**Please be respectful of the rights of the authors and do not make and distribute copies of this eBook available to others.**

Ninth (2023) edition. Previous editions appeared under the following titles:

- Office 365 for Exchange Professionals (May 2015 and September 2015).
- Office 365 for IT Pros (3<sup>rd</sup> edition – June 2016).
- Office 365 for IT Pros (4<sup>th</sup> edition – June 2017).
- Office 365 for IT Pros (5<sup>th</sup> edition – July 2018).
- Office 365 for IT Pros (6<sup>th</sup> edition – July 2019).
- Office 365 for IT Pros (7<sup>th</sup> edition – July 2020).
- Office 365 for IT Pros (8<sup>th</sup> edition – July 2021).

The authors issue regular updates for this eBook until they publish a new edition, usually after a year. People who buy the book through [gumroad.com](https://gumroad.com) can use their accounts to download updates as they become available (the View content link in your receipt always accesses the latest available files). Updates are also available for the Kindle edition, but this depends on the willingness of Amazon to make purchasers aware that an update exists. We try to persuade Amazon of this need about once a month. Information about how to access updated files is in our [FAQ](#).

The companion volume for this book has other information that you might find interesting. We include the companion volume with the EPUB/PDF version and is available separately for the Kindle edition.

This is the original version of the 2023 edition published on **1 July 2022** (monthly update #85.5). You can find information about the changes made in each update in [our change log](#) or through our [Facebook page](#).

Tony Redmond took the photo used on the front cover in Dubrovnik, Croatia by in May 2022.

# Table of Contents

<b>Foreword</b> .....	<b>xi</b>
<b>Introduction</b> .....	<b>xiii</b>
What We Cover.....	xiii
PowerShell Examples.....	xiv
The Colored Boxes.....	xiv
Book Updates.....	xv
The Author Team .....	xv
Thanks .....	xvi
Our Sponsor.....	xvi
Comments and feedback.....	xvii
<b>Chapter 1: The Microsoft 365 Ecosystem and Office 365</b> .....	<b>1</b>
Microsoft 365: More than Office 365.....	2
Cloud Infrastructure.....	3
Products and Licenses.....	15
Trial Tenants.....	21
The Commercial Success of the Microsoft Cloud .....	21
Service Level Agreements for Online Services .....	24
Leveraging the Breadth of Office 365.....	27
<b>Chapter 2: Embracing the Microsoft 365 Cloud</b> .....	<b>29</b>
Should You Move to the Cloud?.....	29
What to Do Before You Move .....	30
What To Do While You Move .....	60
What To Do After You Move.....	62
The Cloud Is a Journey.....	63
<b>Chapter 3: Managing Identities</b> .....	<b>64</b>
The Role of Azure Active Directory.....	64
Identity Architectures .....	66
Standalone Identity.....	67
Hybrid Identity Authentication Infrastructure .....	69
Alternate Login ID.....	73
Passwordless Authentication.....	74
Understanding Azure AD Authentication.....	75
Customizing the Tenant Sign-In Page.....	79
Joining Computers to Azure AD .....	81

Guest Access to Azure AD .....	82
Protecting Your Identities.....	88
Controlling Access.....	97
App Registrations and Permissions .....	108
Connecting to LinkedIn .....	110
PowerShell and Azure AD.....	112
<b>Chapter 4: Tenant Management.....</b>	<b>113</b>
Cloud versus On-Premises Management.....	113
Administrative Interfaces .....	115
Managing Licenses, Plans, and Billing .....	123
Managing Integrated Apps.....	124
Managing Feature Releases.....	125
Managing Connectivity .....	127
Protecting Data with Encryption.....	130
Monitoring.....	132
Service Requests.....	140
Customizing the Microsoft 365 Interface.....	145
Reporting .....	147
Backing Up Office 365 .....	152
<b>Chapter 5: Managing User Accounts.....</b>	<b>159</b>
Managing User Accounts in the Microsoft 365 Admin Center.....	159
Enabling Self-Service User Management .....	160
Managing User License Assignments .....	161
Managing User Role Assignments .....	164
Managing Privileged Accounts.....	173
Managing Exchange Online Mailboxes.....	174
Administrator Access to User Mailbox Settings.....	186
Securing the Data of Ex-employees .....	187
<b>Chapter 6: Managing Exchange Online .....</b>	<b>196</b>
Exchange Online.....	196
Native Data Protection .....	198
Managing Mailboxes.....	200
Autodiscover.....	223
Recovering Deleted Mailboxes.....	223
Inactive Mailboxes.....	225
Automatic Mailbox Maintenance .....	231

Archive Mailboxes.....	237
Shared Mailboxes .....	247
Mail Contacts and Mail Users .....	259
Blocking Basic Authentication .....	261
<b>Chapter 7: Mail Flow.....</b>	<b>266</b>
Configuring Mail Flow.....	266
Managing Connectors .....	281
Mail Flow Rules.....	282
Remote Domains .....	290
Device and app mail relay to Exchange Online .....	291
Exchange Online Protection (EOP).....	292
Microsoft Defender for Office 365 (MDO).....	320
Attack Simulation Training.....	328
Investigations .....	333
Explorer .....	334
Monitoring and Troubleshooting Mail Flow.....	336
Transport Limits.....	346
<b>Chapter 8: Managing SharePoint and OneDrive for Business .....</b>	<b>349</b>
SharePoint Online.....	349
OneDrive for Business.....	387
Managing OneDrive for Business.....	396
Migrating to SharePoint Online and OneDrive for Business .....	398
Microsoft Lists.....	400
Delve and Microsoft Search.....	402
How Microsoft Viva and SharePoint Syntex Brings AI to SharePoint .....	408
Other Services Using SharePoint Online and OneDrive for Business .....	412
<b>Chapter 9: Tasks.....</b>	<b>414</b>
Delivering Lightweight Planning.....	414
Planner Basics.....	419
Creating New Plans.....	420
Plan Settings .....	425
Copying a Plan .....	427
Closing or Archiving a Plan.....	428
Planner and Microsoft 365 Compliance.....	429
Deleting Plans and Plan Data.....	429
Creating and Managing Tasks .....	430

Moving Planner Data to a Different Tenant .....	438
Using Planner Offline .....	438
Planner and Guest Users .....	439
Planner, Tasks, and Teams .....	440
Linking Planner and the Microsoft 365 Message Center .....	442
<b>Chapter 10: Managing Video .....</b>	<b>444</b>
The Cloud Video Platform .....	444
Stream User Functionality .....	446
Stream and Teams .....	453
Stream Audit Events .....	458
<b>Chapter 11: Managing Microsoft 365 Groups .....</b>	<b>460</b>
Modern Groups and Distribution Lists .....	460
An Identity and Membership Service .....	460
Group Components .....	464
Implementing Groups .....	468
Azure AD Policy for Groups .....	469
Creating New Microsoft 365 Groups .....	483
Managing Groups with Outlook Clients .....	490
Guest Access to Microsoft 365 Groups .....	492
Controlling Guest Access to Groups .....	502
Removing and Recovering Groups .....	508
Group Expiration Policy .....	512
Dynamic Microsoft 365 Groups .....	516
Groups and Compliance .....	519
Yammer and Groups .....	520
Evaluating Yammer, Groups, and Teams .....	524
Distribution Lists .....	527
Recipient Moderation .....	544
Migration from Email Distribution Lists .....	546
Comparing Groups, Distribution Lists, and Shared Mailboxes .....	550
<b>Chapter 12: Teams Basics .....</b>	<b>551</b>
Workgroup Collaboration .....	551
The Structure of Teams .....	562
Maintaining Team Membership .....	573
Teams Messaging .....	578
Personal (1:1) and Group Chats .....	592

Teams Meetings .....	600
Teams Calling .....	622
Viewing Organizational Information .....	623
Presence and Status.....	625
Files: Linking Teams and SharePoint Online .....	627
Teams for Frontline Workers.....	631
Can Teams Replace Email?.....	632
Teams and Email Interaction .....	636
<b>Chapter 13: Managing Teams.....</b>	<b>640</b>
Keeping Teams in Good Shape .....	640
Creating a Deployment Plan for Teams.....	640
Teams Management.....	641
Creating Teams.....	652
Dynamic Teams.....	660
Hiding Teams from Exchange Online .....	661
Using a Team-Enabled Group as a Distribution List .....	662
Deleting (and Restoring) Channels and Teams.....	663
Channel Moderation.....	664
Managing Settings for a Team .....	665
Guest Access for Teams.....	667
Email Integration for Teams Channels.....	672
Teams and Compliance .....	675
Auditing Teams.....	686
Teams and the Groups Expiration Policy.....	686
Archiving Teams .....	687
Reporting Teams Usage .....	689
Extending Teams.....	691
Teams App Setup Policies .....	695
Teams App Permission Policies.....	697
Teams App Store.....	698
Teams and Bots .....	698
Office Connectors and Teams.....	699
Teams Approvals.....	700
Debugging Teams Clients .....	701
Migration to Teams.....	703
<b>Chapter 14: Managing Teams Calling and Devices.....</b>	<b>704</b>

Teams Calling Fundamentals .....	704
Teams Meeting Enhancements .....	716
Teams Phone .....	720
Teams Devices.....	733
Troubleshooting and Monitoring Calls .....	745
<b>Chapter 15: Managing Clients .....</b>	<b>759</b>
Many Clients, One Service .....	759
Managing the Microsoft 365 Apps Suite.....	762
Using the Microsoft Apps Admin Center .....	771
Managing the Outlook Client Family .....	775
Managing Outlook Web App.....	780
Managing Client Access and Protocols.....	788
Managing OneDrive for Business Clients.....	795
Managing Teams Clients.....	796
Managing Microsoft Authenticator .....	805
Optimizing Microsoft 365 Client Network Access .....	808
<b>Chapter 16: Managing Devices.....</b>	<b>811</b>
Comparing the Three Solutions .....	811
Getting Started with Intune .....	812
Managing Apps .....	815
Managing Devices .....	823
Security by Compliance .....	825
Intune Management .....	827
<b>Chapter 17: Managing Data Governance and Compliance .....</b>	<b>831</b>
Data Governance.....	831
Principles of Data Governance .....	833
Compliance Permissions .....	835
Retention Policies and Publishing Label Policies .....	836
Rules or Principles of Retention .....	838
Retention Policies .....	839
Auto-Label Retention Policies.....	859
Retention and Sensitivity Labels .....	863
Creating New Retention Labels.....	866
Using Retention Labels.....	872
Records Management.....	879
Processing Manual Dispositions .....	882

Event-based Retention .....	886
Removing Retention Labels .....	887
Data Classification Dashboard .....	888
Ingesting Items for Review from External Sources .....	891
Using PowerShell with Retention Labels and Policies .....	892
Moving Data Between Tenants .....	901
Understanding the Exchange Mailbox Lifecycle .....	902
Exchange Mailbox Retention Policies .....	906
<b>Chapter 18: Managing eDiscovery .....</b>	<b>911</b>
Content Searches .....	911
Creating and Running a Content Search .....	914
Auditing of Search Activities .....	931
Data Subject Requests .....	932
Microsoft Purview eDiscovery .....	933
Premium eDiscovery .....	940
Using PowerShell with Content Searches .....	942
Using PowerShell to Manage eDiscovery Cases .....	950
In-place Holds and Litigation Holds .....	953
<b>Chapter 19: Managing Data Loss Prevention .....</b>	<b>955</b>
Leak Prevention with Software .....	955
Microsoft Purview Data Loss Prevention .....	956
Sensitive Information Types .....	957
Microsoft Purview DLP Policies .....	959
Endpoint DLP .....	971
Creating Custom Sensitive Information Types .....	972
Document Fingerprinting .....	976
<b>Chapter 20: Managing Information Protection .....</b>	<b>978</b>
The Need to Protect Data .....	978
Rights Management .....	979
Enabling Rights Management for a Tenant .....	983
Sensitivity Labels .....	985
Protecting SharePoint Online and OneDrive for Business .....	1013
Protecting Email .....	1018
Managing Office 365 Message Encryption .....	1027
Hybrid Protection .....	1036
Protecting Windows Files .....	1037

Managing Sensitivity Labels with PowerShell.....	1039
PowerShell for Rights Management.....	1048
Using Microsoft Defender for Cloud Apps to Protect Office 365 Content.....	1053
Microsoft Information Protection Auditing.....	1054
Cloud Exit for Encrypted Content.....	1055
<b>Chapter 21: Managing Auditing and Reporting .....</b>	<b>1056</b>
Auditing Framework.....	1056
Activity Alerts and Alert Policies.....	1076
Office 365 Cloud App Security.....	1082
Third-Party Auditing Alternatives.....	1087
Exchange Online Administrative Auditing.....	1087
Exchange Online Mailbox Auditing.....	1089
Reporting Workload Activity.....	1094
Communications Compliance.....	1101
Information Barriers.....	1110
<b>Chapter 22: Power Platform .....</b>	<b>1120</b>
In Search of No-Code/Low-Code Automation.....	1120
Power Platform Administration.....	1121
Power Automate.....	1126
Power Apps.....	1135
Power BI.....	1143
Power Pages.....	1146
Power Virtual Agents.....	1147
Teams and the Power Platform.....	1148
<b>Chapter 23: Managing Tenants with PowerShell and the Microsoft Graph .....</b>	<b>1151</b>
The Power of Automation.....	1151
Managing Exchange Online with PowerShell.....	1165
Managing Microsoft 365 Groups with PowerShell.....	1172
Managing Teams with PowerShell.....	1198
Sending Messages with PowerShell.....	1213
Understanding How to Use the Microsoft Graph to Manage Microsoft 365.....	1215
Approaching the Use of Graph API Requests with PowerShell.....	1222
The Microsoft Graph Explorer.....	1230
Using the Microsoft Graph PowerShell SDK.....	1233
Using Azure Automation with Microsoft 365.....	1254
Office Connectors.....	1255

Managing Self-Service Purchases .....	1261
<b>Chapter 24: What don't you know you don't know about Office 365 and Azure AD? .....</b>	<b>1262</b>
Azure Active Directory Recovery .....	1263
Tenant-to-Tenant Migration .....	1268
Practical Auditing in a Hybrid World .....	1275
Group Management .....	1278
About Quest.....	1281
<b>Appendix .....</b>	<b>1282</b>
Annualized Run Rate for the Microsoft Cloud .....	1282
Growth in Office 365 User Numbers .....	1282
Quarterly Performance Against SLA.....	1283

# Foreword

Many people talk about the cloud as though it is made of pixie dust. Toss a few clever phrases around, write a check, and life is as easy as sipping margaritas on the beach. If that sounds like a pile of manure, it's because it is.

The authors of this book write "the Cloud is a Journey." That's why I love this book. Tony Redmond and his fellow authors have been around the block enough times to know manure from masterpieces. They deliver a clear-eyed view of the issues you need to think through moving to the cloud and what to do once you are there. There will be plenty of time for margaritas on the beach, but first, you must use this book to apprentice yourself to masters and learn the art and science of being an Office 365 IT Pro.

Office 365 relieves you from solving hundreds if not thousands of extremely difficult problems. You don't have to plan, size, purchase, and deploy the right server, power, storage, and network systems. You don't have to provision the OS, storage, security, networking, monitoring, management, backup, and other software stacks. You don't have to run the infrastructure 24x7, patch everything on a timely basis, verify that everything continues to work after the patches, and update the systems to take advantage of the latest and greatest set of features. Office 365 does all that for you.

But if Office 365 does all that, do we need IT Pros anymore?

Having spent over four decades in the computer industry, I've lived through, and led through, several major technology transitions. At each of these transitions, some IT Pros fear that their jobs will go away. Jobs change but they rarely go away.

IT Pros used to walk around with an unfolded paper clip in their pocket to toggle dip-switches to configure CD-ROM readers to work on PCs. Then plug-n-play was invented. We got rid of a lot of unfolded paper clips but not many IT Pros. Most learned new skills and prospered.

As soon as one problem goes away, IT Pros move on to work on the next set of issues to help move the business forward. And they became more valuable in the process. There wasn't much business value generated in flipping dip switches.

So it is with Office 365. IT Pros no longer plan, deploy, and operate the infrastructure to run Office applications. That frees them up to focus on things like managing Data Governance and Compliance, eDiscovery, Information Protection, and Data Loss Prevention, all of which are covered in chapters in this book. It should be readily obvious that those topics are far more important and valuable to a business than monitoring disk usage on a server.

Technology transitions like the cloud are not easy. You spend your time becoming really good at something. Perhaps you are the company's go-to person for a certain technology. And then a technology transition comes along, and you must start all over. It's hard, but that is our way. When you choose a career as an IT Pro, you signed up for walking the path of lifelong learning. This book is an excellent companion for that journey.

In this book, you will find many PowerShell examples. PowerShell is a must-have skill for any serious IT Pro. GUIs are pretty and often easy, but they limit your ability to be a highly effective IT Pro. You can't cut and paste mouse clicks. You can't code review mouse clicks. You can't rerun a set of mouse clicks on five thousand user accounts. You can't share your mouse clicks with other people. With PowerShell, you can plan your work, get it reviewed by others, and then perfectly repeat it over and over again. Not with a GUI. With PowerShell, you are part of a community where members help each other. With a GUI, you are on your own.

Lastly, as information expands, expertise narrows. As paradigms shift, expertise expires. Therefore, IT Pros need to be generalists and exhibit a growth mindset. That includes the ability to learn, collaborate, detect, and apply patterns. PowerShell was designed with this in mind. It has a single parser for all cmdlets, so you don't have to relearn how to type a command. It provides a regular verb-noun syntax with the goal of enabling you to think about what you want, type it and get it. You can run interactive commands, simple scripts, or complex scripts. You can run them on Windows, Linux, macOS, and even from the Azure Portal. And it is fun.

Best wishes with your journey to the cloud and Office 365, and congratulations to Tony Redmond, Paul Robichaux, Christina Wheeler, Brian Desmond, Juan Carlos Gonzalez, Ben Lee, and Gareth Gudger for bringing clarity and a wealth of good advice to help you on your way.

Jeffrey Snover

Technical Fellow and Inventor of PowerShell, Microsoft Corporation

# Introduction

Welcome to the Ninth (2023) edition of **Office 365 for IT Pros**, a book focused on the Microsoft 365 cloud productivity suite. The goal of this book is to help tenant administrators, architects, and technologists understand and exploit the capabilities available in the enterprise version of Office 365 and the surrounding Microsoft 365 ecosystem. Office 365 had its 10<sup>th</sup> anniversary on June 28, 2021. We have seen enormous change since its release. It's been a blast tracking, analyzing, and documenting the evolution of Office 365 since we started on the Office 365 for IT Pros path in the summer of 2014.

Some accuse Microsoft of applying branding too liberally with the result that they confuse customers about just what Microsoft 365 means. In the context of this book, Office 365 means the enterprise Office services accessed by tenants via the internet, including Exchange Online, SharePoint Online, OneDrive for Business, Teams, Planner, and Yammer. We also cover the functionality available in the various administrative portals and how to use Power Automate, Power Apps, PowerShell, and the Microsoft Graph to automate administrative processes. Although we cover clients like Outlook, we don't cover applications like Word, Excel, and PowerPoint except in passing.

This is not an official Microsoft publication and Microsoft endorses none of the opinions expressed here in any way. Instead, it's a collection of thoughts, ideas, and perspectives from a team of highly experienced MVPs (members of the Microsoft Most Valuable Professional program).

## What We Cover

This book helps you maximize your use of Office 365. The major topics include:

- Introducing Office 365.
- Cloud Adoption, or what you should do to run an effective cloud onboarding project.
- Managing user identities with Azure Active Directory, including synchronization with on-premises directories and different authentication methods.
- Managing the overall Office 365 framework.
- Understanding the two basic workloads: Exchange Online and SharePoint Online (including OneDrive for Business), including how mail flow works to bring messages into and out of your tenant.
- Working with Microsoft 365 Groups, including how to manage the membership and access service enabled by Groups.
- Understanding the architecture of Teams and how this popular application leverages so many parts of the Microsoft 365 ecosystem.
- Understanding the Teams architecture and how to manage an application built on top of many other Microsoft 365 and Azure components.
- How the new version of Microsoft Stream works.
- Using Microsoft Planner to organize team and group projects effectively.
- Managing Office 365 desktop, mobile, and browser clients, with or without Microsoft Endpoint Manager.
- How data governance and compliance work inside Office 365, including how retention policies and retention labels work across Exchange Online, SharePoint Online, OneDrive for Business, and Teams.
- How Office 365 captures audit records for over 1,500 different events and how to use that audit data to answer questions about how people use (and sometimes abuse) the service.
- Using Power Automate and Power Apps to automate different user and administrative operations.
- Protecting Microsoft 365 content with data loss prevention policies and encryption (sensitivity labels).

- Using PowerShell and the Microsoft Graph APIs to automate common administrative processes within a tenant.

It's a lot of information to cover in a single book. We hope that you'll like what you find here and appreciate the effort we go through to publish the monthly updates to refresh the material and make sure it is as up-to-date as possible.

## Companion Book

Over the years, we have removed content (including entire chapters) that appeared in previous versions and moved it into a companion volume. The intention was to make space for new topics and content that we think is important to tenants today.

We don't often update the material in the companion volume and only plan to fix errors and omissions. We still think that the information in the companion volume is interesting and valuable, but its time in the limelight might have passed or the information is less relevant to current operations and administration.

## Cloud and On-Premises Products

This book is about Office 365. It follows that when we reference "Exchange" or "SharePoint," we mean the cloud version rather than the on-premises code. Where necessary, we are explicit. For instance, we say "Exchange Online" when we mean that a feature belongs to the cloud version. If we say "Exchange" or "SharePoint," the discussion applies to both cloud and on-premises versions. It's easier with applications like Teams and Planner because they don't exist on-premises (and never will).

## PowerShell Examples

Everyone involved in running an Office 365 tenant should have at least a passing acquaintance with PowerShell (and probably the Microsoft Graph APIs). We include many examples of using PowerShell across the book to help readers understand the value of being able to automate operations. Please remember that we write code to illustrate principles, not to create off-the-shelf solutions. Every organization has a certain way of doing things, its coding standards, and code libraries. We hope that our code helps you understand how PowerShell works with Office 365 so that you can take that learning and use it according to the standards laid down for your tenant. Before putting the code into production, you should add better error handling and probably rewrite it to move some code into functions or enable parameter passing, or simply make the code fit better with other scripts used in your tenant. We do not represent any of the code included in the book to be complete answers to a problem. Instead, you should treat our code as a starting point and be prepared to do some additional work to improve, smoothen, and bulletproof the code before using it to process real data.

Readers of previous editions know about our [GitHub repository](#) (see [this article](#) for information). Referencing scripts in GitHub makes the book a little shorter and allows text to flow better on the page. Another advantage is that the code in GitHub is more likely to work because you can download a complete script instead of transcribing code from a book. An increasing number of our scripts use Microsoft Graph API calls to get work done. This reflects the current state of technology, including the fact that some Microsoft 365 workloads don't support a PowerShell module, and we hope that you can use these examples to build solutions to meet administrative or operational needs.

## The Colored Boxes

From time to time we will want to draw your attention to something that we think is important. We use three colors to highlight information. The first type is a note.

**Note:** This is some additional information about a topic that we're discussing. We've included it because we think it adds some value.

We also have some warnings for things that you need to understand.

**Warning:** Warnings or other cautionary notes will appear like this. Try not to ignore these, the lessons were often learned the hard way and we'd hate to see you suffer the same pain.

And there are lots of real-world observations that we think will interest you.

**Microsoft 365 Groups:** Every group is represented as a group object in Azure Active Directory...

## Book Updates

Apart from its multi-platform nature, we also wanted to avoid the static nature that content often takes in traditional technical books. Given that Office 365 changes all the time, it didn't seem to make much sense to say that any text was definitive and that led us to the decision to create a book with content that changes to match what happens inside Office 365.

Due to the fast-changing nature of Office 365, some of the user interface elements illustrated in this book might have changed when you read this book. The same is true for details of how a feature works. Our tenants use the "Targeted Release" option to allow us to see new features before Microsoft releases them to the general Office 365 base. We may cover something here that you might not see yet in your tenant. Coping with a fast-changing (or even ever-changing) environment is just one of the challenges faced by tenant administrators. New features appear, options move around, and options function in a slightly different manner. Things are just very different from the somewhat staid situation that often occurs inside a typical on-premises infrastructure.

Microsoft's documentation has improved dramatically recently but still often fails to keep up to date with the rapid change within Office 365. We do our best to keep an eye on what is happening and what changes, but please forgive us if we overlook some detail that Microsoft recently revealed or updated. Think of this as an opportunity to demonstrate how good a detective you are in seeking the right answer based on the evidence presented in this book, on Microsoft's websites, and in the voluminous amount of text that you will find in blogs scattered around the web. Of course, blog authors are not seers either and their text begins to degrade as soon as it appears, so you must gather evidence and put it in context with what you see in Office 365 at the time when you're trying to solve a problem or get something to work as you believe it should. Welcome to the world of cloud software!

We release updated versions of this book monthly (see [our FAQ](#) for information about downloading updates). Our policy is to fix errors as soon as we find them, or a reader tells us about a problem. We will update (patch) the version that is currently online to give subscribers the opportunity of always being able to fetch the latest content from where they bought the book (Gumroad or Amazon). It's just like fixing bugs in a software program.

## The Author Team

The Office 365 for IT Pros writing team is:

- Tony Redmond.
- Paul Robichaux.
- Ben Lee.

Office 365 for IT Pros

- Brian Desmond.
- Juan Carlos González.
- Christina Wheeler.
- Gareth Gudger.

Our Technical Editor is Vasil Michev. For more information on the team, see [our online bios](#).

## Microsoft MVP Program

Tony, Juan Carlos, Paul, Gareth, Christina, and Vasil are proud members of Microsoft's Most Valuable Professional (MVP) program. See [this page](#) for more information about the MVP Program.

## Thanks

Many people at Microsoft helped us to chase down technical detail or explain how things work inside Office 365. The list of those who have helped is now too long to include here. We extend our thanks to everyone at Microsoft who has helped us chase down a technical issue or answered questions. We owe you a huge debt.

## Our Sponsor

It's hard to find the time to gather information, make sure that it's current, and write it up. An enormous amount of effort has gone into the creation of the original book and the many revisions and rewrites required for this edition. We could not undertake the task without the help and support of our sponsor, Quest Software. We are very grateful for the support extended by Quest and for the support given in the past by our previous sponsors.

Quest helps Office 365 tenants to migrate, manage, and secure Azure Active Directory, Exchange Online, OneDrive for Business, SharePoint Online and Teams. Quest delivers the most comprehensive set of Office 365 and hybrid management solutions, including solutions from [recently acquired Quadrotech](#), [Binary Tree](#) and [Metalogix](#). Quest solutions allow you to approach migrations with confidence, moving workloads to Office 365 with little to no end user disruption. Supported migration scenarios include:

- Active Directory consolidation and restructuring
- Office 365 tenant to tenant (Teams, SharePoint Online, OneDrive for Business, Exchange Online and Azure Active Directory).

## Office 365 for IT Pros

- Google Drive/Box/Dropbox/EFSS to OneDrive for Business, SharePoint Online, or Teams.
- On-premises SharePoint and Exchange to Office 365.

Quest technology enables Office 365 tenants to simplify administration, improve security posture and protect data across Office 365 and Azure Active Directory with solutions for:

- Backup and recovery.
- License management.
- Auditing.
- Group management.
- Reporting, and
- Governance.

For nearly 20 years, customers have used Quest software to migrate, manage and secure Microsoft platforms. Quest continues to set the bar for Microsoft Platform Management, with key products winning industry awards and gaining recognition year after year. Gartner recently named Quest as a Representative Vendor in its 2019 Market Guide for Cloud Office Migration Tools, which provides recommendations for migration scoping, third-party tool evaluation, and how to gain value from such tools post migration. Gartner also cited Quest as the ONLY vendor to deliver all 40 of the 40 essential features and functionalities expected in an Office 365 migration tool.

To learn more about Quest solutions for Office 365, visit <https://www.quest.com/solutions/office-365/>.

## Comments and feedback

Comments about the content as well as pointers to where little errors might have crept into the text are always welcome. Please send your comments, suggestions, and observations to [BookComments@Office365ITPros.com](mailto:BookComments@Office365ITPros.com) or post to our [Facebook page](#).

# Chapter 1: The Microsoft 365 Ecosystem and Office 365

***Tony Redmond***

Microsoft launched Office 365 in June 2011. Much later, it introduced Microsoft 365 by bundling Office 365, Windows 10 Enterprise, and the Enterprise and Mobility Suite. Microsoft then updated the Office 365 plans for small to medium businesses to use Microsoft 365 branding and changed the name of the Office Pro Plus desktop application suite to Microsoft 365 apps for enterprise. Although the marketing team might be happy to have applied Microsoft 365 to as many products and solutions as possible, it created some confusion in the market.

Over a decade later, over 350 million people use Office 365 in 249 countries worldwide. As the cloud Office service, it is the cornerstone of the Microsoft 365 ecosystem. Office 365 is a set of cloud services, referred to as *workloads*. A cloud service is a resource delivered over the Internet, including software resources (Software as a service, or SaaS) or infrastructure (Infrastructure as a Service, or IaaS). Exchange Online and SharePoint Online, the two base Office 365 workloads, are examples of cloud-based services. Some services have roots in on-premises products such as Exchange Server and SharePoint Server. The codebases for these services are very different from their on-premises counterparts, notably because of the engineering effort to run at a massive scale. Other services like Teams and Planner are cloud-only and have no allegiance to any on-premises technology. Indeed, the nature of these services and how they consume other cloud services and microservices (services built for a specific purpose, like Azure Key Vault) means that they will never appear in an on-premises variant.

The basic idea behind cloud services is that customers can transfer the responsibility for running workloads to a cloud provider, who then charges a fixed monthly or annual fee based on some unit of work, such as a user account or mailbox. Customers either start from scratch with a cloud provider or migrate their data across the internet to data centers run by the cloud provider where enough computing, network, and operational capacity exists to handle the work generated by hundreds of thousands of companies. The value proposition is that the massive economy of scale created by cloud providers allows them to deliver the same or better functionality at a lower cost than is possible for on-premises IT to deliver. As more organizations move to the cloud, the economics improve even more (even with Microsoft's first price increase in ten years effective March 1, 2022), which then lets providers enhance and grow their services.

Microsoft 365 is not just one application or workload. Rather, it is a complex ecosystem composed of multiple moving parts connected via components like the Microsoft 365 substrate, common services like Search, Artificial Intelligence, and Machine Learning, and common programming interfaces in the Microsoft Graph APIs. The ecosystem did not develop overnight and is rooted in nearly twenty years of engineering effort. Office 365 is a core part of the Microsoft 365 ecosystem.

It's hard to keep any book about technology completely up to date. We do not attempt to claim that the coverage here is perfect because Microsoft 365 continues to evolve to keep its cloud services "evergreen." A cloud service that stays static is less attractive to its users than one where changes and updates appear all the time. To set some achievable boundaries, this book covers Office 365 in-depth and takes in Microsoft 365 as required.

# Microsoft 365: More than Office 365

Microsoft calls Microsoft 365 “the world’s productivity cloud,” saying that it represents their vision for the future of productivity tools spanning an integrated set of apps and services. The upshot of this marketing activity is that Microsoft liberally applies the Microsoft 365 moniker to a wide range of products offered to consumers and the enterprise. To be clear, this book covers Microsoft 365 as it affects Office 365 for enterprise customers and does not deal with packages offered to consumers or small businesses. Table 1-1 lists the Microsoft 365 packages for the enterprise.

<b>Variant</b>	<b>Target market</b>	<b>Components</b>
<a href="#">Microsoft 365 Enterprise</a>	Companies with more than 300 users.	Windows 11 Enterprise Office 365 (E3 or E5) EMS
<a href="#">Microsoft 365 Business</a>	Small to medium companies (up to 300 users).	Windows 11 Business Microsoft 365 Business Standard EMS
<a href="#">Microsoft 365 Frontline</a>	Customer service and support workers.	Windows 11 Enterprise Office 365 F3 EMS
Microsoft 365 Education	Educational establishments.	Same offerings as for Enterprise, Business, and Frontline
Microsoft 365 Non-Profit	Non-profit organizations.	Same as Microsoft 365 Business
<a href="#">Microsoft 365 Government</a>	U.S. government and state agencies.	Same as Microsoft 365 Enterprise (E3 and E5 bundles)

Table 1-1: Microsoft 365 products

Although the enterprise Microsoft 365 plans include Office 365, customers can still buy Office 365 separately. No difference exists in the functionality available in applications like Exchange Online, SharePoint Online, and Teams in the Microsoft 365 plans over what is available in the Office 365 plans. The differences exist in areas like device and identity management and advanced compliance and data governance features.

At the launch of Microsoft 365, the offering was simply a bundle of several software packages. This isn’t a bad thing, because if Office 365 proves anything, it shows how more functional technology can be when multiple applications are available. Teams, for instance, cannot work if Exchange Online, SharePoint Online, Groups, and OneDrive for Business are unavailable. However, Microsoft has bundled an increasing amount of functionality in the Microsoft 365 plans, especially in the areas of compliance, data governance, and identity management. Two useful tools are available to help understand what’s available, and the costs involved:

- [PDFs with overviews](#) of the Office 365 and Microsoft 365 plans.
- A [Microsoft comparison of the features available to each plan](#), including the costs of subscriptions and add-ons.

Over time, Microsoft introduced components that work across the suite instead of being restricted to individual workloads. Good examples of where this has happened are the management consoles like the Microsoft 365 admin center and the Microsoft Purview Compliance portal. Looking back, the progress to integrate applications enabled Office 365 to progress from being a loose collection of barely cloudified on-premises applications to evolving into an integrated ecosystem. That progression took the best part of six years; it’s happening more rapidly in Microsoft 365.

Evidence exists that an increasing percentage of the user base, particularly in medium to large enterprises (over one thousand seats), see their most cost-efficient licensing arrangement as one built around Microsoft

365. In April 2022, Microsoft said that 45% of Office 365 seats are part of Microsoft 365 plans. Many of these customers buy Microsoft 365 because they want to use Enterprise Mobility and Security and advanced Azure AD features. The influence of Microsoft is seen in the steady growth of Enterprise Mobility and Security seats to 218 million (April 2022), many of whom also use Office 365.

## Cloud Infrastructure

Attention to detail and absolute adherence to well-defined procedures are the hallmarks of how Microsoft runs its cloud infrastructure. Without attention to detail enforced through automated processes and procedures, it would be impossible to manage a service for millions of tenants ranging from small to the very largest companies.

An indication of the scale of Microsoft's cloud businesses is its assertion (June 2019) that it serves [a billion users and twenty million businesses](#). The investment needed to buy land and build data centers, install computing resources, power, and cooling, and automate the management and security of applications and data at the scale of Microsoft 365 is massive. The ability to deliver services to customers at a competitive price is only possible for companies with very deep pockets. Microsoft is one of those companies. Google and Amazon are other examples. Let's look at some aspects of Microsoft's cloud infrastructure.

### Data centers and Regions

Microsoft 365 tenants share a single large logical infrastructure composed of hundreds of thousands of servers spread across multiple Microsoft data centers. Figure 1-1 shows the Office 365 data center deployment in April 2022. By its very nature, this picture is incomplete as it does not show some of the infrastructure that is under development. In addition, it does not convey the deep investment made to create "edge" network termination points set up by Microsoft to bring user traffic quickly into its data centers from all around the world or the internal network that transports tenant data between data centers. In total, the [Microsoft Cloud](#) (Microsoft 365 and Azure) spans well over 200 data centers. Not every Microsoft Cloud data center delivers Office 365 services to customers, but the number of local data centers delivering Office 365 is growing over time.

Microsoft organizes Office 365 data centers into regions. The data center region selected to host the data for new tenants is based on the country (location) selected by the tenant. Since launching Office 365, Microsoft has gradually built out the data center infrastructure. In many cases, new data centers are launched to keep data local ("[in-geo data residency](#)") to accommodate customer choice and satisfy local regulations. Where large regional data centers such as the European Union used to be the focus for Office 365 service delivery, localized service is now available in individual countries like France, Germany, Switzerland, and the U.K. The same is true in Asia-Pacific, where services come from data centers in countries like Japan, South Korea, Singapore, and Australia. Microsoft calls the country-level regions "Go Local," as in "Go Local Japan" or "Go Local Australia." This is an internal Microsoft notation that reflects the purpose of country-level regions.

One big advantage gained by segmenting tenant workload across multiple data center regions is that a fault that affects users in one region seldom spreads to other regions. Known single points of failure that can affect multiple regions do exist, but in general, outages don't affect more than a single workload running in a single region, such as a failure affecting mailboxes running in a single Exchange Online Forest or sites served by a single SharePoint Online farm.

Apart from the ability to serve large customer populations, natural and economic advantages such as ambient temperature (to reduce the need for cooling) or availability of cheap hydroelectric power influence data center placement. Security is of prime concern and Microsoft pays great attention to the physical security of the

buildings (you will not find large signs proclaiming Microsoft's ownership anywhere) as well as cyber-security for the data contained within the buildings.

Because Microsoft's data center infrastructure is constantly growing and expanding, the live location for tenant data also changes. In addition, Microsoft moves workload to rebalance servers across data centers (within the same region) and to make more effective use of available resources. Even though the underlying infrastructure is changing all the time, users can continue to work and access their information from anywhere around the world.

Figure 1-1: Office 365 data center map (source: Microsoft)

## Co-Location of Consumer and Business Services

In addition to its enterprise cloud applications, Microsoft hosts over 400 million Outlook.com users of the consumer email service in the same data centers. Outlook.com mailboxes use Exchange Online with the sole difference between the two services being the feature set exposed to users. Outlook.com mailboxes run on the same server, storage, and network infrastructure as Exchange Online to take advantage of features like Native Data Protection and Exchange Online Protection and the same clients are available for both services. Although the same engineering teams support the two services, the functionality in Outlook.com is much less comprehensive than that available to even the entry-level Exchange Online plan. However, the two services share some features (like the method to connect the Outlook mobile clients) and Microsoft introduces some functionality into one service before they decide to do the same for the other. For example, "Sweep" rules first appeared in Outlook.com and are now available in OWA, while the calendar and calendar sharing features now available in Outlook.com originated in Exchange Online. Taken together, the infrastructure shared by Exchange Online and Outlook.com delivers email service to billions of mailboxes (not all of the mailboxes belong to humans). Microsoft uses the same shared infrastructure approach with OneDrive for Business and the consumer version of OneDrive.

## Number of Servers

As you'd expect, the infrastructure is also massive if looked at in terms of the number of individual servers running different workloads. The last public figure for Exchange Online is 275,000 mailbox servers (September 2020) while that for SharePoint Online is 180,000 servers (May 2019). Add in the servers used for Teams, Planner, Yammer, Azure AD, other Azure services, and supporting services, the number deployed to run Office 365 workloads comfortably surpasses one million physical servers.

Even with so many resources, demand flowing from an event can exert enormous pressure on an online service when user numbers grow dramatically over a short period. During the Covid-19 pandemic, tens of millions of new users were onboarded. In the case of Teams, the number of daily active users increased from 20 million in November 2019 to 75 million in April 2020, creating a surge in user demand that also impacted SharePoint Online, OneDrive for Business, Exchange Online, and other services. To maintain responsiveness for end-users, Microsoft trimmed the functionality of different applications. Background processes didn't run as often and Microsoft adjusted some features to reduce demand, such as Stream dropping the resolution of Teams meeting recordings from 1080p to 720p. Although some interruptions happened, generally Office 365 remained online and handled the swelling load. After Microsoft had the chance to commission new server and storage resources in the data centers, they reversed the feature adjustments.

## Current Data Center Regions

Microsoft publishes information about the [locations of Microsoft 365 data centers](#). The same page includes details of where customer data resides on a country-by-country basis for all the offered services. All data centers deliver core services (Exchange Online, SharePoint Online, and OneDrive for Business). Other services, like Teams and Project Online, might also run in the same data centers. In some cases, other data centers within the region deliver specific services, as in North America where the Planner service runs from data centers in California and Virginia.

The point of delivery for services changes over time and if you are concerned about data sovereignty, you should check with Microsoft to understand exactly where your data are for all applicable applications. Azure AD is another service that can come from another region. For instance, the U.K. region uses Azure AD from the EMEA and U.S. data centers.

## New Data Centers

Once a new data center comes online, a sophisticated migration process moves tenants from other data centers to the new location. The same is true when Microsoft creates a new region. For instance, after the United Kingdom data centers came online, some tenants asked to move their work to those data centers to keep their data remained "in country;" the same happened in France or when Australian and New Zealand tenants moved to the Australian data centers. This work happens behind the scenes (just like regular mailbox moves) so that the eventual switchover is fast and painless. Microsoft has [a documented process](#) to help tenants with specific data residency requirements to request a move for their core data to a new region after it comes online.

The creation of a new data center region normally means that the data center first delivers the base workloads to tenants. It can take some time before the full range of service capabilities is available, including applications (like Teams or Planner) and utilities. Microsoft is currently building out new data center regions in Italy, Poland, and New Zealand.

## Workloads Running Within Data Center Regions

Microsoft distributes work across all data centers within a region to protect data against failure. For instance, the active-active design for Exchange Online Database Availability Groups (DAGs) means that mailbox database copies exist in at least two data centers within a region. In addition, as Microsoft adds data centers to a region, the opportunity exists to spread database copies to those data centers. For instance, new DAGs built for use by Exchange Online in the European Union region might include databases spread across the Amsterdam, Dublin, Helsinki, and Vienna data centers. Spreading data across so many data centers reduces the risk that any individual outage will affect a sizeable number of users. It is a deployment strategy that the

average on-premises administrator could never contemplate because of the investment needed to build out the underlying data centers and network.

Another way to understand what data center region supports data for your tenant is to access the Organization Profile (in the Settings section of the Microsoft 365 admin center). Go to the Data Location section and you will see the region for some, but not all, of the workloads used by the tenant (Figure 1-2). You can confirm these locations against Microsoft's [list of where customer data is stored](#). Microsoft has committed to delivering what it calls the [EU data boundary](#) by the end of 2022, meaning that all services and data used by tenants based in the European Union will remain within the European Union. Customers in Norway and Switzerland will also be able to access the EU data boundary if they wish.

## Data location

As part of our transparency principles, we publish the location where Microsoft stores your customer content. For more information about Microsoft's contractual commitments, see the [Online Services Terms](#).

[Learn more at the Office 365 Trust Center](#)

Service	Data at Rest
 Exchange	European Union
 SharePoint	European Union
 Skype for Business	European Union
 Microsoft Teams	European Union

For applications which you are not subscribed to, please see [Where is my data](#).

Figure 1-2: Data locations for a tenant

Although Azure AD holds most of the information for tenant accounts and configurations in the same data center region as a tenant's data, an exception exists in that Microsoft stores five user-related attributes including the User Principal Name and password hash for tenant accounts in the U.S. This is to make sure that authentication can happen as quickly as possible, no matter where in the world a user is located. For more information on this topic, see Microsoft's [support article on the situation](#) for European customers.

## Sovereign Clouds

A sovereign cloud is a data center region that exists because Microsoft must meet specific requirements imposed by the target customer base or geography. Three sovereign clouds are currently active. The U.S. government cloud (GCC) is a set of special data center regions created to meet the specific security needs of different levels of U.S. government and state authorities; the other is in China. The commercial data center regions, or clouds, are general-purpose in that these regions serve customers from any country and any industry in the coverage area.

## Multi-Geo Microsoft 365

Organizations can choose to distribute Exchange Online, SharePoint Online, OneDrive for Business, Teams, and Microsoft 365 Groups data across different data center regions (multi-geo). This means that the organization has a home region (known as the "central geo") where most of its work runs and one or more satellite geos. Sites including team, communication, and hub sites, created by distributed users are in their

assigned geo-location (otherwise known as the PDL, or “preferred data location”, an attribute of their Azure AD account). Microsoft says that they are exploring how to add multi-geo capabilities to other applications.

The normal use case for multi-geo is an international company that needs to satisfy data sovereignty requirements. For example, a U.S. company might have subsidiaries in France and the UK. Due to the sensitive nature of the work done in EMEA, the company does not want to store the data in the U.S., as would be normal. With multi-geo, they can choose to have user data for the supported workloads stored in local data centers.

Behind the scenes, once a tenant is enabled for multi-geo, Microsoft transfers the data belonging to the selected users to the satellite geos. During the transfer process, users continue to work as normal until the transfer is complete, at which point they switch over. Cross-region synchronization within the tenant’s Azure AD instance ensures that all the users within the tenant see a single worldwide picture and can continue to share work with colleagues without hindrance. The only thing that changes is the location of user data. OneDrive for Business is an exception because the transfer process does not move data belonging to an existing OneDrive account. Instead, administrators must run the *Start-SPOUserAndContentMove* cmdlet to [transfer user data to the new location](#).

Distributing user data across multiple regions causes some technical challenges, one of which is eDiscovery. Organizations need to consider if they wish to run eDiscovery locally or at a global level. See [this page](#) for more information.

Multi-geo capabilities are not a solution to poor network performance. Some people assume that this is the case because “the data is closer to the users.” This is a fallacy because, in most cases, poor network performance is due to issues such as lack of bandwidth or other problems in the link connecting users to Microsoft or poor routing inside the tenant’s internal network. Once inside Microsoft’s data center network, traffic flows from region to region very quickly and users do not see a difference when they move to a local region.

Multi-geo is available for most [general-purpose Microsoft 365 data center regions](#). It is not available for the sovereign clouds. To qualify, organizations must have an enterprise agreement with Microsoft and purchase multi-geo licenses for at least 5% of their accounts (previously, the organization had to license at least 250 accounts). Additional monthly fees of \$2 per user are payable for each user licensed for multi-geo capabilities. The fees cover the connection of the base workloads to different data center regions. Because of the extra cost, the most likely customers for multi-geo are multinational companies with complex data sovereignty needs and relatively large numbers of users. For more information, see the [multi-geo home page](#).

## Relationship with Azure

Microsoft 365 has a strong relationship with Azure, the other major component in Microsoft’s cloud strategy.

- The Office 365 data centers are co-located with Azure data centers.
- Office 365 uses Azure Active Directory as its authentication and identity service.
- Office 365 applications use many Azure services such as Azure Key Vault.

Office 365 applications use Azure Storage heavily and SharePoint Online is its largest single application consumer (using Azure SQL). Teams uses Azure Cosmos DB for its message and media stores. Stream is in the process of moving from Azure storage to SharePoint Online. At this point, the only major Office 365 storage system not running in Azure is Exchange Online mailbox storage, which continues to use physical mailbox servers. According to Microsoft, plans are in place to move Exchange Online to Azure storage.

## Microsoft 365 Substrate

It is an undeniable fact of IT life that it is much easier to process data in a single repository than it is to process data drawn from several. The Microsoft 365 substrate is the single repository for user documents, emails, meetings, tasks, groups, chats, and other data. The Microsoft 365 substrate holds data generated by applications like Exchange Online, SharePoint Online, OneDrive for Business, Yammer, and Teams, either by an application that uses the substrate as its primary repository or as a "digital twin" of data stored elsewhere, which is often a much smaller version holding just the information needed for search and compliance, together with a pointer to the original item.

Exchange Online mailbox databases are the physical implementation of the substrate. Exchange Online mailboxes have stored non-email application data for years. Now, the substrate creates the digital twin items from applications like SharePoint Online, Teams, and Planner and stores the data in hidden mailbox folders. It might seem surprising that Exchange Online databases serve in this role, but the Exchange database engine (ESE) has always been good at managing many different types of data, can scale up efficiently, and runs on low-cost storage. In addition, the Exchange Online Native Data Protection model makes sure that copies of application data exist in four databases, including a lagged database, to ensure robust data availability. ESE also supports "sharding," the ability to connect different chunks of data into a logical whole (for instance, 50 GB mailboxes are combined to form expandable archives), which makes it easy to present data on a per-user or per-tenant basis.

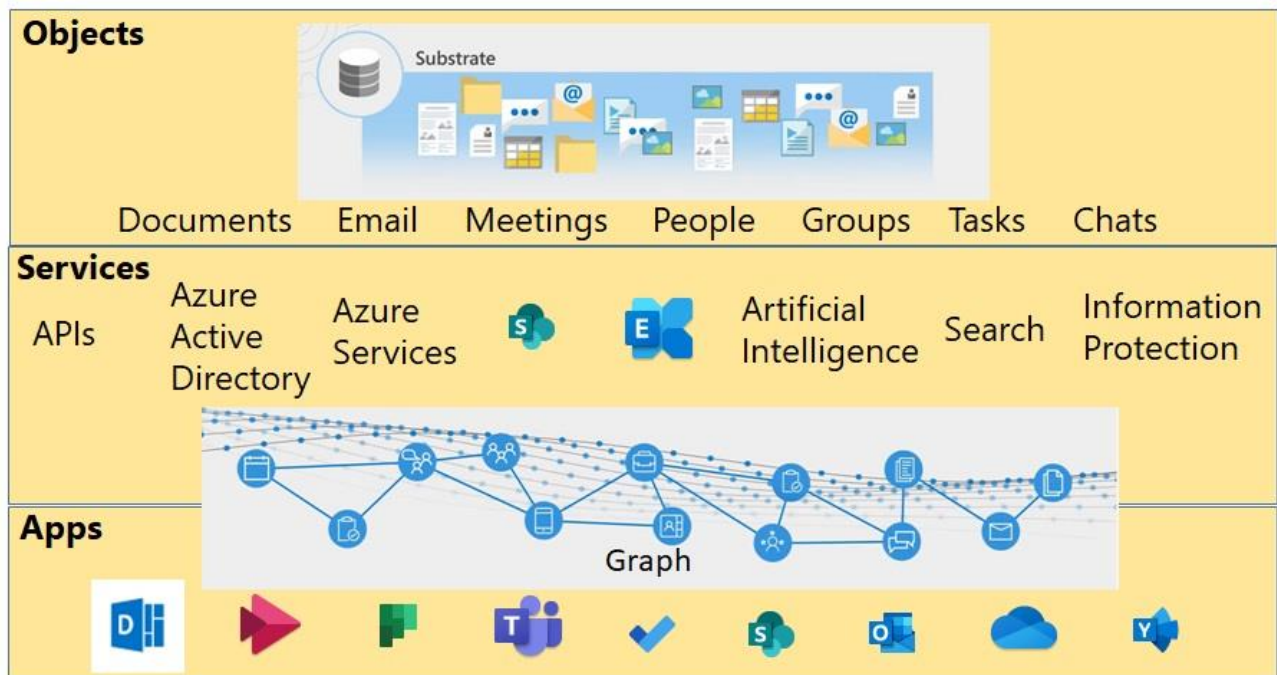

Figure 1-3: The Microsoft 365 substrate

Figure 1-3 shows how the substrate underpins Microsoft 365 with a common data repository for services to process and apps to present to users. SharePoint Online and Exchange Online appear as services because these base workloads deliver services such as email, storage, and document management to other apps in the service.

The existence of the substrate does not mean that applications will migrate to Exchange Online storage. Teams will continue to use Cosmos DB and SharePoint Online will continue to use Azure SQL. What it does mean is that copying data from applications into the substrate gives common services like Microsoft Search, cognitive services, and Artificial Intelligence an integrated platform to work against.

The substrate is the essential foundation for what Microsoft 365 is today. Without the substrate, Microsoft 365 apps couldn't get to data as easily as they can. or integrate with other Microsoft 365 apps or with other services as easily as they now can. It would also be harder for apps to incorporate new technologies like Microsoft Loop components. The substrate also facilitates "graph traversal," the ability to follow information from one graph to another, such as the way that the people card can connect to the LinkedIn graph to retrieve details of a contact's career. And without the substrate, cloud applications would still be like the collection of loosely cloudified on-premises products which formed the original service.

## Tenant Domains

Customers that use Microsoft 365 are tenants of the service. Each tenant occupies a subdomain within the overall Microsoft 365 infrastructure called its service domain. You can think of a tenant as the container for the company within Microsoft 365 and the domain is a sub-domain under the onmicrosoft.com root. For example, the Contoso company might run a tenant domain called contoso.onmicrosoft.com. Each user account has a separate user principal name to sign in (or connect) to applications. For instance, the user principal name *TRedmond@office365itpros.onmicrosoft.com* is an account belonging to the office365itpros tenant.

Tenants often have one or more domains registered in the Internet Domain Name Service (DNS) and want to continue using that domain with Microsoft 365. These domains, sometimes called vanity domains, might be part of the company branding, which is why they must remain in use. To enable this to happen, an organization can register their domains with Microsoft 365 and associate the domains with their tenant. When this happens, user accounts can have user principal names and email addresses belonging to the vanity domains, meaning that we can replace the somewhat clunky service domain addresses like *TRedmond@office365itpros.onmicrosoft.com* with the more elegant and brand-friendly *Tony.Redmond@office365itpros.com*.

Microsoft 365 does not care what name a company gives to its tenant, but you should because you can't change the name of a tenant after its creation. Any change required by corporate restructurings such as a merger, acquisition, or divestiture usually ends up in a tenant-to-tenant migration, an operation that is often expensive and long drawn out. Some flexibility in outward presence is possible by using a new vanity domain for external-facing email addresses and configuring Exchange to handle messages sent to those addresses. However, other applications can surface tenant names in different places (it's now possible to [rename the domain for SharePoint Online](#)), all of which means that some care and attention is necessary to ensure that the tenant name you use is the right one for your company.

## Directories and Identities

Microsoft 365 supports both cloud-pure and hybrid (cloud/on-premises) environments. A key aspect of the support is the ability to reliably authenticate user accounts with Azure AD and on-premises Active Directory. To enable this to happen, a variety of directories and other tools provision, store, maintain, and synchronize identities.

Azure Active Directory is the cornerstone of Microsoft's cloud identity story and acts as the source of authority for cloud user accounts. In hybrid deployments, where the on-premises Active Directory is always the master directory, Azure AD synchronizes with Active Directory to form a seamless view of user accounts and configuration data drawn from both environments. The tool used for this purpose is Azure Active Directory Connect (AAD Connect).

Many of the applications running inside Microsoft 365 need to store information specific to their operation. For instance, Exchange Online uses EXODS, its directory store, to hold information about public folders that

are not mail-enabled. These objects exist only inside Exchange Online and are irrelevant to the other workloads, so there is no reason to store information about them in Azure AD. The same logic applies to workload-specific objects and configuration data used by SharePoint Online (SPODS), Yammer, and Teams. The Identities chapter presents a comprehensive discussion about directory services within Microsoft 365 and the different forms of identities (on-premises, cloud, and hybrid).

## Automation

The Microsoft 365 infrastructure uses a sophisticated workflow engine called "Central Admin" (CA) that is capable of handling more than a hundred million workflow tasks per month. The idea is to automate the common tasks needed to keep services running as much as possible to remove the possibility that human error will compromise systems. The need to avoid human mistakes in the management of cloud systems is seen in the [DNS error that interrupted service in September 2011](#) and the [command typo that knocked out part of the Amazon Web Services](#) infrastructure in March 2017. A smoothly functioning workflow engine also achieves a reliable and robust throughput of actions across the system. Developers create CA tasks as scripted workflows in either C# or PowerShell. CA is responsible for the execution of scheduled tasks to perform actions such as server deployment, database rebalancing within a DAG, and so on. More complex tasks such as the addition of new capacity to the service still require some human intelligence and planning, but the application of a structured model and great attention to detail has enabled Microsoft to reduce the time necessary to complete even very complex tasks down from weeks to days.

Microsoft standardizes server configurations whenever possible. This does not mean that each server uses the same components, as this would be impossible in an industry where components change often. However, it does mean that a server will have the same general characteristics (CPU, disk, memory) and that software is installed in the same way on all servers of a specific type. Low-cost components such as JBOD arrays allow Microsoft to increase the storage available to tenants while still being market competitive. It also means that servers are built from modules to eliminate cabling. Everything is optimized for mass production and servers are integrated into racks at the factory and shipped to the data center ready to be plugged in and brought online.

Exchange is a good example of an application where sustained engineering investment has delivered huge performance improvements and made cloud economics possible. Exchange Online uses JBOD SATA drives to deliver cost-effective storage. Using these disks implies a risk of a higher failure rate than the more expensive "enterprise-class" drives often found in corporate data centers and indeed, across Microsoft's data centers, hard disk failures are the most common event in the tens of thousands of hardware events that are handled monthly. The low cost of storage and Exchange's performance profile makes it possible for Microsoft to offer enterprise users a 100 GB mailbox quota and auto-expanding archives, and to hold a mass of non-user data (such as information about Files usage) in mailboxes. Without low-cost storage, the monthly subscription to a Microsoft 365 enterprise plan would be much dearer.

Software components help to insulate users from the effect of hardware failures. For instance, Exchange's Active Manager will failover a database to a new server quickly if a disk problem is detected. It will also create a new copy of the failed database using the autoreseed feature if replacement disks are available. Across the entire fabric, a CA workflow called "RepairBox" constantly checks for hardware failures and will open support tickets automatically if an issue is detected like a failed disk. A technician can then replace the failed disk (no attempt is made to fix the disk). The same workflow monitors servers for inconsistencies in their state to detect and fix problems with configurations.

Even with such a sophisticated and smooth-running automatic support infrastructure, some problems still occur. For instance, "stragglers" are servers that run out-of-date software versions that might deliver an

inconsistent service to users. The server infrastructure is in a constant state of server refresh to introduce new software builds and new features. As such, with so many servers and so many updates, some server updates do not happen as well as they should, which is the usual reason why a straggler exists.

## Networks

Given that Microsoft 365 is a set of cloud services, it should come as no surprise that the network is a precious resource. Without enough high-quality bandwidth, users will be unable to connect to services, migrations cannot transfer data from on-premises servers, and hybrid connectivity will not work. Microsoft does not control the backbone used by tenants to connect their internal networks to its services as the links making up the backbone are managed by a large set of Internet Service Providers (ISPs) around the world. Although the Internet was originally designed to survive a nuclear holocaust, local failures caused by cable problems, ISP data center issues, and hardware failure can all prevent access to services.

Microsoft cannot control the Internet, but it can control traffic flow within the network that connects its data centers. This is a dedicated and tightly controlled and monitored network. Dark fiber optical connections link the data centers to ensure maximum data flow across the network. Automatic redundancy is deployed so that a temporary outage is contained and automatically addressed. Everything that can be done to ensure that the service is maintained is done, but even so, like all cloud services, the SLA for Office 365 can only be guaranteed at the boundary of the cloud provider's data centers as defined by the edge servers that handle inbound and outbound traffic.

## Monitoring, Telemetry, and Intelligence

The sheer size of Microsoft 365 and the telemetry gathered through user interaction make a colossal set of signals available to Microsoft. For example, in late 2020, Exchange Online processed more than 300 billion messages monthly. Increasingly, Microsoft applies artificial intelligence and machine learning techniques to analyze and make sense of the data. The output is used to guide choices in software engineering investment to create new functionality. For an application like Exchange Online that's been around for a long time and is very mature, the telemetry offers insight into issues that might have lingered without ever being addressed simply because they are not a huge problem at the scale of on-premises servers but are when viewed through the lens of the cloud.

Microsoft uses a "Data Insights Engine" to process the billions of events generated hourly, aggregating and analyzing events to understand how the overall service is running and to detect problems with individual components. The general approach is that if a problem surfaces in many entities or through different signals, then it must be true. By depending on signals from multiple resources you can get close to 100% fidelity when it comes to the automatic detection of problems, or "Red Alerts" as they are known. In addition, by analyzing signals from diverse sources, engineers can focus on where the root cause of the problem is likely to be with a high degree of accuracy and this, in turn, allows the launching of automatic recovery actions with a high degree of confidence that they will fix the problem. Taking a data-driven and analytic approach to the detection and resolution of problems is key to being able to run at scale.

In addition to its signal processing engine, Microsoft uses some much simpler techniques to know when something might be going wrong. For instance, if a spike in page views occurs for the Service Health Dashboard, it might be due to customers checking the dashboard to know whether a problem exists with the service. Such a spike can often be correlated with an output from the signal processing engine but sometimes it leads to a discovery of a problem identified by human beings. Microsoft can record the characteristics of that problem as a recognizable scenario for future automatic identification and resolution. It is also important to say that signals used to identify issues are both active (those generated by specific events) and passive

(those generated by servers and users during normal work). Microsoft uses a process of triangulation to spot abnormalities between the two sets that can point to a developing problem. As in all knowledge, learning how to measure the pulse of cloud operations and figure out what is normal and what's not is an evolving art that requires great dedication and ongoing observation by both automated systems and humans.

## A Constant State of Change

The size and technical complexity of the Microsoft 365 ecosystem create a unique challenge for anyone interacting with the technology. Even more challenging is the way that the ecosystem flexes and changes as different Microsoft engineering groups make software updates available to customers. At Microsoft's FY21 Q3 results briefing in April 2021, [CEO Satya Nadella said](#) that Teams added: "over 300 features over the past year, including more than 100 new capabilities so far in 2021." Adding Exchange Online, SharePoint Online, OneDrive for Business, Yammer, Planner, Azure AD, and solutions like Microsoft Purview Information Protection and Data Lifecycle Management to the mix means that a customer might have to cope with over 500 changes annually.

Inside Microsoft 365, applications introduce new features on an ongoing and constant basis. The changes range from tweaks to a client interface to the introduction of a completely new feature that changes the behavior of an application. This is a major difference between the traditional on-premises model where new software releases often appear on an annual release cycle that customers can then factor into carefully-planned "change windows". Becoming accustomed to the pace of change in the cloud can be quite a challenge for those used to the older way of deploying software updates but it is the method employed by most major cloud services.

The best way for administrators to know what Microsoft is working on is to keep an eye on the online [Microsoft 365 Roadmap](#) (Figure 1-4), which documents planned features coming across Microsoft 365. Although the roadmap sometimes misses an update and you always must keep your eyes peeled on what appears in the service to detect some new functionality, Microsoft refreshes the roadmap regularly and its contents are comprehensive enough to allow tenants to plan for new functionality.

Microsoft organizes the Microsoft 365 roadmap into the following sections:

- **Launched:** Features that Microsoft has deployed to all applicable customers.
- **Rolling Out:** Features that Microsoft is now deploying. As you can imagine with such a large and distributed service, it can take some weeks to deploy new software to every server running in every data center around the world. Microsoft usually posts to [the Microsoft 365 blog](#) or [individual product blogs in the Microsoft Technical Community](#) to inform customers about new features when they begin the roll-out process. The appearance of a post is no guarantee that a new feature will show up in a specific tenant anytime soon as this depends on whether the new feature belongs to the set available in the plans the tenant uses, the length of time that the feature spends in Targeted Release (previously First Release) status, and the time taken for Microsoft to deploy the feature to all applicable tenants after it reached standard release status.
- **In Development:** Features that Microsoft has announced are under development. Microsoft does not commit to delivering any of the features listed here as reasons might emerge to change or cancel a feature before the code reaches tenants.

Each roadmap item has a feature identifier (in the form *ID 61652*). You can match the feature identifier against change notifications announced in the Message Center, part of the Microsoft 365 admin center (see Chapter 4), where a notification includes text such as "This message is associated with Microsoft 365 Roadmap ID 61652". In addition, each item has a date to tell you when Microsoft added it to the roadmap, when the new functionality should be available, and when Microsoft last modified the information for the item. The

integration between Planner and the Message Center is another tool a tenant can use to track change as Microsoft introduces updates into Office 365. See Chapter 9 for more information about the integration with Planner.

It is important to understand that the roadmap gives general guidance as to what might change in the future. The Message Center is a more authoritative view of new developments that apply to your tenant. Roadmap items give a glimpse into the future, but they might not be available for six months or more. Once a development shows up in the Message Center, it's more likely to appear in the following few weeks, meaning that it is time to prepare for change.

The screenshot shows the Microsoft 365 roadmap interface. At the top, there's a navigation bar with 'Microsoft 365' and various links. Below that is a header section with the title 'Microsoft 365 roadmap' and a brief description. A search bar contains the text 'planner'. To the right of the search bar are several filter dropdowns: 'Product', 'Release phase', 'Platform', 'Cloud instance', and 'New or updated'. Below the filters, it says 'Showing 11 updates'. There are three status filters: '3 In development', '0 Rolling out', and '8 Launched'. Below these filters is a list of updates, each with a title and a 'GA' (General Availability) date. The updates listed are:
 

- Microsoft Planner: Rich text and images in Planner task notes (GA: September 2022)
- Microsoft Planner: Recurring tasks (GA: June 2022)
- SharePoint: Planner cards appear within SharePoint team site home page activity feed (GA: May 2022)
- Microsoft Planner: Move tasks to any of your plans (GA: November 2021)
- Microsoft Teams: Tab actions are moving (GA: November 2021)

 At the bottom right of the list, there is a 'Feedback' button.

Figure 1-4: Browsing the Microsoft 365 roadmap

You can apply filters to the roadmap to show updates for specific products. Using filters to navigate the roadmap is useful as the sheer number of documented changes can be overwhelming at first glance. Filters also allow you to zero in on functionality that is most important to your company. This includes application-level features (for example, OneNote or Outlook), service-level features (for example, Exchange Online or SharePoint Online), and even sector capabilities (for example, features due for delivery in GCC).

The roadmap supports a download facility, meaning that you can apply filters to find the set of information you're interested in and then download details of those features to a CSV file, which you can process later with Excel or load into Power BI for further analysis.

**Versions of Software:** Microsoft uses a variety of methods to release software to tenants. If you configure a tenant for *standard release*, it means that you use software that is generally available (GA). This is the most stable version of an application. *Targeted release* means that you can choose for the complete tenant or specific users to see new features sometime before Microsoft makes it generally available. The exact period depends on the app and the complexity of the feature, but it is usually between four and eight weeks. A further delay might then come into play to allow client updates to appear to support new features, especially in desktop clients. All in all, it might take 90 days between Microsoft announcing that a

feature is generally available and everyone in every tenant being able to use the feature. Control over targeted release is through the Organization Profile tab of Org Settings in the Microsoft 365 admin center.

Some product groups run dedicated test programs (*technology adoption programs*, or TAP) to make beta software available for use in customer production environments. TAP software is a targeted release for use by selected customers. Microsoft often talks about *rings* of software releases to describe the progression from initial builds to a targeted release and finally become the standard release. Rings go from the development group (1) to Microsoft (2) to TAP (3) to release (4). Because development never ceases, the only guarantee you have is that the version of software you use today will change over time. The ever-changing nature of the service is why Microsoft calls Office 365 *evergreen software*.

## Command and Control

Microsoft 365 is a massive machine that moves forward at its own pace. Thanks to the roadmap, we know a lot more about what Microsoft is working on for the future than we did in the first few years, but even so, you cannot get away from the fact that customers cede an enormous amount of control to Microsoft when they sign up for cloud services. You accept that Microsoft will deliver a wide range of functionality, but you don't get to vote on what functionality Microsoft will deliver, when users see a new feature, or when changes show up. It just happens. This is a very different experience from the careful control that most IT departments exercise over the computer systems used in-house.

Most of the time this is not a problem and users like to find that new features continually appear. Google proved the attractiveness of an evolving interface to end users when it kept Gmail in what seemed to be a perpetual beta for many years. Even now, new features appear all the time in Gmail and Google Workplace, so Microsoft is simply keeping pace with its competition when it refreshes applications frequently.

However, dealing with a rapid update cadence can be problematic in the following ways:

- **User support:** Originally, two broad categories of users existed – people who access services through desktop clients and seldom make use of browser-based applications such as Yammer and Planner and those who use a browser (the third category is mobile users). In some cases, you don't have a choice because some applications only have a browser interface. Many Exchange users prefer the desktop version of Outlook because it allows them to continue working when offline. To some degree, Outlook insulates users from the ongoing changes that occur within the service. New features only appear after installing a new version of Outlook on a workstation, and even the “click-to-run” version of Outlook is slow to introduce the user interface necessary to support new functionality. On the other hand, those who use OWA to interact with Exchange Online might see new features show up on an ongoing basis. It's worth noting that Microsoft's “One Outlook” initiative intends to bring the different clients closer together, notably by allowing the Outlook desktop clients to share OWA components (this already happens with components like the calendar room finder). Every change in a user interface creates a potential flow of calls to local IT support as users seek information about why the change occurred and what it means to them. This is a very different mode of working from the normal carefully controlled and planned change management practiced by corporate IT departments. On the other hand, the Outlook desktop client is based on what is now an old architecture. More modern desktop clients, like Teams, have auto-update capabilities which means that they pick up new functionality as soon as Microsoft releases updated code.
- **Administration:** Those who manage a tenant work mostly through a set of web portals such as the Microsoft 365 admin center, SharePoint Online admin center, and Teams admin center. Microsoft updates and refreshes these portals over time to accommodate new applications and features, or for their purposes such as rebranding. In addition to the web portals, administrators can use PowerShell

or Graph-based tools to manage applications. Keeping up to date with the release of these features and learning how to manage them with the available tools (also usually dependent on whatever Microsoft provides) can be a challenge for tenant administrators.

- **IT management:** The role of IT management in an on-premises environment is well understood. They accept needs and requirements from the business and work out how best to meet these requests in line with the available budget, the current IT infrastructure, and the knowledge and experience available to the company. The business will continue to generate needs and requirements and Microsoft 365 is now one of the ways that the requests can be satisfied. The big difference is that IT management must accept whatever functionality comes from cloud providers. The task of matching needs and capability is easy if a good match is available within Microsoft 365. Things become a little trickier when functionality changes, as a decision to invest in an on-premises solution or to buy in software from another provider, might be undermined if Microsoft decides to offer equivalent functionality inside Microsoft 365.

The issues listed above are less important to small companies than they are for large companies who tend to have well-entrenched methods to control the introduction of new technology. In the same way, new companies usually embrace new technology faster than older companies do. A further consideration comes from the employee mix, where younger employees more readily embrace rapid change than their older peers do.

Apart from preparing IT Support staff with information about new changes so that they can respond to user queries, it's hard to manage how functionality flexes and changes within the service because of its rapid release cadence. One method that IT departments have used to manage the interaction between Microsoft 365 and end-users is to appoint a change coordinator. This role is to monitor changes, collect information about the changes, and make sure that the information about the changes gets to the right people in a form that makes sense to them and can be used (whenever possible) by the business to gain an advantage. The [Microsoft 365 Roadmap](#) is a prime source of information for this person but they should not limit their scan for information to Microsoft sources. A wealth of tips and advice exists across blogs, social networks, and conferences that need to be mined to form a complete picture of what is going on within Microsoft's cloud ecosystem. And that picture has then to be placed into context with the business goals and needs of the company so that the information is best used.

## Products and Licenses

Every active user in a tenant needs licenses to access functionality. In some cases, that statement is not completely true because situations exist where Microsoft 365 functionality is available to unlicensed users. Microsoft is closing off those holes, so it's best to adopt the attitude that licenses are necessary to use features. A tenant can buy a mixture of products and assign licenses for those products to users based on their individual needs. For example, some users might only need kiosk licenses to gain browser access to applications while others need products that include the Microsoft 365 enterprise apps and sophisticated Teams calling plans. Both sets of licenses exist quite happily within the tenant and administrators can move licenses between users based on the available license pool.

Users can access the applications available through the licenses assigned to their account when they open the [Office portal](#). The portal uses Microsoft Graph queries to display a set of recently used documents tailored for the individual user.

Three terms are important to understand when discussing Microsoft 365 products and licenses:

- **Product names** are how Microsoft refers to licenses. Office 365 E3 is a product, as is Viva Topics or Enterprise Mobility and Security E5.
- Stockkeeping units (**SKUs**) are the internal names used to manage licenses. For instance, the ENTERPRISEPACK SKU refers to Office 365 E3. SKUs also cover add-ons like SharePoint Syntex.
- **Service plans** control access to a licensed feature. You cannot buy a service plan as Microsoft includes them in SKUs. Office 365 E5 includes over 50 service plans. Somewhat confusingly, Microsoft also refers to products like Office 365 E5 which bundles many different service plans into a single offering as “plans.”

Microsoft 365 spans many different products, each of which specifies a range of functionality available to users and administrators. Details of [the current Office 365 enterprise products](#) and [Microsoft 365 enterprise products](#) are available online. Other pages describe offerings targeted at individual professionals and small companies.

## Service Families

Microsoft divides Office 365 into a set of service families, each divided into individual products sold to customers. Table 1-2 lists the service families and plans available in October 2021.

<b>Office 365 Service Family</b>	<b>Available Products</b>
Microsoft 365 Business <i>Available for up to a maximum of 300 users</i>	Microsoft 365 Business Basic Microsoft 365 Business Standard Microsoft 365 Business Premium
Enterprise <i>Available for an unlimited number of users</i>	Office 365 Enterprise F1 and F3 (front line workers) Office 365 Enterprise E1 Office 365 Enterprise E3 Office 365 Enterprise E5
Education <i>Available for an unlimited number of users</i>	Office 365 Education
Nonprofit	Office 365 Nonprofit
Government <i>Available for an unlimited number of users</i>	Office 365 Government E1 Office 365 Government E3 Office 365 Government E5 Office 365 Government F1 + F3
Sovereign Clouds	See <a href="#">this page</a> for information about the plans available in China.

Table 1-2: Service Families and products

Products available in specific markets vary from country to country, as does the pricing. Sometimes differences in tax regimes drive the price charged by Microsoft in a certain country and sometimes the competitive landscape within the country is the primary influence. Customers buy products based on their appropriateness, status, and availability. For instance, you can only buy Education licenses if your organization is a recognized university or another educational establishment. Likewise, nonprofit licenses are only available to organizations that meet Microsoft’s criteria to have nonprofit status. Microsoft makes education and nonprofit licenses available at a large discount compared to enterprise plans.

Government offerings are broadly like the corresponding enterprise plans. However, new applications invariably take longer to show up in the government cloud because of the need to meet specific requirements for cloud services. Teams is a good example. Despite being generally available to enterprise customers since March 2017, the U.S. Government Cloud (GCC) only [qualified Teams for use in July 2018](#). Since then, hundreds of individual Teams features have been through an approval process for deployment in GCC (and the GCC

High and Department of Defense clouds). Some features do not appear in GCC for several months after commercial release. Sometimes it's because of the approval process, and sometimes it's because a feature depends on other software that's not yet approved.

The Microsoft 365 Business products are for small businesses rather than large enterprises. Each includes the basic applications (Exchange Online, SharePoint Online, OneDrive for Business, Teams, Groups, and Planner). The difference between the business and enterprise plans is in the detail and depth of the functionality rather than the individual server applications. For example, if you need access to the widest range of compliance features, you need to buy Microsoft 365 enterprise because those products include that functionality. The assumption here is that individual professionals or small companies probably do not need quite the full range of compliance features.

A challenge that exists when writing about products is that they flex and change over time to reflect competitive pressures, new offerings, and new markets. The best idea for anyone considering moving to the cloud is to do some Internet research to discover what Microsoft offers in your geography and the monthly price per user. You also need to figure out whether the organization qualifies for academic, education, or non-profit licenses. And if you work for a government or state agency, you might find that you qualify to buy government licenses.

## Functionality Available in Office 365 Enterprise

Office 365 enterprise is the major subject of this book. Although E1 is the cheapest Office 365 offering, it still includes the fundamental collaboration capabilities offered by Exchange, SharePoint, and Teams. Office 365 E5 is the most expensive and includes features that every user might not need or want to use. Table 1-3 compares the services in Office 365 E1 plan against the higher-end E3 and E5 products to illustrate the difference in functionality that grows as the price increases. The obvious differences between E1 and E3 are the lack of access to the Microsoft 365 enterprise apps, and the compliance features (mailbox holds, data loss prevention, information protection, encryption, etc.). Office 365 E5 adds more automation and advanced functionality, like Office 365 Cloud App Security and Microsoft Purview eDiscovery Premium. [Microsoft 365 E3 and E5](#) include Office 365 E3 and E5 respectively. The Microsoft 365 E3 and E5 plans also include Windows 11 Enterprise and Enterprise Mobility and Security.

<b>Feature</b>	<b>Enterprise E1 \$8/month</b>	<b>Enterprise E3 \$23/month</b>	<b>Enterprise E5 \$38/month</b>
Office Online (web versions of Word, Excel, etc.)	Yes	Yes	Yes
Office for smartphones and tablets (up to 5 installs per user on PCs/Macs, tablets, and phones)	No	Yes	Yes
Microsoft 365 Apps for enterprise (the click to run Office desktop applications)	No	Yes	Yes
"Basic" Exchange email functionality (mail and calendars)	Yes	Yes	Yes
Advanced Exchange email functionality (100 GB mailbox and 1.5TB archive storage, legal hold, mailbox auditing, Data Loss Prevention)	Yes	Yes	Yes
Teams (conversations and audio/video meetings)	Yes	Yes	Yes
SharePoint Online (team sites)	Yes	Yes	Yes
OneDrive for Business File Storage and Sharing	Yes	Yes	Yes
Yammer Corporate Social Network	Yes	Yes	Yes
Microsoft Stream (Plan 2)	Yes	Yes	Yes
Delve	Yes	Yes	Yes
Basic management (including PowerShell)	Yes	Yes	Yes

Rolling updates	Yes	Yes	Yes
Microsoft Purview Information Protection (rights management)	No	Yes	Yes
Security and Compliance (auditing, search, eDiscovery)	Yes	Yes	Yes
Viva Insights	Yes	Yes	Yes
eDiscovery Premium	No	No	Yes
Advanced data governance (auto-apply, trainable classifiers)	No	No	Yes
Data Loss Prevention (DLP)	No	Yes	Yes (including Teams)
Teams Phone system and audio conferencing	No	No	Yes
Microsoft Defender for Office 365	No	Plan 1	Plan 2
Office 365 Cloud App Security	No	No	Yes
FastTrack onboarding service	Yes	Yes	Yes
Workflow automation with Power Automate (Flow)	Yes	Yes	Yes
Visio web app	Yes	Yes	Yes

Table 1-3: Comparing functionality across Office 365 Enterprise

Cheaper frontline licenses are available to accommodate deskless workers or those who use a shared PC. These plans include email and web-based versions of the Office applications. Mailboxes for F3 users are smaller than other plans (2 GB) and cannot be archive-enabled. Even so, these mailboxes are large enough to meet the needs of many users. Office 365 F1 and F3 include Teams, 2 GB of OneDrive for Business storage, Planner, Yammer, Sway, and Stream. F3 users also get Power Automate, Power Apps, and Exchange Online.

Microsoft 365 is flexible when it comes to altering the number and type of licenses that a tenant owns. Each user has a separate license, so you can mix and match license types within a tenant. The flexibility in licensing means that you can increase or reduce capacity as the number of users grows or declines over time. It also allows you to create a customized mix of licenses in a pool for allocation to users based on their needs. For example, a company of 10,000 users might have some people who only need intermittent access to email and never join online meetings. Kiosk (front-line worker) plans might satisfy these users while the enterprise products serve other users better. Even within the enterprise, a division might exist between users who only need basic functionality and those who need the more extended variety. In some cases, the need for advanced compliance or data governance features drives the choice of Office 365 E5 or Microsoft 365 E5 while factors such as the need to replace an old PBX will convince tenants to buy add-on licenses.

Microsoft publishes [Service Descriptions](#) and [comparisons](#) to guide customers through the functionality available in its current products. As in all negotiations, before you can decide which products are right for your company, you need to understand what functionality you need now, what might be necessary for the future, and the features that you do not need. Once you know the functionality you need, you can discuss licensing requirements and pricing with Microsoft. An independent and more graphical way to view the applications available in the available plans is available in the [Periodic Table of Office 365](#).

Remember that product details change over time, even within specific features. For example, in 2019, Microsoft moved the MyAnalytics (now Viva Insights) and Stream Plan 2 features from Office 365 E5 to E3. Microsoft introduces new features and applications on an ongoing basis. The plan you settled on two years ago might not be the best now. It is sensible to use the annual subscription renewal cycle as a reminder to check the functionality offered in the various products and confirm which is best for your organization.

## Adding Cost

Microsoft is not a charitable organization, and it is in its interest to sell as many licenses for its cloud services to customers as it can. The sources of added revenue for Microsoft are:

- Convincing customers to use higher-priced products. For example, getting organizations to upgrade from Office 365 E3 to Office 365 E5 benefits customers by enabling access to many compliance features. Microsoft gains by charging an extra \$15/month per user.
- Selling plan add-ons. If customers do not want to buy a higher-priced plan, they might be able to buy specific functionality through something like the Viva Topics add-on.
- Expanding to include other cloud services. Tenants have basic access to Azure AD. You might like to buy premium licenses to increase the overall security of the tenant and add functionality through features such as conditional access policies, group access reviews, group expiration policies, and password write-back to an on-premises directory used in hybrid deployments. The same is true of mobile device management, which you can perform at a basic level through the ActiveSync management tools built into Exchange Online but is easier and more functional when you deploy Enterprise Mobility and Security. An alternative to buying separate plans is to upgrade to Microsoft 365 to take advantage of the bundled price for Office 365, Enterprise Mobility and Security, and Windows 11.

Buying options can increase a tenant's monthly bill by a large amount. On the other hand, if the organization needs the functionality and it enables you to decommission older systems (especially on-premises servers), then the cost might be justifiable. Office 365 products include lots of functionality but sometimes you need just a little bit more. For example, assume that you license Office 365 E3 for everyone, but the activity of some accounts might need to be monitored by Office 365 Cloud App Security, which is part of Office 365 E5. You could simply buy some E5 licenses and assign the licenses to those accounts, but it is sometimes possible to buy the specific feature through an add-on. If this is the case, it is usually cheaper to buy exactly what you need rather than to upgrade to the next level. To discover what add-ons are available to you, click **Purchase Services** in the **Billing** section of the Microsoft 365 admin center, which brings you to the [service catalog](#). You can then select whatever add-on you need and decide how many licenses to buy. Microsoft charges for add-ons on a per-user, per month basis. The monthly charge for an add-on varies from country to country.

## Enterprise Mobility & Security and Azure Active Directory Premium

Tenants use Azure AD to store information about user accounts and settings. Although the functionality available in the version of Azure AD is enough to allow users to authenticate and access the apps, some organizations, especially enterprise deployments, pay extra to access the features exposed through Azure AD Premium features. You can buy Azure AD Premium licenses separately or as part of [Microsoft Enterprise Mobility and Security](#) (EMS). From April 2020, the Microsoft 365 Business Premium plan includes Azure AD Premium P1. Table 1-4 lists the functionality available through the EMS plans.

<b>Enterprise Mobility + Security plans</b>	<b>Identity and access management</b>	<b>Managed mobile productivity</b>	<b>Information protection</b>	<b>Identity driven security</b>
<i>EMS Plan E5 (\$16.40/month)</i>	Azure AD Premium P2	Microsoft Endpoint Manager	Azure Information Protection Premium P2	<a href="#">Microsoft Defender for Cloud Apps</a>

<i>EMS Plan E3 (\$10.60/month)</i>	Azure AD Premium P1	<a href="#">Microsoft Endpoint Manager</a>	Azure Information Protection P1	<a href="#">Microsoft Defender for Identity</a>
--	------------------------	--	---------------------------------------	---

Table 1-4: Functionality available in the Enterprise Mobility and Security plans

Table 1-5 lists some of the features supported by Azure AD Premium P1 that are usually of interest to tenants. The [full feature list enabled by Premium licenses is available online](#). Azure AD Premium P1 includes other features, such as [conditional access policies for Exchange Online and SharePoint Online](#), which tenants can deploy to force users to sign in with multi-factor authentication based on a network location. The P2 plan adds identity protection and privileged identity management.

The decision to invest in Enterprise Mobility and Security or Azure AD Premium licenses depends on the value that a tenant can gain from the available functionality. Some tenants will never need any of these features, some will need just one or two features, and some will use all the features. As a decision to use these products is a factor that can influence the overall cost of Microsoft 365 for an organization, it is a factor to include in budget discussions.

<b>Feature</b>	<b>Use</b>
Enhanced multi-factor authentication	Protects other cloud workloads in addition to Office 365.
Password write-back	Enables the write-back of user passwords to an on-premises Active Directory.
Connect health	Delivers information about directory synchronization performed with Azure AD Connect (AAD Connect).
Dynamic groups	Allows groups to have dynamic membership calculated based on queries executed against Azure AD (including dynamic Microsoft 365 Groups).
Group expiration policy	Expires Groups after a predetermined period and allows group owners to renew their groups for a further period.
Advanced reports	Includes reports such as password reset activity and irregular sign-in or anomalous sign-in activity.
Assign licenses via Groups	You can achieve a basic level of automation by using Groups to assign licenses to members of those groups.
Conditional access policies	Control who can access your tenant and the conditions under which they are allowed access.

Table 1-5: Azure AD Premium features of interest to enterprise tenants

## Licensing Requirements for Azure Active Directory

As described above, some Azure AD features need premium licenses. Microsoft says that “a [proper license is required](#) if a user benefits directly or indirectly from any feature covered by that license.” Sometimes Microsoft does not enforce a license requirement to block someone from using a feature and sometimes a partial block is in place. For example, if an administrator account has an Azure AD Premium P1 license, they can use the Azure portal to create dynamic Groups or define a group expiration policy. The Azure portal enforces the license requirement by not revealing the necessary UI unless the user has the correct license. However, no license requirement exists in PowerShell, so you can use it to create dynamic groups or create a policy. It is also true that dynamic groups work even if the accounts that come within the scope of a query do not have a premium license. Microsoft could enforce the requirement at any time in the future, so it is both unwise and contrary to the licensing agreement to take advantage of any gaps you find.

## Buying Through CSPs (Cloud Solution Providers)

Microsoft is not the only company that sells its licenses. You can also buy Microsoft 365 through [Microsoft cloud solution providers](#) to gain the benefit of the insight and knowledge that they have about how to deploy and use Office 365. In many countries, local resellers package Office 365 with other services to suit the local market. You still get the same Office 365 that Microsoft sells along with whatever added benefits the reseller can deliver. The reseller might charge an extra fee on top of the subscriptions levied by Microsoft. The question, therefore, is whether it ever makes sense to buy from a reseller.

The answer depends on exactly what added services you get for the extra fee. For instance, some resellers will take care of the entire migration process for you while others deliver a “white glove” service where they manage any support issues that occur. Dealing with cloud support can be a particularly frustrating area so interacting with a local services company that understands how cloud support works and has direct knowledge of Microsoft 365 to help solve problems without the need for escalation can be very valuable.

## Trial Tenants

Microsoft makes trial tenants available to potential customers with [Office 365 E3 or Office 365 E5 licenses](#) to try for up to 30 days without payment. This is a practical way to try out the functionality available with different products and decide which is the best fit for your company. It is also an excellent method to allow administrators to become accustomed to managing a tenant as they can make as many changes to settings as they like without running the risk of impacting users. You can transform a trial tenant into a production tenant if you want, but in most cases, it is best to start over and treat the trial as a sandbox that can be discarded when no longer needed. For this reason, never use a corporate domain name for a trial.

## Developer Tenants

The Microsoft 365 Developer Program supports the work of developers who need access to Microsoft 365 to build solutions for internal use or to sell to customers. By [signing up for the developer program](#), you can create a fully-functional test tenant with 25 Microsoft 365 Developer E5 licenses. The tenant is available as a general sandbox for development activity from testing code to validating performance. It's an excellent way to host application development, demos, proof of concepts, and deployment and testing of software builds. To facilitate testing, Microsoft has [sample data packs](#) to populate the tenant with test accounts and user data, but you can add your test data too.

The tenant comes with an initial 90-day subscription. If the tenant remains in use for development purposes (using tools like the SharePoint Foundation or Microsoft Graph), Microsoft automatically renews the license every 90 days to ensure that development activity can continue for as long as necessary.

# The Commercial Success of the Microsoft Cloud

Only Microsoft knows the details of how successful its cloud services are and how many paid subscribers each service has. This is commercially sensitive data, and it should come as no surprise that they reveal as little real data about the numbers as they possibly can. Commercial Cloud is an artificial mixture of revenues derived from different Microsoft cloud services including Office 365, Azure, Dynamics 365, and LinkedIn. It is not one of the formal business segments Microsoft uses to report results like Intelligent Cloud or Productivity and

Business Processes. Nevertheless, the number reported for commercial cloud revenues (now referred to as the Microsoft Cloud) is useful because Microsoft has reported comparable data for several years.

## Microsoft Cloud Revenues

In the 2011–2015 period, much of the initial growth for Office 365 came from small to medium business companies that moved from on-premises to the cloud. Today, even the largest enterprises are comfortable with the security, privacy, and operational aspects of cloud services. The growth rate for Office 365 has slowed over the years, but still reflects a continuing movement of work from on-premises systems to the cloud. Today, annualized revenue for the Microsoft Cloud, a large percentage of which comes from Office 365, is a major contributor to Microsoft's overall income. Some estimates put the revenue generated by Office 365 annually at over \$60 billion. Importantly, the revenue comes with a healthy gross margin (reported to be 70% for Microsoft Cloud in Microsoft's FY22 Q2 earnings call).

In their FY16 Q4 results, Microsoft reported that the annualized revenue run rate (ARR) for commercial cloud products [had reached \\$12.1 billion](#). Fifteen months later, when they announced their FY18 Q1 results (October 2017), Microsoft said that the run rate was \$20.4 billion, a remarkable jump of \$8.3 billion over five quarters which comfortably allowed CEO Satya Nadella to attain the goal of \$20 billion set in 2015. To calculate the annualized run rate, Microsoft takes the result achieved in the last month of a reporting period and multiplies it by 12. In April 2022, Microsoft reported revenue for the Microsoft Cloud to be \$23.4 billion, which equates to an \$93.6 billion annualized run rate. Because Microsoft books varying numbers of customer projects over a year, a difference always exists between the actual revenue achieved in a year and the ARR. Nevertheless, the headline figure used for ongoing comparison is the ARR.

Although Azure continues to grow faster than Office 365, the higher prices customers pay for Office 365 subscriptions (computed by Microsoft as the ARPU, average revenue per user) and the number of Office 365 users indicate that Office 365 represents the bulk of the Microsoft Cloud revenue mix. At the FY18 Q3 earnings call, a Goldman Sachs analyst estimated that Azure brought in roughly \$8 billion of the then \$24 billion annualized revenue. The figure for Dynamics 365 was probably another \$1 billion, which implies that Office 365 was then responsible for up to \$15 billion in annualized revenue. At the time, this equated to an ARPU of \$111, or \$9.26 monthly. Microsoft attempts to increase ARPU by moving subscribers to higher-priced plans or by selling add-ons to license additional features. To encourage customers to upgrade, Microsoft restricts access to many new features, especially in the areas of compliance and security, to tenants with high-end licenses. The importance of this tactic to overall cloud revenues can be seen in the [revelation by Microsoft's CFO](#) that in FY20 the E5 SKUs contributed \$7.5 billion in revenue, even though only 5% of the Office 365 user base had these licenses, an increase from the \$4.2 billion recorded in FY19. In July 2021, Microsoft said that 8% of the Office 365 installed base now had Microsoft 365 E5 licenses.

The latest quarterly revenue for the Microsoft Cloud business segment was \$23.4 billion (April 2022). See Table A-1 in the Appendix for a full list of quarterly revenue results since April 2015.

As of July 2022, Office 365 is available in [249 markets and 44 languages](#). It is now easier to say where Office 365 is unavailable (Cuba, Iran, Democratic People's Republic of Korea, Sudan, and Syria).

**Price Increases in 2022:** In August 2021, Microsoft announced [the first major price uplift for Office 365 and Microsoft 365 products](#). Both the Office 365 E3 and E5 plans increased by \$3/month on March 1, 2022. Microsoft justified the price increases because of the new Office 365 apps added since 2011, the volume of individual changes made in that period, the use of artificial intelligence and machine learning to automate processing for organizations and users, and the introduction of better security and compliance functionality. Some will be more convinced than others, with doubters pointing to Microsoft's need to

continue growing cloud revenues to please Wall Street as a more likely driving force. The price increase did not affect Office 365/Microsoft 365 academic and personal products.

## Growth in Usage

The increase in Office 365 users is in line with the growth in revenues. Microsoft uses a concept called *monthly active users* to report usage. This number is not the total of licenses sold to customers. Instead, it reflects those who have licenses who log on and use the service at least once a month (which is not much for anyone using any of the applications). A definition of what monthly active users are for a workload is:

*The maximum daily users performing an intentional action in the last 28-day period across the desktop client, mobile client, and web client.*

Intentional action is something that a user does to perform some measurable activity, like creating and sending a message or scheduling a meeting. For SharePoint Online, countable operations are things like uploading or editing a document, while Teams counts actions like attending an online meeting or starting a chat. The definition of an active user does not count actions like starting or exiting an app. Signals captured in the Microsoft Graph record user actions. The data is deduplicated based on user identifiers (the GUID for user accounts) to ensure that people are not counted twice.

The number of active users reported by Microsoft understates the total usage because it does not include accounts that Microsoft has provisioned for tenants which are not yet in active use, free accounts (such as Microsoft's use of the Service), and trial domains. The numbers are even higher if we speak about mailboxes instead of accounts. The number of cloud mailboxes is considerably higher than the number of cloud user accounts because of shared mailboxes, inactive mailboxes, resource mailboxes, and group mailboxes.

The current reported number of paid Office 365 customer seats is 345 million (April 2022). Given that some seats are paid for but not used, the likely number of active paid seats is probably around 321 million. You can add a few extra million free seats (used by Microsoft and their partners) to this number. Table A-2 in the Appendix details the growth in Office 365 users since November 2015.

## Workload-Specific Usage

When it reports overall numbers for Office 365, Microsoft doesn't break the data down into precise figures for each workload. In November 2019, Microsoft said that SharePoint Online has 100 million monthly active users; they updated the number for [SharePoint Online to 200 million in December 2020](#). Much of the increase in SharePoint usage comes from Teams. Every team has a SharePoint team site and Teams stores shared files and recordings of Teams meetings in SharePoint Online and OneDrive for Business. By itself, Microsoft claims that Teams has 270 million monthly active users but does not break out how many of these users are commercial, personal, or educational.

Given that a very high percentage of active Office 365 users have an Exchange Online mailbox, it's reasonable to assert that Exchange Online is the largest workload and that Exchange Online is hugely influential on the overall success of Office 365. In 2017, Microsoft said that Exchange Online alone handles about 60 billion requests per day from all connected clients (many people use more than one client, and each client handles multiple transactions). At the BUILD 2016 conference, Microsoft revealed that Exchange Online users create more than a trillion meetings monthly and that Exchange Online had processed over 4 trillion outbound messages to that point. The volume of work handled by Exchange Online was massive then and is probably three times larger now given the growth since 2016, even if some of the communications traffic previously handled by email is now in Teams.

Other products benefit from the consistent growth in Office 365. In their FY22 Q3 results briefing, Microsoft revealed that Enterprise Mobility and Security has 218 million users. Microsoft often sells EMS to enterprises

along with Office 365 (standalone or as part of Microsoft 365), which points to high penetration of EMS in Office 365 enterprise tenants. In the same briefing, they said that Azure AD had 550 million monthly active users (fifteen months prior, the reported number was 425 million monthly active users). Previously, Microsoft said that over 200,000 organizations pay to use Azure AD. It's worth remembering that among the 90 billion sign-in events handled daily by Azure, many come from non-Microsoft applications like WorkDay and ServiceNow which use Azure AD as their directory of record.

In September 2017, Microsoft Corporate VP Rajesh Jha said that he expected [more than 70% of the Exchange installed base to be in the cloud by Microsoft's 2019 fiscal year](#). Because it's hard to count on-premises licenses assigned to real people, no one knows the precise number for Exchange on-premises users at the height of its popularity. Some industry sources put the number at around 300 million, so 70% of that base is 210 million. Taking SharePoint into account, the base that Office 365 can grow off is larger. In October 2020, CFO Amy Hood said that Office 365 now accounts for "over 70 percent of our existing Office commercial paid installed base." Using the 258 million paid seats reported by Microsoft at the time, this figure indicates a total base of around 360 million, so there's still some room for Office 365 to grow.

## Service Level Agreements for Online Services

Two formal documents govern the provision of Microsoft Online Services to customers. Microsoft updates both documents quarterly. The [Volume Licensing Online Services Terms](#) lay out the terms under which Microsoft delivers the service to customers. The document is available in multiple languages. More information is in the [Service Level Agreement for Microsoft Online Services](#), also available in multiple languages. This document explains how Microsoft measures the SLA for its Online Services.

Each of the individual workloads has its own SLA definition. For Exchange Online, Microsoft defines downtime to be "Any period when end users are unable to send or receive emails with Outlook on the web." The actual calculation is a little more complex:

*"The "Monthly Uptime Percentage" for a Service is calculated by the following formula:*

$$\mathbf{((User\ Minutes - Downtime)/User\ Minutes) * 100}$$

*where Downtime is measured in user-minutes; that is, for each month, Downtime is the sum of the length (in minutes) of each Incident that occurs during that month multiplied by the number of users impacted by that Incident."*

Incidents might only affect a few users, so the number of user minutes generated by an incident varies. Many incidents are transient, last just a few seconds, and are due to a temporary condition. Over a working day, micro-outages can happen five or six times without disrupting end users. These micro-outages can sometimes be detected as a failure of a page to load or a server to respond promptly. They usually resolve themselves without the need to intervene on the part of either Microsoft or the tenant administrator.

An incident that lasts several hours but only affects a small group of users (for example, in a single data center or region) will not have much effect on the overall SLA. To see any movement in the SLA, a global outage for a couple of hours needs to happen. Due to the distributed nature of the data center infrastructure, incidents usually stay constrained within a single region. High-profile but region-constrained outages like those that affected U.S. tenants in June 2014 and July 2015 seldom move the SLA needle very much. Indeed, a daily glance at the Service Health Dashboard will invariably show that at least one workload is currently experiencing some level of difficulty that might or might not affect your users. This is part of the joy and the pain of sharing in massive multi-tenant infrastructure.

## Financially Backed SLA

If the reported Monthly Uptime Percentage falls under 99.9%, Microsoft guarantees that they will refund customers with a service credit for a set amount ranging from 25% to 100% (for less than 95% availability).

An SLA of 99.9% (“three nines” in high availability parlance) allows a service provider to have total downtime of up to 43.8 minutes per month or 8.76 hours annually. As explained above, lost minutes for Exchange Online accrue when users can’t send or receive mail with OWA. For SharePoint Online, it is *“any period when users are unable to read or write any portion of a SharePoint site collection for which they have appropriate permissions.”* These conditions are in the Service Level Agreement for Microsoft Online Services.

Counting minutes for SLA calculation only happens when Microsoft support records an incident and accepts responsibility for the problem. In most cases, this means that the problem must happen within a Microsoft data center due to a component that is under Microsoft’s control. Anything that happens within the control of the customer, such as a misconfiguration of client software or a local network malfunction, does not count against the SLA. This is logical because Microsoft is responsible only for the parts of the service that it controls.

Microsoft is not the only cloud provider to limit SLA measurement at the boundary of its data centers. No one controls the Internet, and no one controls how data flows from your client to a data center. Many complex steps occur between a client connecting to a cloud service, perhaps using multi-factor authentication from a mobile device, to access and interact with data. It is therefore impossible for a provider to offer an SLA guarantee as measured at the client. Well, perhaps possible because anyone can offer such an SLA, but certainly foolish in terms of their chances of ever meeting the SLA.

Microsoft excludes scheduled downtime from any SLA calculation. This is downtime that Microsoft needs to maintain its service and is advised to customers at least five days before it happens. On the other hand, any sudden outage that comes without warning always counts against the SLA, if Microsoft accepts that the incident is caused by their software or infrastructure and did not happen because of any action taken by the tenant.

At any time, multiple incidents affecting Microsoft services are active across the world. Some incidents are very local and affect a single server. Some are more widespread and degrade the service delivered to large numbers of tenants or even stop an application working for those tenants. Some incidents are transient and go away on their own accord and some linger for days, albeit perhaps without affecting tenants. The point is that an infrastructure that is so large cannot run in a perfect state all the time. Because cloud software depends on hardware, software, and humans, you can be sure that something is always happening for the wrong reason. Of course, users will not care unless an incident stops them from sending emails, accessing documents, conducting a meeting, or some other operation.

In most cases, any issue that affects the SLA is soon obvious because users are unable to connect or do work. Microsoft has automated systems in place to interpret problems and map them against tenants so that the incidents highlighted in the Microsoft 365 admin center are those that might affect smooth operations for your tenant. Details of incidents appear in the Service Health Dashboard (SHD). We discuss how to understand the SHD, navigate within it, and file service incidents for your tenant in Chapter 4.

A summary of incidents for the last 30 days is also available in the Microsoft 365 admin center together with post-incident reports (PIRs) by going to **Service Health** and then selecting [History](#). However, it is easy to forget to check the portal from time to time to see the current status of all parts of the service.

**What is a PIR?** A PIR is a Post-Incident Report with the formal analysis of an *“unplanned customer-impacting service incident”* or outage where there was a *“broad and noticeable impact across a large*

*number of organizations.”* Few incidents that you see in the Service Health Dashboard affect enough tenants for Microsoft to write and publish a PIR. When these incidents do happen, Microsoft makes PIRs available to customers through the Service Health Dashboard. The support team publishes a preliminary PIR within 48 hours of the incident closure followed up by a full and detailed PIR within five business days. A PIR includes the following sections:

- **Incident ID:** Every incident has a unique identifier. For example, EX29054 is an Exchange Online incident.
- **User Experience:** A brief description of the impact on end-users. It might be that the incident affected only administrators if the component involved is something like PowerShell.
- **Customer Impact:** What business impact (if any) the incident caused.
- **Incident Start Date and Time:** In UTC format.
- **Incident End Date and Time:** Logically, the difference between the start and end date is the incident period used to calculate the time lost against SLA.
- **Root Cause:** Microsoft’s explanation of why the incident occurred.
- **Actions Taken:** A timeline of all the actions taken from the time when the incident occurred to its resolution. Sometimes several hours go by before engineers have correlated enough data from multiple tenants to be able to home in on the components that might lie at the root of the problem.
- **Next Steps:** What Microsoft proposes to do to ensure that the same problem will not recur.

As in all administrative documents, sometimes you must read between the lines to understand just what happened and why it happened. The PIR also exists in internal and “customer ready” forms, the former being much more detailed than the latter.

Social media is important to Microsoft when it comes to monitoring the service too. The sheer number of users connecting to Microsoft 365 means that any problem can quickly escalate to affect tens of millions of people. Microsoft monitors information flowing through social media to detect problems that users report (and complain about). This is just one of the ways that they try to figure out the quality of service delivered to end-users.

Seeing a tsunami of updates about a problem with an application like Teams or SharePoint Online is not a reason to panic because the problem might not affect you. Remember that Microsoft 365 uses data centers around the world. Many data centers offer local services to users in a single country. The way services run within a data center means that any problem which appears in a data center likely only affects people connected to that data center. Sometimes this isn’t the case when a component running in a single location fails. For example, this happened when the [Azure AD multi-factor authentication service suffered a couple of outages in late 2018](#). As time goes by, the number of single points of failure declines within the Microsoft 365 infrastructure, but issues can still happen, as occurred with [another authentication outage in March 2021](#).

The average administrator has no real chance of understanding the data used in SLA calculations because much of it is invisible to anyone outside Microsoft. The SLA equation excludes factors such as Internet outages, local network delays, or client misconfiguration. This means that while one tenant believes they receive an excellent service measured against SLA, another tenant who experienced some problems, perhaps some of their own making, has quite a different perception of the service quality received. Beauty is in the eye of the beholder, and it is obvious that the sheer size of Microsoft 365 creates a blurring effect across its regions. Service is excellent overall (as seen in the reported SLA figures) but is awful when experienced by individual tenants affected by different bugs or operational issues.

To be fair to Microsoft, they have met their financial commitment to refund customers when the root cause for obvious outages turned out to be mistakes that were under their control. It is important to recognize that most outages are of short duration and only affect a small percentage of the overall user base.

## Performance Against SLA

Microsoft reports Office 365 SLA performance [against its 99.9% target](#) every quarter. Microsoft aggregates the data for all regions to create a worldwide result and does not give SLA information for individual regions or applications. The latest SLA figure (Q1 2022) was 99.98%. Table A-3 in the Appendix lists all the quarterly SLA results since Q1 2013.

SLA results are available six weeks after the end of the quarter. Remember that the SLA data reported by Microsoft is a unified view taken from across the complete service. Also, failures in some dependent services affecting Microsoft 365 do not impact the SLA. For example, several problems experienced by tenants in 2020 were associated with failures in the Azure infrastructure. Some of these failures influenced the SLA; others did not.

## Leveraging the Breadth of Office 365

When Microsoft CEO Satya Nadella told the audience at the October 2014 Gartner conference that *"Office 365 is the new Exchange and one will cannibalize the other. The key is to ensure that current Exchange customers can transition on their own terms,"* he reflected the reality that many customers selected email as the first workload to move into the cloud. The reason why he called Office 365 "the new Exchange" is that the movement of email into the cloud mimicked the movement of email from expensive mainframe and minicomputers to PC-based Windows NT servers some twenty years previously. Exchange Server was the first Windows server application considered "enterprise-ready." In other words, Exchange could scale to offer the kind of email service needed by the world's largest corporations. Over the next twenty years, Exchange delivered on that promise.

Email is a big reason why many companies decide to move their workloads to the cloud, but what of the other cloud applications? After all, you pay for these applications alongside Exchange, so it is wasteful if you do not seek to take advantage of them. Any plan to migrate should consider what advantages a company can derive from the full spectrum of Microsoft 365 rather than applying a narrow email-centric focus. Here are the services that round things out:

- **SharePoint Online:** While organizations were initially slow to move on-premises SharePoint deployments to SharePoint Online, that point is long past and SharePoint Online now boasts over 200 million daily active users. The mission of SharePoint Online is different from the way organizations often deploy the on-premises variant. SharePoint Online is the document management service for Microsoft 365 applications and is closely integrated with many apps including Teams, Planner, and Yammer.
- **OneDrive for Business:** OneDrive for Business is core to enabling people to work offline or across low-bandwidth environments. Its synchronization client uses differential synchronization to deal with files of up to 250 GB stored in SharePoint Online or personal OneDrive for Business accounts. Microsoft provides "unlimited OneDrive storage" to Office 365 users with enterprise accounts to allow them to move files traditionally kept on local PCs to the cloud.
- **Yammer:** Microsoft bought Yammer in July 2012 to gain its enterprise social networking technology. Since then, Microsoft has integrated Yammer into Microsoft 365 in several ways such as using Azure AD for identity management, using SharePoint Online to store files posted to Yammer, and using the Groups service to manage the membership of Yammer communities. Some commentators observed that Microsoft also acquired a fast-paced web-centric development culture from Yammer which helped them to move to the release cadence expected from cloud services. Yammer is all about

sharing information on an enterprise-wide basis, an aspect that makes it more interesting to larger organizations.

- **Planner** and **Teams** are two applications available to enterprise tenants. Both use Groups to manage team members. Planner focuses on task-based planning for team activities while Teams offers a chat-based workspace for users to work together with audio and video calling, federated communications with Skype consumer users, an application platform, and a replacement for traditional phone systems.
- **Stream**: Stream provides video recording and consumption services to applications. See Chapter 10 for information about managing video.

Perhaps the most interesting thing that has happened since the introduction of Office 365 is how the barriers that existed between on-premises applications disappear when Microsoft has total control of deployment and operations. Relatively few on-premises environments successfully integrate SharePoint and Exchange, but the configuration and operational difficulties go away with the cloud versions. Microsoft takes advantage of this to build new applications that exploit Exchange Online for email and calendaring and SharePoint Online for document management, adding whatever extra software is necessary to complete the picture. Teams and Planner are examples of new applications that could not exist on-premises. Both are unique to the cloud.

If the right licenses are in place, all this functionality is available to tenants. Many companies plan to move to the cloud for a specific purpose and can benefit even more by exploiting the other technologies mentioned above. The best thing is that Microsoft takes care of all the work to deploy and manage the technology, meaning that the normal learning curve needed to master the details of capacity planning, server deployment, and application configuration and installation is not necessary. All efforts can focus on the question of how best to use the features available through SharePoint Online, Teams, Planner, and other applications to solve business problems.

Like any migration, the transition from on-premises servers to their cloud equivalents are projects that benefit greatly from experience. If you don't have the necessary expertise within the company, you should find some experienced consultants to help you plan for and execute the change.

# Chapter 2: Embracing the Microsoft 365 Cloud

**Paul Robichaux**

## Should You Move to the Cloud?

If you pick ten companies from a random selection in any country or industry, you'll find *at least* ten different lists of reasons for or against moving to the cloud. These reasons might include modernizing a creaky or unsupported IT infrastructure, the desire to treat applications like email and document management as utility functionality instead of running software on in-house servers, or fear of a loss of control due to turning over services to an outside provider.

Today's truth is that most enterprises that want the benefits of cloud services have already started taking advantage of them. Organizations that haven't yet moved at least *some* of their workload to the cloud probably either don't want to or cannot because the cloud can't support their business requirements. Industries with heavy regulation or compliance requirements, or unusual security needs such as the ability to process classified information, have historically lagged in cloud adoption. However, even in these unique corners of the market, some companies have decided that the benefits outweigh the risks, costs, or limitations.

This chapter will help you work through some key topics related to moving to the cloud, broken into three broad categories:

- Things you should know or consider *before* you start moving to the cloud. (Even if you've already moved to the cloud, you may find some useful nuggets here as you consider how and when to adopt additional cloud services.)
- Things you should know and consider *while* you prepare and execute your move to the Microsoft 365 cloud.
- Things that you should be prepared to do *after* your cloud migration is substantially complete.

Let's start with some basic terminology. When we refer to "the cloud," you can consider that shorthand for "Microsoft 365 and its related services." We won't cover Microsoft's other cloud services (including Azure or Dynamics 365) or non-Microsoft cloud services such as Amazon Web Services, SAP Hana, or Salesforce.

Next, we'll distinguish between the process of *migrating to the cloud* (meaning the process of moving data and services into Microsoft 365) and *adopting the cloud* (meaning convincing users and business stakeholders to *use* Microsoft 365 once the migration's underway). Migration must always start before adoption, although they will often run in parallel: the first users to migrate start adopting the new system while later waves of users wait to be migrated.

Just understanding the pro- and anti-cloud arguments isn't enough by itself. You must put these arguments in context for your company. Your knowledge about how the company works and its business goals will help you put the points made here into the right context for your business. Never take a consultant's opinion as definitive—or ours, for that matter!

# What to Do Before You Move

Different organizations may have radically different reasons for moving to the cloud. Some do it to replace an unmaintainable or expensive legacy infrastructure; others are chasing improved productivity or shiny features. Regardless of the basic reasons behind a specific migration, there are several important points to evaluate when you're considering a migration to Microsoft 365.

## Dispel Any Lingering Cloud FUD

The use of fear, uncertainty, and doubt (FUD) is a much-beloved tactic to delay or deflect a decision away from certain technology. Salespeople have used FUD (a term first used in 1975 by [Gene Amdahl](#), a former IBM employee whose company was the first real threat to IBM's mainframe business) for decades to try to discourage the adoption of PCs, mini-computers, client-server implementation, the web, social networking, mobile devices, and now the cloud. The tricky thing about FUD is that some of the fears expressed are valid concerns and deserve inclusion in your decision-making process as part of your decision; other fears are over-hyped.

Common FUD-related statements you might have encountered include:

- You can't depend on the cloud (or the Internet).
- Cloud services are immature.
- Cloud platforms are insecure.
- On-premises IT delivers better service to the company and end-users.
- You lose control when you move to the cloud.

These aren't the only specimens of FUD out there, but in every case, it is important to separate fact from fallacy. Let's look at each of the issues listed above.

### Is the Cloud Dependable?

*"You can't depend on the cloud"* can have several meanings. It could be that users or business leaders lack trust that they'll be able to connect to cloud services as easily as they can with on-premises services because they're worried about your internal network services, local Internet connectivity for users, or poor performance. It might mean they believe that your IT department can deliver a more robust service than a cloud provider would. It might mean that you're worried that a cloud provider will remove, change, or limit services once your business has come to depend on them.

You could short-cut the question of whether the cloud is dependable enough for business use by saying "of course it is; look how widely it's used!" That would be true but might not be enough to quell doubts. If we dig a little deeper, we can come up with a better answer, starting with the network.

The network is indisputably the essential link between cloud services and end-users. If you have a slow or unreliable network, your users will have a slow or unreliable cloud experience, period. Your network has three parts that work together to deliver end-to-end connectivity: the internal network used by your users (including its connection to the Internet); the Internet itself; and the network controlled by the cloud provider.

Your existing company network was probably built to connect users to on-premises systems, so it's reasonable to assume that you'll need to upgrade it to support your transition to the cloud. The best way to justify this upgrade is to keep in mind that you're shifting, *not* reducing, the traffic that would formerly have stayed completely within the corporate network. A user who has 50 GB of files stored on a file server and then moves them to OneDrive for Business is still going to generate roughly the same amount of network traffic when she copies, edits, or moves a file, but the traffic's endpoints will be different. One possible

counterargument is that the movement of so many people to partial or permanent telework has offloaded some traffic from corporate networks—but now the experience for a user will only be as good as the quality of her home network... which opens an entirely different set of performance, security, and connectivity problems!

Beyond this basic shift in traffic, you can expect a move to the cloud to generate some extra external network traffic for things such as hybrid connectivity, directory synchronization, and remote administration. Of course, any migration of data to the cloud platforms will generate additional traffic too. Some of this traffic will be short-lived (for example, moving mailboxes from on-premises servers to Exchange Online), while other traffic may recur (such as directory synchronization traffic).

Your move to Microsoft 365 may also cause some brand-new traffic. One example might be new network traffic generated by Teams voice or video calls that traditional PSTN networks used to carry.

Anyone who plans to move to Microsoft 365 needs to pay attention to both their internal network and their Internet connectivity to ensure that enough high-quality network resources are available to handle the expected load. For instance, do you have enough capacity available to handle outbound traffic to Microsoft 365? Are sufficient network egress points in place to handle the outbound traffic or how many access points exist to process internet traffic? Adapting to the cloud's network requirements is often more a project management and budget issue rather than a technical challenge. As we'll discuss later in the book, Microsoft has published some [very specific actionable recommendations](#) for how you should tailor your internal and client networks to work best with the service, and it's critical to understand and adapt those recommendations in your network early on. The most critical recommendation is to reduce the round-trip time required for a packet to travel from a client to the Microsoft network; the devil is in the details of how you do this. In efforts to lower this round-trip time, companies often change their topology by adding content distribution networks (CDNs) or various types of cloud application security (CAS) capabilities.

Before you move any significant amount of your business to the cloud, it's a good idea to gather as much data as you can about the reliability and service quality of the Internet providers you use. Depending on where you're located, you may have multiple providers available to you. Whilst it's probably not possible to know with certainty how a provider's network will work over the long term, a move to the cloud is the perfect opportunity for you to talk to other organizations in your area to understand how your local providers have fared. Most of us have home Internet connectivity and know that different providers differ in speed, service uptime, reliability, customer service, and so on. Does your current business Internet provider deliver the quality and performance you need? If not, the time to look for alternatives is *before* you start your move. Because network performance is so critical, don't accept any migration plan that calls for you to start moving to the cloud until you're happy with the quality and performance of your network. Don't try to change network providers and move to the cloud at the same time.

Microsoft understands Internet connectivity is never perfect, and they want to limit the impact of network failures and slowdowns, so over the years, they've added features to let users continue to work over degraded or unavailable connections. Examples include "[Project Nucleus](#)," the sync technology behind offline and disconnected access to Microsoft Lists, Teams survivable branch appliances (which allows users to continue to make and receive PSTN calls from a local office when the Teams cloud service isn't reachable), and the ability of OneDrive, Outlook, and Teams clients to allow some types of changes to be queued while disconnected. You should expect Microsoft to continue to improve offline support for the Microsoft 365 ecosystem, although this improvement won't be equal across applications and workloads.

After more than a decade of experience with Office 365, it's become clear that the root cause of most user connectivity problems is a problem with the device or its connection to the internet, *not* problems with Microsoft's internal network or the service itself. In particular, the same kinds of DNS problems that have

bedeviled enterprise administrators since the birth of the commercial Internet are still around and still cause problems for users. Microsoft experiences occasional glitches with its network but has built-in enough capacity and alternate network paths to handle most issues.

In summary: the cloud is only as dependable as your ability to connect to it. Taking the time to review your network design and capacity to improve user connectivity will be time and money well spent.

### Is the Cloud Mature?

The second issue often raised by cloud doubters is the claim that the platform is immature. In other words, technologists better understand on-premises deployments because they have managed these deployments for so many years and have met and overcome all their challenges. This argument used to be much more credible when cloud servers were still new and used the same production code that we could run in our on-premises servers. However, after more than a decade of Office 365, this argument is no longer remotely believable; Microsoft has invested incredible amounts of resources in developing, provisioning, securing, and operating the Microsoft 365 services at a scale that no on-premises deployment can even attempt to approach, and with uptime that only a handful of organizations worldwide could deliver. The services now available in Microsoft 365 were purpose-built for the cloud and are deployed, managed, and monitored using high-scale automated tools supported by a server fabric that just does not exist in the on-premises world. That doesn't even begin to mention the huge wealth of features that Microsoft has put into the service but not into the surviving on-premises editions of their products!

Of course, fairness dictates that we recognize that there *are* excellent on-premises deployments of Exchange, Active Directory, and SharePoint that exhibit superb execution, operational maturity, and dependable delivery of service to end-users. On the other hand, many on-premises deployments *don't*. In fact, many on-premises deployments will need some degree of rehab work before they can consider moving to any other platform, whether that is to use a new on-premises version of their existing products, a hybrid deployment, or moving everything to the cloud.

From a maturity standpoint, you can't argue the fact that cloud platforms deliver highly functional software in the form of highly accessible applications across the Internet and do so with a level of reliability and security that would be the envy of many CIOs responsible for internal IT systems.

### Is the Cloud Secure?

No organization will move to the cloud if they believe that their data will be less secure than it is on-premises. When you move to Microsoft 365, you're placing a large bet that Microsoft will do a better job securing your sensitive data than you can do yourself. In this case "securing" means maintaining all three aspects of the security triad: confidentiality, data integrity, and data availability. Add to that the requirement to ensure data privacy, and the additional need in many jurisdictions to maintain [data sovereignty](#), and you quickly find that the degree of security expertise and investment required to maintain a truly strong security posture is outside the budget and capability of the vast majority of on-premises customers.

Microsoft invests roughly US \$1billion each year in security across its entire product line. This investment covers the typical "gates, guards, and guns" measures that most people think of for physical security, but the investment goes much deeper. All Microsoft 365 workloads are designed and implemented per the [Microsoft Security Development Lifecycle](#). This is described as "*a software development process that helps developers build more secure software and address security compliance requirements while reducing development cost.*" On a practical level, this means that data is secured by being encrypted at rest, that auditing information is available, and that the unified audit API is supported to allow customers and third parties programmatic access to information protection and compliance events. For instance, BitLocker is used to protect Exchange Online databases while files stored in [SharePoint Online and OneDrive for Business libraries are individually](#)

[secured](#) with their own 256-bit Advanced Encryption Standard (AES) key. Strict adherence to this standard costs Microsoft money; for example, even the small 3-5% performance penalty imposed by BitLocker encryption adds up quickly when you're talking about millions of disk volumes across hundreds of thousands of servers. However, Microsoft believes that spending heavily on security is a wise investment, as it builds customer trust and credibility for the service. To further build credibility, they make extensive use of their products, including the various Azure and Defender security offerings.

Microsoft does not usually provide specific details about the methods used to protect information because that could potentially undermine security by revealing too much to potential attackers. However, a reasonable amount of information, including several white papers that address the security topic in-depth, is available in the [Microsoft 365 Trust Center](#) and details of the data encryption technologies used by the different workloads [are available online](#). The completeness of the security features developed for Exchange Online and Microsoft 365 in general was enough to warrant the inclusion of Microsoft in the "leaders" section of Gartner's 2015 Magic Quadrant for Secure Email Gateways, a status Microsoft has held since.

The methods used to protect data include:

- **Physical security:** Anyone who has ever visited a Microsoft data center can attest to the extremely high level of security processes and procedures that apply. Access is strictly controlled to the servers and other hardware and every action is verified and logged. Any faulty disk drives are removed and demagnetized before they are destroyed to ensure that customer data cannot be compromised.
- **Reducing the number of administrators:** Microsoft has steadily been reducing the number of employees that have persistent administrative access to applications or the servers running in the data centers. They don't discuss the specifics often, but their goal was to make all administrative access "just in time" (JIT) so that it can be monitored and regulated. Restricting access in this manner ensures that any interaction with customer data is controlled (and audited). The so-called "Lockbox" process ensures that administrators hold zero standing permissions, which removes the problem of how to control the growth of those holding elevated permissions over time. Administrators receive just-in-time permission to perform tasks and have the permissions removed when the task is complete. All administrator access is conducted from specially secured single-purpose workstations known as [privileged access devices](#) that layer additional physical and data security capabilities on top of the existing Windows platform.
- **Customer Lockbox**, a premium E5 feature giving more customer control over access to user data like mailbox content, documents, and chats. Any time an engineer needs access to tenant data, [a request appears in the Microsoft 365 Admin Center](#) for a tenant administrator to review and authorize (or deny). [Customer Lockbox](#) works for Exchange Online, SharePoint Online, OneDrive for Business, and Teams. You can also buy Customer Lockbox as an add-on for any enterprise plan.
- **Extensive auditing:** Microsoft audits all access to tenant data to provide a traceable record of who accessed what data, when, and from where.
- **Data isolation:** Microsoft takes great care to ensure that data cannot leak from one tenant to another (see this document for more information about [how tenant data is isolated](#)).
- **Transport encryption:** Transport Layer Security (TLS) encryption protects information sent between Microsoft 365 data centers and clients and messages sent between Exchange Online tenants. Exchange Online also uses opportunistic TLS to negotiate secure connections with external servers. You can also create transport connectors that use TLS to protect messages sent to specific domains, such as those belonging to trusted partners. Any client, including browsers, which connect to Microsoft 365 services should use TLS 1.2. Microsoft [began to deprecate TLS 1.0 and 1.1 in 2020](#) and formally ended support for those versions in Exchange Online in October 2020, but the protocols still work, at least for now. It will take some time before Microsoft has completely removed earlier versions

from all Exchange Online servers worldwide. When this happens, Exchange Online will no longer send or receive emails from servers that want to connect with the earlier versions. In the meantime, they have added a [new, opt-in endpoint](#) specifically for older clients and services that need the older versions. This page gives the technical details about the [current TLS cipher suites](#) used for encryption. Keep in mind that some devices, such as Teams Room Systems, may require additional updates from their vendors to fully support TLS 1.2.

- **Data at rest encryption:** servers and data in Microsoft 365 data centers are protected by [BitLocker](#). Protection covers both Exchange Online mailbox databases and SharePoint Online and OneDrive for Business document libraries. That means that rogue administrators cannot remove customer information and sell it to other parties or otherwise misuse the content. See [this page](#) for information about the encryption of SharePoint Online, OneDrive for Business, and Exchange Online data.
- **Customer-applied encryption:** Users can choose to protect or encrypt messages using sensitivity labels (Microsoft Information Protection) or S/MIME. To be complete, you might include features such as Data Loss Prevention (Chapter 19), Microsoft 365 Defender for Office 365 (Chapter 7), and information protection using sensitivity labels (Chapter 20) in the overall assessment of security capabilities. Microsoft also offers large enterprises the ability to provide their own security keys which can be used to encrypt data (known as “customer key” or “bring-your-own-key” encryption, discussed in Chapter 4).
- **Endpoint protection:** not only does Microsoft offer its Defender line of products as part of Microsoft 365, but they also run Defender on the servers hosting the workloads, as well as the workstations used by engineers, administrators, and support personnel. In addition, if you subscribe to Windows 365, those Microsoft desktop environments are protected automatically as well.
- **Azure Active Directory security:** Application sign-in and authentication depend on Azure Active Directory, which has its own set of protections. For more information, see [this whitepaper](#). In addition, features such as [Privileged Access Management](#) allow tenants to control administrative access to PowerShell cmdlets that create or edit data. Administrators must request access to specific functions and give a reason for the access. After review, the access might be approved, in which case the administrator can go ahead and execute the task.

Besides these designed-in security measures, there’s one other additional trick Microsoft uses: they automate server configuration and management using Desired State Configuration (DSC). Automation ensures that cloud servers run known configurations and that newly added servers are correctly baselined from the start. The automated and ongoing updating of servers with new versions of the operating system and applications means that a high degree of confidence exists that known bugs are not met in production.

With all this said, it is critical to keep in mind that Microsoft owns the security of the cloud resources and services that you use but *you* are still responsible for the security of your servers, services, and users. As the world saw with the [Exchange Server “HAFNIUM”](#) and ProxyShell attacks throughout 2021, it is *never* safe to assume that you’re immune to attacks; in the case of HAFNIUM, even organizations with no on-premises mailboxes were still vulnerable as long as they maintained at least one Exchange server on-premises. Don’t let the potential of a move to the cloud lead you to skimp on your security practices, procedures, or investments.

## Will I Get Good Service from the Cloud?

Quality can be measured in diverse ways. One way is by measuring how well a service meets its service level agreement (SLA). Microsoft has an excellent track record of meeting and exceeding its SLA for the Microsoft 365 services (although in fairness, they get to unilaterally define the metrics in the SLA). Some argue in favor of counting the number and impact of software flaws as a measurement. This is great for the organization creating the software, but it’s a terrible measure for outsiders (which means “all of us”) who don’t have full

visibility into the range, scope, and the number of bugs. It's a fun fantasy to imagine that any software vendor would eliminate all its bugs, but that's not going to happen for four reasons. These are:

- **Competitive pressures:** Microsoft must respond to technical and feature advances made by its competitors to ensure that its applications remain an attractive offering in the market. Every time you touch code to improve functionality or "make things better," the possibility exists that bugs creep in.
- **Customer demands for "more":** Customers also ask for many different forms of enhancements. Requests vary from a slight change to the way some feature works to an update designed to facilitate the onboarding of large enterprise customers. Microsoft monitors forums, Twitter, and support tickets closely to focus on areas that cause users to have problems and makes changes to improve matters. An example of this is how many changes were made in the Teams application to help customers cope with the upsurge of home working because of the Covid-19 pandemic.
- **A dynamic client base:** A staggering number of client platform combinations (browser, Windows, mobile) and protocols interact with Microsoft 365. Clients have been known to introduce problems (for example, several Apple iOS upgrades have caused issues for Exchange Online), and the support and testing matrix is very complex. Testing complexity creates more possibility for bugs to creep into software and stay undetected until a user meets a problem. It's also the case that sometimes Microsoft clients can cause problems —so the test burden is on the applications *and* the service.
- **Dependencies between services:** Although email is often the first workload moved to the cloud, it is important to understand that many interdependencies exist between what may appear to be separate workloads. A better and more productive view of Microsoft 365 incorporates Exchange Online, SharePoint Online, Teams, OneDrive for Business, Azure Active Directory, Microsoft Information Protection, the Microsoft Graph, and so on. Behind the scenes, a complex set of interconnections link these services. For example, Groups are based on features contributed by Exchange Online and SharePoint Online. eDiscovery depends on features contributed by Exchange Online and SharePoint Online (among others). SharePoint Online is the storage for applications such as Teams while Azure storage supports other applications like Planner and Teams. Each of these workloads and features has its own set of developers, testers, and plans. Maintaining the connections between the different applications requires substantial effort, which is one of the reasons why some of these features are not available on-premises.

It's hard to eradicate software bugs when software evolves and flexes all the time. We accept this situation because we like new features and functionality. Remember that one of the reasons why customers adopt cloud services is the promise of "evergreen technology", to move away from the more restrictive upgrade cycles used in on-premises deployments. With evergreen or ever-evolving technology comes the risk that things don't work quite as well as they should from time to time. That's when you enter the world of cloud support.

### Will I Have to Give Up Control When I Move to the Cloud?

Consumers of cloud services generally don't get to vote on when the service provider introduces, changes, or removes functionality. It just happens. Cloud providers like Microsoft make these changes to meet *their* goals and priorities rather than yours. This is part of the deal you're making when you move to the cloud. Moving to Microsoft 365 means that you're giving up a degree of control, but you're also able to shed the responsibility for installing the latest versions of Windows and Exchange on a server, bringing it up to the latest patch level, and making sure that any required additional products are installed.

Sometimes problems arise when the characteristics of the service change in a way that you prefer it did not. For instance, as part of the replacement of Skype for Business Online with Teams, Microsoft at one point took away the ability for smaller tenants to choose between Skype for Business Online and Teams and forced them

into Teams. You can argue that this was the right decision because Teams is newer and better technology, but some tenants didn't like the feeling of being forced. Microsoft also has an unfortunate habit of introducing features that admins may not want and enabling them by default, as they initially did with self-service license purchasing for Power Platform or the Bing search add-in for the Edge browser.

The positive way of looking at how things flex and change without warning or any ability to influence an outcome when you use cloud services is to not focus on any loss of control over the servers and other infrastructure that you no longer manage. Instead, focus on how best to use all the added hours that you gain and figure out how to use that time more productively.

## Answering Some Additional Questions about the Microsoft 365 Cloud

Besides the basic (but necessary and challenging) work of dealing with FUD questions, some additional considerations may come into play depending on your industry, background, and regulatory requirements.

### What Industry Security Standards Should I Consider?

None of the practices used by Microsoft are secret, and they aren't rocket science. What they *are* is implemented at massive scale and with huge attention to detail—but the basic practices they use to protect and secure data in Microsoft 365 applications are well-known and can be implemented by any company (and indeed, Microsoft [documents how they handle security incidents](#)). (Of course, some of the lessons Microsoft learns from their massive environment don't translate to on-premises environments!)

However, Microsoft realizes that customers want to see independent audits proving that they are following good security practices. Among the other audit-based attestations and certifications that Microsoft has earned, we have:

- [ISO 27001/27002](#): Information Management Security System and Best Practice for Security Controls.
- [SSAE 16 SOC1 Type II](#): Reporting on Controls at a Services Organization.
- [NIST 800-53](#): Security and Privacy Controls for (U.S.) Federal Information Systems and Organizations., Microsoft's audit controls for Microsoft 365 are based on the NIST 800-53A (Rev. 4) special publication.
- [HIPAA](#): U.S. Health Insurance Portability and Accountability Act.
- The [HITRUST](#) Common Security Framework.

A complete set of documents describing how Microsoft meets regulatory requirements and security standards can be found in the [Service Trust Portal](#), including the latest audit reports covering Microsoft 365 and other Microsoft cloud properties. Another [set of documents](#) helps customers perform a risk assessment and understand the compliance of Microsoft cloud services with industry standards and regulations. Microsoft also publishes information about how Microsoft 365 meets requirements that exist in specific geographies, such as the [European Union model clauses](#), which are *"standardized contractual clauses used in agreements between service providers and their customers to ensure that any personal data leaving the EEA will be transferred in compliance with EU data protection law and meet the requirements of the EU Data Protection Directive 95/46/EC."*

The European Union's General Data Protection Regulation (GDPR), in use since May 2018, affects how companies active in the EU gather and handle data. More information on GDPR and how it relates to Microsoft 365 [is available from Microsoft in the service trust portal](#) and Chapter 17. The [Microsoft Compliance Manager](#) gives customers a framework to help them organize the steps to achieve compliance with regulations like GDPR.

In addition, Microsoft sometimes seeks external proof that its applications meet the specific requirements of different industries. For instance, in the financial sector, they commissioned a [report](#) authored by [Cohasset Associates](#) to give an independent opinion as to why the compliance features built into Microsoft 365 meet the electronic records storage, retrieval, and management requirements of rule 17a-4 of the U.S. Securities and Exchange Commission (SEC), Rule 4511 (c) of the Financial Industry Regulatory Authority (FINRA), and regulation 17 CFR of the Commodity Futures Trading Commission (CTFC).

Microsoft also requires that its suppliers meet certification standards. They have a certification program, the [Microsoft Supplier Security and Privacy Assurance](#) program to require vendors who sell software to Microsoft to prove their adherence to privacy and security practices. Within and outside Microsoft's ecosystem, it's important to remember that no software exists in a vacuum; all the components that services like Exchange Online depend on should also receive external oversight and certification. For example, [Azure](#) is certified against the [ISO/IEC 27018](#) code of practice for the storage of personally identifiable information in public clouds.

**Security across the board:** Although Microsoft assigns talented personnel to the tasks of building security solutions and protecting customer data, there is no doubt that sometimes some extra help is necessary for organizations to achieve full protection. For example, tenants can deploy data loss prevention technology for many workloads, but this technology does not protect all the data that exists within companies. It might therefore be necessary to deploy some other solutions to ensure that sensitive data is not transmitted outside the organization. When a company moves workloads to the cloud, it is wise to consider whether some more protection is needed for the full spectrum of data that is in use.

Companies that need more security than the capabilities built into the Microsoft 365 applications have a wide range of options available to harden different components. [Microsoft Defender for Cloud Apps](#) is available to protect cloud applications at an extra monthly cost per user. Other companies that are active in the provision of additional security capabilities include [Mimecast](#), [ForcePoint](#), [Proofpoint](#), and [Skyhigh Networks](#).

## Which Cloud Am I Moving To?

Most of the time, we think of Office 365 as a single cloud service delivered worldwide by Microsoft. It's more than that, of course; there are the other services that Office 365 leverages, such as Azure AD, but there are also multiple independent instances of Office 365 offering what appear to be very similar services, but for specific regions or markets. The best-known example of this is probably the family of Office 365 solutions for government use. The basic Government Community Cloud, or GCC, is a separate instance of Office 365 that is dedicated for use for "United States Federal, State, Local, and Tribal governments, as well as contractors holding or processing data on behalf of the US Government," according to the [GCC service description](#). It's intended for unclassified information but is approved for use with various types of other sensitive information, including tax and financial data and certain types of sensitive law-enforcement-related information. Some of the approvals required to process certain data types (such as [the CJIS certification](#) required for law enforcement use) require special configuration, which of course Microsoft will assist with as part of a consulting engagement. There's a separate GCC instance (known as GCC High) that is approved for handling certain types of sensitive defense information, plus a [US Department of Defense \(DoD\) instance that has its own separate Office 365 cloud](#) implemented in physically separate data centers that have little or no infrastructure in common with the commercial and GCC versions. In late March 2022, Microsoft announced the forthcoming availability of a new cloud, Office 365 Government Secret, that's approved for processing certain types of classified information, joining the Azure Government Secret and [Top Secret](#) clouds.

Figure 2-1 shows the current set of publicly-acknowledged Office 365 clouds for government use.

# Office 365 Government:

Meeting the full spectrum of government data needs

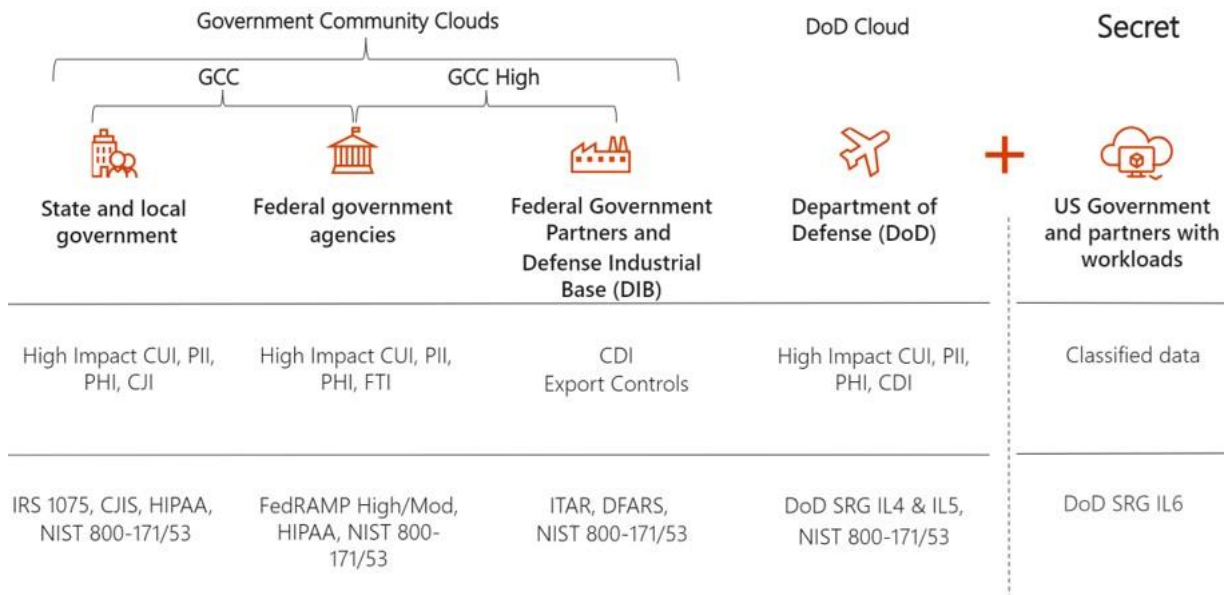

Figure 2-1: the 2022 version of Microsoft's government clouds for Office 365

Other government-specific Office 365 instances exist. To use any of these government-oriented services, you must be sponsored by a government agency and approved by Microsoft. This allows companies that contract to provide services to agencies that use GCC to have GCC tenants also, assuming that their customer agency is willing to sponsor them.

The Chinese government requires that most cloud services doing business in China have local instances that are logically separate from their overseas counterparts. These instances must be maintained by Chinese citizens in Chinese data centers. In the case of Office 365, this service is known as "[Office 365 operated by 21Vianet](#)" (21Vianet being the Chinese company that runs the service for Microsoft). Microsoft carefully emphasizes that they don't operate or manage this service. There used to be a similar service for German customers known as [Office 365 Germany](#), too, but as Microsoft added data centers in Germany, that variant went away. It's interesting to wonder about how much work Microsoft does to create a "containerized" version of the basic Office 365 services for deployment in a new country and to ask whether this will ever become a feature available to commercial customers.

Wherever they're located, each service instance has its own set of supported features. When Microsoft introduces a new feature into "the service," they're really introducing it into dozens of different environments. For example, as of July 2022, Office 365 in China supports Power Apps and Power Automate only for selected customers, and with some missing features (such as the Power Automate mobile app); various Teams features available to commercial customers in North America are still rolling out to tenants homed in other countries and Office 365 Education tenants; [Yammer isn't available in GCC High](#), and file sharing using SharePoint and OneDrive works differently in GCC High than in the lower-security GCC and commercial tenants.

Besides the obvious complications of having different sets of services and functionalities in different cloud environments, many third-party applications and services that work with the commercial Office 365 services may have incompatibilities, or not be supported, within some environments. There's a complex process to get approval to run third-party applications in GCC and GCC High, for example, so you may find that your preferred migration tool, management utility, or other application cannot be installed or run in your

government tenant, or that, when installed, it doesn't work properly. Be sure to check compatibility with your vendors before moving to one of these environments.

The bottom line for these differences is that if you are considering moving to anything other than the standard commercial service, you should take the time to research the differences in features and service capabilities between the well-known baseline services in Office 365 and the specific version that you'll have access to.

### Who's Responsible When the Cloud Breaks?

It's quite tempting to assume that, given all the work and money Microsoft puts into making Microsoft 365 secure and robust, you no longer need to worry. As we saw with the previously-noted HAFNIUM attacks, that's not the case. In fact, even if there isn't an active attack against your organization, you should be aware that Microsoft expects you to bear responsibility for a good part of the overall whole. To be specific, [Microsoft says](#) *"For all cloud deployment types, you own your data and identities. You are responsible for protecting the security of your data and identities, on-premises resources, and the cloud components you control (which varies by service type). Regardless of the type of deployment, the following responsibilities are always retained by you: Data, Endpoints, Account, and Access management."*

Microsoft's position is clear, although you may not have thought of it in those terms. Microsoft [expects that you are responsible](#) for data classification and marking, securing your devices and endpoints, and managing and securing your user identities and associated credentials. You may choose to use Microsoft's tools and services (whether free or paid) to help you with these things, and Microsoft may even assist in some ways (as they do by providing sign-in data and warnings of unusual sign-in activity to you), but they deny responsibility for those aspects of the end-to-end service. That means that you must stay aware of both security threats and potential problems that might interrupt your end users' work, then be ready to remediate any of them that fall under your control.

Given the increasing number of ransomware attacks against hybrid organizations, it's also worth mentioning that attacks (or failures) that knock your on-premises Active Directory infrastructure offline will have an outsize impact on your users' ability to work in the cloud unless you are 100% moved over to cloud-based identities. Part of your planning for a move to the cloud must cover recovery or resilience strategies to let people keep working if any important on-premises infrastructure is compromised or degraded.

### Can I Get Good Support for the Cloud?

Microsoft 365 tenants can get both free and paid support through multiple channels, including forums, telephone and email support, and service requests that flow to dedicated support personnel. Cloud observers often refer to support as the "Achilles' heel" of cloud services because it is so difficult to deliver support in a timely and effective manner to tens of millions of consumers. Many consumer-focused services (such as Netflix, Spotify, and Microsoft Xbox Live) force their users to seek support through self-service forums and community-based support. Now that Microsoft 365 counts more than 340 million active users, the temptation for Microsoft to do the same is strong.

By comparison, on-premises services are usually supported by in-house help desks and support teams (or the work is outsourced to a third party). A company has control over the quality of those services based on the investment made to staff up the help desk and train support personnel. The transition from a position where you have total control over all the moving parts needed to resolve a support ticket to depending on the intervention of cloud support when you do not control many of the moving parts is difficult for many organizations. IT professionals are frustrated with having to deal with phone support, users do not like how long it takes for even simple issues to be resolved, and managers worry about the control they have ceded to the cloud provider.

All of this is true. When you move from a customized in-house solution to use a shared utility infrastructure you must make some adjustments. Think of it like this – if you use a diesel-powered generator to power your house, you have total control over the infrastructure but you’re also responsible for everything that might go wrong with it. But when you sign up with a power company, you hand over responsibility for most of the operations to that provider. All you must do is make sure that the equipment is plugged in and turned on. The same is true of using a utility IT service. You don’t have to maintain the servers or make sure that their networking equipment is functioning, but you must ensure that your equipment is functional. (The interesting extension to this metaphor: some businesses have such specific needs for electricity that it makes sense for them to run dedicated generating plants even though utility-scale electricity is cheap, dependable, and ubiquitous throughout much of the world—this explains one reason why some companies cling so fiercely to their on-premises environments!)

When workloads move to the cloud, the job of the in-house support team changes. Instead of driving a resolution for every problem, the in-house team must manage interactions with Microsoft to work the problem as effectively as possible within the constraints placed on both you and the Microsoft support organization.

You control local equipment and settings and can make sure that you cover all the basics – that the user’s client is configured correctly, that they can connect to the Internet, and whether the problem is unique to a certain user or is shared by a group, and so on. Microsoft’s support, delivered remotely, will focus on making sure that the service is working properly and assist with troubleshooting when they can. This division will usually be invisible to the end-user unless they learn about it when they are asked to check some local setting or variable on their device. Microsoft owns the responsibility for recording the support ticket and following through until the issue is finally resolved. But you should remember that Microsoft support professionals cannot make changes within a data center. All they can do is record, probe, and diagnose problems. Sometimes that will be enough to get a resolution and sometimes they will need to escalate from first-level support through second-level support right up to the elevated heights of the few who can make changes that affect how an application works if that’s what is required to fix a problem.

Progressing a problem through many interactions with different levels of support takes time. Multiple phone calls and email interchanges are likely going to be necessary to keep an issue moving toward resolution. Don’t blame the support personnel – they follow a strict playbook to gather information, suggest fixes, and escalate when required. Think of how you’d function if you had to understand the myriad of different circumstances that customers who report problems are in. It sometimes takes a lot of time to simply understand what’s going on before you can move toward resolution.

Microsoft uses a mixture of subcontractors and Microsoft badged employees to provide first-level support ([access is described here](#)). First-level support handles incoming calls. Like every software-as-a-service vendor, Microsoft wants to resolve as many calls as possible on the first contact, and ideally, that first contact will be handled using automation. They have an elaborate process for call handling. This starts when calls are registered in Microsoft’s ticketing system and a structured approach is taken to recording details of the incident that can lead to a fast resolution if the problem and its solution are already known. Calls that cannot be resolved by first-level staff are escalated to second-level support. These individuals usually possess deeper product knowledge and are better able to diagnose and resolve complex support situations. Because Microsoft uses a [DevOps](#)-based model for its cloud systems, the most difficult calls eventually escalate to the product group responsible for the area where the fault lies. At all times, customer confidentiality and data privacy are respected.

When you report a problem to Microsoft, it is critical to keep careful notes of the date and time for each call or other contact and record to whom you spoke, what was discussed, what actions should occur, their

expected outcome, and when this should happen. Apart from simply being good sense to record information about support incidents, this information will be invaluable if you need to request an escalation or wish to review why a problem is not being resolved, perhaps by contacting the supervisor of the support professional with whom you are working.

Communication with end-users is also critical. They probably won't realize, or care about, the details of the complexity of cloud services, nor should they be expected to understand the links between the client software and an application. They care about being able to get their work done. Making sense of the complexity and managing support calls is the new role for the local IT department. When you communicate with them, try to do so frequently and in clear, plain language, including a timetable for when you will be able to give the next update. Keep in mind that you may need to establish more than one way to notify users of outages or problems since you can't automatically assume that email will be available.

**Limited responsibilities:** Microsoft makes it quite clear what they will and will not support when it comes to calls. Basically, they won't support anything having to do with your networking infrastructure, your hardware, any third-party software, or any Microsoft software that isn't part of Microsoft 365. They also specifically disclaim that they won't support your operational procedures or service management processes.

## Making the Decision to Embrace the Cloud

So far, we have concentrated on removing some of the FUD that surrounds cloud services. Now let's move on to consider a few scenarios—some where the decision to embrace the cloud and move to the cloud is easy, and some where complications might make things a little more "interesting".

### Reasons Why Moving Might Be Easy

As you might expect, the decision to move to the cloud is much easier for some companies than it is for others. Broadly speaking and accepting that these are high-level generalizations, the characteristics of companies in this category include:

**Start-up companies:** Why would any start-up want to create its own IT infrastructure when most, if not all, of the services they might need to use are available in the cloud? Apart from anything else, buying at a fixed cost per month is usually better for cash flow. The (rare) exception to the rule is companies that have been created to develop a product associated with an on-premises server product like Exchange. In this case, it is a good idea to eat your dog food and run some Exchange servers.

**Small to medium companies:** Anecdotal evidence shows that much of the initial migration to Office 365 came from companies with less than 500 employees, many of whom had run older generations of Microsoft servers such as Windows Small Business Server. Replacing old servers (some that resided in the proverbial cupboard or under someone's desk) with the promise of evergreen functionality offered by the cloud is very attractive, especially when the migration of mailbox data is relatively straightforward as the volume is small enough to accomplish a smooth switchover over a weekend. These companies tend to be "all in" the cloud and don't need to operate hybrid environments so they aren't interested in aspects such as federation and single sign-on. Microsoft provides a [FastTrack deployment service](#) for Azure, Microsoft 365, Office 365, and Dynamics to help companies like this that purchase 50 or more licenses (the exact number varies according to [what you buy](#)). The fact that Microsoft considers that many of the onboarding operations necessary to move these companies to the cloud can be executed on an almost factory-like production-line basis indicates the relative ease of the switchover, especially for small to medium companies whose needs do not extend past email. More complex email scenarios (for instance, those involving specific regulatory oversight) and SharePoint migration usually need the services of a specialized migration partner.

**Fortune 500 companies:** Including Fortune 500 companies after small to medium companies might seem strange, but the fact is that most if not all the Fortune 500 companies have some element of work running on Microsoft 365. Sometimes a tenant domain is taken to reserve it for future deployment. Sometimes it is used to test the waters for a planned move to the cloud. And sometimes it is because the company is in the process of moving some, and maybe all, of its workload to Microsoft 365. Hybrid deployments are the usual rule of thumb for very large companies in this category because this approach is most flexible and allows transparent co-existence across the two platforms, including a shared directory, integrated mail flow, and access to data.

**Moving from a non-Microsoft email system:** Microsoft supports the migration of IMAP4-based email systems (including Gmail) to Exchange Online. Older POP3 accounts are more of a challenge because these typically must go through an interim step where messages are downloaded to a PST with Outlook and then imported into Exchange Online, again using Outlook. It's a manual process that can be tiresome. Migration from other email systems such as Lotus Notes or Novell GroupWise can be done using separate tools bought from companies that specialize in the migration area. Table 2-1 lists some of the well-known companies in this space. Take the time to download trial versions of their software to establish the tool that is the right choice for you.

<b>Company</b>	<b>Migration Tool</b>
BitTitan	<a href="#">MigrationWiz</a>
Code Two	<a href="#">Office 365 Migration</a>
Quest	<a href="#">On Demand Migration Migration Manager for Exchange</a>
Skykick	<a href="#">Enterprise Migration Suite</a>

Table 2-1: Email Migration Software

**Strong needs for flexible scaling:** some organizations have strong requirements to scale up or down based on demand. One obvious example is schools and universities, which have long experience in moving from full operations during the academic year to a reduced mode (or even shutdown) over holidays and breaks. Other examples include businesses with high numbers of seasonal or temporary workers. Microsoft's Windows 365 offering is designed to play to this market, but the overall flexibility of Microsoft 365 serves it as well by greatly reducing the requirement to plan, buy, deploy, and manage on-premises infrastructure to provide collaboration tools to users.

**Educational institutions:** Many universities and colleges used earlier versions of Microsoft cloud-based email or have experience running a competitor's cloud-based email. These institutions find it easy to move from on-premises servers to the cloud.

Again, these are generalized comments and individual country-level markets differ in terms of the mix of accounts that have moved to Microsoft 365.

### Reasons Why Moving Might Be Difficult

The categories listed above are examples of organizations that are relatively easy to move. Now let's look at some of the circumstances that can complicate matters. They include:

**Multi-location or multi-national:** It is much easier to coordinate the movement to Microsoft 365 if everyone (users and IT staff) shares a common location. Planning becomes more complex as the number of locations grows and more complex still if multi-national locations are involved. The needs and legal requirements of each country, including security and privacy, should be factored into a migration project. Some applications (including Exchange Online, SharePoint Online, and Teams) have multi-geo capabilities, but others (like Planner and Yammer), do not.

**Tight integration between applications and business processes:** Many companies have integrated email with business processes in some way. For instance, when HR registers a new employee, a mailbox is created automatically, and a welcome message is sent to the mailbox. Exchange Online supports Exchange Web Services (EWS), the Graph API, and PowerShell, so it might be possible to move existing email-enabled processes to the cloud. The same issue might occur if SharePoint is integrated with some business process, but the APIs used on-premises can't be used or are more limited in the cloud. Microsoft's longer-term direction for extensibility is based on the Microsoft Graph covering all its cloud workloads. Alternatively, you could keep some on-premises servers to handle applications that cannot be moved easily into the cloud.

**Large tenants:** The more users are involved, the longer a migration will take. Migrations are never popular exercises as they involve lots of repetitive operations (moving mailboxes or documents) that are prone to problems (corrupt items and other issues) that take a long time to achieve, especially when moving mailbox data across the Internet. Given the right experience, good project management, and network connectivity, it is possible to move several thousand users per week – but it is not easy.

**Capable of running a private cloud:** Small companies have small IT departments and the people working in IT there have to be jacks-of-all-trades who are expected to be able to work with many different technologies. Larger companies can afford to have specialists and specialization tends to enable a more sophisticated IT environment. These companies might have the necessary expertise and operational maturity to be able to run an internal cloud that can host on-premises versions of products like Exchange at a price point comparable to the costs of using the cloud equivalent. On the downside, more functionality is available in the cloud; Exchange Online and SharePoint Online have many features that will never be available on-premises and there are of course no on-premises versions of Yammer, Teams, Stream, or Planner.

**Poor network links to the Internet:** Sometimes we forget that not every company enjoys high-speed and reliable Internet connections. It might be the case that offices are stuck at the end of an extended hub-and-spoke network that simply needs to be upgraded or it might be that poor connectivity is a fact of life in some or all locations. Microsoft 365 users depend on the Internet to connect to Microsoft data centers. The exact bandwidth and latency required are dependent on the client mix (Outlook creates more demand on the network than OWA does, for example), the number of users, and working patterns (always size for peak demand plus contingency). Remember that you also must move user data to the cloud, a process that won't be quick if the network lags.

**Old clients:** As we'll discuss in more detail later in the book, Microsoft defines specific requirements for clients to connect to the service. Exchange Online only supports certain versions of Outlook and browsers, and they are rapidly moving away from supporting legacy protocols such as basic authentication. Organizations with older versions of clients or devices in use should factor upgrades into the migration. Deploying a new version of the desktop Office applications, performing a complete desktop refresh, or replacing all your old multifunction printer/scanner devices is expensive and takes time and attention to detail to ensure no disruption of user productivity. The Microsoft 365 enterprise apps use streaming and virtualization technologies to simplify the installation process; this is an excellent way of addressing the issue of outdated desktop software as it allows workstations to download and install updates automatically.

**Recent on-premises upgrade:** A company that has recently (in the last two years) upgraded its IT infrastructure might not have the appetite to go through the additional step of moving some workload to the cloud. They want to get a return on their on-premises investment. However, this is becoming a less common issue as Microsoft slows down the rate at which they release new versions of on-premises software.

**Special regulatory or operational circumstances.** Organizations that operate in highly regulated sectors, including financial services, life sciences, and aerospace, may have specific requirements that make the cloud inhospitable. Microsoft has steadily been broadening its offering to help address regulatory needs for things

like compliance with US financial reporting laws and EU data privacy laws, but there still may be very specific scenarios where the cloud doesn't support a government or other requirement.

**Institutional distrust.** Some people, and organizations, distrust the fundamental concepts of cloud computing. For example, I've talked to multiple organizations in the European Union who are reluctant to move to Office 365 specifically because it is operated by a US-based company, and they distrust Microsoft's ability to resist demands for access from intelligence agencies either in the US or in their own countries. You can certainly argue whether this distrust is reasonable or rational, but it absolutely exists, and for some organizations, it may be the key factor that slows or blocks their movement to the cloud.

Of course, other complexities exist that are not on this list. For instance, any company that is already running on a hosted email service such as a managed service based on on-premises Exchange will have their own difficulties to overcome.

## The Unique Challenges of Tenant-to-Tenant Migrations

Most of the time, migrating to the cloud is conceptually straightforward: you have some on-premises data and you want it in the cloud. The details of how you accomplish that goal can be quite complex, but the underlying idea is simple. That's not the case for migrations where you want to move data from one Office 365 tenant to a different one; these "tenant-to-tenant" (or just T2T) migrations can be frighteningly complex for a variety of reasons.

You might wonder why anyone would do such a thing. The biggest driver of T2T migrations is merger, acquisition, and divestiture (MAD) activity. For example, it's common in the pharmaceutical industry for company A to buy company B (a merger) and then spin off some part of the company to form a new enterprise, company C (a divestiture). Tenant consolidation is also common; companies that grow through acquisition (as is common in the media and IT industries) don't want to have separate tenants for each acquisition, so part of the process generally involves consolidating data and users from the acquired companies into a single entity. The largest of these that I've personally been involved with was for a large media and advertising company that moved 135 separate Office 365 tenants, with more than 110,000 total users, into a single large tenant—a challenging process at the best of times.

Microsoft does not yet have a single consolidated toolset for performing these migrations, so you will need to choose a third-party tool that meets your needs (such as Quest's [On Demand Migration](#) tool). Some of the issues you should consider when planning a T2T migration include:

- **Workloads:** Migrating Exchange mailbox data and OneDrive files is pretty simple. Past that, workload migration rapidly gets more complex and difficult. For example, if you have extensive SharePoint customizations or lots of Power BI data, flows in Power Automate, or videos stored in Stream, you'll find that different workloads have wildly different levels of support. Part of this is because Microsoft has not provided complete import, export, or migration APIs for some workloads (notably Power Platform and, regrettably, Teams); part of it is because the more complicated the workload, the more individual components or repositories are involved (Teams again).
- **Planning:** as with any large-scale migration, understanding what you have is a critical step in planning and scoping your migration. As you'll see in Chapter 4, the built-in reports Microsoft provides are limited in flexibility and scope, and you'll probably find that they're not usable to plan your migration. Quite apart from that, the logistics of migrating data from one tenant to another in a way that allows users to continue their work are challenging themselves.
- **Dividing the data:** consider a divestiture, as when General Motors sold the assets of its Saab business unit to the Dutch carmaker Spyker. Someone had to decide, for every user, file, and mail message, whether to include that item in the divestiture. Of course, most of this work is automated and pro-forma—if a user named Joelle Smith is moving to the divested unit, the normal assumption is that all

her files and messages should go with her. However, determining what to do with data in SharePoint libraries, OneDrive libraries belonging to users who have left the company before the divestiture or will be laid off as part of the move, and shared repositories in Teams, on file shares, or in Exchange public folders can be a daunting problem of its own.

- **Soft issues:** a surprising number of T2T migration efforts become hung up on completely non-technical points. For example, the 135-to-1 migration I mentioned earlier featured some passionate fights about the naming of conference rooms in the Exchange Online room resource list; each faction had arguments and supporters for the naming scheme they used, and resolving the issue required executive attention. Now multiply that by the number of political, reputational, and control issues we've already discussed, and you'll begin to get a sense of the scope of problems that can arise, and for which migration tools cannot provide any help or even guidance.

## Following the Money

Now that we understand the various categories of companies that might consider moving to Microsoft 365, let's consider the money question.

On the surface, saving money seems like an excellent justification to move to the cloud. Many commentators focus on the fixed per-month subscription fee and compare this to the all-in cost (if it is known) to run an in-house system. Salespeople who want to push the virtues of the cloud love to talk about the fixed price per month, especially if they can get you to focus on the lower-cost plans. Once you start thinking that you can buy cloud services for \$6/month per user, that impression fixes itself in your mind, and a certain view that "the cloud is cheap" forms. It can be very difficult to change this impression, even when you realize that you need one of the more expensive plans and will pay \$23+/month per user.

Invariably the comparison is positive for the cloud because organizations often do not fully understand the complete cost picture and therefore do not factor all the cost elements into the equation. It's true too that the notion of paying a fixed monthly cost is attractive because it allows the company to manage cash flow more precisely than the sometimes-erratic spending patterns of IT. It is also clear that cloud systems are more flexible than in-house systems when the time comes to add or reduce capacity.

## Figuring Out Cloud Costs

You will never quite know what the actual cost base for a cloud deployment is until after you complete the deployment phase (migration of users and applications) and operations stabilize. Only then will you know exactly how much the cloud is costing and where those costs lie.

Before you decide to embrace the cloud, it is wise to figure out exactly what the current on-premises environment costs—assuming you have one. You obviously can't make a 1:1 comparison for workloads such as Teams that don't have an on-premises equivalent. You will need data about your on-premises environments to compare against cloud expenditure to show any savings. Let's discuss the typical cost buckets that you should consider, beginning with an understanding that most organizations don't have a clear understanding of exactly what they spend in any of these categories:

- **Hardware:** An on-premises deployment likely contains several different server roles, including Active Directory, Exchange servers, mail hygiene or bastion servers, SharePoint servers, Skype for Business servers, administration systems (workstations and servers), and servers for ancillary services like backup and restore or network monitoring. Some of these servers might run as virtual machines on a hypervisor (like VMware or Hyper-V). You need to capture details of all the servers involved in the workload to move to the cloud and figure out their annual running cost, including capital depreciation, warranty and support costs, finance charges for leased equipment, replacement cost, power consumption, cooling, and other data center expenses. You'll also need to consider that,

thanks to the normal evolution of things, you might be decommissioning some of those servers anyway (such as Skype for Business servers).

- **Software:** although you will probably save a good bit of money on server OS and application licenses, if you remain in hybrid mode your server count won't go to zero. You may still end up with on-premises servers for Active Directory, directory synchronization and federation, service monitoring, message hygiene, and archiving. Some of these servers might be replaced during the migration but some might not. Of course, you also must buy client access licenses (CALs) for many of Microsoft's services, which means you'll need to map the CALs you currently have for user services to the equivalent Microsoft 365 products. Remember to include all on-premises functionality in your calculations and then find what plans best match your needs. Standalone Exchange Online and SharePoint Online plans exist for those who do not need the full range of functionality available in a plan like Office 365 E3. Kiosk (web-only) plans exist for "frontline" workers, people who do not have workstations and only need intermittent access to applications like Outlook or OneDrive. You must decide whether you need functionality like Defender for Cloud Apps, Advanced Threat Management, or Advanced Compliance to justify buying Office 365 E5, and how many people need such a plan. Another thing to consider is whether it is cheaper to buy a lower-cost plan and then buy add-on components to make specific functionality available to selected users.
- **Legacy Microsoft Office applications:** You might be quite happy to run Office 2010 on your desktops. Unfortunately, Microsoft has a different opinion; they only support a subset of Office versions when connecting to the service (see Chapters 4 and 15 for more details). If you have unsupported versions of Office, you should consider upgrading to Microsoft 365 apps for enterprise to ensure that the Office desktop applications receive updates automatically over the Internet.
- **Complex line of business applications:** Most companies have applications that they have built in-house. These applications range from Visual Basic programs and Excel macros to full-blown database applications. Some of these applications might have dependencies on the workload that you plan to move to the cloud and might therefore need code changes so that they can continue to function afterward. That is, if you can find the code and have someone available who understands how to make the necessary updates to the code. One major factor to consider is that Microsoft 365 does not allow programmatic access to the data that it manages in the same way that is possible on-premises when you control all the moving parts, so programmers must use new APIs (the Microsoft Graph is the preferred approach) to interact with online services. In turn, this might involve some retraining or knowledge acquisition. However, you also get some significant benefits from Microsoft's support of the Power Platform for low-code application development and the possibilities of easier integration with customer- or accounting-oriented data stored in Dynamics.
- **Your network:** The cloud can't function unless you can access its services, and that means connecting across the internet to Microsoft's data centers. You need to understand just what kind of access your company will need to the public Internet to carry the anticipated traffic to Microsoft 365 and all other Internet traffic that your business needs, plus a reasonable uplift for anticipated growth over the next few years (as there is no point in upgrading to a connection that just about copes and runs into problems soon thereafter).
- **Your people:** Running an on-premises environment needs knowledge of and experience with Windows, Exchange, SharePoint, and all the other products that combine to form an enterprise environment. Over time, the people who run IT systems develop a certain insight into the company and how it conducts its business. For that reason, I hesitate to say that companies can achieve workforce savings by transitioning workloads to the cloud. Perhaps it is possible to save by letting some operations staff go because administrators no longer perform tasks such as server maintenance, but usually, you find that other work appears to fill the vacuum left by work now done in the cloud.

For example, in a hybrid environment, someone must manage tasks such as directory synchronization, single sign-on, certificates, and mail flow. Even though Microsoft may be doing the work of running the service in daily operations, someone still must administer those applications on behalf of your company. During the migration period, administrators will have plenty to occupy themselves as workloads move to the cloud. Afterward, they will have new tasks to perform (such as hybrid management) and can take on new responsibilities, such as setting up enterprise voice operations based on Teams or creating a document management strategy for the company that exploits SharePoint Online and replaces old Windows file servers with OneDrive for Business.

- **Change management:** Hopefully, some of your existing staff will have both the desire and the ability to act as change managers for the new deployment. In this role, they can investigate new capabilities that the company has never been able to exploit because of staff unavailability, such as figuring out how best to leverage the Microsoft Graph for business-specific solutions. And they can dedicate time to set up a monitoring framework that deals with both on-premises and cloud components and is available to administrators, support staff, and potentially even users. Change management is an ongoing process, and it's critical—don't be tempted to skimp on the cost! The time and money you will save through properly tracking, anticipating, and dealing with changes in Microsoft's platform dwarfs the cost of implementing an effective change management system even if you must hire additional people.
- **Training:** Moving to the cloud will cause considerable upheaval within your technical infrastructure. That upheaval affects users, administrators, support personnel, and managers alike. Users need training to work with new software (like how mastering the most effective technique to find documents with Microsoft Search or the proper etiquette for using Teams) and how to recognize and cope with common issues, such as a glitch with Internet connectivity that means they cannot connect. If you enable something like multi-factor authentication to augment security or use new features exposed in the service like sensitivity labels and message encryption, users need education on these points too. You'll need to address training for your administrators, your service desk and support staff, anyone involved in network or infrastructure monitoring, your security team, and even the executives or managers who oversee all these services—in fact, educating them may be most important of all as they cannot make good decisions without a thorough understanding of the differences between their old on-premises environment and Microsoft 365.
- **Everything else:** most organizations have third-party products that may or may not be useful in a Microsoft 365 deployment. Security, monitoring, reporting and auditing, backup, compliance, and automation are all areas that are often handled by non-Microsoft products, and you may find that the solutions Microsoft offers for these areas in the service are good enough for your needs... or the opposite. In all cases, before you commit to the extra cost of a third-party product, make sure that you do the research to check if some functionality already exists that satisfies your requirements. Given the speed at which cloud services evolve, it could be the case that an assessment made a year or two ago is no longer valid, so always check to understand the current situation.

## Updating Your Network to Support Cloud Services

In many respects, "the cloud" is shorthand for "the Internet." No cloud project can succeed without reliable high-speed, high-capacity connectivity to the Internet, so the first and most fundamental question that you must answer when considering a move from an on-premises infrastructure to use cloud services is this: can your network infrastructure cope? It is surprising just how many companies discover that they might have difficulty securing enough high-quality bandwidth given how much advertising for Internet providers floods the world, but it does happen. In these instances, all you can do is wait for the local network provider to upgrade their pipes.

Apart from Internet connectivity, organizations that move to the cloud often discover that their internal network infrastructure is not fit for purpose. This is quite normal. You cannot expect a network design created to serve the needs of an internal infrastructure where servers and clients are co-located on the same wide-area network (WAN) to suddenly transform itself to be able to cope with completely different traffic patterns and user demand. Thus, a move to embrace Microsoft 365 is an opportunity to review your network from several perspectives.

- Is your existing internal network configured for maximum performance? For example, customers sometimes find that they have ancient and incorrect network routes that send traffic along suboptimal paths stashed away from previous network upgrades, or that their TCP or IP network settings for things like auto-negotiation aren't properly set. Before your migration starts it would be a good idea to review the underlying quality of your network. You'll want to ensure that you have the most efficient routing possible from where your clients are located to Microsoft's service "front door" locations.
- Do you need to upgrade your internal network to handle a higher volume of client traffic to Microsoft cloud services? We already discussed the need for more bandwidth, but you also need to account for a possible increase in load caused by additional TCP/IP sessions consumed by users as they connect to Microsoft 365. A single user can consume up to 20 sessions to connect to Exchange Online, SharePoint Online, OneDrive for Business, Teams, Planner, and other services. To help, Microsoft publishes information about [network planning and performance tuning](#). Another page covers [network capacity and devices](#), including elements such as WAN accelerators. Another interesting source of information is the [Microsoft Cloud Networking for Enterprise Architects poster](#). This poster shows some of the changes in an on-premises network that tenants might need to make to support connectivity to Microsoft cloud services.
- What ports and IP ranges must be available through firewalls to allow users to connect to cloud services? To help in this task, Microsoft regularly publishes updates for the [URLs and IP address ranges](#) they use with a [web service](#) to inform customers about changes in their network, including updates to route traffic to Microsoft 365 and how to avoid latency and other network challenges.
- If you're upgrading applications as part of your move to the cloud, will those changes themselves require additional network resources? For instance, both the cloud and desktop Microsoft 365 applications have an AutoSave feature to capture changes made to documents during editing sessions so that users do not have to save files. Every AutoSave operation creates an update and syncs it to OneDrive or SharePoint Online. The save might then trigger OneDrive sync operations back to other devices.
- Do you need to make network security changes? For example, if you deploy MFA to protect Microsoft 365 applications, can you use Azure MFA to protect other applications? Is your cloud migration an appropriate time to deploy new services (such as deep packet inspection, WAN acceleration, or cloud application security improvements) or would you be better off doing those separately?

## Understanding Changes in Client Traffic Patterns

Client traffic patterns change with the cloud because the target servers are no longer within the internal network. Instead, clients connect via HTTPS across the Internet to Microsoft 365 and Azure service endpoints. The outbound links that connect your company to the Internet must be able to support the new volume of traffic. The exact type of link needed varies depending on the number of clients that you expect to be active at any time, the type of clients, and the cloud services they will access. Although Microsoft has created a large network of local front-end points of connection (or "edge nodes") to speed traffic to its data centers, unless the link from your company locations to Microsoft's network can carry the amount of traffic your users generate, they will not be able to work as well as they should. Once traffic enters Microsoft's network, it is

carried across fiber to its destination data center. Microsoft's cloud network, including other services like Azure, spans enough fiber to stretch to the moon and back three times. The combination of edge nodes and fiber networks means that it is usually possible to make a fast connection to Microsoft's network, wherever you are in the world. That is, if your local or last-mile connection can carry the traffic.

Microsoft used to post static maps of their network, but instead, they now offer [a flashy interactive model](#). The model shows data flows, renewable energy generators, Azure and Microsoft 365 data centers, and network points of presence, with each type of item clickable so that you can get more information on specific items.

If you run on-premises servers today, you probably have some data to show how much network bandwidth applications and users consume. One rule of thumb is to double (some say triple) this figure and use that amount as the basis for planning. Advice and guidance on this topic evolves over time as cloud services change and knowledge increases, so it is best to ask Microsoft or an experienced consulting company for their recommendation as to the capacity you need – and to then add 30% or so to cater for growth in user demand and to accommodate new applications and features which affect usage patterns and consumption. It is therefore important to keep an eye on changing demand over time.

If this seems like an unnecessarily high increase in bandwidth, consider the experience of companies that deployed Teams for voice and video calling before the COVID-19 pandemic—Microsoft has worked very hard to optimize the codecs used in the service, but users have been so eager to adopt these communication methods that average bandwidth consumption at every customer I've worked with since Teams' debut in 2017 has gone up significantly year-over-year, and above increases in employee count. Organizations that moved rapidly to telework because of COVID-19 often have legacy VPN systems, and people who are used to them; if your users VPN into the corporate network and then connect to Microsoft 365 services, both your network and your users will suffer poor performance—split tunneling (described in Chapter 15) will help with this. If you have a consolidated network where traffic is backhauled from remote offices to a central location, you should also investigate providing a separate link per location. This will deliver better performance and uptime.

Remember that moving to the cloud will not make a bad internal network any better. In fact, if users rapidly adopt new cloud applications (especially features that use more bandwidth, such as video conferencing), you may see a disproportionate impact on your overall network quality. If that network is barely able to cope with the demands of on-premises client-server connections, it will do no better and is likely to do worse when cloud services take over.

During the migration period, the volume of network traffic will be higher than normal because of the need to move information like mailbox data and documents to the cloud. After the migration period is over, network demand should settle into a more predictable load. There will be peaks and valleys in demand, but you should be soon well acquainted with the general shape of network demand for each of your company's locations and be able to make whatever changes are necessary.

### What About ExpressRoute?

Although an expensive option, it is possible to implement a dedicated network connection between your company's network and Microsoft's network, such as [Microsoft's Azure ExpressRoute for Office 365](#) service. ExpressRoute uses a dedicated MPLS connection between your network and Microsoft's network to ensure that traffic flows as if it were on your internal network. Microsoft doesn't recommend the use of ExpressRoute for Microsoft 365, and they won't let you use it unless you're able to persuade them that you should be granted permission. If you think you might need it, read their [service guide](#) first for more details.

### What about Informed Network Routing?

Software-defined network (SD-WAN) solutions have become increasingly common in large enterprises because of their flexibility and capability. Instead of using a fixed network configuration, SD-WAN solutions

can be reconfigured, often automatically, to adjust to changes in loading, network damage or outages, or changing requirements. If you deploy SD-WAN solutions, special devices known as SD-WAN [controllers](#) aggregate usage and quality data and use it to push configuration changes to the network.

Microsoft recently added limited support for SD-WAN integration through a feature they call [Informed Network Routing](#). If you have compatible equipment (limited as of January 2022 to Cisco IOS XE), you can enable performance and network quality data from Office 365 to be funneled to your SD-WAN controllers so that your network will dynamically adapt to changes or problems with the network. This is a promising technology, but in practice, it's still too limited to be useful to most of us. It requires equipment from a specific vendor, and you won't get any real benefit from the feature unless your network has multiple redundant paths to the Internet—if you only have one route to the service in the first place, the adaptive nature of SD-WAN can't do much for you. However, as with many other high-end enterprise technologies, as SD-WAN becomes less expensive and more widely deployed, it may add value to your network.

### Planning for Different Types of Network Traffic

When you plan for new network capacity, make sure that you accommodate four types of traffic that may be required *de novo* as part of your upgrade:

- **User connections to the new cloud environment plus existing work.** Remember that users often make use of company networks to access external social sites such as Facebook and Twitter during work hours. You can try to restrict this access but, in many cases, this is like pushing water uphill, so it is best to include a certain overhead for personal network activity. Different clients often have different network characteristics. For example, Outlook desktop clients consume more bandwidth than OWA. As explained in Chapter 14, Teams voice and video conversations are sensitive to network conditions and need certain basic capabilities to be able to function. Microsoft has [network calculators for Teams and Exchange](#) that help assess likely demand (further information is available [here](#)).
- **Migration of user data to the cloud.** You might be able to move 500 users in a single cutover operation during one weekend—but migrating 50,000 users will probably take a little longer. In either case, you'll be moving data from your internal network across the Internet to a Microsoft data center. Depending on how much data is involved and the available throughput from your network to Microsoft, that movement could take longer than you think. It's also worth considering the impact of where your Office 365 tenant is homed; it's entirely possible, based on its usage location, that you will be migrating data from a physical data center in one country or region to an Office 365 data center in a completely different part of the world. For example, consider a US company that creates a tenant (homed in the US) to consolidate its worldwide operations. As it migrates data from its regional data centers in the UK, EU, and Australia, much of that data will end up by default in US data centers, meaning it must transit from its original location across at least one ocean.
- **Client updates.** The way that Office desktop applications are updated in Office 365 may be different than the way you've upgraded them in the past. Because the default state is to let every device fetch updates whenever it wants to, you may find that your client OS and application updates consume more bandwidth (or at least consume it in different patterns) than they did when you used centralized updates.
- **Administration operations.** Intelligent applications like Outlook isolate users from the effect of network outages and allow them to work offline. However, all Microsoft 365 administrative operations occur online, and a reliable (and fast) network connection is necessary if you want to be sure that administration can be performed without difficulty.

You should also keep in mind that Microsoft has gone through a lot of effort to categorize its network endpoints according to the network priority they should receive; see Chapter 15 for more on how you can work with these categories to prioritize the most important client-facing network traffic to Microsoft's data centers.

## Getting Executive Buy-in and Communications

Few major projects succeed without executive buy-in and support. A good communication plan to explain why the project exists and the benefits expected to accrue to both the company and employees is also important to offset the upheaval that might happen as mailboxes are migrated, networks change, and clients are updated.

Executives should focus on simple messages like:

- We are upgrading our employees to the best-of-breed office productivity software from Microsoft.
- Using the cloud will help us be more flexible and adaptive to changing business circumstances.
- Employees who worked on our previous on-premises systems will now work on more important projects, such as figuring out the corporate strategy for using SharePoint Online, making better use of Teams meetings and the Microsoft Phone System (perhaps as a replacement for a traditional PBX), or determining whether Teams, Yammer, or Microsoft 365 Groups is the most suitable collaboration platform for the business.
- Moving to the cloud is a safe and secure choice.

The communication plan needs to cover:

- A summary of what's happening – the company is upgrading and improving its email and collaborative capabilities by moving to Microsoft 365.
- When the changeover will occur and when employee mailboxes, SharePoint sites, etc. will be migrated.
- What functionality changes and improvements that users will see and how these updates will make work easier. Some simple scenarios might be included, such as how to set up a group mailbox to support project teams.
- Tips and techniques for making a smooth changeover.
- Anything an employee must do to enable connectivity with Microsoft 365. For instance, those running older versions of Outlook or old browsers might have to upgrade their software.

Every company is different, and the suggestions outlined above are merely the start of the discussion about how to lead people through change.

## Working with Microsoft Partners

Not every company moving to the cloud will have the interest, skill, time, and budget to do all the work themselves. Many organizations choose to work with outside Microsoft partners in the hope that doing so will make their journey to the cloud simpler, faster, and/or less expensive.

Microsoft stokes this hope through their [FastTrack program](#), which promises free onboarding aid for customers who buy more than 50 seats and will provide some funding to accredited partners to help with migrations. FastTrack funding can be very helpful to offset the overall cost of a migration. However, FastTrack migrations are very structured and follow a strict playbook, so they might or might not be enough for your needs. A small company that wants to move from on-premises Exchange to Exchange Online will probably be fine, but FastTrack is unlikely to be enough for complicated migrations. This is when you might need to either run the migration yourself or seek the help of a Microsoft partner.

Of course, given enough time to learn and experiment, any experienced Exchange administrator could prepare a tenant and move mailboxes to it. The steps needed to configure hybrid connectivity are largely automated and well understood so that attention to detail and good preparation will get most administrators through the process. In general, the migration of a normal Exchange setup composed of a single organization based on a single Active Directory forest is usually straightforward.

On the other hand, the kinds of details that cause problems may include single sign-on (SSO), combining multiple Exchange organizations, providing identity federation, handling complex mail routing or message hygiene, and hybrid co-existence. As the complexity and/or size of your migration increases, so does the likelihood that you'll need outside help. Of course, during a typical enterprise migration, you'll need to keep your existing on-premises infrastructure running, you might need to engage some outside help to make the project happen in a reasonable period.

When you start considering how to find a reliable partner, you can of course work directly with Microsoft Consulting Services (MCS).

There are many other types of Microsoft partners, though, including partners who also sell migration tools and Microsoft Cloud Solution Providers (CSPs) that specialize in delivering managed services. Many small to medium tenants use CSPs to manage their tenants on an ongoing basis. However, note that some CSPs only resell licenses and don't provide any management or migration services.

Although expensive, MCS has the advantage of being part of Microsoft and offers the reassurance of having a single throat to choke if anything goes wrong. On the other hand, independent partners often offer more realistic opinions about how to run successful projects and the likely pitfalls that exist along the way. In addition, they often have deep knowledge of third-party solutions that can help solve some of the more complex situations that occur in migration projects.

When you consider whether a particular partner is a good fit, here are some things to think about:

- Who will be doing the work, and what are their credentials and experience? Apart from Microsoft certifications, non-Microsoft accreditations such as the CISSP security credential might also be useful, depending on the areas covered in the project.
- Besides accreditations and certifications, you should ask about the experience the partner and its staff have with cloud infrastructures and what projects with similar requirements they have successfully delivered in the past.
- Is the partner a member of the Microsoft Partner Network? A partner who is not a member misses out on many important resources and tools that Microsoft makes available through its network.
- Ask about the skills available in the service provider's Help Desk and how problems are handled. Good partners have substantial resources available to handle a high percentage of problems quickly and effectively without escalating everything to Microsoft. Bad partners take the easy route and act as a channel to Microsoft Support without adding any value.
- What areas of specialization does the partner cover? A partner who specializes in SharePoint or Yammer is probably not a good choice for companies who want to migrate Exchange 2013 to Exchange Online. On the other hand, if your focus is on moving workload from SharePoint on-premises to SharePoint Online, experience with Exchange will not be much help. The deployment of Teams-based voice over IP often needs experience with voice systems, especially when the need arises to replace traditional PBXes. These projects are often done alongside a migration from Skype for Business Online to Teams and might involve hardware such as replacements for room systems.
- If you want to deliver newer parts of the Microsoft 365 suite, or high-end features such as Microsoft Defender for Cloud Apps, information protection, or Advanced eDiscovery, you should find out whether the partner has experience with these lesser-known parts of the platform.

- Application development is different in the cloud. Many newer tools, such as Power Automate and Power Apps, do not have equivalents in the on-premises world and new APIs like the Microsoft Graph are available to expose more data to applications than ever before. If you need to write some code, look for people who know the new tools and APIs before you decide on your partner.
- Do not forget that Microsoft 365 is an ecosystem. Microsoft does not have solutions to every possible feature request or customer need, and it is good to find a partner with knowledge of solutions in areas such as service monitoring and reporting, security, external archiving, backup, and so on.

Apart from these points, you might also ask what contribution the partner makes to the local technical community, how useful their website or blog is in terms of the information that you find there, and whether any of their personnel are Microsoft MVPs as they have background channels to the development group that might be useful in resolving problems that arise during the project. Because Microsoft 365 covers such a wide space, it's also a good idea to understand the area of specialization that the MVPs have. Someone well-qualified in SharePoint Online development technologies might struggle with the finer details of Teams and voice communications.

## Maintaining a “Plan B”

One of the first things I learned during my instrument-flight training: when considering flying in cloudy weather, always have a plan to get out of it *before* you get into it. The Microsoft 365 cloud is no different; as part of your preparation to move into the cloud, you should have a plan to pause or reverse, your migration if you run into trouble or conditions change. Well-planned migrations usually proceed to plan and are successful. Most cloud migrations are, not least because of the expertise available to assist companies in the transition. But wisdom and prudence dictate that you should always have a Plan B – at least in outline – just in case your project experiences problems.

### You Own the Data... But So What?

Whether or not you start your use of Microsoft 365 by migrating existing data into it, you'll certainly use it to create new data. Microsoft makes it clear that tenants [own their data](#):

*"Your data is your business, and you can access, modify, or delete it at any time. Microsoft will not use your data without your agreement, and when we have your agreement, we use your data to provide only the services you have chosen."*

That's reassuring (and obvious!) but, on closer examination raises the issue that there's no obvious way to export the complete set of data contained within a tenant. That means that your ownership doesn't automatically guarantee the ability to pack up your data and take it somewhere else. For instance, you can copy documents from a SharePoint document library to your PC—but is this a realistic approach if you want to capture the entire corpus of information existing in all the SharePoint Online and OneDrive for Business sites within a tenant? That corpus includes lists, document libraries, OneDrive for Business sites, and eDiscovery cases. Even if you move the data items themselves (lists, documents, and so on), you may not be able to capture all the metadata (including audit data and revision histories) for those objects.

Likewise, videos stored in Stream pose a challenge, and if you use Planner, Yammer, Power Automate, and Forms, you need a way to recover their content too. Finally, the increasing role of the Microsoft 365 substrate in knitting different parts of the ecosystem means that apps are more connected and dependent on each other than ever before. Teams is the best example of a cloud-only app that relies on many different components drawn from across Microsoft 365 and Azure. How easy will it be to move content from Teams to another platform?

Third-party software vendors offer utilities to help move content to the cloud, but the same capabilities do not exist to move information back to on-premises servers or other cloud platforms. Given current trends to move away from on-premises servers, this situation is natural as it would take a bold decision to create a migration tool to move content from the cloud.

## Preparing an Exit Plan

No CIO wants to implement a new platform without knowing what will happen if things go wrong. All projects carry a certain element of risk and a project to move a workload to the cloud is no different. Good planning, solid project management, and technical expertise all mitigate the risk, but some cloud projects will end up at a point where management decides that on-premises is the better option. You must then figure out how to move content back from the cloud platform and resume operations on-premises.

Thanks to the engineering investment made by Microsoft to enable hybrid connectivity, Exchange is the easiest application to move back on-premises. Mailboxes can be transferred back to on-premises servers as easily as they can move to the cloud. The only downside is the amount of storage that might have to be deployed to accept inbound mailboxes because users might have become accustomed to the liberal mailbox quotas assigned by Exchange Online. Another complication is how to deal with content stored in inactive mailboxes or auto-expanding archives; it is easy to overlook these items because they do not show up in all administrative interfaces and reports.

Mailboxes and documents are usually easy to move but everything else is hard. You must make sure that you move any customization made to Exchange Online back on-premises so that things like PowerShell scripts, transport rules, Data Loss Prevention rules, retention policies and tags, and so on are moved across. Again, if you are in a hybrid environment these settings should already be duplicated to ensure that the cloud and on-premises platforms remain in tandem, but there's work to be done to make sure that everything is synchronized.

If you choose to use sensitivity labels to protect Microsoft 365 data, you might find that it is difficult to access protected content moved back on-premises because it is no longer possible to decrypt that content. A hybrid configuration will help if you keep a connection to the Azure Information Protection service.

Sadly, it's impossible to move some workloads back to on-premises servers. For instance, if you make a big commitment to Teams as a collaboration platform with or without voice integration, what do you do if things do not work out in the cloud and you decide that the best course is to revert to on-premises? You can move documents back to SharePoint Server, but good luck finding an exact replacement for the suite of capabilities baked into Teams.

## Canceling a Tenant Subscription

As long as you continue paying the monthly subscription fees, Microsoft is quite happy to keep your data online. If an administrator removes a license from a user account, its data stays accessible for 30 days and is then removed. The exception is when a mailbox is put on hold before the account is deleted. In this case, the mailbox is regarded as "inactive" and is retained while the hold remains in force (see Chapter 6 for more information).

What happens if you decide that the cloud is not for you and go ahead and cancel your tenant's subscription? (Hopefully, you will have carefully considered this decision in advance and made a plan to recover all the information from the tenant!) When you cancel a tenant subscription, a formal lifecycle process begins that eventually results in the complete and permanent removal of all tenant data. Table 2-2 lists the steps in the tenant removal process. For more information, see [Microsoft's online documentation](#).

<b>Period</b>	<b>Subscription Status</b>	<b>Effect on data</b>
1-30 days	Expired	Users will see warnings about losing access but can continue accessing their accounts and work with data.
31-120 days	Disabled	Only global or billing administrator accounts can access the tenant to either recover data or reactivate the tenant.
After 120 days	Deprovisioned	An automated process starts to systemically remove all tenant data, including inactive mailboxes and any others that were on hold.
Within 3 days of ending the subscription	Expedited deprovisioning	Upon customer request, the process to remove tenant data can be expedited to ensure that all data is removed within three days of the request.

Table 2-2: When tenant data is removed after a subscription is canceled

Note that the processes that remove tenant data after 120 days are constrained by resource availability. The data might therefore be removed after 120 days, 121 days, or soon thereafter. If you need the data to be removed sooner, you must ask Microsoft to start the expedited deprovisioning process by filing a support request. To confirm that expedited removal should go ahead, Microsoft support gives the tenant a lockout code that the tenant must input to the Microsoft 365 admin center. After entering the code, the services will remove the data within three days. It is critical to understand that once the data is removed it can no longer be recovered or reactivated.

Canceling a tenant is a big step. The responsibility for the decision and what happens afterward stays with the customer, who can decide to let the cancellation process play out or reactivate the subscription within the 120-day grace period.

## Understanding User Adoption Behaviors

You may have had the unhappy experience of taking the time to select a thoughtful gift for someone and then learning that they didn't enjoy it, or even use it (or, in extreme cases, even *unwrap* it)! There's a similar problem with Microsoft 365 migrations: suppose you went through the effort of planning and migrating your organization's users to the cloud, and then they didn't like or use the services in the new environment?

While that sounds painful and unpleasant, it happens with depressing frequency. The process of getting users to adopt new technologies is always tricky because users are human, and humans have a wide range of coping strategies to help them deal with change. Some of those strategies are positive, and others are not. You may see any or all the following behaviors in a typical Microsoft 365 migration:

- **Helplessness.** Pity the users who display this behavior; they are often so beaten down by a steady stream of technical and business changes that they can't even muster the energy to be reluctant or resistant. Working to educate and enable these users can be quite challenging.
- **Malicious compliance.** In the spirit of the original Luddites, who gleefully wrecked industrial machinery at the beginning of the Industrial Revolution, users who display this behavior will "work to rule" in an attempt to slow down or completely derail the pace of change. This behavior is often accompanied by passive aggression that shows up as users complaining that they were "just following your instructions" when something breaks.
- **Resistance.** Some users will forcefully resist change. Sometimes this resistance is rooted in personal fear of obsolescence or not being able to keep up; other times it comes about from concerns about the impact of the change on the business. The actual degree of resistance can vary from flat-out refusal to use a new process, tool, or technology to mild, low-level grumbling.

- **Reluctant acceptance.** Users who show this behavior start as resisters but eventually transition to acceptance of the inevitability of the change. That doesn't mean they have positive feelings about the change, merely that they accept that "it is what it is" and will use the tools on offer.
- **Enthusiasm.** Enthusiastic users are good. However, enthusiasm without knowledge is a bit of a dangerous combination because it encourages experimentation, which may not always be what you want.
- **Evangelism.** This is the best you can hope for when introducing a new technology into your organization. Evangelists not only embrace technical changes; they actively communicate its benefits to other people and encourage them to try it for themselves. Building an active core of evangelists (which I'll discuss shortly) will make your migration much easier by distributing the load of educating and enabling users.

## Enabling and Empowering Users

The keys to getting buy-in and adoption for your Microsoft 365 environment are simple to explain but harder to achieve. Three primary elements will unlock your users' ability and desire to use the new system you're building:

- **What they want and need.** Every human being has certain psychological and physical needs. People want to feel respected; they want to have autonomy in their work and to feel that their work makes a difference. Put squarely in the context of Microsoft 365 deployments, the basic tier of needs is that people want to feel listened to when changes are being proposed; they want to feel like their input is being given due consideration, and they want to be able to do their work without what to them may seem like needless hassle. Depending on your organization, its culture, the national cultures in countries where it operates, and the job roles of individuals, there may be many other wants and needs that you should be aware of. The IT needs of someone working on a factory floor manufacturing car tires will probably be very different from the IT needs of the factory manager, and those in turn will be different from the IT needs of the company CIO. The more you can do to investigate and understand these needs, the easier it will be for you to tailor adoption plans and messaging to meet those needs.
- **What they do and how they do it.** As an IT professional, you probably don't know the details of everyone else's job in your organization (although plenty of people probably think they know *your* job well enough to tell you how to do it)! A basic understanding of the major job *roles* in your organization, though, is key to developing good adoption plans. How many people do you have who would be considered classic information workers? How many front-line workers are there? Of the dozen or so most important or most numerous jobs, how much do you know about what their daily IT life is like and how they use your IT systems to do their job? There's an interplay between wants, needs, and job tasks. For example, if you interviewed a field sales agent, she might say that she *needs* access to data about her customers so she can contact them while she's out working. She needs that access because she *wants* to successfully reach and sell to her customers. To get that access, she will *do* something, such as keeping a printed list of contacts on hand to make sure she can still work when there are IT problems.
- **What they know.** A user who wants to do something but doesn't know how will be frustrated. A user who knows how to do something but doesn't *want* to do it will be inert. Both states are bad for adoption.

## Finding Your Champions

I mentioned the role of evangelists earlier. We all know people who are so eager to adopt new technologies that they wait in line for gadget releases, clamor for early access to beta software, and experiment (perhaps

even recklessly) with their computing tools and environments. You may even *be* one of those people. That adventurous and experimental spirit is a big part of what makes a successful evangelist—the other major part is an ability and willingness to share knowledge, information, and enthusiasm with other people who maybe are not quite as far up the learning curve.

The reason that evangelists are important in your migration is that they can multiply your leverage. By using them as guinea pigs to test your plans, communicators who help spread information throughout the user base, and feedback collectors who give you actionable data about how well the migration's being received by users, you can greatly improve the quality of your migration. A good evangelist is essentially a member of your migration team—with the exception that they will usually be delighted to participate in the process and don't have to be budgeted for and hired because they already work for your organization.

How do you find and connect with these potential evangelists? You probably already have a few names in mind just based on the description at the start of this section. You undoubtedly know people who enthusiastically adopt even the newest and most rickety technology, ask for their department or team to be part of critical pilots, or go out of their way to help other people solve their technical challenges. Approaching these people and asking them to help you plan and evangelize the transition to Microsoft 365 can pay significant dividends; they can give you early feedback, help you improve your communications to end-users, provide early warning of potential problems, and generally help keep the process flowing smoothly.

Microsoft has introduced a tool that they modestly call the "[Champion Management Platform](#)" to help you find and support adoption champions in your organization; it consists of a leaderboard, badges, and some enrollment management tools. Provided as open-source, you can modify and customize it as you see fit to meet your organization's needs.

## Improving Migration Planning and Adoption with Data

If you don't have data about the existing environment before you start your migration, then you are essentially just guessing at some of the most important aspects of the migration, especially how long it will take to complete the migration. Perhaps more importantly, if you have good data about what people are doing with the existing system, you'll be much better able to understand their needs and deliver a post-migration experience that leaves the users more satisfied and more productive than one where you turn them loose in a strange new environment without any guidance or planning.

### Understanding User Activity and Tasks

It's tempting to assume that, based on your understanding of the business, you already know what users do. However, the nuances of how users use the systems you're migrating away from, and how they *might* use the new workloads in Microsoft 365, can have a huge impact on whether users take advantage of the services available to them.

Start with email. Why? It's a familiar workload that, in most organizations, nearly every user will already be using. Using Microsoft or third-party reporting tools to familiarize yourself with which parts of the organization send and receive the most email, how large those messages are, and what types of devices or apps are most used is key.

If you're using an existing IM, conferencing, or telephony system, that should be your next step. Who's using that system, and how much? Is most usage between internal users, or with external parties? It can be very enlightening to compare the amount of email sent and received by a department or team with their usage of Skype for Business, Lync, Zoom, or other conferencing systems to see if you can discern activity patterns that point out where to focus your evangelism and communications first.

File storage and usage are important too. If you have on-premises SharePoint sites, the more you know upfront about how much data they store, how (or if!) it's classified and labeled, who creates and edits the data, and who consumes it, the better able you will be to plan the stages of your migration. For example, if your users depend daily on large on-premises SharePoint document libraries, you will probably prioritize moving those libraries above moving away from an on-premises Skype system as part of the same migration, but you can't make that decision unless you know who's using what services *and* how important those services are to the overall business.

## Deciphering Activity Patterns

Knowing when and how your users use various features of the service is useful. Microsoft makes much of the fact that Teams usage across the service skyrocketed starting in mid-March 2020, and it's been high ever since, but the more interesting aspects of this change are in the details.

Some activity patterns are predictable across organizations—you'll probably see the most activity during weekday mornings, especially on the first day of the work week. If your organization does a lot of seasonal or shift work, you'll probably see different patterns; for example, schools and universities see high activity at the beginning and end of academic terms, but much lower usage in between terms; hospitals and factories tend to see three peaks per day, one per work shift, and so on. However, different organizations may have very different baseline profiles despite these generalities—the number of frontline workers, knowledge workers, shared mailboxes, and so on will all play into what the overall profile looks like. An accounting firm might expect to see more usage at the end of each calendar quarter, with a sharp peak during tax season, while an identically-sized travel company in the same country might see usage spikes corresponding to when people plan their holiday travel.

Measuring the baseline of activity that you see *before* the migration starts is crucial to understanding what "normal" looks like so that you can understand what post-migration usage patterns are telling you about people's use of the service.

Individual workload activity may be steady or there may be bursts. This activity may, or may not, show correlations between workloads, too. If your organization's users send, on average, 10 messages per day, it's reasonable to assume that they'll still send about 10 messages a day after migrating to Exchange Online. On the other hand, if you deploy Teams at the same time, you may find that the average email volume drops because some email conversations have been moved to Teams. In fact, this is a very common usage pattern!

## Understanding User Knowledge

What do users know? That sounds like more of a philosophical question than an actual one. The truth is that knowledge in your user base won't be evenly distributed. Some users will know a great deal, some will know almost nothing, and the majority will fall somewhere in between these extremes. Remember that one key to adoption is equipping users with the knowledge necessary to make use of the new environment. This can be a difficult problem to solve because it isn't a technical issue for the most part. Microsoft has greatly improved the quality of its online help for the desktop and web applications in the Microsoft 365 suite, and there is an ocean of supplemental content from Microsoft, third parties, and the broader IT community covering every aspect of using the service, from basic tutorials about how to format Word documents up to complex and abstruse tutorials on Excel that I don't even pretend to understand. Identifying the training that your users need can be a challenging problem, and you would do well to get your organization's training department involved (if you're fortunate enough to have one).

At a minimum, users will want to know the basics of how to sign in and use the new environment. This doesn't have to be complicated or lengthy training. The simpler and shorter you can make it, the better, because that

makes it easier to update when things change, and shorter “snackable” training is easier for users to access, use, and retain.

You might find it valuable to look over the help desk tickets generated by users over the preceding 12 months and see if you can identify patterns that show you where users need training. For example, if you get a lot of tickets complaining about problems with audio devices in Skype for Business on-premises, it’s probably worth thinking about what users need to know about using devices in Teams, then find (or create) training to help address that specific topic.

## Understanding Wants and Needs to Arouse an Eager Want

The famous salesman and coach Dale Carnegie said that one of the key principles of sales was to “arouse in the other person an eager want,” and it’s this principle you need to adopt to successfully drive the adoption of Microsoft 365. To do this, first put yourself in the shoes of a typical user who will be using the new system. What does this person need to do her job? What are the technical or process obstacles she faces? Are any of those obstacles or needs solved by Microsoft 365?

Microsoft likes to use the phrase “IT hero” to cast a bright spotlight on people who enable business success by deploying their products, and certainly many people are driven by a desire to be recognized as an excellent salesperson, a top-notch developer, or whatever. Think about the different job roles you should have previously identified and what people in these roles need and want. Put these needs and wants in the unique context of the organization—a manufacturing company where everything is managed through rigid monitoring of key performance indicators will tend to produce a different set of needs and wants than a university, for example. Then think about these needs and wants through the lens of the changes you’re preparing to introduce. Your communications can then focus on explaining, as specifically and clearly as possible, how those changes will benefit users. For example, consider an organization where the users have an on-premises Exchange 2013 server that requires users to connect to a VPN when they’re out of the office. This may seem laughably ancient by current standards, but it’s not an uncommon configuration. Explaining to users that the move to the service will do away with the flakiness of VPN connections and improve their Outlook performance will get their attention. By contrast, the usual approach of focusing on features themselves is likely to do nothing for the users; if you’re used to waiting for a minute or more for Outlook to move a single message between folders, having your IT department pitch the move to Office 365 as a way for you to get dark mode in Outlook isn’t going to be very exciting.

### Getting Adoption Help from Microsoft

Microsoft’s continued success in the cloud depends heavily on getting end-users at their customers to *use* the services they’ve bought. To that end, they have a comprehensive site, <https://adoption.microsoft.com/>, that contains a curated set of resources to help you plan how you’ll get users to take full advantage of Office 365 after your migration. There are specific learning paths for each of the major workloads (including [Microsoft Search](#), the first time I’ve seen it treated as equal to SharePoint, Teams, and so on). Having a collection of learning, planning, and training material all in one place is very helpful, but it can seem a little overwhelming to see how much material is there. With that in mind, the earlier you can start browsing the content to get a feel for what’s there, the better; you can also take the list of topic areas and pick one at a time to become more knowledgeable about before moving on to the next one. Of course, Microsoft also offers consulting services, some included with large subscription purchases, and some sold separately, that may be of use to you in your adoption planning.

## Planning for Disaster Recovery and Business Continuity

It's tempting to think that moving your business operations into the cloud means that you can outsource all the worries and planning around disaster recovery (DR) and business continuity (BC) to your cloud provider. Of course, this is an idle fantasy; no cloud provider will ever care as much about your business operations than you do, nor will any provider have the specialized knowledge needed to ensure that your business keeps working smoothly in the event of a disaster. Organizations located in areas where natural disasters are more common (such as California or the Gulf Coast in the US or fire-prone regions of Australia) are already used to the need to plan for operational continuity even during disasters. For example, one US hospital on the Georgia coast proudly showed me their hurricane-recovery plan, which they thought would allow them to keep their office staff working after a hurricane. Unfortunately, their design featured only one Active Directory Federation Services (AD FS) server, located in the hospital data center; if it had failed, none of their users would have been able to log in to the cloud even if they otherwise had power and connectivity.

A complete discussion of DR and BC planning for the cloud is far outside the scope of this book, of course. A robust DR and BC plan will touch on every aspect of your business, from which employees are considered critical to how you communicate with them (e.g., what if email stops working?) to who has the authority and responsibility to declare a disaster. As part of any move to the cloud, you should ensure that you have a plan to deal with problems you might encounter that are unique to *your* cloud deployment. One example might be something like the [2001 Howard Street tunnel fire](#) or the Christmas 2020 bombing in Nashville, both of which affected Internet connectivity over an unexpectedly broad area. Another example might be planning to fail operations or critical communications over to another service or system in case your systems become compromised due to ransomware or an attack like [Solorigate](#).

## What To Do While You Move

Once you've decided to move and have handled all the issues described in the preceding section, you can begin dealing with the unique issues that may arise during the move itself. "During the move" is a pretty vague concept, as for many organizations the move can last months or even years. As one example, a large enterprise with 130,000 seats that I worked with took more than 18 months to fully migrate into a single Microsoft 365 tenant from their previous environment—and while this may seem slow, it was as fast as they were able to go considering all the business and organizational issues they had to resolve along the way.

## The Value of Hybrid Connectivity During a Migration

If you're moving to Microsoft 365 from a Microsoft-based on-premises environment, you will almost certainly end up in hybrid mode, Microsoft's term for an environment where some resources and data are on-premises while others reside in the cloud. In hybrid environments, the goal is to maximize integration between the two environments so that users can sign in with a single identity, use data and services wherever they're provisioned, and move easily between different services.

Any time you see the word "hybrid" used in the context of a Microsoft 365 environment, it means that there is a persistent connection designed to allow data to move between the cloud and on-premises servers. This is different from the typical "cutover" or "switchover" processes you may be familiar with from migrations involving older versions of Exchange—in a typical cutover migration, you'd move all the mailboxes from the source to the target, do some cleanup (such as redirecting mail flow by editing the DNS MX record), and immediately decommission the old system. Hybrid mode is in some ways like the process of raising children from birth: it's an ongoing process that takes a while and may proceed at different speeds and with different constraints in different families.

Various parts of the Microsoft 365 stack take different views of what “hybrid” means. Some services, such as Exchange Online and SharePoint Online, can function effectively in three ways: all on-premises, all in the cloud, or hybrid mode. For example, you can freely mix mail users who have mailboxes in Exchange 2019 servers on-premises with users in the same tenant who have mailboxes in Exchange Online. Of course, some workloads have no hybrid option: Teams, OneDrive for Business, Yammer, Planner, Whiteboard, and Stream have no hybrid capability.

Hybrid connectivity starts with identity management, the foundation of all the services in Microsoft 365. As described in Chapter 3, user identities can be maintained in a hybrid environment through a variety of different methods, including identity federation or the less complex and more easily managed directory synchronization process. Once you have provisioned identities in the cloud so that the service can see them, you can start exploring the cloud by using Microsoft 365 services on a trial basis, either with cloud-hosted identities or identities that come from your on-premises environment. This allows you to transfer some work to the cloud, observe the results, and decide on the best way to proceed. In some cases, the decision will be to move more workloads, and perhaps even to proceed along the line so that most mailboxes are transferred. In others, the decision will be to retain a substantial portion of work on-premises and use cloud applications for tactical purposes, such to support specific types of employees. The transfer of workload follows the pace set by the company and could extend over many years.

The existence of hybrid connectivity means that you can move gradually, as your business needs and user base will allow, instead of having one giant spasm of reconfiguration as in a cutover migration with an older version of Exchange (or a migration from Microsoft’s products to Google Workspace). Hybrid coexistence means you can plan and carry out your migration considering the factors that make it harder to plan for a fast switchover, including the distribution of users across multiple company locations, especially when international employees are involved.

Another major advantage to hybrid connectivity is that it gives customers a “plan B” if moving to the cloud does not deliver the advantages expected when deciding to use Microsoft 365. The same facilities that allow mailboxes to be moved from on-premises to Exchange Online can be used to move mailboxes back to Exchange on-premises. It’s possible that the same tools could be used to move documents from SharePoint Online back to SharePoint Server. Some gaps exist – like how to move public folders back because the public folder migration tools run in one direction – but overall, hybrid connections are two-way and can therefore be regarded as reducing dependency on Microsoft 365 should the need arise.

In early 2021, we saw a giant drawback to hybrid connectivity: the on-premises Exchange hybrid server represents an additional point of vulnerability if it is not properly managed and secured. The fast and broad spread of the HAFNIUM attacks which leveraged zero-day vulnerabilities in Exchange can be partially attributed to poor patching and information security practices at customers who didn’t realize or didn’t take seriously, that they had remaining Exchange servers even after their mailboxes had been moved. In mid-2022, Microsoft finally provided a supported way to remove the hybrid Exchange role from tenants that have completed their migration. However, it is very important that you *not remove the Exchange server*. You can shut it down, and even reformat it—but if you uninstall Exchange on that server, you will cause all sorts of spectacular damage, as described in the full [documentation for removing the hybrid role](#).

Until you’re ready to get rid of those on-premises servers, be sure that your Exchange hybrid servers are patched and protected with the same level of vigilance you provide to domain controllers and other critical server roles.

## Dipping Your Toes into The Cloud

Even after doing extensive research to verify whether Microsoft 365 is the right platform for your company, there is nothing quite like getting your hands dirty to make a technologist happier with a technology. Microsoft makes test drives easy by allowing you to sign up for a 30-day free trial. Essentially, you can create a fully functional test tenant and use it for 30 days to decide whether the cloud works for your company. And if you're still not sure after that period, you can simply discard the original trial, extend the trial, or start again with a new tenant.

Using a trial tenant as a proof of concept is a great way to get a sense of how cloud applications and management work in practice. The exercise will not expose some of the more complicated challenges, such as how to migrate public folder data or how hybrid connections or single sign-on work over an extended period. However, the information gained from a trial is certainly enough to gain a broad understanding of the different parts of the service and how the administrative experience differs from your on-premises environment. You'll be able to figure out how to move work to the cloud and what extra functionality exists – or where functionality gaps exist because something like a preferred third-party add-on is unavailable.

Some companies start with a trial tenant and then convert the trial into a paid-for service after the 30 days. This is OK if you plan for the eventuality and go ahead on that basis. However, you should be aware that Microsoft only provides a [limited capability to move data from one tenant to another](#). Third-party tools are available, but these come at added cost.

All-in-all, it is usually a better idea to regard a trial tenant as no more than a test and to accept that if the company decides to embrace the cloud, you will start over from scratch and use a new tenant.

## What To Do After You Move

If the key phrase for the pre- and trans-migration phases is “measure twice, cut once,” the useful cliché for the post-migration phase is “it’s a marathon and not a sprint.” Ideally, you will have conducted your migration in manageable phases to avoid swamping your service desk and IT team, but no matter how carefully you plan, on “day zero” after each phase you will probably see a spike in support requests as users encounter problems. That’s normal and shouldn’t discourage you—it’s important to deal with those requests quickly to keep users unblocked and to start building forward momentum.

Microsoft has historically tied incentives to adoption; they offer free consulting, license incentives, and other goodies to get their customers to *use* what they’ve already bought. Each year, Microsoft salespeople, and most partners, are given specific numeric targets for various features they’re supposed to focus on. Sales commissions, partner incentives, and even membership in Microsoft’s partner programs are tied to whether sellers can get customers to buy *and use* these targeted features.

The COVID-19 pandemic changed this mindset pretty quickly, since Teams usage in specific and adoption of Microsoft 365, both shot skywards... but we haven’t seen the last of the mindset at Microsoft that calls for continued growth in service usage from customers and partners. More to the point, to get the full value of the Microsoft 365 licenses you’ve purchased, you need to do two things: purchase the right mix of licenses for your needs and then properly assign and utilize them.

## Building Adoption Momentum

Much of the earlier discussion about adoption revolved around understanding what users *were* doing in the previous system. Armed with that understanding, you’ll be better able to assess how users are taking to the new system. Before they will (or can!) adopt the new system, you must work with users to help them:

- **Want the new system.** If users see Microsoft 365 as an unwelcome change forced on them by an uncaring IT department, its adoption will probably be reluctant, slow, and incomplete. On the other hand, if you've properly communicated the benefits to "arouse an eager want," users will look forward to, and embrace, the system.
- **Become capable.** Some of the features in Microsoft 365 will be new, and maybe even strange, to users. Teams is a great example; before the advent of Teams online meetings, most users never could easily record and share meetings and presentations, much less use live captions, machine translation, and the other nifty features that Teams offers. It falls on you to help them understand what's possible and to see the value these new features offer considering what you know about their needs, wants, and job responsibilities. The downside is that if users are to take full advantage of Teams, they may need headsets, webcams, and so on, and so providing these devices may turn out to be an important part of your strategy. License assignment is important here as well; users cannot use features for which they aren't licensed and provisioned.
- **Get the knowledge they need.** Users who want the new system and are enabled to use it, but don't know how, obviously can't adopt it. This is one area where the corps of evangelists you've built can make a huge difference in the success of your adoption planning by providing unofficial help, support, training, and cheerleading.

## The Cloud Is a Journey

If you haven't already started your move to the cloud, what you've just read may have worried you—it seems like there's so much to learn and consider before and during the move that it can be daunting. Good news, though—many, many organizations of all sizes have successfully moved to the cloud before you and there's lots of help available, starting with this book! Microsoft provides a wealth of training material online and in print, and many of your counterparts have published material that will help inform you. If you have already moved to the cloud, you should still be prepared for the fact that Microsoft's always growing, expanding, and changing its cloud services. You'll need to be ready to keep up with Redmond by learning new things and adjusting as things change.

It may help to keep in mind that you're providing a service to help the people you work with—it's easy to get caught up in the technical details of how the service works, what PowerShell cmdlets to use, and so on, but the reason so many customers have given Microsoft their money to subscribe to Microsoft 365 is that they believe that the cloud services will help their end-users work more productively and more securely. The service is just a means to that end.

# Chapter 3: Managing Identities

## **Brian Desmond**

Your online identity, and by extension the authentication process that establishes the identity, is the cornerstone of security in Microsoft 365. Once a user or workload identity is successfully authenticated by Azure Active Directory (Azure AD), access to any authorized resource is automatically granted. Throughout the book, we will distinguish between two separate processes:

- *Authentication* is when a system verifies the identity of a user. For example, the familiar Windows logon process you go through is how Windows authenticates your domain or local user account.
- *Authorization* is when a system decides whether a specific user or workload identity should have access to an object or service.

In its simplest form, the Microsoft 365 authentication process needs an identity, represented by the combination of a User Principal Name (UPN) and something by which their identity can be confirmed. Often the authentication method is a password, but it can also be a specific device such as a FIDO2 token, a biometric gesture, a certificate, or a combination of several methods (also referred to as multi-factor authentication [MFA]). Once Azure AD has confirmed a user's identity, it returns an artifact that an application or service can accept as proof of identity.

Although the default identity and authentication options suit most customers, not all organizations have equal security requirements. Nonetheless, protecting your (digital) identity is an important task; both inside or outside Microsoft 365 or one of its workloads. After all, once someone can gain access to your account, they hold "the key to your kingdom", granting them access to all the data accessible within the boundaries of your identity. To meet the need for stricter security policies dealing with authentication, Azure AD supports a plethora of options to customize and further secure the authentication process, as discussed here.

Because identities and authentication touch on so many aspects of Microsoft 365, it is important to carefully consider the implications of the various identity models and authentication options. The importance of factors such as complexity and cost is different for every organization and can greatly influence the decision as to which solution is best for you.

In this chapter, we explore the various authentication options that are available to you, spanning both cloud-only and hybrid deployments. As you will see, a robust identity infrastructure is fundamental to a successful deployment. Before exploring the available options, we should first look at the Azure AD infrastructure which supports both identities and authentication for Microsoft online services.

## The Role of Azure Active Directory

All the Microsoft 365 workloads depend on Azure AD for identity and directory information. Azure AD provides authentication and authorization for Microsoft 365 workloads as well as third-party applications. While similar in name, you will discover that Azure AD has few other similarities to traditional on-premises AD. However, we will explore how you can extend your AD to have a hybrid relationship with Azure AD.

Since Azure AD is a cloud service, there are significant differences between how on-premises workloads like Exchange Server or SharePoint Server use on-premises Active Directory (AD) versus Azure AD. Some

workloads implement workload-specific directories behind the scenes to bridge this gap. The Azure AD deployment supporting Microsoft 365 is, like most cloud implementations, designed to be a highly available multi-tier, multi-tenant service that is capable of handling load at an immense scale.

Every Microsoft 365 tenant has a corresponding instance within Azure AD, and each instance is isolated from others so that no tenant has access to data belonging to another tenant. When you create a new tenant, a new Azure AD instance is also created. The Azure AD instance is not licensed separately, and you do not pay anything extra for it. As you add users and groups, those objects go into this Azure AD instance.

Azure AD is deployed in multiple Microsoft data centers around the world and [operated with a service level agreement](#) (SLA) of 99.99%. In addition to Office 365, Other Microsoft cloud services like Microsoft Dynamics 365 and Microsoft Endpoint Manager consume Azure AD, as do numerous third-party applications. Microsoft has made significant investments in Azure AD to offer a 99.99% SLA. As with any cloud service, Office 365 has suffered from large-scale outages on occasion, and in some cases, an issue with Azure AD was the root cause of the outage.

To address this, Azure AD includes a [Backup Authentication Service](#) (BAS) that automatically steps into action to process authentication requests from supported applications if the primary service becomes unavailable. To do this, the BAS caches successful authentication requests for three days. The BAS relies on features such as continuous access evaluation and conditional access, discussed later in this chapter, to deliver resilience in a secure and configurable manner.

Like other cloud services, Microsoft updates Azure AD regularly to introduce new features and improve quality. See the [Azure Active Directory release notes](#) for details.

You can access the Azure AD admin center through the Azure Active Directory link in the **Admin centers** section of the Microsoft 365 admin center navigation bar or via the Azure portal.

## Workload-Specific Directories

Because of the way that some workloads work, Azure AD cannot offer the necessary functionality to support all the features required by those services. For example, the mailbox-specific attributes used by Exchange Online are not all stored in Azure AD. The same is true for many of the user profile properties used by SharePoint Online. To support workload-specific needs, and to isolate the configuration and other data owned by a single tenant inside the multi-directory Azure AD architecture, some services add another layer on top of Azure AD. This layer is a workload-specific directory store and is named after the workload:

- Exchange Online Directory Services (EXODS).
- SharePoint Online Directory Services (SPODS).
- Yammer Directory.

This workload-specific directory is essentially a cache of information held in Azure AD combined with workload-specific information. The workload-specific directory is designed to deliver a certain level of redundancy against network or other disruptions. To further explain the concept of workload-specific directory stores, we can use Exchange Online as an example.

### Exchange Online Directory Services

Exchange Online uses EXODS to hold its configuration data, including information about mail-enabled recipients. Exchange Online deploys its service across multiple forests with tenants divided between the forests. Each forest is unique to a data center region (multi-geo tenants spread mail-enabled objects across multiple forests) and uses an instance of EXODS together with a synchronization endpoint that is used to replicate information with the directories used by Microsoft Online Services (for user accounts and licensing), other applications (like SharePoint for mailbox information used in eDiscovery), and Azure AD. The introduction of support for spreading a single tenant's data across multiple data center regions means that

Microsoft has made additional changes to the way these forests are structured and synchronized so that all locations where a tenant's data may exist have complete and consistent data.

Synchronization occurs across the directories on an ongoing and continuous basis to ensure that the latest information is always available to all workloads. Occasionally, glitches can happen with the synchronization process, and you might have to wait for a new user account to be visible.

Exchange Online can create new user accounts during the mailbox creation process. In this case, Exchange Online pushes the information about the new account to the EXODS and Azure AD [in parallel](#). Exchange Online is unique in this capability, which exists because many customers have built extensive mailbox provisioning workflows with PowerShell that would break if forced to connect to Azure AD instead. When on-premises identities synchronize with Azure AD via the directory synchronization process in hybrid deployments, Azure AD is the target, and the resulting objects will synchronize to EXODS afterward.

## Licensing

As explained earlier, each tenant includes a free version of Azure AD that provides all the core functionality necessary to use Microsoft 365 services. For many organizations, the core capabilities of Azure AD are not enough to meet security requirements in the context of today's cyber threats. Microsoft bundles many of the security features that today's organizations require into Azure AD Premium. Azure AD Premium is available in two variants: Azure AD Premium P1 and Azure AD Premium P2. You can purchase Azure AD Premium on an a-la-carte basis, or get it bundled in the Enterprise Mobility + Security (EMS) or Microsoft 365 offerings.

For many organizations, Azure AD Premium P1 is enough, but Azure AD Premium P2 brings a set of governance tools and risk-based controls that can dynamically enforce security policies based on Microsoft's determination of the risk factor of each user and their sign-in attempt. A comparison of the different types of Azure AD licenses is available [here](#). Throughout this chapter, we call out whether a capability requires Azure AD Premium. Unless otherwise noted, you can assume that only Azure AD Premium P1 is necessary.

### Licensing Guest Accounts

Guest accounts need user rights to use Azure AD Premium functionality too. Microsoft's billing model for external identities (including guest accounts) uses telemetry to measure the number of unique identities that access premium Azure AD features monthly. Microsoft does not charge for the first 50,000 unique identities measured in a month and the charge thereafter is small. For instance, access to Azure AD Premium P1 features incurs a charge of \$0.00325 per month for all identities past the 50,000 threshold.

The Azure AD tenant must link to a valid Azure subscription through the External Identities section of the Azure AD admin center to support billing for external identities. Before doing this, the tenant must create the Azure subscription and create a suitable resource group to use.

Microsoft charges for each SMS-based multi-factor authentication request processed for an external identity. The charge levied pays for the telephony fees and is circa \$0.03 per attempt (successful or not). The charge does not apply when external identities use the Microsoft Authenticator app for MFA.

Although Microsoft does not currently enforce licensing restrictions for guest users, it is important to make sure that your licensing plans take this point into account if you deploy applications that support guest accounts, like Microsoft 365 Groups, Teams, and Planner. See [this guide](#) for more information.

## Identity Architectures

There are two options for how you create Azure AD user accounts (also referred to as "identities"):

- **Standalone identity:** In this model, user accounts exist only within the cloud environment and are not linked or related to any other AD forest. This means that a user may (or may not) have an account

in an on-premises AD, as well as an account in the Azure AD tenant that supports the organization's tenant. The accounts may happen to have the same username and password, as well as other attributes, but are separate and independent objects, and need to be managed independently as well. This duplicates administrative effort and introduces risks if attributes conflict or are not maintained correctly. Some organizations use standalone identities for users that do not require an account in their on-premises AD, such as third-party vendors.

- **Hybrid identity:** In this model, user accounts are created and managed in the on-premises AD environment and subsequently synchronized to Azure AD. Azure AD Connect or Azure AD Connect Cloud Sync performs the synchronization. In the hybrid identity model, the on-premises AD forest is the "source of authority", with objects and attributes replicating from on-premises to the cloud. Because the on-premises AD is now the source of authority, an administrator can only change limited aspects of the synchronized identity in Azure AD. More information on these limitations and how to configure Azure AD Connect is in Chapter 5 of the companion volume.

Each approach has its pros and cons. For example:

- Standalone identities are convenient because they do not need an on-premises AD. Many small organizations do not have or want to operate an on-premises AD. However, if an on-premises AD exists, standalone identities can be more time-consuming to manage because organizations must manage two separate accounts for each user. There is no arbitrary threshold for how many user objects you should have before synchronizing identities makes more sense. It typically comes down to how much time and effort an administrator must put into managing dual identities versus maintaining a synchronization infrastructure.
- Hybrid identities simplify administration because all changes occur to the on-premises AD and are then synchronized to the cloud by Azure AD Connect. The hybrid identity model doesn't prevent you from creating and using standalone identities.

You can optionally add identity federation to your hybrid identity design. Federation gives organizations much greater control over how to enforce security policies such as logon hours, third-party multi-factor authentication, and network locations from which users can access cloud resources. Most of the additional controls that federation offers are also available natively in Azure AD if you have Azure AD Premium. It is critical to remember that the identity federation infrastructure must scale to meet performance and workload requirements. It must also be highly available and resilient to failure because Azure AD may not be able to authenticate user logins if the federation service is unavailable.

You can deploy a mixture of these two models. Although it is more common to settle on a single identity model, organizations can choose to combine different identity solutions to fit their specific needs. For example, you may need to provide customers or contractors with access to certain resources. Using standalone identities for these users and hybrid identities for employees allows you to isolate the on-premises environment from customers and contractors. Ultimately, the decision about which identity model to use is driven by the business and technical requirements of the organization.

## Standalone Identity

The on-premises versions of Exchange Server and SharePoint Server use AD as the repository for user objects and to process authentication requests. In the case of Exchange, every mail-enabled object is represented by an AD object. The properties of the objects are managed by different tools, including the Active Directory Users and Computers console, the Exchange Admin Center (EAC), and PowerShell. Much the same division of responsibilities exists in the cloud versions of these services, with the exception that Azure AD is used instead of on-premises AD. For example, Exchange Online uses the same properties for mailboxes, public folders, groups, and other mail-enabled objects as the on-premises version, but these properties are divided across,

and managed through, both Azure AD and EXODS. Although a synchronization process keeps the two online directories in step, Azure AD is always the master.

Every user account has a unique user identifier, known as the User Principal Name (UPN), used to authenticate with Azure AD. For example, *britta.simon@office365itpros.com*.

By default, Microsoft 365 sets the primary SMTP address for a standalone identity to be its user principal name and things usually stay that way. However, this does not have to be the case as the two properties serve different purposes: the UPN identifies the object to Azure AD, and the primary SMTP address routes messages to its mailbox if it is mailbox-enabled.

Administrators often need to change the UPN, SMTP address, and display name for user accounts. In the following example, we use the Microsoft Graph PowerShell SDK to switch names for a cloud-based user from Jane Smith to Jane Jones and update the UPN and primary email address to reflect the same. It is good practice to retain old addresses assigned to accounts in the past so that Exchange can still route replies to those old addresses to the correct mailbox. To set the new values for the account, use the *Update-MgUser* cmdlet. The updated information will synchronize from Azure AD to the workload-specific directories such as EXODS. Finally, we use the *Set-Mailbox* cmdlet to update the mailbox's primary SMTP address to match the new User Principal Name.

```
[PS] C:\> Update-MgUser -UserId Lotte.Vettler@office365itpros.com -Surname Smith -UserPrincipalName Lotte.Smith@Office365itpros.com -DisplayName "Lotte Smith"
[PS] C:\> Set-Mailbox -Identity 'Lotte Smith' -WindowsEmailAddress Lotte.Smith@Office365ITPros.com
```

When you change the UPN for an account, the account owner must provide the new UPN the next time they sign into any Microsoft 365 service.

## Service Accounts

Not all the accounts you use belong to users. Some applications, such as those that monitor workload health or report on various aspects of Microsoft 365, might require the creation of special service accounts used solely for administrative purposes. These accounts usually do not need a mailbox or a license, but probably need the assignment of some form of administrative permissions to be able to view and access data on behalf of the tenant.

Most service accounts have passwords that never expire. This is done on the basis that managing password expiry for service accounts is often complex and time-consuming. While setting service account passwords to never expire is the path of least resistance, you should rotate service account passwords regularly in the same manner that you maintain on-premises service account passwords.

Configuring a password to never expire is easily done with PowerShell. The first example below sets the "password never expires" flag on a service account. The second example scans the set of user accounts and reports those that have this flag set. These examples only apply to cloud accounts. If you synchronize an account from the on-premises AD and password synchronization is enabled, the password of the corresponding cloud account is automatically set to not expire unless you configure Azure AD Connect to apply a password policy to synchronized users. In such cases, it suffices to also configure the on-premises account's password to not expire. Note that after successfully updating the password policy, Azure AD does not return a message. However, Azure AD signals if an error occurs.

```
[PS] C:\> Update-MgUser -UserId Service.Account@Office365ITPros.com -PasswordPolicies "DisablePasswordExpiration"
```

```
[PS] C:\> Get-MgUser -All -Filter "userType eq 'Member'" | Where {$_.PasswordPolicies -eq "DisablePasswordExpiration"} | Format-Table DisplayName, UserPrincipalName
```

While configuring a service account to have a password that never expires is the traditional approach, it also presents security challenges. Service accounts authenticating with a username and password use legacy

authentication methods which are particularly vulnerable to attack. Microsoft plans to block legacy username and password authentication in the future and has announced plans to block basic authentication for many connection protocols for Exchange Online as quickly as possible. The username and password must also be stored somewhere for the application to use it. This presents the risk that attackers could compromise the stored credentials.

Instead of using a username and password, consider using an Azure AD application registration (also known as a service principal). Application registrations can be configured to use a certificate for authentication. Application registrations can also be granted permission to use specific APIs via the Microsoft Graph. This approach requires that the API or PowerShell endpoint that is being called supports modern authentication methods. While this is not yet a possibility for every scenario, we recommend that you begin by investigating this method when you are designing a new script or unattended task.

## Hybrid Identity Authentication Infrastructure

Even after you have synchronized your identities to the cloud, your users will still need a way to authenticate. In a hybrid identity model, there are three ways to do this:

- **Password hash synchronization:** In this model, a cryptographic hash of the user's password, but not the password itself, is synchronized to the cloud. The hashing process is discussed in detail later. When a user requests access to a service component, the password they provide is hashed in Azure AD; if that hash matches the stored hash, the passwords are considered to match. This process relies on directory synchronization but does not require any other servers or components. Combined with Seamless Single Sign-On (discussed later), you can achieve single sign-on (SSO) with password hash synchronization.
- **Pass-through authentication (PTA):** In this model, authentication requests from the service are sent to a queue, where they are retrieved by a small agent that is installed by Azure AD Connect. The agent validates passwords against the on-premises domain controller (DC) and returns a status (success, failure, password expired, or user locked out) to Azure AD. Like password hash synchronization, PTA can be combined with Seamless SSO.
- **Federated authentication:** In this model, authentication requests from the service are passed to a federation server or service. This can be AD FS, or a third-party federation service such as Ping Identity or Okta. The federation server is responsible for authenticating the user by passing an authentication request to an on-premises DC and then returning an authentication token for the user to access cloud services. This process provides the end-user with an SSO experience that can be used to access various Microsoft 365 services.

You can combine password hash synchronization with PTA or federation. This provides a manual fallback mechanism for authentication if the on-premises PTA or federation infrastructure is unavailable. As of November 2019, 91% of Azure AD tenants globally enabled password hash synchronization.

If you are thinking about switching authentication methods, there is a feature that can make this much easier. Rather than switching from federated authentication to password hash synchronization, PTA, or seamless single sign-on for every user at once, you can control which authentication method is used on a per-group basis. To do this, access the Azure AD Connect blade in the Azure AD admin center. Click **Enable staged rollout for managed user sign-in** and you will be taken to the configuration area. Using staged rollout is a great way to test the user experience and better plan what amounts to a major change to your authentication infrastructure.

## Password Hash Synchronization

When directory synchronization is implemented with password hash synchronization, users can log on to services using the same password as their on-premises AD user account. This is referred to as “same sign-on”, which is not to be confused with “single sign-on” even though they both can be abbreviated to SSO.

The concept of synchronizing passwords tends to raise immediate concerns within an organization, as people inevitably assume that real passwords are being transmitted over the Internet and stored on Microsoft servers. The reality is that password hash synchronization is a secure process, and the passwords themselves are not transmitted or stored. Instead, a password hash is used. Despite this, some organizations may still object to the use of password hash synchronization, so it is important to understand what is being synchronized.

On-premises AD stores passwords as hashed values that are said to be *irreversible*. In other words, a password hash cannot be used to determine a user’s plain text password. Azure AD Connect extracts the password hash from AD, combines it with a user-specific salt value, and then hashes the combination 1,000 times before transmitting the hash over a secure HTTPS channel to Azure AD.

When password hash synchronization is enabled, the password complexity and expiration policies of on-premises AD override the policies set in Azure Active Directory. When a password is changed on-premises the new password is synchronized to Azure AD. This process usually occurs in under two minutes. You can [selectively synchronize](#) password hashes using a custom synchronization rule beginning with Azure AD Connect version 1.6.2.4. This adds complexity to your deployment and impacts password writeback so you should only use this capability if it is truly required.

If an on-premises password expires, the expired password will continue to work in Azure AD. This is because when password synchronization is enabled, Azure AD account passwords are set to not expire. For this reason, you should not rely on expiring or changing passwords to prevent a user from logging on. Instead, you should disable the on-premises user account and either force a directory synchronization, or block sign-in for their account in the Microsoft 365 admin center. If you want synchronized passwords to expire in Azure AD, you can configure Azure AD to apply the password policy in your tenant to synchronized users by following [these steps](#). You can use the `Set-MsolPasswordPolicy` cmdlet to configure your tenant’s password policy. Both these settings are global settings for your entire tenant.

Another important benefit of password hash synchronization becomes available if you have Azure AD Premium. With Azure AD Premium, Microsoft provides leaked credential risk event information for users if they discover the user’s UPN and password in a list of stolen/lost credentials. To perform the comparison, password hash synchronization must be enabled. Microsoft applies the same hashing process to the leaked password that is performed on-premises. They then attempt to match the hashed version of the leaked password to passwords in Azure AD. This works even if you use another sign-on methodology. It simply requires password hash synchronization to be enabled. In November 2019, Microsoft stated that they had processed over 5.5 billion leaked credentials and matched them to over 14.2 million Azure AD users. This feature is one of many reasons we strongly recommend that you enable password hash synchronization in your tenant.

## Pass-Through Authentication

PTA, if enabled, allows you to offload authentication from Azure AD to your on-premises AD without the need to deploy AD FS or a third-party federation solution. As such, it can greatly simplify your deployment if you are seeking to keep control of the actual authentication process.

For this to work, you must install and configure one (or more) on-premises PTA connectors to validate user authentication requests. The connectors can be installed as part of Azure AD Connect and are very similar to Azure App Proxy connectors. They share the same architecture; the PTA connector is a customized version of the Azure App Proxy connector.

From a high-level perspective, here are the steps an authentication request goes through when PTA is enabled:

1. The client connects to a service endpoint and is redirected to Azure AD for authentication.
2. The client connects to the Azure AD authentication endpoint and is prompted for credentials.
3. After the user submits their credentials and assuming PTA is enabled, Azure AD encrypts the credential data and holds the authentication request in a queue for validation.
4. The PTA connector makes an outbound connection to Azure and retrieves the authentication request from the queue.
5. The connector decrypts the data from the request and validates the decrypted credentials against the on-premises AD. The result of this verification process is then communicated back to Azure AD.
6. If the credentials were verified successfully, a token is issued, or the MFA flow is started.

## Seamless Single Sign-on

Seamless SSO enables Azure AD to accept a Kerberos ticket from the on-premises AD to authenticate the user if you are using password hash synchronization or PTA. The addition of Seamless SSO to either authentication model enables true SSO for users that are connecting from a domain-joined client computer. SSO is when users authenticate to both the on-premises organization and Azure AD using the same username and password without having to type their credentials again whenever they access a cloud resource. At a high level, this is what happens when Seamless SSO is enabled:

1. The client connects to a Microsoft 365 service and is redirected to Azure AD for authentication.
2. The client connects to the Azure AD authentication endpoint and is challenged for a Kerberos ticket.
3. The client turns to AD and requests a Kerberos ticket for the URL which is associated with Azure AD.
4. Active Directory locates this URL in the service principal name (SPN) of a computer account associated with Azure AD and encrypts a service ticket using that computer account's secret.
5. The client sends back the service ticket it received from AD.
6. Azure AD decrypts the Kerberos ticket using the computer account's secret which it received during the setup of the feature. If the ticket can successfully be decrypted, Azure AD will craft a token for the user.

For Seamless SSO to work, the following requirements must be met:

- Modern authentication must be enabled, and the client must support modern authentication.
- The client must be domain-joined and able to directly communicate with an AD domain controller. This is necessary for it to request a Kerberos ticket. Without direct access to a DC, SSO would fail and the process would fall back to the regular authentication option (username/password). That means that Seamless SSO cannot be used with Mac OS X (unless joined to a domain), mobile devices, or any other device that isn't joined to an AD domain.
- The Azure AD authentication endpoints must be added to the computer's browser Local Intranet zone settings; by default, browsers do not send Kerberos tickets to public endpoints.

Microsoft describes the SSO-feature to be "opportunistic". This means that SSO will be attempted if enabled. However, if anything goes wrong during the process, the authentication process will fall back to the default authentication option. We strongly recommend Seamless SSO combined with password hash synchronization if it meets your business and technical requirements. For more information about configuring Seamless SSO, refer to [this document](#). You should also explore whether hybrid Azure AD join can meet your SSO needs. We discuss hybrid Azure AD join later.

## Federated Authentication

Identity federation offloads credential validation, and optionally MFA, to on-premises federation infrastructures such as AD FS or Ping Identity, or a third-party cloud identity solution. A by-product of configuring identity federation is that it can provide an SSO experience.

**Note:** You can also achieve SSO much more easily with the Seamless SSO feature in Azure AD discussed earlier.

When you federate a domain, the responsibility for validating authentication requests is shifted towards the federation solution. The application that's asking the federation system to perform authentication is known as the *relying party* (because it's relying on the federation service). A federation standard named WS-Fed/WS-Trust is almost always used to federate with Azure AD. The standard specifies the format and content of data and metadata that the service and federation broker can use to negotiate and perform the authentication.

Federation depends on the concept of *claims*, which are statements made by one party about another. For example, the application might send a claim to the federation server that says "the user requesting authentication is coming from IP address 172.16.0.204" and the federation server might reply with a set of claims that includes "the email address associated with the account you are trying to authenticate is britta.simon@office365itpros.com." You can configure AD FS *claims rules* that allow or restrict authentication based on the contents of these claims.

Federation is enabled per domain and all users in Azure AD for whom the domain portion of the UPN (the UPN suffix) matches a federated domain are automatically considered to be federated identities (except if the user is included in a staged rollout group). Even with federated identities, the first authentication request is still received by Azure AD. The user's UPN suffix is examined and, if the domain name is federated, Azure AD will redirect or proxy the authentication request to the customer's federation solution. This process is called *home realm discovery* and needs to be performed for each initial authentication (such as the first time that someone logs on). You can see this process at work when you have federation set up and you visit a logon page; at first, you see the standard Microsoft logon dialog, which contains code that looks at the UPN and determines if it's for a federated user, redirecting to the organization's federation solution if so.

The details of the organization's federation solutions and all the relevant details such as the federation endpoint and certificate information are stored in Azure AD during the federation setup process. The initial request (home realm discovery), and the subsequent redirects all happen within a matter of seconds, often transparent to the user.

Most organizations choose to federate all their domains, but that is not a requirement. As such, you can have multiple authentication methods for different users in different domains of your organization. Information on how to configure identity federation with AD FS is described in Chapter 10 of the companion volume.

When authenticating with Azure AD, you will notice that most of the time the user is asked to enter their email address. However, that is not entirely true. Although the web page or application might ask for the "Email Address" on the screen, the user should enter their logon name (UPN) to complete the logon. Because of this, the general recommendation is to align the user's UPN and primary email address to remove any potential for confusion for the end-users. If your organization can't align the UPN and primary email address, you may be able to use Alternate Login ID, discussed later in this chapter.

### To Federate or Not?

Various elements influence the decision of whether identity federation is the right solution for you. Apart from the added infrastructure that is needed, complexity is often the reason why organizations avoid federation, especially when they must manage the federation solution themselves. Unsurprisingly, password hash synchronization is the most popular authentication method in Azure AD, as it is much easier to deploy and maintain, and it offers a similar login experience to end-users when combined with seamless single sign-on or

a device that is Azure AD or Hybrid Azure AD joined. In addition, users will still be able to authenticate, even when the on-premises infrastructure is down; the only thing that would (temporarily) stop working in such a scenario, is the actual synchronization of passwords.

On the other hand, identity federation (for example, through AD FS) can solve very specific problems, like whether to block authentication from outside the corporate network, limit access to Microsoft 365 services to members of a specific group, or use a third-party MFA solution. These types of problems can also be solved without AD FS if you have Azure AD Premium.

In general, we often recommend that you start with password hash synchronization and Seamless SSO for authentication with Microsoft 365 and Azure AD. If you have complex business or technical requirements that cannot be met without implementing federation, only then should you do so. Be sure to consider the tradeoff of complexity with the requirements you are trying to meet.

### Third-party Federation Solutions

AD FS is not the only federation solution to enable SSO. Several third-party solutions, such as those from Okta, Ping Identity, and OneLogin take a similar approach to federation. The decision to use a third-party solution depends on several factors such as integration with other cloud systems. Different solutions have different requirements and capabilities.

Azure AD also offers advanced SSO features like those supported by third-party vendors. In addition to these SSO features, Azure AD contains additional features such as enhanced multi-factor authentication and self-service password management. Many of these features require users to have a license for [Azure AD Premium](#) or EMS. While these capabilities come at an additional cost, they are worth evaluating along with other third-party solutions.

The pitfall you will run into if you elect to purchase a third-party federation solution is whether you can avoid the cost of Azure AD Premium. Many of the security controls that organizations require to secure their Office 365 implementations are native to Azure AD Premium. Without Azure AD Premium it may be difficult or impossible to implement these controls. Where it is possible to implement substitute controls, the user experience is often lacking. For these reasons, we find that many organizations find Azure AD Premium, or one of the bundles that includes it, is better value than third-party federation solutions.

## Alternate Login ID

Like many other cloud services, Microsoft 365 requires the logon ID to be *Internet routable* because ownership of non-routable domains like internal domains ending in ".local" cannot be verified. Users for which the on-premises UPN suffix does not match any registered domain are given a UPN suffix based on the default routing domain. For instance: *britta.simon@office365itpros.onmicrosoft.com*. Note that the tenant's default domain cannot be federated.

By default, when you configure AD FS, the UPN is used as the primary logon ID for Azure AD. Generally, it is recommended to ensure the UPN matches the user's email address so that they only need to remember their email address to sign in to Microsoft 365. Unfortunately, sometimes you might not be able to change the UPN to match the email address. If you are unable to change the UPN for your users, for example, because a legacy application needs a specific value, you can use a feature called "Alternate Login ID". This feature allows you to specify which attribute – other than the UPN – should be used to sign on to Microsoft 365. For instance, you can configure the actual Email Address attribute to be the new identifier. Although Microsoft supports Alternate Login ID for Hybrid deployments, there are some severe drawbacks from an end-user perspective (like extra authentication prompts). Unless you absolutely cannot reconfigure the UPN, we do not recommend choosing Alternate Login ID.

In [this](#) article, Microsoft describes the end-user experience for various applications and protocols if Alternate Logon ID is configured. Connections from within the corporate network are most likely to work just fine. External access, regardless of the client, can be problematic and result in extra authentication prompts. No matter what approach you use, the end-user experience suffers as soon as Alternate Logon ID is enabled.

You can [configure alternate login ID in AD FS](#), or you can configure it in Azure AD if you use password hash synchronization or PTA. When you [enable alternate login ID](#) in Azure AD (currently in public preview), users will be able to sign in to Azure AD using any email address configured for their account. These email addresses must be in their proxyAddresses attribute and belong to a domain namespace validated in the tenant. You can also use [staged rollout](#) to enable alternate login ID for a subset of your users.

## Passwordless Authentication

Passwordless authentication offers significant security benefits over passwords. By removing passwords, you can remove a significant attack vector. You can also improve user experience by removing the need for users to remember passwords, periodically change passwords, etc. If you have frontline workers that do not frequently use a computer as part of their job, passwordless authentication can reduce the friction involved in deploying IT services to this population. While it is not yet possible to entirely remove passwords, we strongly recommend beginning the journey of exploring how passwordless authentication can be integrated into your organization's IT strategy.

Whether you are in a hybrid or standalone identity model, Microsoft offers four passwordless authentication methods:

- **Text message sign-in:** In this model, users can authenticate to Azure AD with a one-time passcode sent via SMS/text message to their previously registered mobile device.
- **Microsoft Authenticator App:** In this model, users enter their UPN, and Azure AD sends a push notification to the Authenticator app. The user sees a random two-digit number on the sign-in screen and must enter the two-digit number into the Authenticator app. If the user provides the correct number in the Authenticator app, enters a PIN, or provides a biometric (e.g., Apple TouchID), they are signed in to Azure AD.
- **FIDO2 key sign-in:** [FIDO2](#) is an industry standard for authenticating to devices and online services using a standards-based hardware token.
- **Certificate-based authentication (preview):** this model allows users to sign in using a client certificate, typically stored on a smart card.

To use a passwordless authentication method, you must first enable the authentication method. To do this, log in to the Azure AD admin center and navigate to **Security** and then **Authentication methods**. From here, you can enable text message, Microsoft Authenticator, certificate-based authentication, or FIDO2 Security Key sign-in for a group of users, or you can enable it for all users. You can also use a preview feature to configure the Microsoft Authenticator app to show the estimated location of the authentication request and the application that generated the request when the user is prompted for approval. Once you enable a new authentication method or make configuration changes to an existing one, it might take a few minutes to start working.

Text message sign-in has several limitations. The most important limitation right now is that Teams is the only Office thick client application that text message sign-in works with. Otherwise, you can only use text message sign-in with web applications.

FIDO2 sign-in requires users to have a [supported](#) hardware token. Once the user has a hardware token, they can browse to <https://mysignins.microsoft.com>, click **Security Info**, click **Add method**, and choose **Security key**. The user will be walked through the process of pairing their security key with Azure AD. Once this is

complete, the user can click **Sign in with a security key** on future Azure AD sign-in prompts. You can also use FIDO2 keys to sign in to devices with [Windows Hello for Business](#) and to [sign in to AD joined](#) devices.

Certificate-based smartcard authentication is a critical scenario for a relatively small number of organizations, including the United States government. We do not expect that many organizations will use this authentication method unless they already have a mature smartcard deployment. Instead, we recommend that organizations invest in passwordless architectures based on Microsoft Authenticator and/or FIDO2 devices. For information on configuring certificate-based authentication, refer to the [Microsoft documentation](#).

## Temporary Access Pass

One of the challenges to deploying passwordless authentication is how to enroll a user with a FIDO2 token or another authentication method for the first time. If the user has a password, they can use their password (and MFA) to enroll. If they are a new employee, then you must give them a password for their initial sign-on, which defeats the concept of passwordless authentication. To address this challenge, Azure AD has a feature called Temporary Access Pass (TAP).

TAP lets you provide users with a short-duration unique code that the user can use to set up their passwordless credentials. When a TAP is created for a user, they attempt to sign in to Azure AD in the same manner as a normal user. Instead of prompting the user for a password, they will be prompted for their TAP. After entering a valid TAP, the user can enroll their passwordless authentication method such as a FIDO2 token or the Authenticator app. You can also use TAPs to restore access for a user that needs their passwordless credential replaced.

To enable TAP in your tenant, login to the Azure AD admin center and navigate to **Security** and then **Authentication methods**. Next, enable the Temporary Access Pass method. You can configure the lifetime of the TAP, whether it can be used more than once, and the length of the code. Once TAP is enabled, members of the global administrator, privileged authentication administrator, and authentication administrator Azure AD roles can create TAPs for users.

To create a TAP, login to the Azure AD admin center and navigate to **Users** the Azure and then find the user you want to create a TAP for. Click **Authentication methods** and then **Add authentication method**. On the screen that appears, you can create a TAP and optionally specify when it becomes valid. This capability may be useful if you want to create a TAP in advance for a new employee. You can make the TAP valid beginning on their first day of work, for example.

**Note:** If you do not see the Add authentication method button, you might need to click the **Switch to the new user authentication methods experience!** banner on the top of the screen first.

In addition to using the Azure AD admin center to configure TAPs, you can also use the [Graph API](#) to automate TAP management tasks.

# Understanding Azure AD Authentication

Establishing a standalone or hybrid identity to use with Microsoft 365 is only half of the work. Once you have an identity, you must first authenticate before you can access resources online. Leveraging the power of Azure AD, Microsoft 365 offers a variety of authentication options, ranging from the default username/password combination to more advanced authentication solutions.

Before diving into the advanced scenarios, let's first look at how Azure AD performs authentication. The simplest credential is the combination of a username and a password. This option is also the default in Microsoft 365 for all non-federated identities.

When a user attempts to access resources, the service prompts them for credentials. Depending on what client is used, the authentication prompt comes in various forms. Microsoft has worked hard to standardize the appearance of the Azure AD-based logon interface across clients and platforms, so the logon experience is remarkably consistent across devices and applications. No matter the interface, once the user provides a credential, various things happen behind the scenes depending on what client is used and what authentication method has been configured.

## Basic Authentication

When looking at the authentication process in Azure AD, one can distinguish two main approaches to authentication: basic authentication and modern authentication. The former is used when legacy clients (those that do not support modern authentication capabilities) connect to Microsoft 365. The number of these clients in use within Microsoft 365 tenants is steadily shrinking, but there are still examples of older clients and devices that should be updated.

When a basic authentication client connects, a basic authentication prompt is shown instead of the Azure AD-style prompt. Once the user enters their credentials, the credentials are forwarded to the service (e.g., Exchange Online) which, in turn, will connect to the underlying authentication solution (Azure AD or your federated authentication service) to validate the credentials. If the credentials are successfully verified, the service will authorize the client to connect to the resource it requested access to. This process is quite different from modern authentication where the client communicates directly with the authentication endpoint.

**Note:** Microsoft is pushing customers to stop using legacy authentication, or more precisely, to upgrade their clients to versions that support modern authentication. Legacy authentication methods, such as basic authentication, impose major limitations. The biggest limitation is that legacy authentication is subject to common attacks that do not affect modern authentication. In addition, you cannot perform MFA using basic authentication, nor can you exert the same levels of control (through policies) as with the modern authentication options. Because of these limitations, legacy authentication is also highly susceptible to attack. On October 1, 2022, Microsoft will disable basic authentication for seven email connectivity protocols in Exchange Online.

## Modern Authentication

Modern authentication enables improved authentication for a variety of clients, including Office 2013 (with the latest updates) and newer, Office for iOS and Android, the native iOS mail app, the Outlook mobile application, and Teams. Modern authentication is based on the use of the OAuth 2.0 authorization protocol. Modern authentication allows enabled clients to take advantage of the following:

- SAML-based sign-in with third-party MFA providers.
- Smart card-based authentication.
- Passwordless authentication.
- True multi-factor authentication.
- SSO across apps through token sharing (for example, the Office desktop apps).
- Application of Azure AD conditional access policies.

## Authentication Flows

As briefly discussed earlier, the biggest difference between modern authentication and legacy (basic) authentication methods lies in how the authentication happens and how communication flows between the client and Azure AD. Figure 3-1 depicts the authentication flow of a desktop client with modern authentication enabled:

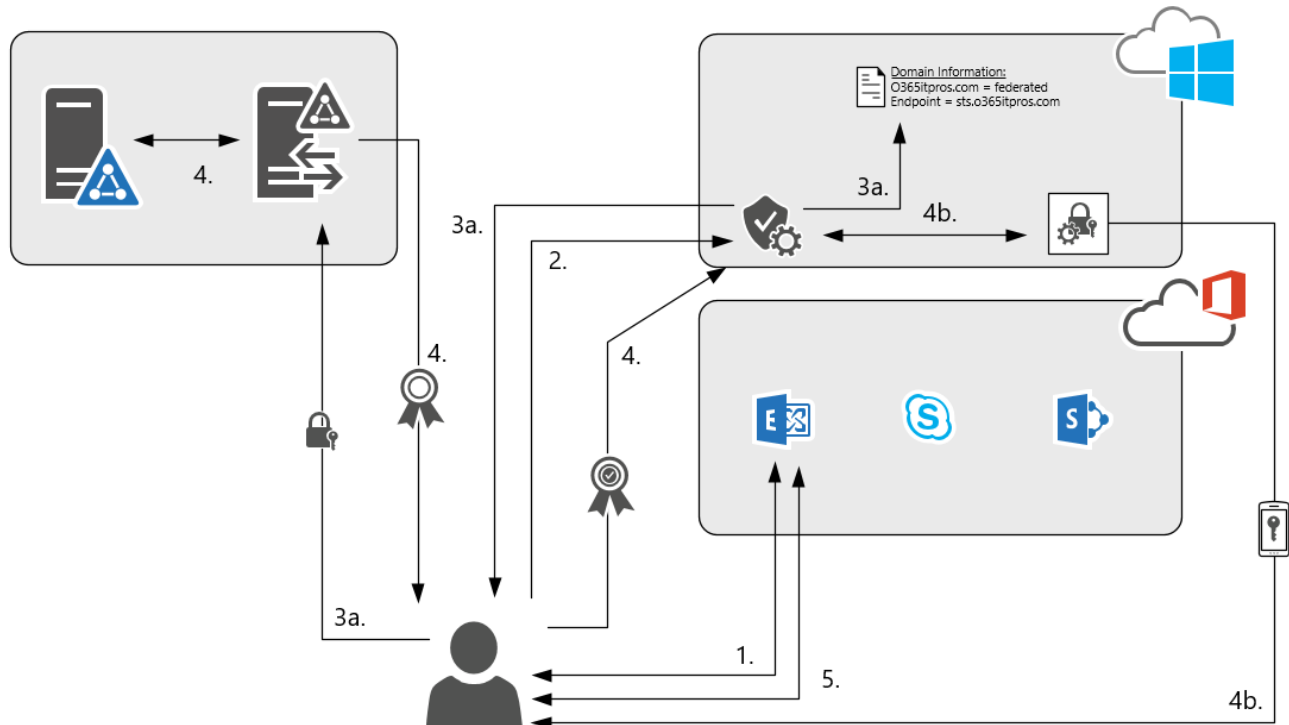

Figure 3-1: Modern authentication flow

1. The Outlook desktop client connects to Exchange Online and is redirected to Azure AD for authentication.
2. The client connects to the Azure AD authentication endpoint and is prompted for credentials. Because modern authentication is enabled, the client displays the forms-based modern authentication credential dialog.
3. After the user submits their credentials, Azure AD first verifies the identity type of the user. It does so by looking at the user's UPN and verifying what type of authentication the user is configured to use.
  - a. If the user is federated, the client is redirected to their identity provider. Depending on what client the user is connecting with and how the endpoint is configured, the user might need to enter additional credentials.
  - b. If Seamless SSO is enabled, the user's browser is challenged for a Kerberos service ticket to identify the account. If the browser returns a service ticket to Azure AD, the service ticket is validated, and the user is signed in.
  - c. If PTA is enabled, the user's request is passed on to the on-premises AD via PTA agents.
  - d. If the user's password is managed in Azure AD (standalone identity or using password hash synchronization), the username/password combination is verified by Azure AD itself.
4. When the credentials are successfully validated, one of the following happens:
  - a. In the case of federated authentication, the application receives a token (from the identity provider) and is then redirected to Azure AD where the user receives an artifact that identifies the user.
  - b. If MFA is required, and the user's federation service did not tell Azure AD that MFA was already performed, the user is first requested to enter additional verification after which (if successfully validated) the identifying artifact is created and returned.
5. The client is now redirected to the service it initially connected with (for example, Exchange Online). Using the artifact previously received from Azure AD, the client can now access the online resource.

Following successful authentication, Azure AD issues two tokens to the user: an access token and a refresh token. The access token is short-lived, meaning it has a limited lifespan (one hour by default). An app like OWA uses the access token to authenticate to Exchange Online. The refresh token, which can remain valid

indefinitely, is used to request new access tokens from Azure AD when they expire. With a valid refresh token, the user does not have to re-authenticate. Instead, the refresh token is used to obtain a new access token from Azure AD. The flow described above assumes the client has no valid refresh token, which would be the case when the refresh token expired or when the client has not yet connected to Azure AD.

Several things control the validity of the refresh token, such as how often it is used or whether the user changes their credentials. When the refresh token expires, the user must sign in again. Depending on the client, and how authentication is implemented, this might require a user to provide their credentials again. If true SSO is used, re-authentication should happen automatically and is fully transparent for the end-user. If no SSO is configured, the user will be presented with an authentication form.

## Revoking Access/Tokens

As mentioned in the previous sections, Azure AD authentication uses two types of tokens: access and refresh tokens. The access token ultimately grants you access to the online service: with a valid access token, you can access the requested service and do something like opening a mailbox. You can continue to work with the service until the access token expires or you interrupt or close the active session (like closing the browser window). When an access token expires, the client can acquire a new access token using a valid previously-received refresh token. If a valid refresh token exists, the user does not have to re-authenticate.

Because of how these tokens are used, organizations sometimes face a new challenge: what if you need to revoke someone's access immediately? The same problem also exists in an on-premises organization to a certain extent: when you disable an account in Active Directory, subsequent authentications are no longer allowed, but the user is not forced to close any open session/applications being used at that time.

Access tokens cannot be revoked. This means that once someone gets a valid access token, they can keep using that token for up to its maximum lifetime. You can, however, revoke the refresh tokens which prevents the user from acquiring a new access token when it expires, and thus force the user to re-authenticate (which will fail, if you disable the account). To revoke valid refresh tokens for a user, log in to the Azure AD admin center and navigate to **Users**, find the user you want to revoke the refresh tokens for, click **Profile**, and then click **Revoke sessions** on the toolbar. You can also revoke all the refresh tokens for an account by running the following PowerShell commands:

```
[PS] C:\> $UserId = (Get-MgUser -UserId Andy.Ruth@Office365itpros.com).Id
Invoke-MgInvalidateUserRefreshToken -UserId $UserId
```

Although revoking access tokens is not ideal, it will at least prevent the user from continuing to obtain valid access tokens. Some organizations need to customize the default sign-in frequency behaviors. If you have Azure AD Premium, you [can use a feature](#) of conditional access to control how frequently users must sign in to access applications.

Modifying lifetimes for tokens was a previously acceptable approach to mitigating risk. A better approach is for tokens to automatically get revoked when a risk event occurs. Microsoft has taken the first steps towards this with a feature called [Continuous Access Evaluation](#) (CAE). With CAE, when a risk event occurs, the workload (Exchange Online, SharePoint Online, OneDrive for Business, or Microsoft Teams) is notified so that it can take near real-time action to revoke access. When CAE is enabled, the one-hour access token lifetime discussed earlier is increased to 28 hours for CAE-capable applications. Since the workload is continuously evaluating the validity of the access token, the increased lifetime does not present a new or additional security risk.

The events below currently trigger a notification to the subscribing workloads:

- The user account is disabled/blocked.
- The user account is deleted.
- The user's password is changed (or reset).

- MFA becomes mandatory for the user.
- Refresh tokens are administratively revoked for the user.
- Azure AD Identity Protection detects elevated risk for the user.

CAE is enabled by default in all tenants. If you want to disable CAE or modify the behavior of CAE, you can do this with a conditional access policy (discussed later in this chapter). You can use conditional access to place CAE in strict enforcement mode for some or all users. In strict enforcement mode, CAE will revoke access if a user's IP address changes or when the client [lacks the capabilities to handle CAE processing](#).

## Modern Authentication in a Hybrid Environment

As of Exchange Server 2013 CU19, Exchange Server 2016 CU8, and Skype for Business Server 2015 CU5, modern authentication [is also supported](#) for on-premises Exchange servers, provided that a full hybrid configuration has been set up. This is good news, as it allows you to align the authentication capabilities (and experience) cross-premises.

The way modern authentication works on-premises is very similar to how it does in Exchange Online. However, instead of being a native capability, the on-premises Exchange or Skype for Business servers will pass authentication requests to Azure AD and use the OAuth tokens Azure AD returns instead of using the native on-premises authentication mechanisms. In effect, when a user attempts to connect to Exchange or Skype for Business, they are redirected to Azure AD to authenticate there. Once a user authenticates successfully, they will receive access and refresh tokens from Azure AD which can then be used to authenticate to Exchange or Skype for Business on-premises.

Note that enabling modern authentication for Exchange or Skype for Business on-premises is an all-or-nothing scenario; you cannot enable it on a per-user basis.

# Customizing the Tenant Sign-In Page

Tenants can customize the sign-in page presented to users when they sign in via Azure AD. Customizing the sign-in page lets you apply your organization's look and feel by modifying background colors and images as well as replacing the Microsoft logo. Applying your organization's brand has the added security benefit of giving your users a recognizable place to enter credentials. Customization is not hard, but it usually takes some homework to identify the right images and colors. Partnering with your marketing or internal communications teams is usually the best way to be successful.

When a user accesses resources from another organization using Azure AD B2B Collaboration, the branding experience changes slightly to provide context about the user's organization and the organization they are accessing. In this scenario, the background image (element 1) changes to the background of the organization that owns the resource. The remaining elements represent the user. For example, if a user from the Coho Vineyard is accessing a resource in Contoso's tenant, they will see Contoso's background image and the Coho Vineyard's banner logo, username hint, and sign-in page text.

The branding elements you choose apply to all your users, with one exception. You can define different branding elements based on the user's language. The user's language is determined dynamically by information provided by their web browser about language settings on their computer. To configure branding, login to the Azure AD admin center and navigate **Company branding**. If you edit the default settings, they will apply to all users. To create different branding settings based on user language, click **New language** on the toolbar.

If your organization uses AD FS or another identity provider, the branding settings in Azure AD will not be visible in some scenarios. You should also customize the sign-in page for your identity provider. More information about branding AD FS' sign-in pages is located [here](#). You will find that the customization

elements are very similar to Azure AD. If you're running AD FS on Windows Server 2019, don't forget to [enable paginated sign-in](#). This makes the AD FS sign-in process much more like Azure AD.

Figure 3-2 shows the sign-in page with all the available branding elements customized. The numbers in Figure 3-2 correspond to the branding elements in Table 3-1. Pay attention to the notes in Table 3-1 too. For the best user experience, you will need to select images that work best with how Azure AD displays the branding elements.

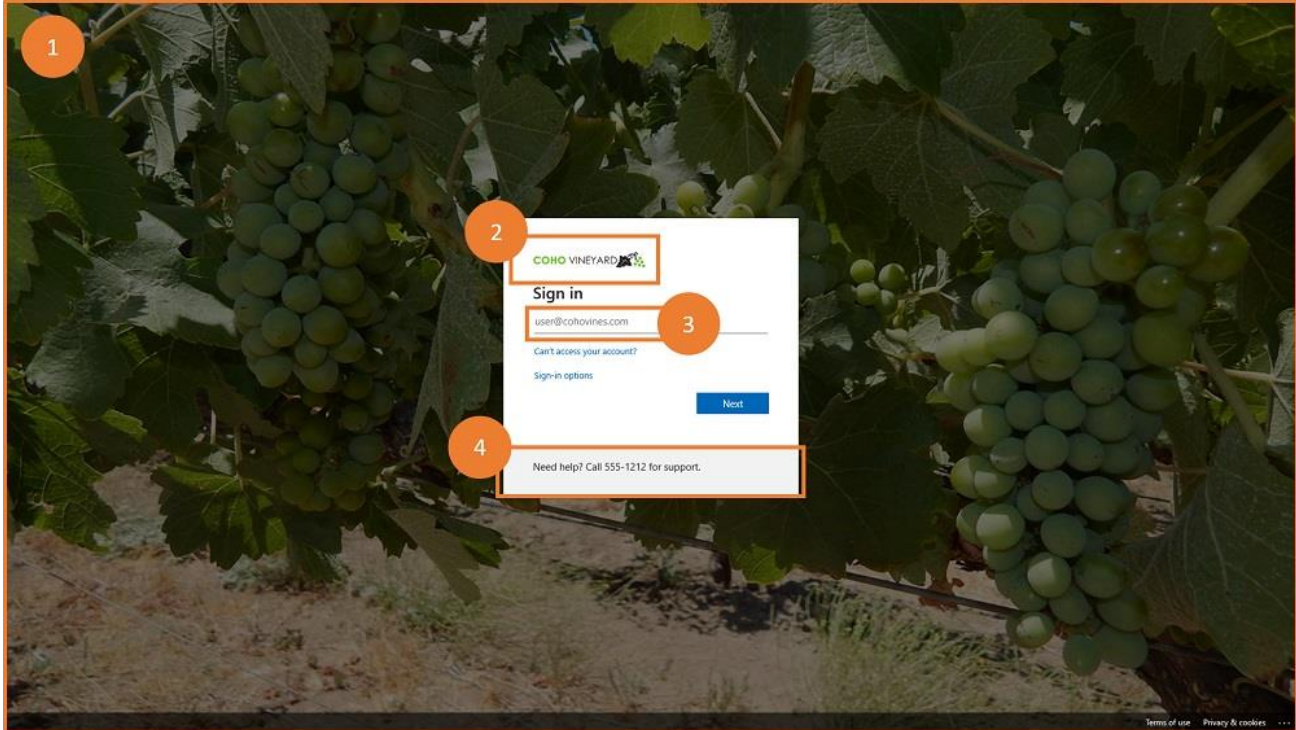

Figure 3-2: A Branded Azure AD sign-in page

#	Element	Requirements	Notes
1	Background image	<b>Dimensions:</b> 1920x1080px <b>Format:</b> PNG, JPG, or JPEG <b>Size:</b> 300KB or less	<ul style="list-style-type: none"> <li>This image is dynamically cropped based on screen size. Avoid using an image that includes text.</li> <li>Minimize the file size where possible to improve page load speeds.</li> </ul>
2	Banner logo	<b>Dimensions:</b> 280x60px <b>Format:</b> Transparent PNG, JPG, or JPEG <b>Size:</b> 10KB or less	<ul style="list-style-type: none"> <li>Use a transparent PNG file</li> <li>This image is shown in automatically generated email communications and other places like the MyApps portal.</li> </ul>
3	Username hint		<ul style="list-style-type: none"> <li>Text displayed as a reminder to the user about how to format their sign-in name.</li> </ul>

## Joining Computers to Azure AD

Windows 10 and newer versions (and to a more limited extent, earlier versions of Windows) support the concept of joining client computers to Azure AD. There are two different ways to join Azure AD: 1) Azure AD join only and 2) hybrid Azure AD join. In the first scenario, the client computer only has a relationship with Azure AD. Rather than signing into the device with a local account, users sign in with their Azure AD credentials. This can be a standalone identity or a hybrid identity. In the second scenario, the client computer remains joined to an AD domain (in the same manner it has for decades), but the device also maintains a parallel relationship with Azure AD. Users sign in with their AD credentials and the computer also acquires a primary refresh token (PRT) used to authenticate with Azure AD (and in turn dependent resources like Office 365 workloads).

Azure AD join can be useful for any organization, including smaller organizations that do not have an on-premises AD forest. If you have a workforce that primarily works remotely, you can achieve the benefits of domain join without the need to have network connectivity to reach a DC. Even if a client computer is solely joined to Azure AD, if there is an AD forest, that user can [seamlessly access](#) traditional resources and applications that use Kerberos authentication when they are on the network. Azure AD join requires no specific configuration to begin using the feature. You can control who can join a device to Azure AD by signing into the Azure AD admin center and navigating to **Devices** and then **Device settings**. Configure the **Users may join devices to Azure AD** setting. We also recommend that you require MFA to join a device. The best way to enforce this requirement is with a conditional access policy. We discuss conditional access and applying a policy to user actions later in this chapter.

Hybrid Azure AD join requires some initial configuration to use the feature. Windows 10 and newer devices locate the Azure AD tenant they should attempt to hybrid join by searching AD for a service connection point (SCP). The easiest way to create the SCP is to use Azure AD Connect. The configure device options task in Azure AD Connect will create the SCP record for you. If you use federated authentication, you will need to make sure that your identity provider supports Hybrid Azure AD join. AD FS supports hybrid Azure AD join, however, it must be configured to [issue certain claims](#) specific to computers. Azure AD Connect will also configure AD FS for you.

After configuring hybrid Azure AD join, you can begin using a client computer's identity as an input to conditional access, discussed later. You can also achieve SSO from Azure AD joined and hybrid Azure AD joined devices without configuring seamless SSO. Microsoft Edge and Mozilla Firefox (beginning with version 91) natively support this form of SSO, however, you can also deploy an [extension](#) for Chrome if your organization uses it. In both cases, the browser can submit your PRT to Azure AD at sign-in. The PRT identifies the user, whether they have performed MFA (or not), and the device. You can check on the PRT as well as the general health of a device's Azure AD relationship by running **dsregcmd /status** from a command prompt.

# Guest Access to Azure AD

Azure AD provides a rich and flexible fabric for bringing external people into your tenant in the form of guest accounts with Azure AD Business-to-Business (B2B). A guest is an external user whose account and credentials exist outside your tenant (often in another tenant). Azure AD B2B is the component of Azure AD that enables guest accounts to work. One of the most valuable benefits of Azure AD B2B is the ability for guest users to authenticate using their organization's credentials while accessing an application in another organization's tenant. For example, a user from contoso.com needs access to a file stored in SharePoint Online in the Office365ITPros.com tenant. The user from contoso.com will authenticate to Office365ITPros.com using their contoso.com credentials, rather than a separate username and password. This also means that when the user's contoso.com account is deactivated (such as when they leave the organization), their access to Office365ITPros.com will also be deactivated.

Azure AD assigns [guest accounts a more restrictive set of permissions](#) than it does to member accounts. However, you can change the **Guest users' permissions are limited** setting to No in the Azure AD admin center if you want guest accounts to have the same default permissions to see information in the directory (like group memberships) as member accounts do. Guest accounts can have administrative roles and execute functions associated with those roles.

Because guest accounts are Azure AD objects that share many of the characteristics of user accounts, applications can use guest accounts to control access to content. Azure AD uses email addresses to create user principal names to identify guest accounts. The email address can point to another tenant domain within Microsoft 365, an email domain for a company that doesn't have a tenant, or a consumer email service, like Gmail.com or Yahoo.com. You can view a list of guest accounts in a tenant through the Users section of the Microsoft 365 admin center, the Users section of the Azure AD admin center, the Contacts section of the Recipients tab in EAC, or by running the command:

```
[PS] C:\> Get-MgUser -All -Filter "userType eq 'Guest'" | Format-Table DisplayName, UserPrincipalName
```

You can edit properties of guest users through the Microsoft 365 admin center or Azure AD admin center. You can't make changes to guest accounts through EAC because the list of guests displayed there is for informational purposes only. It is common practice to update visible properties such as display names, telephone numbers, job titles, and addresses for guests. And as we'll see later, it is also possible to upload a photo for a guest account.

## Creating Guest Users

You can create guest users through [the Azure portal](#) by creating a **New guest user** rather than a **New user**, and the account creation process allows you to add the new guest user to groups. You can also create guest users with [PowerShell](#), but the most common method used is when applications issue invitations to external users, which is what happens when you add a guest to an Office 365 group or team. If you have regular user accounts created for external people in your tenant, these accounts can be [converted into guest accounts](#).

When Azure AD or an application add a new guest, it calls [the Invitation API to create and send an invitation](#) via email to the user's address to tell them that they have been invited to start using an application in the tenant. In addition to allowing applications to send customized invitations, the API supports the inclusion of a link for the user to access the application, like the access information needed for someone to join a group or team.

The *UserState* of a guest user created when an invitation is generated is *PendingAcceptance*. This is enough to allow the guest user to be added to a group. At this stage, the guest user is a placeholder. When the guest redeems the invitation, the *ExternalUserState* property changes to *Accepted* and Azure AD puts the account

into a state where it can access tenant resources. You can find out what accounts are in a specific state with the `Get-MgUser` cmdlet. In this example, we list the guest accounts in a pending acceptance state. The `ExternalUserStateChangeDateTime` property is the timestamp for the last account update.

```
[PS] C:\> Get-MgUser -All -Filter " userType eq 'Guest' and ExternalUserState eq 'PendingAcceptance' | Format-List -Property DisplayName, UserPrincipalName, ExternalUserState, @{e={Get-Date($_.ExternalUserStateChangeDateTime) -format g};n="Invitation Issued"}
```

It is important to realize that a guest user often uses their email address to sign in (ideally, the primary email address and the UPN are the same in their home tenant). The [New-MgInvitation](#) cmdlet has a parameter named `ResetRedemption` that indicates to Azure AD that the invitation is to change the email address used to sign in. All the other properties of the guest user are unaffected. After the user redeems the invitation sent to the new email address, the guest user switches to that address. This approach preserves access to all resources available to the guest user. The ability to change the email address for a guest account is [currently a preview feature](#).

## Guest Sources

The source for the guest is a property of the user object that tells Azure AD where the guest comes from and how it will authenticate. You can see the source by looking at the profile of guest accounts in the Azure portal, where accounts have one of [four sources](#):

- Users from **other tenants** have “External Azure Active Directory” as their source. These guests sign into Azure AD using the credentials from their home tenant.
- Users of **Microsoft consumer services** such as Outlook.com have a “Microsoft account” as their source. These guests sign into their Microsoft account (MSA).
- Users of **other services** such as Google.com also have “Microsoft account” as the source. In this case, guests sign into the Microsoft account created for them during the invitation redemption process and use those credentials to access resources.

The source for the guest account for anyone who has not redeemed an invitation is “**Invited User**.” When the redemption process is complete, the source changes to one of the sources listed above.

The host tenant extending invitations to guests can require multi-factor authentication to force guests to use a mixture of credentials: their password and another authentication method (like a one-time code sent to the guest’s mobile device).

All applications that use the Azure AD B2B collaboration framework generate and redeem invitations in the same manner. The difference is the link contained in the invitation – it can point to an individual team, group, or other application and the application referenced must be ready to allow access to that guest. SharePoint is an exception in that it creates a guest user account in your tenant when an external user from another tenant redeems a sharing invitation to a document or folder with the usual one-time code mechanism. SharePoint does this to allow these users to use their tenant credentials to open the shared documents with the Office desktop apps.

## Audit Records for Guest Additions

Azure AD captures details of the addition of a new guest account in an “*Add User*” audit record. Other audit records are captured for “*Add member to group*” events when a new member joins a group. Together, these audit records give enough information to allow administrators to track and report when new guests join groups in the tenant. To extract the information, use the Audit log search feature in the Microsoft Purview Compliance portal, or use the PowerShell `Search-UnifiedAuditLog` cmdlet. Several examples of how to use the cmdlet to extract, refine, and analyze audit log data are included in Chapter 21.

## Federated Identity Providers

Azure B2B Collaboration supports federated identity providers. Federation means that guest users can sign in to access tenant resources without needing to create a Microsoft account or account in the local tenant. The first [federated identity provider is Google](#), where support is available for sign-ins for guest accounts using the Gmail.com domain. [Federation with Facebook](#) is also supported. See [this article](#) for information about how to configure federation between Microsoft and Google. Teams also supports federated authentication for Gmail accounts.

## One-time Passcodes

One-time passcodes (OTP) for guest accounts allow users with any email address to authenticate using codes sent to their mailbox. The codes last for 24 hours. During this period, the user can access any resource they have been granted access to in the tenant. The [process to enable OTP](#) is simple and once the policy is active, any guest account whose email address is not part of an Azure AD tenant, a Microsoft account, or belongs to a federated identity provider, will receive a one-time code that they can use to redeem their invitation. The initial token lasts 24 hours and once it expires, the user must receive another code to reauthenticate.

## Creating Invitations

You can reproduce what an application does when it generates an invitation to a guest with a series of PowerShell commands. It is critical to understand that this code is an example not intended for production use. Instead, it illustrates some of the processing that occurs when a group owner invites a new guest to join a group.

First, we run the *New-MgInvitation* cmdlet to generate and send an invitation to the email address of the guest we want to add, in this case, [John.Doe@outlook.com](mailto:John.Doe@outlook.com). If the user accepts the invitation, the redirect URL brings them to the specified URL.

```
[PS] C:\> New-MgInvitation -InvitedUserDisplayName "John Doe" -InvitedUserEmailAddress
John.Doe@outlook.com -SendInvitationMessage:$True -InviteRedirectUrl
https://office365itpros.sharepoint.com/sites/GroupName
```

When you generate an invitation to a guest, Azure AD checks whether a guest users already exists in the host tenant. If one exists, it is used. If not, Azure AD creates a new guest user. You can check this by running the *Get-MgUser* cmdlet after sending the invitation. The account has a *UserType* of "Guest" and the User Principal Name is based on the email address used in the invitation. In our example, the UPN is `John.Doe_outlook.com#EXT#@office365itpros.onmicrosoft.com`. If you don't want Azure AD to send a standard invitation email, set the *SendInvitationMessage* switch to `$False`. You can later send your own customized message to the guest to invite them to join the tenant.

After they receive the message containing the invitation, the guest clicks the link to accept the invitation. If their account is already validated, they can go ahead and access the resource pointed to by the URL. If the guest account has never been used before, accessing a resource causes a redemption process to begin during which the account is validated. Following successful validation, the guest can go ahead and access the resources to which they have been given access. Azure AD updates the guest account to set its *ExternalUserState* property to `Accepted` and the *ExternalUserStateChangeDateTime* property with the current timestamp. We can therefore check for outstanding guest acceptances with some code to retrieve all guest accounts whose state is not accepted.

```
[PS] C:\> [array]$Guests = Get-MgUser -All | ? {$_.UserType -eq 'Guest'} | Sort DisplayName
ForEach ($Guest in $Guests) {
    If ($Guest.ExternalUserState -ne "Accepted") {
        Write-Host $Guest.DisplayName, $Guest.UserState, $Guest.Mail, $(Get-
Date($Guest.ExternalUserStateChangeDateTime) -Format g) }}
```

It all sounds simple, but the dependency on directory replication makes this approach to creating guests difficult to use in practice. For that reason, it is best to use the applications that you want to use guests with to invite those guests so that Azure AD creates their accounts through the redemption process.

## Restricting Guest Access

The [Azure AD Guest user access restrictions policy](#) in the [External collaboration settings blade](#) of the Azure AD admin center allows tenants to control the level of access guests have to Azure AD information. Three options are available:

- Guests have the same access as members (most inclusive) setting means guests have the same access to directory data as regular users in your directory.
- Guests have limited access to properties and membership of directory object settings. Guests don't have permissions for certain directory tasks, such as enumerating users, groups, or other directory resources. This is the default setting.
- Guests are restricted to properties and memberships of their directory objects (most restrictive). The ability to set this level of restricted access is currently in preview.

Most Microsoft 365 apps currently are unaffected if the most restrictive level is selected. This might change in the future as product groups work out how to exploit the feature. For instance, Teams might not allow guests to see details of team membership.

## Cleaning Up Old Guest Accounts

Many reasons exist to justify the creation of a guest account in a Microsoft 365 tenant. For example:

- An external expert is asked to review a document stored in SharePoint Online and receives a sharing link for this purpose. The link creates a guest account.
- Someone is asked to join a Microsoft 365 group or team. A guest account is created when the invitation is issued.

Over time, the reason why an external person has a guest account in a tenant might wane. For example:

- A guest account is used to review a shared document and is not needed thereafter.
- External people leave a team (or teams) and their guest account remains in Azure AD.
- People leave an employer and move on to new challenges. Their guest account is invalid because they can no longer authenticate using the Azure AD instance for the tenant of their old employer.
- Projects come to a natural end and the associated teams and/or private channels and their guest members are no longer needed.

You can, of course, leave guest accounts in place on the basis that they might be needed in the future, but usually, it is a better idea to clean things up and remove these accounts when they are no longer used, especially because these accounts have access to tenant resources. Several ways exist to control the longevity of guest accounts in a tenant:

- You can use the script covered in the PowerShell chapter (see the section “Finding Inactive Guest Accounts”) to find groups with external members and then check the individual members of each group.
- You can check guest accounts based on their activity level. The “Finding Inactive Guest Accounts Based on Activity” section in the PowerShell chapter describes how to use data from the audit log and email tracking logs to calculate the last activity for guest users. If a guest hasn't been active for months, perhaps it is time to remove their account.
- You can deploy [Azure AD Access Reviews](#) to force group owners to check the memberships of the groups they manage and attest that group members should keep or lose their status. Example reviews include all members of Microsoft 365 groups or Inactive guest accounts (accounts that

haven't been used for a set period). Access Reviews requires Azure AD Premium P2. A Graph API is available for programmatic access to access reviews (see this [example script](#)).

After target accounts are identified for removal, you can ask group owners to remove them or do so programmatically or through an administrative portal. Here's an example of using the *Remove-UnifiedGroupLinks* cmdlet to remove a member. If an account is a group owner, remember to remove it from the owner list first.

```
[PS] C:\> Remove-UnifiedGroupLinks -Identity "GDPR Planning Mark II" -LinkType Member -Links JackSmith_hotmail.com#EXT#
```

To remove a guest account completely, run the *Remove-MgUser* cmdlet:

```
[PS] C:\> Remove-MgUser -UserId JackSmith_hotmail.com#EXT#@office365itpros.onmicrosoft.com
```

Alternatively, you can leave it to individual guests to decide when it is time to remove their account from your tenant. A user can belong to up to 500 Azure AD tenants. They can choose to leave a tenant and remove their guest account at any time. To leave a tenant, the user goes to the Azure AD [Organizations page](#) via their Account details (they can also navigate to the page via the Teams desktop or browser clients). Azure AD lists the tenants where the user has a guest account. To leave a tenant, select **Leave organization**, and then confirm the decision with **Leave** (the user might have to sign into the tenant first). Azure AD then removes the guest account from the chosen tenant directory, signs the user out of the tenant, and sends an email to confirm that they have left the organization and can no longer access applications in that tenant. Leaving an organization only removes the guest account; it does nothing to remove any data which the user created in that tenant.

The guest account stays in a soft-deleted state for 30 days following removal. During this period, the tenant administrator can restore the guest account, or complete the process by removing the account permanently. When a guest account is removed, it loses all access to SharePoint and OneDrive documents, libraries, and lists that it has been granted access to on an individual basis or through a group. It also loses access to all Teams it was a member of in the tenant.

**Entitlement management:** [Azure AD entitlement management](#) is functionality to enable tenants to manage access to groups, applications, and sites at scale. You define access packages to describe the resources users can access and then assign the packages to users, making it easy to remove access to multiple resources at one time by removing an account's access to a package. Entitlement management requires Azure AD Premium P2.

## Cross-Tenant Settings

One of the challenges is the potential to allow guests from competitors access to tenant resources or to allow users from your organization to join teams and groups in a competitor's tenant. To mitigate this, Azure AD provides controls to limit guest collaboration. These controls come through external collaboration settings, as well as a preview capability called cross-tenant access settings.

Cross-tenant access settings are the primary control that you should plan to use where possible. The primary limitation of cross-tenant access settings is that they cannot control the invitation of consumer identities (e.g., Gmail) or other email domain names that are not verified in an Azure AD tenant. For these scenarios, you should use external collaboration settings.

You can find both groups of settings by signing into the Azure AD admin center and navigating to **External Identities**. External collaboration settings allow you to determine what email domain names can be invited to collaborate with your tenant as B2B guests. You can use the following settings under **Collaboration restrictions**:

- **Allow invitations to be sent to any domain (most inclusive)** – this allows B2B collaboration in your tenant with any guest user
- **Deny invitations to the specified domains** – this allows B2B collaboration in your tenant with any guest user, except guests from the domain names listed (e.g. a competitor)
- **Allow invitations only to the specified domains (most restrictive)** – in this scenario, you must whitelist individual domain names that you will allow guests into your tenant from

An important distinction between external collaboration settings and cross-tenant access settings, which we'll discuss next, is that external collaboration settings only control guests coming *into* your tenant. You must use cross-tenant access settings to control what tenants your users can be guests in. With cross-tenant access settings, you can apply much finer-grained control of guest behavior in your tenant ("inbound" access) and where your users can be guests ("outbound" access).

Rather than a domain name-based approach, cross-tenant access settings work on a tenant basis. You can control what guest users in a given tenant can access your tenant, as well as what applications they can access in your tenant. You might choose to allow all users in another tenant to become guests in your tenant, or you might choose to only allow specific users to access specific applications as a guest. The granularity of control that you choose will be a balance of managing risk and the operational overhead. You can apply similar controls in the opposite (outbound) direction to control what tenants your users can become guests in and what applications they can access in those tenants.

To configure controls for a specific tenant, go to **Cross-tenant access settings (Preview)**, and then click **Add organization** on the toolbar. Enter a domain name valid for the tenant you want to configure and then click **Add**. Note that these settings will apply to the entire tenant, not just that domain name. You will see that the *Inbound access* and *Outbound access* columns say *Inherited from default*. You can configure the defaults on the **Default settings** tab. These defaults apply to all tenants, even if they are not listed on the **Organizational settings** tab. Click **Inherited from default** and then choose **Customize settings** to configure tenant-specific settings:

- **External users and groups** – You can choose to **Allow access** or **Block access** from this tenant (inbound) or to this tenant (outbound). For inbound access, if you choose to **Select external users** and groups, you must provide the object identifiers for the individual users and groups that you want to allow access for. You can obtain the identifiers from an administrator in the external tenant. For outbound access, you can select the users and groups from your tenant allowed to become guests in the tenant.
- **Applications** – If you **Select applications**, you can choose the applications in your tenant that guests have inbound access to. For outbound access, if you **Select applications**, you must provide the application ID from the external tenant that users in your tenant can access. You can obtain the application ID from an administrator of the external tenant.

For inbound access settings, you can also configure trust settings for the external tenant. We discuss how these settings work in the Cross-Tenant Trust section in the discussion about Conditional Access. You might find that cross-tenant access settings do not work quite how you would expect, especially if you have used external collaboration settings before. External collaboration settings control what domain names can receive an invitation to become a guest. These invitations are often generated when a user tries to share content in SharePoint, OneDrive for Business, or Microsoft Teams. When a domain is not permitted to be invited, the user will receive an error message when they try to send an invitation. With cross-tenant access settings, users will still be permitted to send invitations to users in tenants that are not allowed to collaborate. When the guest tries to accept the invitation to collaborate, they will receive an error message that they are not permitted to access your tenant. We expect that this inconsistent experience will evolve as the preview of cross-tenant access settings matures.

# Protecting Your Identities

Microsoft has made significant investments in delivering features in Azure AD (and even on-premises) to combat the threats to identities. In today's world, every organization should have MFA deployed across the enterprise and enforced for all users. In October 2019, despite the widespread availability of MFA, Microsoft reported that MFA protects fewer than 10% of enterprise Azure AD accounts. Even with MFA, passwords are still a problem. Traditional password policies that require frequent password changes and complexity rules that are difficult to comply with lead to people picking even worse passwords. Azure AD Password Protection is Microsoft's approach to mitigating some of the risks of passwords.

End users are ultimately the most familiar with their behaviors. Azure AD makes sign-in logs available for users to review directly by visiting <http://mysignins.microsoft.com>. Information about each of the user's sign-in attempts including whether they succeeded and where the attempt was made are all presented in a searchable list. This same data is available tenant-wide to administrators in the Azure AD sign-in logs.

## Password Protection

Users often choose poor passwords. Sometimes they reuse passwords between services; other times they choose easily guessed passwords. Microsoft has long tried to educate both users and administrators about the rules of good password hygiene, and the on-premises Windows Server operating system has a long-standing [password filter feature](#) that allows you to install custom code to check proposed passwords when users try to change them on-premises. Two similar sets of Azure AD features are available to do this: [one for standalone identities](#) and the other for hybrid identities that are synchronized to the cloud.

First, for user accounts homed in the cloud, Azure AD applies a global banned password list when a password change is requested. All the old standards, such as "passw0rd" and "password123," are here, as are many others; the list is gleaned from password breach data that the Microsoft Security Intelligence center gathers, as well as from other factors. The suggested new password is first put through a set of normalization rules (similar in concept to the way phone numbers are normalized in Skype/Teams), then checked against the global bad password list, then checked against the organization's custom bad password list if you've defined one. The global banned password list is available to all tenants, but defining custom banned passwords requires an Azure AD Premium license for each user.

The on-premises equivalent of this feature is more complex. To use it, you install an agent on your DCs that checks password change requests against the Azure AD banned password list. There is also a proxy agent, which downloads the password policy from the service and makes it available to the DCs. When a user tries to change her password, the local DC agent (which is implemented using the password-filter mechanism that's long been part of on-premises AD) checks it against the most recent list and either allows or blocks the change. The good news: this approach means that your cloud and on-premises identities receive the same protection and use the same banned-password lists. The bad news is that the on-premises capability requires you to purchase Azure AD Premium licenses for each user.

**Hardening User Passwords:** Azure AD allows accounts to have passwords of up to 256 characters. Increasing the password length by just a single character dramatically increases the time to brute-force guess the password. However, as computers become increasingly more powerful, the processing needed to brute-force guess a password also decreases, and continually increasing the password length is not a long-term solution. If you want to use a long 200-character password, feel free, but there is a better solution now. After years of telling users that they needed long, complex passwords, the US National Institute of Standards and Technology (NIST) introduced a [new set of recommendations](#):

1. Use pass phrases instead of passwords. Phrases are easier for humans to remember.
2. Choose phrases with unique associations that only you will know.

3. Eliminate character-composition requirements.
4. Do not require passwords to expire.
5. Ban common passwords, to keep the most vulnerable passwords out of your system.
6. Educate users not to re-use their passwords for non-work-related purposes.
7. Enforce the use of multi-factor authentication wherever possible.
8. Enable risk-based multi-factor authentication challenges.

The [full NIST recommendation](#) makes for interesting reading, but if you implement the suggestions above, you'll greatly increase your security and, not incidentally, make your users happy. In addition to hardening user passwords, you should also monitor authentication attempts to track and report suspicious activities. Both options are discussed later.

Password Protection helps protect you from password spray attacks. Password spray attacks are a common technique used by adversaries to test common passwords and evade detection. In a password spray attack, an adversary will try the same password (for example, Winter2021) on hundreds or even thousands of accounts at a time. Because only one failed authentication occurs per-user account, typical detections for brute force attacks are bypassed. You can use Attack Simulation Training in Defender for Office 365, discussed in Chapter 9, to simulate a password spray attack against your tenant.

## Password Writeback

Password writeback allows users and administrators to change or reset Azure AD passwords and have that password propagated to the on-premises user account in real-time. The ability to write back passwords is integrated with Azure AD's [self-service password reset](#) (SSPR) capability and licensed through Azure AD Premium.

This is how password writeback works:

1. The user clicks a link to request a password change.
2. The user enters their old and new passwords (or completes one or more challenge gates in the case of a forgotten password).
3. The selected password is encrypted with a special key that was created during the setup of the password writeback feature for that specific tenant.
4. The encrypted password is sent over HTTPS to a tenant-specific service bus endpoint which is used to communicate with the on-premises password writeback service. Communications on this bus are protected by a shared credential that was created during the setup of the password writeback feature and is only known to your organization and Azure AD.
5. The writeback feature looks for the user account in the on-premises AD. To find a match, the *sourceAnchor* is used to look up the user in the Azure AD Connect connector space. From there, the object is traced back through the metaverse to AD.
6. If the user account is found, the password is reset. If the reset is successful, the user is notified.
7. If the password reset operation fails, an error is returned to the user. One of the reasons the password reset might fail is when it does not satisfy the on-premises password policy. If the password writeback service running inside of Azure AD Connect is unavailable, the operation will also fail.

The password writeback features can also be deployed without using password hash synchronization; you can also deploy password writeback alongside AD FS. You can also enable users to unlock their on-premises AD account using SSPR and password writeback without also changing their password.

**Real World:** You might expect Azure AD Connect to always connect to the nearest domain controller (DC). Azure AD Connect will prefer the PDC emulator (PDCE) role holder for its connections because the PDCE is considered the master authoritative source for password changes. If the connection is made to a DC in a

different site or over a slower connection, a variety of problems might occur like delayed password synchronization or slow synchronization performance.

## Configuring Password Writeback

Password writeback can be enabled as part of the Express and Custom installation modes for Azure AD Connect, or through PowerShell. The easiest way to enable password writeback is to select the password writeback option in the Optional Features section of the Azure AD Connect setup wizard. If you let the setup wizard configure the service account for Azure AD Connect, you do not need to make any further changes in AD.

If you used a custom service account, you must delegate the service account permissions to reset passwords and unlock accounts. The easiest way to delegate permissions is with the *Set-ADSyncPasswordWritebackPermissions* PowerShell cmdlet included in the *ADSyncConfig* PowerShell module.

## Configuring Self-Service Password Reset

The password writeback feature also works when an administrator changes the password for a user from the Azure AD admin center, but it is most useful when combined with the SSPR capability in Azure AD so that users can update their password without having to worry about the passwords getting out of sync.

Unlike most other features, password reset is not managed from the Microsoft 365 admin center. The link in the admin center redirects to the Azure AD admin center. After signing into the Azure AD admin center, open the **Password reset** blade. Once SSPR has been enabled, you can modify the policy to control various aspects of the password management features in Microsoft 365/Azure AD, such as whether users are required to provide multiple verification methods (to verify their identity), and if so, what verification options they should use.

We typically recommend that you enable only a few of the available verification methods for SSPR. Specifically, we suggest that you use the mobile app notification, mobile app code, and mobile phone options if they will work for your organization. Security questions are useful in situations where your users might need to reset their password in a location without access to their phone, or where you cannot require your users to provide a mobile phone to enroll. Be very careful when you pick your security questions. Security questions should capture details that only a user will know, and that cannot be easily researched by an adversary on social media.

Unfortunately, SSPR only lets you choose a single set of verification methods for all your users today. As a result, you will need to enable the methods that work best for everyone in your organization. You can also require your users to periodically confirm their SSPR registration details are still correct. We recommend that you configure this setting to be once or twice a year. After all, if the details are no longer correct, the user will be forced to call for support which defeats the point of SSPR.

## Using Self-Service Password Reset

Before users can use SSPR, they may need to configure additional verification options. If a user is not enrolled for MFA, they must register for SSPR through a process that is almost identical to MFA enrollment. In April 2020, Microsoft formally released a feature to “converge” the MFA and SSPR registrations, so users only need to register once. Once users have registered via the converged registration process, they are enrolled in MFA and SSPR. Microsoft enables the SSPR feature in tenants created after August 15, 2020. However, SSPR is disabled by default in pre-existing tenants to allow organizations time to plan for and adopt the converged registration experience. By September 30, 2022, Microsoft will complete enabling converged registration for tenants that do not already have it enabled.

To enable converged registration in your tenant, login to the Azure AD admin center. From there, select **Users** > **User Settings** and then click the **Manage user feature settings** link. Configure the **Users can use the**

**combined security information registration experience** setting. We recommend that you enable converged registration if you have not already.

Once the verification process is completed, there are several ways a user can change his password. One way is to go through the Office portal, click Settings (the cogwheel), and select **Password**. This will take you to the page where you can change the password. Alternatively, if the user forgot their password, they could click the **"Can't access your account"** link on the sign-in page after having entered the wrong password. This brings them to the online password reset portal where they are guided through a few steps to verify their identity based on the verification options they provided. If the user is successfully verified, the password can be reset.

## User Risk and Self-Service Password Writeback

Azure AD Premium P2 includes Microsoft's Identity Protection capabilities. One of the capabilities of Identity Protection is the ability to measure and report on risk scores for individual users. For example, if Microsoft finds a valid password for a user in a list of leaked credentials on the Internet, the user's risk score will be rated high.

You can configure the user risk policy in Azure AD to act when a user's risk score is rated by Microsoft as high. There are two actions you can take in the user risk policy. The first option is to block the user from further sign-in until manual action is taken. The other option enables self-remediation. The next time the user signs in, after completing MFA, they will be forced to change their password. The password change is written back to the on-premises AD using password writeback. The user risk policy is configured by accessing the Security blade inside the Azure AD admin center and then opening Identity Protection.

## Multi-Factor Authentication

Because of how people use them, passwords are inherently insecure. Some years ago, it would take a computer a very long time to crack or guess a password. As such, even the simplest passwords were secure enough to protect against most forms of attacks. However, as hardware became more powerful, the time needed for a computer to crack a password decreased exponentially. Today, with the right hardware, a simple six-character password can be cracked in a matter of minutes! To make it harder for passwords to be brute-force guessed, or at least to increase the time it takes, we are taught to use longer and more complex passwords. Unfortunately, research has shown that requiring longer, more complex passwords that periodically expire can lead to the selection of passwords that are sometimes easier to guess.

When you think about it, authentications are based on a combination of three things: something you know (such as a pass phrase), something you have (like a physical token), or something you are (a biometric marker of some kind). Traditional password-based authentication combines your username with something you know, but anyone else who knows the same thing can pretend to be you.

To explain why you should use MFA to secure access to user accounts, let's first take a somewhat simplistic look at how typical authentication against Azure AD is performed. Figure 3-3 illustrates the steps involved when a user tries to authenticate using a client like SharePoint Online. For the sake of simplicity, the finer details are omitted, as we only want to understand the principles behind standard authentication.

1. The user connects to the resource. For example, this might be SharePoint Online.
2. Because the client is unauthenticated, Azure AD will send the client a "challenge"; the user is asked to provide his credentials.
3. The user (client) enters his credentials (a username and password) and sends them to the authentication service which, in turn, will verify the credentials.
4. If the credentials are verified, the resource is "unlocked", and the user is granted access.

Figure 3-3: Traditional authentication flow

The last step is not entirely correct. Upon successful authentication, the client will get a token which it then can use to request access to a specific resource (like SharePoint Online). This is the difference between authentication (getting a token) and authorization (being allowed to access a resource). The exact contents of the four steps may vary according to how the application is implemented, too, but for the sake of brevity, let's just assume the user is granted access to the resource after the authentication happened.

An attacker who manages to steal a password, either by brute force guessing or through social engineering, might be able to leverage the stolen password to access multiple sites. Users who pick weak passwords, write passwords down, store them insecurely, or give them up to social engineering attempts aren't necessarily to blame; although many credential thefts are the result of user carelessness, it's difficult to blame non-technical users for making these mistakes when an average user must keep track of multiple credentials, each with its length and strength requirements. Although password management tools can help with remembering passwords, those tools are often protected by a single password themselves.

Since knowing a user's password allows an attacker to perfectly impersonate the user, poor password management means that users are vulnerable to impersonation. To help fix this, we have several options. One is to make it harder to guess or crack passwords; another is to harden systems, and train users, to reduce the chances that an attacker can steal the password. A third option is to require the user to provide more than one type of authentication factor, which is where the "multi-factor" part of MFA comes in.

The principle behind MFA is that you add a second (or even third) factor from the "something you have" or "something you are" categories. Typically, MFA is implemented as a combination of a password with a smartcard, one-time generated code, mobile app notification, or biometric information such as a fingerprint, facial recognition, or an iris scan. To gain access to a system, an attacker would have to have access to both the additional token and the user's password. Although adding an additional factor to the authentication is a huge leap forward in terms of security, it does not take away all risks that entail the use of passwords.

**Real-world:** MFA is a valuable security measure, but it is not a replacement for good password and account management, and it has vulnerabilities of its own. For example, there have been several high-profile targeted attacks where the attacker took control of the target's mobile phone number by convincing the mobile carrier to issue a new SIM so that the attacker received the MFA authentication code required to execute a password change ([here's one example](#)). Even with MFA deployed and enforced, you should still be monitoring your users' logon activity for anomalies, and where possible, you should discourage the use of SMS MFA. Recent NIST [guidance](#) also recommends against using SMS MFA.

## Office 365 MFA

Office 365 includes simple MFA capabilities through a feature called Office 365 MFA. Apart from Office 365 MFA, other solutions can provide multi-factor authentication, including Azure MFA and various third-party MFA solutions. Office 365 MFA leverages the Azure MFA platform. Although Office 365 MFA and Azure MFA are very similar in terms of functionality, the latter requires Azure AD Premium. The biggest difference

between Azure MFA and Office 365 MFA is that the latter can only be used to secure access to first-party Office 365 workloads (e.g., Exchange Online, SharePoint Online, etc.).

Azure MFA extends beyond these workloads and can also be used to protect other cloud and on-premises resources. Both Azure MFA and Office 365 MFA support the following additional authentication options:

- Mobile app ([Microsoft Authenticator](#)) available for Android and iOS:
  - Notification: the user receives a notification in the mobile app to ask them to confirm their identity by clicking the **Approve** button. Once the user confirms, they log in automatically.
  - Verification Code: the mobile app generates a new code every 30 seconds. After the user enters the current code (on-screen), the sign-in process continues.
  - Authenticator app sign-in: Also known as “passwordless sign-in”, in this mode the standard Microsoft sign-in dialog will display a two-digit number and generate a request to the Authenticator app asking you to tap or enter the matching number on-screen. This method lets users log in using their phone with no typing or password entry. See the [documentation](#) for more details on how to set this up.
- Phone call. The user receives a phone call, asking them to confirm that they are signing in by pressing the # key. After confirming, the user logs in automatically; no code is necessary.
- Text Message (SMS). A one-time passcode (6 digits) is sent to the user’s mobile device. This code must be entered before the sign-in process can continue.
- Oath Hardware Token. The user uses a physical token that generates a random one-time passcode every thirty or sixty seconds. These tokens are often useful in scenarios where the user cannot access their mobile phone when they need to complete MFA.
- Additional [third-party authentication methods](#), including those from RSA Data Security and Duo Security. If you want to use a third-party authenticator, you need Azure AD Premium licenses.

In February 2019, Microsoft noted that less than 9% of accounts with administrative access to Azure AD had MFA protection enabled. Although some excuses can be offered for not using MFA to protect accounts used to run PowerShell against Microsoft 365 endpoints, that excuse is less valid now that all the key PowerShell modules support MFA. You should secure all administrative accounts with MFA. Microsoft is making it easier to do so by introducing security defaults to all tenants that don’t already use MFA or conditional access policies. We cover the features available in security defaults later in this chapter.

## Configuring Accounts for MFA

Configuring accounts for MFA is straightforward. The simplest way to do so is through the Microsoft 365 admin center. Log in and navigate to **Users** and then **Active Users** and select **Multi-factor authentication**. From the MFA page, you can select users, individually or in groups, and enable them for MFA with a single click. Through the **service settings** tab, an administrator can control additional options, such as:

- Whether a user can generate app passwords.
- What additional verification options are available? By default, all options are enabled (mobile app verification/notification, text message (SMS), or phone call). Microsoft [strongly recommends](#) that you focus on using the mobile (authenticator) app for MFA.

You can configure the MFA registration policy for your tenant by accessing the Azure AD admin center, selecting **Security, Identity Protection**, and then **MFA registration policy**. You can also determine when a user can manage their MFA enrollment by using a conditional access policy. This is discussed in more detail later.

To set the MFA methods for a user account through the Azure AD admin center, find the user account, select **Authentication methods**, and then add the desired method. To reset the MFA enrollment for a user account, select **Require re-register multi-factor authentication** from the [...] menu.

**Note:** If your organization has Azure AD Premium licenses, you should use conditional access policies to require MFA rather than the script in this section. Conditional access policies offer significant flexibility compared to simply setting a user's MFA state to "Enforced".

If your organization has Azure AD Premium P2, you can configure an MFA registration policy to ensure that all your users are registered for MFA. If you wait for a user to be prompted to enroll for MFA, and you exempt users from MFA when they are coming from a trusted location or device, an adversary could enroll for MFA on a user's behalf and the user might not know. An MFA registration policy will ensure the user is prompted to enroll for MFA even if they would ordinarily be exempted from performing MFA during a sign-in.

## Scripting MFA Enablement

An administrator can also use PowerShell module to configure MFA or to enable/disable MFA for users. In the following example, we enable an account for Phone-based MFA necessary parameter values. You must be signed into the Microsoft Graph with the *UserAuthenticationMethod.ReadWrite.All* permission and select the beta profile for the command to work. This script shows how to use Microsoft Graph PowerShell SDK cmdlets to work with SMS-based MFA challenges. The script:

- Declares the value of the identifier used for mobile phone numbers (the value is always the same).
- Gets the identifier for the target user account.
- Populates a hash table with the phone number to use and its type. The phone number must have a space between the international code and the local number. It should be unique within a tenant but doesn't have to be.
- Runs the *Get-MgUserAuthenticationPhoneMethod* cmdlet to check if a mobile phone number is already present in the account.
- If a phone number does not exist, the script runs the *New-MgUserAuthenticationPhoneMethod* to add it as an authentication method to the account.
- Alternatively, if a phone number exists, the script runs the *Remove-MgUserAuthenticationPhoneMethod* cmdlet to remove the old number and then adds the new number.

```
[PS] C:\> $MobilePhoneId = "3179e48a-750b-4051-897c-87b9720928f7"
$UserId = (Get-MgUser -UserId Lotte.Smith@Office365itpros.com).Id
$Params = @{
    PhoneNumber = "+353 862267785"
    PhoneType = "mobile"}
$AuthPhone = Get-MgUserAuthenticationPhoneMethod -UserId $UserId -ErrorAction SilentlyContinue
If (!$AuthPhone) { # No authentication methods are there, so proceed
    New-MgUserAuthenticationPhoneMethod -UserId $UserId -BodyParameter $Params }
Else {
    Remove-MgUserAuthenticationPhoneMethod -UserId $UserId -PhoneAuthenticationMethodId
$MobilePhoneId -Erroraction Stop
    New-MgUserAuthenticationPhoneMethod -UserId $UserId -BodyParameter $Params }
```

The next time the account signs in, they will get an SMS MFA challenge (Figure 3-5).

Similar cmdlets are available to enable FIDO2 (*New-MgUserAuthenticationFido2Method*), the Microsoft Authenticator app (*New-MgUserAuthenticationMicrosoftAuthenticatorMethod*), temporary passwords (*New-MgUserAuthenticationTemporaryAccessPassMethod*), and so on.

Depending on the selected verification method, the user may need to complete some extra steps. For instance, if the Authenticator app is selected, the user must install the app on their phone and scan a QR code to link the application to Azure AD, and by extension to the tenant. Once the added verification method is configured, the user's enrollment is complete and the next time they sign in, they will use multi-factor authentication.

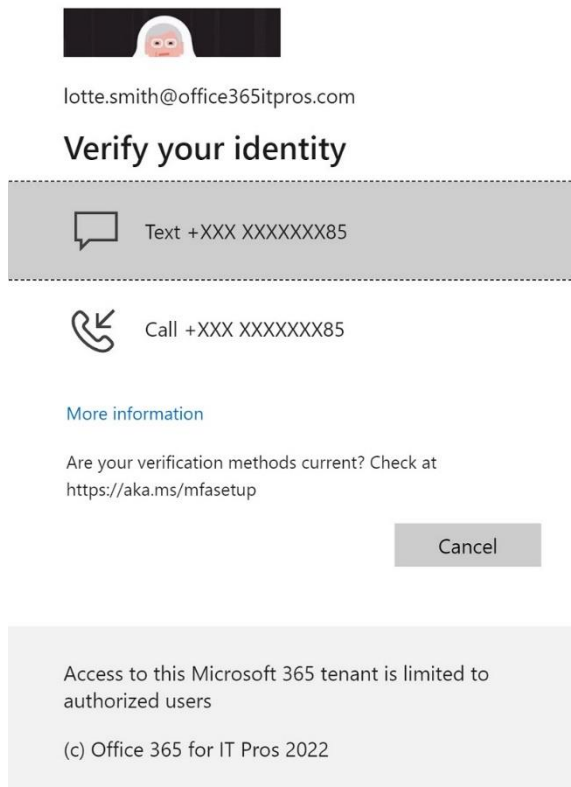

Figure 3-5: MFA sign-in using SMS

## Listing Office 365 MFA-Enabled Accounts

When managing Office 365 MFA for multiple users, it is useful to know which users are enabled for MFA, whether users have completed the onboarding process, or the verification options configured. You can access this information in the Azure AD admin center by accessing the **Usage & insights** blade and then selecting **Authentication methods activity**. From here you will be able to see (and export) information about MFA and SSPR enrollment. Note that accounts need an Azure AD Premium P1 or P2 license to access the Usage & insights blade.

It's also possible to retrieve the information about the authentication methods used by Azure AD accounts using cmdlets in the Microsoft Graph PowerShell SDK. See [this article](#) and example script.

## Tracking MFA Sign-ins

Like any other sign-in to Azure AD, all MFA-enabled sign-in appear in the [Azure AD sign-in log](#). You can view the log interactively or download events to a CSV file and examine them afterward in Excel or Power BI. The MFA Required column in the CSV file tracks whether an account is MFA enabled or not, while the status code captures the outcome of a sign-in attempt. Important codes include:

- **0**: Success.
- **50058**: An application tried to perform a silent sign-in (using an access token) to an MFA-enabled account but could not complete.
- **50076**: The user did not pass the MFA challenge because they did not respond in the allowed time.
- **50074**: The user did not pass the MFA challenge. For instance, they input an incorrect code. You can see the authentication method used in the MFA Auth Method column.

To look up the meaning of an Azure AD error code, use [this tool](#).

## Using MFA

Users sometimes need some time to become accustomed to dealing with MFA challenges, but since so many other cloud services and applications support it (including Google's applications, Facebook, Apple iCloud, and almost every online banking system), MFA quickly becomes routine, needing minimal effort or thought. We recommend receiving notifications to the mobile app for authentication requests as the default MFA method. Because the mobile app needs a connection to the Internet to receive notifications, you might not always be able to use the app, for instance, when roaming in a foreign country or while you are on an airplane. In these cases, you can revert to another method, such as generating a verification code in the mobile app.

By default, the user's preferred additional verification option is used. If the user registered for multiple verification options, they can select a different method when their preferred verification method is (temporarily) unavailable or when the user doesn't respond to a challenge within a period. For instance, when the mobile app is unavailable because of a lack of Internet connectivity, a phone call or text message can be requested instead. To register for added verification options, the users must access their **My Sign-Ins** page. On the My Sign-Ins page, click **Security info**. From the Security info page (Figure 3-6), users can add extra phone numbers, configure the authenticator app, manage their SSPR registration (e.g., security questions and alternate email addresses), create app passwords, or change the preferred authentication method.

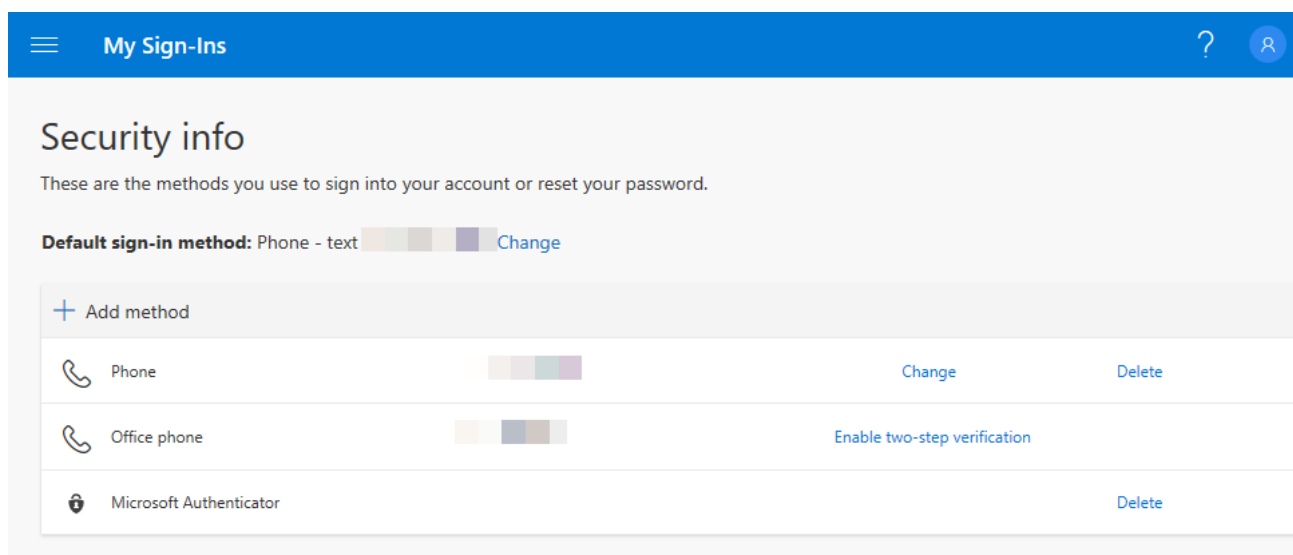

Figure 3-6: Changing MFA Verification Options for an account

Sometimes users complain about receiving too many authentication or MFA prompts from Azure AD. This can be a result of your tenant's policies; other times it is a result of devices or browsers missing important plugins or software updates. Microsoft has created an Azure Log Analytics Workbook to help diagnose authentication prompt frequency. This workbook is called [Authentication Prompts Analysis](#).

## Encouraging Use of the Authenticator App

If you have had MFA deployed for some time, chances are your users may be using a mixture of voice calls, SMS messages, and the Authenticator app to perform MFA. The Authenticator app provides the most secure verification, and it offers additional valuable capabilities such as one-time pass codes, passwordless sign-in, and authentication broker support on iOS devices. It is difficult to convert users from voice calls or SMS to the Authenticator app, though.

Azure AD can encourage this conversion through an in-line prompt to set up Authenticator. This prompt comes after the user completes their sign-in and MFA and only if they have not yet enrolled in the Authenticator app. To enable this prompt, log in to the Azure AD admin center and navigate through **Security > Authentication Methods > Registration Campaign**. From here you can enable the prompt, configure how

many days an end-user can ignore (snooze) the prompt, and optionally, target the prompt to a subset of your users.

In addition to this feature that prompts users to set up Authenticator, you can also enroll directly in the Authenticator app without scanning a QR code. Simply add a **Work or school account** in the Authenticator app and then click **Sign in** when prompted.

## Controlling Access

For most organizations, the thought of allowing access to all their data from anywhere, at any time, on any device is not palatable. Microsoft has recognized this concern and made the conditional access features a core capability of Azure AD Premium. With conditional access, you can exercise substantial granularity in controlling the who, what, when, and where of all connections.

### Conditional Access Policies

By default, all users with a valid license can access resources available to their account if they can reach the service endpoint and log in. Sometimes, an organization might want to limit who can access resources, or perhaps control from which locations users can access those resources. Most Microsoft 365 applications do not provide such functionality. Instead, they leverage the advanced capabilities of Azure AD Premium and Microsoft Endpoint Manager.

Figure 3-7: Settings available when creating a new conditional access policy

Conditional access policies define rules that determine when and how a user or workload identity can access an application. Azure AD evaluates characteristics of the session such as the IP address, location, device, and sign-in risk score. If the device is enrolled with Microsoft Endpoint Manager, the device's compliance with organizational policy as well as security risk determined by Microsoft Defender for Endpoint (MDE) can also factor into the conditional access policy. Collectively, these factors allow you to create policies to apply granular decisions about what sessions can access applications. These factors can also apply to certain activities such as whether a user can view documents in SharePoint Online, or view *and* download documents.

Numerous ways exist to restrict access to resources using conditional access policies. You can restrict who is allowed access to a resource, define which devices can be used to access resources or control from what locations an app or service can be used. You can also add restrictions based on the characteristics of the user

login; for example, if a user logs on from an unknown location, you can require them to authenticate with MFA even if the device itself would normally be trusted.

Before diving into an example of a conditional access policy, it is useful to know that each policy consists of one or more *conditions*, each of which can have a set of linked controls as illustrated in Figure 3-7. Conditions may have exceptions.

Conditions you can apply to the policy include:

- **Users or workload identities** sets which users, groups, directory roles, or service principals the policy should apply to. You can choose to include or exclude individual users or groups for the policy, or you can include or exclude all guest users or holders of specific Azure AD directory roles. You can also apply the policy to built-in directory roles such as Global Administrators. Finally, you can apply the policy to service principals via the workload identities capability. This lets you restrict the use of service principals (also known as app registrations). Service principals often have highly privileged access to data in your tenant.
- **Cloud apps or actions** define which applications the policy applies to or what user behaviors the policy applies to. You can choose to enable the policy for all applications or select the applications for which it should be valid. Applications include the various Office 365 workloads or a third-party application that you have configured to rely on Azure AD for authentication, like Salesforce, Workday, Facebook for Work, etc.

Applying conditional access policies to individual Microsoft 365 workloads presents challenges to maintaining a consistent security posture. Microsoft has addressed this challenge by introducing a virtual application that represents all the workloads. This app can be selected in the **Cloud apps** section of a conditional access policy and is aptly named **Office 365**. Note that currently [some workloads](#), such as Microsoft Planner are not included in the Office 365 virtual application. Where possible, we recommend that you attempt to target your conditional access policies to the Office 365 virtual application rather than to individual workloads. Targeting individual workloads provides more flexibility but it also introduces hidden complexities due to the interdependencies of various workloads. A similar virtual application called **Microsoft Azure Management** is also available to target policy to Azure management tools like the Azure Portal, PowerShell, etc.

In addition to applications, you can also control when a user can register for MFA and SSPR (**Register security information**) and/or register or join a hybrid device (**Register or join devices**). This control is useful if your organization has a security policy that requires users to register for MFA/SSPR from a trusted device or location. To control what happens when the user registers or joins a hybrid device, you must also disable the corresponding MFA settings under **Devices > Device Settings** in the Azure AD admin center.

Finally, you can create conditional access policies that are triggered when users perform specific tasks in supported applications by using Authentication contexts. Authentication contexts modify a conditional access policy from applying to *all* access to an application to specific tasks (e.g., downloading sensitive information) within the application.

- **Conditions** define characteristics of the authentication attempt which lead to a policy to be applied or not. Examples of conditions include:
  - **Sign-in risk** evaluates the risk that the sign-in attempt is coming from someone other than the authorized user. Microsoft evaluates sign-in risk using a complex supervised [machine learning model](#). To use this condition, the target account must have Azure AD Premium P2.
  - **User risk** evaluates the risk of the individual user that is attempting to access the application. For example, a user whose password is in a list of leaked credentials is considered high risk. To use this condition, the target user must have Azure AD Premium P2.

- **Device platforms** determine from which OS platform the authentication must be made before an action is considered. Options include Windows, iOS, Android, macOS, and Linux.
- **Locations** specify locations that will trigger the policy when the user logs in; locations are determined based on the IP of the client making the request, the user's Global Positioning System (GPS) location reported by the Authenticator app, or the country Microsoft infers the user is coming from. You can define a set of known (trusted) corporate locations by IP address range.  
To define a location based on IP address, country, or GPS location, go to **Security > Conditional Access > Named Locations** in the Azure AD admin center and click **Countries location** (country or GPS location) or **IP ranges location** on the toolbar.
- **Client apps** determine what application type (browser, ActiveSync, mobile client, legacy authentication, etc.) should trigger the policy. Policies created before July 2020 only apply to the selected types of client apps (or "Other clients" for legacy authentication). All new policies apply to all client apps, including legacy authentication, by default.
- **Filters for devices** let you target the policy based on attributes of the device object in Azure AD. For example, you might want to have one conditional access policy apply to personal mobile devices, while another policy might apply to mobile devices that the organization owns. In combination with Intune, you can do this by creating a device filter rule. A filter rule of *device.deviceOwnership -eq "Personal"* will apply your policy only to devices marked as personally-owned in Microsoft Intune. A filter rule *of device.trustType -eq "ServerAD"* will apply your policy only to devices that are hybrid Azure AD joined.

On the controls side (which you access through the link labeled **Grant**) you can choose from the following controls. There is also a radio button to control requiring any one of the actions selected (an *OR* condition) or all of them (an *AND* condition):

- **Block Access:** this is self-explanatory.
- **Grant (Allow) access,** with or without the following optional requirements:
  - **Require multi-factor authentication.**
  - **Require device to be marked as compliant.** For this option to work, the device must be enrolled in Microsoft Intune and targeted with a compliance policy. The rules in the compliance policy determine if the device will be marked compliant (or not).
  - **Require Hybrid Azure AD joined device** verifies whether the computer is simultaneously joined to the on-premises AD and Azure AD tenant.
  - **Require approved client app** lets you restrict whether applications must be accessed through a [supported](#) client application instead of through a third-party application or a bare API.
  - **Require app protection policy** allows you to restrict connections to apps that are subject to a Microsoft Endpoint Manager app protection policy applied in your tenant.
  - **Terms of use** allows you to require users to view and accept text stored in a PDF document before they access an application. You must first create a terms of use document in Azure AD before you can use this control. To create a terms of use document, go to **Security > Conditional Access > Terms of use** in the Azure AD admin center and click **New terms** on the toolbar.
  - **Require password change** allows you to force a user to change their password through SSPR. This grant is usually combined with the user risk condition to lower the user's risk score.
- **Session:** this control lets you restrict what authenticated users can do within the context of a specific application session:
  - **Use app enforced restriction** lets you enforce what users can do in Exchange Online or SharePoint Online such as printing and downloading attachments/files.

- **Use Conditional Access App Control** integrates with Microsoft Defender for Cloud Apps (MDCA) to apply deep controls to actions users take within an application. This control proxies all the user's access to the application through MDCA.
- **Sign-in frequency** lets you control how often the user must re-authenticate.
- **Persistent browser session** controls how long the user can remain signed-in to browser-based applications.
- **Customize continuous access evaluation** allows you to disable CAE (discussed earlier in this chapter) or enable strict enforcement mode.
- **Disable resilience defaults** provides the option to disable the safeguards of the BAS during an Azure AD outage. The BAS still evaluates tokens using CAE to ensure they are valid (e.g., due to the deletion or disabling of a user account) but assumes that conditions in a conditional access policy that were previously satisfied when a cached token was issued (such as group membership) are still valid. If you are uncomfortable with these assumptions, you can enable this session control, but, in the event of an Azure AD outage, any users included in the conditional access policy cannot take advantage of the BAS.

As you begin building conditional access policies, you must be careful not to inadvertently impact user access to workloads and other applications. To help with this, Azure AD allows you to enable conditional access policies in report-only mode. When a conditional access policy is enabled in report-only mode, you will be able to see the expected effect of the policy when you review the Azure AD sign-in logs. Users will not be affected since the policy is not fully enabled.

One important caveat to this is the device compliance requirement discussed earlier. Even if a policy is enabled in report-only mode, if you require device compliance in that policy, users of iOS, Android, and macOS devices may be prompted to select a certificate if their device is not compliant. You can avoid this behavior by excluding iOS, Android, and macOS devices from your policy while it is in report-only mode.

Whether your CA policy is enforced or in report-only mode, you can troubleshoot CA behavior from the sign-ins log in the Azure AD admin center. You can access the sign-ins log in the context of the entire tenant, a specific application (e.g., Exchange Online), or a specific user. If you click on a sign-in and then click on a specific CA policy in the Conditional Access tab of the details pane, you can see what policies were applied to the sign-in. The Policies blade supports search, sort, and filtering, which makes it easier to manage many CA policies.

## Require MFA for External Connections

To illustrate the capabilities of the platform, consider the following scenario: a company employs sales representatives who travel often as part of their job. Sales representatives are permitted to use personal devices, so there is a mix of iOS, Android, and Windows devices in use. The company's security policy requires that all external connections to Microsoft 365 from sales reps must use an additional authentication factor for access from outside the corporate network.

We can break down the scenario into the following elements to create a new conditional access policy that meets the software company's requirements:

1. The policy should apply to all users who are part of the sales department. Because all sales representatives are part of a group called "Sales", the policy can easily be applied to the latter.
2. Even though a conditional access policy can apply to many cloud applications (including non-Microsoft applications), it must only be applied to Office 365. Be careful applying conditional access policies to only a subset of applications. You can inadvertently forget to require MFA in some scenarios which would present a security risk.
3. Only logon attempts from outside the corporate network should require an additional authentication factor.

4. Given that all sales representatives can choose personal devices, the policy should apply, regardless of the device used to access resources.

To create a policy meeting these four requirements, log in to the Azure AD admin center and navigate to **Security** and then **Conditional Access**.

1. Click **New policy** and name the policy "*Require additional authentication for external sales users*". Under **Assignments**:
  - a. Click **Users or workload identities**, select **Select users and groups**, and select the *Sales* group. Do not forget to click **Done** to save your progress before moving onto the **Cloud apps** blade.
  - b. Under the **Cloud apps** blade, select Office 365.
  - c. Under **Conditions**, click **Locations**, click **Yes** to enable this section and then click **Exclude**. There, select **All trusted locations**.
  - d. Under **Access Controls**, click **Grant**, and then select **Require multi-factor authentication** and **Require one of the selected controls**.
2. Under **Enable policy**, click **On**.

**Note:** Before you can create a new policy, you should configure your known locations. This can be done by going to **Security > Conditional Access > Named locations** and defining the IPv4 and IPv6 address ranges that are used for Internet egress in your organization. For most organizations, these ranges will be network address translation (NAT) addresses defined on your firewalls. If your organization uses public IP space on your network, this might also be the IP addresses of client computers and/or member servers. You should not include private IP addresses (e.g., 10.0.0.0/8, 172.16.0.0/12, or 192.168.0.0/16).

Without the information on known locations, the conditional access engine cannot determine if an authentication request stems from inside or outside of the corporate network, and the machine-learning systems that help rate sign-in risk miss an important signal. Named locations are also shown in the sign-in logs, making the logs much easier to interpret with context for an IP address.

When you configure named locations, you can optionally mark those locations as "trusted". If you mark a location as trusted, Azure AD allows you to target a conditional access policy to "all trusted locations" without individually listing them. Trusted location information is also used as a signal to Azure AD's security reporting functionality.

Now, if someone from the sales department tries to authenticate to Exchange Online, no matter whether they access it through the Outlook mobile app, desktop Outlook, OWA, or an Exchange ActiveSync client using modern authentication, they will be prompted for additional authentication factors if the authentication is attempted from outside the known corporate locations.

The above example illustrates one of many possible scenarios in which conditional access can be very useful. For more information on conditional access, have a look [here](#).

## Require MFA for All Privileged Roles

Privileged access to Microsoft 365 and Azure AD should always require MFA, with no exceptions. You might even consider requiring a hybrid Azure AD joined device or a device that is compliant with Intune as additional protection. Azure AD makes this easy to do by applying your conditional access policy to built-in directory roles. You should exclude "break glass" or "emergency access" accounts from this policy in case there is ever a situation where the MFA service is unavailable, or you do not have access to a device that will pass tests (if you require this)! Ideally, break-glass accounts should have as [few dependencies for authentication](#) as possible.

To achieve this, you will need to create a new conditional access policy. Configure the conditional access policy with the following settings:

- **Assignments > Users or workload identities** – Include **Directory roles** and select the built-in directory roles you want to include. We recommend that you select all the roles unless you have a valid business or technical reason not to. Exclude **Users and groups** and select your break glass accounts.
- **Cloud Apps or actions** – Include **All cloud apps**.
- **Access Controls > Grant** – Check the **Require multi-factor authentication** checkbox.

If you want to also require hybrid joined or Intune compliance devices, select the corresponding checkboxes on the Access Controls > Grant screen. Once you are ready, configure the **Enable policy** setting to **On**. Your changes will take effect immediately.

## Disable Basic Authentication for Exchange Online

Authentication policies allow tenants to disable basic authentication for email connection protocols such as POP3 and IMAP4. The [documentation on how to apply authentication policies](#) to enforce this change is mandatory reading before you make this change and the process is also explained in Chapter 7. If you have Azure AD Premium, you can (and should) also use conditional access to restrict the use of basic (legacy) authentication across all services that use Azure AD. Remember that many attacks against tenants try to exploit weaknesses in basic authentication, so it makes sense to deploy an authentication policy to disable basic authentication for as many protocols as possible and assign it to all accounts.

**Note:** Exchange 2019 Cumulative Update (CU) 1 and newer allows you to turn off legacy authentication for your on-premises Exchange servers. This change is strongly recommended. See this [blog post for more details](#).

## Restricting Legacy Access with Conditional Access

Microsoft recommends the use of conditional access policies to block legacy clients. This seems like a straightforward thing to do, but there are some nuances. For example, it is a bad idea to block these clients without first looking at your sign-in logs to see which applications your users are using with legacy authentication, and how many of them there are. Turning off every scan-to-email device in a large organization at once, for example, would not be good.

To block legacy clients, you will need to create a new conditional access policy. Configure the conditional access policy with the following settings:

- **Assignments > Users or workload identities** – Include **All users**.
- **Cloud apps or actions** – Select **All cloud apps**.
- **Conditions > Client apps** – Check the **Exchange ActiveSync clients** and **Other clients** checkboxes.
- **Access Controls** – Select **Grant** and then **Block access**.

Unlike other conditional access policies, this change may take up to 24 hours to become fully effective. You should test with a small set of pilot users before you target the policy to all the users in your tenant.

## Restricting Access to the Outlook Mobile Application

While blocking access from legacy clients that do not support MFA is an important first step to securing email access, you may want to go a step further and require the use of Outlook Mobile to access Exchange Online. You can simply require the use of Outlook Mobile, or, you can go a step further and require that Outlook Mobile be managed by a Microsoft Endpoint Manager App Protection policy.

To do this, you will need to configure a new conditional access policy with the following settings:

- Cloud apps or actions – Select **Office 365 Exchange Online**.
- Conditions > Client Apps – Select **Mobile apps and desktop clients**.
- Conditions > Device platforms – Select **Android, iOS, and macOS**.
- Grant – Select **Require approved client app**.

If you need to ensure that users are connecting with an instance of Outlook Mobile that is managed with an App Protection policy from your organization, also select **Require app protection policy** in the **Grant** menu and ensure **Require all the selected controls** are selected. For more information on App Protection policies, refer to Chapter 16.

**Note:** You must select macOS under device platforms due to a change Apple made in iOS 13. Beginning with iOS 13, iPads are identified as macOS devices. It is very important to note that this policy will also apply to connections from Office applications on Mac devices!

We recommend that you start by assigning this policy to a small number of users or groups to test functionality. Once you are satisfied with the results of the CA policy, you can target the CA policy to all users in your tenant.

**Note:** If you have an on-premises Exchange organization that is configured for Hybrid Modern Authentication (HMA), this CA policy will also affect client access to on-premises mailboxes.

## Controlling SharePoint Downloads

A common requirement is to restrict downloading content from SharePoint Online to corporate devices. At the same time, users should be allowed to view content through browsers on unmanaged devices. This can be accomplished with a combination of conditional access policies and configuration in SharePoint.

First, you will need to configure SharePoint Online. To do this, complete the following steps:

1. Access the SharePoint admin center.
2. Browse to **Policies > Access Control**.
3. Select **Unmanaged devices**.
4. Select **Allow limited, web-only access**.

Next, log in to the Azure AD admin center and navigate **Security** and then **Conditional Access**.

**Note:** You will find two new policies prefixed with [SharePoint admin center]. **Disable these policies immediately! They are automatically enabled by SharePoint Online and are very restrictive.**

SharePoint will also disable legacy authentication access (e.g. from Office 2010 and outdated Office 2013 clients) to SharePoint Online when you make this change.

Configure a new conditional access policy with the following settings:

- Cloud apps or actions – Select **Office 365 SharePoint Online**.
- Conditions > Device platforms – Choose **Select device platforms** and then select **Windows**.
- Conditions > Device state (Preview) – Select **Exclude** and then **Device Hybrid Azure AD joined** and **Device marked as compliant**.
- Session – Select **Use app enforced restrictions**.

This policy will enforce restrictions on all Windows devices. If the Windows device is hybrid Azure AD joined or Intune compliant, users will have complete access to SharePoint documents. If the user is not using a hybrid Azure AD joined (or Microsoft Endpoint Manager compliant) Windows device, they will only be able to view documents in the web browser. Downloads and printing will be disabled, and the user will see a notification across the top of the browser.

Mobile devices and Macs will not be affected by the policy. To apply restrictions on mobile devices and Macs, you need to add Microsoft Endpoint Manager to the solution and adjust your policy to target all device platforms. We discuss Microsoft Endpoint Manager device compliance and app protection policies in more detail in Chapter 16.

While the example in this section targets all of SharePoint, you can also enforce policies on a site-by-site basis. Microsoft documents this in [this document](#). Regardless of the path you choose, your changes might take ten-to-fifteen minutes to become effective.

## Require MFA and a Hybrid Joined Device When Accessing Labeled SharePoint Sites

While the previous example applies to SharePoint as a whole, chances are you have certain SharePoint sites that contain much more sensitive information. To protect this information, you may need to require more assurance that the data is being accessed in a manner that meets your security policies. In this example, we will combine multiple Microsoft 365 features with conditional access. Specifically, we will require users who access data in a Microsoft 365 group labeled with a Microsoft Information Protection (MIP) sensitivity label called *Highly Confidential* to connect with a hybrid Azure AD joined device and perform MFA every time they access the data. We will accomplish this using a feature of conditional access called authentication context.

Authentication context is currently in public preview but is available in all tenants. With authentication context, applications can request that Azure AD re-evaluate authentication and authorization when a user takes certain actions. You can define up to 25 authentication contexts in your tenant that applications can use in their request. These contexts are simply a name that you can choose from a list in the application and your conditional access policy. For example, you might create a context called *Require MFA*, and another called *Require Trusted Location*. Today, Microsoft lets you use authentication context in SharePoint Online as well as via Microsoft Defender for Cloud Apps (MDCA). The interface is [publicly available](#) and third-party applications and in-house developers are free to use authentication context as well. Applications retrieve the contexts you have configured via the Graph API.

To begin, we will first create an authentication context for our example. To do this, log in to the Azure AD admin center and navigate to **Security, Conditional Access**, and then **Authentication context (Preview)**. Click **New authentication context** on the toolbar and create a context with the following values:

- Name – Require MFA and Hybrid Joined Device
- Description – This authentication context requires the user to complete MFA and have a hybrid Azure AD joined device
- Public to apps – Checked

Next, we will create a conditional access policy to enforce our requirements. Configure a new conditional access policy with the following settings:

- Users or workload identities – Select **All users**.
- Cloud apps or actions – Select **Authentication context (preview)** and then check the **Require MFA and Hybrid Joined Device** context.
- Grant – Select **Require multi-factor authentication** and **Require Hybrid Azure AD joined device**. Select **Require all the selected controls**.
- Enable Policy – **On**.

We now have an authentication context and a conditional access policy that will enforce it, but, we have not yet created a trigger for the authentication context to be requested. To do this, we will configure our MIP label. For this step, we assume that a sensitivity label called *Highly Confidential* already exists in the tenant. If you have not worked with MIP labels before, refer to Chapter 23 for more information.

Browse to the [Microsoft Purview Compliance portal](#) and go to **Information protection**. Double click the Highly Confidential label and click **Edit label** to begin editing it. Configure the following settings:

- Scope – Check **Groups & sites**.
- Groups & sites – Check **External sharing and Conditional Access settings**.
- External sharing & device access
  - Check **Use Azure AD Conditional Access to protect labeled SharePoint sites**.

- Select **Choose an existing authentication context (preview)**.
- Select **Require MFA and Hybrid Joined Device** from the dropdown list.
- Session – **Sign-in frequency** configured to 1 hour.

Configuring the sign-in frequency session control to one hour requires users to complete MFA again if their session is longer than one hour. This achieves a variation of the requirement to ensure that users re-complete MFA any time they access content labeled *Highly Confidential*.

Once you save your changes, SharePoint sites labeled *Highly Confidential* will begin triggering the conditional access policy we created earlier. There are many ways to label a site. One method is to assign the label to the group in Teams. To do this, find the Team, right-click, and click **Edit Team**. Set the **Sensitivity to Highly Confidential**.

While the authentication contexts feature is in public preview, you will find that there are several limitations to which clients and applications support authentication context. Microsoft documents those limitations [here](#). We recommend that you review this list before trying authentication contexts out in your organization.

## Policy Templates

The conditional access policy examples we have illustrated so far are very commonly deployed. While creating policies by hand provides the most flexibility for customization, and enables you to learn the platform, it also introduces opportunities for inadvertent errors and gaps in coverage. To help mitigate this possibility, Microsoft also provides a set of templates for commonly used policies that you can start with. To access the templates, login to the Azure AD admin center and navigate **Security > Conditional Access** and select **New policy > Create new policy from templates (Preview)** on the toolbar. Microsoft documents the set of approximately fourteen templates [here](#).

## Security Defaults

While we recommend licensing Azure AD Premium P1 (at a minimum) for all the users in your tenant, this may not be possible. You can achieve some of the most critical conditional access controls discussed earlier by enabling security defaults in your tenant. When you enable security defaults, you will get the following protections for your entire tenant, free of charge:

- Mandatory MFA for every privileged sign-in. This applies to members of [thirteen privileged](#) Azure AD roles as well as access to Azure management APIs including the Azure portal, CLI, and PowerShell modules.
- Mandatory MFA registration for all users using the Microsoft Authenticator app.
- MFA on an as-necessary basis for regular users once they're registered for MFA.
- Block legacy authentication protocols for all users, except for Exchange ActiveSync.

To enable security defaults, access the Properties blade inside the Azure AD admin center and then click **Manage security defaults**. Once you enable security defaults, the protections listed above will take effect immediately for your entire tenant. If you have Azure AD Premium, you can only enable security defaults if there are no conditional access policies enabled in your tenant. Since security defaults cannot be scoped to specific users for testing, we recommend using conditional access policies instead if you have Azure AD Premium. Newly provisioned Azure AD tenants have security defaults enabled by default and Microsoft is in the process of enabling security defaults in existing tenants that do not have compensating security controls already enabled..

## Cross-Tenant Trust

When guest users from another organization access resources in your tenant via Azure AD B2B, conditional access policies also apply to the guest users. This can create end-user experience issues because the user may

be required to enroll for MFA in both their home tenant and your tenant. You can configure Azure AD to trust the MFA that was performed in a user's home tenant to satisfy MFA requirements in conditional access policies. You can also require a user's device to be trusted by their home tenant to satisfy device compliance and/or hybrid Azure AD join requirements in your conditional access policies. These capabilities are part of a preview feature called cross-tenant access settings.

To configure cross-tenant access settings, log in to the Azure AD admin center and navigate to **External Identities** > **Cross-tenant access settings (Preview)**. You can configure your tenant to trust MFA and device identity from a guest's tenant globally by selecting **Default settings** and clicking **Edit inbound defaults**. On the **Trust settings** tab, you can check the following boxes:

- **Trust multi-factor authentication from Azure AD tenants** – if the user completes MFA in their home tenant, that MFA will also satisfy the require multi-factor authentication grant control in your conditional access policies.
- **Trust compliant devices** – if the user's device is marked as compliant by Intune or a partner solution in their home tenant, the device will also satisfy the device state filters in your conditional access policies.
- **Trust hybrid Azure AD joined devices** – if the user's device is hybrid Azure AD joined to their home tenant, the device will also satisfy the device state filters in your conditional access policies.

You may find that globally trusting these factors from any guest's tenant does not meet your security and risk management requirements. Instead, you can trust individual tenants. To do this, click **Add organization** on the **Organizational settings** tab. Enter a domain name registered in the guest's tenant and click **Add**. You can configure the same trust factors discussed above just for this tenant. Note that while you only need to specify one domain name in the guest's tenant, the trust settings will apply to the entire tenant, even if multiple domains are verified.

You can also use cross-tenant access settings to control a feature called Azure AD B2B Direct Connect. Teams is the first application to use B2B Direct Connect in its shared channels feature. Shared channels allow users to join a Teams channel without having a B2B guest account in the channel's home tenant. Users can also see the channel in their Teams client without changing tenants. The default cross-tenant access settings block B2B Direct Connect for all users in your tenant and inbound connections from external tenants.

There are two sets of settings for B2B Direct Connect. Inbound access settings allow you to control which external tenants can access your tenant. Outbound access settings control the users from your tenant can access resources in external tenants. You can enable Inbound or Outbound access globally, or you can enable it only for select users (or groups).

## Restricting Access to a Single Tenant

Throughout this chapter, we discuss several ways you can restrict user access using a wide variety of built-in features like custom claim rules or conditional access. However, none of these options address the problem of a user authenticating against another tenant. You might wonder why this is important or how this is different from disallowing someone to authenticate by disabling their account. In the latter scenario, the user is not able to log in to the corporate tenant, but that does not prevent them from accessing other tenants, using another identity. From a data leakage standpoint, this is a potentially dangerous situation as the user can log on to another tenant and copy corporate data to a repository on that tenant. The reason why a user can log in to various tenants is that most of the endpoints are the same for all tenants, worldwide. Blocking the endpoint would not be a smart move unless you want to block access to Microsoft 365 entirely. Here is an example to further illustrate the problem.

A user, Erica, works for a company that uses Exchange Online for corporate email, and she also has a personal tenant for her personal email. When no tenant restrictions exist, Erica can log in to either or both tenants from

her desk at work, but there is nothing to prevent her from signing into her personal tenant while at work. To lower the risk of intentional or accidental data leakage, the security team at Erica's employer wants to prevent Erica and her co-workers from signing into tenants other than the corporate tenant while at work. As mentioned earlier, blocking the sign-in endpoint (for example, through a proxy server) would also prevent Erica from signing into her company's tenant, and thus prevent her from doing her job.

Of course, other ways exist to restrict access. For instance, an administrator can define a set of internal IP addresses from which a user can authenticate into the corporate tenant. Although this effectively prevents someone from accessing the tenant outside the corporate network, it does not solve the problem described above.

To help organizations control access, Microsoft supports a feature known as "[tenant restriction](#)." The way this feature works is quite simple. When a user authenticates with Azure AD, the authentication platform also checks for an (HTTP) header called *Restrict-Access-To-Tenants*. The value of this header holds the names of all the tenants the user can access. You also need to add the *Restrict-Access-Context* header, which specifies the GUID of your tenant, so the service knows which tenant to apply the restrictions to. If these headers hold the name of the tenant the user is trying to access, the sign-in proceeds. If not, they receive an error message and are blocked from signing in. The message informs the user that *Your network administrator has restricted what organizations can be accessed. Contact your IT department to unblock access.*

For this feature to work, there must be a proxy server between the user and the internet that performs SSL inspection. Anything that can add an HTTP header will suffice. If you want to make sure that control is always exerted over user sign-ins, including outside the corporate network, users must always access the internet through a proxy server that can inject the header. To ensure this happens, other countermeasures (such as ensuring the user cannot modify proxy settings, etc.) must be present. Otherwise, users can bypass the restriction themselves. In addition, the proxy server should be accessible from outside the corporate network if you want to restrict access to a single tenant, regardless of the user's location. One way to achieve this is to use a "proxy-as-a-service" such as ZScaler.

The tenant restriction capability is not something you configure in Azure. Instead, it relies solely on your network infrastructure to inject the header. Currently, the feature only works with modern authentication, which is fine for most of Microsoft's applications, but if you use other applications or built-in ActiveSync apps, you must block access for those "legacy" apps if you want to maintain the restriction. You only need to apply the restriction to the authentication process (only for the Azure AD endpoints). There is no need to force users to connect through a proxy server to access applications such as Exchange Online.

Given the dependency on modern authentication, and because you cannot control how other tenants operate, if those tenants still allow legacy authentication (basic authentication), users can bypass the restriction. Thus, the feature in its current form only really is useful to control the potential for data loss if you fully control the endpoint, and thus prevent the use of applications that do not use modern authentication. With that said, it is a clunky way to prevent data loss; it is much less flexible or capable than Azure Information Protection (AIP), although (unlike AIP) it requires minimal client-side configuration.

You can use the feature for free with Office 365, but you must buy an Azure AD Premium license if you want to restrict access to other applications that rely on Azure AD for authentication.

Restricting access to a single tenant might or might not be useful. If preventing data leakage is a priority, anything you can do to make it harder for people to share information in an unauthorized manner can be helpful. Although the feature will most likely not prevent malicious users from leaking data, it can stop most regular users from (accidentally) leaking sensitive data to another tenant. Of course, it is only a small cog in a much bigger picture as many other features like DLP policies (Chapter 21) and Microsoft Information Protection (Chapter 23) help to safeguard your data.

# App Registrations and Permissions

Thus far we have focused on how users and their devices work with Azure AD. Azure AD also plays a very important role in supporting the integration of different Microsoft 365 workloads (for example, how Microsoft Teams gains access to SharePoint and Exchange Online), as well as third-party and in-house developed applications. Microsoft controls the permissions held by first-party applications like Teams, but the permissions that you grant third-party and custom-developed applications are controlled by you as the tenant administrator. There are two types of permissions that can be granted: delegated and application. Delegated permissions are used when an application (such as a website) signs the user in and then calls an API on behalf of the user. Application permissions are used when there is no user sign-in, such as in a background process or service.

Permissions are granted by consenting to different API permission scopes that are defined on various applications and resources. In Figure 3-8, a user is allowing an application to take various actions in Azure AD, Exchange Online, and SharePoint through a process known as consent. Azure AD manages and tracks consent and brokers the issuance of tokens that enable applications to communicate and use their permissions.

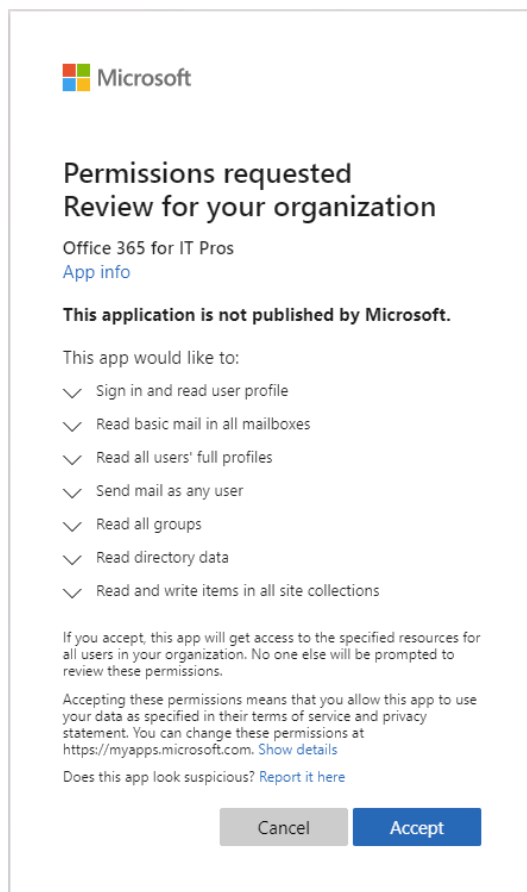

Figure 3-8: Granting Graph API permission consent to an app

Some of the permissions granted in Figure 3-8 are extremely broad and in the hands of an attacker or a poorly written application could present a significant security risk. For example, this application can read information about every user and group in the tenant, read email messages, send email as a user, and read and write any file in SharePoint. Historically, many organizations did not pay much attention to these consent requests, and they even allowed users to independently consent to certain application permissions.

Attackers have taken advantage of this historically overlooked vulnerability through avenues such as phishing attacks that induce users to grant [illicit consent](#). Once granted consent, the attacker might use their new

access to read a user's email or send a message impersonating them, for example. This gives the attacker a foothold and higher powers to expand their dominance.

## Controlling Consent

To combat the risks of granting illicit consent and over-privileged applications, Azure AD lets you control what types of permissions end users can consent to and provides an approval process for users to request consent for higher levels of permission. To configure this, browse to **Enterprise Applications > Consent and permissions** in the Azure AD admin center. Under **User consent settings**, you can configure what types of permission users can independently consent to. You can also decide whether owners of Microsoft 365 groups can grant an application access to the data in their groups.

For user consent for applications, we recommend that you choose the Microsoft recommended setting, **Allow user consent for apps from verified publishers, for selected permissions**, or the more conservative choice of **Do not allow user consent**. In a small organization, the conservative approach is likely practical, but, in a larger organization, the number of requests you will receive for relatively low-risk permissions is probably not manageable. The middle ground attempts to address this. Applications that are from verified publishers have completed an identity verification process with Microsoft and the publisher has agreed to certain terms and conditions. You can choose which permissions you consider low risk, including a curated list that Microsoft recommends.

Whether or not to allow users to grant access to group data is a question of risk tolerance. Your groups may contain very sensitive data that you would not want to risk granting access to a third-party application. This may mean that you require an administrator to grant consent on a per-request basis. You must however be prepared for the volume of approval requests that this may generate.

If you choose a restrictive setting for either user consent or group data consent, which we recommend you do, you will need a process to manage requests. Azure AD offers a solution to this with an approval process governed through a feature called admin consent workflow. To enable the approval process, browse to **Enterprise Applications > User settings** in the Azure AD admin center and configure the following settings:

- Users can request admin consent to apps they are unable to consent to – Yes.
- Who can review admin consent requests – Specify a list of users, one or more groups of users, or a built-in directory role.
- Selected users will receive email notifications for requests – Yes.
- Selected users will receive request expiration reminders – Yes.
- Consent request expires after (days) – 14.

Once you have enabled the admin consent workflow and configured the user consent settings discussed earlier, end-users will receive a modified version of the prompt in Figure 3-8 when they try to access an application requiring some permissions they cannot grant consent for. Instead, the user will be prompted to provide a business justification and submit a request for approval. The reviewers specified earlier will receive an email notifying them of the request that they can approve or deny under **Enterprise Applications > Admin consent requests** in the Azure AD admin center.

## Reviewing Existing Permissions

The admin approval workflow and restrictions on user consent add significant security for new requests, but they do not do anything for existing permission consents. In some organizations, the number of applications granted access to various permissions may be substantial. Some of these permissions may also be risky or even granted to an illicit application. You will need to create a process to evaluate previously-granted permissions and determine if they should remain.

This [blog post](#) explains how to use a script to collect an inventory of granted permissions. The script even attempts to determine the relative risk of different permission grants so you can focus your evaluation on the best place. While the script is helpful, the number of entries in a large organization can number in the thousands.

The App Governance add-on for Microsoft Defender for Cloud Apps (MDCA) aims to simplify the evaluation of permissions and provide continuous insight on the potential risks that your organization is exposed to through overly-permissioned apps.

## Restrict Workload Access to Approved IP Addresses

When you have app registrations that must hold sensitive or privileged access to support the functionality of an application or business process, you should take steps to control when that access can be used.

Conditional access can be used to do this using the workload identities preview. With this feature, you can create a conditional access policy, like the examples we discussed earlier in the chapter, which applies to app registrations. This feature requires Azure AD Premium P2.

In this example, we will restrict an app registration called *Office 365 for IT Pros* from being used except when running from approved IP addresses. You can use the egress IP address ranges of the data center(s) that host the application using this app registration. To configure the approved IP address ranges, log in to the Azure AD admin center and navigate to **Security > Conditional Access > Named locations**. If you have not configured a named location before, we discuss this in detail earlier in the Conditional Access section of this chapter.

Next, select **Security** and then **Conditional Access**.

1. Click **New policy** and name the policy "*Restrict Workload Access to Approved IP Addresses*". Under **Assignments**:
  - a. click **Users or workload identities** and select **Workload identities (Preview)** under **What does this policy apply to?**. Next, click **Select service principals** and select the Office 365 for IT Pros app registration from your tenant. Do not forget to click **Select** to save your progress.
  - b. Under **Conditions**, click **Locations** followed by **Exclude**. Select **All trusted locations**.
  - c. Under **Access Controls**, click **Grant**, and then select **Block access**.
2. Under **Enable policy**, click **On**.

Once this policy is enabled, the selected service principal can authenticate only from a trusted location that you configure. Note that the feature does not currently support service principals configured for multi-tenant use.

## Connecting to LinkedIn

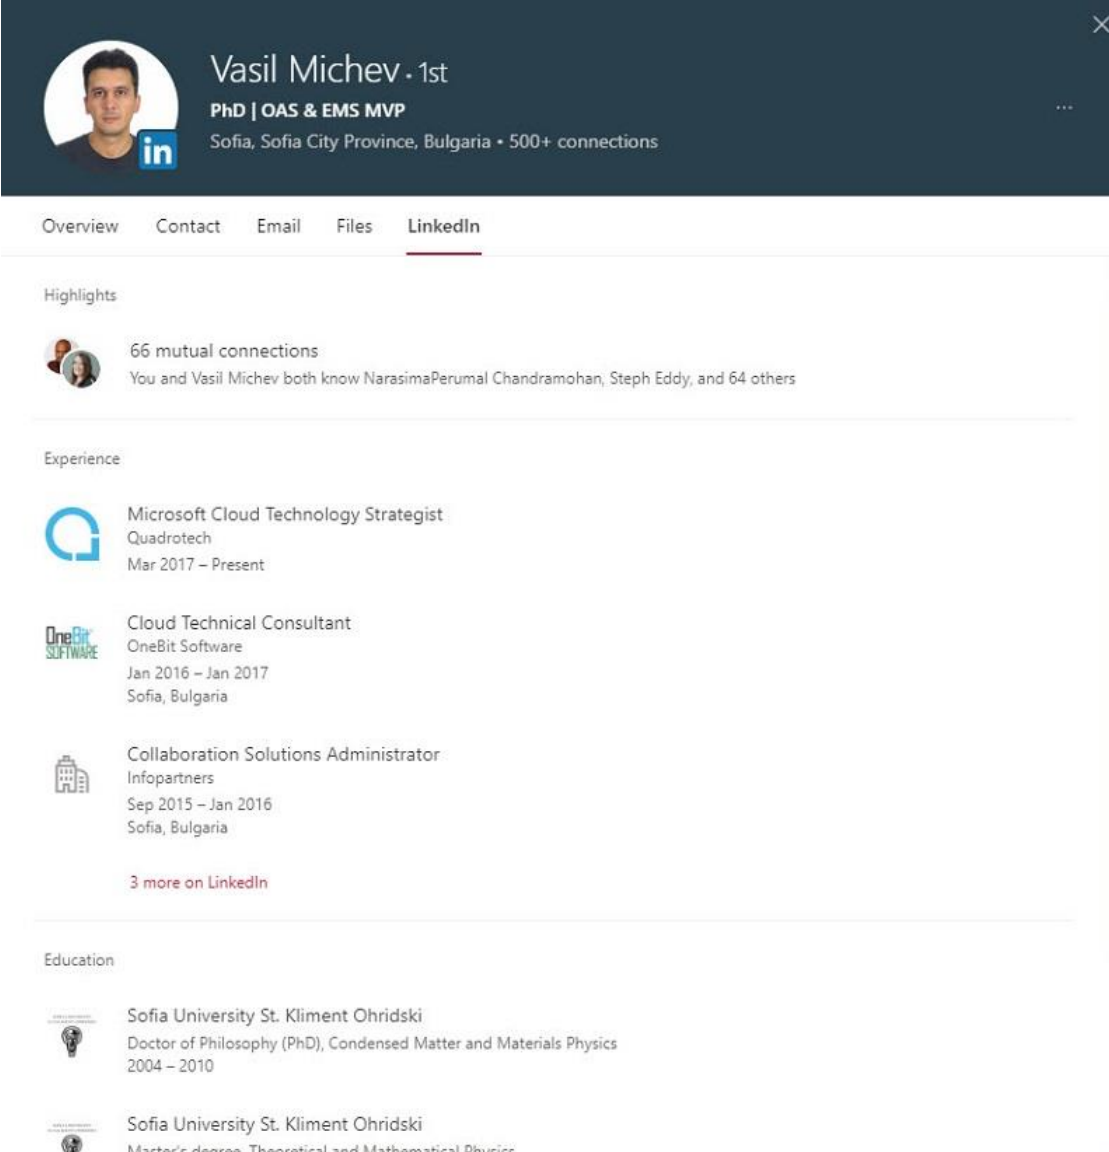

According [to LinkedIn](#), 830 million people are members of their professional network. Ever since Microsoft bought LinkedIn in June 2016, the two companies have looked for ways to co-operate, including the ability to connect LinkedIn to Azure AD. By default, all tenants except those in France and Germany have a LinkedIn connection enabled. Tenants of the sovereign clouds do not support the LinkedIn connection, so you cannot use the feature if your tenant is in the China or U.S. Government clouds. Enabling the connection only allows users to decide if they want to connect their Azure AD account to their LinkedIn account. No data is ever exchanged unless authorized by the user to whom the data belongs.

To control the connection, go to the **User Settings** section of the Azure AD admin center. You can then set the connection to allow all users to connect, some users to connect, or no users to connect. If you decide to restrict the connection, you select a security group containing the set of users allowed to connect their accounts to LinkedIn.

If the tenant allows users to access LinkedIn, a LinkedIn logo appears in the people cards displayed by applications such as OWA, Teams, and SharePoint Online. Apps can display publicly available information from matching profiles. Before LinkedIn reveals more detailed information such as job history or details about the user's connections, the user must connect to their LinkedIn account. The search can happen for both internal and external recipients and result in three outcomes:

- The person is a LinkedIn contact: You see the private profile for the person as shared with their LinkedIn contacts (Figure 3-9).
- The person has a LinkedIn account but is not a contact: You see the public profile of the person and can send them a LinkedIn invitation to connect.
- LinkedIn cannot find a match: Either the person doesn't have a LinkedIn account or several matching LinkedIn accounts are found. In this case, you can choose the best match.

The screenshot displays a LinkedIn profile for Vasil Michev - 1st. The profile header includes a circular profile picture, the name "Vasil Michev - 1st", and the text "PhD | OAS & EMS MVP" and "Sofia, Sofia City Province, Bulgaria • 500+ connections". Below the header is a navigation bar with tabs for Overview, Contact, Email, Files, and LinkedIn. The main content area is divided into sections: Highlights, Experience, and Education. The Highlights section shows "66 mutual connections" and lists "You and Vasil Michev both know NarasimaPerumal Chandramohan, Steph Eddy, and 64 others". The Experience section lists three roles: "Microsoft Cloud Technology Strategist" at Quadrotech (Mar 2017 - Present), "Cloud Technical Consultant" at OneBit Software (Jan 2016 - Jan 2017, Sofia, Bulgaria), and "Collaboration Solutions Administrator" at Infopartners (Sep 2015 - Jan 2016, Sofia, Bulgaria). The Education section lists two degrees from Sofia University St. Kliment Ohridski: "Doctor of Philosophy (PhD), Condensed Matter and Materials Physics" (2004 - 2010) and "Master's degree: Theoretical and Mathematical Physics".

Figure 3-9: Viewing LinkedIn profile information for a contact

The important thing to remember about the LinkedIn connection is that users control it. Although the tenant decides if the connection can be used, users decide if they want to connect their Azure AD account with their LinkedIn account.

## Fetching Email Addresses from LinkedIn

Another feature gained when someone connects their LinkedIn account to their account is that email addresses for first-degree LinkedIn contacts are included in the people suggestion list used by Microsoft 365 browser applications when the user addresses an email or shares documents. In addition to LinkedIn contacts, the suggested people list includes tenant and guest users and Outlook's auto-complete list. As an example of use, when you create a message with OWA and begin typing an address into the TO: or CC: field, OWA checks what you type against the suggested people list and shows any matches that it finds.

## PowerShell and Azure AD

Microsoft is [transitioning away](#) from the AzureAD PowerShell module. The Azure AD module uses the Azure Graph API, which Microsoft plans to [deprecate](#). As a replacement, Microsoft recommends that you use the [Microsoft Graph PowerShell SDK](#) module. If you are familiar with the AzureAD module, you will find the same tasks are possible with the new module, albeit with different syntax. As the name implies, the foundation for the Microsoft Graph PowerShell SDK is the set of Graph APIs, which cover much more than Azure AD accounts and is constantly evolving. New features first come to the "beta" endpoint before transitioning to the stable "v1.0" endpoint. All the tasks you can accomplish in the Azure AD admin center are not yet available in the Graph API.

More information about the Microsoft Graph PowerShell SDK is in the chapter covering managing your tenant with PowerShell.

# Chapter 4: Tenant Management

***Paul Robichaux***

There are many ways to manage tenants. As the service has evolved to add new features, capabilities, and apps, different products have adopted different administrative workflows. Depending on the task you're trying to perform, the functionality of the tools Microsoft provides may lead you towards one approach or another. Sometimes there's more than one way to perform the same task; in those cases, each approach will have its pros and cons. For example, the web-based admin interfaces described in this chapter are simple to use and make it easy to perform one-time tasks such as adding a domain name to the tenant. However, for bulk administrative tasks such as changing the department attribute for multiple users, PowerShell is more efficient, which is why we've devoted a complete chapter (Chapter 23) to this topic.

It's important to remember that in a hybrid environment where you're using directory synchronization, changes to users, groups, and other objects stored in on-premises Active Directory must occur in the on-premises Active Directory because it's the source of authority. As you learned in the preceding chapter, changes you make to cloud copies of on-premises objects won't necessarily replicate back. For example, to change a user's surname you must make the change using the on-premises Active Directory management tools and then allow directory synchronization to synchronize the change into Azure AD. The Microsoft 365 admin center and PowerShell will warn you when you try to change an attribute in the cloud synchronized from on-premises AD.

Because there are so many individual services in the Microsoft 365 portfolio, Microsoft hasn't succeeded in unifying administration into a single portal or a single PowerShell module, although they are making some moves to do so across Microsoft 365 and by using the Microsoft Graph as a single point of data access. It wouldn't make sense to do so because the workloads are so different; a single unified toolset would be complex, slow, and confusing to use and would limit the ability of the product groups that develop each service to optimize and improve their admin experiences.

Part of learning to manage the service is becoming comfortable with a sometimes-confusing variety of web-based admin portals, PowerShell modules, and endpoints that we can use. In the next section, we'll start exploring some of this variety to help you understand what tools to use and when.

## Cloud versus On-Premises Management

Any seasoned professional experienced in managing on-premises infrastructures should already be aware that some level of control and visibility is lost when a company migrates workload to the cloud. Microsoft's platform is sold as "Software as a Service" (SaaS), which transfers the responsibility for running the service to Microsoft. You give up access to anything relating to the underlying hardware, networking, and software. You don't get to select the make and model of servers used to run the service, nor do you get to choose the specifications and sizing of those servers.

Microsoft manages the storage for Microsoft 365 applications and services, both in terms of quotas assigned to individual applications and users and overall storage performance. At most you may need to help your end-users with managing their mailboxes and sites within the quota limits that the service imposes, through a combination of user education and policy controls (e.g., retention policies). Microsoft also manages the network and Internet connectivity for the service. You only need to ensure that adequate bandwidth is available to reliably connect to Microsoft 365 across the internet. Similarly, you must manage any firewalls or other network devices such as web proxies that affect the connectivity of your users to the service.

The underlying operating system and all the software running on Microsoft's servers are also out of your hands. Microsoft surfaces a lot of configuration options for you that apply to the users in your tenant, as well as some reporting tools such as message tracing. However, you simply do not get access to Windows event log data, performance log data, or any of the other log types that Windows and the applications generate. Similarly, you do not get access to stop or restart services on the servers or perform server reboots. On the positive side, you also don't need to perform any Windows patching or upgrades for Exchange, SharePoint, and other applications.

Because many common administrative operations you have to perform to manage on-premises servers become unnecessary, some IT professionals view the movement to the cloud as a loss of "control" and fear the impact that the cloud will have on their careers. Another way to look at it is that you are allowing the same people who develop the product to run it for you within a defined set of parameters. All the time that you previously spent monitoring, managing, and fixing server hardware, operating systems, and application installations is now available for you to spend on helping to deploy features to your end-users, align the configuration of different workloads with your organization's policies, and act as a broker between your company and Microsoft as a service provider. On the bright side, when something goes wrong, a Microsoft engineer wakes at 3 am to answer a pager instead of you.

## Break Glass Administration

An obvious difference between cloud and on-premises management is that Microsoft 365 won't allow you to sign into the console of a physical computer when all else fails and you need to access a server. Other factors which can limit the ability to sign into an administrator account include a working internet connection to Azure AD, blocks imposed by conditional access policies, the ability to satisfy multi-factor authentication challenges, and so on. During the setup of a new tenant, you nominate an account to be the global tenant administrator. This account is all-powerful and should be protected with multi-factor authentication and a complex password. In general, you should not use the global administrator account for day-to-day operations. As discussed later, it is better to assign limited administrative roles to accounts to allow them to perform specific tasks.

Because an outage might interfere with the ability of administrators to sign into their regular accounts, you should create one or more "break glass" accounts. These are highly-privileged accounts (perhaps holding the global administrator role) intended for use in emergencies with the following characteristics:

- Cloud account only (to remove any dependency on account synchronization with an on-premises directory). The user principal name for the account uses the tenant service domain (*tenant.onmicrosoft.com*). Consider giving break-glass accounts obscure names to draw attention away from their true purpose.
- Multiple layers of authentication such as MFA protect the account. However, you should take care to [minimize the number of dependencies used by authentication](#) to ensure that the account is available when needed. For instance, you should exclude break glass accounts from conditional access policies to ensure that a policy doesn't block a sign-in attempt for the account.

The account password for break glass accounts should be complex and deliberately obscure. Because these accounts have access to the entire Microsoft 365 tenant, it's important to store the password for break glass

accounts securely. The details of the storage location for the passwords and how administrators can access the passwords will vary from organization to organization. The important thing is that the process to retrieve passwords and use the break glass accounts is proven and effective. After each use of a break glass account, you should change its password and update the new password in the secure locations.

## Administrative Interfaces

The [Microsoft 365 admin center](#) is used to configure items shared across the applications that make up the platform, such as domain names, billing details, and license assignments. Some frequently used administrative functions are also in the Microsoft 365 admin center. For example, you can create a new cloud-only user account complete with a mailbox without opening the Exchange admin center. Users with Global administrator, Service administrator, Billing administrator, or application-specific administrator rights will have access to the Microsoft 365 admin center.

### Using the Microsoft 365 Admin Center

Figure 4-1 shows the current version of the Microsoft 365 admin center. Expect to see more changes as Microsoft continues to evolve its functionality and publish a [detailed change log](#) to help you keep track. The organization name shown in the top left-hand corner of the *Home* page of the Microsoft 365 admin center is a link. Clicking it takes you to the organizational settings page. More interestingly, if there are multiple tenants associated with a single organization (as determined by the existence of a partner-of-record relationship) there will be a small icon next to the organization name to indicate that you can switch between organizations by clicking the name.

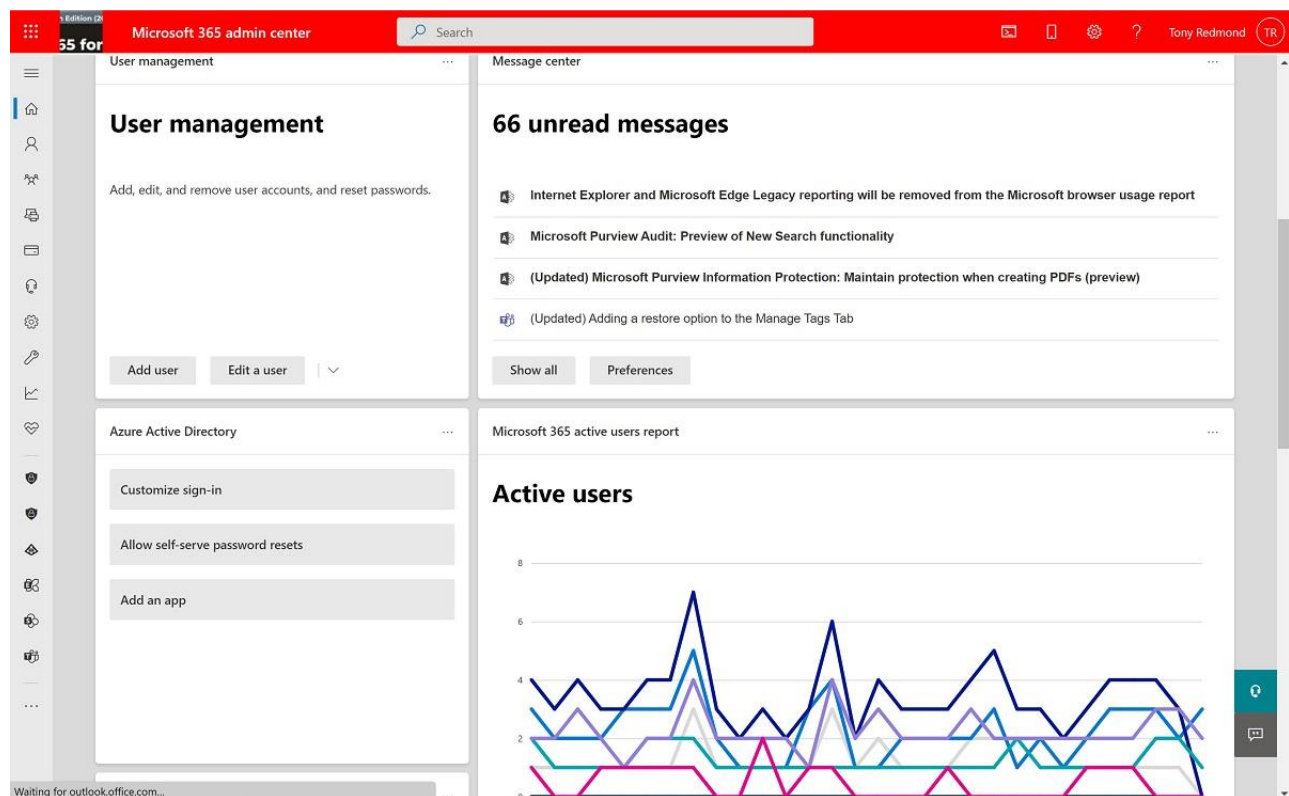

Figure 4-1: The Microsoft 365 admin center

You can customize the home page of the admin center to display specific tiles and the order and layout for the tiles (which Microsoft calls “cards”). The default set of cards you see include cards for message center notifications, reviewing your billing, and working with support incidents. You can customize the set of cards shown in the portal by reordering them, removing them, or adding new ones with the **Add cards** link. As a

customization example, tenants that synchronize Azure AD with an on-premises Active Directory can add a card showing the directory sync status to your home page. Clicking the card reveals other information about your directory sync status, including the version of the directory synchronization client (Azure AD Connect) installed in the on-premises environment.

The navigation pane on the left side of the admin center has expandable menus for different categories of tasks. The tasks that are available throughout the menu are those that Microsoft thinks are commonly performed by administrators. In some cases, a complex administrative task is provided with a user-friendly wizard in the admin center, while the workload-specific admin portal for that task will have a more complicated process involved. In other cases, admin tasks initiated from the Microsoft 365 admin center simply launch a wizard from one of the workload-specific admin portals. To manage the service, you'll have to use a mix of the native admin center functionality and the workload-specific admin centers. Microsoft frequently adds new functionality in the Microsoft 365 admin center, and otherwise rearranges things, to keep us all on our toes. You may see a small bullet icon next to new or renamed menu items when Microsoft wants to highlight changes.

For smaller tenants, you may notice a slightly different, and less detailed, "essentials view" targeted at tenants with 10 or fewer users. This view provides a stripped-down, card-based interface to a few common tasks that smaller tenants will be most likely to use.

## Microsoft 365 Admin Center Functionality

Assuming your account has the necessary permission, and you view the full version of the Microsoft 365 admin center, here's what you'll see:

- In the **Users** section, you can manage user accounts, contacts, guest users, and deleted users, change user license assignments, and change multi-factor authentication settings.
- The **Teams & groups** section allows you to create and manage Microsoft 365 Groups, Exchange distribution lists, shared mailboxes, and security groups. You can see the properties for security and distribution lists that are homed on-premises and synchronized to the cloud, and you can edit properties for cloud-homed objects. See Chapter 8 for more detail about Microsoft 365 Groups.
- The **Roles** section shows you a list of the roles available for assignment to accounts. From this page, you can see the roles available in your tenant and, manage role assignments. By selecting a role, you can also see which users are assigned to it and what specific permissions it has. See Chapter 5 for more on role assignments.
- The **Resources** section is where you can manage room and equipment mailboxes and SharePoint Online sites (although some SharePoint links in this section just take you to the SharePoint Online portal).
- In the **Billing** section, you can manage subscriptions, buy, and allocate licenses, and update payment details. This is also where you can buy added services, either separately or as part of a bundle. For example, if your organization uses Office 365 Enterprise E3 you can buy Microsoft Defender for Cloud Apps as a standalone license or buy the full Office 365 Enterprise E5 license which includes an Office 365-specific subset of MDCA, as well as other features.
- In the **Support** section, you can submit and monitor the progress of service requests for problems that you have encountered with your tenant. Any open Customer Lockbox requests appear here.
- The **Settings** section contains several tools for controlling the configuration of different parts of the service. For example, you use this section to manage the DNS domains associated with your tenant, what third-party applications and add-ins are available, how Microsoft Search works in the tenant, what individual services such as Cortana or Teams are enabled in the tenant, and what integrated applications (formerly known as "Office add-ins") are available. You can also apply restrictions to services such as preventing guest user access to Microsoft 365 Groups or Teams. Security and privacy settings for the organization are also in this section, including the password policy for cloud

identities, Customer Lockbox configuration, and sharing controls. The organization profile is also configured in this section, which includes company and contact details, and the options for configuring Targeted Release (previously known as First Release) for the advanced deployment of new features. This section also contains a link that allows you to see and manage any digital partner of record (DPoR) assignments in your tenant.

- In the **Setup** section, Microsoft presents a list of specific actions you can take to set up your tenant. For example, there are quick-access buttons for configuring self-service user password reset, applying a basic set of data loss prevention rules, and starting the process of migrating user data from other services.
- The **Reports** section presents a dashboard view of the usage of individual services such as Exchange Online, OneDrive, and Teams. You'll also find detailed activity reports, plus the Productivity Score reports. More information about reporting is in Chapter 21.
- The **Health** section is where you can access the Service Health Dashboard (SHD) to see the current health status of workloads in addition to details of outages, service history for the previous 30 days, and planned maintenance. The Health section also includes access to Message Center, where notifications for new and changed features in your tenant are published by Microsoft, a summary of your directory synchronization status identical to the one available in the dirsync status card, the network connectivity toolset, and controls for gathering product feedback from your users and sending it to Microsoft. The SHD, network connectivity tools, feedback tools, and Message Center are discussed later in this chapter.
- The **Admin centers** section has shortcuts to other administration consoles for services that you are licensed to use, such as Azure AD, Exchange Online, the Compliance portal, Teams, and Endpoint Manager.

By default, the Microsoft admin center collapses some of these items, meaning that they don't appear at first sight; you can use the **Show all** link at the bottom of the left navbar to reveal all available options. By hovering over any top-level item, you'll see a pin icon appear; clicking it will pin that item to the left navbar so that it's visible in the condensed view.

Let's take a quick look at the other workload-specific admin portals.

## Managing Exchange

The Exchange admin center (EAC) is a web-based console used to manage elements of Exchange Online including mail contacts, mail users, role assignment policies, OWA mailbox policies, public folders, and hybrid connectivity. Some elements, such as distribution lists and mail flow rules, are also available through other consoles. Two versions of EAC are available:

- The ["classic" older form of the EAC](#) is like the version available for Exchange on-premises servers. In the legacy EAC, you see a switch in the top right corner labeled "Try the New Exchange Admin Center." In September 2021, Microsoft [announced that they will retire this version of EAC](#) on September 1, 2022.
- Microsoft built the [modern EAC](#) for Exchange Online. The functionality available in the new EAC reflects that Microsoft 365 replaces many workload-specific features (like compliance and auditing) with service-wide equivalents managed through other consoles like the Microsoft Purview Compliance portal.

You only need to go to EAC when a Microsoft 365 console does not support an action. For example, the new EAC is the only GUI for an administrator to recover mailbox items for a user.

## Managing Microsoft Teams

When Microsoft first introduced Teams, there were separate admin portals and PowerShell interfaces for Teams and Skype for Business Online. The Teams admin center has replaced the older Skype admin center, and all management for Teams is performed in the [new portal](#). You can also navigate there by going to the **Admin centers** section and then clicking **Teams**. More information about using the Teams admin center is in Chapter 13.

## Managing SharePoint Online and OneDrive for Business

SharePoint Online of course has its own set of management tools; the URL to access them follows the SharePoint pattern of using the tenant name plus “sharepoint.com” instead of having a *Microsoft.com* address. For example, a tenant named Contoso will have a SharePoint admin center URL of <https://contoso-admin.sharepoint.com>. The SharePoint admin center looks a great deal like the Microsoft 365 admin center, with a similar card-based display mechanic and left-hand navigation bar. OneDrive for Business administrative settings are now integrated into the SharePoint Online admin center. For more information on using the SharePoint admin center, see Chapter 8.

## Using the Microsoft Purview Compliance Portal and Microsoft 365 Defender

The Microsoft 365 portfolio includes a broad set of security and compliance features available to tenants depending on the licenses purchased. Microsoft’s original 2016-era vision was to provide a single portal to manage them all, so the original Security & Compliance Center brought together compliance features from across the entire service with a specific focus on those that apply to multiple workloads rather than being specific to an application. Since then, Microsoft has added a large amount of new security- and compliance-related functionality. This growth led Microsoft to first merge the security and compliance functionality into Security & Compliance Center and then to break it back out again. As of July 2022, the current state of play is that we have two independent portals for this functionality:

- [Microsoft 365 Defender](#) (formerly called “Microsoft 365 Security Center”)
- [Microsoft Purview compliance portal](#). This used to be called the Compliance center but, as part of the ongoing global rebranding of all Microsoft 365 compliance features to use the Purview name, it got a new name.

The old Security & Compliance center at <https://protection.office.com> still exists but its links all point to the new pages; if at any point you see a page titled “Security & Compliance”, then you’re not looking at the new versions. The old page will probably disappear in the future. When you visit the Microsoft 365 Defender portal, it will offer to enable the portal-redirectation setting (**Settings** > **Email & collaboration**) that, when enabled, will redirect you from *protection.office.com* to *security.microsoft.com*.

As part of the rollout of the new centers, Microsoft has added a “getting started” interface that offers to lead you through a few of the major changes, as well as a way to provide feedback. Once you’ve dismissed this welcome section, you’ll see the familiar card-based interface like the one in the Microsoft 365 admin center. You can customize the appearance of the security and compliance centers by moving the widgets around to suit the needs of your tenant; the **Add cards** button at the top of the pages will allow you to make changes.

### Using the Purview Compliance Portal

The in-depth material covering classification, compliance, and related topics later in this book will be useful, but a summary may help as a quick reference. Figure 4-2 shows the layout of the Microsoft Purview

Compliance portal. The following sections form the Compliance portal; all are accessible through the left navigation bar.

- **Compliance Manager** is a new toolset that combines a scoring system (known as Compliance Score) with a set of recommendations that you can apply to improve your score. Microsoft also includes assessment templates for specific compliance regimes (such as GDPR or US state-level data breach notification laws) that you can run against your tenant to see how you do. For more on this, see Chapter 17.
- **Data classification** is where an organization manages the application of retention and sensitivity labels to control the protection and retention of user content through tools like the Content explorer and Activity Explorer. Chapter 18 covers retention labels and the policies used to distribute labels to workloads. Chapter 20 covers sensitivity labels.
- **Data connectors** create and manage connections to outside data sources that you want to include in your compliance coverage. For example, you can purchase a license to a connector that allows you to ingest data from AT&T's SMS network to archive and apply compliance policies to employee text messages.
- **Alerts** is where you view security alerts for the tenant. These alerts are created by alert policies, which allow you to set conditions that match the activity for which you would like to be alerted. There are dozens of alert conditions available covering a wide range of possible security concerns such as malware detection, file and folder sharing, DLP policy matches, permissions changes, and many more. Chapter 17 covers activity alerts and alert policies in more detail.

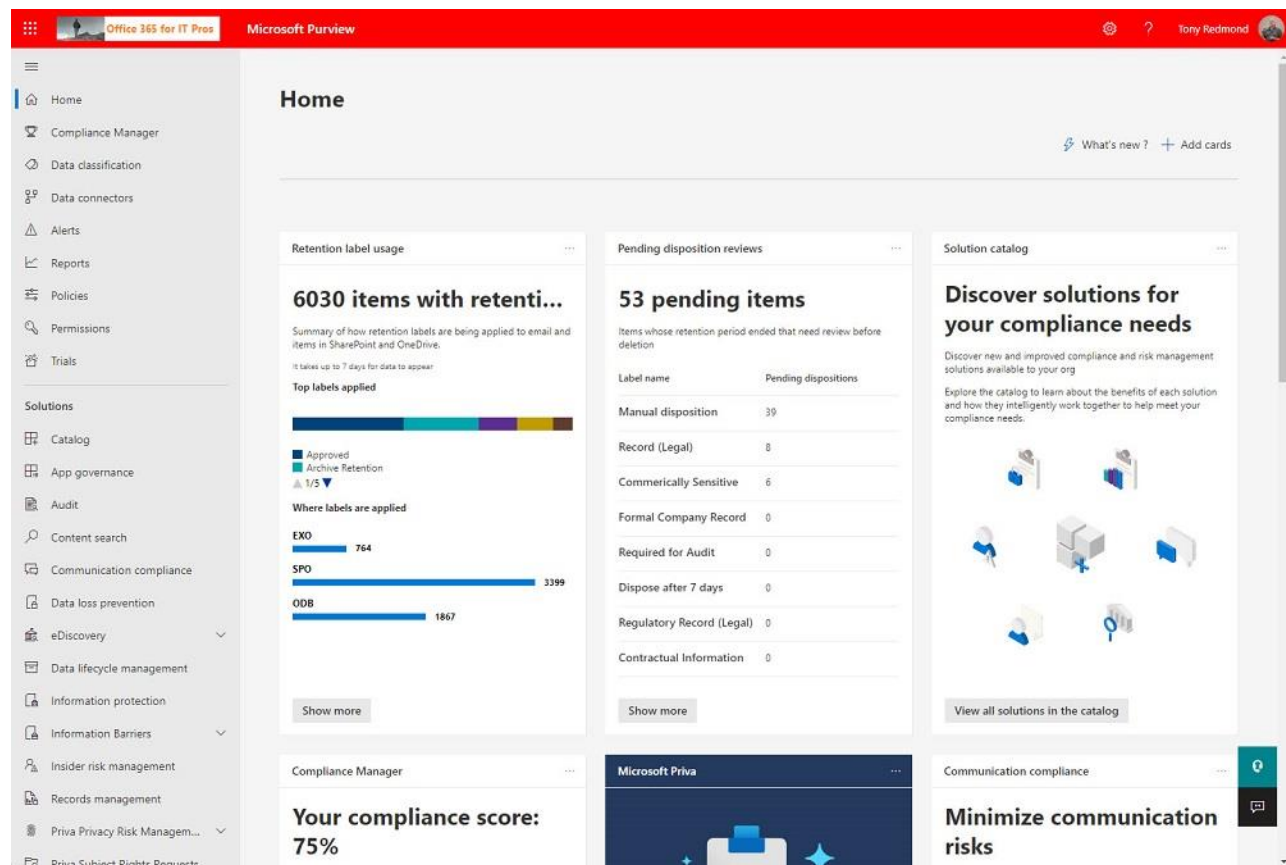

Figure 4-2: The Microsoft Purview Compliance Portal

- **Reports** gives you tools to view and download security and compliance-related reports from a dashboard customized for the tenant. The exact set of reports revealed in the dashboard depends on the functionality licensed by the tenant and can include, DLP, Defender for Office 365, and anti-

malware reports. You can schedule some of these reports for distribution via email to whoever you need to get the information. Chapter 21 covers reports.

- **Policies** – This is intended to eventually be the primary management location for all your compliance and governance policies, including policies for data loss prevention and alerting. For example, this section gives you links to manage DLP policies for content stored or transmitted through Exchange Online, Teams, OneDrive for Business, and SharePoint Online (Chapter 19).
- **Permissions** - View role assignments that allow users access to compliance functionality and data. You can assign compliance roles (but not Azure AD roles) from this section. Users who hold the Global administrator right will have access to the Security and Compliance centers. You can use the roles listed in the Permissions tab to grant selective access to other users.
- **Trials** is essentially like the old SkyMall catalogs that used to grace every seatback pocket on commercial flights in the US; it's where Microsoft advertises trial versions of services that they hope you'll buy.
- **Solutions** – This section collects the tools you can use to take various compliance-related actions. For example, the audit logs, content searches, data loss prevention, and information protection toolsets are all linked from here. The best place to start is probably the **Catalog** section, which provides a simple grid view of different compliance-related tools in Microsoft 365 along with short explanations of what they do.

## Managing Microsoft 365 Defender

[Microsoft 365 Defender](#) is a complex beast. Its unified portal has replaced the previous Security Center as well as the Office 365 Advanced Threat Protection portal. The sections and capabilities you see in your tenant may vary according to the region hosting your tenant, whether it's a commercial, academic, or government tenant, and the licenses you've purchased.

The Defender left navigation rail divides into at least three sections. You can customize which items are shown with the **Customize navigation** link at the very bottom.

The top section covers the broad functional categories that are available in the Defender suite. These options appear for every tenant:

- **Home** returns to the main Microsoft 365 Defender page.
- **Incidents & alerts** shows you data about security incidents that Microsoft has detected in your tenant.
- **Actions & submissions** collects data about messages that users have reported as spam, phishing, or malware. By default, entries from the last 7 days are shown, but submitted messages are kept for up to 30 days. For any user-submitted report, you can forward the report to Microsoft and tag it as clean, malware, phishing, or spam, or you can use the message to start an automated investigative process.
- **Secure score** provides access to the secure score dashboard described later in this chapter.
- **Trials** contains links to other Microsoft security and compliance services that you might want to try.

If you have assigned Defender for Office 365 licenses to accounts (either by buying them or starting a 90-day trial), you'll see additional categories:

- **Hunting** lets you perform security-related queries to look for suspicious activity, as well as configure custom detection rules to specify things that you want to be considered suspicious.
- **Actions & submissions** adds an Action center that lets you review messages or attachments that look suspicious (or that were reported by users) and then optionally send them to Microsoft for further analysis.
- **Learning hub** contains an extensive set of documentation, videos, and other learning materials to help you figure out how and when to use the Defender suite.

One of the interesting features of the new Microsoft 365 Defender portal is that it unifies data formerly stored across modules; for example, if you had both Defender for Office 365 and Microsoft 365 Defender for Endpoint, you'd have to look in two separate places to get a comprehensive view of incident data. Now all the incident data (or actions, or hunting rules, etc.) across all Defender workloads are collected into a single interface.

The **Email & collaboration** section is next. Every Office 365 customer will see some of the options here; some specific options (such as the Campaigns item) require the Defender for Office 365 P2 SKU, which you may or may not have purchased.

- **Investigations** lets you view the results of [automated investigation](#) processes triggered either by the service itself or by you, in response to items shown in the **Explorer** pivot or
- **Explorer** lets you query messages to look for specific patterns; you can filter and query by date or content, and there are predefined pivots that will show you what the service has characterized as phishing messages, malware, or campaigns. One interesting view in Explorer will show you all the URLs in the selected set of messages, which is interesting in a creepy sort of way when you realize how many clickable objects show up in users' inboxes each day.
- **Review** shows a simple card-based interface that gives you easy access to the Action Center, quarantine, and user blocking portions of the portal.
- **Campaigns** shows how the service has categorized phishing messages that appear to be part of structured campaigns. Microsoft [says](#) that a campaign "is a coordinated email attack against one or many organizations" and having a view that shows which campaigns may currently be targeting your users is very useful in responding quickly.
- **Threat tracker** shows the results of queries you've defined in Explorer—after you've defined a query, you'll see the query here and can use this view to review what threats may be associated with it.
- **Exchange message trace** redirects to the message tracing tools in the EAC, described in Chapter 7.
- [Attack simulation training](#) lets you run "benign cyberattack simulations" in Microsoft's words. The goal is to let you simulate various kinds of phishing attacks through SMS, web pages, and emails to see how your users respond and tailor your user education, policies, and response policies to improve your security. This feature requires licensing for Microsoft Defender for Office 365
- **Policies & rules** contains links that give you access to assorted security policies from throughout the Microsoft 365 platform. For example, there are links to alerting policies, device configuration and compliance policies for Intune (see Chapter 16), and anti-malware and anti-phishing policies from Defender ATP.

If you've purchased Microsoft 365 Defender for Endpoints, you'll see its capabilities, including device inventory, vulnerability management, and device configuration management, under a section in the left navbar labeled **Endpoints**. Microsoft has more details on how Defender for Endpoint is integrated with the new Microsoft 365 Defender interface [in this article](#).

Below the **Email & collaboration** section, you may see other sections depending on what other Microsoft products and services you've purchased. Below all those, if any, you'll see a standardized set of additional options:

- **Reports** accesses security-related reports including summaries of mail flow, user-reported phish or spam messages, and potentially compromised users. You can't customize these reports, but you can schedule them to be mailed, or download them.
- **Audit** lets you search the unified audit log; you can also see and change any audit retention policies applied to your tenant.
- **Health** contains links to the Microsoft 365 message center and service health dashboard.

- **Permissions** and **Settings** do what you'd expect—note that these sections are both very bare-bones since most of the other interesting permissions and settings controls are in the primary Admin center.

## Managing Other Microsoft 365 Services

There are many other services in Microsoft 365 besides the “big four”: Exchange, Teams, SharePoint, and OneDrive for Business. Microsoft has been adding new services at a rapid pace since it first launched the service.

Yammer is an enterprise social network for enterprises and teams. The Yammer admin portal includes options to activate your Yammer network, customize the appearance, manage users and policies, and perform community management tasks. The URL for the Yammer admin portal will vary based on your tenant domain, but you can use the general admin URL to access the portal, which then redirects to your specific tenant URL automatically.

Power Automate and Power Apps are two of the main components of what Microsoft calls the Power Platform. Microsoft bundles the administrative elements for these components together into a [single admin center](#). See Chapter 23 for more information.

Dynamics 365, the latest version of Microsoft's venerable customer relationship management (CRM) system that competes with Salesforce, has a link in the **Admin centers** section. However, the link takes you to an error page if clicked while logged in to an account that doesn't have admin permissions on the organization's Dynamics 365 instance.

## Managing Azure Services

The Azure management portal administers other Microsoft cloud services for your tenant, or for separate Azure subscriptions that your organization also has. If The link in the Microsoft 365 admin center takes you to the [Azure AD portal](#). You can navigate from there to the entry point for the [Azure portal](#) to manage the other Azure services that your tenant users and manage Intune mobile device and application policies.

Among the most common management operations are tasks such as creating new user accounts, updating their properties, and managing their permissions. As you learned in Chapter 3, Microsoft 365 supports standalone and hybrid identities in a variety of configurations. The thing that all identity types have in common is that the service relies on Azure AD, so it's helpful to have some familiarity with the Azure AD management tools.

When you open the Azure AD portal, you'll see that it has categories for managing users, groups, roles, devices, Azure AD Connect, and password reset (along with several other categories). It also has links to controls for conditional access policies, reports for risky logins and suspicious sign-ins, and troubleshooting tools. A complete exploration of this section is far outside the scope of this book, but we've covered selected parts of Azure AD in Chapters 3 and 16. It is well worth your time to explore the settings here, as many features and settings exist to improve the security and functionality of your environment that you may not be familiar with.

## Service Administration Apps for Mobile Devices

Microsoft ships a tenant management app for Android and iOS. The management apps can perform common administrative tasks from a PC or mobile device including editing or removing users, resetting passwords, turning email forwarding on or off, and viewing service health information. You can review billing alerts, items posted to the Message Center, and service health notifications. In fact, you can have the app post push notifications when specific service health notifications are issued. However, the management apps do not support managing any aspect of a hybrid configuration.

## ServiceNow Integration

As much as Microsoft might wish it otherwise, ServiceNow is the most popular IT service management (ITSM) solution in the world. It's common for Microsoft 365 administrators and support desk staff to have ServiceNow more or less permanently open in one tab with various Microsoft admin portals open in other tabs. In a welcome move, Microsoft published an [app in the ServiceNow app store](#) that provides some integration between the two. If you install the app in your ServiceNow instance, you can review SHD items and open new tickets with Microsoft. This is a useful capability and it'll be interesting to see what Microsoft does to enhance it in the future.

## Managing Licenses, Plans, and Billing

Everyone who wants to use an application besides the administration tools needs a license. Because Microsoft controls all aspects of the service, they can be more insistent on this point than they are with on-premises Client Access Licenses (CALs). You cannot use an application like Exchange Online without a license and an account that has its license removed will end up losing all its data. License management is therefore an important part of administration, with the goal being to ensure that you have enough licenses to allow people to work while not paying for unused licenses. The **Billing** section in the admin portal allows you to buy licenses, see and manage the licenses you have, and get various types of billing notifications.

The **Licenses** option in the Billing section in the admin portal provides an overview of the licenses available to, and used by, a tenant. As we can see in Figure 4-3, some Office 365 E5 licenses are unassigned. This might become an issue if the situation persists because Microsoft charges for every license monthly even if no one uses the license.

**Note:** There are several ways to buy licenses. Depending on what subscriptions you have, and whether you have a licensing agreement with Microsoft, you may buy licenses directly through the web portal, through a reseller or partner, or directly from Microsoft. For partner and Microsoft purchases, the license term and cost are whatever you negotiate; for purchases directly through the portal, the licenses you buy cover a 12-month term, but you may pay for them monthly or annually. In either case, you pay up front. Microsoft doesn't give refunds for unused licenses. As you add licenses, you will see them "roll in" at renewal time. For example, suppose that on January 1 you create a new tenant and buy 100 Office 365 E5 licenses. Then in March, you buy another 100 licenses. Come January 1 next year, all 200 licenses will renew at the same time.

The usage reports in the Microsoft 365 admin center provide you with a basic view of who uses the services and what licenses they have, allowing you to decide about reallocating licenses or reducing the number of licenses that you're paying for.

The **Requests** and **Auto-claim policy** pivots in this view are covered in Chapter 5, as they deal with automating (at least partly) the process of assigning licenses to specific users.

You can also perform some license management tasks in the **Your products** section under the **Billing** section, as shown in Figure 4-3. Functionally the two areas of the portal are very similar, allowing you to assign licenses or buy more if you have no unused licenses. The "Settings & actions" section in each license card allows you to take appropriate actions, including installing the Office desktop apps (if licensed) or assigning licenses to users. The **Your products** section also includes pivots for Azure subscriptions, purchased applications, and usage benefits associated with enterprise agreements (EAs) or other purchase contracts.

## Your products

These are products owned by your organization that were bought from Microsoft or 3rd-party providers. Select a product to manage product and billing settings or assign licenses.

SendGrid - Free	1	Active: Renews on 7/3/2021	anton.sutjak@quadr	

Figure 4-3: Managing licenses in the Products and Services section of the admin portal

The other items in the **Billing** node allow you to select and set up payment methods for your bills, choose who gets billing notifications and in what language and format, and buy new products—but all of these options are simple enough that we won't discuss them further here.

For more information on how to assign licenses to users, see Chapter 5.

## Managing Integrated Apps

Microsoft has worked for literally decades to make Office an extensible platform, both because it enables them to extend and improve the platform and also because it enables their partners to do so, which in turn helps tie customers to it. This strategy has continued into the present day, leading to the new Integrated Apps page under the settings tab in the Microsoft 365 admin center. The controls here allow you to select and deploy add-ins that run inside various Office clients. Figure 4-4 shows the view from a sample tenant. You may notice that the caption at the top refers to applications developed by Microsoft partners, yet some of the applications (such as FindTime) shown in the list are from Microsoft. If you use the **Get apps** button to jump to the AppSource marketplace for Microsoft 365 Apps add-ins, you'll find several dozen add-ins, many of which come from Microsoft, so don't let the "partner" wording fool you.

Any add-in written to use the [correct set of APIs](#) can be deployed and managed here. The beauty of this approach is that a well-written add-in for, say, Outlook will work in any recent version of Outlook, including the desktop, mobile, and web versions. The advantage of using the **Integrated apps** page is that you can select an add-in, optionally create a test deployment, and then specify which users can access the app (just you, the entire organization, or a list of users or groups you specify). Because these apps are add-ins downloaded and run by the client application, you don't have to do anything further to deploy these capabilities to users.

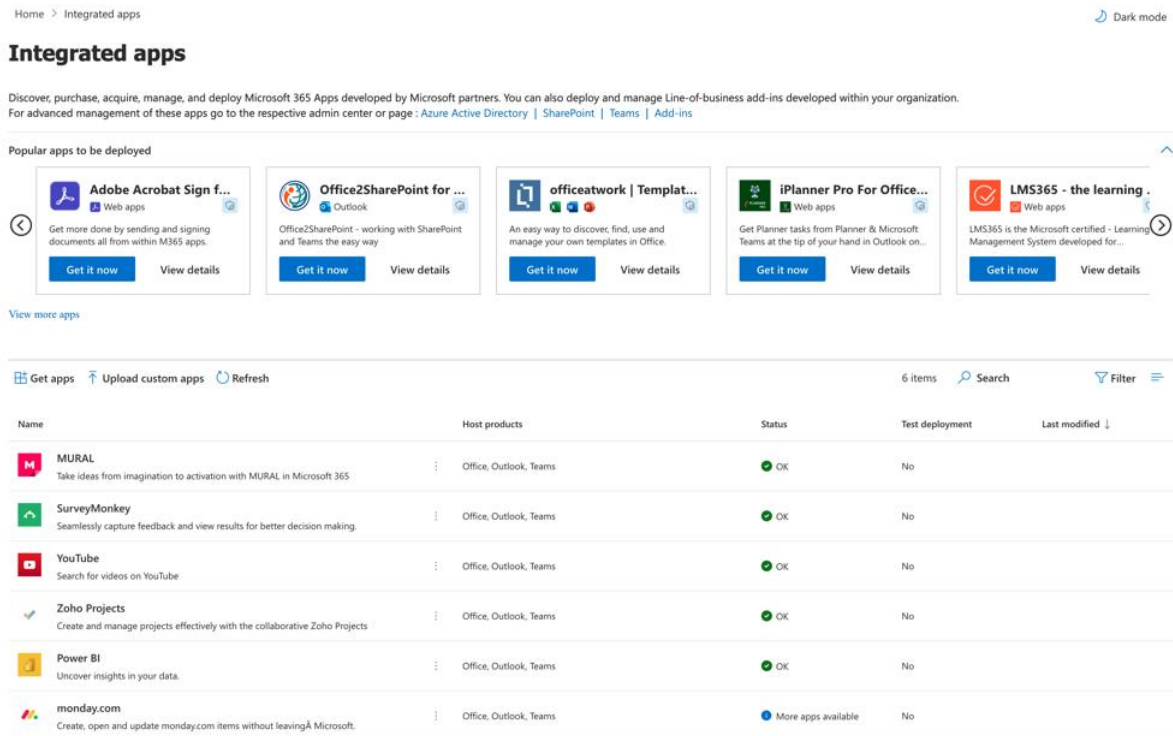

Figure 4-4: The Integrated apps view lets you centrally install and publish Office add-ins to users

**Protecting against app-based attacks:** The **Integrated Apps** node in the Settings section of the Microsoft 365 admin center controls whether users can allow applications to access their data, such as their calendar. By default, the setting is on. Because some malware exploits work by gaining access to user data ([here is an example](#) that encrypts user data for ransom), you might prefer to turn the setting off. It is worth emphasizing again that unless users are aware of threats and sensitive to granting access to their data, the possibility always exists that they will succumb to an attack if they are targeted. Microsoft refers to these as “[illicit consent grants](#)” and they have documentation and tools to help you review what applications users have consented to, including [two PowerShell scripts](#) that create a set of CSV files holding details of access granted by users to applications and their publishers.

## Managing Feature Releases

Microsoft uses a series of “rings” to control the release of new features. In general, the first ring is the development team, the next is Microsoft, the third is composed of tenants who have nominated themselves by signing up for “Targeted Release,” and the last is general availability (also known as “standard release”). This approach varies by workload; individual applications, such as Teams or Planner, may use more rings in their deployment model.

“Standard release” is the term Microsoft uses when they make a feature available to all tenants licensed for the functionality. Tenants who opt for Targeted Release see new features (or updates to existing features) a few weeks ahead of general availability. However, for some new applications, the period covered by Targeted Release can extend up to several months.

The ability to control how new features become available to tenant users is through **Release preferences** in the **Organization profile** pivot, available through the **Settings > Org settings** section of the Microsoft 365 admin center. Three options are available:

- Standard release for everyone.
- Targeted release for everyone.
- Targeted release for selected users (Figure 4-5).

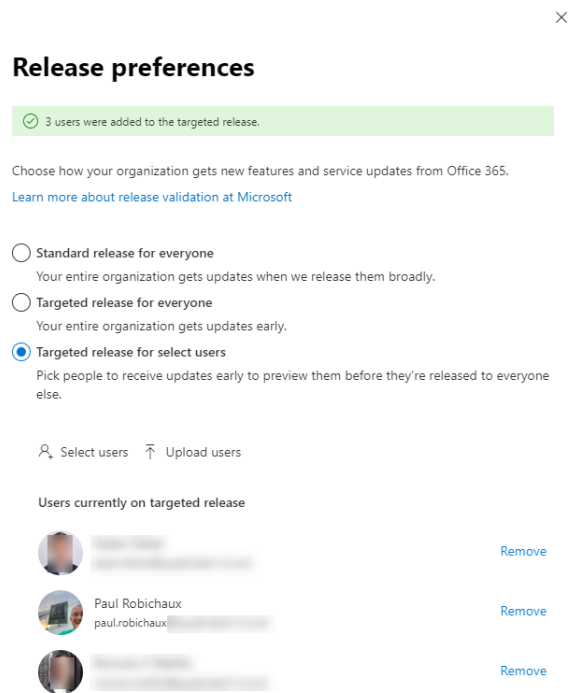

Figure 4-5: Enabling Targeted Release for a tenant

The last option allows the administrator to nominate specific individuals or groups (referred to as a staged rollout) while the remainder of the users continues to access the functionality available in the standard release. For example, you might decide that only the IT department should be exposed to a new application to allow some experience to be gathered about its functionality and so drive a decision about how it might be used within the organization.

Switching an account from Targeted Release to Standard Release or vice versa can take up to 24 hours before the switch is completed. Keep in mind that putting a user in Targeted Release just enables their ability to see or use a feature; client-side features implemented in the Microsoft 365 Apps software won't be visible to the user until she downloads the appropriate version of the software. Depending on your organizational policies, this may add an extra delay before the new features become available.

Although Microsoft's goal is to move features from Targeted Release into general availability reasonably quickly, the exact period between the two phases can vary from feature to feature. Timings can be affected by user feedback, bug reports, or the discovery of flaws such as performance or scalability issues that must be addressed before a feature can be made available to all. The shortest period is a week or so. The longest (to date) is six months. The rate of change also varies within applications. Exchange Online tends to see more new features over a certain period than SharePoint Online while the rate of change for new features can also be high. Yammer and Teams do not use Targeted Release because they use different mechanisms to give early access to new features to a select group of tenants.

Even when a feature is released to general availability, it doesn't mean it shows up everywhere at once. It can take a few weeks before every tenant in every data center sees a new feature. The exact speed of deployment depends on the results of Targeted Release deployments, plus other factors such as local market support. Microsoft also often staggers feature release dates by geography. In general, features tend to appear first in North America, the UK, Western Europe, and Australia, then in other areas. For example, more than two years after the first release of Teams phone calling features, the feature isn't available worldwide yet.

Another factor in feature availability is the type of tenant you have. In general, enterprise tenants get features first, and education and government tenants (including those in the Government Community Cloud,

or GCC) come later, if at all. The small-business versions of Microsoft 365 fall somewhere in the middle. Keep in mind that Microsoft appears to believe that they will make the most money by delivering all their features to all tenants everywhere, so this is their aim; when they don't make a feature available in a region or to a type of tenant, it's either because engineering, operational, or legal constraints exist to prevent it or because the feature requires enough investment that it may not be profitable for them to deploy it.

When new features arrive in your tenant, they will almost always be enabled by default for all users with the necessary licenses, regardless of your Organization Profile settings. That includes features such as Microsoft Teams and Planner that Microsoft added as service plans to current products; in other words, Microsoft added the features to existing licenses such as Enterprise E1, Enterprise E5, and so on, rather than creating separately licensed services like Intune or the various Dynamics 365 services. Applications that don't require a separate license are also usually enabled by default. Note that over time, some applications may change their licensing status; as one example, Whiteboard, which originally had no license, is now a licensed service plan within the Office 365 SKUs, which means that tenants can control if users have access to Whiteboard.

Features released in Public Preview before General Availability are not enabled by default; however, they will become enabled once the feature reaches General Availability. The approach of enabling features by default makes adoption easier but is a concern for organizations that have strict change management procedures, or those who want to control the rollout of new features so that they can provide appropriate training to their IT support staff and end-users. It is important to maintain awareness of the changes that are rolling out to customers by monitoring your Message Center notifications and keeping an eye on other sources of early information such as the [Microsoft 365 roadmap](#).

**Mastering Targeted Release:** Targeted Release allows tenants to gain faster access to new functionality. However, there is a downside to the value gained by seeing new features earlier than the norm. Microsoft tests new code before making it available through Targeted Release, but it is well known that frayed edges (bugs) can appear in new software when exposed to the stresses of production workloads. Other common challenges include new features showing up in user interfaces without warning or any sign as to how they should be used with little or no available documentation. Selective Targeted Release is available to allow some users in a tenant to access new features earlier, but this option is sometimes not supported by an application.

To mitigate these downsides of Targeted Release, some companies run two tenants: a "production" tenant for most users and another trial tenant configured as Targeted Release for a small subset of users responsible for testing new software as it appears. This is analogous to the situation often found in the on-premises world where customers keep a test environment to deploy new builds of Exchange as Microsoft makes them available.

It is important to realize that the appearance of a new feature to tenants who have enabled Targeted Release does not mean that the feature will be made available for all tenants soon afterward. Microsoft can and does use time to gain knowledge of how customers use a feature and can adapt and change the feature over an extended period before deciding that the software is suitable for general consumption and ready to be rolled out globally. Targeted Release is a large-scale beta program, and no assumption should be made when or if any feature will be available just because Microsoft makes the functionality available to tenants configured for Targeted Release.

## Managing Connectivity

Each of the workloads in Microsoft 365 has its unique requirements for connectivity. There are two basic invariants: every service needs reliable and correct DNS information, and every service needs to be able to pass traffic on TCP port 443 to allow TLS-protected HTTP communications. Individual services may have additional connectivity requirements for various features. This seems easy to deal with in theory... right up until users start complaining that some feature or another in their clients isn't working properly.

Some years ago, Microsoft introduced a tool called the Exchange Remote Connectivity Analyzer (ExRCA) for troubleshooting on-premises connectivity for MAPI and Exchange ActiveSync. Over the years that tool has grown in scope and power and is now known as the [Microsoft Remote Connectivity Analyzer](#) (Figure 4-6). It currently supports more than two dozen tests for Exchange, Teams, on-premises Skype for Business and Lync, and Office 365.

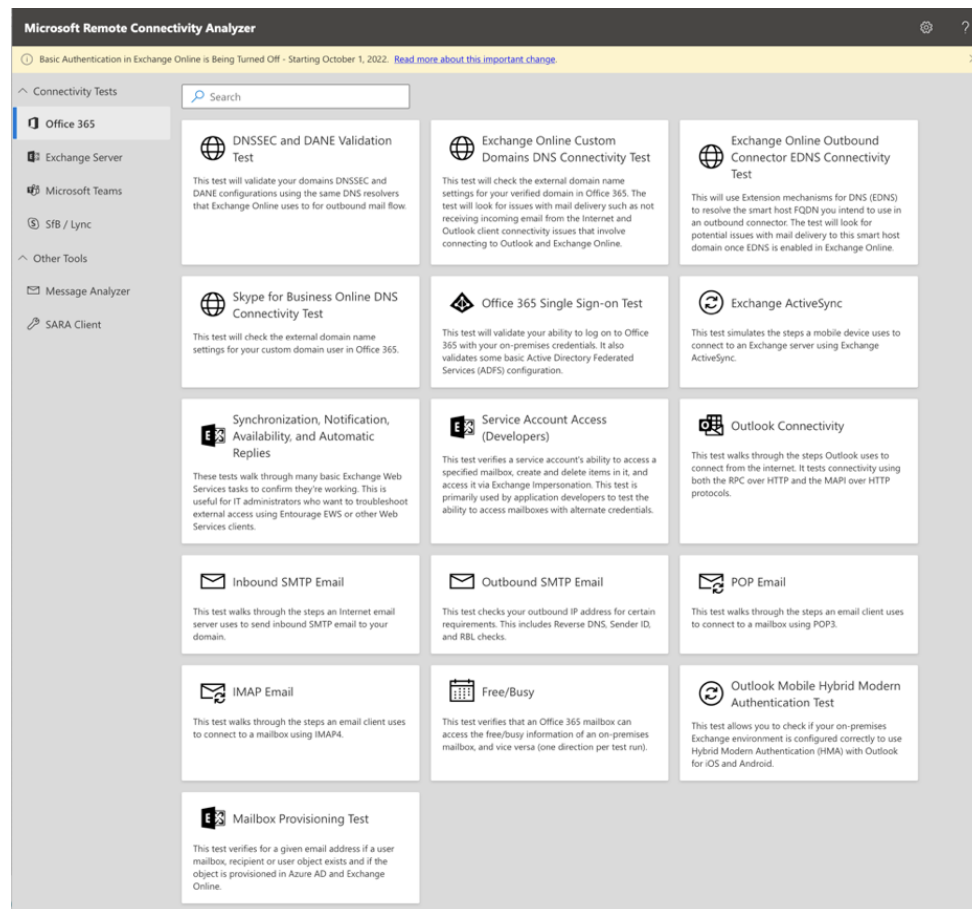

Figure 4-6: The Microsoft Remote Connectivity Analyzer main page

Currently, the analyzer supports the following tests on the Office 365 tab. Some tests require you to provide valid credentials for an active Office 365 account that's licensed for the workload you're testing because the test requires logging into a mailbox or Teams account; others (such as the Outlook Mobile modern authentication test) require an email address but not a password:

- **DNSSEC/DANE:** this test checks the DNS records you have defined using the same DNS resolution path that Exchange Online users. If any of these tests fail, so will DANE resolution for your domain.
- **Exchange Online custom domain test:** this test validates whether the specified custom domain is correctly set up and has valid MX records for mail flow into the service.
- **Exchange Online outbound EDNS test:** this test validates whether your DNS infrastructure can handle the [DNS extensions](#) required for using DNSSEC.
- **Skype for Business DNS connectivity:** this test checks for the presence and correctness of the DNS records needed for Skype/Lync hybrid connectivity.
- **Office 365 single-sign on test:** this test verifies whether single sign-on to the service works correctly.
- **Exchange ActiveSync test:** this set of tests emulates a mobile device and makes Exchange ActiveSync requests for synchronization to ensure that EAS network traffic works properly:
- **Synchronization, notification, availability, and automatic replies test:** this set of tests checks various Exchange Web Services (EWS) network flows that are used by Outlook clients.

- Service account access test: this test verifies whether the specified account is correctly configured to use Exchange impersonation for service account-level access to mailboxes.
- Outlook connectivity test: as its name suggests, this test suite does an end-to-end test of all the steps performed by the Windows Outlook client for it to connect over RPC or MAPI over HTTP.
- Inbound SMTP email test: this test checks whether the DNS and network configuration of your tenant is correct so that outside servers can send mail to it.
- Outbound SMTP email test: the inverse of the inbound SMTP test, this test checks whether your outbound IP address has correct reverse DNS, Sender ID, and real-time block list (RBL) settings.
- POP email test and IMAP email test: these tests perform the same steps that a POP or IMAP client takes to verify connectivity.
- Free/busy connectivity test: this test verifies that a cloud mailbox can access on-premises free/busy data, and vice versa.
- Outlook Mobile hybrid modern authentication test checks to see whether you've correctly set up hybrid modern authentication between Exchange Online and your on-premises Exchange environment.
- Mailbox provisioning test: this test checks to ensure that the specified mailbox is correctly provisioned in the service and that all the required directory attributes have valid values.

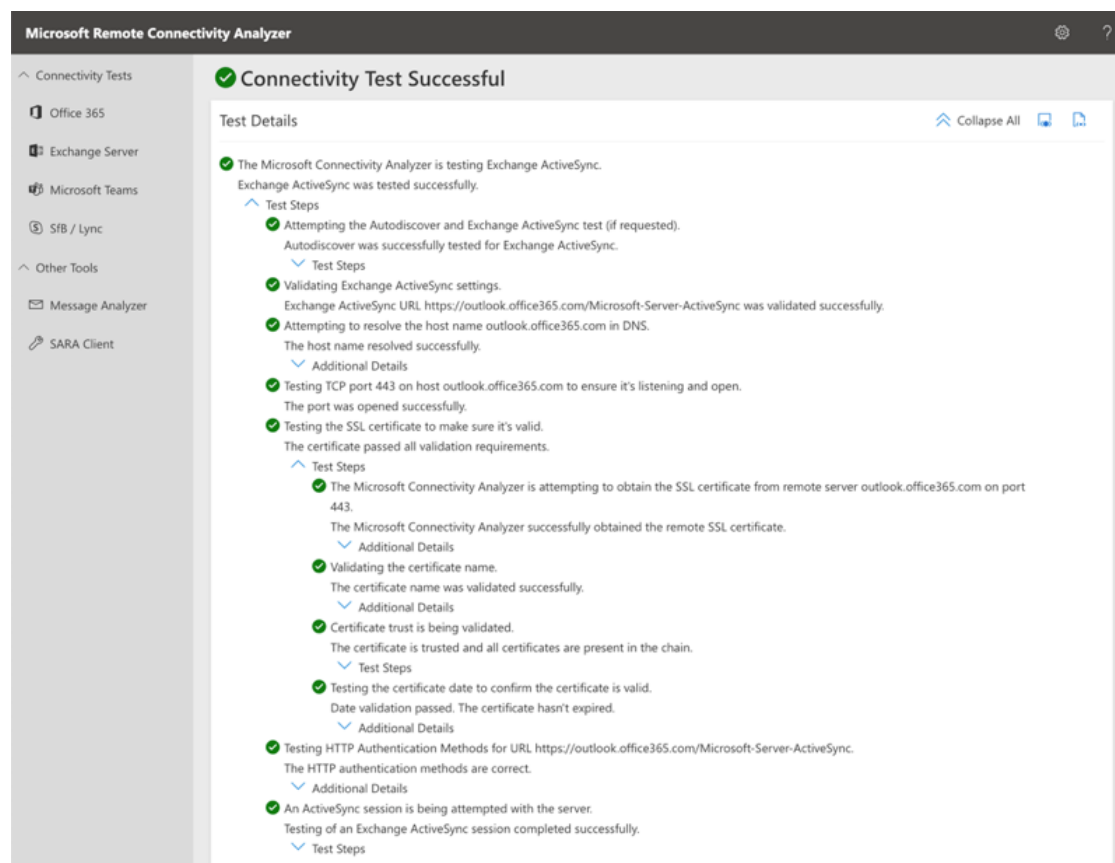

Figure 4-7: Running a test with the Microsoft Remote Connectivity Analyzer

On the Microsoft Teams tab, there's a separate set of tests:

- Teams Calendar Tab: this test verifies that the Teams service can connect to an Exchange mailbox.
- Teams Meeting Delegation: this test checks whether a specified account has the right permissions to schedule Teams meetings on behalf of a delegate.
- Teams Meeting Recording: this test verifies whether the specified account has permission to record a meeting and store the resulting recording.

- Teams Exchange Integration: this test checks whether the Teams services can connect to Exchange mailboxes; you can run this against either on-premises or cloud mailboxes.
- Teams Channel Meeting: this test checks to see whether the specified account can schedule a Teams channel meeting.
- Teams Voicemail: use this test to verify that the selected account can retrieve and store voicemail messages.
- Teams Presence Based on Calendar Events: this test will check to see if Teams can read calendar items and use them to update Teams presence.

The analyzer's tests are very simple to use. In general, you'll supply an email address or DNS domain, provide a password if required, and run the test. RCA presents the results of each test in a clear, easy-to-understand format (Figure 4-7). In most cases, these tests alone will give you enough information to figure out the specific element of your network, DNS, or on-premises environment that's misconfigured and lead you to get it fixed.

## Protecting Data with Encryption

Encryption is a complicated subject. The legal, technical, operational, and business implications of where, when, and how data are encrypted could easily fill a series of books. As described in Chapter 2, Microsoft uses two primary strategies for encrypting data: some data are encrypted in transit, and some are encrypted while at rest.

In general, encryption works best when it is automatic and ubiquitous, and Microsoft has done pretty well at building ubiquitous transport and at-rest encryption into the service (as [detailed here](#)). For example, by default, all communications to and from the service are protected with TLS, and servers running the Microsoft 365 applications all use BitLocker to protect their physical disks. However, Microsoft offers several additional [encryption services](#) that may be of use to you. For example, you can require the use of mobile-device encryption on Android and iOS or iPadOS devices through Intune, and you can create conditional access policies that only allow encrypted devices to connect to various services. If you have the infrastructure for it, you can enable or require the use of S/MIME for messages, and so on. Keep in mind that not every encryption feature is globally available; Microsoft 365 tenants in particular regions or government-associated clouds may not have the same features as commercial tenants.

### Service Encryption

The basic level of data-at-rest encryption provided in Microsoft 365 is called [service encryption](#). Along with the Windows-standard BitLocker tool, Microsoft has built a tool called [Distributed Key Manager](#) to ensure that the BitLocker recovery keys are protected and secured. Microsoft [describes DKM's function](#) by saying

*"Only members of a specific security group in Active Directory Domain Services can access those keys to decrypt the data that is encrypted by DKM. In Exchange Online, only certain service accounts under which the Exchange processes run are part of that security group. As part of standard operating procedure in the data center, no human is given credentials that are part of this security group and therefore no human has access to the keys that can decrypt these secrets."*

The good news is that, even if you never change any default settings, every file and message stored by the service will be encrypted by Microsoft using the BitLocker and DKM combination.

### Customer Key

One of the longest-running arguments in the encryption world is "who holds the key?" As you might imagine, some organizations want to retain complete control over the use of encryption in their enterprise.

This is usually for one (or both) of two reasons: they either don't want encryption used by an attacker to lock up data or they don't trust a third-party service provider (which in this case would include Microsoft) not to peek at their data. One solution to this is to encrypt data using a key that only the customer has access to. Microsoft offers a capability known as [Customer Key](#) (CK) that allows you to hold the root keys used by the service encryption system. You create keys and upload them to Azure Key Vault, then create data encryption policies (DEPs) that specify which keys to use to encrypt which data items. Microsoft manages encryption keys for any services that don't have DEPs defined.

You can currently define three types of DEPs:

- **Exchange Online mailboxes:** these DEPs are applied per mailbox and only encrypt the mailboxes they're applied to; when you apply a DEP to a mailbox, the mailbox is moved and then encrypted as part of the move.
- **SharePoint Online and OneDrive for Business:** this DEP type applies to content stored in SharePoint or OneDrive, including Teams files. You can create a single DEP per tenant unless you're using multi-geo, in which case you can create one per geo.
- **Multi-workload DEPs** apply to multiple workloads and components for all users in the tenant. You can encrypt additional Teams data (including 1:1 chats, group chats, meeting chats, conversations in channels, chat notifications, and images and videos). When you create a DEP at the tenant level it is applied in addition to, not as a replacement for, any DEPs that are currently in force on Exchange, OneDrive, or SharePoint data. The tenant-level DEPs will encrypt all data held by Exchange Online, meaning you no longer have to assign DEPs to individual mailboxes; for Teams, you can only encrypt data created after the time the policy is applied (meaning you can't encrypt historical data).

The [setup process](#) for CK is quite complex, so you should carefully consider whether you have the needed skill set and operational maturity to make use of it; it's easy to create a situation where your data items are encrypted in ways that might render them unusable in the future if you lose access to a particular key.

## Double-Key Encryption

Microsoft also supports another encryption mechanism that uses *two* keys: one that Microsoft has, and one that only your organization has. Data protected with this mechanism (known as [Double-Key Encryption](#), or DKE) is encrypted twice: first with your key and then with Microsoft's. Microsoft never has access to your key, so they can never read your protected data. For this reason, though, data protected with DKE can't be processed by several useful service features, including transport rules, content search, and eDiscovery. Sensitivity labels (see Chapter 23) can apply protection to files using DKE.

DKE requires you to set up a key-management system of your own, build and install a connector, and deploy sensitivity labels that end users can use to tag specific documents as needing DKE protection. Microsoft makes the point very clearly that DKE is only intended for the most critical items that need the heaviest protection and isn't intended to replace the use of CK or other protection mechanisms for everyday use.

## Protecting Items with Information Protection

Microsoft 365 already includes a broad set of features for protecting messages, documents, and containers. As described in Chapter 23, you can create sensitivity labels to automatically mark specific items as requiring protection; you can use [Purview Message Encryption](#) (OME) to enforce encryption for email messages under various conditions, and you can apply rights-management restrictions to control which users can do what with specific items based on their origin, location, or sensitivity. Microsoft broadly lumps these capabilities together under the heading of "information protection"; the encryption features enabled in their information protection solution are intended to reduce the risk of accidental or purposeful disclosure of sensitive data to unauthorized people, but they aren't necessarily intended to protect against other threats.

## TLS Certificate Updates

The certificates that Microsoft uses to provide Transport Layer Security (TLS) protection are all issued by root certificate authorities. Between January 2022 and October 2022, Microsoft is moving its certificate issuance to a new root CA, replacing Baltimore CyberTrust with DigiCert. This change should be transparent to most tenants and administrators. However, if you have applications that are hard-coded (or “pinned”) to use a specific root CA for certificate validation, this change may break your applications. Microsoft maintains a [page explaining the change](#).

## Handling the TLS 1.x Deprecation

As you read in Chapter 2, Microsoft has been planning to stop supporting older versions of the TLS protocol for some time. To prevent any unpleasant surprises for your users and applications, it’s important to know which endpoints still use the older versions. One way to do this is to use [Azure Log Analytics](#) to query your Microsoft 365 log data to reveal the details. Here’s an example query:

```
SigninLogs
| extend details = parse_json(AuthenticationProcessingDetails)
| mv-expand details
| where details.key == "Legacy TLS (TLS 1.0, 1.2, 3DES)"
| extend LegacyTLSEnabled = details.value
| project-away details
| where LegacyTLSEnabled == true
| project TimeGenerated, AppDisplayName, AppId, UserPrincipalName, Identity, ClientAppUsed, IPAddress
```

## Monitoring

Although Microsoft 365 removes much of the responsibility for ongoing support and maintenance for its applications away from administrators, the need still exists for tenants to know how well the services function and if any technical issues exist that might affect the availability or quality delivered by a service at any time. The Microsoft 365 admin center includes mechanisms to understand the current health of applications while third-party applications are also available to increase and improve the quality of monitoring. Service health and other important notifications are available in the left pane of the Microsoft 365 admin center, in the **Health** section.

### Service Health Dashboard

The **Service health** menu item under the **Health** section of the Microsoft 365 admin center takes you to the Service Health Dashboard (SHD). Microsoft uses the SHD to communicate the current health status for each of the services consumed by your tenant. Each service is displayed with an icon showing whether it is currently healthy, has an active incident that is causing an impact on customers (in other words, something is broken), or has a non-incident advisory. Advisories represent conditions Microsoft wants you to know about but aren’t confirmed as active incidents, such as planned maintenance scheduled for different regions. Figure 4-8 shows how the SHD displays the current service state and any known problems.

Using the **Customize** button, you can customize the SHD to only tell you about the state of services you care about. You can control this in two ways: what you see in the SHD, and what items Microsoft sends you email notifications about. For instance, if you don’t use Intune, it’s unlikely that you will care about knowing when Intune has an outage.

Clicking on an incident displays extra information, including ongoing details of the investigation for an incident, which may span multiple messages posted by Microsoft over a period. After Microsoft resolves an incident, they often inform customers what happened in more detail through the publication of a post-incident review (PIR). Microsoft uses Azure-based machine translation to translate advisories; if you enable

this feature and then use the admin center in a language other than English, the service will try to translate the incident title, user impact, and incident history.

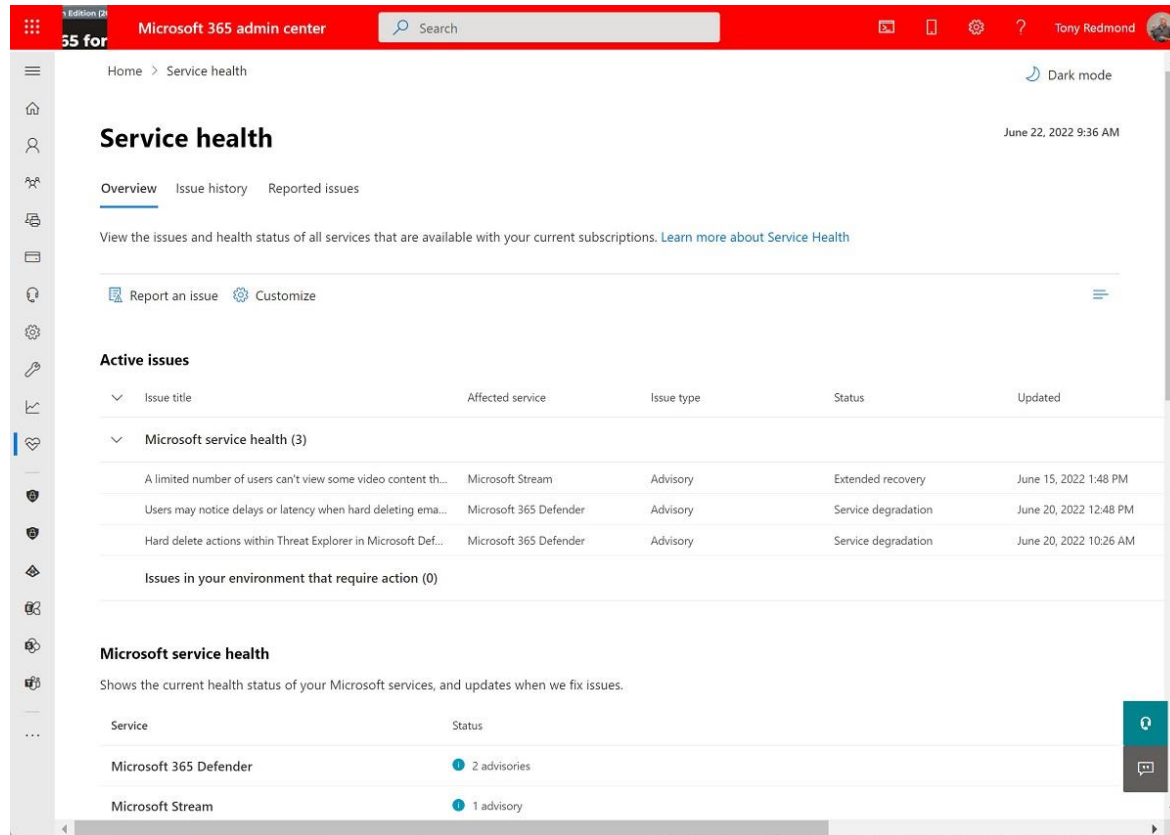

Figure 4-8: Viewing the list of current incidents in the Service Health Dashboard

Sometimes the SHD may alert you to issues that require you to take some sort of action. An example might be that you have a certificate that's about to expire. Issues that require administrative intervention are in the "Issues in your environment that require action" section and, as the name implies, aren't problems with the service... but they will turn into problems if you don't take the required action to resolve them. Microsoft will probably continue to roll out new features to detect environmental issues over time, so you should make checking this item a regular part of your work.

Because of the sheer scale of the service, you can expect that an outage is occurring somewhere in the service at any given point in time. The SHD is a view of problems determined by Microsoft as potentially affecting your tenant, rather than every single issue impacting any tenant across the service. It is also possible that your tenant experiences an issue that the SHD does not show. With that said, it is common to experience problems with the service that affect your users or your entire tenant without seeing it in the SHD.

Microsoft's automated monitoring systems are sometimes slow to detect a problem. In some cases, multiple customers need to report issues and escalate the issues beyond level 1 support teams before Microsoft accepts the issues as confirmed incidents. At that point, Microsoft might add details of the incident to the SHD. Furthermore, you might be experiencing an issue with your tenant that is due to a misconfiguration on your part, not a service fault. For example, if you misconfigure your DNS records and your Exchange Online recipients stop receiving emails, that is not something that the SHD will alert you to because it is not a fault with the service itself. Regardless of any limitations or issues with the timeliness of information, the SHD is a useful resource for administrators.

Microsoft continues to develop the capabilities and intelligence behind the SHD. For example, when logging a new service request the portal tries to proactively inform you of known issues, as well as notifying you

when Microsoft detects actions by your users that may lead to a support request such as clients connecting with out-of-date versions of Outlook. Microsoft also uses telemetry data and machine learning to detect issues, to reduce the amount of time between an incident occurring and the first notification posted to the SHD. There is also a feedback mechanism built into the SHD so that customers can rate the accuracy and usefulness of the information that Microsoft communicates to them.

## Reporting an Issue

You can use the button labeled “Report an issue” at the top of the SHD to register a problem with services such as Exchange Online, SharePoint Online, and Teams. Microsoft says that these reports are correlated with other telemetry data and used to trigger internal investigation (and presumably verification) of potential problems so they can decide which ones are serious enough to pass on to the engineering team and treat as “incidents,” the formal name for service problems that require investigation and repair. It remains to be seen how useful this feature will be either for tenant admins or Microsoft; the risk of false alarms seems high, so the prudent course (which Microsoft also recommends) is to continue to file support tickets in addition to using “Report an Issue.”

## Highlighting Incident Notifications in Outlook

The idea behind incident notifications is simple: when you have Outlook for Windows open for an account that has Microsoft 365 global administrative privileges, the service will post notifications in a new admin notifications pane to tell you about potential problems in your tenant. You might be excused for not having known about this feature before for a simple reason: good security practice dictates that you don’t use your normal work account—you know, the one you’re probably running Outlook against—for administrative tasks. If you’ve followed the normal best practice of assigning separate accounts for your global administrator role holders to use for day-to-day work, you may never see these notifications. Now that you know this feature exists, it might be worth testing it with your global admin accounts to see if you find it worthwhile.

## Getting Incident Notifications via Email

Tenants can opt to receive email notifications of incidents. Even though this capability lags far behind the monitoring notifications provided by third-party products, it’s still good to have. If you want to receive email notifications, enable them by going to the SHD and clicking the **Customize** icon, then choosing Email, then checking the “Send me email notifications for service health incidents” checkbox. Settings changes may take up to 8 hours to take effect, and of course, when you don’t receive an email announcing an outage, it may mean that there *is* no outage, or that one is happening but that it affects mail flow to your specified recipients in some way.

## Receiving Updates for Active Incidents

When you open an individual incident notification, you may notice a link labeled “Manage notifications for this issue.” You can use it to specify up to two email addresses that Microsoft will use to send updates on that specific incident, including any status changes or resolution information. This isn’t quite the same as the “Send me email notification for service health incidents” checkbox mentioned above—the “Manage notifications” link will send you updates only for the specific incidents where you’ve enabled it.

## Programmable Access to Service Incident Information

Microsoft offers the [Microsoft Graph-Service Health and Communications API](#) to help administrators get programmatic access to:

- Notification messages for service updates posted to the Message Center.
- Incident and advisory messages posted to the Service Health dashboard.
- Overview of current workload status.

- Historical incident information.

If you're curious, this [PowerShell script](#) is an example of how to fetch the same set of messages displayed in the Message Center from the API and process them into a form that can be consumed in different ways, such as posting to a Teams channel, export to Power BI, or formatted in an HTML page.

## Other Sources of Service Information

Microsoft maintains a global status page at <https://status.office.com>, but it normally says nothing more than "This site is updated when service issues are preventing tenant administrators from accessing Service health in the Microsoft 365 admin center. Alternatively, customers can reference <https://www.twitter.com/MSFT365Status> for additional insights into widespread, active incidents." Let that sink in: it's a dashboard to check the health of the *real* dashboard.

Users have access to a simple end-user-facing status page at <https://portal.office.com/servicestatus>, although it's not much use for identifying issues.

Finally, given the importance of Azure AD and other Azure-based services to all the Microsoft 365 components, [the Azure status page](#) can also be a useful source of information when things aren't working quite as well as they should be.

## Message Center

The Microsoft 365 admin center dashboard also includes a view of the most recent messages from the Message center. The various product and service operations teams use the Message center to notify customers of changes such as updated features and user interfaces, as well as changes that may interrupt service such as IP address range changes. Items shown in the Message Center are supposed to be specific to a tenant rather than the more general view of what is changing found in the roadmap.

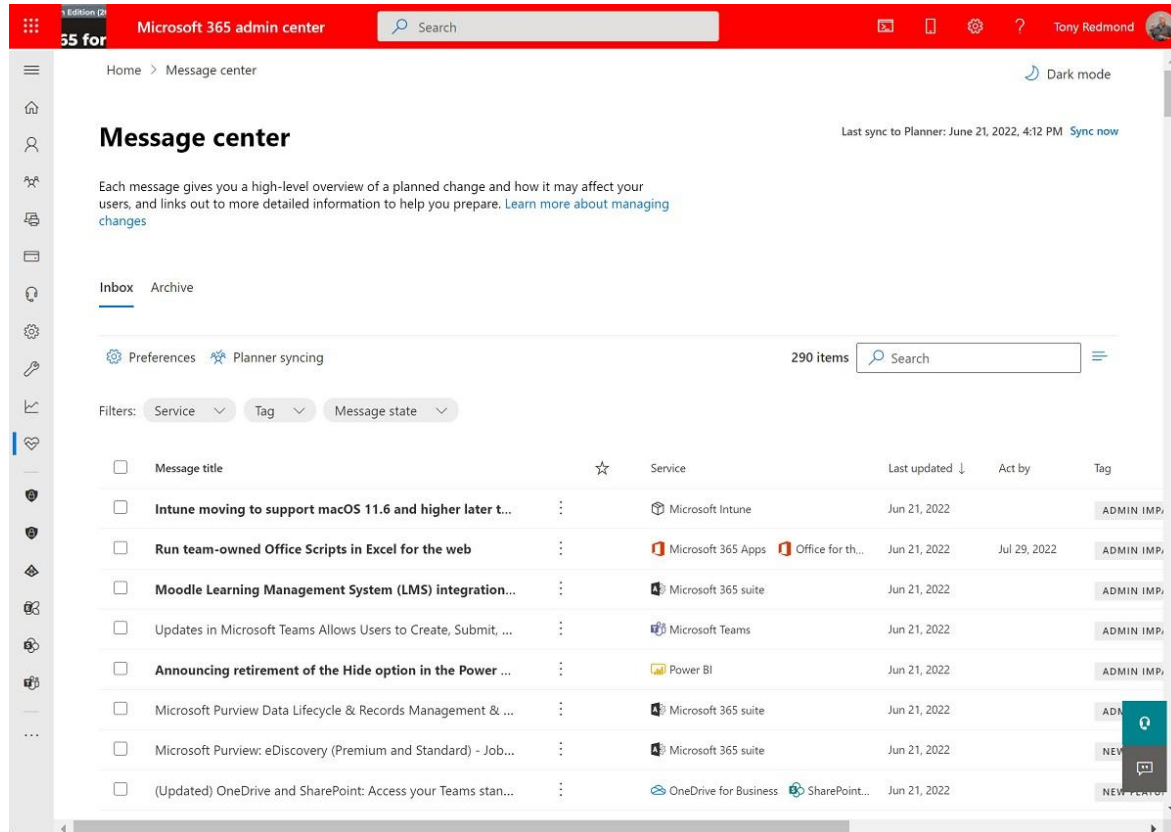

Figure 4-9: Message Center notifications about functionality updates

To make sure that you don't miss anything important, you should access the Microsoft 365 **Message Center** from time to time to review the notifications posted there (Figure 4-9). If you find something interesting in the notices, you can select **Share** to send the notice to someone else via email and include a personal message to add some context about the change. The email includes the complete text of the update notice. Microsoft added tags to notifications, along with controls to let you filter by tags, the services affected, or the state of the notifications. Tags include "Major Update," "Admin Impact," "New Feature," "Data Privacy," and "User Impact." These tag names are self-explanatory, but they are nonetheless useful to help you filter and sort through the steady river of notifications issued by the service.

In early 2022, Microsoft started showing the affected workloads, and the number of affected users per workload, in some Message Center notifications. This is meant to help you prioritize your handling of those changes.

As described in Chapter 9, you can also have Message Center notifications synchronized to Planner, so you can track every change and make sure that any change which might impact your organization is assigned to the appropriate people for action.

## Major Updates

The **Major updates** tag in Message Center features major changes to a service. Microsoft posts these updates at least 30 days before they come into effect. To decide whether a change falls into this category, Microsoft considers how the change might affect users and the tenant with questions such as:

- Does the change affect **the way people work daily**? For example, the introduction of the Focused Inbox changed the way that people deal with new emails. Changes to meetings, delegations, and sharing and access control are also in the "daily productivity" bucket.
- Does the change affect **how the tenant customizes the service**? For example, if Microsoft changes a theme or web part, it might affect how pages render and overwrite a change made by the tenant.
- Does the change **increase or decrease capacity**? A good example is when Microsoft changed the default storage quota for mailboxes (for enterprise plans) to 100 GB. Another example is the change in how OneDrive for Business manages storage quota.
- Does the change affect **what users see**? Any change that might affect the ability of a help desk to support users or change how users access functionality is a major update. A minor branding change such as the replacement of "Office 365" with "Microsoft 365" for the Admin Center is not in this category but forcing people to use content searches instead of workload-specific searches is. Changing a URL used by a feature also falls into this category.
- Does the change introduce **a new service or application**? Microsoft needs to tell tenants when they launch a new application like To-Do or Teams.
- Does the change **require administrative action**?
- Does the change involve **the storage location for data**? Often, applications launch with storage in the U.S. As the roll-out proceeds across the world, storage moves into other data center regions. Customers need to be told where their data is stored, such as when Teams moved its data services into the U.K. or India data center regions.

Once you see a notice about a major forthcoming change, it's a good idea to search for more information such as the blogs written up by people who have tested the change or already have the change in production in their tenant. Independent information added to Microsoft formal documentation creates a more complete picture of what you can expect to see happen in your tenant.

## Message Center Preferences

Despite Microsoft's efforts to improve the relevance of Message center items, some of the messages appearing in your tenant's Message center might not be directly relevant to you. For instance, if you do not use Office 365 Mobile Device Management, you are probably uninterested in any of those messages. You

can filter the messages you see by clicking the **Preferences** link and selecting the services you want to know about.

Message center preferences include the choice to have Microsoft send you a weekly email digest of new messages. Even if it is not a substitute for keeping your eyes open and looking out for information about developments inside the service, the weekly digest is a practical way to stay updated with Microsoft announcements. By default, Microsoft has historically sent the weekly digest to the global administrator for the tenant and addresses the note to both the primary and backup email addresses for that account. A third address is also available for use as the tenant wishes. You can use this address to send copies of the mail digest to a distribution list, a Microsoft 365 Group, or to a team channel for other people to learn about changes. If you do not wish to receive the mail digest, uncheck the boxes for one or more of the addresses and save your preferences.

Unfortunately, Microsoft changed this default so that admins who customized the digest settings before April 2022 will keep their defaults, but users who are granted an admin role after that date will get the digest for four weeks as a trial.

Users holding specific administrative roles can also receive update notifications. Originally, only global admins could see Message Center messages, but as of now users who hold roles such as Teams administrator or Exchange administrator receive messages (which they can opt-out of) for the workloads they manage.

## Automatic Translation

Update messages are composed in English. Administrators who use non-English languages can have the Microsoft 365 admin center translate messages to another language by selecting their preferred language through the admin center settings (cogwheel). If some difficulty occurs in understanding the translated version of a message, you can choose to view the message in English selecting English from the drop-down list of available languages. This is a dynamic choice that reverts to the language selected in settings when you navigate away from the Message Center.

## Managing User Feedback

Getting useful feedback from users is one of the key challenges of making software. Just like every other software company, Microsoft is eager to collect feedback from its users; it uses that data (which might include direct feedback, crash logs, survey results, or metadata about application usage) to see what people think about its products and services and how they can be improved. It may seem sometimes like the Microsoft 365 product teams aren't listening to the feedback their users generate, but nothing could be further from the truth—it's just that getting good-quality feedback is difficult, and at the scale of the service, it's also difficult to parse and interpret it.

There are several interlocking sets of settings that control what happens to this feedback and who can see it:

- The native Windows, macOS, Android, or iOS crash-dump systems all have controls over whether crash logs from an application failure are automatically shared with the application vendor; in general, I encourage users to enable these settings so that the vendors can identify patterns of crashes caused by OS updates, product bugs, and so on.
- Most of the Microsoft 365 apps have an "[in-product feedback](#)" feature (usually in **Help > Feedback**) that lets users submit feedback directly to Microsoft while using Excel, Outlook, or other apps. This feature set requires a relatively modern client version (see [this link's "Before you begin" section](#) for a full version-requirement table).
- Teams has a "Give feedback" feature in its desktop and web clients, and a similar feature in the mobile versions, that you can control with the `Set-CsTeamsFeedbackPolicy` cmdlet.

The admin center includes a **Product feedback** item under the **Health** section in the left navbar; here you'll see all of the feedback that users have submitted. However, before you see anything, users must submit some feedback... and before they can do so, you must enable that by creating a feedback policy with the Office cloud policy service, as described in Chapter 6. You can specify whether users can submit feedback, whether Microsoft can follow up with users who do so, and whether the feedback may contain log files, content snippets, or other organization-specific metadata that might potentially be sensitive.

Starting in February 2022, Microsoft added a new feedback mechanism that you can use to gather net promoter score (NPS) data from your users. It uses the same policy mechanism as the product feedback system described above but collates the data and uses it to present NPS data that you may find helpful as a guide for your adoption and rollout planning. They've made various other tweaks to this feature (including labeling feedback as positive, neutral, or negative) and there is probably more to come here.

Somewhat confusingly, there's a *completely different* mechanism for anyone to submit general feedback for a range of Microsoft 365 services. The [homegrown feedback portal](#) uses the Dynamics 365 Customer Service module, and the portal's design makes it easy to submit and share ideas with engineering groups.

## Network Connectivity Health Monitoring

It makes sense that Microsoft would know a great deal about network connectivity health at the service level, and they're making a subset of what they know visible in the admin center. The **Network connectivity** link under the **Health** section in the left navigation bar shows you data from client-side telemetry to illustrate the performance and quality of your sites' connectivity to the Microsoft network. These data are collected in three ways:

1. Enable Windows Location Services (WLS) on at least two machines in each location that are running Windows OneDrive clients (provided you have version 19.232 or later). When you do this, all the OneDrive clients in your domain will aggregate to the same metro area—that is, if you have 50 computers in Huntsville, they will appear as a single location at the city level. Microsoft also rounds location information obtained from WLS to the nearest 300-square-meter grid square.
2. Use the Locations tab to define a list of locations and corresponding public IP addresses; Microsoft will group clients whose service traffic enters their network from this public IP as “belonging” to that location.
3. Have users run the [Microsoft 365 network connectivity test](#) manually.

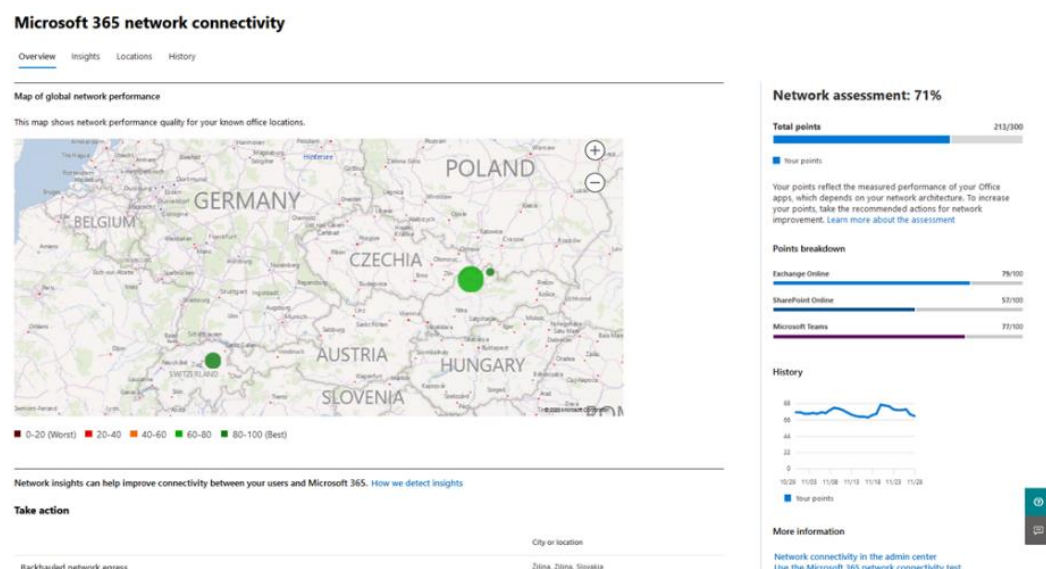

Figure 4-10: The network connectivity view shows you what Microsoft knows about your network quality

The resulting data is presented as a performance map and a series of scores, along with a list of recommendations, as shown in Figure 4-10. Microsoft has plans to continue enhancing this connectivity map by ingesting more telemetry signals from clients and refining the machine learning models that are used to produce insights and recommendations. This is exactly the type of application for which “big data” gathered at a very large scale can provide interesting results; the larger the number of clients that report for any given area, the more resolution Microsoft has for identifying potential network problems.

## Exchange Online Health Monitoring

Exchange Online and Google Gmail together delivered the practical reality of email as a utility service that “just works.” With that said, sometimes Exchange Online *doesn't* “just work,” so demand thrives for solutions to help administrators get early warning, and better insight into, problems that affect email routing and delivery. The huge wealth of telemetry that Microsoft gathers throughout the Exchange Online service is mostly reserved for internal use; it wouldn't do you any good to know the temperature of an individual disk sitting somewhere in an Exchange server pod anyway. However, Microsoft is slowly moving to provide first-party tools to help answer the most common concerns service administrators have: is there a problem? If so, is it *my* problem or *Microsoft's* problem? And what do I do about it?

In February 2021, Microsoft added a public preview of [Exchange Online health monitoring](#) to the service, and that feature has improved over time to [cover other Microsoft 365 services](#). However, you probably can't use it, because you must have at least 5,000 licenses of E3 or E5 licenses from either Office 365 or Microsoft 365 before you can enable the feature. When you do, you'll see health data shown on the **Health > Service health** page. The data collected by the service includes a list of advisories or incidents, plus links to show specific scenario-based data that may help identify problems in one of three categories: problems with the service itself (labeled as “Infrastructure” by Microsoft), problems with third-party network connectivity, and problems with your infrastructure (labeled as “Your org”).

Right now, Exchange Online has the most health monitoring data available. You can see rolling 30-minute counts of the number of users who have logged in (using either basic or Modern Authentication), the number of messages delivered without delay (the time count starts from when the service receives the message), and the number of active users. This last metric deserves a bit more explanation: Microsoft counts an active user as one who has read at least one email using a supported client (all versions of Outlook, plus the native iOS and Android mail clients). A user who sends mail, syncs mobile device folders without reading anything, creates a task item, etc. won't be counted as active. This leads to the unfortunate possibility that at times when you'd normally have low message reading activity, you might find that the health monitoring system doesn't indicate a problem.

For now, there are no real alerting or notification capabilities built into this dashboard. The dashboard will show you incident notifications when selected [mailboxes are nearing their quota](#), when a [Mailbox Replication Service \(MRS\) source mailbox is running slowly](#), or when [outbound messages queues start to build](#). As a place to check when you suspect that there might be a problem, this is a useful tool, but as a means of getting early warning of a newly emerging problem, it will require some refinement to be useful since you won't get a proactive notification

## Health Monitoring for Priority Users

In addition to the overall tenant health monitoring features, you can see health information for [priority accounts](#). You can tag users as VIPs by adding them through the **Users > Active users** view, or by adding them in the **Setup > Organizational knowledge** view. If you'd rather use PowerShell, you can call the `Set-User` cmdlet with the `-Vip` flag, like this:

```
[PS] C:\> Set-User Tony.Redmond -Vip:$true
```

Once you designate an account as a priority user, you'll see some additional health monitoring data, plus the ability to generate alerts when a priority user's account has mail flow problems. You can designate any licensed user as a priority user.

If you have assigned an account a Microsoft Defender for Office 365 Plan 2 license, you can also benefit from a feature Microsoft calls "priority account protection." This is essentially a set of additional quarantine reports and filtering options that let you more easily sift through and deal with quarantined messages sent to your priority users. For example, alerts on accounts that are marked as priority accounts display a unique tag in the alert list.

## Better Network Connectivity with Informed Routing

Microsoft gathers a cornucopia of network performance data across the service that it uses to tune its internal networks and to present the data described in the preceding section. They've been working on an additional use for this data, too: using it as a feedback mechanism to help you tune *your* network. If you're using a supported software-defined wide area network (SD-WAN) solution, a new feature called [informed network routing](#) allows your on-premises SD-WAN equipment to read network data coming *from* the service. The basic idea behind informed network routing is that the service (especially the front doors you connect to) can provide real-time feedback on the performance and reliability of your connections to the service, and your SD-WAN can reconfigure itself as needed to optimize traffic flow to the service. It's a fascinating idea, but as of June 2022 the feature is still in an opt-in preview, and it only works with a single vendor's SD-WAN solution. As Microsoft expands the scope of what this feature can do, it will be interesting to see how much practical value it provides for organizations that are comfortable allowing performance metrics from a single service to drive their network configuration with minimal human intervention.

## Monitoring Systems

As with many Microsoft products, there is a [System Center Management Pack for Microsoft 365](#). Organizations that are running System Center Operations Manager (SCOM) can create alerts and monitoring dashboards for the health of their tenant. Tenants who do not use SCOM implementation can consider a solution based on the various Microsoft Graph APIs available for monitoring and management. You can develop your scripts or software solutions based on the information available through the API or invest in a third-party monitoring solution that can do it for you. Examples of third-party monitoring products include Quest Nova, MessageOps Monitor, Analyzer for Office 365, and 365 Command by Kaseya.

## Service Requests

Service requests are problem reports filed with Microsoft, although you are almost certainly going to be working with third-party support engineers under contract with Microsoft rather than blue-badged Microsoft employees. [Telephone support](#) is also available if urgent problems occur. Because a lot of configuration and other information will need to be given to support engineers, it is logical that calls should be made only by users with administrative access to the tenant.

When you submit a service request, it is routed to a Microsoft support center covering the Microsoft 365 region for the tenant. The support request is examined by a support engineer who will probably call the tenant administrator to discuss the reported problem and to look for added information to help diagnose its cause. Because of the scale of the worldwide service, Microsoft follows a carefully structured approach to gathering and checking facts about service requests. At times, it can be frustrating for a tenant administrator when a support agent asks them what appears to be much the same question several times or to be asked to test components that are known to be failing, but it is all part of the process. Eventually, the problem will either be solved or escalated to second-level support (this can take several days) and, if necessary, to the

product group that supports the workload where the problem exists. Remember, support engineers cannot make changes to code or to how the service works as this kind of intervention can only happen through a process controlled by the product group. Microsoft is rightly cautious about making changes because a small change made for the benefit of a single tenant might have a ripple effect elsewhere within the service that impacts multiple tenants. In general, support engineers can only access tenant data when you allow them to do so. The need to preserve customer confidentiality and privacy is paramount, even if this slows things down at times. You should mentally prepare yourself to be asked to look up and provide data that you might think the service engineers should already have access to.

Naturally, before you add a new service request, it is a good idea to do some troubleshooting of your own as you might discover the answer much faster than through the Microsoft support process. Use your favorite search engine to check for obvious solutions and, if nothing turns up, try asking a question in a community forum such as [Microsoft Q&A](#) (the allegedly-official support site) or the [Microsoft Technical Community](#). Don't be lazy and expect someone else to do the work to solve your problem. Always take the time to investigate and share information in your requests to prove that you have done some troubleshooting for the problem and the results of your investigation. People in support forums generally want to help, but only if you are prepared to help yourself first. Even if the support forums do not help, the information you gather in your investigation will give invaluable background to the Microsoft support engineers who work on the service request.

## Creating a New Service Request

To add a new service request, click **Support** and then **New service request** from the Microsoft 365 admin center. You'll then go through a three-step process.

In the first step, you enter a few search terms, and the admin center will suggest some potentially helpful articles. Microsoft's intent here is to get you to solve your problem, whenever possible, using the search results instead of opening a support case. Microsoft uses a mixture of machine learning and telemetry that they have for your tenant, and searches against their support databases to find potential solutions based on the text you enter. As is typical of Microsoft search technologies, the quality of results here may vary widely. If you don't find any relevant or useful results, you can click the **Contact support** link to go to the second step.

In step two, you give some details about the problem you need help with. You'll need to specify who should be contacted, their email address and phone number, and whether you prefer an email or phone response. You can also specify a preferred language.

When you click the **Contact me** button, your request will be queued for action. The wait time for a response is usually quite short, but it will depend on the number of cases that the support representatives are dealing with. IT professionals love to complain when they have been let down by a poor support experience, so you will always find stories of very long waits for a call back from Microsoft. If the delay for a call back is too great a risk for your organization then you should consider a Premier Support contract to get faster support. You can request a specific callback time, which will help reduce the frustration inherent in playing phone tag with support engineers, and if you specify your time zone, they might even honor it (hopefully avoiding late-night phone calls). However, they have removed the option to request contact via email, which is not a good tradeoff.

Note that when you send a support request, if the phone number or email address you supply isn't listed in your organization profile, Microsoft will send a unique PIN to the registered email addresses that *are* in the support profile. This helps reduce the risk of spoofing but means that, if you're not watching for the PIN, your support case may languish until you've supplied it. Microsoft recommends making sure that customers update their profile email and phone details to avoid this problem.

When you create a support request, you can add attachments such as screenshots or network traces; these, along with the contents of the problem description field, are the only real ways that your assigned support engineer will have to learn about the problem before you talk to them. Be sure to be clear and descriptive.

When Microsoft receives a service request, they assign it a service request identifier such as 10312033. You should give this identifier to Microsoft whenever you communicate with the support team, as it allows them to track the progress of a service request through Microsoft's support and escalation systems. You should also receive a message from the support engineer assigned to the service request. The subject of this message has some tracking information to capture the interaction between support staff and tenant administrators in Microsoft's support databases. To keep a record of the case as it unfolds, reply to the message whenever you have something to add or want to request an update. It is a good idea for you to keep your record of interactions with Microsoft just in case this data is necessary to prove that a problem hasn't received enough or timely attention.

The details that you add to a service request can be extraordinarily useful to the support engineer assigned to handle the case. You should give information such as:

- Detailed steps to reproduce the problem. If the problem surfaces in different ways, include steps for each way that you know to reproduce the issue.
- Is the problem still evident after you sign out and sign back into Microsoft 365? An expired token can cause a failure to connect to a service, so it's important to check that the account with the problem is authenticated.
- Scoping information for the problem's impact. Does it affect one user, all users, or something in between? Are all the affected users in the same geographic region?
- If the problem occurs only in one location, is there something special about how users connect to the service or the Internet from that location?
- Has anything changed recently? For example, have you made any configuration changes that might be related to the problem?
- Did this functionality ever work, or did it stop working at some point?
- Screenshots showing any error messages that are visible to users.
- PowerShell commands and the output from those commands to help support engineers to understand the problem.
- Background information such as the version number of clients (including browsers) that are affected by the issue. Make sure that you use a browser supported by Microsoft 365 and try to replicate the problem on different browsers to narrow the conditions under which the problem appears. For instance, the Edge and Chrome browsers can behave differently from the Brave Browser. Does the problem occur with all browsers or just a specific browser? Can it be reproduced on multiple workstations or just one that is running a certain version/build of an operating system? Does the problem happen if you open a private or incognito browsing session?
- If the problem affects a hybrid component, details of the hybrid connection and other associated components such as how directory synchronization is performed and whether single sign-on is used.

Just like in any support system, the various kinds of problems that can occur need different periods to resolve. Some issues might never be resolved because they need substantial engineering investment that Microsoft considers unjustified or unnecessary. Microsoft should resolve straightforward problems in a day or so, but to be brutally honest, as the service grows, any problem that can't be addressed by a simple troubleshooting script is likely to linger. It's very difficult to attract and retain good support engineers, and Microsoft has struggled with doing so over the last few years. Problems that need engineering intervention, the acquisition of more detailed diagnostic data, or are simply complex will need more time. Microsoft is usually good at keeping tenant administrators up to date with the progress of service requests through

email. Updates are posted to the service request and are visible through the Microsoft 365 admin center. And if things go quiet, you can always email the assigned engineer to ask for an update.

## Gathering Tenant Information

While you work through a service request with Microsoft, you might be asked to give some information about your tenant, usually to allow the support engineer to understand what version of the software the tenant is running. Remember that a tenant can choose to use software released to the Targeted Release or Standard Release rings or a mixture of both. Even within these rings, Microsoft deploys software at different intervals to reach every tenant in all regions. It is impossible to deploy new software to everyone at the same time, so it is important to know what configuration is active within a tenant when you meet a problem.

The Microsoft 365 admin center doesn't provide a built-in way to gather and report tenant configuration, so you must use PowerShell for this purpose. Two cmdlets are especially important. The *Get-OrganizationConfig* cmdlet returns information about Exchange Online and some generic tenant data while *Get-SPOTenant* returns information about SharePoint Online. You will find examples of *Get-OrganizationConfig* in use for different purposes in other chapters, but we will concentrate on its use to report tenant data here. The information reported by the cmdlet changes over time and is difficult to review on-screen. It is usually best to dump the output to a text file and review it with an editor, which will also make it possible to extract information to share with Microsoft support. In the following example, the first command lists several important settings that might be of interest when troubleshooting a support case while the second redirects the output to a text file.

```
[PS] C:\> Get-OrganizationConfig

Name                : office365itpros.onmicrosoft.com
ObjectVersion       : 16500
ReleaseTrack        : FirstRelease
SharePointUrl       : https://office365itpros.sharepoint.com/
MapiHttpEnabled     : False
IsLicensingEnforced : True
IsTenantAccessBlocked : False
IsTenantInGracePeriod : False
RBACConfigurationVersion : 0.1 (15.20.218.12)
AdminDisplayVersion : 0.20 (15.20.218.12)
ServicePlan         : BPOS_S_E15_0

[PS] C:\> Get-OrganizationConfig > Config.txt
```

For instance, settings such as the *RBACConfigurationVersion* and *AdminDisplayVersion* will tell engineers what version of the software runs inside the tenant. The *ReleaseTrack* setting shows if the tenant uses Targeted Release for all or some users, while the *ServicePlan* setting shows the basic plan configured for the tenant.

SharePoint Online does not report as much configuration data for a tenant as Exchange Online does, but the devil might be in the detail when engineers are debugging a problem. Here is what the *Get-SPOTenant* cmdlet reveals:

```
[PS] C:\> Get-SPOTenant

StorageQuota                : 44032
StorageQuotaAllocated       : 20174
ResourceQuota               : 10900
ResourceQuotaAllocated      : 1900
CompatibilityRange          : 15,15
ExternalServicesEnabled     : True
NoAccessRedirectUrl         :
SharingCapability           : ExternalUserSharingOnly
DisplayStartASiteOption     : True
StartASiteFormUrl           :
```

```
ShowEveryoneClaim           : True
ShowAllUsersClaim          : True
OfficeClientADALDisabled   : False
ShowEveryoneExceptExternalUsersClaim : True
SearchResolveExactEmailOrUPN : False
RequireAcceptingAccountMatchInvitedAccount : False
ProvisionSharedWithEveryoneFolder : False
SignInAccelerationDomain    :
```

Sometimes, you might be asked for the tenant identifier. This is a unique value for the tenant used in different places by Microsoft 365 and Azure AD. One way to retrieve the identifier is to use the *Get-MgOrganization* cmdlets. This example uses *Get-MgOrganization*:

```
[PS] C:\> Get-MgOrganization | Format-List Id, DisplayName

ObjectId                DisplayName
-----
a662313f-14fc-43a2-9b7a-d2e27f4f3478 Office 365 for IT Pros
```

The *ObjectId* reported by the cmdlet is the tenant identifier. This is important information to have because it's the unique value used by Microsoft 365 to identify the tenant. You'll need to know this information if you ever want to sign up for a Microsoft beta program.

Alternatively, input your tenant domain name into this [website](#) to retrieve the identifier. The site uses information published on the internet to allow OAuth 2.0 sign-ins to function to report the tenant identifier.

## Customer Lockbox

When Microsoft support personnel are working on an issue for you, they may need access to some user data to resolve the problem. These situations are rare, as most of the support operations performed by Microsoft are automated. Where possible, any support tasks performed by support engineers are isolated from customer data. However, there will always be some cases, such as when Microsoft support is trying to help a customer with problems with mailbox contents, that access to the user data is necessary.

Customer Lockbox is an extension of Microsoft's Lockbox system for managing "just in time" access to the service infrastructure by support staff. Multiple levels of authorization are required before support staff can gain access. Upon approval, the support engineers receive access limited in scope and duration to the minimum needed for the task. Lockbox also includes comprehensive audit logging of any activities that support staff perform.

Under normal circumstances, support engineers receive approval from a Microsoft manager to access customer data. When a tenant enables the customer lockbox feature, an added approval by the customer is necessary before Microsoft support can access user data (this requirement does not cover access to system data such as logs). Microsoft sends the Customer Lockbox request as an email notification which administrators or users with the customer lockbox approver role can approve or deny in the **Support** section of the Microsoft 365 admin center. Access requests have a time limit (12 hours by default), and a scheduled cleanup task removes the support personnel's access automatically upon resolution of the issue or when the time expires.

Actions performed by Microsoft support or by the automated systems used in the service are captured in the audit log for the tenant. Like any other audit log records, they are accessible using PowerShell or APIs to allow third-party security monitoring systems to extract and include data in reports and dashboards.

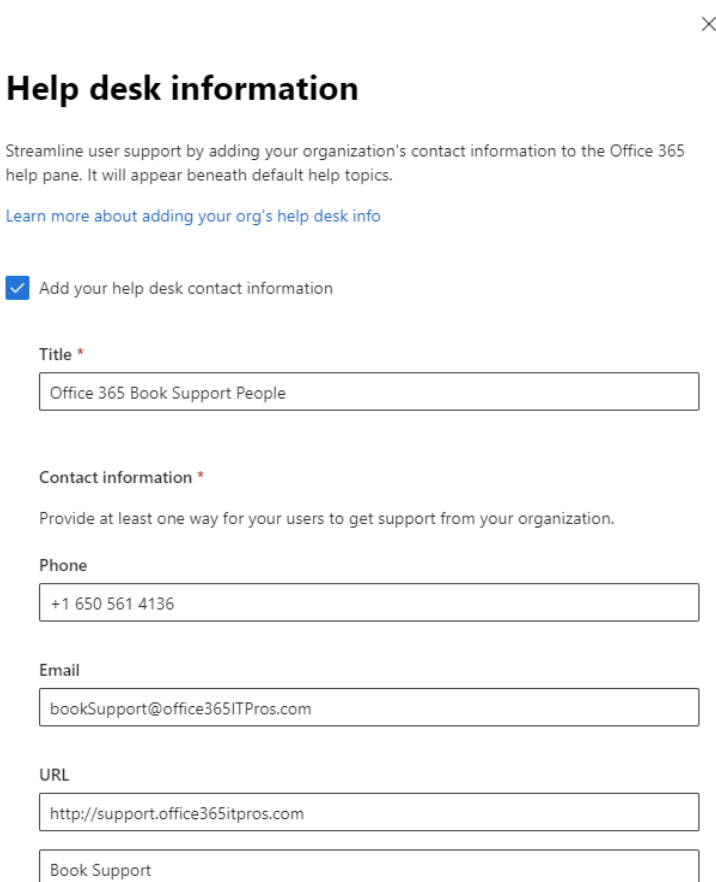

To enable Lockbox for a user, the user will have to have an Enterprise E5 license *or* the Advanced Compliance license.

# Customizing the Microsoft 365 Interface

One of the big selling points behind Microsoft 365 is that it has a consistent and familiar interface, both for users and administrators. Microsoft doesn't want any of us going overboard with interface customizations; they have included a few features to help tailor the Microsoft 365 client interfaces to the needs of specific organizations though.

## Creating Custom Help

Tenants can create a custom help card to be displayed alongside the standard help text revealed when a user clicks the question mark (?) icon in a browser while accessing an application. The idea is that you can provide users with tenant-specific information to allow them to seek help if they have a problem. To create a custom help desk card, open the Microsoft 365 admin center and go to **Settings** -> **Org settings** and then click the **Organization profile** pivot. Click the edit icon beside **Help desk information**.

**Help desk information** ×

Streamline user support by adding your organization's contact information to the Office 365 help pane. It will appear beneath default help topics.

Book Support

Figure 4-11: Populating custom help desk information

Office 365 displays the input screen shown in Figure 4-11 and you can enter:

- A title.
- Phone number details.
- Email address.
- Web page.

The next time a user signs in using a web browser, they see the custom help desk card when they access help.

Office 365 supports a single custom help card per tenant. You can't, for instance, have location-specific help information presented to users. For this reason, if you manage a tenant that has users distributed in multiple locations or countries, you should make sure that the information provided in the custom help card is valuable for all users. For instance, it does not make sense to direct a user in Japan to a help desk in the U.S. if that help desk is unable to speak Japanese or is only available during U.S. working hours.

## Custom Tiles

When users sign into the Microsoft 365 portal, or when they click the waffle menu (the App Launcher) from a browser application such as OWA, a list of tiles for the applications and services to which they have access appears. Users can select apps to appear in the launcher from their My Apps page, which lists all the apps known to the tenant. The apps that appear in My Apps come from several sources:

- Standard apps licensed from Microsoft as part of the plan assigned to the user account. For example, OneDrive for Business and Stream.
- Apps that are developed for or by the tenant. Administrators then configure the app to assign it to individual users. These might be line-of-business applications that are registered in Azure AD or applications written by ISVs and stored in the Azure application marketplace, such as DocuSign, DropBox, or Citrix GoToMeeting.
- Apps created with the Office 365 API Tools for Visual Studio that allow users to sign in using their Microsoft 365 credentials. These apps automatically show up on the My Apps page.
- Web apps from AppSource that support single sign-on, such as the [Starbucks app](#).

Custom tiles are available to accounts that have an Exchange Online mailbox and are the simplest and easiest way to customize the App Launcher. Essentially, a custom tile serves as a pointer to a web page. The URL defined as part of a custom tile can bring a user to a SharePoint site, Microsoft 365 Group document library, external website, or any other page accessible through a URL. The custom tiles that are defined for a tenant are listed in the My Apps page displayed to users and can be pinned to the App Launcher from there.

To add a custom tile, login to the Admin Center and navigate to **Settings** -> **Org settings**, and then click the **Organization profile** tab, then choose **Custom app launcher tiles**. Click + and you'll be able to add a custom tile by specifying the name of the tile, the URL that the tile should invoke when clicked, a description (purely for administrative purposes), and a URL for an image for the tile icon. The image must be in JPEG format and should be sized at 50 x 50 pixels. It is easiest if the image file is stored in a SharePoint library as this means that it is accessible to users. In addition, make sure that all users have at least read-only access to the tile image. If users don't have access to the image file, a blank space is shown for the tile in the My Apps library.

**Hiding launcher tiles:** Many administrators want to hide specific applications from users by removing the application tiles in the app launcher for all (or some) users in the tenant. Unfortunately, there's no way to do this. The list of tiles the user sees is dynamically built based on the licenses you've granted them. Users may add and remove tiles themselves but there's no way for you as a tenant administrator to do this in bulk. If you don't want users to use an application, instead of hiding it in the launcher and hoping they don't stumble across it, you'll have to remove the license (or deactivate the application) for those users. You can also hide [all custom tiles](#) or set up [application collections](#) that have predefined sets of tiles for users to see.

## Managing Themes

Microsoft has long offered the ability to apply themes or skins to various applications. This ability started with Outlook Web Access in Exchange 2000 or so, although creating themes for on-premises OWA was always sort of a hit-or-miss proposition and wasn't generally supported. With the move towards cloud-based services, Microsoft has provided a more robust theming mechanism that allows you, or your users, to select

themes that apply to the Microsoft 365 admin center and various applications. There's a similar facility in the [Microsoft 365 Apps](#) as well. The drawback? You can't customize these themes very much.

If you open the **Organization profile** settings for your tenant in the Microsoft 365 admin center (under Org settings), you can select **Custom themes** to edit items like:

- The corporate logo for display on Microsoft 365 web pages. The selected logo file must be sized precisely at 200 x 30 pixels and be less than 10 KB. Files in SVG format are best because these are supported by mobile apps. You can also associate a link that users go to when they click the logo.
- The navigation bar color. This should match the color of the background image.
- Text and icon color. This should highlight text and icons when overlaid on the navigation bar.

Of the other available settings, the most important one is probably the **Prevent users from overriding their theme** checkbox. If for some incomprehensible reason you need to exert a kindergarten level of control over your users' choices of theme, this is where you'd do it.

Speaking of themes: Microsoft occasionally releases new ones for users. Currently, there are more than 50 themes available to users under the gear settings icon. Some themes are whimsical, while others are merely solid-color sets.

You can create up to five separate themes of your own and then [assign them to members of specific Microsoft 365 Groups](#). Microsoft originally referred to this as "conglomerate branding" but now seems to prefer the term "group branding." Each of the themes can have a unique experience, including separate company logos (and a logo variant for dark mode).

## Reporting

Microsoft 365 includes a few different sets of reports that may prove useful. The Microsoft 365 Admin center contains a reporting section with an activity dashboard and a handful of reports that give organizations a view into the adoption level for the different services they buy with their subscriptions. For example, the email activity report might show a healthy amount of usage, justifying paying for Exchange Online mailboxes, while the SharePoint or OneDrive for Business reports might show a different level of usage that prompts the organization to either reconsider the licensing of that feature or embark on an adoption project to encourage more use. Similarly, the Activations report lets an organization analyze the consumption of licenses bought for their end-users. For example, if you assign international calling licenses to users who do not use them, then you can reassign the licenses to other users who need them rather than buying more licenses.

In addition to these canned reports, there are two more detailed and more flexible reporting tools that you should know about. The first is the Productivity Score toolset, which tells you what users are doing with the service. The second is the Secure Score toolset, which is part of Microsoft 365 Defender and gives you a synoptic view of your tenant's security.

See Chapter 20 for more information about reporting and auditing, including the Microsoft 365 Usage Analytics pack for Power BI and some third-party reporting alternatives.

## Microsoft Productivity Score

The Productivity Score section of the Admin center purports to solve a long-running problem: how do you know how effective people are at their jobs? It pulls data from individual users' activity in the service, data from their calendars, and telemetry from various applications, and synthesizes that data into a series of measures that allegedly show how productive they're being. Figure 4-12 shows an example Productivity Score dashboard; a glance will show that there's an aggregate score but that the aggregate is a composite of several individual measures.

## Productivity Score

Productivity Score provides insights into your organization's digital transformation journey through its use of Microsoft 365 and the technology experiences that support it. Your organization's score reflects people and technology experience measurements and can be compared to benchmarks from organizations similar to yours.

### People experiences

#### Communication

Organizations that use a variety of ways to communicate support different work styles, needs, and preferences.

0% of the people in your org use two or more modes to communicate.

#### Meetings

When people use online meeting tools effectively, they can save up to 104 minutes a week.

0% of meetings in your org follow one or more meeting best practices.

#### Content collaboration

When people collaborate with online files, they can save up to 100 minutes a week.

15% of the people in your org collaborate with online Microsoft 365 files.

#### Teamwork

When people share information and collaborate in a shared workspace, they can save up to 4 hours a week.

10% of people in your org are contributing to shared workspaces.

#### Mobility

Access to email and files, and communication with teammates on any device help people get work done on their schedule.

9% of the people in your org use apps across multiple platforms.

### Your organization's score: 31%

Total score: 250/800 points

■ Your org ▼ Peer benchmark

Your organization's Productivity Score is the total of its people experiences and technology experiences scores, which are each comprised of several categories of data. Scores are not provided at the individual user level.

Score components 250/800 points

People experiences: 24/500

Technology experiences: 226/300

▼ Peer benchmark

Figure 4-12: Viewing the Productivity Score for a tenant

Clicking on one of the scorecards in the overview report shows a more detailed analysis of that specific scorecard. For example, Figure 4-13 shows the details used to calculate the content collaboration scores shown in the overview.

While the idea of an overall score measuring the productivity of an organization seems tantalizing at first thought, there are some problems with this approach. First, it immediately calls to mind the mostly-obsolete discipline of [scientific management](#), with its rigid emphasis on measuring every activity of every worker and continuously iterating to remove all inefficiencies of process or execution. There are good reasons why most organizations don't ruthlessly try to optimize every minute of workers' work times (not least of which is the importance of good labor relations in industries or countries where workers' unions are common).

Second, it's fair to question whether the data Microsoft presents tells you anything useful or actionable. Is it valuable to know, for example, what percentage of meetings have at least one user with video turned on? Perhaps. There doesn't seem to be any meaningful research showing that enabling video makes meetings X% more productive, so it's hard to quantify the impact of knowing e.g., that 20% of an organization's meetings have one person with video turned off. And if having a meeting where one person turns their video feed on is good, what about meetings where two people enable video? Are those meetings twice as productive?

Third, Microsoft can necessarily only gather metrics from things the service can see. If your users use non-Microsoft tools (e.g., Zoom, Dropbox, Google Meet, etc.), then Microsoft won't know what they're doing and cannot, therefore, try to estimate their productivity. And of course, the service knows nothing about meeting participants who are physically present in hybrid meetings (something that will become increasingly common as Microsoft Teams Room systems become more widely used post-pandemic).

## Content collaboration

We measure the number of people who create, read, and collaborate (edit and share) online for this part of your score. When people collaborate with online files, each person saves an average of 100 minutes, or almost 2 hours, per week. [See the evidence](#)

On April 22, 2021, we changed how the collaborators metric is calculated. As a result, you may see a reduction in your score. [Learn more about the scoring change](#)

### 15% of people in your org collaborate with online Office files

When people create and read files online, they are more likely to collaborate online as well. We define content collaboration as one person creating and sharing an Office file, and then at least one other person reading it. This data contributes to your overall productivity score. [How we calculate your organization's score](#)

Peer benchmark

[View content collaboration resources](#)

### Number of readers, creators, and collaborators over time

### Explore how your org collaborates

#### 30% of people who use Office create files in OneDrive or SharePoint

Creating files in OneDrive or SharePoint means they're backed up, available from other devices, and set up for real-time collaboration.

##### People creating files, by location

[View related content](#)

#### 100% of people share files as an email attachment

Sharing a link to a file in the cloud instead of attaching a copy in email makes sharing more secure and allows users to collaborate in real time.

##### People sharing files in email, by type

[View related content](#)

#### 0% of people share content externally

Customize SharePoint's external sharing settings to help people collaborate with external partners or people in your organization who have different licenses.

##### People sharing content

[View related content](#)

#### 2% of people collaborate on 4 or more Office files

Invite people to learn about saving and sharing files in the cloud, co-authoring in real time, and collaborating with @mentions.

##### People collaborating, by number of shared files

[View related content](#)

Figure 4-13: Details of the data used to calculate the content collaboration score in the dashboard

Fourth, the individual metrics that Microsoft gathers in the “People in your organization” section are questionable at best. For example, on the meetings detail page, for each user you can see the date of their last meeting, how many meetings they attended, how many hours those meetings took, how many meetings had video, and how many meetings had screen sharing enabled. (There are a few additional columns as well). The first two users listed in my organization have, respectively, “meetings attended” values of 39 and 81. Does that mean the second user is twice as productive as the first one? Or maybe half as productive? The idea that an individual or organization’s productivity can be measured by such a low-resolution metric brings to mind physicist Wolfgang Pauli’s lament that a theory “[is not even wrong](#).”

Fifth, Microsoft sometimes moves the goalposts—for example, as detailed in MC251864, they changed the way that the “Content collaboration” metrics are calculated in late April 2021, and they are free to change any or all the metric calculations in the future. On one hand, it’s good that they evolve the metrics as they come to understand whether a specific metric can lead to a measurable insight. The August 2021 retirement of the “embed link in email content” insight is a good example of removing something that didn’t provide any useful insight. On the other hand, changing the metrics and insights available means your ability to track trends in the productivity score over time will be affected.

Besides all of these points, there are legitimate privacy concerns in some organizations, and almost immediately after Microsoft released the Productivity Score feature, they were broadly roasted in the tech media for it, so they [backtracked and modified the feature](#) so that it no longer shows user-specific data. This doesn’t change the fact that most of the data about what users are doing remains available to administrators; you can still see how many meetings people have gone to and so on.

With all that said, there are certainly some useful data items highlighted in the Productivity Score report. The “Technology experiences” section, for example, summarizes data about device startup time, network connectivity, and Microsoft 365 application health that are useful in understanding what tools people are using and how well they work. This data is both useful and actionable in a way that much of the more

collaboration-focused data isn't. As Microsoft continues to refine the utility of the metrics and the associated analysis and recommendations, we'll have to see if this feature becomes more valuable.

## Microsoft Secure Score

Microsoft acknowledges that it can be difficult for an administrator to understand how to best secure a tenant. Many places exist in administrative consoles where you can tweak settings that affect how things work. In addition, a multitude of data exists within applications that administrators should check on an ongoing basis. Therefore, it makes sense to measure a tenant against a set of predetermined standards and score the tenant based on the actions taken to increase security. At the same time, Microsoft 365 can flag outstanding actions to the administrator, who then decides whether to implement the action and so increase their tenant score. This feature was called Microsoft Secure Score, and, after a few false starts, that seems to be the name used throughout Microsoft 365 now for this functionality. The Secure Score dashboard allows administrators to:

- Track the progress of their score over time.
- Understand the actions that contribute to the current tenant score.
- Understand how they can improve their score by completing various actions.

Secure Score now lives in the Microsoft 365 Defender portal. Here's how it works.

### Microsoft Secure Score

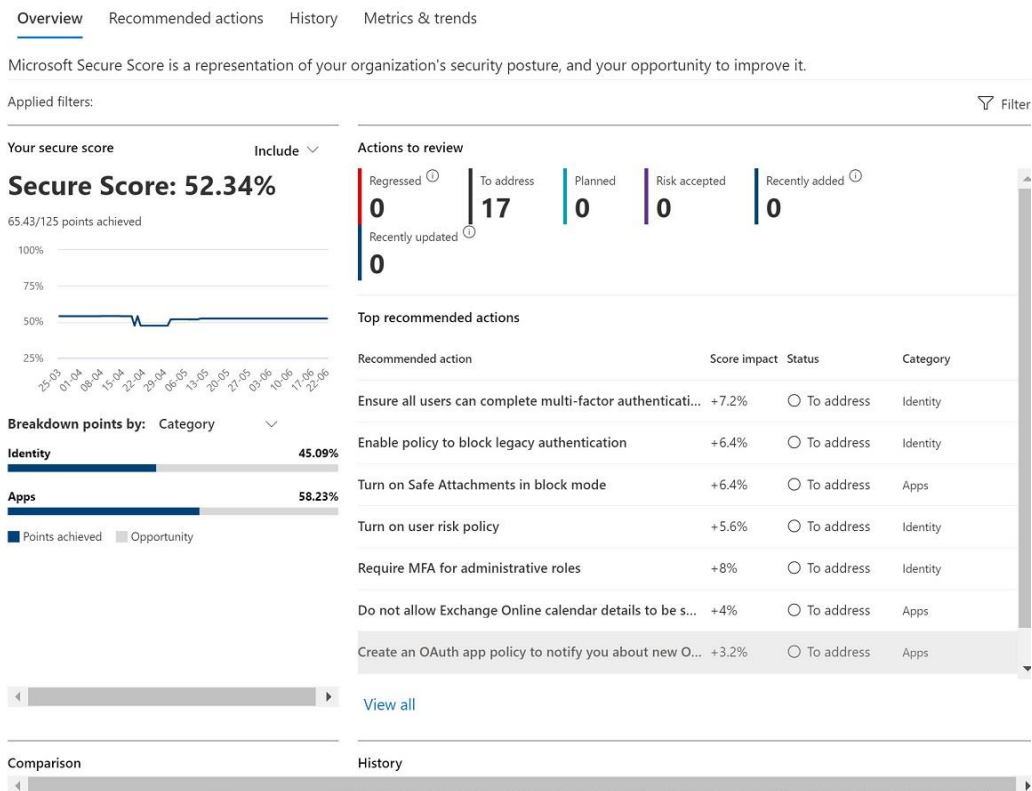

Figure 4-14: Viewing the Secure Score for a tenant

When you go to <https://security.microsoft.com/securescore> or click the **Secure score** link in the left navbar, you'll see a dashboard like the one shown in Figure 4-14. This version represents a significant change since its introduction in that the score is now shown as a percentage instead of a raw number of points, and it is gradually incorporating data from more settings and workloads across the Microsoft 365 platform. This dashboard summarizes your overall security score, calculated based on inputs drawn from multiple sources in the tenant including Azure AD, Enterprise Management + Security (EMS), and various Defender services, in

whichever combination you have them. As you enable more security features, your score goes up. The dashboard includes a list of recommended actions that, if taken, will increase your score. Keep in mind that some security features will increase your score but will irritate users or make it harder for them to do their jobs.

Over time, Microsoft gradually adds both new measurements and new recommendations to Secure Score, so your score will fluctuate even if you don't change anything.

The "Include" dropdown allows you to choose different metrics to measure your score against, and the filter icon lets you choose categories of score items that will, or will not, be included when the score's calculated, while the other areas of the dashboard show actions that you may want or need to take to improve your overall score. The pivot at the top of the dashboard lets you see specific actions that Microsoft recommends taking to boost your score, as well as a history of what your score has looked like over the last 90 days.

Suppose you configure Microsoft Information Protection to allow tenant users to protect confidential content; that adds five percent to your score. Even better, if users store documents in OneDrive for Business, adding AIP is worth ten percent. Although you can argue that OneDrive for Business is a more secure location for documents than a local hard drive or a network file share, assigning ten points to this measurement seems like more of an encouragement to do better. Other controls are easier to understand and more fundamental in terms of security. For instance, administrator accounts should use multi-factor authentication and there should be less than five global administrators within a tenant.

Secure Score combines percentages awarded for the measured aspects into a tenant score. The "Comparison trend" chart shown under the **Metrics & trends** pivot widget in the dashboard shows your organization's score compared to other organizations with a similar number of licensed seats and other organizations in the same industry you're in.

In addition to the base Secure Score mechanism, Microsoft also calculates a [separate identity security score](#) for Azure AD. Here's what Microsoft's [Chris Hallum said](#) about the apparent disparity between the identity score and the "real" Secure Score:

*"The vision for Microsoft Secure Score is that it will be the centralized user experience for all security-related points and Improvement Actions across Microsoft 365 and Azure workloads. Individual products can include a secure score experience scoped to their workload however they must align to the Microsoft Secure Score design patterns and branding. They must also forward their score and improvement action data to Microsoft Secure Score so that it can provide the end-to-end super set the view for an organization's security posture."*

Reviewing your identity score data, along with the list of [best practices recommended for Azure AD administrators](#), and then making appropriate changes can quickly boost your Secure Score overall *and* for identity management. At Ignite 2018, Microsoft said that organizations that follow the Secure Score recommendations are 30 times less likely to be breached, although they have been suspiciously quiet about updates to this metric since then.

When you review individual actions, you'll see a comprehensive page showing lots of information about the action including a description of the proposed change, what state the service thinks you're in now, what the user impact of the proposed change is, and any historical information about changes to this setting in the past. You can mark individual actions with an action plan that tells the system what you plan to do about the risk; Microsoft also helpfully includes a list of implementation steps, although they have some room to improve the display of HTML content there.

It's also the case that the Secure Score mechanism may fail to notice and score an action you're already taking or may recommend actions whose true impact can't be scored. For example, the "Review permissions & block risky OAuth applications connected to your corporate environment" score item promises 15 percent

if you use Defender for Cloud Apps to “block access to a risky OAuth app,” but the precise definition of “risky” is missing, so presumably you can earn 15 percent by blocking *any* OAuth app.

Interestingly, Microsoft 365 keeps the score data for only 3 months, so if you want to see longer-term trends, you’ll have to track the scores yourself. You can [access Secure Score data through Graph](#) to facilitate this.

The engineering team responsible for Secure Score constantly reviews threats and operational processes to ensure accuracy and relevance. Microsoft assesses feedback from the tenants as they analyze tenant scores to understand any gaps and weaknesses that might exist and fix the issues. The score for a tenant is likely to change over time as Microsoft adjusts its scoring scheme and measurements. Administrators should review their tenant’s Secure Score regularly to ensure that they leave no gaping holes for attackers to exploit.

## Backing Up Office 365

Do you need to back up your Office 365 data? This is a complex question. Interestingly, no one questions the value of backup for on-premises data. Why are things different in the cloud?

On one hand, many experienced administrators believe that it isn’t strictly necessary to take backups of cloud-based data. In fact, Microsoft only takes limited backups for SharePoint Online. They don’t take backups of Exchange Online, Teams, Planner, Yammer, or other applications. Microsoft doesn’t provide APIs specifically designed for backups for their cloud applications. Backup vendors must resort to using protocols or APIs not intended to stream large quantities of data to copy data across the Internet to another data center (whether in Azure or another cloud provider). In addition, cloud applications are often interconnected in ways that don’t exist on-premises. The result of this interconnection is that some workloads are much easier to back up and restore. Backing up the documents from a SharePoint site is relatively straightforward, but restoring them in such a way that Microsoft 365 Groups and Teams work properly is a different challenge.

On the other hand, many organizations believe that backups are a good thing because they want to have a method of restoring user and configuration data should the need arise. The need might arise from what I’ve started to call “the four Ms”:

- Malicious changes, such as those made by ransomware or a disgruntled employee.
- Mistakes, such as the infamous mass deletion of Teams chat messages caused by an administrator who misconfigured KPMG’s retention policies.
- Mishaps at the cloud service provider—a more polite way to say “data loss caused by Microsoft”
- Migrations often benefit from having a comprehensive backup of the “before” state in case problems occur during the migration.

As further ammunition, some companies cite [Microsoft’s Shared Responsibility model for cloud services](#) and point to its assertion that customers are always responsible for their data. In other words, Microsoft takes no responsibility for protecting data and it’s up to customers to ensure that they can recover. This is true in general terms but ignores the fact that many Microsoft 365 apps like Exchange Online and SharePoint Online include data protection and retention capabilities to mitigate against data loss.

The writing team for this book is not against backups. Our perspective is that the decision to use backups is one that each company must take after careful consideration of how Microsoft 365 works, the likelihood that problems will arise, the cost and extra complexity of a backup solution, and how quickly data can be retrieved from backup and the operational steps necessary to retrieve data, and so on. But the most important thing is to understand the full spectrum of technology available to a tenant and how to use it to mitigate some or all the reasons why people think they need backups. Following that review, if you still consider that backups are important, it’s a good and rational decision.

## What If You Do Nothing?

Before deciding to use a third-party backup solution, we should understand how out-of-the-box features can reduce the risk of data loss and where gaps might exist. You can think of this as the “do nothing” question: what level of data protection do you get if you don’t buy or configure anything and just rely on the data protection measures in the service?

To answer this question, it’s often useful to look at what Microsoft itself does. When Exchange first introduced the concept of “native data protection,” with multiple copies of each mailbox database substituting for keeping backups, many administrators were horrified, but in practice, this approach has worked very, very well when implemented properly—so taking guidance from the team that builds and runs the service is a valuable way to start.

As an example of a potential gap, many backup vendors point to the fact that a disaffected administrator or user might remove data in the period before they leave the company; they claim that backups offer a robust solution to this potential problem. This is true, but if you have the right licenses (see the [Information Governance section](#) of this page), retention policies can mitigate the problem by automating the process of keeping data for extended periods. Retention policies cover information in:

- Exchange mailboxes and public folders.
- SharePoint Online sites and OneDrive for Business accounts, including video recordings of Teams meetings and all Stream content.
- Teams channel (regular, private, and shared) and chats (personal and group).

For greater protection, preservation locks can secure retention policies and stop administrators from being able to change retention settings. Putting all mailboxes on litigation hold will stop their removal if a rogue administrator deletes some user accounts. And you can lock Exchange Online down further by using [Privileged Access Management](#) to limit what administrators can do to specific time-limited operations.

In fairness, though, these measures protect you against data loss but they don’t deliver some of the other benefits of backup—for example, maintaining a physically separate copy of your data isn’t something that retention policies can help with.

It’s also fair to point out that some Microsoft data protection features such as auto-label policies that find and apply retention labels to sensitive data need extra investment because of their licensing requirements. This element should be kept in mind as you consider the cost of a third-party backup because it might be cheaper to buy the backup instead of upgrading your user licenses, especially if the tenant supports many users with low-cost licenses (like Office 365 E1 or A1, or Microsoft 365 F3). On the other hand, if you need some extra features that are only available in a higher-priced plan, you might decide to use the money that would otherwise be spent on a backup service to take advantage of the high-end protection features bundled in that plan.

## Backup Considerations

When we discuss the service from a backup perspective, the following aspects should be considered to decide what data should and can be backed up. Knowing what data to backup and why the backup is necessary will drive the choice of the backup technology to use. You should consider:

- Backup of the **base storage workloads**: SharePoint Online, Exchange Online, OneDrive for Business, and the configuration and user information held in Azure AD.
- Backup of **applications that use Azure** for all or part of their storage: For example, how do you handle the text and graphics for Teams messages stored in Azure Cosmos DB or the tasks and plans used by Planner?

- Backup of **applications that use multiple components** such as Teams, Planner, and Groups. The lack of backup solutions capable of dealing with workloads outside Exchange and SharePoint is currently the biggest challenge facing those who consider using third-party backups.

In addition, you should consider:

- **How are backups processed?** A backup product might be able to process the volume of data generated by a small tenant and struggle to process the volume created by a large tenant. The backup application must move data from Microsoft's data centers to the backup location, which might mean that the data must travel via the internet, so network considerations and the ability of the backup vendor to process inbound data come into play. On the other hand, if the backup location uses Azure, the data might stay within the Microsoft data center network and the transfer is faster and easier, but you may have to pay ingress and egress fees to move the data.
- **What APIs are used for backups?** Microsoft 365 includes many APIs that can interact with mail, documents, tasks, groups, and so on. However, not every API can stream large volumes of data to a backup destination, so some testing should occur to ensure that a backup application can handle the quantity of data produced by a tenant, especially at peak load.
- **What data are backed up?** Some backup vendors have ported their on-premises products to work in the cloud. Applications like Teams and Planner don't have on-premises equivalents, so on-premises backup products can't deal with their data. Thus, you might select a product that can copy Exchange Online mailboxes and SharePoint Online documents but ignores everything else. You'll be much better off looking for cloud-native products that are explicitly designed to work on Microsoft 365.
- **How often is the data backed up?** A daily backup might be enough to deal with small tenants, but constant and ongoing backups (trickle mode) might be necessary to process the quantity of data produced by large tenants.
- **Where is the backup data stored?** Most backup vendors propose using their own cloud data center to hold backup data. This approach is perfectly acceptable if it meets the customer's data at rest and data sovereignty requirements. Unsurprisingly, few backup vendors can aspire to the same widespread distribution of data centers that Microsoft has, but a growing number of backup vendors use Azure or Amazon Web Services bulk storage as a backup target. Some vendors claim that having backups in Azure is preferable (for speed and security) because data travels across the Microsoft data center network from the service to the backup location while transfer to Amazon involves an internet connection.
- **How accessible is the backup?** If the backup is in the cloud, what SLA does the vendor give about its availability to restore? Is the SLA limited in terms of the amount of data, number of mailboxes or sites, or any other factor?
- **How easily and rapidly can the data be restored?** Having a backup copy of data is one thing; being able to restore it is another. How quickly can data be brought online within an application from the backup copy? Can the data be merged with live data or will it overwrite what's there (for example, does a complete document library need to be restored). Another factor to consider is how much effort is needed on the part of the backup vendor and tenant administrators to restore data. The ideal situation is to have a restore process that automatically connects to the backup source and inserts the data into the target repository in such a way that it is immediately usable without further administrator intervention.
- **Can data be restored in context?** Restoring a single mailbox or single document library is straightforward. It is much more complex to rebuild a compound entity like a Group, plan, or Team as it was at a point in time. This is because those entities depend on multiple components, each of which must be restored in such a way that the links between the different components are preserved and accurate. Data that cannot be restored in context might still be valuable, but it will be raw and

need manipulation before it is fully usable again. Another interesting question is posed by protected content (encrypted email, documents, and other items) as the backup solution must be able to backup and restore this content too. It's also wise to ask about the granularity of restored data to ensure that it is possible to restore something like a single document into a SharePoint Online document library.

- **How much does the backup cost per user per month?** What basis is used for this calculation (per site, mailbox, licensed user, etc.). How does the cost vary as additional applications are included in the mix?
- **Does the backup vendor comply with any industry or regulatory standards that might apply to your tenant?** Such regulations include the European Union General Data Protection Regulation (GDPR), the U.S. Health Insurance Portability and Accountability Act (HIPAA), Service Organization Control (SOC), and the U.S. Federal Risk and Authorization Management Program (FedRAMP).

In short, backing up cloud application data is not simply a matter of stretching the application-centric technology and techniques used to process on-premises data. The complexity and interconnectivity of Microsoft 365 make it a radically different environment that demands a different approach to backup.

## Backup for Exchange Online

Microsoft is deadly serious when it says that native data protection is the best approach for Exchange. This means that four copies of each database exist, including a lagged copy, and that data is spread across at least two data centers to ensure resilience. Users must recover deleted items if they make a mistake and if they don't do this before the default 14-day retention period (extendible to 30 days), they won't be able to retrieve the data.

Given that hundreds of thousands of mailbox servers run inside Exchange Online, all deployed in Database Availability Groups, the use of native data protection is understandable when you consider how many pieces of backup media might be used to copy mailbox data (according to Microsoft, some 1.1 exabyte of mailbox data was in use in September 2018), not to mention the enormous cost of managing and validating the backups and handling and storing the backup media.

Third-party software companies offer online cloud-based backups that can extract data from Exchange Online and send the data to their repositories from where the data can be retrieved if necessary. However, the cost of these services might not be justified for the benefit gained, especially if data is protected by features such as litigation holds. Other issues to consider include if the backup product can deal with expandable archives and encrypted content. Being able to stream data out of Exchange Online is easy (usually, backups use Exchange Web Services to connect to mailboxes and read their contents); it can be much more challenging to restore data in such a way that it is usable. For instance, if the mailbox holds email encrypted with Microsoft Information Protection sensitivity labels or S/MIME, how will the user be able to access this content in a restored mailbox?

Don't use backup utilities that extract mailbox data and store it in PSTs. This is a terrible idea from a performance, logistical, data protection, and compliance standpoint.

## Backup for SharePoint Online

Unlike Exchange Online, SharePoint Online doesn't have native data protection built into the product. Accordingly, Microsoft takes backups for SharePoint Online site collections (these backups cover OneDrive for Business too). Here is what happens:

- Microsoft backs up the content in site collections every 12 hours (approximately). The backups are kept for 14 days.

- Tenant administrators have no control over backups or restores. If a restore is necessary, it can only be started by contacting Microsoft support. Microsoft will ask you to say the best time for the restore (i.e. a time when the required information was known to exist in the site collection). Determining that time can be quite a challenge!
- Microsoft cannot restore a single item, folder, document, list, or library. A full site restore is the only option. The restore is targeted at the URL for the site collection and will therefore overwrite whatever data currently exists in the site collection. If you need to preserve data in a site collection that is to be restored, you must copy or move all the information that exists in the collection before the restore is done and then readjust the content afterward as needed.

Before running to ask Microsoft support to restore a site collection, it's important to understand that SharePoint Online allows information to be recovered in three other ways:

1. The **Restore this library** option (in the settings menu for document libraries) allows site owners and administrators to recover files within a document library to a point in time within the last 30 days (OneDrive for Business has a similar feature). Restore this library is intended to deal with scenarios such as a mass deletion of files by a disgruntled employee or the infection of files through malware. If you know when an incident happened, you can restore the library to a point just before the incident occurred. Restore this library depends on [versioning](#), the ability to store different versions of files created over time. The versions can be created through the auto-save functionality built into the Microsoft 365 desktop and online apps or the files can be saved explicitly. If you don't enable versioning for a document library, you might not be able to roll back to previous versions of files. If only one version of a file exists and it's the one that is compromised, SharePoint won't be able to recover it.
2. Deleted documents and other items are held in the [SharePoint recycle bin for up to 93 days](#). SharePoint's recycle bin is arranged in two parts. The site recycle bin is available to users and is sometimes called the first phase recycle bin. If items are removed from the site recycle bin, SharePoint moves them into the site collection recycle bin (second phase). Administrators can retrieve items from the site collection recycle bin. After the 93-day period elapses, background jobs remove files from the site collection recycle bin. If you can't restore a file because it's outside the 30-day window for a restore from the document library, you can look in the site recycle bin and retrieve the file from there.
3. If a site is under the control of a retention policy, SharePoint keeps items removed by users or automatically by background jobs in a special hidden library called the Preservation Hold library. The items stay in the Preservation Hold library until their retention period expires, which could be several years. Administrators can retrieve files if needed from the Preservation Hold library. See Chapter 18 for more information about data governance for SharePoint Online.

Although SharePoint gives administrators and users the ability to retrieve files deleted in error or corrupted in some way, two factors deserve consideration when deciding if external backups are necessary. First, some user education is needed to make people aware of how to use the **Restore this library** feature and how to recover deleted files from the recycle bin. Second, the methods of recovery listed above require manual intervention to restore content to sites. Better automation, the ability to deal with multiple sites at one time, and more granular restores are reasons advanced by third-party backup vendors to justify the purchase of their products for SharePoint Online. The basic idea behind these solutions is to use remote agents that make scheduled connections to applications like SharePoint Online to grab information and copy it out to some other data center or cloud service.

Remember that SharePoint Online includes many other elements than just documents and lists such as customizations made to the search schema or term store. It's a good idea to ask your potential backup

vendors what other SharePoint Online elements they can back up—losing e.g. the term store could cause a major problem.

The decision whether to invest in a third-party backup solution for SharePoint Online largely depends on the faith a tenant puts into the way that Microsoft manages SharePoint data and the perceived risks that exist. The increasing prevalence of ransomware raises the question of how you might recover from an attack, short of paying the ransom. The usual proposed solution is to restore to a point in time before the infection occurred. This might be possible with the functionality built into SharePoint Online (if you catch the problem early) but broad-scale recoveries from malice or mistakes might be easier with a third-party backup. As in the case of any ISV solution, you should test products thoroughly to ensure that they meet your needs, including aspects such as security, privacy, and data at rest.

## Backup for Teams, Planner, and Other Apps

Traditional backup products address the need to copy information belonging to an individual workload. For example, you take backups to protect data in on-premises Exchange databases or SharePoint sites. The different nature of the service creates problems for this approach because new functionality is built by combining features taken from different workloads. Take Planner as an example. Data is held in group mailboxes managed by Exchange Online, group document libraries managed by SharePoint Online, and the Tasks service running in Azure.

Teams is similar in the way that it brings data and functionality together from multiple sources to deliver to users and introduces still more complications. For instance, Teams can use Planner as one of its resources. Currently, there is no comprehensive public API available meant for backing up Teams or Planner data; some structural information (for example, the channels in a team) can be extracted using the Graph API, but no API exists to allow the totality of user data to be backed up from Teams and its associated apps.

This makes Teams the [most challenging of all Office 365 applications](#) from a backup perspective. This is slowly changing; for example, Microsoft has [released a Teams export API](#), but it only handles 1:1 and group chat messages, meaning that there are still several other data items (and many metadata items) that aren't available through the API and thus cannot be reliably backed up or restored. Worse, this API carries a charge to the customer—that is, if you use a backup product that calls the export API, you will incur a charge for every message read through the API.

Worst of all, there is no corresponding *restore* API to match the export API. It is critical to understand that your ability to restore Teams data will probably fall far short of your expectations, as Microsoft has *no* supported APIs for ingesting Teams channel content with original metadata. Ask any vendor you're thinking about working with to demonstrate a full end-to-end backup and restore cycle on a Team that you choose before you pull out your credit card.

**Note:** Backing up the compliance records captured for Teams chats and channel conversations in Exchange Online is not enough – the items are incomplete and cannot be restored into Teams chats or channel conversations in a usable fashion.

Likewise, no backup APIs exist for Planner, Stream, or Yammer, so care should be taken when considering how to extract information from these applications for backup purposes.

## Protection Against Ransomware

Despite the cautious attitude to third-party backup technology for Office 365 expressed here, it is possible to make a case to use backups to protect against the consequences of a ransomware attack. The most likely targets of ransomware are documents and email, both of which are adequately covered by backup solutions. It's also possible to restore documents and emails to other locations if Office is unavailable. For these

reasons, it is worthwhile considering using backups to have copies of data available should a ransomware attack succeed against your tenant.

Of course, it is much better to avoid being attacked, or at least to avoid being compromised by a successful attack. Before seeking solace in backups, organizations should make sure to secure their tenants by eliminating basic authentication (as far as possible), using multi-factor authentication for all accounts, and educating users about techniques such as phishing and business compromise email.

## Service Changes Affecting Backup Technology

Backup technology changes over time to improve functionality and make it easier to backup and restore Microsoft 365 data. It's also true that the service's feature set changes over time, which can make it harder for an organization to copy all the data in use. For instance, the lack of a suitable API to extract Teams data for backup is a problem for tenants who use Teams. Likewise, if you enable auto-expanding archives for Exchange Online mailboxes, you might find that your selected backup product is unable to process this type of archive mailbox.

Technology changes at a fast cadence, especially in the cloud. The need for external backups might not be the same today as it was a couple of years ago. For this reason, it's wise to review your backup strategy (or rather, the need for backups) on an ongoing basis to make sure that your organization only uses what is necessary instead of following the dogma that often comes from on-premises systems.

# Chapter 5: Managing User Accounts

**Paul Robichaux**

In the on-premises world, a user's account typically contained both identifying information (such as a security ID, or SID), plus all the settings that applications and devices need to decide what the user can do. As part of their effort to make Microsoft 365 fully hybrid, Microsoft has effectively split apart this traditional binding. In Microsoft 365, user identities (described in Chapter 3) control authentication to the service; other metadata associated with user accounts, such as the Office 365 licenses assigned and the management roles (if any) assigned to the account, control how the user may interact with the service. These two sets of data no longer must be stored in the same place. For example, Exchange and Teams have their own separate shadow copies of some user attributes that they use for its own purposes. In this chapter, we'll discuss how to manage the accounts themselves and the most important metadata associated with them.

## Managing User Accounts in the Microsoft 365 Admin Center

Many of the day-to-day admin tasks you'll deal with involve user accounts. The **Users** item in the left navigation bar of the Microsoft 365 admin center allows you to manage users, contacts, guest users, and deleted users separately, apply different filters to view only the set of users you need to work with, and quickly take common actions on those accounts. For example, the view in Figure 5-1 uses the licensed users filter to exclude guest users and other unlicensed accounts; the drop-down menu shows actions that you can take on the current selection.

The controls in these pages give you quick access to the users and contacts in your tenant, whether those accounts are synchronized from an on-premises Active Directory or natively homed in the cloud. When you look at the details for an individual user, you can, with one click, delete the user or block them from signing in or changing their password; with a few more clicks, you can easily assign roles, change their multi-factor authentication settings, and perform other common individual tasks.

Keep in mind that, following the guidance in Chapter 3, where you initially create user accounts matters a lot. Some properties are cloud-only (such as the set of assigned Office 365 licenses), whereas others (such as the account's password hash) may either be cloud-native or synced from the on-premises Active Directory, depending on where the account lives. The admin center tools are written so that they hide much of the complexity of setting properties for user accounts. You can view and change most properties without worrying about where the account is homed. However, you can't use the admin center to edit some key properties of on-premises accounts synchronized to the cloud using Azure AD Connect. For example, you can't edit a synchronized user's first or last name or change their email addresses, as those attributes are authoritative from the on-prem directory.

When you add a user from the admin center, the account will always be created in the cloud. You'll be prompted to specify some basic information about the user; you can have the service generate a password for you or you may specify one, and you can assign any of the licenses you've already purchased for the tenant. You may also save the user configuration as a template to speed up the configuration of future users

with similar settings. Templates allow you to specify profile information such as location and department, the service domain, and the licenses to assign.

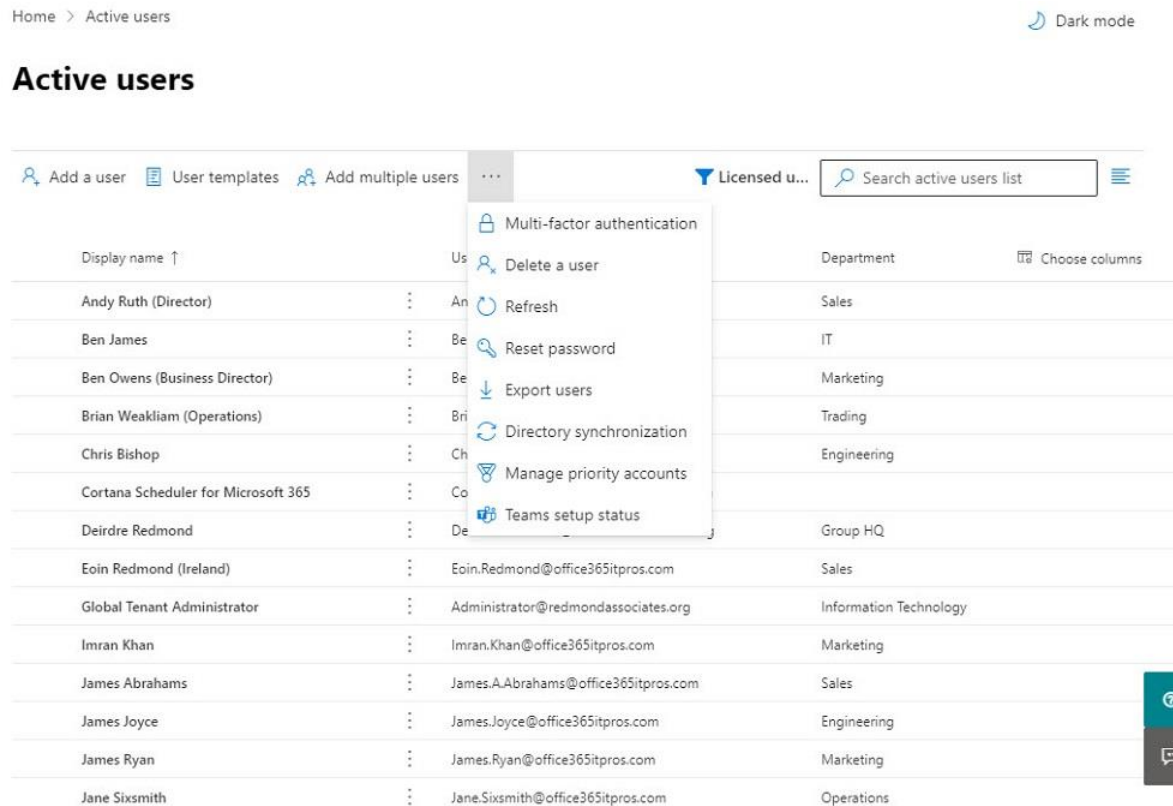

Figure 5-1: Viewing licensed users in the Active Users section of the admin center

The user detail view features tabs that allow you to see and manage devices associated with the user, review and change license assignments, and change email- and OneDrive-related settings. Because these controls are straightforward, there's no need to go into them in detail except for a few notes of interest.

Microsoft continues to gradually roll out better integration between different user-related actions. For example, when you delete a user, you can optionally choose to also remove that user's licenses and/or mailbox delegate permissions or grant another user access to the deleted user's OneDrive files or email, using a simple set of checkboxes. You should expect Microsoft to continue adding support for these kinds of multi-step operations under the banner of "improving efficiency" throughout all the admin center experiences.

## Enabling Self-Service User Management

Any Microsoft 365 user can log into [portal.office.com](https://portal.office.com); this is often how users get access to desktop application software. Most users don't know this, though, and fewer still understand the difference between the Azure AD and Microsoft 365 portals, the *My account* link, and what data and actions are available from each. When a user logs in and clicks on their profile icon in the upper-right corner, then chooses the [View account link](#), they'll see a view similar to Figure 5-2, from which they can see and change many of the settings associated with their account. For example, they can see what devices they have installed Microsoft apps on and what licenses or subscriptions are assigned to them (including ones they've purchased). Since the introduction of the view, Microsoft has added sign-in [information](#) from the Azure AD portal, and it's reasonable to expect that they will continue to add more self-service data and actions in this view so that users can directly manage their accounts to the extent that it's reasonable.

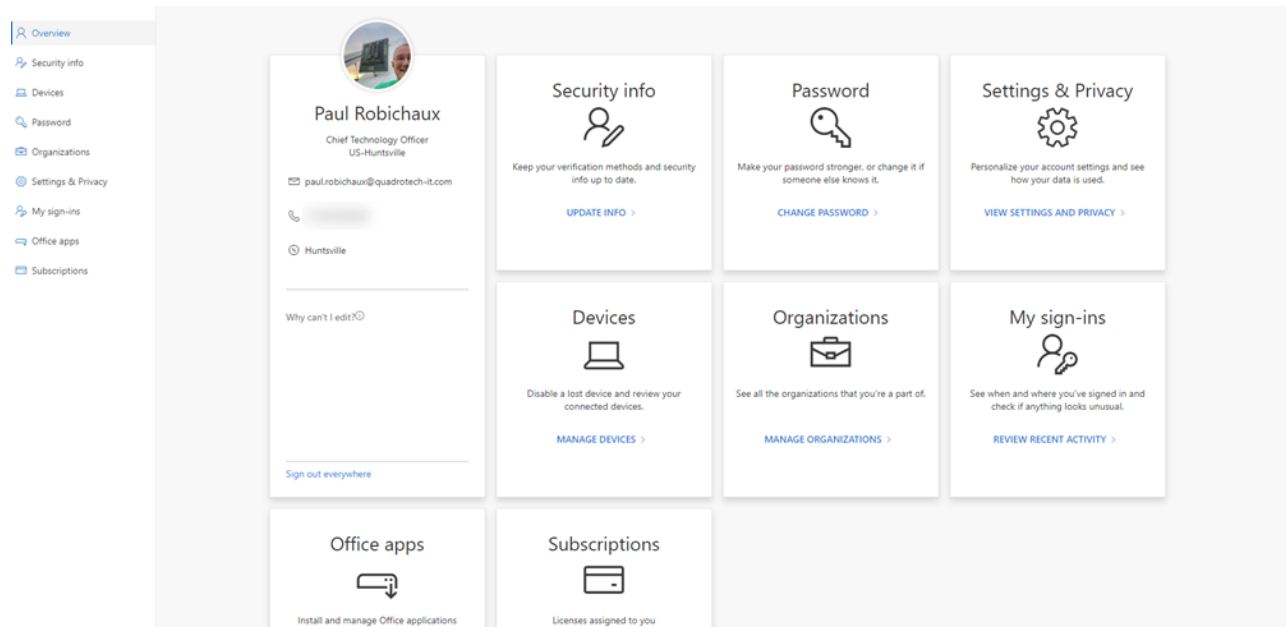

Figure 5-2: The integrated account view is available to all users

## Managing User License Assignments

Every user needs a license to use the service. While there are a few workloads or capabilities that Microsoft doesn't charge for (e.g., the free trial-version licenses formerly available for Teams and Power BI), the major workloads are all tied to licenses, so users will need one to use them. Normally you'll assign licenses to users when you bring their accounts into the service, either as part of a migration or when you onboard a new user. You can do this manually with the admin center, via a custom provisioning script, or using third-party products such as Quest's On Demand License Management tool. By the same token, when a user leaves, you may wish to reclaim the license, bearing in mind the limitations covered later.

### Azure AD Group-Based License Management

Managing licenses for a large user population has been a pain point for many customers. Automation is essential, as manual methods are far too time-consuming for any environment with a high rate of change, such as dealing with new and departed users, or licensing sub-features and extra applications.

In the past, some customers have invested quite a lot of time into scripting solutions based on AD group membership. These scripts typically require that the user be added to a group whose members should receive an Enterprise E5 license, and the custom script runs the necessary PowerShell commands to assign that license. This approach becomes challenging with more complex licensing scenarios such as sub-SKU features and assigning multiple products to an individual user (e.g., Enterprise E5 plus Project and Visio).

To solve these challenges Microsoft made group-based license management available through the Azure portal. The feature originally required a paid or trial subscription for Azure AD Premium P1 or greater. This subscription may be purchased on its own, but it's already included with Microsoft 365 Enterprise E3 or A3 and higher, and all the E plans of Office 365 Enterprise can natively use group-based licensing, so you probably won't have to buy anything. However, at the end of August 2021, Microsoft announced that a new licensing platform, originally promised in the first quarter of 2022 but still not released as of July 2022, will allow you to use group-based licensing [without an additional Azure AD Premium license](#)—a very welcome change.

The groups that you can assign licenses to can either be created in Azure AD or synchronized from on-premises Active Directory. The license assignments can either be static (i.e., to the members of a group) or

dynamic (e.g., based on user attributes such as *ExtensionCustomAttribute1*). For some organizations, a department-based model will be the preferred approach, with licenses assigned to groups representing the different departments within the organization. For others, a product-based approach will be more appropriate, with each type of license being assigned to a single group, and the users being added to that group regardless of which department they are in. If you're using static groups instead of dynamic groups then you will need to directly add the user accounts to the group, as nested groups will not be supported for group-based licensing until the 2022 licensing platform is delivered.

Transitioning from direct license management to group-based license management is simple. Once you put the group-based license assignments in place, users can have both a direct and group license assignment listed for their account for the same type of license. However, they will only consume a single paid license during this time, allowing you to remove the direct license assignments slowly to ensure there are no unexpected results. License assignments will fail if there are no available licenses to assign. The solution is to purchase more licenses, then force the group-based license assignment to reprocess.

As Microsoft rolls out new features to your tenant they will usually be enabled by default. This will apply to group-based license assignments as well, with new sub-SKU features being enabled by default. As new features arrive you should review your group-based licenses to ensure that any new sub-SKU features are enabled or disabled to meet your organization's requirements.

To configure the group-based licensing assignments, you use the Azure portal. After logging in to the Azure portal choose **Azure Active Directory** from the list of services in the portal, and then select **Licenses**. The **All products** view shows you what licenses your tenant currently holds.

Select a product license and click on the **Assign** button. From **Users and Groups**, choose the group that you want to assign licenses to, and then click on **Select**. In the **Assignment options**, you can select the sub-features for the license that you've chosen to assign to the group. In the example shown in Figure 5-4, all the EM+S features are enabled for the newly licensed users.

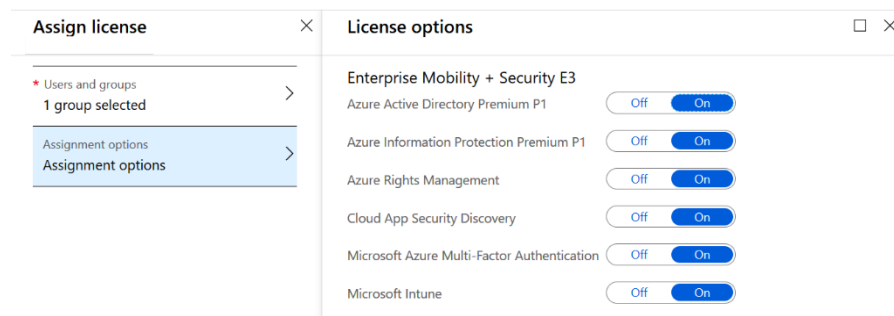

Figure 5-4: Configuring sub-SKU features for a license assignment

Click **Review + Assign** when you're happy with your selections to create the license assignment. If there are any errors at this stage, you'll receive a notification in your Azure portal. License assignments are updated almost instantaneously, but for on-premises Active Directory groups, you should expect the normal directory synchronization delay before group membership changes flow through to license assignment changes.

If you've already been using direct license assignments for your users, you will see each user in the Azure portal listed with an **Assignment Path** of both *Direct* and *Inherited*. To complete the transition from direct license assignment to group-based license assignment the direct assignment must be removed. You can select one or multiple users, and then click the **Remove** button. You should approach this with some caution, removing the direct license assignments for users in small batches so that you can be sure that you do not inadvertently leave your users unlicensed for an application that they are still using.

To reduce the risk of licenses being accidentally removed from users, if a user is removed from a group that is managing their license assignments the associated Microsoft 365 services will initially go into a suspended state, instead of a deleted state. The user will not be able to access and use those licensed services, but their

data will be safe while their IT administrators correct the licensing mistake. If the license removal was intentional, the suspended services will eventually age out to a disabled state and will begin their normal deletion and final purge processes.

User accounts can be members of multiple groups for license assignment. For example, if a user is a member of a group that is assigned the Enterprise E3 license, and a member of a group that assigns the Enterprise Mobility and Security E3 license, the cumulative effect will be that both licenses are assigned to that user. This allows you to approach group-based licensing in a modular fashion, instead of needing to create separate groups for all possible combinations of license assignments in your organization.

## Allowing Users to Buy Licenses

It's obviously to Microsoft's benefit to sell as many licenses as possible to the service. To help in this goal, in January 2020, Microsoft introduced a self-service purchase mechanism to allow people with a valid Azure AD account in a tenant to effectively bypass their IT departments and buy licenses for the Power Platform products (Power Automate, Power Apps, and Power BI). They have since added other parts of Microsoft 365 (Visio, Project, Power BI Premium, and Power Automate so far); in August 2021 they added the ability for users to buy licenses for the new Windows 365 Enterprise and Windows 365 Business offerings. Starting in January 2022 users can sign up for 30-day trials of Project and Visio using the self-service mechanism. Self-service purchases are not available to Government, Nonprofit, and Education tenants. All data management and access policies enabled by the company apply to self-service purchased services. Also, data created from products with these licenses remains owned and controlled by the organization.

By default, this capability is turned on. Turning it off requires you to use the *MSCommerce* PowerShell module, as described in Chapter 23.

## Allowing Users to Request Licenses

In an ideal world, we'd always have a big enough budget to buy enough of the right licenses to assign every user exactly what she needs. In practice, this doesn't happen much, so sometimes users don't have the licenses they need. Besides permanent assignments, it is sometimes the case that a user needs a license for a specific assignment or task. To help solve this problem, in the same way that you might check out a book from the library, Microsoft allows users to request licenses on their own, but only if you block self-service purchases first. The way this currently works is a little weird: users click the "buy now" link from the product page on Microsoft.com, then enter their email address. If the domain matches a domain that's enrolled in the service, the user logs in with her credentials, then is presented with a form. The contents of the form may vary depending on what you've done. Let's say that Alice wants to buy Visio licenses for herself, Bob, and Carlos:

- If the organization enables self-service purchases, Alice goes to the Microsoft.com page for Visio, supplies her payment information (which must be a valid credit card), logs in to the tenant, and specifies the email addresses for Bob and Carlos. The purchase proceeds and the licenses are assigned to those users.
- If you want to force Alice to use your organization's existing license process, you can go to the **Billing > Licenses** section of the admin center and click on the **Requests** pivot, then click the **Use your existing request process instead** link. This page allows you to set a message that users see when they try to buy a self-service license (e.g. "To request a product, file a service ticket at <https://help.internal/>"). Alice will see this message but isn't prompted for anything else; her request won't appear in the admin center.
- If the organization doesn't have a specific process, then when Alice tries to make a self-service purchase, she'll see the same form as described earlier, asking for payment details and so on, but when she submits the request, it will appear on the **Requests** pivot. You can approve or reject

individual requests, and for requests you approve, you can choose which users in the request are approved (e.g., you can accept the requests for Alice and Carlos but reject Bob). Remember that accepting the request allows it to be completed for the original purchaser, just as if you had enabled self-service purchases directly. The purchased licenses aren't considered as part of your tenant subscriptions.

## Assigning Licenses with an Auto-Claim License Policy

In addition to having a license assigned automatically through group membership, manually by admin action, or manually by the user herself, you can control license assignments through an *auto-claim policy*. This policy allows a user to automatically receive a license when they try to use a workload for which they are currently unlicensed—think of it as a just-in-time automated license assignment. The auto-claim policy is triggered the first time an unlicensed user signs into the workload, and the resulting license stays assigned to the user until you do something to remove it. Teams is currently the only Microsoft 365 app to support auto-claim.

Each tenant can have a single auto-claim license policy, configured in the Licenses section of the Microsoft 365 admin center. The policy specifies:

- The apps covered by the policy.
- The license to assign when an unlicensed user signs into the specified apps for the first time. Obviously, the plan should license the use of the app.
- One of more backup licenses to assign should no available licenses exist for the primary assignment. The backup licenses are in priority order and the claim is made for the first available license in that order.

For more information, read [this article](#).

## Managing User Role Assignments

Microsoft 365 (and some of its key workloads, notably Exchange Online and Azure AD) offers customers a variety of administrative roles that you can assign to users who need to perform management tasks. Much like on-premises environments, there is no single “admin” level permission that someone needs to perform some management tasks for your tenant should have. Instead, a set of pre-configured administrative roles and groups is available to allow the assignment of limited but necessary permissions to administrators to do their job. This model is called role-based access control (RBAC). Keep in mind that the service and workload-specific roles are different from the Azure roles that you may wish to assign; for more information on Azure AD role management, see [Microsoft's documentation](#).

### Assigning Administrative Roles to Users

There are several ways to assign a privileged role to a user. The easiest way is probably to select and edit their account in the Microsoft 365 admin center. You can then assign an administrative role to the user by clicking the **Manage Roles** link on the user settings page. You can also use the Roles section in the Azure AD portal to assign some roles, or even break out the [Microsoft Graph PowerShell](#) module and do it from the command line.

By default, no user account receives an administrative role. The exception is for the account that is created when a company signs up for a new tenant, which is assigned the **Global admin** role. This default account is based in the cloud and will remain permanently available unless you delete it. You should keep at least one cloud-based Global admin account available so that you can log in even if AD FS or Azure AD Connect is broken for your tenant.

Global admin holders get complete administrative access to all features within Microsoft 365, including individual services such as Exchange Online and Teams. Naturally, every organization will have at least one Global admin. While having too many of these accounts is a security problem, it's a good idea to keep multiple accounts to give you redundancy in case the one person with administrator permissions isn't available when you need them.

## Assigning Roles with Azure AD Groups

If you have an Azure AD Premium P1 or P2 license, you can [assign Azure AD roles to groups](#). This is a little more complex than the way that you'd accomplish the same task with on-premises AD. You must create the group in Azure AD, then give it the **Azure AD roles can be assigned to the group** option (which changes the *isAssignableToRole* property on the group object). Then you can assign roles to the group, then add users to the group. *isAssignableToRole* is an immutable property, so you cannot role-enable existing groups, and you cannot disable role assignment from a group once you've set this flag.

By default, only Global Administrators and Privileged Role Administrators can create groups with this flag set or manage the membership of such groups. Although you can delegate this ability, you should be careful when doing so to prevent accidentally giving people excess privileges. For the same reason, you cannot use dynamic groups with role assignments; all assignments to role-enabled groups must be done manually. These groups can be managed through the Microsoft Graph, provided that the caller has the *RoleManagement.ReadWrite.All* permission; the ordinary *Groups.ReadWrite.All* permission won't work.

## Assigning Roles Directly to Users

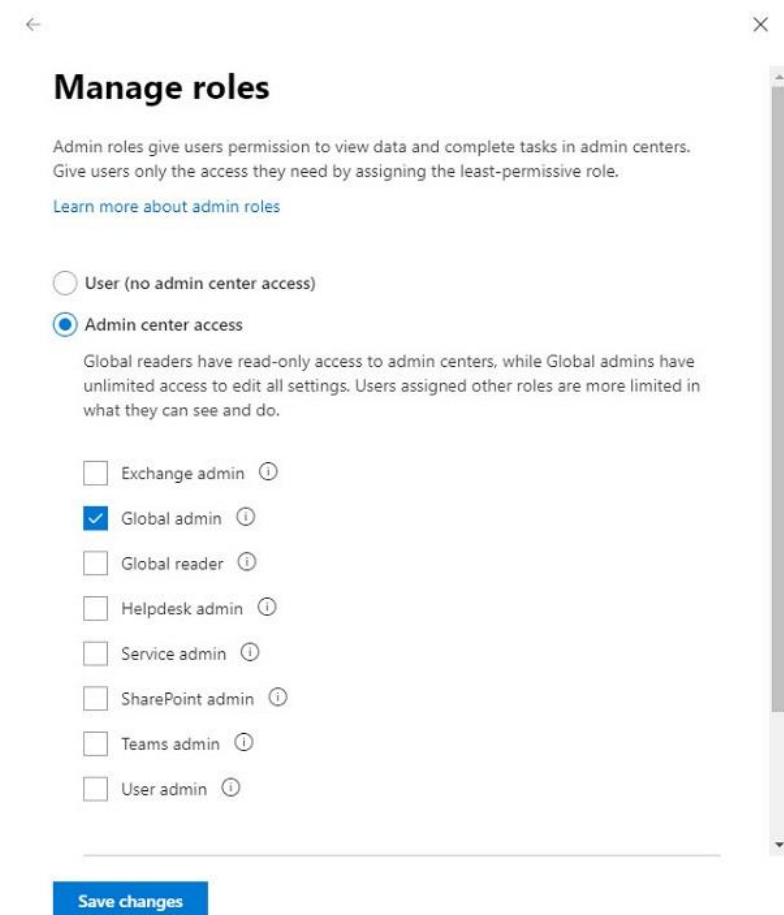

Figure 5-5: Assigning administrative roles to a user account

In the user management interface, you can assign a user to the **Global admin** role or assign them to one or more customized administrator roles (Figure 5-5). When you assign a user to one of these roles you must

give an alternative email address for them to use when they need to recover a lost password for their admin account.

## Understanding the Built-In Roles

The familiar security principle of “least privilege” dictates that you should only grant users whatever limited admin access is necessary for them to do their job. With more than 60 roles scattered throughout the Azure AD and Microsoft 365 portals, it can be difficult to track which roles do what, or even what all the roles *are*. Microsoft groups these roles into two basic groups: the first group (labeled with “Admin center access”) grants access to specific admin centers in the Microsoft 365 ecosystem:

- **Global Administrator:** you already know what this is—the all-powerful master admin account that can do anything, anywhere, within the tenant.
- **Exchange Administrator:** Users with this role use the Exchange Online admin center to manage mailboxes, groups, anti-spam policies, and access activity reports in the Microsoft 365 admin center. An Exchange Admin becomes an Organization Management role group member in Exchange Online, which is a high privilege role group. Exchange Online has a more granular permissions model known as Role-Based Access Control (RBAC), which you can use to assign least privilege permissions instead. RBAC is discussed later.
- **Global reader:** this is like the old “Exchange view-only administrator” role in on-premises Exchange; users who hold this role can read, but not change, most non-security-related settings in both Azure AD and Microsoft 365. Note that at its initial launch, the Global reader role worked with Microsoft 365 admin center, Exchange admin center, Teams admin center, Security center, Compliance portal, Azure AD admin center, and Device Management admin center, but not with SharePoint or some Teams management features; you may find that it doesn’t completely work with all workloads.
- **Helpdesk admin:** Delegating responsibility for password resets can relieve some of the support burden from IT teams. Many processes created to reset user passwords involve the need for an authorized person to check the identity of the user before any change is made to their password, for example by having them walk up to their desk and show a company identification badge. Once the user is recognized, the authorized person sends the request to the help desk. Giving that authorized person the right to reset the password themselves can save time. However, there is no granularity when it comes to assigning this admin role through the Microsoft 365 admin center. Helpdesk admins can reset any other user or helpdesk administrator’s password, but not other types of admin users. They could reset the password for someone in a completely different location, or someone whose identity is unverified. As such it is important to be careful to only assign this role to trusted individuals.
- **Service support admin:** Formerly known as the Service admin role, this role grants the ability to manage service requests and to access the Service Health Dashboard. You should assign the Service support admin role to users who are members of the Exchange administrator, Teams administrator, or SharePoint administrator groups to allow them to raise support tickets for those services. The role also gives the holder read-only access to information about groups, users, and licenses, which means that it is a good role to assign to people who want to know about license usage within a tenant. Interestingly, Microsoft changed the name of this role to match the role name in the Microsoft Graph API, rather than leaving the UI alone and changing the role name in the API definition.
- **SharePoint Administrator:** This role grants the ability to manage SharePoint Online, which also affects OneDrive for Business, as well as creating and managing sites, and managing user profiles. SharePoint admins can assign other users with administrative permissions within SharePoint Online for sites and term stores. They can also access activity reports in the Microsoft 365 admin portal.

- **Teams Administrator:** Users with this role can manage all aspects of Teams (including policies and calling) but cannot assign or remove user licenses. They can also manage Microsoft 365 Groups, which makes sense given how Teams uses them.
- **User Administrator:** This role can manage users, groups, passwords, service requests, and see the Service Health Dashboard. This admin role is ideal for a help desk or low-level support person. Although a User admin role holder can remove other user accounts, they cannot remove the account belonging to a Global admin nor can they reset passwords for Billing admins, Global admins, or Service admins.

Other admin roles are grouped according to service category (e.g., “Collaboration”, “Devices,” and “Identity”). Microsoft is continually moving and adding roles as they expand the set of supported role features. There are currently more than 80 individual roles, the details of which you can find [documented here](#).

## Creating Custom Roles

In addition to the built-in roles, you can create your own custom roles in Azure AD. These custom roles draw from the same set of permissions as the built-in roles—think of the built-in permissions as a deck of cards from which you can draw the specific cards you want to. You can’t make up a new “13 of diamonds” card, and you can’t make up your own new permission. However, you can combine these existing permissions into custom roles that grant exactly the access you want to grant to role holders. To create custom roles, you must have Azure AD Premium P1 or P2 licenses. The mechanics of setting up custom roles will be familiar to anyone who’s used custom roles in Exchange on-premises or Exchange Online: first you create a new role, then you add permissions to the role, then you assign the role to users. You can create these roles using the Azure AD portal, PowerShell via the *New-MgDirectoryRole* cmdlet, or through Microsoft Graph. All 3 approaches are [documented here](#).

## Using the Roles Section of the Admin center

The Roles section in the Microsoft 365 admin center may be easier to use for assigning roles, because it gives you a single list of all the supported roles and allows you to filter, search, and sort them. You can export a CSV file showing which users have been granted roles in the tenant, or you can see and change assignments for any individual role. Clicking on a role will give you a short list of capabilities the role has, plus tabs for viewing and changing user assignments and viewing a comprehensive list of the role’s permissions (which, sadly, you cannot change).

The Roles page uses multiple pivots (or tabs) at the page top. All the Azure AD roles are on the Azure AD pivot, while Exchange roles are on the Exchange pivot. Microsoft will occasionally add or remove pivots here as they make changes to the admin centers (for example, Intune used to have its own pivot here, but it’s now gone again.)

## Listing Who Holds Administrative Roles

The list of roles above may not be exhaustive because Microsoft adds new roles over time. To find the full set of currently-known roles that are active in your tenant, and the people who hold these roles, you can run this PowerShell command:

```
[PS] C:\> Get-MgDirectoryRole | % {$Role = $_.DisplayName; Get-MgDirectoryRoleMember -ObjectId $_.ObjectId} | Format-Table @{"Name"="Role"; Expression = {$Role}}, DisplayName, UserPrincipalName -AutoSize
```

In the list, you will likely see several service accounts alongside user accounts. For example, the Microsoft 365 admin center holds the Adhoc License Administrator role while a service like Secure Score holds both the Directory Readers and Directory Writers roles. In addition, apps like Secure Score use [service principals](#) as a

way to hold roles that allow them to access information such as the tenant directory. This code tells you what service principals have been assigned Azure AD roles in a tenant:

```
[PS] C:\> $Roles = Get-MgDirectoryRole
Foreach ($Role in $Roles) {
    $RoleMembers = $Null
    $RoleMembers = (Get-MgDirectoryRoleMember -ObjectId $Role.ObjectId)
    If ($RoleMembers) {
        ForEach ($RoleMember in $RoleMembers) {
            If ($RoleMember.ObjectType -eq "ServicePrincipal") {Write-Host $Role.DisplayName "service
principal:" $RoleMember.DisplayName }}
    }}
}}
```

You can assign administrative roles to licensed or unlicensed users. An unlicensed user does not have access to any licensed feature, such as an Exchange Online mailbox or being able to install the Microsoft 365 apps for enterprise on their computer. However, they can log in to admin portals and use PowerShell to perform management tasks. Administrators who perform content searches and want to preview search results need an Exchange Online mailbox to be able to see the results. In general, third-party services and tools that require the use of privileged or service accounts are likely to send mail to those accounts, so be sure you're paying attention to their mailboxes.

**Note:** Microsoft 365 uses the alternative email address for account recovery if the password for the account is lost. In some cases, the alternative email address is needed when the administrator is unable to access their account or mailbox at all. Therefore, it is best to use an email address that is independent of the tenant. This raises some obvious security concerns; someone could use the alternative email address to reset the password for the administrator account. You should ensure that the alternative email address is well protected by a strong password and multi-factor authentication. Services such as Outlook.com or Gmail can offer the necessary level of security.

## Exchange Online Administrative Roles

Exchange Online has its own administrative roles or management role groups (Figure 5-6), some of which link to Microsoft 365 admin roles and others that are independent. You can see the Exchange Online admin roles by logging in to the Exchange admin center and navigating to the **Roles > Admin roles** section.

Global admins automatically have Organization Management rights in Exchange Online. Users assigned the Global admin role join an Exchange Online role group called **TenantAdmins\_XXXXX**, where the last five characters in the group name are unique to your tenant. The TenantAdmins group is nested in the Organization Management role group and is displayed as **Company Administrators**. Organization Management is a powerful admin role that has access to manage all the features of Exchange Online, so you can see why the Global admin role should only be assigned to selected administrators in your organization.

Users who get the Exchange administrator role also automatically have Organization Management rights in Exchange Online. From an Exchange Online perspective, this is the same level of admin rights that a Global admin receives, but an Exchange service administrator is not granted any other admin rights within Microsoft 365 itself, such as managing billing, subscriptions, or domain names.

Helpdesk Administrator holders are automatically granted View-Only Organization Management rights in Exchange Online. Users assigned the Password admin role join an Exchange Online role group called **HelpdeskAdmins\_XXXXX**. The HelpdeskAdmins group is nested in the View-Only Organization Management role group and is displayed as **Helpdesk Administrator**. This role group can view the configuration and recipient details within Exchange Online but can't make any modifications, other than resetting user passwords.

## Admin roles

Admin role groups give users permission to view data and complete tasks in the Exchange admin center and use the Powershell cmdlets. Give users only the access they need by assigning the least-permissive role. [Learn more](#)

Role group ↑	Description
CLBAccessApprovers_-444955902	
Compliance Management	Membership in this role group is synchronized across services and managed centrally. This role group is not manageable through Microsoft Exchange. Members of this role group may include cross-service helpdesk or password administrators, as well as external partner groups and Microsoft Support. By default, this group is not assigned any roles. However, it will be a member of the View-Only Organization Management role group and will inherit the rights of that group.
ComplianceAdmins_1744690546	
Discovery Management	Members of this management role group can perform searches of mailboxes in the Exchange organization for data that meets specific criteria.
<input type="radio"/> ExchangeServiceAdmins_53add	Membership in this role group is synchronized across services and managed centrally. This role group is not manageable through Microsoft Exchange. Members of this role group include Exchange-Online service administrators only. By default, this group may not be assigned any roles. However, it will be a member of the Organization Management role group and will inherit the capabilities of that role group.
GlobalReaders_1331601875	Membership in this role group is synchronized across services and managed centrally. This role group is not manageable through Microsoft Exchange. Members of this role group may include auditor. By default, this group is not assigned any roles. However, it will be a member of the View-Only Organization Management role group and will inherit the rights of that group.
Help Desk	Members of this management role group can view and manage the configuration for individual recipients and view recipients in an Exchange organization. Members of this role group can only manage the configuration each user can manage on his or her own mailbox. Additional permissions can be added by assigning additional management roles to this role group.
HelpdeskAdmins_7ae4b	Membership in this role group is synchronized across services and managed centrally. This role group is not manageable through Microsoft Exchange. Members of this role group include Exchange-Online service administrators only. By default, this group may not be assigned any roles. However, it will be a member of the Organization Management role group and will inherit the capabilities of that role group.

Figure 5-6: Exchange Online RBAC role groups

**Note:** You might notice in the Exchange admin center that a View-Only Organization Management role group member can create distribution lists and manage distribution lists that they have created. This is due to the default role assignment policy for users in Exchange Online which permits anyone to create and manage their distribution lists.

Aside from the Exchange Online admin roles inherited from admin roles, several other Exchange Online role groups also exist for granularly assigning rights to different users within your organization:

- **Compliance Management** – members of this role group can manage Data Loss Prevention, Information Rights Management, and Retention. In addition, members of this role group can view audit logs as well as all configuration and recipient attributes in the organization. Managing features such as DLP and IRM is often part of a more general security and information compliance role in an organization, not necessarily a duty performed solely by Exchange administrators, and this role group allows those users to be assigned the admin rights they need without having broader Exchange admin rights. Note that a separate set of roles govern access to the Purview compliance portal, discussed later.
- **Discovery Management** - members of this role group can perform discovery searches of mailbox data in Exchange Online, export search results to PST files, and configure legal hold on mailboxes. Microsoft has deprecated the eDiscovery experience in EAC (and it isn't even present in the modern EAC) in favor of using the Purview toolset, so you may not run into this role much in the future.
- **Help Desk** – members of this role group can view and manage the same individual recipient attributes that the users can view and manage for themselves. For example, users can log in to Outlook Web App and change personal details such as their phone number and street address or

update their password. Help Desk role group members can therefore also change the user's phone number, street address, or reset their password. This role group is suitable for low-level support staff, or for service accounts that automatically synchronize attributes such as phone numbers and street addresses from other systems such as an HR database.

- **Hygiene Management** – members of this role group have view-only access to Exchange configuration and recipients, and they have permission to manage some aspects of the transport system, mostly settings for anti-spam and anti-malware filtering, which are actually now in the Defender portal. You'll normally assign this role to people who manage your anti-malware appliances or services, and perhaps to select members of your organization's security team.
- **Organization Management** – members of this role group have access to manage all features of Exchange Online, except for the rights that the Discovery Management role group allows. As discussed earlier, Global admins and Exchange service administrators are automatically made members of this role group. You can also assign membership of this directly in Exchange Online, but you may find it better to assign the Exchange service administrator role instead as this will force the addition of an alternative email address for lost password recovery.
- **Recipient Management** – members of this role group have access to manage recipient objects in Exchange Online. Recipient objects include mailbox users, shared mailboxes, group mailboxes, resource mailboxes, distribution lists, contacts, and other mail-enabled objects. Recipient Management members can also perform mailbox migrations, message traces, and reset passwords. This role group is ideal for day-to-day tenant administration and is often assigned to first and second-level support teams. However, it is also suitable for general use by higher-level administrators who want to separate their admin accounts into low and high privilege use. For example, a Global admin or Exchange service administrator may have a separate admin account that is only granted Recipient Management rights. They can use the low privilege account for general administrative tasks, running report scripts, and so on, and only log on to the higher privilege account for the less frequent tasks that require those higher admin rights.
- **Records Management** – members of this role group are granted rights to perform compliance-related tasks such as configuring or viewing audit logs, configuring journaling, performing message traces, managing retention policies, and configuring transport rules.
- **Security Administrator, Compliance Management, Global Reader, Security Operator, and Security Reader** – although you will see these role groups in the Exchange admin center, they only appear here because the role groups are used across multiple Microsoft products (including Information Protection and the Purview portal). The Security Reader role group grants read-only access to Azure AD, Azure Identity Protection, Azure Privileged Identity Management, and all audit logs and sign-in reports. The Security Administrator role group grants the same access as Security Reader, plus the ability to configure security services. You won't manage membership in these role groups yourself; instead, you'll assign access to the services, and when you do, the role group membership will be automatically updated.
- **UM Management** – members of this role group can manage the Unified Messaging settings for the organization, as well as configure UM properties on mailboxes. This role group was only used for the now-deprecated Unified Messaging features.
- **View-Only Organization Management** – this role group gives read-only access to all recipient properties and configuration settings for the organization. This role group is ideal for anyone who needs broad visibility of the organization without the right to make changes. One scenario where this level of access is useful is for reporting scripts and tools that need to be able to read a wide range of information about the organization.

As you can see, a wide range of pre-configured administrative roles exists in Exchange Online to suit different requirements. Chapter 7 describes these roles, and their uses, in more detail.

## Assigning Security- and Compliance-Related Roles

The security and compliance features in Microsoft 365 support a set of permissions defined in RBAC role groups that allow the separation of responsibilities across different sets of users. The role groups are like those used by Exchange Online, except that these role groups only apply to the functionality available through the security and compliance portals and have no connection to the role groups used by Exchange Online, even though some of them share the same name.

To see the definitive version of the available roles and to assign or remove roles to users, go to the **Permissions** section of the Microsoft Purview Compliance portal or the **Permissions** section of the Microsoft 365 Defender admin center (see Chapter 4 if you need a refresher on the difference between these two). Each of these admin centers shows the same set of roles; there are also some roles associated with Azure AD that will be displayed in these admin centers but must be managed through the Azure AD admin center.

Here's a partial list of the roles you can assign to users:

- **Reviewer** - members of this role group can view the list of e-discovery cases that currently exist. Case managers can assign specific documents in an eDiscovery case for a reviewer to analyze or use a limited set of the analysis features in Microsoft Purview. Members of this group can see only the documents that are assigned to them.
- **Records Management** – members of this role group can manage retention and compliance features related to how long user data is stored and what policies are applied and enforced to archive or expire it.
- **Security Operator** – members of this role group can manage security alerts, view security reports, and view security settings.
- **Insider Risk Management** – members of this role group can manage and control the insider risk policies applied to users in a tenant.
- **Compliance Data Administrator** – members of this role group are typically IT administrators who are responsible for configuring security and compliance settings and policies, such as mobile device management, DLP, and preservation. Compliance administrators can also manage settings for reports in the Compliance portal.
- **Security Administrator** - membership of this role group is not intended to be managed by you directly through the security or compliance portals (although you can do so). Instead, Microsoft intends you to grant users access through the Security Administrators role in Azure AD. This role group may include Microsoft Support or external partners.
- **Security Operator** - this allows holders to read security reports and view all security settings, but they can't change any of them.
- **Compliance Administrator** – identical to the Compliance Data Administrator role, except that holders cannot manage data loss prevention settings.
- **Security Reader** - like the Security Administrator role, this role group is not intended to be managed by you. It gives read-only access to security and compliance features.
- **Supervisory Review** - members of this role group can create supervisory review policies for the organization, which determine the type of content that will be subject to supervisory review, and who will be performing the reviews.
- **Organization Management** - members of this role group can perform the same tasks as Compliance Administrators. They can also configure permissions for the Compliance portal and configure audit logging for the organization. Global admins are automatically added to this role group.
- **Mailflow Administrator** - this role group grants its members access to the mail flow dashboard. Users who are members of the Global admin or Exchange admin role groups will already have access

to this dashboard, but if you grant membership in Mailflow Administrator to users they will only have access to the dashboard, not to other Exchange or Microsoft 365 management features.

- **eDiscovery Manager** - members of this role group can perform searches across workloads, and apply holds to Exchange Online mailboxes, SharePoint Online sites, and OneDrive for Business libraries. An eDiscovery Manager has access to specific eDiscovery cases. When you grant a user the eDiscovery Manager permission, you can also grant them eDiscovery Administrator privileges, which allows the user to view and edit all eDiscovery cases for the organization.
- **Data Investigator** – a new role group whose holders can perform mailbox, SharePoint, and OneDrive searches using the new investigation features in the Compliance portal.
- **Service Assurance User** – members of this role group can access the Service assurance section in the Compliance portal, where they'll find reports, documents, and audit reports related to how Microsoft handles customer data.
- **Global Reader** – this role group allows the holder to read all reports, alerts, and settings for security and compliance features, similar in concept to how Exchange View-Only Administrator works.
- **Quarantine Administrator** - This role allows holders to manage mail quarantine settings and items in the Compliance portal.

You can create custom role groups. The **Create** button on the Permissions page allows you to create a new role group by specifying the base roles you want to use for the new role group, then assigning it to a set of users. It's important to know that your custom role group will get all the privileges assigned to the base roles you pick—there's no way to remove a specific privilege from the roles you create.

Like any other role assignment, the tenant administrator should review what accounts hold which roles regularly to ensure that users do not retain privileged access for longer than required. The eDiscovery Manager role group is particularly powerful because of the two sub-roles that it contains. eDiscovery Managers have access to all their assigned cases. eDiscovery Administrators have access to all cases and can assign themselves to a case. Although dependent on the volume of eDiscovery workload within the tenant, the usual situation is to have only a few eDiscovery Administrators and more eDiscovery Managers. However, in a small tenant, the same people might comprise the two groups.

## Administrative Units

[Administrative units](#) (AUs) are containers for objects, like organizational units on-premises. AUs allow you to group your users into logical units, then scope management tasks to the AU instead of the entire organization. For example, you could create an AU for all the users in the Sales department, or all users working in Slovakia; then you could grant permission for an ordinary user (let's call her Dagny) to perform user management tasks only on the users in a specific AU.

Like on-premises OUs, the real power of AUs is the ability to give Dagny permission to perform various tasks against *only those users* who are in the scope of an AU. This is very important for large organizations. The limited-scope admin roles (such as Exchange administrator) that exist control *what* their holders can do, but they don't restrict *which users* those role holders can manage.

The simplest way to create AUs is to use the Azure portal, as [described here](#). One nice optimization to this process is that you can create role assignments scoped to the group at the time you create the group itself. Of course, you can also create those role assignments separately by editing the properties of the AU in the Azure portal.

After you've created the group, you need to [add members](#) (which can be users or device objects). Device support is still in preview, though.

Finally, you need to add role assignments that are scoped to the AU. The result is that Dagny, or whoever else has been granted permissions on the AU, can exercise the privileges of the assigned role, but only on

users who are in the targeted administrative unit. The Microsoft 365 Admin center will filter out any users who aren't in the selected AUs, so Dagny won't even see them. If Dagny uses PowerShell instead, she will see users who are out of scope for her AU permissions, but she can't modify them; role scoping only applies to write operations.

If you prefer to manage your AUs with PowerShell, you can; the documentation linked above has examples for each of the cmdlets you'll need to use.

## Managing Privileged Accounts

Best practice in the Windows community is to perform administrative actions with dedicated administrator accounts rather than assigning the necessary permissions to user accounts. This is done to restrict permissions to a limited set of accounts rather than allowing for user accounts to gather a proliferation of permissions, sometimes for doubtful reasons. It also ensures that you do not have to perform regular reviews of highly permissioned accounts to remove permissions from accounts that do not need them. Inside the Microsoft data centers, very few administrators have elevated permissions, and great care is taken to ensure that permissions are only granted when needed and for a minimum period and that they are only used from privileged access workstations (PAWs), dedicated computers specifically configured for high security.

You can certainly bring the practice of using dedicated accounts for administrative tasks forward into Microsoft 365. However, given that the service is a very different environment that hosts many different workloads and the need for permissioned access is reduced because there are fewer administrative tasks to perform (no server management, for instance), perhaps this is a good time to consider whether a better approach could be taken.

### Privileged Identity Management

Microsoft offers two features to manage privileged access to user information. The first is [Azure AD Privileged Identity Management \(PIM\)](#), a framework for the management of privileged access to applications that depend on Azure AD, such as Microsoft 365. Using PIM, you can manage temporary elevation of user accounts to grant administrative privileges, such as Global Administrator. A user can be permanently eligible to elevate their permissions, or you can require the user to request approval each time they require elevated permissions. PIM will elevate the user's permissions for the time needed, then revoke the permissions afterward. Added controls such as enforcing multi-factor authentication (MFA) are also available in PIM, as well as an audit trail and activity report. PIM is available for customers who have Azure AD Premium P2 licenses, whether bundled with the Enterprise Mobility + Security E5 license or purchased separately.

### Privileged Access Management

The second feature is [Privileged Access Management \(PAM\)](#), which is generally available for Exchange Online. Other workloads will be added over time. Microsoft considers PAM to be a compliance feature now, so each user who requests or responds to a PAM request must have either an E5-equivalent (the Office 365 or Microsoft 365 E5, A5, G5, etc. SKUs) or an E3 license plus the Microsoft 365 E5 Compliance or Microsoft 365 E5 Insider Risk Management licenses.

PAM works on the basis that administrators create requests for authorization when they want to perform privileged tasks. Policies controlling individual cmdlets or RBAC roles or role groups state whether requests receive automatic approval or need manual review. These requests are routed to a set of approvers (a mail-enabled security group). Anyone in the group can approve a request through the Microsoft 365 Admin Center or with PowerShell. Once approved, the requester can execute the task for as long as the approval still is valid (the default is four hours).

In addition to considering who has permissions, you should also take steps to check the use of permissions through auditing. The audit log collects a vast array of events for administrative and user actions. You can use the audit log search in the Compliance portal to examine these events and export them for later analysis should the need arise.

## Managing Exchange Online Mailboxes

Early email systems only supported user mailboxes. Today's email systems are a lot more sophisticated and support many different mail-enabled objects designed for different purposes. Exchange Online supports the following recipient types:

- User mailboxes.
- Shared mailboxes.
- Room and resource mailboxes.
- Discovery mailboxes.
- Distribution lists.
- Public folders and public folder mailboxes.
- Mail contacts and mail users.
- Group mailboxes (used by Groups and Teams).
- Scheduling mailbox (for internal use only).

Exchange Online uses but does not allow tenant administrators access to system mailboxes. These mailboxes include arbitration mailboxes, such as that used to generate the Offline Address Book, the health mailboxes used by Managed Availability probes, and mailboxes created for system test purposes. On the other hand, the Exchange Online mailboxes you can manage have some unique characteristics not found on-premises, many of which we will meet here.

### The Link Between EXODS and Azure AD

Mail-enabled objects, including user mailboxes and groups, exist in both the Exchange Online directory service (EXODS) and Azure AD. This arrangement allows Exchange to control some extra properties for mail-enabled objects over and above the set available in Azure AD, but it also means that many attribute changes have to be written twice—once to each copy. Background processes synchronize EXODS and Azure AD. These processes use an identifier called *ExternalDirectoryObjectId* stamped on EXODS objects to link to Azure AD. The identifier does not feature in on-premises Exchange, but its importance is high enough for Exchange Online to display it as a default property when you run the *Get-ExoMailbox* cmdlet:

```
[PS] C:\> Get-ExoMailbox -Identity TRedmond

ExternalDirectoryObjectId : eff4cd58-1bb8-4899-94de-795f656b4a18
UserPrincipalName         : Tony.Redmond@office365itpros.com
Alias                     : Tony.Redmond
DisplayName                : Tony Redmond
```

Exchange cmdlets accept the *ExternalDirectoryObjectId* as a valid identity. In other words, this works:

```
[PS] C:\> Get-ExoMailbox -Identity eff4cd58-1bb8-4899-94de-795f656b4a18
```

*ExternalDirectoryObjectId* can also be used with cmdlets from other PowerShell modules. For example, this snippet retrieves the *ExternalDirectoryObjectId* for a mailbox and uses it to fetch information about the Azure AD user account to which the mailbox belongs.

```
[PS] C:\> $ObjectId = (Get-ExoMailbox -Identity Kim.Akers).ExternalDirectoryObjectId
Get-MgUser -UserId $ObjectId
```

The same technique works for Groups. In this example, we use the *ExternalDirectoryObjectId* to list the members of a group.

```
[PS] C:\> $ObjectId = (Get-UnifiedGroup -Identity ExchangeGoms).ExternalDirectoryObjectId
[array]$Members = Get-MgGroupMember -GroupId $ObjectId
ForEach ($Member in $Members) {Get-MgUser -UserId $Member.Id | Select -ExpandProperty DisplayName}
```

When an *ExternalDirectoryObjectId* is unavailable for an Exchange object, it means that the object is specific to Exchange and doesn't exist in Azure AD. Discovery mailboxes used to hold the results of old-style Exchange eDiscovery searches are an example of such objects.

## User Mailboxes

An on-premises Exchange administrator who begins working with Exchange Online mailboxes won't notice much difference between cloud mailboxes and their on-premises counterparts. You can't manage databases or move mailboxes around because Microsoft takes care of these activities, but the essentials of managing mailbox properties are similar. Many of the techniques used to work with mailboxes through the EAC or PowerShell are the same on both platforms.

Some features available on-premises are not in Exchange Online. The cmdlet extension agent is an example. This agent often runs in on-premises deployments to automate the population of mailbox properties during the creation of a new mailbox. For instance, you might set the time zone and language for a mailbox so that its owner has a seamless introduction to OWA the first time they access their mailbox.

Because Microsoft 365 is a massive multi-tenant infrastructure, it is logical that Microsoft imposes some throttles and controls over the resources that an individual user can consume, the size of mailboxes, and the volume and type of messages that the system handles. These limits exist to protect the integrity and performance of Exchange Online and are [documented online](#). Microsoft reviews the limits regularly and updates them in line with experience and user demand. You should acquaint yourself with these limits as they might influence the details of your deployment.

**Data Caching:** Exchange Online is a very different environment to an Exchange on-premises deployment, so it would be unreasonable to expect that everything will work the same. Caching is an example. Sometimes a change that you make to an object takes a few seconds – or even a few minutes – to be effective throughout Exchange Online. It might even take some time for a new object to appear because of the need for synchronization across different parts of Microsoft 365. This is quite normal and is a side-effect of the caching of data to improve performance and responsiveness within the service. The change or new object will appear eventually. Just have faith!

## Creating a New Mailbox

Because cloud mailboxes must have a Microsoft 365 account, the EAC does not include the ability to create a new mailbox. You can:

- Create a new account through the Microsoft 365 admin center and assign it an Exchange Online license. The mailbox is available a few moments after you create the account.
- Create mailboxes on-premises and synchronize them with Azure AD using a tool like AADConnect (hybrid mailboxes).
- Create a new account and mailbox through PowerShell.

Apart from instructing Exchange to create a mailbox for an account, the Exchange Online license assigned to an account controls some mailbox settings, such as its storage quota and access to other products such as SharePoint Online. [More information](#) is available online about the consequences of assigning or removing licenses to or from accounts. If you create accounts with PowerShell, you must make sure that the new

accounts are fully provisioned and licensed. Accounts created without a license will not be able to access any applications until they become licensed.

Once created, you can change the settings for Exchange Online mailboxes through the Microsoft 365 admin center, EAC, or PowerShell. Management of the settings for hybrid mailboxes always happens through the on-premises environment. One major difference between on-premises and cloud mailboxes is that Exchange Online does not apply naming policies to new objects. In practical terms, this means that you cannot control the format of display names. If your company organizes address lists using the last name, and first name convention, you must input the display name according to that policy or run a fix-up script afterward to ensure that all mailboxes follow the same naming convention.

**Display Names and Avatars:** There are many places in Microsoft 365 applications where user photos (avatars) are displayed, if available in the user account. If not, initials taken from the display name serve as a fallback. For instance, the avatar for the user Paul Robichaux will display PR. However, if you use the last name and first name convention for display names, the avatar will display RP. The apparently “wrong” choice of initials can be hard for users to understand.

## Editing a Cloud Mailbox

Many of the properties of Exchange Online mailboxes, including permissions, forwarding settings, and visibility in the GAL, can be set through the Microsoft 365 admin center. If you need access to the full set of mailbox properties, click the **Edit Exchange properties** link in the properties dialog to open the EAC mailbox properties page. At this point in the evolution of Exchange Online, you might rarely if ever go to the classic or modern EAC for anything, as most of the things you might commonly manage are available elsewhere.

**A note on mailbox aliases:** As its name implies, an alias is another name or way for Exchange to recognize a mailbox. Microsoft’s help suggests that *“The user’s alias is the portion of the email address on the left side of the @ symbol. It must be unique in your organization.”* However, although the advice is to be unique, Exchange Online currently allows you to create multiple mail-enabled objects with the same alias. This is a habit to be avoided because it can create confusion when processing objects, especially with PowerShell. Microsoft [announced that this will change](#), but they pushed back the original April 2022 implementation date—it is now due to be service-wide by the end of July 2022 but there haven’t been any updates to that date in a while.

## Creating a Mailbox with PowerShell

PowerShell is often used to script the creation of new user accounts and mailboxes because it allows companies to tie the creation of an account into other processes, such as the creation of a new HR record and access records, the printing of an employee badge, and so on. On-premises administrators are familiar with the concept of creating and updating mailboxes with PowerShell because the *New-Mailbox* cmdlet has been used for this purpose for well over ten years. The *New-Mailbox* cmdlet exists in Exchange Online but the environment in which it functions is very different, largely because of the multi-tenant nature of Microsoft 365 and the need to license users before they can access functionality. Exchange Online strictly enforces the need for mailboxes to be licensed and will remove unlicensed mailboxes if they don’t get a license within 30 days of creation. Thus, you cannot take scripts used to create mailboxes on-premises and expect to be able to use them with Exchange Online. Invariably, some adjustment is necessary, if only to assign a license to a new mailbox immediately after its creation.

One point of difference you need to be aware of is the difference between a mailbox and a remote mailbox. You know what a mailbox is: it’s homed either in the cloud or on-premises, in the same location as its

associated account object. A remote mailbox is a cloud mailbox associated a mail user object stored in an on-premises Active Directory. You'll create remote mailboxes when you want your users anchored in on-premises AD but their mailboxes in Exchange Online. Most likely, this will already have been done for you as part of your migration to Exchange Online.

It is not the intention to discuss how to use PowerShell to create Exchange Online mailboxes or how to write a bulk mailbox creation process (the Microsoft 365 admin center includes [an option for bulk account creation](#)). A scan of the Internet will provide many examples of code that you can examine and repurpose to suit your needs, including some from Microsoft (for instance, [a script to create multiple mailboxes](#) is available as is one to [assign licenses to multiple mailboxes](#)). Instead, this walkthrough will help you understand the differences that exist between Exchange on-premises and Exchange Online.

Remember that if you run a hybrid deployment, the on-premises environment is always the master, and Azure AD is the replica. Mailboxes and user accounts are created on-premises and then synchronized to Azure AD. However, even if you run a hybrid deployment and will never create cloud-based mailboxes, it's good to understand what happens when a new cloud mailbox is created from scratch. The basic steps in the process are as follows:

1. Make sure that your PowerShell session loads the necessary modules. You need both the Exchange Online and Azure AD cmdlets to create mailboxes and manipulate the underlying Azure AD objects. See Chapter 23 if you need more background on this.
2. Run the *New-RemoteMailbox* cmdlet to create a new user account and its Exchange Online mailbox.
3. Run the *Set-User* cmdlet to update the on-premises directory with the organizational and personal settings for the user object.
4. Run the *Update-MgUser* cmdlet to set the correct country code (location) for the new mailbox in the cloud. You assign a country to a user account to ensure that Microsoft 365 makes the services designated for that country available to the user. For example:

```
[PS] C:\> Update-MgUser -UserId Kim.Akers@Office365itpros.com -Country Germany
```

5. Assign a license to the user.

Creating a new mailbox with the *New-Mailbox* cmdlet on an on-premises Exchange server usually completes in a matter of seconds. The same is not true for Exchange Online. Although the cmdlet and syntax are the same, the creation of the new object across EXODS and Azure AD takes some time to synchronize across the directories.

**Generating passwords with PowerShell:** The need to use secure passwords that satisfy policy exists when you create new mailboxes. You can find lots of ways to approach the task of generating a secure random password in PowerShell on the web. Always be careful to test and check the code in any PowerShell scripts that you download from the web before using them in production.

## Updating Mailbox Attributes

Some of the attributes commonly populated for mailboxes are not set with the *New-Mailbox* or *Set-Mailbox* cmdlets. These are attributes controlled by Azure AD and are common to all Exchange recipient objects, whether or not they have a mailbox, and are updated with the *Set-User* cmdlet. As it happens, many of these attributes are useful when creating filters to create dynamic distribution lists or address lists, so it is important to give some attention to making sure that they hold the correct values. For example, the code shown below updates the user object for the mailbox that we just created with the organizational and personal information that you might expect to find in the corporate directory. The example shown here updates several properties, including the *Manager* property with a value that points to the name of the new user's direct manager. The update will fail if Azure AD cannot find the manager.

```
[PS] C:\> Set-User -Identity "Kim Akers" -City "Dublin" -CountryOrRegion "Ireland" -Department
"Marketing Operations" -Title "VP Marketing (New Products)" -Manager "Paul.Robichaux" -Office
"Dublin HQ" -Company "Popular Books"
```

Once the new mailbox exists, you can update its settings with *Set-Mailbox* and other cmdlets. For instance, here is how to enable an archive mailbox with the *Enable-Mailbox* cmdlet.

```
[PS] C:\> Enable-Mailbox -Identity "Kim Akers" -Archive
```

## Add User Photos to Mailboxes

Given the graphic nature of applications, it's a good idea to update a new mailbox with a suitable photo after it's created. The photo then shows up in the GAL, the people card, and apps like Teams which display user avatars. Several PowerShell cmdlets are available to administrators to update user photos.

- The Exchange Online *Set-UserPhoto* cmdlet updates the photo data in a mailbox. *Set-UserPhoto* can also update a photo for a group mailbox (be sure to specify the *GroupMailbox* switch). You cannot use *Set-UserPhoto* to update other mail-enabled objects, like distribution lists or mail contacts.
- The Teams *Set-TeamPicture* cmdlet updates the photo data for a team. This is analogous to running *Set-UserPhoto* to update the photo for a group mailbox. In most cases, it's best to use *Set-UserPhoto* to avoid the need to load another module.
- The Azure AD *New-MgUserPhoto* and *Update-MgUserPhoto* cmdlets writes photo data to an Azure AD user account. Use this cmdlet when you wish to update photo data for an Azure AD account that doesn't have an Exchange Online mailbox, like a guest account. As the cmdlet name suggests, the cmdlet processes thumbnail (small) photos. It does not generate the larger size photos which look better in Teams meetings. For this reason, you should always use *Set-UserPhoto* to upload photos for tenant accounts.

Exchange Online and Azure AD synchronize photo data to make sure that user accounts have the latest picture. After a short delay to allow the apps to refresh their caches, an updated photo will be active across the ecosystem.

Image files for user photos can be in JPEG or PNG format and should be 648 x 648 pixels. This is the largest resolution supported. Behind the scenes, Exchange Online generates smaller 64 x 64 and 96 x 96-pixel thumbnails for apps to use when small thumbnails are appropriate. Most digital photos are much larger (in pixels) so some resizing is needed. Square photos are best as they won't be cropped. Usually, the best results are obtained when the user faces directly into the camera. The photos must also be less than 500KB in size.

Although it can take 30 seconds or more to update a picture for a mailbox, running *Set-UserPhoto* is simple:

```
[PS] C:\> Set-UserPhoto -Identity James.Smith@office365itpros.com -PictureData
([System.IO.File]::ReadAllBytes("c:\Temp\James.Smith.jpg")) -Confirm:$False
```

If you want to check if a mailbox already has a picture (to avoid overwriting it), use the *Get-UserPhoto* cmdlet. This cmdlet returns *\$Null* if a mailbox does not hold photo data.

```
[PS] C:\> If (Get-UserPhoto -Identity Kim.Akers@Office365ITpros.com) {Write-Host "Kim has a photo"}
```

If you make a mistake and upload the wrong image, you can restart by removing the image with the *Remove-UserPhoto* cmdlet:

```
[PS] C:\> Remove-UserPhoto -Identity James.Smith@office365itpros.com -Confirm:$False
```

An example of how to scan user mailboxes to [find mailboxes without photos can be downloaded from GitHub](#).

## Allow Users to Update Their Photos

Exchange Online, Teams, and the Office portal give users the ability for users to update their photos, but this capability is controlled through the *SetPhotoEnabled* setting in the OWA mailbox policy assigned to the mailbox. The use of OWA mailbox policies means that organizations can decide to allow some users to manage their photos while barring others from doing so. In the latter case, the organization takes responsibility for updating user photos by:

- Building a connection to a system holding suitable photos, like an HR system.
- Building a special app to manage user photos (although Microsoft is deprecating the relevant Exchange Web Services APIs).
- Using a commercial tool, like [Photos for Office 365 from Code Two Software](#).

By default, the *SetPhotoEnabled* setting is *\$true*, meaning that users can upload a photo from apps. If this setting is off (as it may be in a legacy tenant) users will see a message such as “*picture options are disabled by policy*” if they try to change their photo. To allow users to upload and update their photos, either:

- Update the OWA mailbox policies so that *SetPhotoEnabled* is *\$True* in all policies, or:
- Create or update an OWA mailbox policy with *SetPhotoEnabled* set to *\$True* and assign this policy to the mailboxes of accounts you want to allow to upload photos.

For example, to update an OWA mailbox policy, run the *Set-OWAMailboxPolicy* cmdlet:

```
[PS] C:\> Set-OWAMailboxPolicy -Identity OWAFullAccess -SetPhotoEnabled $True
```

To assign an OWA mailbox policy to a mailbox, use the *Set-CASMailbox* cmdlet:

```
[PS] C:\> Set-CASMailbox -Identity Chris.Bishop -OWAMailboxPolicy OWAFullAccess
```

Changes to an OWA mailbox policy take up to 30 minutes before they are effective.

## Mailbox Plans

When you create a new Exchange Online mailbox, the new mailbox inherits many of its settings from a mailbox plan. Four mailbox plans are available within a tenant to accommodate the different Exchange Online plans included in Microsoft 365 and Office 365 products. To see the set of mailbox plans, run the *Get-MailboxPlan* cmdlet:

```
[PS] C:\> Get-MailboxPlan | Format-Table DisplayName, IsDefault, Name
```

DisplayName	IsDefault	Name
ExchangeOnlineEnterprise	True	ExchangeOnlineEnterprise-8fc1c029-5e32-485e-9810-179fb4701447
ExchangeOnlineDeskless	False	ExchangeOnlineDeskless-bc1e76cc-4c0b-491c-a518-3a0a43cbf78e
ExchangeOnline	False	ExchangeOnline-12c139bc-eafa-4a43-b4d2-e285f83e075d
ExchangeOnlineEssentials	False	ExchangeOnlineEssentials-1a1bf516-90d5-4c4b-a047-5b3544ad9826

The role of the mailbox plan is to be a template holding settings for mailbox properties. When you create a new mailbox, the new mailbox inherits settings from the mailbox plan chosen by Exchange Online. Most mailboxes are created along with new accounts via the Microsoft 365 admin center. When this happens, Exchange Online uses the license assigned to the account to select the mailbox plan to apply to the new mailbox. Table 5-1 lists the Office 365 and Microsoft products and the associated mailbox plans.

Products	Mailbox Plan
Exchange Online Kiosk Microsoft 365 F3 Office 365 F3	<i>ExchangeOnlineDeskless</i>

Exchange Online Plan 1 Microsoft 365 E1 Office 365 E1	<i>ExchangeOnline</i>
Exchange Online Plan 2 Microsoft 365 E3/E5 Office 365 E3/E5	<i>ExchangeOnlineEnterprise</i>
Microsoft 365 Business Basic	<i>ExchangeOnlineEssentials</i>

Table 5-1: Licenses and Mailbox plans

In the output for the *Get-MailboxPlan* cmdlet shown above, the Exchange Online Enterprise plan is marked as the default. If you create a user mailbox without a license, Exchange Online uses the default plan to populate its settings. Mailboxes that don't need licenses, like shared and resource mailboxes, use the Exchange Online mailbox plan. An administrator can specify the mailbox plan to use when creating a new mailbox with the *New-Mailbox* cmdlet.

To check how many mailboxes have each mailbox plan, we can check the plan registered for each mailbox. Note that the filter used to find mailboxes requires the distinguished name for the mailbox plan.

```
[PS] C:\> $Report = [System.Collections.Generic.List[Object]]::new()
$MbxPlans = Get-MailboxPlan
ForEach ($Plan in $MbxPlans) {
    $Dn = (Get-MailboxPlan -Identity $Plan.Name).DistinguishedName
    [Array]$Mbx = Get-ExoMailbox -Filter "MailboxPlan -eq '$Dn'" -Properties MailboxPlan -ResultSize
    Unlimited # Find mailboxes with the plan
    If ($Mbx) {
        ForEach ($M in $Mbx) {
            $ReportLine = [PSCustomObject][Ordered]@{
                Name           = $M.DisplayName
                UPN             = $M.UserPrincipalName
                Plan            = $Plan.DisplayName }
            $Report.Add($ReportLine) }
        }
    } #End ForEach
$Report | Group Plan | Format-Table Name, Count
```

Name	Count
ExchangeOnlineEnterprise	43
ExchangeOnline	17

The *Set-MailboxPlan* cmdlet configures settings in mailbox plans while the *Get-MailboxPlan* cmdlet reports the settings. Because the idea behind mailbox plans is to configure basic mailbox settings, not every property configurable with the *Set-Mailbox* cmdlet is available in a mailbox plan. The settings cover:

- Mailbox quotas and warning thresholds.
- Message send and receive size.
- Deleted items retention period.
- Mailbox retention policy.
- User role assignment policy.

In this example, we use *Set-MailboxPlan* to update the Exchange Online enterprise plan to update the largest supported message size for send and receive to 125 MB, change the deleted item retention period from 14 to 30 days, and assign a new default mailbox retention policy.

```
[PS] C:\> Set-MailboxPlan -Identity ExchangeOnlineEnterprise -MaxSendSize 125MB
-MaxReceiveSize 125MB -RetainDeletedItemsFor 30.00:00:00 -RetentionPolicy "General Mailbox
Retention Policy"
```

Somewhat frustratingly, although *Get-MailboxPlan* returns a large set of mailbox properties and values, *Set-MailboxPlan* is unable to update most settings. If you want to update a mailbox property outside the set supported by mailbox plans, you must run *Set-Mailbox* after creating the mailbox. For instance, you might want to write a value into one of the custom attributes.

Modifying the settings of a mailbox plan does not affect existing mailboxes. If you want to change settings for existing mailboxes, you'll need to run the *Set-Mailbox* or *Set-CASMailbox cmdlets*. However, if the license assigned to a user mailbox changes, Exchange Online applies the settings for the relevant plan to the mailbox (this doesn't happen immediately as it takes some time for Exchange to detect and react to the license change).

Each mailbox plan has a corresponding CAS mailbox plan. This mimics the relationship between *Set-Mailbox* and *Set-CasMailbox* where the first cmdlet updates essential mailbox settings while the second deals with connectivity. In this instance, the *Set-CASMailboxPlan* cmdlet allows administrators to control the following settings.

- Enabling Exchange ActiveSync.
- Enabling IMAP4 and POP3.
- OWA mailbox policy.

Here's an example of disabling the POP3 and IMAP4 protocols in all mailbox plans:

```
[PS] C:\> Get-CASMailboxPlan | Set-CASMailboxPlan -PopEnabled $False -IMAPEnabled $False
```

You can check the protocol settings by running the *Get-CASMailboxPlan* cmdlet to return the different protocol settings:

```
[PS] C:\> Get-CASMailboxPlan -Identity ExchangeOnlineEnterprise | Format-List DisplayName,
ImapEnabled, PopEnabled, MapiEnabled, ActiveSyncEnabled, OwaEnabled, OutlookMobileEnabled
```

```
Name                : ExchangeOnlineEnterprise
ImapEnabled         : False
PopEnabled          : False
MAPIEnabled         : True
ActiveSyncEnabled   : True
OWAEnabled          : True
OutlookMobileEnabled : True
```

## Recipient Limits

The default recipient limit for an Exchange Online mailbox is 500. This means that the mailbox owner can send messages addressed to up to 500 recipients. The limit exists to ensure that Exchange Online mailboxes do not consume large quantities of resources by sending messages to large numbers of recipients. You can update the recipient limit for a mailbox to anything from between 1 to 1,000 through the EAC or with PowerShell. For example, this command sets the limit to 900 for the chosen mailbox:

```
[PS] C:\> Set-Mailbox -Identity James.Ryan -RecipientLimits 900
```

To set a new recipient limit for every user mailbox in the tenant, use a command like this:

```
[PS] C:\> Get-ExoMailbox -RecipientTypeDetails UserMailbox -ResultSize Unlimited | Set-Mailbox -
RecipientLimits 900
```

Although the usual request is to increase the recipient limit to deal with situations such as the distribution of internal newsletters, a use case exists to reduce the limit to restrict the ability of specific users to communicate with large numbers of recipients.

If you want a new default recipient limit to apply for new mailboxes, you can update the setting in the appropriate mailbox plans. For example, this command updates the value for enterprise mailboxes:

```
[PS] C:\> Set-MailboxPlan -Identity ExchangeOnlineEnterprise-8fc1c029-5e32-485e-9810-179fb4701447 -RecipientLimits 750
```

## Multi-Geo Mailboxes

When Exchange is configured for multi-geo operation, a tenant can distribute mailboxes across the home region (for example, the United States) and one or more satellite geo locations (for example, the United Kingdom, France, and Norway), depending on where users are and the need to satisfy local data sovereignty. In multi-geo tenants, Azure AD user accounts have a *PreferredDataLocation* property to record the data center region where a user's data should be stored. Exchange Online synchronizes the value of *PreferredDataLocation* into the *MailboxRegion* property for mailbox objects stored in EXODS. This property is blank for mailboxes in single-geo tenants. Exchange Online uses *MailboxRegion* to know where user mailboxes and archive mailboxes are stored (both primary and archive mailboxes must be in the same region).

## Configuring a Mailbox-Enabled Account

Creating a new mailbox with the *New-Mailbox* cmdlet also creates a new user object in Azure AD. Creating a new mailbox doesn't assign a license and until the account is assigned a license for Exchange Online, the user won't be able to sign into the mailbox. To allow sign-on, we must update the account with a Microsoft 365 location code for the country where the account is located and assign a license. A license must be assigned to a new account within 30 days to avoid it being blocked and placed into Microsoft 365's automatic deletion routine.

The Microsoft 365 admin center shows the country to which a user is assigned. You can use the same country names with PowerShell, but the country code can also be passed – FR for France, DE for Germany, IE for Ireland, and so on. A tenant can accommodate users in multiple countries, and you can update a user's location as many times as you like, and the multi-geo capability available to large tenants allow them to distribute mailboxes across multiple data center regions. You can't update a tenant's location after it is created because the location determines factors such as billing and the data centers used to hold user data.

Two country properties exist for user accounts. The *Country* property is used for display and sort purposes. You can assign anything you like to the *Country* property for an account because the *Update-MgUser* cmdlet does not validate the input to ensure that the country exists. However, because the *Country* property is used for sort and display purposes, including the filters used for objects like dynamic groups, these values must be accurate and consistent.

The *UsageLocation* property, which uses the 2-character [ISO 3166 code for a country](#), is much more important because it controls the services that can be provided to the account. For this reason, *Update-MgUser* checks input to ensure that a valid country code is assigned to an account. Instances exist where certain functionality is unavailable in a specific country, as in the case of a voice calling plan. It is therefore essential to be accurate when you set the *UsageLocation* value for an account. Here's an example of setting the two country properties:

```
[PS] C:\> Update-MgUser -ObjectId Kim.Akers@Office365ITPros.com -Country "Ireland" -UsageLocation IE
```

As explained previously, it can take some time before updates to the new account synchronize across all workloads. You need to take this factor into account if you plan to script the creation of new mailboxes. After we update the user object with a valid location code, we can assign it a license. We do this by running the *Set-MgUserLicense* cmdlet. See Chapter 23 for information about how to manipulate licenses through PowerShell, including how to perform this task using the Azure AD cmdlets.

After you assign a license, we should have a licensed user with a functioning mailbox. You can confirm the assignment of the license to the user by examining their account through the Microsoft 365 admin center. It is easy to assign licenses to accounts through the Microsoft 365 admin center, especially when dealing with the finer points of turning on or off different services licensed by a plan. However, it is often more efficient to use PowerShell when you want to check the licenses that are already assigned to accounts or to reallocate licenses to accounts, as might be the case if you choose to upgrade a plan for selected users.

## Email Primary and Proxy Addresses

Mail-enabled objects have one or more addresses that allow the Exchange transport service to route messages to them. Exchange Online mailboxes usually have several SMTP proxy addresses (also known as email aliases), any of which can be used to send email to the mailbox. A mailbox always has an address for the onmicrosoft.com service domain used by the tenant. Administrators can assign other addresses to mailboxes for any of the domains owned by the tenant. The set of addresses is stored in the *EmailAddresses* attribute for mail-enabled objects. For instance, here's a typical set for a mailbox:

```
[PS] C:\> Get-ExoMailbox Jane.Sixsmith | Select -ExpandProperty EmailAddresses
smtp:Jane.Sixsmith+Amazon@office365itpros.com
SMTP:Janey@office365itpros.com
smtp:Jane.Sixsmith@office365itpros.com
SPO:SPO_edc2687c-5939-41d1-9ab1-24a7dc43ac6e@SPO_b662313f-14fc-43a2-9a7a-d2e27f4f3478
SIP:Jane.Sixsmith@office365itpros.com
smtp:Jane.Sixsmith@office365itpros.onmicrosoft.com
```

Each address is of a certain type. In this case, there are SMTP addresses, an address used by SPO (SharePoint Online) to synchronize information about documents created by the mailbox's owner with the Microsoft 365 substrate. You should not remove this address as internal Microsoft processes manage its creation and removal. The SIP address is used for SIP messaging communications, such as Teams calls.

One of the four SMTP addresses has a capitalized prefix. This is the primary address, which means that it is the one Exchange inserts as the reply address for outbound messages so that recipients use the address when they reply to messages. It is best practice to use the same address for both the User Principal Name and primary SMTP address for a Microsoft 365 account. For example, to set the primary SMTP address for a mailbox with PowerShell, run the *Set-Mailbox* cmdlet to set the *WindowsEmailAddress* attribute.

```
[PS] C:\> Set-Mailbox -Identity Jimmy.Jones -WindowsEmailAddress Jimmy@office365itpros.com
```

If the address selected as the primary is not already present in the mailbox properties, Exchange will add the address and make it the primary.

Except for plus addresses (see below), only administrators can assign multiple email proxy addresses to mailboxes, distribution groups, shared mailboxes, group mailboxes, mail contacts, and mail users using tools including the Microsoft 365 admin center, EAC, and PowerShell.

### Sending Email Using Proxy Addresses

Exchange Online supports the ability for users to send email using any of the secondary SMTP proxy addresses (otherwise known as email aliases) assigned to their mailbox. This is especially useful when a tenant supports multiple domains, as in the case of a corporate merger, and users need to send messages using proxy addresses for different domains. To allow users to send email using proxy addresses, update the Exchange organization configuration using PowerShell (below) or through the Mail flow settings in the EAC:

```
[PS] C:\> Set-OrganizationConfig -SendFromAliasEnabled $True
```

After updating the configuration, it can take several hours for all the mailbox servers used by the tenant to receive the change. Once this process completes, users can use the From field in the message compose form to select and use a proxy address. OWA users must select the proxy addresses they wish to use through the

Compose and Reply section of OWA settings to make addresses available for use. Outlook desktop and Outlook mobile users can insert proxy addresses in the From field for new messages. After sending, the proxy address appears for recipients in place of the sender's primary SMTP address.

## Plus Addressing

An SMTP address is composed of a local part and a domain. The domain routes messages to the server identified in the domain's MX record in DNS. The local part is the user address used to identify the eventual recipient. Exchange Online supports plus addressing, meaning that users can add a suffix (an arbitrary tag chosen by them) to the local part of their SMTP address. A plus sign divides the suffix from the local part. For example:

*Kim.Akers@Office365itpros.com* is a "normal" SMTP address.

*Kim.Akers+SomeValue@Office365itpros.com* is an SMTP address with a plus suffix.

When the transport service processes an inbound email with a plus address, it removes the plus sign and suffix and uses the remainder to deliver the message.

The idea behind plus addresses is that you can use them to find out if companies are sharing (or selling) your email address for marketing (or spamming) purposes. For instance, if a website asks for an email address before granting access to some content, you can create a plus address and use the name of the website as the suffix. If you later find that spam or other unwanted email arrives using that plus address, you know that the site shared your address. You can then use inbox rules to filter or block messages from that address.

Consumer mail systems like Outlook.com and Gmail support plus addressing. You can use plus addressing in two ways:

- **Administrator controlled:** The tenant assigns plus addresses as SMTP proxy addresses to mailboxes. These addresses are persistent like any other SMTP proxy address, which means that they can be used with features like sending using a proxy address described above. Administrators can assign plus addresses to mailboxes and groups through the EAC or PowerShell, but not through the Microsoft 365 admin center.
- **User-initiated:** Users can create their own plus addresses as needed by adding the plus sign followed by whatever text they want to use as a suffix to their regular email address when they give email addresses to other organizations. For instance, if doing business with Contoso, you could tell Contoso to send you an email at *First.Last+Contoso@tenant.com*.

Currently, the *AllowPlusAddressInRecipients* setting in the Exchange organization configuration controls how Exchange Online processes plus signs found in email addresses. The value can be:

- **\$True:** The Exchange transport service uses the plus sign to indicate that it can remove the tag after a plus sign and deliver the message using the remaining address. For example, Exchange will take the address *Tony.Redmond+eCommerce@office365itpros.com* and deliver the message to *Tony.Redmond@office365itpros.com*. This is the default for any new tenant.
- **\$False:** This is the default for older tenants where the possibility exists that valid email addresses exist containing the plus sign. This setting means that Exchange treats the plus sign as a literal character that's part of the email address and will only deliver messages if it can find a match in the proxy addresses assigned to a recipient. For example, if an administrator assigns *Tony.Redmond+eCommerce@office365itpros.com* as a proxy SMTP address to a mailbox, Exchange can deliver the message to that mailbox. It will not strip the "+eCommerce" portion off and attempt to deliver to [Tony.Redmond@office365itpros.com](mailto:Tony.Redmond@office365itpros.com).

The *AllowPlusAddressInRecipients* organization setting must be set to True to allow users to create their own plus addresses as described above. You can update the setting through the Mail flow settings in the EAC or by running the *Set-OrganizationConfig* cmdlet:

```
[PS] C:\> Set-OrganizationConfig -AllowPlusAddressInRecipients $True
```

When plus addressing is active, any intermediate gateway which processes inbound email must focus on the domain for routing. If the gateway attempts to do directory lookups to check recipient addresses and cannot handle plus addresses, the lookups might fail and cause the rejection of messages.

In April 2022, Microsoft removed the organization setting and make plus addressing available by default in all tenants. Any proxy addresses containing plus characters remaining for mail-enabled objects will not work as before because Exchange Online will no longer attempt to match the complete address (including the plus sign and tag) on inbound messages against its directory. This could lead to the non-delivery of email. If your organization wishes to opt out of plus addressing, run the command:

```
[PS] C:\> Set-OrganizationConfig -DisablePlusAddressInRecipients $True
```

See [this article](#) for details of PowerShell code to locate and remove plus addresses from mail-enabled recipients.

## Custom Attributes

Exchange Online supports two sets of custom attributes or properties for mail-enabled objects. Tenants can update these attributes as they wish to support their own needs. For example, you could use a custom attribute to store a staff number or an office location code. Note that these custom attributes are properties of the mailbox object associated with a user.

The two sets are:

- *CustomAttribute1* through *CustomAttribute15*: These attributes can store a single value.
- *ExtensionCustomAttribute1* through *ExtensionCustomAttribute5*: These attributes can store multiple values.

Apart from their numbers, the difference between the fifteen custom attributes and the five extension attributes is that the custom attributes can be updated through EAC. Extension attributes are only accessible through PowerShell.

To illustrate the difference between the two types of custom attributes, if you run this command:

```
[PS] C:\> Set-Mailbox -Identity "Kim Akers" -CustomAttribute5 "Custom", "Attribute", "5"
```

Exchange Online stores the string "Custom Attribute 5" in the attribute. But if you run this command:

```
[PS] C:\> Set-Mailbox -Identity "Kim Akers" -ExtensionCustomAttribute5 "Custom", "Attribute", "5"
```

Exchange Online returns an array of "5, Attribute, Custom." You can therefore do this to fetch the attribute and put it into an array variable:

```
[PS] C:\> $Values = Get-ExoMailbox -Identity Kim.Akers | Select -ExpandProperty  
ExtensionCustomAttribute5
```

And because it is an array rather than a string, we can use the information contained in the attribute differently. For example, to add an item to the array:

```
[PS] C:\> Set-Mailbox -Identity "Kim Akers" -ExtensionCustomAttribute5 @{Add="Great"}
```

Or to remove an item:

```
[PS] C:\> Set-Mailbox -Identity "Kim Akers" -ExtensionCustomAttribute5 @{Remove="Attribute"}
```

The custom attributes (but not the extension attributes) support server-side filtering for fast access. Thus, we can do this:

```
[PS] C:\> Get-EXOMailbox -Filter {CustomAttribute1 -ne $Null} -Properties CustomAttribute1 |
Format-Table DisplayName, CustomAttribute1
```

One note of caution. If you are synchronizing objects from an on-premises Active Directory and use these attributes, make sure to include the attributes in the synchronization set.

## Administrator Access to User Mailbox Settings

Occasionally, users need help from an administrator to update mailbox settings. Two methods are available:

1. Click the user avatar in the top right-hand corner of EAC and select **View another mailbox** from the menu. EAC displays a picker dialog to select the mailbox that you want to manage. The selected user's settings open in a browser window using a modified form of OWA Options. The user making the changes and the mailbox to which the changes are applied are clearly shown. Apart from needing to be a member of at least the Recipient Management role group, no special access rights need to be granted to the administrator to allow them to change settings for a user in this way. It is also possible to call up OWA Options directly by inputting a link to take you to the user mailbox. For example:

<https://outlook.office365.com/ecp/Frank.Clonan@Office365ITPros.com>

2. Through PowerShell. Exchange Online supports a set of cmdlets to allow administrators to manipulate different personal mailbox settings, or options usually selected by users. You can use these cmdlets to configure a mailbox on behalf of a user or to check that certain settings are in place. An account that performs maintenance on user accounts through PowerShell should be assigned the Recipient Management role. If the need exists to view the data in the mailbox, the account needs *Full Access* permission.

Using a browser to change user settings is easiest when you only have one or two mailboxes to update. PowerShell is the preferred method when changes need to be applied to multiple mailboxes, or when you want to update mailbox settings in a script that creates a new mailbox.

Administrators whose accounts are granted the RBAC User Options role can manage settings for any user mailbox. This example grants Tony Redmond full rights over the mailbox owned by Kim Akers.

```
[PS] C:\> Add-MailboxPermission -Identity 'Kim Akers' -User 'Tony Redmond' -AccessRights FullAccess
-AutoMapping $False
```

Note the use of the *AutoMapping* parameter. If omitted, Autodiscover will open the mailbox because it recognizes that the user has full access to the mailbox. As in the situation where you are configuring a mailbox for another user, this is probably not what you want to happen. Setting *AutoMapping* to *\$False* instructs Autodiscover to ignore the mailbox when it builds the list of resources available to Outlook. The user can edit their mailbox settings to open any extra mailboxes that they have access rights to at any time. For more information, see the section on *AutoMapping* later. To remove *FullAccess* rights, run the *Remove-MailboxPermission* cmdlet:

```
[PS] C:\> Remove-MailboxPermission -Identity 'Kim Akers' -User 'Tony Redmond'
-AccessRights FullAccess
```

# Securing the Data of Ex-employees

Over time, some employees will leave the organization. Many departures are expected and planned for, some are amicable, and some will be immediate and potentially traumatic. For legal reasons, you might need to preserve the employee's mailbox in the latter case. In an on-premises environment, you can preserve mailboxes by disabling the user account. If needed, you can reenable the account to restore a mailbox to full running order. The same is true for in the cloud, but you probably do not want to pay the monthly license for an unused account only kept in case the organization needs some of the information in its mailbox in the future. Removing the need for licenses is why inactive mailboxes are so valuable.

When you delete a user account through the Microsoft 365 admin center (Figure 5-7), the following points in the removal workflow need consideration:

- **License:** Cancel the license held by the deleted account or keep it for later reassignment to another account.
- **Mailbox:** Exchange Online removes all the proxy email addresses (primary address and any secondary addresses). In addition, Exchange removes all delegate permissions from the mailbox, but you can grant permission to allow another user to access the mailbox content and retrieve information. As shown in Figure 5-7, the reassignment cannot happen until after the removal of any holds on the mailbox. Alternatively, if the account has an Office 365 E3 or E5 license, you can place a hold on the mailbox before deleting the account. Exchange Online will then make the mailbox inactive (see Chapter 6) and retain it in that state until the hold lapses.
- **OneDrive for Business:** To review and retrieve important information held in the user's OneDrive for Business account, you can grant access to another user. Apart from documents, the account might hold information shared with other users through applications, like Teams meeting recordings, whiteboards, and Loop components. By default, access lasts for 30 days after which OneDrive permanently removes the information, so the person granted access must review and retrieve information in that period. A tenant can increase the retention period for deleted OneDrive accounts by updating the setting in the SharePoint admin center from 30 (the default) up to 3650 days (ten years).

The Microsoft 365 admin center can remove only cloud accounts. On-premises accounts are only manageable with an on-premises administration tool. In addition, the workflow does not address access to information in other workloads. For instance, if the user you want to delete is the sole owner of some Groups or Teams, the deletion process does not make sure that the groups/teams remain with at least one owner. The same is true for traditional SharePoint sites where the deleted user might be the sole administrator. In other words, treat the user removal workflow as something that deals with the user's data held in cloud mailboxes and OneDrive for Business accounts while ignoring the user's activity in other workloads. We'll come back to this topic shortly.

Remember that it might be a good idea to create an autoreply to let senders know that the person is no longer with the organization. This is a separate action that the Microsoft 365 admin center does not perform when removing an account.

Microsoft's account removal process is reasonable and suits the needs of many organizations. However, sometimes you might want to use a different process, especially if some element of discord is present when someone leaves. For this reason, we should discuss the different steps you can take to preserve all the data that a person might have access to when the time comes for them to leave the organization.

## Delete Andy Ruth (Director)

You can restore deleted users and their data, except for calendar items and aliases, for up to 30 days after you delete them. Data on their connected devices will be removed, as well as the following:

 Office 365 E3, Power BI (free), Microsoft Stream Trial will be unassigned and available for other users

Email aliases will be removed   
[View email aliases](#)

Mailbox delegate permissions will be removed   
[View mailbox delegate permissions](#)

Give another user access to Andy Ruth (Director)'s OneDrive files for 30 days after the user is deleted

  Kim Akers 

Give another user access to Andy Ruth (Director)'s email   
Andy Ruth (Director) has been placed on legal hold. Data can't be assigned to other users until the legal hold is removed

Delete user

Figure 5-7: Steps to delete a user account when removed through the Microsoft 365 admin center

## Blocking a User Account

The first and most essential action is to secure access to the user's account to prevent any unauthorized removal of data. We can then put their mailbox and other data into a suitable status for long-term preservation. Normally, when a user authenticates to connect to a Microsoft 365 application, they create a session with that application. The session receives an access token and a refresh token from Azure AD. Usually, an access token is valid for an hour. When that period elapses, an automatic reauthentication process kicks in to get a new access token to allow the session to continue. This interaction happens if the refresh token is still valid, and the account credentials are the same. The refresh token has a defined lifetime. This architecture leads to the occasional result that a user with a blocked or deleted account still has a valid refresh token and can still access some workloads. Because each session has a separate refresh token, you might have sometimes noticed that a user might be able to still sign in on one device after a password change or account blockage while other devices disallowed sign-in.

With the introduction of continuous access evaluation (CAE), as described in the Azure AD chapter, individual services can receive notifications that tell them when an account is blocked, has expired, or has critical security events posted against it. Because the client may still present an unexpired, valid-looking token even after events such as password changes, CAE enables the workloads to reject the token based on notification of a password change, account deletion, or similar event. Exchange Online and SharePoint Online may also receive risk events from Azure AD that indicate that the client's tokens shouldn't be trusted.

When the Microsoft 365 admin center blocks an account, it also sets the account's *RefreshTokensValidFromDateTime* property to the current date and time (this is the same as the forced sign-

out option for an account available in the Microsoft 365 admin center). Forcing apps to sign out means that any existing refresh tokens used by apps are invalidated and cannot be renewed. Because the forced sign-out invalidates the refresh tokens, the next time an app attempts to use its refresh token to renew its access, it discovers that the token has expired and so forces the user to reauthenticate. Because the account is blocked, the user cannot reauthenticate. In addition, the CAE mechanism will immediately revoke the refresh and access tokens.

You can manually block sign-ins, initiate forced sign-outs, and reset account passwords from the Microsoft 365 admin center. Any of these actions will flag the account for CAE, meaning that in nearly real-time the workloads will reject any previously issued tokens for that account. To block an account, select the account from the list of active users, edit its settings, and select **Block this user** from the set of icons under the user's name. Blocking an account from signing in through the Microsoft 365 admin center is the right approach when you manage the departure of a single employee. Using PowerShell commands is better when you need to secure a set of accounts quickly or you want to automate the process to secure an account for a departing employee.

To manually block an account using PowerShell, you can do the following:

- Block the account by running `Update-MgUser`. (This will trigger a CAE event, so you could stop here if you like.)
- Force a sign-out from apps by invalidating refresh tokens with a Graph API request. This will also trigger a CAE event.
- Create and set a new password for the account to allow administrator access once the time comes to recover information from apps. Naturally, the new password only works after unblocking the account by running `Update-MgUser -AccountEnabled:$True`. Password changes also trigger CAE events.

```
[PS] C:\> $UserId = (Get-MgUser -UserId Lotte.Vettler@Office365itpros.com).Id
Update-MgUser-UserId $UserId -AccountEnabled:$False
$Uri = "https://graph.microsoft.com/v1.0/users/$($UserId)/microsoft.graph.revokeSignInSessions"
Invoke-MgGraphRequest -Uri $Uri -Method Post
$NewPassword = @{}
$NewPassword["Password"] = "!NewYorkCity2022?"
$NewPassword["ForceChangePasswordNextSignIn"] = $True
Update-MgUser -UserId $UserId -PasswordProfile $NewPassword -AccountEnabled:$True
```

Some consequences flow from disabling a user account, including that Teams removes the disabled account from its membership rosters. While you might expect this to happen for org-wide teams, it often surprises administrators when they discover the removal of disabled accounts from other Teams. A Teams background process performs the removal, and this could take place several days after disabling the account. If an administrator reenables the account, Teams adds the account back to membership rosters. Again, this process can take some time. Other issues exist, as [documented here](#). An alternative to blocking an account is to change its password and force a sign-out from all sessions. The account remains active but is inaccessible unless a person has the new password.

## Permanently Removing User Accounts and Mailboxes

When you delete a user account, it remains in the Azure AD recycle bin for 30 days. You can remove the account permanently (hard deletion) beforehand by:

- Selecting the account in the Deleted users section of the Azure AD admin center and deleting it there.
- Running the `Remove-MgDirectoryObject` cmdlet

Permanent removal means that *no recovery is possible*. Azure AD synchronizes the removal to workload-specific directories, such as EXODS, to ensure the removal of any workload-specific objects such as the user's mailbox. Microsoft cannot recover user objects after permanent removal and cannot recover any workload-

related data either. Remember, Microsoft does not take backups of Azure AD or Exchange Online. It is therefore clear that deciding to make a user account irrecoverable should only happen when you are certain that it's safe to remove the object and its data.

## Putting a User Mailbox on Litigation Hold

After blocking the user account, you should place its mailbox on litigation hold to ensure that no one can remove information from the mailbox. As an example, this command places a mailbox on litigation hold and updates the *RetentionComment* property with details of who applied the hold and the date of its application.

```
[PS] C:\> Set-Mailbox -Identity 'Bad Employee' -LitigationHoldEnabled $True  
-RetentionComment ("Employee Terminated on " + (Get-Date) + " by "  
[System.Security.Principal.WindowsIdentity]::GetCurrent().Name)
```

You can create a core eDiscovery case (Chapter 18) whose only purpose is to manage a hold on mailboxes for ex-employees. Create a hold within the eDiscovery case and add the mailboxes that you want to keep to the hold. You can also add the OneDrive for Business sites belonging to ex-employees to the hold if you want to preserve their contents.

Risk always exists that a soon-to-be-terminated employee might hear of their impending fate in advance and not react well to the news. They might then decide to remove information from their mailbox and other data repositories (shared mailboxes, group mailboxes, Teams conversations, SharePoint Online document libraries, their OneDrive for Business personal site, and so on) before management makes the formal announcement. This is a tricky situation because of the lack of backups for cloud applications, but it is somewhat mitigated by the ability to assign retention policies to SharePoint Online sites to stop people from removing information.

Placing the mailboxes of affected employees on hold as soon as possible after management decides that the employees are leaving will preserve the mailbox contents no matter what steps their owners take to remove information, but it does create the possibility that employees will learn about their impending departure when HR asks IT to place mailboxes on hold. One way to fix this issue is to create a special RBAC role that allows HR representatives to place mailboxes on hold. This will not stop a maliciously-minded individual from erasing data from SharePoint Online or their OneDrive for Business account, but you can ask Microsoft support to help recover information removed from SharePoint using the backups that they take.

## Long-term Mailbox Preservation

Two choices exist as to how to preserve the mailbox for the long term. You can convert it into a shared mailbox or make it an inactive mailbox.

- **Convert to a shared mailbox:** An EAC option exists for this purpose. Converting to a shared mailbox removes the need for a license (unless the new shared mailbox has an archive mailbox, you place the shared mailbox on hold, or assign it a larger quota than the default 50 GB) and keeps the mailbox contents online so that whoever needs to access the mailbox can open it. Note that this option does *not* guarantee data preservation or immutability, as anyone with permission to access the shared mailbox can modify it unless you have applied a hold. You should check that full delegate auditing is enabled for the mailbox (see Chapter 21) so that Exchange records whatever actions the delegates take with items in the mailbox. Because the purpose of the shared mailbox is to preserve information, you should prevent people from sending messages to the mailbox by changing its SMTP address and hiding it from the GAL. You also need to remove the mailbox from the membership of any distribution lists and Groups to which it belongs and revoke its access to other SharePoint Online sites. Converting the mailbox of a departed employee to a shared mailbox is a simple and effective way to preserve mailbox contents that is preferable if you think that someone

will need to access the information in the mailbox in the short term. If you have the necessary licenses, you should put the mailbox on hold if you need to retain its contents for compliance purposes.

- **Convert to an inactive mailbox:** If no need exists for short-term access to the mailbox contents, you might prefer to “warehouse” the mailbox by making it inactive. As explained earlier, two prerequisites exist: first, the mailbox must be on hold before the account is removed. Second, the account must have a license that supports retention policies to allow the mailbox to be put on hold. Once the mailbox is on hold, it is safe to remove the user account because Exchange Online will keep the mailbox until the hold lapses, or the tenant removes all holds which apply to the mailbox. No one will be able to log into the mailbox and no need exists for a license. When a mailbox is made inactive, Exchange removes it from address lists and distribution lists. A mailbox can stay in the inactive state for a sustained period, but you can recover or restore an inactive mailbox if needed. Information held in the mailbox remains available for eDiscovery searches.

Exchange Online Plan 2 (included in Office 365 E3 and E5) or the Exchange Online Archiving add-on license are needed for retention policies. Because of this, mailboxes belonging to accounts with lower-cost licenses like frontline workers can't be made inactive and therefore their mailboxes must be converted into shared mailboxes if the need exists to retain these mailboxes for compliance purposes.

As noted earlier, you can run the *Remove-MgUser* cmdlet to remove a user account. Removing a user account releases the licenses assigned to the account. You can either reassign the licenses to other accounts or reduce the number of licenses that you pay for each month.

The steps needed to disable and preserve an employee's account in a hybrid deployment are different. Remember that in this scenario, the on-premises Active Directory is the master and all changes to accounts and mailboxes must happen on-premises and then synchronize to Azure AD, which usually creates a delay before a guaranteed block exists for an account.

## Dealing with Other Workloads

Of course, because information exists in many other places in Microsoft 365 workloads than the user's mailbox, administrators need to do some added work to look for and recover anything considered valuable. These include:

- The equipment was issued to the employee. PSTs and documents might be on the hard drive of the user's PC and hold information invisible to administrators unless they can gain physical access to the drive. In terms of the potential for information leakage, PSTs are especially vulnerable as users can remove them from the organization on easily portable USB thumb drives along with copies of documents downloaded from SharePoint and OneDrive for Business sites. You can scan the audit log to figure out whether the ex-employee downloaded an excessive number of files during their last weeks of employment, but it is impossible to know whether they copied messages from Outlook to a PST and took that PST with them. Copies of documents and messages protected with sensitivity labels cannot be accessed when someone leaves the organization because the ex-employee needs to authenticate using a valid account before they can open the content. This is a good reason to use sensitivity labels to protect confidential information.
- Given the widespread use of mobile devices, a terminated employee probably used a personal mobile device to access their mailbox. Because of caching, it might be possible to use cached credentials to connect to the mailbox with a mobile device even after the employee leaves. Given that a user might have multiple mobile devices, it is best to issue a remote wipe for all ActiveSync devices registered with the mailbox. Any future attempt to access the mailbox via ActiveSync will wipe the device that issues the connection request. Depending on how the mobile device vendor has implemented the ActiveSync protocol within the email client, the wipe might affect some or all

personal data. To wipe all the ActiveSync devices connected to a user account, run the following PowerShell command:

```
[PS] C:\> Get-MobileDevice -Mailbox 'Bad Employee' | Clear-MobileDevice
```

- Microsoft Endpoint Manager has more selective wipe capabilities for its managed devices than ActiveSync has. See [this page](#) for information about how to perform a full or selective wipe of a mobile device with Microsoft Endpoint Manager.
- The employee's OneDrive for Business site. Because this site stores personal information belonging to the removed user, its contents are out of sight to administrators unless you take steps to recover data after the removal of a user account. By default, unless the site is on hold, after the removal of a user's account, their OneDrive for Business site becomes a candidate for removal after 30 days by a background process (the My Sites Clean Up timer job). A message goes to the user's manager to warn that this will happen, and a second reminder goes 3 days before SharePoint Online removes the data. However, if the information in Azure AD does not allow SharePoint Online to decide who is the user's manager, SharePoint obviously cannot send the notification. If 30 days is too short a retention period, you can increase it to anything up to 3,650 days. For instance, this command sets a retention period of one thousand days.

```
[PS] C:\> Set-SPOTenant -OrphanedPersonalSitesRetentionPeriod 1000
```

- You can ensure continued access to the OneDrive sites owned by ex-employees by configuring the SharePoint Online settings to automatically assign a secondary owner to OneDrive for Business sites. Go to the **More features** page of the "new" SharePoint admin portal, open the **User Profiles** item, click **Setup My Site** under **My Site Settings**, verify that the **Enable access delegation** box is checked, and then select a user account to be the secondary owner. If Azure AD does not hold details of a manager for the removed user, SharePoint sends the reminders to preserve data to the secondary owner, who can then arrange for a review of the data and the capture of anything that needs preservation to another location (for example, another user's OneDrive for Business site or a SharePoint Online team site).
- SharePoint Online team sites and traditional sites that the user manages. The other users who have access to these sites can continue to work with the information held in the libraries and lists and the SharePoint Online administrator can grant ownership to these sites to a different user.
- Groups and Teams. If the user is the sole owner of a group or team, you should assign that role to another user. If you want to capture information about the conversations that an employee has participated in, you can run a content search against the group mailboxes for the teams they belong to and their mailbox for items. Once the search is complete, you can then export the results to a PST or ZIP file.
- The user might have created some videos in Stream that the organization might want to keep for reuse. When you remove an account, the videos owned by the account remain accessible in Stream. However, it's best to assign ownership for those videos to another person so that they can maintain permissions and settings. A Stream administrator can reassign video ownership.
- The user might have created some whiteboards to share ideas and concepts, including in Teams meetings. When you remove an account from Azure AD, any whiteboards the account owns are also removed. The [Invoke-TransferAllWhiteboards](#) cmdlet can be used to transfer ownership of whiteboards from one user to another.
- You can recover Microsoft Forms created by an ex-employee and transfer them to another user. See [this page](#) for information.

It is sensible to review the list of data sources annually as the potential places where users can store valuable corporate data might grow as the feature set available within Microsoft 365 expands.

**Removing Calendar Events:** When someone leaves the organization, their mailbox may be the organizer of events that exist in other peoples' calendars. In many cases, you might want to remove those events from calendars to allow someone else to reschedule replacement events (or not, as the case might be). The *Remove-CalendarEvents* cmdlet cancels future events organized by a specific mailbox and sends out cancellation notices. For example, this command cancels all meetings organized by Nancy Anderson from today's date, which is probably what you would do for an employee leaving the organization. Remember to run the cmdlet before you remove the mailbox.

```
[PS] C:\> Remove-CalendarEvents -Identity "Jim.Doe@Office365itpros.com" -CancelOrganizedMeetings
```

On the other hand, if the user is going away for an extended period and will eventually return, you can run the cmdlet to cancel events for a date range. See [this page](#) for more information about the cmdlet.

## Handling Inbound Email for Ex-Employees

When you convert a user mailbox to a shared mailbox, the mailbox keeps all the assigned email addresses and can continue to receive emails sent to the mailbox. Someone will need to process messages that arrive in the mailbox to let the senders know that the intended recipient no longer works at the company.

Alternatively, you can change the assigned email addresses so that Exchange will "bounce" (send a non-delivery notification) any new messages sent to the mailbox.

You can let people who try to contact the now-departed employee receive the normal non-delivery notification or you can create a better experience by telling them why the person they tried to contact is no longer available. This PowerShell code sets up internal and external auto-replies for the mailbox and adds a MailTip that is visible to internal users. We also hide the mailbox from all address lists and enable mailbox auditing to track any access that occurs to the mailbox.

```
[PS] C:\> Set-MailboxAutoReplyConfiguration -Identity "Terminated Employee" -InternalMessage "The person you are emailing no longer works for us. Please refer communications to Mr. Manager" -ExternalMessage "Mr. Terminated Employee is no longer an employee of this company." -AutoReplyState Enabled
```

```
Set-Mailbox -Identity "Terminated Employee" -MailTip "Terminated Employee has left the company. Please do not send any more mail to their mailbox" -HiddenFromAddressListsEnabled $True
```

Auto-replies and MailTips inform users about people that are no longer with the company if the mailbox still exists in an active state. However, we might want to remove the mailbox completely after harvesting any useful data in it. Exchange Online does not have a way to inform correspondents that a mailbox is no longer in use, but we can do this by creating a shared mailbox to hold the email addresses previously assigned to removed mailboxes or the old addresses of user mailboxes that have been converted to shared mailboxes. In effect, you use the shared mailbox (which does not need a license) to redirect inbound messages so that the senders will receive some information to inform them that their correspondent is no longer available.

Although Exchange Online limits the number of SMTP proxy addresses that you change assign to a mail-enabled object, a shared mailbox can easily hold 400 email addresses. If you need to keep a higher number of addresses for departed employees, you can spread the addresses over several mailboxes. One technique is to create a shared mailbox for each department so that external senders can receive an autoreply giving them details of a new contact within the department.

Of course, the shared mailbox will act as a black hole if you simply add the email addresses of departed employees to it. To complete the process, you should create an autoreply for the shared mailbox so that Exchange Online will respond to the senders after it delivers inbound messages for the addresses assigned to the shared mailbox. Ideally, the autoreply will tell the sender that they should not use the address in the future.

Although there might be some value gained by receiving email in the shared mailbox, often companies do not want to accumulate messages from people who have left. It can be an onerous task, not to mention a potential breach of personal privacy, if someone accesses the shared mailbox to process and respond to the messages found there, so the best solution is often to institute an automatic bounce mechanism to suppress inbound messages. This can be achieved with the combination of a distribution list and a transport rule. Here's how:

- Create a normal distribution list and add the shared mailbox (or mailboxes if necessary) to its membership. Make sure that the group owner (by default, the administrator who creates the group) is not added to the membership as they will not be able to receive new mail once the transport rule created in the next step implements a block for group members.
- Now create a transport rule to intercept messages sent to the members of the distribution list and return a rejection notice to the senders. We provide suitable text to explain why the rule rejects messages.

```
[PS] C:\> New-TransportRule "Block Email to Disabled Mailboxes" -SentToMemberOf "Disabled Mailboxes" -RejectMessageReasonText "Unfortunately the person with whom you attempted to communicate is no longer with our company." -Enabled $True
```

Once enabled, the rule will reject any message sent to one of the SMTP addresses assigned to the shared mailboxes in the distribution list. It is a simple but effective way to provide a better user experience.

## When Someone Dies

All of us will die someday. In large organizations, statistics show that the likelihood exists that one or more employees will die per 10,000 annually, depending on the average age of employees. Given the era we live in, when we do pass on, we will leave behind many digital assets, among which might be a corporate mailbox. It's a good idea to have a procedure to preserve the mailboxes and other information belonging to dead employees. The steps that you might take are like those that you use to preserve content in mailboxes for terminated employees and include:

- Disabling or blocking the account.
- Deciding if the mailbox should become an inactive mailbox or remain online. Alternatively, if you run a hybrid deployment, you could move the mailbox back to an on-premises database that is reserved for this purpose. The purpose of keeping the mailbox is to allow for the retrieval of any valuable information from the mailbox within a retention period decided by HR and/or the legal department and in compliance with applicable regulations such as GDPR. Some arrangements should be put in place to extract personal information from the mailbox and give it to the employee's family. For instance, some people store passwords and other valuable information in their mailboxes that might be needed by their family following their death. Personal and corporate data might also need to be recovered from the user's OneDrive for Business site. After retrieving whatever information is considered valuable from the mailbox, you might move it into an inactive state and keep the mailbox for a further period.
- Removing the mailbox from any distribution lists and the Groups/Teams to which it belongs. You can discover what groups a mailbox belongs to by looking at the mailbox properties via EAC or by running some PowerShell code (an example is in Chapter 11). If you make a mailbox inactive, its membership in distribution lists and groups is automatically canceled.
- If the mailbox remains online, remove the mailbox's access to any shared mailboxes. You can consider adding the mailbox to a special "Departed Employees" distribution list, which is hidden from the GAL. Some companies like to use a transport rule that blocks any incoming messages sent to the members of the "Departed Employees" group. The rule might also generate a customized NDR back to senders to inform them of the sad demise of the intended recipient. As described

above, you can use the *RejectMessageReasonText* parameter for the *New-TransportRule* cmdlet to create a thoughtful response to messages sent to a deceased employee. An alternative is to set an auto-reply message on the user's mailbox by either logging onto the mailbox or using the *Set-MailboxAutoReplyConfiguration* cmdlet (explained in Chapter 6).

Eventually, the retention period for policies applying to the mailbox or retention labels assigned to mailbox items will elapse, and you will either remove the user's account or cancel the hold that keeps their mailbox inactive.

Remember that a user is likely to have responsibility for documents and other information in other places across the service and that some effort is necessary to track down this information and transfer it to the safekeeping of another user.

**Humane effectiveness:** Although it is good to have a well-documented process to handle what happens when users die, it is also good if an organization can show some humanity. Some large businesses delegate the authority to manage the process of securing the digital assets of deceased employees to joint HR/IT teams who can flex and alter the process as necessary to meet the needs of any specific circumstances that might arise. The IT members of the team ensure that the technical processes are followed while HR ensures that everything is done humanely and thoughtfully. It is a good approach to follow.

## Compromised Accounts

A compromised account is one where someone outside the tenant (an attacker or hacker) manages to gain access to the account resources. Usually, this is because the attacker obtains the credentials necessary to sign in to the account, perhaps because their account credentials are compromised through a breach of another site.

Signs of unusual activity such as missing data, new rules or a forwarding address appearing in the mailbox that the user can't remember setting up, or strange emails from the mailbox might be indications of a compromised account. The steps necessary to secure the account and prevent further unauthorized access are:

- Block the account.
- Reset the account password and enable it for multi-factor authentication if not already done.
- Check all the mailbox settings to ensure that inbox rules, sweep rules, and forwarding addresses are valid (if a forwarding address exists outside the organization, ask if a business purpose exists for forwarding email to that address).
- If the account has administrative access, check what data might have been compromised through this access, validate that the access is needed, and remove it if not.
- The audit log can help you find what data the account has accessed recently. You should check any documents the account uploaded to SharePoint or OneDrive for Business to ensure that they don't contain malware.
- When the account is completely checked out, unblock it and give the new password to the user.

Microsoft's advice on the topic is in [this support article](#).

# Chapter 6: Managing Exchange Online

**Tony Redmond**

Two base workloads are the critical underpinning for much of the work within a tenant: Exchange Online for email, and SharePoint Online (including OneDrive for Business) for document management. Access to these workloads is reason enough for many companies to move to the cloud. This chapter reviews Exchange Online and discusses how it differs from its on-premises counterpart when it comes to what's stored inside online mailboxes and how to manage these objects.

## Exchange Online

For many companies, email is the first workload that they move into the cloud. Given the popularity of Exchange since its introduction in 1996, it was therefore unsurprising that many of the early organizations that moved to the cloud were migrations from on-premises Exchange servers.

Exchange Online is the cloud-based version of Exchange. Or is it? Both products share common roots and common functionality, but the version of Exchange that runs inside the cloud is very different from its on-premises counterpart. As we will see, the difference is somewhat inevitable given that Exchange Online must function inside a massive multi-tenant infrastructure while Exchange on-premises is designed to be able to serve the needs of many different customers, each of whom might adopt a different method to deploy and manage Exchange.

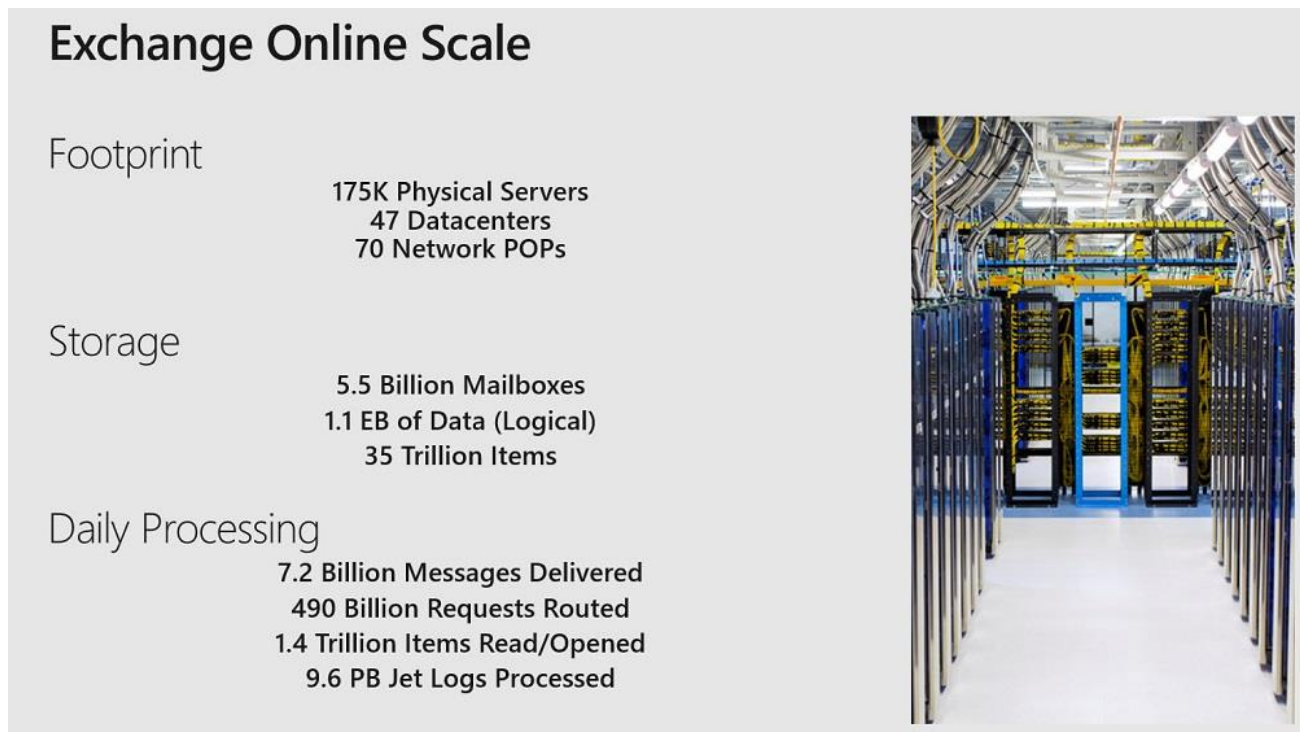

Figure 6-1: The scale of Exchange Online (source: Microsoft – Ignite 2018 conference)

The number of Exchange Online servers grows in line with the number of Office 365 accounts. At the Ignite conference in October 2018, Microsoft said that Exchange Online used 175,000 physical servers (Figure 6-1). Two years later, at the TEC 2020 conference, Microsoft reported that the number of Exchange Online servers had increased to 275,000, the number of data centers supporting Exchange Online had grown to 56, and 155 network point of presence (POPs) existed to carry client traffic to Microsoft's data center network. The email infrastructure delivered 10 billion messages daily while blocking two billion spam messages. Microsoft hasn't published updated numbers for Exchange Online since 2020, but given the growth in demand for Office 365 accounts, you can imagine how the numbers reported above have grown.

Microsoft's claim for Exchange Online to span five and a half billion mailboxes seems enormous in the context of 345 million paid Office 365 subscriptions, but the figure includes Outlook.com users ([400 million switched over to use the Exchange Online infrastructure in 2017](#)), shared mailboxes, group mailboxes, resource mailboxes, special cloud-only mailboxes used for compliance, and a very large number of system mailboxes used by the Microsoft 365 substrate. In other words, user mailboxes are a small minority of those active inside Exchange Online.

## Consumer Email

Exchange Online and Outlook.com share the same physical infrastructure. Outlook.com users receive service from mailboxes running on Exchange Online servers and connect to their mailboxes using a modified version of OWA. The functionality exposed in the consumer version of OWA is controlled to ensure that consumer accounts do not have the same level of functionality that's available to Exchange Online users; it's also segmented in terms of the functionality available to premium and free accounts. However, functionality developed for one platform does show up in the other. For example, the Sweep feature first appeared in Outlook.com before Microsoft decided to make it available to Exchange Online users. On the other hand, the Encrypt email feature first appeared in Exchange Online before it showed up in Outlook.com. Sharing the same physical infrastructure makes it very easy for Microsoft to switch features between the consumer and business platforms.

## Exchange Online Data Center Operations

Unlike the other Microsoft 365 services, Exchange Online still uses physical servers. The servers in the available pool receive updates on a rolling basis. Up to 10% of the servers are offline at any point. When the time comes to upgrade a server, Microsoft puts the server into maintenance mode, messaging queues are drained, and any active databases hosted by the servers move to other servers. The servers then leave the active pool. The refresh applies the latest version of the operating system, any required patches, and the latest build of Exchange to create a fully up-to-date server, which is then reintroduced into the operating pool. The passive copies of databases hosted by the server use the normal log shipping and replay mechanism to update themselves when the server comes back online. Eventually, the upgraded server becomes a candidate for database activation and the update cycle completes. Microsoft uses the wipe-and-load technique because it is a much simpler process than trying to keep servers updated with Windows and Exchange patches, service packs, and other fixes. At any point in time, Exchange Online servers run a variety of software versions because of their position in the refresh cycle. This can account for why some tenants see slightly different functionality than others. Given the number of servers in use, it is inevitable that some servers will not function as smoothly as they should. When this happens, Microsoft often finds that it is more cost-effective and simpler to shoot the server and remove it from the service than to try to perform a potentially complex hardware diagnosis and fix.

An on-premises administrator who paid a visit to a data center and reviewed how Microsoft runs Exchange Online would see some very familiar things, but many operation details are very different. The fundamentals of running a messaging system stay the same – users authenticate against Azure AD to connect to mailboxes

to receive and send emails. Messages exist in databases on Exchange mailbox servers and are transported to their destination via transport servers. Connectors link servers together and to the rest of the Internet via SMTP. Database replication hums along in the background to ensure that copies of user mailboxes are in four databases spread across at least two data centers. Apart from the sheer size of the infrastructure to support both Exchange Online and Outlook.com, the structure of mailboxes in databases running in Database Availability Groups spread across mailbox servers is very recognizable.

**The Largest Migration?** In February 2021, the [UK National Health Service](#) (NHS) completed the migration of 2.1 million mailboxes from on-premises servers to Exchange Online. About 2.3 petabytes of data was moved over six months at rates of up to 83,000 mailboxes daily. The NHS is the largest single Office 365 tenant. As far as we know, this is the largest mailbox migration to Exchange Online performed to date.

## Native Data Protection

Many people are struck by the fact that Microsoft does not backup the Exchange Online mailbox databases. Instead, Native Data Protection, a resiliency strategy formed by many different features incorporated into the Database Availability Groups, Information Store service, and transport service, protects data and removes the need for backups.

### Database Availability Groups

The Database Availability Group (DAG) is the cornerstone of Exchange Online storage. Mailboxes are stored in mailbox databases deployed in a DAG. Each DAG has sixteen mailbox servers spread across the data centers within a region. For instance, within the EMEA region, DAG member servers are in the Amsterdam, Dublin, Helsinki, and Vienna data centers. Each mailbox database has four copies distributed across servers in the data centers. The active copy is accessed by clients while the three other copies, one of which is lagged (kept seven days behind the active copy), synchronize with the active copy using log shipping and replay. Exchange captures transactions in transaction logs. Log shipping copies transaction logs generated by the active database copy to the servers holding passive copies. The target servers check the transaction logs as they arrive, and if the logs are valid, replay their contents to update the passive copy.

Because the DAG member servers are connected using Microsoft's high-speed data center network, the copy and replay operations are almost instantaneous. If a problem occurs with the active server, Exchange decides which of the passive copies to activate and switches it to service client connections. The previously active server then becomes a host for a passive copy.

Exchange Online servers use the ReFS file system (available in Windows Server 2012 or later) to gain better protection for data and to verify the integrity of data written to disk. The Exchange servers use a mixture of SSD (for the metacache) and JBOD RAID arrays and can automatically swap a replacement disk into an array should one fail.

### Database Engine Checks

Apart from log shipping and replay (which include consistency checks), the DAG includes other features to ensure that physical or logical corruption does not creep into databases. These include:

- **Single-bit correction:** The database engine detects and fixes single-bit CRC errors that result from hardware problems. The errors are corrected and flagged so that Microsoft's operations team can investigate.
- **Database consistency checker:** A background process reads and checks database pages for checksum failures. Any failed page is automatically fixed. The scheme used makes sure that every page is checked in a database every seven days.

- **Lost flush detection:** Lost flushes happen when the operating system (or disk) reports that a write happened, but the write operation did not complete (or is written to the wrong place). This represents logical corruption. To prevent this from happening, the database engine checks pages as it writes them to passive database copies. If a problem is found, it is fixed through single page patching.
- **Single page patching:** This is a process to replace bad database pages with good pages from other database copies in the DAG. If the problem is detected in a passive copy, the database engine copies the good page from the active database using the transaction log shipping and replay mechanism. If the problem is in the active database, the good page can come from any passive copy.

These features also exist in the on-premises version of Exchange.

## Other Exchange Resiliency Features

In addition to the DAG and database engine features, Exchange builds resilience into the transport service so that messages are always sent, even when failures occur. Shadow Redundancy means that the transport service takes a (shadow) copy of each message it receives. If Exchange ever thinks that a message might not have been processed, it can resubmit the shadow copy. The Safety Net queue captures copies of messages as they pass through the transport pipeline. If a failure occurs in the transport service or with a database, Exchange can replay messages from the Safety Net queue to the active database copy. Any redundant copies discovered during the replay are suppressed and not exposed to users.

Behind the scenes, Exchange Online servers are rebalanced on an ongoing basis to ensure that each takes approximately the same amount of user load. In addition, Microsoft withdraws mailbox servers from service to update their software as the need arises. These operations force mailboxes to be moved between databases. The Mailbox Replication Service (MRS) moves mailboxes between databases. During the moves, MRS checks mailbox contents for problems and if it detects problem items, it attempts to correct the items. If this isn't possible, MRS skips the corrupt items.

## Tenant-Controlled Resiliency Features

Tenants can control some mailbox management features that assist in resiliency. These include:

- **Single Item Recovery (SIR):** This feature ensures that Exchange Online retains messages that users purge (hard delete) in the Recoverable Items folder of mailboxes until the deleted item retention period expires. The maximum deleted item retention period is 30 days.
- **In-place and Litigation holds:** Holds make sure that Exchange keeps select items or all items in a mailbox for the set retention period. If a mailbox is deleted when it is subject to a hold, it becomes inactive, meaning that it is retained until the hold elapses. Holds can also be set by retention policies.
- **Large mailbox quotas:** Many enterprise licenses include 100 GB mailbox quotas. In effect, many users do not need to delete messages. If they do, the messages go into the Deleted Items folder and stay there until the user empties the folder. Even then, the deleted items go into the Recoverable Items folder (which can have another 100 GB quota) from where they can be recovered if needed for up to 30 days (the deleted items retention period).
- **Expanding archives:** Mailboxes can be archive-enabled. An archive mailbox is designed for long-term storage and its basic quota is 100 GB. However, tenants can opt for expandable archives, which means that the archive is composed of 50 GB "chunks" linked into a logical entity.
- **Retention labels and policies:** To ensure that important information is kept for defined periods, users can apply retention labels to folders and items. Exchange Online does not remove items under retention control until the retention period elapses. See the Compliance chapter for more information about Microsoft 365 retention policies and processing.

The combination of the DAG, database copies, database engine features, transport copies, and tenant-controlled resiliency features are enough for Microsoft to conclude that they do not need backups for Exchange Online mailbox data. Your situation might be different, but in many cases, tenants do not need to invest in a third-party backup service either and full consideration should be given to how to maximize the use of out-of-the-box functionality to decide if Native Data Protection meets the perceived need for backups.

## Managing Mailboxes

Exchange Online mailboxes hold a mixture of default, system, and user-created folders. The default folders are the set of well-known folders like the Inbox that exist in every mailbox. Some people only ever use a small set of default folders – Inbox, Sent Items, and Deleted Items – while others are dedicated filers and store items away in carefully-selected folders. Colloquially, the two types of users are “pilers” and “filers.” If its limits are respected, Exchange doesn’t care how data are organized in a mailbox. Limits for internal mailbox structures include:

- Maximum number of items per mailbox folder: 1 million
- Maximum number of items in the Recoverable Items folder: 3 million
- Maximum number of subfolders per mailbox folder: 10,000 (including the root folder)
- Maximum folder hierarchy depth: 300

Most won’t encounter a mailbox’s internal limits, but many have exceeded their storage quota.

You’ll find that we use PowerShell to manage many mailbox settings. To run these commands, you must connect a session to the [Exchange Online Management](#) endpoint.

### Unique Mailbox Identifiers

In June 2022, Exchange Online changed the way that it generates the Name and Distinguished Name properties for new mailboxes. Instead of using the *MailNickName* property from the Azure AD account as the basis for the *Name* and *DistinguishedName* properties, Exchange uses the Azure AD object identifier for the account when it creates new mailboxes. EXODS stores the object identifier (also called EDOID) for Azure AD accounts and groups in the *ExternalDirectoryObjectId* property.

The aim is to guarantee uniqueness for the *Name* and *DistinguishedName* properties to avoid issues when account data synchronizes from Azure AD to Exchange Online when accounts are homed on-premises. The problem arises because Active Directory creates objects in multiple organizational units whereas Azure AD creates objects in a single organizational unit named after the tenant. Thus, an Active Directory object with a *Name* property of John.Smith will cause a synchronization conflict if a similarly named object exists in a different organizational unit. Because Exchange Online stores the EDOID in the *Name* property for new mailboxes, including those created as remote mailboxes from the on-premises EAC, Azure AD no longer synchronizes the *Name* property with Active Directory.

The example below illustrates the new format for the *Name* and *DistinguishedName* properties:

```
[PS] C:\> Get-ExoMailbox -Identity b67c8bd7-a8d3-4358-b42f-cd51821f7ba3 -Properties Name
ExternalDirectoryObjectId : b67c8bd7-a8d3-4358-b42f-cd51821f7ba3
UserPrincipalName : Sue.P.Pickett@office365itpros.com
Alias : Sue.P.Pickett
DisplayName : Sue Pickett
Name : b67c8bd7-a8d3-4358-b42f-cd51821f7ba3
DistinguishedName : CN=b67c8bd7-a8d3-4358-b42f-cd51821f7ba3,
OU=Office365itpros.onmicrosoft.com,OU=Microsoft Exchange Hosted
Organizations,DC=EURPR04A002,DC=prod,DC=outlook,DC=com
```

Exchange Online will not update the properties of mailboxes created before the change became effective. However, if you want, you can update mailbox properties. For example:

```
[PS] C:\> $ExternalDirectoryObjectId = Get-ExoMailbox -Identity Kim.Akers@Office365itpros.com |
Select -ExpandProperty ExternalDirectoryObjectId
Set-Mailbox -Identity $ExternalDirectoryObjectId -Name $ExternalDirectoryObjectId
```

After you update the Name property, Exchange Online updates the Distinguished Name property to match.

## Calendar Permissions

While granting delegate access via Outlook or OWA are the normal ways for users to allow other people access to a folder like their calendar, administrators can run the *Add-MailboxFolderPermission* cmdlet to do the same. For example, this command gives delegate access to Michael Harty for the calendar of Kim Akers. The Editor access right is needed to create and edit items in the folder, and the sharing permission flags tell us that the delegate can see private items in the target calendar. In this case, *SendNotificationToUser* is specified to send a sharing notification to the new delegate to tell them that they can now access someone else's calendar. In some cases, you will not want to generate a sharing notification as the potential exists that the recipient might unwittingly refuse the invitation.

```
[PS] C:\> Add-MailboxFolderPermission -Identity Kim.Akers@office365itpros.com:\Calendar -User
Michael.Harty@office365itpros.com -AccessRights Editor -SharingPermissionFlags Delegate,
CanViewPrivateItems -SendNotificationToUser $True
```

FolderName	User	AccessRights	SharingPermissionFlags
Calendar	Michael Harty	{Editor}	Delegate, CanViewPrivateItems

To remove delegate access from a mailbox, run the *Set-MailboxFolderPermission* cmdlet and set the *SharingPermissionFlags* parameter to None.

Exchange holds details of delegate access in a hidden item in the user mailbox. Sometimes this item can become corrupted, and the user will no longer be able to add or remove delegates. In this case, you should run the *Remove-MailboxFolderPermission* cmdlet with the *ResetDelegateUserCollection* parameter to force Exchange to recreate the hidden item.

```
[PS] C:\> Remove-MailboxFolderPermission -Identity Kim.Akers@office365itpros.com:\Calendar
-ResetDelegateUserCollection
```

This action has the side-effect of removing the flags which enable delegate access. To complete the fix, you must recreate the delegate settings with *Set-MailboxFolderPermission*. For example, this command re-establishes Michael Harty as a delegate to manage the calendar in the mailbox of Kim Akers.

```
[PS] C:\> Set-MailboxFolderPermission -Identity Kim.Akers@office365itpros.com:\Calendar -User
Michael.Harty@office365itpros.com -AccessRights Editor -SharingPermissionFlags Delegate,
CanViewPrivateItems
```

## Regional Settings

When you create a new Exchange Online mailbox, none of its regional properties are set. These are the properties that define the language used to interact with the mailbox, the time zone that the mailbox owner is in, and their preferred date format. The first time someone logs into a mailbox with OWA, the client prompts them for this information, sets the properties, and creates a set of default folders in the mailbox based on the language setting. For example, mailboxes that use the English language have an *Inbox* folder, while mailboxes configured for French have *Boîte de réception*. If you connect to a brand-new mailbox with an Outlook desktop or a mobile client, the mailbox takes the language setting of the client and creates the default folders based on that value, but the other regional settings might not be set. To see the default regional configuration for a mailbox, we run this command:

```
[PS] C:\> Get-MailboxRegionalConfiguration -Identity 'Rob Young'
```

If necessary, you can run the *Set-MailboxRegionalConfiguration* cmdlet to tweak the regional settings. In this example, the mailbox language, time zone, and date format match the settings for a Dutch user working in the Netherlands. Notice the use of the *LocalizeDefaultFolderName* parameter, set to *\$True* to force Exchange Online to create the default folder names in the target mailbox using specified language:

```
[PS] C:\> Set-MailboxRegionalConfiguration -Identity 'Rob Young' -Language n1-NL
-TimeZone 'W. Europe Standard Time' -DateFormat 'd-M-yyyy' -TimeFormat 'HH:mm'
-LocalizeDefaultFolderName:$True
```

Exchange Online can be picky about the date and time formats used when updating mailbox regional configurations. The formats must be valid for the selected language. Sometimes it can be difficult to know what acceptable values are for date and time formats. A practical approach is to use OWA to change the regional settings for a mailbox and then examine the values for the mailbox's regional configuration. You can then reuse those values with other mailboxes. To know the values for the timezone setting, you can run this PowerShell code to report the values stored in the system registry:

```
[PS] C:\> $TimeZone = Get-ChildItem "HKLM:\Software\Microsoft\Windows NT\CurrentVersion\Time zones"
| ForEach {Get-ItemProperty $_.PSPath}; $TimeZone | Sort-Object Display | Format-Table PSChildname,
Display -Auto
```

Users can select their language and region settings through OWA. The selected language controls the language used in the OWA interface. It has less effect when using Outlook because the user interface is set by the version of Outlook installed on the workstations. A user can switch their language setting for OWA at any time, which can lead to interesting results if someone selects a language that they don't understand.

## Auto replies and Out of Office Notifications

Out of Office or OOF ([Out of Facility](#)) are names used for the autoreply feature which allows mailboxes to send automatic replies after the arrival of new messages. The *Get-MailboxAutoReplyConfiguration* and *Set-MailboxAutoReplyConfiguration* cmdlets retrieve and set the autoreply settings for a mailbox, including shared mailboxes. Users receive autoreply messages when they send emails to mailboxes that have an autoreply message configured and enabled. Exchange Online also displays a recipient's autoreply in clients like Outlook desktop when adding the recipient to a message. To discover which mailboxes have autoreply set and the time the autoreply lapses, you can use the following command:

```
[PS] C:\> Get-ExoMailbox -RecipientTypeDetails UserMailbox | Get-MailboxAutoReplyConfiguration |
Where {$_.AutoReplyState -eq "Scheduled" -or $_.AutoReplyState -eq "Enabled"} |
Format-List MailboxOwnerId, StartTime, InternalMessage
```

The first check looks for auto-replies scheduled for a specific period, the second finds mailboxes where the autoreply is enabled without dates. The *InternalMessage* property reveals the HTML-formatted text of the auto-reply message for internal correspondents (*ExternalMessage* holds the text seen by external correspondents).

### Setting Autoreply for Mailboxes

You can use the *Set-MailboxAutoReplyConfiguration* cmdlet to create an autoreply for a user who has gone on vacation and forgotten to let anyone know. Another scenario is when public holidays occur, and you want to set the autoreply for customer-facing shared mailboxes to let anyone who sends an email to the company know that a response will be delayed. In both instances, you enable autoreply, set a time limit, and create separate messages for internal and external audiences. You can also instruct Exchange Online that auto-replies go only to external people who are contacts of the mailbox owner (select *All* instead of *Known* if you want the auto-reply to go to anyone external who sends a message to the mailbox).

If you create an autoreply for a certain period, make sure that you set the *AutoReplyState* parameter to be "Scheduled" rather than "Enabled" as failure to do this will enable the autoreply for the mailbox at once rather than in the future. Exchange Online servers run using UTC, so if you specify a time (rather than just a date) in the start and end times, make sure that you convert the time into UTC. For example, the command below starts auto-replies at 19:30 UTC and ceases at 17:00 UTC on the respective dates.

```
[PS] C:\> Set-MailboxAutoReplyConfiguration -Identity "Kim Akers" -StartTime "04-Nov-2019 19:30"
-AutoReplyState "Scheduled" -EndTime "08-Nov-2019 17:00" -InternalMessage "Kim Akers is attending
the Microsoft Ignite event in Orlando and will respond to your message after she returns on November
10" -ExternalMessage "Kim Akers is on vacation" -ExternalAudience 'Known'
```

Note that when you view the autoreply configuration for a mailbox, PowerShell converts the times from UTC into the time zone applied to the local workstation. To turn off autoreply for a user, set the *AutoReplyState* property to "Disabled":

```
[PS] C:\> Set-MailboxAutoReplyConfiguration -Identity "Kim Akers" -AutoReplyState Disabled
```

Here's another example. In this case, we want to add auto-replies to all shared mailboxes to cover the period of a public holiday so that anyone who sends a message to the mailboxes will receive a reply to tell them that the user's out of the office. Note the use of HTML tags to add some basic formatting to the external message.

```
[PS] C:\> $HolidayStart = "04-Aug-2020 17:00"
$HolidayEnd = "6-Aug-2020 09:00"

$InternalMessage = "Expect delays in answering messages to this mailbox due to the holiday between
<b> + $HolidayStart + "</b> and <b> + $HolidayEnd + "</b>"
$ExternalMessage = "Thank you for your email. Your communication is important to us, but please be
aware that some delay will occur in answering messages to this mailbox due to the public holiday
between <b> + $HolidayStart + "</b> and <b> + $HolidayEnd + "</b>"

$Mbx = (Get-ExoMailbox -RecipientTypeDetails SharedMailbox | Select DisplayName, Alias,
DistinguishedName)
ForEach ($M in $Mbx) {
# Set auto reply
Write-Host "Setting auto-reply for shared mailbox:" $M.DisplayName
Set-MailboxAutoReplyConfiguration -Identity $M.DistinguishedName -StartTime $HolidayStart -
AutoReplyState "Scheduled" -EndTime $HolidayEnd -InternalMessage $InternalMessage -ExternalMessage
$ExternalMessage -ExternalAudience 'All' -CreateOOFEvent:$True }
```

## Autoreply Settings for Calendar Processing

OWA includes some settings to process incoming calendar requests during periods when autoreply is active for a mailbox. These settings are not yet visible to Outlook, but because they are acted upon by the server, their effect is felt when set by OWA. The options are:

- **Block my calendar for this period:** Other users will see this user's calendar as blocked out if they try to schedule a meeting during the period when autoreply is active. The *CreateOOFEvent* switch set by *Set-MailboxAutoReplyConfiguration* determines if Exchange creates a calendar event corresponding to the OOF period.
- **Automatically decline new invitations for events that occur during this period:** If new event invitations arrive, they can be automatically declined. The *AutoDeclineFutureRequestsWhenOOF* property controls this setting.
- **Decline and cancel my meetings during this period:** This option scans the user's calendar for meetings that are in place for the period when the autoreply will apply. Meetings that the user was invited to attend will be declined while meetings that they set up will be canceled. The *DeclineAllEventsForScheduledOOF* property controls this setting.

The settings can be controlled with PowerShell using the *Set-MailboxAutoReplyConfiguration* cmdlet.

## Calendar Configuration

The *Get-MailboxCalendarConfiguration* and *Set-MailboxCalendarConfiguration* cmdlets manage calendar settings. For example, this command configures the calendar to use Greenwich Mean Time (GMT) as the time zone with a starting time for the workday of 8:30 A.M.:

```
[PS] C:\> Set-MailboxCalendarConfiguration -Identity "Kim Akers" -WorkingHoursTimeZone "GMT Standard Time" -WorkingHoursStartTime 08:30:00
```

The cmdlet also controls the appearance of a user's calendar when viewed through OWA (Outlook uses different settings based on the time and time zone configured for the PC). For example, this command makes Monday the first working day of the week, starts a new year on the first day of the year, changes the default time increment from 30 minutes to 15 minutes, sets the weather unit to be Celsius, and defines the user's location to be County Dublin, Ireland. Figuring out the right longitude and latitude for a user's location might seem hard, but online tools help (like [this example](#)) or you can experiment by inputting different locations into the Weather section of the OWA Calendar options and noting what values are set.

```
[PS] C:\> Set-MailboxCalendarConfiguration -Identity "Kim Akers" -WeekStartDay Monday -FirstWeekOfYear FirstDay -TimeIncrement FifteenMinutes -WeatherUnit Celsius -WeatherLocations "{LocationId:9480;Name Dublin, County Dublin;Latitude:53.348;Longitude:-6.248}"
```

You can also use *Set-MailboxCalendarConfiguration* to control the scheduling of Teams online meetings by default by Outlook clients. A mailbox setting is available to override the organization setting created using *Set-OrganizationConfig*, but only for OWA and Outlook Mobile clients. Outlook desktop uses a different method to control if online meetings are the default for an individual account. This example configures online meetings as the default for the specified mailbox:

```
Set-MailboxCalendarConfiguration -OnlineMeetingsByDefaultEnabled $True -Identity Kim.Akers
```

### Automated Processing for Room Mailboxes

New room mailboxes receive a default value of *AutoAccept* for the *AutoProcessing* calendar property (before the default was *AutoUpdate*). The idea behind the change is to speed acceptance of meeting requests for room mailboxes. If this change doesn't fit with your corporate policies, make sure that you update new room mailboxes after creation. For example:

```
[PS] C:\> Set-CalendarProcessing -Identity NewRoom -AutomateProcessing AutoUpdate
```

For more information about how to control the processing of booking requests for room mailboxes, see [the online documentation](#).

### Viewing Details of User Availability

By default, Exchange Online makes limited free and busy information for mailboxes available to other tenant users to allow them to see when other people might be able to attend a meeting. The default setting is *AvailabilityOnly*, meaning that a user can see when someone is busy, but can't see any details about the reserved time slot. Many organizations choose to upgrade the setting to allow people to see details of slots reserved in other users' calendars. There's no organization-wide setting to control how the calendar works. Instead, you must update the permission granted to the special Default user for each calendar. The *Set-MailboxFolderPermission* cmdlet can update the permission. For instance, this code looks for mailboxes to update and runs *Set-MailboxFolderPermission* to update the access rights for the calendar folder for the Default user to *LimitedDetails*. The *LimitedDetails* setting allows other users to see the title, location, and status (out of office, tentative, etc.) for time slots.

```
[PS] C:\> # Find mailboxes that we have not yet reset the default sharing view
[array]$Mbx = Get-ExoMailbox -RecipientTypeDetails UserMailbox, RoomMailbox -ResultSize Unlimited -Filter {CustomAttribute13 -ne "Open" -and CustomAttribute13 -ne "Blocked"}
```

```

$CalendarName = "Calendar" # English language calendar folder
ForEach ($M in $Mbx) {
Write-Host "Processing" $M.DisplayName
# You can hard-code the calendar name (above) or try and find a local language value.
# This is one way to look for local values...
# $CalendarName = (Get-ExoMailboxFolderStatistics -Identity $M.UserPrincipalName -FolderScope
Calendar |?{$_.FolderType -eq "Calendar"}).Name
# Either way, you need to end up with a valid calendar folder reference
# - Like Tony.Redmond@office365itpros.com:\Calendar
$CalendarFolder = $M.UserPrincipalName + ":\\" + $CalendarName
Set-MailboxFolderPermission -Identity $CalendarFolder -User Default -AccessRights LimitedDetails
Set-Mailbox -Identity $M.ExternalDirectoryObjectId -CustomAttribute13 "Open"
} # End Foreach

```

Users in an organization might not use English-language versions of OWA or Outlook, in which case their Calendar folder might have a different name. The code above handles the situation by using the *Get-ExoMailboxFolderStatistics* cmdlet to look for the calendar folder and fetch its name. This cmdlet is expensive in terms of processing overhead, which is why the call is commented out. However, if you need to deal with multiple languages, you'll need to uncomment the command and take the hit.

After updating the permission, the code uses *Set-Mailbox* to update the *CustomAttribute13* attribute so that the next time it runs, it won't process this mailbox. In addition, the code ignores any mailbox with Blocked in *CustomAttribute13* to handle the situation where you don't want to share calendar details for some confidential mailboxes.

## Automatic Meeting Shortening

Meeting shortening means reducing the time assigned to an event by a set amount depending on its desired length. The idea is to allow users to have a buffer between meetings to have an opportunity to recharge before the next event. Outlook and OWA allow individual users to set how long they would like to reduce short (under an hour) and long (over an hour) meetings and whether the buffer should be at the start or end of the period. Tenants can apply default settings by updating the Exchange Online organization configuration with PowerShell. It's critical to understand that once a user selects their settings, the organization defaults do not apply to them.

Three organization-wide settings are available to control event shortening:

- **ShortenEventScopeDefault:** Sets whether event shortening is in effect (0 or none) or applies to ending meetings early (1 or *EndEarly*) or starting later (2 or *StartLate*). This parameter must be set to 1 or 2 before you can amend the periods.
- **DefaultMinutesToReduceShortEventsBy:** The number of minutes to shorten events by if they are scheduled for one hour or less. The default is five.
- **DefaultMinutesToReduceLongEventsBy:** The number of minutes to shorten events by if they are scheduled for over one hour. The default is 10.

To turn on event shortening for the organization and select to end events early, we run:

```
[PS] C:\> Set-OrganizationConfig -ShortenEventScopeDefault EndEarly
```

Using *Get-OrganizationConfig* to examine the settings afterward shows the current configuration:

```
[PS] C:\> Get-OrganizationConfig | fl defaultmin*, short*

DefaultMinutesToReduceShortEventsBy : 5
DefaultMinutesToReduceLongEventsBy   : 10
ShortenEventScopeDefault             : EndEarly
```

Like any organization-wide setting, some time is necessary to allow clients and servers to pick up new values. For now, there's no way for administrators to use PowerShell to update these settings for individual mailboxes as Microsoft hasn't upgraded the *Set-MailboxCalendarConfiguration* cmdlet.

## Controlling Calendar Requests for Mailboxes

The *Set-CalendarProcessing* cmdlet controls how the Resource Booking Assistant processes meeting requests arriving in user and room mailboxes. For example, this command sets the properties controlling the processing of forwarded meeting notifications and external meeting requests:

```
[PS] C:\> Set-CalendarProcessing -Identity "Kim Akers" -RemoveForwardedMeetingNotifications $True -ProcessExternalMeetingMessages $True
```

It's common to have conference rooms that the organization reserves for specific people. To accomplish the goal, we update the calendar processing configuration to block accepting requests from anyone except members of a distribution list:

```
[PS] C:\> Set-CalendarProcessing -Identity "Room 101" -BookInPolicy "Senior Leadership Team"
```

Users who attempt to book a room receive email responses to tell them if the calendar assistant has accepted or denied their request or when the request awaits approval by a delegate who manages reservations for the room. You can update the meeting responses by setting the *AddAdditionalResponse* switch to *\$True* and providing the text to insert into the responses in the *AdditionalResponse* property. This example shows how to add HTML-formatted text, including an emoji:

```
[PS] C:\> Set-CalendarProcessing -Identity "Room 101" -AddAdditionalResponse $True -
AdditionalResponse '<h2>Welcome to the Corporate Room Scheduling System</h2><p>We have a few basic
rules for you to follow.</p><ol><li>Please keep the room tidy and remove rubbish at the end of your
meeting.</li><li>Please do not change the settings of the AV equipment.</li><li>Please clean the
whiteboard before you leave.</li><li>Advise Corporate Meetings if you have any problems by sending
email to mailto:<a href="mailto:corporatemeetings@office365itpros.com">Corporate
Meetings.</a></li></ol><p><strong>Room 101</strong> can hold up to <strong>12</strong> people.
Please do not exceed this capacity.</p><p>If you need <strong>catering</strong>, please contact
Trina at 147-1497.</p><p>Thanks for meeting with us!&nbsp;</p><p>&nbsp;</p>'
```

## How Outlook Processes Inbound Meeting Updates

The *VisibleMeetingUpdateProperties* setting in the tenant Exchange Online organization configuration controls how the Outlook (for Windows) client processes meeting updates. In the past, each time a meeting organizer updated any property of a meeting, like its title, location, date, or body (description), email notifications go to all meeting attendees. The attendees then had to process the update. Outlook can auto-process meeting updates, meaning that Outlook automatically applies updates to the event in attendee calendars without the need for any human interaction. Notifications are still emailed but are moved to the Deleted Items folder after Outlook processes the updates.

In general, updating meeting updates without requiring user intervention is welcome. However, some of the updates might contain information that users want to see. For instance, the default configuration is to only show update notifications to users if the meeting location changes or a change is made to any detail of the meeting within 15 minutes of its start. Outlook processes (and hides) any other change, such as an update to the meeting subject or the body of the meeting notice, which is where details such as agendas are often published. Outlook always shows a meeting notification if any of the following conditions are true:

- A change is made to the meeting date, time, or recurrence pattern.
- The notification is for a delegated shared calendar.
- The recipient is @mentioned in the meeting body.
- The recipient has not yet responded to the meeting (in effect, the notification acts as a prompt for them to respond).

You can change how Outlook behaves by running the *Set-OrganizationConfig* cmdlet to update the settings in *VisibleMeetingUpdateProperties*. For example, this command forces Outlook to display updates for any change

to the meeting location or body 120 minutes or less before it starts, or a change at any time to the online (Teams or Skype for Business Online) details or meeting subject.

```
[PS] C:\> Set-OrganizationConfig -VisibleMeetingUpdateProperties Location:120, Body:120,
OnlineMeetingLinks, Subject
```

The setting applies to all mailboxes in the tenant. You can't change how Outlook works on a per-mailbox basis.

## Generating Automatic Calendar Events from Email

When it processes inbound email, a background Exchange agent scans messages to figure out if the messages relate to events generated by airlines, hotels, and other sources like booking agencies. If an event is detected, user settings control how Exchange processes the event. The settings to control automatic event detection are found in the **Calendar** section of OWA Options. Go to **Events from email** to select how Exchange should process each of the event types. You can choose to:

- **Don't show event summaries in email or calendar:** This choice stops processing these events.
- **Only show event summaries in an email:** Exchange delivers event information in an email but won't create a calendar event.
- **Show event summaries in email and calendar:** Exchange delivers event information in email and uses that information to create a calendar event based on the information in the email, such as the time and date for a flight together with the airline booking reference, the name of the departure, and destination airports. Details of the extracted event are added to the message. If several events (such as flights in a single reservation) are detected, separate calendar events are created for each event.

Event settings can be manipulated with PowerShell by running the *Set-EventsFromEmailConfiguration* cmdlet (this used to be done with the *Set-MailboxCalendarConfiguration* cmdlet). For example, to set rental car event processing to Email only while making sure that flight reservations are created in the calendar, run:

```
[PS] C:\> Set-EventsFromEmailConfiguration -Identity Kim.Akers@Office365itpros.com -
FlightReservationProcessingLevel Calendar -RentalCarReservationProcessingLevel Email
```

Unlike other Exchange Online cmdlets, you must identify the target mailbox using one of the SMTP proxy addresses assigned to the mailbox. You cannot pass an alias, display name, distinguished name, or user principal name. This means that regular pipeline processing is not possible. For instance, you can't do this to have flight reservations created as calendar events:

```
[PS] C:\> Get-ExoMailbox -RecipientTypeDetails UserMailbox | Set-EventsFromEmailConfiguration -
FlightReservationProcessingLevel Calendar
```

Instead, you can do this:

```
[PS] C:\> $Mbx = (Get-ExoMailbox -RecipientTypeDetails UserMailbox)
$Mbx.ForEach( { Set-EventsFromEmailConfiguration -FlightReservationProcessingLevel Calendar
-Identity $_.PrimarySmtpAddress } )
```

To disable a setting for an event, set it to *Disabled*. For instance, here's how to disable event creation for all events:

```
[PS] C:\> Set-EventsFromEmailConfiguration -Identity Kim.Akers@Office365itpros.com
-FlightReservationProcessingLevel Disabled -LodgingReservationProcessingLevel Disabled
-ParcelDeliveryProcessingLevel Disabled -RentalCarReservationProcessingLevel Disabled
```

As you can see, you must disable each event type separately.

To check the current event processing settings for a mailbox, run the *Get-EventsFromEmailConfiguration* cmdlet:

```
[PS] C:\> Get-EventsFromEmailConfiguration -Identity Kim.Akers@Office365itpros.com
```

```

DisableReason          : None
CreateEventsFromEmailAsPrivate : False
EntityTypeProcessorLevelSettings : {RentalCarReservation, EventReservation,
FlightReservation...}
Identity               :
IsValid                : True
ObjectState            : New

```

This reveals the option to create events as private entries in the calendar (off by default) but doesn't tell us what each of the event type settings is. We find out with:

```
[PS] C:\> Get-EventsFromEmailConfiguration -Identity Kim.Akers@office365itpros.com | Select -ExpandProperty EntityTypeProcessorLevelSettings
```

Name	Value
RentalCarReservation	Disabled
FlightReservation	Disabled
LodgingReservation	Disabled
ParcelDelivery	Disabled

You can reset to default values (all events set to email with no automatic calendar events created) as follows:

```
[PS] C:\> Set-EventsFromEmailConfiguration -Identity Kim.Akers@Office365itpros.com -ResetSettings
```

Before Exchange can process an email to extract event information, Microsoft must recognize the sending organization (like an airline). The full list of recognized senders [is available online](#). Microsoft updates this list on an ongoing basis, with organizations joining when they realize the value of having their email create events in user calendars.

## Room Mailboxes, Workspaces, and Room Lists

Room mailboxes are a special form of resource mailbox marked for use as a meeting location. You create new room mailboxes through the Resources section of the EAC or with PowerShell. As described below, the Outlook Places service helps users find rooms for meetings, but it's still a good idea to include some location information in the display name for a room. Here's how to create a new room mailbox with PowerShell:

```
[PS] C:\> New-Mailbox -Name "SF Executive Meeting Room" -Displayname "San Francisco Executive Meeting Room" -Alias SFExecMeeting -Room
```

A workspace is a form of room mailbox to represent a place like an individual desk, a small meeting room used for calls, or other space where people work. The first step to creating a workspace is to create a room mailbox and set its type to be a workspace:

```
[PS] C:\> Set-Mailbox -Identity "Floor 1 Desk 17" -Type Workspace
```

A room list is a special form of distribution list composed exclusively of room mailboxes. No other type of recipient (including resource or equipment mailboxes) can be a member of a room list. The idea behind room lists is that they are a convenient way to segregate the different conference or meeting rooms available within an organization so that you have a room list per building or location. The room lists can then be used to select the best location when scheduling a meeting from Outlook or OWA. This is probably not a feature that is of much interest to small companies, but it can be valuable in large campus scenarios (like Microsoft's own Redmond HQ) where many multi-floor buildings can host meetings.

Room lists are managed with PowerShell. Here is an example of how to create a new "HQ Rooms" list. Note the use of the *IgnoreNamingPolicy* parameter to override the distribution list naming policy in force for the organization.

```
[PS] C:\> New-DistributionGroup -Name "HQ Rooms" -Members "Room 101", "Room 102", "Room 103"
-RoomList -IgnoreNamingPolicy
```

You can use this command to discover the room lists that already exist within a tenant:

```
[PS] C:\> Get-DistributionGroup -RecipientTypeDetails RoomList
```

Editing the membership of a room is done using the *Update-DistributionGroupMember*, *Add-DistributionGroupMember*, and *Remove-DistributionGroupMember* cmdlets. You will see an error if you try to add a recipient that is not a room mailbox to a room list.

The *Remove-DistributionGroup* cmdlet removes a room list.

```
[PS] C:\> Remove-DistributionGroup -Identity "Old HQ Rooms"
```

## The Outlook Places Service and Location Metadata for Room Mailboxes

The Outlook Places service helps users find suitable locations when scheduling meetings using the Room Finder feature in OWA and Outlook (both clients use the same component). Outlook Places uses metadata for room mailboxes together with room lists. Each room list represents a building, which the Room Finder groups into cities based on the City property for room mailboxes (Figure 6-2). After the user selects a building, they can choose a room or workspace to schedule. The list of rooms includes room characteristics using icons for capacity, video, audio, display, and wheelchair access (workspaces don't support room characteristics). You can create custom characteristics for a room using the Tags parameter for the *Set-Place* cmdlet. For example, you could use Tags to show that the room needs a special key to gain entrance.

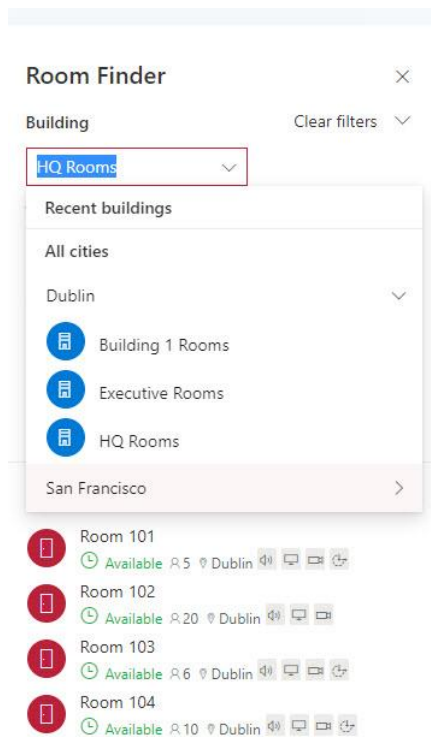

Figure 6-2: Outlook's room finder uses location metadata

The *Set-Place* cmdlet updates the location metadata for a room mailbox. For example, this snippet updates most of the properties available for a location:

```
[PS] C:\> Set-Place -Identity "SF Room 101" -CountryOrRegion "United States" -City "San Francisco" -
Floor 1 -Capacity 54 -Street "10 Sutter Street" -GeoCoordinates "37.790507; -122.400274" -Building
"Western HQ" -State CA -PostalCode 94104 -Phone "+1 206 177 4151" -Label "Training" -VideoDeviceName
"Crestron Flex UC-M150-T" -Tags "Training room"
```

It can take up to a day before updated metadata is available to clients. The *Get-Place* cmdlet retrieves information about a location. For example:

```
[PS] C:\> Get-Place -Identity DublinConfRoom@Office365itpros.com | Format-List
```

If the *PlacesEnabled* setting in the OWA mailbox policy assigned to a user mailbox is *\$True*, OWA displays location information to users in the room card when meetings are scheduled or viewed. If geocoordinates are available for a location, the Directions link calls the Bing Maps Locations API to generate directions to the location. Exchange Online uses a specific format to store geocoordinates for a location that is different from the format used by other applications (for instance, Google Maps uses a comma instead of a semi-colon to separate the latitude and longitude data). Outlook Mobile also consumes geocoordinates (if available) to show a map to a location, but only when scheduling a new meeting.

## General Mailbox Configuration

The *Get-MailboxMessageConfiguration* and *Set-MailboxMessageConfiguration* cmdlets retrieve and set the general properties of a mailbox. These settings control how OWA behaves. Although some are also respected by Outlook, you'll have to use a Group Policy Object or the [Office cloud policy service](#) to exert any real control over Outlook settings, including the roaming client settings supported by Outlook for Windows which are stored in mailboxes.

An example of how to use the *Set-MailboxMessageConfiguration* cmdlet is to create an autosignature for OWA to apply to new messages. This code defines some basic text for the autosignature and sets the default format for new messages created with OWA to "Plain text" (rather than the default HTML):

```
[PS] C:\> Set-MailboxMessageConfiguration -Identity "Kim Akers" -AutoAddSignature $True  
-SignatureText "From the desk of Kim Akers" -DefaultFormat PlainText
```

The equivalent command to create an HTML-format signature is shown below. In this instance, some simple HTML code creates the autosignature. The last parameter suppresses autosignatures for replies.

```
[PS] C:\> Set-MailboxMessageConfiguration -Identity "Kim Akers" -AutoAddSignature $True  
-SignatureHTML "<h3>From the Desk of Kim Akers</h3>" -DefaultFormat HTML -AutoAddSignatureOnReply  
$False
```

This is a simple example of creating a signature for OWA. You can download [a more comprehensive script from GitHub](#) to create a customized signature for every mailbox in the tenant. The signature includes user properties (name, title, etc.), a company logo, a clickable link for the user's email address, and links for Facebook and Twitter. Only OWA uses the signature defined by *Set-MailboxMessageConfiguration*; Outlook or Outlook Mobile use different autosignatures. If you want to from stop users changing the signature using OWA options after updating it in their mailboxes, you can do so using the technique [explained in this article](#).

**Autosignatures:** Apart from allowing users to create autosignatures using their client of choice or using the *Set-MailboxMessageConfiguration* cmdlet to create autosignatures for OWA with PowerShell, two other methods exist to control autosignatures. First, you can use an Exchange transport rule to insert an autosignature. This method has the advantage that it works for all clients and can use data extracted from Azure AD to populate the autosignature. Second, you can use a commercial ISV product to manage autosignatures. Examples of ISVs that provide this service include [Code Two Signatures](#), [Exclaimer](#), and [Outlook Signatures](#). ISV products cost, but they are very capable and provide the ability to manage autosignatures much more easily than is possible with either PowerShell or transport rules.

**Note:** Microsoft is in the process of introducing roaming signatures for Outlook for Windows with the goal of general availability in October 2022 (Microsoft 365 roadmap item 60371). Roaming signature means that Outlook stores the signature information in user mailboxes. One consequence of this initiative is that all Outlook clients will support multiple signatures in the same way that Outlook for Windows already does.

This feature is already available in OWA, and it can cause problems for scripts written to update user signatures with *Set-MailboxMessageConfiguration*. No PowerShell cmdlet or Graph API is currently available to manage roaming signatures.

Other common settings that you might consider updating for mailboxes include:

- **AlwaysShowBCC:** Display the *BCC:* control when composing new messages.
- **AlwaysShowFrom:** Display the *From:* control when composing new messages.
- **CheckForMissingAttachments:** If *True*, OWA checks messages before sending to check for the presence of attachments based on message text.
- **EmailComposeMode:** Set to *Inline* (default) to compose new messages in a pane within the same windows or *SeparateForm* to always launch a separate window for new messages.
- **EmptyDeletedItemsOnLogoff:** Controls whether OWA empties the Deleted Items folder when the user logs out.
- **HideDeletedItems:** Controls whether deleted items appear in conversation views. By default, clients show deleted items, so this property is set to *False*. Both Outlook and OWA respect this property.
- **IsReplyAllTheDefaultResponse:** Controls whether reply-all is the default response for messages. If *True*, a response to a message includes all recipients (this is the default value). Set the property to *False* to force OWA to create responses only addressed to the sender of the original message.
- **ReadReceiptResponse:** Controls how OWA generates read receipts for new messages delivered to the mailbox. The values are *DoNotAutomaticallySend* (prompt), *AlwaysSend*, and *NeverSend*. This setting applies only to OWA. See [this article for an explanation](#) of how read receipts work and how to control the relevant settings for OWA and Outlook.
- **NewItemNotification:** Set to *All* (default) to instruct OWA to signal the arrival of new messages (divided into the categories of email, fax, and voicemail) in every way that it can. Other values include *Sound* (a tone announces the arrival) and *EmailToast* (a pop-up “toast” notification signals the arrival).
- **PreviewMarkAsReadBehavior:** Controls how OWA sets the read status of messages. The default is *OnSelectionChange*, meaning that OWA marks a message as read if the user selects another message. If set to *Delayed*, OWA marks the item as read if the user spends more than the time specified in the **PreviewMarkAsReadDelayTime** property (by default, 5 seconds). You can also set this value to *Never*, meaning that the unread status of a message never changes no matter what the user does in the preview pane.
- **MailSendUndoInterval** sets how long OWA waits before sending a message. The interval allows the sender to stop the message if they've made a mistake or need to add something.

Microsoft updates PowerShell to allow scripting control over OWA options as new features appear in Exchange Online.

## MailTips

A MailTip is some informational text displayed by Exchange when a recipient is added to a message in Outlook desktop and OWA. Some MailTips are system-generated, and you can't affect the text they display, such as those generated when messages are addressed to moderated recipients or when a recipient's mailbox is full (a situation more unusual in the cloud than on-premises given the size of Exchange Online mailboxes). Others are controlled through the organizational configuration.

Although Exchange Online includes [protection against email reply-all storms](#), this only works for relatively large tenants. MailTips help users to avoid doing something bad like creating a reply-all email storm by inadvertently sending a message to a large distribution list. Several settings in the Exchange Online organization configuration control how clients see MailTips. To view the settings, run this command:

```
[PS] C:\> Get-OrganizationConfig | Format-List mailtip*
```

```
MailTipsAllTipsEnabled : True
MailTipsExternalRecipientsTipsEnabled : True
MailTipsGroupMetricsEnabled : True
MailTipsLargeAudienceThreshold : 10
MailTipsMailboxSourcedTipsEnabled : True
```

The values have the following meanings:

- **MailTipsAllTipsEnabled:** Set to True to instruct clients to use MailTips.
- **MailTipsExternalRecipientsTipsEnabled:** Set to True to have clients highlight messages addressed to external recipients.
- **MailTipsGroupMetricsEnabled:** Set to True to have Exchange Online calculate the number of members in distribution lists. This data is used to establish if the large audience threshold is exceeded in messages. A background process checks distribution lists periodically, so don't expect the numbers used to be 100% accurate.
- **MailTipsLargeAudienceThreshold:** The default is 25. It's lower here as a reminder that there might be a better way to share information with large audiences, such as a post in a Teams channel. Of course, if you don't use Teams, you could increase the threshold right up to the maximum number of recipients an Exchange Online user can address in a message (1,000).
- **MailTipsMailboxSourcedTipsEnabled:** Set to True to have Exchange Online look at mailbox data such as auto-reply messages to generate MailTips.

## Custom MailTips

Custom MailTips are text messages of up to 175 characters assigned to any valid mail-enabled recipient type including mailboxes, shared mailboxes, group mailboxes, mail contacts, distribution lists, and dynamic distribution lists.

For example, these commands set custom MailTips for a mailbox, a Microsoft 365 group, and the mail user object created for a guest account:

```
[PS] C:\> Set-Mailbox -Identity Oisin.Johnston -MailTip "Working 9 to 12 at present. Ping me on Teams if urgent"
[PS] C:\> Set-UnifiedGroup -Identity BankingTeam -MailTip "Messages to this Group are delivered to external guest members"
[PS] C:\> Set-MailUser vasil_michev.org#EXT# -MailTip "Be Careful with Vasil"
```

You can also look for objects with custom MailTips. For instance, here's how to do it for mailboxes:

```
Get-ExoMailbox -ResultSize Unlimited -Properties MailTip | ? {$_.MailTip -ne $Null} | Format-List
DisplayName, MailTip

DisplayName : Oisin Johnston
MailTip      : <html>
              <body>
                Working 9 to 12 at present. Ping me on Teams if urgent
              </body>
              </html>
```

Exchange Online stores MailTips in HTML format.

Users or the owners of distribution lists or groups cannot set MailTips unless their account holds the Exchange Online administrator role. Like many mailbox settings, it takes a few hours before clients pick up MailTip changes.

## Translated MailTips

Exchange Online operates in a multinational, multilingual environment. When you create a custom MailTip, it becomes the default for all languages. To create language-specific translations for a MailTip, you update the multi-valued *MailTipTranslations* property for an object. For example, this command sets up Spanish, French,

and German translations for a mailbox. Clients configured in these languages display the language-specific value. If no value exists for the client language, the default MailTip is used.

```
[PS] C:\> Set-Mailbox -MailTipTranslations @{Add="ES: Buzón no en uso activo", "FR: Boîte aux lettres non utilisée", "DE: Mailbox nicht aktiv genutzt"} -Identity CServices
```

## MailTips for AutoReplies

Exchange generates automatic MailTips for mailboxes that have an autoreply set to inform users of the current mailbox status. You can't control the generation of autoreply tips. Users might continue to see an autoreply MailTip even after the autoreply expires for a mailbox or is explicitly disabled. This is because Exchange Online caches autoreply information to prevent it from having to look up mailbox autoreply data every time a user adds a recipient to a message. The cached data is refreshed every hour. Exchange Online supports MailTips in the same way as on-premises Exchange.

## Folder Level Permissions

You can add folder-level permissions to allow a user to access a folder in someone else's mailbox. For instance, you might want someone to check new messages that arrive when you are on vacation. In this example, we permit Marc Vigneau to access the Inbox folder for Kim Akers:

```
[PS] C:\> Add-MailboxFolderPermission -Identity "Kim Akers:\inbox" -User "Marc Vigneau" -AccessRights Reviewer
```

Automapping is the process Outlook uses to connect to mailboxes automatically. This does not apply to folder-level permissions. The user who receives the permission must add the other user's folder as a shared folder. In addition, it can take several hours for Exchange to propagate the new permission and make it effective.

## Controlling Email Sent by Delegates

Delegate settings refer to the ability to give a user the right to access another person's mailbox. These rights include the ability to send messages on behalf of the mailbox owner or as the mailbox owner, or the *SendOnBehalfOf* and *SendAs* permissions. By default, when messages are sent by a delegate using these permissions, the outbound messages are stored in the Sent Items folder of the delegate's mailbox. This is because the *MessageCopyForSentAsEnabled* and *MessageCopyForSendOnBehalfEnabled* settings are set to *\$False*.

Mailbox owners often want to have copies of messages sent to them by a delegate. To force Exchange to create copies of these messages for the mailbox owner, set the properties to *\$True*. For example:

```
[PS] C:\> Set-Mailbox -Identity TRedmond -MessageCopyForSendOnBehalfEnabled $True -MessageCopyForSentAsEnabled $True
```

Similar control can be exerted over messages sent by delegates for a shared mailbox.

## Junk Mail Settings

The *Get-MailboxJunkEmailConfiguration* and *Set-MailboxJunkEmailConfiguration* cmdlets handle how to process junk email for a mailbox. A hidden Inbox rule (called Junk E-mail rule) holds the settings, which control the delivery of messages to the Junk Email folder based on the spam confidence level (SCL) and the safelist defined for the mailbox. Exchange Online applies the rule to all inbound messages – but only if it is enabled. It's therefore important to ensure that the rule is enabled for all mailboxes. To check, we can run a command like this:

```
[PS] C:\> $Mbx = Get-ExoMailbox -RecipientTypeDetails UserMailbox -ResultSize Unlimited
ForEach ($M in $Mbx) {
```

```
If ((Get-MailboxJunkEMailConfiguration -Identity $M.Alias).Enabled -eq $False) {
    Write-Host $M.DisplayName "mailbox has junk email disabled" }}
```

New mailboxes get a default rule to handle junk mail processing, but only after the mailbox is opened in Outlook (in cached mode) or OWA. The most interesting of the rule settings are the trusted senders and blocked sender lists. Both are multivalued properties. The following example adds an entry to the blocked senders and domains list (because we do not want to receive messages from this domain), specifies that Exchange should always treat the user's contacts as safe senders, and replaces the set of trusted domains.

```
[PS] C:\> Set-MailboxJunkEMailConfiguration -Identity "Kim Akers"
-BlockedSendersAndDomains @{Add="Badgirls.com"} -ContactsTrusted $True
-TrustedSendersAndDomains "Microsoft.com", "Office365.com", "Outlook.com"
```

Note that the rule supports a maximum of 1,024 contacts, but only if the *ContactsTrusted* setting in the mailbox's junk mail rule is set to *\$True*.

## Viva Insights Mailbox Settings

Viva Insights (previously MyAnalytics - see Chapter 6 in the Companion Volume) generates messages delivered to user mailboxes which you might want to control. These are system messages because they do not travel through the Exchange Online transport service. Instead, Microsoft 365 inserts the messages directly into mailboxes.

Several Viva Insights features can be individually enabled or disabled using the *Set-MyAnalyticsFeatureConfig* cmdlet. The same cmdlet also controls whether mailboxes opt into the collection of Microsoft Graph signals for email and calendar activity used to generate insights. The individual features are:

- **Email-digest:** If enabled, a mailbox receives a monthly digest generated from their activity containing insights for collaboration, network, focus, and wellbeing.
- **Dashboard:** If enabled, a mailbox has access to the Viva Insights dashboard.
- **Add-in:** If enabled for a mailbox, Outlook loads the Insights add-in.

The default values for these settings come from the MyAnalytics (Viva Insights) tenant settings in the Org settings of the Microsoft 365 admin center. New mailboxes are enabled automatically for Viva Insights. Users can disable Insights for their mailbox through the [Viva Insights home page](#). Alternatively, administrators can run the *Set-MyAnalyticsFeatureConfig* to control the settings. For instance, to disable Viva Insights for a mailbox, use a command like:

```
[PS] C:\> Set-MyAnalyticsFeatureConfig -Identity Vasil.Michev@office365itpros.com -PrivacyMode "opt-out"
```

Opting out from Insights disables all features. Mailboxes can be enabled for Insights but disabled for individual features. For example, many users don't like the monthly digest arriving in their inbox. To stop the digest, run *Set-MyAnalyticsFeatureConfig* to set the enabled state for the Email-digest feature to False:

```
[PS] C:\> Set-MyAnalyticsFeatureConfig -Identity Vasil.Michev@office365itpros.com -PrivacyMode "opt-in" -Feature Email-Digest -IsEnabled $False
```

You cannot enable or disable multiple features in one command. If you want to disable both the email digest and Outlook add-in, you must run *Set-MyAnalyticsFeatureConfig* twice.

Organizations can disable the daily briefing by updating the **Briefing email** settings in the Org settings section of the Microsoft 365 admin center. On an individual level, users can opt-out by unsubscribing, or an administrator can run the *Set-UserBriefingConfig* cmdlet. For example:

```
[PS] C:\> Set-UserBriefingConfig -Identity Oisin.Johnston@office365itpros.com -Enabled $False
```

Unlike most cmdlets in the Exchange Online Management module, the *Set-MyAnalyticsFeatureConfig* and *Set-UserBriefingConfig* cmdlets accept the user principal name for an account as the input identity instead of the display name, alias, object identifier, or distinguished name as with other Exchange Online cmdlets.

## Controlling Email Forwarding

When an organization assigns an Exchange Online mailbox to a user, they probably want that person to use the mailbox for email and keep messages in the mailbox for compliance purposes. It is possible that some users prefer to use another email system and will forward messages to that system using either a forwarding address created using OWA settings or a rule. No matter how forwarding occurs, messages leave the control of retention and other data governance policies, which is a bad thing. It's also the case that attackers often plant a mail forwarding rule to capture email from accounts that they wish to learn more about before launching a business email compromise attack. For instance, they might try to insert a mail forwarding rule or set up a forwarding address in the CFO's mailbox to discover information about the trading patterns of a company.

For historic reasons, Exchange Online supports two methods to forward email from a mailbox. The methods use different mailbox attributes, but both instruct the transport service to redirect messages to another SMTP address with the option to also deliver a copy to the original mailbox.

- A user can set the *ForwardingSmtpAddress* through OWA options or an administrator can set email forwarding for a mailbox through the Microsoft 365 admin center. Setting the *ForwardingSmtpAddress* attribute is the preferred approach. Because the mailbox owner can set up email forwarding through OWA, if an administrator creates a forward for a mailbox, its existence is known to the mailbox owner.
- An administrator can set the *ForwardingAddress* attribute through EAC through the **Manage email forwarding** option or by running the *Set-Mailbox* cmdlet. This redirect is invisible to the mailbox owner.

A significant difference between the two attributes is that *ForwardingSmtpAddress* supports any valid SMTP address, including those belonging to external domains. Microsoft recommends that you should use *ForwardingSmtpAddress* whenever possible. *ForwardingAddress* only supports addresses that are known to the tenant, including mail-enabled contacts pointing to external addresses. The properties of a mailbox can have both forwarding attributes set with different SMTP addresses. When this happens, Exchange Online will forward copies of all inbound messages to both addresses.

Here is an example of using the *Set-Mailbox* cmdlet to set a forwarding address for a mailbox. In this instance, the *DeliverToMailboxAndForward* property is set to *\$True* to instruct Exchange Online to forward a copy of any inbound messages to the supplied address and keep a copy in the mailbox.

```
[PS] C:\> Set-Mailbox -Identity "Andy Ruth" -ForwardingSmtpAddress Andy.Ruth@yandex.com -DeliverToMailboxAndForward $True
```

When you set up email forwarding for a user through the Microsoft 365 admin center, the forwarding address is written into the mailbox's *ForwardingSmtpAddress* attribute, and any value found in the *ForwardingAddress* attribute is cleared. Apart from checking that the input address is formatted properly, no attempt is made to confirm that messages can be redirected to the email address input as the forwarding destination. The administrator is notified that *"the mailbox owner will be able to view and change these forwarding settings"* (because they will be able to see the redirect address through OWA Options). If the need exists to hide forwarding, the administrator should use EAC or PowerShell to set up the redirect through the *ForwardingAddress* attribute.

Both the *Set-Mailbox* cmdlet and the Microsoft 365 admin center flag warnings if redirect addresses are detected in both attributes. *Set-Mailbox* will allow you to write redirect addresses into the two attributes, but

the Microsoft 365 admin center insists on removing the redirect contained in the *ForwardingAddress* attribute before it will update the email forwarding settings.

## Blocking Email Forwarding

Where organizations once allowed all users to forward messages, it's now more common to find restrictions in place. The easiest way to apply central control over email forwarding is to use the organization's [outbound spam filter policy](#) (see the Mail Flow chapter) to disable forwarding for mailboxes. If you allow some users to forward messages, you should check what email users forward and why and implement further blocks where necessary. Three approaches are available.

1. **Check for and stop users forwarding messages.** The *Get-ExoMailbox* command below lists all mailboxes with a populated forwarding address. We check both *ForwardingSmtpAddress*, which can redirect to an external address and *ForwardingAddress* (which only accepts internal addresses).

```
[PS] Get-ExoMailbox -RecipientTypeDetails UserMailbox -Filter {ForwardingAddress -ne $null -or ForwardingSMTPAddress -ne $Null} -ResultSize Unlimited -Properties ForwardingSmtpAddress, DeliverToMailboxAndForward | Format-Table DisplayName, ForwardingSmtpAddress, DeliverToMailboxAndForward -AutoSize
```

DisplayName	ForwardingSmtpAddress	DeliverToMailboxAndForward
Vasil Michev (Technical Guru)	smtp:vasil@contoso.com	True
Ståle Hansen	smtp:stale.hansen@fabrikam.com	True
Eoin Redmond	smtp:Eoin@contoso.com	True

After checking who's forwarding email outside the organization, we can remove the automatic forwarding with a variant of the command:

```
[PS] C:\> Get-ExoMailbox -RecipientTypeDetails UserMailbox -Filter {ForwardingSmtpAddress -ne $Null} -ResultSize Unlimited | Set-Mailbox -ForwardingSmtpAddress $Null
```

2. **Remove the ability of users to create rules to forward messages to external domains.** When forwarding is disabled for a domain, Exchange Online detects that this is the case and delivers new inbound messages to the original mailbox. You can block forwarding for all external domains as follows:

```
[PS] C:\> Get-RemoteDomain | Set-RemoteDomain -AutoForwardEnabled $False
```

Because good business reasons might exist to justify forwarding to certain external domains, a more granular approach can be taken to disable the ability for users to forward messages to selective external domains. This approach is often used to stop users from forwarding messages to consumer email services. For instance, let's assume that you don't want users to be able to forward messages to Yahoo.com accounts. You need to define Yahoo.com as a new external domain and then block forwarding to that domain. Here's how:

```
[PS] C:\> New-RemoteDomain -DomainName "*.yahoo.com" -Name "Yahoo.com"
[PS] C:\> Set-RemoteDomain -Identity "Yahoo.com" -AutoForwardEnabled $False
```

3. **Remove the ability of users to set forwarding through OWA options.** This approach needs you to update the default user role assignment policy because the OWA options are controlled by the policy. If you'd like the challenge of figuring out how to make the necessary changes, much of the same technique is used later to allow users to edit but not create distribution lists. You can find a [complete description of the required steps](#) online.

In the past, transport rules were commonly used to block forwarded messages to specific domains. The implementation of the block in the outbound spam policy removes the need to use these rules and they should be retired.

Power Automate offers several templates to allow users to forward new messages moved into a folder. These flows can forward messages to external addresses. None of the standard Exchange Online management tools stop Power Automate forwarding messages. However, [a transport rule](#) can block the forwarding of messages using Power Platform (flow).

Naturally, as in the case of any action that removes a facility that some people might be using, it's a good idea to capture the business reasons why a policy exists for email forwarding and to communicate why blocks are being enforced and how the changes might affect users before anything is done.

## Reporting Forwarding

If the outbound spam policy for the organization allows some users to forward messages, the Auto forwarded message report available in the Reports section of the EAC gives an insight into forwarding activity. In addition, the Microsoft 365 Defender admin center includes a default alert policy called *Creation of forwarding/redirect rule* to flag alerts when users create rules to forward messages outside the tenant. To round things out, it's possible to use PowerShell to check which mailboxes are forwarding messages. The steps required are:

- Creates a collection of user and shared mailboxes.
- Checks if the mailbox has a forwarding address set and reports it if found. We don't check the *ForwardingAddress* property because although it can forward messages to an address known in the directory, we are more concerned about mail going outside the tenant.
- Checks if any rules exist in the mailbox. If rules exist, check if any forward messages (including forward as an attachment).
- Check the forwarding addresses to see if the recipient is known to the tenant directory (including guest accounts) and report any forwarding address found.
- Optionally, if the forwarding address is unknown (does not exist in the directory), remove the rule from the mailbox.

You can [download an example script from GitHub](#).

Even if you did not remove the offending rules, you could run the script periodically to discover whether people are attempting to forward emails outside the organization, and if so, what are the target domains.

## Mailboxes Forwarding Email Must be Licensed

If you're in a situation where someone leaves the business and you want to keep their mailbox active and forward new messages to someone else for processing, remember that the mailbox (account) must remain licensed to allow forwarding to happen. In these scenarios, it might be better to convert the mailbox to a shared mailbox. A license is only needed then if the mailbox is larger than 50 GB or has an archive.

## Maximum Message Size

Exchange Online allows mailboxes to send and receive messages up to a maximum of 150 MB. The actual size of messages supported by a mailbox is set by the *MaxSendSize* and *MaxReceiveSize* properties, which can be changed using the *Set-Mailbox* cmdlet or by editing mailbox properties through the EAC (the values are available through the mailbox features page). For example, this command sets the send and receive size to 100 MB for the Kim Akers mailbox:

```
[PS] C:\> Set-Mailbox -Identity 'Kim Akers' -MaxSendSize 100MB -MaxReceiveSize 100MB
```

Although it is great to be able to send large messages, it is quite another matter to make sure that the recipient will be able to receive them as you probably have zero influence over the connectors and configuration of the email systems involved in the transfer of the message after it leaves Exchange Online. This is especially important in a hybrid situation as it is probable that the on-premises servers support

message sizes significantly smaller than the values supported by Exchange Online. It is also important to understand that the message size used for this purpose is the size of the message after it is coded into BASE64/MIME format to allow it to be accepted by other mail systems. This process can add up to a third to the size of a message, so a 60 MB message as seen by the user might become an 80 MB message when presented to the transport system for transmission. In turn, this might end up exceeding the permitted threshold and cause some bewilderment to the user.

## Enabling Third-Party Cloud Attachments

Working inside Exchange Online, it's natural to use "cloudy attachments" stored in SharePoint Online or OneDrive for Business document libraries. Your company might use other cloud-based document storage repositories like Dropbox or Google Drive, and you might want to allow users to add attachments to messages from these repositories. The *AdditionalStorageProvidersAvailable* setting in OWA mailbox policies controls access to both first-party and third-party storage providers. By default, this setting is *\$True*. If you block access to third-party storage providers, you must update OWA mailbox policies to ensure that they exert the same control over users. For example:

```
[PS] C:\> Get-OWAMailboxPolicy | ? {$_.ThirdPartyFileProvidersEnabled -eq $False} | Set-OWAMailboxPolicy -AdditionalStorageProvidersAvailable $False
```

OWA mailbox policy settings only apply to OWA clients and do not affect Outlook desktop or mobile. After making the change to the policy, wait an hour or so to allow the cached policy to be refreshed.

## Mailbox Quotas

The size of the assigned storage quota is a major difference between on-premises mailboxes and their cloud counterparts. Although it is still common for on-premises mailboxes to have relatively small quotas of between 2 and 10 GB, Exchange Online assigns a basic 100 GB quota to mailboxes with enterprise E3 and E5 plans, 50 GB to E1 and education plans, and 2 GB to frontline worker plans. Competitive pressure is one reason why Microsoft offers very large mailbox quotas for Exchange Online. For instance, Google Workspace plans include between 30 GB and "as much as you need" storage. Table 6-1 lists the current quotas assigned to [different types of mailboxes](#).

	<b>Frontline worker (F3)</b>	<b>Enterprise E1 (and Gov/Edu Equiv.)</b>	<b>E3 and E5</b>
Primary mailbox size	2 GB	50 GB	100 GB
Archive mailbox size	N/A	50 GB	Unlimited
Shared mailbox size	N/A	50 GB	50 GB
Resource mailbox size	10 GB	50 GB	100 GB
Group mailboxes	50 GB	50 GB	100 GB
Public folder mailboxes	N/A	50 GB	100 GB

Table 6-1: Exchange Online mailbox sizes

If a shared mailbox has an Exchange Online Plan 2 license, its quota increases to 100 GB, and it can have an archive. In the past, some unlicensed shared mailboxes had a 100 GB quota. These mailboxes can keep the erroneous quota if their status does not change (for example, administrators do not convert a shared mailbox to a user mailbox and back to become a shared mailbox). New shared mailboxes receive a 50 GB quota.

You do not have to assign the full quota to mailboxes and can restrict users to lower amounts. As you can see in the PowerShell example below, three properties control how Exchange applies a mailbox quota:

- The *IssueWarningQuota* property tells Exchange the point at which nagging messages should be sent to the mailbox owner to tell them that they are approaching the quota limit.

- The *ProhibitSendQuota* property marks the limit at which Exchange will no longer accept new outbound messages from the mailbox.
- The *ProhibitSendReceiveQuota* property tells Exchange when to cut off both outbound and inbound service to the mailbox.

For example, this code sets a warning limit of 23 GB, stops the user from sending messages at 25 GB, and stops the mailbox from receiving messages when the mailbox size reaches 30 GB.

```
[PS] C:\> Set-Mailbox -Identity TRedmond -ProhibitSendQuota 25GB -ProhibitSendReceiveQuota 30GB -IssueWarningQuota 23GB
```

You can scan for user mailboxes that have a certain quota and increase their quota with a command like:

```
[PS] C:\> $Mbx = (Get-ExoMailbox -RecipientTypeDetails UserMailbox -PropertySet Quota -ResultSize Unlimited)
[double]$QuotaCheck = 75161927680 # bytes - 70 GB in this case
Foreach ($M in $Mbx) {
    [double]$Quota = $M.ProhibitSendQuota -replace "(.*\(|,| [a-z]*\)", "" # value in bytes
    If ($Quota -lt $QuotaCheck)
    { Write-Host "Updating" $M.UserPrincipalName "quota of" $M.ProhibitSendQuota "to 75GB"
      Set-Mailbox -Identity $M.UserPrincipalName -ProhibitSendQuota 74GB -ProhibitSendReceiveQuota 75GB -IssueWarningQuota 72GB}
}
```

Clients display available quotas in different ways. The mailbox settings section in Outlook's "backstage" (available from the File menu) tells users how much quota they have consumed and how much remains. OWA gives more comprehensive information in the Storage section of its settings. OWA also displays a warning message to users at the bottom of the folder list once they consume 90% of their mailbox quota. The message contains a link to the storage section of settings to allow the user to remove some messages from the mailbox to free quota.

### Extra Space Available to Exchange Online Mailboxes

In addition to their basic quota, Exchange Online mailboxes also have a recoverable items quota of 30 GB, which is automatically increased to 100 GB if the mailbox is put on hold. The added quota accommodates the need to keep held items in mailboxes for extended periods. If necessary, it is possible to increase the recoverable items quota past 100 GB, but only by filing a support request with Microsoft. Altogether, the total available storage available per enterprise user mailbox is between 230-300 GB made up of the primary mailbox, primary archive, and recoverable items.

Exchange Online mailboxes also store data created by Exchange, other Office 365 applications, and the Microsoft 365 substrate in hidden folders. This data is inaccessible to users. The amount of system data can exceed user data, meaning that the overall storage occupied by a mailbox can be much larger than anyone expects. We'll dive into this aspect later.

**Moving very large on-premises mailboxes to Exchange Online:** The 100 GB mailbox quota assigned to enterprise Exchange Online user mailboxes is more than enough to store email for most people. Some on-premises users might have mailboxes larger than 100 GB, and if this is the case, you'll need to shrink these mailboxes before the Exchange Mailbox Replication Service (MRS) can move them to Exchange Online. Simply because of the amount of data to transfer, large mailboxes take longer to move and are somewhat more problematic than smaller mailboxes. With this in mind, it's a good idea to review the sizes of all large on-premises mailboxes before starting the migration process to make sure that they are at least 10 GB under the 100 GB quota (to allow for some growth) and if not, to reduce their size. It's also important to remove any items larger than 150 MB as items larger than this aren't supported by Exchange Online. If a mailbox is on litigation hold, a large proportion of the mailbox might be occupied by held items, in which case the Recoverable Items folder will be quite big. Users are unlikely to want to prune items out of a massive mailbox and will probably take too long to make a serious dent in the size, so the best approach is

to assign a mailbox retention policy to the oversized on-premises mailboxes to have the Exchange Managed Folder Assistant remove older items in the background (for instance, by deleting any message older than 2 years or moving old messages into the archive mailbox). Once the assistant has processed the mailboxes, you should be all set to move them to the cloud.

## Offline Storage

In a practical sense, once a quota is larger than 20 GB, adding more storage is nearly meaningless for the average user because it takes so long to fill the remaining quota, even if they move large amounts of old mail from their on-premises mailbox. From a user perspective, modern clients hide many of the complexities of large mailboxes. Outlook for Windows, for instance, supports up to 100,000 items per folder. Some degradation is likely when approaching any client limit, so users should be coached to keep the number of items in a folder well under this amount. Clients that work offline can also control the amount of information that they download from a mailbox. Here are some points to remember about offline storage:

- Outlook desktop's OST slider allows users to choose a synchronization period. Outlook desktop supports a range from 3 days to "everything." Outlook uses the synchronization period to decide what to download from the user-visible folders in the mailbox on the server to their offline folder replica file (OST). Virtual desktop clients often use smaller synchronization periods to reduce the amount of synchronized data. For laptops and other non-shared PCs, restricting the synchronization period to a year or less is an effective way to ensure that the OST stays a reasonable size (in the 4 GB to 10 GB range, depending on the number of items synchronized to the OST). The performance of larger OST files can suffer even on PCs equipped with fast SSDs.
- The OST slider does not affect the synchronization of the Contacts or Calendar folder. The assumption here is that users will want access to their complete calendar and all their contacts when working offline.
- Registry settings can be set by group policy or manually to control [the "slider window"](#) and whether Outlook synchronizes the contents of [public folder favorites and shared mailboxes](#). It is a good idea to review the set of shared mailboxes configured for use with Outlook periodically to remove mailboxes that are seldom accessed.
- Adding extra calendars or having too many items in calendar folders can [cause synchronization problems](#) with any version of Outlook for Windows.
- The [maximum size of an OST file is 50 GB](#). If your mailbox is larger, move the slider to reduce the amount of synchronized data. Remember that if you synchronize shared folders and other mailboxes, they also must fit within the 50 GB limit.
- Outlook must run in cached Exchange mode to access Groups.

Tenants considering a virtual desktop infrastructure (VDI) deployment need to pay extra attention to the amount of data cached by Outlook and perhaps consider OWA as a replacement client in these environments. If Outlook must be used, it's a good idea to consider VDI-specific solutions like the [FSLogix Office Container](#) (acquired by Microsoft in November 2018) to achieve good performance for users.

## Folder Associated Information

Administrators sometimes comment that the number of items reported in a folder by a client differs from the server-side data that they see when running a cmdlet like *Get-ExoMailboxFolderStatistics*. The difference is the hidden items (folder associated information or items, known also as FAIs) that Exchange stores in folders for different purposes such as to hold configuration settings (like the town chosen for a weather display in Outlook's calendar), RSS feeds, and retention policies. The FAIs are usually small and do not take up much space in the context of an overall mailbox, but they are very important to Exchange and its clients. The Inbox

folder is the location for most FAs. A test revealed that Outlook reported 8,734 items in the Inbox, but more were found with the following command:

```
[PS] C:\> Get-ExoMailboxFolderStatistics -Identity TRedmond -FolderScope Inbox | Select
ItemsInFolder

ItemsInFolder
-----
          9585
```

FAs account for most of the difference between the numbers reported for the Inbox by Outlook and the cmdlet. You can check this by using the MFCMAPI utility to examine the folder's associated items table.

## Other System Items in Mailboxes

A mailbox holds both items accessible to users through clients and system items hidden in folders that clients never reveal. System folders exist to hold data for application purposes. On-premises mailboxes have far fewer system folders than cloud mailboxes do because the Microsoft 365 substrate and applications use Exchange Online mailboxes to store a broader range of information. Most of the system data is in the Non-IPM part of the mailbox, which email clients do not access. Their focus is on content stored in the IPM (interpersonal messaging) section under a root folder called Top of Information Store. Folders in the IPM part of the mailbox include well-known folders like Inbox, Sent Items, and Calendar. Some applications, like To-Do, store data in IPM folders because the data is also exposed and used in email clients.

A good example of system data storage is how the substrate captures Teams compliance records in the *TeamsMessagesData* folder in the non-IPM section of group mailboxes (for channel conversations) and user mailboxes (for personal chats). System folders are usually hidden and do not appear in clients. The substrate creates these items to support Microsoft Search, machine learning, artificial intelligence, and other centralized services.

To illustrate just how much invisible data exists in a mailbox, let's use the *Get-ExoMailboxFolderStatistics* cmdlet to reveal what's stored in the *Non-IPM* part.

```
[PS] C:\> $Folders = Get-ExoMailboxFolderStatistics -Identity TRedmond -FolderScope NonIPMRoot
$Folders.Count
304
[PS] C:\> $Folders[0] | Select Identity, ItemsInFolderAndSubFolders, FolderAndSubFolderSize

Identity  ItemsInFolderAndSubFolders FolderAndSubFolderSize
-----
TRedmond\                451900 20.24 GB (21,727,913,262 bytes)
```

304 folders holding 451,900 items and occupying 20.24 GB. By comparison, here's what is in the visible folders in the same mailbox.

```
[PS] C:\> $Visible = Get-ExoMailboxFolderStatistics -Identity TRedmond -FolderScope All
$Visible.Count
92
[PS] C:\> $Visible[0] | Select Identity, ItemsInFolderAndSubFolders, FolderAndSubFolderSize

Identity  ItemsInFolderAndSubFolders FolderAndSubFolderSize
-----
TRedmond\Top of Information Store 38360 4.907 GB (5,268,429,234 bytes)
```

So, 92 folders against 304 and only 38,360 items in 4.907 GB against the whopping 451,900 stored in the invisible folders. If we look at the data in more detail and review the ten largest folders based on number of items, we gain some insight into the situation (you might find different folders in different mailboxes):

```
[PS] C:\> $Folders | Sort ItemsInFolder -Descending | Select -First 10 | Format-Table -Property
@{e="Name"; width=30}, @{e="FolderSize"; width=30}, ItemsInFolder
```

Name	FolderSize	ItemsInFolder
AllItems	3.901 GB (4,189,011,735 bytes)	24244
NoArchiveTagSearchFolder853...	3.869 GB (4,154,389,586 bytes)	24122
Audits	145.1 MB (152,185,788 bytes)	22781
TeamsMessagesData	1.667 GB (1,789,639,942 bytes)	16402
SPOOLS	1.155 GB (1,239,922,031 bytes)	6517
SpoolsSearchFolder	1.155 GB (1,239,922,031 bytes)	6517
Inbox	1.398 GB (1,501,199,889 bytes)	5270
Unified Inbox	1.367 GB (1,467,696,501 bytes)	5133
Sent Items	786.9 MB (825,137,524 bytes)	4731
EdgeSyncEntities	39.61 MB (41,531,884 bytes)	4675

Microsoft does not document how Exchange or other workloads use the items in hidden folders, so a little guesswork is necessary. Among the folders you might find when looking through the non-IPM part of a mailbox are:

- System folders are hidden from users. For instance, The **Audits** folder holds mailbox audit records (which are also transmitted to the audit log). The **Calendar Logging** folder holds change details for calendar items. Folders are present to store compliance data, such as **TeamsMessagesData** (Teams compliance records) and **Yammer**. OWA [stores items used for its People Favorites feature](#) in hidden “persona” folders while the [Planner integration with the Microsoft 365 message center](#) uses a hidden folder to hold calendar reminders for assigned tasks.
- Data stored by apps: Forms stores forms as PDFs and responses to forms as CSV files in the **c9a559d2-7aab-4f13-a6ed-e7e9c52aec87** folder under the **ApplicationDataRoot** folder. Likewise, Sway uses the **905fcf26-4eb7-48a0-9ff0-8dcc7194b5ba** subfolder to store any files created by the user in HTML format. In both cases, the application attaches its files to email messages to avoid the need to create extra MAPI message classes. Applications often store information in Exchange Online to include their data in search indexes and expose it to content searches.
- Search Folders used by different features. MAPI search folders don’t store copies of mailbox items, so they don’t occupy any storage. Instead, they store links to items chosen by applying search criteria (such as “All PDF attachments”). The real items exist in other folders. Even so, *Get-ExoMailboxFolderStatistics* reports the full item size. For example, the **GraphFilesAndWorkingSetSearchFolder** folder records details of attachments and files accessed by a user and is used by the OWA Files feature; the folder starting with **OwaFV15.1AllFocused** holds items in the *Focused* view for the Focused Inbox (another folder starting with **OwaFV15.1AllOther** holds items in the *Other* view).

To discover the set of mailbox folders that consume storage quota, you can use a command like this:

```
[PS] C:\> Get-ExoMailboxFolderStatistics -Identity James.Ryan -Folderscope NonIPMRoot | where
{($_.TargetQuota -like 'User') -and ($_.FolderSize -like "*GB*" -OR $_.FolderSize -like "*MB*")} |
Sort Name | Format-Table Name, FolderSize, ItemsInFolder
```

Administrators don’t need to worry about Exchange mailbox storage in the same way as they do on-premises. This underscores a key point about the cloud: you don’t worry about how a service is delivered if the service works reliably and meets your needs.

**Folder Limit for Cmdlets:** The *Get-ExoMailboxFolderStatistics* and *Get-MailboxFolderStatistics* cmdlets both can return data for a maximum of 1,000 folders. Although it’s uncommon to find mailboxes with more than a thousand folders, the storage of data (“digital twins”) in mailboxes by the Microsoft 365 substrate on behalf of other applications has increased over time. Users aren’t aware of the issue because these are system folders stored in the non-IPM part of the mailbox, but scripts can run into problems if they encounter a mailbox with more than a thousand folders.

## User Role Assignment Policies

Exchange Online controls access to features using role-based access control (RBAC), a method of ensuring that people who need to do something have the right to do it. By default, Exchange Online has a single-user role assignment policy to control several aspects of user functionality. Elsewhere in the book, we update a user role assignment policy to control whether users can create distribution lists and add personal retention tags to their mailbox retention policy. For now, all we need to do is introduce the concept that user role assignment policies exist. Each policy divides into roles, each of which controls some aspect of functionality, such as:

- **MyContactInformation:** Enables users to update their contact phone numbers and address.
- **MyProfileInformation:** Enables users to update their name information, such as their display name.
- **MyDistributionGroups:** Controls what actions users can take with distribution lists.
- **MyDistributionGroupMembership:** This allows users to control their membership in the distribution lists they join.

Not every tenant uses all these roles. Some, like text messaging, are remnants of technology that was once more important than it is now. Descriptions of the [full set of user roles](#) are available online.

## Autodiscover

Microsoft originally introduced Autodiscover to stop users from having to create a “profile” with the details of the server and database hosting their mailbox before they could connect MAPI clients like Outlook to Exchange. Since its introduction, Autodiscover has proven to be extremely valuable and has expanded to give information to clients about other resources (such as the location of public folders, the OAB, and Exchange Web Services). Equipped with this information, clients know about these resources and how to access them when needed. Clients that use Autodiscover (desktop Outlook, Outlook for Mac, and many Exchange ActiveSync clients) can connect to Exchange Online to retrieve all the information necessary to configure settings in the user profile. The technical details about where their mailbox is located are invisible to the user. See this post for a description of [how to use Autodiscover in scripts](#).

**Autodiscover and Teams:** Exchange 2016 CU3 and later on-premises servers run Autodiscover V2. Teams clients need this version to connect to Exchange on-premises servers to retrieve calendar events and other information from mailboxes.

Simplifying the first connection to a mailbox is an important contribution to making it easier to onboard new users. All a user needs to know is their Microsoft Online Services identifier (usually the same as their SMTP email address) and password. With this information, Autodiscover can connect to Exchange Online, retrieve information about the services provided by Exchange Online, and return the information to the client as an XML-formatted manifest. You can see the contents of the manifest by using Outlook’s “Test Email Auto-configuration” function. Do not include the Guessmart and Secure Guessmart Authentication methods as they only work with IMAP4 and POP3 servers. The Autodiscover process is a little more complicated in hybrid deployments because the first connection goes to the on-premises organization and then to Exchange Online.

## Recovering Deleted Mailboxes

When you remove an account, a clock starts ticking and the Azure AD object for the user account stays in a soft-deleted state for a 30-day retention period. During this time, you can recover and restore the data belonging to the user, including their mailbox. Once the retention period elapses, Azure AD removes all traces of the user account, and the account becomes irretrievable. You can use the **Deleted users** view in the Microsoft 365 admin center (Figure 6-3) to see the set of deleted users that are still within the 30-day

retention period. The list includes any deleted guest accounts. You can select a user from this list and restore their account, including their mailbox, at any time until their retention period expires.

To restore a user account, select their entry to view the details of the account. If you're sure that you want to restore it, click **Restore user** and give details of what the password should be for the restored account (you can assign one, force the user to create one when they first sign in, or have a password auto-generated). Azure AD will then restore the user account to its pre-deletion state, including the mailbox (if they had one) as well as memberships of any distribution lists, Groups, and Teams to which the account belonged. It takes between 15 minutes and 30 minutes before the system restores an account fully. After the restore operation finishes, the user should be able to log on and use their account as before. See the PowerShell chapter for information about how to restore deleted accounts with PowerShell.

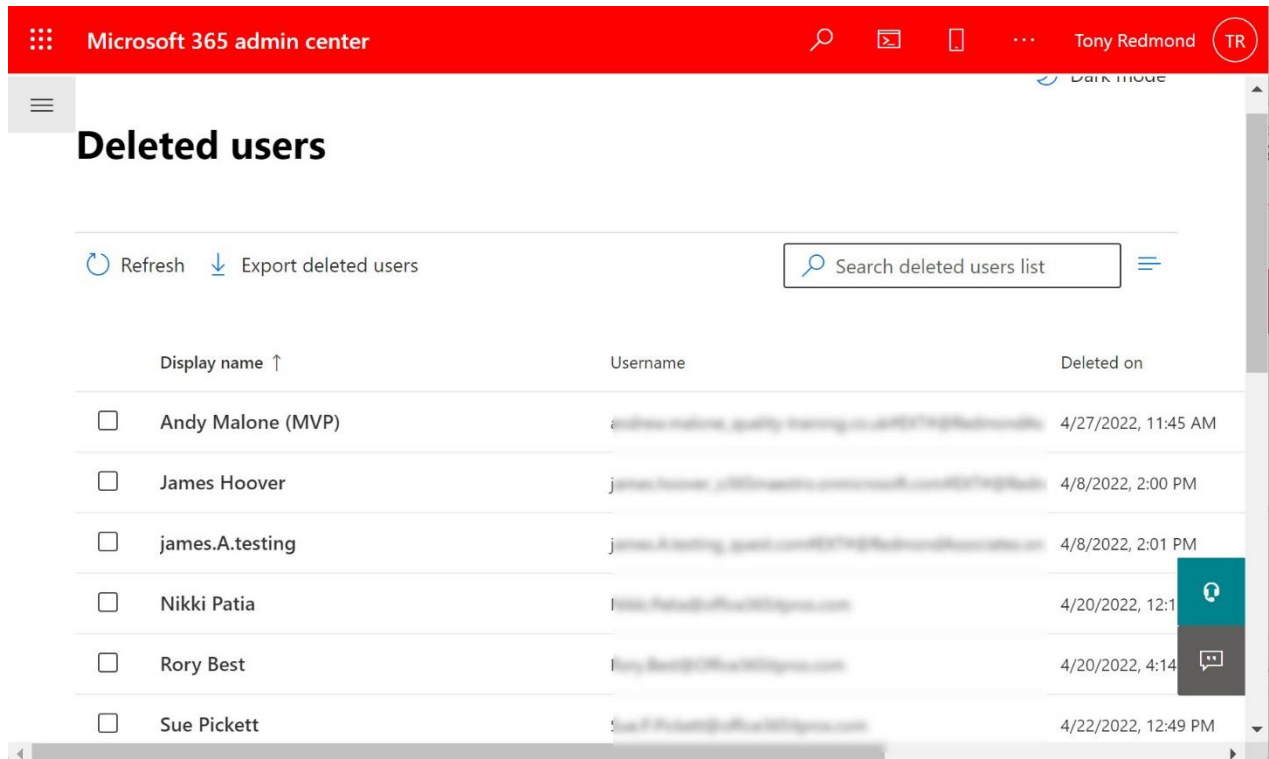

Figure 6-3: Viewing a deleted user in the Microsoft 365 admin center

Restored accounts might not receive licenses automatically and you should check the assigned licenses (and apps enabled or disabled for plans like Office 365 E3) after restoring an account to make sure that the account recovers full functionality. If you don't assign a license to a restored account, Exchange Online removes its mailbox in 30 days. The exception is if the mailbox is subject to a hold and you delete the user account which owns the mailbox. In this case, it becomes an inactive mailbox.

**Mailbox Recovery Troubleshooter:** Situations arise when administrators have discovered that they have removed the wrong mailbox and do not know what they should do to execute a recovery. To reduce issues in this area, Microsoft created a [mailbox recovery troubleshooter](#), a walk-through guide as to what an administrator needs to do to recover a mailbox. It is not a wizard and processing a successful recovery needs some skill in PowerShell and knowledge of the various PowerShell modules that are involved, but at least it's a step forward towards automated recovery.

## Removing an Unlicensed Mailbox

The usual methods to remove a mailbox from a Microsoft 365 account are to delete the account or take the Exchange Online license away from the account. If you remove the Exchange license from an account, Exchange notices the absence of the license and deprovisions the mailbox, putting the mailbox into a

disconnected state. The mailbox remains in this state for 30 days. During this time, you can reconnect the mailbox by restoring the account or adding the license back to the account. After the 30 days elapses, the Managed Folder Assistant permanently deletes the mailbox from its database.

When Exchange Online acknowledges the license removal, it sets the mailbox's *SkuAssigned* property to *\$False*. At this point, you can accelerate the removal process by running the *Disable-Mailbox* cmdlet (the cmdlet won't work if Exchange thinks the mailbox is licensed). Data in unlicensed mailboxes is not discoverable.

It's usually best to leave disconnected mailboxes for the Managed Folder Assistant to deal with and only use *Disable-Mailbox* when an urgent need exists to purge a mailbox immediately. Given the obvious compliance issues that might arise when a mailbox is purged especially when retention holds are in place, it's wise to document the reasons why this action is necessary and seek management approval before proceeding.

## Inactive Mailboxes

Sometimes you want to remove a user account because the account holder does not work for the company any longer. However, you need to keep the information in their mailbox for an extended period for legal or regulatory purposes or because it is a source needed for an eDiscovery case. In the on-premises world, you could disable the user's Active Directory account and leave their mailbox online. When the time comes to remove the account, you could export the mailbox to a PST if necessary to keep a copy of the mailbox.

Keeping unused mailboxes is not as straightforward in the cloud. The big difference is that you pay a monthly license fee for each account, so although you can disable (block) an account, you continue paying as long as the account and its mailbox remain online.

To address the problem of how to retain information in mailboxes potentially needed for eDiscovery after removing their owners' accounts, Microsoft created the concept of inactive mailboxes. These are online mailboxes belonging to accounts that no longer exist in Azure AD. The deciding factor to remove a mailbox when removing its account or making it inactive is whether any holds existed on its owner's account. The [holds that force Exchange Online to retain an inactive mailbox](#) include both org-wide holds (that apply to all mailboxes), litigation holds, and the holds placed by retention policies. Common ways to place a hold on a mailbox include:

- Put the mailbox on litigation hold. The hold covers the entire contents of the mailbox.
- Include the mailbox within the scope of a Microsoft 365 retention policy that keeps items covered by the policy for a defined retention period. The hold covers all content matching the hold criteria (which might be the complete mailbox and its archive).
- The presence of retention labels with a retain then delete or retain action on one or more items in a mailbox. Users can assign labels to mailbox items manually or the system can do so using an auto-label policy. In this instance, the hold is on the labeled items and once their retention period expires, the mailbox becomes available for deletion.
- Include the mailbox in a Core or Premium eDiscovery case that includes an in-place hold that includes the mailbox within its scope. eDiscovery cases allow you to use a query to select and hold a subset of the content in a mailbox. Do not input any search conditions if you want to hold everything in the mailbox (the equivalent of a litigation hold).
- Older in-place holds belonging to Exchange eDiscovery searches remain valid. Given that Microsoft deprecated these searches in 2020, the number of such holds remaining is now minimal.

Adaptive scopes support inactive mailboxes. Some organizations use this capability to ensure that they retain inactive mailboxes for a defined period. To do this, they create an adaptive scope to find inactive mailboxes and use this with a retention policy. The retention period set in this policy makes sure that the expiration of

other retention policies or labels do not cause the removal of inactive mailboxes. In effect, the policy acts as a retention backstop. For more information about retention policies, see the chapters covering eDiscovery and Compliance.

When an administrator deletes an Azure AD account, a 30-day countdown starts. During this time, administrators can recover the deleted account through the Deleted Users section in the Microsoft 365 admin center. The mailbox is inactive at this point because of the deletion of its corresponding user account. After 30 days, Azure AD permanently removes the user account and evaluates if the mailbox continues to be inactive because one or more holds exist on the mailbox. Remember that the personal data belonging to an account usually spans much more than a mailbox. Extra steps are necessary to secure all the information belonging to an account. We'll get to this point soon.

Because an inactive mailbox is no longer associated with an Azure AD account, it does not need a license. You can't sign into an inactive mailbox. If you want to access its contents, you must restore or recover the mailbox. You can also export the data from an inactive mailbox by running a content search and exporting the search results to a PST.

Exchange Online retains an inactive mailbox until the termination of the last hold on the mailbox. When this happens, Exchange Online puts the mailbox into a soft-deleted state and no longer considers it to be inactive. Exchange Online keeps mailboxes transitioning from the inactive state for 183 days before proceeding to permanent removal. The retention period (the soft-deleted date) commences when the mailbox moves out of the inactive state and not when the holds lapsed.

**Inactive Mailboxes and SMTP Addresses:** It's possible to have an inactive mailbox with the same SMTP address as an active mailbox. This works because the inactive mailbox is invisible for routing purposes, so the transport service only ever delivers emails sent to the address to the active mailbox. However, it's a horrible idea to allow this situation to occur because it's bound to cause confusion. One way around the problem is to remove all SMTP addresses from a mailbox and to assign it a new SMTP address before deleting its account. Ideally, the new SMTP address should be something that will never be used in production, like *Inactive.Andy.Ruth@Office365itpros.com*. This must be done before the mailbox becomes inactive because once it is inactive, you can't update its properties.

## Hybrid Inactive Mailboxes

Some problems exist in hybrid configurations where:

- The user account is on-premises.
- Their primary mailbox is on-premises or in the cloud.
- The mailbox is archive-enabled, and the archive is in the cloud.

In this scenario, you cannot make the mailbox inactive by deleting the user account. Microsoft has acknowledged the problem, but no solution is currently available. Two workarounds exist:

**Convert the mailbox into a shared mailbox.** This approach allows the retention of the archive. The shared mailbox must have at least an Exchange Online Plan 1 license. To make the shared mailbox more like an inactive mailbox, hide it from Exchange address lists and replace the email addresses for the mailbox with something that people are unlikely to guess.

**Transfer all the content from the archive back into the primary mailbox.** This can be done using Exchange Web Services ([here's a script](#) to show how), but only if the resulting size of the primary mailbox remains under 100 GB. When the transfer is complete, disable the archive and wait for Exchange to process the command (allow an hour or so), and then delete the user account.

Taking everything into consideration, the best solution is to convert the mailbox into a shared mailbox.

## Finding Inactive Mailboxes

The Data lifecycle section of the Microsoft Purview Compliance portal includes a tab to show details of inactive mailboxes. Although you can see what mailboxes are inactive and some details of the inactive mailboxes, you can't recover, restore, or do much else with the information.

The *Get-ExoMailbox* cmdlet can list any inactive mailboxes that exist in a tenant. This command retrieves the list of inactive mailboxes. The *WhenSoftDeleted* property tells us how long Exchange has kept the mailbox. Remember, this date commences upon the original deletion. The fact that some inactive mailboxes are present well after 30 days since their deletion tells us that holds remain on these mailboxes.

```
[PS] C:\> Get-Mailbox -InactiveMailboxOnly | Sort WhenSoftDeleted -Descending | Format-Table
DisplayName, WhenSoftDeleted
```

DisplayName	WhenSoftDeleted
-----	-----
Jack Smith	17/06/2021 15:37:53
Sanjay Patel	26/11/2020 14:10:56
Nancy Anderson	03/10/2021 13:14:05
Boris Johnstone	29/05/2022 09:23:00

If you check for soft-deleted mailboxes, you'll find that inactive mailboxes are in the returned set. This is because inactive mailboxes are technically in a soft-deleted state. The difference between the two sets is that Exchange Online permanently removes soft-deleted mailboxes which aren't inactive 30 days after they enter the soft-deleted state while inactive mailboxes remain untouched until the removal of the last hold. This command generates a list of soft-deleted mailboxes:

```
[PS] C:\> Get-ExoMailbox -SoftDeletedMailbox -Properties WhenSoftDeleted | Format-Table DisplayName,
WhenSoftDeleted
```

Although inactive mailboxes aren't in use, they need some management. Most of the time, these tasks amount to responding to an occasional need to recover or restore an inactive mailbox. But it's also a good idea to keep an eye on the set of inactive mailboxes and know why they are in that state. Inactive mailboxes are not visible within EAC (an [inactive mailboxes page](#) in the Data lifecycle management section of the Microsoft Purview Compliance portal lists inactive mailboxes), and it is easy to miss the fact that holds are in place for some deleted (and now inactive) mailboxes. For this reason, it is sensible to update the account properties of inactive mailboxes so that they become more obvious to administrators. For instance, you could update the display name for inactive mailboxes to mark their status. Hopefully, the visual reminder is enough to stop administrators from making embarrassing mistakes.

## Making Inactive Mailboxes with Holds

Inactive mailboxes remain in a soft-deleted state because they come within the scope of one or more holds. The type of hold isn't important: what is important is that the hold must exist before removing the Azure AD account. It is the combination of deleted account and an on-hold soft-deleted mailbox that makes an inactive mailbox. Data in inactive mailboxes remain indexed and discoverable for eDiscovery, but retention policies process inactive mailboxes to remove the information not required by the holds.

Although an inactive mailbox does not need a license, the account owning a mailbox must have a suitable license to allow the assignment of a hold on the mailbox before the user account is removed. Before administrators can assign retention policies to a mailbox, the owning account must have an Exchange Plan 2 or Exchange Online Archiving license. The Office 365 E3 and E5 plans include Exchange Plan 2.

You can put an inactive mailbox on litigation hold. This is useful when a hold associated with an eDiscovery search is about to lapse and you do not want this action to force Exchange Online to remove the inactive mailbox. To put an inactive mailbox on litigation hold, use the command:

```
[PS] C:\> Set-Mailbox -Identity "Jill Smith" -InactiveMailbox -LitigationHoldEnabled $True
```

## Removing Org-Wide Holds from Inactive Mailboxes

When a mailbox is inactive, a mixture of org-wide and specific holds might apply to it. The presence of any hold is enough to retain an inactive mailbox. As the tenant creates new org-wide holds, those holds apply to both active and inactive mailboxes (if you use an adaptive scope, it can be set to apply to mailboxes in a specific state, such as inactive). The net effect is that the number of org-wide holds that apply to inactive mailboxes can grow over time, which might then mean that some inactive mailboxes exist for longer than they should because the tenant applied extra org-wide holds after the mailboxes became inactive. This goes against the principle that organizations should be able to control the retention of information.

To solve the problem, the *Set-Mailbox* cmdlet supports the *ExcludeFromOrgHolds* and *ExcludeFromAllOrgHolds* parameters.

- **ExcludeFromOrgHolds:** Takes one or more GUIDs pointing to org-wide holds as input and excludes these holds from the evaluation of whether to keep an active mailbox.
- **ExcludeFromAllOrgHolds:** Excludes all org-wide holds from the evaluation of whether to keep an inactive mailbox.

When you exclude org-wide holds, Exchange will only keep an inactive mailbox if a specific hold exists on the mailbox or an org-wide hold is present. If no other holds exist, Exchange removes the mailbox.

For example, let's assume that you have many inactive mailboxes and want to clean up the set. To remove org-wide holds from the evaluation used by the Managed Folder Assistant to decide if an inactive mailbox is still subject to a hold, we retrieve the identifiers for the holds by running the *Get-OrganizationConfig* cmdlet:

```
[PS] C:\> Get-OrganizationConfig | Select -ExpandProperty InPlaceHolds
mbx9696959111f74ecda8a40aef97edd2c2:1
grp703105e3b8804a1093bb5cb777638ea8:1
mbx19200b9af08442529be070dae2fd54d3:1
grp6a1654abdba4712a43c354e28a4d56c:1
mbx703105e3b8804a1093bb5cb777638ea8:1
mbxc1e2d6f1785d4bf8a7746a26e58e5f66:1
```

Holds applying to user mailboxes are prefixed by "mbx." We can pass the identifiers in the *ExcludeFromOrgHolds* parameter as a comma-separated list. The example below passes the identifiers for two org-wide holds. The values used for the hold identifiers are in the same format as those reported by *Get-OrganizationConfig*. Notice that Exchange Online uses distinguished names to identify inactive mailboxes to ensure that it can find the mailboxes.

```
[PS] C:\> $InactiveMbx = (Get-Mailbox -InactiveMailboxOnly -ResultSize Unlimited)
ForEach ($Mbx in $InactiveMbx) {
  Write-Host "Removing Specific Org-Wide holds from" $Mbx.DisplayName
  Set-Mailbox -Identity $Mbx.DistinguishedName -ExcludeFromOrgHolds
  "mbx9696959111f74ecda8a40aef97edd2c2:1", "mbx19200b9af08442529be070dae2fd54d3:1" -Confirm:$False
  -Force}
Write-Host "Checking inactive mailboxes again"
$InactiveNow = (Get-Mailbox -InactiveMailboxOnly -ResultSize Unlimited)
Write-Host "$InactiveMbx.Count - $InactiveNow.Count" "mailboxes processed to exclude selected org-
wide holds "
```

In this example, we exclude all org-wide holds, so there's no need to pass any hold identifiers. Because you're now removing all org-wide holds from the evaluation of inactive mailboxes, it's even more important to make sure that you are happy for Exchange to remove all inactive mailboxes not covered by a specific hold.

```
[PS] C:\> $InactiveMbx = (Get-Mailbox -InactiveMailboxOnly -ResultSize Unlimited)
ForEach ($Mbx in $InactiveMbx) {
  Write-Host "Removing Org-Wide holds from" $Mbx.DisplayName
  Set-Mailbox -Identity $Mbx.DistinguishedName -ExcludeFromAllOrgHolds -Confirm:$False -Force}
```

```
Write-Host "Checking inactive mailboxes again"
$InactiveNow = (Get-Mailbox -InactiveMailboxOnly -ResultSize Unlimited)
Write-Host ($InactiveMbx.Count - $InactiveNow.Count) "mailboxes excluded from all org-wide holds"
```

If you examine the properties of an inactive mailbox after running *Set-Mailbox* to exclude some or all org-wide holds, you'll see that the GUIDs for the excluded holds are present in the mailbox's *InPlaceHolds* property and that Exchange prefixes each hold with a minus sign. This indicates that the Managed Folder Assistant should exclude the hold when evaluating the mailbox. For instance:

```
[PS] C:\> Get-ExoMailbox -Identity David.Pelton | Select -ExpandProperty InPlaceHolds

-mbxc1e2d6f1785d4bf8a7746a26e58e5f66
-mbx703105e3b8804a1093bb5cb777638ea8
-mbx19200b9af08442529be070dae2fd54d3
-mbx9696959111f74ecda8a40aef97edd2c2
-mbx6a1654abda4712a43c354e28a4d56c
UniH26c5d797-0fd3-496d-92ac-4f405700c917
```

The hold that is keeping this inactive mailbox is the last one on the list (it doesn't have a minus sign). This identifier points to a specific in-place hold.

Don't exclude org-wide holds from inactive mailboxes without understanding exactly what holds are keeping mailboxes in the inactive state as you cannot retrieve an inactive mailbox after Exchange removes it.

## Removing the Azure AD User Object for an Inactive Mailbox

Normally you must wait 30 days for a deleted mailbox to become fully inactive because its matching user account remains in the deleted objects section of Azure AD to allow administrators to recover the account and reconnect the mailbox during that period. You can discover which inactive mailboxes are in this state by running this command:

```
[PS] C:\> Get-Mailbox -InactiveMailboxOnly | ?
{![string]::IsNullOrEmpty($_.ExternalDirectoryObjectId)} | Format-Table DisplayName,
ExternalDirectoryObjectId

DisplayName ExternalDirectoryObjectId
-----
Imran Khan b8eef43d-6854-4d77-9e03-745cf2e11e11
```

If necessary, you can remove a user account by first deleting the account and then removing the deleted object. For example:

```
[PS] C:\> $UserId = (Get-MgUser -ObjectId David.Jacobs@Office365itpros.com).Id
Remove-MgUser -UserId $UserId
$Uri = "https://graph.microsoft.com/beta/directory/deleteditems/" + $UserId
Invoke-MgGraphRequest -Method Delete -Uri $Uri
```

Alternatively, you can remove a soft-deleted account through the Users section of the Azure AD portal. Select the Deleted Users view, then select the account you want to remove, and then click the **Delete permanently** button.

Usually, it's best to let nature take its course and let user accounts move through the 30-day account retention process until Azure AD purges the accounts and their mailboxes become inactive, but you never know when you might want to accelerate the process.

## Restore or Recover Inactive Mailboxes

In addition to being able to export the contents of inactive mailboxes through eDiscovery searches, you can also [retrieve information by restoring or recovering an inactive mailbox](#). When you restore an inactive mailbox, Exchange Online merges the contents of the mailbox into another mailbox. This might be done when

a user needs to work with the information contained in a mailbox that belonged to an ex-employee. Restoring data from an inactive mailbox leaves the inactive mailbox intact and still available for eDiscovery.

## Restore an Inactive Mailbox

The first step is to run the *Get-Mailbox* cmdlet to return a list of inactive mailboxes and identify which mailbox to restore. Several of the inactive mailboxes might share the same or a similar display name or other attributes, so we need a unique value for the mailbox to pass to Exchange Online to restore the mailbox. The Distinguished Name is best for this purpose, so we'll use that.

```
[PS] C:\> $Inactive = (Get-Mailbox -InactiveMailboxOnly -Identity "Jill Smith").DistinguishedName
```

We can now set up the restore with the *New-MailboxRestoreRequest* cmdlet to ask Exchange Online to fetch the data from the inactive mailbox and move it into a target mailbox. Remember, a restore operation leaves the inactive mailbox intact, so this is in effect a copy operation. The *AllowLegacyDNMismatch* switch allows the *New-MailboxRestoreRequest* cmdlet to process the restore request even though the distinguished names (DN) of the inactive and target mailboxes do not match. Normally, to safeguard against the misdirection of items to a mailbox that they don't belong to, *New-MailboxRestoreRequest* would refuse to copy items into a target mailbox if a DN mismatch existed. We proceed even though we know a mismatch exists, so we override the natural caution of the cmdlet by telling it that it's OK to go ahead and copy the items:

```
[PS] C:\> New-MailboxRestoreRequest -SourceMailbox $Inactive -TargetMailbox
Abrus@Office365ITPros.com -TargetRootFolder "Jill Smith Old Mailbox" -AllowLegacyDNMismatch
```

Name	TargetMailbox	Status
MailboxRestore	Abrus	Queued

The restore operation continues in the background. You can check it by running the *Get-MailboxRestoreRequest* cmdlet. When the status is "Completed," all the data from the inactive mailbox should be in the target mailbox. The target root folder specified in the restore request ("Jill Smith Old Mailbox") is in the target mailbox with all the folders and items that belonged to the inactive mailbox underneath that root.

If the inactive mailbox owns an archive, you can restore items out of the archive and direct them to either the archive of a target mailbox or to the target mailbox itself. *New-MailboxRestoreRequest* supports the *SourcesArchive* switch to control whether to copy items from the primary (the default) or archive mailbox and the *TargetsArchive* switch to control whether to restore items to the primary mailbox of the target or into its archive. Restoring items to an archive mailbox has the value of creating a clear separation between the restored items and the owner's items in the target mailbox.

## Recover an Inactive Mailbox

Recovering an inactive mailbox means the transformation of a mailbox into one that is usable by a new user. To make this happen, we run the *New-Mailbox* cmdlet to create a new mailbox and instruct Exchange Online to populate that mailbox with the inactive mailbox.

```
[PS] C:\> $Inactive = (Get-Mailbox -InactiveMailboxOnly -Identity "Jill Smith").DistinguishedName
```

```
[PS] C:\> New-Mailbox -InactiveMailbox $Inactive -Name "Joe Healy" -FirstName Joe
-LastName Healy -DisplayName "Joe Healy" -MicrosoftOnlineServicesID "Joe.Healy@Office365ITPros.com"
-Password (ConvertTo-SecureString -String "Testing123!" -AsPlainText -Force)
-ResetPasswordOnNextLogon $True
```

In this case, we take the inactive mailbox of Jill Smith and use it to create a new mailbox under the control of Joe Healy, a new account. After *New-Mailbox* completes, the old inactive mailbox is gone, and its content is in the Joe Healy mailbox. To complete the process and make the mailbox fully operational, you must assign a license to the new mailbox.

You cannot use the recover method for an inactive mailbox while its user account still exists in Azure AD (for 30 days following the removal of the account). During this period, you can use the standard Recover Deleted Users option to restore the account and reactivate the mailbox, but you can't recover the data to a new mailbox. To test whether the user object still exists for an inactive mailbox, run *Get-Mailbox* as shown below. In this case, Exchange returns a GUID, so you know that the object still exists.

```
[PS] C:\> Get-Mailbox -InactiveMailboxOnly -Identity 'Jill Smith' | Select ExternalDirectoryObjectID
ExternalDirectoryObjectId
-----
636578d1-89fd-42e6-8b1d-237c96635a95
```

If you recover an inactive mailbox, any holds that existed on the mailbox when it was removed are not active. Instead, Exchange enables single item recovery for the mailbox and puts a retention hold in place for 30 days to be sure that nothing is removed through the application of retention policies in that time.

## Automatic Mailbox Maintenance

Like on-premises Exchange, the Managed Folder Assistant (MFA) runs on a workcycle basis to apply retention policies to mailboxes and clean out deleted items that have exceeded their retention period. The SLA for the MFA calls for it to process mailboxes at least once weekly, but MFA often processes mailboxes more regularly. You can't affect when mailbox management happens because this happens automatically, but you can affect how MFA processes mailboxes by changing the mailbox properties that govern retention policy. To view details of a mailbox's assigned retention policy, open the *Manage mailbox policies* section of mailbox properties in EAC. The *Manage mailbox archive* section of mailbox properties shows if the mailbox has an archive and if so, how much quota the archive uses. Alternatively, you can run the *Get-ExoMailbox* cmdlet to retrieve the same information:

```
[PS] C:\> Get-ExoMailbox -Identity TRedmond -PropertySets Archive -Properties DisplayName,
RetentionPolicy | Format-Table DisplayName, RetentionPolicy, ArchiveName

DisplayName      RetentionPolicy      ArchiveName
-----
Tony Redmond     Management retention policy  {Grubby old stuff}
```

Exchange Online assigns the default Messaging Retention Management (MRM) retention policy to all mailboxes upon creation, including migrated on-premises mailboxes. In contrast, an on-premises administrator must make an explicit choice to assign a retention policy to a mailbox. The rationale for having a default retention policy in place for all mailboxes is that it allows MFA to exert some level of control over mailbox contents.

Figure 6-4 shows some of the retention tags included in the Default MRM Policy, with the "Default 2 year move to archive" tag selected. This is a default tag, meaning that the Managed Folder Assistant applies its action to all items not governed by a more explicit retention tag. The action is to move items to the archive once they are 730 days (2 years old). In effect, MFA checks the retention period on items each time it processes a mailbox and will move any older than 2 years to the archive mailbox. Logically, this action can only happen if a mailbox has been archive-enabled. If not, MFA ignores the directive contained in the default archive tag. Unlike other retention policies that you might be aware of, the default MRM policy used by Exchange Online does not include a default delete tag, so if items are not archived, they continue to accumulate in the primary mailbox unless the user deletes them.

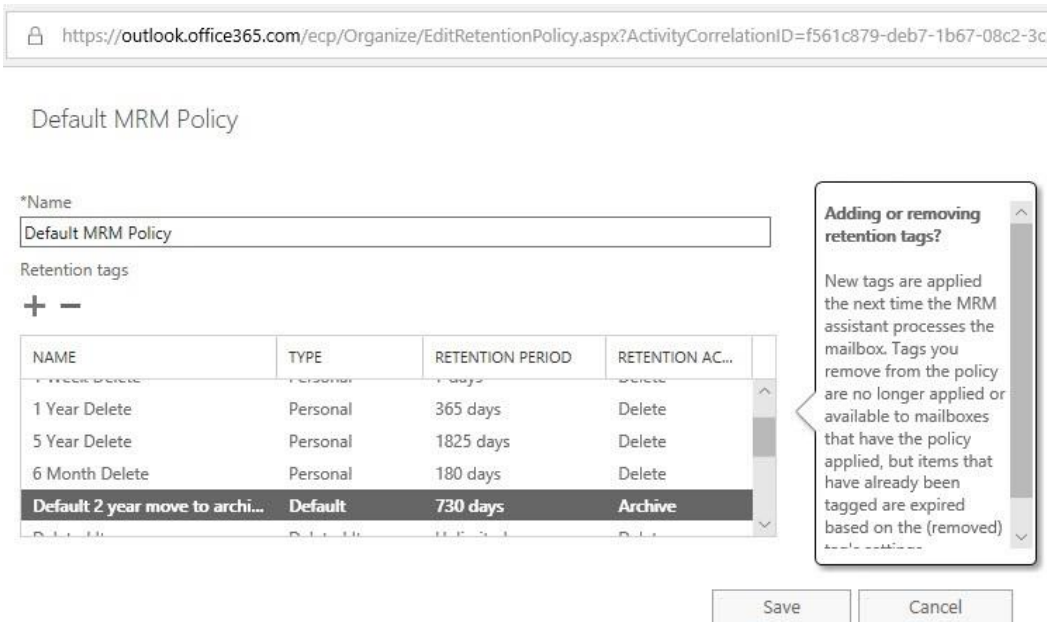

Figure 6-4: Retention tags in the Default MRM Policy for Exchange Online

## Mailbox Data Retention

Exchange Online uses what Microsoft calls Native Data Protection to protect data. Here are some aspects of mailbox management to consider:

- Each mailbox database has at least four copies spread across two data centers within the host Office 365 region. One of these is a lagged copy.
- As explained in the Compliance chapter, the default retention policy applied to Exchange Online mailboxes does not force the removal of items from the Deleted Items folder. You can change this behavior by changing the retention policy assigned to user mailboxes. If not, items stay in the Deleted Items folder until the user empties the folder or the items move to an archive mailbox.
- Exchange Online enables Single Item Retention (SIR) for every mailbox so that items moved into Recoverable Items stay in the database for the full retention period set on the mailbox. The default for the deleted items retention period used to be 14 days but (since 2017) it is 30 days, which is also the longest period you can set for this property. Exchange retains deleted Calendar items for up to 120 days.
- If you want to update older mailboxes, you can do so with this command:

```
[PS] C:\> Get-ExoMailbox -RecipientTypeDetails UserMailbox -Properties RetainDeletedItemsFor | ?
{$_ .RetainDeletedItemsFor -Lt 30} | Set-Mailbox -RetainDeletedItemsFor 30
```

If the deleted items retention period for a mailbox does not update when you run the command, check its *UseDatabaseRetentionDefaults* property. This must be *\$False* before you can update *RetainDeletedItemsFor*. Some older mailboxes have this property set to *\$True* (it's a legacy of the on-premises heritage of Exchange Online).

- Compared to the frequent access for items in primary mailboxes, archive mailboxes usually experience infrequent access. The default retention period moves items from the primary mailbox to the archive after they are two years old.

## Recovering Deleted Items

It is possible users will discover that they need to recover some items after they empty the Deleted Items folder, or a retention policy removes items from the folder. Exchange Online's Single Item Recovery feature ensures that deleted items remain in Recoverable Items for the full deleted items retention period configured for the mailbox.

Under Recoverable Items, two important sub-folders hold items:

- The **Deletions** folder stores deleted items removed from the Deleted Items folder (by emptying the complete folder or removing individual items) or items removed from other folders with the SHIFT+Delete command. While items remain in the Deletions folder, users can recover them by opening the Deleted Items folder and then using the **Recover items deleted from this folder** feature supported by Outlook or OWA (Figure 6-5).
- The **Purges** folder (which is invisible to clients like Outlook) stores items removed from Deletions. For example, if someone uses the Recover Items feature to find items and then purges them, Exchange removes the items from Deletions into Purges. The items remain there until the deleted items retention period passes or, if the mailbox is on hold, any relevant holds elapse.

As explained below, it's also possible for administrators to recover items on behalf of users by running PowerShell cmdlets or using an option in the EAC. Once the retention period elapses, the Managed Folder Assistant removes the items from the database the next time that it processes the mailbox. At this point, the items become irrecoverable.

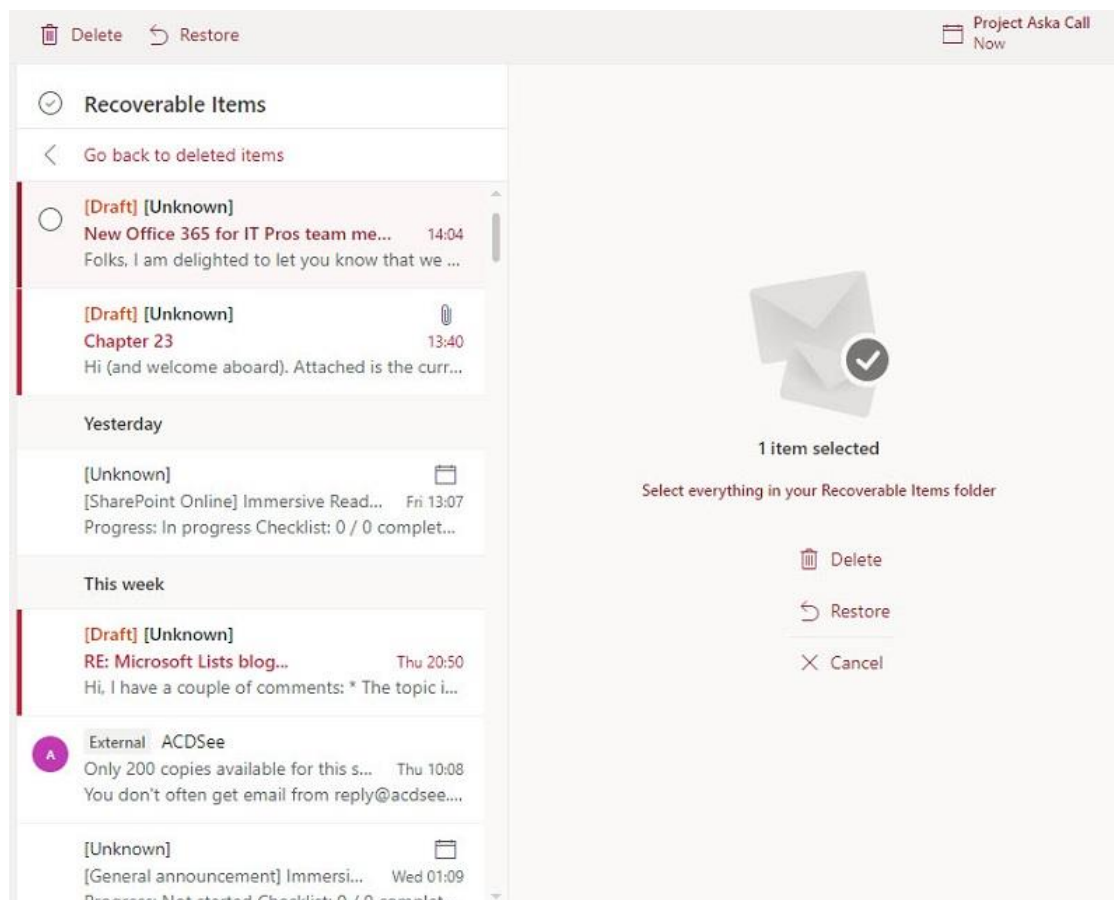

Figure 6-5: OWA lists recoverable items

Microsoft does not take backups of Exchange Online mailbox databases. Once Exchange removes an item from a database, it is permanently gone and no number of appeals to Microsoft Support will result in its

recovery. For this reason, some administrators place some mailboxes on a permanent in-place hold or a litigation hold. The logic is as follows:

- An in-place hold keeps deleted items needed by the hold in the hidden Purges subfolder of the Recoverable Items folder until the hold lapses. The in-place hold feature is not part of every plan and a mailbox needs to have at least an E3 or Exchange Online Plan 2 license before an administrator can put the mailbox on hold.
- Problems are more severe if items are irrecoverable for mailboxes belonging to executives or other critical personnel.
- Users will not remember to protect every piece of sensitive information – the system must do this for them.
- Exchange Online makes sufficient quota available to the Recoverable Item folder (and its sub-folders) to store deleted mailbox items to satisfy the requirements of Single Item Recovery or in-place holds.
- Deleted items under hold are invisible to the user and clients. An administrator can retrieve these items by executing an eDiscovery search. Once found, exporting the search results to a PST makes the items available for return to the user (or, in the case of an investigation, to investigators).

It is difficult to estimate how much of the Recoverable Items quota a hold will consume. Even a busy mailbox will remove less than 10 GB of unwanted messages annually and a hyperactive mailbox will consume perhaps 20 GB. The default quota is therefore capable of holding five years of deleted items – and probably more for less active mailboxes. However, when you have the combination of a busy mailbox and litigation hold (or multiple in-place holds), you need to keep an eye on the growth of Recoverable Items to ensure that a mailbox does not exceed its quota ([premium monitoring](#) includes this capability). Once the quota consumed approaches 85% of its limit, it's time to talk to Microsoft Support to see if they can assign some additional mailbox quota. If not, you might need to take another approach, such as:

- Use the Mailbox Folder Assistant (MFA) to remove duplicate items from Recoverable Items. Often a surprising amount of information accumulates that can be safely removed without compromising the effectiveness of a hold. To have the MFA scan and remove duplicate items, run the *Start-ManagedFolderAssistant* cmdlet and specify the *HoldCleanup* parameter. For example:

```
[PS] C:\> Start-ManagedFolderAssistant -Identity Kim.Akers -HoldCleanup
```

- Use retention tags and policies to [move data from Recoverable Items to the archive mailbox](#) (and exploit auto-expanding archives).
- After securing approval to do so, [delete some items from the Recoverable Items folder](#).

## Administrator Recovery of Deleted Items

Sometimes, users need help to recover items. In the past, an administrator had to sign in to the user mailbox to perform recovery on behalf of the user. The problem with this approach is that it compromises the privacy of the mailbox. For this reason, Exchange Online includes two cmdlets to help administrators recover user data without needing to access the mailbox with a client:

- *Get-RecoverableItems* searches the Deleted Items folder and the Purges and Deletions sub-folders within Recoverable Items of the target mailbox to find items. The administrator doesn't need to sign into the target mailbox, which can be a user or a shared mailbox.
- *Restore-RecoverableItems* finds and copies items from Deleted Items and the Purges and Deletions sub-folders of Recoverable Items to their original folders.

The basic idea is that you use *Get-RecoverableItems* to construct a search to find the desired items and then use the search results as input to *Restore-RecoverableItems* after you've found the right items. Before trying to run these cmdlets, make sure that the account you use to sign into PowerShell holds the Exchange "Mailbox

Import Export" RBAC role. To find out who has the role already, you can run the following command. In this example, the members of the Organization Management role group have the role as does the Administrator account.

```
[PS] C:\> Get-ManagementRoleAssignment -Role "Mailbox Import Export" | Format-Table RoleAssigneeName
RoleAssigneeName
-----
Organization Management
Administrator
```

An example of using *Get-RecoverableItems* to search a mailbox for items is shown below. The search looks for any item of type *Ipm.Note* (messages) moved into Recoverable Items during a certain period. This happens when the user or the Managed Folder Assistant moved the item into its current folder. For instance, if a mailbox has a retention policy that moves items from Deleted Items into Recoverable Items after 120 days, the Managed Folder Assistant might have processed the items found by the search above at least four months ago. A user can bypass Deleted Items and send an item direct to Recoverable Items by using the *SHIFT+Delete* key combination. In this case, the *LastModifiedTime* property (used for date filters) is the date when the user executed *SHIFT+Delete*.

```
[PS] C:\> Get-RecoverableItems -Identity Kim.Akers -SourceFolder RecoverableItems -FilterStartTime "2/16/2018 10:00:00" -FilterEndTime "2/20/2018 17:00:00" -FilterItemType Ipm.Note
```

## Location of Deleted Items

Administrators can recover deleted Items from three locations, each referred to as a source folder:

- **DeletedItems:** The Deleted Items folder from the user's mailbox.
- **RecoverableItems:** The Deletions subfolder in the Recoverable Items folder of the user's mailbox.
- **PurgedItems:** The Purges subfolder in the Recoverable Items folder. Deleted items kept due to a retention policy stay here until the retention period set in the policy expires.

These names are language-independent. You cannot search folders in the archive mailbox. To search for deleted items across all locations, don't pass a *SourceFolder* parameter to *Get-RecoverableItems*. For example, this search finds all deleted items for Kim Akers' mailbox:

```
[PS] C:\> $Items = Get-RecoverableItems -Identity Kim.Akers
```

Capturing the items returned by a search in an array makes it easier to process them afterward:

## Finding Deleted Items

Although you could go through every deleted item from all locations to find something to restore, it's better when the user for whom you're restoring items gives some hints about the items they want to recover. Users might not be sure when an item was deleted, but they should be able to tell you something about the message subject. Here's an example of using *Get-RecoverableItems* to find a message by subject.

```
[PS] C:\> $Items = (Get-RecoverableItems -Identity Kim.Akers -SourceFolder RecoverableItems -SubjectContains "disgruntled")
```

Be aware that a search based on *SubjectContains* finds any item which contains the provided string in its subject, so it's good to be as precise as possible. For instance, this search would find items with subjects like "Disgruntled at work" or "Handling disgruntled employees."

The example of the data returned for an item in Recoverable Items is shown below.

```
LastParentPath      : Junk Email
LastParentFolderID  : EBA28A7861EE1F4485DA85FE1279C88C000009CA9700
OriginalFolderExists : True
Identity            : Kim.Akers
```

```
MailboxIdentity      : b662313f-14fc-43a2-9a7a-d2e27f4f3478\ea58dd70-4581-4190-aeef-52075e470846
ItemClass           : IPM.Note
Subject            : How to Catch Attacks by Disgruntled Employees
EntryID            : 00000000E4D17F986EC65C4EB677E1EB8F1015F20700EBA28A7861EE1F4485DA85FE1279C
                   : 88C0000000001140000EBA28A7861EE1F4485DA85FE1279C88C0005228415330000
SourceFolder       : Recoverable Items\Deletions
```

Obviously, the more precise the search, the more likely you are to find the right item. For instance, it's possible that the user will be able to give an approximate period when an item was deleted, so you could use that to refine the search. For example:

```
[PS] C:\> $Items = (Get-RecoverableItems -Identity Kim.Akers -SourceFolder PurgedItems -
FilterStartTime "13-Jun-2020 00:17" -FilterEndTime "13-Jun-2020 00:35")
```

A date-based search only works against a single location.

## Searching for Specific Types of Deleted Items

You can specify different types of items to look for, but you cannot combine different item types in a search. Instead, if you want to find items of multiple types, don't pass a *FilterItemType* parameter and the search will return items of all supported items. If needed, you can then apply a filter using PowerShell to isolate the required items. The valid item types include:

- IPM.Note: A standard email message item.
- IPM.Appointment: A calendar meeting or appointment.
- IPM.Task: A task.
- IPM.Contact: A contact.
- IPM.File: A file stored in the mailbox. These include files created by Office 365 as the result of some processing.

## Restoring Deleted Items

Once you are happy that your search finds the right items, you can proceed to recovery. The *Restore-RecoverableItems* cmdlet takes the same search that you use to find items and restores each item to its original location. You can input the same search as you used to find the item, but if multiple items are returned and you only want to restore a single item, pass the *EntryID* (a unique identifier) for the item. For example, let's assume that the search returned twenty items. The items are stored in the *\$Items* variable, so we can pass a reference to the exact item we want to restore with:

```
[PS] C:\> Restore-RecoverableItems -Identity Kim.Akers -EntryID $Items[0].EntryID -SourceFolder
RecoverableItems
```

The response to a successful restore will confirm the folder the item has been restored to:

```
RestoredToFolderPath : Junk Email
RestoreToFolderId    : EBA28A7861EE1F4485DA85FE1279C88C000009CA9700
WasRestoredToOriginalFolder : True
WasRestoredSuccessfully : True
Identity             : Kim.Akers
MailboxIdentity      : b662313f-14fc-43a2-9a7a-d2e27f4f3478\ea58dd70-4581-4190-aeef-52075
                   : e470846
ItemClass           : IPM.Note
Subject            : How to Catch Attacks by Disgruntled Employees
EntryID            : 00000000E4D17F986EC65C4EB677E1EB8F1015F20700EBA28A7861EE1F4485DA85
                   : FE1279C88C000000001140000EBA28A7861EE1F4485DA85FE1279C88C00052284
                   : 15330000
SourceFolder       : Recoverable Items\Deletions
```

Of course, if you wanted to, you could create a processing loop to process a batch of mailboxes and restore the messages, possibly after an administrator makes a mistake and deletes messages in error using a content search purge. Here's an example:

```
[PS] C:\> $Mbx = (Get-ExoMailbox -RecipientTypeDetails UserMailbox -Filter {CustomAttribute1 -eq "IT"} | Select Alias, DisplayName)
Write-Host "Recovering items for" $Mbx.Count "mailboxes..."
ForEach ($M in $Mbx) {
    Write-Host "Checking mailbox" $M.DisplayName
    Restore-RecoverableItems -Identity $M.Alias -SourceFolder RecoverableItems -SubjectContains "Important and Critical Message" }
```

## Recover Deleted Items in EAC

The EAC includes a GUI for the *Get-RecoverableItems* and *Restore-RecoverableItems* cmdlets to recover items for user and shared mailboxes (Figure 6-6). The GUI leverages the cmdlets and can do much of the functionality described above. The differences are:

- EAC offers fixed date ranges (7, 14, and 30 days).
- EAC can process a single mailbox at a time.

Deleted on	Entry ID	Subject line	Item type	Folder type	Original folder

Figure 6-6: Recover deleted items in the Exchange admin center

When an administrator recovers items on behalf of a user by running the cmdlet in PowerShell or the EAC, Exchange Online generates a *Restore-RecoverableItems* audit record for each recovered item in the audit log. An example script showing how to report these audit records can be [downloaded from GitHub](#).

## Archive Mailboxes

The motivation to introduce archive mailboxes (also known as “in-place archives” or “online archives”) for Exchange arose for many reasons. Over the years, Microsoft did not like the fact that customers deployed third-party products like Symantec Enterprise Vault to offload information from user mailboxes to a separate repository. Often there was good reason to move data, especially when Exchange mailbox quotas were small, and databases ran on expensive SAN storage. Moving data to secondary storage managed by other products allowed Exchange mailboxes to continue without the need for increased quotas, albeit with “stubs” left behind in mailboxes as pointers to the actual items. If you plan to move previously archived items from external

repositories back into Exchange Online, it is important to ensure that the stubs are “rehydrated” (become fully complete Exchange items) as part of the process.

From a Microsoft perspective, moving information out of Exchange databases implied a certain loss of control as the data could be as easily migrated to a different server as moved back to Exchange. Another issue that has become increasingly important is that PST data are invisible to compliance and data governance features. An example of how important it is for companies to protect their commercial interests and business reputation is seen in [the Sony hack of December 2014](#) when hackers stole and shared valuable contractual information held in PSTs. The messages revealed to the public had details of negotiations, strategies, opinions about business partners, and so on. It would have been so much better had this data been securely kept in online databases rather than being vulnerable to hackers.

Small mailbox quotas encouraged the proliferation of PSTs and created a plague of insecure and potentially corruptible files holding valuable user information. Because email messages are commonly shared between multiple users, PST data usually includes a high percentage of duplicate items. The existence of so much duplicated information slows down the transfer of data from PSTs to online mailboxes. In addition, users can attempt to protect PSTs with passwords that range from very easy to very difficult to crack. If you gather PSTs from users for migration, you must remove passwords from the PSTs to make their data accessible for migration processing. Some third-party PST migration engines can deduplicate content extracted from PST before ingestion and crack open any password-protected files to extract the information contained within. These are valuable features that you should consider and evaluate during any PST migration (eradication) project.

Because PST migration is often tiresome and expensive, a better solution is to encourage users to keep their data online. The solution to allow online storage to replace PSTs came about in two parts. To make it feasible to provide very large mailbox quotas to users, Microsoft engineered the mailbox database engine to support JBOD. This effort included the introduction of the Native Data Protection features used within Exchange Online today. Archive mailboxes, first introduced in Exchange 2010, are the second part. At that time, the plan envisaged that larger mailboxes meant that no one would ever want to use a PST because their mailbox had so much available space. The accompanying archive mailboxes are the repository for long-term information and avoided the need for Exchange customers to buy a third-party archiving product. Mailboxes have become larger and archive mailboxes are in common use, but users have not yet discarded PSTs. It takes a long time and much effort for Outlook users to break working habits based on PSTs, including using these files as shared repositories when much better options exist like Groups or SharePoint team sites.

**Keeping everything in the primary mailbox:** [Enterprise plans \(E3 - E5\)](#) grant 100 GB primary mailbox quotas to users, which then creates a question of whether archive mailboxes are necessary. After all, 100 GB should be enough to hold as much data as anyone would want to keep. Although large mailboxes enable people to avoid using archive mailboxes, a workable case exists to separate information into the data which needs to be on hand and items users must keep for reference purposes. In this scenario, the items you need on-hand remain in the primary mailbox, and those needed for reference (or compliance) go into the archive. Good retention policies help users achieve the split by automatically moving items into the archive after a set period (two years is the default).

Archive mailboxes are now available to any Exchange on-premises or cloud mailbox except those using online frontline (kiosk) plans. Some plans [limit the combined storage for primary and archive mailboxes](#) but plans E3 and above allow “unlimited” storage. This used to mean unlimited in that auto-expanding archive mailboxes could grow to well over 2 TB. Such massive mailboxes caused operational difficulties, such as problems moving mailboxes between databases, so Microsoft decided to limit the size of archive mailboxes to 1.5 TB.

Microsoft offers Exchange Online Archiving to allow on-premises customers to use a cloud-based archiving service. In this scenario, mailboxes hosted on Exchange on-premises servers can connect to unlimited Exchange Online archive mailboxes without having to perform a full hybrid deployment. The reverse (archive

on-premises and mailbox in the cloud) is unsupported. Exchange Online Archiving is also available as an add-on plan for Exchange Online kiosk mailboxes.

An archive mailbox is an online-only extension of the primary mailbox. The link between the two is through the *ArchiveGuid*, a property of the user mailbox that points to the location of the archive. Other archive-related properties set when a mailbox becomes archive-enabled include:

- **ArchiveDatabase:** The Exchange Online database holding the archive mailbox.
- **ArchiveName:** A user-friendly name for the archive mailbox that shows up in a client's resource list. You can change the name to whatever value you like. For example, "Joe's Online Archive."
- **ArchiveQuota:** The current storage quota assigned to the archive. The current default for Exchange Online is 100 GB. Administrators can apply to Microsoft support to have the quota increased.
- **ArchiveWarningQuota:** The threshold for the user to receive warning messages to tell them that space is running out in the archive. The current default is 90 GB.
- **ArchiveStatus:** Set to "Active" when the archive mailbox is available to a user. It is set to "None" when an archive mailbox is not present.
- **ArchiveState:** Set to "Local" when the mailbox and archive are on the same platform (the case when Exchange Online hosts both).

To assign an archive to a mailbox, select the mailbox in the EAC, go to the Others section in mailbox properties, and use the Manage mailbox archive option to enable or disable the archive. Alternatively, edit the mailbox properties, go to the mailbox features section, scroll down to archiving, and click **Enable**. The equivalent PowerShell command is:

```
[PS] C:\> Enable-Mailbox -Identity 'Joe Smith' -Archive
```

Only Outlook desktop and OWA support client access to archive mailboxes. Outlook Mobile does not include this capability because the necessary API support is unavailable. The same is true for mobile clients based on the ActiveSync protocol, such as the native mail app client on iOS and Android devices.

Shared and room mailboxes can both be enabled with an archive. Although there are many reasons why you might need an archive for a shared mailbox, the case is much less obvious for a room mailbox. You can't enable an archive for a group mailbox. If you archive-enable a shared or room mailbox, remember that you need to assign at least an Exchange Online Plan 1 license to the mailbox.

You can check for mailboxes that have archives by running the *Get-ExoMailbox* cmdlet with the *Archive* switch. The first command below returns a list of archive-enabled mailboxes. The second returns a simple count of archive-enabled mailboxes.

```
[PS] C:\> Get-ExoMailbox -Archive -RecipientTypeDetails UserMailbox -PropertySet Archive -Properties DisplayName -ResultSize Unlimited | Format-Table DisplayName, ArchiveName
```

DisplayName	ArchiveName
Deirdre Redmond	{Deirdre's Online Archive}
Tony Redmond	{Grubby old stuff}
Jeff Guillet	{Jeff's Archive}
Kim Akers	{In-Place Archive - Kim Akers}

```
[PS] C:\> (Get-ExoMailbox -Archive -ResultSize Unlimited -RecipientTypeDetails UserMailbox).Count
15
```

Disabling an archive removes the ability of the mailbox owner to access the content held in the archive. The data in the archive remains there and does not move back to the primary mailbox. Disabling an archive means that you break the connection between the primary and archive mailboxes. To disable an archive with EAC, open mailbox properties and select the **Manage mailbox archive** link, and then set the state to Off. Exchange Online allows disablement of an archive only if no in-place or litigation holds exist for a mailbox. This

restriction exists to ensure that no one can remove data potentially needed for eDiscovery from Exchange Online. The PowerShell command to disable an archive is:

```
[PS] C:\> Disable-Mailbox -Identity 'Joe Smith' -Archive
```

Although disabling an archive prevents user access to the archive, it does not remove the content from its database. Instead, a 30-day retention period starts. During this time, you can recover the archive and reconnect it to the primary mailbox by re-enabling the archive. Exchange Online removes the archive mailbox after the 30-day deleted mailbox retention period expires. If you examine mailbox properties after disabling an archive, you'll see that the *ArchiveGuid*, a unique value used by Exchange to find the archive mailbox within a database, is a set of zeros. This is how clients know that they shouldn't try to open an archive for this mailbox. However, Exchange preserves the original value of the *ArchiveGuid* in the mailbox's *DisabledArchiveGuid* property, which means that it is easy to re-establish the link to the archive by running the *Enable-Mailbox* cmdlet. After the archive is re-enabled, the two GUID values should be identical.

```
[PS] C:\> Get-ExoMailbox -Identity 'Joe Smith' -PropertySet Archive | Format-List *ArchiveGuid
```

```
ArchiveGuid           : 00000000-0000-0000-0000-000000000000
DisabledArchiveGuid : d7c65fee-c983-4eac-8fa3-6381a8673212
```

```
[PS] C:\> Enable-Mailbox -Identity 'Joe Smith' -Archive | Format-List *ArchiveGuid
```

```
ArchiveGuid           : d7c65fee-c983-4eac-8fa3-6381a8673212
DisabledArchiveGuid : d7c65fee-c983-4eac-8fa3-6381a8673212
```

Several of the PowerShell cmdlets that are commonly used to work with mailboxes include an *Archive* switch to point them to the archive rather than the primary mailbox. The *Get-ExoMailboxStatistics* and *Get-ExoMailboxFolderStatistics* cmdlets are good examples:

```
[PS] C:\> Get-ExoMailboxStatistics -Identity 'Kim Akers' -Archive
[PS] C:\> Get-ExoMailboxFolderStatistics -Identity 'Kim Akers' -Archive
```

```
DisplayName           : Online Archive - Kim Akers
MailboxGuid           : afc1e472-0826-498e-b990-85de223e809d
DeletedItemCount     : 508953
ItemCount             : 75218
TotalDeletedItemSize : 40.34 GB (43,317,558,017 bytes)
TotalItemSize        : 9.129 GB (9,802,226,010 bytes)
```

Note that the *DeletedItemCount* and *TotalDeletedItemSize* properties reported by *Get-ExoMailboxStatistics* refer to information stored in the Recoverable Folders structure. The storage occupied by these items does not count against mailbox or archive quotas. They do apply against the overall 1.5 TB limit for an auto-expanding archive mailbox.

The Data lifecycle management section of the Microsoft Purview Compliance portal also includes a list of archive mailboxes. The same functionality is available there to set up and manage archive mailboxes as through the EAC.

**Naming archives:** The default name for an archive mailbox is *"In-Place Archive – User"* (for example, *"In-Place Archive – Tony Redmond"*). However, you can assign whatever name you like by running the *Set-Mailbox* cmdlet. The name can be at least 80 characters (the largest value I have tested). OWA is the only archive-capable client that will display the name that you assign as Outlook ignores the value and uses a normalized name of *"Online archive – primary SMTP address"*. There is no reason why the two client development teams decided to display different default names for archive mailboxes or why Outlook did not follow OWA in allowing the display of user-specific names. It is just another Exchange quirk.

## Moving Information into Archive Mailboxes

After a mailbox is archive-enabled, it appears automatically in client interfaces. OWA recognizes the archive the next time the user connects to Exchange Online, and the Outlook desktop client learns that the archive exists when it refreshes the list of available resources through the Autodiscover process. When the archive appears, the user can move information to it by creating folders and dragging and dropping items from their primary mailbox.

Exchange Online uses mailbox plans to assign default values to new mailboxes. One of the values in a mailbox plan defines the retention policy for the mailbox. This isn't a Microsoft 365 retention policy. Instead, it's an Exchange mailbox retention policy that can contain a default archive tag to control how items move from the primary mailbox into the archive (if a mailbox is archive-enabled). For instance, if the default archive tag defines a retention period of two years, the Managed Folder Assistant moves items that don't have another retention tag from the primary to the archive mailbox once they reach two years old. The items go into a folder with the same name.

Using a default archive tag means that archive mailboxes grow on an ongoing basis as items move from the primary mailboxes. To remove items from the archive, the retention policy can include a default delete tag. For instance, if the retention period for the default delete tag is five years, the MFA will:

- Obey the retention period specified in the default archive tag and move items from the primary mailbox to the archive after two years.
- Obey the retention period specified in the default delete tag to remove items from the archive after a further three years (the items reach the five-year limit).

In addition, when a mailbox is archive-enabled, MFA moves items captured because of retention processing in the Purges, Versions, and DiscoveryHolds sub-folders under the Recoverable Items folder one day after their creation (depending on when the MFA processes a mailbox, the actual move might take place two or three days after creation). This action frees up space in the Recoverable Items quota assigned to mailboxes (100 GB when a mailbox is archive-enabled) to allow the primary mailbox to store more time-critical data such as the items in the Deletions folder.

Of course, most users are blissfully unaware of the boring details of retention policies. They might not even notice the movement of items from the primary mailbox to the archive mailbox until they look for something and can't find it because the item is not where they thought it should be – in their mailbox. Of course, the item is still available, and it is, in a roundabout way, still in their mailbox. It is just invisible in some respects because the user doesn't know where it is or understand how it got there.

Microsoft defines archive mailboxes as personal repositories. [Microsoft explicitly prohibits](#) the use of transport rules, journal rules, auto-forwarding, or other methods to move information into a mailbox from multiple sources for archiving purposes. However, it is permissible to import data from multiple PSTs that might have originated from multiple users into an archive mailbox. The difference between the two is that using an archive mailbox as an archive destination creates the potential that the archive mailbox will expand on an ongoing basis to cope with the items moving into the archive. On the other hand, if you perform a once-off import to an archive mailbox, its content will probably not change all that much in the future as the archive is essentially historical rather than live. In other words, it's a question of dealing with "hot" data that is constantly growing or "cold" data imported once and hardly ever accessed thereafter.

## Effective Use of Archive Mailboxes

Because primary user mailboxes can hold up to 100 GB, many users can quite happily get along by just using their primary mailbox and never need to use an archive. Consider the following:

- It will take most users several years to accumulate 10 GB of mailbox data. Some users accumulate 20 GB+ of new mailbox content annually, but they are exceptional. On the other hand, people have had quite a while to accumulate information in their mailboxes at this point and many of the mailboxes that move to Exchange Online are already up at the 20 GB mark (or higher).
- In the past, many caveats were expressed about the desirability of holding more than 2 GB in the primary mailbox. Apart from the cost of storage, most problems related to offline access and the need to synchronize such a large amount of data to an OST file whose internal structure was never designed to cope with large volumes. These issues have largely been dealt with today due to faster networks and smarter Outlook synchronization. The larger amounts of data synchronized to clients do slow down OST access speeds, a factor that can be handled by equipping laptops with SSDs that effectively disguise the inefficiency of the OST.
- Archive mailboxes can only be accessed online. Outlook does not synchronize any archive folder into the OST. While the bulk of data moved into the archive might never be accessed again, the potential that someone might need an archived item when a network connection is not available does exist.
- Searches can find items stored in archives but only if the user specifies that Outlook should search "All Mailboxes." Searching the archive in OWA needs the user to be positioned within an archive folder. Neither of these operations is especially intuitive to someone who might be unaware that they have an archive.
- ActiveSync clients cannot access archive mailboxes because the protocol does not support this type of resource. The same is true for Outlook for iOS and Android clients.
- Users seldom want to decide what items should be always available (and in their primary mailbox) and those that can be safely moved into the archive. Expecting users to decide on a data storage strategy is an act of folly.

With these points in mind, it should come as no surprise to find that some tenants avoid the use of archive mailboxes and tell users to exploit the storage now available in primary mailboxes. Indeed, some companies have reversed course and decided to only use primary mailboxes. In some cases, they have had to move information back from archives to primary mailboxes. Apart from dragging and dropping items from folder to folder using Outlook or OWA or exporting archive items to a PST and importing them back into the primary mailbox, there is no in-built method to do this. In most cases, the solution is to create a script to move items using a combination of PowerShell and Exchange Web Services.

On the other hand, some tenants consider archive mailboxes to be the perfect answer to the problem of unmanaged and proliferating PSTs and make strenuous efforts to import data from user PSTs into archive mailboxes so that everything is online and available for compliance. The availability of Microsoft's Import Service, which allows tenants to load PSTs into Azure for later import into user mailboxes (primary or archive) has spurred many companies to consider how they should deal with PSTs in the future. Moving information from PSTs into archive mailboxes exposes the data for compliance purposes, but this is an exercise that involves much more than ingesting data from individual PST files. Before importing anything, you must decide how to collect the PSTs, clean them up (remove corruptions), crack passwords set on the PSTs, and possibly deduplicate the content so that the import processes clean information. Remember the adage that rubbish in equals rubbish out.

Another effective use of archive mailboxes is to hold data migrated from older POP3 or IMAP4 systems. It is also fair to say that companies who have moved data back from third-party archiving solutions to Exchange Online find archive mailboxes to be a natural evolution. In summary, the decision to use or ignore archive mailboxes comes down to the circumstances and business conditions that exist within a tenant.

**PST Import Tools:** Many tools are available to help you move data from user PSTs into primary or archive mailboxes. Like any software utility, you should carefully test the software in your environment to discover which product best meets your needs. Once you have collected and prepared (made sure no corruption

exists) the PSTs, you can use the Import service to either upload the PSTs over the network or send them on hard drives to a Microsoft data center for processing. In either case, the PST data will be ingested into Azure and can be imported from there into user mailboxes.

## Auto-Expanding Archives

The mailbox quotas assigned in enterprise plans are more than enough to handle the storage requirements for most users. The low demand for user interaction makes it practical to allow archive mailboxes to have much higher storage limits than primary mailboxes. In turn, a greater storage capacity allows archive mailboxes to act as long-term repositories to replace PSTs ingested through the Import service. Microsoft's solution is the "auto-expanding archive," meaning that the archive mailbox can expand as it fills.

User or shared mailboxes with E3 and E5 licenses or with the Exchange Online Plan 2 license or the Exchange Online Archiving add-on can use auto-expanding archives. To figure out whether a mailbox is eligible, you can check its persisted capabilities, which expose the licenses assigned to a mailbox. In this case, the presence of *BPOS\_S\_Enterprise* means that the mailbox can use auto-expanding archives. The other values are *BPOS\_S\_ArchiveAddOn* (Exchange Online Archiving) and *BPOS\_S\_Archive* (Exchange Online Plan 2).

```
[PS] C:\> Get-ExoMailbox -Identity TRedmond -Properties PersistedCapabilities | Select -ExpandProperty PersistedCapabilities
```

```
BPOS_S_ThreatIntelligenceAddOn  
BPOS_S_EquivioAnalytics  
BPOS_S_CustomerLockbox  
BPOS_S_Analytics  
BPOS_S_Enterprise
```

In some respects, the technique used to expand archives borrows from the auto-split capability built into public folder mailboxes. When a public folder mailbox approaches 50 GB, the Mailbox Replication Service creates a new mailbox and (MRS) transfers folders to the new mailbox to balance the load.

**Auto-Expand Archive Limits:** A 1.5 TB limit for auto-expanding archives applies from November 1, 2021. While there are thousands of terabyte-plus archives in use, the limit is unlikely to affect many tenants. If the change affects your organization, you should contact Microsoft support. A script to report how close archive-enabled mailboxes are to the limit is [downloadable from GitHub](#).

[Microsoft's guidelines](#) say that only individual or shared mailboxes with a growth rate that does not exceed 1 GB per day support expandable archives. The reason for this restriction is to ban the use of archive mailboxes as targets for the migration of non-personal data from legacy services. It is perfectly acceptable to use an archive mailbox as a migration target for personal data such as PSTs.

### Enabling Auto-Expanding Archives

To enable auto-expanding archives, run the *Set-OrganizationConfig* cmdlet to update the tenant configuration:

```
[PS] C:\> Set-OrganizationConfig -AutoExpandingArchive
```

Once set, the new configuration ensures that all existing archives become auto-expanding, and any new archives are auto-expanding. The process of enabling existing archives can take some time to complete due to the need for the Managed Folder Assistant to process each mailbox. Only [a subset of Exchange Online clients](#) can access an auto-expanding archive. Other clients can access information in the primary archive but cannot access any data moved into an auxiliary archive.

If you do not want to enable auto-expanding archives for all mailboxes, you can control the capability on an individual basis using the *Enable-Mailbox* cmdlet. An archive must already exist for the mailbox before you can make it auto-expanding. For instance, to enable an auto-expanding archive for Kim Akers:

```
[PS] C:\> Enable-Mailbox -Identity "Kim Akers" -AutoExpandingArchive
```

In a hybrid deployment, you can enable auto-expansion for a cloud archive where the primary mailbox is on-premises. However, if you do this, you will not be able to move the archive back to Exchange Server.

Some thought and planning are necessary for the deployment of auto-expanding archives. Enablement is a one-way process. No method exists to collect the pieces of an auto-expanding archive together to make them into a single "standard" archive mailbox. In addition, you cannot move a mailbox with an auto-expanding archive to an on-premises server until Microsoft releases a version of Exchange Server which supports the transfer of these mailboxes. In the interim, if you want to move items out of an auto-expanding archive to transfer data to another mail system or an on-premises server, you will have to export the needed data to PSTs. Running an eDiscovery content search to find and export the data is an effective way to achieve this goal. You can make a mailbox with an auto-expanding archive inactive by putting it on hold and then removing the user account. Although this allows for the long-term preservation of mailboxes for compliance purposes, you should still review your procedures covering how to remove user accounts from the tenant to ensure that everything works as you expect.

When you enable auto-expanding archives for a mailbox, Exchange:

- Increases the normal 100 GB quota for the primary mailbox to 110 GB and modifies the quota warning threshold from 90 GB to 100 GB.
- If the mailbox comes within the scope of a hold, Exchange increases the Recoverable Items quota from 100 GB to 110 GB.

It can take up to 30 days before the process to enable auto-expansion for an archive completes. The changes to the primary mailbox quotas reflect the fact that expanding archives are more likely used by busy mailboxes, so it makes sense to give the primary mailbox a little extra headroom to ensure that the mailbox can continue operating while the process to enable the auto-expanding archive is active.

One limitation is that if you need to search auto-expanding archives with OWA or Outlook, you can only search within a specific folder. eDiscovery content searches can find information stored in any part of an auto-expanding archive, which also supports litigation and in-place holds as normal.

In many cases, it is preferable to enable auto-expanding archives for selected accounts instead of a complete tenant. Those accounts are usually those that have a genuine business need to keep massive quantities of information for certain periods.

## How an Archive Mailbox Expands

When you enable a mailbox for archiving, it starts with a single 110 GB archive mailbox. After the occupied space within the archive mailbox approaches the transition threshold (90 GB), a mailbox assistant automatically provisions a new archive mailbox. Exchange calculates the occupied size from the total size of folders in the archive mailbox with their *Movable* flag set to *\$True* or the *FolderType* set to *DeletedItems* or *RecoverableItems*.

To find the set of mailboxes with expandable archives, run the command:

```
[PS] C:\> Get-ExoMailbox -ResultSize Unlimited -RecipientTypeDetails UserMailbox, SharedMailbox | ? {$_.MailboxLocations -like "*AuxArchive*"} | Format-Table DisplayName, MailboxLocations
```

To gain an insight into the current state of the primary archive for an individual mailbox, we can use PowerShell to scan the folders in the primary archive to report the occupied space. Later in this section, we discuss how to retrieve the GUID for the primary archive to use as input for the *Get-ExoMailboxFolderStatistics* cmdlet.

```
[PS] C:\> $CheckUser = Read-Host "Enter User to check"  
$UserGuid = (Get-ExoMailbox -Identity $CheckUser | Select -ExpandProperty ExternalDirectoryObjectId)
```

```

$MLO = (Get-MailboxLocation -User $UserGuid | Select MailboxLocationType, MailboxGuid | ?
{$_MailboxLocationType -eq "MainArchive"})
$Folders = (Get-ExoMailboxFolderStatistics -Identity $MLO.MailboxGuid.Guid | Select FolderPath,
Movable, FolderType, Name, ItemsInFolder, FolderSize)
$NumFolders = 0; $TotalSize = 0
$Folders | Add-Member -MemberType ScriptProperty -Name FolderSizeInBytes -Value {$this.FolderSize -
replace "(.*\(|,| [a-z]*\)", ""}
ForEach ($F in $Folders) {
    If ($F.FolderType -eq "DeletedItems" -or $F.FolderType -eq "RecoverableItems" -or $F.Movable -eq
$True) {
        $TotalSize = ($TotalSize + $F.FolderSizeInBytes)
        $NumFolders++ }
}
$TotalSizeGB = [math]::round($TotalSize/1GB, 3)
$ThresholdPercent = ($TotalSizeGB/90).ToString("p")
Write-Host $NumFolders "movable folders found. Occupied space" $TotalSize "bytes or" $TotalSizeGB
"GB." "At" $ThresholdPercent "of 90 GB transition threshold"

Enter User to check: TRedmond
92 movable folders found. Occupied space 5834011419 bytes or 5.433 GB At 6.04% of the 90 GB
transition threshold

```

After provisioning, the new archive mailbox is a “chunk” or “shard,” or more correctly “auxiliary archive,” and joins the overall archive. Exchange links the GUID for the new auxiliary archive with the GUIDs of the existing auxiliaries and primary archive to form a chain or set of mailboxes that the Information Store considers a single logical entity. The expansion of an archive to form an archive chain occurs without user intervention and without affecting supported clients, which continue to query the Information Store for data and receive data back without knowing which part of the archive holds the data.

The Managed Folder Assistant coordinates the movement of information out of the primary archive to an auxiliary archive to reduce the size of the primary archive under the transition threshold. This exercise aims to move enough data to the auxiliary archive to get the primary archive under 50% of its current size. So, if the primary archive grows to 95 GB, the Managed Folder Assistant examines the folders in the primary archive and selects enough to move approximately 47.5 GB to the auxiliary archive. The Deleted Items and Recoverable Items folders are not movable, but the Managed Folder Assistant can create sub-folders under these folders in the target archive and move content there.

The Mailbox Replication Service moves the data from the primary to the auxiliary archive and takes care of ongoing synchronization to ensure that any changes made to data while the move progresses are in the moved data. The copying of content occurs in the background. To ensure that no data loss occurs during the rebalancing of the archive, the primary archive keeps the copied data for 30 days. When this period elapses, the Managed Folder Assistant flushes the copied data from the primary archive to release the space.

## Archive Links

Archives link to their primary mailboxes by storing the GUID pointing to the archive as a mailbox property. The GUID is enough for Exchange to find the archive in a database. The auto-expanding archive replaces the single GUID that connects the mailbox to the archive with a linked list of GUIDs. Each of the GUIDs points to a separate auxiliary archive of up to 50 GB, which Exchange Online combines with the other auxiliary archives and the primary archive to form a logical archive mailbox.

You can see the details of the GUIDs by running the *Get-ExoMailbox* cmdlet to examine a mailbox’s properties. If you look at the *MailboxLocations* property, you will see something like this:

```

[PS] C:\> Get-ExoMailbox -Identity TRedmond -Properties MailboxLocations | Select -ExpandProperty
MailboxLocations

1;0370f354-2752-4437-878d-cf0e5310a8d4;Primary;eurprd04.prod.outlook.com;d96ca5a2-340d-4c83-be33-
d4a7a8c9b1d6
1;afc1e472-0826-498e-b990-85de223e809d;MainArchive;eurprd04.prod.outlook.com;e46d4e31-3734-47dc-
801d-5d59f9988766

```

The information about mailbox locations reported by *Get-ExoMailbox* divides into two sections: one for the primary mailbox and the second for the archive. Only the primary mailbox and the primary archive are shown here. If other auxiliary archives are present, the archive section lists them as mailboxes 2, 3, 4, and so on. The information for the two mailboxes is:

Primary mailbox:

- The *ExchangeGUID* (which ties the mailbox back to a user account).
- "Primary" to show that this data refers to the user's primary mailbox.
- If, as in this case, the mailbox database is in Exchange Online, the name of the Exchange Online forest is noted (eurprd04).
- The GUID of the database holding the mailbox.

Archive mailbox:

- The *ArchiveGUID* (which is only present when a mailbox is archive-enabled).
- "MainArchive" to show that this data is an archive set. When auxiliary archives are part of the set, they are tagged with "AuxArchive."
- The name of the Exchange Online forest hosting the archive mailbox. This value is empty for on-premises mailboxes.
- The GUID of the database holding the archive.

In this case, the mailbox and the archive are in the same database (you can confirm this by using *Get-Mailbox* to examine the *Database* and *ArchiveDatabase* properties). And, as you would expect, both the primary and archive mailboxes are in the same Exchange Online forest. Another way of accessing information about these archives is with the *Get-MailboxLocation* cmdlet. For example:

```
[PS] C:\> Get-MailboxLocation -User TRedmond | Sort MailboxLocationType -Descending | Format-Table MailboxGUID, MailboxLocationType
```

MailboxGuid	MailboxLocationType
0370f354-2752-4437-878d-cf0e5310a8d4	Primary
afc1e472-0826-498e-b990-85de223e809d	MainArchive
bb131464-1461-147e-b774-41646ddadd11	AuxArchive

In this case, the *MailboxGuid* property for the user's primary mailbox and all the parts of the archive are more obvious. The *MailboxGuid* is needed if you want to check how much data Exchange has moved to an auxiliary archive. For example:

```
[PS] C:\> Get-ExoMailboxStatistics -Identity bb131464-1461-147e-b774-41646ddadd11 | Format-Table ItemCount, TotalItemSize
```

ItemCount	TotalItemSize
30225	4.398 GB (4,722,299,639 bytes)

We now know that Exchange has moved a certain amount of data to the auxiliary archive.

**Migrating Large On-Premises Archives:** On-premises archive mailboxes can grow past 100 GB. At this point, they can no longer be migrated to Exchange Online using the online migration tools. The reason is that even for auto-expanding archives, the initial quota assigned by Exchange Online is all that's available until the auto-expansion provisioning process completes. Even then, an auto-expanding archive cannot add storage dynamically in the middle of an online migration. For this reason, two options exist if you have large on-premises archive mailboxes to move to Exchange Online: reduce the archives to under 100 GB and use the online migration tools or find a different migration tool. One approach is to export archive data to PSTs and import the PSTs into Exchange Online using the Office 365 Import Service. A third-party

migration service might be able to automate much of the processing needed to get the data imported into Exchange Online.

## Outlook's Archive Folder

Exchange Online mailboxes include an Archive folder as one of the default folder set created inside all mailboxes. Apart from a user being able to apply a retention tag to the Archive folder to move items in the folder to the archive mailbox after a period, the Archive folder has no relationship to the "online archive." Instead, Microsoft envisages the Archive folder as a convenient place to move items from the Inbox after a user has finished processing the items but wishes to keep them for a period.

The advantage of putting items in the Archive folder rather than removing them or having Exchange Online move them to the archive mailbox is that items in the Archive folder are available to mobile clients. Items in the archive mailbox are inaccessible to mobile clients because the protocols used by these clients only support primary mailboxes. Items in the Archive folder are also available offline while items in the archive mailbox are only accessible when a network connection is available. Sometimes that network connection is not fast enough to allow easy access to archived items, including searching those items. Because local searches can process cached copies of the Archive folder, searches complete faster, and items are more accessible.

Outlook, OWA, and Outlook Mobile support one-click (or swipe) options to allow users to easily move items to the Archive folders. The idea is that a user can quickly move through their Inbox to triage items by reading, removing, or archiving items as required. Because it is a mailbox folder, you can synchronize the Archive folder to other mobile clients, but one-click access will not be available unless the developer of the client incorporates the necessary GUI.

## Shared Mailboxes

Shared mailboxes have been part of the Exchange product since Exchange 2000. They meet the need to have a mailbox to handle messages that a team of people might process, such as the team staffing a support desk. The implementation of shared mailboxes in Exchange Online is like that found on-premises, with the disabled user object used to instantiate the shared mailbox created in Azure AD. Shared mailboxes have many uses, including:

- To allow groups of users shared access to functional email. For example, all the support agents who staff a help desk can use a shared mailbox to review and respond to messages sent to the help desk by users asking for help. Sometimes these mailboxes are called functional mailboxes and are often used to ensure that incidents can be managed effectively by multiple people across shift boundaries. A major attraction of this use is that messages sent in response come from the shared mailbox rather than the individual user.
- To allow users access to the mailbox of a colleague who has left the company. This is done by changing the personal mailbox into a shared mailbox and assigning access to the mailbox to those who need access. This technique is used extensively in on-premises organizations.

Mailbox delegation goes together with shared mailboxes because there is not much point in creating a shared mailbox if you cannot then access the mailbox. Because a shared mailbox is linked to a user object in Azure AD, access to its contents must be gained by delegating or granting permissions over the mailbox to other users. The *Get-ExoMailbox* cmdlet enables us to discover the set of shared mailboxes known in a tenant:

```
[PS] C:\> Get-ExoMailbox -RecipientTypeDetails SharedMailbox | Format-Table Name, DisplayName, Alias
```

Name	DisplayName	Alias
----	-----	-----

<b>Customer Services</b>	<b>Customer Services</b>	<b>CServices</b>
<b>Book Feedback</b>	<b>Book Feedback</b>	<b>BookComments</b>
<b>Help Desk</b>	<b>Corporate Help Desk</b>	<b>HelpDesk</b>

A shared mailbox can be hosted by Exchange Online or, in a hybrid environment, on-premises. In this instance, the shared mailbox is known as a remote shared mailbox when accessed from the other platform. It is best to keep shared mailboxes on the same platform as used by the accounts that have delegated access to the mailboxes. In other words, if you want to move some shared mailboxes to Exchange Online, move the mailboxes that access those shared mailboxes to Exchange Online too. Exchange Online places no limit on the number of shared mailboxes that you can create within a tenant.

## Licensing, Quotas, and Limitations of Shared Mailboxes

By default, a shared mailbox does not need a license. However, once a feature described in Table 6-2 is enabled for a shared mailbox, you should assign a license. Go to the Active users view in the Microsoft 365 admin center, select the shared mailbox, edit its properties, and assign the license under **License and Apps**.

<b>Feature</b>	<b>License</b>
Enable an archive for a shared mailbox.	Exchange Online Plan 1 or Exchange Online Archiving.
Place a hold on a shared mailbox (this includes the mailbox being a custodian in a Microsoft 365 Advanced eDiscovery case).	Exchange Online Plan 2.
Exceed the default 50 GB mailbox quota.	Exchange Online Plan 2.

Table 6-2: Licensing requirements for shared mailboxes

Microsoft documentation has always said that the default quota for shared mailboxes is 50 GB. Because of some errors in the provisioning process, many shared mailboxes received a 100 GB quota without the need for a license. These mailboxes keep their 100 GB quota unless the mailbox state changes. For example, if you convert a shared mailbox to be a user mailbox and then convert it back again, the shared mailbox object then needs a license to keep its 100 GB quota. New shared mailboxes receive the correct 50 GB quota.

Here's a PowerShell script to report on the set of shared mailboxes in a tenant. The report shows the current number of items in each mailbox, the size of the mailbox, the assigned quota, whether it is licensed, and if it has an archive. In this case, only one shared mailbox is licensed, one was previously licensed but had the license removed, and the others have never been licensed. All the mailboxes existed before Microsoft put the new provisioning process in place, so they all have 100 GB quotas.

```
[PS] C:\> $SMbx = Get-ExoMailbox -RecipientTypeDetails SharedMailbox -ResultSize Unlimited -
PropertySet All
$Report = [System.Collections.Generic.List[Object]]::new()
ForEach ($S in $SMbx) {
    $Archive = "Disabled"
    If ($S.ArchiveName -ne $Null) { $Archive = "Enabled" }
    $Quota = $S.ProhibitSendReceiveQuota.Split("(")
    $Stat = (Get-ExoMailboxStatistics -Identity $S.UserPrincipalName | Select ItemCount,
TotalItemSize)
    $ShMbxSize = $Stat.TotalItemSize.Value
    $Size = $ShMbxSize.ToString().Split("(")[0]
    $ReportLine = [PSCustomObject]@{
        Mailbox      = $S.DisplayName
        TotalItems   = $Stat.ItemCount
        MailboxSize  = $Size
        Quota        = $Quota[0]
        Licensed     = $S.SkuAssigned
        Archive      = $Archive }
    $Report.Add($ReportLine)}
$Report | Format-Table Mailbox, TotalItems, MailboxSize, Quota, Licensed, Archive -AutoSize
```

Mailbox	TotalItems	MailboxSize	Quota	Licensed	Archive
Customer Services	213	7.484 MB	100 GB	False	Enabled
Book Feedback	301	7.278 MB	100 GB		Enabled
Redirect for Removed Mailboxes	198	814 KB	100 GB		Disabled
Redmond Shared Events	3777	190.5 MB	100 GB		Disabled
Company Information	252	897.4 KB	100 GB		Disabled

If a shared mailbox without a license exceeds 50 GB, Exchange stops delivering email to the mailbox. You can assign a license to the mailbox to restore delivery. Because Exchange caches mailbox information, the newly licensed status, and the 100 GB quota, take about 15 minutes to become effective, after which email delivery recommences.

If you convert a user mailbox holding more than 50 GB to a shared mailbox (often done to keep mailboxes for ex-employees), Exchange continues to deliver mail to the mailbox while the mailbox is licensed. In most cases, people convert user mailboxes to shared mailboxes to free up licenses, so if you go ahead and do this, Exchange detects that the mailbox holds more than 50 GB and ceases email delivery. You can restore delivery by removing content from the mailbox to get it under the 50 GB quota or by assigning a new license.

Moving shared mailboxes from on-premises Exchange organizations will fail if they hold more than 50 GB and the MailUser object for the target shared mailbox in Exchange Online is unlicensed. To allow migrations to succeed (up to the 100 GB quota), assign a license to the MailUser object. This limitation exists for all migrations performed by the Mailbox Replication Service (MRS) or third-party migration utilities.

An unlicensed shared mailbox can be placed on hold or archive-enabled as Exchange Online does not perform a licensing check before enabling the feature. These are technical licensing breaches that will only come to light in an audit. Even if the mailboxes continue to work without a license, the danger always exists that Microsoft might turn on code to enable restrictions to stop unlicensed shared mailboxes from working, so it's best to make sure that the correct licenses are in place.

Although companies often use shared mailboxes for functional purposes, apart from inbox rules, Exchange doesn't have any out-of-the-box way to automate the processing of messages arriving in a shared mailbox, so a mailbox delegate must sign into the mailbox to handle new emails. Performance for a shared mailbox can be problematic if more than twenty users try to access it concurrently. Finally, users who have an Exchange Online frontline/kiosk license cannot add delegates to their mailbox, but they can access a shared mailbox if someone makes them a delegate for that mailbox.

## Creating a New Shared Mailbox

New shared mailboxes are created through the **Groups** section of the Microsoft 365 admin center. Not much information is needed to create a shared mailbox (Figure 6-7). After you click Add, Exchange Online needs a short delay to provision the mailbox and make it ready to add the users who will access and use the mailbox. Remember that users do not log into a shared mailbox as happens with a regular mailbox and that access to its contents occurs by opening the mailbox as a secondary resource within Outlook or OWA.

✕

## Add a shared mailbox

Email can be sent to and from the name and email address of the shared mailbox, rather than an individual. After you create the shared mailbox, you can add members who can read and reply to email.

Name \*

Email \*

 @  

[Save changes](#)

Figure 6-7: Creating a new shared mailbox with the Microsoft 365 admin center

## Mailbox Delegates and Permissions

After creating a shared mailbox, you must assign permission to the mailbox to allow access to those who need to work with it (its delegates). You can assign permissions when creating a new shared mailbox or by editing the mailbox object in the Microsoft 365 admin center or through PowerShell. Mailboxes support three delegate permissions:

- **Full Access** permission allows a user to open the shared mailbox and access its contents. Full Access does not mean that a user has *SendAs* permission. Microsoft 365 refers to this permission as “Read and manage mail to this mailbox.”
- **Send As** permission allows a user to send messages from the shared mailbox that appear as if the messages came from the shared mailbox rather than the user. In effect, a user with this permission can impersonate the mailbox. This is the best situation when you want replies to conversations started from the mailbox to flow back to the shared mailbox.
- **Send On Behalf Of** permission means that a user can send an email on behalf of the mailbox. Unlike the Send As permission, the name of the user who sends the message is obvious. You can only set this permission for a shared mailbox through PowerShell.

Full Access permission allows a user to work with all folders and items inside the shared mailbox. Users need both Full Access and Send As permissions to work with a shared mailbox as if it was their personal mailbox. In addition to shared mailboxes, which is why these are the two permissions featured in the admin centers, Exchange Online supports the assignment of the Send As and Send on Behalf of permissions to user and group mailboxes.

After creating a shared mailbox with the Microsoft 365 admin center or EAC, you can use the **manage mailbox permissions** option (Microsoft 365 admin center) or **Manage mailbox delegation** option (EAC) to define permissions for the shared mailbox. As noted above, the following permissions are available for shared mailboxes:

- Read and manage (Full Access).
- Send As.

Figure 6-8 shows that two users have full access to a shared mailbox (oddly, three have the Send As permission). Because Exchange Online caches permissions for better performance, it can take up to an hour for the new permission to be effective. In addition to a refresh of the server caches, clients must learn that

users have permissions for a shared mailbox. For example, Outlook clients learn about access to a shared mailbox through its Autodiscover process, which runs every 15 minutes for this purpose.

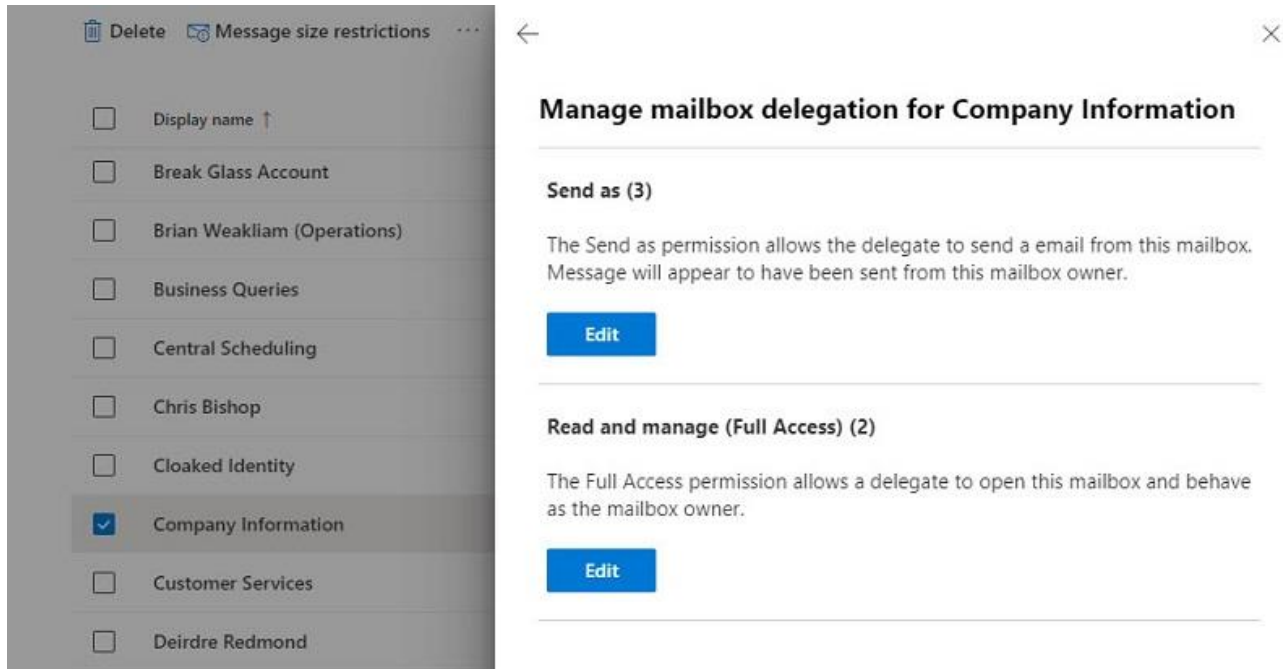

Figure 6-8: Assigning delegate permissions for a shared mailbox (EAC)

If you need to assign access to a shared mailbox to multiple users, it is often more convenient to assign permission to a distribution list, which must be a security-enabled group. You cannot assign permissions for a shared mailbox to a normal distribution list because these groups are not security principals, and you cannot assign permissions to a group or a dynamic distribution list either.

You can edit the delegate permissions for a shared mailbox to add or remove members or work with individual permissions. Select the mailbox in the Microsoft 365 admin center or EAC and use **Manage mailbox permissions** or Manage mailbox delegation to assign or remove individual permissions. Once again, it will take a little while before the amended permissions become fully active across the tenant.

**Shared mailbox or Groups:** On the surface, Groups seem like a better and more modern choice as the basis for team sharing than a shared mailbox. That statement might be true if the requirement is to collaborate based on shared documents, meetings in the group calendar, and threaded conversations with perhaps a link to a plan managed by Planner. However, shared mailboxes still have some unique strengths. For instance, shared mailboxes allow access to a full range of folders rather than the limited set used in a group mailbox. In addition, shared mailboxes support shared contacts and tasks while these are unavailable to groups. Shared mailboxes also support categories, rules, and Outlook add-ins, all of which can be very important to customer support or sales teams. The point is that the two types of mailboxes are suitable for different purposes. Think about how people need to share information and what type of information they need to work with before you select which type to use.

## Handling Messages Sent from Shared Mailboxes

If you use a shared mailbox for customer communications or a similar purpose, you probably want to keep any replies sent by people using the *SendAs* or *Send on Behalf of* permission in the mailbox. The default behavior is that Exchange keeps messages in the mailbox of the person who sends a message, even if they are replying as or on behalf of the shared mailbox. This is fine for personal mailboxes, but not so good for shared mailboxes. Consider the example of a mailbox used to receive customer comments or complaints where a team of support agents accesses the mailbox. If an agent answers a message, their mailbox stores the reply

and none of the other team members know that the customer has received a response (or what that response said).

You can control these settings with PowerShell by running the *Set-Mailbox* cmdlet. For example, this command tells Exchange to retain copies of messages sent using the Send As and Send on Behalf Of permissions in a shared mailbox.

```
[PS] C:\> Set-Mailbox -Identity SharedMailbox -MessageCopyForSentAsEnabled $True
-MessageCopyForSendOnBehalfEnabled $True
```

To ensure consistency and enable these settings across all shared mailboxes in the tenant, the command is:

```
[PS] C:\> Get-ExoMailbox -RecipientTypeDetails SharedMailbox -PropertySet All | ?
{$_ .MessageCopyForSendAsEnabled -eq $False -or $_ .MessageCopyForSendOnBehalfEnabled -eq $False} |
Set-Mailbox -MessageCopyForSendOnBehalfEnabled $True -MessageCopyForSentAsEnabled $True
```

Somewhat along the same vein is the situation that occurs when a member removes items from a shared mailbox. Logically, you might think that these items would go into the Deleted Items folder of the shared mailbox. However, Outlook moves such items into the Deleted Items folder of the delegate's mailbox. To change this behavior, update the system registry by creating a new DWORD value at:

```
HKEY_CURRENT_USER\Software\Microsoft\Office\[xxx]\Outlook\Options\General\DelegateWastebasketStyle
```

Replace [xxx] with 15.0 for Outlook 2013, and 16.0 for both Outlook 2016 and Outlook 2019. Set the value to 4 (four) and restart Outlook. Deleted items will now stay in the Deleted Items folder of the shared mailbox, which is really where they should be.

## Creating and Managing Shared Mailboxes with PowerShell

The PowerShell command to create a new shared mailbox is straightforward as all you must specify is the name. However, it's good practice to specify an alias, and primary SMTP address (which must belong to the tenant domain) to make sure that they have the expected values. Other important mailbox properties such as the MRM policy, RBAC role assignment policy, and mailbox quotas are set automatically. This command is an example of how to create a new shared mailbox.

```
[PS] C:\> New-Mailbox -Shared -Name "End User Services" -Alias Shared.EndUserServices
-PrimarySmtpAddress "EndUserServices@Office365ITPros.com"
```

Remember to create a unique alias for the new shared mailbox. In the example above, the alias is created by prefixing "Shared" and a period in front of a value derived from the mailbox's display name. This should be enough to ensure uniqueness.

After creating the new shared mailbox, we need to add some members. Somewhat confusingly, we need to run two different cmdlets to grant the full set of permissions over the mailbox. The reason why this situation exists is that we need to grant a user permission to open the mailbox and work with folders and then the right to send as (impersonate) the mailbox. In other words, the first is an access right, the second is the right to do something for the mailbox. In this example, we use the *Add-MailboxPermission* and *Add-RecipientPermission* cmdlets to grant Kim Akers *FullAccess* rights to the mailbox and then the *SendAs* permission.

```
[PS] C:\> Add-MailboxPermission -Identity 'Book Feedback' -User 'Kim Akers' -AccessRights FullAccess
```

```
[PS] C:\> Add-RecipientPermission -Identity 'Book Feedback' -Trustee 'Kim Akers' -AccessRights
SendAs -Confirm:$False
```

You can remove any extraneous permissions with the *Remove-MailboxPermission* or *Remove-RecipientPermission* cmdlets. For example:

```
[PS] C:\> Remove-MailboxPermission -Identity 'Book Feedback' -User 'Kim Akers' -AccessRights
FullAccess -Confirm:$False
```

```
[PS] C:\> Remove-RecipientPermission -Identity 'Book Feedback' -Trustee 'Kim Akers' -AccessRights SendAs -Confirm:$False
```

It is sensible to conduct periodic reviews of the permissions that are assigned to shared mailboxes and to remove permissions that are no longer needed. You can use the *Get-ExoMailboxPermission* and *Get-RecipientPermission* cmdlets to check who has access to a mailbox and what they can do. Here is an example of using the *Get-RecipientPermission* cmdlet to view details of accounts that have the *SendAs* permission for a mailbox. The same command works for both shared and personal mailboxes.

```
[PS] C:\> Get-RecipientPermission -Identity 'Book Feedback'
```

Identity	Trustee	AccessControlType	AccessRights	Inherited
Book Feedback	NT AUTHORITY\SELF	Allow	{SendAs}	False
Book Feedback	Tony Redmond	Allow	{SendAs}	False
Book Feedback	Kim Akers	Allow	{SendAs}	False

The *Get-ExoMailboxPermission* cmdlet returns access permissions for a mailbox. In the past, the full set included many system accounts and management role groups that have access to mailboxes. Today, the set is limited to users and system entries like NT AUTHORITY\SELF. In this example, we use the *Get-ExoMailboxPermission* cmdlet to check the permissions for a mailbox and trim the returned set to only report delegated user accounts:

```
[PS] C:\> Get-ExoMailboxPermission -Identity 'Book Feedback' | ? {$_.User -like "*@*"} | Format-Table User, AccessRights
```

User	AccessRights
Tony.Redmond@office365itpros.com	{FullAccess}
Kim.Akers@office365itpros.com	{FullAccess}

A more complete script to create a report of all non-standard permissions (FullAccess, Send on Behalf Of, and SendAs) currently present on user and shared mailboxes is [available on GitHub](#).

We can also use the permissions on shared mailboxes to discover the list of shared mailboxes that a user can access:

```
[PS] C:\> Get-ExoMailbox -RecipientTypeDetails SharedMailbox | Get-MailboxPermission -User "Kim.Akers@Office365itpros.com"
```

## Send on Behalf Of permission

Exchange Online also supports assigning the *Send on Behalf Of* permission for a mailbox. The difference in terms of functionality between the *SendAs* and *Send on Behalf Of* permissions is the degree of impersonation implied. When a user sends a message on behalf of another person, the message is marked as such and you know that someone else has taken responsibility for composing the message. The *Send On Behalf Of* permission is intended to cover scenarios such as when an assistant processes emails on behalf of an executive. You know that the executive did not personally send the message (because that fact is clear in the message header), but the message has still come from their mailbox. In the world of letter-writing, using the *Send on Behalf Of* permission to send a message is the equivalent of signing a letter for someone and adding "pp" (per pro) beside your signature.

You can use the *Set-Mailbox* cmdlet to grant the *Send on Behalf Of* permission to a shared mailbox, just like you can grant the permission to send messages on behalf of distribution lists or dynamic distribution lists with the *Set-DistributionGroup* and *Set-DynamicDistributionGroup*, or indeed, for a Microsoft 365 Group using the *Set-UnifiedGroup* cmdlet. The same syntax is used in all cases. For instance, to grant the permission for the Customer Services shared mailbox to Jill Smith:

```
[PS] C:\> Set-Mailbox -Identity "Customer Services" -GrantSendOnBehalfTo "Jill Smith"
```

The command above overwrites any existing permission. To add someone to the list of those allowed to send on behalf of a mailbox, use this format to add the user.

```
[PS] C:\> Set-Mailbox -Identity "Customer Services" -GrantSendOnBehalfTo @{Add="Terry.Hegarty"}
```

You can pass a comma-separated list of user accounts to grant permission at the same time, as in this example:

```
[PS] C:\> Set-Mailbox -Identity "Customer Services" -GrantSendOnBehalfTo
@{Add="Ken.Bowers","James.Ryan"}
```

To view the accounts that hold *Send on Behalf Of* permission to mailboxes, you can run this command:

```
[PS] C:\> Get-ExoMailbox -RecipientTypeDetails SharedMailbox -Properties GrantSendOnBehalfTo | ?
{$_GrantSendOnBehalfTo -notlike ""} | Format-Table Name, GrantSendOnBehalfTo
```

Even if you grant an account the *FullAccess* and *Send on Behalf Of* permissions to a mailbox, this is different from giving the account the *Send As* permission. *Send As* is a different permission to assign users the ability to send messages as if the sender is the mailbox owner. If a user has both the *Send As* and *Send on Behalf Of* permissions for a mailbox, the client applies the *Send As* permission when they send a message.

Remember to change the behavior for Sent Items storage as described earlier if you want to keep copies of messages sent using the *Send As* or *Sent on Behalf Of* permissions in the mailbox.

## Mailbox Automapping

Like their on-premises counterparts, Exchange Online shared mailboxes can be auto-mapped as an Outlook resource who have full access to the mailboxes. Automapping means that Autodiscover returns details of the shared mailbox in the XML manifest generated when an Outlook client queries the server to discover the set of resources available to it. Because the shared mailbox is part of its resource set, Outlook automatically opens the shared mailbox. Automapping occurs every time the Autodiscover component refreshes information for Outlook, so it will occur shortly after Outlook starts and every 60-90 minutes thereafter. After Outlook refreshes its set of resources, the shared mailbox appears in the set of resources just like any other mailbox.

An example of the XML from an Autodiscover manifest to define a shared mailbox as a resource is below.

```
<AlternativeMailbox>
  <Type>Delegate</Type>
  <DisplayName>Editing Team</DisplayName>
  <SmtpAddress>EditingTeam@Office365ITPros.com</SmtpAddress>
  <OwnerSmtpAddress>EditingTeam@Office365ITPros.com</OwnerSmtpAddress>
</AlternativeMailbox>
```

Including a shared mailbox in the Autodiscover manifest means that the Outlook desktop client opens the mailbox no matter what workstation the user uses to run Outlook. Although automapping usually is convenient, you might not always want to automap a shared mailbox for all users. If so, you must remove the *FullAccess* permission for the mailbox from that user's account and then grant it again, this time specifying that auto-mapping should not occur. No options are available to control automapping in the administrative portals, so it must be done through PowerShell. Another way of handling the issue is to use the *Remove-MailboxPermission* cmdlet. For example, this command removes all automapping for the shared mailbox passed in the identity parameter. After running the command, users who have Full Access to the shared mailbox will continue to have access but automapping will not happen.

```
[PS] C:\> Remove-MailboxPermission -Identity 'Customer Services' -ClearAutoMapping
```

You can clear the complete set of mailbox permissions from a mailbox by running *Remove-MailboxPermission* with the *ResetDefault* switch. This instructs Exchange to reset the mailbox back to its default state by removing all delegated permissions. The *Send As* and *Send on Behalf Of* permissions are unaffected.

```
[PS] C:\> Remove-MailboxPermission -Identity 'Customer Services' -ResetDefault
```

Note that you cannot simply flip the automapping switch from *\$True* to *\$False* once a set of permissions exist. If you make a mistake, you must remove the permissions and then add them back to the mailbox, making sure that the correct automapping choice is in place this time. In this example, we use the *Remove-MailboxPermission* cmdlet to remove the permission from the mailbox and then the *Add-MailboxPermission* cmdlet to add the permission back again:

```
[PS] C:\> Remove-MailboxPermission -Identity "Shared Mailbox" -User "UserWithAccess"
-AccessRights FullAccess
[PS] C:\> Add-MailboxPermission -Identity "Shared Mailbox" -User "UserWithAccess"
-AccessRights FullAccess -AutoMapping:$False
```

The next time Outlook refreshes its list of resources from Autodiscover, it will remove the shared mailbox. Alternatively, you can close and re-open Outlook to accelerate the process.

## Delegated Folder-Level Permissions

Outlook and OWA support folder-level permissions to allow delegates access to specific folders in a mailbox. This is an older form of delegate access that has existed in Outlook for almost 20 years to support the classic manager-assistant scenario where the manager delegates access over their inbox and calendar to the secretary to allow that user to process inbound emails. You can find more information about how to use folder-level delegation in this [support article](#).

Folder-level permissions are set with the *Set-MailboxFolderPermission* cmdlet and retrieved with *Get-MailboxFolderPermission* (or *Get-ExoMailboxFolderPermission*). As an example of their use, [this script](#) generates a report of all folder-level delegated permissions in a tenant. As with mailbox permissions, it is wise to conduct periodic reviews of folder-level permissions to ensure that people don't hold permissions that they no longer need.

## Who Sent That Mail?

One of the questions that often occurs is who sent a certain message from a shared mailbox. The question does not arise when someone uses the *Send on Behalf Of* permission because their name appears in the message header, but *SendAs* takes the name of the shared mailbox and does not tell you who created and sent the message. If mailbox auditing is enabled for the shared mailbox (it is by default), Exchange captures audit records for actions such as *SendAs* and you can search those records to discover the sender. In this example, we run the *Search-MailboxAuditLog* cmdlet to find the audit records for the Customer Services shared mailbox for a selected five-hour period and then filter the records to focus on those for *SendAs* events. We then display the name of the user who signed into the shared mailbox and the date and time of the event. By comparing the date and time with the timestamp in the message header, you know who sent the message.

```
[PS] C:> Search-MailboxAuditLog -Identity "Customer Services" -LogonTypes Delegate -StartDate "1-May-2022 12:00" -EndDate "31-May-2022 17:00" -ShowDetails -Operations SendAs| Select
LogonUserDisplayName, LastAccessed
```

The Office 365 audit log ingests the mailbox audit records from Exchange alongside audit data generated by other applications. You can search these records using the audit log search in the Microsoft Purview Compliance portal or by running the *Search-UnifiedAuditLog* cmdlet. If you suspect you know who sent the message, you can refine the search by passing their email address as the value for the *UserIDs* parameter.

Otherwise, the search returns all audit records for all mailboxes where *SendAs* events occurred. See the Auditing chapter for an example of how to search the audit log for *SendAs* events.

## Accessing Shared Mailboxes

Once created, users can access the new shared mailbox through Outlook or OWA. If a user has *FullAccess* permission for a mailbox, they do not have to do anything specific as an auto-mapping process kicks in to inform Outlook to include the shared mailbox in the list of resources that it opens. For more information on opening and using shared mailboxes in Outlook, see [this support article](#).

You can override auto-mapping by including a shared mailbox in an Outlook profile. This is an explicit instruction to open the mailbox for every Outlook session and is the older method used to access a shared mailbox. In this case, you click **More Settings** when editing the profile, go to the Advanced tab and click **Add** to enter the names of the shared mailboxes that you want Outlook to open. You can use the SMTP address, alias, or display name to tell Exchange which shared mailbox to use.

If you use Outlook in cached Exchange mode, Outlook depends on the OAB to check unknown addresses (except when using SMTP addresses). The new shared mailbox will not be present in the OAB until after Exchange Online has updated the OAB files and distributed them to clients. This process can take 24 hours or more, so if you want to send messages as the shared mailbox in the interim, use the online Global Address List (which has the shared mailbox because the mailbox joins the address list once after its creation) to lookup the name that you enter in the "From:" field. If you do not do this, Exchange Online cannot deliver the messages because the address you enter does not include the necessary information to allow Exchange to check it against its address lists, and you will receive a non-delivery notification containing the following error:

**This message could not be sent. Try sending the message again later, or contact your network administrator. Error is [0x80070005-00000000-00000000].**

### Opening Shared Mailboxes in OWA

Although OWA does not use Autodiscover or have a profile, the client can also open and use shared mailboxes. To access a shared mailbox, expand the full set of folders in your mailbox and right-click **Folders** in the list of OWA resources, and select the "**Add shared folder**" option from the menu. Then input all or part of the name of the shared mailbox to search for it in email contacts and the directory (Figure 6-9). OWA validates that you have the correct permissions and if all is in order, will open the mailbox and display it in the folder list. This operation will not affect the set of resources shown in Outlook, just like auto-mapping does not influence the set of folders available to OWA. Both clients function independently of each other.

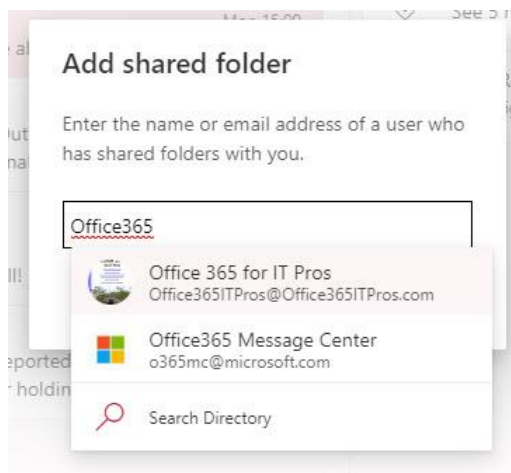

Figure 6-9: Choosing a shared mailbox to open with OWA

A good way of gaining access to a shared mailbox that exposes all the functionality available to the mailbox owner is to click the mailbox icon in the top right-hand corner of the menu bar and then **Open another**

**mailbox.** This method opens another session with the shared mailbox. Once a shared mailbox is open, you can access its contents in the same way as any other mailbox. You can send messages as if they came from the mailbox if you have the *SendAs* permission. You can select the mailbox to use by inputting the name of the shared mailbox into the "From:" field of the message so that the message comes from the shared mailbox rather than you.

The same technique works to open individual folders assigned to delegate users with folder-level permissions.

**Logging on to a shared mailbox:** The usual course of events is to grant access to a shared mailbox and have users open the shared mailbox as an added resource in either Outlook or OWA. However, at the time of writing, it is possible to change the password for the account for the shared mailbox and log on to the mailbox directly, without going anywhere near a user's account. Using this method is frowned upon for several reasons. First, it depends on password sharing, which is never a good thing, and second, according to Microsoft's Terms and Conditions, once you perform a direct logon to an account, you need to license that access because the mailbox is considered as no longer shared.

## Converting a Shared Mailbox to a Regular Mailbox

The EAC includes a method to convert a shared mailbox to a regular mailbox (and vice versa). Once the conversion is complete, you must assign a license and reset the password. The license is necessary to allow the newly regularized mailbox to have full functionality while the reset password allows the person who takes ownership of the mailbox to access it. Shared mailboxes have user accounts that no one logs into (unless they assign a license to the account), so they do not need a password. Instead, access to the shared mailbox is gained by giving permissions to the users who need to access the mailbox.

The EAC converts a shared mailbox by running the *Set-Mailbox -Type 'Regular'* command. The reverse is also possible, in which case the EAC runs the *Set-Mailbox -Type 'Shared'* command. In neither instance does the EAC do anything to assign a license or remove a license, nor does the EAC handle conversions of several mailboxes at one time. If you want to script the entire process, including the granting or removal of a license, you need to run some PowerShell commands. Here's how to convert a regular mailbox to a shared mailbox

```
[PS] C:\> Set-Mailbox -Identity "Shared@Office365ITPros.com" -Type Shared
```

If you want to convert a shared mailbox to a regular mailbox:

```
[PS] C:\> Set-Mailbox -Identity "Shared@domain.com" -Type Regular
```

After converting a mailbox to be a shared mailbox, you should remove any licenses it has. When you convert a shared mailbox to be a regular mailbox, you need to assign an Exchange Online license (either individually or part of a product like Office 365 E3). The commands to assign and remove licenses are covered in the PowerShell chapter.

## Redirecting Mail Sent to a Shared Mailbox

Companies often use shared mailboxes as the basis for customer communication. Things are a little more complicated when you have different teams of customer support agents, each using a shared mailbox, but you still want to have all communications recorded in a central mailbox for compliance or other purposes, such as integration with a CRM system that archives and categorizes customer interactions. You can achieve the goal by using a couple of mailbox properties.

Our scenario is as follows: our customer services team handles many different products. We want each product to have its own identity when email links are published on web pages and in other communications, so we create a set of shared mailboxes, one for each product, like this:

- Diapers.

- Cosmetics.
- Cars.

In addition, we have a central Customer Services shared mailbox.

Taking care of outbound emails is simple. The customer service agents simply make sure that they are sending messages as the Customer Services mailbox and that Outlook is configured to store the message in the shared mailbox rather than their personal mailboxes. The email address of the central mailbox will be stamped into the outbound message header so that any response from the customer will flow back into the central mailbox.

Inbound mail is redirected by setting two properties on each of the product mailboxes. The forwarding address is set to the central mailbox while the deliver and forward property is set to *\$True* to instruct Exchange Online to both forward a copy of the message to the central mailbox and keep a copy in the brand mailbox. The address selected for the forwarding address must belong to a mail-enabled object belonging to the tenant, including other mailboxes, public folders, mail contacts, shared mailboxes, and distribution lists.

A case can be argued not to forward a copy of the message to the brand mailbox (by setting the *DeliverToMailboxAndForward* flag to *\$False*) but this means that someone must process all the new mail arriving at the central mailbox and forward it on for attention. It is much better to have one copy captured centrally and another going direct to the people who must deal with the customer. In this scenario, the central copy acts as a customer contact record while the copy delivered to the "action" mailbox initiates the response.

**Sending an acknowledgment from a shared mailbox:** It is a common requirement to want to issue an acknowledgment for messages that arrive in a shared mailbox. For example, when people send an email to a customer services mailbox, it is good to have them receive a response to say that their email will be answered soon (or whatever is the right text). There is no obvious way to set up an auto-reply message for a shared mailbox, but it is easily done:

- Click your photo in the OWA menu bar.
- Select **Open another mailbox**.
- Enter the name of the shared mailbox and click OK.
- When OWA opens the shared mailbox, click **Options** (cogwheel) then all Outlook settings, and select **Mail**, then **Automatic replies**, and create the automatic reply.

Another way to connect is to include the email address of the shared mailbox in the URL for OWA. For example, <https://outlook.office.com/owa/bookcomments@office365ITPros.com/>. You can then go to Options as before. This procedure is the best approach if you want to use a text editor to format the content of an autoreply. Alternatively, if you are interested in basic text auto-replies, you can use the *Set-MailboxAutoReplyConfiguration* (explained earlier) to set internal and external auto-replies for shared mailboxes. The thing about auto-replies is that Exchange only sends a single response per correspondent. If you want responses for every email, you must use Outlook to create an Inbox rule that forces the server to create a reply to every message using a template.

## Using Mobile Devices with Shared and Delegated Mailboxes

Shared mailboxes are a very convenient method for teams to have access to information on which they need to work together. Given the highly mobile nature of today's workforce, it is natural to assume that you will be able to use shared mailboxes on smartphones or tablets, but this isn't the case. The Exchange ActiveSync protocol only supports access to personal mailboxes. Most mobile email clients bundled with Android and iOS phones use ActiveSync and are limited by the functions built into the ActiveSync protocol, which don't support shared mailboxes.

Current versions of Outlook Mobile (iOS and Android) use a different protocol called the Microsoft sync technology to connect clients to Exchange Online (and Outlook.com). The Microsoft sync technology includes

[support for shared mailboxes](#) and [delegate access to user mailboxes](#) along with other advanced features that will never be supported by ActiveSync. These features are available when the target (shared or user) mailbox and the mailbox of the delegate user both use Exchange Online.

To have delegated access to another person's mailbox with Outlook Mobile, a user must be assigned:

- Full access permission to the delegated mailbox. This means that the delegated user has unrestricted access to all folders in the mailbox.
- Either *Send As* or *Send On Behalf Of* permission to send messages for the delegated mailbox.

No other mobile client uses the Microsoft sync technology, which means that if you want to access shared mailboxes using a mobile client in a robust and supported manner, use Outlook Mobile.

## Mail Contacts and Mail Users

Exchange Online supports both mail contacts and mail users and includes the two object types in address lists (by default, All Contacts, the GAL, and the OAB), which makes the objects addressable by any Outlook client. Third-party clients can also access and use these objects with the appropriate code. The differences between the two objects are:

- A mail contact is a pointer to a user of an external email system.
- A mail user has an external email address but also has Microsoft 365 credentials and can sign in to access resources such as SharePoint Online or OneDrive for Business sites. Mail user objects are a relic of on-premises systems which only Exchange uses. Other applications such as Microsoft 365 Groups, Teams, SharePoint Online, Yammer, and Planner use Azure B2B Collaboration to enable guest access to their data.

Organizations often use mail contacts to provide users with a GAL (and OAB) entry that points to a known, valid email address. Often, mail contacts hold contact details for external business partners, such as a Public Relations agency. You can create a mail contact with the EAC or Microsoft 365 admin center by completing six fields:

- First Name: Optional.
- Last Name: Optional.
- Initials: Optional.
- Display Name: The name that appears in the GAL. It's a good idea to mark the object as being external to the company and to include a visual clue about which organization the contact belongs to.
- Alias: The alias must be unique, and it can't have any spaces.
- External email address: An SMTP address that is external to the tenant.

Remember that in a hybrid environment, management of mail contacts and mail users is on-premises with changes synchronized to Exchange Online.

## Using PowerShell to Create Mail Contacts

The *New-MailContact* and *Set-MailContact* cmdlets are available to create and update mail contacts. In this example we first create a new mail contact, setting their preferred mail format to be HTML, and then run the *Set-MailContact* cmdlet to enforce moderation and to inform senders that moderation applies to any message sent to this address. Note that you cannot create a mail contact with an SMTP address already used by another mail-enabled object, including guest accounts.

```
[PS] C:\> New-MailContact -ExternalEmailAddress "Danny.Flowers@contoso.com" -LastName "Flowers"
-DisplayName "Danny Flowers (Contoso)" -FirstName "Danny" -Name "Danny Flowers" -MessageBodyFormat
HTML -Alias Danny.Flowers
```

```
[PS] C:\> Set-MailContact -Identity Danny.Flowers -ModeratedBy "Kim Akers" -ModerationEnabled $True
-MailTip "Message will be moderated before dispatch"
```

After creating a mail contact in Exchange Online, a synchronization process creates a contact object in Azure AD. The *Get-MgContact* cmdlet retrieves details about Azure AD contacts.

```
[PS] C:\> Get-MgContact -OrgContactId (Get-MailContact -Identity
AlexW@o365maestro.onmicrosoft.com).ExternalDirectoryObjectId
```

You don't have to worry about the contact objects held in Azure AD. They exist for internal purposes and are not used for mail routing.

Some of the mail contact settings supported by Exchange on-premises, such as the ability to set the maximum message size, are unavailable in Exchange Online. Others, such as phone numbers and organizational information, are updatable with the *Set-Contact* cmdlet. In this example, we use PowerShell to read a simple CSV containing a set of records and create mail contacts for each object found. You can see how the *New-MailContact* cmdlet first creates the new object before the code uses *Set-Contact* to update some extended properties.

```
[PS] C:\> $InputContacts = import-csv c:\temp\inputcontacts.csv
Write-Host $InputContacts.Count "contacts found"
ForEach ($Contact in $InputContacts) {
    $Alias = $Contact.First + "." + $Contact.Last
    # Real simple code to make sure that we have an alias
    If ($Alias -eq $Null) { $Alias = $Contact.Name.Split(" ")[0] + "." + $Contact.Name.Split(" ")[1] }
    If ((Get-Recipient -Identity $Contact.EmailAddress -ErrorAction SilentlyContinue) -eq $Null) {
        # Recipient is not known, so we can add them
        Write-Host "Adding contact" $Contact.EmailAddress
        New-MailContact -Name $Contact.Name -ExternalEmailAddress $Contact.EmailAddress -Alias $Alias
        -FirstName $Contact.First -LastName $Contact.Last
        # Update country and phone numbers
        Set-Contact -Identity $Alias -MobilePhone $Contact.MobilePhone -Phone $Contact.WorkPhone -
        CountryOrRegion $Contact.Country -Company $Contact.Company }
}
```

You can even add a photo to mail contacts. Outlook displays these photos when users view contacts in the GAL. Here's how to use the *Import-RecipientDataProperty* cmdlet to add a photo. For best results, size the JPG file at 150 x 150 pixels (or smaller).

```
[PS] C:\> Import-RecipientDataProperty -Identity "John Contoso" -FileData ([Byte[]](Get-Content -
Path "c:\temp\DefaultGuestPicture.jpg" -Encoding Byte -ReadCount 0)) -Picture
```

## Creating Mail Users

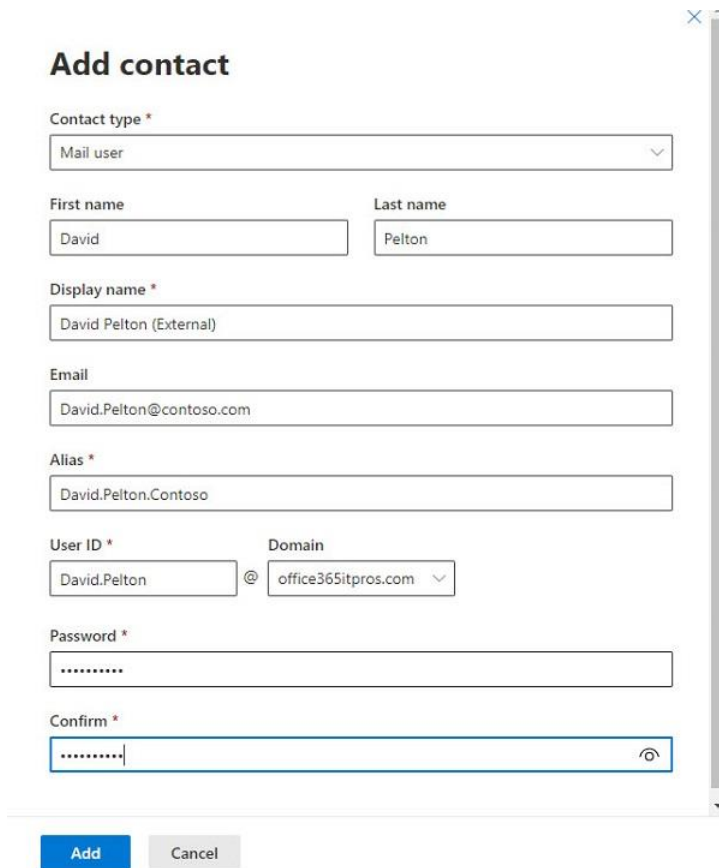

Although you can create the new mail user object by running the *New-MailUser* cmdlet, the easiest way to create a mail user is with EAC (you can't create mail users through the Microsoft 365 admin center). As shown in Figure 6-10, you must give a valid SMTP email address to point to the user's mailbox on an external email system.

Behind the scenes, Exchange Online creates a user object in Azure AD which appears in the Microsoft 365 admin center. However, the new user object must be assigned a license before the account can access any services.

Mail user objects can be manipulated with the *Set-MailUser* cmdlet. For example:

```
[PS] C:\> Set-MailUser -Identity "David Pelton" -CustomAttribute10 "External Recipient"
```

Azure AD creates mail user objects when apps like Teams and Planner add guest accounts (you'll see a record for the *New-SyncMailUser* cmdlet in the audit log). Exchange links the mail user objects to the guest accounts and will remove the mail user object on the deletion of the associated guest account.

**Add contact**

Contact type \*  
Mail user

First name: David      Last name: Pelton

Display name \*  
David Pelton (External)

## Blocking Basic Authentication

Basic authentication means what it says - a basic mechanism to authenticate a connection to a service. Basic authentication is simple to use and simple to abuse, which is why attackers try to exploit its simplicity in exploits like [password spraying attacks](#). Exchange Online supports many different mailbox connection protocols from ActiveSync to POP3 to IMAP4 to MAPI. Supporting now-obsolete email connection protocols reflects the fact that Exchange has been around since 1996. On a positive note, supporting multiple protocols allows people to use their client of choice to connect to their mailbox. Unfortunately, the profusion of connection protocols creates a problem because each protocol must be secured to stop attackers from probing for protocol weaknesses that they can use to penetrate a tenant. To address the issue, Microsoft will disable basic authentication for connections to Exchange Online for a set of email protocols (see list below). The protocols are on the list because experience shows that they are vulnerable to attack. Microsoft's plan of record is to:

- Disable basic authentication for the target set in new tenants. This already happens.
- Disable basic authentication for protocols in the target set when telemetry shows that tenants do not use basic authentication with these protocols. Tenants get a 30-day notice in the message center in the Microsoft 365 admin center when Microsoft plans to block basic authentication for a protocol. This process is now happening.
- Begin to selectively block the connection protocols for randomly selected tenants for 12-36 hours starting in early 2022. The idea is to allow tenants to judge what effect a permanent block for these protocols will have.

- Block basic authentication for the listed protocols (except SMTP AUTH) [on October 1, 2022](#). This is a permanent block for Exchange Online. Microsoft is likely to remove the exemption for SMTP AUTH in the future.

To check if Microsoft has blocked some or all protocols, run the *Get-OrganizationConfig* cmdlet and examine the *BasicAuthBlockedApps* property. The value returned will be in a range from 0 (zero – no protocols are blocked) to 255 (all protocols are blocked):

```
[PS] C:\> Get-OrganizationConfig | Select BasicAuthBlockedApps
```

```
BasicAuthBlockedApps
```

```
-----  
255
```

The value of *BasicAuthBlockedApps* is a bitmask composed of values for each protocol. Zero (0) means that basic authentication is not blocked for any protocols. The values for each of the targeted protocols are:

- Exchange ActiveSync (EAS): 1
- Exchange Web Services (EWS): 2
- POP3: 4
- IMAP4: 8
- Remote PowerShell: 16
- MAPI over RPC (Outlook Anywhere): 32
- Offline Address Book (OAB): 64
- RPC: 128

The driving force behind the removal of basic authentication for email connections is to encourage organizations to deploy clients and applications which support modern authentication, such as any modern Outlook client. PowerShell connections can use MFA with the Exchange Management PowerShell module or move to [PowerShell within Azure Cloud Shell](#). In the interim, you can prepare for the deprecation of basic authentication by using [authentication policies](#) to [control the connectivity protocols available to mailboxes](#). Although Microsoft will block basic authentication for many connectivity protocols, authentication policies will remain active and useful afterward because they control basic authentication for other protocols that Microsoft won't block.

Azure AD conditional access policies are another way to block connection attempts based on protocol and should be used whenever organizations need to exert precise control over inbound connections to a tenant. In comparison to the granular control that can be exerted by conditional access policies, authentication policies are a basic and blunt weapon. However, authentication policies offer one great advantage: conditional access policies are processed post-authentication. If you deploy an authentication policy to block basic authentication, most attempted attacks to compromise accounts will be blocked at the first hurdle. This is the reason why tenants should create and use an authentication policy to block basic authentication for as many protocols as possible.

## Creating an Authentication Policy

The easiest way to create and manage the default authentication policy for a tenant is through the Modern Authentication section in Org Settings in the Microsoft 365 admin center. If an authentication policy doesn't already exist, it is created and populated with the settings you choose. Thereafter, if you edit the settings (for instance, to block basic authentication for a protocol), the default authentication policy is updated. Before you can block basic authentication, you must enable modern authentication for the tenant and be sure that users have clients that support modern authentication, like Outlook, as older clients will not be able to connect if you disable basic authentication for protocols through a policy.

You can have multiple authentication policies in a tenant, each of which allows basic authentication for a different set of protocols. Non-default authentication policies can only be managed through PowerShell. To create a new policy, run the [New-AuthenticationPolicy](#) cmdlet. For example:

```
[PS] C:\> New-AuthenticationPolicy -Name "No Basic Auth"
```

```
RunspaceId : fd030e40-053a-404c-90f9-3cf9f2c2dcef
AllowBasicAuthActiveSync : False
AllowBasicAuthAutodiscover : False
AllowBasicAuthImap : False
AllowBasicAuthLogExport : True
AllowBasicAuthMapi : False
AllowBasicAuthOfflineAddressBook : False
AllowBasicAuthOutlookService : False
AllowBasicAuthPop : False
AllowBasicAuthReportingWebServices : False
AllowBasicAuthRest : False
AllowBasicAuthRpc : False
AllowBasicAuthSmtplib : False
AllowBasicAuthWebServices : False
AllowBasicAuthPowerShell : False
AdminDisplayName :
ExchangeVersion : 0.20 (15.0.0.0)
```

You can see that the only protocol enabled for basic authentication is Log Export, which is probably not going to be used by an attacker.

If you want to change a policy setting to allow basic authentication for a protocol, run the [Set-AuthenticationPolicy](#) cmdlet. For example:

```
[PS] C:\> Set-AuthenticationPolicy -Identity "No Basic Auth" -AllowBasicAuthPop:$True
```

After you've created the authentication policies you need, you assign the policies to user accounts to control basic authentication connections for those accounts. If a user account is not assigned an explicit authentication policy, Exchange Online applies the organization's default policy.

If you decide to apply a non-default authentication policy, the best approach is to run the *Set-User* cmdlet to assign the policy to target accounts. At the same time, you should reset the refresh token for the account to the current date and time. This will force Exchange to request clients which use basic authentication for connections to reauthenticate using modern authentication. This code uses the *Get-Recipient* cmdlet to find all current mailboxes:

```
[PS] C:\> Get-ExoMailbox -RecipientTypeDetails UserMailbox -ResultSize Unlimited | Set-User -AuthenticationPolicy "No Basic Auth" -STSRefreshTokensValidFrom $([System.DateTime]::UtcNow)
```

Remember that if you want the non-default authentication policy to apply to new mailboxes, you must assign the policy to new accounts following their creation.

## Checking Policies Are Applied to Accounts

To check that the policy is assigned to accounts, run the *Get-User* command to fetch the set of user mailboxes and report the policy assigned to the account. You should see that each account is assigned the desired authentication policy and the account's refresh token is reset to the time when you ran the *Set-User* command.

```
[PS] C:\> Get-User -RecipientTypeDetails UserMailbox -ResultSize Unlimited | Format-Table DisplayName, AuthenticationPolicy, Sts*
```

DisplayName	AuthenticationPolicy	StsRefreshTokensValidFrom
Deirdre Smith	No Basic Auth	21 Oct 2018 14:30:42
Tony Redmond	No Basic Auth	21 Oct 2018 14:31:06

```
TempAdminAC No Basic Auth 21 Oct 2018 14:31:11
```

Authentication policies don't come with any sophisticated methods for tracking when they are applied or how effective they are. Apart from finding out whether people use obsolete clients to connect to mailboxes, the biggest issue you might face is that disabling basic authentication for PowerShell forces accounts to use multi-factor authentication when they connect to Exchange Online. This isn't a problem with the Exchange Online Management module because it includes native support for modern authentication.

Limiting basic authentication for connections using an authentication policy only affects Exchange Online and doesn't affect other Microsoft 365 workloads.

## Defining a Default Authentication Policy

Exchange Online assigns the default authentication policy for the tenant to new accounts. Unless you define a default authentication policy in the organization configuration, the value assigned is `$Null`, meaning that no policy is assigned. To change this, run the `Set-OrganizationConfig` cmdlet and set a default policy. In this example, we set the default authentication policy to be "No Basic Auth":

```
[PS] C:\> Set-OrganizationConfig -DefaultAuthenticationPolicy "No Basic Auth"
```

Exchange Online validates that the authentication policy exists and won't update the organization configuration if it can't find the specified policy. You can check the value of the current default authentication policy with the `Get-OrganizationConfig` cmdlet:

```
[PS] C:\> Get-OrganizationConfig | Format-List DefaultAuthenticationPolicy
```

```
DefaultAuthenticationPolicy : No Basic Auth
```

## SMTP Authenticated Submissions

Many SMTP-enabled devices like printers and scanners submit messages to Exchange Online using [SMTP AUTH client submission](#) (SMTP AUTH) by logging in with a simple username and password. These connections do not support modern authentication methods such as multi-factor authentication or certificate-based authentication, which means that any account set up to be used for SMTP AUTH might be a target for attacks that depend on finding a username and password combination to penetrate accounts.

If you don't need to use SMTP AUTH, you should disable these connections at either a tenant or mailbox level. To disable at the tenant level, run the command to update the Exchange transport configuration:

```
[PS] C:\> Set-TransportConfig -SmtClientAuthenticationDisabled $True
```

If you leave SMTP AUTH enabled in the transport configuration, you can disable the feature selectively at the mailbox level. To find out what mailboxes are enabled, run the command:

```
[PS] C:\> Get-CasMailbox | ? {$_.SmtClientAuthenticationDisabled -eq $Null -or  
$_.SmtClientAuthenticationDisabled -eq $False } | Format-Table DisplayName
```

To disable the feature, change the command to:

```
[PS] C:\> Get-CasMailbox | ? {$_.SmtClientAuthenticationDisabled -eq $Null -or  
$_.SmtClientAuthenticationDisabled -eq $False } | Set-CasMailbox -SmtClientAuthenticationDisabled  
$True
```

When a mailbox is blocked from SMTP AUTH, it can't be used to submit messages to Exchange Online by running the PowerShell `Send-MailMessage` cmdlet (as explained in the PowerShell chapter, PowerShell scripts can send messages using the Outlook Graph API instead). Many PowerShell scripts use `Send-MailMessage` to send emails for different purposes from welcoming new users to a tenant to reporting the results of a

background job. Until Microsoft delivers a more secure mechanism for email submission, you should minimize the number of accounts used by scripts and make sure that these accounts remain enabled for SMTP AUTH.

As noted earlier, Microsoft will disable basic authentication for email connectivity protocols for all tenants on October 1, 2022. Reflecting the widespread use of SMTP AUTH in applications and multi-function devices and prioritizing the elimination of basic authentication like POP3 and IMAP4 that attackers target most frequently, Microsoft has made an exception for SMTP AUTH. Here's the situation:

- Microsoft will not disable SMTP AUTH if the protocol is used by a tenant.
- If SMTP AUTH is not in active use, Microsoft will disable SMTP AUTH (using the transport configuration setting) along with other unused connection protocols in tenants starting in September 2021.
- If a tenant discovers that they need to reenable SMTP AUTH, they can do so by running *Set-CASMailbox* to enable the protocol for selected mailboxes.
- SMTP AUTH will remain available to tenants who choose to use it after the general block on basic authentication for email connection protocols effective October 1, 2022.

Eventually, Microsoft will disable SMTP AUTH across Exchange Online. To prepare for this eventually, organizations can replace SMTP AUTH with Graph API calls (see the example in the PowerShell chapter) or use [OAuth 2.0 for SMTP AUTH connections](#). Developers can use these capabilities to upgrade applications that use SMTP AUTH with basic authentication to use modern authentication instead.

# Chapter 7: Mail Flow

## Gareth Gudger

This chapter focuses on mail flow and managing the features available in Exchange Online, Exchange Online Protection, and Microsoft Defender for Office 365 to ensure that messages transit securely and reliably from senders to recipients. Managing mail flow covers much more than ensuring the successful delivery of messages. It is also about keeping you safe from threats such as malware, targeted phishing attacks, spoofing, spam, and (accidental) data loss.

Administrators perform the tasks discussed here through the Exchange admin center (EAC), the Microsoft 365 Defender portal, and PowerShell cmdlets. Many examples use PowerShell because it is often easier and quicker to update a setting with PowerShell and the commands are much less prone to change than any of the GUI-based tools. In any case, we will begin with a discussion about configuring mail flow.

## Configuring Mail Flow

Before Exchange Online accepts messages for your domains, you must add and confirm your email domains in the tenant. The process for adding domains to a tenant is [covered in Microsoft's documentation](#). After the domain(s) are added to the tenant, you must decide when to configure the domain's MX records to point to Exchange Online Protection (EOP) so that sending organizations know where to route email.

The information to set up the necessary DNS records for your domain(s) is automatically returned in the wizard while adding domain(s) to the tenant. For mail flow purposes, only the MX and SPF records are initially relevant. As soon as you configure extra protection features, like DKIM (explained later), additional DNS records might be required.

**Real-world:** If you do not add your custom domains to your tenant, Exchange Online only accepts messages for the tenant's default service domain, which is in the form of *tenantname.onmicrosoft.com*. This is not very useful if you want your tenant to process email for all your domains, but it allows you to set up a test tenant to verify certain features without registering a new domain.

## Mail Exchanger (MX)

When you configure your domain to use EOP, the MX record for that domain points to a hostname in the form of *domain-tld.mail.protection.outlook.com* rather than an IP address. The following example illustrates how to resolve an MX record for a domain configured in EOP:

```
[PS] C:\> Resolve-DnsName office365itpros.com -Type MX
```

Name	Type	TTL	Section	NameExchange	Preference
office365itpros.com	MX	3572	Answer	office365itpros-com.mail.protection.outlook.com	0

When a sending server queries the MX record for the domain *office365itpros.com*, the A record *office365itpros-com.mail.protection.outlook.com* is returned. Next, the sending server will try to translate that hostname into an IP address, for which it needs to perform an extra DNS query. Before responding to the query, Microsoft's servers perform an internal lookup to check the region the tenant belongs to. Once the region is known, the service responds with the IP addresses of the EOP systems within the same region of the tenant.

**Real-world:** When you add a new domain to your tenant, you are asked to configure various DNS records, including the MX record for your domain. In a greenfield deployment, it is probably okay to go ahead and configure the MX record to point to EOP. However, reconfiguring the MX record for an existing domain will break your mail flow.

Switching from your current solution to EOP should be done at the right time. When strictly depends on your migration approach. Typically, you reconfigure your MX record once your pilot for Exchange Online is complete, or you wait until most of your users have been migrated to Exchange Online. The time for changing your MX record is when you have ensured your configuration is ready to accept messages for on-premises recipients from EOP. For more information, see [this Microsoft article](#).

## Sharing SMTP Namespaces

Many organizations use one or more unique SMTP domain names (for example, office365itpros.com). Those organizations sometimes need to share a common SMTP domain name across multiple environments to present a single domain name to the outside world.

Sharing an SMTP namespace with another tenant is not possible because you cannot register a domain name in more than one tenant. Because of this, it is technically impossible to share a common email domain without an elaborate scheme. Because address rewriting is not possible with Exchange Online, we will not discuss sharing an address namespace between multiple tenants. However, we will discuss how you can share a namespace across a tenant and one or more on-premises Exchange organizations.

Sharing a domain name across an on-premises organization and Microsoft 365 is easier than sharing a namespace across multiple tenants. There are several ways you can do this:

- **Use a third-party or custom broker service** that "catches" all incoming emails and routes those messages to the backend system hosting the recipient mailboxes. For the broker service to determine what host to direct a message to, you must synchronize the recipient information from all connected systems to a specific location where the broker service can access it; sometimes, this is a directory of the broker service itself. An example of such a service capable of handling routing for various backend systems is Mimecast. The downside of this approach is that it introduces another component in the mail flow process, increasing your solution's complexity and cost.
- **Reconfigure domains in Exchange from Authoritative to Internal Relay.** By default, verified domains in Office 365 are added as authoritative in Exchange Online. This means that Exchange Online will accept and handle mail flow for the domain if a recipient exists in the tenant directory. If a recipient's email address does not exist, Exchange Online generates a Non-Delivery Report (NDR). When you reconfigure a domain as an Internal Relay domain, Exchange Online first tries to deliver the message locally. If no matching recipient is found, the message can be forwarded to another mail system through a connector. If no connector is found to match the address, Exchange performs an MX lookup to decide how to route the message.
- **Setup routing domains** and configure each environment to forward messages to specific recipients using the configured forwarding address (based on the specific routing domain). This is the approach used in a hybrid deployment.

It can quickly become tricky to manage this solution with multiple environments: the first environment (Exchange Online) must forward messages to the second environment. The second environment forwards messages to the third, and so on. The last environment to receive messages must then reject unknown recipients. If you do not reject unknown recipients and forward the emails back to any of the previous environments, you will introduce a mail loop. Mail loops occur when messages go to recipients that do not exist in any environment.

## Sender Policy Framework (SPF)

The Sender Policy Framework (SPF) record is part of the [SPF validation system](#), created to protect from the receipt of spoofed messages. The receiving server does this by evaluating the purported sender domain's SPF record. The receiving email system will use the information on the SPF record to determine whether the email was received from a messaging system authorized to send emails from that domain.

When a message is received from an external system, the receiving system examines the IP address of the prior server in the mail flow chain. It then looks for an SPF record for the sender's domain. Then, one of two things can happen:

1. If an SPF record is found, the IP address is verified against the values specified in the SPF record. Depending on how the record is configured, this will either generate a neutral result or a "soft" or "hard failure."
2. If no record is found, the SPF lookup is considered a "soft failure."

The suggested SPF record for Exchange Online looks like the example below. The record specifies that only the servers specified in the SPF record for `spf.protection.outlook.com` can send messages on behalf of this domain:

```
v=spf1 include:spf.protection.outlook.com -all
```

If another server not listed on the SPF record for `spf.protection.outlook.com` tries to send messages for this domain, a hard failure should be generated because the `"-all"` parameter is specified.

The syntax of the SPF record controls how the receiving system should treat a failure:

- **-all**. The minus sign shows that any SPF failure should be considered a hard fail. Whether the hard fail results in the message being rejected depends on how it is configured in the receiving server's anti-spam solution.
- **~all**. The tilde shows that any SPF failure should be treated as a soft fail; the message will be accepted unless the receiving system rejects soft fails.
- **?all**. The question mark indicates that the domain owner is neutral towards the use of SPF records. A failure will not generate a soft or hard fail. Instead, it will generate a neutral result. The message should be accepted regardless of the result.

If EOP is the only system that will send messages for your domain(s), the suggested SPF record will suffice. However, if other systems also send emails for your domain(s), you must manually tweak the suggested SPF record to include those systems. For instance, if a marketing platform sends an email from an address belonging to one of your custom domains, the SPF record should be modified to include that system. In the example below, we add the required entry for the marketing platform to our SPF record to `include:servers.office365itpros.org`.

```
v=spf1 include:spf.protection.outlook.com include:servers.office365itpros.org -all
```

In the scenario where an on-premises organization uses EOP to protect outbound email, you should also include the public IP address for the on-premises Exchange server in the SPF record. In this example, `1.2.3.4` is the public IP of the on-premises Exchange Server(s) that are sending emails to EOP:

```
v=spf1 include:spf.protection.outlook.com ip4:1.2.3.4 -all
```

**Note:** Like the examples shown above, some SPF records use the `include` statement to point to another SPF record. This tells the recipient to trust everything in your SPF record and trust everything in the SPF record identified by the `include` statement. The challenge is that this SPF record might also contain an `include` statement(s), which in turn point to additional SPF record(s), which might also contain another

layer of *include* statements and so on. This has the potential to cascade into many SPF records. Every time a hostname or pointer to another record is added to an SPF record (such as the *include* statement), a new DNS lookup is triggered to try and resolve the hostname to an IP address. The total number of lookups must not exceed ten, as this will cause the SPF check to fail. Therefore, when you add an *include* statement, it is prudent to review what the target SPF record permits on your domain's behalf. It is also worth noting that the SPF record behind the *include* statement can change at any time. A single SPF record is also limited to 255 characters.

Creating and updating SPF records is not a trivial task, mainly because most email administrators do not need to do it very often. However, various tools on the internet can help. For instance, [this site](#) helps generate the SPF record to configure in your external DNS, and [this site](#) can help you check you do not exceed the maximum of ten DNS lookups.

**Real-world:** Although not all organizations check for a sender's SPF records, it is important to configure the records for the domain to reduce the risk of encountering email delivery issues elsewhere. Organizations do not always know what other mail systems send messages on behalf of their domain. For instance, a company's marketing department might periodically send messages through a third-party solution. In such cases, you should change your domain's SPF record to include the third-party solution.

If you cannot obtain that information, the best practice is to use a different domain for the marketing department, such as `marketing.office365itpros.com`. Make sure that the namespace uses a different public IP address and SPF record than your corporate main SMTP namespace. That way, if the domain `marketing.office365itpros.com` (or the underlying public IP) gets blocked, it will not affect email delivery for the main corporate namespace.

It is recommended to add SPF records for all your internet domains, even those that do not send mail. Bad actors will use your domain regardless of whether you do. For domains that do not send mail, you can protect them with an SPF record that hard fails all senders. For example, `v=spf1 -all`.

While SPF records have long been a critical component of email security, they are no longer the only DNS records you need to implement to maintain a modern email system.

## Domain Keys Identified Mail (DKIM)

Domain Keys Identified Mail (DKIM) allows an organization to add a cryptographic signature to outgoing emails. This signature, which is based on the message's headers and body, is added in a DKIM-specific header called *DKIM-Signature*. The purpose of DKIM-signing a message is to allow a remote organization to verify whether the message originated from a platform authorized to send messages from a given domain. A DKIM signature does not encrypt the contents of the message body or any attachments. DKIM should be a part of the baseline configuration for your email message flow.

Figure 7-1 illustrates how DKIM works: The sending server signs the message with a DKIM signature (1). The DKIM signature contains both a selector name and domain name (2), which the receiving server uses to perform a DNS lookup against the sender's DNS zone (3). The returned DNS record contains the matching public key (4), which the receiving server uses to match the DKIM header in the email. The receiving server adds the DKIM result (pass or fail) to the message header (5). The message is then queued for delivery (6). DKIM not only confirms the origin of the email but also that no one has tampered with the message during transit.

DKIM supports multiple keys per domain. This is useful in situations where an organization operates multiple email platforms, wants to delegate control of DKIM signatures to individual departments within the organization, uses a third-party service to send messages on behalf of one of the organization's domains, or when administrators want to update one of the keys without affecting current mail flow. To support multiple

keys, a “selector” is prepended to the domain name and recorded as part of the DKIM-Signature header. For instance: “selector.\_domainkey.domain.com.” With the selectors in place, each system (or third-party solution) can use a different selector and still generate valid DKIM signatures.

By default, Exchange Online verifies incoming DKIM signatures and signs outbound messages – even when you have not configured DKIM records. Exchange Online uses the “selector1” and “selector2” selectors.

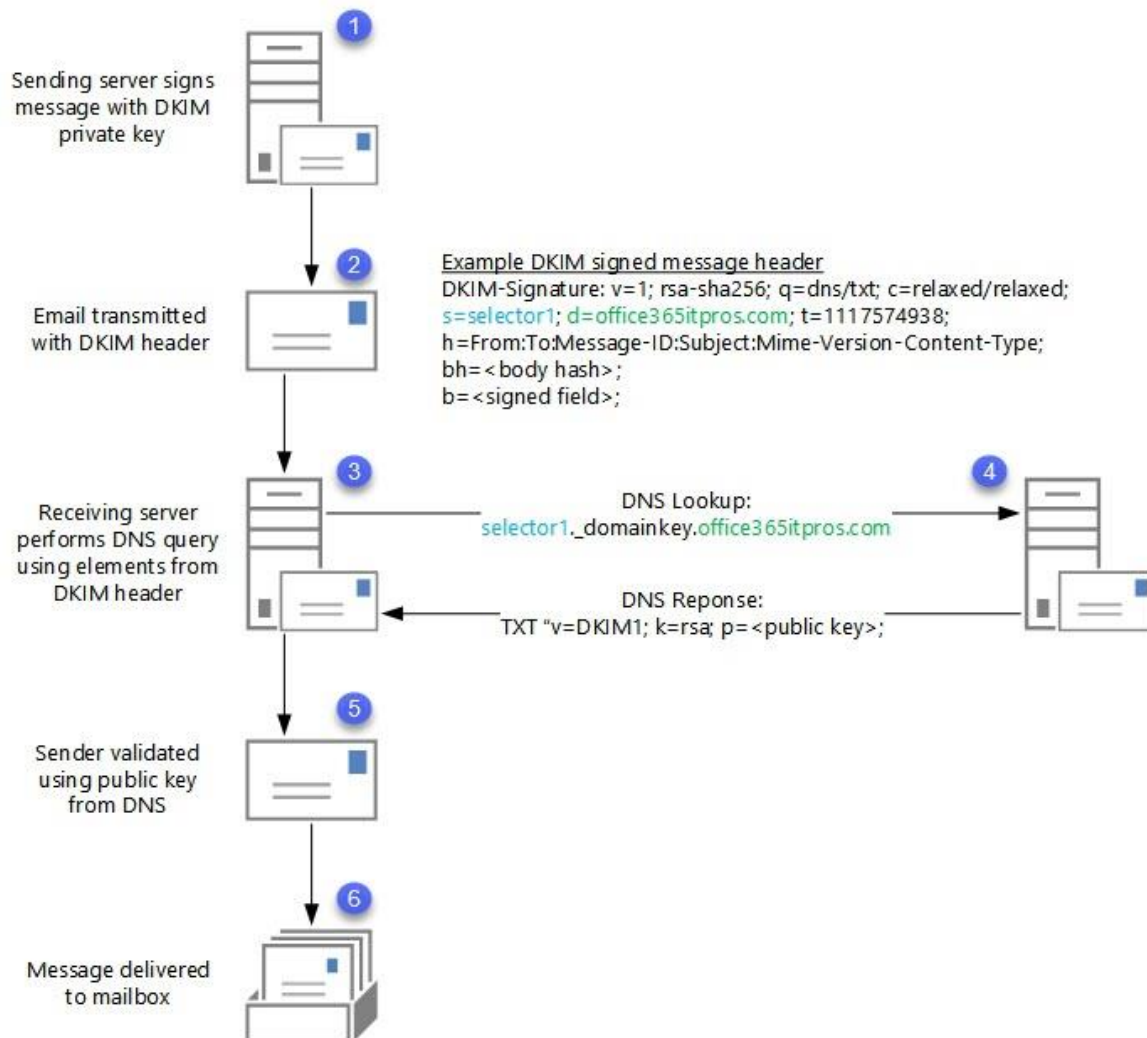

Figure 7-1: How EOP performs a DKIM lookup on incoming mail

## DKIM Verification

After an inbound message is processed, the result of the DKIM verification process is written to the *Authentication-Results* header of the message. Depending on the outcome of the test, the header will show either *dkim=pass*, *dkim=none*, or *dkim=fail*, followed by a more human-readable explanation of the result in parentheses. For instance, the following *Authentication-Results* header reveals that the sender did not sign the outgoing message:

```
authentication-results: office365itpros.com; dkim=none (message not signed) header.d=none;
```

However, if the message was signed and the DKIM signature is successfully verified, the header will look similar to this:

```
authentication-results: office365itpros.com; dkim=pass (signature was verified)  
header.d=office365itpros.com;
```

## Configuring DKIM Signing

Typically, several steps are necessary to enable the signing of outbound messages. However, as described in the section below, you do not necessarily have to perform these steps if you only use Exchange Online as a mail service. This is because Microsoft enables DKIM signing by default and uses a clever workaround to ensure that signatures are valid.

If you manually configure DKIM for your domain to associate signatures with vanity domains assigned to the tenant and not just the default service domain (*tenantname.onmicrosoft.com*), you must publish two DNS records for the vanity domain name for which you want to enable DKIM signing. Each record points to a specific target based on a combination of your domain and tenant name. For example, imagine you have a vanity domain called "office365itpros.com" and a tenant named "mycompany.onmicrosoft.com." The value of the CNAME records would then be the following:

```
selector1._domainkey.office365itpros.com CNAME
selector1-office365itpros-com._domainkey.mycompany.onmicrosoft.com
```

and

```
selector2._domainkey.office365itpros.com CNAME
selector2-office365itpros-com._domainkey.mycompany.onmicrosoft.com
```

The target of the CNAME record always starts with either *selector1* or *selector2*, followed by a hyphen and the domain MX key. The domain MX key is the first part of the MX record for your domain from the domains information page. The last part of the CNAME target is your tenant domain name. This is the default domain automatically created when you sign up for a Microsoft 365 tenant and is in the form of *<name>.onmicrosoft.com*. After publishing the DNS records, the easiest way to enable DKIM signing is through the Defender portal ([security.microsoft.com](https://security.microsoft.com)) under **Threat management > Policy > DKIM**. First, select the domain you want to enable DKIM and toggle the Sign messages for this domain with DKIM signatures slider to Enabled for the domain name you wish to enable DKIM.

Alternatively, you can enable DKIM signing with PowerShell:

```
[PS] C:\> New-DkimSigningConfig -DomainName office365itpros.com -Enabled $true
```

Domain	Enabled
-----	-----
office365itpros.com	True

If the CNAME records are unavailable or if the records were created incorrectly, the above command will emit the following warning:

```
WARNING: Config is created but cannot be enabled since CNAME records are not published. Please
enable this policy using Set-DkimSigningConfig once CNAME records are published.
```

If you have recently updated your DNS records and set the CNAME record, you might need to wait for DNS caches to update. After sufficient time has passed, you can attempt to enable the configuration again using the following command:

```
[PS] C:\> Set-DkimSigningConfig -Identity office365itpros.com -Enabled $true
```

If you continue receiving the warning message, try comparing the CNAME records you created with the values EOP expects. To retrieve the correct selector CNAME values, run the following command:

```
[PS] C:\> Get-DkimSigningConfig | fl *CNAME*
```

```
Selector1CNAME: selector1-office365itpros-com._domainkey.mycompany.onmicrosoft.com
Selector2CNAME: selector2-office365itpros-com._domainkey.mycompany.onmicrosoft.com
```

It can take up to one hour after you configure DKIM before the changes have successfully replicated to all EOP servers. Once the new DKIM settings are replicated, all messages are automatically signed as the vanity domain rather than the tenant domain. For example, the following output is from a test message sent to an external recipient when the source tenant has enabled DKIM signing. Note the *dkim=pass* reference:

```
Authentication-Results: spf=pass (sender IP is 1.2.3.4) smtp.mailfrom=office365itpros.com; dkim=pass (signature was verified) header.d=office365itpros.com; dmarc=bestguesspass action=none header.from=office365itpros.com; compauth=pass reason=109
```

```
DKIM-Signature: v=1; a=rsa-sha256; c=relaxed/relaxed; d=office365itpros.com; s=selector1; h=From:To:Date:Subject:Message-ID:Content-Type:MIME-Version; bh=WeG072W2hUk4jdiG4YKREVB5fA4PaMBqox2yZKnVYI=;
```

```
b=mSTzjicUsZiAJizFSwmW0EpaNYBjUFXDoFQNaAgFwpbDhCcun5P5W+MYPxRRx5//KANWT8hsv559VEU/E6PCENAQbRUnJ/CgbiQRcoh6+X5+vtisdXenC7gnc0TOXWDAK1sqh46mzW3Ls1vGVH4xdzFV6i7spZR0Mif2cd/qtU=
```

Along with the signature (shown prepended by *b=*), the DKIM header also includes additional information, represented as tags used during the DKIM verification process. For instance, it indicates which selector was used (*s=selector1*) and a list of headers used during the signing process (*h=*). Trying to decipher the headers can be extremely tedious and is usually unnecessary. To learn more about the finer details of the DKIM header and the various tags it can have, read [RFC6367](https://tools.ietf.org/html/rfc6367).

## Default DKIM Signing

DKIM is a vital tool to fight spoofed messages. As such, Microsoft automatically signs all outbound email traffic, even when the customer has not set up DKIM or configured any specific DKIM DNS records. You might wonder how Microsoft can do that, especially because they do not control the DNS zone for your domains? However, Microsoft controls one DNS zone directly linked to your Office365 tenant: the default tenant service domain *<tenantname>.onmicrosoft.com*. This allows them to create a DKIM signature based on the tenant domain and still correctly represent your organization. The following example shows a *regular* DKIM signature as you would expect when you have configured DKIM and the appropriate DNS records:

```
From: sender@office365itpros.com
DKIM-Signature: v=1; a=rsa-sha256; c=relaxed/relaxed; d=office365itpros.com; s=selector1; h=From:To:Date:Subject:Message-ID:Content-Type:MIME-Version; bh=<body hash>; b=<signed field>;
```

Now, take a look at the following example of a DKIM signature when you have not explicitly configured DKIM. Notice the selector (*s=*) and domain (*d=*) fields:

```
From: sender@office365itpros.com
DKIM-Signature: v=1; a=rsa-sha256; c=relaxed/relaxed; d=o365itpros.onmicrosoft.com; s=selector1-o365itpros-com; h=From:To:Date:Subject:Message-ID:Content-Type:MIME-Version; bh=<body hash>; b=<signed field>;
```

Based on the above information, you can reconstruct the actual DNS records being referenced to the following value: **selector1-o365itpros-com.\_domainkey.o365itpros.onmicrosoft.com**.

Using the *Resolve-DNSName* cmdlet, you can then verify that the record exists:

```
[PS] C:\> Resolve-DnsName selector1-microsoft-com._domainkey.microsoft.onmicrosoft.com -Type TXT
v=DKIM1; k=rsa;
p=MIGfMA0GCSqGSIb3DQEBAQUAA4GNADCBiQKBgQCKHq3ztGI1R8a1D+7oZiaG5mTUttFdF01pKHRBZCPFG4sugV1EfF5F6Jpwb
JDzZmyI1qYfTgUkmY0vbHsoYvW7rddLKVTh+vE1SZ5P9coIHrw759hXbpPDSQ9JNP8aN+Bfng6YMEwnOGA+PL+ZpyvswcB0jz9M6
yMvowOxChv5QIDAQAB; n=1024,1435867504,1
```

The key returned by the record is used by the target system to verify the DKIM signature and is no different from the record otherwise used when manually configuring DKIM. After all, when setting up explicit DKIM signing for Exchange Online, you do not create a TXT record with the key; you create a CNAME record pointing to the same TXT record in Microsoft's DNS zone for your tenant illustrated in the example.

### Automatic DKIM Key Rotation

Microsoft uses two different keys for DKIM signing. As mentioned earlier, several reasons exist why two keys are used. Still, the most important one is that it allows Microsoft to rotate (update) the keys approximately every six months without affecting the DKIM verification process.

Here's how this works: messages are signed using one of the two selector keys at any given time. For instance, *selector1*. When Microsoft wants to update the key value behind *selector1*, they do not just update it. If they were to do that, messages in transit would be invalidated because their DKIM signature has not yet been verified. This is because the recipient's system queries the key value as it processes the message. As such, if the key value is updated between the moment a message is signed (with the old value) and checked (with the new value), the verification process will fail, and the DKIM Signature is considered invalid.

To overcome this problem, Microsoft uses a two-step process to update the key values. In the above example, Microsoft first switches to using the key value behind the second selector (*selector2*). Any new message sent by Exchange Online from then on is signed with this new key. When remote systems process those messages, they will query the key value for *selector2* instead of *selector1*. Messages still signed by the first selector key can still be verified because the key value is still publically available in DNS.

After about a week, Microsoft removes the DNS entry of the first selector key. This leaves ample room for messages to be delivered and verified, removing the need for that key to be in DNS. For the next six months, outbound emails are signed with *selector2*, and then the process repeats – a new *selector1* is created, email traffic starts to use the new selector value, and a week later, *selector2* is removed. Using a two-step process, Microsoft avoids invalidating messages still in transit and potential delays in DNS propagation.

### DKIM With Third-Party Email Filters

If you route outbound email via a third-party filtering or email hygiene service, you should ensure that this service does not invalidate Microsoft's DKIM signature on outbound messages. If the third-party service rewrites the email or adds new content to the message body, then the DKIM signature will be invalid, and your recipients will see DKIM failure errors (probably just in the headers, but they might reject your email because it fails). Therefore, it is often important to ensure that the last sending system is the system that applies the DKIM signing, remembering that this might not be EOP.

## Domain-based Message Authentication, Reporting, and Conformance (DMARC)

Domain-based Message Authentication, Reporting, and Conformance (DMARC) is a method for authenticating messages that build upon SPF and DKIM. It proves particularly useful in preventing phishing attacks. This is when an attacker spoofs a legitimate domain to trick the recipients into visiting a malicious website and possibly revealing personal information such as passwords. Spoofing a message means that the spammer places a value in the RFC5322 *From* field that is not their domain and uses a value from another domain to pretend that the email is from that organization instead. The RFC5322 *From* header is the one that is shown in clients such as Outlook. Because of this, spoofed messages are hard to differentiate from legitimate emails for end-users.

DMARC specifies what action the receiving server should take if SPF or DKIM validation fails for an email received from your domain. Without DMARC to inform the receiving system what the intent of the sending

system is (concerning quarantine or rejection), the receiver may still decide not to reject messages if either SPF or DKIM validation fails.

Similar to SPF and DKIM, DMARC requires a DNS TXT record that the receiving party can query. A typical DMARC record looks like the following:

```
v=DMARC1; p=reject; pct=50; rua=mailto:postmaster@office365itpros.com;
ruf=mailto:dmarcfailures@office365itpros.com; fo=1
```

- **V** specifies the DMARC protocol version.
- **P** recommends the action the receiving system should take if SPF and DKIM validation fail. Possible actions are:
  - **Reject**
  - **Quarantine**
  - **None** (monitor mode)
- **PCT** gives the percentage of messages subjected to the DMARC policy. The default is 100.
- **RUA** (or *reporting URI for aggregate reports*) contains the email address(es) to which aggregate reports should be sent.
- **RUF** (or *reporting URI for forensic reports*) contains the email address(es) to which forensic reports should be sent.
- **FO** (or *forensic options*) can have a value of 0 or 1. 0 is implied if the *fo* field is absent from the DNS record.
  - 1 = Send forensic reports when either DKIM or SPF fails.
  - 0 = Send forensic reports when both DKIM and SPF fail.
- **SP** (or *sub-domain policy*) is not shown in the above example. If this field is absent from the DNS record, all subdomains inherit the policy from the parent domain (defined with *p=*). If you want a different policy for all subdomains than the parent policy, include *sp=*. For example, if you know you have no subdomains, then add *sp=reject*. This will automatically reject all subdomains as you do not send emails from them. If you have specific subdomains, add a DMARC record for that domain with its policy to override the parent policy.

Aggregate reports are reports the receiver sends daily to the email address specified in the “*rua*” field, containing information such as how many emails have been received and if these messages passed SPF and DKIM tests. Forensic reports are better known as failure reports and are sent to the recipients specified in the “*ruf*” field each time DMARC fails. These reports are extremely useful for figuring out why messages fail DMARC processing. Note that most large email providers (for example, Exchange Online, Gmail, and Yahoo) do not send forensic reports regardless of if you request them in your DMARC record.

## How DMARC Works

The following steps outline how DMARC processes a message:

1. A user receives a message. For example, from *emails@office365itpros.com*.
2. The receiving server will verify if *office365itpros.com* has a DMARC policy (DNS record).
3. Does the message pass SPF/DKIM validation?
  - a. For SPF, does the RFC5322 *From* field and the envelope sender (RFC5321 *MailFrom* or RFC5321 EHLO domain) header match?
  - b. For DKIM, does the RFC5322 *From* match the DKIM signing domain (*d=header*).
4. If the SPF and/or DKIM alignment checks fail, the message fails DMARC processing, and the action specified in the DMARC policy is executed.

If we apply this logic to the DMARC example policy from above, this means that a spoofed message (which would fail SPF or DKIM) would be *rejected*, and a failure report would be sent to [dmarcfailures@office365itpros.com](mailto:dmarcfailures@office365itpros.com):

```
v=DMARC1; p=reject; pct=50; rua=mailto:postmaster@office365itpros.com;
ruf=mailto:dmarcfailures@office365itpros.com; fo=1
```

If you decide to create a DMARC record for your domain, it is best to configure DMARC in *monitor mode* first. This allows you to sift through the failure reports to understand better why any messages from your domain fail DMARC processing. DMARC processing does not always fail because a message is spoofed. Sometimes messages come from a legitimate server that is not included in the SPF record or does not do DKIM signing. The more messages your environment processes, the more failure reports you will receive. For large organizations, going through the failure reports can be very time-consuming. Luckily third-party services exist, which you can specify in the DMARC policy. These services will then process the failure reports for you and provide you with a summary of the failures and the reasons.

**Real-world:** If your domain is a target for many spoofed messages, which is often the case for more prominent and well-known organizations, enabling DMARC might decrease the amount of phishing and spoofed email messages your organization receives. However, if you are a smaller organization, the risk from spoofed emails is likely just as high, as lots and lots of organizations are getting business compromise attack emails, and the end-users are responding and revealing passwords or transferring money, etc. Therefore, we recommend that each domain starts with a policy of none; this allows time to monitor and remediate any legitimate mail failing DMARC. Once all legitimate messages have been remediated, these domains should be transitioned to a policy of quarantine and, finally, a policy of reject.

## DMARC Processing on Inbound Messages

Exchange Online performs DMARC processing on inbound messages if a DMARC policy exists for the sender's domain. Just like SPF and DKIM processing, the result of the DMARC test is written to the *Authentication-Results* header:

```
authentication-results: spf=pass (sender IP is 1.2.3.4) smtp.mailfrom=phishing.com; dkim=none
(message not signed) header.d=office365itpros.com; dmarc=fail action=quarantine
header.from=office365itpros.com; compauth=fail reason=000
```

In this example, the DMARC test failed because the alignment between the RFC5322 *From* address and the envelope sender did not match (phishing.com does not equal office365itpros.com). Therefore, the composite authentication result of SPF, DKIM, and DMARC together (the compauth value) shows a failure, and the reason code means the message failed explicit DMARC authentication.

If the SPF domain in the *mailfrom* header does not match the *From* header on a message entering Exchange Online, it is marked as junk. This is because the *mailfrom* header could match a valid SPF record but be unrelated to the domain that appears in the client application (the *From* header). This scenario results in spoofed emails being marked as valid in terms of SPF. Therefore, EOP requires that the *mailfrom* and *from* header values match to stop EOP considering the message a spoofed email.

Because many organizations employ complex routing instead of just EOP (third-party vendors or on-premises routing, for example), Microsoft cannot always guarantee that a DMARC failure constitutes an actual failure. For this reason, Microsoft will not reject the message even when the DMARC policy is configured with a reject action. Instead, EOP will add the "action=oreject" value to the *authentication-results* header (or "oquarantine" as another lesser seen example), which mail flow rules can use to override the verdict for such messages. Most emails in this category are rejected before reaching the end user's mailbox, but messages can also be rescued from the spam filter by a mail flow rule or allow lists.

## Configuring DMARC

DMARC looks easy to set up, and to an extent, it is – you just add a valid TXT record in public DNS, and the aggregate emails appear within 48 hours in the mailbox identified in the “rua” value of the TXT record. However, the processing of these aggregate emails is more complex. Several services on the internet, such as Dmarcian and Agari, will take these aggregate emails and produce the analytics for you.

Once you have the analytics for your domain, you can tweak your SPF and DKIM configuration to ensure that all your legitimate senders are within scope. Spoofing senders would be outside the scope of your SPF or DKIM records – you would then increase your DMARC policy to  $p=quarantine$  and then eventually  $p=reject$ .

Getting there is the hard part. To help customers with this, Microsoft partners with Valimail to [offer Valimail Monitor](#) as a free service for Microsoft 365 customers to get started with DMARC. This will help you monitor your mail flow and help you work towards enforcing compliance.

## DNS Authentication of Named Entities (DANE) for SMTP

When mail servers transfer mail, they first must agree to use TLS to protect the connection, and if so, which version of TLS. During this initial handshake, these packets are unencrypted. The servers then upgrade the connection TLS after negotiating a common TLS protocol. Mail then transfers over this secure TLS connection.

The challenge is the initial unencrypted handshake. During this unencrypted state, packets are subject to man-in-the-middle and downgrade attacks. To answer this problem, the industry created a new standard called [DNS Authentication of Named Entities](#) (DANE).

DANE allows an organization to publish details of the TLS protocols it supports through a special DNS record in their external DNS. These DNS records are known as TLSA records. The example below illustrates what a TLSA record might look like for the office365itpros.com domain.

```
_25._tcp.office365itpros.com. IN TLSA 3 1 1  
e1c362c8c03a15023fff83831a70d6fce33203d499a3f3d0b13243a1ac689088
```

TLSA records are not exclusive to mail flow. In the example above, the TLSA record exists for TCP 25, which is the port used by SMTP. Multiple TLSA records could exist in external DNS to serve several TCP ports. For example, an external web application that leverages HTTPS could publish TLSA records for TCP 443.

When a mail server that supports DANE wishes to send an email, it performs a DNS query against the recipient's external DNS to see if the TLSA DNS record exists. If the record exists, it is retrieved with DNSSEC, which secures the DNS records by signing the TLSA records in DNS using public-key cryptography. The existence of the certificates enables servers to know that an attacker has not tampered with the TLSA records using a man-in-the-middle attack.

Figure 7-2 illustrates how DANE for SMTP works: the sending server queries the external DNS of the recipient domain for their MX record (1), which is returned (2). The sending server then queries the external DNS of the recipient domain for a TLSA record for TCP 25 (3). If a TLSA record for TCP 25 exists, it is returned via DNSSEC (4). This returned record contains the certificate fingerprint. Next, the sending server initiates a TLS connection to the recipient server (5) using the previously retrieved MX record. The recipient server responds with its certificate fingerprint (6). Finally, the sending server matches the certificate fingerprint transmitted from the recipient server to the fingerprint received from the TLSA record (7). If the fingerprints match, the connection is established, and mail is sent (8). If the fingerprints do not match, the sending server drops the connection.

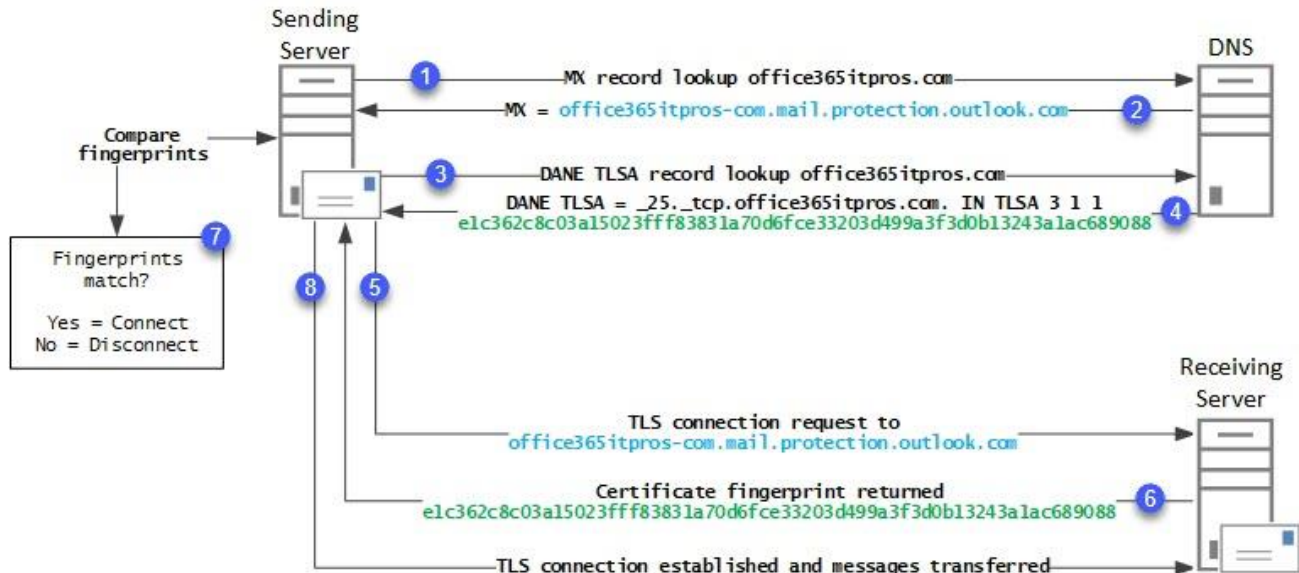

Figure 7-2: How DANE for SMTP prevents downgrade and man-in-the-middle attacks

**Note:** Outbound support for DANE is enabled in all tenants and will not require any tenant administrator action. Inbound support for DANE is slated for release in December 2022.

## MTA Strict Transport Security (MTA-STS)

MTA Strict Transport Security (MTA-STS) is a security technology developed by the Messaging, Malware, and Mobile Anti-Abuse Working Group (M3AAWG). MTA-STS combats the same problem as DANE: how to secure mail flow from man-in-the-middle and downgrade attacks? The main differences are that MTA-STS does not require DNSSEC and uses TXT records instead of TLSA records.

The benefit of MTA-STS is that it is easier to deploy. For example, if your external DNS provider does not support DNSSEC or TLSA records, you cannot use DANE. However, all DNS providers should support TXT records, the only DNS requirement for MTA-STS.

When checking MTA-STS, the sending server looks for a TXT record in the recipient domain with a value of `_mta-sts`. Using `office365itpros.com` as an example, the TXT record is `_mta-sts.office365itpros.com`. The example below illustrates what an MTA-STS TXT record might look like for the `office365itpros.com` domain.

```
_mta-sts.office365itpros.com. 3600 IN TXT v=STSV1; id=20220301000000Z;
```

`v=STSV1` identifies the version of MTA-STS used by the recipient domain. In the example above, this is version 1. Currently, version 1 is the only version of MTA-STS.

The `ID` value identifies the current version of the MTA-STS policy. If the ID value changes, the sender retrieves the latest policy from `https://mta-sts.<domain name>/.well-known/mta-sts.txt`. If the ID value is the same, the sender uses a previously cached copy of the recipient's policy file. This helps eliminate unnecessary HTTPS requests to the server hosting the policy file.

**Note:** Each time you publish a new MTA-STS policy, you should update the ID published in DNS. This alerts senders that your policy has changed and to retrieve a new policy file. Using an ID that specifies a date and time format is recommended, but this ID could be whatever you desire.

One can argue that the lack of DNSSEC means that the retrieval of the TXT record could be subject to man-in-the-middle attacks. However, even if a bad actor changed the ID's value before returning it to the sender, it would merely instruct the sender to download a new policy file from a known location that the recipient owns. The best a bad actor could do is return that no MTA-STS TXT record exists.

The known location used by MTA-STS is always `https://mta-sts.<domain>/.well-known/mta-sts.txt`. This path, file name, and file extension are mandatory for MTA-STS. In addition, the policy file is only retrieved over HTTPS. This means the webserver that hosts the policy file must have a valid third-party certificate. Using `office365itpros.com` as an example, the certificate must contain a subject name (or subject alternate name) of `mta-sts.office365itpros.com`. Alternatively, a wildcard certificate could also be used.

The example below illustrates what the contents of this policy file could contain.

```
Version: STSv1
mode: enforce
mx: office365itpros-com.mail.protection.outlook.com
max_age: 604800
```

**Version** identifies the version of MTA-STS in use. In our example, this is version 1.

**The mode** has three possible values: "enforce," "testing," and "none."

- **Enforce** instructs a sender not to transmit messages to any host that fails certificate validation. Or if the host does not support STARTTLS or TLS 1.2 (and greater).
- **Testing** instructs a sender to transmit messages (including to hosts that fail certificate validation) and provide reports to the recipient of any failures. This mode helps administrators identify and remediate any misconfigured legitimate mail exchangers before enforcing the policy.
- **None** instructs the sender to transmit all messages and treat the recipient domain as if it had no MTA-STS policy.

**MX** defines all MX records served by this policy. This could be a single MX record, like in our example above, or multiple MX records, each entered onto a separate line. Wildcards are also permitted. In the example above, we define Office 365 as a valid MX record for `office365itpros.com`. MTA-STS requires that the hosts defined in the MX records support TLS 1.2 or greater.

**Max age** defines how long (in seconds) a sender should cache this policy. In our example above, 604,800 is 7 days in seconds. This instructs the sender to discard the policy file after 7 days.

Figure 7-3 illustrates how MTA-STS works when in enforce mode: the sending server queries the external DNS of the recipient domain for their MX records (1), which are returned (2). The sending server then queries the external DNS of the recipient domain to see if a `_mta-sts` TXT record exists (3). If the `_mta-sts` TXT record exists (4), the sender checks the ID to see if it has changed since the last time it retrieved the `_mta-sts` record (5). If the ID has changed, the sender performs an HTTPS request to retrieve the MTA-STS policy file from `https://mta-sts.office365itpros.com/.well-known/mta-sts.txt` (6). If the ID is the same, the sender uses a previously cached copy of the MTA-STS policy. With a policy of "Enforce," the sender then checks all MX records defined in the policy, starting with the lowest priority MX record first (7). If the host passes certificate validation, the mail is transmitted (8). If the host fails certificate validation, MTA-STS proceeds to the next MX record in the policy. Mail is not transmitted if all hosts fail certificate validation (9).

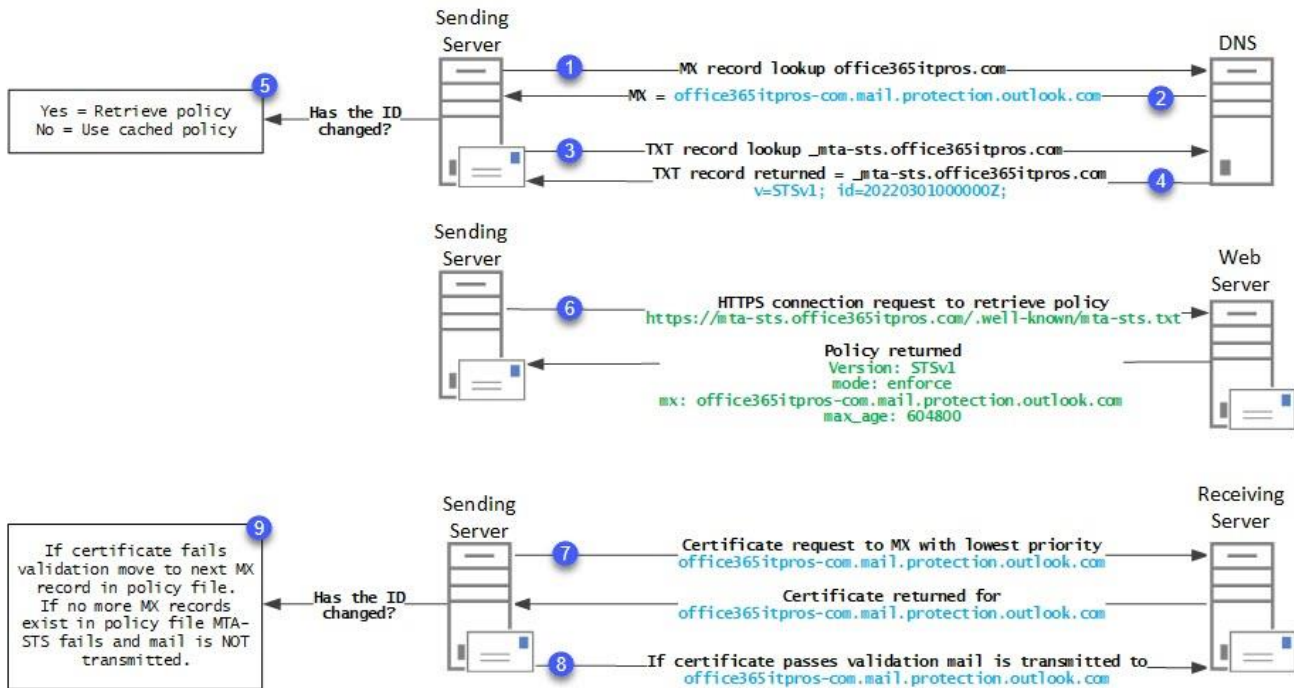

Figure 7-3: How MTA-STS prevents downgrade and man-in-the-middle attacks

**Note:** There is no detriment to having both MTA-STS and DANE configured on your domains. This allows you to cover more senders who may only support one of the technologies.

## Authenticated Receive Chain (ARC)

The challenge with methods used to authenticate outbound email is that they do not account for forwarding. Consider a scenario where `microsoft.com` sends a message to `office365itpros.com`, and a rule at `office365itpros.com` then forwards that message to `contoso.com`. When `contoso.com` queries the headers of the forwarded `microsoft.com` email, it will attribute the sender of the email as `office365itpros.com`. This will fail both SPF and DMARC because `office365itpros.com` is not a valid Microsoft sender.

Authenticated Receive Chain (ARC) combats this by adding a series of email headers that encrypt and store the original SPF and DMARC results to forwarded messages. The receiving system can then make decisions based not just on the SPF and DMARC information it calculates (for example, SPF might fail if the message was forwarded) but on the SPF and DMARC decisions of the original receiving system.

ARC works by utilizing three new headers. First, the *ARC-Authentication-Results* header contains the original SPF and DMARC results. The *ARC-Message-Signature* header stores information about the state of the headers as created by the forwarding system (so that the final receiver can trust what was recorded). Lastly, the *ARC-Seal* header snapshots the *ARC-Authentication-Results* and *ARC-Message-Signature* headers so that the receiver knows if they have been tampered with.

When the email arrives at the receiving server, the system reads the *ARC-Authentication-Results*. If the forwarding system is trusted, the server can base its decision to classify the email as junk or deliver the email on what the original receiver determined (i.e., did the message pass SPF and DMARC on original delivery even though it will fail, on either or both tests, upon forwarding). The *ARC-Message-Signature* and *ARC-Seal* are used to prove the validity of the *ARC-Authentication-Results* header. For example, the *ARC-Message-Signature* hashes some headers from the message (listed in the *h* tag) and stores that hash in the *bh* tag. Changes to the message headers or body that invalidate the ARC headers are easily detected.

Each forwarding of the message creates a new ARC header set starting with an incrementing number (i=2; i=3 etc.). Within the *ARC-Authentication-Results*, you will see that spf=pass, dmarc=pass, and dkim=pass for alignment purposes. An example of what the ARC headers look like in a message header is shown below:

<i>ARC-Authentication-Results</i>	<code>i=1; mx.microsoft.com 1; spf=pass smtp.mailfrom=office365itpros.com; dmarc=pass action=none header.from=office365itpros.com; dkim=pass header.d=office365itpros.com; arc=none</code>
<i>ARC-Message-Signature</i>	<code>i=1; a=rsa-sha256; c=relaxed/relaxed; d=microsoft.com; s=arcselector9901; h=From:Date:Subject:Message-ID:Content-Type:MIME-Version:X-MS-Exchange-SenderADCheck; bh=message-body-hash; b=hash-of-headers-in-h-tag</code>
<i>ARC-Seal</i>	<code>i=1; a=rsa-sha256; s=arcselector9901; d=microsoft.com; cv=none; b=hash</code>

The keys used to sign the hashes are in public DNS under the existing DKIM headers. In the above example, the selector (s=) is arcselector9901. The public key for this selector can be found in a TXT record called arcselector9901.\_domainkey.microsoft.com.

Microsoft 365 tenants trust each other. This means forwarding between tenants results in ARC headers, and the final receiving tenant can use the SPF and DMARC results of the original receiver.

### Adding trusted forwarders (ARC sealers) to your tenant

You may have a situation where you need to add your own trusted forwarders (ARC sealers) to your tenant. This could occur if Office 365 does not trust a forwarder that you need to trust, or you use a third-party message hygiene service in front of EOP that supports ARC sealing.

You can add a list of trusted forwarders (ARC sealers) using the Defender portal. From the **Defender portal**, navigate to **Policies and rules > Threat Policies > Email authentication settings**. From the *Email Authentication Settings* page, select the **ARC** tab. Click the **Add** button to add a trusted sealer. If you have previously added a trusted sealer and need to add more, click the **Edit** button to update the list of trusted sealers. You can also use the *Edit* button to remove trusted sealers from the tenant.

Check [this article](#) for more information on ARC and adding trusted sealers to your tenant.

## Sender Rewrite Scheme (SRS)

Authentication of your email messages with DMARC, DKIM, and SPF improves the reputation of your domain and brand by reducing spoofing and increasing the likelihood of detection of spoof attacks against the domain. However, some problems exist with these techniques. The primary issue is that SPF lists the IP addresses used for outbound emails. If your messages are delivered to another service that forwards them on again (using mail flow rules, distribution lists with external members, or inbox rules, for example), then the SPF information published for your domain makes the forwarding service appear to be a generator of spoofed email.

The Sender Rewrite Scheme (SRS) changes the P1 (or envelope from address) of auto-forwarded (or redirected) messages so that the receiving next-hop sees that the sender is the forwarding service and not the original sender. The goal is to try and avoid an SPF failure. SRS does this by changing the P1 header from the original sender's address and domain to an address that encapsulates the original sender's address but is really the forwarding service. Note, though, that this means that NDRs sent to these newly rewritten addresses will no longer return to the original sender but to the forwarding service, which in this case is Exchange Online. Exchange Online then unwraps the SRS rewritten header and sends the NDR back to the original sender. NDRs that cannot be unwrapped will go to a bounces@<default-accepted-domain> mailbox, which you need to create. The P2, or the *From* address the user sees in the email client, will not be changed. For example:

Before SRS is implemented, the P1 address is: *brian@office365itpros.com*

After SRS is implemented and the initial receiving tenant forwards messages from the original sender, the P1 address might be something like this:

```
sales+SRS=f2ss=IX=office365itpros.com=brian@itpros.com
```

This is best explained as:

```
<Forwarding Mailbox Username>+SRS=<Hash>=<Timestamp>=<Original Sender Domain>=<Original Sender Username>@<Forwarding Mailbox Domain>
```

Now that the forwarded email comes from the forwarding tenant and not the original system, it should not fail SPF. More details about the implementation of SRS are available on the [Exchange Blog](#).

## Managing Connectors

EOP uses connectors to control inbound and outbound mail flow. By default, Exchange Online uses hidden connectors to allow messages to be sent between the tenant and the internet. However, if you have a requirement, such as delivering mail to a smart host or forcing TLS, you need to leverage a custom connector.

Connectors do more than enable mail flow with external organizations; they also apply security settings such as transport layer security (TLS). The receiving server almost always specifies requirements for TLS. Exceptions to this rule can exist, for instance, when a connector is configured to require (or force) TLS on a specific connector. By default, EOP will always try to negotiate TLS with the receiving server. This is called opportunistic TLS. When TLS cannot be used, the sending server (EOP in this case) will revert to using an unencrypted connection. However, if the recipient's message system supports TLS, EOP uses TLS for the connection.

Messages destined for the on-premises Exchange environment in a hybrid deployment are, by default, always secured with TLS and require a valid, trusted digital certificate. The same is true for messages sent to domains protected by EOP. However, if you often communicate with a business partner or send highly confidential information, you might want to enforce specific security settings, such as requiring TLS encryption. There are several ways in which TLS encryption can be enforced. For instance, you can require the certificate to encrypt the traffic with a specific subject name. To configure specific TLS settings for a remote organization, you must create a custom connector.

### Creating a connector

You can use the *New-InboundConnector* and *New-OutboundConnector* cmdlets to create connectors via PowerShell. However, the EAC wizard is much easier to work with. You do not have to specify what type of connector you want to create (inbound/outbound). Instead, you specify the source and target systems, and the wizard will automatically create the right connector. To open the wizard, open the EAC and navigate to **Mail flow > Connectors > Add a connector**.

For example, suppose we need to route mail to a specific domain through a smart host (rather than delivering to its MX record). For this, we can create an outbound partner connector. To do this, launch the connector wizard from **Mail Flow > Connectors > Add a connector**. Select Office 365 as the source and Partner Organization as the destination. Click **Next**. Give the connector a **Name** and **Description**. On this page, you can also choose whether to enable the connector as part of the wizard. You may wish to uncheck **Turn it on** if you want to enable this connector later manually. Click **Next**. On the *Use of connector* page, add your target domains in the **Only when email messages are sent to these domains** field. Click **Next**. On the *Routing* page, check **Route email through these smart hosts** and enter a fully qualified domain name (FQDN) or IP.

Click **Next**. On the *Security Restrictions* page, specify whether to require TLS and the requirements for the certificate. Click **Next**. Validate the connector and click **Next**. Click **Create connector**.

According to Microsoft, many reported mail flow problems are caused by incorrectly configured connectors. To reduce the number of problems due to misconfiguration, when creating an outbound connector (from Office 365 to somewhere else), the wizard tries to validate the connector is functional before creating it. Then, an attempt is made to send a test message to a recipient you specify. The test is successful if the wizard can connect and deliver the message to the remote environment. If the validation fails, you can select to override the failure in the wizard and create the connector.

Using our example above, we can create this connector with PowerShell using the *New-OutboundConnector* cmdlet. We specify the scope of this connector with the *RecipientDomains* parameter and the delivery target with the *UseMXRecord* and *SmartHosts* parameters. The *TlsSettings* and *TlsDomains* parameters specify the TLS security when transferring mail over the connector.

```
[PS] C:\> New-OutboundConnector -Name "Contoso Outbound Connector" -ConnectorType Partner -
RecipientDomains contoso.com -TlsSettings DomainValidation -TlsDomain *.contoso.com -UseMXRecord
$false -SmartHosts mail.contoso.com
```

To review the properties of the connector (whether created in the EAC or PowerShell), you can use the *Get-InboundConnector* or *Get-OutboundConnector* cmdlet. In the example below, we retrieve the properties of the *Contoso Outbound Connector*.

```
[PS] C:\> Get-OutboundConnector "Contoso Outbound Connector" | Format-List

Enabled                : True
UseMXRecord            : False
Comment                :
ConnectorType          : Partner
ConnectorSource        : Default
RecipientDomains       : {contoso.com}
SmartHosts             : {mail.contoso.com}
TlsDomain              : *.contoso.com
TlsSettings            : DomainValidation
IsTransportRuleScoped : False
RouteAllMessagesViaOnPremises : False
CloudServicesMailEnabled : False
AllAcceptedDomains    : False
SenderRewritingEnabled : False
TestMode               : False
LinkForModifiedConnector : 00000000-0000-0000-0000-000000000000
ValidationRecipients   :
IsValidated            : False
LastValidationTimestamp :
Name                   : Contoso Outbound Connector
```

For more information on creating connectors with PowerShell, check the [New-InboundConnector](#) and [New-OutboundConnector](#) Microsoft articles.

## Mail Flow Rules

A modern messaging system must be able to handle the various requirements an organization might have. It is no longer enough for a server to send messages from point A to point B. As an organization evolves, its messaging system must offer the right feature set to support the changing requirements of that organization.

One could compare the changing behavior of interacting with a messaging system to how people interact with the post office. Where before it was good enough to deliver a written letter to its recipient, today the post office offers many additional services. For instance, when you move to a new house, you can request the post office to automatically forward mail addressed to your old location to your new home. This not only

gives you the time to inform all users about the address change, but more importantly, it prevents mail from being returned to sender or, worse: delivered at the wrong address.

The general idea behind mail flow rules is very like the above example. It provides Exchange Online with a way to dynamically handle incoming or outgoing messages based on one or more criteria. But, as you will see, you can use mail flow rules for much more than forwarding messages to a different email address. Mail flow rules also support Data Loss Prevention (Chapter 19) and Information Protection (Chapter 20).

The way mail flow rules work in Exchange Online is very similar to how they operate in on-premises Exchange, with the main exception that Exchange Online mail flow rules have more conditions and actions to choose from. As a result, an organization can create up to 300 different mail flow rules.

## Mail Flow Rule Conditions

Conditions (also known as predicates) define when a mail flow rule should be triggered. For instance, a condition can be used to check for a specific value in the sender's email address, or it can look for the existence of an attachment. The easiest way to build a new mail flow rule is to use the EAC, as you can select conditions from a drop-down list.

A rule can contain multiple conditions, in which case the message must match all individual conditions before any actions are triggered (logical "AND" configuration). You must create separate mail flow rules if you need to match several conditions in a logical "OR" configuration. If a single rule must apply for different values of the same condition, then add multiple values to a given condition. If multiple values are specified, the message must match one of the values assigned to the condition (logical "OR" configuration).

**Note:** It is also possible to create a "catch-all" rule. If you do not specify a condition (or you select *[Apply to all messages]*), the mail flow rule will be applied to every message that flows through the organization.

## Mail Flow Rule Exceptions

Exceptions are, just like conditions, used to scope the applicability of mail flow rules. Exceptions are used in conjunction with 'regular' conditions to exclude matches against (one of) the primary condition(s). Each condition has a matching exception.

Multiple exceptions can be configured for a given rule, in which case a single match is needed for the rule to be skipped (logical "OR" configuration). Similarly, you can specify multiple values for a given exception, and the rule will be skipped if any of the values are encountered.

**Note:** Any predicate can be used if messages are unencrypted when they are processed. S/MIME encrypted messages (not to be confused with messages protected with sensitivity labels or Office 365 Message Encryption) cannot be processed by mail flow rules based on conditions that inspect the contents of the message. In any other case, mail flow rules with conditions based on a message's envelope header will still work correctly.

For a comprehensive list of mail flow predicates and exceptions, check this [Microsoft article](#).

## Mail Flow Rule Actions

Actions ultimately carry out a task on the message. Each action uniquely affects the message, either by changing some of the message's properties or altering the routing behavior of the message. Amongst other actions, you can, for instance, re-route, reject, mark as spam, or silently redirect a message.

A mail flow rule can include multiple actions. Each rule has a priority number and the transport service processes applicable rules in ascending order of priority. This means that if you want to execute actions in multiple rules on a message, you must plan the rules so that the desired actions run in the correct order. In

determining the priority order for rules, you should consider the possibility that a rule might cause all further processing to stop after it completes because it includes the *Stop processing more rules* option. Rules also stop processing if a rule's action is to drop (delete) a message, as the next rule will not have a message to process. Something similar happens if the action is set to moderate the message (sent for approval): Exchange won't process lower priority rules until the message is approved. After approval, the transport service evaluates the remaining rules against the message.

**Note:** Over the years since the introduction of EOP, the options for spam and malware filtering have expanded. This means fewer reasons to use mail flow rules for spam/malware filtering. For example, the malware filter includes attachment protection settings, thus avoiding the need to look for attachments by file extension name in a mail flow rule.

For a complete list of all actions available for a mail flow rule, check [this article](#).

## Mail Flow Rule Properties

Apart from the building blocks detailed above, each mail flow rule also has properties that control various aspects of its processing. These include:

- **Priority** determines the order in which rules are processed. By default, Exchange Online orders mail flow rules by creation date, but you can override the processing order by adjusting the value of the priority property. Rules are processed from the lowest to the highest value.
- **Audit this rule with severity level** allows you to “tag” a rule as either *Low*, *Medium*, *High*, or *Not specified severity*, making it easier to filter or group the data in the mail flow rule reports.
- **Choose a mode for this rule** gives you the option to test a rule before turning it on (explained below).
- Optionally, you can toggle the **Activate this rule on the following date** and/or **Deactivate this rule on the following date** checkboxes to “schedule” the rule to be active only during a given time.
- The **Stop processing more rules** setting effectively stops mail flow rule processing after the given rule has executed its actions. Any mail flow rule with lower priority will not be affected.
- Turning on the **Defer the message if rule processing does not complete** option will cause the message to be resubmitted for reprocessing in the event of a failure to process the given mail flow rule.
- The selection under the **Match sender address in message** dropdown allows you to specify whether matches against any conditions or exceptions, including the sender address, are performed against the header value, the envelope value, or both.
- Lastly, the **Comment** field is available to store additional information about the rule, such as its creation date, the reason for a given modification, etc.

Apart from all the properties listed above, you can also toggle a mail flow rule On or Off by selecting the corresponding checkbox in the list of rules presented in the EAC or via the *Enable-TransportRule* or *Disable-TransportRule* cmdlets.

## Creating a New Mail Flow Rule

As mentioned earlier, the easiest way to create a new mail flow rule is to use the wizard in the EAC, as it allows you to select conditions, exceptions, and actions from a drop-down list. The EAC also allows you to select a pre-configured mail flow rule from a list of templates. These templates cover common scenarios, such as allowing a specific message to bypass spam filtering. The conditions, exceptions, and actions are already pre-selected depending on the template you selected. You only need to specify a unique value(s) for any of the specified properties. For instance, if you select the **Bypass spam filtering...** template, the **Set the spam**

**confidence level (SCL) to...** action has already been pre-selected, and you then select which SCL value you want to apply to the message.

You can build a mail flow rule from scratch using the EAC. By default, if you select **Create a new rule**, you will only see a subset of conditions and actions. However, clicking the **More options** link gives you the complete list of available conditions, exceptions, and actions.

## Testing New Mail Flow Rules

Before you put a new mail flow rule into production, it is wise to verify that the rule does what you expect it to. You can verify whether a mail flow rule works by enabling it in test mode. You will have the following options to choose from when creating a new mail flow rule:

- Enforce (default).
- Test with policy tips.
- Test without policy tips.

The **Enforce** option triggers the rule if all the conditions of the rule are met. However, **Test without policy tips** will stop the rule action from running because the rule is in test mode. But how do you know the rule has worked if it does not fire? The answer is to add the **Generate incident report and send it to** action.

The **Generate incident report and send it to** action sends an email to the selected recipient with information about the message that caused the rule to trigger. In test mode (with Test without policy tips enabled), Exchange Online generates and sends the incident report email. Still, the other actions specified in the rule, such as setting a disclaimer, are not performed. The incident report action allows you to select the properties of the message you want to include in the incident report. For example, if you are working with sensitive information or local legislation prevents you from accessing the contents of a message without notifying the user, you can opt not to include the original mail and make sure that the incident report only reveals non-crucial information about the message. An example of an incident report email appears below, where we see that the disclaimer rule “Corporate Disclaimer” was triggered. Because the rule was in test mode, the actual disclaimer was not applied and, therefore, not seen by the recipient.

```
Report Id: bbc7457a-64a9-44c5-a246-1b7d35db116b
This email was automatically generated by the Generate Incident Report action.
Message Id: <VI1PR06MB1183C94FCA77A1BFB979A927C9560@VI1PR06MB1183.eurprd06.prod.outlook.com>

Subject: Incident Report Testing
Recipients: jane.doe@office365itpros.com
Severity: Low
Override: No
False Positive: No
Rule Hit: Corporate Disclaimer, Action: ApplyHtmlDisclaimer, GenerateIncidentReport
```

Incident Reports are an easy way to check the effectiveness of a mail flow rule and, at the same time, gather information about what kind of messages will trigger the rule. This will allow you to decide whether the mail flow rule meets your expectations. Once you decide that the mail flow rule is ready for production, you can edit the mail flow rule and choose to **Enforce** it. Do not forget to remove the action to send an incident report, or you will receive a report each time the rule is triggered!

## Monitoring Mail Flow Rule Usage

One measurement of the effectiveness of a mail flow rule is the number of times it triggers. Of course, there might be cases where you hope a mail flow rule never triggers, such as when a mail flow rule enacts an *ethical wall* to prevent two departments from communicating with one another. This is often seen in financial institutions where regulations define that market researchers cannot communicate with brokers to avoid a conflict of interest or (in-)voluntary market manipulation.

The Exchange Admin Center includes the “Exchange Transport Rule” report dedicated to mail flow rules. The report gives you a breakdown of all the individual mail flow rule matches in either graphical or table view. In addition, you can also group the results by the audit severity value, which we described earlier. Like many of the other Exchange-related reports, you can schedule this report to be emailed to specified recipients on a weekly or monthly basis. We will discuss this report and others later.

The *Get-MailDetailTransportRuleReport* cmdlet searches for specific transport-rule related events. For instance, it can be used to search for 'hits' within a given timeframe or to look for actions that have been performed because a mail flow rule was executed. The example shown below reports all mail flow rule hits in the past 5 days and lists the date and time, message subject, action taken, and rule that was executed:

```
[PS] C:\> Get-MailDetailTransportRuleReport -StartDate (Get-Date).AddDays(-5)
-EndDate (Get-Date) | Format-List Date, Subject, Action, *Rule*
```

If you need to search for hits of a specific mail flow rule, you can use the following command:

```
[PS] C:\> Get-MailDetailTransportRuleReport -TransportRule "Check for sensitive data"
```

The cmdlet has many more parameters that allow you to refine the results further. For instance, you can look for messages from a specific sender:

```
[PS] C:\> Get-MailDetailTransportRuleReport -StartDate (Get-Date).AddDays(-5)
-EndDate (Get-Date) -Sender Joe@office365itpros.com
```

The dashboard reports and the data generated by the PowerShell cmdlets come from Microsoft's reporting data warehouse. The only downside to this approach is that the information in the data warehouse isn't always up to date. It can take up to a day before these cmdlets return complete data. If you are looking for an immediate way to measure mail flow rules, adding an incident report is preferred.

## Mail Flow Rule Limitations

Microsoft limits the amount of transport and journal rules each tenant can create. These limitations protect the service by limiting the amount of routing logic applied to each message. Table 7-1 lists the rule limits.

<b>Feature</b>	<b>Limit</b>	<b>Additional Information</b>
Journal Rules	300	The maximum number of journal rules that can be created in a tenant
Mail Flow Rules	300	The maximum number of mail flow rules that can be created in a tenant

Table 7-1: Transport rule limits

## Common Use Cases for Mail Flow Rules

Because of the many available conditions, mail flow rules are useful in a myriad of scenarios. It would be impossible to list all the use cases here, but we will look at some of the more common scenarios and tasks. The examples from the scenarios described below should provide you with enough insights into the capabilities of mail flow rules so that you can produce viable solutions to any unique requirements you have.

### Organization-wide Disclaimers

Sometimes legal or regulatory requirements dictate the need for an organization to add disclaimer text to outbound messages. Mail flow rules can handle this requirement because one of the actions available to a mail flow rule is the ability to prepend or append a disclaimer to a message. The content of the message can be plain text, but it can also include HTML code to make it more dynamic.

Additionally, you can include certain variables based on the attributes of a user's Azure AD account to insert user-specific values in the disclaimer. For instance, by adding *%%DisplayName%%* to the disclaimer text, Exchange Online inserts the sender's display name into the text.

However, when you add a disclaimer to all outgoing messages, the user experience may not be what you expect. For example, in Figure 7-4, when you append a disclaimer to a message, the transport service adds the disclaimer text to the end of the message. Of course, this is precisely where you would expect it to be for a new message (1). However, if you reply to an email thread, you will notice that the disclaimer is added at the very bottom of the entire thread, not after the latest reply (2). This might be perfectly acceptable for a disclaimer, but it looks strange for signatures.

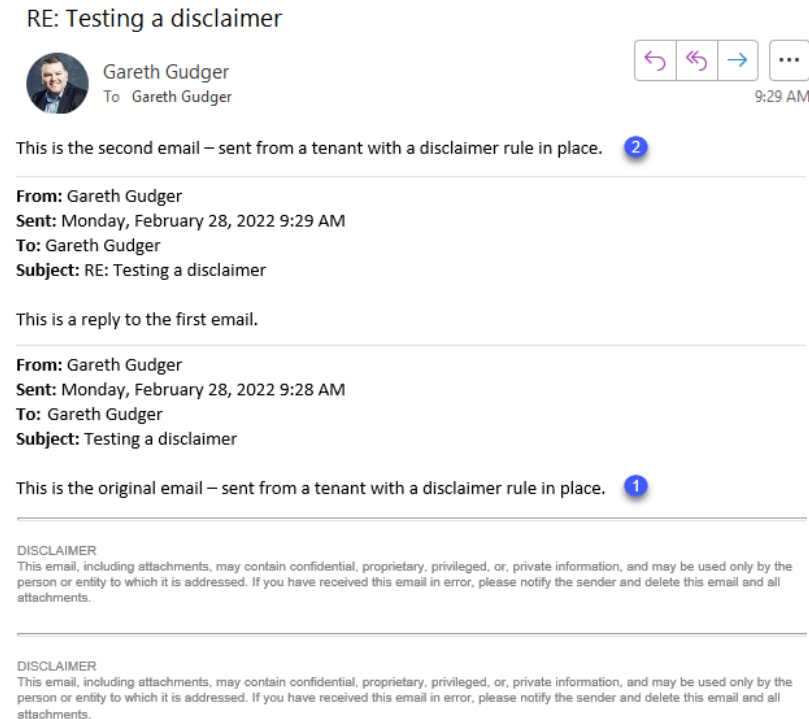

Figure 7-4: The disclaimer text added by a mail flow rule appears at the bottom of a message

Although you cannot make a mail flow rule add text at the end of the latest message, you can stop the rule by adding disclaimer text or signature if one already exists by adding an exception to the rule. This PowerShell example shows how:

```
[PS] C:\> New-TransportRule -Name "CompanyDisclaimer" -Enabled $True
-SentToScope "NotInOrganization" -ApplyHtmlDisclaimerLocation "Append"
-AppllyHtmlDisclaimerText "<br><hr><font face='Arial' color='Gray' size='1'><br>DISCLAIMER<br>This
email, including attachments, may contain confidential, proprietary, privileged, or, private
information, and may be used only by the person or entity to which it is addressed. If you have
received this email in error, please notify the sender and delete this email and all
attachments.<br></font>"<table border="0"> <tr><td>Column1</td> <td>Column2</td></tr><tr><td
colspan="2"><div style="font-size:10pt; font-family:'verdana'">This is the disclaimer text and it
cannot exceed 5,000 characters. </div></td></tr></table>"
-ExceptIfSubjectOrBodyContainsWords "This email, including attachments, may contain confidential,
proprietary, privileged, or, private informationThis is the disclaimer text, and it cannot exceed."
```

The first time the message is processed, the rule runs and adds the disclaimer because it's improbable that the phrase used by the exception is present in the body or subject. However, on any subsequent occasion, the message or its replies pass through the transport service, such as when a recipient sends a further reply, the rule exception prevents the insertion of the disclaimer because the body now contains the exact words added by the same rule the first time the message was processed.

**Note:** One important limitation of mail flow rules is that the total size of the disclaimer cannot exceed 5,000 characters. This includes the text and any HTML tags or Cascading Style Sheet (CSS) code you might add.

## Bypass Spam Filtering

As discussed later, EOP automatically collects allowed and blocked sender settings from the junk mail settings manipulated by users with Outlook and Outlook Web App. Sometimes, an organization might want to centrally control which senders receive automatic approval and those marked as spam. For instance, this will be necessary if you introduce a new corporate communications tool that sends messages from an external system.

To achieve this goal in Exchange Online, you can use a mail flow rule to add a message header set to a specific value. In this case, the header is the "SCL" header (Spam Confidence Level) which will be set to a value of "-1". The value of the SCL header determines if a message should be sent to the user's junk email folder at the end of the processing pipeline. Table 7-2 describes the values used for the SCL header in Exchange Online:

<b>SCL Value</b>	<b>Meaning</b>
-1	The message is deemed safe because the sender is safe-listed, the sender's server is on an IP safe list, or the recipient is on the safe-recipient list. Therefore, the content filtering engine does not process the message.
0, 1	After processing by the content filtering engine, the message was deemed to be clean.
5, 6	After processing by the content filtering engine, there is reasonable confidence to mark the message as spam.
9	After processing by the content filtering engine, there is no doubt (high confidence) that the message is spam.

Table 7-2: SCL header values in Exchange Online

In the following PowerShell example, a new mail flow rule is added to create a safe list that will automatically mark messages from the office365itpros.com domain as safe:

```
[PS] C:\> New-TransportRule -Name DomainSafeList -SenderDomainIs "office365itpros.com" -SetSCL "-1"
```

**Real-world:** Care should be taken with setting blanket safe list rules like those shown above. If the domains or senders in question have their email address spoofed so that a message does not come from the user or organization who owns the mailbox but instead from someone acting as that sender or domain, EOP will mark the email as safe. This is because the rule checks the domain or user and not doesn't do anything to validate the reliability of the sender. Anti-phishing rules are recommended as a replacement for blanket allow lists.

## Conditional Mail Routing

Conditional Mail Routing allows you to use mail flow rules to alter the default routing behavior for specific messages that match the conditions of a mail flow rule. However, if you want to control the behavior for all outbound messages, it is better to create a custom connector instead.

Consider the following scenario: You represent a large organization with multiple types of users—for instance, an educational institution with students, staff, and faculty. You use Exchange Online for both types of users but want email from staff and faculty to be routed to the internet through an on-premises appliance that offers various features like journaling, signatures, secure messaging, etc. Even though these features also exist in Exchange Online, you previously invested in the solution and do not want to lose out on those investments. If you created a regular outbound connector, all messages would be routed through the external appliance, including those from students. So instead, you create a new connector, only to be used by a mail flow rule which defines that outbound messages sent by faculty and staff mailboxes should be routed through the new connector.

This scenario is an excellent example of how conditional mail routing can help an organization meet regulatory requirements without making extensive changes to other parts of the configuration and leveraging

prior investments. Although conditional mail routing adds a layer of complexity to the entire solution by splitting the message routing logic, it can be extremely valuable if carefully planned and used for the right purposes.

**Real-world:** The most common use of conditional mail routing is to ensure that messages sent to specific users or applications are either encrypted with TLS or sent directly to a specific system. The latter option requires the outbound connector to be configured with a smart host. As such, the MX records for the recipient's domain are ignored, and messages are delivered directly to the specified smart host. This is also done to ensure messages are sent to servers in a specific region. Often the recipient's organization does not have the infrastructure to dynamically (and geographically) route incoming messages directly to servers in the same region as the mailbox. In such a case, the sender's organization can then use conditional mail routing to accomplish the task.

Conditional mail routing relies on mail flow rules to check the properties or content of a message. The mail flow rules will redirect the message to the selected connector if a specific condition is met. Thus, before creating a mail flow rule to redirect messages to a specific connector, you must first set up a connector and configure it for conditional mail routing. To do this, create a custom outbound connector and select the option **Only when I have a transport rule set up that redirects messages to this connector** when asked *'When do you want to use this connector?'*

In the following example, we will configure a mail flow rule to redirect all messages sent to "kim.akers@office365itpros.com" through the custom connector *Outbound to Office365ITPros*. We will only configure the basic settings to make this rule work. Start by opening the new mail flow rule wizard from the EAC, select **Mail Flow**, navigate to **Rules**, click on the plus sign to show the drop-down menu, and select **Create a new rule...**

By default, the list of actions displayed on the screen is limited and does not allow redirecting messages through a specific connector. To enable access to the more advanced options, you must first select **More options...** After clicking the link, the additional settings will be displayed.

1. Specify a descriptive name for the rule. This will ensure that you can easily find the rule in the list of rules.
2. Select a condition to which the message should apply. For this example, select **The recipient is...** If you haven't created a contact for the recipient, type it manually in the *check* names field and then hit Enter. For example, type *kim.akers@office365itpros.com*.
3. From the actions drop-down menu, select **Redirect the message to...** and **the following outbound connector**.
4. Select **Outbound to Office365ITPros** from the list of available connectors.

After saving the mail flow rule, it is enabled and will apply to any outbound message sent to kim.akers@office365itpros.com.

## Identifying External Senders

Adding a warning message to emails from external senders is a common use case for mail flow rules. For many organizations, this warning message is a core part of end-user training to identify and report potential phishing messages. The downside to using a mail flow rule is that the warning message is often unsightly and might be included in future replies to the sender. You can enable external email tagging in Exchange Online to transition away from a mail flow rule (if you have one). Exchange Online's external email tagging functionality is available in Outlook, OWA, Outlook Mobile, and Outlook for Mac.

To enable external email tagging, run the following command in Exchange Online PowerShell:

```
[PS] C:\> Set-ExternalInOutlook -Enabled:$true
```

When Exchange Online marks a message as external, it sets the *IsExternalSender* MAPI property for the message to True. Clients check for the property and display the warning if it is True.

You can specify external email domains that Exchange should not treat as "external." For example, you might have messages from a third-party training system that should appear to be from an internal sender. To add a domain to the list of allowed external senders by running the following command:

```
[PS] C:\> Set-ExternalInOutlook -AllowList @{Add="Office365ITPros.com"}
```

## Exporting and Importing Mail Flow Rules

Although mail flow rules can be enabled in test mode, it can sometimes come in handy to experiment with a few settings in a test tenant. Once testing is complete, you can export the rule(s) from a test tenant and import them into the production tenant. To export mail flow rules from a tenant, run the following command while connected to Exchange Online PowerShell:

```
[PS] Set-Content C:\ExportTransportRules.xml -Value ((Export-TransportRuleCollection).FileData -Encoding Byte)
```

**Be careful when importing:** The *Import-TransportRuleCollection* cmdlet overwrites the existing mail flow rules in the target tenant with the content of the XML file. This command is a rip and replace. In this example, this means the mail flow rules you export from the test tenant will overwrite the rules in the production tenant. To ensure you have a rollback option, export rules from the target tenant before import.

Next, connect to the target tenant and run the following command to import the ruleset:

```
[PS] C:\> Import-TransportRuleCollection -FileData (Get-Content -Path C:\ExportTransportRules.XML -Encoding Byte -ReadCount 0)
```

Confirm

Importing a rule collection will overwrite all existing rules in that collection. Do you want to continue?

[Y] Yes [A] Yes to All [N] No [L] No to All [?] Help (default is "Y"): Y

## Remote Domains

Any email domain not registered with your tenant is considered a remote domain. By default, you can deliver email to any remote domain. However, an organization might want to limit what messages get sent to remote organizations, or maybe they want to control the message format. This is where remote domain configuration settings are useful.

A remote domain allows you to control:

- **Out of Office replies.** Allow or deny replies to be sent to the domain. You can also control whether the internal or external out-of-office response is sent.
- **Automatic replies and forwarding.** You can control if a user-generated rule can automatically reply to or forward messages to the remote domain.
- **Message reporting.** This allows you to control whether message status notifications should be sent to the remote domain. For instance, you can prevent non-delivery reports from being sent to a remote domain or configure that meeting forward notifications are sent; by default, meeting forward notifications are only sent within the organization.
- **Format of the message.** Allows you to define if a message should be sent in rich text and what MIME character set should be used, if at all.

**Note:** The settings you specify for a remote domain override any user-specific settings, for instance, configured through the *Set-MailboxAutoReplyConfiguration* cmdlet. If you want to modify default settings for all other unlisted domains, you must modify the default remote domain.

You can add a new remote domain or configure an existing one by going to **Mail flow** and **Remote domains** in the EAC.

Automatic message forwarding is a common action that attackers take when they compromise a mailbox. Because this threat exists, Exchange Online does not allow automatic forwarding by default. You can amend the default policy to allow users to auto-forward email, but this is a terrible idea. Instead, if some users need to auto-forward email from their mailboxes, you can create a custom outbound spam filter policy. The custom policy specifies the email addresses of users who can auto-forward their email outside the organization.

## Device and app mail relay to Exchange Online

Even in the digital world, people still print many documents. Often, these documents are scanned again for digital archiving. For years, scanners could email scanned messages. Despite sending email messages, many of these devices do not support authentication and can only send plain, unauthenticated SMTP messages. Scanned messages mostly go to internal recipients anyway. However, the same is not always true for some line-of-business (LOB) applications. For example, the application might need to send a message to an external recipient when an order is updated.

This is not a problem for Exchange on-premises because you can scope your firewall to accept messages from specific device or application IP addresses. However, it's not that simple with EOP. Because EOP is publicly available on the internet, allowing unauthenticated SMTP would open the door to spammers to use EOP as an "open relay." Today, there are four possible solutions:

- If your device or application supports authentication, you configure it to use the credentials of an Exchange Online mailbox to send messages internally and externally. This method requires the device to support TLS 1.2 and send mail over port 587. Microsoft refers to this method as **SMTP Auth**.

**Note:** Using TLS 1.0 and TLS 1.1 with SMTP Auth is unsupported. Microsoft has stated they will block TLS 1.0 and TLS 1.1 to the smtp.office365.com endpoint in 2022. Therefore, any devices or applications that require these older protocols will need to leverage the new endpoint of smtp-legacy.office365.com. To activate this [legacy endpoint](#), tenant administrators must run *Set-TransportConfig -AllowLegacyTLSClients \$true*.

- If the device or application either does not support authentication, does not support TLS, or can only use port 25, you can use **Direct Send**. Note that this can only be used to send mail to internal recipients in your tenant. Any external recipient will be rejected. Mail will also be heavily scrutinized and be subject to anti-spam policies and could be flagged as spam.
- If your device needs to send mail to external recipients, another option is to use a **custom connector** to identify and authenticate all on-premises devices and applications that need to send email messages. This option will likely require network configuration changes to ensure that all outbound connections from these devices and applications to Exchange Online originate from a specific set of IP addresses.
- A custom or third-party SMTP relay solution is used to forward messages to Exchange Online on behalf of the SMTP device or application. For instance, the IIS SMTP service can be used to create a custom SMTP relay solution. The SMTP service will accept unauthenticated messages from devices and applications within your network and, in turn, forward the messages to Exchange Online using the credentials of an Exchange Online mailbox.

For information on configuring each of these relay methods, check this Microsoft [article](#).

**Managing hybrid mail flow:** While it is possible to eliminate your last on-premises Exchange server for management tasks, many organizations maintain Exchange servers for SMTP relay for on-premises devices and apps. In those scenarios, it is easier to keep routing those emails through the existing Exchange Servers configured for secure hybrid mail flow.

The other aspect is security. Many enterprises leverage firewall rules to govern what devices and apps can send outbound mail. For security-conscious organizations, they want to minimize the number of outbound SMTP connections to the absolute minimum. To use an analogy, they do not want to swiss-cheese their firewall. In this scenario, security dictates that only a handful of known and centrally managed Exchange servers (or 3<sup>rd</sup>-party relays) can send outbound mail.

## Exchange Online Protection (EOP)

Exchange Online Protection (EOP) is Microsoft's cloud-based email filtering service. EOP includes a set of message hygiene features to sanitize inbound and outbound mail flow and remove threats from messages. EOP protects all emails exchanged between Exchange Online (including between tenants) and external sources. Protection is in place to divert spam and malware and to guard against potential data loss. There are three configurations for EOP:

- **Exchange Online (cloud-only) deployment.** Although EOP is a separate feature, it is an integral part of and tightly integrated into Exchange Online. If you have an Exchange Online tenant, you automatically use EOP.
- **Standalone.** Organizations that do not use Exchange Online can route email traffic to EOP to use it as an email hygiene service. This can be for an on-premises Exchange environment or another email solution (hosted or on-premises).
- **Hybrid deployments.** In this scenario, EOP protects the traffic between the cloud and the on-premises servers. In a non-centralized mail flow approach, EOP can protect on-premises mailboxes as it does in a standalone deployment.

Exchange Online provides redundancy and load-balancing within a data center region. This also satisfies regulatory requirements that might need data to remain within a particular geographical area, such as the EU data processing guidelines. EOP running in country-level data centers (like Norway, France, or the United Kingdom) processes messages for tenants in those countries. EOP running in data centers in the United States (US) processes messages for US tenants. This means that it is vital to be aware of the correct namespace to use when routing messages so that you do not route to the wrong data center and have the message declined.

### How EOP Processes Email

The filtering system in EOP consists of multiple layers and processes to handle inbound and outbound messages. To understand how Exchange Online processes messages, let us review the diagram shown in Figure 7-5, which shows how EOP uses inbound mail filtering to protect Exchange Online mailboxes.

The transport service routes email from source to destination unless the message triggers some component of the service that deems the message unsafe, in which case the properties of the message are changed, or the message is routed to the quarantine or rejected outright.

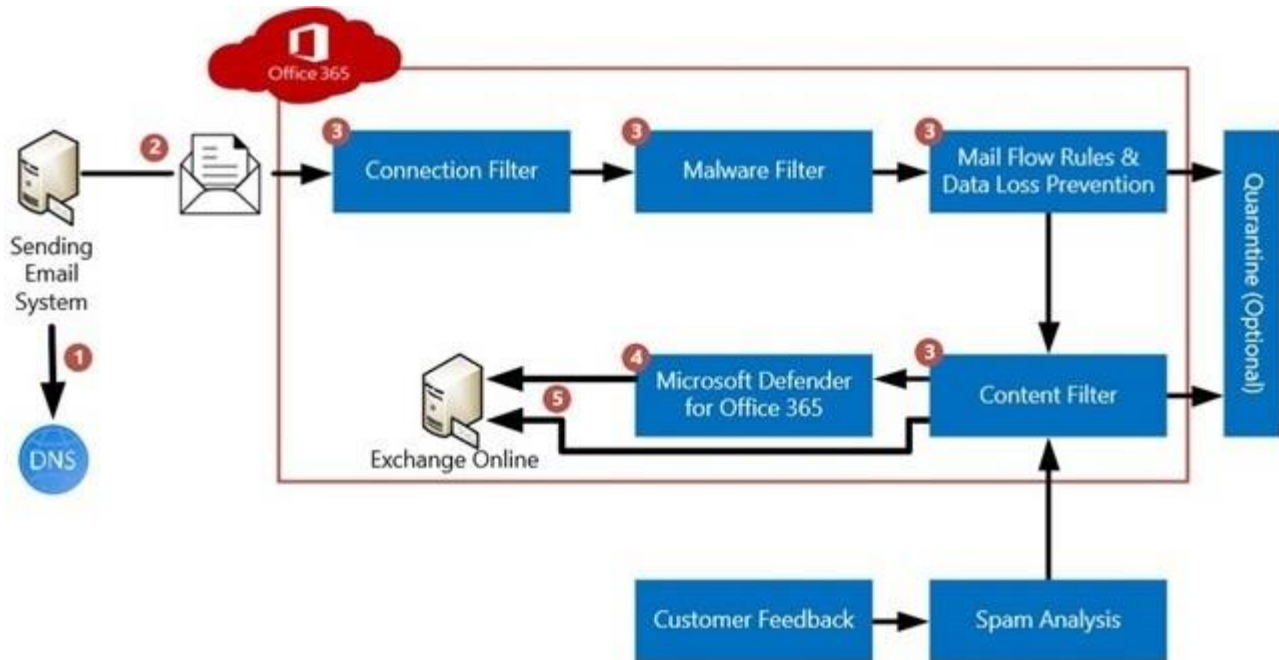

Figure 7-5: How EOP protects email

Figure 7-5 shows the route a message takes through EOP:

1. The sender's mail server looks up the domain MX record information (in our example, the MX record resolves to EOP).
2. The MX record resolves to the data centers in the primary region to which the tenant belongs. The sending mail server then tries to deliver the message to the MX endpoint retrieved earlier. To accept messages from the internet, you do not need to configure anything. The default connector in Exchange Online (which is invisible to the administrator) automatically accepts all messages.
3. Before the message is delivered to the recipient(s), it goes through several layers of filtering:
  - a. **Connection Filtering.** The connection filter is the first layer of defense. It checks several items, including the sender's reputation. In addition, an administrator can define an IP allow/block list to allow or block connections from specific IP addresses. Administrators can also opt into the safe list, a curated list of IPs Microsoft has deemed safe. By enabling this option, all safe list members bypass spam filtering.
  - b. **Anti-Malware filter.** This filter inspects the message for malware and viruses. If a message is deemed malicious, it is removed from the mail pipeline by default. However, it is not rejected at this stage because the sender does not get a notification or non-deliverable response that you might expect when a message fails to reach its target. Configuring anti-malware rules will be covered later.
  - c. **Policy Enforcement.** The policy filter checks messages against configured mail flow rules (including those created by data loss prevention (DLP) policies). If a message matches a rule, the action(s) configured for that rule or policy are applied to the message.
  - d. **Content Filtering** is where the content of messages goes through checks to determine whether the message is spam or phishing based. If a message is considered spam, phishing, bulk, or high-confidence phishing, it can be deleted, sent to the user's Junk Email folder, or quarantined within EOP, depending upon the settings and rules you have configured.
4. If the tenant has Microsoft Defender for Office 365 licenses and the right policies are in place, messages will receive additional scanning before moving on to the next step.
5. If the message was not dropped, rejected, or quarantined, it is delivered to the recipient(s).

**Hybrid mail flow** is handled slightly differently. Messages received from the on-premises organization are marked as "internal" and bypass content filtering (anti-spam). However, if the hybrid mail flow is not correctly configured, internal senders could be treated as anonymous and external to the organization. This could cause messages from internal senders to be incorrectly quarantined, moved to junk, or outright rejected.

Outbound messages are also scanned and evaluated:

1. Outbound messages first go through the **Anti-malware filter**, where they are scanned for known viruses.
2. Next, messages make their way through the **Policy Enforcement** engine. Here, messages are evaluated using configured policies such as mail flow rules, email encryption, and data loss prevention (DLP) rules. If a message matches one of the rules, the action from that rule is applied to the message.
3. The **Content Filtering** process exists to decide if sent messages are spam. A variety of techniques are used, and if a message is likely to be spam, two things can happen:
  - a. The message is routed through EOP's *High-Risk Delivery Pool*. This pool of EOP servers is used to send messages flagged as potentially being spam. This means that regular mail flow will not be affected if one of the IP addresses in the high-risk pool is blocked. Out-of-office messages are also sent via the high-risk delivery pool.
  - b. Depending on the configuration, and the characteristics of the email, it can also be quarantined.
4. If a message is considered safe, it is routed to its destination through the regular outbound pool. Unlike the high-risk pool, these servers are only used to send messages considered safe.

**Queuing:** Sometimes, the mail server to which EOP should deliver messages may be (temporarily) unavailable. Queuing will only happen for "transient errors" such as connection time-outs, refused connections, or other SMTP errors with 4XX error codes. Any "hard failure," such as invalid recipients, authentication mismatch, or failures shown by an SMTP 5XX error code, will generate a non-delivery report (NDR). In hybrid mail flow from on-premises, the Hybrid Wizard changes the mail flow configuration so that some 5XX error codes are downgraded to less severe 4XX error codes.

EOP will automatically try to re-deliver queued messages approximately every five minutes until it can successfully deliver the message. If the message cannot be delivered within 48 hours, the message expires, and an NDR is generated. Reports on messages that have been queued for over one hour are available in the Exchange admin center under **Reports > Mail Flow Report > Queued Messages Report**.

## Zero-hour Auto Purge (ZAP)

Despite all the efforts to fight spam and malware, malicious messages can escape the scrutiny of EOP's multiple scanning engines and be delivered to user inboxes. Many reasons could result in anti-malware code not classifying a message as spam or malware. Sometimes this is because the sender (still) has a good reputation, or perhaps because the spam or malware in the email was so new that the malware signature database in EOP is unable to recognize the vulnerability exploited by the attacker.

Zero-hour Auto Purge (ZAP) retroactively deals with malware, spam, and phishing that penetrates defenses by continuously monitoring EOP for signature updates.

- If a new malware signature is detected that matches a signature in a previously delivered message, ZAP retroactively removes the attachment or message from each user's mailbox.
- If a new phishing or spam signature is detected that matches a signature in a previously delivered message, ZAP retroactively takes the action of the anti-spam policy, which could include moving the

message to quarantine, moving the message to the user's junk email folder, deleting the message, or to take no action.

- The opposite is true for false positives: ZAP can move misidentified messages back into the user's mailbox.

ZAP is enabled by default and can be turned off through PowerShell via the *Set-HostedContentFilterPolicy* cmdlet (for phish and spam) or the *Set-MalwareFilterPolicy* cmdlets (for malware). ZAP will only work if the following conditions exist:

1. The user's junk email filtering is enabled. By default, this is true.
2. The spam filter policy is configured to apply any action except *Add X-Header*. The default is to move messages to the junk email folder.

Note that mail flow rules and end-user inbox rules take precedence over ZAP.

To verify if ZAP is enabled, you can use the following cmdlets:

```
[PS] C:\> Get-HostedContentFilterPolicy | Select PhishZapEnabled,SpamZapEnabled

PhishZapEnabled SpamZapEnabled
-----
                True           True

PS C:\> Get-MalwareFilterPolicy | Select ZapEnabled

ZapEnabled
-----
          True
```

Although the actions are transparent to the end-user, information remains for the administrator in the message's routing information. Look for the mention of **Zero-Hour Auto Purge (ZAP)** in the details of the message trace. If the information is there, it means ZAP intervened.

## Directory-based Edge Blocking (DBEB)

By default, EOP will reject any message addressed to recipients it does not recognize, that is, for which EOP cannot find a matching mail-enabled object in the directory. This feature is known as directory-based edge blocking (DBEB) and offers several benefits, especially when a domain is under a dictionary attack by a spammer. DBEB is enabled for each authoritative accepted domain within Exchange Online and blocks messages at the perimeter network.

When you register a new domain with Microsoft 365, the domain is automatically configured as *Authoritative*, designating Exchange Online as your primary (and only) mail system. All valid recipients should then be represented by an object within Exchange Online, giving the system confidence that every recipient not matched against an existing object should be considered invalid. In turn, DBEB will reject messages addressed to invalid recipients, even before the message reaches the filtering layers. For this reason, messages rejected by DBEB are not visible in the message trace logs.

In a hybrid deployment, the transport service must be able to deal with email-enabled recipients homed on-premises. The same is true in a standalone scenario where EOP protects an on-premises organization. Directory synchronization is then used to synchronize on-premises recipients to Exchange Online. However, directory synchronization does not synchronize all recipient types. For instance, dynamic distribution groups are not synchronized. As such, [without extra configuration](#), messages will be rejected. Two options exist to avoid the dropping of messages for missing recipients:

1. Create a mail contact for the missing recipients. This will ensure that a valid recipient exists in the tenant, and DBEB will accept the message, after which it is forwarded to the on-premises environment.

2. Reconfigure the domain as an *Internal Relay* domain instead of *Authoritative*.

In the latter scenario, DBEB will be disabled automatically. However, messages for recipients not found in Azure AD will be forwarded to the on-premises organization or, if you do not have a dedicated connector, to where the MX record points. Thus, you might also need to configure an outbound connector scoped to the domain name. For instance, if you have configured the domain *office365itpros.com* as an internal relay domain, you should also create an outbound connector, as illustrated in the following PowerShell example:

```
[PS] C:\> New-OutboundConnector -Name "To On-premises"  
-RecipientDomains "office365itpros.com" -ConnectorType "OnPremises"  
-SmartHosts "onpremises.office365itpros.com" -UseMXRecords $False
```

When running the *New-OutboundConnector* cmdlet, it is important to include the *OnPremises* connector type. In this example, the connector is scoped to include only the *office365itpros.com* domain. However, you might have multiple relay domains. If you want to forward all messages for all accepted domains to a specific smart host without specifying each domain individually, you can use the *-AllAcceptedDomains* switch instead. This will ensure that a single connector is used for all known accepted domains.

```
[PS] C:\> New-OutboundConnector -Name "To On-premises" -AllAcceptedDomains $True  
-ConnectorType "OnPremises" -SmartHosts "onpremises.office365itpros.com" -UseMXRecords $False
```

The benefit of using the *AllAcceptedDomains* parameter is that new accepted domains are automatically included in the scope of the outbound connector.

## Preset Security Policies

Preset security policies allow an organization to quickly deploy their message hygiene and Microsoft Defender for Office 365 policies with a few simple clicks. Microsoft provides two predefined security policies: standard and strict. Think of these as policies Microsoft is curating and managing on your behalf. All you need to do is select which users or groups of users you want to include in the preset policies. If your organization needs a custom policy, then the preset security policies will not work for your organization.

You can deploy these policies by navigating to **Policies and rules > Threat Policies > Preset security policies**. Clicking the **Manage protection settings** link (under either *Standard Protection* or *Strict Protection*) allows you to add users to either policy. Users can be added individually, through group membership, or through their primary domain. Once you complete the wizard, these policies are created automatically under Anti-Phishing, Anti-Spam, Anti-Malware, Safe Attachments, and Safe Links. However, unlike custom policies, these policies cannot be edited, deleted, or disabled through the regular policy screens. For example, in Figure 7-6, we can see that the strict protection policy is disabled. However, even though the strict protection policy is disabled, it is still present on the other policy screens. The strict protection policy is only deleted from the other policy screens when all users, groups, or domains have been removed from the policy.

To disable the policy, navigate to the **Preset security policies** page and toggle the switch to the left (disabled). If you would rather delete the policy, click the **Manage protection settings** link under the policy you wish to delete. From the wizard, set the **Apply Protection** checkboxes to **None** on the *Apply Exchange Online Protection* and *Apply Defender for Office 365 protection* pages. Click **Confirm**. The policy toggle will now be greyed out and removed from all policy screens.

You can learn more about preset security policies and how their management differs from Microsoft's [documentation](#).

Policies & rules > Threat policies > Preset security policies

## Preset security policies

<p><b>Standard protection</b></p>  <p>A baseline protection profile that protects against spam, phishing, and malware threats.</p> <ul style="list-style-type: none"> <li>✓ Balanced actions for malicious content</li> <li>✓ Balanced handling of bulk content</li> <li>✓ Attachment and link protection with Safe Links and Safe Attachments</li> </ul> <p><input checked="" type="checkbox"/> Standard protection is on</p> <p><a href="#">Manage protection settings</a></p>	<p><b>Strict protection</b></p>  <p>A more aggressive protection profile for selected users, such as high value targets or priority users.</p> <ul style="list-style-type: none"> <li>✓ More aggressive actions on malicious mail</li> <li>✓ Tighter controls over bulk senders</li> <li>✓ More aggressive machine learning</li> </ul> <p><input type="checkbox"/> Strict protection is off</p> <p><a href="#">Manage protection settings</a></p>

Figure 7-6: Preset Security Policies in EOP

## Anti-Spam Protection

As defined in Wikipedia, email spam is unsolicited, undesired, or illegal email messages. It should come as no surprise that the various anti-spam features in EOP work together to:

1. Reduce the amount of spam that is delivered to a user's inbox; and
2. Reduce the number of false positives; messages are marked as spam but are not.

When an organization uses Exchange Online, spam filtering for inbound messages is enabled by default and cannot be disabled. However, an administrator has a multitude of options to adjust the settings for the different anti-spam features, including the ability to create custom antispam policies for different groups of users.

### Anti-spam Inbound Policy

Inbound spam filtering can be accessed from the **Defender portal** and navigating to **Policies and rules > Threat Policies > Anti-spam policies**. The *Anti-spam policies page* lists the default three policies (which cannot be disabled) and any custom anti-spam policies you have defined.

To create a new policy, select **Create Policy > Inbound**. This will launch a wizard to guide you through the policy creation. The elements of that wizard are the same as if you edit a custom policy. We will cover that next.

To customize an existing policy, select that policy, and the properties pane will be displayed. The properties pane lets you customize what constitutes spam and what actions to take on that spam.

From the policy properties pane, you can perform the following actions:

- Enable or disable the policy with the **Turn on** or **Turn off** buttons. These buttons are absent for the default policy as it is always enabled.
- Change the processing order of the policy with the **Increase Priority** or **Decrease Priority** buttons. These buttons are absent from the default policy because it always has the lowest priority.
- Delete the policy with the **Delete policy** button. The default policy cannot be deleted.

- The **Edit description** link allows you to change the name and description of the policy. The description field is a great way to document any changes you have made to the policy. Note that the default policy cannot be renamed, so the name field will be greyed out if you are editing the default policy.
- **Edit users, groups, and domains** allow you to define the scope of the policy. This section is not present on the default policy because the default policy is the catch-all for anyone not defined in a custom policy. Custom policies have priority over the default policy and are always processed first. If you have multiple custom policies that scope the same set of users, then the policies are processed in order of priority, where the lowest number (zero) is processed first.
- **Edit spam threshold and properties** allow you to configure what constitutes spam or bulk email (we will cover this in the next section).
- **Edit actions** define what actions to take on messages marked as spam, high confidence spam, phishing, high confidence phishing, and bulk mail. These actions are as follows:
  - **Move message to Junk Email Folder** delivers the message to the user but deposits the message into the user's junk folder. This could be a helpful training tactic as it may prompt the user to scrutinize the source and content of the message.
  - **Prepend subject line with text** delivers the message to the user but modifies the subject line. This is useful if you want to provide a visual cue to the user by prepending the subject line with BULK or SPAM as an example. Like moving the message to the user's junk folder, this is also a helpful training tactic to get the user to scrutinize the message.
  - **Quarantine message** prevents delivery of the message to the user and instead delivers the message to a quarantine. A quarantine policy dictates how the user interacts with a message in the quarantine. You can define a different quarantine policy for different types of mail. For example, the quarantine policy on high confidence phish could be much more restrictive than the policy on bulk email. Quarantine policies are discussed later in this chapter.
  - **Redirect message to email address** prevents delivery of the message to the user and instead delivers the message to someone else. This option is helpful for egregious phishing that you want to redirect to a SecOps mailbox for analysis.
  - **Add X-header** adds a header to the message. This header can be targeted by mail flow or inbox rules for additional actions.
  - **Delete message** does precisely as the name implies. The message is deleted and cannot be recovered.
  - **No action** does precisely as the name prescribes. The message is forwarded to the user without modification.

**Note:** Not all actions are available to each spam or phishing type. For example, *No action* is only available to an email defined as bulk. On the other hand, the only actions for high confidence phish are Quarantine and Redirect messages.

- **Retain spam in quarantine for this many days** defines how long messages are kept in quarantine if the quarantine action and a quarantine policy have been selected.
- **Enable spam safety tips** define whether safety tips should be displayed to users in an Outlook client. This is useful if you deliver spam to the user's mailbox (e.g., prepend subject or move to junk) but want to provide additional warnings about the message.
- **Enable zero-hour auto-purge (ZAP)** allows Exchange Online to reach into a mailbox and take retroactive action on previously delivered mail. This is useful for zero-day exploits that are only identified after the delivery of mail to a user's inbox. You can also choose whether to

enable ZAP for phishing messages, spam messages, or both. It is best practice to do the latter.

- **Edit allowed and blocked senders and domains** allow an administrator to define safe and blocked senders. These can be in the form of individual senders or an entire domain (we will cover this in a later section).

## Spam Thresholds and Properties

As mentioned in the previous section, an administrator can fine-tune what constitutes spam and bulk mail by clicking the **Edit spam threshold and properties** link in an Anti-spam inbound policy.

The first control is a **Bulk email threshold** slider. This slider dictates at what level bulk email should require an action to be taken. The recommended value is 7, on a scale of 1 through 9. This means any bulk email with a rating of 7 or higher is subject to the bulk email action defined in the policy.

The rating is also known as a Bulk Complaint Level (BCL). EOP applies a BCL rating on every message and applies that rating in the **X-Microsoft-Antispam** header in a field called "BCL." The field can have the values described in Table 7-3.

<b>BCL Value</b>	<b>Meaning</b>
0	The message is not from a bulk email sender.
1,2,3	The message is from a known bulk sender but is unlikely to generate many complaints.
4,5,6,7	The message is from a known bulk sender and can generate many complaints.
8,9	The message is from a known bulk sender and is likely to generate a high number of complaints.

Table 7-3: BCL header values

The inbound spam policy lets you increase the spam score on messages if any of the following are enabled:

- Image links to a remote website (rather than using embedded images)
- URLs containing IP addresses (rather than using a registered domain name)
- URLs that redirect to another port (rather than using the standard HTTP or HTTPS ports)
- URLs that use a top-level domain of BIZ or INFO

The inbound spam policy lets you mark messages as spam if any of the following are enabled:

- Messages with no content
- HTML code with IFRAME, FORM, EMBED, or OBJECT tags
- Messages with Javascript or VBScript
- Offensive words in the subject or body (this is a curated list by Microsoft that cannot be modified)
- Senders that hardfail SPF
- Senders that hardfail sender ID
- Backscatter (we discuss Backscatter later in the chapter)
- Messages received in specific languages or from specific countries

Each of these settings can be configured as **On** or **Off**. You should consider each of these options with care. Changing a setting might increase the likelihood of a message being marked as spam which tends to have a more significant impact on the productivity of your end-users than the occasional spam message.

Some settings also have the option to be configured in **Test** mode. Configuring a setting in test mode can take additional actions such as adding an X-Header or BCC the message to a mail recipient. Testing is a great way to determine what these settings are operating in the way you expect before fully enabling them. While a setting is in test mode, the original email will be delivered to the user's inbox.

## Spam Allow and Block Lists

You may have a scenario where you need to allow or block a sender or domain globally for the entire organization or a group of users. To allow or block a sender or domain globally for the entire organization, you can modify the **Anti-spam inbound policy (Default)**. From the pop-out window, select **Edit allowed and blocked senders and domains**. You can add entries to the allowed senders, allowed domains, blocked senders or blocked domains list. You can also use the *Set-HostedContentFilterPolicy* cmdlet for this purpose.

If you want to scope these allow or blocklists to a specific group of users and not the entire organization, you will need to create a new antispam policy. From the **Threat Policies > Anti-spam policies** page, click **Create Policy > Inbound**. Give the policy a name and description and click **Next**. The *Users, groups, and domains* page allows you to scope this new policy to either one or more users, one or more groups, or one or more of your accepted domains. The next series of pages will ask you to specify the antispam policy properties, antispam actions, and finally, the allow and block lists unique to this policy, and by extension, the users scoped to the policy.

When building allow lists, remember that Microsoft's [Secure by Default](#) approach will disregard customer-defined entries if the message is deemed to contain malware or is classified as high confidence phishing. Instead, these messages will be delivered to the quarantine regardless of their presence in an allow list or modification by a transport rule (e.g., changing the message header to SCL -1 to bypass filtering)

**Real-world:** If migrating from another filtering solution to EOP, I recommend not migrating your allow and blocklists. First, based on the age of these lists, it is questionable which entries are still valid. Second, there is no direct apples-to-apples comparison regarding filtering solutions. Each solution is different. An action taken by one solution may not have been taken by another resulting in redundant entries in your allow/blocklists. When migrating to EOP, this is a good time to start with a clean slate.

## Connection Filter Policy

The connection filter policy allows administrators to maintain a list of allowed and blocked IP addresses. You can access this IP list from the **Defender portal** and navigating to **Policies and rules > Threat Policies > Anti-spam policies > Connection filter policy (Default)**.

It is not possible to create a custom connection filter policy. This means the IPs in the connection filter policy impact all users. Therefore, it is impossible to scope IPs to specific users, groups, or domains like you can with other policies.

To add or remove an IP address, select the **Connection filter policy (Default)**. From the pop-out window, select **Edit connection filter policy** and add the individual IP addresses or address ranges.

Selecting the **Turn on safe list** checkbox includes a list of safe IPs vetted by Microsoft to your connection filter rules.

## Anti-spam Outbound Policy

To stay on top of situations where an internal recipient sends spam messages, an administrator can change the default outbound policy to generate notifications when EOP deems a message suspicious or when a user is blocked from sending messages. In the **Defender portal**, go to **Policies and rules > Threat Policies > Anti-spam policies**. Here you will find any custom policies that have been created, as well as the default policy set. Note that you cannot disable any default policies; however, you can modify their settings.

In addition to the default outbound spam filter policy, you can create custom outbound spam policies to set different notification addresses and sending limits and apply them to specific senders. To create a new outbound policy, click **Create policy** and select **Outbound** from the drop-down menu.

Another reason for custom outbound policies is to define which users or groups can automatically forward messages outside the tenant. This policy does not impact automatic forwarding to internal recipients. Automatic forwarding is any messages automatically forwarded via an inbox rule, mail flow rule, or mailbox forwarding. This is an instrumental setting for organizations concerned with data exfiltration and needs to block some or all users from automatically forwarding messages outside the organization. You can set this policy to **On – Forwarding is enabled** or **Off – Forwarding is disabled**.

The recipient limits in the outbound spam filter policies should not be confused with tenant-wide customizable recipient limits. Recipient limits are the maximum number of recipients you can add per message, with a default of 500 and a range of 1 to 1000 that can be set per mailbox. The outbound spam filter policy allows you to set a maximum number of recipients per hour or per day across all the emails sent by that user in the time interval. If users exceed this number, they can be blocked from sending mail until the following hour or day, or an alert can be generated. The maximum number of recipients you can set per interval of an hour or day is 10,000. When using the default value ("0"), Microsoft determines the number of messages that will trigger the action based on activity rather than a fixed number.

When Exchange Online blocks a user that continuously sends emails that it classifies as spam, the user will receive NDRs for outgoing messages that provide specific information on what they need to do to unblock their account. Blocked accounts show up in the Defender portal under **Review > Restricted Entities**. From there, an administrator can review blocked accounts and unblock them. You can also configure the outbound malware settings in the malware policy to notify administrators when internal users are blocked.

You can also unblock an account by running the *Remove-BlockedSenderAddress* cmdlet. For example:

```
[PS] C:\> Remove-BlockedSenderAddress -SenderAddress Joe.Bowers@office365itpros.com -Reason "Account OK"
```

Note that an administrator can only unblock an account so many times. If the limit for an account has been reached, even the administrator will receive an error, and a support ticket must be opened for investigation.

## Anti-Spam Message Headers

EOP updates the Spam Confidence Level (SCL) header to show whether it considers a given message as spam. The SCL header consists of a single digit that does not explain why a message is considered spam. To provide administrators with additional information, EOP also inserts [two extra headers](#) into each message:

- **X-Forefront-Antispam-Report** is used to provide information on the anti-spam processing of the message; and
- **X-Microsoft-Antispam** provides information specific about bulk mail and phishing results.

The *X-Forefront-Antispam-Report* header consists of many different values, each revealing more information about the message, such as where it was sent from and the result of individual anti-spam tests. The following shows what this header typically looks like:

```
X-Forefront-Antispam-Report:
CIP:199.59.150.72;IPV:NLI;CTRY:US;EFV:NLI;SFV:NSPM;SFS:(8156002)(31570200002)(2980300002)(438002)(286005)(199004)(189003)(64016003)(53416004)(2616005)(19627405001)(110436001)(956004)(476003)(126002)(733005)(18926415007)(118246002)(85226003)(53386004)(606006)(336012)(6486002)(58536013)(106002)(106466001)(2160300002)(36756003)(246002)(16586007)(36736006)(486006)(33656002)(356003)(8676002)(7696005)(26005)(1096003)(620700001)(59450400001)(966005)(551544002)(33964004)(7636002)(84326002)(6306002)(25786009)(53946003)(236005)(4290100001)(146002)(7596002)(16003)(6916009)(270700001)(579004);DIR:INB;SFP:;SCL:1;SRVR:VI1PR0301MB2318;H:spruce-geese-ac.twitter.com;FPR:;SPF:Pass;LANG:en;PTR:spruce-geese-ac.twitter.com;A:0;MX:1;
```

At first sight, it may seem hard to make some sense of the information in the header. However, if you take a closer look, you will see that the header consists of several different fields of which the following give more insight into the anti-spam decision-making process:

- **CIP** has the IP address of the server that delivered the message to EOP. This IP address should be specified when using the IP allow or block list, and the IP address should be listed in the senders' SPF record.
- **IPV** field has two values and is used to decide whether the connecting IP was found on an IP allow list or not.
  - **IPV:CAL**. The message passed anti-spam filtering because the connecting IP address was found on an IP allow list.
  - **IPV:NLI**. The IP address was not found on any IP reputation list.
- **CTRY** specifies the likely country from where the message was received. EOP uses the connecting IP address to determine the country, which may or may not be the same as the original message.
- **SFV** field specifies why a message was marked as spam or not as spam and has several values:
  - **SFV:SFE**. Filtering was skipped, and the message was let through because it was sent from an address on an individual's safe sender list.
  - **SFV:BLK**. Filtering was skipped, and the message was blocked because it was sent from an address on an individual's blocked sender list.
  - **SFV:SPM**. The message was marked as spam by the content filter.
  - **SFV:SKS**. The message was marked as spam before the content filter processed the message. This includes the scenario when a mail flow rule marks a message as spam.
  - **SFV:SKA**. The message skipped filtering and was delivered to the inbox because it matched a safe sender or safe domain list in an anti-spam policy.
  - **SFV:SKB**. The message was marked as spam because it matched an anti-spam policy's blocked sender or blocked domain list.
  - **SFV:SKN**. Before the content filter processed the message, the message was marked as not spam. This includes the scenario when a mail flow rule is used to mark a message as safe.
  - **SFV:SKI**. The content filter skipped processing the message because it was received by the on-premises environment and thus marked as *internal*.
  - **SFV:SKQ**. The message was released from quarantine and was sent to the intended recipients.
  - **SFV:NSPM**. The message was not spam and was sent to the intended recipients.
- **SCL** gives the Spam Confidence Level of the message and denotes the likelihood of the message being spam. The higher the number, the more likely the message is spam.
- **H** specifies the HELO or EHLO string of the connecting mail server.
- **SPF** specifies information about the SPF record lookup result for the message.
- **LANG** specifies the language the message was written in.
- **PTR** identifies the PTR record of the sending IP address (also known as the reverse DNS address).
- **ARC** shows the Authenticated Received Chain headers.
- **CAT** shows the category of the protection policy applied to the message. Multiple policies process a given message, but only the value corresponding to the highest priority one will be stamped in this header, as detailed in the [documentation](#).
- **SRV:BULK** specifies that the message was marked as a bulk email message.
- **SFTY** identifies if the message is a phishing message. The "safety" header value indicates the type of phishing, such as a URL, internal phishing, domain impersonation, etc. SFTY will also indicate if the setting was overridden with a safe sender or domain setting so you can determine if an email was allowed through because of your existing overrides.

The **X-Microsoft-Antispam** header looks like this:

```
UriScan:;BCL:1;PCL:0;RULEID:(7020095)(5600026)(4605076)(4608076)(1401150)(8001031)(1402068)(71702078);SRVR:VI1PR0301MB2318;
```

And this header shows the following components:

- **BCL** specifies the Bulk Complaint Level of the message on a scale of 0-9. If the value is 8 or 9, the email comes from a sender that generates many complaints.
- **PCL** specifies the Phishing Confidence Level of the message on a scale of 0-9. If the value is 0-3, the email is unlikely to be phishing. An email with a value of 4-9 is likely to be a phishing email.

## Message Tracing and Anti-Spam Headers

Often message tracing is used to understand why a message was marked as spam. You must request an Extended Trace report to receive details on why the message was marked as spam. The returned CSV file holds some extra data, including the anti-spam headers explained previously.

Once the search completes, open the CSV file and look at the *custom\_data* field. Note that the example below was trimmed at the end for brevity.

```
S:AMA=SUM|v=0|action=|error=|atch=0;S:AMA=EV|engine=M|v=0|sig=1.193.3192.0|name=|file=;S:AMA=EV|engine=A|v=0|sig=201503191928|name=|file=;S:AMA=EV|engine=K|v=0|sig=19.3.201518:28:0|name=|file=;S:CFA=AS|sfv=NotSpam|rsk=Low|sc1=0|bc1=0|score=|sfs=(601004)|sfp=0|fprx=|mlc=|mlv=|list=1|di=|rd=mail-db3on0089.outbound.protection.outlook.com|h=emea01-db3-...
```

The field contains helpful information regarding the various filters that processed the message. For example, the data from the anti-malware agent is displayed after **S:AMA** (Anti-Malware Agent). Similarly, the anti-spam information is displayed after the **S:SFA** (Spam-Filtering Agent). Finally, information on mail flow rules is shown after **S:TRA** (Transport Rule Agent). Once you have extracted the data, you can use the information explained in the anti-spam message headers topic to understand the decisions of the anti-spam agent.

## Anti-Malware Protection

EOP automatically scans inbound messages for malware. The term malware covers a variety of malicious items such as viruses and spyware. EOP uses a multi-layered approach to detect malware using multiple anti-malware engines to scan messages for malicious code in the message body or attachments.

Unlike anti-spam configuration options, you cannot alter how malware is processed. However, you can control what type of attachments are denied automatically or how users are notified when an email contains malware or a blocked attachment type. The former option is also referred to as **Common Attachment Filtering**. By default, EOP maintains a list of common attachment file types often associated with malware. Among other file types, the default attachment filter will block all .exe, .vbs, and .reg files. By editing the default anti-malware policy or creating a new one, you can add or remove file types to control whether emails containing such attachments are quarantined automatically.

**Note:** EOP blocks attachments in other places than the common attachment filtering settings. For example, OWA extends the list of file types blocked. This block does not affect how Outlook or Outlook Mobile works. Adding additional extensions to the common attachment filter stops these attachments from reaching the user, regardless of their client.

### Custom Malware Policy

The default malware policy is sufficient to suppress malware for most tenants. However, if you need a different policy for a subset of your users, you can create a new malware policy. To create a new policy, navigate to the **Defender portal > Policies and rules > Threat Policies > Anti-malware** and click **Create**.

You can scope the custom policy to a subset of users based on the following conditions:

- **The recipient is** (select a single- or multiple recipients).
- **The recipient domain is** (all recipients within the selected domain(s)).
- **The recipient is a member of** (select group).

Custom policies always precede the default policy and are processed in ascending order. Therefore, the lower the policy priority, the sooner it will be processed.

Like the default policy, the custom policy lets you define common attachment types to block. This is useful if you want to have different common attachment blocks for different groups of users. For example, you may block fewer attachment types for your IT department than your general user population. By default, a new custom policy will have 10 executable types preselected. But you can select up to 96 common attachment types to block. If you need to block additional attachment types not included in the common attachment type filter, you will need to define a transport rule.

Apart from configuring a common attachment filter, you can also configure administrator notifications and toggle the ZAP feature (although it is best to keep this enabled).

**Note:** To notify users of quarantined malware, you must deploy a quarantine policy. A quarantine policy allows you to define user notifications and can be attached to the anti-malware policy.

## Anti-Phishing

Phishing is an attempt to steal something of value from a company. This could range from the exfiltration of sensitive information (such as credit card numbers or personally identifiable information) to encouraging someone to take action that will result in some loss for them. Phishing typically involves impersonation where a bad actor uses an email address that mimics a vendor, partner, customer, or employee to create trust. A typical example is a bad actor using an email address that impersonates a C-level executive requesting money be wired to what will invariably be the attacker's bank account.

The Anti-Phishing policy has several measures to protect companies from these attacks. Like other EOP policies, you manage the anti-phishing policy through the Defender portal. Navigate to **Policies and rules > Threat Policies**, then select **Anti-phishing**. From there, you can view and edit the default policy or click **Create** to make a new policy. The Default policy will always apply and cannot be deleted.

When configuring a policy, you have the following options:

- **Name and Description.** As you can create multiple policies for your organization, it is a clever idea to use a clear name or at least describe the intent of the policy.
- **The Users, Groups, and Domains.** This page specifies the users the policy will be run against. This can be set to all your users or a subset of your users, like all recipients in a specific domain or members of a distribution group. You can also exclude specific users from the policy.

Once these general settings are configured, you can configure the phishing threshold and protection settings for the policy:

- **Phishing email threshold** determines how aggressive machine learning should be when determining what a phish is. Values are from 1 – Standard to 4 – Most Aggressive. The Standard preset security policy (covered earlier) uses a value of 2. However, Microsoft deems 1 to be an appropriate default value. Therefore, it is best to start the threshold at 1 and gradually increase it to meet your organization's needs.
- **Enable users to protect** and **Enable domains to protect** define what email addresses or domains are scrutinized while scanning for incoming phishing attacks. Typically, it would be best to protect high-value users like your C-level executives or people with high privileges within your organization. You can protect up to 350 users (depending on license). To protect all the domains assigned to the tenant, check **Include domains I own**. You can also **Include custom domains** that allow you to add a domain not included in your tenant or that of a partner, vendor, or customer.
- To ensure trusted domains or senders, such as a partner, vendor, or customer, are never treated as impersonators, you can optionally add them to the **Manage trusted senders and domains** allow list.

- Enable/disable **Mailbox Intelligence (Recommended)** to allow the policy to use Microsoft Graph for user email signals. This helps ensure that people you have communicated with before are not treated as spoofed senders.
- Enable/disable the use of **Intelligence for impersonation protection (Recommended)** to enable enhanced impersonation. This also allows actions to be taken on emails impersonating a user.
- Enable/disable **Spoof Intelligence (Recommended)**, which allows you to define who can send mail on behalf of your domains (for example, a bulk mailing service). While the option to enable this setting is part of the anti-phish policy, the allow list is maintained through **Policies & rules > Threat policies > Tenant Allow/Block Lists > Spoofing**.

**Real-world:** The terminology in the wizard is a little ambiguous. “Enable users to protect” and “Enable domains to protect” do not define to whom a policy applies. Instead, these are the email addresses and domains for which anti-phishing will compare the P2 header information of incoming messages. So, for example, you configure ceo@office365itpros.com as a user to protect and office365itpros.com as a domain to protect and apply the policy to all users in your organization. Then, whenever a message is received from ceo@office365itpros.com (note the look-a-like address), that message will be flagged as a phishing attempt if the person receives an email from that address for the first time.

With the phishing thresholds defined, we can now turn to the actions in our policy. An action is performed whenever a phishing threshold has been met.

**Note:** Some actions may be greyed out if you did not enable the corresponding phishing threshold on the prior page of the wizard. For example, “If message is detected as impersonated user” is greyed out, click the **Back** button, select **Enable users to protect**, and define a list of users to protect.

The following actions are available:

- **If message is detected as an impersonated user, impersonated domain, or if mailbox intelligence detects an impersonated user**, you can perform the following actions from the respective drop-down.
  - **Redirect message to other email addresses.** This is useful if you need to send the message to an internal security response team for analysis. The redirection will not deliver the message to the original recipient.
  - **Move message to the recipients’ Junk Email folders** does precisely as the action describes. With proper email security training, delivering the message to the junk email folder is a great way to have users pause and scrutinize the email. This ensures mail is still delivered in the case of a false positive, which could be reported by the user while instilling caution that the message ended up in junk.
  - **Quarantine the message** takes the junk folder concept one step further by keeping the message out of the user’s mailbox and off their devices. The added benefit of the quarantine is that it is out of sight and therefore out of mind. Generally, users only review the quarantine to look for a solicited message they have not received. As phishing emails should be unsolicited, the user will not miss the email they did not expect to receive. Depending on the quarantine policy, proper email security training is still needed as users can release the message to their inbox.
  - **Deliver the message and add other addresses to the Bcc line** sends the suspect message as a blind carbon copy to an internal security response team and delivers it to the intended recipient. This is useful when you have an internal security team to review (mildly) suspicious messages but do not want to delay delivery to the original recipient. Note that this action delivers to the original recipient’s inbox.

- **Delete the message before it's delivered** deletes the message during transport. This is a definitive action, and the message is irrecoverable. Any analysis must be done using the information in message trace logs.
- **Don't apply any action** means that no action applies to the message.
- **If the message is detected as spoof**, only has the actions **Move message to the recipients' Junk Email folders** and **quarantine the message** from the list above. This means you must take corrective action on a spoofed message.
- **Safety Tips and indicators** determine what the user may see in their Outlook client. Safety Tips are available across all Outlook clients, including Outlook for Windows, Outlook for Mac, Outlook on the Web, and Outlook Mobile.
  - **Show first contact safety tip (Recommended)** identifies when you receive an email from someone you know but are using a different email address than what EOP has seen before.
  - **Show user impersonation safety tip, and Show domain impersonation safety tip** informs the user whenever a user or a domain is being impersonated by the sender.
  - **Show user impersonation unusual character safety tip** informs a user when an unusual character is detected in the sender's address. An example of this is a [homoglyph attack](#). A homoglyph attack is when a bad actor swaps a character from one alphabet for a similar or identical-looking character from another. For example, a bad actor may swap out the letter "e" from the Latin alphabet for the letter "e" from the Cyrillic alphabet (Unicode 435). To the human eye, these look identical but are very different.
  - **Show (?) for unauthenticated senders** changes the picture (or initials in the absence of a picture) in the sender's profile card to a question mark. This is when Exchange Online cannot authenticate the sender via sender authentication (e.g., SPF, DKIM, & DMARC). This is explained in greater detail in the *Safety Tips* section below.
  - **Show "via" tag** shows a safety tip if the from address (displayed to the user in their email client) does not match the mailfrom attribute in the message header. An example of this safety tip could be [john.smith@contoso.com](mailto:john.smith@contoso.com) on behalf of [jane.doe@office365itpros.com](mailto:jane.doe@office365itpros.com).

**Note:** The first contact safety tip previously required the presence of a transport rule to apply *X-MS-Exchange-EnableFirstContactSafetyTip* to the email header. While Exchange Online still supports this header, it is no longer required to display a first contact safety tip.

Like other policies, you can also manipulate the policy with PowerShell using the *Get-AntiPhishPolicy* and *Set-AntiPhishPolicy* cmdlets. For example, run the following command to retrieve a list of all anti-phishing policies.

```
[PS] C:\> Get-AntiPhishPolicy
```

To enable mailbox intelligence for the default policy, use the following command.

```
[PS] C:\> Set-AntiPhishPolicy -EnableMailboxIntelligence $True -Identity "Office365 AntiPhish Default"
```

If you enabled an anti-phishing policy when Microsoft first released the feature, a default policy called *"Office365 AntiPhish Default"* is in your tenant. In these circumstances, it is probably best to update the default policy and remove your policy and let the default policy do the work.

## Anti-Spoofing

Spoofing is when someone sends messages using your email domain through an email system other than your primary (internal) messaging system. Often a malicious attacker tries to impersonate a legitimate person's email address to convince the recipient of the message to perform actions helpful to the attacker. The concept of spoofing is not new, and over the last few years, another form called "insider spoofing" has emerged and quickly gained popularity with attackers. Insider spoofing sometimes referred to as a spear-

phishing attack, is no different from regular spoofing, except that the message appears to be coming from an internal recipient, making it much harder for the recipient to figure out if a message is invalid or not. Typically, insider-spoofing impersonates highly-ranked employees (such as a C-level executive) and targets other employees to convince them to take action, such as sending a wire transfer.

Fighting spam and phishing is an ongoing task. A newer form of insider spoofing is where user accounts are compromised (maybe due to a phishing attack), and the spoof emails are sent from compromised accounts. The malicious actor logs in as the user and sends an email from a compromised user's real mailbox. Protection against this attack includes using multi-factor authentication with appropriate password policies and protections.

Although features such as SPF records, DKIM signing, and DMARC help to detect and repel spoofing attacks, only a minority of organizations have successfully adopted some or all these features, so gaps are left for attackers to exploit.

To detect spoofed messages, Microsoft processes each incoming message, inspects the various TO and FROM headers in the message, and compares the values. For example, several checks are performed if a message is sent to someone inside your organization and the FROM field matches an internal domain. If the message was sent from inside the organization, or the message was received through a host or service which may send messages on your behalf (for example, because the host is present in the SPF record), the message is deemed to be legitimate. However, if the message does not pass any of these tests, or if it was received by a host with a bad reputation, the message could be considered spoofed.

When the anti-spoofing feature intervenes to mark a message as spam, the value **SFTY:9.5** is added to the *X-Microsoft-Antispam* header, which also has information about the results of other scanning engines:

```
X-Microsoft-Antispam: UriScan:;BCL:0;PCL:0;RULEID: (71701004) (71702002);SRVR:BY2PR12MB0565;SFTY:9.5
```

For more information on the X-Microsoft-Antispam header, check [this article](#).

Besides the anti-spoofing protection described above, Microsoft offers the Spoof intelligence feature.

## Spoof Intelligence

There can be legitimate reasons that justify the spoofing of your email domain(s). For instance, if you have hired an external marketing company to send electronic surveys to your customers or employees, or if you have a business application that sends notification emails to your internal users. However, differentiating between legitimate and malicious attempts to spoof your domain is not easy, especially because features like SPF, DKIM, or DMARC are often not used or poorly implemented. It is also true that none of these features protect your tenant when accounts are compromised.

Spoof intelligence controls which senders can send messages on behalf of your organization. The Spoof Intelligence dashboard is located at <https://security.microsoft.com/spoofintelligence>. Alternatively, you can access the dashboard by opening the **Defender portal** and navigating to **Policies & rules > Threat Policies > Tenant Allow/Block Lists > Spoofing > View Spoofing Activity**. Using the Spoof Intelligence dashboard, you can allow or revoke a specific sender's permission to spoof your domain. Additionally, when you open the dashboard, you can see a list of senders known to have sent messages on behalf of others (including your domains) in the past 7 days.

Additional details help you determine if a sender should be allowed to spoof messages. For instance, the policy tries to show who the actual sender is next to the information about which users were spoofed. EOP obtains the specific sender information by looking at the reverse DNS (PTR) record of the sending server's IP address. If no PTR record is found, the IP address is displayed in the report.

**Note:** Legitimate senders often have a PTR record that enables Exchange Online to look up and display the sender's hostname or domain name information. Extra caution is advised if no PTR record is found, as

it is highly likely that the sender should not be allowed to spoof your domain. Unfortunately, even malicious senders can have a PTR record!

Although you cannot stop a (malicious) sender from trying to spoof your domain, the Spoof Intelligence feature controls how EOP handles incoming emails. If a sender is not explicitly allowed to spoof one or more users within your organization (domain), messages from that sender will be marked as spoofing attempts, and users will be notified of the fact.

From the Spoof Intelligence dashboard (Figure 7-7), you can change how EOP handles the spoof by selecting **Allow to spoof** or **Block from spoofing**.

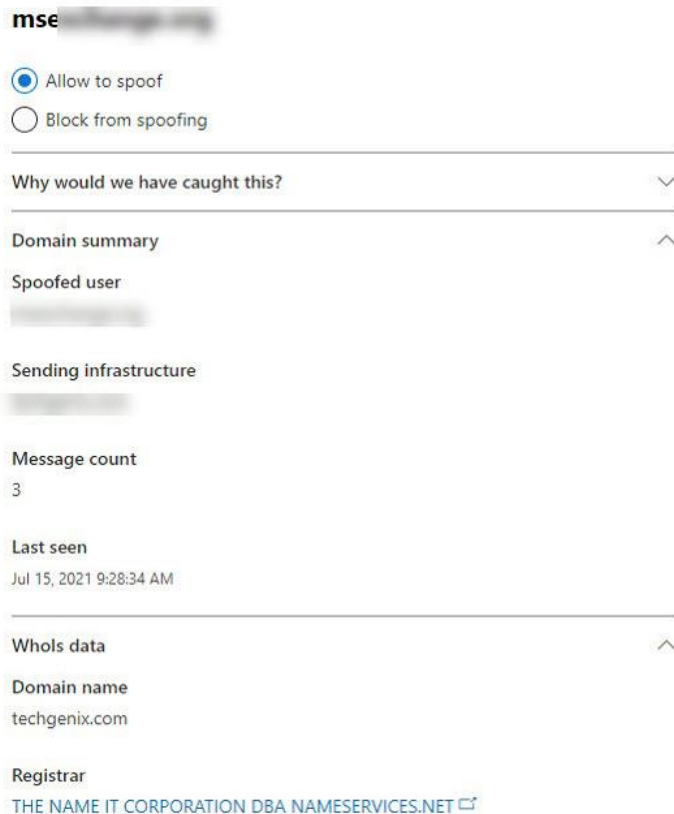

Figure 7-7: Spoof Intelligence Dashboard Action Pane

You can also control the Spoof Intelligence through PowerShell. This is done via the Tenant Allow/Block List (TABL) cmdlets. To get a list of current entries in the Tenant Allow/Block List, we leverage the *Get-TenantAllowBlockListSpoofItems* cmdlet. In the example below, we have two static entries in our list. These two entries identify that *contoso.com* and *fabrikam.com* have been allowed to spoof *office365itpros.com*.

```
[PS] C:\> Get-TenantAllowBlockListSpoofItems | Format-Table SpoofedUser, SendingInfrastructure, SpoofType, Action, Identity
```

SpoofedUser	SendingInfrastructure	SpoofType	Action	Identity
office365itpros.com	contoso.com	External	Allow	7323b926-3334-8d4a-ee09-b94e35f3467
office365itpros.com	fabrikam.com	External	Allow	24f1b37a-766e-0cc1-ca88-7e487732914b

Let's change *contoso.com* to a block rather than an allow. To change an existing entry in the Tenant Allow/Block List, we can leverage the *Set-TenantAllowBlockListSpoofItems* cmdlet. In the example below, we take the ID for *contoso.com* (retrieved from the *Get-TenantAllowBlockListSpoofItems* output above) and specify a block action against the *office365itpros.com* domain.

```
[PS] C:\> Set-TenantAllowBlockListSpoofItems -Identity office365itpros.com\Default -Action Block -
Ids 7323b926-3334-8d4a-ee09-b94e35f3467
```

After making the changes, you can use the *Get-TenantAllowBlockListSpoofItems* command again to verify that the changes were applied correctly. If you need to add a new entry, rather than modify an existing entry, you leverage the *New-TenantAllowBlockListSpoofItems* cmdlet. Similarly, you can remove an entry with the *Remove-TenantAllowBlockListSpoofItems* cmdlet.

In addition to the anti-spoofing features designed to stop spoofed messages from being delivered to the user inboxes, administrators can also request the **Spoof Mail Report**. The report is accessible through the Defender portal or PowerShell. To get the report in PowerShell, use the following command:

```
[PS] C:\> Get-SpoofMailReport | Select Date, Direction, Action, SpoofedSender, TrueSender, SenderIP

Date           : 14/04/2016 0:00:00
Direction      : Inbound
Action         : GoodMail
SpoofedSender  : Boss.Man@office365itpros.com
TrueSender     : hubspot.com
SenderIp       : 50.31.57.0/24

Date           : 11/04/2016 0:00:00
Direction      : Inbound
Action         : CaughtAsSpam
SpoofedSender  : CEO-of-the-company@office365itpros.com
TrueSender     : someonlinemarketingservice.com
SenderIp       : 1.2.3.4/24
```

The report displays information about spoofed messages, like the information in the Spoof Intelligence policy. In addition, it can show you what spoofed messages were received, whom they were impersonating, and who sent the message. In the above example, the top message was sent by an authorized service, as that message was classified as **GoodMail**.

The report serves multiple purposes. First, it helps you understand how many messages inside your organization are spoofed. More importantly, it tells you which account is being spoofed most and can reveal spear-phishing attempts. Secondly, the report enables you to generate a list of hosts sending messages on your behalf. You can then use this list to verify if authorized senders are correctly configured and whether you have represented them on your SPF records, lowering the likelihood of them being marked as spam.

## Message Quarantine

By default, Exchange Online protection routes low confidence spam and phish to the users' junk email folder and high confidence spam and phish, plus messages containing malware, to the quarantine. The quarantine is a vault where marked messages are held instead of delivered to a user's mailbox. Messages can remain in the quarantine for up to 30 days, after which Exchange removes the messages permanently (the default is 15 days). Depending on your quarantine policy, end users can perform any number of actions against quarantined messages, or possibly, no actions at all, which require administrator intervention.

### Quarantine Policy

Quarantine policies in Exchange Online Protection allow you to define what end users can and cannot do in the message quarantine portal. For example, you could define a policy that allows some users to release messages to their inbox and block other users from performing this action. Similarly, you could define different quarantine policies for different threat policies. For example, you could send users quarantine notifications on messages containing spam but not send notifications on messages containing malware.

To view the default policies or create a custom policy, open the **Defender portal** and navigate to **Policies and rules > Threat Policies > Quarantine Policy**.

The default policies *DefaultFullAccessPolicy* and *AdminOnlyAccessPolicy* cannot be modified. The *DefaultFullAccessPolicy* allows users to release the message to their inbox, block the sender, delete the message, and preview the message. In contrast, the *AdminOnlyAccessPolicy* does not allow any user actions. The intention of assigning *AdminOnlyAccessPolicy* to a threat policy is to only allow administrators to act on messages. This is useful when you do not want users to release harmful messages, such as high confidence phishing messages.

To create a custom policy, select **Add custom policy** from the **Quarantine Policy** screen. Give the policy a name that describes its purpose and click **Next**. On the *Recipient Message Access* page, choose either **Limited Access** (which includes all permissions listed below except allowing recipients to release a message) or **Set Specific Access (Advanced)** to specify actions users can perform in the portal. These actions include:

- **Allow recipients to release a message from quarantine** allows the user to release the message to their inbox. This box controls whether the user sees this button in both the quarantine portal and the quarantine notification.
- **Allow recipients to request a message to be released from quarantine;** allow a user to request a message released to their inbox by an administrator. An administrator is notified based on the settings defined in the alert policy (Defender portal > Policies and rules > Alert Policy). By default, this alert goes to quarantine administrators, security administrators, and members of the organization's management role. This box controls whether the user sees this button in both the quarantine portal and the quarantine notification.
- **Delete** allows the user to delete the message from the quarantine portal. The message is not delivered to the user's inbox. This box only controls the button in the quarantine portal.
- **Block sender** allows the user to block future messages from the sender. This box controls whether the user sees this button in both the quarantine portal and the quarantine notification.
- **Preview** allows the user to view the message from the quarantine portal without needing to release it to their inbox. This is useful if the user needs to review the message before acting.

**Note:** The *Allow recipients to release* 5are not honored if applied to an antimalware policy. Users will never be able to release messages with malware regardless of the quarantine policy settings.

With your actions selected, click **Next**. The quarantine notification page allows you to **Enable** whether users should receive quarantine notifications. Using our prior example where we have a different policy for spam versus malware, we may want users to receive notifications for spam in quarantine but not for messages containing malware. Once you have picked your notification setting, select **Submit** to create the policy.

## Quarantine Settings in Protection Policies

To change the quarantine policy assigned to a threat policy, navigate to the **Defender portal > Policies and rules > Threat Policies** and click on the threat policy you wish to configure. You can assign a quarantine action (and quarantine policy) to spam, high confidence spam, phishing, high confidence phishing, bulk mail, user impersonation, domain impersonation, spoofing, malware, and safe attachments. For this example, let's modify the default anti-spam policy. To do this, select **Anti-spam** from the threat policies screen and select **Anti-spam inbound policy (Default) policy**. From the pop-out screen, select **Edit actions**. Under the **Actions** section. Select **Quarantine message** from the **Spam message action** dropdown. When we pick the quarantine action, another drop-down is displayed to allow the selection of the quarantine policy. Let's select **DefaultFullAccessPolicy** and click **Save**. This selection will allow users to perform the following actions on low confidence spam: release the message to their inbox, block the sender, delete the message, and preview the message

## Customizing Quarantine Notifications

The quarantine policies allow us to define whether users receive quarantine messages or not. If you want to change the frequency of those messages or customize the look and feel of the quarantine notification, navigate to **Policies and rules > Threat Policies > Quarantine Policy > Global Settings**.

From the *Quarantine Notification Settings* screen, you can make the following changes.

- **Display Name** allows you to customize the sender shown in the message notification.
- **Disclaimer** allows you to add your custom disclaimer to the bottom of the quarantine notification.
- **Choose language** allows you to customize display names and disclaimers in multiple languages. If you select multiple languages from the drop-down, select each language (not the X) to toggle the display name and disclaimer fields to that language. You can also select Default from the drop-down if you do not wish to specify language-specific display names and disclaimers.
- **Use my company logo** replaces the Microsoft logo on the quarantine notification with your company logo. You can upload your company logo via the **Microsoft 365 Admin Center** by navigating to **Settings > Org Settings > Organization Profile > Custom themes**.
- **Send end-user spam notifications (days)** provides a drop-down where you can specify the frequency of days a notification is sent. It is worth noting that this notification only occurs when new messages end up in the quarantine. Therefore, I recommend a frequency of every day.

## Releasing Messages from Quarantine

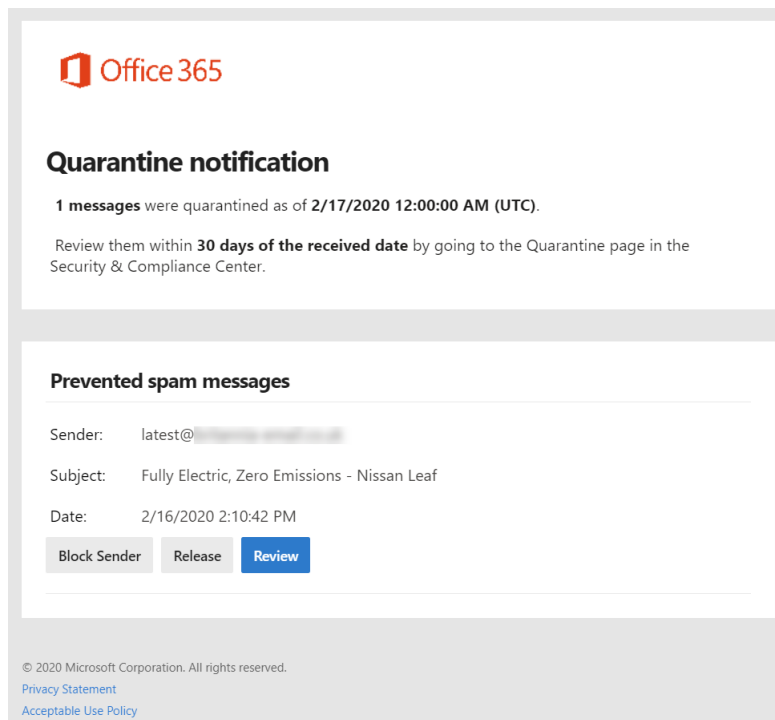

Figure 7-8: A notification that a user has potential spam to handle

Several ways exist to release a message from the quarantine. The fastest and easiest way for a user is to click the **Release** link for the message in the notification digest email, as shown in Figure 7-8. End users with full access to a shared mailbox will also perform quarantine actions for messages sent to the shared mailbox. If the user does not have full access permissions, they will not be able to perform quarantine actions. A user can also click **Review** to preview the message from the quarantine portal before releasing it. From the quarantine portal, the user can also click **Release**.

**Note:** The buttons in the notification email (and quarantine portal) will differ depending on the quarantine policy you have assigned to each quarantine action in your threat policies. If the quarantine policy is set to **Allow recipients to release a message from quarantine**, the **Release** button is available to end-users.

## Quarantine Portal

Users can also log in to the quarantine portal instead of waiting for email notifications to arrive. To access messages held in quarantine, the user must have a valid Microsoft 365 account and an Exchange Online or EOP license.

After signing into the [quarantine portal](#), the user sees a list of their quarantined messages. This list also includes quarantined messages for shared mailboxes where the user is a delegate. The user can search the list based on sender, subject, or, less likely, the message ID. In addition, filtering options such as the date and time the message was received can be applied to focus on specific messages. Depending on the quarantine policy, the user can take the following actions on any message:

- **Release:** Exchange delivers the message to the user's inbox, and they have the option to report it as a false positive to Microsoft.
- **Request release:** Sends a message to an administrator requesting the message be released on behalf of the user.
- **View message header:** Lists the routing information and other message properties with a link to the [Microsoft Message Header Analyzer tool](#).
- **Preview message:** Displays a safe copy of the message.
- **Remove from quarantine:** Permanently deletes the message from the user's quarantine. The message is not released to the mailbox.
- **Block sender:** The sender is added to the user's blocked sender list.

Administrators can work with quarantined messages and files for the entire organization. To grant access to the admin quarantine, use the Quarantine role or the Quarantine Administrator role group within the Defender portal. In addition, members of the Security Administrators and Organization Management role groups also get access to the admin quarantine.

To access the admin quarantine, open the Defender portal and navigate to **Review > Quarantine** or use the direct [link to the quarantine](#). Administrators see a rollup view of all quarantined messages. The interface is like the end-user interface. The difference is that an administrator can see quarantined emails or files for the entire organization and has more options to manage a message. For example, an administrator can release the message to different/additional recipients, download a local copy of the message and attachment, or submit the message to Microsoft for further analysis.

Figure 7-9: Viewing quarantined messages in the Microsoft 365 Defender portal

In larger environments, the message quarantine might hold thousands of messages. Working with large quantities of messages through the Defender portal might prove challenging. PowerShell can be a better fit for such scenarios, especially when performing bulk actions on messages in the quarantine. For instance, using the *Get-QuarantineMessage* cmdlet, an administrator can look for specific messages in the quarantine. For example, this query looks for high confidence phishing messages:

```
[PS] C:\> Get-QuarantineMessage -QuarantineTypes HighConfPhish | Select ReceivedTime, SenderAddress, Subject, Expires
```

ReceivedTime	SenderAddress	Subject
07/08/2020 00:35:43	pat@casey.net	tony.redmond@ You have 3 messages
04/08/2020 09:45:38	mundobabyp1aza@hotmail.com	Request For Quotation 800014
29/07/2020 18:12:09	account-update@amazon.com	#External: Amazon security alert: Sign-in from new

To release a message from the quarantine, the *Release-QuarantineMessage* cmdlet can be used. This example looks for messages addressed to a certain user that are marked as spam and releases them for delivery. It's unwise to release high confidence phishing messages unless you are certain that the messages are OK.

```
[PS] C:\> Get-QuarantineMessage -RecipientAddress James.Ryan@Office365itpros.com -QuarantineTypes Spam | Release-QuarantineMessage -ReleaseToAll
```

## Configuration Analyzer

One excellent feature of Exchange Online Protection is the configuration analyzer. The analyzer makes recommendations on how to improve a tenant's email security posture, further protecting an organization from bad actors, malware, and spam. The analyzer can be accessed by navigating to **Policies and rules > Threat Policies > Configuration analyzer**.

The **Standard recommendations** tab lets you know how your custom policies match the *Standard Protection* preset security policy. Similarly, the **Strict recommendations** tab measures your custom policies against the *Strict Protection* preset security policy.

In Figure 7-10, the analyzer recommends changing the bulk email threshold in our *Default* policy. It shows our current value of 7, the date the value was set, and the recommended change to a value of 6. To apply the recommendation, we would select the checkbox on that row and click the **Apply recommendation** button. Alternatively, we could click the **View Policy** button to be taken to the properties of the *Default* policy.

### Configuration analyzer

The configuration analyzer can help identify issues in your current configuration, and help improve your policies for better security. [Learn more.](#)

The **Configuration drift analysis and history** tab is an audit log of all changes to each threat management policy, whether modified via the policy or by clicking the adopt button through the recommendations screen.

## Tenant Allow/Block Lists (TABL)

While you can generally trust Exchange Online Protection to make the right decision about things like spoofing, sometimes you need to explicitly allow (or block) specific senders from spoofing mail recipients or domains in your tenant. With Tenant Allow/Block Lists (TABL), you can configure up to 1,024 spoof pairs. A pair is a spoofed domain or user and the actual sending domain, user, or IP address.

To manage the spoofing pairs, go to **Policies and rules > Threat Policies > Tenant Allow/Block Lists** in the **Defender** portal. Click the **Spoofing** tab and click **Add**. From the *Add new domain pairs pane*, add a unique spoof pair to each row, where the first entry on the row is the entity to be spoofed, and the second entry identifies the sender, domain, or IP doing the spoofing. You can then specify whether this is an **Internal** or **External** spoof and whether to **Allow** or **Block** the spoof. Click the **Add** button when you have your desired configuration.

Similarly, you may have a situation where you need to block a specific file, URL, or sender. Tenant Allow/Block Lists lets you configure blocks for up to 500 files, up to 500 URLs (or URL patterns), and up to 500 senders (depending on license). To add one of these blocks, select the relevant tab from the *Tenant Allow/Block Lists* page and click the **Block** button.

To block a sender, you must add each email address or domain as a comma-separated list (or add one entry per row). To block URLs, you need to list a URL or a pattern. For example, you could include just office365itpros.com, or if you needed to include all the subdomains, you could specify ~office365itpros.com.

Managing file exceptions is a little bit harder. You will need to provide the SHA256 hash of the file to add it to the list. There are lots of tools that can compute the hash. Microsoft's [documentation](#) for this feature shows you an easy way to compute the hash value using certutil.exe.

Once you have entered all the URLs, files, or senders to block, you can optionally add an expiration date. This will automatically remove the block entries at the defined time, or you can specify that the entries have no expiration. You can also add a note, which is helpful if you need to describe why the block was implemented.

## Identifying and reporting messages

The following sections outline how users can manage their safe sender and block lists, how users and administrators report junk and phish messages to Microsoft, and how safety tips help users identify suspicious emails.

### Informing users with Safety Tips

To increase visibility to end-users on messages containing potential threats such as spam, malware, spoofing, or phishing, Microsoft includes visual cues in messages to warn users when they meet potentially dangerous messages. Safety tips work in much the same manner as mail tips. These cues are tags inserted into messages by EOP as it processes email before delivery to end-users. For example, whenever a message is considered suspicious, Exchange inserts a safety tip. Similarly, if a message is received from a trusted sender, the notification will make this clear. EOP supports four safety tips (red, green, yellow, and grey). Table 7-4 lists the types of safety tips supported by EOP.

<b>Color</b>	<b>Safety Tip</b>	<b>Condition</b>
<i>Red</i>	<b>Suspicious.</b> These messages are likely to contain phishing scams and should not be opened.	EOP detects the presence of a known phishing message, or the message characteristics are such that EOP considers the message likely to be a scam. See <a href="#">this article</a> for an explanation of why messages are assigned red safety tips.

<i>Yellow</i>	<b>Unknown.</b> The message is spam.	EOP has scanned the message, and it has failed the standard anti-spam tests.
<i>Green</i>	<b>Trusted.</b> The message is from a trusted source.	Microsoft has a list of domains owned by trusted sources (such as itself). Messages from these domains are considered trusted.
<i>Grey</i>	<b>Safe.</b> An informational tab that indicates the message has been marked safe by the tenant or user.	The message is from a domain considered to be safe by the tenant (for example, the IP address for the server is in the <a href="#">IP allowed list</a> ), or on the user's safe senders list, or it was put in the user's Junk Email folder and subsequently moved back to the Inbox to indicate its safe status.

Table 7-4: Types of safety tips

Safety tips can be enabled or disabled for a tenant by updating the policies used by EOP. For example, the `Set-HostedContentFilterPolicy <name> -InlineSafetyTipsEnabled` command is used to configure safety tips via PowerShell. We do not recommend that you disable Safety Tips.

#### Unauthenticated Sender Safety Tip

The unauthenticated senders feature works in conjunction with the analytics gathered by Exchange Online to figure out if the sender is who they say they are or if the sender is spoofing someone else. This is known as sender authentication. If the message sender fails the authentication tests (SPF, DKIM, or DMARC), Exchange replaces the initials/photo shown next to the sender's display name with a question mark. However, a failure does not automatically result in an icon replacement because Microsoft uses extra technologies to help determine if a message is safe even though it failed authentication.

Not every message that fails to authenticate is malicious. However, you should be careful about interacting with messages that cannot authenticate if you do not recognize the sender. Or, if you recognize a sender that normally does not have a '?' in the sender image but suddenly starts seeing it, that could signify that the sender is being spoofed.

The sender authentication feature is enabled via an option in the anti-phish policy. Inside the actions section of the policy, you can disable this feature not to show "?" icons. While this feature is enabled by default, we do not recommend that you disable it.

Exchange Online will never mark senders in your safe sender list as spoofed – even if they are spoofed – and this also applies for messages marked as safe due to mail flow rules, anti-spam policies, and the safe senders specified in those policies as well. Administrators can deal with false positives caused by sender authentication by adding the sender and sending infrastructure to the anti-phishing Spoof Intelligence insight.

For more information on authenticated senders, check the following [Microsoft article](#).

#### How users mark mail as junk, phish, or safe

Exchange Online allows users to control specific junk email settings themselves. Within Outlook and Outlook Web App, a user can do the following:

- Mark a sender as safe
- Mark a sender as blocked
- Add a recipient to a safe-recipient list

In Outlook Web App, when a user right-clicks a message and selects **Mark as Junk**, the message is automatically moved to the Junk Email folder, and the sender is also added to the blocked sender list. More specifically, the information is stored as part of the mailbox configuration in the following AD attributes:

- msExchSafeSenderHash
- msExchSafeRecipientHash
- msExchBlockedSenderHash

This information is accessed by EOP and taken into consideration when processing messages. Messages from safe senders are automatically marked as “not spam.” In contrast, messages from blocked senders will be forwarded to the user's junk email folder or the quarantine, depending on the policy configuration. It is important to note that EOP will not honor the safe sender list if EOP considers a message to be high-confidence phishing. This is because a domain or sender that has been safe-listed might become compromised, leading to a possible compromise of the recipient's mailbox. If you need to have a sender or domain bypass this test, you can still do so with a mail flow rule that adjusts the SCL header on the message.

In a hybrid deployment, these attributes are also written back into the on-premises organization. It is also crucial in a hybrid deployment scenario where the MX records point to the on-premises organization instead of EOP. The write-back capability ensures that Edge Transport servers correctly process messages for cloud-based mailboxes. Note that when an on-premises mailbox is protected by EOP (or a cloud-based mailbox by Edge Transport servers), there can be a delay of at least thirty minutes between a user adding an address to one of the lists and the information being available to EOP or the Edge Transport servers. This is due to the directory synchronization interval and the worker process in Exchange Online that reads the safe and blocked sender lists and writes them to the Exchange Online directory.

In addition to the safe and blocked sender lists, users can configure client-specific settings. In Outlook, the **Junk Email Options** allow you to:

- View or edit the **Safe Senders, Safe Recipients, and Blocked Senders** list.
- Toggle the setting to automatically **trust email from my contacts**.
- Adjust in-client junk email filtering through the general **Options** tab.
- Block messages from specific **countries or regions**. For instance, if a user selects to block messages from Canada (CA), all messages from a domain ending with .ca will be marked as spam.
- Block messages written in an **unfamiliar language**.

Under the **Options** tab, you will find settings that control Outlook's built-in junk email filter. The selection there should always be set to **No Automatic Filtering** for mailboxes leveraging EOP. Otherwise, you will find Outlook making decisions based on its older and less reliable junk email filter. You can also configure Outlook to remove junk email rather than move it to the Junk Email folder.

**Note:** EOP uses only the safe senders, safe recipients, and blocked sender lists. All other features are client-specific and will only affect messages after being delivered to the user's mailbox. However, it should be noted that EOP also provides country- and language-based protection, which can be configured separately in the anti-spam filter policy.

To access the corresponding settings in OWA, click **Settings** (cog wheel) and then **View all Outlook settings**. From there, select **Mail > Junk email**. Apart from the aforementioned lists, you will find settings to restrict message delivery to only people from your trusted lists, to consider all contacts as trusted, and to control whether messages you mark as junk are automatically reported to Microsoft.

**Note:** Outlook has separate tabs for Safe Senders and Safe Recipients, but OWA only shows a single list called **Safe Senders and domains**. If a user makes changes via OWA options, their Safe Recipients list is merged with the Safe Senders list, and that list is copied into both Safe Senders and Safe Recipients in Outlook. Also, any Safe Senders and Safe Recipients from an internal domain are removed automatically from these lists shortly after being added.

Lastly, administrators can review or configure junk email settings on a user's behalf via *the Get-MailboxJunkEmailConfiguration* and *Set-MailboxJunkEmailConfiguration* cmdlets. It is important to note that if you disable the junk email rule using *Set-MailboxJunkEmailConfiguration*, this only disables the user's individually defined junk email lists and junk email settings stored in their mailbox. Junk emails identified by EOP will still be processed and delivered to the user's mailbox as dictated by the anti-spam policies defined in the tenant.

## How users report junk and phishing email

Microsoft develops many of the features to combat spam and malware based on data harvested from inbound emails delivered to Exchange Online and Outlook.com. Using machine learning techniques, Microsoft distills valuable information from the data to improve the efficiency of its protection features. However, because spammers continually introduce new techniques to bypass checks, it is impossible to guarantee that every threat will be detected. As a result, sometimes messages slip past EOP. Users can report these messages (also known as false negatives) by sending them to Microsoft for analysis. If Microsoft's Spam Analysis Team confirms that the message meets the spam classification criteria, they update the EOP filtering systems to block similar messages in the future. Similarly, users can also report false positives. These are messages that EOP detected as spam but are not.

Tenant administrators can decide whether to allow users to report messages to Microsoft. When users believe they have received a phishing email, they can use the **Report Message** drop-down option () in Outlook or OWA to report the message to Microsoft. Messages marked as phishing are automatically moved to the Deleted Items folder.

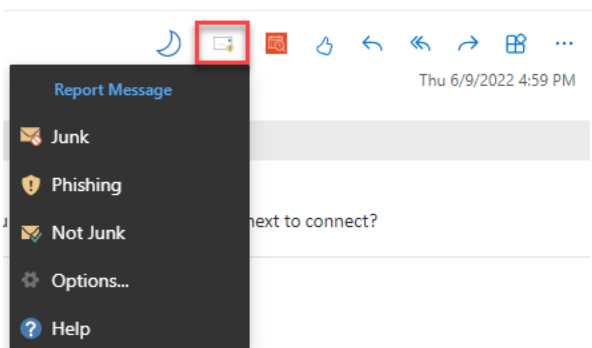

Figure 7-11: Marking a Phishing message with OWA

[The Report message add-in client plugin](#) (Figure 7-11) is available for Outlook and OWA. The add-in [can be enabled by administrators](#) to allow users to submit suspicious messages to Microsoft.

## How administrators report junk and phishing email

The **Submissions** feature, found under the **Actions & Submissions** section of the Defender portal, gives administrators the ability to upload information to Microsoft about messages that should have been blocked or those that are false positives. The information can be the message (in .eml or .msg format), Message ID, a URL found inside the message, or an attachment. Figure 7-12 shows an example of an administrator submitting a false positive using the Message ID to Microsoft

After you submit your findings to Microsoft, you can view the outcome of the analysis. In addition, the report will provide you with information about any policies that have acted on the message, as well as an examination of any URLs and attachments found within. For example, a common scenario is that the message was allowed by a personal exemption by the end-user or via a mail flow rule.

The page will also allow you to review user-submitted messages under the **User reported messages** tab. The experience also allows you to start an investigation (if your tenant has the necessary Microsoft Defender for Office 365 Plan 2 license). Additional information about the Submissions feature can be found in the [online documentation](#).

## Delisting Your IP Address from the Office 365 Block List

Although Microsoft does not add an IP address to the block list for no reason, sometimes this happens erroneously. Common causes for an IP address to be listed is because it was repeatedly found as the source of spam, malware, spoofed, or phishing messages. In addition, you will find yourself on the list if you have an open relay or do not pay enough attention to outbound messages.

When your IP address appears in the block list, messages sent to Exchange Online recipients fail, and a Delivery Status Notification (DSN) goes to the sender with the following information:

*1.7.1 Service unavailable; Client host [1.2.3.4] blocked using Blocklist 1; To request removal from this list, please forward this message to delist@messaging.microsoft.com*

Like most third-party block list providers, you can use a web form to request removal from the Block List. The form is located at <https://sender.office.com> and takes you through three simple steps:

1. You must enter your email address and the IP address to be delisted.
2. A verification email is sent to the email address.
3. If the verification was successful, you can now continue to delist the IP address.

Once the delist request has been received, the IP address is typically removed within 30 minutes.

## Using a Third-Party Filtering Solution Before EOP

Organizations often consider that they can gain added protection by deploying other email filtering solutions alongside EOP. Although this approach is practical from a technical perspective, it could adversely affect some anti-spam features, including IP throttling, IP blocklists, bulk mail filtering, or anti-spoofing in EOP. This is also why Microsoft recommends against using an added filtering solution with EOP.

For instance, EOP relies on IP throttling to prevent the delivery of spam messages: when a message is received from a new IP address, EOP throttles the incoming connection by issuing an SMTP 450 error. The error indicates a transient error, which means the sending server should retry later. Legitimate servers usually retry

the connection, while most spammers do not. The reason for not retrying is quite simple: the added effort to interpret the error message and then try again later is often too much trouble for spammers. Even though the feature does not stop a spammer from sending messages, it greatly reduces spam delivered to Exchange Online mailboxes. However, when a second filtering solution is used in front of EOP, all messages delivered to your organization originate from a single set of IP addresses. This renders the IP throttling feature useless.

When Exchange Online detects that your MX record does not resolve to EOP, it automatically disables some EOP anti-spam features. An example of one feature they disable is IP throttling. EOP also cannot perform IP reputation blocks, sender authentication checks such as SPF and DMARC, spam filter rules, and more. Therefore, it is imperative to ensure that the third-party solution you choose performs all the same tests as EOP. For example, if you have a security device as your first hop that does not do anti-spam filtering, Microsoft will also not perform all the anti-spam filtering they could otherwise do.

**Filtering hybrid mail:** It is unsupported to use a third-party filtering solution in a hybrid deployment for messages sent between the on-premises organization and Exchange Online. This is because a third-party filtering solution can remove important message headers, like the *X-MS-Exchange-Organization-AuthAs* header, from the message.

When the *X-MS-Exchange-Organization-AuthAs* headers are no longer present, problems can occur. For example, messages might not be recognized as originating from within the same organization. This could lead to internal messages being treated as spam or an external out-of-office message being returned rather than its internal counterpart. For this reason, messages must flow uninterrupted between Exchange Online and the on-premises Exchange servers.

If additional filtering is desired, or you have the requirement to terminate all inbound connections in the perimeter network, you must use a Microsoft Exchange Edge Transport server. The Edge Transport server is the only additional filtering solution that authenticates like an Exchange server in the same manner as the internal Exchange servers. You can continue using a third-party filtering solution to process all external messages entering and leaving your organization to and from the internet.

## Enhanced Filtering for Connectors

If you use an email filtering solution or email gateway other than EOP, you must configure Enhanced Filtering for Connectors. The Enhanced Filtering for Connectors option allows tenants whose MX record does not resolve to Exchange Online to determine the true source of an email. It is used when messages are routed via on-premises servers or a third-party cloud filtering service, both of which make the email seem to come from that source instead of its true origin. Knowing the actual email source, you can fine-tune your spam, phishing, and mail flow rules.

Enhanced Filtering, or skip listing, is a complex routing configuration. In a hybrid scenario, the recommended solution is to route the email directly to EOP by setting the domain MX record to Exchange Online. This is not always possible, however. For example, if you are migrating to Exchange Online, your MX record will resolve to your on-premises Exchange organization until later in the migration project. During this period, or if your MX record remains configured to a third-party email filtering solution, you must ensure that EOP is aware of your internal IP addresses (if routing via on-premises) and/or the IP address range(s) belonging to the third-party filtering service. This includes any analysis or intermediary SMTP servers in your routing pipeline after spam, phishing, and malware filtering services.

When EOP is aware of the IP ranges belonging to other services you trust, it skips those IP address ranges in the SMTP headers to determine the true source of the email. Microsoft's Intelligent Security Graph has information about the trustworthiness and reliability of these sources based on their previous history. This information can be applied to inbound emails. When Enhanced Filtering is not configured, the information in

the previous step in the received SMTP header is all that Exchange Online knows about the previous sender, which is likely to be your on-premises infrastructure or the last server in the third-party cloud infrastructure.

To enable Enhanced Filtering, open the **Defender portal**, go to **Policies and Rules > Threat Policies > Enhanced Filtering**, or use <https://security.microsoft.com/skiplisting>. Enhanced Filtering can be enabled for a subset of users for test purposes. Any email addressed to recipients outside your test user pool will not be processed through Enhanced Filtering. Therefore, if you want to test the feature and some of your pilot users receive email using multiple proxy addresses, you should include all the addresses in the Enhanced Filtering configuration. Once your pilot is complete, you can update the configuration to apply to the entire organization.

When you configure Enhanced Filtering by associating the IP addresses of trusted network ranges with the relevant connector, email domain authentication (aka DKIM, DMARC, and SPF) will improve. Now that EOP can determine the source of the email, it can check this information against anti-spoof technologies and explicitly allow, quarantine, or reject email based on the sender infrastructure.

Two SMTP headers are added to messages after Enhanced Filtering is enabled. These are:

- **X-MS-Exchange-ExternalOriginalInternetSender** shows the true source of the message. This should not be in the IP range of the on-premises servers or your third-party filter. If it is, you have not configured skip listing correctly.
- **X-MS-Exchange-SkipListedInternetSender** shows the true source of the message and is used for reporting purposes.

Enhanced Filtering replaces custom mail flow rules often used to prevent double filtering. These mail flow rules set the spam confidence level (SCL) to -1 so that messages skip EOP filtering.

## Microsoft Defender for Office 365 (MDO)

Microsoft Defender for Office 365 (MDO) is a set of features designed to answer zero-day exploits or new methods built by attackers to bypass and fool protection systems such as EOP. In the current threat landscape of email, having a zero-day malware and link protection service that operates on both internal and externally sourced emails should be considered by all tenant administrators as a required purchase. By providing features such as safe attachments, safe links, safe documents, and advanced anti-phishing controls, MDO can significantly increase your organization's security posture.

Microsoft Defender for Office 365 is included in Microsoft 365 E5 and Office 365 E5 and is also available as an add-on. Like most other services available in Microsoft 365, you can enable the added protection for your entire organization or just a select group of users. However, until you buy at least one license, Microsoft Defender for Office 365 is unavailable through the Defender portal.

In hybrid deployments, messages sent between on-premises Exchange servers and Exchange Online bypass MDO scanning. This is because the connectors created in the hybrid configuration set the Spam Confidence Level (SCL) header to -1 to tell EOP to bypass any additional anti-malware or anti-spam filtering.

### Built-in Protection

Built-in protection is a baseline default policy defined by Microsoft for all Microsoft Defender customers. This policy enables a base configuration for Safe Links and Safe Attachments and is applied to every user in your tenant.

This policy cannot be disabled, but users, groups, or domains can be excluded from the policy by navigating to **Policies and rules > Threat Policies > Preset security policies** and selecting **Add exclusions** under the *Built-in protection* section.

It is not recommended to exclude users from the built-in policy. Instead, if you wish to give your users a different configuration, either create custom Safe Links and Safe Attachment policies and assign those custom policies to those users or assign those users to the strict or standard preset security policies. These policies will always take precedence over the built-in protection policy, so there should be no need to exclude users from the built-in protection.

If a user is assigned to multiple policies, policy precedence occurs in the following order.

1. Strict protection preset security policy
2. Standard protection preset security policy
3. Custom security policies (by order of priority)
4. Built-in protection policy

The built-in protection policy ensures every user has Safe Link and Safe Attachment protection in the event they are accidentally removed from all custom or preset security policies.

For a comprehensive list of built-in protection policy settings and how they differ from the standard, strict, and default custom policy settings, check the [Microsoft documentation](#).

## Safe Attachments

*Safe Attachments* deliver extra protection against zero-day malware. EOP uses multiple anti-virus scanning engines to process incoming (and outgoing) messages. However, these engines use “signature” files to detect known viruses and malware. You can compare it to a database that has the essential characteristics of a virus to enable the anti-virus engine to recognize an instance of the virus when it occurs in email. The problem with this approach is that when a new virus is created, time is needed for security researchers to decipher the virus and construct its signature and then update the database. During this period, messages holding the virus will likely penetrate past standard scanning and arrive in user mailboxes. When MDO is enabled, messages with attachments are rerouted to a virtual sandbox environment where the content is subjected to a “behavioral analysis” based on machine learning. During this process, the attachment is run or opened, scanned, and observed to determine whether it is malicious or not. If no suspicious activity is detected, the message is released for delivery to the user’s mailbox.

Each of the MDO features works as an ‘add-on’ to EOP. This means that messages are only subject to additional scanning or processing if none of the other EOP features have found anything suspicious about the message. In the case of Safe Attachments, a message is only rerouted when EOP’s anti-malware engine successfully processes the message and does not detect a threat. The rerouting of the message itself is fully transparent to the end-user.

In addition to protecting attachments in inbound emails from external sources, Safe Attachments file protection is also available for Microsoft Teams, SharePoint Online, and OneDrive for Business. The option to enable MDO for mailboxes is driven by a policy that applies to whomever the policy is configured for. The option to enable MDO protection for OneDrive for Business, SharePoint Online, and Microsoft Teams is a global setting.

### Configuring a Safe Attachments Policy

Even when you assign an MDO license to an account, the Safe Attachments feature will not process any messages until you have created a policy. To create a policy, navigate to **Policies and rules > Threat Policies > Safe Attachments** in the Defender portal and click **Create**. A policy consists of several elements:

- **Safe Attachments unknown malware response** defines what action Safe Attachments should take when a potentially dangerous attachment is detected. The available options are *Off*, *Monitor*, *Block*, *Replace*, or *Dynamic Delivery*.

- **Monitor** can be helpful when you are first enabling the feature because it allows you to assess how well Safe Attachments are performing. Although unsafe attachments are still delivered to the recipient, all the reporting features are available.
- **Block** will quarantine both the attachment and the message.
- **Replace** mode will quarantine the unsafe attachment and deliver the original message.
- **Dynamic Delivery** will ensure that the message body is delivered instantly while the attachment is being analyzed. Once the attachment has been processed, it is reattached to the original message. Should the attachment be considered malware, it will quarantine the attachment.
- **Off** disables any action taken by safe attachments.
- **Quarantine Policy** defines which quarantine policy to use when the Block, Replace, or Dynamic Delivery actions place an attachment and message into quarantine.
- Whether to **redirect malicious attachments** to other recipients. This might be interesting if you do not want to lose the original attachment, even if it is considered unsafe. Caution is advised if you do decide to open the delivered attachment. Some organizations use this feature to send a copy of a malicious attachment to a security operations center (SOC) for further review.
- **Apply the Safe Attachments detection response if scanning can't complete** determines the action to take when message processing times out or a message could not be processed due to an underlying error. With this checkbox deselected, the message is delivered normally to the user. With this checkbox selected, any attachments with processing errors or timeouts are automatically treated as malware. The message then follows the same action identified in the unknown malware response (e.g., off, monitor, block, replace, or dynamic delivery).

In addition to these options, you must also define the scope of the policy to define which users the policy applies.

- **The Recipient is.** Allows you to select one or more individuals from your organization. This can be helpful if you need to single out a handful of users. However, it is better for larger groups of people to use one of the other conditions.
- **The Recipient domain is.** Allows you to enable a policy for all recipients that use a specific domain. You can select both custom and default domains here. The latter makes it ideal for testing the feature if your tenant does not have a custom domain.
- **The Recipient is a member of.** Enables you to select one or more groups to which the user must belong. If the user does not belong to one of the selected groups, the safe attachments feature will not be executed.

To enable Safe Attachments protection for SharePoint, OneDrive, and Microsoft Teams, you need to click **Global settings** at the top of the page and toggle the switch **Turn on Microsoft Defender for Office 365 for SharePoint, OneDrive, and Microsoft Teams**.

**Note:** It can take up to 30 minutes before a new policy, rule, or setting is fully active.

## Safe Documents

Dubbed **Safe Documents for Office clients**, the feature leverages Microsoft Defender for Office 365 to scan documents before allowing users to open them outside of protected view mode in Microsoft 365 desktop applications (Version 2004, build 12730 or greater). This feature is technically not part of Microsoft Defender for Office 365 and requires a Microsoft 365 E5 or Microsoft 365 E5 Security license.

Safe Documents prevents users from opening a document received from an external source until the document can be checked against Microsoft's threat defense cloud. Since there are certain privacy considerations at play, the feature is not enabled by default. Still, it can be toggled on from the **Safe**

**attachments** > **Global settings** page by selecting **Turn on Safe Documents for Office Clients** or via the `Set-AtpPolicyForO365` cmdlet.

## Safe Links

Phishing messages often include malicious links that redirect users away from legitimate sites to sites under the attacker's control. When EOP processes these messages, a high probability exists that these links are already flagged as malicious, and the message will be caught by the anti-malware or anti-spam engine. Unfortunately, this is not always the case. Sometimes, malicious links are not known yet, or perhaps the link was not yet activated when the message was processed. The weakness in this approach to securing messages is that it only protects messages at delivery. If an attacker updates a malicious web page after it has been delivered, the traditional anti-malware protection can do nothing. Usually, this is where computer-based security software kicks in, but with more users responsible for their own devices under BYOD policies, organizations do not always control what endpoints are used.

The *Safe Links* feature analyzes links at the time they are clicked. To do so, it checks the link in real-time in selected clients or rewrites any hyperlinks in email messages when EOP receives them. Safe Links will, by default, only rewrite links if the sender of the message is from an anonymous source, like external senders, and if the link is in the FQDN format. For example, a link with only a server name (no dots) is not rewritten. Rewriting links for internal senders is disabled by default but can be turned on in the Safe Links policy. This protects against a scenario where a mailbox's login details are compromised. A malicious actor uses the compromised mailbox to send bad links that appear to come from a trusted sender.

For Safe Links in email, the link in the message body is rewritten during delivery in EOP. Once the email is delivered to the recipient, the underlying link looks like this:

```
https://eur02.safelinks.protection.outlook.com/?url=http%3A%2F%2Fwww.spamlink.contoso.com%2F&data=02%7C01%7Cbrian%40nbconsult.co%7C321a4fc34c294a14231908d754b5f730%7C69daf98459d5415ba9b1aa3b30b4a677%7C0%7C637071012816511154&sdata=eYvY4TOvBEPJIOZvilGeNclnLIX0q0nQeFfLF9tjAc%3D&reserved=0
```

**Note:** The base URL (\*.safelinks.protection.outlook.com) will always be the same, the information that follows varies on the message and the link(s) within that message.

Outlook hides the link and shows a popup with the target URL so that users do not see the complicated nature of the rewritten link. Opening the message in a non-Microsoft client or an older Microsoft client will still show the rewritten link. When Safe Links is enabled for Office applications, the user does not see the full link. Instead, they only see the destination the link takes the user to if the target is not flagged as malicious.

Outlook desktop also protects URLs in message subjects, URLs in nested email attachments, and URLs in S/MIME signed messages. This is achieved by processing the link at the time of the click, even if EOP did not rewrite the URL. For example, links within S/MIME protected messages are not rewritten; therefore, the message is not rendered invalid while the link is still protected. Indeed, any text that looks like a hyperlink that is made clickable by Outlook is now protected, even though it is not seen as a link when being processed by EOP. No URL rewriting is done; the protection exists solely within the Outlook client.

When a user clicks a link in a message, the Safe Links feature checks the reputation of the remote host (website) against a set of spam lists. This usually happens within a matter of seconds and does not produce any significant delays for the user. When a website is not on one of the spam lists, the user is redirected to the requested website. However, when a match is found, the user will be stopped from accessing the remote website and receive a warning that they should not proceed.

Depending on how you configure the Safe Links policy, the user can be presented with the choice to continue to the website, despite the warning. By default, users are prevented from clicking through to malicious

websites. If you do allow blocked links to be clicked through, the click is registered and will show up in the *URL threat protection* report in the Defender portal. We do not recommend that you allow users to access links deemed to be unsafe.

## URL Detonation

The Safe Links feature uses a list of known malicious targets to understand if a dangerous link is included in a message. This is great if a URL is known to be malicious. However, whenever an attacker creates a new malicious web page, some time will elapse between the web page being accessible and when it is first reported as malicious and, after that, blocked. The URL Detonation feature attempts to intervene during that time by actively scanning URLs in messages before allowing users to access the targets. When a link is considered malicious or points directly to executable content, and the user attempts to access the link, a warning pop-up window (colored yellow) is shown. The user is prevented from opening the target location until scanning is finished. Unlike the Safe Links feature, there is nothing to configure for the URL Detonation feature apart from turning the option on.

It is also possible to delay the email's delivery to the end-user until the links in the email are scanned (just like scanning the attachments). The option to control this behavior is turned off by default. Check the **Wait for URL scanning to complete before delivering the message** option in the Safe Links policy to turn it on. With this option set, any message containing a URL considered malicious is redirected to the user's Junk Email folder.

## Configuring a Safe Links Policy

To create a Safe Links policy, open the **Defender portal** and navigate to **Policies and rules > Threat Policies > Safe Links**.

When creating a new policy scoped to a subset of your users, you have the following options:

- Scope the policy to users, groups, or domains.
- Select whether URLs should be rewritten in emails from external senders.
- Select whether URLs should be rewritten in emails from internal senders.
- Control the behavior of the URL detonation feature (detailed above).
- Provide a set of URLs that will not be rewritten in emails.
- Select whether Safe Links should check URLs in Microsoft Teams (URLs are not rewritten).
- Select whether Safe Links should check URLs in Office apps (URLs are not rewritten).
- Select whether to track user clicks.
- Select whether to allow users to click through to the original URL.
- Display organization branding and warning pages.

If you need to create a custom list of URLs to block, check the earlier section in this chapter on Tenant Allow/Block Lists (TABL).

**Real-world:** The choice to fully block users from navigating to websites that Safe Links blocks could be very invasive. This is especially true when the protected link is accidentally blocked. To block or not block the final link is a security question, and in most cases, as the blocked site is malicious, it is best to ensure that the user cannot click through to the target site. Note that Safe Links does not stop a user from manually copying and pasting the source link into a browser to open the website from there. While the *Safe Links* feature does increase security, it is by no means a replacement for end-user training and added protection on the endpoint itself.

## Testing Microsoft Defender for Office 365 features

Testing Safe Links is simple. All you need to do is send a message or write a document that includes the following URL: <http://www.spamlink.contoso.com>.

To verify whether MDO scans incoming attachments, it is enough to send a message that includes a regular (safe) attachment of a type that could include malicious code. This can be anything from an executable to a Word or PowerPoint file or a PDF file. Because the regular anti-malware feature will not detect anything in the file, the message will be rerouted through MDO for additional scanning. Therefore, ensure that the attachment type is not blocked by the common attachment type filter.

If you are considering migrating to MDO from another email filtering system, you can enable MDO in evaluation mode. Evaluation mode will provide a log of threats that MDO would have protected you from that your existing email filtering system missed. You can enable evaluation mode in the Defender portal by navigating to **Policies and rules > Threat Policies** and clicking **Evaluation Mode**. It is important to note that the evaluation mode will not alert you to threats already mitigated by your existing email filtering service since those messages or attachments will never reach MDO. You can learn more about evaluation mode and how it works with third-party email gateways in Microsoft's [documentation](#).

## Reporting on Microsoft Defender for Office 365

MDO leaves some information within the message headers. For example, using a tool, such as Microsoft's [Message Header Analyzer](#), you can check the message headers for the following information:

1. The *Received headers* section identifies any delays between EOP servers. A delay, however, does not prove that MDO processed the message – for example, internal routing errors could result in delays that have nothing to do with MDO.
2. In the *Other headers* section, a new header, "X-MS-Exchange-Organization-SafeAttachmentProcessing," is present. The header indicates that the Safe Attachment feature processed the message. Note that this header has no value.

Both elements together can provide you with a first impression of whether MDO processed the message. However, the best way to discover how MDO processed a specific message is by running a message trace. Figure 7-13 shows a series of MDO events as they appear in message trace results. The fourth line from the bottom is one of the MDO information rows and is shown in the popup that appears when hovering the mouse over the row.

Figure 7-13: Message Trace results

The first DEFER event (hidden by the popup in Figure 7-13) shows that the message is rerouted to the MDO scanning environment. Next, the event called Advanced Threat Protection gives information about the outcome of the scanning process. In this case, the attachment was scanned, and the message was redirected back to EOP for delivery to the recipient within six seconds.

## Reporting on Message Latency

With the extra layers of security provided by Microsoft Defender, including the ability to detonate attachments in a sandbox, administrators may be concerned about how much latency this adds to message

delivery. In the previous section, we provided an example message trace that indicated 6 seconds were added by Microsoft Defender before the message was delivered. However, to enable administrators to better visualize this for their entire tenant Microsoft aggregates all message trace data into the *Message Latency* report.

## Mail latency report

50th percentiles   90th percentiles   99th percentiles

This report shows all latency within the mail filtering and delivery pipeline. It does not include client or network latency. [Learn more about this report](#)

Filters: Date (UTC): 4/14/2022-4/26/2022   Message view: Inline detonation

Figure 7-14: Mail Latency Report

You can access this report from the **Defender portal** under **Reports > Email & collaboration > Email & collaboration reports**. The **Mail Latency** report (Figure 7-14) contains a bar chart and a table. The percentile tabs across the top allow you to switch the chart between the 50<sup>th</sup>, 90<sup>th</sup>, and 99<sup>th</sup> percentiles. Each bar identifies the average latency of all messages in a given day. Filters allow you to change the date range or narrow down the scope to only messages that were detonated in a sandbox.

## Reporting on Safe Attachments

In addition to the information provided by message traces, Microsoft includes several reports that give statistical information on processed messages. You can access these reports in **Defender portal** under **Reports > Email & collaboration > Email & collaboration reports**. The **Threat Protection Status** report shown in Figure 7-15 is an example.

The reports available in the GUI are interactive and allow you to adjust the filters on the fly. For example, you can change which file types are shown or alter the date range. However, the information that fuels these reports comes from underlying message trace information. For example, suppose you specify a custom date range that goes beyond 30 days. In that case, Exchange Online generates a historical search automatically, and you will have the ability to download the CSV report later instead of viewing it interactively on screen. More information on message traces and historical searches is in the Message Tracing section.

The reports are also available as tables showing the underlying data. To see this information and explore further (such as message ID, to and from information), click **View data by** drop-down and select something other than **Overview** (for example, *View data by Email > Phish*).

## Threat protection status

The Threat protection status report provides information about threats found prior to email delivery, covering relevant detection technologies, policy types, and delivery actions. [Learn more about this report](#)

Figure 7-15: Safe Attachments reports

### Reporting on Safe Links

Reporting on Safe Links is available in the **Defender portal** under **Reports > Email & collaboration > Email & collaboration reports > URL protection report** widget > **View Details** button.

The **URL threat protection** report has two views. The default view shows the resulting action of each click. By default, this includes blocked clicks, blocked but clicked through, block by tenant admin, blocked by tenant admin but clicked through, click through during scan, and pending scan. Clicking the filter button, you can include allowed clicks, modify the date range for the report, and filter to specific domains or recipients. If your Safe Links policy has the **Do not track user clicks** option selected, this report will contain incomplete data.

### URL threat protection

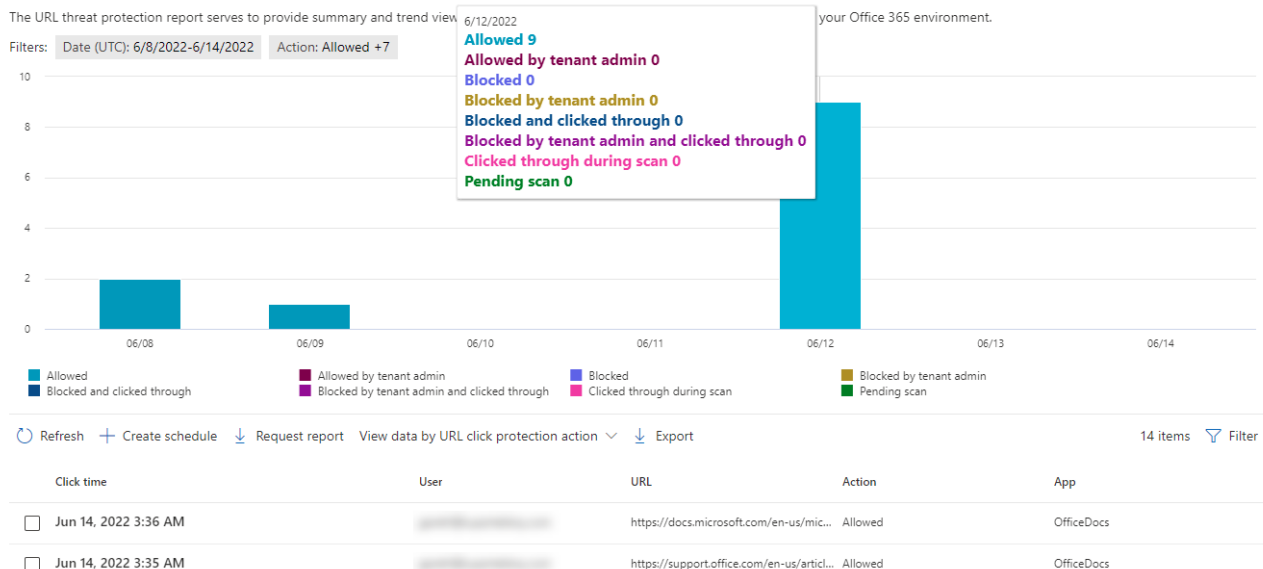

Figure 7-16: URL threat protection report, highlighting the URL click protection action view

Figure 7-16 illustrates the URL threat protection report, highlighting the URL click protection action view. The report shows URLs that resulted in a block page, those block pages where the user clicked through to the

actual destination (if enabled in the policy), and those URLs that were the result of scanning a direct attachment as part of the URL. The actual URLs are displayed below the chart in a table.

The second view is the **URL click by application**, which shows a breakdown across the different applications that support Safe Links. This can give insight into whether users are clicking links in email or other Microsoft 365 Apps (Word, Excel, Teams, etc.).

The basic function of the Safe Links report is to show links that were received. If enabled, the report can also detect and show what links were clicked and by whom. This makes a compelling argument for using the report because it allows you to understand which of your users might need extra security training.

If a URL appears in your Safe Links report that you consider safe, you can add the URL or the domain to your Safe Links allow list. Always do due diligence on URLs. A reason exists for the URL to be blocked. Just because your organization might use the target website does not mean the content is safe.

## Attack Simulation Training

Despite the best efforts of Microsoft Defender for Office 365 (or any other email security solution), it is still possible for malicious emails to reach end-user mailboxes. Therefore, a comprehensive security program will include end-user security awareness training and periodic testing of the program's efficacy. One of the tests is whether end users fall for phishing messages or open attachments to suspicious emails. If you have Microsoft Defender for Office 365 Plan 2, you can automate this testing with Attack Simulation Training.

Attack simulation training can simulate a spear-phishing attack that attempts to harvest valid credentials through phishing messages. A spear-phishing campaign will send sample phishing emails to your users that link them to a realistic webpage that attempts to collect their credentials. If a user clicks the link and enters their credentials, they will be flagged for follow-up. Attack Simulator can also send suspicious-looking emails with attachments that will be tracked if they are opened, or in the case of an attachment with a malicious link, the user will be taken to a page to try and collect their credentials.

You can also use the Attack Simulator to perform password spray attacks and password testing on users in your tenant. Attackers use these techniques to test common, weak passwords against a broad set of users in a tenant. Once the attacker identifies the password for an account, they can use the account for malicious purposes. Multi-factor authentication is a crucial defense against these attacks. [Azure AD Password Protection](#) also works to prevent the use of weak passwords in hybrid environments.

To try out [Attack Simulation Training](#), access the **Defender portal** and navigate to **Email & collaboration > Attack simulation training**.

The **Overview** tab compiles the information of your attack simulation strategy into the following widgets:

- The **Recent Simulations** widget shows any recent simulations. Clicking the **View all simulations** button takes you to the *Simulations* tab. Clicking the **Launch a simulation** button launches the attack simulation wizard (covered in the next section). Note that this widget does not show any of the automated attack simulations.
- The **Recommendations** widget identifies simulated attacks you should launch or schedule for your organization.
- The **Simulation coverage** widget identifies the percentage of users who have and have not received a simulated attack. Clicking the **Launch simulation for non-simulated users** button allows you to create a simulated attack to remedy that gap.
- The **Training completion** widget identifies the percentage of users who have completed the required security awareness training. Clicking the **View training completion report** button shows how each user is progressing with their security awareness training. This report can be exported as a CSV.

- The **Repeat offenders** widget identifies users who have consecutively failed the simulated attacks. Clicking the **View repeat offenders report** button gives you a graph identifying the number of users who have failed each social engineering technique. This includes providing credentials to a fake portal, opening attachments that contain malware, and clicking malicious links. The chart below the graph identifies each user, how often they have repeated the offense, and the simulation types they have failed.
- The **Behavior impact on compromise rate** widget tries to determine the efficacy of the security awareness training and how susceptible the organization's user base is to compromise as a percentage. Clicking **View simulations and training efficacy report** expands the data surfaced by the widget into a more detailed report. This report identifies each simulation, the predicted compromise rate, the actual compromise rate (how well the organization did), the total target users, and how many of those total users fell victim to the simulated attack.

The **Simulations** tab identifies all currently configured simulations and their state (we will cover launching an attack simulation in the next section). States include simulations in draft (saved but not yet submitted), scheduled, in progress, completed, failed, and canceled.

If you select a simulation, you can review the report of that simulated attack. This includes how many users were compromised by the simulation, how many users reported the simulation as a phishing attack, which payloads were used in the simulation, recommended actions to protect users from this type of attack, and the progress of any user awareness training attached to this simulation. Other details include when the simulation was launched, when the simulation will end, how many users were targeted, and the current status of the simulation. To cancel a simulation, select the three dots on the far right of the simulation entry, and click **Cancel Simulation**.

The **Automations** tab allows you to automate one or more attack simulations (we will cover setting up an automated attack simulation in a later section).

The **Simulation content library** tab allows you to create your own custom payloads. Customizing the payload is helpful since you can create a phishing message or fake logon portal that is a more realistic representation of your organization using your logo, color scheme, and other convincing content.

Microsoft offers many different email payloads, including emails with the purpose of credential harvesting, delivering malware as either an attachment or a link, inserting links to websites with malicious code, or convincing the user to grant OAuth consent. Depending on the payload selected, you can configure the sender's display name and email, the subject, phishing links, a malware attachment, language, and theme. You can also import or copy an email into the text editor. A code editor is also available for advanced configuration of the email.

Microsoft offers several templates to create your own fake login portal, including fake portals for LinkedIn, GitHub, and Microsoft. These templates can then be customized either in the text or code editors.

The simulation content library tab also contains the end-user notifications. End-user notifications can be customized, offering either positive reinforcement if the user submitted the simulation as phish or a failure notification if the user fell victim to the simulated attack. This could include links to additional security training and reminders for the user to complete that training.

The **Settings** tab allows you to define what is considered a repeat offender. A repeat offender is someone who has fallen victim to consecutive simulations. The default number is two but can be set higher.

## Launching a simulated attack

To launch a simulation, click the **Launch a simulation** button. The *Select Technique* page (Figure 7-17) identifies all social engineering types, including:

- **Credential harvest** includes an email that links to a fake portal designed to trick users into inputting their credentials on a malicious website.
- **Malware attachment** includes an email with an attachment designed to run malicious code or a macro to compromise or gain access to the user's device, allowing the bad actor to launch additional attacks.
- **Link in attachment** includes an email with an attachment that has an embedded URL. The embedded URL takes the user to a fake portal to trick the user into entering credentials.
- **Link to malware** includes an email with a URL to a malicious file (for example, mimicking a well-known sharing site like SharePoint Online or Dropbox) which could contain malicious code or macros.
- **Drive-by URL** includes an email with a URL to a website that runs malicious code designed to compromise or gain access to the user's device, allowing the bad actor to launch additional attacks.
- **OAuth consent grant** uses an app created by a bad actor, prompting the user to grant permissions to the app. This could allow the app to harvest data or perform other attacks on the user.

Select a technique and click **Next**. Give the simulation a **Name** and **Description** and click **Next**.

From the *Select payloads and login page*, select the payloads sent to users. A payload can contain both an email and a login portal. You can also test each payload from this page by clicking the **Send a test** button. This test is sent to the currently logged-in user. This test is not included in the simulation reporting. When you have selected your desired payload, click **Next**.

On the *Target Users* page, you can include either specific users or groups or the entire organization. Selecting specific users is a great way to test an attack simulation on a small scale before targeting the entire organization. Scope the users for the automated simulation and click **Next**.

On the *Assign training* page, you can assign training to users.

- Select **No training** if you don't want to add any follow-up training to the attack simulation.
- If you want to add a custom training URL, which could be directed to an internal learning management system or security training portal, select **Redirect to custom URL** and enter the appropriate URLs.
- If you want to use security training curated by Microsoft, select **Microsoft training experience (Recommended)**. The Microsoft training experience includes a dozen videos between 3 and 7 minutes. When you select the Microsoft training experience, you can either **Assign training for me (Recommended)** or **Select training courses and modules myself**.

With the custom URL or Microsoft training experience, you can set a training due date of 7, 15, or 30 days.

On the *Select end user notification* page, pick whether to notify users about the results of their participation in the attack simulation. This is a great way to provide positive reinforcement if a user correctly identified and reported a message as phishing or an opportunity to provide security training and awareness to users who fell victim to the simulation. Options include:

- **Do not deliver notifications** if you do not wish to have user involvement with the simulation.
- **Microsoft default notification (recommended)** if you want to use the default Microsoft notifications. This selection allows you to define the delivery preferences for the Microsoft notifications (such as when to deliver the notification) and allows you to review the notification layout before sending.
- **Customized end user notification** if you want to provide your own notifications. We discuss notifications in greater detail while covering the *Simulation content library* tab.

On the *Launch Details* page, select whether to execute the simulation as soon as the wizard is complete or schedule the simulation to start later. With either selection, you must also define (in days) when the simulation should end. The default is two days, ranging from 2 to 30 days. With the launch schedule defined, click **Next**.

Before submitting the simulation, you can test it. Click the **Send a test** button to send the simulation to the currently logged-on user. If the test looks good, click the **Submit** button.

## Automating a simulated attack

To create a new automated attack simulation, click the **Create Automation** button. Next, enter a **Name** and **Description**, then click **Next**.

The *Select Social Engineering Technique(s)* page (Figure 7-17) allows you to select one more attack simulation. Select the simulations you want to automate and click **Next**. From the *Select payloads and login page*, you can manually select or randomize the payloads sent to users. A payload can contain both an email and a login portal. Click **Next**.

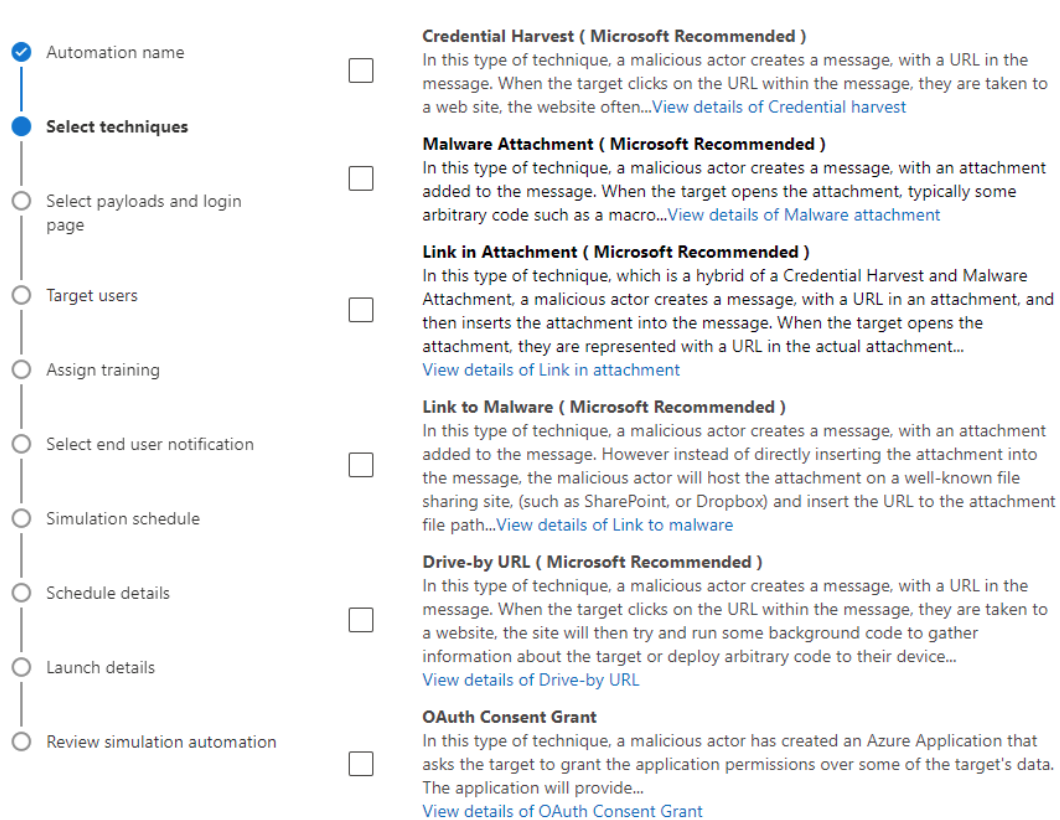

Figure 7-17 Automated Attack Simulator Setup Wizard showing Social Engineering Techniques

The *Target Users*, *Assign Training*, and *Select end user notification* pages are identical to the launch simulation wizard covered in the previous section. For more details on these pages, see the previous section.

On the *Simulation Schedule* page, you can choose whether to create a **Randomized** or **Fixed** schedule to launch the attack simulation. Click **Next**.

- If you selected a fixed schedule, the *Schedule Details* page will ask for **Simulation Start** and **Simulation End** dates. Select a date from each date picker. You can then define how often the simulation reoccurs and whether the reoccurrence is monthly or weekly. If you select weekly, you can choose the day of the week for the occurrence. If you selected monthly, you can choose the day of the month for the occurrence.
- If you selected a randomized schedule, the *Schedule Details* page will ask for **Simulation Start** and **Simulation End** dates. Select a date from each date picker. Then, from the *Simulation Scoping* section, pick which days of the week the randomizer can send simulated attacks. For example, if your organization only works Monday through Friday, you may only wish to select weekdays. The needs of the business should also dictate this schedule. For example, if client invoicing or payroll is every

Friday, you may not wish to launch simulated attacks on that day. You can also choose to randomize the delivery times of the simulation emails.

With the schedule and reoccurrence settings defined, click **Next**.

On the *Launch details* page, you can select additional options such as whether to include the same users on each simulation, whether to target repeat offenders who had fallen victim to the simulation, whether to enable region-aware delivery (so phishing messages are sent during working hours), and whether to use unique payloads for different users. Once you have your options defined, click **Next**.

Review the simulation settings and click **Submit**.

When you submit a simulation, it is saved in a disabled state. To enable the simulation, select it from the **Automations** tab and click the **Turn on** button. When enabled, the *Status* column will switch to *Active* and show the next launch time. If you wish to disable the simulation, select it from the *Automations* tab and click the **Turn off** button. The *Status* column will report *Inactive*, and the *Next launch time* column will be blank. You can also delete a simulation from this tab.

## Using Third-Party Attack Simulators

Some organizations might prefer to use third-party attack simulators to send phish or impersonated emails to their end-users. Traditionally, using third-party simulators requires adding those organizations to various allow lists under several policies, so Microsoft would not act on the simulated attack.

With the advent of Microsoft's [Secure by Default](#) initiative, customer-defined entries in IP allow lists, sender allow lists, domain allow lists, and transport rules are not honored if the message contains malware or is classified as high confidence phish. Therefore, if you previously added your third-party vendor for email attack simulation to any of these lists, their simulations will be blocked. Instead, you should transfer these configurations to Advanced Delivery.

### Configuring Advanced Delivery

To add a third-party attack simulator, open the **Defender portal** navigate to **Policies and rules > Threat Policies > Advanced Delivery**, and select the **Phishing Simulation** tab. From this tab, click **Add**. The *Add Third-Party Phishing Simulation* dialog (shown in Figure 7-18) lets you add all **Sending Domains**, **Sending IPs**, and **Simulation URLs** associated with the third-party attack simulator.

### Add Third Party Phishing Simulations

Phishing simulations are attacks orchestrated by your security team and used for training and learning. Simulations can help identify vulnerable users and lessen the impact of malicious attacks on your organization.

Third party phishing simulations require at least 1 entry for **Sending domain** and at least 1 entry for **Sending IP** categories below. Simulations URLs to allow is an optional field. Specify URLs here to not block or detonate on for your phishing simulation.

The screenshot shows a configuration interface for adding third-party phishing simulations. It is divided into three sections, each with a title and a count of items, and a search input field below it. The first section is 'Sending Domain (1 items)' with a search box containing 'psm.knowbe4.com'. The second section is 'Sending IP (1 items)' with a search box containing '147.160.167.15'. The third section is 'Simulation URLs to allow (0 items)' and is currently empty.

Figure 7-18: Adding third-party phishing simulations

## Investigations

Investigations, or Automated investigation and response (AIR), are part of Microsoft Defender for Office 365 Plan 2. AIR runs a security playbook after an alert is triggered within your organization, either as an automatic response to well-known phish/malware events or manually by an administrator. As part of the playbook, additional information about the event is gathered, and a set of actions is returned as recommendations. However, AIR does not automatically perform remediation actions - an administrator must manually approve recommended remediations.

To access the ongoing and recently completed investigations list, open the **Defender portal**, and navigate to **Investigations**.

By default, this dashboard is filtered to show investigations from the last 24 hours. You can expand this date range by modifying the filter. The filter also lets you scope the dashboard to a specific status or investigation type. For example, you could filter the results to focus on investigations that uncovered compromised users.

To get the properties on a specific investigation, click the **Open in new window** icon. This will launch a new page with the following tabs.

- **Investigation graph** gives you a visual overview of the selected item. You can click on the individual graph components to be transported to one of the other tabs. For example, the investigation graph in Figure 7-19 shows that 7 entities were analyzed (1 email, 1 file, and 5 clusters). If you click the entities analyzed icon, it transports you to the entities tab.
- **Alerts** list the alert that triggered the investigation. You can select each alert to get the details on what caused the alert. Using our example from Figure 7-19, this alert was caused due to ZAP retroactively detecting malicious content in an email. In our case, the alert identified the email (noting the recipient, subject line, sender address, sender IP, and date sent.)
- **Mailboxes** lists impacted users. You can select each user and click the **More details about user** link if you want to see all investigations that the user has been a part of in the last 7 days. This is useful to see if the user is a victim of repeated digital attacks.

- **Evidence** identifies all email items related to the investigation, including the originally reported item and any items found as part of the hunting phase. This could include the message body, attachments, and subject line.
- **Entities** include all the individual objects part of the investigation, such as the user, message, files, IP addresses, etc.
- **Log** gives details on the execution of different steps of the investigation.
- **Pending Actions** lists the actions Exchange Online is recommending taking. For example, the action could be to soft or hard delete the message. From here, the admin can either **Approve** or **Reject** the action. If an admin rejects the action, they must provide a reason. From the action screen, the admin can view the message headers, download the email for further analysis, or open the item in Explorer (covered in the next section).

Figure 7-19 shows the investigation graph of an investigation.

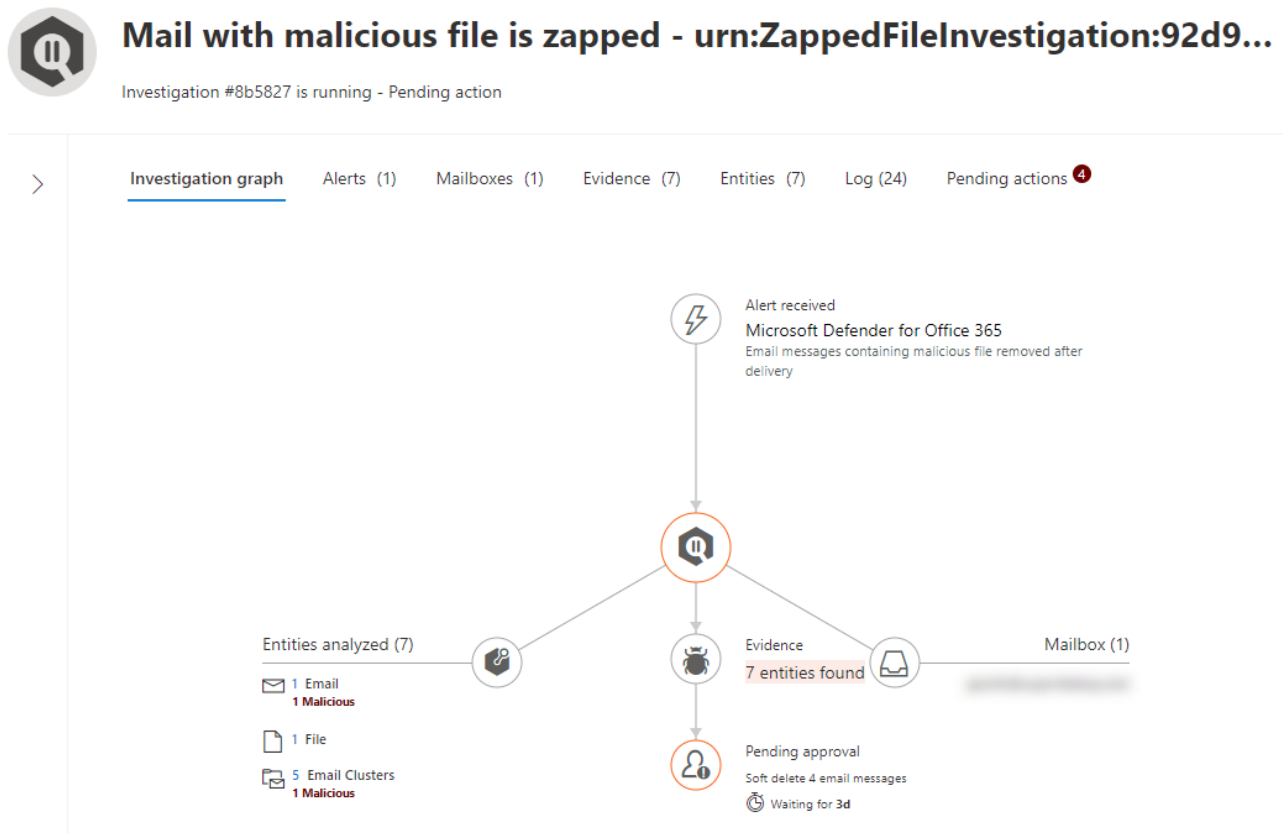

Figure 7-19: Investigation graph of an investigation

## Explorer

Explorer is a great way to see what actions Exchange Online takes on email. The top half of the dashboard displays a stack graph (Figure 7-20) identifying the quantity of email that has been delivered normally, delivered to junk, or blocked. The bottom half of the dashboard provides the individual data making up the graph.

By default, the graph only shows the last two days, but this date range can be increased to the last 30 days using the date and time pickers at the top of the screen. Once you pick a new start or end date and time, click the **Refresh** button.

You can also filter results. For example, to filter all actions taken on messages from a specific sender, select **Sender** from the drop-down, type the sender's email address and click the **Refresh** button. Note that you can

filter multiple values by providing a comma-separated list in the text box. In our example, we could type multiple sender email addresses separated by a comma. There are dozens of other filters, such as looking at messages coming to or from a specific connector, actions taken, impersonated users and domains, and more.

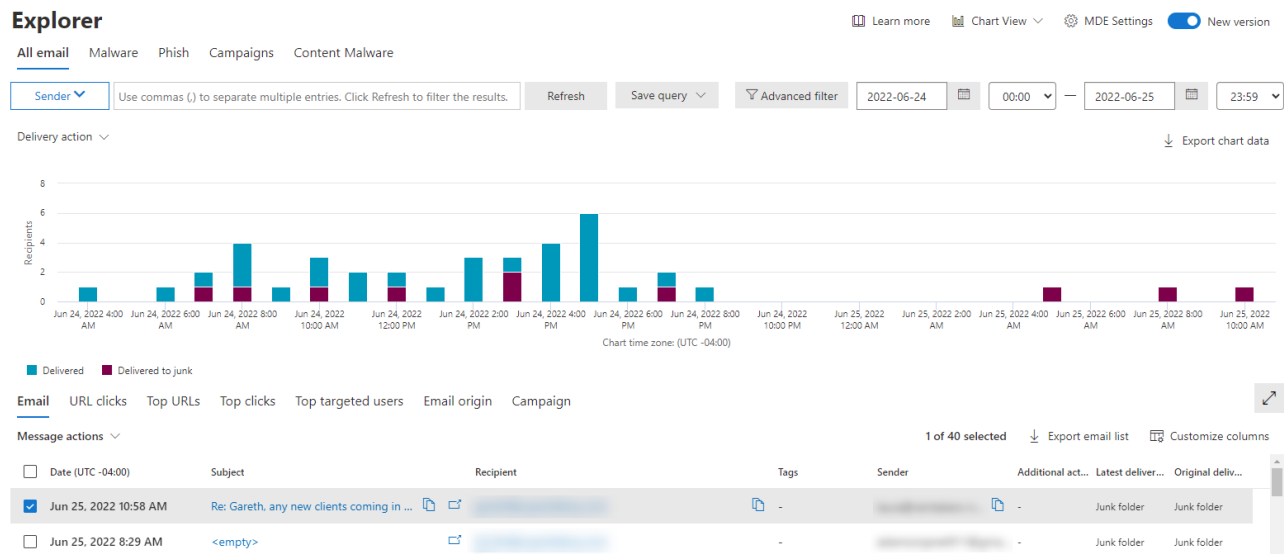

Figure 7-20: Explorer showing mail delivered, delivered to junk, or blocked

If you want to apply multiple conditions to your filter, click the **Advanced filter** button. This filter pane allows you to select one or more conditions and the operator to connect these conditions (for example, an OR operator).

The table in the lower half of the dashboard has multiple tabs allowing you to scope the table to specific results. This includes email, URL clicks, top URLs, top clicks, top targeted users, email origin, and campaigns. Each tab returns different data.

For example, the default **Email** tab identifies each email's delivery date, subject, recipient, sender, and delivery action. Selecting an email and clicking the **Open in new window** button brings up additional detail about that email. This additional detail includes a timeline through Exchange Online, a detailed analysis of the email (which includes message headers, policy actions, and more), if the email contained any attachments or URLs (and any malicious verdicts), and if the emails were related or similar to any other emails. For additional analysis, an admin can preview or download the email from this view.

In contrast, the **Top URLs** tab identifies how many emails a URL appeared. The count columns can also be sorted, allowing you to identify the top URLs found in blocked and junked emails. Selecting a URL allows you to see which emails included the link, as well as WHOIS information on who owns the domain attached to the link. You can view more about the email that contained a URL by clicking the **Open in new window** button.

The **Top Targeted Users** is a great way to identify who is targeted by these digital attacks. Each user identified will have a corresponding number of attempts by their email address. Selecting the user will filter explorer to just that user.

You can also save your queries using the **Save Query** button. This is useful if you need to track a specific event over time. Saved Queries appear in the **Defender portal** on the **Threat Tracker** page.

## Threat Tracker

Threat tracker allows you to access all your previously saved queries from Explorer. Select a query and click the **Explore** link to use a saved query. This will launch that query on the **Explorer** page. For more information, check the previous section on Explorer.

Threat Explorer allows you to modify an existing query by clicking the **Edit** button. You can also delete saved queries by clicking **Delete**.

# Monitoring and Troubleshooting Mail Flow

Microsoft provides a variety of tools and reports to help you keep track of mail flow in your organization. For example, when something goes wrong, tools like message tracing let you explore precisely what happened to a message so that you can troubleshoot a problem. In addition, if you look deep into email messages, there are a plethora of diagnostic message headers that EOP and Exchange Online add to help explain precisely what happened to the message when Microsoft processed the item.

## Mail Flow Dashboard

The mail flow dashboard (accessed through the Home tab of the Exchange Admin Center) is a collection of widgets and reports with associated alerts and recommendations to help you review your mail flow at a glance and identify potential issues.

Figure 7-21 shows the mail flow dashboard. As with most other dashboards, you can customize the arrangement of the widgets to suit your needs. Most of these widgets link back to a mail flow report under the Reports > Mail Flow section in the Exchange Admin Center.

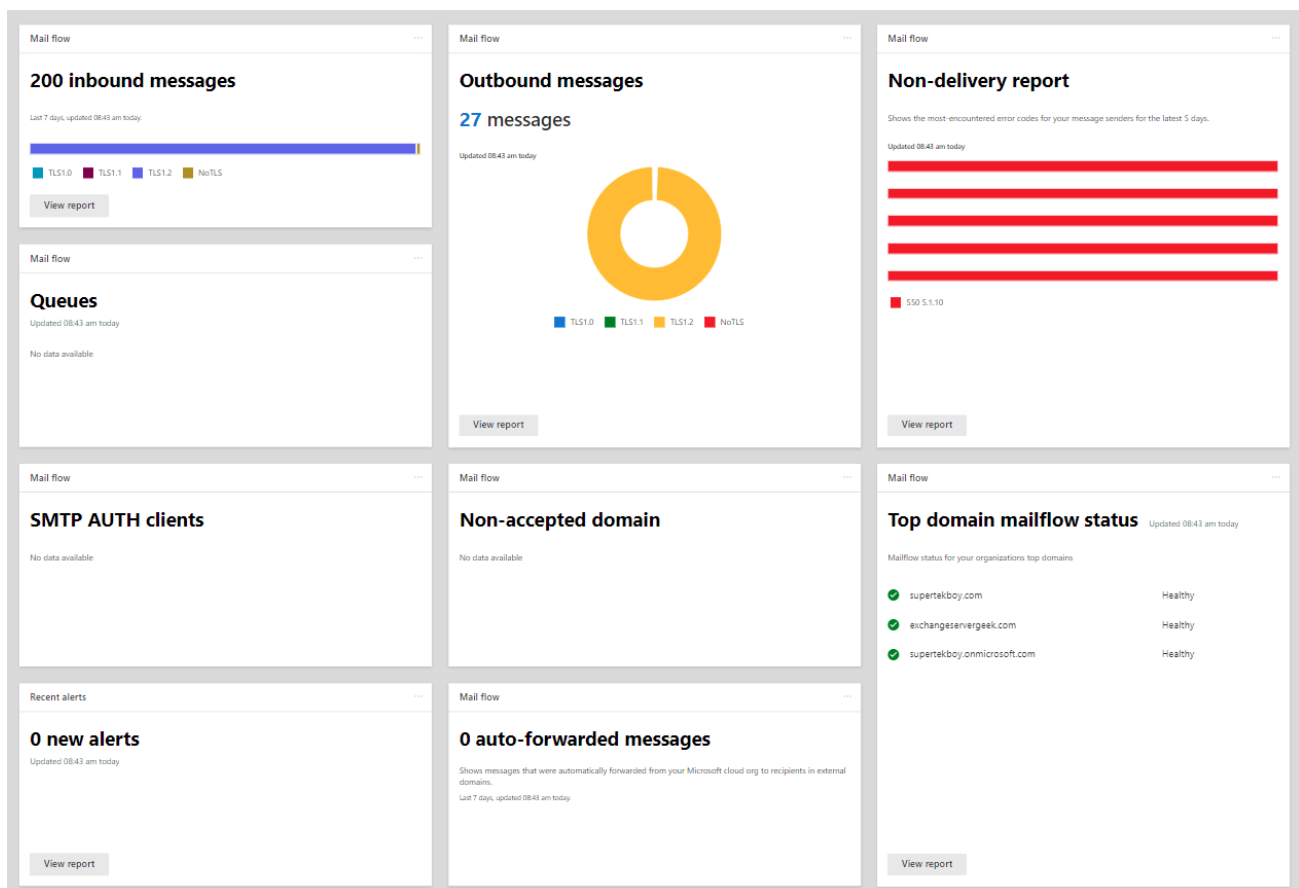

Figure 7-21: Mail Flow Dashboard

## Inbound Messages

The inbound messages widget (Figure 7-21) displays the number of inbound messages received in the last 7 days. Below the graph, a legend identifies each TLS protocol (including messages received without TLS). You

can select each TLS protocol in the legend to focus the graph on just that protocol. Selecting the **View Report** button redirects you to the inbound messages report (under **Reports > Mail Flow**).

The inbound messages report (Figure 7-22) provides greater detail than the widget. This dedicated screen displays daily mail volume, percentage of mail received by TLS protocol, and a detailed line item report breaking down daily mail by each connector.

The various drop-downs allow you to change the date scope between 7, 30, and 90 days (including a custom date range) or select a specific inbound connector (or all inbound connectors). You also have the option to filter the results with the **Filter > New Filter** button. To export the report to CSV, click the **Export** button. Alternatively, click the **Request Report** button to send the report directly to your email.

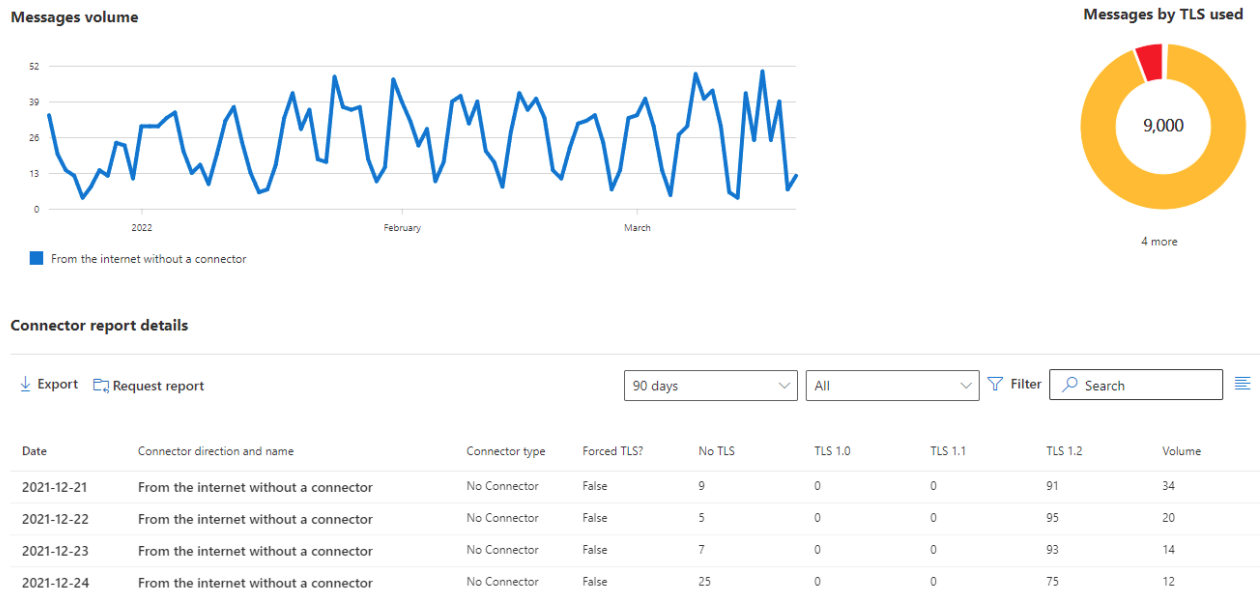

Figure 7-22: Inbound messages report

## Outbound Messages

The outbound messages widget (Figure 7-21) displays the number of outbound messages received in the last 7 days as a donut chart. Below the chart, a legend identifies each TLS protocol (including messages received without TLS). You can select each TLS protocol in the legend to focus the chart on just that protocol. Selecting the **View Report** button redirects you to the outbound messages report (under **Reports > Mail Flow**).

The outbound messages report is identical to the inbound report shown in Figure 7-22. Like the inbound report, you can see outbound mail volume by day, percentage of mail sent by TLS protocol, and a detailed line item report breaking down daily mail by outbound connector.

The drop-downs also operate similarly to the inbound report, allowing you to change the date scope, select a specific outbound connector, or filter the results. To export the report to CSV, click the **Export** button. Alternatively, click the **Request Report** button to send the report directly to your email.

## Non-Delivery Report

This widget shows the most common error codes over the last 5 days, including the number of times that an error was recorded on a given day. For example, Figure 7-21 shows that our only error code in the last 5 days is 550 5.1.10, which equates to "Recipient not found." A fairly innocuous error that is likely due to a mistyped email address.

The **View Report** button redirects you to the non-delivery report (located under **Reports > Mail Flow**). This report gives us a detailed overview of the volume of error codes we have received each day; selecting a key

on the legend filters the graph to that specific error code. This is useful when we want to identify patterns in our errors. For example, in Figure 7-23, we primarily receive error 550 5.1.10 as identified by the widget. However, on 3/10/22 and 3/7/22, we also received error code 550 5.7.133, which means we do not have permission to send it to a distribution list. We can then take the message IDs under the Sample Messages column and perform a message trace to investigate the failure further.

## Non-delivery report

Monitor messages that aren't getting delivered to the intended recipients. When a message can't be delivered, the sender gets an emailed non-delivery report (NDR) with an error code that indicates why the message wasn't delivered. This page shows the details of the NDRs and helps you troubleshoot the issues. [Learn more](#)

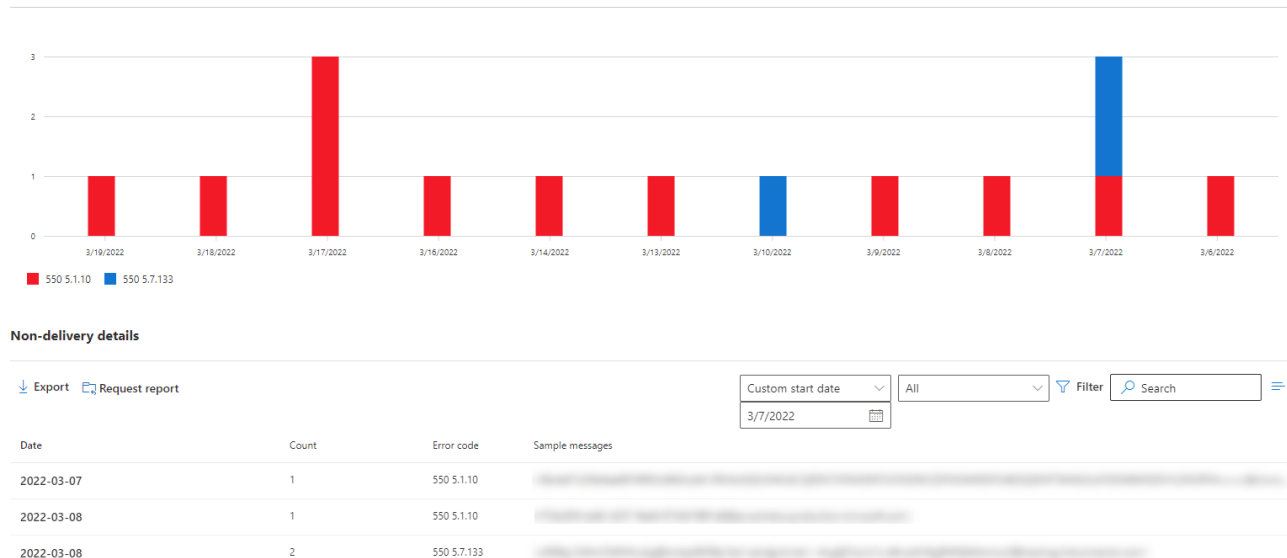

Figure 7-23: Non-delivery report

## Queues

The **Queues** widget is another default part of the dashboard. The Queues widget shows you the number of messages stuck in a mail flow connector for more than one hour. If the number shown is greater than zero, you can click it to go through a series of flyout reports showing information such as the number of queued messages and the connector name (linked through to EAC, where you can fix the connector in error).

The number of queued messages can also be clicked through to show a message trace report for the items stuck in the queue, showing further information on the problem. For example, a queue containing the wrong smart host might show the target host refused to allow an SMTP connection, otherwise known as a socket error.

A companion report is available for this widget by navigating to **Reports > Mail Flow > Queued messages report**.

## SMTP AUTH Clients

Clients that connect directly to SMTP servers are known as SMTP AUTH clients. An example of an SMTP AUTH client could be a multi-function printer performing scan-to-email that relays directly to Exchange Online via smtp.office365.com, rather than an on-premises mail server. The TLS version used by these clients is visible in this widget. This widget will be empty if you do not leverage SMTP AUTH clients.

Understanding the TLS version used for SMTP AUTH is vital as Microsoft is deprecating the use of TLS 1.0 and TLS 1.1 from their primary smtp.office365.com endpoint. Any client needing TLS 1.0 and TLS 1.1 must use the legacy-smtp.office365.com endpoint instead (see the Device and app mail relay to Exchange Online section).

A companion report is available for this widget by navigating to **Reports > Mail Flow > SMTP AUTH clients report**.

**Note:** To reduce your attack surface, Microsoft recommends that organizations enable SMTP AUTH only on mailboxes that require access to the protocol. See the Exchange Online chapter for more information on this topic.

## Non-Accepted Domain

The non-accepted domain widget identifies email relayed from your on-premises environment using a domain not registered in Office 365. For example, if an on-premises application sends mail as "app@office365itpros.co.uk" and the only domain in your tenant is "office365itpros.com," this widget will identify that issue.

Making sure to only send messages from domains registered to your tenant is incredibly important. Microsoft will reject any mail where the *From* address does not match one of the domains in your tenant. This is particularly important in tenant-to-tenant migrations where a domain is removed from one tenant and added to another. During this transition, any on-premises relays must be updated to the new tenant.

A companion report is available for this widget by navigating to **Reports > Mail Flow > Non-accepted domains report**.

## Top Domain Mail Flow

You must have the correct MX record published in DNS to receive emails for a domain. A change in the MX record could result in an email outage. This widget gives you a high-level overview of potential health issues for your registered domains (including the tenant domain). A green checkmark and a status of *Healthy* indicate everything is good.

Selecting the **View Report** button (Figure 7-24) redirects you to the *Top domain mail flow status report* (located under **Reports > Mail Flow**). This report gives us a detailed overview of each domain, its health, the previous and current MX records (if it has recently changed), and if you have received an email to that domain in the past 6 hours.

### Top domain mailflow status report

Domain	Domain status	Previous Mx Record	Current Mx Record	Emails received (past 6 hours)
<input type="checkbox"/> supertekboy.com	Healthy	supertekboy-com.mail.protection.outlook.com	supertekboy-com.mail.protection.outlook.com	Yes
<input type="checkbox"/> exchangeservergeek.com	Healthy	exchangeservergeek-com.mail.protection.outlook.c...	exchangeservergeek-com.mail.protection.outlook.com	No
<input type="checkbox"/> supertekboy.onmicrosoft.com	Healthy	supertekboy.mail.protection.outlook.com	supertekboy.mail.protection.outlook.com	No

Figure 7-24: Top Domain Mailflow Status Report

This report will also identify when domains have expired, which would result in the domain no longer resolving and causing mail flow and other issues.

## Recent Alerts

Security is always something to review on an ongoing and consistent basis. The **Recent Alerts** widget identifies if any of your Exchange Online mailboxes are potentially compromised. The most common item displayed here is alerts on forwarding rules (see the next widget report). Click the **View Report** button to see a report of all alerts in the last 90 days. This report is also accessible by navigating to **Mail Flow > Alerts**.

## Auto-Forwarded Messages

The auto-forwarded messages widget is designed to help you combat a common approach to data exfiltration. For example, this often happens during a business email compromise attack when the attacker

wishes to understand a victim's mail traffic patterns before they send a phishing email to try and lure someone into taking action, such as making a payment. It is recommended that you limit this behavior so that email is only forwarded outside the organization when justified by business reasons.

The widget identifies the number of forwarded items in the past week, including messages forwarded by a user via an inbox rule, their OWA forwarding options, or an administrator who has configured a transport rule or SMTP forwarding.

A companion report is available for this widget by navigating to **Reports > Mail Flow > Auto-forwarded messages report**. The **Summary** tab identifies all forwarded messages, the method used to forward those messages (inbox rules, mail flow rules, or SMTP forwarding), and the forwarding users and domains. The **New Activity** tab shows any new forwarding in the past 7 days.

It is prudent to frequently review this information and block or remove any rules that forward emails as appropriate. It is also worth noting that you can create alert policies to signal an alert when a user forwards emails from their account. Also, Microsoft Secure Score awards a higher score to tenants who do not allow email forwarding.

## Other Widgets

Other widgets (not shown in Figure 7-21) include:

- **Migration Batch** identifies the success or failure of recent migration batches to or from Office 365. Selecting the View Report button takes you to the Reports > Migration tab, where you can dive into the nature of the success or failures of each batch.
- **Mailboxes** provide quick links to everyday administrative actions such as adding a shared mailbox, managing email forwarding, or hiding a mailbox from address lists.
- **Training and Guide** provide links to Exchange Online documentation and training for administrators.

## Reports

Most widgets described in the previous section link to a report under **Reports > Mail Flow**. However, the reports tab also contains additional reports that do not have a corresponding widget. These reports are discussed below.

### Mail flow map report

The *Mail flow map* report provides a visualization of mail flow in Office 365. This is useful to identify trends or anomalies in your mail routing.

- The center of the visualization is Office 365. This shows the count of internal messages in the tenant.
- Messages coming into the tenant, including mail from the internet and any custom connectors, are shown to the left of Office 365.
- Messages leaving the tenant, including mail to the internet and any custom connectors, are shown to the right of Office 365.

The table below the visualization identifies each domain exchanging mail with your tenant in the last 90 days. You can also refine this report by clicking the **Filter** button. For example, to only see messages received by a specific domain, select **Send or receive domain** option from the *Field* drop-down, pick an operator and specify the domain. You can export these results for further analysis to CSV by clicking the **Export** button.

### Mailboxes exceeding receiving limits

The *Mailboxes exceeding receiving limits* report identifies mailboxes that could be throttled due to exceeding transport limits. When mailboxes are throttled, they will experience delays in sending and receiving mail. Throttling has a clear impact on users and the business, so keeping on top of any potential throttling is vital.

This report comprises a heatmap that shows the top 10 mailboxes impacted in the last 24 hours and a table of all mailboxes that exceed transport thresholds.

For a complete list of transport limits, see the Transport Limits section.

## Reply-all storm protection report

The *Reply-all storm protection report* identifies when a reply-all storm was triggered based on the thresholds configured by the tenant admin. By default, reply-all protection blocks replies to an email thread for 6 hours if it had detected more than 10 reply-all messages within 60 minutes to a thread with over 2,500 recipients. These values (aside from the 60-minute detection window) are configurable from the **Exchange Admin Center** by navigating to **Settings > Mail Flow**.

The goal of reply-all storm protection is to stop chain emails impacting the organization. The *Reply-all storm protection report* identifies each message that triggered reply-all protection. This can be useful if you need to provide guidance or training to the message originator to prevent a reply-all storm in the future. The report attributes could also be used if you need to perform a content search to remove the offending messages.

The configurable ranges for the reply-all storm protection can be found in the Transport Limits section.

## Exchange Transport Rule Report

The *Exchange transport rule* report identifies triggered transport rules in a given period. This data is represented by a graph (Figure 7-25), which identifies the daily volume of each triggered rule, and a donut chart, which breaks down rule volume by direction and severity. You can select a key from each chart legend to focus on a specific component. For example, you can select the outbound key to focus solely on the volume of rules triggered on outbound mail flow.

### Exchange Transport Rule report

View matches for the mail flow rules that are set up for your organization. You can manage these rules in the Exchange Admin Center. [Learn more](#)

Figure 7-25: Exchange Transport Rule report

By default, this report shows the volume for the last 7 days. However, like all other reports, it is possible to change this timespan to 7, 30, or 90 days (including a custom date range). In addition, it is possible to focus the graph on a specific rule, mail flow direction, or severity using the drop-downs. This is useful to see whether a rule is triggering more in one direction than the other (e.g., inbound versus outbound) or if you are looking for rules categorized as high severity.

## Non-Delivery Reports

Whenever a mail server cannot deliver a message because of a hard failure, it generates an NDR and sends the NDR to the message's originator. This happens so that the sender knows the message failed. Compare it to snail mail being "returned to sender" because the post office could not deliver the letter to its destination.

NDRs hold information about why the message delivery failed. The following example illustrates the typical information found in an NDR, saying that the recipient does not exist in the remote email system:

### 550 5.1.10 RESOLVER.ADR.RecipientNotFound; Recipient not found by SMTP address lookup

The receiving server generates the information in an NDR. Historically, the recipient's messaging system generates the NDR and sends it back to the originator. However, most modern messaging systems now generate NDRs based on the receiving server's information at the originating system, which significantly enhances the user experience, as outlined below.

Regular NDR messages are not very helpful for most users and often leave them wondering what to do next. On the other hand, NDRs typically also contain other details which are helpful for an administrator trying to figure out what happened.

Your message to [UserX@domain.com](mailto:UserX@domain.com) couldn't be delivered.

UserX wasn't found at [domain.com](http://domain.com)

michael Office 365  
**Action Required** Recipient  
 Unknown To address

#### How to Fix It

The address may be misspelled or may not exist. Try one or more of the following:

- Send the message again following these steps: In Outlook, open this non-delivery report (NDR) and choose **Send Again** from the Report ribbon. In Outlook on the web, select this NDR, then select the link "**To send this message again, click here.**" Then delete and retype the entire recipient address. If prompted with an Auto-Complete List suggestion don't select it. After typing the complete address, click **Send**.
- Contact the recipient (by phone, for example) to check that the address exists and is correct.
- The recipient may have set up email forwarding to an incorrect address. Ask them to check that any forwarding they've set up is working correctly.
- Clear the recipient Auto-Complete List in Outlook or Outlook on the web by following the steps in this article: [Fix email delivery issues for error code 5.1.10 in Office 365](#), and then send the message again. Retype the entire recipient address before selecting **Send**.

If the problem continues, forward this message to your email admin. If you're an email admin, refer to the **More Info for Email Admins** section below.

Figure 7-26: Layout for NDR message(s)

When a user reports an NDR, it is normal to investigate to try to rectify the problem. However, when a remote system responds that a user is not known or that the remote mailbox is full, there is nothing that you can do except wait for the remote server to fix the problem. Microsoft has invested in the layout and text in the NDRs generated by Exchange Online to reduce support calls. These messages are more descriptive and helpful than is the norm with other SMTP-compliant email systems. In some cases, the advice given helps the user to resolve the problem themselves. Figure 7-26 is a good example. The problem is clear, and the steps necessary to deliver the message to the intended recipient are there for the user to take. In addition, the NDR still has

information that could be helpful to the administrator, like the original message headers and SMTP error code.

## Backscatter Filtering

Spammers often send messages to random recipients on the internet and use someone else's email address to spoof the "From:" header. When one of these messages is sent to an invalid recipient, the receiving email server can generate an NDR, which is sent back to the spoofed email address instead of the spammer. These NDR messages are referred to as backscatter.

NDR messages are very useful. They can tell someone who sent a message that it was not successfully delivered, for instance, because the recipient's mailbox is full or maybe because the email address is invalid. However, false NDR messages are a nuisance for end-users, as anyone who has ever received one for a message they know they did not send will understand.

EOP applies a unique signature to each outgoing message to reduce backscatter. The signature is stored in an SMTP header called *x-microsoft-antispam-prvs*, as illustrated in the following example:

```
x-microsoft-antispam-prvs:  
<AM3PR04MB4028F8BB1D18D36001E6876D9E60@AM3PR04MB402.eurprd04.prod.outlook.com>
```

If an NDR message is generated for a legitimate message, it will include the signature header. When EOP processes the message, the header is recognized, and the NDR message is considered valid. However, if the received NDR message does not have the header, Exchange Online considers the message to be backscatter.

If you use EOP to protect on-premises mailboxes in a standalone configuration or a hybrid deployment, but EOP does not handle outbound mail flow, you should enable the NDR Backscatter feature. Go to the **Defender portal > Policies & rules > Threat policies > Anti-spam**, select the **Anti-Spam inbound policy (Default)** and click **Edit spam threshold and properties**. Under **Mark as spam**, toggle **NDR backscatter** to **On**. In on-premises configurations where EOP protects both inbound and outbound mail flow, you do not need to enable the NDR Backscatter feature because the *x-microsoft-antispam-prvs* header is added to all outbound messages automatically.

## Message Tracing

Most Exchange administrators know the following problem: a user calls the helpdesk to report, "Person X sent me a message a few hours ago, but I still haven't received it." Sometimes messages are misaddressed, the sender has not sent the email, or they are not delivered when expected, or the message was sent but never arrived in the recipient's inbox. For instance, a mail flow rule might forward the message to a different mailbox, or the message may go into the user's junk email folder instead of the inbox.

Message tracing proves particularly helpful to troubleshoot scenarios like the ones mentioned earlier as it allows you to figure out what happened to a message, like when it was delivered or why it was rejected, quarantined, or perhaps deferred. Exchange Online keeps message tracking data for 90 days. Today, you can trace message in several ways:

- Through the **Mail flow > Message trace** section of the EAC.
- Using PowerShell with the *Get-MessageTrace* and *Get-HistoricalSearch* cmdlets.

Exchange Online separates traces into recent messages (up to ten days old) and those over a longer timeframe (from ten to ninety days old). Recent message traces are done interactively, and you see the results on-screen. However, if you need to track messages older than ten days or if you need to create a report with extended information, you use a *historical search* instead. Unlike Exchange on-premises servers, message tracking information only exists online for a limited period before it moves into the reporting data warehouse. Historical searches run in the background, and the results are emailed to you as a CSV file once the search is complete. It may take several hours for a historical search to complete.

## Tracing Messages

To use message tracing in the Exchange admin center, go to the **Mail flow > Message trace** section. You can create new custom traces, choose from one of the pre-defined or previously saved trace reports and view the results of finished/pending traces. The pre-defined trace options are a great way to quickly start a trace you regularly use with the same options. Most of the time, however, you will create a new (custom) trace using one of the following parameters:

- **Sender and Recipient** allow you to specify who sent or received the message. If you need to specify an external sender's address in the recipient picker, type it in manually and click **OK**.
- **Time range**. By default, a trace is scoped to the last 48 hours. However, you can edit the scope to span up to the last 90 days. You can also provide a custom scope with specific start and end dates and times (within the last 90 days). Searches over ten days old are performed as background searches, and the results are emailed to you once they are complete.
- **Delivery status** allows the administrator to target messages based on what action was performed. Among other things, you can specify to search for quarantined messages, filtered as spam, failed, or messages that have yet to be cataloged with getting status. If you are unsure what happened to the message, the default selection of **All** works best.
- **Message ID**. Each message has a unique message ID. You can find the ID from the message headers to scope the message trace to a single message.
- **Direction** specifies if the message was sent (outbound) or received (inbound).
- **Original client IP address** is the IP address of the sender's messaging service/server.

When executing a historical or **extended report** search, you must also specify the following:

- **Report Title**. The subject of the email that is sent to the notification email address.
- **Notification email address** of the person to whom the report should be sent.

**Real-world:** Exchange Online automatically decides when to start a historical search. You can quickly distinguish between a regular search from a historical search when creating a new trace. When the text on the **Search** button changes to **Next**, a historical search is created instead, and you will have to wait for the results to be emailed to you. This is true for all traces for which you request an extended report, regardless of the date range.

## Viewing Trace Results

There are two ways to view trace results: interactively (when running a regular search) or through a CSV report (when running a historical or extended report search). The information exposed through the CSV files can be great for reporting purposes. The format of the file makes it easy to sort through the information and create custom views quickly. However, extended reports are restricted to including a sender or recipient or message ID. Standard searches can be time-based only with no other restrictions. On the other hand, the interactive results are generally more interesting for troubleshooting purposes for various reasons: they show you more information on the various events that apply to the message while in transit. In addition, you can quickly find related messages, making troubleshooting easy.

Each trace result details the status of the message and the actual message events. The events include information about the message as it made its way through the various filtering mechanisms in EOP. Although you can derive the same information from the raw message events, the way results are displayed on screen makes it easy to find information about whether a message was delivered successfully and, in case it was not, why not.

In addition to the message status, each trace has extra information in a more human-readable format. For example, it might tell you how to fix a problem when a message was not delivered successfully, or it will tell

you if a message was forwarded to another recipient. Figure 7-27 shows an example where a message goes to a mailbox that cannot accept the message. Note how the GUI makes it easy to find the status and cause of the problem and suggest a solution.

## Message Center Major Change Update Notification

Copy report text below Prepare and email extended report

Sender	Recipient
o365mc@microsoft.com	[REDACTED]

Received Processed Not delivered

**Status**  
Office 365 received the message that you specified, but couldn't deliver it to the recipient due to the following error:

**Error:** 550 5.1.10 RESOLVER.ADR.RecipientNotFound; Recipient [REDACTED] not found by SMTP address lookup

A non-delivery report (NDR) message was sent to o365mc@microsoft.com. The NDR might provide more details about why the email message wasn't delivered and how to fix the issue.

**How to fix it**  
Ask the sender (o365mc@microsoft.com) to follow the instructions in the NDR to fix this issue. The NDR might also include specific information for email admins. If the sender is unable to fix the issue, ask them to forward you the NDR and then follow the guidance for email admins.

**Message events**

Date (UTC)	Event	Detail
6/25/2021, 8:17 AM	Receive	Message received by: BY5... Message received by: BY5PR11MB4465.namprd11.prod.outlook.com using TLS1.2 with AES256
6/25/2021, 8:17 AM	Fail	Reason: [[LED=550 5.1.10 ... Reason: [[LED=550 5.1.10 RESOLVER.ADR.RecipientNotFound; Recipient [REDACTED] not found by SMTP address lookup];[MSG=];[FQDN=]; [IP=];[LRT=]]

Figure 7-27: Viewing trace results in the Exchange Admin Center

## Tracing Messages with PowerShell

Tracing messages in PowerShell is easy. The sole difference from the approach taken by the Exchange admin center is that you use different cmdlets to start a regular or historical search. A regular search, which can trace messages for up to ten days, is started using the *Get-MessageTrace* cmdlet. For instance, to view all messages from the past 48 hours, run the following command:

```
[PS] C:\> Get-MessageTrace -StartDate (Get-Date).AddDays(-2) -EndDate (Get-Date) | Select Received, SenderAddress, RecipientAddress, Subject
```

Received	SenderAddress	RecipientAddress
9 Oct 2018 08:16:39	michel@eightwone.com	tony.redmond@office365itpros.com
9 Oct 2018 08:14:43	newsletter@bloomandwild.com	deirdre.smith@office365itpros.com
9 Oct 2018 08:13:20	michel@eightwone.com	ben.owens@office365itpros.com...

Additional parameters are available for *Get-MessageTrace* to scope trace results, such as looking for messages sent by specific mailboxes.

In this example, we pipe the results to the *Out-GridView* cmdlet, which makes it easier to peruse the message trace information:

```
[PS] C:\> Get-MessageTrace -StartDate (Get-Date).AddDays(-2) -EndDate (Get-Date) | Select Received, SenderAddress, RecipientAddress, Subject | Out-GridView
```

An example script showing how to use the *Get-MessageTrace* cmdlet to report mail sent externally for selected mailboxes is [described in this article](#).

## Extra Detail in Message Traces

When you run a message trace in the Exchange admin center, Exchange Online automatically returns extra routing information with more details about what happened to the message while it was in transit. When using PowerShell traces, to get the same results, pipe the results from the message trace to the *Get-MessageTraceDetails* cmdlet as shown below:

```
[PS] C:\> Get-MessageTrace -StartDate (Get-Date).AddDays(-2) -EndDate (Get-Date) | Get-MessageTraceDetail | Select MessageID, Date, Event, Detail, Data | Out-GridView
```

## Historical Message Traces

The *Start-HistoricalSearch* cmdlet launches a historical search and is used similarly to *Get-MessageTrace*. For instance, to start a search for messages from a certain sender in the past 75 days and send the report to `admin@office365itpros.com`, you would use the following PowerShell cmdlet:

```
[PS] C:\> Start-HistoricalSearch -ReportTitle "Historical Search" -NotifyAddress "admin@office365itpros.com" -StartDate (get-date).AddDays(-75) -EndDate (Get-Date) -ReportType MessageTraceDetail -Sender Kim.Akers@office365itpros.com
```

JobId	SubmitDate	ReportTitle	Status	Rows
ef59-4710-81f3-f511e0bc2222	8 Oct 2018 16:14:04	Historical Search	NotStarted	0

The *ReportType* parameter controls how much detail is returned. For instance, to include the full routing details, the *ReportType* is changed to *MessageTraceDetail*. The results from the historical search are sent by email rather than displayed on a screen, so piping the output to the *Out-GridView* cmdlet will have no effect. The *Get-HistoricalSearch* cmdlet can be used to check the status of searches.

```
[PS] C:\> Get-HistoricalSearch | ? {$_.Status -eq "InProgress"} | Select SubmitDate, ReportTitle, Status | Format-Table -AutoSize
```

SubmitDate	ReportTitle	Status
8 Oct 2018 16:14:04	Historical Search	InProgress

With *Get-HistoricalSearch*, it is not possible to search for all messages in one search. You need to include a sender, recipient, or message ID.

# Transport Limits

The Radicati Group [Email Statistics Report for 2018-2022](#) estimates that over 3.8 billion people used email in 2018, with the number expected to grow to over 4.2 billion email users by the end of 2022. In total, these accounts send and receive roughly 281 billion messages per day. With so many people using email, it is no wonder that email is the most popular medium for sending unsolicited messages (spam).

As a result, Microsoft imposes several transport-related limits on its service to protect its service from those who would like to abuse Exchange Online by using it to send spam and to ensure that every tenant is treated equally. As you plan to use Exchange Online and EOP for your message routing, you should be familiar with the limits Microsoft imposes.

Without limits, a single user could, in theory, send hundreds of thousands of messages daily. As a result, the transport subsystem would consume enormous resources to process those messages and reduce its capacity

to process legitimate emails. To address this, transport limits are imposed at various levels and are the same for all tenants, regardless of the license plan you subscribe to. Table 7-5 lists the various limits imposed in Exchange Online. See [this page for the complete list of limits](#) imposed by Microsoft for other plans.

<b>Feature</b>	<b>Limit</b>	<b>Additional Information</b>
<i>Recipient rate limit</i>	10,000 recipients per day	To discourage the delivery of unsolicited bulk messages, Exchange Online has recipient limits that prevent users and applications from sending large volumes of email.
<i>Recipient limit</i>	500 recipients	The number of recipients you can add to a single message defaults to 500, but a value from 1 to 1000 can be set per mailbox or as a tenant-wide default.
<i>Message rate limit</i>	30 messages per minute	The number of messages the transport subsystem will process per minute, sometimes referred to as the throttling threshold, over SMTP client submission.
<i>Message size limit (Outlook)</i>	150 MB	The maximum size of a message when sent through Outlook.
<i>Message size limit (OWA)</i>	112 MB	The maximum size of a message when sent through Outlook Web App.
<i>Message size limit (Outlook for Mac)</i>	150 MB	The maximum size of a message when sent through Outlook for Mac.
<i>File attachments limit</i>	250 attachments	The maximum amount of attachments that can be added to a single message.
<i>Subject length limit</i>	255 characters	The maximum length of a message subject.
<i>File attachment size limit (Outlook)</i>	150 MB	The maximum size of a single attachment when sent through Outlook.
<i>File attachment size limit (OWA)</i>	112 MB	The maximum size of a single attachment when sent through Outlook.
<i>File attachment size limit (Outlook for Mac)</i>	150 MB	The maximum size of a single attachment when sent through Outlook for Mac.
<i>SMTP Authenticated Submission limit</i>	3 concurrent connections	Three concurrent connections are allowed to send email messages at the same time from the same mailbox. This limit typically impacts third-party email clients and devices such as multi-function printers configured to log in to a single mailbox. The mailbox the client or device authenticates into allows three concurrent connections as well as storing the items it sends in the Sent Items folder.
<i>Reply All Storm Protection</i>	10 reply-all messages to over 2,500 recipients in 60 minutes (default settings)	Further replies to the conversation are blocked for six hours. An NDR is sent to people who try to respond during this time, saying that the "conversation is too busy with too many people" and educating them not to use Reply-All. The number of recipients, responses, and block duration is <a href="#">customizable</a> . The 60-minute detection window is not.
Scanning limits for the content of attachments	1MB	The mail flow rule conditions enable you to examine the content of message attachments, but only the first 1 MB of the text extracted from an attachment is inspected. This 1 MB limit refers to the text extracted from the attachment, not the attachment's file size. For example, a 2 MB file may contain less than 1 MB of text, so all of the text would be inspected

Table 7-5: Transport limits for Exchange Online

In general, Microsoft does not grant exceptions to any of these limits. Although you can raise a support request to increase the limits, the chances of succeeding are slim. Instead, many of these limits can be worked around. A good example is the 10,000 recipients per day limit. It is common for large organizations to broadcast corporate communication messages to all users. If you have more than 10,000 users, you will not be able to send the message to everyone at once. Instead of adding individual recipients to a message, you should use a distribution group. Each distribution group can hold up to 100,000 recipients and is counted only as a single recipient.

Another example is an organization where the marketing department must send customers messages. At a rate of 30 messages per minute, 'only' 43,200 messages can be sent per day. Microsoft recommends using a third-party mass-mailing service for this purpose, such as SendGrid or MailChimp.

**Real-world:** The actual message size can vary from one client to another and is also different for messages routed outside Exchange Online. In the latter scenario, messages could grow roughly 33% because of extra encoding, effectively lowering the maximum size from 150MB to approximately 112 MB. The above limits also used to be much lower. Over time, Microsoft gradually increased the maximum supported message sizes, but they did not change the default maximum message size. As such, even a new tenant imposes a 35 MB message size limit for every user by default. An [excellent article](#) outlines how to determine a user's current configured limit and how you can modify that limit to a value within the boundaries of the supported maximum sizes described in Table 7-5.

# Chapter 8: Managing SharePoint and OneDrive for Business

**Juan Carlos González**

SharePoint Online and OneDrive for Business are core workloads giving tenants the ability to store documents and information and build modern workplace solutions and services on top of both platforms. This chapter focuses on describing how to manage both services (collectively referred to by Microsoft as **ODSP**) using their admin centers, PowerShell, and available APIs. We also describe some basic SharePoint concepts and points to consider when migrating from SharePoint on-premises and on-premises file servers to SharePoint Online and OneDrive for Business. Finally, we cover how applications and services such as Microsoft Lists, Microsoft Search and Microsoft Viva use SharePoint as their platform.

## SharePoint Online

[SharePoint Online](#) is a core Microsoft 365 service used by more than 200,000 organizations worldwide for Intranets, Team Sites, and Content Management among other scenarios. It is also a key building block for other workloads and services such as Microsoft Teams and Planner. In April 2022, Microsoft said that organizations create 8 million new active sites and generate 100 petabytes of SharePoint Online content monthly. Much of SharePoint's success is driven by a thriving developer community and the many applications they create to run on top of SharePoint. Some of those applications are available for SharePoint Online and more will come, which in turn creates further opportunities for tenants to exploit the platform.

Organizations can use SharePoint Online as a standalone service to build Intranet, Extranet, or other types of portals, or to deliver content management services to other applications. Microsoft 365 Groups and Teams are great examples where applications include SharePoint Online in collaborative experiences:

- **Teams:** Each team has its own SharePoint site. Every regular channel inside the team has its own folder to store messages and files shared between team members. Private and shared channels each have a separate SharePoint Online site restricted to the membership of the channel.
- **Planner:** Stores attachments for tasks in the SharePoint Online site belonging to the underlying Group.

Managing documents and other files is the common thread running through SharePoint Online. In fact, SharePoint has returned to its roots and moved away from an attempt to be an application platform to concentrate on what it excels at. The Microsoft 365 substrate together with the Graph and its growing collection of REST-based APIs is the platform; SharePoint Online contributes the ability to manage large collections of documents and metadata in that platform and offers native extensibility through building blocks such as the SharePoint Framework (SPFx), PnP extensibility model, Site Scripts and Site Templates, Microsoft Lists, Power Apps or Power Automate. SharePoint Online is a critical piece of the overall story. Any deployment that seeks to move workload into the cloud must incorporate SharePoint Online into the plans to extract full value from its cloud investment.

Although some feel that the importance of SharePoint Online is less than Exchange Online sometimes appears to be within the Microsoft 365 ecosystem, they are wrong. SharePoint Online is a critical part of Microsoft 365 and Microsoft 365 could not function without SharePoint Online. It is as simple as that.

**Sites and Site Collections:** In SharePoint on-premises and the early days of SharePoint Online, it was common to discuss information architectures based on creating several site collections or several subsites under a single site collection. Today, thanks to the influence of applications like Teams and Groups, most site collections consist of one site and Microsoft has moved away from talking about site collections in favor of sites. Although a site collection is the more correct term and still appears in the documentation, a site is equally valid and is, in most cases, what you deal with.

## Basic SharePoint Online Concepts

Those who have not used the on-premises version of SharePoint are probably unaware of the basic concepts that underpin the operation of the application. Here is a quick guide to the major SharePoint terms and components.

### Sites

[Since 2016](#), Microsoft has modernized SharePoint and delivered change over several waves of enhancements. Modern team sites and communication sites, Hub sites, modern site pages, new SharePoint start page, or Power Apps and Power Automate integration are some examples of the enhancements introduced.

A **Site** is the basic building block for SharePoint Online and is the place where content is kept and managed. To enable easier administration and to ensure that sites that have a common purpose are grouped together, sites are organized into **Site Collections**. Within Microsoft 365, the rule is to use single-site collections. For example, the sites used by Groups (including those used by Teams and Yammer) are single-site collections. This book refers to site collections as sites.

Sites are the entry point to the SharePoint Online start page. SharePoint Online decides what sites appear on a user's start page based on the user's recent activity. Signals stored in the Microsoft Graph gathered from user interaction with SharePoint Online team sites and group document libraries (including those used by Teams) are the basis for suggested sites. From the home page, you can create new sites (modern team sites or communication sites) and news items posted to any site the current user can access.

Each site can have its own security, layout, theme, navigation, regional settings, and custom search settings. A site can also have workflows built-in to ensure that the information held on the site is processed in a specific manner. The latest form of sites is known as modern SharePoint Online sites, including "group-enabled" team sites, modern team sites, and communication sites. A "Group-enabled" site is associated with a Microsoft 365 Group, which is responsible for the management of the site membership. [Communication sites](#) are mobile-friendly and configured to communicate and dynamically display information. Their role is to serve up information to users drawn from different sources available to SharePoint. Finally modern team sites are similar to "group-enabled" team sites but without an underlying Microsoft 365 Group.

A Home site is a particular kind of Communication site bringing together news, events, embedded video and conversations, and other resources to deliver an engaging experience that reflects your organization's voice, priorities, and brand. Currently, there is a limitation of having a single Home site per SharePoint tenant.

### Hub Sites

Communication sites present news and visually rich content, making them the best choice for sites around a single topic. The list of web parts available for Communication sites and the pages are mobile-friendly. They are a great solution for building real-world Intranets. Hub Sites provide the glue to group modern sites with a common purpose which share elements such as branding or navigation.

[Hub sites](#) integrate multiple Communication, Modern Team sites, and even classic sites together to build a real Intranet or general-purpose portals such as employee portals, division portals, or department portals. For example, it is possible to have several enterprise departments, each with its Team site for collaboration, together with multiple Communication sites with news and updates, interconnected to become an information gateway, without having to create the sites as a single hierarchical collection.

**Hub Site Limits:** The [number of Hub Sites that can be created by](#) a tenant is currently limited to 2,000.

A Hub site can aggregate news, events, and highlighted contents from all its associated sites and fulfill some other valuable functions: it adds consistent branding across all sites and a common menu, making it easier to navigate between the sites. Each hub site includes cumulative analytics for its connected sites through the site usage page. Users can search within the complete Hub site components and can use the digest option to organize selected news stories to go out as an email summary including images and links.

## Tenant Home Site

You can designate a Communication site as the Home site for the tenant by running the *Set-SPOHomeSite* cmdlet or through the [Home site setting](#) in the SharePoint Online Admin center. The site can be registered as a hub site but can't be associated with a hub. After executing the cmdlet, access to the Home site is available in the SharePoint mobile App. In addition, the Home site is automatically set to be an organizational news site and configured for organization-wide search. You can run the cmdlet again to switch the Home site to a different site.

## Modern Information Architectures for SharePoint Online

Before the arrival of modern SharePoint Online sites, the typical SharePoint deployment followed a classic pattern based on a hierarchical structure of sites and subsites with inherited permissions, navigation, and common branding. This architecture pattern is used extensively in the on-premises world and many organizations brought the approach to SharePoint Online. While popular, architectures based on this pattern can be difficult to maintain, inflexible, and sometimes suffered performance problems., Microsoft introduced a different information architecture based on single-site collections that can be associated with a Hub site (see the information about Hub sites later in this chapter). The new approach has a flat structure that makes it easy to share navigation, branding, and other elements. It is known as a *Flat Information Architecture* and is the [de facto standard promoted by Microsoft](#) for the design of SharePoint Online deployments.

## SharePoint Search

SharePoint Online uses Microsoft Search Service to create content indexes from the files kept on sites. The Search box on the SharePoint Online home page allows users to find content using different scopes (Sites, Files, People, and News). In the case of the Files and Sites scopes, Microsoft Search returns all the sites (including OneDrive for Business sites) and files and/or folders the user has access to that contain the search term. News and people scopes provide results of any news containing the search term and any user whose user profile includes that term. The way that Microsoft Search displays results is like the approach taken by Delve, with the difference being that the results of SharePoint searches can include sites, documents, people, and news while the results from Delve searches provide references to "boards" and "people." Each site also has a search capability, but in this case, the scope of the search is limited to the site.

## Pages

Modern pages are one of the key building blocks of any SharePoint Online site. They are fast, easy to author, and support rich multimedia content to make sure that they look great on any device, in a browser, or within the SharePoint mobile app. Examples of how to use modern Sites and pages are showing status and trip reports, guides, and frequently asked questions. SharePoint Modern pages are built with modern Web Parts that can be customized based on business needs, supporting the addition of documents, videos, images, site

activities, Yammer feeds and increasingly more items as Microsoft releases new Web Parts. In addition, the user experience of adding content to modern pages is different: just click the plus sign and pick a Web Part from the toolbox to start customizing a modern page. Using SPFx, developers can build custom Web Parts that show up directly in the toolbox. SPFx also supports the creation of SPFx extensions to customize specific areas in SharePoint modern pages such as the page footer and page header, or modern list and document libraries, by placing new actions in the list/document library command bar or the item/document menu or customizing Microsoft Search in SharePoint Online. Microsoft Viva Connections uses SPFx through the deployment of out-of-the-box Adaptive Cards Extensions (ACE) or custom ones to the Viva Connections dashboard.

## Apps

Sites can include **Apps** (or Add-ins) and Web Parts to expand the functionality available through the site. If enabled, site administrators or users with full control permission can add custom apps developed by the organization or by third parties to a site using the SharePoint store.

**Document libraries** and **Microsoft Lists** are very common examples of Add-ins used with SharePoint sites. Document libraries manage documents belonging to the site. Microsoft Lists are a great way to [create business Apps](#) to share, store and track information of interest either for individual (personal Lists) or workgroup purposes.

On an ongoing basis, Microsoft adds new features to improve the overall user experience when working with Microsoft Lists and Document libraries. Examples include:

- Allowing users to create a new list from scratch, create a new list from an existing list or template, or create a list from an Excel Table.
- Adding a new rich-text editor for text fields in lists and document libraries.
- Conditionally show or hide columns in a list or a document library form based on a value in another column.
- Being able to customize list and document library forms using JSON code.

## Metadata

Document management systems depend on metadata to organize and find information. Although users do not need to add metadata to documents (apart from a title and file name) when they add them to a SharePoint document library, it is a good idea to coach people to pay attention to the titles, tags, and comments that they can add to documents, plus any other metadata considered necessary for certain types of documents. The big pay-off is that documents with good metadata are easier to find with SharePoint Search, Delve, and eDiscovery searches.

## File Versioning

Versioning is a useful feature that does not exist for documents stored on local drives or file shares. File versioning allows you to keep multiple versions of documents and revert to an earlier version if necessary. For example, a file might become corrupt because of a hardware or software problem or the files in a document library might be encrypted by a cyberattack. File versioning supports many SharePoint features, including:

- Users can restore a previous version of a document to become the current version with the Version history option in the SharePoint Online and OneDrive for Business browser clients. Restoration of a previous version is also possible for any file synchronized with the OneDrive sync client through the Version history option in File Explorer, macOS Finder, and OneDrive Activity Feed.
- Microsoft 365 Enterprise Apps (desktop) and Online applications (Word, Excel, and PowerPoint) use file versioning for document AutoSave. These apps can open a previous version of a document and compare its content against the current version. Apps can also restore a previous version.

- The continual synchronization of changes made to documents permits real-time updates for co-authoring of Office documents.
- SharePoint Online and OneDrive for Business can restore document libraries to a point in time within the past 30 days.

[SharePoint Online supports the concept of major and minor versions](#) while OneDrive for Business only supports major versions. However, there is no technical difference between a major and minor version of a document. Both represent updates to files and the difference between the two exists in how a user regards the number and importance of changes they made in a version. By default, SharePoint Online and OneDrive for Business libraries support [a minimum of one hundred major versions](#). You can't disable versioning in library settings through the versioning settings page for a given Document library and you must choose a value between 100 and 50,000 for the number of versions kept. To use versioning on lists, you must enable it first.

Keeping hundreds of versions of documents might seem excessive, but if those versions are not present, it might not be possible to recover important documents to a specific point in time. Organizations that don't want to enable minimum versioning must run *Set-SPOTenant* to disable the feature. To disable the feature, download the latest version of the PowerShell module for SharePoint Online and run the command:

```
[PS] C:\> Set-SPOTenant -EnableMinimumVersionRequirement $False
```

## AutoSave

The AutoSave feature in Microsoft 365 Apps (Word, PowerPoint, and Excel) automatically captures changes made to documents stored in SharePoint and OneDrive for Business libraries. The idea is that a user can work on a document without having to worry about saving it because any change they make is saved to the server on an ongoing basis. The feature isn't supported for files stored on local or shared drives. AutoSave uses versioning to capture edits made using the Office desktop applications and online apps. AutoSave is unsupported for non-Office files because only the Office apps can synchronize small differential changes back to SharePoint to create new versions on the server.

New versions aren't generated for each change made to a document. Sets of changes are gathered by the server and are periodically committed to create a version. During a session, a new version might be generated every ten minutes or so, depending on the volume and type of edits in a document. For instance, pasting a large amount of text into a document usually forces Word to create a new version. If the app loses connection to the server, the server creates a new version to make sure that no data is lost.

A long editing session can easily generate 20-30 versions of a document. In some cases, SharePoint Online keeps many more versions. For instance, the chapter files for this book typically generate several hundred versions over the course of a year. The storage requirement for versions is mitigated using shredded storage in SharePoint Online to capture and store versions efficiently. The BLOBs used for document storage are broken up into "shreds" (roughly 64KB). As users update documents and create versions, SharePoint only needs to update the affected shreds. When documents are opened, SharePoint combines the shreds and delivers the complete file.

Continuously saving documents as changes occur makes the Office co-authoring feature more seamless. Updates made to a file by one user are synchronized to the server and back to the copies open by other users within seconds. Co-authoring is possible without AutoSave, but users must manually refresh their copies of documents to see changes.

You can [change AutoSave options in the Microsoft 365 Apps or update group policy settings](#), but you cannot affect how the cloud Office apps save document edits.

## SharePoint Online Quotas and Limits

Many of the [SharePoint on-premises boundaries and limits](#) are present in its cloud counterpart, but there are also [some specific limits](#) that only apply to SharePoint Online. For instance, a tenant can create up to two million sites and a single site can store up to 25 TB of information.

On-premises SharePoint servers use SQL databases to store site data. SharePoint Online also uses SQL (or rather Azure SQL), but the management of storage is much simplified in that Microsoft takes care of this for tenants. The storage limit for a tenant is calculated based on the Microsoft 365 licenses owned by the tenant plus any added storage the tenant buys from Microsoft. Briefly, the storage quota for a tenant is:

*1 TB plus 10 GB per licensed user plus purchased storage*

Thus, a tenant with 200 licensed users has a SharePoint Online storage base of 3 TB. If this is insufficient, the tenant can buy an unlimited (in practice) [amount of extra storage](#). The added monthly charge is based on the amount of added storage. If your storage requirements decrease, you can change the amount of added storage or cut it altogether. In addition, users with a frontline worker license don't add any storage to the available pool for a tenant.

The Export option in the Active Sites section of the SharePoint admin center downloads a CSV file which includes storage information for each site. If you prefer, you can write your own version with PowerShell, perhaps using [this sample script from GitHub](#).

## Managing SharePoint Online

The management of SharePoint Online follows the same approach as other workloads, through a dedicated portal and PowerShell. This section describes how to manage SharePoint using both approaches.

### The SharePoint Online Admin Center

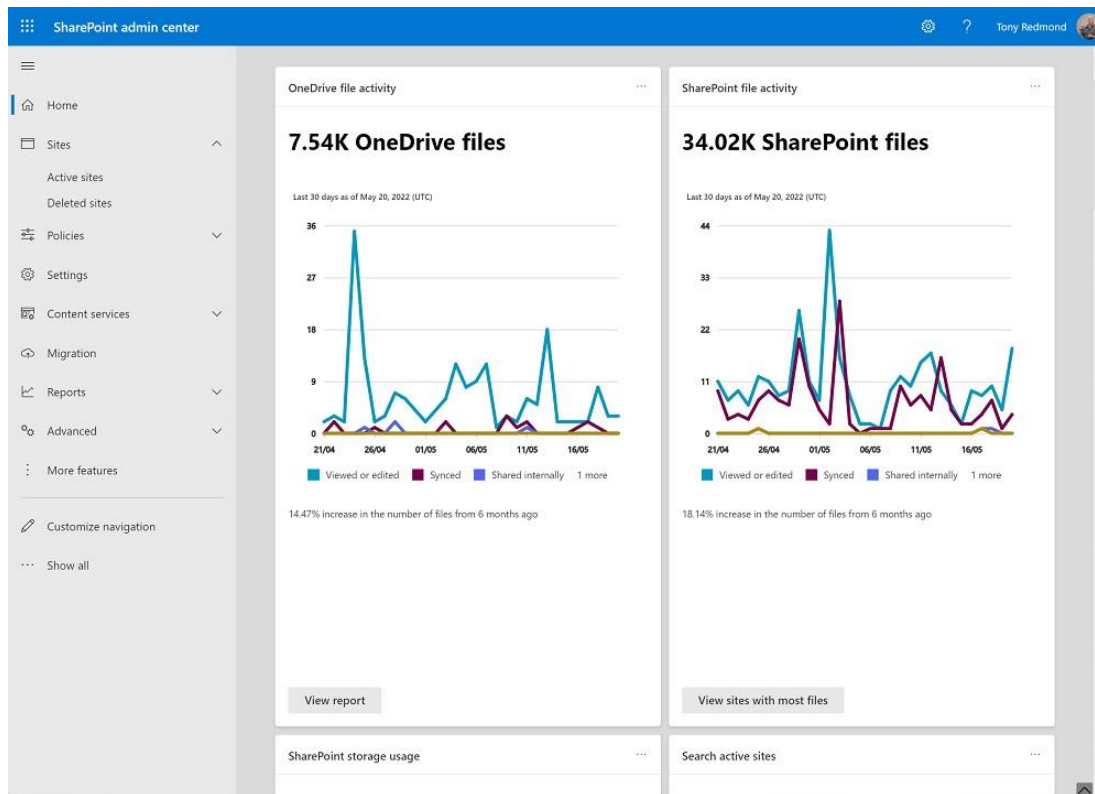

Figure 8-1: The SharePoint Online admin center

The SharePoint Online admin center (Figure 8-1) is the portal for administrative access to SharePoint Online and OneDrive for Business. To access the portal, select **SharePoint** from the **Admin Centers** section in the

Microsoft 365 admin center, or type the URL *https://[tenant]-admin.sharepoint.com* into a browser. Note that the "-admin" part in the SharePoint admin center is critical as this tells SharePoint that you want to access the administrative portal instead of sites.

The SharePoint Online admin center displays site information in a list view that allows the administrator to apply filters, add extra columns to expose information such as the sensitivity label assigned to sites, or find sites connected to a Microsoft 365 Group. Site management in the SharePoint admin center includes an option to export site data to a CSV file. The SharePoint admin center shares the same look and feel with other Microsoft 365 admin centers. Along with site management, the SharePoint admin center includes features such as displaying a summary of the SharePoint activities in the tenant and relevant messages from the Message Center and the Service Health status.

The integration of Groups and SharePoint team sites means that when Microsoft 365 Groups are available in a tenant, when a new team site is created, SharePoint creates a new Group to manage site membership. During group creation, the provisioning process creates a mailbox to hold a shared inbox and the Group calendar, a OneNote notebook, a Planner Plan for task management, and a SharePoint team site. Each Group gets a Modern home page, document library, lists, and business apps. Management of group membership is possible using a variety of interfaces, including PowerShell and the Microsoft 365 admin center. A group-enabled site can also be linked to Teams. If you create a team for a site, you can also add site resources such as pages or lists as tabs in the General channel of the new team. Additionally, managing modern team sites lines up to a great degree with the administration of Microsoft 365 Groups by following usage guidelines, naming conventions, and classification, meaning that there are some site administration tasks that team sites rely on that are controlled within the SharePoint admin center (like storage quota or the ability to adhere to a custom site provisioning experience) and some others through the Microsoft 365 admin center; this divergence might be addressed in the SharePoint admin center.

**Classic SharePoint admin center features availability:** Some classic SharePoint admin center features are still available in SharePoint Online, but Microsoft has started retiring some of its components. Initially, the following classic pages are going to be retired: Site collections, Sharing, Access Control, and Geolocation.

## Admin roles to Manage SharePoint Online

To administer SharePoint Online, several administrator roles can be assigned to users:

- The **Global Administrator** role. When Microsoft 365 provisions a new tenant, SharePoint Online creates several default sites and adds the Global admin as the primary administrator for each site.
- The **SharePoint Online Administrator** role. Accounts holding this role have access to the SharePoint Online admin center and can manage settings for SharePoint Online and OneDrive for Business.
- The **Global Reader** role gives read-only access to all the information and settings available in the SharePoint admin center.
- The **Site administrator** is assigned to users by a SharePoint Online administrator or a global administrator to give the assigned users permissions to manage a specific site. A single site can have several administrators, but only one primary administrator. Group owners are automatically added as Site administrators for sites that are group-enabled, including those used by Teams. The SharePoint Online administrator can assign permissions to the primary site administrator when creating a site and can add more administrators for the site afterward. Site administrators do not have access to the SharePoint Online Admin Center. A site administrator can be added to a site in three different ways: from the Active site list in the SharePoint admin center, PowerShell, and the site settings page.

## Managing Active Sites and Deleted Sites

The Active sites list in the SharePoint admin center manages active (not deleted) sites. To see the details of a specific site, select it in the list and click the “i” button or the site name to display the site details panel with site usage statistics and site properties (Domain, URL, Template, etc.). Administrators can change the default All Sites list view at any point to use one of the default views (like Microsoft 365 Groups sites) or a custom view. For a selected site, the following management actions are available:

- **Edit:** Allow administrators access to the site details panel where they can update different site settings.
- **Permissions:** Depending on the site type, you can change/modify Group owners (Group sites) for the selected site or change/modify primary and secondary site admin (Classic sites and Communication sites).
- **Hub:** You can promote the selected site to become a [Hub site](#) (“Register as hub site” option) or to join the site to an existing Hub site (“Associate with a hub site” option). If the site is already a Hub site, a SharePoint admin can change the Hub site settings (Display name and the users that can associate new sites to the Hub) or unregister the site as Hub site. Finally, if the site is already joined to a Hub site, the Hub site association can be changed using the “Change hub association” option.
- **Sharing:** This option configures the external sharing capability for the site (Sharing options for SharePoint sites are detailed later). From the sharing setting panel, it is also possible to access the global sharing settings page.
- **Delete:** It deletes the selected site by moving it to the site recycle bin.
- **Storage:** If manual quota management is enabled, you can modify the storage quota for the site selected.

If the site selected is the root site in the tenant, a “Replace site” option is available. The organization can replace the root site with any other site in the tenant if that site is a team site or a communication site. The replacement site cannot be a hub site or connected to a Microsoft 365 group.

Logically, to create SharePoint sites, use the **Create** button. Currently, it’s possible to create modern team sites (with or without associates Microsoft 365 groups), communication sites, a content center site for SharePoint Syntex, and (but not recommended) classic sites. In the Active Sites section, you can execute the following bulk edit options:

- **Sharing:** Configure the same sharing option for the selected sites.
- **Hub associations:** Associates the selected sites with a Hub site in the tenant.
- **Delete:** Deletes the selected sites and move them to the Sites recycle bin.

When you select a site from the Active sites view, SharePoint opens the site details panel to display information about the site in four sections:

- **General:** Displays several modifiable site properties (Site name, Site Url, Hub association, and Storage limits) along with some that are not (site template, if the site connects to a Microsoft 365 Group, domain, site description, creation date, and who created the site). If the site is a Hub site, you cannot edit the Hub association here. For team-connected sites, a banner flags the site as “Connected to Microsoft Teams.” If the team has any channel sites (used for private and/or shared channels), the panel shows the number of channel sites together with a link to access additional details of those sites. SharePoint administrators cannot access the content of a channel site unless they are a member of the private or shared channel owning the site.
- **Activity:** Gives information about recent site activity such as Last site activity, files stored for the site, the number of views in the last 30 days, the number of files viewed/edited in the last 30 days, and storage usage. The statistics displayed here are usually two or three days old.

- **Permissions:** Gives the same information about site permissions as shown in the “Permissions” action in the Active sites list together with lists of the membership of the default SharePoint Groups in the site (Owners, Members, and Visitors).
- **Policies:** Change the Sharing settings of the site or assign a sensitivity label to the site. Before you can assign a sensitivity label with container management settings to SharePoint sites, the labels must exist and be published to users to allow them to apply the labels to sites.

Hovering over the name of a user (on the Active sites list or in the details panel) lets you see details about the user. An edit link is available in some sections to allow admins to change site properties.

Deleted sites in the tenant are listed in the Deleted sites section in the SharePoint admin center. An administrator can select any deleted site and restore it using the “Restore” option. To permanently remove a site, just click the “Permanently delete” option.

**Renaming Sites:** The SharePoint admin center includes the ability to partially change the URL of a site by renaming the site. This is done by selecting the site and editing the name in the site details panel. A detailed overview of the process to rename a site [is explained here](#). You can also rename site URLs with PowerShell using the *Start-SPOSiteRename* cmdlet. Be aware that some consequences of site renaming exist, as [explained in Microsoft’s documentation](#).

### Controlling Site Creation

It is possible to allow users to create new Sites Collections or restrict creation to only administrators. Because of the tight connection that Team Sites have with Microsoft 365 Groups (including Teams), this is not a simple matter as you must consider whether you want users to be able to create sites, group-enabled sites, or both.

The basic control over Site creation is achieved by showing or hiding the Create site command on the SharePoint home page of the root site. This is the button that invokes the Create Site wizard. A SharePoint tenant setting controls whether the button appears on the page for all sites. To access the setting, open the SharePoint admin center and then **Settings**. On the Settings page, click on **Site creation** and then simply switch on/off the **Let users create new sites** option.

### Creating a Group-Connected Team Site

If the SharePoint settings for a tenant allow the creation of group-connected sites and the user can create Microsoft 365 Groups, the team site creation process creates a group. The new group holds the membership for the site and the Microsoft 365 Groups membership service is used to allow site members access to group resources.

Unlike the creation process used by OWA, Outlook, PowerShell, or an Admin console, SharePoint creates the new team site at once rather than waiting for the first user to access the site. In effect, this is the opposite of what happens when OWA or another email client creates a new group, where Exchange Online creates the group mailbox first to allow conversations to occur and notifications to go to new group members. After SharePoint creates the new group object in Azure AD, a process of forwarding directory synchronization makes the existence of the new group known to Exchange Online and forces the creation of the group mailbox. While this process proceeds, the user can build out the contents of the SharePoint team site with new lists, document libraries, a customized home page, and so on. The same creation process to set up a new team site and group occurs when a user invokes this choice from OneDrive for Business.

**Connect existing SharePoint Team Sites to new Microsoft 365 Groups:** Existing SharePoint sites, including classic sites, can be connected to a new group (or “groupified”) using *the Set-SPOSiteOffice365Group* cmdlet, CSOM API, or using the **Connect to new Microsoft 365 Group** feature available in site settings options. When this happens, the existing content, hierarchy, and permissions for a site stay intact, and SharePoint Online connects the site to a new group and populates with the group membership using the existing site membership. The owner can adjust the group membership after

creation. A tenant or SharePoint Online Administrator can disable this option by selecting the option **Prevent site collection administrators from connecting sites to new Microsoft 365 groups** in the **Settings** page in the classic SharePoint admin center. Microsoft [gives detailed information](#) about what SharePoint sites can be connected to a new Microsoft 365 Group, a [scanner tool](#) to analyze if existing SharePoint sites are suitable to be connected to Groups, and PowerShell scripts to enable modern features in the Sites and configure group membership.

### Settings and Permissions for Group-enabled Sites

When a new group-enabled team site is created, SharePoint creates a team site to host the document library and shared notebook for the group. The gear (options) menu for a site reveals the Site Information panel used to customize the details published to users about the site as well as its classification, or label defining the importance of the information held in the site and the Hub site association in case the site is not a Hub itself. Also, the owner can access the Site Permissions panel and set the desired level of access for different member types.

The default configuration for a group-enabled site is that group owners have SharePoint full control permissions over the site, while group members have SharePoint Edit permissions. If the site is public, every account in the tenant excluding external users has SharePoint Edit permissions. Amend the permissions for the site to restrict access as needed but be aware that because you are working with Microsoft 365 Groups rather than individual user accounts (as is the case for on-premises SharePoint or classic sites), you should take care to ensure you do not interfere with the ability of group members to access the resources available to the group, or for group owners to manage the group. It is also possible to select an individual user account and give them full control of the site. This permission is a SharePoint permission over the team site and does not make the user an owner of the group.

One of the permissions you can assign to a site is "Share Site Only" access, which means that the owner can give someone access only to the SharePoint resources instead of all the resources belonging to the group. Also, it is possible to assign a user read-only access to the site, which removes their ability to edit or remove data from the site (they might still be able to share files from the site). Assigning read-only access to users is a good approach to take for sites holding information (like HR documents) and it is necessary to make the site content generally available.

Apart from the ability to set access to site control through these settings, it is unwise to try and use traditional SharePoint access control over team sites used with groups because these controls expect to deal with individual users rather than when an identity is shared by group members.

### Hub Sites

A Hub site is a modern team site, or a communication site registered as a Hub using PowerShell, or a site converted to be a Hub site using the "Register as hub site" option in the SharePoint admin center. [Registering a hub site with PowerShell](#) can be done with cmdlets from the SharePoint Online module or PnP cmdlets (we discuss how to manage SharePoint Online with PowerShell later). To use the following example, you must use the latest version of the PnP module. The code opens a connection to the tenant and then creates a team site, elevates it to a Hub site, and associates other sites with the Hub.

```
[PS] C:\> Connect-SPOService -Url https://<TenantName>-admin.sharepoint.com
Connect-PnPOnline -SPOManagementShell # Will ask for the site URL
New-PnPSite -Type TeamSite -title "New SiteColl" -alias "NewSite" -Description "New SiteColl"
# Create a new Site
Register-PnPHubSite -Site https://<TenantName>.sharepoint.com/sites/NewSite # Register the SiteColl
as a Hub site
New-PnPSite -Type TeamSite -title "Sub-SiteColl" -alias "SubSite" -Description "Sub-SiteColl"
# Create a sub-sitecollection
Add-PnPHubSiteAssociation -Site https://<TenantName>.sharepoint.com/sites/SubSite -HubSite
https://<TenantName>.sharepoint.com/sites/NewSite # Associate the subsite to the Hub site
```

Associating a site with a Hub site is a task that only site administrators and site owners can do. Hub owners can manage visitor permissions for the Hub site itself and sites joined to the Hub. This feature, off by default, can be enabled by a Hub owner through the Site permissions panel for the Hub site. When enabled, a new SharePoint Group with read permissions is created in the Hub site and Hub owners can add the users, Groups and security groups that later can optionally be synchronized to any Site joined to the Hub. The synchronization of visitor permissions from the Hub site to a site joined to the Hub must be explicitly done for each site.

A [Hub site can be associated with another Hub site](#) as a way to expand search results across multiple Hubs in an organization allowing in fact to define information architectures with more than two levels deep. Hub to Hub association is a very simple process that can be done in the SharePoint admin center:

- In the active sites list, select an existing Hub site.
- Edit the Hub settings through the Hub settings panel.
- In the **Parent hub association** field, select the Hub to associate with.
- Save the changes.

Some limitations exist for Hub sites: there's no workflow around the publishing process, anyone who has edit permissions for a site can change any element of that site, and any new story pushes older ones down the stack, making it impossible to create a "Most important" news that stays always at the top. Additionally, Hub sites cannot be nested, limiting their potential as well, and they cannot deal with multiple languages. It is foreseeable that Hub sites will mature in the future because they are ongoing work.

### SharePoint Spaces

SharePoint Spaces creates mixed reality experiences on SharePoint sites. When enabled on a site (go to the Site settings page and enable the Spaces feature on the Sites features page), users can create spaces by defining a structure, background, and theme. The next step is to add Web Parts to visualize 3D objects, 360-degree images, videos, 2D images, and text. Once a space is ready, it can be viewed in a web browser or with a mixed reality headset.

### Modernization of Classic Sites

Although Microsoft introduced modern sites, it's still common to find classic sites in use. Microsoft recommends that tenants upgrade classic sites to take advantage of modern site technology. To help this modernization, Microsoft and the SharePoint community have released tools to speed up the upgrade process:

- Microsoft automatically updates any classic site with a home page that isn't customized with a modern page.
- The [SharePoint Modernization Scanner](#) is a tool originally built by the PnP Community to identify the work that must be done to modernize sites.
- The [Enable-SPOCommSite](#) cmdlet (in the SharePoint Online module) converts a classic team site (STS#0 template) that meets the requirements described in [this link](#) into a Communication site.

### Managing Performance for SharePoint Sites

A key factor in the success of any SharePoint site is achieving good performance when navigating across pages on a given site. To optimize performance in SharePoint sites, two out-of-the-box tools are available:

- [Site performance page](#): is accessible by Site owners and editors through the site settings menu. This page provides access to the Page Diagnostics for SharePoint tool that identifies any performance issue present on modern SharePoint pages and suggests actions to address issues found. Page Diagnostics for SharePoint tool uses a browser extension available for Microsoft Edge and Google Chrome.

- [SharePoint Portal Launch Scheduler](#): a feature to launch specific SharePoint sites that are expected to receive high volumes of traffic using a phased deployment. The tool also includes, if needed, an automatic redirect for existing sites. The SharePoint Portal Launch Scheduler is available through the `New-SPOPortalLaunchWaves` cmdlet.

## Managing Access Control

The SharePoint admin center includes settings through the Access control policies page that can be used to control access to SharePoint Online sites and OneDrive for Business accounts:

- **Unmanaged devices**: Settings to control how unmanaged devices can access SharePoint sites, OneDrive for Business (ODFB), and information stored there. Access control to SharePoint Online and ODFB is done through the creation of conditional access policies, which require an [Azure AD Premium Subscription](#). Among other settings, these policies can exert control over access from devices that are not compliant or joined to a domain (unmanaged devices). By default, SharePoint Online and OneDrive contents are accessible from unmanaged devices but it's possible to configure limited access or even block access through Azure AD conditional access policies, including the use of authentication contexts with sensitivity labels. You can also apply conditional access policies at the site level as explained in [this link](#). The Identities chapter contains examples of how to process unmanaged devices in conditional access policies.
- **Idle session sign-out**: Disabled by default, [this setting](#) is a mechanism to first warn and then sign out users on unmanaged devices if they have been inactive for a period and they don't opt to stay signed in when they sign into SharePoint Online, OneDrive for Business, or Microsoft 365. Two settings can be configured when this setting is enabled: the idle session period (15 minutes minimum, 24 hours maximum) and the warning notice (one minute minimum, 30 minutes maximum). Idle session timeout can also be configured running the `Set-SPOBrowserIdleSignOut` cmdlet. For example, this command enables a session timeout and sets a warning period of 45 minutes (2700 seconds) and a forced sign-out after an hour (3600 seconds). The timeout values apply to both SharePoint Online and OneDrive for Business sessions.

```
[PS] C:\> Set-SPOBrowserIdleSignOut -Enabled $True -WarnAfter (New-TimeSpan -Seconds 2700) -SignOutAfter (New-TimeSpan -Seconds 3600)
```

- **Network location**: When enabled, it lists the IP addresses from which access to SharePoint and ODFB is allowed.
- **Apps that don't use modern authentication**: Enabled by default, the setting blocks access to SPO from Apps that don't use modern authentication. Office 2013 or earlier clients are examples of Apps that don't use modern authentication and can pose a potential security problem for the information stored in SharePoint Online. In general, it's recommended to use this setting to block access for older clients.
- **Limit OneDrive access**: This setting limits the use and access of OneDrive for Business to users in specific (up to 10) security/Microsoft 365 groups.

## Managing Global SharePoint and OneDrive Settings

These Global Settings are managed through the Settings section in the SharePoint admin center:

- **Default admin center**: Toggles the default admin center for SharePoint Online. If the setting is on (it's off by default), the SharePoint admin center is opened.
- **Home site**: Allows to select an existing site to be set as Home site in the tenant. The site chosen can be removed at any point and replaced with a different site.
- **Notifications**: Controls if users of the SharePoint mobile app receive notifications about site activity.
- **Pages**: This section allows administrators to change global settings for creating and commenting on modern SharePoint pages. By default, both settings are enabled.

- **Site creation:** In this section, configure the managed path and time zone to be used when a new SharePoint site is created and if end users can create sites from the SharePoint home page.
- **Site storage limits:** Defines how the available SharePoint storage is managed. Two options are available: Automatic and Manual.
- **Link to the Classic settings page:** Gives access to several other settings from the classic SharePoint admin center.
- **Stream:** Defines the default destination for the Stream app launcher tile. There are three possible destinations to choose from:
  - Automatically switch to Stream (on SharePoint) when recommended: This is the setting configured by default and it means that Microsoft controls what version of Stream users access through the app launcher
  - Stream (on SharePoint).
  - Stream (Classic).

OneDrive settings that can be configured in this section are explained later.

## Managing Content Services

The content services section in the SharePoint Admin Center manages and publishes Content Types and managed metadata for a SharePoint Online tenant.

### Term Store

The Term Store is a central location to [create and store taxonomies, which](#) can be used in three ways:

- Create manage metadata fields that allow to classify a document or a list of items through a term that is part of a specific taxonomy.
- Configure the global navigation of an Intranet solution deployed in the tenant.
- Improve end user experience when using search capabilities utilizing the search dictionaries that contain specific Term sets to provide features such as including or excluding words for query spelling correction.

A custom taxonomy consists of a Group, at least a term set in the Group, and terms in a term set. The maximum number of levels of nested terms in a custom taxonomy is seven. The Term Store also contains enterprise keywords and hashtags as a mechanism to allow users to tag content with existing or new keywords created by end users. As part of the modernization of the Term Store, an increase in the number of terms available has increased from 200,000 to 1,000,000. Finally, the filters panel in modern Document libraries has been enhanced to support managed metadata.

### Content Type Gallery

The Content type gallery is a central location to manage and publish custom types to any site in the tenant. To create a new content type:

- Access the Content type gallery in the SharePoint Admin center and click **Create content type**.
- Type the information required to create a content type (Name, Description, Parent content type, and Category) and click on Save.

After the content type is created, click its name in the list of content types to access to the content type details page where you can take the following actions:

- Modify the details of the content type.
- Add site columns to the content type. You can choose between adding existing site columns or creating new columns. To create a new site column, provide the name, description, category, and column type. Depending on the column type, you might need to configure additional settings.
- Publish the content type so it can be used on any site in the tenant.

- Access to advanced content type settings such as the document template to use (only for document types), permissions to enable/disable the modification of the content type, and enabling/disabling the update of the content type on sites and lists when it's updated.
- Access to the content type policy settings.
- Delete the content type.

To use the content type in an existing document library:

- Browse the document library where you want to use the content type, click **+ Add column**, and then **Content type** to open the Add content type panel.
- In the panel, select the content type you want to add to the document library and click **Apply**. Note that before applying the content type you can optionally indicate if a specific view based on that content type is added to the library or if the content type columns should be added to the current view.

Any published content type in the Content Type Gallery can also be added to a site by using the [Add-PnpContentTypesFromContentTypeHub](#) cmdlet. If the content type already exists in the site, the published version is synchronized to the site.

## Managing Reports

The Reports section provides access to Content services and Data access governance reports. Content services reports are available only for tenants with a SharePoint Syntex subscription. The reports contain insights about the usage of terms and terms sets in the global Terms store across the tenant:

- **Terms store operations:** A graph showing details of the Terms store operation over the last 15 days.
- **Terms store composition:** Displays an overview of the number of terms in the Term store identifying the terms distribution (regular, hashtag, and keywords). From this report, it's possible to promote keywords to become terms in the Term store.
- **Open and closed term sets:** Indicates the total number of term sets and the distribution between open and closed term sets.
- **Terms without synonyms:** It reflects the percentage of terms in the Terms without synonyms or abbreviations specified.

Two types of [Data access governance reports](#) are available:

- **Sharing links** reports monitor sharing activity across the tenant and identify potential oversharing situations. Three kinds of sharing reports identify the sites where users create the highest number of "Anyone", "People in your organization" and "Specific people" links. It's possible to run all reports together or one by one. It can take a few hours to generate these reports.
- **Sensitivity labels applied to files** reports the sites including files with a specific sensitivity label. To get a report for a specific label, you need to add the report and then run it. Note that you cannot create more than ten sensitivity labels reports.

## Managing Advanced SPO Settings

The SharePoint admin center also includes the ability to manage some advanced settings in the platform such as API Management or Geo locations when multi-geo is enabled for the tenant:

- **API access:** From this section Admins can approve/reject permissions requested by third-party APIs that can be called by SharePoint Framework (SPFx) solutions and custom scripts. An administrator can easily approve or reject a request from the list using the Approve or reject panel.
- **Geo locations:** Lists available geo locations for the tenant. From here an administrator can add new satellite locations.

## Managing SharePoint Online Services and Settings

As in SharePoint on-premises, you can manage some of the core services as well as key settings. This section provides an overview of the services and settings that can be managed through the shortcuts provided in the **More features** section in the SharePoint admin center.

### User Profiles

Identity management for Microsoft 365 is centralized in Azure AD, but each core workload also has its own directory (SharePoint Directory Store or SPODS in the case of SharePoint Online) that is synchronized bidirectionally with Azure AD. Although SharePoint Online does not allow administrators to manage Azure AD users directly, it includes the [User Profiles](#) service as a mechanism to modify existing user properties or add new properties. Behind the scenes, a SharePoint Timer Job imports account information from Azure AD into the User Profiles service.

In the User profiles service page, Manage User Properties and Manage User Profiles links are most used by a SharePoint Online Admin. The first link takes us to a page that lists all the user profile properties and from where we can create new properties. The second link redirects to a central location from which we can look for a specific user profile to modify some of his/her properties and their visibility (only for some of the properties), delete the user profile, grant/control access to the user's OneDrive or [add additional administrators to users' OneDrive accounts](#). Depending on the subscription purchased, some of the properties needed to take full advantage of SharePoint Online features might be blank, so they must be manually or automatically filled (via PowerShell). An example of such properties is the Work email property that is empty in standalone SharePoint Online plans used for sharing functionality and alerts.

### Records Management

Despite its name, the Records management section in the SharePoint Online Admin Center simply allows administrators to [create new Send To connections](#) that can be used by a [Content Organizer configured on a SharePoint site](#) to route documents to a specified location (a document repository or a records center). It is also possible to configure Send To connections to be used by end users, so they can manually copy, move or move and leave a link when a document is selected in a document library.

### Search

Search is one of the core features in SharePoint Online that administrators [can customize](#) to ensure that end users have a great experience when searching documents by content and metadata through any site in the tenant. The search administration in SharePoint Online includes the following items:

- **Search Schema:** This option provides access to the list of managed properties and crawled properties in the tenant. An Administrator can update existing managed properties or create new ones. Each managed property can be mapped to one or more crawled properties. A crawled property is just content and metadata that is extracted during a crawl from an item stored in SharePoint, such as a document, a SharePoint page, or a list item. A good overview of crawled and managed properties can be found in [this Microsoft article](#).
- **Search Dictionaries:** Allows the creation of [a list of terms in the Term store](#) to include or exclude company names extracted from the contents indexed by the search engine or to include or exclude words for query spelling correction.
- **Query Suggestions:** Using this option we can upload query suggestions to the search engine so when the user enters some search criteria in the search box, search suggestions for that search criteria are shown.
- **Result Sources:** The ability to [limit searches to a subset of search results](#) is achieved through Result Sources. From the Result sources page, a SharePoint Online administrator can review existing Result sources or create new ones. The Result sources managed at this level can be used for all sites. A Site administrator or a site owner can manage result sources for a site.

- **Query Rules:** Search results can be improved through [Query rules](#) that give a mechanism to specify conditions and actions to promote the relevance of the search results that meet those conditions. As an example, we could create a query rule that boosts technology news in our Intranet that are tagged with a specific category so when someone searches for that news category, all the news in that category is displayed on the top of search results. Over the time Query rules in SharePoint online search will be replaced using answers in Microsoft Search.
- **Remove Search Results:** Lists the URLs removed from search results.
- **Usage Reports:** To evaluate how users are performing searches in SharePoint Online, a set of predefined reports is available. The reports provide insights about the number of queries performed by users, top search queries, queries with no results, abandoned queries, or query rules usage. While these reports are still available, the recommendation for search analytics across Microsoft 365 and SharePoint online is to use Microsoft Search insights.
- **Search Center Settings:** This page allows administrators to define the URL of the Global Search Center in the tenant and the search results loading strategy used in the tenant.
- **Export Search and Import Search Configuration:** Those options provide a simple mechanism to export to a text file any customization done in search configuration (query rules, result sources, result types, ranking models, and site search settings) or to import a search configuration file.
- **Crawl Log Permissions:** This page lists the users with read access to crawl log information in the tenant.

Changes done in the search administration page are applied to the whole tenant, but it's also possible to customize search at the site level.

## Secure Store

The [Secure Store service](#) is designed to manage and store the credentials needed to connect to an external data source. Credentials are just one of the settings of a Secure Store Target Application that also defines the mapping between them and a group of users in SharePoint Online, who can use the credentials to access the external data source. A Secure Store Target Application can be used by services such as Business Connectivity Services (BCS) to connect to an external system and integrate data in SharePoint Online sites in the form of SharePoint external lists, external data columns, default BCS Web Parts or a custom solution.

## Apps

SharePoint Online can be extended through [Apps or Add-ins](#). In general, two types of Apps can be added to a SharePoint site:

- **SharePoint Add-ins**, [defined by Microsoft as self-contained extensions](#) that may include logic and data deployed in the cloud, SharePoint components (such as Content types, Lists, Document libraries, etc.), and client-side scripts.
- **Web Parts and Extensions created with the SharePoint Framework.** SPFx Web Parts can be added to both classic and modern pages. SPFx extensions can only be used in the modern SharePoint experience.

SharePoint Apps are only installable from the SharePoint Store or the [global App Site](#). A tenant can have only one global App Site, a special type of site that needs to be created by a SharePoint Online Administrator. SPFx solutions (Web Parts, Extensions, and Adaptive Cards Extensions) for SharePoint sites, Microsoft Teams, and Viva Connections can also be distributed from the global App Site. From the global App Site, an Admin can distribute custom Apps or browse and install Apps that meet the business requirements directly from the SharePoint Store. End users can request new Apps to be added to a site through the My Apps page by browsing the SharePoint Store to select and request an app. Tenant administrators can then approve or deny the app requests. Finally, site owners can delete requested apps, even if administrators approve their installation, from the My requests section on the My Apps page.

For more granular Apps deployment and isolation, Apps catalogs can be created in specific sites. To create an App catalog, connect to SharePoint Online with PowerShell and run the following command:

```
[PS] C:\> $sSiteCollectionUrl = "https://<Site_Collection_Url>"  
[PS] C:\> Add-SPOSiteCollectionAppCatalog -Site $sSiteCollectionUrl
```

You can only install Web Parts and Extensions deployed to a site catalog in the root site and any site created in the collection, but not in any other site. To create a site catalog, the user executing the *Add-SPOSiteCollectionAppCatalog* must be a site admin for the global App catalog.

## Hybrid Picker

SharePoint Online and SharePoint On-Premises can be integrated and connected in a hybrid deployment. Assuming the [pre-requisites required for a hybrid deployment](#) are met, the list of hybrid features currently available is the following:

- **OneDrive redirection:** If enabled, on-premises users are redirected to OneDrive for Business.
- **Hybrid search:** provides the ability to combine on-premises and cloud search results in the same search index to make it possible to search content from both cloud and on-premises sources in the on-premises farm. On the other hand, hybrid federated search allows to search content from on-premises and cloud indexes in a single search center.
- **Hybrid App Launcher:** This feature allows access to services such as Teams or Stream in the on-premises App launcher.
- **Business to Business (B2B) Extranets:** By using this feature, it is possible to create an Extranet in SharePoint Online to collaborate with partners, so they don't have access to any on-premises data.
- **Hybrid Taxonomy:** Delivers a mechanism to replicate taxonomies created in SharePoint Online to SharePoint on-premises. In a nutshell, hybrid taxonomy allows an organization to have a shared taxonomy between SharePoint Online and SharePoint on-premises.
- **Hybrid Self-Service site creation:** If enabled, any user that creates a new site is redirected to the self-service site creation page in SharePoint Online.

## InfoPath Forms Services and Business Connectivity Services

[InfoPath Forms Services](#) and [BCS Services](#) are two legacy services supported by SharePoint Online. InfoPath enables tenants to easily design electronic forms that can be deployed to any SharePoint site in the tenant using InfoPath Designer 2013 as an authoring tool. The latter provides a simple mechanism to connect a SharePoint site to external business data sources such as SQL Azure Databases or any other one exposed by a Windows Communication Foundation (WCF) service.

Microsoft has committed to support [InfoPath Forms Services 2013 and InfoPath 2013 clients](#) until 2026 and has positioned Power Apps as its natural replacement. The general recommendation about InfoPath usage in SharePoint Online is to avoid the creation of new InfoPath Forms and carefully plan the migration of existing ones to Power Apps or custom solutions built using any of the frameworks and platforms provided by Microsoft (including SPFx).

BCS supports the integration of data stored in external sources in SharePoint sites through SharePoint external lists, BCS Web Parts or external data columns can be added to existing lists and/or document libraries. While Microsoft has not made an official statement about the future of BCS in SharePoint, they have not made any kind of investment in BCS since the release of SharePoint 2013. In SharePoint Online, the integration of external data in SharePoint sites can be achieved by using a combination of modern cloud technologies and platforms such as Power Apps, Power Automate, Azure Logic Apps, or cloud development patterns.

## Managing SharePoint Online with PowerShell

The SharePoint Online Management Shell is a Windows PowerShell module designed for command-line operations and inclusion in PowerShell scripts. The module enables batch processing for tasks like reports and is the only way to achieve some management tasks in SharePoint Online and OneDrive for Business.

Microsoft updates the SharePoint Online Management Shell regularly. The updates include new cmdlets, new parameters for cmdlets, and other tweaks. If you use PowerShell to work with SharePoint Online, it's important that you use the latest module. See the PowerShell chapter for advice about how to update PowerShell modules.

### Connecting to SharePoint Online with PowerShell

The *Connect-SPOService* cmdlet is used to connect to the SharePoint administration endpoint for a tenant (the same used by the SharePoint admin center). To build the *endpoint*, take the normal SharePoint root URI for your tenant (like <https://office365itpros.sharepoint.com/>) and insert an "-admin" after the tenant name. For example:

```
[PS] C:\> Connect-SPOService -URL "https://office365itpros-admin.sharepoint.com"
```

The SharePoint Online module is designed for administrative tasks, so you should always connect with an account that has Global Administrator or SharePoint Administrator rights for the tenant.

### Basics of SharePoint Online Cmdlets

To see the available SharePoint Online cmdlets, run:

```
[PS] C:\> Get-Command -Module "Microsoft.Online.SharePoint.PowerShell"
```

The current cmdlets available in the module can be divided into several types:

- Tenant-Level cmdlets like *Get-SPOTenant* and *Set-SPOTenant*.
- Site-Level cmdlets like *Get-SPOSite* and *Set-SPOSite*.
- Cmdlets for specific operations like *Start-SPOSiteRename*, *Invoke-SPOSiteSwap*, and *Test-SPOSite*.

It's very common to want to retrieve information about the sites in a tenant. To do this, run the *Get-SPOSite* cmdlet. The *Limit* parameter specifies that all sites are to be returned.

```
[PS] C:\> Get-SPOSite -Limit All
```

This command returns all types of sites found in the tenant, including redirect sites (created because of site URL renames), hub sites, the global App site, Group sites, and sites used by Teams private and shared channels. In most cases, it is best to be more precise when using *Get-SPOSite* to find sites by specifying the template for the type of sites you want to process. For instance, this command returns the sites connected to Teams:

```
[PS] C:\> Get-SPOSite -Limit All | ? {$_.IsTeamConnected -eq $True}
```

While this command returns the set of sites connected to Teams private channels:

```
[PS] C:\> Get-SPOSite -Limit All -Template "TEAMCHANNEL#0"
```

Alternatively, you can run this command to list the channel-connected sites together with the type of channel:

```
[PS] C:\> Get-SPOSite -Limit All | ? {$_.IsTeamsChannelConnected -eq $True} | Format-Table Title, TeamsChannelType
```

For Modern Pages, SharePoint Online displays usage information (the number of views) and allows users to like and enter comments for pages. It is possible to disable this feature via PowerShell. At the tenant level it can be done by running the following command:

```
[PS] C:\> Set-SPOTenant -SocialBarOnSitePagesDisabled $True
```

Alternatively, you can disable the feature for specific sites by running the *Set-SPOSite* cmdlet and passing the URL for the site. For example:

```
[PS] C:\> Set-SPOSite -Identity https://Office365itpros.sharepoint.com/Projects/ -
SocialBarOnSitePagesDisabled $True
```

## Combining SharePoint Online and Other Objects

Sometimes you need to retrieve information about a SharePoint Online site for use elsewhere. For example, if you want to include a document library belonging to a group, team, or team private channel on an eDiscovery case or content search, you need to specify the site's URL as a search location.

If you use PowerShell to examine a group's properties, you will see three SharePoint Online URLs returned for the site, the document library, and the shared OneNote notebook. The value returned by the *Get-UnifiedGroup* cmdlet (part of the Exchange Online module) in the *SharePointSiteUrl* property is the one needed when you wish to add a site to content searches, found using the *Get-UnifiedGroup* PowerShell cmdlet:

```
[PS] C:\> Get-UnifiedGroup -Identity "Office 365 for IT Pros" | Format-List Share*Url

SharePointSiteUrl      : https://Office365ITPros.sharepoint.com/sites/0365ITPros
SharePointDocumentsUrl : https://Office365ITPros.sharepoint.com/sites/0365ITPros/Shared Documents
SharePointNotebookUrl  : https://Office365ITPros.sharepoint.com/sites/0365ITPros/SiteAssets/Office
365 for IT Pros Notebook
```

The URL retrieved from the group can be used with *Get-SPOSite* to find further information about the site belonging to the group.

It's also possible to discover what group a site belongs to by using the *GroupId* property stored for the site. For example:

```
[PS] C:\> Get-UnifiedGroup -Identity (Get-SPOSite -id https://office365itpros.sharepoint.com/sites/
0365ITPros).GroupId.Guid -Detailed | Format-Table DisplayName, SharePointSiteURL

DisplayName      SharePointSiteUrl
-----
Office 365 for IT Pros https://office365itpros.sharepoint.com/sites/0365ITPros
```

Many SharePoint Online sites are connected to a Microsoft 365 group (with or without Teams). To find the group information for a team site, run the *Get-SPOSite* cmdlet with the *Detailed* parameter to return the group identifier in the *GroupId* property. You can then use the identifier with the following cmdlets:

- *Get-MgGroup*: to return details of the Azure AD group.
- *Get-UnifiedGroup*: to return details about a Microsoft 365 group.
- *Get-Team*: to return details of a team if the group is team-enabled.

For example, this code returns the display name of the Azure AD group that holds the membership of each group-connected site. Not all sites created with the *Group#0* template might have corresponding Microsoft 365 groups. This can happen after the deletion of a group if the site is retained by a retention policy.

```
[PS] C:\> [array]$Sites = Get-SPOSite -Template "GROUP#0" -IncludePersonalSite:$False -Limit All
Write-Host "Processing" $Sites.Count "sites"
ForEach ($Site in $Sites) {
    $GroupId = (Get-SPOSite $Site.Url -Detailed).GroupId.Guid
    $Group = Get-MgGroup -GroupId $GroupId -ErrorAction SilentlyContinue
```

```
If ($Group) {  
  Write-Host ("SharePoint Online site {0} is connected to the Azure AD group {1}" -f $Site.Title,  
$Group.DisplayName) }  
}
```

## Enabling or Disabling Web Parts

Modern pages in SharePoint sites can be customized with modern Web Parts to show information from other Microsoft 365 services and non-Microsoft services such as Twitter, Kindle, or YouTube. SharePoint Administrators [can use PowerShell to hide specific web parts from end users](#) by running the *Set-SPOTenant* cmdlet to set the *DisableWebPartIds* property. For example, to hide the Web Part for Twitter, you run this command:

```
[PS] C:\> Set-SPOTenant -DisableWebPartIds f6fdf4f8-4a24-437b-a127-32e66a5dd9b4
```

Multiple Web Parts GUIDs can be specified in a comma-separated list. To view a list of disabled Web Parts, you can use the *Get-SPOTenant* cmdlet. To re-enable some disabled web parts, run *Set-SPOTenant* and specify only the GUIDs for the Web Parts that you want to be disabled in *DisabledWebPartIds*. To re-enable all Web Parts, run:

```
[PS] C:\> Set-SPOTenant -DisabledWebPartIds @()
```

## Enabling or Disabling the Weekly SharePoint Auto Digest e-mail

The SharePoint Auto-News Digest feature allows tenants to send a weekly automated email to users containing the latest News posts that they have not yet read that might be relevant to them. This feature is enabled by default and can only be disabled in two ways:

- Users can stop receiving the Auto Digest e-mail by clicking on the unsubscribe link present at the bottom of the digest e-mail.
- SharePoint Admins can completely disable it by running the *Set-SPOTenant* cmdlet to set *EnableAutoNewsDigest* to *\$true*.

```
[PS] C:\> Set-SPOTenant -EnableAutoNewsDigest $True
```

## Enabling or Disabling the SharePoint App bar

The [SharePoint App bar](#) and the SharePoint start page give users direct access to relevant sites, news feeds, lists and files. To help an organization use the App bar or mitigate situations where it might impact site customizations built with SPFx extensions, SharePoint Admins can disable the App bar using the *Set-SPOTemporarilyDisableAppBar* cmdlet. For example:

```
[PS] C:\> Set-SPOTemporarilyDisableAppBar $True
```

To reenable the SharePoint App bar, run:

```
[PS] C:\> Set-SPOTemporarilyDisableAppBar $False
```

## Enabling or Disabling the Link to Return to Classic SharePoint

Modern SharePoint lists and document libraries can include a link to "Return to classic SharePoint" in the lower left corner of the page to revert the current list or library back to classic mode. On the contrary, the classic mode for lists and document libraries has a hint to "Exit classic experience". To control the visibility of those links, a SharePoint Admin can hide both by executing the *Set-SPOTenant* cmdlet to set *DisableBackToClassic* to *\$true*:

```
[PS] C:\> Set-SPOTenant -DisableBackToClassic $True
```

## Disable Creation of New SharePoint 2013 Workflows

Although Microsoft [has deprecated](#) SharePoint 2013 workflows in SharePoint Online, it's still possible to create new SharePoint 2013 workflows in a tenant. To disable the creation of new workflows, a SharePoint Admin can use the *StopNew2013Workflows* parameter in the *Set-SPOTenant* cmdlet:

```
[PS] C:\> Set-SPOTenant -StopNew2013Workflows $True
```

Existing SharePoint 2013 workflows won't be affected when this setting is true and will continue running. If necessary, the workflows can be modified. Microsoft strongly recommends that organizations move 2013 workflows to Power Automate. To help, an open-source [SharePoint 2013 Workflow assessment tool](#) is available. The tool provides usage data of SharePoint 2013 Workflows and generates a Power BI report to help plan the migration to Power Automate.

## PowerShell and SharePoint Sharing

As discussed earlier, you can limit the ability of users to share content with others in different ways. The SharePoint PowerShell module has several cmdlets that work with sharing settings. The most basic example is how to limit the type of sharing for a tenant using the *Set-SPOTenant* cmdlet. In this example, we allow sharing with authenticated external users. To disable external sharing, set the value to *Disabled*, or use *ExternalUserAndGuestSharing* if you want to allow the generation of anonymous guest links (or to allow these links to be used in team sites).

```
[PS] C:\> Set-SPOTenant -SharingCapability ExternalUserSharingOnly
```

In the next example, we create a list of external domains that we allow users to share content with and add an extra level of security for sharing links by setting *RequireAcceptingAccountMatchInvitedAccount* to *\$True* to ensure that only the account (email address) that receives a sharing invitation can redeem it to access the shared content. If you leave this setting at the default (*\$False*), then anyone who has a link can use it to access the information.

```
[PS] C:\> Set-SPOTenant -SharingAllowedDomainList "locklan.com.au Microsoft.com"  
-SharingDomainRestrictionMode AllowList -RequireAcceptingAccountMatchInvitedAccount $True
```

To revert to the default configuration, reverse the settings:

```
[PS] C:\> Set-SPOTenant -SharingAllowedDomainList $Null -SharingDomainRestrictionMode None  
-RequireAcceptingAccountMatchInvitedAccount $False
```

SharePoint Online supports anonymous guest links that site owners (or users with full control permission for a site) can send to external people to allow them to access site content. The trouble with guest links is that anyone who has the link can use it, so if you decide to allow these links, it is best to force the links to expire after a period (expressed in days). As shown below, a tenant administrator can run the *Set-SPOTenant* cmdlet to assign a default expiry period in the *RequireAnonymousLinksExpireInDays* setting. Users can send guest links that expire sooner than the default, but they cannot exceed it. This setting applies to links sent from both SharePoint Online and OneDrive for Business.

```
[PS] C:\> Set-SPOTenant -RequireAnonymousLinksExpireInDays 10
```

## Site Swap

Site Swap allows SharePoint Admins to replace the location of a SharePoint root site with another site using *Invoke-SPOSiteSwap*. For example, this [PowerShell command performs a Site swap](#):

```
[PS] C:\> Invoke-SPOSiteSwap -SourceURL  
https://office365itpros.sharepoint.com/sites/NewMarketingComms -TargetURL  
https://office365itpros.sharepoint.com -ArchiveURL  
https://office365itpros.sharepoint.com/sites/OldMarketingComms
```

*Invoke-SPOSiteSwap* requires the [following attributes](#) to be configured:

- *SourceURL* parameter indicates the site that is going to replace the root site.
- *TargetURL* parameter indicates the root site to be swapped.
- *ArchiveURL* parameter indicates the new URL for the former root site.

Once the cmdlet is invoked, a background job performs the site replacement and after some minutes and some occasional 404 errors, the new root site will be available.

There are also some restrictions in this feature that should be considered before making a Site swap. The source or target sites can't be associated with a modern Team Site or a Hub Site.

## SharePoint PnP PowerShell Module

The functionality available through the SharePoint Online PowerShell module is limited and restricted to basic administration tasks performed by a SharePoint Online administrator, such as managing sites and tenant settings. To get extra functionality, use the cmdlets available in the [SharePoint PnP PowerShell cmdlets project on GitHub](#), part of the Patterns & Practices community initiative.

To install the PnP PowerShell module from [the PowerShell Gallery](#), run this command:

```
[PS] C:\> Install-Module -Name PnP.PowerShell -Force
```

Many good examples of using the SharePoint PnP cmdlets are available on the web.

## Sharing

As the application name implies, sharing documents, folders, and sites with internal and external users is an important SharePoint feature. Microsoft's terminology can be confusing because of the way SharePoint documentation refers to "external users." For SharePoint, an external user is someone outside the tenant. That user might have a guest user account in the tenant, created by an administrator, or because they were invited to join a Group or a Team. On the other hand, an external user can also be an ad-hoc recipient of a sharing invitation, in which case they authenticate with an access code, or they can receive an anonymous link, which allows anyone with the link to access the content.

The current advice is that SharePoint Online sharing should use the following approach:

- Use Groups and Teams to control ongoing access for external users to content in SharePoint team sites. External people who join Groups and Teams automatically get a guest user account as part of the invitation process and use those accounts to access the document library belonging to the team or group they join.
- Use guest user accounts to control access for external users for a sustained period to content in traditional SharePoint sites. You can create these accounts in the Users section of the Azure AD blade of the Azure portal. SharePoint creates guest accounts when someone shares a site with an external user.
- Use one-time passcodes (OTP) for one-time access for external users. The one-time passcodes are one-time eight-digit numbers sent to an email address contained in a sharing invitation to allow them to open content. Codes are good for 15 minutes.

## SharePoint and Azure B2B Collaboration

The long-term direction for SharePoint Online is to use Azure B2B Collaboration to control sharing. This means that when someone creates a sharing link, SharePoint creates a guest account in the tenant. The sharing link contains an invitation for that person, much like adding someone to a team or group creates a sharing invitation that the external recipient must accept before they can access resources. When the person uses the sharing link and goes through an OTP challenge to validate their credentials, the invitation is accepted, and the guest account becomes fully active and thereafter can use their guest account to access

tenant resources. The resources include individual documents, folders, and sites shared with them and where their account is added to the membership of Groups (including Teams). When the [integration with Azure B2B](#) collaboration is enabled, SharePoint Online creates guest user accounts for all types of sharing recipients as described in Table 8-1.

Target Sharing Recipient	Sharing Steps	Guest account created
Microsoft (MSA) account.	Sharing link sent. User goes through the account validation process. Sharing happens.	Yes
Account in another directory (for example, Zoho Mail). Gmail can federate with Azure AD, in which case users sign-in directly.	Sharing link sent. User redeems OTP. Sharing happens. User must redeem a new OTP for each session.	Yes
Account in another Azure AD tenant, including those without Office 365 (like Yandex.com).	Sharing link sent. User redeems OTP. Sharing happens. User doesn't need OTP for future access.	Yes

Table 8-1: Guest accounts created by sharing activities in SharePoint Online

More information about how to manage guest accounts is in the Managing Users chapter.

**Site People View:** The SharePoint browser interface keeps track of external people with whom users share resources. Sometimes, errors creep into the list of external people, such as when people enter incorrect email addresses into sharing links. To remove these errors and prevent them from showing up as suggested users in sharing dialogs, a site administrator can access the list by adding `/_layouts/people.aspx?MembershipGroupId=0` to the site URL. This exposes the All People view listing all the internal and external users with access to the site. You can remove users from this list whose entry is incorrect for some reason (like a bad email address) or who no longer have access to site resources.

## Sharing Controls

SharePoint Online supports up to 50,000 external shares per securable object (a site, a list/document library, a folder, or a(n) item/document), which should be enough for even the most dedicated sharer. For performance reasons, Microsoft recommends keeping the number of shares on an object to 5,000 or less. Somewhat confusingly, the settings that control how users can share SharePoint content are in two administrative consoles:

- **Microsoft 365 admin center:** Select Settings, then Org settings, and then sharing. A link to the sharing controls is in the Sharing side panel.
- **SharePoint admin center:** Select Policies and then Sharing.

The same basic settings for sharing controls are made available through any of these consoles and the same values appear in each. However, you will find some differences in presentation and emphasis. On the other hand, the Microsoft 365 admin center presents a somewhat more simplified view of sharing controls than either of the other consoles. And of course, you can use PowerShell to adjust settings too.

The **Sharing** section of the SharePoint admin center (exposes the settings to control how sharing with external people occurs within a tenant. Sharing occurs through the exchange of sharing links between the person sharing a file or folder with some other internal or external person. The sharing link is a revocable secret to allow access to designated content. The link can be transferrable or confined to a set of recipients.

SharePoint Online and OneDrive for Business support four types of sharing links, listed here in order from the most permissive to the most restrictive:

- **Anyone:** Also called anonymous sharing, this is the loosest permission. It allows users to share files and folders with anyone who has an email address. SharePoint sends an email with a link to allow the recipient access to the content, but anyone who subsequently has access to the link can use it to access the associated content. If you allow anonymous sharing, you can limit the lifetime of a link (to say, 7 days) and restrict access to view-only rather than view and edit.
- **New and existing guests:** Users can share with external users if those users can authenticate themselves by signing into the tenant using a guest account or by using a verification code.
- **Existing guests:** Users can share with external people, but only if the target users already have a guest account in the tenant directory. It is a good idea to create guest accounts when users need to share information with known external people over a sustained period. Guest users use their credentials to access content shared with them.

**Only people in your organization.** In other words, users cannot share files or folders with external people. Microsoft 365 Apps such as Teams and Lists use the same controls to create sharing links for content within and outside the tenant.

**Shared with information in the sharing control.** The sharing control used across Microsoft 365 [lists the set of people](#) whom a file, a folder, or a list item is already shared with so that document owners know how many people already have access to a file and who they are.

If you do not change the default sharing setting, users can create Anyone links. Changing the sharing setting for a tenant can be a slow process and can take several hours before a change is effective. The sharing settings also allow you to control the type of link created when a user shares a document with someone (choose from Specific people; Only people in your organization; Anyone with this link) as well as the [default permission](#) (View, View and edit for Files; View, View, edit and upload for Folders). Because users usually accept the default link type, you should set the default permission to view-only. We can also restrict users so that they can only share files with authenticated external users who belong to specific domains. The sharing settings apply to every SharePoint Online site and OneDrive for Business account in a tenant.

You can also [customize sharing for a site including the](#) per-site Anyone Link expiration policy, but you cannot make sharing more permissive at a site level than it is for the tenant. [Per-site Anyone Link expiration](#) can be configured through the Sharing option in the SharePoint Admin Center or using the *Set-SPOSite* cmdlet to set the *AnonymousLinkExpirationInDays* parameter that overrides the tenant policy and set a more or less restrictive expiration policy for target sites. This parameter controls how all anonymous/anyone links that have been created (or will be created) will expire after the set number of days. It only applies if the parameter *OverrideTenantAnonymousLinkExpirationPolicy* is set to true. For example, the following command sets a 10-day Anyone link expiration period for the <https://Office365itpros.sharepoint.com/sites/Confidential> site:

```
[PS] C:\> Set-SPOSite -Identity https://Office365itpros.sharepoint.com/sites/Confidential -AnonymousLinkExpirationInDays 10 -OverrideTenantAnonymousLinkExpirationPolicy $True
```

Administrators can also override the Anyone Link expiration period for OneDrive for Business sites by running the *Set-SPOSite* cmdlet and passing the desired expiration period in the *AnonymousLinkExpirationInDays* parameter.

## Advanced Settings for External Sharing

The advanced settings for external sharing include:

- Create an allow list for external domains with which you are happy for users to share files. Conversely, you can create a block list to prohibit sharing with specified domains. You can have either a block or

an allow list; you cannot have both. You can enter a maximum of 120 domain names separated by spaces.

- Restrict external sharing only to users that are members of a specific security group in the tenant.
- Control whether external users must accept sharing invitations from the same email address used in the invitation. In other words, an external user cannot sign in from *DomainA* to accept an invitation sent to them in *DomainB*.
- Control whether external users can share items they do not own (a bad idea, normally).
- Define the number of days after which access for guest users to a Site and OneDrive for Business expires.
- Establish how long a verification code sent to external users is valid before they must re-authenticate. The default value for this setting is 30 days.

## Expiring Access Policy

The expiring access policy allows organizations to control how long (between 30 and 730 days) external users can access SharePoint Online and OneDrive documents. The mechanism works by placing an expiration date on the sharing links created for external users. When the expiration date approaches, site owners receive prompts in the SharePoint Online and OneDrive for Business browser GUIs and via email to manage expiration. They can either [extend access or let the access expire](#).

To enable the Expiry access policy for a tenant, access the sharing policy in the SharePoint Online admin center and edit the *Guest access to a site or OneDrive will expire automatically after this many days* setting. Alternatively, run the *Set-SPOTenant* cmdlet. For example:

```
[PS] C:\> Set-SPOTenant -ExternalUserExpireInDays 60 -ExternalUserExpirationRequired $True
```

Administrators can override the tenant guest expiration setting for individual sites by running the *Set-SPOSite* cmdlet. For example:

```
[PS] C:\> Set-SPOSite -Identity "https://office365itpros.sharepoint.com/sites/CriticalSite1" -OverrideTenantExternalUserExpirationPolicy $True -ExternalUserExpirationInDays 730
```

It's important to underline that this setting applies only to sharing links, direct permission changes, and SharePoint group membership and does not apply to guest access to SharePoint Online sites granted through the membership of Microsoft 365 Groups. Guests who are members of Microsoft 365 Groups can continue to access the content of the group-connected sites for as long as they are members of those groups. Setting an expiring access policy for a tenant or site applies only to sharing granted after the policy becomes effective and only for the sharing links created for guest accounts.

## Other Settings for External Sharing

There are other Sharing settings available in the admin center Sharing section:

- Enable (default option) or disable the setting to display the names of people who viewed their files.
- Provide site owners with the ability to display the names of the people who viewed files or pages in SharePoint.
- Shorten links or change their default permission.

## Per-Site Sharing controls

Admins can configure Sharing settings at the site level. Select a site from the Active sites list, select an existing site and click **Sharing**. In the Sharing settings panel, you can then select the following configurations:

- Change the current **External sharing** setting to another value such as Anyone or Existing guests only. The choice of permitted values depends on the global sharing setting at the tenant level. The external

sharing capability for a site can also be set by assigning a sensitivity label with container management to the site. See the Information Protection chapter for more information.

- Create a list of **external domains** which site members are allowed to share site contents.
- Set the **default sharing link type**. Note that to choose the *Anyone with the link* setting, the site must first be configured to allow anonymous sharing. This link type also allows users to override the default *link expiration*.
- Override the **default link permission** (view or edit) for sharing links.

If external sharing is disabled on a site, an administrator can configure a custom sharing help link to explain why external sharing is disabled or how to request a policy change. This feature can be enabled by running the PowerShell command `Set-SPOTenant -CustomizedExternalSharingServiceUrl <url-address>`.

**Per-Site Sharing Links default to people with existing access.** A SharePoint Admin can also set the default sharing link for a site to “People with existing access” by running the `Set-SPOSite cmdlet` with the `-DefaultLinkToExistingAccess` parameter. Once the setting is applied, any user sharing a file or a folder from the site will get an existing access link that does not change permissions on the file or folder being shared.

## Link Settings to Control Access to Documents

Sharing links created by SharePoint Online and OneDrive for Business can [block recipients from downloading copies](#) when an Office document is shared anonymously, to all users in the organization, or to specific people. To block downloads, a user edits the sharing link settings and toggles the “Block download” setting (Figure 8-2). When a sharing link blocks downloads, recipients can use Office Online to view the content.

As the name implies, an *Anyone* link allows anyone with a link to open the associated content. When a password is set, people must enter the password before SharePoint Online displays the content. The password is a custom word set by the sharer when they create the link: the sharer must transmit the password to authorized recipients separately (it is a bad idea to include the password as a comment sent with the link). The presence of the password means that the content is safe if the link is forwarded or reshared with others (unless the password is also shared). The ability to block the download of other file types (images, 3D, PDF, and more) is also supported and it's [the default setting for some audio and video files](#). For added protection, you can also set a password when sharing a file or folder using *Anyone* links. As the name implies, an *Anyone* link allows anyone with the link to open the content the link points to.

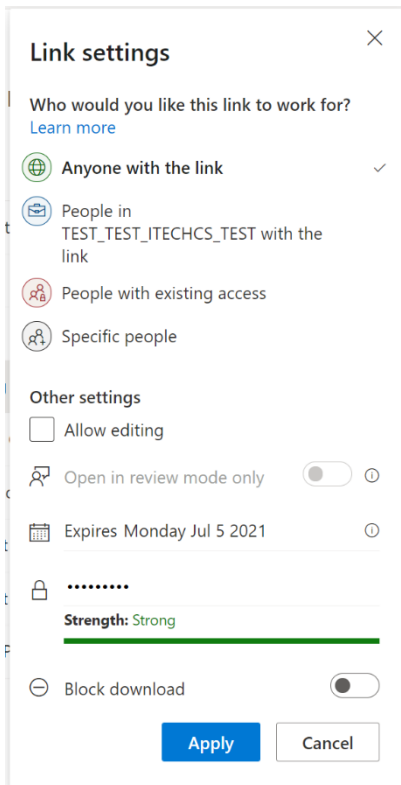

Figure 8-2: Editing a sharing link to block downloads and set a password

**Open in review mode in Word Online.** Users can choose to share Word documents with the "Open in Review mode" option. When enabled, recipients can only open the Word file in the online app with the "Reviewing" mode enabled. While in Reviewing mode, users can suggest changes (using the track changes feature) and make comments, but they cannot make edits that can't be tracked. Owners of the document have the option to accept or reject the suggestions made by the recipient.

## User Experience When Accessing a Shared File

When a user shares a file, recipients receive a link to the file previewer. The link does not automatically download the file. If they want to download the file using a download link, users must open the file details pane, click on More detail at the bottom of the pane, and then use the Copy action next to the Path section.

## Sharing with Microsoft 365 Groups or Teams

Every group has a SharePoint site with a document library. This applies whether the group supports conversations through Outlook, Yammer, or Teams. SharePoint sets the sharing capability for the sites belonging to new groups to *ExternalUserSharingOnly*, which is a level of access enough to allow guest accounts to work with content in the document libraries.

During the creation of a new group or team, SharePoint Online provisions a site to hold the document library and other resources. The tenant sharing settings control what sharing group users can do for files in the document library, but a group owner or tenant administrator can make the sharing more restrictive by changing the *SharingCapability* setting for the group's site. The values that you can set are equivalent to the four settings available for the SharePoint tenant as explained above. Again, we list the permissions below from most restrictive to most permissive.

- **Disabled:** External sharing is not possible.
- **ExistingExternalUserSharingOnly:** Sharing is only possible with external people who already have a guest account in the tenant directory.

- **ExternalUserSharingOnly:** Users can share documents freely with external people with guest accounts and can invite authenticated external users to share documents using one-off time-limited codes. This is the default setting applied to sites created for new groups if a tenant supports guest access.
- **ExternalUserAndGuestSharing:** Users share documents freely with guest users and authenticated external users and can also create links that can be used by anyone who can access the link (also called anonymous or guest link sharing). Be careful about using this sharing capability because it means that any group member can share documents from the document library with anyone else by emailing a sharing link to that person. While acceptable for libraries that do not hold confidential material, this setting should never be present for libraries that hold anything other than documents intended for public access.

The tenant sharing setting prevails over the setting for a site. If you want to use a setting like *ExternalUserAndGuestSharing* for the site belonging to a group, you must first make sure that the organization allows anonymous sharing. To check the tenant setting, use the SharePoint admin center or connect to SharePoint Online with PowerShell and run this command:

```
[PS] C:\> Get-SPOTenant | Select SharingCapability
SharingCapability          : ExistingExternalUserSharingOnly
```

To check the sharing capability for a group, run the command (A connection to both SharePoint Online and Exchange Online is required):

```
[PS] C:\> $sGroupName="Office365forITPros"
Get-SPOSite -Identity (Get-UnifiedGroup -Identity $sGroupName).SharePointSiteUrl | Select
SharingCapability
SharingCapability          : ExistingExternalUserSharingOnly
```

In this instance, the sharing capability for the site matches that of the tenant and is appropriate to support guest access to the site's document library through Groups or Teams.

Other sites might implement a different sharing model to that used by Groups. If you want to align the two sharing models, you can restrict sharing to external users who already have guest accounts in your tenant directory. When this happens, administrators must create guest accounts in the directory before users can invite the holders of those accounts to access their documents. You should also allow SharePoint users to search for guest accounts in the people picker used to select with whom to share a document. By default, guests do not show up in the people picker, so to enable them to appear, you need to run the *following cmdlet*:

```
[PS] C:\> Set-SPOTenant -ShowPeoplePickerSuggestionsForGuestUsers $True
```

Not all team sites are linked to Groups as some are still of the classic variety to serve specific purposes. To list all the team-enabled sites in a tenant, use this cmdlet, which includes the template for group-enabled sites to isolate the set we want to see:

```
[PS] C:\> Get-SPOSite -Template "GROUP#0" -IncludePersonalSite:$False
```

Taking this a little further, here is how to loop down through the set of group-enabled team sites and report some information about the sharing activity for each site.

```
[PS] C:\> $SiteNumber = 0
ForEach ($Site in Get-SPOSite -Template GROUP#0 -IncludePersonalSite:$False)
{
    $SiteNumber++
    Write-Host "Site number: " $SiteNumber " " $Site.Url
    Write-Host "Owned by: " $Site.Owner
```

```
Write-Host "Sharing: " $Site.SharingCapability
Write-Host "-----"
Get-SPOExternalUser -SiteUrl $Site.Url
}
```

**Tracking Document Sharing Through Audit Records:** Each time someone shares a document or folder, SharePoint records the event in an audit record. You can search the audit log to retrieve and analyze these records to understand what sharing occurs within a tenant. See Reporting and Auditing chapter for details.

## Move Files and Keep Sharing

When users move files from a SharePoint site to another site, from a SharePoint site to OneDrive, or from OneDrive to a SharePoint site, they have the option to retain sharing of the file with the same people at the new destination. When this option is used, those with access to the file receive an email to tell them that the file has been moved and that they have a new link or direct permissions to match those at the source location.

## Sharing with LinkedIn Contacts

If a tenant is configured to connect to LinkedIn, Microsoft 365 users can connect their accounts to their LinkedIn accounts (see Managing Users chapter for details). When an account is connected to LinkedIn, first-degree contacts are downloaded from LinkedIn and included in the “suggested people” list used by browser interfaces such as the SharePoint Online and OneDrive for Business clients. The suggested people list also includes tenant users (including guest accounts) and email addresses from Outlook’s auto-complete list.

When the user next shares a document from SharePoint Online or OneDrive for Business or the online Office apps, the name they enter is checked against the suggested people list. If a match is found against a LinkedIn contact and the user goes ahead and shares the document, the sharing invitation is sent to the contact’s email address.

## At a Glance Summaries in Sharing Emails for Word Documents

When a user shares a Word document, the notification to inform the recipient about their access to the document includes a list of key points in the text and the time estimated to read the content. Files identified as sensitive by Data Loss Prevention policies will not include this information.

Administrators can disable the feature for the tenant by running the *Set-SPOTenant* cmdlet:

```
[PS] C:\> Set-SPOSite -IncludeAtAGlanceInShareEmails $False
```

## Sharing from Microsoft Lists

Sharing capability for Microsoft Lists is achieved in two ways:

- By granting access to the entire list with specific permission (Full control, Edit, View) to specific users, mail enabled security groups, Microsoft 365 Groups, or security groups. In practice, granting access in this way implies the creation of unique permissions for the list.
- Through the sharing link generated when a specific list item is shared through the universal sharing dialog.

## Managing Sharing and Access Request Settings

Site admins and site owners can manage **Sharing and access request settings** directly from the site permissions panel (through the **Change sharing settings** link). This simplifies the previous experience which involved first going to the Advanced permissions settings page and then selecting the “Access Request Settings” option in the ribbon. Configuring settings through the new experience uses a simple configuration panel where a site admin or a site owner can:

- Modify sharing permissions by choosing one of the following options: “Site owners and members can share files, folders, and the site,” “Site members can share files and folders, but only site owners can share the site” and “Only site owners can share files, folders and the site.”
- Allow or deny access requests to the site. This setting, enabled by default, also includes the choice to direct site access requests to site owners or are sent to a specific e-mail address. A custom message for the access request page can be also added here.

## Managing Access to Files and Folders in SharePoint Online

The **Manage access** pane makes it easy for people to manage access permissions, remove individual recipients from shared links, and stop sharing overall. This pane, available for both SharePoint Online and OneDrive for Business, shows up when the user clicks the **Manage access** link under the **Has access** link in the files/folder details pane. From here, the user can easily grant access to the selected file/folder or manage existing sharing permissions.

## Sharing Reports for SharePoint Online and OneDrive for Business

Site owners can generate a CSV file to report site content shared with any user. The option is available on the Site usage page. To create a Sharing report, a site owner browses the site usage page and clicks the **Run report link** in the **Shared with external users** section. When prompted, the user selects a folder to save the CSV report and then clicks **Save**. Once the report is generated, SharePoint sends a notification to say the CSV file is available in the chosen location. The report contains a row for every file or folder shared by the user with [the following information](#): File/Folder path, item type (Web, Folder, Document), permission level applied to the item (Total Control, Collaborate, Read), user name, user e-mail, user or group type (Internal, External, SharePoint Group, Security Group or Microsoft 365 Group), link identifier, link type (Anyone, People in the organization with the link, People with existing access or Specific people) and the link ID used to access the item.

A similar sharing report feature is available for OneDrive for Business, the difference being that instead of focusing on the sharing activities for everyone on a site basis, the OneDrive variant only looks at sharing of a specific user’s personal files. The **Run sharing report** link used to generate a sharing report is available on the modern OneDrive settings page. An example of how to use the Microsoft Graph to report sharing within OneDrive is [posted here](#).

## Tracking Shared Files

The *Set-SPOTenant* cmdlet also controls a setting often used by administrators to keep track of files shared with external users. The example shown below sets the *BccExternalSharingInvitations* setting to *\$True* to force SharePoint Online to generate a BCC message to a nominated list of email addresses (in a comma-separated list with no spaces) each time a user shares a file stored in a SharePoint Online or OneDrive for Business document library with an external person. The users specified in the *BccExternalSharingInvitationsList* parameter will receive a message saying that the user wishes to share a file with the addressee of the message.

```
[PS] C:\> Set-SPOTenant -BccExternalSharingInvitations $True -BccExternalSharingInvitationsList administrator@Office365ITPros.com
```

**OneDrive for Business Notifications:** SharePoint Online controls many settings for OneDrive for Business, among which are notifications for events connected with sharing files. The Sharing settings available in the SharePoint admin center allow you to opt for users to receive notifications via email when:

- Users invite external users to access shared files.
- External users accept invitations and open shared files.
- Users create or update an anonymous link used to share files.

## SharePoint Online Extensibility Options

Traditionally, one of the strongest characteristics of SharePoint has been its natural extensibility: an organization can change the system to meet business requirements in several ways. Unfortunately, the introduction of SharePoint Online initially featured a strong reduction of the extensibility options when compared to SharePoint on-premises. This was due to the intrinsic multitenant design of the platform and because Microsoft wanted to reduce the fragility of custom development.

SharePoint Online inherited from its on-premises counterpart the Add-ins model as a customization mechanism. This model supports the creation of integrated applications in the platform while running totally outside the main structure. Furthermore, it was (and still it is) impossible to install and run server-side code in SharePoint Online, something that removes the possibility to create traditional SharePoint artifacts such as classic Web Parts, Timer Jobs, Event Handlers, etc. Slowly, as the SharePoint Online platform matures and evolves, substitutes for older integration mechanisms have been added to SharePoint Online through the natural integration with other platforms (Azure, Power Automate), the work done by the SharePoint Team with SPFx and specific SharePoint community initiatives such as the PnP project.

### SharePoint Add-ins and the Global App Site

SharePoint Add-ins are self-contained pieces of functionality that extend the capabilities of SharePoint to solve business problems. Add-ins don't have custom code that runs within SharePoint Online: all custom logic moves to servers outside the SharePoint platform. Keeping custom code out of SharePoint guarantees that the Add-in can't harm SharePoint or reduce the performance of the system.

The Global App Site makes internal custom Apps available for users to install when they search apps using the "From my organization" filter on the Site Contents page. Site owners can add these apps to customize sites with specific functionality or to display information. After a Global App site has been created, it is possible to upload any custom App that the organization has developed by copying the manifest document to a document library and setting some properties. The global App Site also supports the management of app requests from users, checking how Add-ins are used, and the maintenance of license information.

The Global App Site is not created by default in a new tenant but can be added from the SharePoint admin center. In the More features section, click the "Open" button under Apps, select App Catalog, and then follow the steps to create a new App Site in the tenant. This creates a Global App Site, meaning that every Add-in uploaded to the App Site will be available for all sites in the tenant. But tenant administrators can choose to enable "Site App Catalogs" for specific sites so that solutions deployed to the Site App Catalogs can only be installed on that specific site.

Site App Catalogs are configured and managed using PowerShell and the Global App Site must exist already. Use the *Add-SPOSiteCollectionAppCatalog* cmdlet to create a Site App Catalog, indicating the site where the app catalog should be created with the *-Site* parameter. An "Apps for SharePoint" document library will be added to the site to deploy SharePoint Add-ins and SPFx solutions. To disable the Catalog, use the *Remove-SPOSiteCollectionAppCatalog* cmdlet indicating the site in the *-Site* parameter; this prevents new components from being added and any previously installed components from executing their code. It is not possible to enumerate with PowerShell all the site collections in the tenant that have the Site App Catalog enabled, but it's possible to see those Site App Catalogs through the "Site App Catalogs" list in the Global App Site. This is a hidden list that stores a record for every Site App Catalog created in the tenant. In addition, be aware that although solutions installed in Site App Catalogs can only be used in these specific sites, they can theoretically use resources from other sites in the tenant.

### SharePoint Framework (SPFx)

SPFx is a Page and Web Part development model that empowers client-side development, integration with SharePoint Online and on-premises, and integration with the Microsoft Graph. It is based on open source

tooling and JavaScript technologies. SPFx is used in SharePoint as the extensibility paradigm for the client-side development framework to allow developers to implement new functionality in SharePoint.

SPFx is used extensively by Microsoft to build the modern user experiences seen in SharePoint Online, but external developers can use the same technology, tools, and techniques to build more productive experiences and apps that are responsive and mobile-ready.

From the infrastructure point of view, the files required for SPFx are just JavaScript archives plus the accompanying style sheets, graphics, and other required files that should be deployed to an accessible place for the client computers. This can be implemented using the SharePoint Content Delivery Network (CDN), a SharePoint document library, the Azure CDN, or any other available private or public CDN. Additionally, a manifest file must be deployed to the SharePoint Catalog, so that SharePoint is aware of the existence of the components. Normally a distribution package is created by the developers and delivered to the administrators that install them in the SharePoint Catalog, in a similar way as for SharePoint Add-ins.

## Microsoft 365 Patterns and Practices (PnP)

The [Microsoft 365 Patterns and Practices community](#) initiative comprises components aimed at enhancing the functionality of SharePoint on-premises and Online in several ways, filling the development and infrastructure gaps left by Microsoft. The components include:

- [PnP Framework](#), a .NET standard 2.0/.NET 5.0 library targeting Microsoft 365 containing useful extensions to extend SharePoint and Microsoft 365 APIs.
- [PnP Transformation Framework](#), a generic solution designed to transform any web-based/content-based solution into a modern SharePoint Online Portal.
- [PnP PowerShell cmdlets](#).
- [PnP Scripts Samples](#), a web site with several samples demonstrating how to use PowerShell in different use cases about getting information and managing SharePoint Online and other Microsoft 365 workloads.
- [PnP Core SDK](#), a unified object model to work with SharePoint Online and Teams that is agnostic to the underlying APIs. Over the time, the developers plan to extend the SDK to support other Microsoft 365 workloads.
- **A complete [PnP Provisioning Engine](#)** is included in the PnP Framework.
- [PnPJS](#), a JavaScript library to help consume SharePoint and Office 365 APIs securely.
- PnP tools, such as the PnP SPFx Yeoman Generator, the CLI for Microsoft 365, or the Microsoft Graph PowerShell SDK among others.
- [PnP guidance](#).
- **Ready to use solutions** such as the [PnP Starter Kit](#).
- **The SharePoint look book**, a [free service](#) to deploy customized sites in a SharePoint tenant based on a selected site template. The service includes several ready-to-use templates. Each template consists of a customized home page, lists, document libraries, and custom Web Parts.

Using PnP reduces the development effort needed to work with SharePoint. For example, to create a new list or document library using PowerShell requires the use of the SharePoint CSOM API (create a context, recall the web and site objects, create a new List object, execute the operation, etc.), as well as some knowledge about programming and the internal structure of the service. With PnP PowerShell cmdlets, you only need to connect to SharePoint Online for a tenant and use *New-PnPList* as follows:

```
[PS] C:\> Connect-PnPOnline -Url "https://tenantname.sharepoint.com/sites/namesitecollection" -
SPManagementShell
[PS] C:\> New-PnPList -Title "PnPList" -Template GenericList -Url "Lists/PnPList"
```

The *Connect-PnPOnline* cmdlet needs valid user credentials to make the initial connection to the tenant. Then a new list called "PnPList" is created using the *New-PnPList* cmdlet and the *Template* parameter to specify the

list template to use. Be aware that the connection is only valid for the given URL endpoint; if you want to use another site, you need to make a new connection.

Provisioning is probably the most used and most powerful PnP feature. The recommended way to provision in SharePoint Online is to create a new "standard" object in SharePoint, and then apply all the customizations using scripting (thus not creating new templates as traditionally used). The PnP provisioning engine is powerful enough to create and modify almost any element in a site: the creation of subsites, Lists, Libraries, Custom Fields, Content Types, views, attach users, etc. There are several cmdlets and ways to provision them using PnP:

- Make a template (just an XML file) that contains all the elements to be created, deleted, or modified, and run the *Invoke-PnPSiteTemplate* cmdlet pointing to the XML file and URL endpoint. The creation of fully customized SharePoint objects using this way is possible (and recommended).
- Manually create all the customization required in a dummy site and generate the XML template using the *Get-PnPSiteTemplate* cmdlet. Then, the template can be used to provision as many clones as necessary using *Invoke-PnPSiteTemplate*.
- PnP Provisioning Engine and XML templates can easily be used in .NET code, so the same process described to get and apply a provisioning template with PowerShell can be done programmatically.
- There are also specific PnP cmdlets to manage some provisioning objects. For example, to create a new view for the early created List, use:

```
[PS] C:\> Connect-PnPOnline -Url "https://tenantname.sharepoint.com/sites/namesitecollection"
[PS] C:\> $myList = Get-PnPList -Identity "Lists/PnPList"
[PS] C:\> Add-PnPView -List $myList -Title "myView" -SetAsDefault -Fields ID,Title,Created
```

## Site Scripts and Site Templates

Site scripts and site templates are [extensibility mechanisms for SharePoint Online](#) that allows administrators to create, deploy and apply templates to [modern and classic sites based on a specific site template](#). Site scripts and site templates can be applied during site creation, as part of a hub association, or to existing sites. End users with the required permissions can also apply [scenario-based templates](#) or organization templates to existing SharePoint sites by using the *Apply a site template* option in the site settings menu. This option is also based on the site scripts and templates extensibility model.

The following site types support site scripts and site templates:

- Modern Team Sites linked to a Microsoft 365 Group (GROUP#0).
- Modern Team Sites not linked to a Microsoft 365 Group (STS#3).
- Communication sites (SITEPAGEPUBLISHING#0).
- Channel site templates (TEAMCHANNEL#0, TEAMCHANNEL#1). The latter template is now generally used for sites belonging to both private and shared channels.

**Site templates and Hub Sites:** Site templates can be [applied to Hub Sites to apply to the associated sites too](#). This option is an optional setting for a given hub site and requires the site template and site script to already be available in the tenant.

Site templates are always based on an out-of-the-box template, and can be deployed through PowerShell as follows:

```
[PS] C:\> Add-SPOSiteDesign -Title "HR Site" -WebTemplate "64" -SiteScripts "<ID>" -Description "HR Department Site"
```

Site templates always reference one or more site scripts (by their identifiers) to apply the customizations defined by the script. *WebTemplate 64* is the identifier for the Modern Team sites while 68 is for Communication sites and 69 for Teams channel sites. It's important to note that there is a limit of 100 site scripts and 100 site templates per tenant.

A site script is a JSON file defining the customizations to be added to a new site (where the site template is the actual template to define the site). Site scripts are uploaded to a gallery at the tenant level, making them available for all sites. Site scripts are deployed using the *Add-SPOSiteScript* cmdlet, which returns the ID to be used by *Add-SPOSiteDesign*:

```
[PS] C:\> Add-SPOSiteScript -Title "Create HR lists" -Content $mySiteScript -Description "Creates lists for HR site"
```

In the above example, the *\$mySiteScript* variable contains the JSON string with the actions to implement.

**Site template JSON Schema:** Microsoft updates the [JSON Schema](#) regularly. The schema defines all the actions and sub-actions that can be included in a site template. To simplify the creation of a Site template, there is a [free online tool](#) to visually define the JSON structure for a specific Site Design.

## Using PowerShell to Apply Site Templates

A site template can be applied to an existing site by using the Apply a site template option in the settings menu for a site or by running the *Invoke-SPOSiteDesign* or *Add-SPOSiteDesignTask* cmdlets. The first option allows the site administrator to view all the site templates available and apply them to the site while updating site templates with PowerShell is a good way to automate updates across a set of sites. The two cmdlets take a different approach in how they implement site templates:

- *Invoke-SPOSiteDesign* applies the site template to the site immediately.
- *Add-SPOSiteDesignTask* adds the site template application to a schedule to be run as a background job. In addition, this cmdlet extends the 30-action limit in a site script that is applied synchronously to 300 actions (or 100,000 characters). More information about the limits applying to site scripts and site templates [can be found in Microsoft's documentation](#).

Site scripts can also be generated from existing sites, lists, and document libraries, which means that existing site settings, lists, and document libraries can be easily ported to another site. The *Get-SPOSiteScriptFromList* cmdlet can be used to autogenerate a site script from a list. Alternatively, the *Get-SPOSiteScriptFromWeb* cmdlet can autogenerate a site script that includes the following site settings: branding, theme, regional settings, sharing capability, and the lists and document libraries specified in the *IncludedLists* parameter:

```
[PS] C:\> $sSPOSiteUrl=" https://redmondassociates.sharepoint.com/sites/0365ExchPro"
[PS] C:\> Get-SPOSiteScriptFromWeb -WebUrl $sSPOSiteUrl -IncludeBranding -IncludeTheme
-IncludeRegionalSettings -IncludeSiteExternalSharingCapability
-IncludedLists("Lists/ListName1", "Lists/ListName2")
```

**Discover which site templates are applied to a site:** The *Get-SPOSiteDesignRun* cmdlet shows all the site templates that have been applied to an existing site. The *Get-SPOSiteDesignRunStatus* cmdlet returns the result of each action from every site script in a site design. Site owners can also [view templates](#) through the View template history link available in the Site Information panel.

## Configuring Site Regional Settings with Site scripts

Site scripts can set default regional settings for new sites. This is important if you want to ensure that sites display the correct document creation and modification times in local format when accessed through a browser. By default, SharePoint Online sets the default time zone to Pacific Daylight Time (UTC -8), which is fine for people in Redmond but not so good for users elsewhere in the world. You can always update these settings by accessing the Regional Settings of a site. However, given that Teams and Groups create many of the new SharePoint Online sites and their owners are usually people with little knowledge of SharePoint internals, it is best if the settings are correct from the start.

An example of [how to configure regional settings](#) is available on GitHub. The steps are straightforward. First, create a JSON-formatted input file holding the settings that you want to use. In this example, I select GMT as

the default time zone, that we use the 24-hour format instead of the 12-hour format, and that Ireland is the default country (locale id or LCID). Examples of other locale ids are 3082 (Spain), 5129 (New Zealand), and 1035 (Finland). A [full list of locale ids](#) is available online.

```
{
"$schema": "schema.json",
"actions": [
  {
    "verb": "setRegionalSettings",
    "timeZone": 2, /* Greenwich Mean Time */
    "locale": 6153, /* Ireland */
    "sortOrder": 25, /* Default */
    "hourFormat": "24"
  }
],
"bindata": { },
"version": 1
}
```

Save the JSON data to a file. Then connect to SharePoint Online with PowerShell and execute the following command to retrieve the settings from the file and load them into a variable (*\$SiteScript*). Make sure you install the latest version of the SharePoint Online PowerShell module before trying to use the site template cmdlets.

```
[PS] $SiteScript = (Get-Content "C:\Temp\RegionalSettings.json" -Raw | Add-SPOSiteScript -Title "Set Ireland Regional Values" -Description "Sets locale, time zone, and hour setting for Ireland")
```

Now run the *Add-SPOSiteDesign* cmdlet to load the settings as default regional values.

```
[PS] C:\> Add-SPOSiteDesign -Title "Set Ireland Regional Values" -WebTemplate "64" -SiteScripts $SiteScript -Description "Applies Ireland regional settings" -IsDefault
```

To test that the change is effective, create a new team or group and examine the regional settings for the site that SharePoint Online provisions. Open the site with SharePoint, select Site Contents, then Site Settings, and then Regional settings. The locale and time zone settings should be the values set in the script. Alternatively, you can apply the site template to an existing site through the Site templates dialog available in the settings menu, just select the desired site template and click on the "Apply to site" button.

If you make a mistake, you can update the site design with the *Set-SPOSiteDesign* cmdlet or remove the site template and start over. Run the *Get-SPOSiteDesign* cmdlet to return a list of site templates in the tenant and note the identifier (Id) for the design you want to remove. Then run the *Remove-SPOSiteDesign* cmdlet to remove it.

```
[PS] C:\> Get-SPOSiteDesign

Id                : f466a1da-e2a2-4107-b558-35954ad199de
Title             : Default
WebTemplate       : 64
SiteScriptIds    : {9e287dd9-b2b1-4ceb-8649-998f43b24c1d}
Description      : Applies Ireland regional settings
PreviewImageUrl  :
PreviewImageAltText :
IsDefault        : True
Version          : 1

[PS] C:\> Remove-SPOSiteDesign -Identity f466a1da-e2a2-4107-b558-35954ad199de
```

Setting default regional settings for new sites with a site script does not update regional settings for existing sites. If you want those sites to use the correct time zone and locale, you can either update the settings manually or use a script. Here's an example that looks for Microsoft 365 Groups that are provisioned for SharePoint and then applies a site template (identified with a GUID) to each site.

```
[PS] C:\> $SitesUpdated = 0
$DesignID = " f466a1da-e2a2-4107-b558-35954ad199de"
$Groups = (Get-UnifiedGroup | ? {$_SharePointSiteUrl -ne $Null} | Select SharePointSiteUrl,
DisplayName, Alias)
ForEach ($G in $Groups) {
    Try {
        Write-Host "Processing" $G.SharePointSiteUrl "for group" $G.DisplayName
        Invoke-SPOSiteDesign -Identity $DesignID -WebUrl $G.SharePointSiteURL -ErrorAction Stop
        $SitesUpdated++
        Set-UnifiedGroup -Identity $G.Alias -CustomAttribute13 "Site Design Updated" }
    Catch {
        Write-Host "Problem Processing" $G.SharePointSiteURL}
}
Write-Host $SitesUpdated "sites updated successfully. You need to check the following and update
them manually"
Get-UnifiedGroup -Filter {CustomAttribute13 -eq $Null} | Sort DisplayName | Format-Table
DisplayName, SharePointSiteURL
```

The list of groups generated at the end of the script includes all groups that we cannot update. In some cases, this is because SharePoint is not fully provisioned for the group (a more common problem for older groups) and no one has ever tried to access the document library. If the site does not exist, we cannot update its regional settings. In other instances, the account used to run the script might not have the necessary permissions to update site settings. Administrators can update these sites manually as time allows.

## Managing Built-In Site Templates

SharePoint administrators can control which of the built-in site templates are available to site creators. To retrieve the current state of specific built-in site templates, run the [Get-SPOBuiltInSiteTemplateSettings](#) cmdlet. Then, to show or hide a template, run the [Set-SPOBuiltInSiteTemplateSettings](#) cmdlet. For example, to hide the "Event planning" site template, run the following command:

```
[PS] C:\> Set-SPOBuiltInSiteTemplateSettings -Identity '9522236e-6802-4972-a10d-e98dc74b3344' -
isHidden $true
```

## Additional Features in SharePoint Online

Apart from the day-to-day business of site and service management, several operations exist that only need to be performed on an on-demand basis. We cover these actions here.

### Tenant Rename

Currently available in preview, Tenant rename allows organizations to [change the SharePoint domain name](#) using the following steps:

- Add and verify the new domain name in the custom domain names blades in the Azure AD portal.
- Initiate the SharePoint tenant rename using the *Start-SPOTenantRename* cmdlet with the attributes *DomainName* and *ScheduledDateTime* configured with the target domain name and the date and time to start the rename process. For example, this command instructs SharePoint Online to begin the domain rename process on July 31, 2022, at 10:25 UTC.

```
[PS] C:\> Start-SPOTenantRename -DomainName "NewDomainName" -ScheduledDateTime "2022-07-31T10:25:00"
```

- Give the tenant rename process some time (it can take several hours or even days depending on the number of SharePoint sites and OneDrive accounts to process) before starting to review if everything works as expected under the new domain.

To check the status of the rename operation, use the *Get-SPOTenantRenameStatus* cmdlet. Similarly, the *Get-SPOSiteRenameState* cmdlet checks the state of a specific site.

## Microsoft Defender for Office 365

[Microsoft Defender for Office 365](#) can be enabled on E5 tenants or E3 tenants to run check files in document libraries to make sure that they're not infected with malware. Microsoft Defender for Office 365 P1 is also available in Microsoft 365 Business Plans.

Microsoft Defender for Office 365 works across all SharePoint Online and OneDrive for Business sites in a tenant. It uses a mixture of technologies, including advanced threat heuristics generated from intelligence gathered by Microsoft about malware to find suspect files. Instead of scanning all files, which would consume enormous server resources, Microsoft Defender for Office 365 focuses on blocking the spread of malware. When a user shares a document, it checks whether sharing should go ahead. If all is well, sharing proceeds as normal. If not, SharePoint locks the file and disables the ability to download, open, or share it. The user can remove the file to solve the problem. See the Mail Flow chapter for additional information about Microsoft Defender for Office 365.

## Restore This Library for SharePoint Online

To help recover documents from accidental deletions, a malware attack, or other data loss, the Restore this library feature (available to administrators and site owners in the library settings panel) is a self-service recovery mechanism to allow site administrators and site owners to roll back changes made to a document library to any point in time during the last 30 days. You can select from several out-of-the-box restore points (Yesterday, One week ago, Three weeks ago, Custom date and time), or use a slider to move through the set of changes for the library to select any point up to the 30-day limit (Figure 8-3). The changes that can be rolled back include updates to document properties such as title or assigning a retention label.

After you select a restore point, SharePoint prompts you to confirm to go ahead with the restore, and if confirmed, SharePoint rolls back all the changes from the library to the chosen point in time to restore the library to its state at that time.

Restore HR Department - Documents

If something went wrong, you can restore this library to a previous time. Select a date preset or use the slider to find a date with unusual activity in the chart. Then select the changes that you want to undo.

Select a date

Three weeks ago All changes after 3/21/2020, 12:00:00 AM will be rolled back

Restore Cancel

Move the slider to quickly scroll the list to a day.

Days ago

Select a change in the list below to highlight it and all the changes before it. Then select the Restore button to undo all the highlighted changes.

Change	File name
2 days ago - 4/9/2020 (3)	
Renamed by Juan Carlos González Martín 4:44:23 PM	HR Document #31.docx > HR Document #6.docx
Renamed by Juan Carlos González Martín 4:44:09 PM	HR Document #21.docx > HR Document #5.docx

## Multi-Geo Support for SharePoint Online

[Multi-Geo support for SharePoint Online and OneDrive for Business](#) is a mechanism to control where data from both services are stored at rest to meet data residency requirements when users work in multiple geographies. [Multi-Geo capabilities are available as an add-on to specific Office 365 Plans](#) for Enterprise Agreement (EA) customers with a minimum of 250 paid licenses. For more information about multi-geo, including pricing, contact your Microsoft account team.

## Encryption for SharePoint Online and OneDrive for Business Storage

Files in SharePoint Online and OneDrive for Business are protected by unique, per-file keys that are exclusive to a tenant. The keys (AES 256-bit), which are created and managed by the SharePoint Online service itself or by customers (when customer-managed keys are used), are used to encrypt files stored in SharePoint Online and OneDrive for Business.

## Comments on non-Office files in SharePoint Online and OneDrive for Business

The Office 365 file viewer supports more than 350 file types and includes the ability for users to collaborate and communicate about non-Office files with comments and replies. Anyone who opens a non-Office file can view the comments through the details pane and leave additional comments. File owners will receive notifications when someone comments on their files. Notifications are also sent to users when someone leaves a reply to their comments. Users may unsubscribe from these e-mail notifications via the "Unsubscribe" link in the notification e-mail.

## Intelligent File card in SharePoint Online and OneDrive for Business

The File card in SharePoint Online and OneDrive for Business incorporates several [intelligent features](#) to quickly get deeper information about relevant activities happening around the document (edits, mentions, and comments), document statistics (number of views, number of viewers and details about who viewed the file), suggestions about to whom share the document based other people the current user frequently works with, and [conversations](#) happening in e-mail or Teams about the document.

## Enabling Loop Components in Applications

Microsoft's Fluid framework is a technology ([now available as open source software](#)) designed to help developers build better collaborative applications using "live" components. The big selling point for the Fluid framework is its synchronization capabilities, which allow components to coordinate updates made by multiple people to the same content and coherently present the information. Apart from the new Microsoft Loop application, scheduled for availability sometime in 2022, Microsoft 365 supports loop components in Teams chat messages, email in OWA and Outlook for Windows, and Microsoft Whiteboard. See the Teams architecture chapter for more information about the implementation of loop components in Teams.

Microsoft controls the use of loop components in Microsoft 365 applications using a setting in the SharePoint Online tenants configuration. ***IsLoopEnabled*** controls the availability of Loop components in applications like Teams, OWA, and Outlook desktop. This setting replaces the older ***IsFluidEnabled*** setting, which is due for deprecation in November 2022. A related ***IsWBFluidEnabled*** setting controls if Whiteboard uses OneDrive for Business storage. Microsoft will retire this setting after Whiteboard completes its transition to OneDrive for Business in all tenants.

You can update the settings with the *Set-SPOTenant* cmdlet. For example:

```
[PS] C:\> Set-SPOTenant -IsLoopEnabled $True -IsWBFluidEnabled $True
```

To disable the setting, update it to `$False`. Due to an issue with offline access to Loop components in items recovered by eDiscovery searches, some organizations do not allow the use of Loop components. Microsoft is working on an offline access capability, but this is not yet available.

# OneDrive for Business

OneDrive for Business (or OD4B as it is known in the Microsoft 365 ecosystem) is a cloud-based file sharing service based on SharePoint Online to provide users with a personal storage space. From an administrative perspective, a OneDrive account behaves like a personal version of a SharePoint document library. Microsoft Search indexes all the information stored in OneDrive, meaning that it is discoverable and available for compliance purposes.

Referring to anything as a personal storage space is a bit of a mouthful. In a practical sense, users can store anything in their OneDrive for Business account, just like they would do with a personal network share on an old-fashioned file server. Indeed, the prime purpose of OneDrive for Business is to help companies to wean themselves off file servers by moving the content held on the servers into the cloud. Users who have personal files stored in network shares can move their information to OneDrive for Business while Teams or SharePoint Online team sites are good homes for organizational or shared information.

## Access on Multiple Devices

The big advantage of using OneDrive for Business from a user's perspective is that once they store files on OneDrive, the files are available from any device. When network connectivity was not as pervasive and capable as it is now, it would not have been possible to contemplate such a movement, but it is now. Although you need to have network access to browse OneDrive for Business sites, the OneDrive sync client allows users to work with files copied to a local cache. Some restrictions exist in terms of the types of files and the names of files that OneDrive for Business supports. It is sensible to check on the [current limits and restrictions](#) before you start a project to help users move their information from file servers. The limits for the current OneDrive sync client are much higher than in earlier versions, so you should confirm whether any limits that stopped a project moving forward still exist. It is also sensible to implement whatever controls are necessary for client synchronization (discussed in the next section) at the start of a migration project instead of trying to retrofit some restrictions afterward.

The ability of OWA, Outlook, and Teams to access files held in OneDrive for Business gives further encouragement to use the service. For example, users can upload files to OneDrive for Business and then send a link to the attachment (a "cloudy" attachment). Users can also save attachments from Outlook or OWA direct to OneDrive for Business or to the document libraries in Groups where they are members. The intention behind making these features available is to help users change their habit of storing email attachments on their local PC and refocus toward cloud-based storage instead. Whether it is possible to break the "always send full copies of attachments by email" habit is debatable. What is for sure is that breaking the habit needs people to change their personal workflow, and that is always hard.

Another advantage gained by keeping files in OneDrive for Business is that users can grant others the right to edit the document in place, which might encourage better collaboration. By using cloudy attachments, recipients get to see the latest version of the information they receive because access is always to the version held in OneDrive for Business rather than a personal copy, thus avoiding the problem that someone might update a copy received in email by the time you read an attachment.

**Install OneDrive as a Progressive Web App:** OneDrive can be [installed as a Progressive Web App](#) in Microsoft Edge, Google Chrome, or any other modern web browser that supports Progressive Web Apps.

## OneDrive for Business Contents and Limits

The first time a user accesses OneDrive for Business, SharePoint Online provisions the site. Once the site is ready, the user can upload files to the site and share those files (or complete folders). Users can attach files

from OneDrive to messages as easily as local files. To ensure that users have enough space to move their personal information from old file servers, [depending on their license type](#), users receive up to 1 TB of online storage, which comes from an allocation that is separate to and not counted against the pooled storage used for SharePoint Online. Tenants that have five or more licenses for E3 or higher enterprise plans (plus government and academic equivalents) can take advantage of “unlimited storage”.

OneDrive assigns a default storage quota of 1 TB to each user for their personal site, which should be enough to move personal files off file shares and even from local PC hard drives. If you want to adjust the OneDrive for Business storage for an account, you can either send a support ticket to Microsoft or ask an administrator to run the *Set-SPOSite* cmdlet to increase the quota. Here is how to increase the storage quota from the default 1 TB to 5 TB for the *Tony.Redmond@Office365ITPros.com* account.

```
[PS] C:\> Set-SPOSite -Identity
https://office365itpros-my.sharepoint.com/personal/tony_redmond_office365itpros_com -StorageQuota
5242880
[PS] C:\> Get-SPOSite -Identity
https://office365itpros-my.sharepoint.com/personal/tony_redmond_office365itpros_com | Format-List
```

Later, if the account approaches the 5 TB storage limit, you can increase the quota to 10 TB (set the value to 10485760). You can keep on increasing the quota in 5 TB chunks as the need arises. An attempt to increase the quota will only succeed if the used quota is approaching a chunk boundary. In other words, you cannot increase the quota assigned to an account from 3 TB or 15 TB but must first increase the quota to 10 TB and then wait until the storage used passes 12 TB or thereabouts before upping the quota to 15 TB.

To check the quota assigned to each user and how much of the quota they use, you can run the following PowerShell snippet.

```
[PS] C:\> Get-SPOSite -IncludePersonalSite $True -Limit All -Filter "Url -like
'my.sharepoint.com/personal/'" | Select Owner, StorageUsageCurrent, StorageQuota
```

Owner	StorageUsageCurrent	StorageQuota
james.gangley@office365itpros.com	1	1048576
brian.weakliam@office365itpros.com	1	1048576
tony.redmond@office365itpros.com	3727	5242880

No error checking is in this simple code, so you will see an error if an attempt is made to check a user's OneDrive site that has not yet been provisioned because the user has never used OneDrive. To fix that problem, you can request OneDrive for Business to provision a site for the user by running the *Request-SPOPersonalSite* cmdlet. The input is a comma-separated list of email addresses for the users for which OneDrive is to create sites. You can specify up to 200 email addresses in the list.

```
[PS] C:\> Request-SPOPersonalSite -UserEmails "Sanjay.Ramaswamy@office365itpros.com,
David.Pelton@office365itpros.com" -NoWait
```

OneDrive uses a timer job to create the sites. The actual time when the sites will exist depends on system load.

## Information Views in OneDrive for Business

OneDrive for Business includes several views to give the user the ability to see their information as well as the information they have shared with other users and the information other users have shared with them. Table 8-2 details the current information views included in OneDrive for Business.

Information View	Information View Details
My files	Shows the files and folders stored in the user's OneDrive for Business account.
Recent	Shows a list of recent files the user has worked on, including the date and time of the last access.

Shared	Two additional information views are available. "Shared with you" shows the files shared with the user including the person sharing the file and the last file activity. This view also includes the "Popular around you" section that surfaces files recommended to the user based on his/her working relationships. This section is intended to help find relevant and trending information faster and to also discover content the user might not have been aware of. "Popular around you" only shows the information the user can access and does not change file permissions. "Shared by you" shows the files the user has shared with other users and the last file activity.
Quick access	Provides access to the different Document libraries the user has access to. Document libraries are in two categories: "Frequent" and "Followed". From the Shared libraries view, users can create new Document libraries and/or access the SharePoint Online landing page.

Table 8-2: Information Views in OneDrive for Business

## Sharing in OneDrive for Business

Sharing is one of the key capabilities provided by OneDrive for Business driven by the same features previously described for SharePoint sites.

### OneDrive for Business Link open receipt

When a user opens a file or folder shared from OneDrive for Business, the service sends an e-mail to the sharing user to notify them that the file or folder has been opened. The notification e-mail also includes a link to file or folder permissions management to review how the file or folder was shared and even remove the sharing link.

### Customer Branding in Sharing Email

If a tenant configures Azure AD with custom branding for the organization, their [logo appears in the sharing e-mail sent](#) when a file is shared from OneDrive for Business or SharePoint Online. Information about how to apply custom branding for Azure AD is in the Identities chapter.

## Request Files

The Request files feature allows users to create a special sharing link to ask other users to upload files to a specific folder. When a user selects a OneDrive for Business folder and clicks "Request files," OneDrive generates a file request link. Anyone can use this link to upload files to the target folder, but they cannot view, edit, or see who else may have uploaded files using the link. When someone uses the Request files link, he/she is redirected to a special page where he/she can indicate the files to be uploaded together with some personal details (First Name and Last Name) to let the requestor know who uploaded them to the folder.

## Add Shortcut to OneDrive

The Add Shortcut to OneDrive feature allows users to add shortcuts to SharePoint Online and OneDrive for Business folders where they commonly access files. The folders can be:

- Folders shared with the user from OneDrive or SharePoint.
- Folders in any SharePoint Online document library the user can access.

Shortcuts appear in OneDrive's My Files view. Folders pointed to by Shortcuts can be accessed from any OneDrive App, synced across all devices, and shared like any other folder owned by the user. Owner information is visible in the Sharing column to differentiate it from the user's own content. The group name appears for content shared from sites owned by Microsoft 365 groups. Shortcuts to shared folders retain all

policy, compliance, and permissions settings from the source. Shortcuts [can be moved from the Files root in OneDrive to a public or shared folder](#).

## OneDrive Client and Synchronization

A key OneDrive for Business benefit is the ability to synchronize content stored in SharePoint Online document libraries and OneDrive for Business accounts to workstations using the OneDrive Sync Client. System requirements for the OneDrive Sync Client, including the list of supported platforms and operating systems, are in [this support article](#). In addition, [Microsoft has previews of a native OneDrive for Business Sync Client](#) for ARM devices for Windows and Mac OS and Apple Silicon devices.

The support lifecycle of the OneDrive Desktop application (sync app) follows the Windows support lifecycle, meaning that support for Windows 7 and Windows 8.1 will end on January 10, 2023.

The synchronization mechanism depends on the host operating system and application. For Windows, OneDrive uses the Windows Push Notification Service (WNS) to synchronize files. The basic approach is:

- A change occurs in a file stored in Microsoft 365. WINS notifies the OneDrive sync client of the change.
- The OneDrive sync client adds the change to its Internal Server Changes Queue. If the change involves file metadata, like renaming or deleting a file, the client processes the change immediately. Otherwise, the sync client starts a download session to update the local copy of the file.
- When a file change happens locally, WINS notifies the OneDrive sync client that it needs to update the copy in Microsoft 365.
- The client starts a session to upload the file to Microsoft 365.

The synchronization mechanism differs depending on the file type. For non-Office files, the client uses Background Intelligent Transfer File (BITS) sessions. The client transfers files smaller than 8 MB in a single HTTPS request. It divides larger files into chunks and transmits them separately to the service. Each chunk has a unique identification and separate key for protection. After the client has transmitted all the chunks, the server can reassemble the file. This mechanism allows the OneDrive sync client to process very large files up to the 250 GB current limit.

Office applications have built-in synchronization capabilities to enable features like autosave and co-authoring. The OneDrive sync client offloads synchronization processing to the relevant Office application, which sends changes to SharePoint Online or OneDrive for Business. This can only happen when the Office application is active. If it is not and it must copy an Office document, the OneDrive sync client processes it like it would any other file.

### OneDrive Sync Client and Files on Demand

The OneDrive for Business sync client (OneDrive.exe) shares a common code base with the OneDrive consumer client. It supports OneDrive for Business and SharePoint sites, including the document libraries used by Groups and Teams, and can perform read/write synchronization of document libraries with more than 20,000 files, including required metadata. The client is integrated with Windows File Explorer to allow users to choose which files have local copies and which are copied on demand (when needed). A feature called Differential Sync copies only the parts of files changed during edit sessions instead of the entire file. This feature is especially important when the OneDrive sync client processes large files up to its 250 GB limit. The sync client can pause synchronization in low-bandwidth environments (such as when connected to Wi-Fi on an airplane). The synchronization problems experienced by some users in the past are largely gone and the synchronization of documents from SharePoint Online and OneDrive for Business to and from local storage is reliable.

**Restrictions and Limitations in OneDrive for Business Synchronization:** OneDrive for Business can sync both OneDrive for Business libraries as well as SharePoint Online document libraries from team sites, but there are some [documented restrictions and limitations](#) that must be considered when synchronizing files to a local workstation. The file size limit for both SharePoint Online and OneDrive for Business is 250 GB. This limit applies to web uploads and synchronization activities.

The **Sync** section of the OneDrive for Business admin center includes the **Show the Sync button on the OneDrive site** setting to control access to the sync client for the tenant. You can hide the button completely if you do not want users to be able to synchronize OneDrive to their workstations.

Files On-Demand is a feature that allows users to control local storage for files held in OneDrive for Business or SharePoint Online sites. The feature is managed through the **Settings** tab of the OneDrive sync client, where users can set the checkbox to enable Files on Demand for their account. Afterward, they can select how to store remote files locally for the folders from OneDrive and any synchronized SharePoint site that they want to see on the device. Synchronized files can be in the following states:

- **Online-only files** are in OneDrive or SharePoint sites but appear in File Explorer to let the user know that they exist. These files occupy no disk space on the local computer.
- If users open online-only files, File Explorer downloads them from the host site and makes the files **locally available**. A locally available copy can be opened at any time, even if a network connection to a document library is unavailable. When a network connection becomes available, the OneDrive sync client synchronizes any changes made on the workstation with the host site.
- Users can also decide to mark files as **Always keep on this device**. This means that the OneDrive sync client copies these files from the host site to make them available locally even if the user never opens them.

File Explorer uses different icons to show users the status of files. Online-only files have a cloud icon, while locally-available copies have a white circle with a green checkmark, and files always present on the device have a green circle with a white checkmark (Figure 8-4).

Figure 8-4: Files On-Demand icons

When the OneDrive sync client is processing a file, the icon changes to two curved arrows in a circle. To change the synchronization status of a file, select it (or several files at one time), and use the right-click menu. You can see the icon showing the synchronization state of the files in the Status column. Files on Demand settings are unique to a device. If you use several devices, you must configure the settings on each device.

**Reset the OneDrive Sync Client:** Sometimes the OneDrive sync client can experience issues that cannot be resolved through normal troubleshooting techniques such as pausing synchronization for a short time or stopping and restarting the sync client. If necessary, you can resolve the problems by resetting OneDrive by typing the following instruction in the Windows command line:

```
%localappdata%\Microsoft\OneDrive\onedrive.exe /reset.
```

This command forces OneDrive to perform a complete synchronization of all connected personal and business sources, including the user's OneDrive for Business account and any SharePoint Online document

libraries they have opted to synchronize. After running the reset, you might need to manually restart OneDrive. As the operation resets all OneDrive settings, if the user has selected to synchronize specific folders, they must [make the folder selection](#) again.

## Files on Demand Prerequisites

Files On-Demand prerequisites for Windows 10 and Windows Server 2019 are detailed in [this support article](#). Prerequisites for Mac OS are explained in [this other article](#). Files On-Demand is part of the [Storage Sense](#) feature, so when disk space runs low, OneDrive frees up space automatically by moving back the oldest files (not marked as “always keep on device”) to a cloud-only state

**Support for UPN changes in the OneDrive sync client:** the OneDrive sync client for both Windows & Mac automatically syncs the correct OneDrive location after a user’s UPN changes. To learn how UPN changes affect OneDrive, see this [Microsoft article](#).

## Disable Windows Permission Inheritance in Folders Synced Read-Only

Through [this setting](#) in the Group Policy for OneDrive for Business, admins can instruct the sync client to manage permission inheritance for folders that are synced as read-only on a Windows Computer. When enabled, the performance of the sync client is better when synchronizing folders for which the user has only read-only permissions.

## Smart Upload Management

[Automatic bandwidth management for upload](#) controls the sync client upload rate based on bandwidth availability. In this mode, OneDrive consumes only unused bandwidth to cause no interference with any other network application. Smart Upload Management uses the Windows LEDBAT (Low Extra Delay Background Transport) protocol and is available on devices running Windows 10/11 or Windows Server 2016 (or later).

## OneDrive Sync Client Mass Delete Prompt

OneDrive monitors the removal of files from a device and prompts for confirmation if the user deletes many synchronized files on their computer at one time. If the user didn’t intend to delete so many files, they can tap **Restore Files** to recover. If not, OneDrive removes the files from the device and the cloud locations. If a user wants to skip the new behavior, they can select the Always remove checkbox to skip the prompt for future mass deletes.

## Error Resolution for Illegal File and Folder Names in OneDrive

There are situations where the OneDrive client can’t sync a file or a folder because its name contains invalid characters. To solve the problem, the OneDrive client includes a **Rename** button to automatically fix these sync problems when file and folder names meet the following criteria:

- Beginning or ending with a space.
- Beginning or ending with a period.
- Containing unsupported [Unicode](#) code points.
- Named with [surrogate](#) pair issues.

In all these situations, OneDrive replaces the illegal character with an underscore. As detailed in [this support article](#), there are still other invalid characters that cannot be renamed by the Sync client. To help users fix invalid characters, Microsoft created the [Incident deflection feature for the Sync Client](#), an in-app resolution to sync errors. For example, when the sync client meets an invalid condition like using an asterisk “\*” symbol or any file name starting with “~\$.” In these situations, the OneDrive sync client renames the file and continues with the upload.

## Request Assistance Feature

A [“Get Help” option](#) in the OneDrive activity center is available for end users so they can initiate a support ticket in case they have problems with the Sync client. Administrators can turn off this setting by running the PowerShell command:

```
[PS] C:\> Set-SPOTenantSyncClientRestriction -DisableReportProblemDialog $True
```

## Sync Machine Specific Files

The OneDrive sync client is designed to ignore machine-specific files used by File Explorer on Windows and Finder on macOS, but situations exist where these files might end up in OneDrive such as during a file migration. To prevent the visible errors displayed when those files are copied to OneDrive, the Sync client will delete the erroneous copy without touching the local copy.

## Per-machine Sync Client Installation

instead of installing the OneDrive Sync client for each user account under the “%localappdata%” folder, you can install a shared version of the sync client under the “Program Files (x86)” directory. This means that all the profiles on the computer use the same OneDrive.exe binary. This installation mode enables the following features to help in the transition from the previous generation sync client:

- Automatic transitioning from the previous OneDrive sync client (Groove.exe).
- Automatic conversion from per-user to per-machine.
- Automatic updates when a new version is available.

## Exclude Specific Files from Upload

[This setting](#) prevents the sync client from uploading specific files to OneDrive or SharePoint sites. Excluded files appear in File Explorer with a “do not enter” icon in the Status column. This setting is supported from version 20.201 of the OneDrive for Business client. It can be set in the admx/adml files. Once enabled, the sync client will not upload new files that match the specified restrictions. There is no impact on existing files uploaded to OneDrive and SharePoint.

## Controlling Sync Client Auto-pause Behavior

OneDrive users can [control the OneDrive sync client’s auto-pause behavior](#) on their PCs when they are connected to a metered network or if the device is in battery saver mode. The options to control this behavior are found in the Settings menu.

## Controlling Client Synchronization

A common issue often raised by management and those responsible for the protection of the intellectual property is the potential undesirability of allowing users to synchronize documents to their PC, possibly including a PC at home. The same synchronization issue occurs for SharePoint Online document libraries too. Users often store confidential information on home PCs (the blurring of home and work life encourages this practice). It’s also true that various blocks can prevent this behavior (such as [restricting synchronization to domain-joined PCs](#)). However, users have been swapping data between PCs ever since floppy diskettes and will likely find new methods of moving information to desired locations as quickly as IT closes off loopholes.

**Automatic Updates:** Microsoft releases updates to the new OneDrive client independently of other updates. The updates are downloaded and installed automatically on client computers unless a [group policy is implemented to control OneDrive updates](#). Like many current Microsoft products, OneDrive updates are released in “rings”. You can update a PC to receive updates faster by configuring a system registry DWORD value called **EnableTeamTier\_Internal** at HKEY\_CURRENT\_USER\Software\Microsoft\OneDrive. Set the value to 1 if you want to receive early updates (fast ring) or 0 (zero) to receive updates as normal (slow ring).

Several approaches can help control the content held in OneDrive for Business sites. First, sensitivity labels (see Information Protection chapter) can protect confidential information so that only the intended recipients can open protected files. Second, Data Loss Prevention policies can stop users from inadvertently sharing sensitive information outside the company. Third, as mentioned above, you can configure SharePoint Online so that the OneDrive sync client will only copy files to workstations that belong to specific on-premises Active Directory domains. The intention here is to stop corporate data from ending up on PCs not managed by the organization, such as home devices.

**Protecting OneDrive for Business:** A [Microsoft script](#) helps administrators to configure rights management for users' OneDrive for Business sites. The script can also reverse the process if necessary (some problems have been reported with the sync client when protection is enabled). To use the script to remove protection from sites, change the line `$list.IrmEnabled = $true` to be `$list.IrmEnabled = $false`.

As shown below, the synchronization block is set by running the `Set-SPOTenantSyncClientRestriction` cmdlet to enable checking against a set of known domains, each of which is identified by a GUID. You can use the `Get-ADForest` PowerShell cmdlet to return the set of domains in an Active Directory forest and then `Get-ADDomain` cmdlet to find the `ObjectGUID` for each domain (see [this page](#) for information how to determine the `ObjectGUID` for a domain).

```
[PS] C:\> Set-SPOTenantSyncClientRestriction -Enable
-DomainGuids 'Domain-GUID1; Domain-GUID2; Domain-GUID3'
```

When the block is in place, users see that they cannot synchronize OneDrive for Business libraries for offline access on an unmanaged PC. Administrators can use information in the audit log (See Managing Reporting and Auditing chapter) to create a report to highlight computers that OneDrive blocks from syncing files to discover whether users have tried to take files offline and then take the necessary action to tell those users why this facility is unsupported.

Although this synchronization block will not stop mobile clients from using OneDrive for Business, it does block Mac clients. For this reason, you should not implement the block if Mac clients are in use in your organization. Another restriction is to constrain users to upload files with a set of known extensions. For example, if you do not want to have users uploading executables, zipped files, and PSTs to OneDrive for Business, you can run the following cmdlets.

```
[PS] C:\> Set-SPOTenantSyncClientRestriction -ExcludedFileExtensions "exe;zip;rar;pst"
```

```
[PS] C:\> Get-SPOTenantSyncClientRestriction
```

TenantRestrictionEnabled	AllowedDomainList	BlockMacSync	ExcludedFileExtensions
False	{}	False	{exe, zip, rar, pst}

Separate each file extension with a semi-colon and do not leave any extra spaces. The `Get-SPOTenantSyncClientRestriction` cmdlet can check that the proper restriction is in place. If necessary, you can clear the set of excluded files by setting the property to `$Null`. The setting only controls the OneDrive.exe Windows client, so you can add excluded files to a OneDrive for Business site with another client before the exclusion kicks in to prevent file synchronization with the PC.

**Blocking OneDrive Consumer:** OneDrive sync client can synchronize both OneDrive for Business and OneDrive consumer accounts to a single PC. However, some organizations do not want to allow users to synchronize their OneDrive consumer accounts to corporate PCs. It's possible to block this through a Group Policy setting called `DisablePersonalSync`. See [this Microsoft page](#) for information on how to control the setting and to learn about other Group Policy settings used with OneDrive.

The last approach that you can take is to remove the temptation for users to synchronize files from certain document libraries by hiding the Sync button for those libraries. If the Sync button is not available for a

document library, users cannot start the synchronization process. To do the job, you need to write some PowerShell code that uses the SharePoint CSOM API. Fortunately, [a script exists](#) to help start the job. You can take that code and change it to meet your needs. For instance, you might use a CSV as the input to specify the target sites to disable synchronization. It is important to realize that removing the Sync button will not interfere with or stop synchronization if the user previously set it up for a document library. However, it stops new synchronization.

It might seem that controlling client synchronization is a big issue for OneDrive, but it is not really. Similar issues to those listed above often happen in how people use (or abuse) personal file shares. The best thing about ODFB is that all the features of Microsoft 365 security and data governance protect the information in user sites. In addition, because OneDrive for Business is an area of focus for Microsoft, a reasonable expectation exists that more features will become available over time.

### Prevent Users Syncing Libraries Shared from Other Organizations

[B2BSync](#) allows users to sync SharePoint and ODFB content shared with them by people from other organizations. This feature works with the external sharing integration previously described and requires recipients to have a guest user account in Azure AD. B2BSync can be disabled through the *BlockExternalSync* setting as described in the `adm\OneDrive.admx` and `OneDrive.adml` files.

### Allow Syncing OneDrive Accounts for Specific Organizations

This [setting in the OneDrive for Business policy](#) prevents users from uploading files to other organizations by creating a list of allowed organization IDs (Tenant IDs). When enabled, users see an error if they try to add an account from a prohibited organization. This setting takes priority over Block syncing OneDrive accounts for specific organizations.

### Configure OneDrive to Automatically Sync SharePoint Team Site Document Libraries

This feature allows administrators to [automatically connect and synchronize specific SharePoint team site document libraries](#) as part of a OneDrive deployment. To help configure a team site to sync automatically, a new group policy (“Configure team site libraries to sync automatically”) is available for admins to deploy.

Once deployed, the OneDrive sync client automatically syncs the contents of the shared library as online-only files the next time the user signs in, within an 8-hour window to help distribute network load. Once configured, the user cannot stop syncing the shared library unless the policy is disabled. Disabling the policy however will not unmount the shared library on behalf of the user, but the option to stop syncing the library will be available to them.

### PC Folder Backup

[PC folder backup](#) simplifies the process to move user contents located in well-known PC folders (Desktop, Documents, and Pictures folders) to OneDrive for Business. The feature was previously known as KFM (Known Folder Move). PC folder backup automatically syncs user content held in several well-known PC file locations to OneDrive for Business. To start using this feature, end users only need to click on a PC folder backup toast notification or click the **Manage backup** button under the Backup tab of OneDrive Client settings. Before the OneDrive sync client starts synchronization, it checks for the presence of any unsupported files and then begins to copy the folders from the workstation to OneDrive. Well-known folders are created in the user’s OneDrive using the same locale present in the user’s workstation. PC folder backup works on Windows 7, 8, 10, and 11 workstations.

PC folder backup also comes with the ability to silently redirect Windows known folders to OneDrive without user interaction. To enable this setting, a group policy must be enabled.

To keep admins aware of the PC folder backup deployment status, Microsoft [provides a PowerShell Script](#) to generate a report with the following information:

- PC folder backup eligibility, indicating if PC folder backup is possible for the current device.
- PC folder backup status, reports if the known folders have been moved to ODFB.
- PC folder backup GPO State: lists the GPOs in use.

The script is intended to run on a single device, but it can be modified to be run across all the devices in an organization.

## OneDrive Sync Health Reports

The [OneDrive sync health reports](#) section in the Microsoft 365 Apps Admin Center is a dashboard to check and identify OneDrive sync app versions, sync status, sync errors on individual devices, and monitor the deployment of OneDrive features such as KFM. To feed that dashboard, Admins can configure the OneDrive sync client to send health and diagnostics data by using the Group Policy Object [EnableSyncAdminReports](#). Note that [sync health reports for macOS](#) are currently in preview.

The dashboard includes a summary of how well OneDrive synchronization works within the organization in terms of how many devices have at least one sync error, the percentage of computers synchronizing known folders (KFM), and the percentage of computers with the current version of the OneDrive sync client. The Details tab provides deeper and more granular information on the OneDrive sync status for each user in the organization. Administrators can use this information to track sync errors, review error details, and do some basic troubleshooting tasks before contacting users experiencing sync problems. The Issues tab shows an aggregated view of the top sync errors happening to end users including the number of affected devices.

## Restore a OneDrive for Business Account

Ransomware has the nasty habit of infecting important documents, no matter what their location. If an attack happens against a OneDrive site, you can use **Restore Your OneDrive** (click the cogwheel to expose the option) to restore files from the document library versions to a point in time. OneDrive comes with some out-of-the-box restore points (such as a week ago), but you can select any point up to a 30-day limit. When you select a restore point, OneDrive prompts you to confirm to go ahead with the restore, and if confirmed, OneDrive restores files as they were at that point.

The consumer version of OneDrive also supports the ability to restore synchronized files to a point in time. However, the feature is only available if you have a paid subscription (Microsoft 365 Personal or Microsoft 365 Family).

# Managing OneDrive for Business

While OneDrive for Business is a core service in Microsoft 365, it no longer has a dedicated administrative console. Instead, all the required OneDrive admin features are part of the SharePoint admin center. Currently, the following OneDrive admin controls are available in the SharePoint admin center (Settings page):

- Notifications: Enable/Disable device notifications about OneDrive activities.
- Retention: Set the default OneDrive retention period for deleted users.
- Storage: Set the default OneDrive storage that applies to all the users in the tenant.
- Sync: Manage the following OneDrive sync controls:
  - Show/Hide the sync button in OneDrive and SharePoint Document libraries.
  - Enable synchronization only on devices joined to specific domains that are identified by a GUID.
  - Block the upload of specific files in OneDrive.

Admins can also manage specific settings of OneDrive sites through the user details panel in the Microsoft 365 Admin center. Specifically, the following OneDrive options can be administered through the panel:

- Storage limit: By default, this setting honors the global OneDrive storage limit value, but it can be overridden to set a specific value for the user.
- Manage external sharing: This setting updates the global OneDrive sharing setting to another sharing option.
- Create an Admin link to the user's OneDrive so the administrator is added as a OneDrive admin.

## Using PowerShell to Manage OneDrive for Business

Although Microsoft offers no specific tools to manage OneDrive for Business with PowerShell, the same principles and guidelines used for SharePoint Online apply. A SharePoint Admin can also use the SharePoint Online Management Shell, PnP Cmdlets, and SharePoint and Microsoft 365 APIs to manage OneDrive. For example, to generate a CSV file with details of the storage quota, consumption, and percentage of storage used for the OneDrive for Business sites, run the following PowerShell code:

```
[PS] C:\> $ODFBSites = Get-SPOSite -IncludePersonalSite $True -Limit All -Filter "Url -like 'my.sharepoint.com/personal/'" | Select Owner, Title, URL, StorageQuota, StorageUsageCurrent | Sort StorageUsageCurrent -Desc
$TotalODFBGBUsed = [Math]::Round(($ODFBSites.StorageUsageCurrent | Measure-Object -Sum).Sum /1024,2)
$Report = [System.Collections.Generic.List[Object]]::new()
ForEach ($Site in $ODFBSites) {
    $ReportLine = [PSCustomObject]@{
        Owner      = $Site.Title
        Email      = $Site.Owner
        URL        = $Site.URL
        QuotaGB    = [Math]::Round($Site.StorageQuota/1024,2)
        UsedGB     = [Math]::Round($Site.StorageUsageCurrent/1024,4)
        PercentUsed = [Math]::Round(($Site.StorageUsageCurrent/$Site.StorageQuota * 100),4) }
    $Report.Add($ReportLine)}
$Report | Export-CSV -NoTypeInformation c:\temp\OneDriveSiteConsumption.CSV
Write-Host "Current OneDrive for Business storage consumption is" $TotalODFBGBUsed "GB. Report is in C:\temp\OneDriveSiteConsumption.CSV"
```

Because many different types of sites exist in SharePoint Online the code needed to create a storage report for SharePoint Online sites is a little more complicated. An example script is [available in GitHub](#).

## Modern OneDrive Settings

The modern OneDrive settings page gives access to the minimum settings required by any user to manage his/her OneDrive for Business site. Compared with the classic OneDrive for Business admin options, the new settings page only includes two sections: Notifications and More settings. Notifications are all about enabling/disabling the different notifications related to OneDrive activities:

- Reminders for missed Sharing emails.
- Notifications sent when OneDrive detects massive files deletion over a short period.
- Notifications sent when others reply to user comments.
- Notifications sent when others comment on the user's documents.
- Notifications sent when the recipient clicks the link in a sharing e-mail.
- Notifications sent when others upload files to file requests.

Additional settings include links to different OneDrive configuration options such as Manage guest expiration, Site administrators, Run sharing report, Regional and language settings, Site features and storage metrics. The page also includes a link to the classic OneDrive settings page.

# Migrating to SharePoint Online and OneDrive for Business

A very common need from any organization that is on Microsoft 365 or thinking to start the Microsoft 365 journey is the migration of corporate assets (On-Premises and/or in other cloud services) to SharePoint Online and ODFB.

## Moving Windows File Servers to SharePoint

Moving individual files from a network file share to a SharePoint document library, perhaps one used by a Group or a Team can be a tiresome process. The OneDrive sync client is often used to move files between different libraries, and you can use it to move files from network shares too. Here's how:

- Synchronize the target SharePoint document library to a workstation with the OneDrive sync client.
- Map the source network file share on the workstation.
- Use File Explorer to copy files from the source network share to the folder holding the synchronized content from the SharePoint document library.
- The OneDrive sync client will then synchronize the copied files to the document library.

This is an effective approach when you have a few hundred files to move. Things become more complicated when you have more files to process. At this point you can consider:

- Run a PowerShell script to move files. Microsoft's SharePoint PowerShell module does not have cmdlets to directly copy files to SharePoint Online or OneDrive, but it provides cmdlets to migrate on-premises contents by creating a migration package that can be submitted to be [imported by the Office 365 Import service](#).
- The SharePoint [Patterns and Practice \(PnP\) module](#) includes cmdlets to copy contents to a SharePoint document library. Here is [an example of a script that uses the PnP module](#) to copy files from a network file share to a SharePoint document library.
- Use Microsoft's free SharePoint migration tool (see the section later).
- Use the Migration manager.
- Use a commercial third-party product. These products vary in terms of capability and cost, so some testing is necessary to figure out which best suits your circumstances.

## SharePoint Migration Tools

Microsoft's free [SharePoint Migration Tool](#) can move files from on-premises SharePoint Server (2010, 2013, and 2016) sites, file servers, and [Azure file shares](#) to SharePoint Online sites. The tool also supports migration to ODFB. The sole requirements are to be able to read data from the sources and write to the target sites. After checking that access is available, the tool extracts documents from the source and creates a set of XML manifests and content. The tool then uploads the content package to a secure location in Azure and invokes a migration job in SharePoint Online to fetch the content and import it into the target locations. [Version 3 of the toolset](#) includes features such as:

- Select SharePoint Online Sites, ODFB, or Teams in Microsoft Teams as possible destinations for a given migration.
- For SharePoint Server to SharePoint Online migrations, choose to migrate the site structure as it is in the source (if using a classic information architecture) or promote all the subsites to site collections and associate them with a hub site.
- Create the destination site for a migration in case it does not exist.

- JSON and CSV support for bulk migrations.
- [Migrate full out of the box SharePoint sites](#) including some site features (those included in [this list](#)), some Web Parts (those included in [this list](#)), Pages, Site Description, Site Icons, Site Navigation, Content Types, and also existing taxonomies defined in the Manage Metadata Term Store.
- Migrate SharePoint lists created using a [list template supported by the tool](#).
- (Public Preview) Migrate SharePoint Server 2010 out of the box list workflows, including Approval and Collect feedback workflows, to Power Automate Flows.
- SharePoint Server subfolder selection.
- Document sets and document templates.
- Select Teams and channels directly from the destination selection page.
- Ability to create sites during file share migration.
- Support for migrating SharePoint on-premises Record libraries.
- Support for migrating basic SharePoint on-premises settings such as site logo, title, description, and some other general settings.
- Support for migrating files up to 250 GB.
- Provide feedback to Microsoft from the tool.

See the [Migration Resources Center](#) and SharePoint Migration Tool [release notes](#) for more information about the SharePoint Migration Tool.

**PowerShell support for the SharePoint Migration Tool:** There are [eight PowerShell cmdlets](#) documented to automate migrations to SharePoint Online using the SharePoint Migration Tool. A sample migration script showing how to use the cmdlets can also be found in the cmdlet documentation

Migration utilities typically work on the basis that they move documents and metadata from a source to a target destination (a SharePoint Online site). Inevitably, some documents end up in the wrong place and need repositioning to the correct destination afterward. Until Microsoft upgraded SharePoint's "Move to" feature to allow the movement of files to a different site, rearranging documents post-migration was difficult and time consuming. Now, you can move documents to any folder in a SharePoint Online or OneDrive for Business site to which you have write access. Moving is different from copying because a move includes all the versions of a file instead of just the final version. In addition, moves preserve metadata between source and target destinations by matching column names (if a column name does not exist for the target, the move drops that metadata). Moves also respect compliance policies.

You cannot beat the zero-cost price point for the Microsoft migration tool. However, the tool offers a limited feature set and if you have more complex requirements to move documents, schema changes, metadata, and customizations, you might need a more sophisticated approach to migration such as those available from Quest, AvePoint, or Sharegate. All SharePoint migration utilities use the same APIs and are subject to being throttled. Third-party migration products usually have their own ways to increase throughput or minimize throttling to move data to SharePoint Online more quickly, and this might be a factor in your planning if you have large quantities of data to move. See [this page](#) for more information about likely throughput for SharePoint and OneDrive for Business migrations.

You should decide early on what migration tool to use for your project. Making that choice can absorb a lot of effort to analyze, test, assess, and eventually decide. Do not underestimate the importance of this work.

**On-Premises inventory/audit:** Before starting a migration to SharePoint Online, it's advisable to make an inventory/review of the contents and structures to be migrated so any issue that surfaces during the migration is found beforehand. Microsoft's [SharePoint Migration Assessment Tool](#) (SMAT) helps identify the impact of migrating from SharePoint 2010 / 2013 to SharePoint Online. As reflected in Microsoft's documentation, SMAT also includes [support for the identity migration](#) from SharePoint On-Premises to SharePoint Online. Of course, as with the SharePoint Migration Tool, there are also commercial inventory

tools that give more detailed information about a SharePoint Farm and issues that can arise when starting a migration project. The SharePoint Documentation Toolkit from SysKit and Metalogix Expert from Quest are examples of third-party inventory/auditing tools.

## Migration Manager

[Migration manager](#) includes a set of migration tools designed to simplify complex migrations where it is necessary to create migration tasks on several migration machines and orchestrate the tasks to a successful conclusion. Migration Manager is integrated into the SharePoint admin center. For the migration of file shares, the process managed by the Migration manager has four steps:

- Install the Migration manager agent in each server from where information is to be migrated to SharePoint Online sites.
- [Scan and assess the file shares](#): The Migration manager performs this step automatically after a data source is added to the service. The scans provide an overview of the contents to be migrated in terms of size, the number of files, or issues that might affect the migration. Scan log files are also available for download to enable deep analysis and troubleshooting on individual files identified.
- Create migration tasks by typing the path of the file share to be migrated and the destination location (a OneDrive for Business site, a Microsoft Teams team, or a SharePoint site).
- Monitor how migration is progressing across the different clients and access reports generated automatically by the Migration manager.

Migration Manager currently supports the migration of contents from file shares, [Box](#), [Google Workspace](#), [Dropbox](#), and [Egnyte](#) to SharePoint Online and/or OneDrive for Business.

## Microsoft Lists

Microsoft Lists is an app that allows end users to create custom lists using a dedicated space hosted in OneDrive for Business (personal lists) or shared lists stored in a SharePoint Online site. [A lightweight version of Microsoft Lists](#) (currently in preview) is also available for small businesses and individuals that don't have a Microsoft 365 but regularly use Microsoft Accounts (MSA).

Users can install the Microsoft Lists app as a Progressive Web App in Microsoft Edge, Google Chrome, or Firefox. A Microsoft List is a modern version of a traditional SharePoint list created from scratch or by using one of eight out of the box templates (including Issue tracker, Employee onboarding, and Event itinerary). Users can also create lists from an existing list or Excel worksheet in their OneDrive for Business account or from lists in SharePoint sites the user can access. Microsoft Lists incorporate features such as:

- Add new list views to show list data in different formats (List, Calendar, Gallery, Board).
- Apply rich formatting at different levels in a List without writing a line of code through column formatting, view formatting, and Forms customization. Additionally, list forms can be customized with PowerApps or the Lists Forms layout designer.
- Create simple business rules to notify when a change in a list record happens (a column changes, a column value changes to something, creation or deletion of an item, and so on). The integration of Power Automate enables the creation of more sophisticated business processes tied to a list. Business rules are supported in Microsoft Lists and regular Document libraries.
- Export list content to an Excel or CSV file.
- Mention someone in a list comment by using "@".
- Ability to easily share a personal list created by the user in OneDrive for Business with other users.
- [Create a Power BI report from list data with a single click](#). This feature requires either a Microsoft 365 E5 or Power BI Pro license.

- Work offline with list data synchronized locally using the [Project Nucleus technology](#) enabled for users through the Nucleus service plan included in all Microsoft 365 SKUs. Synchronization is on by default for eligible lists as explained in [this support article](#). Administrators can manage the sync settings for Lists through [a specific group policy](#).

Lists can be accessed through the Lists app (which presents both personal and shared lists), the SharePoint app bar, the Site contents page in a SharePoint site, the Lists app in Teams, or through the mobile Lists App available for iOS and Android. A Global or SharePoint admin can control the following [Microsoft Lists settings](#):

- Disable the creation of personal lists by running the *Set-SPOTenant* cmdlet to set the *DisablePersonalListCreation* property to *\$True*. This setting stops users from creating personal lists in OneDrive for Business.
- Disable built-in list templates that are not relevant for an organization by running the *Set-SPOTenant* cmdlet to populate the *DisableModernListTemplateIds* with the set of disabled templates. For example, to hide the Issue tracker list, run the following command:

```
[PS] C:\> Set-SPOTenant -DisableModernListTemplateIds 'C147E310-FFB3-0CDF-B9A3-F427EE0FF1CE'
```

To re-enable a built-in list template, write its GUID into the *EnableModernListTemplateIds* property.

- Disable list comments in any Microsoft Lists list by running the *Set-SPOTenant* cmdlet to set the *CommentsOnListItemsDisabled* property to *\$True*. Note that list comments can be disabled per list through the list settings page.

## Custom List Templates

In addition to the default set of list templates available for Microsoft Lists, a SharePoint administrator can add custom list templates using the following steps:

- Extract the site script from the desired list using the *Set-SPOSiteScriptFromList* cmdlet.
- Run the *Add-SPOSiteScript* cmdlet to add the site script extracted to the list of available site scripts in the tenant.
- Run the *Add-SPOListDesign* cmdlet to add the custom list template to the organization lists catalog.
- (Optional) Run the *Grant-SPOSiteDesignRights* cmdlet to indicate who can see and use the custom list template.

The following script is an example of the process:

```
[PS] C:\> $SPOListURL="https://office365itpros.sharepoint.com/Lists/Projects"
$SPOSiteScriptFromList=Get-SPOSiteScriptFromList -ListUrl $SPOListURL
Add-SPOSiteScript -Title "Corporate Projects" -Description "List that contains Corporate Projects"
-Content $SPOSiteScriptFromList
Add-SPOListDesign -Title "CompanyDevices" -SiteScripts fcbd3f82-28bb-4de0-b9bb-3e0cb6e6125e
```

After the script executes, users will see the new custom template in the *From your organization* tab in the *Create a list* dialog. To remove a custom list template, run the *Remove-SPOListDesign* cmdlet. To grant permissions on a custom list to specific people in the organization, administrators can run the [Grant-SPOSiteDesignRights](#) cmdlet to pass the identifier for the custom template and the list of people allowed to view the template.

## Formatting of Columns, List Views, and List Forms

Document library and list columns can be customized with JSON or using the Format column designer through the "Format this column" setting available for any column in modern lists and document libraries:

- Advanced mode formatting allows site designers to change the column look and feel with JSON code in different ways, as described in [this How-To article](#).

- Format column designer allows non-developers to add conditional color coding to SharePoint columns, apply color and rounded styling for each choice (Choice pills template), and Data Bars for numeric columns without needing to create JSON scripts (Figure 8-5). The Format column designer also supports defining rules that must be met to apply a color to the column.

Similarly, designers can customize list views with JSON code and/or use the Format view designer to:

- [Apply alternating row styles to the list without writing any JSON code](#). The Format view designer also supports rules creation to define the conditions to apply alternating row styles on lists and document libraries. Column and List View formatting is also supported in the [new enhanced quick edit view](#) in SharePoint lists and document libraries.
- Visually configure the fields to be displayed in cards and their order in views created with the Gallery or Board layouts. A developer can use the [Gallery/Board](#) formatter to define custom cards layouts or field values inside a card using the same JSON syntax used for column formatting.
- [Customize the list command bar](#): modify basic aspects (icon and/or text), hide and/or reposition existing options.

It's also possible to customize List forms with JSON code. The following areas in a List form can be currently customized with JSON: List form header, body, and footer.

Title	Device Type	Numer of Devic...	Purchase Date
Surface Pro 7	Tablet	30	6/15/2020 12:00 ...
Surface Book 2	Laptop	20	6/15/2020 12:00 ...
iPhone	Smart Phone	50	
iPad	Tablet	8	
Screen 15''	Other	10	
Screen 17''	Other	11	
Count		6	Sum
		6	129

Figure 8-5: Sample of modern list customized using JSON Column formatting

## Delve and Microsoft Search

Delve is an app that is heavily associated with SharePoint Online and OneDrive for Business. Apart from offering users the ability to search for documents across all sites and accounts that they have access to, Delve replaces the User Profile functionality found in SharePoint on-premises. Users can update profile settings such as the projects they have worked on, skills, and contact information (if allowed by the organization).

Delve was the first application to exploit Graph queries to display documents of interest to a user. This capability is available to Microsoft 365 applications through the Graph Insights API. Three types of insights are available: people, meetings, and items (documents). See this article for more information about how to control

[the use of insights within applications](#). Delve chapter in the companion volume contains more information about Delve.

## Microsoft Search

Microsoft Search is available throughout Microsoft 365 to perform searches in clients like OWA, OneDrive for Business, SharePoint Online, and Teams. Microsoft Search is designed to only show results relevant to the user who performs the search. Results are security trimmed, meaning that each user can only see results for documents and other objects that he/she can access. Microsoft Search does not change permissions.

Connecting Microsoft Search to services like SharePoint Online sites, OneDrive for Business, Exchange Online, Teams, and Yammer means that Bing can include content from these services in its searches. This capability known as [Microsoft Search for Bing](#) is another way to expose content stored in SharePoint Online, OneDrive for Business, and Teams to users.

Microsoft Search is enabled by default in Microsoft 365. No setup is necessary, but, as described here, it's possible to streamline and improve the overall Microsoft Search experience for users. [Management of Microsoft Search settings is through the Search and Intelligence section](#) under Settings in the Microsoft 365 admin center.

The first task is to verify that **Microsoft Search in Bing** is enabled for the tenant through the Configurations tab. You can then configure settings such as Acronyms, Bookmarks, Floor plans, Locations, and Q&A to improve the findability of content. See [this page](#) for more information.

Behind the scenes, the services connect to Microsoft Search in Bing (this process might take up to 24 hours to complete), and users see a **Work** link in the result bar to expose results from the organization when they use Bing.com to search or configure Bing as the default search engine for their browser. Clicking the link shows results from the connected sources (Figure 8-6), divided into the following sections:

- **People:** People in the tenant's directory.
- **Groups:** Microsoft 365 Groups and distribution lists related to the search term.
- **Sites:** SharePoint sites in the tenant matching the search term.
- **Files:** Documents found in SharePoint and OneDrive for Business libraries accessible to the user.
- **Messages:** [Messages from Teams chats and channel conversations and Outlook](#) (Exchange Online). Users can only search their personal mailbox. They won't find items in shared mailboxes or other user mailboxes they have delegated rights to.
- **Yammer:** Messages from Yammer communities and personal conversations (the Yammer network must run in Microsoft 365 mode).
- **Power BI:** Datasheets and other Power BI components matching the search.
- **Learning:** Content from both the organization and learning partners such as LinkedIn learning.
- Any custom vertical configured by an Admin.

Brief snippets appear for the most relevant hits in each category. Links are available to bring the user to the underlying applications to view content or perform more exhaustive searches. Users only see information that they can access, and Bing filters the results based on the permissions held by that user.

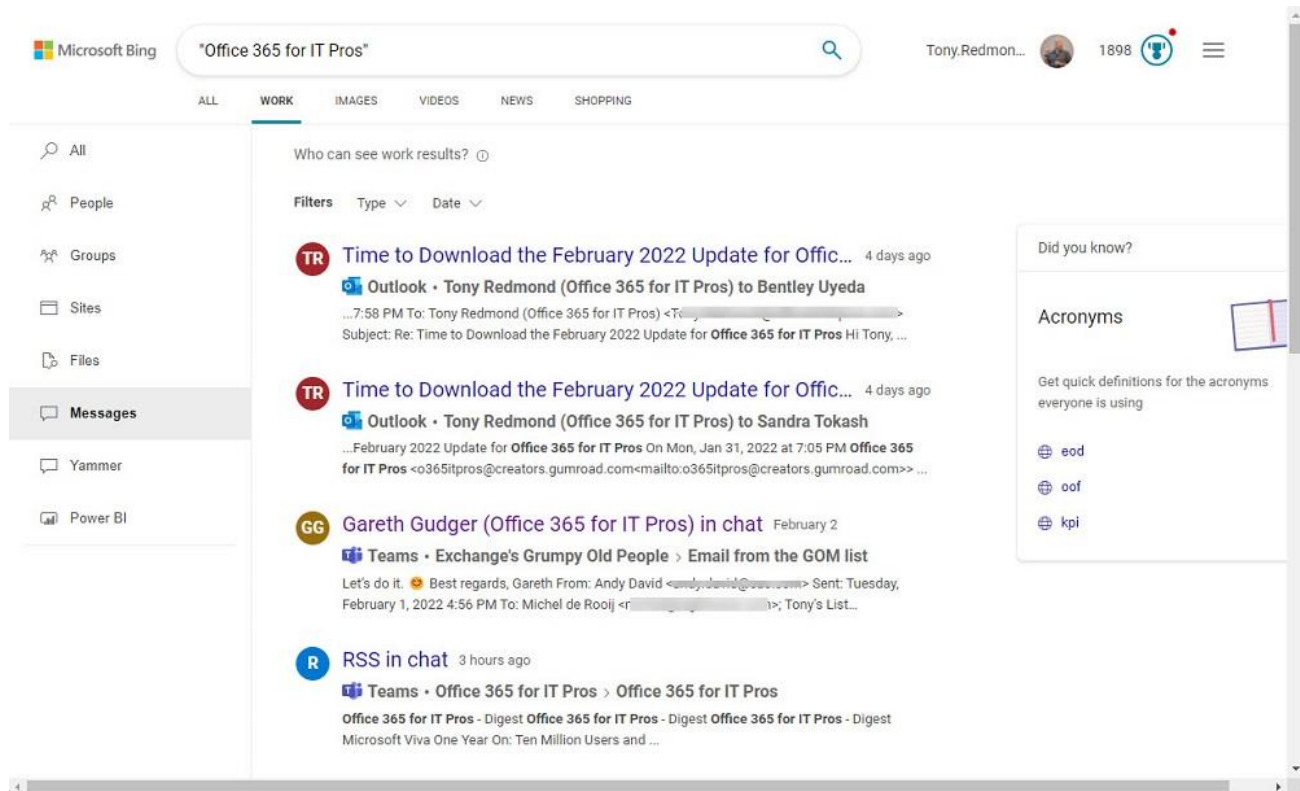

Figure 8-6: Integrating Office 365 sources into Bing search results

Integrating Microsoft 365 sources with Bing is only useful if people use Bing as their preferred search engine and is useless when they use other search engines like Google or DuckDuckGo. However, if your corporate standard is Bing, integrating Microsoft 365 workloads into Bing search results is a surprisingly useful and worthwhile extension.

Note that SharePoint search and the search feature in Office.com also present results drawn from across Microsoft 365 like conversations from Teams and Outlook. One difference is that Microsoft Search in Bing covers Yammer whereas the other searches do not.

## Admin Roles for Microsoft Search

There are two specific Admin roles to manage Microsoft Search in Microsoft 365:

- **Search admin:** This role can manage all the settings that can be configured in Microsoft Search administration including creating and managing search result content, defining query settings, and all the content-management that can be done with the Search editor role.
- **Search editor:** Create, manage, and delete editorial content in Microsoft Search such as frequently asked questions and answers, important places and locations or Floor plans.

## Acronyms

To help users find terms that might have multiple references within an organization terminology, Microsoft search provides Acronyms. An Acronym is a type of searchable term supported by Bing, Microsoft 365, and SharePoint. To get answers to an Acronym search, users must enter a specific search pattern in the Search box. For instance, if users are looking for the term DLP (Data Loss Prevention), they should use queries such as *What is DLP, Define DLP or DLP means*.

There are two types of Acronyms in Microsoft Search:

- **Admin-curated acronyms:** created by users with the Search admin role in the Microsoft Search administration.

- **System-curated acronyms:** mined by Microsoft Search from user's personal email and documents and publicly available data within the organization. Bear in mind that mined acronyms from new e-mails and documents can take up to 7 days to appear in Microsoft Search results.

Acronyms can be added to Microsoft Search in two ways:

- **Manually:** Acronyms are created by Search administrators and defined by the following fields: Acronym (Mandatory), stands for (Mandatory, spelled out abbreviation), Description (Brief description of the acronym), and Source (URL of the page or website where the users should go for more information about the acronym). Once an acronym is saved, it must be published before it can be used in Microsoft Search.
- **Automatically:** Importing a CSV file that contains all the Acronyms to be added to Microsoft Search.

## Bookmarks

Bookmarks are a way to provide shortcuts to most-visited internal or external resources in an organization or corporate applications used to complete tasks such as entering vacation time or reporting expenses. Microsoft Search includes some predefined Bookmarks and additional Bookmarks can be manually added or imported in bulk through a CSV file or from SharePoint Promoted results from sites.

A Bookmark is defined by the following elements: Title (Mandatory), URL (Mandatory, URL to an internal website or page), Bookmark description, Keywords (Mandatory, search terms commonly used to find the Bookmark), Reserved keywords, and Categories (To organize and group Bookmarks). A Bookmark can have several keywords and several bookmarks can share the same keyword. Some optional Bookmark settings can be configured such as the Dates when the result is going to be available, countries where it's going to be available, or the Groups (Security groups or Microsoft 365 Groups) that can use the Bookmark.

Existing and new Bookmarks can be edited when required. If a Bookmark is not ready to use yet, it can be saved as a draft before being published. Several Bookmarks can be imported/edited in bulk by using the Import action.

To simplify the process of creating and curating Bookmarks, Microsoft Search generates [recommended Bookmarks](#) by scanning content across SharePoint sites to identify potential bookmarks. A recommended bookmark includes the following mined information: URL, Title, Description, and Keywords. Administrators make the final decision to publish or reject the recommended bookmarks.

## Floor Plans

Floor Plans are used to find people and meeting rooms within a building. Follow [these steps](#) to enable Floor Plans in Microsoft Search:

- Get the list of codes used to identify the user's Office locations.
- Verify each user has the Office location properly informed. You can do that verification through the users' list in the Microsoft 365 Admin Center.
- Make a search to find a user and verify the Office location is appearing correctly (In case you have just updated the Office location, you may need to wait up to 72 hours for the updates to be visible in the search results).
- Prepare Floor plans files that must be in DWG format. Each DWG file should contain at least 10 rooms marked with labels.
- Add building locations to Microsoft Search through the Locations section in the Microsoft Search Administration.
- Start the process to enable Floor Plans in Microsoft Search. In Floor plans select Get started and wait until the process finishes. Bear in mind this process can take up to 48 hours to be completed.

- Follow the wizard to add Floor plans to Microsoft Search. For each floor uploaded enter the floor number represented in the Floor plan file and then the building code that can be found on user's office location.
- Publish the Floor plans so they can be available in search results when users search for a co-worker's office.

## Locations

To find addresses and locate the organization's buildings, Microsoft Search includes Locations. A Location has the following attributes: Name (Mandatory), Country or region (Mandatory), Address, Keywords (Mandatory), and Reserved keywords. Locations can be added individually or imported in bulk using the import feature. After adding or updating locations, it can take several hours for the new data to appear in search results.

## Q&As

Q&As enable [rich-text answers to user questions](#) instead of just providing links to web pages. As in the case of Bookmarks, once a Q&A is added or changed, it's immediately available for users. In case a Q&A and Bookmark share the same keyword, the Bookmark result appears first.

To manually create a Q&A, navigate to the Q&A section in the Microsoft Search Administration and click on Add. In the Add Q&A panel, you need to add the following properties: Title (Mandatory), URL (URL to an internal website or page), Answer description (Mandatory, a brief description of the answer. You can apply some formatting to the description using a rich text toolbar or using existing HTML content), Keywords (Mandatory, search terms commonly used for the Q&A) and Reserved keywords. A Q&A can have several keywords and several Q&As can share the same keyword. Finally, as happens with Bookmarks, there are some optional Q&A settings that can be configured such as the Dates when the result will be available, countries where it's going to be available or the Groups (Security groups or Microsoft 365 Groups) that can use the Q&A and targeted variations to provide different Q&A messages based on the user's device and location.

Existing and new Q&As can be edited when required. If a Q&A is not ready to use yet, it can be saved as a draft before being published. Several Q&As can be imported/edited in bulk by using the Import action.

## Microsoft Search Usage Reports

[Usage reports](#) covering Microsoft search requests over the last 7, 14, 31 days or 12 months are available to search administrators to help them understand how end users look for content across Microsoft 365 and specifically in SharePoint Online using out of the box search boxes. Microsoft Search Usage Reports also help identify possible issues faced by end users when they search Microsoft 365 sources. The following reports are currently available.

- **Query volume trend graph:** Displays the total number of search queries over the selected time frame. This report includes query volume trends and periods of high and low search activity.
- **Top queries:** Displays the most commonly used search queries. It can help understand the types of information users search for.
- **No results queries:** Shows searches that return no results.
- **Abandoned queries:** Shows popular searches where users do not click on the results or the results have a low number of click throughs. This might indicate that the search results do not include information users consider useful or interesting.

The No result queries and Abandoned queries reports give search administrators insight that can help them improve the discoverability of content and identify search queries that don't return useful information and therefore create user dissatisfaction. To improve matters, search administrators can create new answers in Microsoft Search to improve search results or ingest new content by configuring Microsoft Graph Connectors.

At the Site level, [Site admins have the same reports](#) plus an Impressions by result type report with insights about the number of results by type for the last 31 days. Over time, those reports will replace some of the search usage reports available in the SharePoint Online search service.

## Customizing the Microsoft Search User Experience

The [user experience in Microsoft Search can be customized](#) in the following ways:

- **Modifying existing verticals and creating new ones** to show results of a certain type or from certain content. There are seven default Search verticals that tenants can modify: All, People, Files, Sites, News, Images, and Power BI. Note that's not the case for the [Messages](#) and Viva Learning Search verticals. To create a new vertical, you must provide a name, a valid content source, optionally a KQL (*Keyword Query Language*) query against the content source, and also optionally custom filters. Note that a connector to a data source must be created and the content indexed (it can take up to 48 hours to index a Connector) before it is effective. Custom filters, which are based on search managed properties, can be added to new and existing verticals. Custom Search verticals are visible to users when they make searches in the [Microsoft Office Home](#), SharePoint at different levels (SharePoint Home page or Sites), and Bing. Once you add a new Search vertical to Microsoft Search, it might take some time before users can view it.
- **Adding new Result types** from content sources and customizing the layout for the data indexed using result layouts designed with the [Search Layout Designer](#). A Result type allows to show search results to be displayed in different ways through one or more conditions and result layouts to use for search results that meet the conditions defined. To display results on a Search vertical, at least one Result Type must be created. A Search vertical can have multiple Result types as a mean to distinguish different types of search results. For example, you could have a Search vertical to display ServiceNow support tickets and use different visualizations depending on the severity of the support case opened by end users. To create a new Result type, you must provide a name, a content source to be used to render search results, the rules (this is an optional setting) to be used to distinguish search results depending on the conditions met and a results layout to display the search results.
- **Creating custom result layouts** to customize search results using the Search Layout Designer. A result layout can be created from scratch or any of the existing layouts provided in the tool. Once the layout is ready, the JSON definition must be exported for use in the Result type creation process.

## Microsoft Graph Connectors

[Microsoft Graph Connectors](#) support the indexing of third-party data hosted on-premises or in public/private clouds to integrate data into Microsoft Search results. Currently, there are thirteen default Connectors available in Microsoft Search (some in preview): Azure DevOps, JIRA, ADLS Gen2, Oracle SQL database, ServiceNow, CSV, File share, Microsoft SQL Server, Enterprise websites, MediaWiki, Salesforce, Confluence, and Azure SQL. In the future, Microsoft plans to add more built-in connectors, and it is possible to [create custom connectors and add them to Microsoft Search](#). A [Microsoft Graph connectors gallery](#) is available with more than 100 connectors created by Microsoft partners.

Before creating Search verticals and Results types, a Connector to a supported data source must first be created. A Connector is created through a step-by-step process that depends on the data source being added. For instance, to create a Connector to index data for a web site, the following settings are needed:

- **Name:** the connection by providing a connection name, ID, and Description. In this step, you must acknowledge that Microsoft will index data from the data source in the Microsoft 365 tenant.
- **Connection settings:** URL of the website to be indexed, the authentication type to be used (None, Basic) and the credentials (if required) to connect the website. The URL indicated in this step is the URL that initiates the crawl and is used for authentication.
- **Add URLs to exclude:** this is an optional step that allows admins to exclude URLs from search results.

- **Schema:** Defines the schema for the results that will be indexed. In this step, a list of the source properties indexed is shown. For each property, at least one of the following attributes must be set: Queryable, Searchable, Retrievable.
- **Manage search permissions:** For this data source there is no support for ACLs (Access Control Lists), so any user in the organization will be able to make searches against it.
- **Refresh settings:** It allows to indicate the refresh schedule interval for content crawling. This data source only supports full crawls.

Once a Connector is configured, it can be saved in a Draft state or published for use in Search verticals and Result types. Bear in mind that you must wait for some time until the connector starts indexing contents.

## Microsoft Search in SharePoint Online and OneDrive for Business

[Microsoft Search is integrated with Microsoft 365 and all its core workloads](#), including SharePoint Online and OneDrive for Business. For SharePoint Online, the integration is available in two ways:

- The search box added to the Microsoft 365 navigation bar to collect search queries that lead to results tailored for the signed-in user:
  - When the user clicks on the search box, Microsoft Search lists the last applications, files, contacts, and news the user interacted with.
  - As soon as the user types a search term, Microsoft Search immediately suggests search results that meet the search criteria.
  - If the search results returned are not the ones expected by the user, he/she can always expand the results and be redirected to the search results page.
- A dedicated Microsoft Search settings page is available through the Site settings page on a given site. Here a site admin can:
  - Create custom result types based on any of the Search connectors configured in Microsoft Search administration.
  - Create custom verticals to display search results coming from the custom result types configured in the tenant.

**Limitations when configuring Microsoft Search in a Site:** Some limitations currently exist when Microsoft Search is configured for a specific site such as the inability to modify a custom result type or a search vertical once they are created.

For OneDrive for Business, users can search Files and Folders not only in OneDrive but also in any shared library they can access across the tenant. The search box in OneDrive for Business includes a dropdown to allow users to choose where they want to search.

## How Microsoft Viva and SharePoint Syntex Brings AI to SharePoint

Under the umbrella of Microsoft Viva and SharePoint Syntex, Microsoft has introduced a set of new AI Services in SharePoint Online to recognize content types, extract information and knowledge, and automatically organize it into topics. Those AI services have the following [main features](#):

- Automatically recognize topics across contents and conversations, organize related information, and add generated topics to pages curated by subject matter experts. Topic pages created are available through a knowledge center, a SharePoint site that uses a set of specific Web Parts. For every topic

discovered, the AI generates topic cards with a summary of the topic, connected people, and resources. Topics cards appear automatically across Microsoft 365 in applications like Outlook, Word, SharePoint modern pages, Teams, and results posted by Microsoft Search. This technology is available in **Microsoft Viva Topics**.

- Capture content, extract information and automatically classify content employing image and text recognition, forms processing, and machine teaching. The first technique identifies objects in scanned or uploaded images and extracts text from images and PDFs, while the second permits to establish rules to automatically detect important information in forms and extract that information as metadata. Machine teaching uses AI models to recognize information in unstructured documents such as contracts, proposals, or training materials. This technology is now available in **SharePoint Syntex**.

SharePoint Syntex and Viva Topics licenses each cost \$5/user monthly.

## SharePoint Syntex

[SharePoint Syntex](#) was the first product in the Microsoft Content Services initiative. It is available as an add-on for Office 365 and Microsoft 365 plans. SharePoint Syntex uses machine teaching and AI Models integrated into the platform to automatically capture, recognize, and extract key information to ensure that uploaded documents are properly stored and classified in SharePoint document libraries. If configured in the AI Models, Syntex can [apply retention labels](#) or [sensitivity labels](#) automatically to the documents processed.

Among the SharePoint Syntex capabilities are:

- [Prebuilt models options for invoices and receipts](#) that can be configured to detect and extract a set of standard fields present in these file types. These prebuilt models can be published globally (tenant-level) or locally (site level) so they can be discovered and used by end users.
- [Local mode creation](#): Users can create and train local understanding models in sites outside of a Content Center site. These models can then be applied to libraries in those sites.
- [Content assembly](#): Supports the conversion of a Word document into a template by defining placeholders in the document for dynamic text. This template can be used later to generate new documents by filling values in the placeholders either manually or selecting data from a SharePoint list.
- Two specific SharePoint Syntex site templates accelerators: Content center site template and Contract management accelerator.

To evaluate the capabilities of SharePoint Syntex without the need to acquire licenses or even start a trial, Microsoft provides a content center site template to evaluate how document understanding models are created, trained, and managed. Models created in the center can be trained to classify content and extract information but cannot be applied in a document library to run against uploaded files. To get advice on where SharePoint Syntex might fit in an organization, Microsoft offers a [SharePoint Syntex Assessment](#) service. The output is a Power BI report with recommendations based on factors such as the size and structure of libraries, existing use of metadata or content types, and use of retention labels. SharePoint Syntex Assessment is included as a module in the Microsoft 365 Assessment Tool.

### Advanced Search Options Powered by SharePoint Syntex

As explained in the Microsoft Search section, the default user experience when searching is limited to typing a search term and getting results meeting those criteria. When SharePoint Syntex is added to a tenant, the search box in Document libraries is enhanced with the following search filters: Keywords, File name, People, Modified date, and File type. These search filters are present in Document libraries of all SharePoint sites, but they are not available in other SharePoint search locations including the SharePoint tenant landing page.

## Microsoft Viva Topics

[Viva Topics](#) uses artificial intelligence, Graph APIs, and Microsoft Search to analyze, capture and categorize the information from SharePoint Online sites to identify and generate Topics. Originally a Microsoft Research initiative called [Project Alexandria](#), Viva Topics searches bodies of information to find material to highlight as topics in applications. A topic is a phrase or term that is significant for a given organization, has related resources such as a page or site, and provides knowledge to corporate users. While the potential exists for many types of topics, Viva Topics initially recognizes the following types: Project, Event, Organization, Location, Product, Creative work, and Field of study. Users with edit permissions in the SharePoint Syntex service can [create/merge topics from taxonomy terms](#) (through both the SharePoint admin center and the site-level term stores). This process can take up to 24 hours.

To generate topics, artificial intelligence scans the sites selected by administrators to identify a set of suggested topics. The suggested topics appear in the Viva Topics center, a special SharePoint Online site used to manage the lifecycle of topics from suggestion to publication. To publish a topic, SharePoint creates a page called a topic card. Applications can then display topic cards to users when they detect relevant content in news items, posts, and messages.

A topic page can contain the following information:

- Alternate names and acronyms for the topic.
- A short description of the topic.
- People who might be knowledgeable about the topic.
- Files, pages, and sites that are related to the topic.

Like SharePoint Syntex, Microsoft Viva Topics is available as an add-on. To start using Viva Topics, you need to [follow a step by step process](#) where you have to define the following:

- SharePoint sites are used as sources of information to generate and build topics. By default, the Viva Topics setup wizard recommends including all the sites in the tenant.
- If necessary, topics to be excluded from the Viva Topics mining process. Those topics are identified through a list of names added to a CSV file with a specific structure. For every topic in the file, the following information is required: Name, MatchType (Exact/Partial). Once the CSV file is uploaded into the backend, changes will be effective within 24 hours.
- The users can view discovered topics generated from contents and conversations they have access to. Note that to view discovered topics in the Viva Topics center, user accounts must have a Viva Topics license.
- Users who act as knowledge managers process the topics generated automatically by the AI. Knowledge managers can also create topics from scratch.
- The URL and Name for the SharePoint site to host the Viva Topics center, which is the fulcrum for topic management and publication. The Viva Topics App for Teams can also be used for topic management. Currently [deploying the app](#) requires the creation of an app manifest file with PowerShell.

After configuring Viva Topics, users with the required permissions and a Viva Topics license can start to build a **Knowledge Network** in the Viva Topics center [taking into account considerations such as](#):

- Viva Topics AI requires some time (up to 14 days), as many contributors as possible (between 50 and 100 active users), and at least a minimum of 20,000 input files to identify potential topics and generate topics for review based on evidence (alternate names, acronyms, descriptions, people, pages, or sites related to each topic). Note that Viva Topics only supports English language documents, with more languages due to be added in the coming months.

- Topics generated by the AI must be confirmed, reviewed, curated, connected with other topics, and published by knowledge managers to make the topics [available for use in different Microsoft 365 Apps and Services](#) such as Microsoft Search, SharePoint Online pages, Microsoft Teams, OWA, or Microsoft Word.
- Knowledge managers can track topics discovered by the AI using the [Topic management dashboard](#). This dashboard also provides insights into how Topics are progressing between the different statuses available (Suggested, Confirmed, Published, Removed).
- Knowledge Managers can create additional topics in the Knowledge Network to expand the network and cover information not discoverable in the source locations. From May 2022, knowledge managers can add links to external pages to topics.

**Viva Topics Insights:** This is a dashboard available for Viva Topics administrators that visualizes the count of the files processed and topics that are discovered from those files. These insights are part of the Insights tab under the Search & intelligence section in the Microsoft 365 admin center.

Each topic has its own dedicated page in the Viva Topics Center site. When a knowledge manager publishes a topic page, a background process creates a topic card from the contents of the page and makes it available to applications that support Viva Topics. Users with Viva Topics licenses can then insert topic cards by typing a hash sign (#) followed by all or part of a topic name. Viva Topics shows the set of available topics and the user chooses one to insert in the text. Licensed readers can then see the topic card when they view text in a supported application.

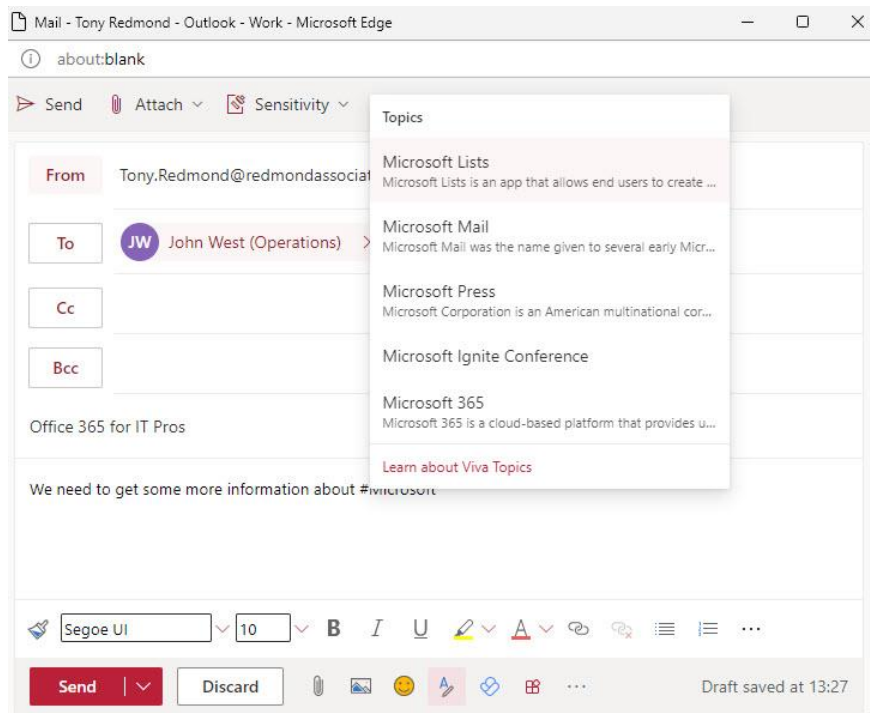

Figure 8-7: Including a topic in an OWA message

The set of applications supporting Viva Topics in text includes:

- SharePoint Online news items
- SharePoint search results.
- The Office Online apps.
- OWA (Figure 8-7).
- Teams chat.

Developing a knowledge network takes time and patience. It is not a one-off operation that can be completed and left to run on its own. To be effective, knowledge managers must monitor and manage the topics in the network and ensure that they are kept up to date.

## Microsoft Viva Connections

[Microsoft Viva Connections](#) provides native integration of a modern SharePoint site as an App in Microsoft Teams. Viva Connections enables end users to directly access and browse corporate resources published on the site directly within Teams, in other words, it brings the modern Intranet into Teams. Deploying Viva Connections requires a SharePoint Admin to [follow a step by step process](#) that involves the following actions:

- (Recommended, but not mandatory) Set up a SharePoint home site by running the *Set-SPOHomeSite* cmdlet or the Home site setting in the SharePoint admin center
- (Recommended, but not mandatory) Enable global navigation in the home site and customize any navigation link required for end users.
- (Recommended, but not mandatory) Set up the Viva Connections dashboard that can be customized with custom dashboard cards.

Once the SharePoint Admin has done his/her job, a Teams Admin is required to perform the following actions:

- Browse the Manage apps section in the Teams admin center. Look for the Viva Connections Teams App, verify it's enabled, and change (if required) the following parameters:
  - The name for the app. This name will appear in the Teams navigation bar once the app is deployed.
  - A short and long description of the app.
  - Privacy policy and terms of use.
  - Company name and company website.
  - Large and small app icons (sized at 192x192 and 28x28 pixels).
- (Optional) Manage and pin the app by default for corporate users by modifying an existing Setup policy or creating a custom one as [described here](#).

Microsoft Viva Connections does not need a specific license. Any user with a Microsoft 365 license can use Viva Connections.

## Other Services Using SharePoint Online and OneDrive for Business

SharePoint Online and OneDrive for Business are not only core workloads but also a key part of other services in combination with other services such as Exchange Online and Azure AD:

- **Microsoft 365 Groups.** Each time a Group is created, a site with a default home page with four Web Parts and a single document library is provisioned for the Group. In the same way, each time a team site is created, a Group is provisioned. Group members can easily store files, create lists, and document libraries and subsites.
- **Planner,** the task management application is deeply integrated into SharePoint Team sites through the Planner Web Part, which allows developers to [incorporate plans in pages](#) in a site.
- **Teams** uses Microsoft Groups as their membership service, which means each time a Team is created, a Group is created behind the scenes together with all its building blocks (an Azure AD Object, an Exchange Online mailbox, and a team site). Again, all the documents generated through team activity are stored in a document library. Teams also uses OneDrive for Business to store files shared in

personal chats. In addition, each time a private channel or a shared is created for a Team, a new site is created in SharePoint Online.

- **Yammer** can be configured to use native mode for Microsoft 365. In this mode, each time a Yammer community is created, a special type of group is provisioned including a team site, a Planner Plan, and a OneNote notebook. All the files uploaded to the community are stored in a document library within the site.

SharePoint Online can also take advantage of other cloud services:

- **Microsoft Power Apps** can customize list and document libraries and forms or create standalone Apps that do not require the author to write any code to [create custom forms that are mobile ready](#). The user only needs to click on the “PowerApps” action in a list to either create a custom app or customize the list forms. [A modern PowerApps Web Part](#), still in preview, supports the rendering of Power Apps in SharePoint pages.
- **Power Automate** enables users to design and deploy business processes that work with SharePoint lists and document libraries (see Power Platform chapter for more information about how to build Power Automate apps).

# Chapter 9: Tasks

**Paul Robichaux**

## Delivering Lightweight Planning

The quality of planning done for a project can spell the difference between success and failure. In the 1960s, project-planning tools were mostly restricted to extremely large engineering-focused projects such as NASA's manned lunar missions. However, as computer power and capability became more democratized, so did project planning and scheduling methodologies. Some of the early successes of third-party PC software included Borland's Sidekick utility and Lotus Agenda, both DOS-based tools including a to-do list manager. Since then, the modern business world has been inundated with tools and strategies to help people better manage their work, from David Allen's seminal book [Getting Things Done](#) to bullet journals and Kanban boards.

Microsoft's portfolio has long included Microsoft Project, a sophisticated planning product. Perhaps the kindest thing that can be said about Project is that it is easier to use than its competitors—which does *not* mean it's easy for a newcomer to manage. Every version of Outlook has included a tasks module to create and track tasks alongside email and calendar items, and since the early 2000s, Microsoft provided mobile device access to synchronize these tasks with Exchange mailboxes. Today, Microsoft 365 has a Task ecosystem where multiple applications generate tasks that share many common elements. The fact that we have Outlook, Microsoft To Do, Microsoft Planner, Microsoft Project, and various features to flag or assign items in other Office 365 applications can be confusing. It helps to reduce confusion once you know that Microsoft now thinks of tasks as falling into three categories:

- **Me tasks** belong to an individual who is usually the person who creates, manages, and views the tasks. For example, my list right now in Microsoft To Do includes "update GPS," "pay mortgage," and "reorder cat food." Usually, people manage tasks of this nature with To Do or Outlook, but you could also use tasks in apps like Planner, To Do, Outlook, or access the task objects programmatically using the Graph API.
- **We tasks** are owned, shared, or worked on by a team. While you could use a shared task list in To Do, it's much more natural to think of these tasks as those associated with plans in Planner.
- **Organizational tasks** represent shared work items defined by an organization. Think of the work a retail company must do each time they open a new store. From site selection to hiring and training to putting out signs on the sidewalk, there's a repeatable process followed each time, but the people who create the process aren't the same ones who carry it out. For example, the local store manager usually hires store staff. Teams includes the ability to publish tasks making up a work plan based on an organizational structure (the team targeting hierarchy). See [this article](#) for more information.

## Multiple Clients for Managing Your Tasks

Based on this division of task ownership, the way Microsoft has organized its task management applications makes more sense. There are a few organizing principles. First is that it's okay—in fact, desirable—for there to be multiple ways to access, edit, and update the same set of tasks. The use of a common task object across Microsoft 365 is why Tasks created in Outlook show up in the To Do app and vice versa. Second, the service should always try to collect all the tasks that "belong to" you in one place. In this case, "belong to" means both tasks that you created and those assigned to you, no matter the type. That's why the Teams Tasks app shows both your personal tasks and tasks assigned to you in Planner plans.

Another organizing principle is that Microsoft distinguishes between task management and project management. As individual people, we all have tasks to manage, but managing larger-scale projects requires different tools.

Table 9-1 shows a summary of some of Microsoft's task management ecosystem. With that summary in mind, we can dig into the individual applications in more detail.

<i>Individual ("Me")</i>	<i>Team ("We")</i>	<i>Company ("Org")</i>
Outlook Tasks	Planner (including Tasks in Teams)	Project Server / Project Online
Microsoft To Do	Microsoft Lists	Teams organizational tasks

Table 9-1: The continuum of task management from to-do items to projects

## Planner

Microsoft Planner is a lightweight task-oriented planning application whose big advantage and unique selling point is its integration with other Microsoft 365 workloads facilitated by using the membership and identity services of Microsoft 365 Groups. Planner is available for tenants with enterprise licenses in both commercial and [U.S. government clouds](#), the Business Premium and Business Essentials SKUs, and most educational and non-profit SKUs. As Microsoft's newest task management solution, Planner competes with Project Online, other Microsoft offerings like SharePoint Online, third-party offerings that plug into Microsoft 365 for task management (like [Tasks In A Box](#)), and third-party products. It's a fair question to ask what Planner's purpose is given this crowded space.

Part of the answer comes from the fact that the same engineering group develops Planner, Project, and Project Online, which means that it's no surprise that Planner and the web version of Project share some code. In the spectrum of Microsoft project management software, Planner is "Project lite," an entry-level task management application. Although Planner lacks many of the features of Project, like dependencies between tasks, its user interface offers better sorting and filtering of tasks and people often consider Planner easier to work with for many projects.

Probably the most accurate way of thinking about Planner is that it is Microsoft's version of the popular and widely used Trello application, which is itself an app that embodies [Kanban-style planning methodology](#). Trello has been around for a while and the two applications share many visual similarities in layout and visual design, albeit with slightly different naming conventions. For instance, Trello lists are equivalent to Planner buckets. See [this page for a comparison](#) between Planner and Trello.

## Microsoft To Do

Most of us try pretty hard to organize our own lives for the better. Whether electronic or paper, to-do lists often help people to prioritize and get things done. Almost every system designed to help people with office-oriented tasks has included some form of to-do list alongside email and a calendar. Microsoft bought the Wunderlist application in 2015, then promptly threw it away and built a new app on top of its cloud infrastructure, called Microsoft To Do. To Do is described as a "simple and intelligent to-do list app that empowers users to keep track of and focus on the things they need to get done."

To Do is supported for both Microsoft 365 and Microsoft consumer accounts. The To Do mobile (for iOS or Android), Windows 10, and browser clients use the Outlook Tasks Graph API to store task info in the Tasks folder of either an Outlook.com or Exchange Online mailbox. If users create a new list with the app, the to-do items for that list go into a sub-folder under Tasks named for the list. Tasks created using Outlook.com or Exchange Online synchronize with the To Do service. If you flag a message in Outlook, it shows up in To Do as a task in a separate (and optional) *Flagged Email* view. You can use To Do to edit details of the task, assign steps (individual checklist items for the task), mark it as important, set reminders, and add the task to the *My Day* view. Although it seems simple, this feature made To Do much more useful than before and convinced

some people who were dedicated users of Outlook Tasks to adopt To Do as their personal task management app. In addition, To Do tasks can be integrated with Microsoft's Cortana personal assistant, allowing you to add tasks by voice from Windows PCs, mobile devices with the Cortana app, Xbox One devices, and a variety of other voice-enabled devices. Being able to shout "Hey, Cortana, add 'buy cat food' to my to-do list" is surprisingly useful (when it works, that is).

By default, Microsoft enables To Do for users with [eligible Microsoft 365 subscriptions](#). There's no longer a way to control To Do on a tenant-wide basis, but you can control access for individual users by editing the options bundled in the Microsoft 365 license assigned to the user to remove or allow access to the application. Like many Microsoft 365 client applications, there's an "Insider" program for To Do that allows you to get early access to new features in the client and service. There are separate insider programs for Windows, [Android](#), and iOS.

## Microsoft Project

At the high end, Project is Microsoft's headline project and task management application. While To Do is intended to manage personal tasks, and Planner helps you manage tasks for your team or workgroup, Project is the kind of tool you'd use if you wanted to launch a space mission, build a hospital, or do something similarly complex. Originally launched for DOS in 1984, the capabilities of the Project application have expanded dramatically since. The latest iteration is composed of Project clients and servers, the latter being available in on-premises and [cloud](#) versions. Project is a powerful and sophisticated time and task management application that is much beloved by professional project managers. It can handle the complexities involved in very large projects such as the design and construction of major infrastructure projects. Like many highly functional software packages, learning to use Project can be overwhelming and it can take a long time to become proficient in its use. Those who have mastered Project will probably consider Planner to be simplistic and deficient in terms of charting, dependencies, and other areas. However, it is worth underlining again that Microsoft does not intend Planner to take on the kind of complex, heavy-duty planning requirements that Project is meant for. In short, Project is the right tool to use when you must coordinate multiple milestones, dependencies, and complicated schedules. If needed, you can [connect tasks managed in Project Online with Planner](#). However, you cannot transfer tasks from Planner to Project or convert a plan into a project or vice versa.

## Outlook Tasks

Outlook's Task functionality dates to its original debut back in the early 1990s. Don't expect much from Outlook as a task manager: you can create and manage lists of tasks, assign due dates, and so on. Perhaps the best task-related feature in Outlook is the ability to treat a flagged message as a task, or maybe the ability to drag a message into the Tasks folder to treat it as a task. When you absorb Microsoft's principle of "many clients, one task," it's easier to let go of the concept of using Outlook for task management instead of the easier-to-use and more-functional To Do and Planner clients.

## Microsoft Lists

At first glance, Microsoft Lists seem very similar to Planner. However, while some crossover exists, the two applications are very different.

- Planner is an out-of-the-box general-purpose task management application for teams. You don't need to customize anything to start creating and managing tasks. It's all done for you in the app. The downside is that you can't customize how Planner works.
- The Lists app is more of a toolbox to create customized applications to track and process different forms of data. You can use Lists to manage tasks, but you'll need to define what a task is and any associated components, like attachments, links, and so on.

Today, no connection exists between Planner and Lists. Microsoft has talked about how the two applications could interact in the future, but no solid plans for this are yet public.

## The Planner Back-End

Because Planner supports shared tasks and plans, there's more to it than just another front-end that reads tasks from users' Exchange Online mailboxes. Before we go any further, it's probably helpful to understand that the fundamental object type in Planner is the *plan*. Think of a plan as a container for tasks that "belong" together because they're related to the same project or owned by the same user or group.

### Planner, Microsoft 365 Groups, and Applications

Planner originally had a dependency on Microsoft 365 Groups. Every Group can have a corresponding plan; if a plan exists in a Group, the plan belongs to that Group. Originally, a Group could only have a single plan, the default plan, but this situation changed to accommodate the need for Teams to support multiple plans through channel tabs. The membership of a team depends on the underlying Microsoft 365 group. However, each channel inside a team can have multiple plans, all of which belong to the team (and the Group). One unique feature of the integration between Planner and Teams is that when you're assigned a task in Planner, the assignment [appears in the activity feed in your Teams client](#) (although thankfully you can turn this integration off).

Group-enabled SharePoint team sites can also create multiple plans, all of which are associated with the team site. You can add these plans (or the default plan for the Group) as links accessible from the home page of the team site or embed one or more plans in site pages using the Planner web part, deciding whether the web part displays boards or charts. The Planner hub does not display the name of the underlying team site that a plan belongs to, so it is wise to include the name of the site when naming a plan.

Ideally, a user needs to have an Exchange Online mailbox to enjoy the full functionality available in Planner, particularly the close connection with the underlying Microsoft 365 Group. If a hybrid user has an on-premises mailbox, they are unable to add a comment to a task using OWA or Outlook. Marking plans as favorites is also a feature that does not work properly when a user does not have a cloud mailbox. However, a hybrid user whose mailbox is on-premises can post comments to tasks through the Planner application.

### Lightweight Plans: Plans without Groups

In early 2021, Microsoft announced plans for "roster containers," a new way of creating plans without needing to use a Microsoft 365 Group to host the plan. Instead, the container has a membership roster (or list). Microsoft hasn't yet said how they will use roster containers, but it's likely to be associated with features like Teams shared channels, which use external federation rather than Azure B2B Collaboration to allow the sharing of information with people from external tenants.

The release of the roster container feature was [delayed for several months](#). Microsoft then announced plans to roll out support for "lightweight Plans" (the new name for the roster containers feature) in September 2021. For now, you'll only be able to create and work with lightweight Plans using the Graph API. Now that [Loop components are available in Teams chat](#), Microsoft will bring support for lightweight Planner plans in Teams chats, as opposed to the simple to-do list component now available. This will be a significant upgrade because the existing fFuid task component stores tasks in the Loop components file, which lives in the originator's OneDrive for Business account—meaning that these tasks break the principle of "see your tasks everywhere." We'll have to see if Microsoft delivers on this promise fully with lightweight Plans; expect to see further updates here as this feature evolves.

### Planner Services

Planner stores the metadata for plans, including information describing the tasks and buckets that make up each plan, in an Azure data service, protected with using Azure Storage Service Encryption and complying

with the Service Organization Controls Report [SOC 1](#), SOC-2, and SOC-3 standards, plus ISO 27001. [Planner is deployed in some, but not all](#), country-level Microsoft 365 data center regions, so your Planner services may come from a regional data center. For example, Planner data for tenants in Australia is hosted in Australia, but tenants in Brazil have Planner data held in the US.

Planner uses the Microsoft 365 Groups service for membership and access control. Each plan is owned by a Group and multiple plans can be created per Group (or team). The links to the Group and its resources used to store conversations and attachments are part of the plan metadata.

Planner data is accessible through the Microsoft Graph API. However, Microsoft hasn't made an API available to backup and restore Planner data, or to move plans to another Office 365 tenant. There are third-party tools available to migrate plans from one tenant to another, but they can't capture 100% of the plan's data because not all the objects and fields are available through the public Graph API endpoints.

## Planner Clients

Like many other Microsoft 365 workloads, Planner's first client was browser-based, followed by mobile apps for [iOS](#) and [Android](#) and integration with Teams as an app and channel tab. One of the chief useful features of these clients is that they can aggregate all tasks assigned to a user in a single view on the "My Tasks" page, so no matter what team or Group the original plan is in, all the tasks an individual is responsible for appear in a single place. As with Outlook, new Planner features usually show up in the web version first. Another useful feature of the iOS client is the ability to select Planner as the target to share an item (like a website, Facebook post, tweet, or another interesting snippet). You can post the item to any plan you can access.

No desktop client currently exists for Planner. Interestingly, the Planner team did start work on one, but deferred work on it in favor of providing integration between Planner and Teams. Microsoft has an iCalendar connector to link tasks assigned to a user to their Outlook calendar (see the later section). In the meantime, a third-party add-in is available in the Office Store from [iGlobe](#) that makes Planner appear as an Outlook resource (just like public folders). You can navigate between tasks and view their details. Another tool from the same company [gives a reporting capability](#) for Planner.

SharePoint Online supports a Planner web part that can be added to a page for a modern site. The web part displays tasks from a plan belonging to the underlying Group. If a plan doesn't exist, you can create it and then add it to the web part.

## Programmatic Access to Planner Data

Planner supports a [Graph API](#) endpoint to support integration with outside solutions. There's also a [PowerShell module](#) but the process for using it is complicated: you have to download the PowerShell module itself, unblock the PowerShell module (.psm1) file and an accompanying DLL, set the execution permissions for the module on the workstation you're using, and import the module. After all this work, you get a limited set of PowerShell cmdlets that only a Global admin role holder can run. That's probably why Microsoft calls the existing PowerShell module the "Planner Tenant Admin" module. However, you can still use PowerShell with Planner to do other useful things. You can:

- Use the PowerShell cmdlets for Groups to manage details of the groups used by Planner.
- Use Graph calls made through PowerShell to access Planner data.

An article describing how to use the Planner API with PowerShell to fetch data about all the plans accessible to a selected user is [posted here](#). The article explains how to create an app to interact with the Graph, assign the needed permissions to the app to access Planner data, and obtain an access token for the app to fetch data through the Graph. These are common steps used to create an app to use with the Graph.

After connecting, the code finds the set of Groups the user belongs to. Not every Group has a plan, and some Groups have multiple plans, so the code loops through each Group to see if plan data is available. Here's the PowerShell code to call the Graph to retrieve the plans for a Group:

```
[PS] C:\> $PlanURI = 'https://graph.microsoft.com/v1.0/groups/' + $Group.GroupId + '/planner/plans'
[array]$Plans = Invoke-WebRequest -Method GET -Uri $PlanURI -ContentType "application/json" -Headers
$Headers
```

If plan data is found, the code loops through each plan to find details about the plan, tasks, and buckets. Here's a snippet of those commands:

```
[PS] C:\> ForEach ($Plan in $Plans.Value) {
    $PlanId = $Plan.Id
    $PlanNumber++
    $PlanCreated = Get-Date($Plan.CreatedDateTime) -format g
    $PlanOwner = $Plan.Owner # Microsoft 365 Group
    $PlanTitle = $Plan.Title
    $BucketURI = 'https://graph.microsoft.com/v1.0/planner/plans/' + $PlanId + '/buckets/'
    $Buckets = Invoke-RestMethod -Method GET -Uri $BucketURI -ContentType "application/json" -
Headers $Headers
    $NumberBuckets = $Buckets.Value.Count
    $TasksURI = 'https://graph.microsoft.com/v1.0/planner/plans/' + $PlanId + '/tasks/'
    $Tasks = Invoke-RestMethod -Method GET -Uri $TasksURI -ContentType "application/json" -
Headers $Headers
```

After fetching the Graph data, normal PowerShell commands process the data to create a report listing the number of tasks (and the status of the tasks) and buckets in each plan, when the plan was created, and the number of days since the last task was posted as an indicator whether the plan is active.

The script isn't perfect, but it is a working example of how to combine PowerShell with the Graph to interact with plan data. An example of how to use PowerShell and the Graph to do real work with Planner is in Alexander Holmset's script to [move Planner data from one tenant to another](#).

## Planner Basics

You can access the Planner application with your normal Microsoft 365 credentials by:

- Clicking the Planner icon in the Microsoft 365 app launcher.
- Navigating to the Planner Hub at [tasks.office.com](https://tasks.office.com).
- Selecting Planner from the [...] menu of a Microsoft 365 Group when working with conversations in OWA.
- Navigating to it from a Yammer community.

The Outlook integration with Groups doesn't support Planner. We'll discuss the Teams integration later.

The Planner web application uses a streamlined interface composed of a navigation pane to the left and a details pane to the right. The user interface accommodates a range of screen sizes and form factors and resizes elements to fit the available space. Figure 9-1 shows how the Planner Hub displays Microsoft 365 Groups as Plans in the navigation pane. Plans marked as favorites show up on top. If you select a plan as a favorite, the groups in the favorites section of Outlook and OWA include the associated Group for the plan.

The "Assigned to me" link in the navigation pane displays tasks assigned to the user from all plans, while the **All** pivot lists all the Groups to which the user belongs, even if these Groups have no plan information associated with them. The **Recent** pivot exposes Groups where recent activity has occurred, but not necessarily planning activity. To work with a plan, click the name of an existing plan or create a new plan. You can force a plan to open in Teams by selecting the "..." menu next to a plan in the **Recent** or **All** pivots and selecting the **Open in Microsoft Teams** command.

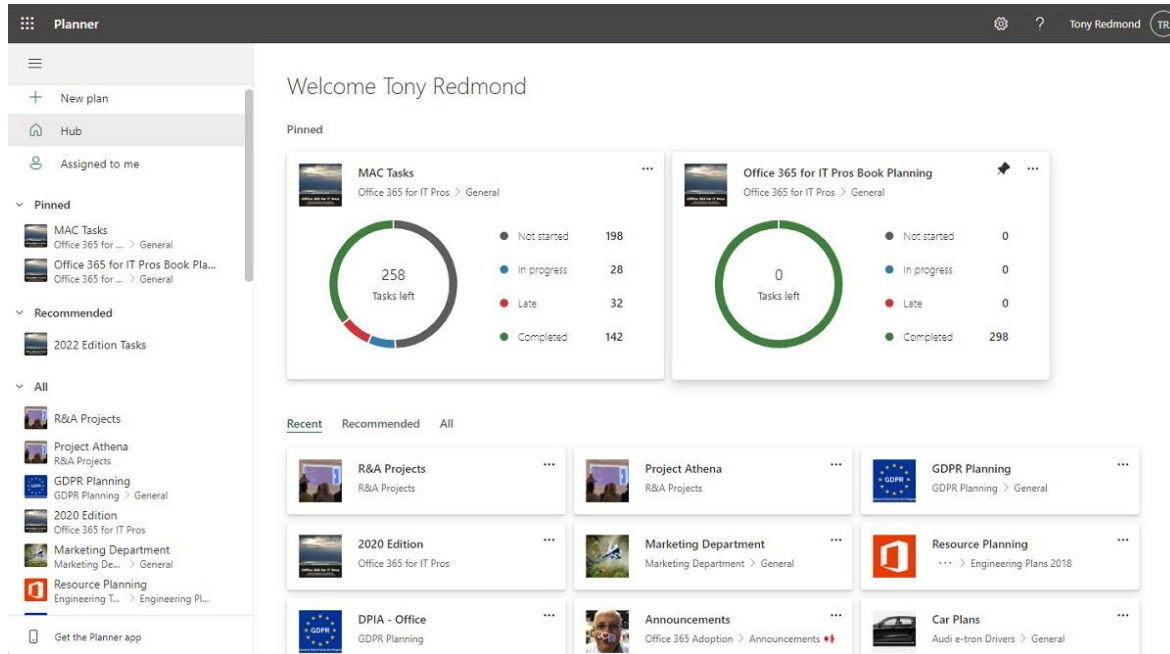

Figure 9-1: The Planner Hub

## Creating New Plans

You can create a new plan through the **New plan** command. There's no separate policy available to control plan creation, so Planner uses the creation settings from the Azure AD policy for Groups. If a user is allowed to create new Groups, she can create a plan and a new Group at the same time. If she's not allowed to create new Group objects, Planner will still allow her to create a new plan, but she must choose an existing Group to contain it. Planner doesn't give you a way to see multiple plans that belong to the same Group together; they'll still be treated separately. Plans created in an existing Group take on the properties of that Group (for example, public or private access) and are immediately available to its members.

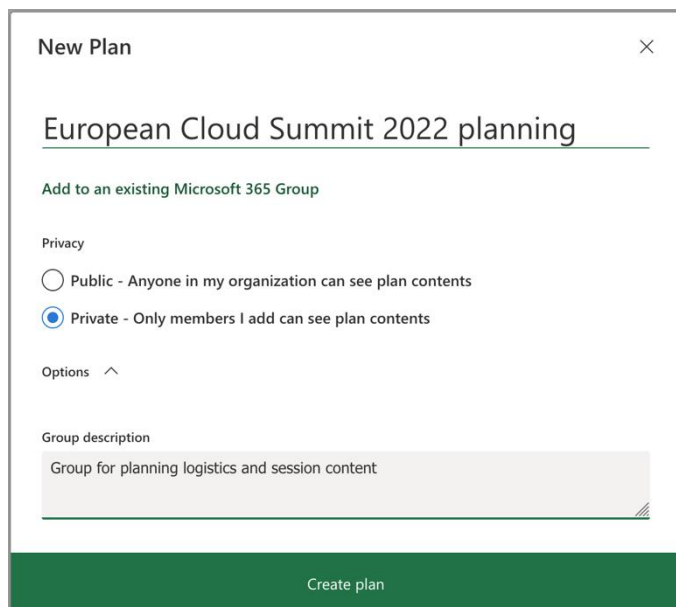

Figure 9-2: Creating a new plan

Figure 9-2 shows the interface to collect information about a new plan for a user who's allowed to create new Groups. The first choice to make is where to create the new plan, which can either be attached to an existing

Microsoft 365 Group (or team) or created from scratch. If you opt to attach the new plan to an existing Group, the next step is to select the target Group or team.

Figure 9-3 shows how the Planner hub displays multiple plans belonging to a Group called GDPR Planning. The default plan for the Group takes the name of the Group while the other plans have the Group name shown under their name.

Figure 9-3: Multiple plans for a Group

## Provisioning New Groups

If you choose to create a new plan, Azure AD creates a brand-new Group to host the plan. A Microsoft 365 Group created by Planner is the same as any other Group with a SharePoint team site and other resources. If a Group naming policy is in force, the names given to new groups or teams must comply with the policy. The exception is for plans created by tenant administrators, who do not come under the control of the naming policy.

After creating a new plan, the next thing to do is to add some members. Click Members in the menu bar to add tenant users and guest users to the membership of the Group. Remember that these people are now full members and therefore have access to the other resources belonging to the Group.

## Planner Tasks, Buckets, and Boards

Tasks form the basic building block for a plan. Each task describes a piece of work, including information such as the person assigned the work, start and end dates, and a priority for the task. Planner uses a card metaphor to display information about tasks. You can customize the cards to display different information about the tasks such as including a graphic, an expanded description, or even a checklist item.

Planner organizes tasks into “buckets” and arranges the buckets on a “board” (the analogy is to pin index cards with details of tasks to a corkboard). Think of a bucket as a collection of tasks that constitute a major section of a plan, or a collection representing tasks in a specific state. Each plan begins with a “To Do” bucket. You can rename this bucket and create as many other buckets as you need. For instance, some teams use buckets to track tasks for recurring meetings like weekly team briefs. They create a new bucket for each meeting and move tasks still outstanding from previous weeks to the new bucket, which then becomes the central focus of discussion for what needs to be done this week.

You can even use buckets to coordinate several plans within a single overarching plan. In this scenario, each plan, or sub-plan, becomes a bucket. If you remove a bucket from a plan, you also remove all the tasks in the bucket.

Tasks belong to an individual plan. You can move a task between plans in a Group and (from October 2021) to a plan owned by another Group.

Tasks are arranged for display in six ways:

- **Buckets:** This grouping allows you to view the tasks assigned to each bucket. Some people use buckets to group tasks by importance, some to divide up a project into logical pieces of work, and some to show task status by having buckets with tasks that are completed, on hold, not started, or whatever other status you would like to use.

- **Assigned to (person):** This grouping displays the tasks assigned to each person. By default, the view only shows tasks that are in progress or not started. You can add the completed tasks to the list by scrolling to the bottom of the list and clicking “Show Completed.”
- **Progress:** This view shows tasks in the three stages supported by Planner – Not Started, In Progress, and Completed. Figure 9-4 shows an example of tasks for a plan grouped by progress with the completed tasks listed in a column.
- **Labels:** This view groups tasks into the labels (or categories) that you can assign to tasks.
- **Priority:** This view creates a virtual bucket for each of the priorities you can assign (Urgent, Important, Medium, and Low).
- **Due date:** Tasks not started or in progress are arranged according to the date set for their completion as:
  - Late.
  - Today.
  - This week.
  - Next week.
  - Future.
  - No date.

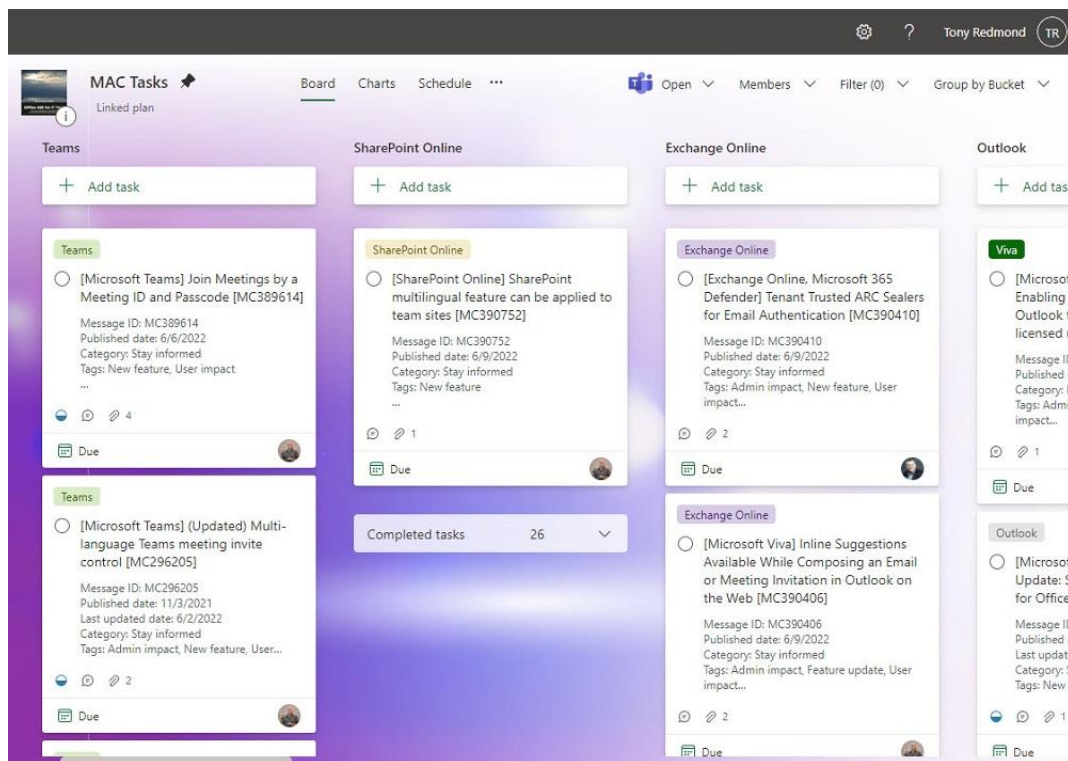

Figure 9-4: Tasks for a plan grouped and viewed by progress

Keep in mind that, when you move a task, some of its items may not move because they remain associated with the original Group—so moving a task will currently cause it to lose its labels and comments.

Planner lists tasks in a bucket in the order of creation. There is no way to select a preferred sort order such as by the due date. If you have assigned priorities to your tasks, you can use the display by priority view to see tasks grouped by the different priorities. A nice touch in the UI is that when you click a member’s icon, Planner highlights the Teams tasks assigned to that person.

Buckets are primary elements of the Planner user interface. Unless you use a very wide screen, though, it is best not to have more than five or six buckets per plan; with too many buckets, the user interface becomes

cluttered, and it can be difficult to find an individual task. If you think you will need to use more than six buckets to organize tasks, perhaps it is best to split them across multiple plans.

**Arranging buckets:** You can display the tasks for a plan in different groupings. If you use buckets to arrange tasks into segments of a plan, you can group the tasks by bucket and then drag and drop the buckets into whatever order makes sense to create an overall view of the plan. Grouping by priority is a useful feature that helps make up for the lack of a sort-by-priority option. You cannot reorder the other grouping (by progress or by assignee) in this manner.

## Task Filters

Because plans can span hundreds of tasks, Planner supports filters for views to allow users to focus on different collections of tasks. Apart from being able to group tasks in buckets, you can filter by:

- **Due date:** Select Late, Today, This week, Next week, Future, or No date.
- **Priority:** Select Urgent, Important, Medium, or Low.
- **Label:** Select one of the 25 labels assignable to tasks.
- **Bucket:** Select one of the buckets in the plan to see only tasks associated with that bucket.
- **Assignment:** Select a plan member to see the tasks assigned to them.
- **Progress:** Select to see all tasks with a specific state of progress.

As shown in Figure 9-5, you can combine one or more values for the different filters to highlight specific tasks. In this case, we want to see any task scheduled for this week in the Teams bucket.

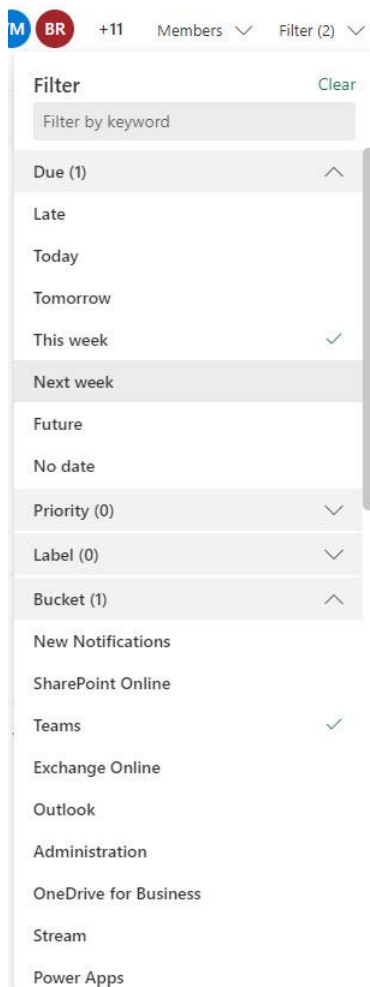

Figure 9-5: Applying filters to tasks

One common complaint is that it's difficult to search Planner items to find specific tasks. Filtering by keyword gives you similar results as being able to search the title field of your tasks, but there is currently no way to search tasks by labels or description.

## Charts

The Charts view presents another way of looking at the tasks in a plan with the screen divided into a chart view of the complete plan and a list of selected tasks on the right-hand side of the screen. In this case, tasks are listed by bucket, but you can apply any of the filters available in Planner to display matching tasks.

With just four charts available (status, bucket, priority, and members), Planner has limited ability to present graphic views of tasks. A simple embellishment would be to allow graphs to chart information for one or more selected buckets rather than a plan. Another obvious enhancement is the addition of a timeline view as people often measure the progress of plans by date. It would be very convenient to be able to drag and drop tasks along a timeline and have their due dates adjusted to match. Microsoft has committed to considering a timeline view in the future but has said that they are unlikely to add more complex or project-oriented charts such as Gantt or burndown charts to Planner as these are more suitable for a product like Project.

## Schedule View

The Schedule view (Figure 9-6) presents open tasks in a calendar, which is a natural way for many people to think about the priority order for their work. The view is like OWA's calendar and lists all open tasks in the plan unless the view is filtered (see below). Clicking a task reveals its full details.

Dates aren't assigned to tasks by default; if you don't assign correct dates, you won't get correct results.

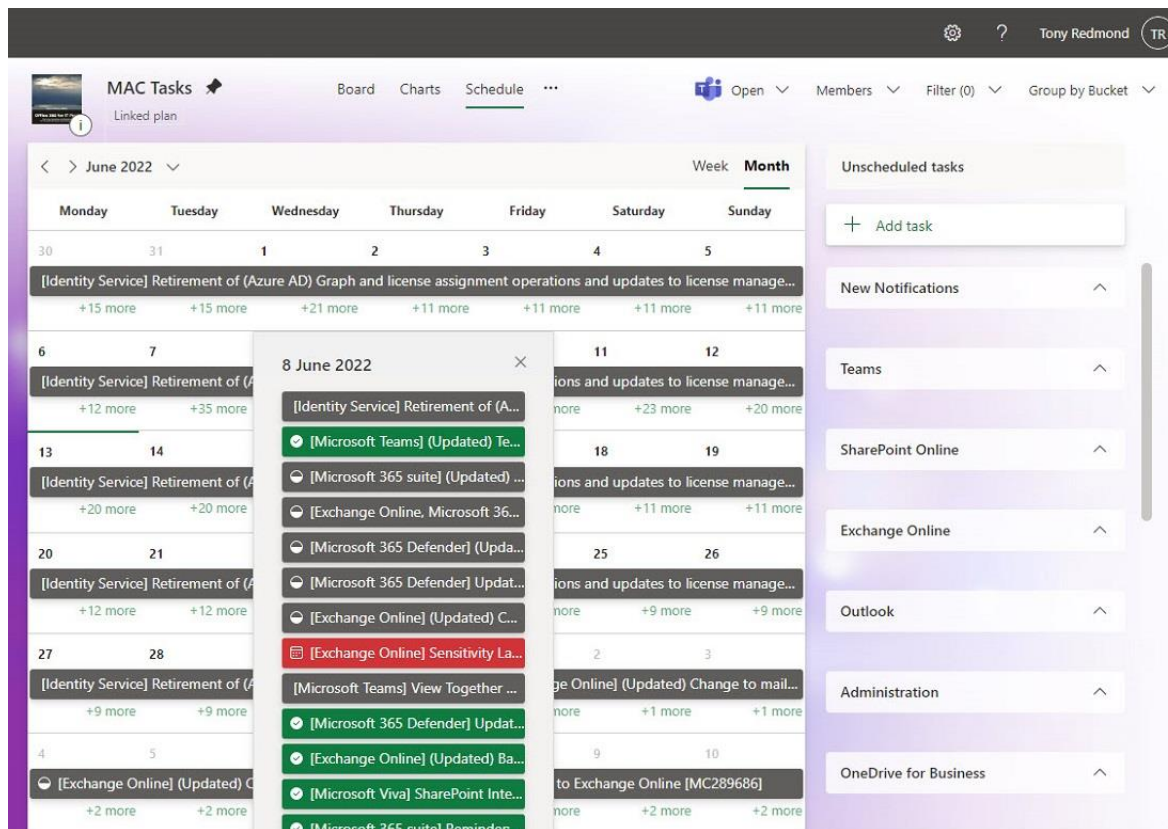

Figure 9-6: Planner's schedule view

You can add new tasks into the calendar or drag and drop existing tasks to assign them new due dates and put them into the proper position in the plan.

## Opening Linked Plans

If a plan has a label that says “Linked plan” under its name, that means that its content will be visible in other applications. For now, that means either Teams, SharePoint, or both. In Teams, if you add a plan as a channel tab, it becomes linked, and you’ll see it in the tab, in the Teams tasks app, and in Planner. For SharePoint, you can add a plan as a web part to any page, at which point it will be considered as linked.

Linked plans can be viewed and edited either in the Planner applications or in the linked applications. You’ll see a button labeled **Open** in the Planner menu bar (just to the left of the **Members** pulldown) that, when selected, lets you choose where to open the linked plan.

## Plan Settings

The options available in the ellipsis menu [...] in the menu bar for a plan are:

- Links to other Group resources. These choices open new browser tabs.
  - **Conversations:** Opens OWA to view email conversations in the Group mailbox.
  - **Members:** Opens OWA to view Group membership. Group owners can add, modify, or remove members here.
  - **Files:** Opens the document library in the SharePoint team site belonging to the Group.
  - **Notebook:** Opens the shared OneNote notebook belonging to the Group.
  - **Sites:** Opens the home page of the SharePoint team site belonging to the Group.
- **Pin:** As with other parts of Microsoft 365, Planner lets you pin items that you want to refer to often. Pinned plans show up in a separate Group in the left navigation rail. If you pin a plan, its Group also appears in the list of favorite groups in OWA or Outlook. If the plan’s already pinned, this command changes to **Unpin**.
- **Copy plan:** Creates a copy of the plan in a new Microsoft 365 Group. See details in the section below.
- **Export plan to Excel:** Creates an Excel worksheet with all the tasks in the plan. Each task occupies a single row. Once you have the plan in Excel, you can print it, combine multiple plans for analysis, or do anything else you can do with an Excel file.
- **Copy link to plan:** Copies a URL for the plan to the Windows clipboard. The link will start with *tasks.office.com*, then include the tenant name and a unique ID for the plan (e.g. <https://tasks.office.com/redmondassociates.org/en-US/Home/PlanViews/knwuDbAxtE2A7iYVAEJ-vpYAFE4L>). When pasted into a browser, it opens the plan.
- **Plan settings** are divided into three tabs:
  - **General:** Change the plan name and the background used by Planner. The backgrounds are generated automatically by the PowerPoint Designer component based on the title of the plan. Any Group member can change the plan background, and Designer does suggest different backgrounds to different people. You can’t force Planner to use a specific background like a corporate logo. Group owners can also delete the plan here (the Group remains intact when a plan is removed, and other plans attached to the Group are unaffected).
  - **Group:** (only visible to Group owners) Change the display name and description of the underlying Microsoft 365 Group. If the tenant uses sensitivity labels for container management, you can select a label to apply to the Group. A label setting dictates the privacy (public or private) of the Group. If sensitivity labels are not used, the Group owner can choose the privacy setting and classification for the Group.
  - **Notifications:** Planner sends two kinds of notifications (Figure 9-7). The first type of notification is via email when tasks are assigned or completed. Only Group owners can change this setting. Individual users can choose to receive notifications when they are

assigned a task and when a task assigned to them is late. Notifications for task assignments are generated when the assignment happens and are sent by email, a notification in the Teams Planner app, and using a push notification to the Planner mobile app. Late task notifications are generated by a background process and arrive only by email. Messages include a link to open Planner and interact with the relevant task.

- **Add plan to Outlook calendar:** Publishes the plan as an iCalendar feed that can be consumed by Outlook. This process is explained later.
- **Leave plan:** A member of a Group can leave a plan at any time. Group owners can't leave a Group if this action would leave the Group without an owner.

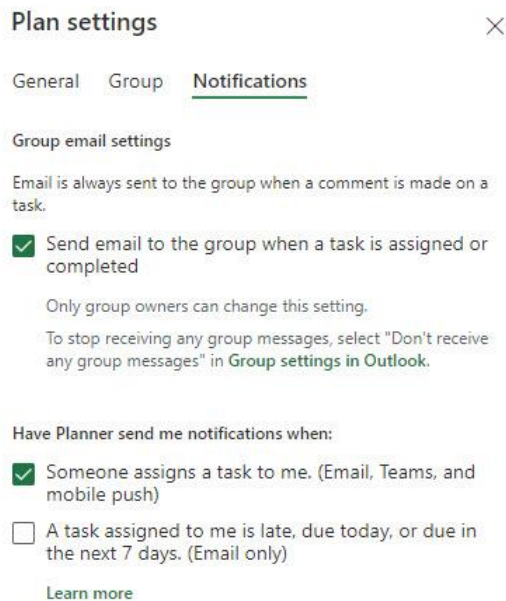

Figure 9-7: Email notification settings for a plan

Plans can span hundreds of tasks. No restrictions exist on how tasks are assigned. The tasks can be left unassigned or assigned to a single user. The largest plan I have used included over 500 tasks (you can assign up to 300 tasks to an individual user within a single plan). A user can have multiples of this number in terms of open tasks spread across different plans.

You may make mistakes when setting up a plan and want to start over. A complete bucket can be selected by clicking its name and then **Delete Bucket** from the ellipsis menu. If you want to remove the complete plan, go to the ellipsis menu for the plan, select **Plan Settings**, and then **Delete Plan** (see below).

## Private or Public

The privacy setting assigned to its underlying Microsoft 365 Group controls whether a plan is public or private. If public, any tenant user can view plan content but cannot change it. If a non-member wants to update tasks, they must join the Group (using OWA or Teams). If the plan is private, only members have access. If you change the plan's access type, you change the access type for the underlying Group and its team (if enabled).

The method used to change the privacy setting for a plan depends on if the tenant uses sensitivity labels for container management. If a tenant uses sensitivity labels for container management (see Chapter 20), choosing a new sensitivity label imposes the privacy setting inherited from the selected label. If sensitivity

labels are not used, Group owners can edit the properties of the plan or run the *Set-UnifiedGroup* cmdlet. For example, to set a Group (and its plan) to be private:

```
[PS] C:\> Set-UnifiedGroup -Identity "My Big Plan" -AccessType Private
```

Because access to a plan depends on its Group, changing a plan's access type might have some unexpected consequences. In the case of changing a plan from private to public, the intention might be to reveal details of a plan to invite comments from outside the project team on the set of tasks defined for the project. This is laudable, but perhaps the project team does not want to expose the other shared resources (documents, conversations, calendar, and notebook) to all and sundry. Some thought is necessary to figure out whether a plan should be public or private when it is created or if you edit a private plan to change its status to public.

Remember that if a sensitivity label is assigned to the Group, the privacy setting in the label controls whether the Group is private or public. In this case, you can't change the access setting without changing the sensitivity label.

## Copying a Plan

Copying an existing plan solves the problem where many similar projects exist in an organization, all of which have the same basic structure and need. The idea is that you can save some time by creating a template of a plan for these projects and then copying the plan to create a new plan as each new project spins up. You can copy a plan to an existing Group or create a new Group to host the copied plan. Although the choice to copy a plan is revealed to all users, only those allowed to create new Microsoft 365 Groups can create new plans (and Groups) in this manner.

The **Copy plan** option is available in the ellipsis menu when a plan is open or when viewed through the Planner hub. In either case, when you copy a plan, Planner does the following:

- Copies the plan data to the selected Group. By default, the display name of the new Group is "Copy of" appended to the display name of the source plan. You can override this and compose a different display name and description before you copy the plan (or afterward). The plan's photo is not copied.
- Copies the bucket structure, label assignments, and the tasks (including the chosen details of the tasks) to the new plan.
- Sets the person who copies the plan to be the owner of the new plan (and if a new Group is created, they become the owner of the new Group). Members of the source Group are not added to the new Group, so you must add new Group members after the new plan is copied.
- Sets the privacy and classification settings to the selected values.

Figure 9-8 shows the dialog used to collect information for a plan before copying. In this case, the copy creates a new Microsoft 365 group. If your tenant uses sensitivity labels for container management, the access to the plan is set by the sensitivity label you choose.

Copying a plan creates a new plan based on the source plan's structure. The following information is not copied from the source plan:

- Task assignments, due dates, and progress (all tasks are marked "Not started").
- Comments (stored as conversations in the Group mailbox).

Copying even a very complex plan is very fast. Once Planner finishes, you can open the copied plan to complete the process of establishing the new plan by adding a description and photo, removing unwanted buckets and tasks, updating task descriptions and due dates, and assigning tasks to plan members.

## Closing or Archiving a Plan

Apart from abandoning a plan, Planner doesn't include a way to close or archive a plan. No option exists to mark a plan as "done" or place it into a read-only mode. Planner doesn't support the Microsoft 365 information governance framework so you can't apply retention policies to manage completed tasks. If you want to clear out a plan before starting afresh (for instance, at the start of a new year), you must remove old tasks manually. Another approach is to create a new bucket called "Archive" and move all the completed tasks to it before starting work on the next stage of a plan.

Some organizations use the Export to Excel feature to create a monthly copy of plan data in a worksheet that is then stored in SharePoint Online. Although this is a manual process, it has the benefit of creating a snapshot of the plan when the export occurred.

Archival is not just a matter of simply moving tasks to some other repository because tasks often have associated documents and comments. This data is stored in SharePoint Online and Exchange Online. It is reasonably easy to copy the documents held in the SharePoint site belonging to the Group but more problematic to copy the conversations (comments) from the Group mailbox. Even if you write the necessary code to extract the necessary information from the Group mailbox, the challenge still exists to link everything together in a way that you can reliably rebuild a plan if needed.

# Planner and Microsoft 365 Compliance

Archiving inevitably brings compliance to mind. As discussed in this book, Microsoft 365 includes a comprehensive suite of data governance technology designed to work across the service. In early 2021, Microsoft announced that Planner will create “digital twins” (compliance records, sometimes called secondary copies) of tasks in Exchange Online mailboxes to ensure their availability for eDiscovery and other compliance purposes. The implementation involves:

- Planner creates compliance records for tasks assigned to a single user in the *AllToDoTasks* folder in the hidden part of their Exchange Online mailbox.
- For tasks assigned to multiple users, Planner creates a copy of the compliance record for the task in the *AllToDoTasks* folder in each user’s Exchange Online mailbox.
- Compliance records for tasks assigned to hybrid and guest users are in the special cloud-only hidden mailboxes used to hold compliance items.

It’s important to emphasize that the data held in Exchange Online is for compliance purposes only. Task data in the Planner data store in Azure remain the repository of record.

Unassigned tasks are ignored until they are assigned to a team member. Compliance records are generated when tasks are created or edited. Planner does not go back to generate compliance items for old tasks, meaning that records for these tasks do not exist unless they are updated.

Initially, the Planner compliance records will be used for eDiscovery purposes to allow Planner data to be found when content searches process user mailboxes. Because they are stored in Exchange Online mailboxes, the records are indexed and can be found by content searches. Later, Microsoft is likely to include Planner support in other compliance features such as retention policies and communication compliance policies.

In addition to the compliance records, Microsoft Search indexes the documents and comments belonging to plans stored in SharePoint Online and Exchange Online to make sure that they are discoverable. Finally, although Group creation and updates (like adding a new member to a plan) generate audit records, plan actions such as creating a new bucket or task creation, update, assignment, deletion, and completion do not.

## Deleting Plans and Plan Data

To delete a plan, choose **Plan settings** from the ellipsis menu and then **Delete this plan**. Upon confirmation, Planner removes the plan and all its tasks. Removing a plan from Planner does not remove tabs in Teams channels linked to the plan. You’ll have to do this manually.

To delete the underlying Microsoft 365 Group, choose **Plan settings**, then the **Group** pivot, and then **Delete this Group**. If you go ahead, the entire Microsoft 365 Group and all its provisioned resources are removed and put into a soft-deleted state. The resources might include a team, the Group mailbox, the SharePoint Online site, the shared notebook, and so on. If you remove a Group accidentally, you can recover it using the procedure described in Chapter 11.

When you remove a user from Azure Active Directory, their [Planner data is not deleted](#). This is intentional, as a plan will normally be a collaborative object accessed by multiple people, and it would be rude to just wipe it out when the creator’s account is removed. If you want to remove plans, tasks, or other data from Planner when a user leaves, you will have to log in with appropriate privileges and remove it manually.

# Creating and Managing Tasks

Creating a new task is very straightforward. Click **Add task** and enter details of the task such as the bucket it belongs to, the due date, and the person to whom you assign the task. You can also select an existing task and copy elements of the task (such as the description, checklist, attachments, and labels) to create a new task. To copy a task, click the ellipsis [...] menu when editing the task that you want to copy, select the elements to copy, and give the copied task a new name.

A task can also be copied to another plan (even to plans owned by other groups). The person copying the task can select any plan they belong to and choose a target bucket in that plan. When a task is copied between plans, only the progress, dates, description, and checklist are copied. You'll have to assign the task after it is copied to the target plan and add attachments and labels.

Although each task must have a name, the names do not have to be unique. You can create as many tasks as you want with the same name and assign them all to the same person, which might be a little confusing. Task names can be up to 254 characters long. If you try to use a longer name, Planner trims the name back to the limit. Special characters are fully supported and a task name such as "1"\$%^&\*()\_+{}|;:@'~#><.,.?/\\" is possible, even if it doesn't mean very much to anyone. On the upside, plenty of opportunities exists to dream up some interesting code names for tasks, especially because you can also use emoji in task titles.

## Adding Tasks from Teams

Microsoft lets you quickly add a task from within Teams, which is immensely useful as a way to quickly capture things that you need to do. The "More actions" context menu for any personal or group chat message will contain a "Create task" item; when you select it, it takes the selected message text and uses it as the title of the new task. The notes for the task will contain a link to the thread. You can also create tasks from channel conversations, in which case you can select whether the task should be stored as a personal task for you or in a plan associated with one of the teams that you're a member of. Keep in mind that an individual Team may have more than one plan associated with it.

## Assigning Tasks

You can assign a task to one or more people. Planner populates the drop-down list used for task assignment, with the Group membership divided into those assigned to the task and those who are not (yet).

When you assign a task to someone, Planner can notify them, depending on what notification settings are in effect. By default, Planner will email a notification to the Group to tell the assignee about their new task. If you use Outlook to access the Group mailbox, these notifications serve as the starting point for conversations about the task. Any comments made about the task become part of this conversation. Planner adds the comments to the conversation in the Group mailbox and circulates copies of the comments to members who have previously commented on the task.

You can also control whether Planner will attempt to send notifications of task assignments to individual users. These notifications are sent via email, push notifications to the Planner mobile app, and through Teams; this setting is at the plan level and is accessed through the plan settings interface (click the [...] menu and select **Plan settings**). You can't control which methods are used to send notifications. However, users can still turn task assignment notifications off in the Teams or Planner apps themselves, which will override the plan settings value.

If needed, you can leave tasks unassigned until the right person is available to take on a task. As already noted, if someone leaves a Group, their tasks stay assigned to them until someone reassigns the tasks to another team member. No bulk reassignment function is available to move a set of tasks to someone else

within one plan or across all plans in a tenant, such as when someone leaves the company and the need arises for others to take over this work. For this reason, it is sensible to check whether an individual has any assigned tasks when they leave the company.

Like the other applications which use Microsoft 365 Groups to manage their membership, everyone in a Group shares equal access to the plan. Anyone can create or edit a task. Anyone can assign a task to another member or reassign a task that they have received to someone else. And they can remove a task or update the progress of a task. It's all very self-liberating and empowering if you're prepared for this mode of working. At present, none of these changes are audited or tracked (although you can see which team member completed each task).

If you need a more hierarchical form of management where only defined members can add, change, or assign tasks, then you need to use traditional project management software such as Project Online. Another option is to use [the "Project" template for SharePoint Online](#) to create a site to hold tasks for a project. Out of the box, this will not deliver the same kind of user interface that Planner provides, nor will it have the same close connection to the Group, but because it is based on SharePoint Online, it is possible to customize and organize the site to meet your requirements.

## Adding Users to the Group Via Task Assignment

An owner can add any account from the tenant directory, including guest users, to the Group membership by assigning them to a task, including when a plan is accessed through a channel tab in Teams. It's logical to say that someone can't be assigned a task unless they can access the plan but the result is that the newly added member has access to all the resources available to the Group, including its document library. In other words, you cannot add someone to a plan without also adding them to Group membership. No facility exists to allow someone to have view-only access to a plan.

Planner warns owners when they add new people by assigning tasks to highlight that the user will join the Group membership. However, it's easy to overlook the warning and end up with people having access to Group resources when this is not desired.

## Fleshing Out Task Details

Newly created tasks won't usually contain much information— just enough to be able to populate the card. This might be enough for some plans but not for others. To add more details to a task, select it to reveal the task dialog box (Figure 9-9), which allows you to view and update the task metadata. Because the task shown here comes from the Message Center in the Microsoft 365 admin center, it is already populated with data, including:

- The title is set to the title of the notification posted in the Message Center.
- Progress is set to Not started.
- Priority is set to Medium.
- The start date is the date posted in the Message Center.
- Notes come from the text of the notification.
- Attachments might be available. In this case, a graphic is available. Weblinks are also commonly included.

Examples of changes you might want to make include:

- Set the expected end date for the task. As discussed earlier, the start and end dates are important if you plan to use the Schedule view to manage tasks.
- Assign the task to Group members.
- Add more attachments.
- Add checklist items.

- Use the 25 colored labels to give a visual marker to the task. To assign a label, click Add label. You can then pick a label or give a new name to a label.
- Decide what to show on the task card.
- Mark the task as complete or in progress.
- Set a different priority.

The screenshot shows a task card in Microsoft Planner. At the top, it has a title "[Microsoft Teams] Teams meetings, end of meeting notification [MC22...]" and a subtitle "Last changed moments ago by you". Below the title is the creator's name, "Tony Redmond", with a profile picture. There is an "Add label" button. The task is categorized under "Teams" in the "Bucket" field. The "Progress" is set to "In progress" and the "Priority" is "Medium". The "Start date" is "18/09/2020" and the "Due date" is "30/09/2020". There is a "Notes" section with a "Show on card" checkbox checked. The notes contain a message ID (MC222346), a published date (17/09/2020), and a paragraph of text about alerting Teams meeting participants. Below the notes is a "Checklist 0 / 2" section with a "Show on card" checkbox unchecked. The checklist items are "Blog post", "Update book", and "Add an item". At the bottom, there is an "Attachments" section with an "Add attachment" button.

Figure 9-9: Details of a task

Microsoft has previously announced, twice, that the task notes field will gain support for rich text and images, which is useful both to emphasize or highlight certain parts of a task but also when pasting notes into a task from another source. This capability depends on a new Microsoft Graph API, which is initially supported only in the Tasks app for Teams and the Planner web app. Behind the scenes, two task note fields exist: one for plain text and one for rich text. Rich text notes are converted to plain text and synced to the plain text field, but the reverse is not true; for now, if you edit the plain-text version, its changes will overwrite the contents of the rich-text version. That means if you add rich text to a task note in the Planner web client, then edit that task note on (say) the iOS version, the edits you make in iOS will overwrite the existing content and formatting in the rich text note you see in Planner. Their latest update pegs this feature for a September 2022 delivery... stay tuned.

You cannot customize or otherwise change the metadata available for tasks. In other words, you cannot add new fields for users to complete to describe or categorize a task. This is one key advantage that Microsoft Lists offers as you can customize the fields available for the items in each list.

The task name is the default information shown in the card, but if you prefer, you can display other elements in task cards. For instance, it is often easier to pick out a specific item by scanning a list for an image, so Planner allows you to use graphic files added as attachments to tasks on the task card.

Checklist items (such as those listed in Figure 9-9) allow task owners to note activities and things to do for a task. In one way, you could consider checklist items to be sub-tasks. However, checklist items have no formal connection to the outcome of a task because you can mark a task as complete even if many checklist items are unfinished. The idea here is that a checklist item is not a formal activity to complete before a task can finish. Instead, it is a free-form reminder of something that should happen, and tasks can complete with incomplete checklists. However, to encourage a sense of achievement, Planner displays a progress bar to reflect the completion of checklist items. Also, Planner displays “confetti” (an animation) when the last checklist item is complete. Unlike comments, checklist items are part of the plan metadata and Planner doesn’t generate email updates to Group members when checklists change.

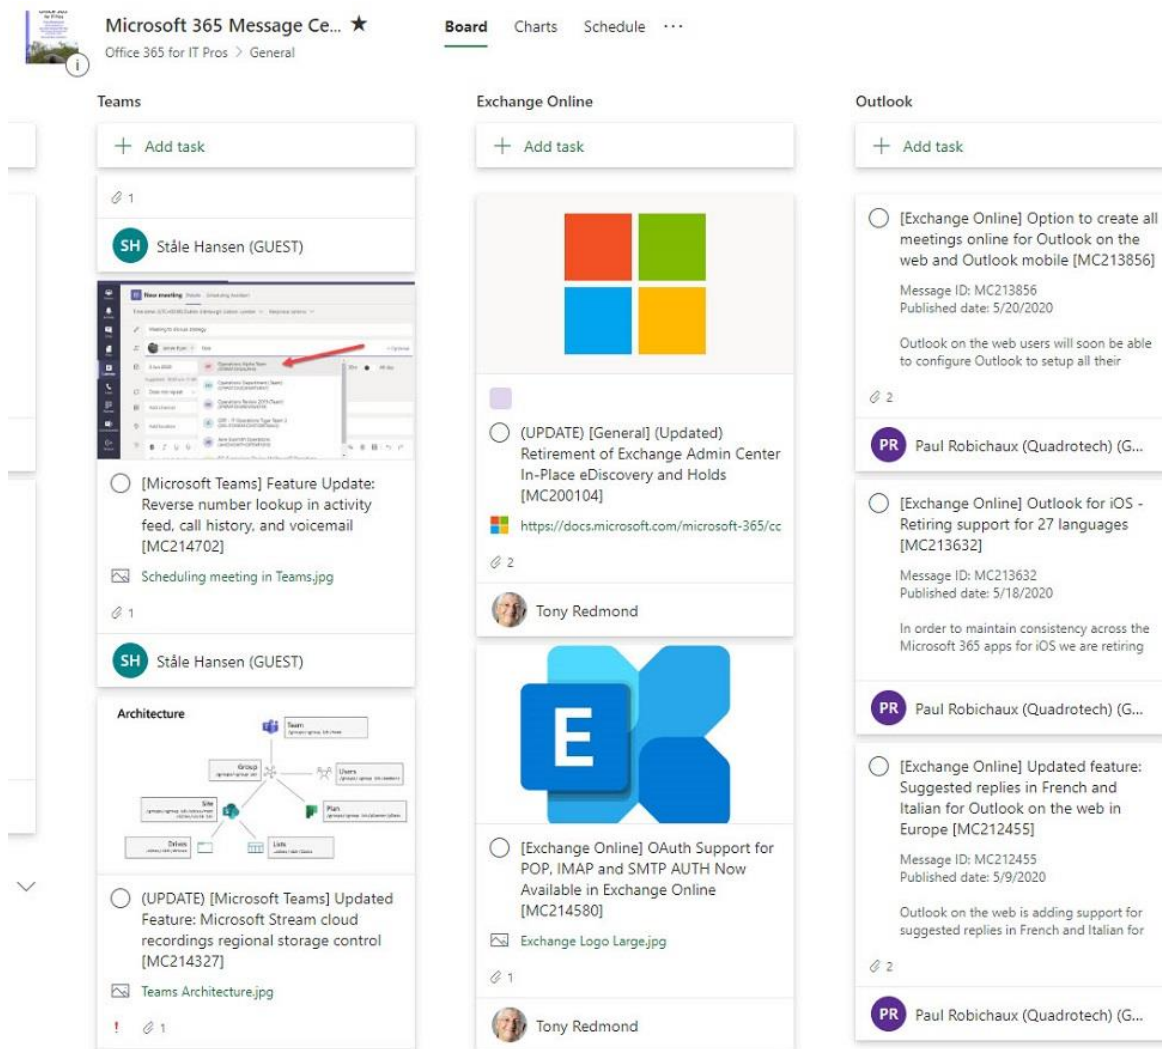

Figure 9-10: Using graphics to highlight tasks

You can add the following attachments to a task:

- A file from your computer. This includes files stored in any network location available to the PC, such as the OneDrive and SharePoint sites synchronized to the PC.

- A file from the SharePoint document library associated with the Group that owns the plan.
- A URL.

Planner stores the files uploaded as attachments for a task in the Documents folder of the Group document library (you cannot select a different folder). The same folder is used for attachments uploaded to tasks for any plan belonging to the Group. You cannot upload the same file twice as it would cause a duplicate file in the folder, but once you upload a file to the library, you can attach it to multiple tasks. If you try to create a link attachment that points to a link already attached to the task, Planner overwrites the original link. You can attach up to nine files or links to a task.

Task cards with graphic previews (Figure 9-10) take up more screen real estate than text-only cards, but sometimes you want to highlight a specific item and a graphic can be an effective way of doing this. The task card can also display checklist items or the free-form text description of the task. You can add up to 20 checklist items to a task.

The different elements of a task show up in the user interface for the task cards too. The visual hints that you can add to cards give a quick insight into the tasks within a plan, bucket, or assigned to a specific user. A big difference exists between a card that displays a simple line of text when compared to one which uses graphics. What you add to a card in terms of comments, attachments, and checklist items help plan members understand the full context of a task, including the task owner and their progress towards completion. A lot of information about a task is therefore available at a glance.

Unlike Project, Planner tasks have no dependencies on each other. You cannot link one task to another in any way except by making sure that they are arranged in display order so that one follows another as needed. This situation is problematic for some, but it reflects the general “let’s make it simple” design philosophy followed throughout Planner.

## Task Status

Managing tasks effectively requires you to update task status as the work unfolds. At any time, you can mark a task status as complete or incomplete, edit the dates associated with the tasks, or add or remove new tasks. Eventually, everything will come together and all the tasks on a board will be complete. And then, when all the tasks across all boards are complete, the plan is complete.

Planner allows a task to be in just three states – not started, in progress, and completed. There is none of the precision and exactitude of measuring a task to be say 87% complete. On the other hand, the simplicity is appealing as it is easy to know whether a task has started, is being worked on, or has finished.

## No Recycle Bin

Once you mark a task as completed, Planner draws a line through it and leaves the task in a completed state. You can delete the task if you want by selecting it and using the Delete option in the [...] menu. But be aware that once you delete a task it’s gone for good and can’t be recovered. Planner doesn’t have a recycle bin and there’s no way, even for Microsoft, to restore a deleted task.

## Restricting Task Deletion

By default, any user who has access to a plan can create, remove, or edit tasks in that plan. It would be nice if Microsoft provided more granular control over this behavior. For now, the best you can do is to block people from removing tasks they didn’t create. Blocked users can still delete tasks they created or edit any task in the plan. To do this, use the *Set-PlannerUserPolicy* PowerShell cmdlet with the *-BlockDeleteTasksNotCreatedBySelf* flag, like this:

```
[PS] C:\> Set-PlannerUserPolicy -UserAadIdOrPrincipalName andy.ruth@contoso.com  
-BlockDeleteTasksNotCreatedBySelf $true
```

Of course, you can use the same cmdlet to unblock a user and allow them to go back to deleting other people's tasks just by using `$false` as the parameter for `BlockDeleteTasksNotCreatedBySelf`.

## Labels

To highlight tasks, you can assign one or more of the 25 labels (sometimes called categories or tags) available for a plan. Colors (Blue, Purple, etc.) corresponding to the label color are used as the default names. Planner displays the assigned labels in the task card. Because you can use labels to group or filter tasks, they are a useful way to flag high-priority tasks or tasks that may need specific attention from someone.

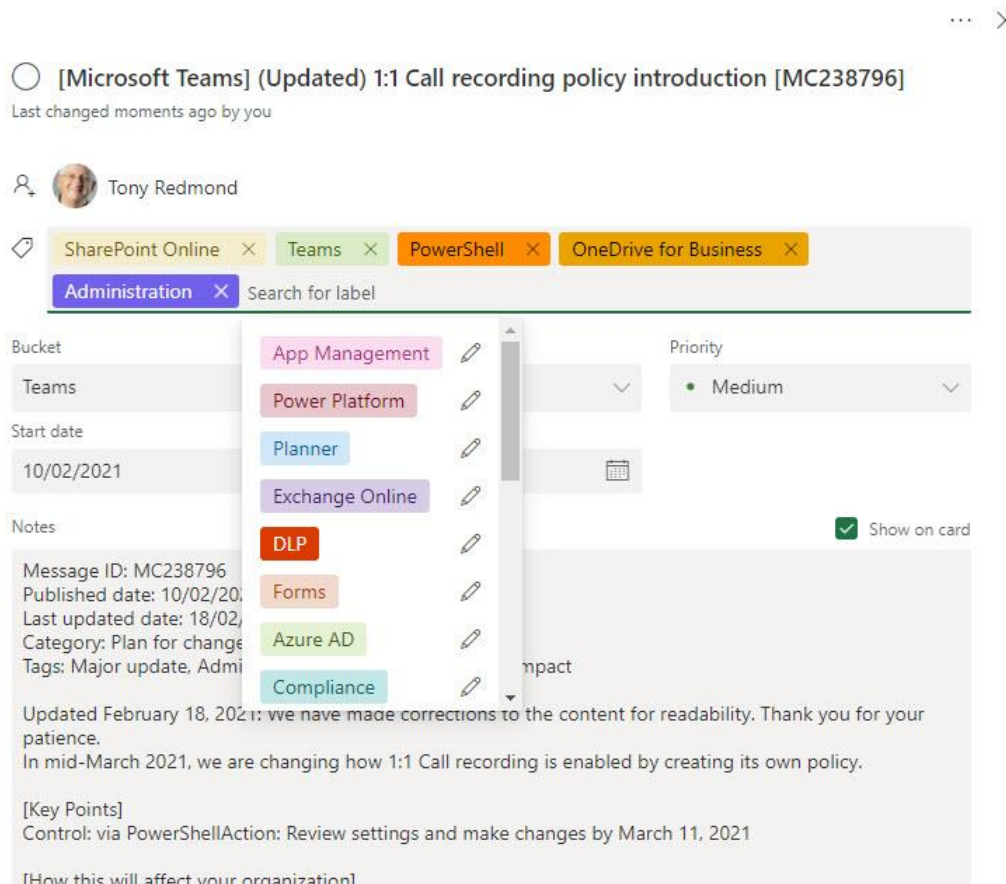

Figure 9-11: Assigning labels to a task

You can't change the colors used for labels, but you can change the names to assign names more appropriate to the plan such as Urgent, Action, or Critical with these steps:

- Access a task.
- Select Add label to expose the current set of labels.
- Select the pencil icon alongside the label you want to change and input the new name (Figure 9-11).

Labels can be renamed using the web or mobile clients by any member of a plan. This aspect of the user interface encourages freedom of operation but seems a little odd in the context of an application designed to help people organize work. For instance, if I name the red label *Important*, I am not sure that I want someone else to rename it to *Can be ignored* without asking why the label name is currently *Important*. These customizations are specific to the individual plan.

## Comments and Conversations

While the work is ongoing to complete tasks, some communication between the Group members is likely, and that's where conversations come in. Or rather, "comments" that Group members make about tasks, for this is how Planner refers to them.

As tasks are created and assigned to people, conversation items are created in the Group mailbox. People who choose to follow the Group Inbox receive these items in their mailbox, meaning that when you create a new plan for an existing Group that has a large set of existing subscribers, a certain amount of message traffic is likely to be generated as tasks are created, assigned, and perhaps reassigned. The email notifications help members keep track of task assignments as well as to know when tasks are complete without having to open the plan.

Figure 9-12 shows that a task has four comments with a new comment being prepared. The text editor used for comments is rudimentary and does not support common text formatting shortcuts such as CTRL+B or bold selected words. If you want to emphasize text in comments, you will have to use another client.

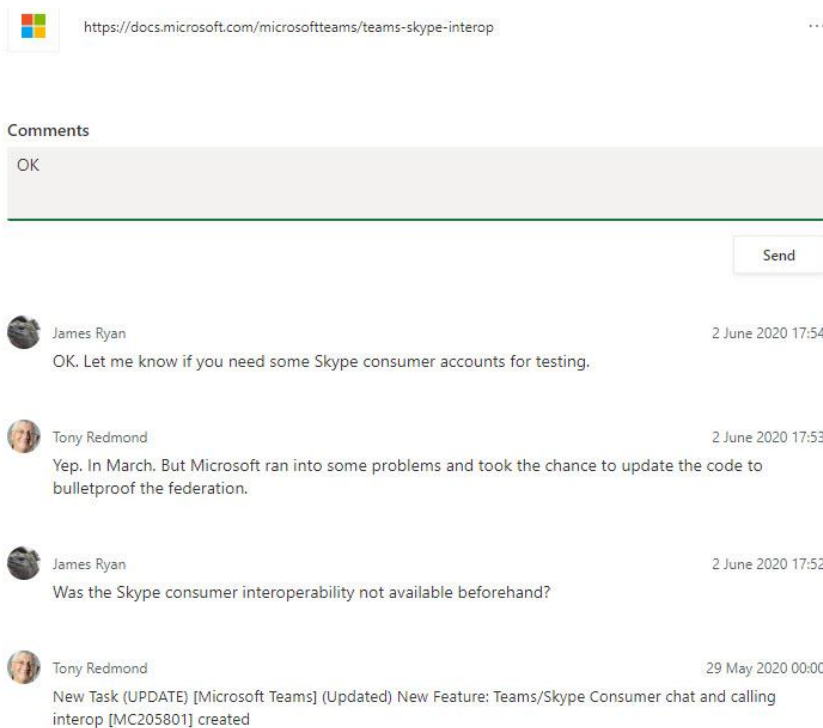

Figure 9-12: Comments for a task

The comment posted when a new task is created is one thread in the Group mailbox; the other comments form a threaded conversation for the task. Unlike task notifications, members don't receive copies of comments in email unless they have commented on a task. Members who receive comments in email can either reply directly to the message, or they can use the link embedded in the message to open Planner and go to the task and add a comment there. Posts added to the conversation through email appear as comments for the task. And, as you'd expect, if you delete a conversation, all the comments for the associated task disappear.

Behind the scenes, Planner uses the [Graph API](#) to post comments to the Group mailbox. When a user contributes to a conversation, the item is submitted through the Exchange Online transport system to apply transport rules before the comment shows up in conversations. For example, a rule might block someone from posting sensitive data such as credit card information. Another might stop the posting of any text holding an offensive term.

## Printing Planner Data

Planner includes no method to print information about a plan such as a list of tasks assigned to a user or a schedule view of tasks due in the coming week. This is a much-requested feature that is partially provided by the ability to send tasks to Outlook (see below), from where users can print the information as needed. Alternatively, you can export tasks to an Excel worksheet and format and print task information from Excel.

## Synchronizing Tasks to Outlook Calendars

Outlook calendar synchronization is automatically enabled for tenants with Planner as part of their subscription (to disable the feature, follow the [instructions in this article](#)). When a user wants to connect Planner to Outlook, they select **Assigned to me** in the navigation pane and click the ellipsis menu to reveal the choice to **Add “Assigned to me” to Outlook calendar**. Click the button and then select **Publish**. Planner generates an iCalendar link to the All Tasks view. The link looks something like this:

```
https://tasks.office.com/b662313f-14fc-43a2-9a7a-d2e27f4f3478/Calendar/User/Qi6exSZyQkC737py0An6HpYAAZ1X?t=0_95716443-a6d2-425b-a936-27fc76a889be_2018-05-10T12%3a29%3a13.4330492%2b00%3a00
```

Now click **Add to Outlook**. Planner launches OWA at the Calendar subscription window, copies the iCalendar link from Planner, and creates a default name for the new calendar (you can overwrite the name if you wish). By default, the calendar is created in the “Other calendars” section, but you can move it to one of the other sections. Click **Import** to continue. OWA creates a new calendar folder in the user’s mailbox and synchronizes details of “Not Started” and “In Progress” tasks assigned to the user. You can’t filter the tasks as the connector is configured to fetch all open tasks assigned to the user.

Synchronization is one-way from Planner to Outlook. New items do not synchronize at once because Outlook refreshes Planner data via the connector every three to four hours. You can’t force synchronization to happen. The information synchronized to the calendar for a task includes:

- **Date:** Planner items are scheduled for all-day calendar slots as Planner bases task assignments on days rather than hours. If a task has a due date, the calendar item is scheduled for that day. If it has both start and due dates, the item is scheduled for that period.
- **Location:** None added as Planner does not capture this data.
- **Progress:** The status of the task in Planner.
- **Checklist:** A note about how many checklist items exist and are complete.

Calendar entries created through the connector do not tell you what plan or bucket within a plan a task belongs to, but each entry has a link to Planner to bring the user back to the original task, where whatever changes are necessary can be made. Changes are then synchronized back to Outlook. Although the user cannot edit details of the planner task, they can add a reminder to a task.

If you prefer not to use the iCalendar connector, you can also link Outlook to Planner using [several standard Power Automate templates](#) published by Microsoft. Power Automate is good at inserting items into a calendar. It is less successful at tracking changes made to tasks such as completing tasks or synchronizing changes made to a task like changing its name, due date, or status. This is probably because the [set of triggers](#) supported by Planner for the connector available to Power Automate only covers task creation, assignment, and completion, and not task updates.

## Working with Planner Tasks in To Do

To Do clients support visibility of assigned tasks (from all plans) in To Do clients where the tasks appear in the *Assigned to Me* list. The bi-directional synchronization supports some actions against Planner tasks performed in To Do. Users can:

- Update the completion date for the task.
- Mark a task as completed or incomplete (but not mark a task as in progress).
- Add checklist items.
- Update the task description.
- Hide completed tasks.

You must enable this integration from the To Do client; there's currently no way to do so from within the Planner interface. Open the settings page for your To Do client (the exact location will depend on whether you're using Windows, the web, or macOS), then find the "Connected apps" section, then toggle the "Assigned to you" control as shown in Figure 9-13.

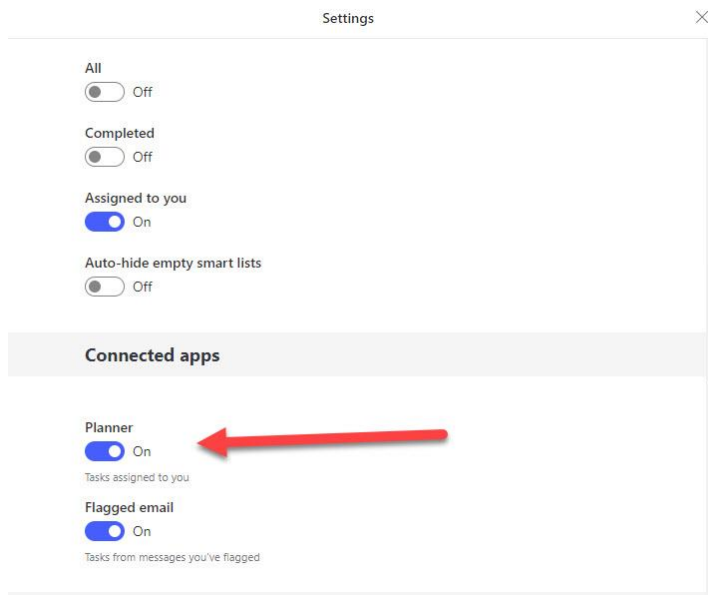

Figure 9-13: Enabling Planner integration with To Do

You can't change assignees, add attachments, or change the tabs for tasks. You also can't create new tasks. However, an Open in Planner link is available to open the task in Planner if a user needs to perform one of these actions.

## Moving Planner Data to a Different Tenant

Many Microsoft 365 workloads have formally defined processes for moving data from one tenant to another. APIs exist to import and export data from some workloads, and both Microsoft and clever third-party vendors have used these to provide a way to move workload data between tenants. Planner data can be moved between tenants, but it requires that you open a support request with Microsoft to accomplish the move. Before they will execute a requested move, you [must authorize it](#) using the rather scary-sounding `AllowTenantMoveWithDataLoss` flag with the `Set-PlannerConfiguration` cmdlet. No plans or task data are moved when Microsoft runs the move operation, so it's not clear why you'd ask Microsoft to do such a move instead of using a tool such as [MVP Sean McAvinue's PowerShell script](#).

## Using Planner Offline

The Planner iOS client can display tasks when offline but cannot update anything unless the client is connected. However, the Planner browser app includes more extensive offline capability. While you can't connect to Planner without a network connection, if the connection becomes unavailable during a session, you can continue working with tasks. When offline, you can:

- Add a new task to a plan.
- Update task properties like progress (not started, completed), start and due dates, notes, comments, and priority.
- Add or remove a web link or file attachment.
- Add or remove checklist items for a task.
- Move tasks between buckets.
- Assign tasks to team members.

You cannot:

- Start Planner when offline.
- Add a SharePoint item to a task.
- Create a new plan for an existing Group or with a new Group.

Using the cached data, Planner charts and the schedule view are both available when offline. When the network link is restored, Planner synchronizes any changes made offline to the server.

## Planner and Guest Users

Planner supports the Azure B2B Collaboration model for guest access. As explained in Chapter 11, to join a Group, external users receive and redeem an invitation. During the redemption process, if the external user doesn't already have a guest account, Azure AD creates one for them in the tenant directory. The same membership as used for Microsoft 365 Groups and Teams controls access to Planner, and a guest can be added to a Group through Outlook or Teams. Once a guest user becomes a member, their membership automatically allows access to the plans associated with the Group, including any plans created in channels belonging to a team. If a guest user already exists in the tenant directory, an owner can add them to a plan by assigning them a task.

To access Planner, guest users must specify the service domain of the tenant to which they want to connect. Planner can't switch guests between tenants, so the connection is always to a specific tenant. For example, to access plans in the `office365itpros.com` tenant, a guest connects to the URL `https://tasks.office.com/office365itpros.onmicrosoft.com`. If you're already signed into Planner in your browser, you should use a private browser session to connect to Planner in another tenant. After successful authentication, the Planner browser client displays the set of plans available to the guest. These plans include those created before Planner supported external access.

Planner displays a restricted user interface to guest users by removing choices they cannot use (Figure 9-14). Guests can create, assign, and edit tasks, change task status, post comments, add checklist items and even update a plan's background. However, guests cannot create new plans because they cannot create new Microsoft 365 Groups. Likewise, they cannot remove a plan. Guests can edit a plan's name, but they cannot change other plan settings, like its privacy level (which a sensitivity label might control). Finally, guests cannot browse the host tenant to look for plans (and Groups) to join.

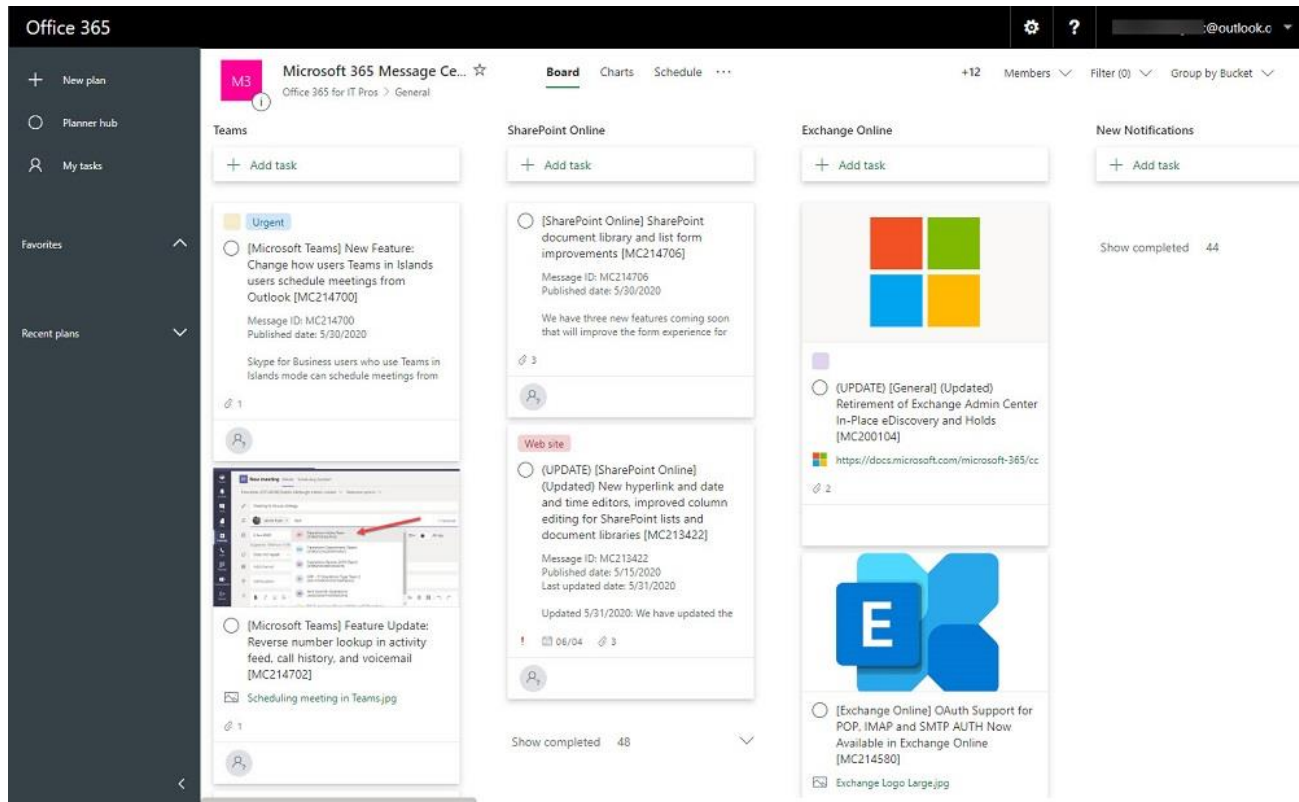

Figure 9-14: The Planner interface for a guest user

## Planner, Tasks, and Teams

Teams can be used with Planner in most enterprise, government, and education plans. One point to consider during any implementation that includes frontline workers is that Teams is available for frontline (F1) licenses while Planner is not.

Teams and Planner share two points of integration. First, a user can open the Tasks app to access all their tasks, including personal tasks created in Outlook or To and tasks assigned to them through their membership of a team or Group. The Tasks app replaces the earlier Planner app for Teams and continues the [overall Microsoft strategy](#) of providing multiple endpoints for creating and managing tasks that all end up working against the same data store.

The second point of integration is when Planner is added through a channel tab to access the tasks in a plan belonging to a team. We'll discuss this method shortly.

### Tasks in Teams

The Tasks in Teams app delivers an integrated view of personal and team tasks. The app is called *Tasks by Planner and To Do* for now, but Microsoft plans to rename it to simply *Tasks* at some unstated future date.

As shown in Figure 9-15, the Tasks app divides tasks into:

- **My tasks:** these items are personal (not shared with anyone else) and include tasks created in the app, To Do, and Outlook. These tasks are managed by To Do.
- **Shared tasks:** these tasks come from Planner plans associated with the teams or groups the user belongs to. Each group or team that you're a member of that has an associated plan appears here. All the plans owned by the team or Group appear under the team, together with the name of the tab and the channel name. For example, Book planning is the name of the tab in the General channel of the Office 365 for IT Pros team. The name of the channel is often the same as the name of the plan, but it

doesn't have to be. If a channel is hidden, then any plan linked to a tab in that channel is also hidden. Tasks shows these plans as hidden lists. You can see the tasks in a hidden list by clicking the list to expose details of the plan and then selecting the plan.

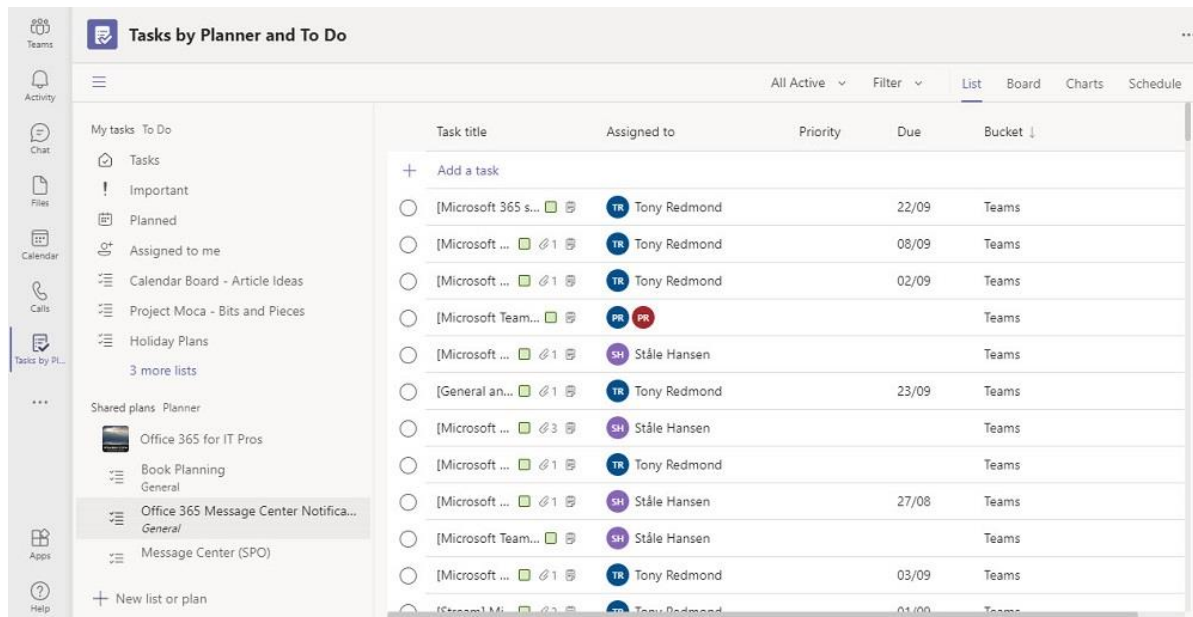

Figure 9-15: Planner and To Do Tasks are available in the Tasks app for Teams

When you open a list to work with tasks, the app presents the appropriate user interface to interact with the tasks. For personal tasks, you see the To Do interface; if the Planner manages the task, you see the Planner interface (Figure 9-16). You can't move or copy a personal task to Planner or make a Planner task a personal item.

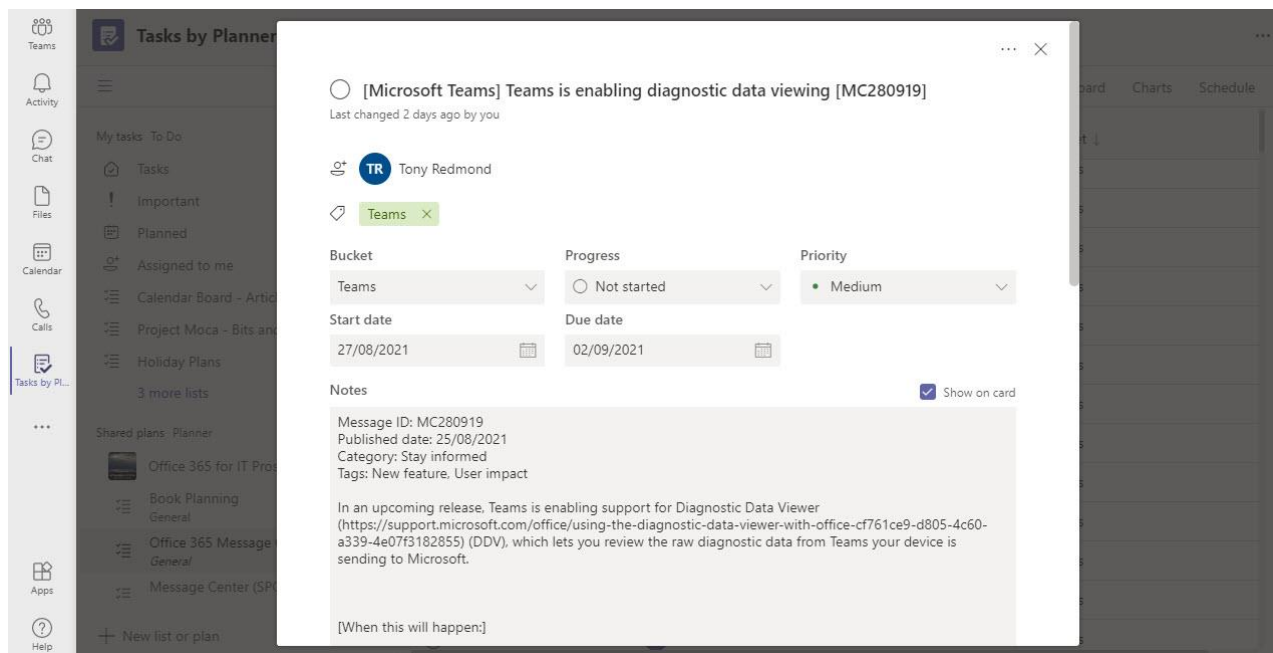

Figure 9-16: Working with a Planner task through the Teams app

Working with a task happens in the same way as in the native app and Teams writes any changes made through the app back to the native repository using Graph APIs. Due to the need to refresh client-side caches, a slight delay occurs – before the change appears in the native app, but this shouldn't be a problem because people don't usually rush to check To Do or Planner after updating a task in Teams. One minor difference

between the Planner browser app and the app in Teams is that Teams doesn't send email notifications about task updates or closures.

Apart from delivering a single integrated view of personal and work tasks, the app can do some things that aren't available in the standalone apps. For example, in the list view, you can select multiple tasks and edit them at one time. This is a great way to assign new people to tasks (perhaps after someone has left a team) or to update the completion status or set a new due date for a set of tasks.

## Accessing Plans Through Teams Channel Tabs

Sometimes people need to concentrate on work items belonging to a single plan. This is best accomplished by adding a Planner tab to a team channel. As it turns out, according to Microsoft's telemetry, Planner is the most popular channel tab in Teams.

If a plan hasn't already been created for the underlying Group, Teams creates it and attaches the plan to the tab. If one or more plans already exist for the Group, you can select one and attach it to the tab. You can then work with the tasks in the plan through Teams or click the **Go to website** (globe) icon in the set of options at the top right-hand corner of the pane. This launches Planner and loads the tasks for the plan into a browser tab.

## Removing a Plan from a Channel

To remove a plan accessed through a channel tab, open the plan, select the arrow next to the tab, and then **Remove**. You now have a choice:

- **Remove the plan from Teams:** This is the default and leaves the plan accessible through the Planner browser interface. If needed, you can add the plan back to Teams.
- **Permanently remove the plan:** To do this, select the checkbox *Permanently delete this plan and all its tasks*. This removes the plan data from the Planner Azure service. The plan is then irrecoverable through any interface.

Unlike removing a plan through the Planner browser interface, removing a plan through Teams does not affect the Group or any other resource attached to the Group or team.

# Linking Planner and the Microsoft 365 Message Center

As an example of what's possible with Planner, Microsoft released a service to synchronize notifications about changes in Microsoft 365 services from the Message Center in the Microsoft 365 admin center (described in chapter 4) to create tasks in a target plan. Each time Microsoft announces a change in the service, a new task is created that can be assigned to the person or team responsible for communicating and managing that type of change within the organization. A Power Automate flow runs on a scheduled basis to synchronize information from the Message Center to Planner. The integration is enabled through an option above the list of messages in the Message Center (Figure 9-17). When you select the option, you can choose which types of Message Center notifications you want to be synchronized, and which plan you want them copied into. Synchronization occurs once a day.

## Message center

Each message gives you a high-level overview of a planned change and how it may affect your users, and links out to more detailed information to help you prepare. [Learn more about managing changes](#)

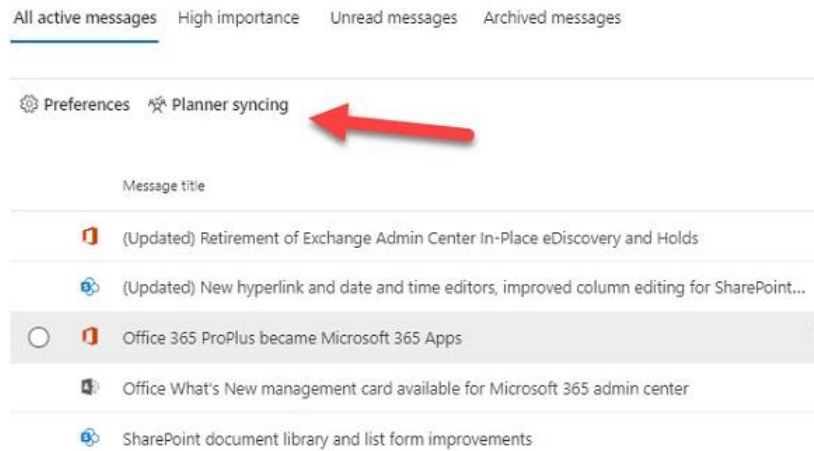

Figure 9-17: Planner synchronization of Microsoft 365 updates

Tasks synchronized from the Microsoft 365 Message Center have start dates assigned by Microsoft but no due dates. The start dates are associated with the work being done by Microsoft to introduce a new feature instead of when a feature might be available in a tenant. If you don't adjust task dates after synchronization, it's easy to end up with a schedule full of red (overdue) tasks. For this reason, it's important to assign tenant-specific dates for tasks when assigning tasks to users.

The practical value of this feature is that it lets you capture change notifications in a single plan so that you can review the changes and possibly act, such as assigning tasks to other users, sending out notification emails, making infrastructure changes, and so on. It can be difficult to remember to keep up with the volume of change notifications in the Message Center, which has poor search functionality and no way to deeplink to an individual notification. Copying these changes into Planner gives you a much more flexible way to track and manage these changes, and it's a nice touch that highlights how well different parts of the Microsoft 365 platform work together. To learn more, see [this blog post](#).

# Chapter 10: Managing Video

**Tony Redmond**

## The Cloud Video Platform

Stream is the Microsoft 365 enterprise video service that allows users to upload, view, and share videos securely. Given the proliferation of video-sharing apps like YouTube available to consumers and the preference of some users to consume information through videos, the role of video communications within businesses is growing. It is undeniable that many people are more accustomed to and prefer to learn from short-form videos than from reading memos and reports. The role of the new Stream is less about the management of Microsoft 365 video content; its focus has moved to enable the best possible playback of video and audio content stored in SharePoint Online and OneDrive for Business.

Information about the architecture and management of Stream Classic is available in Chapter 14 of the Companion Volume.

## Stream on SharePoint

Stream is in the middle of a transition from its original Azure-based storage to using SharePoint Online and OneDrive for Business (ODSP). The new Stream, also called Stream on SharePoint, is the version that uses ODSP storage. The move to ODSP solves multiple problems afflicting classic Stream including:

- Storage of video content in country-level data centers to satisfy local data residency rules.
- Inclusion of video content in information governance (retention) and information protection policies.
- Ability to search and find the spoken words captured in transcripts of Teams meeting recordings in eDiscovery cases.
- Access for external users through standard SharePoint Online external access and sharing controls.
- Video content can be included in backup processing for SharePoint Online and OneDrive for Business.
- Increased storage quota for video content, particularly in OneDrive for Business (important as Teams meeting recordings often consume substantial amounts of storage).
- Programmable access to video content through the Graph API.

Because the new Stream is built on top of ODSP, it follows that many of the services created for Stream classic are no longer necessary. For example, Stream doesn't use Azure blob storage, so its quota management system is defunct. ODSP permissions replace the Stream classic permissions model, and so on. The transition allows the Stream developers to concentrate on media management and playback instead of recreating wheels that are already available. In effect, Stream on SharePoint is really more of a set of services to manage video storage and playback instead of an app.

Stream hosted on SharePoint doesn't have a Stream portal in the same way that Stream classic or the older Office 365 Video application do. Instead, if an organization wishes to have a video portal (for example, to allow access to videos about the business), they need to use a different approach. For example:

- A SharePoint site tailored to highlight and feature selected videos.
- A channel in a team dedicated to the same purpose.
- Organization videos published through [Viva Learning](#).
- Videos published through a Yammer community.

As described later, the transition to the new Stream is complete for Teams meeting recordings. The latest information about the migration of content from classic Stream to ODSP is that the [migration tool is in private preview with some customers](#). Microsoft has not yet revealed the date for when the migration tool will become generally available. A preview of the new Stream client is available, and tenants can switch the Stream tile in the Microsoft 365 app launcher to point to the new Stream instead of Stream classic.

## Stream Licensing

Stream is included in all enterprise plans (including DoD, GCC, and GCC High), the education plans, and the front-line worker plans. It is also included in the Business and Business Premium plans. See [this page](#) for more licensing information. The Stream functionality available to Office 365 E3 and E5 tenants includes advanced features like speech-to-text and closed captions, transcript and caption generation, and searches.

## Stream Browser Client

Stream supports video upload and viewing through a wide range of browsers, including Microsoft Edge and the current versions of Chrome, Brave, and Safari. Currently, a preview version of the new Stream client is available. A setting in the SharePoint admin center controls the behavior of the Stream app tile in the Microsoft 365 app launcher. Three values are available:

- The default option is to **Automatically switch to Stream (on SharePoint)**. Microsoft controls this option and will set it after the migration of existing Stream content is complete.
- **Stream (on SharePoint)** directs users to the preview GUI for the new Stream. The user can switch to the classic Stream GUI if they want.
- **Stream (Classic)** forces people to use the classic Stream GUI.

The new Stream client is a composite of a browser interface to manage videos and the standard OneDrive web audio and video player to play videos and control their settings. If you play a video from the OneDrive for Business or SharePoint Online clients, you use the same player. The client uses Microsoft Search to find and display videos stored in Microsoft 365 apps, including those stored as attachments in user mailboxes. Because the new app is based on ODSP, it works differently from the classic Stream browser app. Until the migration of older Stream content is complete, the new app only has access to this content:

- Teams meeting recordings (both your recordings and ones shared with you).
- Videos that you upload to the new client (or OneDrive for Business). This includes video files uploaded through applications like Yammer and Teams.
- Videos shared with you by other users.
- Video file attachments for emails in your Exchange Online mailbox.

The preview of the new Stream client is missing some functionality that's available in the older client, including:

- Video recording (screen capture) direct from the client to a video stored in Stream.
- Trim a video. Trimming allows an owner to remove some extraneous content from the start and end of a video.
- Replace a video. Sometimes a trim isn't enough, and videos need a little more post-production work to iron out imperfections. Video owners can download a video, process it with a video editor like [TechSmith Camtasia](#) or Microsoft Clipchamp, and upload the updated version. The ability to replace a video is important because this retains the link used for the original video and avoids the need to replace it in places like Teams channel tabs or SharePoint pages.

Microsoft publishes [an online spreadsheet](#) to compare the functionality available in the new Stream client against the classic client. It describes what features are available, those under development, and functionality that will not be available in Stream 2.0.

The remainder of this chapter focuses on the new Stream client.

## Management Client

Unlike Stream classic, the new Stream doesn't have a switch to reveal administrative settings. Much of the need for those settings disappeared with the transition to ODSP because standard ODSP and Microsoft 365 settings control aspects like sharing, storage quotas, recovery of videos for deleted users, and retention. The ability to organize videos through Microsoft 365 Groups by storing videos in the SharePoint team site belonging to the groups is still there, even if a dedicated GUI to perform group-based video management is unavailable.

## Network Demand

Like any video application, Stream benefits from good network performance between servers and clients. Microsoft publishes articles to help administrators understand the characteristics of network performance for Stream, including [Video delivery and network overview](#) and [how to scale video delivery for Stream](#). The current advice is for the classic client, but it should not be very different from what's necessary for the new client.

## Stream and Other Microsoft 365 Apps

Like many other Microsoft 365 apps, Stream uses components from across Microsoft 365 and contributes functionality to other apps. Examples of how Stream integrates with other applications and services include:

- Stream classic can use Microsoft 365 Groups to manage access to videos. This functionality is not available in the new Stream app.
- You can link a Stream channel to a Teams channel tab to allow users to play videos from the channel. Stream channels are currently available only in the classic client. You can also paste a link to a Stream video in a channel conversation or personal chat for readers to access.
- Yammer can playback Stream videos. You can paste the link for a Stream video into a Yammer message and readers can then play the content back inline.
- The SharePoint web part for Stream can highlight a video, channel, or list of videos (from all of Stream) on a page.
- [Forms can collect feedback](#) through quizzes, polls, and surveys for videos through the *Interactivity* tab for a video. This functionality is only available in the classic client.

Other apps can use [Stream's implementation of oEmbed](#) to display videos or channels.

## Stream User Functionality

Stream's user functionality divides into these major sections:

- Uploading video content.
- Managing videos.
- Video playback.

The Stream client (Figure 10-1) uses the same design "language" as other Microsoft 365 apps. At the top of the client, the recommended list of videos contains files that you've worked with, recently watched, or those that Stream believes are of interest. One of the videos listed is in the recommended list because it is linked to a recent meeting (see the sharing section below). Filters control the videos shown beneath the recommended set, including one to display videos marked by the user as favorites. If the selected filter is set to All, Stream displays the full set of videos available to the user in Microsoft 365 locations, including any found in email

attachments. The videos include those that the user owns and those that they can access because of access gained through a sharing link, Teams chat, or direct access.

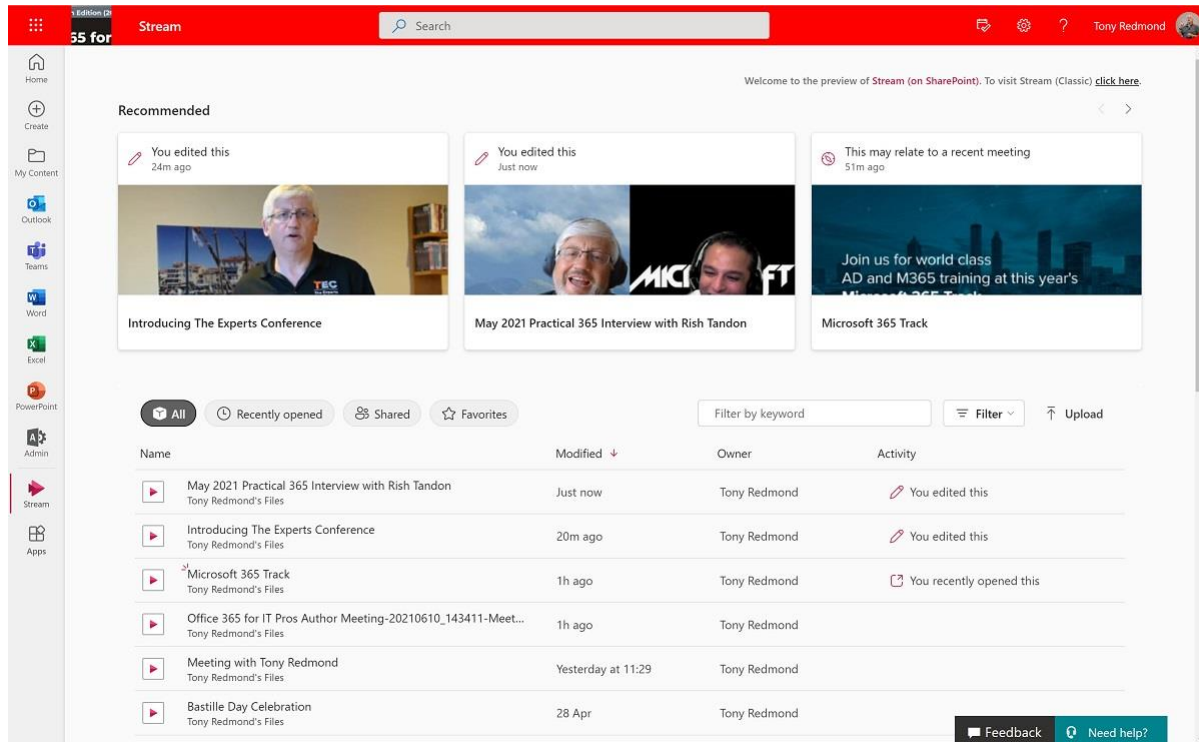

Figure 10-1: The new Stream client (preview)

No matter how someone accesses Stream content, Stream won't show them a video unless their account has the right to view it.

## User Settings

The user settings available for the new Stream browser client are minimal. Currently, they are limited to selecting a theme and deciding whether to use dark mode.

## Uploading and Accessing Videos

To upload a video, click the upload link and select the source files (in the [supported file formats](#) – audio-only files are not supported). You can also drag and drop a file to the client. A newly-uploaded video receives the default permission in the target site or account. Recordings of Teams channel meetings are available to team members while recordings of Teams personal calls are available to the participants.

After uploading a video, the owner can:

- Play the video.
- Open the location of the video. This option opens a new browser tab positioned in the OneDrive or SharePoint folder where the file is located.
- Share the video.
- Add a link to the video to a calendar meeting. Stream uses the OWA meeting request screen to compose the meeting invitation. Make sure that the recipients of the invitation have access to the video. The client uses meeting insights to highlight videos sent in meeting invitations before the event occurs to give the user the chance to review the content beforehand.
- Add a link to the video to To-Do. This action creates a bare-bones personal task in To Do.
- Mark the video as a favorite. This adds the video to the set listed through the Favorites link.
- Hide the video. The Stream client doesn't show the video in its list.

- Download a copy of the video.

Opening a video with the Stream video player allows the owner to manage some settings for the video (Figure 10-2). People who watch the video use the same player, but they can't change the settings.

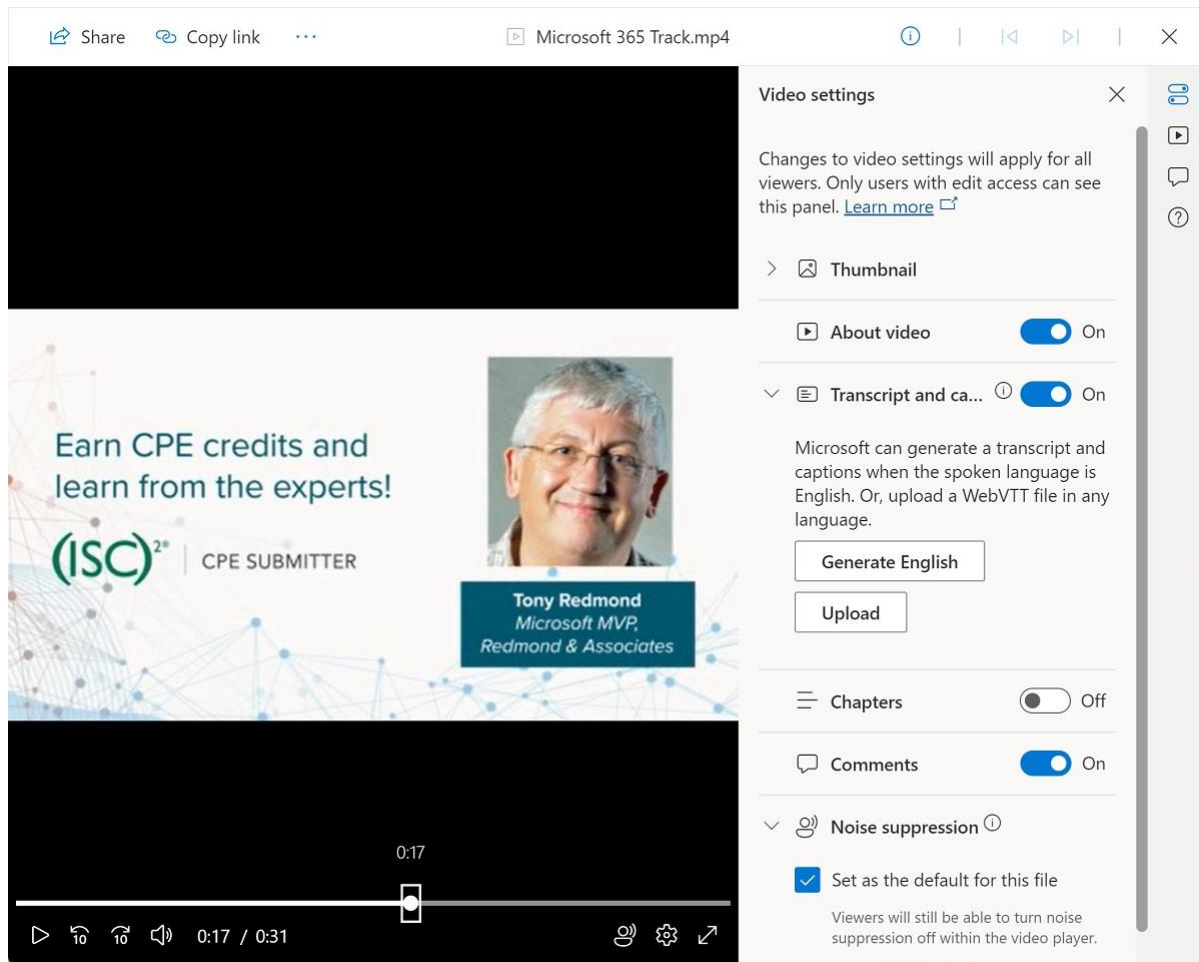

Figure 10-2: Options available in the Stream video player

The video settings are available in an item in an overlaid menu on the video player. The full set of menu items are :

- **Video settings:** Opens a pane to allow the video owner to turn on different options.
- **About the video:** If enabled by the owner, displays some details about the video. The owner can add some text to describe the video or rename the video if necessary. A basic text editor is available to enter content, including bulleted lists and hyperlinks. Pasting text from another source is supported.
- **Transcript:** Opens a pane to show the transcript (and chapter markers, if used).
- **Comments:** Opens a pane to show any comments posted for the video. Stream uses the same commenting facilities available for Office documents stored in ODSP.

The video settings are:

- **Thumbnail:** Select a frame from the video to use as the thumbnail displayed for the video by the Stream client. To select a frame, move the pointer in the seekbar (the time bar under the video) to select an appropriate frame.
- **About video:** Controls if any information is available for display to users when they watch the video. The text entered about a video is indexed and discoverable using SharePoint search. It's a good idea to include information about a video such as the time and place of the recording, important parts of the video, and perhaps some hyperlinks for users to find more information about the topic.

- **Transcript and captions:** Stream doesn't generate captions or a transcript for uploaded videos unless the owner requests this to happen. For videos where the spoken language is English, Stream can generate a transcript. Teams meeting recordings use the captions generated during the recording.
- **Chapters:** To help organize videos, creators can insert chapter markers in files to help users navigate within a video to find the information they're interested in. If the owner enables chapter markers, Stream displays the markers in the timeline shown by the player. See [this article](#) for more information.
- **Noise suppression:** Users can enable noise suppression if they want when playing a video. This control affects if noise suppression is the default for a video. It should be turned on if significant background noise is present.

## Storage Quotas

The storage consumed by video files is charged against the SharePoint Online (for videos owned by Microsoft 365 Groups) and OneDrive for Business (for personal videos) storage quotas. OneDrive for Business [offers 1 TB of storage for Microsoft 365 business accounts and "unlimited storage" for enterprise accounts](#). The impact of storing Teams meeting recordings is moderated by the application of an automatic expiration policy. Videos expire after 120 days unless the video owner overrides the expiration period by changing it (or removing the expiration) or applying a retention label to the file. Upon expiration, video files follow the normal OneDrive for Business recycle process.

The exact size of a video file depends on its format, quality, and length. As a guide, expect to use approximately 7.5 MB per minute of 1080p MP4 video with smaller amounts consumed for lower-quality video (the storage required per minute doesn't vary for Teams meeting recordings saved to One Drive for Business). Stream counts the original file size of the uploaded video against the quota and doesn't take other factors such as the size of transcoded videos and caption files into account.

## Other Ways to Get Video Content into Stream

Other ways are available to get video content in supported formats into Stream, including:

- With the Stream mobile app. This uploads the file to Stream classic.
- Making a screen capture video with Stream. This capability is not yet available with the new Stream client.
- Recording a Teams meeting.
- Uploading a video file to a Teams chat or Yammer conversation.
- Running a Live Event with Teams or Yammer.

In all cases, once the video is uploaded, Stream processes it to create the playback files, captions, and transcript.

## Sharing Stream Videos

Because the new Stream stores its files in ODSP, sharing a video is very much like sharing any other SharePoint or OneDrive file. To share a video, select a video and select Share from the [...] menu to expose the following sharing mechanisms:

- **Email.** ODSP generates a sharing link and inserts it into an email addressed to the link recipients. The sharing link settings control what the recipients can do with the video. For instance, the settings can block downloads. Recipients of the sharing link can be inside or outside the organization.
- **Copy link.** The user can copy the sharing link to the clipboard and share the link elsewhere as needed. For example, you can create a Teams channel tab to point to a specific video. Make sure that the permissions set on the link allow the intended audience to access the file.

- **Teams.** ODSP uses the Share to Teams feature to post the link to the video to a personal chat, group chat, or channel. This is the only method supported to share a video file stored in a user mailbox. The process is the same as that used to share an item from Outlook to Teams (see Chapter 12).

If you want to start a video playback at a specific point, you can add an instruction to the link. For example, this instruction tells Stream to start the video at the 180 second mark.

```
&nav={"playbackOptions":{"startTimeInSeconds":180}}
```

For instance, a link containing the instruction for a video stored in a user's OneDrive for Business account might look like this:

```
https://office365itpros-my.sharepoint.com/:v:/g/personal/james_ryan_office365itpros.com/ETbXnV4vB-pMsfv9LK81d9MBtTS9KQIBnZaHNq9LxcrfMQ?e=qoCLkw&nav={"playbackOptions":{"startTimeInSeconds":180}}
```

## Transcripts

A Stream transcript is made up of individual timecoded captions in Web Video Text Tracks, or WebVTT (VTT) format. For English language videos, Stream can generate a transcript by interpreting the voice track to create captions along with the corresponding timecode. For example, here are three segments from a transcript.

```
00:00:26.645 --> 00:00:30.965
We'll talk about it. I
have my viewpoint on it as well.
00:00:30.965 --> 00:00:35.015
OK, OK, so let's get things
going and what we might want to
00:00:35.015 --> 00:00:39.335
do is then if we can just take
some of the snippets out of this.
```

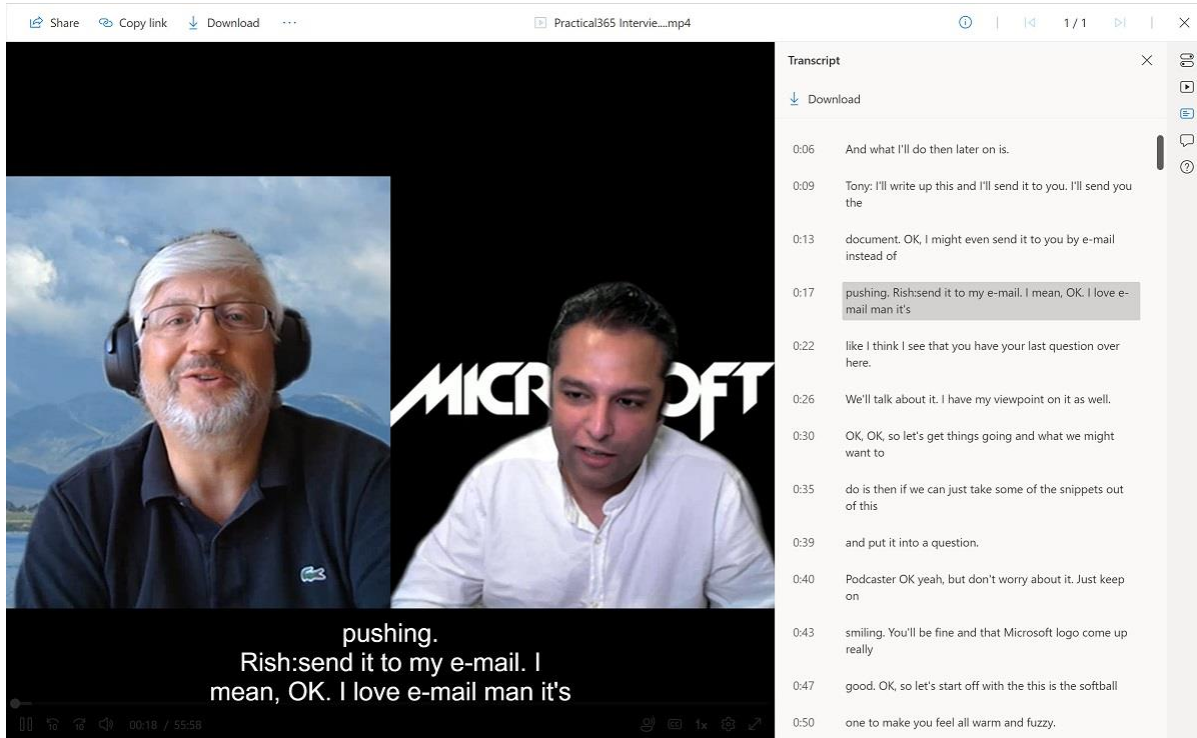

Figure 10-3: Playing a Stream video with its transcript

Figure 10-3 shows the transcript as displayed in the Stream viewer. You can see how the individual captions appear in the transcript, including the three shown above. Selecting a caption repositions the player at that

point in the video. You can also see how Stream displays the same text under the video when the user enables closed captions.

Automatic transcript generation is very helpful and, generally, it does a reasonable job of interpreting the spoken words in a video. However, the nature of automatic text generation is that it can always do with a little help. If you want to improve the quality (accuracy) of the captions:

- Download the transcript file and amend it with any text editor. Unless you use a VTT editor (here's a [free online example](#)), don't edit the time codes – just the text.
- Delete the existing transcript.
- Upload the amended file.

You can create misunderstood words, add speaker attribution (an example is shown in Figure 10-3), or include other details that might be useful to the watcher.

## Noise Suppression

Noise suppression isolates speech from background noise in the audio feed to make it clearer and more distinct. Video owners can update the details of videos to enable noise suppression. When noise suppression is enabled, viewers have the option to keep noise suppression on or disable it during video playback.

Most videos qualify to be processed for noise suppression. The criteria include:

- The video is two hours or shorter, and no larger than 3 GB.
- An audio track is available, but not when multiple audio tracks in different languages exist in a video.
- The video is not a recording of a Teams meeting. This is because noise suppression is automatically done when Teams meetings are recorded.

Noise suppression is not available for recordings of Live Events. You can't disable noise suppression on a tenant-wide level.

## Viewership Statistics

When people view videos using the web player, Microsoft 365 captures statistics to help video owners understand how engaged viewers are with the content. Not everyone watches a video from end to end, and it can be important to know what parts of a video attract the most engagement or where viewers begin to drop off. To see the viewership statistics for a video, use the Open File Location option to go to the video's storage location in OneDrive for Business or SharePoint Online and hover over the file to display its details card. Then click the Views link. You'll then see the number of views per week, who viewed the video, and its ability to retain viewers (Figure 10-4) over time.

Viewership retention is different from the number of viewers. If someone opens a video at any point, they count as part of the total viewership. Retention depends on how many of the total viewers saw a specific point in the video. For instance, Figure 10-4 reports that 80% of the viewership saw the video at the 14-second mark with 100% viewership attained before and after this point. That kind of graph indicates viewers dipping in and out of the video. The number of views includes "rewatches," or occasions when someone goes back and reviews a part of a video again. The statistics include these events when someone goes back to a part of a video during a viewing session. Usually (as seen in this case), viewership drops off toward the end of a video but it's more unusual to see a dip at the start. This is probably caused by people skipping ahead to avoid the opening credits. The viewership chart aggregates data for the entire lifetime of a video: you cannot choose to view data for specific periods.

Viewership data is tied to a specific version of a file. If you edit a video and upload the new content to Stream, statistics accrue for that version and don't inherit the data for the older video.

Stream adjusts the data points in the time chart depending on a video's duration. If a video is short (under 200 seconds), a data point appears for each second. For longer videos, Stream adjusts the graph by aggregating data over longer periods. For example, a 10-minute video uses 3-second data points.

Figure 10-4: Statistics for a video

## Stream Mobile Apps

Stream mobile apps are also available for [iOS](#) and [Android](#). The current versions of the mobile clients only work with the videos stored in classic Stream. Versions based on SharePoint storage are under development.

With the mobile clients, users can browse channels and groups to find and play videos (Figure 10-5), add videos to watchlists, like a video or make comments about its content, edit, delete, and share their videos, and download videos for offline access. Users can choose to minimize data consumption by streaming videos in standard definition format or use more data for higher fidelity. The automatic transcript (captions) is supported on mobile clients. [This page](#) has the latest details about the Stream mobile apps.

Being able to record and upload videos on mobile devices is an especially popular feature. When recording on a mobile device, the Stream mobile app supports these features:

- Swap between the available cameras on the device. The default camera selected for a new video is rear-facing, but you'll probably want to use the front-facing camera for in-person shots.
- Record multiple clips before uploading the video to Stream. When all the clips are recorded, you can drag and drop them into the order you want the clips to appear in the video.

- Include photos from the device in a clip. For example, you could take a picture of a new product and tape a commentary for the picture.
- Annotate (draw), add emojis, or apply filters to a clip.
- Trim clips by removing content from the front or end of a video.

When the creator uploads the video, Stream processes it and prepares the content for publication. Before the upload, the creator should make sure to assign the language to a video to allow Stream to generate an automatic transcript. Users can also upload videos from the device's camera roll or a cloud storage app like OneDrive.

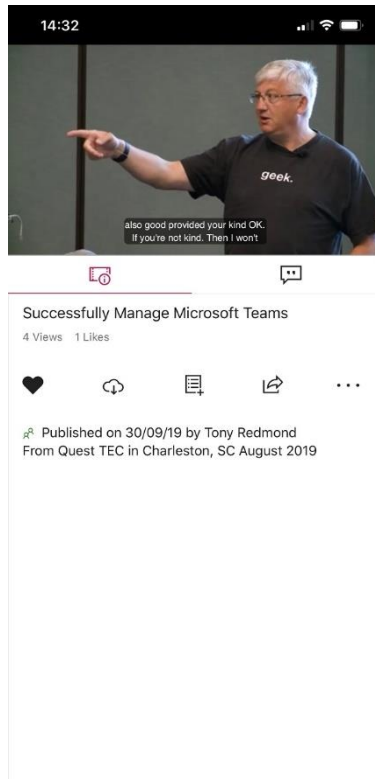

Figure 10-5: Watching a video on Stream for iOS

Other mobile applications can be used to create videos, many of which offer functionality over and above what's available in the Stream mobile app. The advantage of the Stream app is its integration with Microsoft 365, which makes it easy to upload and share videos. See [this page](#) for more information about recording and editing Stream videos on Android and iOS devices.

## Stream and Teams

Teams makes use of functionality from many Microsoft 365 and Azure apps. In the case of Stream, Teams uses the following features:

- Recording of Teams meetings.
- Publishing Stream videos via a channel tab.
- Recording of Live Events. After the end of a live event, the video stream automatically transitions from a live feed to an on-demand recording. The recording is available online and accessible to attendees and other users for 180 days. If the organizer of a live event wants to keep the recording for longer, they must download the video and upload it to Stream. The storage of a live event recording counts against the Stream quota for the tenant.

Teams is the first workload to transition to the new Stream architecture. Stream stores all new Teams meeting recordings in OneDrive for Business (personal meetings) or SharePoint Online (channel meetings). Older recordings and other videos remain in Azure until Microsoft makes migration tools available to move this content to SharePoint Online and OneDrive for Business.

## Recording Teams Meetings

Recordings can be made for Teams private meetings (including group chats), channel meetings, ad-hoc (“meet now”) meetings, personal (1:1) meetings (including VOIP and PSTN calls), and live events (see above). The organizer and participants of Teams meetings can record meetings if the Teams meeting policy assigned to their accounts enables this option. The person who starts a recording is deemed to be the owner. Meeting organizers can update the options for individual meetings so that a recording starts automatically when a meeting commences (the first person with the presenter or owner role joins the call).

A separate setting in the meeting policy enables meeting organizers to generate automatic transcripts using the Teams desktop client. Transcript generation was originally available only for meetings held in U.S. English (or rather, meetings detected by Teams as being in U.S. English). Today, Teams supports an expanded range of languages for live caption and transcript generation including other variants of English, German, French, Italian, Spanish, Russian, Hindi, Arabic, Finnish, Danish, Swedish, Japanese, Korean, Chinese, and Dutch.

When a Teams meeting is recorded, Teams adds a bot to the call to capture the voice and video stream from participants (even if the meeting is voice-only). Recordings use a 3x3 view (the last nine speakers). Once the meeting ends or the recording is halted, Teams stores the recording as an .MP4 file as follows:

- For **personal meetings**: the Recordings folder of the OneDrive for Business account of the meeting organizer. The exception is when a participant with co-organizer or presenter rights records the meeting. In this case, that person is the owner, and the recording goes into their OneDrive for Business account. However, the meeting organizer has edit rights to the recording. The same occurs if meeting options dictate automatic recording. In this case, the person holding the presenter role who first joins the meeting becomes the owner of the recording, and Teams creates the MP4 file in their OneDrive for Business account and grants the meeting organizer edit access.
- For **channel meetings**: the Recordings folder for the channel in the SharePoint document library belonging to the team. For example, General\Recordings. The exception is for meetings in private channels. The sites used for private channels don’t need individual folders as exist for normal channels in the team site, so recordings go into the root of the document library of the private channel’s site. The person who starts a channel recording has edit rights to the file.
- For **1:1 calls and group chats**: the Recording folder of the OneDrive for Business account of the person who records the meeting.

If the meeting is left active, the recording ceases after four hours. Access rights for recordings stored in OneDrive for Business do not include external meeting participants, including guest accounts. If external access is needed for a recording, the owner must grant access.

Teams also posts a link to the recording in the meeting chat or channel. The MP4 file can be edited or processed by whatever tools are available to trim or otherwise adjust the recording. If available, meeting transcripts are available in the same place.

Different processing applies for recordings of 1:1 calls. These meetings can only be recorded if both participants use Teams clients and the meeting policy assigned to one of the participants allows them to record the meeting. Recordings are unsupported if one of the participants uses a dial-in number or connections through federation (external access). It’s also important to understand that only participants from the host tenant have (read) access to the recordings by default. External participants, including guest users,

cannot access the recording unless the meeting organizer shares the recording with them. Table 10-1 summarizes how meeting participants can access Teams meeting recordings.

<b>Type of meeting</b>	<b>Who can view recording</b>	<b>Access to recording</b>
Group chat	All chat participants from the host tenant.	Recording posted in meeting chat and in the OneDrive for Business account of the person who starts the recording.
Private or ad-hoc meeting	All participants from the host tenant.	Recording posted in the meeting chat and in the OneDrive for Business account of the person who starts the recording. The recording is also available in meeting recap. Meeting participants from the same tenant have read-only access rights to the recording. External participants, including guest accounts, must be assigned permission to access the recording.
Channel meeting	Members of the team owning the channel.	Recording posted in the meeting chat in the channel and the Recording folder of the channel folder in the SharePoint site belonging to the team.
1:1 meeting	Both participants (if in the same tenant).	Recording posted in the chat and in the OneDrive for Business account of the person who starts the recording. The other party has read-only access if they have a tenant account.
VOIP and PSTN calls	Call owner.	Recording and transcript are available in the call history and call details.

Table 10-1: Access to Teams recordings

No matter how a recording is made, only the owner can download or remove the video. The owner can upload the recording to Stream if they wish to share the content to a wider audience (except externally, as Stream doesn't support this type of sharing).

**Sharing Permissions in OneDrive:** Permissions for meeting recordings stored in OneDrive are limited to internal users, even if guests participate in the call. If it is necessary to share a recording with an external user, the owner (the person who started the recording) must update the sharing list to include that user. Channel recordings stored in SharePoint can be accessed by any team member. Another thing to remember is that only the owner can download the recording from OneDrive. Other participants in personal meetings receive view-only permission and are blocked from downloading.

## Recordings for VOIP and PSTN Calls

Teams users who place calls to VOIP or PSTN recipients can record the call and generate a transcript if the calling policy assigned to their accounts have the following settings enabled:

- *AllowCloudRecordingForCalls*: Controls if the user can record PSTN and VOIP calls. By default, the setting is True.
- *AllowTranscriptionForCalling*: Controls if the user can generate a transcript of a call. By default, the setting is False.

For example, to update the default Teams calling policy to allow users to record calls and generate transcripts, the command is:

```
[PS] C:\> Set-CsTeamsCallingPolicy -Identity Global -AllowCloudRecordingForCalls $True -AllowTranscriptionForCalling $True
```

Meeting recordings are stored in the OneDrive for Business account of the user who starts the recording and is available with the transcript in the call history and call details.

## Retention of Teams Recordings

Most recordings of Teams meetings age rapidly. Time and activities overtake the matters discussed and the value of the recording diminishes over time. For this reason, many organizations want to remove Teams meeting recordings sooner than other content. Microsoft has committed to delivering a special retention policy to process Teams meeting recordings which can be used by all tenants with Teams licenses. This feature isn't yet available, so for now only tenants with the necessary Office 365 E5 or Microsoft 365 E5 compliance licenses can create an auto-label policy to apply retention labels to the recording files stored in SharePoint Online and OneDrive for Business. Alternatively, if you don't have the licenses for auto-label policies, you can train users to apply retention labels manually.

Background labeling processes find content identified by policy criteria (a keyword query, sensitive information type, or trainable classifier). In the case of Teams meeting recordings, a keyword query of *(ProgID:Media AND ProgID:Meeting)* locates the MP4 files. These are programmable identifiers set on recordings when Teams creates the files. You can test the effectiveness of the query by using it with SharePoint search to find Teams meeting recordings available to you.

When specifying the locations covered by the policy, make sure that you include all the locations where recordings might be found:

- OneDrive for Business (personal meetings).
- Microsoft 365 Groups (channel meetings). This includes the SharePoint sites connected to teams.
- SharePoint Online. This covers any copies of recordings moved from the SharePoint sites connected to teams.

When the auto-label policy matches the query against a file, it applies the retention label specified in the policy settings. The retention period in the label dictates how long the recording remains in place. Once the retention period (say, six months) lapses for recordings, background processes remove the files. See Chapter 17 for more information about retention policies and labels.

Compliance administrators can track auto-label activity through the Activity Explorer in the Microsoft 365 compliance center. Another way to check the progress of auto-labeling is to run the PowerShell script [downloadable from GitHub](#) to report the recording files which receive a retention label together with information about how long it takes auto-labeling to happen after the creation of recordings.

## Auto-Expiration of Teams Meeting Recordings

Microsoft says that 96% of Teams meeting recordings are not rewatched 60 days after the original meeting and 99% are not watched after 110 days. To help preserve storage quota, Teams marks an auto-expiration date on each recording. Unlike retention labels, which need Office 365 E3 or above, auto-expiration works for all SKUs which include Teams.

Originally, Teams used a 60-day retention period. Following customer feedback, Microsoft increased this to 120 days, which is the expiration period for recordings created by enterprise users. Recordings for users with Office 365 A1 licenses have a 30-day retention period. It doesn't matter if the recording is in SharePoint Online or OneDrive for Business. Users can change the expiration period for individual recordings by updating file properties through the file details pane (selecting preset values of 14, 30, or 60 days, a custom date, or *Never Expire*). Organizations can set a default expiration period for newly created recordings using the Teams meeting policy assigned to user accounts. The auto-expiration settings can be managed by updating meeting policies in the Teams admin center. Alternatively, you can use PowerShell. For example, to set the default

expiration period for recordings of meetings made by people assigned the *VIP User Meeting Policy*, run the command:

```
[PS] C:\> Set-CsTeamsMeetingPolicy -Identity "VIP User Meeting Policy"
-NewMeetingRecordingExpirationDays 180
```

The minimum retention period is one day, and the maximum is 9,999 days (which should be enough for anyone). You can also set retention to -1, meaning that recordings of team meetings never expire. The expiration period for A1 users can only be reduced from the default 30 days.

Background processes run to evaluate recordings and check their expiration date. If the process detects an expired file, the process moves the file into the recycle bin and clears the expiration date field. Users receive email notifications when expired recordings move into the recycle bin. If necessary, they can rescue important recordings from the recycle bin for up to 90 days after deletion. Once moved back from the recycle bin, the recording has no expiration date set and will therefore not be evaluated for deletion again.

To help users understand when a recording approaches expiration will see visual indications in:

- Beside the link to the meeting recording in the meeting chat. Anyone with view access to the recording sees the expiration notice.
- Two weeks before expiration, a red icon appears beside the MP4 files for files in the Recordings folder of OneDrive for Business accounts (personal meetings) or SharePoint Online sites (channel meetings).

Auto-expiration applies only to new recordings. Existing recordings do not have an expiration period. Auto-expiration is only available for meeting recordings and cannot be used with other file types held in OneDrive for Business and SharePoint Online.

If you move a file with an expiration date to another site, the expiration date stays with the file and remains active. Copying a file creates a new file without an expiration date. The same applies if you download a meeting recording and then upload it to a different site to create a new file. Retention labels take precedence over auto-expiration. In other words, if a recording has a retention label, that's what governs how it is kept (or removed). For this reason, you should assign suitable retention labels to important recordings if you want to make sure that Microsoft 365 will not remove the files.

## Searching Spoken Words in Teams Meeting Transcripts

When Teams generates a transcript for a meeting, it stores the spoken words in the Exchange Online mailbox of the person who starts the transcript (for personal meetings) or group mailbox (for channel meetings). After the meeting finishes, a background process copies the information from Exchange Online to match the words with segments in the video recording. This process accomplishes two goals. First, the playback of the meeting recording can display the transcript in a separate pane. Second, Microsoft Search indexes the spoken words to make it possible for users to search meeting transcripts based on words spoken during the meeting and captured in the transcript. Searching for spoken words in meetings can be done using SharePoint Online search or in OneDrive for Business. In both cases, the search is scoped to only reveal words from meetings the user is entitled to access.

Including spoken words from meetings in Microsoft Search indexes will eventually mean that it will be possible for eDiscovery investigators to include this information in their searches. This isn't possible today, probably because of the need for work to link the transcript and video recording intelligently in search results (for both preview and export).

## Commenting on Videos

Stream videos stored in OneDrive or SharePoint support the ability for users to comment on their content. Although users typically receive view-only permission for video and audio files, Stream makes an exception to

allow users to post comments via a button included in the set of overlaid options available during video playback. People with edit permission for a video can remove comments or prevent the posting of comments by updating video settings.

Apart from the per-video control over comments, organizations can remove the ability for people with view-only permission to post comments through a tenant setting. To do this, run the *Set-SPOTenant* cmdlet from the SharePoint Online module and change the value of *ViewersCanCommentOnMediaDisabled* from the default (False) to True:

```
[PS] C:\> Set-SPOTenant -ViewersCanCommentOnMediaDisabled $True
```

## Including Stream in a Teams Channel Tab

To make it easy for people to find videos, team owners and administrators can create channel tabs to connect to a video. To create the connection, enter the URL (retrieved with the Share option in Stream or from the browser address bar) for the video into the Teams dialog screen. The tab name is set to be the name of the video, but you can rename the tab if necessary.

## Stream Audit Events

Stream classic generates specific audit events as users interact with videos through the classic clients. In Stream 2.0, SharePoint Online generates the audit events because videos are processed just like any other file stored in a SharePoint site or OneDrive account.

You can search audit data with the audit log search feature in the Microsoft Purview Compliance portal or using the PowerShell *Search-UnifiedAuditLog* cmdlet. Chapter 21 explains how to search using either method, but for illustration purposes, the code below shows how to search the audit log and return the count of videos upload and modification actions by individual users.

- When a client uploads a video, it initially creates a file with a ~tmp prefix. For example, ~tmp7C\_Microsoft 365 Track.mp4. A *FileUploaded* event captures this action.
- Stream processes the video, updates its settings, and renames the file (in the example above, the renamed file is Microsoft 365 Track.mp4). These actions generate two *FileModified* audit events. One logged for the video owner (rename the file), the other for app@sharepoint (update the video settings).

The code below removes the events generated by the system app@sharepoint account from the reported data.

```
[PS] C:\> $EndDate = (Get-Date).AddDays(1); $StartDate = (Get-Date).AddDays(-30)
[array]$Records = (Search-UnifiedAuditLog -Operations FileUploaded, FileModified -StartDate
$StartDate -EndDate $EndDate -Formatted -ResultSize 5000)
If (!$Records) {Write-Host "No audit records found - exiting!"; break}

$StreamRecordings = [System.Collections.Generic.List[Object]]::new()
ForEach ($Rec in $Records) {
    $AuditData = $Rec.AuditData | ConvertFrom-Json
    If (($AuditData.SourceFileExtension -eq "mp4")) {
        $RecordingFileName = $AuditData.SourceFileName
        $DateLoc = $RecordingFileName.IndexOf("-202")
        If ($DateLoc -eq -1) {$Topic = $RecordingFileName} Else
            {$Topic = $RecordingFileName.SubString(0,$DateLoc)}
        $DataLine = [PSCustomObject] @{
            Workload      = $AuditData.Workload
            Date          = $Rec.CreationDate
            User          = $Rec.UserIds
            Recording     = $RecordingFileName
            Topic         = $Topic
        }
    }
}
```

```

        Site           = $AuditData.SiteURL
        FullURL        = $AuditData.ObjectId
        Folder         = $AuditData.SourceRelativeURL
        Operation      = $Rec.Operations }
    $StreamRecordings.Add($DataLine)
} #End If
} #End For

$UploadedFiles = $StreamRecordings | ? { $_.User -ne "app@sharepoint" }
$UploadedFiles | Sort {$_.Date -as [DateTime]} -Unique -Descending | Out-GridView

$UploadedFiles | Group-Object User | Sort Count -Descending | Format-Table Name, Count

```

Name	Count
Jane.Nix@office365itpros.com	74
James.Ryan@office365itpros.com	22
John.Hubbard@office365itpros.com	1
James.Joyce@office365itpros.com	1
Ben.Owens@office365itpros.com	1

To see a summary of activity for individual video files, change the *Group-Object* command slightly to:

```
[PS] C:\> $UploadedFiles | Group-Object Topic | Sort Count -Descending | Format-Table Name, Count
```

Some Stream-specific events are available such as actions logged for transcript creation, deletion, and access. This code will find those audit records.

```
[PS] C:\> $Operations = "FileTranscriptContentAccessed", "FileTranscriptCreated",
"FileTranscriptDeleted"
[array]$Records = (Search-UnifiedAuditLog -Operations $Operations -StartDate $StartDate -EndDate
$EndDate -Formatted -ResultSize 5000)
```

One issue in moving away from Stream-specific audit events to the more general-purpose events generated by SharePoint Online is that the Stream activities can be a small percentage of the overall set of audit events found by a search. SharePoint Online and OneDrive for Business generate many *FileModified* audit events as users work with Office documents, especially if the AutoSave feature is used as this can generate multiple events as AutoSave saves modified versions of files during a session.

# Chapter 11: Managing Microsoft 365 Groups

**Tony Redmond**

## Modern Groups and Distribution Lists

Microsoft has used different names for modern groups since their introduction in November 2014, including Office 365 Groups, Outlook Groups, Groups in Outlook, and now [Microsoft 365 Groups](#). To simplify matters, we use “Groups” unless we need to refer specifically to another type of group, such as a mail-enabled security group.

[In April 2017](#), Microsoft said that “*more than 10 million people rely on [Groups](#) in Outlook every month to work together and get things done.*” At that time, Office 365 had roughly 100 million active users, so Groups enjoyed 10% penetration. The number of people who rely on Groups is now much higher because the primary mission for Groups is the membership service for over 20 Microsoft applications, including Teams, SharePoint, Yammer, and Stream. In particular, the dramatic growth in Teams drove the creation of a huge number of Groups. While in some ways Groups continue to be a “better distribution list” for the email-centric community, the role of Groups in membership management across Microsoft 365 is its more important function.

## An Identity and Membership Service

The basic idea behind Groups is to bring people, information, and applications together to enable better communication and collaboration. We can summarize how Groups work in three steps:

1. Users create and manage groups using their client of choice. The client depends on the purpose for which they want to use the group. For instance, if they believe that group members prefer to communicate via email, they should create the group with Outlook. If they prefer using chat or threaded conversations, they might choose Teams or Yammer.
2. The new group object exists in both Azure AD and Exchange Online. Azure AD is the *system of record* and is responsible for synchronizing information about the new group to other workloads across Microsoft 365 (for example, Planner and SharePoint Online) to make those applications aware that a new group is available. In some respects, because both types of group control access to resources, you can think of a Microsoft 365 group as having some of the same characteristics as a security group. The big difference between the two types is that a Microsoft 365 group has both members and owners while a security group has just members. In addition, a workload must recognize Groups as a valid security mechanism before Groups can control access to resources.

The Exchange Online directory holds email-related information about Microsoft 365 Groups, including their proxy addresses. When you use Exchange clients or cmdlets from the Exchange Online PowerShell module to update Groups, a dual-write mechanism commits the updates simultaneously in Azure AD and Exchange Online. Following a successful update, Azure AD synchronizes the changes with other application directories.

3. Group members select the tools they need to get work done from the range of applications that support Groups. For example, a team might choose to connect a plan via a channel tab.

We will explore how these steps work in practice through the rest of this chapter.

## Applications that use Microsoft 365 Groups

A wide range of Microsoft 365 applications uses Groups as a membership service. Table 11-1 lists some of the major applications which use the Groups service.

<b>Group</b>	<b>Focus</b>	<b>Storage</b>
Outlook	Email-based conversations within public or private teams. Limited to "more than" 1,000 members. Dynamic membership supported.	Exchange Online mailbox
Microsoft Teams	Personal chats and channel-based conversations. The membership limit for an individual team is 25,000.	Azure Cosmos DB
Microsoft Planner	Task-based plans used by public or private teams. Shares the same limit as Teams.	Azure data service
Yammer Communities	Open, idea sharing, collaboration at scale. The membership limit for these groups is up to 50K if synchronized to an on-premises AD and higher if not.	Yammer
SharePoint sites	Structured document and information management.	SharePoint
Stream	Controls access to video content in the Microsoft Stream service.	Stream (moving to OneDrive for Business and SharePoint Online)
Power BI	Controls access to workspaces.	Power BI

Table 11-1: The various kinds of groups available within Microsoft 365

The only real limit for groups is imposed by [Azure AD](#), where "any number of objects can be members of a single group," or, if you synchronize with an on-premises directory, an Azure AD group object is limited to 50,000 members.

## Core Principles

Figure 11-1 illustrates how three core principles combine to form the architecture of Microsoft 365 Groups. These are:

**Azure AD is the directory of record.** When you create a new group, two writes occur in tandem. The first is to Azure AD to create the object that becomes the definitive identity for the new group. The second is to the EXODS directory to create the group mailbox. This process ensures that the new group can begin to function immediately. After Exchange Online creates the new group mailbox, it updates the group object in Azure AD with information such as its email address. Provisioning processes create other components like the SharePoint Online document library and the shared OneNote notebook.

Azure AD propagates information about group properties and members using a "forward synchronization" process to the directories used by individual applications to enable those applications to recognize and respect the membership of groups. For instance, if a user updates the membership of a group using OWA, writes occur to update the membership information held in Azure AD and EXODS. Notifications occur to make other group-enabled applications aware of the change. You can think of group membership as a form of "access all areas" pass that is valid for access to all the resources available to the group.

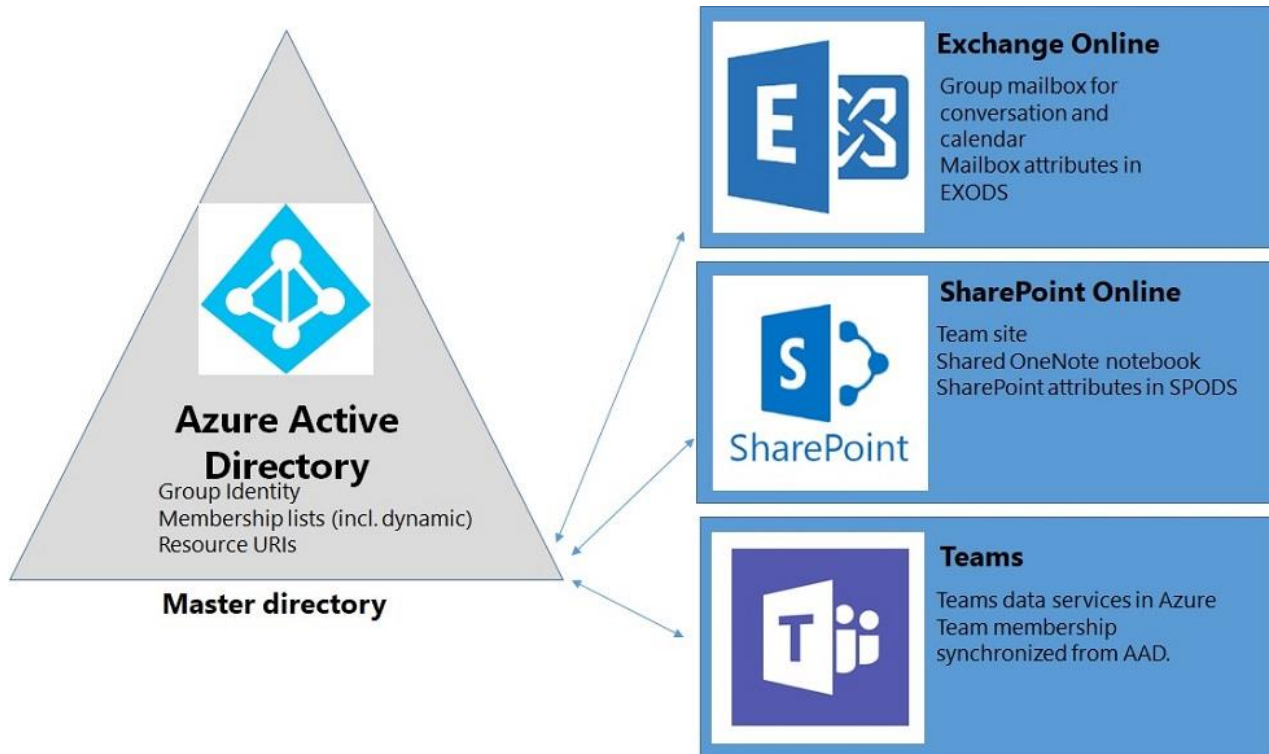

Figure 11-1: The loosely coupled Groups architecture

Although notifications are the primary mechanism used to inform workloads of changes to which they should respond, applications might not respond at once to the notifications as they might have other items to process. The forward synchronization process, which runs in the background on a timed basis, acts as a backstop by making sure that all workloads apply any outstanding updates consistently. The focus of the synchronization process is scale rather than immediacy. In other words, a change might take one or two minutes (or sometimes much longer, depending on the load on the service) before replication fully occurs across all directories. Although the change might not be immediate, it will happen. This is important because as more applications use Groups as a membership service, the interaction between those applications and Azure AD becomes more complex. Typically, if an application has a separate directory (like Teams or Yammer), the application updates both directories and relies on synchronization to spread the change to other workloads.

Viewed in the context of Azure AD, Groups are mail-enabled groups that have members and owners. The Groups service manages membership for apps like Teams and Planner and therefore controls access to the resources available through these apps, some compare Groups to security groups (in the loosest sense).

In hybrid environments, tools like AAD Connect can synchronize group membership to an on-premises Active Directory where the groups show up as distribution lists. You need to pay some care and attention to the synchronization process to make sure that everything works as expected. See the Identities chapter for more information.

**Federated resources are drawn from multiple applications.** Microsoft 365 spans a growing set of applications, each of which delivers specific functionality. Each application controls its data stores. Federation allows Microsoft to select from the functionality available in existing applications and expose that functionality to users through new applications and their clients. Thus, a group has the following components:

- A mailbox to store threaded conversations from Exchange Online. The Microsoft 365 substrate uses the group mailbox for other purposes, such as holding compliance records generated for Teams and Yammer. The group mailbox includes a shared calendar, which Teams uses for both the team and channel calendars.

- A SharePoint Online team site, including a document library to allow group users to share documents and other files.
- A shared OneNote Online notebook. The notebook is in the Site Assets document library of the SharePoint site.
- Other applications can add components to the mix. For example, Teams adds several Azure-based data services to hold its conversations, chats, and graphics.

A Yammer-based group uses similar components, with the difference being that the group mailbox holds only compliance and substrate data. When Teams creates a group, members communicate through chats and only use the group mailbox for the calendar. Stream uses groups to control what videos are available to group members. Likewise, Power BI can use a group to control the workspaces that are available to users.

The single identity for the group means that members automatically gain access to all the application resources available to the group to create an integrated end-to-end user experience across Microsoft 365. Federation allows Microsoft to introduce new applications to Microsoft 365 more easily and with less disruption to other applications than would be the case if each application depends on its resources. Members of the group can then use whatever functionality is available in an application. The functionality and its data remain under the control of each application.

**Loose coupling with groups and applications.** Apart from their dependency on membership and identity services, applications that use Groups operate independently of Groups and can exist independently of each other. Applications are aware of each other because they share the common linkage through Groups and respect the common identity represented by a group. When changes occur in an application, other applications become aware of the changes through a synchronization process. For example, if a user creates a new group with Outlook, the notification that arrives from Azure AD to Exchange Online forces the provisioning of a new group mailbox to hold group conversations and the calendar. The presence of a new group object in Azure AD makes SharePoint Online aware that some work is necessary to update itself when someone tries to use the new group.

Although it is easy to see how Groups can replace some usage of email distribution lists, they cannot replace all distribution lists. For example, you cannot nest a group inside other Microsoft 365 groups. In addition, Exchange distribution lists support all types of email-enabled objects in their memberships, like mail users and mail contacts. Because Microsoft 365 uses groups to control access to applications and data, only Azure AD users and guest accounts can be members.

The fact that a group has a single identity with a single set of permissions is a major part of the value of Groups. It means that groups can act as a means of access to different Microsoft 365 applications, which is how applications like [Forms](#) and Power BI use Groups. Forms, for instance, uses Groups as the way to share forms between users in what it calls "Group forms." Because a group is a single identity, when members join a group, they gain access to all the components available to that group with the same rights to the content as other members. If you need to implement granular access to information, you should use whatever mechanisms are supported by individual applications rather than trying to transform the team identity of a group into a set of individual custom permissions.

## Groups Basics

Before we examine the details of how Groups work, we should first consider some of the basic ideas behind how Microsoft views these objects and how this affects their evolution as a major Microsoft 365 component. Here are some of those ideas:

**A focus on self-service:** Microsoft wants Groups to be easy for users to set up on an on-demand basis. By default, anyone can create a new group (as we will discuss later, you can control this through settings in the Azure AD policy for Groups). Users creating objects that consume system resources without oversight fly in

the face of traditional IT practices where IT exerts control over what a user can and cannot do. The idea is that by making groups easy to create, users can collaborate as they see fit and work together in ad-hoc or formal teams. Remember that resources are more abundant inside Microsoft 365 than is the case in most on-premises deployments, so a reduced focus on the need to control resources is an understandable position to take.

**Public by default:** Originally, Microsoft made groups public by default to encourage people to join and take part in as many groups as possible. It seemed like a good idea in 2015. After several years, the experience of deployments and customer feedback moved Microsoft to believe that groups should be private by default. The change aligns Groups with Teams as both apps use private as the default access type. It has the side effect of making groups less discoverable, but it is easy to set a group to be public after creation if you want to follow the original philosophy.

**Simple permissions:** The history of IT is full of stories about people getting into trouble with permissions. Either they do not have the right permissions to do the job, or their account has permissions that are unnecessary, which means that the user ends up accessing data that they should not. Once a user is a member of a group, they have full access to the contents available to that group, no matter what application provides and manages that content. If someone leaves the group, they lose access to the information belonging to the group. It is as simple as that. The downside of this approach is that non-members have complete access to some information held in public groups.

**Sharing is easy:** Users can share personal documents stored in their OneDrive for Business account with other people, including external users (if allowed by the tenant sharing policy). Members of groups can share documents from the group document library with other users and other groups just as easily. Thus, you should never put a document into a group document library unless you want to grant full control over that information to every other member of the group.

**A shared memory:** As discussed before, administrators often bolted public folders to distribution lists to record contributions for later review. Groups incorporate a shared memory from the start in that once someone joins a group, they enjoy full access to all the information that has accumulated in the group since its initiation. Nothing is secret or hidden from group members. The shared memory makes it easy for new members to quickly familiarize themselves with the work of the group without the need for an existing member to send them messages or documents or update them with details of group meetings. Everything is present for the new member to explore.

**A growing experience:** Members might begin by taking part in group conversations, just as they have used distribution lists for decades. Over time they can become more fully involved in the work of the group and begin to use the other facilities to interact with other people. Since their introduction, Microsoft has steadily added new features to Groups. More importantly, as shown in their use by the Teams and Planner applications, Groups have become the keystone for Microsoft 365 collaboration.

# Group Components

## Members and Owners

- The functionality enabled through Groups is based on the single identity represented by the group objects stored within Azure AD. The single identity and simple permissions model create a low-touch need for administration. Membership information exists as sets of links that connect back to user accounts. Three types of members exist:
- **Owners:** These users can update group properties and add members and owners to the group. A user must be a group member before they can be an owner.

- **Members:** These users have full access to all the resources of the group. However, they must connect to the group to access conversations. Members can add new members to a public group or request that an owner adds someone to a private group.
- **Subscribers:** These are members who have opted to receive copies of conversations and group calendar events via email. A group does not have to have any subscribers, which is the normal case for the groups used by Microsoft Teams where conversations occur through chats rather than email. To ensure that they can participate in group conversations, Exchange adds guest accounts to the subscriber list when they join a group. This also applies to groups enabled for Teams.

Group membership can be dynamic or static. You can create dynamic Groups through the Azure AD admin center where the membership types are “dynamic user” (dynamic group) and “assigned” (static or normal group membership). When you create a dynamic group, you must also specify the query for Azure AD to find group members. Dynamic groups can also be created using PowerShell or the Groups Graph API. You cannot change the membership type for a group from dynamic to static afterward. Dynamic groups can be constructed using the membership of other Azure AD groups, including Microsoft 365 groups with assigned or dynamic membership and distribution lists.

Azure AD user accounts can be present in all categories of membership. Guests can only be present as Members and Subscribers and cannot be group owners. Members can elect to take part in conversations via email, in which case they join the set of subscribers. Except for dynamic groups, administrators and group owners manage the three types of members by manipulating the links belonging to the group. You can do this through group-enabled applications like OWA or Teams, the Outlook mobile apps, or by running the set of PowerShell *\*-UnifiedGroupLinks* cmdlets as discussed in the PowerShell chapter.

**No way to Print Group Membership:** No Microsoft application includes a method to print or report the details of the membership of a group. As [explained in this article](#), it's easy to create a report with PowerShell.

## Ownerless Groups Policy

Most of the Microsoft 365 apps prevent the removal of a group's last owner. However, the deletion of an account (for example, when someone leaves the company) might result in some groups falling into an ownerless state. Although this is not a good condition, the group continues to function. New members can continue to join if the group is public but membership requests to join private groups stay unapproved because no owner exists to process requests.

You can check for ownerless groups with PowerShell.

```
[PS] C:\> [array]$Groups = (Get-UnifiedGroup -ResultSize Unlimited | Select DisplayName, ManagedBy) $Groups | ? {$_.ManagedBy.Count -eq 0}
```

After finding an ownerless group, administrators can add a new owner by updating the group through the Microsoft 365 admin center or EAC or by running the *Add-UnifiedGroupLinks* cmdlet.

The Group Ownership Governance policy (aka the ownerless group policy) automates the process of finding and fixing ownerless groups. Configured in the Microsoft 365 Groups section in Org settings in the Microsoft 365 admin center, the policy uses background processes to periodically check for ownerless groups. For each ownerless group, Microsoft 365:

- Examines the group membership and makes a random selection from the active tenant accounts in the membership to become potential group owners. The administrator sets the number of accounts that Groups can invite to become the group owner. This number can be from 1 to 90. Active means that the account performs some activity in the group in the last 90 days.
- Sends an invitation by email to the potential group owners to ask them to take on the role.

- Actions the response of those invited to become group owners.
- Continues the process for the number of weeks (up to 7) set in the policy.

Microsoft 365 captures audit records for all the actions involved in sending out and processing responses to invitations to become group owners.

The governance policy can process all or selected groups. It can also constrain the selection of new group owners to the members of a security group. This feature allows an organization to restrict group ownership to specific accounts instead of having random people chosen (potentially to become owners of very important groups). No special license is necessary if the policy allows random selection, but if opt for restricted selection, all the members of the groups which come within the scope of the policy require Azure AD Premium P1 licenses. See [this article](#) for more information.

## Group Privacy (Access Type)

A group can be private or public (the default for a new group is private). A private group is one where the group owners control the membership. This is the most suitable group to use when group content is confidential. If a group's membership is open, anyone can view its membership, but not the content unless they join the group. Users can ask to join a private group, and Exchange then sends their request to join to the group owners. Any of the group owners can allow or deny a request to join.

You can change the default access type for groups created by Outlook clients by updating the organization configuration. This setting does not affect groups created from non-Outlook endpoints.

```
[PS] C:\> Set-OrganizationConfig -DefaultGroupAccessType Public
```

Public groups are open to any user in the tenant. Anyone can join a public group if they wish. A user can enroll other users into public groups without their permission (the newly enrolled users can then decide whether they want to take part in the group).

You can change the access type for a group using the following methods:

1. **OWA:** Select the group, edit its properties, and switch the type. For more details, see the section about creating and updating groups with OWA later.
2. **Outlook:** Select the group, then **Edit Group** and update the setting.
3. **Teams:** Select a team and use **Edit Team** to change the setting.
4. **Outlook mobile:** Expand the Groups section in resources and select the group, edit its properties, and change the privacy setting.
5. **Planner:** Select a plan and then **Planning settings**, then choose the Privacy setting in the **Group** tab.
6. **EAC** or **Microsoft 365 admin center:** Select the group and edit its settings.
7. **PowerShell:** Run the *Set-UnifiedGroup* cmdlet and set the *AccessType* property to be either Private or Public.

```
[PS] C:\> Set-UnifiedGroup -Identity TestGroup -AccessType Private
```

If your tenant uses sensitivity labels for container management, the sensitivity label assigned to the group controls its privacy setting and you can only update the privacy setting by changing the sensitivity label.

## Email Conversations

Aside from sharing documents, the basic way members communicate within a group is through threaded conversations. The individual items in message threads exist in the Inbox folder of the group mailbox for Outlook-based Groups or the Yammer data store for Yammer communities. In either case, clients create a view to sort the items sent to the group and present them as threaded conversations. Users can contribute to

conversations through the clients or by sending an email. In either case, items flow through the normal transport processing pipeline.

The calendar is the other major folder used in a group mailbox. It functions much like any other calendar in a personal or shared mailbox, with the notable exception that you can't use granular permissions with group calendars.

**Accessing folders in group mailboxes:** Although group mailboxes have a complete set of default folders that can hold items, clients usually only expose the Inbox and Calendar folders. The folders function in much the same way as in other mailboxes. For instance, junk mail sent to a group goes into the Junk Email folder (but no one knows about these messages). The Sent Items folder stores copies of messages generated by clients, such as notifications to users that someone has assigned them a task using Planner. If a group is team-enabled, you also find compliance records for standard channel conversations in the *TeamsMessagesData* folder. If the group is subject to a hold, the folders retain copies of items until the hold lapses. You can view the complete set of folders in a group mailbox by running this command:

```
[PS] C:\> Get-MailboxFolderStatistics -Identity GroupName | Format-Table Name, ItemsInFolder
```

Unless you are curious and want to explore the mailbox, no real reason exists to access the other folders and you can safely leave them alone. However, if you want to, you can access the folders in a group mailbox by adding the mailbox as a shared folder with OWA. OWA treats the group mailbox exactly like a shared mailbox and you can open any of the folders and examine the items it holds.

## Auto-Reply for Group Mailboxes

Group mailboxes support auto-reply messages. This is useful when the need exists to inform people about some special processing for messages that arrive in a group mailbox. For example, to tell:

- Customers about the procedure to process messages sent to a group.
- Internal people to inform them that a group is team-enabled, and all conversations occur in the team. Although most team-enabled groups are hidden from Exchange clients and are not included in Exchange address lists like the GAL, this doesn't stop people sending emails to the SMTP addresses of the groups.
- People when a group (or team) is not in active use or archived.

Setting an auto-reply for a group mailbox is just like setting one for a user mailbox. In this example, we use the *Set-MailboxAutoReplyConfiguration* cmdlet to create an auto-reply. The message sent to external people tells them that the mailbox is not in use. Because the group is team-enabled, the message used for internal people includes a mailto: link to the email address for a team channel. The recipient can click on the link to send their message to Teams.

```
[PS] C:\> Set-MailboxAutoReplyConfiguration -Identity "Office 365 for IT Pros" -ExternalMessage "Sorry, this mailbox doesn't accept email" -AutoReplyState Enabled -InternalMessage 'Please! We use Teams for communication, so send your message to <a href = "mailto:943a5091.office365itpros.com@emea.teams.ms">Teams</a> and it will be dealt with there.'
```

## Moving Personal Email to Groups

Users can move items from personal mailboxes to Groups using drag and drop in either OWA or Outlook. You can move items from any mailbox to which you have access. The moved items go into the inbox folder in the group mailbox. If you reply to the item, the recipient list includes all the recipients from the original message plus the group.

## Group Document Libraries

Apart from conversations and the shared calendar, the most obvious difference between Groups and traditional email distribution lists is the Files functionality available through the SharePoint team site owned by a group. When you create a new group, the provisioning process uses a site template called **GROUP#0** to create a SharePoint Online site for the team site. You cannot change the template to apply other settings, such as assigning a storage quota (which you can update afterward using the *Set-SPOSite* cmdlet). All the limits applied to SharePoint sites apply to the sites used by Groups.

Users can add content to document libraries using the following methods:

- Drag and drop files from any location accessible to your PC (local drives, OneDrive for Consumers, file servers, etc.). However, you cannot drag and drop files from another SharePoint Online site or group document library. We will discuss later how to move files from a SharePoint Online site to a group document library.
- Upload files or the contents of entire folders.
- Create files from scratch using Office Online applications.
- Save files into the document library from desktop Office applications.
- Save attachments received by email into the document library using Outlook or OWA.
- Use the OneDrive Sync client to upload and manage files.

When a file is in a Group's document library, the group controls its permissions. All documents in the library inherit the permissions to allow group members equal access to the content. SharePoint checks permissions when a user requests access to a file by checking the group membership. The storage used by group document libraries counts against the overall allocation for the tenant.

If the group is public, any user in a tenant can join the group and access the files in the document library. It is also important to remember that the group owns the content in the group document library rather than the original authors. If someone leaves a group, all the content they authored or amended remains behind.

**Document Library Regional Settings:** The regional settings for document libraries created for Groups inherit their time zone and locale (country) from the account which creates the group. Group members see date and timestamps for documents as if they were in that time zone. You can change the site's time zone and locale (country) by updating the Regional Settings (in Site Information). Sites created in the SharePoint admin center use the regional settings defined in the Site creation settings.

## Implementing Groups

Microsoft 365 Groups are a platform for user-driven collaboration. In an ideal world, or a small tenant, this approach works, and users create the right number of groups, each used for its assigned purpose. Allowing everyone to create new groups in larger organizations is more problematic because the potential then exists that underused or unwanted groups will linger in the directory and absorb resources. The latter point is debatable because Microsoft controls the resources and tenants do not incur any cost when a user creates a group. In general, it is better to set out a well-defined set of rules to govern the creation of groups and communicate them to users upfront than to attempt to apply rules retrospectively and control a sprawl of unwanted groups.

Here are some simple questions to help show the need for a new group:

- **What purpose will the group serve?** If the person who wants to create a group cannot say why the group is necessary and how it differs from existing groups, then there is a fair chance that the new group is unnecessary. Sometimes you cannot avoid creating a new group, as in the case when a Planner creates a new plan (from scratch or by copying an existing plan), which results in the

automatic creation of a group to support the membership and conversations for the plan. See the Tasks chapter for more information about Microsoft Planner.

- **Who is the intended audience for the group?** Is the group to be public (anyone can join it) or private (restricted to a defined set of users)? Does the group need to support guest access?
- **What app will people use to access the group?** The available options include Outlook, Teams, and Yammer. Each app brings its own set of advantages and disadvantages to the table. The best answer depends on factors like the organization's culture, strategic direction for collaboration, and above all, the desired functionality. For example, an Outlook-based group is a good choice for a team that needs to receive and process inbound communications from customers. A team is a good choice for small working groups who need to work on projects. A Yammer community works well for cross-organization communication, especially when the organization is very large. The thing to remember is that it is important to select the right technology to meet the need of those who will use it instead of trying to force one answer for all.

## Group Controls

The default situation is that anyone in a tenant can create a new group. In the following pages, we'll get into the details of how to apply different levels of controls to restrict the creation of groups. For now, we can summarize by saying that controls over group creation are available at these levels.

**Azure AD (directory):** the Groups section of the Azure AD admin center has a setting to control if users can create new Microsoft 365 groups. The *Users can create Microsoft 365 groups in Azure portals, API or PowerShell* setting is in the General settings section for Groups in the Azure AD admin center. By default, the setting is On. If it is turned off, users won't be able to create new Microsoft 365 groups even if allowed by the Azure AD directory policy for Groups. A similar setting in the Azure AD admin center controls the ability of users to create new security groups.

**Microsoft 365 (all workloads):** The Azure AD directory policy for Groups is a method to control different aspects of groups, one of which is to disable the ability of all users to create new groups and replace this with a restricted set of people permitted to create groups. A security group is usually the best method to define the set of users. Restricting group creation is an Azure AD Premium P1 feature.

**App-level:** Outlook clients use a setting in the OWA mailbox policy to define if a user can create a new group through Outlook (including OWA and Outlook mobile). This control does not require any additional licenses.

It's up to each organization to decide what level of control they wish to exert over group control, including the use of third-party software to impose group creation request and approval workflows. You can also implement a group creation workflow using a Power Apps flow (many templates exist for this task).

## Azure AD Policy for Groups

The Azure AD policy for Groups stores several settings to control different aspects of Groups. Applications retrieve settings from the policy to know how they should interact with Groups. Table 11-2 lists the policy settings.

<b>Policy setting</b>	<b>Use</b>
<i>AllowToAddGuests</i>	Controls whether users can invite external accounts to become guest members of Groups (and Teams). By default, this setting is <i>True</i> , meaning that group owners can add guests.
<i>AllowGuestsToAccessGroups</i>	Controls whether guests can access content held in the SharePoint site belonging to Groups. By default, the value is <i>True</i> .
<i>AllowGuestsToBeGroupOwner</i>	Controls whether guests can be group owners. This setting is not operational.

<i>ClassificationDescriptions</i>	Comma-separated descriptive pairs for the classifications available in the tenant.
<i>ClassificationList</i>	Stores a comma-separated list of valid classification values to give users a visual indication of what is stored in different Groups.
<i>CustomBlockedWordsList</i>	A list of words that the tenant does not wish group owners to use in the names of new groups.
<i>DefaultClassification</i>	Sets the default classification to apply to new groups.
<i>EnableGroupCreation</i>	Controls whether users can create groups. By default, this value is <i>True</i> and any user can create a new group.
<i>GroupCreationAllowedGroupId</i>	Points to the object identifier (GUID) of a security, distribution, or Microsoft 365 group whose members can create new Groups. This group is used if the <i>EnableGroupCreation</i> setting is <i>False</i> .
<i>GuestUsageGuidelinesUrl</i>	Defines a URL displayed in client user interfaces to remind users about guidelines for how to share company information with guests. For example, <a href="http://mydomain.com/GuestUserAccessO365Groups.html">http://mydomain.com/GuestUserAccessO365Groups.html</a>
<i>PrefixSuffixNamingRequirement</i>	Used by the group naming policy to define if it should apply a prefix and a suffix to the display names of new groups.
<i>UsageGuidelinesUrl</i>	Defines a URL displayed in client user interfaces to give guidelines about the creation and usage of Groups. For example: <a href="http://mydomain.com/HowtoUseO365Groups.html">http://mydomain.com/HowtoUseO365Groups.html</a>
<i>EnableMIPLabels</i>	Tells Groups to use sensitivity labels instead of text-based classifications.

Table 11-2: Settings in the Azure AD Groups policy

While you can configure the *AllowGuestsToBeGroupOwner* setting to *True* to allow guests to become owners of groups, this capability is not exposed in the Groups or Teams user interfaces.

**Get Azure AD Right Too:** It's amazing how often you need to look up Azure AD for something to do with a group. For instance, you might want to know where the owner of a group works or who their manager is. If the directory isn't populated accurately, you'll get bad results. It is always best to ensure that the information held in Azure AD is as accurate as possible (it will never be 100%) before building any script or other procedure that depends on a directory lookup.

## Licensing Groups Functionality

If you use Groups or Teams without changing any setting in the Azure AD Groups policy, the only license needed is the one included in plans like Exchange Online, Teams, or Office 365 E3. Things become more complex if you decide to utilize some of the more advanced features enabled and controlled through policy settings because Microsoft requires accounts to have Azure AD Premium P1 licenses to benefit from the added functionality. Microsoft's view is that these features reduce administrative effort or make groups more productive for organizations, so they price the features accordingly as extensions of the basic Azure AD capabilities bundled with every tenant.

The general rule is that any account that benefits from a feature must be licensed. Sometimes this rule is easy to understand, as in the case of dynamic Groups where the requirement is to license the accounts found by the queries used to populate group membership. For instance, if you create a dynamic group based on a query that finds all users with mailboxes in the tenant, it means that you need licenses for all those accounts. In other cases, the logic is harder to follow. For example, if you implement a policy to control the creation of new groups, you must license every account in the group allowed to create new groups plus the administrators who manage the policy. On the other hand, if you use the expiration policy to control how long groups exist before their owners must reconfirm that the groups are needed, you only need licenses for the members belonging to the groups to which you apply the expiration policy.

Table 11-3 summarizes the licensing requirement for the features you can activate or control through the Azure AD Groups policy. See this [support article](#) for more information.

Feature controlled by a group policy setting	Requires Azure AD Premium P1
Allow non-admin users to create groups	No
Restrict the ability to create new groups to a defined set of accounts	Yes
Use the expiration policy to force the renewal of groups after a set period	Yes
Create and use dynamic Groups	Yes
Apply group naming policy	Yes
Apply default classification to new groups	Yes
Provide URL with usage guidelines to internal users	Yes
Provide URL with usage guidelines to guests	Yes
Allow guests to access groups	No
Force new groups to have classification selected from a predefined list	Yes

Table 11-3: License requirements for features controlled by group policy settings

The requirement for Azure AD Premium licenses to use certain features makes them less attractive than if Microsoft bundled the functionality into the standard plans as it does for Microsoft 365 Business Premium plan. However, you might have other reasons to acquire Azure AD Premium licenses, such as buying subscriptions for the Enterprise Security and Mobility suite or some Microsoft 365 plans, so the problem might not be as big as it seems.

## Guest Access Licenses

[Guest access to Microsoft 365 applications](#) is included in all Microsoft 365 Business Standard and Premium plans and Enterprise subscriptions, which means that you do not need to assign licenses to guest users to access applications like Groups, Teams, and Planner. However, Microsoft's [guidance for B2B collaboration licensing](#) sets out the rules for guest access to "paid" (premium) Azure AD features like conditional access policies. Briefly, Microsoft allows tenants 50,000 free authentication activities for premium activities monthly. Access past this threshold is charged against an Azure subscription taken out by the tenant. See [this article](#) for more information.

## Creating and Updating the Groups Policy

By default, a tenant does not have an active Groups policy, and applications use default settings. To change any settings, we first create a directory setting object to hold the policy settings from the correct template. Azure AD loads default values into the new policy and you can then update those settings. Some of the examples described here use cmdlets in the Azure AD Preview module.

Several directory settings templates exist in the instance of Azure AD used by a tenant, including one to hold group policy settings. A different template is available to control guest access for specific groups (explained later). To see the available templates in a tenant, use the *Invoke-MgGraphRequest* to query the templates API:

```
[PS] C:\> Get-MgDirectorySettingTemplate | ? {$_.DisplayName -like "*group*"} | fl DisplayName, Values, Id
```

```
DisplayName : Group.Unified
Values      : {NewUnifiedGroupWritebackDefault, EnableMIPLabels, CustomBlockedWordsList,
              EnableMSStandardBlockedWords...}
Id          : 62375ab9-6b52-47ed-826b-58e47e0e304b
DisplayName : Group.Unified.Guest
```

```

Values      : {AllowToAddGuests}
Id         : 08d542b9-071f-4e16-94b0-74abb372e3d9

```

The directory template used to create the Groups policy for the tenant has the display name "Group.Unified" while the one used to amend settings for a specific group is called "Group.Unified.Guest." The templates have identifiers of *62375ab9-6b52-47ed-826b-58e47e0e304b* and *08d542b9-071f-4e16-94b0-74abb372e3d9* respectively. The identifiers are the same in all tenants.

To create a new Groups policy to hold customized settings for the tenant, we run the *New-MgDirectorySetting* cmdlet to create the new policy from the template.

```

[PS] C:\> $PolicyId = (Get-MgDirectorySettingTemplate | ? {$_.DisplayName -eq "Group.Unified"}).Id
New-MgDirectorySetting -TemplateId $PolicyId

```

When the *New-MgDirectorySetting* cmdlet runs, it creates a new directory settings object. Any application that can access Azure AD can then check the settings to know what it needs to do to respect the policy. For example, when a user tries to create a new group, the client can verify that the user can take this action. To view the policy settings, run the *Get-MgDirectorySetting* cmdlet. In this case, many of the settings have non-default values.

```

[PS] C:\> Get-MgDirectorySetting | ?{$_.DisplayName -eq "Group.Unified"} | ForEach Values

```

Name	Value
CustomBlockedWordsList	
ClassificationDescriptions	General Usage:Anyone can access,External Access:Available outside the company,Internal Only:Must not be shared with external people,Confidential: Can only be disclosed with management permission
DefaultClassification	General Usage
PrefixSuffixNamingRequirement	
AllowGuestsToBeGroupOwner	False
AllowGuestsToAccessGroups	True
GuestUsageGuidelinesUrl	
GroupCreationAllowedGroupId	A3c13e4d-7083-4448-9224-287f10f23e10
AllowToAddGuests	True
UsageGuidelinesUrl	http://office365itpros.com/GroupGuidelines.html
ClassificationList	General Usage,External Access,Internal Only,Confidential
EnableGroupCreation	False

We will discuss how to update individual settings in the Groups policy using the *Update-MgDirectorySetting* cmdlet over the next few pages. Remember that the names of policy settings are case-sensitive, so be sure to type the names exactly as shown here (for example, "AllowToAddGuests" rather than "Allowtoaddguests"). If you use the wrong name, Azure AD cannot update the policy. Another thing to consider is that Exchange Online distributes mailboxes for a tenant across multiple servers that can run inside different Microsoft data centers, so it can take an hour or so before new or updated settings are active across a tenant. Finally, if you make a mistake and want to start over with a new group policy, you can do so by removing the directory settings object:

```

[PS] C:\> $PolicyId = (Get-MgDirectorySetting | ? {$_.DisplayName -eq "Group.Unified"}).Id
Remove-MgDirectorySetting -DirectorySettingId $PolicyId

```

In the rest of this section, we cover how to update the settings in the Groups policy to control classifications, group creation, naming, and group guidelines.

## Container Management for Groups, Sites, and Teams

Groups, Teams, and SharePoint sites are *containers* for information associated with Groups. Some host internal discussions, some hold confidential information that the tenant wants to keep restricted within the organization, and some exist to share information with guests. To help users understand how sensitive or confidential the information stored within a container is, Groups introduced the notion of classifications. A

classification is a text-only marker (like “Secret” or “Confidential”) assigned to a group and displayed by applications. A text-only marker can deliver a visual reminder to users when they work with important data, but the marker is no more useful than a sticker applied to a paper document. If you’ve deployed sensitivity labels in the tenant, you can replace classifications with labels. When you assign a sensitivity label to a group, Azure AD stamps settings defined in the label on the group. Today, the label settings for groups cover:

- **Privacy:** The group is private or public.
- **Guest access:** Whether the group owner can add guests to the membership.
- **Unmanaged devices:** Controls how group members can access content in the group’s SharePoint site when they connect with an unmanaged device.

Microsoft is gradually extending the number of label settings that apply to groups, such as external sharing behavior for SharePoint. Sensitivity labels have other settings, such as encryption and marking, but these settings are not applied to containers or to the individual items of data held in the containers. If you want to protect individual documents or messages, you can assign sensitivity labels to those items.

A sensitivity label doesn’t need to have container management settings. Any label without these settings is excluded by client applications when they display the list of labels available for assignment to a group, team, or site. For debugging purposes, you can check the set of labels by entering the following into a browser (replacing *tenant* with your tenant’s name):

```
https://tenant.sharepoint.com/_api/GroupSiteManager/GetGroupCreationContext
```

A tenant can choose to use classifications or sensitivity labels to mark groups. They cannot use both. In either case, when you apply a classification or sensitivity label to a group, the marking is synchronized across workloads. Clients connecting to the workloads can display the marking prominently in their user interfaces. (Figure 11-2).

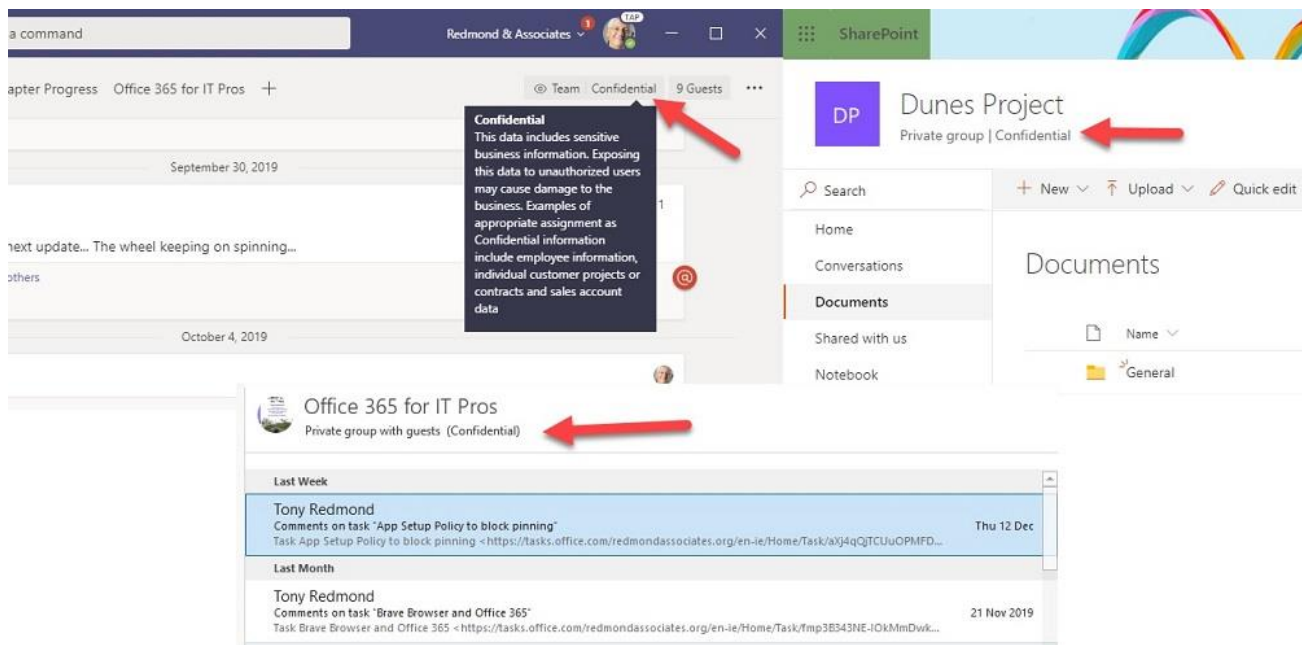

Figure 11-2: Sensitivity markings in Teams, SharePoint, and Outlook

To assign or update sensitivity labels for groups you can use:

- **Client applications:** OWA, Outlook, Outlook mobile, Teams, Teams mobile, SharePoint browser client.
- **Administrative portals:** SharePoint admin center (you can add a sensitivity column to see the labels applied to sites), Azure AD admin center, Teams admin center.
- **APIs:** PowerShell (*Set-UnifiedGroup* and *Set-SPOSite*). Support is also available to [assign sensitivity labels to Groups via the Graph API](#).

To use sensitivity labels instead of classifications, follow the directions in the Information Protection chapter to enable sensitivity label support for SharePoint Online. Then, update the groups policy to enable sensitivity labels.

```
[PS] C:\> $TenantSettingsId = (Get-MgDirectorySetting | ? {$_.DisplayName -eq "Group.Unified"}).Id
$templateId = (Get-MgDirectorySettingTemplate | ? {$_.DisplayName -eq "Group.Unified"}).Id
Update-MgDirectorySetting -TemplateId $TemplateId -DirectorySettingId $TenantSettingsId -Values
(@{'name'='EnableMIPLabels';'value'='true'} | ConvertTo-Json)
```

Like updates to any policy, changes can take some time to become active in all applications. Before making the switch, make sure that you have defined an appropriate set of sensitivity labels to use with groups.

## Creating Group Classifications

If you don't choose to use sensitivity labels, you can use text-only classifications as visual markers for groups. The *ClassificationList* setting in the Groups policy holds a list of classifications defined as a comma-separated list within quotes without spaces between the values. For example:

*"Confidential,External Access,Top Secret"*

The PowerShell commands shown below demonstrate how to update the classification settings for a tenant. The following steps occur:

- Fetch the existing settings.
- Update the *DefaultClassification* setting to be "Confidential." The default classification must exist in the classification list. Azure AD applies the default classification to a new group if the owner does not select another classification. Using a default classification is a feature requiring Azure AD Premium P1 licenses.
- Update the variable holding the *ClassificationList* setting with a comma-separated list of classifications. Some tenants use over 100 classifications, but it is often wiser to have a more restricted set so as not to confuse users.
- Update the variable holding the *ClassificationDescriptions* setting with more expanded explanations of what each classification means.
- Run the *Update-MgDirectorySetting* cmdlet to update the Groups policy with the new settings.

```
[PS] C:\> # Fetch current directory setting and extract values
$TenantSettings = Get-MgDirectorySetting | ? {$_.DisplayName -eq "Group.Unified"}
$Values = $TenantSettings.Values
($Values | ? Name -eq 'DefaultClassification').Value = "Confidential"
($Values | ? Name -eq 'ClassificationList').Value = "General Usage,External Access,Internal
Only,Confidential"
($Values | ? Name -eq 'ClassificationDescriptions').Value = "General Usage:Anyone can
access,External Access:Available outside the company,Internal Only:Must not be shared with external
people,Confidential:Can only be disclosed with management permission"
Update-MgDirectorySetting -DirectorySettingId $TenantSettings.Id -Values $Values
```

## Assigning and Changing Classifications

Usually, when creating a group, the owner selects the value that best describes the information held in the group from the list defined in the policy. Placing a classification on a group is optional and does not affect how the group works. Adding or updating a new classification or removing a classification from the list does not affect classifications placed on existing groups.

The *ClassificationDescriptions* setting is associated with the classification list. Although you do not need to provide descriptions, it is usually a good idea to give people a hint about which classification is the most appropriate for a new group or team. The classification might be enough, but if not, you can give some extra information for each classification in the form of a short description. Azure AD will not complain if you input long descriptions (say, more than 100 characters), but the space reserved to display descriptions in the user

interface of different applications might, so it is best to keep descriptions short and snappy. Make sure to include a description for each classification in the *ClassificationList* setting.

You can find the classifications assigned to groups with a simple PowerShell command:

```
[PS] C:\> Get-UnifiedGroup | ? {$_.Classification -ne $Null} | Format-Table DisplayName, Classification
```

To change a group's classification after creation, tenant administrators or group owners can edit the property through a client. For example, in the Teams desktop or browser clients, use **Edit team** and then change the setting. In the SharePoint Online browser app, the classification is available in **Site information**, while in OWA and Outlook you can change the classification through the **Edit group** option. Alternatively, use the *Set-UnifiedGroup* cmdlet to make the change. Make sure that you use a value from the list in the policy as otherwise, the cmdlet will fail:

```
[PS] C:\> Set-UnifiedGroup -Identity Hydra -Classification "General Usage"
```

Groups created with PowerShell do not have a classification unless one is specified when running the *New-UnifiedGroup* cmdlet. To fix the problem, you can run this command to assign a default classification to all unclassified groups:

```
[PS] C:\> Get-UnifiedGroup | ? {$_.Classification -eq $Null} | Set-UnifiedGroup -Classification "Internal Only"
```

## Switching from Classifications to Sensitivity Labels

No automated migration process is available to replace classifications assigned to groups with sensitivity labels. To start, you need to understand how classifications are used within the organization and figure out which sensitivity label is the most appropriate replacement. After you know how to replace the classifications, you can update groups manually or write some PowerShell to read classifications from groups and assign the most appropriate label. The code below uses a simple *Switch* statement to select the label to assign based on the classifications assigned to a group. After selecting the label, the script calls the *Set-UnifiedGroup* cmdlet to update the group. The classification for each group remains unchanged.

```
[PS] C:\> # Switching starts...
$PublicLabel = "2fe7f66d-096a-469e-835f-595532b63560"
$InternalLabel = "27451a5b-5823-4853-bcd4-2204d03ab477"
$SecretLabel = "81955691-b8e8-4a81-b7b4-ab32b130bff5"
$ConfidentialLabel = "1b070e6f-4b3c-4534-95c4-08335a5ca610"
# Find groups in the tenant that haven't already been assigned a sensitivity label
$Groups = Get-UnifiedGroup -ResultSize Unlimited | ? {$_.SensitivityLabel -eq $Null}
If ($Groups.Count -eq 0) { Write-Host "Congratulations - you've switched over to sensitivity labels"
}
Else {
  ForEach ($Group in $Groups) {
    Switch ($Group.Classification)
    {
      "General Use"      {$LabelToApply = $InternalLabel}
      "External Access" {$LabelToApply = $PublicLabel}
      "Internal Only"   {$LabelToApply = $SecretLabel}
      "Confidential"    {$LabelToApply = $ConfidentialLabel}
      Default           {$LabelToApply = $InternalLabel }
    }
    Write-Host "Processing" $Group.DisplayName
    Set-UnifiedGroup -Identity $Group.DistinguishedName -SensitivityLabelId $LabelToApply
  }
}
```

As you can see, we define variables to hold the GUIDs for several sensitivity labels. You can discover the GUIDs for labels by running the *Get-Label* cmdlet (after connecting to the compliance endpoint).

It takes a little while for the new label settings to synchronize from Exchange Online to SharePoint Online and Teams. To check that the right label is assigned to a site, you can run the *Get-SPOSite* cmdlet and examine the *SensitivityLabel* property. For example:

```
[PS] C:\> Get-SPOSite -Identity https://office365itpros.sharepoint.com/sites/BankingTeam | Format-Table Title, SensitivityLabel
```

```
Title          SensitivityLabel
-----          -
Banking Team   f5b1ba01-59f5-4ba0-b73b-f60e348cdc6e
```

## Controlling Group Creation

If a tenant allows unrestricted creation of Groups, each licensed user in the tenant can exploit twenty-two separate ways available across a spectrum of clients and applications to create up to 250 groups. A thousand-user tenant therefore might end up with 25,000 user-created groups to add to the groups created by administrators. Allowing people to create the groups they think they need through a self-service model is in line with Microsoft's original view that control over groups should be user-led. Although the model gives users the power to decide what groups they need to collaborate with their colleagues, it's easy to see how chaos can result and why, in most cases, it is better when administrators put some thought and planning into the process of group creation and maintenance. This is especially true in large enterprises.

Previous experience with user-controlled creation of shared objects, such as the mayhem that often occurred in public folder hierarchies when anyone could create top-level folders in the early versions of Exchange, proves that if you allow users free rein to create new objects, you can expect a rapid expansion of those objects, many of which duplicate the purpose of other objects. The usual upshot of creating many groups for no good reason is user confusion. People do not know which groups to use for what reason, especially if you do not implement a naming policy and groups with duplicate names arise from Teams, Yammer, and Outlook. This can lead to chaos in the GAL with groups scattered amongst other mail-enabled recipients. Creating groups often leads to groups used for a period and then left to decay. It is to impose order on potential madness that tenants decide to exert control over who can create new groups. The group expiration policy helps to clean up unused groups and should be used whenever possible (if you have the necessary Azure AD Premium licenses). We discuss how the expiration policy works later.

Apart from the setting in the Azure AD admin center described above, administrative interfaces are not subject to the same controls over group creation as imposed on clients. Users holding administrative roles for the tenant, including Exchange Administrator, can create new groups using PowerShell or an administrator portal even when blocked by application-level controls. On the other hand, those holding administrative roles cannot create groups using clients like OWA or Teams unless they are allowed by policy. The administrative roles that can create new groups are:

- Global Administrator.
- Team Service Administrator (in the Teams admin center or Azure AD admin center).
- User Administrator (in the Microsoft 365 admin center or Azure AD admin center).
- Exchange Administrator (in the Exchange admin center or Azure AD admin center).
- SharePoint Administrator (in the SharePoint admin center or Azure AD admin center).
- Directory Writers (in the Azure AD admin center).
- Groups admins (in the Microsoft 365 admin center and Azure AD admin center).

In addition, groups created through administrator interfaces do not come within the scope of the group naming policy.

When a group creation policy is in place, Teams users cannot create new teams unless they're allowed by policy. However, if they are owners of Microsoft 365 Groups that are not team-enabled, they can create new teams from those groups.

## Using the Azure AD Policy to Control Group Creation

Follow these steps to create the settings to control the creation of new groups through the Groups policy.

**Create a group for the set of authorized users:** You need to know the set of users who can create new Groups. To define the set of authorized users, you create a group to hold their names. This can be a distribution list, a security group, or a group. A security group is the best choice for two reasons. First, if you create new groups through SharePoint, you need a security group to control this process. Second, unless you mail-enable the group, a security group does not appear in the GAL and is therefore less likely to be known to users. If you restrict group creation and do not specify a group for authorized users, only administrators can create new groups.

**Add the set of authorized users to the group:** Because Groups only exist in the cloud, the users who create new groups must have accounts homed in the cloud. Make sure that you add all the people you want to be able to create new groups as members of the security group. Being an owner of the group is insufficient. Include those who hold administrative roles so that they can create new groups from applications. Make sure that the members of the group have Azure AD Premium P1 licenses.

**Prepare to edit the Azure AD policy:** Because no user interface exists for this purpose, you must create the policy and populate its settings using PowerShell. The first step is to retrieve the object identifier for the group that you just created to hold the set of authorized users. This is easily done by running the *Get-MgGroup* cmdlet:

```
[PS] C:\> Get-MgGroup -Filter "displayName eq 'GroupCreationControl'"
```

Note the value of the *Id* property for the group you want to use.

**Use PowerShell to update the Azure AD policy:** Two controls are used for group creation:

- Set the **EnableGroupCreation** setting to *False* to show that only authorized users can create groups. To reset and allow anyone to create groups, update the setting to *True*.
- Populate the **GroupCreationAllowedGroupId** setting with the object identifier of the group holding the list of authorized users. This is the *Id* property retrieved using the *Get-MgGroup* cmdlet as described above. No check is done to establish what the identifier points to when you use it in a policy setting, so it is easy to make a mistake and end up in a situation where only an administrator can create a group. For this reason, you should avoid typing the identifier in manually and instead copy the value from the group properties shown in the Azure AD admin center or use PowerShell to retrieve the value.

**Members Only!** It's critical to understand that only the members of the nominated control group can create new Microsoft 365 groups. A common mistake is for an administrator to create the control group (and so become the owner) and then assume that they can create new groups. Administrators can create new groups, but only through administrative interfaces. They will be unable to create new groups using applications like Teams because they are not a member of the control group.

Together, the two policy settings tell applications that only the members of the authorized group can create new groups. In this example, we fetch the object identifier for the new group used to control group creation and the current settings of the Groups policy. The values are placed into variables and used to update the two settings with the necessary values. You can retrieve the group identifier of the security group with the *Get-MgGroup* cmdlet as described previously. We then write the new values for the settings back into the policy.

```
[PS] C:\> $GroupId = (Get-MgGroup -Filter "displayName eq 'GroupCreationControl').Id
$TenantSettings = Get-MgDirectorySetting | ? {$_.DisplayName -eq "Group.Unified"}
$Values = $TenantSettings.Values
($Values | ? Name -eq 'EnableGroupCreation').Value = "false"
($Values | ? Name -eq 'GroupCreationAllowedGroupId').Value = $GroupId
Update-MgDirectorySetting -DirectorySettingId $TenantSettings.Id -Values $Values
```

After making the changes, you can check that the settings are as you expect. This code retrieves the name, identifier, owners, and current membership of the group used to control group creation.

```
[PS] C:\> $Values = (Get-MgDirectorySetting | ?{$_.DisplayName -eq "Group.Unified"}).Values
$GroupId = $Values |?{$_.Name -eq "GroupCreationAllowedGroupId"} | Select -ExpandProperty Value
[array]$Owners = (Get-MgGroupOwner -GroupId $GroupId)
[array]$OwnerNames = $Null
ForEach ($Owner in $Owners) {
    $OwnerNames += (Get-MgUser -UserId $Owner.Id).DisplayName }
[string]$OwnerNames = $OwnerNames -join ", "
Write-Host ("The name of the group defined to control group creation is {0} and its identifier is {1}. Its owners are {2}." -f (Get-MgGroup -GroupId $GroupId).DisplayName, $GroupId, $OwnerNames)
Write-Host ""
Write-Host "The accounts allowed to create new Microsoft 365 groups are:"
$Members = Get-MgGroupMember -GroupId $GroupId
ForEach ($Member in $Members) {(Get-MgUser -UserId $Member.Id).DisplayName }
```

Exchange Online stores details of some group policy settings in its organization configuration, so the following command also reveals who can create new groups:

```
[PS] C:\> $Members = Get-MgGroupMember -GroupId (Get-OrganizationConfig).GroupsCreationWhiteListedId
ForEach ($Member in $Members) {(Get-MgUser -UserId $Member.Id).DisplayName }
```

**Test that the new policy works:** A user included in the membership of the authorized user group should be able to create new groups from any application that supports the policy, including Planner, Teams, Dynamics, Stream, SharePoint Online, and OneDrive for Business as well as the Outlook and Teams mobile apps. Applications signal errors when a user who is not allowed to create a group tries to create a new group (something like *"The group couldn't be created. Your admin hasn't given you permission to create a new group"*).

**Lack of Granularity in the Creation Policy:** The use of a single policy to control group creation makes things simple. The downside is that once you restrict creation, the decision applies to all applications that use Groups for membership services. For instance, you might want to control the creation of new Plans but not Teams, but the same policy applies to both applications, as it does to Stream, SharePoint, and the other group-enabled applications. You should consider this point when you decide to apply restrictions to group creation.

A script demonstrating how to control the group creation settings in the Azure AD policy [is downloadable from GitHub](#).

## Changing the Group for Authorized Group Creators

Over time, you might want to swap the group specifying the set of users allowed to create groups for another group, perhaps for testing purposes. You can change the group specified in the policy by updating the *GroupCreationAllowedGroupId* setting in the policy with the identifier for the group. Like the code used to establish a group to control creation, we retrieve the identifier for a group called "Authorized Users" and use it to update the policy.

```
[PS] C:\> $GroupId = (Get-MgGroup -Filter "displayName eq 'Authorized Users').Id
$TenantSettings = Get-MgDirectorySetting | ? {$_.DisplayName -eq "Group.Unified"}
$Values = $TenantSettings.Values
($Values | ? Name -eq 'GroupCreationAllowedGroupId').Value = $GroupId
Update-MgDirectorySetting -DirectorySettingId $TenantSettings.Id -Values $Values
```

## OWA Mailbox Policy and Group Creation

Originally, OWA was the first client to support Groups and the *GroupCreationEnabled* setting in the OWA mailbox policy was the original mechanism to control group creation. This was acceptable when only Exchange Online clients could access Groups. Although many other applications now use Groups, the OWA mailbox policy is still in force today. The rule is as follows:

- Users allowed by the Azure AD policy for groups to create groups can always do so in non-Outlook apps (like Teams and Planner).
- Users allowed by the Azure AD policy for Groups to create groups can only do so in Outlook or OWA if the *GroupCreationEnabled* setting in the OWA mailbox policy assigned to their mailbox is *True*.

In other words, if you want to create groups through OWA or Outlook, the OWA mailbox policy assigned to your mailbox must have *GroupCreationEnabled* set to *True*. To understand the situation with policies and mailboxes in a tenant, this code looks for OWA mailbox policies that allow group creation and then reports the set of mailboxes assigned any of those policies:

```
[PS] C:\> [array]$OWAPolicies = Get-OWAMailboxPolicy | ? {$_.GroupCreationEnabled -eq $True} |
Select -ExpandProperty Identity
Write-Host ""
Write-Host "OWA Mailbox policies allowing group creation:"
Write-Host ""
$OWAPolicies
[array]$Mailboxes = Get-CasMailbox | ? {$_.OWAMailboxPolicy -in $OWAPolicies } | Select DisplayName,
OWAMailboxPolicy
Write-Host ""
Write-Host "The OWA Mailbox policy assigned to these mailboxes allows them to create Microsoft 365
Groups:"
$Mailboxes
```

The use of the OWA mailbox policy has persisted for longer than expected. It is now an anachronism in the context of modern group management. Nevertheless, while the policy setting persists and is respected by clients, it's important to make sure that the correct values exist in the policies assigned to users who are allowed to create groups by the Azure AD Groups policy. One way to do this is to assign an OWA mailbox policy with *GroupCreationEnabled* set to *True* to the members of the group allowed to create groups. Here's how to do this with PowerShell. The steps are:

- Find the group defining the accounts that can create groups set in the Azure AD Groups policy.
- Find the membership of the group.
- Loop through the membership and use the *Set-CASMailbox* cmdlet to update their mailbox with an appropriate OWA mailbox policy. In the example below, the OWA policy called "OWAFullAccess" has *GroupCreationEnabled* set to *True*.

The code is:

```
[PS] C:\> $TenantSettings = Get-MgDirectorySetting | ? {$_.DisplayName -eq "Group.Unified"}
$GroupId = $TenantSettings.Values | ? {$_.Name -eq "GroupCreationAllowedGroupId"} | Select -
ExpandProperty Value
$AuthorizedUsers = (Get-MgGroupMember -GroupId $GroupId | Select -ExpandProperty Id)
ForEach ($Mbx in $AuthorizedUsers) {
    Set-CASMailbox -Identity $Mbx -OwaMailboxPolicy OwaFullAccess }
```

Remember that this is a one-time operation. If you update the membership of the Azure AD group defined in the policy, you'll need to run the script again to make sure that all members have the appropriate OWA mailbox policy.

## The Groups Admin Role and Group Creation

The *GroupCreationAllowedGroupId* setting in the Azure AD policy for Groups allows tenants to dictate which users can create new groups. However, being allowed to create new groups by policy does nothing to allow

people to manage groups thereafter, so this work had to be done by tenant administrators. The situation is manageable in small tenants but becomes more problematic as the number of groups grows.

The Groups admin role is designed to solve the problem. This is a standard Microsoft 365 administrative role that can be assigned to user accounts through the Microsoft 365 admin center, Azure AD admin center (where the role is called Groups Administrator), or PowerShell. When assigned, the Groups Admin role allows the holder to manage the following actions for Groups:

- Create, edit, delete, and restore Microsoft 365 groups and Azure AD security groups.
- Create, edit, and delete group creation, expiration, and naming policies.

Groups admins can manage groups and group policies through administrative interfaces such as the Microsoft 365 admin center or PowerShell. Holding the role does not allow users to create new groups through client interfaces like OWA. If you want administrators to be able to create groups using all applications, you must add them to the group defined to control group creation in the Azure AD policy for Groups.

An [Azure AD custom role](#) can also be used for fine-grained control over group creation.

## Azure AD Group Naming Policy

Exchange Online has a naming policy that applies to distribution lists. Settings in the Azure AD for Groups policy can similarly control the display name generated for new groups created by applications like Teams and Yammer. You can update the policy with the Microsoft Graph or with PowerShell (see below) or you can use the Azure AD admin center (Figure 11-3).

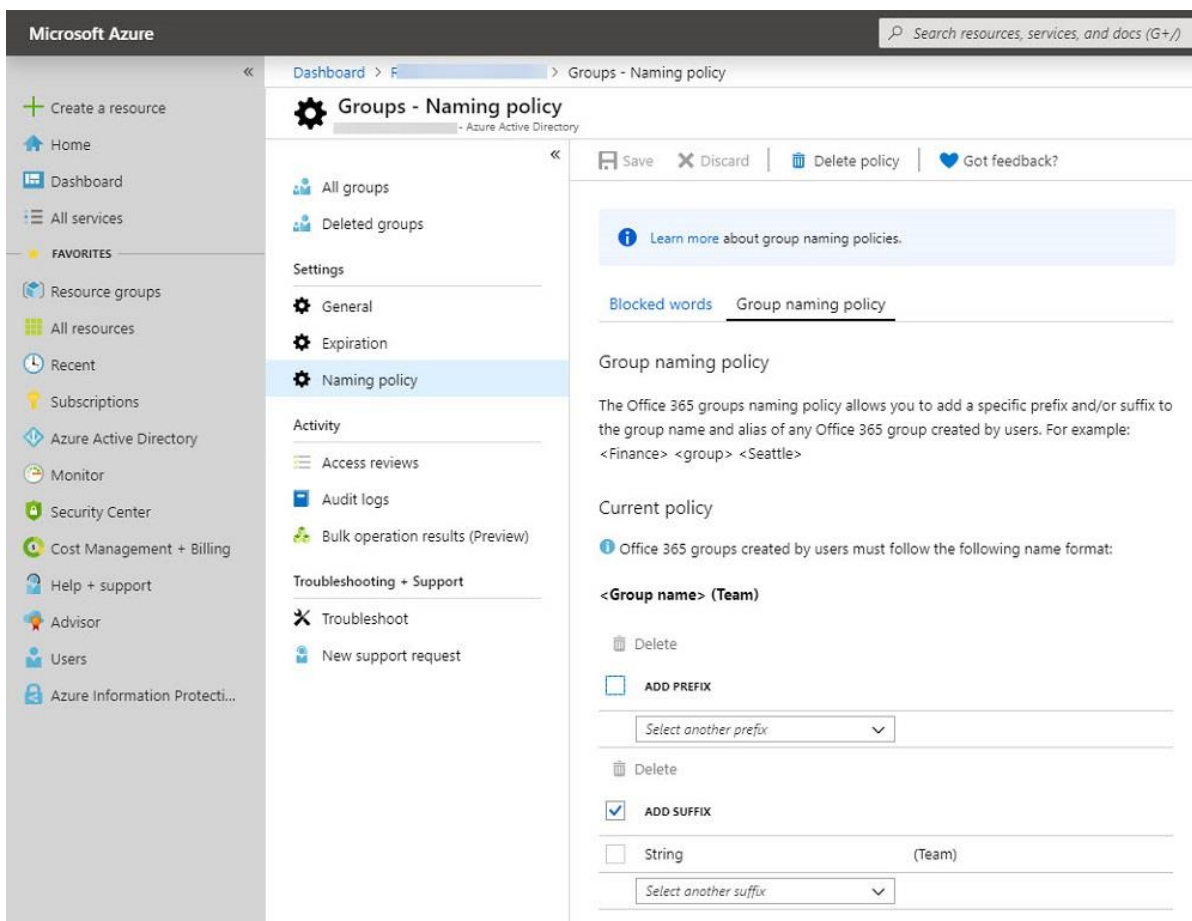

Figure 11-3: Working with the Azure AD policy for Groups in the Azure AD admin center

## Settings for the Groups Naming Policy

Two settings in the Groups policy control the form of display names users can give to groups when they create new groups or update the display name of existing groups:

- The ***PrefixSuffixNamingRequirement*** setting is a pattern controlling whether the group name has a prefix and suffix. The pattern can include fixed strings or reference user attributes such as the department, company, or office of the user who creates the group. Attribute values come from the information held in Azure AD from the account of the user creating the group. You can combine multiple attributes in a display name. Although combining multiple attributes to create a display name might seem like a good idea, it is best to favor simplicity over complexity when selecting what Azure AD attributes to use to construct a display name. The policy ignores values that are missing in the directory. If the tenant uses a naming policy for Exchange distribution lists, it is wise to use different prefixes for the two types of groups. Finally, the display name created for a group can be up to 256 characters. If you tend to use very long names for groups, you must ensure that the application of prefixes and/or suffixes to display names does not exceed the 256-character limit.
- The ***CustomBlockedWordsList*** holds a set of words that users cannot include in group names. These might be words that you consider offensive or have other reasons to exclude. Companies often include business terms that they do not want people to use in group names such as “CEO” to avoid the possibility that users communicate with the wrong person or group. The check against blocked words is case-insensitive and you do not have to enter the blocked words alphabetically. For practical purposes, you can enter as many words as you like in the list as Azure AD sets no upper limit. The Azure Active Portal allows you to upload a CSV containing blocked words to add to the policy.

The naming policy does not apply when administrators create groups. The assumption is that these users know what kind of display name to give to a group.

### Deciding on a Prefix or Suffix for Group Names

The original thinking about group names followed that of Exchange distribution lists and largely preferred using a prefix instead of a suffix to mark groups. The logic behind the choice is that this allowed users to find all the groups together in the Global Address List (GAL) and other address lists.

Useful as this approach is for applications that use the GAL, the reasons for using a prefix are less valid for applications like Teams, Yammer, and SharePoint which also create groups but don't use the GAL. A suffix is often a better approach for these applications because it is less visually intrusive as the marking moves to the end of the screen space reserved by the application to list group names (like the list of teams shown to the left of the Teams client). The choice to use a prefix or suffix is heavily influenced by what applications are in use within the tenant.

### Naming Policy in Action

Here is an example of how to update the settings used for the group naming policy. In this case, we want to add the prefix “O365Grp-” to the names of newly-created groups (and existing groups when a group owner updates their properties). We also specify a set of custom blocked words.

```
[PS] C:\> $TenantSettings = Get-MgDirectorySetting | ? { $_.DisplayName -eq "Group.Unified" }
$Values = $TenantSettings.Values
($Values | ? Name -eq 'PrefixSuffixNamingRequirement').Value = "O365Grp-[GroupName]"
($Values | ? Name -eq 'CustomBlockedWordsList').Value =
"Sexy,Stupid,Giggles,Funny,CFO,CEO,Shit,Payroll"
Update-MgDirectorySetting -DirectorySettingId $TenantSettings.Id -Values $Values
```

A small change is made to use a suffix instead of a prefix. For example, let's assume that we want to add the suffix “ (Team)” to the display names of new groups. The *PrefixSuffixNamingRequirement* setting for the policy is then:

```
$Settings["PrefixSuffixNamingRequirement"] = "[GroupName] (Team)"
```

After a naming policy is in effect, clients apply the policy when users create new groups or edit the display name for an existing group. [Many of the applications](#) which create Groups support the naming policy. Clients check the name entered by the user rather than the name as it will be after the application of the prefix and/or suffix dictated by the policy (what Microsoft refers to as the “decorated” name). Another point to remember is that the check for blocked words is for complete words rather than substrings. This is to avoid problems where a blocked word is part of another legitimate word (think “ass” as part of “class”).

The screenshot shows the 'New group' form in Office Web App (OWA). On the left, there is a 'New group' header and a description: 'Working together on a project or a shared goal? Create a group to give your team a space for conversations, shared files, scheduling events, and more. Read group usage guidelines'. Below this is an illustration of four people's heads. On the right, the form fields are:
 

- Group name:** 'Stupid silly payroll'. Below it, a preview shows 'O365Grp-Stupid silly payroll' with a red error message: 'The name can't contain 'Stupid''.
- Email address:** 'stupidssillypayroll'. Below it, a preview shows 'O365Grp-stupidssillypayroll@Office365ITPros.com' with a red error message: 'The address can't contain 'Stupid''.
- Description:** A text box with the placeholder 'Tell people the purpose of your group'.
- Settings:**
  - Privacy:** 'Private - Only approved members can see what's inside'.
  - Classification:** 'Confidential'.
  - 'Send all group conversations and events to members' inboxes. They can stop following this group later if they want to.'

 At the bottom are 'Create' and 'Discard' buttons.

Figure 11-4: OWA detects a blocked word in the name of a new group

Some differences exist in the detail of how a client applies the naming policy. In general, web-based clients like OWA (Figure 11-4) and Teams generate a preview of the group name after the application of the policy together with warnings when a user types in a blocked word for a group name. Other clients, like Outlook desktop and Outlook mobile clients, enforce the policy without giving so many visual clues as users type in names. Instead, these clients flag errors when they check the policy before trying to create or edit a group.

### Updating Group Display Names with PowerShell

When you implement a naming policy for groups, its effect is not retrospective, and the naming policy will not apply to existing groups. If you want to bring those groups into line with the policy, you must update the display name for older groups. One solution is to use PowerShell to make a one-time pass to find and update non-compliant group names. The example [script available on GitHub](#) extracts the group naming policy for the organization and uses it to figure out the display names for groups that don't currently follow the policy. The example works when either a prefix or suffix is used to create the display names for groups. Because it's PowerShell code, you can include other conditional processing. For instance, team-enabled groups might use one form of display names while those not used with Teams might have another.

If you implement a group naming policy, you might end up with some groups having display names set by policy and others named outside the policy guidelines. For example, if administrators create new groups or teams, the new objects take the display name as entered by the administrator. All other groups or teams in

the organization follow a different convention, meaning that you do not achieve the goal of having a common naming scheme for groups. If this happens, you can use code like that shown above to adjust the names of the non-compliant groups.

## Group Policy Settings in Exchange Organization Configuration

For convenience (mostly for OWA), copies of some group policy settings are held in the Exchange Online organization configuration. You can view these settings by running the *Get-OrganizationConfig* cmdlet:

```
[PS] C:\> Get-OrganizationConfig | Format-List Group*,Data*
GroupsCreationEnabled      : False
GroupsCreationWhitelistedId : 12cb915b-2365-4bed-baf6-6257b3543273
GroupsUsageGuidelinesLink  : Http://office365exchange.com/GroupGuidelines.html
GroupsNamingPolicy         : O365Grp-[GroupName]
DataClassifications        : <DataClassifications
Default="Confidential"><Classifications><Classification Name="General Use"
Description="Anyone can access" /><Classification Name="External Access" Description="Available
outside the company" /><Classification Name="Internal Only" Description="Must not be shared with
external people" /><Classification Name="Confidential" Description="Can only be disclosed with
management permission" /></Classifications></DataClassifications>
```

The group settings in the organization configuration are read-only and cannot be updated with the *Set-OrganizationConfig* cmdlet.

## Creating New Microsoft 365 Groups

If permitted by policy, a user can create new Microsoft 365 Groups through the following interfaces:

- **Admin portals:** The Microsoft 365 admin center, Exchange admin center (which also includes the option to upgrade a distribution list), Teams admin center (create a new team), and Azure AD admin center.
- **Email clients:** OWA, Outlook for Windows or Mac (Microsoft 365 Apps), Outlook for iOS and Android.
- **Applications integrated with Groups:** These applications include Power BI, Dynamics 365, Teams, Stream, Yammer, Flow, and Microsoft Planner.
- **SharePoint Online:** Create a new team site or link an existing team site to a Group; you also have the option to create a group from a hub site.
- **OneDrive for Business:** Create a new group-enabled site.
- **Programmatically:** With PowerShell using the *New-UnifiedGroup* (Exchange Online module), *New-MgGroup* (Microsoft Graph PowerShell SDK), or *New-Team* (Microsoft Teams module) cmdlets; or through the [Microsoft Graph Groups API](#).

The list of possible ways to create a group grows all the time. Depending on the apps and configuration used in your tenant, you might have other methods available for group creation than those listed above.

Administrators most likely create new groups through the Microsoft 365 admin center, EAC, or PowerShell while users are likely to use OWA or Outlook. To create a new Group from the Microsoft 365 admin center, navigate to the **Active teams and groups** page in the **Teams and Groups** section and select **Add a Group**. Make sure that you select *Microsoft 365* as the group type to create. The group creation wizard then gathers basic properties for the new group. These properties are:

- **Group name.** This is the display name visible to users through the directory. Make sure that the name conveys the intention and purpose of the group because it is highly likely that this is the sole information people will use when they decide whether to join the group. It is sensible to check the directory beforehand to ensure that the name you want to use does not clash with an existing object such as another group, a team, a distribution list, or a shared mailbox. You can rename a group after

creation by editing its properties or by running the *Set-UnifiedGroup* cmdlet to update the *DisplayName* property. The display name for a group can be up to 256 characters and can contain periods.

- **Description.** A free-text description to inform users about the intended use of the group. You can add whatever you like here but the text should tell users and administrators why the group exists and its intended use. In a multi-lingual organization, you might like to include translations of a text explaining the group's purpose in multiple languages. If a group holds confidential information, it is wise to make that fact known to group members here.
- **Owners and members.** You must add at least one owner to manage the group and its membership (it's generally better to have at least two owners in case one leaves the organization). You can add some group owners and members when you create the group or build out the group membership afterward by either adding new members or, for dynamic groups, by changing the query used by Azure AD to calculate its membership. You cannot nest a group inside another Microsoft 365 group, nor can you add a traditional distribution list to become a group.
- **Group settings.** Administrative interfaces such as the Microsoft 365 admin center allow administrators to assign an email address to a new group. User clients, such as OWA or Outlook, collect details of the group name for Exchange Online to create a unique SMTP email address and **Alias** (or mail nickname) for the new group. Exchange Online derives the alias by removing any spaces from the group name before checking against the directory to make sure that the value is unique. If not, the user must change something in the alias to make it unique (for instance, appending a number to its end). You can add periods to the alias if the period has other text on both sides. For example, "Sales.Group.1" is OK, while "Sales.Group.1." is not (see the documentation for the [New-UnifiedGroup](#) cmdlet for more information). Exchange Online then combines the default email domain for the tenant with the alias to form the SMTP address, which also must be unique. For example, if the alias is *SalesProfessionals* and the tenant's default email domain is *contoso.onmicrosoft.com*, the SMTP address will be *SalesProfessionals@contoso.onmicrosoft.com*. After creation, an administrator can add more email addresses to the group or change the primary email address. For instance, groups can have an address from a vanity domain. Azure AD prohibits the use of certain well-known or "highly-privileged" reserved aliases to avoid any possibility that users create groups with these words. Prohibiting the assignment of reserved aliases to groups is not unique to Azure AD (Google Workplace also includes this restriction). The reserved aliases include "abuse", "admin", "administrator", "hostmaster", "majordomo", "postmaster", "root", "secure", "security", "ssl-admin", and "webmaster." Only administrators can create groups that include these terms in identifiers (the Microsoft 365 admin center and EAC won't allow administrators to create distribution lists or mail-enabled security groups with a reserved alias).
- **Sensitivity.** If your organization uses sensitivity labels for container management, you can assign a label to the group. As explained in the Information protection chapter, the new group inherits several settings from the label
- **Privacy.** A group can either be Public, which means that anyone can join a group and access the resources available to the group (notebook, mailbox, calendar, document library, plan, and so on), or Private (the default), in which case only nominated members can access the group resources. Azure AD does not mark private groups in any special way within the directory, so they appear alongside public groups. For this reason, it is a good idea to consider giving a confidential group a name that does not create interest (or gossip) on the part of users. For instance, a group called "Planning 2020 Layoffs" is likely to attract unwanted attention! If users want to join a private group, they can apply to do so. A request then goes via email to the group owners, who then decide whether to add the user to the group membership. After creating a private group that needs to remain confidential, you can hide its existence from address lists to prevent the group from appearing in the GAL. Remember that you can change a group access type later.

- **Team-Enabled.** The Settings section includes the option to create a team for the new group. Use this option when a group's function is to manage the membership of a team rather than hosting Outlook conversations, so you should choose it to make the group available in Teams. It's entirely possible to access a group through Outlook and Teams, but it's more usual to choose one or the other. If you choose to team-enable a new group, make sure that the chosen group owners have Teams licenses as otherwise, they won't be able to access Teams. To help, when you come to assign group owners, the owner picker shows you which accounts have Teams licenses.
- **Role assignment:** You can [assign an Azure AD administrative role](#) to the group. Only private groups should hold Azure AD administrative roles. Assignment is permanent and cannot be reversed, so if a mistake is made, you must remove the group and recreate it.

Click **Next** to review the settings for the new group and then **Create group** to complete the process. After a short pause, the new group is ready for use.

## Managing Groups in the Microsoft 365 Admin Center

Some group settings are updatable only after the creation of a new group. These include:

- **Language.** The default language is the one for the user who creates the group. You can change the language at any time. Exchange Online uses the selected language in messages sent to group members, such as in the footer of copies of conversations. It has no impact on the content of group discussions or anything else belonging to the group.
- **Send copies of group conversations to members' inboxes.** The default is "On" for groups created using the Microsoft 365 admin center or an Outlook client. This means that the group adds new members automatically to its subscriber list. Subscribers receive copies of conversations and meetings via email and do not need to access the group mailbox unless they want to. Members can contribute to conversations by replying to the messages they receive. Individual users can disable or enable this setting as they like. Groups do not generate daily or weekly digests of conversations. Apart from guest members, groups used with Teams do not add new members to the subscriber list because their conversations are in Teams.

You can update settings through the Microsoft 365 admin center, Exchange admin center, Outlook clients, or PowerShell. In the Groups section of the Microsoft 365 admin center, you can do the following:

- Filter to only show all groups, team-enabled groups, or dynamic groups.
- Add group owners and members.
- Edit group settings, such as a group's display name, description, and whether to hide it from Exchange address lists.
- Allow external addresses to send emails to a group.
- Assign a new primary SMTP address for a group.
- Enable a group for Teams.
- Recover deleted groups.
- Export details of the groups to a CSV file. If a filter is applied, only the filtered groups are included in the export file.

## Updating Group Membership

After making sure that the new group is set up correctly, the next step is to build the group membership. To do this in the Microsoft 365 admin center, go to the Groups section, and select the group. Under the *Members* tab, you can add group owners and members, including guests.

Using a GUI works well when you need to add a small number of users. Scrolling up and down within a large list to find the right person to add to a group can lead to mistakes, as can searching the GAL to find the right person when they have a common surname. For instance, many organizations have multiple users named

“John Smith” or “Tom Jones.” The Microsoft 365 admin center shows the user principal names for group members, but these can also be similar and hard to decipher. Large tenants often solve the problem by including organizational prefixes like departments in display names to help people find the right user.

OWA automates the process somewhat by allowing group owners to import members from distribution lists or other groups. When this happens, Exchange Online expands the membership of the input group, and adds eligible accounts to the group membership, so it is an effective way to add many members quickly. It is possible to add members to groups programmatically, including the conversion of some types of traditional email distribution lists to become Groups. Updating group membership through PowerShell is not to everyone’s taste, but it can be the most efficient way to approach the task.

**Limits:** All software has limits and Groups are no different. Apart from the limits imposed by the underlying applications such as SharePoint Online storage quotas or the number of items that a folder can store in an Exchange Online mailbox (well over 100,000), Microsoft documents some specific limits for Groups. The most important are:

- A group can have up to 100 owners. The client user interfaces (including PowerShell) will prevent an attempt to add more. If you hit the limit, you must demote an existing owner before you can add a new one.
- An individual user cannot create more than 250 groups. This limit exists to speed up retrieval of the groups owned by an individual from Azure AD. However, the limit could become a factor in large tenants where central control governs the creation of new groups. The simple workaround is to make sure that you reassign ownership for newly-created groups to a different user and remove the account that created the group from its owner list. The limit does not apply to global tenant administrators.
- Outlook Groups with more than 1,000 users are supported with the caveat that access to the group mailbox (for conversations and calendar) will be slow. By contrast, the reduced number of connections to the group mailbox allows team-enabled groups to support 10,000 members.

A tenant can support up to 500,000 Groups. These limits apply to all Groups, including those used with Teams, Yammer, Planner, Dynamics 365, and Power BI. The number can be increased by Microsoft if necessary.

## Welcome Notifications

When you add someone as a member of a group using the Outlook apps or the admin tools (including PowerShell), the system generates a welcome notification for the user and sends it to them via email. The notification tells the person that they are now a member of the group, whether the group is public or private, and how many others are members. A link in the message (View group in Outlook) opens the group conversations using OWA. Exchange Online creates the notification in the language of the user (based on mailbox settings), but the footer information in copies of conversations received by group subscribers is in the language assigned to the group.

The exception to this rule is when a Teams client creates a group to manage the identity and membership of a team. The conversation activity for these groups takes place within Teams, so as users join these teams, Exchange Online generates the welcome message for the team instead of the group. The content of the two types of messages is similar, with the big difference being that the link in the Teams welcome message loads the target team in a browser.

## Creating Microsoft 365 Groups from the Azure AD Admin Center

Although you can create a new Microsoft 365 group from the [Azure AD admin center](#), this is not recommended. To create a group, select Active Directory, then Groups, and then create a new group. Set the membership type to Assigned and the group type to Microsoft 365. After you add members, Azure AD signals

Exchange Online to create the new group mailbox and SharePoint Online to create the new team site. The process of fully-provisioning group resources takes longer than it does when creating groups elsewhere too.

The synchronization process eventually completes, and the new group is available. However, because the Azure AD admin center focuses exclusively on managing Azure AD, it does not update the email-related properties managed in the Exchange Online directory. For example, you cannot assign the primary SMTP address for a new group to anything but the service domain for the tenant. By comparison, when you create a new group with OWA, Outlook, or EAC, you can populate those attributes (like if members receive updates via email) to create a fully-functional group.

## Updating Group Properties

Once the group exists, you can update its properties. Group maintenance operations like updating properties or membership are usually performed through the Microsoft 365 admin center or EAC. However, the admin centers don't support access to some group properties. For instance, you cannot add a MailTip or change the property which hides team-enabled groups from Exchange clients. You can manage these properties through PowerShell, which is one reason why some administrators script the creation of groups to ensure that their properties comply with the standards set for the tenant. For example, this command updates several properties for a new group, including a new primary SMTP address based on a vanity domain, a new alias, modification of the access type for the group, notes about the purpose of the group and allowing external users to contribute to group conversations by sending emails to the group.

```
[PS] C:\> Set-UnifiedGroup -Identity ProductMarketingGurus -PrimarySmtpAddress ProductMarketigGurus@Office365ITPros.com -Alias ProductGurus -AccessType Private -Notes "Product Marketing Discussions - Private Group" -RequireSenderAuthenticationEnabled $False
```

## Non-Latin Group Names

Exchange Online generates the primary email address for new groups based on the group identifier (alias), which is in turn based on the group name. When clients run in non-English languages, group owners can input non-Latin characters in the group name. Behind the scenes, clients generate the identifier and primary email address from the group name. Some clients use the [internationalized domain name](#) (IDN) standard to deal with non-Latin characters. Although this is generally a good thing and creates valid identifiers and email addresses, it can result in the creation of email addresses that are not user-friendly. To avoid the problem, use a group identifier (alias) that only includes basic Latin characters. Alternatively, you can assign a new primary SMTP address to the group post-creation.

## Email Address Policies and Groups

By default, Exchange Online assigns a newly created Group a primary SMTP address belonging to the tenant's default domain plus a secondary address for the service domain (the one ending in onmicrosoft.com). You can assign extra SMTP addresses to groups after creation, but you might want to assign SMTP addresses from separate domains depending on who creates the group.

Email address policies control the primary SMTP addresses Exchange Online assigns to new groups. Any of the known domains for the tenant are usable for this purpose. For example, this email address policy dictates that all new groups receive their primary SMTP address from the Office365itpros.com domain. The groups also receive a secondary proxy address from the service domain:

```
[PS] C:\> New-EmailAddressPolicy -Name Groups -IncludeUnifiedGroupRecipients -EnabledEmailAddressTemplates "SMTP:@office365itpros.com" -Priority 1
```

See [this page](#) for more information. Chapter 3 in the companion volume covers the use of address policies within a tenant.

## Assigning Send As and Send On Behalf Of Permissions to Groups

How to assign the *Send As* and the *Send On Behalf Of* permissions to mailboxes is explained in Chapter 6. You can also grant these permissions to Groups, or rather to the group mailboxes, to let group members (and non-group members) send messages as if they were the group (*Send As*) or on behalf of the group (*Send On Behalf Of*).

You can assign permissions by editing the group properties in EAC or through PowerShell. With EAC, edit the group and go to the group delegation settings. Enter the names of the users to whom you wish to assign the *Send As* and *Send On Behalf Of* permissions and then **Save**. Two cmdlets manage the permissions through PowerShell. The *Add-RecipientPermission* cmdlet assigns the *SendAs* permission and the *Set-UnifiedGroup* cmdlet assigns the *Send On Behalf Of* permission. Here is an example of how to set the two permissions:

```
[PS] C:\> Add-RecipientPermission Microsoft365Gurus@Office365ITPros.com -AccessRights SendAs -Trustee Kim.Akers@Office365ITPros.com
```

```
[PS] C:\> Set-UnifiedGroup -Identity "Microsoft 365 Gurus" -GrantSendOnBehalfTo @{"Add="John.Smith@Office365ITPros.com"}
```

After users have been assigned permissions, they can use [OWA or Outlook to send messages](#) as if they were the group.

## Controlling Group Email Traffic

For new groups created with OWA, the default setting is to subscribe members to the group. This means that Exchange Online distributes copies of any message sent to the group to all members, including tenant users and guests. Members can control the communications they wish to receive through **Manage Group Email** in the cogwheel menu, selecting whether to receive all messages, replies to their posts, calendar events, or no messages. They can also subscribe using the link in the group card displayed by Outlook.

The group's *AutoSubscribeNewMembers* property is *True* to subscribe members or *False* if not. You can change the *AutoSubscribeNewMembers* settings by:

- Editing the group properties with OWA or Outlook
- Updating the **Subscribe members** setting for the group in the Microsoft 365 admin center
- Running the *Set-UnifiedGroup* cmdlet. For example:

```
[PS] C:\> Set-UnifiedGroup -Identity Office365ITPros -AutoSubscribNewMembers:$False
```

Groups created by Teams set the *AutoSubscribeNewMembers* property to *\$False* because members of these groups don't communicate via emails. To see a list of groups that do not distribute copies of conversations and events to members, use the command:

```
[PS] C:\> Get-UnifiedGroup | ? {$_.AutoSubscribeNewMembers -eq $False } | Select Displayname
```

To receive copies of group conversations and events, members join the group's subscribers list. The *Get-UnifiedGroupLinks* cmdlet can report the subscriber list for a group:

```
[PS] C:\> Get-UnifiedGroupLinks -Identity Office365ITPros -LinkType Subscribers
```

No way exists to view the subscribers of a group except via PowerShell. The membership view presented by Outlook clients lists individual users as either an owner or a member and doesn't display any information about subscribers.

When a group is "chatty" with many conversations, some members might decide that they do not wish to receive updates via email and are quite happy to access the conversations in the group mailbox instead. Tenant users can control the updates they receive for a group through email through settings available in OWA, Outlook for Windows, Outlook for Mac, and Outlook mobile. Guests can ask a group owner to remove

them from the group's subscriber list if they do not want to receive updates. Even after removing a group member from the subscriber list, they continue to receive any conversations or replies posted to the group where replies include the special @ mention in the text (for instance, @Tony). The same is true when you explicitly add someone to the TO: or CC: list of a message sent to a group. Remember that the settings to control updates sent by email are specific to a group. If you want to stop updates arriving in your Inbox for every group you belong to, you must remove your account from the subscriber list for each group.

In OWA, the group card allows users quick access to different group resources (like conversations and files) and settings including the ability to control subscriptions. To access a group's card, find a message sent to the group and click on the group name in the message header. You can then move the **Follow in inbox** slider in the group card from **Off** to **On** (Figure 11-5) to control whether you receive updates via email. Behind the scenes, moving the slider to **Off** removes your account from the group's subscriber list while moving it to **On** adds your account to the subscriber list. Outlook for Mac and Outlook for iOS also support group cards with the **Follow in Inbox** setting for a group.

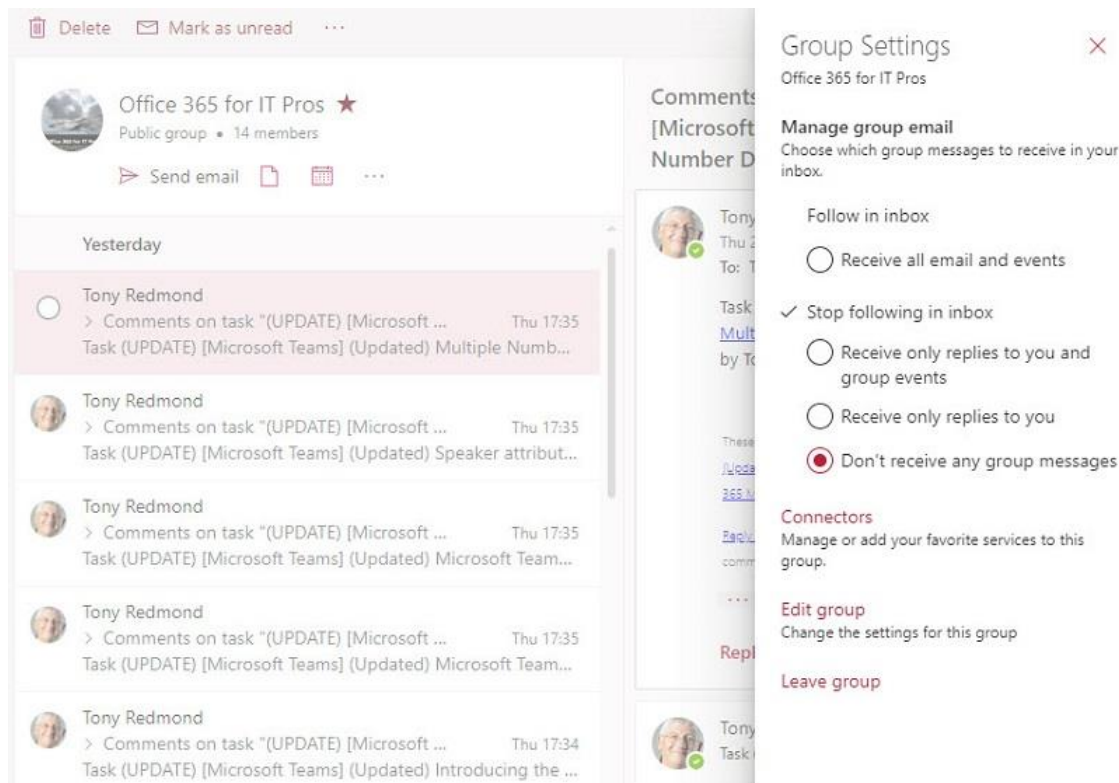

Figure 11-5: The Follow in Inbox setting controls if a user receives updates for a group by email

## Groups and Transport

Every group has an SMTP email address. Members and others (if allowed by the group settings) can use that address to route email to groups just like any other recipient. The messages eventually arrive at the Exchange Online mailbox server that hosts the active copy of the group mailbox. At this point, the Exchange transport service processes the messages before delivery to the group mailbox. All messages are subject to whatever processing the tenant implements through transport rules.

In addition to sending emails to groups, clients can post new conversations and reply to existing conversations. Depending on the client, the mechanism to post to a group is slightly different. Outlook handles a message posted to a group conversation much like any other message. Upon submission, the normal Outlook synchronization mechanism picks up the change in the local folder and dispatches the message to the Exchange Online transport service. Eventually, Exchange delivers the message to the group

mailbox where it shows up in a conversation. The item posted to the group stays in the user's Sent Items folder.

By default, the Exchange Online transport service does not deliver copies of messages posted by a user to their Inbox. If users want to receive copies of messages, they can either:

- Add their email address as a CC or BCC recipient.
- Use OWA settings to enable the *Send me a copy of email I send to a group* option (in the Groups section). An administrator can do this for a user by running the *Set-MailboxMessageConfiguration* cmdlet to set *EchoGroupMessageBackToSubscribedSender* to True. For instance:

```
[PS] C:\> Set-MailboxMessageConfiguration -EchoGroupMessageBackToSubscribedSender $True -Identity Jane.Sixsmith
```

The first approach works on an on-demand basis. In other words, the user receives copies of messages they post when they add their email address as a recipient. The second works for all groups where the user is a member of the group's subscriber list. Selecting *Receive all email and events* in the Follow in Inbox option described above adds a user to the subscriber list for a group.

OWA and mobile clients do not support offline working as the Outlook desktop clients do. Because all posts must go through the transport service, the possibility exists that a short delay might be obvious between the time when a user sends a post to the group and the post showing up in a conversation. The delay comes about through the need for the transport system to process the message through its pipeline to allow rules and routing to occur. To give the user confidence that their post succeeded, OWA and mobile clients create a "fake" post in the conversation that is only visible to the submitter. Behind the scenes, email processing continues and if a transport rule decides for some reason to reject the post, it does not deliver it to the group mailbox. The submitter will receive a non-delivery notification to tell them that an administrative rule blocked their contribution. At this point, OWA removes the fake post so that it no longer appears in the conversation. The transport service usually processes messages very quickly and the time elapsed between submission and removal is very short, but if delays occur, users might report a "disappearing item" if they ignore the non-delivery notification. It is all by design.

## Managing Groups with Outlook Clients

Users allowed to create new Groups can do this with Outlook (desktop, OWA, and mobile). Group owners can also update the settings of their groups through these clients. In this section, we review how to create a new group using Outlook desktop and the management options available in OWA.

The dependency on the group mailbox for conversation storage means that Outlook Groups have a lower membership limit than other applications which use the Microsoft 365 Groups membership model. However, the limit is soft and based on practice, and Outlook groups don't break if they have larger memberships. The limit exists because we know that concurrent access to a shared mailbox becomes problematic as the number of connections grows. Not every member will access the mailbox (to read conversations or look at the calendar) at the same time, so 2,500 members is a "safe" limit, assuming normal usage patterns. If you have groups where members seldom access the mailbox, you can have more members. There are groups in production today that surpass this number of members by a considerable margin because their owners know only a small percentage of the membership ever access the group concurrently.

## Creating and Editing Microsoft 365 Groups with Outlook (for Windows)

Three methods exist to create a new group with Outlook:

- Right-click on **Groups** in Outlook's resource navigation tree and then **New Group**.
- Click the **New** drop-down list in the **Home** section of Outlook's ribbon and then select **Group**.
- Click **New Group** in the group ribbon.

Figure 11-6 shows the information about the new group. You can select public or private for the privacy setting and select a value from the set of classifications defined in the Azure AD policy for Groups (if set). If the tenant uses sensitivity labels for container management, the selected label controls group settings like privacy and guest access. You can update the group to change the settings afterward. When all details are input, click **Create** to create the new group. After Outlook creates the group, you can add members by inputting the names of individual users, guest accounts, or groups. If you add a group as a member, Outlook expands its membership and adds any cloud mailboxes found in the membership to the membership of the new group. The account used to create an Outlook group joins the group automatically as an owner. Later, you can add or remove group members by selecting **Group Settings**.

Figure 11-6 is a screenshot of the "Create Group" dialog box in Outlook. The dialog has a title bar with a question mark and a close button. The main content area is titled "Create Group" and contains the following fields and options:

- Name:** A text box containing "Company Group Initiative". Below it, the text "Group name: Company Group Initiative" is displayed.
- Email address:** A text box containing "CompanyGroupInitiative" with a green checkmark on the right. Below it, the text "Group email address: CompanyGroupInitiative@office365itpros.com" is displayed.
- Description:** A text box containing "A group to coordinate all aspects of the company growth initiative project." To the right of the text box is a link for "Group Usage Guidelines".
- Sensitivity:** A dropdown menu currently showing "Limited Access".
- Privacy:** A dropdown menu currently showing "Public - Anyone in your organization can see group content." Below this dropdown, the text "The privacy setting is determined by the sensitivity you select." is displayed.
- Checkboxes:** A checked checkbox with the text "Send all group email and events to members' inboxes. They can change this setting later."
- More Settings:** A link labeled "More Settings".
- Create Button:** A button labeled "Create" with the text "You'll be able to add members after you select Create." next to it.

Figure 11-6: Creating a new group with Outlook for Windows

Group owners can update the properties of a group. You can change the name of the group, its description, its membership, privacy setting, the language used in messages generated by the group, and whether people from outside the group can send emails to the group to take part in group conversations. Other properties, like the primary SMTP address, are either invisible or you cannot change through Outlook. The component used to edit group settings is shared with OWA.

## OWA Group Management

The Manage Groups section at the bottom of the OWA's folder list and the Groups section in OWA's People section allow group members and owners to see details of the groups they belong to (including group membership), perform actions like leaving the group, and access the different resources associated with a group. Owners can edit the settings of a group. For example, in Figure 11-7, we see that the group is under the control of the Groups expiration policy and that it is due to expire in 18 days. The owner can go ahead

and renew the group or, if the group has served its function and is obsolete, allow it to expire and enter the removal cycle. During the removal cycle, owners have 30 days during which they can recover a deleted group. To do this, open the *Deleted* link under Groups, select the group you want to restore, and click the **Restore** button.

Notice that OWA puts groups with outstanding actions at the top of the list. One of the flagged groups has a pending join request while the others are awaiting renewal. To change group settings, use the **Edit** option.

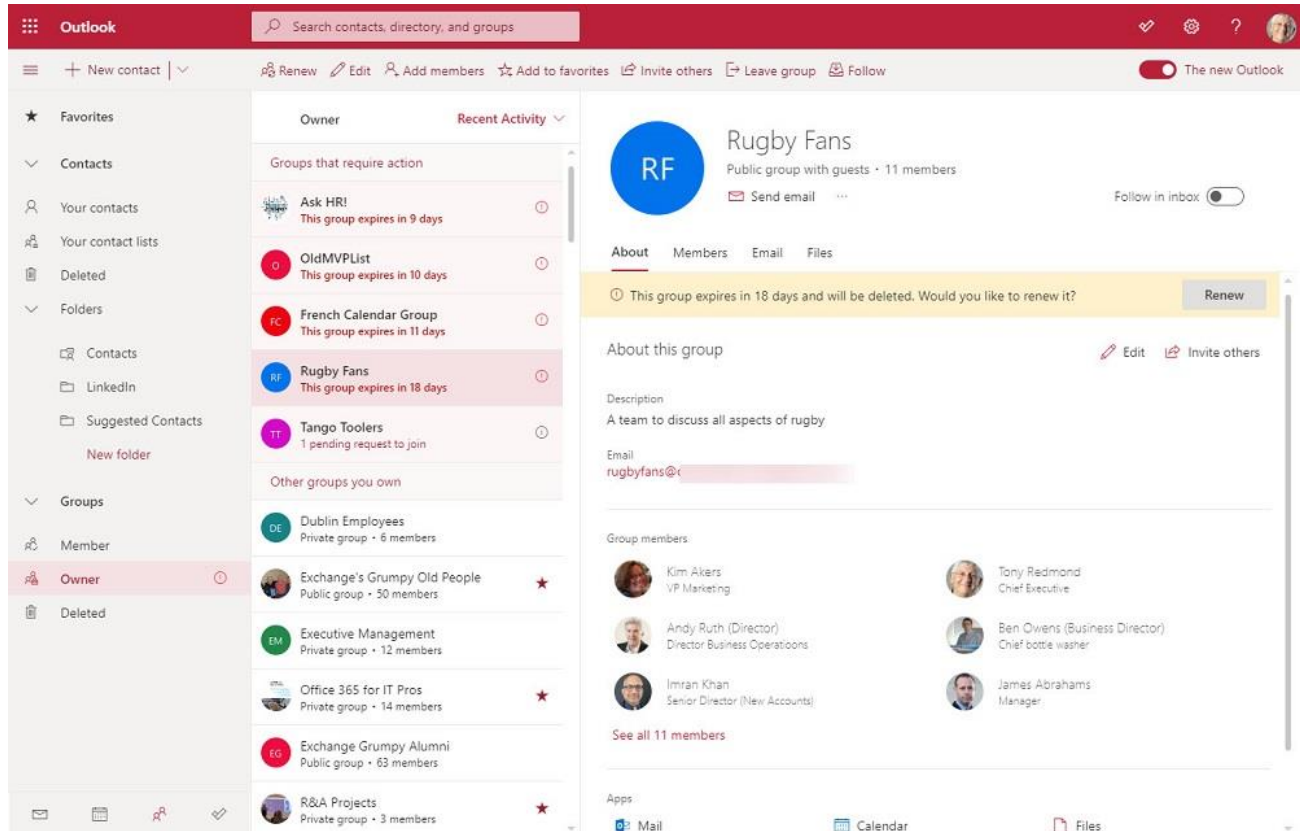

Figure 11-7: Managing the settings for a Group with OWA

## Guest Access to Microsoft 365 Groups

Microsoft 365 applications that support guest user access leverage the [B2B collaboration framework](#) for Azure AD to create and manage guest accounts. Microsoft 365 Groups use [Azure AD guest accounts](#) to enable access for external people to resources controlled by the tenant. Groups, Teams, SharePoint, and Planner support guest access. If an organization's Yammer network runs in Microsoft 365 native mode, [guests can be added to Yammer communities](#) using Azure B2B collaboration, but only if the guests have Microsoft accounts. A single guest account can be a member of multiple groups and teams. Any application that supports Azure B2B Collaboration can use existing guest accounts to grant access to their resources.

Apart from the membership limits that exist for different types of groups, there is no specific limit on the number of guests who can join a group (or team). For example, you can have a group with 1 local member (the owner) and 2,499 guests. See the Identities chapter for more information about the management of guest accounts in Azure AD.

### Guests Blocked by Risky Sign-in Policy

Tenants can control the type of sign-ins accepted by Azure AD by configuring an [Azure AD sign-in risk policy](#) that blocks suspicious sign-ins once the circumstances surrounding a sign-in reaches a set threshold. If their

accounts are deemed to be at risk, guest users attempting to sign-into the tenant can be blocked by policy. When this happens, the user's account cannot be unblocked in the tenant hosting their guest account. Instead, an administrator in their home tenant must [unblock the account](#) by taking an action such as resetting the account password or dismissing the risk detections.

## Adding Guests to a Group

Apart from administrative interfaces, you can use OWA, Outlook, or the Outlook and Teams mobile apps to add guest members to groups. A group owner or a tenant administrator can add a guest while other group members can request an owner to add a guest. For public groups, members can add guests to the group unless barred by policy (for instance, the sensitivity label assigned to the group might not allow guest members). In either case, when you add a guest to a group, an invitation is generated and sent to the guest to join the group. To start, open the group and click the *members* link (which shows the current number of members) to display the complete group membership, including any guests. Now click the **Add Members** icon and enter the email address of the guest you want to add. If the group settings allow guest access, the email address is checked against the tenant directory and your email address autocomplete list (Figure 11-8).

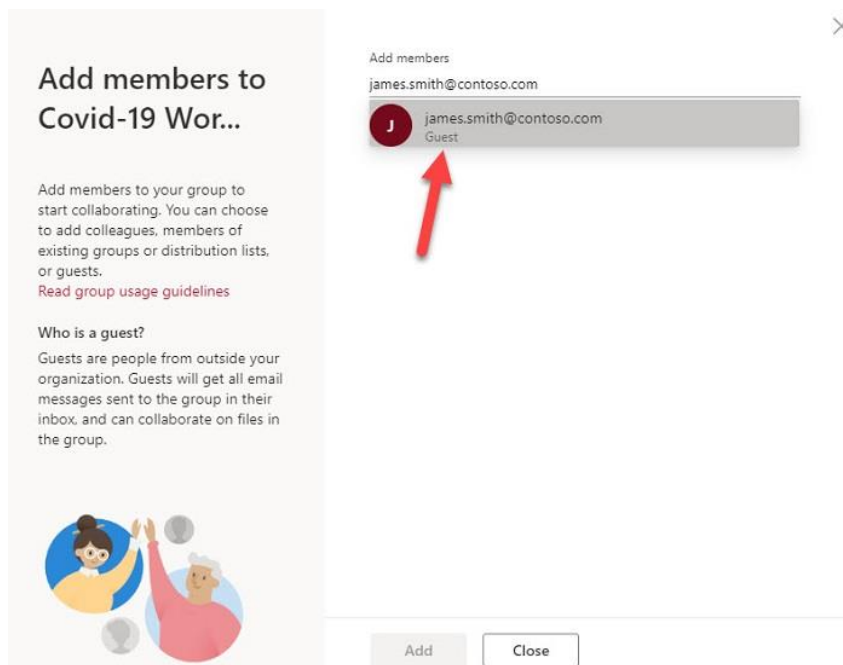

Figure 11-8: Adding a guest to a group with OWA

You are not restricted to using addresses already known to the directory as any valid email address is acceptable. If you input the email address of an account belonging to the tenant, they join the group as a regular member instead of a guest. Azure AD adds the guest to the group's membership and generates the email invitation after you click **Add**.

If group settings (for the tenant or a specific group) block guest access, OWA displays an error to say that you must contact an administrator to add a guest. OWA also flags an error if you try to add an email address for a guest that already exists for an unsupported object (like an email-enabled public folder).

**Guests and the Microsoft 365 admin center:** You can edit the membership of a group via the Microsoft 365 admin center and can add a guest to a group's membership there, providing that the guest account already exists in the directory. You can create new guest accounts in the Azure AD admin center or with an application that supports Azure B2B Collaboration, such as Groups or Microsoft Teams.

When OWA lists group members, it adds a "Guest" suffix to the display name of guest members as a visual reminder that this member is external. OWA also displays MailTips to warn users whenever they post new

conversations. These visual indications serve as a warning that members should not share or discuss confidential material within the group.

## How Guests Join a Group

When a guest is added to the membership of a group, Groups checks Azure AD to confirm whether a guest account for the email address exists in the tenant. If not, Azure AD creates a new guest account. An invitation then goes to the guest to let them know that they are now a member of the group. Should the guest wish to decline the invitation, the message has a link to allow the guest to leave the group. If not, they can click the link to access the group shared document library and confirm their membership.

If a guest does not receive (or loses) the email notification to tell them about their new membership status, the group owner can send them the URL for the document library. The guest can input the URL into a private browser session and go through the sign-in process to connect to the group. The private session makes sure that existing cached credentials don't interfere with the process. The URL for a group document library is in this form:

*<https://mytenant.sharepoint.com/sites/groupalias/>*

Another approach is to remove the user from the group and then add them again to force the regeneration of the invitation. This is perhaps the easiest way to solve the problem of lost invitations.

Some guests who receive invitations to join a group find that they cannot log into Microsoft 365 to access the group using the email address specified in the invitation. This might be because they have the same address registered elsewhere in Microsoft 365 (as a user in another tenant) and for a Microsoft consumer service, like OneDrive personal. In this case, the solution is to either use a different address to invite the guest or ask them to [rename their personal Microsoft consumer account](#).

A guest can also receive an invitation to a file held in a group document library through the action of sharing a document belonging to the group as a "cloudy attachment" (one where the attachment is a link to the content held in a OneDrive for Business or SharePoint Online library rather than a complete copy of the document). Clicking the attachments invokes the invitation to access the document.

If the guest chooses to accept the invitation, two conditions can occur. First, they might already have a Microsoft (MSA) or Microsoft 365 account linked to the email address used for the invitation (including a consumer account for a service like Outlook.com). If so, they can use this account to authenticate with Microsoft 365 and access the group files.

If they do not have a Microsoft account, a redirect occurs to [invitations.microsoft.com](https://invitations.microsoft.com) and the user can sign-up for a Microsoft account, including creating a password, which in turn becomes the guest account in the tenant. Creating a fully functional guest account needs the guest to prove that they own the email address associated with the account. Azure AD sends a verification code to the email address specified by the person extending the invitation. When prompted, the user gives the code to authenticate their address and complete the activation process, the guest account can then access the group.

**Finding group files:** Guests who have accounts in other tenants cannot add external groups to their set of favorite groups. Instead, to ensure fast access, they should bookmark the link contained in the invitation message as a favorite in their browser. Clicking the bookmark will then bring the guest to the Files section of the group.

## What Guests Can Access in Groups

Applications supporting the Azure B2B collaboration framework dictate what happens after someone accepts an invitation to access content managed by the application. In most cases, guests access group resources via browsers or mobile clients. Traditional desktop clients don't usually support guest access. You can't, for

instance, configure Outlook to open a group in another tenant to see the conversations in the inbox or the group calendar. Instead, Exchange Online uses an indirect access model to allow guests to participate in group interactions via email. They send emails to the group to contribute to conversations and receive responses via email, including copies of calendar events posted to the group calendar. Guests can then decide if they want to add these events to their calendars.

External people who are not group members can participate in conversations via email if the group's *RequireSenderAuthenticationEnabled* property is *False*. Generally, it is a bad idea to allow open access to a group because it creates the possibility that an attacker who obtains the group's email address will use it to send malware to the group, which can end up being copied to group members.

The *RequireSenderAuthenticationEnabled* setting does not affect guest members because they authenticate through their guest accounts. The exception to this rule is where the primary SMTP address of a guest is different from the email address used for their invitation. When this happens, attempts to respond to a conversation fail because the email address on the inbound item does not match the address of a group member. An easy workaround is to set *RequireSenderAuthenticationEnabled* to *False*, which allows any external user to email the group. Alternatively, you can create a guest to allow the person to log in using their normal UPN and send messages to the group using their primary SMTP address.

Guests can access to the SharePoint Online sites belonging to the groups to which they belong. They can use the SharePoint browser interface to open, add, edit, and remove items from the sites. In addition, people can share individual documents in document libraries from other SharePoint sites with guest accounts.

Table 11-4 summarizes the access available to guests to resources managed by Groups.

<b>Workload</b>	<b>Feature</b>	<b>Guests can access?</b>
Exchange Online	Contribute to conversations in the group mailbox	Yes (via email)
Exchange Online	View items in the group shared calendar	No direct access, but can receive updates via email
Exchange Online	Search group conversations	No
Exchange Online	Browse Global Address List for tenant (note: guests can use the Azure AD admin center to view directory information if enabled by the tenant)	No. (Note: Guests don't appear in any default Exchange address list)
SharePoint Online	Access a single document	Yes – via specific sharing invitation
SharePoint Online	Access the complete team site owned by the group/team	Yes
SharePoint Online	Search group documents	Yes
OneNote	Access group shared notebook	Yes
Information Protection	Members can post encrypted conversations to group conversations but cannot access messages protected with sensitivity labels. Guests cannot read files protected with sensitivity labels in the document library unless they are explicitly granted access by the labels.	No (apart from encryption)
Planner	Access plan associated with group	Yes
Teams	Access channel conversations in the team owned by the group and files stored in the group's SharePoint site. Conduct personal chats with other tenant members. Access private channels.	Yes
Power BI	Access Power BI workspace associated with group	No
Dynamics 365	Access customer data associated with group	No
Groups	Browse Azure AD for groups to join	No

Groups	Perform group management	No
--------	--------------------------	----

Table 11-4: Group functionality available to guests

## Restricting Guest Access to Confidential Material

A basic principle of the Microsoft 365 Groups membership model is that every member enjoys the same access to resources belonging to the group such as its document library, plans, and regular team channels. Owners maintain group membership and settings and have the same access to group resources as other members. The model is simple and easy to understand and manage, but some potential downsides exist that tenant administrators need to understand.

Consider files stored in a group's SharePoint document library. When a guest member joins a group, they receive the same access rights to documents and other files held in the document library. They can view, print, add, edit, check out, and perform all the file management actions available to other group members, including the ability to remove items. Two issues might occur:

- Guests will remove information from libraries.
- Guests can access confidential material.

The first issue is easily handled by using retention labels to prevent permanent deletion of important information. The second can be dealt with by using specific locations to store confidential information that external people should not access.

For instance, let's assume a project team needs some advice about a complex contract document from an external legal advisor. Three approaches are available:

- Allow the advisor full access to the group where the contract is stored along with other project files.
- Create a specially-defined group or team.
- Create a private or shared channel in a team and invite the external advisor to access the information through the channel.

The answer depends on the relationship with the external advisor and the need of the external advisor to access other supporting information that might not exist in a designated location.

If you store confidential material alongside other files in the document library, can you make sure that guests cannot access this content? The answer is yes, but you must apply sensitivity labels with encryption to protect the files from external access. As explained in the Information Protection chapter, a sensitivity label with encryption uses rights management to define the rights that users have over items. Users must be able to authenticate their access before SharePoint Online will decrypt and expose the content. Authors always hold full rights over files while other users might only be able to read the material. If a label does not grant rights to external users, they cannot open files protected by that label.

Sensitivity labels do not encrypt document metadata, so guest users can see the title and author information for protected files in a document library, even if they cannot open the content. Protected files circulated as email attachments to external people will also be inaccessible if the external users do not have the rights to open the files.

In all cases, it's important to understand the reasons for granting access to guests to a group or team and what resources they have access to if they become members before issuing any invitations.

## Mail User Objects Created for Guest Accounts

The creation of a mail user object in the Exchange Online directory (EXODS) happens the first time the guest joins a group or team in a tenant. The mail user object is a convenient holder of the guest account's email address to allow Exchange Online to route email to the guest. Exchange Online creates a mail user object even if a mail contact object with the same email address already exists. SharePoint Online and OneDrive for

Business also create guest accounts with associated mail user objects for sharing links. However, if you update an existing sharing link to add new guests, it doesn't result in the creation of mail user objects for the added accounts (perhaps because there's no need to send emails to them).

To mark their special purpose, mail user objects for guest accounts have a *RecipientTypeDetails* value of *GuestMailUser*. Do not remove one of these special mail user objects. If you do, you'll also remove the associated guest user account and the guest will lose any access they have to resources within the tenant, including sharing links and memberships of teams and groups.

By default, Exchange Online hides the mail user object for guest accounts from address lists. However, you can update the *HiddenFromAddressLists* property for a mail user object to force its inclusion in the GAL. Remember that it will take a day or so before newly unhidden objects appear in the OAB, but once unhidden, the objects show up in the online GAL and users can then address messages to the guest like any other recipient. Make sure that a mail contact for the guest isn't already present as un hiding the mail user object will then create a duplicate in the GAL.

```
[PS] C:\> Set-MailUser -Identity Julia.Foran_Contoso.com#EXT# -HiddenFromAddressListsEnabled $False
```

The presence of the mail user objects allows us to add guest accounts to groups using the *Add-UnifiedGroupLinks* cmdlet. In this example, we pass the alias created for the mail user object to tell Exchange Online which guest we want to add to the membership. As you can see, the alias is based on the UPN for the guest account.

```
[PS] C:\> Add-UnifiedGroupLinks -Identity MyGroup -LinkType Member -Links  
Julia.Foran_Contoso.com#EXT#
```

Alternatively, you can use the *New-MgGroupMember* cmdlet to add the guest to the group's membership.

```
[PS] C:\> $NewUser = (Get-MgUser -UserId  
John.Doe_outlook.com#EXT#@office365itpros.onmicrosoft.com).Id  
$GroupId = (Get-MgGroup -Filter "startsWith(displayname, 'Office 365 Adoption')" ).Id  
New-MgGroupMember -GroupId $GroupId -DirectoryObjectId $NewUser
```

Guests participate in group conversations via email, so we must make sure that they receive copies of group conversations via email. If the *AutoSubscribe* property for the group is *\$True*, new members automatically join the subscriber list when they become a member. If not, we need to add them as a subscriber.

```
[PS] C:\> Add-UnifiedGroupLinks -Identity MyGroup -LinkType Subscriber -Links  
John.Doe_outlook.com#EXT#
```

## Giving Guests a Face

Given the collaborative nature of Groups and Teams, it makes sense to update guest accounts with suitable photos. It's much better when people get a visual reminder of whom they work with. Applications like Planner, OWA, SharePoint, Teams, and OneDrive display photos if they are available for guest accounts. For example, the left-hand screen in Figure 11-9 shows a conversation within Teams where a guest account has a photo. This is a much nicer visual reminder about the person than the anonymous circle with two letters used for guests without photos.

Administrators can't upload a photo to a user or guest account through the Microsoft 365 admin center, but you can through the Azure AD admin center. Go to the Users section, select the guest account, and upload a JPEG or PNG file. The file must be less than 100 KB. If users can't give you a suitable photo, you might be able to use their profile picture from their LinkedIn.com account, as these photos are correctly sized and well under the 100 KB limit. If you must downsize a large picture, a 100 x 80-pixel size usually works. To have a better-populated directory, it is a good idea to update other information about the guest into Azure AD at the same

time, such as their first name, last name, display name, job title, company name, and contact details. Applications can then include this information in contact cards.

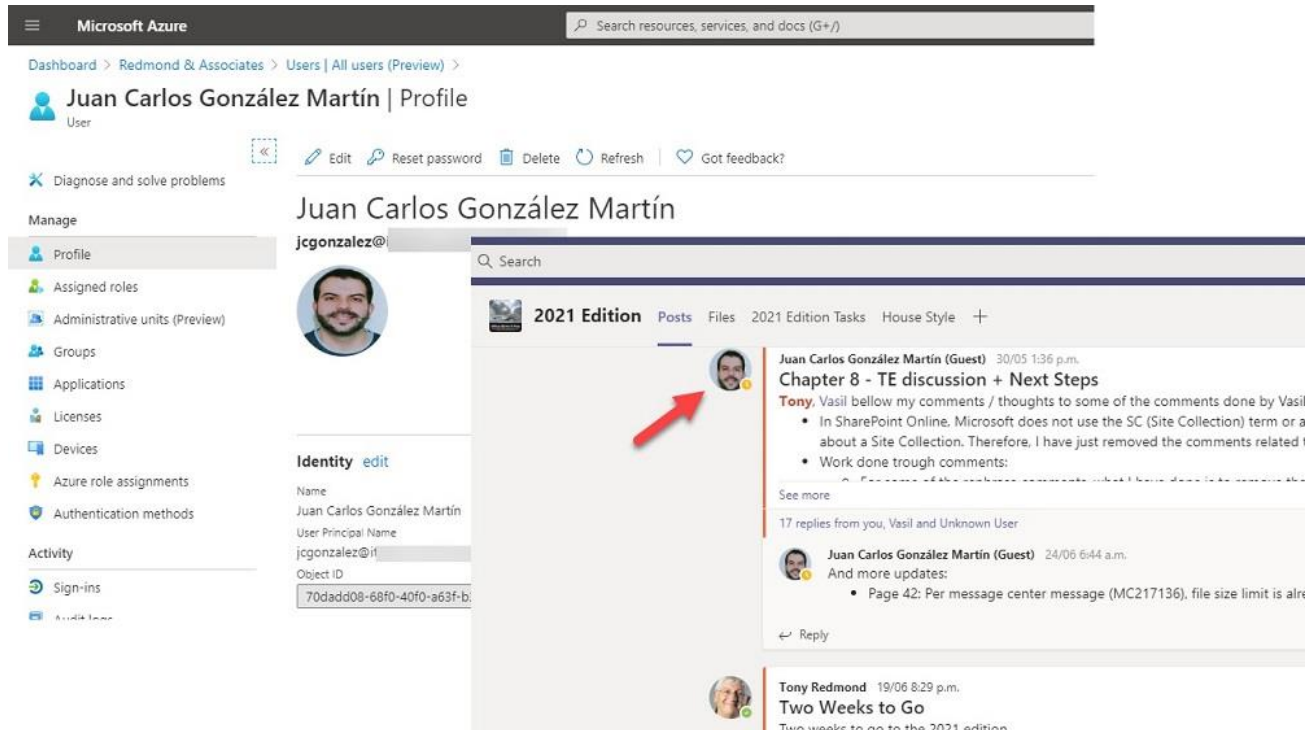

Figure 11-9: Using photos for Guest accounts

After updating guest accounts with photos, the background jobs responsible for synchronizing Azure AD with Microsoft 365 applications will make the images available in apps. This process might take up to a day to complete. To force Teams to synchronize, always update another attribute of the account, like the display name. This “tickles” Teams to let the app know that it should synchronize the account. Browser clients pick up newly available photos first. Mobile and desktop clients must synchronize their local caches with the workload directory. This can add another day or so before new images appear.

Another advantage of adding photos to guest accounts is that Outlook Mobile displays the photos when displaying messages from guests. Outlook and OWA can retrieve thumbnails from LinkedIn based on a person’s email address, but Outlook Mobile depends on thumbnails stored in user and guest accounts.

## Adding Guest Photos with PowerShell

You can also update the picture for Azure AD accounts using the `Set-MgUserPhotoContent` cmdlet. For example:

```
[PS] C:\> Set-MgUserPhotoContent -UserId a7eae252-3220-4254-91b2-c73918989a75 -InFile
c:\temp\GuestPhoto.jpg
```

You can then take this technique further to update all guest accounts in the tenant. For instance, let’s say that you want to flag guest accounts with a special image unless a photo is already present for an account. The idea is that the image will give people a visual clue of the guest’s status. This code does the job, even if it’s not very fast.

```
[PS] C:\> [array]$Guests = Get-MgUser -Filter "UserType eq 'Guest'" -All | Sort DisplayName
ForEach ($Guest in $Guests) {
    $PhotoExists = $Null
    $PhotoExists = Get-MgUserPhoto -UserId $Guest.Id -ErrorAction SilentlyContinue
    If (!$PhotoExists) {
        Write-Host "Photo does not exist for" $Guest.DisplayName "- updating with default guest logo"
        Set-MgUserPhotoContent -UserId $Guest.Id -Infile C:\Temp\DefaultGuestPicture.jpg
        Sleep -Seconds 3 }
}
```

```
Else { Write-Host "Photo found for" $Guest.DisplayName }
}
```

## Adding a Photo to Your Guest Account in Other Tenants

Applications do not allow guest users to update their photos, but this can be done with PowerShell. First, create a new PowerShell session and run the *Connect-AzureAD* cmdlet to connect to the target domain that hosts the guest account (unfortunately, the cmdlets in the Microsoft Graph PowerShell SDK don't allow guests to update their photos). Use the tenant service domain (the one with onmicrosoft.com) to connect.

```
[PS] C:\> Connect-AzureAD -TenantDomain remotedomain.onmicrosoft.com
```

If you don't know the service domain for a tenant, you can connect using the tenant GUID (a service like [What's My Tenant ID](#) tells you the GUID to use). For example, this command connects to Microsoft's tenant:

```
[PS] C:\> Connect-AzureAD -Tenant 72f988bf-86f1-41af-91ab-2d7cd011db47
```

In either case, you will be asked to authenticate. Use your normal account (it is linked to the guest account). Then, if you need to find the service domain, run the *Get-AzureADTenantDetail* cmdlet as follows:

```
[PS] C:\> $ServiceDomain = (Get-AzureADTenantDetail | Select -ExpandProperty VerifiedDomains |
?{$_.Name -Like "*onmicrosoft*"}).Name
```

The user principal name for your guest account in the tenant is usually composed of:

- The user principal name for your account in your home tenant, replacing the @ sign separating the username from the domain with an underscore.
- The string #EXT#@.
- The service domain of the target tenant.

Taking *Tony.Redmond@office365itpros.com* as an example, the user principal name for the guest account is *Tony.Redmond\_office365itpros.com#EXT#@remotedomain.onmicrosoft.com*.

Run the *Set-AzureADUserThumbnailPhoto* cmdlet to update the guest account. These commands create a variable to store the user principal name for the guest account, update the guest account with a photo, and check that photo data is present for the account.

```
[PS] C:\> $UserId = Tony.Redmond_office365itpros.com#EXT#@remotedomain.onmicrosoft.com
Set-AzureADUserThumbnailPhoto -ObjectId $UserId -FilePath c:\temp\tr.jpg
Get-AzureADUserThumbnailPhoto -ObjectId $UserId
```

It can take several days before the photo shows up in all applications.

## Managing Guest Account Properties with PowerShell

Details of guest accounts are available by running the *Get-MgUser* cmdlet. Here are three examples:

1. You can pass the user principal name of the guest account. The format of the user principal name assigned to a guest account is *username\_domainname#EXT#@servicedomain*.
2. You can search Azure AD for a guest account using a property of the account like the display name.
3. You can look for all guest accounts known in the tenant by looking for accounts with the *UserType* property set to "Guest".

```
[PS] C:\> Get-MgUser -UserId Michael_yandex.com#EXT#@office365itpros.onmicrosoft.com | Format-Table
UserPrincipalName, DisplayName
```

UserPrincipalName	DisplayName
-----	-----
michael_yandex.com#EXT#@office365itpros.onmicrosoft.com	Flayosc Worker

```
[PS] C:\> Get-MgUser -Search 'DisplayName:Michael' -ConsistencyLevel Eventual | Format-Table
UserPrincipalName, DisplayName
```

```
UserPrincipalName          DisplayName
-----
michael_yandex.com#EXT#@office365itpros.onmicrosoft.com  Flower Guru
```

```
Get-MgUser -Filter "Usertype eq 'Guest'" -All | Format-Table DisplayName, ProxyAddresses
```

Azure AD processes guest accounts like any other account. The *Update-MgUser* cmdlet updates the properties of an account, including guests. For example, here is how to change an account's display name:

```
[PS] C:\> $User = Get-MgUser -Search 'DisplayName:Michael Van Horenbeeck' -ConsistencyLevel Eventual
Update-MgUser -UserId $User.Id -DisplayName "Michael Van Hybrid"
```

Other attributes of the Azure AD object for a guest account include:

- **ObjectType:** User.
- **AccountEnabled:** True.
- **CreationType:** Invitation. You cannot change this.
- **Mail:** The SMTP email address for the guest.
- **MailNickName:** A modified version of the email address to show that this is a guest. For example, *Flowers\_outlook\_com#EXT#*. This attribute is a unique alias for the account.
- **OtherMails:** A multi-valued attribute used for different purposes for different sorts of accounts (for instance, accounts enabled for MFA store their "rescue" email address in this attribute). Guest accounts hold their SMTP email address in this attribute. SharePoint Online uses the attribute to control external file sharing, so if you remove this attribute for an account, you remove the ability for the user to access any files shared with them.
- **UserPrincipalName:** Used in the same manner as the UPN for other Azure AD accounts.
- **UserType:** Guest.

If you use the *Get-UnifiedGroupLinks* cmdlet to examine the membership list for a group that has guests, you'll see that the name assigned to guests is based on the first part of their user principal name.

```
[PS] C:\> Get-UnifiedGroupLinks -Identity BRK3001 -LinkType Members
```

```
Name          RecipientType
-----
TRedmond      UserMailbox
amitgutta.microsoft.com#EXT#  MailUser
chris.fiessinger_microsoft.com#EXT#  MailUser
e.zenz_microsoft.com#EXT#  MailUser
benny.niaulin_share-gate.com#EXT#  MailUser
t.redmond_live.com#EXT#  MailUser
flowers_outlook.com#EXT#  MailUser
```

In a hybrid environment where group membership synchronizes with an on-premises Active Directory via AADConnect, the synchronization process excludes guests because guest accounts do not exist in on-premises directories.

## Resetting Membership for Guests

Occasionally the creation process for a guest account does not complete as planned. The guest account exists in Azure AD and the guest shows up in a group's membership list, but whenever the guest attempts to access the group files, they receive an error telling them that their account is not in the tenant directory.

The quickest and simplest solution is to recreate the guest account. To do this, you must remove the account through the Microsoft 365 admin center or with PowerShell. Here's how to do the job with PowerShell:

```
[PS] C:\> Remove-MgUser -UserId t.redmond_live.com#EXT#@Office365ITPros.onmicrosoft.com
```

Now go back to a client and re-add the guest to force the creation of a new guest account. Everything should now work! The big downside with this method is that permanently removing a guest account also removes the membership for that user to all Groups and Teams and removes sharing permissions that the user might have in SharePoint and OneDrive for Business sites. For this reason, you should not remove a guest account without first thinking about the potential consequences.

## Mail Contacts and Guest Accounts

A basic rule of email transport is that an addressable object must have a unique email address. In other words, you cannot have two objects in a directory that share the same email address. Guest accounts are an exception because they can share an email address with a mail contact. If you add a new guest account and give the same email address as a mail contact, Groups creates the guest account based on the properties of the mail contact. You cannot do the reverse and create a mail contact using the email address of an existing guest account.

The need to support two objects with the same email address exists because the two objects serve different purposes. A mail contact exists to allow users to send emails to external contacts, individually or through a distribution list. Guest accounts also have email addresses. However, guest accounts don't appear in address lists (see below) but can gain authenticated access to application resources in a tenant.

### Including Guests in Exchange Address Lists

By default, guest accounts (or rather, the mail user objects created for guest accounts) do not appear in Exchange address lists. You can see the list of guest accounts known to Exchange Online with the command:

```
[PS] C:\> Get-Recipient -RecipientTypeDetails GuestMailUser | Format-Table DisplayName,
HiddenFromAddressListsEnabled, PrimarySmtpAddress
```

DisplayName	HiddenFromAddressListsEnabled	PrimarySmtpAddress
Chris Burger	True	Chris@burger.com
Jon Vickers	False	flayosc32@outlook.com
Benjamin N Smith	True	benjamin.n.smith@contoso.com
James Tracey	True	

We can see the guests that appear in Exchange address lists (*HiddenFromAddressListsEnabled* is *\$True*) and guests who have not yet accepted an invitation to join the tenant (its *PrimarySmtpAddress* is blank). If you want an account to show up in Exchange address lists (to allow users to email the guest), update the mail user object for the guest:

```
[PS] C:\> Set-MailUser -Identity vasil_michev.com#EXT# -HiddenFromAddressListsEnabled $False
```

The guest account appears in online Exchange address lists soon afterward. It will be included in the offline GAL the next time Exchange Online generates OAB updates and Outlook clients download and process updates.

Even if you do not update guest accounts to appear in address lists, you can still include them in distribution lists by updating the group membership with PowerShell. Here are two examples of how to add a guest to a distribution list:

- The first uses a lookup against Azure AD to fetch the registered email address for a guest user.
- The second uses the name of a mail user object created for a guest account. You could also pass the full user principal name for the account.

```
[PS] C:\> Add-DistributionGroupMember -Identity DL1 -Member (Get-MgUser -UserId
stale.hansen_cloudway.no#EXT#@office365itpros.onmicrosoft.com).Mail
Add-DistributionGroupMember -Identity "External Suppliers List" -Member
ExternalPerson_outlook.com#EXT#
```

## Guests in SharePoint and OneDrive for Business Pickers

If you want guests to show up in the people pickers used by SharePoint Online and OneDrive for Business, you can run the *Set-SPOTenant* cmdlet to update behavior for the tenant or *Set-SPOSite* for a specific site. For example:

```
[PS] C:\> Set-SPOTenant -ShowPeoplePickerSuggestionsForGuestUsers $True
```

# Controlling Guest Access to Groups

Four distinct pieces come together to control guest access to Groups:

- Azure AD must allow invitations to external users to join groups.
- The settings for Microsoft 365 Groups in the Microsoft 365 admin center must allow people outside the organization to access group content (see below).
- SharePoint Online must allow sharing of content stored in SharePoint and OneDrive for Business sites with external users.
- The Azure AD policy for Groups must allow guests to become members of groups.

These settings must be in place before Teams supports guest user access.

Because guest access for Outlook Groups primarily focuses on group document libraries, it follows that a prerequisite for sharing to occur is that SharePoint external sharing must be enabled for the tenant. This setting is available in the Sharing section of the SharePoint admin center. If a tenant does not allow sharing, guest access to Groups cannot work. SharePoint Online allows you to restrict sharing with users in specific domains (a whitelist). However, applications ignore this whitelist when adding guests to groups. If you want to prevent guests from domains outside the whitelist from becoming members of groups, you should implement the block policy available for groups and conduct a periodic check of group memberships. We will get to these topics shortly.

The Azure AD settings for the tenant must also allow invitations to go to guests. For instance, if you disable the “Members can Invite” setting in the **User Settings** section for Azure AD in the Azure portal, group owners cannot send invitations to people outside the organization.

## Group Settings for Guests

By default, Microsoft 365 tenants support guest accounts as members of Microsoft 365 Groups. If you want to disable this capability, edit the Microsoft 365 Groups settings in the org-wide settings section of the Microsoft 365 admin center (Figure 11-10) and uncheck both:

- **Let group owners add people outside your organization to Microsoft 365 Groups as guests.** Unchecking this setting removes the ability of group owners to add new guests. Administrators can still add guests to groups.
- **Let guest group members access group content.** Unchecking this setting removes the ability of guest members to access any group resources which are not explicitly shared with them. Existing guest members of groups will lose access to group resources.

A separate Microsoft Teams setting (*Allow guest access in Teams*) controls if team owners can add guests. You can have a situation where the tenant supports guest access outside Teams. For instance, you might want to allow guests to share SharePoint Online documents but not permit guests to be members of Teams.

### Microsoft 365 Groups

Choose how guests from outside your organization can collaborate with your users in Microsoft 365 Groups. [Learn more about guest access to Microsoft 365 Groups](#)

- Let group owners add people outside your organization to Microsoft 365 Groups as guests
- Let guest group members access group content  
If you don't select this, guests will still be listed as members of the group, but they won't receive group emails or be able to access any group content. They'll only be able to access files that were directly shared with them.

Figure 11-10: Microsoft 365 admin center settings for guest access to Groups

Optionally, you can use PowerShell or sensitivity labels to update the settings for a group to allow or deny guest access to that group. We discuss how to do this later.

## Using the Groups Policy to Control Guest Access

The Azure AD Policy for Groups applies to all applications that support guest access to groups, including Teams and Planner. The policy settings are independent of the sharing controls for SharePoint Online, which means that you can disable guest access as a member of groups while keeping the ability for users to issue invitations to external users to share specific items in SharePoint libraries and lists.

The Azure AD policy for Groups includes two settings to control guest access to groups. The *AllowToAddGuests* setting controls whether group owners can add guest user accounts to the membership of groups and teams. By default, the value of the setting is *True*, meaning that owners can add guests to any group in the tenant where the group settings do not block guests (we'll discuss how to block guest access to individual groups shortly). The *Get-MgDirectorySetting* cmdlet exposes the relevant policy settings:

```
[PS] C:\> $Settings = (Get-MgDirectorySetting | ? {$_.DisplayName -eq "Group.Unified"} | Select -ExpandProperty Values )

$Settings | ? {$_.Name -Like "*Allow*"}

Name                               Value
----                               -
AllowGuestsToAccessGroups          True
AllowToAddGuests                   True
```

### Stopping Guests Joining Group Membership

PowerShell cmdlets in the Azure AD module manage the settings in the Azure AD Policy for Groups. As an example, these commands update the *AllowToAddGuests* setting in the policy to *False* to stop owners from adding guest members. The organization-wide block on adding guest users set in the policy applies even when individual groups have a group-specific *AllowToAddGuests* setting of *True*. In other words, the organization-wide setting trumps an individual group setting.

```
[PS] C:\> $TenantSettings = Get-MgDirectorySetting | ? {$_.DisplayName -eq "Group.Unified"}
$Values = $TenantSettings.Values
($Values | ? Name -eq 'AllowToAddGuests').Value = "false"
Update-MgDirectorySetting -DirectorySettingId $TenantSettings.Id -Values $Values
```

Administrators can add guests to groups even if the *AllowToAddGuests* policy setting is *False*. The control applies only to owners. Administrators can add a guest using:

- **PowerShell:** By running *Add-UnifiedGroupLinks*, *Add-TeamUser*, or *New-MgGroupMember*.
- **Admin centers:** Through the Microsoft 365 admin center, the Azure AD admin center, the SharePoint admin center, or the Teams admin center.

Guest accounts that already exist in the tenant directory can join group membership immediately. However, if you need to add a new guest account to a group, you must first create the guest account through the Azure AD admin center. Once the guest account exists in the tenant directory, it can be added to a group's membership. The guest won't be able to access any resources until they redeem their invitation to join the tenant.

## Turning Off Guest Access

If you update the *AllowGueststoAccessGroups* setting in the Azure AD Policy for Groups to *False*, guests lose access to the groups to which they belong after a brief period to allow cached directory settings to refresh. Think of this as "flipping a switch" to turn access on or off if the need suddenly arises to limit sharing for a tenant. You can restore access later by updating the Groups policy. Guests will continue to have access to individual files for which they have received sharing invitations.

## Blocking Guest Access for Selected Groups

Individual groups inherit the settings of the organization policy and use these values unless overridden by settings for individual groups. When a group owner tries to add a new guest to the membership of a group or team, Groups checks the settings of the target group to check if it can proceed with the action. If allowed by the overall organization policy to control guest access to groups, the next check is against the setting for the target group to see if it supports guests. If both checks pass, Azure AD can add a guest to the group's membership.

Two methods exist to control guest access for individual groups:

- The method described below uses PowerShell to manipulate template settings for the group to block guest access.
- The settings for sensitivity labels include the ability to control guest access. When an administrator or owner applies a sensitivity label to a group, the group inherits the container management settings, including that for guest access.

In both cases, the group's *AllowToAddGuests* setting is updated to block or allow guest access.

### Blocking Guest Access to a Group with PowerShell

The *Get-MgGroupSetting* and *Update-MgGroupSetting* cmdlets retrieve and update group settings. The process to update the settings for an individual group is very like the one used to manipulate a policy setting in the organization policy. The first step is to retrieve the object identifier for a group and store it in a variable. We can do this by running the *Get-UnifiedGroup* cmdlet to retrieve the *ExternalDirectoryObjectId* property for the group. The object identifier is a GUID used to find and update the group object within Azure AD. For example:

```
[PS] C:\> $ObjectId = (Get-UnifiedGroup -Identity "Sales Professionals").ExternalDirectoryObjectId
```

Now, check that a settings object exists for the group. A group will have a settings object if it has a sensitivity label or if someone created the object using PowerShell:

```
[PS] C:\> $GroupSettings = Get-MgGroupSetting -GroupId $Group
```

If the *\$Settings* variable does not hold a value after running the command, you know that the group does not yet have a settings object. This is fine because it simply means that the group obeys the organization-level settings. To block guest access for the group, we create a settings object for the group as follows:

- Create a new directory setting template object using the values of the "Group.Unified.Guest" template object from Azure AD.

- Create a new group setting and populate the setting with a hash table containing the name *AllowToAddGuests* and the value *\$False*.
- The *ObjectId* pointing to the group comes from the command above.

Here's the code:

```
[PS] C:\> $GroupTemplateId = (Get-MgDirectorySettingTemplate | ? {$_.DisplayName -eq
'Group.Unified.Guest'} | Select -ExpandProperty Id)
New-MgGroupSetting -GroupId $ObjectId -TemplateId $GroupTemplateId -Values
(@{'name'='AllowToAddGuests';'value'='false'} | ConvertTo-Json
```

Note that you can't override the setting for guest access imposed by the sensitivity label assigned to the group with PowerShell.

After the block is in place, any attempt to add a guest generates an error. Existing guests remain in place and are unaffected by the block. To make sure that no guests have access to the group, you must remove existing guests from the group membership after you block guest access.

To reset a group to allow guests, you reverse the process and either set the value for the *AllowToAddGuests* setting to *\$True* and then update the settings object again or remove the policy from the group. This code uses the *Get-MgGroupSetting* cmdlet to read the values from the group and the *Update-MgGroupSetting* cmdlet to update the settings.

```
[PS] C:\> $GroupId = (Get-UnifiedGroup -Identity "Sales Professionals").ExternalDirectoryObjectId
$GroupSettings = Get-MgGroupSetting -GroupId $GroupId
Update-MgGroupSetting -GroupId $GroupId -TemplateId $GroupTemplateId -Values
(@{'name'='AllowToAddGuests';'value'='false'} | ConvertTo-Json) -DirectorySettingId
$GroupSettings.Id
```

Administrators can always add a guest to a group if necessary. Here is an example of a command to add a guest to a group with PowerShell. For this command to work, the guest account must already exist in the tenant directory.

```
[PS] C:\> Add-UnifiedGroupLinks -Identity "Confidential Group" -LinkType Member -Links
SomeUser_outlook.com#EXT#
```

The exception is for dynamic groups, where Azure AD calculates the group membership by running a query against the directory. You must adjust the query to make changes to the membership of a dynamic group as you cannot add an individual member.

See the PowerShell chapter for information about how to use a script to find groups matching certain criteria and block guest access to those groups.

## Restricting Guest Accounts to Certain Domains

Tenants can deploy an Azure AD policy called the *B2BManagementPolicy* to manage the domains that guest users can come from. To access the policy, go to the **External Identities** section in the Azure AD admin center, select **External collaboration settings**, and scroll down to **Collaboration restrictions**. Three values are available:

- Allow invitations to be sent to any domain (most inclusive): This is the default setting, and it means that invitations to join Groups and Teams can go to users in any other domain.
- Deny invitations to the specified domains: You can create a policy to block invitations going to specific domains. Microsoft believes that using a deny list is the most common scenario as most organizations know the domains with whom they do not wish to share information. For example, you might decide to block guest users with consumer email addresses, and block domains like Gmail.com, Yandex.com, Outlook.com, Yahoo.com, and so on. Including the domains of competitors in a deny list

is also sensible. When a deny list is in place, Azure AD blocks any attempt to invite someone to join a group or team if the invitee has an email address in one of the blocked domains.

- Allow invitations only to the specified domains (most restrictive): You can create a policy with an allow list, meaning that invitations can only go to domains in the list. Azure AD blocks any attempt to generate invitations to any other domain that is not on the list.

Applications do not implement blocks. This is done by Azure AD when an application tries to create a new guest account from a prohibited domain.

To create a policy with a deny list, click the deny list button and enter the domains to include and then Save (Figure 11-11). You can add up to 60 domains to a block or allow list. After you populate a list, the policy applies to all applications that use Azure B2B collaboration for external sharing, including Groups and Teams.

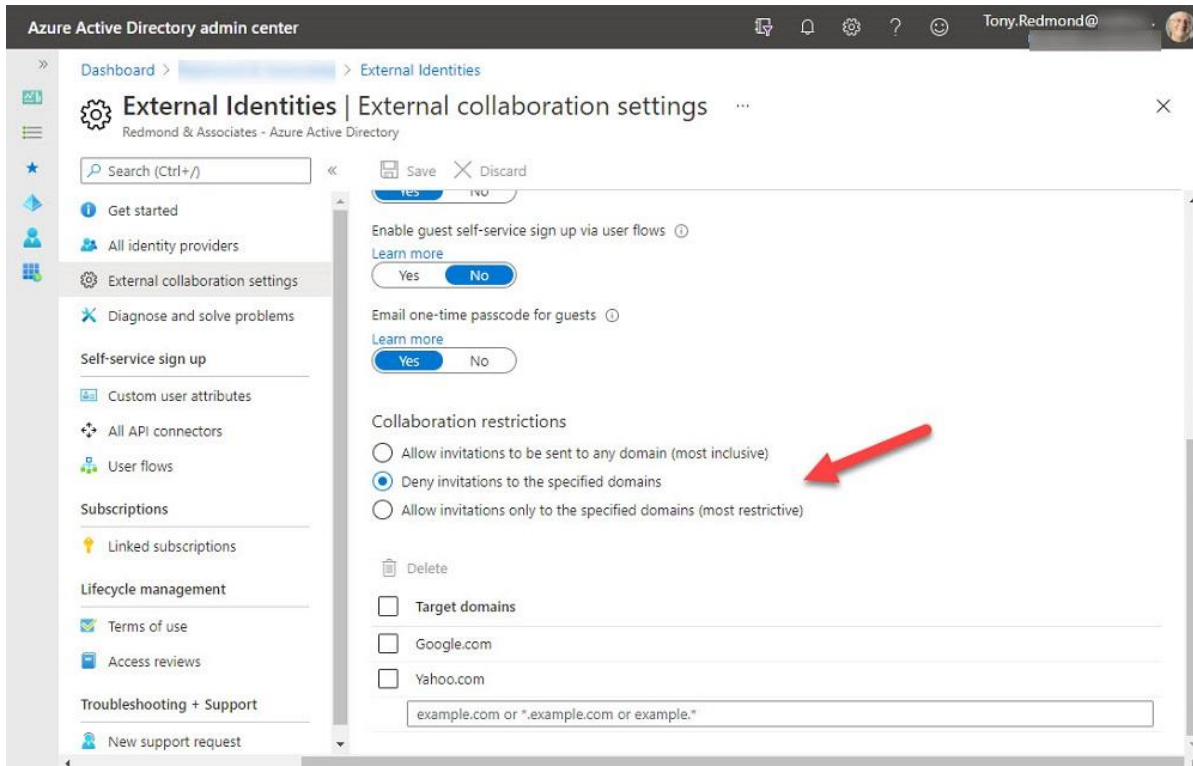

Figure 11-11: Adding domains to the deny list in the Azure B2B collaboration policy

Remember that the policy stops only the creation of new guest accounts. If you want to remove guest accounts from certain domains, you need to take separate action. We'll consider how best to do this shortly.

A tenant can only have a single deny or allow list. If you think that an allow list will work better than a deny list that is already in place, you must remove the current deny list and then create the allow list. The external collaboration list is separate from [a similar list to restrict sharing](#) for OneDrive for Business and SharePoint Online. One list blocks the ability to issue invitations to join groups or teams, and the other blocks sharing invitations for documents or folders.

If you create a deny or allow list to control access to certain domains, you should synchronize the domains with the [SharePoint Online restricted domains setting](#). Failure to do this can lead to inconsistencies. For example, a guest user might discover that they can view conversations in a team but cannot access the SharePoint document library.

### Finding the Source Domains for Guest Accounts

Before you create your collaboration policy, it's a good idea to check the domains where guests currently in the directory come from. This is easily done with a few lines of PowerShell. This code:

- Finds guests in the tenant.
- Extracts the domain from the user principal name for each guest and stores it in a list.
- Sorts the list and creates a hash table to count the occurrences for each domain, and then sorts the hash table in descending order.
- Outputs the result.

```
[PS] C:\> $Domains = [System.Collections.Generic.List[Object]]::new()
[array]$Guests = (Get-MgUser -Filter "UserType eq 'Guest'" -All | Select DisplayName,
UserPrincipalName, Mail, Id | Sort DisplayName)
ForEach ($Guest in $Guests) {
    $Domain = ($Guest.Mail.Split("@")[1])
    $Domains.Add($Domain)
}
$DomainsCount = @{}
$Domains = $Domains | Sort
$Domains | ForEach {$DomainsCount[$_]++}
$DomainsCount = $DomainsCount.GetEnumerator() | Sort -Property Value -Descending
$DomainsCount
```

Name	Value
----	-----
microsoft.com	59
outlook.com	11
quest.com	6
hotmail.com	5
gmail.com	4
emea.teams.ms	4

## Using PowerShell to Manage Domain Deny or Allow Lists

We can manage the Azure AD policy for external collaboration with PowerShell. For example, to see details of the current B2B Collaboration policy, use this code to run a Graph request against the policy endpoint:

```
[PS] C:\> $Uri = "https://graph.microsoft.com/beta/legacy/policies"
$Policy = Invoke-MgGraphRequest -Uri $Uri -Method Get
$B2BPolicy = $Policy.Value | ? {$_.displayName -eq 'B2BManagementPolicy'}
```

Name	Value
----	-----
deletedDateTime	
isManagementRestricted	
alternativeIdentifier	
definition	{{"B2BManagementPolicy":{"InvitationsAllowedAndBlockedDomainsPolicy":{"BlockedDomains...
keyCredentials	{}
id	14c3fc40-25fd-4f32-a0f0-c3fdd22f7de8
displayName	B2BManagementPolicy
type	B2BManagementPolicy
isOrganizationDefault	True
createdDateTime	08/12/2021 13:59:32

You can update the definition part of the policy with PowerShell, but it's easier and likely to be more accurate to update the policy through the Azure AD admin center.

## Finding Guests from Blocked Domains

Even with an Azure B2B Collaboration policy in place, some unwanted guests might already exist in group memberships. These unwanted guests might have joined groups before you implemented the policy or slipped in because a domain is not in the policy's blocked list. To fix the problem, you can scan the memberships of groups with guests to identify guests from blocked domains. The script works by first reading the set of blocked domains from the definition property in the Azure AD B2B Collaboration policy.

```
[PS] C:\> $Uri = "https://graph.microsoft.com/beta/legacy/policies/14c3fc40-25fd-4f32-a0f0-
c3fdd22f7de8/definition"
$Data = Invoke-MgGraphRequest -Uri $Uri -Method Get
```

```
$Policy = $Data.Value | ConvertFrom-Json
$BlockedDomains =
$Policy.B2BManagementPolicy.InvitationsAllowedAndBlockedDomainsPolicy.BlockedDomains
```

The script then finds Groups (including Teams) with guest members.

```
[PS] C:\> $Groups = Get-UnifiedGroup -ResultSize Unlimited -Filter {GroupExternalMemberCount -gt 0}
```

Finally, the code checks the guest members in each group to find if any come from blocked domains.

```
[PS] C:\> $Members = Get-UnifiedGroupLinks -Identity $Group.ExternalDirectoryObjectId -LinkType
Member | ? {$_.RecipientTypeDetails -eq "GuestMailUser" } | Select ExternalEmailAddress,
DisplayName, ExternalDirectoryObjectId
ForEach ($Guest in $Members) {
    $Domain = $Guest.ExternalEmailAddress.Split("@")[1]
    If ($BlockedDomains -contains $Domain) {
        Write-Host ("Found guest user {0} ({1}) in group {2}" -f $Guest.DisplayName, $GuestEmail,
$Group.DisplayName) }
}
```

Finally, the script generates a report of the guest accounts from blocked domains and outputs it as a CSV file. You can [download the full script from our GitHub repository](#). A blunter way to solve the problem is to look for guest accounts from a specific domain and remove them from Azure AD. This action removes the account from the membership of any group they belong to and stops access to any document shared through a sharing link.

```
[PS] C:\> $BadAccounts = [System.Collections.Generic.List[Object]]::new()
[Array]$Guests = (Get-MgUser -Filter "UserType eq 'Guest'" -All | Select Displayname,
UserPrincipalName, Mail, Id | Sort DisplayName)
ForEach ($Guest in $Guests) {
    If (($Guest.Mail.Split("@")[1]) -eq "Gmail.com") {
        $BadAccounts.Add($Guest.UserPrincipalName) }
} #End Foreach
If ($BadAccounts) { Write-Host ("Removing {0} bad accounts" -f $BadAccounts.count) }
ForEach ($BadAccount in $BadAccounts) { Remove-MgUser -UserId $BadAccount }
```

## Removing and Recovering Groups

The nature of all IT systems is that some groups become unwanted soon after creation or that the use of a group declines over time to a point where it falls into disuse. You might then decide to remove the group from the tenant. As noted previously, you can remove a group from the Microsoft 365 admin center, EAC, OWA, Outlook, a mobile app, or from a group-enabled application like Teams. When you remove a group, the action removes all the connected resources belonging to the group from SharePoint, Planner, Teams, Yammer, and so on. In addition, group owners or tenant administrators can remove a group by running the *Remove-UnifiedGroup* or *Remove-Team* cmdlets. In this example, we remove a group and suppress the prompt to continue that the cmdlet usually needs before it proceeds:

```
[PS] C:\> Remove-UnifiedGroup -Identity "Offshore Traders" -Confirm:$False
```

In addition to explicit removals by owners or administrators, if you operate an expiration policy, Azure AD removes groups automatically when they expire after a set period (explained later). In all cases, a removed group and any associated resources first enter a soft-deleted state and stay there for 30 days. During this time, an administrator or group owner can restore the group to make it accessible again to users. Alternatively, they can force the permanent removal of the group, which means that the resources of the group become irrecoverable. Table 11-5 lists the data recovered for a soft-deleted group.

<b>Group Resource</b>	<b>Data restored</b>
Azure AD Object	Group object, properties, and membership.
Exchange Online mailbox	Group mailbox holding conversations and group calendar. Also, the SMTP email address. Note – if the SMTP address has been assigned to another group, you cannot restore the original group until you update the SMTP address for that group.
SharePoint Online Team site	Group document library, including the shared OneNote notebook and the folders used by channels within Teams. The site is retained by SharePoint Online for up to 93 days. During this time, the site URL cannot be reused.
Planner	Group shared plan, including the plans created for channels within Teams.
Teams	Team channels and associated messages and metadata such as team and channel properties.
Yammer	Conversations in Yammer data store (for Yammer communities).

Table 11-5: Data restored when recovering a soft-deleted group

## Auditing Group Deletions

When you (soft) delete a group, Azure AD notes the details in a “Delete Group” audit record in the audit log. Later, when it removes a group permanently, Azure AD captures a “Hard Delete Group” audit record. Permanent deletion happens when the *Microsoft Online Service Garbage Collector process* runs, so the exact period when a group is in a soft-deleted state will vary from 30 days to perhaps a few days afterward.

The report and auditing chapter contains many examples of how to interrogate the audit log to understand when events occur. For instance, to look back and see when the garbage collector permanently removes groups, we look for “Delete Group” operations (audit records for both soft-delete and hard-delete actions are returned). We can then parse the audit data from the events found using the *Search-UnifiedAuditLog* cmdlet to generate a report using code like:

```
[PS] C:\> $StartDate = (Get-Date).AddDays(-90); $EndDate = (Get-Date)
[array]$Records = (Search-UnifiedAuditLog -StartDate $StartDate -EndDate $EndDate -Operations
"Delete Group")
$Report = [System.Collections.Generic.List[Object]]::new()
  ForEach ($Rec in $Records) {
    $AuditData = ConvertFrom-Json $Rec.Auditdata
    If ($AuditData.ResultStatus -eq "Success") {
      $ReportLine = [PSCustomObject]@{
        Timestamp = Get-Date $AuditData.CreationTime -Format g
        User      = $AuditData.UserId
        Action    = $AuditData.Operation
        Status    = $AuditData.ResultStatus
        GroupId   = $AuditData.Target.id[1]
        Group     = $AuditData.Target.id[3]}
      $Report.Add($ReportLine)}
$Report = $Report | Sort GroupId -Unique
$Report = $Report | Sort {$_.Timestamp -as [DateTime]} -Descending
$Report | Format-Table Timestamp, User, Group -AutoSize
```

The script sorts the report data twice. The first sorts by the group identifier to remove duplicate audit records which sometimes turn up in the audit log. The second sorts by date. The output is something like:

TimeStamp	User	Group
18/05/2022 16:37	Tony.Redmond@office365itpros.com	2021 Edition Book
15/04/2022 10:01	ServicePrincipal_1342cefb-7a89-4ee2-af90-c8443053e1e8	Plastic Production (Team)
30/03/2022 17:46	Administrator@office365itpros.com	March 2023 Sales Operations
25/03/2022 17:49	Administrator@office365itpros.com	Sun Seekers
15/03/2022 11:10	James.Ryan@office365itpros.com	Analytics Anonymous

These actions are all soft deletes. The hard deletes to remove the groups permanently happened a month later. The system removals are listed with "Certificate" as the User.

## Recovering a Deleted Group

As explained earlier, during the 30-day soft-deleted period, group owners can restore groups with OWA. Administrators can recover groups through the Microsoft 365 admin center, EAC, or with PowerShell. To recover a group with the Microsoft 365 admin center, select **Deleted groups** under the Teams & Groups section.

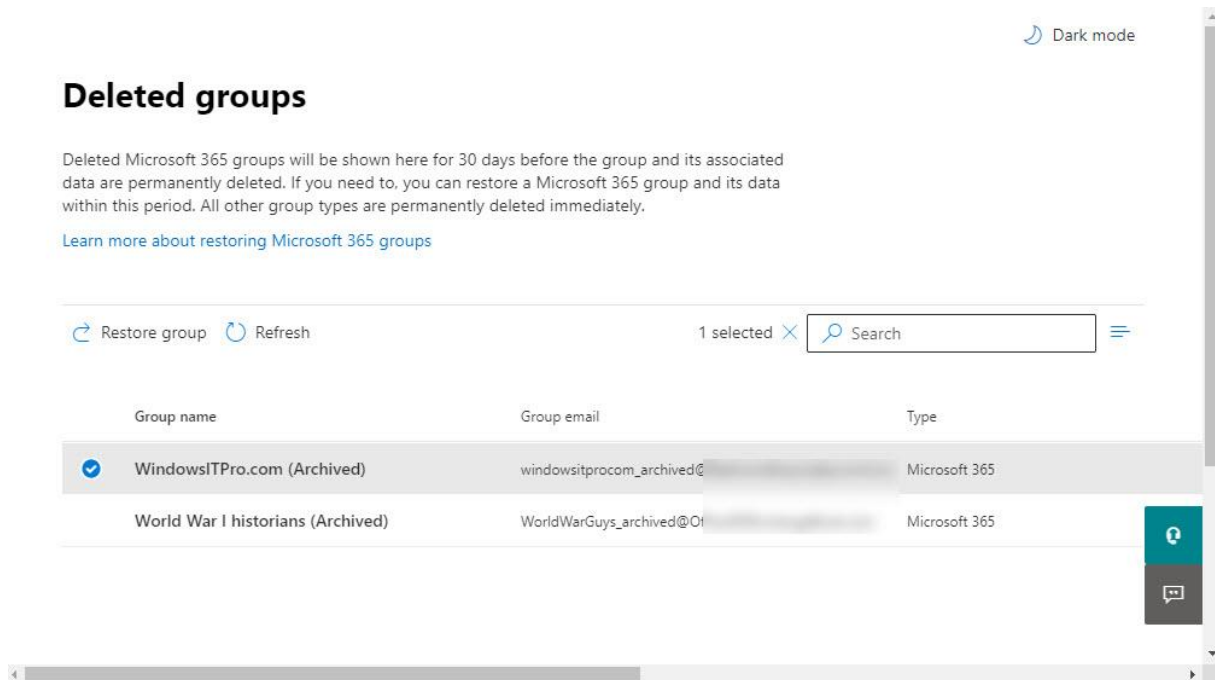

Figure 11-12: The Microsoft 365 admin center lists a set of deleted groups

In Figure 11-12 we see a set of deleted groups that have not exceeded their 30-day soft-deleted retention period. To restore a group, select it and either:

- Use the **Restore group** option in the group header.
- Click the group name to bring up the details pane, which has some basic information about the (display name, description, and email addresses), and click the **Restore group** button.

Both options perform the same processing to restore the deleted group. After a short delay, the group object is restored in Azure AD and begins the process of notifying the associated workloads to reconnect. As discussed later, it takes a little while for resources like the SharePoint site, a plan, or a team to be reconnected.

### Recovering a Deleted Group with PowerShell

The PowerShell command to list the set of deleted Microsoft 365 Groups is:

```
[PS] C:\> Get-UnifiedGroup -ResultSize Unlimited -IncludeSoftDeletedGroups:$True | ?
{$_ .WhenSoftDeleted -ne $Null} | Sort WhenSoftDeleted | Format-Table DisplayName,
PrimarySmtAddress, WhenSoftDeleted
```

You can mimic the steps taken by the Microsoft 365 admin center to recover a deleted group as follows. First, retrieve the object identifier for the group you want to recover:

```
[PS] C:\> $Object = (Get-UnifiedGroup -Identity "Group to Recover"
-IncludeSoftDeletedGroups).ExternalDirectoryObjectId
```

Now, use the identifier to recover the group.

```
[PS] C:\> Undo-SoftDeletedUnifiedGroup -SoftDeletedObject $Object
```

## Reconnecting Group Resources

Because many different applications use Groups, the recovery of a deleted group involves several complex operations. Recovery of a simple group (one that uses Exchange and SharePoint resources only) usually happens within a few minutes and should be complete within an hour. Depending on the current load within the service, recovery of a group that is enabled for Teams or Planner might take up to 24 hours before all the data is reconnected. The added delay is due to the need to synchronize multiple directories and often to ensure that data for Teams and Planner stored in Azure data services are restored correctly. It is also the case that when you restore a dynamic group, it can take up to 24 hours before Azure AD runs the query to calculate the group membership.

The first stage in recovery is to restore the group using the option available in the Microsoft 365 admin center or the Azure AD admin center. Once the group object is restored, Azure AD notifies each of the attached workloads to tell them to reconnect. As the workloads respond to the instruction, the full set of group resources come online to construct a fully-functional group.

Restoring the directory objects is only the first stage in the recovery process and does not mean that users can use the membership represented in the directory to access group contents. To perform further validation and before telling users that they can work with the group, you should check each of the workloads used by the group using clients to confirm that the expected conversations, files, plans, and chats are present. If you use a browser, make sure that you clear the browser cache or create a private session to avoid any problems caused by stale data. Teams is usually the last application to have its data restored and available to users.

If a workload is not ready an hour or so after the restore, wait for another hour, and check again. Because the restoration process involves many different connections, it could be that one of the steps in the process is waiting for another step to complete.

### Time Limit for Recovery

You have 30 days to recover a group following its deletion. After this period elapses, you might still be able to recover some information for a deleted group. For example, administrators might be able to recover files from the SharePoint recycle bin. If a hold is active for the group, you can run a content search to find information in the group mailbox and document library and export those items. However, you will have individual items and cannot reassemble them into a functioning group because the group object no longer exists in Azure AD.

## Recovering Individual Documents and Items

The possibility always exists that someone will remove a document in error, which then brings the question of how best to restore the now-deleted document. The first place to look is in SharePoint's recycle bin where items stay for up to 93 days after deletion (across the first and second stages). If the item isn't in the recycle bin and you have a backup, you might be able to recover the document from the backup. To prevent SharePoint from deleting items after 93 days, you can assign a retention label to important documents or apply a retention policy to entire sites. Users can delete documents with retention labels or those that come within the scope of a retention policy, but SharePoint keeps the retained items in the preservation hold library, and administrators can restore documents from there.

When someone removes an email conversation from a group, the item goes into the Deletions folder in the group mailbox and stays there for 14 days, after which the Managed Folder Assistant permanently removes the item from the mailbox database. You cannot use the standard Recover Deleted Items feature in Outlook or OWA because it is not available for group mailboxes. During the 14-day retention period, an administrator can recover deleted items by running the *Get-RecoverableItems* and *Restore-RecoverableItems* cmdlets to view and restore deleted items as these cmdlets work with group mailboxes.

Backup solutions from ISVs offer the ability to backup and restore documents selectively, which is a better outcome than having to restore a complete site. AvePoint has a backup solution for Groups that can restore conversations.

## Group Expiration Policy

Although it is possible to restrict the ability to create new groups to a select set of users, even in the most tightly managed tenant, some groups eventually reach their best-by date and become disused. If this happens, it is good to track down those groups, recover anything valuable stored in the group resources, and then remove the groups to reduce GAL debris. Groups are not unusual in this respect. Experience shows that the same falloff in usage over time happens for shared mailboxes, distribution lists, public folders, and other objects shared by teams of people.

To help administrators manage potentially obsolete groups, Azure AD supports the group expiration policy to control how long groups can exist within a tenant before the groups need to be renewed. If groups expire, Azure AD can automatically remove them from the tenant. The expiration policy can apply to some or all groups, no matter which application creates a group, or how people use the group and its resources.

A disabled group expiration policy exists for every tenant. An enabled expiration policy is an Azure AD Premium feature requiring licenses for every member of a group coming within the scope of the policy. Administrators also need an Azure AD Premium P1 license to configure the policy. If you access the Azure Portal without this license, you will not see the UI controls for the policy. However, you can manipulate the policy settings with PowerShell even if your account does not have a license. To work with the expiration policy, go to the [Azure AD admin center](#) and navigate to **Expiration** under Group Settings to see the current policy settings. You can now enable the policy, define settings and the groups that come under the scope of the policy, and then click **Save** to make the policy effective.

The settings in the group expiration policy are:

- The **group lifetime**: The default is 365 days, but you can select a higher or lower value. For example, you could use 730 days to make groups expire after two years. Consider setting a high number of days in the policy initially so that older groups do not expire when you enable the policy and to allow group owners to become used to the idea of expiring groups. For example, Microsoft started with a group lifetime of 360 days and subsequently reduced the period to 180 days.
- The **default notification address**. This handles the situation where a group has no owner. You can specify a single address (usually an administrator) to receive these notifications, the address of a distribution list or group, or the SMTP addresses for multiple recipients (separated by semi-colons).
- The **groups that come under the scope of the policy**. Initially, the value is **None**, meaning that the policy is in the default disabled state and groups do not expire. Selecting **All** means that every group in the tenant comes within its scope. The **Selected** button allows you to apply the policy to one or more groups, up to a maximum of 500 groups. You pick the target groups for the policy from a list of all groups in the tenant (for example, you might decide to exclude all the groups used by Teams from the policy and only include the groups that Teams doesn't use). This is easy to do in a small tenant but can become very tiresome for larger tenants which might span thousands of groups. In this case, you can use PowerShell to script to include the right groups within the scope of the policy. We explore how to manage the expiration policy through PowerShell in the PowerShell chapter. Figure 11-13 illustrates the settings of a group expiration policy that applies to the selected groups.

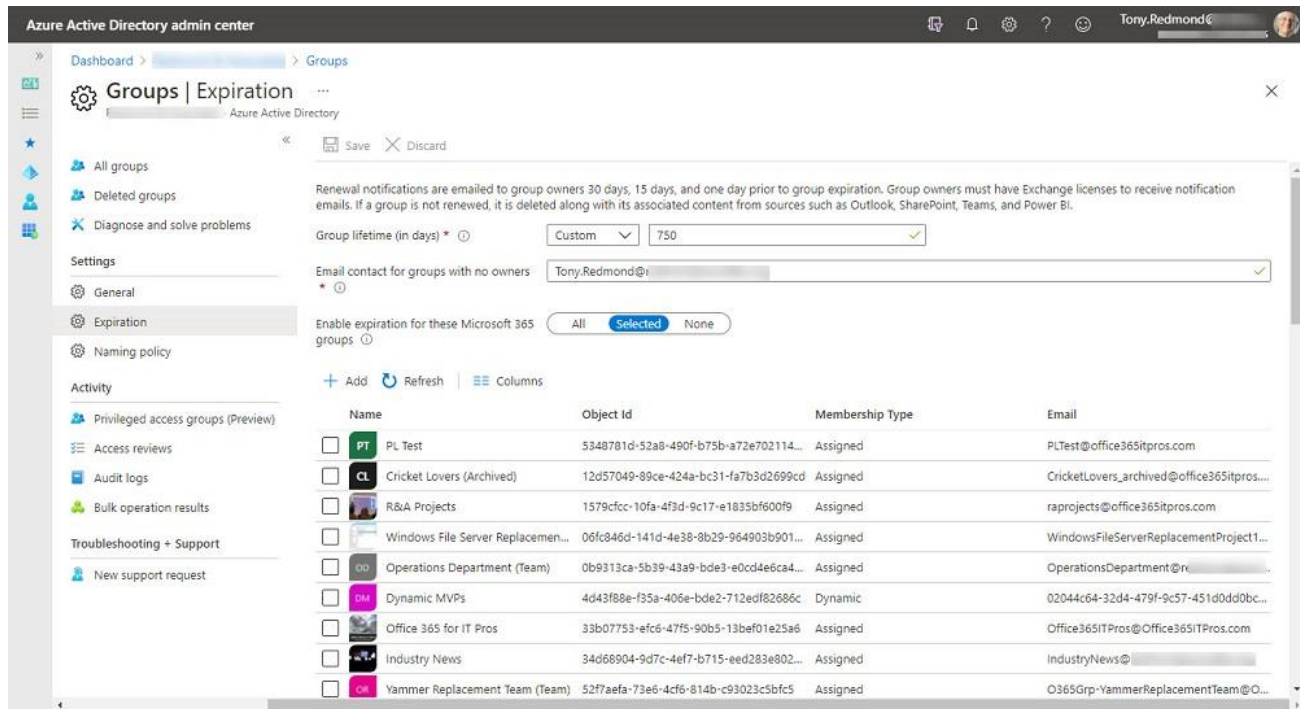

Figure 11-13: Updating the group expiration policy settings

If you change the scope of the policy from **All** to **Selected**, the policy ceases to apply to the groups outside the selected set.

## Automatic Renewal

Originally, Groups used an age-based renewal mechanism with the sole criterion for renewal being the time since the original creation date of the group and then, following a renewal, the date of the group's last renewal. Group owners had to renew groups manually, even if the groups are very active. An example of where this might cause a problem is when you use a policy covering all groups in the tenant, including a group used to limit the users who can create new groups. Eventually, that group will expire like every other group. If you ignore the notification, Azure AD removes the group when its expiration period elapses, which means that no one except an administrator will then be able to create a group.

The expiry policy uses a check for group activity. When the time comes to renew a group, Groups looks for evidence that the group is active. A background process called the Activity Tracking Service monitors group activities logged in the Microsoft Graph when users perform activities such as:

- SharePoint Online (group document library): View, edit, download, share, or upload files.
- OWA: Join a group, read, or send messages to group conversations, or like a message. Note: sending emails to contribute to a group conversation is not considered a renewal activity. The interaction must happen through OWA.
- Teams: Interact with a channel in the team.
- Yammer (network configured in Microsoft 365 mode): View a post in a Yammer community or use Outlook to respond to a Yammer interactive message.

It's obvious from this list that group renewal never considers some common activities when calculating group activity. For example, the process ignores adding tasks to Planner plans. Even in the workloads which are covered, many activities go unremarked, like participation in Teams meetings, using apps in channels, or assigning retention or sensitivity labels to SharePoint documents.

Many signals for the selected set usually exist for an active group, and when the time comes for renewal, Azure AD renews the group for a further period without the need for owner intervention. If the renewal

process finds no activity signals for a group, the group owners receive group expiry notification messages and must go through the normal renewal process. At the Ignite 2020 conference, Microsoft said that 79% of all groups coming within the scope of an expiration policy automatically renewed because of their activity. That's an impressive number, but the fact that 21% of groups didn't auto-renew because of a lack of activity gives pause for thought as it means that over a fifth of all groups created did not have enough activity (as measured by the limited set of signals) to allow Exchange Online to auto-renew them.

## Logging the Renewed Date

The *renewedDateTime* property of a group holds the last renewal time for a group (or the time of creation). Azure AD maintains the property to know when a group expires. After you renew or restore a group, Microsoft 365 updates its *renewedDateTime* property with the current date and time to give a new starting point for the group's expiry countdown. Records for the update to group properties are logged in the Audit logs section of the Azure AD admin center. In Figure 11-14, we can see the record captured when a group's renewal date was updated to 20 July 2019. Records noting group updates are also captured in the audit log.

## Expiry Notifications

No one wants a system to remove data without warning. When an expiration policy is active, Azure AD checks the last renewed date for every group covered by the policy. The auto-renewal process takes care of groups that are active (see the discussion below). For groups that have no activity signals in the Graph, warning notifications are sent to group owners to tell them when their groups need renewal.

Exchange Online sends expiry notifications using email irrespective of how groups are created or used. Group owners must check their mailbox regularly for expiry notifications. If not, they might overlook a notification to say a group is about to expire and Azure AD will remove the group unexpectedly. Teams exposes the expiration date for a team in its settings (*Manage team > Settings > Team expiry*) and allows team owners to renew the underlying group for the lifetime defined in the policy. As explained earlier, group owners can also renew a group through the **Manage groups** section of OWA.

Three warning notifications are sent before Azure AD removes a group:

- 30 days before the group expires.
- 15 days before the group expires.
- One day before the group expires.

For example, if the expiry interval is 365 days (one year), the timeline in Table 11-6 applies. (You cannot change these intervals as they are hardcoded).

<b>Days</b>	<b>Action</b>
1	Group created (or renewed).
335	First expiry notification sent to group owners.
350	Second expiry notification sent to group owners.
364	Final warning sent to group owners.
365	Expiry period reached. Azure AD soft-deletes the group.
395	The 30-day soft-delete retention period expires. Azure AD removes the group permanently.

Table 11-6: Timeline for Group Expiry

When they receive notifications, group owners decide whether to renew the group or let it expire. To help owners decide whether they wish to renew the group, notifications include links to:

- **Outlook:** Open the group and view the conversations that are taking place to see the last time that anyone was active. If the group is used for Teams, none of these events are captured.
- **SharePoint:** Open the document library in a browser to reveal the documents stored there. Because Teams uses the SharePoint library to hold its files, including a folder for each channel in a team, this is a valuable indicator of activity in a team.
- **Teams:** If the group is team-enabled, open the team, and expose the channels, conversations, and apps inside the team.
- **Group details:** Open Azure AD in a browser to reveal information about group members and owners.

## Group Renewal

To renew a group, an owner clicks the **Renew group** button in the notification message. This brings them to the Azure portal to renew the group. Three things can happen:

1. If the group still exists and has not expired, Azure AD renews the group and signals success. An "Updated Group" audit record is captured because the renewal updates the group's *RenewedDateTime* property. The same action occurs when a group is renewed from Teams.
2. If the group is soft-deleted, Azure AD restores it and sets a new expiration date.
3. If the group is hard deleted (permanently removed from the tenant), the owner sees an error message. The group is no longer recoverable.

If you decide not to renew a group and let it proceed to deletion, consider preserving any valuable information that exists in these resources before the deletion happens. This is not an automatic process, and it will take time and effort to retrieve information.

After the expiration period expires, Exchange Online soft-deletes the group and sends a final email to the group owners to inform them about the group deletion. All group resources are removed at this point – the group mailbox, Yammer community, team, plan, and SharePoint site, but kept in a restorable state. A group owner can restore the group for up to 30 days following the deletion. The notification message shows the drop-dead date, and once this period passes, the group becomes irrecoverable.

Normally, Azure AD soft deletes expired groups. However, special processing occurs if groups expire at the point when a tenant enables the policy. In this case, a special form of notification is sent to the owners and treats these notifications as second reminders. In effect, even though their groups are already technically expired, the owners have 15 days to renew these expired groups.

## Restoring Expired Groups

When a group expires, the expiration process moves the group into a soft-deleted state and its owners get a confirmation that Azure AD removed the group. The notification includes a **Restore group** button that the owner can click to restore the group and bring it back from the dead. Group owners can also restore a group through OWA.

Like any other soft-deleted group, Azure AD permanently removes the group after 30 days, so you have limited time to restore a group. Alternatively, you can use the steps described earlier to recover a group.

## Dynamic Microsoft 365 Groups

Microsoft 365 Groups support both static (fixed) and dynamic membership. Static membership is where you add and remove people from group membership via a client or programmatically (for example, with PowerShell). Dynamic groups compute their membership by running a query against Azure AD. Because of the processing load required to maintain dynamic group membership, Azure AD restricts the number of dynamic groups permitted per tenant to 5,000.

Dynamic membership is useful when you have groups that change often and whose membership can be determined by reference to one or more attributes of user accounts. For example, the people who work in the Madrid office, or everyone in the Engineering department. Teams, Outlook, and Yammer support dynamic groups.

The available methods to create a dynamic group are:

- Create the group from the Azure portal, setting its type to be "Microsoft 365" and then setting its membership type to be "Dynamic User."
- Create the group using PowerShell by running the *New-MgGroup* cmdlet. Due to the difficulties of making sure to build correctly-formed complex queries, we recommend using this method only for dynamic groups that use simple queries.

In all cases, when a group has dynamic membership, you cannot update group membership through OWA, Outlook, or the PowerShell *\*-UnifiedGroupLinks* cmdlet, and the only methods available to change membership are:

- Alter the Azure AD query to find another set of users.
- Update the properties of individual accounts in Azure AD so that they come under the scope of the query used to calculate group membership.

As noted above, although you can create a dynamic group with PowerShell, the usual approach is to manage these groups through the Azure AD admin center. Go to the [Groups section](#) and click **New Group**. Make sure that you select *Microsoft 365* for the group type and *Dynamic User* for the membership type and enter a name and description for the new group. The final step is to configure rules for the dynamic query used to find group members.

You have a choice of using a simple rule or an advanced rule to form the query. A simple rule checks against the value of an attribute like Department, City, or Country. An advanced rule combines checks against multiple properties to find the accounts to include in the group and includes some of the more complex checks using operators like *-in*, *-notin*, and *-any*. The *-in* and *-notin* operators are especially valuable in comparing the value of user attributes against a list of values (such as countries or department codes). The maximum size of an advanced rule is about 3,000 characters.

In Figure 11-15, we see an advanced rule based on a modified version of one of the [examples suggested by Microsoft](#). The intention is to find accounts assigned Office 365 E5 licenses, and it's done using a query of:

```
user.assignedPlans -any (assignedPlan.servicePlanId -eq "2f442157-a11c-46b9-ae5b-6e39ff4e5849" -and assignedPlan.capabilityStatus -eq "Enabled")
```

The query checks the service plans assigned to accounts and looks for an enabled license for the plan identified by the GUID. In this case, the GUID is for Microsoft 365 advanced auditing, included in Office 365 E5. It's highly unlikely that Office 365 accounts have disabled advanced auditing, so it's a good check. See the section in Chapter 23 covering license management with PowerShell to understand how to find plan GUIDs.

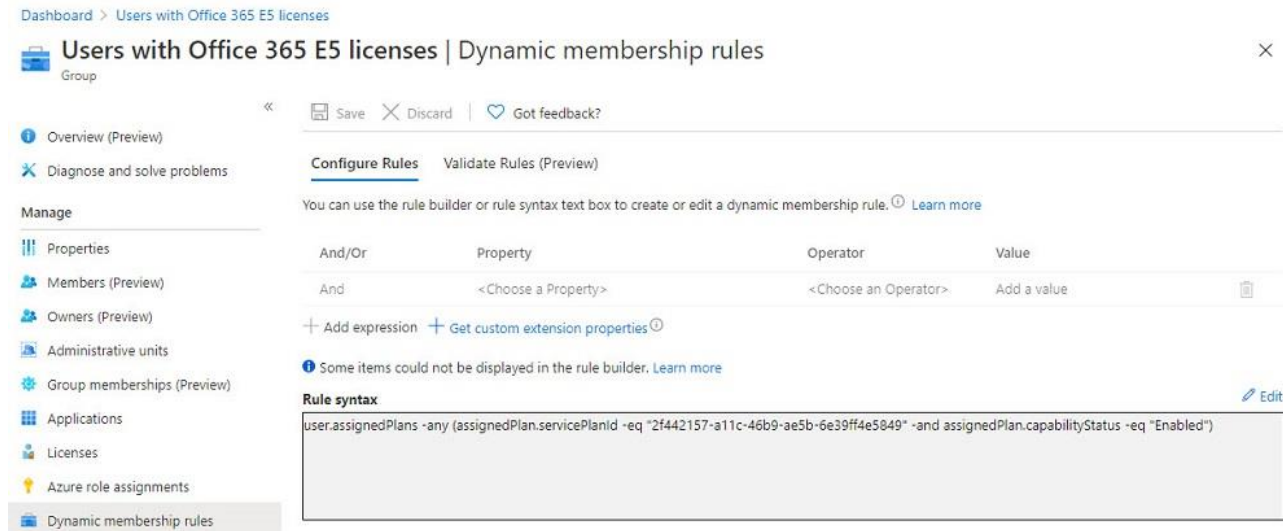

Figure 11-15: Creating rules for dynamic membership of a Microsoft 365 group

The **Validate Rules** option allows you to input accounts to see if they match the criteria set for the group, which is a useful way of checking the effectiveness of the query.

When the query is complete, save it, and create the group. After creation, it can take a little time before the new group shows up everywhere within Microsoft 365. This is because of the need to synchronize information between Azure AD and other workloads. It will also take Azure AD some time to calculate the membership of the group. The two biggest factors are the overall size of the tenant directory and the number of matching entries. Azure AD can easily support dynamic groups of more than 10,000 members and Microsoft has reported (Ignite 2020) that they've created and used a dynamic group containing more than 100,000 members. When Azure AD completes its scan for matching objects, you will see "update complete" as the membership process status in the overview properties for the group together with a timestamp when the Azure AD last calculated group membership calculation. A list of members is available through the **Members** link in group properties. Azure AD does not include disabled accounts when calculating dynamic group membership.

If you update the query for a dynamic group, Azure AD will perform another scan to recalculate group membership. Although the exact time needed for this process to complete depends on the current load on the service, the size of the tenant directory, and the number of matching objects, you can expect that a change to the membership rules should be active within a few hours.

## Checking Dynamic Membership

If you are uncertain about the query or want to confirm that it will generate the expected results, you can use the *Get-MgUser* cmdlet to execute a similar query against Azure AD and check the results that it reports. If the results from both queries match, you know that everything is working as expected. Here is an example of how to query Azure AD with an advanced query:

```
[PS] C:\> Get-MgUser -All -Filter "Department eq 'IT' and Country eq 'Ireland'" | Format-Table DisplayName, Department, Country
```

DisplayName	Department	Country
Andy Ruth (Director)	IT	Ireland
David Pelton (Sales)	IT	Ireland
Luka Abrus (Sales)	IT	Ireland

You can then compare the membership calculated with the filter with the data reported by running the *Get-UnifiedGroupLinks* cmdlet against the group.

```
[PS] C:\> Get-UnifiedGroupLinks -Identity "IT Ireland" -LinkType Member
```

Or, if you want to go back to Azure AD, you can read the membership from the group:

```
[PS] C:\> $GroupId = (Get-UnifiedGroup -Identity "Marketing Department").ExternalDirectoryObjectId
$Members = (Get-MgGroupMember -Group $GroupId)
ForEach ($Member in $Members) { Get-MgUser -UserId $Member.Id | Select DisplayName }
```

## Dynamic Group Owners

Like any other group, a dynamic group must have at least one owner. The ownership of a dynamic group is static in that these members are not affected by the query used to compute the normal group members. Instead, group owners are added and removed individually to the group using the Azure AD admin center or with PowerShell.

## User Access to Dynamic Groups

User access to dynamic Groups works identically to groups that have static membership. Every time someone tries to access a group resource, Azure AD checks whether they have the necessary permission and if so, the user gains access. Like regular Groups, messages sent to a dynamic group exist as conversations in the group mailbox. Groups automatically adds members as subscribers so that they receive copies of all contributions to group conversations via email. One difference between a static and dynamic group is that Groups does not add the user who creates the group to the member list. This is because the query for the group defines the membership. Unless the account that creates the group comes within the scope of the query, the group owner is not a member and therefore cannot access group resources. Likewise, the group owner is not part of the subscriber list.

Groups does not notify members when they lose access to dynamic groups due to a change in the query that populates the group membership or because their account details have changed. The first time someone is likely to discover that they no longer are a member is when they try to access some group resources.

**Hybrid Dynamic Groups:** Groups are unique to Microsoft 365. Only Azure AD can calculate the membership of dynamic groups. For this reason, hybrid deployments always route messages addressed to these groups to Exchange Online. If you enable group writeback with the AADConnect tool, the directory synchronization process ensures that the value of the *targetAddress* attribute for dynamic groups uses the service domain (i.e., onmicrosoft.com) rather than any vanity domain belonging to the tenant. By routing messages sent to these groups via onmicrosoft.com, Exchange Online processes the message through its transport service and queries Azure AD to discover the group membership, and then delivers copies of the message to individual group members. More information about using the AADConnect writeback feature in hybrid deployments is available in the companion volume and [online](#).

## The Cost of Dynamic Groups

Using dynamic groups means that you need to buy Azure AD Premium P1 licenses for administrators who create and update dynamic groups plus any user whose account falls under the scope of a filter used by a dynamic group. In other words, if you create a dynamic group that has a filter that resolves to every person in the organization, you need to buy an Azure AD Premium P1 license for all those users. In most cases, it is better to use a standard dynamic distribution list to communicate with large sets of employees because you

avoid any licensing issues and will not exceed the supported limit for group membership. If you want to use something like an “All Employees” group to foster a sense of collaboration rather than simply a means of sending out information, a public Yammer-based group might be a better choice.

Microsoft does not enforce the licensing requirement for dynamic groups. Those who create or update the queries for dynamic groups need a license before the Azure AD admin center allows them to change queries, but the query used in groups returns all matching accounts found in the directory even if some do not have the necessary license. Microsoft might enforce the licensing restriction in the future. When that happens, queries will return licensed accounts only.

Because dynamic groups come at a cost, you should be careful to decide which groups should be dynamic, and which can stay with static membership. Before creating a new dynamic group, ask whether the membership is likely to change over time. If you expect a low turnover in group membership, then static membership is a better choice as it will not incur an extra cost and the membership is not dependent on the directory. On the other hand, organizations that manage many groups whose membership is volatile (such as the students who sign up for a class) and can calculate group membership by querying one or more of the supported directory attributes for dynamic membership might be able to justify the cost.

**Using Dynamic Groups with Teams and Planner:** You can use a dynamic group with Teams but not with Planner, which depends on fixed team membership. Dynamic groups are intended for groups whose membership is highly volatile and whose communication is email centric.

## Comparing Email Dynamic Distribution Lists and Dynamic Microsoft 365 Groups

Experience in using Exchange dynamic distribution lists suggests that dynamic membership is a popular feature. Some obvious differences exist in the implementations of the two types of dynamic groups. Table 11-7 compares the two ways to create objects with dynamic membership inside Office 365.

<i>Attribute</i>	<i>Dynamic distribution list</i>	<i>Microsoft 365 dynamic list</i>
Resolved against	Exchange Online Directory (EXODS)	Azure Active Directory
Used for	Email	Teams, Outlook Groups, Yammer
Purpose	Send email	Send email and manage access to Microsoft 365 resources like SharePoint sites
Supported objects	Any mail-enabled recipient type (including hybrid objects)	Azure AD user and guest accounts
Licensing	Included in Exchange Online	Azure AD Premium P1
Syntax for query rules	OPATH	ODATA
Filters based on	<a href="#">Exchange object attributes</a>	<a href="#">Azure AD object attributes</a>

Table 11-7: Comparing Exchange Online dynamic distribution lists and dynamic Microsoft 365 groups

## Groups and Compliance

As explored elsewhere in this book, compliance technology exists to help companies follow the regulatory and legal frameworks that apply to their business activities. Groups use Microsoft 365 compliance features rather than workload-specific features. For example, you can include group mailboxes and the group document libraries in simple content searches, or the searches associated with eDiscovery cases. Retention policies can apply to content held in group mailboxes and document libraries and group owners can apply

retention labels to conversations to keep those items for compliance purposes. Table 11-8 outlines the functionality supported by Groups in different search and hold scenarios.

	<b><i>Include group mailbox</i></b>	<b><i>Include group document library</i></b>	<b><i>Create in-place hold on data</i></b>
Retention policies	Can keep or remove selected group conversations or Team channel messages	Can keep or remove selected files in group document libraries	Can impose in-place hold to keep items for defined periods
Content searches	Yes	Yes	Yes
Core and Premium eDiscovery cases	Yes	Yes	Yes

Table 11-8: Compliance features applied to Groups

Yammer-based groups hold their discussions in the Yammer data store. Compliance records for eDiscovery are generated if the Yammer network is configured in Microsoft 365 native mode.

**Controlling Group Creation and Compliance:** One aspect of compliance sometimes overlooked is the desirability of controlling group creation. If you allow everyone to create groups, you might end up with an unmanageable mess. Not only will obsolete and unwanted groups clutter up the tenant, but their presence does make it harder to figure out what groups hold information needed for compliance purposes. If compliance is of concern, consider applying a policy to control group creation so that you know what groups exist, their purpose, and whether they should come under the control of compliance policies.

## Yammer and Groups

Microsoft bought Yammer for \$1.2 billion in June 2012 to gain a presence in the enterprise social networking market. Facebook defines the concept of a social network to many people, a feeling emphasized by the film of the same name that charts the development of Facebook from an application used to connect college students in an electronic yearbook to a platform that supports billions of users today. Facebook is a public social network that is open to anyone who cares to join. An enterprise social network, like Yammer, offers much the same communication and collaboration facilities as you find in Facebook, but inside the confines of a single enterprise. Of course, you can stretch the concept of a single enterprise to a public space, as in the case of Microsoft's original Office 365 Network where Yammer hosted over 88,000 members discussing technical issues and ideas in the many groups that reflect the different interests of customers. Microsoft transitioned the Office 365 Network from Yammer to a new platform in September 2016.

Microsoft enables Yammer for all enterprise tenants, and the app supports browser, Apple iOS, Android, and Mac clients. Once activated, you can use Yammer in diverse ways. Some find that Yammer is an excellent way to introduce users to cloud applications. Yammer behaves very much like other social networking networks and users who are familiar with those applications can quickly become productive with Yammer. Given a well-curated set of groups for people to go to find and share information, Yammer can quickly become a success factor in a roll-out, especially when the number of potential users who might contribute to conversations is more than can be accommodated by Groups or Teams.

Yammer supports sharing across groups (in other words, you can cross-post a conversation to have it appear in multiple groups). It is also possible to search for content across the groups to which you belong. And of course, Yammer comes with the compulsory marks of approval seen in other social networking products - the infamous "Like" and emoticons. Yammer also boasts integrations with various other applications such as Dynamics 365 and Salesforce.com.

Yammer brings its distinct blend of collaborative capabilities to the mix. It is collaboration writ large, created with the enterprise in mind. Yammer is best when used by hundreds or thousands of contributors meeting in groups dedicated to different topics, especially when contributors are geographically remote from each other. Some examples of Yammer communities are cross-company knowledge sharing or distributing information on behalf of specific parts of the business, such as an HR discussion group or an IT suggestions group.

Any consideration of collaboration should take Yammer into account. You should lay out the needs of the organizations and map those needs against the different Microsoft 365 applications available. You can then decide which type of group is best suited to specific scenarios. Although the question seems a tough one to answer, the reality is that most organizations will find the choice relatively straightforward. Most tenants will standardize on a certain type of collaboration and use it wherever possible. Those who have used email in the past will continue to do so with Outlook-based groups while organizations that deployed Yammer will continue to use Yammer communities. Teams has replaced email for many internal communication scenarios and is often easier to deploy than Yammer, so it's another factor to take into account.

## The Evolution of Yammer

Anyone looking at the collaboration options available will probably conclude that some overlap exists. Why use Groups instead of Yammer or vice versa? How do these applications compare to Teams, which some commentators speculate will eventually replace Yammer? These applications allow users to contribute to discussions and preserve contributions so that they are accessible to other users who join the debate after it starts. The applications support the sharing of files and are accessible through a browser interface – and that is pretty much where the similarities end. Yammer's focus is on social networking capabilities for large enterprises (the largest customer Yammer networks support well over 100,000 members) while Groups and Teams support much smaller memberships.

Because Outlook groups can act as distribution lists, they are easy to deploy. Users who interact with Outlook Groups through email and never access the shared resources will probably think of them as another form of distribution lists. You send messages to groups and copies arrive in the mailboxes of any member who subscribes to the group. Given the large population of Exchange Online mailboxes, Outlook groups have a lot of room to grow.

Yammer is different. You can certainly interact with Yammer communities through email, but the experience is less seamless. Although Microsoft enables Yammer for enterprise plans and does the heavy lifting of implementation, the decision to deploy Yammer inside a company needs more thought and preparation than simply turning it on. Such an approach will invariably result in a couple of active groups (for some period) and a lot of stagnation. Any project to introduce a new form of collaboration to an enterprise, even though people are aware of the power of social networking through their exposure to consumer versions, needs planning, evangelism, leadership, endorsement from executive level, and a whole lot of energy applied to get the network going, including the identification of suitable ways to use the network to solve real-life business problems. An electronic chat room is nice to have but worthless in the long term; an active social network that brings people together on an ongoing basis to debate, refine, and drive solutions to identifiable and quantifiable business issues is invaluable.

## Yammer Network Modes

Yammer organizes its communities into a network. Older Yammer deployments could support multiple networks within a single tenant, but now it's more common to find a single network per tenant. The network mode describes the functionality available to the network and can be one of three modes:

- [Native mode for Microsoft 365](#). As of January 2020, all new Yammer enterprise networks start in native mode (and can't change to any other mode).

- Non-native mode. All Yammer external networks are in this mode. External networks are those which support people outside the organization.
- Hybrid mode.

Best results with Microsoft 365 are possible when a Yammer network runs in native mode:

- Microsoft 365 administrative tools can manage Yammer users and communities. Groups manage the membership of Yammer communities and Yammer respects the group creation policy. A special group is created for the “*All Company*” community with no membership. All tenant administrators are added as owners of this group. In the case of other communities, Yammer network admins must have the appropriate Microsoft 365 permissions to manage the membership of communities where they are not listed as group owners. The Groups used by Yammer are inaccessible to clients of other group-enabled applications (like Outlook).
- Each community can access resources like a SharePoint Online team site. The files uploaded to a Yammer community are stored in a document library on its team site.
- All communities can use Microsoft 365 Live Events.
- Yammer generates compliance records for conversations. The compliance records for a discussion are in the group mailbox belonging to the Yammer community and can be discovered by content searches.

Moving a Yammer network to native mode is not something that you do on a whim. It is a one-time irreversible process performed using the Microsoft 365 alignment tool. The tool checks all the settings in a network and makes whatever changes are needed to transition to native mode. For instance, all Yammer users must have Azure AD accounts, all communities must be connected to Groups, and all files must be stored in SharePoint Online. If necessary, the tool makes changes to objects or removes items (like external users or users who can't be found in Azure AD) to make the network compliant. When the process is complete, you cannot change to another mode. See [this page](#) for more information.

## Yammer Communities

Yammer traditionally referred to its collection of users as “groups.” In late 2019, Microsoft announced that Yammer would now use “communities” instead as this word more accurately reflects the kind of knowledge sharing and community building that Yammer is good at. Communities still use Groups to manage their identities and membership and connect to group-provisioned resources like SharePoint sites.

When a Yammer community uses a Microsoft 365 group, you can work with the group using the Groups cmdlets in the Microsoft Graph PowerShell SDK and Exchange Online modules, or by using Graph API queries. For example, you can set the classification or access type for a Yammer community by running the *Set-UnifiedGroup* cmdlet. You can also recover a deleted Yammer community using the process to recover a deleted Outlook group. Although you can add members to a Yammer community using the *Add-UnifiedGroupLinks* cmdlet, it is best to manage membership through Yammer and this minimizes any directory synchronization lag.

Yammer communities in networks configured in Microsoft 365 native mode support Azure B2B collaboration guest user accounts. The functionality only works for external accounts in other Office 365 tenants. Microsoft hopes to support external access for Microsoft Service Accounts soon.

## Yammer Discussions

Leaving Microsoft Teams aside, tenants have a choice of technology to host group discussions: Yammer or Exchange (Outlook Groups). The major difference between Yammer communities and Outlook Groups is that Yammer keeps its conversations in the Yammer data store while an Outlook group stores its conversations as items in the Inbox folder in a group mailbox. A Yammer community that uses the Groups service is easily identifiable because it lists links to the group-connected resources provisioned for the group (Figure 11-16).

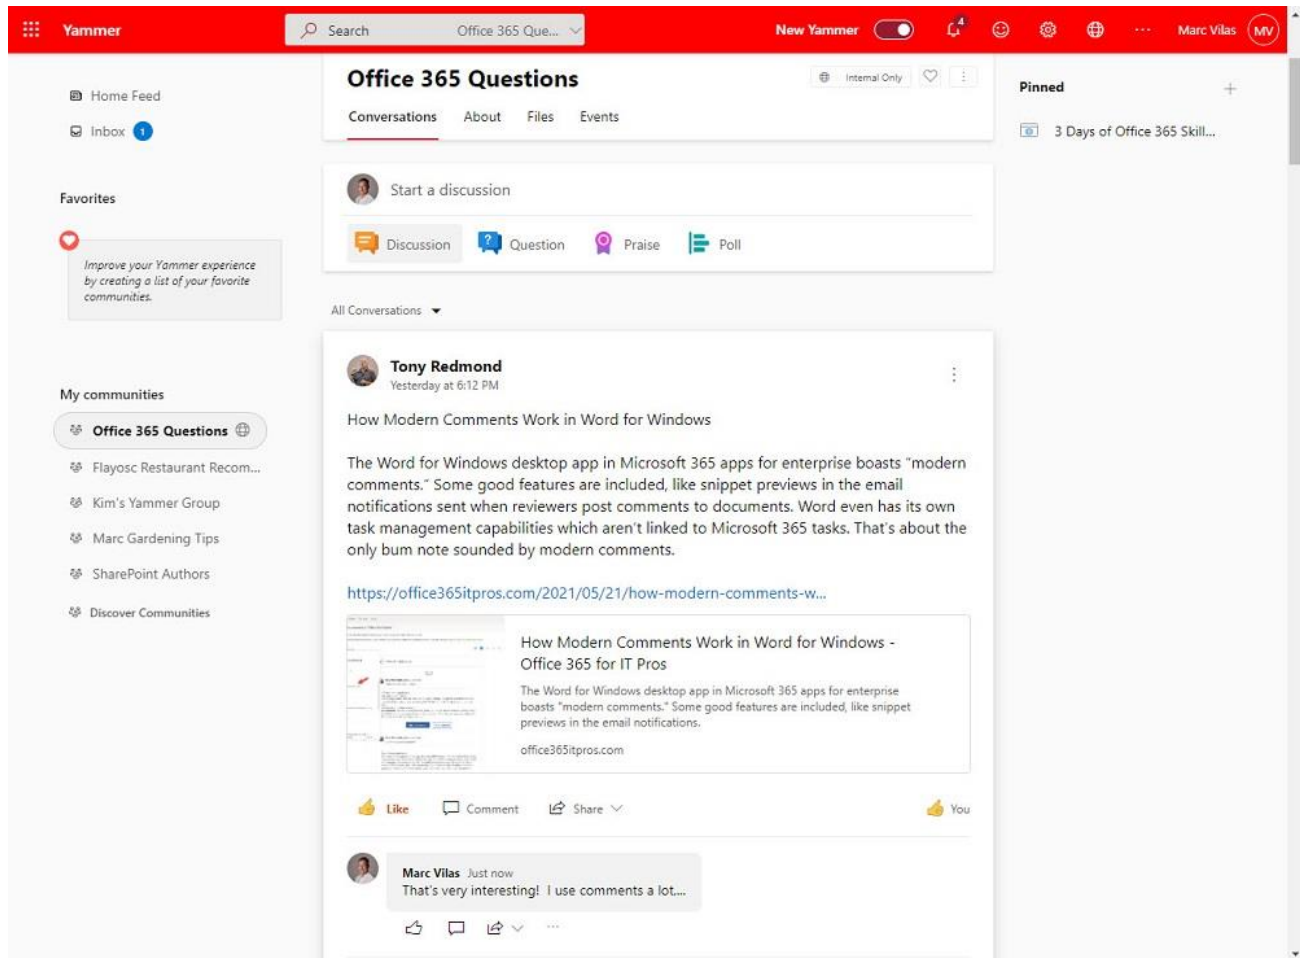

Figure 11-16: A discussion in a Yammer community

Yammer supports marking communities as “official,” as a way of increasing the status of a community and the discussions contained there. For instance, an organization might mark an HR Community as official to encourage people to ask questions relating to HR policies and regulations there. Among the other features Yammer supports are:

- Mark conversations as announcements to give them extra importance. Community members receive email notifications for announcements even if they disable email notifications for Yammer.
- Threaded conversations.
- Delegate access (users can allow others to post on their behalf in communities both people belong to).
- Feature a conversation (pin it to the top of the feed).
- Ask and answer questions. You can also change a regular conversation to become a question. Yammer uses different formatting to highlight questions in user feeds.
- View insights (statistics) about a conversation.
- Restrict posting of new topics in communities to administrators.

Although you cannot transform a Yammer community to become an Outlook group or vice versa, it is possible to run the two types of groups alongside each other. After all, both use a common group framework, and the only major differences are the storage of conversations and the clients that people can use to access a group. Outlook and OWA cannot access conversations in a Yammer community. Access to conversations in a Yammer community is only possible through the Yammer browser and mobile clients. Although they do not use Exchange Online for messaging, members of Yammer communities can still send messages and users can also send messages to Yammer communities.

## Actionable Notifications

As conversations happen in Yammer communities, members can choose to receive notifications via email. Traditionally, the notifications were simple messages with a clickable link to open a browser and go to the conversation. Notifications include a *“fully-interactive Yammer thread”* with the ability to:

- See the complete Yammer conversation.
- Like a comment in the conversation.
- Share the conversation with another Yammer community.
- Know how many people have already seen the conversation.
- Add people to a conversation.
- Post a comment to the conversation from OWA, including attaching files and images or @mentioning people in a comment.
- Vote in polls.

Actionable notifications only work in OWA. Other clients see the older-style notifications.

## Yammer Compliance Records

When a network is configured in native mode, Yammer stores compliance records in the *MessageIngestion\Yammer* folder in the non-IPM part of user and group mailboxes. The records are created by the Microsoft 365 substrate when people post new messages to Yammer communities or private conversations. Records are available for different forms of Yammer posts, including polls, questions, discussions, and so on. Graphics and GIFs included in posts are captured. Reactions to posts are the only element that the substrate does not capture.

The example below uses the *Get-ExoMailboxFolderStatistics* cmdlet to examine and report what it finds in the Yammer folder:

```
Get-ExoMailboxFolderStatistics -Identity "Company-Wide Debate" -Folderscope NonIPMRoot -
IncludeOldestAndNewestItems | ?{$_.FolderType -eq "Yammer"} | Format-Table Name, ItemsInFolder,
NewestItemReceivedDate
```

```
Name      ItemsInFolder NewestItemReceivedDate
-----
Yammer    6213 1 Aug 2021 12:12:17
```

When run against a user mailbox, the code reports the number of Yammer compliance records created for posts to communities and private messages sent by that user. Using compliance records is often used to track activity in groups. This script in the [Office 365 for IT Pros GitHub](#) repository generates an activity report for Yammer communities using the compliance records, including calculating how long it has been since anyone posted to a community.

## Data Residency for European Union Tenants

In May 2019, Microsoft announced that new European Union tenants could choose to have their data stored in Microsoft data centers in Europe. Before making this decision, organizations should be aware of the [current restrictions](#), some of which have a significant impact on Yammer functionality.

## Evaluating Yammer, Groups, and Teams

Occasionally, Microsoft 365 offers too many ways to get work done. Selecting the right tool for team collaboration is one of those times. Groups offer a solid choice for teams to work together based on email while Microsoft Teams delivers a chat-based workspace that works well for small to medium teams. Groups, Teams, and Yammer support guest user access (the Yammer network must run in Microsoft 365 mode).

Because many factors drive the choice of the best collaboration tools for an organization, it is hard to make a choice and say that any one tool will handle all circumstances and contexts. No collaboration tool ever invented in the history of technology has been able to make that claim in any credible sense. To help you figure out the best choice of tools for use inside your tenant, Table 11-9 lists some of the points that you can consider when comparing the different group/team-centric collaboration methods supported by Microsoft 365.

<i>Characteristic</i>	<b>Groups</b>	<b>Yammer Communities</b>	<b>Microsoft Teams</b>
Built on Microsoft 365 technologies	<i>Exchange Online</i> (conversations and calendar). <i>SharePoint Online</i> (team site) <i>OneNote</i> (shared notebook). <i>Planner</i> (plans) Connectors (if enabled).	<i>Yammer</i> (conversations). <i>Exchange Online</i> (group mailbox). <i>SharePoint Online</i> (team site). <i>OneNote</i> (shared notebook). <i>Planner</i> (plans).	Azure data services (messages and media items). <i>Exchange Online</i> (calendar). <i>SharePoint Online</i> (document library). <i>OneNote</i> (shared notebook). <i>Planner</i> (plans). Connectors, Bots, Apps, and Tabs (all if enabled).
Clients	Outlook for Windows or Mac (Microsoft 365 Apps), OWA, Outlook mobile.	Browser, Windows and Mac desktops, and mobile clients.	Browser, Windows, Mac, and Linux desktops, and mobile clients.
Scalability	Maximum of 2,500 members (dynamic groups are also supported).	The membership limit is > 50,000 (unless synchronized with an on-premises directory).	Membership limit of 25,000 per team. Dynamic groups are supported.
Access	Default private but can be set to public.	Default public (any user can join), can be set to private.	Default private but can be set to public.
Communication style	Choice of direct access to conversations or by sending email to the group. Contributions can be short or long. A group can host thousands of conversations.	Threaded discussions that occur over wide-ranging topics. Contributions are usually short and entered directly through the browser. Interaction through email is possible via actionable messages.	Support for personal and shared (channel) messages organized in threaded conversations, which are usually very short. Interaction through email is possible via actionable notifications. Email support for mailing to channels is also available.
Search	Outlook constrains search to conversations within a single group. Office.com supports searching across all groups and teams to find messages and documents.	Search across Yammer communities to which a user has access.	Search within all teams, a single team, and a channel (including associated files). Office.com search finds messages and documents.
Group purpose	Team-based collaboration centered on email and shared documents. Good choice for teams that work together on an ongoing basis for a prolonged period. Replacement for	Wider (up to the entire company) collaboration and sharing of ideas. A good choice is to host open discussion forums, groups dedicated to sharing knowledge and	Teams working on projects. A good choice for teams that need to work on a specific problem or issue. A team can have up to 200 channels to use to segment discussions.

	traditional email distribution lists.	information with a broader community, and when a “community of interest” form of collaboration is required.	Private channels are available for a subset of team membership. Shared channels are available for collaboration with external users.
Management	Microsoft 365 admin center and EAC. A wide range of PowerShell cmdlets and Graph APIs are available to interact with mailbox and group.	Yammer administration console. No PowerShell support, apart from being able to use some of the Groups or PowerShell SDK cmdlets to manage group properties. No Graph API support for access to Yammer content.	Teams admin center. A Teams PowerShell module is available, and management of team-enabled groups can be done using the cmdlets in the Exchange Online module. Good support in Graph APIs.
External access	Support for tenant and guest users with some limitations for users with on-premises mailboxes.	Support for tenant and guest users (for networks configured in Microsoft 365 mode).	Support for tenant and guest users (and external users with shared channels) with some limitations for users with on-premises mailboxes.
Support for Microsoft 365 compliance and data governance features	Support for content searches, eDiscovery cases, retention labels, and retention policies. Actions are captured in the audit log.	If the network runs in Microsoft 365 mode, Yammer creates compliance records for discussions. Files stored in SharePoint are indexed and discoverable. Actions are captured in the audit log.	Compliance records are captured in Exchange mailboxes. These are indexed and discoverable and can be included in content searches and eDiscovery cases. Teams retention policies are supported. Teams supports DLP. Actions are captured in the audit log.
Data sovereignty	Supported in all Microsoft 365 data center regions. Multi-geo deployments are supported.	Hosted in U.S. and EMEA data centers.	Hosted in most Microsoft 365 data center regions. Multi-geo deployments are supported.

Table 11-9: Comparing different Microsoft 365 collaborative applications

Some guidelines are necessary to help administrators and users select the best form of collaboration technology for a specific task. The following might serve as a basis for discussion:

- An Outlook group is an excellent choice when a team requires a collective repository where they can share documents, a OneNote notebook, and a calendar, and discuss topics through email. It is likely that the group has a well-defined purpose and might be part of the organizational structure, like a department or location. Because these groups often serve as a direct replacement for traditional distribution lists, the email traffic can be relatively high compared to the number of files generated in the document library. Together, the files and conversations held in the group represent its collective history and are valuable in terms of bringing new members up to speed with the group’s activities. Groups and the Outlook apps offer the most comprehensive support for the Microsoft 365 data governance framework.
- Microsoft Teams is a good choice for small to medium projects where sets of people come together to execute specific tasks. Deadlines are likely to be in place for the team to achieve and this

encourages a certain kind of focused and rapid conversation between team members that Microsoft refers to as “high-velocity chats”. The chats tend to be short and informal. The intention behind a team is to get work done rather than to accumulate knowledge. When the project or work item completes, the team members might disband and come together in other teams.

- Yammer communities are an effective way to share knowledge broadly within large communities. They work well as public forums within companies, where Yammer can be the basis for communities who share a common interest. Unlike Teams and Groups, which configure their groups to be private or public, Yammer communities often host unstructured audiences that flex over time. The information held in Yammer communities is often not as specific as found in Groups or Teams but is no less valuable. Indeed, the knowledge developed through the contributions of the higher number of users supported by Yammer often has long-lasting value for the entire company.

Considerable overlap exists between the various methods. An Outlook group might be as good a choice as a team in some circumstances. Some companies use nothing but Yammer and are quite happy with their choice. Some will find that Teams revolutionize the way that small groups work. All of which proves that collaboration is uniquely individual to a company or organization. No one size fits all, which is why choice exists within Microsoft 365.

## Distribution Lists

Distribution lists or distribution groups have existed in email systems since the early days of the technology. A distribution list is a collection of known email recipients which gives users the ability to send emails to everyone on the list through a single recipient. The membership of a distribution list is composed of mail-enabled recipients registered in the Exchange Online directory and accessible through the GAL:

- User and shared mailboxes.
- Mail-enabled public folders.
- Other distribution lists, including dynamic distribution lists.
- Mail contacts. You can include a Teams channel in a distribution list by creating a mail contact using the channel’s email address.
- Mail users (including those created for guest accounts).
- Microsoft 365 Groups (these objects can only be added using PowerShell).

A single distribution list can span up to 100,000 members. The Exchange Online transport system calculates the total recipient count after expanding the distribution list, including any nested distribution lists and dynamic distribution lists in the membership. If you use Azure AD Connect to synchronize with an on-premises directory, a lower maximum of 50,000 members applies. After it expands the set of individual recipients, Exchange figures out how best to route a copy of the message to each recipient. It is at this point that Exchange imposes other limits, such as the 25 MB maximum message size that can be sent to distribution lists of up to 99,999 members.

If your tenant uses large distribution lists (more than 5,000 members), Exchange forces you to configure delivery management restrictions for those lists to lessen the possibility of people sending messages to the lists in error. Sending a 5 MB message to a distribution list containing 100,000 recipients imposes a huge load on the service. Limitations include specifying a set of mailboxes allowed to send messages to large lists or imposing moderation on those lists so that messages must be approved before Exchange distributes copies to all members.

Normally, the sole purpose of the distribution list is to act as a convenient way to send messages to multiple people. Alternatively, a distribution list can be a mail-enabled security group (MESG), which means that you can use it to send mail and control access to resources, such as access to a shared mailbox. You cannot change a distribution list to make it a mail-enabled security group or vice versa.

The perceived wisdom expressed by Microsoft and many others is that Microsoft 365 Groups are more functional and productive than distribution lists and that users will benefit if organizations upgrade distribution lists to become Groups. For this reason, Microsoft offers multiple methods to convert distribution lists. Notwithstanding the features available to Groups, valid reasons still exist to continue using distribution lists, including:

- The ability to include different mail-enabled recipient types in group membership. For instance, mail contacts, mailboxes, and other groups.
- No licensing requirement to use dynamic distribution lists.
- Easier interoperability with other third-party email systems.
- Ability to nest distribution lists.

Microsoft is aware of where the functionality of Groups lags behind the capabilities of distribution lists and is working to close the gap, so this is an area to monitor over time.

## Creating a New Distribution List

The Groups section of the EAC offers the opportunity to create a new Microsoft 365 group, a distribution list, mail-enabled security group, or a dynamic distribution list. The group type tells EAC which UI to display to gather information about the properties of the new group. When you choose a distribution list, the GUI displays some text to convince you to create a new Microsoft 365 group instead, which is fine if you need the extra features like a SharePoint Online site.

To simplify the creation of distribution lists, just a few settings are needed, divided into Basics and Settings. The two basic settings are:

- **Name:** The *Name* property of the distribution list must be unique. If you don't supply a value for the *DisplayName* property, it takes the value assigned to the *Name* property. The *DisplayName* is the one listed in the GA and it's important to give some thought to its composition. Ideally, the name should convey the reason why the group exists, how to use it, and what its membership might be. Groups created by administrators are not subject to the organizational group naming policy as this only applies to user-created groups. We will discuss how to create a group naming policy and how to restrict users from being able to create groups later.
- **Description:** An optional free-text description to explain the purpose of the distribution list. In some cases, administrators note who requested the creation of the list and capture some background for its expected use.

The settings dictating the basic operation of the distribution list are:

- **Group mail address** (Primary SMTP address): To ensure uniqueness, I typically create the username part of the mail address from the name of the distribution list (separating words with full stops). The domain can be chosen from any of the tenant's registered domains. The list also receives an alias from the tenant's service domain.
- **Communication:** A checkbox to note if people outside the tenant can send emails to the list.
- **Joining the group:** This can be open (anyone can join), closed (members must be added by a list owner), or owner approval (people can apply to join but must be approved).

Once the EAC creates the distribution list, you can go ahead and add its membership and amend other details of the list (Figure 11-17). The person who creates the distribution list is automatically an owner but is not a member. The ideal situation is to have two or more owners. This is more important with a security group because, apart from administrators, only owners can add or remove members from a security group. You can choose to add owners to the membership so that they receive messages sent to the group, but this is not necessary. The ownership of a group can include other groups as well as individual users.

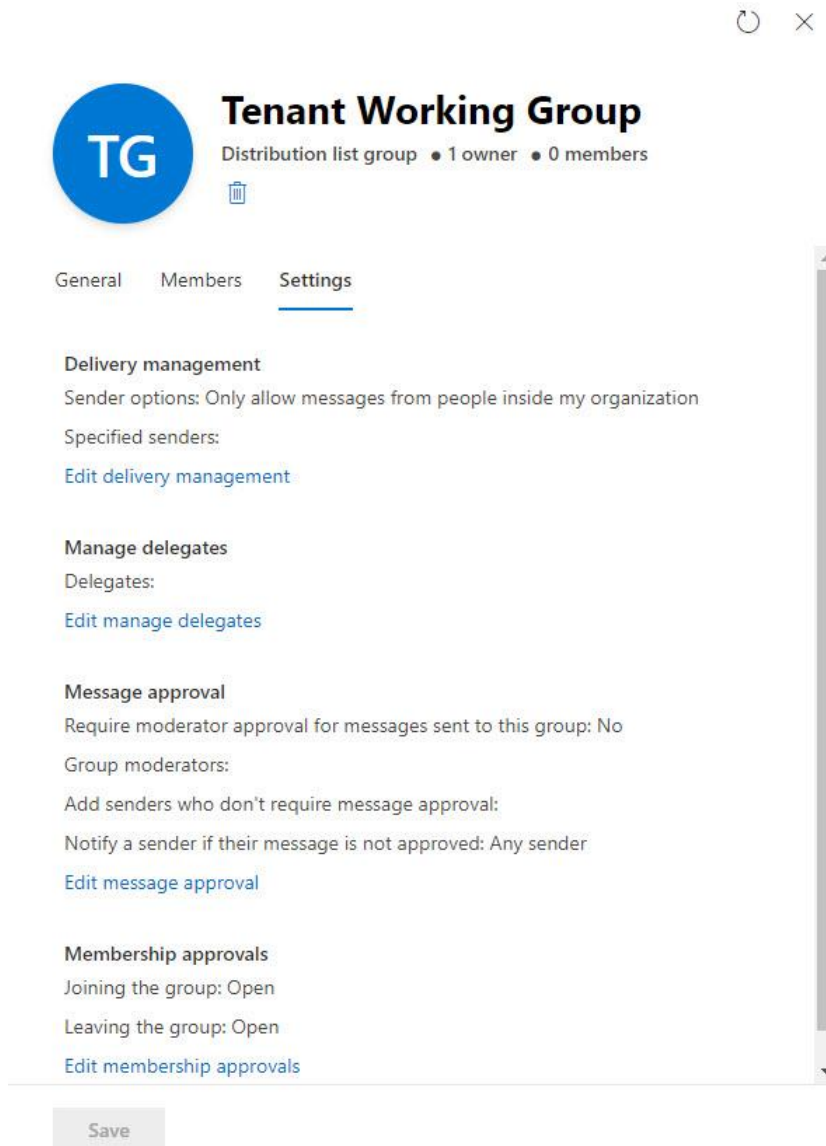

Figure 11-17: Amending the settings for a distribution list

Users can browse available groups that they belong to or which they own through the **Distribution groups** section of OWA options. Options are also available to join a group and leave a group. Joining a group involves a user first searching the directory to find the group and then creating a request to join it. Exchange automatically approves requests to join open groups and rejects them for closed groups. Otherwise, Exchange sends requests to join these groups to the group owner(s) for approval.

The *MemberJoinRestriction* and *MemberDepartRestriction* properties control how users can join or leave distribution lists. You can update a distribution list with the *Set-DistributionGroup* cmdlet. This example sets the group properties so that an owner must approve requests to join but a user can leave without approval.

```
[PS] C:\> Set-DistributionGroup -Identity "All Company" -MemberJoinRestriction ApprovalRequired -MemberDepartRestriction Open
```

The options to control user-initiated joining and leaving of a group do not exist for either mail-enabled security groups or dynamic distribution lists. Mail-enabled security groups are security principals that can grant access to other resources. It makes sense that only the group owners should be able to control who enjoys that access. Exchange Online calculates the membership of a dynamic distribution list by running a query against the Exchange directory service. An administrator can decide whether the results of a query will

find a specific object by adjusting the object's properties (for instance, they change the value of an attribute used by the query), but unless the owner is also an administrator, they cannot influence the query results.

Other properties of distribution lists often updated with PowerShell include:

- **RequireSenderAuthenticationEnabled:** The default is *\$True*, meaning that Exchange Online will deliver messages to the group only when the sender can authenticate (the sender belongs to the tenant). Exchange rejects messages generated by external senders unless this property is *\$False*. Normally, you do not want external people sending emails to internal distribution lists, but some good exceptions exist. For example, when a distribution list route messages from external parties (like customers or partners) to a public folder or Teams channel.
- **RejectMessagesFrom, RejectMessagesFromDLMembers, RejectMessagesFromSendersOrMembers and AcceptMessagesOnlyFrom, AcceptMessagesOnlyFromDLMembers, AcceptMessagesOnlyFromSendersOrMembers:** Exchange Online allows for reasonably granular control over who can send to a distribution list. You can block specific users or members of other distribution lists with the Reject\* properties or block everyone except those specified in the Accept\* properties. The EAC populates the Accept\* properties when you edit a distribution list to update its delivery management parameters. All the objects specified in these lists must be known to Exchange Online and can include mail contacts and mail users. If you try to add a user via their SMTP address, Exchange Online checks the address against the Exchange directory service and rejects it if the address does not match a mail-enabled object.

When updating a reject or accept list for a group, you must update the relevant *\*SendersOrMembers* property and Exchange Online will sort out the individual object types and update the properties accordingly. For instance, here is how to update a group so that it will only accept messages from two mailboxes and the members of another group:

```
[PS] C:\> Set-DistributionGroup -Identity "Executive Committee"
-AcceptMessagesOnlyFromSendersOrMembers "Ben Owens", "CEO Mailbox", "Vice Presidents"
```

- **GrantSendOnBehalfTo:** Controls who has the right to send messages on behalf of the distribution list.
- You can also assign the **SendAs** right to a user for a distribution list. For example, here is how to assign the *SendAs* permission for the Executive Committee distribution list to the CEO Mailbox user.

```
[PS] C:\> Add-RecipientPermission -Identity ExecCommittee -Trustee "CEO Mailbox" -AccessRights
SendAs
```

**Note:** To protect resources, Exchange Online [enforces limits](#) on the number of recipients that can exist for an individual message (500) and the total number of recipients that a mailbox can send messages to in a single day (10,000). These specific limits exist to prevent tenants using Exchange Online from as a bulk email service. When Exchange Online checks messages against these limits, distribution lists, and dynamic distribution lists count as a single recipient, even if the use of these groups means that a message addresses many more recipients than allowed by the limit after the transport service expands groups into individual addressees.

## Blocking BCC Delivery to Distribution Lists

Distribution lists can often become very chatty, which leads members to create inbox rules to filter messages sent to the list to stop emails from cluttering up their inbox. People can get around inbox rules by addressing the distribution list as a BCC recipient. Inbox rules can process TO and CC recipients, but not BCC recipients because these recipients are not present in the message header.

To solve the problem, you can set the *BccBlocked* property of a distribution list to `$True`. By default, the value is `$False`. When set to `$True`, the transport service blocks any message sent to the distribution list as a BCC recipient and the sender receives a non-delivery notification with code 5.7.138. To block BCC deliveries to a distribution list, run the *Set-DistributionGroup* cmdlet:

```
[PS] C:\> Set-DistributionGroup -Identity "Message Board Posting" -BccBlocked $True
```

## Reporting Distribution List Membership

You can use the EAC, the People app, or Outlook to view the membership of a distribution list, but neither interface does a good job with distribution lists of more than 20 or so recipients. The best experience is through the People interface in OWA, which makes it easy to scroll through large memberships. However, none of the interfaces provided by Microsoft allow you to print off the membership of a distribution list, so unless you invest in a third-party reporting product (see the discussion about standard usage reports in Chapter 21), it's necessary to create custom reports using PowerShell. For example, this one-liner extracts all the members of the Executive Committee distribution list and outputs some of their details into a CSV file.

```
[PS] C:\> Get-DistributionGroupMember -Identity "Executive Committee" | Select-Object Name,
DisplayName, PrimarySmtpAddress | Export-CSV "c:\temp\ExecutiveCommittee.csv" -NoTypeInformation
```

A script to create a report of distribution list membership [is available on GitHub](#).

## Updating Distribution List Membership with PowerShell

The membership of a distribution list is composed of backward links to the EXODS objects for the mail-enabled recipients that make up the membership of groups. EXODS is used instead of Azure AD because some mail-enabled objects which can be members of distribution lists, like mail-enabled public folders, do not exist as Azure AD objects. To view the membership of a distribution list, use the EAC or the Microsoft 365 admin center. If you view it through the Azure AD admin center, objects not in Azure AD are missing.

So much for reporting. Updating group membership is more interesting. We can use the *Update-DistributionGroupMember* cmdlet to update the complete group membership at one time, overwriting anything that might already exist. As shown below, the input to the cmdlet is a comma-separated list of identities (aliases, display names, or email addresses) for the group members. Make sure that Exchange can resolve all the identities. If even one is erroneous, the update will fail.

```
[PS] C:\> Update-DistributionGroupMember -Identity "Blog Writers" -Members @("TRedmond", "Bowens")
```

Alternatively, you can use the *Add-DistributionGroupMember* cmdlet to add a single object to a group or *Remove-DistributionGroupMember* to remove a member. For example:

```
[PS] C:\> Add-DistributionGroupMember -Identity "Blog Writers" -Member VanHybrid
Remove-DistributionGroupMember -Identity "Blog Writers" -Member VanHybrid -Confirm:$False
```

Here's another example of a script to add a mailbox to a set of distribution lists. A single-column CSV file holds the aliases of the target distribution lists. After checking that the input mailbox is valid, the *Import-CSV* cmdlet imports the set of distribution lists from the file and stores it in an array. A loop then moves through the array to add the mailbox to each of the target lists.

```
[PS] C:\> $CheckName = Read-Host "Enter Name of mailbox to add"
Try {
    $Mbx = Get-ExoMailbox -Identity $CheckName -ErrorAction Stop | Select -ExpandProperty
    PrimarySmtpAddress}
Catch {
    Write-Host "No mailbox can be found called" $CheckName; break }

$DLs = Import-CSV "C:\Temp\InputDLs.csv"
```

```
ForEach ($DL in $DLs) {  
    Try {  
        Add-DistributionGroupMember -Identity $DL."DL Alias" -Member $Mbx -ErrorAction Continue }  
    Catch {  
        Write-Host "Couldn't add" $Mbx "to DL" (Get-DistributionGroup -Identity $DL."DL  
Alias").DisplayName }  
}
```

Sometimes people change jobs and need to transfer membership of several distribution lists to another person. This is easily scripted with PowerShell, as evident [in this example](#).

## User Updates of Distribution Lists

Users with cloud mailboxes can edit the membership of the distribution lists that they own using Outlook or OWA. However, distribution list owners should select the online Global Address List rather than the Offline Address Book (OAB) as this will ensure that up-to-date group membership is available and that updates occur quickly. You can still update group membership through the OAB, but everything seems to happen much slower.

Things are much trickier in a hybrid environment where those with Exchange Online mailboxes cannot manage on-premises distribution lists, even if they are a registered owner. The same is true for those who have on-premises mailboxes as they cannot edit distribution lists created in the cloud. Permissions and the ability of Outlook to support cross-platform editing of the membership of distribution lists are the main reasons. In hybrid environments, you are better off using OWA to edit distribution list membership unless you are positively sure that the mailbox and group are on the same platform.

## Including a Microsoft 365 Group in a Distribution List

You can include a Microsoft 365 group in the membership of a distribution list, but only through PowerShell. The Microsoft 365 group is treated like a nested distribution list composed of mailboxes and guest accounts (mail contacts). To add a group, run the *Add-DistributionGroupMember* cmdlet. For example:

```
[PS] C:\> Add-DistributionGroupMember -Identity P365.Authors -Member ExchangeMVPs
```

## Removing a Distribution List

The *Remove-DistributionGroup* cmdlet removes a distribution list. Once you remove a list, it's irrecoverable and will need to be recreated if removed in error. This command is an example of removing a distribution list without using a confirmation prompt:

```
[PS] C:\> Remove-DistributionGroup -Identity P365.Authors -Confirm:$False
```

## Including a Teams Channel in a Distribution List

As discussed in Chapter 12, the email integration for Teams creates email addresses used to send emails to a channel in a team. Messages sent to a channel appear as new conversations in the channel. Teams also captures a copy of messages delivered to the channel in the SharePoint site belonging to the team. To add a team channel email address to a distribution list, create a new mail contact with the address and add the mail contact to the distribution list.

## Including a Guest Account in a Distribution List

Groups, Teams, Planner, and SharePoint are among the apps which use Azure B2B Collaboration to share resources with external people using guest accounts. Exchange Online represents guest accounts as mail users, but the mail user objects for guest accounts don't show up in address lists, so you can't add them to a distribution list through EAC or a client UI. Instead, you can add them to a distribution list via PowerShell. This code adds the mail user object for the guest account JohnSmith@outlook.com to a distribution list:

```
[PS] C:\> Add-DistributionGroupMember -Identity MyDL -Member JohnSmith_outlook.com#EXT#
```

## Discovering Distribution Lists and Groups Someone Belongs to

You can discover the distribution lists to which a user belongs by examining their mailbox properties through EAC or the Microsoft 365 admin center. Here's how to do it with PowerShell:

```
[PS] C:\> $Dn = (Get-ExoMailbox -Identity Kim.Akers).DistinguishedName
Get-DistributionGroup -Filter "Members -eq '$Dn'"
```

You can replace *Get-DistributionGroup* with the *Get-ExoRecipient* cmdlet to report the different types of groups to which someone belongs. We sort the output to report membership of the different types of groups based on the *RecipientTypeDetails* (group type) information.

```
[PS] C:\> Get-ExoRecipient -Filter "Members -eq '$Dn'" -Properties RecipientTypeDetails | Sort
RecipientTypeDetails | Format-Table DisplayName, RecipientTypeDetails
```

You can use a variation of this command to focus on membership of a specific group type. For instance, this command creates a list of Microsoft 365 Groups to which the user belongs because we specify that we only want to see data with *RecipientTypeDetails* set to *GroupMailbox*.

```
[PS] C:\> Get-Recipient -Filter "Members -eq '$Dn'" -RecipientTypeDetails GroupMailbox | Format-
Table DisplayName
```

## Dynamic Distribution Lists

Traditional email distribution lists work very well. However, some well-known deficiencies exist. Maintenance of group membership to ensure accurate delivery of messages remains an issue, especially for groups with frequent membership changes. Dynamic distribution lists do not have fixed membership. Instead, the Exchange transport service calculates the membership by resolving a query (recipient filter) against the EXODS directory to return the current set of members. The recipients can be any type of mail-enabled object supported by Exchange, including user and shared mailboxes, public folders, mail contacts, and other distribution lists.

In the past, the transport service performed resolved the directory query on an on-demand basis as messages arrived addressed to the list. Because the query fetches the latest recipient information from the directory, this approach guarantees that the recipient set used to address messages is always up to date. However, resolving on-demand queries can create a heavy demand on system resources, especially when the recipient filter is complex.

Taken together with the fact that most list memberships do not change very often, in late 2021, Microsoft moved Exchange Online to a timed calculation model like that used for Azure AD dynamic groups. This means that the transport service calculates the memberships of dynamic distribution lists:

- At least once daily.
- After the recipient filter changes.
- Following the creation of a new dynamic distribution group.

In the case of the last two scenarios, it can take up to two hours before group membership is available for use. You can see when the transport service last updated the membership for dynamic distribution lists by running the *Get-DynamicDistributionGroup* cmdlet and examining the *CalculatedMembershipUpdateTime* property. For example:

```
[PS] C:\> Get-DynamicDistributionGroup | Format-Table DisplayName, CalculatedMembershipUpdateTime
```

DisplayName	CalculatedMembershipUpdateTime
Company-DDG	12/12/2021 20:00:36
Dublin users	12/12/2021 20:00:36
Office 365 Gurus	12/12/2021 20:00:36
AuthorizedGroupCreators	12/12/2021 20:00:36

Dynamic Distribution Lists are simple, robust, and work well when you need to communicate with a changeable set of mail-enabled recipients. The key to a successful deployment is to make sure that EXODS (and by extension, Azure AD) is populated with accurate data to allow recipient filters find the correct recipients. With that thought in mind, let's discuss how recipient filters work.

## Recipient Filters

Recipient filters are OPATH queries executed against the directory to return a set of objects. A query can vary from very simple lookups such as "all the users in the London office" or "everyone who works for the Accounting department" or "all full-time employees" to more complex queries involving lookups against multiple recipient attributes. The weak point for a recipient filter is the accuracy of the data in the queried repository. If the properties of EXODS objects are not populated with accurate data, then incomplete or erroneous sets of recipients will be found when the transport service uses the queries to find the set of recipients to route messages. On the other hand, if EXODS is well maintained (or Azure AD, as many attributes synchronize from Azure AD to EXODS) with the information required to support effective queries, dynamic distribution lists work very well.

Once you know the query to find the desired recipient set, creating a new dynamic distribution list is not difficult. The EAC interface helps administrators to compose the query used to determine distribution list membership. Each condition that you add to the query is a rule that checks an attribute of the objects that fall under the scope of the query (all recipient types, user mailboxes, and so on) against one or more text values. In Figure 11-18, we check the Company attribute for user mailboxes to look for a specific value. If multiple acceptable values exist for an attribute, input each value separated by a comma.

Groups > Add a group

**Assign users**

Group owners have unique permissions. They can add or remove members, delete conversations from the shared inbox, and change group settings. Group owners can also rename the group, update the description, and more.

Owner

Members  
 Specify the type of recipients that will be members of this group.

All recipient types

Only the following recipient types

- Users with Exchange mailboxes
- Mail users with external email addresses
- Resource mailboxes
- Mail contacts with external email addresses
- Mail-enabled groups

Membership in this group will be determined by the rules you set below

Add another rule

Figure 11-18: Defining settings for a dynamic distribution list

**Dynamic Distribution Lists and Azure AD:** Dynamic Distribution Lists are an Exchange object and are only registered in EXODS, the Exchange Online directory. They do not appear in Azure AD because they

are not Azure AD objects like accounts, distribution lists, security groups, Microsoft 365 groups, and dynamic Microsoft 365 groups.

## How Recipient Filters Work

Dynamic distribution lists use one of two types of recipient filters:

- **Precanned filters** are used when a DDL is created through the EAC. Precanned filters are restricted to queries against a small number of object properties such as the department, city, and 15 customizable attributes.
- **Custom filters** are created when you use PowerShell to define a recipient filter. Custom filters are more powerful and flexible than precanned filters because a wider set of properties can be included in a query. Once you apply a custom filter to a DDL, you won't be able to edit the filter through the EAC.

The EAC UI restricts queries to a limited set of mailbox properties selected because they are the most popular:

- StateOrProvince.
- Company.
- Department.
- Any of the 15 single-value custom attributes (*CustomAttribute1* through *CustomAttribute15*).

When you save a dynamic distribution list with either EAC or PowerShell, Exchange writes its recipient filter into the list properties after applying some extra processing to the filter to ensure that it finds the right objects. This means that a relatively simple recipient filter as viewed in the EAC GUI looks very different when viewed through PowerShell using the *Get-DynamicDistributionGroup* cmdlet. For example:

```
[PS] C:\> Get-DynamicDistributionGroup -Identity "Microsoft 365 Gurus" | Select RecipientFilter,
RecipientFilterType

RecipientFilter      : (((((RecipientType -eq 'UserMailbox') -and (CustomAttribute1 -like 'Exchange'))
--and (Alias -ne $null))) -and (-not(Name -like 'SystemMailbox{*}')))) -and (-not(Name -like
'CAS_{*}')))) -and (-not(RecipientTypeDetailsValue -eq 'MailboxPlan')))) -and (-
not(RecipientTypeDetailsValue -eq 'DiscoveryMailbox')))) -and (-not(RecipientTypeDetailsValue -eq
'PublicFolderMailbox')))) -and (-not(RecipientTypeDetailsValue -eq 'ArbitrationMailbox')))) -and (-
not(RecipientTypeDetailsValue -eq 'AuditLogMailbox')))) -and (-not(RecipientTypeDetailsValue -eq
'AuxAuditLogMailbox')))) -and (-not(RecipientTypeDetailsValue -eq
'SupervisoryReviewPolicyMailbox')))) -and (-not(RecipientTypeDetailsValue -eq 'GuestMailUser')))) -
and (-not(Name -like 'SystemMailbox{*}') -and (-not(Name -like 'CAS_{*}')) -and (-
not(RecipientTypeDetailsValue -eq 'MailboxPlan')) -and (-not(RecipientTypeDetailsValue -eq
'DiscoveryMailbox')) -and (-not(RecipientTypeDetailsValue -eq 'PublicFolderMailbox')) -and (-
not(RecipientTypeDetailsValue -eq 'ArbitrationMailbox')) -and (-not(RecipientTypeDetailsValue -eq
'AuditLogMailbox')) -and (-not(RecipientTypeDetailsValue -eq 'AuxAuditLogMailbox')) -and (-
not(RecipientTypeDetailsValue -eq 'SupervisoryReviewPolicyMailbox'))))
RecipientFilterType: Custom
```

The recipient filter shown above looks for user mailboxes that have “Exchange” in *CustomAttribute1* and excludes all the various types of system mailboxes. The filter seems very complex and difficult to construct, but you don't have to insert these exclusions as Exchange creates them automatically.

When you see *Custom* as the *RecipientFilterType*, you know that PowerShell was used to create a custom recipient filter (see example below). If you see *Precanned*, you know that the recipient filter is based on the pre-prepared queries (like “all mail-enabled recipients”) available through EAC. Only dynamic distribution lists with precanned filters can have their recipient filters updated through the EAC. Although the other properties of dynamic distribution lists which have custom filters can be maintained through EAC, PowerShell must be used to edit their custom recipient filters.

## Checking the Effectiveness of a Recipient Filter

The EAC doesn't include a way to check the effectiveness of a recipient filter. In other words, how to be sure that the filter will find the right set of recipients when the Exchange transport service resolves it against the directory to compute the list membership. However, you can check with PowerShell by inputting the filter to

the *Get-Recipient* cmdlet. For example, here's how to check the recipient filter for the Microsoft 365 Gurus dynamic distribution list:

```
[PS] C:\> Get-Recipient -RecipientPreviewFilter (Get-DynamicDistributionGroup -Identity "Microsoft 365 Gurus").RecipientFilter
```

Name	RecipientType
Jeff.Guillet	UserMailbox
Tony.Redmond	UserMailbox
Paul.Robichaux	UserMailbox

In this instance, if you expect the query should return three mailboxes, it works. If not, the fault is either in the query (it searches for the wrong data) or the underlying data (does not contain the right values). Testing the results of a query is important not only because the results will reveal any flaw in your logic and identify whether the filter returns the correct recipient set when the query executes against the directory. It will also tell you how many recipients are in the selected set. Equipped with that knowledge, we can construct some guidelines to help administrators maintain dynamic distribution lists. For example, your organization might use the following guidelines for both standard and dynamic distribution lists:

- Any distribution list with more than 200 recipients should have a MailTip to highlight the fact to users. Exchange Online automatically displays a MailTip to tell the sender how many people will receive their email, but you can add another MailTip to urge additional caution when sending to very large distribution lists.
- Any distribution list with more than 500 recipients should be moderated to ensure that people do not inadvertently broadcast to distribution lists such as "The Entire Company". Moderated distribution lists are also a good way to stop email storms that result when users reply-all to very large distributions.

After you create a new dynamic distribution list or update the recipient filter for an existing list, the Exchange transport service resolves the recipient filter against the directory to compute the set of members. This process can take up to two hours. When it is complete, you can run the *Get-DynamicDistributionGroupMember* cmdlet to check what recipients Exchange will use when someone addresses a message to the list.

```
[PS] C:\> Get-DynamicDistributionGroupMember -Identity "Microsoft 365 Gurus"
```

Name	RecipientType
Tony.Redmond	UserMailbox
Jeff.Guillet	UserMailbox
Paul.Robichaux	UserMailbox

Even if the members do not appear in the same order, the memberships reported by *Get-Recipient* and *Get-DynamicDistributionGroupMember* for the same list should be the same.

Finding the set of dynamic distribution lists a user belongs to is a two-step process. After fetching the distinguished name of their mailbox, we use the distinguished name to check the membership of each dynamic distribution list as it passes through the pipeline:

```
[PS] C:\> $Dn = (Get-ExoMailbox -Identity Chris.Bishop).DistinguishedName
Get-DynamicDistributionGroup | ? {(Get-DynamicDistributionGroupMember -Identity
$_PrimarySMTPAddress | ? {$_DistinguishedName -eq $Dn})}
```

## Creating and Managing Dynamic Distribution Groups with PowerShell

PowerShell is a good way to create lists with both simple recipient and complex custom recipient filters. Our example requires a relatively simple recipient filter, as shown below where two precanned attributes are specified in parameters passed to the *New-DynamicDistributionGroup* cmdlet. The first checks for a value in

*CustomAttribute9* using the *ConditionalCustomAttribute9* parameter; the second limits the set of recipients returned to mailbox users by specifying that value in the *IncludedRecipients* parameter. After the new list is created, the *Set-DynamicDistributionGroup* cmdlet updates the list to add a manager (owner) and a MailTip. The person specified as the list manager must exist in the GAL.

```
[PS] C:\> New-DynamicDistributionGroup -Name DynamicPowerApps -DisplayName "Power Platform Experts DL" -ConditionalCustomAttribute9 PowerPlatform -IncludedRecipients MailboxUsers -PrimarySmtpAddress PowerPlatform@office365itpros.com -Alias Power.Platform
Set-DynamicDistributionGroup -Identity Power.Platform -ManagedBy James.Joyce@office365itpros.com -MailTip "People with real expertise in Power Platform"
```

## Complex Recipient Filters

Recipient filters support [a much wider set of filterable properties](#) than the set exposed by the EAC when composing query rules, but you can only use these properties by creating a custom recipient filter and writing the filter into the dynamic distribution list using PowerShell. Take the example where we want to create a dynamic distribution list to communicate with users whose mailboxes have been placed on litigation hold. To accomplish the goal, we follow these steps:

- Build the filter and test its effectiveness by using it with the *Get-Recipient* cmdlet.
- Update an existing dynamic distribution list or create a new dynamic distribution list with the tested filter.

For example, here's how to define and test a filter to find mailboxes on litigation hold based in Dublin.

```
[PS] C:\> $Filter = "((LitigationHoldEnabled -eq '$True') -and (StateOrProvince -eq 'Dublin') -and (RecipientType -eq 'UserMailbox'))"
```

```
Get-Recipient -RecipientPreviewFilter $Filter
```

Name	RecipientType
TRedmond	UserMailbox
James.Ryan	UserMailbox

Another example is a filter that looks for accounts with a certain job title that the organization has not disabled (the *ExchangeUserAccountControl* setting for a mailbox is set to *AccountDisabled* when the owning Azure AD account is blocked). This requires a filter that's slightly more complex to cover the range of job titles that might be in use. The need to specify multiple variants of the property is explained by the lack of wildcard support preceding a value in recipient filters (like *"\*architect"*). You can use wildcards after the value (like *"architect\*"*). The net result is that a filter for multiple variants of a value can end up with many *-or* clauses:

```
[PS] C:\> $Filter = "((Title -eq 'Architect') -or (Title -eq 'Senior Architect') -or (Title -eq 'Principal Architect') -and (ExchangeUserAccountControl -ne 'AccountDisabled'))"
```

Note that system values like *\$True* and string literals are enclosed in single quotes. If you don't do this, OPATH will signal an error. After testing the filter and verifying the accuracy of the chosen filter, we can use it when creating a dynamic distribution list. In this case, we use the filter to find accounts on litigation hold in Dublin:

```
[PS] C:\> New-DynamicDistributionGroup -Name "Dublin Mailboxes on Litigation Hold" -DisplayName "Dublin User Mailboxes on Litigation Hold" -Alias DublinLitigation -PrimarySmtpAddress Dublin.Litigation@Office365itpros.com -RecipientFilter $Filter
```

```
Set-DynamicDistributionGroup -Identity DublinLitigation -ManagedBy Legal.Assistant@Office365itpros.com -MailTip "People under litigation hold in Dublin"
```

Dynamic distribution lists which address sets of people like those under litigation hold might be deemed confidential. In this situation, you can hide them from address lists by setting their *HiddenFromAddressLists* property to *\$True*:

```
[PS] C:\> Set-DynamicDistributionGroup DublinLitigation -HiddenFromAddressListsEnabled $True
```

Anyone who needs to send messages to a hidden dynamic distribution list can do so by using its SMTP address. Messages sent to dynamic distribution lists with queries that don't find any recipients go into a void. Exchange doesn't generate a non-delivery notification for the sender because the address for the dynamic distribution list is valid: the problem is that the list query doesn't return any recipients, which is a valid condition. This is a good reason for testing the recipient filter for a dynamic distribution list to make sure that it finds the correct set of recipients.

## Finding Inactive Distribution Lists

Another common request is to know if any distribution lists are inactive and are therefore candidates for removal. Exchange Online does not include a way to find and report inactive distribution lists, so we must create one with PowerShell. The key points to remember are:

- A distribution list is active when people use it to address messages.
- Evidence of distribution list activity can be found in the message tracking logs by running a message trace to find events noting the expansion of distribution list memberships.
- Exchange Online keeps message tracking logs online for up to 10 days, after which the information is moved into data repositories and kept there for an extra 80 days. Thus, online searches can only look back 10 days to find expansion events. See Chapter 7 for more information about running message traces from the Exchange admin center.

With these points in mind, we can write a script to collect expansion events from the message tracking logs for the last 10 days and store the results in a table. We can then check the distribution lists in the tenant against the table to discover if we find a match. If we do, we know that the distribution list was used in the last ten days. If not, it was inactive at that time. Apart from reporting each list as it is checked, the script also outputs the results to a CSV file.

```
[PS] C:\> $EndDate = Get-Date; $StartDate = $EndDate.AddDays(-10); $Messages = $Null; $Page = 1
Write-Host "Collecting message trace data for the last 10 days"
Do
{
    $PageOfMessages = (Get-MessageTrace -Status Expanded -PageSize 5000 -Page $Page -StartDate
$StartDate -EndDate $EndDate | Select Received, RecipientAddress)
    $Page++
    $Messages += $PageOfMessages
}
Until ($PageOfMessages -eq $Null)

$MessageTable = @{}
$MessageTable = ($Messages | Sort RecipientAddress -Unique | Select RecipientAddress, Received)
$DLs = Get-DistributionGroup -ResultSize Unlimited
Write-Host "Processing" $DLs.Count "distribution lists..."
$Results = ForEach ($DL in $DLs) {
    If ($MessageTable -Match $DL.PrimarySMTPAddress) {
        [pscustomobject]@{Name = $DL.DisplayName ; Active = "Yes"}
        Write-Host $DL.DisplayName "is active" -ForegroundColor Yellow }
    Else {
        [pscustomobject]@{Name = $DL.DisplayName ; Active = "No"}
        Write-Host $DL.DisplayName "inactive" -ForegroundColor Red }
}
$Results | Export-CSV c:\Temp>ListofDLs.csv -NoTypeInformation
```

Given that message traces give us a limited ten-day window to detect inactive distribution lists, this is not a practical technique for a production-quality solution. Nevertheless, the method gives us the basis to develop the technique further into something that might work. For instance, you could run a script every ten days and merge the results over a few months to give a more precise view of inactive and active lists.

## Controlling User-Created Distribution Lists

The set of OWA options controllable on a per-mailbox basis includes a “distribution groups” link to allow users to manage distribution lists they belong to and those that they own. To see the set of distribution lists owned by a user, select **OWA Options**, then **General**, and then **Distribution groups**. OWA decides what options are available for a user to work with distribution lists by evaluating if the “*MyDistributionGroups*” and “*MyDistributionGroupMembership*” roles are in the user role assignment policy assigned to their mailbox.

In Figure 11-19 we can see that both roles are present in the default role assignment policy used by Exchange Online. Note that users can only create standard distribution lists – they cannot create security groups or dynamic distribution lists. As explained earlier, the ability for a user to create a new Microsoft 365 Group is controlled by a setting in the Azure AD policy for Groups.

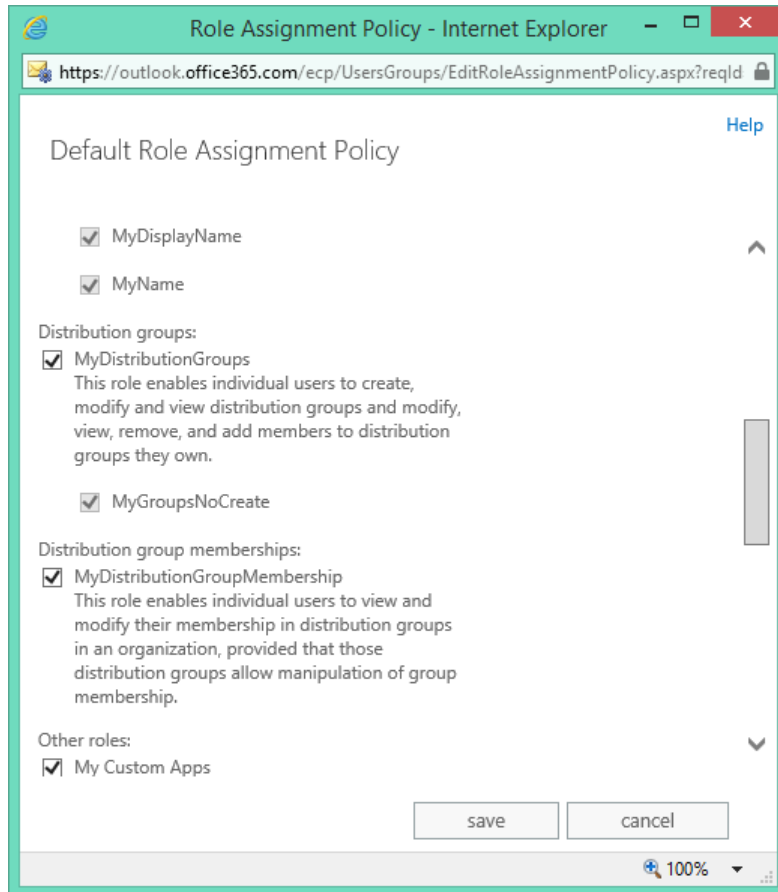

Figure 11-19: Distribution list entries in the default user role assignment policy

Even if your tenant deploys a distribution list naming policy, to prevent “directory anarchy”, many organizations also like to control who can create new distribution lists, and do not want users to create new distribution lists without oversight. You can remove the ability of users to create new distribution lists by unchecking the *MyDistributionGroups* option in the default role assignment policy as OWA will not then display the UI. However, a subtler approach is also possible that allows users to see the distribution lists to which they belong and to edit the membership of distribution lists that they own. Given that some organizations are migrating distribution lists to Microsoft 365 Groups, it makes sense to leave users with the ability to work with distribution lists that they already have while blocking their ability to create any more.

To achieve the goal, you must create a new user role assignment policy and amend it to remove the setting which allows users to create new distribution lists. Here are the steps:

- Go to the Permissions section of classic EAC, click **user roles**, and then **[+]** (the plus sign) to create a new user role assignment policy. Give the policy a suitable name and description and check all the

boxes to allow users access to the various items of functionality. In effect, you start by cloning the default user role assignment policy. In this example, the new policy is "Restricted Group Management".

- Using PowerShell, define a new management role that is based on the existing *MyDistributionGroups* role. We will call the new management role *MyGroupsNoCreate*.

```
[PS] C:\> New-ManagementRole -Name "MyGroupsNoCreate" -Parent MyDistributionGroups
```

- The new management role still allows users to create new distribution lists. To remove that ability, we have to remove the reference (or role entry) to the *New-DistributionGroup* cmdlet from the *MyGroupsNoCreate* management role. This command breaks the link.

```
[PS] C:\> Remove-ManagementRoleEntry MyGroupsNoCreate\New-DistributionGroup -Confirm:$False
```

- A user role assignment policy consists of a set of connections between management roles and the policy. The new user role assignment policy that we created in the first step still contains a reference to the standard *MyDistributionGroups* role. We need to remove it before we can add the altered management role that we have just created.

```
[PS] C:\> Remove-ManagementRoleAssignment "MyDistributionGroups-Restricted Group Management" -Confirm:$False
```

- Now we add a management role assignment to link the *MyGroupsNoCreate* role to the "Restricted Group Management" policy.

```
[PS] C:\> New-ManagementRoleAssignment -Name "MyGroupsNoCreate-Restricted Group Management" -Role MyGroupsNoCreate -Policy "Restricted Group Management"
```

- We can then check that the correct roles exist in the "Restricted Group Management" policy. You should find a link to the *MyGroupsNoCreate* in the list and no reference to *MyDistributionGroups*. Remember that *MyGroupsNoCreate* has all the functionality of *MyDistributionGroups* except the link to the *New-DistributionGroup* cmdlet. Because they cannot run the cmdlet, a user to whom we assign this policy can do everything except create a new distribution list.

```
[PS] C:\> Get-ManagementRoleAssignment -RoleAssignee "Restricted Group Management" | Format-Table Name, Role -AutoSize
```

To prove that everything works, we apply the Restricted Group Management policy to a mailbox:

```
[PS] C:\> Set-Mailbox -Identity 'Nancy Anderson' -RoleAssignmentPolicy "Restricted Group Management"
```

Then, after waiting ten minutes or so to ensure that any cached permissions are clear, we log in to validate that when the user accesses the **Distribution groups** option in the **General** section of OWA options, they still see the set of distribution lists that they belong to in addition to the distribution lists that they own. What we want to see is that the plus sign (+) icon that allows them to create a new distribution list is missing, as it is in Figure 11-20.

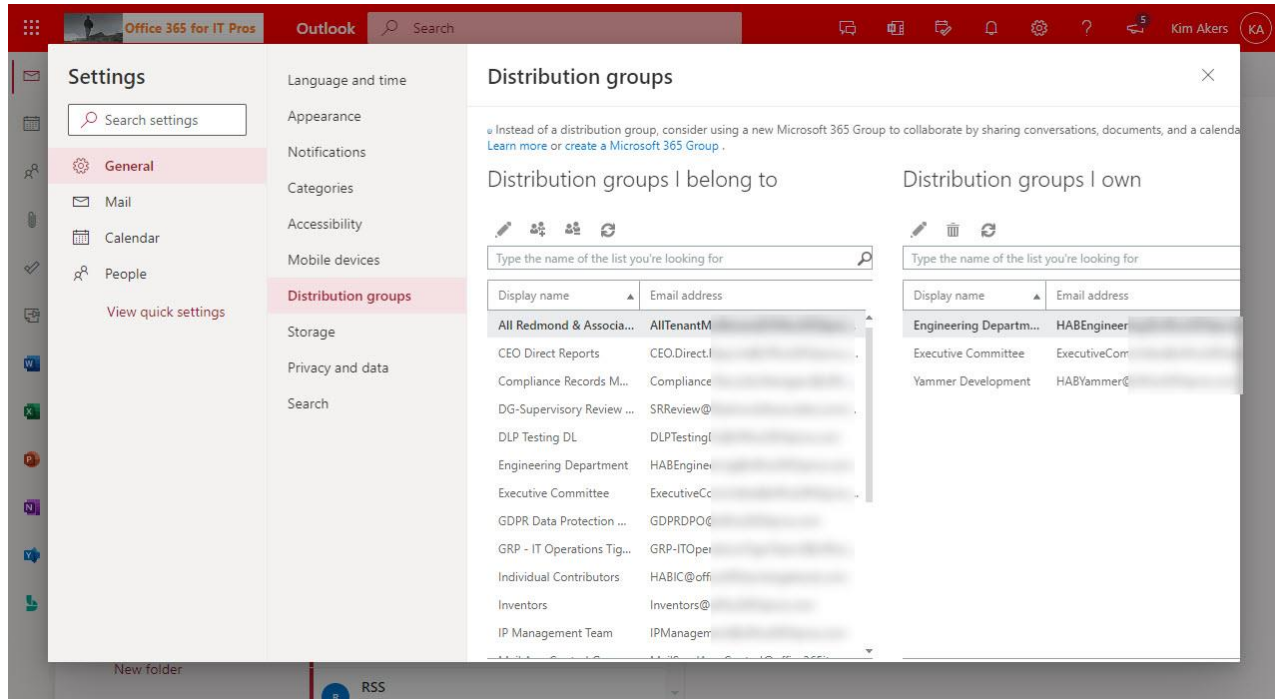

Figure 11-20: The effect of the restricted user role assignment policy

## Distribution List Naming Policy

If you allow users to create new distribution lists, you can expect that some will not be as disciplined as you might like when naming their distribution lists. No one likes to see entries such as “Billy-Bob’s Fishing Aficionados” show up in the GAL. The name does not convey a sense of the true business purpose behind its existence. To help guide users, organizations can create a distribution list naming policy. The policy can include:

- A prefix to apply to the user-supplied name for a new distribution list. The prefix can be multi-part and consist of text strings and the values of attributes for the user account stored in Azure AD. The policy forces the insertion of a blank character if the user account does not store a value for the chosen attribute.
- A suffix to add to the user-supplied name for a new distribution list. Again, you can use both text and attribute values.
- Barred or forbidden words that users cannot include in the name for a new distribution list. For instance, you can prohibit potentially offensive terms by including them in the policy.

To configure the distribution list naming policy, go to the **Groups** section of the EAC, select the distribution list tab and then **Add naming policy**. Figure 11-21 shows the screen to define the components of the naming policy. The parameters selected indicate that all names should be prefixed with “DL-” (the text string DL plus a hyphen) followed by the value of the Department attribute for the user’s account and then another string value containing a space. The policy should generate names for distribution lists like *DL-Sales Members*, *DL-Accounts Team 1*, *DL-CEO Office Executives*, *DL-Finance Volleyball team*, and so on.

One reason why organizations use a naming policy is to ensure that distribution lists appear in a single section within the GAL. Adding the department name ensures that the distribution lists belonging to a department are found together. Behind the scenes, Exchange Online stores details of the distribution list naming policy as settings in the tenant organization configuration. You can view the settings with the *Get-OrganizationConfig* cmdlet:

```
[PS] C:\> Get-OrganizationConfig | Format-Table Distr* -AutoSize
```

```
DistributionGroupDefaultOU DistributionGroupNameBlockedWordsList DistributionGroupNamingPolicy
```

{XXX, Cheese}
DL-<Department> <GroupName>

×

## Edit group naming policy

Policy
Blocked words

Add prefixes and suffixes to new group names.

**Current policy**  
DL-<StateOrProvince> "<GroupName>

**Create a policy**

Text	DL-		×
Attribute	Department		×
Text			×

[Add prefix](#)

**AND**  
Select a suffix to add to the end of group names

[Add suffix](#)

Save

Figure 11-21: Creating a distribution list naming policy

These properties have the following meanings:

- The *DistributionGroupBlockedWordsList* property holds words that cannot be used in a group name.
- The *DistributionGroupNamingPolicy* property defines the pattern for names. In the example shown below, the policy consists of four elements:
  - A text string "DL-."
  - <Department> means that the Department value stored in the user's Azure AD account is inserted.
  - Another space is then inserted.
  - <GroupName> means the name of the distribution list as supplied by the user.
- The *DistributionGroupDefaultOU* property is only used in on-premises deployments. However, it still appears in the Exchange Online organization configuration.

It is possible to create or amend the naming policy through PowerShell. For instance:

```
[PS] C:\> Set-OrganizationConfig -DistributionGroupNamingPolicy "DL-<Department> <GroupName>"
```

To remove the distribution list naming policy, set the value of *DistributionGroupNamingPolicy* to *\$Null*:

```
[PS] C:\> Set-OrganizationConfig -DistributionGroupNamingPolicy $Null
```

The distribution list naming policy applies to user-created distribution lists and has no retrospective effect. You must update the names of existing distribution lists if you want them to follow a new policy. To do this, use PowerShell to find distribution lists with non-compliant names and then update their names according to

the naming policy. The old EAC allows administrators to create distribution lists without applying the policy: the new EAC does not.

if an administrator creates a distribution list with PowerShell, they can pass the *IgnoreNamingPolicy* parameter to instruct Exchange Online to not apply the policy. For example:

```
[PS] C:\> New-DistributionGroup -Name "Tiger Team" -Members Jill.Smith@Office365itpros.com, Ben.Owens@office365itpros.com, Kim.Akers@office365itpros.com -IgnoreNamingPolicy
```

The distribution list naming policy does not apply to dynamic distribution lists or mail-enabled security groups because users cannot create these types of groups. The policy does not apply to Microsoft 365 Groups, which use a separate naming policy.

Defining a distribution list naming policy for Exchange Online can also affect the way that on-premises distribution lists synchronize in hybrid deployments. To make everything consistent, Exchange applies the naming policy to distribution lists belonging to the on-premises organization when they synchronize with Azure AD objects with AADConnect. Thus, an on-premises distribution list might have a different name in the on-premises directory than that shown in Azure AD unless you make sure to apply the same naming policy in both environments.

## Migrating On-Premises Distribution Lists to Exchange Online

Exchange Online doesn't include any out-of-the-box method to migrate a distribution list from an on-premises Exchange organization to Exchange Online. When an on-premises organization is synchronized with Exchange Online in a hybrid deployment, the suggested method is to remove the distribution list from on-premises and recreate it as a brand-new object in the cloud. For anything but simple lists with just a few members, this is a tiresome process, but it reflects the fact that transferring a distribution list to the cloud can be quite complex because:

- The owner(s) of the distribution list might not have their account(s) in the cloud. An on-premises user cannot manage a cloud-based distribution list.
- Objects for mail-enabled members of the distribution list might not exist in the cloud. For example, a mail contact in the on-premises environment might not be synchronized to the cloud.
- The distribution list might hold other distribution lists.
- The proxy addresses for the on-premises distribution list must be transferred to the new list.
- Some properties of distribution lists refer to other directory objects that must exist in the target environment before they can be used. For example, the property that controls the ability of users to send emails on behalf of the list.

It is possible to write a PowerShell script to concurrently connect to Exchange on-premises and Exchange Online and perform the processing to transfer a distribution list. The script must:

- Check that all the prerequisites are satisfied for the transfer to go ahead. For example, are all the members of the list known in the cloud.
- Create the target distribution list in Exchange Online.
- Read information about the source distribution list from Exchange on-premises and update the properties of the target distribution list.
- Assign a new proxy address to the source distribution list and transfer it to the target distribution list.
- Update the membership of the target distribution list with the membership of the source list.
- Hide the source distribution list from address lists so that the only list that is visible to users is the target. Eventually, if the transfer worked and no problems are found, the old list is removed.

An example of a migration script for distribution lists is [available on GitHub](#) (the documentation [is here](#)). As with any script, you should test it carefully and adapt the code where necessary to meet the needs of your deployment.

# Recipient Moderation

Moderation (or “message approval”) means that a message must first be reviewed and approved by a nominated moderator before Exchange Online can deliver it to the addressee. Up to ten moderators can be assigned responsibility to control messages sent to the following recipient types:

- User Mailboxes.
- Shared Mailboxes.
- Distribution Lists.
- Dynamic Distribution Lists.
- Mail Contacts.
- Mail Users.
- Mail-enabled Public Folders.
- Group mailboxes.

Teams supports moderation for messages posted to channels by restricting the ability to post to certain members.

Moderation for individual recipients (mailboxes, mail contacts, or mail users) is intended to “protect” the recipients against inappropriate email, often because the recipients are sensitive in some way. For example, it’s reasonably common to impose moderation on the mailboxes of senior executives so that an executive assistant or another moderator can review inbound messages before passing approved items to the executive. Moderation for distribution lists is often imposed to ensure that posts to very large distributions only appear when it is appropriate to share the content with so many people. In other words, you might not want to have everyone in the company be allowed to send messages to the 50,000-recipient “All Company” distribution list. In all cases, you can arrange for select users to bypass the requirement for moderation so that their messages are delivered to the recipient without going through the approval process.

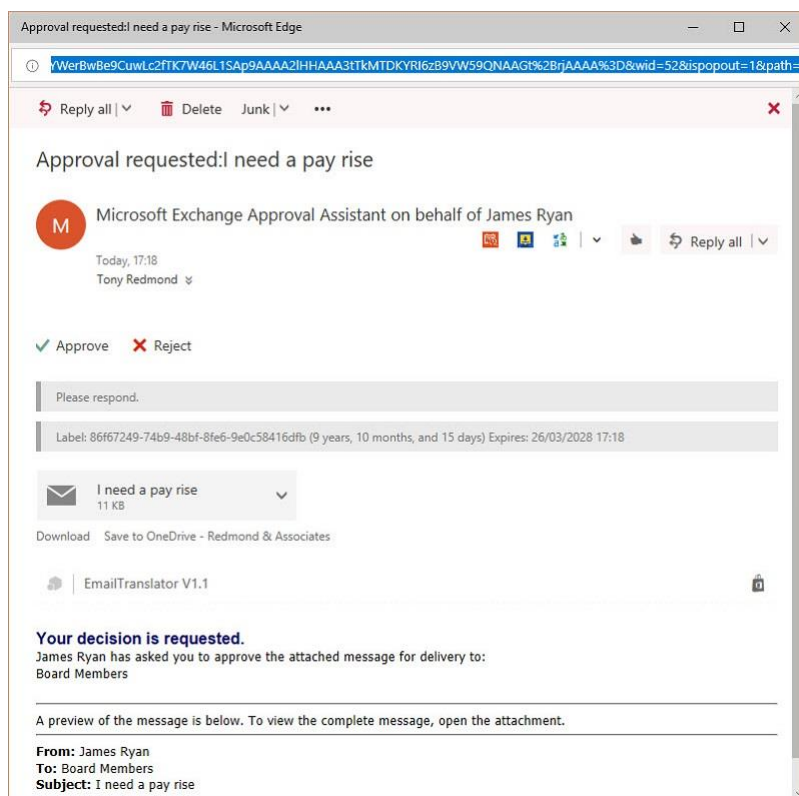

Figure 11-22: A message arrives for moderation

A moderated recipient can have multiple moderators, in which case all the nominated moderators receive copies of messages for approval (Figure 11-22). However, no quorum must be available before a message can be delivered as a simple approval from a single moderator suffices. If a message is declined by a moderator, Exchange Online returns it to the original sender. Logically, a moderator can send a message to the recipient that they are moderating without gaining further approval as can the owner of a distribution list.

A message awaiting moderation is held in an arbitration mailbox (you have no control over which arbitration mailbox is used) and should be processed within two days. However, the process that expires messages waiting in the arbitration mailbox runs on a weekly workcycle, which means that senders will receive notification that moderation has not occurred any time between two and nine days after the original message is sent – a tenant administrator can do nothing to accelerate the approval process. It is also interesting to note that Exchange Online throttles the number of expired moderation notifications to [300 per hour](#), which means that in periods when heavy usage is made of message moderation, some senders might not receive notifications that their messages have expired while awaiting moderation.

To set up moderation for a distribution list through EAC, edit the object's properties and select Message approval in the settings (Figure 11-23). Here you can set the flag to enable moderation and input the names of the users to act as moderators. Notice that you also can input the names of distribution lists or users who will bypass moderation and select who receives notification if their messages are not approved.

Figure 11-23: Editing the moderation settings for a distribution list

The EAC does not display the message approval UI for mailboxes, groups, contacts, mail users, or public folders, so you must set up moderation for these objects using PowerShell. For example, this command enables moderation for a mailbox and sets up three moderators. We also select a distribution list whose members bypass moderation.

```
[PS] C:\> Set-Mailbox -Identity "CEO Mailbox" -ModerationEnabled $True  
-ModeratedBy "Steve Smith", "Bill Jones", "CEO Assistant"  
-BypassModerationFromSendersOrMembers "Executive Committee"
```

Similar properties to enable moderation can be set through the *Set-DistributionGroup*, *Set-DynamicDistributionGroup*, *Set-MailContact*, and *Set-MailUser* cmdlets. When an object is enabled for moderation, Exchange Online creates an automatic MailTip that is displayed to users to inform them that a message will be moderated and might be delayed when they address a message to the object.

**Moderation for nested distribution lists:** Distribution lists (but not dynamic distribution lists) support the *BypassNestedModerationEnabled* parameter. If set to *\$True*, any nested distribution lists that also need moderation are governed by the decision of the moderator of the distribution list to which a message is addressed. If a moderator approves a message, it will be delivered to the members of all the nested distribution lists too. The default value of the flag is *\$False*, meaning that delivery to each moderated distribution list must be approved, but in most cases, it's reasonable to set the flag to *\$True* and allow the first moderator to control approval.

## Migration from Email Distribution Lists

Microsoft is keen that tenants should replace distribution lists with Groups. To make the move easy for tenants, five methods are available:

- Administrators can migrate individual distribution lists using the function available in the EAC.
- Group owners can migrate individual distribution lists using the function available in OWA.
- Administrators can run the PowerShell scripts created by Microsoft to migrate batches of distribution lists at one time.
- Administrators can run the *New-UnifiedGroup* cmdlet to convert an individual distribution list to a group.
- Tenants can create their versions of PowerShell scripts to perform custom migrations.

None of these methods work with distribution lists belonging to on-premises organizations. To convert these groups, you must first move them to Exchange Online, and then, when the groups are "cloud-owned", you can go ahead and convert them. Of course, it might be simpler to recreate the on-premises distribution lists as Groups and then remove them from the on-premises organization.

Email distribution lists have been around for a long time. Different forms of distribution lists exist, some of which are easy to convert while others are very difficult to move to Groups today. It is safe to say that it is relatively easy to code the steps to migrate a simple distribution list managed by Exchange Online that only has cloud mailboxes in its membership. Things become more challenging when the need arises to process distribution lists with the following characteristics:

- **Dynamic distribution lists:** Groups supports dynamic Groups, but no conversion facilities are available to migrate dynamic email distribution lists to become dynamic Groups. This could be due to some of the difficulties created by the fact that the two types of groups support different sets of member objects. For example, you can create a dynamic distribution list that includes several types of mail-enabled objects that are not all supported by Groups.
- **Nested distribution list:** It is common to meet distribution lists where the membership contains other (nested) distribution lists. For example, an "All Company" list might include several other groups, each of which might include people who work in a business unit or other division of the company. In turn, each divisional list might include other distribution lists for its operating units that hold the actual mail-enabled recipients. Nested distribution lists are not supported by Microsoft's migration toolset.

- **Mail-enabled universal security groups:** These groups are not migrated because Groups cannot act as a security principal.
- **Distribution lists that include more than mailboxes:** Groups only support user and guest accounts as members. They do not support some of the other kinds of mail-enabled recipients often found in email distribution lists, such as public folders.
- **Distribution lists with advanced settings:** Lists with send on behalf of settings or are hidden from address lists, or that have restrictions on who can join a group.

Microsoft summarizes the situation by saying that its toolset can deal with “*cloud-managed, simple, non-nested distribution lists.*” Email distribution lists that Microsoft’s migration toolset cannot process must stay in place until they are either not needed and you can remove them safely or Groups evolve to a point where they can serve as a replacement. In some cases, as in the example of nested or dynamic distribution lists used by organizations to send messages to a very large number of users, that point might never come. Remember too that some clients still in use do not support Groups, so do not plan to move away from distribution lists until all clients are prepared.

In this context, migrating an email distribution list to a group is only a question of moving members from one group to another. Any other assets used with an email distribution list, such as an associated public folder, are unaffected by the migration.

## Migration from the Exchange Administration Center

The classic version of the EAC supports the bulk migration of one or more distribution lists to Groups. The process is simple. If EAC detects that the tenant has some distribution lists that it considers eligible for migration, you can invoke a wizard to do the work. Eligibility means that the distribution lists are cloud-based rather than on-premises objects, do not include nested lists, the membership is composed of mailboxes only, and [meets other criteria](#) (see above).

### Bulk upgrade DLs to groups in Outlook

Upgrading DLs to groups in Outlook gives both existing and new members access to prior conversations and a simpler way to manage membership. [Learn more about bulk upgrades](#)

Figure 11-24: Bulk conversion of distribution lists in the classic EAC

The conversion process is painless. Select the groups that you want to migrate (Figure 11-24) and click **Start Upgrade**. The conversion wizard processes each group in turn in the background, running a command like that shown below to convert each distribution list in turn. To be sure that the wizard converts the right

distribution list, Groups references the group with its unique identifier instead of the alias, display name, or distinguished name.

```
[PS] C:\> New-UnifiedGroup -DlIdentity 'bf6aba7a-6dbc-4f2f-8e94-ae97289945d7'  
-ConvertClosedDlToPrivateGroup:$true -DeleteDlAfterMigration:$true
```

If successful, the wizard removes the old distribution list and a brand-new group exists, complete with the membership and other properties of the old group including its email addresses. The fact that the new group has the email addresses previously assigned to the old group means that users can reply to messages sent to the old group with a guarantee that Exchange can route those replies to the correct destination.

To check the progress of the conversion process, select “upgraded DLs” from the drop-down list and then **Refresh**. You might need to do this several times as EAC does not signal the successful conversion of a distribution list. The appearance of the new group on the list is the only way to know when the new group is ready to go.

When you convert a distribution list, you might consider changing the display name of the new group to reflect that it now offers added resources to its membership. This step is manual and is not performed by the conversion wizard.

The modern version of the EAC also supports upgrading distribution lists to Microsoft 365 groups, but only for individual distribution lists. The same process takes place to perform the upgrade.

**Upgrade Failure with Email Address Policies:** If you use email address policies (see the companion volume) to assign SMTP email addresses from a specific domain to newly created groups, you cannot use EAC or PowerShell to convert distribution lists to Groups. EAC will accept distribution lists for conversion and never do anything thereafter and any attempt through PowerShell throws the error that the distribution list cannot be migrated “*due to an email policy set by your IT administrator.*” The only solution is to convert the distribution list through a multi-step manual process as described later.

## User-Controlled Conversion

Many users manage distribution lists, which they might control on behalf of a business unit or just to help do their job better. If they are owners of groups, they can transfer the members of a distribution list to a new group by using OWA to edit the membership of the group and include the distribution list as a new member. When OWA saves the group, it expands the membership of the distribution list and adds individual members to the group. Although this is an effective way of moving members from email distribution lists to Groups, the obvious downside is that the old distribution list stays behind, leading to “GAL clutter”.

OWA allows owners of distribution lists to convert their groups. Behind the scenes, a background job periodically scans for distribution lists that are cloud-managed and only hold objects that can be members of Groups. The job uses other factors to find suitable distribution lists for conversion, such as those that have fewer than a hundred owners. When the processing completes, a list of convertible distribution lists owned (or managed by) the user is available for display by OWA. However, the choice to migrate distribution lists only appears when the user can create new groups as it obviously would not make sense to allow people who cannot create new groups to attempt a migration.

The set of eligible distribution lists appears at the top of the Groups section in OWA. The “DL” prefix appears before the name of the distribution lists to show that they are not groups. To migrate a distribution list, click on it. OWA then displays a screen with some details of the selected group and a big “Upgrade” button. Click to go ahead with the migration. A new group replaces the old distribution list and takes on all the properties of the source list.

## Microsoft's PowerShell Scripts

PowerShell is a terrific way to automate the process of converting distribution lists. Microsoft has [scripts available in the download center](#) to migrate all eligible distribution lists found in a tenant:

- **Get-DIEligibilityList.ps1**: Scans the tenant to find distribution lists to create a report detailing the distribution lists that can be migrated to Groups along with those that cannot (for one of the reasons given above). The output of the script is a text file (DIEligibility.txt) that you can review.
- **Convert-DistributionGroupToUnifiedGroup.ps1**: Converts all eligible distribution lists in a tenant to Groups.

The scripts are effective but can only deal with distribution lists that have the same characteristics discussed above.

## The DIY Approach to Converting Distribution Lists

Another example of how to approach the task of converting an email distribution list to a Microsoft 365 group is posted on [GitHub](#). Like all PowerShell scripts, the code is easily altered to meet the needs of a certain scenario. The basic set of tasks that a conversion script needs to perform include:

- Check whether a group with the same alias exists. The script could exit if this is the case or continue by migrating the distribution list to a new group with a different alias.
- Check whether the distribution list being migrated is a simple distribution list (type equals *MailUniversalDistributionGroup*). You could migrate the membership of a universal mail-enabled security group to a group but not the security principal. There is probably some good reason why the security principal exists, so it is probably best not to migrate these groups unless you are sure that the security element is resolved.
- Gather information about the owners (managers) and members of the input distribution list.
- Update the alias of the input distribution list with a new value to allow the reuse of the existing alias for the new group.
- Check whether the new group should be public or private. One way to do this is to look at the *MemberJoinRestriction* property of the input list. If this is "Closed" or "ApprovalRequired", then it is reasonable to assume that a private group should be the result.
- Create the new group by running the *New-UnifiedGroup* cmdlet.
- Migrate the properties of the input distribution list to the new group. A direct match of all properties does not exist, but a reasonable number of properties are common to both distribution lists and Microsoft 365 groups.
- Add the members of the new group by reading the membership information from the input distribution list and using the *Add-UnifiedGroupLinks* cmdlet to update the membership of the group. Some checking is necessary to ensure that only mailboxes are added to the group. Mail-enabled public folders and shared mailboxes are supported for distribution lists but not for Groups. In addition, you must expand the membership of nested distribution lists to figure out the set of valid members and then add them to the group.
- Because distribution lists act as a single address to distribute emails to members, it is reasonable to expect that the substitute group would behave comparably. Accordingly, you can also add the members of the group as subscribers so that they receive new copies of conversations via email.
- Add the owners of the new group by running the *Add-UnifiedGroupLinks* cmdlet. Users must be members of the group before they can be added as owners.
- Hide the old distribution list from the GAL so that users pick up and start using the replacement group.

The solution gathers the necessary PowerShell commands together into a script, like the version [available on GitHub](#). Since that script was written, Microsoft has updated the *New-UnifiedGroup* cmdlet so that it can convert a distribution list to a group if it is an “eligible” group.

A script built to migrate groups can be as complex as you think necessary to handle the kind of distribution lists found in your tenant. The caveat is that you should not migrate every distribution list without thinking. In some cases, a simple distribution list is the right tool for the job, and you do not need to create the added overhead and complexity that goes along with a group (document library, group mailbox, and so on).

## Comparing Groups, Distribution Lists, and Shared Mailboxes

Although Microsoft dedicates an impressive amount of development effort to support and enhance the capabilities of Groups, situations do exist when you should use a distribution list, a dynamic distribution list, or a shared mailbox rather than a group. You can use the following questions to help guide your choice:

- Is the intended use of the group to distribute email to a set of people? If so, then a standard distribution list is probably the best choice. Remember, if you need to, you can convert a standard distribution list to a group.
- Does the group span more than Exchange Online mailboxes? Groups support a limited set of recipient types (Exchange Online user mailboxes and guest users) while standard distribution lists support all mail-enabled recipient types – mailboxes, mail users, mail contacts, public folders, resource mailboxes, and other groups.
- Do you want to have access to more than the Inbox and Calendar folders and allow group members to move items between mailbox folders? If so, a shared mailbox is a better solution. The same is true if you want to use other mailbox features, such as assigning categories to messages.
- Do you want to preserve earlier contributions and conversations shared between members of the group? You can do this with the old-fashioned combination of a public folder (to hold the content) and distribution list or with a shared mailbox, but the added functionality available to a group means that it is a better long-term solution.
- Do you want dynamic membership of groups based on Azure AD attributes? You can have dynamic membership of Groups, but only with extra cost. In addition, if you want to have groups whose membership has more than Microsoft 365 user and guest accounts, then dynamic distribution lists are the right choice.
- Is the communication flow within the workgroup purely internal and the ability to send outbound emails is unnecessary? If so, Teams might be a better choice.

The arguments for Groups are often based on the use of a common identity to access resources drawn across from the service. They are much less email-centric than standard distribution lists are, so the question often comes down to the fundamental choice of whether you just need email or to exploit that common identity across Exchange Online, SharePoint Online, Teams, Planner, Power BI, and so on.

# Chapter 12: Teams Basics

**Tony Redmond**

## Workgroup Collaboration

Teams is Microsoft 365's workgroup application for consumer, enterprise, government, and education customers. The central concept behind Teams is that it delivers workspaces that bring people together to collaborate through chats, files, meetings, and associated applications. Chats, or conversations, can be private (often 1:1 but can involve more users) or public, in which case they occur in channels (ways to organize discussions) within a team. A chat is usually a more dynamic exchange of views than is the norm with email. Microsoft calls this "high-velocity" communication because many interactions might occur between the participants over a brief period. In addition, the chats tend to be shorter than email, with many contributions consisting of just a few words. Applications like Facebook, Twitter, and WhatsApp have popularized interactive chat in the consumer space, and companies like Bloomberg and Reuters have long offered real-time chat applications for the financial world, and unsurprisingly, this modality is popular in the world of personal communications.

Apart from conversations, Teams is a strong meeting and calling platform. People connect with audio or video streams to share information in a very natural fashion. The movement from in-person to virtual meetings was accelerated by the Covid-19 pandemic, generating billions of "collaboration minutes" monthly along with associated recordings, transcripts, captions, and files. Teams meetings bring together hundreds of participants in a highly interactive format, complete with screen and application sharing, chat, and recordings. Teams Live Events cater for much larger events such as company-wide "all hands" meetings where the number of presenters is typically limited. The calling side of Teams allows organizations to replace traditional phone systems. More on this topic in the chapter about Teams Devices and Calling.

Microsoft's [Teams Adoption Guide](#) sets out their vision and intent for Teams. We'll explore the concepts and ideas described in the guide throughout this chapter. We also describe the Teams architecture and how Teams integrates different Microsoft 365 components to deliver its functionality along with lots of practical information about how to use Teams. We develop the information presented here to explore how to manage Teams in a Microsoft 365 tenant in the next chapter.

## Teams User Base

At the Ignite 2018 conference, Microsoft announced that Teams was the fastest-growing business application in the company's history. Teams achieved that status just two years after its launch. Accenture is the largest Teams deployment and has a user community of more than 527,000. In December 2020, Accenture said that their use of Teams included [900 million minutes of audio conferencing and 90 million minutes of video conferencing](#) monthly. Microsoft put the number of audio minutes consumed by Accenture monthly at over one billion just a month later when reporting their [FY21 Q2 results](#). Microsoft said that the U.S. Department of Veterans Affairs also had more than 500,000 users.

In October 2021, Microsoft said that 138 organizations have more than 100,000 Teams users and more than 3,000 organizations have more than 10,000 Teams users (in January 2021, the numbers were 117 and 2,700 organizations respectively). 93 of the Fortune 100 use Teams. While these numbers are big and the number of large Teams deployments is growing fast, Teams still has plenty of room to grow into the Office 365 user base (Azure AD serves well over 200,000 organizations, most of which use Office 365).

For the overall user base, Microsoft changed their method of reporting [Teams usage in July 2021](#) from daily active users to monthly active users. They claimed that Teams has “nearly 250 million” monthly active users, but did not specify the breakdown across commercial users, education users, and personal users.

An active user is someone who does something with an application. For Teams, it means that they send a message, participate in a meeting, and so on. A big difference exists between active users and licensed users. Organizations often acquire licenses well before they deploy a product, and because Teams is bundled into many Microsoft 365 products, the number of people who can use Teams is potentially much higher.

**Teams and U.S. Government Cloud:** Due to the need to achieve compliance with several government security standards, the introduction of Teams features in the GCC, GCC High, and DoD clouds often lags several months after commercial availability. It’s not clear if the numbers for Teams users cited by Microsoft include the massive [U.S. Department of Defense contracts](#).

## Teams as the Modern Outlook

When Microsoft launched Outlook 97, they delivered an application that brought together the tools an office professional needed to get their work done. The notion of velocity was somewhat different then as it might take several hours to send and receive emails, especially over dial-up connections. While products like IRC and VAX Notes existed, the idea of unstructured, fluid, rapid, dynamic chats between team members chats was rare in an era when network bandwidth was scarce. Real-time video calling to the desktop or a smartphone was many years in the future. Even with its now ancient roots, since its introduction, Outlook has been the standard yardstick for measuring the effectiveness of office productivity tools. Microsoft sometimes refers to Teams as “Modern Outlook.” This doesn’t mean that Teams replaces Outlook. Rather, Teams is a new take on an integrated application that reflects the way that a growing part of the workforce work today. Teams lacks the email and personal calendar capabilities that Outlook has and is an application that focuses on internal rather than external communications. Instead, Teams includes other features to attract people to consider making this application the place where they spend a lot of their working time:

- Threaded conversations arranged in channels and organized in teams. Channels form the basis of Teams communications for groups of people within and outside the tenant. Conversations are persistent, meaning that they endure over time unless messages are removed by users, administrators, or by policy. Members who join a team can reference earlier conversations because they persist in the channels. Private and shared channels are exceptions as users must join the channel membership before they can access the messages in these channels.
- Chats (aka instant messaging), including federated interoperability with Teams users in other tenants and Skype consumer users. You can even chat with yourself!
- Video and audio meetings.
- Access to SharePoint Online document libraries and OneDrive for Business to store files.
- Extensibility through connectors, bots, apps, actionable messages, and tabs.

Table 12-1 compares some aspects of Outlook and Teams. This is not an attempt to say that one application is better than the other because both applications are firmly rooted in their time. In some ways, the difference between the two reflects the change in how people work now compared to when Microsoft created the first Outlook client. Another difference between the two is that Outlook is a personal tool that extends into some areas of sharing while Teams builds sharing into its core.

Another difference is that Outlook supports connections to mailboxes on-premises and cloud platforms (including non-Microsoft email servers). Teams focuses exclusively on Microsoft 365. The way Microsoft builds Teams by weaving together Microsoft 365 components makes it impossible to contemplate it working in most on-premises organizations.

Extensibility and adaptability are core to the Teams paradigm, which results in a far broader range of options to make Teams work in the way that individual teams need the platform to behave (in this respect, Teams follows the same approach taken by SharePoint). Through extensions built by partners and with automatic updating of clients, Teams adapts to changing circumstances in a way that Outlook has never could. Perhaps this is the major difference between the two applications.

	<b>Outlook</b>	<b>Teams</b>
<i>Communications</i>	Email for both internal and external communications.	Conversations are organized in personal chats and channels. Support for inbound email only. No outbound email.
<i>Collaboration/sharing</i>	Public Folders.	Files (SharePoint)/OneDrive for Business.
<i>Calendar</i>	Personal and shared.	Team calendar app (synchronized with Outlook). A <a href="#">channel calendar app</a> is also available.
<i>Sharing</i>	Shared mailboxes.	Private, shared, and regular channels and group chats.
<i>Integrated applications</i>	None.	SharePoint, OneDrive, Planner, OneNote, Power BI, Shifts, Whiteboard, Forms, and other integrated applications.
<i>Video/Instant Messaging</i>	None.	Video and audio meetings with chat, transcription, recording, and integrated meeting notes (including large meetings and webinars).
<i>Extensibility</i>	Outlook add-ins, connectors, and actionable messages.	Bots, connectors, tabs, apps, and actionable messages.
<i>Clients</i>	Outlook desktop (Windows and Mac), OWA, and Outlook mobile apps.	Desktop (Windows and Mac), browser, and mobile platforms.

Table 12-1: Comparing Outlook and Teams

Even with all its quirks and flaws, after over twenty years of polishing, Outlook still fits well into the work habits of hundreds of millions of people (perhaps because they have used Outlook for years). The growing number of Teams users is evidence of its acceptance in the modern world of work. Microsoft sometimes refers to Outlook and Teams as two hubs for teamwork, and that's about the best way to look at the two.

Intelligently used, Teams focuses on rapid, brief, informal conversations while Outlook continues as the go-to client when people need to communicate outside the tenant or communicate in a more formal and structured manner inside the tenant. Some refer to this mix-and-match approach as "right-sizing" email, meaning that email continues for all manner of communications while Teams handles some of the less formal interaction that typically happens within tight groups focused on a common purpose. Companies can choose to continue focusing on email as their primary method for collaboration, move to Teams, or mix and match the two styles to meet the needs of different sets of employees within the organization.

## Teams Versions

Teams is available in five mainstream versions:

- **Enterprise:** This is the version that's part of enterprise (and equivalent academic and government) plans and is the focus of the discussion here. The Microsoft 365 Business plans also include Teams. The enterprise version of Teams is the only one that supports the Microsoft Phone system.
- **Teams for Your Personal Life (aka Teams Personal):** Originally [launched in preview in June 2020](#), the version of Teams aimed at helping people to organize aspects of their personal lives is available for the Teams mobile clients and Windows desktop and browser clients. The clients support different

features tailored to the operating system, but all clients support personal chat (up to 250 participants), video and audio calls, and calendar scheduling of meetings. The application uses a Microsoft personal account for access to the Outlook.com mailbox and calendar and OneDrive shared file storage. Users can switch between work and personal accounts as easily as switching between different tenants. The Teams personal product requires the use of Microsoft Service accounts (MSAs). Windows 11 includes a version of Teams personal which includes chat and calling capabilities. This client is based on a new Teams architecture which Microsoft hopes to deliver in the enterprise desktop client sometime during 2022.

- **Exploratory/Trial:** If you have a Microsoft 365 plan that doesn't include Teams, Microsoft offers the [Teams Exploratory license](#). Users with a valid tenant account can sign up for the exploratory experience and receive a license for the software components needed for Teams, some of which, like Exchange Online, Forms, Planner, and Stream, their account might already hold. Tenant administrators can stop users from signing up for the Teams Exploratory license by disabling the option to let users install trial apps and services in the **User owned Apps and Services** section under Settings in the Microsoft 365 admin center.
- **Free:** Available to [organizations with 300 or fewer users](#) (some free organizations created since 2020 can technically support up to 500,000 users) who do not have an existing Office 365 or Azure AD tenant, Teams Free uses the same architecture running on the same infrastructure as its enterprise counterpart. The user interface is mostly the same and supports the full range of Teams clients. Users of the free version use accounts from vanity domains that are not associated with Azure AD domains or consumer domains such as Outlook.com or Gmail. However, behind the scenes, every Teams Free deployment has an Azure AD tenant to store its accounts and groups. Teams Free supports chats, audio calling, guest user access, online meetings, calling, and the Office Online apps, and includes 10 GB of storage for files within channels (SharePoint Online) and 5 GB per user (OneDrive for Business) for personal storage. Teams Free supports the installation of many apps. The target markets for the free version include SMBs, non-profit organizations, and schools.
- **Essentials:** Introduced in December 2021 for \$48/user per year, Teams Essentials is very like Teams Free. The major differences are higher participant numbers for meetings and group chats (300 versus 100), longer meetings, more storage, and Microsoft support. For an extra \$12/user per year, the Microsoft 365 Business Basics product includes Teams along with Microsoft 365 functionality (Exchange Online, SharePoint Online, Stream, Planner, etc.).

The big differences between the Enterprise and Free versions are:

- *Scalability.* The membership limit for teams in the enterprise version is 25,000 (tenant and guest accounts).
- *Storage:* The storage available for the free version tops out at 610 GB (for 300 users), after which customers must buy extra storage from Microsoft.
- *Access to Phone System features* such as PSTN calling and scheduled meetings (because the free version lacks an Exchange Online mailbox to use to schedule meetings).
- *Compliance.* The enterprise version captures records for compliance and audit purposes and supports retention and data loss prevention policies.
- *Office Collaboration:* The desktop versions of the Office applications include added collaboration and security features (like support for protected documents).
- *IT Controls:* The enterprise version includes tools for the administration of Teams, including automation through PowerShell and Microsoft Graph.
- *Extensions:* The enterprise version of Teams supports extra first- and third-party apps, like Stream, Planner, and Dynamics 365.

One of the interesting aspects of Teams Free and Teams Essentials is that these use a hidden Azure AD tenant. In effect, when using these versions, you connect to a tenant that hides many enterprise features in the GUI.

This means that if an organization wishes to upgrade, it is [relatively straightforward for Microsoft to convert an organization](#) to a full-blown tenant. As you'd expect, because all versions share a common platform, Microsoft updates the code for all versions concurrently. This doesn't mean that Teams Free and Teams Essentials will gain new features over time as it's quite likely that Microsoft will only expose new features if a competitive need exists.

## Industry-Specific Versions

Microsoft has several packaged versions of Teams developed for different verticals. These include:

- [Teams for Healthcare.](#)
- [Teams for Education.](#)
- [Teams for Frontline Workers.](#)
- [Teams for Government.](#)
- [Teams for Nonprofit.](#)
- [Teams for Retail.](#)

Each package includes apps and customizations tailored for the vertical. For example, Teams for Healthcare includes the Virtual Visits app, while Teams for Retail includes apps like Shifts, Approvals, and Walkie-Talkie.

## Teams Architecture

The Teams architecture integrates many facets of Microsoft 365 and exploits functionality from different Microsoft 365 applications and components. Figure 12-1 shows the major components in the Teams architecture, divided into the presentation layer (clients) and the back-end services, which run in Microsoft data centers. Some of the terms used might be unfamiliar to you:

- The current (and original) version of Teams uses [Electron](#) to build the desktop and web versions. Electron is an open-source framework based on Chromium and Node.js developed through GitHub. Electron allows developers to reuse web components to create a desktop GUI. Microsoft designed Teams to be a cross-platform application, so all clients reuse as much code as possible. Much of the Teams code is in TypeScript or Node.js and although Angular was the original framework, the current implementation uses React.js and Edge Chromium to make it easier to share components with other Office applications (as in the Files channel tab with SharePoint Online). The desktop version of Teams is a wrapper (Electron) around the website while the mobile clients combine React Native with platform-specific components like Objective-C (iOS) and Java (Android). In June 2021, Microsoft said that the next version of Teams (2.0) will move away from Electron to use React and the [Edge WebView2 control](#) instead. Office 365 apps like Outlook already use Edge WebView2 for components like the calendar room finder and the Teams meeting add-in.
- **Intelligent Communications** is the media stack used by Teams for functionality such as video and audio conferencing. Skype consumer uses the same stack, which is very different from the old on-premises code base used by Skype for Business Server. Because the Intelligent Communications stack runs in the cloud, changes and evolution occur at a more rapid pace.
- **Experimentation** is a configuration service used for Intelligent Communications components.
- **MRU** means "Most Recently Used," a service used to keep track of files accessed by users through Teams.
- **WAC** means "Web App Companion," more commonly known as the [Office Web Apps Server](#).
- The email service used by Teams allows channels to accept inbound messages. Teams does not support outbound email.
- **AAD** is Azure Active Directory, used by Teams to authenticate tenant and guest users, manage group membership, and for extended services such as group settings and expiration policies, conditional access policies, and so on.

- The **Notification Service** generates notifications for users that appear in their Activity Feed. Applications can post their notifications to the Activity Feed using the [activity feed notification API](#).
- Teams uses **Exchange Online** to access Information Governance services such as the processing of retention and data loss prevention policies for personal chats and channel conversations.
- Microsoft captures a great deal of **Telemetry** data for Teams operations. The data is anonymized.

Teams includes an experimentation layer to support the deployment of different features to targeted tenants. The layer allows Teams to deploy new features to targeted sets of users for testing at different stages of the development process. Users within Microsoft see a very early version of the feature, customers who sign up for testing through the Technology Adoption Program (TAP), or people who choose to enable preview features access features under development. Normal tenants only see the feature when Microsoft makes the software generally available. Chapter 15 discusses the preview channels used by Teams in more detail together with information about how Microsoft links Teams preview with the Current Channel (Preview) for Microsoft 365 apps for enterprise.

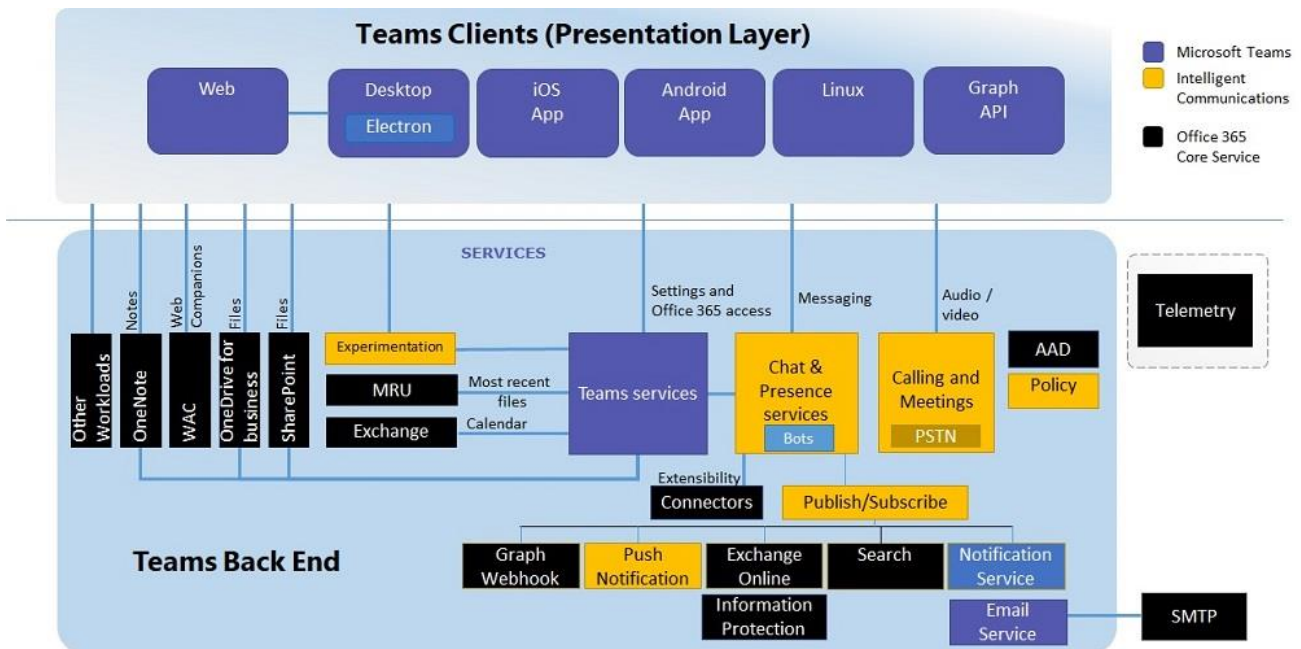

Figure 12-1: Teams Architecture (source: Microsoft)

Because the Teams architecture spans many interconnected pieces, triggers and notifications are used extensively to inform components when they need to do something. For instance, when a user posts a message into a conversation, Teams generates a new thread (for a new conversation) or adds the message to a reply chain (for an existing conversation). The members of the team or private channel hosting the conversation (known as the “roster”) need to know that a new message is available. This happens through direct notifications to desktop and browser clients connected to the Teams service and via platform-specific push notifications to mobile clients. At the same time, the new message synchronizes with clients.

In the background, components receive notifications about new messages to initiate further processing. For example, Teams might need to check a message against one or more data loss prevention policies. For compliance purposes, the Microsoft 365 substrate also captures one or more copies of the message and stores these items in Exchange Online. An update goes to the Activity Feed for each recipient, @mentions in the message might generate notifications in Teams or the operating system, and so on. In other cases, such as adding a new member to a team, result in the capture of audit records in the audit log. In other words, actions within Teams can generate a cascade of further actions across a range of Microsoft 365 services.

## Teams Building Blocks

Figure 12-2 boils Teams down into five major building blocks.

- Teams clients are available in desktop, browser, and mobile versions. Clients share a common code base, meaning that features should be easy to roll out concurrently and that people have access to the same functionality across all clients. However, some differences in functionality are often observed across clients. Sometimes Microsoft deliberately targets the release of a new feature in a specific client. For instance, being able to forward a personal chat to a channel first appeared in the mobile clients.
- Teams consumes a range of services drawn from other applications like Exchange Online and SharePoint Online to avoid recreating any wheels. See the later section covering dependencies on other services.
- Teams has its own set of microservices to manage different elements within its infrastructure. We discuss these microservices in the next section.
- The voice, audio, and telephony components used by Teams share a common infrastructure with the Skype consumer service.
- Teams consumes many Azure services. For performance reasons, the chat service stores recent chats in memory and commits its data to [Azure Cosmos DB](#). Teams stores images inserted in conversations in an Azure media store. Another example is the use of Azure B2B collaboration to support guest user access to Teams.

Microsoft publishes [architectural diagrams for Teams online](#) in PDF and Visio formats.

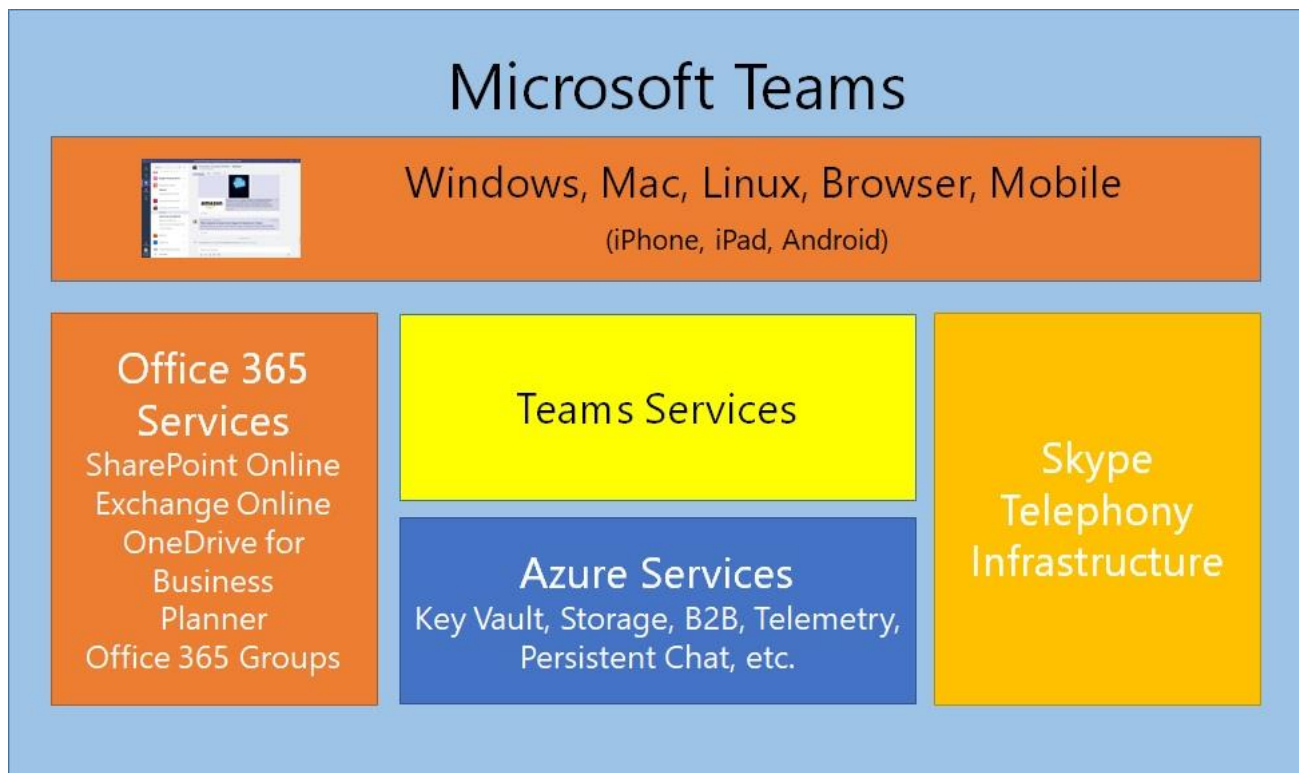

Figure 12-2: Building blocks for Teams

## Teams Microservices

Figure 12-3 shows the set of microservices Teams uses to run various parts of its infrastructure. The purpose of most of the microservices is clear. For example, the compliance microservice generates audit records about activities that occur in Teams, such as the creation or deletion of a channel. It also captures copies of personal and channel conversations for compliance purposes. Like all applications, Teams has some settings that are

individual to it, like the settings that control whether users can remove or edit messages. The configuration microservice manages these settings and works with the Azure AD synchronization microservice to manage other settings that affect Teams, like whether users can create new teams.

Azure AD synchronization also makes sure that changes to the groups that underpin Teams flow from Groups to Teams and Teams to Groups. It is important to ensure that membership and ownership changes are effective, user properties (like photos, job titles, and reporting relationships) become known to Teams, and that Teams executes its side of management actions like the deletion of a group (and its associated team). The expected synchronization interval is less than 15 minutes, but the defined SLA (internal to Microsoft) is 24 hours, so it might take some time before changes made in Azure AD appear in Teams or vice versa. The Azure AD synchronization microservice is also responsible for the recovery of Teams components when an administrator recovers a soft-deleted group (see the Groups chapter for details).

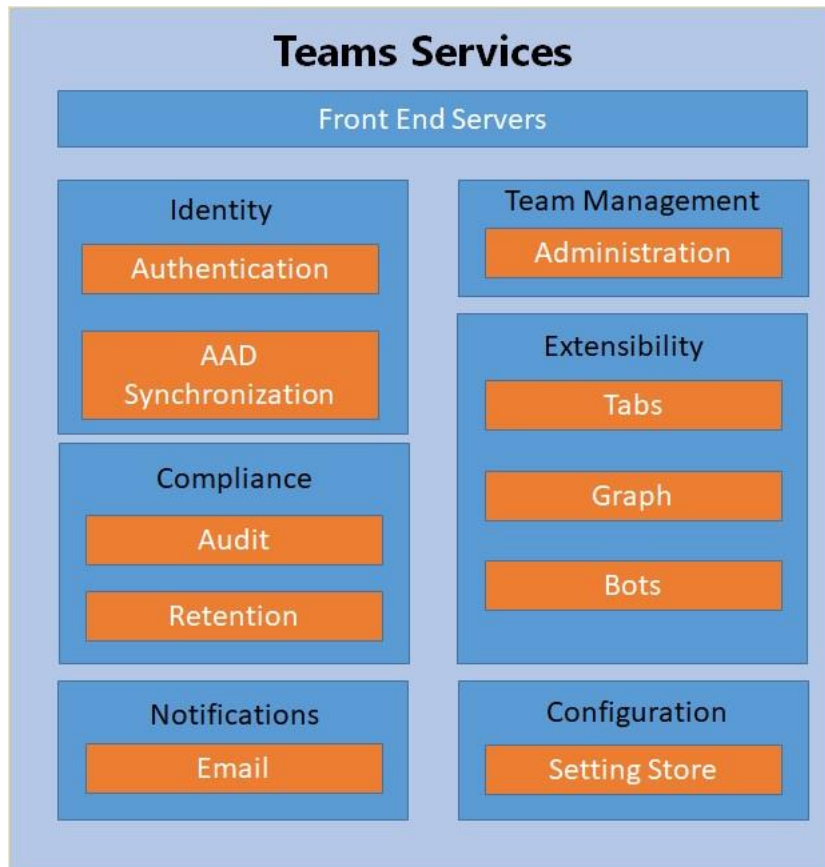

Figure 12-3: Micro-services used by Teams

**The impact of Covid-19 on Teams services:** During the early days of the Covid-19 pandemic, Microsoft experienced a surge in demand for Teams services as people started to work from home. Microsoft saw a dramatic rise in Teams meeting minutes along with knock-on effects on other services like Stream (to store meeting recordings). Coping with the unexpected rise in usage over a short period forced Microsoft to review the Teams architecture and change how services consume resources. The result was successful and Microsoft managed to cope with the growth in demand to become better prepared to scale in the future. For more information, read this [Microsoft blog post](#).

## Teams is a Collection of Apps

Apps form the basic framework of Teams. Some apps are fundamental to Teams, others are optional. Some come from Microsoft, others from third parties, and others are line of business applications unique to an organization. Administrators can control the apps made available to users through app setup and permissions policies (explained in the next chapter).

- **Fundamental Apps.**
  - **Teams:** Access to teams and channels, including the applications, bots, and connectors installed in the channels.
  - **Activity:** The activity feed.
  - **Chat:** Personal and group chats. This also includes federated chat with users in other tenants and Skype consumer users.
  - **Files:** Lists recent files accessed by a user (inside and outside Teams), files used in Teams, downloads, and cloud storage (like Google Drive).
  - **Calendar:** Access to the user's Exchange Online calendar.
  - **Calls:** Access to the Teams calling subsystem to make VOIP calls to other Teams subscribers and external parties (external calls and PSTN connections are available only after buying a calling plan).
- **Microsoft First-Party Apps for Teams:**
  - **Tasks by Planner:** Access to group (Planner) tasks and personal (To Do) tasks.
  - **Yammer Communities:** Access to Yammer communities.
  - **Insights:** Viva Insights for Teams combines insights from Viva Insights, Workplace Analytics, Wellbeing, and third-party data sources.
  - **Stream:** Access to videos managed by the Stream service.
  - **Forms:** Conduct polls (including during meetings) and questionnaires.
  - **Channel Calendar:** Access to meetings scheduled within a channel.
  - **Lists:** Access to Microsoft Lists stored in SharePoint Online.
  - **Approvals:** Basic approval workflow based on Power Automate.
  - **OneNote:** Access to OneNote notebooks.
  - **Praise:** Recognize the achievements of co-workers. The Viva Insights app includes Praise and allows users to track praise they have sent and received over the previous six months.
  - **Shifts:** Front-line worker shift setup and management.
  - **Wiki:** Access to a personal Wiki (like that used for channels and meetings).

The list of first-party apps has grown over time and can be expected to increase further.

## Dependencies on Other Microsoft 365 Components

Along with its microservices, Teams consumes a range of services drawn from other parts of Microsoft 365. These dependencies are:

- **Groups.** A group exists for each team. The group object is in Azure AD and the members of the group are the members of the team.
- **Exchange Online.** The Teams Calendar app displays information synchronized from the calendar folder in the signed-in user's mailbox (the channel calendar app reads information about channel meetings from the group mailbox belonging to the team). The contacts used in the Calls application are in the user's mailbox, as is their profile picture (avatar). The Microsoft 365 substrate captures compliance records for channel conversations in the group mailbox belonging to the team while the compliance records for personal and group chats are in the mailboxes of chat participants. Users with on-premises mailboxes can use Teams, with [some limitations](#), notably that on-premises users must have mailboxes on Exchange 2016 CU3 (it's best to use the latest available version of Exchange Server) servers to create and view meetings. This requirement exists because the Teams middle layer uses Autodiscover V2 to find how to retrieve mailbox and calendar data. Read more about [how Teams retrieves calendar information from Exchange on-premises servers](#) and how to [troubleshoot common issues](#).
- **SharePoint Online:** The Teams Files functionality (for channels) stores documents in a SharePoint team site provisioned during the creation of a new team. Teams users do not need a SharePoint

license (in many cases, users have a SharePoint Online license through one or more of the product licenses assigned to their account) to access Files, but SharePoint Online must be available within the tenant. Teams does not support SharePoint on-premises.

- **OneDrive for Business:** Users require a OneDrive for Business license to be able to share files in personal and group chats (including loop components) and to store recordings of the meetings they organize. OneDrive for Business licenses are in products like Office 365 E3 and E5.
- **Microsoft Forms:** Teams meetings use Forms for meeting polls and quizzes.
- **Planner/To Do:** The Tasks by Planner app integrates tasks created in Planner and To-Do. Team members can access Planner plans through channel tabs.
- **Power Automate:** The Teams Approvals app uses Power Automate for its workflow.
- **Microsoft Bookings:** The Teams [Virtual Visits app](#) depends on Bookings.
- **Whiteboard:** Teams meetings can share whiteboards to allow collaboration around a shared canvas.
- **Yammer:** The Teams Community app gives users access to Yammer communities. Parts of the Microsoft Viva suite use Yammer for conversations and comments.

In addition to these base services, Teams takes advantage of other Microsoft 365 components to extend its functionality as required by channel tabs and apps. Examples of other Microsoft 365 components used by Teams include Stream, Microsoft Information Protection, OneNote, the Office Online apps, connectors, Power BI, and actionable messages.

**Teams and Service Plan Licensing:** Products like Office 365 E3 and Office 365 E5 include access to the service plans for all the Microsoft 365 components listed above, meaning that users can use the individual services as needed. However, administrators can disable selected service plans. For instance, they could decide to disable Forms and Power Automate because the organization considers these services unnecessary. If this happens, users cannot access the standalone services, and they won't be able to use Teams features that depend on those services.

## Teams Limits

Microsoft's service limits for Teams are [documented online](#). Because of its dependencies on other Microsoft 365 components, some of the limits applying to Teams come from those components. For example, while Teams can support hundreds of thousands of teams in a tenant, only 5,000 of those teams can have dynamic membership due to a restriction placed by Azure AD.

Each team has a fully provisioned SharePoint Online team site to hold files, the shared notebook, lists, and the wiki. The storage used by team sites comes from the overall quota available to SharePoint Online in the tenant. Usually, SharePoint manages storage automatically and assigns storage to individual sites as necessary. You can also configure SharePoint for manual storage and [set specific limits on sites](#). If necessary, organizations can buy extra storage to increase the overall amount available to the tenant.

Microsoft has not documented any restrictions on the number of conversations, messages, or graphics that Teams can hold for a tenant in its Azure-based services. Teams does not apply any numeric or storage quotas for messages in a single team or channel.

**Teams mega-tenants:** Some tenants need to support more Azure AD objects than allowed by [the service limits](#). For instance, some education tenants need to go past the limit for groups (500,000). Microsoft has a process to allow customers who need to exceed the documented limits. If you're in this situation, contact Microsoft support and ask how to increase the limits applying to your tenant.

## Teams Storage

We've already mentioned how Teams uses different cloud locations to store its data, such as how SharePoint Online stores the files created through the Files interface. Table 12-2 describes how Teams stores the different

types of data used by its components. The dependencies that exist with other parts of the Microsoft cloud are obvious.

<b>Data</b>	<b>Primary Storage</b>	<b>Other Storage</b>
Messages	The Chat service stores its messages in Azure Cosmos DB.	Compliance records (copies of messages) are in group and personal Exchange Online mailboxes.
Images	Media service (Azure) using blob storage.	Any images referenced in messages are copied into compliance records and stored in Exchange Online.
Files	Personal files are in users' OneDrive for Business accounts. Files shared in channels are in the team's SharePoint document library.	
Voicemail	Personal Exchange mailboxes.	
Recordings	Meeting recordings are in OneDrive for Business (personal meetings) or SharePoint Online (channel meetings).	Links to recordings posted in the meeting chat.
Calendars	Group and personal Exchange mailboxes.	
Contacts	Personal Exchange mailboxes.	
Telemetry	Microsoft data warehouse (inaccessible to customers).	
Meeting resources	Transcripts, attendance, and registration reports are in the Exchange mailbox of the meeting organizer.	

Table 12-2: Where Teams stores its data

The messages making up Teams channel conversations and personal chats form "reply chains" (the original topic and all subsequent replies). Messages for channel conversations remain in the Teams store unless removed by retention policies or the deletion of the team. Unlike channel messages, which the hosting team owns, participants in a personal or group chat collectively "own" the messages in a conversation. Messages remain in the Teams store unless removed by retention policies or following the removal of the accounts of all participants.

## Geographic Location of Teams Data

Like other non-core workloads, Microsoft does not store the Teams-specific data in every data center region. This data includes personal chats and channel conversations, teams and channel metadata for a tenant, and media inserted into chats (data inserted by Teams into SharePoint and Exchange exists in the data center region to which a tenant belongs). The Microsoft 365 substrate captures copies of chats in group and user mailboxes to make them available for searches and eDiscovery. The storage for images and media used in chats (except for Giphy GIFs, which Teams stores as a URL to the original file) runs in an Azure-based Media service deployed alongside the chat service.

Although Teams is not yet available in every data center region, Microsoft plans to deploy the necessary Azure services to support Teams more broadly to satisfy customer data sovereignty concerns. Microsoft documents the [current set of data center locations for Teams data online](#).

Some data accessed through Teams might be in other data center regions. For instance, in a multi-geo situation, the SharePoint team site (holding documents, the shared notebook, and wiki) used by a team running in the same region as the person who created the Microsoft 365 group for the team. The user's personal Teams data such as the compliance records captured for personal and group chats and any OneDrive for Business documents shared in chats are in the satellite region. Remember that Microsoft's commitment to data sovereignty only extends to the data that they manage and does not include third-party

data accessible through Teams. For instance, if you create a tab for Trello, the data manipulated through that tab are in Trello's cloud and might be outside the region.

## Teams Advanced Communications

The Teams Advanced Communication add-on is available for all Office 365 and Microsoft 365 plans. It covers several enterprise capabilities including:

- Customization for Together mode background scenes.
- Deployment of custom Teams policy packages.
- Custom screens for meeting pre-join and lobby screens.
- Advanced real-time telemetry for user communications.

More information on the current capabilities licensed by the add-on [is available online](#).

## The Structure of Teams

A team can have up to 10,000 members. The basic structure for a team is a set of channels that give members a framework to organize conversations (discussions composed of "persistent" chats) and other relevant information, activities, and applications. A channel is a dedicated section within a team used by members to communicate about a topic, like a space to organize a project that the team must manage. All team members can see everything in a channel, so if you want to keep something private, you must do so in a personal chat. Only the people involved in a personal chat can see what goes on there.

Private teams limit access to any team resources to people added as team members, including guest members. Public teams are open to anyone who wishes to join. When someone joins a team, they can work with the resources available to the team. When they leave a team, they lose access to those resources. Although some restrictions do exist for guest members, the principle that all members share equal access to team resources holds true.

## Owners and Members

Teams use Groups to manage team membership, which means that the roles available within a team are owners (who manage the team) and members. An owner is also a member and there should be at least two owners for each team to make sure that someone is always available to handle basic administration such as adding new members. If all the owners leave a team (perhaps because they leave the organization), a tenant administrator can promote a member to become an owner or add a new owner to the team. Unlike Groups, Teams does not support the concept of subscribers who receive copies of any new posts for a conversation via email. If a member wants to see what is happening inside a team, they must open it to join in the conversation.

Microsoft recommends that you should allow Teams users to create new groups. If limited by policy, users cannot create new Teams because of the dependency on Groups. Although such an approach is liberating for users because they can create new teams as and when they like, it creates some management challenges that we will get to later.

A team owner can promote any other team member except a guest to become an owner. To do this, use **Manage team** to display the current membership and then click the down arrow in the role column beside the member's name to select Owner. When someone is a group owner, they automatically become an owner (or administrator) of the associated team and can perform actions such as adding or removing users, adding new channels and connectors, and so on. To remove owner status, reverse the process and change Owner to Member. If you want to remove an owner from a team, you must first demote them to Member status and then go ahead and remove them by clicking the **X** alongside their name (Teams displays the X when you

move the screen cursor over the role column). If an owner removes a user from a team, they also lose their membership in the underlying group. You cannot have a situation where a subset of the members of a group can access the associated team and other members cannot.

Like any other group, a team can have up to a hundred owners. An individual user can create up to 250 teams. However, a global administrator can create as many teams as they need to within a tenant.

## Communications Rosters and Disabled Accounts

The membership of each team comes from its Microsoft 365 group and Azure AD is the directory of record. Internally, Teams uses the concept of communication rosters or people who can communicate with each other, to control access to features. For example, in hybrid environments, you can have disabled AD accounts synchronized with Azure AD. Because these users cannot communicate with the other team members, Teams excludes these accounts from its rosters even though they are present in the underlying group (you can see this by running the *Get-MgGroupMember* or *Get-TeamUser* cmdlets against the group). Organizations often disable the accounts of ex-employees to stop them from accessing applications. Disabled accounts can't sign into Microsoft 365, so Teams suppresses their presence because they can't participate in conversations, share files, or otherwise engage with the rest of the members. The membership of private channels is another example of a roster used by Teams.

Teams also removes blocked Azure AD accounts from the rosters of regular and org-wide teams. A Teams background process scans for blocked accounts and removes them from the rosters (but not from the underlying Microsoft 365 Groups). This process can take some time to happen. Upon the unblocking of the account, Teams restores the account to team rosters. Some [issues exist in this process](#) that you should be aware of.

## The General Channel

Channels divide conversations into logical sections within a team. Every team has a default channel called "General," which is the physical embodiment of the team. You cannot remove or rename the General channel.

The General channel is often where team owners post information about the team's goals and charter and discuss topics such as what those goals should be or how to reach them. Teams used to post messages in the General channel about people joining or leaving the team, or team events such as the creation of new channels. These messages no longer appear in the General channel and are now visible in the channel's information pane, accessible through the **(i)** icon in the channel header. The Office 365 audit log also captures events about member removal and deletion or channel operations.

Even with the removal of system messages, it is still best to avoid having discussions in the General channel. Instead, reserve the General channel for team announcements and important posts. You can do this by editing channel settings to restrict the ability to post new topics to team owners.

## Managing Channels

To support discussions, you should create a set of channels in the team and encourage users to post in those channels rather than the General channel. Before moving the focus of conversations away from the General channel, team owners should think about how to use channels to organize the work of the team. A well-thought-out, well-named, and logical channel structure avoids the potential that the team becomes a confusing mess. When the overall structure of the team is known, you can create the channels and encourage users to think about which channel is best for their posts.

In addition to conversations, channels host tabs, apps, connectors, and bots. These components allow owners to equip teams with the necessary functionality needed by members. You can also mail-enable a channel by asking Teams to generate an SMTP email address for the channel (see Chapter 13). When a channel is email-

enabled, authorized users can send emails to the channel to start conversations. The email capability only extends to inbound communications as Teams does not support the ability to send email as a channel or on behalf of a channel.

Teams supports three types of channels:

- A **regular channel** is available to all team members. This is the default type of channel created by Teams. The General channel is always a regular channel. Each team can have up to 200 regular channels.
- A **private channel** is available to a subset of the team members. A team can support up to 30 private channels, each of which has a dedicated SharePoint site to hold the files for the channel. Like a regular channel, you can add tabs (except Forms, Stream, and Planner) and connectors to private channels. A private channel supports up to 250 members, all of whom must become members of the team owning the private channel before they can join the channel membership.
- Individual teams can host **shared channels**. The membership (or roster) of a shared channel is composed of individual members and teams from the host tenant or external tenants who want to collaborate on a common topic. People who aren't members of the host team can join a shared channel. A team can support up to 200 shared channels, with each channel having a dedicated SharePoint site connected to the home team.

Table 12-3 compares the capabilities available in the three types of channel. The limited support noted for channel tabs, apps, and bots for shared and private channels reflects the need for app developers to support these channels and the authentication models used to limit access to channel membership.

<b>Capability</b>	<b>Standard channel</b>	<b>Private channel</b>	<b>Shared channel</b>
