0 bytes)	0	0 B (0 bytes)
SearchDiscoveryHoldsFolder	0 B (0 bytes)	0	0 B (0 bytes)
Purges	5.707 MB (5,984,254 bytes)	753	5.707 MB (5,984,254 bytes)
Versions	5.402 MB (5,664,866 bytes)	53	5.402 MB (5,664,866 bytes)

Add the *Archive* switch to the cmdlet parameters if you want to see data for the archive mailbox.

If the mailbox exceeds the Recoverable Items quota:

- The user cannot remove items from their mailbox.
- The Managed Folder Assistant cannot move (hard-delete) items into the Recoverable Items.
- Write-on-protect cannot take copies if users alter items subject to a litigation or in-place hold.
- Exchange cannot save audit items if mailbox auditing applies to the mailbox.

You can take three actions to restore the Recoverable Items folder to normal working order. First, you can ask Microsoft to increase the recoverable item quota for the problem mailboxes. This might take a day or so to be effective and during that time the mailbox might experience problems such as those listed above. The second solution is to run the Managed Folder Assistant and instruct it to clean up duplicate items that might be present in Recoverable Items. This step should have an immediate effect and restore the mailbox to good health. To run the Managed Folder Assistant in clean-up mode, use a command like this:

```
[PS] C:\> Start-ManagedFolderAssistant -Identity TRedmond -HoldCleanup
```

Check the reported data for the Recoverable Items folder after the Managed Folder Assistant completes and hopefully you will discover that the overall size goes down. For more information about how to track what the Managed Folder Assistant does, see the section “Logging the Managed Folder Assistant” later.

The last action is to follow [the procedure laid down by Microsoft](#) to use PowerShell to clean up Recoverable Items.

## Exchange Mailbox Retention Policies

As we know, retention policies allow administrators to control how long data workloads retain or remove data. Both Exchange Online and Exchange on-premises servers support mailbox retention policies. Although these policies only cover Exchange mailboxes, they are still important where tenants want to impose the same retention regime for both online and on-premises mailboxes. In addition, mailbox retention policies can apply control at the level of individual folders instead of applying the same settings to a complete mailbox. Finally, mailbox retention policies can move items to archive mailboxes, something that is still not possible with Microsoft 365 retention policies.

Mailbox retention policies instruct the Managed Folder Assistant (MFA) about how long users can keep mailbox content (the retention period) and what to do once the retention period lapses (the retention action). The choice for retention action is to either remove the item (recoverable or permanent) or move it to the archive mailbox. A mailbox can have only one retention policy, and often the mailbox receives this policy

when created through the application of mailbox plan settings (see the Managing Exchange chapter). Many mailbox retention policies can exist within a tenant to ensure that the needs of different user groups are met.

A mailbox retention policy consists of one or more tags. These are:

- **Tags for the default mailbox folders (folder tags):** Among the default folders are the Inbox, Sent Items, and Deleted Items folders. Folder tags control how long items remain in these folders and what happens once the retention period elapses. Items in folders with folder tags inherit these tags unless the mailbox owner assigns them a personal tag.
- **Personal tags:** Users can apply these tags to any mailbox item and any folder except an Exchange default folder. A personal tag always has precedence over any other tag.
- **Default tags:** A mailbox retention policy can include a default delete tag and a default archive tag. The first determines the deletion of items not under the control of a folder or personal tag. The second determines when MFA moves items into the archive.

A mailbox retention policy commonly contains several folder tags, some personal tags, and one or both default tags.

Details of how to create and manage Exchange mailbox retention policies are in Chapter 8 of the companion volume.

## How MFA Processes Retention Policies

MFA processes both Microsoft 365 retention policies and mailbox retention policies against mailboxes. When MFA processes a mailbox to apply a retention policy, it examines the mailbox to “stamp” folders and items according to policy settings. MFA updates several MAPI properties for mailbox items with information, including:

- A GUID for the retention policy. Administrators can update the display name of a name, but its GUID (the retention identifier) is immutable.
- Retention period. The number of days that an item can stay in the folder before MFA removes it.
- Retention expiry. The calculated date when MFA will remove an item.
- Retention flags, including whether the item inherits the retention tag from the parent folder, or a user assigned the tag to the item.
- Archive period. The number of days that an item can stay in its folder before MFA moves it into the archive.
- Archive date. The calculated date when MFA will move an item to the archive.

In addition to processing normal messages, MFA can process compliance records for Teams, Yammer, and Planner. If a mailbox only has a mailbox retention policy, MFA ignores the compliance records. If it has a Microsoft 365 retention policy, MFA processes the compliance records for Planner along with other mailbox content. Special Microsoft 365 retention policies apply to Teams compliance records and Yammer compliance records.

### Logging the Managed Folder Assistant

You can use the *Export-MailboxDiagnosticLogs* cmdlet to find out the last time that the Managed Folder Assistant processed a mailbox and what happened during the run. The “Elc” (Electronic life cycle) properties in the report contain details of MFA activity. For example, the *ElcLastRunSuccessTimeStamp* tells you the date and time that MFA last successfully processed the selected mailbox while *ElcLastRunDeletedFromDumpsterItemCount* holds the total number of items removed from the Recoverable Items folder (the famous “dumpster”). In this truncated version of the output, we can see the last successful run of the assistant was at 01:03 on 12 April 2020 and that MFA removed 554 items (from all folders under the mailbox root), archived 16 items, and moved 556 items from the Recoverable Items structure to the archive.

```
[PS] C:\> $Log = Export-MailboxDiagnosticLogs -Identity James.Ryan -ExtendedProperties
$xml = [xml]($Log.MailboxLog)
$xml.Properties.MailboxTable.Property | ? {$_.Name -like "ELC*"}

Name                                     Value
----                                     -
ElcLastRunTotalProcessingTime           97103
ElcLastRunSubAssistantProcessingTime    61121
ElcLastRunUpdatedFolderCount           9
ElcLastRunTaggedFolderCount             0
ElcLastRunUpdatedItemCount              881
ElcLastRunTaggedWithArchiveItemCount    0
ElcLastRunTaggedWithExpiryItemCount     881
ElcLastRunDeletedFromRootItemCount      554
ElcLastRunDeletedFromDumpsterItemCount  0
ElcLastRunArchivedFromRootItemCount     16
ElcLastRunArchivedFromDumpsterItemCount 556
ELCLastSuccessTimestamp                  12/04/2020 01:13:48
```

## MFA Workcycle

MFA runs on a workcycle basis where a goal is set and the server hosting the mailbox figures out how to meet the goal, taking system load and available resources into account. In an on-premises deployment, the MFA workcycle aims to process every mailbox at least once daily. However, in Exchange Online, the workcycle used for the MFA aims to process every mailbox at least once weekly. The larger quotas granted to Exchange Online mailboxes is one reason why it is safe to extend the workcycle. However, although the formal workcycle goal is weekly, experience (and observation of mailbox statistics as described above) proves that MFA can process mailboxes up to five times weekly. If system resources are available, Exchange Online releases the resources to background processes like MFA, and this accounts for any discrepancy between formal workcycle goals and what happens in practice.

Knowing how to check whether MFA has processed a mailbox, we can write some code to check all user mailboxes. It's easy to amend this code to select a different group of mailboxes for processing, such as all those belonging to a department. In addition, the script only reports two of the ELC properties and you could add others as needed, such as the count of items moved to an archive mailbox.

```
[PS] C:\> $Mbx = Get-Mailbox -RecipientTypeDetails UserMailbox -ResultSize Unlimited
$Report = [System.Collections.Generic.List[Object]]::new()
ForEach ($M in $Mbx) {
    $LastProcessed = $Null
    Write-Host "Processing" $M.DisplayName
    $Log = Export-MailboxDiagnosticLogs -Identity $M.Alias -ExtendedProperties
    $xml = [xml]($Log.MailboxLog)
    $LastProcessed = ($xml.Properties.MailboxTable.Property | ? {$_.Name -like
"*ELCLastSuccessTimestamp*"}).Value
    $ItemsDeleted = $xml.Properties.MailboxTable.Property | ? {$_.Name -like
"*ELcLastRunDeletedFromRootItemCount*"}
    If ($LastProcessed -eq $Null) {
        $LastProcessed = "Not processed"}
    $ReportLine = [PSCustomObject]@{
        User           = $M.DisplayName
        LastProcessed  = $LastProcessed
        ItemsDeleted   = $ItemsDeleted.Value}
    $Report.Add($ReportLine)
}
$Report | Select User, LastProcessed, ItemsDeleted
```

## Forcing MFA to Process a Mailbox

If you need the Managed Folder Assistant to process a mailbox urgently, for instance, to publish the retention policy information to a mailbox, you can run the *Start-ManagedFolderAssistant* cmdlet to request Exchange Online to process the retention settings for the mailbox.

```
[PS] C:\> Start-ManagedFolderAssistant -Identity "Ben Owens"
```

If all goes well, MFA refreshes the retention settings for the mailbox and new tags and labels are available to users. Sometimes kicking the MFA convinces it to do the right thing and process a mailbox, sometimes it does not. The problem is that Exchange Online throttles background processing and does not allow mailbox assistants like MFA to run on demand. Microsoft wants to smoothen server load to reduce the risk that background processing interferes with the ability to be responsive to clients, which is why a seven-day workcycle exists for mailbox assistants. Telling MFA to process a mailbox will have an effect if MFA considers that it is reasonable to go ahead because it has not processed the mailbox recently. Running *Start-ManagedFolderAssistant* several times to convince MFA to start processing is a fruitless exercise.

The *Start-ManagedFolderAssistant* cmdlet supports an *-InactiveMailbox* switch to force immediate processing of inactive mailboxes. In the past, Microsoft has swapped between MFA processing inactive mailbox and not. The current state is that MFA processes inactive mailboxes and applies Exchange mailbox retention policies and retention policies against their content. One difference exists in the processing done for active and inactive mailboxes in that MFA does not process archive tags when it deals with inactive mailboxes.

## Stopping MFA Processing a Mailbox

Times occur when you might want to stop the Managed Folder Assistant from processing one or more mailboxes. For example, when you want to remove items from a mailbox when it is on hold because that information should not be in the mailbox as when someone forwards a message with confidential information to mailboxes that should not receive them. To remove the items from a mailbox that is on hold, you must release the holds temporarily, remove the items, and then replace the holds. During this time, MFA might process the mailbox and remove other items. To stop this from happening, you can disable MFA temporarily by running the *Set-Mailbox* cmdlet to set the *ElcProcessingDisabled* flag.

```
[PS] C:\> Set-Mailbox -Identity "Kim Akers" -ElcProcessingDisabled $True
```

When the holds are in place again, you can reverse the process and release MFA by switching the value to *\$False*. You cannot disable MFA processing if a preservation lock applies to the mailbox.

## Moving from Exchange Retention Policies

Exchange mailbox retention policies have been in use since Exchange 2010. Microsoft's long-term direction is to move away from workload-specific processing, like that done by mailbox policies, to use retention policies instead, whenever it makes sense for a tenant. If you are a new tenant starting with a retention strategy, the right decision is to use retention policies. However, if you have been using mailbox retention policies for many years and have a hybrid tenant, that decision is not quite so clear-cut.

To make retention policies available to other workloads, Microsoft evolved and expanded the core principles behind Exchange retention policies. In doing so, they have dropped some Exchange-specific features, like the ability to move items to archive mailboxes. Losing the ability to archive items automatically is regrettable but this action is only valid for Exchange and does not apply to other applications. A more fundamental problem for some is the loss of granularity in that an Exchange retention policy can include tags for default folders, personal tags, and a set of default tags to control deletion, archival, and voicemail. By comparison, a retention policy applies the equivalent of a single default tag (to remove or keep content) to mailboxes.

Retention policies create in-place holds when they include a retention action. The holds apply for all locations covered by a policy and last until the policy's retention period expires, meaning that users cannot remove content from Exchange, SharePoint, OneDrive for Business, Teams, or Groups if that content comes within the scope of the policy. The integration of in-place holds into retention policies is an advantage over Exchange mailbox retention policies.

Significant differences in functionality exist between the two types of retention policies. The most attractive feature of retention policies is that they apply to many locations rather than just Exchange Online. Another

good point in their favor is that you can combine Exchange retention policies with retention policies and labels, even if that might be a double-edged sword in terms of the resulting complexity in retention processing. Being able to apply a single consistent policy across multiple workloads is a huge advantage, but that advantage might be reduced because of the loss of some of the granular processing available in Exchange retention policies. The decision to move to retention policies will therefore need considerable thought and preparation on the part of tenants.

Every tenant is different and although it might be easy for a cloud-only tenant with relatively simple retention needs to go ahead and embrace retention policies, the situation is probably very different for large and complex tenants that already have a well-defined retention strategy in place. Things become even more complicated for hybrid tenants, who often want to use the same processes on-premises and in the cloud.

Experience and time will allow us to develop better answers. In the meantime, new tenants should start with retention policies and labels while older tenants test, compare, and contemplate what is their best course of action. For instance, you might decide on a strategy based on four stages:

1. Remove personal tags from Exchange Online mailbox retention policies and replace the tags with Microsoft 365 retention labels with the same name and retention settings. Users will begin using the retention labels to retain new items while the older retention tags will age out over time.
2. Remove folder tags from Exchange Online mailbox retention policies and replace them with Microsoft 365 retention policies. This means that no folder-specific retention processing is available because the retention policies apply the same settings and actions to the complete mailbox.
3. Replace default deletion tags in Exchange Online mailbox retention policies with Microsoft 365 retention policies. This is a natural consequence of step 2 and the only action required once a Microsoft 365 retention policy processes mailboxes is to remove the default deletion tag from the mailbox retention policy.
4. Eventually, limit the use of Exchange Online mailbox retention policies to moving items to archive mailboxes. When Microsoft 365 retention policies support this action, you can remove the default archive tags from Exchange Online mailbox retention policies.

This is an outline of tactics to move to Microsoft 365 retention policies that need to be adjusted to meet the unique circumstances of individual organizations. For example, you should run Exchange Online mailbox policies (with all tags intact) and Microsoft 365 retention policies alongside each other for a few weeks or so to make sure that no interregnum happens when retention processing does not occur for mailboxes. MFA will resolve any inconsistencies (such as having a personal tag and retention label with the same name).

The availability of the older workload-specific functionality allows organizations time to make the transition. It's a wise approach because the nature of retention is that items often require retention for long periods, and no one wants software to force them to change their data governance strategy in such a way that it might affect terabytes of retained content.

# Chapter 18: Managing eDiscovery

**Tony Redmond**

The Microsoft Purview Compliance portal is the administrative interface for cross-service compliance and protection operations, including the tools Microsoft creates to help tenants to find information needed for investigations, now gathered under the Microsoft Purview banner. In this chapter, we cover:

- **Content searches:** How to search through locations (sites, mailboxes, teams, etc.) to find information. Information found by content searches can be exported for review by investigators or subject matter experts.
- **Microsoft Purview eDiscovery (Standard) – previously Core eDiscovery:** How to run eDiscovery operations spanning searches, holds, and exports. Standard eDiscovery is available to tenants with Office 365 E3 licenses to organize content searches (including exports) and in-place holds into cases to make it convenient for investigators to process information. A single eDiscovery case can span multiple searches and holds. The holds are *in-place*, meaning that the items that come within the scope of the hold remain inside the host repositories (for instance, an Exchange mailbox or a SharePoint document library).
- **Microsoft Purview eDiscovery (Premium) – previously Advanced eDiscovery:** Uses completely different technology to process high-end eDiscovery cases which typically cover much higher volumes of data than Standard eDiscovery cases do. The organization of Premium eDiscovery cases is different too. eDiscovery Premium requires Office 365 E5 or Microsoft 365 Advanced Compliance licenses.

eDiscovery is a specialized subject and not everyone is interested in how to run searches, create holds on different resources, or export results. However, given the massive increase in data stored by companies and the litigious nature of the world, it is likely that many tenants will meet the need to run some form of search in any given year, even just to find a document or message that a user thinks they have lost. With that thought in mind, we begin by looking at content searches.

## Content Searches

The design goal for eDiscovery technology is to meet the needs of investigation professionals who need to pursue a compliance query from start to finish, potentially to the point where a company produces evidence in court to prove wrongdoing or other legal points. Searching for evidence is where investigations begin, and that is why content searches are so important.

Before beginning the process to create a content search, you should know:

- **What locations to search:** You can search Exchange Online user mailboxes (including shared and inactive mailboxes), group mailboxes, Exchange Online public folders, SharePoint Online and OneDrive for Business sites, tasks (To-Do), Sway, and Forms (owned by Microsoft 365 Groups). Any information held in mailboxes, including compliance records for Teams channel and private conversations or Yammer messages, is available. Planner tasks are discoverable if compliance records have been captured when tasks are created or edited (see the Planner chapter). Yammer messages are discoverable (and can be found in Exchange Online mailboxes) if the network is configured in native mode.

- **The keyword query to use to find information:** Content searches depend on the content indexes created and updated by Microsoft Search. As users create information using a supported workload, Microsoft Search automatically processes the information and adds it to its content indexes. Queries can be all-encompassing (“find everything”), basic (“search for this term”), or very complex.

Content searches use the Microsoft 365 server fabric, which means that a tenant can run multiple concurrent searches. No limitation exists on the number of mailboxes or sites that you can include in a search as Microsoft designed this generation of search technology to be able to handle the demands of the largest tenant. While content searches take care of finding and exporting information from Microsoft 365 locations, if you need to apply a hold to keep email and documents until investigators no longer need that information, you create an eDiscovery case. The holds processed by eDiscovery cases depend on content searches to find the information to hold. Content searches can also be part of an eDiscovery case, where investigators can use a set of searches to interrogate various locations using different queries to retrieve the information that they need. Table 18-1 lists some scenarios where content searches are useful.

<b>Scenario</b>	<b>Search action</b>
Assess the risk to the business from data shared by users with external people from SharePoint Online or OneDrive for Business sites	Include the <i>ViewableByExternalUsers</i> keyword in the search and set it to True. In order to exclude the aspx files used by SharePoint Online, the full query is <i>ViewableByExternalUsers:true AND ContentType:document NOT FileExtension:aspx</i> .
Find documents that hold more than a certain number of sensitive information types (as defined for Data Loss Prevention – see chapter 19)	Include the <i>SensitiveType</i> keyword in the search and specify the sensitive information type to look for and the number of instances of that type that must be in a document for the search to retrieve it. For instance, <i>SensitiveType:"Credit Card Number 5.."</i> finds documents that have more than five credit card numbers. See <a href="#">this page</a> for more information.
Investigate whether anyone sent emails holding confidential information to a specific address outside the organization	Include the <i>Recipients</i> keyword and specify their SMTP email address in a search. For example, <i>Recipients:"TRedmond@Yandex.com"</i>
Investigate whether mailboxes have received a specific phishing message (or not)	Include the <i>Sender</i> and <i>Subject</i> keywords with values to search. For example <i>Sender:"SomeGuy@FortuneForYou.com" AND Subject:"I have transferred \$100million to you"</i>
Check that a message that has some specific text in its body is not circulating within the organization	Include the <i>Body</i> keyword in the query. For example, <i>Body:"We are about to be taken over by MegaCorp"</i>

Table 18-1: Content search scenarios

From July 2022, Microsoft limits the number of search jobs that tenants and individual users (administrators) can run. Jobs include searches and exports. The limits are outlined in Table 18-2.

<b>eDiscovery Premium</b>	<b>Tenant Limit</b>	<b>User limit</b>
Concurrent job limit (any jobs)	100	50
Concurrent job limit (tenant wide job)	50	25
<b>eDiscovery Standard</b>		

Concurrent job limit (any jobs)	50	25
Concurrent job limit (tenant-wide jobs)	5	5
Maximum number of jobs per day	500	
Maximum data size limit per day	2 TB	

Table 18-2: Search job limits

Microsoft says that the limits should not interfere with normal tenant operations and exist to ensure service stability and reliability. Searches can be resource-intensive operations, especially if asked to search through a large number of locations, such as all sites or all mailboxes. The limits exist to stop some organizations running too many jobs at the same time. From a marketing perspective, they also help to emphasize the difference between eDiscovery Standard and Premium.

## Limiting Search Sources for Better Results

A content search can scan tens of thousands of target repositories and return multiple terabytes of results. To ensure that searches execute in a reasonable time, it is important to limit the number of locations where the search looks for relevant information by either restricting the number of targets or by refining the search query so that it excludes irrelevant items from the search results. As the foundation for successful searches is based on precision, the latter approach is always the best one to pursue.

As a very large multi-national company, Microsoft follows many legal and regulatory requirements around the world. Its litigation team uses eDiscovery to manage investigations and has written a [white paper to explain how it handles eDiscovery cases](#). In 2017, Microsoft said that its use of Microsoft 365 compliance technology contributed to an annual cost saving of some \$4.5 million. Your mileage might vary.

## Content Search Scalability

The speed and scalability available to Microsoft 365 content searches originate from the way that the searches use the Microsoft 365 infrastructure. A limit exists for the on-premises searches performed by either Exchange or SharePoint based on the load that a single server can manage. For instance, the older In-place Hold and eDiscovery tool used in Exchange on-premises servers ([retired from Exchange Online in mid-2020](#)) uses a single server to control searches and uses synchronous connections to all the mailbox servers that host mailboxes within the scope of the search. The search eventually collates the results returned by individual servers to form the set of found items.

Content searches use the Microsoft 365 server fabric to process searches and split work across multiple servers. Asynchronous messages pass between the servers doing the work to keep them updated about search progress. This implementation reduces the potential for failure and parallelizes the workload to scale up to deal with far higher volumes of data (such as over 700,000 mailboxes in a single operation). Microsoft gathers statistics about the time needed to complete content searches and cites the guidelines shown in Table 18-3.

<b>Number of mailboxes</b>	<b>Average search time</b>
100	30 seconds
1,000	45 seconds
10,000	4 minutes
25,000	10 minutes

50,000	20 minutes
100,000	25 minutes

Table 18-3: Average time for content searches (source: [Microsoft](#))

Searches need some time to spin up, so the time cited by Microsoft is indicative rather than precise. Once the search starts, it rapidly processes target locations to find items based on the keywords and conditions in the search criteria. The number of mailboxes included in a search is the biggest single factor influencing how long the search will take. Apart from user-created items in the mailbox, the Microsoft 365 substrate stores many other items in user and group mailboxes, including “digital twin” copies of data from SharePoint Online and OneDrive for Business and compliance records for workloads like Teams and Yammer. Online mailboxes are usually larger than their on-premises counterparts and can have large recoverable items and archive components. All contribute to the number of items stored in mailboxes and increase the time needed to search mailboxes. The bottom line is that if you want fast records, be precise about the mailboxes included in a search.

Content searches also include some retry logic to handle the situation where a required mailbox or site is offline for some reason. Usually, a retry is enough to complete a search. See this page to understand more about [the limits applying to content searches](#).

## SharePoint and Exchange Support for Sensitive Information Types

You can combine keywords to build a search query that covers multiple conditions. SharePoint Online and Exchange Online have different abilities to use keywords. Some of the keywords are specific to documents and some to mailbox items. For example, you cannot include the *ViewableByExternalUsers* keyword in a search that scans Exchange Online mailboxes because this kind of sharing concept does not exist for Exchange. In addition, although both SharePoint Online and Exchange Online support [sensitive information types](#) (like credit card numbers, passport numbers, and national identification numbers) used by Data Loss Prevention and retention policies, only searches of SharePoint content support these keywords. If you include unsupported keywords in a search, the search ignores them when it builds its results. This [page gives guidance about the keywords](#) that you can use for Exchange and SharePoint locations.

## Creating and Running a Content Search

You must be a member of the Compliance eDiscovery Manager or Organization Management role groups to be able to create and execute a content search. In addition, an account used to conduct compliance searches should have a functional Exchange Online mailbox. Although no strict licensing requirement exists for a mailbox, the preview function for search results does not work if the account used for searching has no mailbox.

To access content searches, open the Microsoft Purview Compliance portal and go to the **Content Search** section. You then see a list of the existing searches for the tenant. You can select a search and continue working with it to amend its search criteria and run new queries or create a new search. In the example explained below, we create a new search from scratch. After naming the search and adding a description, we define the locations, keywords, and conditions to frame the search.

### Search Locations

After assigning a suitable name to the search, the next step is to define where the search should scan for matching items. The three basic locations (Figure 18-1) are:

- **Exchange mailboxes:** All Exchange Online mailboxes, including inactive mailboxes. Searching Exchange mailboxes also covers Teams and Yammer messages because the Microsoft 365 substrate captures compliance records for Teams and Yammer conversations in Exchange personal mailboxes (for personal and group chats and Yammer private messages, including the call records for people who participate in meetings or calls) and group mailboxes (for Teams channel and Yammer community conversations).
- **SharePoint sites:** Includes all SharePoint sites and OneDrive for Business accounts. Searching SharePoint includes the sites created to store Teams files, including the wiki (.mht file) created for each channel.
- **Exchange public folders:** If your organization uses public folders, you can search for information stored in any public folder. You cannot search a subset of public folders.

Checking the *Add App content for On-Premises users* option instructs the search to include the cloud-only mailboxes used to store compliance records captured for Teams and Yammer messages sent by hybrid, guest, and federated users.

## Locations

### Specific locations

Status	Location	Included	Excluded
<input checked="" type="checkbox"/> On	Exchange mailboxes <small>Microsoft 365 Groups Teams Yammer user messages</small>	All <a href="#">Choose users, groups, or teams</a>	None
<input checked="" type="checkbox"/> On	SharePoint sites <small>OneDrive sites Microsoft 365 Groups Teams Yammer user messages</small>	All <a href="#">Choose sites</a>	None
<input type="checkbox"/> Off	Exchange public folders		

Add App Content for On-Premises Users. [Learn more](#)

Next

Figure 18-1: Specifying target locations for a content search

## Adding Exchange Online Mailboxes

To refine the set of Exchange mailboxes, click the **Choose users, groups, or teams** link and then use the search box to find the target mailboxes, Microsoft 365 groups, and distribution lists. You can't add dynamic distribution lists to a search. When the set of mailboxes is input, the search expands the current membership of distribution lists and adds the individual mailboxes to the set of target mailboxes.

**Disconnected mailboxes and Content Searches:** Although content searches can scan inactive mailboxes, you can't include disconnected mailboxes in a content search. These are mailboxes belonging to Microsoft 365 accounts where an administrator removes the Exchange Online license from the account. Disconnected mailboxes stay in a soft-deleted state for 30 days following the removal of the license before Exchange Online permanently deletes them from the system. If disconnected mailboxes are in the set of mailboxes used for existing searches, the search ignores them when it generates results.

Continue to add mailboxes (remember to select mailboxes from the list and then click **Choose**) until you have added the desired target selections to the search.

## Adding SharePoint Online and OneDrive for Business Sites

Click **Choose sites** to add new locations to the set of SharePoint and OneDrive sites. For each site, enter its URL or part of its display name into the search box (Figure 18-2). When you've found the full set of sites for the search, click **Add** to add them to the search criteria.

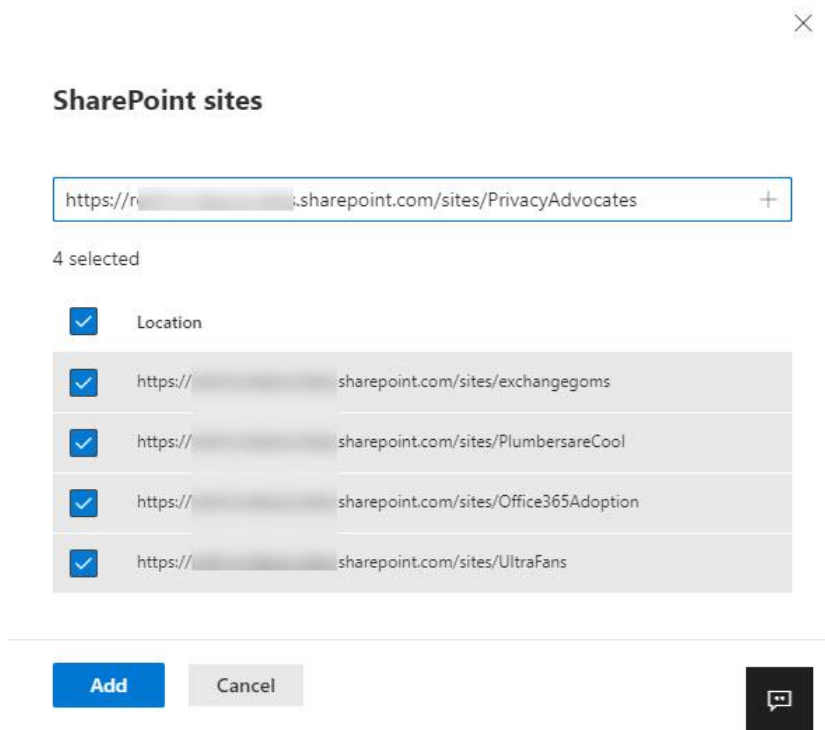

Figure 18-2: Specifying SharePoint Online sites for a content search

To add specific SharePoint Online and OneDrive for Business sites to a search, you must know the complete URL for the target sites. You can find the URL by opening the site in a browser and copying the URL, or you find the site URL with PowerShell. The `Get-SPOSite` cmdlet returns all the sites in a tenant, including their URLs, and is the obvious way to find a site URL, including for OneDrive for Business accounts. To find a list of all OneDrive for Business sites in the tenant, connect to SharePoint Online with PowerShell and run the command below. You could also export the list to a CSV file to keep as a handy reference:

```
[PS] C:\> Get-SPOSite -IncludePersonalSite $True -Limit All -Filter "Url -like '-my.sharepoint.com/personal/'" | Select Owner, Url | Sort Owner
```

If a site belongs to a Microsoft 365 Group or Team, you can find the URL with the command:

```
[PS] C:\> Get-UnifiedGroup -Identity MyGroup | Select SharePointSiteURL

SharePointSiteUrl
-----
https://mytenant.sharepoint.com/sites/mygroup
```

## Adding SharePoint Sites for Teams Private and Shared Channels

Teams private and shared channels keep their conversations and files separate from the other parts of the team to ensure that only channel members can access this content. Each private or shared channel has a dedicated SharePoint site, which is a child of the site owned by the team. Searching the parent team

automatically includes the conversations in a private channel (using the compliance records in the team's group mailbox). To search for conversations in a shared channel, you must add one or more members of the channel to search the compliance records stored in the personal mailboxes. If you want to add the SharePoint site belonging to a private or shared channel to a content search, you need to know its URL. The easiest way is to open the channel in Teams and use the "Open in SharePoint" option in the Files tab to open the channel site in the SharePoint browser interface. Then you can copy the URL shown in the browser navigation bar.

On an admin level, because the settings of these sites come from the parent team site, the SharePoint admin center does not manage the sites used by private or shared channels, but PowerShell can manage the sites. For example, when run by a SharePoint administrator, this PowerShell code returns all the sites belonging to private and shared channels and uses the group identifier to retrieve the team name from the Microsoft 365 group before writing out the display name and site URL.

```
[PS] C:\> [array]$Sites = Get-SPOSite -Template "TeamChannel#1"
ForEach ($Site in $Sites) {
    $SPOSite = Get-SPOSite -Identity $Site.url -Detailed
    $Group = Get-UnifiedGroup -Identity $SPOSite.RelatedGroupID.Guid
    Write-Host "Team" $Group.DisplayName "owns channel site" $Site.URL }
```

Notice that the SharePoint template used for the sites used by both private and shared channels is "TeamChannel#1." This is the current template used by Microsoft when it creates private and shared channel sites. Older private channel sites might have the TeamChannel#0 template. To return sites with both templates, use a command like:

```
[PS] C:\> [array]$Sites = Get-SPOSite -Limit All | ? {$_.Template -eq "TeamChannel#0" -or
$_.Template -eq "TeamChannel#1"}
```

When you examine the URLs created for sites used by private or shared channels, you'll see the following naming convention:

*<https://tenant.sharepoint.com/sites/TeamName-PrivateSharedChannelName>*

For example, the site for the "Legal Discussions" private (or shared) channel owned by the "Corporate Acquisition Planning 2020" team is:

*<https://tenant.sharepoint.com/sites/CorporateAcquisitionPlanning2020-LegalDiscussions>*

## Search Keywords and Conditions

Content searches run queries composed in the Keyword Query Language (KQL) against content indexes to find information. You can use either the condition card builder or KQL editor to compose a query. The KQL editor is also available to create content queries for Premium eDiscovery searches.

The condition card builder allows you to add keywords and conditions in a GUI while the KQL editor supports auto-completion for searchable properties and conditions along with checking for acceptable input, such as the available operators for a property. New search administrators usually find it easier to start with the condition card builder while those who are more experienced use the KQL editor. You can toggle between the condition card builder and the KQL editor as needed while working on a query. This is useful because you can compose a query with the condition card builder that has an error. When you toggle to the KQL editor, the editor highlights any syntax problems it detects to allow you to fix them. The KQL editor is there to make it easier for people to compose queries that don't contain obvious syntax errors. However, there's no guarantee that a query passed by the KQL editor will work or, if it does, will find the information you expect. For this reason, it's important to understand the fundamentals of KQL queries.

Queries are formed from keywords and conditions. The keywords are free-text expressions, meaning that you can use individual words or complete multi-word phrases. If you include phrases, you must enclose them in

double quotation marks. You can leave the keywords box empty if you want to search for everything in the locations that you choose.

Keywords support prefix matching, which means that you can include the wildcard operator (\*) with the beginning or end of a word (for instance, "Office\*"). You can combine free-text expressions with KQL operators such as OR, AND, NOT, and NEAR. For example, this query finds items in SharePoint Online or OneDrive for Business that include the keywords NDA, "Non-disclosure agreement," or "non disclosure" in Word or PDF formats. The reason for specifying non-disclosure and non disclosure is to pick up documents that use either variant:

```
(NDA OR "Non-disclosure agreement" OR "non disclosure") AND (filetype:doc* OR filetype:pdf)
```

This query uses a wildcard operator to find spreadsheets containing "Microsoft 365 Groups" and a special relative date comparison to specify that we're looking for spreadsheets modified in the current year:

```
("Microsoft 3*" AND "Groups") AND (filetype:xls*) AND (LastModifiedTime = "this year")
```

Other special date comparisons include today, yesterday, this week, this month, last month, and last year. We can also find items using date ranges. This query looks for any document or message created in October 2020 which includes the word *shareholder* within 10 terms of the word *agreement* where the author is Tony Redmond.

```
("shareholder" NEAR(10) "agreement") AND (Author:"Tony Redmond") AND (LastModifiedTime >= 2020-10-01 AND LastModifiedTime <= 2020-10-31)
```

To preserve the order in which words appear, use ONEAR instead of NEAR.

### Define your search conditions

Figure 18-3: Entering keywords and contents for a content search

If you include multiple free-text expressions in a query, KQL combines the expressions in the search using the AND operator. If you enter an operator in lowercase (like "and"), the search will offer to uppercase the operators when it checks the query. You should always accept this offer as uppercasing the operators makes

their purpose obvious (and lowercase operators don't work). Figure 18-3 shows an example of a search using some keywords to tell the search that we're interested in items where the words crisis and finance or found within 10 characters of each other together with a date condition to limit the scope of the search.

The Show keyword list checkbox allows you to input a keyword in each row of a list. The reason why you would want to do this instead of typing all the keywords into the keyword box is that the search generates statistics for each keyword. When the search runs, you can review the statistics to understand which keyword is most effective in terms of search results.

If you toggle to use the KQL editor for the query shown in Figure 18-3, you'll see the query in KQL format:

```
crisis NEAR(10) pandemic(c:c)(date=2019-03-01..2022-01-24)
```

The KQL editor supports cut and paste, so you can copy a complex query from one search, paste it into another, and modify the keywords and conditions as needed.

**Keywords with non-English characters:** By default, content searches are language-neutral. However, if you find that a search does not return the expected results, the cause might be that some of the keywords use non-English characters (such as Chinese). You can force a search to be language-sensitive by clicking the **Query-language-country/region** icon  on the top of the search query box and then selecting a language country culture code value for the search (for example, Chinese – Hong Kong SAR).

## Search Conditions

Conditions narrow searches by filtering the results generated by the keywords. When you specify a condition, the search adds a clause (shown using the (c:c) operator) to the search query used to find results. For example, you might only be interested in items created by a certain person, in which case you use the author condition to specify the person. To apply a further filter, you could add the created (date) condition to focus on items created in a certain period. When the search query runs, items must satisfy the keyword query and one or more conditions before the search includes them in the results.

To make it easy for you to include conditions in searches, the **Add conditions** button in the condition card builder exposes a dialog listing the most common conditions. [Some conditions](#), like Sender/Author, are valid conditions for searches against both Exchange Online and SharePoint Online items. Others are specific to a workload. If you attempt to add a condition that won't work for the chosen target locations, the Microsoft Purview Compliance portal flags an error to tell you which condition has a problem. For instance, if you try to use the message type condition to search SharePoint Online, you'll see an error because SharePoint doesn't support that condition. To proceed with the search, you must remove the condition.

To complete a condition and add it to the search criteria, you must define what the condition checks for. For instance, if you add a retention label condition to the search, you must say what compliance tag (classification label) or tags you want to look for. If you add a date to a search, you must input the date range for the search and say whether you want to look for items between two dates, before a date, or after a date.

Remember that people can change their names for good reasons, such as marriage or divorce, which means that you might need to include addresses for people other than their current user principal name or primary SMTP address. Queries can handle this situation by including variants of names in the sender/author condition.

**Hybrid SharePoint searches:** If a hybrid connection is in place, it is possible to use hybrid SharePoint searches to find content stored within on-premises SharePoint farms. However, when you run content searches, the search filters out the results from the on-premises sources because no method exists to allow

Microsoft 365 to apply holds to on-premises SharePoint data or to export data from an on-premises SharePoint location.

## Run the Search

After defining the search criteria, the Microsoft Purview Compliance portal launches a preview for the search automatically. Before this happens, the portal checks the query for any syntax errors and identifies any potential improvements. The search then runs the query against the target locations. A preview search is not a full search. Instead, the preview uses content indexes to retrieve a sample of items that a full search will find to allow the search author to decide if the criteria are accurate enough to find the desired information. The preview also generates estimates for the number of items a full search will find. The actual number of items that a full search will find will probably differ from the preview, but the difference is usually of minor importance. For instance, preview searches against SharePoint sites often include ASPX files (used by SharePoint) that are of no interest to an investigator. It's also possible that users create or delete items matching the search criteria between the time of a preview search and when the actual search happens, or indeed that a lag in indexing stops a file from appearing in a preview when a subsequent search finds it.

A full search might have to process thousands of mailboxes and sites, so it is better to get quick results back from a preview rather than having to wait for the full search to complete. Equipped with the preview information, you can assess the effectiveness of the query and then tweak the search parameters. The process of tweaking search criteria might need multiple iterations before you are happy with the results delivered by the search and proceed to perform the full search and export its results.

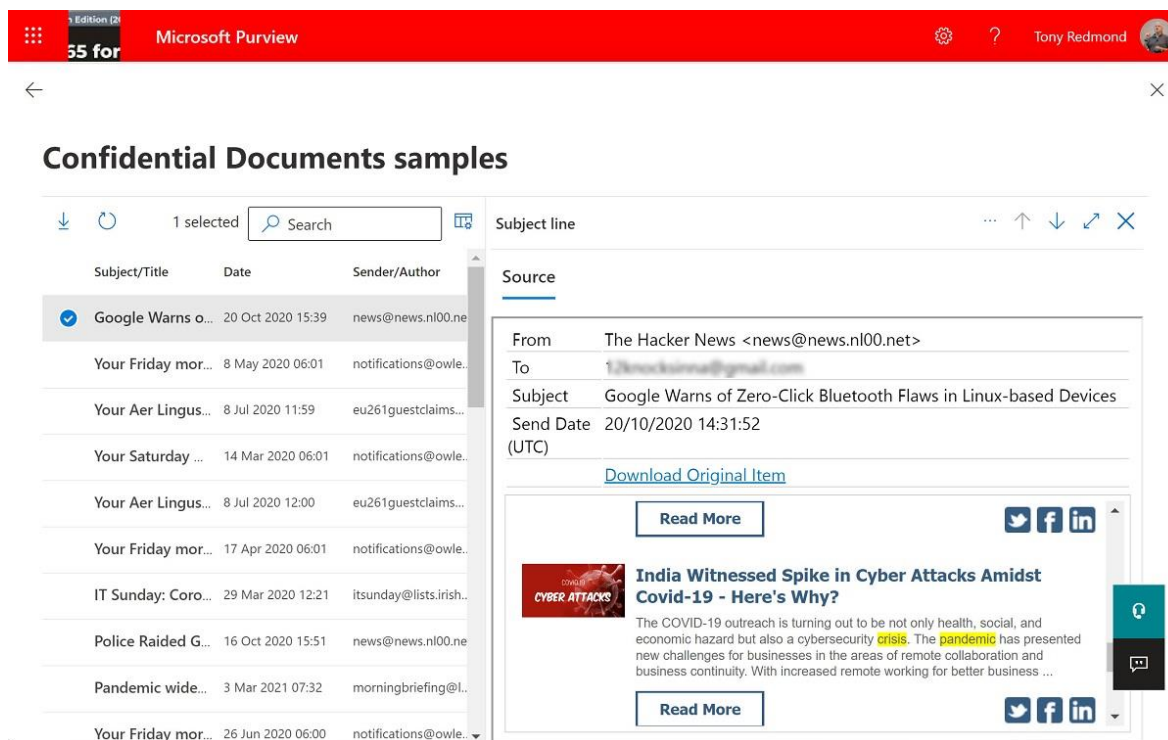

Figure 18-4: Reviewing sample items retrieved by a content search

When the preview search is ready, the search selects samples from the top locations (those that hold the most matches). You can view the items retrieved by the preview search by selecting the **Review sample** option from the search summary. As shown in Figure 18-4, sample items include email messages, Teams compliance records, and files (list items are not available for preview). If an item has an attachment, it also shows up as viewable if the attachment is an Office document. Preview can decrypt protected files and messages too. Naturally, the fewer the number of results, the less time it will take for the search to show the preview results.

If the preview of the source for a found item displayed in the viewing pane isn't sufficient to fully understand the content of an item, you can use the *Download Original Item* link in the item preview pane to download a copy of the item for review.

The Microsoft Purview Compliance portal [limits the number of items selected for preview](#). This is acceptable because the intention behind the preview sample is to help investigators understand the effectiveness of the search query in terms of finding the required data. The preview sample is not a tool to browse through the complete set of items uncovered by a search. Table 18-4 lists the limits for the preview screen in terms of its ability to display items found by searches.

<b>Limit</b>	<b>Number</b>
Maximum number of items per user mailbox displayed	100
Maximum number of items from all mailboxes displayed (the newest items are shown)	1,000
Maximum number of items found in SharePoint Online and OneDrive for Business sites displayed	200
Maximum number of SharePoint Online and OneDrive for Business sites that can be previewed for search results	200
Maximum number of items per public folder mailbox displayed	100
Maximum number of items from all public folder mailboxes displayed	200
Maximum number of public folder mailboxes that can be previewed	500

Table 18-4: Display limits for search preview

The search summary screen includes search statistics for the estimated items that a full search will find (Figure 18-5). The three sets of statistics are:

- **Search content:** Displays the estimated items for the locations scanned (SharePoint and Exchange), the number of locations with hits (matching results), the number of matching items found, and the size of those items.
- **Condition report:** Displays the location type (SharePoint or Exchange), the condition (search query used), the number of locations with hits, the number of matching items found, and the size of those items. If you use a keyword list, you can see how effective each keyword is in terms of locating items (a result recorded as Primary means the complete search query; Keyword means the results from a specific keyword). You can also see whether any unindexed items matched the query. Unindexed items are often graphic files like a bitmap or JPEG file, or the MP4 files used for Teams meeting recordings.
- **Top locations:** The sites and mailboxes where most matching items were found, including the number of those items and their size.

Figure 18-5: Reviewing statistics for a preview search

## Expired Searches

If you look at the details of a search and see that *"the search has expired,"* you know that it is more than seven days since the last run of the search. As such, Microsoft 365 considers the result results to be unreliable because it doesn't include potentially important information added to the search locations in the last week. To proceed to use other search features such as exporting results, you must first rerun the search to make it current.

## Exporting Search Results

Eventually, you will be happy that a search finds the right information. At this point, you might want to export the files and messages found by the search to perform a more detailed examination of individual items, give the data to external investigators, or make it available to someone who does not have the necessary permission to run searches in the Microsoft Purview Compliance portal. The export function allows you to extract search results from the source locations, copy them to a secure holding point in Azure, and then copy the data from Azure to PSTs (for messages), individual files, or ZIP files. You can also export a report of the search results, meaning that instead of exporting the actual data, the search creates and exports reports listing the files and messages that it would export for a search.

A content search export can process items found in up to 100,000 mailboxes and will fail if a search covers more than this number. If you need to export information from larger location sets, you should use Premium eDiscovery.

## Selecting Export Options

To begin, make sure that the search is current as you will not be able to export results if they are more than seven days old. It is a good idea to refresh search results before beginning an export as this ensures that the exported data will be completely up to date. To start the export job, select **Export results** from the **Actions** menu. Figure 18-6 shows the screen used to gather information for the export process. While the search always exports SharePoint and OneDrive documents as individual files, you can export items extracted from Exchange mailboxes to:

- **A single PST for all Exchange content:** This option is convenient for investigators and is usually the best option when dealing with small amounts of information. Exchange Online does not include the *New-MailboxExportRequest* cmdlet available in the on-premises version to export content from a mailbox to a PST. However, you can mimic the functionality by creating a content search for all content in a single mailbox and exporting the results (the entire mailbox) to a PST.
- **To multiple PSTs** (one per mailbox): This choice allows the people who must process the results to split the workload across multiple individuals. If an export processes more than 10 GB of data, the job will automatically split into multiple PSTs, each of which is up to 10 GB (it is possible to change this limit with [a registry setting](#)).
- **To individual MSG files:** This choice exists because some third-party investigation tools do not support importing data from PST files. In addition, if you want to export messages encrypted with rights management, you must export them as individual files. The export job writes a copy of each message uncovered by the search to the target destination in the file system. The administrator can then move the copied files from there as needed. The export job organizes the individual MSG files into a folder structure. The folder for a mailbox is named after the user principal name of its owner. Underneath this root, the found items are divided into:
  - **Recoverable items:** Items extracted from folders in the Recoverable Items structure are here. For example, if an item was purged by the user but kept due to a hold placed on the mailbox, it is in the *Recoverable Items\Purges* folder in that user's mailbox.
  - **Top of Information Store:** The export job places items extracted from folders visible in the user's mailbox here. The export job creates a separate file system folder for each folder in the mailbox where the search found a matching item. Given the complex folder structure that exists within some mailboxes, the 260-character maximum path to a Windows folder may be reached. When this happens, the export job truncates the folder names to stay within the limit.
- **To a compressed (zipped) folder:** This option includes both Exchange and SharePoint content. Exchange items are in separate MSG files (with attachments) while items found in SharePoint and OneDrive are exported as individual files. Exporting to a compressed folder avoids the issue that sometimes arises when the file path to a SharePoint item exceeds 260 characters. Like PST files, if an export exceeds 10 GB, the search splits the export into multiple ZIP files (you can use the same registry setting mentioned above to control PST sizes to change the maximum size for a ZIP). Note that files in a ZIP folder only have the modified date for files, not the created dates. However, the created date is stored in the XML manifest for the export job.

**Export results**

When you start this export, we'll begin getting these search results ready for download. This may take a while depending on the size of your search results. [Learn more](#)

**Population**  
Searchable Files: Confidential Documents

**Output options**

All items, excluding ones that have unrecognized format, are encrypted, or weren't indexed for other reasons

All items, including ones that have unrecognized format, are encrypted, or weren't indexed for other reasons

Only items that have an unrecognized format, are encrypted, or weren't indexed for other reasons

**Export Exchange content as**

One PST file for each mailbox

One PST file containing all messages

One PST file containing all messages in a single folder

Individual messages

Enable de-duplication for Exchange content

Include versions for SharePoint files

Export files in a compressed (zipped) folder. Includes only individual messages and SharePoint documents.

**Estimation**

After starting the export, a new export object with name "Confidential Documents\_Export" will be created in the Export table. To see status and download results, select the "Export" menu option.

**Export** **Cancel**

Figure 18-6: Defining settings to export items found by a content search

If the search includes SharePoint or OneDrive for Business sites, you have the choice to include versions for documents found by the search. Versions are only available for documents if versioning is enabled for document libraries. Versions come from the preservation hold library of the sites where the search finds documents. You'll recognize these as versions because their name is composed of the original file name plus a date-based identifier created by SharePoint to make the file name unique.

Due to the way that Exchange Online delivers individual copies of messages to mailboxes, a search will likely find multiple copies of a message. To export just a single copy, enable the de-duplication option for Exchange content. Each message has a unique identifier, so when de-duplication is enabled, the export processes only the first copy of a message returned by the search. If it's important to recover a copy from specific mailboxes (perhaps for legal reasons), you can always run another export to recover copies for each mailbox where a message exists.

System data found by a search in a user mailbox, such as the information used by Viva Insights, doesn't appear in a preview, but the search exports this data to a folder called *Other Office 365 Data*. This data also includes Microsoft Forms owned by the user. Search exports metadata and Forms Q&A in JSON format. These items don't appear in search previews.

## Decrypting Search Results

The export process decrypts email messages protected with sensitivity labels including any attachments, but only if you export messages as individual MSG files. Protected items exported to a PST remain encrypted. Search marks items decrypted by the export process with “Decoded” in the Decode Status column of the Results.csv file in the export destination.

The Standard eDiscovery and content search export process does not decrypt protected documents exported from SharePoint Online and OneDrive for Business sites. If necessary, you can decrypt these files by running PowerShell cmdlets from an account that holds rights management super-user privilege. See the section on this topic in the Information Protection chapter. The Premium eDiscovery export process can decrypt protected documents, so if you have the necessary licenses, you can use this facility to export decrypted copies of protected files.

## Handling Partially or Unindexed Items

Tenants are likely to have a certain percentage of unindexed or partially indexed items in Exchange Online, SharePoint Online, or OneDrive for Business sites. More will be in Exchange than the other workloads simply because users generate more messages than documents. Partially indexed means that the index contains an item’s metadata (like subject, author, and creation date) but some or all of the item’s content might not be. Content searches can find partially indexed items using metadata.

The reasons why these items exist are varied. Some attachments or documents might be in an unsupported format; some items are too large (greater than 150 MB); some messages have more attachments than the supported maximum (250); and some formats have specific limits, like Excel’s 4 MB limit. The limits for content searches [are available online](#) and the statistics reported for a content search tell you how many unindexed items were found. To help organizations understand the number of these items in their tenant, Microsoft wrote a PowerShell script to analyze how many partially indexed Exchange Online items exist and report the reasons why indexing failed. You can read [the article online](#) and fetch a modified version of [the script from GitHub](#).

Partially indexed items can be of interest to investigators, and you should include these items in exports if you want to be sure that an investigation can consider every possible issue. After all, a human might make sense of a file included in an export where a search cannot. Three options are available:

- **All items, excluding unindexed items.** This is the default and means that the search only exports items meeting the search criteria. Unindexed (partially indexed) items are excluded.
- **All items, including unindexed items:** The export includes unindexed items, but only if the search also finds items matching the search criteria in a site.
- **All unindexed items:** The export includes all unindexed items from all sites in the search, even if the search does not find matching items.

The usual process is to exclude unindexed items from exports and then decide whether a deeper examination is necessary incorporating these items.

## Downloading Exported Results

After selecting the options for the export job, click **Export**. A background process starts to extract the information from source locations and copy it to the holding area in Azure. To follow the progress of the export job, click the **Export** tab in the menu bar to see a list of all the export jobs processed for searches. Select the export job for your content search (it has the same name as the content search with a suffix of “\_Export”), to display the status for the export job. Any search which uncovers tens of thousands of items spanning gigabytes of data will need some time to export the matching data. In this case (Figure 18-7), the number of search results is small, and we can see that the export is complete.

Before going ahead to download the exported results from Azure, we must copy the export key. The export key is a [shared access signature](#) to grant access to the secure storage area holding the export results in Azure and is of the form:

```
?sv=2014-02-14&sr=c&si=eDiscoveryBlobPolicy9%7C0&sig=PpqtiOKpBMzZPtA1ksuY8iciP6jsYYI2VHePjDXY45w%3D
```

The export key becomes the credentials to authorize the download of the exported data using the Microsoft 365 eDiscovery Export Tool. Essentially, the report key is a token that Azure Data Services recognizes when offered by a process that wishes to access some data belonging to another entity. You cannot use the key to access data held in Exchange Online or SharePoint Online with a browser or another client. After copying the export key to the clipboard, you can paste it into Notepad or another editor to make sure that it is always at hand. However, if you are ready to go ahead and download the results, click **Download Results**. It doesn't matter if the search has not finished preparing data for export yet because the export tool checks with the search when it downloads information and will pause to let the export complete.

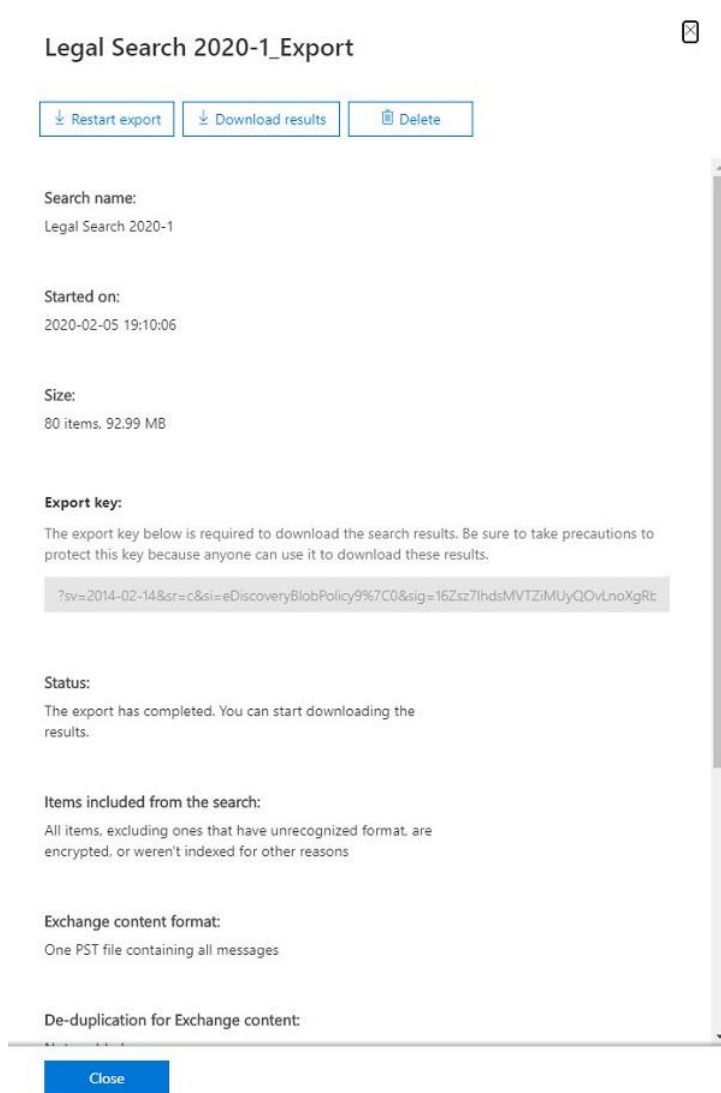

Figure 18-7: Preparing to download the exported results from a search

You must use the Microsoft Edge browser to download and install the export tool. You can use any other browser supported by Microsoft 365 to perform all other search functions. The first thing to do is configure Edge to enable *ClickOnce* support (the ability to [install and run an application created with the ClickOnce technology](#)). To do this, open a tab in edge and go to `edge://flags/#edge-click-once` and make sure that the value in the drop-down list is Enabled. If you don't do this, the export tool won't be able to run.

**After Edge downloads the export tool, it installs the tool on the workstation if necessary and then starts the tool. When export results are available in Azure, you can proceed** with the export by entering (paste) the export key and the target location for the tool to copy the exported data (Figure 18-8). The export tool then authenticates its access with Azure and downloads the exported data to the selected destination, including metadata for SharePoint and OneDrive documents. If you don't choose to use the advanced option to name the PST to hold exported Exchange content, Purview exports the results to a file called Exchange.PST. If necessary, you can use **Restart Export** to recommence the export process. This action removes any earlier search results stored in Azure and then recopies the search results from the search locations to the holding location in Azure.

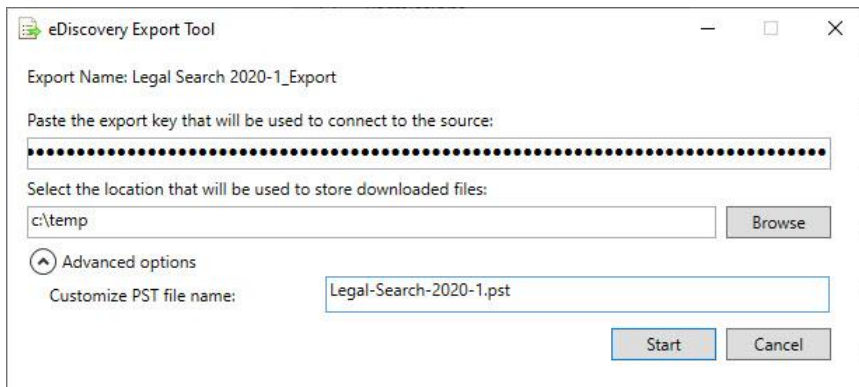

Figure 18-8: The eDiscovery Export tool begins to export information from Azure

The export job creates several sub-folders in the destination to hold the export data. The folder named after the date and time of the export includes an Electronic Discovery Reference Model manifest listing all the exported items. The Exchange folder holds the PST files used to export the data. Figure 18-9 shows the content exported from a SharePoint Online document library. In this case, the export job copied the files to a ZIP file. Once exported to disk, it is easy to give the information found by a search to an external company, such as specialized legal investigators. The external company can then apply whatever tools they choose to analyze the search results.

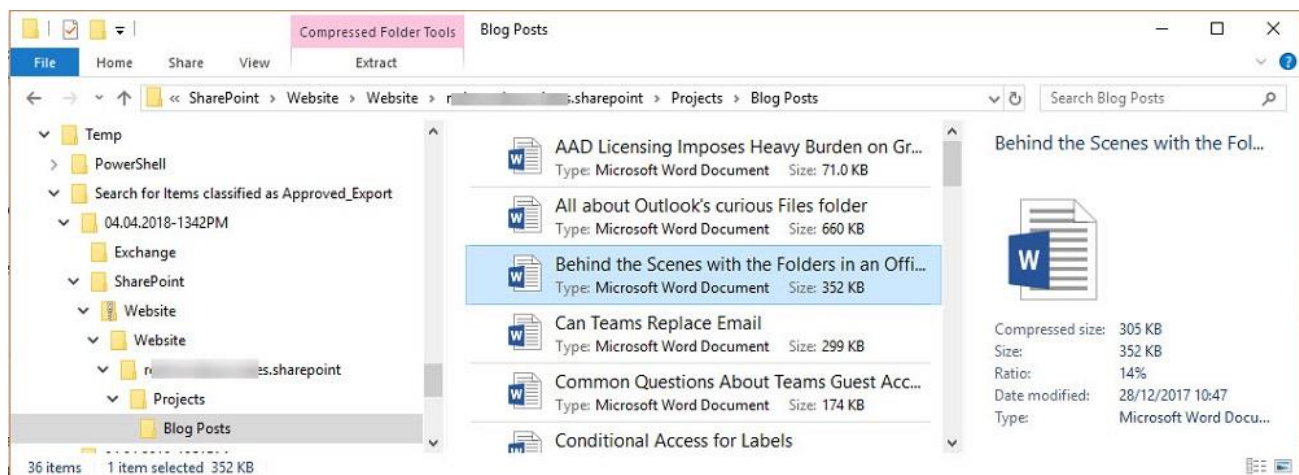

Figure 18-9: SharePoint documents exported from a search

You can export up to 2 TB of data for a single search from up to 100,000 mailboxes (you can [use PowerShell to export results for a larger number of mailboxes](#)). If a search finds more than this amount of data, you will have to split the search to get under the 2 TB limit. One way of doing this is to create several searches, each of which uses the same keyword query but different date ranges. Reflecting that it is a multitenant environment, Microsoft 365 limits a tenant to exporting 2 TB of data in a single day. A tenant can run up to ten export jobs concurrently, but a single user can only run three of those exports.

## Protected Documents and Searches

If support for sensitivity labels is enabled for SharePoint Online, the content of documents protected with rights management (Microsoft Information Protection) are indexed and can be found by a content search. If not, a content search cannot find protected documents based on their content and must rely instead on metadata such as the document title, comments, or tags.

Protected documents found by a search are exported like any other item, but they continue to be encrypted and cannot be examined by an investigator unless an arrangement is made to decrypt the files.

The Information Protection chapter contains some advice about how accounts assigned with super-user permission for information protection can run PowerShell code to find and decrypt protected files exported for a search. This is especially important for GDPR data subject requests (and possibly for data erasure requests) because someone must check the content of documents to understand whether they relate to a data subject.

## Export Search Report

Being able to review search results gives investigators insight into the kind of information uncovered by a search. However, it would be unreasonable to try to preview every item found by a search, especially when large numbers are involved, in which case an investigator might want to make a broader check of the data uncovered by a search before going ahead to export the data. To export the reports for a search, select the search and then **Export results** from the **Actions** menu. This downloads the same reports (the XML manifest, summary log, and results log) holding details of the information included in the full set of downloaded search results. When you choose to export the report, an export job generates the reports and stores them in Azure. You receive an export key to access the data and can use the same download tool to export the reports to the nominated destination. After checking that the correct results are available, you can then continue to perform a full export.

**Export for third-party review:** The eDiscovery industry spans many companies that specialize in the analysis of information recovered from IT systems like Microsoft 365. Microsoft has a program to support the export of information recovered by searches in a form that third-party applications can interpret and analyze. The export data exists in a location in Azure Data Services controlled by the third-party. Contact Microsoft to get an up-to-date list of certified partners if you are interested in this capability.

## Reopening a Search

You can go back and open a search at any time. Select **Content search** in the Microsoft Purview Compliance portal to list the available searches and select the one you want to work with, and then **Edit search** from the **Actions** menu. If the last search is less than seven days old, you can preview results with the **Review sample** option to see how accurate the search criteria are before making changes. If the search is older, you need to rerun the search before you can preview the sample results.

## Compliance Boundaries

When you have the permission to create and run content searches, you can look for anything across the set of supported locations in a tenant, including the ability to pry into sensitive mailboxes or hunt for interesting documents stored in document libraries that you would not otherwise be able to see. Compliance Security Filters allow tenants to impose control over the data visible to investigators by establishing boundaries for searches. Large companies often divide administrative and other responsibilities along geographic or divisional lines. When the time comes to conduct content searches, they might not want those who run the search to be able to include search locations outside their business, country, or region. This makes a lot of

sense: someone running a content search to respond to a discovery action in France does not necessarily need to look at German mailboxes. Apart from respecting user privacy, Compliance Security Filters also mean that content searches return a smaller amount of data for investigators to review.

A Compliance Security Filter creates a restrictive view of mailboxes or SharePoint and OneDrive sites within a tenant. When users that conduct searches come within the scope of a filter, they cannot see any data returned by searches except that given by the restrictive view. Therefore, we can set things up that U.S.-based eDiscovery administrators only can see results from mailboxes located in U.S. data centers or that only certain eDiscovery administrators can search particularly sensitive SharePoint sites.

Before starting to plan your filter strategy, you should read the Microsoft [support article about Compliance Security Filters](#) and [this blog post](#). The key point to note is that you can only create and manage filters through PowerShell. To guide you in creating a filter, answer the following questions:

- **Who will the filter apply to?** You can specify individual users or use the name of a Compliance role group, including a role group created specifically for this purpose. You cannot use a distribution list, Microsoft 365 Group, or security group to define a set of users.
- **What can the users do?** You can restrict users to individual compliance actions (Export, Preview, Purge, Search) or "All". You cannot specify two or three actions. In most cases, you will want to use Search or All.
- **What can the users see?** You can combine mailbox and SharePoint locations into a single filter that works across multiple workloads. In both cases, you can have filters that look for specific objects (mailboxes or sites) or content (based on KQL queries).

With these points in mind, here is a simple filter that applies to a single named user to allow them to perform all compliance actions while restricting them to searching mailboxes with a specific value in their *CustomAttribute6* property. To create the Compliance Security Filter, connect to the compliance endpoint and run this command:

```
[PS] C:\> New-ComplianceSecurityFilter -FilterName VikFraudSearch -Users "Marc Vigneau" -Filters "Mailbox_CustomAttribute6 -eq 'POI'" -Action All
```

To add a mailbox to the set that searches performed by the users identified in the filter can find, we update the *CustomAttribute6* property as follows:

```
[PS] C:\> Set-Mailbox -Identity Kim.Akers -CustomAttribute6 POI
```

After updating the mailboxes, you can test the filter to check the set returned with *Get-Recipient*:

```
[PS] C:\> Get-Recipient -RecipientType UserMailbox -RecipientPreviewFilter {CustomAttribute6 -eq 'POI'}
```

Now that we know that the filter is valid and returns a set of mailboxes, we can test it with a search. Log into the Microsoft Purview Compliance portal using the account of one of the users restricted by the filter. The user must have the necessary permission to run searches. Create a new search for all mailboxes with a query that you know will find some information. Launch the search and wait for it to complete. The results should reflect the filter in terms of the number of locations scanned and the amount of information found.

Now log into the Microsoft Purview Compliance portal as another administrator who is not restricted by the filter and run the same search again. This time the results should be very different. Figure 18-10 shows an example of a content search run by restricted (left) and unrestricted (right) eDiscovery administrators. The restricted search only scans 2 mailboxes while the unrestricted search looks through 468. The number of found items is also different, as you'd expect.

Figure 18-10: The result of applying a search filter

Microsoft suggests many other examples of Compliance security filters [in its documentation](#), including how to filter mailboxes based on the ISO 3166-1 code (for example, 124 is the three-digit code for Canada while 372 is the code for Ireland). One example of obvious interest is a filter that restricts access to confidential or sensitive mailboxes. The code to create such a filter first finds the distinguished name of a distribution list called the "Senior Leadership Team". The members of the list are the mailboxes that we want to restrict. We include the distinguished name in the filter to stop anyone who runs a search against these mailboxes from being able to preview items found by the search.

```
[PS] C:\> $DG = (Get-DistributionGroup -Identity SLTDL).DistinguishedName
New-ComplianceSecurityFilter -FilterName NoSLTPreview -Users All -Filters "Mailbox_MemberOfGroup -ne '$($DG)'" -Action Preview
```

The *Get-ComplianceSecurityFilter* cmdlet reveals the details of the filter:

```
[PS] C:\> Get-ComplianceSecurityFilter -FilterName NoSLTPreview
FilterName : NOSLTPREVIEW
Description :
Action     : Preview
Users      : {all}
Filters    : {Mailbox_MemberOfGroup -ne 'CN=DL Senior Leadership
Team,OU=tenant.onmicrosoft.com,OU=Microsoft Exchange Hosted
Organizations,DC=EURPR04A002,DC=prod,DC=outlook,DC=com'}
```

This kind of filter effectively stops casual browsing of preview samples from sensitive mailboxes by people who should know better. It does not stop searches from finding items, nor does it stop eDiscovery administrators from being able to export items found by the searches. The downside of using a filter is that it applies to all content searches, including those executed by people that might legitimately have reason to preview content found in the sensitive mailboxes.

Users cannot preview items found by a content search in the designated mailboxes, but they can preview documents and other items (like PDFs) found in sites covered by searches. To ensure full confidentiality for the Senior Leadership Team, you need to define a site filter to protect these locations. This filter restricts access to documents found in the document library. In this context, "All" means members of the eDiscovery manager role group rather than all users.

```
[PS] C:\> New-ComplianceSecurityFilter -FilterName NoSLTPreviewDocs -Users "All" -Filters "Site_Site -ne 'https://tenantname.sharepoint.com/sites/SLTGroup'" -Action Preview
```

You can create a filter with clauses for multiple workloads (a filter list). Here is a filter with two clauses: one for U.S.-based mailboxes and the other for a specific SharePoint site:

```
[PS] C:\> New-ComplianceSecurityFilter -FilterName CountryFilter -Users annb@contoso.com -Filters "Mailbox_CountryCode -eq '840'", "Site_Site -eq 'https://tenant.sharepoint.com/sites/Confdocs'/" -Action All
```

## The Effect of Filters on Content Searches

In its documentation, Microsoft explains that:

*"The permissions filter is added to the search query when a Content Search is run. The permissions filter is essentially joined to the search query by the **AND** Boolean operator."*

and:

*"In a Content Search query, multiple permissions filters are combined by **OR** Boolean operators. So results will be returned if any of the filters are true. In a Content Search, all filters (combined by **OR** operators) are then combined with the search query by the **AND** operator."*

If you use multiple filters, the filters are joined with the query (AND) and then combined (OR). This allows the search to find all the content per the query and then apply each filter to arrive at a combined set of results. The exact results that any action (search, preview, or export) produces depend on the actions specified in each filter. The ability to combine filters with content searches creates a great deal of flexibility in what you can do to control searches, even if it might take some time and effort to arrive at the filters needed to generate the desired result.

Note that you cannot exclude specific public folders using a search filter. The filters only work for user and group mailboxes and SharePoint and OneDrive sites.

# Auditing of Search Activities

Administrators and eDiscovery managers access and view user content through content searches. Being able to access messages, documents, and other potentially sensitive user content is necessary as otherwise, you'd never be able to perform a compliance search and export its results. Because searches use privileged access to user data, the Microsoft Purview Compliance portal captures audit records when investigators create and run content searches and eDiscovery cases, and for search actions against results like preview, export, and purge. Having audit information to hand enables organizations to ensure that they meet their requirements to protect confidential user information under regulations such as GDPR.

You can review the audit records for search activities through the audit log search in the Microsoft Purview Compliance portal. This is a reasonable approach when you know the time and date when an activity occurred, and you only need to review a small number of activities.

If you want to process a lot of audit records, perhaps to verify that administrators are not abusing their access to user information, it is better to use PowerShell to interrogate the audit log and extract the records you might be interested in analyzing. This example (see Chapter 21 for a more extensive discussion of using audit

log data) extracts records captured when users view, export, or preview the results of content searches, and outputs a CSV file. The CSV file can be opened and reviewed in Excel or imported into Power BI.

```
[PS] C:\> $StartDate = (Get-Date).AddDays(-7) ; $EndDate = Get-Date
$Records = (Search-UnifiedAuditLog -StartDate $StartDate -EndDate $EndDate -Operations
"SearchExportDownloaded", "SearchViewed", "ViewedSearchPreviewed" -ResultSize 1000)
If (!$Records) {
    Write-Host "No audit records for content search activities found." }
Else {
    Write-Host "Processing" $Records.Count "audit records..."
    $Report = [System.Collections.Generic.List[Object]]::new()
    ForEach ($Rec in $Records) {
        $AuditData = ConvertFrom-Json $Rec.Auditdata
        $ReportLine = [PSCustomObject]@{
            TimeStamp = Get-Date ($Rec.CreationDate) -format g
            User       = $AuditData.UserId
            Action     = $AuditData.Operation
            Exchange   = $AuditData.ExchangeLocations
            SharePoint = $AuditData.SharePointLocations
            Query      = $AuditData.Query }
        $Report.Add($ReportLine)
    }
}
$Report | Export-Csv c:\temp\SearchAuditRecords.csv -NoTypeInformation
```

Microsoft Purview captures audit records for many other content search and eDiscovery activities, and it is easy to modify the PowerShell code shown above to include multiple other activities and export those records for later analysis.

## Data Subject Requests

According to [Microsoft's Data Subject Guide](#), 90% of an organization's data stored in Microsoft 365 is in Word documents, Excel spreadsheets, PowerPoint presentations, OneNote files, and Outlook messages. The data are indexed and searchable. Some data cannot be found by content searches, so the information you can find through a DSR case is not necessarily all the personal information belonging to a data subject existing in a tenant. For instance, videos featuring the user stored in Stream cannot be found through eDiscovery, so extra effort is needed to review and retrieve this information if necessary.

Article 15 of the GDPR grants a data subject (a person) the right to have a data controller (the organization owning a tenant) provide them with a copy of their data. To help tenants respond to these requests, the Microsoft Purview Compliance portal supports the creation and management of special eDiscovery cases, called [Data Subject Request \(DSR\) cases](#). These cases are created under User data search in the eDiscovery section. This capability is free as the cases use a customized version of regular content searches.

A DSR includes a content search for the personal data belonging to a defined individual. An eDiscovery case is created including a search of the person's mailbox (if it exists), all public folders, Teams chats and channel conversations, and SharePoint Online and OneDrive for Business sites for any information relating to the data subject. If the tenant's Yammer network is configured in native Microsoft 365 mode, its messages can be included in the search.

Things to remember about DSRs include:

- The search locations are not dynamic. If new mailboxes or sites are added to the tenant after you create the DSR, the search will not look in those locations.
- A DSR can only search cloud locations. If you run a hybrid organization, you must run separate searches to find relevant information in the on-premises locations. Exchange 2010 and later and SharePoint 2010 and later include the ability to run eDiscovery searches that can be tailored as DSRs.
- GDPR says that DSRs must be responded to within a month of the request. It is therefore important to keep an eye on the progress of DSRs and highlight instances when DSRs are delayed.

- DSRs do not address the need to remove information about a data subject (the right to be forgotten defined in article 17). However, the reports generated for a DSR will tell you where data matches are found and allow you to then check the individual items to decide whether items should be removed. Remember, not all data found for a data subject needs to be removed as it is legally permissible to keep data under certain circumstances, such as to comply with a legal obligation.

When you are happy that the searches return the information necessary to satisfy the data subject request, you can export the information as normal and prepare it to give to the data subject. A further check is always needed to exclude any information in the exported data that is unrelated to the data subject. For instance, if the name of the data subject is common (like John Smith), some of the matches returned by the searches probably do not refer to the data subject. It is also possible that some of the information is commercially sensitive and needs review by the business and potentially by legal advisors before it can be released.

## Priva Subject Rights Requests

The Priva Subject Rights Requests solution is part of the [Microsoft Priva privacy management suite](#). It is a more developed and comprehensive version of DSR processing which Microsoft licenses on a per-request basis. Organizations can run a free trial of Priva Subject Rights Requests for up to 90 days or 50 requests (whichever limit is reached first). Priva Subject Rights Requests include:

- Customized content searches to find information relating to a data subject.
- Retrieval of information to an Azure blob storage container for review (annotation, tagging, redaction, etc.). During retrieval, Priva attempts to identify high-priority items for reviewers to consider.
- Generation of reports.
- Integration with Teams for collaboration (by default, each request creates a team for those working on the request to use with the person who creates the request being the team owner).
- Workflow based on Power Automate (customizable by the organization).
- Processes requests in line with compliance regulations including GDPR, the California Consumer Privacy Act (CCPA), UK Data Protection Act (UDPA), U.S. State Breach Notification Laws (USBNL), and U.S. Patriot Act (USPA).

# Microsoft Purview eDiscovery

Content searches are useful in a variety of situations. Sometimes it is to find information that a user has “lost,” and sometimes it is to find information for more serious reasons, such as looking for evidence of corporate or personal malfeasance needed to prove a point for internal or external purposes. If the information exists in an indexed location, content searches will find it.

Good as content searches are at finding information, searching is only part of the eDiscovery lifecycle. And while the results of an individual search might be critical to proving or disproving a point, many eDiscovery projects involve teams of investigators using multiple searches looking for different sets of information. eDiscovery cases deliver the structure needed by investigators to organize their work, including searches, holds, and exports.

Microsoft Purview eDiscovery functionality divides into standard and premium. Standard eDiscovery is available to tenants with E3 licenses; you need E5 licenses or the Microsoft 365 E5 Compliance license to use Premium eDiscovery.

## Standard eDiscovery

To access the cases created by standard eDiscovery, go to the **eDiscovery** section in the Microsoft Purview Compliance portal and select Standard. This reveals the set of eDiscovery cases available to the logged-in user

(Figure 18-11). Some of the cases are "Active," meaning that investigators might still be working on these cases. Closed cases are still available, and investigators can reopen them if necessary.

## eDiscovery (Standard)

 Remove from navigation

After creating an eDiscovery case and choosing who has access to it, use the case to search for email, documents, Skype for Business conversations, Teams data, and other content in your organization. You can then preserve the content and export the search results for further analysis. [Learn more](#)

Figure 18-11: A set of Standard eDiscovery cases

## eDiscovery Case Components

If you open an eDiscovery case, you see that its major parts are:

- **In-place holds to ensure that users cannot remove information.** Holds ensure that Microsoft 365 workloads retain information needed for an eDiscovery case in their original location. A hold covers a set of locations (Exchange mailboxes, SharePoint and OneDrive for Business sites, and Exchange public folders) and criteria to specify the items in those locations that come under the scope of the hold. A hold can be as broad as to include all items in all available locations within a tenant or as specific as to hold just one or two items found with a highly-specific phrase in a selected mailbox.

All items that fall under the scope of the hold stay in the specified sites and mailboxes (including those used by Microsoft 365 Groups). Users can try to remove items that come under the scope of the hold, but if this happens, the workloads keep a copy of the item until the hold expires. In-place holds on Exchange mailboxes include both the primary and archive mailboxes. Standard content searches do not include the ability to place holds on sources. Note that a user account must have at least an Exchange E3 license before you can place it on hold. The license must stay assigned to the account for the duration of the case. An eDiscovery case can include multiple holds, each of which has its own target set of locations and hold criteria.

- **Searches are used to gather** information of interest to the case. The searches in an eDiscovery case behave very much like content searches. An eDiscovery case might only have one search, but it might equally deploy multiple searches, each of which focuses on different material. Each search covers a different aspect of the case and might look for content based on different queries, various locations,

or even content created in different languages. The intention is that multiple searches allow investigators great flexibility in how they approach looking for information because they can create a series of searches to interrogate information with different criteria. The searches created for eDiscovery cases do not appear along with other content searches because they belong to an eDiscovery case. Both types of searches use the same technology to find information using the content indexes populated from Exchange Online and SharePoint Online data. The names assigned to searches belonging to eDiscovery cases must be unique and not clash with standalone content searches.

One difference between regular content searches and those executed within an eDiscovery case is that in a case, you can specify the special *"Locations on hold"* target for a search, meaning that you want to search the held content in all the locations included in a case. For example, assume two holds exist for the case. The first covers two mailboxes and two sites and the second span a further twelve mailboxes. In this instance, *"Locations on hold"* means searching the held content in the fourteen mailboxes (including their archive mailboxes if these exist) and two sites. If the scope of any of the holds belonging to a case changes (for example, the addition of new locations), the scope of *"Locations on hold"* changes to match the holds when you refresh the search results. Searching against on-hold content is a current workflow scenario in eDiscovery situations where investigators place locations such as mailboxes or sites on hold before starting to search those locations.

- **Exports of information gathered by the searches.** An eDiscovery case might use several searches to find different sets of information. You can export results from a single search using the same steps as for exporting results for a normal content search, or you can combine the results of multiple searches belonging to a case into a single set of data to give to external investigators.

When you combine results from multiple searches, the search combines the queries using the OR operator to form an overall query and runs the query against the locations to generate the search results. In other words, the search results created for export come from a single search instead of manually combining the sets generated for the individual content searches. The results of the searches are deduplicated so that the export includes only a single copy of an item found in a location. Because of the way that a combined search brings multiple search queries into one, the overall keyword limit for a query (500) might be met. If so, you will see an error and the search will end. To achieve the desired result, you must combine fewer searches or simplify the queries.

## Case Members

Each case has one or more members, each of whom must be a member of the eDiscovery Manager role group. The members are the only people who can access the results of the searches associated with a case. The eDiscovery Manager role group divides into two sub-groups:

- **eDiscovery Managers** deal with specific cases. They only have access to the content belonging to those cases. When a user accesses the Microsoft Purview Compliance portal, they can only see the cases where they are the eDiscovery Manager. They cannot see the cases belonging to other eDiscovery Managers.
- **eDiscovery Administrators** have oversight over all eDiscovery cases and can view and edit any case within the tenant regardless of who is the eDiscovery Manager for the case. To access a case, an eDiscovery administrator adds themselves as a member of the case.

Logically, a very small set of users within a tenant should be eDiscovery Administrators.

## Case Management

When you open the eDiscovery section, the Microsoft Purview Compliance portal shows you all the cases that your account manages or has access to. You can then select an existing case or **Create a case** to initiate a new case. When you open an existing case, you can use the **Settings** tab to access the properties of that case, including the members working on the case and its status. Figure 18-12 shows that the selected case has three members plus anyone who is a member of the Senior Investigators role group.

Figure 18-12: Viewing members for a Standard eDiscovery case

You can use the same form to manage the status of the case by closing or removing the case. Due to the nature of corporate investigations, eDiscovery cases are often long projects that span several years. It is not unknown for cases to last five years or more.

## Creating a New eDiscovery Case

From the eDiscovery section of the portal, click **Create a case** to begin. You can then input the name of the new case and some details to describe the need for its creation. Figure 18-13 shows a typical situation. The name of the case clearly shows its intent while the description tells anyone reviewing the case what its purpose is and who authorized the investigation. Click **Save** to continue and be returned to the portal.

### New case

Cancel

Figure 18-13: Creating a new Standard eDiscovery case

Creating a new case creates the eDiscovery case container for searches, holds, and other activities. Nothing much exists in the case at this point, so we should select and open the case to begin adding these elements. The case screen then displays to allow us to access the different components.

## eDiscovery Case Holds

The next step is to create one or more holds to preserve the content needed for the case. You can use multiple holds for an eDiscovery case but in most cases, one hold that applies to Exchange mailboxes and SharePoint and OneDrive for Business sites is enough. Click **Holds** to access that section of the case and then **Create (+)** The steps to create a hold are:

- **Name the hold.** Assign a unique name for the hold along with an optional description. Ideally, the description should tell an eDiscovery manager the intention behind the hold and link the hold to the eDiscovery case. For instance, if the case name is "Investigation 2020-003," then you might call the holds in the case "Investigation 2020-003 #1," "Investigation 2020-003 #2," and so on, following whatever naming convention makes sense.
- **Define the locations** the hold will cover. The locations divide into:
  - Exchange email: User, shared, and group mailboxes. Group mailboxes include group conversations and calendars for Microsoft 365 Groups and the compliance records created for Teams and Yammer conversations. Compliance records for Teams personal chats and private channel conversations come from user mailboxes. If you select a distribution list, Exchange expands the membership and adds valid mailboxes to the hold.
  - SharePoint Online sites (including those used by Teams and Microsoft 365 Groups) and OneDrive for Business accounts.
  - Exchange public folders. You can include or exclude all public folders, but you cannot select specific public folders.
- **Define the search criteria** to find items to hold. The criteria are like those used for content searches and include keywords and conditions.

A hold does not have to include a query, and if it does not, it means that you want to apply a hold to every item in the selected locations. You do this when you want to preserve complete mailboxes or sites because you are unsure of the material that you want to hold. Figure 18-14 shows the summary for the creation of a new hold.

Figure 18-14: Creating a hold for a Standard eDiscovery case

After creating the hold, the Microsoft Purview Compliance portal publishes its details to the workloads for the selected locations. It can take some time to synchronize across all workloads to make the hold effective everywhere, but it should certainly be in place within a few hours.

To view information about a hold, select it to reveal a details pane. Here you find the current hold statistics provided by the relevant workloads to show how many items come under the scope of the hold, the date and time of the last modification for the hold, and some statistics about the items which come within the scope of the hold. If a change is needed for the hold parameters, you can edit the hold settings.

**Applying Holds to Teams Private Channels:** Two steps are necessary to apply a hold to information belonging to a Teams private channel. First, you assign the hold to the SharePoint site for the private channel by specifying the URL of the site. Second, you add at least one mailbox of a member of the private channel to the hold. Compliance records for messages posted to private channels are copied to the mailboxes of all members, so messages for the private channel come within the scope of the hold when you add a member's mailbox. The hold might lapse if that member's account is removed from Microsoft 365, so it's best to add at least two member mailboxes.

## eDiscovery Case Searches

After applying a hold to make sure that users can no longer remove any content that we might need for our eDiscovery case, we move on to searching. The simplest eDiscovery case has just one search, but more complex cases might use multiple searches, each of which takes a different approach to look for material of interest. The idea is that an investigator can use different searches to home in on the information they need. Apart from the ability to use different queries to focus on different material in each search, the searches in a case might target different locations. One search might focus on a set of mailboxes and look for a specific item. A second search might look for some documents in a SharePoint Online site and a third might concentrate on a single user and retrieve a much wider range of content from their mailbox. Like other

searches, you can reiterate several times to refine the results retrieved by search criteria until you find the desired content.

Click **Searches** to go to the search page and then **New search** to create a new search. The same steps to create a regular content search occur when creating a search in a Standard eDiscovery case. These are:

- Name the search.
- Identify the target locations from Exchange mailboxes, SharePoint sites, and Exchange public folders. Select all locations or choose individual mailboxes or sites. If you want the search to apply only to locations on hold for the case, select **Locations on hold**.
- Enter the keywords and conditions for the search to find items.
- Review the search parameters and submit them for processing.

The Microsoft Purview Compliance portal goes ahead and launches a preview search. When the preview search finishes, you can review sample items to understand if the search finds the right items.

## eDiscovery Case Exports

After investigators run searches to find the information they need, they can then export the search results. This process works like exports for content searches, with the notable exception that you can select to export the results for multiple searches in the same operation. The same general approach is used.

- Access the search whose results you want to export.
- Click the **Actions** button and select **Export Results**.
- Set the export characteristics:
  - Decide what items the search finds to include in the export (all items, all items except those that are in an unrecognized format, encrypted, or indexed, or just the items in an unrecognized format, encrypted, or unindexed).
  - Decide what PST structure to use for mailbox items (one PST per mailbox, one PST for everything, one PST with all messages in a single folder) or to use individual MSG files.
  - Decide whether to deduplicate the search output.
  - Decide whether to include versions (if available) for SharePoint and OneDrive for Business documents.
- A background job named "Search Name\_Export" then exports the search data to a secure Azure location.
- When the search data is available, you download it to a workstation using a secure key generated by Microsoft 365 as credentials to access the data.
- Investigators use the downloaded PSTs, MSG files, and documents to review the information and assess its content.

## Closing eDiscovery Cases

Eventually, when the investigation for an eDiscovery case winds down, the case manager can close the case by selecting the **Close case** option. When you close a case, the underlying workloads release the holds for the case. It can take some time for workloads to process the hold release commands. After the workloads respond to confirm that they have removed the holds, the case status is set to closed, and the time and date of closure and the user who invoked the closure are captured in the case properties. Later, if the case records are not needed, you can remove the case after first releasing any holds belonging to the case. These holds are inactive, but they exist in case someone wants to reopen the case and reestablish the holds, so they must be removed before you can remove the case.

**Warning!** Depending on the age of the data involved, closing a case could result in background maintenance processes removing the items that are no longer on hold. Exchange Online keeps mailbox

items until the deleted items retention period expires while SharePoint Online and OneDrive for Business keep items for 30 days after the hold terminates to avoid any inadvertent data loss. Even so, closing a case is not something to do on a whim. If you make a mistake and need to reactivate a case, the case manager can reopen the case. However, reopening a case does not reestablish the holds that were previously in place and they will have to be recreated by going to the Holds section of the case, selecting each hold, and then taking the **Turn It On option** in the action pane. The gap in time between removing the original holds and reapplying new holds creates the potential that data will be removed from the sources during this period. The exact amount of data that might be lost is unpredictable because it depends on whether the background processing to remove data from sources has run and removed data.

## Premium eDiscovery

The cost of large-scale eDiscovery actions can be staggering. It is expensive enough to retrieve all the items necessary to satisfy a discovery order handed down by a judge. It can be extraordinarily expensive to individually process each piece of information delivered in response to a discovery order. The number of individual messages or documents can easily mount into the low millions and, when very large companies are involved, quickly grow into tens or hundreds of millions of items. The problem then becomes how to locate the proverbial needle in the haystack.

In the early days of eDiscovery, it was common to print off copies of emails and documents for lawyers to review. This process was tedious, paper-bound, and expensive. Lawyers are paid by the hour and lots of IT effort was necessary to generate the material. However, the technique worked reasonably well then because a small volume of email or electronic documents was involved, and the major focus was on paper documents and communications such as faxes and telexes. Today, the situation has changed because paper files are no longer the focus of business documentation and the volume of items stored and available to be discovered has grown massively. If a discovery order turns up 50,000 items, you don't want to incur the cost of having a professional check each item.

### Basics of Premium eDiscovery

Although the standard approach to eDiscovery (hold, search, and export) is suitable for investigations that generate tens of thousands of items, human examination of every item retrieved by a search is a time-consuming and expensive exercise. To address the problem, Premium eDiscovery applies algorithms to refine very large sets of search data retrieved to make it easier for investigators to find what they are looking for. Premium eDiscovery is currently capable of ingesting data sets spanning up to several million items. Microsoft expects that they will be able to lift the limit and at that point, Premium eDiscovery will be able to process as much data as any organization might need.

Consider a situation where a search uncovers a hundred thousand items. The choices are then to:

1. Refine the criteria for content searches to return the most precise set of discovered information and then review all the found items to decide which are useful and which are not. This is an acceptable tactic for relatively targeted searches where the desired material can be accurately described in terms of search criteria. For instance, looking for evidence that a specific phrase was discussed in an email sent between four known individuals.
2. Ingest the output of content searches, use analysis to parse the set of discovered files, and home in on the material that needs close examination, followed by a review of sample items by expert investigators to find items that are of relevance and those that are not. The items deemed to be of relevance are then fed through machine learning algorithms to construct filters (think of them as very complex search queries) that are used to interrogate the complete set of files to locate the desired information.

The first choice described above is roughly what's possible using the Standard eDiscovery features. The second is what becomes feasible with Premium eDiscovery.

The current implementation of Premium eDiscovery uses a workflow described in the [Electronic Discovery Reference Model](#) (EDRM). The stages in the workflow are:

- **Identification:** Knowing whose data should be searched is essential to an investigation. People who might own information needed by the investigation are called **data custodians** or **people of interest**. These are Microsoft 365 accounts that you might want to add to a Premium eDiscovery case and search for data (Figure 18-15). The mailbox and OneDrive for Business site (custodial locations) for each custodian can be included in the case along with other locations they access, such as Teams, shared mailboxes, and SharePoint sites.
- **Preservation:** After you add custodians to a case, you can create **in-place holds** to preserve selected data needed for the case. You can also add holds that cover people who aren't custodians. Premium eDiscovery includes the ability to **send notifications** to custodians by email to tell them that their accounts are under hold and then track responses from the custodians.
- **Collection:** After identifying relevant data sources, you collect information from those sources by using a **special form of content search**. Information remains in the data sources and users can continue to work with it as usual.
- **Processing:** Once searches have located relevant data for the case, you process the data. Like when you export results from a content search, the eDiscovery case **copies data found by searches** to an Azure storage location called a review set. The review set is a static view of the case data that can be analyzed and reviewed for relevance.
- **Review:** Investigators can now look at specific items in the review set to decide if they have the right information or need to query the data to reduce the set to what is most relevant to the case. Investigators can annotate and tag items during this phase. If necessary, case managers can [load data from outside Microsoft 365](#) for inclusion in the review.
- **Analysis:** Premium eDiscovery includes a set of tools to help reduce the data from the review set down to the most relevant information. Reducing the amount of data for investigators (and lawyers) to consider limits the costs of eDiscovery.
- **Production and Presentation:** When the final set of most relevant items is identified, you can export them from the review set. Export can be in the native format of documents or an EDRM-specified format suitable for ingestion into third-party review applications used by external experts.

Premium eDiscovery can process exports involving up to 5 million documents or 500 GB (whichever is smaller). To deal with such large amounts of data, the export splits processing across multiple ZIP files, which investigators can later combine in a single location to reform the complete set. One thing to be aware of is that Premium eDiscovery processing is slower than many people expect. It takes time to perform the complex background processing performed by many actions. Patience is certainly an advantage when dealing with these cases.

Premium eDiscovery is a specialist activity and apart from assigning the necessary permissions to accounts used by investigators, it is unlikely that most tenant administrators will need to become involved in these cases. Instead, it will probably be specialized compliance managers that create and run the cases.

Figure 18-15: Custodians for a Premium eDiscovery case

**Premium eDiscovery Licensing:** While the accounts of users who create the input set for a Premium eDiscovery search only need Office E3 licenses, every user included in the scope of a Premium eDiscovery analysis needs an Office E5 license or Microsoft 365 E5 compliance license. This might sound like Premium eDiscovery is an expensive proposition, but the purpose of the content search is to refine the set of content for Premium eDiscovery to analyze. Refining the input set should mean a reduction in the number of users covered by the set too, so the number of Office E5 licenses you need is probably less than you think. From April 16, 2021, users need an appropriate license to create new Premium eDiscovery cases. Cases created before that date remain accessible to administrators without a license.

## Using PowerShell with Content Searches

Many compliance operations are quite complex, and it is usually best to execute eDiscovery and search operations through the portal. The information about running searches with PowerShell offered here gives some insight into what happens in the background so that you have a starting point for further investigation, if necessary. Remember that to run these cmdlets, you must connect a PowerShell session to the compliance endpoint. In addition, the account used must have the required Compliance permissions to perform whatever action you wish to take. If the account does not have the right permissions, not all cmdlet parameters are available. For example, if the account does not hold the eDiscovery Manager role, you cannot add the export action to a search.

### Creating and Running a New Content Search

To create a new content search, run the *New-ComplianceSearch* cmdlet, followed by the *Start-ComplianceSearch* cmdlet to start the search with the specified query to find items. For example, let's assume that we are interested in finding out whether any items exist in user mailboxes that have a specific phrase in their subject delivered in a certain period. Perhaps these items belong to a potential phishing attack. This command creates a simple content search to look for items based on some subject text delivered in a certain date range.

```
[PS] C:\> New-ComplianceSearch -Name "Look for Phishing Items" -Description "A search to locate suspicious phishing items" -PublicFolderLocation All -ExchangeLocation All -ContentMatchQuery '(Subject: "Phishing") AND (Received:06/01/2016..04/05/2021)' -AllowNotFoundExchangeLocationsEnabled $True
```

Setting *AllowNotFoundExchangeLocationsEnabled* to *\$True* means that the search will check the cloud-only mailboxes used to hold data for hybrid (on-premises) and guest accounts.

After creating the search, we use the *Start-ComplianceSearch* cmdlet to execute the query. Over the lifetime of a search, any time it has been longer than seven days since the search was run, you should run *Start-ComplianceSearch* to scan the target locations and refresh the results.

```
[PS] C:\> Start-ComplianceSearch -Identity 'Look for Phishing Items'
```

The *Get-ComplianceSearch* cmdlet fetches information about the search. For instance, this command checks the status of the search:

```
[PS] C:\> (Get-ComplianceSearch -Identity 'Look for Phishing Items').Status
```

The search status begins with "Starting" as the search engine initializes and evaluates the search parameters. It moves to "InProgress" when the search processes items in the target location. The search status reaches "Completed" when search results are ready for review. The number of items returned by the search is always interesting, so we can see this data with:

```
[PS] C:\> (Get-ComplianceSearch -Identity 'Look for Phishing Items').Items
```

Although content searches are much faster than their on-premises counterparts, a search across many locations can take some time to complete. Inside a script, we might want to have a loop to check the search status and then continue to some other processing once the search completes. Here is a simple loop that checks the search status every five seconds.

```
[PS] C:\> $Search = "Contoso Review of Patent Information for Project Alpha"
Start-ComplianceSearch -Identity $Search
do
{
    Write-Host "Searching..."
    Start-Sleep -s 5
    $Test = (Get-ComplianceSearch -Identity $Search).Status
}
While ($Test -ne 'Completed')

Write-Host "All done. Items found:" (Get-ComplianceSearch -Identity $Search).Items
```

The full output of the *Get-ComplianceSearch* cmdlet includes more detail than the search status and the number of found items. For example, the information returned about this content search shows the number of items found by the search in different mailboxes:

```
[PS] C:\> Get-ComplianceSearch -Identity 'Search for Phishing Items' | Format-List Items, Size, SearchStatistics
```

The information delivered in the *SearchStatistics* property is in JSON format. To see the essential statistics, do the following:

```
[PS] C:\> $Stats = Get-ComplianceSearch -Identity "Contoso Review of Patent Information for Project Alpha" | Select -ExpandProperty SearchStatistics
$Data = $Stats | Convertfrom-Json
$Data.ExchangeBinding.Search

Name           :
Sources        : 12
SourcesRaw     : 12
ContentItems   : 684
ContentSize    : 154.32 MB
```

```
ContentSizeRaw : 161813705
HasFaults      : False
```

To see the search results for each location, examine the *SuccessResults* property:

```
[PS] C:\> Get-ComplianceSearch -Identity 'Contoso Review of Patent Information for Project Alpha' |
Select -ExpandProperty SuccessResults
```

```
Location: Kim.Akers@office365itpros.com, Item count: 34, Total size: 24165076
```

There can be many lines of information detailing locations where a search finds items, including the special mailboxes used to store compliance records generated by Teams and Yammer by guest and hybrid accounts. To report the set of locations where a search finds information, we can use [subexpressions and the special \\$Matches hashtable](#) to capture results. For example:

```
[PS] C:\> [array]$Results = Get-ComplianceSearch -Identity "Project Derrigimlagh" | Select-Object
-ExpandProperty SuccessResults
$RecipientList = [System.Collections.Generic.List[Object]]::new()
$Data = $Results -Split '[\r\n]+'
ForEach ($Item in $Data) {
    If ($Item -match 'Location: (\S+),.+Item count: (\d+)' -and $Matches[2] -gt 0) {
        $RecipientDetails = [PSCustomObject][Ordered]@{
            "Recipient"      = $Matches[1]
            "Items found"    = $Matches[2] }
        $RecipientList.Add($RecipientDetails)
    } # End if
} #End ForEach Data
```

```
$RecipientList
```

Recipient	Items found

A content search with a broad search query is likely to return hundreds or even thousands of items. The easiest way to validate that the search finds items of interest is by reviewing the sample items retrieved by the search through the GUI (Figure 18-16). Apart from anything else, this allows you to examine the items carefully to ensure that the search is working as expected. The next step is then to export the items for closer examination or to refine the search keywords and conditions to focus on a more refined set.

## Look for Phishing Items samples

The screenshot displays an email search results interface. On the left, a list of search results is shown with columns for Subject/Title, Date, and Sender/Author. The selected item is an email from Patrick Peterson (Agari) dated Mar 5, 2020, with the subject '[Webinar] KnowBe4 & Agari: Transforming Phishing Protection March 18'. On the right, the detailed view of this email is shown, including the 'From', 'To', 'Subject', and 'Send Date' fields. The body of the email contains a message about a new partnership with KnowBe4, aimed at combating phishing and BEC attacks. A red arrow points to the word 'phishing' in the subject line of the selected email in both the list and the detailed view.

Figure 18-16: Viewing sample items found by a content search

## Searching SharePoint and OneDrive for Business

The locations searched by the example query used above are user mailboxes and public folders, including the cloud-only mailboxes holding compliance records for non-tenant users. We can add OneDrive for Business and SharePoint sites to the set of search locations, but only if the target resources support the query. In this case, if we try to add non-Exchange locations to the search by running the *Set-ComplianceSearch* cmdlet, we will see a warning message because the search query is based on email-specific properties (Subject and Received date) that OneDrive for Business and SharePoint Online don't support.

Here is how to create a content search that specifically targets SharePoint and OneDrive for Business sites. In this case, we search for any item stored in any site (the *SharePointLocation* parameter is set to "All") that includes some credit card information (the search uses the sensitive information type to find these files – see Chapter 19 for more information). We can further refine the search query by only looking for items created on or after 1 January 2015:

```
[PS] C:\> New-ComplianceSearch -Name "SPO and OD4B search for credit card data"
-Description "A search of SharePoint and OneDrive to locate files containing credit card data"
-SharePointLocation "All" -ContentMatchQuery '(SensitiveType:"Credit Card Number:2..") AND
(created>=01/01/2015)'
```

Once again, after creating a new content search, we start it with the *Start-ComplianceSearch* cmdlet to retrieve some results.

The example query searches all sites. If we try to refine the set of sites that we want to search, we can do so by specifying the URL for each site as shown below. In this instance, we also add a couple of Exchange Online mailboxes to the search locations. This will cause an error because the search properties we are trying to use are not available for all locations.

```
[PS] C:\> Set-ComplianceSearch -Identity "SPO and OD4B search for credit card data" -
SharePointLocation "https://office365itpros.sharepoint.com/sites/O365ITPro/",
"https://office365itpros.sharepoint.com/Projects/" -ExchangeLocation "Tony Redmond", "Paul
Cunningham"
```

PowerShell allows you to go ahead with the content search even though the problem with search properties is flagged. It is a mistake to do this as the net effect is usually to find everything in the search location that does

not support the properties used in the search query. In this example, because we use search properties specific to SharePoint and OneDrive for Business but have included some Exchange mailboxes, the search returns every item in those mailboxes, which is probably not what you intended.

See this [blog post](#) and this [support article](#) for tips about how to format KQL queries to interrogate SharePoint and OneDrive for Business sources.

## Content Search Actions

Behind the scenes, many of the actions you take after a search runs use the *New-ComplianceSearchAction* cmdlet to add a new action to the search. For example, when you export data from a search, the cmdlet runs to add an export action to the search. The following parameters are the most used:

- *SearchName*: The name of the search to add an action.
- *NotifyEmail*: The email address(es) of users to receive a notification when an action is complete.
- *NotifyEmailCC*: The email address(es) of CC recipients for notification messages.
- *Scope*: Specifies what kind of items (indexed, unindexed, both indexed and unindexed) the search will process.
- *Preview*: Add an action to preview items found by the search.
- *Export*: Add an action to export items found by the search to a PST or folder.
- *EnableDeDupe*: Removes duplicate messages during exports of search items.
- *IncludeSharePointDocumentVersions*: Input *\$True* to include all versions of discovered SharePoint documents or *\$False* to include only the most recent version. Remember that SharePoint Online captures many versions of Office documents during edit sessions due to the autosave feature.
- *RetryOnError*: Retry the search if an error occurs. Do not specify this parameter when using a content search action to remove items from mailboxes as it will stop the action.
- *Purge*: Add a search action to remove items found by the content search. Exchange Online is the only workload to support purging items. Because the search depends on the content indexes, it cannot remove [unindexed items](#) (like encrypted messages that aren't protected by sensitivity labels) from mailboxes. Users who don't hold the compliance Organization Management role cannot use the purge action.
- *PurgeType*: Specify how the content search should remove items. Items can be soft-deleted by passing the *SoftDelete* value. Users can recover soft-deleted messages during the deleted items retention period (default 14 days). You can also specify *HardDelete* to force hard deletion, which makes the items irrecoverable by the user.

You cannot add a new action to a search if the search is in progress or the search results are stale. For export operations, a search is stale if it is more than seven days old. For destroy or purge operations, a search stays usable until it is more than ten days old.

## Using a Content Search to Purge Mailbox Items

Administrators often need to purge items from mailboxes to eliminate:

- Phishing messages before users have the chance to read them and activate the harmful links.
- Messages that hold malicious attachments (viruses or other code).
- Messages sent in error and hold information that the organization would like to withdraw (insofar as is possible). You cannot retrieve messages that users send outside the organization or when delivered by Outlook to a PST.

In these circumstances, the usual approach is to create a search targeting the mailboxes holding the problem messages. The easiest way to do this is to create the search in the Microsoft Purview Compliance portal and refine it by tweaking search criteria until you are happy that the search finds the right messages. Because you

are going to remove data from user mailboxes, the search must be as precise as possible. Think of keyhole surgery rather than a massive incision. To help focus the search, you should capture the essential characteristics of the targeted message and use these as the basis of the search. For instance:

- An exact word or phrase that occurs in the message subject. For example: "Great Opportunity to Purchase." You can use this phrase for the Subject property in the search query.
- The sent date for the message, or even a limited date range. Use this date as the Received property in the search query.
- The SMTP address of the sender.

Combining several properties will generate a more precise search than when you rely on a single property, such as the message subject. You can use the search preview facility to examine the details of the items found by the search and verify that the search criteria are correct and working as expected.

You can create a purge action for a search against a maximum of 50,000 mailboxes. If you need to purge items from more mailboxes, you must split processing across multiple searches. In addition, a purge action can only remove ten items at a time from a mailbox. You cannot create a purge action for a search covering data held in SharePoint Online or OneDrive for Business.

Another thing to consider is the effect of litigation and in-place holds. If holds are in place for mailboxes, it might not be possible for a content search hard delete purge to remove items. The search can find the items, but any attempt to remove the items fails because they are on hold. Soft delete purges will work because the items remain in the mailbox. The golden rule is that if you want to hard-delete mailbox data, make sure to first remove any holds covering the mailboxes.

**Look before you leap:** No one wants to remove items from user mailboxes in error. Before committing a search to remove items, it is best to check that the search completes successfully and finds the right items. Use the Preview function to verify that the items you expect to find are present and that no unanticipated items have turned up. You might need to refine the search query several times before the search does exactly what you want it to do and is ready to go ahead and remove the items.

## Using the Purge Action

When you are happy the search finds the correct results, add the *Purge* action to the search. Note that you can only do this if you are a member of the *Compliance Organization Management* role group. For example, this command invokes the search called "Look for Phishing Items" and instructs it to soft delete any items matching the search criteria. Before the cmdlet starts the purge, you must confirm that the action should proceed.

```
[PS] C:\> New-ComplianceSearchAction -SearchName "Look for Phishing Items" -Purge -PurgeType SoftDelete
```

After a few minutes, check the status of the purge operation by running the *Get-ComplianceSearchAction* cmdlet. The purge reports its progression in percentage terms from zero to 100. The name of the action is formed by combining the search name and a "\_Purge" suffix. Given that the name of the search referenced above is "Look for Phishing Items," the name of the action is "Look for Phishing Items\_Purge." The following command retrieves the progress of the purge action.

```
[PS] C:\> Get-ComplianceSearchAction -Identity "Look for Phishing Items_Purge" | Format-Table SearchName, JobStartTime, JobProgress, Status -AutoSize
```

SearchName	JobStartTime	JobProgress	Status
Look for Phishing Items_Purge	18/08/2019 19:04:38	100	Completed

To see how many items were purged, look at the Results property of the purge action.

```
[PS] C:\> (Get-ComplianceSearchAction -Identity "Look for Phishing Items_Purge").Results
Purge Type: SoftDelete; Item count: 4; Total size 104080; Details: {Location: ; Item count: 2; Total
size: 20443; Failed count: 0; ,
Location: ; Item count: 1; Total size: 54554; Failed count: 0; ,
Location: ; Item count: 1; Total size: 29083; Failed count: 0; }
```

If you need to remove more than 10 items, let the purge job complete, remove it, and then resubmit. Do this until all the items are removed:

```
[PS] C:\> Remove-ComplianceSearchAction -Identity " Look for Phishing Items_Purge " -Confirm:$False
[PS] C:\> New-ComplianceSearchAction -SearchName "Look for Phishing Items" -Purge -PurgeType
SoftDelete
```

You can purge items with content search actions in two ways:

- The *HardDelete* action moves items into the *Purges* subfolder of Recoverable Items. Users can't access items in the Purges folder. The items remain in the mailbox until they are removed by the Managed Folder Assistant (see below).
- The *SoftDelete* action moves items into the *Deletions* subfolder of Recoverable Items. Users can recover items from Deletions using the Recover Deleted Items feature in Outlook and OWA.

The Managed Folder Assistant processes items held in the Purges or Deletions folders and removes the items after all retention mechanisms expire. These include:

- The mailbox's deleted items retention period (items are kept between 14 and 30 days) together with Single Item Recovery to ensure that items can't be removed until the deleted item retention period passes.
- A personal retention tag is applied to the item.
- Retention policies (Microsoft 365 or Exchange Online) are applied to the mailbox.

Items remain in place to be available for eDiscovery. It's important to remember this because a search will continue to find items in mailboxes even when they have been removed from user view by a purge. In other words, even after you run a content search and purge its results, the messages remain until anything holding them back is removed. However, mailbox owners can no longer access or recover any hard-deleted items.

Of course, software being software, it is wise to verify results when a risk exists that a malicious email might wreak havoc on mailboxes. After running any command to remove items, you can review the properties of the search to see the mailboxes where items were removed, or (if you have permission), sign into a mailbox that you know held a problem item to check that the items are gone.

You can download an example script to create and run a search to find mailbox items before using a search action to purge the discovered items [from GitHub](#). Note that the *Search-Mailbox* cmdlet remains available at the time of writing and can be used to remove items from mailboxes.

## Be Sure About Removal

The removal of items from a user mailbox through a search generates a *SearchResultsPurged* audit record in the audit log, which tells you what query was used. Neither this audit record nor the *Get-ComplianceSearchAction* cmdlet reports the locations from which items were purged, but (using the *Search-UnifiedAuditLog* cmdlet) you should also find a matching *HardDelete* or *SoftDelete* record in the audit log that contains details of the purged items. The lack of obvious feedback on what the search action did is a good reason why you need to make sure that the content search returns the items you want to purge. To validate the results of the content search, use the preview function and then, if necessary, export the items to a PST (you might need to export the items anyway to keep evidence of what is removed from user mailboxes).

**Limit any possible damage:** Removing data from user mailboxes is an operation that is fraught with error. The potential of making a mistake and removing something that you should not delete is always there. To

reduce the potential for harm, purging based on a content search will only remove a maximum of 10 items from a mailbox per run (if the search covers multiple mailboxes, more than ten items can be removed in a single run). The purge function is an “incident response” feature to remove small amounts of problematic data from user mailboxes. Limiting removal to ten items should not be a problem unless malware floods mailboxes through multiple attacks over a short period. Purges should use a precise, focused search to find data. The ideal situation is to find and remove a single item. In addition, by limiting deletion to 10 items per mailbox, search and destroy operations finish much faster (Microsoft reckons on being able to process 100,000 mailboxes in 30 minutes). Using soft deletes rather than permanent removals allows users to recover items if the search removes them in error. If you need to purge more than 10 items from a mailbox, you must run a purge action multiple times, removing the purge action and recreating it each time.

## Exporting Search Data

When a content search is tuned to find the right data, the next step is usually to export the data to allow expert examination and review. For email, the export can be to PSTs or as individual messages while exports from SharePoint or OneDrive are as individual documents, including earlier versions if necessary.

You can use PowerShell to automate the export to Azure part of an export operation. After that, things become trickier to call the tool used to download results from Azure and pass the necessary access token to the tool (see [this discussion for a suggested solution](#)). The example below shows how to start the export process for search results. In this case, we want to export messages in PSTs (the format is “*FxStream*”) with messages for each mailbox stored in a separate PST. A loop tracks the progress of the job. When complete, the data is ready in Azure to be downloaded.

```
[PS] C:\> $Search = "Investigation LD-17166"
New-ComplianceSearchAction -SearchName $Search -EnableDedupe $True -Export -Format FxStream
-ArchiveFormat PerUserPST -Scope BothIndexedAndUnIndexedItems
$ExportJob = $Search+"_Export"
Write-Host "Export started at" (Get-Date)
do
{
    Start-Sleep -s 3
    $ExportStatus = (Get-ComplianceSearchAction -Identity $ExportJob -Details)
    Write-Host "Current status:" $ExportStatus.Status "% progress:" $ExportStatus.JobProgress
}
While ($ExportStatus.Status -ne 'Completed')
Write-Host ""
Write-Host "Export ended at" (Get-ComplianceSearchAction -Identity $ExportJob).JobEndTime
```

To download the exported results, select the search in the Microsoft Purview Compliance portal, followed by **Download exported results**. The export key is visible. Copy the export key to the clipboard. Later, you will paste the key into the download tool to authorize it to copy data from Azure to the export target destinations (such as PSTs or individual files).

If you want to restart an export, run the *Remove-ComplianceSearchAction* cmdlet to remove the exported data from Azure. Remember to append “\_Export” to the end of the content search name to create the name of the export action.

```
[PS] C:\> Remove-ComplianceSearchAction -Identity "Investigation_#2_Export"
```

# Using PowerShell to Manage eDiscovery Cases

You can use PowerShell to create and manage eDiscovery cases. To create a case, use the *New-ComplianceCase* cmdlet.

```
[PS] C:\> New-ComplianceCase -Name "Stock Trading Case Reference 2017-001"
```

The *Get-ComplianceCase* cmdlet returns details of an eDiscovery case. However, because an eDiscovery case is a wrapper around content searches and holds, it does not return much information as no members or sources have yet been added.

```
[PS] C:\> Get-ComplianceCase -Identity "Stock Trading Case Reference 2017-001"
```

```
RunspaceId      : 883d2fb0-ef1b-484f-918d-bedf1930ef11
TenantId        : b662313f-14fc-43a2-9a7a-d2e27f4f3478
Identity        : 2fd9411c-3fd4-4293-a6f1-8fca699f51ed
Name            : Stock Trading Case Reference 2017-001
Description     :
CaseType        : eDiscovery
Status          : Active
ClosingStatus   : Unknown
CreatedDateTime : 11/01/2017 18:13:32
LastModifiedDateTime : 11/01/2017 18:13:32
ClosedDateTime  :
LastModifiedBy  : Tony Redmond
ClosedBy        :
ObjectState     : New
```

Note: a Premium eDiscovery case is a special form of eDiscovery case. You can retrieve these cases by specifying the *CaseType* parameter:

```
[PS] C:\> Get-ComplianceCase -CaseType Adv
```

After finding the case to work with, we can update its details. For instance, we can add some members to the case with the *Update-ComplianceCaseMember* cmdlet, specifying the user principal name or display name for each member in a comma-separated string. For example:

```
[PS] C:\> Update-ComplianceCaseMember -Case "Stock Trading Case Reference 2017-001" -Member "Tony Redmond", "Kim.Akers@Office365ITPros.com"
```

The *Update-ComplianceCaseMember* cmdlet replaces the existing member list for a case. If the user who runs the cmdlet does not specify their name, the cmdlet includes it automatically. If you want to add a specific user to an existing member list, use the *Add-ComplianceCaseMember* cmdlet.

To make sure that no one can remove information needed by the case, we must set up a hold to retain information. A hold includes a rule and a policy. We create the rule with the *New-CaseHoldRule* cmdlet. The simplest form of rule has no query, in which case all content in the search sources is covered. For instance:

```
[PS] C:\> New-CaseHoldRule -Policy "Stock Trading Case Reference 2017-001" -Name "Stock Trading Case Reference 2017-001"
```

It's more usual to include a query, defined in KQL syntax. This example sets up a condition to look for any item where the words "stock" and "trading" occur near each other.

```
[PS] C:\> New-CaseHoldRule -Policy "Stock Trading Case Reference 2017-001" -Name "Stock Trading Case Reference 2017-001" -ContentMatchQuery "Stock NEAR(10) Trading"
```

We now use the *New-CaseHoldPolicy* cmdlet to add the hold policy for the case. The hold policy defines the locations that the case covers. Sources are

- Exchange mailboxes.
- Public folders.
- SharePoint and OneDrive sites.

You can include either individual mailboxes or distribution lists. The membership of groups is expanded into individual mailboxes and added to the policy. You can also include public folders by passing the "All" value to the *PublicFolderLocation* parameter. SharePoint sites are specified with the site URL. For example:

```
[PS] C:\> New-CaseHoldPolicy -Case "Stock Trading Case Reference 2017-001" -Name "Stock Trading Case Reference 2017-001" -ExchangeLocation "Nancy Anderson", "Sanjay Patel" -SharePointLocation https://office365itpros-my.sharepoint.com/personal/ben_owens_office365itpros_com -PublicFolderLocation All -Enabled $True -Comment "Search sources added programmatically"
```

To check that the hold exists, we can run this command:

```
[PS] C:\> Get-CaseHoldPolicy "Stock Trading Case Reference 2017-001"
```

Or, to see all holds in place for all eDiscovery cases:

```
[PS] C:\> Get-ComplianceCase | % {Get-CaseHoldPolicy -Case $_.Name}
```

After you create an eDiscovery case, you probably want to create one or more content searches and link the searches to the case. We discussed the creation of content searches earlier. This example is like those reviewed then with the exception that we use the *Case* parameter to associate the search with the case.

```
[PS] C:\> New-ComplianceSearch -Name "Stock Trading Case Reference 2017-001 - Search 1" -Description "Search associated with Case Reference 2017-001" -ContentMatchQuery "Stock NEAR(10) Trading" -Case "Stock Trading Case Reference 2017-001" -ExchangeLocation "Nancy Anderson", "Sanjay Patel"
```

Once the search is available, you can start it in the normal manner by calling the *Start-ComplianceSearch* cmdlet.

The queries and search locations used in the content searches for eDiscovery cases do not have to match the hold rule or policy. This is because a case might span multiple searches, each of which looks for different information from different sources. The combination of all those results constitutes the information for case investigators to review.

## Removing Cases

You can remove a case by running the *Remove-ComplianceCase* cmdlet, but only after removing any holds associated with the case. For example, let's assume that we want to remove the Contoso Alpha Case July 2015 case. To remove the holds, we issue the command:

```
[PS] C:\> Get-CaseHoldPolicy -Case "Contoso Alpha Case July 2015" | Remove-CaseHoldPolicy
```

The command to remove the holds is published to the workloads. It takes some time for the workloads to process the removals. When this process finishes, and no holds show up when you run the *Get-CaseHoldPolicy* cmdlet for the case, you can run the *Remove-ComplianceCase* cmdlet:

```
[PS] C:\> Remove-ComplianceCase -Identity "Contoso Alpha Case July 2015"
```

## PowerShell and Data Subject Requests

GDPR data subject requests are special forms of eDiscovery cases. The same is true for Subject Rights Requests created in the Privacy management solution. To view details of these cases, you must specify the case type. Regular cases have a case type of "eDiscovery," which the *Get-ComplianceCase* cmdlet assumes if no other type is present. For example, to see DSR cases, specify the DSR case type.

```
[PS] C:\> Get-ComplianceCase -CaseType DSR
```

Name	Status	CreatedDateTime
James Ryan DSR	Active	30/04/2018 21:08:19
Tony DSR	Active	01/05/2018 15:10:56

To list Privacy management cases, specify the *PrivacyManagementDSR* type. To access details of an individual case, pass the name of the case:

```
[PS] C:\> Get-ComplianceCase -CaseType DSR -Identity "James Ryan DSR" | Format-List
```

```
Identity           : 16a90128-1e5b-4506-a6ca-160d0992fbaf
Name               : James Ryan DSR
Description        : James Ryan DSR
CaseType           : DSR
Status             : Active
ClosingStatus      : Unknown
CreatedDateTime    : 30/04/2018 21:08:19
LastModifiedDateTime : 30/04/2018 21:08:19
ClosedDateTime     :
LastAccessTime     : 01/01/0001 00:00:00
LastModifiedBy    : Tony Redmond
```

The other cmdlets used with eDiscovery cases work as documented with DSRs.

One specific aspect of GDPR DSRs is that the regulations say that they should be processed within 30 days. We can check the remaining time for active cases with some code like that shown below, which highlights any case that has seven days or less left to respond:

```
[PS] C:\> $Cases = (Get-ComplianceCase -CaseType DSR | ? {$_.Status -eq "Active"})
ForEach ($Case in $Cases) {
    $Days = (New-TimeSpan -Start $Case.CreatedDateTime -End (Get-Date)).Days
    If ($Days -gt 23) {
        $DaysLeft = (30 - $Days)
        Write-Host "Warning!" $Case.Name "has only" $DaysLeft "days remaining to complete and
respond..." }}
```

## Adding eDiscovery Managers

Although it is usually best to manage the membership of sensitive role groups through the portal, you can add or remove users from the eDiscovery role groups through PowerShell. To do this, connect to the compliance endpoint and run the *Add-RoleGroupMember* (to add an eDiscovery Manager) or *Add-eDiscoveryCaseAdmin* cmdlet (to add an eDiscovery administrator). For example, these cmdlets add a user to the eDiscovery Managers role group and then check that the user is in the group:

```
[PS] C:\> Add-RoleGroupMember -Identity eDiscoveryManager -Member "James Abrahams"
[PS] C:\> Get-RoleGroupMember eDiscoveryManager
```

Only an eDiscovery administrator can add another user to the eDiscovery Administrators role group. If you hold this status, you can run the cmdlets to add a user and check that the add worked as follows:

```
[PS] C:\> Add-eDiscoveryCaseAdmin -User "James Abrahams"
[PS] C:\> Get-eDiscoveryCaseAdmin
```

## Reporting Holds for eDiscovery Cases

The [Office 365 for IT Pros GitHub](#) repository contains a modified version of [a Microsoft script](#) to report the holds that exist for eDiscovery cases. You can use it as an example of how to navigate through eDiscovery cases to unpick and report on components.

The expected output is something like shown below, with cases organized by status and the holds described for active cases. The result of the analysis is held in the *\$Report* variable, so it is very possible to create different reports from the data without changing the script.

EDiscovery Cases found: 9  
 Active Cases: 7  
 Closed Cases: 2  
 Active Holds: 11

Case	Status	Created	HoldCreated
Board Minutes	Closed	28/04/2017 19:14	
Contoso Investigation	Closed	28/04/2017 19:14	
Improper management transactions (LD-2018-002)	Open	04/04/2018 18:03	04/04/2018 18:19:55
Inactive Exchange Mailboxes	Open	28/04/2017 19:14	28/04/2017 19:12:27
Personal Harassment Investigation LD-2018-001	Open	04/04/2018 17:31	04/04/2018 17:38:33
Personal Harassment Investigation LD-2018-001	Open	04/04/2018 17:31	04/04/2018 17:44:42
Project Alpha Foxtrot	Open	28/04/2017 19:14	28/04/2017 19:12:27
Stock Trading Case Reference 2017-001	Open	28/04/2017 19:14	28/04/2017 19:12:27
Stock Trading Case Reference 2017-001	Open	28/04/2017 19:14	15/02/2018 17:16:56

## In-place Holds and Litigation Holds

An eDiscovery case can include one or more in-place holds to ensure that workloads retain information even if someone tries to remove or edit it. Each hold has a search query to find the information, which stays in the source location until something happens, like a user trying to remove or edit the content. At this point, Exchange Online captures a copy of the original content. Holds applied by Exchange and SharePoint or by retention policies and eDiscovery cases all keep content in place. It is an efficient mechanism that avoids the need to duplicate information unnecessarily.

Figure 18-17: Placing a mailbox on litigation hold

Litigation or legal hold is a somewhat cruder but very effective mechanism available for Exchange Online mailboxes. A litigation hold places the entire mailbox on hold for a set period or indefinitely. Again, all items stay in place, but every deletion means that Exchange keeps a copy of the deleted item. As you can imagine,

many of the items contained in mailboxes fall into the banal category and are of no interest whatsoever to discovery actions. However, there are instances where it is necessary to keep everything so that there is no chance of missing anything which might remotely be of interest. A litigation hold keeps everything in a mailbox, as will an in-place hold that has no search criteria. You can use litigation holds alongside in-place holds. All mailbox content is held when a mailbox is subject to both types of hold.

Placing a mailbox on litigation hold is easy. First, select the mailbox owner's account in the Microsoft 365 Admin Center, go to the **Mail** tab, and select **Manage litigation hold**. If a hold is already in effect on the mailbox, you'll see when it was set and by whom. To enable litigation hold for a mailbox, check *Turn on litigation hold* and enter values for the optional properties as shown in Figure 18-17.

- **Hold duration:** How long the hold will last in days. Leave blank to set an indefinite hold.
- **Note visible to user:** Text entered here to explain the reason for the hold is visible to the mailbox owner in the Account Settings section of Outlook's "backstage."
- **Web page with more information:** A URL to a web page that should contain more information for the user to know why the organization puts mailboxes on hold and what it means to them. It might also include relevant citations of local laws governing user privacy and the steps taken by the organization to ensure that user privacy is respected. If present, Outlook displays a *More information* link in Account Settings. No check is made to ensure that the URL is reachable.

Click **Save changes** to make any changes to hold settings effective.

To make a litigation hold effective, Exchange Online updates several mailbox properties:

- **LitigationHoldEnabled:** Set to True.
- **LitigationHoldDate:** Set to the time and date when an administrator applies the hold to the mailbox. For example, 2-Feb-2022 19:45:50.
- **LitigationHoldOwner:** Set to the account that placed the mailbox on hold.
- **LitigationHoldDuration:** Set to the retention period. For example, 90.00:00:00, or 90 days.
- **RetentionComment:** The free-text note to inform the user that their mailbox is on hold. You don't have to enter this comment if you do not want to.
- **RetentionUrl:** The URL pointing to a page holding additional information.

You can also set litigation hold on by setting mailbox properties in EAC or with PowerShell. Here is an example of putting a mailbox on litigation hold using PowerShell is:

```
[PS] C:\> Set-Mailbox -Identity "Ben Owens" -LitigationHoldEnabled $True  
-LitigationHoldDate "1-May-2018 19:45:00" -LitigationHoldOwner "Administrator"  
-LitigationHoldDuration 90.00:00:00 -RetentionComment "Your mailbox is on hold"  
-RetentionUrl "http://www.contoso.com/compliance.htm"
```

A hold can be indefinite. If you want to pass a duration in days, Microsoft's documentation states that the limit is 2555 days (7 years), but the cmdlet is happy to accept 100,000 days (>273 years). I doubt anyone now alive will be worrying if such a hold expires before its due date.

# Chapter 19: Managing Data Loss Prevention

## ***Tony Redmond***

It would be nice if users handled confidential or sensitive information correctly all the time, but that is not how things happen in real life. It is human nature to err, and a common mistake is including confidential or sensitive information in emails or via a document shared with external people. Data Loss Prevention (DLP) is a technology designed to prevent users from sharing sensitive information inappropriately. Policies encapsulating rules to dictate the sharing of sensitive information are how organizations deploy DLP. First introduced in Office 365 for Exchange Online, DLP covers Exchange Online, SharePoint Online, Teams, and OneDrive for Business, with plans in place to extend coverage further to protect data drawn from across Microsoft 365.

This chapter describes:

- Data Loss Prevention concepts.
- How Microsoft Purview implements DLP.
- How to build suitable DLP policies to help applications prevent the loss of sensitive information.
- How to know whether your DLP policy is effective.

Data Loss Prevention is not a magic bullet and its capabilities do not extend to every method that someone can use to share data with another person. For instance, someone could post sensitive information like a credit card number in a Facebook conversation. You can handle that issue through third-party monitoring software, but user education might be equally effective. DLP is just another part to fit into the compliance puzzle that contributes to the overall security of information within companies.

## Leak Prevention with Software

The need to prevent the loss (or leakage) of sensitive information such as credit card numbers, personal information like passport numbers, and so on is well understood, possibly because there have been many instances in which company or personal information has been compromised by being made public deliberately or accidentally. Graphic examples exist where large public companies have lost millions of records. The result can be brand erosion, legal expenses, customer loss, and an almost guaranteed public relations disaster. It is easy for a user to attach a document and send it to someone else; it is also easy to make a mistake that ends up with information leaking outside the organization. For example, you might not notice that Outlook has auto-completed an address with the wrong recipient and end up sending a confidential attachment outside the company. The speed of modern email systems makes any attempt to recall messages futile, so if someone realizes that they have made a mistake, all they can do is call the recipient and ask them to remove the content from their system.

Companies devote enormous effort to protecting IT systems. Much of the focus in the past has been on erecting traditional security barriers to stop attackers from penetrating internal systems. This approach might keep out hackers and scammers, but it does nothing to prevent employees from causing data loss, usually by accident. DLP is not new, and vendors have offered solutions for the last decade or so. Microsoft entered the space with Exchange 2013. Although a late entrant to the DLP market, Microsoft enjoys certain advantages over third-party solutions because of its ability to deeply integrate DLP checks into clients and servers:

- Integration of DLP functionality to protect email into Outlook, which is a critical desktop application in large enterprises. The integration analyzes text using a mixture of algorithms including pattern matching and [regular expressions](#) as users type into a message body to detect possible sensitive information considered to be of concern to the company. OWA also includes the ability to perform DLP checking. Both clients display policy tips to users when they detect sensitive information so that users become more aware of the kind of data that they are dealing with before they send messages with that content.
- Integration of DLP functionality into the desktop and online versions of other Office applications such as Word, Excel, and PowerPoint. The inclusion of DLP checks throughout the Office suite means that users have less chance of making mistakes.
- The ability to implement checking at points where data is guaranteed to pass through. For Exchange Online, checking happens in the transport system as all messages must pass through it before leaving the system or are delivered to internal recipients. Sensitive information can therefore be intercepted in messages by integrating DLP checks into the transport flow. For documents stored in SharePoint Online and OneDrive for Business, a crawler to detect sensitive information checks files in document libraries as users add or share content. The crawler is already indexing all content stored in SharePoint and OneDrive for Business sites, so adding a check for sensitive content there creates the desired oversight. When DLP policies are deployed to protect Teams, the examination happens in the chat service.

The need to protect against the disclosure of confidential data does not exist in a vacuum. To be effective, it is important to incorporate DLP into an overall corporate compliance strategy alongside other tools to protect data both inside and outside the organization. For example, the strategy should consider how to use sensitivity labels to encrypt and protect the most confidential content so that even when this material circulates outside the organization, it continues to be protected and cannot be accessed except by authorized people. It's also important to consider how to protect data created before the introduction of the compliance strategy as old documents and messages can contain highly confidential information.

Clients display policy tips when a DLP violation is detected to emphasize that user education and policy communication is very important. People must know why the policy tips appear and what they should do next. It is also important to stress that DLP is not a guaranteed block against users sharing sensitive data. If someone wants to send information externally, they will be able to find another way to do so.

DLP policies to process Exchange Online, SharePoint Online, and OneDrive for Business items require an Office 365 E3 license (or, for Exchange Online only, an Exchange Online E2 license). However, DLP transport rules will block messages in violation of policy no matter what license a user has. DLP for Teams requires Office 365 E5 or Microsoft 365 E5 Compliance licenses.

The importance of DLP and its growing use is illustrated by statements made by Microsoft at the Ignite 2017 conference, when they reported that DLP use within Office 365 tenants had a year-over-year increase of 600% while the number of users protected by DLP grew by 750% in the year to September 2017. That growth has tapered off a little, but there's still lots of interest in using DLP, especially in enterprise tenants.

## Microsoft Purview Data Loss Prevention

Microsoft's goal is to implement a common DLP capability across multiple workloads based on checks evaluated against common conditions and data types (including retention and sensitivity labels) existing within files and messages. DLP currently covers:

- Exchange Online.
- SharePoint Online and OneDrive for Business.
- Teams chats and channel conversations.

- Windows 10 devices (endpoint DLP).

Microsoft Purview DLP policies are managed through the Microsoft Purview compliance portal and are the focus of future development. Some organizations use DLP policies implemented through Exchange transport rules (ETRs) to ensure that the same policy coverage can be implemented for on-premises servers. For more information on ETRs, see the Exchange Online chapter in the companion volume.

The biggest advantage of Microsoft Purview DLP policies is their cross-workload nature. As of March 2021, [the range of conditions, actions, and exceptions available to process email](#) through Microsoft Purview DLP policies are more capable than those available in ETRs, which means that there is no reason to deploy new ETRs.

In October 2021, Microsoft announced that they will [remove the ability to maintain ETRs in the Exchange admin center sometime in the April-June 2022 period](#) (it'll still be possible to make changes with PowerShell).

This is a strong signal that Microsoft is close to the point when they will remove DLP ETRs from Exchange Online. Organizations using DLP ETRs should begin the process of transitioning DLP ETRs to Microsoft Purview DLP policies, taking the following into account:

- The rules implemented in ETRs always take precedence over Microsoft Purview DLP policies when processing email. This is natural because ETRs are explicitly designed to process email. It also means that messages that are blocked by an ETR will never be checked by a Microsoft Purview DLP policy.
- Messages that pass through ETRs are processed by Microsoft Purview DLP policies and could be blocked at this point if the rules detect a condition that calls for this action. If a “stop processing” action is invoked by an ETR, it will not affect the processing of Microsoft Purview DLP policies.

Conversion from ETRs to Microsoft Purview DLP policies is not automatic. An effort is needed to plan the conversion, create and test the new policies, and ensure that the combination of old and new policies function together during the conversion period. To ease the transition, Microsoft has developed [a playbook to help tenants move from ETRs to Microsoft Purview DLP](#). With the playbook in hand and feature parity attained between the two sets, most organizations have no good reason to remain using ETRs. The transition requires careful planning and attention to detail and the switchover should happen at a time of low user demand such as a holiday period.

## Sensitive Information Types

The basis for a DLP policy is understanding what kind of sensitive data you want to protect and how you want to protect the data. Several common data types come to mind when you consider what kind of information you prefer users to not mishandle. Credit card numbers or passport numbers are obvious examples of data usually regarded as sensitive. Although credit cards use a worldwide format, personally identifiable information (PII) and other sensitive information types differ from country to country.

It would not make much sense if Microsoft required tenants to analyze the essential characteristics of data types like credit card numbers and passport numbers to create custom definitions to match these types. Mistakes would happen, and inconsistencies in definitions would abound. Fortunately, Microsoft Purview includes [over two hundred and sixty definitions of sensitive information types](#) for use in DLP policies and other solutions. Some of the data types are like other types (for example, the definition for passport numbers or driving licenses often does not vary much between countries). Among the set of standard sensitive information types are:

- ABA routing numbers.
- Credit card numbers.
- U.S. Social Security numbers.
- Canada bank account numbers.
- European Union debit card numbers.

- Australian passport numbers.
- German driver's license numbers.
- European Union tax identification number.

Over time, Microsoft has expanded the inventory of sensitive information types to increase coverage for data loss prevention and other capabilities. Many of the sensitive information types added recently are to detect country-level data like passports, identity cards, and bank numbers. In addition to new types, Microsoft also tweaks existing definitions to improve their accuracy.

You can see the current set of sensitive information types available in Microsoft Purview by running the `Get-DlpSensitiveInformationType` cmdlet (after connecting to the compliance endpoint):

```
[PS] C:\> Get-DlpSensitiveInformationType | Format-Table Name, Description
```

Name	Description
Canada Driver's License Number	Detects Canadian driver's license number.
EU Debit Card Number	Detects European Union debit card number.
Israel National ID	Detects Israeli national identification number.
Credit Card Number	Detects credit card numbers for American Express, Diner...
U.S. Social Security Number (SSN)	Detects formatted and unformatted US social security nu...
German Passport Number	Detects German passport numbers or Reisepass.

Sensitive information types break down into bundled and unbundled entities. An unbundled entity is a sensitive information type that stands on its own. It can be used in a DLP policy to detect specific information, or it can be used as part of a bundled entity. Each sensitive information type is defined by describing its characteristics in the form of some recognizable pattern, often captured in a regular (regex) expression. For instance, a social security number is a nine-digit number usually formed in three groups of three, two, and four digits separated by hyphens. Many passports have some alpha characters followed by seven digits, and so on.

A bundled entity is simply a collection of sensitive information types managed as a single type. For example, if you use the *All Medical Terms and Conditions* type to detect content in a DLP policy, DLP finds any medical term or condition found in SharePoint, Exchange, and Teams content to which the policy applies.

The use of sensitive information types is not restricted to DLP. You can use sensitive information types in:

- DLP policies.
- Communications compliance policies.
- Auto-labeling policies (retention labels by background processes).
- Auto-apply retention labels (by applications).
- Auto-apply sensitivity labels (by applications).

Later we cover how to create custom sensitive information types. You can use custom sensitive information types in the same way as standard sensitive information types.

**A simple number is never enough:** A sixteen-digit number is not by itself enough evidence to prove that it belongs to a credit card. DLP applies several tests to ensure that data contained in message bodies or attachments are sensitive. In the case of credit cards, the first check compares the number with the Luhn algorithm to ensure that it matches the rules set down for credit card numbers. DLP looks for further evidence such as the presence of a card expiry date (like 11/26), a name, or a CVC/CVV (card verification value). If these elements exist near the credit card number, it lends weight to the argument that the data matches the policy, and enough confidence exists to invoke the policy actions. The same is true of nine-digit U.S. social security numbers that do not have a checksum. If DLP applied a test of just looking for nine-digit numbers, the likely result is that many false positives would be signaled. In this case, the extra evidence is the presence of the word "SSN" in conjunction with nine-digit numbers. Different validation rules are employed to process the various sensitive information types so the thing to remember is that DLP

must be reasonably confident that a violation exists before it will signal a policy tip to the user or block a message.

## Bypassing DLP Checks

It's important to recognize that scanning based on sensitive information types will only detect instances where data matches the patterns defining the data type. If someone wants to get around DLP checking, they can by disguising text to avoid the pattern being detected. For instance, if you use a DLP policy to block email going outside the organization if messages contain credit card numbers, people can get around the block by spelling out the numbers (for example, use "six" instead of 6) or by including a picture of a credit card number. Messages with these variants of credit card numbers will be passed by the policy because the detection routines don't examine graphic data or look for blocks of text that might be a credit card number. In other words, DLP policies can catch most occurrences when people misuse sensitive data, but DLP checks will not detect disguised data.

## Microsoft Purview DLP Policies

To understand how Microsoft Purview DLP policies work across multiple workloads, we'll go through the process of setting up a new policy and see what happens when the policy is operational. First, some broad concepts:

- A DLP policy is composed of rules, locations, and actions. The locations are where the DLP service checks for policy violations. These can be Exchange Online mailboxes, SharePoint Online sites, OneDrive for Business accounts, and Teams chats and conversations.
- Each rule defines conditions that the DLP service applies against data to decide if any violations exist. DLP policies don't need many rules to be effective. For example, the [DLP policy to prevent users from sharing Teams meeting recordings outside the organization](#) uses one simple rule.
- The rules tell the DLP service what actions to take if it detects a violation. For instance, a rule violation could stop users from sharing a document.
- A rule can allow a user to override an action.
- Rules can display policy tips to users to help them understand why it is a problem if they share some information.
- Rules can also generate incident reports to inform compliance administrators when violations occur.

Now that we understand the basics, let's discuss some differences which exist when the DLP service processes different forms of content.

## Checking Documents for Sensitive Data

Despite the obvious differences that exist between processing email and documents, the same need exists to find a single point in the system to apply policies reliably. Using transport rules for Exchange DLP policies guarantees that the transport system will apply policies to all messages as they pass through the transport pipeline. Microsoft Purview DLP policies do not use Exchange transport rules. Instead, DLP policy checking occurs during the indexing of Exchange messages. This happens quickly enough to ensure that violations are detected and stopped before messages leave the organization.

A similar natural chokepoint does not exist for SharePoint Online, so Microsoft needed to take a different approach to offer protection for SharePoint and OneDrive for Business libraries. To detect DLP violations in documents, SharePoint Online uses a mixture of real-time policy evaluation together with a special "crawler" process and a background timer job to find documents containing sensitive data. Microsoft refers to this as a mixture of synchronous and asynchronous checking that applies equally well to new documents as users upload files to document libraries and to existing documents as users update their content.

Crawlers create content indexes by scanning all the document libraries in sites to look for new or changed material to index. The DLP crawler looks for sensitive information types in new or changed documents and can detect them soon after an update occurs (as fast as indexing occurs). However, background processes are subject to throttling and checking might not happen if servers are under a heavy processing load. When system load reduces, the crawler detects any lingering violations as it processes items for content indexing. Excel posed a difficulty in terms of how it stored data in spreadsheets and Microsoft had to create a special file handler to ensure that DLP could detect sensitive information types in these files.

Synchronous or real-time evaluation does not mean the kind of in-place checking that occurs in Outlook when the body of messages is examined for matches against applicable DLP policies as the user updates the message body. Nor is it like the OWA implementation where message content is sent to the server for examination periodically. Real-time checking for SharePoint and OneDrive documents means that the content is examined when documents are added, changed, or shared.

When SharePoint detects a violation, it applies the rules specified in the DLP policy. If the policy rules block access to items containing restricted data outside the organization, SharePoint and OneDrive for Business incorporate the check into the file-sharing dialog so that users cannot commit DLP violations (Figure 19-1). The idea is that prevention at the outset is better than fixing a problem after a violation occurs. If the policy calls for the generation of an incident report, this is when the DLP service creates and sends it.

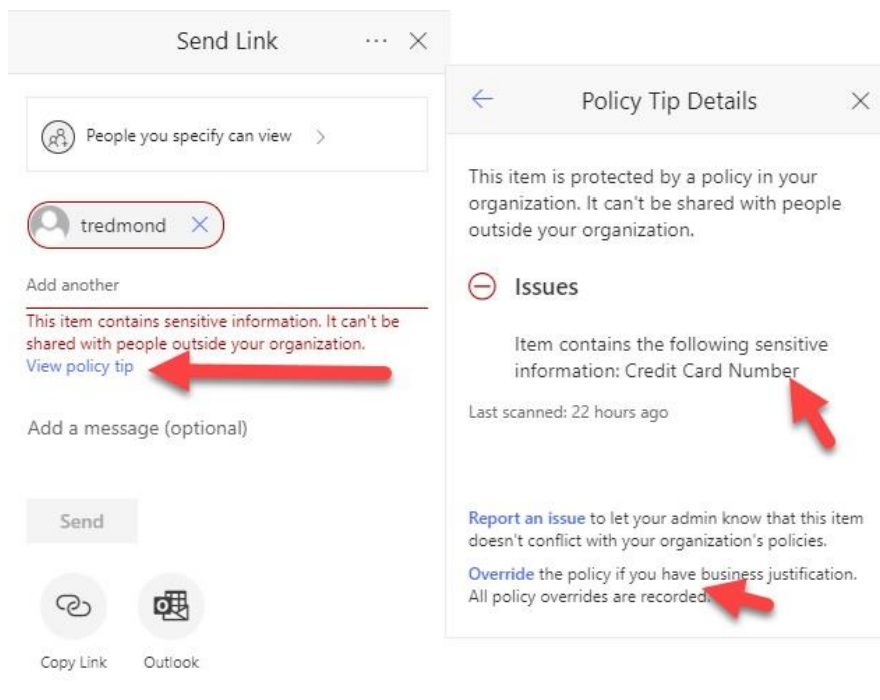

Figure 19-1: DLP blocks a user from sharing a file

Detection of a violation can also cause the display of a policy tip defined in the policy, but only in applications that support the necessary user interface, like SharePoint's browser interface. Policies might allow users to override the blocks imposed on documents holding sensitive information. If so, users can do this through the browser by opening the document properties, viewing the policy tip, and clicking **Override**.

SharePoint does not generate and send incident reports when the crawler detects a violation in content that existed before a rule became active. If SharePoint generated incident reports when it scanned content after an administrator adds a new rule or updates an existing rule, it is easy to imagine how the results might be a mail storm of thousands of incident reports. In a practical sense, it would be impossible to go through all the incident reports and resolve all the newly-detected violations. DLP still enforces any blocking actions contained in the rules; suppression occurs only for the incident reports.

## Sensitive by Default

Because DLP policies are not processed immediately for new files uploaded to SharePoint Online and OneDrive for Business libraries, a short period exists when users can share sensitive data outside the tenant and cause data leakage. If this is a problem, you can configure SharePoint Online to treat all new files as sensitive by default until they have been processed by a DLP policy. To do this, you:

- Run the *Set-SPOTenant* cmdlet in the SharePoint Online PowerShell module to block access to new files. It can take up to 15 minutes before the change is effective. The block applies to all sites in the tenant and you can't exclude sites from its effect.

```
[PS] C:\> Set-SPOTenant -MarkNewFilesSensitiveByDefault BlockExternalSharing
```

- Implement at least one DLP policy to scan all the SharePoint sites in the tenant.

With the block in place, users can still share documents with external people (if not blocked by the sharing settings for the tenant), but those people will be unable to access the content until the document is processed by DLP. The result of the processing will either pass the document for external access (because DLP doesn't detect a policy violation) or block it (because DLP detects some content that violates the policy if shared externally).

To revert the block, run *Set-SPOTenant* to allow sharing without waiting for DLP processing:

```
[PS] C:\> Set-SPOTenant -MarkNewFilesSensitiveByDefault AllowExternalSharing
```

Sensitive by default is an effective way to stop external sharing from SharePoint Online until DLP processing is done (Microsoft is working on its implementation for OneDrive for Business). However, it's a broad-brush policy that covers all sites in a tenant. Applying sensitivity labels to restrict access to documents containing important information might be a better approach, especially when auto-label policies are used to find and apply labels to documents at rest.

## Policy Tips

Overriding a policy tip through the **Override the policy** link allows a user to go ahead and share a document when a DLP policy would otherwise block this action. SharePoint records user overrides in the audit log in a "DLPRuleUndo" audit entry. The *ExceptionInfo* section of the audit entry captures the override text:

```
{
  "Reason": "Override",
  "Rules": [
    "413957f5-c3ab-4765-9322-33d2983dabfe"
  ],
  "Justification": "This document is authorized for sharing!"
}
```

**Mobile Policy Tips:** The OneDrive for Business mobile apps for Android and iOS support DLP policy tips. The clients download the DLP policy from Microsoft Purview when it connects, and the application is then able to scan text input into documents for sensitive information types and, if detected, display the correct prompt. The Teams mobile clients also support DLP policies in that they report violations in the activity feed, show when messages are blocked, and allow authors to override a block if allowed by policy.

## Teams DLP Policy Processing

Teams clients don't scan for DLP violations as users enter text or when items are indexed. Instead, Teams checks messages against DLP policies after users send messages and clients submit those messages to the Chat service. Both personal chats and channel conversations (including private channels) are monitored. Teams DLP policies only work for users with an Exchange Online mailbox.

Teams DLP policies can be scoped to cover all users or to include or exclude up to 1,000 selected accounts. Instead of specifying individual user accounts, distribution lists or mail-enabled security groups can be used to define to whom Teams applies a policy. Using distribution lists or security groups is an excellent way to set the scope for policies that apply on a country-wide or department-level basis. For example, a policy can be applied to Japanese users to prevent the sharing of Japanese identity card numbers. A background process checks for membership changes to relevant distribution lists and security groups to ensure that policies include new members and stop applying to accounts removed from membership. It can take up to 30 minutes after the creation of a new distribution list or security group before it can be used in a policy.

**Note:** Because all Teams messages pass through a message aggregator, DLP policies applied to the host team also apply to messages posted to conversations in Teams private and shared channels and the documents stored in the SharePoint sites belonging to the private channels. However, because private channels don't have an identity within the tenant, you can't add a private or shared channel as an explicit inclusion or exclusion in a Teams DLP policy.

Teams messages remain inside the company, so the division between internal and external users is harder to make than it is for SharePoint or OneDrive, where it's obvious when a document is shared with an internal or external account. When you create a DLP policy for Teams, remember that guest users and federated external users (including those who join meetings) are considered external to the organization; tenant users are inside. Because of this separation, it might be easiest to create separate DLP policies for Teams for external and internal users. In this respect, Teams is different from Exchange and SharePoint. DLP policies applied to email and documents usually focus on external sharing rather than internal communications.

## Checking Teams Messages

As messages flow through the chat service, Teams compares message content against the criteria defined in DLP policies covering Teams locations. The normal matching procedure is used to identify sensitive data specified in the policies by comparing values like credit card numbers together with accompanying information. If a violation is detected, Teams generates a block signal to a "Rethook" (a mechanism used by Teams to flag actions to clients) to instruct clients to block the message. After they receive the signal, the client used by the person who sent the blocked message tells them that the block is in place (Figure 19-2) and, if the policy allows, offers them the chance to override the block (through the *What can I do* link). Users who received a blocked message might see its content momentarily but once the block is in place, the message is hidden, and they can't see it any longer.

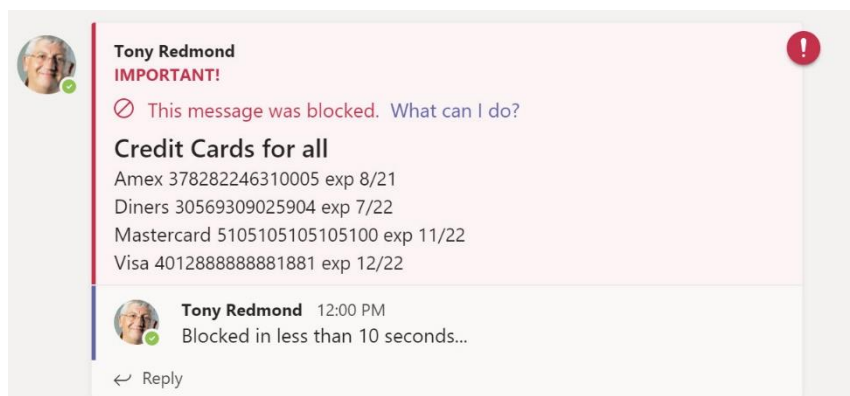

Figure 19-2: Teams blocks a message containing credit card numbers

Users receive a notification in their Activity Feed when Teams blocks one of their messages. In addition, if the user is logged into Teams with a mobile device, they'll receive a notification on the device that their message is blocked.

**Teams DLP Policy Recommendation:** Organizations that use Teams but don't have any Teams DLP policies see a Microsoft recommendation in the Microsoft Purview compliance portal that a policy should

exist to protect Teams messaging. Accepting the recommendation creates a pre-packaged Teams DLP policy to protect against the sharing of financial data, passport and social security numbers, and credit card numbers. You don't have to accept the policy settings as defined and can edit them before making the policy effective. Remember that you might need extra licenses to use Teams DLP policies.

## DLP Audit Records

When a DLP policy blocks an item, it records that fact in an audit entry in the audit log. You can see these entries in the audit log (search for the *DLPRuleMatch* operation). Alternatively, you can view DLP events in the report viewer. Click the *DLP policy matches* widget in the dashboard to be brought to the report viewer and then click *View details* table to see information about the DLP matches for all services covered by DLP policies

DLP events are also accessible via the [Office 365 Management Activity API](#), a REST-based API covering audit information gathered from Exchange Online, SharePoint Online, OneDrive for Business, and Azure AD that's intended for ISVs to develop analysis and reporting products. Two types of DLP events are logged. One is a non-sensitive event and contains data such as the document or email that triggered a violation, the user, the policy rule, actions taken, and the type of sensitive data involved. The other is a sensitive event and returns all the data for non-sensitive events plus the value of the data, such as a credit card number.

## Default DLP Policy

It is always good to have a building block to start with when approaching the introduction of new technology. To help tenants start with DLP, Microsoft includes a default DLP policy to protect credit card information for tenants where DLP is not already in use. Credit cards are the most common data protected by active DLP policies, so they are a natural choice for companies to start their DLP journey. If your tenant has a default DLP policy, you must edit and enable it to make the policy active.

## Creating Microsoft Purview DLP Policies

After becoming used to DLP policy structure and operation, the next step is to create a policy tailored for your organization. You can edit the default DLP policy or create a new one. To create a new DLP policy, go to the Data loss prevention section of the Microsoft Purview Compliance portal and click **Create policy**. Figure 19-3 shows a set of policies for a tenant, one of which is disabled. Note the offer to update the policies to extend coverage to Teams. Do not accept this choice unless you have the necessary Office 365 E5 licenses.

Figure 19-3: DLP policies

Before you go ahead and create a new policy, it is worthwhile to chart out what kind of sensitive data you want to protect and where is that data kept. Every DLP policy follows the same basic structure:

- **Locations:** What workloads to protect. You can choose from Exchange Online, SharePoint Online, OneDrive for Business, and Teams. Yammer is covered if the tenant network operates in Microsoft 365 mode. DLP policies do not currently cover Planner but do cover the SharePoint content associated with this app. You can scope the policy to include or exclude specific mailboxes, sites, or teams. The account pickers for Exchange Online, Teams, and OneDrive for Business support distribution lists and security groups to make it easier to apply policies to large sets of people without having to select each account individually. DLP evaluates distribution lists periodically to detect membership changes.
- **Optional Locations:** DLP is spreading its ability to analyze content to detect violations in different places. For example, you can [use DLP to monitor non-Microsoft apps like DropBox via Microsoft Defender for Cloud Apps](#), [Windows 10 devices via EndPoint DLP](#), or [scan on-premises resources](#). Microsoft deems these to be advanced capabilities, so you'll need appropriate licenses like Microsoft 365 E5 Compliance.
- **Rules:** What kind of protection do you want to achieve. Rules specify what kind of sensitive data you want to protect, conditions that say what must happen before a violation occurs, and actions that the policy takes afterward. Actions include user notifications and the creation of incident reports.

## Basic DLP Policy Settings

You can then start to flesh out the policy by creating the different sections of the policy. The policy creation wizard is divided into these parts:

- **Choose the information to protect:** To make it easier for customers to create DLP policies, Microsoft Purview includes a large number of DLP templates, each of which defines a set of sensitive information types that organizations commonly need to protect in certain fields of activity. For instance, if you want to avoid the loss of personal data, you can select **Privacy** to see templates such as "U.S. Personally Identifiable Information (PII) Data" or "U.K. Privacy and Electronic Communications.". When you select a template as the basis for a policy, the wizard automatically creates the necessary DLP rules to protect the information defined by the sensitive information types defined in the template. If none of the standard sets work for you, select **Custom**, which allows you to construct your own rule set.
- **Name your policy:** If you select a template, the policy name inherits the template name. You can overwrite the name with your own choice. You can also enter a description for the policy. Some organizations used this to refer to internal documentation for the policy, including information about who created the policy.
- **Choose Locations:** The policy wizard displays a set of supported locations with a slider for each location. If you leave the slider on for a location, the policy applies everywhere in the location (for instance, every SharePoint Online site in the tenant). Alternatively, you can select to include or exclude specific:
  - Exchange mailboxes. Specify all mailboxes or select mailboxes to include or exclude. You can use distribution lists to include or exclude sets of mailboxes covered by a policy, but you can also add or exclude individual mailboxes by typing their names into the search field. Dynamic distribution lists can scope DLP policies for mailboxes based on attributes in their Azure AD accounts.
  - SharePoint sites. Specify all sites or enter the URL for the sites that you want to protect (up to a maximum of one hundred sites) or choose to include or exclude specific sites. If you need to include or exclude more than a hundred individually-specified sites in a policy, consider using an org-wide policy.
  - OneDrive for Business accounts. Specify All or select mailboxes using distribution lists or individual mailboxes for inclusion or exclusion. The limit of a hundred accounts also applies.

- Teams. Choose all to cover all teams or select individual accounts by name or using a distribution list to include or exclude in a policy.
- **Policy settings:** Each policy contains at least one rule used to match items with potential violations. If you create a policy from a template, you can accept the default processing settings for the rules copied along with the template. For instance, a rule might be set up to block content when shared outside the organization. If the default rule settings don't do what you want, you can customize the rules or create new rules from scratch. A policy created from a template is likely to have at least two rules, each of which should be checked to ensure that the settings in one rule cannot interfere with settings in other rules. We will discuss rule settings in more detail later.
- **Enable policy:** Define whether the policy is on or off, or if it is in test mode.
- **Review your settings:** Before you save a policy, you can review its settings to ensure that everything is as you expect. Click **Create** to continue.

When you create a new DLP policy or update an existing policy, Microsoft Purview checks the policy to ensure that it is valid. For example, you might have input the URL for a subsite instead of a site. If this happens, the error is flagged, and you must fix the problem before you can save the policy. Once everything is satisfactory, Microsoft Purview publishes the new policy to the various workloads to enact the policy. A certain amount of complexity is involved to publish a policy to all the workloads as multiple servers are involved. Microsoft's SLA is for a new or updated policy to be effective within an hour of publication, but the experience of many is that this SLA is often breached and that you might have to wait up to a day before everything settles down and new DLP rules are active.

A further delay occurs before workloads begin to detect violations. SharePoint relies on the crawler within the content indexing process to detect sensitive data within documents. SharePoint does not index content immediately after an item is updated and (depending on system load) the crawler might take between ten minutes to an hour before it processes an updated document. It can take up to an hour before a new DLP policy for Teams or an update to a DLP policy for Teams is effective. The exact time varies depending on the current load on the Teams infrastructure.

## Resolving Multiple Potential Violations

Large organizations or those with complicated DLP requirements will likely use several DLP policies. This creates the possibility that an item will match several policies. In this situation, the following applies:

- DLP policies have a priority order for evaluation from 0 (most important) downwards. Policies are evaluated in this order.
- Rules within DLP policies also have a priority order.
- DLP rules can be set to stop the processing of other rules when a match is detected.
- In general, DLP applies the most stringent policy on the basis that it is better to be safe rather than sorry.
- The exception is where a rule in a high-priority policy stops the processing of other rules. In this case, the violation flagged by this rule is used and any other potential violation which might be detected by rules in lower-priority policies is ignored.

With this guidance in mind, organizations should:

- Order DLP policies so that the most important policy is assigned the highest priority.
- Order rules within DLP policies so that the most important rule is assessed first.

## Default Rule Settings

If you don't customize the rules in a DLP policy, the rules inherit some default settings, including:

- **Who can receive sensitive content:** DLP can apply the policy inside or outside the organization. People with email addresses belonging to a domain registered for the tenant in the Microsoft 365 admin center are internal; those with addresses belonging to other domains are considered external.
- **How DLP protects content:**
  - **Display policy tips:** It is usual to display policy tips to users to tell them that a problem exists with a document.
  - **How many instances of sensitive data exist in an item before DLP flags a violation:** The default for a rule is that 10 instances of the same sensitive information type (for example, a credit card number) must be present in a file or message before a violation occurs. You can reduce or increase the number of matches to change how the rule works. If you want to make a rule easier to match, reduce the instance count (for example, from 10 to 7). Likewise, to make it harder to match, increase the count.
  - **Who receives the incident report and what is in the incident report:** Typically, incident reports go to a DLP administrator, who checks the incident to assess whether it is valid and if a violation is present, decides what action to take to resolve the violation.
  - **Restrict or encrypt access:** Should sharing the information in a detected item be blocked or encrypted? Encryption is only supported for Exchange Online messages. For SharePoint and OneDrive content, you can restrict access to content after detecting a DLP violation. As shown in Figure 19-4, the normal situation is to block external access to the content while allowing internal users continued access. The options are:
    - Block everyone from accessing the content.
    - Block people outside the organization. Anyone with a tenant account can access the content, including guest users.
    - Block people who can access the content through an Anyone link.

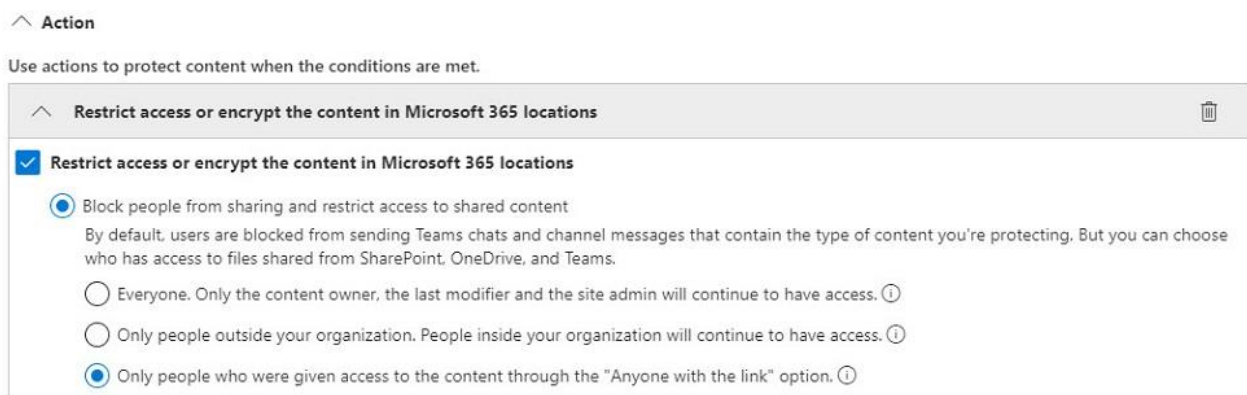

Figure 19-4: Customizing access to content setting for a rule in a DLP policy

When you opt to block external users from seeing sensitive content that violates a DLP policy, the SharePoint and OneDrive for Business sharing dialog includes a warning to users if they try to share sensitive content outside the tenant. The warning appears in real-time and helps to educate users about the need to protect sensitive content.

## Advanced Rule Settings

To have full control over the rule settings, select **Create or customize advanced DLP rules** when creating a new policy. You can then use the full rules editor to edit rules copied from the template (or created from scratch) to meet your exact needs. The settings for rules are:

- **Rule name:** Free-text name assigned to the rule.
- **Description:** A brief description of what the rule does.

- **Conditions:** The type of data present in the content and the context surrounding the data (for example, the number of instances of some sensitive data) to cause the rule to fire. For example, a rule might ignore content where a single credit card number is present but fire when it finds more than three instances of credit card numbers. Figure 19-5 shows where to change the number of detected sensitive data instances for a policy to check (in this case, at least one credit card number must be present in an item to fire the rule).  
DLP conditions can include aspects of documents or messages that must be present for the rule to fire. These conditions might only apply to a single kind of data. For example, a rule might check for email messages sent from a specific IP address or email with attachments that cannot be scanned or can only partially be scanned, or a rule could look for attachments of a specific type or those that are password protected. Another example of a condition is when you use a document property to identify documents that come within the scope of a policy. Any managed property supported by SharePoint search can be used in this manner. Finally, if sensitivity labels exist in the tenant, a DLP rule can include a condition that a certain label must be present for the rule to fire.
- **Exceptions:** Define whether any conditions exist that will cause the rule not to fire. The exceptions include if the content has a specific form of sensitive data (or label), and the sharing of content inside or outside the organization. Exchange Online policies can focus on a characteristic of email (IP address, attachment type, and recipient domain).
- **Actions:** What happens when a violation occurs. The action is to restrict access to the content by removing permissions for everyone except the primary site administrator (or global administrator), site owner, and the person who last changed the item. Microsoft Purview automatically restores the original permissions when the owner or person who last changed the document acts to remove the offending content and bring the document back into compliance. Encryption is available to protect email with sensitive content, but only for policies scoped to apply to Exchange content. See the note below.
- **User notifications:** DLP supports two forms of notifications. First, it can send email notifications to the site owner (or other designated users) and whoever last changed the item to inform them that a problem exists and why (for instance, someone shares the item with external people and includes a debit card number). A link in the message allows the recipient to open the document and fix the problem detected by the policy. The second method is to flag the problem visually with a policy tip. You can customize the text of the policy tip to add organization-specific advice to users.
- **User overrides:** The rule can allow users to override the block because of a false positive. In other words, the user (who knows the content and can put it into business context) says that the rule is incorrect to flag an item for a policy violation. When this happens, DLP removes the block and records the text given by the user to justify the override for auditing purposes.
- **Incident reports:** You can arrange for email notifications to go to one or more people when a policy detects problems. These notifications are known as incident reports. Each report has enough information about the problem to allow an administrator or compliance officer to understand whether a problem exists and if so, whether they need to take further action.

You can also set rule priority to have DLP execute the rules in a certain order and terminate processing after a rule matches conditions and is executed.

Figure 19-5: Defining settings for an individual rule in a DLP policy

When you finish working with the settings for a rule, click **Save** to return to the rule set so that you can edit the next rule. When all the rules are to your liking, click **Next** to return to the policy. Remember that if you make a mistake or want to change something, you can always edit the policy and then update settings for individual rules or the policy.

**Email message type exceptions:** DLP supports exceptions based on the message type. These are used in cases where you might not want to apply rules to read receipts or automatic replies. Care should be taken with the three types which cover encrypted email. Encrypted means S/MIME encrypted; Signed means S/MIME signed; and Permission Controlled means that a sensitivity label or OME template protects the message. The latter is the type usually required to process Exchange Online messages.

## Confidence Levels and Match Accuracy

DLP policies match data found in documents and emails against sensitive information types by looking for patterns and other forms of evidence. The primary element (like a regular expression) in a pattern for a sensitive information type defines the basic match for that type. Secondary elements (like keyword lists) add evidence to confirm that a match truly is an example of a sensitive information type. The more evidence is gathered, the higher the match accuracy and the more confidence exists that the data found is an instance of the sensitive information type. Microsoft refers to the match accuracy as the confidence level. Policy rules use the confidence level to decide whether action is necessary when matches are found.

The higher the percentage confidence level specified by a rule, the more evidence DLP must find before it can match a rule. Three confidence levels are used:

- Low (65% match accuracy).
- Medium (75% match accuracy).
- High (85% match accuracy).

For instance, to meet the bar set for a low confidence match for a credit card number, text must be in the right format (sixteen digits) and pass [Luhn's algorithm](#) to establish that the number could be a credit card. To

increase the confidence that the number is a credit card to 85% confidence, the rule looks for other evidence like a keyword (such as "Visa" or "Amex") or an expiry date in the MM/YY format.

If a policy includes multiple rules that check for the same sensitive information type, the suggestion is to:

- Set the minimum and maximum confidence level for the rule that takes the least aggressive action when a low-confidence match is found.
- Set the confidence level range for the rule that takes more aggressive action when a match is detected with higher confidence.

The idea is that content with lower confidence matches receives an action with less impact on the user (like displaying a policy tip) while content with higher confidence matches gets a more restrictive action (like being blocked).

## Rule Priority

Each rule in a policy receives a priority number in the order in which it is created. When DLP evaluates content against a policy, it processes the rules in priority order; if the content matches multiple rules, DLP applies the most restrictive action. For example, if rule 1 displays a policy tip to users and rule 6 restricts access to the content, DLP applies the settings from rule 6. In addition, the policy tip for the most restrictive rule is displayed to the user.

## Protecting Sensitive Email with Encryption

If DLP detects outbound emails containing sensitive content, you can have Exchange apply encryption to the messages before they leave your tenant. You can choose to apply any of the Microsoft Information Protection templates (not sensitivity labels, because a label might not include encryption) available in the tenant to messages, including the default Encrypt Only and Do Not Forward templates. See Chapter 20 for more information about how to create and use Microsoft Information Protection to protect documents and email.

If you choose to apply encryption to messages in a DLP policy, that policy can only cover Exchange. You can't apply encryption to documents through a DLP policy.

## GDPR Support

Tenants that come within the scope of the European Union's General Data Protection Regulation (GDPR) need to meet specific requirements for the protection and use of personal data. To help, Microsoft Purview includes six common sensitive information types for use in DLP policies or to classify sensitive data. The information types include:

- EU Debit Card Number.
- EU Driver's License Number.
- EU National Identification Number.
- EU Passport Number.
- EU Social Security Number (SSN) or equivalent ID.
- EU Tax Identification Number (TIN).

In addition, Purview includes many country-specific sensitive information types like the Estonia Driver's License Number.

Microsoft Purview includes a General Data Protection Regulation DLP template. If you create a DLP policy using this template, DLP adds the six EU-wide sensitive information types listed above to the policy. You can edit the policy to include other sensitive information types or include the EU data types in other policies.

An example of the difficulties involved in detecting content using sensitive information types happened when emails imported into SharePoint Online caused DLP to flag violations for the EU TIN sensitive information type because eight- and nine-digit numbers in the email headers resembled tax identification numbers. Microsoft

resolved the problem by adjusting the data definition to look for more proof that a number was a TIN before flagging a violation.

## Sample Test Data

When you start working with DLP, the issue of how to generate good test data to use to check policies always arises. The [DLPtest site](#) offers several different sets of sample data, including social security numbers and credit card numbers, that you can use for testing.

## PowerShell support for DLP policies

DLP policies use several cmdlets (included in the compliance module) to work with policies and rules. The cmdlets include:

*New/Get/Set/Remove-DlpCompliancePolicy*: Create, access, manipulate, and delete DLP policies. For example:

```
[PS] C:\> Get-DlpCompliancePolicy -Identity 'Confidential Patent Information DLP Policy'
```

*New/Get/Set/Remove-DlpComplianceRule*: Create, access, manipulate, and remove the rules used in DLP policies. For example, here is how to check the settings for a rule (edited output shown):

```
[PS] C:\> Get-DlpComplianceRule -Policy 'Check for SSN Data' | Format-List

ParentPolicyName           : Credit Card data check
ContentContainsSensitiveInformation: {System.Collections.Hashtable, System.Collections.Hashtable, System.Collections.Hashtable}
AccessScope                 : NotInOrganization
ContentPropertyContainsWords : {}
Workload                   : Exchange, SharePoint, OneDriveForBusiness
BlockAccess                 : True
GenerateIncidentReport     : {DLPIncidents@Office365ITPros.com}
IncidentReportContent      : All
NotifyUser                  : {SiteAdmin, LastModifier, Owner, Tony.Redmond@office365itpros.com}
NotifyAllowOverride        : WithJustification
NotifyEmailCustomText      : You can't keep this kind of information in documents!
NotifyPolicyTipCustomText  : Whoops - bad SSN data found here
ReadOnly                    : False
Priority                     : 0
Comment                     : A rule to detect SSN data in documents
Disabled                    : False
CreatedBy                   : Tony Redmond
```

We can tell that this rule:

- Is associated with the DLP policy "Credit Card data check".
- Looks for three types of sensitive data (the hashtable references in the *ContentContainsSensitiveInformation* property – the names are not shown).
- Checks information shared with users outside the tenant (scope is "NotInOrganization").
- Scans for three supported workloads (Exchange, SharePoint Online, OneDrive for Business).
- Blocks access to content deemed to contain sensitive data.
- Generates a DLP incident report.
- Generates an email notification to the site administrator, the last user who modified the content, its owner, and a nominated other user.
- Allows the policy tip to be overridden with a business justification.
- Is active (*Disabled* is False).

Given that DLP policies can be reasonably complex to set up, it is best to manage DLP policies and rules through the Microsoft Purview Compliance portal and only use PowerShell to check individual objects as needed.

# Endpoint DLP

[Microsoft Purview Endpoint DLP](#) is a solution that uses signals generated by actions performed on Windows 10 workstations to evaluate against DLP policies. Supported actions include copying files to removable media like a USB or to a network share, printing files, uploading to a cloud app, or copying data to the clipboard. The code necessary to detect actions and submit them for evaluation is incorporated into Windows 10 (version 1809 or later) and the Edge or Chrome browsers. No additional agent is necessary to monitor activity on a workstation.

Before you can use Endpoint DLP, you need Microsoft 365 E5 licenses or either the Microsoft 365 E5 information protection and governance or compliance add-ons. Workstations used by licensed accounts can be onboarded (enabled) through the Microsoft Purview compliance portal to start the flow of signals for DLP evaluation, unless administrators have already enrolled the devices for Windows Defender, in which case Endpoint DLP works without any further configuration.

Once a workstation is enabled, actions taken by the user are monitored for potential violations against policy using the same kind of conditions as used to monitor Office 365 activity. For example, attempts to upload documents containing credit card numbers can be detected and stopped. Supported file formats include Office documents, PDF, text, and source code.

Endpoint DLP settings for the organization can be adjusted in the Microsoft Purview compliance portal to reduce the amount of noise in signals by excluding certain folders like the recycle bin, temp folder, or folders used for non-work files. It's also possible to allow uploads to specific cloud services without generating a violation. Policy thresholds can be set to generate alerts when multiple events of the same type happen over a short period. For instance, a policy could alert administrators if someone prints more than twenty documents assigned the Confidential sensitivity label.

When Endpoint DLP is available in a tenant, DLP policies can cover a target location called Devices, just like choosing SharePoint or Exchange as policy locations. The normal approach is to separate device policies from those used with Office 365 workloads, but you can combine them. Device policies have separate settings for restrictions to enforce when policies match conditions (Figure 19-6).

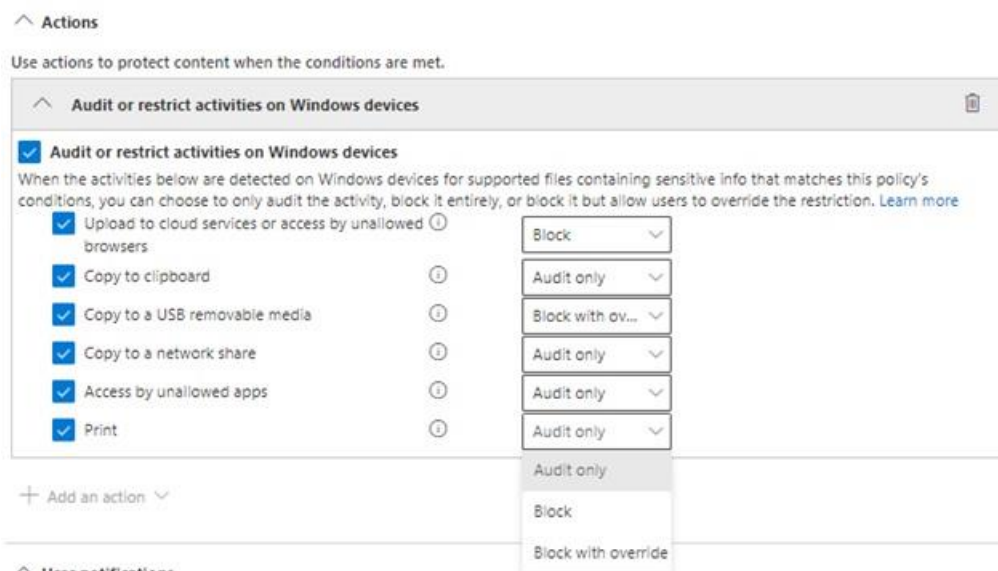

Figure 19-6: Endpoint settings in a DLP policy

Edge is the preferred browser because it understands how to respect endpoint DLP policies, and you can block other browsers from accessing files protected by policies. For instance, you could block Firefox from opening a Word document if a specific retention label is present.

Apart from being used by DLP, the signals generated by devices can be gathered and analyzed in a SIEM. An example using Azure Sentinel is [described in this article](#).

# Creating Custom Sensitive Information Types

Although a large set of standard sensitive information types exists, organizations often have specific ideas about the characteristics of confidential data which are not satisfied by the set of standard sensitive information types. You can create your own custom sensitive information types through the **Data Classification** section of the Microsoft Purview Compliance portal. Custom sensitive information types can be used in DLP policies, retention policies, and auto-label policies. They can be created from scratch or by copying one of the standard types and altering the copy to meet requirements.

The basic need for any sensitive information type is a pattern to detect matches in messages and documents. The simplest patterns have a primary element to instruct how to detect a specific type of sensitive information and a confidence level when a match occurs. A pattern with just a primary element might define its confidence level as medium for any match, while patterns with supporting elements that add more evidence that a match exists might increase the confidence level as supporting elements are found near the matched element. The following methods can be used as a primary element:

- **Regular expression:** A Regex to detect certain patterns of data. Sites like [regex101.com](https://www.regex101.com) are useful to help form regular expressions. For example, a regular expression of `\s[A-Z]{3}-[0-9]{4}\s` can be used to match project numbers like "PRJ-1384" or "PRO-1847".
- **Keyword list or Keyword dictionary:** Both ways to define keywords (like "Finance" or "Funding") that you want to use for matching. Typically, these methods are used as supporting elements rather than for primary matching.
- **Function:** Microsoft publishes a [set of functions](#) for different types of data, such as an Alabama driver's license. You can use these functions to create custom sensitive information types.

Supporting elements add confidence that matched data is what you are looking for and not just a random collection of letters and numbers. For example, as noted above, a social security number is described by a number in the format 999-99-9999 with added evidence coming from the keywords "SSN" or "Social Security" near (in terms of characters) the number. The same is true for credit cards, where the 16-digit number is confirmed by words such as "credit card," "Visa," "MasterCard," "expiry date," and so on.

## The Azure AD Password Sensitive Information Type

In general, it's bad practice to circulate passwords in messages, so let's see how we can stop people from sending Azure AD passwords in email and Teams messages. Some cases exist when sending passwords around is necessary, such as when an administrator resets a password for a user (a tenant can enable [self-service password reset](#) to let users reset their passwords). To detect Azure AD passwords, we need a regular expression to detect passwords matching Azure AD password policies. By default, Azure AD password requirements are:

- A minimum of 8 characters and a maximum of 256 characters.
- Requires three out of four of the following:
  - Lowercase characters.
  - Uppercase characters.
  - Numbers (0-9).
  - Symbols (@ # \$ % ^ & \* - \_ ! + = [ ] { } | \ : ' , . ? / ` ~ " ( ) ; and blank space)

Many suggested regular expressions to validate Azure AD passwords are shared on the internet. However, when you input regular expressions to use with DLP policies, Microsoft validates the code to ensure that it works and will perform well (the [rules are documented here](#)). Most of the suggested expressions do not meet

Microsoft's rules. Fortunately, MVP James Cussen [created an expression](#) that passes the test and matches passwords, which we can use to illustrate how to create a custom sensitive information type. Here's the expression:

```
((?=[\S]*?[A-Z])(?=[\S]*?[a-z])(?=[\S]*?\d)|(?=[\S]*?[A-Z])(?=[\S]*?[a-z])(?=[\S]*?[^\a-zA-Z0-9])|(?=[\S]*?[A-Z])(?=[\S]*?\d)(?=[\S]*?[^\a-zA-Z0-9])|(?=[\S]*?[a-z])(?=[\S]*?\d)(?=[\S]*?[^\a-zA-Z0-9]))[\s]{8,256}
```

The regular expression matches strings in the right format for Azure AD passwords. To provide additional evidence that a string is a password, we can add a supporting element in the form of a keyword list. Typically, when people send passwords in messages, they include some explanatory text. Therefore, if a keyword occurs close to the matched password, the likelihood increases that the term is a password. For instance, someone might send a message saying "Here's your new password: AzurePW123!@." The string AzurePW123!@ matches the regular expression and becomes the anchor for DLP to look for keywords within the window set for keyword proximity checks. The window extends to the left and the right of the match, which means that a match against "password" occurs because the keyword is within a few characters of the anchor. The confidence that a good match exists is therefore higher.

In Figure 19-7, a keyword list of terms that help to confirm passwords is visible. If an organization is multi-lingual, you should include terms from different languages as shown here. It is also a good idea to consider including some misspellings of terms in the keyword list, such as "passwrđ" or "passwrod" as there's no guarantee that people will spell everything correctly when they send messages.

## Edit keyword list

Keyword lists identify the words and phrases you want this info type to detect. For example, the keyword list to identify Netherlands VAT numbers is 'VAT number, vat no, vat number, VAT#'. [Learn how to create keyword lists](#)

☰ Choose from existing keyword lists

ID \*

Password components

Keyword group #1 \* ⓘ

Case insensitive

password, pwd, passcode, passwd, wachtwoord, mot de passe, Passwort, contraseña

Case sensitive

Enter keywords, separated by commas. Each keyword is limited to 50 characters, and exact casing is required to detect matches.

Word match  String match

Figure 19-7: Defining a keyword list

The components used to define the pattern for the new custom sensitive information type are:

- The primary element is a regular expression to detect the pattern of a valid Azure AD password.
- The supporting element is a keyword list of password terms.

- The confidence level is medium to start. This level is set when a match occurs against the primary element. It will increase to high confidence if DLP also detects a keyword from the keyword list in the supporting element.
- The character proximity defines how close one of the password terms must be to the primary element. Purview usually suggests a proximity window of 300 characters, but in this instance, it is better to adjust the proximity window to around 80 characters because the likelihood is that any mention of a supporting term will be very close to the password. If policies using the custom sensitive information type generate too many false positives, you can consider reducing the proximity to 50 or 60 to see if that reduces false positives. The option to check for anywhere in the document is not suitable because it is likely to result in many false positives.

Figure 19-8 shows the components of the new pattern during the creation phase. The primary element is saved with a name for easy reference later as is the keyword list. After defining the pattern, we set the recommended confidence level to look for in policies. The final step is to save the new type.

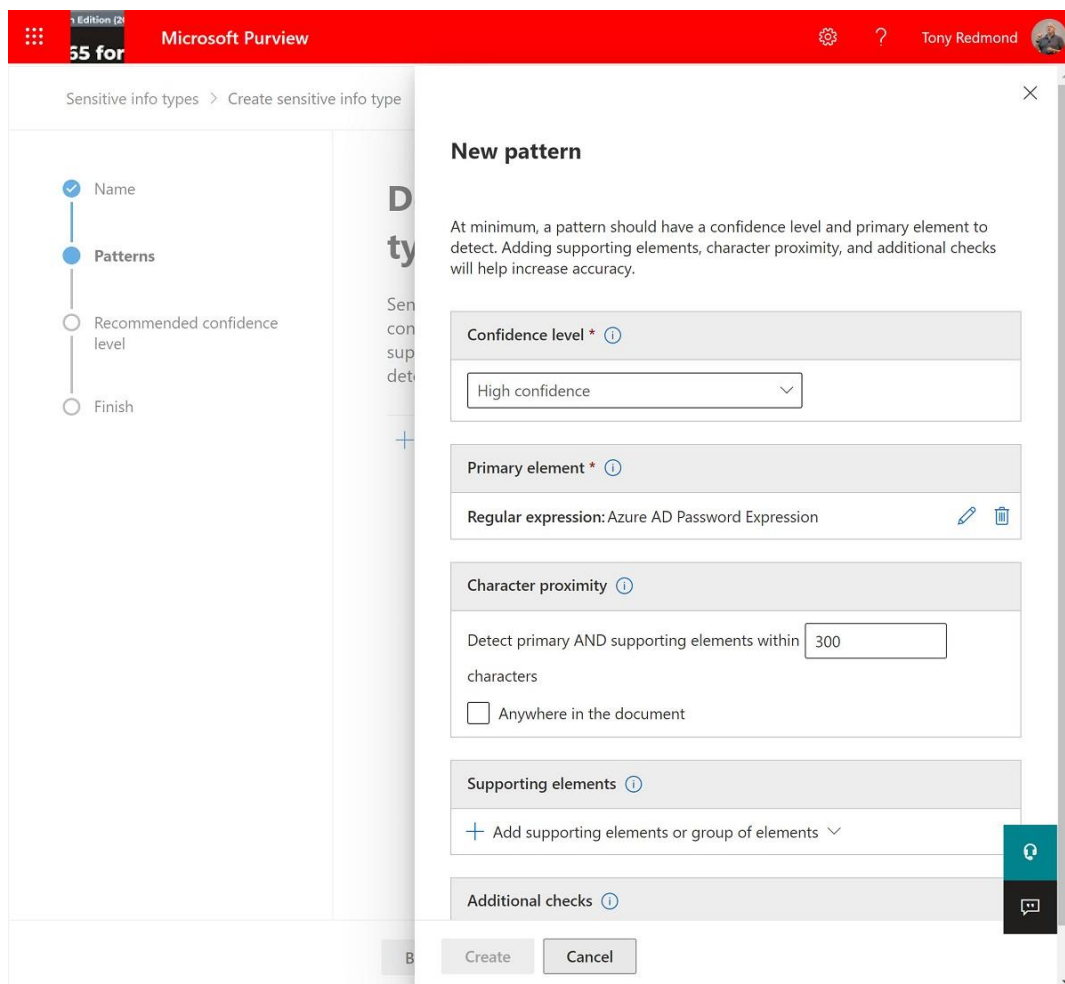

Figure 19-8: Defining a new custom sensitive information type

## Testing a Custom Sensitive Information Type

After creating a new custom sensitive information type, it is wise to test it before attempting to use the new type in a policy. Select the custom sensitive information type from the set available in the tenant. Test is one of the available options.

At least two text files are needed for testing. One should contain a set of values that you expect the sensitive information type to detect; the other contains values that it shouldn't. For a more comprehensive test, you can create a suite of text files to check various combinations against the new type.

Click **Test** and browse to select a test file that you've prepared. Microsoft Purview uploads the file and tests its contents against the custom sensitive information type in the same way that a comparison occurs in a DLP policy. You'll then see the results of the test and the matches (Figure 19-9). We can see that the test made three matches using the primary element for three passwords found in the test file (65% confidence). The level of confidence increased to 75% because some of the keywords listed in the secondary element were detected within the defined proximity window.

**Match results**

We have detected the following in *TestPwd.txt*

- Azure Active Directory password**  
65% Confidence - 3 matches

Matches	Supporting elements
TestStuff124298!	"password", "password", "pwd"
NewThingToTry56@	"pwd", "password"
GatheringDust12	"password", "pwd", "password"

- Azure Active Directory password**  
75% Confidence - 3 matches

Matches	Supporting elements
TestStuff124298!	"password", "password", "pwd"
NewThingToTry56@	"pwd", "password"
GatheringDust12	"password", "pwd", "password"

Back Finish Cancel

Figure 19-9: Testing a custom sensitive information type

After the new custom sensitive information type passes its tests, you can go ahead and deploy it like any of the out-of-the-box types. It's important to test the custom sensitive information type in a variety of circumstances before you put it into production. For example, you should consider if it is necessary to exclude some email addresses from the policy (the easiest way to do this is to create a distribution list and use it to hold the accounts allowed to send passwords). Another thing to consider is whether a policy that works well for Teams (which mostly deals with internal communication) is equally effective for emails when you can exert less control over what external people might include in messages. The policy described here will, for instance, block email invitations for Zoom online meetings because the links to the meetings contain "pwd" and the string identifying the meeting looks like an auto-generated password. Finally, it's a good idea to consider how best to explain the rationale for the policy to end users so that people know what to do if the policy blocks their messages, including how they can override the policy (if policy settings allow an override).

The new custom sensitive information type can be managed in PowerShell. For instance, here's how to list all the custom sensitive information types in the tenant. The example we just defined shows up together with other types created by document fingerprinting (covered later).

```
[PS] C:\> Get-DlpSensitiveInformationType | ? {$_.Publisher -ne "Microsoft Corporation"} | Format-Table Name, Publisher
```

Name	Publisher
U.S. Tax Documents	Office 365 for IT Pros
U.S. Tax Form W-8BEN	Office 365 for IT Pros
U.S. Tax Form W-4 (2015)	Office 365 for IT Pros
U.S. Tax Form 1040 (2014)	Office 365 for IT Pros

## Custom Keyword Dictionaries

In addition to defining custom sensitive information types, you can set up keyword dictionaries. A dictionary is a set of keywords that you want to check for in DLP policies. For instance, you could define a set of inappropriate words like *blast*, *damn*, and *bugger* that you don't want people using in internal email and Teams messages or a set of product code words that you do not want people to share outside the company.

The easiest way to create a keyword dictionary is with a simple editor like Notepad. Put each word on a separate line and save the file in Unicode format. You can then load the file into a PowerShell variable and use the variable to create the dictionary. In this example, we read the contents of a file called *Codewords.txt* and use it to create a dictionary with the *New-DlpKeywordDictionary* cmdlet.

```
[PS] C:\> $FileData = Get-Content c:\temp\Codewords.txt -Encoding Byte -ReadCount 0
[PS] C:\> New-DlpKeywordDictionary -Name CodeWords -Description "Code Words for major projects"
-FileData $FileData

RunspaceId      : 3ab0f9ee-24ff-40c7-901c-c2bd8e43a830
Identity        : c1247f79-8cdd-4137-91a0-9c6dfb79192e
Name            : CodeWords
Description     : Code Words for major projects
KeywordDictionary : bitterball
                  gandalf
                  redsnark
                  torchcraft
                  x1050
                  x1051
                  x1052
                  yellowplane

IsValid        : True
ObjectState    : Unchanged
```

To update a keyword dictionary, use the [Set-DlpKeywordDictionary](#) cmdlet. You can input a new set of terms interactively or load them from a file. After the keyword dictionary is created, you can use it as a primary or secondary element when creating a new custom sensitive information type.

## Document Fingerprinting

Microsoft supports a comprehensive set of standard sensitive information types for use in DLP policies, but they cannot be aware of data that is uniquely sensitive to a company, like forms used in HR hiring processes, capital acquisition requests, employee review forms, and so on. Most companies would not like this information to be circulated externally and probably have security and privacy policies to govern external disclosure. DLP can help to educate users that confidential company documents should not be circulating in emails unless good business reasons exist.

Like the recognizable patterns that can be used to detect instances of data like social security numbers, documents have characteristics in terms of layouts, fields, and text blocks. You can use a process called fingerprinting to capture the characteristics of a document and create a digital signature in the form of a hash value. That signature, or fingerprint, then becomes a valid sensitive information type that can be used in DLP processing.

Microsoft Purview can create a digital fingerprint from a document in any of the formats supported by Microsoft Search. This includes any of the Microsoft Office formats plus Adobe PDF, so most documents used in corporations are candidates to serve as the basis of a digital fingerprint. It is always best to select a blank form rather than one that is filled in so that the resulting fingerprint is not affected by text or other markings

that will not appear in other copies of the form. Sample documents should not be password-protected or be graphic-heavy (text-based documents generate the best results).

Two methods exist to create document fingerprints:

- The first is in the Manage Document Fingerprints section under Data Loss Prevention in the classic **Exchange admin center**. The document fingerprints created here are used with Exchange transport rules. We describe the process to create document fingerprints via the EAC in Chapter 8 of the Companion Volume.
- The second option is to use **PowerShell** (compliance module). [Document fingerprints](#) are used to create new sensitive information types that can be used across Microsoft 365. This is the preferred approach and is described below.

After locating a suitable template file, use the *Get-Content* cmdlet to read the content of the file into a variable. In this case, I'm using the Irish Personal Tax Form 11.

```
[PS] C:\> $IrishTax11 = Get-Content "C:\Temp\Ireland Tax Form 11.pdf" -Encoding byte -ReadCount 0
```

Next, create a digital fingerprint from the variable generated by Get-Content:

```
[PS] C:\> $IrishTaxFingerPrint = New-DlpFingerprint -FileData $IrishTax11 -Description "Ireland Tax Form 11"
```

Finally, create a new sensitive information type from the fingerprint:

```
[PS] C:\> New-DlpSensitiveInformationType -Name "Ireland Tax Form 11" -Fingerprints $IrishTaxFingerPrint -Description "Ireland Personal Tax Form 11"
```

Microsoft 365 responds by listing the properties of the new sensitive information type. You can also check by running a command like:

```
[PS] C:\> Get-DlpSensitiveInformationType -Identity "Ireland Tax Form 11" | Format-Table Name, Type, Description
```

Name	Type	Description
Ireland Tax Form 11	Fingerprint	Ireland Personal Tax Form 11

The new sensitive information type is now usable in Purview DLP policies or Exchange transport rules

# Chapter 20: Managing Information Protection

## **Tony Redmond**

This chapter discusses how to use information protection technology to protect email, documents, and other files. The topics covered include:

- The rights management service and Microsoft Purview Information Protection (MIP).
- Office 365 Message Encryption (OME).
- How to protect documents and messages with sensitivity labels.
- How to protect SharePoint Online document libraries and lists and OneDrive for Business sites.
- How rights management templates work and how sensitivity labels use rights management.
- Using PowerShell with protected content.

In some quarters, rights management enjoys a reputation of being a technology difficult to understand, implement, and manage. It is certainly true that deploying this kind of protection for on-premises infrastructures can take significant effort. Hopefully, we'll prove that although Microsoft Purview Information Protection uses many of the same concepts as found in on-premises deployments, it is easier to implement rights management-based protection in the cloud because Microsoft takes care of maintaining the infrastructure to issue and check user rights to access information.

## The Need to Protect Data

We live in a world where encryption is pervasive for both businesses and consumers. It is unthinkable to consider conducting a banking transaction through a website not protected with encryption. Even so, an awful lot of email traffic still moves over unencrypted SMTP links (Exchange Online uses TLS to secure mail traffic in transit), perhaps because setting up reliable encryption for email has always run into the difficulties of agreeing on a common standard for external transmission and the cost of deploying and supporting an infrastructure to assure secure email internally. The earliest versions of Exchange Server included the Key Management Server (KMS) to manage the storage and distribution of keys for message encryption. At the time, the great hope was that the availability of KMS would encourage many organizations to adopt encryption to protect email. That hope never fully materialized.

Rights management delivers the capability to protect confidential messages or documents to control what recipients can do with the content (enforce usage restrictions). Without protection, an email recipient can forward messages they receive, print the messages, cut and paste message content, and so on. Rights management implemented through sensitivity labels allow an organization to define sets of rights that users apply to messages and documents to restrict what a recipient can do. The functionality protects companies by allowing them to circulate confidential or sensitive information under control and avoid situations such as "information leakage" which happens when, for instance, a disaffected employee forwards messages to journalists or other interested parties. Another example of similar functionality in a different context is the use of DRM to protect music downloaded from various sites. In addition, settings also control how long users can access information, after which the information becomes inaccessible. Microsoft offers several ways to deploy rights management to protect content:

- On-premises customers can deploy a Rights Management (RMS) server to manage the encryption keys used to protect data by both on-premises and hybrid users. [Hold your own key](#) (HYOK), which also uses keys managed by on-premises servers, extends the coverage to cloud applications. Because the complexities involved in using HYOK to protect data differ from customer to customer, we do not cover the topic here.
- Tenants can generate encryption keys and import the keys into Microsoft's data centers, where the keys are under the control of the tenants. This implementation is known as [Bring your own key](#) (BYOK) or HYOK.
- The most common method to implement rights management in the cloud is when Microsoft manages the encryption keys for tenants (a Microsoft managed key, or MMK). As with BYOK and HYOK, the keys issued to tenants protect information including Exchange Online messages and SharePoint Online and OneDrive for Business document libraries and lists.

Although the concept of rights management extends back to the early 1990s, Microsoft began implementing the technology for products like Exchange and Outlook in the middle of the decade. Rights management proved capable of protecting information, but customers did not take to the technology for a few reasons. Part of this was because of the culture shift needed inside companies to take the protection of information seriously, including strong executive leadership to champion the case for deploying the technology. Part of the reason was due to the extra infrastructure plus the time needed to deploy and run Active Directory Rights Management Services (AD RMS), the service underpinning protection within an on-premises environment. Because Microsoft delivers the required infrastructure and integration for cloud services, tenants need to dedicate less effort to secure protection.

The work to expand protection across Microsoft 365 is a journey. Newly-introduced capabilities include auto-application of sensitivity labels for Exchange Online messages in transit. We'll get to the new functionality as the chapter unfolds.

## Rights Management

Microsoft 365 uses the Azure Rights Management protection service as the foundation for rights management and encryption to allow users to protect information through features like:

- **Office 365 Message Encryption (OME)**, a set of features to encrypt Exchange Online email including:
  - Out-of-the-box encryption for the Outlook and OWA clients through special *Encrypt Only* and *Do Not Forward* options. When OME encrypts a message, it places a special wrapper around the message that Exchange Online or Outlook.com recipients can automatically decrypt. Other recipients can access the content through the OME portal. OME's ability to protect email sent to any recipient using the Encrypt Only feature can replace the need to deploy S/MIME or other third-party tools. Outlook mobile clients can create and read messages protected by OME.
  - Recipients of encrypted messages outside the tenant can read the content in the OME portal by authenticating their access to the portal or using a one-time passcode. The same occurs when "unenlightened" clients (ones that don't understand rights-management based encryption) connect to Exchange Online. For instance, if someone uses an IMAP4 client to connect to Exchange, they must go to the OME portal to read any protected messages they receive.
  - Protection applied to outbound email by email transport (mail flow) rules. For example, a rule can ensure that any message sent to a partner domain is encrypted. Transport rules can apply the standard OME *Encrypted* and *Do Not Forward* protection as well as sensitivity labels defined in the tenant.

- Users and policies assign **Sensitivity labels** to messages and documents. While some labels only apply visual markings to content, others can invoke protection with rights management permissions. Clients that apply and process sensitivity labels use the MIP Software Development Kit. MIP is a framework or platform for developers inside and outside Microsoft to add protection to applications.
- **Information Rights Management protection** for documents downloaded from SharePoint document libraries. This form of protection is now obsolete and should be replaced by sensitivity labels.

Some differences might exist in the capabilities depending on the data center region used by your tenant. For example, the sovereign cloud region in [China](#) does not support the full suite of protection capabilities and users within these clouds have limited options to protect email and documents. Check with Microsoft about the current situation.

## Protection and Permissions

Rights management protects Items through a set of rights or permissions granted to a recipient. Logically, the author or originator of content always has full control over the content. You can compare applying a sensitivity label to a message as being analogous to registering a postal letter. The recipient is only able to open and access the content if the rights management service recognizes their access – the recipient gains access by having a known account (authenticated against Azure AD) with access rights defined by the sensitivity label that the application can apply to the item. If protected content ends up in the hands of an unknown user, they will not be able to access the content because it will stay within an encrypted “wrapper” that only intended users can open.

It is important to understand the available rights do not cover every possible circumstance or method that a recipient might use to interact with protected content. For example, if you don't grant the right, recipients can't take a screen capture of the content on Windows devices because Windows respects the denial of the right. However, iOS and Mac devices allow screen captures because those operating systems do not permit applications to restrict screen captures. This difference in behavior between operating systems illustrates the point that rights management can go so far in restricting deliberate attempts to share protected content (taking a photo of a screen with a mobile device is another way around rights management). Rights management is therefore part of an overall solution to manage critical and sensitive information: it is not a complete answer if deployed without supporting user education, policies, and possibly other technology.

### Other Ways of Using Protection

In addition to allowing authors to decide what level of protection to assign to their work by applying a label to a message or document, administrators can create transport rules to apply labels to messages that meet certain criteria as the messages travel through the transport pipeline. This is an excellent way to automatically protect confidential messages if you can create criteria to find those messages. For example, all messages that mention the word “Confidential” in the message subject or all messages sent to the “Corporate Planning” distribution list. Transport rules protect messages without user intervention and users cannot override what they do. Best of all, this approach works for messages sent from any client.

Protecting messages through transport rules allows great control over information circulated through email. It also means that the content of any message sent externally is inaccessible because external recipients cannot retrieve the use licenses necessary for decryption. Fortunately, you can use encryption to protect messages sent to external recipients in a way that they can access the content securely.

While more difficult to manage, it is possible to use [an on-premises Active Directory RMS server](#) to deliver a Rights Management service to users. That setup is outside the boundaries of the discussion presented here.

## Licensing Requirements for Microsoft Information Protection

Microsoft 365 has two Information Protection service plans. The standard version is part of Office 365 E3 and the premium version is bundled with Office 365 E5. These service plans govern the functionality available through sensitivity labels to protect email and documents in Exchange Online, SharePoint Online, and OneDrive for Business. The Office 365 E3 license covers the use of sensitivity labels to manually classify and protect content stored in Exchange Online, OneDrive for Business, and SharePoint Online. The Office 365 E5 license enables functionality like automatic labeling at rest and label analytics. Tenants don't need licenses to apply sensitivity labels to items using Exchange Online transport rules.

All Microsoft 365 licenses include the ability to consume protected documents (in other words, to open protected documents). For instance, an account with an Office 365 E5 license could protect a document with a sensitivity label and circulate the document to users with frontline (F1) licenses. Even if allowed to, those users are not licensed to change the protection on the document, but they can certainly open and view its content. They can also upgrade their capabilities with a premium license to gain the ability to apply protection to documents.

Office 365 Message Encryption is part of the Office 365 E3 and E5 plans (enterprise, academic, and government) plus Microsoft 365 Business Premium. For other plans like Exchange Online Plan 1 or 2, you'll need to purchase the Microsoft Information Protection add-in.

Premium licenses such as Microsoft 365 E5, Microsoft 365 E5 Compliance, and Microsoft 365 E5 Information Protection and Governance cover advanced functionality like automatic labeling. When you see references to premium licenses in this chapter, we usually mean that the feature under discussion needs one of the above licenses. However, given the number of features and plans available in this space, the issue of licensing can be quite complex and it's wise to check exactly what you need. Microsoft [publishes guidance](#) to help tenant administrators and licensing coordinators understand when premium licenses are required. A useful [Microsoft 365 compliance comparison spreadsheet](#) is also available to show which license covers each feature. The spreadsheet also identifies gaps in terms of desirable features not covered by licenses held by a tenant.

In some cases, a feature might not enforce the stated licensing requirement. This could be because the necessary code is not yet available. The code might or not appear soon. In any case, a tenant must have licenses to use functionality. It's a bad place to be in if features the business depends on suddenly stop working because Microsoft updates its license enforcement code.

### Licensing the Protection of Content Stored Outside Microsoft 365

Your organization may want to protect files both inside and outside Microsoft 365. Office 365 E3 and E5 licenses cover the use of sensitivity labels and OME to protect documents and messages stored inside its repositories and to protect emails sent outside the organization. To apply sensitivity labels to files stored in external repositories or to files belonging to applications that don't include native support for Microsoft Information Protection, you must:

- Deploy the unified labeling client to workstations.
- Assign Information Protection licenses to accounts that apply protection to external files.

Licenses are available standalone or bundled in the Enterprise Mobility and Security and Microsoft 365 enterprise plans. The basic rule here is that using the unified labeling client to protect a file (or to change the protection on a file), requires a license. On the other hand, no license is necessary for someone who only opens and accesses the content in protected files.

The unified labeling client does not check licenses. If an organization has a Microsoft Information Protection subscription, all clients within the organization can download the policy and use labels. The use of labels is what invokes the need for a license, so to avoid this happening you can force the workstations used by

unlicensed users to run the client in [protection-only mode](#) to stop clients from downloading policies. See [this page](#) for more information.

## The Flow of Protection

When a tenant activates rights management (the default state), clients use an automatic process to receive certificates from the rights management service to allow users to access protected content even when they work offline. The service keeps a copy of the user's Rights Account Certificate (RAC) so that it can issue it to another workstation if the user connects from there. Once authenticated, users can send and receive protected messages or apply sensitivity labels to protect files. When a user protects a message or document (for example, by applying a sensitivity label), the client embeds a unique key (the content key) in the item's header. To protect an item, the client encrypts it (and any attachments which support protection) using the AES 256-bit symmetric encryption algorithm. The content key persists with the item even if the author edits it to create an updated version. Rights management protects the content key with another key (the tenant key), which is common across all protected content. Either Microsoft or the tenant can manage the tenant key.

When it encrypts information, the client generates a certificate called the publishing license which includes a policy with the usage rights for recipients (individual users or groups) as well as any other restriction, such as an expiry date. Like all the licenses used by rights management, the publishing license is an [XrML certificate](#). The settings stored in the publishing license come from the sensitivity label selected to protect the content. The client signs the publishing certificate with a user certificate. The client also encrypts the publishing certificate and the content key using the tenant key. Finally, the client combines the encrypted content with the signed and encrypted publishing certificate to create the protected item. This step ensures that the publishing certificate always stays with the encrypted content. If necessary, the rights management service can use the information in the publishing certificate to create a use license in cases when the template used by a sensitivity label is inaccessible for some reason.

When a recipient reads protected content, the client extracts the publishing certificate from the protected item and sends it and the user certificates to the rights management service, which decrypts and evaluates the set of rights for the item. The service then extracts the content key from the publishing certificate and uses it to create an encrypted use license holding the set of rights allowed to the user and returns the license to the client. The client decrypts the use license with the user's private RAC key to extract the content key, which it uses to decrypt the content before displaying it to the recipient. The client also handles the enforcement of rights given to the user by policy, including limiting access if the license is valid for a certain period. When a use license for an item expires (usually after 30 days), the user must reauthenticate with Azure AD to get another license.

Mobile clients like Outlook for iOS use a simpler transactional flow. When mobile clients protect content, they send the selected policy to the server and receive a publishing license and symmetric key to protect the item. To consume protected content, the client sends the policy to the service and requests a use license. The service responds with the necessary keys and policy information to allow the client to open and display the content.

## External Users

Protection works on the basis that a recipient can authenticate themselves using an Azure AD account or a Microsoft Service Account (MSA) associated with an email address. Therefore, you can send protected items to people in other tenants and other email domains, providing that the policy used allows those recipients rights over the item. See [this document](#) for more information about how to use protection to secure documents shared with people outside your tenant.

Azure AD federates with some other directories, such as Gmail and Yahoo, to allow users of those services to authenticate by signing into that service. Otherwise, the external user must sign in using an MSA account or a [one-time passcode](#) before they can access the document.

## Contacting the Microsoft Information Protection Team

If you have a technical issue with anything related to Microsoft Purview Information Protection (including the SDK, unified labeling client, or another aspect of the technology) or wish to discuss a requirement your organization might have, you can join the conversation with the [MIP team in Yammer](#).

# Enabling Rights Management for a Tenant

Before you can protect content, the rights management service must be enabled. Microsoft [enables rights management automatically](#) for eligible tenants. In other words, if you have an eligible plan like Office 365 E3 or E5 or buy the Azure Information Protection add-on for other plans, you do not have to enable Rights Management. Users with other Office 365 licenses can consume sensitivity labels applied to content but need to have an upgraded license to apply labels to content. See [this documentation](#) for information about enabling the protection service in a tenant.

## Configuring Rights Management for Exchange Online

Although Microsoft configures Exchange Online so that you can use OME and sensitivity labels without doing anything else, you might wish to change some of the settings for the rights management configuration. This section explains how to make those changes. We'll discuss how to configure other relevant settings for how OME handles messages sent to other email systems and protection for SharePoint Online later.

### Configure Exchange Online

The *Get-IRMConfiguration* cmdlet reports the current rights management configuration for Exchange Online while the *Set-IRMConfiguration* cmdlet is used to update settings. Microsoft configures rights management for all eligible tenants and sets the *AzureRMSLicensingEnabled* property in the IRM configuration to *\$True* to enable Exchange Online to use the Azure Information Protection service. See [this page](#) for more information.

### Test the Configuration

To test the configuration, we run the *Test-IRMConfiguration* cmdlet. The templates listed in the results are the default (customizable) set created for a tenant called *Confidential* and *Confidential View Only* and the special *Encrypt* and *Do Not Forward* options created by OME. Of course, you want to see "PASS" as the overall test result.

```
[PS] C:\> Test-IRMConfiguration -Sender Tony.Redmond@Office365itpros.com

Results : Acquiring RMS Templates ...
          - PASS: RMS Templates acquired.  Templates available: Redmond & Associates -
Confidential View Only, Redmond & Associates - Confidential, Encrypt, Do Not Forward.
          Verifying encryption ...
          - PASS: Encryption verified successfully.
          Verifying decryption ...
          - PASS: Decryption verified successfully.
          Verifying IRM is enabled ...
          - PASS: IRM verified successfully.

OVERALL RESULT: PASS
```

If you do not see similar output to that shown above, it is probably because your tenant configuration uses the earlier IRM stack. Repeat the steps to configure IRM and then retest to confirm that the new configuration is in place.

## Check the IRM configuration

Run the *Get-IRMConfiguration* cmdlet to check the rights management configuration. If any changes are necessary, you can make them with the *Set-IRMConfiguration* cmdlet. For example:

```
[PS] C:\> Set-IRMConfiguration -InternalLicensingEnabled $True  
-ClientAccessServerEnabled $True -EnablePdfEncryption $True
```

In most cases, you do not have to amend the default configuration to use start protecting email. If you want to, you can investigate settings such as:

- **AutomaticServiceUpdateEnabled:** Controls if new Information Protection features are automatically enabled in the tenant. The default is *\$True* and it is best to leave this setting alone unless you have good reason to block the deployment of a new feature into your tenant.
- **AzureRMSLicensingEnabled:** This should always be *True* as it controls the ability of Exchange Online to connect to Azure Rights Management.
- **ClientAccessServerEnabled:** Default is *\$True*. Controls whether OWA and ActiveSync clients (including Outlook for iOS and Android) can use IRM to protect and decrypt messages. When true, Exchange Online can fetch use licenses from the rights management service on behalf of these clients (see below).
- **DecryptAttachmentForEncryptOnly:** Controls if Exchange Online decrypts attachments for messages protected with the *Encrypt Only* feature. The default is *\$False*, meaning that attachments remain encrypted, even when downloaded. If you change this control to *\$True*, Exchange Online decrypts the attachments, and recipients have full control over the files. (Note: the older *DecryptAttachmentFromPortal* setting is deprecated).
- **EDiscoverySuperUserEnabled:** Default is *True*, which allows members of the Discovery Management RBAC management role group to access protected information found through (now deprecated) Exchange Online eDiscovery searches.
- **EnablePdfEncryption:** Set to *\$True* to enable OWA and Outlook Mobile clients to apply sensitivity labels or standard OME templates to protect messages with PDF attachments. These clients include the necessary code to apply protection to PDF attachments, but Outlook desktop clients do not. To extend coverage to messages with PDF attachments sent from Outlook desktop clients, use an Exchange mail flow rule or DLP rules to apply a suitable sensitivity label to messages with PDF attachments. When users download protected PDFs, they can be opened with [an app that supports the ISO standard for PDF encryption](#), including the Edge browser.
- **InternalLicensingEnabled.** Default is *\$True*. Controls whether licenses are automatically granted to internal recipients to allow them to access protected content.
- **JournalReportDecryptionEnabled:** Default is *True*. Controls whether the Exchange Online transport service uses its IRM super-user privilege to decrypt protected messages copied by journal rules to an external journaling system. When this happens, the journal recipient receives a journal report with two attachments. One holds the original message, the other the decrypted copy. Decryption works for both the default (*Encrypt Only* and *Do Not Forward*) options and custom sensitivity labels.
- **SearchEnabled:** Default is *True*. Controls whether OWA can search protected items in a mailbox.
- **SimplifiedClientAccessDoNotForwardDisabled:** Set to *\$False* to make the *Do Not Forward* option available for messages in OWA.
- **SimplifiedClientAccessEnabled:** Controls if the Protect button is available in OWA. Set to *\$False* if you don't want users to apply protection to messages. This control is now obsolete as the Protect button has been replaced by the Sensitivity button.
- **SimplifiedClientAccessEncryptOnlyDisabled:** Controls if the *Encrypt Only* option is available in OWA. Set to *\$False* to disable the option.
- **TransportDecryptionSetting:** Default is *Optional*. Controls the access to protected messages for the transport service as they pass through the transport pipeline. *Optional* means that the transport

service tries to decrypt protected messages so that the content is available for checking by transport and DLP rules or by anti-virus agents. However, transport will continue to process and deliver the message even if decryption is not possible. You can disable any attempt to decrypt messages by setting this value to *Disabled*. Setting it to *Mandatory* means that transport will reject any messages that it cannot decrypt and return a non-delivery report to the sender. The transport service automatically re-encrypts decrypted messages when they reach the end of the transport pipeline.

To make things easier for OWA users, if the *ClientAccessServerEnabled* setting in the IRM configuration is *\$True*, Exchange Online imports keys from the Rights Management Trusted Publishing Domain (TPD) and is thereafter able to decrypt content locally on behalf of clients so that OWA can display protected content inline within message windows. Some Exchange ActiveSync clients use the same approach, which is known as prelicensing.

## Bring Your Own Key (BYOK)

Microsoft 365 allows customers who need the highest possible degree of control over all aspects of security the ability to have full control over their tenant key, the element that serves as the root of trust for protection. The key is “pinned” or imported to a FIPS140-2 hardware security module (HSM), usually kept under tight control at a customer’s premises. In collaboration with Thales E-Security, Microsoft uses a secure process to transfer the key from a customer and import it into the Microsoft data centers into [Azure KeyVault](#) to make the key available to serve as the basis for protection. The process is free but needs a good deal of planning and coordination. Both SharePoint Online and Exchange Online support Azure KeyVault, so once a tenant imports its key to become the tenant key, that key becomes the base for encryption for SharePoint and Exchange content, except when encryption is applied through sensitivity labels as the rights management templates used by these labels are cloud-based. See [this link](#) for more information about BYOK.

# Sensitivity Labels

The original implementation of cloud-based rights management followed the approach taken for on-premises deployments and used rights management templates to protect content. Microsoft Information Protection underpins the rights-management driven encryption side of sensitivity labels. Given the complex nature of anything to do with encryption, the deployment of sensitivity labels can take time to achieve, especially in large, complex companies. The basics of sensitivity labels are:

- Administrators manage sensitivity labels in the Information Protection section of the Microsoft Purview Compliance portal. Administrators must publish sensitivity labels to users through label policies before users can apply labels to content.
- The settings defined in sensitivity labels allow the labels to perform three major functions:
  - Apply visual markings such as headers and footers to Office documents and messages.
  - Protect the content of files with rights-management based encryption (Microsoft Information Protection). Encryption is persistent and remains until someone with the necessary authority removes the label. To gain access to protected content, users must authenticate.
  - Manage containers (Teams, Microsoft 365 Groups, and SharePoint Online team sites).Labels don’t have to perform all functions. The scope set for a label establishes its use. Applications use the defined scope to decide if they should reveal a label to users. For instance, client user interfaces do not reveal labels used solely for container management when displaying the set available to users to protect files.
- Applications use the Microsoft Information Protection SDK to incorporate code to recognize and support the protection (encryption) applied through sensitivity labels. Within Office 365, support is available in Exchange Online, SharePoint Online, and OneDrive for Business. Users apply labels to messages and documents through the Microsoft Office apps. Other applications like Power BI use

sensitivity labels to protect objects and when users export content. Teams uses sensitivity labels to manage team settings but doesn't currently use sensitivity labels to protect conversations and chats. Files protected by sensitivity labels are viewable in Teams. A preview is available where [sensitivity labels can protect Azure Purview objects](#).

- The Office 365 E3 and E5 plans include a license to apply sensitivity labels manually to documents. All Office 365 users can consume (read) files protected by sensitivity labels.
- Document understanding models generated by SharePoint Syntex can apply both retention and sensitivity labels files stored in document libraries.
- Sensitivity labels support manual (explicit assignment) by users or automatic assignment by policy (implicit assignment). A label assigned explicitly by a user cannot be replaced by a label assigned by an auto-label policy.
- The unified labeling client can apply labels to files stored outside Office 365 and to non-Office files such as PDFs. Users need a Microsoft Information Protection license to apply sensitivity labels to files stored outside Office 365.

## Retention and Sensitivity

Some confusion might exist over the functions of retention labels and sensitivity labels; a summary of the differences and similarities is:

- Documents and messages can have a single sensitivity label and a single retention label, but not multiple labels of either type.
- Retention labels are only valid within Microsoft 365. A sensitivity label is persistent and remains with an item until removed by someone with the right to do so.
- Both types of labels are applicable manually (by a user) or automatically by an auto-label policy. It's also possible to use the presence of sensitivity labels as a condition for the auto-application of retention labels.
- Sensitivity labels support container management. Retention labels can be the default for a container like a SharePoint site, but they have no management function.

## Marking Important Content

Applying a sensitivity or protection label (think of a label as an adhesive sticker) to a document or email marks the item as having a certain level of importance to the organization. Usually, the higher the sensitivity of the content, the more stringent the protection invoked by the label. Some labels are purely visual indicators for a certain kind of content, like "Public." Others impose visual markings on documents and email to help users understand that the information is more sensitive; for instance, a label named "Confidential" might insert a footer and watermark in documents when applied. The most interesting type of label uses rights management to protect the most sensitive content. For example, a "Secret" label might use permissions to grant view-only access to anyone in the tenant while blocking access to anyone external.

The people who create and manage information often best understand the sensitivity or confidentiality of the content. The ability to apply labels to items is increasingly pervasive across Microsoft 365, meaning that it is very easy for information generators to apply appropriate labels as they create new content. Once applied, the labels are persistent and remain in place for the lifetime of items. Labels can be removed or replaced with other labels by people with permission to make those changes.

Microsoft Endpoint Manager and Microsoft Defender for Cloud Apps support sensitivity labels. Policies can apply labels to ensure that users don't copy unprotected content to a third-party app like DropBox or removable storage like a USB drive.

## Files, Messages, and Containers

Sensitivity labels support:

- **Files and messages:** The traditional use of sensitivity labels is to apply visual markings and protection to files and email. The definition of files includes Power BI and Microsoft Purview schematized data assets like SQL.
- **Containers:** If configured for the tenant, labels can apply management settings to Teams, Microsoft 365 Groups, and SharePoint Online sites. Applying labels to containers does not protect the items stored in the containers. Microsoft is building out the set of controls settable through labels to make this capability more useful and powerful. Only administrators and container owners can apply labels to containers.

Configuration for container support is a one-time operation involving an update for the *EnableMIPLabels* setting in the Azure Active Directory Policy for Microsoft 365 Groups using PowerShell. When the value of the setting is True, applications that support container management know that they should replace the older text-only classifications with sensitivity labels. Here are the necessary commands:

```
[PS] C:\> Connect-MgGraph
$TenantSettingsId = (Get-MgDirectorySetting | ? {$_.DisplayName -eq "Group.Unified"}).Id
$TemplateId = (Get-MgDirectorySettingTemplate | ? {$_.DisplayName -eq "Group.Unified"}).Id
Update-MgDirectorySetting -TemplateId $TemplateId -DirectorySettingId $TenantSettingsId -Values
(@{'name'='EnableMIPLabels';'value'='true'} | ConvertTo-Json)
```

Before users can apply sensitivity labels to files, messages, or containers, the labels must be published via label policies.

Assigning sensitivity labels to files and messages for visual marking and protection through rights management-based encryption is known as information protection. Applying labels to containers is container management. The settings defined for a label sets its scope, which can be:

- Information protection only (file, email).
- Container management only (site, unifiedgroup).
- Both information protection and container management (file, email, site, unifiedgroup).

When the Microsoft Purview Compliance portal displays a list of labels, it shows the scope for each label as its content type (listed in parenthesis above). As discussed later, it is often easier to manage sensitivity labels when organizations create dedicated and separate sets of labels for the two purposes.

Applications check labels to understand their scope and filter out the labels that they cannot use. For example, the set of labels available in the Office apps includes labels with information protection settings. The set displayed in the Teams client when someone creates a new team is those that have container management settings.

## Native Support in Microsoft 365 Apps

Native support means that an app includes the necessary code (built using the MIP SDK) to fetch policy and label information from the unified store and comply with policy settings, including encryption, as users assign sensitivity labels to items. Microsoft Office is a good example of an application that replaced the need to run a separate client with native support. Among the advantages gained by the integration are better cross-platform support, increased performance, lower memory demand, and avoiding problems that can happen when apps like Word or PowerPoint load add-ins. In addition, native support for sensitivity labels is included in the regular updates issued for the Office apps and you don't have to update a separate component each time an update is available.

The downside is that the apps don't display the information protection toolbar inserted into apps by the old AIP client (because of screen constraints in mobile clients). Instead, interaction with sensitivity labels is through the Sensitivity button to apply, update, or remove sensitivity labels when working with Office files. The user's signed-in account appears at the top of the list of labels revealed by the Sensitivity button. Documents assigned a label display the name of the label in the bottom information bar. A label icon appears when the applied label doesn't include encryption and a padlock icon when it does.

Page 1 of 2    659 words    English (Ireland)    Secret

Native support for sensitivity labels is available in the Office mobile apps, the desktop apps for Windows and Mac, and the Office Online apps. Table 20-1 summarizes the current support for sensitivity labels in different client platforms.

<b>Client</b>	<b>Notes</b>
Microsoft 365 Apps for Windows (Outlook, Word, PowerPoint, Excel)	Office desktop clients for Windows and Mac include native support for sensitivity labels as described in this section. You can access sensitivity labels with older versions of the Microsoft 365 Apps by installing the <a href="#">Unified Labeling client</a> . The presence of this client on a workstation exposes the Sensitivity button in the app menu to allow users to work with sensitivity labels. The MSI versions of Outlook (2016 or 2019) don't include the necessary code for sensitivity labels.
Office online apps	Supported by Word Online, PowerPoint Online, and Excel Online.
Office mobile apps	Available for Word, PowerPoint, Excel, and Outlook mobile on iOS and Android.
Other non-Office files	Use the unified labeling client to apply labels to these files. You can then import the files into SharePoint Online or OneDrive for Business.

Table 20-1: Client support for sensitivity labels

## Unified Labeling Client

If you don't use a version of the Office apps which includes native support for sensitivity labels or want to apply sensitivity labels to files stored outside Office 365, you can deploy the unified labeling client. The unified labeling client:

- Adds the Sensitivity button to the menu bar of the Office desktop applications to allow users to assign sensitivity labels to Office files. The Office applications in Microsoft 365 apps for enterprise include these UI elements. The code to encrypt and decrypt files is in the unified labeling client.
- Integrates with Windows File Explorer to allow users to assign sensitivity labels to files stored outside Microsoft 365 through a Classify and Protect option in the right-click menu.
- Installs a viewer to allow the display of protected content when an application doesn't include the necessary Microsoft Information Protection code to process rights management and encryption.
- Installs a PowerShell module to allow administrators to manage protected files.

The unified labeling client is available only for Windows. The [generally available version of the Unified Labeling version of the client](#) applies sensitivity labels to content stored inside Microsoft 365. The unified client uses the Information Protection SDK, gets its label and policy information from the unified store, and manages labels through the Microsoft Purview Compliance portal. Although designed for use with Microsoft 365 content, you can apply sensitivity labels to files stored in external locations like a Windows drive. See [this page](#) for the release history of the unified labeling client. The unified labeling client entered maintenance mode on January 1, 2022. This means that Microsoft will no longer develop new features for the client as they concentrate on expanding native support for sensitivity labels in applications. However, Microsoft will support the unified labeling client and issue bug fixes for problems reported by customers.

Microsoft developed an older version of the AIP client ([the classic client](#)) to apply labels to files stored outside Microsoft 365 but [deprecated the classic client](#) on March 31, 2021, and no longer supports its use.

A comparison of [the unified labeling client and the labeling incorporated in Office applications](#) (on Windows) is available online. To assist with user adoption of sensitivity labels, [Microsoft has published some information](#) to help educate users about how and when to apply labels to content.

### Third-Party Support for Microsoft Information Protection

An SDK is available to help ISVs develop integrated solutions based on MIP. [Some examples](#) include:

- Symantec DLP integration with MIP: decrypts protected content for DLP scanning.
- McAfee MVISION: applies labels to sensitive content discovered during scans.
- Relativity Trace: examines protected content during communication monitoring.
- VMware Boxer and Workspace ONE: apply labels to protect sensitive content.

### Double Key Encryption

Double key encryption is a form of protection where the customer holds one key and Microsoft holds the other. Both keys are needed to decrypt content and the mechanism is intended to allow customers to protect their most confidential and sensitive information. As Microsoft only has one key, they cannot access the protected information. [Double-key encryption](#) requires Office 365 E5 or Microsoft 365 E5 licenses and supports sensitivity labels.

## Planning Sensitivity Labels

Before creating any sensitivity labels, it is sensible to chart out a plan for protection within the tenant. The plan should include a discussion of points such as:

- **Consider applying a default label:** The policies used to publish sensitivity labels to users can dictate a default label for documents and messages. One school of thought is that people are more likely to understand the use of labels if new documents and messages receive a default label. If you choose to go along this path, consider not using encryption with the default label. The argument against applying default labels is that the application of a sensitivity label should have some purpose, and rights management-based protection is a great way to convey the level of importance, confidentiality, or sensitivity of an item. Users should therefore make considered decisions about the right label to apply to a specific item. The decision as to which course to take is highly dependent on the organizational culture and the goals for the deployment of sensitivity labels. MIP applies default labels to new Office documents and to existing documents when a user modifies those files.
- **Restrict the number of labels.** Although an organization can deploy up to 500 labels, it's debatable if more than a small number of labels meet the needs of all but some corner cases. Using the keep it simple principle, the set of labels available to "the average user" shouldn't include more than ten labels to make it easy for the user to understand what label to apply when. The general set of labels published to all users can be supplemented with extra labels for specific groups if they are needed.
- **Scope labels.** Sensitivity labels can be applied to items such as files and messages. They can also apply settings to containers, such as Teams and SharePoint sites. The settings defined in a label determine its scope. Although you can have "cross-over" or multi-purpose labels, it is usually simpler and therefore better to separate labels into a set used for information protection and a different set used for container management.
- **Names and descriptions associated with company workflow and culture are more understandable.** For example, if "Confidential" has been used in the company to mark highly sensitive documents for years, it's a good choice to use it as a label name. Don't put confidential information (like "Company Merger") in label names – choose a code name instead. Test your label names with real users before committing to the final set of names. Include a description of the kind of information that the label is intended to be used with. For files and emails, the description should tell the user about the level of sensitivity of the information that the label is appropriate to be used with.

For containers, the description should say something about the settings that will be applied, such as privacy, guest access, and the site sharing capability.

- **Choose enduring label names.** Labels can be assigned to items for many years. Choose names that will last rather than those associated with one-time events. Give labels used for container management names different from those used for information protection.
- **Use sublabels sparingly.** Sub-labels are variations of a parent label. If a label defines the sensitivity of an item, a sub-label allows the sensitivity to be varied for a certain scenario. If you have too many sub-labels, it might make it difficult for users to understand which variation applies.
- **Protection and marking are applied by labels.** Some labels are designed to serve as visual indicators of an item's sensitivity without taking any protective action. Other labels will impose actions such as marking and/or encryption. The protection given by a label should match the expected sensitivity set by its name, and the rights assigned in the label must support its use within the organization (or outside, if labeled items are shared with external people). Remember that a label can also apply visual marking to items (watermarks, headers, and footers), so consider if this is needed.
- **Involve more than IT.** It's unlikely that IT understands every business and legal ramification flowing from how information is used within the company, so involve other expertise before settling on a final design.

The goal is to create a practical set of sensitivity labels that make sense to people and meet business requirements without over-complicating matters. It's bad to have labels that people never use, and good when sufficient labels are available to allow users to select granularity in terms of confidentiality. In some cases, it might be possible to have a general-purpose label such as "Company Confidential" that allows full access to any tenant account while blocking external access. Such a label might deliver enough protection for a large percentage of use cases. In other circumstances, specific labels might be necessary to restrict access to certain sets of users or to grant rights to selected groups of users. In other words, the plan should define a set of labels to meet the needs of the business while limiting the number of labels to a manageable set.

The plan can be laid out in a form like that shown in Table 20-2, ordering the set of labels used for information protection in order of sensitivity from least sensitive to most confidential. The Microsoft Purview Compliance portal organizes sensitivity labels in this order. Office applications use the order to know whether a user has replaced a label with one of higher or lower sensitivity.

<b>Label Name</b>	<b>Description</b>	<b>Marking</b>	<b>Protection</b>	<b>Extended Protection</b>
Public	Content approved for sharing outside the company	Footer	None	None
Internal	Content that should remain internal but can be shared	Footer	None	None
Confidential	Content that should remain inside the company	Footer	Yes	None
Secret	Content that should never go outside the company	Footer and watermark	Yes	7-day expiry
Ultra	"Eyes-only" content for restricted circulation	Footer and watermark	Yes, restricted to certain groups	3-day expiry

Table 20-2: Planning Sensitivity Labels for Information Protection

If you like to use colors to highlight different types of labels, you can include the color (hex value) for each label in the plan. Some recommend the use of a traffic light scheme for labels where labels with a green color are for general access, yellow labels mark confidential material, and red is used for labels with the highest level of confidentiality.

In addition to the set of general-purpose sensitivity labels, the plan might include labels for use by certain projects or departments. For instance, you could create a label for the Legal Department to mark documents associated with a patent application or other aspects of intellectual property.

Figure 20-1 shows a set of sensitivity labels displayed in the Microsoft Purview Compliance portal. Remember that the portal lists labels in priority order with the most important labels at the bottom of the list. The labels are in the order described above, with some of the labels created for use by projects and departments coming after the general-purpose set. The names of the labels appear rather than the display names, which is what users see in applications. Usually, the name and display name are the same for a label, but they can differ.

The screenshot shows the Microsoft Purview Information Protection portal. The left sidebar contains navigation options like Home, Compliance Manager, Data classification, and Solutions. The main content area is titled 'Information protection' and shows a list of sensitivity labels. The labels are ordered from lowest to highest sensitivity. A context menu is open over the 'Office 365 Book Source' label, showing options to 'Add sub label', 'Move up', and 'Move down'.

Secret	9	File, Email	Tony Redmond	2 Aug 2021 17:53:50

Figure 20-1: A set of Sensitivity Labels in the Microsoft Purview Compliance portal

You can also see the choices available in the ellipsis menu to reorder labels or to create a sublabel. When you move a label up in the order, its level of sensitivity decreases. For instance, the Public label, which is at the top of the list, is used to mark less sensitive information than the Secret label further down the list. Conversely, if you move a label down, Office applications regard the label as being more sensitive. You can also use the *Set-Label* cmdlet to assign a priority to a sensitivity label. For example:

```
[PS] C:\> Set-Label -Identity "Eyes Only" -Priority 26
```

Label names should leave users in no doubt as to the relative importance or sensitivity of the information in an item. After all, they have no idea of the position a label has within the list managed by Microsoft 365: all they see is the label name, so it's critical to give the labels meaningful and understandable names. Because label names might appear in mobile applications on devices with limited screen estate, it's best if the names are short rather than long.

**Note:** If you use different labels for container management and information protection, the position of the container management labels in the priority order affects the signaling of label mismatches as documents are uploaded. See the later discussion on this topic.

## Sublabels

Sensitivity labels used for information protection can have sublabels. This means that you have a main or group label that isn't used for labeling. Instead, the main label is a container that serves as a logical collection of other related labels, each of which can have different marking and encryption settings. Although main labels appear in applications, you can't assign them to content. Instead, users can select from one of the sublabels, which is then assigned to the content.

## Labels Outside a Policy

Sensitivity labels become available by publishing the labels in a policy to all or some users in a tenant. The users included in the policy form the target set for the policy. Sometimes users will receive items with a sensitivity label that isn't available to them in the policy published to their account. In this case, because policies include all label definitions, including those unavailable to the user, the client can display the label. However, the user won't be able to apply the label to other items.

## Planning for Container Management

If you use sensitivity labels for container management, a separate implementation plan should describe the set of labels for assignment to Teams, Groups, and Sites. Table 20-3 describes an example of what a container label plan might look like. Once again, the plan describes labels from least sensitive to most confidential.

<b>Label Name</b>	<b>Description</b>	<b>Privacy</b>	<b>Guests Allowed</b>	<b>Sharing</b>	<b>Endpoint</b>
General Access	Container holding non-sensitive, general-purpose information.	Public	Yes	Anyone	Unrestricted
Guest Access	Container holding restricted information.	Private	Yes	Existing guests	Web access
Limited Access	Container holding restricted information.	Private	No	Existing guests	Web access
Secret Access	Container holding highly confidential material.	Private	No	No external	Block Access

Table 20-3: Planning Sensitivity Labels for Container Management

Some organizations like to include a sensitivity label to mark groups and teams dedicated to non-business use, such as sports or other non-work activities. Such a label would have the same settings as the "General Access" label described above.

Given the more limited set of setting permutations available for container management, it's normally the case that fewer container management labels exist than the set of information protection labels. Keeping to a small set is good in any case because it makes it easier for container owners to choose and apply the right label.

## Rescoping Labels for Container Management

Given that sensitivity labels started with a single scope (files and email), it is possible that an organization has labels used for both information protection and container management and now wishes to separate labels into two distinct sets. The suggested approach is:

1. Create a set of new labels specifically for container management. Make sure that these labels do not have information protection (files and email) settings. Give names to labels that reflect their use for container management and make sure that the descriptions used are informative and give guidance to container owners about the proper use of each label.
2. Publish the new labels to make them available to container owners. It's best to use a separate label publication policy for the labels used for container management. Optionally, you can choose to force users to assign a label to new containers and choose a label that will be applied by default to new containers.
3. Unpublish the information protection labels that have container management settings. This must happen before you can remove the container management settings.
4. Remove the container management settings from the set of information protection labels. Within a few hours, these labels should no longer be available to assign to new containers. Existing labels and their settings will remain in place in the containers to which they are applied.
5. Republish the information protection labels to make them available to users again. The labels can now only be applied to files and email.
6. Map the set of new container management labels to the set currently applied to containers. Some of the mappings will be 1:1, other labels might be able to replace multiple labels, and some new labels might not be used. For example, this mapping might be used:

<b><i>New container management label</i></b>	<b><i>Current information protection label</i></b>
General access	Public
Guest access	(None)
Limited access	Internal Employee confidential Market sensitive Financial data
Confidential access	Confidential Secret Ultra-confidential

7. Update the containers with new labels as defined by the mapping exercise. This won't take long to do manually if there are only a few containers to update. If not, it's easy to script it with PowerShell (an [example is available from GitHub](#)). The functioning of the containers won't be affected if the new labels have the same settings as the old labels. In some cases, it will be more appropriate to apply a new label to a container. These cases can be handled on an individual basis after the remapping exercise is complete.

As always, testing is recommended before you make a change like this in a production environment.

## Tracking Label Changes for Containers

Organizations use sensitivity labels to apply policies to containers, but group, site, and team owners can change the label assigned to their containers, which might affect the settings applicable to the container. Microsoft doesn't support locked labels for containers (defined here as labels that cannot be changed by group owners), so organizations need to make arrangements to monitor label changes and respond appropriately. This [article discusses an example of how to approach the problem](#).

## Creating a New Sensitivity Label

Management of sensitivity labels is through the Information Protection section of the Microsoft Purview Compliance portal. Creating a new sensitivity label goes through six steps:

1. **Name:** This is the name that users see in applications. You can also add a tooltip that the apps display when users hover over the label name and an administrative description that can be whatever makes sense for your organization.
2. **Encryption:** Decide if the label invokes rights management. If yes, you need to decide what rights (permissions) to assign to different users and groups receive. A label used purely for marking purposes doesn't need to use encryption.
3. **Marking:** Decide if the label should insert text in the header or footer of documents and messages, or as a watermark (documents only).
4. **Site and Group settings:** A label can control settings for Microsoft 365 Groups, SharePoint Online sites, and Teams. The range of settings includes privacy, guest access, external sharing capability, and access from unmanaged devices.
5. **Auto-labeling:** Office apps can automatically apply a default label to emails and documents if their content matches a sensitive information type (like a credit card number) or classifier (like a resume).
6. **Endpoint data loss prevention:** Microsoft Endpoint Manager app protection policies check files to ensure that users do not move the files to unauthorized devices or storage. The definition of a managed device is one known to Azure AD through Microsoft Endpoint Manager. If a device isn't known to Azure AD, it is unmanaged and therefore liable for restriction if dictated by the label.

After going through the steps, you can review and change settings before finally saving the new label. In the following example, we create a new sensitivity label called "Employee Restricted" that protects (encrypts) files and documents and applies markings to items. To finish up, we create a label policy to publish the new label so that it shows up in applications for assignment to items by users.

### Naming

As shown in Figure 20-2, creation of a new label starts with the population of four label properties:

- **Name:** The name must be unique. Internally, Microsoft Purview also creates an immutable GUID for internal use.
- **Display name:** Clients display this value to users. Unlike the label name, you can update the display name later by editing the label in the Microsoft Purview Compliance portal or with the *Set-Label* PowerShell cmdlet.
- **Description for users:** Clients display this text to users in a tooltip to help them understand how to use the label. Apps like Word display the information when a user hovers over a label in the list shown by the Sensitivity button
- **Description for admins:** Users never see this text. It is for administrative purposes and intended to hold notes about the use and history of the label. Although it is mandatory to enter values for the other properties, you do not have to enter anything here.

## New sensitivity label

### Define the scope for this label

Labels can be applied directly to files, emails, containers like SharePoint sites and Teams, schematized data assets, and more. Let us know where you want this label to be used so you can configure the applicable protection settings. [Learn more about label scopes](#)

- Files & emails**  
Configure encryption and content marking settings to protect labeled emails and Office files. Also define auto-labeling conditions to automatically apply this label to sensitive content in Office, files in Azure, and more.
- Groups & sites**  
Configure privacy, access control, and other settings to protect labeled Teams, Microsoft 365 Groups, and SharePoint sites.
- Schematized data assets (preview)**  
Apply labels to files and schematized data assets in Azure Purview. Schematized data assets include SQL, Azure SQL, Azure Synapse, Azure Cosmos, AWS RDS, and more.  
 ⓘ To apply this label to Azure Purview assets, you must first turn on labeling for Azure Purview. You can do this from the Labels page. [Learn more about labeling for Azure Purview](#)

**Back** **Next** **Cancel**

Figure 20-3: Setting the scope for a new sensitivity label

As explained earlier, sensitivity labels have a scope that defines their use. In this instance, the label is available for both files and email and containers (groups and sites). To make things simple, we'll configure this label to

have a scope of Files and Email. Figure 20-3 shows that both Files and Email and Groups and Sites are configured, so we'll uncheck the second box.

If you [enable the preview feature](#), you can amend the scope of the label to support its application to files and Microsoft Purview schematized data assets, including SQL, Azure SQL, Azure Synapse, Azure Cosmos, and AWS RDS.

Because we've chosen to limit the scope of the label to files and email, the next step is to decide on what kind of protection the label can apply to these items. The choices are:

- **Marking:** Apply custom headers, footers, and watermarks. Be aware that if a label applies a custom header or footer to a document, it overwrites any header or footer information already present. This is a replacement operation, not a merge of some label-specified text with whatever's already there.
- **Encryption:** Use rights management encryption to limit access to content.

You don't need to choose either of these options. If you don't, the label becomes a purely visual indicator that users can assign to files and emails. In most cases, you'll choose to apply either marking or encryption or both.

## Encryption and Permissions

The encryption settings allow you to configure the type of protection to apply to items or to remove encryption from items. Labels that remove encryption can only be applied by people who have sufficient usage rights (Export or Full Control) for the label currently applied to an item or be the owner of the message or document. Super-users (see later) can also remove encryption from items.

When a label applies encryption (Figure 20-4), rights management defines the protection given to items. The settings are:

- **Assign Permissions now or let users decide:** The heart of rights management is the permissions given to recipients of an item. Permissions are granted by the author to individual accounts, groups, or collections of people (such as every authenticated user in a tenant). For sensitivity labels, you can decide to create a set of predefined permissions that will be the same for all labeled items, or you can allow users to assign permissions when they apply a label to messages or documents. If you assign predefined permissions, you must add permissions for at least one user or group.
- **User access to content expires:** If never, the user can continue to access labeled content without hindrance. In some cases, like a draft for a plan, you will define an expiry date. In others, you know that content is only valuable for a certain period, so you can set access to expire a specific number of days after a user applies the label to an item.
- **Allow offline access:** When a label allows offline access, the use license obtained by the user and downloaded along with the content is used to access the content. The use license is a certificate that attests to the user's right to access content and the encryption key used to decrypt the content. The normal validity of a use license is 30 days (you can choose any period between 1 and 100 days), during which the user does not need to reauthenticate to prove their access. However, you can block offline access completely (for very sensitive information) or allow access for limited periods when offline. You can then further limit access by requiring the application to check with the rights management service when online after a set period to ensure that access is still valid and hasn't been revoked. When a check is performed, group membership is re-evaluated to ensure that someone who gains access through group membership is still a member.

Figure 20-4: Configuring the encryption settings for a sensitivity label

If you decide the label should have predefined permissions, assign them in the **Assign permissions to specific groups** section of the form. Click the *Assign permissions* link to display the form to enter permissions (Figure 20-5). It is common practice to grant the Viewer permission to **All users and groups in the organization** as a catch-all to ensure that any account belonging to the tenant can read files. This is especially true for sensitivity labels intended for application to information that is freely available within a tenant such as confidential messages sent to large distribution lists or documents intended for internal consumption that are posted to intranet sites. The other permission types are:

- **Any authenticated users:** Grants access to anyone with an authenticated identity. The item will be accessible to anyone in any other Office 365 (Azure AD) domain or with a Microsoft Services account. Depending on the federation configuration for the tenant, the definition of an authenticated user might be even wider, including users who authenticate using a one-time passcode.
- **Users or groups:** Grants access to specific users or groups in the tenant. Use this option to assign specific rights to people who need it to interact with the content. For example, if you want a set of people to have full control over documents, assign the Co-Author permissions to a distribution list or Microsoft 365 group (this can be a dynamic group) containing these people. It's always easier to use a distribution list or group than to specify permissions for individual users.
- **Specific email address or domains:** Grants access to specific people outside your tenant (by email address) or complete domains. Use this option when you need to collaborate with protected content with people outside your tenant. For example, if you wanted to share protected information with

Microsoft, add Microsoft.com as the domain and assign an appropriate permission (like Viewer). You cannot grant permissions to the guest accounts used by applications such as Teams and SharePoint Online. Instead, you must add explicit assignments using the email addresses of the accounts (or grant access to Microsoft 365 Groups containing the accounts). External users must be able to authenticate before they can access the content. In practice this means:

- Using an Azure AD account (probably belonging to another Office 365 tenant).
- Using a Microsoft Services account, like Outlook.com.
- Using an account from a federated directory (Gmail.com or Yahoo.com). These accounts must create a Microsoft Services account using their email address.
- Another email or identity service. These accounts need a Microsoft Service account using their email address.
- On-premises directories. These accounts need to register for [RMS for Individuals](#) using their corporate email address. RMS for Individuals is a free service for users who need to open files encrypted by Microsoft Information Protection.

✕

## Assign permissions

Only the users or groups you choose will be assigned permissions to use the content that has this label applied. You can choose from existing permissions (such as Co-Owner, Co-Author, and Reviewer) or customize them to meet your needs.

Figure 20-5: Assigning predefined permissions for a sensitivity label

## Use Double Key Encryption

For extra security, organizations can run a Double Key Encryption (DKE) service to manage encryption keys. When a sensitivity label uses double key encryption, two keys are necessary to access a protected item's content. Microsoft Information Protection manages one key; the DKE service manages the other key, which remains under the control of the organization. If the DKE service is inaccessible, the content cannot be decrypted. To configure double key encryption for a label, you must provide the URL of the DKE service. Because of the additional cost and complexity, most organizations don't use double-key encryption. [Double-key encryption](#) requires Office 365 E5 or Microsoft 365 E5 licenses. While deploying a DKE service on Azure is the fastest implementation method, it's also possible to [run the DKE service using an on-premises Windows server](#).

## Permissions and Usage Rights

Sets of individual usage rights form the permissions used in sensitivity labels. The usage rights are:

- View content
- View rights.
- Edit content.
- Save.
- Print.
- Copy and extract content.
- Reply.
- Reply all.
- Forward.
- Edit rights.
- Export content.
- Allow macros.
- Full control.

To make usage rights easier to manage and assign, information protection uses predefined permission sets such as Co-Author, Reviewer, and Viewer. Each permission set is composed of a set of usage rights. Assigning predefined permissions to someone is a convenient way of giving them all the usage rights defined in the permissions. However, if none of the predefined permissions meet your needs, you can choose to define custom permissions made up of appropriate usage rights.

When someone receives protected content, information protection checks their signed-in account against the access granted to the users and groups specified in the label. If the account is not present in the list of permissions, they won't be able to open the content. Whenever possible, it is best to grant rights to groups rather than individuals as this makes permissions much easier to manage.

Information protection uses Azure AD accounts to authenticate access to content protected by encryption imposed by sensitivity labels. This isn't an issue if you share documents with people in another Microsoft 365 organization as the recipients authenticate against their home tenant directory. Likewise, it's not an issue if an external recipient has a Microsoft Services account because these accounts also authenticate against a Microsoft directory.

If you need to share protected content with people who don't have an Azure AD account, you can create guest accounts in your directory and the external people can sign in using those accounts, just like external recipients of SharePoint Online sharing links sign in to access shared documents. The [SharePoint Online and OneDrive for Business integration with Azure AD](#) creates guest accounts automatically for sharing. If you use this integration, guest accounts may well exist for the people with whom you share protected content.

If you assign access to an external user in a label, it's a good idea to check if their email address belongs to a Microsoft 365 organization, and if not, create a guest account. Remember to inform the person that they'll need to use the guest account to sign in to access protected content received from your organization. It's also wise to remind the external user that they must use a suitable application to access protected content, such as Microsoft 365 apps for enterprise or the standalone edition of Office 2019. See [this page](#) for more information.

## User-Defined Permissions

If you don't assign preset permissions to a label, you can allow users to control the permissions assigned when they apply the label to an item. You can enable protection for Outlook or the other Office apps, or both (shown in Figure 20-6):

- Outlook: the permissions on the message can be set to either *Do Not Forward* or *Encrypt Only*. Unprotected Office attachments inherit the same protection from the message. Files that have protection (through another label) before being attached to a message keep the protection assigned

by that label, even if the label assigned to the email is more sensitive than one assigned to an attachment.

- Word, PowerPoint, and Excel: the app prompts authors to define the permissions (like Viewer, Reviewer, or Co-Author) they wish other users to receive.

### Encryption

Control who can access files and email messages that have this label applied. Learn more about encryption settings

- Remove encryption if the file or email is encrypted
- Configure encryption settings

Turning on encryption impacts Office files (Word, PowerPoint, Excel) that have this label applied. Because the files will be encrypted for security reasons, performance will be slow when the files are opened or saved, and some SharePoint and OneDrive features will be limited or unavailable. Learn more

Assign permissions now or let users decide?

Let users assign permissions when they apply the label

The labeling behavior for these settings varies depending on which operating system platform is used to apply the label. Learn more

- In Outlook, enforce one of the following restrictions
- Do Not Forward
  - Encrypt-Only
- In Word, PowerPoint, and Excel, prompt users to specify permissions

Figure 20-6: Defining user assigned permissions for a sensitivity label

If you don't set the Outlook checkbox, the label doesn't appear in the set shown in Outlook clients. The same is true for Word, Excel, and PowerPoint if you don't select this setting.

User-assigned permissions is a premium feature limited to the Office apps on Windows and Mac. Online apps don't currently support user-assigned permissions because SharePoint Online doesn't offer the same support for files protected with these labels as it does for files encrypted by labels with fixed permissions. Microsoft is due to deliver [a preview for labels with user-defined permissions in SharePoint Online](#) in July 2022.

### Encryption Applied by OWA and Outlook Mobile

Outlook desktop clients encrypt messages before submitting emails to the Exchange Online transport service for onward processing. Other clients do not include the necessary code to protect messages. These clients stamp outbound messages with the metadata for a label and rely on the transport service to apply appropriate protection. You know if the transport service applies protection to a message if the copy of the message in the Sent Items folder has a label but is unencrypted.

OWA can apply the OME Do Not Forward and Encrypt Only protection to outbound messages before submission to the Exchange transport service, but OWA cannot encrypt messages for sensitivity labels using either preassigned or user-defined permissions. Outlook Mobile always submits messages to Exchange Online for encryption.

### Document Owners

When someone applies a sensitivity label with encryption to a message or document, they are regarded as the owner or issuer of rights for that content. The owner always has the right to access content, even if the policy sets an expiry date. Likewise, the owner can always access content offline or open it after it has been revoked.

### Content Marking

If you decide that a sensitivity label should apply content marking to files and documents, you can configure settings (Figure 20-7) to control the visual indicators inserted by applications after a user applies a label. Word, Excel, and PowerPoint support headers, footers, and watermarks and insert the markings as soon as a

label is assigned to a file, while Outlook only supports headers and footers and inserts the text when a message is saved.

## Content marking

Add custom headers, footers, and watermarks to content that has this label applied. [Learn more about content marking](#)

 All content marking will be applied to documents but only headers and footers will be applied to email messages.

Figure 20-7: Configuring content marking settings for a sensitivity label

Headers and footers can be up to 1024 characters, except for Excel, which limits these markings to 255 characters. Watermarks can be up to 255 characters.

## Performance and Encryption

Microsoft warns that some degradation in performance is possible when accessing protected Word, Excel, and PowerPoint files. This is because users must authenticate with the protection service to establish their right to access the content, after which the app can decrypt the content. These operations are unnecessary for unprotected files. Usually, the slight delay in opening documents is not very noticeable. Large files always take some time to open, so the need to decrypt a large Word document or Excel spreadsheet will add a small amount to the time needed to open these files.

## Client-Side Auto-Labeling with Sensitivity Labels

Client applications like the Office applications and OWA use the MIP SDK to detect sensitive information types or classifiers and apply sensitivity labels automatically when a match is found in a message or document. For example, OWA checks an item's content and applies automatic labeling if matches are found when messages are sent. The check processes the content of the message body (but not header information or the message subject) to decide if a match for the specified sensitive data is present. The other Office applications perform automatic labeling when they save files.

The sensitive information types used for the automatic application of sensitivity labels are those used by other applications such as DLP policies and auto-label policies. Checking for matches uses the same concept of detecting a certain number of occurrences of the data type in content together with meeting a set confidence level that the data type is what it seems before deciding that a match exists (see the DLP chapter for more information).

In Figure 20-8 we see the properties of a sensitivity label with auto-labeling enabled. In this case, the label is applied when a client detects the existence of a single debit card number. Typically, you combine this feature with content marking to apply a header or footer to warn users that sensitive data is present and perhaps

note when the label encrypts content. The *message displayed to the user* property is a policy tip displayed in a banner to communicate with users when their items receive labels automatically.

Several sensitivity labels published in a policy might invoke automatic labeling and match against an item's content. When this happens, the label with the highest priority (as ordered in the sensitivity label policy published to the user) is applied. The automatic application of sensitivity labels is a premium feature.

## Auto-labeling for Office apps

Auto-labeling is supported in Office apps for users who have either Office 365 ProPlus or the Azure Information Protection unified labeling client installed. When we detect sensitive content in email or documents matching the conditions you choose, we can automatically apply this label or show a message to users recommending they apply it themselves. [Learn more about auto-labeling](#)

### Auto-labeling for Office apps

**i** Since encryption is turned on, a large amount of content might be automatically encrypted when this label is applied. Turning on encryption impacts Office files (Word, PowerPoint, Excel) that have this label applied. Because the files will be encrypted for security reasons, performance might be degraded when the files are opened or saved, and some SharePoint and OneDrive features might be limited or unavailable. Figure 20-8: Setting the auto-labeling properties for a sensitivity label

## Configuring Container Management Settings for Sensitivity Labels

Sensitivity labels configured with a scope of "Groups and sites" have additional settings to control the management of containers (teams, groups, and SharePoint Online sites). We suggest that you separate labels used for container management from those used to protect files and email. This approach reduces the number of labels displayed to users and makes it easier for them to select the most appropriate label.

The visual marking aspect of container management via sensitivity labels replaces the previous markings set through text-only classifications defined in the Azure AD policy for Groups (see Chapter 11). Sensitivity labels serve the same purpose as classifications in that users see a visual indicator (like "Secret" or "Confidential") to remind them of the importance or sensitivity of the container. However, sensitivity labels have the extra

benefit of being able to impose access controls on the containers. You can, for instance, assign a label to a team to stop the team owner from being able to invite guests from outside the tenant to join the team membership. To make container management even more useful, Microsoft has said that they plan to increase the range of management settings available through sensitivity labels in the future.

Outlook desktop, OWA, Teams, and SharePoint Online support container management. If you create or edit groups using these apps, you can apply sensitivity labels to the groups. The app will then respect the settings inherited from the applied label and synchronize the label with the other workloads to ensure compliance in those apps.

**Container Labels Don't Affect Content:** It's important to realize that sensitivity labels applied to the container level do not affect the individual messages, conversations, and files stored in these containers. You can certainly assign sensitivity labels to individual files stored in document libraries, but these assignments are independent of anything applied to the container.

Four settings for container controls are available, presented on two screens. You can configure any or all these settings.

**Privacy and external access** (Figure 20-9):

- *Privacy* controls if the group is *Public* (anyone can join) or *Private* (members must be invited to join). The setting can also be set to *None*, which means that the group owner decides which level of access to apply to the group.
- *External user access* controls if the group membership can include guest users. If you block guest users for the group, it assigns an Azure AD policy to the group and sets the value of *AllowedToAddGuests* to *False*. Blocking external access does not remove existing guests from the group membership: it only blocks the addition of new guests.

### Define privacy and external user access settings

Control the level of access that internal and external users will have to labeled teams and Microsoft 365 Groups.

#### Privacy

These options apply to all Microsoft 365 Groups and teams that have this label applied. When applied, these settings will replace any existing privacy settings for the team or group. If the label is removed, users can change it again.

- Public. Anyone in your organization can access the group or team (including content) and add members.
- Private. Only team owners and members can access the group or team, and only owners can add members.
- None. Team and group members can set the privacy settings themselves.

#### External user access

Let Microsoft 365 Group owners add people outside your organization to the group as guests. [Learn about guest access](#)

Figure 20-9: Sensitivity label container management settings for privacy and user access

**External sharing and conditional access settings** (Figure 20-10): These settings control access to content in SharePoint Online team sites. Microsoft requires that any account using sensitivity labels to manage settings for group-connected sites has a premium license.

Two settings are available:

- **Control external sharing from labeled SharePoint sites:** The capability to share documents with external users from a site is controlled by a default setting for the tenant which can be overridden at the site level, which is what happens when a label is applied to a site. The available options are listed below (the relevant value used to set external sharing capability for a site by running the *Set-SPOSite* cmdlet is in parenthesis).
  - **Anyone** (ExternalUserAndGuestSharing): Sharing is allowed with all external users, and documents can be shared using anonymous access links (Anyone links).
  - **New and existing guests** (ExternalUserSharingOnly): Sharing is allowed with new external users, who must accept a sharing invitation and go through an authentication process to create a guest account.
  - **Existing guests** (ExistingExternalUserSharingOnly): Sharing is only allowed with the guest users already in an organization's directory.
  - **Only people in your organization** (Disabled): No sharing with external users is allowed.
- **Use Azure AD Conditional Access to protect labeled SharePoint sites:** Limiting access to unmanaged devices depends on Azure AD conditional access policies. Policy evaluation during the authentication process identifies the managed state of a device (by the organization or managed by the user). If the device is unmanaged, SharePoint Online can apply the restriction set in the label. See [this page for directions](#) on how to create the necessary conditional access policy.

## Define external sharing and conditional access settings

Control who can share SharePoint content with people outside your organization and decide whether users can access labeled sites from unmanaged devices.

### Control external sharing from labeled SharePoint sites

When this label is applied to a SharePoint site, these settings will replace existing external sharing settings configured for the site.

#### Content can be shared with

- Anyone ⓘ  
Users can share files and folders using links that don't require sign-in.
- New and existing guests ⓘ  
Guests must sign in or provide a verification code.
- Existing guests ⓘ  
Only guests in your organization's directory.
- Only people in your organization  
No external sharing allowed.

### Use Azure AD Conditional Access to protect labeled SharePoint sites

You can either control the level of access users have from unmanaged devices or select an existing authentication context to enforce restrictions.

- Determine whether users can access SharePoint sites from unmanaged devices (which are devices that aren't hybrid Azure AD joined or enrolled in Intune).
- ⓘ For this setting to work, you must also configure the SharePoint feature that blocks or limits access to SharePoint files from unmanaged devices. [Learn more](#)
- Allow full access from desktop apps, mobile apps, and the web
- Allow limited, web-only access ⓘ
- Block access ⓘ
- Choose an existing authentication context (preview). Each context has an Azure AD Conditional Access policy applied to enforce restrictions. [Learn more about authentication context](#)

Back

Next

Cancel

Figure 20-10: Configuring external sharing and device access settings for container management

Remember that the external sharing capability assigned to a site cannot be less restrictive than allowed by the tenant-level setting. Microsoft Purview does not check the tenant-level setting when adding sensitivity labels,

so someone can create a label that allows a less restrictive external sharing capability than allowed by the tenant. For instance, if the tenant bars *Anyone* sharing links, a label should not select this level. If a label has an invalid sharing capability, SharePoint Online ignores it when it reads settings from the label.

**Label Synchronization with SharePoint Online:** SharePoint caches the container settings in sensitivity labels to improve performance. This means that changes to label settings that affect the operation of a site, such as an update to the external sharing capability will not become effective for at least 24 hours after the update. Settings imposed by new sensitivity labels apply 15 minutes or so after the publication of a new label to SharePoint.

## Conditional Access and Authentication Context

Highly confidential SharePoint sites often need special attention to ensure that connections are secure. An Azure AD authentication context is a way of marking resources like SharePoint sites as needing special processing by Azure AD conditional access policies. Now [in preview](#), a sensitivity label can be associated with an authentication context in its external sharing settings. When such a link exists, Azure AD invokes conditional access policies which include the authentication context whenever someone attempts to access SharePoint sites stamped with the label. For example, if a conditional access policy with an authentication context requires connections to use multi-factor authentication, attempts to connect to sites with labels linked to the authentication context will fail unless authenticated with MFA. Information about the selected authentication context is in the *ProtectionLevel* value in the *LabelActions* setting of the label.

## Coordinating Label Updates Across Apps

A change made to container settings in one app might have unforeseen consequences for another. For example, an Exchange administrator might apply a label that prohibits guest users to a group with OWA. The SharePoint Online and Teams synchronizes the update for the assigned label, and it becomes active for the site and team. While the newly-assigned label won't stop existing guests from accessing the site or team, it will prevent site and team owners from adding new guests, which could come as a surprise to them. For this reason, it's wise to update group owners before applying a more restrictive label to their group.

## Publishing Sensitivity Labels

Before sensitivity labels show up in applications and users can apply the labels to content or containers, a label policy must publish the labels. A label policy consists of:

- One or more sensitivity labels.
- A target audience. The default audience is everyone in the tenant. You can specify an audience by selecting Microsoft 365 Groups, security groups, distribution lists, or individual users (the sole requirement is that the objects must be mail-enabled, which excludes some security groups). Note that sensitivity label policies publish labels to people while retention label policies publish labels to storage locations like sites and mailboxes.
- Settings to define whether one of the labels in the policy is mandatory and applied to emails and Office documents and if users must give a justification if they remove a label or replace a label with a lower classification. A setting is also available to define a custom help page for users to consult to learn about the proper use of sensitivity labels within the organization. Label use settings don't apply to labels created solely for container management.

Clients that support sensitivity labels learn about new labels or changes to existing labels from the underlying workload. The time required for a client to acquire details about sensitivity labels vary, but you should anticipate that several hours are necessary. It all depends on when the client refreshes its cache of label information.

A tenant can have multiple sensitivity label publishing policies, each of which has different sensitivity labels and target audiences. For instance, you might create a general-purpose policy to publish a default set of sensitivity labels to everyone in the tenant and then have a set of specific policies to publish certain labels to specific groups. Another policy might publish a set of container management labels to users allowed to create groups, teams, and sites. Multiple sensitivity label publishing policies might cover the same user. If this is the case, clients combine the labels from all applicable policies to create a single set of labels to display to the user. In addition, if more than one policy requires mandatory labeling, Office applies the sensitivity label specified in the highest priority policy.

## Select Labels and Target Audiences

To create a policy for a single label, select the label from the list and then click **Publish label**. The policy publication wizard starts with the selected label already added. You can add other labels to the policy with the **Edit** link. Otherwise, you can create a new labels publication policy and add the set of labels you want to publish (Figure 20-11).

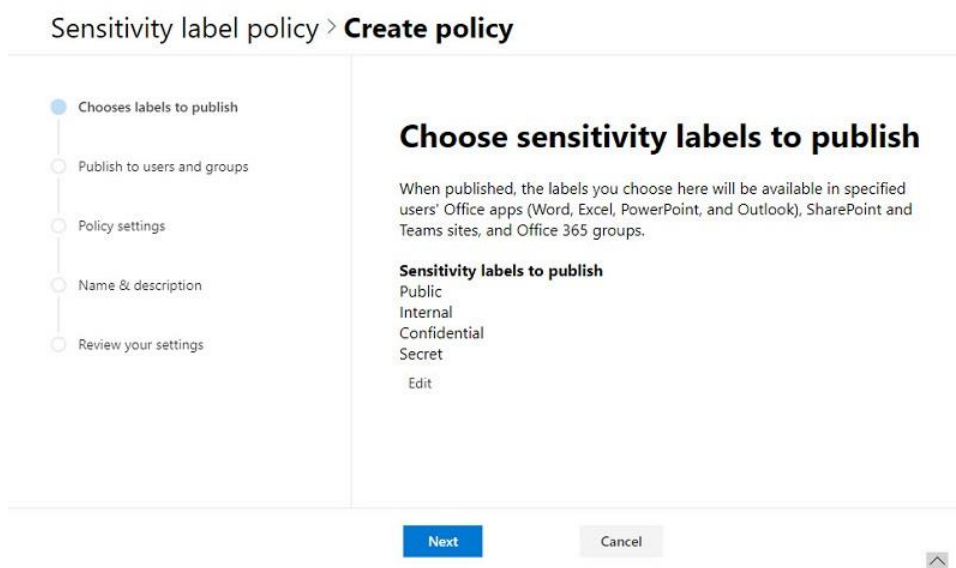

Figure 20-11: Beginning the publication process for a set of labels

The next step is to select the target audience who will be able to use the labels published in the policy. In Figure 20-12, all users and groups receive the policy, which is the norm for labels in general use across the tenant. If you want to limit publication to specific users or groups, click **Choose users or groups**. You can select individual users, Microsoft 365 Groups, or distribution lists. Members of the groups keep access to the labels defined in the policy for as long as they are members. New members added to groups benefit from permissions granted in labels when they join.

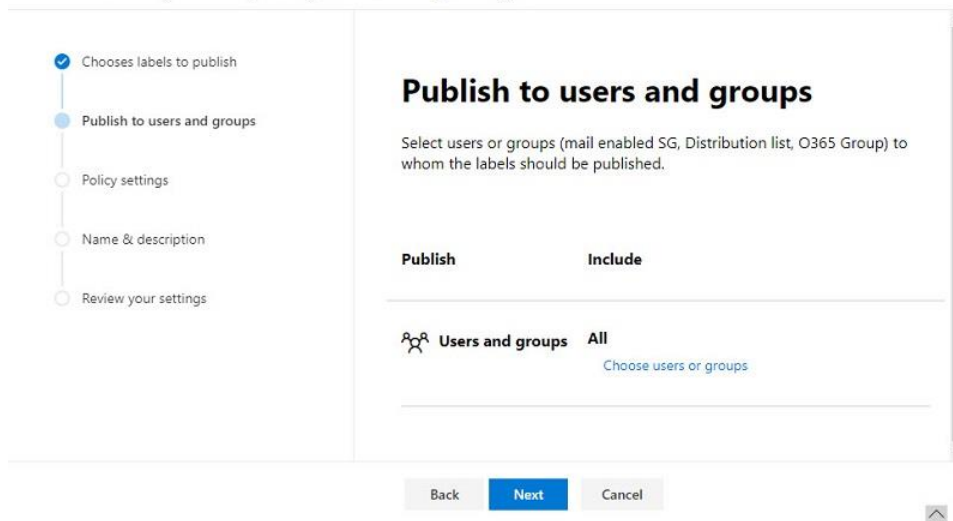

Sensitivity label policy > **Create policy**

Figure 20-12: Specifying the target audience for the sensitivity policy label

When you define a target audience for a policy, make sure that the users in that audience have the necessary rights to access any encrypted content protected by the labels included in the policy. For policies used to publish container management labels, the target users should be the accounts allowed to create new groups. In some tenants, everyone can create new groups; other organizations restrict group creation by policy to the members of a specific group. See the section about the Groups creation policy in Chapter 11 for more information.

### Excluding Mailboxes in a Sensitivity Label Policy

You might notice that the GUI to create sensitivity label policies allows administrators to select All or specific groups as the target (Figure 20-12). All means every user mailbox in the tenant. However, the Microsoft Purview Compliance portal doesn't support the exclusion of specific users when a policy uses the special *All* destination. Fortunately, this is possible with PowerShell. For example, this command excludes the mailboxes of Terry Hegarty and Kim Akers from receiving the labels published in the specified policy:

```
[PS] C:\> Set-LabelPolicy -Identity "General Sensitivity Policy" -AddExchangeLocationException "Terry.Hegarty@Office365itpros.com", "Kim.Akers@office365itpros.com"
```

```
Get-LabelPolicy -Identity "General Sensitivity Policy" | Select ExchangeLocationException
ExchangeLocationException
-----
{Kim Akers, Terry Hegarty}
```

Adding a mailbox to a label publishing policy in this manner does not overwrite the set of excluded mailboxes. To remove an excluded mailbox, run *Set-LabelPolicy* and pass the mailbox name in the *RemoveExchangeLocationException* parameter.

```
[PS] C:\> Set-LabelPolicy -Identity "General Sensitivity Policy" -RemoveExchangeLocationException Kim.Akers
```

Running the cmdlet to add more than a few mailboxes can become tiresome. In these circumstances, it's better to find the set of mailboxes using *Get-ExoMailbox* or another method and pipe the set of mailboxes to *Set-LabelPolicy*. For example, this code extracts the mailbox members of a distribution list into an array and uses the array to add policy exclusions:

```
[PS] C:\> [array]$Members = Get-DistributionGroupMember -Identity "Planner Gurus" | ?
{$_ .RecipientTypeDetails -eq "UserMailbox"} | Select -ExpandProperty PrimarySmtpAddress
```

## Publication Policy Settings

Settings in label publication policies allow the selection of a default label for assignment to new messages and documents. In Figure 20-13, we require users to apply a label to their emails and documents. Default labels only work with clients that support information protection during content creation, such as the Office apps. By comparison, if someone sends an email when connected to Exchange Online via IMAP4 with the Thunderbird client, nothing will happen.

Depending on what types of sensitivity labels a label publishing policy includes, settings are available to control if users must apply labels to:

- Documents.
- Emails (can be the same as for Documents).
- Containers (groups, teams, and sites – if the policy includes these labels).
- Power BI content.

For each content type, you can define a default label to apply. To make it easier to manage, it's often best to have separate label publishing policies for different content types.

You can control if users must provide a free-text justification if they change the assigned label to another label with a lower classification. The justification is logged in the Information Protection logs rather than the Office 365 audit log.

The policy settings for default label assignment are not retrospective, so unlabeled files and emails remain in this state until users or auto-label policies assign them labels. It's easier to deal with unlabeled groups because it's possible to search for unlabeled groups with PowerShell and then assign a suitable label to those groups.

The policy can define a different label for Outlook to apply to new emails or for Power BI to apply to its content. To aid in driving user awareness about information protection, the *Provide users with a link to a custom help page* setting allows organizations to define a web page for users to view if they want added information about how to use sensitivity labels to mark content.

**Policy settings**

Configure settings for the labels included in this policy.

- Users must provide a justification to remove a label or lower its classification**  
Users will need to provide a justification before removing a label or replacing it with a one that has a lower-order number. You can use activity explorer to review label changes and justification text.
- Require users to apply a label to their emails and documents**  
Users will be required to apply labels before they can save documents, send emails, and create groups or sites (only if these items don't already have a label applied).  
Support and behavior for this setting varies across apps and platforms. [Learn more](#)
- Require users to apply a label to their Power BI content**  
Users will be required to apply labels to unlabeled content they create or edit in Power BI. [Learn more about mandatory labeling in Power BI](#)
- Provide users with a link to a custom help page**  
If you created a website dedicated to helping users understand how to use labels in your org, enter the URL here. [Learn more about this help page](#)

Figure 20-13: Defining settings for the sensitivity label policy

If you configure a default label for messages, Outlook creates new messages with the selected label in place. If the user then chooses to send using a different mailbox (group, user, or shared mailbox), Outlook prompts them to justify the removal of the label. This happens because the default label is associated with the original

account, and when the user selects a different address to send from, Outlook removes the default label. It's logical because the account used to send messages might not have permission to use the original label.

The ultimate steps in the publication process are to create a name and description for the policy (you only need to enter a name), review the policy, and then publish it. You can't change the name of a label policy, but you can update its description at any time.

**Audit Who Changes Sensitivity Label Policies:** You might want to know who makes changes to sensitivity label policies. The easiest way to find out is to search the Office 365 audit log for the *Set-LabelPolicy* event. The *AuditData* property in the audit event contains details of the changes made while the user who updated the policy is in the *UserIds* property.

## Some Delay Before Policy Changes Become Effective

Don't expect people to be able to use new or updated sensitivity labels immediately after making changes. The publishing process takes time to enact policy changes by performing tasks like creating or updating labels. Also, multiple services must be updated with the new policy settings. Applications pick up policy updates when they refresh their cache of tenant policies, usually within a couple of hours of an update. At this point, the applications combine the labels published through all the policies that cover the user and present the labels in a single list. Users cannot see details of the policies through which they access labels.

## Multiple Sensitivity Label Policies

You can assign multiple sensitivity label policies to an account. If you do, the account has access to the combined set of sensitivity labels from all assigned policies, and the policy settings which apply are determined by the order the policies are listed in the Microsoft Purview Compliance portal with the [lowest priority policy shown at the top](#) and the highest at the bottom.

## Apply Sensitivity Labels Automatically

For licensing purposes, Microsoft differentiates between manual and automatic application of sensitivity labels to documents and email. The basic rules are:

- Office 365 E3 covers manual application. For instance, a user opens a Word document and selects a sensitivity label.
- Users must have Office 365 E5 or Microsoft 365 E5 compliance licenses to cover the automatic application of sensitivity labels to content. For example, default label assignment to email and documents is automatic labeling, Automatic processing also includes auto-label policies where clients or servers apply labels based on the content of messages or documents.

People might not consider default label assignment as automatic, but it is. A more advanced example is when you create an auto-label policy to assign sensitivity labels based on the content of a document or message. Auto-label policies make it easier for users to do the right thing to protect information but only for new content.

To address the problem, tenants can use server-side processing to auto-label email and documents, sometimes referred to as labeling content at rest (SharePoint Online and OneDrive for Business) or in transit (Exchange Online). Server-side processing happens at scale and isn't dependent on clients, so it's appropriate when tenants have large quantities of information to protect. Organizations can define server-side automatic label policies in the Information protection section of the Microsoft Purview Compliance portal.

## Points to Consider About Server-Side Sensitivity Label Processing

The following conditions apply to server-side sensitivity label processing:

- A tenant can deploy up to 100 auto-label policies to apply sensitivity labels. Each policy can cover all SharePoint Online sites and OneDrive for Business accounts in the tenant (until mid-August 2021, a policy could cover a maximum of ten locations).
- The auto-label process can handle a maximum of 25,000 items per day per tenant.
- Server-side auto-labeling only works for Office documents in Open XML format (older formats like .doc Word documents don't support sensitivity labels). When an auto-label policy applies a sensitivity label to documents, it does not update their modification dates.
- Server-side auto-labeling can replace labels assigned by client-side auto-labeling, but only if the label applied by the client has a lower priority.
- Auto-label policies for SharePoint Online and Exchange Online use different rules to locate items for processing. You can define rules with the same effect for both locations. The rules for Exchange Online processing have additional conditions to match against message properties.
- Policies for Exchange Online can apply to all mailboxes or selected mailboxes.
- When an auto-label policy scans Exchange Online messages, it processes both attachments and message bodies. However, if the policy finds a match, it applies the sensitivity label only to the message. In terms of rights management, the sender of the message is the issuer/owner.
- When a label applies encryption, it encrypts both the message and some attachments. The encrypted attachments are Office documents and PDF files (if *EnablePdfEncryption* is True in the tenant's IRM configuration).
- If an auto-label policy matches messages protected using *Encrypt Only* or *Do Not Forward*, the sensitivity label defined in the policy replaces the protection.
- Encryption applied by sensitivity labels overrides any encryption applied by Exchange mail flow rules or data loss prevention policies. If the sensitivity label doesn't include encryption, then encryption by mail flow rules or data loss prevention policies apply.
- Incoming email passes through the Exchange transport service. It is at this point that auto-label policies evaluate messages and apply labels to matching messages. However, as the sender of these messages doesn't come from your organization, external messages encrypted by an auto-label policy don't have a valid owner. This won't matter in the normal course as recipients will have the necessary rights to read the messages.

Due to the possibility that an administrator mistake in policy configuration might auto-apply incorrect sensitivity labels to large numbers of files, the process of setting up an auto-label policy involves a simulation period where Microsoft 365 reports results of auto-application without assigning labels. This phase allows those responsible for creating auto-label policies to evaluate the effectiveness of the policy settings and adjust where necessary before releasing the policy to assign labels.

SharePoint Online uses a background process to evaluate auto-label policies. The process scans files to find instances of sensitive information types that match the rules set in policies. The scan for Exchange happens when messages pass through the transport pipeline. When a policy detects a match, the process applies the sensitivity label unless a user-applied label exists (explicit assignment always beats auto-assignment). Like labels applied by users, labels applied to documents by auto-label policies remain in place for the lifetime of documents, even if they move out of the target sites processed by policies.

Auto-labels have a simulation or test mode, meaning that you can discover what items match the rules set in a policy. The idea is to allow administrators to tune policy rules by seeing the effect changes to rule conditions have in terms of their ability to detect matching items in the target locations.

## Using Machine Learning to Apply or Recommend Sensitivity Labels

A variant of automatic label assignment uses machine learning to identify patterns in Office documents to decide to apply a sensitivity label automatically. Trainable Classifiers created by Microsoft or custom classifiers created within the tenant describe patterns to identify document types such as a resume (describing a

document with job details) or code (computer code), and some to help identify problematic documents like those containing offensive, threatening, or profane content. Label policy settings then control the automatic application of sensitivity labels. See the section about trainable classifiers in the compliance chapter.

## Removing Sensitivity Labels

It's not a good idea to delete a sensitivity label after users have applied the label to items. When an administrator removes a sensitivity label from the label publishing policies it is in, the label becomes unavailable to clients and invisible to users. Because the label metadata remains in place, any encryption applied by the label is intact. Some apps, like Office, can continue displaying the name of the label. However, users cannot apply unpublished labels to new content.

You can't delete a sensitivity label until after removing it from label publishing policies. If you attempt to delete a label without unpublishing it, Purview flags an error and shows which label policies include the label. To proceed and remove the label from the tenant, you must remove it first from the publishing policies.

After the deletion of a label, the underlying protection template enters an archived state. This ensures that protection remains for labeled content. Users won't be aware that files have labels because applications cannot resolve the label name against an active template. It's not possible to recreate deleted labels through the Microsoft Purview Compliance portal. Instead, you can recreate the label with PowerShell by running the *New-Label* cmdlet and (critically) passing the identifier (GUID) of the removed label in the Identity parameter. This will reconnect the new label to the protection template. After a period to refresh client caches, the reconstituted label should reappear in applications.

Because of the issues involved in deleting sensitivity labels, it is always better to remove unwanted sensitivity labels from all label policies to unpublish them from clients instead of deleting the labels.

The removal of sensitivity labels used for container management is slightly easier. First, create a list of the containers with the sensitivity label you wish to remove. Use the *Get-Label* cmdlet to find the label GUID:

```
[PS] C:\> $LabelGuid = (Get-Label -Identity "Confidential Access").ImmutableId
```

Now find the containers that have this sensitivity label. This example uses the *Get-UnifiedGroup* cmdlet to find the Microsoft 365 groups with the label.

```
[PS] C:\> [array]$Containers = Get-UnifiedGroup -ResultSize Unlimited | ? {$_.SensitivityLabel -eq $LabelGuid.Guid}
Write-Host ("{0} groups found with the sensitivity label {1}" -f $Containers.count, $LabelGuid.Guid)
```

If the check finds some groups with the sensitivity label, you should replace it with the GUID of another label to maintain the settings applied to the containers. A loop like this does the job.

```
[PS] C:\> $NewLabelGuid = "d6cfd185-f31c-4508-ae40-229ff18a9919"
ForEach ($Container in $Containers) {
    Write-Host ("Updating group {0} with new label {1}" -f $Container.DisplayName, $NewLabelGuid)
    Set-UnifiedGroup -Identity $Container.ExternalDirectoryObjectId -SensitivityLabel $NewLabelGuid }
```

Exchange Online will then synchronize the update with SharePoint Online and Teams to make sure that these workloads know that the containers have a different sensitivity label. This process may take a few days to complete. When it is complete, and you see that the containers show the new label in SharePoint Online and Teams, you can remove the sensitivity label that you replaced.

## Remove Locations Rather Than Remove Policies

Along the same line, it's better to make a sensitivity label policy unavailable instead of deleting it as this allows for reinstatement of the policy if needed later. To do this, create a new blank group (or one with just an owner) and edit the policy so that the publication target is just that group. The policy will be withdrawn from

the users and groups it was previously published to and published to the empty group, which has the effect of nullifying the policy and putting it into a state where it cannot be used by anyone. If required, the policy is easily reinstated by editing it to publish the policy to a new set of target users and groups.

## Using Sensitivity Labels with Auto-Signature Products

Many ISV products insert autosignature text into outbound messages. The autosignatures usually include personal details about the sender plus some organizational information and a company logo. If you apply a sensitivity label that protects content with encryption to an email, autosignature products might not be able to process messages because Outlook or OWA encrypts the content when sending the messages. Some products have client-side plug-ins that work by inserting text during message creation. These usually work because the client inserts the autosignature before encryption. [An Outlook API](#) makes it easier for ISVs to apply signatures to protected messages across all Outlook clients.

If you want to send encrypted emails with autosignatures, you should test the available products to find one that supports sensitivity labels. Alternatively, you can use a transport rule to insert an autosignature as messages pass through the transport pipeline. A transport rule can insert autosignature text even when messages are encrypted because Exchange Online uses super-user privilege to decrypt the content, apply the autosignature, and then encrypt the message again.

## Sensitivity Labels and Power BI

If enabled through the [tenant settings section of the Power BI admin portal](#), Power BI users with Pro (not free) licenses can apply sensitivity labels to reports, dashboards, datasets, embedded reports, and dataflows. Sensitivity labels are inherited by Excel spreadsheets generated through Power BI's PivotTable connection and when the Analyze in Excel feature is used. Label inheritance also occurs when new reports or dashboards are created from a dataset. By default, any licensed user can apply sensitivity labels to Power BI objects, but you can restrict access by allowing or excluding specific security groups.

Inside Power BI, sensitivity labels are used as visual markers of the relative sensitivity of the information in items. Labeled objects are not encrypted by labels. However, when objects are exported from Power BI to Excel, PowerPoint, or PDF, encryption is applied to the output file if imposed by the label. Users who export protected information from Power BI can edit the content, but they cannot change the label applied to the file. This is because the owner logged for the file is a service rather than a person, as we can see by running the *Get-AipFileStatus* cmdlet from the AIP module:

```
[PS] C:\> Get-AIPFileStatus "basic data.pptx"
File           : Basic data.pptx
IsLabeled      : True
LabelId        : 81955691-b8e8-4a81-b7b4-ab32b130bff5
Label          : Secret
Method         : Privileged
Date           : 6/16/2020 11:17 AM
RMSGuid        : c7fc2174-097c-4123-9cad-15f1a32cb145
RMSTemplate    : Secret
Owner          : 00000009-0000-0000-c000-000000000000@04dac1c9-6661-42f4-b974-c68551262cff.rms.eu.a
                adrm.com
```

Sensitivity labels appear in the workspace list as a visual reminder to users of sensitive data. Labels are unsupported for template apps, and you can't apply the Do Not Forward label, labels with user-defined permissions, or labels based on HYOK.

# Protecting SharePoint Online and OneDrive for Business

Microsoft 365 includes two methods to protect content stored in SharePoint and OneDrive for Business sites.

- Rights management can protect items downloaded from a library or list. This is the older form of protection also available in SharePoint on-premises designed to limit the set of actions users can take after they download files. It does not protect individual items held in the library or list.
- Sensitivity labels can protect individual documents, folders, and lists in a library. The label and associated protection stay with their assigned items even if the documents move from their original location. This is the preferred mechanism to protect documents stored in SharePoint Online and OneDrive for Business sites. Protection by sensitivity labels is also available for [some components used by SharePoint Syntex](#).

Apart from being an old-fashioned method to protect SharePoint content, the first approach is less preferable because protection depends on files being in a certain library and protection occurs when users download documents from the library. Assigning protection through labels applied to individual files is better because the protection persists no matter where the file travels, including outside the organization.

Optionally, file policies created by Microsoft Defender for Cloud Apps can inspect SharePoint Online documents and if sensitive data is in a document, apply a sensitivity label. [This functionality](#) is outside the scope of this book, but it's worth investigating if your organization uses Microsoft Defender for Cloud Apps.

## Comparing Sensitivity Labels and Traditional SharePoint Protection

Sensitivity labels are the preferred way to protect content stored in SharePoint Online and OneDrive for Business. They are more flexible and powerful than the traditional approach of protecting SharePoint libraries with IRM. The advantages of sensitivity labels include:

- Support for labels in a wide range of clients including desktop, browser, and mobile apps.
- Labels can apply visual markings to content in addition to protection.
- Because rights management underpins labels, granular control is available to control who can do what with a file.
- Labels become part of the metadata of files and messages and protection travels with content as it moves between libraries or outside a tenant.
- Documents can automatically (by label policy, DLP policies, or transport rule) or manually (by users).
- Labels can be used to assign sensitivity markings and some group settings to Microsoft 365 Groups, Teams, and SharePoint containers.
- Documents protected by sensitivity labels support advanced features like co-authoring and auto-save.
- SharePoint Online populates a sensitivity column to show the label applied to files (the column is not available in OneDrive for Business). If you hover over the label, you can see if it was applied manually (by the user) or automatically (by policy).
- Microsoft Search can index documents protected by sensitivity labels. This means that protected content can be found by content searches, available for eDiscovery, and accessible to any feature which depends on the content indexes, like DLP policies.

The benefit of traditional SharePoint “protection on download” is that encryption is applied automatically when files are downloaded from a library. Only people with access to the library can access the files. Users don't have to worry about applying a sensitivity label to protect confidential information.

The long-term strategy for any tenant should be to phase out the traditional SharePoint IRM-based protection and replace it with sensitivity labels as soon as business requirements and user training allow.

## Enabling Sensitivity Labels for SharePoint Online and OneDrive for Business

When users or policies assign sensitivity labels with encryption to Office files stored in SharePoint Online or OneDrive for Business, some functionality cannot process the encrypted content in the same way as it can handle unprotected content. Until you enable support for sensitivity labels in SharePoint Online as described below, several issues exist. For more information, see [this support article](#). If you've invested in applications that update SharePoint Online with elements like custom type schemas, it's important to understand the effect that some [current limitations](#) might have on your deployment.

Exchange transport rules do not have the same issue because Exchange uses super-user permission to examine protected email (and attachments) as messages pass through the transport pipeline.

**Searching for Labeled Documents:** The SharePoint Online search schema includes a managed property called *InformationProtectionLabelId*, which holds the GUID (identifier) for the sensitivity label assigned to a document. You can use this property to search for documents with a specific sensitivity label in SharePoint search or content searches by using the form *InformationProtectionLabelId:GUID*. For example, *InformationProtectionLabelId:2fe7f66d-096a-469e-835f-595532b63560*. The search results are trimmed and only display documents whoever performs the search can access. In the future, you might be able to search using the display name of a label instead of its GUID.

### Supporting Sensitivity Labels in SharePoint Online and OneDrive for Business

To enable support for sensitivity labels in SharePoint Online and OneDrive for Business, follow the directions on [this page](#). You can then enable the opt-in from the Microsoft Purview Compliance portal or by running the following PowerShell cmdlet from the SharePoint Online module:

```
[PS] C:\> Set-SPOTenant -EnableAIPIntegration $True
```

To revert, run the command again and set the switch to *\$False*. This action does not remove any sensitivity labels assigned to documents. If your tenant uses multi-geo capabilities, you must run the command in each data center region (geo-location) used by the tenant.

The following capabilities are enabled by support for sensitivity labels in SharePoint Online:

- Only users (including guest accounts) with access granted by the assigned sensitivity label can open a protected document (the View content right is the minimum needed).
- Apps can use the Microsoft Information Protection SDK to incorporate the necessary functionality to apply and respect sensitivity labels. Office Online and Microsoft 365 apps for enterprise (Windows and Mac) support co-authoring for Excel, Word, and PowerPoint files if everyone involved has the appropriate access to protected files (the feature is in preview for Office mobile). If using the desktop apps, people must [use a version that supports co-authoring of protected files](#). Guest users can't apply sensitivity labels to documents.
- Users can upload protected documents if they have at least viewer permission for the documents. If the uploader doesn't possess sufficient rights, SharePoint will upload the file, but it cannot process the contents.
- SharePoint Online ensures downloaded files retain sensitivity labels. However, if users export protected Office files to a non-Office format (such as PDF), encryption does not protect the exported files.

- A sensitivity column is available in SharePoint Online document views to display labels assigned to documents. In addition, if you hover over a label in the sensitivity label column, SharePoint Online tells you if a user (manual) or policy (automatic) applied the label.
- SharePoint Online and OneDrive for Business decrypt files protected with sensitivity labels to store and index their content. Decryption happens when users upload protected documents to a site for the first time or after editing. Being able to index protected content means that content searches and DLP policies can check both the metadata and content of protected files (SharePoint does not encrypt metadata such as document title and name for protected documents). In addition, Microsoft Search “trims” searches for protected content to ensure that only users who have access to that content see it in the results.

Some limitations currently exist. SharePoint Online cannot process protected documents with labels using:

- **User-defined permissions:** The permissions for these labels are set when a user assigns the label to a Word, Excel, or PowerPoint file using [a supported client](#).
- **Expiring access:** The label settings contain an expiration period after which access to the content is unavailable.
- **Double-key encryption or HYOK:** SharePoint Online doesn't have access to the key managed by the tenant.

The lack of support means that although you can store files protected with these labels in SharePoint Online or OneDrive for Business, SharePoint can't deal with the encryption and doesn't index the content (which affects eDiscovery). Features like preview and auto-save don't work, and labels with these attributes don't show up in Office Online apps. Put another way, the only supported labels are those which apply permissions set by the administrator, do not expire access, and use a single cloud-based encryption key. Some additional limitations exist which Microsoft is working through to resolve. Details of [currently-known limitations of sensitivity label support in SharePoint Online](#) are updated regularly.

When documents assigned supported sensitivity labels with encryption are uploaded into SharePoint Online or OneDrive for Windows, SharePoint Online decrypts their content before storing the document in Azure SQL. This step allows features like indexing and eDiscovery to work. The [metadata describing the sensitivity label](#) remains in place in the file and the data is protected in the store through the encryption at rest applied by Azure SQL. Any time afterward the file is requested, SharePoint checks if it needs to apply encryption and uses the metadata to ensure that the file is correctly protected. For example, encryption is reapplied when someone downloads a document with a label requiring encryption.

## Default Sensitivity Label for Document Libraries

Site owners can define a default sensitivity label for a document library by selecting an appropriate label in the library settings. Any new Office document added to the library will receive the assigned sensitivity label unless it already has a sensitivity label applied by a user or by an auto-label policy. In the case of policy assignment, the default label will replace the assigned label if the assigned label has a lower priority (determined by the priority number for labels set in the Microsoft Purview Compliance portal). Stamping occurs using an asynchronous thread, so the sensitivity label does not appear (or a replacement occur) on the document for one or two minutes after its upload. Existing unlabeled documents in the library remain unlabeled until the next time someone edits the file; at which time the document receives the default label.

The default application of sensitivity labels to new documents is a premium feature that requires Office 365 E5 or another suitable license for all members of the site hosting the document library.

## Sensitivity Label Mismatches

A label mismatch occurs when someone creates or uploads a document to a site that is assigned a higher-level sensitivity label than the site as dictated by the order of sensitivity labels defined in the organization. The order in which labels appear in the list is intended to reflect their relative sensitivity or importance with the

first label (order number 0) being the least sensitive and the last being the most sensitive. As an example of a mismatch, let's assume that a site is assigned the *Confidential* label, at position 4 in the set, and a user uploads a document assigned the *Super Confidential* label, at position 5 in the set. The mismatch occurs because the document label has a higher priority than the site label. Note that the comparison is performed based on the position of parent labels (not sub-labels) within the set of labels in the organization.

When it detects a label mismatch, SharePoint Online sends an *Incompatible sensitivity label detected* email notification to the user who uploaded the document (Figure 20-14) to inform them that the label assigned to the document might be inappropriate for the site. No automatic action happens to rectify the issue and it's left to the user who uploaded the document (who should be in the best position to understand its true sensitivity) to decide what to do to resolve the mismatch.

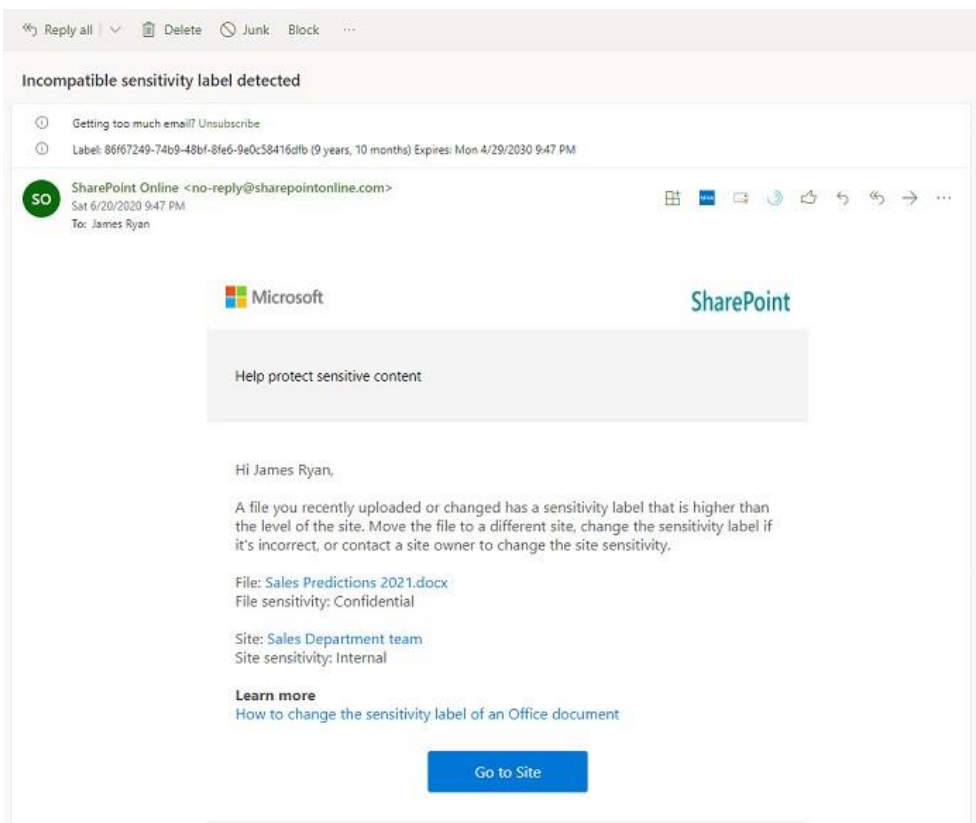

Figure 20-14: Email warning about a sensitivity mismatch for an uploaded document

The message helps to educate users about the different levels of sensitivity labels, but it doesn't explain why this is important. In the example shown, a document labeled as *Confidential* is uploaded to a site labeled as *Internal*. Anyone who is a member of the site can see the document metadata even if they can't open the document. People can learn a lot about a document from its metadata and it's possible that some confidential information might leak because someone can see a document's title. For example, external people might be guest members of the site. The rights assigned in a highly sensitive label might not give some or all guests the ability to open the document to view its content, but the title might tell them what the document is about.

Another reason why mismatches matter is that a site marked with low sensitivity might allow access to people using unmanaged devices. When documents of a higher sensitivity are stored by the site, the risk is created that those documents might be accessed on unmanaged devices, which is not what you might want to happen.

### Label Order Matters for Mismatch Detection

As we know, each sensitivity label has a priority order in the set of labels and the priority order is used to detect mismatches between site labels and document labels. If you separate the labels used for information

protection from those used for container management, you might give the container management labels a higher priority than those used for information protection. In this scenario, you'll never see a mismatch condition occur because the label placed on the container will always have a higher priority than the labels assigned to documents. Conversely, if you place the container management labels at the less sensitive end of the label set, every document labeled will generate a mismatch condition.

If you want label mismatch checking to operate as planned, make sure that each container management label comes **after** all the information protection labels used for documents stored by the site. For instance, a container management label called *Confidential Access* is used to label sensitive sites. An information protection label called *Confidential* is assigned to documents stored in sites labeled with *Confidential Access*. Another information protection label called *Super Confidential* exists which users should not apply to documents stored in sites assigned the *Confidential Access* label. Everything works properly if the priority order used for the labels is as shown below. In this scenario, a mismatch is detected if a document labeled *Super Confidential* is placed in a site labeled *Confidential Access*:

1. Information protection label: *Confidential*.
2. Container management label: *Confidential Access*.
3. Information protection label: *Super Confidential*.

SharePoint won't flag mismatches if the *Confidential Access* label has a higher priority than the *Confidential* and *Super Confidential* labels.

## Searching for SharePoint Files with Sensitivity Labels

Office documents, spreadsheets, and presentations store label information in their file attributes. When you store a labeled file in a SharePoint or OneDrive for Business document library, Microsoft Search captures the label data in crawled properties (something extracted from a file when the SharePoint crawler processes a file). The properties include *Sensitivity*, which stores the local language version of the label applied to the stored document (for example, "Confidential" or "Public"). You can remap the *Sensitivity* crawled property to one of the *RedefinableString* preconfigured managed properties to make the label searchable. The SharePoint schema includes a set of 200 *RedefinableString* managed properties (from *RedefinableString00* to *RedefinableString199*) to allow tenants to customize search behavior.

To make label data searchable, use the Search section of the SharePoint Admin Center to [remap the Sensitivity crawled property](#) to one of the *RedefinableString* properties (for example, *RedefinableString01*). It is also a good idea to give the property an alias (for instance, *SensitivityLabel*) to make it clear what the data is. Because the crawler must process a file before the label data is searchable, you should reindex the sites that hold classified information to force the crawler to find and index the label data. After the label data is added to the index, you can search for it using terms such as "*SensitivityLabel:Confidential*."

## OneDrive for Business Permissions

OneDrive for Business sites are personal and therefore need some individual attention before a site's owner can protect documents. You can read how to apply protection using steps for an individual user or how to use scripts to enable protection for multiple sites [at this link](#). These instructions apply to the older IRM approach to protection. You don't need to do anything special to allow users to apply sensitivity labels to items stored in their OneDrive for Business accounts.

## Protecting Individual Office Documents

Protection is applied to a Word, Excel, or PowerPoint file stored outside Office 365 by selecting a sensitivity label through the **Sensitivity** icon in the Office menu bar. If the sensitivity label includes encryption, the app

applies protection to the file the next time the user (or app) saves the file. Users must sign into a Microsoft 365 account to be able to access the set of sensitivity labels in a tenant.

If the unified labeling client is present on a PC, you can also protect files using the Classify and protect option in File Explorer. Finally, you can run the *Set-AIPFileLabel* cmdlet to protect individual files.

Applications know that files are protected because of metadata inserted in the files. Protection remains when labeled documents are uploaded to SharePoint Online or OneDrive for Business using the browser interface or if they are synchronized to a library with the OneDrive sync client. Protection for files downloaded in SharePoint Online or OneDrive for business also remains unaffected because downloading does not remove the sensitivity label.

## Recognizing Labels Cross-Tenant

Sensitivity labels are specific to and owned by the tenant where they are generated and unknown outside that tenant. Sometimes (for example, during a corporate merger) you might want a tenant to recognize labels owned by other tenants. The owner of the document or message will continue to control the rights assigned by the label, but you can [make some changes to the tenant configuration](#) to recognize and display another tenant's labels.

## Protecting Email

Several methods are available to protect email:

- Users can apply the two default OME options (*Do Not Forward* and *Encrypt Only*) using Outlook desktop (click to run), Outlook for Mac, or OWA. Outlook mobile does not support these options. *Encrypt Only* and *Do Not Forward* are available to tenants after configuring IRM. Users in tenants with Office 365 E3 and E5 can automatically read encrypted messages from other tenants; the IRM configuration must be in place to allow users to initiate new encrypted conversations.
- If configured for the tenant, users can apply sensitivity labels (with encryption) to protect messages. Recipients can only access the protected content if the rights assigned by the label allows them to interact with the content. Outlook Mobile supports sensitivity labels.
- Tenants can apply protection for messages sent to specific domains or sets of recipients by configuring transport rules.

Content searches can scan for and find information in protected messages. However, unless you enable support for sensitivity labels as described later, SharePoint Online and OneDrive for Business only index the metadata of protected documents, which means that searches cannot check attachments for protected messages. To allow transport rules to process protected messages, Exchange Online invokes super-user capability to decrypt. The same occurs to index email content. In addition, Exchange Online Protection can scan the content of encrypted messages to detect malware.

All successful implementations of protection for common Office content such as email and documents involve communication with the user community to explain the need for the technology, how to protect information (including some examples of best practices based on common scenarios), and the consequences (as laid down in HR policies) that might ensue if someone ignores the protection applied to data. No need exists to hit users across the head with a 2-by-4 to enforce policies; instead, all that anyone needs is a common-sense approach from all concerned.

## Enlightened and Unenlightened Email Clients

The Office 365 email clients support inline viewing of protected content. This means that clients decrypt and display encrypted information in the same way as they do for unencrypted messages. At the top of an

encrypted message, clients display an information banner to tell the reader that the message is protected. These applications include the necessary software to use the rights management APIs to retrieve and consume rights policies and licenses. To enable offline access to protected messages, Exchange fetches pre-licenses for messages. Outlook for Windows and Mac (version 16.23.19021400 or later) use these licenses to decrypt the messages without needing further authentication with the server. Browser-based applications, like OWA or OneDrive for Business, run online and connect to the rights management service to obtain use licenses to handle protection for documents.

Table 20-4 lists enlightened email clients on different platforms. Unless they incorporate code from the Microsoft Information Protection SDK (the Samsung Email app for Android is an example of a client which leverages the SDK), other clients know nothing about rights management or its implementation within Microsoft 365. These clients can't obtain the necessary licenses to unwrap the protection around protected messages to display the content. In Microsoft terminology, these clients are called "unenlightened." Users of unenlightened clients must go to the OME portal to open encrypted messages.

<b>Platform</b>	<b>Supported email clients</b>
Windows	Microsoft 365 apps for enterprise (Outlook click to run) OWA Windows 10 Mail app Outlook 2013 SP1 or later
macOS	Microsoft 365 apps for enterprise (Outlook for Mac) OWA
iOS	Outlook for iOS OWA
Android	Outlook for Android Samsung Email app OWA

Table 20-4: Enlightened email clients

Microsoft consumer accounts can use Microsoft 365 apps for enterprise, Outlook mobile, or the OWA browser interface (outlook.com) to access protected email. Accounts belonging to other services can access protected email through the OME portal. See here for more information about [applications that support rights management](#).

## Handling Unenlightened Clients

The Apple mail app for iOS is a good example of an unenlightened application that is popular with users. If an organization makes heavy use of rights management, forcing iOS users to go to the portal to read messages can be a sub-optimal experience. If you want these users to be able to read protected email on their devices, you can configure server-side decryption. The downside of this approach is that decrypted copies of the message then exist on user devices. To enable server-side decryption, run this command:

```
[PS] C:\> Set-ActiveSyncOrganizationSettings -AllowRMSSupportForUnenlightenedApps $True
```

When people use the mail app to view protected messages decrypted on the server, they see a header to tell them that the sender applied protection to the message. Unenlightened apps do not understand or apply the rights assigned to recipients, so a user of the iOS mail app can copy or print the message. However, Exchange Online knows that the original message is protected and, if the user attempts to do something without permission that involves the server, like forwarding the message, the action is blocked when the server processes that message.

In most cases, if you want to protect email within a tenant, it is a better idea to encourage people to use Outlook clients rather than disabling encryption.

## How Rights Management Protects Email

Users can protect email by assigning a sensitivity label (with encryption) or by using the default OME *Do Not Forward* and *Encrypt Only* features. Alternatively, if an organization has invested in S/MIME, it can use this method of protection.

### Protection for Non-User Recipients

The recipient list for a protected message can include a mixture of internal and external recipients, including those who do not use Exchange Online. Subject to the scoping defined for the sensitivity label used to protect a message, recipients will be able to open and access the content. Some restrictions exist when sending protected messages to recipients other than user mailboxes. For example:

- **Protected messages (and attachments) sent to a Microsoft 365 group** can be read by any member of the group, including guest accounts, because they authenticate their access through membership of the group. However, if a group member does not come within the scope of the label used to protect a message sent to the group, they can see that the conversation exists, who contributed to the conversation, and the title of the conversation, but they cannot see the content of the messages that make up the conversation because their credentials do not match the permissions assigned in the template. A banner informs the user that messages can't be displayed. If they click the banner, they see a link to the OME portal. This doesn't help either because the portal won't open protected messages when someone doesn't have the right permissions.
- **Users with full access to a shared mailbox (delegates) can read protected messages delivered to the mailbox** if the client supports this access. This includes access to protected Office attachments. See the section about Outlook access to protected content later.
- **Messages protected with Office 365 Message Encryption** can be sent to a dynamic distribution list. However, the members of the list cannot read the protected content because their email addresses are not in the recipient list.
- **Protected messages sent to the email address of a Teams channel** are rejected by Exchange Online because the transport service cannot re-encrypt the message for delivery to the phantom mailbox used to route messages to Teams. The sender receives a 5.7.1. Delivery Service Notification (DSN). Exchange Online decrypts protected messages to allow transport rules to process their content as the messages pass through the transport pipeline.
- Much the same happens if you try to send **protected messages to a Yammer group**. Again, the transport service cannot re-encrypt the message for onward delivery to Yammer, so it issues a 5.7.1. DSN.

Protected messages keep their status for their entire lifetime. Any replies to messages inherit the same protection to ensure that only the intended recipients can access the entire conversation.

## Office 365 Message Encryption

Office 365 Message Encryption (OME) is a capability available in Office 365 E3 and E5. OME makes two special rights management templates called *Encrypt Only* and *Do Not Forward* available to protect messages. *Encrypt Only* protects messages while allowing the recipient full control over the content. *Do Not Forward* blocks recipients from being able to forward a protected message. Clients encrypt messages protected by these options before they submit the messages to Exchange for onward processing. The only time Exchange applies encryption to email in transit is when a transport rule includes the application of a sensitivity label as an action.

Users can apply *Do Not Forward* or *Encrypt Only* to protect messages addressed to any user of any email system. Outlook and OWA clients connected to Exchange Online and Outlook.com accounts know how to

process OME-protected messages, meaning that the clients can display message contents inline as normal. Recipients using other mail systems must go to the OME portal to read the messages.

*Do Not Forward* and *Encrypt Only* grant viewer permission to all recipients. By contrast, if you apply a sensitivity label to protect messages sent to other domains, the recipients cannot read the content unless the label settings include their email address or their domain in the list of users and groups allowed to access the content. Organizations cannot change these templates to change the permissions assigned to recipients.

Unlike a sensitivity label, which can restrict what a recipient can do after receiving a message, when you use *Encrypt Only* or *Do Not Forward* to protect a message, recipients have full rights over a message. Protection through encryption is like the set of rights defined in sensitivity labels. The sender grants the recipient the right to decrypt and view the content. Put another way, the sender implicitly trusts the recipient to do the right thing with the content when they receive it. This isn't the case with other sensitivity labels, where the assumption is that rights need to be removed from some recipients so that they don't do the wrong thing. The important thing is that both approaches assure the sender that only authorized recipients can access a message and its attachments.

The idea behind *Encrypt Only* is to encourage users to consider the protection of confidential messages as a normal thing to do. Unlike third-party solutions such as S/MIME or PGP, users do not have to configure and manage certificates or install plug-ins. To make the idea even more appealing, encryption works for messages sent to any email address. If they use an enlightened client, a recipient can read encrypted content inline, while users of other email systems can read encrypted messages through the OME portal. These users receive a message with a link to allow them to log into the portal and read the message content. The link lasts for sixty days.

People who receive encrypted messages forwarded to them (by another person, rules, or when a forwarding address is set for a mailbox) cannot read the content because their addresses are not in the original recipient list. However, if a user forwards an encrypted message with OWA or Outlook, the recipient's address is added to the message header, and they can read the encrypted content.

## S/MIME and Microsoft Information Protection

[S/MIME \(Secure/Multipurpose Internet Mail Extensions\)](#) is a protocol that uses X.509 digital certificates to digitally sign, encrypt, or sign and encrypt messages. Like any protection scheme, S/MIME helps people who receive emails to be sure that messages are not tampered with in transit. S/MIME also helps to authenticate the sender; it proves the message is not spoofed. Before sending messages, the sender chooses to sign and/or encrypt the message, which is then processed like any other outbound message. The recipient uses the PKI infrastructure to verify the certificate and confirm the signature of the message. When a message is encrypted by S/MIME, the certificate of the recipient is used. For the sender to encrypt a message, he must have access to the public key of the recipient's S/MIME certificate. This requires the sender to import the recipient's certificate information before encrypting the email. For messages sent within the organization, an administrator can automatically publish that information to the Global Address List.

Outlook desktop, Outlook Mobile, and OWA support S/MIME for signing and encrypting messages. You can use S/MIME signing for both internal and external communications. When the S/MIME setting is enabled, Outlook for iOS and Android automatically disable the **Organize by Thread** setting. This is because S/MIME encryption becomes more complex as a conversation thread grows. By removing the threaded conversation view, Outlook for iOS and Android reduces the opportunity for issues with certificates across recipients during signing and encryption. As this is an app-level setting, this change affects all accounts added to the app.

It is technically possible to combine encryption applied by S/MIME with Microsoft Information Protection (and you can configure a sensitivity label to use S/MIME). However, applying multiple levels of protection only works if you use S/MIME to encrypt a message and then protect it afterward. This can only be done using Outlook desktop (for Windows) because this client is intelligent enough to resolve the inherent conflict

between the two encryption schemes. Of course, just because something is technically possible does not mean that it is feasible in practice. Combining S/MIME and Microsoft protection might result in a message that the recipient cannot process. A more practical approach is to select one scheme and use it everywhere. An organization should only consider using S/MIME if it already has a heavy investment in the technology needed for key management and clients deployed which can consume S/MIME-encrypted messages or if the organization decides to use third-party technology for protection. Outside these circumstances, we recommend that tenants avoid the complications (and extra costs) to deploy, manage, and maintain third-party encryption mechanisms and use the standard features built into Office 365 to protect email and documents.

**Real-world:** When configuring S/MIME, you can use an internal or external (third-party) certificate authority. In both scenarios, the entire certificate chain must be uploaded to Microsoft 365. To do this, you can export the chain from a local machine into an SST file and upload it to Microsoft 365, as described in [this procedure](#). After uploading the certificate, allow at least 30 minutes for the changes to replicate across Exchange Online. If you do not upload the certificate chain, you will see a message that says “An error occurred while sending this S/MIME message. The certificate used to sign this message isn’t trusted by your organization.”

## Encrypt or Protect

Given the choice to encrypt or protect messages, what should you do? Here’s a simple rule of thumb.

- **Encrypt** messages to protect confidential or sensitive data sent to recipients outside your organization. This includes messages sent to Microsoft 365 Groups (which can decrypt and show encrypted content in conversations to group members). The situation for Teams is different because Teams uses “special” email addresses for channels that don’t belong to a regular tenant. When you send an encrypted message to a channel, it is rejected because the Exchange transport service cannot decrypt and re-encrypt the message for the channel email address.
- **Protect** messages with confidential or sensitive data sent to internal recipients. If you define rights in labels for other domains, you can send protected messages to recipients in those domains. If someone receives a message protected by a label that doesn’t assign them the rights to access the content, they won’t be able to open the message.

This rule of thumb is based on the simple fact that OME works for messages sent to any email address, so it is the catch-all solution when a need exists to protect content sent outside the company. Not every destination might be able to understand the limitations imposed by sensitivity labels, but if a label is configured to support recipients in an external domain, it is an excellent way to protect information for the lifetime of the content.

## Protecting Email with Outlook

Outlook desktop clients automatically download the set of sensitivity labels available to users and refresh this information by connecting to the Information Protection service every four hours. Once the client downloads label information, Outlook has two options to protect email:

- The **Sensitivity** button in the menu bar reveals the set of sensitivity labels defined in the tenant and published to your account. Figure 20-15 shows how Outlook desktop (Windows) lists the available sensitivity labels. An Outlook profile can configure accounts from multiple domains, but sensitivity labels are specific to a tenant, so you’ll only see the labels belonging to the tenant configured in the default profile.
- The **Encrypt** button in the **Options** tab applies the OME *Encrypt Only* or *Do Not Forward* templates. The default option is to apply the *Encrypt Only* template. Click the arrow under the button to apply *Do Not Forward* protection to the message.

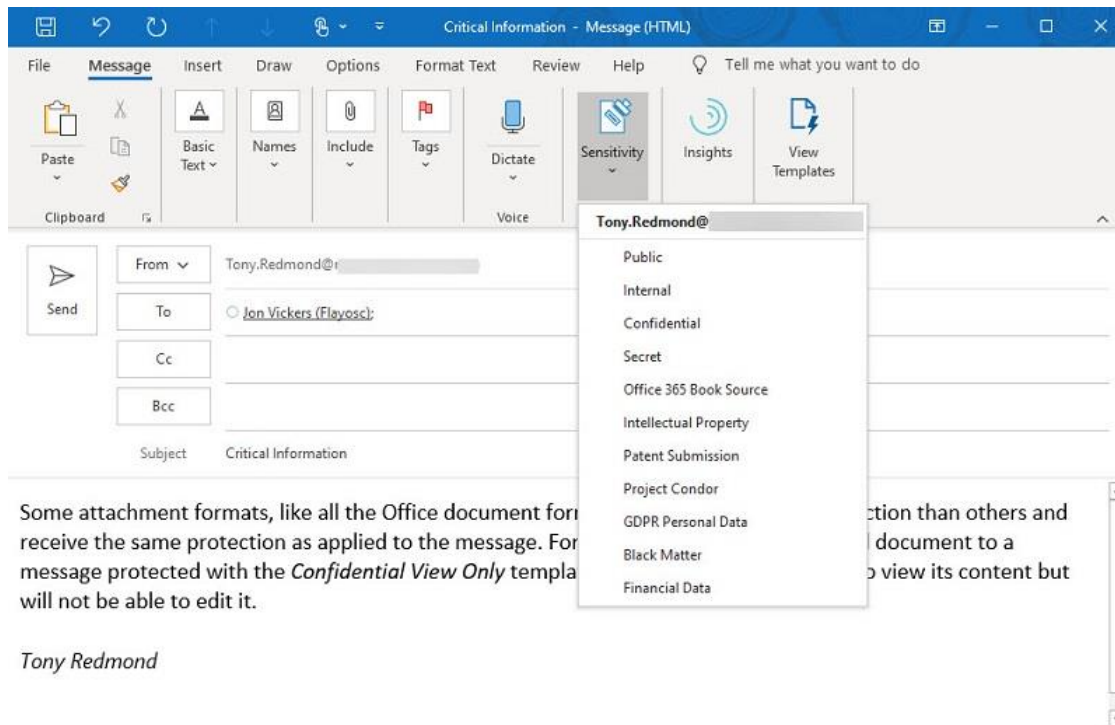

Figure 20-15: Selecting protection for a message with Outlook for Windows

Any replies and forwards (if allowed) created in response to a protected message inherit the same level of protection. Because the author always has full control over the content, they can decide to forward the message to another person, reply to the original message, or apply a different label. Outlook does not support the recall of a protected message. This is not as big a problem as it might seem because the speed of email servers today means that it is almost impossible for a message recall to work, especially when a message travels to another domain.

## Outlook Delegate Access

Delegates are users granted access rights to another user's mailbox or to a shared mailbox. The ability of a delegate with full access to a mailbox to read encrypted messages depends on the client used and the type of mailbox. Only Outlook clients support the ability of delegates to read encrypted messages (and attachments) subject to the following:

- Outlook for Windows clients do not support delegate access to encrypted messages sent to user mailboxes. Delegates can only read encrypted messages if the sender includes the delegate as a TO or CC recipient. In this scenario, the delegate's ability to read the message depends on the rights granted to them as a recipient.
- Outlook for Windows clients support delegate access to encrypted messages sent to shared mailboxes if the delegate has full access and auto-mapping is specified when the delegate receives permission to the mailbox. Auto-mapping is the default used by Exchange Online when delegates receive full access permission through the Microsoft 365 admin center or Exchange admin center. It forces Outlook for Windows to open the shared mailbox as part of the resources available to the delegate.
- The other Outlook clients (OWA, Outlook for Mac, Outlook Mobile, and the Windows Mail app) support delegated access to encrypted messages in both user and shared mailboxes if the delegate has full access to the mailbox.

Microsoft documents [some restrictions that apply to delegate access for encrypted messages](#).

If you wish to prevent users with full access to a user or shared mailbox from being able to view encrypted messages using clients other than Outlook for Windows, you can block their access by running the *Set-MailboxIRMAccess* cmdlet. For example, this command blocks the ability of Kim Akers to read any encrypted messages delivered to the Customer Services mailbox:

```
[PS] C:\> Set-MailboxIRMAccess -Identity Customer.Services@Office365itpros.com -User Kim.Akers@Office365itpros.com -AccessLevel Block
```

To make sure that a block is in place, use the *Get-MailboxIRMAccess* cmdlet:

```
[PS] C:\> Get-MailboxIRMAccess -Identity Customer.Services@Office365itpros.com -User Kim.Akers@Office365itpros.com
```

Identity	User	AccessLevel
-----	----	-----
Customer Services	Kim.Akers@office365itpros.com	Block

A block on delegate access remains in place until an administrator removes it and only affects the ability of a delegate to read encrypted messages using clients that support the block. For instance, the block will stop a delegate reading encrypted messages in a shared mailbox using OWA or Outlook for iOS, but they can switch to Outlook for Windows to see the message content. In addition, blocking access does not hide message subjects, which can contain sensitive information, nor does it prevent a delegate from deleting or moving encrypted messages. The block exists for reading, and only works for clients that support the block.

To remove the block and restore the ability to read encrypted messages to a delegate, run the *Remove-MailboxIRMAccess* cmdlet:

```
[PS] C:\> Remove-MailboxIRMAccess -Identity Customer.Services@Office365itpros.com -User Kim.Akers@Office365itpros.com
```

**Remove Encrypt Only:** Some organizations consider that users should only use sensitivity labels to protect messages and want to remove the standard OME *Encrypt Only* template. The instructions to do this are [available online](#).

## Protecting Email Attachments

Unprotected Office documents (and PDF files if enabled: see the notes about the *EnablePdfEncryption* setting in the tenant IRM configuration earlier) attached to protected messages inherit the same protection as assigned to the message. For example, if you attach a Word document to a message protected with a sensitivity label that only allows edit access for the author, the recipients will be able to view its content but will not be able to edit it. If a higher level of protection is applied to a file before it is attached to a message, that protection is preserved for the attachment.

Figure 20-16 shows a Word document open on an iPhone. This is an attachment to a protected message opened by Outlook for iOS. The user can discover what rights they have over the content by clicking

### Permissions.

Recipients can open and edit attachments in file formats that do not support sensitivity labels, like text files or bitmap images, unless you protect the files with the unified labeling client (covered later) before attaching them to the message. If a user applies a sensitivity label without encryption to a document and attaches the file to a message, Outlook assigns the same label as applied to the message to the document to ensure consistency of protection.

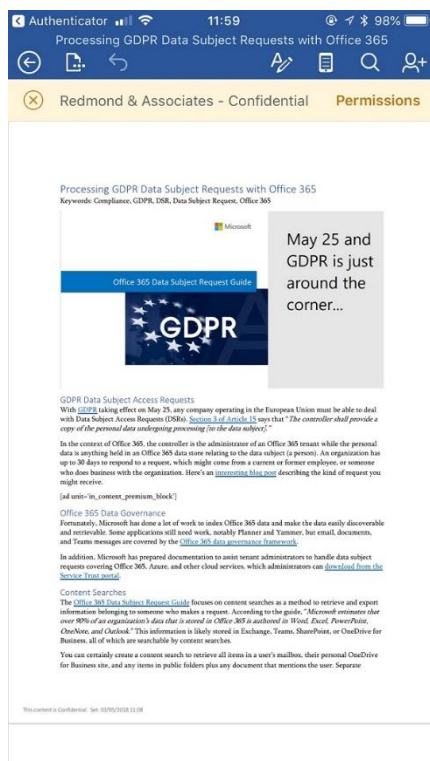

Figure 20-16: A protected Word attachment viewed with Word for iOS

## Automatic Decryption of Encrypt Only Attachments

Dealing with protected attachments is not an issue for Exchange Online clients because they can obtain the necessary use licenses to decrypt the attachments when opening messages. However, if a message using Encrypt Only goes to recipients of other email systems like Gmail, recipients can read the messages after authentication through the OME portal, but they cannot access the contents of a downloaded attachment because the downloaded copy of the attachment remains protected. If you want external recipients to be able to download decrypted copies of attachments, you must update the IRM configuration to instruct Exchange Online to decrypt attachments and remove protection whenever they are accessed or downloaded by an authenticated recipient. The effect is to give recipients full control over the downloaded files. To change the configuration, run this command to update the tenant IRM configuration:

```
[PS] C:\> Set-IRMConfiguration -DecryptAttachmentForEncryptOnly $True
```

This setting only applies to messages protected with the Encrypt Only feature.

## Viewing Rights

When you open a protected item, you see the name of the template and some information about its intended use. Outlook users can click a message header to gain more insight into what they can and cannot do with a protected item (Figure 20-17). It is obvious from the list of rights supported for email that you cannot block every conceivable action that a recipient can take with a message. For instance, although you can remove the Copy right to stop someone from copying text from a message or attachment, including blocking screen captures on Windows devices, you cannot stop someone from taking a screenshot with a smartphone and circulating that image to others. The point here is that protection cannot prevent every kind of unacceptable user interaction with content. Users must accept some responsibility for their actions. Applying a sensitivity label to an item makes users aware that the author protected the information for a reason and that they should therefore deal with that information appropriately. What they do is entirely up to the user.

Figure 20-17: Outlook reveals the rights available for a message

## Protecting Email with OWA

Because OWA runs in online mode, it always uses the current set of sensitivity labels published for a user. In saying this, we should realize that some client-side caching occurs for performance and that a small delay is likely before a new label or a change to an existing label published by the Microsoft Purview Compliance portal becomes available in OWA.

The Sensitivity button is available as an option in the OWA new message window. After a label is set on a message, the label name appears in the banner above the message recipients. In Figure 20-18, we can see that the sensitivity label selected for the message invokes encryption because of the padlock icon beside the label name. A label that applies some markings to items without encryption or simply acts as a visual indicator uses a plain label icon. OWA also displays these icons for labeled items in the read message window. Like Outlook, the protection applied to a message also applies to any of its attachments.

Sensitivity labels can also be applied to replies to messages that aren't previously labeled. In this case, the **Sensitivity** option to apply a label is in the [...] menu of the reply message window. When you assign a sensitivity label to a reply, it does not apply to the previous messages in the thread. However, Exchange automatically assigns the same label to future messages in the thread.

OWA can also use the OME *Encrypt Only* and *Do Not Forward* features to protect messages. Click the [...] menu and you'll find **Encrypt** in the list of menu choices. Using these templates for protection does not assign a sensitivity label to the protected messages.

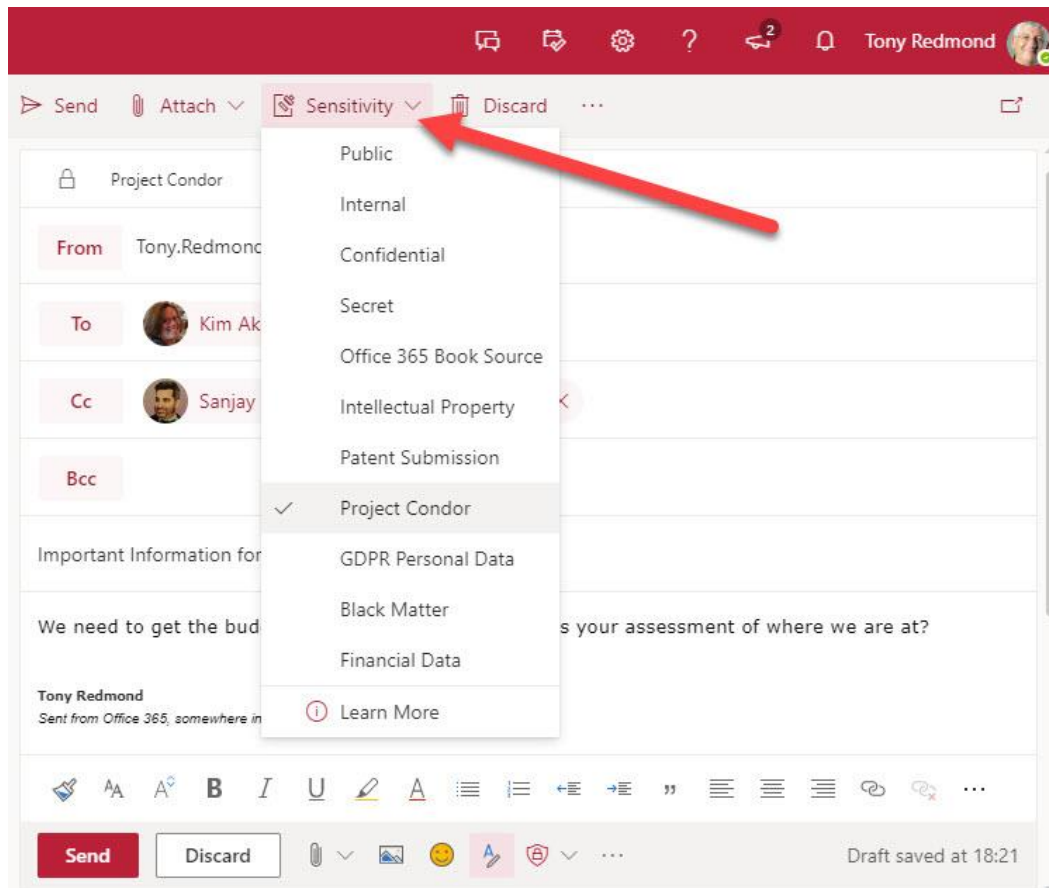

Figure 20-18: Applying protection with OWA

## Microsoft Rights Management Connector

The Microsoft Rights Management (RMS) Connector lets Exchange and SharePoint on-premises servers deployed in a hybrid configuration access the capabilities of cloud-based Information Protection. The connector runs on an on-premises Windows server or a virtual machine. Its role is to act as a communications relay between on-premises servers and the cloud rights management service. The on-premises servers are then able to use the cloud service to protect messages and documents and process protected email in the transport pipeline. In addition, Outlook clients connected to on-premises mailboxes can use the cloud service to access protected email.

For more information about how to install and configure the Rights Management connector, see [this page](#).

## Managing Office 365 Message Encryption

Office 365 Message Encryption (OME) is an online service built on top of rights management to allow users to protect emails sent to recipients in any email system. OME includes:

- The default Encrypt Only and Do Not Forward templates.
- The ability to encrypt messages sent to specific destinations through transport rules. For example, you might decide to encrypt all messages sent to a partner domain. Any sensitivity label with encryption can protect content using a transport rule.
- The message encryption report (available to Office 365 E3 and E5 tenants), is available in the [Reports section of the Microsoft Purview Compliance portal](#). This report details how messages receive protection (by users or by policy) and whether encryption occurs through a default template or sensitivity label. The data is useful in terms of understanding how many people protect email the

organization. Because Exchange Online generates the report data daily, the information is not real-time and can be up to a day behind.

OME-protected messages do not support protecting messages sent to dynamic distribution lists. Exchange Online bifurcates messages to deliver copies to the members of the dynamic distribution list when they pass through the transport pipeline. However, the list members are not present as message recipients, so they never gain the right to open the message. A sensitivity label protects messages sent to dynamic distribution lists if the permissions assigned in the label grant access to everyone who receives a copy.

It's worth emphasizing that OME is all about protecting email without needing the recipient to install any special software. Sensitivity labels can also protect email with encryption, but the big difference is that sensitivity labels also define the actions a recipient can take after they open that content. Organizations can also include sensitivity labels as an action for transport rules to execute on outbound messages.

## Customizing the OME Configuration

When an external recipient (not belonging to another Office 365 tenant or Outlook.com) receives a protected message, they receive a notification message to tell them what they must do to access the content. The notification directs the recipient to sign into the OME portal using an account from one of the federated identity providers. If they cannot sign in or prefer not to, the recipient can get a one-time code to read the content. After signing in, the user sees a modified version of the OWA read message window, which enforces the permissions they have over the content.

You can customize the OME configuration (otherwise known as a branding template) to add custom text used in the notifications and the OME portal. To start, use the *Get-OMEConfiguration* cmdlet from the Exchange Online module to view the details of the standard OME configuration. In this case, the configuration has several customized settings, which we can update further with the *Set-OMEConfiguration* cmdlet.

```
[PS] C:\> Get-OMEConfiguration -Identity "OME Configuration"
TemplateName           : OME Configuration
Image                  : {137, 80, 78, 71...}
ImageUrl              :
EmailText              : Thank you for communicating with our company. To protect our
confidentiality, this message has been encrypted.
PortalText             : Our Great Encrypted Email Portal
IntroductionText      :
DisclaimerText        : Office 365 for ITPros takes no responsibility for the operation of this
portal
ReadButtonText        : Protected Email
OTPEnabled            : True
SocialIdSignIn        : True
ExternalMailExpiryInterval : 00:00:00
PrivacyStatementUrl   :
Identity              : OME Configuration
```

Settings of note are:

- **BackgroundColor:** You can set the background color for OME messages and the portal by passing the hex code color. Usually, people who know about corporate branding will know [the right code](#) to use.
- **DisclaimerText:** A string of up to 1024 characters placed at the bottom of the encrypted message intended as a disclaimer but can convey a different message. If you don't provide a value, OME uses: *"This email message and its attachments are for the sole use of the intended recipient or recipients and may contain confidential information. If you have received this email in error, please notify the sender and delete this message."*
- **EmailText:** A string of up to 1024 characters to tell the recipient that they have received an encrypted message. If you don't provide a value, the default OME text is *"You've received an encrypted message"*

from" plus the SMTP address of the sender. If you change the default message, OME does not include the sender's SMTP address (but it still appears in the message header).

- **Image:** An image file (.png, .jpg, .bmp, or .tiff) of less than 40 KB to show that messages originate from the sender's company. Ideally, you might use a 170x170 pixel version of the company logo. By default, OME does not display a logo.
- **OTPEnabled:** If true (the default), recipients can opt to get a one-time code to access the portal. Set this to False if you want to force users to authenticate using an account from one of the supported providers.
- **PortalText:** A string of up to 128 characters that the OME portal displays when users connect to access a decrypted message.
- **PrivacyStatementURL:** A link to a web page for the company's privacy policy. This link is invoked when a user clicks the Privacy Statement link in an OME notification.
- **ReadButtonText:** A string to display on the Read button in the notification. To make sure that it fits on the button, this text should be no more than 16 characters.
- **SocialIdSignIn:** Defines if a recipient can authenticate to read a message using an identifier from a recognized social network such as Google or Yahoo! If False, the recipient can authenticate using another method such as a one-time password.

Fwd: Looking after our customers during COVID-19

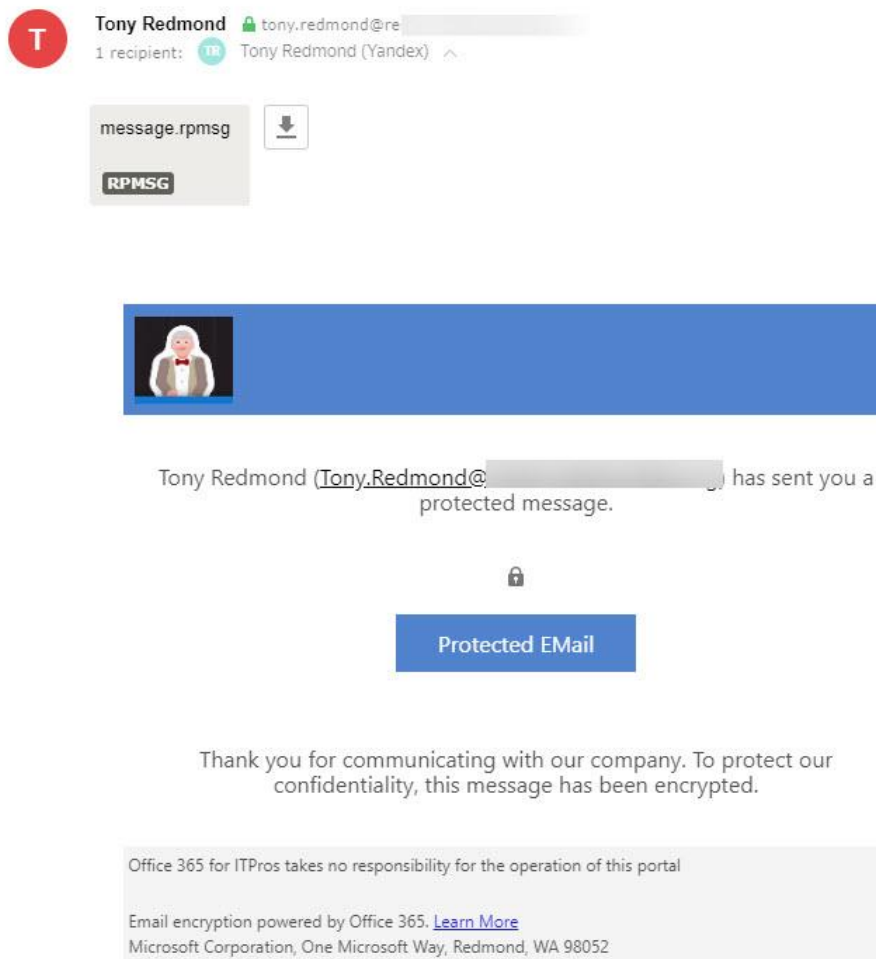

Figure 20-19: The OME notification received to let someone know that they should read some protected email  
For example, this PowerShell command updates several properties in the OME configuration:

```
[PS] C:\> Set-OMEConfiguration -Identity "OME Configuration" -BackgroundColor "#5183cd" -DisclaimerText "We take zero responsibility for anything that happens here." -EmailText "Yippe!"
```

```
You've got some encrypted super-secret email" -PrivacyStatementUrl  
"https://office365itpros.com/privacy.html"
```

Here's how to add a graphic file for the logo displayed in notification messages and the OME portal:

```
[PS] C:\> Set-OMEConfiguration -Identity "OME Configuration" -Image (Get-Content  
"C:\Temp\CompanyLogo.jpg" -Encoding Byte)
```

When you update the OME configuration, Microsoft warns that custom content used in configurations is the tenant's responsibility. In other words, make sure that any graphics and text used are not protected by trademarks or other restrictions.

Figure 20-19 shows the effect of the updated OME configuration. The logo appears at the top of the message, the email text appears under the link, and the customized disclaimer text is in place. The restricted permission attachment (rmsg) is the encrypted content shown when the user accesses the message through the OME portal. Internal recipients do not see notifications unless they use a non-Outlook client that can't obtain the necessary use licenses to decrypt and display the protected content automatically. For example, if you connect to your mailbox using an IMAP4 client, you'll see notifications for protected messages sent by other people in the tenant.

## Advanced Office 365 Message Encryption

The standard OME supports a single branding template, applied by Exchange Online to all protected messages delivered to recipients outside the tenant. Advanced OME adds support for:

- Multiple branding templates and the application of branding templates in transport rules. For instance, you could use a transport rule to protect all messages sent to a partner domain and customize the template that recipients in that domain see. To do this, select the **Apply Custom Branding to OME messages** action in a transport rule along with the custom template to use and the criteria to apply the branding (for example, specific domains). Custom branding templates are updated in the same manner as the general template used by the standard version of OME (see above).
- Expiry of protected email. The custom templates support the ability to expire messages sent to external recipients after a set period of anything from one to 730 days.
- [Revoke access for external recipients to protected email](#). This feature is available in OWA when senders have an Advanced OME license, and the recipient accesses the encrypted content through a link to the OME portal. Alternatively, an administrator can revoke access to a message on behalf of a user using PowerShell (see below).

Advanced OME is an Office 365 E5 feature also licensed using the Microsoft 365 E5 Compliance SKU.

Custom branding is an optional action for transport rules. If you apply custom branding in its own rule, make sure that the rule to apply branding runs (has a lower priority) after any rule which applies encryption. In addition, make sure that any rule which applies encryption or custom branding does not terminate rule processing and let other rules with lower priority run afterward.

## Creating a Custom Branding Template for OME

Custom branding templates are created with PowerShell. This example shows how to create a new branding template and then populate the properties of the new template.

```
[PS] C:\> New-OMEConfiguration -Identity "Office 365 IT Pros Branding"  
  
Set-OMEConfiguration -Identity "Office 365 IT Pros Branding" -DisclaimerText "Office 365 for IT Pros  
takes no responsibility for this portal." -PortalText "Office 365 for IT Pros Secure Messaging"  
-EmailText "Good things happen when you protect email" -ExternalMailExpiryInDays 10  
-IntroductionText "has sent you a secret message" -Image (Get-Content "C:\Temp\SmallBookCover.jpg"  
-Encoding byte)
```

See [this page](#) for more information about how to customize a branding template. Remember that it can take between 15 and 30 minutes for a change made to a transport rule to become effective, so factor this into the time needed to test how custom branding templates work.

To test that branding works, create a transport rule to apply a custom branding template to messages in a specific domain and send a protected message to an account in that domain. When it arrives in the recipient mailbox, check that the custom branding is visible when the recipient opens the message.

## Administrator Revocation of Encrypted Messages

Recipients of protected messages fall into two categories: internal and external recipients. Revocation, which means removing the right of a recipient to view encrypted content, is only possible for link-based messages delivered to individual external recipients because the OME portal controls access to these messages.

Messages to users in other Microsoft 365 tenants or Outlook.com are irrevocable because these users don't need to access the OME portal to read protected messages.

Administrators can revoke a message through PowerShell by finding the identifier of the message to revoke and then running the `Set-OMEMessageRevocation` cmdlet. The easiest method to find a message identifier is to use the [Message Trace feature in the Exchange admin center](#) (or by running a message trace with the `Get-MessageTrace` cmdlet).

Execute a search to find the message, select it in the set of results, and look at its properties. The message identifier is a long string ending in something like "prod.outlook.com." When you have the identifier, run the `Get-OMEMessageRevocation` cmdlet to check that the message is revocable. At this point, Exchange Online knows if the message recipient received a link to the OME portal or could read the message inline. If you see that the message is revocable, run the `Set-OMEMessageRevocation` cmdlet to revoke permission. For example:

```
[PS] C:\> $MessageId =
"AM6PR0402MB3462A8DF67AF7AF9C9F0B20A8BE50@AM6PR0402MB3462.eurprd04.prod.outlook.com"
```

```
Get-OMEMessageStatus -MessageId $MessageId | Select Subject, IsRevocable
```

Subject	IsRevocable
-----	-----
Important Information	True

```
Set-OMEMessageRevocation -Revoke $True -MessageId $MessageId
```

The encrypted email with subject "Plans for next year" and Message ID "AM6PR0402MB3462A8DF67AF7AF9C9F0B20A8BE50@AM6PR0402MB3462.eurprd04.prod.outlook.com" was successfully revoked.

To check the status of the message, you can run the `Get-OMEMessageStatus` cmdlet. The results returned by the cmdlet confirm the revocation of the message:

```
[PS] C:\> Get-OMEMessageStatus -MessageId $MessageId
```

```
RunspaceId      : 4039a474-e2ab-498f-a92c-460154537c8f
Identity        : 04e78939-85a9-4bf8-8d65-9f533648bb37
IsValid         : True
ObjectState     : New
Container       : SystemMailbox{D0E409A0-AF9B-4720-92FE-AAC869B0D201}@office365itpros.onmicrosoft.com
Subject         : Tony Encrypt
ReceivedTime    : 7 Oct 2021 14:03:55
Revoked         : True
```

When the recipient goes to the OME portal and tries to read the protected message, they see "the message has been revoked by the sender" and that they should contact the original sender if they want access to the content. If an administrator revokes a message, there's no way for the original sender to cancel the revocation.

If the administrator makes a mistake and revokes a message incorrectly, the original sender will have to resend the message.

## Using Office 365 Message Encryption with Transport Rules

The basic scenario is when a transport rule protects email sent to a specific destination, which could be a group of users or one or more domains. Messages sent by clients connected to Exchange Online mailboxes must pass through the transport pipeline. As messages flow through the transport pipeline, Exchange Online uses the criteria defined in transport rules to examine messages. If an email matches a rule, Exchange Online applies the action or actions defined in the rule. The rule set can span hundreds of rules to account for different circumstances, and Exchange Online examines each message against each rule until it reaches the end of the rule set, or the action set in a rule causes rule processing to halt.

Adding protection to messages by applying a template is one of the actions available for transport rules. This capability is often used to ensure that protection is applied to messages even if they originate from clients that do not support rights management, such as the default mail apps for iOS and Android. Using transport rules to apply encryption also avoids the need for users to select the right template to apply when they compose a message. If many different templates exist, users might not know what template they can use to protect messages sent to a certain domain or user. For this reason, organizations often use transport rules to apply protection to ensure that confidential information cannot pass in an unencrypted form to recipients outside the tenant. A transport rule can apply protection using criteria such as:

- Any message sent to specific domains.
- Any message sent to specific users.
- Any message that contains a specific phrase in the message text or an attachment.
- Any message that has a specific word in its subject.

When a transport rule protects outbound messages, the senders of those messages might not be aware that this processing occurs because the copy of the item in their Sent Items folder is unprotected. This is because transport rules apply sensitivity labels in the transport pipeline to protect the message copies delivered to recipients. The copy of the message in the sender's mailbox has not been through the transport pipeline and is therefore unprotected. If users want to see a protected copy, they must include their name as a recipient.

## Configuring a Transport Rule for Protection

Transport rules are configured through the **Mail flow** section of the EAC (for more information on this topic, see the discussion about transport rules in Chapter 7). In Figure 20-20, we see details of a transport rule to do the following:

- Monitor messages sent by members of the Executive Committee distribution list; and
- Apply the "Confidential" template to these messages. This is an action in the **modify message security** set.

Microsoft publishes details of a transport rule to encrypt outbound messages with certain sensitive information types (like credit card numbers). The prototype rule they suggest is a good start, but you should [carefully review and adjust the rule](#) to ensure that it meets the need of your tenant.

## Protect Executive Committee messages

Figure 20-20: Applying protection with a transport rule

## Exemptions

Often rules include an exception condition to allow users to override the rule in certain circumstances. For example, if the subject of the message has a specific text pattern, the rule will not apply the sensitivity label. When a rule allows a message to pass without intervention due to an override, because the transport captures the fact that it processed the rule in the message header, Exchange Online will not try to apply the rule again to replies and forwards that flow from the original message.

Another common exception is not to apply protection when the recipient is a member of a specific group. The logic here is that the members of the group might need to change or update the content circulated in emails.

Although distribution lists are an excellent way to specify the users that come under the scope of a transport rule, remember that Exchange Online caches group membership to avoid the performance penalty of going back to Azure AD to expand membership each time a group is in a message header. For this reason, do not expect a change made to a group used in a transport rule to be effective at once. It can take between 30 minutes and an hour before the transport service learns about the new group membership.

**Interlocking protection:** You can apply a mixture of DLP checking and sensitivity labels to make sure that sensitive data does not leave the organization unprotected. If the transport service detects sensitive data protected by a DLP policy in a message, a transport rule can apply a label. This level of interlocking protection helps organizations ensure that people do not misuse sensitive data.

## Handling Protection when Transport Rules Process Protected Messages

Users might protect messages using the default Encrypt Only or Do Not Forward templates that are subsequently processed by a transport rule which also attempts to protect the message. When this happens, the level of protection is adjusted if the protection applied by the rule is more restrictive (higher sensitivity) than chosen by the user, which might affect the rights assigned to recipients.

This is logical because the author has already explicitly applied protection to the message with what they believe is the right level of protection. Overriding protection selected by a user with a rule runs the risk of interference with the recipient's ability to process the message in the way intended by the author.

## Applying Protection in Transport Rules with PowerShell

Two methods are available to apply templates to outbound emails. The traditional approach that we've just explored is to use a transport rule; a newer approach is to specify protection as an action in a DLP policy that fires when the DLP service detects sensitive data in a message. You can find information about how to invoke protection in DLP policies in Chapter 19. Because of the complexities involved in many rules and policies, it is often easier to build them through the relevant GUI (EAC for transport rules, Microsoft Purview Compliance portal for DLP policies), but PowerShell can also be used for the task.

The *New-TransportRule* cmdlet creates a new transport rule. In this example, we create a rule that applies the "Sensitive Board Reports" label to messages sent from one distribution list to another distribution list.

```
[PS] C:\> New-TransportRule -Name "Protect Board Meeting Information" -FromMemberOf "Board Reports"
-SentToMemberOf "Board Members" -ApplyRightsProtectionTemplate "Sensitive Board Reports"
-ExceptIfSubjectContainsWords @("Override") -StopRuleProcessing:$False -Mode Enforce
-Comments "Protect Board Information when circulated" -RuleErrorAction Ignore
-SenderAddressLocation Header
```

Another example is where you want to protect messages that contain sensitive information types such as credit card numbers. A wide range of default sensitive information types are available for use in DLP policies and you can define custom sensitive information types if necessary. Any sensitive information type can be used in a transport rule to identify messages for protection by including it in the *MessageContainsDataClassifications* parameter. Here's a simple PowerShell example that looks for six different sensitive information types. If any are found in a message, Exchange Online applies the Encrypt template.

```
[PS] C:\> New-TransportRule -Name "Encrypt external email with PII content" -SentToScope
NotInOrganization -ApplyRightsProtectionTemplate "Encrypt" -MessageContainsDataClassifications
@(@{Name="ABA Routing Number"; minCount="1"},@{Name="Credit Card Number"; minCount="1"},@{Name="U.S.
/ U.K. Passport Number"; minCount="1"},@{Name="U.S. Bank Account Number"; minCount="1"},@{Name="U.S.
Individual Taxpayer Identification Number (ITIN)"; minCount="1"},@{Name="U.S. Social Security Number
(SSN)"; minCount="1"}) -Mode Enforce
```

Alternatively, you can create a DLP policy that applies a template when messages are shared outside the organization. Two steps are needed to do this with PowerShell. The first creates a DLP policy; the second creates the rule to encrypt email with the same set of sensitive information types specified for the transport rule and attaches the rule to the policy.

```
[PS] C:\> New-DlpCompliancePolicy -Name "Encrypt external sensitive mail" -ExchangeLocation "All"
New-DlpComplianceRule -Name "Encrypt external email with PII content" -Policy "Encrypt external
sensitive mail" -AccessScope NotInOrganization -EncryptRMSTemplate "Encrypt" -NotifyUser
>LastModifier" -NotifyPolicyTipCustomText "This email contains sensitive PII information and will be
encrypted when sent." -NotifyEmailCustomText "This email contains sensitive PII information and will
be encrypted when sent." -ContentContainsSensitiveInformation @(@{Name="ABA Routing Number";
minCount="1"},@{Name="Credit Card Number"; minCount="1"},@{Name="U.S. / U.K. Passport Number";
minCount="1"},@{Name="U.S. Bank Account Number"; minCount="1"},@{Name="U.S. Individual Taxpayer
Identification Number (ITIN)"; minCount="1"},@{Name="U.S. Social Security Number (SSN)";
minCount="1"})
```

Several methods are available to apply encryption via policy to outbound email. It's important to choose either transport rules or DLP policies to protect sensitive data as it is easy to confuse matters if protection is applied for the same content using multiple methods.

## Applying Sensitivity Labels with Transport Rules

If you apply a sensitivity label to a message using a transport rule, the message is protected if the label invokes encryption, but none of the visual markings are applied to the item. Exchange recognizes the presence of a sensitivity label for a message through the presence of an x-header called *msip\_labels*. The value of the header points to the GUID for the sensitivity label. GUIDs are used instead of text values to allow clients to show label names in local languages. If the *msip\_labels* x-header is not present in a message header, clients that understand labels cannot display a label. Therefore, if we want to apply a label to a message, we must do so by adding the label with a client or applying the label with a transport rule as the message passes through the transport pipeline. The technique works for outbound messages. It doesn't work for inbound messages.

Figure 20-21 is an example of applying a label in a transport rule. The rule is very simple and does the following:

- If the message subject or body contains the word *#Confidential*, execute the rule. This is an easy way of allowing people who use clients that don't support rights management (like older Mac devices or mobile devices that don't support an application capable of applying labels to items) to have Exchange protect messages. The rule applies to messages sent inside and outside the organization.
- Apply the Encrypt template to protect the message.
- Add *MSIP\_Label\_1b070e6f-4b3c-4534-95c4-08335a5ca610\_Enabled=True*; as the value of the *msip\_labels* x-header in the message. The closing semi-colon is important as it terminates the x-header.

### Apply Sensitivity Label to Email

The screenshot shows the configuration for a transport rule named "Apply Sensitivity Label to Email".

- Name:** Apply Sensitivity Label to Email
- \*Apply this rule if...:** The subject or body includes... *#Confidential'*
- \*Do the following...:**
  - Apply Office 365 Message Encryption and rights protection to the message with... *Encrypt*
  - and
  - Set the message header to this value... Set the message header '*msip\_labels*' to the value '*MSIP\_Label\_1b070e6f-4b3c-4534-95c4-08335a5ca610\_Enabled=True;*'

Buttons: Save, Cancel

Figure 20-21: Setting a transport rule to add the *msip\_labels* x-header to a message

A big question for anyone wanting to use a sensitivity label in a transport rule is how to find its GUID. The Microsoft Purview Compliance portal doesn't display this information for a sensitivity label, but you can retrieve label GUIDs by running the *Get-Label* cmdlet (see the section covering using PowerShell to manage sensitivity labels). You can combine labels with templates. In other words, even if a label includes protection, you can decide that a transport rule should apply an x-header for one label and protect the message with a

different template (that isn't associated with a label). If you want to use a sub-label, make sure you use its GUID and not that of the parent label.

Remember that the senders of messages processed by this rule will not see a label or protection on the copy of the message in their Sent Items folder because protection only applies to messages that go through the transport pipeline. If you want to check that the rule works as expected, include your address as a recipient and examine the copy of the message delivered in your Inbox with a client that supports sensitivity labels. You should find the *msip\_labels* x-header in the message headers and that the message is both labeled and encrypted. It's also true that the label information will mean nothing to a different email system (or different tenant) because those systems won't be able to translate the GUID into a label. However, the protection will still apply even if the label isn't respected, and that is probably the most important thing.

## Detecting and Blocking Protected Messages in Transport Rules

We know that protected messages have x-headers holding information about the label applied to protect the content. We can exploit this fact to create a transport rule to block messages leaving the organization if their headers include a certain label. In this case, the criteria are:

- Apply to outbound messages.
- Check the *msip\_labels* x-header and if the GUID for the label exists, block the message with the action "Reject the message with the explanation." The text for the explanation is up to you but might be something like "You can't send sensitive messages outside the organization."

For example, let's assume that you have a label with a GUID of *ed4411cc-bec4-444a-b279-c404aaad79d6*. The text that the transport rule should look for in the x-header is:

```
MSIP_Label_ed4411cc-bec4-444a-b279-c404aaad79d6_Enabled=true
```

If found, we know that this message (or one of its attachments) is protected with the label, so the rule can go ahead and block the message.

Exchange Online can read the label metadata for messages and Office attachments. However, it cannot read metadata for protected PDF attachments. Another complication is that OWA and Outlook mobile clients apply protection to messages using special hidden rules executed as items pass through the Exchange Online transport pipeline. It is more efficient to encrypt messages after the processing of other transport rules finishes, so encryption is applied to outbound messages after all tenant-specified rules finish. The net effect is that protection (and the x-header) is only present in messages sent by OWA and Outlook mobile after Exchange has processed all the other rules, so the rule described above can only block protected messages sent by Outlook desktop.

## Hybrid Protection

In a hybrid deployment, the on-premises Active Directory RMS servers support on-premises mailboxes, and Office 365 supports cloud mailboxes. Automatic synchronization of configuration data, including templates, does not occur. You must:

- Export the trusted publishing domain (TPD) data from your on-premises [RMS servers](#).
- Allow [external access](#) to your on-premises servers.
- [Import the TPD data](#) into Azure RMS.
- Enable any on-premises templates that are in use and make them available to cloud users.

It is desirable to ensure that the same templates are available to both cloud and on-premises users and that they run in the same manner. Because no automatic synchronization exists, any time an administrator updates the configuration for either the on-premises or cloud platforms, you must replicate the change to the other platform.

# Protecting Windows Files

The Unified Labeling client integrates with File Explorer to allow users to select and apply protection to files in much the same way as they perform other operations like printing. You can protect multiple files and folders in a single operation. To protect a file, you select the file in File Explorer and select **Classify and Protect** from the right-click menu. The options exist to merely classify a file or to apply full protection where you specify a list of users who can interact with the file together with the permissions you want to give them. For convenience, roles like Viewer – View Only and Co-Owner dictate the actions that recipients can take when they receive protected files. You can select recipients from the corporate GAL or input the email addresses for individual recipients, distribution lists, or complete domains. As you can see in Figure 20-22, you can also add an expiration date after which recipients no longer have access to the content.

After you protect a file, the client updates its properties to reflect the new protection. In some cases, like Office documents, this is a matter of adjusting the built-in attributes that control access to the file. In others, like JPEG files, the client converts the file into another format (in this case, protected JPEG). After protecting the file, you can share it with anyone you like using whatever mechanism is best. For instance, you can attach the file to a message and send it to someone. The protection placed on files works no matter how users share files, including uploading files to cloud sharing services like DropBox.

If the recipient is on the list of the users specified to access the content, they will be able to open it and interact with the content based on the rights granted by the author. Anyone else will be unable to access the content and told that they need to contact the owner to receive a version of the file that includes them in the permissions list. If the file is in a format supported by an application that supports rights management, the recipient can open and interact with the file in that application. However, if the file is in a format that is unsupported by enlightened applications or such an application is unavailable, you can download a [lightweight viewer](#) that understands how to interpret the protection placed on the file and open it for viewing.

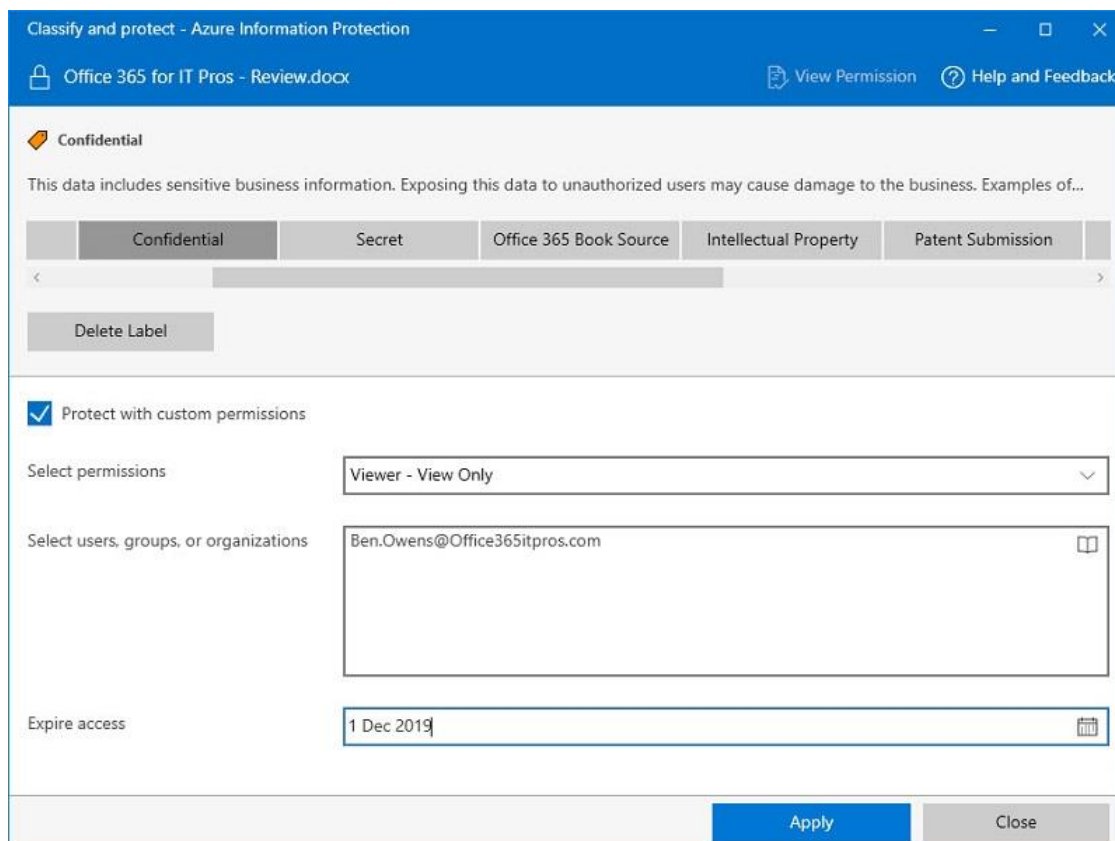

Figure 20-22: Applying a sensitivity label to a Windows file using the Unified Labeling client

As native support for sensitivity labels is available in the Office apps, installation of the unified labeling client on PCs is only necessary when you wish to assign labels to files stored outside Office 365 or to apply a label to a set of files selected in File Explorer (this action can also be performed through PowerShell).

**Disabling Classify and protect:** Some have asked if it is possible to disable the **Classify and protect** option so that it doesn't show up in File Explorer. It is possible by creating a new DWORD value called *LegacyDisable* at *HKEY\_CLASSES\_ROOT\AllFilesystemObjects\shell\Microsoft.Azip.RightClick*. Set the value to 0 (zero) to disable the option. Before doing this, remember that Classify and protect might be the only way that people can apply sensitivity labels to PDFs and other non-Office file types.

## Protected PDFs

[Microsoft and Adobe](#) collaborated to deliver a "native" integration of rights management protection for Adobe PDF documents. Native means that protection applied to PDF files uses the V1.7 of the ISO specification for PDF encryption. Applications that support the standard can open and process the protected content. Protection is unsupported for signed PDFs because this would break the method used to attest to the validity of the signatures.

Unlike earlier third-party implementations of rights-management protected PDFs, which use a PPDF file extension to show the encrypted nature of the files, native-protected files keep their PDF file extension.

To protect PDF files, you need to install the latest version of the [Unified Labeling Client](#). You can then protect PDFs using the **Classify and protect** option in File Explorer to choose a label or to assign custom permissions. You can also apply a label to a PDF using the *Set-AIPFileLabel* cmdlet. Because SharePoint Online can't process protected PDFs, the names of sensitivity labels applied to PDFs outside SharePoint Online do not appear in document views.

To access the content of protected PDFs, you must use a supported reader which understands both the ISO standard and how to display the assigned rights, such as Adobe Acrobat Reader (Microsoft's list of PDF readers that support Information Protection [is available online](#)). To use Acrobat, you need a recent version of Adobe Acrobat Reader or Reader DC and the [Microsoft Information Protection plug-in](#) (the plug-in is bundled with the Adobe installer from June 2022). Only Adobe Reader and not the Adobe Acrobat (paid-for) products support access to protected content. To have the Adobe products display information about the label assigned to protected PDFs, it's necessary to have a DWORD *bShowDMB* with a value of 1 at:

```
HKEY_CURRENT_USER\SOFTWARE\Adobe\Adobe Acrobat\DC\MicrosoftAIP
```

The Edge browser can open PDFs protected with sensitivity labels belonging to any tenant, if the user has the appropriate rights. However, although Edge displays a banner showing that a PDF is protected and tells the user what permission they have, it does not show any information about the assigned label.

Organizations can store protected PDFs in SharePoint Online or OneDrive for Business document libraries, but unless you use the Edge browser, you must download the files and use a supported viewer to view their content as the normal viewer used by SharePoint Online cannot decrypt the files. You can't apply, change, or remove sensitivity labels from PDFs stored in SharePoint Online or OneDrive for Business. Instead, you must download the file and process it with the unified labeling client, and then upload it again.

## PDFs Generated from Office Documents

The production versions of the Microsoft 365 enterprise apps (Word, PowerPoint, and Excel) do not create protected PDFs when they generate PDF files. However, from June 2022, the Office Insider builds (Beta Channel 2206 onward), create protected PDFs for the following actions:

- File – Save as PDF (unsupported for the PDF/A format).
- File – Export as PDF.
- Share – Send a Copy – PDF.

The Print to PDF option removes sensitivity label protection before it can generate a PDF. Because of this, the apps make the option unavailable if mandatory labeling is in force. In addition, password protection is unsupported for protected PDFs.

If the organization has earlier versions of the Office apps in use, protection can be applied to the PDFs generated by Office using the unified labeling client.

## Managing Sensitivity Labels with PowerShell

If you connect a PowerShell session to the compliance endpoint, you can access cmdlets to work with sensitivity labels. The easiest way to connect to the endpoint is to run the *Connect-IPSSession* cmdlet in the Exchange Online Management module. When connected, you can create and manage labels used for information protection and container management.

The *Get-Label* cmdlet returns the set of sensitivity labels defined in a tenant or the properties of an individual label. If encryption is enabled for a sensitivity label, its link to the underlying rights management template is in an object in the *LabelActions* property with the *Type* value set to "encrypt." The *LabelActions* property also holds the GUID for the label in the *TemplateId* field. In this example, we use the *Get-Label* cmdlet to fetch the properties of the Black Matter sensitivity label and then extract the rights definitions from its settings.

```
[PS] C:\> Connect-IPSSession
$Label = Get-Label -Identity "Black Matter"
$Rights = $Null
ForEach ($Action in $Label.LabelActions) {
    $Action = $Action | ConvertFrom-Json
    If ($Action.Type -eq "encrypt") {
        $Rights = $Action.Settings | ? {$_.Value -like "*Identity*"} | Select -ExpandProperty
Value | ConvertFrom-Json
    }
}
If ($Rights) { $Rights | Format-List }

Identity : BoardMembers@Office365itpros.com
Rights   : VIEW,VIEWRIGHTSDATA,OBJMODEL,DOCEDIT,EDIT,PRINT,EXTRACT,REPLY,REPLYALL,FORWARD

Identity : Black.Matter.Team@office365itpros.com
Rights   : VIEW,VIEWRIGHTSDATA,OBJMODEL,DOCEDIT,EDIT,REPLY,REPLYALL,FORWARD

Identity : Sanjay.K.Patel@office365itpros.com
Rights   : VIEW,VIEWRIGHTSDATA,OBJMODEL
```

The rights assigned in this label cover two groups and an individual user. The first set of sets equates to the co-author role. The second equates to the reviewer role and the last to the viewer role.

## Updating Rights in Sensitivity Labels

The *Set-Label* cmdlet updates label properties. For example, here's how to update the display name:

```
[PS] C:\> Set-Label -Identity Ultra -DisplayName "Ultra Confidential"
```

Another example is to use the *Set-Label* cmdlet to update rights assignments for a label. For instance, this command assigns a single set of rights to a domain and a separate set of rights to all authenticated users:

```
[PS] C:\> Set-Label -Identity "Ultra Confidential" -EncryptionRightsDefinitions
"quest.com:VIEW,VIEWRIGHTSDATA,DOCEDIT,PRINT; AuthenticatedUsers:
VIEW,VIEWRIGHTSDATA,OBJMODEL,DOCEDIT,EDIT,REPLY,REPLYALL,FORWARD"
```

The important thing to remember here is that if you run *Set-Label* to update the rights defined for a label, you overwrite the existing rights. It's therefore important that you retrieve the existing rights and include them in the set written back into the label. If you don't, anyone who currently depends on rights to interact with

content protected by the label will lose their access. You don't have to add rights for creators of documents and messages as they always have author rights.

The *New-Label* cmdlet is available to create new labels while the *Remove-Label* cmdlet deletes a label. As explained earlier, it's best not to remove a sensitivity label unless you are sure that the users have not applied the label to protect information. Usually, the better course is to remove the label from all label publishing policies to make it inaccessible to users. The label will continue to work but users cannot the label to new content.

Given the complexity of labels, especially those used with encryption, it is usually best to manage day-to-day updates through the Microsoft Purview Compliance portal and use PowerShell for common operations scripted to remove any chance of an error. For example, let's assume that a label protects content shared with partner organizations. You could:

- Maintain the list of partners in an Excel spreadsheet or other file.
- When a new partner is added, import the list of partner organizations from the file.
- Use the list to create rights definitions and add them to the label.

For more information on how to approach creating such a script, see [this article](#).

Once coded and tested, a process like this is invariably faster, more accurate, and less prone to error than performing a manual update through the GUI (it's also less boring). Any use of label cmdlets, like *New-Label*, *Set-Label*, and *Get-Label*, executed through PowerShell or the Microsoft Purview Compliance portal, is captured in events in the audit log and therefore can be analyzed to understand who is updating labels in the tenant.

## Removing Sensitivity Labels from SharePoint Online and OneDrive for Business Files

Global and SharePoint admins can run the *Unlock-SPOSensitivityLabelEncryptedFile* cmdlet to remove sensitivity labels with encryption from documents stored in SharePoint Online document libraries and OneDrive for Business accounts. The cmdlet is in the SharePoint Online module. It can only remove sensitivity labels belonging to the same tenant; it has no effect when run against documents protected by labels originating outside the tenant.

In effect, the unlock cmdlet delivers the same functionality available to rights management super-users when they use the *Set-AipFileLabel* cmdlet to remove labels from files stored in folders. Because SharePoint Online stores protected files in an unencrypted form (SharePoint applies encryption when users download documents), the cmdlet works by stripping the MIP metadata from documents.

The input parameters to the cmdlet are the full URL for the file and a justification for the removal of the label. These examples remove a label with encryption from files in a SharePoint Online document library and a OneDrive for Business account:

```
[PS] C:\> Unlock-SPOSensitivityLabelEncryptedFile -Justification "Needed to remove label"
-FileUrl https://office365itpros.sharepoint.com/sites/billing/Shared Documents/Invoice Tracking
2020.xlsx
[PS] C:\> Unlock-SPOSensitivityLabelEncryptedFile https://office365itpros-
my.sharepoint.com/personal/kim_akers_office365itpros_com/Documents/Planning.docx -Justification
"Needed to remove label from OneDrive files"
```

Some limitations exist. The only sensitivity labels removed by the cmdlet are those which:

- Include encryption using permissions assigned by an administrator (in other words, an administrator defines the rights for the label when creating or editing the label).
- Do not have user-defined permissions.
- Do not use Double-key encryption (DKE – see earlier section).

The unlock cmdlet doesn't do anything when it processes a file without a label or one with a label that doesn't include encryption.

## Removing Encryption from All Files in a Folder

The need often exists to remove protection from multiple files. Because it's focused on administrative activities, the SharePoint Online PowerShell module does not contain cmdlets to list files in a folder. Suitable cmdlets are available in the SharePoint PnP module. By combining the two we can:

- Connect to a target site and find all the documents in a target folder.
- Use the `Get-FileSensitivityLabelInfo` cmdlet to check each document for the presence of a sensitivity label with encryption.
- If a sensitivity label with encryption protects a document, remove it using the `Unlock-SPOSensitivityLabelEncryptedFile` cmdlet,

```
[PS] C:\> $SiteURL = "https://office365itpros.sharepoint.com/sites/BlogsAndProjects"
$FolderURL= "/Shared Documents/Blog Posts"
$UnLocks++
# Connect to PnP using modern authentication
Connect-PnPOnline -Url $SiteURL -Interactive
# Get all documents in the target folder
$FolderItems = Get-PnPFolderItem -FolderSiteRelativeUrl $FolderURL -ItemType File
Write-Host "Checking" $FolderItems.Count "documents to remove sensitivity labels with encryption"
ForEach ($Item in $FolderItems) {
    $ItemPath = $SiteUrl+$FolderUrl+"/"+$Item.Name
    $ProtectionStatus = Get-FileSensitivityLabelInfo -FileUrl $ItemPath
    If ($ProtectionStatus.ProtectionEnabled -eq $True) {
        Write-Host ("Removing {0} from {1}" -f $ProtectionStatus.DisplayName, $Item.Name )
        $UnLocks++
        Unlock-SPOSensitivityLabelEncryptedFile -FileUrl $ItemPath -JustificationText "Administrator
removed label"
    }
}
Write-Host "All Done." $UnLocks "documents unlocked"
```

When the cmdlet removes a sensitivity label from a file, SharePoint updates the name of the last user to modify a document to *System Account*. If you want to discover the account which ran the cmdlet to remove a sensitivity label, you should check the audit log to examine the *FileSensitivityLabelRemoved* events captured upon the removal of labels. The justification given by the user is captured in the audit event.

An example script [downloadable from GitHub](#) shows how to use a combination of PowerShell and Graph API calls to achieve better performance when the need exists to download large quantities of documents.

## Managing Labels Used for Container Management with PowerShell

Currently, you can't update the label settings applied to a container (Teams, Sites, or Groups) with PowerShell, but you examine the settings in the *LabelActions* property of the label. This property holds the label settings (like encryption, content marketing, and the site and group settings) in JSON format. The site and group settings for a label stored in *LabelActions* are in two sections:

- *protectgroup*: Privacy and external user access. The access type applied by this label is "Public" and group owners cannot invite guest users.
- *protectsite*: Access to SharePoint content from unmanaged devices. Group members can only access documents through online apps using managed devices.

The easiest way to view the label action settings is to extract the settings, convert them from JSON format, and list them like this:

```
[PS] C:\> $LabelActions = (Get-Label "Limited access").LabelActions | Convertfrom-JSON
$LabelActions | Select -ExpandProperty Settings
```

Key	Value
---	----
privacy	public
allowemailfromguestusers	false
allowaccesstoguestusers	false
disabled	false
allowfullaccess	false
allowlimitedaccess	true
blockaccess	false
disabled	false

Sometimes you need to check what labels apply specific controls on containers. This code shows how to build an array of labels with settings to block guest access to groups, teams, and sites. Each entry in the array contains the identifier (GUID) for the label and its display name.

```
[PS] C:\> $Labels = Get-Label
$LabelsBlockingGuests = @{}
ForEach ($Label in $Labels) { # Find out which labels apply blocks to guest users
    $LabelGuestAccess = $True
    $LabelActions = $Label.LabelActions | ConvertFrom-Json
    ForEach ($LabelAction in $LabelActions) {
        If (($LabelAction.Type -eq "protectgroup") -and ($Label.ContentType -Like "*Site*")) {
            $Settings = $LabelAction.Settings
            ForEach ($Setting in $Settings) {
                If ($Setting.Key -eq "allowaccesstoguestusers" -and $Setting.Value -eq "false") {
                    $LabelsBlockingGuests.Add([String]$Label.ImmutableId, $Label.DisplayName)}}
        }
    }
}
Write-Host "The following labels block guest access to Groups, Teams, and Sites"
$LabelsBlockingGuests | Format-Table Value
```

The array is useful in scenarios where it is necessary to check if the label assigned to a group will block guests.

```
[PS] C:\> $LabelDisplayName = $LabelsBlockingGuests.Item($Group.SensitivityLabel.Guid)
If ($LabelDisplayName -ne $Null) { Write-Host "The label assigned to" $Group.DisplayName "doesn't
allow guests"}
```

Another example is to extract the set of labels used for container management. In this case, we build a list with the label identifier, display name, and priority. You could use the list to check if a user has downgraded the sensitivity of a label assigned to a group, team, or site by comparing the priority of the existing label against the label they want to assign.

```
[PS] C:\> $Labels = Get-Label
$ContainerLabels = [System.Collections.Generic.List[Object]]::new()
ForEach ($Label in $Labels) {
    If ($Label.ContentType -Like "*UnifiedGroup*") { # It's a label for container management
        $DataLine = [PSCustomObject] @{
            LabelId      = $Label.ImmutableId
            DisplayName  = $Label.DisplayName
            Priority     = $Label.Priority }
        $ContainerLabels.Add($DataLine) }
}
```

**Label Actions and Advanced Settings:** PowerShell can update both normal and advanced Sensitivity label settings. The normal settings are the set visible when editing labels in the Compliance portal and are in the label's *LabelActions* property. Advanced settings are only accessible with PowerShell. Sometimes, Microsoft moves a setting (like a site's external sharing capability) from the advanced set and makes it available through the Compliance portal. When this happens, the setting moves into the set stored in the *LabelActions* property. The previous advanced setting remains in the label's properties, but the value of the setting in *LabelActions* takes precedence.

## Managing Sensitivity Labels for Containers with PowerShell

You can assign sensitivity labels to containers with PowerShell. Remember to use the GUID of a label instead of its display name. To assign a sensitivity label to a Microsoft 365 group, use the *Set-UnifiedGroup* cmdlet:

```
[PS] C:\> Set-UnifiedGroup -Identity "Banking Team" -SensitivityLabelId "9ec4cb17-1374-4016-a356-25a7de5e411d"
```

Assigning a sensitivity label updates the settings of the group as defined by the label. For instance, if you assign a label that blocks guest access, the group inherits that setting. *Set-UnifiedGroup* won't allow you to assign a sensitivity label to a group unless the group comes within the scope of a label publishing policy containing the label.

The *Set-SPOSite* cmdlet updates the sensitivity label for a SharePoint Online site:

```
[PS] C:\> Set-SPOSite -Identity "https://office365itpros.sharepoint.com/sites/dunesproject" -SensitivityLabel "9ec4cb17-1374-4016-a356-25a7de5e411d"
```

In this example, we search for a set of sites and apply the same sensitivity label to each site in the returned set. If you want to apply the sensitivity label to OneDrive for Business sites at the same time, *Get-SPOSite* will find those sites if you use the *-IncludePersonalSite \$True* parameter in the command.

```
[PS] C:\> $LabelGuid = "27451a5b-5823-4853-bcd4-2204d03ab477"
$Sites = Get-SPOSite -Limit All -Filter "URL -like 'Accounting'"
$Sites | ForEach-Object {Set-SPOSite $_.URL -SensitivityLabel $LabelGuid}
```

Instead of using the *Set-SPOSite* cmdlet to assign a sensitivity label to individual sites and processing multiple sites that way, the *Set-SPOTenant* cmdlet can assign a sensitivity label to multiple SharePoint Online sites. This method is faster when the tenant has more than a thousand sites:

```
[PS] C:\> $Sites | ForEach-Object {Set-SPOTenant $_.url -SensitivityLabel $LabelId }
```

*Set-SPOSite* does not allow assignment of a sensitivity label unless the target site comes within the scope of a label publishing policy containing the label. However, the error is silent, and you won't realize that the assignment failed unless you check the site properties afterward.

To remove labels from one site or a set of sites, use the *Set-SPOSite* cmdlet with the *RemoveLabel* parameter. For example, to remove the labels from the sites in the set used above, we'd run the command:

```
[PS] C:\> $Sites | ForEach-Object {Set-SPOSite $_.URL -RemoveLabel}
```

The *New-UnifiedGroup* and *New-SPOSite* cmdlets support adding a sensitivity label during the creation of a new group or SharePoint site. The *New-Team* and *Set-Team* cmdlets in the Teams PowerShell module have not yet been updated for sensitivity labels. When administrators assign labels to containers from one of the supported workloads, background synchronization processes make sure that the other workloads pick up the change. Yammer-based groups (communities) do not currently support sensitivity labels.

The Microsoft Graph Groups API also supports [assignment of sensitivity labels to Groups](#). However, apart from the MIP SDK, no public API is yet available to assign a sensitivity label to individual documents.

## Fetching Sensitivity Label Information for SharePoint Sites

To respond faster, when used to fetch a set of site objects, the *Get-SPOSite* cmdlet returns a limited set of properties. Sensitivity labels are not one of these properties, so if you want to find out which sites have labels, you must call *Get-SPOSite* to check each site. For example:

```
[PS] C:\> $Sites = Get-SPOSite -Limit All -Template Group#0
Foreach ($Site in $Sites) {
    $SiteDetails = Get-SPOSite -Identity $Site.URL
    If ($SiteDetails.SensitivityLabel.length -ne 0) {
        Write-Host "Site" $SiteDetails.Title "has sensitivity label" $SiteDetails.SensitivityLabel }}

```

## Controlling Default Sharing Links for Sites and Documents

When someone shares a document or folder, SharePoint Online or OneDrive for Business creates a sharing link. The link sets the scope (who can use the link) and permissions (what they can do). The sharing link inherits default settings for the scope and permissions from site settings or the tenant defaults. The default sharing settings can deliver a powerful hint to help people understand the level of confidentiality of information held in a site or individual document by guiding them to a certain mode of sharing. Although users can change a sharing link after SharePoint creates it, they often accept the default settings.

SharePoint administrators can configure the default sharing link settings for sites in the SharePoint admin center or by running the *Set-SPOSite* cmdlet with the *DefaultSharingScope* and *DefaultShareLinkPermission* parameters (which overrides the tenant defaults). This action can also be performed by configuring the advanced settings of a sensitivity label. Even better, the default sharing link settings held in a sensitivity label can apply to:

- SharePoint Online sites: Use the sensitivity label for container management and apply it to a site. The site inherits the settings from the label and overwrites any existing site settings.
- Documents: Apply the sensitivity label to a document. When someone shares the document, the default sharing link settings from the label take precedence over the site setting except when the site settings are more restrictive than the label settings. In that case, SharePoint Online uses the site settings.

Being able to apply default sharing link settings at a document level helps to protect documents stored in a site that should not be shared as widely as permitted by the site settings. For example, you might have a site holding project documents which can be shared with anyone in the organization except for project pricing files which must be restricted to specific people. In this scenario, administrators apply a sensitivity label to the site with a default sharing link settings to allow edit access for anyone in the organization while the pricing documents use a different label whose settings generate sharing links limited to specific people. Being able to control the default sharing link settings through sensitivity labels also helps when users store confidential documents in OneDrive for Business, again because users are likely to accept the default or at least think more about how they share information if they must adjust the sharing link settings before they share a document.

You can only update default sharing link settings for sensitivity labels using the PowerShell *Set-Label* cmdlet. First, run the *Connect-IPPSession* cmdlet from the Exchange Online management module to connect to the compliance endpoint. You can then use the *Set-Label* cmdlet to update sensitivity label settings. These settings are available:

- **DefaultSharingScope** defines the scope of the sharing link. The supported values are *SpecificPeople*, *Organization*, or *Anyone*.
- **DefaultShareLinkPermission** controls what a sharing link recipient can do with a file. The two available options are *Edit* and *View*.
- **DefaultLinkToExistingAccess** is *True* or *False* (default *False*). If set, this overwrites any other sharing link control and sets the link scope to people who already have access.

You can update default sharing link settings separately or together. For example, these commands set the default sharing scope and permission in two steps:

```
[PS] C:\> Set-Label -Identity 'Guest Access' -AdvancedSettings @{DefaultSharingScope = "SpecificPeople"}
[PS] C:\> Set-Label -Identity 'Guest Access' -AdvancedSettings @{DefaultShareLinkPermission = "Edit"}
```

Or set the two values in one command:

```
[PS] C:\> Set-Label -Identity 'Non-Business Use' -AdvancedSettings @{DefaultShareLinkPermission = "Edit"; DefaultSharingScope = "Anyone"}
```

To check the sharing link settings for a sensitivity label, run the *Get-Label* cmdlet. Values only appear for advanced settings after an update:

```
[PS] C:\> Get-Label "Non-Business Use" | Select-Object -ExpandProperty Settings
[contenttype, Site, UnifiedGroup]
[tooltip, Site, team, or group holding information that is confidential to the organization but can be shared with guest users. Private access.]
[displayname, Guest Access]
[defaultsharelinkpermission, Edit]
[defaultsharingscope, Anyone]
```

To enable *DefaultLinkToExistingAccess*, run:

```
[PS] C:\> Set-Label -Identity 'Confidential Access' -AdvancedSettings @{DefaultLinkToExistingAccess = "True"}
```

Like any other changes made to sensitivity labels, it can take up to 24 hours before SharePoint Online respects updates to the default sharing link settings.

## Updating Site Sharing Permissions

Another advanced setting for sensitivity labels controls the sharing permissions for sites. In the SharePoint browser interface, this option is available through *Site Permissions – Site Sharing*. Three settings are available:

- **MemberShareAll:** Site owners and members can share files, folders, and the site. People with edit permissions can share files and folders. This is usually the default setting assigned to new sites.
- **MemberShareFileAndFolder:** Site owners and members, and people with edit permissions, can share files and folders, but only the site owners can share the site.
- **MemberShareNone:** Only site owners can share files, folders, and the site.

To assign a new site sharing permission, run the *Set-Label* cmdlet and update the *MembersCanShare* advanced setting. For example:

```
[PS] C:\> Set-Label -Identity 'General Access' -AdvancedSettings @{MembersCanShare='MemberShareFileAndFolder'}
```

The ability to set sharing permissions for sites through sensitivity labels is currently in preview.

## Advanced Policy Settings

Management of most sensitivity label policy settings occurs through the Microsoft Purview Compliance portal. The unified labeling client supported several [advanced policy settings](#) (or “custom configurations”). Over time, Microsoft is updating sensitivity label policies to support some of the advanced settings in either the GUI or through PowerShell. For example, the label policy created earlier defines the default label to be “Public.” We can create a policy setting to force Outlook to use a different label in the GUI or with PowerShell as follows:

```
[PS] C:\> Set-LabelPolicy -Identity "General Sensitivity Policy" -AdvancedSettings @{OutlookDefaultLabel="2fe7f66d-096a-469e-835f-595532b63560"}
```

To check the normal and advanced settings for a policy, use the *Get-LabelPolicy* cmdlet as shown below. We can see that Outlook uses a different default label to the default label defined for documents, and that container support is enabled to allow super-users to use the *Set-AipFileLabel* cmdlet to remove labels from compressed files.

```
[PS] C:\> (Get-LabelPolicy -Identity "General Sensitivity Policy").Settings
[requireddowngradejustification, true]
[mandatory, true]
[outlookdefaultlabel, 2fe7f66d-096a-469e-835f-595532b63560]
[defaultlabelid, 27451a5b-5823-4853-bcd4-2204d03ab477]
[siteandgroupmandatory, false]
[enablecontainersupport, True]
[disablemandatoryinoutlook, True]
```

Outlook for Windows, Outlook for Mac, Outlook mobile, and OWA read and respect policy settings for:

- **DisableMandatoryInOutlook:** If the sensitivity label policy dictates mandatory labeling, this setting allows Outlook to avoid the need to assign labels to new messages. Set to False if Outlook should apply mandatory labeling, or True to disable mandatory labeling. Even if you disable mandatory labeling for Outlook, it continues to be mandatory for documents created in Word, PowerPoint, and Excel.
- **OutlookDefaultLabel:** If the sensitivity policy dictates mandatory labeling, this setting allows Outlook clients to use a different default label to the one applied to documents (as defined in the *DefaultLabelId* policy setting). The setting contains the GUID (label identifier) for the default label used by Outlook. Note that if a default label is defined for Outlook and mandatory labeling is required (even if disabled for Outlook), Outlook applies its label to all new messages.

Neither PowerShell nor the compliance endpoint validates the name of the advanced setting you update. If you misspell a parameter, PowerShell writes it into the label policy. If you pass an incorrect value, it will end up in the policy too. Always double-check the values you plan to use before updating a policy.

## Locale Settings for Label Names and Tooltips

By default, applications display the name and tooltip defined for a sensitivity label. If you work inside a monolingual organization, this shouldn't cause a problem as the default language is likely the one used by everyone. Inside a multilingual organization, it's a good idea to assign locale-specific values for label names and tooltips. PowerShell is the only supported method to update language values for a sensitivity label. For example, here's how to create a set of locale-dependent display names for the Confidential Access label used for container management. The code does the following:

- Define the label to update.
- Define an array holding the set of supported languages.
- Define an array holding the translated display name for the label in the supported languages.
- Define an array holding the translated tooltips for the label in the supported languages.
- Build JSON structures for the display names and tooltips.
- Run *Set-Label* to update the label settings.

This approach is much easier than the alternative of inputting all the values in one long command.

```
[PS] C:\> $Label = "Confidential Access"
$Languages = @("en-en", "fr-fr","it-it","de-de")
$DisplayNames=@("Confidential Access", "Accès confidentiel","Accesso riservato","Vertraulicher Zugang")
$Tooltips = @("Used for corporate confidential information","Utilisé pour les informations confidentielles de l'entreprise","Utilizzato per informazioni riservate aziendali","Wird für vertrauliche Unternehmensinformationen verwendet")
$DisplayNameLocaleSettings = [PSCustomObject]@{LocaleKey='DisplayName';
Settings=@(
@{key=$Languages[0];Value=$DisplayNames[0];}
```

```
@{key=$Languages[1];Value=$DisplayNames[1];}
@{key=$Languages[2];Value=$DisplayNames[2];}
@{key=$Languages[3];Value=$DisplayNames[3];}}
$TooltipLocaleSettings = [PSCustomObject]@{LocaleKey='Tooltip';
Settings=@(
@{key=$Languages[0];Value=$Tooltips[0];}
@{key=$Languages[1];Value=$Tooltips[1];}
@{key=$Languages[2];Value=$Tooltips[2];}
@{key=$Languages[3];Value=$Tooltips[3];}})
Set-Label -Identity $Label -LocaleSettings (ConvertTo-Json $DisplayNameLocaleSettings -Depth 3 -
Compress),(ConvertTo-Json $TooltipLocaleSettings -Depth 3 -Compress)
```

The key thing is to make sure that the set of language values for the display name matches the set of language values for the tooltips. In the example, both sets have values for default, en-us (U.S. English), French, Italian, and German. If you define a tooltip without a matching display name, the cmdlet will fail to update the label. The length of the tooltips makes them harder to input, so it's wise to compose the command outside PowerShell and paste it into the console.

## Setting Label Colors

The Office click-to-run and online applications support the display of different colors to help users identify labels. Administrators can assign colors to labels through the Microsoft Purview Compliance portal and or PowerShell by running the *Set-Label* cmdlet. For example:

```
[PS] C:\> Set-Label -identity "Confidential" -AdvancedSettings @{color="#008b8b"}
```

The *Set-Label* cmdlet accepts the color for a label in a hex triplet code giving the red, green, and blue combination to build the color. The example above assigns the code for dark cyan to the label. See [this page to interpret hex color codes](#). This code interprets the color settings for labels and translates the hex value using a hash table.

```
[PS] C:\> # Create a hash table to translate color hex values to display values.
$Colors = @{
    "000000" = "Black"
    "0000ff" = "Blue"
    "ff0000" = "Red"
    "ffc0cb" = "Pink"
    "ff8c00" = "Orange"
    "a80000" = "Dark Red"
    "8b0000" = "Darker Red"
    "317100" = "Dark Green"
    "0078d7" = "Dark Blue"
    "8a2be2" = "Bright Violet"
}
$Labels = Get-Label | Select DisplayName, Settings #Fetch label settings
ForEach ($L in $Labels) {
    $ColorFound = ($L.Settings | ? {$_ -match "color"})
    If ($ColorFound) {
        Try {
            $ColorCode = $ColorFound.ToString().Split("#")[1].Split(" ")[0] ; $ColorDisplay =
$Colors[$ColorCode]
            Write-Host "Label" $L.DisplayName "Hex color code is" ("#" + $ColorCode) ("(" +
$ColorDisplay + ")") }
        Catch {
            Write-Host "Error reading configuration for label" $L.DisplayName }
    }
}
```

Applications normally use the Calibri font when listing available sensitivity labels. You can change this by adding an advanced setting to specify which font to use. For example:

```
[PS] C:\> Set-Label -id "Black Matter" -AdvancedSettings @{fontname="Arial"}
```

# PowerShell for Rights Management

If you want to manage the protection service with PowerShell, you must download and install the [AIPService PowerShell Module](#) from the PowerShell gallery (or update the module to make sure that you have the latest release). After installing the module, you can connect to the service on an ad-hoc basis or include commands to connect to the service in your PowerShell profile. When you connect to the service, you can run the `Get-AipService` cmdlet to discover if protection is active (enabled) for the tenant. If the service is not enabled, you won't be able to protect information.

```
[PS] C:\> Import-Module AipService
[PS] C:\> Connect-AipService
A connection to the Azure Information Protection service was opened.
[PS] C:\> Get-AipService
Enabled
```

## Administrator Role for the AIP Service

Your account must have administrative rights for the rights management service before you can run the `Connect-AipService` cmdlet to connect PowerShell to the service. Accounts have administrative rights if they are:

- A global administrator for the tenant.
- A global administrator for the Azure tenant.
- Granted administrator access with the `Add-AipServiceRoleBasedAdministrator` cmdlet. For example, this command grants administrator access to the Kim Akers account. You'll see an error if the account already holds the role.

```
[PS] C:\> Add-AipServiceRoleBasedAdministrator -EmailAddress Kim.Akers@Office365itpros.com
```

To check the current list accounts assigned the AIP Service administrator role, run the `Get-AipServiceRoleBasedAdministrator` cmdlet:

```
[PS] C:\> Get-AipServiceRoleBasedAdministrator | Format-Table DisplayName, Role, EmailAddress
```

DisplayName	Role	EmailAddress
Kim Akers	GlobalAdministrator	SMTP:Kim.Akers@office365itpros.com
Marc Vilas	GlobalAdministrator	SMTP:Marc.Vigneau@office365itpros.com
James Ryan	GlobalAdministrator	smtp:JRyan@Office365itpros.com

The latest version of the AIPService module can [use certificate-based authentication](#) to support scenarios like fetching log information for ingestion into SIEM systems.

## Super-Users

Super-users are accounts that can decrypt any protected content. On-premises deployments often use super-user permissions to decrypt content to allow examination as messages pass through the Exchange transport service or when they review items following retrieval by eDiscovery searches. Assigning highly privileged access like super-user status is something that needs control, restricted to as few people as possible, and audited to track the use of super-user privileges.

However, the cloud is a very different environment. It is under Microsoft's control and tenant administrators do not have access to servers and other basic infrastructure elements that they could use to compromise information. Because Office 365 is a locked-down infrastructure, Microsoft runs a different regime where components decrypt protected content automatically. Transport rules can access protected content, discovery searches uncover protected content with ease, and journaling generates unencrypted reports. You do not

need to nominate any account as a super-user to make any standard functionality in Exchange Online or SharePoint Online work.

A situation might exist where you need to assign super-user status to an account to allow it to access encrypted content. For example, you might recover a set of protected Word documents left by an ex-employee that investigators need to review. Another example is where an eDiscovery search recovers a set of protected documents. Microsoft 365 Search can find protected content, but files remain encrypted when exported in the search results. In both instances, a super-user can decrypt the protected documents. Super-users are even able to decrypt documents if a tenant archives the sensitivity labels used for protection or after a document expires. The only time a super-user is unable to decrypt a document is after the deletion of a template. If the template does not exist, decryption is impossible.

You must enable the super-user feature before you can nominate accounts to be super-users. To enable or disable the super-user feature, first, load the protection cmdlets into a PowerShell session and connect to the rights management service. The set of commands to enable or disable the super-user feature are:

```
[PS] C:\> Connect-AipService
Enable-AipServiceSuperUserFeature
The super user feature is enabled for the Azure Information Protection service.

Disable-AipServiceSuperUserFeature
The super user feature is disabled for the Azure Information Protection service.
```

After enabling the super-user feature, you can add accounts to the super-user list. The email address that you pass must be valid for a user account belonging to the tenant, including those synchronized from on-premises Active Directory. You can add multiple users at one time, separating each email address with a comma. You'll receive an error if you try to add a user who is already on the super user list.

```
[PS] C:\> Add-AipServiceSuperUser -EmailAddress Oisin.Johnston@Office365ITPros.com
Oisin.Johnston@Office365ITPros.com was added to the list of super users for the Azure Information Protection service.
```

The other commands used to manage super-users are straightforward. *Get-AipServiceSuperUser* returns a list of the current accounts that have super-user privilege. Normally this list should be empty and the presence of any account on the list should have justification for the status. To remove an account from the super-user list, run the *Remove-AipServiceSuperUser* command as shown below:

```
[PS] C:\> Remove-AipServiceSuperUser -EmailAddress Oisin.Johnston@Office365ITPros.com
```

Information Protection logs all additions and removals of super users. You can retrieve this information from the AIP Admin log (but not in the Office 365 audit log). This example shows how to download the admin log for the last seven days.

```
[PS] C:\> Get-AipServiceAdminLog -Path "C:\Temp\AipAdminLog.log" -FromTime (Get-Date).AddDays(-7)
```

## Super-User Group

You can also add a super-user group by running the *Set-AipServiceSuperUserGroup* cmdlet. The address specified must point to a Microsoft 365 group or a security group.

```
[PS] C:\> Set-AipServiceSuperUserGroup -GroupEmailAddress MIPSuperUsers@Office365itpros.com
```

If you define a super-user group, the members of the group are all considered super-users. If the group is created with the ability to hold Azure AD roles (something that can only be done when a group is created in the Azure AD portal), it can be used with Azure AD Privileged Identity Management to assign super-user permission for limited periods to individual group members. In other words, instead of having unrestricted super-user access to any protected content in the tenant, the members of the super-user group can only access content when they receive access for a defined period.

## App-Based Super User Permission

The Microsoft Information Protection SDK supports the *Content.SuperUser* permission to allow Graph-based apps access to any protected content in a tenant. Like any other Graph permission, the app must be assigned the permission and consent granted by an administrator before the super user access can be used. See [this page](#) for more information.

## Using PowerShell to Protect Files

A set of PowerShell cmdlets is available to protect and apply labels to one or more files through scripting. These cmdlets are only available when the unified labeling client is present on a Windows workstation. The cmdlets call code in the client to add or remove protection to or from files. Authentication to use the cmdlets is through the account used to sign into the client.

### Retrieving Protection Information

The *Get-AipFileStatus* cmdlet returns protection properties for files, including the classification and templates applied to files.

First, let's check for files in a folder that have a label. Note that the cmdlet cannot return the status for a file if it is open in an application.

```
[PS] C:\> Get-AipFileStatus -Path "C:\Office 365 for IT Pros - Eighth Edition Files" | ?
{$_ .MainLabelId -ne $Null} | Format-Table FileName, MainLabelName, LabelDate
```

Another example shows how to find files in a folder protected by a specific template.

```
PS] C:\> Get-AipFileStatus -Path "C:\Office 365 for IT Pros - Eighth Edition Files" | ?
{$_ .MainLabelName -eq "Viewer - View Only"} | Format-Table FileName, MainLabelName
```

### Applying Protection to Files

To apply a label to files, we need to know the GUID used for the label. The easiest way to get this is to capture the label identifier from a file that we know has the desired classification.

```
[PS] C:\> $LabelId = (Get-AipFileStatus "C:\Temp\Important Staff.XLSX").MainLabelId.Guid
```

You can also find the GUID in the *Label ID* property of a label when viewed through the Microsoft Purview Compliance portal or by running the *Get-Label* cmdlet (after connecting to the compliance endpoint):

```
[PS] C:\> $LabelId = (Get-Label -Identity "Secret").GUID
```

Every use of the *Get-Label* cmdlet creates an audit event in the Office 365 audit log.

We can now use the label identifier to apply the same classification to one or more files. In this case, we look for all Word documents in a folder and its subfolders that do not yet have a label and apply the selected label to those files.

```
[PS] C:\> $TargetLocation = "c:\Temp\"
$TargetFiles = "*.docx"
$Files = (Get-ChildItem ($TargetLocation + $TargetFiles) -File -Recurse)
ForEach ($F in $Files) {
    $FileName = $TargetLocation + $F.Name
    $FileStatus = (Get-AipFileStatus -Path $FileName)
    If ($FileStatus.IsLabeled -eq $False) {
        Set-AIPFileLabel -Path $FileName -Label $LabelId }
}
```

Applying a label to a file updates the file and it can take several seconds to process a file. Be careful when you apply labels to a folder holding many files.

## Reporting Labeled Files

We can use the same technique to generate a report about the labeled and protected files in a folder, including folders holding synchronized files from a SharePoint Online or OneDrive for Business library. This code looks for any Office documents in a folder and then checks each file for the presence of a label. If a label is found, we extract details of the label and any associated rights management template. Note that the *Get-RMSTemplate* cmdlet is available after connecting to Exchange Online.

```
[PS] C:\> $Report = [System.Collections.Generic.List[Object]]::new() # Create output file for report
$Files = (Get-ChildItem "c:\temp\" -Include *.docx, *.xlsx, *.pptx -Recurse)
ForEach ($F in $Files) {
    $FileName = "c:\temp\"+ $F.Name
    $TemplateName = $Null
    $Status = (Get-AipFileStatus -Path $FileName)
    If ($Status.IsLabeled -ne $False) {
        If ($Status.RmsTemplateId -ne $Null) {
            $TemplateId = [GUID]($Status.RMSTemplateId)
            $TemplateName = (Get-RMSTemplate -Identity $TemplateId.Guid -ErrorAction
SilentlyContinue).Name
            If ($TemplateName -eq $Null) {$TemplateName = $Status.MainLabelName }
        }
        $ReportLine = [PSCustomObject]@{
            File           = $F.Name
            IsLabeled      = $Status.IsLabeled
            LabelId       = $Status.MainLabelId
            Label         = $Status.MainLabelName
            Date          = Get-Date($Status.LabelDate) -format g
            RMSGuid       = $Status.RMSTemplateId
            RMSTemplate   = $TemplateName
            Owner         = $Status.RMSOwner }
        $Report.Add($ReportLine)}
}
$Report | Export-CSV -NoTypeInfo c:\Temp\LabeledFiles.csv
```

The output for an individual file that has a sensitivity label with protection is:

```
File       : ABPs and Teams.docx
IsLabeled  : True
LabelId    : 81955691-b8e8-4a81-b7b4-ab32b130bff5
Label      : Secret
Date       : 13 Nov 2018 12:29:42
RMSGuid    : c7fc2174-097c-4123-9cad-15f1a32cb145
RMSTemplate : Secret
Owner      : Tony.Redmond@office365itpros.com
```

After processing the files, the script writes the information collected into a CSV file that can be opened and analyzed with Excel or Power BI.

## Removing Labels

To remove a sensitivity label from a document, run the *Set-AipFileLabel* cmdlet and specify the *RemoveLabel* parameter. You must also give a reason for the removal of the label. This command only works when:

- The logged-in account is an AIP super user.
- The target file is not open in any other application.
- The unified labeling client is on the PC. If you don't install the client, the *AzureInformationProtection* module will not load with the *AIPService* module and you can't run the *Set-AipFileLabel* cmdlet.

For example:

```
[PS] C:\> Set-AipFileLabel "C:\Temp\Important Stuff.docx" -RemoveLabel -JustificationMessage "Label
no longer necessary"
```

Before a super-user can run the *Set-AipFileLabel* cmdlet to remove protection from compressed containers like PST, MSG, ZIP, or RAR files, you must update the advanced settings of the label policy which applies to the super-user account to enable container support. This command is an example of enabling container support for a label policy:

```
[PS] C:\> Set-LabelPolicy -Identity "General Sensitivity Policy" -AdvancedSettings
@{EnableContainerSupport="True"}
```

The *Set-AIPFileLabel* cmdlet only works against items protected with Microsoft Information Protection encryption. It doesn't work against items messages protected with S/MIME, even if a sensitivity label applies S/MIME to an item.

## Processing Protected Documents Found in Content Searches

As an example of how to use the PowerShell cmdlets, let's assume that your organization must respond to a GDPR Data Subject Request (DSR). The Microsoft Purview Compliance portal can create and process DSRs. In this context (see Chapter 18), a DSR is a special form of eDiscovery case that depends on one or more content searches to find information relating to a named individual (the data subject). To satisfy a DSR, we need to find all content relating to a data subject. Protected messages in Exchange Online mailboxes are decrypted when exported by a content search; protected documents stored in SharePoint Online and OneDrive for Business libraries are not.

Before the organization can deliver copies of documents found by searches to the data subject, someone must review the content to make sure that the documents are related to that person. This means that protected documents found by searches must be decrypted to allow the check to proceed. In addition, there's no point in giving someone a set of protected documents that they cannot read.

A content search can export protected documents. When you export the results, you nominate a target folder to receive copies of the found files. Under the target folder, a folder (named after the date and time of the search) holds the search results, including the export summary, manifest, and a folder called SharePoint. Inside the SharePoint folder are folders for each site where the search found items and folders navigating to the point in the site where the search found the content. The path to such a folder might be something like this:

```
C:\Temp\Search for documents_Export\06.05.2018-1106AM\SharePoint\GDPR Planning Mark
II\gdprplanningmarkii\Shared Documents\General
```

The best approach is to gather all the protected documents found by a search in a single folder and process them there. The method used is to examine each file in the target folder and remove the protection if it exists. In this example, after running the *Connect-AIPService* cmdlet to connect to the rights management service with an account granted super user permission, we can form a collection of the files in the target folder and then loop through the set to find any that are protected. We then use the *Set-AipFileLabel* cmdlet to remove the protection.

```
[PS] C:\> $TargetFolder = "C:\Temp\Search for documents_Export\06.05.2018-1106AM\SharePoint\GDPR
Planning Mark II\gdprplanningmarkii\Shared Documents\General"
$Documents = Get-ChildItem -File $TargetFolder
ForEach ($D in $Documents) {
    $ProtectStatus = Get-AipFileStatus -Path $D.FullName
    If ($ProtectStatus.RMSTemplateId -ne $Null) {
        Write-Host $D.Name "is protected with" $ProtectStatus.RMSTemplateName
        $Message = $ProtectStatus.RMSTemplateName + " removed for GDPR DSR"
        Set-AipFileLabel -Path $D.FullName -RemoveLabel -JustificationMessage $Message }
}
```

The output is something like:

```
APC123.docx is protected with Intellectual Property
SPO Protected Content Test.docx is protected with Patent Submission
```

**FileName**

-----

C:\Temp\Search for documents\_Export\06.05.2018-1106AM\SharePoint\GDPR Planning Mark II\gdprplanningmarkii\Shared Documents\General...

C:\Temp\Search for documents\_Export\06.05.2018-1106AM\SharePoint\GDPR Planning Mark II\gdprplanningmarkii\Shared Documents\General...

When all the protected files are unprotected, investigators can review the document content to decide whether to release files as part of the response to the DSR. The same problem of how to deal with protected documents exists for any content search. Remember to remove the account from the list of super users after completing the decryptions.

## Using Microsoft Defender for Cloud Apps to Protect Office 365 Content

[Microsoft Defender for Cloud Apps](#) (MDCA) is a cloud access security broker (CASB) that can ingest and act upon [Office 365 audit information](#). The current set of supported apps includes:

- SharePoint Online.
- OneDrive for Business.
- Exchange Online.
- Teams.
- Dynamics 365.

MDCA is designed to give administrators insight into security-related events for a tenant. Given the number of events that even a small tenant can generate, automation through policies that act when specific criteria are matched is the best way to manage common conditions. For example, what action should happen when someone shares a file outside the tenant or creates a new document in a confidential site. If [Azure Information Protection is integrated with MDCA](#), MDCA retrieves the list of available labels in the tenant hourly, and adding a protection label to Office documents and PDF files is a supported action. Using this capability means that you can automatically apply protection to files matching policy criteria as users interact with them. On the basis that it should not override a decision made by a user, MDCA only applies a label if protection doesn't already exist on a file.

MDCA does not apply protection as users add files to Office 365. Instead, as MDCA ingests events from the Office 365 audit log, it looks for events (like document creation or modification) matching the criteria set in its policies and applies labels as necessary. The elapsed time between something happening a workload and a response occurring in MDCA depends on the ingestion of events from the audit log and the processing of those events in MDCA queues. Depending on the load on the service, the exact time will vary. For example, it might take between ten and twenty minutes before MDCA applies a label to a new file created in a SharePoint document library. If needed to protect an important file overlooked by a policy, an administrator can apply a label to a file from the MDCA dashboard.

The actions taken by MDCA to label files are visible in the Investigate section of its dashboard. You can apply filters to create queries to identify activity for specific applications, users, data ranges, and so on.

MDCA isn't free, but if you are concerned about protecting confidential Office documents stored in SharePoint Online or OneDrive for Business, it's hard to ignore the advantages of using policy-driven application of protection to sensitive content. You could take the manual approach and rely on individual users to do the right thing to protect their documents, but policy-driven automation invariably delivers a more reliable outcome.

# Microsoft Information Protection Auditing

Taking the necessary steps to make protection available to users is one step. Knowing that people use technology to protect important content is another. Microsoft Information Protection captures a wide range of audit data covering [most protection activities](#), such as someone applying a sensitivity label to a document or reading a protected document (but not protected messages). In addition, using the [AIP Scanner](#) generates some discovery actions when it scans sources to find files. Administrators can access the audit data through:

- The Activity Explorer in the Microsoft 365 admin center.
- The Audit feature in the Microsoft 365 admin center.
- The PowerShell `Search-UnifiedAuditLog` cmdlet.

The audit log ingests events for sensitivity labels with the other events generated by workloads. See Chapter 21 for information about how to retrieve and analyze data from the audit log. A [script downloadable from GitHub](#) illustrates how to interpret the content of the events logged for sensitivity label actions.

## Audit Records Captured for Office Applications

When users can assign, remove, or change sensitivity labels to documents using the Office (Word, PowerPoint, and Excel) apps, Microsoft Information Protection captures events for these actions. The events are:

- **SensitivityLabelApplied:** A site owner or administrator applies a sensitivity label to a SharePoint site.
- **FileSensitivityLabelApplied:** A user applies a sensitivity label to an Office document.
- **FileSensitivityLabelChanged:** A user changed a sensitivity label (upgrade or downgrade) for an Office document.
- **FileSensitivityLabelRemoved:** A user removed a label sensitivity from an Office document (in an app or with PowerShell).
- **DocumentSensitivityMismatchDetected:** A mismatch occurs because the sensitivity label applied to a document is higher than the level of sensitivity of the label applied to the site. The `SHAREPOINT\system` account generates the event when it detects the mismatch for a new or edited document.

The desktop versions of Word, Excel, and PowerPoint generate a different set of events:

- **SensitivityLabelApplied:** A user applies a sensitivity label to an Office document. This event differs from that logged for a site because its record type is `SensitivityLabelAction` rather than `SharePoint`.
- **SensitivityLabeledFileOpened:** A user opens a protected Office document on a workstation.
- **SensitivityLabeledFileRenamed:** A user generates a new version of a protected Office document by renaming the file.
- **SensitivityLabelRemoved:** A user removes a sensitivity label from an Office document. Office 365 also captures this event when a user edits a labeled file stored on a local device (not a copy synchronized by OneDrive).

Outlook desktop generates a `MipLabel` event when a user applies a sensitivity label to a message. The exception is when the user protects the message with one of the standard Office 365 Message Encryption templates (Encrypt Only or Do Not Forward). In these cases, Outlook treats the protected messages as if they are documents and logs `SensitivityLabelApplied` events. By contrast, OWA generates `MipLabel` events even when messages use OME. This is because Outlook can apply label-based encryption on the workstation whereas OWA uses the server to encrypt messages.

The Office mobile apps do not generate events when they apply sensitivity labels to messages or documents. In addition, the audit log does not capture events when third-party applications or the unified labeling client apply sensitivity labels to non-Office documents.

**Track that document!** Protected documents usually hold some form of confidential information, and it is good to know who has access to that information and to be able to revoke access if needed. To meet this need, users can track the progress of protected documents by signing into the [document tracking site](#). The ability to track documents is a premium feature (tracking of email messages is unsupported). For more information, see [this page](#). This feature will become more interesting when it is integrated into the Microsoft Purview Compliance portal. Microsoft hasn't said when this will happen.

## Cloud Exit for Encrypted Content

A "cloud exit" is when an organization decides to move some or all its content from a cloud service to some other platform. The other platform could be on-premises or another cloud service. An organization might need to perform a cloud exit after deciding to move all processing back to on-premises servers, to a competing service like Google Workspace, or even temporarily to regain access to content during a major outage. Tenant-to-tenant migrations also need to process protected content before moving data from the source to the target tenant to make sure that users can continue to access the content after they receive new user principal names in that tenant. The bottom line is that organizations that use rights management to protect content move to a new platform, they must do some up-front preparatory work to be able to move protected content to the target platform and maintain access. This often involves the decryption of large numbers of items.

The cloud exit process differs depending on if you use a Microsoft managed key (MMK) or have a company-owned encryption key (HYOK), and is described in [this post by the Information Protection team](#). The majority of Office 365 tenants that use MIP do so with an MMK. To move back on-premises, these organizations must export the keys (TPD) and then import them into an Active Directory rights management server before they can transfer and decrypt the protected content. This is not an operation that happens overnight, so it's necessary to do some up-front planning and preparation. It's also wise to export your tenant keys so that you always have access to this data should a problem arise.

In scenarios where organizations need to decrypt protected content before moving to a new platform, they can use the following approaches to decrypt information stored in Exchange Online, SharePoint Online, and OneDrive for Business:

- The *Set-AipFileLabel* PowerShell cmdlet and a super-user account to remove labels from files.
- The *Unlock-SPOSensitivityLabelEncryptedFile* and a SharePoint administrator account to remove labels from files stored in SharePoint Online or OneDrive for Business. See [this article](#) for an example.
- A content search to find and export protected Exchange Online messages (including protected attachments). Core eDiscovery decrypts the messages during the export process and can generate a separate PST for each mailbox.
- Advanced eDiscovery to find and export protected Office documents stored in SharePoint Online and OneDrive for Business.

None of these methods are fast, especially when tens of thousands of items are involved. They can only deal with content protected by Microsoft encryption technology (sensitivity labels and OME) and not with any other third-party encryption mechanism.

Temporary cloud exits might be necessary to access protected content in the case of an outage. For instance, if you use a third-party backup service to copy Exchange Online mailboxes, then restoring mailboxes to a usable state requires the decryption of any protected messages. Without access to a rights management server and the tenant keys, the mailbox might be restored, but none of the protected content is accessible.

# Chapter 21: Managing Auditing and Reporting

**Tony Redmond**

Microsoft 365 gathers audit information about user and system actions to track the interaction with workloads to add, update, and remove data. This chapter reviews how the audit system gathers audit events from multiple sources into one repository for administrators to query in multiple ways, including Office 365 Cloud App Security and ISV products. We also consider the question of how best to generate reports about user activity and consider the value delivered by the reports included in the standard tools and third-party reporting solutions. Finally, we review communications compliance policies and information barrier policies, two Microsoft Purview solutions that can help Microsoft 365 tenants control the use of information within their organization.

## Auditing Framework

The ability to reliably audit user and administrative operations is an important part of any compliance strategy. Although it is easy to enable auditing for a single workload, creating a common infrastructure to process and store auditing data from many different workloads is more challenging. This is especially true when lines blur between workloads when new applications such as Groups, Teams, and Planner integrate components and data from multiple workloads.

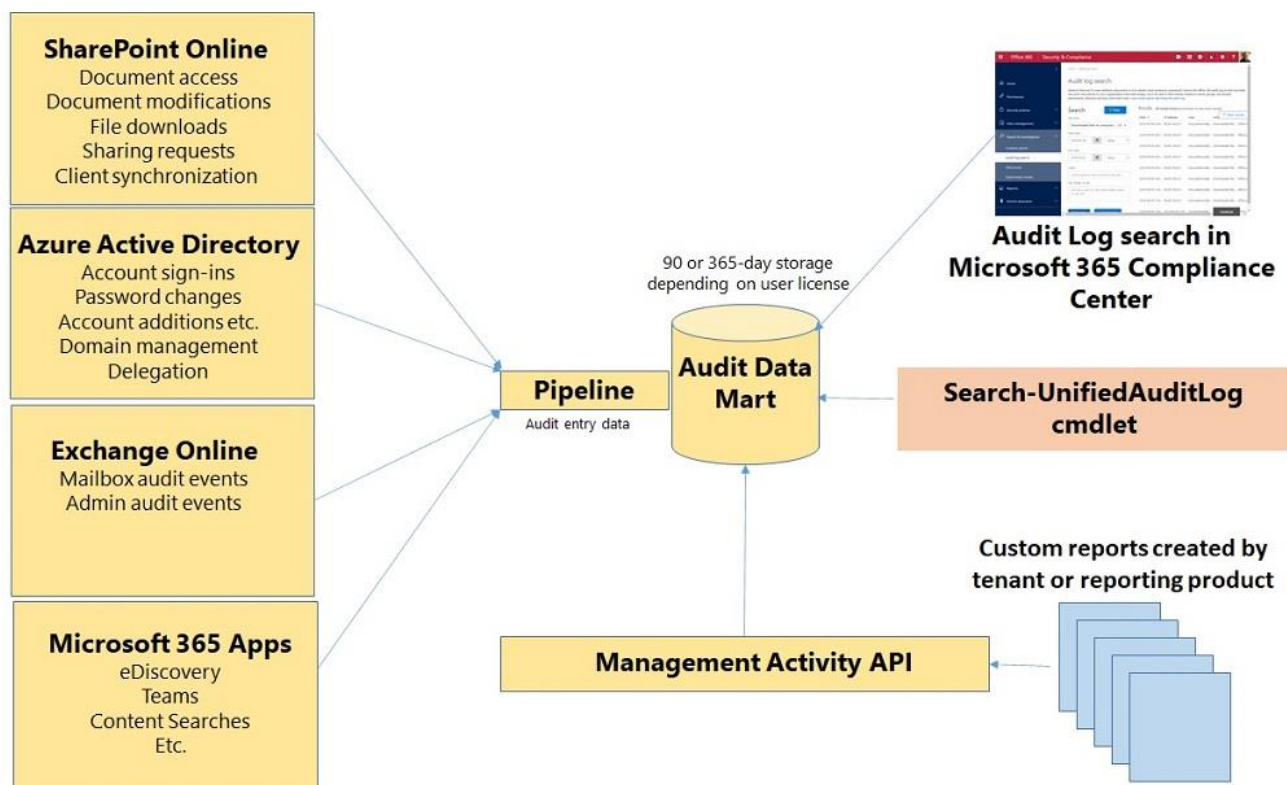

Figure 21-1: Auditing Framework

The background and history of the on-premises Exchange and SharePoint server applications is that each had a different method to enable and control auditing, specific ideas about what audit data to capture, and how to store audit data. Applications also implemented different methods to control access to the audit data. The result is a mess of inconsistencies and no way to ensure audit information remains secure and immutable. Microsoft 365 solves the problem by using a unified auditing framework covering all workloads in the suite. The architecture of the auditing framework in Figure 21-1 includes:

- **Data feeds flow from multiple workloads.** Each workload has varying abilities to capture audit data. It is therefore important to normalize the data retrieved from multiple workloads so that the audit events exist in a consistent format. As the auditing data mart ingests audit events, the ingestion process applies a [common schema](#) to events recorded in different workloads to make sure that all the events include a consistent set of essential information such as a timestamp, the user identity, the client IP address, client type, the action taken, and the object accessed. Events flow into the audit log from many workloads, including Exchange Online, SharePoint Online (including OneDrive for Business), and Azure AD as well as applications like Yammer, Stream, Teams, and Planner. Administrative functions such as eDiscovery operations are also captured. The schema accommodates the need for applications to capture information specific to their activities through product-specific schemas built on top of the common schema. For example, SharePoint Online supports product-specific schemas to describe file operations and sharing events. See [properties of audit log entries](#) for more information.
- **The Audit data mart ingests the data feeds.** The retention period for events stored in the data mart (better known as the audit log) depends on the licenses assigned to user accounts:
  - **Office 365 E3 or Microsoft 365 E3:** 90 days.
  - **Other Office 365 licenses with Microsoft 365 E5 Advanced Compliance add-on:** 365 days (year-long retention of Exchange, SharePoint, and Azure AD audit data is part of [Microsoft Purview Audit \(Premium\)](#).[Microsoft Purview Audit \(Premium\)](#)).
  - **Office 365 E5, Microsoft 365 E5, or Microsoft 365 E5 Compliance add-on:** 365 days.Office 365 Cloud App Security downloads audit data into its store and holds it there for 180 days. If you need to keep audit data for a longer period, third-party products usually extract and store audit data in their repositories for as long as a customer is willing to pay for the storage. The data mart is immutable because administrators cannot remove or change audit records. The data mart must ingest audit entries before records are accessible for reporting purposes. This usually happens within an hour or so but can take longer, depending on the source workload, other activities running within the service, and system events such as software updates. For this reason, the view of audit data is more precise when working with data a day or so after events occur than it is in the short term.
- **Four access methods** are available to consume the audit data:
  - The Audit log search (described below) in the Audit section of the Microsoft Purview Compliance portal. The log search supports ad-hoc queries through a GUI with the ability to export discovered records to a CSV file for later examination.
  - The Exchange Online *Search-UnifiedAuditLog* cmdlet can search the audit data from PowerShell.
  - Cloud App Security for Office 365 consumes audit events. See the later section. Other Office 365 features, such as activity alerts, also depend on audit events.
  - The [Office 365 Management Activity API](#) is available to developers to build third-party tools for audit reporting or analysis (or to extract data for injection into a different audit store – [a GitHub example is available](#)). The Management Activity API is a REST-based web service. The API aggregates actions and events drawn from the source workloads into tenant-specific content blobs, classified by their type and the content they hold (such as Exchange Online, SharePoint Online, or Azure AD). Tenants can use the Management Activity API to build

customized audit analysis tools to handle situations where PowerShell is unviable, as in the case of large-scale tenants where the number of audit records generated daily is too high for PowerShell to process in any reasonable time.

In a multi-geo scenario, some audit data might not be available as expected. For example, if a user has permission to send an email by impersonating another user and the accounts are hosted by different data center regions, Exchange Online captures the *SendAs* audit event in the sender's region but not in the region hosting the mailbox.

**Microsoft 365 workloads generating audit events:** The intention is that audit events should be available and reportable from all workloads. The full set of auditable events is [documented online](#) and includes:

- Exchange Online administrative events.
- Exchange Online mailbox events such as when mailbox delegates send messages (only for user and shared mailboxes, and not for public folder mailboxes or group mailboxes). These events only appear for mailboxes enabled for auditing (the default in Exchange Online).
- Microsoft 365 Groups (created and updated by many different applications). These events are collected by the Azure AD workload.
- SharePoint Online and OneDrive for Business file and folder events.
- SharePoint Online and OneDrive for Business site administration events.
- Azure AD events (like account logins and failed login attempts).
- eDiscovery (events like creating or running a content search), including the use of cmdlets to perform searches and other eDiscovery activities.
- Power BI (see instructions on [how to enable auditing for Power BI](#)).
- Microsoft Information Protection, such as the application of Sensitivity labels to documents.
- Teams, including the creation and removal of teams, channels, connectors, and tabs plus membership management.
- Power Automate (Flow), including the creation and deletion of flows and assignment of permissions.
- Stream, including the creation, removal, and editing of videos, channel activities, uploading and sharing of videos, and even when someone likes a video.
- Threat Intelligence (on the detection of phishing email or malware).
- Office 365 Cloud App Security alerts.

Of the major Office 365 apps, Planner is an outlier when it comes to generating audit events. You can find extra information about Azure AD audit events in the Azure portal. Not all Azure AD events appear in the audit mart. For instance, if you need to investigate failed or suspicious logins, more data is available through the [Azure portal](#).

Some consider that the gathering of audit data from multiple workloads constitutes a Security Incident Event Management (SIEM) or Cloud Access Security Broker (CASB) capability. However, auditing lacks the analysis and investigation features typically found in SIEM or CASB products like Microsoft Sentinel, or available in Office 365 Cloud App Security. The big advantage auditing holds over third-party products is the way that the various workloads integrate auditing into their operations and generate audit events for the audit log.

## Enabling the Audit Log for a Tenant

The audit log collects events generated by user and system activity from workloads on an ongoing basis. Before you can search for events in the audit log, you must enable this capability. If you go to the **Audit** section of the Compliance portal and select **Audit log search** and see a link to **Start recording user and admin activity**, you know that audit searches have not yet been enabled for the tenant. Click the link to turn on the ingestion process to bring audit data in from workloads.

You can also enable the audit log with PowerShell by running the *Set-AdminAuditLogConfig* cmdlet from the Exchange Online module:

```
[PS] C:\> Set-AdminAuditLogConfig -UnifiedAuditLogIngestionEnabled $True
```

The first time you run this command in a tenant, the substrate creates the audit log, and the ingestion of audit events commences. You only need to run the command thereafter if someone pauses the audit log and you wish to reenable it. You cannot pause the audit log through the Compliance portal, but you can do it with PowerShell:

```
[PS] C:\> Set-AdminAuditLogConfig -UnifiedAuditLogIngestionEnabled $False
```

Pausing the audit log allows workloads to capture events, but the events don't show up in the audit log until an administrator releases the pause. When that happens, the flow of events resumes populating the audit log. It might take some time before events flow from all workloads and the ingestion of events into the log stabilizes. During this time, some events might not reach the audit log.

## Searching Audit Events

When a tenant is enabled for auditing, events from the different workloads start flowing into the audit log. Because different methods of auditing are used by the workloads, it should come as no surprise that events flow into the audit log at different intervals after the workloads note details of the underlying actions. Although the exact periods will ebb and flow with demand and volume, the following delays are normal:

- **Exchange Online:** Audit events are available within 30 minutes. Events captured include mailbox audit events configured on a per-mailbox basis and administrative audit events configured for the tenant.
- **Teams:** Audit events for actions such as channel creation show up within 30 minutes.
- **SharePoint Online and OneDrive for Business:** Audit events are often available within 15 minutes but can take up to 30. Typical events include document editing and sharing.
- **Azure Active Directory:** Audit events for user sign-ins are available within 30 minutes and other directory activities within 24 hours.
- **All other workloads:** Audit events are available within 24 hours.

Figure 21-2: Configuring an audit search in the Compliance portal

Selecting **Audit** in the Microsoft Purview Compliance portal displays a form to collect the parameters to create a search of the audit log. Figure 21-2 shows the audit search interface. The process to execute a search is:

- Select the audit events that you want to look for from the drop-down **Activities** list. You can combine events from all the available audit sources in a single search, subject to the 5000-item limit on the

number of entries returned by a search. You might find that some operations are not available in the picker but are available in a PowerShell search. This is because it can take time to update the picker after Microsoft adds new events to the ingestion process.

- Define the date range to use (remembering that audit data are only available for a limited period). The default is to search for the last seven days (not including today). The interface supports searches for events created back as far as 365 days, but audit events for users with Office 365 E3 licenses are available only for 90 days.
- Select the user or users that performed the action you are looking for or leave the **Users** field blank to retrieve data for all users. You can search for specific users, including guest accounts, by entering a couple of characters in the field.
- If you are searching for audit events relating to SharePoint or OneDrive for Business, you can add supplementary information for the search such as the name of a file, folder, or URL. If you want to search for a word in a document title, give the full word rather than a partial substring. For example, if you want to search for events related to a document called "Reporting and Auditing," a search will find it if you specify "Auditing," but will not for "Audit."
- Click **Search** to begin the search.

The usual approach is to start by looking for a specific activity that occurred in a certain time range and then refine the search using tuned criteria to focus on a more precise set of events. You can refine the search by specifying the user whose activity you are interested in or a specific file, folder, or site to which an item belongs. You can combine a wide range of activities drawn from different workloads into a single search. Each event that you include in a search will probably increase the number of entries returned from the audit log and might make it more difficult to find the precise information that you want.

**The GUI Doesn't Show All:** Not every audit record available in the audit log appears in the search results returned in the Compliance portal. This is because many internal events are generated that might confuse or distract a log search. If you want to see the raw information in the audit log, use the `Search-UnifiedAuditLog` cmdlet.

Figure 21-3: Viewing the results of an audit log search

In this instance, the search results listed in the results pane are for *Deleted file events*, so the search will find records associated with files checked into SharePoint Online document libraries. When the audit search displays its results (Figure 21-3), some details are visible about the found events, including the name of the checked-in file. To speed access to the audit data, the portal fetches and displays the most recent 150 entries. If more matching entries exist, the portal retrieves them in batches of 150 records as you scroll down through

the results. In total, the results pane can display 5,000 events. If more than this amount meets the search criteria, the results pane displays the most recent 5,000 events. Although you can examine the details of large data sets of audit records on-screen, you might lose interest in the search by the time you scan through thousands of lines of audit data.

The current UI doesn't include a way to filter records found by a search. For this reason, it's often better to perform a search using PowerShell and capture the output in an array. You can then run queries against the array to locate the exact audit records you want.

**Auditing and Secure Score:** If you enable auditing for your tenant, your Microsoft Secure Score goes up by 15 points. However, enabling auditing is not enough. It's more important to review what's gathered in the audit log regularly to understand what happens in the tenant and be able to detect when something out-of-the-ordinary occurs.

## User and System Events

It is also important to recognize that both user- and system-initiated operations generate audit events. For example, if offline copies of files from SharePoint Online or OneDrive for Business sites exist on the PC for some reason, a background synchronization process checks the sites periodically to ensure that the local cache holds up-to-date copies of the online files. The synchronization process shows up as a series of "Viewed File", "Accessed File", and "Downloaded File" events and might lead the observer to conclude that the user has accessed many files over a brief period.

Another example of an event that occurs as a by-product of user activity is the Accessed File event logged for the JPEG file for a user's profile photo. It is a fact that someone accessed the file, but it is unlikely that the fact will be important in any sense except in circumstances when you absolutely must prove that someone looked at someone else's profile photo. Examples of system-initiated activity include events recorded for the user "*app@sharepoint*", which relate to background processing of SharePoint and OneDrive sites while those generated by "*NT AUTHORITY\SYSTEM (Microsoft.Exchange.ServiceHost)*" belong to Exchange Online background jobs used to update the organization configuration. For instance, each time a user updates a file in a SharePoint library, you should see a matching *app@sharepoint* event as the crawler re-indexes the updated content. *app@sharepoint* also appears in "Added user or group to SharePoint group" events when users join the membership of a group and that change replicates to the SharePoint group for the team site.

For these reasons, you should take care to restrict the extraction of events to a manageable quantity by using a filter such as a limited time or events for selected users. In addition, you should ask yourself why an event might show up rather than jumping to any conclusions. Microsoft recognizes that the amount of audit data generated by a search can be excessive occasionally and that a filter to separate user-started from system-initiated events might be a sensible future enhancement.

**IP addresses in audit records:** If you look up the IP addresses reported in audit logs, you might find some that seem to be in unexpected places. The IP address might be for a home router connected to an ISP or it might be an IP address managed by Microsoft and assigned to one of their data centers. For this reason, products that use IP-based geolocation sometimes report that a connection comes from places that you know the user has never been. For instance, occasionally an audit record pops up to say that I accessed SharePoint Online from Helsinki. Much as I like the Finnish capital, I have not been there for at least 15 years. However, one of Microsoft's EMEA data centers is outside Helsinki and that is where the IP address originated. [Here's a site](#) that takes an IP address and reports its (assumed) location.

## Examining an Audit Record

To see the full details of an audit record found in a search, select it from the search results. Initially, some key information about the event is displayed to allow the reader to decide if this is an event needing further investigation. The information shown includes:

- **Date:** The timestamp recorded by the originating workload when an event occurred.
- **IP address:** The IP address of the originating client. This can be in IPV4 or IPV6 notation. Some workloads, like the Office Online apps, display the IP address of a trusted application calling into the service instead of the actual address of the device. Admin activities and those performed by system accounts for Azure AD updates don't record IP addresses.
- **User:** The user principal name of the account responsible for the event.
- **Activity:** The registered activity for the event. For example, if someone updates a file in a SharePoint Online document library, the registered activity is "modified file."
- **Item:** A description of the activity.

Figure 21-4: Viewing details of an audit record

To expose the extended audit information for an event, click on the event. The information revealed here is much more interesting when seeking to understand exactly what happened to an object. Figure 21-4 shows an example of an audit record for a document updated in a SharePoint Online document library. The information exposed here is what's stored in the audit log. We will get to the details of how to parse audit data with PowerShell soon to consider the purpose of each of these fields in the audit record.

## Exporting Audit Data

To capture audit data for further analysis, you can export the audit events to a CSV file. To export the items found in an audit log search, click **Export** and select **Download all results**. The export process downloads all available results from the audit log matching the search criteria.

The download stores the audit data in a CSV file with a name starting with "AuditLog." You can open the file or save it for further processing. The contents of the CSV are raw in that the export process does not expand and format the information for an audit event in the *AuditData* column. The details about the action taken by a user are stored in [JavaScript Object Notation](#) (JSON) format, so further processing is necessary to format the data for easier reading.

The maximum number of audit events that can be exported at one time is 50,000. If you end up downloading 50,000 events to a CSV file, the potential exists that more matching audit events are available that are not in the downloaded set, so it is a good idea to do another search to find events that might be missing (perhaps by using a different date range) and then merge the two sets of results.

## Searching Audit Data with PowerShell

The audit log ingests more than 1,600 different events generated by a range of workloads. The *Search-UnifiedAuditLog* cmdlet searches and returns data from the audit log. As we'll see, the cmdlet has some quirks to understand to execute successful searches, especially when it comes to interpreting the content of the *AuditData* property because different workloads insert different types of information into this property.

By default, *Search-UnifiedAuditLog* returns 100 audit records for any search request unless you specify the number of records to retrieve in the *ResultSize* parameter (up to 5,000). A single search can process a maximum of 50,000 audit records using page retrieval (see below). With the increasing number of workloads generating data for the audit log, a casual search can return hundreds if not thousands of records. It is important to be as specific as possible with search parameters to restrict the number of records returned.

Because the *Search-UnifiedAuditLog* cmdlet is an Exchange Online cmdlet, before you can view data in the audit log, your account must hold the Exchange View-Only Audit Logs or Audit Logs role. These roles are part of the Compliance Management and Organization Management role groups and can be assigned to [other role groups](#) as needed.

### Simple Audit Search

The simplest form of audit search looks for events of a specific type (referred to as an operation or event) for a single user (referred to as a *UserId*) over a short period. For example, to discover who last updated a document, we can search the audit log with a command like the one shown below:

```
[PS] C:\> Search-UnifiedAuditLog -StartDate 1-Nov-2021 -EndDate 1-Dec-2021 -RecordType
SharePointFileOperation -Operations FileModified, FileModifiedExtended -ObjectIds "Important
File.docx" -ResultSize 5 -Formatted | Format-Table UserIds, CreationDate, Operations
```

UserIds	CreationDate	Operations
tony.redmond@office365itpros.com	11/11/2021 14:35:44	FileModified

In this case, we can limit the number of audit records to retrieve by passing precise parameters:

- The **search period**: State the full date and time to delimit the start and end of the search. You can pass a date on its own, in which case the search uses 00:00 as the time to begin (or end) the search. If you use a date that's more than 365 days in the past, *Search-UnifiedAuditLog* returns an error and tells you the first possible date you can use. However, searches only return events as far back as a year for accounts with premium licenses.
- The **object name**: Pass the full name of the document. You don't need to include the URL of the SharePoint Online site or OneDrive for Business account storing the document. However, a document with the same name can be in multiple sites, so you might need to check the information stored in the *AuditData* property of the returned audit records to identify records belonging to a specific document. The same is true if you use a partial document name (such as ".docx") and the audit search returns events for modifications made to several documents. Audit searches don't support wildcard matching against object names.
- The **operation**: The action performed to generate the audit event. SharePoint Online generates *FileModified* and *FileModifiedExtended* events (operation) when someone updates a file in a document library. Every audit event has an operation, and you can filter audit records by specifying one or more operations to find.
- The **record type**: Bypassing *SharePointFileOperation* in the *RecordType* parameter, we tell *Search-UnifiedAuditLog* that we want to retrieve audit records for SharePoint Online file operations like uploading a new file to a document library. The other valid record types [are listed here](#).

Note that the *ResultSize* parameter is set to 5 to tell *Search-UnifiedAuditLog* that it only needs to find five records. Because Microsoft 365 usually returns audit records sorted by date, the first record is the latest update.

If a search finds audit records for multiple documents, a quick way to extract the records for a specific document is to store the found data in an array and then scan the records. For example, this search recovers all document modification events for a week.

```
[PS] C:\> [array]$Records = Search-UnifiedAuditLog -StartDate 18-Nov-2021 -EndDate 24-Nov-2021 -RecordType SharePointFileOperation -Operations FileModified, FileModifiedExtended -ObjectIds ".docx" -ResultSize 1000 -Formatted
```

To scan the records for a specific document, use the *Contains* method to check the contents of the *AuditData* property:

```
[PS] C:\> [array]$DetailedRecords = $Records | Where-Object {$_.AuditData.Contains("Managing Reporting")}
```

You can also use a free text search against audit records. This is slower than finding records of a certain type and filtering the records to find the right ones. However, it might be helpful at times. Here's an example:

```
[PS] C:\> [array]$Records = Search-UnifiedAuditLog -FreeText "*Reporting*" -Formatted -StartDate 1-June-2022 -EndDate 26-June-2022 -ResultSize 1000
```

**Finding the Right Events:** When searching the audit log, it's important to know what you're looking for. This sounds trite but given the number of audit events captured in any reasonably-sized tenant, looking for records for a specific action can be like searching for the proverbial needle in a haystack unless you know the name of the event. A good approach is to take steps to force the workload to generate an audit event, wait for 30 minutes or so, and then run an audit log search for the period to find the events which appear in the audit log. Delaying the search gives Microsoft 365 time to ingest audit records into the log. You can then examine the audit records captured for the period to find the events you want to analyze and use the *Operations* values logged for these events to perform further searches.

## Workload Audit Data

Audit records consist of two parts:

- A set of general properties populated in the same way by all workloads. These properties include the record type, creation date, operation, and user identifier.
- The *AuditData* property contains information specific to the workload generating the audit event. In most cases, you need to interrogate *AuditData* to discover the most important information about an event. Workloads use schemas to describe the properties they insert into audit records. The schemas are [documented here](#). Some trial and error are often necessary to interpret the payload in audit events. The guide to [detailed properties in audit log records](#) is helpful in this respect.

The *AuditData* property consists of a set of multiple attribute-value pairs separated by a comma (in JSON format). The property can extend to several thousand characters. To format the information and make it easier to follow, specify the *Formatted* parameter with the *Search-UnifiedAuditLog* cmdlet.

```
[PS] C:\> Search-UnifiedAuditLog -StartDate '01-May-2018 09:00' -EndDate '20-Jun-2018 17:00'
-ObjectIds 'Ch 20' -Operations FileModified -Formatted

RecordType      : SharePointFileOperation
CreationDate    : 13/06/2018 14:35:44
UserIds         : tony.redmond@office365itpros.com
Operations      : FileModified
AuditData       : {
  "CreationTime": "2018-06-13T14:35:44",
  "Id": "74746ae0-2fee-4399-18ce-08d3ab2af8fb",

}
ResultIndex    : 1
ResultCount    : 125
```

The audit data is now more legible, and we can see many items of interest, including:

- **RecordType:** The workload that generated the record. Examples of values include:
  - AzureActiveDirectory: For example, add a member to a group.
  - MicrosoftTeams: For example, a user logs onto Teams.
  - ExchangeAdmin: For example, an update of mailbox properties.
  - SharePointFileOperation: For example, a client downloads a file.
- **CreationTime:** The date and time in UTC format when the user performed the activity. If your time zone isn't UTC, you need to adjust this value to get to a local time.

- **Operation:** In this example, *FileViewed* is a SharePoint Online operation logged when someone accesses an item in a document library. The PowerShell search examples described here demonstrate how to search for and interpret events generated by different operations performed in workloads.
- **OrganizationId:** The unique GUID for the tenant.
- **UserKey:** The identity (in this case, achieved through membership of a group) used to gain access to the item.
- **Workload:** The name of the application workload that logged the event. In this case, it is SharePoint Online. Other values are Exchange Online, OneDrive for Business, and Azure AD.
- **ClientIP:** The IP (V4 or V6) address of the client workstation where the action originated is logged. See earlier note about when the IP address might not be for the workstation.
- **ObjectID:** The full path to the object is logged. We can see that this resolves to a document in a SharePoint Online document library.
- **UserID:** The Azure AD account identifier for the account that caused the action to occur.
- **UserAgent:** The client used to invoke the action. In this instance, a user uploaded a file to the document library.
- **SourceFileName:** The name of the file.
- **UserType:** The type of user that performed the action. "0" indicates a normal user; "1" indicates an action taken by an administrator, while "2" means that the action was taken by a Microsoft data center administrator or data center system account. Because we used the *Formatted* switch for the *Search-UnifiedAuditLog* cmdlet, the numeric value 0 is translated to "Regular."
- **EventSource:** Only SharePoint Online uses this field. It is either SharePoint or ObjectModel.

The *ResultIndex* and *ResultCount* properties are interesting if you need to keep track of a large record set. *ResultIndex* tells us the record number within the set returned. *ResultCount* tells us the total number of records returned. We can therefore say that the record shown is the first of 125 returned in the set. If the search encounters an internal timeout, *ResultIndex* will be -1.

It takes time for administrators to become accustomed to the information contained in audit records and to figure out how best to use this data when confronted with questions such as "who interacted with a document" or "who created new documents in this period." Experience with the PowerShell cmdlets and some trial and error soon shows that the audit log is a surprisingly useful source of information.

## Fetching Large Amounts of Audit Data

In large tenants, or where you need to retrieve information about multiple operations over an extended period, it is likely that a search will return more than 5,000 audit records. In this scenario, to make sure that you retrieve all records, you fetch audit data in pages holding up to 5,000 records at a time until no more data is available. This technique supports the retrieval of up to 50,000 audit records. If more than 50,000 matching records exist, you need to split the work across multiple searches, each of which uses different criteria. You store the results of the searches in an external repository (many organizations use Splunk for this purpose) and run the analysis against that repository.

*Search-UnifiedAuditLog* has two parameters to support the retrieval of large data sets:

- The **SessionId** parameter holds a string value to identify a search session. You can use any value you like from a simple number to a GUID generated with the *New-Guid* cmdlet. The presence of a session identifier tells *Search-UnifiedAuditLog* that it might need to fetch several pages of data.
- The **SessionCommand** parameter tells *Search-UnifiedAuditLog* how to handle large amounts of audit data. The returned data might contain duplicate records. This parameter can be set to:
  - *ReturnLargeSet*: The audit records returned are unsorted. You can fetch up to 50,000 audit records using this method but must remember to sort the data once it is all fetched.

- *ReturnNextPreviewPage: Search-UnifiedAuditLog* returns audit records sorted by date. However, you can fetch only a maximum of 5,000 records using this method. If more matching records exist, attempts to fetch the data will result in an error.

The essential steps to fetching large amounts of audit data are:

1. Create a session identifier.
2. Set up a loop to fetch data in pages.
3. Run *Search-UnifiedAuditLog* several times to fetch all available data.
4. For each run of *Search-UnifiedAuditLog*, store the retrieved data.
5. After fetching all pages, sort the data by date and write it out to a CSV file.

In this example, *Search-UnifiedAuditLog* fetches audit data about SharePoint Online file operations in batches of 4,500 records at a time. The only data stored is in the *AuditData* payload from the audit record. The output of statistics after each page is purely for informational purposes.

```
[PS] C:\> $StartTime = Get-Date; $SessionName = (New-Guid).Guid; $OutData = @()
$OutputFile = "c:\temp\Output.csv"
$EndDate = (Get-Date).AddDays(+1); $StartDate = (Get-Date).AddDays(-90)
$i = 0
Write-Host "Searching Office 365 Audit Log..."
Do {
    $ThisSearchStart = Get-Date; $i++
    [array]$Records = Search-UnifiedAuditLog -StartDate $StartDate -EndDate $EndDate -SessionId
$SessionName -SessionCommand ReturnLargeSet -ResultSize 4500 -RecordType SharePointFileOperation
    If (($Records.Count -gt 0) -and ($Records[0].ResultIndex -eq -1)) { # The audit data returned
is bad
        Write-Host "Error occured fetching audit data. Resetting search and pausing before retrying
..." -foregroundcolor Red
        Start-Sleep -Seconds 240 # Wait for 4 minutes
        $i = 0 ; $SessionName = (New-Guid).Guid; $OutData = @() # Go back to zero
        Continue
    }
    If (($Records.Count -gt 0) -and ($Records[0].ResultIndex -ne -1)) { # Got a good page
        $OutData += $Records | Select-Object -ExpandProperty AuditData | ConvertFrom-Json
        Write-Host ("Completed Page #{1}, returned {2} records in {0} seconds. Total records found so
far {3}" -f [math]::Round((New-TimeSpan -Start $ThisSearchStart).TotalSeconds), $i, $Records.Count,
$OutData.Count) }
} Until ($Records.Count -eq 0) # Until we find no more records

$OutData = $OutData | Sort {$_.CreationDate -as [datetime]}
Write-Host ("All done {0} records found in {1} minutes." -f $OutData.Count, [math]::Round((New-
TimeSpan -Start $StartTime).TotalMinutes,3))
```

The check against the *ResultIndex* property handles the situation where *Search-UnifiedAuditLog* sometimes returns duplicate information due to an internal timeout when fetching data. In this situation, *ResultIndex* is set to -1 (minus one). The search is invalid, and the results are possibly duplicated. The only solution is to zeroize everything and restart the search after a short delay.

Even in smaller tenants, you might want to use *Search-UnifiedAuditLog* to fetch audit data to store in an external repository so that the data can be kept for longer than it is in Office 365. A scheduled job could be run daily to fetch all events for the last day for ingestion into the external repository, which could be another cloud service like Splunk or an ISV reporting product like [Quadrotech NovaQuest Nova](#) (ISV products usually employ a range of Microsoft APIs to fetch audit and other data to log details of workload activity). Many compliance problems are only discovered months after an event occurs and you might not be able to find all the evidence required for an investigation.

## Discovering What Audit Operations Exist

As explained above, you can filter audit records by specifying the type of operations to see. For instance, to see who sends emails on behalf of a shared mailbox, you can look for audit events with the *SendAs* operation.

New operations appear in the audit log on an ongoing basis as workloads enable auditing for new features. The question of how best to discover new events therefore exists. Here's what we do to find if a new feature is captured in an audit event.

- First, use the new feature. Ideally, perform actions several times with different accounts.
- Second, wait for at least an hour to allow the ingestion of audit events from the source workload and appear in the audit log.
- Next, run a search to find all audit events for the current day and group and sort the results by operation. Make sure to specify the user principal name of the account which performed the accounts in the *UserIds* parameter.

```
[PS] C:\> [array]$Records = Search-UnifiedAuditLog -StartDate (Get-Date -format dd-MMM-yyyy) -
EndDate ((Get-Date).AddDays(1)) -ResultSize 2000 -Formatted -UserIds Ken.Bowers@office365itpros.com
$Records | Group Operations | Sort Count -Descending | Format-Table Count, Name
```

You should now be able to browse the sorted list of operations to find unfamiliar actions, such as *Set-LabelPolicy* (logged when someone updates a sensitivity label policy). You can take the same approach with the Audit search feature in the Compliance portal, but not all audit events show up there.

Searching the audit log to find new events also uncovers audit events logged when Microsoft updates tenant settings as part of their normal operations. For instance, Microsoft often updates OWA mailbox policies to introduce a control for a new OWA feature. When this happens, you'll find audit events logged for a user called *NT AUTHORITY\SYSTEM (Microsoft.Exchange.ServiceHost)* for the policy updates.

## Practical Examples of Using Audit Information

Audit records hold a wealth of information in the *AuditData* property. To make the information more approachable, we must break out the important pieces from the JSON-formatted data in this property and use the different elements for whatever analysis is required.

### Deciding What Audit Data is Output

All the examples in this section use a generic PowerShell list called *\$Report* as the output for information about audit data. You can use PowerShell to sort, group, or otherwise process the table to display the audit data however you like. Naturally, because each workload generates both a set of common audit data and some information of its own, you might want or need to adjust the code in the examples to meet your specific requirements by adding new outputs to the object or changing what is written into it.

For instance, somewhat confusingly, audit records have two timestamps to record when an action occurred. The date is the same, but the format is different. The *CreationDate* property outputs the timestamp in the locale defined for the workstation where you run the PowerShell script.

*9 Jan 2019 12:18:47*

The *CreationTime* property in *AuditData* holds the timestamp in ISO 8601 format, as in:

*2019-01-09T12:18:47*

The ISO 8601 format is not dependent on the locale and is what PowerShell uses when it outputs the current date and time using a command like:

```
[PS] C:\> Get-Date -Format s
```

You can use either timestamp as they both store the same data. If you prefer to use a different date format in the reports to match whatever format the consumers of the report like to see, change the line that writes the timestamp into the report. For instance, if you use the *CreationTime* property, you can output it in the general date/time pattern in short form – like *9-Jan-2019 12:18*:

```
[PS] C:\> TimeStamp = Get-Date $AuditData.CreationTime -format g
```

## Using Input Arrays

If you are searching for audit events for multiple operations, it is convenient to populate an array with the operations and use the array as input for the search. For example:

```
[PS] C:\> $Operations = @('FileAccessed', 'FileDownloaded', 'FileModified', 'FileDeleted', 'FileUploaded')
```

An array can also hold user identifiers as input. This example populates an array with user principal names fetched by calling the *Get-ExoMailbox* cmdlet.

```
[PS] C:\> [array]$Users = Get-ExoMailbox -Filter {CustomAttribute1 -eq "Sales"} | Select -ExpandProperty UserPrincipalName
```

Once populated, pass the arrays in the same way as you would pass individual operations or user identifiers:

```
[PS] C:\> Search-UnifiedAuditLog -Operations $Operations -UserIds $Users -StartDate $StartDate -EndDate $EndDate -ResultSize 5000
```

## Examining Retrieved Audit Information

Three options exist to examine the information generated by the search and held in the *\$Report* object.

1. If the number of audit records found is small, you can examine the data on the screen.
2. An alternative is to pipe the information in the table to the *Out-GridView* cmdlet. This makes it much easier to review (and sort) the data.

```
[PS] C:\> $Report | Out-GridView
```

3. Once the number of records grows, it is usually easier to export the data as a CSV file:

```
[PS] C:\> $Report | Export-CSV c:\temp\Report.csv -NoTypeInformation
```

We can then open the CSV file with Excel to format the data as desired or load the CSV file into a tool like Power BI to generate graphs, views, and reports from the audit data.

## Tracking Group Creation

The first example creates a report about who created groups, including the workloads used to create the groups. The relevant event to look for is "Add Group." In this example (code [downloadable here](#)), we search for groups created over the last 90 days. The script processes the records to extract information about who created each group, the group name, and the workload used.

The output for the report should look something like the example below. In this case, we see details of the creation of six groups using a variety of workloads from Yammer to Planner (*ProjectWorkManagement*) to Teams. The *Microsoft.Exchange* workload means that an Exchange client (like OWA) created the group. If you see a workload named with a value like "12128f48-ec9e-42f0-b203-ea49fb6af367," it is the Teams PowerShell module.

TimeStamp	Workload	User	GroupName
9 May 2019 19:44	ProjectWorkManagement	James.Ryan@office365itpros.com	0365Grp-James Plan
8 May 2019 22:11	Microsoft Teams Services	Kim.Akers@office365itpros.com	0365Grp-Acquisitio
8 May 2019 19:01	Microsoft.SharePoint	Joe.Richards@office365itpros.com	Nice Airport Watch
8 May 2019 12:36	Microsoft.Exchange	Brian.Weakliam@office365itpros.com	Brian's Nelson Gro
7 May 2019 17:45	Microsoft.Exchange	Vasil.Michev@office365itpros.com	Sandboxes

If you run this script, you might notice that Microsoft has updated some of the workload names. For instance, the current name for Exchange is "Office 365 Exchange Online" while SharePoint is "Office 365 SharePoint Online."

## User Sign-ins

In another example of how to use the same technique to interpret audit events, here's what you might do to report user sign-ins to different workloads. To make things more complicated, we use two different events, one from Azure AD (to handle most workloads) and the other from Teams. Because we can expect to retrieve many audit records for these operations, we also pass the *ReturnLargeSet* value to the *SessionCommand* parameter and specify that we will accept up to 5,000 records. The code is [available on GitHub](#). Another way to get user sign-in information with PowerShell is via the *Get-MgAuditSignInLogs* cmdlet.

Understanding failed user login events is also interesting because these events might be the result of attempts by attackers to penetrate your tenant. You can find code to search for audit events for failed user sign-ins [on GitHub](#).

## Who Updated That File?

People often want to know who made changes to a document. This search finds audit events created when someone creates or edits a specific file over the last 90 days. The script prompts for a file name to search for and stores its name in the *\$FileName* variable. Depending on the document's history, we could find:

- A single *FileUploaded* event when the document is uploaded to SharePoint Online or OneDrive for Business.
- A *FileAccessed* event when a user opens the document.
- A *FileModified* event when a user updates the document. Events also appear from the background process used by SharePoint Online to maintain files. These appear as the *app@sharepoint* user.

If the AutoSave feature is enabled for the document, multiple *FileModified* events can accumulate over a short period. We can extract information about who did what to the document from the *AuditData* field for the audit events, which contains information about the site (including its URL) where the document is stored.

After analyzing the set of audit records found for the document (use the script [downloadable from GitHub](#)), we can list the results:

```
[PS] C:\> $Report | Select Timestamp, User, Action
```

TimeStamp	User	Action
22 Apr 2020 14:40:41	Jane.Maloney@office365itpros.com	FileModified
21 Apr 2020 15:19:03	Jane.Maloney@office365itpros.com	FileModified
21 Apr 2020 15:02:34	Kim.Akers@office365itpros.com	FileModified
21 Apr 2020 15:01:39	Jane.Maloney@office365itpros.com	FileUploaded

SharePoint Online and OneDrive for Business move deleted files through a two-stage recycle bin. Three different audit events capture each stage:

- **FileDeleted:** The original deletion (by a user, a retention policy, or system process).
- **FileDeletedFirstStageRecycleBin:** A user removes a file from the first stage recycle bin. Any member of a team or group can do this. Normally, files stay in the first stage recycle bin for 30 days.
- **FileDeletedSecondStageRecycleBin:** A site administrator (group or team owner or the owner of a OneDrive for Business account) removes a file from the second stage recycle bin. Usually, files remain in the second stage recycle bin until 93 days after their original deletion. At this point, SharePoint Online removes the file permanently and it is irrecoverable (unless a retention label or policy forces SharePoint Online to keep a copy in the site preservation hold library).

Reporting file deletion events is a straightforward process. An example script to illustrate the process [is available in GitHub](#).

## SharePoint Sharing Events

SharePoint logs audit events when users generate sharing invitations with people inside and outside the tenant. Three separate events are recorded:

- *SharingSet*: Someone shares a document with someone else (inside or outside the tenant).
- *SecureLinkCreated*: SharePoint creates and sends a secure link to the target user. This only happens for external users as users with accounts in the tenant directory can use their accounts to access the shared document.
- *SecureLinkUsed*: The target user uses the secure link to access the document. Again, this only happens when external users access a shared document.

You can search for these audit records with a command like:

```
[PS] C:\> [array]$Records = (Search-UnifiedAuditLog -StartDate (Get-Date).AddDays(-30) -EndDate (Get-Date).AddDays(+1) -Operations SharingSet, SecureLinkUsed, SecureLinkCreated -ResultSize 2000)
```

If you then interpret the audit records, you see this kind of sequence when a sharing invitation is generated and used by an external user.

```
TimeStamp : 2018-04-16T16:21:42
User      : tony.redmond@office365itpros.com

User      : tony.redmond@office365itpros.com
SharedType : SPO Sharing Link
Document  : Migration Datasheet.pdf
Action    : SecureLinkCreated
Event     : <Type>View</Type>
Event     : <Permissions granted>Read</Permissions granted>

TimeStamp : 2018-04-16T16:29:45
User      : urn:spo:guest#james.pierrott@yandex.com
SharedType : SPO Sharing Link
Document  : Migration Datasheet.pdf
Action    : SecureLinkUsed
```

Between the records for file accessed and file sharing, you can create a complete picture of what documents are accessed by external users.

## Guest User Access to Documents

Our next example shows how to search the audit log for File Accessed events for guest users. The idea is to understand the files in document libraries guest users have opened. We could expand the search to include File Modified events if you want to know what files guest users update, but this search is enough to prove the point. After finding the data using the [script available from GitHub](#), here's how to sort it to discover the set of documents accessed by each guest.

```
[PS] C:\> $Report | Sort User, Document | Format-Table TimeStamp, User, Document -AutoSize
```

TimeStamp	User	Document
21 Dec 2018 11:39	john_contoso.com#ext#@Tenant.onmicrosoft.com	Summit 2018.one
5 Jan 2019 11:12	mary_contoso.com#ext#@tenant.onmicrosoft.com	Summit 2016.one
6 Jan 2019 09:44	mary_contoso.com#ext#@tenant.onmicrosoft.com	Updates.docx
9 Jan 2019 08:15	terry_contoso.com#ext#@tenant.onmicrosoft.com	Amazon Blurp.docx

We can view the audit data in different ways. For example, to find out how many accesses occurred to each document, you could do this:

```
[PS] C:\> $GroupData = $Report | Group-Object -Property Document
$GroupData | Sort Count -Descending | Select Name, Count
```

Name	Count
Ch 5 - SharePoint Online and OneDrive For Business - Final.docx	17
Project Ambush.docx	11
Interesting data.docx	10
Financial Arrangements 2019.docx	9
Ch 8 - Clients.docx	8
Ch 3 - Basic Workloads.docx	6
Budget 2019.docx	1

## Reporting the Assignment of Retention Labels

The same technique of grouping and sorting data from audit records is useful to report other aspects of Microsoft 365. If you have Office 365 E5 or Microsoft 365 Compliance E5 licenses, you can use the Activity Explorer (see Chapter 17) to see what's happening with retention and sensitivity labels. PowerShell gives you another way to do the job. For instance, to know what the most popular retention label applied to documents is, search for *TagApplied* events, extract the audit data, and put the events into the *\$Report* output. Because audit events often hold different information, this process is slightly complicated by the need to accommodate labels applied as a default for a library and those assigned manually by users. An example script can be [downloaded from GitHub](#). The script generates a list in the *\$Report* variable, and a little grouping and sorting reveals what the most popular retention label is:

```
[PS] C:\> $GroupData = $Report | ? {$_.Type -eq "File"} | Group-Object -Property Label | Sort Count
-Desc | Select @{n="Retention Label"; e={$_.Name}}, Count
```

Retention Label	Count
eBook Content	222
Audit Material	34
Approved	25
Confidential	12
GDPR Personal Data	10
Commercially Sensitive	4

If you see a blank entry in the list, it is for audit events logged when a user removes a retention label from a document. Note that the audit log does not currently capture events for when documents receive retention labels when created in or uploaded to document libraries with a default retention label.

## Who Used the SendAs Permission?

Among the data ingested by the audit log are mailbox audit events from Exchange Online. In the past, you might have used the *Search-MailboxAuditLog* cmdlet to search this information. For example, a common question is who used the *SendAs* permission to send a message impersonating a shared or user mailbox. We can find out by running a command like this:

```
[PS] C:\> Search-MailboxAuditLog -Identity "Customer Services" -LogonTypes Delegate -StartDate
((Get-Date).AddDays(-90)) -EndDate ((Get-Date).AddDays(+1)) -ShowDetails | ? {$_.Operation -eq
"SendAs"} | Select LogonUserDisplayName, LastAccessed
```

LogonUserDisplayName	LastAccessed
James Ryan	2 Nov 2018 12:13:35
James Ryan	2 Nov 2018 11:57:33

You can still use the *Search-MailboxAuditLog* cmdlet to search for mailbox events, but as those events are in the audit log it is better to search there, especially as you can look for events across multiple mailboxes

because the *Search-UnifiedAuditLog* cmdlet is designed to retrieve audit events for multiple users and multiple actions across the entire tenant.

Unlike Exchange on-premises, where all *SendAs* events are generated by delegates sending messages for another mailbox, Exchange Online processes messages sent by other workloads that can show up as *SendAs* actions in audit searches and skew results unless adjustments are applied. Here are some things to consider:

- Audit records with S-1-5-18 captured in the *UserId* property record the generation of a welcome message for a new team.
- Audit records are generated when Teams sends a welcome message.
- Audit records are generated for the group mailbox when a member posts a message to a conversation in an Outlook group using OWA. Records are not generated when messages are posted with other clients or arrive from guest members.
- Audit records are generated for the group mailbox when someone updates a task in Planner.

With these caveats in mind, the script to search for *SendAs* records, process the audit records, and identify events belonging to user or shared mailboxes and those belonging to group mailboxes can be [downloaded from GitHub](#). The former category is normally what people are concerned with because they're looking for instances where someone sent a message from a mailbox rather than posting to an Outlook group or adding a comment with Planner. As you can see in the script, to distinguish between the two categories, we create a hash table of primary email addresses for mailboxes and groups and look up that table for each audit event to decide if it belongs to a user/shared mailbox or a group mailbox.

## Searching for Audit Records Tracking Actions Against an Object

Most auditing attempts to answer "who did what" questions. In other words, you want to know who performed a specific action. Sometimes you need to know what happened to a particular object, like a document or a user. Finding audit events for one or more documents is easy – all you need to do is pass the document names in the *ObjectIds* parameter. In this example, we create an array of document names to search for and then pass the array as the *ObjectIds* parameter for the call to *Search-UnifiedAuditLog*:

```
[PS] C:\> [array]$docs = "New Signature API for Email Signatures.docx", "Controlling default
creation of online meetings with OWA.docx", "Anticipating Microsoft Ignite 2020.docx"
[PS] C:\> [array]$Records = Search-UnifiedAuditLog -ObjectIds $docs -StartDate (Get-Date).AddDays(-
90) -EndDate (Get-Date).AddDays(+1) -ResultSize 500
```

The events found are for all actions performed against the documents, such as being modified or downloaded. The same technique works for users.

```
[PS] C:\> [array]$Users = "Oisin.Johnston@office365itpros.com", "Kim.Akers@office365itpros.com"
[array]$Records = Search-UnifiedAuditLog -ObjectIds $Users -StartDate (Get-Date).AddDays(-90) -
EndDate (Get-Date).AddDays(+1)
```

To emphasize, this search returns events for actions performed for these users (like being added to a group membership) rather than events performed by the users.

Microsoft 365 Groups are not users, so if we want to find the actions performed against a group, we must use the *FreeText* parameter to search audit records for instances of unique values that identify the group we're interested in. Fortunately, the object identifier for a group is a good search term. In this example, we extract the object identifier for a Microsoft 365 group and use it to search for audit events. We then group the audit events to get an overview of the kind of activity performed against our target:

```
[PS] C:\> $ObjectId = Get-UnifiedGroup -Identity "Office 365 for IT Pros" | Select -ExpandProperty
ExternalDirectoryObjectId
[array]$Records = Search-UnifiedAuditLog -FreeText $ObjectId -StartDate (Get-Date).AddDays(-90) -
EndDate (Get-Date) -ResultSize 1000
$Records | Group Operations | Sort Count -Descending | Format-Table Name, Count
```

Name	Count
RecipientChange	17
TabUpdated	10
TabAdded	4
Remove member from group.	3
MemberRemoved	3
Add member to group.	3
Update group.	2
MemberAdded	2
TabRemoved	1
Set-UnifiedGroup	1

The technique also works for finding audit records for security groups (but not for distribution lists). It also works for Azure AD accounts, including guest users, but it's much slower than using the *ObjectIds* parameter. As the name implies, *FreeText* means that a free text search is used to find matching audit events. In a large tenant, a free text search across potentially millions of records won't be fast.

Remember that a single action can result in multiple events. For instance, if you add someone to a group, the *MemberAdded* and *Add member to group* events are captured by different workloads and ingested into the audit log. The duplication is easily detected by comparing the creation date for the events.

## Premium Auditing and Crucial Events

The Microsoft Purview Audit (Premium) solution is available to users with E5 or Microsoft 365 E5 licenses or the Microsoft 365 E5 compliance add-on. The solution covers:

- **Longer retention of audit data.** Instead of purging audit events after 90 days, the retention period for events for Exchange Online, SharePoint Online, and Azure AD is 365 days. The [Microsoft Purview Audit \(Premium\) solution](#) can keep audit data for up to 10 years with an additional per-user license.
- **Audit log retention policies.** Because tenants might not want to hold some audit events for 365 days, they can apply audit log retention policies to remove selected events from the audit log.
- **Crucial or high-value audit events.** These are audit events designed to expose in-depth information for forensic investigation. You don't need to enable the collection of crucial audit events as this happens automatically for all accounts with the appropriate licenses.

The current set of crucial events are:

- **MailItemsAccessed:** Items in a mailbox are accessed (opened) or synchronized.
- **Send:** A message is sent from a mailbox.
- **SearchQueryInitiatedExchange:** A mailbox search is initiated using Outlook desktop or OWA.
- **SearchQueryInitiatedSharePoint:** A search is initiated for a SharePoint site.
- **Other workload events from Forms, Stream, Teams, and Yammer** (see [this link](#)).

Examples of Teams crucial events are:

- **MeetingDetail:** A Teams meeting occurs.
- **MeetingParticipantDetail:** A participant joins a Teams meeting. See [this article](#)

for information about how to find and analyze Teams meetings audit events.

The relevant workloads automatically capture the crucial mailbox events once an account has the necessary license. To capture the search events in Exchange Online, you must update the owner audit configuration for individual mailboxes. For example:

```
[PS] C:\> Set-Mailbox -Identity Kim.Akers -AuditOwner @{Add="SearchQueryInitiated"}
```

## The MailItemsAccessed Event

Exchange Online generates the *MailItemsAccessed* event when licensed users access items in Exchange Online mailboxes using any connectivity protocol from any client. The events are uploaded to the audit log along with other Exchange events. Two kinds of *MailItemsAccessed* events are available: *Sync* (synchronization) and *Bind* (access to a message).

- **Sync events** occur when an Outlook desktop client synchronizes messages from the mailbox to its local cache (the OST for Windows or OLM for Mac). During synchronization, the client downloads copies of all new or changed items from the mailbox and notes any deletions from the server to apply in its local copy. The sync event records that synchronization occurred for a folder. Over a working day, many events record synchronization for folders like Inbox, Sent Items, Deleted Items, and the Calendar, plus any other folder where messages are moved to. In terms of investigation, the assumption is that if a breach occurs and someone can use Outlook to synchronize a folder to a local cache, potentially all items in that folder are copied.
- **Bind events** record access to an individual message. To reduce the number of audit records, Exchange Online generates a single bind event covering access to messages within two minutes. Thus, a bind event might cover access to a single message or ten messages.

To give an idea of the volume of events a user might produce, over two days, 443 *MailItemsAccessed* events were generated for a single mailbox. The majority were Bind events (394), and of these 312 were in the Inbox and 32 in Sent Items. Twenty-five events were captured for the Outbox, which is a transient folder where items exist while awaiting processing by the Exchange transport service. It's also used when Outlook posts to a conversation in an Outlook group, which is why the events for the Outbox folder were captured. The number of events captured by other mailboxes will vary depending on:

- The amount of inbound traffic. For instance, executive mailboxes often have a higher level of traffic. Organizations that use Teams for internal collaboration might find that the level of traffic is lower.
- The actions taken by the mailbox owner (or delegates).
- The number of clients signed into the mailbox.

In the case of very active mailboxes, if more than a thousand events are generated for a mailbox in less than 24 hours, Exchange Online stops generating *MailItemsAccessed* events for that mailbox for 24 hours. Microsoft says that less than 1% of Exchange Online mailboxes are throttled.

## Forensic Investigations of Mailbox Breaches

[Microsoft's documentation](#) lays out the steps that forensic investigators can use to interpret the information captured in *MailItemsAccessed* events if they suspect that an attacker gains access to a mailbox. The basic idea is to:

- Identify when a user's mailbox might have been compromised.
- Discover what folders an attacker might have accessed in the mailbox (Sync events). It is possible that the attacker downloaded (synchronized) the entire mailbox to Outlook.
- Discover the individual messages accessed by the attacker (Bind events). The events store the internet message identifier for messages, which can be used to find the messages in the mailbox.
- Investigate if any messages were sent from the mailbox by the attacker. *Send* events record each message sent. The message subject and its internet message identifier are recorded. Investigators can use this information to discover the recipients of the messages and decide if any information has been sent to an unauthorized address.
- If the account is compromised, the attacker might have performed searches to look for confidential or sensitive information. The *SearchQueryInitiatedExchange* and *SearchQueryInitiatedSharePoint* events record details of searches performed against the mailbox and SharePoint sites. Any evidence of

unusual search activity deserves further investigation to identify if the searches are performed by the account owner or an attacker.

Given the number of audit events that an investigator might have to examine in the steps described above, it's not realistic to use the audit log search GUI. Instead, most investigators use PowerShell to find and analyze audit records to extract relevant and useful information. An example script to parse *MailItemsAccessed* events, including using the *Get-MessageTrace* cmdlet to find the subject of messages (within the last 10 days), can be [downloaded from GitHub](#). Examples of how to parse audit records for the send and search events [are also available](#).

## Audit Log Retention Policies

Microsoft Purview's premium audit functionality includes the ability for tenants to configure audit log retention policies. You define a [retention policy for selected audit events](#) with a set retention period and those items will be purged after that period. A tenant supports up to 50 audit log retention policies.

Management of audit log retention policies is through the [Audit section of the Microsoft Purview Compliance portal](#) or PowerShell (after connecting to the compliance endpoint). This example runs the [New-UnifiedAuditLogRetentionPolicy](#) cmdlet to create an audit retention policy to remove any *SearchQueryPerformed* event executed by the background *app@sharepoint* process after three months instead of the twelve-month retention of audit events if the tenant has E5 licenses.

```
[PS] C:\> New-UnifiedAuditLogRetentionPolicy -Name "90-day Retention SearchQueryPerformed by app@sharepoint" -Description "Remove SearchQueryPerformed events from the app@sharepoint process after 90 days" -RecordTypes SharePoint -Operations SearchQueryPerformed -UserIds "app@sharepoint" -RetentionDuration ThreeMonths -Priority 8
```

### Purging the Audit Log

You can choose to apply retention for any of the events captured in the audit log and keep them for three, six, nine, twelve months, or 10 years. It's a good idea for tenants who either want precise control over the retention of audit data or want to clean up events that don't add much value in terms of investigations. SharePoint is a notoriously "chatty" application when it comes to the capture of audit events, so I can see why tenants might decide to keep important events like *FileUploaded* or *FileAccessed* for as long as possible while removing some of the chatter after 90 days.

## Activity Alerts and Alert Policies

Searching the audit log to find items of interest rapidly becomes boring. It also creates the potential that you might overlook important audit events. Microsoft 365 has two methods to automate checking of user activity within a tenant and alert administrators when something out-of-the-ordinary occurs.

- **Activity alerts** are available to all business tenants. An activity alert checks events recorded in the audit log for specified conditions defined by administrators and fires when those conditions occur.
- **Alert policies** build on the concept of activity alerts and apply extra intelligence to the events recorded in the audit log. Instead of firing when events occur, policies look for patterns of events such as a certain number of file downloads over a brief period. Microsoft includes a set of default alert policies to help tenants understand their use and handle common conditions, including notification of malware attacks or instances when someone gains administrative permissions for Exchange Online. [Several predefined alert policies](#) are available to Office 365 E1 and E3 tenants while the other policies are available to tenants with Office 365 E5, Advanced Threat Protection, or Microsoft 365 E5 Compliance licenses. Tenants can create additional alert policies to meet specific needs or included with apps. For instance, communication compliance policies create alert policies to advise

administrators when a threshold of *SupervisionRuleMatch* events match the conditions monitored to detect possible policy violations occur in a set period.

In both cases, administrators receive notifications via email, and it is then up to the people notified to act to resolve the detected problem. Only accounts that hold the Organization Configuration compliance role can create activity alerts or alert policies.

## Activity Alert and Alert Policies

Experienced administrators know when something is not quite right. At least, their suspicions heighten when they see certain things happening. [Activity alerts](#) help administrators keep up to date with what is happening inside the tenant. Microsoft Purview packages activity alerts into policies to create the mechanism to inform nominated individuals when a certain event occurs. Alert policies try to capture the instinct of experienced administrators to detect patterns of problematic activity, using the ability of software to keep looking for matching patterns repeatedly. When a match occurs between real-time activity as captured in the audit log and the settings defined in a policy, Purview triggers an incident and notifies the recipients defined in the policy. The recipients are then responsible for resolving the incident. Conceptually, you can break down alert policies into four stages:

- **Understand** the normal ebb and flow of user activity to know what you expect to happen within the tenant. This is the activity baseline and can be set manually through your observations and experience or automatically by Microsoft.
- **Define** the characteristics of activity that cause concern and watch for incidents when those characteristics occur. These characteristics are the activity, condition, and threshold checked by an alert policy.
- **Monitor** the events recorded in the audit log against the conditions defined in alert policies.
- **Alert** administrators through email notifications when policy violations occur.

One thing to remember is that Alert policies don't support filtering based on a file or folder name, so you cannot use them to check changes made to a specific item. For instance, if your search is for file check-ins for a document called "Budget" and you use the search to create an alert, Purview generates alerts for all file check-in operations and not just for that document. In addition, activity alerts do not support date ranges, so the alert will fire for any matching activity from when you create it. An alert policy can check for multiple actions across multiple accounts. You can select any of the events logged in the audit log for monitoring. For example, you could have an alert that fires when someone checks a file into a document library or uses the *Send As* permission to send email on behalf of another user.

Purview can trigger alerts for every instance of a certain activity, such as when an administrator grants elevated permissions to another user. It can also trigger alerts based on event aggregation. For instance, users download 50 files from a SharePoint library within 30 minutes. That might be evidence of a hard-working user. On the other hand, it might be a sign that someone is grabbing some valuable intellectual property that they plan to take with them to another job. A more complex form of aggregation is when the threshold for a trigger is set by analyzing up to a week's worth of activities to understand the normal level of activities within the tenant. If something then happens that greatly exceeds the expected norm, the recipients defined in the policy receive notifications.

Purview monitors the stream of audit data flowing from workloads to detect events matching those defined in alert policies. If Purview detects a match, it sends an email notification to the accounts registered for the alert.

Purview creates a set of default alert policies for tenants, including those highlighted in Table 21-1 (see [this page](#) for the most current list and the licensing requirements for some advanced policies).

<b>Alert</b>	<b>Conditions</b>	<b>Severity</b>
<i>Creation of forwarding/redirect rule</i>	Fires when a user creates a rule to redirect or forward their email inside or outside the tenant.	<b>Low</b>
<i>Elevation of Exchange Admin privilege</i>	Fires when an administrator assigns a user account administrative permission for Exchange (for example, adding an account to the Organization Management role group).	<b>Low</b>
<i>Messages have been delayed</i>	Fires when the number of messages waiting to be delivered outside the tenant exceeds 2,000 and the level exists on the queue for an hour.	<b>High</b>
<i>Malware campaign detected after delivery</i>	Fires when an unusually (compared to baseline) number of messages with malware arrive in user mailboxes., Apart from flagging an alert, the problematic messages are removed. [E5/Defender for Office 365]	<b>High</b>
<i>Malware campaign detected and blocked</i>	Fires when Defender detects an attempt by attackers to send an unusual volume of messages with known malware to your tenant. The malware is blocked, and messages do not arrive in user mailboxes. [E5/Defender for Office 365]	<b>Low</b>
<i>Malware campaign detected in SharePoint and OneDrive</i>	Fires when an unusual number of malware detections occur in SharePoint Online and OneDrive for Business sites in the tenant. [E5/Defender for Office 365]	<b>High</b>
<i>Unusual increase in email reported as phish</i>	Fires when there is an increase in the normal volume of email reported by users as phish. [E5/Defender for Office 365]	<b>High</b>
<i>Unusual external user file activity</i>	Fires when external users with access to SharePoint or OneDrive for Business sites in the tenant perform an unusual number of activities like accessing, downloading, and removing files. [E5/Defender for Office 365/AC]	<b>Medium</b>
<i>Unusual volume of external file sharing</i>	Fires when users share an unusual number of files in SharePoint or OneDrive for Business sites with external people outside the tenant. [E5/Defender for Office 365/AC]	<b>Medium</b>
<i>Unusual volume of file deletion</i>	Fires when users remove an unusual number of files from SharePoint or OneDrive for Business sites within a brief period [E5/Defender for Office 365/AC]	<b>Medium</b>

Table 21-1: Default alert policies

You can amend the recipients for alerts generated by the default alert policies, but you cannot change the other settings. The first three policies are available to all enterprise tenants. Access to other policies is through Office 365 E5 (E5), Defender for Office 365, or Microsoft 365 E5 Compliance (AC) licenses. Microsoft introduces new alert policies and updates existing policies as the need arises, including those used for mail flow insights like the alert policy for accepted domains due to expire soon.

The default alert policies cover some generic situations that might or might not apply to your tenant, which is why you can define custom policies. You can only create custom alert policies if your account holds the Manage Alerts role (included in a compliance role group like Organization management). To create a new alert policy, go to the **Policies** section of the Microsoft Purview compliance portal and select **Alert policies**, and then **New alert policy**. You can then add the following information to create the new alert:

- **Name and Description.** These settings are for administrative convenience, and you can enter anything you like. The name appears in dashboards, so it should convey the intent of the alert policy. The description is useful to note who created or last amended the policy and what the policy does.

- **Category:** To help track alerts, you can classify policies into the following categories, which you can use to sort alerts in the **View alerts** page:
  - Information governance. For example, users download more than a certain number of files to their PC over a defined period.
  - Permissions. For example, the elevation of permissions.
  - Mail Flow. For example, Exchange Online Protection detects malware in an email.
  - Threat management. For example, malware outbreaks.
  - Others. This category exists for tenants to use as they wish.
- **Severity:** You can assign alerts detected by the policy to be *Low*, *Medium*, or *High*. The more destructive a condition is, the higher its severity should be.
- **Activity:** The activity that the policy tracks. Alert policies do not yet cover all the activities recorded in the audit log because the intention is that alert policies can deliver near real-time notifications about problems and not all workloads feed events into the audit log that quickly. Microsoft will probably extend coverage across workloads over time. For now, policies can cover most activities in the SharePoint, OneDrive, and Exchange workloads. You can only select a single activity per policy. If activity policies do not support an event you want to check, you can create an activity alert to do the job.
- **Conditions:** For most activities, you can define conditions that must exist before Purview signals an alert. For example, a user downloads a file to a computer with a specific IP address. It is also possible to configure alerts to fire every time a user performs the activity or when users download files from a specific site.
- **Threshold:** How often an activity must occur within a period before a problem condition exists (thresholds aren't available for all types of alerts). The threshold can also be an unusual activity, which is when Purview compares activity for a period against the baseline for the tenant. Setting a threshold too low usually results in many notifications, which can hide real problems (the lowest threshold is 3 activities). Setting the threshold too high means that Purview might not send notifications in situations when administrators need to act. It is easy to tune a threshold after noting how many notifications administrators must process to reach a point where notifications arrive when real problems exist.
- **Email notifications:** You can define that alert notifications go to a list of recipients. Notifications can go to accounts within or outside the tenant. The account that creates a new policy automatically receives notifications while the default policies send notifications to the tenant administrators. You can also set a daily limit for an alert policy so that a policy can only ever generate a certain number of notifications in a single day.

The new policy wizard steps through these sections to create a new alert policy. Figure 21-5 shows how to set the activity and threshold for an alert policy.

Figure 21-5: Defining the conditions for an alert policy

**OneDrive Synchronizations and Alerts:** If you implement alert policies for files downloaded from SharePoint or OneDrive for Business, you should set the threshold for the volume of matches to be higher than the largest number of files in a library synchronized with the OneDrive sync client. If you set a lower number, you will receive alerts each time the OneDrive sync client refreshes its copy of the library.

## Handling Alerts

When Purview detects a pattern of events matching the threshold and conditions set in an alert policy, it triggers an alert and generates an email to the recipient list defined in the policy. The notification tells the recipient:

- The severity level for the alert.
- The policy that triggered the alert.
- The date and time of the alert in UTC.
- The activity that triggered the alert.
- The details of the alert. For example, how many matched activities occurred in what timeframe.

The alert message has a **View incident page** link to open a page with the details of the Defender incident Purview automatically creates for the alert. After viewing the incident, you can manage the alert to decide if the alert is a real incident by recording a status for the alert (Active, In progress, or Resolved) together with any comments to justify the status. You can also classify the incident to indicate if it is expected behavior or a false or true positive. This feedback helps to refine the automatic detection of similar incidents in the future.

Figure 21-6 shows details of an alert generated when a user downloaded a large number of files from a SharePoint Online document library.

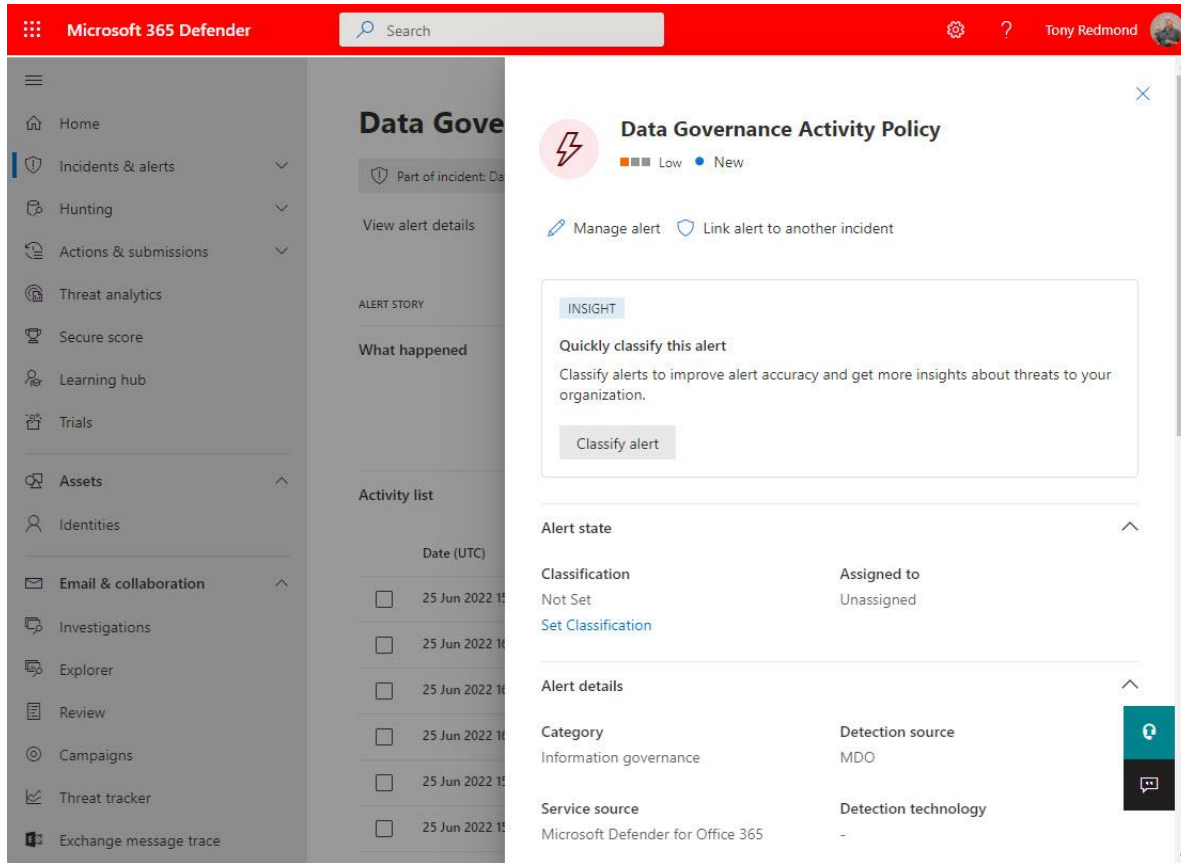

Figure 21-6: Investigating details of an alert

A busy tenant might see many alerts daily. Filters are available to focus on alerts belonging to a certain category or severity level.

## Activity Policies and PowerShell

Because of their complex nature, it is usually best to manage alert policies through the Compliance portal. However, a set of cmdlets are available:

- *Get-ProtectionAlert*: Reports the alert policies defined by the tenant.
- *Set-ProtectionAlert*: Amends an alert policy.
- *New-ProtectionAlert*: Creates an alert policy.
- *Remove-ProtectionAlert*: Removes an alert policy. You cannot remove one of the default alert policies.

For example, to list the set of default alert policies in a tenant, connect to the compliance endpoint with PowerShell and run the command shown below (output edited for space).

```
PS C:\> Get-ProtectionAlert | ? {$_.IsSystemRule -eq $True} | Format-Table Name, Category, AggregationType, AlertScenario
```

Name	Category	AggregationType	AlertScenario
Malware campaign detected after delivery	ThreatManagement	AnomalousAggregation	Protection
Unusual increase in email reported as phish	ThreatManagement	AnomalousAggregation	Activity
Unusual volume of external file sharing	DataGovernance	AnomalousAggregation	Activity
Elevation of Exchange admin privilege	AccessGovernance	None	Activity
Creation of forwarding/redirect rule	ThreatManagement	None	Activity

The *AggregationType* property tells us whether alerts trigger for every occurrence (*None*), based on the volume of the activity in a time window (*SimpleAggregation*), or when the volume of activity greatly exceeds the baseline for the tenant (*AnomalousAggregation*).

## Searching Alerts with PowerShell

Alerts are also recorded in the audit log and can be searched for using the *Search-UnifiedAuditLog* cmdlet. A [script available in GitHub](#) illustrates how to use the technique previously explained to interrogate the audit log for alert records and extract their content. As usual, the contents of the *AuditData* property of the audit records vary from activity to activity. Although this information is useful, the events do not contain details of the status of an alert and interpreting the *AuditData* property can be challenging. Better data is available through the Security/Alerts endpoint in the Graph. An example script showing how to extract current alerts from the Graph and post them to Teams is [available in GitHub](#).

# Office 365 Cloud App Security

Office 365 Cloud App Security (previously called Advanced Security Management) is part of the E5 plan and is also available as an add-on for the other enterprise plans. Unless you use groups to scope the coverage of policies (see the section later), every user in the tenant must have a license for OCAS as it is not possible to exclude the audit data for individual users from the anomaly detection and analysis.

Office 365 Cloud App Security (OCAS) is accessed through the **Manage Advanced Alerts** link in the Policies and Rules section of the [Microsoft 365 Security portal](#). This connects to a special version of [Microsoft Defender for Cloud Apps](#) designed for Office 365. Other [Microsoft 365 licenses](#) are available to extend the coverage and capabilities of Microsoft Defender for Cloud Apps. OCAS keeps up to six months of data about user activities, or twice as much security data as is normally collected for an Office 365 E3 tenant. Data collection begins as soon you enable OCAS for a tenant.

When a tenant opts to use OCAS, Microsoft connects your tenant to an equivalent tenant within the OCAS infrastructure. The link allows the OCAS analytics to extract and analyze the tenant's audit data, which detects suspicious activity and other potential problems. It takes about a week after a tenant is enabled before a satisfactory model exists of its normal activity and builds a baseline to measure suspected anomalies against.

OCAS is part of a long-term plan to give customers much better oversight about what is happening in their tenant based on the data accumulated in the audit log, with the major advantage of the approach being that no need exists to deploy agents or other software to support the gathering and analysis of the data to detect the threats that might lie in the anomalies that are picked up. Analyzing the audit data also reveals how the actions taken by individual users might compromise the security of the organization through suspicious behavior, such as someone downloading all the documents from a library holding confidential information within a brief period. Other indications are considered, such as suspicious IP addresses that might originate from anonymous proxies or known botnets.

OCAS allows administrators to create tenant-specific policies to fire alerts when specific events happen or when a specific pattern of actions occurs. For instance, you could create a policy that will alert administrators by email or SMS whenever certain conditions occur. Microsoft includes many preconfigured anomaly detection policies to get the ball rolling. These policies cover common conditions that should cause suspicion, such as a user logging in from two places widely separated by distance within a brief period. You can add other anomaly detection policies to highlight specific activities that are of concern to the organization. For example, you could create a policy to look for attempted logins from IP addresses outside the corporate IP range. You can tailor policies to turn off or on different risk factors or to increase sensitivity to a risk.

In some respects, apart from the analytics used by OCAS to pick up suspicious activity by correlating events, the technology is not rocket science. You could argue that a skilled administrator who knows what is happening in their tenant is likely to be able to detect and resolve the same kind of issues highlighted by OCAS. However, an application like OCAS scores through its ability to handle massive quantities of

information of the type generated by audit events and to reduce the mass down to what is important. A human can do this too, but will struggle with:

- The volume of data to process (especially as the environment scales).
- The time needed to recognize complex suspicious audit events and to learn the characteristics that mark new threats.
- The need to be consistent in the treatment of events.

It is also likely that the human administrator will forget that some events have happened (or not) in the past, so when something happens, they must consider the event on its merits. Computers are better at remembering things, so OCAS quickly recognizes when an event is rare (and therefore potentially out of the norm) or normal.

In addition, the machine learning that lies behind analytics is much faster at correlating events to detect suspicious activity. Once software learns what it should be looking for, it generally produces more consistent results than a human can, 24 hours a day, 365 days a year, which is why applying technology to automate the collection and validation of information drawn from multiple sources is a good approach to understanding the kind of threat introduced by how individuals behave.

## Alerts

Figure 21-7 shows how alerts appear in the OCAS console. In this case, a set of alerts have been signaled because users have connected to Teams from countries that are not their normal location. Connections are noted from different countries for one account, pointing to someone on a road trip, while another user is flagged from Bulgaria as an infrequent connection. This could be because the user has not connected from this location for a while.

The screenshot displays the OCAS Alerts console. At the top, there's a search bar and navigation icons. The main area is titled 'Alerts' and includes filter options for Status (OPEN, CLOSED), Category, Severity, App, and User name. A table of alerts is shown below, with columns for Alert, Status, and Severity. A dropdown menu is open over the 'App' filter, listing various Microsoft applications. The alert list includes:

Alert	Status	Severity	Time
Impossible travel activity Impossible travel - Chris Bishop	OPEN	High	3/28/21, 6:43 PM
Unusual addition of credentials to an OAuth app (PREVIEW) Unusual addition of credent... - Office 365 - Tony Redmond - MailSendAppDelegat...	OPEN	High	3/25/21, 7:06 AM
Unusual addition of credentials to an OAuth app (PREVIEW) Unusual addition of credent... - Office 365 - Tony Redmond - MailSendApp	OPEN	High	3/24/21, 6:26 AM
System alert: Deprecation of Label Management in the Azure Portal Microsoft Cloud App Security	OPEN	High	3/25/21, 7:06 AM
System alert: Deprecation of Label Management in the Azure Portal Microsoft Cloud App Security	OPEN	High	3/24/21, 6:26 AM

Figure 21-7: Reviewing OCAS alerts

Figure 21-8 shows an alert caused by "impossible travel" for a user. In other words, the IP addresses captured by OCAS for client connections over a certain period originate in multiple countries where it would be impossible for the user to travel between those countries during that time. In this case, the alert flagged

interactions from Ireland and the Netherlands with the 99-minute threshold deemed technically possible to fly between Ireland and the Netherlands. While the problem seems real, it deserves some further examination to figure out if an attacker compromised the user account. The facts are:

- The user signed in from two different IP addresses within a short period.
- The IP addresses indicate connections from Ireland and the Netherlands.
- In both cases, the application was Teams.

The IP addresses were correct, the connections valid, and it looks like a real problem at first glance. Then you realize that:

- Teams uses access tokens to authenticate with different services.
- The tenant is in the EMEA data center region, and the Teams service runs in the region.
- The EMEA data center region includes data centers in Ireland and the Netherlands.

Therefore, the most likely explanation is that the Teams client attempted to use its access token to authenticate. During this process, the original server in The Netherlands data center handled the request to a server in the Dublin data center, which processed the Azure AD secure token login. Azure AD captured details of the connections and sent them to the Office 365 audit log where OCAS picked up the information, analyzed the events, and concluded that evidence existed to point to a potential impossible travel situation. As it happens, I know that this is exactly what transpired, but it's a great example of how tenant administrators need to apply their knowledge about applications and how Microsoft's data center infrastructure operates to assess and resolve a flagged alert.

The screenshot displays the Microsoft Cloud App Security interface. At the top, the title is 'Alerts > Impossible travel activity' with a timestamp of '5/11/21 11:43 PM' and a severity level of 'MEDIUM SEVERITY'. Below the title, there are filters for 'Impossible travel', '2 Services', 'Chris Bishop', '2 IP addresses', and '2 Countries'. A 'Resolution options' dropdown is set to 'Chris Bishop', and a 'Close alert' button is visible. The 'Description' section states: 'The user Chris Bishop (chris.bishop@office365itpros.com) performed an impossible travel activity. The user was active from 51.171.212.129 in Ireland and 84.81.253.164 in Netherlands within 99 minutes. If these are IP addresses that are known and safe, add them in the IP address range page to improve the accuracy of the alerts.' The 'Important information' section lists: 'This user is an administrator in Office 365 (Default)', 'Microsoft Teams (Default) was accessed from Netherlands for the first time in 180 days.', and 'This alert falls under the following MITRE tactic: Initial Access'. The 'Activity log' section shows a table with 10 of 131 activities.

Activity	User	App	IP address	Location	Device	Date
Log on	Chris Bishop	Microsoft...	51.171.212.129	Ireland	Windows	May 11, 2021, ...
Log on	Chris Bishop	Microsoft...	51.171.212.129	Ireland	Windows	May 11, 2021, ...
Log on	Chris Bishop	Microsoft...	51.171.212.129	Ireland	Windows	May 11, 2021, ...

Figure 21-8: Investigating potentially impossible travel

## Resolving Alerts

Cloud App Security assigns alerts a severity of high, medium, or low risk. The risk level is calculated using behavioral analytics to compare normal user interaction against audit data. The analytics are based on

Microsoft's collected knowledge about the threats that exist, and their origin gathered from across Microsoft 365 and other cloud services. Assigning a risk value allows an administrator to filter for high-risk alerts and prioritize their resolution.

Another example of an alert is when an account is detected to have elevated permissions (a "New admin user" alert). Again, if the permissions were assigned purposely, the alert can be resolved, and OCAS knows that it does not have to signal the issue again. However, it could be the case that someone has been assigned permissions in error or that they hold permissions for too long, in which case the resolution is different and might need the account to be suspended or to have its permissions adjusted. User accounts can also be suspended as an action contained in a policy to ensure that action is taken to protect the organization without needing an administrator to do something manually. Suspended users show up as blocked users. If this turns out to be the wrong thing to do, you can reverse the suspension from OCAS or the Microsoft 365 admin center.

An alert may highlight an event that is uninteresting or invalid. In these instances, you can dismiss the alert or mark it as a false positive. These actions are recorded in the Activity Log and the fact that the user's location or their admin status is valid is considered by OCAS when it processes audit events and other data to detect anomalies and suspicious activity in the future.

## Filtered Alerts

OCAS supports activity log filters to focus an investigation on one or more of the Microsoft 365 applications or selected users. The latter filter is valuable when you might be concerned about the activities of a certain individual. You can also search for high, medium, or low severity alerts or for closed alerts. You can also filter by risk category (for example, access control or privileged accounts). The filters can be combined to focus on certain actions, meaning that even a very large volume of alerts can be quickly refined to produce a set of alerts that need to be examined. You can also export alerts to a CSV file if needed.

## Activity Log

The screenshot shows the Microsoft Defender for Cloud Apps Activity Log interface. At the top, there is a search bar and a navigation menu. The main area is titled "Activity log" and includes a "Queries: Select a query" dropdown and a "Save as" button. Below this, there are filters for "App: Microsoft SharePoint Online", "User name: Vasil Michev (Technical Guru) (vasil.mic...)", "Raw IP address: Enter IP address", and "Activity type: FileModified". There is also a "Location: Select countries/regions" dropdown and an "Advanced filters" toggle. The table below shows 1 - 20 of 213 activities. The first activity is "Modify file: file https://..." by "Vasil Michev (Technical Guru)". Below the table, there are options for "SHOW SIMILAR", "General", "User", "IP address", and "Send us feedback...". The table has columns for "Activity", "User", "App", "IP address", "Loc...", "Device", and "Date".

Activity	User	App	IP address	Loc...	Device	Date
Modify file: file https://...	Vasil Michev (Technical Guru)	M...	46.249.81.1...	Bu...	PC Windows 10 10.0	Jun 26...

Figure 21-9: Browsing the OCAS Activity Log to review specific user activity

The activity log contains data from the Office 365 audit log along with other logged items, such as those recorded when an administrator resolves or dismisses an alert. Data is available for the previous 30 days. Many activities generate a large volume of audit log entries, so you'll probably need to use filters to reduce the set to a manageable amount. In the example shown in Figure 21-9, filters extract events relating to file modification activities in SharePoint Online for a certain user. Note the **Save as** option to create a new policy based on the search criteria.

## Policies

The ability to create customized policies to check events and trigger alerts when predetermined conditions occur is one of the most powerful features in OCAS. Using templates or from scratch, you can create various policies to check for various kinds of activity captured in events, including:

- Access policy.
- Activity policy.
- App discovery policy.
- Cloud discovery anomaly detection policy.
- File policy.
- OAuth app policy.
- Session policy.

These policies help administrators to master the vast quantity of events that busy tenants generate. For example, a file policy can check for events when users share documents holding sensitive information with people outside the tenant. You can enable some Data Loss Prevention (DLP) checking to look for specific forms of data, like credit card numbers, and take governance actions, like reporting the problem to a site owner, if the checks discover someone sharing a file when they should not. Administrators can see the results of the policy in the dashboard and opt to receive updates via email or SMS text messages.

It is important to emphasize that OCAS does not replace the DLP policies that you can deploy for workloads. Investigators often review alerts sometime after the fact rather than being actioned at once rather than being brought to the attention of users through visual clues embedded in clients like Outlook or applications like Word. Instead, checking audit events for problems gives the tenant an added layer of protection. The same is true for governance as actions to prevent users from making mistakes are usually better taken through classification and retention policies deeply integrated into individual workloads.

One issue for non-U.S. customers is that OCAS is based on an Azure data store running in a [U.S., U.K, or European data center](#). However, only audit data and information about tenant users and groups are moved to the Azure data store and personal information belonging to tenant users stays within the originating workloads. Microsoft plans to extend OCAS so that its data is stored in other data center regions in the future. When this happens, OCAS data for a tenant will reside in the same region as their other data.

**SIEM integration with OCAS:** You can integrate OCAS with third-party SIEM servers. A SIEM agent runs on the server to pull alerts from OCAS so that you can integrate its alerts alongside alerts generated from other parts of your IT infrastructure. Details of how to perform this integration [are available online](#).

## Scoping Policies to Groups

If you only want to use OCAS to check the activities of a limited set of people, you can tailor policies to limit them to defined groups. These are OCAS groups rather than Azure AD groups. If you want to use Azure AD groups, you must import them into OCAS through the **User groups** choice in the cogwheel menu. Once imported, you can edit OCAS policies and add a group as a filter. Because OCAS then scopes the alerts to just the users in the group, the licensing requirement for OCAS only extends to those users. Make sure that all policies are scoped to groups as otherwise you need to license every user in the tenant.

# Third-Party Auditing Alternatives

Microsoft encourages ISVs to use the [Management Activity API](#) to access audit data through the Microsoft Graph and develop solutions that generate in-depth activity reports, including suspicious or out-of-norm actions, data visualization and analysis to aid planning and oversight for tenants, and to incorporate audit activity in operational dashboards. In short, these solutions will help tenants understand who is accessing their content and whether their compliance framework is working. Quest On Demand Audit (Figure 21-10) is an example of a third-party solution that consumes audit data.

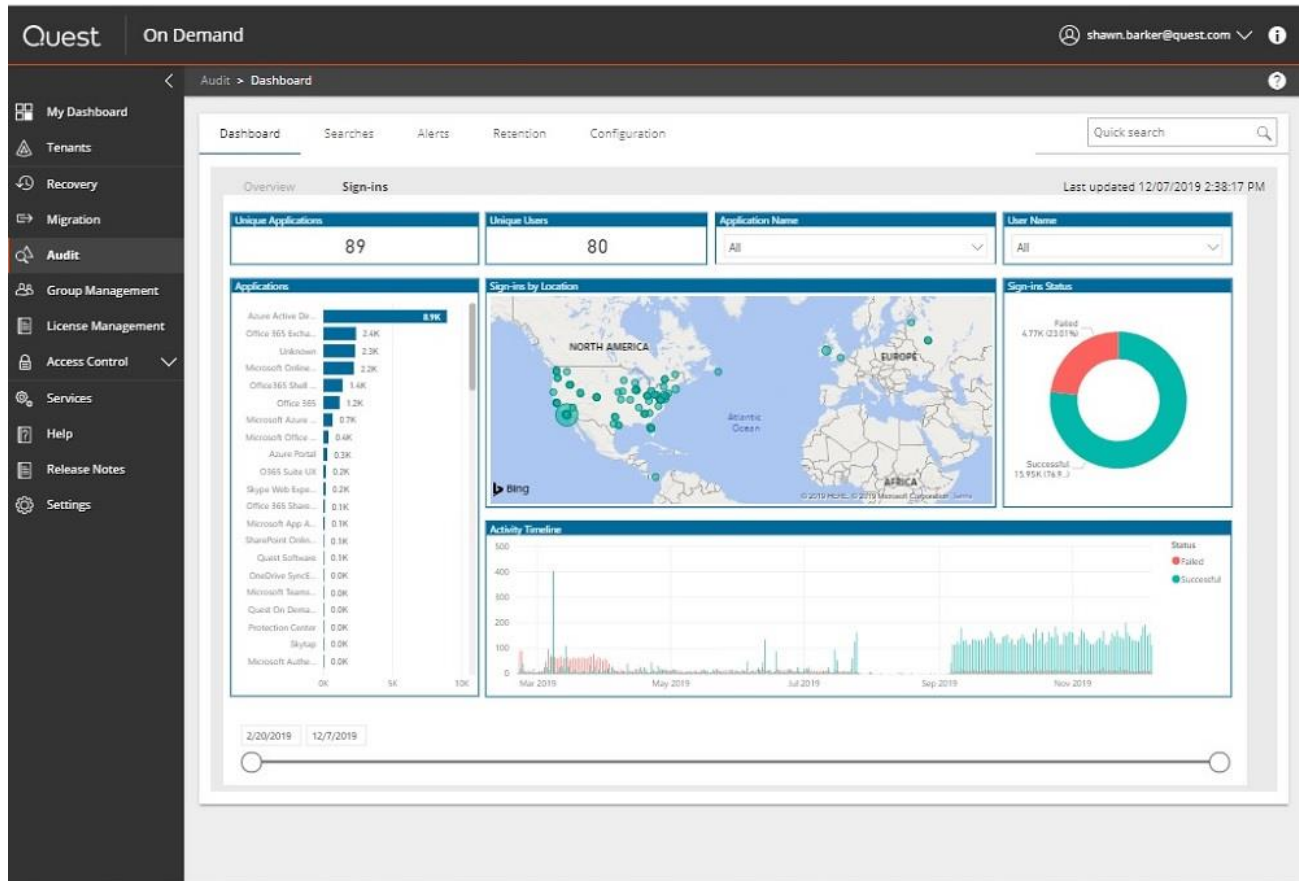

Figure 21-10: Quest On Demand Audit

Apart from taking a different approach to reporting, ISV products often allow tenants to store audit data for longer periods. This is a big advantage for large enterprises that often need to hold audit information for years to meet regulatory requirements. Third-party solutions do not include some of the high-end machine-learning functionality and policy-driven event checking found in OCAS, but they are usually much cheaper and are therefore an interesting choice to investigate if you think a tenant needs more audit reporting and analysis functionality than found in Microsoft 365.

## Exchange Online Administrative Auditing

Exchange administrative auditing is the mechanism used to track the operations performed by administrators when they invoke cmdlets to manage Exchange Online. Another way of putting this is that the audit entries allow the age-old question of “who did that?” to be answered. Administrative auditing is enabled by default for Exchange Online. However, you have little control over what is audited because Microsoft does not allow tenants to change most of the settings in the audit configuration.

Auditing is performed by the Admin Audit Log agent, which is active on every Exchange Online server. The agent evaluates cmdlets as they run against the audit configuration to decide whether the use of the cmdlet needs to be logged. If so, the agent creates an item holding details of the cmdlet and its parameters in the Inbox of the audit mailbox. The audit agent creates separate reports for each object if you execute an action that is performed against several objects. For example, if you use *Get-Mailbox* to fetch a list of mailboxes from a database and then use *Set-Mailbox* to place the mailboxes on litigation hold, the audit agent creates a separate audit event for each mailbox as it is updated.

You can also write custom entries into the audit log with the *Write-AdminAuditLog* cmdlet. This is intended to allow administrators to document actions performed in scripts. Up to 500 characters of text can be inserted in the comment parameter, which is captured in the *CmdletParameters* property of the audit entry:

```
[PS] C:\> Write-AdminAuditLog -Comment "NYC mailboxes placed on litigation hold"
```

## Exchange Online Administrative Audit Configuration

The *Get-AdminAuditLogConfig* cmdlet reveals the administrative auditing configuration used by Exchange Online. An edited version of its output is shown below:

```
[PS] C:\> Get-AdminAuditLogConfig

AdminAuditLogEnabled      : True
LogLevel                  : None
TestCmdletLoggingEnabled  : False
AdminAuditLogCmdlets      : {*}
AdminAuditLogParameters  : {*}
AdminAuditLogExcludedCmdlets : {}
AdminAuditLogAgeLimit     : 90.00:00:00
UnifiedAuditLogIngestionEnabled: True
UnifiedAuditLogFirstOptInDate : 27-Jul-2016 09:00:00
LoadBalancerCount        : 1
RefreshInterval          : 10
PartitionInfo             : {}
```

Apart from *AdminAuditLogEnabled*, which tells us that administrative auditing is in effect, the important settings in the list have the following meanings:

- **LogLevel:** None, meaning that optional information is not captured in audit entries. What is captured is data for *CmdletName* (the name of the cmdlet executed), *ObjectName* (the object that the cmdlet ran against), *CmdletParameters* (parameters passed to the cmdlet), *Caller* (the account used to run the cmdlet), *Succeeded* (whether the cmdlet was successful), and *RunDate* (the date and time when the cmdlet ran).
- **AdminAuditLogCmdlets:** \*, specifying what cmdlets should be audited. In this case, the asterisk means that any cmdlet that creates or changes the properties of an object is recorded. Note that Exchange Online creates far fewer audit entries because it can manage fewer objects. For example, databases and servers are not manageable. Audit entries are never captured for cmdlets that simply retrieve information, like *Get-Mailbox* or *Get-TransportRule*.
- **AdminAuditLogParameters:** \*, meaning that all parameters passed to the audited cmdlets are recorded. For instance, if you use the *Set-Mailbox* cmdlet to modify a setting on a mailbox, the parameter passed to the cmdlet is captured in the audit entry.
- **AdminAuditLogExcludedCmdlets:** Logically, as all cmdlets are recorded, none are excluded.
- **AdminAuditLogAgeLimit:** The default value shown is 90.00:00:00, meaning that audit entries should be kept for 90 days. Administrative events are stored in an Exchange Online arbitration mailbox that is inaccessible to administrators. You cannot change the retention period.

- **UnifiedAuditLogIngestionEnabled:** If True, audit events from workloads are ingested into the audit log. See the earlier section on enabling audit event ingestion for the audit log. The associated *UnifiedAuditLogFirstOptInDate* property records the date when audit log ingestion started.

## Accessing Administrative Audit Log Entries

Several methods are available to access Exchange Online administrative audit events:

- Exchange Online administrative audit log events flow to the Office 365 audit log and can be found in audit log searches performed through the Microsoft Purview Compliance portal or third-party products.
- Some of the reports available in the auditing tab of the compliance management section in the classic EAC, including the “admin audit log report,” use this data. Even more interesting is the “External admin audit log report,” which details the changes made to the tenant’s Exchange Online configuration by Microsoft data center administrators.
- The *Search-AdminAuditLog* and *New-AdminAuditLogSearch* cmdlets can be used to search administrative audit logs through PowerShell. See Chapter 8 in the Companion Volume for some examples of running Exchange audit searches with PowerShell.

In all cases, the preferred method for searching Exchange administrative audit events is to use the Compliance portal or the *Search-UnifiedAuditLog* cmdlet.

## Exchange Online Mailbox Auditing

While administrative auditing helps you understand who changed an administrative setting, mailbox auditing is the way to discover “who did what in that mailbox?” For instance, what account used delegate access to send a message on behalf of a mailbox, or who removed a message from a folder. The audit events captured by mailbox auditing are in three categories of access, each of which has a separate configuration:

- **Owner:** Operations performed by the mailbox owner. Normally there is little point in auditing owner operations as the owner has full control over their mailbox. This was the situation in the on-premises world for many years, but when Microsoft decided to enable mailbox auditing by default, they also decided to enable auditing for owner actions to collect a complete set of audit events for each mailbox. The default configuration for owner actions includes *MoveToDeletedItems*, *SoftDelete*, *HardDelete*, *UpdateFolderPermissions*, *UpdateInboxRules*, and *UpdateCalendarDelegation*.
- **Delegate:** Operations performed by another user who has delegate access to the mailbox via the *SendAs*, *SendOnBehalfOf*, or *FullAccess* permissions. These actions are the usual focus for auditing, especially when multiple delegates have access to a shared mailbox or for mailboxes that hold confidential information, such as the copies of items retrieved by eDiscovery searches that are stored in discovery mailboxes.
- **Administrative:** Operations performed by programs that connect to the mailbox using special administrative access such as a content search.

When auditing is enabled for a mailbox, Exchange captures audit entries for a set of default events for each of the three access categories listed above and stores the data in the Audits sub-folder of Recoverable Items.

Mailbox auditing is only available for user, shared, and group mailboxes. It does not apply to public folder mailboxes or resource mailboxes.

## Mailbox Auditing by Default

Mailbox auditing is enabled by default for all tenants. This means that Exchange Online captures audit records for a default set of actions performed by owners, delegates, and administrative processes in user, shared, and group mailboxes. Exchange Online doesn't support auditing for resource, or public folder mailboxes.

Apart from ensuring the consistent capture of audit records for all user, shared, and group mailboxes (including newly-created mailboxes), the benefit of mailbox auditing by default is that Microsoft manages the auditing configuration to make sure that the audit log ingests events for new mailbox actions as they become available.

To verify that mailbox auditing is enabled for the organization, run the *Get-OrganizationConfig* cmdlet and retrieve the *AuditDisabled* property.

```
[PS] C:\> Get-OrganizationConfig | Select AuditDisabled
```

```
AuditDisabled
-----
False
```

To opt-out of default mailbox auditing and stop Exchange capturing any mailbox audit data for the audit log, change the setting to *\$True*.

```
[PS] C:\> Set-OrganizationConfig -AuditDisabled $True
```

In this case, the organization setting is *False*, so we know that auditing is enabled by default. In this state, you do not need to enable auditing for new mailboxes as Exchange Online takes care of this action. It also means that Exchange Online captures the default set of audit records for all mailboxes, even if the *AuditEnabled* setting for a mailbox is *\$False*. In other words, Exchange ignores the *AuditEnabled* property for a mailbox when default auditing is enabled. If you want Exchange not to capture audit records for a mailbox, you run the *Set-MailboxAuditBypassAssociation* cmdlet as explained later.

### Transmission of Mailbox Events to the Audit Log

When auditing is enabled by default, Exchange Online captures audit events in the *Audits* sub-folder of the *Recoverable Items* folder in the mailbox. You can run the *Search-MailboxAuditLog* cmdlet to interrogate these events. If the license assigned to the mailbox's account is Office 365 E3 or above, Exchange Online can transmit the events to the audit log. Microsoft documentation says that [you must enable mailbox auditing for mailboxes belonging to accounts with Office 365 E3 licenses](#). Our experience is that this isn't necessary and that mailbox events for these mailboxes appear in the audit log along with those from other accounts.

**Mailbox auditing and multi-geo organizations:** Exchange Online does not support cross-geo mailbox auditing. This is particularly obvious in mailbox delegation, such as when a user located in the home region uses their SendAs permission to send messages from a mailbox located in a satellite region. The satellite region does not log the action.

## Audit Actions for User Mailboxes

Table 21-2 lists some of the different actions configurable for capture in each access category. The [complete list of mailbox audit actions](#) is available online.

<b>Action</b>	<b>Description</b>	<b>Owner</b>	<b>Admin</b>	<b>Delegate</b>
<i>ApplyRecord</i>	Mark an item as a record by applying a record or regulatory record retention label.	Yes	Yes	Yes
<i>Create</i>	An item is created in the mailbox.	Yes	Yes	Yes
<i>Copy</i>	An item is copied to another folder.	No	Yes	No

<i>FolderBind</i>	A client opens a mailbox folder, including the original logon to the mailbox. Exchange consolidates folder bind actions and posts a single entry per folder every 24 hours.	No	Yes	Yes
<i>SendAs</i>	A message is sent from the mailbox using the SendAs permission.	No	Yes	Yes
<i>SendOnBehalf</i>	A message is sent from the mailbox using the Send On Behalf Of permission.	No	Yes	Yes
<i>SoftDelete</i>	An item is moved into Recoverable Items.	Yes	Yes	Yes
<i>HardDelete</i>	An item is permanently removed from Recoverable Items.	Yes	Yes	Yes
<i>Update</i>	The properties of an item are updated.	Yes	Yes	Yes
<i>MailItemsAccessed</i>	Messages are synchronized or opened by clients. See earlier section about high-value audit events.	Yes	Yes	Yes
<i>Move</i>	An item is moved into another folder.	Yes	Yes	Yes
<i>MoveToDeletedItems</i>	An item is moved into Deleted Items.	Yes	Yes	Yes
<i>MailboxLogin</i>	The owner logs into the mailbox.	Yes	No	No
<i>RecordDelete</i>	An item marked as a record is soft-deleted.	Yes	Yes	Yes
<i>Send</i>	An email is sent (crucial event). Must be configured before events are gathered.	No	No	No
<i>UpdateCalendarDelegation</i>	Record delegate permissions assigned to the calendar.	Yes	Yes	No
<i>UpdateComplianceTag</i>	A different retention tag is applied to an item.	Yes	Yes	Yes
<i>UpdateFolderPermissions</i>	Record changes to folder permissions, such as allowing a user to view a calendar.	Yes	Yes	Yes
<i>UpdateInboxRules</i>	Record changes to inbox rules.	Yes	Yes	Yes

Table 21-2: Mailbox actions captured for auditing purposes

The *HardDelete* action does not record audit events for items removed using the *Shift+Delete* key combination as this operation only bypasses the Deleted Items folder to move items directly into the Recoverable Items folder. *Shift+Delete* operations are logged as *SoftDelete* actions, which also happens when users remove items from the Deleted Items folder individually or by emptying the entire folder.

**Odd Delegate Audit Records:** You might find some audit records for *SendAs* operations by a delegate for a mailbox that you know has no delegates and wonder what's going on. The answer is usually when a background process impersonates the user to send email. For instance, this happens when Planner generates email notifications when creating new tasks or completing a task (the *ClientInfoString* property is "Client=REST," showing that Planner used the Graph API for this action). The messages that Planner sends are in the Sent Items folder of the mailbox. You can match them with the audit records.

## Updating Mailbox Audit Configurations

To see what actions are captured for a mailbox, run *Get-Mailbox* to fetch details of the *AuditAdmin*, *AuditDelegate*, and *AuditOwner* properties together with the default audit setting for the mailbox:

```
[PS] C:\> Get-Mailbox -Identity "Customer Services" | Format-List Audit*, DefaultAuditSet
```

```
AuditEnabled      : True
AuditLogAgeLimit  : 90.00:00:00
AuditAdmin        : {Update, MoveToDeletedItems, SoftDelete, HardDelete...}
AuditDelegate     : {Update, MoveToDeletedItems, SoftDelete, HardDelete...}
AuditOwner        : {Update, MoveToDeletedItems, SoftDelete, HardDelete...}
DefaultAuditSet   : {Admin, Delegate, Owner}
```

The audit configuration listed above tells us that:

- Auditing is active for the mailbox.
- Exchange keeps audit items for 90 days.
- The set of actions captured for the three categories of access
- Exchange uses the default audit set for each of the three categories.

PowerShell truncates the set of audited events for each category. To see the complete set of audit actions for a category, expand the property holding actions for the chosen category like this:

```
[PS] C:\> Get-Mailbox -Identity "Customer Services" | Select -ExpandProperty AuditDelegate
```

```
Update
MoveToDeletedItems
SoftDelete
HardDelete
SendAs
SendOnBehalf
Create
UpdateFolderPermissions
UpdateInboxRules
```

You can change the set of actions by running the *Set-Mailbox* cmdlet. In this example, we add the *UpdateComplianceTag* action to the set of actions already configured for capture. It can take up to an hour before an updated configuration is effective. Remember too that customizing the set of actions captured for a category stops Exchange from updating the set of default actions should Microsoft introduce new actions in the future.

```
[PS] C:\> Set-Mailbox -Identity James.Ryan -AuditOwner @{Add="UpdateComplianceTag"}
```

To disable auditing for a category, input "None" for the action list. Remember that if mailbox auditing is enabled by default for the organization, Exchange still captures the default set of actions in all three categories.

```
[PS] C:\> Set-Mailbox -Identity "Customer Services" -AuditDelegate None
```

## Managing Default Mailbox Audit Configurations

When mailbox auditing is enabled by default for an organization, Exchange populates the *DefaultAuditSet* property. This property indicates if an admin has changed the default audit configuration set by Microsoft for the Owner, Delegate, and Admin categories for a mailbox. To examine the value run:

```
[PS] C:\> Get-Mailbox -Identity Kim.Akers | Select DefaultAuditSet
```

```
DefaultAuditSet
-----
{Admin, Delegate, Owner}
```

Because the three categories are listed, you know that no change has been made. On the other hand, if you see:

```
DefaultAuditSet
-----
{Admin, Delegate}
```

You know that an administrator has added or removed an action from the Owner set. If a blank value is seen, you know that changes have occurred for all three categories. When the default set is updated, Exchange Online won't update the audit configuration when Microsoft introduces new actions, so it's important to keep to the default set whenever possible and only make changes when necessary. If you want, you can reset

mailboxes by running *Set-Mailbox*. In this example, we scan for mailboxes where the default set is not used and reset those mailboxes.

```
[PS] C:\> $Mbx = Get-Mailbox -RecipientTypeDetails UserMailbox -ResultSize Unlimited | Select Alias,
DisplayName, DefaultAuditSet
$Updates = 0
ForEach ($M in $Mbx) {
    $FullSet = $M.DefaultAuditSet[0] + $M.DefaultAuditSet[1] + $M.DefaultAuditSet[2]
    If ($FullSet -ne "AdminDelegateOwner") {
        $Updates++
        Write-Host "Updating" $M.DisplayName
        Set-Mailbox -Identity $M.Alias -DefaultAuditSet "Admin", "Delegate", "Owner" }}
If ($Updates -eq 0) {Write-Host "No mailboxes updated"} Else {Write-Host $Updates "mailboxes updated
with default audit configuration"}
```

## Mailbox Auditing Bypass

If you want to exclude mailboxes from auditing, you use the *Set-MailboxAuditBypassAssociation* cmdlet to tell Exchange Online not to collect audit events. For example:

```
[PS] C:\> Set-MailboxAuditBypassAssociation -Identity "Kim Akers" -AuditBypassEnabled $True
```

Set the value to `$False` to disable mailbox audit bypass.

Tenant administrators often use the *Set-MailboxAuditBypassAssociation* cmdlet to stop audit events from service mailboxes flooding the audit log. This might have been acceptable in an on-premises environment when the cmdlet first appeared in Exchange 2010. Today, it is not recommended to exclude any Exchange Online mailbox from auditing in this manner. First, Microsoft 365 has much better tools available to search the audit log and a few extra audit events will make no difference. Second, when an account is excluded from mailbox auditing, Exchange does not capture events for any mailbox the account can access. An account could therefore open a shared mailbox and remove items in that mailbox without the recording of any audit data. Last, if you experience something like a Business Email Compromise attack, you need as much audit data as possible to collect to understand how the attack develops and what was its impact.

To see if any mailbox auditing bypasses are in place, run the *Get-MailboxAuditBypassAssociation* cmdlet and filter for accounts with a bypass. It is quite normal to have many mailbox association records returned, including records for guest user accounts and system accounts as these are created when new accounts are created in the tenant. For example, this command finds accounts with mailbox audit bypass enabled.

```
[PS] C:\> Get-MailboxAuditBypassAssociation | ? {$_.AuditBypassEnabled -eq $True} | Format-Table
Name, WhenCreated, AuditBypassEnabled
```

Name	WhenCreated	AuditBypassEnabled
Kim Akers	02/12/2014 15:20:42	True

## Auditing for Group Mailboxes

When mailbox auditing by default is enabled for an organization, audit records are captured for the group mailboxes belonging to Groups. Unlike other mailbox types, you can't change the auditing configuration for group mailboxes. Table 21-3 lists the configuration used to capture audit records for group mailboxes.

Mailbox action	Owner	Delegate	Admin
Create		Y	Y
HardDelete	Y	Y	Y
MovetoDeletedItems	Y	Y	Y
SendAs		Y	Y
SendOnBehalf		Y	Y

<i>SoftDelete</i>	Y	Y	Y
<i>Update</i>	Y	Y	Y

Table 21-3: Audit configuration for group mailboxes

## Reporting Workload Activity

Despite many requests over the years, Microsoft has never delivered good reporting facilities for on-premises applications. This statement was true in the early years of Office 365, but things have improved recently with analytics and usage data appearing in different admin portals. What hasn't changed is the fact that if you want to have truly flexible reporting over extended periods, you should consider ISV products. The Microsoft Graph is increasingly the source of truth for workload activity data, but other sources such as the audit log are also useful.

**Graph Usage Reports:** Microsoft generates a range of workload activity data [accessible through the Microsoft Graph](#). Data for all workloads is not yet available, but you can access information for Exchange Online, SharePoint Online, Yammer, Teams, and OneDrive for Business.

### Using PowerShell to Create Reports

Administrators have used PowerShell for years to generate reports and many examples of scripts to produce nicely-formatted reports are available on the web. You can certainly use PowerShell to create custom versions of some of the standard reports to meet your specific needs. For example, we might want to know the size of user mailboxes. A quick PowerShell query reveals the answer:

```
[PS] C:\> Get-Mailbox -RecipientType UserMailbox | Get-MailboxStatistics | Sort ItemCount
-Descending | Format-Table DisplayName, TotalItemSize, ItemCount -AutoSize
```

DisplayName	TotalItemSize	ItemCount
Tony Redmond	4.116 GB (4,419,110,350 bytes)	36529
Jeff Guillet	1.62 GB (1,739,456,346 bytes)	10411
Vasil Michev (Technical Guru)	1.081 GB (1,161,234,561 bytes)	7019
Deirdre Smith	933 MB (978,334,934 bytes)	6207

Reports like this hold valuable data and are useful on an ad-hoc basis. However, when you set out to use PowerShell, you should realize that:

- PowerShell is an excellent method to query data but is less good when the time comes to format reports for printing. PowerShell can output data in CSV format for later processing in Excel to create charts or to do deeper analysis but generating a report and a few charts in Excel is different from creating a clear and well laid-out report.
- PowerShell has limited ability to analyze data over an extended period (the cmdlets that retrieve data from the reporting data mart sometimes do not give a very granular level of information).
- Exchange Online throttles PowerShell if a script attempts to process details of hundreds or thousands of mailboxes. Throttling ensures that no job soaks available resources and so reduces service to other tenants. It is good if your script can avoid the need to call the *Get-ExoMailbox* cmdlet to create a set of mailbox objects for processing as this is a resource-intensive activity that becomes a candidate for throttling. One way around this is to create lists of mailboxes and store them in CSV files that other scripts can open and process.
- Some components do not support PowerShell or make their data available to PowerShell. Exchange Online has good coverage, but you will not be able to generate reports for Teams or Yammer unless you fetch data from the Graph. An example script showing how to use the Graph APIs with PowerShell to generate usage reports for Exchange Online, SharePoint Online, OneDrive for Business, Teams, and

Yammer workload data and Azure AD user sign-in data is [available in GitHub](#). The data extracted from the Graph is the same as reported in the Microsoft 365 admin center, the Teams admin center, and the Microsoft 365 Usage Analytics for Power BI.

Finally, if you do create custom PowerShell reports, you must be prepared to check and potentially update them regularly to ensure that code does not break when Microsoft introduces updates to cmdlets, new functionality, or new versions of PowerShell. On the upside, some will like the challenge of writing and updating reports, others will find that it is easier and more efficient in the end to buy a reporting package from a company that specializes in this space, and it is always great to be able to reuse the many contributions of PowerShell scripts and code snippets that people make to the community to form the basis of your solution.

## Standard Usage Reports

The Microsoft 365 admin center includes a Reports section (Figure 21-11) offering a set of reports covering various workloads for fixed 7, 30, 90, and 180-day periods. Users do not need full administrative access to access the standard usage reports. Anyone assigned a workload administrator role like the Teams Service administrator, or the Global Reader or Report Reader administrative roles can access the usage reports (see Chapter 4).

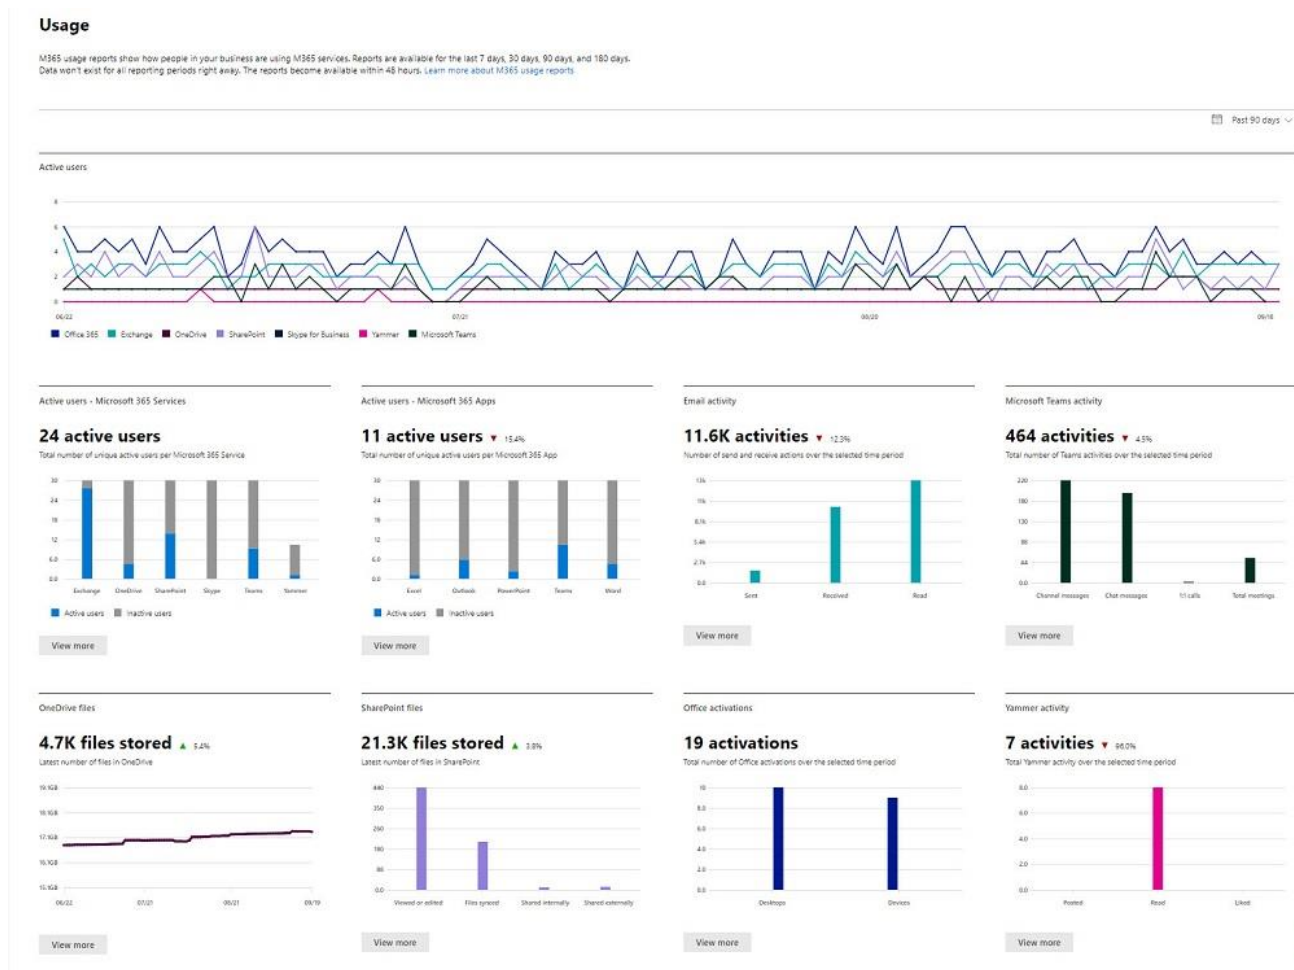

Figure 21-11: Standard workload usage reports for a tenant

The Microsoft 365 admin center features two types of reports:

- **Usage:** How much use people make of different workloads, like how many messages users send and receive using Exchange, meetings attended in Teams, or files viewed or edited with SharePoint. Some

applications, like Planner, do not have usage reports, and some which do, like Teams, report a limited set of actions (mainly in chat and meetings) and don't include any insight into the other ways people interact with the app.

- **Productivity Score** covering remote work elements. Microsoft introduced this section to help tenants understand the impact of employees working from home. The data focuses on collaborative activities (Exchange Online, Teams, Forms, and Yammer) and online document use (SharePoint Online and OneDrive for Business).

The detail and coverage of the reports available in the Microsoft 365 admin center have improved over time and deliver enough information to gain insight into user activity. Microsoft makes up to 180 days of reporting data available to tenants.

The reports for the individual workloads include a grid table containing individual user data. The table holds up to 2,000 entries and can be sorted by the different columns. You can also **Export** to save the report data to a CSV file (you'll need to export the data to sort and analyze user activity if your tenant has more than 2,000 accounts). If you want to preserve the graphics, you can either take a screenshot or use the browser's print to PDF choice to create a PDF file. It is also worth mentioning that you can access additional reports in other admin portals. For example, the Azure AD admin center has reports focusing on directory-centric activities such as password resets, anomalous sign-ins, and rights management, but they are useful in understanding the complete operating environment. The Teams admin center also includes a set of reports about various aspects of Teams usage.

Third-party reporting products make their money by offering a wider range of reports with a more granular level of detail than is available in the standard reports. They also usually give access to information gathered for more than the standard 180-day reporting window or incorporate data gathered from a variety of sources within a customer's IT environment. In comparison to the standard reports, which tend to focus on increasing usage of applications like SharePoint Online or Teams, ISV products often place greater emphasis on understanding what the data means and how to be more effective in areas like license management.

To stay in business, ISV offerings must be better than the reports delivered by Microsoft. Better analysis and insight into business operations are always welcome and this is exactly the advantage that you hope to gain by using a third-party product. To address the need to dive deeper into how workloads and users are performing, ISVs can use the same data from the Microsoft Graph used by the Microsoft 365 admin center to build tailored solutions to satisfy specific customer needs that the standard reports do not address.

## Anonymized Usage Data

Some organizations are uncomfortable with the idea that people holding many administrative roles (including Report Reader) might be able to see sensitive data about user activity. For example, it is easy to discover how many messages the CEO sends and receives or how many Teams meetings he or she attends. Up to September 1, 2021, the default for Microsoft 365 reporting was to show full information about users and groups. From that date, the usage reports in the Microsoft 365 admin center, Teams admin center, and anywhere else which uses the Microsoft Graph usage reports API display anonymized values. Figure 21-12 shows anonymized data in a usage report.

Figure 21-12: Anonymized user data in the email activity report

Anonymization (also called deidentification or obfuscation) means that the Microsoft Graph replaces the personal information for user accounts (like display names and user principal names), groups, and sites with system-generated obfuscated values that cannot be associated with the underlying objects, including GUIDs that could be used to identify an object.

If the organization decides that it is acceptable to display full user information, a global administrator can switch the setting in the **Reports** section of **Org settings** in the Microsoft 365 admin center. This action generates an *UpdatedCFRPrivacySettings* audit record in the Office 365 audit log. Because the setting governs the Microsoft Graph usage reports API, the deidentification setting also applies to usage data fetched by scripts and programs which use the API.

Note that some administrative roles such as Usage summary reports reader or Global reader can never see details of user activity, anonymized or not.

## Microsoft 365 Usage Analytics for Power BI

Tenants can install a [Power BI template app](#) (previously known as the Office 365 adoption content pack) to help understand the usage patterns for several Microsoft 365 workloads. Usage analytics is a pre-built dashboard of graphs and charts. You only need a basic Power BI license to access the dashboard. Together, the graphs and charts form a dashboard for a tenant divided into four areas:

- Executive Summary: A general view of workload usage across the tenant (Figure 21-13).
- Activation/Licensing: How many licensed accounts are in the tenant, how many are active, and what devices they use.
- Product Usage: How much use is made of Exchange Online, SharePoint Online, Teams, Yammer, Microsoft 365 Groups, and OneDrive for Business.
- User Activity: Different views of user activity within the tenant.

The current iteration includes good coverage of Exchange Online, SharePoint Online, OneDrive for Business, Teams, and Yammer. It does not cover other applications like Stream or Planner, so the dashboard covers usage of the base workloads rather than giving a comprehensive view of activities across all workloads. Microsoft might include coverage of the missing applications over time.

The dashboard helps tenants understand the adoption rate and usage for various aspects of usage over the prior twelve months. For instance, how many people use SharePoint Online, Teams, and Exchange Online – or all the covered applications. This kind of information can tell you if you have a license management problem where people have licenses for an application that they do not use.

Another use of the dashboard is to look at usage trends, such as whether email traffic increases over time. These insights into what is happening within the tenant can help you to understand changes in user behavior. For instance, if you make a determined effort to convince people to store documents in SharePoint and OneDrive and access the files there rather than attaching them to email for circulation within the company, a steady uptick in file storage should result. If it does not, then the campaign is unsuccessful, and you might need to take a different approach to convince people to use “cloudy attachments.” Another example is in

Teams, where a reduction in email traffic should match an increase in minutes consumed in instant messaging and conversations. Still another is to measure whether the introduction of Teams causes users to move some of their collaboration with fellow employees away from email to conversations within team channels.

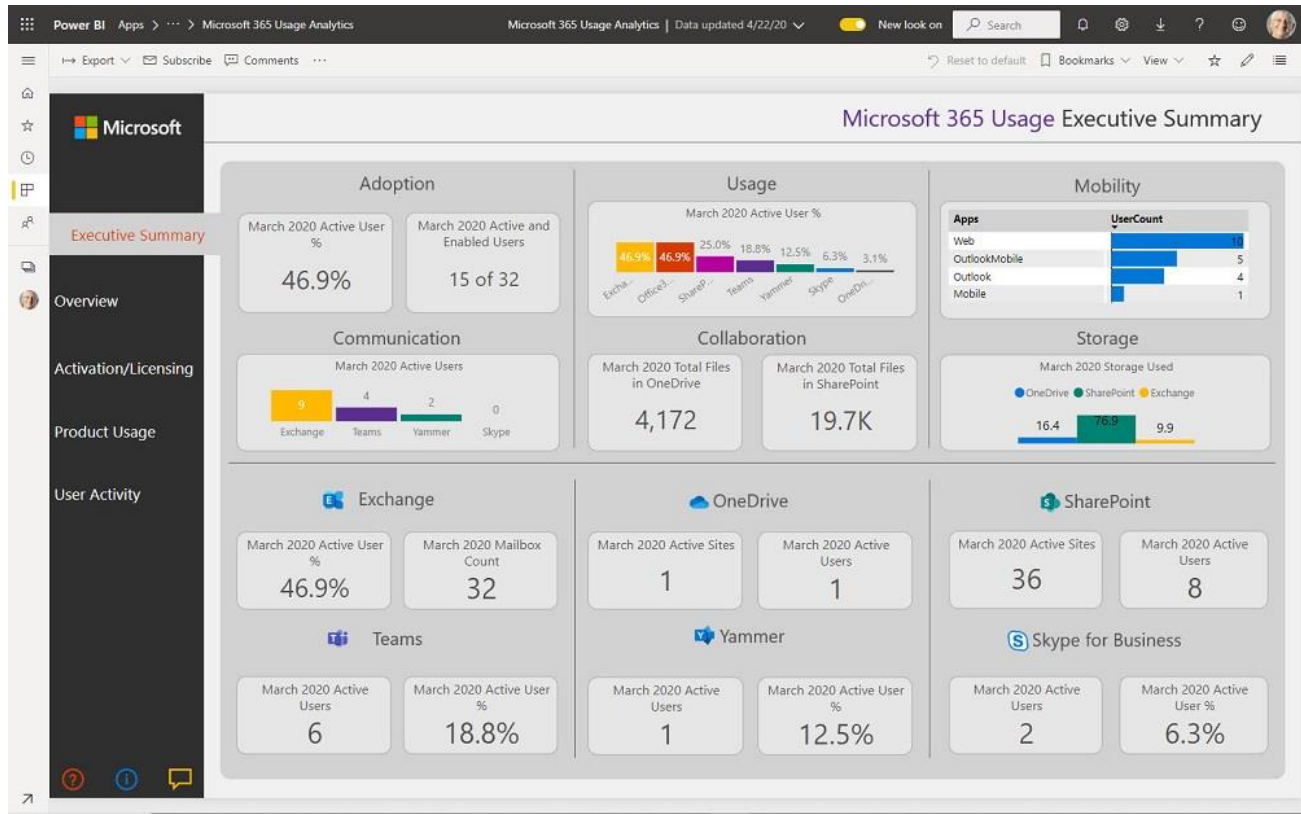

Figure 21-13: Microsoft 365 Usage Analytics dashboard

Microsoft gathers data from across workloads to aggregate and refines the data to refresh the dashboard. The content pack updates weekly by default, but the backend service refreshes data daily, so a tenant can amend the dataset scheduled refresh interval to receive daily updates. However, the actual data lags the current date by between 36 and 48 hours as Microsoft needs this time to gather information and process it for the dashboard. Given the scale of Microsoft 365 and the amount of data that must be processed to generate aggregate statistics for tenants, this delay is understandable. The setting for anonymized data for reports governs whether usernames or anonymous identifiers appear in the dashboard.

## Independent Reporting Products

Few tenant administrators are skilled at generating easy-to-read reports that highlight important data. Programmatic access to the Reporting DataMart is available to allow software developers to use the data belonging to tenants if tenants grant permission for this access. The intention is to allow vendors who specialize in software monitoring and reporting to incorporate usage data into their products to give customers a much better view of what happens inside a tenant than you can get using the basic reports. Apart from the obvious goodness inherent in having a common repository to consult to retrieve operational data about Microsoft 365, the combination of Reporting DataMart and choice of APIs (including PowerShell and the Microsoft Graph) avoids the need for people to create personal methods to extract information.

The number of independent software vendors who create reporting solutions continues to expand. Most of the ISVs that offer reporting solutions focus on pure cloud environments while some include monitoring and reporting for on-premises servers or non-Microsoft cloud workloads. Each product plays to its strengths and employs different approaches to data extraction, analysis, and reporting. Among the criteria you can use to figure out whether you need to use a third-party product instead of the standard usage reports include:

- **Data longevity:** Microsoft stores tenant reporting data for 180 days. This might be insufficient for your needs if you want to chart the usage of applications over a longer period for planning and analysis purposes. Ask for how long the vendor stores tenant reporting data. In addition, ask about the security and privacy controls that are in place to ensure that tenant data cannot be compromised. Ask about how often the product refreshes data from Microsoft 365 workloads to understand how up-to-date the reports are.
- **The number and type of reports:** A limited set of standard usage reports are available in number and in what they report. For example, there are no reports for mobile device usage, perhaps because Microsoft would prefer tenants to use Microsoft Endpoint Manager for mobile device management. A third-party reporting vendor is likely to have hundreds of different reports in their product.
- **Intelligent views:** Looking at a single workload is interesting if you want information about that application, such as the number of active mailboxes in Exchange Online. Things become more interesting when you can compare data extracted from one workload against another. For example, if you have a project to make more use of OneDrive for Business, you will be interested in the number of sites in use and the files and quota used in those sites. It is also interesting to know if the growing use of OneDrive affects email volume and usage.
- **Filtering and Pivoting:** Viewing tables of data through a browser is acceptable for small tenants but rapidly becomes problematic when the number of reported objects grows. For instance, it is difficult to make sense of a table holding details of thousands of mailboxes. The ability to use filters and to view data through pivot tables are huge advantages for large tenants.
- **Access:** The reports available in the Microsoft admin center need some level of administrative access. This is inconvenient when users other than administrators want access too. For instance, a company might want to charge back costs for Exchange Online mailboxes to the operating units of the business. This activity is usually performed by accountants, not tenant administrators, so removing the requirement to have administrative permissions to be able to access reports can be very useful.
- **Delivery:** Not everyone wants to browse a website to access reports. Some products allow reports to be automatically extracted and emailed to users on a scheduled basis.
- **Scale:** How well does the product scale up to deal with the predicted full load of the tenant? Good demos performed against a 5-user tenant might not be so impressive when confronted with the data generated by 20,000 users.
- **Support:** How is support provided? Is support available locally?
- **Cost:** How is the cost of the product calculated?
- **Deployment:** Is any extra software needed to create or view the reports? Is the product fully web-based or do you have to install some software on a workstation or servers to access the reports?

No one product is the best choice for every situation. The best approach is to spend the time to test the software in your environment and make the decision based on what you discover there.

**Gaps and changes:** All third-party reporting products and Microsoft's reports use a single source of truth: the reporting data collected for a tenant. Some third-party products copy that data so that it is retained for longer periods and to perform additional analysis. However, you need to be aware of two issues regarding reporting data. First, the data can change because of a change made by Microsoft. This is what happened when Microsoft changed the way that the *Get-MailboxStatistics* (or *Get-ExoMailboxStatistics*) cmdlet reported system messages stored in user mailboxes (described in the Exchange Online chapter). Second, hiccups and operational glitches sometimes prevent the ingestion of workload data to the reporting data mart, which then creates gaps in reports. Sometimes the gaps are filled in after normal service is restored, sometimes the gaps remain. Keep your eyes open and make sure that if a gap appears, you make Microsoft and/or the third-party reporting vendor aware of the issue.

## Extracting More Detail About Tenant Activity

The standard usage reports include a lot of information about how a tenant consumes resources, but the information is often quite high-level and not as granular as you might like. In addition, the reporting service makes data available for a limited timeframe, usually with a maximum horizon of 180 days, which makes the reporting information provided by the service difficult to use for long-term planning. For example, Figure 21-14 illustrates the pattern of SharePoint Online usage over the last 30 days. The report can show data going back over a maximum of 180 days, but you cannot go back any further to explore questions such as how much growth occurred in the last year or last two years. The bottom part of the report lists the activity of individual users.

Reporting products often use PowerShell to retrieve more information from workloads and Azure AD to build out the data necessary to fill in the knowledge gaps. For example, it is all very well to know that a total of 55 distribution lists exist within a tenant, but it is even better to know the membership of each group and whether the groups are in active use or just taking up dead space in the GAL. To make long-term reports possible and to assure speedy access to information, reporting vendors often download tenant data periodically to repositories that they manage. The data is useful for analyzing trends such as the growth in mailboxes or messaging activity over time. Each product has its set of reports and its unique way to interpret and present information.

Extra reporting capabilities are enabled by Azure AD Premium. For example, if you want detail about a [password-based activity](#) such as user account resets, your account must have an Azure AD Premium license to access that report. See the Azure AD documentation for the [latest information about available reports](#).

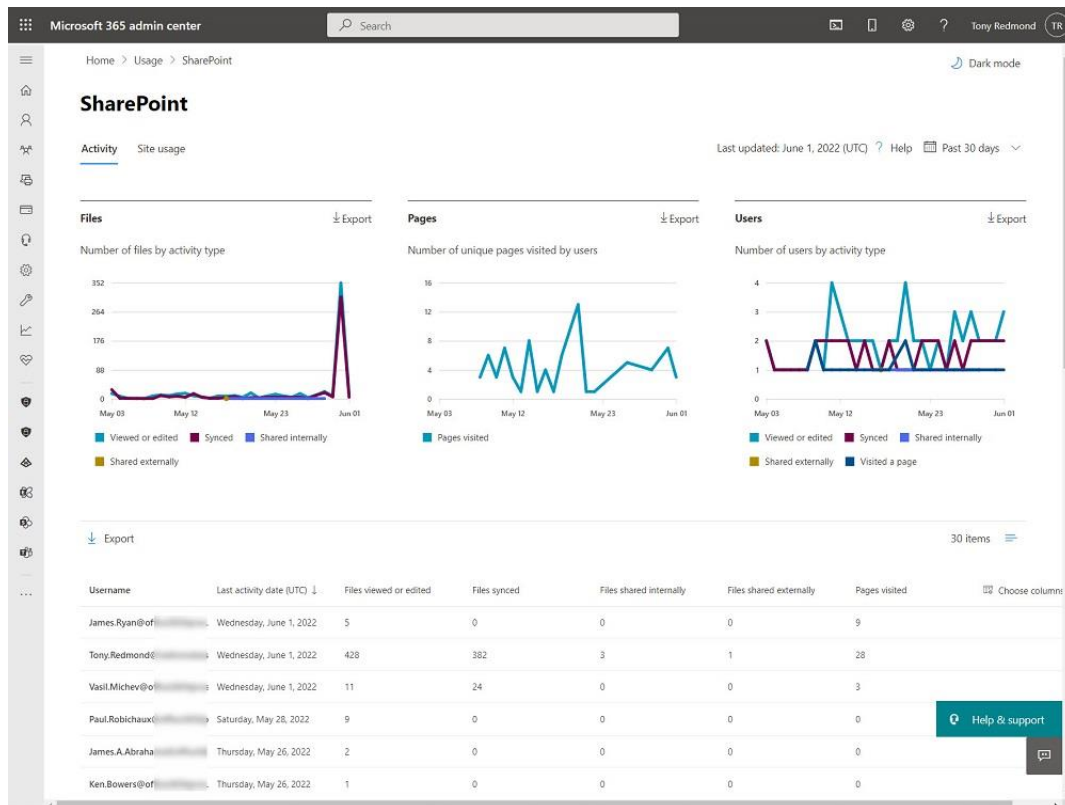

Figure 21-14: Viewing the usage report for SharePoint Online

# Communications Compliance

[Microsoft Purview Communications Compliance](#) is part of the Microsoft 365 Insider Risk solution set. These policies are the third iteration of functionality designed to help organizations monitor communications sent and received by employees. The normal reason why an organization wants to monitor communications is to reduce the potential for risk due to mistakes or deliberate actions by employees in their internal and external communications. The loss caused by inappropriate or illegal communications might be reputational or financial. Either way, it's undesirable, especially for large enterprises, which is why organizations want to proactively detect any potential problems and then prove that they are on top of the situation should the need exist to demonstrate this point to regulators or other corporate bodies.

Although it might seem sneaky and reminiscent of a "big brother" approach to employees, certain industries have regulations that force companies to ensure that they have a supervision policy in place, perhaps only for employees that work in specific areas. For example, [FINRA](#), the U.S. Financial Industry Regulatory Authority, enforces rules governing the activities of brokers and dealers to ensure market transparency and fairness. It was common to find that on-premises organizations created special software called "transport sinks" to capture and examine messages sent between employees. The code ran in the Exchange transport pipeline to examine and capture copies of messages and route the copies to personnel skilled in regulations and compliance, who reviewed the traffic to ensure that no problems exist. Companies often combined transport sinks with transport rules to control how certain groups of users communicated with each other.

Organizations using communication compliance policies must have Office 365 E5, Microsoft 365 E5, or Microsoft 365 E5 Compliance for all accounts covered by the policies.

## Reviewing Microsoft 365 Communications

Communication compliance policies set guidelines for acceptable internal and external communications. In a Microsoft 365 context, communications mean:

- Exchange Online email.
- Teams personal chat and channel communications, including messages sent by users with on-premises mailboxes. The Teams messages reviewed by communication compliance policies are the compliance records captured by the Microsoft 365 substrate and used for eDiscovery (see Chapter 13 for more information).
- Yammer conversations (if the Yammer network runs in Microsoft 365 native mode).
- Messages imported from an external source [through a connector](#) like Bloomberg messaging.

Communications compliance policies depend on messages stored in Exchange Online. Background agents check mailboxes to scan for policy violations in normal messages and the compliance records captured for Teams chat and channel conversations (including records for conversations with external users in other tenants and Skype consumer users).

When the agents detect violations, they copy messages to special mailboxes to make them available for review and resolution. This isn't a real-time process, and you can expect a delay of approximately an hour before policies detect and flag problem messages for review. In most cases, this isn't a problem because compliance checking is a reactive process. In any case, it's usual that policies select only a percentage of detected messages for review, so not every message that could contain a violation will turn up in the portal for review.

## Components of a Communications Compliance Policy

Communication Compliance policies are managed through the Microsoft Purview Compliance portal. A policy includes the following components:

- **Reviewees:** The people (individuals or groups) whose communications come within the scope of the communications compliance policy. You can use email distribution lists or Microsoft 365 groups to define the reviewees for a policy. You can't use dynamic groups or dynamic distribution lists to define reviewees.
- **Locations:** Define the workloads monitored by the policy, including Exchange, Teams, and Yammer.
- **Conditions:** Define the characteristics of communication items policies examine to detect policy violations. The conditions include:
  - Sensitive information types as used elsewhere in Microsoft 365, as in Data Loss Prevention policies.
  - Classifiers, both those provided by Microsoft such as Resumes and Source Code, or those created by the tenant to find items commonly used by the business.
  - Message properties such as message size, attachment type and size, originating domain, and sensitivity label.
- **Sample size:** The percentage of messages which meet the policy conditions captured for review.
- **Reviewers:** The people who will access the items captured for review to decide whether the content of those items complies with the regulations in force. Reviewers process captured items through the Compliance portal and decide whether items are compliant or non-compliant. In the latter case, reviewers can then escalate the situation to the offending user's manager, HR, or some other department for resolution.

An organization can deploy multiple communication compliance policies within their tenant, each of which monitors a set of users. With the structure of a policy in mind, before you can create a new policy, you should answer the following questions:

- What set of users come within the scope of the policy? How is the target set identified?
- Communication between users includes a vast variety of content. How do we focus on the messages for review? For example, are we looking for a specific codeword or terms?
- What is an adequate sample for review? A policy might review 100% of detected messages during the testing or initial deployment phase of deployment to make sure that the conditions specified for the policy are accurate and not too broad. After reaching this point, it's usual to reduce the percentage to 10% or so to lessen the load on reviewers. Experience with supervision policies proves that selecting too high a percentage can generate so many items that reviewers cannot cope with the volume and turnaround reviews in a reasonable time.
- Who will examine the captured traffic? The reviewers need to understand what constitutes a problem when they see it in a message. They also need to understand what is a serious violation that needs immediate action and what is not so serious. Reviewers do not have to be fluent in all the languages used for communications because Microsoft Translator can translate messages into a reviewer's preferred language.
- What happens when a violation occurs? All violations have consequences, but some violations have graver consequences than others. The organization might require an escalation process to allow reviewers to escalate violations to a higher authority for a decision about how to handle a matter, including potentially reporting a case to a regulatory authority.
- User awareness. Before the tenant begins to monitor communications, it is only fair to inform the users whose communication is under review about potential violations and the consequences if a policy detects a problem that proves to be a real issue. This is an area where the company's legal and HR departments have a key role to play.

After determining the answers to these questions, you can go ahead and create a policy, assuming your account holds the right roles.

## Communications Compliance Role Groups

Five role groups support granular management of communications compliance policies and the data captured by policies:

- **Communication Compliance:** Includes all the other communication compliance role groups.
- **Communication Compliance Administrators:** Manages communications compliance policies.
- **Communication Compliance Analysts:** Can view communications compliance message metadata to analyze the effectiveness of policies.
- **Communication Compliance Investigators:** Can view the full body of messages detected by communication compliance policies.
- **Communication Compliance Viewers:** Allows access to communication compliance reports and widgets.

The Communication Compliance role might be the only one used in smaller tenants. The other roles exist to allow granular assignment of permissions to specific people to do certain tasks. For more information, see [this page](#).

## Workflow Considerations

Communications compliance includes simple workflow processing (what Microsoft calls “*flexible remediation workflows*”) to help track and resolve violations, mostly by the dispatch of emails to offenders and their managers and recording the outcome. For the most serious cases, communications compliance is integrated with Microsoft 365 Advanced eDiscovery, allowing for information gathered about violations to be transferred to eDiscovery as prepackaged cases for further investigation and resolution.

Thought must be put into how to integrate what’s available in the application to complement and build on existing HR procedures. For instance, what should happen upon the detection of a violation by an employee? And what escalation steps happen if someone proves to be a serial offender? These are decisions that Microsoft can’t make because every company is different. The implementation of employee monitoring is highly dependent on the industry the organization works in and the applicable regulations.

## Machine Learning and Classifiers

Communication compliance policies can include classifiers to detect types of information. Microsoft 365 uses a variety of classifiers for different purposes and tenants can create their own by going through a training process. During this process, machine learning processes sets of sample documents to build a map of common characteristics that solutions can use to detect the content of the same type. The prepackaged classifiers include:

- Offensive language (now deprecated).
- Profanity.
- Resumes (CVs).
- Source code.
- Targeted harassment.
- Threat.
- Adult images.
- Gory images.
- Racy images.
- Sexual harassment.

Microsoft's text-based classifiers can handle multiple languages (the set grows over time), including English, French, German, Italian, Japanese, Arabic, Dutch, Korean, Spanish, Portuguese, and Chinese (including Chinese traditional). Image-based classifiers are language-independent. Images examined by these classifiers can be in JPEG, GIF, BMP, and PNG formats. Images must be at least 50 x 50 pixels to be assessed. Optical Character Recognition (OCR) scanning for printed or handwritten content embedded in email and Teams messages has [similar size limitations](#).

Supervision policies don't include machine learning and tenants had to define terms of interest to check for. Having classifiers makes it easier for tenants to monitor communications based on well-known and well-understood characteristics. For instance, if someone tells another person that "I hate you," the harassment classifier will recognize the "hate" keyword and the context of its use. Using classifiers and machine learning helps communication compliance policies generate fewer false positives than supervision policies do. We will probably never have zero false positives but eliminating most of these reports eases the load on reviewers.

Even the best machine learning detection experiences problems with the way language flex and evolves. One person's offense is another person's norm, which makes it imperative that reviewers consider messages selected for review in context. For instance, a [scatological reference](#) about someone in an email or Teams chat might be innocuous or offensive, depending on how it is phrased. And calling someone a pile of brown smelly bovine output is likely to pass most machine learning tests. The evolving use of language and the variation of acceptance of different terms can cause many false positives, which is one of the reasons why Microsoft deprecated the offensive language classifier and replaced it with a combination of threat, profanity, and harassment qualifiers, each being more focused and therefore more likely to generate a correct result.

## Anonymized Results

Communication compliance settings include the option to see anonymized usernames (like *Anonyl0-Ibb*) instead of the real display names of users who cause policy matches. You might prefer to select this setting to preserve user privacy during the initial phases of potential violation reviews and investigations.

## Creating a New Communications Compliance Policy

You can create a new policy from scratch, or you can use one of the template policies provided by Microsoft:

- **Regulatory Compliance:** looks for entries in a custom lexicon of words that might indicate violations if present in messages between a specific group of accounts. Internal teams responsible for monitoring regulatory compliance probably deal with violations of this nature.
- **Sensitive Information:** looks for the presence of sensitive information types in messages (Microsoft 365 includes many sensitive information types covering anything from passport numbers to social security numbers). Violations of this policy are like those encountered in Data Loss Prevention processing.
- **Conflict of interest** looks for evidence in communications between users or groups of actions that conflict with the interests of the company.
- **Inappropriate text** uses built-in classifiers to detect text in messages that the organization might consider inappropriate, abusive, or offensive. An example of country-level regulations in this area is [Japan's "power harassment" law](#), which took effect for large companies on 1 April 2020.
- **Inappropriate images** detects adult or "racy" images.

The template policies cover (at least in part) many of the scenarios that create the need to monitor communications, so the quickest way to get going is to create a new policy from a template and amend it afterward to meet your needs. The Inappropriate text template is a good example to start with because it's easy to generate some sample messages for the policy to capture. To create a new policy, click **Create policy** and choose *Detect inappropriate text* from the drop-down list. Several policy settings are pre-populated from

the template, and all you need to do at this point is change the policy name (if you want) and add the users or groups to supervise and the reviewers.

In Figure 21-15, we see the screen used to collect details of the new policy. A distribution list defines the sets of users to monitor, and we've appointed a single reviewer. It's usually best to have more than one reviewer per policy. When you go ahead and create the policy, some background processes run to create the special mailbox used to collect items for review and inform the communications monitoring assistants that a new policy is active. It can take up to an hour for this process to complete setup and a further 24 hours before the assistants begin to monitor messages.

**Monitor communications for conflict of interest**

About this template

Set up a policy to monitor communications between two groups of users across locations like Exchange, Teams, and more. Just choose the two groups whose communications you want to supervise, specify reviewers, and we'll set up the rest.

## Tweaking a Communication Compliance Policy

When you create a policy from a template, you can only change certain policy settings until the setup has finished. If you want access to all policy settings during creation, choose to create a custom policy. Once setup is complete, you can tweak the policy to make it more effective. Common changes include:

- Extend the scope of the policy to include additional users or groups, or to make it apply to all users.
- Exclude selected users from the policy.
- Select the locations to monitor (Exchange, Teams, and Yammer). By default, the policy covers Exchange and Teams. Yammer is only available when the tenant network is in native Microsoft 365 mode.
- Select the direction of communications to monitor. By default, policies check all communications:

- **Inbound:** communications to the recipients specified in the policy from users who do not come under the scope of the policy. Traffic can come from other users within the organization or people outside the organization.
- **Outbound:** communications from the people specified in the policy to anyone else.
- **Internal:** communications between the people included in the policy.
- Amend the policy rules used to detect violations. If you're used to working with data loss prevention rules, you'll find the process very similar.
- Change the percentage of messages to review from the set detected to contain violations.

Figure 21-16 shows the conditions generated for a policy created from the *Inappropriate text* template. As you can see:

- Communications are monitored in all directions.
- Three classifiers are used to identify potential violations. The combination of these classifiers should catch messages containing profane, threatening, harassing, or offensive language subject to the caveats expressed above.
- 100% of all matching messages are selected for review.

## Communication compliance > Edit Identify Bad Words Used by Senior Management

**Choose conditions and review percentage**

**Communication direction \***

- Inbound.** Sent to users you choose to supervise from people not included in this policy.
- Outbound.** Sent from the users you choose to supervise to people not included in the policy.
- Internal.** Sent between the users or groups you identified in this policy.

**Conditions**

By default we will monitor all communications from the users and groups you specified. Add conditions to limit the results to communications matching specific criteria. [Learn more about these conditions](#)

**Content matches any of these classifiers**

Any of these

**Classifiers**

Figure 21-16: Amending conditions and sample percentage for a communications compliance policy

You could add more conditions to improve the effectiveness of the checking. Policies focused on language could be improved by adding a condition to check for particular words or terms that the classifiers might not

catch, such as new slang or a word used in known cases of harassment. Other policies will depend on checking for:

- A lexicon of specific words that might indicate suspicious or problematic behavior.
- Microsoft 365 sensitive information types (social security numbers, credit card numbers, and so on) and custom sensitive information types defined by the tenant.
- Message properties. These include:
  - Specified words or phrases appear in the message body (or its subject). Use KQL syntax to define the query, but do not try to get too complex. Alternatively, you can add a condition that checks for messages where the specified words are not present. You will see an error if the specified query is too complex for a supervision policy.
  - Any attachment to the message includes or does not hold the specified words or phrases.
  - The message has an attachment of a specific type or does not have an attachment of a specific type.
  - An attachment is larger than the specified size (in KB, MB, or GB).
  - The overall message size is larger than the specified size.
  - Messages are sent to or received from a specific domain.
  - Messages have a certain sensitivity label.

Once ready, click **Next** and **Save** to save the updates to the policy. Once again, it will take up to a day before the new policy settings are effective.

## Supervision Mailboxes

Communications compliance policies use special supervision mailboxes to store the copies of messages captured by the background agents for review. These hidden mailboxes can't receive email, and don't appear in any Microsoft 365 administrative interface except PowerShell, where you can run the `Get-SupervisoryReviewPolicyV2` cmdlet to reveal the name:

```
[PS] C:\> Get-SupervisoryReviewPolicyV2 "Regulatory Compliance" | Ft reviewmailbox  
  
ReviewMailbox  
-----  
SupervisoryReview{d7c6eb96-20e5-4cbb-9838-2d230f64efb1}@office365itpros.onmicrosoft.com
```

## Reviewing Captured Messages

The task of a policy reviewer is to examine captured items to decide whether any compliance violation exists. Do not underestimate the amount of work involved in processing several hundred review items, a volume that a busy tenant can easily generate daily. Apart from the opening and reading of each item, the reviewer must understand the context of the communication and how the content fits with regulations. Hours of work might be consumed to process items at a high level of accuracy.

To review messages, navigate to the Communication compliance section of the Compliance portal where you can see a list of the policies and statistics for each policy (Figure 21-17). Policies generate an alert any time processing detects four violations within 60 minutes.

To check waiting items, go to the Policies tab, select a policy, and click the *Pending* link. The items pending review can be filtered to focus on specific recipients, senders, domains, item types, subjects, and other properties. Items can then be grouped by family (for instance, show all email together) or by conversation, which assembles the messages in a Teams or email conversation (like a Teams meeting recording transcript) to allow the reviewer to see how an interaction unfolds. This is important because a remark taken out of context can look quite different when considered amid a full conversation.

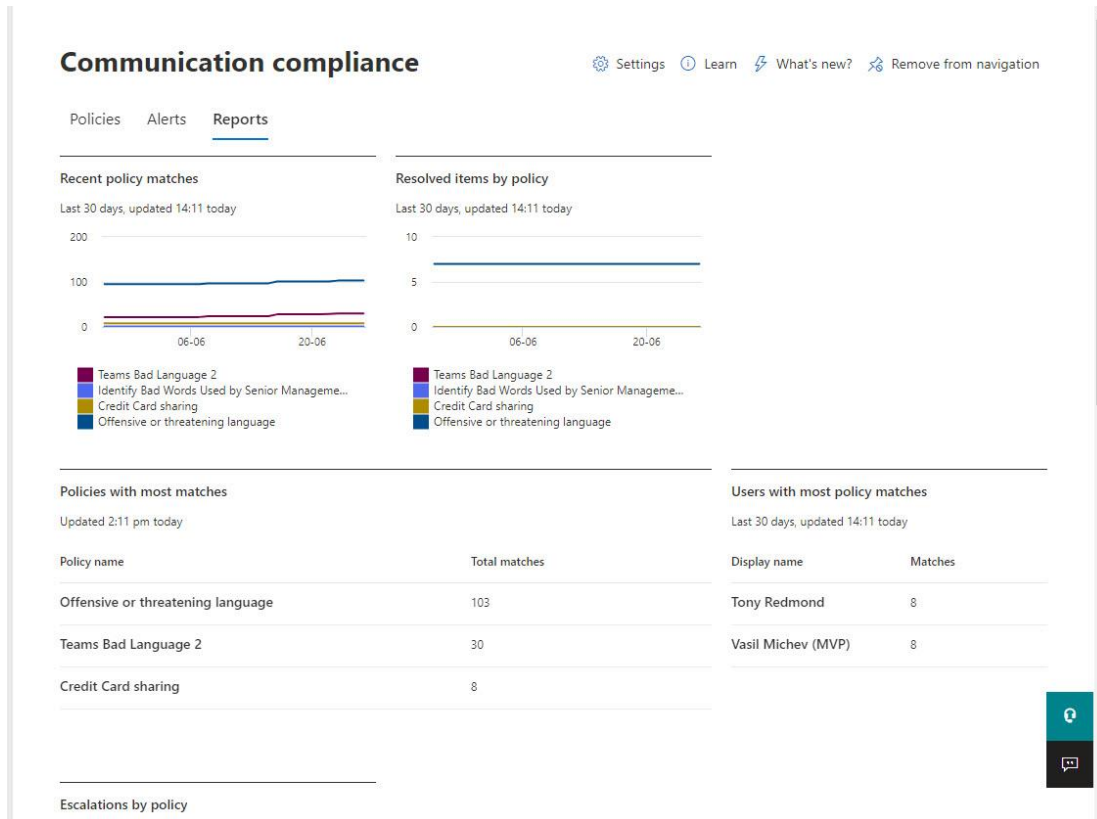

Figure 21-17: Statistics for communications compliance policies

The reviewer can then examine items to decide if a violation is present. The Compliance portal offers three views:

- **Source:** View an item as the user sees it.
- **Plain text:** Strip away all the formatting to show plain text with line numbers. This helps to focus on the words without the distraction of other elements.
- **Conversation:** Show the individual message containing the violation in context within a complete conversation.
- **User history:** Show previous instances when the user had policy violations.

In addition, the reviewer can see the user history to know if the sender of the message has previous violations for the same behavior. First-time offenders often receive more flexibility and understanding than serial offenders do. If the reviewer needs to download an item, they can do so as a message item or PDF.

The item selected for review in Figure 21-18 is a Teams message detected as containing some offensive text. The user history shows that the person sending the message has some other outstanding policy matches awaiting review. This might indicate that some corrective intervention is necessary to help the person modify the text they use in messages. It's likely that reviewers make the decision after checking each of the policy matches to understand the ebb and flow of the conversations and the context of the text detected as policy violations.

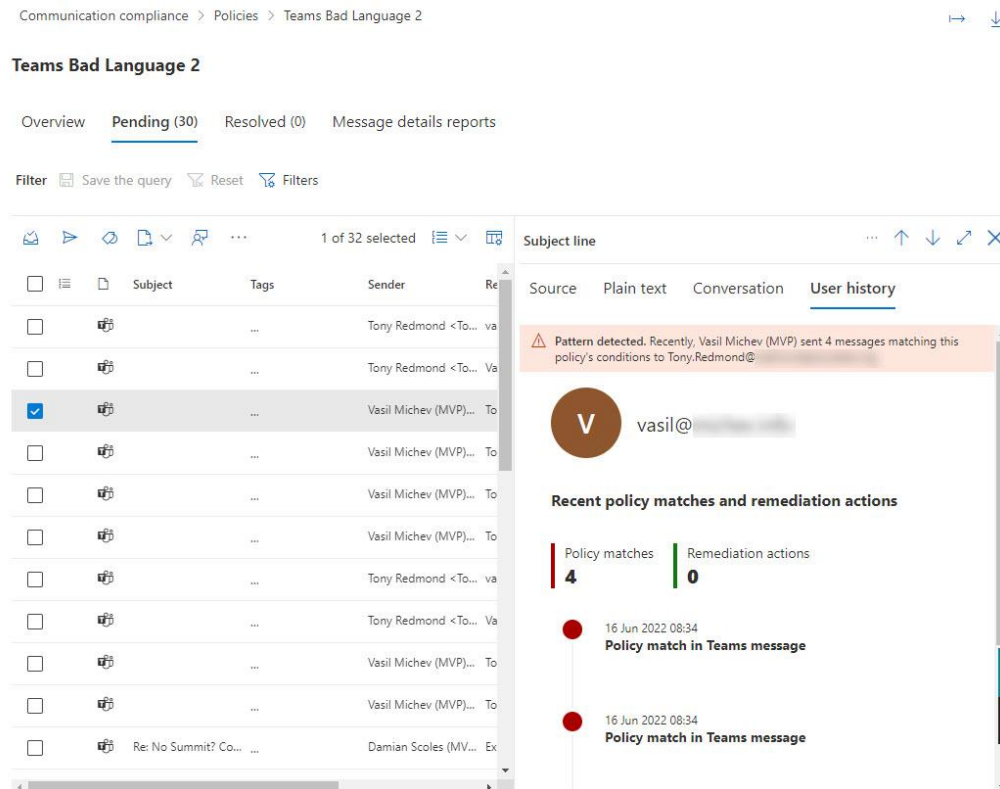

Figure 21-18: Reviewing pending items for a communications compliance policy

The steps that a reviewer can take to progress an item include:

- **Resolve:** Mark the item as resolved, perhaps after some invention. This action removes the item from the pending list. Eventually, the aim is for reviewers to resolve all items on the pending list.
- **Notify:** Send an email to the sender to tell them about the potential violation and (possibly) to ask for their input. Messages created from *Notice Templates* (see below) help ensure that notifications use the right tone and words and include any necessary references to organization policies.
- **Tag as:** Mark the item as compliant, non-compliant, or questionable.
- **Escalate:** Send the message forward to a higher authority for their review and decision. For instance, a message might go to the sender's manager.
- **Escalate for investigation:** Create an advanced eDiscovery case for the item and notify administrators about the new case. This step might be useful when a systematic problem is detected involving multiple people, such as potential insider trading.
- **Report as misclassified:** Help refine the machine learning model by marking an item as not being a problem. This action sends a copy of the misclassified item to Microsoft to help them refine the classifier that marked the item incorrectly.
- **Automate:** Create a [Power Automate flow based on the message](#). You can create a new flow or use a template such as the Notify manager (CC) flow. This flow sends a message to a user's manager when they violate a policy.
- **Show/Hide translation view:** Purview uses Microsoft Translator to translate the plain text of messages from [supported languages](#) into the language of the reviewer.

If the review message comes from Teams and the violation is clear and obvious, the reviewer can remove the message from its source chat or channel conversation.

It's worth emphasizing that these are generic explanations, and a tenant is free to use their interpretation of how to resolve review items based on their business, regulatory environment, and HR policies.

Many of the messages detected by a policy don't need much investigation and reviewers can dismiss them quickly. Reviewers can select multiple messages (or all) and resolve them in a single operation, which speeds up the review process dramatically.

## Notice Templates

Because notifying someone that they might have done something wrong is an exercise fraught with potential problems, compliance communication policies use notice templates to ensure that notifications use the right tone and appropriate wording. Notice templates are available through the Settings section for communications compliance. An organization must add at least one notice template before they can use communications compliance policies.

A template includes email basics such as:

- **The originating mailbox:** It is usually better when notification messages come from a specific mailbox set aside for this purpose instead of an investigator's personal mailbox.
- **Boilerplate CC and BCC recipients:** For instance, notifications might need to be copied to an HR mailbox.
- **Subject:** The subject of notification messages is often dictated by HR or legal guidelines.
- **Message body:** Boilerplate text to inform the recipient why they are being notified and what policy is violated. The text might also include some "next steps" for the recipient to take, such as talking to their manager or contacting HR to arrange for an interview.

When an investigator chooses the *Notify* action, they select a template, and Purview copies the boilerplate settings into a message form. The investigator can then modify the settings as required by taking steps such as including some details about the violation. When everything is ready, they can send the message for delivery as normal to the recipient mailboxes.

## Information Barriers

Exchange has long supported the concept of an [ethical firewall](#), a software barrier to stop defined sets of users from communicating with each other. In the past, organizations wrote bespoke customizations like transport sinks for this purpose. Usually, organizations operating in highly regulated industries deployed ethical firewalls to stop groups of people from communicating. For instance, a bank might stop traders and brokers from communicating. Since the advent of transport rules in Exchange 2007, transport (mail flow) rules are a favorite method to prevent communication between groups. Ethical firewalls continue in Exchange Online, but other methods of communication exist, notably Teams. Information Barriers deliver a cross-workload answer by preventing sets of users from communicating using its supported workloads. Figure 21-19 shows the Information Barrier architecture to control access across Exchange Online, SharePoint Online, Teams, and OneDrive for Business (because of the work needed in the transport system, Exchange Online does not currently support information barriers).

### Information Barrier Architecture

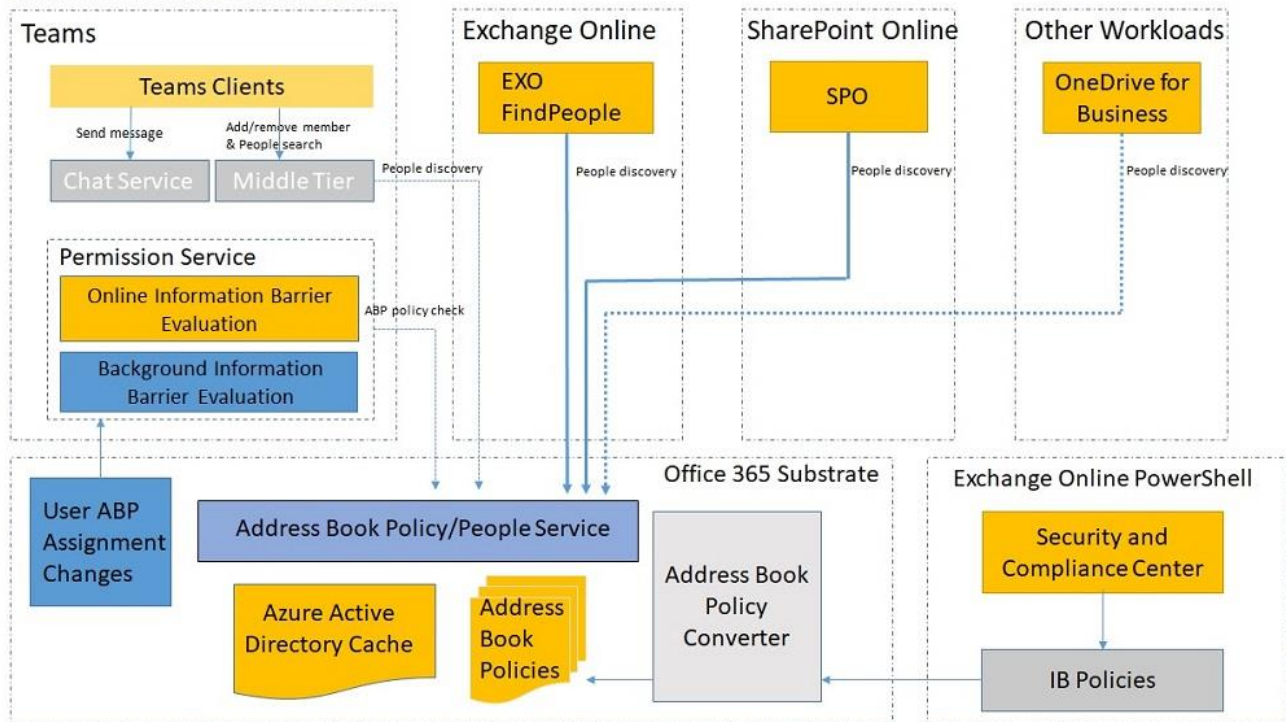

Figure 21-19: Information Barrier architecture (source: Microsoft – Ignite 2018)

Accounts under the control of Information Barrier policies require an Office 365 E5 license or the Microsoft 365 E5 Compliance add-on. An exception exists for education licenses because Microsoft bundles Information Barriers into the A5, A3, and A1 plans. Information Barriers are also part of the Microsoft Insider Risk solution.

The documentation for how to configure Information Barriers is [available online](#). Although global administrators often manage information barrier policies for a tenant, you can restrict permissions by assigning accounts the Information Barrier Compliance Management role as this is all that's needed to manage the policies.

Exchange Online currently doesn't support Information Barriers. However, given that these policies depend on Exchange address book views, it's likely that the eventual implementation of information barriers in Exchange Online will replace Address Book Policies (ABPs), which restrict user access to the directory and have been in use since Exchange 2010. Teams also depends on Exchange to scope directory queries, meaning that you must remove existing ABPs from a tenant before you can define Information Barrier policies. This can be a little tricky if any inactive mailboxes exist with assigned ABPs (assigned before the mailboxes become inactive): you can't remove an ABP if any mailbox (inactive or active) exists with a connection to the ABP, so you need to restore all inactive mailboxes with ABP assignments (restoring an inactive mailbox deletes the assignment) and then remove the ABPs.

## Information Barriers in Teams

As you might expect, workloads implement Information Barriers to match their style of communication. The implementation of Information Barriers in Teams uses several different components, including:

- [Directory scoping](#) to limit the access of users to specific parts of the directory.
- Organization segments (common across all workloads) to define sets of users using queries against Azure AD.
- Information Barrier policies define how segments can or cannot communicate with each other.

- Background processes to apply the settings in Information Barrier policies to personal chats, team memberships, meetings, calls, and (optionally) sharing documents in SharePoint Online and OneDrive for Business.

Each team has a property called *InformationBarrierMode* to control if it comes within the scope of information barrier policy processing. After implementing information barriers for Teams, the property for new teams is set to *Implicit* to mark the team for processing. However, you need to backfill the property for older teams. This is easily done with PowerShell:

```
[PS] C:\> [array]$Teams = Get-UnifiedGroup -Filter {ResourceProvisioningOptions -eq "Team"} -ResultSize Unlimited | ? {$_.InformationBarrierMode -ne "Implicit"}
Write-Host ("{0} teams are being backfilled for Information Barriers" -f $Teams.Count)
ForEach ($Team in $Teams) { Set-UnifiedGroup -Identity $Team.ExternalDirectoryObjectId -InformationBarrierMode "Implicit" }
```

The various modes supported by information barriers are [described here](#).

## Organization Segments

The sets of users used by Information Barrier policies are known as organization segments. Information Barrier policies define which segments can communicate with each other or those blocked from communication. The first step in implementing Information Barriers is to define organization segments for the users whose communication the organization wants to control. You don't have to create segments for the entire organization, but if you don't, the risk exists that some users will be able to communicate where a block should apply.

To define organization segments, you create queries to find Azure AD accounts. Microsoft suggests that you use the same property as the basis for all segments. In other words, if you decide to divide the organization by department, use the department property for all segments. It's also best if the segments don't overlap (multiple segments cover the same set of accounts).

Because Information Barrier policies depend so heavily on Azure AD, it follows that the information in the directory must be accurate. All the properties used to define organization segments must contain appropriate values, so a prerequisite for Information Barriers is to review the state of the directory to ensure that the right data is available. For instance, if you decide to use the department attribute as the basis, you could create a spreadsheet of all accounts including this data to verify its correctness. This PowerShell command does the job:

```
[PS] C:\> Get-MgUser -All -Filter "UserType eq 'Member'" | Select Department, DisplayName, UserPrincipalName, PhysicalDeliveryOfficeName | Sort Department | Export-CSV -NoTypeInfo c:\temp\UsersDepartments.csv
```

## Creating Organization Segments

Information Barrier policies work by either allowing or blocking segments from communicating with each other. To create a policy, we must first define the segments. Each segment has a filter to tell Azure AD what accounts come within its scope. Think of this as similar to the filter used by a dynamic group. In the example scenario, we want to create an ethical firewall for Teams to stop staff in the Trading and Sales departments from communicating with each other. To do this, we need two organization segments: one defines the accounts in the Trading Department, and the other defines the accounts in the Sales Department. Organization segments can include both tenant and guest accounts.

You can manage information barriers through PowerShell or the Microsoft Purview Compliance portal (Figure 21-20). The GUI includes a filter builder that makes it easier to construct complex filters used in organization segments and the conditions for information barrier policies. It's recommended that you start off using the GUI to build segments and policies and use PowerShell whenever necessary for automation.

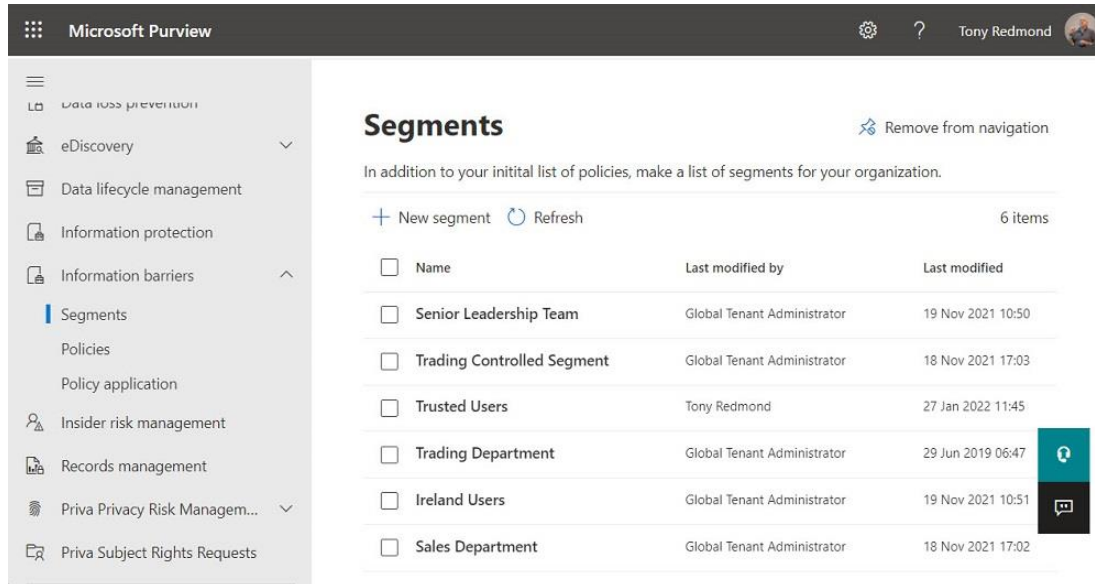

Figure 21-20: Information Barriers in the Microsoft Purview compliance portal.

To use PowerShell, connect to the [compliance endpoint](#). In this example, we create two organization segments.

```
[PS] C:\> New-OrganizationSegment -Name "Trading Department" -UserGroupFilter "Department -eq 'Trading'"
New-OrganizationSegment -Name "Sales Department" -UserGroupFilter "Department -eq 'Sales'"
```

To test the effectiveness of the query used by an organization segment, we can run the query with the *Get-Recipient* cmdlet. For example:

```
[PS] C:\> Get-Recipient -RecipientPreviewFilter {Department -eq 'Sales'}
```

Name	RecipientType
Andy.Ruth	UserMailbox
Eoin.Smith	UserMailbox
JAbrahams	UserMailbox

If you need to replace the filter, use the *Set-OrganizationSegment* cmdlet. To avoid user disruption, it's best to settle on segment definitions before introducing Information Barrier policies into production. However, sometimes organizational changes such as the renaming of a department or other structural updates can force an alteration in a filter. For example:

```
[PS] C:\> Set-OrganizationSegment -Name "HR Department" -UserGroupFilter "Department -eq 'Human Resources and People'"
```

The segments defined above use simple queries. You can construct more complex queries using the [set of filterable attributes supported by information barrier queries](#). The 'co' listed in the set of attributes refers to the country name, like Singapore, Germany, or United Kingdom.

If you can't find a suitable attribute to use, you might be able to use the membership of a distribution list or Microsoft 365 group instead. This example creates a segment based on the membership of a Microsoft 365 group identified by its external directory identifier (the documentation says that you can use the group name, but this doesn't appear to work).

```
[PS] C:\> Get-UnifiedGroup -Identity "Trading Team" | Select ExternalDirectoryObjectId
```

```
ExternalDirectoryObjectId
-----
29b959d6-56ab-4aea-b70d-ffb8397d397f
```

```
New-OrganizationSegment -Name "Trading Controlled Segment" -UserGroupFilter "MemberOf -eq '29b959d6-56ab-4aea-b70d-ffb8397d397f'"
```

After deploying information barrier policies and letting the deployment jobs run to validate segment membership, you can check what policy applies to an individual user with the *Get-InformationBarrierRecipientStatus* cmdlet:

```
[PS] C:\> Get-InformationBarrierRecipientStatus -Identity Andy.Ruth -Identity2 JAbrahams
```

## Creating Information Barrier Policies

After creating the necessary segments, we can create two Information Barrier policies. One policy prevents people in the trading department from communicating with sales, the other blocks reverse traffic. To make it clearer when looking for a policy, it's a good idea to capture the nature of the block in the policy name:

```
[PS] C:\> New-InformationBarrierPolicy -Name "Trading Block Sales" -AssignedSegment "Trading Department" -SegmentsBlocked "Sales Department" -State Inactive
[PS] C:\> New-InformationBarrierPolicy -Name "Sales Block Trading" -AssignedSegment "Sales Department" -SegmentsBlocked "Trading Department" -State Inactive
```

We deliberately create the Information Barrier policies in an inactive state to allow administrators to set everything up (and do some testing) before activating policies across the organization. You can't use a segment in an information barrier policy if it is already in use by another policy (even if that policy is inactive).

Note that you cannot remove an organization segment once an information barrier policy is active. However, you can change its user filter so that the segment no longer applies to any recipients.

## Activating and Debugging Information Barrier Policies

To activate a policy, run the *Set-InformationBarrierPolicy* cmdlet to change the state to Active.

```
[PS] C:\> Set-InformationBarrierPolicy -Identity "Trading Block Sales" -State Active
```

After changing policies to an active state, run the *Start-InformationBarrierPoliciesApplication* cmdlet to begin the process of applying the policy conditions to the affected users.

```
[PS] C:\> Start-InformationBarrierPoliciesApplication
```

It can take some time before the application executes active policies to make them fully effective for users in the relevant organization segments (don't try to start multiple jobs as this generates some horrible errors). The *Get-InformationBarrierPoliciesApplicationStatus* cmdlet returns the status of the information barrier policy application. In this example, the application processed 4,343 recipients.

```
[PS] C:\> Get-InformationBarrierPoliciesApplicationStatus

RunspaceId           : 6f427633-0a48-4f57-9c84-ec5e8bb946f1
Identity             : b4cf044a-e915-4960-9baa-7804415c2a3a
CreatedBy            : Administrator
CancelledBy          :
Type                 : ExoApplyIBPolicyJob
ApplicationCreationTime : 11/16/2021 21:11:54
ApplicationEndTime    : 11/16/2021 22:22:19
ApplicationStartTime  : 11/16/2021 21:11:54
TotalBatches         : 5
ProcessedBatches     : 5
PercentProgress      : 100
TotalRecipients      : 4343
SuccessfulRecipients : 4343
FailedRecipients     : 0
FailureCategory      : None
Status               : Completed
```

By default, the cmdlet returns the status of the last run of the information barrier policy application. To see details of all runs, use:

```
[PS] C:\> Get-InformationBarrierPoliciesApplicationStatus -all:$True
```

The application processes all mail-enabled recipients, including mail contacts. This is to make sure that the address book segmentation functionality works for all recipient types. If the job reports failed recipients, it's probably because those recipients are in multiple organization segments. To resolve the problem:

- Note the identity for the job reported by *Get-InformationBarrierPoliciesApplicationStatus*. In the example shown above, the identity is b4cf044a-e915-4960-9baa-7804415c2a3a.
- Search the audit log to find audit records with the *InformationBarrierPolicyApplication* record type for the date when the application ran and filter the set to find errors belonging to the run.

```
[PS] C:\> [array]$AuditLogs = Search-UnifiedAuditLog -ResultSize 5000 -Formatted -RecordType
InformationBarrierPolicyApplication -StartDate 16-Nov-2021 -EndDate 17-Nov-2021 | Where-Object
{$_ .AuditData.Contains("b4cf044a-e915-4960-9baa-7804415c2a3a")} -and
$AuditData.Contains("IBPolicyConflict") }
```

- Examine the *AuditData* property of each audit record to find the issue reported by the application, noted under *ErrorDetails*:

```
"ErrorDetails": "Status: IBPolicyConflict. Error: IB segment \"352e1fe3-fbee-4980-9208-103ddea4b370\" and IB segment \"93889a38-0cbf-4d0f-a260-005a6a1c4893\" has conflict and cannot be assigned to the recipient \"fdc6b121-44b8-4262-9ca7-3603a16caa3e\".\r\n.",
```

- We can see that the problem is that the conflict is between two segments. To see what the segments are, run the *Get-OrganizationSegment* cmdlet:

```
[PS] C:\> Get-OrganizationSegment | ? {$_ .ExoSegmentId -eq "352e1fe3-fbee-4980-9208-103ddea4b370" -or $_ .ExoSegmentid -eq "93889a38-0cbf-4d0f-a260-005a6a1c4893"} | ft Name
```

```
Name
----
Trading Controlled Segment
Sales Department
```

- To resolve the recipient name, run the *Get-Recipient* cmdlet:

```
[PS] C:\> Get-Recipient -Identity fdc6b121-44b8-4262-9ca7-3603a16caa3e
```

```
Name      RecipientType
----      -
Andy.Ruth UserMailbox
```

You now know why the error happened. The two segments both found the user Andy Ruth. Recipients identified in segments must be unique, so the solution is to update the recipient's properties to move them out of one of the two segments. You can't update a recipient's properties or the filter in an organization segment while the information barriers application is active, so wait until the active job finishes before making any necessary changes.

Microsoft's SLA for the application to detect a change in an account's properties that impact a barrier policy is 24 hours. However, the application usually detects changes like updating someone's department faster (3-4 hours). The thing to realize is that it takes time for workloads to react to changes in the directory and to set expectations accordingly. Updating someone's role at 9 am does not mean that a barrier exists to stop them from communicating with others by 9:30 AM. This is especially true when the directory is in a state of churn due to department reorganizations or other major changes.

If a problem occurs in deploying Information Barrier policies or you make changes to policies, you can run the *Start-InformationBarrierPoliciesApplication* cmdlet to process all active policies.

## Checking User Accounts

After processing an account to activate Information Barrier Policies, the account has an Information Barrier GAL (for the policy applied to the mailbox). This is how Information Barrier policies replace Exchange ABPs.

```
[PS] C:\> Get-Mailbox -Identity Andy.Ruth | Select -ExpandProperty AddressListMembership
\IBPolicyGAL_1bd52480-82f2-4416-814a-022776e46bef
\Default Global Address List
\Mailboxes(VLV)
\All Users
\Offline Global Address List
\All Mailboxes(VLV)
\All Recipients(VLV)
```

The *Get-Recipient* cmdlet also returns organization segment information for the user.

```
[PS] C:\> Get-Recipient -Identity Andy.Ruth | Format-Table InformationBarrierSegments

InformationBarrierSegments
-----
{352e1fe3-fbee-4980-9208-103ddea4b370}
```

We can check the membership of an organization segment by running a query using the GUID for a segment:

```
[PS] C:\> Get-Recipient -RecipientTypeDetails UserMailbox, GuestMailUser | ?
{$_ .InformationBarrierSegments -eq "352e1fe3-fbee-4980-9208-103ddea4b370"} | Format-Table Displayname
```

You'll also see that mailboxes that do not come under the scope of an information barrier policy also receive policy address lists. In effect, although Exchange Online does not support information barrier policies and the mailbox is unrestricted, a policy applies to allow the mailbox owner to communicate with any other user in the organization. Behind the scenes, workloads are aware of policies applicable to mailboxes. Clients use the *FindPeople* API to request this information from the server and receive a restricted or open view in response.

```
[PS] C:\> Get-Mailbox -Identity James.Ryan | Select -ExpandProperty AddressListMembership
\IBPolicyGAL_40ed3838-a6fd-4d1f-aa54-652537d5a708
\IBPolicyGAL_1bd52480-82f2-4416-814a-022776e46bef
\Mailboxes(VLV)
\All Mailboxes(VLV)
\All Recipients(VLV)
\Default Global Address List
\All Users
\Offline Global Address List
```

Outlook desktop users can see the names of the address lists created for Information Barrier policies. As the names are quite obscure, this might cause some questions for the help desk until people realize that they are just internal names.

It might take some time before the organization segments are acceptably accurate and reflect the communication paths allowed by the organization (or by regulation). There's also the small matter of synchronization and client caching to consider as it will take more time for clients to update changes synchronized from Azure AD and respect the blocks imposed by the policy.

## Allowing Communication by Policy

Information Barriers also support the concept of an allow list to allow segments to only communicate with one or more other segments. For example, this command permits communications between accounts in the Group HQ segment with five other segments.

```
[PS] C:\> New-InformationBarrierPolicy -Name "Group HQ Communications" -AssignedSegment "Group HQ"
-SegmentsAllowed "Sales Department", "Marketing", "Research", "Trading Department", "Engineering"
```

If workloads can't find a policy to block or allow communication between two accounts, it assumes that communication is allowed.

## How Teams Uses Information Barriers

Teams imposes blocks to implement Information Barriers at several points.

**Team membership:** If a team owner tries to add someone to a team when a member already exists who is blocked from communicating with the new potential member, Teams won't allow the new member to be added. For existing teams, if a background scan of the membership detects a violation, the Information Barrier Processor removes members to bring the team into compliance. In most cases, removals are processed on a last-in, first-out basis: in other words, the last person who joins a team and causes a violation is removed and existing members are left in place. However, processing depends on when the Information Barrier Processor detects a violation caused by a change to the properties of individual user accounts or updates for organization segments, so removals might happen in a different order.

Any member of a team, including org-wide teams, whose presence causes a policy violation is removed by the Information Barrier Processor. Removal includes owners if they are in violation, meaning that a team can be left ownerless. Audit records for removals are in the audit log where you'll see that the user removing the account from the group is noted as "*ServicePrincipal\_Guid*."

**Information Barriers, Teams, and Guest Users:** One problem that Teams currently has with Information Barriers is that team owners can't add a new guest user account. Existing guest accounts don't cause problems because Teams can check that adding them to a team roster won't violate a policy. However, if you try to add an external person whose account doesn't already exist in the directory, Teams can't validate that the barrier is respected, and the attempt to add the member fails. However, the guest account is created in Azure AD. The workaround is simple: create the guest account through the Azure AD portal or by adding them to the membership of the underlying group using Outlook or OWA. The addition of the new member will be replicated to Teams and any Information Barrier checks will then be imposed. Microsoft is aware that this situation is unsatisfactory and is working on a fix.

**Chats:** Teams won't start the chat if the participants are blocked by policy. At least, Teams will start a chat, but if the chat was created as a 1:1 chat, the only participant will be the person who tries to communicate with the person in violation. In the case of group chats, Teams removes the participants whose presence violates policy and leaves the other participants.

**Joining meetings:** When an account tries to join a meeting, Teams blocks them if other participants blocked by the policy are in the meeting.

**Screen sharing:** Any time someone shares their screen in a meeting, Teams checks for policy violations and won't allow the sharing if a violation is detected.

**VOIP calling:** When someone calls another person or a group, Teams checks the call to make sure that it doesn't violate a policy and terminates the call if a violation is detected.

Users blocked from communicating with each other won't be able to see blocked accounts in organization charts, activity feed, suggested contacts, people cards, and call and chat contacts.

In addition, whenever Information Barrier policies or user accounts are updated, the Information Barrier Policy Evaluation Service evaluates existing chats and team memberships to ensure that no policy violation results from the update. Existing 1:1 chats become read-only if Teams finds that participants are blocked by policy (Figure 17-21). The contents of the chat prior to the detection of the violation remain untouched.

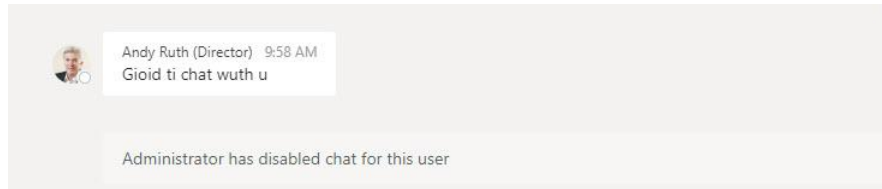

Figure 17-21: An information barrier policy blocks a user from an existing personal chat

## Adding Group Members Using Administrative Interfaces

Although Teams can control the addition of members and how members communicate, it can't control how administrators add members to Groups through administrative interfaces. For instance, you can add a prohibited team member using the Teams admin center or the Microsoft 365 admin center. Likewise, you can do the same by running the *Add-UnifiedGroupLinks*, *Add-TeamUser*, or *Add-MgGroupMember* cmdlets. This is the reason why the Information Barrier Processor exists. It serves as a backstop to eliminate violations introduced through interfaces that do not know (yet) about Information Barrier policies. Here's what happens:

- Someone makes a change to the membership of a group using an administrative interface.
- The change synchronizes to Azure AD.
- The Teams – Azure AD synchronization process detects the violation(s) when it runs to update Teams with changes in Azure AD and blocks the changes. Teams accepts changes that don't violate Information Barrier policies. Clients subsequently download the changes to their local cache.
- The Information Barrier Processor runs later and removes the members in violation from the group.

The Information Barrier Processor serves as a backstop to eliminate violations introduced through interfaces that do not action the settings in Information Barrier policies.

## Information Barriers and SharePoint Online and OneDrive for Business

To use information barriers with SharePoint Online, you associate organization segments with sites, and access to the site is thereafter determined by the segments associated with the site and the information barrier policy assigned to user accounts. Before using information barriers for SharePoint Online and OneDrive for Business, you must first enable the capability by setting tenant properties:

```
[PS] C:\> Set-SPOTenant -InformationBarriersSuspension $False
```

Segment assignment happens automatically for any site connected to Teams. SharePoint admins cannot change the assigned segment for teams-connected sites. For sites not associated with Teams, you can assign segments using the SharePoint admin center or PowerShell. With PowerShell, the first step is to connect to the compliance endpoint and run the *Get-OrganizationSegment* cmdlet to return the set of segments defined in the organization:

```
[PS] C:\> Get-OrganizationSegment | Select Name, EXOSegmentId
```

Name	ExoSegmentId
Trading Department	5517962f-c1e2-4a4b-b905-997d99bdc393
Sales Department	352e1fe3-fbee-4980-9208-103ddea4b370
Group General	c0ccc7f3-c44c-4ef6-a847-e1388bbeclc2

Then assign segments with the *Set-SPOSite* cmdlet:

```
[PS] C:\> Set-SPOSite -id https://office365itpros.sharepoint.com/sites/TradingDepartment
-AddInformationSegment 5517962f-c1e2-4a4b-b905-997d99bdc393
```

A background assistant called the [Information barriers compliance assistant](#) runs every 24 hours to monitor group-connected SharePoint Online sites (excluding those connected to Teams) to detect and remove users who violate IB policies from site membership. Make sure that site owners are part of the segments assigned to the site as otherwise, they won't be able to access the site. In addition:

- SharePoint Online disables the option to use Anyone sharing links (if permitted by the tenant).
- The site and its contents can only be shared with people who match the segments assigned to the site.
- New users can only be added to the site if their segment matches one of those assigned to the site.

If a site has no segments assigned, SharePoint only permits users to share based on the information policy assigned to their accounts. For instance, if a user belongs to the Sales segment and policy blocks interaction with Trading, SharePoint won't allow that user to share content with people in the Trading segment.

The same approach applies to assigning segments to OneDrive for Business sites. In this case, because a OneDrive site is for personal storage, it is even more important to ensure that the assigned segment includes the site owner.

## Audit Events for Information Barriers

Details about the processing of Information Barrier policies are captured in several audit events in the audit log, including:

- *New-ExoInformationBarrierSegment*: when a new organization segment is created.
- *RecipientChange*: when an account is updated because of information barrier settings.
- *ApplyIBPolicy*: when an account is evaluated for information barrier policies.

## The Impossibility of Stopping User Communication

Information Barriers won't stop users from communicating with each other. In fact, in practical terms, no software barrier will stop people from communicating. Information Barriers don't stop users from emailing each other if they know each other's SMTP addresses or decide to use personal email accounts. This is the reason why you might want to use communication compliance policies to check email flowing between different parts of the organization or implement ethical firewalls with transport rules, especially if you want to control communication to specific domains.

It's also true that Information Barriers won't stop users from sending messages to VIP mailboxes, which is why mailbox moderation exists. Because all messages stay within a tenant, Information Barriers are more effective in stopping chat and voice communication with Teams, but again, they won't stop someone using a PSTN number to dial up another Teams user for a voice call.

If blocks stop people from communicating through email and Teams, they will find another route to share information, be it WhatsApp, a simple text message, or a surreptitious note scrawled on a scrap of paper. But that's not the point of Information Barriers or why you would want to deploy these policies. Instead, having policies like this in place helps organizations satisfy regulatory requirements in a demonstrable and provable manner. And if people want to do wrong, HR processes should be defined, available, and communicated to enforce company policy in a way that humans understand.

# Chapter 22: Power Platform

*Christina Wheeler*

## In Search of No-Code/Low-Code Automation

The Microsoft Power Platform is a family of services spanning five main products: Power BI, Power Apps, Power Automate, Power Virtual Agents, and Power Pages (Figure 22-1). These services deliver methods to manipulate, surface, automate and analyze data in a low-code/no-code approach for use with Microsoft 365 and [Dynamics 365](#) (Microsoft's cloud-based customer management system). The Power Platform is based on Dataverse which is the underlying data platform (based on SQL Server) for Dynamics 365. It provides a unified data schema so that applications and services can interoperate.

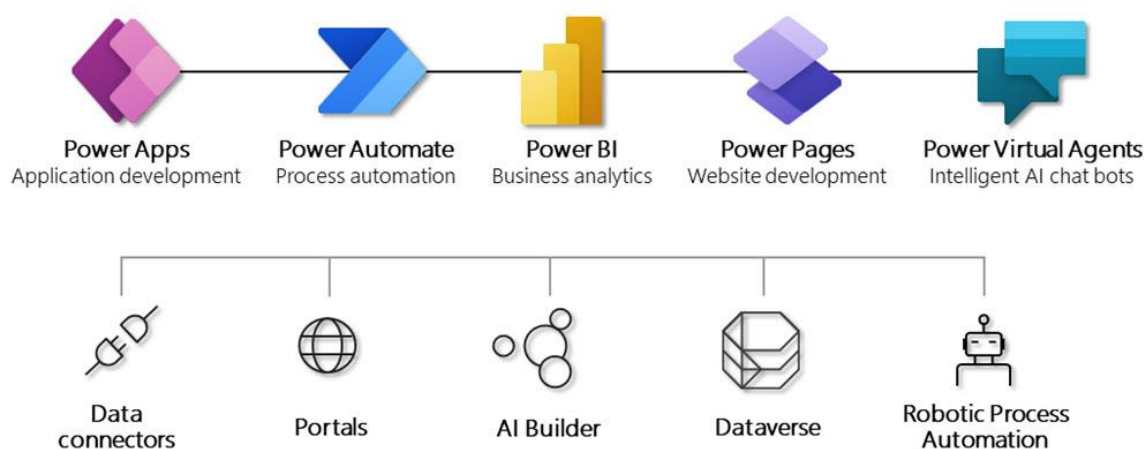

Figure 22-1: Power Platform components

Data Connectors are wrappers around REST APIs (Application Programming Interfaces) to connect other services to interact with the Power Platform components. Currently, there are over 300+ prebuilt connectors available that can connect to Microsoft and non-Microsoft services. These services include SharePoint Online, OneDrive for Business, Twitter, Dropbox, and more. If there's a service you need to communicate with that doesn't have a prebuilt connector, you can create your own custom connector in the Power Platform.

## Microsoft 365 Developer Program

Before we dive into the Power Platform, I want to mention the [Microsoft 365 Developer Program](#). By signing up for the program, you get a free, pre-configured Microsoft 365 tenant (without Windows) that includes 25 E5 licenses. The tenant is renewable every 90 days based on usage. This sandbox tenant is great for learning, building prototypes, or simply testing new features. It includes everything you need for Power Platform development. In addition to the Microsoft 365 Developer Program, you can also sign up for a free [Power Apps Developer Plan](#), which you can add to a free development tenant, to another existing tenant, or can be set up as new. I recommend signing up for both, especially for anyone who is learning and needs an environment to work in separate from production.

# Power Platform Administration

The [Power Platform admin center](#) (Figure 22-2) is the centralized portal for administration tasks for the Power Platform and there are other places in Microsoft 365 where administrators can interact with the Power Platform.

- The [Power Apps Maker portal](#) is where non-administrator accounts access Power Apps.
- The standard Microsoft 365 administrative portal manages aspects that affect Power Platform, such as user accounts, licensing, and auditing.

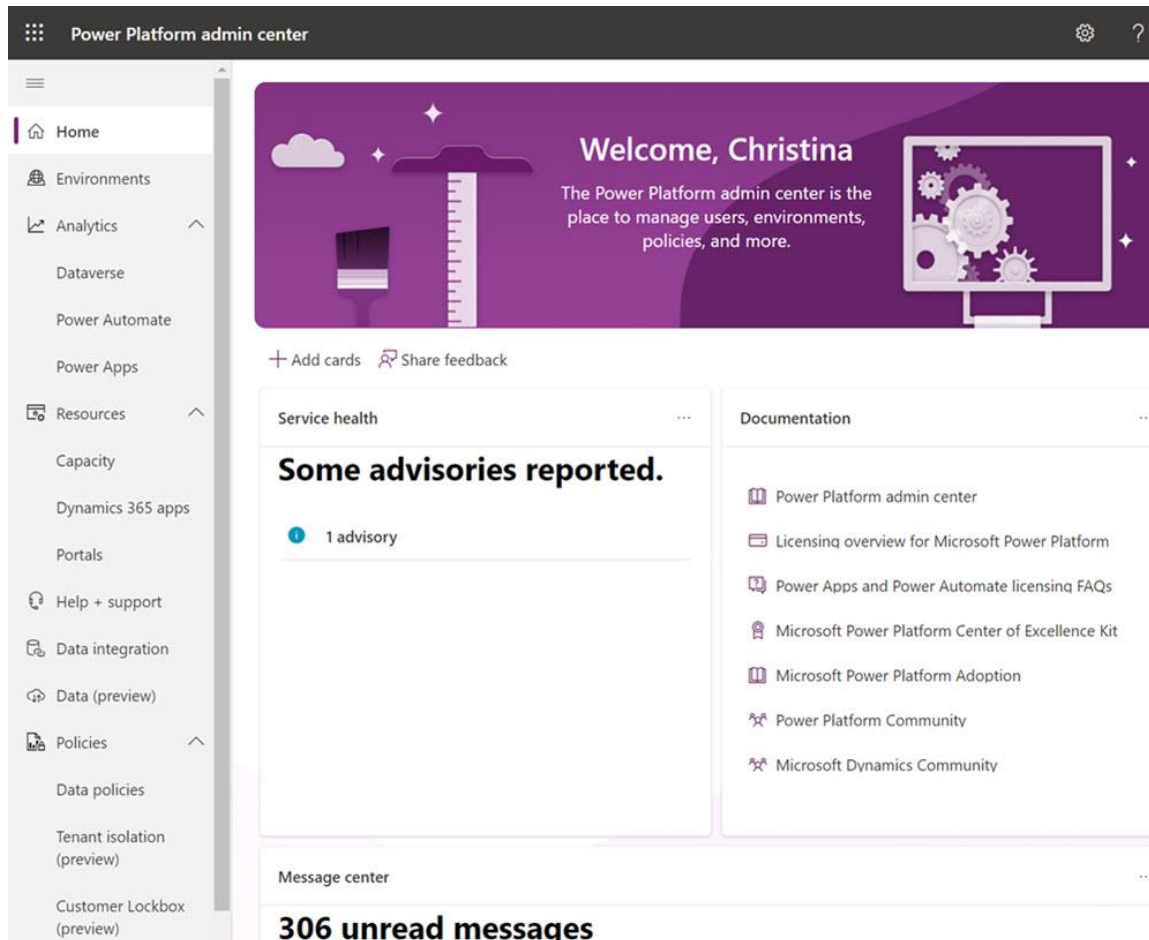

Figure 22-2: The Power Platform admin center

The Power Platform admin center evolves constantly. The capabilities you will find in the current release are:

- **Environments** management. Shows a single list of all your environments, supports sorting on all properties, search across environments, and create/open environments.
- **Analytics** includes detailed views of key metrics for the Dataverse, Power Automate, and Power Apps.
- **Resources** is where you can view and manage the capacity used by Dataverse. It also includes a list of Dynamics 365 apps available to install and configure in the tenant.
- **Help and support**. Provides a list of self-help recommendations and support for Dynamics 365, Power Apps, and Power Automate. Or get real-time support by opening a support ticket.
- The **Data Integration** section is where an administrator can integrate data into Dataverse. It supports integrating data between Dynamics 365 Finance and Operations and Dataverse as well as integrating data into Finance and Operations and Dynamics 365 Sales.

- The gateways (to reach back to on-premises resources and support hybrid integration scenarios) can be managed from the **Data (preview)** section. This includes the ability to set up gateway clusters for load balancing.
- The **Policies** section is an area where new Data Loss Prevention policies can be created and maintained. These policies define what data can be shared with which connector, thus controlling what can be used in flows and apps.

## Environments

If you have a paid plan license for Power Automate or Power Apps, you can use environments to host flows and apps. Simply put, an environment is a space to store and manage the organization's flows, apps, chatbots, connections, custom connectors, and gateways in a geo-located manner. This means the flows and apps that live within an environment are available in the region where the environment is located. Environments are used to separate resources that have different roles, security requirements, or target audiences. This is especially important if you need to apply the EU General Data Protection Regulation (GDPR) in a tenant used worldwide.

When a flow or app is created in a specific environment, it is routed to all data centers in that geographic region which could deliver some performance benefits. You can also create several environments in one physical region to create boundaries inside one geographic area because you can assign different users and policies to environments created in the same region.

Be aware that if the environment is deleted, all resources (flows, apps, connections, custom connectors, and gateways) within the environment are removed. Likewise, because the environment is the isolation boundary for all resources that reside in a specific environment, you can never refer to resources across environments. For example, you cannot create a custom connector in one environment and then create a flow that uses that custom connector belonging to a different environment. However, it is possible to export a flow or app from one environment and import it into a different one.

The type of environments you can create are:

- **Sandbox** - Non-production environment is an isolated environment intended for development and testing separate from production. Requires 1GB of available database capacity.
- **Production** - Intended to use as a permanent environment for production apps, flows, and chatbots. Requires 1GB of available database capacity.
- **Trial (subscription-based)** - Intended for use to develop larger, multiuser solutions and proofs-of-concept. This type of trial has an end date that can be extended.
- **Trial** - This is a standard trial intended for trying new features. Limited to one user and expire after 30 days. The trial plan allows users to extend the trial period two more times after the initial 30 days have ended for a full trial period of up to 90 days. After the full trial has ended Microsoft disables and deletes the environment.

You can create an environment with or without a Dataverse database. To learn more about how to create an environment in the Power Platform admin center, read [this article](#).

### Considerations when creating a new environment

Anytime you create a sandbox or production environment with a Dataverse database, you will have the option to add Dynamics 365 apps (such as Dynamics 365 Sales and Field Services) during the creation process. If you want to add Dynamics 365 apps now or know you will want to add them later, you must select the **Enable Dynamics 365 apps** option during the creation process. Currently, if you don't select this option your database will be provisioned without the support for adding Dynamics 365 apps. This setting cannot be changed later.

Below are some additional points to consider when creating a new environment:

- **When to create an environment with a database** - When creating a new sandbox or production environment with a Dataverse database, you will have the option to add Dynamics 365 apps (such as Dynamics 365 Sales and Field Service) during the creation process by choosing **Enable Dynamics 365 apps**. Currently, this option is only available when creating a new environment and cannot be changed later. Therefore, if you want the ability to install Dynamics 365 apps (even at a later time) then you must enable this on creation. If you do not select Enable Dynamics 365 apps at the time of the database provisioning, you will not be able to make this change later nor will you be able to install Dynamics 365 apps in the environment.
- **When to create an environment without a database** - If you don't need Dynamics 365 apps nor Dataverse and are just creating Power Apps or Power Automate with other data sources, then you can create an environment without a Dataverse database.
- **Dynamics 365 apps and trial environments** - Trial environments currently do not support the ability to enable Dynamics 365 apps. To create a Dynamics 365 trial, you must do so [through this link](#).

## Environment permissions

Power Platform environments without a Dataverse database will automatically have two built-in roles that provide access to permissions within an environment. In the first role, **Environment Admin** can perform all administrative actions in an environment which includes the ability to:

- Add/remove users or groups from the Environment Admin or Environment Maker role.
- Provision Dataverse database for the environment.
- View/Manage all resources created within the environment.
- Set data loss prevention policies.

The second role, **Environment Maker** role can create resources within an environment which includes apps, connections, custom connectors, gateways, and Power Automate flows. Environment Makers can distribute apps they build within an environment to other users within the organization by sharing the app with individual users, security groups, or all users within the organization.

Environments with a Dataverse database will have a **System Administrator** role instead of an **Environment Admin** role for full administrator privileges. For users who need to make apps that connect to a Dataverse database, you must assign them the **System Customizer** role in addition to the **Environment Maker** role.

## Default Environment and Environment Details

Regardless of your license type, there is always a default environment that gets created when the tenant is provisioned. This environment is shared by all users and any licensed user can create flows and apps in it. You cannot delete the default environment, nor can you backup and restore the default environment. The default environment is limited to 32 GB of storage capacity and starts as 1 GB. If you need to store data of more than 32 GB, you should create a production environment instead of using the default environment.

You can view the properties of the default environment or any other environment you created via the Environments page. To open, choose the environment you want to view by selecting it in the Environments list to open its properties page (Figure 22-3). The first panel exposes **Details**. The default environment will not automatically have a Dataverse database. You will know a database hasn't been created if you see the **Add database** section. When a database is not created, the **Security group** section (defining who has access to the environment) offers two options for the environment roles: Environment Admin and Environment Maker. An Environment Maker can create new flows or apps, data connections, and gateways. An Environment Admin can manage data loss prevention policies, add users to environments, and assign admin/maker privileges. An admin can assign users to both roles, allowing them to use the new environment. To create a database for your environment when one does not exist, click on **+ Add database** and proceed to select the desired options, and click the **Add** button.

## Storage

In April 2019, Microsoft introduced Dataverse (*formerly the Common Data Service or CDS*) capacity storage optimized for the Power Platform and Dynamics 365. Dataverse is a secure, cloud-based storage used by the Power Platform. The data itself is stored in a combination of Azure SQL Server and Azure blob storage hosted in the Azure Cloud. Dataverse contains a standard set of tables, columns, and rows (for example, Accounts, Contacts, and various activity types) that are extensible, allowing tenants to add additional data columns to fit business needs. Tables can create relationships with each other, and Business Rules can be created to make fields required, hide fields, and set default values. Each environment can have zero or one Dataverse database.

The Power Platform environment needs at least 1 GB of storage space. Each tenant contains one default environment which includes 1 GB of Dataverse space from the beginning. Additional Environments require extra storage that can be purchased in 1 GB increments. Purchase of extra storage is necessary if the default Environment uses more than the default amount. If the storage capacity is exceeded, the administrator receives a notification about over-capacity usage, and a message is also displayed in the admin center. When a tenant exceeds the storage quota, it is not possible to create a new environment, copy an environment, or restore an environment until additional capacity is purchased.

To review the current storage, sign into the Power Platform admin center and choose **Resources** → **Capacity**. The *Summary* tab provides a tenant-level view of how the organization is using storage capacity. The *Storage capacity* tab gives similar information as found in the Summary tab, but with an environment-level view of where the organization uses capacity. This tab provides statistical details about actual database usage, top database tables and their growth over time, actual file usage, top file tables and their growth over time, actual log usage, and top tables and their growth over time.

## Capacity Limits

Tenants with Power Apps or Power Automate licenses automatically get default capacity. Microsoft increases the capacity for each Power Apps and Power Automate license. Table 22-1 shows the Power Apps and Power Automate capacity limits.

<b>Power Apps capacity Limits</b>	<b>Per license entitlement (Power Apps per-app plan)</b>	<b>Per license entitlement (Power Apps per-user plan)</b>
Dataverse Database Capacity	+ 50 MB	+ 250 MB
Dataverse Log Capacity	+ 0	+ 0
Dataverse File Capacity	+ 400 MB	+ 2 GB
<b>Power Automate capacity Limits</b>	<b>+ Per user</b>	<b>+ Per flow</b>
Dataverse Database Capacity	+ 50 MB	+ 50 MB
Dataverse Log Capacity	+ 0	+ 0
Dataverse File Capacity	+ 200 MB	+ 200 MB

Table 22-1: Power Apps and Power Automate default capacity

## Accessing On-premises Data with the Data Gateway

Often the need to build solutions using Power Platform apps includes a need to integrate data from on-premises data repositories. Traditionally, these repositories include SQL Server databases, documents, and other data stored in SharePoint document libraries and other data stores. To provide connectivity with data stores within a corporate network, the Data Gateway is available (see [this document](#) for software and hardware requirements). The Data Gateway provides one gateway for connecting on-premises data to

multiple cloud services. These cloud services include Azure Analysis Services, Azure Logic Apps, Power BI, Power Apps, and Power Automate. The gateway creates an HTTPS proxy connection that can be accessed securely from these cloud services. It is the same component used by Microsoft's Power BI service. The supported data sources for Data Gateway are:

- SQL Server
- SharePoint
- Oracle
- Informix
- Filesystem (files and file shares)
- DB2

The gateway uses outbound connections, meaning connections are always initiated from the internal network towards the cloud – not the opposite way. Traffic is pushed through Azure Service Bus, which is hidden within Data Gateway's overall architecture. A good practice is to download the Data Gateway executable and deploy it on at least two servers that can access your required data sources. This way Data Gateway provides a highly available setup, as load balancing between the two machines happens automatically. Note that you cannot install Data Gateway on an AD Domain Controller. The machines hosting the Data Gateway can have shared services, but they should be servers, not workstations.

To install Data Gateway, simply download the executable and run through its setup. When you configure the Data Gateway, make sure to store the recovery key in a safe place. You will need it for recovery and when you expand your setup with multiple Data Gateway installations. You also can specify your region, which should be the one where flows are executed to avoid excess latency. If a proxy or a firewall restricts the outbound network connectivity, make certain the ports and destinations are allowed for Data Gateway to operate correctly [following the instructions from Microsoft](#). Once your Data Gateway is successfully installed, you can add data sources in the gateway to make your on-premises data accessible to Power BI, Power Apps, and Power Automate.

## The Microsoft Power Platform CoE Starter Kit

The Power Platform Center of Excellence (CoE) Starter Kit is a collection of tools designed to help drive innovation, improvements, and strategies to adopt and support the Microsoft Power Platform (specifically Power Apps, Power Automate, and Power Virtual Agents). The kit provides tooling and automation (through apps, Power BI analytic dashboards, *and flows*) to help teams build monitoring and automation needed to support a CoE.

The CoE Starter Kit is an open-source initiative that can be downloaded from [GitHub](#). Microsoft provides full [installation and configuration](#) instructions. To use the kit, the administrator accounts must have Premium licenses and Microsoft Power Platform service admin, global tenant admin, or Dynamics 365 service admin rights in the Office 365 tenant.

The Core Components of the Starter Kit (one of the four parts of the Kit) only contains assets relevant to admins. The kit collects many types of information about apps, flows, flow action details, custom connectors, connectors, model-driven apps, shared-with information, chatbots, and logs, before displaying its findings in Power BI dashboards.

## Power Automate

Power Automate is a powerful, built-in workflow engine in the Power Platform that can be used to streamline repetitive tasks and paperless processes. There is a growing demand for retrieving, filtering, accessing, manipulating, and reusing data from Microsoft 365 together with external systems and on-premises data sources without the need for complex custom solutions that can be error-prone and time-consuming to

create. Power Automate aims to provide a user-friendly, powerful engine for automating tasks and integrating data between systems. Power Automate is a fully cloud-based solution of the Power Platform family of services, offering two components: a flow engine and Robotic Process Automation (RPA) capabilities. It allows users to build self-contained workflows that execute when triggered by request (such as when a specific event occurs in a remote system, manually, or as scheduled tasks).

Some might feel that Power Automate is a modern take on the classic Windows Task Scheduler and PowerShell scripting, but with a more polished interface. While that is not an incorrect assumption because both schedule tasks and run scripts for automation, the two are not alike. Task Scheduler is typically used to run backend tasks that users rarely, if ever, need to see, and PowerShell is an administrator tool that requires a solid technical background, while Power Automate is more geared towards delivering value to users – not just administrators or backend services.

Microsoft initially launched Power Automate in 2016 as Microsoft Flow, together with Power Apps. The two share certain capabilities but do not depend on each other. Power Apps is a design and implementation tool for building line of business apps that run in the cloud. Power Automate has matured enormously and now has wide support for integration with many data sources through its use of connectors. It is also one of the few Microsoft services that have remained tightly focused on process automation and integration since its inception.

With Power Automate, the person who builds automation solutions does not need to be a developer. Power Automate does not allow you to call external code unless that code is accessible through an API available to Power Automate through an Open API and REST specified interface. Power Automate is relatively easy for end-users to build small solutions and ramp up to more advanced integration solutions as their skills mature.

Typical solutions power users and administrators might build with Power Automate include:

- Monitor a blog site through its RSS feed for new posts. Once a new post is made (and the RSS feed is updated), send a notification to a mobile phone with links to the new content.
- Free up licenses for disabled accounts.
- Save attachments sent to an unmonitored email address as a file in a SharePoint Online document library.
- Start an approval process when a new request for purchase is made through a SharePoint site.
- Post a weekly status update to a Teams channel detailing changes made to one or more documents.
- Send an email alert to IT administrators when one or more services fail in Microsoft Azure.
- Track changes to an Excel file and create approval requests for certain changes.
- Create to-do items in Microsoft To-Do or Planner for incoming helpdesk requests.

There are three types of flows you can create with the Power Automate service: *Cloud flows*, *Desktop flows*, and *Business Process flows*. A cloud flow is the most used type of flow which enables users to trigger processes automatically based on a trigger, manually, or via a schedule. The three flow types you can create with a cloud flow are:

- **Automated Flows** – An automated flow triggers when a condition is met.
- **Instant Flows** – An Instant Flow is a flow that allows you to start a flow with a click of a button.
- **Scheduled Flows** – A Scheduled Flow is for tasks that need to be automated on a schedule.

In 2020, Microsoft introduced Robotic Process Automation (RPA) capabilities to Power Automate under the name UI Flows (now called Desktop Flows). This feature expands on the automation capabilities of Power Automate, making it possible for bots to perform UI-based tasks centered on a pre-recorded set of UI interactions.

There are two kinds of RPA abilities in Power Automate: attended and unattended. The first means that a bot can record a set of UI actions and then play them back in real-time when necessary. Human interaction must

initiate the process. Unattended RPA requires no human interaction because it is meant for back-end processes.

## Licensing Power Automate

The licensing scheme for the Power Platform is complicated. If you need to manage several types of licenses in a tenant, you might need to consult Microsoft to understand the available options. To help, Microsoft keeps the [Licensing overview for Microsoft Power Platform](#) document updated with detailed information about pricing and licensing different components. The [Power Apps for Microsoft 365 plan](#) is included in most enterprise plans. This license allows users to run a limited number of flows per month with fewer capabilities than found in other plans. For example, it excludes access to premium connectors (all Azure and SQL connectors, HTML connectors, custom connectors, etc.).

Additional premium plans for Power Automate exist:

- **Power Automate per-user plan.** Users with this license can create unlimited cloud flows. Pricing is \$15 per user/month.
- **Power Automate per user plan with attended RPA.** Users with this license can create unlimited cloud flows plus automate legacy applications through attended RPAs and AI. This plan includes 5,000 AI builder credits per month.
- **Power Automate per-flow plan.** Flows implemented with this plan can be run by anyone in the organization. Pricing starts at \$100 per month with a minimum of 5 cloud flows to total \$500 per month.

The premium plans place no limits on trigger frequency or flow runs and instead use a daily capacity limit (5,000 daily API requests). Organizations that need additional capacity for heavy usage scenarios can buy add-on capacity and assign it to specific users or processes.

The UI Flows functionality in Power Automate Attended RPA capabilities costs \$40 per user/month, and Unattended RPA is an add-on costing \$150 per bot/month (on top of the \$40 per/month for the Power Automate plan with Attended RPA).

Unless you block the capability, tenant users can make self-service purchases for Power Platform licenses. The steps needed to prevent this are in Chapter 4. entitlement limitations based on licensing plan.

## Guest Access to Power Automate

You can assign actions in a flow to guest accounts. To use this feature, you must create the guest account and assign it a plan that contains a Power Automate license before assigning it to a flow.

The flow is created as normal and then assigned to the guest account, which receives an email notification to act in the flow. The link in the email routes them to the host tenant. To return to their home tenant, the guest can go to the My Flows page and click the **Go to your org's default environment** link in the notification message or sign out and re-sign to their tenant.

Except for SharePoint flows and Approval flows, connections to any other Azure AD-backed services are created in the context of the user's home tenant, not the tenant that the user is logged into. Currently, there are some limitations for guest access in flows:

- Notification to mobile devices is unsupported for guest users because the Power Automate app for iOS or Android cannot sign users in as guests.
- People picker experiences do not work for guest users because they are not able to query and enumerate members of the tenant but typing the full email address in the selection box works.
- There is no way in the user interface to switch between tenants. Also, the only way to access the flow portal as a guest is through a link in an email.

## Building Automated Solutions with Power Automate

To start to build flows with Power Automate, navigate to <https://powerautomate.microsoft.com> or simply click the Power Automate icon from the app menu. You can create a flow from a pre-defined template or scratch. From the Power Automate front page, click **My flows** in the top navigation bar. This page lists all the existing flows linked to your account with tools to enable or disable, share, and edit each one individually.

### Building Power Automate flows from Scratch

To build a manually triggered, instant cloud flow, follow these steps:

1. From the **My flows** page, click **+ New flow - Instant cloud flow**. You will be prompted with a dialog to define the Flow name and a list of triggers to select from.
2. For this example, set the flow name to **Create calendar event**. Select **Manually trigger a flow** and click **Create**.
3. The Power Automate designer will open with your newly created flow. Here is where you can start building out the actual logic for the flow. Add actions, conditions, and other logical building blocks by clicking **+ New step**. A list of operations will be available for you to choose from (Figure 22-5).

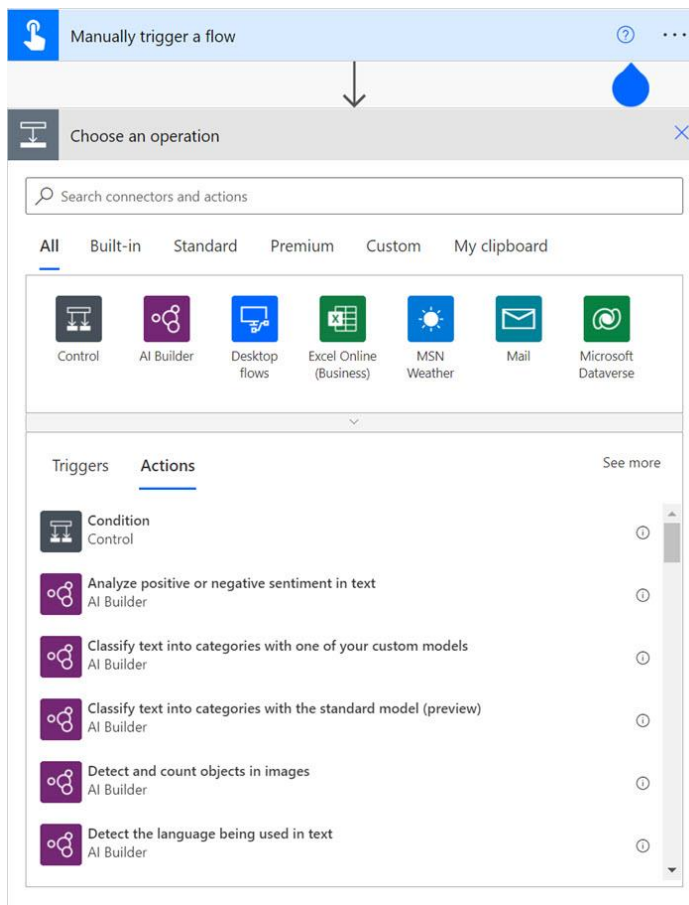

Figure 22-5: Adding a new step for a flow

4. When you scroll down the list of available actions (which numbers are in the hundreds), you can see the vast scope of functionality available for inclusion in a flow. You can connect to external databases, services in Azure, and data stored in on-premises servers. In this case, search for and select **Office 365 Outlook – Create event (V4)** for the first action.
5. Your first action is now transformed into a box with the Outlook icon and some mandatory fields to fill out. Power Automate might prompt you to authenticate as it might not have the authentication token for your account. If prompted, authenticate with an account that has access to the Outlook

calendar you wish to work with. Once authenticated, you can verify the available accounts by clicking the three little dots in the corner of the action.

You can see other options, such as adding a comment for this action (for providing better readability for other editors of this flow), and under *Settings* some specific settings for this action. You can also remove this action should you not need it later. Verify that you are using the desired credentials (in the section **Data - Connections**) to work with the calendar.

6. Next, select the drop-down menu for **Calendar id** and select your calendar. Typically, it is named **Calendar** in English-based interfaces. The name of your calendar might vary if you are using Power Automate with a localized interface. You might also have other calendars visible here, such as those belonging to other users who have granted permission for you to access their calendars. Power Automate also includes an expression language that allows us to specify dynamic values and combine or retrieve data from other actions within the same flow. This way you could dynamically choose a calendar based on data you received earlier in the flow or based on actions the flow is instructed to do.
7. For **Subject**, we can add a fixed string or use the expression language. This would be ideal if you needed to have a date and time or some other dynamic value as part of the event's subject. To keep this example simple type in the following text in the **Subject** field:

```
[Flow] Test event
```

8. For **Start time**, type a date and a time in the future – perhaps the next day. Note the time format, which needs to be in ISO 8601 format, so the 'T' must appear literally to show the beginning of the time element. An example value is:

```
2021-11-01T09:00:00
```

For **End time**, add a similar date and time but a bit later than the start time:

```
2021-11-01T10:00:00
```

In the example, the event starts on the 1<sup>st</sup> of November 2021 at 9 am and ends on the 1<sup>st</sup> of November 2021 at 10 am. Define the Time Zone as well.

You might be wondering what benefits a flow brings if it only supports fixed dates and times for new calendar events. As early said, Power Automate has an expression language that allows us to substitute, generate, and dynamically insert desired values, such as a dynamic date that adds an event 1 day from today. You can access these expressions on the side menu under **Expression**. This provides you with different collections, logical functions, string functions, and similar programming concepts you might need later.

9. Under **Show advanced options** there are many more ways to fine-tune calendar events. For this example, only the mandatory fields (*calendar id, subject, start and end time, and Time zone*) are needed. The event creation action should now look like Figure 22-6

Figure 22-6: Creating the calendar event through Power Automate

10. To change the name of the flow, in the top left corner, click on the original name and replace it with the desired name. Save the flow by clicking **Save** in the top right corner.
11. After saving the flow, you can test it immediately. To test, click on **Test** and then select **Manually** and click **Test**.
12. In the confirmation run flow dialog click **Run flow** to run the flow. After a few seconds, the browser opens directly the flow runs view showing the latest entry in the list.
13. Both the trigger and the action items are visible with a small green checkmark in each corner to indicate the flow worked correctly. Expand the actions to verify the input and output data and troubleshoot for any errors.
14. Now open the calendar where the flow created the event and verify the event is present.
15. At first glance, the calendar event might appear to be an incorrect time. Power Automate uses UTC timestamps while the calendar's owner might configure their calendar to display events in a different time zone. The date and time for the event are correct.
16. Click next on **My flows** within the Power Automate designer browser tab. Find your flow under **Cloud flows**. Click on the more options button (three vertical points) of your flow and click **Turn off** to disable the flow. This will prevent the flow from running every 10 minutes and adding multiple overlapping calendar events.

## Building Power Automate Flows from Templates

Templates are predefined flows you can use in many different scenarios. Via a Power Automate template, you can quickly create new flow instances that only require access to the services defined in the template and additional configuration settings. Microsoft offers several templates to help create a flow in a matter of minutes. You can use the templates as a starting point to implement more refined flows and/or to see how some flow options work. To see the available templates, click on **Templates** in the left navigation bar. You can choose from several hundred examples such as **Create a task in Planner based on Office 365 Outlook calendar event** and **Create a daily summary of Planner Tasks by Bucket**.

## Sharing Flows

If you want to share a flow with a colleague or group in the same tenant, click on the **Share** icon to open the settings page for adding users and groups. Anyone you choose to share your flow with becomes an owner of the flow. They can edit and modify the flow and will also receive access to any connections within the flow. If you chose to authenticate with an Exchange Online mailbox to send emails or create events, those connections become embedded connections when you choose to share the flow with others.

## Building and Running Power Automate Flows in Excel

Excel also supports Power Automate, allowing power users to create new flows within a spreadsheet. This brings the capability to trigger automation from data in Excel and is another way to automate processing. To use Power Automate in Excel, use the **Get add-ins** button in Excel to add the Power Automate Add-in or get it from the [Microsoft Apps Store](#). After installing the add-in, a new Power Automate button in the **Data - Automation** tab or **Insert - Add-Ins - My Add-ins** tab allows the user to select data from a spreadsheet such as a row.

Before Power Automate can interact with data in an Excel file, it must be accessible to Power Automate. You can store the spreadsheet in OneDrive for Business or a SharePoint Online document library and then connect the file to Power Automate.

## Using Data Loss Prevention Policies

It is not a good idea to have your flows retrieve data from a sensitive internal location (such as a SharePoint list that contains salary information) and share the data publicly using something like the Google Drive connector. This is where Data Loss Prevention (DLP) helps. DLP allows you to separate which services can allocate data to the tenant and/or with external sources. [This script](#) creates a report of the flows in use within a tenant and tells you what connectors each flow uses. It is helpful to know what connectors you might need to restrict.

DLP policies allow administrators to set restrictions on usage for Power Automate data handling and data capture. Typically, organizations do not wish to capture or store sensitive information or private data unless it is properly handled and secured. As users build their solutions with plenty of freedom, a reasonable need exists for administrators to set certain boundaries through DLP policies.

To create a new Data Loss Prevention policy, select **Policies > Data policies** in the Power Platform admin center and then click on **+ New policy**. When you create a new policy, you must first give it a **Policy name**, set the **Connectors**, and then set the **Scope**.

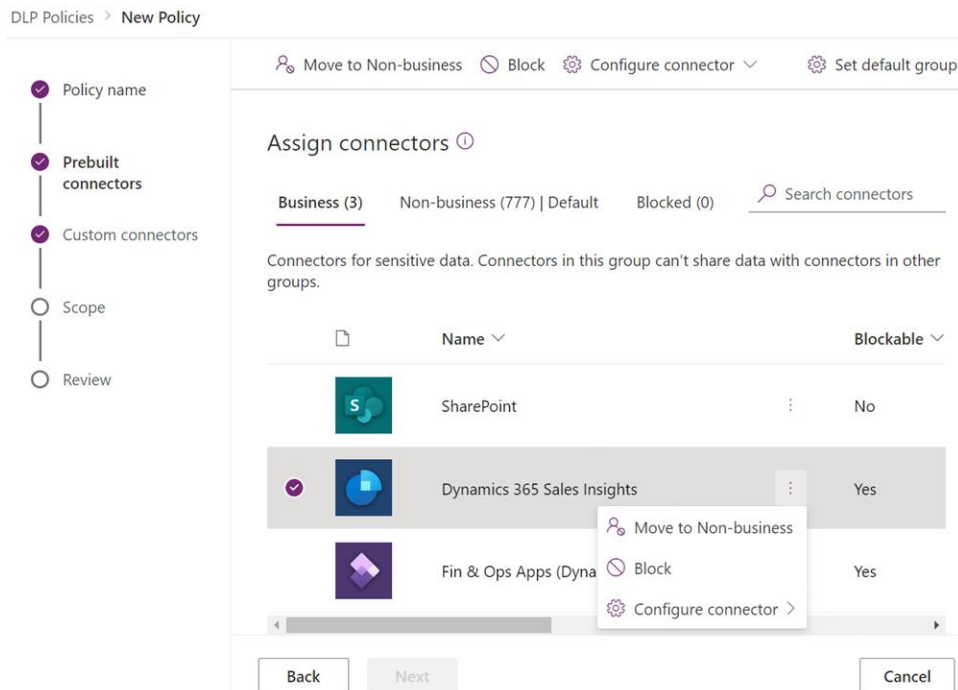

Figure 22-7: Defining data group connectors

**Connectors** are where you define the policy restrictions. In this view, you can define which Power Automate connectors can share business data and which are blocked. You can also set which of these is the default –

can access business data only, or no business data allowed. This model then limits any flows that users create to share data between either group. DLP policies enforce rules which connectors can be used together by classifying the connectors as **Business** or **Non-business**. By default, all services are placed into the "Non-business" classification group. You can freely add and remove connectors from either group simply by clicking on the [...] menu (Figure 22-7) and choosing **Move to Business** or **Move to Non-business**.

If you put a connector in the Business group, data cannot be shared between services in different Data groups and can only be shared with other connectors you added to the same group. One Data group must be designated as the default group. Initially, the "No business data allowed" group is the default group. An administrator can change the default data group using the ellipse button at the top right of each group. New services added to Power Automate will be placed in the designated default group. It is recommended to keep the "No business data allowed" as the default group and manually add services into the Business data after evaluation of the impact of allowing business data to share information with the new service.

**Scope** is where you define the environment's scope. The define scope option defines which **Environments** this policy applies to. An environment is simply an isolation boundary for DLP and data locality. If you have not created any environments yet, you can create a DLP policy that applies to all environments regardless of how many you have in place or plan on creating in the future. You can find extended information about Environments at the start of this chapter.

After you name and save the policy, it is activated automatically for the environment(s) you selected.

Users building flows that violate a DLP policy can create their flows, but Power Automate will put the flows into a suspended state. If a user creates a flow that retrieves data from SharePoint and pushes it to Salesforce (as per the example above), Power Automate will automatically suspend the flow.

When a user flow is suspended, it is not possible to create exceptions within the policy to authorize the use of or more selected flows. If a valid business reason exists to share business data between groups, you can consider editing the DLP policy or asking the user to edit the flow to comply with the DLP policy. Otherwise, the flow will remain irremediably suspended.

## Building Advanced Solutions with Power Automate

Building solutions with Power Automate is straightforward, but things get more complex when flows need to call other flows and when flows must make multiple decisions during its run. It is always best practice to start building a new flow by planning it first:

- How will the flow trigger?
- How many runs do you anticipate for the flow each month?
- Is the flow self-contained or will it call upon other services or third-party APIs?
- What will happen if the flow fails?
- How to log flow activities?

You can always modify flow definitions later. It is also possible to export a flow in a .zip file to keep it as a timestamped copy. This way you can rest assured that you have a copy of your flow before making extensive changes.

Several tools exist to troubleshoot flows. The **Run history** for each flow expands to show each connector input and output data and provides possible exceptions or raw errors the flow encountered. This is the best way to understand why any flow fails or why a single run failed among multiple successful runs. You can also test flows by editing a single flow and clicking on the Test button in the upper right corner. This puts the flow in a test run view and shows a single flow execution in real-time to make debugging easier (Figure 22-8):

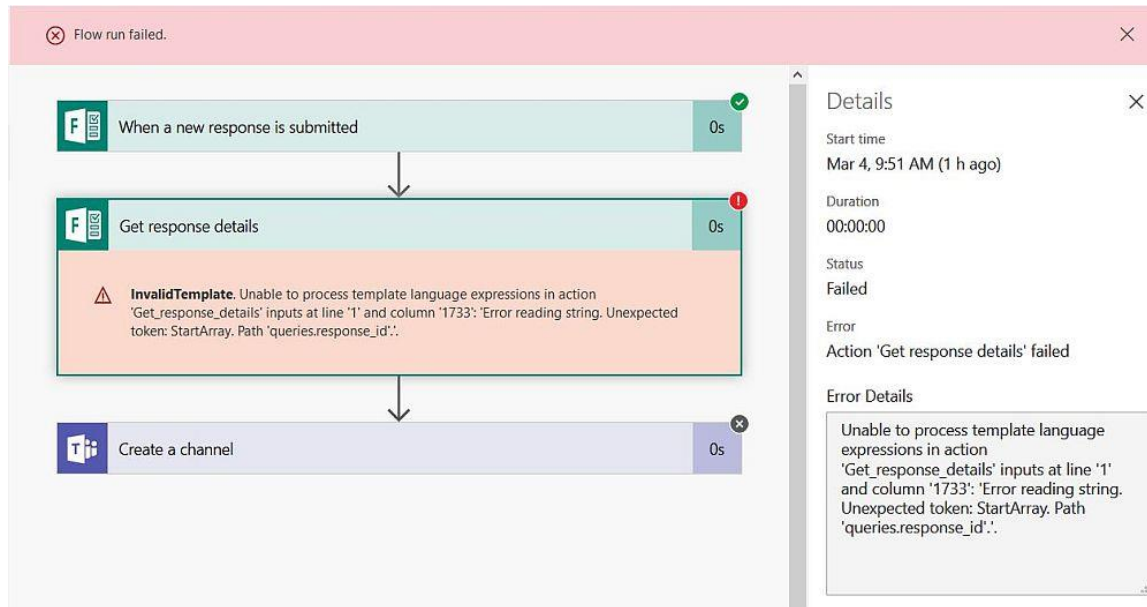

Figure 22-8: Raw output from a flow with execution errors

Flow checker is a tool that can be activated in the upper right corner while editing any flow. It performs an analysis and provides recommendations should the flow have any detected issues.

Certain connectors and triggers also expose settings to allow to further fine-tune how a flow activates and uses these building blocks. For example, when you use the Send Email connector to send email through Exchange Online, you have the option to specify a timeout value and a retry policy.

Some connectors also expose a **Run after** trigger. This can be configured to run if the previous task failed, succeeded, timed out, or skipped. This gives a way to provide further debugging, by sending out data to another API or system if a certain condition was met. If the flow makes a call to a third-party API but it times out, you can alert another system that the API is not answering to avoid further issues in subsequent flow runs.

Over time any account ends up with some flows that are not actively needed or used. Instead of deleting them, disabling allows them to retain their run histories and configuration.

## Extended Examples of Power Automate flows

[Lee Ford's blog](#) explains how to use a Form to allow users to request the creation of a new team and a mixture of Power Automate and Graph API calls to provision the team.

Another example is how to use [Flow to set values for the Asset ID property of documents](#) in SharePoint libraries. The Asset ID property is used for event-based retention processing (see Chapter 18). Like many uses of Power Automate, this example shows how to automate a repetitive task that humans find boring.

See also the article [Combining Microsoft Graph and Flow for Better Administration](#) which explains an example of advanced flows applied to tenant administration.

### API Support for Power Automate

Power Automate supports a Web API to work with flows programmatically. The API is REST-based and supports the ability to list, create, update flows, get all users with whom a flow is shared, share/unshare a flow, and export/import flows.

## Power Automate Desktop and RPA Tools

Power Automate Desktop (PAD) provides RPA (Robotic Process, Automation) capabilities to the Power Platform. RPA attempts to automatically replicate the actions of a user, such as mouse movements, clicks, and keyboard entries, for playback to automate repetitive tasks. RPA tools are often used to build business applications on the fly and for integration with legacy applications.

For a long time, people created "Macros", based on Visual Basic for Applications (VBA) for use in Excel, PowerPoint, and Word to replace repetitive series of keyboard and mouse actions. Macros are potentially dangerous because they have been used as vehicles for malware. PAD flows can be seen as an advanced version of Macros that are more secure because the code is not embedded in Office documents. The resulting flows can be an automation solution for a multitude of processes, not only for Word, Excel, or PowerPoint.

At Ignite 2020, Microsoft announced that PAD is [free to all Windows 10](#) users. Although the Power Automate Desktop app itself is free, the RPA system used to create and save flows to the cloud requires a paid subscription to the Power Platform ([a free trial with limited functionality is available](#)). Power Automate with RPA add-on licensing is only required if you want to publish desktop flows to the cloud.

Power Automate Desktop is already included in Windows 11. If you're running Windows 10, the Power Automate Desktop installer can be [downloaded directly from Microsoft](#).

## Power Apps

Power Apps is a service designed to allow users to build custom business applications without the knowledge of app development or any coding language. Power Apps is essentially a container that allows making apps that can be used across different platforms. Power Apps is designed to work with several different Microsoft data sources such as SharePoint lists and libraries, OneDrive, Excel, Dynamics, and external databases. Some examples of non-Microsoft sources include Dropbox, Box, Twitter, and Facebook.

Historically, the development of apps has involved creating different versions for each operating system they need to run on (one for iOS, one for Android, one for Windows). This essentially triples the development work, triples the support costs, and increases the development resources needed to create business apps. With Power Apps, all the apps run through the app, which takes care of the differences between the operating systems and just allows them to run the apps. There is also a web version of Power Apps, with the same concept but running through any modern web browser instead of a mobile app. Power Apps can also be embedded in other applications, such as SharePoint and Teams.

Typical solutions that power users and administrators might build with Power Apps include:

- Create user interfaces to interact with back-end office solutions to make administrative tasks widely available: hardware and software requests from users, support forms, open new services, and assign licenses.
- Forms to interact with SharePoint Lists and Libraries in a simplified way.
- Requests for provisioning of SharePoint Sites and Site Collections.
- Forms to request guest accounts and other types of administrator tasks.

Power Apps can be easily combined with Power Automate, in such a way that Power Apps works as the user interface and the back-end processes are implemented with Power Automate.

## Licensing Power Apps

The [licensing for Power Apps](#) is like Power Automate where Office 365 users get a non-premium license allowing them to create Apps for Office 365. For Power Apps, there are three additional premium plans:

- **Power Apps per user plan.** It allows users to run an unlimited number of apps, without any feature restrictions. Pricing is \$20 user/month and includes 500 AI Builder service credits per month.
- **Power Apps per app plan.** Allows users to run applications for a specific business scenario based on the full capabilities of PowerApps. Pricing is \$5 user/app/month and includes 250 AI Builder service credits per month. Requires access to the Microsoft 365 admin center with global administrator or billing administrator roles.
- **Pay-as-you-go-plan.** Allows users to run applications without [Power Apps licenses via Azure subscription](#). You only pay for the number of users who used an app in a given month. Pricing is \$10 per active user/app/month. This plan does require an active Azure subscription. This pricing model provides a way for organizations to try out Power Apps without a commitment. It offers the ability to enable additional usage in scenarios where subscription plans are not economical such as in cases where an app is only needed for occasional use for a larger base.

Administrators who need to have access to admin views in Power Automate, Power Apps, and Dataverse do not need a license. Further administration, such as specific Sales and Marketing modules for Dynamics 365 and the use of custom connectors, requires a purchased license.

## Enabling Power Apps for Users

The [Power Platform admin center](#) is the central hub for the administration of Power Apps, Power Automate, and Dataverse. Microsoft enables Power Apps by default for all users in the tenant with E3 or E5 licenses. You need to pay attention to how or when Power Apps is used and the business case(s) to use it. Some organizations disable Power Apps upfront for all users if they do not see an immediate need for the service. Take into consideration that Power Apps is a powerful tool that can improve the acceptance and usability of Office, but users do need to have the necessary training to understand how to use it. See the earlier section about enabling Power Automate to learn how to disable Power Apps for the entire tenant.

Users need a license to access Power Apps. From the Microsoft 365 admin center, navigate to **Users > Active users** and select a user. On the user detail page, select the tab **Licenses and apps**. The list with all product licenses available for the user shows. Expand the **Apps** section, search for **Power Apps for Office 365** and verify it is enabled. If a user account is assigned multiple plans, you only need to enable Power Automate from one plan.

## Building Power Apps

Two types of Power Apps can be created: Canvas apps and Model-driven apps.

- **Model-driven apps** use the Dataverse to configure forms, business rules, and process flows. You create a Model-driven app from the Power Apps site. You start with a data model, building up from the shape of core business data and processes to model forms, views, and other components. Model-driven apps automatically generate a user interface that is responsive across devices. Model-driven apps are used mainly by Dynamics 365.
- **Canvas apps** give the flexibility to arrange the user experience and interface the way you want it. You can start to build Canvas apps from Microsoft tools where the data lives, such as a SharePoint list or a Power BI dashboard, or from the Power Apps site.

Model-driven apps use Dataverse and Canvas apps have the option to use Dataverse as the data source.

**Note:** "Portal" apps can be created from the Power Apps dashboard, but they are not really Power Apps. Portals are internet portals based on Dataverse tables.

It is possible to merge the experiences of canvas and model-driven apps, making hybrid apps where the generated user interface from a Model-driven app can be modified and extended using the Canvas apps possibilities and power.

## Creating a Canvas App

As with Power Automate, there is a web designer for Power Apps. Open [the site](#) or select the Power Apps icon from the app menu. From the site's main page, you can create new apps from scratch or start with a predefined template. Templates help you learn how to build Power Apps and the kind of scenarios to consider using Power Apps. Some applications created using templates are suitable (with some degree of adaption) for production in an enterprise environment.

To see the available templates, click **+ Create** from left navigation menu and scroll down to the **Start from template** section. To follow our example, select **Service Desk**. This application tracks service requests, assignments, and job status, prioritizes jobs, adds notes, and tracks tasks by the assigned technician. The app opens with sample data and is a ready-to-use application deployable to help service desks in any company. Assign the application a name and select to use it in tablet or phone format.

When Power Apps designer studio opens, it shows three panels (Figure 22-9). The left side defaults to the Tree view panel displaying a list of screens in the application. In the center is the canvas with the main app screen. The panel to configure properties and rules for the components on the selected page is on the right.

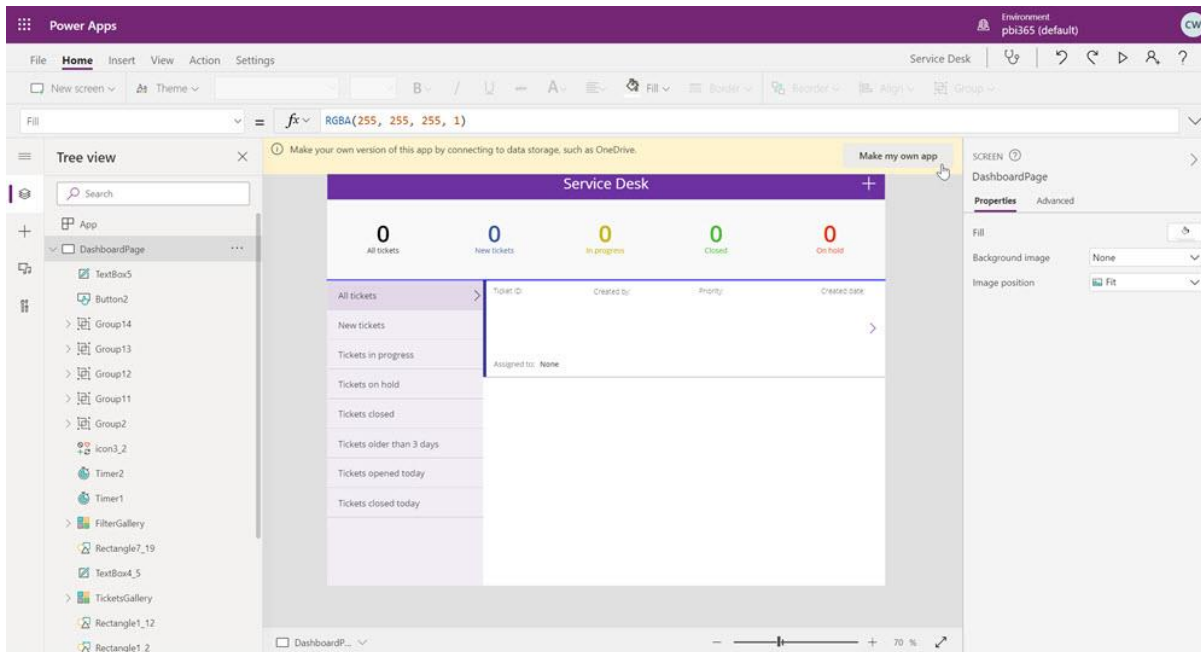

Figure 22-9: Power Apps designer studio

Each screen is composed of controls and there is a plethora of them. Click on the **Insert** tab at the top of the screen and you will see the controls grouped in sections. For example, the **Text** section contains the **Label**, **Text input**, **HTML text**, **Rich text editor**, and **Pen input** controls. There is also a **New screen** button that allows creating new screens for the application with options to start with predefined templates (such as **List**, **Email**, **Tutorial**) or start from **Blank**.

When a control is selected from the left panel of the graphical designer, its properties panel is automatically presented on the panel on the right side. This panel (Figure 22-10) allows the user to configure characteristics of the control (its **Properties**), such as its position in the canvas, its visibility, size, etc. The **Advanced** settings, allow you to configure advanced settings for the app and controls.

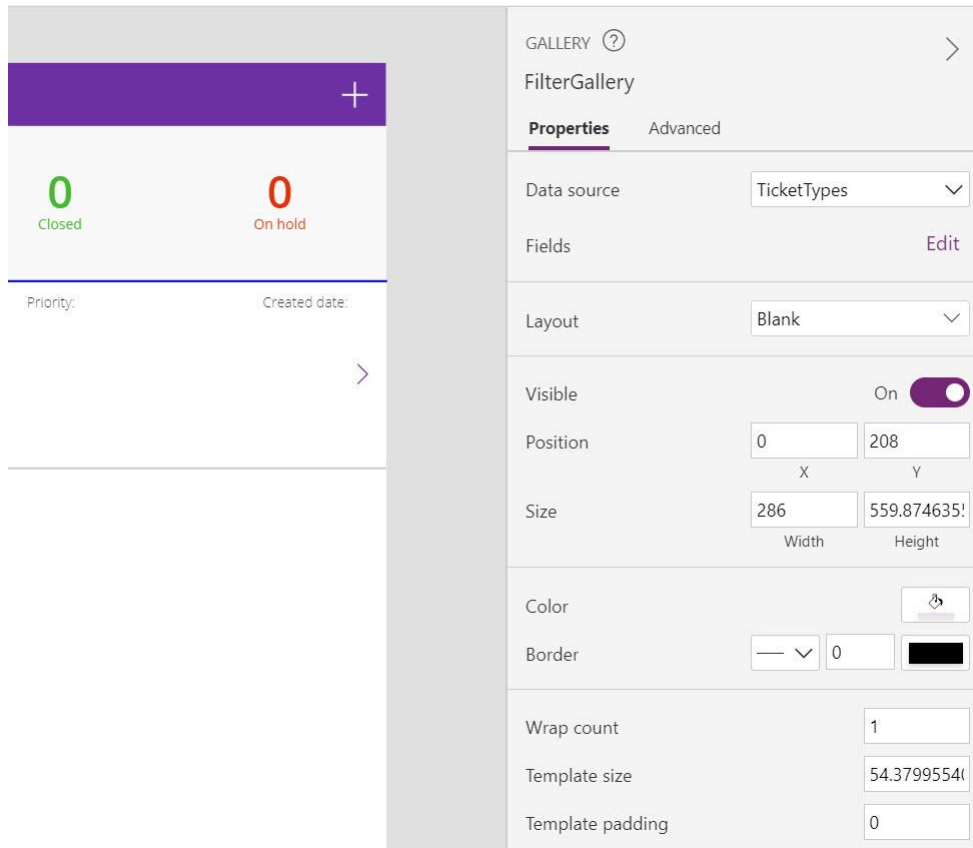

Figure 22-10: The Properties panel with the Advanced link for a selected control

The top-left menu has links to **Insert** controls in the canvas, **View** some essential components that are not reachable from the other windows, and go back to the Advanced properties panel (**Action**).

The **View** menu is important because it gives access to the components that make the application work:

- The **Data sources** are the repositories for the data that the application uses. Several sources can be used, such as Excel, Power Automate, Outlook, OneDrive, and SharePoint. Other services from Azure as the Service Bus and Azure Active Directory; and multiple external sources, such as GitHub, Box, and Dropbox.
- The **Media** menu allows images, videos, and audio to be used in the application.
- **Collections** can be used to store data that users can manage in an app. They are a group of items that can be created manually, or you can put a data source such as a SharePoint list into a collection.
- **Variables** are used to save values through the lifespan of the application, defining its type (text, date, etc.) and initial value.

The top-right menu contains two important buttons: The **App Checker** checks that there are no bugs in the application before it is published. The **Preview** button runs the application for testing before publishing. Use the **Preview** button to run the application (Figure 22-11):

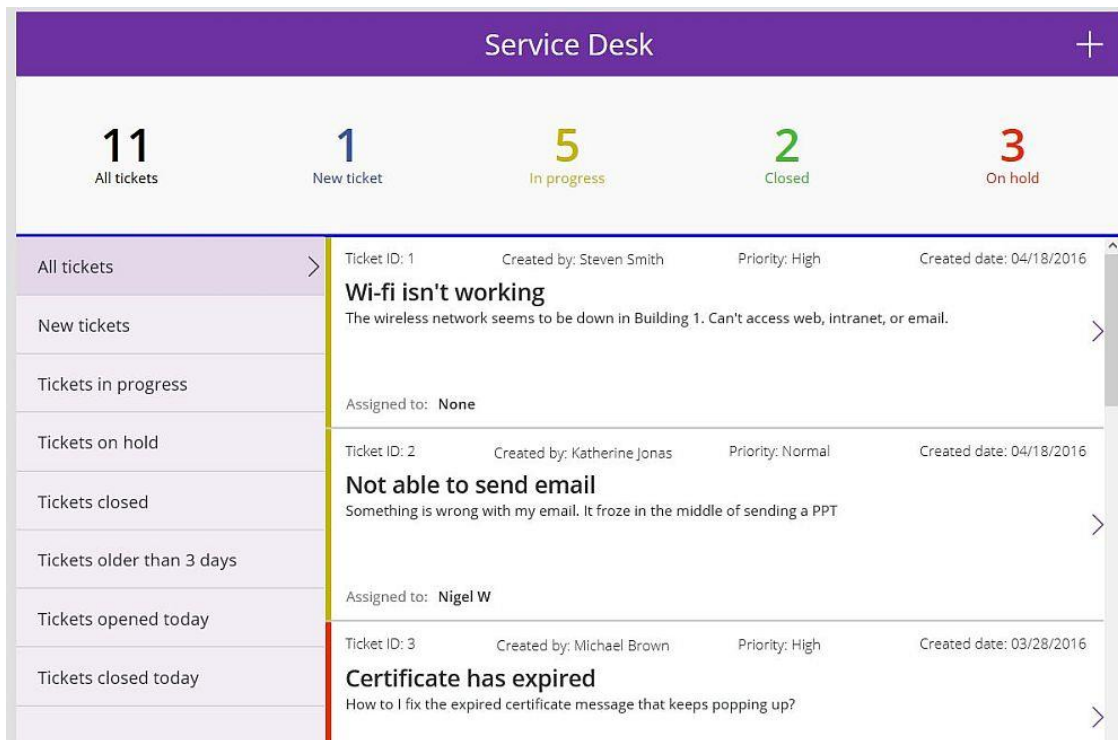

Figure 22-11: The Power Apps application running

The application shows a classification of the tickets saved in the data sources. The application is interactive and fully functional: click on any of the tickets, and the details page opens, allowing the user to modify the state, add comments, etc. New tickets are added using the + button in the upper-right corner. Tickets can be closed, reopened, modified, set on hold, etc., and the totals are shown at the top of the application.

When you are satisfied with the application, go to **File > Save**, define the final name for the application, and use the **Save** button to publish the application and make it available to users.

## Creating a Model-driven App

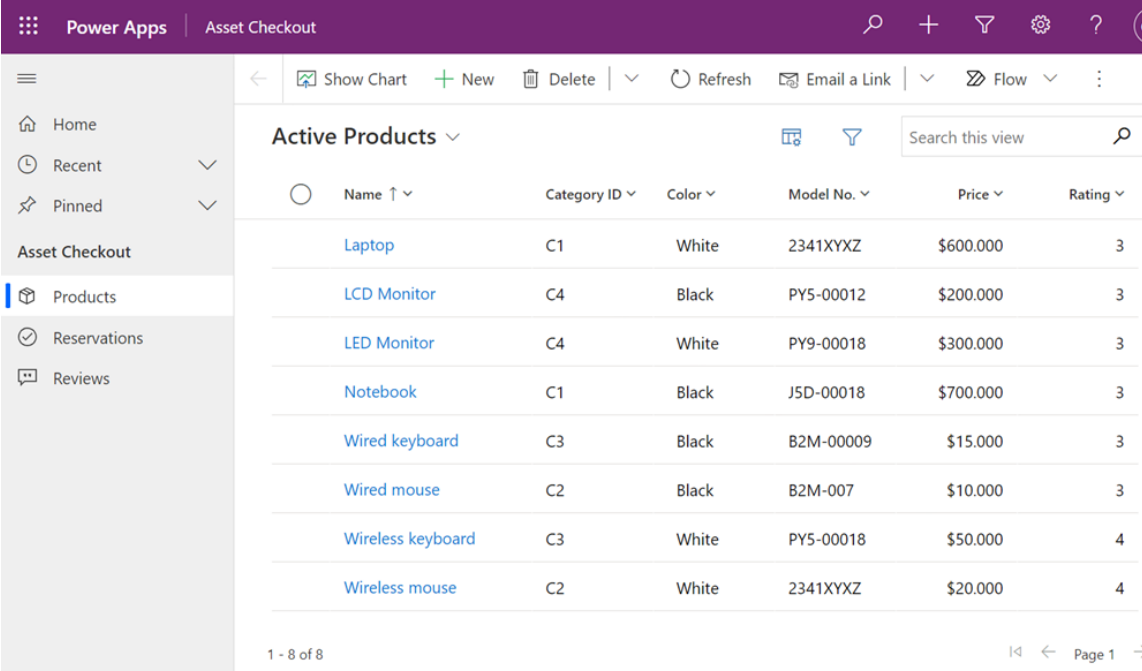

Unlike Canvas apps (where the designer has complete control over app layout), Model-driven app layout is determined by the components added to the app. The creation of Model-driven apps requires three steps:

- Modeling business data - It is important to determine what data the app will need as well as how the data are related to other data. The Model-driven design uses a metadata-driven architecture so designers can customize the application without writing any code.
- Defining business processes - Consistent Business processes are a key aspect of a Model-driven app design. Consistent processes ensure that app users focus on their work and not on remembering to perform a set of manual steps. Processes can be simple or complex and often change over time. To create a process, from the **Model-driven** area select **Settings > Advanced customizations > Open solution explorer**. Then on the left navigation pane in solution explorer select **Processes > New**.
- Composing the app - After modeling data and defining processes you can build the app by selecting and configuring the components needed using the app designer.

**Note:** To work with Model-driven apps you need a database in Dataverse and a separate Environment. To get both, you must have a paid plan account. Remember to assign the license to the users after buying the service from Microsoft.

The apps and user interface for Model-driven apps are based on the Dynamics 365 CE (Customer Engagement) user interface. It's almost always used in combination with Dynamics and seldom-used stand-alone or integrated into other services.

After creating a new Environment, create a new Dataverse database, and be sure you check the option **"Deploy sample apps and data"** at creation time. To start creating a Model-driven app for learning, look to existing templates in the Power Apps gallery. There are three templates for Model-driven apps: Fundraiser, Innovation Challenge, and Asset Checkout. To create a new app based on one of the templates, click on the **Create an app** button and select **Model-driven**. Then assign a name, and description for the app and check **Use existing solution to create the App**. In the following window, you can select an existing solution from a list that includes the three examples. When you are ready to review/modify the copy of the example, use the **Publish** and then the **Play** button to see the app in action, as shown in Figure 22-12.

Name ↑	Category ID	Color	Model No.	Price	Rating
Laptop	C1	White	2341XYZ	\$600.000	3
LCD Monitor	C4	Black	PY5-00012	\$200.000	3
LED Monitor	C4	White	PY9-00018	\$300.000	3
Notebook	C1	Black	J5D-00018	\$700.000	3
Wired keyboard	C3	Black	B2M-00009	\$15.000	3
Wired mouse	C2	Black	B2M-007	\$10.000	3
Wireless keyboard	C3	White	PY5-00018	\$50.000	4
Wireless mouse	C2	White	2341XYZ	\$20.000	4

Figure 22-12: An Asset Checkout model-driven Power App

## Creating a SharePoint Integrated Power Apps app

With Power Apps, you can customize SharePoint Lists and Library forms as was possible with InfoPath before Microsoft deprecated InfoPath. Power Apps has a similar integration with Lists and Libraries and embeds its forms within the SharePoint List or Library.

To start with SharePoint Lists, you can work with an existing modern list or create a new custom list. If you create a new List, ensure it is using the Modern user experience. From the command bar of the list, select **Integrate > PowerApps > Customize forms**. You can then select the fields to show in the list from the available set (Figure 22-13).

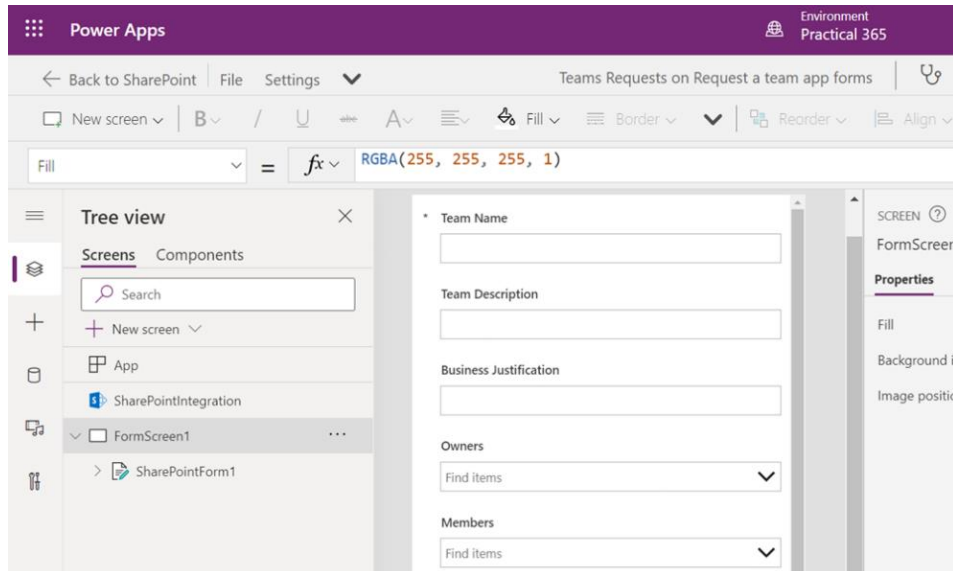

Figure 22-13: A Power Apps Canvas app to replace the default form for a SharePoint List

The complete functionality of Canvas apps is present: you can reorder the fields, change their properties, set conditional formatting to, for example, appear/disappear based on the content of other fields, etc. When you finish, test the app with the **App Checker** button, **Save** and **Publish to SharePoint** the new form.

The Power Apps form replaces the default SharePoint forms automatically. When a user clicks on **+New** to create a new item, the form appears in place of the old form (Figure 22-14):

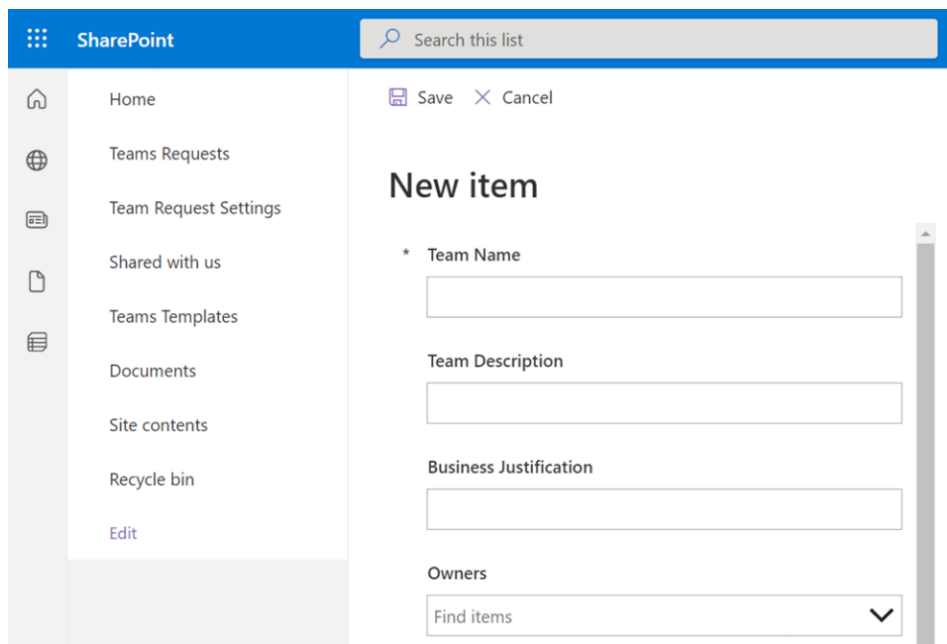

Figure 22-14: A Power Apps Canvas app replacing the default form in a SharePoint List

If changes are needed, the List owner can open the Power App to modify by navigating the same way as when creating a Power App customized form. From the command bar of the list, select **Integrate > PowerApps > Customize forms**.

If you want to change the list back to using the default SharePoint form instead of the Power App customized form, you can re-activate it through the List settings. To re-activate the original form, go to the List in SharePoint, open the **Settings** page by selecting the gear icon near the upper-right corner, and select **List Settings**. On the settings page select the **Form Settings** link under the **General Settings** section. A new page will open. Then select **Use the default SharePoint form** and save the changes. When using the default form,

if you return to the Form Settings page, you will see an extra link **Delete custom form** in the section of Power Apps, under **See versions and usage**. Use this option to remove the Power Apps form.

Take into consideration that if you customize the form for a SharePoint List, the form doesn't appear as an app in Power Apps Studio or Power Apps Mobile. The Power App form can only be opened from the list for which you created it. Anyone with SharePoint permissions (to manage, design, or edit the associated List) can customize the forms. Any guest users that do not have a plan that includes Power Apps will get an error message if they try to access a list form that has been customized using Power Apps.

## Using the Apps

There are several ways to make Power Apps app available to users:

- All Power Apps are mobile-enabled, and Microsoft publishes Power Apps for Android and iPhone. Start the Power Apps phone app and log in with your Microsoft 365 account. A list of apps you have access to appears. Click on any of the apps to open the app and then you can start using it.
- Users can access Power Apps from any modern browser supported by Microsoft 365. When a Power Apps app is published, it gets an identifier that can be used to redirect any browser directly to the app. For example, <https://web.powerapps.com/apps/b0f87da1-1053-4a3f-999f-84a372b1b656>. You can retrieve the identifier and the URL from the app properties (use the details link from the ellipse button in the apps list). The users can bookmark the URL to access the app speedily.
- SharePoint Online has its own Webpart to embed and interact with Power Apps from any modern SharePoint page. Open the SharePoint page where the Power Apps app will be hosted, add the Power Apps Web Part, configure the URL or Identifier of the app, and publish the page.
- Team owners can add Power Apps as a channel tab.

## Moving Power Apps Between Environments

A typical Power Apps administrator activity is moving apps from dev/test to production tenants or between Power Platform Environments. There are two ways to move apps which are via the export/import functionality or by building a Power Apps solution. Canvas apps can be moved using **Export package** under **Apps** and Model-driven apps can be exported using **Export** under **Solutions**. Only the Owner and Co-owner of an app can export a canvas app package. An account must hold the Environment Maker permission to import an app.

To export a Power Apps app, from the main window of the website (<https://web.powerapps.com>) click on the Apps menu on the left side menu to show the list of published apps. Click on the ellipse button ("...") of one app and from the contextual menu select **Export package**.

The **Action** button (Figure 22-15) allows you to select if the packaged solution will be created as a new app or updated as an existing app when imported into a target environment. When you click the **Export** button, Power Apps creates a .zip file and downloads it to the local computer.

To import one package, from the same page with the list of apps use the link **Import package** (menu at the top of the page). A new window opens to upload the .zip file. A second window opens showing the package details; use the **Import** button. If any error occurs, for example, because you try to create an app that already exists, an error message appears indicating the problem found. If the app uses connectors that are not yet configured, the import menu will prompt you to select or create new connections.

## Export package

**Package details**  
Created by Christina Wheeler on 06/27/2022

Name \*  
Space Invaders

Environment  
Christina Wheeler's Environment

Description  
Space Invaders Power App provided by Brian Dang (Power CAT)

**Import setup**

Choose what will happen when each resource is imported to the new environment.

**Create as new**  
This app or flow will be new to the environment when the package is imported.

**Update (default)**  
The app or flow already exists in the environment and will be updated when this package is imported.

**Review Package Content**  
Choose your export options and add comments to provide instruction or add version notes.

## GDPR and Power Apps

The European Union GDPR regulations oblige app developers to manage user personal data in an accountable way. See Chapter 18 for an overview of GDPR and Office 365.

GDPR has two consequences for Power Apps: users can request a data controller (usually a company) to retrieve their data at any moment (“right of data portability”), and they can also require the data controller to remove their data (“right to erasure”) from the system. Power Apps saves personal information in the Environments, Canvas apps, Gateway, Custom Connectors, and Connections.

In general, users can find their information in the Power Apps Portal or using the [App Creator PowerShell cmdlets](#). A user has the right to find and modify their information only. An administrator with Global Administrator or Azure Active Directory Global Administrator rights can do the same for all users. In some cases, a Power Apps paid license plan is required. Microsoft details the actions necessary to [export](#) or [remove](#) personal user data using the Power Apps Portal and/or the PowerShell cmdlets online.

## Power BI

Power BI is a suite of business intelligence (BI) software services, apps, and connectors that work together to provide a way for you to connect, share, and analyse data through reports and dashboards. Power BI is the next-generation business analytics tool comprising several technologies that originated from Excel such as PowerPivot and Power Query. Power BI is packed with collaboration, sharing, and mobile features that are deeply embedded in Microsoft business application solutions. Power BI consists of three main components:

- **Power BI Desktop** – Authoring tool of Power BI used by report designers to access, transform, and model data as well as build the data visualizations on report pages.
- **Power BI Service** – Cloud-based central hub where users can access and interact with dashboards and reports.
- **Power BI Mobile** – Mobile component of Power BI that allows users to interact with published reports using their smartphones and tablets through the Power BI app available on Windows, iOS, and Android devices.

## Licensing Power BI

The licensing options for Power BI include the following:

- **Power BI (free)**. Users can sign up for a free account using a work or school account which provides access to a personal workspace.
- **Power BI Pro**. Users with this standard license can share data, reports, and dashboards with other users who have a Power BI Pro license through shared workspaces. Power BI Pro is included in E5 subscriptions, otherwise the price is \$9.95 per user/month.
- **Power BI Premium**. There are two types of licensing for [Power BI Premium](#) which is capacity-based, and per-user based.
  - **Capacity-based** – This license consists of capacity in the Power BI service exclusively allocated to each organization supported by dedicated hardware fully managed by Microsoft. Capacity can be applied broadly or allocated to assigned workspaces based on the number of users or workload needs with the flexibility to scale up or scale down. Pricing starts at \$4,995 per capacity/month. With this license, report consumers do not require any per-user license however Power BI Pro licensing is needed for report designers who will be designing and publishing content into the Power BI Premium capacity.
  - **Per-User (PPU)** – This license provides the ability for organizations to [license premium features on a per-user](#) basis. Users with this license get Power BI Pro capabilities along with features like paginated reports, AI, and other [premium capacity features](#). Pricing is \$20 user/month.

## Power BI Service

The Microsoft Power BI Services ([app.powerbi.com](http://app.powerbi.com)) is the SaaS part of Power BI. Sometimes referred to as Power BI online, is a cloud-based service where users can view and interact with the reports. Report designers use Power BI Desktop to publish reports to the service and report readers can access the service through shared workspaces. Every user (both free and licensed) receives a personal workspace called *MyWorkspace*. Shared workspaces are available for Power BI Pro or Power BI Premium licensed users.

## Power BI Desktop

Power BI Desktop is a report authoring application used by report designers to build advanced queries, data models, and reports. This application is available to download for free and can be installed on computers running Windows 10 or later. To [get Power BI Desktop](#), you can install it as an app from the Microsoft store or download and install the executable. You do not have to have a Power BI service account to use Power BI Desktop however it is recommended you sign up for the free version if you are not already licensed in Power BI Pro or Premium.

### Using Power BI Desktop

Once you have Power BI Desktop installed you can immediately connect, transform, and build visualizations of your data. Power BI Desktop has three views:

- **Report** – View where you use queries from your data model to build visualizations and arrange them on report pages. In this view, you can add, delete, and manage multiple report pages.
- **Data** – View where you see the data in your report in a data model format and can add measures, create new columns, and manage relationships.
- **Relationships** – View that provides a graphical representation of the relationships established in your data model. In this view, you can add, modify, and manage the relationships.

Power BI Desktop comes with the Power Query Editor. Originating from Excel through PowerPivot, the Power Query Editor is used to connect to one or more data sources. You can shape and transform your data using the Power Query Editor to meet your visualization needs.

While you can create reports directly from the Power BI service, it is recommended you build in Power BI Desktop first and then publish your report to the Power BI service in your individual or shared workspace (Figure 22-16).

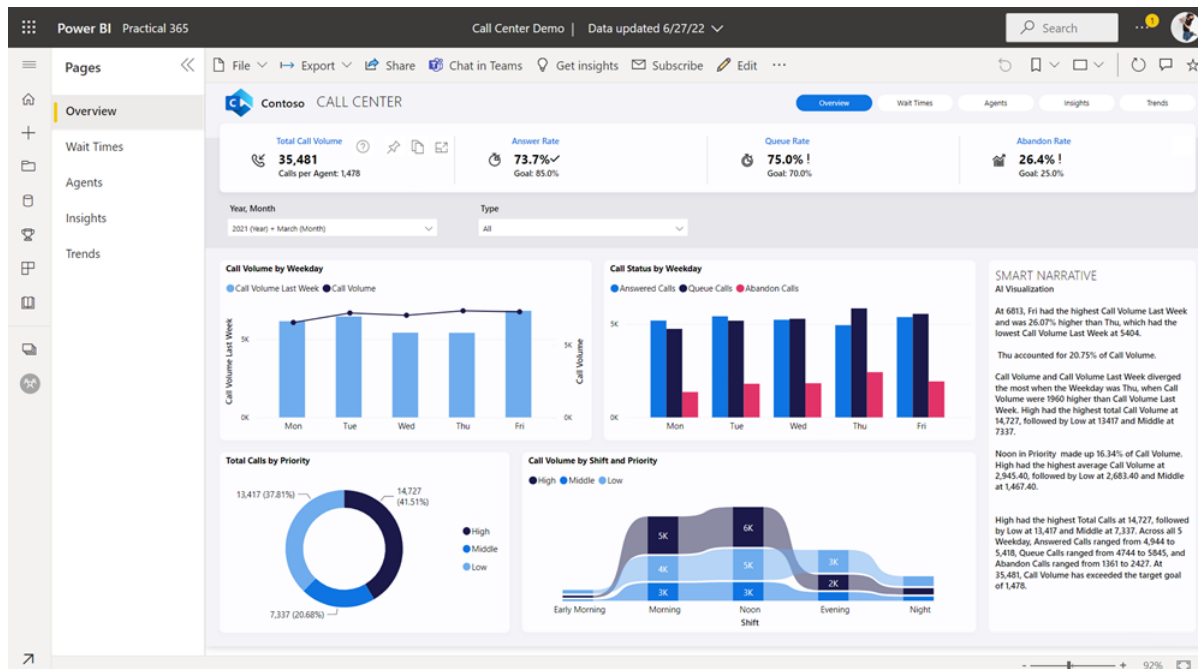

Figure 22-16: Published report displaying in shared workspace called Practical 365

For a getting started guide and tutorials on Power BI Desktop, please visit [Get started with Power BI Desktop](#).

To understand the differences between Power BI Desktop and Power BI Service, please visit [Comparing Power BI Desktop and the Power BI service](#). To learn more about your sharing and collaboration options in Power BI, please visit [Ways to collaborate and share in Power BI](#).

## On-premises Data Gateway

If you need to connect to data within your organization that is not part of the cloud, you can connect using an on-premises data gateway. To learn more about the on-premises data gateway, please visit [this article](#).

## Using Power Apps and Power Automate with Power BI

Power BI is natively a read-only tool, allowing users to see their data but doesn't have built-in capabilities to write back data. Thanks to the integration of Power Apps and Power Automate with Power BI, you can now build Power Apps and Power Automate solutions to provide users the ability to write data back to the source system from within Power BI using the Power Apps and Power Automate visuals.

To learn more, please visit [Power BI data write-back with Power Apps and Power Automate](#).

## Power BI Security

The Power BI Service is built on Azure (Microsoft's cloud computing infrastructure and platform). Power BI uses two primary repositories for storing and managing data that is uploaded from users from Power BI Desktop to the Power BI Services. Data uploaded from users is typically stored in *Azure Blob Storage* and all metadata and system items are stored in *Azure SQL Database*.

For more information on the Power BI architecture, please visit [this article](#) and for more detailed information on Power BI Security, please [read the Power BI Security whitepaper](#).

## Power Pages

At Build 2022, Microsoft announced the evolution of Power Apps portals called Power Pages. Power Pages is the newest member of the Microsoft Power Platform family. It is built on the foundation of Power Apps portals where you can build websites using the new design studio and pre-defined starter templates. Currently, Power Pages is in preview and is available by visiting <https://powerpages.microsoft.com>.

### Design Studio for Power Pages

Power Pages Design Studio is a cloud-based WYSIWYG (what-you-see-is-what-you-get) authoring tool designed for low-code makers to build and style data-centric business sites backed by Dataverse. When you sign up for a trial, an environment will be auto-provisioned for you within your tenant. To build a site simply click on **+ Create a site** to start the creation of your new site.

When first get started with creating a new site, you will be given a list of templates to choose from. Once selected, you will be prompted to provide a site name, web address, and have an option to change the site language. *The site's web address must be unique and will display a message if unavailable and will not let you continue until it's unique.* When ready, click **Done** to proceed to provision the site.

The site will take around 5 minutes to provision and once complete you will be able to see it listed under My sites where you will have the option to preview or edit (Figure 22-17).

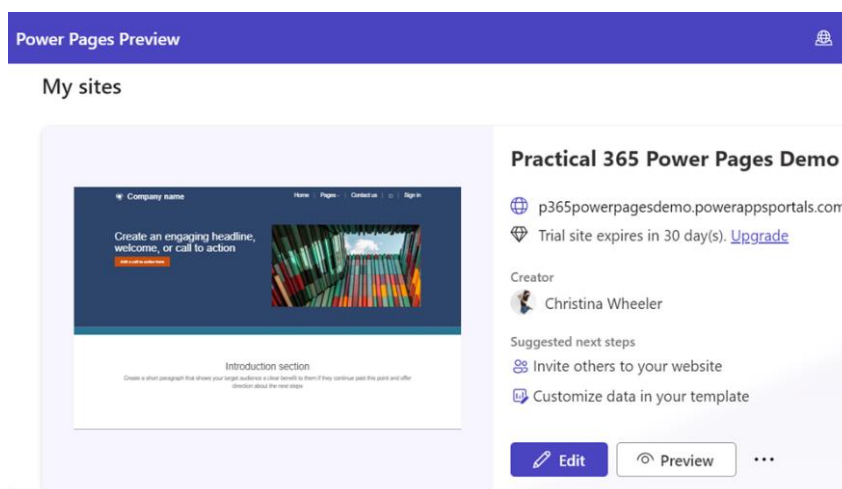

Figure 22-17: Power Pages example website

From here you can click **Edit** to launch design studio. Design studio has four marquee experiences called *workspaces*. The workspaces included are:

- **Pages workspace** - Enables makers to [create and design webpages](#) with no-code and low-code widgets such as lists, forms, text, images, video, and others.

- **Styling workspace** – Enables makers to [apply global site styles](#). There are 13 preset themes available and for each theme, you can customize the color palette, font styles, background color, section margins, and button styles.
- **Data workspace** – Enables makers to easily model, visualize, and manage business data for the site. All data and changes made in the [Data workspace](#) are stored in Dataverse.
- **Set up workspace** – Enables makers and site administrators to [configure site settings](#) such as identity providers for authentication and table permissions.

To dive deeper into Power Pages, please visit [Microsoft Power Pages \(preview\) documentation](#).

To learn more about Microsoft's vision for the future of Power Pages and low-code solutions, please visit [this article](#).

## Power Virtual Agents

"Power Virtual Agents" is the latest service added to the Power Platform. Built on top of Azure's existing Bot Framework Service together with some Artificial Intelligence tools for building bots, Power Virtual Agents enable the development of chatbots with no coding and/or model training requirements. Administrators can take advantage of this service for scenarios such as building a bot to walk a new employee through the onboarding experience.

Power Virtual Agents are created using a guided, no-code graphical interface, which integrates bots with the prebuilt existing Power Platform connectors. Power Automate workflows can be triggered to enable bots to act on behalf of customers. Background processes continuously and automatically monitor the bots to improve their performance using AI and data-driven insights. You can create a bot to be used as a Power Virtual Agents web app (<https://powervirtualagents.microsoft.com>) or as a Power Virtual Agents app in Microsoft Teams (Figure 22-18). If you're new to Power Virtual Agents and want to learn more, I recommend going through the [Quickstart tutorial](#) to create a Power Virtual Agents HR bot in Microsoft Teams.

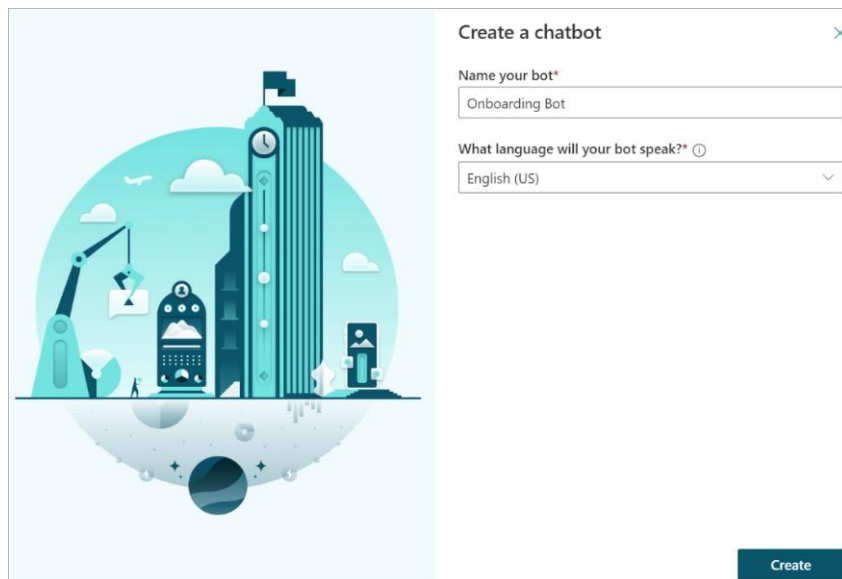

Figure 22-18: Creating a Power Virtual Agents chatbot initial dialog in Teams

## Licensing Power Virtual Agents

To create and manage bots with Power Virtual Agents, you will need to be licensed. The [available licenses for Power Virtual Agents](#) include:

- **Power Virtual Agents per user license.** This license allows you to assign individual licenses to users who need access to create and manage chatbots.
- **Power Virtual Agents per tenant license.** This license allows you to run intelligent chatbots across websites and other channels. You only pay for two-way engagement between users and your chatbots with sessions servicing each end-to-end interaction. This license cannot be assigned to individual users. Price is \$200 per month for 2,000 sessions.

Add-ons available currently are:

- **Power Virtual Agents per tenant (Sessions add-on).** This add-on license allows you to add additional sessions to your Power Virtual Agents plan. Price is \$100 per month for 1,000 sessions and requires a Power Virtual Agent license.

To learn more about Power Virtual agents, please visit [this page](#). Power Virtual Agents' capacity is pooled at the tenant level. To learn more, please visit [Quotas, limits, and configuration values for Power Virtual Agents](#).

## Teams and the Power Platform

Many organizations around the world are using Teams as their central hub for their corporate collaboration. The Power Platform has improved with the integration into Teams. You can leverage the Power Platform and Teams with the ability to do the following:

- Embed a canvas app or a model-driven app as a tab in a team.
- Embed a canvas app or a model-driven app as a personal app.
- Create Power Apps directly in Teams, backed by Dataverse for Teams.
- Create Power Automate flows in Teams.

To embed a Power App as a tab in Teams, you simply click on the + in a team next to the tabs in the channel of the team you want to add it to. Choose Power Apps, then select the Power App you want to embed as a tab in a team (Figure 22-19). For this example, an app called School Transformation Survey is selected to be added as a tab in a team channel.

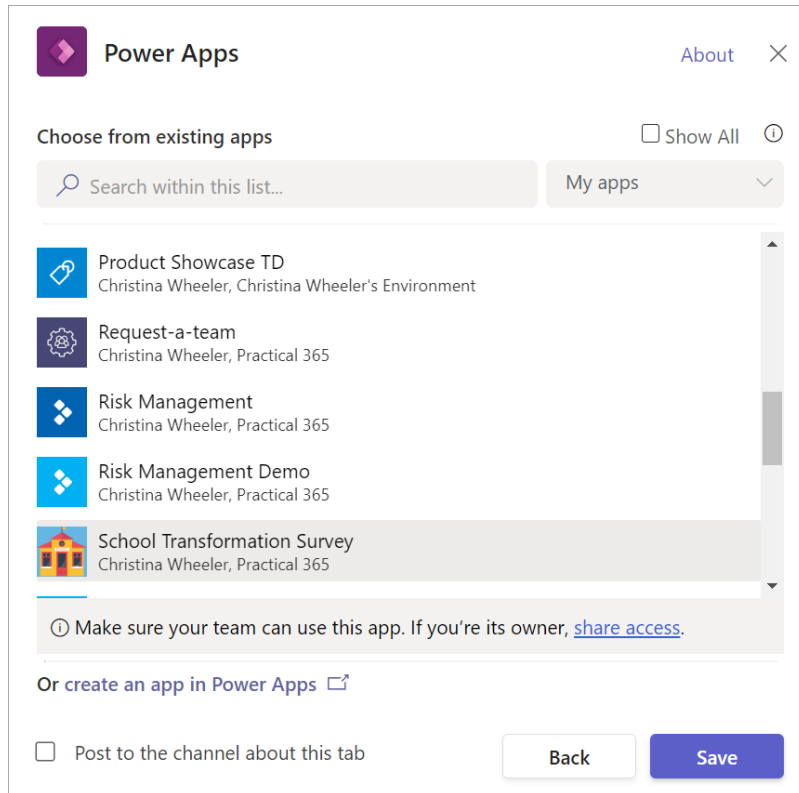

Figure 22-19: Adding a Power App as a tab in a team dialog example

The School Transformation Survey app appears as a tab in a channel (Figure 22-20). This example app was created outside of Teams using Power Apps Studio as a canvas app and is using SharePoint lists as the backend data. You can add any type of canvas app or model-driven app in Teams, or you can create new Power Apps directly inside of Teams using the Power Apps Teams app.

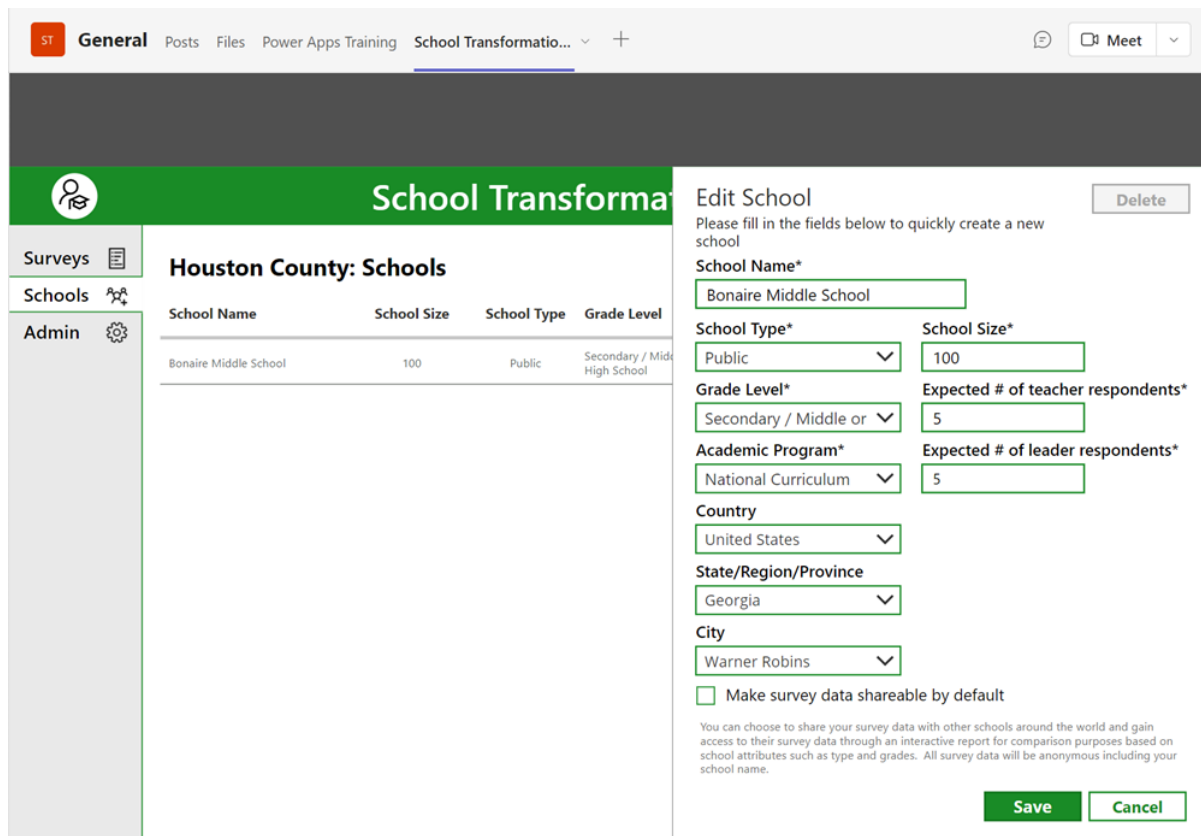

Figure 22-20: Power App embedded as a tab in a team example

For more details on using Power Automate and to see an example of the Request a team Power Platform app template, see the article [Teams + Power Automate: Practical Examples to Automate Tasks](#).

## Dataverse for Teams

When you create a Power App directly in Teams, the backend used is Dataverse. In September 2020, Microsoft introduced Dataverse for Teams which empowers you to create custom apps, bots, and flows in Teams using Power Apps, Power Automate, and Power Virtual Agents. The Dataverse for Teams environment is created automatically when you create a bot or app in Teams or when you install the Power Apps app in Teams and create an app for the first time. Each team can have one Dataverse for Teams environment which is used to store, manage, and share team-specific data, flows, and apps (see the [Dataverse for Teams infographic](#)).

Dataverse for Teams creates a single environment for each team and the capacity is measured with relational, file, and image data. Table 22-4 shows the differences between Dataverse for Teams and Dataverse and Table 22-5 shows Dataverse for Teams service limitations.

<b>Environment lifecycle</b>	<b>Dataverse for Teams</b>	<b>Dataverse</b>
Environments	1 per Team	Unlimited
Maximum size	1 million rows or 2 GB	4 TB or more
Upgrade to Dataverse	Yes	N/A

Table 22-4: Environment lifecycle differences between Dataverse for Teams & Dataverse

<b>Unit</b>	<b>Service limit</b>
Dataverse for Teams environments	5 environments + 1 additional environment for every 20 eligible Microsoft 365 user licenses.
Max storage per tenant (Dataverse for Teams environments)	10 GB + Dataverse for Teams environments × 2 GB (up to a maximum of 19.5 TB).  The 2 GB storage limit can't be extended. If more storage is needed, you can upgrade the environments to Dataverse.

Table 22-5: Environment lifecycle differences between Dataverse for Teams & Dataverse

With the growing amount of data tenants store in Exchange Online, SharePoint Online, OneDrive for Business, and other services, it is natural to consider how best to protect content, especially when the data is confidential or sensitive. Sensitivity Labels and the underlying rights management technology are a good way to protect email and documents, and that is where we go next.

# Chapter 23: Managing Tenants with PowerShell and the Microsoft Graph

*Tony Redmond*

## The Power of Automation

The nature of sharing a massive multi-tenant environment means that Microsoft will never be able to satisfy the unique administrative and automation requirements of every tenant. This chapter discusses how to use PowerShell to manage your tenant. We expect that readers will have some acquaintance with PowerShell, but we'll try to explain how to get work done without plunging too deep into some of the more arcane and complicated aspects of scripting.

Many Microsoft 365 workloads support PowerShell. It's quick and relatively easy to perform an administrative operation in a few lines of script code, which is why we include PowerShell examples to illustrate points in the book. In this chapter, we concentrate on topics that demand more than one or two lines of code, especially for objects that require management on an ongoing basis such as Azure AD accounts, Exchange Online mailboxes, and Microsoft 365 groups. In doing so, we leverage the many examples of how to do different things with PowerShell available in repositories like GitHub, the Microsoft Technical Community, and individual websites. There's no shame in taking code posted by someone and adapting it to solve a problem.

Increasingly, Microsoft 365 applications use Graph APIs to interact with data. We reflect this by covering the basics of running Graph API requests from PowerShell and the Microsoft Graph PowerShell SDK. The combination of easy automation with PowerShell and the power of Graph API requests often delivers the best balance of performance and flexibility, especially in larger tenants.

## Common PowerShell Modules Used with Microsoft 365

Among the modules often used to manage Microsoft 365 tenants are:

- **Azure AD:** Modules are available for both production (AzureAD) and preview (AzureADPreview). The Azure AD Graph API is the foundation of both modules. As noted later, these modules are due for deprecation.
- **Exchange Online:** Manages mailboxes, other mail-enabled objects, and the Exchange Online configuration through the [ExchangeOnlineManagement](#) module.
- **SharePoint Online:** The [Microsoft.Online.Sharepoint.PowerShell](#) module manages sites and other SharePoint administrative objects. If you want access to documents and folders within SharePoint Online sites and OneDrive for Business accounts, use the [SharePoint PnP](#) module.
- **Teams:** The [MicrosoftTeams](#) module manages Teams-specific objects.
- **Microsoft Graph PowerShell SDK:** The cmdlets in this multi-module SDK implement many Microsoft Graph API calls. It is now the preferred option for PowerShell access to Azure AD components.

Full coverage of the Exchange Online, Azure AD, Teams, and Microsoft Graph PowerShell SDK modules is available later. Examples of SharePoint Online management with PowerShell are in the SharePoint chapter.

The modules listed above all support modern authentication, which is what you should use to connect to PowerShell endpoints. This is especially important because of Microsoft's efforts to remove basic authentication from Microsoft 365.

**Other Modules:** Apart from the PowerShell modules created by Microsoft, the PowerShell Gallery holds a variety of third-party modules that might be useful. A good example is the [ImportExcel module](#), which includes cmdlets to interact with Excel workbooks, including the ability to create charts in worksheets.

## Module Installation and Maintenance

To make it easier for ongoing maintenance, install these modules from the PowerShell Gallery rather than by using an MSI file. Do this by running the *Install-Module* cmdlet in a session when signed in as an administrator. For example:

```
[PS] C:\> Install-Module -Name ExchangeOnlineManagement -Force -Scope AllUsers -Repository PSGallery
```

By default, PowerShell considers the PowerShell Gallery to be an untrusted repository (like any other internet source), so PowerShell will prompt you to authorize the installation of modules from the gallery. If you want to make the PowerShell Gallery a trusted resource, connect to PowerShell as an administrator and run the command:

```
[PS] C:\> Set-PSRepository -Name PSGallery -InstallationPolicy Trusted
```

You need to run this command on each workstation where you install PowerShell modules. To see a list of installed modules, use the command:

```
[PS] C:\> Get-InstalledModule
```

Once you've installed a module, you can connect to it using suitable credentials and explore the commands available in the module using the *Get-Command* cmdlet. For example:

```
[PS] C:\> Get-Command -Module Microsoft.Graph
```

Use the *Get-Module* cmdlet to find out the set of modules loaded into a session. Here's how to return the set of loaded modules and their version number:

```
[PS] C:\> Get-Module | Format-Table Name, Version
```

## Updating PowerShell Modules

Microsoft updates PowerShell modules used to manage Office 365 services on an ongoing basis. Although sometimes functionality is dependent on a specific version of a module, you should update the modules used to develop and run PowerShell scripts on an ongoing basis. Most of the modules are now available in the PowerShell Gallery, so you can create a script to check for updates, apply any available updates, and remove old versions from a workstation. The latter step is important to avoid the possibility of errors caused by running obsolete outdated cmdlets.

PowerShellGet, which is the easiest way to work with the Gallery, first appeared in Windows Management Framework (WMF) 5.0, which is essentially PowerShell 5.0. PowerShell 6.0 and later include this functionality too; Windows 10 and Windows Server 2012 R2 or later ship with PowerShell 5.0 or later installed by default, which means that PowerShellGet is already available. For earlier operating systems, you'll either need to upgrade to WMF 5.0 or install PowerShellGet for PowerShell 3.0 or 4.0. Some applications such as Exchange Server are sensitive to changes in the version of WMF installed on the system, so you should not upgrade WMF until you've verified that all your installed software will continue to work.

A script [downloadable from GitHub](#) illustrates how to:

- Define a set of modules to check for updates in the PowerShell Gallery. Tailor the set of modules to meet your needs.
- Use the *Update-Module* cmdlet to check for and apply updates.
- Use the *Get-InstalledModule* cmdlet to check for older versions and the *Uninstall-Module* cmdlet to remove any found.

Ideally, you should check modules for updates monthly. Workload teams update their PowerShell modules at a different pace and it's impossible to predict when a new version will appear.

## Azure Active Directory PowerShell

Many administrative tasks such as user and licensing management, adding and removing domain names, and managing company information in PowerShell can be performed using the Azure AD PowerShell module (referred to by Microsoft as [Azure AD PowerShell for Graph](#)). Microsoft introduced the Azure AD module in 2015 to replace the older Microsoft Online Services ([MSOL module](#)). The MSOL module (created in 2012) is still in use to manage user accounts.

After installing the Azure AD module, connect to your tenant with:

```
[PS] C:\> Connect-AzureAD
```

Microsoft [plans to deprecate the Azure AD and MSOL modules at the end of 2022](#). Their replacement and Microsoft's long-term focus for the development of PowerShell support for Azure AD features is the Microsoft Graph PowerShell SDK. You should use the SDK for any future development and upgrade scripts written using the Azure AD or MSOL modules.

Although Microsoft has scheduled the end of support for the Azure AD and MSOL modules, the cmdlets will continue to work afterward. The exception is license management because, on August 26, 2022, Microsoft 365 adopts a new license management platform. Once the new platform is operational, license information for Azure AD accounts will be accessible only through Graph API requests or the cmdlets in the Microsoft Graph PowerShell SDK.

No automatic migration tool is available to translate code written using cmdlets from the older modules to cmdlets from the SDK. It is a manual process that requires substantial effort to create an inventory of scripts using the older modules, update their code, and test the effectiveness of the new code.

## Microsoft Teams PowerShell

The Teams PowerShell module contains cmdlets to manage elements such as teams, channels, and membership and the ability to create a new session to use the cmdlets for management of Teams policies such as *Get/Set-CsTeamsInteropPolicy*. To manage Teams with PowerShell, there are several sets of PowerShell cmdlets you should be familiar with:

- The [Teams PowerShell module](#) is available in generally available and preview versions. See [the documentation](#) for more information.
- If you need to manage the properties of the Microsoft 365 Groups used by Teams, use the \*-*UnifiedGroup* cmdlets included in the Exchange Online module.
- If you need to manage the properties of the Azure AD group, use the cmdlets in the Microsoft Graph PowerShell SDK.

To connect PowerShell to the Teams endpoint, run the following command.

```
[PS] C:\> Connect-MicrosoftTeams
```

Support for versions of the Teams PowerShell module before 4.0 ceases in mid-June 2022.

## PowerShell for Security and Compliance Features

The easiest way to connect to the compliance endpoint is to run the *Connect-IPPSSession* cmdlet from the Exchange Online management module. For example:

```
[PS] C:\> Connect-IPPSSession
```

The reason why a different PowerShell endpoint exists for compliance is that the functionality managed by the compliance cmdlets supports multiple workloads. Connecting to the compliance endpoint gives access to a range of cmdlets for different tasks such as managing DLP, preservation policies, and eDiscovery cases. For more information, see [Microsoft's documentation for the compliance cmdlets](#).

Many cmdlets with the same name (but slightly different functionality) exist in Exchange Online and the compliance set. For example, if you execute the *Get-RoleGroup* cmdlet against Exchange Online, you see the RBAC role groups defined for Exchange administration. If you connect to the compliance endpoint and run *Get-RoleGroup*, you see a completely different set of role groups. These are the role groups defined for RBAC access to security and compliance features.

## Power Automate and PowerShell

Power Automate support for PowerShell comes in two versions: [Administrator](#) and [Maker](#). The Power Apps PowerShell module also contains the Power Automate cmdlets. Using an administrator session, install the modules as follows:

```
[PS] C:\> Install-Module -Name Microsoft.PowerApps.Administration.PowerShell -Force -Scope AllUsers
Install-Module -Name Microsoft.PowerApps.PowerShell -AllowClobber -Force -Scope AllUsers
```

The current version of the Power Apps module has several dozen cmdlets to monitor Power Automate connector usage, verify what flows exist and run, and delete obsolete flows. Many of these tasks can be performed using the Power Automate portal, but you can automate some of the more tedious tasks with PowerShell. To enumerate the cmdlets, use the command:

```
[PS] C:\> Get-Command *Flow*
```

To test that the installation is successful, run the *Add-PowerAppsAccount* cmdlet to add an account to access Power Automate. This account must be a tenant admin to retrieve information about Power Automate for the tenant. PowerShell prompts for account credentials, which remain valid for up to 8 hours before you need to sign in again.

```
[PS] C:\> Add-PowerAppsAccount
```

If credentials are already available in a variable, you can use them. In this example, the *\$O365Credentials* object holds valid account credentials:

```
[PS] C:\> Add-PowerAppsAccount -Username user@domain.onmicrosoft.com -Password
$O365Credentials.Password
```

Once you're connected with administrative permissions, you can use the *Get-AdminFlow* cmdlet to get a list of all flows currently known in the tenant. Here's an example of how to extract and report the information returned for the flows. Remember to run the *Connect-MgGraph* cmdlet to connect to the Microsoft Graph PowerShell SDK first.

```
[PS] C:\> $Report = [System.Collections.Generic.List[Object]]::new()
$Flows = Get-AdminFlow
ForEach ($Flow in $Flows) {
    $ReportLine = [PSCustomObject] @{
        Created          = Get-Date($Flow.CreatedTime) -format g
        LastModified     = Get-Date($Flow.LastModifiedTime) -format g
        Flow             = $Flow.DisplayName
        CreatedBy        = (Get-MgUser -ObjectId $Flow.CreatedBy.UserId).UserPrincipalName }
}
```

```
$Report.Add($ReportLine) }
```

```
[PS] C:\> $Report | Format-Table Created, CreatedBy, Flow
```

Created	CreatedBy	Flow
10/05/2018 17:04	James.A.Abrahams@office365itpros.com	Create an event in Outlook in the new Planner
09/05/2020 23:30	John.West@office365itpros.com	Sync Microsoft 365 message center to P1...
20/08/2019 15:31	John.West@office365itpros.com	Start approval when a new item is added

The flow identifier is used to retrieve a list of flow runs. In this example, we fetch the identifier for a flow and run the *Get-FlowRun* cmdlet to fetch the run information. You can't fetch flow information for runs executed by another user, so you'll only see runs of the flow executed by your account.

```
[PS] C:\> $FlowId = Get-AdminFlow | ? { $_.DisplayName -Like "*Have I been pwned*" } | Select -
ExpandProperty FlowName
Get-FlowRun $FlowId
```

## Managing Connections to Microsoft 365 Endpoints

With so many different PowerShell management endpoints to connect to, you could easily accumulate a half dozen or more PowerShell functions in your profile to accommodate them all. Fortunately, you can save some time by using the [script written and maintained by MVP Michel de Rooij](#) to connect to the services, including:

- Azure AD.
- Azure Rights Management (Microsoft Information Protection).
- Exchange Online.
- Compliance endpoint.
- SharePoint Online.
- Teams.

The endpoints are liable to change as the service evolves, so you must be prepared to update the script to stay abreast of changes and to tailor its functionality to meet your needs. The script supports connecting to the endpoints with modules that support multi-factor authentication.

## Checking for Connections in Scripts

Before you can run cmdlets, you must connect to the endpoints used by the cmdlets. The number of connections needed depends on the modules that the cmdlets come from. Here's an example of how to check some of the modules used to interact with Microsoft 365 are available in the current session.

```
[PS] C:\> $Modules = Get-Module
If ("ExchangeOnlineManagement" -notin $Modules.Name) {Write-Host "Please connect to Exchange Online
Management before continuing...";break}
If ("MicrosoftTeams" -notin $Modules.Name) {Write-Host "Please connect to Microsoft Teams before
continuing...";break}
If ("Microsoft.Online.Sharepoint.PowerShell" -notin $Modules.Name) {Write-Host "Please connect to
SharePoint Online Management before continuing...";break}
```

**Linux, Mac OS, and Microsoft 365 management:** You can use PowerShell Core V6 (or later) to connect a session to Exchange Online and the compliance endpoint from a Linux or Mac OS X workstation. This is possible because these endpoints support remote sessions. The PowerShell modules for some parts of Microsoft 365, like SharePoint Online or Power Automate, need Windows .NET Core assemblies that do not exist on Linux or macOS, so you cannot connect PowerShell to these services. However, the Microsoft Graph PowerShell SDK modules, which rely only on PowerShell Core, will run just fine on [Mac OS X](#) and [Linux](#).

## Using Azure Cloud Shell with Microsoft 365 PowerShell Modules

Given that Microsoft controls the entire range of Azure compute and storage services, it seems logical that they have introduced products that consume these services to simplify various aspects of IT management. The [Azure Cloud Shell](#) (ACS) is such an example. When you run ACS from an administrative portal or <https://shell.azure.com, a connection occurs to PowerShell Core running on a Linux virtual machine on a Hyper-V host. Commands run on the virtual machine.>

You can connect to ACS from the Microsoft 365 admin center or Teams admin center, both of which include a shell icon in the command bar. ACS signs you in with the same account used to connect to the admin center, and that account must be able to use an Azure subscription to pay for a small amount of Azure storage for temporary files. Naturally, if you plan to do some administrative work, the account must also have the necessary permissions.

Microsoft has updated some PowerShell modules to allow them to run in ACS. You can:

- Connect to Exchange Online by running the *Connect-EXOPSSession* cmdlet. This uses Remote PowerShell to connect, so the newer cmdlets (like *Get-ExoMailbox*) are unavailable.
- Connect to Teams by running the *Connect-MicrosoftTeams -UseDeviceAuthentication* cmdlet. Using device authentication means that you go to <https://microsoft.com/devicelogin> and enter the code shown on the screen to prove your authentication status. Providing the right code allows ACS to connect to a Graph app called MS Teams PowerShell cmdlets and run both the Graph-based cmdlets (like *Get-Team*) and policy management cmdlets (like *Get-CsTeamsMessagingPolicy*).
- Use the *Invoke-RestMethod* or *Invoke-WebRequest* cmdlets to make API calls to the Microsoft Graph. Alternatively, use the Microsoft Graph PowerShell SDK cmdlets, including the *Invoke-MgGraphRequest* cmdlet.

You cannot connect to the SharePoint Online management endpoint via ACS. Other modules might have difficulties unless Microsoft has done the work required to allow them to work with ACS. Given the interconnected nature of Microsoft 365 applications, this can create some insurmountable difficulties with scripts unless developers write the scripts to run with ACS and do not attempt to load modules that cannot run under ACS. For instance, it is possible to write scripts to perform management operations for Teams using the cmdlets in the Teams module along with some Graph API calls (if necessary). However, you need to connect to Exchange Online differently (see above), don't make any calls to SharePoint Online cmdlets, and make sure that you don't use aliases for PowerShell commands like *Sort-Object* which might cause problems for PowerShell Core on Linux.

Although it can be convenient to be able to sign into ACS and run PowerShell cmdlets from administrative portals and browsers, in most situations, it is both more functional and easier to run PowerShell as normal. All modules will load, no special processing occurs, and scripts run as expected.

## Performance

PowerShell commands vary from one-liners to very complex scripts spanning many hundreds of lines. If you only use one-liners and an occasional script, you might not need to worry too much about performance. But once you start with more complicated processing involving multiple steps or thousands of objects, it's wise to consider how to make your PowerShell code run faster. The suggestions made here apply to many types of objects used across Microsoft 365 like mailboxes, groups, teams, distribution lists, or SharePoint sites.

## Object Filtering

PowerShell cmdlets can support server-side and client-side filtering:

- Server-side filtering occurs when you include the *-Filter* parameter in a command. The value passed to the parameter is the filter you want to apply. Server-side filtering is preferable because the remote

server (for example, Exchange Online or Azure AD) applies the filter before it returns a set of objects to the PowerShell session.

- Client-side filtering happens when you use the *Where-Object* (or simply *Where* or the *?* shorthand command) to process an available set of objects. Client-side filtering happens after a server returns a set of objects to extract the objects that you want to work with. Because you must wait for the full set of objects to come from the server before you can apply the filter, the overall time taken to process objects is invariably longer, and often by several factors.

For example, both commands shown below return the same set of objects (Groups with more than 10 guest members). We use PowerShell's *Measure-Command* cmdlet to tell us how long each command takes to execute, and the result is obvious. The server-side filter takes less than 0.3 seconds to return the subset of groups that have more than 10 guest users while fetching all the groups in the tenant and then applying the filter to that set takes about 14 times longer. Your mileage will vary depending on factors such as the current server load, the total number of groups in the tenant, and the complexity of the filter (and the property used). However, server-side filtering is invariably faster and should therefore be used whenever possible when processing objects fetched from servers – mailboxes, groups, sites, teams, and so on.

```
[PS] C:\> Measure-Command {Get-UnifiedGroup -Filter {GroupExternalMemberCount -gt 10}} | Select TotalSeconds
TotalSeconds
-----
0.2947363

[PS] C:\> Measure-Command {Get-UnifiedGroup | ? {$_.GroupExternalMemberCount -gt 10}} | Select TotalSeconds
TotalSeconds
-----
4.2973367
```

## Filtering and Performance with Exchange Online Cmdlets

The newer REST-based Exchange Online cmdlets (discussed later) are an exception to the rule mandating the use of server-side filters whenever possible. According to Microsoft, newer cmdlets like *Get-ExoMailbox* can [return data more slowly using a server-side filter](#) than with a client-side filter. Microsoft is working to address the issue and improve the performance and capabilities of server-side filters for these cmdlets. The root cause for the slowness might be the way that the cmdlets “warm up” during initialization. This is done to ensure speedy access when the cmdlets fetch large numbers of objects. Another downside is that the REST cmdlets do not support the same depth of filtering that their older counterparts do. For example, this query returns a filtered set of mailboxes that do not have mailbox auditing enabled but whose “persisted capabilities” mark them as having an enterprise license (BPOS\_S\_Enterprise) with the advanced auditing feature (M365Auditing):

```
[PS] C:\> Get-Mailbox -Filter "AuditEnabled -ne '$True' -and (PersistedCapabilities -eq 'BPOS_S_Enterprise') -and (PersistedCapabilities -ne 'M365Auditing')" -RecipientTypeDetails UserMailbox | Format-Table DisplayName
```

If you change the code to run *Get-ExoMailbox* instead, you get an invalid filter error. The problem here is likely to be an incompatibility between the way the older cmdlets perform server-side filtering using direct calls to the Exchange directory and the way that the REST cmdlets behave. In the interim, while Microsoft upgrades and improves the REST cmdlets, use these guidelines:

- Use the REST cmdlets whenever possible, especially when it's necessary to retrieve large numbers of mailboxes for processing.
- Try to apply server-side filtering with the REST cmdlets to refine the set of objects returned.
- If the REST cmdlets can't process the filter, use an older RPS cmdlet, or retrieve the data and apply a client-side filter.

In all cases, you should test filters when upgrading from the older cmdlets to the newer cmdlets to make sure that the filters work as expected.

## Using Server-Side Filters with Mail-Enabled Objects

Not every property of an object supports server-side filtering. Cmdlets in the Exchange Online module to process objects like mailboxes, distribution lists, mail contacts, and groups share many [common filterable properties](#). Here are some examples:

- Filter on the custom attributes (1 to 15 for single-value attributes, 1 to 5 for the extension attributes, which accept multiple values).

```
[PS] C:\> Get-ExoMailbox -Filter {CustomAttribute3 -ne $Null}
Get-UnifiedGroup -Filter {ExtensionCustomAttribute5 -eq $Null}
```

- Filter on the member counts for a Microsoft 365 group (total member count and guest member count). Distribution lists and security groups don't maintain counts as part of group properties. If you want this information, you must access the group and count its members.

```
[PS] C:\> Get-UnifiedGroup -Filter {GroupMemberCount -gt 20}
```

- Filter on the display name, name, or alias of mail-enabled recipients.

```
[PS] C:\> Get-DistributionGroup -Filter {DisplayName -like "*Manager*"}
Get-UnifiedGroup -Filter {Name -like "*Office*"}
Get-Recipient -Filter {Alias -like "Jeff"}
```

- Filter on whether groups are hidden from Exchange address lists. Groups like this are usually team-enabled.

```
[PS] C:\> Get-UnifiedGroup -Filter {HiddenFromAddressListsEnabled -eq $True}
```

- Filter on Email addresses. As noted above, *Get-ExoMailbox* supports a limited set of filterable properties. This is one example as *Get-ExoMailbox* doesn't support filtering by email addresses (all addresses or the primary address), so you should use *Get-Mailbox* instead. Note how the cmdlets use an extra filter to return just user mailboxes.

```
[PS] C:\> Get-Mailbox -Filter {EmailAddresses -like "*Office*"} -RecipientTypeDetails UserMailbox
Get-Recipient -Filter {PrimarySmtpAddress -like "Vasil*"} -RecipientTypeDetails UserMailbox
```

- Filter on the created date for a group, or the date when its properties were last updated.

```
[PS] C:\> Get-UnifiedGroup -Filter {WhenCreated -lt "01/01/2016 00:01"}
Get-DistributionGroup -Filter {WhenChanged -gt "01/01/2018 00:01"}
```

- Find the set of groups not enabled for Microsoft Teams.

```
[PS] C:\> Get-UnifiedGroup -Filter {ResourceProvisioningOptions -ne "Team"}
```

- If you want to use a calculated date from the *Get-Date* cmdlet, you need a slightly different format. In this example, we fetch all groups created in the last year.

```
[PS] C:\> [string]$CheckDate = (Get-Date).AddDays(-365)
Get-UnifiedGroup -Filter "WhenCreated -gt '$CheckDate'"
```

When filtering mailboxes and other mail-enabled objects, you can focus on a set of specific recipient types using the *RecipientTypeDetails* parameter. In this example, Exchange Online returns only user mailboxes and not shared mailboxes, room mailboxes, group mailboxes, and so on:

```
[PS] C:\> Get-Mailbox -Filter {EmailAddresses -like "*Office*"} -RecipientTypeDetails UserMailbox
```

While this example returns only distribution groups and ignores mail-enabled security groups and room lists.

```
[PS] C:\> Get-DistributionGroup -RecipientTypeDetails MailUniversalDistributionGroup
```

The *Get-Team* cmdlet returns a set of team objects. It supports some basic filtering on properties like user and privacy type (public or private). However, *Get-Team* does not support server-side filtering. We discuss this topic further in the section about using the Teams PowerShell module.

**Typed Variables Matter:** When you write PowerShell and use the Microsoft 365 modules to access data, consider using typed variables used to receive data fetched by cmdlets. Usually, PowerShell assigns the variable type automatically based on the data in use, but it's often better to be precise. For instance, declaring a variable to be an array is best when cmdlets return single items. One advantage of using an array is that you can be sure the count property works. For example, instead of using:

```
$Variable = Get-ExoMailbox
```

Use:

```
[Array]$Variable = Get-ExoMailbox
```

## Returning All Data

By default, many cmdlets retrieve a limited number of objects from the service. To make sure that you retrieve all the data you need, specify the number of objects to return as a value passed to the *ResultSize* parameter. Alternatively, you can use *Unlimited* to instruct the cmdlet to retrieve as many objects as exist. For example, this command retrieves all user mailboxes:

```
[PS] C:\> Get-ExoMailbox -RecipientTypeDetails UserMailbox -ResultSize Unlimited
```

The more objects returned, the longer it takes to process a command against those objects. Some of the examples explained here include the *ResultSize* parameter and some do not. This is not a general recommendation, and the correct usage depends on how many objects of a certain type exist in a tenant. In some cases, so many objects exist that it is best to retrieve them for processing in batches. The custom attributes available for mail-enabled recipients are useful here because you can assign one of the attributes to hold a batch number and then fetch objects for that batch using a filter. For example:

```
[PS] C:\> Get-UnifiedGroup -ResultSize 2000 -Filter {CustomAttribute15 -eq "Batch7"}
```

As we'll discuss later, the Microsoft Graph PowerShell SDK cmdlets use a different method to retrieve specific amounts of data. Because Microsoft generates these cmdlets from Graph APIs using a process called *AutoRest*, they use the *Top* parameter when it's important to fetch a precise number of records. Some cmdlets also support the *All* parameter to fetch all available data.

## Process Data Remotely

In a small tenant, it is usually unimportant if you run a cmdlet like *Get-UnifiedGroup* without any filters to return all available groups. However, as you scale up to deal with many thousands of groups (or teams), the time necessary to run the command increases. For Exchange Online objects like groups, we can speed things up by having PowerShell run commands on the remote Exchange server to which our session is connected. Things speed up because the remote server has local access to the data and is likely to have more resources available to process the data. By piping the output to the *Select-Object* cmdlet, the amount of data returned is reduced to just the requested properties. To ask the remote server to process a command, we call the *Invoke-Command* cmdlet.

For example, to retrieve the full set of groups and store them in a variable, we can run:

```
[PS] C:\> [array]$Groups = (Get-UnifiedGroup -ResultSize Unlimited | Select-Object DisplayName, Alias, GroupMemberCount, WhenCreated)
```

Another method to fetch data uses the *Invoke-Command* cmdlet. The advantage of this approach is that the server processes all data. This speeds things up by restricting the amount of data that must travel between server and client. In this example, the `$Session` variable points to the remote session connected to Exchange Online. The session identifier can be found with a command like:

```
[PS] C:\> $Session = Get-PSSession -InstanceId (Get-OrganizationConfig).RunspaceId.Guid
```

Now that we know the session, we can send the command to the server:

```
[PS] C:\> [array]$Groups = (Invoke-Command -Session $Session -ScriptBlock {Get-UnifiedGroup -ResultSize Unlimited | Select-Object DisplayName, Alias, GroupMemberCount, WhenCreated})
```

The `$Groups` variable ends up with the same data as in the first example. Running *Get-UnifiedGroup* directly is simpler but slower than running it via *Invoke-Command*. The difference is small (probably 10%) when dealing with 100 groups, but the performance gap widens as more objects are processed, so this technique is something to consider when you use PowerShell to process large numbers of groups.

## Where Method and Where-Object

It's common to form a collection of objects in an array with cmdlets like *Get-UnifiedGroup* or *Get-ExoMailbox* and then filter those objects to find a subset. You can do this by piping the objects through the *Where-Object* cmdlet or by using the *Where* method for the array. For example, we create an array of groups with:

```
[PS] C:\> $Groups = Get-UnifiedGroup -ResultSize Unlimited
```

To find the set of groups that mention "Office 365" in the display name, we can do:

```
[PS] C:\> $Groups | Where-Object {$_.DisplayName -Like "*Office 365*"}
```

Or:

```
[PS] C:\> $Groups.Where({$_ .DisplayName -Like "*Office 365*"})
```

Usually, the *Where* method is 10%-15% faster than using *Where-Object* (or the `?` shortcut). Note that the *Where-Object* cmdlet returns `$Null` if it finds no data with the filter while the *Where* method returns an empty array.

**Don't Limit Your PowerShell Output:** You might notice that sometimes PowerShell limits the output of values and uses an ellipsis (...) to show that some added information is available. The `$FormatEnumerationLimit` preference variable, which has a default value of 4, controls how many items PowerShell displays when a property has multiple items. If you want to be sure to see all available items, set `$FormatEnumerationLimit` to -1 (minus 1). Be aware that changing this value might affect the appearance of some of your reports.

## Select Properties

When you run a cmdlet like *Get-UnifiedGroup* or *Get-Team* to fetch information about a set of groups or teams, the cmdlet returns a set of properties for all matching objects. You might need all properties, but it is more likely that you only need a few. To [speed up processing](#) (because you don't need to loop through the set of objects to extract the needed properties), use the *Select-Object* (or just *Select*) cmdlet to pick the properties you need to process. For example, this command returns four properties for all the Groups in the tenant.

```
[PS] C:\> $Groups = (Get-UnifiedGroup | Select DisplayName, Alias, GroupMemberCount, WhenCreated)
```

Even better, define the set of properties that you want in a variable and use that with the command:

```
[PS] C:\> $Properties = 'DisplayName', 'ExternalDirectoryObjectId', 'Alias', 'PrimarySmtpAddress'
$Groups = (Get-UnifiedGroup | Select $Properties)
```

Note that *Get-UnifiedGroup* returns blank values for some properties unless you explicitly request values to be returned. To ensure that property values are up-to-date and complete, use the *IncludeAllProperties* parameter. This slows processing a little as Exchange Online must calculate some properties before they can be returned.

```
[PS] C:\> Get-UnifiedGroup -IncludeAllProperties
```

If you use the *Invoke-Command* cmdlet to send the command to the server for processing, *Select-Object* runs on the server. Otherwise, PowerShell filters the returned items using the *Select-Object* on the client.

The *Get-UnifiedGroupLinks* is another example of how selecting properties can help performance. This cmdlet returns the members or owners of a group, including a bunch of properties for each object. The set properties returned for local users are roughly equivalent to those returned by *Get-Mailbox* while those returned for guest accounts are the equivalent of *Get-MailUser*. Most people don't realize that calling *Get-UnifiedGroupLinks* results in the retrieval of quite so many properties as you only ever see the properties if you go looking, but it does mean that this is a "heavy" cmdlet in terms of processing overhead because of the work necessary to fetch the properties available through the cmdlet. If you only need a few properties for a group member, use *Select-Object* to fetch those properties after expanding the membership. This technique invariably performs better than using a *ForEach-Object* loop to process each item to extract properties.

**Running PowerShell against Large Numbers of Exchange Online Objects:** If you need to run scripts against large numbers of Exchange Online objects, consider using the [RobustCloudCommand](#) module. Developed by a Microsoft Exchange escalation engineer, the module supports running long-lasting scripts with automatic renewal of Azure AD access tokens.

## Avoid Throttling

Microsoft 365 is a multi-tenant environment and applies a throttle to stop users or processes from consuming more than their fair share of resources. When a throttling condition exists for PowerShell, the service signals a "micro delay" warning. Typically, this only happens when you try to process thousands of objects with resource-intensive cmdlets like *Get-MailboxFolderStatistics* (or *Get-ExoMailboxFolderStatistics*).

If you run into this condition, you can try to avoid throttling by introducing a short delay between each call to the resource-intensive cmdlet by calling the *Start-Sleep* cmdlet. In this example, we loop through a set of groups to find out how many conversation items exist in the mailbox belonging to each group. We report the number and the date the last conversation occurred and then sleep for 250 milliseconds.

```
[PS] C:\> ForEach ($G in $Groups) {
    $Conversations = Get-MailboxFolderStatistics -FolderScope Inbox -IncludeOldestAndNewestItems
                  -Identity $G.Alias | Select ItemsInFolder, NewestItemReceivedDate
    Write-Host $G.DisplayName "has" $Conversations.ItemsInFolder "conversations in the Inbox. The
last is dated" $Conversations.NewestItemReceivedDate
    Start-Sleep -Milliseconds 250 }
```

Like most tuning exercises, it might take a couple of attempts to calculate the right delay needed to avoid throttling.

## Speed Group Retrieval with Get-Recipient

Sometimes you only need to retrieve a list of groups for subsequent processing. In these scenarios, the *Get-Recipient* cmdlet (or the *Get-ExoRecipient* cmdlet from the Exchange Online Management module) is much faster at retrieving objects than *Get-UnifiedGroup* is. You can prove this theory by using the *Measure-Command* cmdlet to report how fast each cmdlet returns information.

```
[PS] C:\> Measure-Command {Get-Recipient -RecipientTypeDetails GroupMailbox}
Measure-Command {Get-UnifiedGroup}
```

*Get-Recipient* doesn't return any group properties, so you need to call *Get-UnifiedGroup* for each group to retrieve these properties and make them available for processing. Note that when we call *Get-Recipient*, we

select the *ExternalDirectoryObjectId* property. This is because a group's *ExternalDirectoryObjectId* (a GUID pointing to the group object in Azure AD) is unique whereas an alias or display name might not be, so when referencing an individual group in a loop, it's best to use *ExternalDirectoryObjectId* because you'll always be sure to access the group you want.

```
[PS] C:\> $Groups = (Get-Recipient -RecipientTypeDetails GroupMailbox | Select DisplayName, ExternalDirectoryObjectId)
ForEach ($G in $Groups) {
    $Site = (Get-UnifiedGroup -Identity $G.ExternalDirectoryObjectId).SharePointSiteURL
    Write-Host "The URL for the SharePoint site for the Group is" $Site }
```

You can use the identifier with the *Set-UnifiedGroup* cmdlet too:

```
[PS] C:\> ForEach ($G in $Groups) {
    Write-Host "Setting value for" $G.DisplayName
    Set-UnifiedGroup -Identity $G.ExternalDirectoryObjectId -CustomAttribute12 "Some value"}
```

*Get-Recipient* supports filtering, but you can only use properties common to all recipient types, like *DisplayName*, the custom attributes, or the alias. Note that because *Get-Recipient* returns all recipient types unless instructed otherwise, you must include a filter for group mailboxes.

```
[PS] C:\> Get-Recipient -Filter {DisplayName -Like "*Sanjay*" -and RecipientTypeDetails -eq "GroupMailbox"}
```

If you need to filter the set of groups using group-specific properties (like the number of guest members or the *HiddenFromExchangeClientsEnabled* flag), use *Get-UnifiedGroup* as described earlier. *Get-Recipient* does not support the group-specific properties.

An alternative approach uses the *Get-MgGroup* cmdlet from the Microsoft Graph PowerShell SDK. *Get-MgGroup* is even faster than *Get-Recipient*. However, it requires you to load an extra module and you must create a registered Azure AD app to run the SDK cmdlets in non-interactive jobs. In addition, *Get-MgGroup* retrieves basic group objects, and you'll still need to run *Get-UnifiedGroup* to retrieve properties that make the group a Microsoft 365 group. More details about running *Get-MgGroup* are in the section covering the Microsoft Graph PowerShell SDK.

## Use PowerShell Lists

Often scripts need to store some data. It's easy to use arrays for storage with statements like:

```
[PS] C:\> $MyMailboxes = @()
$MyMailboxes = "Vasil Michev", "Paul Robichaux"
$MyMailboxes += Get-ExoMailbox -Identity Tony.Redmond | Select -ExpandProperty DisplayName
$MyMailboxes
Vasil Michev
Paul Robichaux
Tony Redmond
```

This works, but it's better to use PowerShell list objects. The reason is that when you use the += operator to add a new item, PowerShell discards and rebuilds the array. This overhead is acceptable for small arrays, but not when dealing with large numbers of objects. PowerShell lists deliver better performance, and you can easily add multiple properties for each item. For example:

```
[PS] C:\> $MyMailboxes = [System.Collections.Generic.List[Object]]::new()
$Mailbox = Get-ExoMailbox -Identity Vasil.Michev -Properties WhenCreated
$MailboxData = [PSCustomObject][Ordered]@{
    UPN = $Mailbox.UserPrincipalName
    Name = $Mailbox.DisplayName
    Age = (New-TimeSpan($Mailbox.WhenCreated)).Days }
$MyMailboxes.Add($MailboxData)
```

## Dates

Properties holding dates for Microsoft 365 objects are often interesting pieces of data to report or query. For instance, you might want to find out the oldest distribution list in the tenant, which we can do for mail-enabled recipients using the *WhenCreated* property. For example:

```
[PS] C:\> Get-DistributionGroup | Sort WhenCreated | Select -First 1 | Format-Table DisplayName, WhenCreated
```

DisplayName	WhenCreated
Exchange MVPs (Only)	27/01/2014 20:37:00

The same technique works for mailboxes, mail contacts, mail users, Microsoft 365 groups, and so on. As we'll discuss when reviewing how to use the *Get-ExoMailbox* cmdlet, Exchange doesn't return date properties like *WhenMailboxCreated* unless you ask for them. In this example, we use that property to report the last user mailbox created.

```
[PS] C:\> Get-ExoMailbox -Properties WhenMailboxCreated -RecipientTypeDetails UserMailbox | Sort WhenMailboxCreated | Select -Last 1 | Format-Table DisplayName, WhenMailboxCreated
```

The examples above depend on the *WhenCreated* or *WhenMailboxCreated* properties being sortable as a date/time value. Sometimes, cmdlets return dates as strings, or a script stores a date as a string. In these cases, you need to tell PowerShell to regard the value as a date for sorting. For instance, let's assume that you want to create a list of guest accounts where the guest has not accepted their invitation. These accounts might be candidates for removal as it's obvious that the guest doesn't want to collaborate with our tenant. Our code grabs the set of guests that haven't accepted their invitation from Azure AD, calculates how many days it is since the account's creation, and stores the report data in a PowerShell list. The dates extracted from Azure AD are strings, so when we examine the data and want to sort the data to show the most recent guest accounts first, we must tell PowerShell to treat the property as a date.

```
[PS] C:\> $Report = [System.Collections.Generic.List[Object]]::new()
[array]$Guests = Get-MgUser -Filter ("UserType eq 'Guest'") -All | ? {$_.ExternalUserState -eq "PendingAcceptance"}
ForEach ($Guest in $Guests) {
    $AccountAge = ($Guest.CreatedDateTime | New-TimeSpan).Days
    If ($AccountAge -gt 365) {
        $ReportLine = [PSCustomObject]@{
            Guest      = $Guest.Mail
            Name       = $Guest.DisplayName
            Date       = $Guest.CreatedDateTime
            Age        = $AccountAge
        }
        $Report.Add($ReportLine) }
} # End ForEach
$Report | Sort {$_.Date -as [DateTime]} -Descending | Format-Table Guest, Date, Age
```

## Error Handling

In general, cmdlets return an error status that a script can interpret to handle different conditions. For example, if you try and access a group that doesn't exist and suppress the output of the error message to the screen, you can examine the error detail logged by PowerShell (in this case the reason is *ManagementObjectNotFoundException*, meaning that the system can't find the object) and then decide what to do next:

```
[PS] C:\> Get-UnifiedGroup -Identity NotThere -ErrorAction SilentlyContinue
$error[0].CategoryInfo.Reason
ManagementObjectNotFoundException
```

The cmdlets in the Teams PowerShell module are based on the Microsoft Graph API and sometimes behave differently compared to how cmdlets from other modules function. First, they don't support the ability to suppress error messages on the screen. Second, the reasons logged for the error conditions are sometimes indistinguishable across different conditions. For instance:

```
[PS] C:\> Get-Team -GroupId Rubbish -ErrorAction SilentlyContinue
get-team : BadRequest in /groups/ endpoint
At line:1 char:1
+ get-team -GroupId test -ErrorAction SilentlyContinue
+ ~~~~~
+ CategoryInfo          : NotSpecified: (:) [Get-Team], HttpRequestException
+ FullyQualifiedErrorId : System.Net.Http.HttpRequestException,Microsoft.TeamsCmdlets.PowerShell.Custom.GetTeam
[PS] C:\> $Error[0].CategoryInfo.Reason
HttpRequestException
```

[PowerShell's Try and Catch construct](#) can be used to handle error conditions more elegantly.

```
[PS] C:\> Try {Get-Team -GroupId 92e84aba-f3f7-4078-9f53-241575ce4d01}
Catch { Write-Host "No team found!"}
```

## Dual Writes for Exchange Online and Azure AD

When cmdlets in the Exchange Online management module update the properties of an object that also exists in Azure AD (like a Microsoft 365 group), they perform dual writes against the Exchange Online directory and Azure AD. This removes the need for synchronization between the two directories. In the case of Groups, it also means that Azure AD can go ahead and replicate updates to workloads like Teams or SharePoint Online.

The dual-write nature of these updates means that a write operation might not work because Azure AD is unavailable (usually momentarily). When this happens, the cmdlets receive a *UnableToWriteToAadException* error. This fact should be considered when building error handling into your scripts, especially when cmdlets update groups.

## Deciding Which PowerShell Cmdlets to Use

With so many PowerShell modules available, it can be confusing to understand the best cmdlet to choose to perform a task. Some choices are easy because modules like Exchange Online management, SharePoint Online, and Teams have clear purposes. Some choices are less clear. For instance, these cmdlets all return some information about a mailbox:

- *Get-MgUser* (from the Microsoft Graph PowerShell SDK).
- *Get-User* (from Exchange Online).
- *Get-Mailbox* or *Get-ExoMailbox* (from Exchange Online).
- *Get-CsOnlineUser* (from Microsoft Teams).

Depending on what task you're trying to perform, you might also need to use one or two of the cmdlets listed above to return some desired information. For example, the *Get-MgUser* cmdlet reveals the licenses held by an account but doesn't return the set of mail-related attributes available through the *Get-Mailbox* or *Get-ExoMailbox* cmdlets. There's currently no single cmdlet that will return every available property for a user account. Over time, you will develop an understanding of which cmdlets are best suited for different tasks. As a rule, use the cmdlets that are most related to the nature of the change or information you are working with. When working with PowerShell for Microsoft 365, remember:

- Use the cmdlets from the Microsoft Graph PowerShell SDK whenever possible for Azure AD account management, license assignment, and tenant configuration tasks of the type performed in the Microsoft 365 admin center. In this book, we use PowerShell SDK cmdlets whenever possible.

Organizations should upgrade scripts that include the Azure AD and MSOL cmdlets (like *Get-AzureADUser* and *Get-MsOUser*) and replace these cmdlets with Microsoft Graph API calls or cmdlets from the Microsoft Graph PowerShell SDK.

- If you work with on-premises accounts synchronized or federated to Azure AD, you'll need to manage most settings for those accounts using cmdlets from the on-premises Active Directory module.
- Use the workload-specific cmdlets (such as *Get-ExoMailbox* or *Get-User* for Exchange Online, or *Get-Team* and *Get-TeamChannel* for Teams) to perform the tasks that you would normally perform in those admin portals.

## Managing Exchange Online with PowerShell

PowerShell is critical to the smooth operation of Exchange Online. Administrators can transfer the skills that they accumulate working with the Exchange Management Shell used for on-premises server management to Exchange Online. However, do not expect that every piece of script that you've developed to help manage on-premises Exchange will move across because a reduced set of cmdlets is available in the cloud. The reason is logical – Microsoft takes care of a lot of the mundane work of operating servers and databases, so you do not need access to the cmdlets used for these purposes. The cmdlets that are available reflect the actions that you can take against different objects. Exchange Online uses the same RBAC mechanism as found in on-premises deployments to control the set of Exchange cmdlets and parameters available to a user. You can check the definitions of management roles to see what cmdlets are available for each role.

[The Exchange Online management module](#) supports Ubuntu 18.04 or later to allow Exchange Online management from Linux devices. The same version supports macOS devices.

### Exchange Online Management Module

Remote PowerShell (RPS) is the default mechanism for administrators to run cmdlets against a server. Although the mechanism works well on-premises, it is less successful in the cloud. To address the problem, Microsoft developed the [Exchange Online Management module](#), which is now the preferred method to run PowerShell against Exchange Online.

When they developed the module, Microsoft optimized several cmdlets for bulk retrieval operations. These cmdlets don't exist in on-premises Exchange PowerShell (see Table 23-1). Microsoft chose to create these cmdlets because their RPS equivalents are the most heavily used and error-prone within Exchange Online. You'll notice that the cmdlets all retrieve objects or settings, and none amend or create settings. This is because *Get-* cmdlets often deal with multiple objects and therefore run for much longer than the short interaction with the server needed by *Set-*, *New-*, or *Remove-* cmdlets.

<b>Remote PowerShell cmdlet</b>	<b>REST-based cmdlet</b>
Get-Mailbox	<i>Get-ExoMailbox</i>
Get-MailboxStatistics	<i>Get-ExoMailboxStatistics</i>
Get-MailboxFolderStatistics	<i>Get-ExoMailboxFolderStatistics</i>
Get-CasMailbox	<i>Get-ExoCasMailbox</i>
Get-Recipient	<i>Get-ExoRecipient</i>
Get-RecipientPermission	<i>Get-ExoRecipientPermission</i>
Get-MailboxPermission	<i>Get-ExoMailboxPermission</i>
Get-MailboxFolderPermission	<i>Get-ExoMailboxFolderPermission</i>
Get-MobileDeviceStatistics	<i>Get-ExoMobileDeviceStatistics</i>

Table 23-1: Remote PowerShell Cmdlets and REST equivalents

Microsoft says that they plan to add more REST-based cmdlets in future releases. For example, the cmdlets Microsoft created to control user access to Cortana briefing emails (*\*-UserBriefingConfig*) are REST-based. In addition, Microsoft is upgrading 800+ older RPS-based cmdlets to:

- Remove dependencies such as the Windows Remote Management (WinRM) service.
- Support modern authentication and remove the requirement to allow accounts to use basic authentication to connect to Exchange Online with PowerShell.
- Improve stability and error handling.

At the time of writing, Microsoft has upgraded approximately all its target cmdlets (in a preview module). To make it easy to run existing scripts, when you connect to Exchange Online, the module loads the older RPS cmdlets as well as the upgraded and new REST-based cmdlets. For version 2.0.6 and above, connecting to the module loads only the set of upgraded cmdlets. To load all cmdlets including those that Microsoft has not upgraded, you must connect using the *UseRPSsession* switch. This connection requires the user account to be enabled for basic authentication for PowerShell:

```
[PS] C:\> Connect-ExchangeOnline -UserPrincipalName Ken.Bowers@office365itpros.com -UseRPSsession
```

The upgraded cmdlets are more robust at handling network or server errors and include support for pagination and automatic retry. Because of multithreading, the REST cmdlets are faster than their RPS equivalents and can run at speeds of up to 8-10 times better. The exact speed increase is highly dependent on the number of objects processed. Small batches of mailboxes or other objects might see an improvement of 2-3 times while commands that process higher numbers (more than a thousand objects) should experience up to ten times better performance.

As you start working with the cmdlets optimized for bulk retrieval, you might notice that the first time you run a cmdlet against a set of objects, it's not quite as fast as you might expect. The impression is especially strong with small sets of objects. The initial slowdown is because the cmdlets support pagination, so when a cmdlet begins to process a set of objects, it sorts the objects to allow the cmdlet to resume processing from a retry point should the need occur. During this period, Exchange evaluates the cmdlet against RBAC to ensure that the user can perform the requested action. I call this the "warm-up" phase, and once it's finished, access to the objects is fast and robust. You don't notice this happening when dealing with large sets of objects because the time used to paginate is a much smaller percentage of the overall run.

**Specify the Right Domain:** If you use the *Organization* parameter with the *Connect-ExchangeOnline* cmdlet, make sure that you specify the service domain for the tenant (the onmicrosoft.com sub-domain) as otherwise, you might [experience some performance problems](#).

## Upgrading Scripts

Converting scripts to use the REST cmdlets is reasonably straightforward. Two big things to remember are that the REST cmdlets optimize how they communicate with Azure AD and minimize the properties retrieved for Exchange objects. Although you can use display names, alias, and even distinguished names to identify mailboxes, it's suggested that you use the mailbox's external directory object identifier (*ExternalDirectoryObjectId*) whenever possible. This is the Azure AD object identifier for the owning account, and it's guaranteed to be unique.

The REST-based cmdlets use the concept of property sets to group properties together into collections that calls can request. You'll always get the minimum property set (15 properties of 255) returned, but in many situations, you'll need to ask Exchange Online to return more information. For example, if you want to work with mailbox quotas, you'll specify that you want the Quota property set in a call like this:

```
[PS] C:\> $Mbx = Get-ExoMailbox -RecipientTypeDetails UserMailbox -ResultSize Unlimited -PropertySets Quota
```

If you need specific properties from a set, specify their name like this:

```
[PS] C:\> Get-ExoMailbox -AuditEnabled, WhenCreated, WhenChanged
```

If you want every available property, fetch the All property set.

```
[PS] C:\> Get-ExoMailbox -PropertySet All
```

## Script Conversion Checklist

Here is a checklist to consider when reviewing code to use the REST-based cmdlets:

1. Make sure that the script connects to the Exchange Online REST endpoint by running the *Connect-ExchangeOnline* cmdlet. This will load both the REST cmdlets and the older RPS cmdlets.
2. Change the cmdlet names from old RPS names to REST cmdlet names. For example, *Get-Mailbox* becomes *Get-ExoMailbox*.
3. Update the Identity parameter used in the scripts to find mailboxes using the object identifier or user principal name.
4. For best performance, only request the properties the script needs to process by specifying the correct property set.
5. Check that the REST cmdlets support all the parameters used in your script. Check that filters used to reduce the number of returned objects work with the REST cmdlets (see earlier discussion).
6. The REST cmdlets return data ordered alphabetically while the older cmdlets order objects by creation date. This might affect how scripts work.
7. Use piping whenever possible to take advantage of the multi-threading built into the REST cmdlets. Unfortunately, in most instances, if you want to manipulate or generate data about objects in the pipeline a *ForEach* loop is necessary.
8. Check your error handling. The complex error handling sometimes created in scripts to deal with RPS issues might not be necessary or need to be adapted for the REST cmdlets.
9. Check your performance after the upgrade. Hopefully, you'll be pleased. You should see at least a 2x-4x performance increase over equivalent RPS cmdlets.
10. Test, test, and test again to ensure the functionality of the script is as expected.

## Certificate-Based Authentication

The Exchange Online Management module supports certificate-based authentication using an app registered in Azure AD to allow unattended execution of the type needed to run scripts as background processes. This is a technique often used for long-running scripts to create reports, perform maintenance, and so on. The basic principles are:

- The app registered in Azure AD is assigned the *Exchange.ManageAsApp* permission and an Azure AD administrative role such as Exchange Service Administrator. This gives the app permission to access Exchange Online objects.
- A self-signed X.509 certificate is uploaded to the Azure AD app. This generates a thumbprint (unique value) usable for authentication. For testing, the easiest way to generate the certificate is by running the *New-SelfSignedCertificate* PowerShell cmdlet.
- When the background process connects to Exchange Online, it passes the object identifier for the Azure AD app, the thumbprint for the certificate, and the tenant's service domain. Together, these elements are enough for Exchange Online to allow authenticated access corresponding to the role assigned to the app. For instance, if the app is assigned the Exchange Service Administrator role, it can interact with Exchange like an administrator signed into Exchange interactively.

See the [Microsoft documentation](#) for more information about how to use the Exchange Online management module cmdlets in unattended scripts.

## Limited Sessions

An account can have up to three active sessions to a remote PowerShell endpoint for Exchange Online. The `Get-PSSession` cmdlet lists the current sessions in use at any time. For example:

```
[PS] C:\> Get-PSSession
```

Id	Name	ComputerName	ComputerType	State	ConfigurationName	Availability
1	ExchangeOnli	outlook.offi...	RemoteMachine	Opened	Microsoft.Exchange	Available

Once three sessions are present, if you need to create a new session, you must either remove a session with the `Remove-PSSession` cmdlet or wait 15 minutes for one of the sessions to time out. For example:

```
[PS] C:\> Remove-PSSession -Id 1
```

After you remove a session, the cmdlets loaded into the session are unavailable. Automatic management of connections to Exchange is a big advantage gained when you connect using the Exchange Online Management module rather than a Remote PowerShell connection.

## Exchange Online Organization Configuration

One reason why administrators use PowerShell to manage Exchange Online is to update settings in the organization configuration. These settings include those to control distribution list naming, public folders, enable or disable connectors for Groups and Teams, use of MailTips, and controls for Exchange web services. Although some of the settings are updatable using a management GUI, most are not because they are controlled by an application. In these instances, the settings are present because the configuration is a convenient place to store and read settings. The documentation for the [Set-OrganizationConfig](#) cmdlet mentions some settings that are only available for on-premises organizations; on the other hand, some settings found in the configuration (like `DirectReportsGroupAutoCreationEnabled`) are artifacts of defunct software that no longer exists.

The `Set-OrganizationConfig` cmdlet sets values while the `Get-OrganizationConfig` cmdlet retrieves values. For example, to enable the Bookings app for the tenant, you run the command:

```
[PS] C:\> Set-OrganizationConfig -BookingsEnabled $True
```

**Throttling PowerShell:** Microsoft throttles the use of PowerShell to ensure that commands do not absorb excessive resources. Throttles are a form of “micro delays” that cause processing to pause for a short period. Although throttles exist for a good reason, they can be problematic when the need arises to process large object sets, such as if you wanted to run the `Get-ExoMailboxStatistics` cmdlet for every mailbox. Two techniques help to avoid throttling. First, use the [Invoke-Command method](#) when you need to process large numbers of objects with PowerShell. Instead of running commands locally, `Invoke-Command` passes the commands to Exchange Online servers for the servers to process. Second, use filters to limit the number of objects requested from the server and the number of properties for each object. Server-side filtering (the cmdlet provides a filter to allow the server to return only the required objects) is much more efficient than client-side filtering (the items are all returned and then filtered with the `Where-Object` cmdlet) and should be used whenever possible. See [this Microsoft article](#) for details of Exchange cmdlets and how to use filters when requesting objects.

Note: The new REST-based cmdlets have very different performance, which means that these cmdlets do not suffer as much from throttling as the older Remote PowerShell cmdlets do. The examples in this book use the REST cmdlets whenever possible.

## Organization Configuration Hydration

Microsoft applies a standard configuration to Exchange Online for new tenants and most tenants use a standard configuration. Microsoft refers to the settings in the standard configuration as *dehydrated*, meaning that although the organization is free to customize standard settings such as role definitions or OWA mailbox policies before this can happen, the settings must be prepared for customization by copying them from the standard configuration. This process is called *rehydration* and tenants with non-standard configurations are *hydrated*.

Rehydration is a one-time operation. It can happen explicitly when an administrator runs the *Enable-OrganizationCustomization* cmdlet, or implicitly when EAC or another administrative interface runs the cmdlet when an administrator updates a setting for the first time. When the cmdlet runs successfully to prepare the organization for customization, it updates the *isHydrated* property in the organization configuration. You can check the property to know if an organization uses a customized configuration:

```
[PS] C:\> Get-OrganizationConfig | Select isDehydrated
```

```
IsDehydrated
```

```
-----  
False
```

## Reporting Mailbox Quota Usage

One of the first PowerShell scripts created after the launch of Exchange 2007 was to report the quotas assigned to mailboxes and the amount of quota consumed by each mailbox. Over time, many variations on this report have appeared. Most of the scripts available on the internet are relatively simple and depend on the *Get-ExoMailbox* and *Get-ExoMailboxStatistics* cmdlets. This book wouldn't be complete if we didn't include an example.

Two things are notable in the code below. First, if you want to do computations with the mailbox quota and usage information returned by the cmdlets, you should convert the data into numbers, which is what the script does. Second, the script checks for mailboxes that are above a threshold of quota used (in this case 85%) to highlight mailboxes that might need to have their quota increased (or remove some items to free quota). The output is a CSV file sorted by the mailbox display name.

```
[PS] C:\> # Set threshold % of quota to use as warning level
$Threshold = 85
Write-Host "Finding mailboxes..."
$Mbx = Get-ExoMailbox -RecipientTypeDetails UserMailbox -PropertySet Quota -Properties DisplayName -
ResultSize Unlimited
$Report = [System.Collections.Generic.List[Object]]::new() # Create output file for report
ForEach ($M in $Mbx) {
    # Find current usage
    Write-Host "Processing" $M.DisplayName
    $ErrorText = $Null
    $MbxStats = Get-ExoMailboxStatistics -Identity $M.UserPrincipalName | Select ItemCount,
TotalItemSize
    # Return byte count of quota used
    [INT64]$QuotaUsed = [convert]::ToInt64((((($MbxStats.TotalItemSize.ToString()).split("(")[-
1]).split(")")[0]).split(" ")[0]-replace '[,]', ''))
    # Byte count for mailbox quota
    [INT64]$MbxQuota = [convert]::ToInt64((((($M.ProhibitSendReceiveQuota.ToString()).split("(")[-
1]).split(")")[0]).split(" ")[0]-replace '[,]', ''))
    $MbxQuotaGB = [math]::Round(($MbxQuota/1GB),2)
    $QuotaPercentUsed = [math]::Round(($QuotaUsed/$MbxQuota),4).ToString("P")
    $QuotaUsedGB = [math]::Round(($QuotaUsed/1GB),2)
    If ($QuotaPercentUsed -gt $Threshold) {
        Write-Host $M.DisplayName "current mailbox use is above threshold at" $QuotaPercentUsed -
ForegroundColor Red
        $ErrorText = "Mailbox quota over threshold" }
    # Generate report line for the mailbox
```

```

$ReportLine = [PSCustomObject]@{
    Mailbox           = $M.DisplayName
    MbxQuota          = $MbxQuotaGB
    Items             = $MbxStats.ItemCount
    MbxSizeGB         = $QuotaUsedGB
    QuotaPercentUsed = $QuotaPercentUsed
    ErrorText         = $ErrorText}
$Report.Add($ReportLine) }
# Export to CSV
$Report | Sort Mailbox | Export-csv -NoTypeInformation MailboxQuotaReport.csv

```

## Figuring Out the Last Login Time for a Mailbox

The last login time is a property reported for a mailbox by the *Get-MailboxStatistics* and *Get-ExoMailboxStatistics* cmdlets. Many assume that this is a timestamp noting the last time that the mailbox owner logged onto their mailbox. Indeed, this is exactly what the property was when *Get-MailboxStatistics* first appeared in Exchange 2007, which is why so many PowerShell scripts use the *LastLogonTime* property to calculate the last login time for a mailbox. For instance, the code below is an example of what is often run for on-premises servers to find user mailboxes and output the *LastLogonTime* and *LastLoggedOnUserAccount* properties.

```

[PS] C:\> Get-Mailbox -RecipientTypeDetails UserMailbox -ResultSize Unlimited | Get-MailboxStatistics | Format-Table DisplayName, LastLogonTime, LastLoggedonUserAccount -AutoSize

```

DisplayName	LastLogonTime	LastLoggedOnUserAccount
Deirdre Smith	22/06/2020 08:48:35	
Tony Redmond	21/06/2020 15:16:03	
TempAdmin	21/06/2020 15:16:03	
Jeff Guillet	19/06/2020 07:14:52	

When *Get-MailboxStatistics* first appeared, it was reasonable to expect that only users connected to mailboxes, so the timestamp was accurate. Over time, the number of mailbox assistants running inside Exchange on-premises and Online servers expanded to perform different background processing and mailbox maintenance. Because multiple processes, like the Managed Folder Assistant, connect to a mailbox daily, using *Get-MailboxStatistics* or *Get-ExoMailboxStatistics* to determine the last login time became less and less accurate.

### Using Mailbox Diagnostics

Exchange Online captures diagnostic information for mailboxes on an ongoing basis. Other values are computed by background assistants using signals logged in the Microsoft Graph. The data is accessible using the *Export-MailboxDiagnosticLogs* cmdlet. Not every action causes Exchange to update a counter. For example, deleting an item in a mailbox folder doesn't update the *LastEmailTimeCurrentValue* count, but creating and sending a message does. Background assistants and other tasks continue to update *LastLogonTime*, which means that the value doesn't represent the last time the user logged onto the mailbox. For example:

```

[PS] C:\> $Log = Export-MailboxDiagnosticLogs -Identity TRedmond -ExtendedProperties
$xml = [xml]($Log.MailboxLog)
$xml.Properties.MailboxTable.Property | ? {$_.Name -like "Last*time*"}

```

Name	Value
LastRecordIdentifiedTime	18/06/2022 05:04:26
LastLogonTime	20/06/2022 10:55:37
LastSharingPolicyAppliedTime	12/04/2020 05:30:55
LastScheduledTimerChangeToken	0xCF2E68845952DA0800000000
LastUserActionTime	18/06/2022 17:38:53
LastUserActionUpdateTime	19/06/2022 05:22:04
LastContactsTimeCurrentValue	16/06/2022 13:50:34
LastEmailTimeCurrentValue	19/06/2022 19:51:36
LastFileTimeCurrentValue	19/06/2022 17:06:00
LastCalendarTimeCurrentValue	16/06/2022 10:44:47

```
LastTasksTimeCurrentValue      18/06/2022 10:32:46
LastProfileTimeCurrentValue    16/02/2019 19:20:25
LastUserActionWorkloadAggregateTime 19/06/2022 19:51:36
```

The existence of these properties means that we can extract and use the information to gain an insight into how people use Exchange Online. A script [described in this article](#) describes how to scan user mailboxes to extract mailbox statistics from the `Get-ExoMailboxStatistics` and `Export-MailboxDiagnosticLogs` cmdlets and Azure AD sign-in information using the `Get-MgAuditLogSignIn` cmdlet to create a report highlighting potentially underused mailboxes. Including Azure AD sign-in information is important. The influence of Teams on communications means that fewer internal messages arrive in user mailboxes, and people might work predominantly in Teams and not check their mailboxes for a few days. Therefore, someone might be very active across Microsoft 365 while their mailbox shows signs of inactivity.

The `LastLogonTime` property outputs the same value as its counterpart in mailbox diagnostics but displays the time in local time rather than UTC. For example:

```
[PS] C:\> Get-ExoMailboxStatistics -Identity TRedmond -Properties LastLogonTime, LastLogOffTime |
Format-List DisplayName, LastLogonTime, LastLogOffTime

DisplayName      : Tony Redmond
LastLogonTime    : 11/04/2022 13:03:10
LastLogoffTime   : 11/04/2022 13:03:59
```

## Using Audit Records to Track Logins

Events captured in the Office 365 audit log (see the auditing chapter) are useful when tracking user mailbox logins. For instance, the code shown below searches the audit log for the last 90 days (you can search back 365 days with Office 365 E5) to retrieve two types of records:

- `UserLoggedIn` comes from Azure AD and tells us when the user account last signed into a service. If someone only uses a single app (like Exchange) with a desktop client, the client only needs to execute a log-in after their token expires. Logins from browser clients (and Teams) are more accurate because they refresh their access tokens every hour. You can also fetch Azure AD sign-in data for accounts [using the Graph API](#) or with the `Get-MgAuditLogSignIn` cmdlet (only for the last 30 days).
- `MailboxLogin` comes from Exchange Online mailbox auditing and tells us the last time the user signed into the mailbox. Two problems make these records less dependable than user logins. First, mailbox auditing must be configured for mailboxes (Exchange Online sets mailbox auditing on by default) and the `MailboxLogin` event must be included in the Owner configuration. Second, the process to ingest Exchange Online audit data into the audit log is much slower than Azure AD events, which means that you might not see the events for some time after they occur.

Combining user login and mailbox login events in the search gives us more confidence that we can find when users last logged in, especially if mailbox auditing captures mailbox login events. While the code is slow to process large numbers of mailboxes and not guaranteed to generate 100% accurate results, the results give us better data to work with.

```
[PS] C:\> [array]$Mbx = (Get-ExoMailbox -RecipientTypeDetails UserMailbox -ResultSize Unlimited -
Properties DisplayName | Select PrimarySmtpAddress, DisplayName, UserPrincipalName)
$StartCheckDate = (Get-Date).AddDays(-90)
ForEach ($M in $Mbx) {
    [array]$AuditRecs = (Search-UnifiedAuditLog -StartDate $StartCheckDate -EndDate (Get-Date) -
UserIds $M.UserPrincipalName -Operations UserLoggedIn, MailboxLogin -ResultSize 1)
    If ($AuditRecs) {
        Write-Host "Last Login date for" $M.DisplayName "is" $AuditRecs[0].CreationDate }
    Else {
        Write-Host "No logins found for" $M.DisplayName "since" $StartCheckDate }
}
```

Records sent by Exchange Online to the audit log originate through user or system activity. They do not record access to non-user mailboxes, such as shared mailboxes or group mailboxes. To retrieve the last activity in a shared mailbox, you could use the *Get-ExoMailboxFolderStatistics* cmdlet to return the last modified date for an item found in the Inbox. Here's an example of how to scan shared mailboxes:

```
[PS] C:\> Get-ExoMailbox -RecipientTypeDetails SharedMailbox -ResultSize Unlimited | Get-ExoMailboxFolderStatistics -IncludeOldestAndNewestItems -FolderScope Inbox | Format-Table Identity, LastModifiedTime -AutoSize
```

Identity	LastModifiedTime
Customer Services\Inbox	25 May 2019 07:45:47
DLPIncidents\Inbox	14 Jan 2019 02:37:28
Redirect for Removed Mailboxes\Inbox	26 May 2019 00:44:09
Redmond Shared Events\Inbox	3 Jul 2019 07:20:19
Company Information\Inbox	22 May 2019 23:37:38
Book Comments\Inbox	10 Aug 2019 16:05:54

The same technique works for group mailboxes if you pipe the output from the *Get-UnifiedGroup* cmdlet to *Get-ExoMailboxFolderStatistics*.

## Managing Microsoft 365 Groups with PowerShell

A broad range of policy-driven features are available to control aspects of Microsoft 365 Groups like naming, creation, and expiry, but you might not like how those features work or want to pay for the extra licenses that they need. You might decide that you prefer to do things differently and that the best way to reach your goal is to write some PowerShell.

Because Microsoft 365 Groups are mail-enabled and enhanced versions of Azure AD groups, standard group management with cmdlets from the Microsoft Graph PowerShell SDK (covered later) can be used to manage many aspects of Groups, including basic properties like display names and group membership. However, if you want to manage email-related properties, such as proxy addresses, you must do this using the Groups cmdlets contained in the Exchange Online management module. Some of the basic cmdlets to work with Groups are:

- *New-UnifiedGroup*: Create a new group.
- *Get-UnifiedGroup*: Return the properties of one or more groups. As noted earlier, sometimes it is faster to use *Get-Recipient* to fetch information about groups.
- *Set-UnifiedGroup*: Manipulate the properties of a group.
- *Remove-UnifiedGroup*: Remove a group and remove all the content contained in the group mailbox, calendar, document library, and notebook. You can run the *Undo-SoftDeletedUnifiedGroup* cmdlet to restore a soft-deleted group within 30 days of its deletion.
- *Add-UnifiedGroupLinks*: Add a user object to the membership of a group. You can add users as a group owner, a member, or a subscriber.
- *Get-UnifiedGroupLinks*: Return information about the membership of a group.
- *Remove-UnifiedGroupLinks*: Remove a member, owner, or subscriber from a group.

Updates applied with the Groups cmdlets use a dual-write process to make sure that changes flow through to the underlying Azure AD group objects. If the target object cannot be updated in both EXODS and Azure AD, the write fails. After successful updates, a synchronization process pushes the changes to applications such as Teams and SharePoint Online.

## Creating New Microsoft 365 Groups

The *New-UnifiedGroup* cmdlet creates a new group. This operation can sometimes take a little time to complete because it creates a new group object in Azure AD followed by synchronization of the new object to EXODS to force the creation of the group mailbox. Only users with Exchange Online mailboxes can run the *New-UnifiedGroup* cmdlet.

In this example, we create a new private group called "Corporate Banking Team." If we want the group to be public, we'd set the *AccessType* parameter to "Public." Remember, you can change a group's access type afterward if needed. Note that the *DisplayName* is a required parameter. In this example, we also set:

- The owner (if you do not specify an owner, the user who runs the cmdlet becomes the group owner).
- The classification of the group to mark it as private. If you use sensitivity labels, specify the identifier (GUID) of the label to apply in the *SensitivityLabel* parameter and do not include the *Classification* parameter.
- *AutoSubscribeNewMembers* so that members are also added to the group's subscriber list to receive updates via email.
- Set the *RequireSenderAuthenticationEnabled* flag to *False* to allow people outside the tenant to communicate with the group.
- Create the membership list. You can add as many members as you like by specifying their alias or primary email address (or their distinguished name, if you like).
- Set the alias of the new group.

```
[PS] C:\> New-UnifiedGroup -DisplayName 'Corporate Banking Team' -AccessType Private -Alias BankingTeam -RequireSenderAuthenticationEnabled $False -Classification "External Access" -Owner TRedmond -Members "Kim Akers", "Ben Owens" -AutoSubscribeNewMembers
```

If you want to add multiple owners, you can do this after creating the group by running the *Add-UnifiedGroupLinks* cmdlet to add the extra owners. Before you can add someone as an owner, you must add them as a group member.

### Groups and the Alias Property

*New-UnifiedGroup* fails if you try to create a new group with an alias already assigned to another group. Although Exchange Online allows mail-enabled objects to have duplicate aliases (or *MailNickname*), it checks the alias value when *New-UnifiedGroup* runs to ensure that the alias is unique and fails if a match exists with another group. However, *New-UnifiedGroup* allows you to create a group with an alias already used for another mail-enabled object, such as a mail contact. The *Set-UnifiedGroup* cmdlet flags an error if you try to update a group with a duplicate alias. Having objects with duplicate aliases is a bad idea. You should always ensure that the alias is unique, which is one of the reasons why Exchange Online changed to create the *Name* and *DistinguishedName* properties of new mailboxes based on the Azure AD object identifier of the owning account.

Because each object has a unique SMTP address, the presence of objects with duplicate aliases does not interfere with mail flow. But because directory synchronization can use the alias as a unique identifier for objects, having objects with duplicate aliases can cause problems, including when you synchronize groups in hybrid configurations. Overall, it is best practice to check whether another mail-enabled object already has the alias that you want to use by running the *Get-Recipient* cmdlet. For example, this command checks whether another mail-enabled recipient has the alias "BankingTeam."

```
[PS] C:\> Get-Recipient -Filter {Alias -eq "BankingTeam"}
```

Because multiple mail-enabled objects can exist with the same alias, it's a bad idea to use the alias as an identity to find groups in scripts. Instead, use a property that is guaranteed to be unique, like the primary SMTP address or the external directory object identifier. For example:

```
[PS] C:\> Get-UnifiedGroup -Identity "BankingGroup@office365itpros.com"
```

## After Creating a Group

After the creation of a group, we can examine its properties with the *Get-UnifiedGroup* cmdlet. Some of the properties that you will see are shown below. Note that if you want to see all available properties for a group, specify the *-IncludeAllProperties* switch to force Groups to return properties such as the *InboxURL* (a URL pointing to the Inbox folder in the group mailbox).

```
[PS] C:> Get-UnifiedGroup -Identity BankingTeam | Format-List

AccessType                : Private
AutoSubscribeNewMembers  : True
ConnectorsEnabled        : True
Alias                     : BankingTeam
ManagedBy                : {Kim Akers, Ben Owens}
EmailAddresses            : {SMTP:BankingTeam@Office365ITPros.onmicrosoft.com}
PrimarySmtAddress        : BankingTeam@Office365ITPros.onmicrosoft.com
Name                     : Corporate Banking Team_89b6fbd74a
DisplayName               : Corporate Banking Team
RequireSenderAuthenticationEnabled: True
MaxSendSize               : 35 MB (36,700,160 bytes)
MaxReceiveSize           : 36 MB (37,748,736 bytes)
RecipientType             : MailUniversalDistributionGroup
Language                  : en-US
SharePointSiteUrl        : https://office365itpros.sharepoint.com/sites/BankingTeam
SharePointDocumentsUrl   : https://office365itpros.sharepoint.com/sites/BankingTeam/Shared
Documents
SharePointNotebookUrl    :
(etc.)
```

Many of the properties supported by Groups are familiar because they are also found in Exchange distribution lists. Groups determines the values of some of these properties automatically and you do not have any control over their values. Several properties are worthy of comment:

- The account that runs the *New-UnifiedGroup* cmdlet becomes a group owner (the *ManagedBy* property) and a group member (the *Members* property). If you do not want this to be the case, you should remove the account from these properties afterward. However, you must ensure that at least one group owner always exists, and that account must also be a group member.
- The recipient type is *MailUniversalDistributionGroup*, which is the same as an Exchange distribution list. However, the *RecipientTypeDetails* property for a group is *GroupMailbox*.
- The URLs for the SharePoint Online resources are not available at once for a new group. These values become available after SharePoint Online provisions the resources.
- Depending on what email address policies are in force, Exchange Online creates one or more email addresses for a new group. The first, or primary address (shown by the SMTP prefix in capitals), uses the alias of the group together with the default SMTP domain for the tenant (as in *BankingTeam@Office365ITPros.com*). The second uses the tenant's service "onmicrosoft.com" domain. If you do not have a vanity domain or do not use this domain as the default, the "onmicrosoft.com" domain becomes the primary address. If you need to change things later, it is easy to add other email addresses or completely rewrite the set of email addresses as needed by running the *Set-UnifiedGroup* cmdlet.
- The language set for the group comes from the tenant. In this case, it is "en-US," meaning U.S. English. If you want users to receive group notification messages in other languages, you can change this value with the *Set-UnifiedGroup* cmdlet.

- The values of the *MaxSendSize* and *MaxReceiveSize* properties control the largest message size that the group mailbox can send and receive. You cannot change these values.
- The *AutoSubscribeNewMembers* property controls whether new members added to the group will receive email notifications for new conversations. In other words, they join the subscriber list. The default is *\$False*. You can set this to *\$True* with the *Set-UnifiedGroup* cmdlet.
- The *RequireSenderAuthenticationEnabled* property works in the same way as a regular distribution list. When set to *\$True*, the group will only accept messages from accounts known to the tenant. Set the property to *\$False* when creating the group or with the *Set-UnifiedGroup* cmdlet afterward if you want to allow external users to be able to send messages to the group.

## Finding Groups

Several ways are available to find a list of groups with PowerShell. You can use:

**Get-UnifiedGroup:** Because this cmdlet returns all available information about groups, this is the preferred cmdlet when dealing with Groups.

**Get-Mailbox:** Group mailboxes are mailboxes, so it follows that you can use the *Get-Mailbox* cmdlet to find groups.

```
[PS] C:\> Get-Mailbox -GroupMailbox
```

The *Get-ExoMailbox* cmdlet does not currently support the *-GroupMailbox* switch.

**Get-Recipient:** Because a group mailbox is a mail-enabled object, it is a recipient. You can find group mailboxes with:

```
[PS] C:\> Get-Recipient -RecipientTypeDetails GroupMailbox
```

*Get-Recipient* is faster than either the *Get-UnifiedGroup* or *Get-Mailbox* cmdlets because it retrieves less information for each object. In many situations, the best approach for performance is to use *Get-Recipient* to fetch a set of groups for processing followed by calling other cmdlets to do whatever's necessary thereafter. As noted in the section about performance, you might need to make calls to *Get-UnifiedGroup* to return specific properties for a group. If preferred, you can use the *Get-ExoRecipient* cmdlet in the same manner.

Always use server-side filters when available to ensure the fastest performance when retrieving groups.

## Creating a List of Groups

This command creates a CSV file listing the alias, display name, group owner, access type (private or public), the counts for group members and external members, and the creation date, and then calls Excel to open the file. You can then sort and order the information as you need.

```
[PS] C:\> Get-UnifiedGroup -ResultSize Unlimited | Sort DisplayName | Select Alias, DisplayName, ManagedBy, AccessType, GroupMemberCount, GroupExternalMemberCount, WhenCreated | Export-CSV -Path C:\temp\TenantGroups.CSV -NoTypeInfo -Encoding Ascii
[PS] C:\> Invoke-Item C:\temp\TenantGroups.CSV
```

In this example, we limit the set of groups to report on to those created within the last 90 days.

```
[PS] C:\> Get-UnifiedGroup |? {$_.WhenCreated -gt (Get-Date).AddDays(-90)} | Format-Table DisplayName, WhenCreated
```

A variant of the above which uses server-side filtering for better performance is:

```
[PS] C:\> Get-UnifiedGroup -Filter ([scriptblock]::create("WhenCreated -gt '$((Get-Date).AddDays(-90))'"))
```

Many variants exist for reporting groups. For example, you might want to look for groups or teams that are inactive. As explained later, we can do this by looking for signs of activity in the conversations stored in group inboxes, team compliance records, or SharePoint documents.

## Setting Group Properties

The *Set-UnifiedGroup* cmdlet manipulates group properties. In this example, we use it to update some of the properties of our newly created group. The example changes the default language for group notifications, changes the email address list, tells Groups that we want new members to automatically join the subscriber list, sets up a MailTip, and updates the display name for the group. Just like any other mail-enabled object, the MailTip will be displayed by Outlook and OWA when a user addresses a message to the group.

```
PS: C:\> Set-UnifiedGroup -Identity BankingTeam -Language 'fr-FR' -PrimaryEmailAddress
'BankingTeam@Office365ITPros.com' -AutoSubscribeNewMembers $True -MailTip 'Corporate Banking is
great fun' -DisplayName 'Fun with corporate banking'
```

The language selected for a group does not affect user contributions. Instead, the choice of group language only affects the information contained at the bottom of notification messages.

## Calendar Access

In some cases, you might not want to allow all the group members to be able to edit items posted to the group calendar. The most common situation is in education when a class shares a group but only the teacher should be able to add or update calendar items. You can set the *CalendarMemberReadOnly* property for a group to restrict add and update access to group owners. For example:

```
[PS] C:\> Set-UnifiedGroup -Identity Classroom1 -CalendarMemberReadOnly $True
```

Currently, the feature only restricts access to group calendar items through OWA.

## Setting Email Addresses

Like any other mail-enabled recipient, a group has at least a primary SMTP address used by Exchange to route email to the group. In addition, a group can have several secondary proxy addresses that Exchange can also use in routing. The difference between a primary and secondary address is that the primary address is stamped on outgoing messages from the group and is therefore the reply address for the group. However, Exchange can route messages using any of the addresses assigned to a group. To set the full set of addresses for a group, run the *Get-UnifiedGroup* cmdlet:

```
[PS] C:\> Get-UnifiedGroup -Identity BankingTeam | Select -ExpandProperty EmailAddresses
smtp:BankingTeam@Office365itpros.com
SMTP:CorporateBanking@Office365ExchangeBook.com
SPO:SPO_b4f8244d-d4ee-46b8-96d5-21d2b6c44c81@SPO_b662313f-14fc-43a2-9a7a-
d2e27f4f3478smtp:BankingTeam@office365itpros.onmicrosoft
smtp:BankingTeam@office365itpros.onmicrosoft.com
```

This group has a primary SMTP address (it has a capitalized SMTP: prefix), two proxy SMTP addresses, one of which is for the service domain (the last in the list), and a proxy address used by SharePoint Online (SPO). To change the primary SMTP address, run the *Set-UnifiedGroup* cmdlet and pass the new address in the *PrimarySMTPAddress* parameter. All proxy addresses must be in one of the domains belonging to the tenant:

```
[PS] C:\> Set-UnifiedGroup -Identity BankingTeam -PrimarySMTPAddress
BankingGroup@Office365itpros.com
```

Setting a new primary address demotes the previous primary address but keeps it as a secondary proxy address. Therefore, in this example, we start with three SMTP addresses and end up with four. If you need to rewrite the set of addresses for a group, use the *EmailAddresses* parameter. For example, here we replace the existing addresses with a new set. Exchange Online assumes that an address is SMTP if you don't specify its

type, and if you don't specify which proxy address is the primary, Exchange Online assumes that it is the first in the list.

```
[PS] C:\> Set-UnifiedGroup -Identity BankingTeam -EmailAddresses  
"SMTP:BankingTeam@Office365itpros.com", "CorporateBanking@office365itpros.com",  
"Banking.Team@office365itpros.onmicrosoft.com"
```

Note that the new set includes an address in the tenant's service domain (onmicrosoft.com). This address is a Microsoft Online Email Routing Address (MOERA) and Exchange Online requires all Microsoft 365 groups to have a MOERA address. Attempts to remove the MOERA address for a group fail if you do not replace the MOERA address at the same time with a new proxy address from the service domain.

To add a new address without affecting the set of current addresses, specify the new address in a hash table. You can add or remove several addresses at one time by including the addresses in a comma-separated list.

```
[PS] C:\> Set-UnifiedGroup -Identity BankingTeam -EmailAddresses  
{Add="BankingGroup@Office365itpros.com"}
```

Similar syntax is used to remove an address. In this case, the command will not work because we are trying to remove the primary address for the group. To remove the primary address, you need to first assign a new primary address to the group before proceeding to remove its old primary address.

```
[PS] C:\> Set-UnifiedGroup -Identity BankingTeam -EmailAddresses  
{Remove="BankingTeam@Office365itpros.com"}
```

## Setting up Private Groups

Some groups exist to share sensitive information between their members. It might be the case that you do not want these groups to be generally known or accessible to non-members, so you can take steps to prevent users from knowing about their existence. The first step is to make sure that the group is private. It does not make sense to have public access to a sensitive group and making the group private prevents any chance that non-members will discover documents belonging to the group through a search performed with SharePoint or Delve. You set the access type for a group by editing its properties or by running the *Set-UnifiedGroup* cmdlet:

```
[PS] C:\> Set-UnifiedGroup -Identity "Senior Managers" -AccessType Private
```

Next, we can hide the group's existence from address lists to prevent it from appearing to users who browse the GAL or another address list to look for groups that they might like to join. This is an important step to take for groups that might have sensitive or controversial words in their name, such as "HR Task Group on Layoff Planning" or "Merger with the Contoso Corporation". To hide a group, run the *Set-UnifiedGroup* cmdlet to set the *HiddenFromAddressListsEnabled* property as follows:

```
[PS] C:\> Set-UnifiedGroup -Identity "Senior Managers" -HiddenFromAddressListsEnabled:$True
```

Hiding a group from the address lists is done by Exchange Online and is only effective for clients that connect to an Exchange mailbox. For instance, if you hide a group, it will still appear in Stream or Planner but not in OWA or Outlook. Members of a hidden group will not be able to see it if they browse an address list. However, they can access the group through a client. For example, if they expand the Groups list in the Outlook desktop client, they can see the hidden group because this list shows all groups to which the user belongs. The usual approach is to have members of hidden groups mark them as favorites so that the groups are easily accessible.

## Groups Hidden from Exchange

Teams uses the *HiddenFromExchangeClientsEnabled* property to hide the Microsoft 365 groups that it creates from Exchange clients like Outlook. If the *HiddenFromExchangeClientsEnabled* property for a group is *\$True*,

Exchange clients do not try to access the group, even if the user is in its membership. If `$False`, the group is available to Exchange clients.

```
[PS] C:\> Set-UnifiedGroup -Identity GroupForTeams -HiddenFromExchangeClientsEnabled
```

Because *HiddenFromExchangeClientsEnabled* is a switch, you do not need to pass `$True` if you want to enable it, but when the time comes to disable the switch, you do have to pass `$False`.

```
[PS] C:\> Set-UnifiedGroup -Identity GroupForTeams -HiddenFromExchangeClientsEnabled:$False
```

## Hidden Membership

The *New-UnifiedGroup* cmdlet supports the *HiddenGroupMembershipEnabled* switch, which conceals the membership of a group from everyone except group members and tenant administrators, who can always see and amend the membership using the Microsoft 365 admin center, EAC, or PowerShell. The *HiddenGroupMembershipEnabled* switch is only available when you create groups through PowerShell, and you cannot change the hidden status of membership afterward by running *Set-UnifiedGroup*. The intention is to block casual viewing of group membership for sensitive groups like those who are working on special projects or (as needed by law in some countries) the students in a certain class. An example of creating a group with hidden membership appears below. Remember to set the group access type to private.

```
[PS] C:\> New-UnifiedGroup -Alias QTX -HiddenGroupMembershipEnabled -DisplayName "Secret Planning Team" -AutoSubscribeNewMembers -AccessType Private
```

To list the groups with hidden membership, use the command:

```
[PS] C:\> Get-UnifiedGroup | ? {$_.HiddenGroupMembershipEnabled -eq $True} | Format-Table DisplayName, Notes, AccessType
```

Teams cannot use groups with hidden membership. The presence of the flag blocks their inclusion in the set of groups presented to an owner to be potentially enabled for Teams.

## Controlling Who Can Send Email to a Group

Like Exchange distribution lists, you can control the individual users and groups who can send messages to a group. To do this, use the *AcceptMessagesOnlyFromSendersOrMembers* parameter to create the set of individual senders and groups from whom the group will accept emails. You might want to do this to protect sensitive groups from unwanted communications. For instance, you might want to allow external users to email the group but restrict this access to some specific email addresses.

The list of individual senders can include mailboxes belonging to the tenant, mail contacts, mail users, and guests. Valid groups include distribution lists, dynamic distribution lists, and Groups. By default, the parameter value is *\$Null*, meaning that anyone can send messages to the group. Exchange Online rejects messages from external senders if the *RequireSenderAuthenticationEnabled* flag for the group is set to *\$True*.

The following example creates a set of allowed senders for a group using a mixture of email addresses, mailbox names, and the group itself. Adding the group to its allowed sender list means that Exchange delivers messages sent by members to the group. You might want to prevent members from sending messages to a group, but this is not usually the desired outcome.

```
[PS] C:\> Set-UnifiedGroup -Identity "Banking Communications" -AcceptMessagesOnlyFromSendersOrMembers Flay@outlook.com, "Ben Owens", "Banking Communications"
```

When Exchange Online creates the allowed sender list for the group, it resolves the addresses specified against Azure AD and writes the values into three group properties:

- **AcceptMessagesOnlyFromDLMembers:** Stores any reference to the groups on the allowed sender list.

- **AcceptMessagesOnlyFrom**: Individual senders on the allowed sender list.
- **AcceptMessagesOnlyFromSendersOrMembers**: The complete list of senders and groups allowed to send to the group.

We can see these properties with the *Get-UnifiedGroup* cmdlet:

```
[PS] C:\> Get-UnifiedGroup -Identity "Banking Communications" | Format-List accept*
AcceptMessagesOnlyFrom           : {flay_outlook.com#EXT#, Ben Owens}
AcceptMessagesOnlyFromDLMembers  : {BankingCommunications_a6275ce562}
AcceptMessagesOnlyFromSendersOrMembers : {flay_outlook.com#EXT#, Ben Owens,
                                         BankingCommunications_a6275ce562}
```

As you can see, the addresses used for guests are obvious because of their unique format.

## Using Exchange Online Cmdlets with Groups

The general rule is that the set of cmdlets created for Groups should be used to interact with groups. However, many other cmdlets in the Exchange Online and Exchange Online Management modules can be used to manage group mailboxes. The presence of a *GroupMailbox* parameter means that a cmdlet supports Groups. The current set that supports this parameter includes:

- *Add-MailboxFolderPermission*.
- *Add-MailboxPermission*.
- *Get-Mailbox*.
- *Get-MailboxFolderPermission*.
- *Get-MailboxPermission*.
- *Get-UserPhoto*.
- *New-MailboxAuditLogSearch*.
- *New-SyncRequest*.
- *Remove-MailboxFolderPermission*.
- *Remove-MailboxPermission*.
- *Remove-UserPhoto*.
- *Search-MailboxAuditLog*.
- *Set-Mailbox*.
- *Set-UserPhoto*.

Although these cmdlets give access to properties that aren't supported by the Groups cmdlets, you will rarely need to use them. The preference is to always manage Groups through the purpose-designed cmdlets instead of looking to use the general-purpose cmdlets.

## Mailbox Identities

Even in cases where a cmdlet does not support the *GroupMailbox* parameter, the *Get-UnifiedGroup* cmdlet uses the same kind of input formats for the Identity parameter (for example, alias or distinguished name) as do the other cmdlets in the Exchange Online module. This means that you can pipe the identity to these cmdlets to retrieve information about group mailboxes. For example, you can use a command like this to discover the number of messages in conversations stored in group mailboxes:

```
[PS] C:\> Get-UnifiedGroup -ResultSize Unlimited | Get-MailboxStatistics | Format-Table DisplayName,
ItemCount, LastLogonTime -AutoSize
```

DisplayName	ItemCount	LastLogonTime
Ignite 2016	235	18 Nov 2019 01:43:34
Managers	252	18 Nov 2019 01:13:52
Board Members (Secret)	262	17 Nov 2019 18:26:59
HR Working Group	265	18 Nov 2019 01:01:35

Mountaineering committee	227 17 Nov 2019 16:43:23
Interesting places to go	244 12 Apr 2018 03:43:17
Sanjay Patel's Favorite Places	222 18 Nov 2019 03:03:36

As pointed out earlier, using *Get-Recipient* to fetch a list of group mailboxes will make this code run faster (and there's an even faster way explained below). For example:

```
[PS] C:\> Get-Recipient -RecipientTypeDetails GroupMailbox -ResultSize Unlimited | Get-MailboxStatistics | Format-Table DisplayName, ItemCount, LastLogonTime -AutoSize
```

The last logon time shown for each group seems interesting. However, it is of little value because no one logs onto group mailboxes and the time reported is based on the last access of a background assistant to the mailbox. Using the *Get-MailboxFolderStatistics* cmdlet, we can also see that items accumulate in other mailbox folders such as:

- **Inbox:** conversation items posted by Outlook clients.
- **Calendar:** items in the group shared calendar.
- **Sent Items:** copies of items posted to the group by some clients. All the other default folders that you would expect to see in a user mailbox are also present.
- **TeamsMessagesData** (in the non-IPM part of the mailbox): compliance records captured for team channel conversations, if the group is team-enabled.
- **Junk Email:** potential spam and malware delivered to the group mailbox.
- **Recoverable items:** items held for eDiscovery and other compliance purposes.

This command reports all the folders in a mailbox (or group mailbox) that hold some items:

```
PS C:\> Get-MailboxFolderStatistics -Identity BankingTeam | ? {$_.ItemsInFolder -gt 0} | Format-Table Name, ItemsInFolder -AutoSize
```

## Using Exchange Online cmdlets with Groups

The [REST-based Exchange Online cmdlets](#) in the Exchange Online Management module support the processing of group mailboxes. These cmdlets don't support the *GroupMailbox* parameter but will process a set of mailboxes retrieved by the *Get-ExoRecipient* cmdlet when specifying a value of *GroupMailbox* in the *RecipientTypeDetails* parameter.

In this example, we use *Get-ExoRecipient* to fetch the set of groups and then pipe each mailbox through *Get-ExoMailboxFolderStatistics* to return the number of items and the date of the latest item in the Inbox folder. Calculated properties are used to create more readable output.

```
[PS] C:\> Get-ExoRecipient -RecipientTypeDetails GroupMailbox -ResultSize Unlimited | Select-Object -Property @{Name = 'UserPrincipalName'; Expression = {$_.PrimarySmtpAddress}} | Get-ExoMailboxFolderStatistics -FolderScope Inbox -IncludeOldestAndNewestItems | Format-Table @{"Name"="Group";"Expression"={$_.Identity.Split("\")[0]}}, ItemsInFolder, @{"Name"="Size";"Expression"={$_.FolderSize.ToString()}}, @{"Name"="Newest Item";"Expression"={$_.NewestItemReceivedDate }}
```

Looking at the date of the latest list in the Inbox tells us the last time an Outlook client posted an item to a conversation in the group. The same technique can be used with the *TeamsMessagesData* folder to discover the last time someone posted a message to a channel conversation in a team-enabled group.

## Managing Group Membership

A newly created group is a lonely place because it has no group members apart from the group owner. We can fix the problem by running the *Add-UnifiedGroupLinks* cmdlet to add some members to the group. In this example, we add Kim Akers to the group.

```
[PS] C:\> Add-UnifiedGroupLinks -Identity BankingTeam -Links Kim.Akers@Office365ITPros.com -LinkType Members
```

In this instance, the user principal name specifies the new member, but you can also use a mailbox alias or display name. The important thing is that the provided value is resolvable to a unique account. Although you can add unlicensed accounts to a Group, users will not be able to access group resources unless they have the right license. For instance, you cannot access the files in a document library unless you have a license to access SharePoint Online.

To add a manager (owner) to the group, we change the *LinkType* to "Owners". A user must be a member of the group before they can become an owner. To add a subscriber to the group, change the *LinkType* to "Subscribers." Members of the subscriber list receive email updates for new messages sent to conversations. Logically, a mailbox must be a member of a group before they can become a subscriber.

If you want to add a large set of members to a group, it is always both more efficient and less liable to throttling to include multiple users in a single call to *Add-UnifiedGroupLinks*. The easiest way to do this is to create an array of the users that you want to add to the group and then use the array as an input to the cmdlet. In this example, we use a variable to hold the mailboxes in the membership of a distribution list. The aliases for each of the accounts in the array can become an input for the *Add-UnifiedGroupLinks* cmdlet to add the users to the group:

```
[PS] C:\> $Members = (Get-DistributionGroupMember -Identity MyDL |
Where-Object {$_.RecipientTypeDetails -eq 'UserMailbox'})
[PS] C:\> Add-UnifiedGroupLinks -Identity MyNew0365Group -LinkType Members -Links
$Members.PrimaryStmpAddress
```

Another example scans for all user mailboxes in the tenant not marked with a value in one of the customized attributes. Again, the resulting array becomes the input to the cmdlet:

```
[PS] C:\> $Users = (Get-Recipient -RecipientPreviewFilter {RecipientTypeDetails -eq "UserMailbox"
-and CustomAttribute3 -ne "N"})
Add-UnifiedGroupLinks -Identity 0365Group -LinkTypeMembers -Links $Users.PrimarySmtpAddress
```

## Creating an All Users Group

It is common for organizations to have an "All Users" distribution list to allow for the distribution of company communications to everyone in a tenant. We can mimic the same approach with Groups by creating a group holding all the mailboxes in the tenant. The steps are simple:

- Create a variable holding the details of all user mailboxes in the tenant.
- Create the group with the *New-UnifiedGroup* cmdlet.
- Populate the membership of the group with *Add-UnifiedGroupLinks*. First, we add users as members of the group and then add them as subscribers.

The array holding the mailbox data (*\$Mailboxes*) contains many different properties for each mailbox. To make sure that we pass unique values, we tell Exchange Online to use the distinguished name property for each mailbox when adding it to the group membership. You could also use the primary SMTP address. Here is the code:

```
[PS] C:\> [array]$Mailboxes = Get-ExoMailbox -RecipientTypeDetails UserMailbox -ResultSize Unlimited
New-UnifiedGroup -Alias AllMailboxes -DisplayName 'Company Communications'
Add-UnifiedGroupLinks -Identity AllMailboxes -LinkType Members -Links $Mailboxes.DistinguishedName
Add-UnifiedGroupLinks -Identity AllMailboxes -LinkType Subscribers
-Links $Mailboxes.DistinguishedName
Get-UnifiedGroupLinks -Identity AllMailboxes -LinkType Members | Format-Table DisplayName
```

In large tenants, you might want to use batches of input objects to update group membership. PowerShell does not flag an error if a user already exists in a member list. Later, we describe a script to create a team for all employees. The script uses similar steps, adjusted to accommodate cmdlets in the Teams PowerShell module.

## Checking Group Membership

The *Get-UnifiedGroupLinks* cmdlet reports the membership of a group. The value passed to the *LinkType* parameter is either *Members*, *Owners*, or *Subscribers* to tell the cmdlet what membership information to display. For example:

```
[PS] C:\> Get-UnifiedGroupLinks -Identity BankingTeam -LinkType Members

Name           RecipientType
----           -
TRedmond       UserMailbox
Kim Akers      UserMailbox
```

As described earlier, *Get-UnifiedGroupLinks* returns an extensive set of properties for an individual member. In other words, when you use the cmdlet to interrogate group membership, Exchange Online returns a lot of useful information about each member including their display name, proxy email addresses, and custom attributes.

## Reporting the Membership of Groups and Teams

Many people ask for a report detailing the membership of groups. You can [download a script from GitHub](#) showing how to create an HTML report with the membership of a group sorted into members and owners. The script also generates a CSV file.

Another common request is to report the set of groups (or teams) someone belongs to. This example uses the *Get-MgUserMemberOf* cmdlet to find the set of groups the requested person belongs to. By default, this cmdlet returns details of membership of any group, so we filter the list to find just Microsoft 365 Groups. The cmdlet returns a set of group identifiers, so we run the *Get-MgGroup* cmdlet to retrieve details for each group. The output is a list holding details for each group usable as an input to another function or to create a CSV.

```
[PS] C:\> $Mailbox = Read-Host "Enter User to check"
$Mbx = (Get-ExoMailbox -Identity $Mailbox)
If (!$Mbx) { Write-Host ("Can't find a mailbox for {0}" -f $Mailbox) }

Write-Host "Checking Microsoft 365 Groups membership for" $Mbx.DisplayName
$FoundGroups = [System.Collections.Generic.List[Object]]::new()
[array]$Groups = (Get-MgUserMemberOf -UserId $Mbx.ExternalDirectoryObjectId | ?
{$_ .AdditionalProperties["groupTypes"] -eq "Unified" } | Select -ExpandProperty Id)
ForEach ($G in $Groups) {
    $GroupDetails = Get-MgGroup -GroupId $G
    $FoundGroup = [PSCustomObject]@{
        GroupName = $GroupDetails.DisplayName
        Mail      = $GroupDetails.Mail
        Id       = $G }
    $FoundGroups.Add($FoundGroup)
} #End For

Write-Host ("{0} is a member of {1} Microsoft 365 Groups" -f $Mbx.DisplayName, $FoundGroups.Count)
$FoundGroups | Select GroupName, Mail
```

To discover the set of groups owned by an account, use the *Get-MgUserOwnedObject* cmdlet to interrogate Azure AD, such as in the example shown below. As in the previous example, the *Get-MgUserOwnedObject* cmdlet returns more than Microsoft 365 groups, so we apply the same filter.

```
[PS] C:\> $Mailbox = Read-Host "Enter User to check"
[array]$Mbx = (Get-ExoMailbox -Identity $Mailbox | Select DisplayName, ExternalDirectoryObjectId)
If (!$Mbx) { Write-Host ("Can't find a mailbox for {0}" -f $Mailbox) }
$FoundGroups = [System.Collections.Generic.List[Object]]::new()
[array]$Groups = (Get-MgUserOwnedObject -UserId $Mbx.ExternalDirectoryObjectId | ?
{$_ .AdditionalProperties["groupTypes"] -eq "Unified" } | Select -ExpandProperty Id)
ForEach ($G in $Groups) {
    $GroupDetails = Get-MgGroup -GroupId $G
    $FoundGroup = [PSCustomObject]@{
```

```

    GroupName = $GroupDetails.DisplayName
    Mail       = $GroupDetails.Mail
    Id        = $G }
    $FoundGroups.Add($FoundGroup)
} #End For

```

```

Write-Host ("{0} is an owner of {1} Microsoft 365 Groups" -f $Mbx.DisplayName, $FoundGroups.Count)
$FoundGroups | Select GroupName, Mail

```

Another approach to finding out what groups a member belongs to is to use the distinguished name of the mailbox in a server-side filter. This approach works for both the *Get-Recipient* cmdlet and the *Get-UnifiedGroup* cmdlet, and it's useful when a script already has the Exchange Online management loaded. In this example, *Get-Recipient* finds the set of group mailboxes and the filter checks the membership of each group to see if the member exists. Apart from not having to call a separate cmdlet to fetch and check group membership, this is a good example of how server-side filtering speeds up processing.

```

[PS] C:\> $Mailbox = Read-Host "Enter User to check"
$SDN = (Get-Mailbox -Identity $Mailbox).DistinguishedName
$Groups = (Get-Recipient -ResultSize Unlimited -RecipientTypeDetails GroupMailbox -Filter "Members -
eq '$SDN'" | Select DisplayName, Alias)
Write-Host $Mailbox "is a member of" $Groups.count "Groups"
$Groups | Select DisplayName, Alias

```

The technique of checking group membership on a per-user basis can be exploited to create a report detailing the membership of every Microsoft 365 group (and team) in a tenant. The common approach to this problem is to create an array of groups and loop down through each group to extract and report its membership. This approach works, but as discussed above, using *Get-UnifiedGroup* and *Get-UnifiedGroupLinks* can be slow when many groups are to be processed. Checking group membership on an account-by-account basis delivers faster results, as evident in [this script from GitHub](#), which you can download to see the technique in action. The script generates three files: an HTML report and two CSV files holding summary per-user data (how many groups a user belongs to and their names) and full membership information for each group.

## Checking if Someone is in a Group

No off-the-shelf cmdlet exists to allow you to check whether a user is already a member of a group. For small groups, it is possible to check by iterating through the membership to look for a match, but once group membership grows past a hundred or so entries, that kind of processing becomes very slow. One way to check is to use code like that shown below to use a filter with the *Get-Mailbox* cmdlet to check the distinguished name of a user against those in the membership of a group. If a value is returned to the *\$Status* variable, the mailbox is in the group's membership. If not, it isn't. This is rough and ready code that does not include error checking.

```

[PS] C:\> $Check = (Read-Host "Enter User to check")
$User = (Get-Mailbox -Identity $Check | Select DisplayName, DistinguishedName)
$CheckGroup = (Read-Host "Enter name of group to check")
$TargetGroup = (Get-UnifiedGroup -Identity $CheckGroup)
$GroupDN = $TargetGroup.DistinguishedName
$Status = (Get-Mailbox -Identity $User.DistinguishedName -Filter "MemberOfGroup -eq '$GroupDN'"
-ErrorAction SilentlyContinue)
If ($Null -eq $Status) { Write-Host ("{0} is not a member of the {1} group" -f $User.DisplayName,
$TargetGroup.DisplayName) }
Else { Write-Host ("{0} is a member of the {1} group" -f $User.DisplayName,
$TargetGroup.DisplayName) }

```

## Dealing with Users and Guests

We can make things a little more efficient by building a hash table from the group membership and then checking a user against the hash table. This is faster than using a simple array and it allows us to deal with

groups that include guest members. In this example, we create a hash table from the membership of the All Employees group. The table consists of keys (user display names) and values (their email addresses), and looks something like this:

Name	Value
Sanjay Patel	Sanjay.Patel@office365itpros.com
Tony Redmond	Tony.Redmond@office365itpros.com
Jack Healy	Jack.Healy@office365itpros.com
Imran Khan	Imran.Khan@office365itpros.com

Guest users have the string "#EXT#" in their name, so we need to do some processing to normalize the names in the table for tenant users and guests. If you want to exclude guests, comment out the lines that process these members. After we build the table, the next thing is to ask for an SMTP address to check for in the group and then look for that address in the hash table. If the code finds a match in the table, we report success.

```
[PS] C:\> $GroupMembers = @{}
# Populate the array with current group membership
$OrgName = "@" + (Get-OrganizationConfig).Identity
$TargetGroup = "All Employees"
Get-UnifiedGroupLinks -LinkType Member -Identity $TargetGroup | % {
    $User = $_.Name.toString()
    # Handle guests
    if ($User -like "*#EXT*") {
        $GuestUPN = $User+$OrgName
        $GuestUser = Get-MgUser -UserId $GuestUPN -ErrorAction SilentlyContinue
        $GroupMembers.Add($GuestUser.DisplayName, $GuestUser.Mail) }
    else {
        # local mailbox
        $LocalUser = (Get-ExoMailbox -Identity $User)
        $GroupMembers.Add($LocalUser.DisplayName, $LocalUser.PrimarySmtpAddress) }
}
$Check = (Read-Host "Enter SMTP address to check")
If ($GroupMembers.Values -Match $Check) {
    Write-Host "User" $Check "is in the group" $TargetGroup }
```

Another approach to the problem is to create an array holding the group identifier and display name of the groups to which someone belongs and then check the object identifier of the target group against the array.

```
[PS] C:\> $Groups = @{}
$Check = (Read-Host "user to check")
$Dn = (Get-Mailbox -Identity $Check -ErrorAction SilentlyContinue).DistinguishedName
If (!(($DN)) { Write-Host "Can't find" $Check; break }
$TargetGroup = (Get-UnifiedGroup -Identity "Office 365 for IT Pros")
# Populate the array with current membership of the target group
Get-Recipient -Filter "Members -eq '$Dn'" -RecipientTypeDetails GroupMailbox | % {
    $GroupName = $_.DisplayName
    $GroupId = $_.ExternalDirectoryObjectId
    $Groups.Add($GroupId, $GroupName) }

If ($Groups.ContainsKey($TargetGroup.ExternalDirectoryObjectId) -eq $True) {
    Write-Host "User" $Check "is in the group" $TargetGroup.DisplayName }
```

## Removing Members from Groups

To remove a member from a group, run the *Remove-UnifiedGroupLinks* cmdlet and follow some simple rules:

- Only a group owner, a tenant administrator, or an Exchange administrator can run the cmdlet. Holders of other roles (like a Teams administrator) can use different cmdlets to update group membership.
- You must specify the link type of the list from which you want to remove the user – Owners, Members, or Subscribers.

- If a user is a group owner, you must remove their owner status first and then remove them as a group member. Remember that if you're removing the only remaining group owner, you should promote another member to be the group owner so as not to leave the group without an owner. Cmdlets stop the removal of the last group owner.
- If a group member has subscribed to the group for email updates, you do not have to remove this link separately as the removal of their membership also removes their subscription.

As an example, here is how to remove Kim Akers as a member of the Banking Team group:

```
[PS] C:\> Remove-UnifiedGroupLinks -Identity BankingTeam -LinkType Members -Links 'Kim Akers'
```

Exchange Online caches link information to improve performance so changing the links for a group might take some time before the change is fully effective across the tenant.

## Removing Guest Users from Groups

As discussed earlier, you might want to remove a certain account from all groups in a tenant. Removing the guest account from Azure AD is a straightforward brute-force solution, but it means that the guest loses any access they have to SharePoint Online and OneDrive for Business gained through sharing links. Removing a guest account is probably a good idea if you discover that some team owners invite a guest from a competitor company to join their teams. However, if you want to remove guests from groups (teams) while leaving the guest account in place, a more surgical approach is needed. Let's discuss what you could do.

This code depends on an exact check against the display name of either an Azure AD member or guest account. If an account is found, the code returns the set of groups the account is a member of.

```
[PS] C:\> $$CheckUser = (Read-Host "user to check")

[array]$User = Get-MgUser -Filter "displayName eq '$($CheckUser)'"
If ($User) {
    Write-Host "Fetching details of groups..."
    [array]$Groups = (Get-MgUserMemberOf -UserId $User.Id | ? {$_.AdditionalProperties["groupTypes"]
    -eq "Unified" } | Select -ExpandProperty Id)
    Write-Host $User.DisplayName "found in" $Groups.Count "Groups"}
Else { Write-Host ("Can't find {0} in Azure AD" -f $CheckUser) }
```

The next step is to remove the membership link from the groups where the user is present. This code asks the administrator if they want to go ahead and remove the user from the groups. Upon confirmation, the code first checks whether a user is a group owner and removes that link before it removes the member link.

```
[PS] C:\> $NextStep = Read-Host $User.DisplayName "found in" $Groups.Count "Groups. Do you want to
remove the user from the groups?"
If ($NextStep.SubString(0,1).ToUpper()-eq "Y")
{
    Write-Host "Removing" $User.DisplayName "from Groups..."
    ForEach ($G in $Groups) { # Process each group the user has been found in and remove
    $GroupDetails = Get-MgGroup -GroupId $G
    # Have to remove them as an owner first
    [array]$Owners = Get-UnifiedGroupLinks -Identity $G -LinkType Owners
    If ($User.Mail -in $Owners.PrimarySmtpAddress) {
        Write-Host "Removing" $User.DisplayName "as owner of group" $GroupDetails.DisplayName
        Remove-UnifiedGroupLinks -LinkType Owners -Links $User.Mail -Identity $G -Confirm:$False -
ErrorAction SilentlyContinue
    } # End Remove as Owner
    # Now remove their membership link
    [array]$Members = Get-UnifiedGroupLinks -Identity $G -LinkType Members
    If ($User.Mail -in $Members.PrimarySmtpAddress) {
        Write-Host "Removing" $User.DisplayName "as member of group" $GroupDetails.DisplayName
        Remove-UnifiedGroupLinks -LinkType Members -Links $User.Mail -Identity $G -Confirm:$False -
ErrorAction SilentlyContinue
    } # End remove as member
    } # End For
} # End If
```

Although this code does an effective job of cleaning up member and owner links for a selected user, it will hit a problem if it tries to remove the last owner for a group because *Remove-UnifiedGroupLinks* will signal an error and fail to remove the owner. Some extra error checking will solve the issue.

## Checking Groups with Guests

Another common reason to examine groups is to understand how many groups have guests and how many guests are in the membership of each group. Remember, it doesn't matter whether guests were added through Groups, Teams, or Planner – the guests all end up in the same membership. We can carry out our task by checking the membership count data held for each group. In this case, we fetch all the groups in the tenant and sort them by total member count. We then output the total member count, the count of guests, and a computed value for the number of users in the tenant.

```
[PS] C:\> Get-UnifiedGroup -Filter {GroupExternalMemberCount -gt 0} | Sort-Object GroupMemberCount -Descending | Format-Table -AutoSize DisplayName, GroupMemberCount, GroupExternalMemberCount, @{Name="Tenant Users"; Expression = {$_.GroupMemberCount - $_.GroupExternalMemberCount}}
```

DisplayName	GroupMemberCount	GroupExternalMemberCount	Tenant Users
Exchange's Grumpy Old Men	62	57	5
Microsoft 365 Discussion	61	55	6
Microsoft 365 Engage 2020 Speakers	42	41	1
Company Communications	28	0	28

The member counts recorded in group properties should only ever be treated as guidance. The actual number might be off by 1 or 2 in some groups before the background process which updates these numbers catches up with recent changes. If you want to be absolute about member counts, you must check the individual members in each group.

## Finding Inactive Guest Accounts

Another aspect of guest management is the removal of accounts after they are no longer required. [Azure AD Access Reviews](#) attempt to solve the problem by requiring group owners to review and approve continued access for guests in the groups that they manage. Access reviews can also look for inactive guest accounts using Azure AD sign-in data. The downside is that Access Reviews require Azure AD Premium P2 licenses.

If you don't have Azure AD Premium P2 licenses, it's still possible to look for potential signs of aging or inactive accounts. One approach is to write a script to look for guest accounts in a tenant directory over a certain age (in this example, a year). The check is based on the account's *CreatedDateTime* value. After finding the set of guest accounts, you can retrieve the set of Microsoft 365 groups that each guest belongs to. The code below creates a report of guest accounts older than one year together with their group membership.

```
[PS] C:\> Select-MgProfile Beta
[array]$GuestUsers = Get-MgUser -Filter "usertype eq 'Guest'" -All
$Today = (Get-Date); $StaleGuests = 0; $Report = [System.Collections.Generic.List[Object]]::new()
# Check each account and find those over 365 days old
ForEach ($Guest in $GuestUsers) {
    $AccountAge = ($Guest.CreatedDateTime | New-TimeSpan).Days
    If ($AccountAge -gt 365) {
        $StaleGuests++
        Write-Host "Processing" $Guest.DisplayName
        $i = 0; $GroupNames = $Null
        # Find what Groups the guest belongs to... if any
        $DN = (Get-Recipient -Identity $Guest.Id).DistinguishedName
        # The distinguished name for some accounts might contain an apostrophe, so we need to handle this
        If ($Dn -like "*'*)" {
            $DNNew = "" + "$($dn.Replace("'", ''))" + ""
            $Cmd = "Get-Recipient -Filter 'Members -eq '$DNNew'' -RecipientTypeDetails GroupMailbox |
Select DisplayName, ExternalDirectoryObjectId"
            $GuestGroups = Invoke-Expression $Cmd }
        Else {
```

```

    $GuestGroups = (Get-Recipient -Filter "Members -eq '$Dn'" -RecipientTypeDetails GroupMailbox
| Select DisplayName, ExternalDirectoryObjectId) }
    If ($GuestGroups -ne $Null) { $GroupNames = $GuestGroups.DisplayName -join ", " }
    $ReportLine = [PSCustomObject]@{
        UPN      = $Guest.UserPrincipalName
        Name     = $Guest.DisplayName
        Age      = $AccountAge
        Created  = $Guest.CreatedDateTime
        Groups   = $GroupNames
        DN       = $DN    }
    $Report.Add($ReportLine) }
}
$Report | Sort Name | Export-CSV -NoTypeInformation c:\Temp\OldGuestAccounts.CSV

```

The code uses distinguished names to perform a server-side check to find groups a guest account belongs to. We might run into a situation where a distinguished name contains special characters like the apostrophe, which is why the code checks for this condition. If the script finds an apostrophe in a distinguished name, it “escapes” the character before attempting to fetch the set of groups the guest account belongs to.

Azure AD sign-in logs are a good source to find the last sign-in date for an account. You can search the Azure AD sign-in logs using the *Get-MgAuditLogSignIn* cmdlet to fetch the information for guest users based on their account identifier. However, it’s easier to request the *Get-MgUser* cmdlet to return sign-in activity data along with the other properties it returns. Here’s an example. Starting off by using the *Get-MgUser* cmdlet to search to find accounts matching whatever the user enters:

```

[PS] C:\> Select-MgProfile Beta
$Guest = Read-Host "Enter name of guest to search for"
$Search = 'DisplayName:' + $Guest
[array]$Guests = Get-MgUser -Search $Search -ConsistencyLevel Eventual -Property SignInActivity
ForEach ($G in $Guests) {
    If ($G.UserType -eq "Guest") {
        If (!(($string)::IsNullOrEmpty($G.SignInActivity.LastSignInDateTime))) {
            $Days = New-TimeSpan($G.SignInActivity.LastSignInDateTime)
            Write-Host ("Guest member {0} last signed in on {1} or {2} days ago" -f $G.DisplayName,
$G.SignInActivity.LastSignInDateTime, $Days.Days ) }
            Else { Write-Host ("No recent Azure AD sign-in data available for {0} ({1})" -f
$G.DisplayName, $G.Mail) }
        }
    }
}

```

## Finding Inactive Guest Accounts Based on Activity

Reviewing guest accounts based on account age or their last sign-ins is certainly a valid approach. However, as Microsoft discovered in the Azure AD group expiration policy, age-based expiration is not necessarily the best approach: activity-based expiration is better. To establish if a guest account is in active use, we can check user activity in:

- The audit log to check if an auditable action happened for the account within the last 90 days.
- The message trace data gathered by Exchange Online to check if anyone sent email to the guest account over the last 10 days.

Writing a script to gather activity information is more complex than the previous example. Our example ([available from GitHub](#)) searches the audit log for three actions (you can add more if you like) that are important to guest accounts:

- *UserLoggedIn*: The guest signs into the tenant. For example, when a guest account signs in to SharePoint Online to edit a shared document.
- *SecureLinkUsed*: A guest accepts the invitation in a secure link to access a document.
- *TeamsSessionStarted*: A guest starts a Teams session. Due to token expiration, this event is logged every hour for the duration of the session.

In addition to checking the audit log, the script also runs a message trace to see if anyone sent messages to the guest's email address. An online check of message trace data can only go back 10 days, but it's a good way to discover if a guest account receives copies of Outlook group conversations via email. Finally, instead of using the *RefreshTokensValidFromDateTime* attribute of the guest account as the basis for calculating its age, this script uses the *creationDateTime* for the account. Because guest accounts authenticate against their tenant's directory, the value of *RefreshTokensValidFromDateTime* is usually the same as the *creationDateTime* for guest accounts, but *creationDateTime* returns an accurate creation timestamp for all Azure AD accounts.

As before, the script captures the names of any groups the guest belongs to. After processing all guest accounts, the script outputs the results to a CSV file. The script flags guests with no evidence of activity for review and potential deletion. One way to automate the deletion is to delete the records for guests that you want to keep from the CSV file and then use the updated file as input to the *Remove-MgUser* cmdlet.

## Removing Guest Accounts

If you find problematic guest accounts, you can remove them selectively or in bulk. This is not something to do without thinking (or testing) as removing a guest account ends any shared access it has to SharePoint Online and OneDrive for Business documents or folders in the tenant as well as its membership of Groups, which then renders access void to Groups, Teams, Planner, Yammer, and any other application which depends on Groups to manage its membership. With that caution in mind, to remove an individual guest account, run the *Remove-MgUser* cmdlet and pass either the account's object identifier or user principal name. For example:

```
[PS] C:\> Remove-MgUser -UserId JohnSmith_yandex.com#EXT#@office365itpros.onmicrosoft.com
Remove-MgUser -UserId 78cbdb6d-6a59-4b45-9925-c78f28dfefal
```

Azure AD doesn't prompt for confirmation before it removes the account. This is one reason why searching for an account using *Get-MgUser -Search* can be so dangerous as it is all too easy to remove the wrong account from the set returned by the search. Following deletion, the account stays for 30 days in a soft-deleted state and can be restored from this state using the *Restore-MgUser* cmdlet or the Azure AD admin center.

On the other hand, if you want to permanently remove a deleted guest account before its 30-day retention period expires, run the *Remove-MgDirectoryDeletedItem* cmdlet. Be careful as this cmdlet doesn't prompt either and once an object is permanently removed from the directory it cannot be recovered, meaning that the guest account must be recreated if it is required afterward. A recreated account has a different object identifier than the deleted account, so it will not regain access to resources that the deleted account had. Here's how to completely remove a guest account from a tenant directory.

```
[PS] C:\> $Id = (Get-MgUser -UserId JohnSmith_yandex.com#EXT#@office365itpros.onmicrosoft.com).Id
Remove-MgUser -UserId $Id
Remove-MgDirectoryDeletedItem -DirectoryObjectId $Id
```

## Bulk Removal

As an example of bulk account removal, this snippet looks for guest accounts belonging to a certain domain (in this case, Badpeople.com) and removes them from Azure AD.

```
[PS] C:\> [array]$Users = (Get-MgUser -Filter "UserType eq 'Guest'" -All | Select DisplayName,
UserPrincipalName, Id)
Foreach ($U in $Users) {
  If ($U.UserPrincipalName -Like "*BadPeople.com*") {
    Write-Host "Removing" $U.DisplayName
    Remove-MgUser -UserId $U.Id }}}
```

Alternatively, if you do not want to remove the guest account from the tenant, you can change the loop to run the *Remove-UnifiedGroupLinks* cmdlet to remove the guest from the membership of groups they belong to. If you only want to remove the guest from or Teams, run the *Remove-TeamUser* cmdlet.

## Synchronizing Groups with Security Groups

You might have a set of security groups that you use to control access to information and want to use the same membership of those security groups with Groups or Teams. No synchronization exists within Microsoft 365 today to keep the membership of a security group aligned with a group or vice versa, but it's reasonably easy to do with PowerShell.

Let's take an example where you have a security group and want to have an equivalent group (or team). In this case, the "eDiscovery Admins" security group is the master, and the "eDiscovery Administrators" group is the replica. Synchronization is done from master to replica. Assuming the group already exists, we fetch the membership of the security group and add any user account found there to the group.

```
[PS] C:\> $M365Group = (Get-UnifiedGroup -Identity "eDiscovery Administrators")
$SecurityGroupId = (Get-MgGroup -Filter "displayName eq 'eDiscovery Admins'").Id
# Grab list of security group members
[array]$SecurityGroupMembers = (Get-MgGroupMember -GroupId $SecurityGroupId)
# Populate the Group with the members of the security group
ForEach ($Member in $SecurityGroupMembers) {
    $MemberDetails = Get-MgUser -UserId $Member.Id
    If ($MemberDetails.UserType -eq "Member") {
        Add-UnifiedGroupLinks -Identity $M365Group.ExternalDirectoryObjectId -LinkType Member -Links
        $MemberDetails.UserPrincipalName }}}
```

This process doesn't handle nested groups, so if the security group includes a nested group, you'll have to extract the membership from that group and process those entries.

After we write the security group membership into the group, we need to do some added processing to fully synchronize the two groups. The security group is the master for membership, and some other members previously added to the group previously might not belong to the security group. To complete synchronization, we need to compare the two lists and remove anyone found in the group who doesn't exist in the security group. Again, this is a straightforward operation:

```
[PS] C:\> $GroupMembers = (Get-UnifiedGroupLinks -Identity $M365Group.ExternalDirectoryObjectId
-LinkType Member)
# Check if any group members do not exist in the security group
ForEach ($i in $GroupMembers) {
    If ($SecurityGroupMembers -Match $i.UserPrincipalName)
        {Write-Host $i.DisplayName "is in security group" }
    Else
        { Write-Host "Removing" $i.DisplayName "from group because they are not in the security group"
-ForegroundColor Red
Remove-UnifiedGroupLinks -Identity $M365Group.ExternalDirectoryObjectId -Links $i.Alias -
LinkType Member -Confirm:$False}
}
Write-Host "Current Membership of" $M365Group.DisplayName
Get-UnifiedGroupLinks -Identity $M365Group.ExternalDirectoryObjectId -LinkType Member | Select
DisplayName
```

To be fully effective, you would need to set up a periodic batch job to synchronize the two memberships. Some more robust error checking and handling of nested groups would improve the script too.

**The GMM Tool:** The Group Membership Management (GMM) tool is [available on GitHub](#) to allow tenant administrators to synchronize the membership of Microsoft 365 groups from source groups at regular intervals.

## Flagging Unowned Groups

All Microsoft 365 groups (and teams) should have at least one owner. If groups end up lacking owners, it means that no one except administrators can add new members or perform other group management functions and that administrators must process group expiry notifications. Here's some PowerShell to flag any Microsoft 365 groups with missing owners:

```
[PS] C:\> $Groups = (Get-UnifiedGroup -ResultSize Unlimited | Select DisplayName, ManagedBy)
$Groups | ? {$_.ManagedBy.Count -eq 0}
```

Another way of looking at group ownership is to check what groups a certain user owns. You can do this by running the *Get-Recipient* cmdlet to return a list of group mailboxes and using a filter on the *ManagedBy* property to extract the groups owned by the person that you want to check. The only complicating factor is that you must use the user's distinguished name in the filter. For example, this PowerShell finds all the groups where Kim Akers is an owner.

```
[PS] C:\> $Dn = (Get-Mailbox -Identity "Kim Akers").DistinguishedName
Get-Recipient -RecipientTypeDetails GroupMailbox -Filter "ManagedBy -eq '$Dn'" | Format-Table
DisplayName
```

Another way is to query Azure AD for information about the objects it believes someone owns:

```
[PS] C:\> $UserId = (Get-ExoMailbox -Identity "Kim Akers").ExternalDirectoryObjectId
[array]$Groups = (Get-MgUserOwnedObject -UserId $UserId | ? {$_.AdditionalProperties["groupTypes"] -
eq "Unified"}) | Select -ExpandProperty Id )

ForEach ($Group in $Groups) {
    Get-MgGroup -GroupId $Group | Select DisplayName, Description }
```

## Checking for Unused Groups

The group expiration policy gives tenants an automated method to age out groups after a set period. However, you might want to check how active groups are before they become candidates to expire to understand the reasons why users create groups and what happens to those groups in the months afterward. To achieve this goal, we can use PowerShell to find any groups where no activity has occurred recently. Depending on their use, groups display different signs of activity. A group used by people who center their activity around Outlook is likely to use conversations heavily while another team might use Teams for their communications. Table 23-2 describes how users interact with groups and the consequent dependency on the two primary workloads.

<b>Type of group</b>	<b>Files stored in SharePoint Online</b>	<b>Items stored in Exchange Online</b>
Groups: documents	Yes	N/A
Groups: conversations and shared calendar	N/A	Yes
Yammer Groups: documents	Yes	N/A
Yammer Groups: discussions and shared calendar	N/A	Yes (calendar)
Group created by Microsoft Planner	Yes	Yes (discussions)
Group created by Microsoft Teams	Yes	Yes (calendar and compliance records)

Table 23-2: Exchange and SharePoint usage in various group types

You can check the potential underuse of groups used for document generation and management by looking for evidence of SharePoint file activity for the site as recorded in the audit log. After connecting a PowerShell session to SharePoint Online and Exchange Online, the code shown below checks to see whether any audit records generated by SharePoint file operations over the last 90 days exist for the site belonging to each

group. If no audit records for SharePoint file operations for a site are available, it's reasonable to assume that not much document-centric activity has taken place for the site, and it is therefore potentially obsolete.

```
[PS] C:\> $WarningDate = (Get-Date).AddDays(-90)
$Today = (Get-Date)
$Groups = Get-UnifiedGroup -ResultSize Unlimited
# This is faster: [array]$Groups = Get-MgGroup -Filter "groupTypes/any(c:c eq 'unified')" -All
# but then you need to fetch the details of each group
$ObsoleteGroups = 0
ForEach ($G in $Groups) {
    If ($G.SharePointSiteUrl) {
        $SPOSite = (Get-SPOSite -Identity $G.SharePointSiteUrl)
        Write-Host "Checking" $SPOSite.Title "..."
        $AuditCheck = $G.SharePointDocumentsUrl + "/*"
        [array]$AuditRecs = (Search-UnifiedAuditLog -RecordType SharePointFileOperation `
            -StartDate $WarningDate -EndDate $Today -ObjectId $AuditCheck -ResultSize 1)
        If (!$AuditRecs) {
            Write-Host ("No audit records found for {0}. The site is potentially obsolete!" -f
                $SPOSite.Title) ; $ObsoleteGroups++ }
        Else
            { Write-Host ("Recent audit record found for {0}. Last access dated {1}" -f $SPOSite.Title,
                $AuditRecs.CreationDate[0]) }
        }
    Else
        {
            Write-Host "SharePoint has never been used for the group" $G.DisplayName
            $ObsoleteGroups++
        }
    }
}
Write-Host $ObsoleteGroups "obsolete group document libraries found out of" $Groups.Count "checked"
```

Microsoft 365 Groups that use emails for communication (Outlook groups) require a different approach because we need to track the activity level for conversations. In this case, we use the *Get-ExoMailboxFolderStatistics* cmdlet to check the date and time for the last item (conversation) added to the Inbox. If that conversation occurred within the last year, all is well, and we can go on. If not, we flag the group as potentially obsolete. Checking the date of the last item is a simple sign of activity. We can improve it by checking how many items are in the Inbox. If just a few items exist, it is a sign that the group processed the first notification message sent following its creation and a couple of other conversations, and then gently fell into decay.

```
[PS] C:\> $Groups = Get-Recipient -RecipientTypeDetails GroupMailbox -ResultSize Unlimited
$ObsoleteGroups = 0; $WarningDate = (Get-Date).AddDays(-365)
ForEach ($G in $Groups) {
    Write-Host "Checking Inbox traffic for" $G.DisplayName
    $Data = (Get-ExoMailboxFolderStatistics -Identity $G.Alias -IncludeOldestAndNewestItems -
        FolderScope Inbox)
    If ($Data.NewestItemReceivedDate -le $WarningDate) {
        Write-Host ("Last Inbox item found in {0} was {1}. Not much going on here!" -f $G.DisplayName,
            $Data.NewestItemReceivedDate); $ObsoleteGroups++ }
    Else {
        Write-Host ("{0} has {1} items in the Inbox. Folder size is {2}" -f $G.DisplayName,
            $Data.ItemsInFolder, $Data.FolderSize) }
    }
}
Write-Host $ObsoleteGroups "Obsolete Groups found out of" $Groups.Count
```

The same approach can be used to check whether groups enabled for Teams or Yammer are active. For Teams, Microsoft 365 saves compliance records for regular channel conversations in the *TeamsMessagesData* folder, while the Yammer folder stores compliance records for conversations in Yammer-enabled groups. This means that we can check the usage of a group by looking at the newest item in the relevant folder. Here's an example for Teams:

```
[PS] C:\> $G = Get-UnifiedGroup -Identity 0365ITPros
```

```
$TeamsData = (Get-ExoMailboxFolderStatistics -Identity $G.Alias -FolderScope NonIpmRoot
-IncludeOldestAndNewestItems | ? {$_.FolderType -eq "TeamsMessagesData"})
Write-Host ("Last Teams conversation created in {0} was {1}." -f $G.DisplayName, $TeamsData.
NewestItemReceivedDate)
```

Note that if you want to process all team-enabled groups, the recommended approach is to use the *Get-Team* or *Get-MgGroup* cmdlets to create a collection of teams and then process each group in the set.

These examples use different methods to find potentially underused groups. It would not take a lot of added effort to add some code to combine the results and make a better decision as to which groups are obsolete and those that only use either SharePoint Online or Exchange Online. An example script that combines checks of Teams, SharePoint Online, and Exchange Online to find and report potentially obsolete Groups and Teams [is described in this post](#). A [Graph-based version of the script](#) is also available and is up to four times faster than the cmdlet equivalent.

You can use the Groups activity report available in the Microsoft 365 admin center to identify inactive groups based on the last activity date, but the nice thing about approaching the problem through PowerShell is that you have a chance to tailor the assessment and the output to meet your needs, such as including details of the group access type or using one of the custom properties that can be assigned to groups to hold information about its status.

A problem shared by both the Groups activity report and any attempt to detect inactive groups via PowerShell is that the focus is on activity created in Exchange and SharePoint.

## Blocking Guest Access to Sensitive Groups

Chapter 11 discusses how to use a policy to disable guest access for a selected group. If you use classifications in your tenant, you probably have a classification like “Company Confidential” or “Secret” to mark groups (or teams) that hold sensitive information. In some cases, you might want to make sure that these groups do not have guest users. Another example is when a school wishes to block guest access to any group used for student communications.

It’s easy to solve the problem with PowerShell if a suitable classification is assigned to sensitive groups. With the classifications in place, we can scan for those groups and then block them all for guest access. In this example, the first step is to collect a set of groups classified as “Confidential.” The code then loops through each group to discover whether group-specific policy settings are in place. If so, the code updates the settings to block guest access. Groups that don’t have a policy setting are controlled by the tenant policy, so the first step is to create policy settings for the group. We can then update the setting to block guest access.

```
[PS] C:\> $GroupTemplate = (Get-MgDirectorySettingTemplate | ? {$_.DisplayName -eq
"Group.Unified.Guest"})
[array]$Groups = (Get-UnifiedGroup -ResultSize Unlimited | Where {$_.Classification -eq
"Confidential"})

ForEach ($Group in $Groups) {
    $GroupSettings = Get-MgGroupSetting -GroupId $Group
    if($GroupSettings) { # Policy settings already exist for the group - so update them
        Update-MgGroupSetting -GroupId $Group.ExternalDirectoryObjectId -TemplateId $GroupTemplate.Id
-Values (@{'name'='AllowToAddGuests';'value'='false'} | ConvertTo-Json) -DirectorySettingId
$GroupSettings.Id
        Write-Host "External Guest accounts prohibited for" $Group.DisplayName
    }
    Else
    { # Settings do not exist for the group - so create a new settings object and update
        New-MgGroupSetting -GroupId $Group.ExternalDirectoryObjectId -TemplateId $GroupTemplate.Id -
Values (@{'name'='AllowToAddGuests';'value'='false'} | ConvertTo-Json
        Write-Host "External Guest accounts blocked for"$Group.DisplayName
    }
}
```

The update is to the Azure AD group. Synchronization to the workload directories must occur before clients learn about the new status for a group and the block becomes effective.

To check that the block works, we can create a list of the groups blocked from having guest members. To do this, run the *Get-UnifiedGroup* cmdlet to check the *AllowAddGuests* property, which is *\$False* for blocked groups. For example, this command reports the display names and classification for all blocked groups. Remember that the block is effective for all clients that populate group membership, including Teams.

```
[PS] C:\> Get-UnifiedGroup -ResultSize Unlimited | ? {$_ .AllowAddGuests -eq $False } | Format-Table
DisplayName, Classification
```

## Using Sensitivity Labels to Block Guest Access

If you use Sensitivity Labels to assign a classification to Groups, you can block guest access to a group by choosing a label that restricts external guest access. After an administrator or owner assigns a label blocking guests from a group, Exchange Online sets the *AllowAddGuests* property of the group to *\$False* and updates the *AllowToAddGuests* setting in the Azure AD policy for the group to block guest access.

You can assign a sensitivity label to a group with the *Set-UnifiedGroup* cmdlet using the label identifier. To find the identifier for labels, run the *Get-Label* cmdlet (from the Security and Compliance module):

```
[PS] C:\> Get-Label | Format-Table DisplayName, Guid
```

Once you know the identifier for the label to apply, run *Set-UnifiedGroup*. For example:

```
[PS] C:\> Set-UnifiedGroup -Identity "Banking Group" -SensitivityLabelId "1b070e6f-4b3c-4534-95c4-08335a5ca610"
```

After a label is assigned with PowerShell, background synchronization updates SharePoint Online and Teams so that these workloads apply the label settings.

## Checking Guests in Sensitive Groups or Teams

When you assign a sensitivity label to a group or team that blocks guest access, any existing guests in the membership are not removed. Unless someone goes and checks, this can lead to a situation where unwanted guests linger in group memberships when they shouldn't. It's relatively straightforward to check the membership of all groups tagged with a specific label to see if they have guest members. Here's some code to do the job:

```
[PS] C:\> Write-Host "Finding confidential Groups..."
[array]$Groups = Get-UnifiedGroup | ? {$_ .SensitivityLabel -eq "c29e68f9-bc4f-413b-a741-6db8e38ad1c6" -and $_.GroupExternalMemberCount -gt 0}
If (!$Groups.Count) { Write-Host "No Groups found with that label"}
Else {
    $Report = [System.Collections.Generic.List[Object]]::new(); $NumberGuests = 0
    Write-Host "Now examining the membership of" $Groups.Count "groups to find guests..."
    ForEach ($Group in $Groups) {
        Write-Host "Processing" $Group.DisplayName
        [array]$Users = Get-UnifiedGroupLinks -Identity $Group.Alias -LinkType Members
        ForEach ($U in $Users) {
            If ($U.Alias -Match "#EXT#" -and $U.ExternalEmailAddress -NotLike "*teams.ms*") {
                $Domain = $U.ExternalEmailAddress.Split("@")[1]
                $ReportLine = [PSCustomObject]@{
                    Email           = $U.Name
                    User            = $U.DisplayName
                    Domain          = $Domain
                    Group           = $Group.DisplayName
                    Site            = $Group.SharePointSiteURL }
                $Report.Add($ReportLine)
                $NumberGuests++ }
        }
    }
}
$Domains = $Report.Domain | Sort -Unique; $DCount = $Domains.Count; $Domains = $Domains -join ", "
```

```
Write-Host ("{0} guests found in {1} confidential groups from these {2} domains: {3}" -f
$NumberGuests, $Groups.Count, $DCount, $Domains)
$Report | Sort Email | Out-GridView
$Report | Export-CSV -NoTypeInformation C:\temp\UnwantedGuests.csv
```

## Archiving Inactive Groups

Projects tend to have a natural lifetime. For example, let's assume that you spin up a group to support the planning and coordination of a financial project. After the project finishes, the group holds conversations about project issues, the calendar of meetings, and all the documents related to the project. Depending on the compliance regime that applies to the company operations, you might have to keep this information for an extended period. Unlike mailboxes, which administrators can put into an inactive state to preserve their content in a state that is inaccessible to users, we need a different approach to archive group content.

Conceptually, the steps to archive a group are easy. The aim is to put the group into a state where we hide the content from general view while the content stays indexed and discoverable for compliance purposes. After finding the set of groups to archive, here's what we might do to make the groups read-only to all but a new group owner:

- Add a new group owner. Ideally, this should be a special compliance administration account instead of a tenant administrator. Remember, before you can add an owner, they must first be a member of the group. Note that Teams cmdlets are used to update membership rosters when a group is team-enabled. This is to ensure that the new roster is active as quickly as possible.
- Check if the group is team-enabled and if so, check for private and shared channels so that you can add the compliance administrator as the owner for each channel.
- Remove all owners from the group's membership list.
- Remove all users from the group's membership list.
- Set *RequireSenderAuthenticationEnabled* property to *\$True* to stop Exchange Online from accepting any external email sent to the group. Guest members are not subject to this check as they can always email a group until their membership is removed.
- Assign a new primary SMTP address to the archived group and remove the old address to stop the delivery of new messages from users inside the tenant.
- Hide the group from Exchange clients (so it doesn't appear in Teams) and from address lists.
- Assign an appropriate sensitivity label to make the archived group private (if your tenant doesn't use sensitivity labels yet, you can change the access type of the group to be private instead).
- Update one of the custom properties available for group mailboxes to record some information about the group's archived status as well as information about who archived the group.

Although Microsoft doesn't offer an out-of-the-box method to archive inactive Groups, (Teams offers the option to archive a team by setting it to read-only mode), we can do the job with PowerShell. You can download a [script from GitHub](#) demonstrating how to archive groups using the steps described above.

A short time after the script runs, the group will disappear from clients. The exact time depends on the client. OWA is the fastest because it reads information from the online directory. It is slowest for Teams because of the need to synchronize the membership changes with Teams. Because we remove people from the group membership, they lose access to any resource available to the group like Planner or SharePoint.

## Archiving Hundreds of Groups

If you're in a situation where you need to archive hundreds of groups (or teams), it might be inconvenient to update and use a group attribute as the indicator that it should be archived. This situation often occurs in education, where large numbers of teams need to be archived at the end of the academic year. In the

enterprise, it might be the case that you scan for inactive groups and teams annually (perhaps using the [Groups and Teams Activity Report](#) PowerShell script) and archive those that aren't in use.

An alternative approach is to:

- Extract details of groups and write the data to a CSV file.
- Review the CSV file in Excel and remove groups that you want to keep (not archive). The advantage here is that someone who isn't skilled in PowerShell but knows how the groups and teams are used can do the review.
- Use the updated CSV file as input to the script.

For example, this code finds groups and creates a CSV file:

```
[PS] C:\> $Groups = Get-UnifiedGroup -ResultSize Unlimited | Select DisplayName, Notes, DistinguishedName, Alias, PrimarySmtpAddress, SensitivityLabel, ExternalDirectoryObjectId
$Groups | Sort DisplayName | Export-CSV -NoTypeInformation c:\temp\GroupsForReview.CSV
```

After editing the file to remove the groups you don't want to archive, we can then replace the call to *Get-UnifiedGroup* in [the script](#) with:

```
$ArchiveGroups = Import-CSV c:\temp\GroupsForReview.CSV
```

The rest of the code in the script is unaltered.

## Group Reactivation

To reactivate the group, all we need to do is to add a new owner, who can then add new members to allow them access to group resources. We should also reverse some of the settings made to group properties to make the group available to clients. The following command shows how to reverse some of the settings:

```
[PS] C:\> Set-UnifiedGroup -Identity ArchivedGroupAlias -HiddenFromAddressListsEnabled $False
-HiddenFromExchangeClientsEnabled:$False -CustomAttribute1 $Null
```

You should also change the assigned email address so that it doesn't include "archived" and update the display name. You don't need to change the setting to require email authentication unless you want to allow external users who are not guests to be able to email the group. Finally, if you use sensitivity labels, you should update the label assigned to the group to be whatever is appropriate for its new role.

## Tracking Archived Groups

As mentioned above, an optional but useful step is to record information about the archival of a group. Two custom properties store the status and information about when the archival occurred together with the username of the account that ran the script. The username comes from the credentials used to sign onto Exchange Online with the PowerShell session. The variable used will be different depending on how you connect. Marking archived groups in this manner makes it easier to find the groups if needed. Here's how we can find the groups archived with the script:

```
[PS] C:\> $Output = @{{Expression = {$_.DisplayName}; Label = "Group name"; width=30}, @{{Expression =
{$_.CustomAttribute2}; Label = "Archived on and by"}}
Get-UnifiedGroup -Filter {CustomAttribute1 -like "*Archived*"} | Format-Table $Output
```

Group name	Archived on and by

## Working with the Group Expiration Policy

Two sets of cmdlets are available to work with the group expiration policy:

- The *\*-MgGroupLifecyclePolicy* cmdlets manipulate the expiration policy settings.
- The *Add-MgGroupToLifecyclePolicy* and *Remove-MgGroupFromLifecyclePolicy* cmdlets are used when you want the expiration policy to process selected groups rather than apply to every group in the tenant. These cmdlets add or remove groups to the policy to bring them under the scope of the policy.

Because all Groups in a tenant can come within the scope of the group expiration policy, you should be aware that the settings you apply through the policy affect all applications that use Groups. In other words, the expiration of a group affects Teams, Planner, Yammer, Power BI, and other applications that use Groups to control their membership.

To retrieve the settings for the current expiration policy, you run this command:

```
[PS] C:> Get-MgGroupLifecyclePolicy | Format-List

AlternateNotificationEmails : Tony.Redmond@office365itpros.com
GroupLifetimeInDays       : 750
Id                        : 23036082-ac71-49ed-a8fd-24db5ad38379
ManagedGroupTypes       : Selected
AdditionalProperties      : {}
```

To update a policy setting, run the *Update-MgGroupLifecyclePolicy* cmdlet. In this case, we set the expiration interval to 750 days and update the backup group owner (the person who receives notifications about expiring groups when no group owner is available).

```
[PS] C:\> Update-MgGroupLifecyclePolicy -GroupLifecyclePolicyId (Get-MgGroupLifecyclePolicy).Id -
GroupLifeTimeInDays 750 -AlternateNotificationEmails Ben.Owens@Office365itpros.com
```

As an example of applying the policy to a selected set of groups instead of every group in the tenant, here is how to make the policy only process groups assigned a specific sensitivity label (identified by its GUID). We need to create a collection of groups marked as such and then add each group to the policy. The following code does the trick if you set the policy to process selected groups rather than all. Note that you cannot assign different expiration periods to individual groups. All groups covered by the policy use the same expiration period.

```
[PS] C:\> $Groups = (Get-UnifiedGroup | ? {$_.SensitivityLabel -eq "d6cfd185-f31c-4508-ae40-
229ff18a9919"})
$Id = (Get-MgGroupLifecyclePolicy).Id
$PolicyId = (Get-MgGroupLifecyclePolicy).Id
ForEach ($G in $Groups) {
    Add-MgGroupToLifecyclePolicy -GroupLifecyclePolicyId $Id -GroupId $G.ExternalDirectoryObjectId }
```

A more developed example scans the set of groups used by Teams and adds any which are not included in the expiration policy.

```
$PolicyId = (Get-MgGroupLifecyclePolicy).Id
$TeamsCount = 0
Write-Host "Fetching list of Teams in the tenant..."
[array]$Teams = Get-MgGroup -Filter "resourceProvisioningOptions/Any(x:x eq 'Team')" -All
ForEach ($Team in $Teams) {
    $Uri = " https://graph.microsoft.com/beta/groups/" + $Team.Id + "/groupLifecyclePolicies"
    $CheckPolicy = Invoke-MgGraphRequest -Uri $Uri -Method Get
    If ($CheckPolicy.Value.Id -eq $PolicyId) {
        Write-Host "Team" $Team.DisplayName "is already covered by the expiration policy" }
    Else {
        Write-Host "Adding team" $Team.DisplayName "to group expiration policy"
        Add-MgGroupToLifecyclePolicy -GroupLifecyclePolicyId $PolicyId -GroupId $Team.Id -ErrorAction
        SilentlyContinue
        $TeamsCount++ }}
Write-Host "All done." $TeamsCount "teams added to policy"
```

To remove a group from the expiration policy, run the *Remove-MgGroupFromLifecyclePolicy* cmdlet and pass the policy identifier and group identifier:

```
[PS] C:\> Remove-MgGroupFromLifecyclePolicy -GroupLifecyclePolicyId $PolicyId -GroupId $GroupId
```

## Reporting Groups Covered by The Expiration Policy

The set of groups covered by the expiration policy is visible in the Azure portal. Although no cmdlet is available to return the set of groups, you can find this information in two ways.

First, you can check each group in the tenant using a Graph request to confirm if a group is covered by the expiration policy:

```
[PS] C:\> [array]$Groups = (Get-Recipient -RecipientTypeDetails GroupMailbox -ResultSize Unlimited | Sort DisplayName)
ForEach ($G in $Groups) {
    $Uri = " https://graph.microsoft.com/beta/groups/" + $G.ExternalDirectoryObjectId +
"/groupLifecyclePolicies"
    $Status = Invoke-MgGraphRequest -Uri $Uri -Method Get
    If ($Status.Value) {
        $Days = (New-TimeSpan -Start $G.WhenCreated -End (Get-Date)).Days
        Write-Host "Group:" $G.DisplayName "Date created:" $G.WhenCreated "days old:" $Days }
}
```

An easier method is to check the group's *ExpirationTime* property, which Groups updates when it assesses a group against the expiration policy. We can therefore find the set of Groups subject to the expiration policy by checking the property. In this example, we find the set of groups with an expiration time set and report them in descending order:

```
[PS] C:\> [array]$ExpirationPolicyGroups = Get-UnifiedGroup | ? {$_.ExpirationTime -ne $Null} | Sort
{$_.ExpirationTime -as [DateTime]}
$ExpirationPolicyGroups | Format-Table DisplayName, ExpirationTime
```

DisplayName	ExpirationTime
GDPR Planning Mark II	28 May 2022 22:23:02
Office 365 for IT Pros	28 Jun 2022 09:42:57
Launch Party	11 Jul 2022 14:36:54
All-Employees	20 Aug 2022 20:23:38

Equipped with this knowledge, we can develop the code to report more interesting information. This version:

- Fetches the set of groups with an expiration time set.
- For each group, fetches the last renewed date from Azure AD.
- Calculates the days remaining before expiration.
- Calculates the age of the group in days (not used in the report, but it could be).
- Outputs a line into the report (a PowerShell list).

After processing all the groups, the report displays sorted by the number of days remaining before the group expires. You could pipe the output to the *Out-GridView* cmdlet to view on screen or to the *Export-CSV* cmdlet to export the data as a CSV file.

```
[PS] C:\> $Report = [System.Collections.Generic.List[Object]]::new(); $Today = (Get-Date)
Write-Host "Finding Microsoft 365 Groups to check.."
[array]$ExpirationPolicyGroups = (Get-UnifiedGroup -ResultSize Unlimited | ? {$_.ExpirationTime -ne
$Null} | Select DisplayName, ExternalDirectoryObjectId, WhenCreated, ExpirationTime )
If (!$ExpirationPolicyGroups) { Write-Host "No groups found subject to the expiration policy -
exiting" ; break }
Write-Host $ExpirationPolicyGroups.Count "groups found. Now checking expiration status."
ForEach ($G in $ExpirationPolicyGroups) {
    $Days = (New-TimeSpan -Start $G.WhenCreated -End $Today).Days # Age of group
    $LastRenewed = (Get-MgGroup -GroupId $G.ExternalDirectoryObjectId).RenewedDateTime
    $DaysLeft = (New-TimeSpan -Start $Today -End $G.ExpirationTime).Days
```

```

    $ReportLine = [PSCustomObject]@{
        Group      = $G.DisplayName
        Created     = Get-Date($G.WhenCreated) -format g
        AgeinDays  = $Days
        LastRenewed = Get-Date($LastRenewed) -format g
        NextRenewal = Get-Date($G.ExpirationTime) -format g
        DaysLeft   = $DaysLeft}
    $Report.Add($ReportLine)
} # End Foreach
CLS;Write-Host "Total Microsoft 365 Groups covered by expiration policy:"
$ExpirationPolicyGroups.Count
Write-Host ""
$Report | Sort DaysLeft | Select Group, @{n="Last Renewed"; e= {$_.LastRenewed}}, @{n="Next Renewal Due"; e={$_.NextRenewal}}, @{n="Days before Expiration"; e={$_.DaysLeft}}

Total Microsoft 365 Groups covered by expiration policy: 55

Group                                Last Renewed                Next Renewal Due            Days before
-----                                -
GDPR Planning Mark II                28 May 2022 22:23          16 Jun 2021 23:23           18
Office 365 for IT Pros                28 Jun 2022 09:42          17 Jul 2021 10:42           48
Launch Party                          11 Jul 2022 14:36          30 Jul 2021 15:36           62
All-Employees                         20 Aug 2022 20:23           8 Sep 2021 21:23           102

```

Two potential issues exist in this code. First, the *Get-UnifiedGroup* cmdlet is slow. Although it will fetch thousands of groups, you'll wait for this to happen. Second, a separate call to the *Get-MgGroup* cmdlet is needed to retrieve the last renewed date for a group because this property is not among those available through *Get-UnifiedGroup*. The solution to speed up the code is to replace these cmdlets with Graph API requests. An explanation of [how to upgrade the code is in this article](#).

## Managing Teams with PowerShell

The Teams PowerShell module is available in the [PowerShell Gallery](#). Microsoft updates the module every few months and you can install or update the module from the PowerShell Gallery. In terms of the administrative control over Teams, the module is capable of handling many of the operations available in the Teams admin center. [Cmdlets are available](#) to create teams (including a team for an existing group), list all teams in the tenant, update settings for teams, and create new channels.

It is best to use the most recent version of the module when working with Teams objects. This is especially true for Teams due to the ongoing work by Microsoft to refresh and improve cmdlets inherited from Skype for Business Online. To update to the latest release, run PowerShell as an administrator and use the following command to download and install the latest module.

```
[PS] C:\> Install-Module -Name MicrosoftTeams -Repository PSGallery -Force -Scope AllUsers
```

After installing the module, you run the *Connect-MicrosoftTeams* cmdlet to connect to the Teams service. To validate that you have the latest module, run the *Get-InstalledModule* cmdlet to check the version number.

```
[PS] C:\> Get-InstalledModule -Name MicrosoftTeams -AllVersions | Format-Table Name, Version
```

```

Name                Version
-----
MicrosoftTeams     4.4.1

```

### Preview Teams PowerShell Module

Microsoft publishes both the production (general availability) and public preview (beta) versions of the Teams module in the PowerShell Gallery. To install the preview release, check the PowerShell Gallery to find the latest

available version (or check the Teams PowerShell [release notes](#)) and then run the *Install-Module* cmdlet. To support the *AllowPreRelease* switch, you might have to update the *PowerShellGet* module as shown below:

```
[PS] C:\> Install-Module -Name PowerShellGet -Repository PSGallery -Force
Install-Module -Name MicrosoftTeams -RequiredVersion "4.5.9-preview" -AllowPreRelease -Scope
AllUsers
```

You can't run the generally available and preview modules together. If you need to switch, run the *Remove-Module* cmdlet to remove the cmdlets and functions for the currently loaded module from memory and then run the *Import-Module* cmdlet to load the desired version of the module (specified in the *Version* parameter).

## Permissions

Your account must have permissions to be able to run some of the Teams cmdlets.

- To create a new team: Tenant administrator, Teams service administrator, or be allowed to create new Groups.
- To change team settings, including updating team membership: Tenant administrator, Teams service administrator, or owner of the target team.
- To list team settings, including team membership: the account must be a member of the team.

## Finding Teams

Many scripts start by fetching the set of teams in a tenant and then go on to process each team. To return the set of teams, run:

```
[PS] C:\> $Teams = Get-Team
```

The *Get-UnifiedGroup* supports a server-side filter for the *ResourceProvisioningOptions* property, which should be set to "Team" when a group is team-enabled. Thus, we can also find the set of team-enabled groups with:

```
[PS] C:\> $Teams = Get-UnifiedGroup -Filter {ResourceProvisioningOptions -eq "Team"}
```

Although you can use *Get-UnifiedGroup* to find the set of team-enabled groups, it's often better to use the *Get-Team* cmdlet when working with teams. Because it does not return the large set of properties processed by *Get-UnifiedGroup*, *Get-Team* is usually faster to fetch objects. However, this approach has some limitations. For example, let's assume that you want to return the list of SharePoint Online sites used by Teams. There's no easy way to get this using the properties returned by *Get-Team*, but information about SharePoint is in the set of properties retrieved by *Get-UnifiedGroup*, so you can run a command like this:

```
[PS] C:\> $Teams = Get-UnifiedGroup -Filter {ResourceProvisioningOptions -eq "Team"}
$Teams | Format-Table DisplayName, SharePointSiteUrl
```

The most important properties returned by *Get-Team* are:

- Group identifier.
- Display Name.
- Description.
- MailNickName (otherwise called Alias).
- Visibility (called access type for Groups).
- Archived (either True or False to show if the team is in an archived state).

The group identifier is the most important value. It is a GUID that uniquely identifies the Azure AD group object for the team and is used as the input to most of the other cmdlets in the Teams module. In addition, you can use the group identifier to fetch information about the underlying group from Azure AD or the mail-enabled properties using the Groups cmdlets.

The list of teams is returned in order of creation date. To view the list in another order, use the *Sort-Object* cmdlet to sort by the *DisplayName*, *Description*, or *GroupId* properties.

```
[PS] C:\> Get-Team | Sort DisplayName
```

To list the teams that the currently logged-in user is a member of, specify the *User* parameter and pass their full User Principal Name:

```
[PS] C:\> Get-Team -User Kim.Akers@Office365itpros.com
```

You cannot use the *Get-Team* cmdlet to fetch details of the teams that another user belongs to. If you want to find the teams that a user belongs to, use *Get-Team* to fetch the full list of teams in the tenant and then *Get-TeamUser* to discover whether the user is a member of each team. The need to check the members of every team ensures that this will not be a fast process! Here's an example of the type of command needed:

```
[PS] C:\> Get-Team | ? {Get-TeamUser -GroupId $_.GroupId | ? {$_ .User -eq "Kim.Akers@office365itpros.com"}}}
```

This is a good example where a Microsoft Graph API delivers much better performance than PowerShell because the Teams endpoint supports the *joinedTeams* API specifically to facilitate fast access to the set of teams a user belongs to. Thus, we can use the *Get-MgUserJoinedTeam* cmdlet to do the job:

```
[PS] C:\> Get-MgUserJoinedTeam -UserId Kim.Akers@office365itpros.com
```

## Combining Teams Cmdlets with Other Modules

The limited properties of team objects returned by *Get-Team* mean that you often need to use other cmdlets, including those in other modules, to solve problems. For example, to get information from Azure AD about the team membership, use the group identifier as the input object identifier for *Get-MgGroupMember*:

```
[PS] C:\> [array]$Members = Get-MgGroupMember -GroupId 129bfa64-3d11-4d6f-b9a9-6c20ec03bd8d
ForEach ($Member in $Members) { Get-MgUser -UserId $Member.Id }
```

Another example is using the group identifier with the *Groups* cmdlets from the Exchange Online management module. For example, here's how to get the membership for the same team using *Get-UnifiedGroupLinks*:

```
[PS] C:\> Get-UnifiedGroupLinks -LinkType Member -Identity 129bfa64-3d11-4d6f-b9a9-6c20ec03bd8d
```

In a more complex example, we use *Get-Team* to update an array with details of the teams in a tenant and then use the *Get-UnifiedGroup* cmdlet to fetch some interesting properties about each group, and the *Get-TeamUser* cmdlet to fetch details of the team owners.

```
[PS] C:\> $Report = [System.Collections.Generic.List[Object]]::new()
[array]$Teams = Get-Team | Sort DisplayName
Write-Host "Reporting" $Teams.Count "teams"
ForEach ($T in $Teams) {
# Fetch information about the team - mostly by getting it from the Unified Group Object
Write-Host "Processing" $T.DisplayName
$G = (Get-UnifiedGroup -Identity $T.GroupId | Select GroupMemberCount, GroupExternalMemberCount,
PrimarySmtpAddress, AccessType, Classification, WhenCreated)
$Owners = (Get-TeamUser -Role Owner -GroupId $T.GroupId | Select Name)
$OwnerNames = $Null
$First = $True
ForEach ($O in $Owners) {
If ($First -eq $True) {
$OwnerNames = $O.Name
$First = $False}
Else {
$OwnerNames = $OwnerNames + ", " + $O.Name }}
$ReportLine = [PSCustomObject]@{
Team = $T.DisplayName
```

```

    Email           = $G.PrimarySmtpAddress
    Members         = $G.GroupMemberCount
    Guests          = $G.GroupExternalMemberCount
    Owners          = $OwnerNames
    Access          = $G.AccessType
    Created         = $G.WhenCreated
    Classification  = $G.Classification }
    $Report.Add($ReportLine) }
$Report | Export-Csv -NoTypeInformation c:\temp\Teams.csv

```

If your tenant uses sensitivity labels instead of classifications, remember to replace *Classification* with *SensitivityLabel*.

## Filtering Get-Team

The *Get-Team* cmdlet does not include a *Filter* parameter to ask the server to return a subset of teams. Instead, the *Get-Team* cmdlet supports several parameters to select common subsets. For instance, you can return a set of teams that are archived by running the command:

```
[PS] C:\> Get-Team -Archived $True
```

To return just the set of private or public teams, use *Private* or *Public* in the *Visibility* parameter. For instance:

```
[PS] C:\> Get-Team -Visibility Public
```

You can also combine these parameters to arrive at a more select subset of teams. For instance, this command returns the set of private teams that are archived that have Tony Redmond in their membership:

```
[PS] C:\> Get-Team -Visibility Private -Archived $True -User Tony.Redmond@office365itpros.com
```

Although server-side filtering isn't available with *Get-Team*, you can apply a client-side filter to the display name, classification, or description properties to find specific teams. For example:

```
[PS] C:\> Get-Team | ? {$_.DisplayName -Like "*Office*"} | Format-Table DisplayName, Description
```

We can combine a filtered lookup for a specific team to return its identifier and use that value to fetch information from Azure AD or the group:

```
[PS] C:\> $Group = (Get-Team | ? {$_.DisplayName -eq "Microsoft 365 Questions"} | Select GroupId)
Get-UnifiedGroup -Identity $Group.GroupId
```

The lack of good filtering for *Get-Team* doesn't matter as much when your tenant only has a few hundred teams. It becomes more of an issue as the number of teams increases.

## Creating New Teams

You can create a new team in two ways: either create a brand-new team from scratch or team-enable an existing group. If you add a new team from scratch, you also need to add some users.

The *New-Team* cmdlet applies in both cases. In this example, we create a new team from scratch and set its access type to *Private*, and apply one of the classifications defined for the tenant. To specify the owner of the new team, pass their User Principal Name in the *Owner* parameter. In this example, we also set the value of the *RetainCreatedGroup* parameter to *True* to tell PowerShell to keep the newly created Microsoft 365 group even if it's unable to create the new team:

```
[PS] C:\> $TeamId = (New-Team -DisplayName "Planning Co-Ordinators" -MailNickName Coordinators
-Description "Team for the folks who make sure we turn up in the right place at the right time"
-Visibility Private -Classification Confidential -Owner James.Ryan@office365itpros.com
-RetainCreatedGroup:$True)
```

**No sensitivity label:** The *New-Team* and *Set-Team* cmdlets do not support a method to assign a sensitivity label to a team. The example shown above assigns an old-style text-only classification. Until Microsoft updates the PowerShell module, you can create teams with sensitivity labels using the Graph API, or you can edit the team using the desktop or browser client to assign a label there.

The *\$TeamId* variable holds the GUID for the newly created team. We can use the GUID to identify the newly created team when we go to populate the team with members and owners. When you specify an owner for a new team, *New-Team* adds them as both a member and as an owner. The same occurs when you run the *Add-TeamUser* cmdlet. This code adds Brian Weakliam as a team member to the team and Don Vickers as both an owner and a member.

```
[PS] C:\> Add-TeamUser -GroupId $TeamId.GroupId -User Brian.Weakliam@Office365itpros.com -Role Member
Add-TeamUser -GroupId $TeamId.GroupId -User Donald.Vickers@Office365itpros.com -Role Owner
```

It's wise to add a delay of a few seconds before proceeding to populate membership for a new team. Waiting for a short period allows the provisioning process between Teams and Azure AD and Teams to complete and Teams to be ready to build the team roster. After populating the team membership, you can proceed to amend group settings and create some channels – or consider posting a welcome message to the General channel in the new team.

## Posting a Welcome Message to a New Team

A new team begins with no content. Sometimes it's nice to give members of the team some guidance about the purpose of the team and how to use it. PowerShell is used for administrative operations and the Teams module doesn't include a cmdlet to create and post messages to a Teams channel, but this can be done by calling the Graph API from PowerShell.

The basic requirement is to register a new app with Azure to act as the entry point for read-write access to Teams via the Graph. The details of how to register an app are described in the Microsoft Graph section. After registering an app, you can use its service principal to authenticate with the Graph to get an access token. The access token contains the permissions which allow the app to execute Graph API requests via PowerShell. In this example, we have created a new team and added the logged-in user to the team (otherwise they won't be able to post to a channel). The identifier for the new team is stored in the *\$GroupId* variable. We find the identifier for the General channel in the target team, use an array to compose some HTML text that we want to post, convert the array to JSON, and then post the message to the channel using the Graph.

```
[PS] C:\> $DisplayName = "Project Condor"
$GroupId = (Get-Team |? {$_.DisplayName -eq $DisplayName}).GroupId
$Description = (Get-Team |? {$_.DisplayName -eq $DisplayName}).Description
$MessageLine = "Team description:" + $Description
$ChannelId = (Get-TeamChannel -GroupId $GroupId |?{$_.DisplayName -eq "General"}).id
$apiUrl = "https://graph.microsoft.com/beta/teams/$GroupId/channels/$ChannelId/chatThreads"
# End up with something like https://graph.microsoft.com/beta/teams/41fd1ff0-099b-46b9-8b55-
e49c8e378383/channels/19:ba56cf956b0a47d991cb953906f605ee@thread.skype/chatThreads
$body = @{}
"rootMessage" = @{}
    "body" = @{}
        "contentType" = 1;
        "content" = "

# Welcome to $DisplayName

<b><i>Welcome to your new Team.</i></b><p>We have some basic rules of Teams etiquette that we would like you to follow to make everyone's life easier: </p><ul><li>Always start a new topic with a <strong>message subject</strong>. </li><li>When you have something to say about a topic, <strong>reply to that topic</strong> and don't start another thread.</li><li>Use <strong>@mentions </strong>to bring something important to the attention of individuals, teams, or a channel.</li></ul><p>$MessageLine</p>" }
}
$bodyJSON = $body | ConvertTo-Json
$msg = Invoke-RestMethod -Headers @{Authorization = "Bearer $accessToken"} -Uri $apiUrl -Method Post -Body $bodyJSON -ContentType 'application/json'

```

Figure 23-1 shows the welcome message generated by the code, which demonstrates the principle of what needs to be done to post to a team using PowerShell and needs some more work before it can be incorporated into the workflow to create a new team.

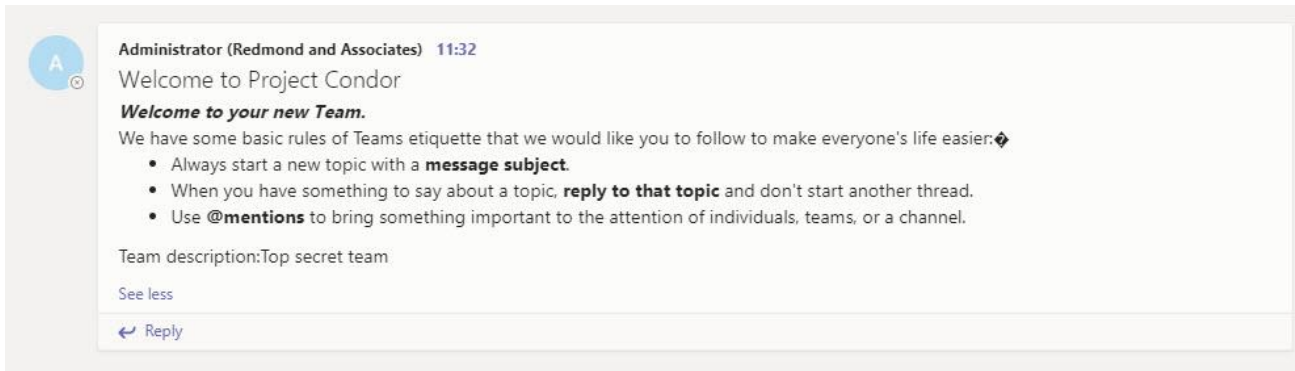

Figure 23-1: A welcome message for a new team generated by a Graph call through PowerShell

## Creating a Team from an Existing Group

To create a new team based on an existing group, run the *New-Team* cmdlet with the identifier (GUID) for the source group passed in the *Group* parameter. In this example, we fetch the group identifier and check if a group description (Notes) is available. If it is, a simple *New-Team* call is sufficient to ensure that the new team inherits the group description. If a description is not available, we create a description and include it in the call to *New-Team*:

```
[PS] C:\> $SourceGroup = Get-UnifiedGroup -Identity "BoardMembers"
If ($SourceGroup.Notes -eq $Null) {
    New-Team -Group $SourceGroup.ExternalDirectoryObjectId -Description "Team created from group" }
Else {
    New-Team -Group $SourceGroup.ExternalDirectoryObjectId }
```

You can only team-enable a group if your account is an owner of the group, a global administrator, or a Teams Service administrator.

## Controlling the Group Alias

The *Alias* property for the group created for a team can be specified in the *MailNickname* parameter for the *New-Team* cmdlet. This is an important property because it controls the generation of the SMTP primary address for the group (and team). If you don't specify a value to the *MailNickname* parameter, Teams generates unique values for the *Name*, *Alias*, and *PrimarySMTPAddress* properties (when the Teams client creates a new team, it creates the alias based on the team's display name). For example, here's what Teams generates for a new team as viewed with the *Get-UnifiedGroup* cmdlet when no value is passed for the *MailNickname*:

```
Name           : msteams_3e8d41_245f9292-29ca-4773-9240-de5fcee03853
Alias           : msteams_3e8d41
PrimarySmtAddress : msteams_3e8d41@office365itpros.com
```

The name given to the team is composed of "msteams," an underscore, and the team's Azure AD object identifier. The alias is derived from the name and the primary SMTP address uses the alias and the default tenant domain. Users only ever see the display name of a team, so having such a value in its name doesn't make any difference.

If you use Teams messaging for communication, you probably aren't concerned about the email address assigned to the group, so generating automatic values for these properties might not be an issue, but if you want to control the email address assigned to a new team, include the name you want to use in the *MailNickname* parameter. For instance, if I pass "Ignite2019" in the *Alias*, the following values are used:

```
Name : Ignite2019_bb966263-a263-4731-8454-afbd7be22b81
Alias : Ignite2019
PrimarySmtpAddress : Ignite2019@office365itpros.com
```

Make sure that the *MailNickName* you specify for *New-Team* is unique as the cmdlet will fail if you try to use a value that already exists for another object in the tenant.

## Creating an All-Employees Team

For tenants with 10,000 or fewer accounts, Teams supports org-wide teams with automatic maintenance of membership based on Azure Active Directory. The advantage of these teams is that Teams updates their membership in the background. We can do the same with PowerShell, with the advantage that we can impose whatever filter or other qualification we want to build the team membership. For example, the team might be built from all employees in one or more countries.

The group identifier is needed to add members to a team. Usually, we would fetch a group identifier using either the *Get-UnifiedGroup* or *Get-MgGroup* cmdlets, but in this case, we put the result of the call to the *New-Team* cmdlet in a variable so that the identifier is available for later use. Another interesting aspect is how we use *Get-Recipient* to fetch a set of current user mailboxes because it's the fastest method to get this data. You could also use *Get-Mailbox*, *Get-Recipient*, or *Get-MgUser* to create a set of input members. In all cases, remember to fetch the right property to get the user's primary email address as this is needed to identify the user when you add them to the team. No attempt occurs to check whether a user has a valid license to use Teams before we add them to the membership.

The last command in this code hides the new team from Exchange clients and sets a sensitivity label to control settings like guest access. Assigning a sensitivity label to a new team is only needed when you use labels for container management. You can't assign a sensitivity label with the *New-Team* or *Set-Team* cmdlets.

```
[PS] C:\> $Tenant = (Get-OrganizationConfig).Name
$Tenant = $Tenant.Split(".")[0]
$TeamName = "All-Employees ("+$Tenant+)"
$NewTeam = (New-Team -DisplayName $TeamName -MailNickName AllEmployeesTeam -Description "All-
employee team" -AllowCreateUpdateChannels $False -AllowDeleteChannels $False -
AllowCreateUpdateRemoveTabs $False -AllowCreateUpdateRemoveConnectors $False -AllowAddRemoveApps
$False)
$Mailboxes = (Get-Recipient -RecipientTypeDetails UserMailbox -ResultSize Unlimited)
$Owner = (Get-TeamUser -GroupId $NewTeam.GroupId -Role Owner)
# Add all the mailboxes except the owner, who's already there
ForEach ($M in $Mailboxes) {
    If ($M.WindowsLiveId -ne $Owner.User) {
        Add-TeamUser -GroupId $NewTeam.GroupId -User $M.WindowsLiveID -Role Member }
}
Set-UnifiedGroup -Identity AllEmployeesTeam -HiddenFromExchangeClientsEnabled -SensitivityLabelId
e42fd42e-7240-4df0-9d8f-d14658bcf7ce
```

The last two commands in the script hide the new team from Exchange clients and restrict the ability of team members to add or remove channels, connectors, and tabs from the team as it's unlikely that you would want to allow members to change the structure of an all-employees team. The resulting team is a skeleton that needs to be built out with channels, tabs, and apps. In addition, you should restrict posts to the general channel and add some owners to moderate what is often a busy forum. Finally, if you add new employees to the company after running the script, you must add them to the membership manually.

If your company has more than 10,000 employees, Yammer might be a better solution for an all-employees forum.

## Viewing and Updating Team Settings

Team settings control how users interact with a team.

- What members can do to affect content within a team.

- What guests can do inside a team.
- What use can be made of “fun” objects like GIFs and stickers inside conversations.

To see what members can do, run *Get-Team* as follows:

```
[PS] C:\> Get-Team -GroupId 72ee570e-3dd8-41d2-bc84-7c9eb8024dd4 | Format-List
AllowCreateUpdateChannels, AllowDeleteChannels, AllowAddRemoveApps, AllowCreateUpdateRemoveTabs,
AllowCreateUpdateRemoveConnectors, AllowOwnerDeleteMessages, AllowUserEditMessages,
AllowUserDeleteMessages, AllowTeamMentions, AllowChannelMentions

AllowCreateUpdateChannels      : True
AllowDeleteChannels            : True
AllowAddRemoveApps             : True
AllowCreateUpdateRemoveTabs    : True
AllowCreateUpdateRemoveConnectors : True
AllowOwnerDeleteMessages       : True
AllowUserEditMessages          : True
AllowUserDeleteMessages        : True
AllowTeamMentions              : True
AllowChannelMentions           : True
```

These values are all true, so we know that members of this team can:

- Create and update channels (*AllowCreateUpdateChannels*).
- Delete and restore channels (*AllowDeleteChannels*).
- Add or remove apps (*AllowAddRemoveApps*).
- Create, update, and remove tabs within channels (*AllowCreateUpdateRemoveTabs*).
- Create, update, and remove connectors within channels (*AllowCreateUpdateRemoveConnectors*).
- Team owners can delete all messages (*AllowOwnerDeleteMessages*).
- Members can delete their messages (*AllowUserDeleteMessages*).
- Members can @mention the team (*AllowTeamMentions*).
- Members can @mention a channel (*AllowChannelMentions*).

Guest members have the same rights as other members. However, you can control the ability of guests to add and remove channels with two settings. In this case, the settings are False, so guests cannot interfere with channels in this team.

```
[PS] C:\> Get-Team -GroupId 72ee570e-3dd8-41d2-bc84-7c9eb8024dd4 | Format-List
AllowGuestCreateUpdateChannels, AllowGuestDeleteChannels

AllowGuestCreateUpdateChannels : False
AllowGuestDeleteChannels       : False
```

To see the “fun stuff” settings for a team, use this command:

```
[PS] C:\> Get-Team -GroupId 72ee570e-3dd8-41d2-bc84-7c9eb8024dd4 | Format-List AllowGiphy,
GiphyContentRating, AllowStickersAndMemes, AllowCustomMemes

AllowGiphy          : True
GiphyContentRating  : moderate
AllowStickersAndMemes : True
AllowCustomMemes    : True
```

These settings tell us that:

- Giphy is enabled for the team (*AllowGiphy*).
- Moderate is selected for Giphy content (*GiphyContentRating*).
- Stickers and Memes are enabled for the team (*AllowStickersAndMemes*).
- Members can upload custom memes and use the memes in team conversations (*AllowCustomMemes*).

## Updating Team Settings

Apart from restricting channel creation for guests, the settings for the team that we've been looking at are quite liberal. You can update the settings for a team using the *Set-Team* cmdlet. Let's assume that we want to exert tighter control over channels, tabs, apps, and connectors and don't want to see custom memes used.

```
[PS] C:\> Set-Team -GroupId 72ee570e-3dd8-41d2-bc84-7c9eb8024dd4 -AllowCustomMemes $False
-AllowCreateUpdateChannels $False -AllowDeleteChannels $False -AllowAddRemoveApps $False
-AllowCreateUpdateRemoveTabs $False -AllowCreateUpdateRemoveConnectors $False
```

Remember that org-wide messaging and other policies applied to user accounts also affect how users interact with Teams and override the settings of an individual team.

## Updating Team Photos

Team owners can run the *Set-TeamPicture* cmdlet to update the image used for the team in listings. You can use PNG, JPEG, or GIF images, but make sure to size the image appropriately (100 x 80 pixels works well). Only owners can update the picture for a team. For example:

```
[PS] C:\> Set-TeamPicture -GroupId 34d68904-9d7c-4ef7-b715-eed283e80243 -ImageFile
c:\temp\TeamFile.jpg
```

If administrators need to update team pictures without becoming a team owner, they can run the *Set-UserPhoto* cmdlet to update the picture for a Microsoft 365 group. This also updates the team picture, so it's the best way to process team pictures centrally. For example:

```
[PS] C:\> Set-UserPhoto -Identity "Privacy Advocates" -PictureData
([System.IO.File]::ReadAllBytes("c:\temp\privacy.jpg")) -GroupMailbox
```

## Working with Team Membership

If you don't pass a value in the user parameter, the *Get-Team* cmdlet returns a list of the teams to which the logged-in user belongs. The cmdlet only returns three properties, the most important being the group identifier, or *GroupId*, which we use with most of the other cmdlets. This is the key to finding the group in Azure AD.

```
[PS] C:\> Get-Team | Format-Table GroupId, DisplayName, Description
```

GroupId	DisplayName	Description
8836e3ca-6531-402a-ac5f-b71c83d6affa	Mail Filter Patent	Discussing the Mail Filter patent
84fe8ec1-d85f-4564-a786-1f7bedd9862c	Engineering Testers	People who do testing for engineering
72ee570e-3dd8-41d2-bc84-7c9eb8024dd4	Office Chat	What's happening in the Office

If you pass the user principal name for an account to *Get-Team*, the cmdlet returns the set of teams that the user is a member of:

```
[PS] C:\> Get-Team -User Jane.Sixsmith@office365itpros.com | Format-Table GroupId, DisplayName,
Description
```

GroupId	DisplayName	Description
e7c971e0-653d-48ed-9611-4935bfebb6ca	Ongoing Budget Discussions	Budget planning team
9367a82e-9c65-4258-86fb-c2eb304c79ef	Privacy Advocates	Privacy in all its shape
15fe15f7-c2b9-4a2c-9ad8-bbd6a11d2d7f	Infrastructure and Technology Plans	Information relating to the

To list the membership of a team, use the *Get-TeamUser* cmdlet. This example outputs the display name (Name), role, and Azure AD account (User) for each member. Guest members are clearly marked.

```
[PS] C:\> Get-TeamUser -GroupId 72ee570e-3dd8-41d2-bc84-7c9eb8024dd4 | Format-Table Name, Role, User
```

Name	Role	User
----	----	----
Tony Redmond	owner	Tony.Redmond@office365itpros.com
Jeff Guillet	member	Jeff.Guillet@office365itpros.com
Administrator	member	Administrator@office365itpros.com
Vasil Michev (MVP)	guest	Vasil@Michev.info#EXT#@Office365itpros.onmicrosof...

You can output members with a specific role by including the `-Role` parameter and passing either *Member* or *Owner*:

```
[PS] C:\> Get-TeamUser -GroupId 72ee570e-3dd8-41d2-bc84-7c9eb8024dd4 -Role Owner
```

`Get-TeamUser` can return the membership of any team if you know the group identifier, which you can find out from Azure AD. For example:

```
[PS] C:\> Get-TeamUser -GroupId (Get-MgGroup -Filter "displayName eq 'Office 365 for IT Pros'").Id
```

Alternatively, use the `Get-UnifiedGroup` cmdlet to retrieve the group identifier:

```
[PS] C:\> Get-TeamUser -GroupId (Get-UnifiedGroup -Identity Hydra).ExternalDirectoryObjectId
```

`Get-TeamUser` returns the group membership for any kind of Azure AD group as the cmdlet does not check that the target group is a Microsoft 365 group. This proves that `Get-TeamUser` is simply another way to call the `Get-MgGroupMember` cmdlet. Likewise, the other `-TeamUser` cmdlets are proxies for the underlying `-MgGroupMember` cmdlets.

## Adding and Removing Team Members

The `Add-TeamUser` cmdlet adds a new member or owner to a team. Although Teams and Groups share a common membership list, you do not have to add an owner as a member of the team first as you do with the `Add-UnifiedGroupLinks` cmdlet. The `-Role` parameter tells `Add-TeamUser` what type of member the user is.

```
[PS] C:\> Add-TeamUser -GroupId 72ee570e-3dd8-41d2-bc84-7c9eb8024dd4 -User
"Don.Vickers@Office365itpros.com" -Role Member
Add-TeamUser -GroupId 72ee570e-3dd8-41d2-bc84-7c9eb8024dd4 -User Tony.Redmond@office365itpros.com -
Role Owner
```

Adding individual members to a team soon becomes a pain when there are more than a couple of new members to process. A simple loop through source data is a good way to add multiple users, as in this example which adds all the members of an email distribution list to a team. The code needs to check whether users in the distribution list are already members of the team, so we create a hash table holding the team members and use that to check a user's status. Building the table is a one-time operation that consumes some resources but checking an item against a hash table is much faster than an iterative loop through team membership. The key to the hash table is the display name of the mailbox or guest; the value is their email address and includes both local and guests. If you do not need to include guests, comment out the lines that create these entries. The table looks like this:

Name	Value
----	----
Robert Wille	rw99@outlook.de
Paul Cunningham	Paul.Cunningham@office365itpros.com
Stanislav Buldakov	sbuldakov@office365itpros.com
Mahmoud Magdy	memagdy@outlook.com

We can use the email address of mailboxes retrieved from the distribution list to check against the hash table to see if a member of a source distribution list is already part of the team. One issue always faced when using distribution lists as a source is how to handle the different recipient types that can be in the list. User mailboxes are straightforward because we can check whether they are in the team and add them if not. But then you must be able to deal with mail contacts, mail users, nested distribution lists, guest accounts, public

folders, and groups. This code only processes mailboxes and ignores the other recipient types. See [this post](#) to get an idea of how complex it can be to create a comprehensive script to report the membership of nested distribution lists.

```
[PS] C:\> $TargetGroupId = "8836e3ca-6531-402a-ac5f-b71c83d6affa"
$SourceDL = "GDPR Working Group"
#Create hash table to look up existing team members
$TeamMembers = @{}
Get-TeamUser -GroupId $TargetGroupId | % {
    $User = $_.User.toString()
    # Handle guests
    if ($User -like "*#EXT#") {
        $GuestUser = Get-MgUser -UserId $User
        $TeamMembers.Add($GuestUser.DisplayName, $GuestUser.Mail) }
    else {
        # local mailbox
        $Email = $_.User
        $User = $_.Name
        $TeamMembers.Add($User, $Email) }
}
$DLUsers = Get-DistributionGroupMember -Identity $SourceDL
ForEach ($U in $DLUsers) {
    Switch ($U.RecipientType){
        "UserMailbox" { # Mailbox - check and add if not found
            If ( $TeamMembers.ContainsValue($U.PrimarySmtpAddress)) -eq $False)
            { Add-TeamUser -GroupId $TargetGroupId -User $U.PrimarySmtpAddress -Role Member
              Write-Host "Mailbox" $U.Name "added to team" }
        }
        "MailUser" { # Could be a guest user
            Write-Host "Can't add Mail User" $U.Name "to the team. Please add them as a guest
user"; Break }
        "MailContact" {
            Write-Host "Teams doesn't support Mail contacts" $U.Name "not added"; Break }
        "MailUniversalDistributionGroup" {
            Write-Host "Need to do something with this nested DL" $U.Name; Break }
    }
}
```

The *Remove-TeamUser* cmdlet removes a member from a team. You do not have to specify the user's role. If you remove a team owner, the account is also removed as a member. The exception is when the owner being removed is the only owner for the team. In this scenario, Teams requires you to assign someone else (a current user or a new member) to be an owner to ensure that the team is not left ownerless.

```
[PS] C:\> Remove-TeamUser -GroupId 72ee570e-3dd8-41d2-bc84-7c9eb8024dd4 -User
"Don.Vickers@Office365itpros.com"
```

A tenant administrator or an account holding the Microsoft 365 User Management admin role can add a member to any group (and team) by fetching the group identifier with the *Get-UnifiedGroup* cmdlet and using it with *Add-TeamUser* to update membership for the selected team. This works even if a group is not team-enabled. For example:

```
[PS] C:\> Add-TeamUser -GroupId (Get-UnifiedGroup -Identity "Stock Market
Club").ExternalDirectoryObjectId -User Donald.Vickers@office365itpros.com -Role Member
```

Because a team always has an underlying group, you also can use the cmdlets that work against groups to view or modify team membership. However, any changes made through cmdlets like *Add-UnifiedGroupLinks* take extra time to be effective within Teams as the change must synchronize from Azure AD to Teams, so overall it is best to use the Teams cmdlets to manipulate team membership with PowerShell.

## Working with Channels

Channels can be standard (regular), private, or shared. To return the channels in a team, use the *Get-TeamChannel* cmdlet:

```
[PS] C:\> Get-TeamChannel -GroupId 72ee570e-3dd8-41d2-bc84-7c9eb8024dd4
```

Id	DisplayName	Description
19:534ebe8882364e68acd46935b126fdca@thread.skype	General	Exchange Grumpy Old ...
19:f1dc5034b5d54d01b97b14f2d37dfc31@thread.skype	The EHL0 blog	Posts from the EHL0 ...
19:d286c7126d6a406f84fb74981e9276c2@thread.skype	MVP Tweets	Tweets from MVPs
19:96a1c26a207642b8bbf7822cfd606f75@thread.skype	Bug Tracking	

This output doesn't show the channel type. To see this information, run *Get-TeamChannel* and specify the channel type (Standard, Private, or Shared) in the Membership parameter:

```
[PS] C:\> Get-TeamChannel -GroupId $GroupId -MembershipType Private
```

You cannot update the settings of the General channel. For other channels, the only settings updateable with the *Set-TeamChannel* cmdlet are the channel name and description. In this example, we update the name and description of a channel:

```
[PS] C:\> Set-TeamChannel -GroupId 72ee570e-3dd8-41d2-bc84-7c9eb8024dd4 -CurrentDisplayName "Service Updates" -NewDisplayName "Updates for Service Incidents" -Description "Incident information extracted from the Service Management API"
```

The *New-TeamChannel* cmdlet adds a channel to a team. For instance:

```
[PS] C:\> New-TeamChannel -GroupId 72ee570e-3dd8-41d2-bc84-7c9eb8024dd4 -DisplayName "Bug Tracking" -Description "A place to track bugs as we discover them in our favorite product"
```

If you don't specify the membership type for a new channel, Teams creates a standard channel. To create a private or shared channel, set its *MembershipType* to the appropriate type and make sure to include a channel owner, who must be a member of the team.

```
[PS] C:\> New-TeamChannel -GroupId $GroupId -DisplayName "Project Hydra" -Description "Discussions about the Hydra Project" -MembershipType Private -Owner Tony.Redmond@office365itpros.com
```

Once set, you can't change a channel type.

The *Remove-TeamChannel* cmdlet deletes a channel from a team. When you remove a private or shared channel, you also remove the SharePoint site belonging to the channel.

```
[PS] C:\> Remove-TeamChannel -GroupId $GroupId -DisplayName "Project Hydra"
```

## Private Channel Membership

You can populate the membership of a private channel with the *Add-TeamChannelUser* cmdlet. If you want to add a new owner for the channel, make sure that you add them as a member first. Here's an example:

```
[PS] C:\> Add-TeamChannelUser -GroupId $GroupId -DisplayName "Legal Discussions" -User Oisin.Johnston@Office365itpros.com
Add-TeamChannelUser -GroupId $GroupId -DisplayName "Legal Discussions" -User Oisin.Johnston@Office365itpros.com -Role Owner
```

To list the members in a private channel, run the *Get-TeamChannelUser* cmdlet.

```
[PS] C:\> Get-TeamChannelUser -GroupId $GroupId -DisplayName "Legal Discussions"
```

To remove a member from a channel, run the *Remove-TeamChannelUser* cmdlet. For example:

```
[PS] C:\> Remove-TeamChannelUser -GroupId $GroupId -DisplayName "Legal Discussions" -User
James.Ryan@office365itpros.com
```

Teams won't allow you to remove the last owner from a channel. If you need to remove someone who is the last owner, you'll have to add a member as the owner and then remove the old owner.

## Shared Channel Membership

Adding a member to a shared channel uses the same syntax as a private channel, but only if the member you add has a tenant account. You cannot invite an external member from another tenant using the *Add-TeamChannelUser* cmdlet, nor can you use the cmdlet to invite a team from the home tenant or an external tenant.

The *Get-TeamChannelUser* cmdlet doesn't list teams that are members of a shared channel. The cmdlet only returns individual members from the home and external tenants.

## Checking for Active Teams

Administrators often ask for a way to know what groups are enabled for Teams or the other resources available to groups. The *Get-UnifiedGroup* cmdlet returns the basic properties of groups, including the number of members, the URL for SharePoint resources, and whether connectors are enabled, including if a group is team-enabled. If you're already working with the Exchange Online PowerShell module and don't want to load another module just to fetch a list of teams, it's reasonable to use *Get-UnifiedGroup* for this purpose. However, in most situations, the *Get-Team* cmdlet is the right way to find the team-enabled groups in a tenant.

Knowing the set of teams in a tenant is one thing. Figuring out if the team is active is another. One approach to test for team activity is to use the *Get-ExoMailboxFolderStatistics* cmdlet to check the group mailbox to see if compliance records are present. As explained earlier, the substrate generates compliance records for messages in all standard channel conversations within a team. If the folder in a team's group mailbox holds some items, it is a good sign that the team has been active. The caveat is that the group mailbox does not hold compliance records for conversation activity in private and/or shared channels, so this activity does not show up when you check the number of compliance records in the group mailbox.

The script ([downloadable from GitHub](#)) makes a collection of all teams in the tenant and runs *Get-ExoMailboxFolderStatistics* for each team to check its activity level. The script generates a report with details of each team, including the last time something happened in a channel and the number of conversations per day. The script also assigns an active status based on the number of conversations per day. Again, it is easy to adjust the code to process a team differently. The code extract below shows how to extract the conversation statistics for a team:

```
[PS] C:\> $TeamsData = (Get-ExoMailboxFolderStatistics -Identity $G.Alias -FolderScope NonIpmRoot -
IncludeOldestAndNewestItems | ? {$_.FolderType -eq "TeamsMessagesData"})
If ($TeamsData.ItemsInFolder) {
    Write-Host "Processing" $G.DisplayName
    $TimeSinceCreation = (Get-Date) - $TeamsData.CreationTime
    $Count++
    $ChatCount = $TeamsData.ItemsInFolder
    $NewestChat = $TeamsData.NewestItemReceivedDate
    $ChatsPerDay = $ChatCount/$TimeSinceCreation.Days
    $ChatsPerDay = [math]::round($ChatsPerDay,2)
} #End if
If ($TeamsData.ItemsInFolder -eq 0) {
    Write-Host "No Teams compliance records found for" $T.DisplayName -foregroundcolor Red
    $ChatsPerDay = 0
    $NewestChat = "N/A"
    $ChatCount = 0
}
If ($ChatsPerDay -gt 0 -and $ChatsPerDay -le 2) { $ActiveStatus = "Moderate" }
```

```
Elseif ($ChatsPerDay -gt 2 -and $ChatsPerDay -le 5) { $ActiveStatus = "Reasonable"}
Elseif ($ChatPerDay -gt 5) { $ActiveStatus = "Heavy" }
```

The output of the script is a CSV file, which can be opened with Excel to format the data to meet your requirements. Several properties included in the report are extracted from groups. If you want to include extra group properties, you can add them to the *Select* statement piped from the call to *Get-UnifiedGroup* and include the properties in the output line generated for each group. It's also easy to get a quick oversight of the activity level within the tenant by grouping the assigned activity status like this:

```
[PS] C:\> $Report | Group ActiveStatus | Sort count -Descending | Format-Table Name, count
```

Name	Count
Moderate	38
Inactive	27
Reasonable	1

The *Get-ExoMailboxFolderStatistics* cmdlet is expensive in terms of the system resources it consumes, so running it to check hundreds of groups is impractical if you intend to create the report very regularly. The solution explored here is imperfect and flawed, but it shows what is possible by combining Teams cmdlets with cmdlets from other modules.

## Archiving a Team

The *Set-TeamArchivedState* cmdlet archives a team. As explained in the Managing Teams chapter, the archive process puts the messaging part channels into a read-only mode. Team members can access conversations, but they cannot add new topics. Team owners and administrators can add or remove members and can unarchive the team when they want. Optionally, the SharePoint Online site belonging to the team can also be put into a read-only state. In this code snippet, we put the group identifier for the team to archive into a variable and use it as input to *Set-TeamArchivedState*. The *SetSPOSiteReadOnlyForMembers* parameter controls if the SharePoint Online site is read-only (\$True) or not (\$False). The default is \$False.

```
[PS] C:\> $TeamId = "bd2c9ef7-909f-4466-8375-2467eb826c63"
Set-TeamArchivedState -GroupId $TeamId -SetSPOSiteReadOnlyForMembers:$True -Archived:$True
```

## Cmdlets to Manage Teams Policies

Some of the cmdlets to manage Teams policies originated in Skype for Business Online. Microsoft has modernized these cmdlets to remove the need to use basic authentication and incorporated the cmdlets in the Teams PowerShell module. In most cases, you won't need to use the cmdlets to create a new policy or tweak policy settings because it's easier to do this through the Teams admin center. However, if you want to apply a new or updated policy to many accounts, it's easiest and much faster to do this with PowerShell. Table 23-3 lists the seven most important cmdlet sets for policy management.

<b>Cmdlet Set</b>	<b>Purpose</b>
*-CsTeamsAppPermissionPolicy	Controls which apps Teams users can access. See <b>Permissions policies</b> under Teams apps in the Teams admin center.
*-CsTeamsAppSetupPolicy	Controls the set of apps pinned to the Teams app bar. See <b>Setup policies</b> under Teams apps in the Teams admin center.
*- CsTeamsCallingPolicy	Controls the calling policies available within a tenant. See <b>Calling policies</b> under Voice in the Teams admin center.
*- CsTeamsChannelsPolicy	Controls the org-wide settings for channels. See <b>Teams policies</b> under Teams in the Teams admin center.
*- CsTeamsFeedbackPolicy	Controls the display of feedback surveys and the Give feedback option for Teams clients. This policy isn't available in the Teams admin center.

*- <i>CsTeamsMeetingPolicy</i>	Controls the type of meetings users can create and the features they can use in meetings. <b>See Meeting policies</b> under Meetings in the Teams admin center.
*- <i>CsTeamsMessagingPolicy</i>	Controls the messaging features available to users. See <b>Messaging policies</b> in the Teams admin center.

Table 23-3: Important Teams policy cmdlets

Each set has a *Get-* cmdlet (fetch policy settings), *Set-* cmdlet (update policy settings), *New-* (create new policy of the type) and *Grant-* cmdlet (assign a policy to a user). For example, to assign a new Teams app permissions policy to all mailboxes in a tenant, you could run this code:

```
[PS] C:\> $Mbx = Get-Mailbox -RecipientTypeDetails UserMailbox -ResultSize Unlimited | Select
DisplayName, UserPrincipalName
ForEach ($M in $Mbx) {
    Write-Host "Processing" $M.DisplayName
    Grant-CsTeamsAppPermissionPolicy -PolicyName "New Teams App Permissions Policy" -Identity
    $M.UserPrincipalName }
```

The identity used as the input for the *Grant-* cmdlets is the account's user principal name. In the example above, Exchange Online mailboxes are used as the source of the identity. Another way of finding a set of accounts to use as input for granting a policy is to use the *Get-CsOnlineUser* cmdlet to fetch the set of users enabled for Teams. For example:

```
[PS] C:\> Get-CsOnlineUser | Grant-CsTeamsMessagingPolicy -PolicyName "Advanced Users"
```

## Update Teams Client Settings

The *Set-CsTeamsClientConfiguration* cmdlet updates the general client settings policy to control features such as email integration and whether the organization tab appears in channels. For example, this command updates the global client settings policy to disable Google Drive as a valid cloud storage location:

```
[PS] C:\> Set-CsTeamsClientConfiguration -AllowGoogleDrive $False -Identity Global
```

## Update Guest Settings for Teams

The settings that control the set of Teams functionality available to guests are managed with the *Set-CsTeamsGuestMessagingConfiguration* cmdlet. For example, to allow guests to chat with other users:

```
[PS] C:\> Set-CsTeamsGuestMessagingConfiguration -AllowUserChat $True
```

You can also disable chat during meetings for all or some users through the *MeetingChatEnabledType* setting in the *CsTeamsMeetingPolicy*. By default, the setting is *Enabled* to allow chat during meetings. To disable chat, change the setting to *Disabled* in a meeting policy and assign that policy to the target set of users.

## Using Cmdlets from Other Modules to Manage Teams

As obvious from the examples here and elsewhere in the book, other cmdlets in the Exchange Online and Azure AD modules are often useful when dealing with Teams. For instance, every group has twenty custom attributes for tenant-specific use. Fifteen (*CustomAttribute1* through *CustomAttribute15*) support single-value properties and five (*ExtensionCustomAttribute1* through *ExtensionCustomAttribute5*) support multi-value properties. You can populate these attributes with whatever values you need. For instance, you might want to add a department name to each team to track how many teams each department uses. In this example, we use the first single-value attribute to hold a department name.

```
[PS] C:\> Set-UnifiedGroup -Identity Team1 -CustomAttribute1 Marketing
```

Updating a multi-value attribute uses a different syntax:

```
[PS] C:\> Set-UnifiedGroup -Identity Team1 -ExtensionCustomAttribute1 @{Add="IT"}
```

When the attributes are set, you can easily retrieve just the teams for a specific department or generate reports sorted by department. For example, to process the teams that belong to the IT department, we can do something like this to fetch a list of groups stamped with a departmental value and then extract the membership for each team.

```
[PS] C:\> $Teams = (Get-Recipient -RecipientTypeDetails GroupMailbox -Filter  
{ExtensionCustomAttribute1 -eq "IT"})  
ForEach ($Team in $Teams) {  
    Write-Output $Team.DisplayName  
    Get-TeamUser -GroupId $Team.ExternalDirectoryObjectID  
    Write-Output "" } }
```

## Sending Messages with PowerShell

When you strip everything away, mail servers like Exchange Online are all about sending messages. Normally, you use a client to compose and send messages, but it is possible to do the job with PowerShell. Being able to create and send messages in code is often useful when the need exists to dispatch notification messages.

Three methods are available:

- **The *Send-MailMessage* cmdlet:** This is the most common method in use today. *Send-MailMessage* uses the SMTP AUTH protocol to connect to Exchange Online with basic authentication.
- **The *.Net SmtplibClient Class*:** You might come across older scripts that use a combination of the [.NET SmtplibClient](#) and [MailMessage](#) classes to send emails from PowerShell. This method exploits the .NET mechanism available to any programming language to create and send SMTP messages. Microsoft has deprecated this method and you should replace the code in any script which uses it to send an email.
- **The *SendMail* call from the Outlook Graph API:** Like other Graph APIs, *SendMail* uses modern authentication. As explained in the section about the Graph, it is relatively straightforward to convert a script using *Send-MailMessage* to use the Graph.

In the future, Microsoft might upgrade the *Send-MailMessage* cmdlet to force the SMTP AUTH protocol to use modern authentication. Until then, if you want to move away from basic authentication, you must use the Graph.

### Using Send-MailMessage

The code needed to create and send a message using the *Send-MailMessage* cmdlet is very simple. This example uses what's known as the authenticated client submission method (because it connects to a mailbox) and the following steps occur:

- Make sure that TLS 1.2 is used by the workstation where the script is run to negotiate a connection to Exchange Online. If this isn't done, Exchange will refuse the connection.
- Check whether suitable credentials to allow the script to send the message through an Exchange Online mailbox are available. If not, call the *Get-Credential* cmdlet to collect the credentials.
- Set up some basic parameters such as the SMTP server and port number to use. For Exchange Online, the server is smtp.office365.com and the port is 587.
- Create a basic HTML style for the body of the message.
- Add some text for the body. The example shows using text that includes HTML formatting commands. This approach works well for simple text, but for more complicated messages it's easier to create the HTML content in a text file and then read it into a variable using the *Get-Content* cmdlet. Apart from anything else, using a text file means that the script code doesn't need to be edited every time you want to change the message text.

- Populate the message parameters in an array and call *Send-MailMessage* to dispatch the message via the nominated mailbox. Exchange won't allow you to connect to a mailbox and messages with *Send-MailMessage* if the mailbox is blocked for SMTP AUTH submissions.

```
[PS] C:\> [Net.ServicePointManager]::SecurityProtocol = [Net.SecurityProtocolType]::Tls12
If (-not $SmtpCred) {
    $SmtpCred = (Get-Credential)}
$MsgFrom = $SmtpCred.UserName
$SmtpServer = "smtp.office365.com" ; $SmtpPort = '587' ; $MsgSubject = "Action Required"

$htmlhead="<html>
<style>
    BODY{font-family: Arial; font-size: 10pt;}
    H1{font-size: 22px;}
    H2{font-size: 18px; padding-top: 10px;}
    H3{font-size: 16px; padding-top: 8px;}
</style>"

$htmlBody = "<body>
<h1>Group Non-Activity Notification</h1>
<p><strong>Generated:</strong> $Date</p>
Please review the activity in the $GroupName group as it doesn't seem to have been used too
much recently. Perhaps we can remove it?"
$htmlMsg = $htmlHead + $htmlBody
# Construct the message parameters and send it off...
$msgParam = @{
    To = "Vasil.Michev@office36itpros.com"
    From = $MsgFrom
    Subject = $MsgSubject
    Body = $htmlMsg
    SmtpServer = $SmtpServer
    Port = $SmtpPort
    Credential = $SmtpCred }
Send-MailMessage @msgParam -UseSSL -BodyAsHTML
```

This code could be enhanced to include multiple addressees (separate the addresses with commas), including BCC and CC recipients, or by adding one or more attachments. If you want to send messages to more than a few recipients, remember that Exchange Online limits the number of messages any individual mailbox can send to 30 per minute. With this limit in mind, you might need to include a delay of a second or two after sending each message.

Very importantly, Exchange Online sends the messages created using this method using the credentials of a mailbox-enabled account. The mailbox must exist, and it must have enough remaining quota to store the copies of the messages in the Sent Items folder.

Exchange Online also supports direct send and connector-based methods to send messages from SMTP-enabled appliances. Often appliances use these methods to send notification messages when they finish processing a job. See [this article](#) for more information on these methods.

## Sending Multiple Messages

You can use the techniques explained above to send a message to multiple recipients. For example, you could read a list of addresses from a CSV file and loop through the set to create and send a message to each address. When you generate multiple messages like this, you need to be aware of two important points:

1. If you send more than 200 or so messages from a mailbox in a short period, Exchange Online will suspect that either the mailbox is sending spam or an attacker has compromised the account owning the mailbox. In either case, Exchange Online will block the mailbox from sending messages and flag a high-priority alert to the administrator. You can release mailboxes from a restricted status by [going to this page](#).

2. When sending a continuous stream of messages, a single SMTP connection is used. Exchange Online allows the connection to be open for a maximum of ten minutes before it drops. If you build a pause between messages into your script (with the *Start-Sleep* cmdlet), make sure that the number of messages processed multiplied by the number of seconds paused between each message does not exceed 600. If it does, reduce the number of messages or reduce the pause between each message.

# Understanding How to Use the Microsoft Graph to Manage Microsoft 365

The basic workloads originally brought the tools used on-premises to cloud automation. After its introduction in Exchange 2007, the focus for Exchange was PowerShell, which quickly became part of the Exchange administrator's toolkit as a powerful way to automate common operations. SharePoint also supports PowerShell, but the coverage of the SharePoint PowerShell module is less comprehensive and powerful than its Exchange counterpart. For this reason, developers usually prefer the SharePoint PnP ([Patterns and Practice](#)) initiative when they want to extend SharePoint functionality. For more information about SharePoint PnP, see the discussion in Chapter 8.

## The Microsoft Graph APIs

The services composing Microsoft 365 create a different environment from the on-premises world. For programmatic access to both user and system data, Microsoft's focus for development is a common method for programmatic access to all manner of entities taken from workloads drawn from across Microsoft 365. This is the [Microsoft Graph](#), a set of REST-based API that interact with endpoints for different workloads drawn from across Microsoft 365. An endpoint is something like mail, contacts, calendar, or groups. The Graph connects the different endpoints and the entities hosted by the endpoints. For example, interacting with a team means using data from:

- Azure AD (user and group).
- Exchange Online (mailbox and team calendar).
- SharePoint Online (site).
- Teams (rosters, channels, tabs, and other team-specific information).

Once a program successfully authenticates, it can consume any of the Graph APIs using standard HTTP requests without needing to reauthenticate. A program can fetch some data from Azure AD (like the membership of Microsoft 365 group for a team), discover who the team owners are, and retrieve details of events in the team calendar and the SharePoint Online sites used by shared channels. Despite the variation in the entities the program interacts with, the format of the requests are similar, and all the requests use the same access token granted by the authentication process.

Microsoft has deliberately made the Graph approachable by including support for a wide choice of development technologies. Programmers can use their preferred language to issue HTTP requests against the Graph endpoints. For example, GET requests fetch data while POST requests write data. Most of the time, requests follow the same approach whether they deal with user, group, or device data. However, because different product groups are responsible for different APIs, it's inevitable that some differences in implementation exist, even if the approach appears to be unified.

The Microsoft Graph is a critical part of Microsoft's platform. Microsoft developers use Graph APIs to create new applications like Teams and the mobile apps for many workloads within Microsoft 365. The Microsoft Graph also includes data from other services, such as the Microsoft partner portal and Microsoft's consumer

cloud services, meaning that programmers can mix and match data drawn from multiple sources within the same application. By using the Graph APIs, programmers can do the following:

- Access data from multiple applications.
- Traverse information users access to track their usage of the service.
- Understand data trends to be able to find data that is important to the tenant or groups of users.
- Build new tools and applications using Microsoft 365 data.

As programmers start to use the Microsoft Graph to build applications on top of Microsoft 365, Microsoft hopes that they will view Microsoft 365 as a complete fabric rather than limiting their vision in the same way as they would when working with a single application. This is the approach taken to create applications like Teams.

Although you can grab a PowerShell script from the Internet and run it straight away (subject to the execution policy on a workstation), the additional complications which exist, notably the need to create a registered app and set up whatever authentication the application uses, means that the same is not true for Graph-based applications. Once someone knows the process, taking code from elsewhere and adapting it to run in a tenant is reasonably straightforward.

## V1.0 and Beta

Workloads often support two endpoints. The V1.0 endpoint is the production-ready fully-supported version. It is the endpoint that Microsoft wants people to use. The beta endpoint is under active development and API requests executed against this endpoint or the results they return can differ over time. Microsoft can change the beta endpoint without warning and without any documentation, so some risk exists in using this endpoint over V1.0. However, sometimes developers need to use the beta endpoint because it supports specific functionality required by their code. Accessing license information for Azure AD accounts is a good example of functionality that was only available through the beta endpoint for a long time.

Although it is preferable to use the V1.0 endpoint whenever possible, it's certainly permissible to use the beta endpoint, even in production, once you understand the risk. Indeed, many of the Microsoft administrative portals have used the beta endpoint to make new features available to customers. However, after Microsoft upgrades the V1.0 endpoint to support whatever feature you need, it's wise to redo your code to use it rather than the beta endpoint.

## Graph Permissions

Not all is rosy and perfect with the Graph. In exchange for its power, some conditions exist to gain entry. One example is the requirement that Graph applications must authenticate against Azure AD; to make your code do this you have to have a good understanding of how Modern Authentication (OAuth 2.0) works and how to request the necessary permissions to run the API requests necessary to interact with data. Likewise, your Graph applications must gain consent to use (the right) permissions in the target Azure AD tenant to work. Graph permissions break down into two sets:

- **Delegated permissions** operate as if a signed-in user runs the query. Some Graph APIs, like Planner, only support delegated permissions. An app using delegated permissions can never gain more permission than the signed-in user. For example, even if the app is granted the *User.ReadWrite.All* permission (the ability to read and write the user profile of every account in the organization), the app can only access the accounts that the signed-in user can. If the signed-in user holds the global administrator or user administrator role, the app can use the administrative permissions assigned to their account to access all accounts. If not, the app can only update the profile of the signed-in user's account. See [this article](#) for more information about how delegated permissions combine with those held by an account to create the set of effective permissions for use with data.

- **Application permissions** run without a signed-in user. These permissions are suitable for unattended automation such as apps running as background services or as daemons. Because apps receive the full benefit of application permissions, only administrators can grant consent when an app receives these permissions. Unlike the limitation placed on delegated permissions, an app can use an application permission like *User.ReadWrite.All* to access every user account in the tenant.

Apart from guessing what Graph permissions are necessary for an action, three methods are available to find this information:

1. Use the Graph Explorer (explained below). After running a query, the Modify permissions tab shows what permissions allow the query to run.
2. Read the Graph documentation. The documentation for each API lists the delegated and application permissions it supports.
3. Use the *Find-MgGraphPermission* and *Find-MgGraphCommand* cmdlets from the Microsoft Graph PowerShell SDK. These cmdlets list the permissions necessary to perform actions against different objects (like users or groups) with SDK cmdlets. See the later explanation for more detail.

Sometimes these methods will list several permissions which support an action. The Graph operates on a least permission model, meaning that you should select the permission with the least capabilities to perform an action. For example, to list users, use the *Users.Read.All* permission instead of the *Users.ReadWrite.All* permission. As we'll discuss later, the danger exists that apps used to run Graph API requests can become over-permissioned over time, so it's wise to keep an eye on the set of permissions an app has.

## Registered Azure AD Apps

To execute Graph API requests, a PowerShell script must prove it has the permissions to run the requests. In many situations, administrative processing requires permission to access data across a range of accounts using application permissions as described above. In these scenarios, it is necessary to register an app in Azure AD. A registered app acts as a container to hold permissions and secrets (see below). It also has a service principal that can authenticate with Azure AD to secure an access token confirming the permissions held by the app. According to a Microsoft Graph architect, you can think of a service principal as a convenient object to hold consents granted to an app. The service principal takes the same name as the registered app. You can use the service principal to track sign-ins by the app through the Azure AD admin center or via a query to the Graph *SignIn* API.

To register a new app, go to the App registrations section of the Azure AD admin center. You'll then need to add:

- The name of the app. The name doesn't matter as only administrators will likely see this detail. However, it is a good idea to give apps names that indicate their function.
- The supported account types. In most cases, this choice is *accounts in the organization only*. However, you can create apps that can run in any Azure AD tenant.

You can then add app secrets and certificates to the app for use in authentication and define the set of permissions from the Microsoft Graph and other APIs that you want the app to use. Figure 23-2 shows the properties of an app called *GetTeamsList*. The application (client) identifier and the directory (tenant) identifier are critical elements needed for authentication. We can also see that the application has an app secret and that its use is limited to the organization.

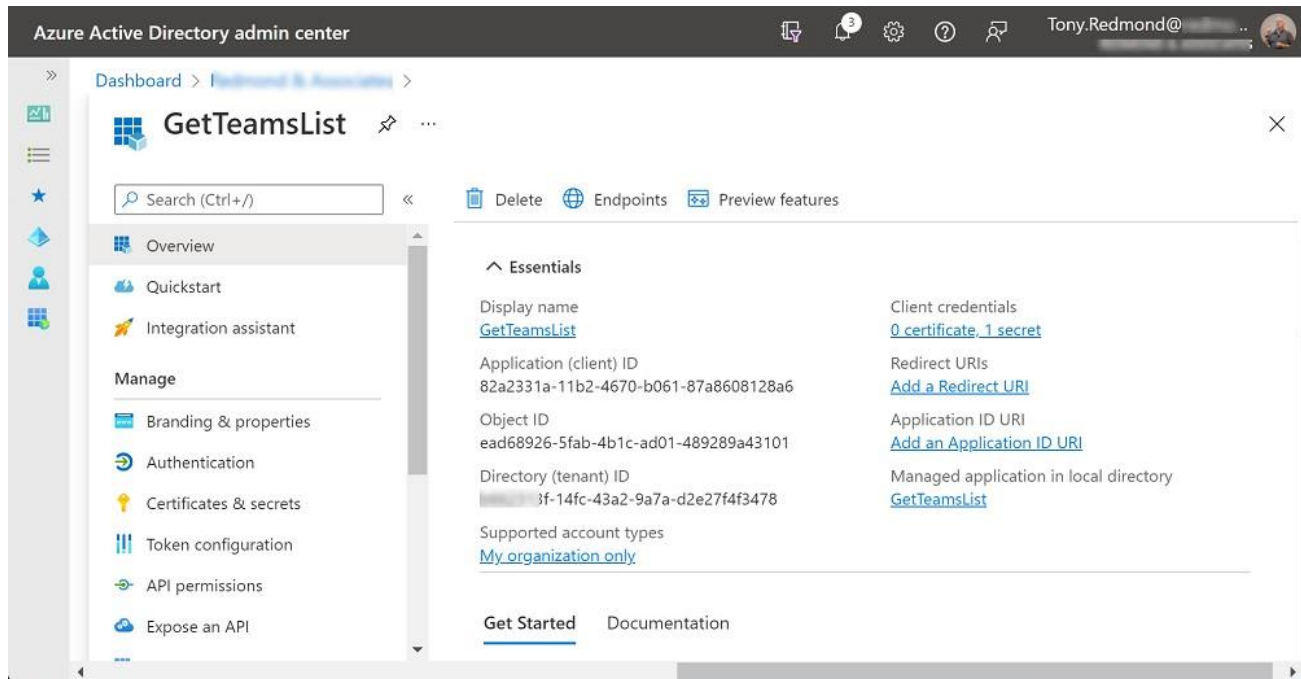

Figure 23-2: Properties of a registered application in the Azure AD admin center

The API permissions option in the menu allows administrators and app owners to define permissions in the set that an app can use. You can browse through the set of permissions available for the Graph and other APIs and mark those needed by the app (Figure 23-3). As noted above, before it can use an application permission, an administrator must grant consent to the app (see the Identities chapter). If limited to their data, a user can sometimes grant approval for an app to use a permission. The important point is that you should limit the permissions granted to an app to those necessary for the app to function.

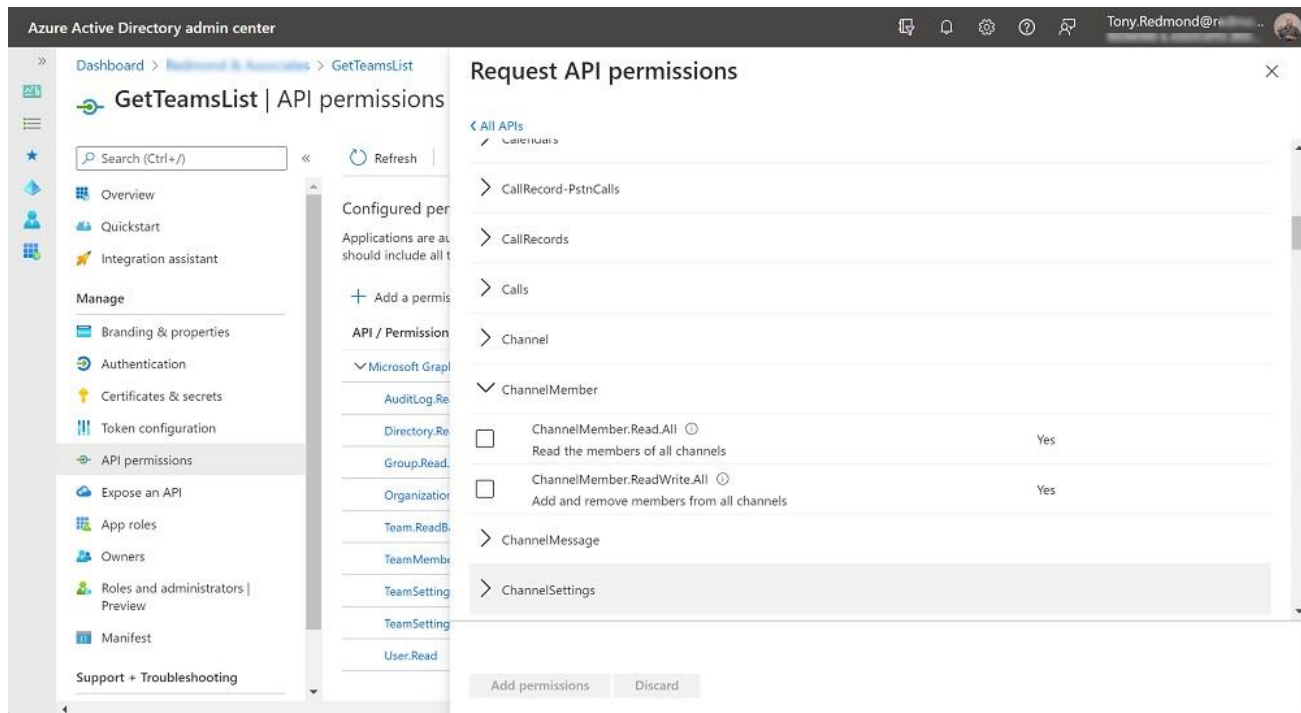

Figure 23-3: Adding permissions to a registered application

If you're unsure about the permissions needed by an app, you can use the Graph Explorer to run a test query and see what permissions the Explorer reports, and then grant consent for those permissions to the app. Sometimes an app needs unexpected permissions to access data. For instance, if a group has a hidden

membership, an app needs the *Member.Read.Hidden* permission to read its membership. Hackers often try to have elevated permissions assigned to apps that they use to retrieve data, so it's a good idea to [keep an eye on consents](#) granted to apps within the organization. It's also wise to limit the permissions granted to individual apps to make sure that they do not become targets for compromise.

## Client Secrets and Certificates

For unattended operations, apps can authenticate with client secrets or certificates. A client secret is a string generated by Azure AD for a registered app. The developer wishing to use the client secret must note it down at the time of creation as thereafter Azure AD obscures the string. A client secret can last up to 24 months. Using client secrets is convenient during the development and testing of a script intended for unattended operation, such as a script executed on a scheduled basis by an Azure Automation runbook. However, when the time comes to deploy the script in production, client secrets can represent a potential security vulnerability because if an attacker secures the application identifier for a registered app, the tenant identifier, and the client secret, they can use the three pieces of information to authenticate using the service principal for the app and access whatever data the app has permission to access. Although attackers can also compromise certificates, it requires more effort and certificates are safer. For this reason, you should use certificates to authenticate unattended jobs.

Equipped with:

- The application (client) identifier.
- The tenant (organization) identifier.
- A certificate or app secret to prove its identity.
- Consent to use permissions necessary to access data.

We can proceed to ask Azure AD for an access token to use in a PowerShell script.

## Getting an Access Token

Azure AD issues [OAuth 2.0 and OpenID Connect bearer tokens](#) to applications when they authenticate. Three types of tokens are available:

**ID tokens** prove a user's identity. For example, after a user enters their credentials into a client to sign in to Azure AD successfully, Azure AD issues an id or authentication token. The client can then use the id token to access resources as the signed-in account.

**Access tokens** obtain access to additional resources over and beyond what is available through an authentication token. When you create a registered app in Azure AD and use the service principal of the app to authenticate against Azure AD, the list of permissions granted to the app allows access to the additional resources such as data accessed through Graph API requests.

**Refresh tokens** are obtainable using either an Id or access token. Tokens have fixed lifetimes and expire (become invalid) at the end of the time. The usual lifetime for an access token issued to an app to access resources via the Graph API is one hour. Apps that support Azure AD continuous access evaluation (CAE) extend token validity to 28 hours because the apps can revoke access immediately when necessary. An app that makes just a few Graph API requests through PowerShell and then exits might only need the original access token. However, if the app executes Graph API requests for longer than the lifetime of the access token, it must use the refresh token (from the original access token) to acquire a new access token before the original token expires. If the app doesn't refresh its access token, any Graph API requests run after the access token expires will fail.

Sample PowerShell code to obtain an access token using an Azure AD registered app is below. You can see definitions for the application identifier, tenant identifier, and client secret in variables used to construct a URI

and body for input to the *Invoke-WebRequest* cmdlet. The URI points to the endpoint responsible for issuing the access tokens.

```
[PS] C:\> # Define the values applicable for the application used to connect to the Graph
# These variables vary from tenant to tenant and app to app
$AppId = "82a2331a-11b2-4670-b061-87a8608128a6"
$TenantId = "b662313f-14fc-43a2-9a7a-d2e27f4f3478"
$AppSecret = 'Mco7Q~D-IQTsaQYSRPLo01ctw4b1Hsw0D_zQ9'

# Construct URI and body needed for authentication
$uri = "https://login.microsoftonline.com/$tenantId/oauth2/v2.0/token"
$body = @{
    client_id      = $AppId
    scope          = "https://graph.microsoft.com/.default"
    client_secret  = $AppSecret
    grant_type     = "client_credentials"
}
# Get OAuth 2.0 Token
$tokenRequest = Invoke-WebRequest -Method Post -Uri $uri -ContentType "application/x-www-form-urlencoded" -Body $body -UseBasicParsing
# Unpack Access Token
$Token = ($tokenRequest.Content | ConvertFrom-Json).access_token
```

The *\$Token* variable stores the access token issued by Azure AD. If you examine the token, it won't make much sense because the token is a structured JSON web token object encoded in [base64url](#) and signed. However, if you copy the variable and paste it into [the jwt.ms site](#), the site decodes the token, and you can see that it contains a list of claims:

```

}
.[Signature]
```

The deciphered token divides into three parts: header, payload, and signature. The aim of a token is not to hide information, so the signature is not protected by encryption. Instead, it's signed using a private key by the issuer of the token. Details of the algorithm and private key used to sign an access token are in its header. An application can [validate the signature of an access token](#) if necessary, but this is not usually done when

running a PowerShell script. The payload is the location for the claims made by the token and is the most interesting place to check.

The list of claims in the payload of an access token includes simple claims and scopes (groups of claims). A claim is an assertion about something related to the token. In this case, the claims tell us about the tenant, the app name, the app identifier, the security token service (STS) which issued the token, and the issuance time for the token and its expiration time (both in Unix epoch time, where 1644837672 means 11:21:12 GMT on February 14, 2022). Scopes are a logical grouping of claims, and they can serve as a mechanism to limit access to resources. The roles claim contains a scope of Graph API permissions starting with *TeamSettings.ReadWriteAll* and ending with *AuditLog.Read.All*. Therefore, we know this app has consent from the organization to use the permissions stated in the scope when it executes Graph API requests.

After obtaining an access token, the script can then use the token to make Graph APIs requests. For instance, here's how to retrieve the set of user accounts from Azure AD (note the escaping required by PowerShell before the *\$filter* operator). The access token is in the *\$Headers* variable included in the *Invoke-RestMethod* command.

```
$Headers = @{Authorization = "Bearer $token"}  
  
Write-Host "Fetching user information from Azure AD..."  
$Uri = "https://graph.microsoft.com/v1.0/users?&`$filter=userType eq 'Member'"  
[Array]$Users = (Invoke-RestMethod -Uri $Uri -Headers $Headers -Method Get -ContentType  
"application/json")  
$Users = $Users.Value
```

## Summarizing Graph Access for PowerShell Scripts

In summary, to use Graph API requests in a PowerShell script, you need to:

- Register an app in Azure AD. As explained earlier, the app is the point of interaction with Graph APIs.
- Know the tenant identifier. As mentioned above, several ways exist to retrieve the tenant identifier. The important thing is that you know the identifier when the time comes to authenticate the app to Azure AD.
- Grant consent for the permissions needed by the Graph API requests the app runs to access data. [Microsoft documentation](#) lists the available permissions and those needed to perform different operations. Ensure that an administrator grants the app consent only for the permissions required to access the data it processes and isn't over-permissioned.
- Use the app identifier, app secret, and tenant identifier to [request an access token](#) from the token endpoint (other methods can be used with PowerShell to authenticate an app against the Graph – [here's an example](#)). The response to a successful request is an access token that attests to the right of the app to use its assigned permissions to access data. The authorization header for Graph API calls includes the access token. Access tokens expire after an hour, so the app must renew the token periodically during long-running programs.
- Use the PowerShell [Invoke-WebRequest](#) or [Invoke-RestMethod](#) cmdlets to send HTTPS queries to run against the Graph. For example, you use a GET command to request information. *Invoke-RestMethod* understands the format of the output generated by REST APIs and parses the JSON output to create PowerShell objects. We recommend using *Invoke-RestMethod* with Graph API calls whenever possible.
- To use [advanced queries against Azure AD](#) (for objects like groups, members, and owners), the header passed in the query must include *ConsistencyLevel = eventual*. Consistency is a concept used by distributed databases to describe the accuracy of data given that the query must fetch from multiple places (as in a Graph database). [Eventual means that the data is highly available but might suffer from accuracy](#) due to write latency or other influences.
- The script processes the data returned by the Graph. It's usually best to convert the data from JSON format to make it more accessible in PowerShell.

- If the app receives consent for the necessary permission, it can add data by sending a POST request to the Graph API. You can update data with a PATCH command and remove information with a DELETE command.

Using Graph APIs in PowerShell scripts is not difficult to master or hard to code. Practice makes perfect.

# Approaching the Use of Graph API Requests with PowerShell

Traditionally, the role of PowerShell was to automate administrative operations. You can also use Graph APIs to automate administrative operations and access content stored in different repositories, like Teams, Outlook, and Planner, making it possible to read and write conversations, files, and shared calendars, none of which PowerShell can access. To close the gap between PowerShell and the Microsoft Graph, developers can combine PowerShell and the Graph by making Graph API calls using the *Invoke-RestMethod* and *Invoke-WebRequest* cmdlets. As described later, the [Microsoft Graph PowerShell SDK](#) makes it easier to include Graph API calls in scripts using PowerShell cmdlets which act as a wrapper around Graph API calls.

Although it might seem a good idea to always use Graph API calls to access Microsoft 365 data through PowerShell, we recommend a more measured four-step approach:

- **Sketch out the solution:** Understand what source data is available and how to access it. Define the expected output and the processing needed to achieve the result. Make an initial selection of PowerShell modules and Graph APIs which might be useful, understanding that some data is only accessible to the Graph (and might need a beta API). In addition, some Graph APIs have limitations, such as the lack of administrator access to Planner data. Do an internet search to see if anyone has already written code to do what you want or something similar. Never reinvent the wheel if someone else has one to use.
- **Code in PowerShell first:** It's often wise to write the initial code in PowerShell before introducing any Graph APIs. The code you write might work well enough to be the solution you need without doing any further work. This is often the case when a small amount of data is involved (say, fewer than a couple of thousand mailboxes or groups), in which case PowerShell can do the job in a reasonable timeframe without any need to introduce Graph API calls. Staying with PowerShell cmdlets avoids the overhead of creating a registered app in Azure AD, maintaining client secrets, including API calls in scripts, and so on, all of which are important factors to consider. The caveat here is that scripts written for background processing that use certificate-based authentication may need to use registered apps.
- **Speed Things Up:** Usually, the biggest advantage gained through using Graph APIs is speed, especially when fetching large numbers of objects. The next step is to find places in the code where cmdlets like *Get-UnifiedGroup* take a long time to execute and consider replacing those cmdlets with Graph APIs.
- **Adjust for Production:** Every tenant has their view on how to run PowerShell scripts in production. After developing a script that runs interactively, you might need to change it to run as a background process using Azure Automation. During this process, you'll probably need to change the authentication method to use certificates instead of client secrets or user/password credentials. Because people adjust scripts for production usage, the code explained in books and articles is often intended to demonstrate principles rather than be a fully worked-out solution.

The most important point in the checklist is the internet search for code. For example, many working examples of using Graph APIs in scripts are available in the [Office 365 for IT Pros GitHub repository](#). If you don't find a suitable script to remove the need to create anything new, you'll probably find the basis or starting point for what you want to do. Given the rich search facilities available, it is astonishing that people

post questions in forums when it is perfectly obvious that they haven't done the basic research to uncover details that can help solve their problem.

## Comparing PowerShell and the Graph

Table 23-4 compares PowerShell cmdlets and Graph API calls. This is not an extensive comparison. Instead, it serves to underline the point that PowerShell is easier to work with data, but Graph API calls are faster. In general terms, a good approach to take is to prototype and prove that a solution works with PowerShell, and then attempt to replace PowerShell cmdlets with Graph API calls to increase performance where necessary.

	<b>PowerShell</b>	<b>Graph API calls</b>
<i>Access</i>	Must load appropriate module before using cmdlets. Interaction through command-line, ISE, or scripts.	Must use a registered Azure AD app to connect to Graph API endpoints after obtaining an access token. Interaction through programs (including scripts).
<i>Data returned</i>	PowerShell objects.	CSV, JSON, or OData.
<i>Filters</i>	Depends on the cmdlet. Supports both server-side and client-side filtering.	Depends on the API call. Graph APIs return data (filtered if necessary) and the client can apply extra filters.
<i>Processing</i>	PowerShell supports extensive methods to process objects of different .NET types.	Graph API calls fetch and update data. Any language capable of calling the Graph API can process the data returned by the API.
<i>Use for</i>	Ad-hoc queries and maintenance. Scripts that run against a few hundred objects.	Structured regular maintenance involving anything up to tens of thousands of objects.

Table 23-4: Comparing PowerShell cmdlets and the Graph API

## Graph Pagination

To maintain performance and conserve resources, the Graph returns a limited set of objects when you make calls to fetch information about Groups, Teams, and other types of data. This is referred to as a page of data and several pages might need to be retrieved to fetch the full set of objects you want to process. [The Graph documentation](#) says "When a result set spans multiple pages, Microsoft Graph returns an `@odata.nextLink` property in the response that contains a URL to the next page of results." In effect, the nextlink is a URL to tell the Graph the next set of data to return if an application wishes to request that data.

Therefore, when a script uses the `Invoke-WebRequest` cmdlet to fetch Graph data, the code should check the presence of the nextlink to see if more data is available and continue doing so until the nextlink is null. Here's an example that fetches all the teams in a tenant. The code:

- Fetches the first page of data using `Invoke-WebRequest`. Notice the use of the escape (backtick) character when forming the Uri because a \$ sign precedes the Graph filter qualifier.
- Details of the retrieved teams are inserted into a [PowerShell hashtable](#). A hashtable can only contain two properties (key and value), so it's suitable for storing the group identifier (GUID) and the display name for each team. If you want to store more information, create and populate an array or use a [generic list](#) instead.
- Examine the nextlink and if it is not null, make a further call to fetch the next page of data. As the code fetches each page, it updates the data in the hashtable.
- This process continues until the nextlink is null. The hashtable now holds details of all teams.

```
[PS] C:\> $headers = @{Authorization = "Bearer $token"}
$uri = "https://graph.microsoft.com/V1.0/groups?`$filter=resourceProvisioningOptions/Any(x:x eq 'Team')"
```

```
$Teams = Invoke-WebRequest -Method GET -Uri $Uri -ContentType "application/json" -Headers $headers |
ConvertFrom-Json
$TeamsHash = @{}
$Teams.Value.ForEach( {
    $TeamsHash.Add($_.Id, $_.DisplayName) } )
$NextLink = $Teams.'@odata.NextLink'
While ($NextLink -ne $Null) {
    $Teams = Invoke-WebRequest -Method GET -Uri $NextLink -ContentType $ctype -Headers $headers |
ConvertFrom-Json
    $Teams.Value.ForEach( {
        $TeamsHash.Add($_.Id, $_.DisplayName) } )
    $NextLink = $Teams.'@odata.NextLink' }
```

To process the teams, we can loop down through the information in the hashtable and extract the group identifier and the display name for each team. The GUID can be used to fetch more data using cmdlets like *Get-Team*, *Get-UnifiedGroup*, and so on.

```
[PS] C:\> ForEach ($Team in $TeamsHash.Keys) {
    $TeamId = $($Team); $TeamDisplayName = $TeamsHash[$Team] #Populate variables for the team
    Write-Host "Team" $TeamDisplayName "now being processed" }
```

The same technique works with other Graph endpoints, including those used to retrieve documents from a SharePoint library, or sign-in information for Azure AD accounts. [This article](#) includes a useful PowerShell function to retrieve information from the Graph using pagination to fetch all available data.

## Graph Speed

Although it is more complicated to create a PowerShell script that uses Graph API calls, the Graph API calls are much faster at fetching data. This isn't so important when only a tenant only has a few hundred mailboxes, accounts, or groups; it becomes more interesting once several thousand objects are involved.

A good example of where the combination of PowerShell and Graph APIs work well is to retrieve and process large collections of groups. PowerShell can do this using the *Get-UnifiedGroup* cmdlet, but progress is slow in an organization where large numbers of groups exist. The same is true for the *Get-Team* cmdlet in the Teams module (very slow in the past but improved in recent versions of the Teams module). In these scenarios, fetching information using the [Graph API for Groups](#) with PowerShell offers the prospect of much better performance. Depending on the processing done by a script, it can be between four and ten times faster to use Graph calls instead of PowerShell cmdlets.

Although faster, it can be less convenient to retrieve group information with the Graph because:

- The script must do some up-front processing to connect to the Graph and secure an access token.
- The Groups Graph API works across all group types, including distribution lists and security groups. Several calls are often necessary to retrieve the information delivered by *Get-UnifiedGroup* such as the URLs for the SharePoint Online team site belonging to the group, the sensitivity label assigned to the group, or the count of members and guest members.
- Some attributes stored in the Exchange Online Directory such as the set of fifteen custom attributes, five extension attributes, mailbox quota settings, and MailTips aren't available through the Graph.
- Graph APIs use pagination to control the amount of data returned for a call. Scripts must retrieve pages of available data until no more is available.

Leaving the complexities aside, the sheer speed of access is the trump card for the Graph. Although some additional work might be necessary to fetch all the data a script needs, access via the Graph APIs is always faster than pure PowerShell. As an example, using the *Get-UnifiedGroup* cmdlet to retrieve details of 200 groups might take 20 seconds while the initial Graph query to fetch the set of available Microsoft 365 groups using a filter takes less than half a second. The query is:

```
[PS] C:\> $Uri = https://graph.microsoft.com/v1.0/groups?`$filter=groupTypes/any(a:a eq 'unified')
```

If you just need the set of Teams-enabled groups, the filter is:

```
[PS] C:\> $Uri =
'https://graph.microsoft.com/v1.0/groups?' $filter=resourceProvisioningOptions/Any(x:x eq 'Team')
```

An alternative is to use the beta version of the Teams List API:

```
[PS] C:\> $Uri = "https://graph.microsoft.com/beta/teams"
```

In all cases, once you know the query to run, we execute it as follows:

```
[PS] C:\> [array]$Data = Invoke-WebRequest -Method GET -Uri $Uri -ContentType "application/json" -
Headers $headers | ConvertFrom-Json
```

The array returned by the query contains another array called *Value*. The data for the groups or teams is in this array. For example, to fetch the first element in the array, we use *\$Data.Value[0]*.

The Teams and Groups activity report ([downloadable from GitHub](#)) contains examples of retrieving group information such as SharePoint information, member counts, and attributes specific to Microsoft 365 Groups. Another example showing how to report Teams settings not available through the Teams PowerShell cmdlets [is available on GitHub](#). The script checks the channels for all teams in a tenant and reports the email addresses of those that are mail-enabled.

## Advanced Queries Against Azure AD Objects

Many Graph API requests are straightforward. Some are more complicated and require the Graph to perform more processing to satisfy the request. Given the fundamental role played by Azure AD, it makes sense for Microsoft to optimize queries against Azure AD directory objects perform as well as possible. To do this, Azure AD indexes properties often used in queries and holds the index in a separate store. To use these properties, you run [advanced Azure AD queries](#) (some Microsoft Graph PowerShell SDK cmdlets like [Get-MgGroup](#) also support advanced queries). Advanced queries have the *ConsistencyLevel* header set to *Eventual* and use the *\$count=true* query string.

An example of a simple query is to find Azure AD group objects:

```
[PS] C:\> $uri = "https://graph.microsoft.com/v1.0/groups"
[array]$Data = Invoke-WebRequest -Method GET -Uri $Uri -ContentType "application/json" -Headers
$headers | ConvertFrom-Json
[array]$Groups = $Data.Value
```

The data returned in the *\$Data* array contains Microsoft 365 groups, security groups, and distribution lists. To make it easier to process, we extract the array containing the group information and store it in *\$Groups*. To refine the set returned to a specific type, we need to apply a filter. This example of an advanced query fetches the set of distribution lists by applying a filter to check that the *MailEnabled* property is True and that the group type is not "Unified" (a Microsoft 365 group):

```
[PS] C:\> $Uri = "https://graph.microsoft.com/v1.0/groups?' $filter=MailEnabled eq true and not
groupTypes/any(c:c eq 'unified')&' $count=true"
[array]$Data = Invoke-WebRequest -Method GET -Uri $Uri -ContentType "application/json" -Headers
$headers | ConvertFrom-Json
[array]$DLs = $Data.Value
```

The query returns all distribution lists except room lists (unlike regular distribution lists, these objects usually don't exist in Azure AD). The set includes mail-enabled security groups (the *SecurityEnabled* property is True). To find just mail-enabled security groups, the query is:

```
[PS] C:\> $Uri = "https://graph.microsoft.com/v1.0/groups?' $filter=Mailenabled eq true and
SecurityEnabled eq true and not groupTypes/any(c:c eq 'unified')&' $count=true"
```

Not all properties of Azure AD objects support all operators. For instance, to find the set of Microsoft 365 groups with an expiration date set, you'd assume that you could filter based on the property holding the expiration date not being null. However, that's not the case (see [the limitations in queries for various Azure AD objects](#)), and you end up checking against an arbitrary date in the past using the greater than or equal to operator, which is supported:

```
[PS] C:\> $uri = "https://graph.microsoft.com/beta/groups?$`filter=ExpirationDateTime ge 2014-01-01T00:00:00Z AND groupTypes/any(a:a eq 'unified')&`$count=true"
```

An alternative approach is to fetch the complete set of objects and use a client-side filter to extract the objects you want to process. Although effective, this method could be slow.

## Graph Filters and OData Syntax

PowerShell developers who start using Graph calls might miss some of the flexibility of PowerShell when it comes to applying filters to Graph API requests.. Two examples using the Office 365 Service Communication API demonstrate the point. First, let's assume that you want to find the set of issues in a tenant for the last seven days. To do this, you include [a filter in OData syntax](#) to tell the Graph to return only incidents with a start date within the last week. OData filters use sortable dates. We can get a sortable date seven days back from the current date with:

```
[PS] C:\> $DaysRange = (Get-Date).AddDays(-7)
$DaysRangeZ = Get-Date($DaysRange) -format s
```

*\$DaysRangeZ* now contains a value like 2021-07-29T14:41:09, which is a sortable date. However, it won't work if used in a query like this:

```
[PS] C:\> $Uri =
"https://graph.microsoft.com/beta/admin/serviceAnnouncement/issues?`$filter=startDateTime ge
$DaysRangeZ"
```

The reason is that the Graph requires a Z at the end of a sortable date. You can see this in the example of looking for groups with an expiration date described above. After adding a Z, this URI works:

```
[PS] C:\> $Uri =
"https://graph.microsoft.com/beta/admin/serviceAnnouncement/issues?`$filter=startDateTime ge
$DaysRangeZ" + "Z"
```

Now let's assume that we want to add another property to the filter so that the query retrieves open incidents only. The *isResolved* property is True or False to indicate the status of an incident. PowerShell is happy checking against False with either a lower- or upper-cased initial letter. The Graph demands lower case, meaning that we need to use true or false in Graph API requests, like this:

```
[PS] C:\> $Uri =
"https://graph.microsoft.com/beta/admin/serviceAnnouncement/issues?`$filter=startDateTime ge
$DaysRangeZ" + "Z and IsResolved eq false"
```

The above illustrates that the Graph is more particular with the syntax of its requests than PowerShell is. It can be infuriating at times to have code that appears perfectly good be rendered unacceptable due to a minor imperfection. The Graph Explorer is very helpful at resolving syntax issues, so be sure to use it to test Graph API requests before you include them in scripts.

## Lambda Qualifiers

In some of the examples used to date, you might have noticed that the construct of the filter includes /any. This means that the filter operates against a multi-value property, like the set of email addresses assigned to a

mail-enabled object or the licenses assigned to a user account. For example, this query uses a [lambda qualifier](#) to find Azure AD accounts assigned an Office 365 E3 license:

```
[PS] C:\> Uri = https://graph.microsoft.com/beta/users?`$filter=assignedLicenses/any(s:s/skuId eq 6fd2c87f-b296-42f0-b197-1e91e994b900)
```

The **/any** operator in the filter *"iteratively applies a Boolean expression to each member of a collection and returns true if the expression is true for any member of the collection, otherwise, it returns false"*. In this case, the filter examines the *assignedLicenses* property of each account to find instances where the Skuld (one of the values stored in the property) matches the GUID for Office 365 E3. Using [Microsoft's documentation](#) to interpret the components of the lambda /any qualifier, we can see that:

- **assignedLicenses** is the parameter, or the property to which the filter is applied. The property can contain a collection of values or a collection of entities. In this case, the *assignedLicenses* property for an account contains a collection of one or more license entities. Each license is composed of the Skuld and any disabled plans unavailable to the license holders.
- **s:s** "is a range variable that holds the current element of the collection during iteration." The interesting thing is that you can give any name you like to the range variable. In this case, it could be *license:license* or even *rubbish:debris*. It's just a name for a variable.
- **Skuld** is the subparam, or value within the property being checked. When there's only one value in a collection (as when you check for team-enabled groups), you don't need to specify a subparam. In the case of *assignedLicenses*, it is needed because we want to match against the Skuld within the collection of entities in the *assignedLicenses* property.
- **6fd2c87f-b296-42f0-b197-1e91e994b900** is the value to match against items.

Lambda qualifiers exist because it's more difficult to filter against complex properties than it is to filter against simple strings, like this straightforward filter looking for any accounts with a display name starting with Tony:

```
[PS] C:\> $Uri = https://graph.microsoft.com/v1.0/users?`$filter=startswith(displayName, 'Tony')
```

Knowing when a lambda qualifier is needed in a query is a matter of figuring out if a property is multi-valued, checking Microsoft's documentation, or finding an example of a working query created by someone else. Or a combination of all the above.

## Sending Email with the Graph

Earlier we covered how to use the *Send-MailMessage* cmdlet to send messages through PowerShell. *Send-MailMessage* depends on the SMTP AUTH protocol and basic authentication. The Graph *SendMail* API call can replace *Send-MailMessage* in scripts. *SendMail* can be used in two ways, [depending on the permissions](#) held by the app which calls it:

- If the app has the *Mail.Send* application permission, the app can send email as any user or shared mailbox (but not a group mailbox) in the organization. An administrator must give consent to an app to use application permissions.
- If the app has the *Mail.Send* delegate permission, the app can send mail as the signed-in user.

To convert a script to use the *SendMail* API, we need:

- A registered app in Azure AD.
- Assignment of the *Mail.Send* permission to the app.
- Script code to call the app, get an access token, and build and send the message.

Code to get an access token is like that used by any script wishing to use the Graph APIs. From a conversion perspective, the work is to remove the code used to create and send a message with *Send-MailMessage* and replace it with the format used to construct a message for *SendMail*. The following points should be noted:

- The SMTP address for the sender must be resolvable against the tenant directory. The *To* and *CC* addresses must be valid SMTP addresses.
- Attachments must be Base64-encoded before being added to the message. You can attach a file of up to 3 MB and send it in one operation. Larger attachments [need a different approach](#). Remember to assign the correct MIME type to the attachment.
- The message structure is described in JSON. Here's an example of a message with one *To* and two *CC* recipients and an attachment. The HTML content for the message is defined in the `$htmlMsg` variable.

```
# Create message body and properties and send
$MessageParams = @{
    "URI" = "https://graph.microsoft.com/v1.0/users/$MsgFrom/sendMail"
    "Headers" = $Headers
    "Method" = "POST"
    "ContentType" = 'application/json'
    "Body" = @(
        @{
            "message" = @{
                "subject" = "A test message"
                "body" = @{
                    "contentType" = 'HTML'
                    "content" = $htmlMsg }
            }
        }
    )
    "attachments" = @(
        @{
            "@odata.type" = "#microsoft.graph.fileAttachment"
            "name" = $AttachmentFile
            "contentType" = "application/vnd.openxmlformats-officedocument.wordprocessingml.document"
            "contentBytes" = $ContentBase64 })
    "toRecipients" = @(
        @{
            "emailAddress" = @{ "address" = "Chris.Bishop@office365itpros.com" }
        } )
    "ccRecipients" = @(
        @{
            "emailAddress" = @{ "address" = "Vasil.Michev@office365itpros.com" }
        },
        @{
            "emailAddress" = @{ "address" = "James.Ryan@office365itpros.com" }
        } )
    }
} | ConvertTo-JSON -Depth 6
} # Send the message
Invoke-RestMethod @MessageParams
```

A full script to illustrate these concepts is [available from GitHub](#).

## Scoping Graph Applications to Specific Exchange Online Mailboxes

If applications built with the Graph APIs have the necessary permissions, they can read and write information into many types of data, including Exchange Online mailboxes. Because mailboxes can store confidential information, Exchange Online supports [application access policies](#) to limit access to sets of mailboxes defined through membership of a mail-enabled security group. When an application access policy is in place, apps covered by the policy can access only the mailboxes that are members of the security group. See [this page](#) for more information.

Application access policies are protocol agnostic. [They also govern the use of the Exchange Web Services \(EWS\) API](#), including when programs use EWS for impersonation (to behave as if the program was a mailbox's owner) to access mailboxes. If a policy blocks access to a set of mailboxes, a program cannot use EWS to impersonate those mailboxes and access the data within the mailboxes.

Using an application access policy to control access to apps that use the *SendMail* API is a good use case. As you'll recall, if an administrator grants consent to an app to use the application *Mail.Send* permission, the app

can send mail from any user or shared mailbox in the organization. This is a dangerous situation as it creates the possibility that someone could use an app to send unauthorized messages. An application access policy can restrict access to the app so that messages can be sent only from certain mailboxes. You can only create an application access policy in PowerShell. For example:

```
[PS] C:\> New-ApplicationAccessPolicy -AppId 970e01d1-ce75-46ba-a054-4b61c787f682 -  
PolicyScopeGroupId SendMailApp.Control@office365itpros.com -AccessRight RestrictAccess -Description  
"Restrict access to app allowed to send email using the Graph SendMail API"
```

This policy:

- Applies to the registered app with identifier 970e01d1-ce75-46ba-a054-4b61c787f682.
- Restricts access to the mailboxes defined in the mail-enabled security group SendMailApp.Control@office365itpros.com.

In other words, the app can only use the *Mail.Send* API to create and send messages using the mailboxes of a member of the security group. This [blog post](#) explains how to check service principals in a tenant to discover those which use Exchange Online mailbox permissions. It's wise to perform checks like this periodically to ensure that apps don't abuse permissions.

## Tenant Privacy Controls

The [Microsoft Graph Insights resource type](#) is used by applications to access *insights* such as the set of documents viewed, modified, or shared by a user. Insights appear in different Microsoft 365 apps including Viva Insights, Workplace Analytics, and the user profile card. The Microsoft Graph calculates insights using signals gathered from apps about a user's activity and spanning information in their mailbox, OneDrive for Business account, and files they have access to in SharePoint Online or other users' OneDrive for Business accounts. Three types of insights are available:

- **Item insights:** Recommendations about documents available to a user which they might be interested in. This information shows up in the profile card in the "Files" section.
- **Meeting insights:** When users open a meeting in their calendars, Outlook displays [insights relevant to the meeting](#), such as documents and emails covering the content of the meeting.
- **People insights:** Information about [people deemed to be relevant to an individual](#) and who have a "public relationship" with that individual. For example, they have the same manager (as noted in Azure AD) or share a common membership of a public group or distribution list with fewer than 30 members. People insights show up on the profile card in the "works with" section, with the people who appear ranked in order of the public and private communication (direct email or meetings rather than group-based communications) between the listed individuals and the owner of the profile card.

Tenants control the display of insights through organization settings. Meeting insights are either enabled or disabled for the entire organization, while tenants can disable item and people insights for a specific Microsoft 365 group or security group. Administrators can modify settings for item and meeting insights in the Search & intelligence section of Settings in the Microsoft 365 admin center. Users can disable item insights for their account through the Privacy tab of their [MyAccount page](#) (this action does not add them to the group used by the tenant to disable item insights for selected users). Controls for people insights are only available through the Microsoft Graph.

The people insight control is available through <https://graph.microsoft.com/beta/organization/GUID-org-id/settings/peopleinsights> (insert your tenant identifier to create a complete URI). If you run a query against the URI, the API returns the following information:

- *isEnabledInOrganization*: This setting controls if people insights are available within an organization. By default, the setting is enabled (true). If disabled, no insights are created.

- *disabledForGroup*: This setting holds the GUID (object identifier) for an Azure AD group. The Microsoft Graph excludes the members of the group when it generates people insights.

The PowerShell code below shows how to query the Graph to retrieve the current settings for people insights using the *Invoke-RestMethod* cmdlet. The second part of the code fetches a set of accounts stored in a CSV file and updates the Azure AD group used to exclude accounts for people insights. The code used to connect to a registered Azure AD application and secure an access token is omitted.

```
[PS] C:\> $TenantId = (Get-MgOrganization).Id
$Uri = "https://graph.microsoft.com/beta/organization/" + $TenantId + "/settings/peopleinsights"
$Settings = Invoke-RestMethod -Uri $Uri -Method Get -ContentType "application/JSON" -Headers
$Headers -UseBasicParsing

If ($Settings.isEnabledInOrganization -ne $True) {
    Write-Host "Insights control setting not set for the tenant" ; break }
Else {
    $DisabledGraphInsightsGroup = $Settings.disabledForGroup }

[array]$CurrentMembers = Get-MgGroupMember -GroupId $DisabledGraphInsightsGroup

Write-Host "Adding users to the Disabled Graph Insights Group"
$Users = Import-CSV $InputCSV
ForEach ($User in $Users) {
    If ($User.ObjectId -notin $CurrentMembers.Id) {
        Write-Host "Adding" $User.Name
        New-MgGroupMember -GroupId $DisabledGraphInsightsGroup -DirectoryObjectId $User.ObjectId }
}
```

## The Microsoft Graph Explorer

There is nothing like using a tool to understand what it can do. To understand the capabilities of the Microsoft Graph, you can fire up the [Graph Explorer](#), a web application that allows users to execute Graph API requests (or queries) against real data. The Graph Explorer supports GET, POST, PUT, PATCH, and DELETE requests, and exposes the responses to those requests, including details like request bodies, responses, code, and headers. The application generates code snippets for API requests in C#, Java, JavaScript, and Go to copy and use elsewhere. In some cases, PowerShell examples using the cmdlets from the Microsoft Graph PowerShell SDK are available for Graph requests.

The idea behind the Graph Explorer is that it helps programmers understand the kind of calls they need to construct to interact with various endpoints and the format of the results returned through their interaction. It is particularly helpful in understanding the format of Graph API requests, including how filters are used, and the type of data returned by requests.

The Graph Explorer supports running requests against:

- Test data. You don't need to sign in to use these requests.
- Tenant data. You must sign in to use these requests. If you use an administrator account, you can see tenant-wide data. Otherwise, you're limited to your own data. If necessary, you can grant the Graph Explorer consent to use the permissions necessary to run the requests.
- The V1.0 and the beta endpoints.

The input field for the Graph query to run includes an IntelliSense-like auto-complete capability, so you can see the available calls as you type in the input box. For instance, assume that we select *https://graph.microsoft.com/beta/me/* as a starting point. Underneath the field, you see a list of calls organized (somewhat alphabetically) starting with *https://graph.microsoft.com/beta/me/activities* and then *https://graph.microsoft.com/beta/me/agreementacceptances* and so on.

To help users experiment with Graph requests, the Graph Explorer includes:

- **Getting started queries**, a small set of requests against personal data such as *my mail* or *my photo*.
- **Sample queries** organized into capabilities (like notifications) and product functionality (like Teams, Planner, OneDrive, and Outlook Calendar). some interesting requests to investigate include:

<https://graph.microsoft.com/V1.0/groups>: List all the groups in a tenant.

[https://graph.microsoft.com/v1.0/me/transitiveMemberOf/microsoft.graph.group?\\$count=true](https://graph.microsoft.com/v1.0/me/transitiveMemberOf/microsoft.graph.group?$count=true): List all the Microsoft 365 Groups that the logged-on user belongs to in a tenant.

<https://graph.microsoft.com/V1.0/me/joinedTeams>: List all the Teams that the logged-on user belongs to in a tenant.

- **Resources**, a list of the available Graph APIs. If you select a resource, the Graph Explorer loads the basic URI for the resource into the query. For example, if you select the *groupLifecyclePolicies* resource, Explorer loads the <https://graph.microsoft.com/v1.0/groupLifecyclePolicies> query. Some of the requests (like this one) can run as is. Others need additional information, like a tenant identifier.

After you enter a specific query or select one of the “Getting Started” examples, click **Run Query** to have the Graph return the requested data. For instance, Figure 23-4 shows the results of a call to fetch data from <https://graph.microsoft.com/v1.0/organization>, a query that returns details of the tenant (organization). You can see details of some of the SKUs (products) available in the tenant.

The screenshot shows the Microsoft Graph Explorer interface. The top navigation bar includes the Microsoft logo, 'Microsoft Graph', and various utility links like 'Explore', 'Graph Explorer', 'Docs', 'API', 'Learn', 'Developer Program', and 'Support'. The main area is titled 'Graph Explorer' and shows a tenant 'Redmond & Associates'. The query bar contains the URL 'https://graph.microsoft.com/v1.0/organization' and a 'Run query' button. Below the query bar, the 'Request body' is empty, and the 'Response preview' shows a successful GET request with a status of 'OK - 200 - 640ms'. The response is a JSON object with the following structure:

```

{
  "technicalNotificationMails": [
    "Tony.Redmond@"
  ],
  "tenantType": "AAD",
  "directorySizeQuota": {
    "used": 1427,
    "total": 300000
  },
  "privacyProfile": null,
  "assignedPlans": [
    {
      "assignedDateTime": "2022-02-28T19:48:47Z",
      "capabilityStatus": "Enabled",
      "service": "exchange",
      "servicePlanId": "b74d57b2-58e9-484a-9731-aecbba954f0"
    },
    {
      "assignedDateTime": "2022-02-28T19:48:47Z",
      "capabilityStatus": "Enabled",
      "service": "exchange",
      "servicePlanId": "c815c93d-0759-4bb8-b857-bc921a71be83"
    },
    {
      "assignedDateTime": "2022-01-24T14:55:49Z",
      "capabilityStatus": "Enabled",
      "service": "exchange",
      "servicePlanId": "c815c93d-0759-4bb8-b857-bc921a71be83"
    }
  ]
}

```

Figure 23-4: Using the Graph Explorer to test Graph API calls

The Graph Explorer retains details of requests you run for 30 days. You can go back and rerun a query at any time or download the set of requests and responses to a [.HAR file](#), which can be opened by any text editor.

When you list sets of objects like Groups or Teams, you see an identifier for each object. You need the identifier (a GUID) to navigate to the next level. For instance, this URL includes a group identifier <https://graph.microsoft.com/V1.0/groups/72ee570e-3dd8-41d2-bc84-7c9eb8024dd4>. If you include the URL in a query executed by the Explorer, you get back the properties of the group in JSON format. For example:

```

{
  "@odata.context": "https://graph.microsoft.com/V1.0/$metadata#groups/$entity",
  "id": "72ee570e-3dd8-41d2-bc84-7c9eb8024dd4",
  "deletedDateTime": null,

```

```

"classification": "External Access",
"createdDateTime": "2016-09-29T18:37:00Z",
"description": "Exchange Grumpy Old Men (and Women too)",
"displayName": "Exchange's Grumpy Old Men",
"groupTypes": [
  "Unified"
],
"mail": "ExchangeMVPs@office365itpros.org",
"mailEnabled": true,
"mailNickname": "exchangegoms",
"membershipRule": null,
"membershipRuleProcessingState": null,
"onPremisesLastSyncDateTime": null,
"onPremisesProvisioningErrors": [],
"onPremisesSecurityIdentifier": null,
"onPremisesSyncEnabled": null,
"preferredLanguage": null,
"proxyAddresses": [
  "SMTP:ExchangeMVPs@office365itpros.org",
  "smtp:exchangegoms@office365itpros.onmicrosoft.com"
],
"renewedDateTime": "2016-09-29T18:37:00Z",
"resourceBehaviorOptions": [],
"resourceProvisioningOptions": [],
"securityEnabled": false,
"theme": null,
"visibility": "Private"
}

```

The set of properties returned for a group by the Graph is different from the set returned by the PowerShell *Get-UnifiedGroup* cmdlet. This is because Exchange Online incorporates some extra information about the group mailbox when *Get-UnifiedGroup* returns data for a group (one of the reasons why the cmdlet is slow).

You can also copy the Graph code used as examples in Microsoft's documentation and run the API requests in the Graph Explorer to see how the Graph responds. For instance, the URI below returns sign-in data for Azure AD accounts.

*https://graph.microsoft.com/beta/users?\$select=displayName,userPrincipalName,mail,id,CreatedDateTime,signInActivity,UserType&\$top=999*

Full documentation about the various Microsoft Graph APIs is [available online](#).

## Graph Explorer Permissions

The Graph Explorer works with delegated permissions. In other words, you can access your own data (or test data), and if your account holds administrative roles, API requests run by the Graph Explorer can access data available to those roles too.

Requests executed through the Graph Explorer might require additional permissions to the set already assigned before they can run successfully. For instance, by default, the Explorer does not have permission to read items in a user's mailbox. Before it can proceed, the user must modify its assigned permissions and provide consent to the Graph Explorer app to use the *Mail.ReadBasic*, *Mail.Read*, and *Mail.ReadWrite* permissions.

To see the set of permissions needed to allow a query to run, click the Modify permissions tab. If you have an administrator account, you can consent on behalf of the organization to allow the Graph Explorer to use the required permission, such as *Mail.Read*. The signed-in user can also consent to permissions to allow the Graph Explorer to access their data. Understanding app permissions and assigning only the permissions necessary for an app to access the data it needs to process are fundamental to working with Graph API-based apps.

## Using the Graph Explorer for Real Work

If you sign into the Graph Explorer with an administrator account, you can manipulate tenant data. Microsoft does not intend the Graph Explorer to be an administrative tool, but situations exist where the Graph Explorer can do real work and avoid the necessity to write some code. Two examples are:

- [Customizing the Office 365 profile card](#) to expose additional information.
- [Updating privacy controls for document insights](#) derived from signals collected in the Graph.

In both cases, the only supported method to make changes in a tenant is via the Graph. Microsoft does not provide access in an administrative GUI like the admin center nor does a PowerShell cmdlet exist that can update these settings. However, the process to use the Graph Explorer to apply the updates is straightforward:

- Know your tenant identifier. The tenant identifier is available in the overview section of the Azure AD admin center. The suggested approach is to use the *Get-MgOrganization* cmdlet from the Microsoft Graph PowerShell SDK. For example:

```
[PS] C:\> $TenantId = (Get-MgOrganization).Id
```

- Know the URI for the endpoint to access. For example, to update the profile card, you interact with <https://graph.microsoft.com/beta/organization/{tenantid}/settings/profileCardProperties> (insert the tenant identifier in the placeholder to create the real URI). If you've been using a beta endpoint, it's a good idea to check periodically to see if Microsoft has upgraded an API to a fully-supported V1.0 version. If they do, you should change your code to use the supported version, always being aware that the change could affect how a query runs or the data it returns.
- Know the type of request you need to run. A GET command retrieves information, and a PUT command creates something, while you use PATCH commands to update existing data.
- Run the query.
- Check that an OK response (often 200, but other values are used) is returned. Check that the right data now exists.

Given the size and distributed nature of Office 365, it can take up to 24 hours before a change made to Graph settings is effective within applications.

## Using the Microsoft Graph PowerShell SDK

The [Microsoft Graph PowerShell SDK](#) is a compound module (it spans over 30 sub-modules) supporting modern authentication to many Graph APIs from PowerShell, using both delegate and application ([certificate only](#)) permissions. The SDK supports both the V1.0 (generally available) and beta Graph APIs. SDK cmdlets support PowerShell 5.1 and 7 on Windows, macOS, and Linux.

Microsoft's direction is to focus on Graph APIs for access to Microsoft 365 and other data (like Azure AD). As the process unfolds, Microsoft will deliver PowerShell access to Microsoft 365 data via the SDK rather than increasing the number of modules available for individual workloads. Some major workloads like Exchange Online and Teams are likely to continue with their separate modules while others, like Planner, will use the SDK. This might be because of the number and type of cmdlets in the module or the lack of support for certain functionality in the Graph APIs. For instance, the Exchange Online management module supports hundreds of cmdlets, some of which (like *Get-ExoMailboxFolderStatistics*) have no equivalent Graph API. The same is true of Teams, where many of the policy management cmdlets don't have a matching Graph API.

Microsoft's adoption of new platforms and deprecation of old software will force organizations to move away from older modules to the SDK. For example, the [license management cmdlets in the Azure AD module will cease working](#) after August 26, 2022, when Microsoft 365 moves to a new license management platform.

Because of the deprecation of the Azure AD Graph API, Microsoft plans to retire and remove support for the Microsoft Services Online (MSOL) and Azure AD modules. To help developers transition from these modules to the Microsoft Graph PowerShell SDK, Microsoft publishes a [cmdlet map](#), a way to find a suitable replacement for an older Azure AD or MSOL cmdlet in the SDK. Although useful to have a cmdlet map, it's important to understand that knowing which SDK cmdlet Microsoft recommends for an Azure AD cmdlet does not mean that the cmdlet parameters are the same or the cmdlet returns the same data in the same format. Careful testing is necessary to validate that upgraded scripts work as expected.

## SDK Modules

The Microsoft Graph PowerShell SDK spans over 30 sub-modules and several thousand cmdlets. Each module contains the cmdlets needed to interact with a different Graph API focusing on a specific area such as reporting or user accounts. Among the sub-modules are:

- Calendar: Microsoft.Graph.Calendar
- Compliance: Microsoft.Graph.Compliance.
- Device Management: Microsoft.Graph.DeviceManagement.
- Sign-ins: Microsoft.Graph.Identity.Signins.
- Mail: Microsoft.Graph.Mail.
- People: Microsoft.Graph.People.
- Planner: Microsoft.Graph.Planner.
- Reports: Microsoft.Graph.Reports.
- Security: Microsoft.Graph.Security.
- Teams: Microsoft.Graph.Teams.
- Users: Microsoft.Graph.Users.

When you download and install the SDK from the [PowerShell Gallery](#), the installation includes all the sub-modules. To install the SDK, run the command:

```
[PS] C:\> Install-Module Microsoft.Graph -Scope AllUsers -Force
```

## SDK Cmdlets

To find the cmdlets available for specific tasks, you can use the *Get-Command* cmdlet with some inspired guesswork. For example, to find the cmdlets available for groups, sign into PowerShell on a workstation where the SDK is installed and run the command:

```
[PS] C:\> Get-Command -Module Microsoft.Graph* *MgGroup*
```

Microsoft uses a process called *AutoRest* to generate SDK cmdlets from Graph APIs automatically. The process also generates the cmdlet documentation, which accounts for why the documentation is sometimes difficult to understand. The cmdlets follow the normal PowerShell naming convention of *verb-(optional prefix)noun* and map the http request made to the Graph APIs to the verb:

- GET https requests result in Get- PowerShell cmdlet, like *Get-MgUser*.
- POST and PUT https requests result in *New*, *Add*, or *Update* PowerShell cmdlets, like *New-MgUser*.
- PATCH https requests map to *Update*- or *Set*- PowerShell cmdlets, like *Update-MgUser*.
- DELETE https requests map to *Remove* PowerShell cmdlets, like *Remove-MgUser*.

Microsoft publishes new versions of the SDK modules monthly. Currently, the SDK doesn't include cmdlets for every Graph API call, but as explained earlier, you can make Graph API calls from PowerShell without needing to use the SDK. When upgrading scripts, the choice is to use either the SDK cmdlets or Graph API calls. Although usually a matter of personal choice, most developers seem to prefer using direct calls to Graph APIs in scripts. This situation will change over time as the SDK matures, Microsoft removes some of the unfinished

edges, and the SDK supports more scenarios. Because the SDK is under active development, you should always download the latest version from the PowerShell gallery before evaluating it as the basis for a new project.

## Connecting with Connect-MgGraph

The first step is to connect to the Graph using the *Connect-MgGraph* cmdlet. The SDK supports modern authentication, so you can connect using any supported method, including multi-factor authentication, using a FIDO2 key, or with a certificate. When you run *Connect-MgGraph*, be sure to specify the identifier of the tenant to which you want to connect. If you don't specify a tenant, *Connect-MgGraph* will choose the last tenant you signed into during the current session (which might not be the one you want to connect to). A session lasts until you run *Disconnect-MgGraph* (see below) and can be reinitiated multiple times by running *Connect-MgGraph*. If you work across multiple tenants, it's important to disconnect your session after you finish working with a tenant as otherwise you might end up inadvertently running commands in one tenant when you expect that the session is connected to another.

Behind the scenes, the Graph SDK keeps an encrypted token cache and will refresh the token as needed to allow you to continue working with Graph commands.

```
[PS] C:\> Connect-MgGraph -TenantId "828e1143-88e3-492b-bf82-24c4a47ada63"
```

After connecting, the session signs into your account. The permission scope for the connection comes from the well-known service principal (enterprise app) registered in Azure AD for the SDK. If you've never signed in with the Graph SDK before, it creates a service principal called *Microsoft Graph PowerShell* with an AppId of *14d82eec-204b-4c2f-b7e8-296a70dab67e* and requests a limited set of permissions. If you're an administrator, you can grant consent for these permissions on behalf of the organization. The service principal is the object that runs Graph API requests, not the account used to sign into PowerShell, so any administrative roles held by the account have no influence over application permissions usable during the session; they only affect delegate permissions.

Unlike other PowerShell modules that inherit the permissions held by the signed-in account, the SDK operates on a least-privilege basis. In other words, if you want to do something with an SDK cmdlet, you must check if the service principal used by the SDK has the permission to perform that action. If not, an administrator must grant consent to allow the action to proceed. This principle holds for interactive sessions with the SDK, in which case the Microsoft Graph PowerShell service principal receives the permission, or registered Azure AD apps used with certificate-based authentication using something like an Azure Automation runbook. In the latter case, the service principal for the app receives the permission.

For example, permission to read directory information is necessary to use the *Get-MgUser* cmdlet to retrieve a set of Azure AD accounts. With an interactive session, a user can request the set of permissions they need (for all the SDK cmdlets they plan to use) using the *Scope* parameter when connecting to the Graph as follows:

```
[PS] C:\> $RequiredScopes = @"Directory.AccessAsUser.All", "Directory.ReadWrite.All"  
Connect-MgGraph -Scopes $RequiredScopes
```

Connecting with a scope containing permissions not already held by the Microsoft Graph PowerShell service principal causes Azure AD to prompt for consent for those permissions. If granted, Azure AD adds the extra permissions to the set already held by the service principal. If an administrator does not grant consent, the permissions available in the session are those already consented plus those that the user has through any administrative roles assigned to their account. Users can grant consent to permissions necessary to access their own data.

Over time, the permissions held by the service principal grow from the initial set granted at the creation of the service principal plus any other permissions granted subsequently. In other words, the service principal

collects aggregated permissions over time. For this reason, it's not recommended to use the Graph SDK cmdlets interactively because if you do, over time a distinct possibility exists that the service principal will become very over-permissioned and therefore becomes a security risk. The same risk of permission creep exists for registered apps but is less evident than for the service principal used by the Microsoft Graph PowerShell SDK, if only because the way the SDK interacts with many different types of data.

Apart from going through and removing individual permissions, the only resolution for an over-permissioned service principal is its removal and recreation, at which time an administrator can grant consent for limited permissions to the new service principal. Here's how to remove the service principal using Graph SDK cmdlets (naturally):

```
[PS] C:\> $Sp = Get-MgServicePrincipal -top 999 | ? { $_.AppId -like "14d82eec-204b-4c2f-b7e8-296a70dab67e" }
Remove-MgServicePrincipal -ServicePrincipalId $sp.Id
```

In some situations, you'll need to use the beta profile to have access to certain commands and data. This is equivalent to specifying the beta endpoint when issuing Graph API requests. To select the beta profile, run the *Select-MgProfile* cmdlet:

```
[PS] C:\> Select-MgProfile beta
```

To check that you're connected to the right tenant with the right profile and permissions, we can extract information about the tenant with the *Get-MgOrganization* cmdlet, the current connection with the *Get-MgContext* cmdlet, and the profile used with the *Get-MgProfile* cmdlet and display some useful information:

```
[PS] C:\> Select-MgProfile beta
$Details = Get-MgContext
$Scopes = $Details | Select -ExpandProperty Scopes
$Scopes = $Scopes -Join ", "
$ProfileName = (Get-MgProfile).Name
$OrgName = (Get-MgOrganization).DisplayName
CLS
Write-Host "Microsoft Graph Connection Information"
Write-Host "-----"
Write-Host " "
Write-Host ("Connected to Tenant {0} ({1}) as account {2}" -f $Details.TenantId, $OrgName,
$Details.Account)
Write-Host "+-----+
-----+"

Microsoft Graph Connection Information
-----

Connected to Tenant a662313f-14fc-43a2-9a7a-d2e27f4f3475 (Office 365 for IT Pros) as account
Global.Administrator@office365itpros.com
+-----+
Profile set as beta with the following scopes defined: Directory.AccessAsUser.All,
Directory.ReadWrite.All, openid, profile, User.Read, email, Group.Read.All, Group.ReadWrite.All
```

The permissions listed above include those inherited from the service principal and any others requested by the user for the session.

When you're finished interacting with the Graph, remember to close off the session by running *Disconnect-MgGraph* to sign the session out from the Graph. Disconnecting the session removes the encrypted token cache and prevents a session from being reinitialized.

```
[PS] C:\> Disconnect-MgGraph
```

The description above covers an interactive session. This is a good way to get to know the Graph SDK cmdlets and debug scripts in preparation for operational use. Because of the issues with consent and the service principal, Microsoft recommends that operational scripts have separate apps registered in Azure and use certificate-based authentication ([app-only access](#)). You can certainly write and test the code using the interactive client, but once the code is complete, it's time to run it using a separate app with a scoped permission set. This approach means that you can restrict the permissions assigned to apps to only the set needed by the processing done by the script. The downside of using separate apps with scoped permissions is that over time you might accumulate many registered apps in Azure AD which require management.

## Paging

Earlier, we discussed the topic of pagination for Graph API requests. Pagination allows developers to retrieve pages of data until they fetch all items matching a Graph API query. Unlike Graph requests, SDK cmdlets handle pagination automatically. Cmdlets that can handle large quantities of objects include an `All` parameter. The `All` parameter instructs the cmdlet to fetch pages of data asynchronously until no more pages are available. This approach delivers better performance than waiting for all pages to be collected in memory. For example:

```
[PS] C:\> # Fetch all Azure AD user accounts and all groups
[array]$AllUsers = Get-MgUser -All
[array]$AllGroups = Get-MgGroup -All
```

You can limit the amount of data returned by specifying the `Top` parameter. For instance, to fetch the first 10 users, run:

```
[PS] C:\> Get-MgUser -Top 10
```

If you use the `Invoke-MgGraphRequest` cmdlet to run a Graph query, your code must deal with pagination. For example, this command runs a query to return the set of users in a tenant and includes a parameter to request the count of the objects found:

```
[PS] C:\> [array]$UserCount = Invoke-MgGraphRequest -Uri
"https://graph.microsoft.com/beta/users?`$count=true" -Headers @{ConsistencyLevel='eventual'}
```

If we examine the number returned for the count, we see a value:

```
$UserCount
Name Value
----
@odata.context https://graph.microsoft.com/beta/$metadata#users
@odata.count 517
@odata.nextLink
https://graph.microsoft.com/beta/users?$count=true&$skiptoken=m~AQAn0zc3MGE2YmZjZTE5...
Value {System.Collections.Hashtable, System.Collections.Hashtable,
System.Collections.Hash...
```

The user account data is stored in the `$UserCount.Value` hash table. However, if you examine the count of objects, you'll see it is 100. This is the default number of objects returned by the Users Graph API (the number of returned items differs from API to API). To get more data, use the `@odata.nextlink` link returned in `$UserCount` to fetch successive pages until the nextlink value is null. For instance:

```
[PS] C:\> [Array]$MoreUsers = Invoke-MgGraphRequest -Uri $UserCount."@odata.nextlink" -Method Get
```

## Permissions

As noted earlier, the permissions available in an SDK session depend on those granted to the service principal used in the connection. Given the number of Graph permissions available, it can be hard to know what

permissions are needed unless you're told. The *Find-MgGraphPermission* cmdlet helps. For example, let's assume that you want to find permissions related to users. This command does the trick and shows all the permissions requiring administrator consent (output edited for space):

```
[PS] C:\> Find-MgGraphPermission User | ? {$_.Consent -eq "Admin"} | Format-Table Consent, Name, Description
```

Consent	Name	Description
Admin	CrossTenantUserProfileSharing.Read	Allows the application to list and query user
Admin	CrossTenantUserProfileSharing.Read.All	Allows the application to list and query any
Admin	CrossTenantUserProfileSharing.ReadWrite	Allows the application to list and query user
Admin	CrossTenantUserProfileSharing.ReadWrite.All	Allows the application to list and query any
Admin	User.Export.All	Allows the app to export data (e.g. customer
Admin	User.Invite.All	Allows the app to invite guest users to the
Admin	User.ManageIdentities.All	Allows the app to read, update and delete
Admin	User.Read.All	Allows the app to read the full set of profile
Admin	User.ReadWrite.All	Allows the app to read and write the full set

To find more details about the permission, use the *Find-MgGraphPermission* cmdlet to examine its properties:

```
[PS] C:\> Find-MgGraphPermission "User.ReadWrite.All" | ? {$_.PermissionType -eq "Application"} | fl
```

```
Id           : 656f6061-f9fe-4807-9708-6a2e0934df76
PermissionType : Application
Consent       : Admin
Name         : IdentityRiskyUser.ReadWrite.All
Description   : Allows the app to read and update identity risky user information for your
                organization without a
                signed-in user. Update operations include dismissing risky users.

Id           : 741f803b-c850-494e-b5df-cde7c675a1ca
PermissionType : Application
Consent       : Admin
Name         : User.ReadWrite.All
Description   : Allows the app to read and update user profiles without a signed in user.
```

The *Find-MgGraphCommand* cmdlet reports what SDK cmdlets are available to process objects and the permissions they use. The cmdlet takes a URI parameter to know what objects you're interested in. This corresponds to the Graph endpoint for an object, like */groups/* for Groups and */users/* for user accounts. For example, this command shows that two cmdlets are available. One gets a set of users; the other creates a new account:

```
[PS] C:\> Find-MgGraphCommand -Uri /users/ -ApiVersion V1.0
```

```
APIVersion: v1.0
```

Command	Module	Method	URI	OutputType	Permissions
Get-MgUser	Users	GET	/users	IMicrosoftGraphUser1	{DeviceManagementApps.Read.All,
New-MgUser	Users	POST	/users	IMicrosoftGraphUser1	{DeviceManagementApps.ReadWrite.All,

If we add a qualifier to indicate that we want to see commands which process individual user accounts, we see three cmdlets:

```
[PS] C:\> Find-MgGraphCommand -Uri "/users/{id}" -ApiVersion V1.0
```

```
APIVersion: v1.0
```

Command	Module	Method	URI	OutputType	Permissions
Get-MgUser	Users	GET	/users/{user-id}	IMicrosoftGraphUser1	{DeviceManagementApps.Read.All,
Remove-MgUser	Users	DELETE	/users/{user-id}		{DeviceManagementApps.ReadWrite.All
Update-MgUser	Users	PATCH	/users/{user-id}		{DeviceManagementApps.ReadWrite.All

The output truncates the permissions, so to find out what permissions a cmdlet supports, we run a command like (output truncated for space):

```
[PS] C:\> Find-MgGraphCommand -Command Get-MgUser -ApiVersion V1.0 | Select -ExpandProperty Permissions
```

Name	IsAdmin	Description
Directory.AccessAsUser.All	True	Access the directory as
Directory.Read.All	True	Read directory data
Directory.ReadWrite.All	True	Read and write directory
User.Read	False	Sign you in and read your
User.Read.All	True	Read all users' full
User.ReadBasic.All	False	Read all users' basic
User.ReadWrite	False	Read and update your
User.ReadWrite.All	True	Read and write all users' full

You now have a reasonable idea of what permission you need for any specific action.

In some instances, applications restrict access to data so that the only data available is that which the user is entitled to access through the application. For instance, a user must be a member of a team to be able to access the tags available to that team. Therefore, if they use the *Get-MgTeamTag* cmdlet to retrieve tags for a team, the cmdlet happily returns tags for any team the signed-in user is a member of but won't for any team they don't belong to. In Graph terms, the cmdlet uses delegate permission to return information the user can see whereas application permission is necessary to return data for all teams.

The solution is to create a registered Azure AD application, assign the necessary permission to the application, and use certificate-based authentication to connect the app to the SDK endpoint. The SDK recognizes that the app has consent to use specific application permissions and allows access to all data. See [this article for more information](#).

## Invoke-MgGraphRequest

The *Invoke-MgGraphRequest* cmdlet makes Graph API calls where a suitable SDK cmdlet is unavailable or doesn't return the same information as an API call does. One advantage of this cmdlet is that you can use the example code (Uri) shown in the Graph API documentation. For example, this call retrieves the groups an Azure AD user is a member of (using the [List memberOf call](#)):

```
[PS] C:\> $Uri = "https://graph.microsoft.com/beta/users"
$GroupType = "microsoft.graph.group"
$User = Get-MgUser -UserId Chris.Bishop@office365itpros.com
[Array]$Groups = (Invoke-MgGraphRequest -Uri "$Uri/$(($user.Id)/memberOf/$GroupType)").Value
```

The result stored in the *\$Groups* array is the first 100 groups the user belongs to. If more groups are available, the *@odata.nextLink* value contains the Uri to the next page. The command retrieves the information about groups from the Value property returned by the query.

## The Use of \$Null

*\$Null* is an [automatic PowerShell variable](#) that can be used in comparisons and to set values. It's often used to reset other variables or to clear values set on object properties. SDK cmdlets are not particularly good at handling *\$Null* and many reject its use. For example, despite being legitimate PowerShell code, this command to clear the mobile phone for a user won't work:

```
[PS] C:\> Update-MgUser -UserId Terry.Hegarty@office365itpros.com -MobilePhone $Null
```

Instead, to clear the property, it's necessary to write a space into it:

```
[PS] C:\> Update-MgUser -UserId Terry.Hegarty@office365itpros.com -MobilePhone " "
```

If you want to use a Null value instead of a space, you can do so by running *Invoke-MgGraphRequest*. For example:

```
[PS] C:\> $Uri = "https://graph.microsoft.com/v1.0/users/Terry.Hegarty@office365itpros.com"
Invoke-MgGraphRequest -Uri $Uri -Method Patch -Body @{mobilePhone' = $Null}
```

Problems using \$Null also exist when filtering or searching for objects that have null values (or spaces) in properties. For example, these commands don't work.

```
[PS] C:\> Get-MgUser -Filter "Country eq $Null"
Get-MgUser -Search "Country:$Null" -ConsistencyLevel Eventual
```

Needless to say, the way that the SDK handles PowerShell \$Null values is not a good situation to encounter, especially when converting scripts to replace old Azure AD cmdlets that handle \$Null properly. It's certainly something to consider during the conversion process.

## Azure AD Account Management

To perform Azure AD account management operations, connect to the SDK endpoint with *User.ReadWrite.All* and *Directory.ReadWrite.All* permissions. First, let's create a new account. To do this, we must create a password object in a hash table. The table contains the password for the account and a setting to force the user to change their password when they first sign into Microsoft 365:

```
[PS] C:\> $NewPassword = @{}
$NewPassword["Password"] = "!NewPassword2022!"
$NewPassword["ForceChangePasswordNextSignIn"] = $True
```

To create the new account, run the *New-MgUser* cmdlet.

```
[PS] C:\> New-MgUser -UserPrincipalName "June.Brown@Office365ITPros.com" -DisplayName "June Brown
(Sales Operations)" -PasswordProfile $NewPassword -AccountEnabled -MailNickName June.Brown -City NYC
-CompanyName "Office 365 for IT Pros" -Country "United States" -Department "Sales Operations" -
JobTitle "GM Operations" -BusinessPhones "+1 676 830 1101" -MobilePhone "+1 617 4466615" -State "New
York" -StreetAddress "1, Avenue of the Americas" -Surname "Brown" -GivenName "June" -UsageLocation
"US" -OfficeLocation "NYC"
```

The usage location is a [two-character ISO-3166 country code](#) to show where the account consumes services, and it's important to set the value correctly so that the license assignment works properly. After creating a new account, you'll need to assign it some licenses. We'll get to that topic soon.

To make changes to the account, run the *Update-MgUser* cmdlet:

```
Update-MgUser -UserId June.Brown@Office365itpros.com -JobTitle "Senior Sales Manager" -State CA
```

The Microsoft Graph currently treats email proxy addresses as read-only properties for users and groups. You cannot use the *Update-MgUser* cmdlet to add or remove a proxy address from an Azure AD account. However, if you update an account's user principal name, *Update-MgUser* automatically updates the account's primary SMTP address to match the user principal name. This is likely due to adherence to Microsoft's best practice that the two properties should match whenever possible. If you need to update the set of proxy addresses for an account or change its primary SMTP address, use the *Set-Mailbox* cmdlet. These commands add a new proxy address and set it as the primary SMTP address:

```
[PS] C:\> Set-Mailbox -Identity $UserId -EmailAddresses @{Add="Johnnie.West@Office365itpros.com"}
Set-Mailbox -Identity $UserId -WindowsEmailAddress Johnnie.West@Office365itpros.com
```

To update a user's manager, we must find the identifier for the manager's Azure AD account and pass it to the *Set-MgUserManagerByRef* cmdlet. Here's how:

```
[PS] C:\> $ManagerId = (Get-MgUser -UserId Chris.Bishop@office365itpros.com).Id
Set-MgUserManagerByRef -UserId June.Brown@office365itpros.com `
```

```
-AdditionalProperties @{
  "@odata.id" = "https://graph.microsoft.com/v1.0/users/$ManagerId" }
```

Because the manager property is resolved by reference, we check its value by running *Get-MgUser* and then fetching the information retrieved by expanding the Manager property:

```
[PS] C:\> $ManagerData = Get-Mguser -UserId $UserId -ExpandProperty Manager
$ManagerData.Manager.AdditionalProperties['displayName']
```

Chris Bishop

Deleting an account is done using the *Remove-MgUser* cmdlet. The cmdlet doesn't prompt for confirmation:

```
[PS] C:\> Remove-MgUser -UserId June.Brown@Office365itpros.com
```

Deleted accounts go into the Azure AD deleted items container and remain there for 30 days before Azure AD deletes them permanently. See this article for information about how to [list the set of soft-deleted user accounts](#). After finding the identifier of the account to restore, run the *Invoke-MgGraphRequest* cmdlet to perform the action, like this:

```
[PS] C:\> $Uri = "https://graph.microsoft.com/beta/directory/deleteditems/388d29d7-4c72-476d-be96-53060043122e/restore"
Invoke-MgGraphRequest -Method Post -Uri $Uri
```

To delete an account permanently and make it irrecoverable, use a Delete command:

```
[PS] C:\> $Uri = "https://graph.microsoft.com/beta/directory/deleteditems/388d29d7-4c72-476d-be96-53060043122e"
Invoke-MgGraphRequest -Method Delete -Uri $Uri
```

To retrieve sets of users, run the *Get-MgUser* cmdlet with parameters to tell Azure AD what to fetch. The parameters are:

- **All:** Fetch all matching objects.

```
[PS] C:\> [array]$Users = Get-MgUser -All
```

- **Top:** Fetch between 1 and 999 matching objects.

```
[PS] C:\> [array]$Top500 = Get-MgUser -Top 500
```

- **Filter:** Apply a server-side filter against account properties. For example, here's how to get the set of guest accounts in a tenant:

```
[PS] C:\> [array]$Guests = Get-MgUser -Filter "usertype eq 'Guest'" -All
```

Conversely, to get the set of tenant accounts:

```
[PS] C:\> [array]$Users = Get-MgUser -Filter "usertype eq 'Member'" -All
```

To find the accounts in a specific country:

```
[PS] C:\> Get-MgUser -filter "Country eq 'Ireland'"
```

Here's another example of how to use the *startsWith* filter. In this case, the filter compares two different properties to find objects:

```
[PS] C:\> Get-MgUser -Filter "startsWith(displayname, 'Ken') or startsWith(UserPrincipalName, 'Kim')"
```

This command returns the set of member accounts created between two dates. The trailing Z is important as without its inclusion, the Graph will not consider the dates as valid:

```
[PS] C:\> Get-MgUser -Filter "createdDateTime ge 2022-01-01T00:00:00Z and createdDateTime le 2022-04-01T00:00:00Z and usertype eq 'Guest'"
```

- **Search:** Search a property for a value and return all matching accounts. This example applies a search to the *DisplayName* property to return all accounts with the string "Paul" found in that property. You must enclose the name of the property and the value to search for in single quotes. It's also necessary to include the *ConsistencyLevel* parameter because searching is an advanced query.

```
[PS] C:\> Get-MgUser -Search 'DisplayName:Paul' -ConsistencyLevel Eventual
```

You can combine Search and a Filter. For example:

```
[PS] C:\> Get-MgUser -Search "Country:Ireland" -ConsistencyLevel Eventual -Filter "startsWith(displayname, 'James')"
```

**Graph X-Ray:** The Graph X-Ray extension for Edge and Chrome gives developers a peek into the Graph API commands issued by the Azure AD admin center. It can help you to understand the format of a command and offers the chance to download commands in a PowerShell script. See [this article](#) for more information.

## Assigning Azure AD Roles to User Accounts

The *Get-MgDirectoryRole* returns the set of Azure AD roles known in the tenant. To assign a role to a user account, retrieve the identifiers for the role and the user to whom to assign the role. For example:

```
[PS] C:\> $ExoAdminRoleId = Get-MgDirectoryRole | ? {$_.displayName -eq "Exchange administrator"} |
Select -ExpandProperty Id
$UserId = (Get-MgUser -UserId Brian.Weakliam@Office365itpros.com).Id
```

Then assign the role using the *New-MgDirectoryRoleMemberByRef* cmdlet, passing the identifier of the role to assign and the user:

```
[PS] C:\> New-MgDirectoryRoleMemberByRef -DirectoryRoleId $ExoAdminRoleId -BodyParameter
@{"odata.id" = "https://graph.microsoft.com/v1.0/directoryObjects/($UserId)"}
```

To check that the user now has the role assignment, use the *Get-MgDirectoryRoleMember* cmdlet to fetch the set of accounts assigned the role, and check the names:

```
[PS] C:\> RoleMembers = Get-MgDirectoryRoleMember -DirectoryRoleId $ExoAdminRoleId
ForEach ($RoleMember in $RoleMembers) {
    Write-Host $RoleMember.AdditionalProperties["displayName"]}
```

Currently, the Microsoft Graph PowerShell SDK doesn't include a cmdlet to remove a role assignment. You can remove role assignments through the Azure AD admin center, or by [running a Graph query](#).

## Azure AD Group Management

The types of groups included in Azure AD are:

- Microsoft 365 groups/Teams (including groups used by Yammer).
- Security groups.
- Dynamic Azure AD groups (including those used by Microsoft 365 groups/Teams).
- Distribution lists.
- Mail-enabled security groups.

This section discusses how to use SDK cmdlets to create, update, remove, and restore Azure AD Groups.

### Creating New Azure AD Groups

The *New-MgGroup* cmdlet creates Microsoft 365 groups, dynamic groups, and security groups. It can't create distribution lists or mail-enabled security groups (these are essentially Exchange Online rather than Azure AD

objects). Although *New-MgGroup* can create groups of different types, it is often better to use the dedicated cmdlet for a particular type of group to ensure that Microsoft 365 performs all the necessary provisioning, like *New-UnifiedGroup* or *New-Team*. Here's an example of how to create a new Microsoft 365 Group with *New-MgGroup*:

```
[PS] C:\> $Group = New-MgGroup -Description "Banking Team" -DisplayName "Banking Managers and Others" -MailEnabled:$True -SecurityEnabled:$True -MailNickname "BankingGroup" -GroupTypes "Unified"
```

It's a good idea to capture the result of the cmdlet in a variable. If the command is successful, you'll then have a variable containing properties of the new group including its identifier. As we'll see, you'll need the identifier to interact with the group using other SDK cmdlets.

Although this command successfully creates a new Microsoft 365 group, we don't recommend that you use *New-MgGroup* in this way. It's better to use the *New-UnifiedGroup* cmdlet because it gives more control over group properties such as its privacy setting, sensitivity label, and visibility. It doesn't make sense to create a new group and then run the *Set-UnifiedGroup* cmdlet to update its properties. The same logic applies if you want to create a new team as the easiest method is to use the *New-Team* cmdlet.

## Dynamic Microsoft 365 Groups

The *New-UnifiedGroup* cmdlet doesn't support the creation of dynamic Microsoft 365 groups. Instead, you use the *New-MgGroup* cmdlet and mark the group as being a unified (Microsoft 365 group) with dynamic membership. For example:

```
[PS] C:\> $Group = New-MgGroup -DisplayName "Salespeople in France" -Description "Dynamic group containing all salespeople based in France" -MailEnabled:$True -SecurityEnabled:$False -MailNickname SalesPeopleFrance -GroupTypes "DynamicMembership", "Unified" -MembershipRule "(User.Department -eq ""Sales"" and User.Country -eq ""France"")" -MembershipRuleProcessingState "On"
```

Looking at the *New-MgGroup* command, we see:

- Exchange Online uses the value passed in the *MailNickname* parameter to create the SMTP address of the group (in this case, SalesPeopleFrance@Office365ITPros.com) and the group's alias. If the alias is not unique, Groups adds a four-digit suffix to make it unique.
- The *MailEnabled* and *SecurityEnabled* switches are both defined. *MailEnabled* must be True, but you can set *SecurityEnabled* to be True or False.
- Specifying *Unified* in the *GroupTypes* parameter tells Azure AD to create a Microsoft 365 group. You must include both *DynamicMembership* and *Unified* in *GroupTypes* to create a dynamic Microsoft 365 group.
- *MembershipRuleProcessingState* determines whether Azure AD evaluates group membership on an ongoing basis to find the most up-to-date member set. If you are in the middle of a migration, you can pause processing (set the value to Paused) to stop the evaluation of group membership against Azure AD. In this case, the most recent member set is used.

If you're used to building Exchange dynamic distribution lists, you might find that [a limited set of properties](#) are available to build the membership rule for a dynamic Microsoft 365 group. This is because the properties available are those defined in the Azure AD schema rather than the scheme for the Exchange Directory. Even so, because the request used to retrieve the membership of a dynamic group can become quite complex, it is usually easier to use the GUI in the Azure AD admin center to create dynamic Microsoft 365 groups.

To team-enable the dynamic group, run the *New-Team* cmdlet and specify the identifier of the newly-created group:

```
[PS] C:\> New-Team -GroupId $Group.Id
```

Alternatively, a group owner can team-enable a dynamic Microsoft 365 group through the Teams desktop client.

## Searching for Groups

The *Get-MgGroup* cmdlet fetches details of Azure AD groups. To retrieve a single group, use its display name as a filter:

```
[PS] C:\> Get-MgGroup -Filter "DisplayName eq 'Leadership Team'"
```

If you add the *All* parameter, you'll get all the groups in the tenant.

```
[PS] C:\> [array]$Groups = Get-MgGroup -All
```

The command returns groups of all types. To filter out the various types of groups, we can check different properties to identify each type of group. Table 23-5 lists some useful properties to check.

<b>Property</b>	<b>Used by</b>
MailEnabled = True	Distribution lists Microsoft 365 groups Mail-enabled security groups
SecurityEnabled = True	Security groups Mail-enabled security groups
GroupTypes = Unified	Microsoft 365 groups
GroupTypes = DynamicMembership	Dynamic Azure AD groups
GroupTypes = Unified, DynamicMembership	Dynamic Microsoft 365 groups
ResourceProvisioningOptions = Team	Team-enabled Microsoft 365 groups

Table 23-5: Filter possibilities for different types of Azure AD group

The simplest filters are those which find groups based on a property. For example, to find all security-enabled groups:

```
[PS] C:\> Get-MgGroup -Filter "securityEnabled eq true" -All
```

Find all mail-enabled groups:

```
[PS] C:\> Get-MgGroup -Filter "mailEnabled eq true" -All
```

The *GroupTypes* and *ResourceProvisioningOptions* properties require complex filters with [Lambda operators](#). For example, to find the set of Microsoft 365 groups in the tenant:

```
[PS] C:\> [array]$M365Groups = Get-MgGroup -Filter "groupTypes/any(c:c eq 'unified')" -All
```

To find the set of dynamic Microsoft 365 Groups:

```
[PS] C:\> Get-MgGroup -Filter "groupTypes/any(c:c eq 'dynamicmembership') and groupTypes/any(x:x eq 'unified')" -All
```

To find the set of Microsoft 365 groups enabled for Teams:

```
[PS] C:\> [array]$Teams = Get-MgGroup -Filter "resourceProvisioningOptions/Any(x:x eq 'Team')" -All
```

In addition, client-side filter can refine the results returned by the server. For instance, after fetching all security-enabled groups, we use a client-side filter to find the set with dynamic membership:

```
[PS] C:\> [array]$SecurityGroups = Get-MgGroup -Filter "securityEnabled eq true" -All |  
[array]$DynamicSecurityGroups = $SecurityGroups | ? {$_.GroupTypes -eq "DynamicMembership"}
```

The filters used by *Get-MgGroup* are server-side, meaning that the data is filtered when the server returns it to PowerShell. Because they're Graph-based and return fewer properties than cmdlets like *Get-UnifiedGroup*, these commands are very fast, which makes them worth considering if you have scripts that fetch subsets of groups for processing.

## Updating Group Properties and Membership

PowerShell modules like Exchange Online and Azure AD usually include *Set-* cmdlets to update the properties of objects. The SDK uses *Update-Mg\** cmdlets, so to update a group, you run the *Update-MgGroup* cmdlet. For example:

```
[PS] C:\> Update-MgGroup -GroupId $Group.Id -Description "Everyone involved with sales in France"
```

You cannot use *Update-MgGroup* to add or remove email proxy addresses for a group because the Microsoft Graph treats the *proxyAddresses* attribute as read-only. If you need to change a proxy address for a group, use an Exchange Online cmdlet like *Set-UnifiedGroup* instead.

The *New-MgGroupMember* cmdlet populates group membership (for non-dynamic groups). In this example, we fetch the group identifier, use *Get-MgUser* to find a set of suitable group members, and finally add them to the group:

```
[PS] C:\> $GroupId = (Get-MgGroup -Filter "displayName eq 'Sales Operations Team').Id
[array]$Users = Get-MgUser -Filter "department eq 'Sales'"
ForEach ($User in $Users) {
    New-MgGroupMember -GroupId $GroupId -DirectoryObjectId $User.Id }
```

Unfortunately, checking that the right members are present afterward is not as simple as it should be (and is with either the *Get-AzureADGroupMember* or *Get-UnifiedGroupLinks* cmdlets). Instead of *Get-MgGroupMember* returning a list of group members, meaning that to see information like the display names or user principal names for group members, you must pipe the output to the *Get-MgUser* cmdlet:

```
[PS] C:\> Get-MgGroupMember -GroupId $GroupId -All | ForEach {Get-MgUser -UserId $_.Id}
```

Adding a group owner is a little complicated because the owner is stored by reference to its object rather than as a simple property. The *New-MgGroupOwnerByRef* cmdlet, which adds the manager for a group, requires the identifier for the owner's account to be passed in a hash table:

```
[PS] C:\> New-MgGroupOwnerByRef -GroupId $GroupId -AdditionalProperties
@{"@odata.id"="https://graph.microsoft.com/v1.0/users/2a3b60f2-b36b-4758-8533-77180031f3d4"}
```

Remember that synchronization to workloads is necessary before owner or member deletions take full effect across Microsoft 365.

## Removing Group Members

To remove a group owner, you need to know the group identifier and the identifier for the owner's account. You can then run the *Remove-MgGroupOwnerByRef* cmdlet. For example:

```
[PS] C:\> $GroupId = (Get-MgGroup -Search 'DisplayName:Ultra Fans' -ConsistencyLevel Eventual).Id
$UserId = (Get-MgUser -UserId Sean.Landy@Office365itPros.com).Id
Remove-MgGroupOwnerByRef -DirectoryObjectId $UserId -GroupId $GroupId
```

The cmdlet won't allow you to remove the last owner of a group. If you want to remove the user as a group member, run the *Remove-MgGroupMemberByRef* cmdlet:

```
[PS] C:\> Remove-MgGroupMemberByRef -DirectoryObjectId $UserId -GroupId $GroupId
```

## Removing and Restoring Groups

The *Remove-MgGroup* cmdlet removes a Microsoft 365 group or security group. For example:

```
[PS] C:\> Remove-MgGroup -GroupId f6dd8a3e-d50c-4af2-a9cf-f4adf71ec82b
```

The cmdlet can't remove distribution lists or mail-enabled security groups.

## Finding Deleted Groups

Azure AD uses a two-phase deletion process for groups. First, a deleted group enters a soft-deleted state where it remains for 30 days. During this time, administrators can restore the group using options in the Microsoft 365 and Azure AD admin centers. After the 30-day retention period lapses, Azure AD removes the group permanently and it is then irrecoverable.

During the soft-deleted retention period, it's possible to restore the group using the *Restore-MgGroup* cmdlet after using the *Get-MgDirectoryDeletedItem* cmdlet to return find the correct group identifier to use. For example:

```
[PS] C:\> Restore-MgGroup -GroupId 314bab9d-af9b-43b8-b627-af38075d40b0
```

However, some issues exist with these cmdlets in the current version of the SDK. Instead, we can use a Graph API query to fetch the set of deleted groups. In this example, the query executed by the *Invoke-MgGraphRequest* cmdlet retrieves details for up to 100 deleted groups and displays them using the *Out-GridView* cmdlet.

```
[PS] C:\> Connect-MgGraph
Select-MgProfile Beta
$uri =
"https://graph.microsoft.com/beta/directory/deleteditems/microsoft.graph.group?`$select=id,displayName,groupTypes,deletedDateTime&`$orderBy=displayName%20asc&`$top=100"
[array]$Groups = (Invoke-MgGraphRequest -Uri $Uri).Value
If (!$Groups) { write-Host "No deleted groups available for recovery" ; break }
$Report = [System.Collections.Generic.List[Object]]::new(); $Now = Get-Date
ForEach ($Group in $Groups) {
    $PermanentRemovalDue = Get-Date($Group.deletedDateTime).AddDays(+30)
    $TimeTillRemoval = $PermanentRemovalDue - $Now
    $ReportLine = [PSCustomObject]@{
        Group           = $Group.DisplayName
        Id              = $Group.Id
        Deleted         = $Group.deletedDateTime
        PermanentDeleteOn = Get-Date($PermanentRemovalDue) -format g
        DaysRemaining  = $TimeTillRemoval.Days
    }
    $Report.Add($ReportLine)
}
$Report | Sort {$_.PermanentDeleteOn -as [datetime]} | Out-GridView
```

To restore a deleted group, run a POST query and pass the identifier for the group to restore. Once again, the *Invoke-MgGraphRequest* cmdlet runs the query:

```
[PS] C:\> $Uri = "https://graph.microsoft.com/beta/directory/deleteditems/8783e3dd-66fc-4841-861d-49976f0617c0/restore"
Invoke-MgGraphRequest -Method POST -Uri $Uri
```

The newly restored group should be available and ready for users within an hour.

## Using Advanced Azure AD Queries Against Groups

*Get-MgGroup* supports [advanced queries against Azure AD](#). As discussed earlier, an advanced query is one that the Microsoft Graph resolves against a separate property store. It's not always obvious when an advanced query is necessary. Microsoft could hide this need in code instead of forcing PowerShell coders to remember when they must add the *ConsistencyLevel* parameter to mark a query as advanced. Searching the display name of groups for a term is an example of an advanced query.

```
[PS] C:\> [array]$Groups = Get-MgGroup -Search "'displayname:Office 365'" -ConsistencyLevel Eventual
```

Another example is to use the *Filter* parameter to find groups which start with a value. For instance, we might want to find groups whose display name starts with Office:

```
[PS] C:\> [array]$Groups = Get-MgGroup -Filter "startsWith(DisplayName, 'Office')" -ConsistencyLevel Eventual
```

## Managing Account Licenses

To start our discussion about how to manage licenses through PowerShell, let's review some terms used by Microsoft:

- A **SKU** (traditionally, a "stock keeping unit") is something a customer can purchase, like Office 365 E3. SKUs can be bought on a subscription or trial basis. A SKU is often referred to as a **product** or **license**. To demonstrate the intermingling of terms, when you manage user accounts through the Microsoft 365 admin center, the GUI shows that you assign licenses to accounts.
- A **service plan** is a license for an individual feature included in a SKU. For example, Microsoft Bookings, Microsoft Planner, and Mobile Device Management for Office 365 are service plans included in the Office 365 E3 SKU. You cannot buy a service plan as these items are always part of products. In the Microsoft 365 admin center, the individual service plans listed for a user account are called **apps**.
- Organizations can buy **add-on licenses** to access an individual capability. For example, you can purchase Viva Topics add-on licenses to use this capability to build a knowledge network. Add-on licenses are assigned to user accounts to allow access to the capability.

Because product names and service plan names differ from language to language, Microsoft 365 uses GUIDs to identify SKUs and service plans. Microsoft documents the [product names and their SKU identifiers](#) online. This is a very useful page to bookmark because you'll often need to know what the identifier is for a product or service plan. The page also lists the services plans that are included in each product, including the service plan identifiers.

Now that we understand the structure of licenses, we can proceed to interact with those available in a tenant using cmdlets from the Graph SDK. To see license information in user accounts, you must connect to the Graph with the beta profile. Your session needs the *Directory.ReadWrite.All* permission to set licenses.

```
[PS] C:\> $RequiredScopes = @(Directory.ReadWrite.All)
Connect-MgGraph -Scopes $RequiredScopes
Select-MgProfile Beta
```

### Fetching License Information

The *Get-MgSubscribedSku* cmdlet reports the set of products known in a tenant. Before a SKU shows up in a tenant, the organization must subscribe for at least one license (free or paid-for). This command shows the list of SKU identifiers, the SKU names, and the consumed units (allocated licenses).

```
[PS] C:\> Get-MgSubscribedSku | Format-Table SkuId, SkuPartNumber, ConsumedUnits
```

SkuId	SkuPartNumber	ConsumedUnits
1f2f344a-700d-42c9-9427-5cea1d5d7ba6	STREAM	3
b05e124f-c7cc-45a0-a6aa-8cf78c946968	EMSPREMIUM	4
4016f256-b063-4864-816e-d818aad600c9	TOPIC_EXPERIENCES	9
6fd2c87f-b296-42f0-b197-1e91e994b900	ENTERPRISEPACK	25
f30db892-07e9-47e9-837c-80727f46fd3d	FLOW_FREE	9
a403ebcc-fae0-4ca2-8c8c-7a907fd6c235	POWER_BI_STANDARD	7
26d45bd9-adf1-46cd-a9e1-51e9a5524128	ENTERPRISEPREMIUM_NOPSTNCONF	4

The output for the examples in this section are edited. Typically, many more product and service plans are available within a tenant.

Among the list of SKUs, we see products like Office 365 E3 (*EnterprisePack*), Viva Topics (*Topic\_Experiences*), and Office 365 without PSTN (*EnterprisePremium\_NoPSTNConf*). To discover the set of service plans covered

in a product, filter for the product and select the *ServicePlans* property. The *AppliesTo* property indicates if the service plan applies:

- Tenant-wide (like Microsoft Search). These service plans are marked as **Company** can only be enabled or disabled for the complete tenant.
- Per-user basis (like Whiteboard). You can disable service plans marked as **User** to control the functionality available to individual user accounts.

```
[PS] C:\> Get-MgSubscribedSku | ? {$_.SkuPartnumber -eq 'ENTERPRISEPACK' } | Select -ExpandProperty ServicePlans | Format-Table AppliesTo, ServicePlanId, ServicePlanName
```

AppliesTo	ServicePlanId	ServicePlanName
User	b76fb638-6ba6-402a-b9f9-83d28acb3d86	VIVA_LEARNING_SEEDED
Company	db4d623d-b514-490b-b7ef-8885eee514de	Nucleus
Company	2b815d45-56e4-4e3a-b65c-66cb9175b560	ContentExplorer_Standard
User	94a54592-cd8b-425e-87c6-97868b000b91	WHITEBOARD_PLAN2

At a user account level, assigned licenses are in the *AssignedLicenses* property. In this output, we see that the user has three products, and that some service plans are disabled in two products.

```
[PS] C:\> Get-MgUser -UserId Andy.Ruth@Office365itpros.com | Select -ExpandProperty AssignedLicenses | Format-List
```

```
DisabledPlans      : {aebd3021-9f8f-4bf8-bbe3-0ed2f4f047a1, a23b959c-7ce8-4e57-9140-b90eb88a9e97}
SkuId              : 6fd2c87f-b296-42f0-b197-1e91e994b900
AdditionalProperties : {}

DisabledPlans      : {bea4c11e-220a-4e6d-8eb8-8ea15d019f90}
SkuId              : b05e124f-c7cc-45a0-a6aa-8cf78c946968
AdditionalProperties : {}

DisabledPlans      : {}
SkuId              : 4016f256-b063-4864-816e-d818aad600c9
AdditionalProperties : {}
```

The easiest way to interpret the GUIDs is to search [Microsoft's product names and identifiers page](#), where we find that:

- 6fd2c87f-b296-42f0-b197-1e91e994b900 is Office 365 E3, and the two disabled service plans are Kaizala (aebd3021-9f8f-4bf8-bbe3-0ed2f4f047a1) and Sway (a23b959c-7ce8-4e57-9140-b90eb88a9e97).
- b05e124f-c7cc-45a0-a6aa-8cf78c946968 is Enterprise Mobility and Security E5, and the disabled service plan is Rights management (bea4c11e-220a-4e6d-8eb8-8ea15d019f90).
- 4016f256-b063-4864-816e-d818aad600c9 is Viva Topics.

After a while, you might even get to recognize some of the more common product and service plan identifiers.

Service plans can exist in multiple products licenses assigned to a single account. Microsoft 365 only cares that a service plan is available when it checks if an account is licensed to use some functionality. To make it easy to check the license status of a service plan, accounts have an *AssignedPlans* property. We can exploit this to find accounts that can use a certain capability. For instance, let's assume that we want to check on accounts that can use Teams. The Teams1 service plan is included in many Microsoft 365 products, and its service plan identifier is 57ff2da0-773e-42df-b2af-ffb7a2317929. This code creates a quick report.

```
[PS] C:\> $TeamsServicePlanId = "57ff2da0-773e-42df-b2af-ffb7a2317929" #Teams
$PlanUsers = [System.Collections.Generic.List[Object]]::new()
[array]$Users = Get-MgUser -All -Filter "Usertype eq 'Member'"
ForEach ($User in $Users) {
    If ($TeamsServicePlanId -in $User.AssignedPlans.ServicePlanId) {
```

```
$Status = ($User.AssignedPlans | ? {$_.ServicePlanId -eq $TeamsServicePlanId} | Select -
ExpandProperty CapabilityStatus )
$ReportLine = [PSCustomObject] @{
    User      = $User.DisplayName
    UPN       = $User.UserPrincipalName
    Department = $User.Department
    Country   = $User.Country
    Enabled   = $Status }
$PlanUsers.Add($ReportLine) }
}
```

## Find Unlicensed Accounts

Many accounts do not have or need licenses, including:

- Accounts used by Exchange Online shared mailboxes that are smaller than 50 GB or have an archive mailbox.
- Accounts used by Exchange Online room, equipment, or resource mailboxes.
- Guest accounts created by SharePoint Online in Azure AD to share documents with external users.
- Guest accounts created by Azure B2B collaboration for use in applications like Microsoft 365 Groups and Teams.
- Administration accounts (if they don't need to use a mailbox).

To find the set of members (non-guest) accounts that don't have assigned licenses, use this command:

```
[PS] C:\> [array]$UnlicensedAccounts = Get-MgUser -Filter "assignedLicenses/`$count eq 0 and
userType eq 'Member'" -ConsistencyLevel eventual -CountVariable Records -All
$UnlicensedAccounts | Sort DisplayName | Format-Table DisplayName, Mail
```

The Records count variable specified in the command returns the count of records in \$Records.

## Assigning Licenses to User Accounts

The *Set-MgUserLicense* cmdlet assigns licenses to user accounts. You need to know:

- The UPN or object identifier of the target account.
- The SKU identifier of the product you wish to license for the account.

With this information, we can assign a license. In this example, we assign a Viva Topics license (the product identifier is 4016f256-b063-4864-816e-d818aad600c9).

```
[PS] C:\> Set-MgUserLicense -UserId "Terry.Hegarty@Office365itpros.com" -AddLicenses @{SkuId =
'4016f256-b063-4864-816e-d818aad600c9'} -RemoveLicenses @()
```

You must pass an empty array in the *RemoveLicenses* parameter. This applies even if you don't want the command to remove any licenses. If the command completes without an error, the assignment worked (or the account already holds the license), but you can check by reviewing the set of product identifiers stored in the account:

```
[PS] C:\> $Products = (Get-MgUser -UserId Terry.Hegarty@Office365itpros.com).AssignedLicenses.SkuId
$Products
a403ebcc-fae0-4ca2-8c8c-7a907fd6c235
4016f256-b063-4864-816e-d818aad600c9
6fd2c87f-b296-42f0-b197-1e91e994b900
```

Table 23-6 lists some common error conditions that occur during license assignments.

<b>Reason</b>	<b>Example error</b>
No licenses for the specified product are available.	Subscription with SKU 26d45bd9-adf1-46cd-a9e1-51e9a5524128 does not have any available licenses.

The license is unknown in the tenant (a subscription for the license has never existed).	License e82ae690-a2d5-4d76-8d30-7c6e01e6022e does not correspond to a valid company License.
An invalid identifier for a service plan in a compound license is specified.	Service plan 2078e8df-cff6-4290-98cb-5408261a760a for license 26d45bd9-adf1-46cd-a9e1-51e9a5524128 is not valid.
Attempt to remove a license from an account that it doesn't have.	User does not have a corresponding license.

Table 23-6: License assignment errors

To find accounts where error conditions exist for license assignments, run this request:

```
[PS] C:\> $Uri =
'https://graph.microsoft.com/v1.0/users?`$filter=provisionedPlans/any(p:p/provisioningStatus eq
'Error')&`$count=true'
$Data = Invoke-MgGraphRequest -Uri $Uri -Method Get -Headers @{ConsistencyLevel='eventual'}
ForEach ($D in $Data.Value) { Write-Host ("Error found for {0} {1}" -f $D.displayname,
$D.UserPrincipalName) }
```

You'll need to check each account to determine what caused the error condition to exist.

## More Complex Assignments

Viva Topics is a simple license to assign. Products like Office 365 E3 or E5 include multiple service plans, some of which are for functionality that organizations do not want people to use. For example, in academic settings, colleges might not want students to use Yammer for Education, while business tenants might not want people to use Microsoft Bookings, Sway, Kaizala, and so on. To assign a compound license like Office 365 E3 without disabling any service plans, all you need is the product identifier. We know that is 6fd2c87f-b296-42f0-b197-1e91e994b900 (see above). To disable selected service plans, we need to know their identifiers. In this example, we use:

- Microsoft Bookings: 199a5c09-e0ca-4e37-8f7c-b05d533e1ea2
- Yammer Enterprise: 7547a3fe-08ee-4ccb-b430-5077c5041653
- Microsoft Kaizala Pro Plan 3: aebd3021-9f8f-4bf8-bbe3-0ed2f4f047a1

Be careful when you disable a service plan. Because of the interconnected nature of Microsoft 365, you might find that disabling a service plan affects the ability of other features to work properly. For instance, if you disable Stream, Teams won't be able to save meeting recordings.

To start, create a hash table containing the license information. Entries exist for the product and the disabled service plans:

```
[PS] C:\> $LicenseOptions = @{SkuId = "6fd2c87f-b296-42f0-b197-1e91e994b900"; DisabledPlans =
@("199a5c09-e0ca-4e37-8f7c-b05d533e1ea2", "7547a3fe-08ee-4ccb-b430-5077c5041653", "aebd3021-9f8f-
4bf8-bbe3-0ed2f4f047a1")}
```

Then run *Set-MgUserLicense* to assign the license:

```
[PS] C:\> Set-MgUserLicense -UserID Terry.Hegarty@Office365itpros.com -AddLicenses
@($LicenseOptions) -RemoveLicenses @()
```

You can also pass the disabled service plans in an array. For example:

```
[PS] C:\> $LicenseOptions = @("199a5c09-e0ca-4e37-8f7c-b05d533e1ea2", "7547a3fe-08ee-4ccb-b430-
5077c5041653", "aebd3021-9f8f-4bf8-bbe3-0ed2f4f047a1")
$Office365E3Sku = "6fd2c87f-b296-42f0-b197-1e91e994b900"
Set-MgUserLicense -UserID Terry.Hegarty@Office365itpros.com -AddLicenses @{SkuId = $Office365E3Sku;
DisabledPlans = $LicenseOptions } -RemoveLicenses @()
```

To reenable a disabled service plan, remove the service plan from the list of disabled plans and run the command again. In this example, the service plan for Microsoft Bookings is not present in the list of disabled plans specified in the `$LicenseOptions` variable, so it is enabled when we run `Set-MgUserLicense`:

```
[PS] C:\> $LicenseOptions = @"7547a3fe-08ee-4ccb-b430-5077c5041653", "aebd3021-9f8f-4bf8-bbe3-0ed2f4f047a1"

Set-MgUserLicense -UserId Terry.Hegarty@Office365itpros.com -AddLicenses @{SkuId = $Office365E3Sku; DisabledPlans = $LicenseOptions } -RemoveLicenses @()
```

To check the status of disabled service plans in an account, run the `Get-MgUserLicenseDetail` cmdlet:

```
[PS] C:\> Get-MgUserLicenseDetail -UserId Terry.Hegarty@office365itpros.com | ? {$_.SkuId -eq "6fd2c87f-b296-42f0-b197-1e91e994b900"} | Select-Object -ExpandProperty ServicePlans | Sort ProvisioningStatus
```

AppliesTo	ProvisioningStatus	ServicePlanId	ServicePlanName
User	Disabled	aebd3021-9f8f-4bf8-bbe3-0ed2f4f047a1	KAIZALA_O365_P3
User	Disabled	7547a3fe-08ee-4ccb-b430-5077c5041653	YAMMER_ENTERPRISE
User	Disabled	199a5c09-e0ca-4e37-8f7c-b05d533e1ea2	MICROSOFTBOOKINGS
User	Success	57ff2da0-773e-42df-b2af-ffb7a2317929	TEAMS1

To assign multiple licenses to an account in a single operation, create a hash table containing details of the licenses to add and pass the hash table to `Set-UserMgLicense` in the `BodyParameter` parameter instead of using the `AddLicenses` parameter. In this example, we assign licenses for Office 365 E3 and Viva Topics and disable the service plans for Bookings, Yammer, and Kaizala from the Office 365 E3 license:

```
[PS] C:\> $LicenseParams = @{
    AddLicenses = @(
        @{ DisabledPlans = @"199a5c09-e0ca-4e37-8f7c-b05d533e1ea2", "7547a3fe-08ee-4ccb-b430-5077c5041653", "aebd3021-9f8f-4bf8-bbe3-0ed2f4f047a1"
          SkuId = "6fd2c87f-b296-42f0-b197-1e91e994b900" }
        @{ DisabledPlans = @()
          SkuId = "4016f256-b063-4864-816e-d818aad600c9"
        })
    RemoveLicenses = @() }

Set-MgUserLicense -UserId John.Wilson@office365itpros.com -BodyParameter $LicenseParams
```

It's also possible to assign licenses to an account by copying the assignment information from another account. This approach works well when you have configured an account with all the necessary licenses and service plans and need to assign the same licenses to multiple accounts. For example:

```
[PS] C:\> $SourceLicenses = (Get-MgUser -UserId John.Wilson@Office365itpros.com).AssignedLicenses
[array]$TargetUsers = Get-MgUser -Filter "Country eq 'United States' and Usertype eq 'Member'" -All
ForEach ($User in $TargetUsers) {
    Write-Host "Processing" $User.DisplayName $User.Id
    Set-MgUserLicense -UserId $User.Id -AddLicenses $SourceLicenses -RemoveLicenses @() }
```

## Removing a Service Plan from Multiple Accounts

Microsoft often adds a service plan to a product to support the deployment of a new feature. For example, when they made Microsoft Bookings available to Office 365 E3 and E5 licensees, Microsoft introduced a service plan for Microsoft Bookings. It might be the case that an organization is unprepared for their users to access a new feature after deployment and need some extra time to prepare training and support. In this scenario, you could remove the service plan from assigned licenses.

This is an example of removing the Kaizala service plan from accounts assigned Office 365 E3 licenses. The code:

- Sets up the license information to remove.
- Runs `Get-MgUser` to find the set of tenant users.

- Checks each account to see if it has Office 365 E3, and if so, check that the Kaizala service plan is enabled.
- Updates the account to disable the Kaizala service plan.
- Reports the actions taken.

```
[PS] C:\> $RemovePlan = "aebd3021-9f8f-4bf8-bbe3-0ed2f4f047a1" #Kaizala
$LicenseOptions = @{SkuId = "6fd2c87f-b296-42f0-b197-1e91e994b900" ; DisabledPlans = $RemovePlan}
$Report = [System.Collections.Generic.List[Object]]::new()
$TenantUsers = Get-MgUser -Filter "UserType eq 'Member'" -All

ForEach ($User in $TenantUsers) {
    Write-Host "Checking licenses for" $User.DisplayName
    #Check that Office 365 E3 is assigned
    If ("6fd2c87f-b296-42f0-b197-1e91e994b900" -in $User.AssignedLicenses.SkuId) {
        Foreach ($Plan in $User.AssignedPlans) {
            If ($Plan.ServicePlanId -eq $RemovePlan -and $Plan.CapabilityStatus -eq "Enabled") {
                Write-Host ("Removing service plan {0} from account {1}" -f $Plan.Service, $M.DisplayName) -
                ForegroundColor Red
                Set-MgUserLicense -UserId $User.Id -AddLicenses @($LicenseOptions) -RemoveLicenses @(
                $LicenseUpdateInfo = "Kaizala service plan removed from account " + $User.UserPrincipalName + "
on " + (Get-Date) + " from Office 365 E3"
                Write-Host ("Service plan {0} removed from SKU {1} for {2}" -f $Plan.Service, $SelectedSku,
$User.DisplayName)
                $ReportLine = [PSCustomObject][Ordered]@{
                    DisplayName = $User.DisplayName
                    UPN = $User.UserPrincipalName
                    Info = $LicenseUpdateInfo
                    SKU = "Office 365 E3"
                    "Service Plan" = $Plan.Service
                    "ServicePlanId" = $Plan.ServicePlanId }
                $Report.Add($ReportLine)
            } # End if
        } # End ForEach
    } #End if for Office 365 E3 check
} # End ForEach mailbox
```

## Removing Licenses

To remove licenses from a user account, specify the license identifiers in an array and pass the array to the *Set-MgUserLicense* cmdlet in the *RemoveLicenses* parameter. For example:

```
[PS] C:\> [array]$LicensesToRemove = "4016f256-b063-4864-816e-d818aad600c9", "6fd2c87f-b296-42f0-
b197-1e91e994b900"
Set-MgUserLicense -UserId "John.Wilson@Office365itpros.com" -AddLicenses @() -RemoveLicenses
$LicensesToRemove
```

*Set-MgUserLicense* cannot remove a license from an account if the [assignment is via group membership](#).

Another way to remove multiple licenses from an account is to pass the license information in a hash table and pass it in the *BodyParameter* parameter:

```
[PS] C:\> $LicenseParams = @{ AddLicenses = @()
    RemoveLicenses = @("4016f256-b063-4864-816e-d818aad600c9",
    "6fd2c87f-b296-42f0-b197-1e91e994b900") }
Set-MgUserLicense -UserId John.Wilson@office365itpros.com -BodyParameter $LicenseParams
```

## Reporting Assigned Licenses

We can easily find the set of products (SKUs) used in a tenant. With this list, we can find the licenses assigned to user accounts for each product. For example, this code loops through the set of SKUs to report the users with assigned licenses:

```
[PS] C:\> $Report = [System.Collections.Generic.List[Object]]::new()
[array]$Skus = Get-MgSubscribedSku
ForEach ($Sku in $Skus) {
```

```
Write-Host "Processing license holders for" $Sku.SkuPartNumber
$SkuId = $Sku.SkuId
[array]$SkuUsers = Get-MgUser -Filter "assignedLicenses/any(x:x/skuId eq $SkuId)" -All
ForEach ($User in $SkuUsers) {
    $ReportLine = [PSCustomObject] @{
        User      = $User.DisplayName
        UPN       = $User.UserPrincipalName
        Department = $User.Department
        Country   = $User.Country
        SKU       = $Sku.SkuId
        SKUName   = $Sku.SkuPartNumber}
    $Report.Add($ReportLine) }}
$Report | Sort User | Out-GridView
```

Note the use of the filter with the *Get-MgUser* cmdlet to find accounts assigned a specific SKU identifier.

The report above lists accounts and the individual licenses each account holds. With a small change to the code, you could report the data from a license perspective by finding the set of accounts for each license:

```
[PS] C:\> [array]$Skus = Get-MgSubscribedSku
$Report = [System.Collections.Generic.List[Object]]::new()
ForEach ($Sku in $Skus) {
    $SkuId = $Sku.SkuId
    [array]$SkuUsers = Get-MgUser -Filter "assignedLicenses/any(x:x/skuId eq $SkuId)" -All
    $ReportLine = [PSCustomObject][Ordered]@{
        Sku           = $Sku.SkuId
        Product       = $Sku.SkuPartNumber
        'Consumed Units' = $Sku.ConsumedUnits
        'Calculated Units' = $SkuUsers.Count
        'Assigned accounts' = $SkuUsers.UserPrincipalName -Join ", " }
    $Report.Add($ReportLine)
} # End ForEach
$Report | Sort Product | Out-GridView
```

[This article](#) describes a more comprehensive treatment of reporting license assignments to user account.

Another way of reporting assigned licenses is to check against the *AssignedLicenses* property in user accounts. This code looks for accounts assigned the Office 365 E3 license and reports how many it finds:

```
[PS] C:\> [array]$AllUsers = Get-MgUser -Filter "UserType eq 'Member'" -All | Select Id,
AssignedLicenses, UserPrincipalName, DisplayName
[array]$O365E3Users = $AllUsers | Where-Object {$_.AssignedLicenses.SkuId -contains "6fd2c87f-b296-
42f0-b197-1e91e994b900"}
Write-Host ("You have {0} tenant accounts and {1} have Office 365 E3 licenses." -f $AllUsers.Count,
$O365E3Users.Count)
```

## Interacting with Teams

To explore how the SDK cmdlets can interact with Teams, this example shows how to post messages to a team channel. First, we use the *Get-MgUser* cmdlet to list all Azure AD accounts with a display name starting with "Paul." After finding the account we want to use, we then call the *Get-MgUserJoinedTeam* cmdlet using the object identifier for that account to find a list of the teams the chosen account belongs to:

```
[PS] C:\> $RequiredScopes = @("User.Read.All","Group.ReadWrite.All","ChannelMessage.Send")
Connect-MgGraph -Scopes $RequiredScopes -TenantId "828e1143-88e3-492b-bf82-24c4a47ada63"
Get-MgUser -Filter "startsWith(displayname, 'Paul')" -All | Format-Table DisplayName, Id
Get-MgUserJoinedTeam -Userid aff4cd58-1bb8-4899-94de-795f656b4a18
```

After selecting a team and storing its identifier in a variable, we find the identifier for the team's General channel and use it to post a high-priority message to the channel. To perform this operation, the scope for the Graph connection must include the *ChannelMessage.Send* permission, which is why it's included in the scope listed above.

```
[PS] C:\> $TeamId = "82ae842d-61a6-4776-b60d-e131e2d5749c"
```

```
$ChannelId = Get-MgTeamChannel -TeamId $TeamId | ? {$_.DisplayName -eq "General"} | Select -ExpandProperty Id
$Message = (New-MgTeamChannelMessage -TeamId $TeamId -ChannelId $ChannelId -Body @"Content="PowerShell and the Graph SDK can do great things" } -Subject "Greetings to PowerShell fans" -Importance "High")
```

Getting a little more complicated, let's assume that we create a report or similar information in HTML format that we want to publish to the channel. This can be done by specifying a *ContentType* in the *Body* parameter:

```
[PS] C:\> $Message = (New-MgTeamChannelMessage -TeamId $TeamId -ChannelId $ChannelId -Body @"Content = $HTMLContent; ContentType = "html" } -Subject "Report about Teams activity" -Importance "High")
```

In both cases where we post a message, the *\$Message* variable captures the response from Teams. The variable includes an identifier for the message posted to the channel which can be used to post a response. For example:

```
[PS] C:\> $Response = New-MgTeamChannelMessageReply -TeamId $TeamId -ChannelId $ChannelId -ChatMessageId $Message.Id -Body @"Content = "Invaluable!" }
```

## Using Azure Automation with Microsoft 365

Azure Automation allows background jobs such as PowerShell scripts to run on virtual sandbox machines managed by Azure. It is a convenient mechanism to execute long-running PowerShell scripts such as those which must process large quantities of mailboxes, groups, or teams, or to retrieve information from the audit log to export to an external repository. The basic concepts are:

- Jobs run under the control of an Azure Automation account. The account is associated with an Azure subscription to pay for the resources consumed by any processing. The automation account owns resources such as runbooks, credentials, schedules, and modules. It also has a [RunAs account](#), which leverages several assets created for the automation account, including:
  - An Azure AD application with a service principal and a self-signed certificate. The service principal can hold API permissions such as Graph API permissions and be a member of Azure AD role groups.
  - An automation certification asset called *AzureRunAsCertificate* holding the private key used by the Azure AD application. The certificate is valid for one year and is renewable.
  - An automation connection called *AzureRunAsConnection* holding the application identifier, certificate thumbprint, Azure subscription identifier, and tenant identifier. Runbooks use this connection to authenticate to access Azure resources. The information is also usable to secure an access token to connect to the Graph.
- A runbook is where developers create the PowerShell code they wish to run as background jobs. Writing code in a runbook is like writing code in the PowerShell ISE. You can paste code into the runbook, but some work is probably necessary to update the code to make it ready to run under Azure Automation. For example, code in a sandbox is non-interactive, so any prompts or outputs won't work. Developers can execute a runbook in a test pane to validate that the code works before releasing it for production use.
- Credentials can be anything from a username/password combination (stored securely in the automation account, but not recommended for production use) to certificates and certificate thumbprints used for certificate-based authentication. Many PowerShell modules support certificate-based authentication, so runbooks should use this method when possible.
- PowerShell modules adapted for Azure Automation are available for loading into an Automation account to make them available to PowerShell scripts executing in a runbook. Most Microsoft 365 modules (Exchange Online, SharePoint Online, SharePoint PnP, Azure AD, Teams, the Microsoft Graph PowerShell SDK, etc.) are available.

- When a runbook is ready for production use, it can link to a schedule in the automation account to execute on regular basis, such as daily or weekly. The schedule can have a predetermined end or be ongoing.

For more information on using Azure Information with Microsoft 365 workloads, see these articles:

- [Using Azure Automation with Exchange Online PowerShell.](#)
- [Using Azure Automation with the Microsoft Graph PowerShell SDK](#) (send email).
- [Using Azure Automation and PowerShell to create documents in SharePoint Online.](#)

Like the service principal used by interactive sessions with the Microsoft Graph PowerShell SDK, tenant administrators and developers should take care to ensure that the API permissions assigned to automation accounts do not accrue over time and result in overly-permissioned accounts.

## Office Connectors

Connectors allow you to link a feed from a cloud data source to Groups, Teams, and Yammer. The idea behind a connector is that it brings information from the source application to the attention of group members, who consume the information through connector cards. Each card contains a snapshot of information about an item available in the network source. The information is intended to allow the reader to know what's going on, but if they want the full story, they need to go to the source. Usually, the card contains a hyperlink to get to the full content. Connectors are linked to:

- **An Outlook group:** Cards are posted as conversations in the group inbox. Group members can read and respond to cards in the conversation or via email (if they subscribe to the group).
- **A channel in a team:** Cards are posted as new topics in the channel. Team members can read and respond to cards in the channel.
- **Yammer community:** Cards are posted as new topics in the feed. Community members can read and respond to cards like normal posts. This functionality is only supported for Yammer communities connected to Groups.

Connectors support an extensive set of network sources, including those featured on project activities (Trello, Asana, and Wunderlist), customer relationships (Salesforce, Dynamics 365, and Zendesk), news sources (Bing News and RSS feeds), and developer tools (GitHub and Visual Studio). In addition, the *Incoming Webhook* connector is available as a generic link to allow developers to fetch data from other services to a group or team. Programmers can use the webhook to create a link to a group for a company-specific system or some other network data source for which a connector does not exist.

## Actionable Cards

Some connectors, like those from GitHub or Trello, use [actionable or adaptive cards](#), which allow the reader to take quick actions using buttons in the card without having to navigate to the source application. Many inbound messages have a link to bring the user to a website to conduct a transaction such as responding to an inbound customer request or deciding how to process an item. The idea behind actionable cards is that you avoid the need for the reader to switch context by enabling them to execute tasks within the message. Clients like Outlook and Teams can interpret code held in the message to make interactive UI elements available to the reader. Cards can have buttons, dropdown lists, date pickers, and text input boxes.

For more information, see the [Adaptive Cards website](#).

## Adding a New Connector to a Group

To create a new connector for a group, select the group from the list of groups shown in OWA resources, and then open the [...] menu. Select Settings from the menu to display the Group Settings pane and then click the

Connectors link. OWA opens the Office connectors page, where you can see the list of available connectors and can choose to add a new connector or configure one that's already connected to the group.

Connectors often need some form of authentication for the network source. For instance, if you connect Yammer to a group, you must use a valid Microsoft 365 account. Other connectors, like the RSS feed, don't need to be authenticated. For instance, to set up an RSS feed for blog posts relating to this book, all you need to enter is the URL for the blog feed (<https://office365itpros.com/feed/>). After saving the connector, you can close the Office connectors page and return to OWA. Most connectors post a welcome or initial message to the group to inform members that the connector.

You can configure a group with multiple connectors of the same type and use multiple connectors for different sources to gather information from multiple places into a single group. There are many interesting ways that you might consider using connectors with Groups. For instance, you might set up connectors to link to a corporate RSS feed so that group members automatically see updates about important corporate initiatives without having to constantly check the company blog. In addition, the group then serves as an index for blog posts and because the items are in the group mailbox, the messages are discoverable and easily searched. Remember that the messages posted by connectors are only snippets of the information that exists in the network source. Even so, the snippet might be helpful in an eDiscovery investigation.

A key point to understand is that the messages created by connectors simply inform group members about new information. If they find an interesting topic, the group members can discuss that information in group conversations, perhaps after checking out the full content from the original source.

## Using the Incoming Webhook Connector

Connecting something like an RSS feed to a group is a good use for a connector. Being able to use a data source as a source to post cards to a group (or to a channel in a team) is even more interesting. Microsoft makes this possible with the Incoming Webhook connector, which receives incoming HTTP requests holding cards formatted in JSON (the payload) and routes the information to a destination group or team. The *webhook address* generated when the Incoming Webhook connector is linked to a group or team is used by programs to find the connector for future communications. When the group receives inbound information, it uses the information to create a new card. If received by a team, the team creates a new conversation in the target channel. All we need to do to connect a data source to a group or team is:

1. Find the data source to use.
2. Decide on the destination – an Outlook group or a channel in a team.
3. Create an Incoming Webhook connector for the destination.
4. Extract data from the source and format the data as a JSON payload.
5. Post the data to the webhook address.

Any data source that you can access to extract relevant data and format for submission to the connector can be used to send items to Groups or Teams via the incoming webhook connector. You can use most programming languages to extract, format, and send the data. Sending information to a group has the advantage that the cards can be emailed to group members so that they know when action is needed. Items sent to Teams need people to open the host channel to review the content.

The example presented here posts tickets to a group created for support staff when user mailbox quotas exceed a set threshold. For example, the mailbox size is more than 95% of the assigned quota. The information needed to check mailbox sizes and quotas is easily achieved with the *Get-ExoMailbox* and *Get-ExoMailboxStatistics* cmdlets (see the script to report mailbox quotas described earlier).

## Creating an Incoming Webhook Connector

To create the connector, select the group that you want to use and access it from OWA. Select **Manage Connectors** from Group settings (gear icon), and then **Incoming Webhook** from the list of available connectors. Click **Add** to start creating the connector and add (Figure 23-5):

- The name of the connection.
- An image file if you do not want to use the default icon for the connector. OWA seems to ignore the custom image while Outlook displays it.

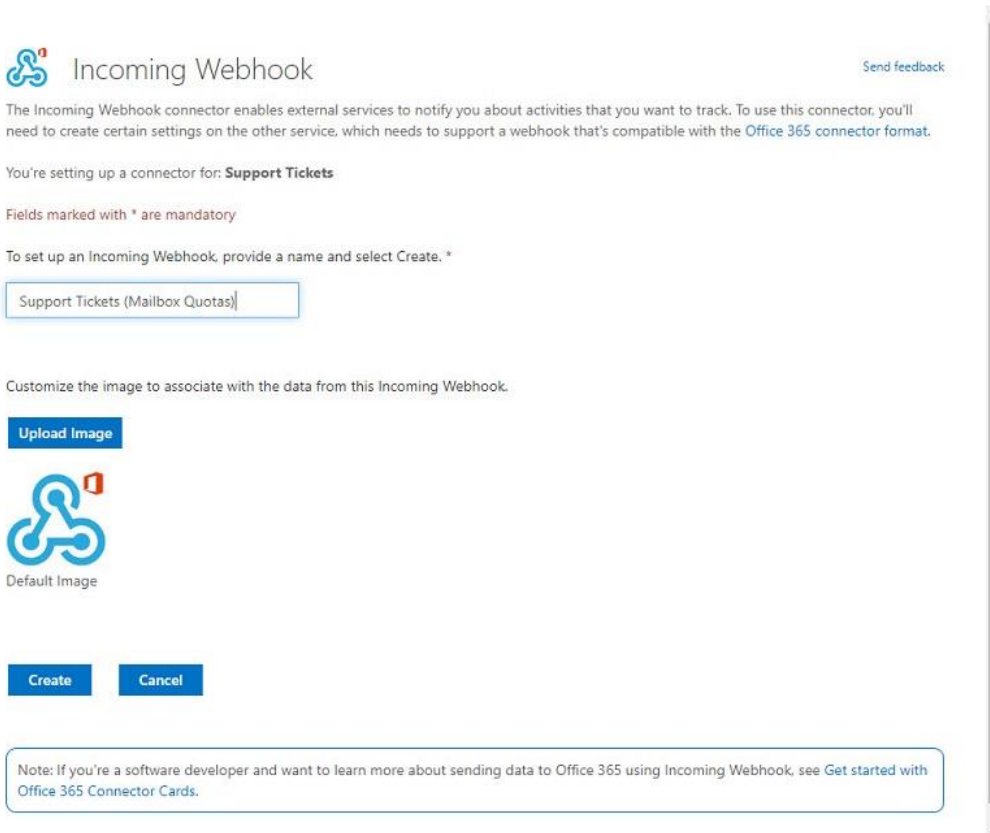

Figure 23-5: Creating a new Incoming Webhook connector

Click **Create** when ready to go ahead. The connector is then created along with its webhook URL, which you can use with the source application to route data through the connector. The easiest way to get the URL is to copy it to the clipboard using the option available in the form. If you forget to save the webhook URL, you can always retrieve it by selecting the connector and editing its properties. Click **Done** to complete the creation process.

### Webhook URL Format

The format of a webhook looks like this:

```
https://office365itpros.webhook.office.com/webhookb2/7aa49aa6-7840-443d-806c-08ebe8f59966@c662313f-14fc-43a2-9a7a-d2e27f4f3478/IncomingWebhook/8592f62b50cf41b9b93ba0c0a00a0b88/eff4cd58-1bb8-4899-94de-795f656b4a18
```

The parts of the webhook are:

- **Tenant name** (taken from Azure AD): In this case, Office365itpros.
- **Webhook root**: webhook.office.com/webhookb2.
- **Group identifier**: The Azure AD identifier for the Microsoft 365 group. In the example, this is 7aa49aa6-7840-443d-806c-08ebe8f59966.

- **Tenant identifier:** The Azure AD identifier for the tenant. In the example, this is c662313f-14fc-43a2-9a7a-d2e27f4f3478. The group and tenant identifiers are separated by an at (@) sign.
- **Provider name:** This is always *"IncomingWebhook."*
- **Alternate identifier:** Another GUID to make the URL unique because a group or channel can support multiple webhooks. In this case, it's 8592f62b50cf41b9b93ba0c0a00a0b88.
- **Group owner:** The Azure AD identifier (GUID) for the group owner. Or rather, the account of the owner who adds the webhook to the group.

To update the URL for a connector, select it and use the Update URL option. Then copy the new URL and update the source application (or PowerShell script) used to generate the inbound data.

## Setting up a Webhook Connector for Teams

Much the same approach is followed to create the webhook connector for a team channel. Go to the channel that you want to use to hold the messages and select Connectors from the menu. Then input the same kind of information given to create a connector for a group. The webhook uses the same format for Teams, with the only difference being that the webhook points to a channel in a team instead of the inbox in a group mailbox.

One thing to remember when posting to Teams is that the maximum message size is 25 KB. If you try to post a larger message, you'll see a *"Microsoft Teams endpoint returned HTTP error 413"* error.

## Creating payloads for an Incoming Webhook connector

We want to send information about service incidents to the group. To collect the information to insert into the payload, we use PowerShell to analyze mailbox quotas and report any over the threshold. Creating the payload means that we format the input data to make it ready for submission to the webhook. In doing so, it is important to remember the following points:

- It can take some time and practice to learn how to use PowerShell to create the JSON content. It is best to start with a basic card and then gradually build up the full content for the cards you want to create.
- Posting to the connector depends on making sure to format the payload correctly. You might be able to convert your payload to JSON successfully using the *ConvertTo-JSON* cmdlet only to find that the *Invoke-RestMethod* cmdlet rejects the payload when processing it for submission to the connector. All of which leads to hours of fun debugging payloads.

This code takes details about a mailbox that's over the threshold and creates a suitable payload in a PowerShell variable. The different elements that we want to report are formed into name-value pairs.

```
[PS] C:\> # $M is the current mailbox being processed
If ($QuotaPercentUsed -gt $Threshold) {
    Write-Host $M.DisplayName "current mailbox use is above threshold at" $QuotaPercentUsed -
Foregroundcolor Red
    $ErrorText = "Mailbox quota over threshold"
    # Log support incident
    $NotificationBody = ConvertTo-Json -Depth 4 @{
        Text = "Support Ticket"
        Title = "New Support Ticket Logged at " + (Get-Date -Format U)
        Summary = "The mailbox size of " + $M.DisplayName + " exceeds the quota warning threshold"
        sections = @(
            @{}
            facts = @(
                @{}
                name = "Mailbox name"
                value = $M.DisplayName
            },
            @{}
            name = "Current mailbox size (GB):"
            value = $QuotaUsedGB
        ),
    },
}
```

```
@{
  name = "Current mailbox quota (GB):"
  value = $MbxQuotaGB
},
@{
  name = "Percent of mailbox quota used:"
  value = $QuotaPercentUsed
},
@{
  name = "Number of mailbox items"
  value = $MbxStats.ItemCount } ) } ) }
# Post support incident via webhook
```

After populating the payload with information about the mailbox, the *Invoke-RestMethod* cmdlet sends the payload to the connector identified by the webhook address stored in the *\$Webhook* variable. The webhook address is generated by Office 365 when it creates the connector. The same approach is taken to post to webhooks pointing to a group or a team channel.

```
[PS] C:\> $PostStatus = (Invoke-RestMethod -ContentType "Application/Json" -Method Post -Body
$NotificationBody -Uri $WebHook) Submitting the Payload
```

If everything goes well, the cmdlet responds with 1 (one) to show that the post was successful. And of course, a new card should appear in the target group or team channel (Figure 23-6).

Figure 23-67: Details of a support ticket posted to a team channel

The example described here is incomplete. It has no error checking nor does not check whether a support ticket already exists for a mailbox. Some additional code will easily address these deficiencies and create an [operational-quality script](#). However, it serves to illustrate the principle of using the Incoming Webhook connector to deliver data from a source to a group or team.

This is a simple example of the information that can be included in a card. Other elements can be included to enhance the card further. For example, the code described in [this blog post](#) creates message cards for new updates fetched from the RSS feed for the Microsoft 365 roadmap. The cards include a More Info button with a hyperlink to the item on the roadmap site. For a full explanation of how to format the JSON payload for an Office connector, see the [Reference for the Adaptive card format](#).

## Using a Template

Another method used to create messages for posting to a connector is to create a template with fields that are replaced with values when you want to post a message. For example, this template has four fields that we replace for each service incident we post.

```
[PS] C:\> Notification = @"
{
  "@type": "MessageCard",
  "@context": "https://schema.org/extensions",
  "summary": "Exchange Online Notification",
```

```

    "themeColor": "0072C6",
    "title": "Mailbox Quota Threshold Exceeded",
    "sections": [
      {
        "facts": [
          {
            "name": "Mailbox:",
            "value": "DISPLAYNAME"
          },
          {
            "name": "Current Quota (GB):",
            "value": "MBXQUOTAGB"
          },
          {
            "name": "Quota used (GB):",
            "value": "QUOTAUSEDGB"
          },
          {
            "name": "Percent Quota used (%):",
            "value": "QUOTAPERCENTUSED"
          }
        ],
        "text": "Exchange Online Mailbox Support Ticket. Please increase the quota for this mailbox or remove some items to get its size under the threshold"
      }
    ]
  }
"@

```

To replace the fields, we extract information for a mailbox into variables and use the PowerShell `replace` method to insert values into the template. This example processes a set of mailbox objects in an array, updates the template with information for each mailbox, and posts the message.

```

[PS] C:\> ForEach ($M in $Mbx) {
    $Body =
    $Notification.Replace("DISPLAYNAME","$M.Mailbox").Replace("MBXQUOTAGB","$M.MbxQuotaGB").Replace("QUOTAUSEDGB","$M.QuotaUsedGB").Replace("QUOTAPERCENTUSED","$M.QuotaPercentUsed")
    $Command = (Invoke-RestMethod -uri $WebHook -Method Post -Body $Body -ContentType 'application/json') }

```

If you're interested in exploring the possibilities that exist in posting messages to channels via the inbound webhook connector, consider the use of the `PSTeams` module ([available in GitHub](#)), which is designed to assist in the process.

## Disabling Office Connectors

The wide range of available connectors makes it easy to see how groups and teams can serve as one-stop collections for inbound information gathered from different cloud sources. However, if you do not want to use connectors, you can disable them for a specific group or the entire tenant. To disable connectors for an individual group, run the `Set-UnifiedGroup` cmdlet to set the `ConnectorsEnabled` property to `$False`. Disabling connectors for a group also disables the ability to add connectors to the team associated with the group, if a team exists for the group.

```

[PS] C:\> Set-UnifiedGroup -Identity "Service Communications" -ConnectorsEnabled:$False

```

If you want to disable connectors for a complete tenant, run the `Set-OrganizationConfig` cmdlet to set the `ConnectorsEnabled` property to `$False`. This command blocks the ability to create connectors for all Office components.

```

[PS] C:\> Set-OrganizationConfig -ConnectorsEnabled:$False

```

Disabling connectors on a tenant-wide basis naturally takes precedence. You cannot block connectors for a tenant and then selectively enable connectors for some groups. Unfortunately, apart from opening each

group to see whether it has any configured connectors, there is no quick way to scan all the groups within a tenant to find which groups have connectors and the sources for the connectors.

## Managing Self-Service Purchases

As described in Chapter 5, Microsoft 365 includes a feature that allows users to buy licenses for certain products. Individual users receive the bills for these licenses, but the data generated with the licenses remains part of the organization and is subject to all the organization's retention, security, and eDiscovery policies. Despite this, many administrators don't want users buying licenses outside of the normal IT controls. You can prevent them from doing so, but it requires PowerShell.

Cmdlets in the *MSCommerCe* PowerShell module control the ability of users to make self-service purchases in a tenant. To make changes, download the latest version of the module from [the PowerShell gallery](#), and then log into PowerShell using a global administrator or billing administrator account. You can then install the module and connect to the *MSCommerCe* endpoint:

```
[PS] C:\> Install-Module -Name MSCommerCe
Import-Module MSCommerCe
Connect-MSCommerCe
```

Run the *Get-MSCommerCeProductPolicies* cmdlet to see what products are available for self-purchase:

```
[PS] C:\> Get-MSCommerCeProductPolicies -PolicyId AllowSelfServicePurchase
```

ProductName	ProductId	PolicyId	PolicyValue
Project Plan 3	CFQ7TTC0KXNC	AllowSelfServicePurchase	Disabled
Visio Plan 1	CFQ7TTC0KXN9	AllowSelfServicePurchase	Disabled
Project Plan 1	CFQ7TTC0KXND	AllowSelfServicePurchase	Disabled
Power Apps	CFQ7TTC0KPOP	AllowSelfServicePurchase	Disabled
Power BI Pro	CFQ7TTC0L3PB	AllowSelfServicePurchase	Disabled
Power Automate	CFQ7TTC0KPON	AllowSelfServicePurchase	Disabled
Visio Plan 2	CFQ7TTC0KXN8	AllowSelfServicePurchase	Disabled

You can disable self-service selectively for any product by running the *Update-MSCommerCeProductPolicy* cmdlet, or, as in this example, disable self-service purchases for all products:

```
[PS] C:\> Get-MSCommerCeProductPolicies -PolicyId AllowSelfServicePurchase | ? {$_.PolicyValue -eq "Enabled" } | ForEach {Update-MSCommerCeProductPolicy -PolicyId AllowSelfServicePurchase -ProductId $_.ProductId -Enabled $False }
```

# Chapter 24: What don't you know you don't know about Office 365 and Azure AD?

*Matthew Vinton, Jeff Shahan, Bryan Patton, and Sofya Serna Perez*

For over 20 years, Quest Software has added value to the Microsoft platform. We offer a wide range of solutions that complement the functionality that Microsoft provides, from streamlining the process of modernizing to newer platforms like Office 365 to making it far easier to manage and secure an on-premises, cloud or hybrid environment. Here, we focus on just four of the challenges you need to be prepared for as you move to the Microsoft cloud:

- **Azure Active Directory recovery:** If you have a cloud-only IT infrastructure, you might think that the native Azure AD and Office 365 tools are sufficient to ensure fast recovery of any accounts, groups or attributes that might be accidentally or deliberately deleted. If you have a hybrid IT infrastructure, you might think that native tools combined with your on-premises backup and recovery solution are sufficient. But the reality is far more complex. In the first section of this chapter, we'll explain what native tools and on-prem solutions do and do not cover, and how to get the enterprise-level recovery capabilities you need.
- **Tenant-to-tenant migration:** With the rapid adoption of Office 365 around the world and the explosion in merger and acquisition (M&A) activity in recent years, more and more IT pros face the challenge of merging two or more tenants, often on extremely tight timelines. There are no native tools to help, and the process is even more complicated if any of the entities involved in the M&A has a hybrid AD environment. In the second part of this chapter, we'll review the challenges involved in tenant-to-tenant migrations and explain how Quest solutions can help ensure a secure and successful project.
- **Hybrid auditing:** With Microsoft 365, organizations get multiple advancements in auditing, including capable searching and alerting over a unified audit stream of normalized data. However, many IT pros still face a steep challenge: effectively auditing the on-premises Active Directory being synched to their tenant and accurately correlating that on-prem data with the Microsoft 365 audit stream to get a unified view of the IT ecosystem. In the third part of this chapter, we'll review why overcoming this challenge is difficult with native tools, why SIEM solutions also fall short, and how Quest solutions deliver the hybrid auditing you need for strong security.
- **Group management:** While Microsoft has greatly improved the capabilities of Microsoft 365 Groups, most IT professionals also oversee hundreds or even thousands of groups originating from their on-premises Active Directory. Unfortunately, there are no native tools to help you manage your on-premises AD groups and cloud groups together in a consistent manner. Instead, you're stuck addressing them separately with different tools. This fractured approach makes it difficult to avoid group sprawl and authorization creep, leaving your organization vulnerable to security risk. In the final section of this chapter, we'll discuss the challenges of managing groups across a hybrid environment and explain how Quest can simplify group management, regardless of where the group originates.

# Azure Active Directory Recovery

As discussed earlier in this book, Microsoft offers several strategies for backing up and recovering data in Office 365 that might be changed or lost, from database availability groups with lagged copies for Exchange Online to true backups for SharePoint Online. However, you share responsibility for backup and recovery with Microsoft, as detailed in your service agreement. While Microsoft provides tools that help you recover some items, you should consider investing in software like Quest On Demand Recovery to get the comprehensive recovery capabilities you need to ensure productivity and business continuity.

## Why Azure Active Directory Needs to Be Part of Your Recovery Strategy

Azure Active Directory is the authentication and authorization system for Microsoft 365. If a user accesses any Microsoft 365 services, they have an Azure Active Directory account. The core processes of authenticating a user and authorizing them to access the correct resources are quite similar in Azure AD and on-premises AD.

However, there are important differences. In particular, Azure AD does not have equivalents to Group Policy, discretionary access control lists (DACLS) or hierarchical objects such as organizational units. Moreover, Azure AD has objects and properties that do not exist in on-premises AD, including:

- **Roles:** Roles enable users to perform specific tasks such as adding or changing users, resetting user passwords, managing user licenses, and managing domain names. Examples of roles include Application Developer, Cloud Application Administrator and Directory Reader.
- **Licenses:** A user cannot use a licensed service until their account has been assigned a license. If that license attribute is lost, the user cannot access those services until it is restored.
- **Multi-Factor Authentication (MFA) settings:** MFA settings control whether a user must provide an additional form of verification, such as a code from their cell phone or a fingerprint scan, during sign-in. MFA is deployed using Conditional Access policies.
- **Conditional Access policies:** These policies provide additional control over access by requiring MFA under certain conditions or enforcing other restrictions. For example, a policy might block or grant access from specific locations or require the use of organization-managed devices for certain applications.
- **Dynamic group definitions:** These complex, attribute-based rules automatically adjust a user's group membership. For example, if a user transfers from the Sales department to Marketing (and their Azure AD user object is updated accordingly), a dynamic group definition could automatically remove them from groups associated with Sales and add them to groups associated with Marketing.
- **Applications and service principals:** Applications and service principals define how non-Office 365 applications interact with Azure AD. They are used for external applications that need access to Azure AD data, and they are also used to provide single sign-on (SSO) for federated applications. Service principals rely on applications to act as a defining template for their configuration. Every service principal has an application somewhere, either in the same tenant as the service principal or in another tenant.

## What Can and Cannot Be Recovered from the Recycle Bin

Any of these Azure AD objects and properties could get deleted and need to be restored. To help, Microsoft offers the Azure AD Recycle Bin. However, the Recycle Bin was never intended to be an enterprise-level recovery solution, and it's critical to understand what it can and cannot do.

First, not all objects go through the Recycle Bin when they are deleted. Certain types of objects are “soft deleted,” which means they do get put into the Recycle Bin, but other objects are “hard deleted” — they are not put into the Recycle Bin and therefore cannot be recovered from it.

Azure AD objects that are soft deleted include:

- User and guest accounts.
- Microsoft 365 groups (including associated data such as properties, members, e-mail addresses, Exchange Online shared inbox and calendar, SharePoint Online team site and files, OneNote notebook, Planner, Teams, and Yammer group and group content).
- Azure AD applications.

Azure AD objects that are immediately hard deleted include:

- Security groups.
- Distribution groups.
- Service principals.
- Conditional access policies.
- Devices.

Second, soft-deleted objects remain in the Recycle Bin for only 30 days. After that, they are permanently deleted.

Third, many Azure AD objects have complex configurations or specific interactions with other systems. Those details are not captured by the Recycle Bin and cannot be restored from it.

Finally, the Recycle Bin is for deleted objects only. If an object has been changed rather than deleted, the Recycle Bin cannot help you restore the object to its previous state.

## How to Recover Soft-Deleted Objects from the Recycle Bin

You can recover soft-deleted users, Microsoft 365 groups and Azure AD applications from the Recycle Bin using PowerShell. You can also recover users and Microsoft 365 groups — but not Azure AD applications — using the Microsoft 365 admin center.

### How to Recover a Soft-Deleted User using PowerShell

The simplest way to recover a user using PowerShell is to use the older Microsoft Online cmdlets:

```
[PS] C:\> Connect-MsolService
Get-MsolUser -ReturnDeletedUsers
Restore-MsolUser -UserPrincipalName <UPN of deleted user>
```

### How to Recover a Soft-Deleted Microsoft 365 Group using PowerShell

To recover a soft deleted group, we will use the newer Graph-based PowerShell cmdlets:

```
[PS] C:\> Connect-AzureAD
Get-AzureADMSDeletedGroup
Restore-AzureADMSDeletedDirectoryObject -Id <ObjectID of deleted group>
```

### How to Recover a Soft-Deleted Azure AD Application using PowerShell

Just like with the Microsoft 365 group, we will again use the Graph-based PowerShell cmdlets. This procedure is like the one for recovering a group, but there is a specific cmdlet for executing application recovery.

```
[PS] C:\> Connect-AzureAD
Get-AzureADDeletedApplication
Restore-AzureADDeletedApplication -ObjectId <ObjectID of deleted application>
```

## How to Recover a Soft-Deleted User or Group using the GUI

To recover a soft-deleted user from the Microsoft 365 admin center, go to **Users \ Deleted users**, select the user and then click **Restore user**. To restore a soft-deleted group, go to **Groups \ Deleted Groups**, select the group and then click **Restore group**.

## Recovery in Hybrid Environments

Many organizations use a hybrid model where they synchronize their on-premises Active Directory to the cloud using Azure AD Connect. They often believe that the recovery strategy they have in place for their on-premises Active Directory will also cover Azure AD due to the synchronization, thereby making up for the limitations of the Azure AD Recycle Bin. The truth is more complex than that.

When a user or a group is deleted from the on-premises Active Directory (or excluded from Azure AD Connect synchronization), what happens to the associated hybrid cloud object will differ based on the type of object:

- **Hybrid user objects** will be soft-deleted from Azure AD. If the on-premises user object is recovered or brought back into synchronization scope, the hybrid user will be restored from the soft-deleted state. If the user object has aged out of the soft-delete status and become permanently deleted, Azure AD Connect will create a new hybrid cloud user object based on the on-premises user object.
- **Security groups** will immediately be hard deleted from Azure AD. If the on-premises group is recovered or brought back into synchronization scope, Azure AD Connect will create a new hybrid cloud security group based on the on-premises group.

When Azure AD Connect creates the new user object or security group, that object will lack the cloud-only attributes of the deleted object, such as roles, conditional access policies and licenses. This can have serious real-world consequences.

## Potential Disruptions to Users and Continuity of Service

Let's consider just two real-life examples of how relying on just the Azure AD Recycle Bin in concert with your on-prem solution can cause serious problems for your users — and your service continuity.

### Scenario 1: Security Group Deprovisioned

Suppose you have several Active Directory OUs with security groups that are being synched to Azure AD to grant certain users access to specific SharePoint Online sites. You also have a rule that whenever a security group exceeds its attestation period, it is moved into a deprovisioning OU to await final decommissioning.

Now suppose a security group that enables a key team to access critical data misses its attestation deadline and is therefore moved. As soon as Azure AD Connect detects that the group is no longer in scope, it will remove the security group in the cloud. As a result, users who were members of that group will lose their access to the sites they need and start logging tickets.

To correct the issue, you'll move the security group back into the proper OU, and Azure AD Connect will create a new security group in Azure AD. That security group will have the same name and the same members — but it will be assigned a new ID, so the process will not restore the users' access to the SharePoint Online data.

To restore access using native tools, you'll need to consult your documentation about which SharePoint Online sites the group needs to have access to (or scramble to figure it out), and then re-apply the new group to those sites. This process takes time and effort, adding to IT workload and hurting user productivity.

### Scenario 2: Conditional Access Policy Modified

Suppose you are using Azure AD Conditional Access policies to require an extra form of authentication if a user from outside the corporate network attempts to access a sensitive application and to block access entirely from

certain IP addresses. Then you discover that the authentication controls you want are no longer in place for that application. Where does the issue lie? Is the application no longer associated with the proper Conditional Access policy? Has the policy changed? Has the security group that controls who the Conditional Access policy applies to changed?

The Recycle Bin offers no benefit here, since it is for deleted objects only; improper modifications to objects are not stored in the Recycle Bin and therefore cannot be recovered from it. To ensure you can restore any object that might be improperly changed, you'll need complete, current documentation of the configuration of all your Azure AD objects — which is virtually impossible to create and maintain using manual methods.

## Going Beyond the Recycle Bin: True Enterprise-level Recovery

As we have seen, recovering data in Azure AD using native tools works well if the scenario fits two fairly rigid guidelines:

- You want to recover an Azure AD user, Microsoft 365 group or Azure AD application that was deleted (not modified).
- No more than 30 days have passed since the object was deleted.

For other scenarios, you need a backup and recovery solution like [Quest® On Demand Recovery](#).

### Quest On Demand Recovery

On Demand Recovery records the configuration of most objects in Azure AD and recreates them when you request their recovery. This enables the recovery of objects that cannot be restored from the Recycle Bin, including the following:

- Users that were deleted more than 30 days ago.
- Azure AD applications that were deleted more than 30 days ago.
- The configuration of Microsoft 365 groups deleted more than 30 days ago.
- Security groups.
- Distribution lists.
- Devices.
- Conditional access policies.
- Service principals.

Moreover, On Demand Recovery backs up and restores the individual properties of each of these objects, so you can easily and precisely revert many configuration changes as well as outright deletions. On Demand Recovery backs up Azure AD three times per day, enabling the recovery of many Azure AD objects to a specific point in time.

For hybrid environments, On Demand Recovery integrates with [Quest Recovery Manager for Active Directory](#), which protects your on-premises AD. If a portion of a given recovery needs to be completed on premises and a portion in the cloud, On Demand Recovery can orchestrate the entire recovery with a single click.

There are a few things that On Demand Recovery is not able to back up and therefore cannot recover. In particular, there is no way to access a password for a user or certificates for service principals; you will need to reset the password or upload the certificate again.

### Avoiding Disruptions to Users and Service Continuity

Let's consider how On Demand Recovery handles the problematic recovery scenarios discussed earlier.

#### **Scenario 1: Security Group Deprovisioned**

When the users in the security group that was deprovisioned lose their access to the SharePoint Online site they need and start logging tickets, you can get them back to work quickly and easily with On Demand Recovery.

Log into On Demand Recovery and unpack a backup made before the OU was moved. On Demand Recovery clearly shows the changes that can be recovered (Figure 24-1). To restore the group that was deleted from Azure AD, simply choose the group and click **Restore**.

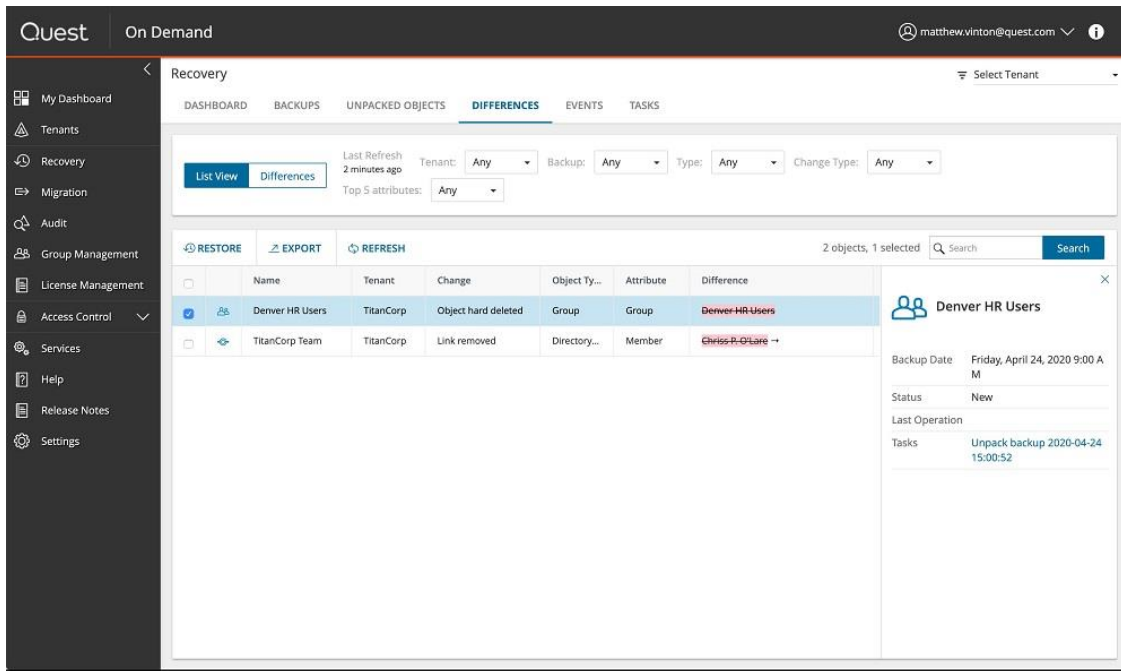

Figure 24-1: On-Demand Recovery enables the recovery of a wide range of deleted objects in a single click

On Demand Recovery performs the following actions to make the group whole again:

1. Since the Azure AD group is based on an on-premises AD group that needs to be reverted to an earlier state, On Demand Recovery dispatches a command to the on-premises instance of Recovery Manager for Active Directory, telling it to restore the AD group to a state prior to the recovery point, where it is in its normal OU.
2. On Demand Recovery then initiates a delta sync of Azure AD Connect so that the group is re-created in the cloud. As noted earlier, even though the group looks the same as it did before, it has a new object ID, so it won't be recognized by any of the services that need to use it to secure information or provide access to application.
3. On Demand Recovery also backs up many locations where security groups are used, such as service principals, SharePoint sites and conditional access policies. Therefore, the solution configures the SharePoint site to use the new group to secure access to the data, restoring access to the end users.

Remember, all this entire process happens automatically; all you need to do is click **Restore**.

### **Scenario 2: Conditional Access Policy Modified**

On Demand Recovery can also help you out when you discover that the expected authentication controls are no longer in place for a specific application. Log into On Demand Recovery and unpack a backup made prior to the controls being missing. The Differences tab (Figure 24-2) shows the differences between the live Azure AD and the backup. You can clearly see that the Conditional Access policy was changed. To revert the change, simply choose it and click **Restore**.

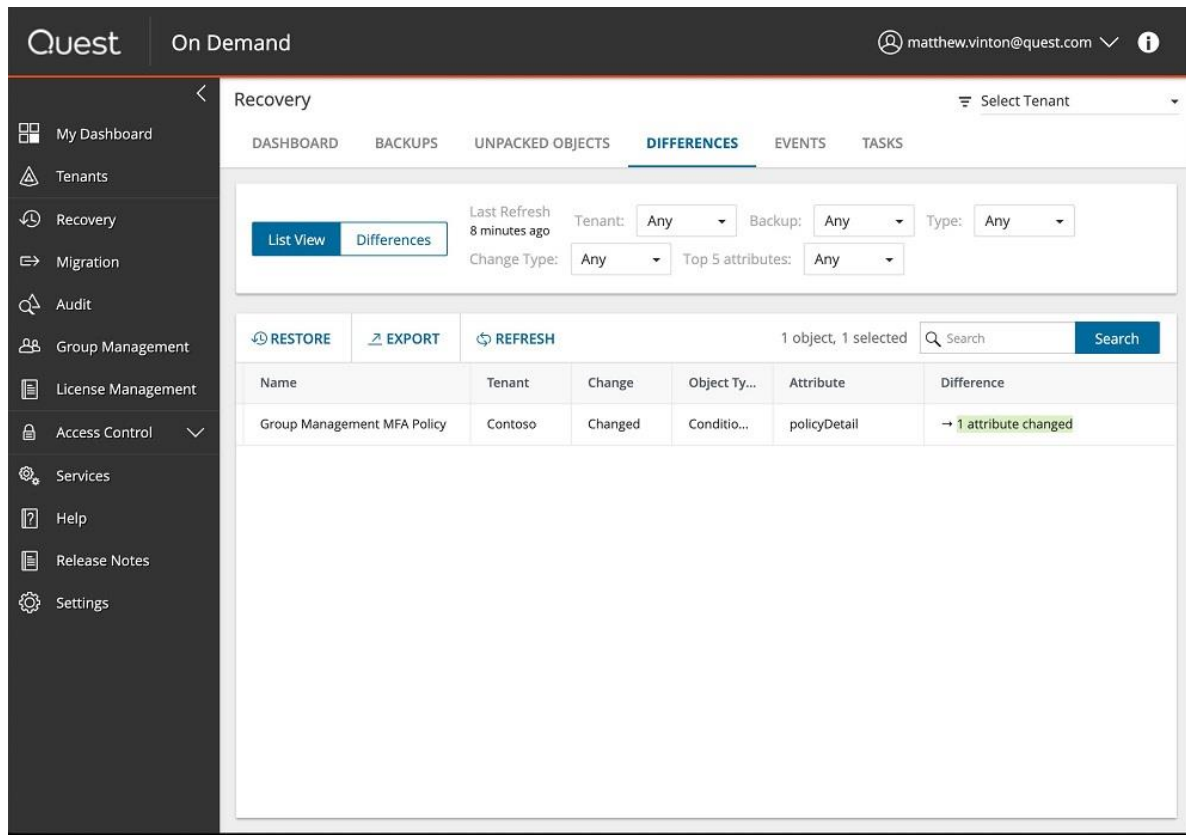

Figure 24-2: On-Demand Recovery enables reversion of unwanted changes to an object's attributes

## Summary – Azure Active Directory Recovery

Azure Active Directory provides authentication and authorization for all the critical Office 365 resources your organization depends upon every day, so it needs to be fully accounted for in your backup and recovery strategy. Native tools were never intended to be a comprehensive recovery solution, and even the best on-prem solution cannot protect the cloud-only objects and attributes it never sees. Be sure you have true enterprise-level recovery capabilities across your entire IT environment.

## Tenant-to-Tenant Migration

Now let us shift focus to another key challenge of Office 365 and Azure AD deployments: migrations. For more than 20 years, Quest has been a leader in IT migration. As Microsoft turned its attention to the cloud, Quest continued to fill the gaps left behind, enabling customers to migrate to the Office 365 platform.

As adoption of the platform increased, a new need came to the forefront: migrating users and content from one tenant to another. Indeed, the recent dramatic increase in mergers and acquisitions has made tenant-to-tenant migrations a top concern for organizations around the world. Since there are no native tools to facilitate this process, Quest again stepped up to help. Here, we detail the technical challenges involved in a tenant-to-tenant migration and explain how Quest solutions ensure a quick and automated project.

### Overview

In any migration, the business requirements present two competing forces: technical requirements and political requirements. These forces drive your decisions and will influence your migration process. The political forces will drive your technical challenges, and the technical challenges will push back on the political requirements. This section will focus on the technical challenges and point to where they can push back on the political

requirements. For example, if a larger entity buys a smaller entity, the political requirement will be to maintain the branding for the UPN and SMTP Reply-To addressing. Unless the entity is very small and can be migrated in a big-bang migration with an outage over a weekend, you are going to need to push back in order to execute the migration in a phased process that minimizes risk and impact to the end users.

## Technical Challenges

### Timelines

Many migration projects have a target end date handed down by the business, often driven by the need to present a unified branding to the external world as soon as possible. But these imposed deadlines often fail to consider factors such as the volume of data and workloads involved and the need to execute the migration without hurting user productivity. For example, a big-bang migration over a weekend is feasible only if the entity being acquired is very small and some amount of downtime is acceptable. Most of the time, migrations need to be executed in a phased process that minimizes risk and impact to the users and service continuity.

Tight migration timelines are especially an issue for SharePoint Online data and Exchange Online archive mailboxes:

- **SharePoint Online (and OneDrive for Business) Data:** Migration tools cannot directly migrate data into SharePoint Online without being throttled to a snail's pace to maintain service quality. Specifically, when SharePoint data is moved using the Microsoft migration API, the data is stored temporarily in Azure storage and then moved to SharePoint Online. This process is transparent to both users and the migration tool. While a migration tool could move data from the source into the migration pipeline, the process for publishing the data into SharePoint Online is a shared process and runs at its own pace. Execution time depends on the type of content and metadata being migrated. Large files with minimal metadata will migrate faster than small files with heavy metadata.
- **Exchange Online Archive Mailboxes:** Exchange Online allows for an unlimited size of the archive mailbox for some licensing plans. Initially, the archive mailbox is provisioned for 100GB. Today there is no automated way to force the archive mailboxes to increase the available storage. It can take up to 30 days for the additional storage space to be provisioned. There is currently no way to migrate an archive mailbox larger 100GB.

### Distributed Migration Teams

In larger organizations, the migration team will be segregated in ways that can present technical and political challenges. For example, the on-prem Active Directory to on-prem Active Directory migration workstream will be handled by the identity management team; workstation migration and OneDrive for Business will be handled by the desktop team; Exchange Online will be handled by the messaging team; and SharePoint Online will be handled by the SharePoint team. This distribution of work will require project teams to communicate and work together effectively, since one team's tasks will need to be completed to allow another team to start their work.

### Azure AD Connect (or Other On-Prem to Tenant Sync Engine)

Most tenant-to-tenant migrations today involve at least one hybrid environment that uses Azure AD Connect or some other synchronization engine like Microsoft Identity Manager. This presents a technical challenge. Since nearly all an object's attributes are mastered in the on-prem Active Directory, the object should be created on premises and synchronized to the tenant prior to migrating the workload. It could be created by your migration tool and matched to the on-prem object after the workload migration, but there are fewer moving parts to deal with if you complete the directory object migration before starting the workload migration.

## Federation

Since all objects authenticated via federation are authenticated back to the authoritative repository, they must be created in those repositories prior to their creation in Azure AD. This will present challenges for distributed project teams working independently. It will also impact forest trusts and UPN suffix routing during a DNS domain move between AD domains/forests and tenants.

## DNS Domains

One common political requirement in M&As is maintain the current login and email addresses, since they reflect the current branding of the organization being migrated. It is common for the primary SMTP address to be the same as the login ID. However, there is only one technical option for meeting this political requirement: a big-bang migration. This is because a DNS domain can be registered in only a single tenant at time.

If a big-bang migration is not an option, you are going to have to reset the political requirements based on what is technically possible, which is to maintain the public-facing SMTP address during the migration while using a temporary login ID, and at the end of the migration, move the DNS domain and change the login ID and SMTP addresses.

Quest On Demand Migration offers a Domain Coexistence add-on that can maintain brand or rebrand SMTP addressing during a phased migration.

## DNS Domain Move

The DNS domain must be completely removed from one tenant before it can be registered in another tenant. This presents a window during which inbound SMTP messages could bounce. Microsoft states that the removal of DNS domain from a tenant can take anywhere from five minutes to a day to execute.

To minimize the time this process will take for the domain to be removed, there are two options:

1. Delete all the objects from the tenant before removing the DNS domain from the tenant.
2. Remove all references to the domain in the attributes of objects before removing the domain from the tenant.

If Azure AD Connect or another sync engine is in use, these changes must be made on premises and allowed to replicate to the cloud.

There are several ways to eliminate the worry about bounced messages during this process. If the MX record points host that is unavailable, each message will be queued on the sending SMTP server until it expires.

## Domain Move Process

This is a rough outline of how to move a DNS domain; things like an active on-prem AD-to-AD migration or any type of directory synchronization running between the source tenant's AD and target tenant's AD are not considered. This process will remove (DELETE) all objects in the scope of the domain to be migrated from the source tenant.

1. Change the TTL for the current MX records to 1 or 2 minutes so the changes will quickly propagate when the process is complete.
2. Wait for the old TLL time plus 10 mins to ensure that TTL is applied to all cached sending servers.
3. Change the MX record to point to a host that does not exist.
4. Wait for the current TLL time plus 10 mins to ensure that all sending servers are queueing the messages.
5. Suspend the source Azure AD Connect from synchronizing.
6. Extract all source attribute values for user and group objects:
  - a. ProxyAddresses
  - b. Mail
  - c. UserPrincipalName

- d. msRTCSIP-PrimaryUserAddress
7. Reconfigure the source Azure AD Connect to exclude all objects in scope of the migration from the sync scope.
8. Back up the source tenant using a solution such as Quest On Demand Recovery, so that you can roll back from the soft and hard deletes in the next step and ensure that the proper entitlements are restored.
9. Execute a full replication cycle to remove all objects from the tenant.
10. Remove the DNS domain from the source tenant.
11. If a trust needs to be maintained, remove the UPN suffix from the forest.
12. Stop any directory sync running between the source AD and the target AD, since it could create issues when you make changes to the target objects as part of this procedure.
13. Suspend the target Azure AD Connect from synchronizing.
14. Add the source UPN suffix as a UPN suffix in the target forest.
15. Using the attributes extracted from the source objects, write the following to the target objects:
  - a. ProxyAddresses
  - b. Reply-to address
  - c. UserPrincipalName
  - d. msRTCSIP-PrimaryUserAddress
16. Set the *TargetAddress* attribute to **@%TargetTenant%.mail.onmicrosoft.com**.  
Note: The format of the target address attribute is "SMTP:LocalPart@domain".
17. Add the DNS domain to the target tenant.
18. Enable Azure AD Connect.
19. After the sync process is completed, validate that each ProxyAddress has been properly populated.
20. Change the MX and TTL to point back to Microsoft's shared service.

## Licensing

You cannot move licenses from one tenant to another, so before you begin your migration, you need secure the number and types licenses needed to cover the users involved, along with licenses for any additional services and workloads they will require. Failure to do this has stopped several migration efforts dead in their tracks.

## What Cannot Be Migrated

There are Office 365 workloads and settings that cannot be migrated by any tool, including the following:

### Licensing Entitlements

While a migration tool might be able to migrate a workload and enable the license type associated with it (or enable specific entitlements inside the license type), there is no way to enumerate the source license entitlement for an object and apply it for the target users. This may be because most tenants do not have the same type of licensing available.

### Application Entitlements

Azure AD application entitlements are not migrated. For example, a migration cannot preserve who has an entitlement for Box.com or SalesForce.com. However, Quest On Demand Migration can enable users to retain access to applications from their target accounts until the service is established in the target tenant.

### Certain Microsoft Teams Content

Microsoft Teams is an open platform, so organizations can make use of additional services and entitlements. Unfortunately, not all these content types can be migrated. For example, you can add a Microsoft Stream channel or video as a tab in Microsoft Teams, but you cannot migrate Stream video content because there is no

API or other method to access the data for migration. As the Teams platform matures, migration of more of its content will likely be fully supported.

## Tenant-Joined Workstations

There is no way to move a tenant-joined workstation to another tenant. Most organizations still maintain an on-prem Active Directory, so is not usually an issue for migrations. However, we are starting to see more customers asking about this type of support.

## Settings Outside Exchange Online Mailboxes

Most data in Exchange Online mailboxes is migrated. However, settings outside of the mailboxes are not migrated, including:

- **Litigation holds** — Litigation holds on Exchange Online mailboxes should be enabled after the content is migrated and before users access the mailbox.
- **Retention policies** — These are system settings that need to be configured by system administrators.

## What Can Be Migrated

[Quest On Demand Migration](#) is a SaaS migration tool that enables you to easily and securely consolidate Office 365 tenants — while enabling users to continue to communicate and collaborate seamlessly throughout the migration. On Demand Migration supports the following crucial workloads:

### Accounts and Groups

On Demand Migration supports tenant-to-tenant migration including hybrid organizations. User and group objects from the source tenant can be created directly in the target tenant or merged into existing objects in the target tenant.

### Exchange Online Mailboxes

On Demand Migration can migrate both primary mailbox content and archive mailbox content. You can perform address rewriting to maintain a single domain brand for all or selected users. Moreover, it enables you to avoid user frustration and a flood of helpdesk tickets by migrating the following:

- Recoverable items (the hidden data for users on litigation hold).
- Outlook Web Access (OWA) rules.
- Mailbox delegation.
- Folder permissions.

Note that Exchange Online requires that a user be mailbox-enabled in order to be assigned access to an Exchange resource.

### Resources and Applications

On Demand Migration can enable users to maintain access to source resources and applications. This is done by creating a guest account and granting that guest account the same level of access to the resource. Supported resources include:

- SharePoint Online.
- Resource roles.
- Applications assigned.

### Outlook Profiles

During the mailbox migration, each user's Outlook profile must be reconfigured to point to the new tenant and mailbox. On Demand Migration makes this easy: You simply deploy a small utility called the Client Update Agent

to the users' machines, and it connects to your migration project to know when the profile needs to be updated and what settings to use. One good option is to send users a notification with a link to a self-extracting archive that executes the agent.

Note: Autodiscover can present a challenge based on the domain/forest membership of the client host. We have found that setting Outlook to exclude the service connection point lookup (`ExcludeScpLookup=1`) can help address this issue.

## OneDrive for Business

On Demand Migration can migrate users' OneDrive data to the new tenant, giving them continued access to their data. The process preserves document versions, as well as the metadata and permissions associated with each document. You can filter the data based on folder, type, date, or size to exclude unwanted content and increase migration speed.

## SharePoint Online

On Demand Migration migrates documents and other valuable data stored in classic and modern SharePoint sites, document libraries and lists. The process ensures continued access and compliance by preserving site and document permissions and metadata. For even more advanced SharePoint migration capabilities, Quest offers [Metalogix Essentials for Office 365](#). For instance, Essentials for Office 365 supports the migration of SharePoint workflows, SharePoint Designer workflows, Nintex workflows and Nintex forms.

## Public Folders

On Demand Migration makes it easy to preserve shared data stored in public folders, along with all associated permissions and delegation. You can filter data by folder, type and date to speed the migration.

## Microsoft Teams

Microsoft Teams has become the hub of communication and collaboration in Office 365, so it's vital to migrate it effectively. On Demand Migration can:

- Discover all Teams in the source tenant, including team members and groups.
- Provision Teams and channels in the target tenant.
- Preserve user and group access and permissions.
- Migrate files stored in Teams channels.
- Migrate all conversations.
- Rename or merge Teams during the migration.

## Considerations and Tips

Quest has been in the migration business for years, and this extensive exposure to real-world scenarios has enabled us to gain some insights and observations that can be helpful when planning your tenant-to-tenant migration.

### Check Microsoft throttling limits and regulations.

In order to ensure service availability and strong performance for users, Office 365 is designed to throttle discretionary workloads like migrations. When use of the Office 365 platform skyrocketed early in the Covid-19 pandemic, Microsoft tightened its throttling limits for all data migrations into Office 365 tenants during business hours. Evening and weekend hours for the region of your tenant will not be impacted.

Therefore, we recommend scheduling migration jobs to run outside of the business hours of your tenants. Staying on top of the latest throttling policies will help you avoid migration delays, as well as measure the benchmark speeds properly so you can forecast the timeline for the project more accurately.

### Back up your source tenant before shutting it down.

In an ideal world, completing your migration and conducting user acceptance testing to validate the results of the project would be enough to safely shut down the source tenant. In the real world, there are many scenarios where a safety net is needed: You migrated a large volume of data, you had limited resources to perform thorough post-migration verification, the timelines were tight. In addition, there is always the chance of human error. Any of these could result in some data being lost or corrupted during the migration, but the issue not being immediately apparent.

Therefore, it's wise to have a solid backup of the source tenant. Having an easy way to restore the data you need can save you a lot of time, as well as all the headaches that you'd face due to business disruptions.

### Take advantage of the opportunity to clean up.

Avoid taking stale and unused content into the new environment. Analyze your source environment to identify the content that can be archived during the migration or simply left behind.

Also look for ways to clean up permissions. For instance, if permissions were poorly maintained in SharePoint Online, they can be stripped off during the migration. If the migration is being driven by a merger, acquisition or divestiture, be sure to analyze and plan the desired permissions structure and address it during the migration process.

In many cases, organizational changes will also require changes to the taxonomy or information architecture of the tenant, so a copy-paste type of migration will not suffice. A robust migration solution will help you reorganize teams, departments and groups in the process of the migration.

Migrations are also great in addressing data sprawl. The Office 365 platform is all about empowering users. However, a lack of governance can lead to many types of data sprawl, including a proliferation of groups, teams, SharePoint Online sites. The problem with sprawl is not just the space that the data takes up and the effort involved in managing it; sprawl can put the security of the whole company at risk and make collaboration difficult. Doing a thorough inventory and identifying excessive objects prior to the migration and merging the entities can help minimize data sprawl across Office 365.

### Over-communicate with your users about the migration.

Business users are often very busy and tend to skim through communications sent by IT teams. Make sure your messages about the upcoming migration are very clear and include detailed directions for users. This will help reduce the volume of help desk tickets and calls after the migration. Communication is especially important in scenarios like One Drive for Business migrations, since users may feel their privacy has been violated when there is new data in their One Drive and they do not know where it came from.

### Consider the level of fidelity you need.

Determine how you want to migrate your content: Do you need all metadata and versions to be migrated, or would just the latest version of each document with basic metadata be sufficient? If retaining all metadata and versioning is required, be sure to choose a robust migration solution that supports full-fidelity migrations.

## Summary – Tenant to Tenant Migration

With M&A activity, organizational restructuring and other business changes on the rise, IT pros need to be prepared to deliver accurate, complete, and efficient tenant-to-tenant migrations. Balancing the technical challenges and political requirements is tough enough without struggling with complex and error-prone manual processes. A comprehensive solution that automates the migration process, time after time, can be a very wise investment.

# Practical Auditing in a Hybrid World

Chapter 20 of this book provides a detailed explanation of the native Microsoft 365 auditing capabilities. In particular, Microsoft 365 customers can leverage a unified audit stream with normalized data, and the Microsoft 365 Security and Compliance Center provides capable searching and alerting of that audit stream.

However, as we've seen, many organizations use a hybrid model in which their on-premises Active Directory is synched to the cloud using Azure AD Connect. Since on-prem Active Directory enjoys none of the auditing benefits of the Microsoft 365 platform, maintaining security in these hybrid environments is a steep challenge. Let's briefly review why effective hybrid auditing is crucial to security and then explore the options for getting the insight you need.

## How Active Directory Can Impact Azure Active Directory

A hybrid model, where identity information in Azure Active Directory is controlled by on-premises Active Directory, can open Azure Active Directory to security vulnerabilities. For example, here are three examples of attacks against Azure AD that use on-premises Active Directory.

**Example 1: An on-prem service account that is made hybrid can be used to compromise Azure AD.**

Applications in Azure Active Directory normally use special accounts called service principals to obtain privilege in the directory. Sometimes, however, the required access cannot be provided by a service principal (for example, because there is no API for accomplishing what the application needs that can be used with a service principal).

In those situations, organizations often have the application use a regular user account — either an Azure AD user account or a hybrid AD service account (an on-premises AD service account that's synchronized to Azure AD). Using an Azure AD user account is less than optimal: Because user accounts used by applications typically cannot use multifactor authentication, they are more vulnerable than properly protected administrative accounts. But using a hybrid account is even worse. While it might seem convenient, leveraging a hybrid service account opens Azure AD up to all the vulnerabilities that plague on-premises AD, including Kerberoasting, Golden Ticket generation and password spraying.

To mitigate this risk, it is important to have visibility into both Azure AD and Active Directory. You can use simple searches to alert you whenever a service account is made hybrid so you can prevent its use in the cloud. If there are already hybrid service accounts in use, it is critical to keep a close eye on the activity of those accounts in both directories.

**Example 2: A hybrid account that is made the owner of an Azure AD service principal could misuse that service principal.**

Azure AD service principals can be quite powerful, so it's essential to monitor them. A service principal can be assigned an owner, who can manage many aspects of it. There is no restriction on the owner who may be assigned to a service principal — so a hybrid account could be made the owner of an Azure AD service principal.

In that case, the hybrid account would gain a great deal of power in Azure AD. In particular, an owner may assign an application-specific password (sometimes known as a secret) or a certificate so that the service principal can log in. While a service principal couldn't be used to log into an administrative portal, it could be used to manipulate the directory through Azure AD PowerShell cmdlets.

To manage this risk, it is important to have clear visibility into both Azure Active Directory and Active Directory. Identify any service principal that has a hybrid user as its owner, and either remove that owner or configure

greater scrutiny of the activity of the service principal. In addition, alerts on any change to the ownership of powerful service principals should be created.

### Example 3: An on-prem password spraying attack can enable attackers to gain a foothold in Azure AD.

In a password spraying attack, hackers test multiple likely passwords across a long list of accounts, attempting to log in to any account to establish a foothold and begin reconnaissance. To avoid tripping account lockout policies, attackers usually try only a few passwords on each account at irregular and infrequent intervals. As a result, password spraying can be difficult to detect.

Azure AD has several features that help mitigate the risk of these attacks. Multifactor authentication can make an account password only part of what is needed to log on. In Azure AD Premium P1, weak passwords can be detected and blocked by Azure AD Password Protection. And in Azure AD Premium P2, password spray attacks can be spotted through anomaly detection.

But for most organizations, Azure AD in hybrid mode bypasses most of these mitigations. To make work more convenient for users, they employ Azure AD Connect, ADFS, Azure AD Pass-through Authentication or other tools that allow on-premises credentials to be used for access in the cloud. This architecture makes on-premises Active Directory a tempting target for password spray attacks. Unless Azure AD Password Protection is deployed on-premises, users will be able to set weak passwords. Moreover, any endpoint in Active Directory that is exposed to an attacker could be used to carry out password spraying attacks away from the detection capabilities of Azure AD.

Managing this risk involves not only auditing on-premises authentication activity but having the ability to analyze and correlate it on a wide-scale, statistical level in order to detect any increase in failed authentications across the entire domain, which is a tell-tale sign of a password spraying attack.

## The Trouble with Active Directory Auditing

To properly secure a hybrid Microsoft 365 tenant, therefore, administrators need visibility into Active Directory as well as Azure AD. The challenges with Active Directory auditing will be familiar to many administrators with a history in Active Directory administration, but here is a brief summary:

- **Active Directory audit logs are very decentralized.** To get an accurate picture of Active Directory activity, administrators must analyze the Security event log on each domain controller where auditing is enabled.
- **Active Directory audit logs have a poor signal to noise ratio.** Multiple events are sometimes generated for a single audited action. Events can often contain irrelevant or obfuscated information, such as GUIDs rather than recognizable object names.
- **Log data can be short-lived.** Directory auditing information is written into the Security event log, which is highly active and regularly overwritten.
- **Active Directory audit logs are incomplete.** Critical aspects of Active Directory, such as Group Policy, are either partially audited or not audited at all.

## Hybrid Directory Auditing Adds Another Wrinkle

Organizations with a hybrid Azure Active Directory face an additional challenge: correlation.

Because Active Directory can affect Azure Active Directory (and in limited circumstances, Azure AD can affect on-premises Active Directory), understanding the behavior of the complete system requires administrators to not only review and act on security signals coming from each platform, but to correlate those signals.

Typically, this task involves manually correlating activity from two different auditing systems. In a worst-case scenario, it requires looking directly into Active Directory domain controller logs in order to find audit data corresponding to the activity found in the Microsoft 365 audit stream.

## ADFS Introduces Even More Dependencies on Active Directory

Microsoft has been recommending that organizations shift away from Active Directory Federation Services (ADFS) for some time, as it leverages Active Directory to authenticate Azure Active Directory accounts, which has significant ramifications for both reliability and security.

But, for many organizations, migrating away from ADFS may take some time. While ADFS remains in place, the organization will have additional requirements for hybrid Azure Active Directory auditing, since both Active Directory changes and authentications need to be audited. Furthermore, relying on ADFS reduces the capability of Azure AD risk detection, which helps administrators identify and act on unusual or risky sign-in activity.

## Overcoming the Challenges of Hybrid Auditing

To tackle the challenges of auditing a hybrid Azure Active Directory environment, most organizations require more than the native capabilities. Many of them leverage a security information and event management (SIEM) solution or a dedicated auditing system like Quest Change Auditor for Active Directory.

### SIEM Solutions

SIEM tools, such as Splunk and Microsoft Azure Sentinel, are powerful systems designed to aggregate security signals from many different sources. They are often used to correlate on-premises Active Directory activity with activity in the Microsoft 365 platform, but they can also accept data from network devices or low-level endpoint auditing tools like Sysmon.

However, SIEM systems can be very expensive, as well as complex to configure and operate. In larger organizations, they are often managed exclusively by security teams — which means that AD administrators have little or no access to the data.

Additionally, SIEM systems aggregate and analyze security events, but they don't produce them. This makes them susceptible to the same noise and blind spots inherent in native Active Directory auditing.

### Hybrid Active Directory Auditing Systems

Another common approach to hybrid auditing is to use a purpose-built solution such as On Demand Audit from Quest. These systems produce independent audit information from on-premises Active Directory, ingest audit events from the Microsoft 365 unified audit log, and then normalize and combine both of those sources into a single audit stream.

For instance, On Demand Audit agents capture activity from Active Directory domain controllers that it is not possible to "see" natively, such as changes to Group Policy settings and DCSync style attacks. These events are collected in an on-premises server and then forwarded to the cloud-based On Demand Audit platform, where they are combined with information from one or more Microsoft 365 tenants. As a result, IT pros can include information from both on-premises and Microsoft 365 signals in a single search or alert, such as the following:

- A search that encompasses a user's activity both on-premises and in the cloud
- An alert that is triggered whenever an account with "service" somewhere in its name or description is made hybrid
- A search that reveals who modified a hybrid security group that controls SharePoint data and when the change was made

Some hybrid Active Directory auditing systems even include pre-defined indicators of critical or risky activity. For instance, On Demand Audit considers all the following events to be indicative of “critical activity”:

- A change to AD schema configuration
- An unusual increase in sign-in failures for Azure AD or on-premises Active Directory
- A change to the membership of a critical AD group
- A change to a critical Azure AD role

## Summary — Hybrid Auditing

To secure a hybrid tenant, IT administrators need to be able to effectively audit both Azure Active Directory and the attached on-premises Active Directory, and correlate and analyze the data from both environments. Options include native tools, SIEM products and third-party auditing solutions.

# Group Management

## Microsoft 365 Groups

Office 365 adds exciting new capabilities to and poses new challenges for group management. Just like Active Directory, Office 365 has both security and distribution groups. These groups can exist as cloud-only objects managed either through the Microsoft 365 admin center, the Azure AD Portal, or the Exchange Online admin center (and their corresponding PowerShell and API interfaces). But they can also be hybrid. Hybrid security and distribution groups can be used for all the same things as cloud-only groups can, but they are managed by traditional on-premises tools and APIs (Active Directory and Exchange, respectively).

In 2014, Office 365 introduced a new group type called Office 365 Groups (now Microsoft 365 Groups). These groups are cloud-only. A Microsoft 365 group cannot be hybrid. It can provide authorization to resources like a security group can, it can function as a distribution list like a distribution group can, and it can also connect resources such as a SharePoint team site and plan. In addition, Microsoft 365 Groups underpin Teams.

## The Pain of Groups

While groups are a foundational and very useful aspect of directory services, managing groups can be problematic. The fundamental problem with groups is well understood: Over time, the accuracy of both the membership of a group and the purpose of the group tend to drop. This can cause everything from annoyances, like having the Exchange Global Address List (GAL) populated with long list of defunct entries, to serious problems, such as the very real security risk of having users collecting group memberships for every new role they take on but never being removed from old ones.

## Successfully Managing Groups

The fundamental ingredients to making groups less painful are also well understood. There are three techniques that play a part in successful group management:

### Reporting on Group Usage

There are a wide variety of tools that provide some level of reporting on group utilization across an environment. These tools can find where a group is being used, such as to secure a folder in a file system or to secure access to a SharePoint list.

Being able to report on groups is important. Unfortunately, group reporting has limitations. No tool is able to report on everywhere a group could potentially be used. And even more fundamentally, group reporting is

mostly useful in the context of a group clean-up project as performed by IT. When the project is over, groups resume their drift toward inaccuracy.

## Dynamic Groups

The membership of dynamic groups is determined through rules. For example, a group might be defined to contain any user whose Department attribute is "HR" and whose Office attribute is "Denver". When the user's attributes change, their group membership changes automatically.

Dynamic groups are very useful for making group management less painful. Their main weakness is that they are appropriate only for certain types of groups; many groups simply cannot be defined in any other way than ad-hoc.

## Self-Service Group Management

The core concept of self-service group management is that management of groups is pushed outside of information technology and into the general organizational process.

End users can make a request to join a group, and owners of those groups can decide whether to allow the user to join. End users can request the creation of groups and can manage the membership of groups that they have created. A scheduled process regularly prompts group owners to certify the accuracy of the membership of each of their groups, as well as the need for the continued existence of the group itself. All these activities are done without having to have IT staff directly involved.

Taking a self-service approach to group management has its shortcomings. If group ownership is not well defined, then you can end up with orphaned and abandoned groups. Moreover, it is possible that group owners will not carry out their responsibilities properly, even when prompted to — the "rubber stamping" problem.

Ultimately, though, a combination of these three techniques is the best way to minimize group sprawl and atrophy.

## Native Microsoft 365 Group Management

The addition of Office 365 to an organization's technical stack often makes group management harder. Usually, their on-premises Active Directory groups still exist and still have to be managed. Some of those groups will likely become hybrid groups that act as the "source of truth" for the cloud. And, as explained earlier, Office 365 adds a new cloud-only group type (the Microsoft 365 group) that not only proliferates quickly but can directly contain the organization's data.

To assist with these challenges, Microsoft has introduced several new capabilities. Most of these capabilities are tied to specific Azure AD license tiers, which will be denoted below (accurate as of the date of writing).

If your organization is licensed for Azure AD Premium P1, Microsoft enables dynamic membership rules for security groups and Microsoft 365 groups. This lets the group membership be determined by combinations of user or device properties and kept up to date automatically. This option works just for cloud-only security and Microsoft 365 groups; distribution groups and hybrid groups need not apply.

Azure AD Premium P1 also adds group expiration policies, naming policies and self-service group membership for Microsoft 365 and cloud-only security groups. Just as with dynamic groups, this works only for cloud-based groups, and only for security and Microsoft 365 groups.

For organizations with Azure AD Premium P2, Microsoft adds one more additional capability: group attestation, which Microsoft calls "access review." Group owners are reminded on a regular basis to review the membership of the groups they manage for accuracy.

## Where Native Group Management Breaks Down

The native group management capabilities covers all three of the key techniques for controlling group pain: reporting, dynamic rule-based groups, and self-service and attestation. So, what's the hitch? The core problem is clear: The native capabilities cover only a portion of the group types that are going to be in nearly every organization's production environment.

Distribution groups, hybrid groups and on-prem-only groups need to be covered by a different solution.

## Quest On Demand Group Management

On Demand Group Management from Quest is designed to fill these functionality gaps. This software-as-a-service (SaaS) solution adds straightforward self-service group management and attestation for the full complement of groups in the Microsoft technology stack.

It delivers self-service and attestation for cloud-only security groups and Microsoft 365 groups, similar to the capabilities in Azure AD Premium P1 and P2. And on top of that, it provides support for cloud-only distribution groups, hybrid groups of all types, and even on-prem-only security and distribution groups. Here are some of the key features of this innovative solution:

### Group Lifecycle Management

On Demand Group Management is designed to manage the lifecycle of groups from inception to removal. Each step of group management can involve independent approval processes.

When a group is created On Demand Group Management prompts the requester to classify the group. This classification determines several aspects of the group:

- What its naming pattern needs to be
- What kind of group it is (on-premises, cloud-only, security, Microsoft 365, etc.)
- What its sensitivity label is
- Whether the group is available for self-service request
- Whether and how often it needs to be attested to

If the group is included in the list of groups that are available for users to request, then end users can request to join the group, request to manage the group, or request to leave the group.

And if the group category is configured to have an attestation or review period, users that are responsible for the group will be periodically asked two key questions: Is this group still necessary? Is the membership of this group still correct? When the group is deemed no longer necessary by its owners, it will be removed from whichever directory it exists in, ending its lifecycle.

### Support for All Kinds of Groups

On Demand Group Management treats all Microsoft groups in the same way. It interfaces with the management APIs for Azure AD, Exchange Online, Active Directory and on-premises Exchange, depending on the type of group.

Hybrid and on-prem-only group management is particularly sophisticated. In order to provide lifecycle management for these groups, ODGM utilizes an agent that is installed on an on-premises member server that interfaces with Active Directory and Exchange APIs.

### Simple Implementation

There are many reasons why an organization might not have solved its group management problem, but complexity is often a big one.

Therefore, On Demand Group Management is designed to be simple to implement. It is a SaaS solution, so there is no need to size and deploy a server platform to support it. And it also has sensible default configuration settings, which make it easier to start using the solution effectively.

## Summary – Group Management

Your groups are essential to your business — from strong security to effective collaboration and user productivity, so you need to have control over all them throughout their full lifecycle. In particular, be sure you have reporting, dynamic rule-based groups, and self-service and attestation for all your various groups, including the types not covered by native group management capabilities: distribution groups, hybrid groups and on-prem-only groups.

## About Quest

Master the challenges of managing Office 365 with Quest, your go-to vendor for moving, managing and securing Azure Active Directory, Exchange Online, OneDrive for Business, SharePoint Online and Teams. Quest delivers the most comprehensive set of Office 365 and hybrid management solutions, including solutions from [recently acquired Quadrotech](#), [Binary Tree](#) and [Metalogix](#). With Quest solutions, you can:

- Move all your workloads to Office 365 with little to no disruption to end users.
- Reduce the time, clicks and scripts needed to manage your Office 365 or hybrid environment.
- Extend your existing security and compliance framework to your ever-evolving Office 365 environment.

To learn more about Quest solutions for Office 365, visit [quest.com/solutions/office-365](https://quest.com/solutions/office-365).

# Appendix

This appendix holds interesting information about Microsoft 365 that fits better here rather than interrupting the flow of text in a chapter.

## Annualized Run Rate for the Microsoft Cloud

Table: A-1 lists the annualized run rate for the Microsoft Cloud business segment as reported in Microsoft quarterly results. The big leap in FY19 is accounted for [Microsoft's September 2018 announcement](#) that they would include results for LinkedIn in the commercial cloud segment on an ongoing basis (LinkedIn accounted for [\\$6.75 billion revenue](#) in Microsoft's FY19 results).

<b>Quarter results</b>	<b>Reported annualized revenue run rate (ARR) for the Microsoft Cloud</b>
FY15 Q3 (April 2015)	\$6.3 billion
FY15 Q4 (July 2015)	\$8.0 billion
FY16 Q4 (July 2016)	\$12.1 billion
FY17 Q1 (October 2016)	Over \$13 billion
FY17 Q2 (January 2017)	Over \$14 billion
FY17 Q3 (April 2017)	\$15.2 billion
FY17 Q4 (July 2017)	\$18.9 billion
FY18 Q1 (October 2017)	\$20.4 billion
FY18 Q2 (January 2018)	\$21.2 billion (based on \$5.3B revenue reported for the quarter)
FY18 Q3 (April 2018)	\$24 billion (\$6B revenue)
FY18 Q4 (July 2018)	\$27.6 billion (\$6.9B revenue)
FY19 Q1 (October 2018)	\$39 billion (\$9.77B revenue)
FY19 Q2 (January 2019)	\$40.4 billion (\$10.1B revenue)
FY19 Q3 (April 2019)	\$40.96 billion (\$10.24B revenue)
FY19 Q4 (July 2019)	\$44 billion (\$11B revenue)
FY20 Q1 (October 2019)	\$46.4 billion (\$11.6B revenue)
FY20 Q2 (January 2020)	\$50 billion (\$12.5B revenue)
FY20 Q3 (April 2020)	\$53.2 billion (\$13.3B revenue)
FY20 Q4 (July 2020)	\$57.2 billion (\$14.4B revenue)
FY21 Q1 (October 2020)	\$60.8 billion (\$15.2B revenue)
FY21 Q2 (January 2021)	\$66.8 billion (\$16.7B revenue)
FY21 Q3 (April 2021)	\$70.8 billion (\$17.7B revenue)
FY21 Q4 (July 2021)	\$78 billion (\$19.5B revenue)
FY22 Q1 (October 2021)	\$82.8 billion (\$20.7B revenue)
FY22 Q2 (January 2022)	\$88.4 billion (\$22.1B revenue)
FY22 Q3 (April 2022)	\$93.6 billion (\$23.4 B revenue)

Table: A-1: Annualized revenue run rate for the Microsoft Cloud

## Growth in Office 365 User Numbers

Table A-2 details the growth in Office 365 user numbers since November 2015. For several years Microsoft reported the number of monthly active users every six months during their April and October earnings. In

April 2020, Microsoft switched to reporting the number of paid seats instead, citing 258 million then. You could assume that a paid seat is an active seat, but that isn't always the case. In the October 2021 earnings call, Microsoft said that the number of paid commercial Office 365 seats grew 17% year-over-year (the same percentage cited in January and July 2021). If usage tracks paid seats, we can therefore estimate the number of active seats as shown below.

<b>Date</b>	<b>Microsoft number for monthly active Office 365 users</b>	<b>Microsoft number for paid seats</b>
November 2015	60 million	
April 2016	70 million	
October 2016	85 million	
April 2017	Over 100 million	
October 2017	120 million	
April 2018	135 million	
October 2018	155 million	
April 2019	180 million	
October 2019	200 million	
April 2020	230 million (estimated)	258 million
October 2020	245 million (estimated)	278 million (estimated)
April 2021	264.5 million (estimated)	296.7 million
July 2021	280 million (estimated)	315 million (estimated)
October 2021	290 million (estimated)	325 million (estimated)
April 2022	321 million (estimated)	345 million

Table A-2: Growth in Office 365 user numbers over time

*Note: Estimated numbers shown since April 2020 are based on long-term growth for Office 365 seats as reported by Microsoft when they share this data in quarterly results. The estimates use the growth rate per month since the last reported number.*

## Quarterly Performance Against SLA

Table A-3 details the performance against SLA since figures first became available in 2013. The highlighted figure is the most recent published quarterly result.

<b>Q1 2013</b>	<b>Q2 2013</b>	<b>Q3 2013</b>	<b>Q4 2013</b>	<b>Q1 2014</b>	<b>Q2 2014</b>	<b>Q3 2014</b>	<b>Q4 2014</b>
99.94%	99.97%	99.96%	99.98%	99.99%	99.95%	99.98%	99.99%
<b>Q1 2015</b>	<b>Q2 2015</b>	<b>Q3 2015</b>	<b>Q4 2015</b>	<b>Q1 2016</b>	<b>Q2 2016</b>	<b>Q3 2016</b>	<b>Q4 2016</b>
99.99%	99.95%	99.98%	99.98%	99.98%	99.98%	99.99%	99.99%
<b>Q1 2017</b>	<b>Q2 2017</b>	<b>Q3 2017</b>	<b>Q4 2017</b>	<b>Q1 2018</b>	<b>Q2 2018</b>	<b>Q3 2018</b>	<b>Q4 2018</b>
99.99%	99.97%	99.985%	99.988%	99.993%	99.98%	99.97%	99.98%
<b>Q1 2019</b>	<b>Q2 2019</b>	<b>Q3 2019</b>	<b>Q4 2019</b>	<b>Q1 2020</b>	<b>Q2 2020</b>	<b>Q3 2020</b>	<b>Q4 2020</b>
99.97%	99.97%	99.98%	99.98%	99.98%	99.99%	99.97%	99.97%
<b>Q1 2021</b>	<b>Q2 2021</b>	<b>Q3 2021</b>	<b>Q4 2021</b>	<b>Q1 2022</b>			
99.97%	99.98%	99.985%	99.976%	99.98%			

Table A-3: Office 365 SLA performance since 2013
