**COMMENTS:** Eq. 11.35a may be used to solve a wide variety of problems, beyond those associated with two-fluid heat exchangers, involving constant surface temperature conditions.

## PROBLEM 11.69

**KNOWN:** Inlet and outlet temperatures of natural gas and seawater in an LNG vaporizer. LNG flow rate and properties of its liquid and vapor phases, as well as phase change temperature and latent heat of vaporization. Overall heat transfer coefficients for three sections of the vaporizer. Seawater properties.

**FIND:** Required vaporizer heat transfer area.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat transfer between the heat exchanger and the surroundings, (2) Constant properties, (3) Parallel flow.

**PROPERTIES:** Given. NG:  $c_{p,l} = 4200 \text{ J/kg}\cdot\text{K}$ ,  $c_{p,v} = 2210 \text{ J/kg}\cdot\text{K}$ ,  $h_{fg} = 575 \text{ kJ/kg}$ ,  $T_f = -75^\circ\text{C}$ . SW:  $c_{p,sw} = 3985 \text{ J/kg}\cdot\text{K}$ .

**ANALYSIS:** Application of the conservation of energy principle to the gas stream yields

$$\begin{aligned}
 q &= \dot{m}_{\text{NG}} \left[ c_{p,l} (T_f - T_{c,i}) + h_{fg} + c_{p,v} (T_{c,o} - T_f) \right] = q_A + q_B + q_C \\
 &= 150 \text{ kg/s} \left[ 4200 \text{ J/kg}\cdot\text{K} (-75 - (-155)^\circ\text{C}) + 575 \times 10^3 \text{ J/kg}\cdot\text{K} + 2210 \text{ J/kg}\cdot\text{K} (8 - (-75)^\circ\text{C}) \right] \\
 &= 50.4 \times 10^6 \text{ W} + 86.3 \times 10^6 \text{ W} + 27.5 \times 10^6 \text{ W} = 164 \times 10^6 \text{ W} = 164 \text{ MW}
 \end{aligned}$$

The flow rate of seawater is

$$\dot{m}_{\text{sw}} = q / \left[ c_{p,sw} (T_{h,i} - T_{h,o}) \right] = 164 \times 10^6 \text{ W} / \left[ 3985 \text{ J/kg}\cdot\text{K} (10^\circ\text{C}) \right] = 4120 \text{ kg/s}$$

Recognizing that the outlet conditions of Section A (B) serve as inlet conditions to Section B (C), we may analyze the vaporizer on a section-by-section basis.

Section A The heat capacity rates are

$$\begin{aligned}
 \text{NG: } \dot{m}c_{p,l} &= 150 \text{ kg/s} \times 4200 \text{ J/kg}\cdot\text{K} = 630 \times 10^3 \text{ W/K} = C_{\text{min},A} \\
 \text{SW: } \dot{m}c_{p,sw} &= 4120 \text{ kg/s} \times 3985 \text{ J/kg}\cdot\text{K} = 16.4 \times 10^6 \text{ W/K} = C_{\text{max},A} \\
 C_{r,A} &= C_{\text{min},A} / C_{\text{max},A} = 630 \times 10^3 / 16.4 \times 10^6 = 0.0384
 \end{aligned}$$

Continued...

### PROBLEM 11.69 (Cont.)

The effectiveness is

$$\varepsilon_A = \frac{q_A}{C_{\min,A}(T_{h,i,A} - T_{c,i,A})} = \frac{50.4 \times 10^6 \text{ W}}{630 \times 10^3 \text{ W/K} \times (20 - (-155)^\circ\text{C})} = 0.457$$

and the NTU is determined from Equation 11.28b

$$\text{NTU}_A = -\frac{\ln[1 - 0.457(1 + 0.0384)]}{1 + 0.0384} = 0.620; A_A = \frac{\text{NTU}_A C_{\min,A}}{U_A} = \frac{0.620 \times 630 \times 10^3 \text{ W/K}}{150 \text{ W/m}^2 \cdot \text{K}} = 2600 \text{ m}^2$$

while the outlet temperature of the seawater is

$$T_{h,o,A} = T_{h,i,A} - q_A / C_{\max,A} = 20^\circ\text{C} - 50.4 \times 10^6 \text{ W} / 16.4 \times 10^6 \text{ W/K} = 16.9^\circ\text{C}$$

Section B The heat capacity rates are

$$\text{NG: } C_{\max,B} \rightarrow \infty$$

$$\text{SW: } \dot{m}c_{p,sw} = 4120 \text{ kg/s} \times 3985 \text{ J/kg} \cdot \text{K} = 16.4 \times 10^6 \text{ W/K} = C_{\min,B}$$

$$C_{r,B} = C_{\min,B} / C_{\max,B} = 0$$

The effectiveness is

$$\varepsilon_B = \frac{q_B}{C_{\min,B}(T_{h,i,B} - T_{c,i,B})} = \frac{q_B}{C_{\min,B}(T_{h,o,A} - T_f)} = \frac{86.3 \times 10^6 \text{ W}}{16.4 \times 10^6 \text{ W/K} \times (16.9 - (-75)^\circ\text{C})} = 0.0572$$

and the NTU is determined from Equation 11.28b

$$\text{NTU}_B = -\frac{\ln[1 - 0.0572]}{1} = 0.0588; A_B = \frac{\text{NTU}_B C_{\min,B}}{U_B} = \frac{0.0588 \times 16.4 \times 10^6 \text{ W/K}}{260 \text{ W/m}^2 \cdot \text{K}} = 3720 \text{ m}^2$$

while the outlet temperature of the seawater is

$$T_{h,o,B} = T_{h,i,B} - q_B / C_{\min,B} = 16.9^\circ\text{C} - 86.3 \times 10^6 \text{ W} / 16.4 \times 10^6 \text{ W/K} = 11.7^\circ\text{C}$$

Section C The heat capacity rates are

$$\text{NG: } \dot{m}c_{p,v} = 150 \text{ kg/s} \times 2210 \text{ J/kg} \cdot \text{K} = 332 \times 10^3 \text{ W/K} = C_{\min,C}$$

$$\text{SW: } \dot{m}c_{p,sw} = 4120 \text{ kg/s} \times 3985 \text{ J/kg} \cdot \text{K} = 16.4 \times 10^6 \text{ W/K} = C_{\max,C}$$

$$C_{r,C} = C_{\min,C} / C_{\max,C} = 332 \times 10^3 / 16.4 \times 10^6 = 0.020$$

The effectiveness is

$$\varepsilon_C = \frac{q_C}{C_{\min,C}(T_{h,i,C} - T_{c,i,C})} = \frac{q_C}{C_{\min,C}(T_{h,o,B} - T_f)} = \frac{27.5 \times 10^6 \text{ W}}{332 \times 10^3 \text{ W/K} \times (11.7 - (-75)^\circ\text{C})} = 0.958$$

Continued...

### PROBLEM 11.69 (Cont.)

and the NTU is found from Equation 11.28b

$$NTU_C = -\frac{\ln[1 - 0.958(1 + 0.020)]}{1 + 0.020} = 3.69; A_C = \frac{NTU_C C_{\min,C}}{U_C} = \frac{3.69 \times 332 \times 10^3 \text{ W/K}}{40 \text{ W/m}^2 \cdot \text{K}} = 30,600 \text{ m}^2$$

Therefore, the total heat transfer area for the vaporizer is

$$A = A_A + A_B + A_C = 2600 \text{ m}^2 + 3720 \text{ m}^2 + 30,600 \text{ m}^2 = 36,900 \text{ m}^2 \quad <$$

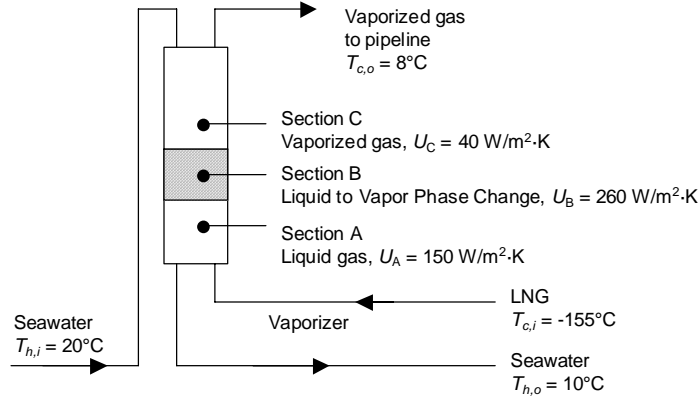

**COMMENTS:** (1) The scheme may not be feasible in a cold-weather port due to the potential of freezing the seawater. In cold-weather ports, approximately 2% of the natural gas will be burned, with the combustion products sent through the vaporizer to supply the necessary heating. See B. Eisentrout, S. Wintercorn and B. Weber, "Study Focuses on Six LNG Regasification Systems," *LNG Journal*, July/August, pp. 21 – 22, 2006. (2) For a counterflow vaporizer with sea water introduced at the top of the heat exchanger, the required area is  $A = 23,700 \text{ m}^2$ , a 36% size reduction. See Problem 11.70.

## PROBLEM 11.70

**KNOWN:** Inlet and outlet temperatures of natural gas and seawater in an LNG vaporizer. LNG flow rate and properties of its liquid and vapor phases, as well as phase change temperature and latent heat of vaporization. Overall heat transfer coefficients for three sections of the vaporizer. Seawater properties.

**FIND:** Required vaporizer heat transfer area.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat transfer between the heat exchanger and the surroundings, (2) Constant properties, (3) Counterflowing fluids.

**PROPERTIES:** Given. NG:  $c_{p,l} = 4200 \text{ J/kg}\cdot\text{K}$ ,  $c_{p,v} = 2210 \text{ J/kg}\cdot\text{K}$ ,  $h_{fg} = 575 \text{ kJ/kg}$ ,  $T_f = -75^\circ\text{C}$ . SW:  $c_{p,sw} = 3985 \text{ J/kg}\cdot\text{K}$ .

**ANALYSIS:** Application of the conservation of energy principle to the gas stream yields

$$\begin{aligned} q &= \dot{m}_{\text{NG}} \left[ c_{p,l} (T_f - T_{c,i}) + h_{fg} + c_{p,v} (T_{c,o} - T_f) \right] = q_A + q_B + q_C \\ &= 150 \text{ kg/s} \left[ 4200 \text{ J/kg}\cdot\text{K} (-75 - (-155)^\circ\text{C}) + 575 \times 10^3 \text{ J/kg}\cdot\text{K} + 2210 \text{ J/kg}\cdot\text{K} (8 - (-75)^\circ\text{C}) \right] \\ &= 50.4 \times 10^6 \text{ W} + 86.3 \times 10^6 \text{ W} + 27.5 \times 10^6 \text{ W} = 164 \times 10^6 \text{ W} = 164 \text{ MW} \end{aligned}$$

The flow rate of seawater is

$$\dot{m}_{\text{sw}} = q / \left[ c_{p,sw} (T_{h,i} - T_{h,o}) \right] = 164 \times 10^6 \text{ W} / \left[ 3985 \text{ J/kg}\cdot\text{K} (10^\circ\text{C}) \right] = 4120 \text{ kg/s}$$

Recognizing that the NG (cold stream) outlet conditions of Section A (B) serve as NG inlet conditions to Section B (C), and that the SW (hot stream) outlet conditions of Section C (B) serve as the SW inlet conditions for Section B(A), we may write

$$\begin{aligned} T_{h,i,C} &= T_{h,i} = 20^\circ\text{C} ; T_{h,i,B} = T_{h,i,C} - q_C / \dot{m}_{\text{sw}} c_{p,sw} = 20^\circ\text{C} - 27.5 \times 10^6 \text{ W} / (4120 \text{ kg/s} \times 3985 \text{ J/kg}\cdot\text{K}) = 18.3^\circ\text{C} \\ T_{h,i,A} &= T_{h,i,B} - q_B / \dot{m}_{\text{sw}} c_{p,sw} = 18.3^\circ\text{C} - 86.3 \times 10^6 \text{ W} / (4120 \text{ kg/s} \times 3985 \text{ J/kg}\cdot\text{K}) = 13.1^\circ\text{C} \\ T_{c,i,A} &= T_{c,i} = -155^\circ\text{C} ; T_{c,i,B} = T_f = -75^\circ\text{C} ; T_{c,i,C} = T_f = -75^\circ\text{C} \end{aligned}$$

Section A The heat capacity rates are

$$\text{NG: } \dot{m} c_{p,l} = 150 \text{ kg/s} \times 4200 \text{ J/kg}\cdot\text{K} = 630 \times 10^3 \text{ W/K} = C_{\text{min},A}$$

Continued...

### PROBLEM 11.70 (Cont.)

$$\text{SW: } \dot{m}c_{p,\text{sw}} = 4120 \text{ kg/s} \times 3985 \text{ J/kg} \cdot \text{K} = 16.4 \times 10^6 \text{ W/K} = C_{\text{max,A}}$$

$$C_{r,A} = C_{\text{min,A}} / C_{\text{max,A}} = 630 \times 10^3 / 16.4 \times 10^6 = 0.0384$$

The effectiveness is

$$\varepsilon_A = \frac{q_A}{C_{\text{min,A}}(T_{h,i,A} - T_{c,i,A})} = \frac{50.4 \times 10^6 \text{ W}}{630 \times 10^3 \text{ W/K} \times (13.1 - (-155)^\circ\text{C})} = 0.476$$

The NTU is determined from Equation 11.29b

$$\text{NTU}_A = \frac{1}{C_{r,A} - 1} \ln\left(\frac{\varepsilon_A - 1}{\varepsilon_A C_{r,A} - 1}\right) = \frac{1}{0.0384 - 1} \ln\left(\frac{0.476 - 1}{0.476 \times 0.0384 - 1}\right) = 0.653$$

and the area of Section A is

$$A_A = \frac{\text{NTU}_A C_{\text{min,A}}}{U_A} = \frac{0.653 \times 630 \times 10^3 \text{ W/K}}{150 \text{ W/m}^2 \cdot \text{K}} = 2740 \text{ m}^2$$

Section B The heat capacity rates are

$$\text{NG: } C_{\text{max,B}} \rightarrow \infty$$

$$\text{SW: } \dot{m}c_{p,\text{sw}} = 4120 \text{ kg/s} \times 3985 \text{ J/kg} \cdot \text{K} = 16.4 \times 10^6 \text{ W/K} = C_{\text{min,B}}$$

$$C_{r,A} = C_{\text{min,B}} / C_{\text{max,B}} = 0$$

The effectiveness is

$$\varepsilon_B = \frac{q_B}{C_{\text{min,B}}(T_{h,i,B} - T_{c,i,B})} = \frac{q_B}{C_{\text{min,B}}(T_{h,i,B} - T_f)} = \frac{86.3 \times 10^6 \text{ W}}{16.4 \times 10^6 \text{ W/K} \times (18.3 - (-75)^\circ\text{C})} = 0.0563$$

and the NTU is determined from Equation 11.29b

$$\text{NTU}_B = -\frac{\ln[1 - 0.0563]}{1} = 0.0579 \quad ; \quad A_B = \frac{\text{NTU}_B C_{\text{min,B}}}{U_B} = \frac{0.0579 \times 16.4 \times 10^6 \text{ W/K}}{260 \text{ W/m}^2 \cdot \text{K}} = 3660 \text{ m}^2$$

Section C The heat capacity rates are

$$\text{NG: } \dot{m}c_{p,v} = 150 \text{ kg/s} \times 2210 \text{ J/kg} \cdot \text{K} = 332 \times 10^3 \text{ W/K} = C_{\text{min,C}}$$

$$\text{SW: } \dot{m}c_{p,\text{sw}} = 4120 \text{ kg/s} \times 3985 \text{ J/kg} \cdot \text{K} = 16.4 \times 10^6 \text{ W/K} = C_{\text{max,C}}$$

$$C_{r,C} = C_{\text{min,C}} / C_{\text{max,C}} = 332 \times 10^3 / 16.4 \times 10^6 = 0.020$$

The effectiveness is

$$\varepsilon_C = \frac{q_C}{C_{\text{min,C}}(T_{h,i,C} - T_{c,i,C})} = \frac{q_C}{C_{\text{min,C}}(T_{h,i,C} - T_f)} = \frac{27.5 \times 10^6 \text{ W}}{332 \times 10^3 \text{ W/K} \times (20 - (-75)^\circ\text{C})} = 0.874$$

and the NTU is found from Equation 11.29b

Continued...

**PROBLEM 11.70 (Cont.)**

$$\text{NTU}_C = \frac{1}{0.020-1} \ln\left(\frac{0.874-1}{0.874 \times 0.020-1}\right) = 2.09; A_C = \frac{\text{NTU}_C C_{\min,C}}{U_C} = \frac{2.09 \times 332 \times 10^3 \text{ W/K}}{40 \text{ W/m}^2 \cdot \text{K}} = 17,300 \text{ m}^2$$

Therefore, the total heat transfer area for the vaporizer is

$$A = A_A + A_B + A_C = 2740 \text{ m}^2 + 3660 \text{ m}^2 + 17,300 \text{ m}^2 = 23,700 \text{ m}^2 \quad <$$

**COMMENTS:** (1) The scheme may not be feasible in a cold-weather port due to the potential of freezing the seawater. In cold-weather ports, approximately 2% of the natural gas will be burned, with the combustion products sent through the vaporizer to supply the necessary heating. See B. Eisentrout, S. Wintercorn and B. Weber, "Study Focuses on Six LNG Regasification Systems," *LNG Journal*, July/August, pp. 21 – 22, 2006. (2) For a parallel flow vaporizer with sea water introduced at the bottom of the heat exchanger, the required area is  $A = 36,900 \text{ m}^2$ , a 55% larger heat exchanger. See Problem 11.69.

## PROBLEM 11.71

**KNOWN:** Heat dissipation by electronics in sealed enclosure and dissipation from air-handling fan, mass flow rate of air, dimensions of concentric tube tower, temperature of ground water, heat transfer coefficients at top and bottom surfaces.

**FIND:** Temperature of the hot plate,  $T_2$ , for infinite and zero conduction resistance in the inner concentric tube. Determine whether maximum temperatures are maintained below  $80^\circ\text{C}$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat transfer between the device and the surroundings, (2) Constant properties.

**PROPERTIES:** Table A.4 (air) ( $\bar{T} = 300\text{ K}$ ):  $c_p = 1014\text{ J/kg}\cdot\text{K}$ ,  $\mu = 185 \times 10^{-7}\text{ N}\cdot\text{s/m}^2$ ,  $k = 0.0263\text{ W/m}\cdot\text{K}$ ,  $Pr = 0.707$ .

**ANALYSIS:** The overall heat transfer coefficient associated with the concentric tube section of the device depends on the values of the inside and outside convective heat transfer coefficients,  $h_i$  and  $h_o$ . For the inside convection coefficient, the Reynolds number is

$$Re_D = \frac{4\dot{m}}{\pi D \mu} = \frac{4 \times 0.0325\text{ kg/s}}{\pi \times 0.100\text{ m} \times 185 \times 10^{-7}\text{ N}\cdot\text{s/m}^2} = 22370$$

Since  $L/D = 10\text{ m}/0.100\text{ m} = 100$ , the flow is fully-developed and turbulent. Using the Dittus-Boelter correlation,

$$Nu_D = 0.023 \times (22370)^{4/5} \times 0.707^{0.4} = 60.43 ; h_i = 60.43 \times 0.0263\text{ W/m}\cdot\text{K} / 0.100\text{ m} = 15.90\text{ W/m}^2 \cdot \text{K}$$

For the annulus, the characteristic length is the hydraulic diameter,  $D_h = D_o - D_i = 0.150\text{ m} - 0.100\text{ m} = 0.050\text{ m}$ . Hence, the Reynolds number for the annular flow is  $Re_D = 22370 \times 2 = 44740$ . Therefore, the annular flow is also turbulent and fully-developed. Using the Dittus-Boelter correlation,

$$Nu_D = 0.023 \times (44740)^{4/5} \times 0.707^{0.3} = 108.9 ; h_o = 108.9 \times 0.0263\text{ W/m}\cdot\text{K} / 0.050\text{ m} = 57.28\text{ W/m}^2 \cdot \text{K}$$

Continued...

### PROBLEM 11.71 (Cont.)

The overall heat transfer coefficient is  $U = (1/h_i + 1/h_o)^{-1} = 12.44 \text{ W/m}^2 \cdot \text{K}$ , assuming no wall conduction resistance. The heat capacity rates of the two air streams are identical and are  $C_{\min} = C_{\max} = \dot{m} c_p = 0.0325 \text{ kg/s} \times 1014 \text{ J/kg} \cdot \text{K} = 32.73 \text{ W/K}$ . The relative heat capacity rate is  $C_r = 1$ . Hence,  $\text{NTU} = UA/C_{\min} = 12.44 \text{ W/m}^2 \cdot \text{K} \times \pi \times 0.100 \text{ m} \times 10 \text{ m} / [32.73 \text{ W/K}] = 1.19$ . From Eq. 11.29a, the effectiveness is  $\varepsilon = \text{NTU} / (1 + \text{NTU}) = 1.19 / 2.19 = 0.543$ . The heat transfer rate in the concentric tube, counter-flow heat exchanger,  $q_{\text{HX}}$ , is

$$q_{\text{HX}} = \varepsilon C_{\min} (T_{h,i} - T_{c,i}) = 0.543 \times 32.73 \text{ W/K} (T_{h,i} - T_{c,i}) \quad (1)$$

$$q_{\text{HX}} = \dot{m} c_p (T_{h,i} - T_{h,o}) = 0.0325 \text{ kg/s} \times 1014 \text{ J/kg} \cdot \text{K} (T_{h,i} - T_{h,o}) \quad (2)$$

At Surface 1, the heat flux is

$$q_1'' = \frac{(q + P)}{A_c} = \frac{(50 \text{ W} + 10 \text{ W})}{(\pi (0.15 \text{ m})^2 / 4)} = \bar{h}_1 (T_{h,o} - T_1) = 40 \text{ W/m}^2 \cdot \text{K} (T_{h,o} - T_1) \quad (3)$$

At Surface 2, the heat flux may be expressed as

$$q_2'' = \frac{q}{A_c} = \frac{50 \text{ W}}{(\pi (0.15 \text{ m})^2 / 4)} = \bar{h}_2 (T_2 - T_{f,o}) = 60 \text{ W/m}^2 \cdot \text{K} (T_2 - T_{f,o}) \quad (4)$$

By considering a control volume about the fan,

$$P = 10 \text{ W} = \dot{m} c_p (T_{f,o} - T_{c,o}) = 10 \text{ W} = 0.0325 \text{ kg/s} \times 1014 \text{ J/kg} \cdot \text{K} (T_{f,o} - T_{c,o}) \quad (5)$$

For the control volume in the vicinity of Surface 1,

$$P + q = \dot{m} c_p (T_{h,o} - T_{c,i}) = 50 \text{ W} + 10 \text{ W} = 0.0325 \text{ kg/s} \times 1014 \text{ J/kg} \cdot \text{K} \times (T_{h,o} - T_{c,i}) \quad (6)$$

For the control volume in the vicinity of Surface 2,

$$q = \dot{m} c_p (T_{h,i} - T_{f,o}) = 50 \text{ W} = 0.0325 \text{ kg/s} \times 1014 \text{ J/kg} \cdot \text{K} \times (T_{h,i} - T_{f,o}) \quad (7)$$

Equations (1) through (7) may be solved simultaneously to yield the following results.

$U = 12.44 \text{ W/m}^2 \cdot \text{K}$  (zero conduction resistance):

$T_2$	$T_{f,o}$	$T_{c,i}$	$T_{c,o}$	$T_{h,i}$	$T_{h,o}$	$q_{\text{HX}}$
137.6°C	90.49°C	88.06°C	90.19°C	92.01°C	89.88°C	70.1 W

$U = 0 \text{ W/m}^2 \cdot \text{K}$  (infinite conduction resistance):

$T_2$	$T_{f,o}$	$T_{c,i}$	$T_{c,o}$	$T_{h,i}$	$T_{h,o}$	$q_{\text{HX}}$
135.5°C	88.37°C	88.06°C	88.06°C	89.88°C	89.88°C	0 W

Neither case provides acceptable maximum temperatures.

<  
Continued...

### **PROBLEM 11.71 (Cont.)**

**COMMENTS:** (1). The heat transfer coefficients at Surfaces 1 and 2 are relatively small. Improved performance would result by increasing the surface area available for transfer through, for example, addition of fins. (2). Significantly improved performance would result by replacing the air and fan arrangement with liquid water and a pump. (3) See Hadim, Mehmedagic, and Wendell, "A New GEOPOLE Cooling Technique for Outdoor Electronic Enclosures," *International Journal of Energy Research*, Vol. 30, pp. 459 – 470, 2006, for more information.

## PROBLEM 11.72

**KNOWN:** Inlet and outlet temperatures and flow rates for a shell-and-tube heat exchanger with a single shell and 100 tubes making two passes. Tube inner and outer diameters and length. Heat transfer coefficient for ethylene-glycol water mixture flowing in shell.

**FIND:** (a) Heat transfer rate and outlet temperatures when the tubes are copper. (b) For nylon tubes, heat exchanger length required to transfer the same amount of energy as in part (a).

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat loss to the surroundings, (2) Constant properties, (3) Fully developed water flow in tubes.

**PROPERTIES:** Table A.6, water ( $T \approx 300$  K):  $k = 0.613$  W/m·K,  $c_p = 4179$  J/kg·K,  $\mu = 855 \times 10^{-6}$  N·s/m<sup>2</sup>,  $Pr = 5.83$ . Ethylene-glycol water mixture (given):  $\rho = 1040$  kg/m<sup>3</sup>,  $c_p = 3660$  J/kg·K. Copper ( $T \approx 300$  K):  $k_c = 401$  W/m·K. Nylon (given):  $k_n = 0.31$  W/m·K.

**ANALYSIS:** (a) We begin by finding the heat transfer coefficient for the flow in tubes. The Reynolds number is

$$Re_D = \frac{4\dot{m}_1}{\pi D_i \mu_c} = \frac{4 \times 2.5 \text{ kgs}/100}{\pi \times 0.0036 \text{ m} \times 855 \times 10^{-6} \text{ N} \cdot \text{s}/\text{m}^2} = 1.03 \times 10^4$$

Hence the flow is turbulent and we can use the Dittus-Boelter correlation,

$$h_c = (k/D_i)0.023 Re_D^{4/5} Pr^{0.4} = (0.613 \text{ W}/\text{m} \cdot \text{K}/0.0036 \text{ m})0.023(1.03 \times 10^4)^{4/5}(5.83)^{0.4} \\ = 1.29 \times 10^4 \text{ W}/\text{m}^2 \cdot \text{K}$$

Then UA can be found from

$$UA = \left[ \frac{1}{h_i \pi D_i} + \frac{\ln(D_o/D_i)}{2\pi k_c} + \frac{1}{h_o \pi D_o} \right]^{-1} LN \\ = \left[ 6.85 \times 10^{-3} + 2.15 \times 10^{-5} + 7.62 \times 10^{-3} \right]^{-1} \text{ W}/\text{m} \cdot \text{K} \times 0.8 \text{ m} \times 100 = 5522 \text{ W}/\text{K}$$

Continued...

**PROBLEM 11.72 (Cont.)**

Using the  $\varepsilon$ -NTU method,  $C_{\min} = C_h = 2.5 \text{ kg/s} \times 3600 \text{ J/kg}\cdot\text{K} = 9000 \text{ W/K}$ ,  $C_{\max} = 2.5 \text{ kg/s} \times 4179 \text{ J/kg}\cdot\text{K} = 10,450 \text{ W/K}$ ,  $C_r = 0.861$ , and  $\text{NTU} = \text{UA}/C_{\min} = 0.614$ . Then from Eq. 11.30a,

$$\varepsilon = 2 \left\{ 1 + C_r + (1 + C_r^2)^{1/2} \times \frac{1 + \exp\left[-\text{NTU}(1 + C_r^2)^{1/2}\right]}{1 - \exp\left[-\text{NTU}(1 + C_r^2)^{1/2}\right]} \right\}^{-1} = 0.378$$

and from Eqs. 11.18, 11.19, 11.6b, and 11.7b,

$$q = \varepsilon C_{\min}(T_{h,i} - T_{c,i}) = 0.378 \times 9000 \text{ W/K} (80 - 20)^\circ\text{C} = 204 \text{ kW} \quad <$$

$$T_{h,o} = T_{h,i} - q/C_h = 80^\circ\text{C} - 204,000 \text{ W}/9000 \text{ W/K} = 57.3^\circ\text{C} \quad <$$

$$T_{c,o} = T_{c,i} + q/C_c = 20^\circ\text{C} + 204,000 \text{ W}/10,450 \text{ W/K} = 42.7^\circ\text{C} \quad <$$

(b) In order to maintain the same heat rate, we must have the same effectiveness, which means that NTU and UA must be the same as in part (a). When the tubes are nylon, we can recalculate UA from Eq. (1),

$$\begin{aligned} \text{UA} &= \left[ \frac{1}{h_i \pi D_i} + \frac{\ln(D_o/D_i)}{2\pi k_n} + \frac{1}{h_o \pi D_o} \right]^{-1} \text{LN} \\ &= \left[ 6.85 \times 10^{-3} + 2.78 \times 10^{-2} + 7.62 \times 10^{-3} \right]^{-1} \text{W/m}\cdot\text{K} \times 100 \times L \text{ (m)} = 5522 \text{ W/K} \end{aligned}$$

Solving for L,

$$L = 2.33 \text{ m} \quad <$$

**COMMENTS:** (1) The nylon tube bundle is significantly larger due to nylon's low thermal conductivity relative to the copper. Based upon a nylon density of  $1150 \text{ kg/m}^3$ , the masses of the two tube bundles are 0.83 kg and 0.39 kg for the copper and nylon, respectively. The cost difference between the two raw materials is negligible. However, the nylon heat exchanger may ultimately be less expensive when assembly costs are considered. Time-consuming and expensive brazing, joining, and welding processes associated with construction of the copper heat exchanger are avoided with use of materials such as nylon. (2) With  $L/D \approx 200$ , the fully developed assumption is excellent. (3) The properties of the cold stream should have been calculated at the mean temperature of 304 K, very close to the assumed value.

### PROBLEM 11.73

**KNOWN:** Heat exchanger operating in parallel-flow configuration.

**FIND:** Expression for  $R_{lm}/R_t$  which doesn't involve temperatures. Plot result.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat loss to surroundings, (2) Negligible change in kinetic and potential energy.

**ANALYSIS:** (a) For the exchanger, the rate equation is

$$q = UA\Delta T_{lm}$$

and we can define thermal resistances as

$$R_t = (T_{h,i} - T_{c,i})/q \quad \text{or} \quad R_{lm} = (\Delta T_{lm})/q = 1/UA.$$

Using the rate equation and the definition of effectiveness, find the thermal resistance based upon the inlet temperatures of the hot and cold fluids as

$$R_t = C_{min} (T_{h,i} - T_{c,i})/C_{min} \cdot q = 1/\varepsilon C_{min}.$$

The ratio of these resistances is

$$\frac{R_{lm}}{R_t} = \frac{1/UA}{1/\varepsilon C_{min}} = \frac{\varepsilon}{UA/C_{min}} = \frac{\varepsilon}{NTU}$$

and for the parallel flow, concentric tube configuration using Eq. 11.28a,

$$\frac{R_{lm}}{R_t} = \frac{1 - \exp[-NTU(1 + C_r)]}{NTU(1 + C_r)} = \frac{1 - \exp(-B)}{B}$$

where  $B = NTU(1 + C_r)$ . Evaluating the ratio for various values of  $B$ , find

$B$	$R_{lm}/R_t$
0.1	0.95
0.5	0.79
1.0	0.63
3.0	0.32
5.0	0.20
10.0	0.10

**COMMENTS:** (1) For  $C_{max} \rightarrow \infty$ ,  $C_r \rightarrow 0$ ; hence  $B \rightarrow NTU$ . (2) For  $C_{max} \approx C_{min}$ ,  $B \rightarrow 2NTU$  or  $B \sim C_{min}^{-1}$ . (3) For  $B \ll 1$ ,  $R_{lm}/R_t \rightarrow 1$ . (4) For  $B \gg 1$ ,  $R_{lm}/R_t \rightarrow B^{-1}$ . (5) We conclude that care must be taken in representing heat exchangers with a thermal resistance, recognizing that the resistance will depend on flow rates for wide ranges of conditions.

### PROBLEM 11.74

**KNOWN:** Required power for automobile. Overall heat transfer coefficient for radiator, analyzed as a cross-flow heat exchanger with both fluids unmixed. Inlet temperature of air for cooling.

**FIND:** (a) Required heat transfer area if engine efficiency is 35%, water inlet and outlet temperatures are 400 and 330 K, respectively, and air flow rate is 3 kg/s. (b) Required heat transfer area and engine coolant (water) mass flow rate if vehicle is powered by 50% efficient fuel cell, water inlet and outlet temperatures are 335 and 330 K, respectively, and air flow rate is proportional to radiator surface area. (c) Required heat transfer area and coolant (water) outlet temperature for fuel cell powered vehicle if air flow rate is 3 kg/s.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat loss to the surroundings, (2) Constant properties, (3) Negligible fouling factors.

**PROPERTIES:** Table A.6, water: ( $\bar{T}_m = 365$  K):  $c_p = 4209$  J/kg·K; Table A.4, air ( $\bar{T}_m \approx 350$  K):  $c_p = 1009$  J/kg·K.

**ANALYSIS:** (a) We can determine how much heat must be removed by the radiator as follows. The required mechanical power is 9 kW, which is 35% of the total engine power, i.e.  $P_{tot} = 9 \text{ kW}/0.35 = 25.7 \text{ kW}$ . The waste heat is 65% of the total power, or

$$q = 0.65P_{tot} = 0.65 \times 25.7 \text{ kW} = 16.7 \text{ kW}$$

Then from Eq. 11.6b,

$$C_h = q/(T_{h,i} - T_{h,o}) = 16.7 \text{ kW}/(400 - 330)\text{K} = 239 \text{ W/K}$$

The heat capacity rate for the air is

$$C_c = (\dot{m}c_p)_c = 3 \text{ kg/s} \times 1009 \text{ J/kg} \cdot \text{K} = 3027 \text{ W/K}$$

Continued...

**PROBLEM 11.74 (Cont.)**

Thus  $C_{\min} = C_h$ ,  $C_r = 239/3027 = 0.0789$  and  $\varepsilon = q/C_{\min}(T_{h,i} - T_{h,o}) = 0.699$ . Then from Fig. 11.14,  $NTU \approx 1.25$ , and we can refine this estimate by solving Eq. 11.32 iteratively, to yield  $NTU = 1.26$ . Thus,  $UA = NTU \times C_{\min} = 1.26 \times 239 \text{ W/K} = 301 \text{ W/K}$ . With  $U = 400 \text{ W/m}^2 \cdot \text{K}$ ,

$$A = UA/U = 301 \text{ W/K} / 400 \text{ W/m}^2 \cdot \text{K} = 0.752 \text{ m}^2 \quad <$$

(b) With 50% efficiency,  $P_{\text{tot}} = 9 \text{ kW}/0.50 = 18 \text{ kW}$  and  $q = 0.50P_{\text{tot}} = 9 \text{ kW}$ . Then

$$C_h = q/(T_{h,i} - T_{h,o}) = 9 \text{ kW}/(355 - 330)\text{K} = 360 \text{ W/K}$$

and

$$\dot{m}_h = C_h / c_{p,h} = 360 \text{ W/K} / 4209 \text{ J/kg} \cdot \text{K} = 0.0855 \text{ kg/s} \quad <$$

The heat capacity rate for the air is unknown, but can be expressed as follows, where the “o” subscript refers to the baseline conditions of part (a),

$$C_c = (\dot{m}c_p)_c = (\dot{m}_o c_p)_c \frac{A}{A_o} = 3027 \text{ W/K} \frac{A}{0.752 \text{ m}^2} = (4025 \text{ W/m}^2 \cdot \text{K})A$$

Assuming the hot fluid is still the minimum fluid,  $C_{\min} = 360 \text{ W/K}$ ,

$$\varepsilon = q/C_{\min}(T_{h,i} - T_{c,i}) = 9 \text{ kW}/[360 \text{ W/K}(355 - 300)\text{K}] = 0.455 \quad (1)$$

$$C_r = (360 \text{ W/K} / 4025 \text{ W/m}^2 \cdot \text{K})A^{-1} = (0.0895 \text{ m}^2) A^{-1} \quad (2)$$

$$NTU = UA/C_{\min} = (400 \text{ W/m}^2 \cdot \text{K}/360 \text{ W/K})A = (1.11 \text{ m}^2)A \quad (3)$$

And from Eq. 11.32,

$$\varepsilon = 1 - \exp \left[ \left( \frac{1}{C_r} \right) (NTU)^{0.22} \left\{ \exp \left[ -C_r (NTU)^{0.78} \right] - 1 \right\} \right] \quad (4)$$

Substituting Eqs. (1), (2), and (3) into Eq. (4),

$$0.455 = 1 - \exp \left[ \left( \frac{A}{0.0895 \text{ m}^2} \right) (1.11 \text{ m}^{-2} A)^{0.22} \left\{ \exp \left[ -\frac{0.0895 \text{ m}^2}{A} (1.11 \text{ m}^{-2} A)^{0.78} \right] - 1 \right\} \right]$$

Solving iteratively for A results in

$$A = 0.576 \text{ m}^2 \quad <$$

Note that  $C_c = 2.30 \text{ kg/s} \times 1009 \text{ J/kg} \cdot \text{K} = 2319 \text{ W/K}$ , so that our assumption that the hot fluid is the minimum was correct.

Continued...

### PROBLEM 11.74 (Cont.)

(c) With the same coolant (water) flow rate as in part (a),  $C_h = 239 \text{ W/K}$ . Then

$$\varepsilon = q/C_{\min}(T_{h,i} - T_{c,i}) = 9 \text{ kW}/[239 \text{ W/K}(355 - 300)\text{K}] = 0.685 \quad (5)$$

$$C_r = (239 \text{ W/K} / 4025 \text{ W/m}^2\cdot\text{K})A^{-1} = (0.0594 \text{ m}^2) A^{-1} \quad (6)$$

$$NTU = UA/C_{\min} = (400 \text{ W/m}^2\cdot\text{K}/239 \text{ W/K})A = (1.67 \text{ m}^2)A \quad (7)$$

And substituting Eqs. (5), (6), and (7) into Eq. (4),

$$0.685 = 1 - \exp \left[ \left( \frac{A}{0.0594 \text{ m}^2} \right) (1.67 \text{ m}^{-2}A)^{0.22} \left\{ \exp \left[ -\frac{0.0594 \text{ m}^2}{A} (1.67 \text{ m}^{-2}A)^{0.78} \right] - 1 \right\} \right]$$

Solving iteratively for A results in

$$A = 0.723 \text{ m}^2 \quad <$$

The outlet temperature of the coolant (water) is calculated from Eq. 11.6b,

$$T_{h,o} = T_{h,i} - q/C_h = 355 \text{ K} - 9000 \text{ W}/239 \text{ W/K} = 317 \text{ K} \quad <$$

**COMMENTS:** (1) The heat that must be rejected from the radiator when the fuel cell is used is  $9000 \text{ W}/16700 \text{ W} \times 100 = 53\%$  of that associated with the internal combustion engine. (2) As seen in Part (b), using the fuel cell and increasing the flow rate of the coolant results in a significantly smaller radiator size. (3) As seen in Part (c), if the coolant flow rate is the same as that of the internal combustion engine the coolant exits the radiator at a lower value since its residence time in the radiator is larger. (4) Reduced radiator sizes will provide opportunities to enhance streamlining of the front of the vehicle and will reduce drag forces, further increasing fuel economy. The radiator size can be reduced significantly with the fuel cell in place if a metal hydride hydrogen storage system is on board and waste heat from the fuel cell is used to desorb the hydrogen, as discussed in Example 7.5.

## PROBLEM 11.75

**KNOWN:** Air conditioner modeled as a reversed Carnot heat engine, with refrigerant as the working fluid, operating between indoor and outdoor temperatures of 23 and 43°C, respectively, removing 5 kW from a building. Compressor and fan motor efficiency of 80%.

**FIND:** (a) Required motor power assuming negligible thermal resistances *between* the refrigerant in the condenser and the outside air and *between* the refrigerant in the evaporator and the inside air, and (b) Required power if thermal resistances are each  $3 \times 10^{-3}$  K/W.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Ideal heat exchanger with no losses, (2) Air conditioner behaves as reversed Carnot engine.

**ANALYSIS:** (a) With negligible thermal resistances, the Carnot cycle and reversed heat engine can be represented as shown above. Hence, from Chapter 1

$$\dot{w}_{\text{ideal}} = q_H - q_L = q_L \left[ \left( \frac{T_H}{T_L} \right) - 1 \right] = 5 \text{ kW} \left[ \left( \frac{316 \text{ K}}{296 \text{ K}} \right) - 1 \right] = 0.3378 \text{ kW}.$$

Considering the fan power requirement and the efficiency of the motor,

$$\dot{w}_{\text{act}} = (\dot{w}_{\text{ideal}} + \dot{w}_{\text{fan}}) / \eta_c = (0.3378 + 0.200) \text{ kW} / 0.8 = 0.672 \text{ kW}. \quad <$$

(b) Consider now thermal resistances of  $R_t = 3 \times 10^{-3}$  K/W on the high temperature (condenser) and low temperature (evaporator) sides.

*Low side:* in order to remove heat from the room,  $T_C < T_i$ . That is

$$T_i - T_C = q R_t = 5 \text{ kW} \left( 3 \times 10^{-3} \text{ K/W} \right) = 15 \text{ K}$$

$$T_C = T_i - 15 \text{ K} = 23^\circ\text{C} - 15 \text{ K} = 8^\circ\text{C}.$$

*High side:* in order to reject heat from the condenser to the outside air,  $T_H > T_o$ ,

$$T_H - T_o = q_H R_t = q_c \left( \frac{T_H}{T_C} \right) R_t$$

$$T_H - (43 + 273) \text{ K} = 5 \text{ kW} \left[ \frac{T_H}{(8 + 273)} \right] 3 \times 10^{-3} \text{ K/W} \quad T_H = 333.9 \text{ K} = 61^\circ\text{C}.$$

The work required for this cycle is

$$\dot{w}_{\text{ideal}} = q_H - q_L = q_L \left[ \left( \frac{T_H}{T_L} \right) - 1 \right] = 5 \text{ kW} \left[ \left( \frac{61 + 273}{8 + 273} \right) - 1 \right] = 0.943 \text{ kW}$$

$$\dot{w}_{\text{act}} = (\dot{w}_{\text{ideal}} + \dot{w}_{\text{fan}}) / \eta_c = (0.943 + 0.2) \text{ kW} / 0.8 = 1.43 \text{ kW}. \quad <$$

The effect of finite thermal resistances in the evaporator and condenser is to increase the power by a factor of two.

## PROBLEM 11.76

**KNOWN:** Flow rate and pressure of saturated vapor entering a condenser. Number and diameter of condenser tubes. Water flow rate and inlet temperature. Tube outside convection coefficient.

**FIND:** (a) Water outlet temperature, (b) Total tube length, (c) Effect of fouling on mass condensation, (d) Effect of water flow rate and inlet temperature on condenser performance.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat loss to surroundings, (2) Constant properties, (3) Negligible wall conduction resistance and fouling (initially).

**PROPERTIES:** Water (given):  $c_p = 4178 \text{ J/kg}\cdot\text{K}$ ,  $\mu = 700 \times 10^{-6} \text{ kg/s}\cdot\text{m}$ ,  $k = 0.628 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 4.6$ ; Table A.6, Sat. steam (355 K):  $h_{fg} = 2.304 \times 10^6 \text{ J/kg}$ ; With fouling:  $R_f'' = 0.0003 \text{ m}^2\cdot\text{K/W}$ .

**ANALYSIS:** (a) From an energy balance,  $q_h = \dot{m}_h (i_{h,i} - i_{h,o}) = \dot{m}_h h_{fg} = q_c = \dot{m}_c c_{p,c} (T_{c,o} - T_{c,i})$ , or

$$T_{c,o} = T_{c,i} + \frac{\dot{m}_h h_{fg}}{\dot{m}_c c_{p,c}} = 280 \text{ K} + \frac{1.5 \text{ kg/s} \times 2.304 \times 10^6 \text{ J/kg}}{15 \text{ kg/s} \times 4178 \text{ J/kg}\cdot\text{K}} = 335.1 \text{ K}. \quad <$$

(b) Since  $C_r = 0$ ,  $\text{NTU} = -\ln(1 - \varepsilon)$ , where

$$\varepsilon = \frac{q}{q_{\max}} = \frac{\dot{m}_c c_{p,c} (T_{c,o} - T_{c,i})}{\dot{m}_c c_{p,c} (T_{h,i} - T_{c,i})} = \frac{(335.1 - 280) \text{ K}}{(355 - 280) \text{ K}} = 0.735$$

Hence,  $\text{NTU} = -\ln(1 - 0.735) = 1.327 = \text{UA}/C_{\min}$ . The overall heat transfer coefficient is given by  $1/U = 1/\bar{h}_i + 1/\bar{h}_o$ . For the internal tube flow,

$$\text{Re}_D = \frac{4\dot{m}_{c,1}}{\pi D \mu} = \frac{4 \times 15 \text{ kg/s} / 100}{\pi (0.01 \text{ m}) 700 \times 10^{-6} \text{ kg/s}\cdot\text{m}} = 27,284$$

Hence, assuming fully developed flow with the Dittus-Boelter correlation,

$$\text{Nu}_D = 0.023 \text{Re}_D^{4/5} \text{Pr}^n = 0.023 (27,284)^{4/5} (4.6)^{0.4} = 149.8$$

$$\bar{h}_i = (k/D) \text{Nu}_D = \frac{0.628 \text{ W/m}\cdot\text{K}}{0.01 \text{ m}} 149.8 = 9408 \text{ W/m}^2\cdot\text{K}$$

and  $U = [(1/9408) + (1/5000)]^{-1} \text{ W/m}^2\cdot\text{K} = 3265 \text{ W/m}^2\cdot\text{K}$ . Hence, the heat transfer area is

$$A = \dot{m}_c c_{p,c} (\text{NTU}/U) = 15 \text{ kg/s} (4178 \text{ J/kg}\cdot\text{K}) (1.327 / 3265 \text{ W/m}^2\cdot\text{K}) = 25.5 \text{ m}^2$$

and the tube length is  $L = A/N\pi D = 25.5 \text{ m}^2 / 100\pi(0.01 \text{ m}) = 8.11 \text{ m}$ . <

(c) With fouling, the overall heat transfer coefficient is  $1/U_w = 1/U_{wo} + R_f''$ . Hence,

Continued...

**PROBLEM 11.76 (Cont.)**

$$1/U_w = \left(3.063 \times 10^{-4} + 3 \times 10^{-4}\right) \text{m}^2 \cdot \text{K}/\text{W}$$

$$U_w = 1649 \text{ W}/\text{m}^2 \cdot \text{K}.$$

$$\text{NTU} = UA/C_{\min} = \left(1649 \text{ W}/\text{m}^2 \cdot \text{K} \times 25.5 \text{ m}^2\right) / \left(15 \text{ kg}/\text{s} \times 4178 \text{ J}/\text{kg} \cdot \text{K}\right) = 0.671$$

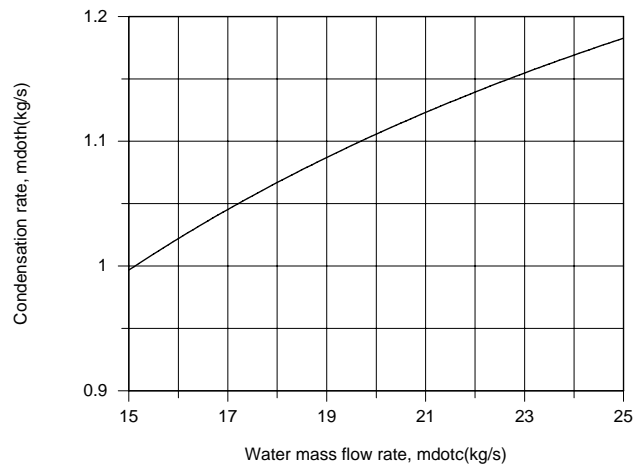

From Eq. 11.35a,  $\varepsilon = 1 - \exp(-\text{NTU}) = 1 - \exp(-0.671) = 0.489$ . Hence,  $q = \varepsilon q_{\max} = 0.489 \times 15 \text{ kg}/\text{s} \times 4178 \text{ J}/\text{kg} \cdot \text{K}(355 - 280)\text{K} = 2.30 \times 10^6 \text{ W}$ . Without fouling the heat rate was

$$q = \dot{m}_h h_{fg} = 1.5 \text{ kg}/\text{s} \times 2.304 \times 10^6 \text{ J}/\text{kg} = 3.46 \times 10^6 \text{ W}.$$

$$\text{Hence, } \dot{m}_{h,w} / \dot{m}_{h,wo} = 2.30 \times 10^6 / 3.46 \times 10^6 = 0.666. \quad \leftarrow$$

The condensation rate with fouling is then  $\dot{m}_{h,w} = 0.666 \times 1.5 \text{ kg}/\text{s} = 0.998 \text{ kg}/\text{s}$ .

(d) The prescribed water inlet temperature of  $T_{c,i} = 280 \text{ K}$  is already at the lower limit of available sources, and it would not be feasible to consider smaller values. In addition, with  $\bar{h}_i$  already quite large, an increase in  $\dot{m}_c$  is not likely to provide a significant improvement in performance. Using the *Heat Exchanger and Correlations Tools* from IHT, the following results were obtained for  $15 \leq \dot{m}_c \leq 25 \text{ kg}/\text{s}$ .

Over the specified range of  $\dot{m}_c$ , there is approximately an 18% increase in the heat rate, and hence in the condensation rate. This increase is, in part, due to the increase in  $\bar{h}_i$  from 9408 to 14,160  $\text{W}/\text{m}^2 \cdot \text{K}$ , which increases  $U$  from 1649 to 1752  $\text{W}/\text{m}^2 \cdot \text{K}$ , as well as to a reduction in  $T_{c,o}$  from 316.6 to 306.0 K, which increases the mean driving potential for heat transfer.

**COMMENTS:** There is a significant reduction in performance due to fouling, which can not be restored by increasing  $\dot{m}_c$ . The desired performance could be achieved by oversizing the condenser, that is, by increasing the number of tubes and/or the tube length.

## PROBLEM 11.77

**KNOWN:** Rankine cycle with saturated steam leaving the boiler at 2 MPa and a condenser pressure of 10 kPa. Net reversible work of 0.5 MW.

**FIND:** (a) Thermal efficiency of ideal Rankine cycle, (b) Required cooling water flow rate to condenser at 15°C with allowable temperature rise of 10°C, and (c) Design of a shell and tube heat exchanger (one shell and multiple tube passes) to satisfy condenser flow rate and temperature rise.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible loss from condenser to surroundings, (2) Ideal Rankine cycle, and (3) Negligible thermal resistance on condensate side of exchanger tubes.

**PROPERTIES:** *Steam Tables*, (Wark, 4<sup>th</sup> Edition): (1)  $p_1 = p_4 = 10 \text{ kPa} = 0.10 \text{ bar}$ ,  $T_{\text{sat}} = 45.8^\circ\text{C} = 319 \text{ K}$ ,  $v_f = 1.0102 \times 10^{-3} \text{ m}^3/\text{kg}$ ,  $h_f = 191.83 \text{ kJ/kg}$ ; (3)  $p_2 = p_3 = 2 \text{ MPa} = 20 \text{ bar}$ ,  $h_g = 2799.5 \text{ kJ/kg}$ ,  $s_g = 6.3409 \text{ kJ/kg}\cdot\text{K}$ ; (4)  $s_4 = s_3 = 6.3409 \text{ kJ/kg}\cdot\text{K}$ ,  $p_4 = 0.10 \text{ bar}$ ,  $s_f = 0.6493 \text{ kJ/kg}\cdot\text{K}$ ,  $s_g = 8.1502 \text{ kJ/kg}\cdot\text{K}$ ,  $h_f = 191.83 \text{ kJ/kg}$ ,  $h_{fg} = 2392.8 \text{ kJ/kg}$ ; *Table A-6*, Water ( $T_{\text{sat}} = 293 \text{ K}$ ):  $c_{p,c} = 4182 \text{ J/kg}\cdot\text{K}$ ,  $\mu = 1007 \times 10^{-6} \text{ N}\cdot\text{s/m}^2$ ,  $k = 0.603 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 7.0$ . Note:  $1 \text{ bar} = 10^5 \text{ N/m}^2 = 10^5 \text{ Pa}$ .

**ANALYSIS:** (a) Referring to Chapter 1 and your thermodynamics text, find that

$$\eta = \frac{w_{\text{net}}}{Q_H} = \frac{w_t - w_p}{Q_H} = \frac{(h_3 - h_4) - v_1(p_2 - p_1)}{h_3 - h_2}$$

where the net work is the turbine minus the pump work. Assuming the liquid in the pump is incompressible,

$$w_p = v_1(p_2 - p_1) = 1.0102 \times 10^{-3} \text{ m}^3/\text{kg} (2 \times 10^6 - 10 \times 10^3) \text{ N/m}^2 = 2.01 \text{ kJ/kg}.$$

To find the enthalpies at states 2, 3, and 4, consider the individual processes. For the *pump*,

$$h_2 = h_1 + w_p = (191.83 + 2.01) \text{ kJ/kg} = 193.84 \text{ kJ/kg}.$$

Since the exit state of the boiler is saturated at  $p_3 = 2 \text{ MPa}$ ,

$$h_3 = h_g = 2799.5 \text{ kJ/kg}.$$

$$Q_H = h_3 - h_2 = (2799.5 - 193.84) \text{ kJ/kg} = 2605.7 \text{ kJ/kg}.$$

Since the process from 3 to 4 is isentropic,  $s_4 = s_3$ , hence

$$x_4 = (s_4 - s_f) / (s_g - s_f) = (6.3409 - 0.6493) / (8.1502 - 0.6493) = 0.759$$

$$h_4 = h_f + x h_{fg} = [191.83 + 0.759(2392.8)] \text{ kJ/kg} = 2007.5 \text{ kJ/kg}.$$

Continued ...

**PROBLEM 11.77 (Cont.)**

$$w_t = h_3 - h_4 = (2799.5 - 2007.5) \text{ kJ/kg} = 792.0 \text{ kJ/kg}.$$

Substituting appropriate values, the thermal efficiency is

$$\eta = \frac{(792.0 - 2.01) \text{ kJ/kg}}{2605.7 \text{ kJ/kg}} = 0.303 = 30.3\%.$$

<

(b) From an overall balance on the cycle, the heat rejected to the condenser is

$$Q_c = Q_H - w_{\text{net}} = [2605.7 - (792.0 - 2.01)] \text{ kJ/kg} = 1815.7 \text{ kJ/kg}.$$

Since the net reversible power is 0.5 MW, the required steam rate (h) is

$$\dot{m}_h = \dot{W}_{\text{net}} / w_{\text{net}} = 0.5 \times 10^6 \text{ W} / (792.0 - 2.01) \text{ kJ/kg} = 0.6329 \text{ kg/s}.$$

Hence, the heat rate to be removed by the cold water passing through the condenser is

$$q_c = Q_c \cdot \dot{m}_h = \dot{m}_c c_{p,c} (T_{c,\text{out}} - T_{c,\text{in}})$$

$$1815.7 \text{ kJ/kg} \times 0.6329 \text{ kg/s} = 1.149 \times 10^6 \text{ W} = \dot{m}_c \times 4182 \text{ J/kg} \cdot \text{K} (25 - 15) \text{ K}$$

$$\dot{m}_c = 27.47 \text{ kg/s}$$

<

where  $c_{p,c} = c_{p,f}$  is evaluated at  $T_2$ ,  $T_{c,\text{in}} = 15^\circ\text{C}$  and  $T_{c,\text{out}} - T_{c,\text{in}} = 10^\circ\text{C}$ , the specified allowable rise.

(c) To design the heat exchanger we need to evaluate  $UA$ . Considering the shell-tube configuration and since  $C_r = C_{\text{min}}/C_{\text{max}} = 0$ ,

$$\varepsilon = 1 - \exp(-NTU) = 1 - \exp\left[-(UA/C_{\text{min}})\right]$$

$$\varepsilon = \frac{q}{q_{\text{max}}} = \frac{q_c}{\dot{m}_c c_{p,c} (T_h - T_{c,i})}$$

$$\varepsilon = \frac{1.149 \times 10^6 \text{ W}}{27.47 \text{ kg/s} \times 4182 \text{ J/kg} \cdot \text{K} (45.7 - 15) \text{ K}} = 0.326$$

$$0.326 = 1 - \exp\left(-\frac{UA}{27.47 \text{ kg/s} \times 4182 \text{ J/kg} \cdot \text{K}}\right)$$

$$UA_s = 45,372 \text{ W/K}$$

where  $C_{\text{min}} = \dot{m}_c c_{p,c}$ . Our design process will involve the following steps: select tube diameter,  $D = 15 \text{ mm}$ ; set  $u_m = 2 \text{ m/s}$  in each tube and find number of tubes; perform internal flow calculation to estimate  $\bar{h}_c$  and then determine the length.

$$\dot{m}_c = \rho A_c \text{Nu}_m = \left(1.010 \times 10^{-3} \text{ m}^3/\text{kg}\right)^{-1} \left(\pi (0.015 \text{ m})^2 / 4\right) 2 \text{ m/s} \times N = 27.47 \text{ kg/s}$$

$$N = 78.5 \approx 79.$$

Continued ...

### PROBLEM 11.77 (Cont.)

For flow in a single tube,

$$\text{Re}_D = \frac{4 \dot{m}_t}{\pi D \mu} = \frac{4(27.47 \text{ kg/s}/79)}{\pi(0.015\text{m})1007 \times 10^{-6} \text{ N}\cdot\text{s}/\text{m}^2} = 29,310.$$

Assuming the flow is fully developed and using the Dittus-Boelter correlation,

$$\text{Nu} = \frac{hD}{k} = 0.023 \text{Re}_D^{0.8} \text{Pr}^{0.4} = 0.023(29,310)^{0.8} (7.00)^{0.4} = 187.7$$

$$h = 0.603 \text{ W}/\text{m}\cdot\text{K} \times 187.7/0.015\text{m} = 7544 \text{ W}/\text{m}^2 \cdot \text{K}.$$

Hence, the tube length is

$$UA_s = h(\pi DL)N = 45,372 \text{ W}/\text{K}$$

$$L = 45,372 \text{ W}/\text{K} / 7544 \text{ W}/\text{m}^2 \cdot \text{K} \times \pi(0.015\text{m})79 = 1.6\text{m}$$

and our design has the following parameters:

$$N = 79 \text{ tubes}$$

$$L = 1.6\text{m}$$

$$D = 15 \text{ mm}.$$

<

**COMMENTS:** (1) The selection of the tube diameter and water velocity values (15 mm, 2 m/s) was based upon prior experience; they seemed reasonable. We could, however, establish other requirements which would influence these choices such as allowable pressure drop and standard tube sizes.

### PROBLEM 11.78

**KNOWN:** Rankine cycle with saturated steam leaving the boiler at 2 MPa and a condenser pressure of 10 kPa. Heat rejected to the condenser of 2.3 MW. Condenser supplied with cooling water at rate of 70 kg/s at 15°C.

**FIND:** (a) Size of the condenser as determined by the parameter, UA, and (b) Reduction in thermal efficiency of the cycle if U decreases by 10% due to fouling assuming water flow rate and inlet temperature and the condenser steam pressure remain fixed.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible loss from condenser to surroundings, (2) Ideal Rankine cycle, (3) For fouled operating condition,  $\dot{m}_c$ ,  $T_{c,i}$  and  $p_4$  remain the same.

**PROPERTIES:** *Steam Tables* (Thermodynamics text): See previous problem for calculations to obtain cycle enthalpies;  $h_1 = 191.83$  kJ/kg,  $h_4 = 2007.5$  kJ/kg.

**ANALYSIS:** (a) For the condenser, recognize that  $C_{\min} = C_c$ , and  $C_r = C_{\min}/C_{\max} = 0$ ,

$$\varepsilon = \frac{q}{q_{\max}} = 1 - \exp(-NTU) = 1 - \exp(-UA/C_{\min})$$

$$C_{\min} = \dot{m}_c c_{p,c} = 70 \text{ kg/s} \times 4182 \text{ J/kg} \cdot \text{K} = 292,740 \text{ W/K}$$

$$q_{\max} = C_{\min} (T_h - T_{c,i}) = 292,740 \text{ W/K} (45.7 - 15) \text{ K} = 8.987 \times 10^6 \text{ W.}$$

$$q = q_h = 2.30 \times 10^6 \text{ W}$$

$$\frac{2.30 \times 10^6 \text{ W}}{8.987 \times 10^6 \text{ W}} = 0.256 = 1 - \exp\left(-\frac{UA}{292,740 \text{ W/K}}\right)$$

$$UA = 86,538 \text{ W/K.} \quad <$$

(b) In the fouled condition, U is reduced 10%, hence

$$U_f A = 0.9 UA = 77,884 \text{ W/K}$$

and

$$NTU_f = \frac{U_f A}{C_{\min}} = \frac{77,884 \text{ W/K}}{292,740 \text{ W/K}} = 0.266$$

$$\varepsilon_f = 1 - \exp(-NTU_f) = 1 - \exp(-0.266) = 0.234.$$

Continued ...

### PROBLEM 11.78 (Cont.)

If we operate the cycle at the same back pressure  $p_4 = 10 \text{ kPa}$  so that  $T_h = 45.7^\circ\text{C}$ , the heat removal rate must decrease,

$$q_h = \varepsilon q_{\max} = 0.234 \times 8.987 \times 10^6 \text{ W} = 2.103 \times 10^6 \text{ W}$$

since  $q_{\max} = C_{\min} (T_h - T_{c,i})$  remains the same. From the previous problem, we found the heat rejected as

$$h_4 - h_1 = (2007.5 - 191.83) \text{ kJ/kg} = 1815.7 \text{ kJ/kg}$$

and hence the cycle steam rate through the *fouled* condenser is

$$\dot{m}_{h,f} = q_h / (h_4 - h_1) = 2.103 \times 10^6 \text{ W} / 1815.7 \text{ kJ/kg} = 1.158 \text{ kg/s.}$$

For the *unfouled* condenser of part (a), the steam rate was

$$\dot{m}_h = 2.3 \text{ MW} / 1815.7 \text{ kJ/kg} = 1.267 \text{ kg/s.}$$

Hence, we see that fouling reduces the steam rate by 8.5% when  $U$  is decreased 10%. Since  $p_4$  remains the same, the thermal efficiency remains unchanged,

$$\eta = 30.3\%$$

<

as calculated in the previous problem. However, the net work of the cycle will decrease 8.5%.

**COMMENTS:** Fouling of the condenser heat exchanger has no effect on the thermal efficiency of the cycle since the back pressure at the condenser is maintained constant. The effect is, however, to reduce the heat rejection rate while maintaining exchanger flow rate and inlet temperature fixed. Comparing the conditions:

Parameter	Clean	Fouled	Change (%)
UA, W/K	86,538	77,884	-10.0
$\varepsilon$	0.256	0.234	-8.6
$q_h$ , MW	2.300	2.103	-8.6
$\dot{W}_{\text{net}}$	--	--	-8.6

## PROBLEM 11.79

**KNOWN:** Concentric tube heat exchanger with prescribed conditions.

**FIND:** (a) Maximum possible heat transfer, (b) Effectiveness, (c) Whether heat exchanger should be run in PF or CF to minimize size or weight; determine ratio of required areas for the two flow conditions.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat loss to surroundings, (2) Constant properties, (3) Overall heat transfer coefficient remains unchanged for PF or CF conditions.

**PROPERTIES:** Hot fluid (given):  $c = 2100 \text{ J/kg}\cdot\text{K}$ ; Cold fluid (given):  $c = 4200 \text{ J/kg}\cdot\text{K}$ .

**ANALYSIS:** (a) The maximum possible heat transfer rate is given by Eq. 11.18.

$$q_{\max} = C_{\min} (T_{h,i} - T_{c,o})$$

The minimum capacity fluid is the hot fluid with  $C_{\min} = \dot{m}_h c_h$ , giving

$$q_{\max} = \dot{m}_h c_h (T_{h,i} - T_{c,o}) = 0.125 \frac{\text{kg}}{\text{s}} \times 2100 \frac{\text{J}}{\text{kg}\cdot\text{K}} (210 - 40) \text{K} = 44,625 \text{ W} \quad <$$

(b) The effectiveness is defined by Eq. 11.19 and the heat rate,  $q$ , can be determined from an energy balance on the cold fluid.

$$\varepsilon = q / q_{\max} = \dot{m}_c c_c (T_{c,o} - T_{c,i}) / q_{\max}$$

$$\varepsilon = 0.125 \text{ kg/s} \times 4200 \text{ J/kg}\cdot\text{K} (95 - 40) \text{K} / 44,625 \text{ W} = 0.65 \quad <$$

(c) Operating the heat exchanger under CF conditions will require a smaller heat transfer area than for PF conditions. The ratio of the areas is

$$\frac{A_{\text{CF}}}{A_{\text{PF}}} = \frac{q / U \Delta T_{\ell m, \text{CF}}}{q / U \Delta T_{\ell m, \text{PF}}} = \frac{\Delta T_{\ell m, \text{PF}}}{\Delta T_{\ell m, \text{CF}}}$$

To calculate the LMTD, first find  $T_{h,o}$  from overall energy balances on the two fluids.

$$T_{h,o} = T_{h,i} - \frac{\dot{m}_c c_c}{\dot{m}_h c_h} (T_{c,o} - T_{c,i}) = 210^\circ\text{C} - \frac{0.125 \times 4200}{0.125 \times 2100} (95 - 40)^\circ\text{C} = 100^\circ\text{C}$$

Using Eq. 11.15 with  $\Delta T_1$  and  $\Delta T_2$  as shown below, find  $\Delta T_{\ell m} = (\Delta T_1 - \Delta T_2) / \ln(\Delta T_1 / \Delta T_2)$ .

Substituting values, find

$$\frac{A_{\text{CF}}}{A_{\text{PF}}} = \frac{[(210 - 40) - (100 - 95)] / \ln(170/5)}{[(210 - 95) - (100 - 40)] / \ln(115/60)} = \frac{46.8^\circ\text{C}}{84.5^\circ\text{C}} = 0.55 \quad <$$

**COMMENTS:** In solving part (c), it is also possible to use Figs. 11.11 and 11.12 to evaluate NTU values for corresponding  $\varepsilon$  and  $C_{\min}/C_{\max}$  values. With knowledge of NTU it is then possible to find  $A_{\text{CF}}/A_{\text{PF}}$ .

## PROBLEM 11.80

**KNOWN:** Inlet and outlet temperatures for a shell-and-tube heat exchanger with two shells, each with 10 tubes making eight passes. Heat transfer coefficient for oil flowing in shell. Mass flow rate of water in tubes. Tube diameter.

**FIND:** Is the required tube length sufficiently small to fit in an 8 m long facility, if the floor space must be at least 2.5 times the length of the heat exchanger?

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat loss to the surroundings, (2) Constant properties, (3) Negligible tube wall thermal resistance and fouling effects, (4) Fully developed water flow in tubes.

**PROPERTIES:** Table A.5, unused engine oil: ( $\bar{T}_h = 130^\circ\text{C}$ ):  $c_p = 2350 \text{ J/kg}\cdot\text{K}$ . Table A.6, water ( $\bar{T}_c = 50^\circ\text{C}$ ):  $c_p = 4181 \text{ J/kg}\cdot\text{K}$ ,  $\mu = 548 \times 10^{-6} \text{ N}\cdot\text{s/m}^2$ ,  $k = 0.643 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 3.56$ .

**ANALYSIS:** From the overall energy balance, Eq. 11.7b, the heat transfer required of the exchanger is

$$q = \dot{m}_c c_{p,c} (T_{c,o} - T_{c,i}) = 2.5 \text{ kg/s} \times 4181 \text{ J/kg}\cdot\text{K} (85 - 15)^\circ\text{C} = 7.317 \times 10^5 \text{ W}$$

Hence from Eq. 11.6b,

$$\dot{m}_h = \frac{q}{c_{p,h} (T_{h,i} - T_{h,o})} = \frac{7.317 \times 10^5 \text{ W}}{2350 \text{ J/kg}\cdot\text{K} (160 - 100)^\circ\text{C}} = 5.19 \text{ kg/s}$$

The required tube length may be obtained using the  $\epsilon$ -NTU method. We first calculate the heat capacity rates,  $C_h = \dot{m}_h c_{p,h} = 12,195 \text{ W/K}$ ,  $C_c = \dot{m}_c c_{p,c} = 10,453 \text{ W/K}$ . Thus,  $C_{\min} = C_c$ , and  $C_r = C_{\min}/C_{\max} = 0.857$ . Then from Eq. 11.21,

$$\epsilon = \frac{T_{c,o} - T_{c,i}}{T_{h,i} - T_{c,i}} = \frac{(85 - 15)^\circ\text{C}}{(160 - 15)^\circ\text{C}} = 0.483$$

Using Eqs. 11.31c, 11.31b, 11.30c, 11.30b, and 11.31d, in that order, we find,  $F = 1.06$ ,  $\epsilon_1 = 0.311$ ,

Continued...

**PROBLEM 11.80 (Cont.)**

$$E = \frac{2/\varepsilon_1 - (1 + C_r)}{(1 + C_r^2)^{1/2}} = \frac{2/0.311 - (1 + 0.857)}{(1 + 0.857^2)^{1/2}} = 3.47$$

$$(\text{NTU})_1 = -(1 + C_r^2)^{-1/2} \ln\left(\frac{E - 1}{E + 1}\right) = -(1 + 0.857^2)^{-1/2} \ln\left(\frac{3.47 - 1}{3.47 + 1}\right) = 0.451$$

$$\text{NTU} = n(\text{NTU})_1 = 2 \times 0.451 = 0.901$$

Thus  $UA = \text{NTU} \times C_{\min} = 9420 \text{ W/K}$ . To find the required tube length, we must know the heat transfer coefficient for the water flow. We calculate the Reynolds number from Eq. 8.6, with the water flow rate per tube as  $\dot{m}_1 = \dot{m}_c / N = 0.25 \text{ kg/s}$ ,

$$\text{Re}_D = \frac{4\dot{m}_1}{\pi D \mu_c} = \frac{4 \times 0.25 \text{ kg/s}}{\pi(0.025 \text{ m})548 \times 10^{-6} \text{ N} \cdot \text{s/m}^2} = 23,234$$

Hence the flow is turbulent, and from Eq. 8.60,

$$\text{Nu}_D = 0.023 \text{Re}_D^{4/5} \text{Pr}^{0.4} = 0.023(23,234)^{4/5} (3.56)^{0.4} = 119$$

and

$$h_c = \frac{k_c}{D} \text{Nu}_D = \frac{0.643 \text{ W/m} \cdot \text{K}}{0.025 \text{ m}} 119 = 3060 \text{ W/m}^2 \cdot \text{K}$$

Hence  $U = [1/h_c + 1/h_h]^{-1} = 354 \text{ W/m}^2 \cdot \text{K}$  and we can find the required tube length from

$$L = \frac{UA}{UN\pi D} = \frac{9420 \text{ W/K}}{354 \text{ W/m}^2 \cdot \text{K} \times 10 \times \pi \times 0.025 \text{ m}} = 33.9 \text{ m}$$

This is the total tube length for all ten tubes in both shells, therefore the length of the heat exchanger shell must be

$$L_{\text{shell}} = L/(8 \times 2) = 2.12 \text{ m}$$

Therefore the room would have to be  $2.12 \text{ m} \times 2.5 = 5.3 \text{ m}$ .

Yes, the floorspace of 8 m is sufficiently long to service the heat exchanger. <

**COMMENTS:** (1) With  $L/D = 33.9/0.025 = 1356$ , the assumption of fully developed conditions throughout the tube is justified. (2) The floor-to-ceiling height must be sufficiently large to stack one shell above the other.

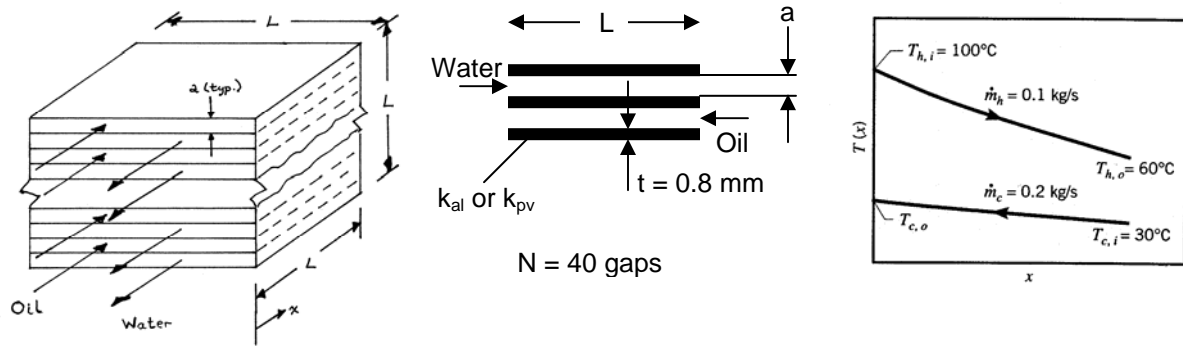

## PROBLEM 11.81

**KNOWN:** Configuration of a cubical plate-type heat exchanger with 40 gaps. Fluid flow rates, inlet temperatures, and desired oil outlet temperature.

**FIND:** (a) Core dimension,  $L$ , of the heat exchanger, when the sheet thickness is 0.8 mm, for aluminum and PVDF sheets. (b) Plot core dimension as a function of sheet thickness for aluminum and PVDF over the range  $0 \leq t \leq 1$  mm.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat loss to the surroundings, (2) Constant properties, (3) Negligible fouling factors, (4) Laminar, fully developed conditions for the water and oil, (5) Identical gap-to-gap heat transfer coefficients. (6) Heat exchanger exterior dimension is large compared to the gap width.

**PROPERTIES:** Table A.6, water ( $\bar{T}_c \approx 35^\circ\text{C}$ ):  $\mu = 725 \times 10^{-6} \text{ N}\cdot\text{s}/\text{m}^2$ ,  $k = 0.625 \text{ W}/\text{m}\cdot\text{K}$ .  
 Table A.5, unused engine oil ( $\bar{T}_h = 353 \text{ K}$ ):  $\mu = 3.25 \times 10^{-2} \text{ N}\cdot\text{s}/\text{m}^2$ ,  $k = 0.138 \text{ W}/\text{m}\cdot\text{K}$ . Aluminum (given):  $k_{al} = 237 \text{ W}/\text{m}\cdot\text{K}$ . PVDF (given):  $k_{pv} = 0.17 \text{ W}/\text{m}\cdot\text{K}$ .

**ANALYSIS:** (a) From Example 11.2, assuming the flow is still laminar,

$$h_c = 7.54k/D_h = 7.54k/2a, \quad h_c a = 7.54 \times 0.625 \text{ W}/\text{m}\cdot\text{K} / 2 = 2.36 \text{ W}/\text{m}\cdot\text{K} \quad (1a)$$

$$h_h = 7.54k/D_h = 7.54k/2a, \quad h_h a = 7.54 \times 0.138 \text{ W}/\text{m}\cdot\text{K} / 2 = 0.520 \text{ W}/\text{m}\cdot\text{K} \quad (1b)$$

and the overall convection coefficient, including the wall thermal resistance, is given by

$$U^{-1} = 1/h_c + t/k_w + 1/h_h = a/(h_c a) + t/k_w + a/(h_h a) \quad (2)$$

where  $(h_c a)$  and  $(h_h a)$  are constants given by Eq. (1). In addition, from Example 11.1, the required log mean temperature difference and heat transfer rate are  $\Delta T_{lm} = 43.2^\circ\text{C}$  and  $q = 8524 \text{ W}$ , respectively. Thus with  $A = (N-1)L^2$ , we have

$$U^{-1} = \frac{A \Delta T_{lm}}{q} = \frac{39 \times 43.2^\circ\text{C} \times L^2}{8524 \text{ W}} = 0.198 \text{ K}/\text{W} L^2 \quad (3)$$

Continued...

### PROBLEM 11.81 (Cont.)

The core dimension,  $L$ , is related to the gap dimension,  $a$ , and sheet thickness,  $t$ , (neglecting the exterior plates) by the expression

$$L = Na + (N-1)t \quad (4)$$

Thus, Eq. (3) becomes

$$U^{-1} = 0.198 \text{ K/W} [Na + (N-1)t]^2 \quad (5)$$

Equating Eqs. (2) and (5), we can solve the resulting quadratic equation for  $a$ ,

$$a/(h_c a) + t/k_w + a/(h_h a) = 0.198 \text{ K/W} [Na + (N-1)t]^2$$

$$Aa^2 + Ba + C = 0, \quad a = \frac{-B \pm \sqrt{B^2 - 4AC}}{2A}$$

where

$$A = 0.198 \text{ K/W} N^2 = 0.198 \text{ K/W} \times 40^2 = 316 \text{ K/W}$$

$$B = 2(0.198 \text{ K/W})N(N-1)t - \frac{1}{h_c a} - \frac{1}{h_h a}$$

$$= 0.395 \text{ K/W} \times 40 \times 39 \times 0.0008 \text{ m} - \frac{1}{2.36 \text{ W/m} \cdot \text{K}} - \frac{1}{0.520 \text{ W/m} \cdot \text{K}} = -1.85 \text{ m} \cdot \text{K/W}$$

$$C = (0.198 \text{ W/K})(N-1)^2 t^2 - \frac{t}{k_w}$$

$$= (0.198 \text{ K/W})39^2(0.0008 \text{ m})^2 - \frac{0.0008 \text{ m}}{237 \text{ W/m} \cdot \text{K}} = 1.89 \times 10^{-4} \text{ m}^2 \cdot \text{K/W}$$

We have used  $k_w = k_{al}$  in evaluating  $C$ . Thus

$$a = \frac{-B \pm \sqrt{B^2 - 4AC}}{2A} = \frac{1.85 \pm \sqrt{1.85^2 - 4 \times 316 \times 1.89 \times 10^{-4}}}{2 \times 316} \text{ m}$$

$$= 1.04 \times 10^{-4} \text{ m or } 0.0058 \text{ m}$$

See the Comments for a discussion of the two different solutions. Hence from Eq. (4), when the sheets are aluminum,

$$L_{al} = \begin{cases} 0.0354 \text{ m} \\ 0.261 \text{ m} \end{cases} \quad <$$

Continued...

### PROBLEM 11.81 (Cont.)

Repeating the calculations for PVDF, we find only one (positive) solution,  $a = 0.00771$  m, for which

$$L_{pv} = 0.340 \text{ m}$$

(b) The calculations were keyed into the *IHT* workspace and solved for  $0 \leq t \leq 1$  mm. The solution is shown below for aluminum and PVDF sheets.

**COMMENTS:** (1) We can check the Reynolds number to see if the flow is truly laminar. The largest Reynolds number would be for water, since it is less viscous and has a higher flow rate. Thus  $Re = 4\dot{m}_1 / \mu P \approx 4\dot{m} / (N/2) / 2\mu L$ . For the smaller value of  $L$ ,  $Re = 779$ . Hence the flow is laminar for both oil and water. (2) As expected, utilization of PVDF results in a larger heat exchanger due to its lower thermal conductivity. (3) For aluminum sheets, there are two solutions. The very small spacing gives rise to high heat transfer coefficients that enable a small heat exchange area. The larger spacing corresponds to smaller heat transfer coefficients that require a larger heat exchange area. For PVDF, the thermal resistance of the sheets is larger and it is impossible to increase the value of  $U$  sufficiently to enable the smaller channel solution. (4) Manufacturing of the smaller channels would pose a challenge, and the pressure drop could be prohibitively large. Fouling could also be more of a problem in the smaller channels. (5) If the heat exchanger didn't have to be cubical, there could be solutions with superior properties with respect to pressure drop and manufacturing constraints.

## PROBLEM 11.82

**KNOWN:** Shell and tube heat exchanger for cooling exhaust gases with water.

**FIND:** Required surface area using  $\epsilon$ -NTU method.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat loss to surroundings, (2) Constant properties, (3) Gases have properties of air.

**PROPERTIES:** Table A-6, Water, liquid ( $\bar{T}_c = (85 + 35)^\circ\text{C}/2 = 333\text{ K}$ ):  $c_p = 4185\text{ J/kg}\cdot\text{K}$ .

**ANALYSIS:** Using the  $\epsilon$ -NTU method, the area can be expressed as

$$A = \text{NTU} \cdot C_{\min} / U \quad (1)$$

where NTU must be found from knowledge of  $\epsilon$  and  $C_{\min}/C_{\max} = C_r$ . The capacity rates are:

$$C_c = \dot{m}_c c_{p,c} = 2.5\text{ kg/s} \times 4185\text{ J/kg}\cdot\text{K} = 10,463\text{ W/K}$$

Equating the energy balance relation for each fluid,

$$C_h = C_c (T_{c,o} - T_{c,i}) / (T_{h,i} - T_{h,o}) = 10,463\text{ W/K} (85 - 35) / (200 - 93) = 4889\text{ W/K}.$$

Hence,

$$C_r = C_{\min} / C_{\max} = C_h / C_c = 4889 / 10,463 = 0.467.$$

The effectiveness of the exchanger, with  $q_{\max} = C_{\min} (T_{h,i} - T_{c,i})$  and  $C_{\min} = C_h$ , is

$$\epsilon = q / q_{\max} = C_h (T_{h,i} - T_{h,o}) / C_h (T_{h,i} - T_{c,i}) = (200 - 93) / (200 - 35) = 0.648.$$

Considering the HXer to be a single shell with 2,4,...tube passes, Eqs. 11.30b,c are appropriate to evaluate NTU.

$$\text{NTU} = -\left(1 + C_r^2\right)^{-1/2} \ln \frac{E - 1}{E + 1} \quad E = \frac{2/\epsilon - (1 + C_r)}{\left(1 + C_r^2\right)^{1/2}}.$$

Substituting numerical values,

$$E = \frac{2/0.648 - (1 + 0.467)}{\left(1 + 0.467^2\right)^{1/2}} = 1.467 \quad \text{NTU} = -\left(1 + (0.467)^2\right)^{-1/2} \ln \frac{1.467 - 1}{1.467 + 1} = 1.51.$$

Using the appropriate numerical values in Eq. (1), the required area is

$$A = 1.51 \times 4889\text{ W/K} / 180\text{ W/m}^2 \cdot \text{K} = 40.9\text{ m}^2. \quad \leftarrow$$

**COMMENTS:** Figure 11.12 could also have been used with  $C_r$  and  $\epsilon$  to find NTU.

### PROBLEM 11.83

**KNOWN:** Dimensions, fluid flow rates, and fluid temperatures for a counterflow heat exchanger used to heat blood.

**FIND:** (a) Outlet temperature of the blood, (b) Effect of water flowrate and inlet temperature on heat rate and blood outlet temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat loss to surroundings, (2) Constant properties.

**PROPERTIES:** Table A.6, Water ( $\bar{T}_m \approx 55^\circ\text{C}$ ):  $c_p = 4183 \text{ J/kg}\cdot\text{K}$ .

**ANALYSIS:** (a) Using the  $\varepsilon$  - NTU method, we first obtain  $C_h = (\dot{m}_h c_{p,h}) = (0.10 \text{ kg/s} \times 4183 \text{ J/kg}\cdot\text{K}) = 418.3 \text{ W/K}$  and  $C_c = (\dot{m}_c c_{p,c}) = (0.05 \text{ kg/s} \times 3500 \text{ J/kg}\cdot\text{K}) = 175 \text{ W/K} = C_{\min}$ . Hence,  $(C_{\min}/C_{\max}) = 0.418$  and

$$\text{NTU} = \frac{UA}{C_{\min}} = \frac{(500 \text{ W/m}^2\cdot\text{K})\pi(0.055 \text{ m})(0.5 \text{ m})}{175 \text{ W/K}} = 0.247.$$

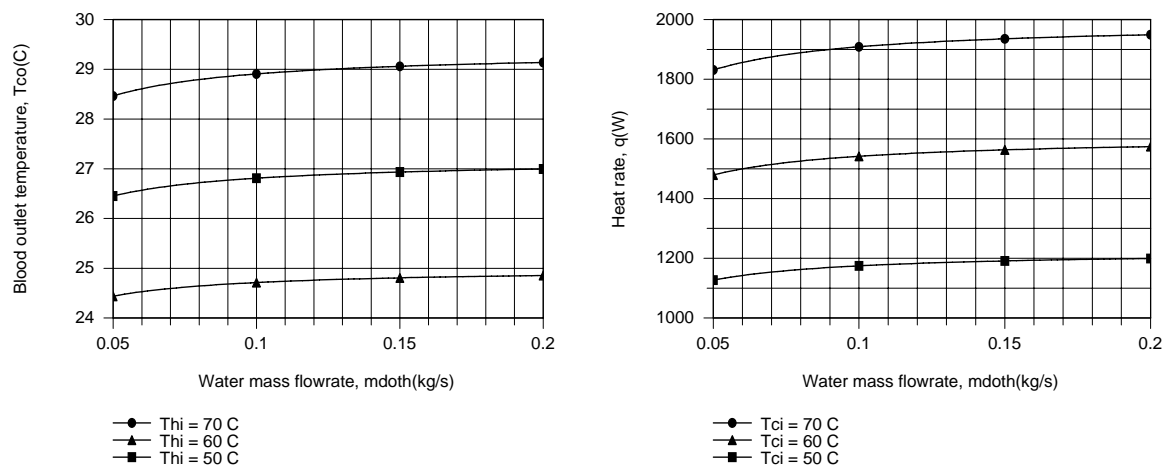

From Eq. 11.29a,  $\varepsilon = 0.21$ . Hence, from Eq. 11.22

$$q = \varepsilon C_{\min} (T_{h,i} - T_{c,i}) = 0.21(175 \text{ W/K})(60 - 18)^\circ\text{C} = 1544 \text{ W}.$$

From Eq. 11.7,

$$T_{c,o} = T_{c,i} + \frac{q}{C_c} = 18^\circ\text{C} + \frac{1544 \text{ W}}{175 \text{ W/K}} = 26.8^\circ\text{C}$$

(b) Because the variation of  $C_{\min}/C_{\max}$  with  $\dot{m}_h$  does not have a significant effect on  $\varepsilon$  for the prescribed NTU,  $T_{c,o}$  and  $q$  increase only slightly with increasing  $\dot{m}_h$ .

However, the water inlet temperature does have a significant effect, and accelerated heating is achieved with  $T_{h,i} = 70^\circ\text{C}$ .

**COMMENTS:** With  $\dot{m}_h = 0.2 \text{ kg/s}$  and  $T_{h,i} = 70^\circ\text{C}$ , the outlet temperature of the blood is still below the desired level of  $T_{c,o} \approx 37^\circ\text{C}$ . This value of  $T_{c,o}$  could be increased by increasing  $L$  or  $T_{h,i}$ .

## PROBLEM 11.84

**KNOWN:** Inlet temperatures and flow rates of water (c) and ethylene glycol (h) in a shell-and-tube heat exchanger (one shell pass and two tube passes) of prescribed area and overall heat transfer coefficient.

**FIND:** (a) Heat transfer rate and fluid outlet temperatures and (b) Compute and plot the effectiveness,  $\epsilon$ , and fluid outlet temperatures,  $T_{c,o}$  and  $T_{h,o}$  as a function of the flow rate of ethylene glycol,  $\dot{m}_h$ , for the range  $0.5 \leq \dot{m}_h \leq 5 \text{ kg/s}$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat loss to surroundings, (2) Constant properties, and (3) Overall coefficient remains unchanged.

**PROPERTIES:** Table A-5, Ethylene glycol ( $\bar{T}_m \approx 40^\circ\text{C}$ ):  $c_p = 2474 \text{ J/kg}\cdot\text{K}$ ; Table A-6, Water ( $\bar{T}_m \approx 15^\circ\text{C}$ ):  $c_p = 4186 \text{ J/kg}\cdot\text{K}$ .

**ANALYSIS:** (a) Using the  $\epsilon$ -NTU method we first obtain

$$C_h = (\dot{m}_h c_{p,h}) = (2 \text{ kg/s} \times 2474 \text{ J/kg}\cdot\text{K}) = 4948 \text{ W/K}$$

$$C_c = (\dot{m}_c c_{p,c}) = (5 \text{ kg/s} \times 4186 \text{ J/kg}\cdot\text{K}) = 20,930 \text{ W/K}.$$

Hence with  $C_{\min} = C_h = 4948 \text{ W/K}$  and  $C_r = C_{\min}/C_{\max} = 0.236$ ,

$$\text{NTU} = \frac{UA}{C_{\min}} = \frac{(800 \text{ W/m}^2 \cdot \text{K})15 \text{ m}^2}{4948 \text{ W/K}} = 2.43.$$

From Fig. 11.12,  $\epsilon = 0.81$  and from Eq. 11.22

$$q = \epsilon C_{\min} (T_{h,i} - T_{c,i}) = 0.81(4948 \text{ W/K})(60 - 10) \text{ K} = 2 \times 10^5 \text{ W}.$$

From Eqs. 11.6 and 11.7, energy balances on the fluids,

$$T_{h,o} = T_{h,i} - \frac{q}{C_h} = 60^\circ\text{C} - \frac{2 \times 10^5 \text{ W}}{4948 \text{ W/K}} = 19.6^\circ\text{C}$$

$$T_{c,o} = T_{c,i} + \frac{q}{C_c} = 10^\circ\text{C} + \frac{2 \times 10^5 \text{ W}}{20,930 \text{ W/K}} = 19.6^\circ\text{C}.$$

(b) Using the *IHT Heat Exchanger Tool, Shell and Tube*, and the *Properties Tool* for Water and Ethylene Glycol,  $T_{c,o}$ ,  $T_{h,o}$ , and  $\epsilon$  as a function of  $\dot{m}_h$  were computed and plotted.

At very low  $C_{\min}$ , (low  $\dot{m}_h$ ) note that  $\epsilon \rightarrow 1$  while  $T_{h,o} \rightarrow T_{c,i}$ . As  $\dot{m}_h$  increases, both fluid outlet temperatures increase and the effectiveness decreases.

### PROBLEM 11.85

**KNOWN:** Flow rate, specific heat and inlet temperature of gas in cross-flow heat exchanger. Flow rate and temperature of water which enters as saturated liquid and leaves as saturated vapor. Number of tubes, tube diameter and overall heat transfer coefficient.

**FIND:** Required tube length.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat loss to surroundings, (2) Constant gas specific heat.

**PROPERTIES:** Table A-6, Saturated Water, ( $T = 450 \text{ K}$ ):  $h_{fg} = 2.024 \times 10^6 \text{ J/kg}$ .

**ANALYSIS:** Use effectiveness-NTU method

$$\varepsilon = \frac{q}{q_{\max}} = \frac{q}{C_{\min}(T_{h,i} - T_{c,i})} = \frac{q}{\dot{m}_h c_{p,h}(T_{h,i} - T_{c,i})}$$

$$q = \dot{m}_c h_{fg} = 3 \text{ kg/s} \times 2.024 \times 10^6 \text{ J/kg} = 6.072 \times 10^6 \text{ W}$$

$$\varepsilon = \frac{6.072 \times 10^6 \text{ W}}{10 \text{ kg/s} \times 1120 \text{ J/kg} \cdot \text{K} (1400 - 450) \text{ K}} = 0.571 \quad C_{\min} / C_{\max} = 0.$$

From Fig. 11.15, find

$$NTU \approx 0.8 \approx U_o N \pi D_o L / C_{\min}$$

$$L \approx \frac{0.8 \times 10 \text{ kg/s} \times 1120 \text{ J/kg} \cdot \text{K}}{50 \text{ W/m}^2 \cdot \text{K} \times 500 \pi \times 0.025 \text{ m}} = 4.56 \text{ m.} \quad <$$

**COMMENTS:** The gas outlet temperature is

$$T_{h,o} = T_{h,i} - q / \dot{m}_h c_{p,h} = 1400 \text{ K} - 6.072 \times 10^6 \text{ W} / 10 \text{ kg/s} \times 1120 \text{ J/kg} \cdot \text{K} = 857.9 \text{ K.}$$

## PROBLEM 11.86

**KNOWN:** Gas flow conditions upstream of a tube bank of prescribed geometry. Flow rate and inlet temperature of water passing through the tubes.

**FIND:** (a) Overall heat transfer coefficient, (b) Water and gas outlet temperatures, (c) Effect of water flow rate on heat recovery and outlet temperatures.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Constant properties, (3) Negligible heat loss to the surroundings, (3) Negligible tube fouling and wall thermal resistance, (4) Fully developed water flow, (5) Gas properties are those of air.

**PROPERTIES:** Table A.6, Water (Assume  $\bar{T}_m \approx 340$  K):  $c_p = 4188$  J/kg·K,  $\mu = 420 \times 10^{-6}$  N·s/m<sup>2</sup>,  $k = 0.660$  W/m·K,  $Pr = 2.66$ ; Table A.4, Air (Assume  $\bar{T}_m \approx 600$  K):  $c_p = 1051$  J/kg·K,  $\nu = 52.7 \times 10^{-6}$  m<sup>2</sup>/s,  $k = 0.047$  W/m·K,  $Pr = 0.69$ .

**ANALYSIS:** (a) For the prescribed conditions,  $U = (1/h_i + 1/h_o)^{-1}$ . For the *internal* flow, with  $\dot{m}_{c,1} = 0.025$  kg/s,

$$Re_D = \frac{4\dot{m}_{c,1}}{\pi D \mu} = \frac{4 \times 0.025 \text{ kg/s}}{\pi (0.025 \text{ m}) 420 \times 10^{-6} \text{ N}\cdot\text{s/m}^2} = 3032.$$

Hence, from the Gnielinski correlation,

$$Nu_D = \frac{(f/8)(Re_D - 1000)Pr}{1 + 12.7(f/8)^{1/2}(Pr^{2/3} - 1)} = \frac{(0.0454/8)(3032 - 1000)2.66}{1 + 12.7(0.0454/8)^{1/2}(2.66^{2/3} - 1)} = 16.3$$

where  $f = (0.79 \ln Re_D - 1.64)^{-2} = 0.0454$

$$h_i = \frac{k}{D} Nu_D = \frac{0.660 \text{ W/m}\cdot\text{K}}{0.025 \text{ m}} 16.3 = 431 \text{ W/m}^2 \cdot \text{K}.$$

For the external flow,  $V_{\max} = \frac{0.05 \text{ m}}{(0.05 - 0.025) \text{ m}} 5.0 \text{ m/s} = 10.0 \text{ m/s}$ . Hence

$$Re_{D,\max} = \frac{V_{\max} D}{\nu} = \frac{10 \text{ m/s} \times 0.025}{52.7 \times 10^{-6} \text{ m}^2/\text{s}} = 4744$$

From the Zukauskas correlation and Tables 7.5 and 7.6,  $\overline{Nu}_D = (0.97) 0.27 Re_{D,\max}^{0.63} Pr^{0.36} (Pr/Pr_s)^{1/4}$ .

Neglecting the Prandtl number ratio,

$$\overline{Nu}_D = (0.97) 0.27 (4744)^{0.63} (0.69)^{0.36} = 47.4$$

$$\overline{h}_o = \frac{k}{D} \overline{Nu}_D = \frac{0.047 \text{ W/m}\cdot\text{K}}{0.025 \text{ m}} 47.4 = 89.1 \text{ W/m}^2 \cdot \text{K}.$$

Continued...

### PROBLEM 11.86 (Cont.)

Hence,  $U = (1/431 + 1/89.1)^{-1} = 73.9 \text{ W/m}^2\cdot\text{K}$ . <

(b) The fluid outlet temperatures may be determined from the  $\epsilon$ -NTU method. With  $\dot{m}_c = 2.5 \text{ kg/s}$ ,  $C_c = \dot{m}_c c_{p,c} = 2.5 \text{ kg/s} \times 4188 \text{ J/kg}\cdot\text{K} = 10,470 \text{ W/K}$ . With  $C_h = \dot{m}_h c_{p,h} = 2.25 \text{ kg/s} \times 1051 \text{ J/kg}\cdot\text{K} = 2365 \text{ W/K}$ ,  $C_{\min}/C_{\max} = C_{\text{mixed}}/C_{\text{unmixed}} = 2365/10,470 = 0.23$ . Hence, with  $A = N\pi DL = 100\pi \times 0.025 \text{ m} \times 4 \text{ m} = 31.4 \text{ m}^2$ ,

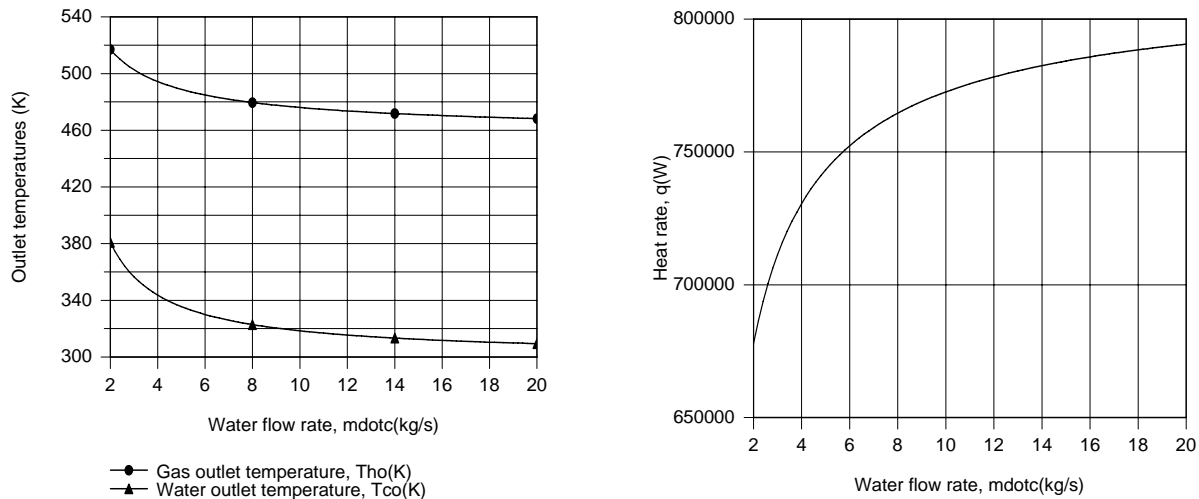

$$\text{NTU} = \frac{UA}{C_{\min}} = \frac{73.9 \text{ W/m}^2\cdot\text{K} (31.4 \text{ m}^2)}{2365 \text{ W/K}} = 0.98$$

From Fig. 11.15,  $\epsilon \approx 0.61$ . From Eq. 11.18,  $q_{\max} = C_{\min}(T_{h,i} - T_{c,i}) = 2365 \text{ W/K}(800 - 300)\text{K} = 1.18 \times 10^6 \text{ W}$ . Hence,  $q = \epsilon q_{\max} = 0.72 \times 10^6 \text{ W}$ . From Eq. 11.6b,

$$(T_{h,i} - T_{h,o}) = \frac{q}{C_h} = \frac{0.72 \times 10^6 \text{ W}}{2365 \text{ W/K}} = 304 \text{ K} \quad T_{h,o} = 496 \text{ K} \quad <$$

From Eq. 11.7b,  $(T_{c,o} - T_{c,i}) = \frac{q}{C_c} = \frac{0.72 \times 10^6 \text{ W}}{10,470 \text{ W/K}} = 69 \text{ K} \quad T_{c,o} = 369 \text{ K} \quad <$

(c) Using the appropriate *Heat Exchangers, Correlations and Properties* Toolpads of IHT, the following results were obtained.

With increasing  $\dot{m}_c$  (and  $\dot{m}_{c,1}$ ),  $h_i$  increases, thereby increasing  $U$  and  $q$ . However, because the total resistance is dominated by the gas-side condition,  $\dot{m}_c = 20 \text{ kg/s}$  only yields  $U = 83.9 \text{ W/m}^2\cdot\text{K}$ , despite the fact that  $h_i = 2180 \text{ W/m}^2\cdot\text{K}$ . Because the extent to which  $q$  increases with increasing  $\dot{m}_c$  is much smaller than the increase in  $\dot{m}_c$  itself,  $T_{c,o}$  decreases with increasing  $\dot{m}_c$ . Hence, there is a trade-off between the amount of hot water and the temperature at which it is delivered. If, for example, the temperature must exceed  $50^\circ\text{C}$  ( $T_{c,o} > 323 \text{ K}$ ),  $\dot{m}_c$  cannot exceed  $8 \text{ kg/s}$ . To maintain an acceptable value of  $T_{c,o}$ , while increasing  $\dot{m}_c$ ,  $\dot{m}_h$  (and  $V$ ) should be increased, thereby increasing  $h_o$ , and hence  $U$  and  $q$ .

**COMMENTS:** If the air and water property functions of IHT are used to evaluate properties at appropriate mean values of the inlet and outlet fluid temperatures and Eq. 11.34a is used to evaluate  $\epsilon$ , the following, more accurate, results would be obtained for Parts (a) and (b):  $\epsilon = 0.565$ ,  $q = 0.677 \times 10^6 \text{ W}$ ,  $T_{c,o} = 364.6 \text{ K}$ ,  $T_{h,o} = 517.5 \text{ K}$ ,  $h_i = 383 \text{ W/m}^2\cdot\text{K}$ ,  $h_o = 86.3 \text{ W/m}^2\cdot\text{K}$  and  $U = 70.5 \text{ W/m}^2\cdot\text{K}$ .

### PROBLEM 11.87

**KNOWN:** Tube arrangement in steam-to-air, cross-flow heat exchanger. Flow rate  $\dot{m}_c$  and inlet temperature of air. Condensing temperature of steam.

**FIND:** (a) Air outlet temperature for  $\dot{m}_c = 12 \text{ kg/s}$ , (b) Effect of  $\dot{m}_c$  on air outlet temperature, heat rate and condensation rate.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat loss to surroundings, (2) Negligible steam side convection and tube wall conduction resistance, (3) Mean air temperature is 350 K.

**PROPERTIES:** Table A.4, Air (Assume  $\bar{T}_c \equiv (T_{c,i} + T_{c,o})/2 \approx 350 \text{ K}$ , 1 atm):  $\rho = 0.995 \text{ kg/m}^3$ ,  $c_p = 1009 \text{ J/kg}\cdot\text{K}$ ,  $\nu = 20.92 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.030 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.700$ ;  $T_s = 400 \text{ K}$ :  $\text{Pr} = 0.690$ .

**ANALYSIS:** (a) For a single-pass, cross-flow heat exchanger with one fluid mixed and the other unmixed, Fig. 11.15 can be used to obtain  $\epsilon$ , where  $C_{\min}/C_{\max} = C_{\text{mixed}}/C_{\text{unmixed}} = 0$  and  $\text{NTU} = UA/C_{\min} = U(\pi DL)N/\dot{m}_c c_p$ . From Eq. 11.5,  $U = \bar{h}_o$ , and the Zukauskas correlation may be used to estimate  $\bar{h}_o$ .

The upstream velocity may be obtained from  $\dot{m}_c = \rho VA \approx \rho V N_T L S_T$ . Hence,

$$V = \frac{\dot{m}_c}{\rho N_T L S_T} = \frac{12 \text{ kg/s}}{0.995 \text{ kg/m}^3 \times 30 \times 2 \text{ m} \times 0.14 \text{ m}} = 1.44 \text{ m/s}.$$

For aligned tubes,

$$V_{\max} = \frac{S_T}{S_T - D} V = \frac{0.14 \text{ m}}{(0.14 - 0.07) \text{ m}} 1.44 \text{ m/s} = 2.88 \text{ m/s}$$

$$\text{Re}_{D,\max} = \frac{V_{\max} D}{\nu} = \frac{2.88 \text{ m/s} \times 0.07 \text{ m}}{20.92 \times 10^{-6} \text{ m}^2/\text{s}} = 9637.$$

From Table 7.5, select values of  $C = 0.27$  and  $m = 0.63$ . Hence,

$$\overline{\text{Nu}}_D = 0.27 \text{Re}_{D,\max}^{0.63} \text{Pr}^{0.36} (\text{Pr}/\text{Pr}_s)^{0.25}$$

$$\overline{\text{Nu}}_D = 0.27 (9637)^{0.63} (0.70)^{0.36} (0.70/0.69)^{0.25} = 77.1$$

$$\bar{h}_o = \overline{\text{Nu}}_D \frac{k}{D} = 77.1 \frac{0.030 \text{ W/m}\cdot\text{K}}{0.07 \text{ m}} = 33.0 \text{ W/m}^2\cdot\text{K}.$$

Hence,

$$\text{NTU} = \frac{\bar{h}_o \pi D L N}{\dot{m}_c c_p} = \frac{33.0 \text{ W/m}^2\cdot\text{K} \times \pi (0.07 \text{ m}) 2 \text{ m} (1200)}{12 \text{ kg/s} \times 1009 \text{ J/kg}\cdot\text{K}} = 1.44.$$

From Fig. 11.15, find  $\epsilon \approx 0.77$  and then determine

Continued...

**PROBLEM 11.87 (Cont.)**

$$\varepsilon = \frac{q}{q_{\max}} = \frac{\dot{m}_c c_{p,c} (T_{c,o} - T_{c,i})}{\dot{m}_c c_{p,c} (T_s - T_{c,i})} = \frac{T_{c,o} - T_{c,i}}{T_s - T_{c,i}}$$

$$T_{c,o} = T_{c,i} + \varepsilon (T_s - T_{c,i}) = 300 \text{ K} + 0.77 (400 - 300) \text{ K} = 377 \text{ K} = 104^\circ \text{ C}$$

<

(b) With  $q = \varepsilon q_{\max} = \varepsilon C_c (T_s - T_{c,i})$  and the condensation rate given by Eqs. 10.34 and 10.27,

$$\dot{m}_{cd} = \frac{q}{h'_{fg}} \approx \frac{q}{h_{fg}}$$

the foregoing model may be used with the Heat Exchangers, Correlations and Properties Toolpads of IHT to determine the effect of  $\dot{m}_c$  on  $T_{c,o}$ ,  $q$  and  $\dot{m}_{cd}$ .

Since  $\bar{h}_o$  increases with increasing  $\dot{m}_c$ ,  $q$  must also increase. However, since the increase in  $q$  is proportionally less than the increase in  $\dot{m}_c$ ,  $T_{c,o}$  decreases with increasing  $\dot{m}_c$ .

The condensation rate increases proportionally with the increase in  $q$ , and if the objective is to maximize the condensation rate, the largest value of  $\dot{m}_c$  should be maintained.

**COMMENTS:** If the objective is to heat the air, there is obviously a trade-off between maintaining elevated values of the flow rate and outlet temperature.

## PROBLEM 11.88

**KNOWN:** Steel balls cooled in an oil bath.

**FIND:** Derivation of the expression for the modified effectiveness of Comment 4 of Example 11.8.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Spatially uniform bath and ball temperature at any instant, (2) Constant properties, (3) Negligible heat losses from bath.

**ANALYSIS:** From Comment 4 of Example 11.8,

$$\Delta E_{\max} = C_{t,\min}(T_{h,i} - T_{c,i}) \quad ; \quad \varepsilon^* = \frac{\Delta E}{\Delta E_{\max}} \quad ; \quad \text{NTU}^* = \frac{UA\Delta t}{C_{t,\min}} \quad (1, 2, 3)$$

Combining Eqs. (1) and (2) yields

$$\Delta E = \varepsilon^* C_{t,\min}(T_{h,i} - T_{c,i}) \quad (4)$$

Assuming  $C_{t,\min} = C_{t,h}$ , it follows that  $\varepsilon^* = \frac{T_{h,i} - T_{h,f}}{T_{h,i} - T_{c,i}}$  (5)

and therefore,

$$\frac{C_{t,\min}}{C_{t,\max}} = \frac{m_h c_h}{m_c c_c} = \frac{T_{c,f} - T_{c,i}}{T_{h,i} - T_{h,f}} \quad (6)$$

Note that Eqs. (1) through (6) are analogous to Eqs. 11.18, 11.19, 11.24, 11.22, 11.25 and 11.26 in the text.

From Comment 3 of Example 11.8,

$$\ln\left(\frac{\Delta T_2}{\Delta T_1}\right) = \ln\left(\frac{T_{h,f} - T_{c,f}}{T_{h,i} - T_{c,i}}\right) = -UA\left(\frac{1}{C_{t,h}} + \frac{1}{C_{t,c}}\right)\Delta t = -\text{NTU}^* \left(1 + \frac{C_{t,\min}}{C_{t,\max}}\right)$$

Continued...

### Problem 11.88 (Cont.)

or

$$\frac{T_{h,f} - T_{c,f}}{T_{h,i} - T_{c,i}} = \exp \left[ -NTU * \left( 1 + \frac{C_{t,\min}}{C_{t,\max}} \right) \right] \quad (7)$$

Equation (7) is identical in form to Eq. 11.27 in the text.

Noting the analogy between Eqs.(1) through (7) with the equations in the text, we may proceed in a manner identical to that of the text, after Equation 11.27, obtaining

$$\epsilon^* = \frac{1 - \exp[-NTU * (1 + C_{t,r})]}{1 + C_{t,r}} \quad <$$

**COMMENTS:** The derivation is straightforward, once the analogy between the parallel-flow concentric tube heat exchanger analysis is recognized.

## PROBLEM 11.89

**KNOWN:** Dimensions and maximum allowable temperature of an electronic chip. Thermal contact resistance between chip and heat sink. Dimensions and thermal conductivity of heat sink. Inlet temperature and convection coefficient associated with air flow through the heat sink.

**FIND:** (a) Inlet air velocity using an appropriate correlation from Chapter 8, (b) Chip power,  $q_c$  and the outlet temperature of the air exiting the channels. (c) Chip power and air outlet temperature for air velocity half of the value calculated in part (a).

### SCHEMATIC

**ASSUMPTIONS:** (1) Steady state, (2) One-dimensional heat transfer in fins and base, (3) Isothermal chip, (4) Negligible heat transfer from top of chip, (5) Uniform convection coefficient over exposed surfaces, (6) Negligible radiation, (7) Negligible axial conduction in the heat sink, (8) Laminar flow, (9) Combined entry length.

**PROPERTIES:** Given. Aluminum,  $k_{hs} = 180 \text{ W/m}\cdot\text{K}$ . Air ( $T = 300 \text{ K}$ ; Table A.4)  $\rho = 1.1614 \text{ kg/m}^3$ ,  $c_p = 1007 \text{ J/kg}\cdot\text{K}$ ,  $k = 0.0263 \text{ W/m}\cdot\text{K}$ ,  $\nu = 15.89 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $Pr = 0.707$ .

**ANALYSIS:** (a) The hydraulic diameter is  $D_h = 4A_c/P = 4L_f(S - t)/[2(S - t) + 2L_f] = 4 \times 0.0018 \text{ m} \times 0.015 \text{ m}/[2 \times 0.0018 \text{ m} + 2 \times 0.015 \text{ m}] = 0.00321 \text{ m}$ . From the specified convection coefficient,

$$\overline{Nu}_{D_h} = \frac{\bar{h}D_h}{k} = \frac{100 \text{ W/m}^2 \cdot \text{K} \times 0.00321 \text{ m}}{0.0263 \text{ W/m}\cdot\text{K}} = 12.22$$

$$\text{Using Eq. 8.58 } \overline{Nu}_{D_h} = 12.22 = \frac{\frac{3.66}{\tanh\left[2.264Gr_{D_h}^{-1/3} + 1.7Gz_{D_h}^{-2/3}\right]} + 0.0499Gz_{D_h} \tanh\left(Gz_{D_h}^{-1}\right)}{\tanh\left(2.432Pr^{1/6}Gz_{D_h}^{-1/6}\right)}$$

from which  $Gz_{D_h} = 204 = (D_h/W)Re_{D_h}Pr = (0.00321/0.02) \times Re_{D_h} \times 0.707$ . This yields  $Re_{D_h} = 1800$ . The flow is in the upper laminar range. From the definition of the Reynolds number,

$$u_w = \frac{Re_{D_h} \nu}{D_h} = \frac{1800 \times 15.89 \times 10^{-6} \text{ m}^2/\text{s}}{0.00321 \text{ m}} = 8.89 \text{ m/s} \quad <$$

(b) The resistances between the chip and the channel flow are due to the chip-heat sink interface ( $R_{t,c}$ ), the base of the heat sink ( $R_{t,b}$ ) and the fin array resistance ( $R_{t,o}$ ). The resistance values are:

$$R_{t,c} = R_{t,c}''/W^2 = 2 \times 10^{-6} \text{ m}^2 \cdot \text{K/W}/(0.02 \text{ m})^2 = 0.005 \text{ K/W}$$

Continued...

**PROBLEM 11.89 (Cont.)**

$$R_{t,b} = L_b / (k_{hs} W^2) = 0.003 \text{ m} / (180 \text{ W/m} \cdot \text{K} \times [0.02 \text{ m}]^2) = 0.042 \text{ K/W}$$

$$R_{t,o} = \frac{1}{\eta_o h A_t} \text{ where } \eta_o = 1 - \frac{N A_f}{A_t} (1 - \eta_f) \text{ and } A_t = N A_f + A_b$$

where  $A_f = 2WL_f = 2 \times 0.02 \text{ m} \times 0.015 \text{ m} = 6 \times 10^{-4} \text{ m}^2$  and  $A_b = W^2 - N(tW) = (0.02 \text{ m})^2 - 11(0.182 \times 10^{-3} \text{ m} \times 0.02 \text{ m}) = 3.6 \times 10^{-4} \text{ m}^2$ . With  $mL_f = (2\bar{h}/k_{hs}t)^{1/2}L_f = (200 \text{ W/m}^2 \cdot \text{K} / 180 \text{ W/m} \cdot \text{K} \times 0.182 \times 10^{-3} \text{ m})^{1/2}(0.015 \text{ m}) = 1.17$ ,  $\tanh(mL_f) = 0.824$  and Eq. (3.87) yields  $\eta_f = (\tanh mL_f) / mL_f = 0.824 / 1.17 = 0.704$ . It follows that  $A_t = 6.96 \times 10^{-3} \text{ m}^2$ ,  $\eta_o = 0.719$  and  $R_{t,o} = 2.00 \text{ K/W}$ . Accounting for the air flow within the heat sink only, the value of the minimum heat capacity rate is

$$\begin{aligned} C_{\min} &= \dot{m}c_p = u_w L_f (S - t)(N - 1)\rho c_p \\ &= 8.89 \text{ m/s} \times 0.015 \text{ m} \times 0.0018 \text{ m} \times 10 \times 1.1614 \text{ kg/m}^3 \times 1007 \text{ J/kg} \cdot \text{K} = 2.80 \text{ W/K} \end{aligned}$$

The NTU is

$$\text{NTU} = UA / C_{\min} = \frac{1}{(R_{t,c} + R_{t,b} + R_{t,o})C_{\min}} = \frac{1}{(0.005 \text{ K/W} + 0.042 \text{ K/W} + 2.00 \text{ K/W})2.80 \text{ W/K}} = 0.174$$

while the effectiveness is found from Eq. 8.35a.

$$\varepsilon = 1 - \exp(-\text{NTU}) = 1 - \exp(-0.174) = 0.160$$

yielding a heat rate of

$$q_c = 0.160 \times 2.80 \text{ W/K} (85 - 20) \text{ K} = 29.1 \text{ W} \quad <$$

The temperature of the air exiting the heat sink is found from

$$T_o = T_\infty + q_c / C_{\min} = 20^\circ\text{C} + 29.1 \text{ W} / (2.80 \text{ W/K}) = 30.4^\circ\text{C} \quad <$$

(c) If the air flow velocity is halved,  $Gz_{D_h} = 102$  and  $\bar{h} = 75.2 \text{ W/m}^2 \cdot \text{K}$

yielding  $mL_f = 1.016$  and  $\tanh(mL_f) = 0.768$ . Following the steps described in part (b),  $\eta_f = 0.769 / 1.0183 = 0.756$  and  $\eta_o = 0.768$ . Also,  $R_{t,o} = 2.48 \text{ K/W}$ ,  $\text{NTU} = 0.281$  and  $\varepsilon = 0.245$ . The heat rate is  $q_c = 22.4 \text{ W}$  and the outlet air temperature is  $T_o = 36.0^\circ\text{C}$ . <

**COMMENTS:** (1) Without accounting for the increase in the air flow temperature, the answer for Part (a) is (from Problem 3.144)  $q_c = 31.8 \text{ W}$ . As expected, the increasing air temperature, as it makes its way through the heat sink, reduces the heat transfer rate. (2) The heat rate in Part (c) is reduced because of the combined effects of (i) decreasing value of the convective heat transfer coefficient and (ii) decreasing average temperature difference between the chip and the coolant. (3) Although the flow is laminar, the value of the heat transfer coefficient is relatively high. How much would the allowable heat rate increase (or decrease) if the flow in Part (a) was treated as turbulent?

## PROBLEM 11.90

**KNOWN:** Dimensions of aluminum heat sink. Temperature and velocity of coolant (water) flow through the heat sink. Power dissipation of electronic package attached to the heat sink.

**FIND:** Base temperature of heat sink.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Average convection coefficient associated with water flow over fin surfaces may be approximated as that for a flat plate in parallel flow, (2) All of the electric power is dissipated by the heat sink, (3) Transition Reynolds number of  $Re_{x,c} = 5 \times 10^5$ , (4) Constant properties, (5), Water does not exit the upper surface of the heat sink.

**PROPERTIES:** Given. Aluminum,  $k_{hs} = 180 \text{ W/m}\cdot\text{K}$ . Water,  $\rho = 995 \text{ kg/m}^3$ ,  $c_p = 4178 \text{ J/kg}\cdot\text{K}$ ,  $k_w = 0.62 \text{ W/m}\cdot\text{K}$ ,  $\nu = 7.73 \times 10^{-7} \text{ m}^2/\text{s}$ ,  $Pr = 5.2$ .

**ANALYSIS:** The heat transfer rate is

$$q = P_{\text{elec}} = \varepsilon C_{\min} (T_b - T_{c,i}) = \varepsilon C_{\min} (T_b - T_{\infty}) \quad (1)$$

$$\text{where } \varepsilon = 1 - \exp(-NTU) = 1 - \exp(-UA/C_{\min}) = 1 - \exp(-1/[(R_b + R_{t,o})C_{\min}]) \quad (2)$$

The base resistance is  $R_b = L_b/k_{hs}(w_1 \times w_2) = 0.01\text{m}/180\text{W/m}\cdot\text{K}(0.10 \text{ m})^2 = 5.56 \times 10^{-3} \text{ K/W}$  and from Eqs. 3.107 and 3.108,

$$R_{t,o} = \left\{ \bar{h} A_t \left[ 1 - \frac{N A_f}{A_t} (1 - \eta_f) \right] \right\}^{-1} \quad (3)$$

The Reynolds number is  $Re_{w_2} = u_{\infty} w_2 / \nu = 3 \text{ m/s} \times 0.10 \text{ m} / 7.73 \times 10^{-7} \text{ m}^2/\text{s} = 3.88 \times 10^5$ , and the flow is laminar. Hence,

$$\bar{h} = \left( \frac{k_w}{w_2} \right) 0.664 Re_{w_2}^{1/2} Pr^{1/3} = \left( \frac{0.62 \text{ W/m}\cdot\text{K}}{0.10 \text{ m}} \right) \times 0.664 \times (3.88 \times 10^5)^{1/2} (5.2)^{1/3} = 4443 \text{ W/m}^2 \cdot \text{K}$$

The fin area is  $A_f = 2w_2(L_f + t/2) = 0.2 \text{ m} (0.055 \text{ m}) = 0.011 \text{ m}^2$  while the total surface area of the array is  $A_t = N A_f + A_b = N A_f + (N - 1)(S - t)w_2 = 6(0.011 \text{ m}^2) + 5(0.008 \text{ m})0.1 \text{ m} = 0.070 \text{ m}^2$ . The fin parameter  $m = (2\bar{h}/k_{hs}t)^{1/2} = ([2 \times 4443 \text{ W/m}^2 \cdot \text{K}] / [180 \text{ W/m}\cdot\text{K} \times 0.01 \text{ m}])^{1/2} = 70.3 \text{ m}^{-1}$  and  $L_c = L_f + t/2 = 0.050 \text{ m} + 0.010/2 \text{ m} = 0.055 \text{ m}$ . Hence, Eq. 3.94 yields  $\eta_f = \tanh(mL_c)/(mL_c) = 0.259$ .

Continued...

### PROBLEM 11.90 (Cont.)

Hence,

$$R_{t,o} = \left\{ 4443 \text{ W/m}^2 \cdot \text{K} \times 0.070 \text{ m}^2 \left[ 1 - \frac{0.066 \text{ m}^2}{0.070 \text{ m}^2} (1 - 0.259) \right] \right\}^{-1} = 0.0107 \text{ K/W}$$

The heat capacity rate is  $C_{\min} = \rho(N-1)L_f(S-t)u_{\infty}c_p = 995 \text{ kg/m}^3 \times (6-1) \times 0.050 \text{ m} \times (0.018 \text{ m} - 0.010 \text{ m}) \times 3 \text{ m/s} \times 4178 \text{ J/kg}\cdot\text{K} = 24,940$ .

Equations (1) and (2) can be combined to yield

$$\begin{aligned} T_b &= T_{\infty} + \frac{P_{\text{elec}}}{\left[ 1 - \exp\left(-\frac{1}{(R_b + R_{t,o})C_{\min}}\right) \right] C_{\min}} \\ &= 17^{\circ}\text{C} + \frac{1800 \text{ W}}{\left[ 1 - \exp\left(-\frac{1}{(5.56 \times 10^{-3} \text{ K/W} + 0.0107 \text{ K/W})24,940 \text{ W/K}}\right) \right] 24,940 \text{ W/K}} \\ &= 46.3^{\circ}\text{C}. \end{aligned}$$

<

**COMMENTS:** (1) The outlet water temperature is  $T_{c,o} = T_{c,i} + P_{\text{elec}}/C_{\min} = 17^{\circ}\text{C} + 1800 \text{ W}/24,940 \text{ W/K} = 17.1^{\circ}\text{C}$  and the assumption of constant water temperature made in Problem 7.29 is valid. (2) The hydrodynamic boundary layer thickness at the exit of the heat sink is  $\delta = 5w_2 Re_{w2}^{-1/2} = 0.80 \text{ mm}$  which is much less than  $S - t = 8 \text{ mm}$ . Hence, the assumption of flow over a flat plate is reasonable. (3) For this problem, reduced water flow rates, or use of a gaseous coolant may invalidate the assumption of constant coolant temperature and a heat exchanger-based analysis would be needed. (4) To ensure against coolant loss from the upper surface of the heat sink, a shroud would normally be added.

## PROBLEM 11.91

**KNOWN:** Dimensions of aluminum heat sink. Temperature of air entering the heat sink and specified base temperature.

**FIND:** Plot of the allowable power dissipation and air exit temperature as a function of air velocity over the range  $1 \text{ m/s} \leq u_\infty \leq 5 \text{ m/s}$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Average convection coefficient associated with air flow over fin surfaces may be approximated as that for a channel composed of isothermal parallel plates of width  $L_f$ , (2) All of the electric power is dissipated by the heat sink, (3) Laminar flow, (4) Constant properties, (5), Air does not exit through the upper surface of the heat sink.

**PROPERTIES:** Given. Aluminum,  $k_{hs} = 180 \text{ W/m}\cdot\text{K}$ . Air,  $\rho = 1.145 \text{ kg/m}^3$ ,  $c_p = 1007 \text{ J/kg}\cdot\text{K}$ ,  $k = 0.027 \text{ W/m}\cdot\text{K}$ ,  $\nu = 16.4 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $Pr = 0.706$ .

**ANALYSIS:** Assuming laminar flow, from Eq. 8.58 the average Nusselt number (for a hydraulic diameter of  $D_h = 4A_c/P = 4L_f(S-t)/[2(S-t) + 2L_f] = 4 \times 0.05 \text{ m} \times (0.018 \text{ m} - 0.010 \text{ m})/[2 \times (0.018 \text{ m} - 0.010 \text{ m}) + 2 \times 0.050 \text{ m}] = 0.0138 \text{ m}$ ) is,

$$\overline{Nu}_{D_h} = \frac{\frac{3.66}{\tanh\left[2.264Gr_{D_h}^{-1/3} + 1.7Gz_{D_h}^{-2/3}\right]} + 0.0499Gz_{D_h} \tanh\left(Gz_{D_h}^{-1}\right)}{\tanh\left(2.432Pr^{1/6}Gz_{D_h}^{-1/6}\right)} \quad (1a)$$

$$\text{where } Gz_{D_h} = (D_h / w_2)Re_{D_h}Pr = (0.0138 / 0.01) \times (u_{\text{air}} \times 0.0138 \text{ m} / 16.4 \times 10^{-6} \text{ m}^2/\text{s}) \times 0.706 \quad (1b)$$

$$\text{and } \bar{h} = Nu_{D_h}k / D_h = Nu_{D_h} \times 0.027 \text{ W/m}\cdot\text{K} / 0.0138 \text{ m} \quad (1c)$$

The total resistance consists of the base and fin resistances in series. The base resistance is  $R_b = L_b/k_{hs}(w_1 \times w_2) = 0.01\text{m}/180\text{W/m}\cdot\text{K}(0.10 \text{ m})^2 = 5.56 \times 10^{-3} \text{ K/W}$  and from Eqs. 3.107 and 3.108,

$$R_{t,o} = \left\{ \bar{h}A_t \left[ 1 - \frac{NA_f}{A_t}(1 - \eta_f) \right] \right\}^{-1} \quad (2)$$

The fin area is  $A_f = 2w_2(L_f + t/2) = 0.2 \text{ m} (0.055 \text{ m}) = 0.011 \text{ m}^2$  while the total surface area of the array is  $A_t = NA_f + A_b = NA_f + (N - 1)(S - t)w_2 = 6(0.011 \text{ m}^2) + 5(0.008 \text{ m})0.1 \text{ m} = 0.070 \text{ m}^2$ . To find the fin efficiency, note that the fin parameter,  $m$ , is

Continued...

### PROBLEM 11.91 (Cont.)

$$m = (2\bar{h}/k_{hs}t)^{1/2} = ([2 \times \bar{h} \text{ W/m}^2\cdot\text{K}]/[180 \text{ W/m}\cdot\text{K} \times 0.01 \text{ m}])^{1/2} \quad (3)$$

and  $L_c = L_f + t/2 = 0.050 \text{ m} + 0.010/2 \text{ m} = 0.055 \text{ m}$ . From Eq. 3.94, the fin array efficiency is

$$\eta_f = \tanh(mL_c)/(mL_c) = \tanh(m \times 0.055 \text{ m})/(m \times 0.055 \text{ m}) \quad (4)$$

The minimum heat capacity rate is

$$\begin{aligned} C_{\min} &= u_{\infty} \rho c_p (N-1)(S-t)L_f \\ &= u_{\infty} \times 1.145 \text{ kg/m}^3 \times 1007 \text{ J/kg}\cdot\text{K} \times (6-1) \times (0.018 \text{ m} - 0.010 \text{ m}) \times 0.050 \text{ m} \end{aligned} \quad (5)$$

and the effectiveness is

$$\begin{aligned} \varepsilon &= 1 - \exp(-NTU) = 1 - \exp(-UA/C_{\min}) = 1 - \exp\left(-\frac{1}{(R_{t,o} + R_b)C_{\min}}\right) \\ &= 1 - \exp\left(-\frac{1}{(R_{t,o} + 5.56 \times 10^{-3} \text{ K/W})C_{\min}}\right) \end{aligned} \quad (6)$$

The heat transfer rate may be expressed as

$$q = P_{\text{elec}} = \varepsilon C_{\min} (T_b - T_{\infty}) = \varepsilon C_{\min} (70^{\circ}\text{C} - 20^{\circ}\text{C}) \quad (7)$$

and the outlet air temperature is

$$T_o = T_{\infty} + P_{\text{elec}}/C_{\min} \quad (8)$$

Equations 1 through 7 can be solved using IHT as noted in Comment 1. The allowable power and exit air temperatures are shown below.

Continued...

## PROBLEM 11.91 (Cont.)

**COMMENTS:** (1) The IHT code is shown below. (2) Values of the Reynolds number range from 841 to 4205 for air velocities ranging from 1 m/s to 5 m/s. Hence, the flow will be transitioning to a turbulent state at velocities greater than approximately 3 m/s. (3) To dissipate  $P_{\text{elec}} = 70 \text{ W}$ , it is necessary to provide an air velocity of  $u_{\infty} = 3.3 \text{ m/s}$ , corresponding to a Reynolds number of 2775. (4) Increasing air velocity has two effects, (i) the heat transfer coefficient is increased (from 13 to  $28 \text{ W/m}^2\cdot\text{K}$  for the range of velocities considered here), and (ii) the average air temperature is reduced, as evident in the graph above.

## PROBLEM 11.92

**KNOWN:** Chip and cooling channel dimensions. Water flow rate and inlet temperature. Temperature of chip at base of channel. Chip thermal conductivity.

**FIND:** Water outlet temperature and chip power.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Incompressible liquid with negligible viscous dissipation, (2) Flow may be approximated as fully developed and channel walls as isothermal for purposes of estimating the convection coefficient, (3) One-dimensional conduction along channel side walls, (4) Adiabatic condition at end of side walls, (5) Heat dissipation is exclusively through fluid flow in channels, (6) Constant properties.

**PROPERTIES:** Table A-6, Water ( $\bar{T}_m = 300\text{K}$ ):  $c_p = 4179\text{ J/kg}\cdot\text{K}$ ,  $\mu = 855 \times 10^{-6}\text{ kg/s}\cdot\text{m}$ ,  $k = 0.613\text{ W/m}\cdot\text{K}$ ,  $Pr = 5.83$ .

**ANALYSIS:** Since the heat sink's bottom surface temperature is spatially uniform, and axial conduction is neglected, the heat sink's thermal behavior corresponds to a single stream heat exchanger. We may use Equation 11.22 to determine the heat transfer rate,

$$q = \varepsilon C_{\min}(T_{h,i} - T_{c,i}) \quad (1)$$

where  $C_{\min} = C_c = \dot{m}_c c_{p,c}$  and  $C_r \rightarrow 0$ . From Section 11.2 and the discussion surrounding Equations 8.45b and 8.46b, we note that the term  $1/UA$  used in the definition of NTU corresponds to the overall thermal resistance between the two fluid streams of a heat exchanger. In this example,  $UA = 1/R_{\text{tot}}$  where  $R_{\text{tot}}$  is the total thermal resistance between the bottom of the heat sink and the fluid. Therefore, Equation 11.35a may be written as

$$\varepsilon = 1 - \exp(-NTU) = 1 - \exp\left(-\frac{UA}{C_{\min}}\right) = 1 - \exp\left(-\frac{1}{R_{\text{tot}} C_{\min}}\right) \quad (2)$$

Once  $C_{\min}$  and  $R_{\text{tot}}$  are evaluated, the effectiveness can be found from Equation 2, and the heat rate may be determined from Equation 1.

**Determination of  $R_{\text{tot}}$ .** The channel sidewalls act as fins, and a *unit* channel/sidewall combination is shown in schematic (a), where the total number of unit cells corresponds to  $N = L/S$ . With  $N = 50$  and  $L = 10\text{ mm}$ ,  $S = 200\text{ }\mu\text{m}$  and  $\delta = S - W = 150\text{ }\mu\text{m}$ . Alternatively, the unit cell may be represented in terms of a single fin of thickness  $\delta$ , as shown in schematic (b). The thermal resistance of the unit cell may be obtained from the expression for a fin array, Eq. (3.108),  $R_{t,o} = (\eta_o h A_t)^{-1}$ , where  $A_t = A_f + A_b = L(2H + W) = 0.01\text{ m}(4 \times 10^{-4} + 0.5 \times 10^{-4})\text{ m} = 4.5 \times 10^{-6}\text{ m}^2$ . With  $D_h = 4(H \times W)/(2(H + W)) = 4(2 \times 10^{-4}\text{ m} \times 0.5 \times 10^{-4}\text{ m})/(2(2.5 \times 10^{-4}\text{ m})) = 8 \times 10^{-5}\text{ m}$ , the Reynolds number is  $Re_D = \rho u_m D_h/\mu = \dot{m}_1 D_h/A_c \mu = 10^{-4}\text{ kg/s} \times 8 \times 10^{-5}\text{ m}/(2 \times 10^{-4}\text{ m} \times 0.5 \times 10^{-4}\text{ m}) 855 \times 10^{-6}\text{ kg/s}\cdot\text{m} = 936$ . Hence, the flow is laminar, and assuming fully developed conditions throughout a channel with uniform surface temperature, Table 8.1 yields  $Nu_D = 4.44$ . Hence,

Continued...

### PROBLEM 11.92 (Cont.)

$$h = \frac{k}{D_h} \text{Nu}_D = \frac{0.613 \text{ W/m}\cdot\text{K} \times 4.44}{8 \times 10^{-5} \text{ m}} = 34,022 \text{ W/m}^2 \cdot \text{K}$$

With  $m = (2h/k_{ch}\delta)^{1/2} = (68,044 \text{ W/m}^2 \cdot \text{K} / 140 \text{ W/m}\cdot\text{K} \times 1.5 \times 10^{-4} \text{ m})^{1/2} = 1800 \text{ m}^{-1}$  and  $mH = 0.36$ , the fin efficiency is

$$\eta_f = \frac{\tanh mH}{mH} = \frac{0.345}{0.36} = 0.958$$

and the overall surface efficiency is

$$\eta_o = 1 - \frac{A_f}{A_t} (1 - \eta_f) = 1 - \frac{4.0 \times 10^{-6}}{4.5 \times 10^{-6}} (1 - 0.958) = 0.963$$

The thermal resistance of the unit cell is then

$$R_{\text{tot}} = (\eta_o h A_t)^{-1} = (0.963 \times 34,022 \text{ W/m}^2 \cdot \text{K} \times 4.5 \times 10^{-6} \text{ m}^2)^{-1} = 6.78 \text{ K/W}$$

*Determination of  $C_{\text{min}}$ .* The minimum heat capacity rate is

$$C_{\text{min}} = \dot{m}_1 c_p = 10^{-4} \text{ kg/s} \times 4179 \text{ J/kg}\cdot\text{K} = 0.4179 \text{ W/K}$$

From Equation 2,

$$\varepsilon = 1 - \exp\left(-\frac{1}{R_{\text{tot}} C_{\text{min}}}\right) = 1 - \exp\left(-\frac{1}{6.78 \text{ K/W} \times 0.4179 \text{ W/K}}\right) = 0.297$$

and from Equation 1, the heat rate per channel is

$$q_1 = \varepsilon C_{\text{min}} (T_h - T_{c,i}) = 0.297 \times 0.4179 \text{ W/K} \times (350 \text{ K} - 290 \text{ K}) = 7.46 \text{ W}$$

and the chip power dissipation is

$$q = Nq_1 = 50 \times 7.46 \text{ W} = 373 \text{ W} \quad <$$

The outlet temperature follows from an energy balance on a channel,

$$q_1 = C_{\text{min}} (T_{m,o} - T_{m,i}), \quad T_{m,o} = T_{m,i} + \frac{q_1}{C_{\text{min}}} = 290 \text{ K} + \frac{7.46 \text{ W}}{0.4179 \text{ W/K}} = 307.8 \text{ K} \quad <$$

**COMMENTS:** (1) With  $L/D_h = 125$  and  $(L/D_h)_{\text{fd}} \approx 0.05 \text{ Re}_D \text{ Pr} = 273$ , fully developed flow is not achieved and the value of  $h = h_{\text{fd}}$  underestimates the actual value of  $\bar{h}$  in the channel. The coefficient is also underestimated by using a Nusselt number that presumes heat transfer from all four (rather than three) surfaces of a channel.

### PROBLEM 11.93

**KNOWN:** Dimensions, particle diameter, and porosity of bronze foam sheet. Temperature of upper and lower surfaces of foam. Velocity and inlet temperature of air flowing through foam.

**FIND:** Convection heat transfer rate to air accounting for both the increase in the air temperature as it flows through the foam and thermal resistance due to conduction in the foam. Whether actual heat transfer rate would be greater, less, or the same.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Constant properties, (3) Heat transfer coefficient between foam and air can be determined from packed bed analysis, (4) Foam behaves as extended surface, (5) Effective thermal conductivity of foam can be found from Maxwell's relation, (6) Negligible radiation transfer.

**PROPERTIES:** Table A-1, Commercial bronze ( $T \approx 325$  K):  $k_b = 52$  W/m·K. Table A-4, Air ( $T \approx 325$  K):  $\rho = 1.0782$  kg/m<sup>3</sup>,  $c_p = 1008$  J/kg·K,  $k = 0.0282$  W/m·K,  $\nu = 18.41 \times 10^{-6}$  m<sup>2</sup>/s,  $Pr = 0.704$ .

**ANALYSIS:** Following Example 11.7, the air flow can be treated as flow through a single stream heat exchanger, exchanging heat with a surface at  $T_s$  through a single fin resistance. Due to symmetry, the foam sheet can be treated as a fin of length  $L/2$  with an insulated fin tip.

Because the fin is foam and the air flows through it, the heat transfer coefficient can be found from the packed bed analysis of Equation 7.81:

$$\varepsilon \bar{j}_H = \varepsilon \frac{\bar{h}}{\rho c_p V} Pr^{2/3} = 2.06 Re_D^{-0.575}$$

where  $Re_D = VD/\nu = 10 \text{ m/s} \times 0.0006 \text{ m} / 18.41 \times 10^{-6} \text{ m}^2/\text{s} = 326$

$$\begin{aligned} \bar{h} &= \frac{2.06 \rho c_p V}{\varepsilon} Re_D^{-0.575} Pr^{-2/3} \\ &= \frac{2.06 \times 1.0782 \text{ kg/m}^3 \times 1008 \text{ J/kg} \cdot \text{K} \times 10 \text{ m/s}}{0.25} (326)^{-0.575} (0.704)^{-2/3} = 4060 \text{ W/m}^2 \cdot \text{K} \end{aligned}$$

The surface area of the sintered particles can be found as follows, where  $N$  = number of particles:

$$\begin{aligned} V_p &= N\pi D^3/6 = (1 - \varepsilon)V_{\text{tot}} = (1 - \varepsilon)WtL \text{ and} \\ A_{p,t} &= N\pi D^2 = 6(1 - \varepsilon)WtL/D = \frac{6 \times 0.75 \times 0.04 \text{ m} \times 0.01 \text{ m} \times 0.04 \text{ m}}{0.0006 \text{ m}} = 0.12 \text{ m}^2 \end{aligned}$$

Continued...

### PROBLEM 11.93 (Cont.)

For a slice of the foam of length  $dx$ , the surface area of foam in contact with the air is  $dA_s = A_{p,t}dx/L$ . Thus,

$$dq_{\text{conv}} = \frac{\bar{h}A_{p,t}dx}{L}(T(x) - T_\infty)$$

By analogy with  $dq_{\text{conv}} = hPdx(T(x) - T_\infty)$  for a solid fin, we find

$$P_{\text{eff}} = \frac{A_{p,t}}{L} = \frac{0.12 \text{ m}^2}{0.04 \text{ m}} = 3.0 \text{ m}$$

From Equation 3.25, with  $k_s = k_b$ ,

$$\begin{aligned} k_{\text{eff}} &= \left[ \frac{k_f + 2k_b - 2\varepsilon(k_b - k_f)}{k_f + 2k_b + \varepsilon(k_b - k_f)} \right] k_b \\ &= \left[ \frac{(0.0282 + 2 \times 52 - 2 \times 0.25 \times (52 - 0.0282)) \text{ W/m} \cdot \text{K}}{(0.0282 + 2 \times 52 + 0.25 \times (52 - 0.0282)) \text{ W/m} \cdot \text{K}} \right] \times 52 \text{ W/m} \cdot \text{K} = 34.7 \text{ W/m} \cdot \text{K} < \end{aligned}$$

The fin efficiency is given by Equation 11.4, where  $A_c$  is the fin cross-sectional area,  $A_c = Wt = 0.04 \text{ m} \times 0.01 \text{ m} = 4 \times 10^{-4} \text{ m}^2$ . We first calculate

$$mL_f = \sqrt{\bar{h}P_{\text{eff}}/k_{\text{eff}}A_c}(L/2) = \sqrt{4060 \text{ W/m}^2 \cdot \text{K} \times 3 \text{ m}/(34.7 \text{ W/m} \cdot \text{K} \times 4 \times 10^{-4} \text{ m}^2)} \times 0.02 \text{ m} = 18.7$$

Then

$$\eta_f = \frac{\tanh(mL_f)}{mL_f} = \frac{\tanh(18.7)}{18.7} = 0.0535$$

The fin is inefficient because it is significantly longer than it needs to be to maximize heat transfer between the air and foam. From Equation 3.97, the fin resistance is

$$R_{t,f} = 1/\bar{h}A_{p,t}\eta_f = 1/(4060 \text{ W/m}^2 \cdot \text{K} \times 0.12 \text{ m}^2 \times 0.0535) = 0.0384 \text{ K/W}$$

Note that the fin surface area is  $A_{p,t}$ , since this is the area for heat transfer between the foam and air. Following the approach in Example 11.7,

$$\begin{aligned} C_{\text{min}} &= \dot{m}_c c_{p,c} = \rho V A_{c,b} c_p \\ &= 1.0782 \text{ kg/m}^3 \times 10 \text{ m/s} \times (0.04 \text{ m})^2 \times 1008 \text{ J/kg} \cdot \text{K} = 17.4 \text{ W/K} \end{aligned}$$

Continued...

### PROBLEM 11.93 (Cont.)

$$\varepsilon = 1 - \exp(-NTU) = 1 - \exp\left(-\frac{1}{R_{t,f} C_{\min}}\right) = 1 - \exp\left(-\frac{1}{0.0384 \text{ K/W} \times 17.4 \text{ W/K}}\right) = 0.776$$

Finally,

$$q = \varepsilon C_{\min}(T_s - T_{c,i}) = 0.776 \times 17.4 \text{ W/K} \times (80^\circ\text{C} - 20^\circ\text{C}) = 810 \text{ W} \quad <$$

This is probably close to the correct answer, although temperature gradients in the streamwise direction in the foam are not accounted for. The actual value would therefore be less than 810 W. <

**COMMENTS:** The solution to Problem 7.113 was achieved in two ways: (a) assuming the foam temperature is uniform at  $T_s$  and accounting for the variation of air temperature in the flow direction, and (b) assuming the air temperature is uniform at  $T_i$  and accounting for the variation of foam temperature in the  $x$ -direction. Both of these approaches significantly overestimate the actual heat transfer rate.

## PROBLEM 11.94

**KNOWN:** Dimensions, particle diameter, and porosity of bronze foam heat sink attached to silicon chip. Chip temperature. Velocity and inlet temperature of air flowing through foam.

**FIND:** Heat transfer rate from chip.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, (2) Constant properties, (3) Heat transfer coefficient between foam and air can be determined from packed bed analysis, (4) Foam behaves as extended surface, (5) Effective thermal conductivity of foam can be found from Maxwell's relation, (6) Air flows uniformly through foam rather than being diverted toward open region above heat sink, (7) Negligible radiation transfer.

**PROPERTIES:** Table A-1, Commercial bronze ( $T \approx 323$  K):  $k_b = 52$  W/m·K. Table A-4, Air ( $T \approx 325$  K):  $\rho_a = 1.0782$  kg/m<sup>3</sup>,  $c_{p,a} = 1008$  J/kg·K,  $k_a = 0.0282$  W/m·K,  $\nu_a = 18.41 \times 10^{-6}$  m<sup>2</sup>/s,  $Pr = 0.704$ .

**ANALYSIS:** Following Example 11.7, the air flow can be treated as flow through a single stream heat exchanger, exchanging heat with a surface at  $T_s$  through a single fin resistance. Because the fin is foam and the air flows through it, the heat transfer coefficient can be found from the packed bed analysis of Equation 7.81:

$$\varepsilon \bar{j}_H = \varepsilon \frac{\bar{h}}{\rho c_p V} Pr^{2/3} = 2.06 Re_D^{-0.575}$$

where  $Re_D = VD/\nu = 5 \text{ m/s} \times 0.0006 \text{ m} / 18.41 \times 10^{-6} \text{ m}^2/\text{s} = 163$

$$\begin{aligned} \bar{h} &= \frac{2.06 \rho c_p V}{\varepsilon} Re_D^{-0.575} Pr^{-2/3} \\ &= \frac{2.06 \times 1.0782 \text{ kg/m}^3 \times 1008 \text{ J/kg} \cdot \text{K} \times 5 \text{ m/s}}{0.25} (163)^{-0.575} (0.704)^{-2/3} = 3030 \text{ W/m}^2 \cdot \text{K} \end{aligned}$$

The surface area of the sintered particles can be found as follows, where  $N$  = number of particles:

$$\begin{aligned} V_p &= N\pi D^3/6 = (1 - \varepsilon)V_{\text{tot}} = (1 - \varepsilon)W^2L \text{ and} \\ A_{p,t} &= N\pi D^2 = 6(1 - \varepsilon)W^2L/D = \frac{6 \times 0.75 \times (0.025 \text{ m})^2 \times 0.01 \text{ m}}{0.0006 \text{ m}} = 0.0469 \text{ m}^2 \end{aligned}$$

Continued...

### PROBLEM 11.94 (Cont.)

For a slice of the foam of length  $dx$ , the surface area of foam in contact with the air is  $dA_s = A_{p,t} dx/L$ . Thus,

$$dq_{\text{conv}} = \frac{\bar{h}A_{p,t} dx}{L} (T(x) - T_\infty)$$

By analogy with  $dq_{\text{conv}} = hPdx(T(x) - T_\infty)$  for a solid fin, we find

$$P_{\text{eff}} = \frac{A_{p,t}}{L} = \frac{0.0469 \text{ m}^2}{0.01 \text{ m}} = 4.69 \text{ m}$$

From Equation 3.25, with  $k_s = k_b$ ,

$$\begin{aligned} k_{\text{eff}} &= \left[ \frac{k_f + 2k_b - 2\varepsilon(k_b - k_f)}{k_f + 2k_b + \varepsilon(k_b - k_f)} \right] k_b \\ &= \left[ \frac{(0.0282 + 2 \times 52 - 2 \times 0.25 \times (52 - 0.0282)) \text{ W/m} \cdot \text{K}}{(0.0282 + 2 \times 52 + 0.25 \times (52 - 0.0282)) \text{ W/m} \cdot \text{K}} \right] \times 52 \text{ W/m} \cdot \text{K} = 34.7 \text{ W/m} \cdot \text{K} \end{aligned}$$

The fin efficiency is given by Equation 11.4, where  $A_c$  is the fin cross-sectional area,  $A_c = W^2 = (0.025 \text{ m})^2 = 6.25 \times 10^{-4} \text{ m}^2$ . We first calculate

$$mL = \sqrt{\bar{h}P_{\text{eff}} / k_{\text{eff}} A_c} L = \sqrt{3030 \text{ W/m}^2 \cdot \text{K} \times 4.69 \text{ m} / (34.7 \text{ W/m} \cdot \text{K} \times 6.25 \times 10^{-4} \text{ m}^2)} \times 0.01 \text{ m} = 8.09$$

Then

$$\eta_f = \frac{\tanh(mL_f)}{mL_f} = \frac{\tanh(8.09)}{8.09} = 0.124$$

From Equation 3.97, the fin resistance is

$$R_{t,f} = 1 / \bar{h}A_{p,t}\eta_f = 1 / (3030 \text{ W/m}^2 \cdot \text{K} \times 0.0469 \text{ m}^2 \times 0.124) = 0.0570 \text{ K/W}$$

Note that the fin surface area is  $A_{p,t}$ , since this is the area for heat transfer between the foam and air. Following the approach in Example 11.7,

$$\begin{aligned} C_{\text{min}} &= \dot{m}_c c_{p,c} = \rho V A_{c,b} c_p \\ &= 1.0782 \text{ kg/m}^3 \times 5 \text{ m/s} \times 0.01 \text{ m} \times 0.025 \text{ m} \times 1008 \text{ J/kg} \cdot \text{K} = 1.36 \text{ W/K} \end{aligned}$$

Continued...

**PROBLEM 11.94 (Cont.)**

$$\varepsilon = 1 - \exp(-NTU) = 1 - \exp\left(-\frac{1}{R_{t,f} C_{\min}}\right) = 1 - \exp\left(-\frac{1}{0.0570 \text{ K/W} \times 1.36 \text{ W/K}}\right) = 1.0$$

Finally,

$$q = \varepsilon C_{\min}(T_s - T_{c,i}) = 1.0 \times 1.36 \text{ W/K} \times (70^\circ\text{C} - 27^\circ\text{C}) = 58.4 \text{ W} \quad <$$

**COMMENTS:** (1) With a fin efficiency of unity, the foam temperature is essentially uniform at  $T_s$ , and the heat transfer rate is identical to that which would be found from a packed bed analysis that ignored the conduction resistance in the foam. This is an indication that the heat sink design could be improved to reduce its weight without significantly sacrificing performance. (2) The heat sink poses a resistance to air flow, and much of the air would be diverted around the foam block toward the open area above it, reducing its performance. The design could be altered to inhibit diversion of the air to the open region.

## PROBLEM 12.1

**KNOWN:** Opaque, horizontal plate, well insulated on backside, is subjected to a prescribed irradiation. Also known are the reflected irradiation, emissive power, plate temperature and convection coefficient for known air temperature.

**FIND:** (a) Emissivity, absorptivity and radiosity and (b) Net heat transfer per unit area of the plate.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Plate is insulated on backside, (2) Plate is opaque.

**ANALYSIS:** (a) The emissivity of the plate according to Table 12.1 is

$$\varepsilon = \frac{E}{E_b(T_s)} = \frac{E}{\sigma T_s^4} = \frac{1200 \text{ W/m}^2}{5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times (227 + 273)^4 \text{ K}^4} = 0.34. \quad <$$

The absorptivity is related to the reflectivity by Eq. 12.3 for an opaque surface. That is,  $\alpha = 1 - \rho$ . By definition, the reflectivity is the fraction of irradiation reflected, such that

$$\alpha = 1 - G_{\text{ref}} / G = 1 - 500 \text{ W/m}^2 / (2500 \text{ W/m}^2) = 1 - 0.20 = 0.80. \quad <$$

The radiosity,  $J$ , is defined as the radiant flux leaving the surface by emission and reflection per unit area of the surface (Eq. 12.4).

$$J = \rho G + \varepsilon E_b = G_{\text{ref}} + E = 500 \text{ W/m}^2 + 1200 \text{ W/m}^2 = 1700 \text{ W/m}^2. \quad <$$

(b) The net heat transfer to the surface is determined from an energy balance,

$$q''_{\text{net}} = q''_{\text{in}} - q''_{\text{out}} = G - G_{\text{ref}} - E - q''_{\text{conv}}$$

$$q''_{\text{net}} = (2500 - 500 - 1200) \text{ W/m}^2 - 15 \text{ W/m}^2 \cdot \text{K} (227 - 127) \text{ K} = -700 \text{ W/m}^2. \quad <$$

An alternate approach to the energy balance using the radiosity, Eq. 12.5,

$$q''_{\text{net}} = G - J - q''_{\text{conv}}$$

$$q''_{\text{net}} = (2500 - 1700 - 1500) \text{ W/m}^2$$

$$q''_{\text{net}} = -700 \text{ W/m}^2.$$

**COMMENTS:** (1) Since the net heat rate per unit area is negative, energy must be added to the plate in order to maintain it at  $T_s = 227^\circ\text{C}$ . (2) Note that  $\alpha \neq \varepsilon$ . Hence, the plate is not a gray surface, as described in Section 1.2.3. (3) Note the use of radiosity in performing energy balances. That is, considering only the radiation processes,  $q''_{\text{net}} = G - J$ .

## PROBLEM 12.2

**KNOWN:** Horizontal, opaque surface at steady-state temperature of  $77^\circ\text{C}$  is exposed to a convection process; emissive power, irradiation and reflectivity are prescribed.

**FIND:** (a) Absorptivity of the surface, (b) Net radiation heat transfer rate for the surface; indicate direction, (c) Total heat transfer rate for the surface; indicate direction.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Surface is opaque, (2) Effect of surroundings included in the specified irradiation, (3) Steady-state conditions.

**ANALYSIS:** (a) From the definition of the thermal radiative properties and a radiation balance for an opaque surface, according to Eq. 12.3,

$$\alpha = 1 - \rho = 1 - 0.4 = 0.6.$$

(b) The net radiation heat transfer rate from the surface is

$$q''_{\text{rad}} = E + \rho G - G = (628 + 0.4 \times 1380 - 1380) \text{ W/m}^2 = -200 \text{ W/m}^2.$$

Since  $q''_{\text{rad}}$  is negative, the net radiation heat transfer rate is *to* the surface.

(c) Performing a surface energy balance considering all heat transfer processes, the local heat transfer rate is

$$q''_{\text{tot}} = q''_{\text{rad}} + q''_{\text{conv}}$$

$$q''_{\text{tot}} = -200 \text{ W/m}^2 + 28 \text{ W/m}^2 \cdot \text{K} (77 - 27) \text{ K} = 1200 \text{ W/m}^2.$$

The total heat flux is shown as a positive value indicating the heat flux is *from* the surface.

**COMMENTS:** (1) Note that the surface radiation balance could also be expressed as

$$q''_{\text{rad}} = J - G \quad \text{or} \quad E - \alpha G.$$

Note the use of radiosity to express the radiation flux leaving the surface.

(2) From knowledge of the surface emissive power and  $T_s$ , find the emissivity as

$$\varepsilon \equiv E / \sigma T_s^4 = 628 \text{ W/m}^2 / (5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4) (77 + 273)^4 \text{ K}^4 = 0.74.$$

COMMENT: Since  $\varepsilon \neq \alpha$ , we know the surface is not gray, as discussed in Section 1.2.3.

### PROBLEM 12.3

**KNOWN:** Thickness and temperature of aluminum plate. Irradiation. Convection conditions. Absorptivity and emissivity.

**FIND:** Radiosity and net radiation heat flux at top plate surface, rate of change of plate temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Plate temperature is uniform, (2) Plate is opaque,  $\tau = 0$ .

**PROPERTIES:** Table A-1, Pure aluminum ( $T = 400$  K):  $\rho = 2702$  kg/m<sup>3</sup>,  $c = 949$  J/kg·K.

**ANALYSIS:** The radiosity is equal to the sum of emitted and reflected radiation:

$$\begin{aligned} J &= \rho G + \varepsilon E_b = (1 - \alpha)G + \varepsilon \sigma T^4 \\ &= (1 - 0.14) \times 1000 \text{ W/m}^2 + 0.76 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times (400 \text{ K})^4 \\ &= 1963 \text{ W/m}^2 \end{aligned} \quad <$$

The net radiation heat flux from the plate is equal to the radiosity minus the irradiation:

$$q''_{\text{rad}} = J - G = 1963 \text{ W/m}^2 - 1000 \text{ W/m}^2 = 963 \text{ W/m}^2 \quad <$$

The rate of change of the plate temperature can be found from an energy balance on the plate, accounting for heat loss by both radiation and convection,

$$\begin{aligned} \frac{dT}{dt} &= -\frac{q_{\text{conv}} + q_{\text{rad}}}{\rho c V} = -\frac{q''_{\text{conv}} + q''_{\text{rad}}}{\rho c L} = -\frac{h(T - T_{\infty}) + q''_{\text{rad}}}{\rho c L} \\ &= -\frac{40 \text{ W/m}^2 \cdot \text{K} \times (400 \text{ K} - (30 + 273) \text{ K}) + 963 \text{ W/m}^2}{2702 \text{ kg/m}^3 \times 949 \text{ J/kg} \cdot \text{K} \times 0.005 \text{ m}} = -0.378 \text{ K/s} \end{aligned} \quad <$$

**COMMENTS:** (1) The values given for absorptivity and emissivity correspond to solar irradiation and room temperature emission for anodized aluminum. (2) The surroundings temperature is not needed for this solution since the irradiation value is given.

## PROBLEM 12.4

**KNOWN:** Temperature, absorptivity, transmissivity, radiosity and convection conditions for a semitransparent plate.

**FIND:** Plate irradiation and total hemispherical emissivity.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Uniform surface conditions.

**ANALYSIS:** From an energy balance on the plate

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$2G = 2q''_{\text{conv}} + 2J.$$

Solving for the irradiation and substituting numerical values,

$$G = 40 \text{ W/m}^2 \cdot \text{K} (350 - 300) \text{ K} + 5000 \text{ W/m}^2 = 7000 \text{ W/m}^2. \quad <$$

From the definition of the radiosity J,

$$J = E + \rho G + \tau G = E + (1 - \alpha)G.$$

Solving for the emissivity and substituting numerical values,

$$\varepsilon = \frac{J - (1 - \alpha)G}{\sigma T^4} = \frac{(5000 \text{ W/m}^2) - 0.6(7000 \text{ W/m}^2)}{5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (350 \text{ K})^4} = 0.94. \quad <$$

Hence,

$$\alpha \neq \varepsilon$$

and the surface is not gray for the prescribed conditions.

**COMMENTS:** The emissivity may also be determined by expressing the plate energy balance as

$$2\alpha G = 2q''_{\text{conv}} + 2E.$$

Hence

$$\varepsilon \sigma T^4 = \alpha G - h(T - T_{\infty})$$

$$\varepsilon = \frac{0.4(7000 \text{ W/m}^2) - 40 \text{ W/m}^2 \cdot \text{K} (50 \text{ K})}{5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (350 \text{ K})^4} = 0.94.$$

## PROBLEM 12.5

**KNOWN:** Rate at which radiation is intercepted by each of three surfaces (see Example 12.1).

**FIND:** Irradiation,  $G$  [ $\text{W}/\text{m}^2$ ], at each of the three surfaces.

**SCHEMATIC:**

**ANALYSIS:** The irradiation at a surface is the rate at which radiation is incident on a surface per unit area of the surface. The irradiation at surface  $j$  due to emission from surface 1 is

$$G_j = \frac{q_{1-j}}{A_j}$$

With  $A_1 = A_2 = A_3 = A_4 = 10^{-3} \text{ m}^2$  and the incident radiation rates  $q_{1-j}$  from the results of Example 12.1, find

$$G_2 = \frac{12.1 \times 10^{-3} \text{ W}}{10^{-3} \text{ m}^2} = 12.1 \text{ W}/\text{m}^2 \quad <$$

$$G_3 = \frac{28.0 \times 10^{-3} \text{ W}}{10^{-3} \text{ m}^2} = 28.0 \text{ W}/\text{m}^2 \quad <$$

$$G_4 = \frac{19.8 \times 10^{-3} \text{ W}}{10^{-3} \text{ m}^2} = 19.8 \text{ W}/\text{m}^2. \quad <$$

**COMMENTS:** The irradiation could also be computed from Eq. 12.18, which, for the present situation, takes the form

$$G_j = I_1 \cos \theta_j \omega_{1-j}$$

where  $I_1 = I = 7000 \text{ W}/\text{m}^2 \cdot \text{sr}$  and  $\omega_{1-j}$  is the solid angle subtended by surface 1 with respect to  $j$ . For example,

$$G_2 = I_1 \cos \theta_2 \omega_{1-2}$$

$$G_2 = 7000 \text{ W}/\text{m}^2 \cdot \text{sr} \times$$

$$\cos 30^\circ \frac{10^{-3} \text{ m}^2 \times \cos 60^\circ}{(0.5 \text{ m})^2}$$

$$G_2 = 12.1 \text{ W}/\text{m}^2.$$

Note that, since  $A_1$  is a diffuse radiator, the intensity  $I$  is independent of direction.

## PROBLEM 12.6

**KNOWN:** A diffuse surface of area  $A_1 = 10^{-4} \text{ m}^2$  emits diffusely with total emissive power  $E = 5 \times 10^4 \text{ W/m}^2$ .

**FIND:** (a) Rate this emission is intercepted by small surface of area  $A_2 = 5 \times 10^{-4} \text{ m}^2$  at a prescribed location and orientation, (b) Irradiation  $G_2$  on  $A_2$ , and (c) Compute and plot  $G_2$  as a function of the separation distance  $r_2$  for the range  $0.25 \leq r_2 \leq 1.0 \text{ m}$  for zenith angles  $\theta_2 = 0, 30$  and  $60^\circ$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Surface  $A_1$  emits diffusely, (2)  $A_1$  may be approximated as a differential surface area and that  $A_2/r_2^2 \ll 1$ .

**ANALYSIS:** (a) The rate at which emission from  $A_1$  is intercepted by  $A_2$  follows from Eq. 12.11 written on a total rather than spectral basis.

$$q_{1 \rightarrow 2} = I_{e,1}(\theta, \phi) A_1 \cos \theta_1 d\omega_{2-1}. \quad (1)$$

Since the surface  $A_1$  is diffuse, it follows from Eq. 12.16 that

$$I_{e,1}(\theta, \phi) = I_{e,1} = E_1/\pi. \quad (2)$$

The solid angle subtended by  $A_2$  with respect to  $A_1$  is

$$d\omega_{2-1} \approx A_2 \cos \theta_2 / r_2^2. \quad (3)$$

Substituting Eqs. (2) and (3) into Eq. (1) with numerical values gives

$$q_{1 \rightarrow 2} = \frac{E_1}{\pi} \cdot A_1 \cos \theta_1 \cdot \frac{A_2 \cos \theta_2}{r_2^2} = \frac{5 \times 10^4 \text{ W/m}^2}{\pi \text{ sr}} \times (10^{-4} \text{ m}^2 \times \cos 60^\circ) \times \left[ \frac{5 \times 10^{-4} \text{ m}^2 \times \cos 30^\circ}{(0.5 \text{ m})^2} \right] \text{ sr} \quad (4)$$

$$q_{1 \rightarrow 2} = 15,915 \text{ W/m}^2 \text{ sr} \times (5 \times 10^{-5} \text{ m}^2) \times 1.732 \times 10^{-3} \text{ sr} = 1.378 \times 10^{-3} \text{ W}. \quad <$$

(b) From section 12.3.3, the irradiation is the rate at which radiation is incident upon the surface per unit surface area,

$$G_2 = \frac{q_{1 \rightarrow 2}}{A_2} = \frac{1.378 \times 10^{-3} \text{ W}}{5 \times 10^{-4} \text{ m}^2} = 2.76 \text{ W/m}^2 \quad (5) <$$

(c) Using the IHT workspace with the foregoing equations, the  $G_2$  was computed as a function of the separation distance for selected zenith angles. The results are plotted below.

Continued...

### PROBLEM 12.6 (Cont.)

For all zenith angles,  $G_2$  decreases with increasing separation distance  $r_2$ . From Eq. (3), note that  $d\omega_{2-1}$  and, hence  $G_2$ , vary inversely as the square of the separation distance. For any fixed separation distance,  $G_2$  is a maximum when  $\theta_2 = 0^\circ$  and decreases with increasing  $\theta_2$ , proportional to  $\cos \theta_2$ .

**COMMENTS:** (1) For a diffuse surface, the intensity,  $I_e$ , is independent of direction and related to the emissive power as  $I_e = E/\pi$ . Note that  $\pi$  has the units of [sr] in this relation.

(2) Note that Eq. 12.12 is an important relation for determining the radiant power leaving a surface in a prescribed manner. It has been used here on a total rather than spectral basis.

(3) Returning to part (b) and referring to Figure 12.10, the irradiation on  $A_2$  may be expressed as

$$G_2 = I_{1,2} \cos \theta_2 \frac{A_1 \cos \theta_1}{r_2^2}$$

Show that the result is  $G_2 = 2.76 \text{ W/m}^2$ . Explain how this expression follows from Eq. 12.18.

## PROBLEM 12.7

**KNOWN:** Furnace with prescribed aperture and emissive power.

**FIND:** (a) Position of gauge such that irradiation is  $G = 1000 \text{ W/m}^2$ , (b) Irradiation when gauge is tilted  $\theta_d = 20^\circ$ , and (c) Compute and plot the gage irradiation,  $G$ , as a function of the separation distance,  $L$ , for the range  $100 \leq L \leq 300 \text{ mm}$  and tilt angles of  $\theta_d = 0, 20$ , and  $60^\circ$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Furnace aperture emits diffusely, (2)  $A_d \ll L^2$ .

**ANALYSIS:** (a) The irradiation on the detector area is defined as the power incident on the surface per unit area of the surface. That is

$$G = q_{f \rightarrow d} / A_d \quad q_{f \rightarrow d} = I_e A_f \cos \theta_f \omega_{d-f} \quad (1,2)$$

where  $q_{f \rightarrow d}$  is the radiant power which leaves  $A_f$  and is intercepted by  $A_d$ . From Eqs. 12.7 and 12.12,

$\omega_{d-f}$  is the solid angle subtended by surface  $A_d$  with respect to  $A_f$ ,

$$\omega_{d-f} = A_d \cos \theta_d / L^2. \quad (3)$$

Noting that since the aperture emits diffusely,  $I_e = E/\pi$  (see Eq. 12.17), and hence

$$G = (E/\pi) A_f \cos \theta_f \left( A_d \cos \theta_d / L^2 \right) / A_d \quad (4)$$

Solving for  $L^2$  and substituting for the condition  $\theta_f = 0^\circ$  and  $\theta_d = 0^\circ$ ,

$$L^2 = E \cos \theta_f \cos \theta_d A_f / \pi G. \quad (5)$$

$$L = \left[ 3.72 \times 10^5 \text{ W/m}^2 \times \frac{\pi}{4} (20 \times 10^{-3})^2 \text{ m}^2 / \pi \times 1000 \text{ W/m}^2 \right]^{1/2} = 193 \text{ mm}. \quad \leftarrow$$

(b) When  $\theta_d = 20^\circ$ ,  $q_{f \rightarrow d}$  will be reduced by a factor of  $\cos \theta_d$  since  $\omega_{d-f}$  is reduced by a factor  $\cos \theta_d$ . Hence,

$$G = 1000 \text{ W/m}^2 \times \cos \theta_d = 1000 \text{ W/m}^2 \times \cos 20^\circ = 940 \text{ W/m}^2. \quad \leftarrow$$

(c) Using the IHT workspace with Eq. (4),  $G$  is computed and plotted as a function of  $L$  for selected  $\theta_d$ . Note that  $G$  decreases inversely as  $L^2$ . As expected,  $G$  decreases with increasing  $\theta_d$  and in the limit, approaches zero as  $\theta_d$  approaches  $90^\circ$ .

### PROBLEM 12.8

**KNOWN:** Radiation from a diffuse radiant source  $A_1$  with intensity  $I_1 = 1.2 \times 10^5 \text{ W/m}^2 \cdot \text{sr}$  is incident on a mirror  $A_m$ , which reflects radiation onto the radiation detector  $A_2$ .

**FIND:** (a) Radiant power incident on  $A_m$  due to emission from the source,  $A_1$ ,  $q_{1 \rightarrow m}$  (mW), (b) Intensity of radiant power leaving the perfectly reflecting, diffuse mirror  $A_m$ ,  $I_m$  ( $\text{W/m}^2 \cdot \text{sr}$ ), and (c) Radiant power incident on the detector  $A_2$  due to the reflected radiation leaving  $A_m$ ,  $q_{m \rightarrow 2}$  ( $\mu\text{W}$ ), (d) Plot the radiant power  $q_{m \rightarrow 2}$  as a function of the lateral separation distance  $y_o$  for the range  $0 \leq y_o \leq 0.2 \text{ m}$ ; explain features of the resulting curve.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Surface  $A_1$  emits diffusely, (2) Surface  $A_m$  does not emit, but reflects perfectly and diffusely, and (3) Surface areas are much smaller than the square of their separation distances.

**ANALYSIS:** (a) The radiant power leaving  $A_1$  that is incident on  $A_m$  is

$$q_{1 \rightarrow m} = I_1 \cdot A_1 \cdot \cos \theta_1 \cdot \Delta \omega_{m-1}$$

where  $\omega_{m-1}$  is the solid angle  $A_m$  subtends with respect to  $A_1$ , Eq. 12.7,

$$\Delta \omega_{m-1} \equiv \frac{dA_n}{r^2} = \frac{A_m \cos \theta_m}{x_o^2 + y_o^2} = \frac{2 \times 10^{-4} \text{ m}^2 \cdot \cos 45^\circ}{[0.1^2 + 0.1^2] \text{ m}^2} = 7.07 \times 10^{-3} \text{ sr}$$

with  $\theta_m = 90^\circ - \theta_1$  and  $\theta_1 = 45^\circ$ ,

$$q_{1 \rightarrow m} = 1.2 \times 10^5 \text{ W/m}^2 \cdot \text{sr} \times 1 \times 10^{-4} \text{ m}^2 \times \cos 45^\circ \times 7.07 \times 10^{-3} \text{ sr} = 60 \text{ mW} \quad <$$

(b) The intensity of radiation leaving  $A_m$ , after perfect and diffuse reflection, is

$$I_m = (q_{1 \rightarrow m} / A_m) / \pi = \frac{60 \times 10^{-3} \text{ W}}{\pi \times 2 \times 10^{-4} \text{ m}^2} = 95.5 \text{ W/m}^2 \cdot \text{sr}$$

(c) The radiant power leaving  $A_m$  due to reflected radiation leaving  $A_m$  is

$$q_{m \rightarrow 2} = q_2 = I_m \cdot A_m \cdot \cos \theta_m \cdot \Delta \omega_{2-m}$$

where  $\Delta \omega_{2-m}$  is the solid angle that  $A_2$  subtends with respect to  $A_m$ , Eq. 12.7,

Continued ...

**PROBLEM 12.8 (Cont.)**

$$\Delta\omega_{2-m} \equiv \frac{dA_n}{r^2} = \frac{A_2 \cos \theta_2}{(L_o - x_o)^2 + y_o^2} = \frac{1 \times 10^{-4} \text{ m}^2 \times \cos 45^\circ}{\left[0.1^2 + 0.1^2\right] \text{ m}^2} = 3.54 \times 10^{-3} \text{ sr}$$

with  $\theta_2 = 90^\circ - \theta_m$

$$q_{m \rightarrow 2} = q_2 = 95.5 \text{ W/m}^2 \cdot \text{sr} \times 2 \times 10^{-4} \text{ m}^2 \times \cos 45^\circ \times 3.54 \times 10^{-3} \text{ sr} = 47.8 \text{ } \mu\text{W} \quad <$$

(d) Using the foregoing equations in the *IHT* workspace,  $q_2$  is calculated and plotted as a function of  $y_o$  for the range  $0 \leq y_o \leq 0.2$  m.

From the relations, note that  $q_2$  is dependent upon the geometric arrangement of the surfaces in the following manner. For small values of  $y_o$ , that is, when  $\theta_1 \approx 0^\circ$ , the  $\cos \theta_1$  term is at a maximum, near unity. But, the solid angles  $\Delta\omega_{m-1}$  and  $\Delta\omega_{2-m}$  are very small. As  $y_o$  increases, the  $\cos \theta_1$  term doesn't diminish as much as the solid angles increase, causing  $q_2$  to increase. A maximum in the power is reached as the  $\cos \theta_1$  term decreases and the solid angles increase. The maximum radiant power occurs when  $y_o = 0.058$  m which corresponds to  $\theta_1 = 30^\circ$ .

### PROBLEM 12.9

**KNOWN:** Flux and intensity of direct and diffuse components, respectively, of solar irradiation.

**FIND:** Total irradiation.

**SCHEMATIC:**

**ANALYSIS:** Since the irradiation is based on the actual surface area, the contribution due to the direct solar radiation is

$$G_{\text{dir}} = q''_{\text{dir}} \cdot \cos \theta.$$

From Eq. 12.17 the contribution due to the diffuse radiation is

$$G_{\text{dif}} = \pi I_{\text{dif}}.$$

Hence

$$G = G_{\text{dir}} + G_{\text{dif}} = q''_{\text{dir}} \cdot \cos \theta + \pi I_{\text{dif}}$$

or

$$G = 1000 \text{ W/m}^2 \times 0.866 + \pi \text{ sr} \times 70 \text{ W/m}^2 \cdot \text{sr}$$

$$G = (866 + 220) \text{ W/m}^2$$

or

$$G = 1086 \text{ W/m}^2.$$

<

**COMMENTS:** Although a diffuse approximation is often made for the non-direct component of solar radiation, the actual directional distribution deviates from this condition, providing larger intensities at angles close to the direct beam.

## PROBLEM 12.10

**KNOWN:** Daytime solar radiation conditions with direct solar intensity  $I_{\text{dir}} = 2.10 \times 10^7 \text{ W/m}^2 \cdot \text{sr}$  within the solid angle subtended with respect to the earth,  $\Delta\omega_{\text{S}} = 6.74 \times 10^{-5} \text{ sr}$ , and diffuse intensity  $I_{\text{dif}} = 70 \text{ W/m}^2 \cdot \text{sr}$ .

**FIND:** (a) Total solar irradiation at the earth's surface when the direct radiation is incident at  $30^\circ$ , and (b) Verify the prescribed value of  $\Delta\omega_{\text{S}}$  recognizing that the diameter of the earth is  $D_{\text{S}} = 1.39 \times 10^9 \text{ m}$ , and the distance between the sun and the earth is  $r_{\text{e-S}} = 1.496 \times 10^{11} \text{ m}$  (1 astronomical unit).

**SCHEMATIC:**

**ANALYSIS:** (a) From Eq. 12.22 the diffuse irradiation is

$$G_{\text{dif}} = \pi I_{\text{dif}} = \pi \text{ sr} \times 70 \text{ W/m}^2 \cdot \text{sr} = 220 \text{ W/m}^2$$

The direct irradiation follows from Eq. 12.18, expressed in terms of the solid angle

$$G_{\text{dir}} = I_{\text{dir}} \cos \theta \Delta\omega_{\text{S}}$$

$$G_{\text{dir}} = 2.10 \times 10^7 \text{ W/m}^2 \cdot \text{sr} \times \cos 30^\circ \times 6.74 \times 10^{-5} \text{ sr} = 1226 \text{ W/m}^2$$

The total solar irradiation is the sum of the diffuse and direct components,

$$G_{\text{S}} = G_{\text{dif}} + G_{\text{dir}} = (220 + 1226) \text{ W/m}^2 = 1446 \text{ W/m}^2 \quad <$$

(b) The solid angle the sun subtends with respect to the earth is calculated from Eq. 12.7,

$$\Delta\omega_{\text{S}} = \frac{dA_{\text{n}}}{r^2} = \frac{\pi D_{\text{S}}^2 / 4}{r_{\text{e-S}}^2} = \frac{\pi (1.39 \times 10^9 \text{ m})^2 / 4}{(1.496 \times 10^{11} \text{ m})^2} = 6.74 \times 10^{-5} \text{ sr} \quad <$$

where  $dA_{\text{n}}$  is the projected area of the sun and  $r_{\text{e-S}}$ , the distance between the earth and sun. We are assuming that  $r_{\text{e-S}}^2 \gg D_{\text{S}}^2$ .

**COMMENTS:** Can you verify that the direct solar intensity,  $I_{\text{dir}}$ , is a reasonable value, assuming that the solar disk emits as a black body at 5800 K?  $(I_{\text{b,S}} = \sigma T_{\text{S}}^4 / \pi = \sigma (5800 \text{ K})^4 / \pi = 2.04 \times 10^7 \text{ W/m}^2 \cdot \text{sr})$ . Because of local cloud formations, it is possible to have an appreciable diffuse component. But it is not likely to have such a high direct component as given in the problem statement.

### PROBLEM 12.11

**KNOWN:** Directional distribution of solar radiation intensity incident at earth's surface on an overcast day.

**FIND:** Solar irradiation at earth's surface.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Intensity is independent of azimuthal angle  $\theta$ .

**ANALYSIS:** Applying Eq. 12.18 to the total intensity

$$G = \int_0^{2\pi} \int_0^{\pi/2} I_i(\theta) \cos \theta \sin \theta \, d\theta \, d\phi$$

$$G = 2\pi I_n \int_0^{\pi/2} \cos^2 \theta \sin \theta \, d\theta$$

$$G = (2\pi \text{ sr}) \times 80 \text{ W/m}^2 \cdot \text{sr} \left( -\frac{1}{3} \cos^3 \theta \right) \Big|_0^{\pi/2}$$

$$G = -167.6 \text{ W/m}^2 \cdot \text{sr} \left( \cos^3 \frac{\pi}{2} - \cos^3 0 \right)$$

$$G = 167.6 \text{ W/m}^2.$$

<

## PROBLEM 12.12

**KNOWN:** Hemispherical and spherical arrangements for radiant heat treatment of a thin-film material. Heater emits diffusely with intensity  $I_{e,h} = 169,000 \text{ W/m}^2 \cdot \text{sr}$  and has an area  $0.0052 \text{ m}^2$ .

**FIND:** (a) Expressions for the irradiation on the film as a function of the zenith angle,  $\theta$ , and (b) Identify arrangement which provides the more uniform irradiation, and hence better quality control for the treatment process.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Heater emits diffusely, (2) All radiation leaving the heater is absorbed by the thin film.

**ANALYSIS:** (a) The irradiation on any differential area,  $dA_s$ , due to emission from the heater,  $A_h$ , follows from its definition, Section 12.3.3,

$$G = \frac{q_{h \rightarrow s}}{dA_s} \quad (1)$$

Where  $q_{h \rightarrow s}$  is the radiant heat rate leaving  $A_h$  and intercepted by  $dA_s$ . From Eq. 12.12,

$$q_{h \rightarrow s} = I_{e,h} \cdot dA_h \cos \theta_h \cdot \omega_{s-h} \quad (2)$$

where  $\omega_{s-h}$  is the solid angle  $dA_s$  subtends with respect to any point on  $A_h$ . From the definition, Eq. 12.7,

$$\omega = \frac{dA_n}{r^2} \quad (3)$$

where  $dA_n$  is normal to the viewing direction and  $r$  is the separation distance.

*For the hemisphere:* Referring to the schematic above, the solid angle is

$$\omega_{s-h} = \frac{dA_s}{R^2}$$

and the irradiation distribution on the hemispheric surface as a function of  $\theta_h$  is

$$G = I_{e,h} A_h \cos \theta_h / R^2 \quad (1) <$$

*For the sphere:* From the schematic, the solid angle is

$$\omega_{s,h} = \frac{dA_s \cos \theta_s}{R_o^2} = \frac{dA_s}{4R^2 \cos \theta_h}$$

where  $R_o$ , from the geometry of sphere cord and radii with  $\theta_s = \theta_h$ , is

Continued...

### PROBLEM 12.12 (Cont.)

$$R_o = 2R \cos \theta_h$$

and the irradiation distribution on the spherical surface as a function of  $\theta_h$  is

$$G = I_{e,h} d A_h / 4R^2 \quad (2) <$$

(b) The spherical shape provides more uniform irradiation as can be seen by comparing Eqs. (1) and (2). In fact, for the spherical shape, the irradiation on the thin film is uniform and therefore provides for better quality control for the treatment process. Substituting numerical values, the irradiations are:

$$G_{\text{hem}} = 169,000 \text{ W/m}^2 \cdot \text{sr} \times 0.0052 \text{ m}^2 \cos \theta_h / (2\text{m})^2 = 219.7 \cos \theta_h \text{ W/m}^2 \quad (3)$$

$$G_{\text{sph}} = 169,000 \text{ W/m}^2 \cdot \text{sr} \times 0.0052 \text{ m}^2 / 4(2\text{m})^2 = 54.9 \text{ W/m}^2 \quad (4)$$

**COMMENTS:** (1) The radiant heat rate leaving the diffuse heater surface by emission is

$$q_{\text{tot}} = \pi I_{e,h} A_h = 2761 \text{ W}$$

The average irradiation on the *spherical surface*,  $A_{\text{sph}} = 4\pi R^2$ ,

$$\bar{G}_{\text{sph}} = q_{\text{tot}} / A_{\text{sph}} = 2761 \text{ W} / 4\pi (2\text{m})^2 = 54.9 \text{ W/m}^2$$

while the average irradiation on the *hemispherical surface*,  $A_{\text{hem}} = 2\pi R^2$  is

$$\bar{G}_{\text{hem}} = 2761 \text{ W} / 2\pi (2\text{m})^2 = 109.9 \text{ W/m}^2$$

(2) Note from the foregoing analyses for the *sphere* that the result for  $\bar{G}_{\text{sph}}$  is identical to that found as Eq. (4). That follows since the irradiation is uniform.

(3) Note that  $\bar{G}_{\text{hem}} > \bar{G}_{\text{sph}}$  since the surface area of the hemisphere is half that of the sphere.

Recognize that for the hemisphere thin film arrangement, the distribution of the irradiation is quite variable with a maximum at  $\theta = 0^\circ$  (top) and half the maximum value at  $\theta = 30^\circ$ .

### PROBLEM 12.13

**KNOWN:** Hot part,  $\Delta A_p$ , located a distance  $x_1$  from an origin directly beneath a motion sensor at a distance  $L_d = 1$  m.

**FIND:** (a) Location  $x_1$  at which sensor signal  $S_1$  will be 75% that corresponding to  $x = 0$ , directly beneath the sensor,  $S_o$ , and (b) Compute and plot the signal ratio,  $S/S_o$ , as a function of the part position  $x_1$  for the range  $0.2 \leq S/S_o \leq 1$  for  $L_d = 0.8, 1.0$  and  $1.2$  m; compare the  $x$ -location for each value of  $L_d$  at which  $S/S_o = 0.75$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Hot part is diffuse emitter, (2)  $L_d^2 \gg \Delta A_p, \Delta A_o$ .

**ANALYSIS:** (a) The sensor signal,  $S$ , is proportional to the radiant power leaving  $\Delta A_p$  and intercepted by  $\Delta A_d$ ,

$$S \sim q_{p \rightarrow d} = I_{p,e} \Delta A_p \cos \theta_p \Delta \omega_{d-p} \quad (1)$$

when

$$\cos \theta_p = \cos \theta_d = \frac{L_d}{R} = L_d / (L_d^2 + x_1^2)^{1/2} \quad (2)$$

$$\Delta \omega_{d-p} = \frac{\Delta A_d \cdot \cos \theta_d}{R^2} = \Delta A_d \cdot L_d / (L_d^2 + x_1^2)^{3/2} \quad (3)$$

Hence,

$$q_{p \rightarrow d} = I_{p,e} \Delta A_p \Delta A_d \frac{L_d^2}{(L_d^2 + x_1^2)^2} \quad (4)$$

It follows that, with  $S_o$  occurring when  $x = 0$  and  $L_d = 1$  m,

$$\frac{S}{S_o} = \frac{L_d^2 / (L_d^2 + x_1^2)^2}{L_d^2 / (L_d^2 + 0^2)^2} = \left[ \frac{L_d^2}{L_d^2 + x_1^2} \right]^2 \quad (5)$$

so that when  $S/S_o = 0.75$ , find,

$$x_1 = 0.393 \text{ m} \quad \leftarrow$$

(b) Using Eq. (5) in the IHT workspace, the signal ratio,  $S/S_o$ , has been computed and plotted as a function of the part position  $x$  for selected  $L_d$  values.

Continued...

**PROBLEM 12.13 (Cont.)**

When the part is directly under the sensor,  $x = 0$ ,  $S/S_o = 1$  for all values of  $L_d$ . With increasing  $x$ ,  $S/S_o$  decreases most rapidly with the smallest  $L_d$ . From the IHT model we found the part position  $x$  corresponding to  $S/S_o = 0.75$  as follows.

$S/S_o$	$L_d$ (m)	$x_1$ (m)
0.75	0.8	0.315
0.75	1.0	0.393
0.75	1.2	0.472

If the sensor system is set so that when  $S/S_o$  reaches 0.75 a process is initiated, the technician can use the above plot and table to determine at what position the part will begin to experience the treatment process.

## PROBLEM 12.14

**KNOWN:** Surface area, and emission from area  $A_1$ . Size and orientation of area  $A_2$ .

**FIND:** (a) Irradiation of  $A_2$  by  $A_1$  for  $L_1 = 1$  m,  $L_2 = 0.5$  m, (b) Irradiation of  $A_2$  over the range  $0 \leq L_2 \leq 10$  m.

**SCHEMATIC:**

**ASSUMPTIONS:** Diffuse emission.

**ANALYSIS:** (a) The irradiation of Surface 1 is  $G_{1-2} = q_{1-2}/A_2$  and from Example 12.1,

$$q_{1-2} = I_1 A_1 \cos \theta_1 \omega_{2-1} = I_1 A_1 \cos \theta_1 A_2 \cos \theta_2 / r^2$$

Since  $\theta_1 = \theta_2 = \theta = \tan^{-1}(L_1/L_2) = \tan^{-1}(1/0.5) = 63.43^\circ$  and  $r^2 = L_1^2 + L_2^2 = (1\text{m})^2 + (0.5\text{m})^2 = 1.25 \text{ m}^2$ ,

$$G_{1-2} = I_1 A_1 \cos^2 \theta / r^2 = 1000 \text{ W/m}^2 \cdot \text{sr} \times 2 \times 10^{-4} \text{ m}^2 \times \cos^2(63.43^\circ) / 1.25 \text{ m}^2 = 0.032 \text{ W/m}^2 \quad \leftarrow$$

(b) The preceding equations may be solved for various values of  $L_2$ . The irradiation over the range  $0 \leq L_2 \leq 10$  m is shown below.

**COMMENTS:** The irradiation is zero for  $L_2 = 0$  and  $L_2 \rightarrow \infty$ .

### PROBLEM 12.15

**KNOWN:** Emissive power of a diffuse surface.

**FIND:** Fraction of emissive power that leaves surface in the directions  $\pi/4 \leq \theta \leq \pi/2$  and  $0 \leq \phi \leq \pi$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Diffuse emitting surface.

**ANALYSIS:** According to Eq. 12.15, the total, hemispherical emissive power is

$$E = \int_0^{\infty} \int_0^{2\pi} \int_0^{\pi/2} I_{\lambda, e}(\lambda, \theta, \phi) \cos \theta \sin \theta \, d\theta \, d\phi \, d\lambda.$$

For a diffuse surface  $I_{\lambda, e}(\lambda, \theta, \phi)$  is independent of direction, and as given by Eq. 12.17,

$$E = \pi I_e.$$

The emissive power, which has directions prescribed by the limits on  $\theta$  and  $\phi$ , is

$$\begin{aligned} \Delta E &= \int_0^{\infty} I_{\lambda, e}(\lambda) \, d\lambda \left[ \int_0^{\pi} d\phi \right] \left[ \int_{\pi/4}^{\pi/2} \cos \theta \sin \theta \, d\theta \right] \\ \Delta E &= I_e [\phi]_0^{\pi} \times \left[ \frac{\sin^2 \theta}{2} \right]_{\pi/4}^{\pi/2} = I_e [\pi] \left[ \frac{1}{2} (1 - 0.707^2) \right] \end{aligned}$$

$$\Delta E = 0.25 \pi I_e.$$

It follows that

$$\frac{\Delta E}{E} = \frac{0.25 \pi I_e}{\pi I_e} = 0.25.$$

<

**COMMENTS:** The diffuse surface is an important concept in radiation heat transfer, and the directional independence of the intensity should be noted.

## PROBLEM 12.16

**KNOWN:** Spectral distribution of  $E_\lambda$  for a diffuse surface.

**FIND:** (a) Total emissive power  $E$ , (b) Total intensity associated with directions  $\theta = 0^\circ$  and  $\theta = 30^\circ$ , and (c) Fraction of emissive power leaving the surface in directions  $\pi/4 \leq \theta \leq \pi/2$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Diffuse emission.

**ANALYSIS:** (a) From Eq. 12.14 it follows that

$$E = \int_0^{\infty} E_\lambda(\lambda) d\lambda = \int_0^5 (0) d\lambda + \int_5^{10} (100) d\lambda + \int_{10}^{15} (200) d\lambda + \int_{15}^{20} (100) d\lambda + \int_{20}^{\infty} (0) d\lambda$$

$$E = 100 \text{ W/m}^2 \cdot \mu\text{m} (10 - 5) \mu\text{m} + 200 \text{ W/m}^2 \cdot \mu\text{m} (15 - 10) \mu\text{m} + 100 \text{ W/m}^2 \cdot \mu\text{m} (20 - 15) \mu\text{m}$$

$$E = 2000 \text{ W/m}^2 \quad <$$

(b) For a diffuse emitter,  $I_e$  is independent of  $\theta$  and Eq. 12.17 gives

$$I_e = \frac{E}{\pi} = \frac{2000 \text{ W/m}^2}{\pi \text{ sr}}$$

$$I_e = 637 \text{ W/m}^2 \cdot \text{sr} \quad <$$

(c) Since the surface is diffuse, use Eqs. 12.13 and 12.17,

$$\frac{E(\pi/4 \rightarrow \pi/2)}{E} = \frac{\int_0^{2\pi} \int_{\pi/4}^{\pi/2} I_e \cos \theta \sin \theta d\theta d\phi}{\pi I_e}$$

$$\frac{E(\pi/4 \rightarrow \pi/2)}{E} = \frac{\int_{\pi/4}^{\pi/2} \cos \theta \sin \theta d\theta \int_0^{2\pi} d\phi}{\pi} = \frac{1}{\pi} \left[ \frac{\sin^2 \theta}{2} \right]_{\pi/4}^{\pi/2} \phi \Big|_0^{2\pi}$$

$$\frac{E(\pi/4 \rightarrow \pi/2)}{E} = \frac{1}{\pi} \left[ \frac{1}{2} (1^2 - 0.707^2) (2\pi - 0) \right] = 0.50 \quad <$$

**COMMENTS:** (1) Note how a spectral integration may be performed in parts.

(2) In performing the integration of part (c), recognize the significance of the diffuse emission assumption for which the intensity is uniform in all directions.

## PROBLEM 12.17

**KNOWN:** Diffuse surface  $\Delta A_o$ , 5-mm square, with total emissive power  $E_o = 4000 \text{ W/m}^2$ .

**FIND:** (a) Rate at which radiant energy is emitted by  $\Delta A_o$ ,  $q_{\text{emit}}$ ; (b) Intensity  $I_{o,e}$  of the radiation field emitted from the surface  $\Delta A_o$ ; (c) Expression for  $q_{\text{emit}}$  presuming knowledge of the intensity  $I_{o,e}$  beginning with Eq. 12.13; (d) Rate at which radiant energy is incident on the hemispherical surface,  $r = R_1 = 0.5 \text{ m}$ , due to emission from  $\Delta A_o$ ; (e) Rate at which radiant energy leaving  $\Delta A_o$  is intercepted by the small area  $\Delta A_2$  located in the direction  $(40^\circ, \phi)$  on the hemispherical surface using Eq. 12.10; also determine the irradiation on  $\Delta A_2$ ; (f) Repeat part (e), for the location  $(0^\circ, \phi)$ ; are the irradiances at the two locations equal? and (g) Irradiation  $G_1$  on the hemispherical surface at  $r = R_1$  using Eq. 12.18.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Diffuse surface,  $\Delta A_o$ , (2) Medium above  $\Delta A_o$  is also non-participating, (3)  $R_1^2 \gg \Delta A_o, \Delta A_2$ .

**ANALYSIS:** (a) The radiant power leaving  $\Delta A_o$  by emission is

$$q_{\text{emit}} = E_o \cdot \Delta A_o = 4000 \text{ W/m}^2 (0.005 \text{ m} \times 0.005 \text{ m}) = 0.10 \text{ W} \quad <$$

(b) The emitted intensity is  $I_{o,e}$  and is independent of direction since  $\Delta A_o$  is a diffuser emitter,

$$I_{o,e} = E_o / \pi = 1273 \text{ W/m}^2 \cdot \text{sr} \quad <$$

The intensities at points  $P_1$  and  $P_2$  are also  $I_{o,e}$  and the intensity in the directions shown in the schematic above will remain constant no matter how far the point is from the surface  $\Delta A_o$  since the space is non-participating.

(c) From knowledge of  $I_{o,e}$ , the radiant power leaving  $\Delta A_o$  from Eq. 12.13 is,

$$q_{\text{emit}} = \int_{\text{h}} I_{o,e} \Delta A_o \cos \theta \sin \theta d\theta d\phi = I_{o,e} \Delta A_o \int_{\phi=0}^{2\pi} \int_{\theta=0}^{\pi/2} \cos \theta \sin \theta d\theta d\phi = \pi I_{o,e} \Delta A_o = 0.10 \text{ W} \quad <$$

(d) Defining control surfaces above  $\Delta A_o$  and on  $A_1$ , the radiant power leaving  $\Delta A_o$  must pass through  $A_1$ . That is,

$$q_{1,\text{inc}} = E_o \Delta A_o = 0.10 \text{ W} \quad <$$

Recognize that the average irradiation on the hemisphere,  $A_1$ , where  $A_1 = 2\pi R_1^2$ , based upon the definition, Section 12.3.3,

$$\bar{G}_1 = q_{1,\text{inc}} / A_1 = E_o \Delta A_o / 2\pi R_1^2 = 63.7 \text{ mW/m}^2$$

where  $q_{1,\text{inc}}$  is the radiant power incident on surface  $A_1$ .

Continued...

**PROBLEM 12.17 (Cont.)**

(e) The radiant power leaving  $\Delta A_o$  intercepted by  $\Delta A_2$ , where  $\Delta A_2 = 4 \times 10^{-6} \text{ m}^2$ , located at  $(\theta = 45^\circ, \phi)$  as per the schematic, follows from Eq. 12.10,

$$q_{\Delta A_o \rightarrow \Delta A_2} = I_{o,e} \Delta A_o \cos \theta_o \Delta \omega_{2-o}$$

where  $\theta_o = 45^\circ$  and the solid angle  $\Delta A_2$  subtends with respect to  $\Delta A_o$  is

$$\Delta \omega_{2-o} = \Delta A_2 \cos \theta_2 / R_1^2 = 4 \times 10^{-6} \text{ m}^2 \cdot 1 / (0.5 \text{ m})^2 = 1.60 \times 10^{-5} \text{ sr}$$

where  $\theta_2 = 0^\circ$ , the direction normal to  $\Delta A_2$ ,

$$q_{\Delta A_o \rightarrow \Delta A_2} = 1273 \text{ W/m}^2 \cdot \text{sr} \times 25 \times 10^{-6} \text{ m}^2 \cos 45^\circ \times 1.60 \times 10^{-5} \text{ sr} = 3.60 \times 10^{-7} \text{ W} \quad <$$

From the definition of irradiation, Section 12.3.3,

$$G_2 = q_{\Delta A_o \rightarrow \Delta A_2} / \Delta A_2 = 90 \text{ mW/m}^2$$

(f) With  $\Delta A_2$ , located at  $(\theta = 0^\circ, \phi)$ , where  $\cos \theta_o = 1$ ,  $\cos \theta_2 = 1$ , find

$$\Delta \omega_{2-o} = 1.60 \times 10^{-5} \text{ sr} \quad q_{\Delta A_o \rightarrow \Delta A_2} = 5.09 \times 10^{-7} \text{ W} \quad G_2 = 127 \text{ mW/m}^2 \quad <$$

Note that the irradiation on  $\Delta A_2$  when it is located at  $(0^\circ, \phi)$  is larger than when  $\Delta A_2$  is located at  $(45^\circ, \phi)$ ; that is,  $127 \text{ mW/m}^2 > 90 \text{ mW/m}^2$ . Is this intuitively satisfying?

(g) Using Eq. 12.18, based upon Figure 12.10, find

$$\bar{G}_1 = \int_h I_{1,i} dA_1 \cdot d\omega_{0-1} / A_1 = \pi I_{o,e} \Delta A_o / \Delta A_1 = 63.7 \text{ mW/m}^2 \quad <$$

where the elemental area on the hemispherical surface  $A_1$  and the solid angle  $\Delta A_o$  subtends with respect to  $\Delta A_1$  are, respectively,

$$dA_1 = R_1^2 \sin \theta d\theta d\phi \quad d\omega_{0-1} = \Delta A_o \cos \theta / R_1^2$$

From this calculation you found that the *average* irradiation on the hemisphere surface,  $r = R_1$ , is  $\bar{G}_1 = 63.7 \text{ mW/m}^2$ . From parts (e) and (f), you found irradiations,  $G_2$  on  $\Delta A_2$  at  $(0^\circ, \phi)$  and  $(45^\circ, \phi)$  as  $127 \text{ mW/m}^2$  and  $90 \text{ mW/m}^2$ , respectively. Did you expect  $\bar{G}_1$  to be less than either value for  $G_2$ ? How do you explain this?

**COMMENTS:** (1) Note that from Parts (e) and (f) that the irradiation on  $A_1$  is not uniform. Parts (d) and (g) give an average value.

(2) What conclusions would you reach regarding  $G_1$  if  $\Delta A_o$  were a sphere?

## PROBLEM 12.18

**KNOWN:** Intensities of radiating various surfaces of known areas.

**FIND:** Surface temperature and emitted energy assuming blackbody behavior.

**SCHEMATIC:**

**ANALYSIS:** For blackbody emission,  $T = \left(\frac{E}{\sigma}\right)^{1/4}$  and  $E = \pi I$ . Therefore,

$$T = \left(\frac{\pi I_e}{\sigma}\right)^{1/4} ; \quad q_e = AE = A\pi I_e \quad (1,2)$$

Equations (1) and (2) may be used to find T and  $q_e$  as follows. <

Problem	$I_e$ (W/m <sup>2</sup> ·sr)	A (m <sup>2</sup> )	T (K)	$q_e$ (W)
Example 12.1	7000	10 <sup>-3</sup>	789	22
Problem 12.8	1.2 × 10 <sup>5</sup>	10 <sup>-4</sup>	1606	37.7
Problem 12.12	169,000	0.0052	1750	2761
Problem 12.14	1000	2 × 10 <sup>-4</sup>	485	0.628

**COMMENTS:** If the surface is not black, the intensity leaving the surface will include a reflected component.

## PROBLEM 12.19

**KNOWN:** Diameter and temperature of burner. Temperature of ambient air. Burner efficiency.

**FIND:** (a) Radiation and convection heat rates, and wavelength corresponding to maximum spectral emission. Rate of electric energy consumption. (b) Effect of burner temperature on convection and radiation rates.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Burner emits as a blackbody, (2) Negligible irradiation of burner from surrounding, (3) Ambient air is quiescent, (4) Constant properties.

**PROPERTIES:** Table A-4, air ( $T_f = 408 \text{ K}$ ):  $k = 0.0344 \text{ W/m}\cdot\text{K}$ ,  $\nu = 27.4 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\alpha = 39.7 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.70$ ,  $\beta = 0.00245 \text{ K}^{-1}$ .

**ANALYSIS:** (a) For emission from a blackbody

$$q_{\text{rad}} = A_s E_b = \left( \pi D^2 / 4 \right) \sigma T^4 = \left[ \pi (0.2\text{m})^2 / 4 \right] 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (523\text{K})^4 = 133 \text{ W} \quad <$$

With  $L = A_s/P = D/4 = 0.05\text{m}$  and  $\text{Ra}_L = g\beta(T_s - T_\infty) L^3 / \alpha\nu = 9.8 \text{ m/s}^2 \times 0.00245 \text{ K}^{-1} (230 \text{ K}) (0.05\text{m})^3 / (27.4 \times 39.7 \times 10^{-12} \text{ m}^4/\text{s}^2) = 6.35 \times 10^5$ , Eq. 9.30 yields

$$\bar{h} = \frac{k}{L} \overline{\text{Nu}}_L = \left( \frac{k}{L} \right) 0.54 \text{ Ra}_L^{1/4} = \left( \frac{0.0344 \text{ W/m}\cdot\text{K}}{0.05\text{m}} \right) 0.54 (6.35 \times 10^5)^{1/4} = 10.5 \text{ W/m}^2 \cdot \text{K}$$

$$q_{\text{conv}} = \bar{h} A_s (T_s - T_\infty) = 10.5 \text{ W/m}^2 \cdot \text{K} \left[ \pi (0.2\text{m})^2 / 4 \right] 230 \text{ K} = 75.7 \text{ W} \quad <$$

The electric power requirement is then

$$P_{\text{elec}} = \frac{q_{\text{rad}} + q_{\text{conv}}}{\eta} = \frac{(133 + 75.7) \text{ W}}{0.9} = 232 \text{ W} \quad <$$

The wavelength corresponding to peak emission is obtained from Wien's displacement law, Eq. 12.31

$$\lambda_{\text{max}} = 2898 \mu\text{m} \cdot \text{K} / 523\text{K} = 5.54 \mu\text{m} \quad <$$

(b) As shown below, and as expected, the radiation rate increases more rapidly with temperature than the convection rate due to its stronger temperature dependence ( $T_s^4$  vs.  $T_s^{5/4}$ ).

Continued ...

### PROBLEM 12.19 (Cont.)

**COMMENTS:** If the surroundings are treated as a large enclosure with isothermal walls at  $T_{\text{sur}} = T_{\infty} = 293 \text{ K}$ , irradiation of the burner would be  $G = \sigma T_{\text{sur}}^4 = 418 \text{ W/m}^2$  and the corresponding heat rate would be  $A_s G = 13 \text{ W}$ . This input is much smaller than the energy outflows due to convection and radiation and is justifiably neglected.

## PROBLEM 12.20

**KNOWN:** Solar flux at outer edge of earth's atmosphere,  $1368 \text{ W/m}^2$ .

**FIND:** (a) Emissive power of sun, (b) Surface temperature of sun, (c) Wavelength of maximum solar emission, (d) Earth equilibrium temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Sun and earth emit as blackbodies, (2) No attenuation of solar radiation enroute to earth, (3) Earth atmosphere has no effect on earth energy balance.

**ANALYSIS:** (a) Applying conservation of energy to the solar energy crossing two concentric spheres, one having the radius of the sun and the other having the radial distance from the edge of the earth's atmosphere to the center of the sun

$$E_s \left( \pi D_s^2 \right) = 4\pi \left( R_{s-e} - \frac{D_e}{2} \right)^2 q''_s.$$

Hence

$$E_s = \frac{4 \left( 1.5 \times 10^{11} \text{ m} - 0.65 \times 10^7 \text{ m} \right)^2 \times 1368 \text{ W/m}^2}{\left( 1.39 \times 10^9 \text{ m} \right)^2} = 6.37 \times 10^7 \text{ W/m}^2. \quad <$$

(b) From Eq. 12.32, the temperature of the sun is

$$T_s = \left( \frac{E_s}{\sigma} \right)^{1/4} = \left( \frac{6.37 \times 10^7 \text{ W/m}^2}{5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4} \right)^{1/4} = 5790 \text{ K}. \quad <$$

(c) From Wien's displacement law, Eq. 12.25, the wavelength of maximum emission is

$$\lambda_{\max} = \frac{C_3}{T} = \frac{2898 \mu\text{m} \cdot \text{K}}{5790 \text{ K}} = 0.50 \mu\text{m}.$$

(d) From an energy balance on the earth's surface

$$E_e \left( \pi D_e^2 \right) = q''_S \left( \pi D_e^2 / 4 \right).$$

Hence, from Eq. 12.26,

$$T_e = \left( \frac{q''_S}{4\sigma} \right)^{1/4} = \left( \frac{1368 \text{ W/m}^2}{4 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4} \right)^{1/4} = 279 \text{ K}. \quad <$$

**COMMENTS:** The average earth temperature is higher than 279 K due to the shielding effect of the earth's atmosphere (transparent to solar radiation but not to longer wavelength earth emission).

## PROBLEM 12.21

**KNOWN:** Small flat plate positioned just beyond the earth's atmosphere oriented such that its normal passes through the center of the sun. Pertinent earth-sun dimensions from Problem 12.20.

**FIND:** (a) Solid angle subtended by the sun about a point on the surface of the plate, (b) Incident intensity,  $I_i$ , on the plate using the known value of the solar irradiation about the earth's atmosphere,  $G_S = 1368 \text{ W/m}^2$ , and (c) Sketch of the incident intensity as a function of the zenith angle  $\theta$ , where  $\theta$  is measured from the normal to the plate.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Plate oriented normal to centerline between sun and earth, (2) Height of earth's atmosphere negligible compared to distance from the sun to the plate, (3) Dimensions of the plate are very small compared to sun-earth dimensions.

**ANALYSIS:** (a) The pertinent sun-earth dimensions are shown in the schematic (a) above while the position of the plate relative to the sun and the earth is shown in (b). The solid angle subtended by the sun with respect to any point on the plate follows from Eq. 12.7,

$$\omega_{S-p} = \frac{A_S \cos \theta_p}{L_{S,p}^2} = \frac{\left(\frac{\pi D_S^2}{4}\right) \cos \theta_p}{(R_{S,e})^2} = \frac{\pi (1.39 \times 10^9 \text{ m})^2 / 4 \times 1}{(1.5 \times 10^{11} \text{ m})^2} = 6.74 \times 10^{-5} \text{ sr} \quad (1) <$$

where  $A_S$  is the projected area of the sun (the solar disk),  $\theta_p$  is the zenith angle measured between the plate normal and the centerline between the sun and earth, and  $L_{S,p}$  is the separation distance between the plate at the sun's center.

(b) The plate is irradiated by solar flux in the normal direction only (not diffusely). Using Eq. 12.18, the radiant power incident on the plate can be expressed as

$$G_S \Delta A_p = I_i \cdot \Delta A_p \cos \theta_p \cdot \omega_{S-p} \quad (2)$$

and the intensity  $I_i$  due to the solar irradiation  $G_S$  with  $\cos \theta_p = 1$ ,

$$I_i = G_S / \omega_{S-p} = 1368 \text{ W/m}^2 / 6.74 \times 10^{-5} \text{ sr} = 2.03 \times 10^7 \text{ W/m}^2 \cdot \text{sr} \quad <$$

(c) As illustrated in the schematic to the right, the intensity  $I_i$  will be constant for the zenith angle range  $0 \leq \theta_p \leq \theta_{p,o}$  where

$$\theta_{p,o} = \frac{D_S/2}{L_{S,p}} = \frac{1.39 \times 10^9 \text{ m}/2}{1.5 \times 10^{11} \text{ m}}$$

$$\theta_{p,o} = 4.633 \times 10^{-3} \text{ rad} \approx 0.27^\circ$$

For the range  $\theta_p > \theta_{p,o}$ , the intensity will be zero. Hence the  $I_i$  as a function of  $\theta_p$  will appear as shown to the right.

## PROBLEM 12.22

**KNOWN:** Evacuated, aluminum sphere ( $D = 2\text{m}$ ) serving as a radiation test chamber.

**FIND:** Irradiation on a small test object when the inner surface is lined with carbon black and at  $600\text{K}$ . What effect will surface coating have?

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Sphere walls are isothermal, (2) Test surface area is small compared to the enclosure surface.

**ANALYSIS:** It follows from the discussion of Section 12.4 that this isothermal sphere is an enclosure behaving as a blackbody. For such a condition, see Fig. 12.11(c), the irradiation on a small surface within the enclosure is equal to the blackbody emissive power at the temperature of the enclosure. That is

$$G_1 = E_b(T_s) = \sigma T_s^4$$

$$G_1 = 5.67 \times 10^{-8} \text{W/m}^2 \cdot \text{K}^4 (600\text{K})^4 = 7348 \text{W/m}^2.$$

<

The irradiation is independent of the nature of the enclosure surface coating properties.

**COMMENTS:** (1) The irradiation depends only upon the enclosure surface temperature and is independent of the enclosure surface properties. (2) Note that the test surface area must be small compared to the enclosure surface area. This allows for inter-reflections to occur such that the radiation field, within the enclosure will be uniform (diffuse) or isotropic. (3) The irradiation level would be the same if the enclosure were not evacuated since, in general, air would be a non-participating medium.

## PROBLEM 12.23

**KNOWN:** Diameter of spherical fuel pellet. Pellet emissivity and absorptivity. Laser power and number of lasers. Laser entrance hole diameters.

**FIND:** (a) Maximum fuel temperature for direct laser irradiation. (b) Maximum fuel temperature for irradiation using the enclosure.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady state conditions. (2) Negligible irradiation from surroundings. (3) Uniform temperature inside enclosure. (4) Enclosure behaves as a blackbody. (5) Negligible heat loss through enclosure walls.

**PROPERTIES:** Given:  $\varepsilon = 0.8$ ,  $\alpha = 0.3$ .

**ANALYSIS:**

(a) An energy balance on the spherical pellet yields

$$\dot{E}_{in} = \dot{E}_{out} = \alpha NP = (\pi D_p^2) \varepsilon \sigma T_p^4$$

or

$$T_p = \left( \frac{\alpha NP}{\varepsilon \sigma \pi D_p^2} \right)^{1/4} = \left( \frac{0.3 \times 200 \times 500 \text{ W}}{0.8 \times 5.67 \times 10^{-8} \text{ W/m}^2 \text{K}^4 \times \pi \times (1.8 \times 10^{-3} \text{ m})^2} \right)^{1/4} = 15,970 \text{ K} \quad <$$

(b) An energy balance on the enclosure yields

$$\dot{E}_{in} = \dot{E}_{out} = NP = 2 \left( \pi D_{LEH}^2 / 4 \right) \sigma T_e^4$$

or

$$T_e = \left( \frac{2NP}{\sigma \pi D_{LEH}^2} \right)^{1/4} = \left( \frac{2 \times 200 \times 500 \text{ W}}{5.67 \times 10^{-8} \text{ W/m}^2 \text{K}^4 \times \pi \times (2.0 \times 10^{-3} \text{ m})^2} \right)^{1/4} = 23,020 \text{ K}$$

Since the enclosure temperature is assumed to be uniform,  $T_p = T_e = 23,020 \text{ K}$  <

**COMMENTS:** (1) The temperature of the pellet is increased by 44% by placing it in the enclosure. (2) The actual maximum temperature of the pellet in the enclosure can be much less than calculated if the area of the laser entrance holes is not small relative to the interior area of the enclosure. (3) The temperatures are extremely high, as required. (4) This problem is motivated by the U.S. National Ignition Facility at the Lawrence Livermore National Laboratory. The lasers used to heat the 1.8 mm diameter pellet occupy a facility that is 10 stories tall with a footprint the size of three football fields.

### PROBLEM 12.24

**KNOWN:** Isothermal enclosure of surface area,  $A_s$ , and small opening,  $A_o$ , through which 70W emerges.

**FIND:** (a) Temperature of the interior enclosure wall if the surface is black, (b) Temperature of the wall surface having  $\epsilon = 0.15$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Enclosure is isothermal, (2)  $A_o \ll A_s$ .

**ANALYSIS:** A characteristic of an isothermal enclosure, according to Section 12.4, is that the radiant power emerging through a small aperture will correspond to blackbody conditions. Hence

$$q_{\text{rad}} = A_o E_b(T_s) = A_o \sigma T_s^4$$

where  $q_{\text{rad}}$  is the radiant power leaving the enclosure opening. That is,

$$T_s = \left( \frac{q_{\text{rad}}}{A_o \sigma} \right)^{1/4} = \left( \frac{70\text{W}}{0.02\text{m}^2 \times 5.670 \times 10^{-8} \text{W/m}^2 \cdot \text{K}^4} \right)^{1/4} = 498\text{K.} \quad <$$

Recognize that the radiated power will be independent of the emissivity of the wall surface. As long as  $A_o \ll A_s$  and the enclosure is isothermal, then the radiant power will depend only upon the temperature.

**COMMENTS:** It is important to recognize the unique characteristics of isothermal enclosures. See Fig. 12.11 to identify them.

### PROBLEM 12.25

**KNOWN:** Sun has equivalent blackbody temperature of 5800 K. Diameters of sun and earth as well as separation distance are prescribed.

**FIND:** Temperature of the earth assuming the earth is black.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Sun and earth emit as blackbodies, (2) No attenuation of solar irradiation enroute to earth, and (3) Earth atmosphere has no effect on earth energy balance.

**ANALYSIS:** Performing an energy balance on the earth,

$$\begin{aligned} \dot{E}_{in} - \dot{E}_{out} &= 0 \\ A_{e,p} \cdot G_S &= A_{e,s} \cdot E_b(T_e) \\ \left(\pi D_e^2 / 4\right) G_S &= \pi D_e^2 \sigma T_e^4 \\ T_e &= (G_S / 4\sigma)^{1/4} \end{aligned}$$

where  $A_{e,p}$  and  $A_{e,s}$  are the projected area and total surface area of the earth, respectively. To determine the irradiation  $G_S$  at the earth's surface, equate the rate of emission from the sun to the rate at which this radiation passes through a spherical surface of radius  $R_{S,e} - D_e/2$ .

$$\begin{aligned} \dot{E}_{in} - \dot{E}_{out} &= 0 \\ \pi D_S^2 \cdot \sigma T_S^4 &= 4\pi [R_{S,e} - D_e/2]^2 G_S \\ \pi (1.39 \times 10^9 \text{ m})^2 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (5800 \text{ K})^4 &= 4\pi [1.5 \times 10^{11} - 1.27 \times 10^7 / 2]^2 \text{ m}^2 \times G_S \\ G_S &= 1377.5 \text{ W/m}^2. \end{aligned}$$

Substituting numerical values, find

$$T_e = \left(1377.5 \text{ W/m}^2 / 4 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4\right)^{1/4} = 279 \text{ K.} \quad <$$

**COMMENTS:** (1) The average earth's temperature is greater than 279 K since the effect of the atmosphere is to reduce the heat loss by radiation.

(2) Note carefully the different areas used in the earth energy balance. Emission occurs from the total spherical area, while solar irradiation is absorbed by the projected spherical area.

## PROBLEM 12.26

**KNOWN:** Solar power concentrated into cavity, energy storage rate for salt, salt temperature, cavity opening diameter.

**FIND:** Thermal energy delivered to the Rankine cycle.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Temperatures are not changing with time. (2) Negligible irradiation from surroundings and convective losses. (3) Cavity opening area is small relative to cavity surface area.

**ANALYSIS:**

(a) An energy balance on the control volume shown in the schematic yields

$$q_R = q_{sol} - \dot{E}_{st} - q_{loss}$$

where the heat loss through the cavity opening is

$$q_{loss} = \frac{\pi D_s^2}{4} \sigma T_{salt}^4 = \frac{\pi (1 \text{ m})^2}{4} \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times (1000 + 273 \text{ K})^4 = 117,000 \text{ W} = 0.12 \text{ MW}$$

Hence the heat transfer to the Rankine cycle is

$$q_R = 7.50 - 3.45 - 0.12 = 3.93 \text{ MW}$$

<

**COMMENTS:** (1) The radiation heat loss through the cavity opening is relatively small, but could be reduced further by decreasing the size of the cavity opening. Reducing the size of the opening would require more expensive heliostats and mirrors in order to more precisely direct the concentrated solar irradiation into the cavity. (2) Convection losses through the cavity opening may be large, necessitating placement of a radiatively-transparent window over the cavity opening.

## PROBLEM 12.27

**KNOWN:** Spectral distribution of the emissive power given by Planck's distribution.

**FIND:** Approximations to the Planck distribution for the extreme cases when (a)  $C_2/\lambda T \gg 1$ , Wien's law and (b)  $C_2/\lambda T \ll 1$ , Rayleigh-Jeans law.

**ANALYSIS:** Planck's distribution provides the spectral, hemispherical emissive power of a blackbody as a function of wavelength and temperature, Eq. 12.30,

$$E_{\lambda,b}(\lambda, T) = C_1 / \lambda^5 [\exp(C_2 / \lambda T) - 1].$$

We now consider the extreme cases of  $C_2/\lambda T \gg 1$  and  $C_2/\lambda T \ll 1$ .

(a) When  $C_2/\lambda T \gg 1$  (or  $\lambda T \ll C_2$ ), it follows  $\exp(C_2/\lambda T) \gg 1$ . Hence, the  $-1$  term in the denominator of the Planck distribution is insignificant, giving

$$E_{\lambda,b}(\lambda, T) \approx (C_1 / \lambda^5) \exp(-C_2 / \lambda T). \quad <$$

This approximate relation is known as *Wien's law*. The ratio of the emissive power by Wien's law to that by the Planck law is,

$$\frac{E_{\lambda,b,Wien}}{E_{\lambda,b,Planck}} = \frac{1/\exp(C_2 / \lambda T)}{1/[\exp(C_2 / \lambda T) - 1]}.$$

For the condition  $\lambda T = \lambda_{max} T = 2898 \mu\text{m}\cdot\text{K}$ ,  $C_2/\lambda T = \frac{14388 \mu\text{m}\cdot\text{K}}{2898 \mu\text{m}\cdot\text{K}} = 4.966$  and

$$\frac{E_{\lambda,b}|_{Wien}}{E_{\lambda,b}|_{Planck}} = \frac{1/\exp(4.966)}{1/[\exp(4.966) - 1]} = 0.9930. \quad <$$

That is, for  $\lambda T \leq 2898 \mu\text{m}\cdot\text{K}$ , Wien's law is a good approximation to the Planck distribution.

(b) If  $C_2/\lambda T \ll 1$  (or  $\lambda T \gg C_2$ ), the exponential term may be expressed as a series that can be approximated by the first two terms. That is,

$$e^x = 1 + x + \frac{x^2}{2!} + \frac{x^3}{3!} + \dots \approx 1 + x \quad \text{when} \quad x \ll 1.$$

The *Rayleigh-Jeans* approximation is then

$$E_{\lambda,b}(\lambda, T) \approx C_1 / \lambda^5 [1 + (C_2 / \lambda T) - 1] = C_1 T / C_2 \lambda^4.$$

For the condition  $\lambda T = 100,000 \mu\text{m}\cdot\text{K}$ ,  $C_2/\lambda T = 0.1439$

$$\frac{E_{\lambda,b,R-J}}{E_{\lambda,b,Planck}} = \frac{C_1 T / C_2 \lambda^4}{C_1 / \lambda^5} [\exp(C_2 / \lambda T) - 1]^{-1} = (\lambda T / C_2) [\exp(C_2 / \lambda T) - 1] = 1.0754. \quad <$$

That is, for  $\lambda T \geq 100,000 \mu\text{m}\cdot\text{K}$ , the Rayleigh-Jeans law is a good approximation (better than 10%) to the Planck distribution.

**COMMENTS:** Wien's law is used extensively in optical pyrometry for values of  $\lambda$  near  $0.65 \mu\text{m}$  and temperatures above  $700 \text{ K}$ . The Rayleigh-Jeans law is of limited use in heat transfer but of utility for far infrared applications.

## PROBLEM 12.28

**KNOWN:** Various surface temperatures.

**FIND:** (a) Wavelength corresponding to maximum emission for each surface, (b) Fraction of solar emission in UV, VIS and IR portions of the spectrum.

**ASSUMPTIONS:** (1) Spectral distribution of emission from each surface is approximately that of a blackbody, (2) The sun emits as a blackbody at 5800 K.

**ANALYSIS:** (a) From Wien's displacement law, Eq. 12.31, the wavelength of maximum emission for blackbody radiation is

$$\lambda_{\max} = \frac{C_3}{T} = \frac{2898 \mu\text{m} \cdot \text{K}}{T}$$

For the prescribed surfaces

Surface	Sun (5800K)	Tungsten (2500K)	Hot metal (1500K)	Skin metal (305K)	Cool metal (60K)	
$\lambda_{\max}(\mu\text{m})$	0.50	1.16	1.93	9.50	48.3	<

(b) From Fig. 12.3, the spectral regions associated with each portion of the spectrum are

Spectrum	Wavelength limits, $\mu\text{m}$
UV	0.01 – 0.4
VIS	0.4 – 0.7
IR	0.7 - 100

For  $T = 5800\text{K}$  and each of the wavelength limits, from Table 12.1 find:

$\lambda(\mu\text{m})$	$10^{-2}$	0.4	0.7	$10^2$
$\lambda T(\mu\text{m} \cdot \text{K})$	58	2320	4060	$5.8 \times 10^5$
$F_{(0 \rightarrow \lambda)}$	0	0.125	0.491	1

Hence, the fraction of the solar emission in each portion of the spectrum is:

$$F_{\text{UV}} = 0.125 - 0 = 0.125 \quad <$$

$$F_{\text{VIS}} = 0.491 - 0.125 = 0.366 \quad <$$

$$F_{\text{IR}} = 1 - 0.491 = 0.509. \quad <$$

**COMMENTS:** (1) Spectral concentration of surface radiation depends strongly on surface temperature. (2) Much of the UV solar radiation is absorbed in the earth's atmosphere.

## PROBLEM 12.29

**KNOWN:** Thermal imagers operating in the spectral regions 3 to 5  $\mu\text{m}$  and 8 to 14  $\mu\text{m}$ .

**FIND:** (a) Band-emission factors for each of the spectral regions, 3 to 5  $\mu\text{m}$  and 8 to 14  $\mu\text{m}$ , for temperatures of 300 and 900 K, (b) Calculate and plot the band-emission factors for each of the spectral regions for the temperature range 300 to 1000 K; identify the maxima, and draw conclusions concerning the choice of an imager for an application; and (c) Considering imagers operating at the maximum-fraction temperatures found from the graph of part (b), determine the sensitivity (%) required of the radiation detector to provide a noise-equivalent temperature (NET) of 5°C.

**ASSUMPTIONS:** The sensitivity of the imager's radiation detector within the operating spectral region is uniform.

**ANALYSIS:** (a) From Eqs. 12.34 and 12.35, the band-emission fraction  $F(\lambda_1 \rightarrow \lambda_2, T)$  for blackbody emission in the spectral range  $\lambda_1$  to  $\lambda_2$  for a temperature T is

$$F(\lambda_1 \rightarrow \lambda_2, T) = F(0 \rightarrow \lambda_2, T) - F(0 \rightarrow \lambda_1, T)$$

Using the *IHT Radiation | Band Emission* tool (or Table 12.1), evaluate  $F(0 \rightarrow \lambda, T)$  at appropriate  $\lambda \cdot T$  products:

*3 to 5  $\mu\text{m}$  region*

$$F(\lambda_1 \rightarrow \lambda_2, 300 \text{ K}) = 0.1375 - 0.00017 = 0.01373 \quad <$$

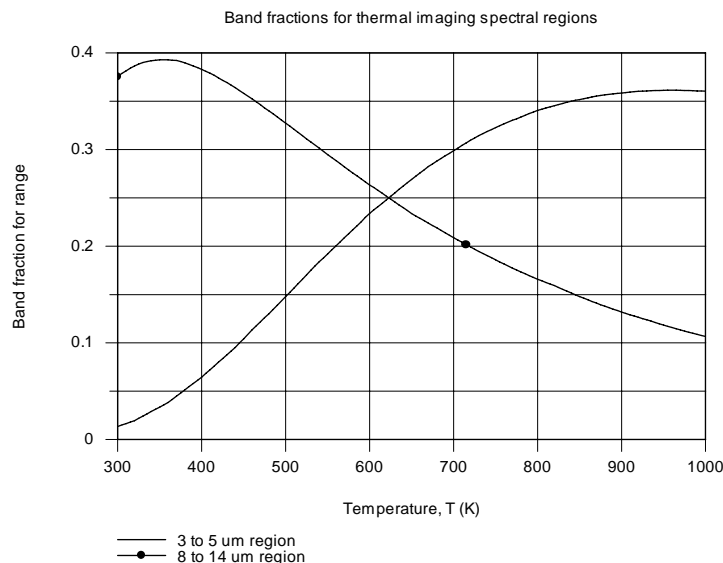

$$F(\lambda_1 \rightarrow \lambda_2, 900 \text{ K}) = 0.5640 - 0.2055 = 0.3585 \quad <$$

*8 to 14  $\mu\text{m}$  region*

$$F(\lambda_1 \rightarrow \lambda_2, 300 \text{ K}) = 0.5160 - 0.1403 = 0.3757 \quad <$$

$$F(\lambda_1 \rightarrow \lambda_2, 900 \text{ K}) = 0.9511 - 0.8192 = 0.1319 \quad <$$

(b) Using the *IHT Radiation | Band Emission* tool, the band-emission fractions for each of the spectral regions is calculated and plotted below as a function of temperature.

Continued ...

### PROBLEM 12.29 (Cont.)

For the 3 to 5  $\mu\text{m}$  imager, the band-emission factor increases with increasing temperature. For low temperature applications, not only is the radiant power ( $\sigma T^4$ ,  $T \approx 300 \text{ K}$ ) low, but the band fraction is small. However, for high temperature applications, the imager operating conditions are more favorable with a large band-emission factor, as well as much higher radiant power ( $\sigma T^4$ ,  $T \rightarrow 900 \text{ K}$ ).

For the 8 to 14  $\mu\text{m}$  imager, the band-emission factor decreases with increasing temperature. This is a more favorable instrumentation feature, since the band-emission factor (proportionally more power) becomes larger as the radiant power decreases. This imager would be preferred over the 3 to 5  $\mu\text{m}$  imager at lower temperatures since the band-emission factor is 8 to 10 times higher.

Recognizing that from Wien's displacement law, the peaks of the blackbody curves for 300 and 900 K are approximately 10 and 3.3  $\mu\text{m}$ , respectively, it follows that the imagers will receive the most radiant power when the peak target spectral distributions are close to the operating spectral region. It is good application practice to choose an imager having a spectral operating range close to the peak of the blackbody curve (or shorter than, if possible) corresponding to the target temperature.

The maxima band fractions for the 3 to 5  $\mu\text{m}$  and 8 to 14  $\mu\text{m}$  spectral regions correspond to temperatures of 960 and 355 K, respectively. Other application factors not considered (like smoke, water vapor, etc), the former imager is better suited with higher temperature scenes, and the latter with lower temperature scenes.

(c) Consider the 3 to 5  $\mu\text{m}$  and 8 to 14  $\mu\text{m}$  imagers operating at their band-emission peak temperatures, 355 and 960 K, respectively. The sensitivity  $S$  (% units) of the imager to resolve an NET of  $5^\circ\text{C}$  can be expressed as

$$S(\%) = \frac{F(\lambda_1 - \lambda_2, T_1) - F(\lambda_1 - \lambda_2, T_2)}{F(\lambda_1 - \lambda_2, T_1)} \times 100$$

where  $T_1 = 355$  or  $960 \text{ K}$  and  $T_2 = 360$  or  $965 \text{ K}$ , respectively. Using this relation in the *IHT* workspace, find

$$S_{3-5} = 0.035\%$$

$$S_{8-14} = 0.023\%$$

<

That is, we require the radiation detector (with its signal-processing system) to resolve the output signal with the foregoing precision in order to indicate a  $5^\circ\text{C}$  change in the scene temperature.

### PROBLEM 12.30

**KNOWN:** Tube furnace maintained at  $T_f = 2000$  K used to calibrate a heat flux gage of sensitive area  $5 \text{ mm}^2$  mounted coaxial with the furnace centerline, and positioned  $60 \text{ mm}$  from the opening of the furnace.

**FIND:** (a) Heat flux ( $\text{kW/m}^2$ ) on the gage, (b) Radiant flux in the spectral region  $0.4$  to  $2.5 \mu\text{m}$ , the sensitive spectral region of a solid-state (photoconductive type) heat-flux gage, and (c) Calculate and plot the heat fluxes for each of the gages as a function of the furnace temperature for the range  $2000 \leq T_f \leq 3000$  K. Compare the values for the two types of gages; explain why the solid-state gage will always indicate systematically low values; does the solid-state gage performance improve, or become worse as the source temperature increases?

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Graphite tube furnace behaves as a blackbody, (3) Areas of gage and furnace opening are small relative to separation distance squared, and (4) Extension tube is cold relative to the furnace.

**ANALYSIS:** (a) The heat flux to the gage is equal to the irradiation,  $G_g$ , on the gage and can be expressed as (see Section 12.3.3)

$$G_g = I_f \cdot \cos \theta_g \cdot \Delta\omega_{f-g}$$

where  $\Delta\omega_{f-g}$  is the solid angle that the furnace opening subtends relative to the gage. From Eq. 12.7, with  $\theta_g = 0^\circ$

$$\Delta\omega_{f-g} \equiv \frac{dA_n}{r^2} = \frac{A_f \cos \theta_g}{L^2} = \frac{\pi(0.0125 \text{ m})^2 / 4 \times 1}{(0.060 \text{ m})^2} = 3.409 \times 10^{-2} \text{ sr}$$

The intensity of the radiation from the furnace is

$$I_f = E_{b,f}(T_f) / \pi = \sigma T_f^4 / \pi = 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (2000 \text{ K})^4 / \pi = 2.888 \times 10^5 \text{ W/m}^2 \cdot \text{sr}$$

Substituting numerical values,

$$G_g = 2.888 \times 10^5 \text{ W/m}^2 \cdot \text{sr} \times 1 \times 3.409 \times 10^{-2} \text{ sr} = 9.84 \text{ kW/m}^2 \quad <$$

(b) The solid-state detector gage, sensitive only in the spectral region  $\lambda_1 = 0.4 \mu\text{m}$  to  $\lambda_2 = 2.5 \mu\text{m}$ , will receive the band irradiation.

$$G_{g, \lambda_1-\lambda_2} = F(\lambda_1 \rightarrow \lambda_2, T_f) \cdot G_{g,b} = \left[ F(0 \rightarrow \lambda_2, T_f) - F(0 \rightarrow \lambda_1, T_f) \right] G_{g,b}$$

Continued ...

### PROBLEM 12.30 (Cont.)

where for  $\lambda_1 T_f = 0.4 \mu\text{m} \times 2000 \text{ K} = 800 \mu\text{m}\cdot\text{K}$ ,  $F_{(0-\lambda_1)} = 0.0000$  and for  $\lambda_2 \cdot T_f = 2.5 \mu\text{m} \times 2000 \text{ K} = 5000 \mu\text{m}\cdot\text{K}$ ,  $F_{(0-\lambda_2)} = 0.6337$ . Hence,

$$G_{g,\lambda_1-\lambda_2} = [0.6337 - 0.0000] \times 9.84 \text{ kW} / \text{m}^2 = 6.24 \text{ kW} / \text{m}^2 \quad <$$

(c) Using the foregoing equation in the *IHT* workspace, the heat fluxes for each of the gage types are calculated and plotted as a function of the furnace temperature.

For the black gage, the irradiation received by the gage,  $G_g$ , increases as the fourth power of the furnace temperature. For the solid-state gage, the irradiation increases slightly greater than the fourth power of the furnace temperature since the band-emission factor for the spectral region,  $F_{(\lambda_1 - \lambda_2, T_f)}$ , increases with increasing temperature. The solid-state gage will always indicate systematic low readings since its band-emission factor never approaches unity. However, the error will decrease with increasing temperature as a consequence of the corresponding increase in the band-emission factor.

**COMMENTS:** For this furnace-gage geometrical arrangement, evaluating the solid angle,  $\Delta\omega_{f-g}$ , and the areas on a differential basis leads to results that are systematically high by 1%. Using the view factor concept introduced in Chapter 13, the results for the black and solid-state gages are 9.74 and 6.17  $\text{kW}/\text{m}^2$ , respectively.

### PROBLEM 12.31

**KNOWN:** Bandgap of photovoltaic material. Relationship between wavelength and energy state of photon. Inter-band gap efficiency. Half of incident photons not converted to electricity are absorbed as thermal energy. Solar irradiation and associated blackbody temperature.

**FIND:** Wavelengths of solar irradiation corresponding to material's band gap. Overall efficiency. Heat absorption per unit surface area.

**SCHEMATIC:**

**ASSUMPTIONS:** Wavelength distribution of solar irradiation corresponds to a blackbody at 5800 K.

**ANALYSIS:** The lower boundary of the band-gap,  $B = 1.1$  eV, corresponds to a wavelength of

$$\lambda_2 = \frac{1240 \text{ eV} \cdot \text{nm}}{B} = \frac{1240 \text{ eV} \cdot \text{nm}}{1.1 \text{ eV}} = 1127 \text{ nm} = 1.127 \mu\text{m}$$

Similarly, the upper boundary,  $B = 1.8$  eV, corresponds to  $\lambda_1 = 0.689 \mu\text{m}$ . Thus, the wavelength range corresponding to the band gap is

$$0.689 \mu\text{m} \leq \lambda \leq 1.127 \mu\text{m} \quad \leftarrow$$

The fraction of the irradiation that falls in this wavelength range can be found from Table 12.1. With  $T = 5800$  K,  $\lambda_1 T = 0.689 \mu\text{m} \times 5800 \text{ K} = 4000 \mu\text{m} \cdot \text{K}$ ,  $\lambda_2 T = 6540 \mu\text{m} \cdot \text{K}$ , thus

$$F_{(\lambda_1 \rightarrow \lambda_2)} = F_{(0 \rightarrow \lambda_2)} - F_{(0 \rightarrow \lambda_1)} = 0.7647 - 0.4809 = 0.2838$$

Hence the overall efficiency is

$$\eta = \eta_{bg} F_{bg} = 0.50 \times 0.2838 = 0.1419 \quad \leftarrow$$

If half of the irradiation that is *not* converted to electricity is absorbed as thermal energy, then the fraction absorbed is  $0.5 \times (1 - 0.1419) = 0.4290$ . Thus, the absorbed energy is

$$q = 0.4290 \times 1000 \text{ W/m}^2 = 429 \text{ W/m}^2 \quad \leftarrow$$

**COMMENT:** The irradiation that is neither converted to electricity nor converted to thermal energy is reflected from or transmitted through the material.

### PROBLEM 12.32

**KNOWN:** Geometry and temperature of a ring-shaped radiator. Area of irradiated part and distance from radiator.

**FIND:** Rate at which radiant energy is incident on the part.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Heater emits as a blackbody.

**ANALYSIS:** Expressing Eq. 12.12 on the basis of the total radiation,  $dq = I_e dA_h \cos\theta d\omega$ , the rate at which radiation is incident on the part is

$$q_{h-p} = \int dq = I_e \iint \cos\theta d\omega_{p-h} dA_h \approx I_e \cos\theta \cdot \omega_{p-h} \cdot A_h$$

Since radiation leaving the heater in the direction of the part is oriented normal to the heater surface,  $\theta = 0$  and  $\cos\theta = 1$ . The solid angle subtended by the part with respect to the heater is  $\omega_{p-h} = A_p \cos\theta_1 / L^2$ , while the area of the heater is  $A_h \approx 2\pi r_h W = 2\pi(L \sin\theta_1)W$ . Hence, with  $I_e = E_b / \pi = \sigma T_h^4 / \pi$ ,

$$q_{h-p} \approx \frac{5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (3000 \text{ K})^4}{\pi} \times \frac{0.007 \text{ m}^2 (\cos 30^\circ)}{(3 \text{ m})^2} \times 2\pi (1.5 \text{ m}) 0.03 \text{ m}$$

$$q_{h-p} \approx 278.4 \text{ W}$$

<

**COMMENTS:** The foregoing representation for the double integral is an excellent approximation since  $W \ll L$  and  $A_p \ll L^2$ .

### PROBLEM 12.33

**KNOWN:** Aperture of an isothermal furnace emits as a blackbody.

**FIND:** (a) An expression for the ratio of the fractional change in the spectral intensity to the fractional change in temperature of the furnace aperture, (b) Allowable variation in temperature of a furnace operating at 2000 K such that the spectral intensity at 0.65 μm will not vary by more than 1/2%. Allowable variation for 10 μm.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Furnace is isothermal and aperture radiates as a blackbody.

**ANALYSIS:** (a) The Planck spectral distribution, Eq. 12.30, is

$$I_{\lambda}(\lambda, T) = C_1 / \pi \lambda^5 \left[ \exp(C_2 / \lambda T) - 1 \right].$$

Taking natural logarithms of both sides, find  $\ln I_{\lambda} = \ln \left[ C_1 / \pi \lambda^5 \right] - \ln \left[ \exp(C_2 / \lambda T) - 1 \right]$ . Take the total derivative of both sides, but consider the  $\lambda$  variable as a constant.

$$\frac{dI_{\lambda}}{I_{\lambda}} = \frac{d \left[ \exp(C_2 / \lambda T) - 1 \right]}{\left[ \exp(C_2 / \lambda T) - 1 \right]} = \frac{\left\{ \exp(C_2 / \lambda T) \right\} (C_2 / \lambda) (-1/T^2) dT}{\left[ \exp(C_2 / \lambda T) - 1 \right]}$$

$$\frac{dI_{\lambda}}{I_{\lambda}} = \frac{C_2}{\lambda T} \cdot \frac{\exp(C_2 / \lambda T)}{\left[ \exp(C_2 / \lambda T) - 1 \right]} \cdot \frac{dT}{T} \quad \text{or} \quad \frac{dI_{\lambda} / I_{\lambda}}{dT / T} = \frac{C_2}{\lambda T} \cdot \frac{1}{1 - \exp(-C_2 / \lambda T)} \quad <$$

(b) If the furnace operates at 2000 K and the desirable fractional change of the spectral intensity is 0.5% at 0.65 μm, the allowable temperature variation is

$$\frac{dT}{T} = \frac{dI_{\lambda}}{I_{\lambda}} / \left\{ \frac{C_2}{\lambda T} \frac{1}{1 - \exp(-C_2 / \lambda T)} \right\}$$

$$\frac{dT}{T} = 0.005 / \left\{ \frac{14,388 \mu\text{m} \cdot \text{K}}{0.65 \mu\text{m} \times 2000 \text{K}} / \left[ 1 - \exp \left( \frac{-14,388 \mu\text{m} \cdot \text{K}}{0.65 \mu\text{m} \times 2000 \text{K}} \right) \right] \right\} = 4.517 \times 10^{-4}.$$

That is, the allowable fractional variation in temperature is 0.045%; at 2000 K, the allowable temperature variation is

$$\Delta T \approx 4.517 \times 10^{-4} T = 4.517 \times 10^{-4} \times 2000 \text{K} = 0.90 \text{K}. \quad <$$

Substituting with  $T = 2000 \text{K}$  and  $\lambda = 10 \mu\text{m}$ , find that

$$\frac{dT}{T} = 3.565 \times 10^{-3} \quad \text{and} \quad \Delta T \approx 3.565 \times 10^{-3} T = 7.1 \text{K}. \quad <$$

**COMMENTS:** Note that the power control requirements to satisfy the spectral intensity variation for 0.65 μm and 10 μm conditions are quite different. The peak of the blackbody curve for 2000 K is  $\lambda_{\text{max}} = 2898 \mu\text{m} \cdot \text{K} / 2000 \text{K} = 1.45 \mu\text{m}$ .

### PROBLEM 12.34

**KNOWN:** Variation of spectral, hemispherical emissivity with wavelength for two materials.

**FIND:** Nature of the variation with temperature of the total, hemispherical emissivity.

**SCHEMATIC:**

**ASSUMPTIONS:** (1)  $\epsilon_\lambda$  is independent of temperature.

**ANALYSIS:** The total, hemispherical emissivity may be obtained from knowledge of the spectral, hemispherical emissivity by using Eq. 12.43

$$\epsilon(T) = \frac{\int_0^\infty \epsilon_\lambda(\lambda) E_{\lambda,b}(\lambda, T) d\lambda}{E_b(T)} = \int_0^\infty \epsilon_\lambda(\lambda) \frac{E_{\lambda,b}(\lambda, T)}{E_b(T)} d\lambda.$$

We also know that the spectral emissive power of a blackbody becomes more concentrated at lower wavelengths with increasing temperature (Fig. 12.12). That is, the weighting factor,  $E_{\lambda,b}(\lambda, T)/E_b(T)$  increases at lower wavelengths and decreases at longer wavelengths with increasing  $T$ . Accordingly,

*Material A:*  $\epsilon(T)$  increases with increasing  $T$  <

*Material B:*  $\epsilon(T)$  decreases with increasing  $T$ . <

### PROBLEM 12.35

**KNOWN:** Initial and final object temperature. Variation of spectral emissivity with wavelength for two coatings.

**FIND:** Which coating cools faster.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Surface is a diffuse emitter, (2) Negligible radiation from low-temperature vacuum chamber to object, (3) The spectral emissivity distribution can be approximated as a step change.

**ANALYSIS:** The object cools by radiation to the surroundings, and the object will cool faster if its emissivity is greater. The total, hemispherical emissivity is given by Equation 12.43, and changes with time as the temperature of the object changes. From Equation 12.43,

$$\begin{aligned}\varepsilon(T) &= \frac{\int_0^{\infty} \varepsilon_{\lambda} E_{\lambda,b} d\lambda}{E_b(T)} = \frac{\varepsilon_1 \int_0^{\lambda_c} E_{\lambda,b} d\lambda + \varepsilon_2 \int_{\lambda_c}^{\infty} E_{\lambda,b} d\lambda}{E_b(T)} \\ &= \varepsilon_1 F_{(0 \rightarrow \lambda_c)} + \varepsilon_2 (1 - F_{(0 \rightarrow \lambda_c)})\end{aligned}$$

where  $\lambda_c = 10 \mu\text{m}$  is the cut-off wavelength at which the emissivity changes from  $\varepsilon_1$  to  $\varepsilon_2$ . For coating A,  $\varepsilon_1$  is the higher value and  $\varepsilon_2$  is the lower value, and vice versa for coating B. At the initial temperature of 1000 K, we find  $\lambda_c T = 10,000 \mu\text{m}\cdot\text{K}$ , and from Table 12.1,  $F_{(0 \rightarrow \lambda_c)} = 0.914$ . Therefore coating A has the higher emissivity value over 91.4% of the spectrum and has the higher total emissivity. At the final temperature of 500 K, we find  $\lambda_c T = 5000 \mu\text{m}\cdot\text{K}$ , and from Table 12.1,  $F_{(0 \rightarrow \lambda_c)} = 0.0634$ . Thus, coating A still has the higher emissivity value.

Coating A will cause the object to cool faster. <

**COMMENTS:** The emissivity of coatings A and B are the same when  $F_{(0 \rightarrow \lambda_c)} = 0.5$ . From Table 12.1, this occurs at a temperature of  $T = 411 \text{ K}$ . Below this temperature, coating B will cause faster cooling than coating A. If the object were to be cooled below 411 K, a more complex analysis would be required to determine which coating would lead to the fastest cooling over the entire time period.

### PROBLEM 12.36

**KNOWN:** The total directional emissivity of non-metallic materials may be approximated as  $\varepsilon_\theta = \varepsilon_n \cos \theta$  where  $\varepsilon_n$  is the total normal emissivity.

**FIND:** Show that for such materials, the total hemispherical emissivity,  $\varepsilon$ , is 2/3 the total normal emissivity.

**SCHEMATIC:**

**ANALYSIS:** From Eq. 12.42, written on a total rather than spectral basis, the hemispherical emissivity  $\varepsilon$  can be determined from the directional emissivity  $\varepsilon_\theta$  as

$$\varepsilon = 2 \int_0^{\pi/2} \varepsilon_\theta \cos \theta \sin \theta d\theta$$

With  $\varepsilon_\theta = \varepsilon_n \cos \theta$ , find

$$\varepsilon = 2 \varepsilon_n \int_0^{\pi/2} \cos^2 \theta \sin \theta d\theta$$

$$\varepsilon = -2 \varepsilon_n \left( \cos^3 \theta / 3 \right) \Big|_0^{\pi/2} = 2/3 \varepsilon_n$$

<

**COMMENTS:** (1) Refer to Fig. 12.16 illustrating on cartesian coordinates representative directional distributions of the total, directional emissivity for nonmetallic and metallic materials. In the schematic above, we've shown  $\varepsilon_\theta$  vs.  $\theta$  on a polar plot for both types of materials, in comparison with a diffuse surface.

(2) See Section 12.5 for discussion on other characteristics of emissivity for materials.

### PROBLEM 12.37

**KNOWN:** Metallic surface with prescribed spectral, directional emissivity at 2000 K and 1  $\mu\text{m}$  (see Example 12.7) and additional measurements of the spectral, hemispherical emissivity.

**FIND:** (a) Total hemispherical emissivity,  $\epsilon$ , and the emissive power,  $E$ , at 2000 K, (b) Effect of temperature on the emissivity.

**SCHEMATIC:**

**ANALYSIS:** (a) The total, hemispherical emissivity,  $\epsilon$ , may be determined from knowledge of the spectral, hemispherical emissivity,  $\epsilon_\lambda$ , using Eq. 12.43.

$$\epsilon(T) = \int_0^\infty \epsilon_\lambda(\lambda) E_{\lambda,b}(\lambda, T) d\lambda / E_b(T) = \epsilon_1 \int_0^{2\mu\text{m}} \frac{E_{\lambda,b}(\lambda, T) d\lambda}{E_b(T)} + \epsilon_2 \int_{2\mu\text{m}}^{4\mu\text{m}} \frac{E_{\lambda,b}(\lambda, T) d\lambda}{E_b(T)}$$

or from Eq. 12.34,

$$\epsilon(T) = \epsilon_1 F_{(0 \rightarrow \lambda_1)} + \epsilon_2 [F_{(0 \rightarrow \lambda_2)} - F_{(0 \rightarrow \lambda_1)}]$$

From Table 12.1,

$$\lambda_1 = 2 \mu\text{m}, \quad T = 2000 \text{ K}: \quad \lambda_1 T = 4000 \mu\text{m} \cdot \text{K}, \quad F_{(0 \rightarrow \lambda_1)} = 0.481$$

$$\lambda_2 = 4 \mu\text{m}, \quad T = 2000 \text{ K}: \quad \lambda_2 T = 8000 \mu\text{m} \cdot \text{K}, \quad F_{(0 \rightarrow \lambda_2)} = 0.856$$

Hence,

$$\epsilon(T) = 0.36 \times 0.481 + 0.20(0.856 - 0.481) = 0.25 \quad <$$

The total emissive power at 2000 K is

$$E(2000 \text{ K}) = \epsilon(2000 \text{ K}) \cdot E_b(2000 \text{ K})$$

$$E(2000 \text{ K}) = 0.25 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times (2000 \text{ K})^4 = 2.27 \times 10^5 \text{ W/m}^2. \quad <$$

(b) Using the *Radiation Toolpad* of IHT, the following result was generated.

Continued...

### PROBLEM 12.37 (Cont.)

At  $T \approx 500$  K, most of the radiation is emitted in the far infrared region ( $\lambda > 4 \mu\text{m}$ ), in which case  $\varepsilon \approx 0$ . With increasing  $T$ , emission is shifted to lower wavelengths, causing  $\varepsilon$  to increase. As  $T \rightarrow \infty$ ,  $\varepsilon \rightarrow 0.36$ .

**COMMENTS:** Note that the value of  $\varepsilon_\lambda$  for  $0 < \lambda \leq 2 \mu\text{m}$  cannot be read directly from the  $\varepsilon_\lambda$  distribution provided in the problem statement. This value is calculated from knowledge of  $\varepsilon_{\lambda,\theta}(\theta)$  in Example 12.7.

### PROBLEM 12.38

**KNOWN:** Expression for spectral emissivity of titanium at room temperature.

**FIND:** (a) Emissive power of titanium surface at 300 K. (b) Value of  $\lambda_{\max}$  for emissive power of surface in part (a).

**SCHEMATIC:**

**ANALYSIS:** (a) Combining Eqs. 12.40 and 12.43, the emissive power is given by

$$E(T) = \varepsilon(T)E_b(T) = \int_0^{\infty} \varepsilon_{\lambda}(\lambda, T)E_{\lambda, b}(\lambda, T)d\lambda = I_1 + I_2 + I_3$$

where

$$I_1 = \int_0^{0.3 \mu\text{m}} \varepsilon_{\lambda}(\lambda, T)E_{\lambda, b}(\lambda, T)d\lambda \leq \int_0^{0.3 \mu\text{m}} E_{\lambda, b}(\lambda, T)d\lambda = F_{(0 \rightarrow 0.3 \mu\text{m})}E_b(T)$$

$$I_2 = 0.52 \int_{0.3 \mu\text{m}}^{30 \mu\text{m}} \lambda^{-0.5} E_{\lambda, b}(\lambda, T)d\lambda$$

$$I_3 = 0.1 \int_{30 \mu\text{m}}^{\infty} E_{\lambda, b}(\lambda, T)d\lambda = 0.1F_{(30 \mu\text{m} \rightarrow \infty)}E_b(T)$$

From Table 12.1, with  $\lambda_1 T = 0.3 \mu\text{m} \times 300 \text{ K} = 90 \mu\text{m} \cdot \text{K}$  and  $\lambda_2 T = 30 \mu\text{m} \times 300 \text{ K} = 9000 \mu\text{m} \cdot \text{K}$ ,

$$F_{(0 \rightarrow 0.3 \mu\text{m})} \approx 0$$

$$F_{(30 \mu\text{m} \rightarrow \infty)} = 1 - F_{(0 \rightarrow 30 \mu\text{m})} = 1 - 0.890029 = 0.110$$

Thus

$$I_1 \approx 0$$

$$I_3 = 0.1 \times 0.110 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times (300 \text{ K})^4 = 5.05 \text{ W/m}^2$$

The integral  $I_2$  must be evaluated numerically. Making use of Eq. 12.30 for  $E_{\lambda, b}$ ,

$$I_2 = 0.52 \int_{0.3 \mu\text{m}}^{30 \mu\text{m}} \lambda^{-0.5} \frac{C_1}{\lambda^5 [\exp(C_2/\lambda T) - 1]} d\lambda$$

Continued...

### PROBLEM 12.38 (Cont.)

This integral can be evaluated using the INTEGRAL function of IHT. The result is  $I_2 = 61.16 \text{ W/m}^2$ . Thus,

$$E(T) = I_1 + I_2 + I_3 = 0 + 61.16 \text{ W/m}^2 + 5.05 \text{ W/m}^2 = 66.2 \text{ W/m}^2 \quad <$$

(b) The value of  $\lambda_{\max}$  is the value of  $\lambda$  for which  $E_\lambda$  is maximum. The maximum in  $E_{\lambda,b}$  occurs for  $\lambda_{\max}T = 2898 \mu\text{m}\cdot\text{K}$ , or at 300 K,  $\lambda_{\max} = 9.66 \mu\text{m}$ . However, for  $E_\lambda = \varepsilon_\lambda E_{\lambda,b}$ , the maximum will be shifted because of the dependence of  $\varepsilon_\lambda$  on  $\lambda$ . We consider

$$\frac{dE_\lambda}{d\lambda} = \frac{d(\varepsilon_\lambda E_{\lambda,b})}{d\lambda} = \varepsilon_\lambda \frac{dE_{\lambda,b}}{d\lambda} + \frac{d\varepsilon_\lambda}{d\lambda} E_{\lambda,b} = 0$$

Considering the range  $0.3 \mu\text{m} \leq \lambda \leq 30 \mu\text{m}$ , for which  $\varepsilon_\lambda = 0.52\lambda^{-0.5}$ , this becomes

$$\begin{aligned} 0.52\lambda^{-0.5} \frac{dE_{\lambda,b}}{d\lambda} - 0.5(0.52\lambda^{-1.5})E_{\lambda,b} &= 0 \\ \lambda \frac{dE_{\lambda,b}}{d\lambda} - 0.5E_{\lambda,b} &= 0 \end{aligned} \quad (1)$$

Then

$$\begin{aligned} \frac{dE_{\lambda,b}}{d\lambda} &= \frac{-5C_1}{\lambda^6 [\exp(C_2/\lambda T) - 1]} + \frac{-C_1 \exp(C_2/\lambda T)}{\lambda^5 [\exp(C_2/\lambda T) - 1]^2} \left( -\frac{C_2}{\lambda^2 T} \right) \\ \frac{dE_{\lambda,b}}{d\lambda} &= -5 \frac{E_{\lambda,b}}{\lambda} + \frac{E_{\lambda,b} \exp(C_2/\lambda T)}{[\exp(C_2/\lambda T) - 1]} \left( \frac{C_2}{\lambda^2 T} \right) \end{aligned} \quad (2)$$

Substituting Eq. (2) into Eq. (1) and simplifying,

$$\frac{\exp(C_2/\lambda T)}{[\exp(C_2/\lambda T) - 1]} \left( \frac{C_2}{\lambda T} \right) = 5.5 \quad (3)$$

Solving this implicit equation for  $C_2/\lambda T$  yields

$$\frac{C_2}{\lambda T} = 5.477$$

Thus

$$\lambda_{\max} = \frac{C_2}{5.477T} = \frac{1.439 \times 10^4 \mu\text{m}\cdot\text{K}}{5.477 \times 300 \text{ K}} = 8.76 \mu\text{m} \quad <$$

$E_{\lambda,b}$  will be smaller in the ranges  $\lambda < 0.3 \mu\text{m}$ , and  $\lambda > 30 \mu\text{m}$ .

**COMMENTS:** Because the titanium has an emissivity that increases with decreasing wavelength, the value of  $\lambda_{\max}$  is smaller than would have been predicted with use of Wien's displacement law,  $\lambda_{\max,W} = 2898 \mu\text{m}\cdot\text{K}/300\text{K} = 9.66 \mu\text{m}$ .

### PROBLEM 12.39

**KNOWN:** Spectral directional emissivity of a diffuse material at 2000K.

**FIND:** (a) Total, hemispherical emissivity, (b) Emissive power over the spectral range 0.8 to 2.5  $\mu\text{m}$  and for directions  $0 \leq \theta \leq \pi/6$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Surface is diffuse emitter.

**ANALYSIS:** (a) Since the surface is diffuse,  $\varepsilon_{\lambda,\theta}$  is independent of direction; from Eq. 12.42,  $\varepsilon_{\lambda,\theta} = \varepsilon_\lambda$ . Using Eq. 12.43,

$$\varepsilon(T) = \int_0^\infty \varepsilon_\lambda(\lambda) E_{\lambda,b}(\lambda, T) d\lambda / E_b(T)$$

$$E(T) = \int_0^{1.5} \varepsilon_1 E_{\lambda,b}(\lambda, 2000) d\lambda / E_b + \int_{1.5}^\infty \varepsilon_2 E_{\lambda,b}(\lambda, 2000) d\lambda / E_b.$$

Written now in terms of  $F_{(0 \rightarrow \lambda)}$ , with  $F_{(0 \rightarrow 1.5)} = 0.2732$  at  $\lambda T = 1.5 \times 2000 = 3000 \mu\text{m}\cdot\text{K}$ , (Table 12.1) find,

$$\varepsilon(2000 \text{ K}) = \varepsilon_1 \times F_{(0 \rightarrow 1.5)} + \varepsilon_2 [1 - F_{(0 \rightarrow 1.5)}] = 0.2 \times 0.2732 + 0.8 [1 - 0.2732] = 0.636. \quad <$$

(b) For the prescribed spectral and geometric limits, from an equation similar to Eq. 12.15,

$$\Delta E = \int_{0.8}^{2.5} \int_0^{2\pi} \int_0^{\pi/6} \varepsilon_{\lambda,\theta} I_{\lambda,b}(\lambda, T) \cos \theta \sin \theta d\theta d\phi d\lambda$$

where  $I_{\lambda,e}(\lambda, \theta, \phi) = \varepsilon_{\lambda,\theta} I_{\lambda,b}(\lambda, T)$ . Since the surface is diffuse,  $\varepsilon_{\lambda,\theta} = \varepsilon_\lambda$ , and noting  $I_{\lambda,b}$  is independent of direction and equal to  $E_{\lambda,b}/\pi$ , we can write

$$\Delta E = \left\{ \int_0^{2\pi} \int_0^{\pi/6} \cos \theta \sin \theta d\theta d\phi \right\} \frac{E_b(T)}{\pi} \left\{ \frac{\int_{0.8}^{1.5} \varepsilon_1 E_{\lambda,b}(\lambda, T) d\lambda}{E_b(T)} + \frac{\int_{1.5}^{2.5} \varepsilon_2 E_{\lambda,b}(\lambda, T) d\lambda}{E_b(T)} \right\}$$

or in terms  $F_{(0 \rightarrow \lambda)}$  values,

$$\Delta E = \left\{ \phi \left|_0^{2\pi} \times \frac{\sin^2 \theta}{2} \right|_0^{\pi/6} \right\} \frac{\sigma T^4}{\pi} \left\{ \varepsilon_1 [F_{0 \rightarrow 1.5} - F_{0 \rightarrow 0.8}] + \varepsilon_2 [F_{0 \rightarrow 2.5} - F_{0 \rightarrow 1.5}] \right\}.$$

From Table 12.1:  $\lambda T = 0.8 \times 2000 = 1600 \mu\text{m}\cdot\text{K}$   $F_{(0 \rightarrow 0.8)} = 0.0197$

$\lambda T = 2.5 \times 2000 = 5000 \mu\text{m}\cdot\text{K}$   $F_{(0 \rightarrow 2.5)} = 0.6337$

$$\Delta E = \left\{ 2\pi \times \frac{\sin^2 \pi/6}{2} \right\} \frac{5.67 \times 10^{-8} \times 2000^4}{\pi} \frac{\text{W}}{\text{m}^2} \cdot \{0.2 [0.2732 - 0.0197] + 0.8 [0.6337 - 0.2732]\}$$

$$\Delta E = 0.25 \times (5.67 \times 10^{-8} \times 2000^4) \text{ W/m}^2 \times 0.339 = 76.89 \text{ kW/m}^2. \quad <$$

## PROBLEM 12.40

**KNOWN:** Spectral emissivity distribution of diffuse surface. Surface temperature range.

**FIND:** Temperature at which the emissive power is minimized.

**SCHEMATIC:**

**ASSUMPTIONS:** Surface is a diffuse emitter.

**ANALYSIS:** The emissive power is  $E(T) = \epsilon(T)E_b(T)$ . It is known that  $E_b(T)$  increases with  $T$ , but it is not immediately obvious how  $\epsilon(T)$  varies with temperature since as temperature increases, the heaviest weighting of the spectral emissivity distribution shifts from higher to lower wavelengths. From Eq. 12.43,

$$\begin{aligned} \epsilon(T) &= \frac{\int_0^\infty \epsilon_\lambda E_{\lambda,b} d\lambda}{E_b(T)} = \frac{\epsilon_1 \int_0^{\lambda_1} E_{\lambda,b} d\lambda + \epsilon_2 \int_0^{\lambda_2} E_{\lambda,b} d\lambda + \epsilon_3 \int_0^{\lambda_3} E_{\lambda,b} d\lambda}{E_b(T)} \\ &= \epsilon_1 F_{(0 \rightarrow \lambda_1)} + \epsilon_2 (F_{(0 \rightarrow \lambda_2)} - F_{(0 \rightarrow \lambda_1)}) + \epsilon_3 (1 - F_{(0 \rightarrow \lambda_2)}) \end{aligned}$$

where  $\lambda_1 = 4 \mu\text{m}$ ,  $\lambda_2 = 6 \mu\text{m}$ ,  $\epsilon_1 = 0.75$ ,  $\epsilon_2 = 0.10$ , and  $\epsilon_3 = 0.50$ . At  $T = 300 \text{ K}$ ,

$$\lambda_1 T = 1200 \mu\text{m}\cdot\text{K}, \quad \lambda_2 T = 1800 \mu\text{m}\cdot\text{K}.$$

From Table 12.1,

$$F_{(0 \rightarrow \lambda_1)} = 0.002134, \quad F_{(0 \rightarrow \lambda_2)} = 0.039341.$$

Thus,

$$\epsilon(300 \text{ K}) = 0.75 \times 0.002134 + 0.10 \times (0.039341 - 0.002134) + 0.50 \times (1 - 0.039341) = 0.486$$

and

$$E(300 \text{ K}) = \epsilon(300 \text{ K})\sigma T^4 = 0.486 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K} \times (300 \text{ K})^4 = 223 \text{ W/m}^2$$

Repeating these calculations over the temperature range  $300 \leq T_s \leq 1000 \text{ K}$ , the following plots can be generated.

Continued...

### PROBLEM 12.40 (Cont.)

It can be seen that  $\epsilon(T)$  has a minimum around 570 K, however

the minimum value of  $E$  occurs at 300 K

<

and is  $E_{\min} = 223 \text{ W/m}^2$ .

**COMMENTS:** The blackbody emissive power varies as  $T^4$ . The variation of emissivity with temperature is nowhere near as strong and therefore does not give rise to a local minimum in emissive power.

### PROBLEM 12.41

**KNOWN:** Directional emissivity,  $\varepsilon_\theta$ , of a selective surface.

**FIND:** Ratio of the normal emissivity,  $\varepsilon_n$ , to the hemispherical emissivity,  $\varepsilon$ .

**SCHEMATIC:**

**ASSUMPTIONS:** Surface is isotropic in  $\phi$  direction.

**ANALYSIS:** From Eq. 12.42 written on a total, rather than spectral, basis, the hemispherical emissivity is

$$\varepsilon = 2 \int_0^{\pi/2} \varepsilon_\theta(\theta) \cos \theta \sin \theta d\theta.$$

Recognizing that the integral can be expressed in two parts, find

$$\varepsilon = 2 \left[ \int_0^{\pi/4} \varepsilon_\theta(\theta) \cos \theta \sin \theta d\theta + \int_{\pi/4}^{\pi/2} \varepsilon_\theta(\theta) \cos \theta \sin \theta d\theta \right]$$

$$\varepsilon = 2 \left[ 0.8 \int_0^{\pi/4} \cos \theta \sin \theta d\theta + 0.3 \int_{\pi/4}^{\pi/2} \cos \theta \sin \theta d\theta \right]$$

$$\varepsilon = 2 \left[ 0.8 \frac{\sin^2 \theta}{2} \Big|_0^{\pi/4} + 0.3 \frac{\sin^2 \theta}{2} \Big|_{\pi/4}^{\pi/2} \right]$$

$$\varepsilon = 2 \left[ 0.8 \frac{1}{2} (0.50 - 0) + 0.3 \times \frac{1}{2} (1 - 0.50) \right] = 0.550.$$

The ratio of the normal emissivity ( $\varepsilon_n$ ) to the hemispherical emissivity is

$$\frac{\varepsilon_n}{\varepsilon} = \frac{0.8}{0.550} = 1.45.$$

<

**COMMENTS:** Note that Eq. 12.42 is based on the assumption that the directional emissivity is independent of the  $\phi$  coordinate. If this is not the case, then Eq. 12.41 would need to be evaluated.

### PROBLEM 12.42

**KNOWN:** Incandescent sphere suspended in air within a darkened room exhibiting these characteristics:

*initially:* brighter around the rim

*after some time:* brighter in the center

**FIND:** Plausible explanation for these observations.

**ASSUMPTIONS:** (1) The sphere is at a uniform surface temperature,  $T_s$ .

**ANALYSIS:** Recognize that in observing the sphere by eye, emission from the central region is in a nearly normal direction. Emission from the rim region, however, has a large angle from the normal to the surface.

Note now the directional behavior,  $\epsilon_\theta$ , for conductors and non-conductors as represented in Fig. 12.16.

Assume that the sphere is fabricated from a *metallic* material. Then, the rim would appear brighter than the central region. This follows since  $\epsilon_\theta$  is higher at higher angles of emission.

If the metallic sphere oxidizes with time, then the  $\epsilon_\theta$  characteristics change. Then  $\epsilon_\theta$  at small angles of  $\theta$  become larger than at higher angles. This would cause the sphere to appear brighter at the center portion of the sphere.

**COMMENTS:** Since the emissivity of non-conductors is generally larger than for metallic materials, you would also expect the oxidized sphere to appear brighter for the same surface temperature.

### PROBLEM 12.43

**KNOWN:** Surface area, temperature, and emissivity of the heated surface  $A_1$ . Surface area and orientation of area  $A_2$ . Distance  $L_1$  between the two surfaces.

**FIND:** (a) Distance,  $L_2$ , between the two surfaces associated with maximum irradiation on surface 2, when surface 1 emits diffusely with  $\varepsilon = 0.85$ . (b) Distance associated with maximum irradiation, when the directional emissivity of surface 1 is  $\varepsilon_\theta = \varepsilon_n \cos\theta$ . (c) Plot irradiation on surface 2 for  $0 \leq L_2 \leq 10$  m.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Surfaces can be treated as differential areas.

**ANALYSIS:** (a) Treating both surfaces as differential areas, from Eq. 12.7 and Example 12.1,

$$\omega_{2-1} = A_2 \cos\theta_2 / r^2$$

Then from Eq. 12.11 the total radiation from surface 1 to surface 2 is,

$$q_{1-2} = I_{e1} A_1 \cos\theta_1 \omega_{2-1} = (\varepsilon_1 E_{b1} / \pi) A_1 \cos\theta_1 (A_2 \cos\theta_2 / r^2) \quad (1)$$

Since  $\cos\theta_1 = \cos\theta_2 = L_2 / r$  and  $r^2 = L_1^2 + L_2^2$ , Eq. (1) can be written

$$q_{1-2} = (\varepsilon_1 E_{b1} / \pi) A_1 A_2 L_2^2 / (L_1^2 + L_2^2)^2 \quad (2)$$

We can find the value of  $L_2$  corresponding to the maximum value of  $q_{1-2}$  by differentiating Eq. (2) with respect to  $L_2$  and setting the derivative equal to zero,

$$\frac{dq_{1-2}}{dL_2} = \frac{\varepsilon_1 E_{b1}}{\pi} A_1 A_2 \left( \frac{2L_2(L_1^2 + L_2^2) - 4L_2^3}{(L_1^2 + L_2^2)^3} \right) = 0$$

$$L_{2,crit} = L_1$$

<

Continued...

**PROBLEM 12.43 (Cont.)**

(b) We repeat the calculation for the case in which surface 1 is no longer diffuse. The radiation heat transfer rate is still given by Eq. (2), except that the emissivity is the value for radiation in the direction corresponding to  $\theta_1$ . That is,

$$q_{1-2} = (\epsilon_{n1} \cos \theta_1 E_{b1} / \pi) A_1 A_2 L_2^2 / (L_1^2 + L_2^2)^2 = (\epsilon_{n1} E_{b1} / \pi) A_1 A_2 L_2^3 / (L_1^2 + L_2^2)^{2.5} \quad (3)$$

Differentiating Eq. (3),

$$\frac{dq_{1-2}}{dL_2} = \frac{\epsilon_{n1} E_{b1}}{\pi} A_1 A_2 \left( \frac{3L_2^2 (L_1^2 + L_2^2) - 5L_2^4}{(L_1^2 + L_2^2)^{3.5}} \right) = 0$$

$$L_2 = \sqrt{3/2} L_1 = 1.225 L_1$$

(c) Eqs. (2) and (3) were keyed into the *IHT* workspace and the following graph was generated.

**COMMENTS:** (1) The value of  $L_{2,crit}$  is independent of the object's temperature or emissivity, but does depend on the directional nature of the emissivity. If the detector is calibrated to respond to the proximity of a diffuse object and the object emits as a typical non-metallic material, an error of  $(1.225 - 1)/1.225 = 18\%$  results. (2) The value of  $L_{2,crit}$  can be changed by changing the separation distance,  $L_1$ . (3) The temperature and emissivity of the hotter surface must be relatively high, otherwise the reflected component will dominate and the device will not work.

## PROBLEM 12.44

**KNOWN:** Temperature of polished stainless steel. Spectral emissivity distribution.

**FIND:** Total hemispherical emissivity using 5-band integration. Emissive power.

**SCHEMATIC:**

**ASSUMPTIONS:** Spectral hemispherical and normal emissivities are equal.

**ANALYSIS:** From Equation 12.43,

$$\epsilon(T) = \frac{\int_0^{\infty} \epsilon_{\lambda} E_{\lambda,b} d\lambda}{E_b} = \frac{\sum_{i=1}^5 \epsilon_i \int_{\Delta\lambda_i} E_{\lambda,b} d\lambda}{E_b} = \sum_{i=1}^5 \epsilon_i F_{(\lambda_{i-1} \rightarrow \lambda_i)} = \sum_{i=1}^5 \epsilon_i (0.2)$$

The last equality results from the choice that each band contains 20% of the blackbody emission. The median wavelength for the first band is chosen such that  $F_{(0 \rightarrow \lambda_m)} = 0.1$ . Interpolating in Table 12.1,

$F_{(0 \rightarrow \lambda_m)} = 0.1$  when  $\lambda_{m,1} T = 2195 \mu\text{m}\cdot\text{K}$ . For  $T = 800 \text{ K}$ ,  $\lambda_{m,1} = 2195 \mu\text{m}\cdot\text{K}/800 \text{ K} = 2.74 \mu\text{m}$ . From

Figure 12.17,  $\epsilon_1 = \epsilon_{n,1} \approx 0.35$ . The following table can be constructed for all the bands:

Band	$F_{(0 \rightarrow \lambda_m)}$	$\lambda_m$ ( $\mu\text{m}$ )	$\epsilon$
1	0.1	2.74	0.35
2	0.3	3.90	0.31
3	0.5	5.14	0.28
4	0.7	6.99	0.26
5	0.9	11.73	0.20

Thus,

$$\epsilon = (\epsilon_1 + \epsilon_2 + \epsilon_3 + \epsilon_4 + \epsilon_5)(0.2) = (0.35 + 0.31 + 0.28 + 0.26 + 0.20)/5 = 0.28 \quad <$$

The surface emissive power is

$$E = \epsilon \sigma T^4 = 0.28 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K} \times (800 \text{ K})^4 = 6500 \text{ W/m}^2 \quad <$$

**COMMENTS:** Estimating the average emissivity value directly from Figure 12.17 might suggest an average value of about 0.4, leading to a 40% error in the emissive power calculation. Much of the high emissivity data plotted in Figure 12.17 are for regions for which there is negligible blackbody radiation at 800 K (see Figure 12.12).

## PROBLEM 12.45

**KNOWN:** Radiation thermometer responding to radiant power within a prescribed spectral interval and calibrated to indicate the temperature of a blackbody.

**FIND:** (a) Whether radiation thermometer will indicate temperature greater than, less than, or equal to  $T_s$  when surface has  $\varepsilon < 1$ , (b) Expression for  $T_s$  in terms of spectral radiance temperature and spectral emissivity, (c) Indicated temperature for prescribed conditions of  $T_s$  and  $\varepsilon_\lambda$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Surface is a diffuse emitter, (2) Thermometer responds to radiant flux over interval  $d\lambda$  about  $\lambda$ .

**ANALYSIS:** (a) The radiant power which reaches the radiation thermometer is

$$q_\lambda = \varepsilon_\lambda I_{\lambda,b}(\lambda, T_s) \cdot A_t \cdot \omega_t \quad (1)$$

where  $A_t$  is the area of the surface viewed by the thermometer (referred to as the target) and  $\omega_t$  the solid angle through which  $A_t$  is viewed. The thermometer responds as if it were viewing a blackbody at  $T_\lambda$ , the spectral radiance temperature,

$$q_\lambda = I_{\lambda,b}(\lambda, T_\lambda) \cdot A_t \cdot \omega_t. \quad (2)$$

By equating the two relations, Eqs. (1) and (2), find

$$I_{\lambda,b}(\lambda, T_\lambda) = \varepsilon_\lambda I_{\lambda,b}(\lambda, T_s). \quad (3)$$

Since  $\varepsilon_\lambda < 1$ , it follows that  $I_{\lambda,b}(\lambda, T_\lambda) < I_{\lambda,b}(\lambda, T_s)$  or that  $T_\lambda < T_s$ . That is, the thermometer will always indicate a temperature lower than the true or actual temperature for a surface with  $\varepsilon < 1$ .

(b) Using Wien's distribution in Eq. (3), find

$$I_\lambda(\lambda, T) = \frac{1}{\pi} C_1 \lambda^{-5} \exp(-C_2 / \lambda T)$$

$$\frac{1}{\pi} C_1 \lambda^{-5} \exp(-C_2 / \lambda T_\lambda) = \varepsilon_\lambda \cdot \frac{1}{\pi} C_1 \lambda^{-5} \exp(-C_2 / \lambda T_s).$$

Canceling terms  $(C_1 \lambda^{-5} / \pi)$ , taking natural logs of both sides of the equation and rearranging, the desired expression is

$$\frac{1}{T_s} = \frac{1}{T_\lambda} + \frac{\lambda}{C_2} \ln \varepsilon_\lambda. \quad (4) \quad <$$

(c) For  $T_s = 1000\text{K}$  and  $\varepsilon = 0.9$ , from Eq. (4), the indicated temperature is

$$\frac{1}{T_\lambda} = \frac{1}{T_s} - \frac{\lambda}{C_2} \ln \varepsilon_\lambda = \frac{1}{1000\text{K}} - \frac{0.65 \mu\text{m}}{14,388 \mu\text{m} \cdot \text{K}} \ln(0.9) \quad T_\lambda = 995.3\text{K}. \quad <$$

That is, the thermometer indicates 5K less than the true temperature. The ratio of the emissive power by Wien's distribution to that by the Planck distribution is,

$$\frac{E_{\lambda,b,\text{Wien}}}{E_{\lambda,b,\text{Planck}}} = \frac{1/\exp(C_2 / \lambda T)}{1/[\exp(C_2 / \lambda T) - 1]}.$$

Continued...

### Problem 12.45 (Cont.)

For the condition  $\lambda T = 0.65 \mu\text{m} \times 1000 \text{ K} = 650 \mu\text{m}\cdot\text{K}$ ,  $C_2/\lambda T = 14388 \mu\text{m}\cdot\text{K}/650 \mu\text{m}\cdot\text{K} = 22.14$  and

$$\frac{E_{\lambda,b}|_{\text{Wien}}}{E_{\lambda,b}|_{\text{Planck}}} = \frac{1/\exp(22.14)}{1/[\exp(22.14)-1]} = 0.995. \quad <$$

Thus, Wien's spectral distribution is an excellent approximation to Planck's distribution for this situation.

### PROBLEM 12.46

**KNOWN:** Spectral distribution of emission from a blackbody. Uncertainty in measurement of intensity.

**FIND:** Corresponding uncertainties in using the intensity measurement to determine (a) the surface temperature or (b) the emissivity.

**ASSUMPTIONS:** Diffuse surface behavior.

**ANALYSIS:** From Eq. 12.29, the spectral intensity associated with emission may be expressed as

$$I_{\lambda,e} = \varepsilon_{\lambda} I_{\lambda,b} = \frac{\varepsilon_{\lambda} C_1 / \pi}{\lambda^5 [\exp(C_2 / \lambda T) - 1]}$$

(a) To determine the effect of temperature on intensity, we evaluate the derivative,

$$\frac{\partial I_{\lambda,e}}{\partial T} = - \frac{(\varepsilon_{\lambda} C_1 / \pi) \lambda^5 \exp(C_2 / \lambda T) (-C_2 / \lambda T^2)}{\left\{ \lambda^5 [\exp(C_2 / \lambda T) - 1] \right\}^2}$$

$$\frac{\partial I_{\lambda,e}}{\partial T} = \frac{(C_2 / \lambda T^2) \exp(C_2 / \lambda T)}{\exp(C_2 / \lambda T) - 1} I_{\lambda,e}$$

Hence,

$$\frac{dT}{T} = \frac{1 - \exp(-C_2 / \lambda T)}{(C_2 / \lambda T)} \frac{dI_{\lambda,e}}{I_{\lambda,e}}$$

With  $(dI_{\lambda,e} / I_{\lambda,e}) = 0.1$ ,  $C_2 = 1.439 \times 10^4 \mu\text{m} \cdot \text{K}$  and  $\lambda = 10 \mu\text{m}$ ,

$$\frac{dT}{T} = \left[ \frac{1 - \exp(-1439 \text{ K} / T)}{1439 \text{ K} / T} \right] \times 0.1$$

$$T = 500 \text{ K}: \quad dT/T = 0.033 \rightarrow 3.3\% \text{ uncertainty} \quad <$$

$$T = 1000 \text{ K}: \quad dT/T = 0.053 \rightarrow 5.3\% \text{ uncertainty} \quad <$$

(b) To determine the effect of the emissivity on intensity, we evaluate

$$\frac{\partial I_{\lambda,e}}{\partial \varepsilon_{\lambda}} = I_{\lambda,b} = \frac{I_{\lambda,e}}{\varepsilon_{\lambda}}$$

$$\text{Hence, } \frac{d\varepsilon_{\lambda}}{\varepsilon_{\lambda}} = \frac{dI_{\lambda,e}}{I_{\lambda,e}} = 0.10 \rightarrow 10\% \text{ uncertainty} \quad <$$

**COMMENTS:** The uncertainty in the temperature is less than that of the intensity, but increases with increasing temperature (and wavelength). In the limit as  $C_2 / \lambda T \rightarrow 0$ ,  $\exp(-C_2 / \lambda T) \rightarrow 1 - C_2 / \lambda T$  and  $dT/T \rightarrow dI_{\lambda,e} / I_{\lambda,e}$ . The uncertainty in temperature then corresponds to that of the intensity measurement. The same is true for the uncertainty in the emissivity, irrespective of the value of  $T$  or  $\lambda$ .

### PROBLEM 12.47

**KNOWN:** Temperature, thickness and spectral emissivity of steel strip emerging from a hot roller. Temperature dependence of total, hemispherical emissivity.

**FIND:** (a) Initial total, hemispherical emissivity, (b) Initial cooling rate, (c) Time to cool to prescribed final temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible conduction (in longitudinal direction), convection and radiation from surroundings, (2) Negligible transverse temperature gradients.

**PROPERTIES:** Steel (given):  $\rho = 7900 \text{ kg/m}^3$ ,  $c = 640 \text{ J/kg}\cdot\text{K}$ ,  $\varepsilon = 1200\varepsilon_i/T \text{ (K)}$ .

**ANALYSIS:** (a) The initial total hemispherical emissivity is

$$\varepsilon_i = \int_0^{\infty} \varepsilon_{\lambda} [E_{\lambda b}(1200)/E_b(1200)] d\lambda$$

and integrating by parts using values from Table 12.1, find

$$\lambda T = 1200 \mu\text{m}\cdot\text{K} \rightarrow F_{(0-1\mu\text{m})} = 0.002; \lambda T = 7200 \mu\text{m}\cdot\text{K} \rightarrow F_{(0-6\mu\text{m})} = 0.819$$

$$\varepsilon_i = 0.6 \times 0.002 + 0.4(0.819 - 0.002) + 0.25(1 - 0.819) = 0.373. \quad <$$

(b) From an energy balance on a unit surface area of strip (top and bottom),

$$-\dot{E}_{\text{out}} = dE_{\text{st}}/dt \quad -2\varepsilon\sigma T^4 = d(\rho\delta cT)/dt$$

$$\left. \frac{dT}{dt} \right|_i = -\frac{2\varepsilon_i\sigma T_i^4}{\rho\delta c} = \frac{-2(0.373)5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (1200 \text{ K})^4}{7900 \text{ kg/m}^3 (0.003 \text{ m})(640 \text{ J/kg}\cdot\text{K})} = -5.78 \text{ K/s}. \quad <$$

(c) From the energy balance,

$$\frac{dT}{dt} = -\frac{2\varepsilon_i(1200/T)\sigma T^4}{\rho\delta c}, \int_{T_i}^{T_f} \frac{dT}{T^3} = -\frac{2400\varepsilon_i\sigma}{\rho\delta c} \int_0^t dt, \quad t = \frac{\rho\delta c}{4800\varepsilon_i\sigma} \left( \frac{1}{T_f^2} - \frac{1}{T_i^2} \right)$$

$$t = \frac{7900 \text{ kg/m}^3 (0.003 \text{ m}) 640 \text{ J/kg}\cdot\text{K}}{4800 \text{ K} \times 0.373 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4} \left( \frac{1}{600^2} - \frac{1}{1200^2} \right) \text{K}^{-2} = 311 \text{ s}. \quad <$$

**COMMENTS:** Initially, from Eq. 1.9,  $h_r \approx \varepsilon_i\sigma T_i^3 = 36.6 \text{ W/m}^2 \cdot \text{K}$ . Assuming a plate width of  $W = 1 \text{ m}$ , the Rayleigh number may be evaluated from  $Ra_L = g\beta(T_i - T_{\infty})(W/2)^3/\nu\alpha$ . Assuming  $T_{\infty} = 300 \text{ K}$  and evaluating properties at  $T_f = 750 \text{ K}$ ,  $Ra_L = 1.8 \times 10^8$ . From Eq. 9.31,  $Nu_L = 84$ , giving  $\bar{h} = 9.2 \text{ W/m}^2 \cdot \text{K}$ . Hence heat loss by radiation exceeds that associated with free convection. To check the validity of neglecting transverse temperature gradients, compute  $Bi = h(\delta/2)/k$ . With  $h = 36.6 \text{ W/m}^2 \cdot \text{K}$  and  $k = 28 \text{ W/m}\cdot\text{K}$ ,  $Bi = 0.002 \ll 1$ . Hence the assumption is valid.

### PROBLEM 12.48

**KNOWN:** Large body of nonluminous gas at 1200 K has emission bands between 2.5 – 3.5  $\mu\text{m}$  and between 5 – 8  $\mu\text{m}$  with effective emissivities of 0.8 and 0.6, respectively.

**FIND:** Emissive power of the gas.

**SCHEMATIC:** —

**ASSUMPTIONS:** (1) Gas radiates only in specified bands, (2) Emitted radiation is diffuse.

**ANALYSIS:** The emissive power of the gas is

$$E_g = \varepsilon E_b(T_g) = \int_0^{\infty} \varepsilon_{\lambda} E_{\lambda,b}(T_g) d\lambda$$

$$E_g = \int_{2.5}^{3.5} \varepsilon_{\lambda,1} E_{\lambda,b}(T_g) d\lambda + \int_5^8 \varepsilon_{\lambda,2} E_{\lambda,b}(T_g) d\lambda$$

$$E_g = \left[ \varepsilon_1 F(2.5-3.5 \mu\text{m}) + \varepsilon_2 F(5-8 \mu\text{m}) \right] \sigma T_g^4.$$

Using the blackbody function  $F_{(0-\lambda T)}$  from Table 12.1 with  $T_g = 1200$  K,

$\lambda T(\mu\text{m}\cdot\text{K})$	$2.5 \times 1200$	$3.5 \times 1200$	$5 \times 1200$	$8 \times 1200$
	3000	4200	6000	9600
$F_{(0-\lambda T)}$	0.273	0.516	0.738	0.905

so that

$$F(2.5-3.5 \mu\text{m}) = F(0-3.5 \mu\text{m}) - F(0-2.5 \mu\text{m}) = 0.516 - 0.273 = 0.243$$

$$F(5-8 \mu\text{m}) = F(0-8 \mu\text{m}) - F(0-5 \mu\text{m}) = 0.905 - 0.738 = 0.167.$$

Hence the emissive power is

$$E_g = [0.8 \times 0.243 + 0.6 \times 0.167] 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (1200 \text{ K})^4$$

$$E_g = 0.295 \times 117,573 \text{ W/m}^2 = 34,684 \text{ W/m}^2. \quad <$$

**COMMENTS:** Note that the effective emissivity for the gas is 0.295. This seems surprising since emission occurs only at the discrete bands. Since  $\lambda_{\text{max}} = 2.4 \mu\text{m}$ , all of the spectral emissive power is at wavelengths beyond the peak of blackbody radiation at 1200 K.

## PROBLEM 12.49

**KNOWN:** An opaque surface with prescribed spectral, hemispherical reflectivity distribution is subjected to a prescribed spectral irradiation.

**FIND:** (a) The spectral, hemispherical absorptivity, (b) Total irradiation, (c) The absorbed radiant flux, and (d) Total, hemispherical absorptivity.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Surface is opaque.

**ANALYSIS:** (a) The spectral, hemispherical absorptivity,  $\alpha_\lambda$ , for an opaque surface is given by Eq. 12.62,

$$\alpha_\lambda = 1 - \rho_\lambda \quad <$$

which is shown as a dashed line on the  $\rho_\lambda$  distribution axes.

(b) The total irradiation,  $G$ , follows from Eq. 12.19 which can be integrated by parts,

$$G = \int_0^\infty G_\lambda d\lambda = \int_0^{5\mu\text{m}} G_\lambda d\lambda + \int_{5\mu\text{m}}^{10\mu\text{m}} G_\lambda d\lambda + \int_{10\mu\text{m}}^{20\mu\text{m}} G_\lambda d\lambda$$

$$G = \frac{1}{2} \times 600 \frac{\text{W}}{\text{m}^2 \cdot \mu\text{m}} (5 - 0) \mu\text{m} + 600 \frac{\text{W}}{\text{m}^2 \cdot \mu\text{m}} (10 - 5) \mu\text{m} + \frac{1}{2} \times 600 \frac{\text{W}}{\text{m}^2 \cdot \mu\text{m}} \times (20 - 10) \mu\text{m}$$

$$G = 7500 \text{ W/m}^2. \quad <$$

(c) The absorbed irradiation follows from Eqs. 12.51 and 12.52 with the form

$$G_{\text{abs}} = \int_0^\infty \alpha_\lambda G_\lambda d\lambda = \alpha_1 \int_0^{5\mu\text{m}} G_\lambda d\lambda + G_{\lambda,2} \int_{5\mu\text{m}}^{10\mu\text{m}} \alpha_\lambda d\lambda + \alpha_3 \int_{10\mu\text{m}}^{20\mu\text{m}} G_\lambda d\lambda.$$

Noting that  $\alpha_1 = 1.0$  for  $\lambda = 0 \rightarrow 5 \mu\text{m}$ ,  $G_{\lambda,2} = 600 \text{ W/m}^2 \cdot \mu\text{m}$  for  $\lambda = 5 \rightarrow 10 \mu\text{m}$  and  $\alpha_3 = 0$  for  $\lambda > 10 \mu\text{m}$ , find that

$$G_{\text{abs}} = 1.0 \left( 0.5 \times 600 \text{ W/m}^2 \cdot \mu\text{m} \right) (5 - 0) \mu\text{m} + 600 \text{ W/m}^2 \cdot \mu\text{m} (0.5 \times 0.5) (10 - 5) \mu\text{m} + 0$$

$$G_{\text{abs}} = 2250 \text{ W/m}^2. \quad <$$

(d) The total, hemispherical absorptivity is defined as the fraction of the total irradiation that is absorbed. From Eq. 12.51,

$$\alpha = \frac{G_{\text{abs}}}{G} = \frac{2250 \text{ W/m}^2}{7500 \text{ W/m}^2} = 0.30. \quad <$$

**COMMENTS:** Recognize that the total, hemispherical absorptivity,  $\alpha = 0.3$ , is for the given spectral irradiation. For a different  $G_\lambda$ , one would then expect a different value for  $\alpha$ .

## PROBLEM 12.50

**KNOWN:** Temperature and spectral emissivity of small object suspended in large furnace of prescribed temperature and total emissivity.

**FIND:** (a) Total surface emissivity and absorptivity, (b) Reflected radiative flux and net radiative flux to surface, (c) Spectral emissive power at  $\lambda = 2 \mu\text{m}$ , (d) Wavelength  $\lambda_{1/2}$  for which one-half of total emissive power is in spectral region  $\lambda \geq \lambda_{1/2}$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Surface is opaque and diffuse, (2) Walls of furnace are much larger than object.

**ANALYSIS:** (a) The emissivity of the object may be obtained from Eq. 12.43, which is expressed as

$$\varepsilon(T_s) = \frac{\int_0^{\infty} \varepsilon_{\lambda}(\lambda) E_{\lambda,b}(\lambda, T_s) d\lambda}{E_b(T)} = \varepsilon_1 \left[ F_{(0 \rightarrow 3\mu\text{m})} - F_{(0 \rightarrow 1\mu\text{m})} \right] + \varepsilon_2 \left[ 1 - F_{(0 \rightarrow 3\mu\text{m})} \right]$$

where, with  $\lambda_1 T_s = 400 \mu\text{m}\cdot\text{K}$  and  $\lambda_2 T_s = 1200 \mu\text{m}\cdot\text{K}$ ,  $F_{(0 \rightarrow 1\mu\text{m})} = 0$  and  $F_{(0 \rightarrow 3\mu\text{m})} = 0.002$ . Hence,

$$\varepsilon(T_s) = 0.7(0.002) + 0.5(0.998) = 0.500 \quad <$$

The absorptivity of the surface is determined by Eq. 12.52,

$$\alpha = \frac{\int_0^{\infty} \alpha_{\lambda}(\lambda) G_{\lambda}(\lambda) d\lambda}{\int_0^{\infty} G_{\lambda}(\lambda) d\lambda} = \frac{\int_0^{\infty} \alpha_{\lambda}(\lambda) E_{\lambda,b}(\lambda, T_f) d\lambda}{E_b(T_f)}$$

Hence, with  $\lambda_1 T_f = 2000 \mu\text{m}\cdot\text{K}$  and  $\lambda_2 T_f = 6000 \mu\text{m}\cdot\text{K}$ ,  $F_{(0 \rightarrow 1\mu\text{m})} = 0.067$  and  $F_{(0 \rightarrow 3\mu\text{m})} = 0.738$ . It follows that

$$\alpha = \alpha_1 \left[ F_{(0 \rightarrow 3\mu\text{m})} - F_{(0 \rightarrow 1\mu\text{m})} \right] + \alpha_2 \left[ 1 - F_{(0 \rightarrow 3\mu\text{m})} \right] = 0.7 \times 0.671 + 0.5 \times 0.262 = 0.601 \quad <$$

(b) The reflected radiative flux is

$$G_{\text{ref}} = \rho G = (1 - \alpha) E_b(T_f) = 0.399 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (2000 \text{ K})^4 = 3.620 \times 10^5 \text{ W/m}^2 \quad <$$

The net radiative flux to the surface is

$$q_{\text{rad}}'' = G - \rho G - \varepsilon E_b(T_s) = \alpha E_b(T_f) - \varepsilon E_b(T_s)$$

$$q_{\text{rad}}'' = 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left[ 0.601 (2000 \text{ K})^4 - 0.500 (400 \text{ K})^4 \right] = 5.438 \times 10^5 \text{ W/m}^2 \quad <$$

(c) At  $\lambda = 2 \mu\text{m}$ ,  $\lambda T_s = 800 \text{ K}$  and, from Table 12.1,  $I_{\lambda,b}(\lambda, T) / \sigma T^5 = 0.991 \times 10^{-7} (\mu\text{m}\cdot\text{K}\cdot\text{sr})^{-1}$ . Hence,

Continued...

**PROBLEM 12.50 (Cont.)**

$$I_{\lambda,b} = 0.991 \times 10^{-7} \times 5.67 \times 10^{-8} \frac{\text{W}/\text{m}^2 \cdot \text{K}^4}{\mu\text{m} \cdot \text{K} \cdot \text{sr}} \times (400 \text{ K})^5 = 0.0575 \frac{\text{W}}{\text{m}^2 \cdot \mu\text{m} \cdot \text{sr}}$$

Hence, with  $E_{\lambda} = \varepsilon_{\lambda} E_{\lambda,b} = \varepsilon_{\lambda} \pi I_{\lambda,b}$ ,

$$E_{\lambda} = 0.7 (\pi \text{sr}) 0.0575 \text{ W}/\text{m}^2 \cdot \mu\text{m} \cdot \text{sr} = 0.126 \text{ W}/\text{m}^2 \cdot \mu\text{m} \quad <$$

(d) From Table 12.1,  $F_{(0 \rightarrow \lambda)} = 0.5$  corresponds to  $\lambda T_s \approx 4100 \mu\text{m} \cdot \text{K}$ , in which case,

$$\lambda_{1/2} \approx 4100 \mu\text{m} \cdot \text{K} / 400 \text{ K} \approx 10.3 \mu\text{m} \quad <$$

**COMMENTS:** Because of the significant difference between  $T_f$  and  $T_s$ ,  $\alpha \neq \varepsilon$ . With increasing  $T_s \rightarrow T_f$ ,  $\varepsilon$  would increase and approach a value of 0.601.

## PROBLEM 12.51

**KNOWN:** Small flat plate maintained at 400 K coated with white paint having spectral absorptivity distribution (Figure 12.22) approximated as a staircase function. Enclosure surface maintained at 3000 K with prescribed spectral emissivity distribution.

**FIND:** (a) Total emissivity of the enclosure surface,  $\epsilon_{es}$ , and (b) Total emissivity,  $\epsilon$ , and absorptivity,  $\alpha$ , of the surface.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Coated plate with white paint is diffuse and opaque, so that  $\alpha_\lambda = \epsilon_\lambda$ , (2) Plate is small compared to the enclosure surface, and (3) Enclosure surface is isothermal, diffuse and opaque.

**ANALYSIS:** (a) The total emissivity of the enclosure surface at  $T_{es} = 3000$  K follows from Eq. 12.43 which can be expressed in terms of the band emission factor,  $F_{(0-\lambda T)}$ , Eq. 12.35,

$$\epsilon_{e,s} = \epsilon_1 F_{(0-\lambda_1 T_{es})} + \epsilon_2 [1 - F_{(0-\lambda_1 T_{es})}] = 0.2 \times 0.738 + 0.9 [1 - 0.738] = 0.383 \quad <$$

where, from Table 12.1, with  $\lambda_1 T_{es} = 2 \mu\text{m} \times 3000 \text{ K} = 6000 \mu\text{m}\cdot\text{K}$ ,  $F_{(0-\lambda T)} = 0.738$ .

(b) The total emissivity of the coated plate at  $T = 400$  K can be expressed as

$$\epsilon = \alpha_1 F_{(0-\lambda_1 T_s)} + \alpha_2 [F_{(0-\lambda_2 T_s)} - F_{(0-\lambda_1 T_s)}] + \alpha_3 [1 - F_{(0-\lambda_2 T_s)}]$$

$$\epsilon = 0.75 \times 0 + 0.15 [0.002134 - 0.000] + 0.96 [1 - 0.002134] = 0.958 \quad <$$

where, from Table 12.1, the band emission factors are: for  $\lambda_1 T_s = 0.4 \times 400 = 160 \mu\text{m}\cdot\text{K}$ , find  $F_{(0-\lambda_1 T_s)} = 0.000$ ; for  $\lambda_2 T_s = 3.0 \times 400 = 1200 \mu\text{m}\cdot\text{K}$ , find  $F_{(0-\lambda_2 T_s)} = 0.002134$ . The total absorptivity for the irradiation due to the enclosure surface at  $T_{es} = 3000$  K is

$$\alpha = \alpha_1 F_{(0-\lambda_1 T_{es})} + \alpha_2 [F_{(0-\lambda_2 T_{es})} - F_{(0-\lambda_1 T_{es})}] + \alpha_3 [1 - F_{(0-\lambda_2 T_{es})}]$$

$$\alpha = 0.75 \times 0.002134 + 0.15 [0.8900 - 0.002134] + 0.96 [1 - 0.8900] = 0.240 \quad <$$

where, from Table 12.1, the band emission factors are: for  $\lambda_1 T_{es} = 0.4 \times 3000 = 1200 \mu\text{m}\cdot\text{K}$ , find  $F_{(0-\lambda_1 T_{es})} = 0.002134$ ; for  $\lambda_2 T_{es} = 3.0 \times 3000 = 9000 \mu\text{m}\cdot\text{K}$ , find  $F_{(0-\lambda_2 T_{es})} = 0.8900$ .

**COMMENTS:** (1) In evaluating the total emissivity and absorptivity, remember that  $\epsilon = \epsilon(\epsilon_\lambda, T_s)$  and  $\alpha = \alpha(\alpha_\lambda, G_\lambda)$  where  $T_s$  is the temperature of the surface and  $G_\lambda$  is the spectral irradiation, which if the surroundings are large and isothermal,  $G_\lambda = E_{b,\lambda}(T_{sur})$ . Hence,  $\alpha = \alpha(\alpha_\lambda, T_{sur})$ . For the opaque, diffuse surface,  $\alpha_\lambda = \epsilon_\lambda$ . (2) Note that the coated plate (white paint) has an absorptivity for the 3000 K-enclosure surface irradiation of  $\alpha = 0.240$ . You would expect it to be a low value since the coating appears visually “white”. (3) The emissivity of the coated plate is quite high,  $\epsilon = 0.958$ . Would you have expected this of a “white paint”? Most paints are oxide systems (high absorptivity at long wavelengths) with pigmentation (controls the “color” and hence absorptivity in the visible and near infrared regions).

## PROBLEM 12.52

**KNOWN:** Area, temperature, irradiation and spectral absorptivity of a surface.

**FIND:** Absorbed irradiation, emissive power, radiosity and net radiation transfer from the surface.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Opaque, diffuse surface behavior, (2) Spectral distribution of solar radiation corresponds to emission from a blackbody at 5800 K.

**ANALYSIS:** The absorptivity to solar irradiation is

$$\alpha_s = \frac{\int_0^\infty \alpha_\lambda G_\lambda d\lambda}{G} = \frac{\int_0^\infty \alpha_\lambda E_{\lambda b}(5800 \text{ K}) d\lambda}{E_b} = \alpha_1 F_{(0.5 \rightarrow 1 \mu\text{m})} + \alpha_2 F_{(2 \rightarrow \infty)}$$

From Table 12.1,

$$\lambda T = 2900 \mu\text{m}\cdot\text{K}:$$

$$F_{(0 \rightarrow 0.5 \mu\text{m})} = 0.250$$

$$\lambda T = 5800 \mu\text{m}\cdot\text{K}:$$

$$F_{(0 \rightarrow 1 \mu\text{m})} = 0.720$$

$$\lambda T = 11,600 \mu\text{m}\cdot\text{K}:$$

$$F_{(0 \rightarrow 2 \mu\text{m})} = 0.941$$

$$\alpha_s = 0.8(0.720 - 0.250) + 0.9(1 - 0.941) = 0.429.$$

Hence,  $G_{\text{abs}} = \alpha_s G_S = 0.429(1200 \text{ W/m}^2) = 515 \text{ W/m}^2.$  <

The emissivity is

$$\varepsilon = \frac{\int_0^\infty \varepsilon_\lambda E_{\lambda b}(400 \text{ K}) d\lambda}{E_b} = \varepsilon_1 F_{(0.5 \rightarrow 1 \mu\text{m})} + \varepsilon_2 F_{(2 \rightarrow \infty)}$$

From Table 12.1,

$$\lambda T = 200 \mu\text{m}\cdot\text{K}:$$

$$F_{(0 \rightarrow 0.5 \mu\text{m})} = 0$$

$$\lambda T = 400 \mu\text{m}\cdot\text{K}:$$

$$F_{(0 \rightarrow 1 \mu\text{m})} = 0$$

$$\lambda T = 800 \mu\text{m}\cdot\text{K}:$$

$$F_{(0 \rightarrow 2 \mu\text{m})} = 0.$$

Hence,  $\varepsilon = \varepsilon_2 = 0.9,$

$$E = \varepsilon \sigma T_s^4 = 0.9 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (400 \text{ K})^4 = 1306 \text{ W/m}^2. <$$

The radiosity is

$$J = E + \rho_S G_S = E + (1 - \alpha_s) G_S = [1306 + 0.571 \times 1200] \text{ W/m}^2 = 1991 \text{ W/m}^2. <$$

The net radiation transfer from the surface is

$$q_{\text{net}} = (E - \alpha_s G_S) A_s = (1306 - 515) \text{ W/m}^2 \times 4 \text{ m}^2 = 3164 \text{ W}. <$$

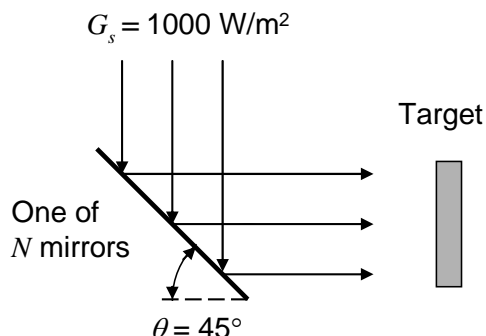

**COMMENTS:** Unless 3164 W are supplied to the surface by other means (for example, by convection), the surface temperature will decrease with time.

### PROBLEM 12.53

**KNOWN:** Solar irradiation, specular reflectivity of polished silver, absorptivity of wood, cumulative irradiation of  $N$  mirrors from  $N$  students,  $G_{s,N} = 70,000 \text{ W/m}^2$  as in Problem 4.51.

**FIND:** (a) Number of students,  $N$ , for first-surface mirrors, (b) Number of students,  $N$ , for second-surface mirrors.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Spectral transmissivity of plain glass as in Problem 12.62, (2) Solar irradiation is that of a blackbody at  $T_s = 5800 \text{ K}$ .

**ANALYSIS:** (a) From the schematic for the first-surface mirror,

$$G_{s,N} = NG_s \rho_m \alpha_w \quad \text{or} \quad N = \frac{G_{s,N}}{G_s \rho_m \alpha_w} = \frac{70,000 \text{ W/m}^2}{1000 \text{ W/m}^2 \times 0.98 \times 0.80} = 90 \quad <$$

where  $\rho_m$  is the reflectivity of the silver surface and  $\alpha_w$  is the absorptivity of the wood.

(b) From the schematic for a second-surface mirror,  $G_{s,N} = NG_s \tau_g \rho_m \alpha_w$  where  $\tau_g$  is the transmissivity of the plain glass. Using Table 12.1,

$$\begin{array}{lll} \lambda_2 = 2.5 \mu\text{m} & \lambda_{2T} = 2.5 \mu\text{m} \times 5800 \text{ K} = 14,500 \mu\text{m}\cdot\text{K} & F(0 \rightarrow \lambda_2) = 0.966 \\ \lambda_1 = 0.3 \mu\text{m} & \lambda_{1T} = 0.3 \mu\text{m} \times 5800 \text{ K} = 1740 \mu\text{m}\cdot\text{K} & F(0 \rightarrow \lambda_1) = 0.033 \end{array}$$

$$\tau_g = 0.9(0.966 - 0.033) = 0.839 \quad \text{and}$$

$$N = \frac{G_{s,N}}{G_s \tau_g \rho_m \alpha_w} = \frac{70,000 \text{ W/m}^2}{1000 \text{ W/m}^2 \times 0.839 \times 0.98 \times 0.80} = 106 \quad <$$

**COMMENTS:** (1) The first-surface mirror is preferred in order to maximize the irradiation of the target. (2) First-surface mirrors are used in applications involving large radiation heat fluxes, such as in laser processing. Use of a second-surface mirrors might lead to excessive heating of the mirror material (glass) and failure of the mirrors.

### PROBLEM 12.54

**KNOWN:** Temperature and spectral emissivity of a receiving surface. Direction and spectral distribution of incident flux. Distance and aperture of surface radiation detector.

**FIND:** Radiant power received by the detector.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Target surface is diffuse, (2)  $A_d/L^2 \ll 1$ .

**ANALYSIS:** The radiant power received by the detector depends on emission and reflection from the target.

$$q_d = I_{e+r} A_s \cos \theta_{d-s} \Delta \omega_{d-s}$$

$$q_d = \frac{\varepsilon \sigma T_s^4 + \rho G}{\pi} A_s \frac{A_d}{L^2}$$

$$\varepsilon = \frac{\int_0^{\infty} \varepsilon_{\lambda} E_{\lambda b}(700 \text{ K}) d\lambda}{E_b(700 \text{ K})} = \varepsilon_1 F_{(3 \rightarrow 10 \mu\text{m})} + \varepsilon_2 F_{(10 \rightarrow \infty)}$$

From Table 12.1,

$$\lambda T = 2100 \mu\text{m}\cdot\text{K}:$$

$$F_{(0 \rightarrow 3 \mu\text{m})} = 0.0838$$

$$\lambda T = 7000 \mu\text{m}\cdot\text{K}:$$

$$F_{(0 \rightarrow 10 \mu\text{m})} = 0.8081.$$

The emissivity can be expected as

$$\varepsilon = 0.5(0.8081 - 0.0838) + 0.9(1 - 0.8081) = 0.535.$$

Also,

$$\rho = \frac{\int_0^{\infty} \rho_{\lambda} G_{\lambda} d\lambda}{G} = \frac{\int_0^{\infty} (1 - \varepsilon_{\lambda}) q''_{\lambda} d\lambda}{q''} = 1 \times F_{(1 \rightarrow 3 \mu\text{m})} + 0.5 \times F_{(3 \rightarrow 6 \mu\text{m})}$$

$$\rho = 1 \times 0.4 + 0.5 \times 0.6 = 0.70.$$

Hence, with  $G = q'' \cos \theta_i = 866 \text{ W/m}^2$ ,

$$q_d = \frac{0.535 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (700 \text{ K})^4 + 0.7 \times 866 \text{ W/m}^2}{\pi} 10^{-4} \text{ m}^2 \frac{10^{-5} \text{ m}^2}{(1 \text{ m})^2}$$

$$q_d = 2.51 \times 10^{-6} \text{ W.} \quad <$$

**COMMENTS:** A total radiation detector cannot discriminate between emitted and reflected radiation from a surface.

## PROBLEM 12.55

**KNOWN:** Small disk positioned at center of an isothermal, hemispherical enclosure with a small aperture.

**FIND:** Radiant power [ $\mu\text{W}$ ] leaving the aperture.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Disk is diffuse-gray, (2) Enclosure is isothermal and has area much larger than disk, (3) Aperture area is very small compared to enclosure area, (4) Areas of disk and aperture are small compared to radius squared of the enclosure.

**ANALYSIS:** The radiant power leaving the aperture is due to radiation leaving the disk and to irradiation on the aperture from the enclosure. That is,

$$q_{ap} = q_{1 \rightarrow 2} + G_2 \cdot A_2. \quad (1)$$

The radiation leaving the disk can be written in terms of the radiosity of the disk. For the diffuse disk,

$$q_{1 \rightarrow 2} = \frac{1}{\pi} J_1 \cdot A_1 \cos \theta_1 \cdot \omega_{2-1} \quad (2)$$

and with  $\varepsilon = \alpha$  for the gray behavior, the radiosity is

$$J_1 = \varepsilon_1 E_b(T_1) + \rho G_1 = \varepsilon_1 \sigma T_1^4 + (1 - \varepsilon_1) \sigma T_3^4 \quad (3)$$

where the irradiation  $G_1$  is the emissive power of the black enclosure,  $E_b(T_3)$ ;  $G_1 = G_2 = E_b(T_3)$ .

The solid angle  $\omega_{2-1}$  follows from Eq. 12.7,

$$\omega_{2-1} = A_2 / R^2. \quad (4)$$

Combining Eqs. (2), (3) and (4) into Eq. (1) with  $G_2 = \sigma T_3^4$ , the radiant power is

$$\begin{aligned} q_{ap} &= \frac{1}{\pi} \sigma \left[ \varepsilon_1 T_1^4 + (1 - \varepsilon_1) T_3^4 \right] A_1 \cos \theta_1 \cdot \frac{A_2}{R^2} + A_2 \sigma T_3^4 \\ q_{ap} &= \frac{1}{\pi} 5.67 \times 10^{-8} \frac{\text{W}}{\text{m}^2 \cdot \text{K}^4} \left[ 0.7(900\text{K})^4 + (1 - 0.7)(300\text{K})^4 \right] \frac{\pi}{4} (0.005\text{m})^2 \cos 45^\circ \times \\ &\quad \frac{\pi/4 (0.002\text{m})^2}{(0.100\text{m})^2} + \frac{\pi}{4} (0.002\text{m})^2 5.67 \times 10^{-8} \text{W} / \text{m}^2 \cdot \text{K}^4 (300\text{K})^4 \\ q_{ap} &= (36.2 + 0.19 + 1443) \mu\text{W} = 1479 \mu\text{W}. \quad < \end{aligned}$$

**COMMENTS:** Note the relative magnitudes of the three radiation components. Also, recognize that the emissivity of the enclosure  $\varepsilon_3$  doesn't enter into the analysis. Why?

### PROBLEM 12.56

**KNOWN:** Spectral, hemispherical absorptivity of an opaque surface.

**FIND:** (a) Solar absorptivity, (b) Total, hemispherical emissivity for  $T_s = 340\text{K}$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Surface is opaque, (2)  $\varepsilon_\lambda = \alpha_\lambda$ , (3) Solar spectrum has  $G_\lambda = G_{\lambda,S}$  proportional to  $E_{\lambda,b}(\lambda, 5800\text{K})$ .

**ANALYSIS:** (a) The solar absorptivity follows from Eq. 12.53.

$$\alpha_S = \int_0^\infty \alpha_\lambda(\lambda) E_{\lambda,b}(\lambda, 5800\text{K}) d\lambda / \int_0^\infty E_{\lambda,b}(\lambda, 5800\text{K}) d\lambda.$$

The integral can be written in three parts using  $F_{(0 \rightarrow \lambda)}$  terms.

$$\alpha_S = \alpha_1 F_{(0 \rightarrow 0.3\mu\text{m})} + \alpha_2 \left[ F_{(0 \rightarrow 1.5\mu\text{m})} - F_{(0 \rightarrow 0.3\mu\text{m})} \right] + \alpha_3 \left[ 1 - F_{(0 \rightarrow 1.5\mu\text{m})} \right].$$

From Table 12.1,

$$\begin{aligned} \lambda T = 0.3 \times 5800 &= 1740 \mu\text{m}\cdot\text{K} & F_{(0 \rightarrow 0.3 \mu\text{m})} &= 0.0335 \\ \lambda T = 1.5 \times 5800 &= 8700 \mu\text{m}\cdot\text{K} & F_{(0 \rightarrow 1.5 \mu\text{m})} &= 0.8805. \end{aligned}$$

Hence,

$$\alpha_S = 0 \times 0.0335 + 0.9 [0.8805 - 0.0335] + 0.1 [1 - 0.8805] = 0.774. \quad <$$

(b) The total, hemispherical emissivity for the surface at 340K will be

$$\varepsilon = \int_0^\infty \varepsilon_\lambda(\lambda) E_{\lambda,b}(\lambda, 340\text{K}) d\lambda / E_b(340\text{K}).$$

If  $\varepsilon_\lambda = \alpha_\lambda$ , then using the  $\alpha_\lambda$  distribution above, the integral can be written in terms of  $F_{(0 \rightarrow \lambda)}$  values. It is readily recognized that since

$$F_{(0 \rightarrow 1.5 \mu\text{m}, 340\text{K})} \approx 0.000 \quad \text{at} \quad \lambda T = 1.5 \times 340 = 510 \mu\text{m}\cdot\text{K}$$

there is negligible spectral emissive power below 1.5  $\mu\text{m}$ . It follows then that

$$\varepsilon = \varepsilon_\lambda = \alpha_\lambda = 0.1 \quad <$$

**COMMENTS:** The assumption  $\varepsilon_\lambda = \alpha_\lambda$  can be satisfied if this surface were irradiated diffusely or if the surface itself were diffuse. Note that for this surface under the specified conditions of solar irradiation and surface temperature  $\alpha_S \neq \varepsilon$ . Such a surface is referred to as a spectrally selective surface.

### PROBLEM 12.57

**KNOWN:** Spectral distribution of the absorptivity and irradiation of a surface at 1000 K.

**FIND:** (a) Total, hemispherical absorptivity, (b) Total, hemispherical emissivity, (c) Net radiant flux to the surface.

**SCHEMATIC:**

**ASSUMPTIONS:** (1)  $\alpha_\lambda = \varepsilon_\lambda$ .

**ANALYSIS:** (a) From Eq. 12.52,

$$\alpha = \frac{\int_0^\infty \alpha_\lambda G_\lambda d\lambda}{\int_0^\infty G_\lambda d\lambda} = \frac{\int_0^{2\mu\text{m}} \alpha_\lambda G_\lambda d\lambda + \int_2^{4\mu\text{m}} \alpha_\lambda G_\lambda d\lambda + \int_4^{6\mu\text{m}} \alpha_\lambda G_\lambda d\lambda}{\int_0^{2\mu\text{m}} G_\lambda d\lambda + \int_2^{4\mu\text{m}} G_\lambda d\lambda + \int_4^{6\mu\text{m}} G_\lambda d\lambda}$$

$$\alpha = \frac{0 \times 1/2(2-0)5000 + 0.6(4-2)5000 + 0.6 \times 1/2(6-4)5000}{1/2(2-0)5000 + (4-2)(5000) + 1/2(6-4)5000}$$

$$\alpha = \frac{9000}{20,000} = 0.45. \quad <$$

(b) From Eq. 12.43,

$$\varepsilon = \frac{\int_0^\infty \varepsilon_\lambda E_{\lambda,b} d\lambda}{E_b} = \frac{0 \int_0^{2\mu\text{m}} E_{\lambda,b} d\lambda}{E_b} + \frac{0.6 \int_2^\infty E_{\lambda,b} d\lambda}{E_b}$$

$$\varepsilon = 0.6 F_{(2\mu\text{m} \rightarrow \infty)} = 0.6 [1 - F_{(0 \rightarrow 2\mu\text{m})}].$$

From Table 12.1, with  $\lambda T = 2 \mu\text{m} \times 1000\text{K} = 2000 \mu\text{m}\cdot\text{K}$ , find  $F_{(0 \rightarrow 2 \mu\text{m})} = 0.0667$ . Hence,

$$\varepsilon = 0.6 [1 - 0.0667] = 0.56. \quad <$$

(c) The net radiant heat flux to the surface is

$$q''_{\text{rad,net}} = \alpha G - E = \alpha G - \varepsilon \sigma T^4$$

$$q''_{\text{rad,net}} = 0.45 (20,000 \text{ W/m}^2) - 0.56 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times (1000\text{K})^4$$

$$q''_{\text{rad,net}} = (9000 - 31,751) \text{ W/m}^2 = -22,751 \text{ W/m}^2. \quad <$$

### PROBLEM 12.58

**KNOWN:** Spectral distribution of surface absorptivity and irradiation. Surface temperature.

**FIND:** (a) Total absorptivity, (b) Emissive power, (c) Nature of surface temperature change.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Opaque, diffuse surface behavior, (2) Convection effects are negligible.

**ANALYSIS:** (a) From Eqs. 12.51 and 12.52, the absorptivity is defined as

$$\alpha \equiv G_{\text{abs}} / G = \int_0^{\infty} \alpha_{\lambda} G_{\lambda} d\lambda / \int_0^{\infty} G_{\lambda} d\lambda.$$

The absorbed irradiation is,

$$G_{\text{abs}} = 0.4 \left( 5000 \text{ W/m}^2 \cdot \mu\text{m} \times 2 \mu\text{m} \right) / 2 + 0.8 \times 5000 \text{ W/m}^2 \cdot \mu\text{m} (5 - 2) \mu\text{m} + 0 = 14,000 \text{ W/m}^2.$$

The irradiation is,

$$G = \left( 2 \mu\text{m} \times 5000 \text{ W/m}^2 \cdot \mu\text{m} \right) / 2 + (10 - 2) \mu\text{m} \times 5000 \text{ W/m}^2 \cdot \mu\text{m} = 45,000 \text{ W/m}^2.$$

Hence,  $\alpha = 14,000 \text{ W/m}^2 / 45,000 \text{ W/m}^2 = 0.311.$  <

(b) From Eq. 12.43, the emissivity is

$$\varepsilon = \int_0^{\infty} \varepsilon_{\lambda} E_{\lambda,b} d\lambda / E_b = 0.4 \int_0^2 E_{\lambda,b} d\lambda / E_b + 0.8 \int_2^5 E_{\lambda,b} d\lambda / E_b$$

From Table 12.1,  $\lambda T = 2 \mu\text{m} \times 1250\text{K} = 2500\text{K}$ ,  $F_{(0-2)} = 0.162$   
 $\lambda T = 5 \mu\text{m} \times 1250\text{K} = 6250\text{K}$ ,  $F_{(0-5)} = 0.757.$

Hence,  $\varepsilon = 0.4 \times 0.162 + 0.8(0.757 - 0.162) = 0.54.$

$$E = \varepsilon E_b = \varepsilon \sigma T^4 = 0.54 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (1250\text{K})^4 = 74,751 \text{ W/m}^2. \quad <$$

(c) From an energy balance on the surface, the net heat flux *to* the surface is

$$q''_{\text{net}} = \alpha G - E = (14,000 - 74,751) \text{ W/m}^2 = -60,751 \text{ W/m}^2.$$

Hence the temperature of the surface is *decreasing*. <

**COMMENTS:** Note that  $\alpha \neq \varepsilon$ . Hence the surface is not gray for the prescribed conditions.

### PROBLEM 12.59

**KNOWN:** Spectral emissivity of an opaque, diffuse surface.

**FIND:** (a) Total, hemispherical emissivity of the surface when maintained at 1000 K, (b) Total, hemispherical absorptivity when irradiated by large surroundings of emissivity 0.8 and temperature 1500 K, (c) Radiosity when maintained at 1000 K and irradiated as prescribed in part (b), (d) Net radiation flux into surface for conditions of part (c), and (e) Compute and plot each of the parameters of parts (a)-(c) as a function of the surface temperature  $T_s$  for the range  $750 < T_s \leq 2000$  K.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Surface is opaque, diffuse, and (2) Surroundings are large compared to the surface.

**ANALYSIS:** (a) When the surface is maintained at 1000 K, the total, hemispherical emissivity is evaluated from Eq. 12.43 written as

$$\begin{aligned}\varepsilon &= \int_0^{\infty} \varepsilon_{\lambda} E_{\lambda,b}(T) d\lambda / E_b(T) = \varepsilon_{\lambda,1} \int_0^{\lambda_1} E_{\lambda,b}(T) d\lambda / E_b(T) + \varepsilon_{\lambda,2} \int_{\lambda_1}^{\infty} E_{\lambda,b}(T) d\lambda / E_b(T) \\ \varepsilon &= \varepsilon_{\lambda,1} F_{(0-\lambda_1)T} + \varepsilon_{\lambda,2} (1 - F_{(0-\lambda_1)T})\end{aligned}$$

where for  $\lambda T = 6 \mu\text{m} \times 1000 \text{ K} = 6000 \mu\text{m}\cdot\text{K}$ , from Table 12.1, find  $F_{0-\lambda T} = 0.738$ . Hence,

$$\varepsilon = 0.8 \times 0.738 + 0.3(1 - 0.738) = 0.669. \quad <$$

(b) When the surface is irradiated by large surroundings at  $T_{\text{sur}} = 1500 \text{ K}$ ,  $G = E_b(T_{\text{sur}})$ . From Eq. 12.52,

$$\begin{aligned}\alpha &= \int_0^{\infty} \alpha_{\lambda} G_{\lambda} d\lambda / \int_0^{\infty} G_{\lambda} d\lambda = \int_0^{\infty} \varepsilon_{\lambda} E_{\lambda,b}(T_{\text{sur}}) d\lambda / E_b(T_{\text{sur}}) \\ \alpha &= \varepsilon_{\lambda,1} F_{(0-\lambda_1)T_{\text{sur}}} + \varepsilon_{\lambda,2} (1 - F_{(0-\lambda_1)T_{\text{sur}}})\end{aligned}$$

where for  $\lambda_1 T_{\text{sur}} = 6 \mu\text{m} \times 1500 \text{ K} = 9000 \mu\text{m}\cdot\text{K}$ , from Table 12.1, find  $F_{(0-\lambda T)} = 0.890$ . Hence,

$$\alpha = 0.8 \times 0.890 + 0.3(1 - 0.890) = 0.745. \quad <$$

Note that  $\alpha_{\lambda} = \varepsilon_{\lambda}$  for all conditions and the emissivity of the surroundings is irrelevant.

(c) The radiosity for the surface maintained at 1000 K and irradiated as in part (b) is

$$\begin{aligned}J &= \varepsilon E_b(T) + \rho G = \varepsilon E_b(T) + (1 - \alpha) E_b(T_{\text{sur}}) \\ J &= 0.669 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (1000 \text{ K})^4 + (1 - 0.745) 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (1500 \text{ K})^4 \\ J &= (37,932 + 73,196) \text{ W/m}^2 = 111,128 \text{ W/m}^2 \quad <\end{aligned}$$

Continued...

### PROBLEM 12.59 (Cont.)

(d) The net radiation flux into the surface with  $G = \sigma T_{\text{sur}}^4$  is

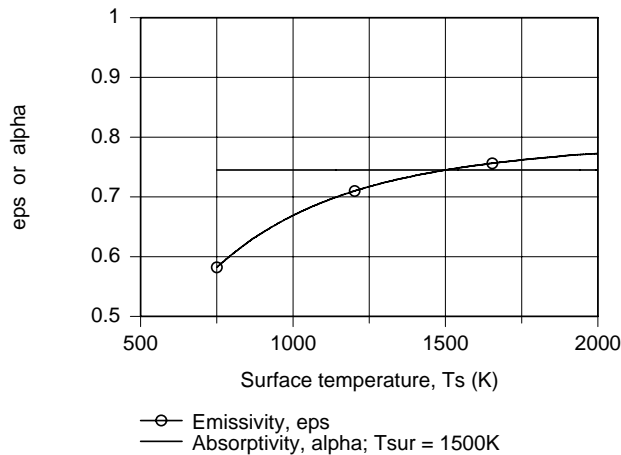

$$q''_{\text{rad,in}} = \alpha G - \varepsilon E_b(T) = G - J$$

$$q''_{\text{rad,in}} = 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K} (1500 \text{ K})^4 - 111,128 \text{ W/m}^2$$

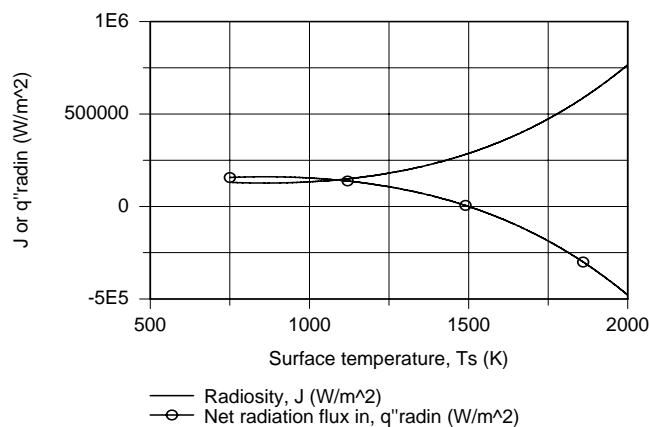

$$q''_{\text{rad,in}} = 175,915 \text{ W/m}^2.$$

(e) The foregoing equations were entered into the IHT workspace along with the *IHT Radiation Tool*, *Band Emission Factor*, to evaluate  $F_{(0-\lambda T)}$  values and the respective parameters for parts (a)-(d) were computed and are plotted below.

Note that the absorptivity,  $\alpha = \alpha(\alpha_\lambda, T_{\text{sur}})$ , remains constant as  $T_s$  changes since it is a function of  $\alpha_\lambda$  (or  $\varepsilon_\lambda$ ) and  $T_{\text{sur}}$  only. The emissivity  $\varepsilon = \varepsilon(\varepsilon_\lambda, T_s)$  is a function of  $T_s$  and increases as  $T_s$  increases. Could you have surmised as much by looking at the spectral emissivity distribution? At what condition is  $\varepsilon = \alpha$ ?

The radiosity,  $J_1$  increases with increasing  $T_s$  since  $E_b(T)$  increases markedly with temperature; the reflected irradiation,  $(1 - \alpha)E_b(T_{\text{sur}})$  decreases only slightly as  $T_s$  increases compared to  $E_b(T)$ . Since  $G$  is independent of  $T_s$ , it follows that the variation of  $q''_{\text{rad,in}}$  will be due to the radiosity change; note the sign difference.

**COMMENTS:** We didn't use the emissivity of the surroundings ( $\varepsilon = 0.8$ ) to determine the irradiation onto the surface. Why?

### PROBLEM 12.60

**KNOWN:** Furnace wall temperature and aperture diameter. Distance of detector from aperture and orientation of detector relative to aperture.

**FIND:** (a) Rate at which radiation from the furnace is intercepted by the detector, (b) Effect of aperture window of prescribed spectral transmissivity on the radiation interception rate.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Radiation emerging from aperture has characteristics of emission from a blackbody, (2) Cover material is diffuse, (3) Aperture and detector surface may be approximated as infinitesimally small.

**ANALYSIS:** (a) From Eq. 12.12, the heat rate leaving the furnace aperture and intercepted by the detector is

$$q = I_e A_a \cos \theta_1 \omega_{s-a}$$

From Eqs. 12.17 and 12.32

$$I_e = \frac{E_b(T_f)}{\pi} = \frac{\sigma T_f^4}{\pi} = \frac{5.67 \times 10^{-8} (1500)^4}{\pi} = 9.14 \times 10^4 \text{ W/m}^2 \cdot \text{sr}.$$

From Eq. 12.7,

$$\omega_{s-a} = \frac{A_n}{r^2} = \frac{A_s \cdot \cos \theta_2}{r^2} = \frac{10^{-5} \text{ m}^2 \times \cos 45^\circ}{(1 \text{ m})^2} = 0.707 \times 10^{-5} \text{ sr}.$$

Hence

$$q = 9.14 \times 10^4 \text{ W/m}^2 \cdot \text{sr} \left[ \pi (0.02 \text{ m})^2 / 4 \right] \cos 30^\circ \times 0.707 \times 10^{-5} \text{ sr} = 1.76 \times 10^{-4} \text{ W}. <$$

(b) With the window, the heat rate is

$$q = \tau (I_e A_a \cos \theta_1 \omega_{s-a})$$

where  $\tau$  is the transmissivity of the window to radiation emitted by the furnace wall. From Eq. 12.61,

$$\tau = \frac{\int_0^\infty \tau_\lambda G_\lambda d\lambda}{\int_0^\infty G_\lambda d\lambda} = \frac{\int_0^\infty \tau_\lambda E_{\lambda,b}(T_f) d\lambda}{\int_0^\infty E_{\lambda,b} d\lambda} = 0.8 \int_0^2 (E_{\lambda,b} / E_b) d\lambda = 0.8 F_{(0 \rightarrow 2 \mu\text{m})}.$$

With  $\lambda T = 2 \mu\text{m} \times 1500 \text{ K} = 3000 \mu\text{m} \cdot \text{K}$ , Table 12.1 gives  $F_{(0 \rightarrow 2 \mu\text{m})} = 0.273$ . Hence, with  $\tau = 0.273 \times 0.8 = 0.218$ , find

$$q = 0.218 \times 1.76 \times 10^{-4} \text{ W} = 0.384 \times 10^{-4} \text{ W}. <$$

## PROBLEM 12.61

**KNOWN:** Approximate spectral transmissivity of 1-mm thick liquid water layer.

**FIND:** (a) Transmissivity of a 1-mm thick water layer adjacent to surface at the critical temperature ( $T_s = 647.3 \text{ K}$ ), (b) Transmissivity of a 1-mm thick water layer subject to irradiation from a melting platinum wire ( $T_s = 2045 \text{ K}$ ), (c) Transmissivity of a 1-mm thick water layer subject to solar irradiation at  $T_s = 5800 \text{ K}$ .

**SCHEMATIC:**

**ASSUMPTIONS:** Irradiation is proportional to that of a blackbody.

**ANALYSIS:** From Eq. 12.61 and incorporating the assumption, the transmissivity is expressed as

$$\tau = \frac{\int_0^{\infty} \tau_{\lambda} E_{\lambda,b} d\lambda}{E_b} = \frac{\tau_{\lambda,1} \int_0^{1.2} E_{\lambda,b} d\lambda}{E_b} + \frac{\tau_{\lambda,2} \int_{1.2}^{1.8} E_{\lambda,b} d\lambda}{E_b} + \frac{\tau_{\lambda,3} \int_{1.8}^{\infty} E_{\lambda,b} d\lambda}{E_b} \quad \text{or}$$

$$\tau = \tau_{\lambda,1} F_{(0-1.2\mu\text{m})} + \tau_{\lambda,2} F_{(1.2-1.8\mu\text{m})} + \tau_{\lambda,3} F_{(1.8\mu\text{m}-\infty)}$$

where  $F_{(1.2-1.8\mu\text{m})} = F_{(0-1.8\mu\text{m})} - F_{(0-1.2\mu\text{m})}$  and  $F_{(1.8\mu\text{m}-\infty)} = 1 - F_{(0-1.2\mu\text{m})} - F_{(1.2-1.8\mu\text{m})}$

(a) For a source temperature of 647.3 K,

$$F_{(0-1.2\mu\text{m})} = 1.414 \times 10^{-5}, \quad F_{(0-1.8\mu\text{m})} = 0.001818$$

$$\tau = 0.99 \times 1.414 \times 10^{-5} + 0.54 \times (0.001818 - 1.414 \times 10^{-5}) = 0.00099 \quad <$$

(b) For a source temperature of 2045 K,

$$F_{(0-1.2\mu\text{m})} = 0.1518, \quad F_{(0-1.8\mu\text{m})} = 0.4197$$

$$\tau = 0.99 \times 0.1518 + 0.54 \times (0.4197 - 0.1518) = 0.295 \quad <$$

(c) For a source temperature of 5800 K,

$$F_{(0-1.2\mu\text{m})} = 0.8057, \quad F_{(0-1.8\mu\text{m})} = 0.9226$$

$$\tau = 0.99 \times 0.8057 + 0.54 \times (0.9226 - 0.8057) = 0.861 \quad <$$

**COMMENTS:** Liquid water may be treated as opaque for most engineering applications. Exceptions include applications involving solar irradiation, irradiation from very high temperature plasmas that can achieve temperatures at tens of thousands of kelvins, and situations involving very thin layers of liquid water.

## PROBLEM 12.62

**KNOWN:** Spectral transmissivity of a plain and tinted glass.

**FIND:** (a) Solar energy transmitted by each glass, (b) Visible radiant energy transmitted by each with solar irradiation.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Spectral distribution of solar irradiation is proportional to spectral emissive power of a blackbody at 5800K.

**ANALYSIS:** To compare the energy transmitted by the glasses, it is sufficient to calculate the transmissivity of each glass for the prescribed spectral range when the irradiation distribution is that of the solar spectrum. From Eq. 12.61,

$$\tau_S = \int_0^{\infty} \tau_{\lambda} \cdot G_{\lambda, S} d\lambda / \int_0^{\infty} G_{\lambda, S} d\lambda = \int_0^{\infty} \tau_{\lambda} \cdot E_{\lambda, b}(\lambda, 5800\text{K}) d\lambda / E_b(5800\text{K}).$$

Recognizing that  $\tau_{\lambda}$  will be constant for the range  $\lambda_1 \rightarrow \lambda_2$ , using Eq. 12.29, find

$$\tau_S = \tau_{\lambda} \cdot F(\lambda_1 \rightarrow \lambda_2) = \tau_{\lambda} \left[ F(0 \rightarrow \lambda_2) - F(0 \rightarrow \lambda_1) \right].$$

(a) For the two glasses, the solar transmissivity, using Table 12.1 for F, is then

<i>Plain glass:</i>	$\lambda_2 = 2.5 \mu\text{m}$	$\lambda_2 T = 2.5 \mu\text{m} \times 5800\text{K} = 14,500 \mu\text{m}\cdot\text{K}$	$F(0 \rightarrow \lambda_2) = 0.966$
	$\lambda_1 = 0.3 \mu\text{m}$	$\lambda_1 T = 0.3 \mu\text{m} \times 5800\text{K} = 1,740 \mu\text{m}\cdot\text{K}$	$F(0 \rightarrow \lambda_1) = 0.033$

$$\tau_S = 0.9 [0.966 - 0.033] = 0.839. \quad <$$

<i>Tinted glass:</i>	$\lambda_2 = 1.5 \mu\text{m}$	$\lambda_2 T = 1.5 \mu\text{m} \times 5800\text{K} = 8,700 \mu\text{m}\cdot\text{K}$	$F(0 \rightarrow \lambda_2) = 0.881$
	$\lambda_1 = 0.5 \mu\text{m}$	$\lambda_1 T = 0.5 \mu\text{m} \times 5800\text{K} = 2,900 \mu\text{m}\cdot\text{K}$	$F(0 \rightarrow \lambda_1) = 0.250$

$$\tau_S = 0.9 [0.881 - 0.250] = 0.568. \quad <$$

(b) The limits of the visible spectrum are  $\lambda_1 = 0.4$  and  $\lambda_2 = 0.7 \mu\text{m}$ . For the tinted glass,  $\lambda_1 = 0.5 \mu\text{m}$  rather than  $0.4 \mu\text{m}$ . From Table 12.1,

$\lambda_2 = 0.7 \mu\text{m}$	$\lambda_2 T = 0.7 \mu\text{m} \times 5800\text{K} = 4,060 \mu\text{m}\cdot\text{K}$	$F(0 \rightarrow \lambda_2) = 0.491$
$\lambda_1 = 0.5 \mu\text{m}$	$\lambda_1 T = 0.5 \mu\text{m} \times 5800\text{K} = 2,900 \mu\text{m}\cdot\text{K}$	$F(0 \rightarrow \lambda_1) = 0.250$
$\lambda_1 = 0.4 \mu\text{m}$	$\lambda_1 T = 0.4 \mu\text{m} \times 5800\text{K} = 2,320 \mu\text{m}\cdot\text{K}$	$F(0 \rightarrow \lambda_1) = 0.125$

<i>Plain glass:</i>	$\tau_{\text{vis}} = 0.9 [0.491 - 0.125] = 0.329$	<
---------------------	---	---

<i>Tinted glass:</i>	$\tau_{\text{vis}} = 0.9 [0.491 - 0.250] = 0.217$	<
----------------------	---	---

**COMMENTS:** For solar energy, the transmissivities are 0.839 for the plain glass vs. 0.568 for the tinted glass. Within the visible region,  $\tau_{\text{vis}}$  is 0.329 vs. 0.217. Tinting reduces solar flux by 32% and visible solar flux by 34%.

### PROBLEM 12.63

**KNOWN:** Spectral transmissivity of low iron glass (see Fig. 12.23).

**FIND:** Interpretation of the greenhouse effect.

**SCHEMATIC:**

**ANALYSIS:** The glass affects the net radiation transfer to the contents of the greenhouse. Since most of the solar radiation is in the spectral region  $\lambda < 3 \mu\text{m}$ , the glass will transmit a large fraction of this radiation. However, the contents of the greenhouse, being at a comparatively low temperature, emit most of their radiation in the medium to far infrared. This radiation is not transmitted by the glass. Hence the glass allows short wavelength solar radiation to enter the greenhouse, but does not permit long wavelength radiation to leave.

## PROBLEM 12.64

**KNOWN:** Spectrally selective, diffuse surface exposed to solar irradiation.

**FIND:** (a) Spectral transmissivity,  $\tau_\lambda$ , (b) Transmissivity,  $\tau_S$ , reflectivity,  $\rho_S$ , and absorptivity,  $\alpha_S$ , for solar irradiation, (c) Emissivity,  $\varepsilon$ , when surface is at  $T_s = 350\text{K}$ , (d) Net heat flux by radiation to the surface.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Surface is diffuse, (2) Spectral distribution of solar irradiation is proportional to  $E_{\lambda,b}(\lambda, 5800\text{K})$ .

**ANALYSIS:** (a) Conservation of radiant energy requires, according to Eq. 12.54, that  $\rho_\lambda + \alpha_\lambda + \tau_\lambda = 1$  or  $\tau_\lambda = 1 - \rho_\lambda - \alpha_\lambda$ . Hence, the spectral transmissivity appears as shown above (dashed line). Note that the surface is opaque for  $\lambda > 1.38 \mu\text{m}$ .

(b) The transmissivity to solar irradiation,  $G_S$ , follows from Eq. 12.61,

$$\tau_S = \int_0^\infty \tau_\lambda G_{\lambda,S} d\lambda / G_S = \int_0^\infty \tau_\lambda E_{\lambda,b}(\lambda, 5800\text{K}) d\lambda / E_b(5800\text{K})$$

$$\tau_S = \tau_{\lambda,b} \int_0^{1.38} E_{\lambda,b}(\lambda, 5800\text{K}) d\lambda / E_b(5800\text{K}) = \tau_{\lambda,1} F_{(0 \rightarrow \lambda_1)} = 0.7 \times 0.856 = 0.599 \quad <$$

where  $\lambda_1 T_S = 1.38 \times 5800 = 8000 \mu\text{m}\cdot\text{K}$  and from Table 12.1,  $F_{(0 \rightarrow \lambda_1)} = 0.856$ . From Eqs. 12.58 and 12.63,

$$\rho_S = \int_0^\infty \rho_\lambda G_{\lambda,S} d\lambda / G_S = \rho_{\lambda,1} F_{(0 \rightarrow \lambda_1)} = 0.1 \times 0.856 = 0.086 \quad <$$

$$\alpha_S = 1 - \rho_S - \tau_S = 1 - 0.086 - 0.599 = 0.315. \quad <$$

(c) For the surface at  $T_s = 350\text{K}$ , the emissivity can be determined from Eq. 12.43. Since the surface is diffuse, according to Eq. 12.67,  $\alpha_\lambda = \varepsilon_\lambda$ , the expression has the form

$$\varepsilon = \int_0^\infty \varepsilon_\lambda E_{\lambda,b}(T_s) d\lambda / E_b(T_s) = \int_0^\infty \alpha_\lambda E_{\lambda,b}(350\text{K}) d\lambda / E_b(350\text{K})$$

$$\varepsilon = \alpha_{\lambda,1} F_{(0-1.38 \mu\text{m})} + \alpha_{\lambda,2} [1 - F_{(0-1.38 \mu\text{m})}] = \alpha_{\lambda,2} = 1 \quad <$$

where from Table 12.1 with  $\lambda_1 T_s = 1.38 \times 350 = 483 \mu\text{m}\cdot\text{K}$ ,  $F_{(0-\lambda T)} \approx 0$ .

(d) The net heat flux by radiation to the surface is determined by a radiation balance

$$q''_{\text{rad}} = G_S - \rho_S G_S - \tau_S G_S - E$$

$$q''_{\text{rad}} = \alpha_S G_S - E$$

$$q''_{\text{rad}} = 0.315 \times 750 \text{ W/m}^2 - 1.0 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (350\text{K})^4 = -615 \text{ W/m}^2. \quad <$$

## PROBLEM 12.65

**KNOWN:** Large furnace with diffuse, opaque walls ( $T_f$ ,  $\varepsilon_f$ ) and a small diffuse, spectrally selective object ( $T_o$ ,  $\tau_\lambda$ ,  $\rho_\lambda$ ).

**FIND:** For points on the furnace wall and the object, find  $\varepsilon$ ,  $\alpha$ ,  $E$ ,  $G$  and  $J$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Furnace walls are isothermal, diffuse, and gray, (2) Object is isothermal and diffuse.

**ANALYSIS:** Consider first the furnace wall (A). Since the wall material is diffuse and gray, it follows that

$$\varepsilon_A = \varepsilon_f = \alpha_A = 0.85. \quad <$$

The emissive power is

$$E_A = \varepsilon_A E_b(T_f) = \varepsilon_A \sigma T_f^4 = 0.85 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (3000 \text{ K})^4 = 3.904 \times 10^6 \text{ W/m}^2. \quad <$$

Since the furnace is an isothermal enclosure, blackbody conditions exist such that

$$G_A = J_A = E_b(T_f) = \sigma T_f^4 = 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (3000 \text{ K})^4 = 4.593 \times 10^6 \text{ W/m}^2. \quad <$$

Considering now the semitransparent, diffuse, spectrally selective object at  $T_o = 300 \text{ K}$ . From the radiation balance requirement, find

$$\alpha_\lambda = 1 - \rho_\lambda - \tau_\lambda \quad \text{or} \quad \alpha_1 = 1 - 0.6 - 0.3 = 0.1 \quad \text{and} \quad \alpha_2 = 1 - 0.7 - 0.0 = 0.3$$

$$\alpha_B = \int_0^\infty \alpha_\lambda G_\lambda d\lambda / G = F_{0-\lambda T} \cdot \alpha_1 + (1 - F_{0-\lambda T}) \cdot \alpha_2 = 0.970 \times 0.1 + (1 - 0.970) \times 0.3 = 0.106 \quad <$$

where  $F_{0-\lambda T} = 0.970$  at  $\lambda T = 5 \mu\text{m} \times 3000 \text{ K} = 15,000 \mu\text{m} \cdot \text{K}$  since  $G = E_b(T_f)$ . Since the object is diffuse,  $\varepsilon_\lambda = \alpha_\lambda$ , hence

$$\varepsilon_B = \int_0^\infty \varepsilon_\lambda E_{\lambda,b}(T_o) d\lambda / E_{b,o} = F_{0-\lambda T} \alpha_1 + (1 - F_{0-\lambda T}) \cdot \alpha_2 = 0.0138 \times 0.1 + (1 - 0.0138) \times 0.3 = 0.297 \quad <$$

where  $F_{0-\lambda T} = 0.0138$  at  $\lambda T = 5 \mu\text{m} \times 300 \text{ K} = 1500 \mu\text{m} \cdot \text{K}$ . The emissive power is

$$E_B = \varepsilon_B E_{b,B}(T_o) = 0.297 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (300 \text{ K})^4 = 136.5 \text{ W/m}^2. \quad <$$

The irradiation is that due to the large furnace for which blackbody conditions exist,

$$G_B = G_A = \sigma T_f^4 = 4.593 \times 10^6 \text{ W/m}^2. \quad <$$

The radiosity leaving point B is due to emission and reflected irradiation,

$$J_B = E_B + \rho_B G_B = 136.5 \text{ W/m}^2 + 0.3 \times 4.593 \times 10^6 \text{ W/m}^2 = 1.378 \times 10^6 \text{ W/m}^2. \quad <$$

If we include transmitted irradiation,  $J_B = E_B + (\rho_B + \tau_B) G_B = E_B + (1 - \alpha_B) G_B = 4.106 \times 10^6 \text{ W/m}^2$ .

In the first calculation, note how we set  $\rho_B \approx \rho_\lambda (\lambda < 5 \mu\text{m})$ .

### PROBLEM 12.66

**KNOWN:** Spectral characteristics of four diffuse surfaces exposed to solar radiation.

**FIND:** Surfaces which may be assumed to be gray.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Diffuse surface behavior.

**ANALYSIS:** A gray surface is one for which  $\alpha_\lambda$  and  $\varepsilon_\lambda$  are constant over the spectral regions of the irradiation and the surface emission.

For  $\lambda = 3 \mu\text{m}$  and  $T = 5800\text{K}$ ,  $\lambda T = 17,400 \mu\text{m}\cdot\text{K}$  and from Table 12.1, find  $F_{(0 \rightarrow \lambda)} = 0.984$ . Hence, 98.4% of the solar radiation is in the spectral region below  $3 \mu\text{m}$ .

For  $\lambda = 6 \mu\text{m}$  and  $T = 300\text{K}$ ,  $\lambda T = 1800 \mu\text{m}\cdot\text{K}$  and from Table 12.1, find  $F_{(0 \rightarrow \lambda)} = 0.039$ . Hence, 96.1% of the surface emission is in the spectral region above  $6 \mu\text{m}$ .

Hence:	Surface A is gray:	$\alpha_S \approx \varepsilon = 0.8$	<
	Surface B is not gray:	$\alpha_S \approx 0.8, \varepsilon \approx 0.3$	<
	Surface C is not gray:	$\alpha_S \approx 0.3, \varepsilon \approx 0.7$	<
	Surface D is gray:	$\alpha_S \approx \varepsilon = 0.3$ .	<

### PROBLEM 12.67

**KNOWN:** A gray, but directionally selective, material with  $\alpha(\theta, \phi) = 0.5(1 - \cos\phi)$ .

**FIND:** (a) Hemispherical absorptivity when irradiated with collimated solar flux in the direction ( $\theta = 45^\circ$  and  $\phi = 0^\circ$ ) and (b) Hemispherical emissivity of the material.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Gray surface behavior.

**ANALYSIS:** (a) The surface has the directional absorptivity given as

$$\alpha(\theta, \phi) = \alpha_{\lambda, \phi} = 0.5[1 - \cos\phi].$$

When irradiated in the direction  $\theta = 45^\circ$  and  $\phi = 0^\circ$ , the directional absorptivity for this condition is

$$\alpha(45^\circ, 0^\circ) = 0.5[1 - \cos(0^\circ)] = 0. \quad <$$

That is, the surface is completely reflecting (or transmitting) for irradiation in this direction.

(b) From Kirchhoff's law, Eq. 12.68

$$\alpha_{\theta, \phi} = \varepsilon_{\theta, \phi}$$

so that

$$\varepsilon_{\theta, \phi} = \alpha_{\theta, \phi} = 0.5(1 - \cos\phi).$$

Using Eq. 12.41 find

$$\varepsilon = \frac{\int_0^{2\pi} \int_0^{\pi/2} \varepsilon_{\theta, \phi, \lambda} \cos\theta \sin\theta d\theta d\phi}{\int_0^{2\pi} \int_0^{\pi/2} \cos\theta \sin\theta d\theta d\phi}$$

$$\varepsilon = \frac{\int_0^{2\pi} 0.5(1 - \cos\phi) d\phi}{\int_0^{2\pi} d\phi} = \frac{0.5(\phi - \sin\phi)}{2\pi} \Bigg|_0^{2\pi} = 0.5. \quad <$$

## PROBLEM 12.68

**KNOWN:** Approximate spectral transmissivity of polymer film over the range  $2.5 \mu\text{m} \leq \lambda \leq 15 \mu\text{m}$ .

**FIND:** (a) Maximum possible total transmissivity for irradiation from blackbody at  $30^\circ\text{C}$ , (b) Minimum possible total transmissivity for irradiation from blackbody at  $30^\circ\text{C}$ , (c) Maximum and minimum possible total transmissivities for a source temperature of  $600^\circ\text{C}$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Irradiation is proportional to that of a blackbody.

**ANALYSIS:** (a) The maximum possible total transmissivity is associated with  $\tau_{\lambda,1} = \tau_{\lambda,5} = 1$ . From Eq. 12.61 and incorporating the assumption, the total transmissivity is written as

$$\tau = \frac{\int_0^{\infty} \tau_{\lambda} E_{\lambda,b} d\lambda}{E_b} = \frac{\tau_{\lambda,1} \int_0^{2.5} E_{\lambda,b} d\lambda}{E_b} + \frac{\tau_{\lambda,2} \int_{2.5}^7 E_{\lambda,b} d\lambda}{E_b} + \frac{\tau_{\lambda,3} \int_7^{13} E_{\lambda,b} d\lambda}{E_b} + \frac{\tau_{\lambda,4} \int_{13}^{15} E_{\lambda,b} d\lambda}{E_b} + \frac{\tau_{\lambda,5} \int_{15}^{\infty} E_{\lambda,b} d\lambda}{E_b}$$

or

$$\tau = \tau_{\lambda,1} F_{(0-2.5\mu\text{m})} + \tau_{\lambda,2} F_{(2.5-7\mu\text{m})} + \tau_{\lambda,3} F_{(7-13\mu\text{m})} + \tau_{\lambda,4} F_{(13-15\mu\text{m})} + \tau_{\lambda,5} F_{(15\mu\text{m}-\infty)}$$

where, at  $T_s = 30^\circ\text{C} + 273 \text{ K} = 303 \text{ K}$ ,

$$F_{(2.5-7\mu\text{m})} = F_{(0-7\mu\text{m})} - F_{(0-2.5\mu\text{m})} = 0.08739 - 1.26 \times 10^{-5} = 0.08738$$

$$F_{(7-13\mu\text{m})} = F_{(0-13\mu\text{m})} - F_{(0-7\mu\text{m})} = 0.4694 - 0.008739 = 0.3820$$

$$F_{(13-15\mu\text{m})} = F_{(0-15\mu\text{m})} - F_{(0-13\mu\text{m})} = 0.5709 - 0.4694 = 0.1015$$

$$F_{(15\mu\text{m}-\infty)} = 1 - F_{(0-15\mu\text{m})} = 1 - 0.5709 = 0.4291$$

Therefore,

Continued...

### PROBLEM 12.68 (Cont.)

$$\tau_{\max} = 1 \times 1.26 \times 10^{-5} + 0.80 \times 0.08738 + 0.05 \times 0.3820 + 0.55 \times 0.1015 + 1 \times 0.4291 = 0.574 <$$

(b) The minimum possible total transmissivity is associated with  $\tau_{\lambda,1} = \tau_{\lambda,5} = 0$ . Hence,

$$\tau_{\min} = 0 \times 1.26 \times 10^{-5} + 0.80 \times 0.08738 + 0.05 \times 0.3820 + 0.55 \times 0.1015 + 0 \times 0.4291 = 0.145 <$$

(c) at  $T_s = 600^\circ\text{C} + 273 \text{ K} = 873 \text{ K}$ ,

$$F_{(2.5-7\mu\text{m})} = F_{(0-7\mu\text{m})} - F_{(0-2.5\mu\text{m})} = 0.7469 - 0.0979 = 0.6490$$

$$F_{(7-13\mu\text{m})} = F_{(0-13\mu\text{m})} - F_{(0-7\mu\text{m})} = 0.9375 - 0.7469 = 0.1906$$

$$F_{(13-15\mu\text{m})} = F_{(0-15\mu\text{m})} - F_{(0-13\mu\text{m})} = 0.9559 - 0.9375 = 0.0184$$

$$F_{(15\mu\text{m}-\infty)} = 1 - F_{(0-15\mu\text{m})} = 1 - 0.9559 = 0.0441$$

Therefore,

$$\tau_{\max} = 1 \times 0.0979 + 0.80 \times 0.6490 + 0.05 \times 0.1906 + 0.55 \times 0.0184 + 1 \times 0.0441 = 0.681 <$$

The minimum possible total transmissivity is associated with  $\tau_{\lambda,1} = \tau_{\lambda,5} = 0$ . Hence,

$$\tau_{\min} = 0 \times 0.0979 + 0.80 \times 0.6490 + 0.05 \times 0.1906 + 0.55 \times 0.0184 + 0 \times 0.0441 = 0.539 <$$

**COMMENTS:** (1) For irradiation from the low temperature source, 43% of the irradiation is in the wavelength range greater than  $15 \mu\text{m}$ . Since the spectral transmissivity is not known in this wavelength range, there is a very large uncertainty regarding the total transmissivity of the polymer film. (2) For irradiation from the high temperature source,  $9.8\% + 4.4\% = 14.4\%$  of the irradiation is in wavelength ranges less than  $2.5 \mu\text{m}$  and greater than  $15 \mu\text{m}$ . Hence, the uncertainty of the total transmissivity of the polymer film is significantly smaller than that associated with the low temperature source. (3) A source temperature exists for which the uncertainty in the total transmissivity is minimum. This temperature is between  $30^\circ\text{C}$  and  $600^\circ\text{C}$ . Why?

### PROBLEM 12.69

**KNOWN:** Thickness, thermal conductivity and surface temperatures of a flat plate. Irradiation on the top surface, reflected irradiation, air and water temperatures, air convection coefficient.

**FIND:** Transmissivity, reflectivity, absorptivity, and emissivity of the plate. Radiosity of the surface. Convection coefficient associated with the water flow.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Opaque and diffuse surface, (2) Water is opaque to thermal radiation.

**ANALYSIS:** The plate is opaque. Therefore,  $\tau = 0$  <

The reflectivity is  $\rho = \rho G / G = (435 \text{ W/m}^2) / (1450 \text{ W/m}^2) = 0.3$  <

The absorptivity is  $\alpha = 1 - \tau - \rho = 1 - 0 - 0.3 = 0.7$  <

Consider an energy balance on the top surface.

$q''_{\text{cond}} = G + q''_{\text{conv}} - \rho G - E$  where  $E = \epsilon \sigma T_s^4$ . Rearranging, we see that

$$\epsilon = \frac{(G + q''_{\text{conv}} - \rho G - q''_{\text{cond}})}{(\sigma T_t^4)}$$

$$= \frac{\left[ 1450 \text{ W/m}^2 + 40 \text{ W/m}^2 \cdot \text{K} \times (260 - 43)^\circ\text{C} - 435 \text{ W/m}^2 \right] - 25 \text{ W/m} \cdot \text{K} \times (43 - 35)^\circ\text{C} / 0.021 \text{ m}}{5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times (273 + 43)^4 \text{ K}^4} = 0.303$$
 <

Since  $\alpha \neq \epsilon$ , the plate is not gray. <

Continued...

### PROBLEM 12.69 (Cont.)

The radiosity associated with the top surface is

$$J = E + \rho G = 0.303 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times (273 + 43)^4 \text{ K}^4 + 435 \text{ W/m}^2 = 606 \text{ W/m}^2 \quad <$$

Consider an energy balance on the bottom surface with  $q''_{\text{cond}} = q''_{\text{conv}}$  which yields

$$\begin{aligned} h_w &= k(T_t - T_b)/[L(T_b - T_{\infty,w})] \\ &= [25 \text{ W/m} \cdot \text{K} \times (43 - 35)^\circ\text{C}]/[0.021\text{m} \times (35 - 25)^\circ\text{C}] = 952 \text{ W/m}^2 \cdot \text{K}. \quad < \end{aligned}$$

**COMMENTS:** (1) The calculated emissivity is extremely sensitive to the plate thickness. Conduction through the plate is much larger than the emission; small changes in the conduction heat flux result in very large changes in the calculated emission. For example, reducing the plate thickness to 20 mm yields a negative emissivity, while increasing the plate thickness to 22 mm yields an emissivity greater than unity. In reality, as the plate thickness is modified, the surface temperatures would also change.

## PROBLEM 12.70

**KNOWN:** Isothermal enclosure at a uniform temperature provides a known irradiation on two small surfaces whose absorption rates have been measured.

**FIND:** (a) Net heat transfer rates and temperatures of the two surfaces, (b) Absorptivity of the surfaces, (c) Emissive power of the surfaces, (d) Emissivity of the surfaces.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Enclosure is at a uniform temperature and large compared to surfaces A and B, (2) Surfaces A and B have been in the enclosure a long time, (3) Irradiation to both surfaces is the same.

**ANALYSIS:** (a) Since the surfaces A and B have been within the enclosure a long time, thermal equilibrium conditions exist. That is,

$$q_{A,\text{net}} = q_{B,\text{net}} = 0.$$

Furthermore, the surface temperatures are the same as the enclosure,  $T_{s,A} = T_{s,B} = T_{enc}$ . Since the enclosure is at a uniform temperature, it follows that blackbody radiation exists within the enclosure (see Fig. 12.11) and

$$G = E_b(T_{enc}) = \sigma T_{enc}^4$$

$$T_{enc} = (G/\sigma)^{1/4} = \left(6300 \text{ W/m}^2 / 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4\right)^{1/4} = 577.4 \text{ K.} \quad <$$

(b) From Eq. 12.51, the absorptivity is  $G_{abs}/G$ ,

$$\alpha_A = \frac{5600 \text{ W/m}^2}{6300 \text{ W/m}^2} = 0.89 \quad \alpha_B = \frac{630 \text{ W/m}^2}{6300 \text{ W/m}^2} = 0.10. \quad <$$

(c) Since the surfaces experience zero net heat transfer, the energy balance is  $G_{abs} = E$ . That is, the absorbed irradiation is equal to the emissive power,

$$E_A = 5600 \text{ W/m}^2 \quad E_B = 630 \text{ W/m}^2. \quad <$$

(d) The emissive power,  $E(T)$ , is written as

$$E = \varepsilon E_b(T) = \varepsilon \sigma T^4 \quad \text{or} \quad \varepsilon = E/\sigma T^4.$$

Since the temperature of the surfaces and the emissive powers are known,

$$\varepsilon_A = 5600 \text{ W/m}^2 / \left[5.67 \times 10^{-8} \frac{\text{W}}{\text{m}^2 \cdot \text{K}^4} (577.4 \text{ K})^4\right] = 0.89 \quad \varepsilon_B = 0.10. \quad <$$

**COMMENTS:** Note for this equilibrium condition,  $\varepsilon = \alpha$ .

## PROBLEM 12.71

**KNOWN:** Temperature and spectral characteristics of a diffuse surface at  $T_s = 500$  K situated in a large enclosure with uniform temperature,  $T_{sur} = 1500$  K.

**FIND:** (a) Sketch of spectral distribution of  $E_\lambda$  and  $E_{\lambda,b}$  for the surface, (b) Net heat flux to the surface,  $q''_{rad,in}$  (c) Compute and plot  $q''_{rad,in}$  as a function of  $T_s$  for the range  $500 \leq T_s \leq 1000$  K; also plot the heat flux for a diffuse, gray surface with total emissivities of 0.4 and 0.8; and (d) Compute and plot  $\varepsilon$  and  $\alpha$  as a function of the surface temperature for the range  $500 \leq T_s \leq 1000$  K.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Surface is diffuse, (2) Convective effects are negligible, (3) Surface irradiation corresponds to blackbody emission at 1500 K.

**ANALYSIS:** (a) From Wien's displacement law, Eq. 12.31,  $\lambda_{max} T = 2898 \mu\text{m}\cdot\text{K}$ . Hence, for blackbody emission from the surface at  $T_s = 500$  K,

$$\lambda_{max} = \frac{2898 \mu\text{m} \cdot \text{K}}{500 \text{ K}} = 5.80 \mu\text{m}.$$

(b) From an energy balance on the surface, the net heat flux to the surface is

$$q''_{rad,in} = \alpha G - E = \alpha E_b(1500 \text{ K}) - \varepsilon E_b(500 \text{ K}).$$

From Eq. 12.52,

$$\alpha = 0.4 \int_0^4 \frac{E_{\lambda,b}(1500)}{E_b} d\lambda + 0.8 \int_4^\infty \frac{E_{\lambda,b}(1500)}{E_b} d\lambda = 0.4 F_{(0-4\mu\text{m})} + 0.8 [1 - F_{(0-4\mu\text{m})}].$$

From Table 12.1 with  $\lambda T = 4 \mu\text{m} \times 1500 \text{ K} = 6000 \mu\text{m}\cdot\text{K}$ ,  $F_{(0-4)} = 0.738$ , find

$$\alpha = 0.4 \times 0.738 + 0.8 (1 - 0.738) = 0.505.$$

From Eq. 12.43

$$\varepsilon = 0.4 \int_0^4 \frac{E_{\lambda,b}(500)}{E_b} d\lambda + 0.8 \int_4^\infty \frac{E_{\lambda,b}(500)}{E_b} d\lambda = 0.4 F_{(0-4\mu\text{m})} + 0.8 [1 - F_{(0-4\mu\text{m})}].$$

From Table 12.1 with  $\lambda T = 4 \mu\text{m} \times 500 \text{ K} = 2000 \mu\text{m}\cdot\text{K}$ ,  $F_{(0-4)} = 0.0667$ , find

$$\varepsilon = 0.4 \times 0.0667 + 0.8 (1 - 0.0667) = 0.773.$$

Hence, the net heat flux to the surface is

$$q''_{rad,in} = 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 [0.505 \times (1500 \text{ K})^4 - 0.773 \times (500 \text{ K})^4] = 1.422 \times 10^5 \text{ W/m}^2. \quad \leftarrow$$

Continued...

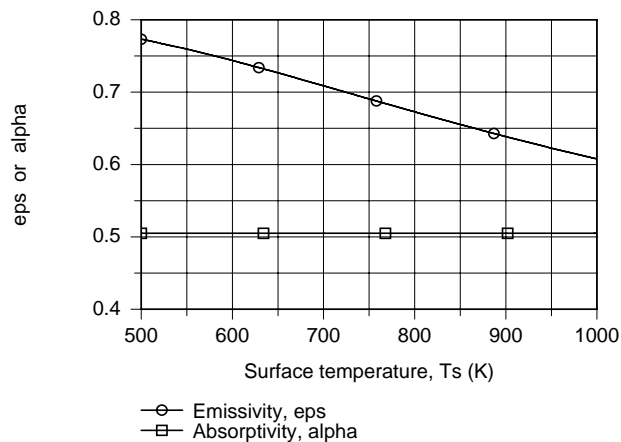

### PROBLEM 12.71 (Cont.)

(c) Using the foregoing equations in the IHT workspace along with the *IHT Radiation Tool, Band Emission Factor*,  $q''_{\text{rad,in}}$  was computed and plotted as a function of  $T_s$ .

The net radiation heat rate,  $q''_{\text{rad,in}}$  decreases with increasing surface temperature since  $E$  increases with  $T_s$  and the absorbed irradiation remains constant according to Eq. (1). The heat flux is largest for the gray surface with  $\epsilon = 0.4$  and the smallest for the gray surface with  $\epsilon = 0.8$ . As expected, the heat flux for the selective surface is between the limits of the two gray surfaces.

(d) Using the IHT model of part (c), the emissivity and absorptivity of the surface are computed and plotted below.

The absorptivity,  $\alpha = \alpha(\alpha_\lambda, T_{\text{sur}})$ , remains constant as  $T_s$  changes since it is a function of  $\alpha_\lambda$  (or  $\epsilon_\lambda$ ) and  $T_{\text{sur}}$  only. The emissivity,  $\epsilon = \epsilon(\epsilon_\lambda, T_s)$  is a function of  $T_s$  and decreases as  $T_s$  increases. Could you have surmised as much by looking at the spectral emissivity distribution? Under what condition would you expect  $\alpha = \epsilon$ ?

## PROBLEM 12.72

**KNOWN:** Opaque, diffuse surface with prescribed spectral reflectivity and at a temperature of 750K is subjected to a prescribed spectral irradiation,  $G_\lambda$ .

**FIND:** (a) Total absorptivity,  $\alpha$ , (b) Total emissivity,  $\varepsilon$ , (c) Net radiative heat flux to the surface.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Opaque and diffuse surface, (2) Backside insulated.

**ANALYSIS:** (a) The total absorptivity is determined from Eq. 12.52 and 12.62,

$$\alpha_\lambda = 1 - \rho_\lambda \quad \text{and} \quad \alpha = \int_0^\infty \alpha_\lambda G_\lambda d\lambda / G. \quad (1,2)$$

Evaluating by separate integrals over various wavelength intervals.

$$\alpha = \frac{(1 - \rho_{\lambda,1}) \int_1^3 G_\lambda d\lambda + (1 - \rho_{\lambda,2}) \int_3^6 G_\lambda d\lambda + (1 - \rho_{\lambda,2}) \int_6^8 G_\lambda d\lambda}{\int_1^3 G_\lambda d\lambda + \int_3^6 G_\lambda d\lambda + \int_6^8 G_\lambda d\lambda} = \frac{G_{\text{abs}}}{G}$$

$$G_{\text{abs}} = (1 - 0.6) \left[ 0.5 \times 500 \text{ W/m}^2 \cdot \mu\text{m} (3 - 1) \mu\text{m} \right] + (1 - 0.2) \left[ 500 \text{ W/m}^2 \cdot \mu\text{m} (6 - 3) \mu\text{m} \right] \\ + (1 - 0.2) \left[ 0.5 \times 500 \text{ W/m}^2 \cdot \mu\text{m} (8 - 6) \mu\text{m} \right]$$

$$G = 0.5 \times 500 \text{ W/m}^2 \cdot \mu\text{m} \times (3 - 1) \mu\text{m} + 500 \text{ W/m}^2 \cdot \mu\text{m} (6 - 3) \mu\text{m} + 0.5 \times 500 \text{ W/m}^2 \cdot \mu\text{m} (8 - 6) \mu\text{m}$$

$$\alpha = \frac{[200 + 1200 + 400] \text{ W/m}^2}{[500 + 1500 + 500] \text{ W/m}^2} = \frac{1800 \text{ W/m}^2}{2500 \text{ W/m}^2} = 0.720. \quad <$$

(b) The total emissivity of the surface is determined from Eq. 12.43 and 12.62,

$$\varepsilon_\lambda = \alpha_\lambda \quad \text{and, hence} \quad \varepsilon_\lambda = 1 - \rho_\lambda. \quad (3,4)$$

The total emissivity can then be expressed as

$$\varepsilon = \int_0^\infty \varepsilon_\lambda E_{\lambda,b}(\lambda, T_s) d\lambda / E_b(T_s) = \int_0^\infty (1 - \rho_\lambda) E_{\lambda,b}(\lambda, T_s) d\lambda / E_b(T_s)$$

$$\varepsilon = (1 - \rho_{\lambda,1}) \int_0^3 E_{\lambda,b}(\lambda, T_s) d\lambda / E_b(T_s) + (1 - \rho_{\lambda,2}) \int_3^\infty E_{\lambda,b}(\lambda, T_s) d\lambda / E_b(T_s)$$

$$\varepsilon = (1 - \rho_{\lambda,1}) F_{(0 \rightarrow 3 \mu\text{m})} + (1 - \rho_{\lambda,2}) [1 - F_{(0 \rightarrow 3 \mu\text{m})}]$$

$$\varepsilon = (1 - 0.6) \times 0.111 + (1 - 0.2) [1 - 0.111] = 0.756 \quad <$$

where Table 12.1 is used to find  $F_{(0 \rightarrow \lambda)} = 0.111$  for  $\lambda_1 T_s = 3 \times 750 = 2250 \mu\text{m} \cdot \text{K}$ .

(c) The net radiative heat flux to the surface is

$$q''_{\text{rad}} = \alpha G - \varepsilon E_b(T_s) = \alpha G - \varepsilon \sigma T_s^4$$

$$q''_{\text{rad}} = 0.720 \times 2500 \text{ W/m}^2$$

$$-0.756 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (750\text{K})^4 = -11,763 \text{ W/m}^2. \quad <$$

### PROBLEM 12.73

**KNOWN:** Diffuse glass at  $T_g = 750$  K with prescribed spectral radiative properties being heated in a large oven having walls with emissivity of 0.75 and 1800 K.

**FIND:** (a) Total transmissivity  $\tau$ , total reflectivity  $\rho$ , and total emissivity  $\varepsilon$  of the glass; Net radiative heat flux to the glass, (b)  $q''_{\text{rad, in}}$ ; and (c) Compute and plot  $q''_{\text{rad, in}}$  as a function of glass temperatures for the range  $500 \leq T_g \leq 800$  K for oven wall temperatures of  $T_w = 1500, 1800$  and  $2000$  K.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Glass is of uniform temperature, (2) Glass is diffuse, (3) Furnace walls large compared to the glass;  $\varepsilon_w$  plays no role, (4) Negligible convection.

**ANALYSIS:** (a) From knowledge of the spectral transmittance,  $\tau_\lambda$ , and spectral reflectivity,  $\rho_\lambda$ , the following radiation properties are evaluated:

*Total transmissivity,  $\tau$ :* For the irradiation from the furnace walls,  $G_\lambda = E_{\lambda, b}(\lambda, T_w)$ . Hence

$$\tau = \int_0^\infty \tau_\lambda E_{\lambda, b}(\lambda, T_w) d\lambda / \sigma T_w^4 \approx \tau_{\lambda 1} F_{(0-\lambda T)} = 0.9 \times 0.25 = 0.225. \quad \leftarrow$$

where  $\lambda T = 1.6 \mu\text{m} \times 1800 \text{ K} = 2880 \mu\text{m} \cdot \text{K} \approx 2898 \mu\text{m} \cdot \text{K}$  giving  $F_{(0-\lambda T)} \approx 0.25$ .

*Total reflectivity,  $\rho$ :* With  $G_\lambda = E_{\lambda, b}(\lambda, T_w)$ ,  $T_w = 1800$  K, and  $F_{0-\lambda T} = 0.25$ ,

$$\rho \approx \rho_{\lambda 1} F_{(0-\lambda T)} + \rho_{\lambda 2} (1 - F_{(0-\lambda T)}) = 0.05 \times 0.25 + 0.5(1 - 0.25) = 0.388 \quad \leftarrow$$

*Total absorptivity,  $\alpha$ :* To perform the energy balance later, we'll need  $\alpha$ . Employ the conservation expression,

$$\alpha = 1 - \rho - \tau = 1 - 0.388 - 0.225 = 0.387.$$

*Emissivity,  $\varepsilon$ :* Based upon surface temperature  $T_g = 750$  K, for

$$\lambda T = 1.6 \mu\text{m} \times 750 \text{ K} = 1200 \mu\text{m} \cdot \text{K}, \quad F_{0-\lambda T} \approx 0.002.$$

Hence for  $\lambda > 1.6 \mu\text{m}$ ,  $\varepsilon \approx \varepsilon_\lambda \approx 0.5. \quad \leftarrow$

(b) Performing an energy balance on the glass, the net radiative heat flux by radiation into the glass is,

Continued...

### PROBLEM 12.73 (Cont.)

$$q''_{\text{net,in}} = E''_{\text{in}} - E''_{\text{out}}$$

$$q''_{\text{net,in}} = 2(\alpha G - \varepsilon E_b(T_g))$$

where  $G = \sigma T_w^4$

$$q''_{\text{net,in}} = 2\left[0.387\sigma(1800\text{K})^4 - 0.5\sigma(750\text{K})^4\right]$$

$$q''_{\text{net,in}} = 442.8 \text{ kW/m}^2.$$

(b) Using the foregoing equations in the IHT Workspace along with the *IHT Radiation Tool, Band Emission Factor*, the net radiative heat flux,  $q''_{\text{rad,in}}$ , was computed and plotted as a function of  $T_g$  for selected wall temperatures  $T_w$ .

As the glass temperature increases, the rate of emission increases so we'd expect the net radiative heat rate into the glass to decrease. Note that the decrease is not very significant. The effect of increased wall temperature is to increase the irradiation and, hence the absorbed irradiation to the surface and the net radiative flux increase.

## PROBLEM 12.74

**KNOWN:** Material with prescribed radiative properties covering the peep hole of a furnace and exposed to surroundings on the outer surface.

**FIND:** Steady-state temperature of the cover,  $T_s$ ; heat loss from furnace.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Cover is isothermal, no gradient, (2) Surroundings of the outer surface are large compared to cover, (3) Cover is insulated from its mount on furnace wall, (4) Negligible convection on interior surface.

**PROPERTIES:** Cover material (given): For irradiation from the furnace interior:  $\tau_f = 0.8$ ,  $\rho_f = 0$ ; For room temperature emission:  $\tau = 0$ ,  $\varepsilon = 0.8$ .

**ANALYSIS:** Perform an energy balance identifying the modes of heat transfer,

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = 0 \quad \alpha_f G_f + \alpha_{\text{sur}} G_{\text{sur}} - 2\varepsilon E_b(T_s) - h(T_s - T_{\infty}) = 0. \quad (1)$$

Recognize that  $G_f = \sigma T_f^4$   $G_{\text{sur}} = \sigma T_{\text{sur}}^4$  (2,3)

From Eq. 12.63, it follows that  $\alpha_f = 1 - \tau_f - \rho_f = 1 - 0.8 - 0.0 = 0.2$ . (4)

Since the irradiation  $G_{\text{sur}}$  will have nearly the same spectral distribution as the emissive power of the cover,  $E_b(T_s)$ , and since  $G_{\text{sur}}$  is diffuse irradiation,

$$\alpha_{\text{sur}} = \varepsilon = 0.8. \quad (5)$$

This reasoning follows from Eqs. 12.69 and 12.70. Substituting Eqs. (2-5) into Eq. (1) and using numerical values,

$$\begin{aligned} 0.2 \times 5.67 \times 10^{-8} (450 + 273)^4 \text{ W/m}^2 + 0.8 \times 5.67 \times 10^{-8} \times 300^4 \text{ W/m}^2 & \quad (2-5) \\ - 2 \times 0.8 \times 5.67 \times 10^{-8} T_s^4 \text{ W/m}^2 - 50 \text{ W/m}^2 \cdot \text{K} (T_s - 300) \text{ K} = 0 & \quad < \\ 9.072 \times 10^{-8} T_s^4 + 50 T_s = 18,466 & \quad \text{or} \quad T_s = 344 \text{ K}. \end{aligned}$$

The heat loss from the furnace (see energy balance schematic) is

$$\begin{aligned} q_{f, \text{loss}} &= A_s \left[ \alpha_f G_f + \tau_f G_f - \varepsilon E_b(T_s) \right] = \frac{\pi D^2}{4} \left[ (\alpha_f + \tau_f) G_f - \varepsilon E_b(T_s) \right] \\ q_{f, \text{loss}} &= \pi (0.050 \text{ m})^2 / 4 \left[ (0.8 + 0.2) (723 \text{ K})^4 \right. \\ & \quad \left. - 0.8 (344 \text{ K})^4 \right] 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 = 29.2 \text{ W}. \end{aligned} \quad <$$

## PROBLEM 12.75

**KNOWN:** Window with prescribed  $\tau_\lambda$  and  $\rho_\lambda$  mounted on cooled vacuum chamber passing radiation from a solar simulator.

**FIND:** (a) Solar transmissivity of the window material, (b) State-state temperature reached by window with simulator operating, (c) Net radiation heat transfer to chamber.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Diffuse behavior of window material, (3) Chamber and room surroundings large compared to window, (4) Solar simulator flux has spectral distribution of 5800K blackbody, (5) Window insulated from its mount, (6) Window is isothermal at  $T_w$ .

**ANALYSIS:** (a) Using Eq. 12.61 and recognizing that  $G_{\lambda,S} \sim E_{b,\lambda}(\lambda, 5800\text{K})$ ,

$$\tau_S = \tau_1 \int_{0.38}^{1.9} E_{\lambda,b}(\lambda, 5800\text{K}) d\lambda / E_b(5800\text{K}) = \tau_1 \left[ F_{(0 \rightarrow 1.9\mu\text{m})} - F_{(0 \rightarrow 0.38\mu\text{m})} \right].$$

From Table 12.1 at  $\lambda T = 1.9 \times 5800 = 11,020 \mu\text{m}\cdot\text{K}$ ,  $F_{(0 \rightarrow \lambda)} = 0.932$ ; at  $\lambda T = 0.38 \times 5800 \mu\text{m}\cdot\text{K} = 2,204 \mu\text{m}\cdot\text{K}$ ,  $F_{(0 \rightarrow \lambda)} = 0.101$ ; hence

$$\tau_S = 0.90 [0.932 - 0.101] = 0.748. \quad <$$

Recognizing that later we'll need  $\alpha_S$ , use Eq. 12.58 to find  $\rho_S$

$$\rho_S = \rho_1 F_{(0 \rightarrow 0.38\mu\text{m})} + \rho_2 \left[ F_{(0 \rightarrow 1.9\mu\text{m})} - F_{(0 \rightarrow 0.38\mu\text{m})} \right] + \rho_3 \left[ 1 - F_{(0 \rightarrow 1.9\mu\text{m})} \right]$$

$$\rho_S = 0.15 \times 0.101 + 0.05 [0.932 - 0.101] + 0.15 [1 - 0.932] = 0.067$$

$$\alpha_S = 1 - \rho_S - \tau_S = 1 - 0.067 - 0.748 = 0.185.$$

(b) Perform an energy balance on the window.

$$\alpha_S G_S - q''_{w-c} - q''_{w-sur} - q''_{conv} = 0$$

$$\alpha_S G_S - \varepsilon \sigma (T_w^4 - T_c^4) - \varepsilon \sigma (T_w^4 - T_{sur}^4) - \bar{h} (T_w - T_\infty) = 0.$$

Recognize that  $\rho_\lambda(\lambda > 1.9) = 0.15$  and that  $\varepsilon \approx 1 - 0.15 = 0.85$  since  $T_w$  will be near 300K.

Substituting numerical values, find by trial and error,

$$0.185 \times 3000 \text{ W/m}^2 - 0.85 \times \sigma \left[ 2T_w^4 - 298^4 - 77^4 \right] \text{ K}^4 - 28 \text{ W/m}^2 \cdot \text{K} (T_w - 298) \text{ K} = 0$$

$$T_w = 302.6\text{K} = 29.6^\circ\text{C}. \quad <$$

(c) The net radiation transfer per unit area of the window to the vacuum chamber, excluding the transmitted simulated solar flux is

$$q''_{w-c} = \varepsilon \sigma (T_w^4 - T_c^4) = 0.85 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left[ 302.6^4 - 77^4 \right] \text{ K}^4 = 402 \text{ W/m}^2. \quad <$$

## PROBLEM 12.76

**KNOWN:** Reading and emissivity of a thermocouple (TC) located in a large duct to measure gas stream temperature. Duct wall temperature and emissivity; convection coefficient.

**FIND:** (a) Gas temperature,  $T_\infty$ , (b) Effect of convection coefficient on measurement error.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Negligible heat loss from TC sensing junction to support, (3) Duct wall much larger than TC, (4) TC surface is diffuse-gray.

**ANALYSIS:** (a) Performing an energy balance on the thermocouple, it follows that

$$q''_{w-s} - q''_{conv} = 0.$$

Hence,

$$\epsilon_s \sigma (T_w^4 - T_s^4) - \bar{h} (T_s - T_\infty) = 0.$$

Solving for  $T_\infty$  with  $T_s = 180^\circ\text{C}$ ,

$$T_\infty = T_s - \frac{\epsilon_s \sigma}{\bar{h}} (T_w^4 - T_s^4)$$

$$T_\infty = (180 + 273)\text{K} - \frac{0.6(5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4)}{125 \text{ W/m}^2 \cdot \text{K}} \left( [450 + 273]^4 - [180 + 273]^4 \right) \text{K}^4$$

$$T_\infty = 453 \text{ K} - 62.9 \text{ K} = 390 \text{ K} = 117^\circ\text{C}.$$

<

(b) Using the IHT *First Law* model for an *Isothermal Solid Sphere* to solve the foregoing energy balance for  $T_s$ , with  $T_\infty = 125^\circ\text{C}$ , the measurement error, defined as  $\Delta T = T_s - T_\infty$ , was determined and is plotted as a function of  $\bar{h}$ .

The measurement error is enormous ( $\Delta T \approx 270^\circ\text{C}$ ) for  $\bar{h} = 10 \text{ W/m}^2 \cdot \text{K}$ , but decreases with increasing  $\bar{h}$ . However, even for  $\bar{h} = 1000 \text{ W/m}^2 \cdot \text{K}$ , the error ( $\Delta T \approx 8^\circ\text{C}$ ) is not negligible. Such errors must always be considered when measuring a gas temperature in surroundings whose temperature differs significantly from that of the gas.

Continued...

### **PROBLEM 12.76 (Cont.)**

**COMMENTS:** (1) Because the duct wall surface area is much larger than that of the thermocouple, its emissivity is not a factor. (2) For such a situation, a shield about the thermocouple would reduce the influence of the hot duct wall on the indicated TC temperature. A low emissivity thermocouple coating would also help.

## PROBLEM 12.77

**KNOWN:** Diameter and emissivity of a horizontal thermocouple (TC) sheath located in a large room. Air and wall temperatures.

**FIND:** (a) Temperature indicated by the TC, (b) Effect of emissivity on measurement error.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Room walls approximate isothermal, large surroundings, (2) Room air is quiescent, (3) TC approximates horizontal cylinder, (4) No conduction losses, (5) TC surface is opaque, diffuse and gray.

**PROPERTIES:** Table A-4, Air (assume  $T_s = 25 \text{ }^\circ\text{C}$ ,  $T_f = (T_s + T_\infty)/2 \approx 296 \text{ K}$ , 1 atm):

$$\nu = 15.53 \times 10^{-6} \text{ m}^2/\text{s}, \quad k = 0.026 \text{ W/m}\cdot\text{K}, \quad \alpha = 22.0 \times 10^{-6} \text{ m}^2/\text{s}, \quad \text{Pr} = 0.708, \quad \beta = 1/T_f.$$

**ANALYSIS:** (a) Perform an energy balance on the thermocouple considering convection and radiation processes. On a unit area basis, with  $q''_{conv} = \bar{h}(T_s - T_\infty)$ ,

$$\begin{aligned} \dot{E}_{in} - \dot{E}_{out} &= 0 \\ \alpha G - \epsilon E_b(T_s) - \bar{h}(T_s - T_\infty) &= 0. \end{aligned} \quad (1)$$

Since the surroundings are isothermal and large compared to the thermocouple,  $G = E_b(T_{sur})$ . For the gray-diffuse surface,  $\alpha = \epsilon$ . Using the Stefan-Boltzmann law,  $E_b = \sigma T^4$ , Eq. (1) becomes

$$\epsilon \sigma (T_{sur}^4 - T_s^4) - \bar{h}(T_s - T_\infty) = 0. \quad (2)$$

Using the Churchill-Chu correlation for a horizontal cylinder, estimate  $\bar{h}$  due to free convection.

$$\overline{\text{Nu}}_D = \frac{\bar{h}D}{k} = \left\{ 0.60 + \frac{0.387 \text{Ra}_D^{1/6}}{\left[ 1 + (0.559/\text{Pr})^{9/16} \right]^{8/27}} \right\}^2, \quad \text{Ra}_D = \frac{g\beta\Delta T D^3}{\nu\alpha}. \quad (3,4)$$

To evaluate  $\text{Ra}_D$  and  $\overline{\text{Nu}}_D$ , assume  $T_s = 25 \text{ }^\circ\text{C}$ , giving

$$\text{Ra}_D = \frac{9.8 \text{ m/s}^2 (1/296 \text{ K})(25 - 20) \text{ K} (0.004 \text{ m})^3}{15.53 \times 10^{-6} \text{ m}^2/\text{s} \times 22.0 \times 10^{-6} \text{ m}^2/\text{s}} = 31.0$$

$$\bar{h} = \frac{0.026 \text{ W/m}\cdot\text{K}}{0.004 \text{ m}} \left\{ 0.60 + \frac{0.387(31.0)^{1/6}}{\left[ 1 + (0.559/0.708)^{9/16} \right]^{8/27}} \right\} = 8.89 \text{ W/m}^2\cdot\text{K}. \quad (5)$$

With  $\epsilon = 0.4$ , the energy balance, Eq. (2), becomes

$$0.4 \times 5.67 \times 10^{-8} \text{ W/m}^2\cdot\text{K}^4 [(30 + 273)^4 - T_s^4] \text{ K}^4 - 8.89 \text{ W/m}^2\cdot\text{K} [T_s - (20 + 273)] \text{ K} = 0 \quad (6)$$

where all temperatures are in kelvin units. By trial-and-error, find

$$T_s \approx 22.2 \text{ }^\circ\text{C}$$

<  
Continued...

### PROBLEM 12.77 (Cont.)

(b) The thermocouple measurement error is defined as  $\Delta T = T_s - T_\infty$  and is a consequence of radiation exchange with the surroundings. Using the IHT *First Law Model* for an *Isothermal Solid Cylinder* with the appropriate *Correlations* and *Properties* Toolpads to solve the foregoing energy balance for  $T_s$ , the measurement error was determined as a function of the emissivity.

The measurement error decreases with decreasing  $\epsilon$ , and hence a reduction in net radiation transfer from the surroundings. However, even for  $\epsilon = 0.1$ , the error ( $\Delta T \approx 1^\circ\text{C}$ ) is not negligible.

**COMMENT:** A trial-and-error solution accounting for the effect of temperature-dependent properties and various values of  $\bar{h}$  yields  $T_s = 22.1^\circ\text{C}$  ( $\bar{h} = 7.85 \text{ W/m}^2\cdot\text{K}$ ).

## PROBLEM 12.78

**KNOWN:** Temperature sensor imbedded in a diffuse, gray tube of emissivity 0.8 positioned within a room with walls and ambient air at 30 and 20 °C, respectively. Convection coefficient is 5 W/m<sup>2</sup>·K.

**FIND:** (a) Temperature of sensor for prescribed conditions, (b) Effect of surface emissivity and using a fan to induce air flow over the tube.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Room walls (surroundings) much larger than tube, (2) Tube is diffuse, gray surface, (3) No losses from tube by conduction, (4) Steady-state conditions, (5) Sensor measures temperature of tube surface.

**ANALYSIS:** (a) Performing an energy balance on the tube,  $\dot{E}_{in} - \dot{E}_{out} = 0$ . Hence,  $q''_{rad} - q''_{conv} = 0$ , or  $\epsilon_t \sigma (T_w^4 - T_t^4) - h(T_t - T_\infty) = 0$ . With  $h = 5 \text{ W/m}^2 \cdot \text{K}$  and  $\epsilon_t = 0.8$ , the energy balance becomes

$$0.8 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left[ (30 + 273)^4 - T_t^4 \right] \text{K}^4 = 5 \text{ W/m}^2 \cdot \text{K} [T_t - (20 + 273)] \text{K}$$

$$4.5360 \times 10^{-8} \left[ 303^4 - T_t^4 \right] = 5 [T_t - 293]$$

which yields  $T_t = 298 \text{ K} = 25^\circ\text{C}$ .

(b) Using the IHT *First Law Model*, the following results were determined.

The sensor temperature exceeds the air temperature due to radiation absorption, which must be balanced by convection heat transfer. Hence, the excess temperature  $T_t - T_\infty$ , may be reduced by increasing  $h$  or by decreasing  $\alpha_t$ , which equals  $\epsilon_t$  for a diffuse-gray surface, and hence the absorbed radiation.

**COMMENTS:** A fan will increase the air velocity over the sensor and thereby increase the convection heat transfer coefficient. Hence, the sensor will indicate a temperature closer to  $T_\infty$ .

## PROBLEM 12.79

**KNOWN:** Diffuse-gray sphere is placed in large oven with known wall temperature and experiences convection process.

**FIND:** (a) Net heat transfer rate to the sphere when its temperature is 300 K, (b) Steady-state temperature of the sphere, (c) Time required for the sphere, initially at 300 K, to come within 20 K of the steady-state temperature, and (d) Elapsed time of part (c) as a function of the convection coefficient for  $10 \leq h \leq 25$   $\text{W}/\text{m}^2\cdot\text{K}$  for emissivities 0.2, 0.4 and 0.8.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Sphere surface is diffuse-gray, (2) Sphere area is much smaller than the oven wall area, (3) Sphere surface is isothermal.

**PROPERTIES:** Sphere (Given) :  $\alpha = 7.25 \times 10^{-5} \text{ m}^2/\text{s}$ ,  $k = 185 \text{ W}/\text{m}\cdot\text{K}$ .

**ANALYSIS:** (a) From an energy balance on the sphere find

$$q_{\text{net}} = q_{\text{in}} - q_{\text{out}}$$

$$q_{\text{net}} = \alpha G A_s + q_{\text{conv}} - E A_s$$

$$q_{\text{net}} = \alpha \sigma T_o^4 A_s + h A_s (T_\infty - T_s) - \epsilon \sigma T_s^4 A_s \quad (1)$$

Note that the irradiation to the sphere is the emissive power of a blackbody at the temperature of the oven walls. This follows since the oven walls are isothermal and have a much larger area than the sphere area. Substituting numerical values, noting that  $\alpha = \epsilon$  since the surface is diffuse-gray and that  $A_s = \pi D^2$ , find

$$q_{\text{net}} = \left[ 0.8 \times 5.67 \times 10^{-8} \text{ W}/\text{m}^2 \cdot \text{K}^4 (600\text{K})^4 + 15 \text{ W}/\text{m}^2 \cdot \text{K} \times (400 - 300) \text{ K} - 0.8 \times 5.67 \times 10^{-8} \text{ W}/\text{m}^2 \cdot \text{K}^4 (300\text{K})^4 \right] \pi (30 \times 10^{-3} \text{ m})^2$$

$$q_{\text{net}} = [16.6 + 4.2 - 1.0] \text{ W} = 19.8 \text{ W} \quad (1) <$$

(b) For steady-state conditions,  $q_{\text{net}}$  in the energy balance of Eq. (1) will be zero,

$$0 = \alpha \sigma T_o^4 A_s + h A_s (T_\infty - T_{\text{ss}}) - \epsilon \sigma T_{\text{ss}}^4 A_s \quad (2)$$

Substitute numerical values and find the steady-state temperature as

$$T_{\text{ss}} = 538.2\text{K} \quad <$$

Continued...

### PROBLEM 12.79 (Cont.)

(c) Using the *IHT Lumped Capacitance Model* considering convection and radiation processes, the temperature- time history of the sphere, initially at  $T_s(0) = T_i = 300$  K, can be determined. The elapsed time required to reach

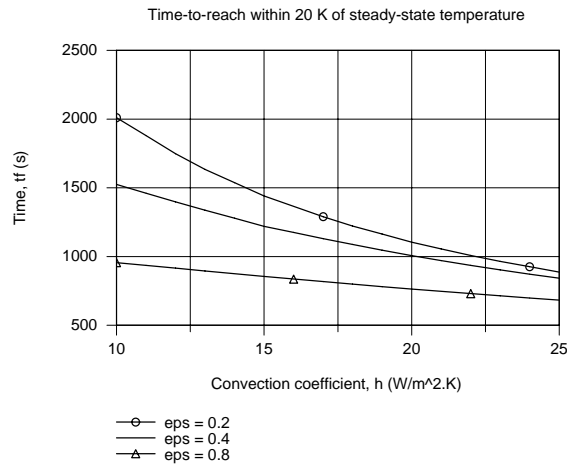

$$T_s(t_0) = (538.2 - 20) \text{ K} = 518.2 \text{ K}$$

was found as

$$t_0 = 855 \text{ s} = 14.3 \text{ min}$$

<

(d) Using the IHT model of part (c), the elapsed time for the sphere to reach within 20 K of its steady-state temperature,  $t_f$ , as a function of the convection coefficient for selected emissivities is plotted below.

For a fixed convection coefficient,  $t_f$  increases with decreasing  $\epsilon$  since the radiant heat transfer into the sphere decreases with decreasing emissivity. For a given emissivity, the  $t_f$  decreases with increasing  $h$  since the convection heat rate increases with increasing  $h$ . However, the effect is much more significant with lower values of emissivity.

**COMMENTS:** (1) Why is  $t_f$  more strongly dependent on  $h$  for a lower sphere emissivity? Hint: Compare the relative heat rates by convection and radiation processes. (2) The steady-state temperature,  $T_{ss}$ , as a function of the convection coefficient for selected emissivities calculated using (2) is plotted below. Are these results consistent with the above plot of  $t_f$  vs  $h$ ?

## PROBLEM 12.80

**KNOWN:** Thermograph with spectral response in 9 to 12  $\mu\text{m}$  region views a target of area  $200\text{mm}^2$  with solid angle  $0.001\text{ sr}$  in a normal direction.

**FIND:** (a) For a black surface at  $60^\circ\text{C}$ , the emissive power in 9 – 12  $\mu\text{m}$  spectral band, (b) Radiant power (W), received by thermograph when viewing black target at  $60^\circ\text{C}$ , (c) Radiant power (W) received by thermograph when viewing a gray, diffuse target having  $\epsilon = 0.7$  and considering the surroundings at  $T_{\text{sur}} = 23^\circ\text{C}$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Wall is diffuse, (2) Surroundings are black with  $T_{\text{sur}} = 23^\circ\text{C}$ .

**ANALYSIS:** (a) Emissive power in spectral range 9 to 12  $\mu\text{m}$  for a  $60^\circ\text{C}$  black surface is

$$E_t \equiv E_b(9-12\ \mu\text{m}) = E_b [F(0 \rightarrow 12\ \mu\text{m}) - F(0 \rightarrow 9\ \mu\text{m})]$$

where  $E_b(T_s) = \sigma T_s^4$ . From Table 12.1:

$$\lambda_2 T_s = 12 \times (60 + 273) \approx 4000\ \mu\text{m K}, \quad F(0-12\ \mu\text{m}) = 0.481$$

$$\lambda_1 T_s = 9 \times (60 + 273) \approx 3000\ \mu\text{m K}, \quad F(0-9\ \mu\text{m}) = 0.273.$$

Hence

$$E_t = 5.667 \times 10^{-8}\ \text{W/m}^2 \cdot \text{K}^4 \times (60 + 273)^4\ \text{K}^4 [0.481 - 0.273] = 145\ \text{W/m}^2. \quad <$$

(b) The radiant power,  $q_b$  (W), received by the thermograph from a black target is determined as

$$q_b = \frac{E_t}{\pi} \cdot A_s \cos \theta_1 \cdot \omega$$

where

$E_t$  = emissive power in 9 – 12  $\mu\text{m}$  spectral region, part (a) result

$A_s$  = target area viewed by thermograph,  $200\text{mm}^2$  ( $2 \times 10^{-4}\ \text{m}^2$ )

$\omega$  = solid angle thermograph aperture subtends when viewed from the target,  $0.001\text{ sr}$

$\theta$  = angle between target area normal and view direction,  $0^\circ$ .

Hence,

$$q_b = \frac{145\ \text{W/m}^2}{\pi\ \text{sr}} \times (2 \times 10^{-4}\ \text{m}^2) \times \cos 0^\circ \times 0.001\ \text{sr} = 9.23\ \mu\text{W}. \quad <$$

Continued ...

### PROBLEM 12.80 (Cont.)

(c) When the target is a gray, diffuse emitter,  $\varepsilon = 0.7$ , the thermograph will receive emitted power from the target and reflected irradiation resulting from the surroundings at  $T_{\text{sur}} = 23^\circ\text{C}$ . Schematically:

The power is expressed as

$$q = q_e + q_r = \varepsilon q_b + I_r \cdot A_s \cos \theta_1 \cdot \omega \left[ F_{(0 \rightarrow 12 \mu\text{m})} - F_{(0 \rightarrow 9 \mu\text{m})} \right]$$

where

$q_b$  = radiant power from black surface, part (b) result

$F_{(0-\lambda)}$  = band emission fraction for  $T_{\text{sur}} = 23^\circ\text{C}$ ; using Table 12.1

$$\lambda_2 T_{\text{sur}} = 12 \times (23 + 273) = 3552 \mu\text{m}\cdot\text{K}, F_{(0-\lambda_2)} = 0.394$$

$$\lambda_1 T_{\text{sur}} = 9 \times (23 + 273) = 2664 \mu\text{m}\cdot\text{K}, F_{(0-\lambda_1)} = 0.197$$

$I_r$  = reflected intensity, which because of diffuse nature of surface

$$I_r = \rho \frac{G}{\pi} = (1 - \varepsilon) \frac{E_b(T_{\text{sur}})}{\pi}.$$

Hence

$$q = 0.7 \times 9.23 \mu\text{W} + (1 - 0.7) \frac{5.667 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times (273 + 23)^4 \text{ K}}{\pi \text{ sr}} \\ \times (2 \times 10^{-4} \text{ m}^2) \times \cos 0^\circ \times 0.001 \text{ sr} [0.394 - 0.197]$$

$$q = 6.46 \mu\text{W} + 1.64 \mu\text{W} = 8.10 \mu\text{W}. \quad \leftarrow$$

**COMMENTS:** (1) Comparing the results of parts (a) and (b), note that the power to the thermograph is slightly less for the gray surface with  $\varepsilon = 0.7$ . From part (b) see that the effect of the irradiation is substantial; that is,  $1.64/8.10 \approx 20\%$  of the power received by the thermograph is due to reflected irradiation. Ignoring such effects leads to misinterpretation of temperature measurements using thermography. (2) Many thermography devices have a spectral response in the 3 to 5  $\mu\text{m}$  wavelength region as well as 9 – 12  $\mu\text{m}$ .

## PROBLEM 12.81

**KNOWN:** Radiation thermometer (RT) viewing a steel billet being heated in a furnace.

**FIND:** Temperature of the billet when the RT indicates 1160K.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Billet is diffuse-gray, (2) Billet is small object in large enclosure, (3) Furnace behaves as isothermal, large enclosure, (4) RT is a radiometer sensitive to total (rather than a prescribed spectral band) radiation and is calibrated to correctly indicate the temperature of a black body, (5) RT receives radiant power originating from the target area on the billet.

**ANALYSIS:** The radiant power reaching the radiation thermometer (RT) is proportional to the radiosity of the billet. For the diffuse-gray billet within the large enclosure (furnace), the radiosity is

$$J = \varepsilon E_b(T) + \rho G = \varepsilon E_b(T) + (1 - \varepsilon) E_b(T_w)$$

$$J = \varepsilon \sigma T^4 + (1 - \varepsilon) \sigma T_w^4 \quad (1)$$

where  $\alpha = \varepsilon$ ,  $G = E_b(T_w)$  and  $E_b = \sigma T^4$ . When viewing the billet, the RT indicates  $T_a = 1100\text{K}$ , referred to as the apparent temperature of the billet. That is, the RT *indicates* the billet is a blackbody at  $T_a$  for which the radiosity will be

$$E_b(T_a) = J_a = \sigma T_a^4 \quad (2)$$

Recognizing that  $J_a = J$ , set Eqs. (1) and (2) equal to one another and solve for  $T$ , the billet true temperature.

$$T = \left[ \frac{1}{\varepsilon} T_a^4 - \frac{1 - \varepsilon}{\varepsilon} T_w^4 \right]^{1/4}$$

Substituting numerical values, find

$$T = \left[ \frac{1}{0.8} (1160\text{K})^4 - \frac{1 - 0.8}{0.8} (1500\text{K})^4 \right]^{1/4} = 999\text{K} \quad <$$

**COMMENTS:** (1) The effect of the reflected wall irradiation from the billet is to cause the RT to indicate a temperature higher than the true temperature.

(2) What temperature would the RT indicate when viewing the furnace wall assuming the wall emissivity were 0.85?

(3) What temperature would the RT indicate if the RT were sensitive to spectral radiation at  $0.65 \mu\text{m}$  instead of total radiation? Hint: in Eqs. (1) and (2) replace the emissive power terms with spectral intensity. Answer: 1365K.

## PROBLEM 12.82

**KNOWN:** Irradiation and temperature of a small surface.

**FIND:** Rate at which radiation is received by a detector due to emission and reflection from the surface.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Opaque, diffuse-gray surface behavior, (2)  $A_s$  and  $A_d$  may be approximated as differential areas.

**ANALYSIS:** Radiation intercepted by the detector is due to emission and reflection from the surface, and from the definition of the intensity, it may be expressed as

$$q_{s-d} = I_{e+r} A_s \cos \theta \Delta \omega.$$

The solid angle intercepted by  $A_d$  with respect to a point on  $A_s$  is

$$\Delta \omega = \frac{A_d}{r^2} = 10^{-6} \text{ sr}.$$

Since the surface is diffuse it follows from Eq. 12.27 that

$$I_{e+r} = \frac{J}{\pi}$$

where, since the surface is opaque and gray ( $\epsilon = \alpha = 1 - \rho$ ),

$$J = E + \rho G = \epsilon E_b + (1 - \epsilon) G.$$

Substituting for  $E_b$  from Eq. 12.32

$$J = \epsilon \sigma T_s^4 + (1 - \epsilon) G = 0.7 \times 5.67 \times 10^{-8} \frac{\text{W}}{\text{m}^2 \cdot \text{K}^4} (500 \text{ K})^4 + 0.3 \times 1500 \frac{\text{W}}{\text{m}^2}$$

or

$$J = (2481 + 450) \text{ W/m}^2 = 2931 \text{ W/m}^2.$$

Hence

$$I_{e+r} = \frac{2931 \text{ W/m}^2}{\pi \text{ sr}} = 933 \text{ W/m}^2 \cdot \text{sr}$$

and

$$q_{s-d} = 933 \text{ W/m}^2 \cdot \text{sr} \left( 10^{-4} \text{ m}^2 \times 0.866 \right) 10^{-6} \text{ sr} = 8.08 \times 10^{-8} \text{ W}.$$

<

### PROBLEM 12.83

**KNOWN:** Small, diffuse, gray block with  $\varepsilon = 0.92$  at  $35^\circ\text{C}$  is located within a large oven whose walls are at  $175^\circ\text{C}$  with  $\varepsilon = 0.85$ .

**FIND:** Radiant power reaching detector when viewing (a) a deep hole in the block and (b) an area on the block's surface.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Block is isothermal, diffuse, gray and small compared to the enclosure, (2) Oven is isothermal enclosure.

**ANALYSIS:** (a) The small, deep hole in the isothermal block approximates a blackbody at  $T_s$ . The radiant power to the detector can be determined from Eq. 12.11 written in the form:

$$q = I_e \cdot A_t \cdot \omega_t = \frac{\sigma T_s^4}{\pi} \cdot A_t \cdot \omega_t$$

$$q = \frac{1}{\pi \text{ sr}} \left[ 5.67 \times 10^{-8} \times (35 + 273)^4 \right] \frac{\text{W}}{\text{m}^2} \times \frac{\pi (3 \times 10^{-3})^2 \text{ m}^2}{4} \times 0.001 \text{ sr} = 1.15 \mu\text{W} <$$

where  $A_t = \pi D_t^2 / 4$ . Note that the hole diameter must be greater than 3mm diameter.

(b) When the detector views an area on the surface of the block, the radiant power reaching the detector will be due to emission and reflected irradiation originating from the enclosure walls. In terms of the radiosity, Section 12.3.4, we can write using Eq. 12.23,

$$q = I_{e+r} \cdot A_t \cdot \omega_t = \frac{J}{\pi} \cdot A_t \cdot \omega_t.$$

Since the surface is diffuse and gray, the radiosity can be expressed as

$$J = \varepsilon E_b(T_s) + \rho G = \varepsilon E_b(T_s) + (1 - \varepsilon) E_b(T_{sur})$$

recognizing that  $\rho = 1 - \varepsilon$  and  $G = E_b(T_{sur})$ . The radiant power is

$$q = \frac{1}{\pi} \left[ \varepsilon E_b(T_s) + (1 - \varepsilon) E_b(T_{sur}) \right] \cdot A_t \cdot \omega_t$$

$$q = \frac{1}{\pi \text{ sr}} \left[ 0.92 \times 5.67 \times 10^{-8} (35 + 273)^4 + (1 - 0.92) \times 5.67 \times 10^{-8} (175 + 273)^4 \right] \text{W/m}^2 \times$$

$$\frac{\pi (3 \times 10^{-3})^2 \text{ m}^2}{4} \times 0.001 \text{ sr} = 1.47 \mu\text{W}. <$$

**COMMENTS:** The effect of reflected irradiation when  $\varepsilon < 1$  is important for objects in enclosures. The practical application is one of measuring temperature by radiation from objects within furnaces.

### PROBLEM 12.84

**KNOWN:** Diffuse, gray opaque disk (1) coaxial with a ring-shaped disk (2), both with prescribed temperatures and emissivities. Cooled detector disk (3), also coaxially positioned at a prescribed location.

**FIND:** Rate at which radiation is incident on the detector due to emission and reflection from  $A_1$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1)  $A_1$  is diffuse-gray, (2)  $A_2$  is black, (3)  $A_1$  and  $A_3 \ll R^2$ , the distance of separation, (4)  $\Delta r \ll r_i$ , such that  $A_2 \approx 2\pi r_i \Delta r$ , and (5) Backside of  $A_2$  is insulated.

**ANALYSIS:** The radiant power leaving  $A_1$  intercepted by  $A_3$  is of the form

$$q_{1 \rightarrow 3} = (J_1 / \pi) A_1 \cos \theta_1 \cdot \omega_{3-1}$$

where for this configuration of  $A_1$  and  $A_3$ ,

$$\theta_1 = 0^\circ \quad \omega_{3-1} = A_3 \cos \theta_3 / (L_A + L_B)^2 \quad \theta_3 = 0^\circ.$$

Hence,

$$q_{1 \rightarrow 3} = (J_1 / \pi) A_1 \cdot A_3 / (L_A + L_B)^2 \quad J_1 = \rho G_1 + \varepsilon E_b(T_1) = \rho G_1 + \varepsilon \sigma T_1^4.$$

The irradiation on  $A_1$  due to emission from  $A_2$ ,  $G_1$ , is

$$G_1 = q_{2 \rightarrow 1} / A_1 = (I_2 \cdot A_2 \cos \theta_2' \cdot \omega_{1-2}) / A_1$$

where

$$\omega_{1-2} = A_1 \cos \theta_1' / R^2$$

is constant over the surface  $A_2$ . From geometry,

$$\theta_1' = \theta_2' = \tan^{-1} [(r_i + \Delta r / 2) / L_A] = \tan^{-1} [(0.500 + 0.005) / 1.000] = 26.8^\circ$$

$$R = L_A / \cos \theta_1' = 1 \text{ m} / \cos 26.8^\circ = 1.12 \text{ m}.$$

Hence,

$$G_1 = (\sigma T_2^4 / \pi) A_2 \cos 26.8^\circ \cdot [A_1 \cos 26.8^\circ / (1.12 \text{ m})^2] / A_1 = 360.2 \text{ W/m}^2$$

using  $A_2 = 2\pi r_i \Delta r = 3.142 \times 10^{-2} \text{ m}^2$  and

$$J_1 = (1 - 0.3) \times 360.2 \text{ W/m}^2 + 0.3 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (400 \text{ K})^4 = 687.7 \text{ W/m}^2.$$

Hence the radiant power is

$$q_{1 \rightarrow 3} = (687.7 \text{ W/m}^2 / \pi) \left[ \pi (0.010 \text{ m})^2 / 4 \right]^2 / (1 \text{ m} + 1 \text{ m})^2 = 337.6 \times 10^{-9} \text{ W}. <$$

## PROBLEM 12.85

**KNOWN:** Infrared thermograph with a 3- to 5-micrometer spectral bandpass views a metal plate maintained at  $T_s = 327^\circ\text{C}$  having four diffuse, gray coatings of different emissivities. Surroundings at  $T_{\text{sur}} = 87^\circ\text{C}$ .

**FIND:** (a) Expression for the output signal,  $S_o$ , in terms of the responsivity,  $R$  ( $\mu\text{V}\cdot\text{m}^2/\text{W}$ ), the black coating ( $\epsilon_o = 1$ ) emissive power and appropriate band emission fractions; assuming  $R = 1 \mu\text{V}\cdot\text{m}^2/\text{W}$ , evaluate  $S_o(\text{V})$ ; (b) Expression for the output signal,  $S_c$ , in terms of the responsivity  $R$ , the blackbody emissive power of the coating, the blackbody emissive power of the surroundings, the coating emissivity,  $\epsilon_c$ , and appropriate band emission fractions; (c) Thermograph signals,  $S_c$  ( $\mu\text{V}$ ), when viewing with emissivities of 0.8, 0.5 and 0.2 assuming  $R = 1 \mu\text{V}\cdot\text{m}^2/\text{W}$ ; and (d) Apparent temperatures which the device will indicate based upon the signals found in part (c) for each of the three coatings.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Plate has uniform temperature, (2) Surroundings are isothermal and large compared to the plate, and (3) Coatings are diffuse and gray so that  $\epsilon = \alpha$  and  $\rho = 1 - \epsilon$ .

**ANALYSIS:** (a) When viewing the black coating ( $\epsilon_o = 1$ ), the scanner output signal can be expressed as

$$S_o = R F(\lambda_1 - \lambda_2, T_s) E_b(T_s) \quad (1)$$

where  $R$  is the responsivity ( $\mu\text{V}\cdot\text{m}^2/\text{W}$ ),  $E_b(T_s)$  is the blackbody emissive power at  $T_s$  and  $F(\lambda_1 - \lambda_2, T_s)$  is the fraction of the spectral band between  $\lambda_1$  and  $\lambda_2$  in the spectrum for a blackbody at  $T_s$ ,

$$F(\lambda_1 - \lambda_2, T_s) = F(0 - \lambda_2, T_s) - F(0 - \lambda_1, T_s) \quad (2)$$

where the band fractions Eq. 12.35 are evaluated using Table 12.1 with  $\lambda_1 T_s = 3 \mu\text{m} (327 + 273)\text{K} = 1800 \mu\text{m}\cdot\text{K}$  ( $F_{0-\lambda_1} = 0.0393$ ) and  $\lambda_2 T_s = 5 \mu\text{m} (327 + 273) = 3000 \mu\text{m}\cdot\text{K}$  ( $F_{0-\lambda_2} = 0.2732$ ). Substituting numerical values with  $R = 1 \mu\text{V}\cdot\text{m}^2/\text{W}$ , find

$$S_o = 1 \mu\text{V}\cdot\text{m}^2/\text{W} [0.2732 - 0.0393] 5.67 \times 10^{-8} \text{W}/\text{m}^2 \cdot \text{K}^4 (600\text{K})^4$$

$$S_o = 1718 \mu\text{V} \quad <$$

(b) When viewing one of the coatings ( $\epsilon_c < \epsilon_o = 1$ ), the output signal as illustrated in the schematic above will be affected by the emission and reflected irradiation from the surroundings,

$$S_c = R \left\{ F(\lambda_1 - \lambda_2, T_s) \epsilon_c E_b(T_s) + F(\lambda_1 - \lambda_2, T_{\text{sur}}) \rho_c G_c \right\} \quad (3)$$

where the reflected irradiation parameters are

Continued...

**PROBLEM 12.85 (Cont.)**

$$\rho_c = 1 - \varepsilon_c \quad G_c = \sigma T_{\text{sur}}^4 \quad (4,5)$$

and the related band fractions are

$$F(\lambda_1 - \lambda_2, T_{\text{sur}}) = F(0 - \lambda_2, T_{\text{sur}}) - F(0 - \lambda_1, T_{\text{sur}}) \quad (6)$$

Combining Eqs. (2-6) above, the scanner output signal when viewing a coating is

$$S_c = R \left\{ \left[ F(0 - \lambda_2, T_s) - F(0 - \lambda_1, T_s) \right] \varepsilon_c \sigma T_s^4 + \left[ F(0 - \lambda_2, T_{\text{sur}}) - F(0 - \lambda_1, T_{\text{sur}}) \right] (1 - \varepsilon_c) \sigma T_{\text{sur}}^4 \right\} \quad (7)$$

(c) Substituting numerical values into Eq. (7), find

$$S_c = 1 \mu\text{V} \cdot \text{m}^2 / \text{W} \left\{ [0.2732 - 0.0393] \varepsilon_c \sigma (600\text{K})^4 + [0.0393 - 0.0010] (1 - \varepsilon_c) \sigma (360\text{K})^4 \right\}$$

where for  $\lambda_2 T_{\text{sur}} = 5 \mu\text{m} \times 360 \text{K} = 1800 \mu\text{m} \cdot \text{K}$ ,  $F(0 - \lambda_2, T_{\text{sur}}) = 0.0393$  and  $\lambda_1 T_{\text{sur}} = 3 \mu\text{m} \times 360 \text{K} = 1080 \mu\text{m} \cdot \text{K}$ ,  $F(0 - \lambda_1, T_{\text{sur}}) = 0.0010$ . For  $\varepsilon_c = 0.80$ , find

$$S_c (\varepsilon_c = 0.8) = 1 \mu\text{V} \cdot \text{m}^2 / \text{W} \{1375 + 7.295\} \text{W} / \text{m}^2 = 1382 \mu\text{V} \quad <$$

$$S_c (\varepsilon_c = 0.5) = 1 \mu\text{V} \cdot \text{m}^2 / \text{W} \{859.4 + 18.238\} \text{W} / \text{m}^2 = 878 \mu\text{V} \quad <$$

$$S_c (\varepsilon_c = 0.2) = 1 \mu\text{V} \cdot \text{m}^2 / \text{W} \{343.8 + 29.180\} \text{W} / \text{m}^2 = 373 \mu\text{V} \quad <$$

(d) The thermograph calibrated against a black surface ( $\varepsilon_1 = 1$ ) interprets the radiation reaching the detector by emission and reflected radiation from a coating target ( $\varepsilon_c < \varepsilon_o$ ) as that from a blackbody at an apparent temperature  $T_a$ . That is,

$$S_c = R F(\lambda_1 - \lambda_2, T_a) E_b(T_a) = R \left[ F(0 - \lambda_2, T_a) - F(0 - \lambda_1, T_a) \right] \sigma T_a^4 \quad (8)$$

For each of the coatings in part (c), solving Eq. (8) using the IHT workspace with the *Radiation Tool, Band Emission Factor*, the following results were obtained,

$\varepsilon_c$	$S_c$ ( $\mu\text{V}$ )	$T_a$ (K)	$T_a - T_s$ (K)
0.8	1382	579.3	-20.7
0.5	878	539.2	-60.8
0.2	373	476.7	-123.3

**COMMENTS:** (1) From part (c) results for  $S_c$ , note that the contribution of the reflected irradiation becomes relatively more significant with lower values of  $\varepsilon_c$ .

(2) From part (d) results for the apparent temperature, note that the error,  $(T - T_a)$ , becomes larger with decreasing  $\varepsilon_c$ . By rewriting Eq. (8) to include the emissivity of the coating,

$$S'_c = R \left[ F(0 - \lambda_2, T_a) - F(0 - \lambda_1, T_a) \right] \varepsilon_c \sigma T_a^4$$

The apparent temperature  $T'_a$  will be influenced only by the reflected irradiation. The results correcting only for the emissivity,  $\varepsilon_c$ , are

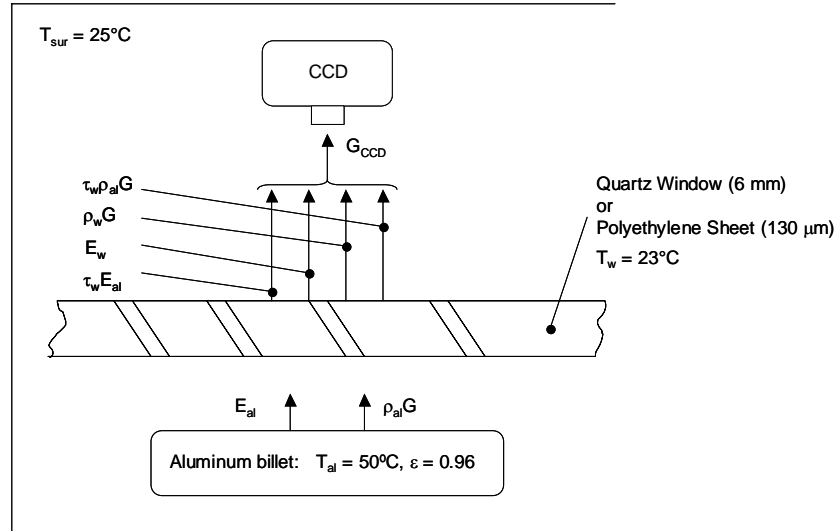

$\varepsilon_c$	0.8	0.5	0.2
$T'_a$ (K)	600.5	602.2	608.5
$T'_a - T_s$ (K)	+0.5	+2.2	+8.5

## PROBLEM 12.86

**KNOWN:** Spectral range of a CCD device used for infrared temperature measurement, thickness of quartz window, transmissivity of polyethylene sheet, emissivity of painted aluminum billet, temperatures of the billet, window and surroundings.

**FIND:** (a) Temperature indicated by the CCD device when quartz window is used, (b) Temperature indicated by the CCD device when polyethylene window is used.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Large surroundings, (2) Diffuse surfaces, (3) Radiative properties do not vary in the spectral range of the CCD device, (4) Reflection from bottom of window is negligible.

**ANALYSIS:** (a) In the spectral range of the CCD detector,

$$G_{\text{CCD},9-12} = \tau_w E_{\text{al}} \left[ F_{(0-12\mu\text{m})} - F_{(0-9\mu\text{m})} \right] + E_w \left[ F_{(0-12\mu\text{m})} - F_{(0-9\mu\text{m})} \right] + \rho_w G \left[ F_{(0-12\mu\text{m})} - F_{(0-9\mu\text{m})} \right] + \tau_w \rho_{\text{al}} G \left[ F_{(0-12\mu\text{m})} - F_{(0-9\mu\text{m})} \right] \quad (1)$$

From Figure 12.23,  $\tau_w \approx 0$  in the spectral range ( $9 \mu\text{m} \leq \lambda \leq 12 \mu\text{m}$ ). Hence, Equation 1 becomes

$$G_{\text{CCD},9-12} = \left[ F_{(0-12\mu\text{m})} - F_{(0-9\mu\text{m})} \right] \left[ \varepsilon_w \sigma T_w^4 + \rho_w \sigma T_{\text{sur}}^4 \right]$$

Since  $\alpha_w + \rho_w = 1$  and  $\alpha_w = \varepsilon_w$  for a diffuse surface that is at the same temperature at the surroundings (see Equation 12.36) it follows that

$$G_{\text{CCD},9-12} = \left[ F_{(0-12\mu\text{m})} - F_{(0-9\mu\text{m})} \right] \sigma T_{\text{sur}}^4 = \left[ F_{(0-12\mu\text{m})} - F_{(0-9\mu\text{m})} \right] \sigma T_d^4$$

where  $T_d$  is the temperature indicated by the detector. Hence,  $T_d = T_{\text{sur}} = 23^\circ\text{C}$ .

<

Continued...

### PROBLEM 12.86 (Cont.)

(b) With the polyethylene sheet as the window and an aluminum temperature of  $T_{al} = 50^\circ\text{C} + 273$  K = 323 K,

$$G_{\text{CCD},9-12} = \tau_w \varepsilon_{al} \sigma T_{al}^4 \left[ F_{(0-12\mu\text{m},323\text{K})} - F_{(0-9\mu\text{m},323\text{K})} \right] + \varepsilon_w \sigma T_w^4 \left[ F_{(0-12\mu\text{m},300\text{K})} - F_{(0-9\mu\text{m},300\text{K})} \right] \\ + \rho_w \sigma T_{sur}^4 \left[ F_{(0-12\mu\text{m},300\text{K})} - F_{(0-9\mu\text{m},300\text{K})} \right] + \tau_w \rho_{al} \sigma T_{sur}^4 \left[ F_{(0-12\mu\text{m},300\text{K})} - F_{(0-9\mu\text{m},300\text{K})} \right]$$

For the window,  $\alpha_w + \rho_w + \tau_w = 1$ . Since  $\alpha_{\lambda,w} = \varepsilon_{\lambda,w}$  for the diffuse surface and since  $T_w = T_{sur}$ ,  $\alpha_w = \varepsilon_w$  as evident in Equation 12.43. Hence,

$$G_{\text{CCD},9-12} = \left[ F_{(0-12\mu\text{m},T_d)} - F_{(0-9\mu\text{m},T_d)} \right] \sigma T_d^4 = \tau_w \varepsilon_{al} \sigma T_{al}^4 \left[ F_{(0-12\mu\text{m},323\text{K})} - F_{(0-9\mu\text{m},323\text{K})} \right] \\ + \sigma T_{sur}^4 (1 - \tau_w) \left[ F_{(0-12\mu\text{m},300\text{K})} - F_{(0-9\mu\text{m},300\text{K})} \right] + \tau_w (1 - \varepsilon_{al}) \sigma T_{sur}^4 \left[ F_{(0-12\mu\text{m},300\text{K})} - F_{(0-9\mu\text{m},300\text{K})} \right]$$

or

$$T_d = \left[ \frac{\tau_w \varepsilon_{al} T_{al}^4 \left[ F_{(0-12\mu\text{m},323\text{K})} - F_{(0-9\mu\text{m},323\text{K})} \right] + (1 - \tau_w \varepsilon_{al}) T_{sur}^4 \left[ F_{(0-12\mu\text{m},300\text{K})} - F_{(0-9\mu\text{m},300\text{K})} \right]}{\left[ F_{(0-12\mu\text{m},T_d)} - F_{(0-9\mu\text{m},T_d)} \right]} \right]^{1/4}$$

Substituting values,

$$T_d = \left[ \frac{0.78 \times 0.96 \times (323\text{K})^4 [0.4576 - 0.2521] + (1 - 0.78 \times 0.96) \times (300\text{K})^4 [0.4036 - 0.2055]}{\left[ F_{(0-12\mu\text{m},T_d)} - F_{(0-9\mu\text{m},T_d)} \right]} \right]^{1/4}$$

A trial-and-error solution, or solution using IHT yields

$$T_d = 317.6 \text{ K} = 44.6^\circ\text{C}$$

<

**COMMENTS:** (1) Materials that are transparent in the visible spectrum, such as quartz, are often opaque in the infrared part of the spectrum. The quartz window does not allow the warm billet to be viewed by the CCD device. (2) This analysis could be extended to calibrate the CCD device so that the indicated temperature is identical to the actual temperature.

## PROBLEM 12.87

**KNOWN:** Diameter, emissivity and temperature of a spherical object. Aperture areas, locations, and spectral transmissivity of the optics of two detectors. Surroundings temperature and irradiation detected at two times.

**FIND:** Velocity of the object, location and time at which the object will strike the  $y = 0$  plane.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Diffuse object, (2) Object travels in a straight line, (3) Object is located above  $y = 2$  m.

**ANALYSIS:** We begin by analyzing the situation at time  $t = 0$ . For Detector A, the irradiation that is detected,  $G_{d,A}$ , is composed of irradiation from the surroundings,  $G_{sur}$ , and irradiation from the object,  $G_{obj}$ . Hence,  $G_{d,A} = G_{sur,d,A} + G_{obj,d,A}$ . The irradiation from the surroundings that is detected is

$$G_{sur,d,A} = \pi I_b F_{(0-2.5\mu m)} \tau_\lambda = E_b(300K) F_{(0-2.5\mu m)} \tau_\lambda$$

$$= 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times 300^4 \text{ K}^4 \times 1.2 \times 10^{-5} \times 0.9 = 4.96 \times 10^{-3} \text{ W/m}^2$$

Therefore,  $G_{obj,d,A} = 5.06 \times 10^{-3} \text{ W/m}^2 - 4.96 \times 10^{-3} \text{ W/m}^2 = 100 \times 10^{-6} \text{ W/m}^2$ . Proceeding as in Example 12.1,

$$G_{obj,d,A} = \left[ I_{obj} A_{obj} \cos \theta_{obj} A_A \cos \theta_A / A_A r_A^2 \right] \times F_{(0-2.5\mu m)} \tau_\lambda$$

Since the projected area of the sphere is a circle,  $A_{obj} \cos \theta_{obj} = \pi D_{obj}^2 / 4$ . In addition,

$I_{obj} = \epsilon_{obj} \sigma T_{obj}^4 / 4$ . Therefore,

Continued...

**PROBLEM 12.87 (Cont.)**

$$100 \times 10^{-6} \text{ W/m}^2 = \left[ 0.95 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times (600\text{K})^4 \times (9 \times 10^{-3} \text{ m})^2 \times \cos \theta_A \times 0.01375 \times 0.9 \right] / 4r_A^2$$

Simplifying the preceding expression results in

$$\frac{\cos \theta_A}{r_A^2} = 57.14 \times 10^{-3} \text{ m}^{-2} \quad (1)$$

We also note that

$$x_{\text{obj},1} = r_A \sin \theta_A, \quad y_{\text{obj},1} = r_A \cos \theta_A \quad (2,3)$$

where  $x_{\text{obj},1}$  and  $y_{\text{obj},1}$  are the x- and y-locations of the object. For Detector B,  $G_{\text{d},B} = G_{\text{sur},\text{d},B} + G_{\text{obj},\text{d},B}$  where  $G_{\text{sur},\text{d},B} = G_{\text{sur},\text{d},A} = 4.96 \times 10^{-3} \text{ W/m}^2$ . Therefore,  $G_{\text{obj},\text{d},B} = 5.00 \times 10^{-3} \text{ W/m}^2 - 4.96 \times 10^{-3} \text{ W/m}^2 = 40 \times 10^{-6} \text{ W/m}^2$ . As for Detector A,

$$G_{\text{obj},\text{d},B} = \left[ I_{\text{obj}} A_{\text{obj}} \cos \theta_{\text{obj}} A_B \cos \theta_B / A_B r_B^2 \right] \times F_{(0-2.5\mu\text{m})} \tau_\lambda$$

Therefore,

$$40 \times 10^{-6} \text{ W/m}^2 = \left[ 0.95 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times (600\text{K})^4 \times (9 \times 10^{-3} \text{ m})^2 \times \cos \theta_B \times 0.01375 \times 0.9 \right] / 4r_B^2$$

Simplifying the preceding expression results in

$$\frac{\cos \theta_B}{r_B^2} = 22.86 \times 10^{-3} \text{ m}^{-2} \quad (4)$$

where

$$x_{\text{obj},1} = r_B \sin \theta_B + 5\text{m}, \quad y_{\text{obj},1} = r_B \cos \theta_B \quad (5,6)$$

Equations 1 through 3 may be solved simultaneously to find all possible positions of the object at  $t = 0$ , as determined from Detector A. Equations 4 through 6 may be solved simultaneously to find all possible positions of the object at  $t = 0$ , as determined from Detector B. These results are plotted below in the first graph. Note that there are two possible locations. Since we know the object is located above  $y = 2 \text{ m}$ , the object is located at the single position shown, which corresponds to  $x_{\text{obj}} = 1.078 \text{ m}$ ,  $y_{\text{obj}} = 3.965 \text{ m}$ .

Now, consider  $t = 4 \text{ ms}$ . The analysis proceeds as for  $t = 0$ , resulting in

$$\frac{\cos \theta_A}{r_A^2} = 28.57 \times 10^{-3} \text{ m}^{-2} \quad (7)$$

$$x_{\text{obj},2} = r_A \sin \theta_A, \quad y_{\text{obj},2} = r_A \cos \theta_A \quad (8,9)$$

$$\frac{\cos \theta_B}{r_B^2} = 51.43 \times 10^{-3} \text{ m}^{-2} \quad (10)$$

Continued...

### PROBLEM 12.87 (Cont.)

$$x_{\text{obj},2} = r_B \sin \theta_B + 5 \text{ m}, \quad y_{\text{obj},2} = r_B \cos \theta_B \quad (11,12)$$

Equations 7 through 9 may be solved simultaneously to find all possible positions of the object at  $t = 4 \text{ ms}$  as determined from Detector A. Equations 10 through 12 may be solved to find all possible positions at  $t = 4 \text{ ms}$ , as determined from Detector B. The two possible positions are shown in the second plot below. Since the object is located above  $y = 2 \text{ m}$ , the object is at the single position shown, which is  $x_{\text{obj},2} = 3.360 \text{ m}$ ,  $y_{\text{obj},2} = 3.903 \text{ m}$ .

The velocity components of the object are

$$v_x = \frac{(x_{\text{obj},2} - x_{\text{obj},1})}{\Delta t} = \frac{(3.360 \text{ m} - 1.078 \text{ m})}{4 \times 10^{-3} \text{ s}} = 571 \text{ m/s} \quad <$$

$$v_y = \frac{(y_{\text{obj},2} - y_{\text{obj},1})}{\Delta t} = \frac{(3.903 \text{ m} - 3.965 \text{ m})}{4 \times 10^{-3} \text{ s}} = -15.5 \text{ m/s} \quad <$$

The object's time of flight is  $t_f = y_{\text{obj},1} / |v_y| = 3.965 \text{ m} / 15.5 \text{ m/s} = 0.256 \text{ s}$  and the object will travel a distance of  $d = v_x t_f = 570.5 \text{ m} \times 0.256 \text{ s} = 146 \text{ m}$ . <

Continued...

**PROBLEM 12.87 (Cont.)**

**COMMENTS:** (1) This is known as an “inverse” problem. Multiple solutions exist to such problems. (2) Use of a third detector would allow one to determine the object’s position in three-dimensional space.

## PROBLEM 12.88

**KNOWN:** Sample at  $T_s = 700$  K with ring-shaped cold shield viewed normally by a radiation detector.

**FIND:** (a) Shield temperature,  $T_{sh}$ , required so that its emitted radiation is 1% of the total radiant power received by the detector, and (b) Compute and plot  $T_{sh}$  as a function of the sample emissivity for the range  $0.05 \leq \epsilon \leq 0.35$  subject to the parametric constraint that the radiation emitted from the cold shield is 0.05, 1 or 1.5% of the total radiation received by the detector.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Sample is diffuse and gray, (2) Cold shield is black, and (3)  $A_d, D_s^2, D_t^2 \ll L_t^2$ .

**ANALYSIS:** (a) The radiant power intercepted by the detector from within the target area is

$$q_d = q_{s \rightarrow d} + q_{sh \rightarrow d}$$

The contribution from the sample is

$$q_{s \rightarrow d} = I_{s,e} A_s \cos \theta_s \Delta \omega_{d-s} \quad \theta_s = 0^\circ$$

$$I_{s,e} = \epsilon_s E_b / \pi = \epsilon_s \sigma T_s^4 / \pi$$

$$\Delta \omega_{d-s} = \frac{A_d \cos \theta_d}{L_t^2} = \frac{A_d}{L_t^2} \quad \theta_d = 0^\circ$$

$$q_{s \rightarrow d} = \epsilon_s \sigma T_s^4 A_s A_d / \pi L_t^2 \quad (1)$$

The contribution from the ring-shaped cold shield is

$$q_{sh \rightarrow d} = I_{sh,e} A_{sh} \cos \theta_{sh} \Delta \omega_{d-sh}$$

$$I_{sh,e} = E_b / \pi = \sigma T_{sh}^4 / \pi$$

and, from the geometry of the shield -detector,

$$A_{sh} = \frac{\pi}{4} (D_t^2 - D_s^2)$$

$$\cos \theta_{sh} = L_t / \left[ \left( \bar{D} / 2 \right)^2 + L_t^2 \right]^{1/2}$$

Continued...

### PROBLEM 12.88 (Cont.)

where  $\bar{D} = (D_s + D_t)/2$

$$\Delta\omega_{d-sh} = \frac{A_d \cos\theta_d}{R^2} \quad \cos\theta_d = \cos\theta_{sh}$$

where  $R = [L_t^2 + \bar{D}^2]^{1/2}$

$$q_{sh \rightarrow d} = \frac{\sigma T_{sh}^4}{\pi} A_{sh} \left[ \frac{L_t}{[(D_s + D_t)/4]^2 + L_t^2} \right]^2 \frac{A_d}{[(D_s + D_t)/4]^2 + L_t^2} \quad (2)$$

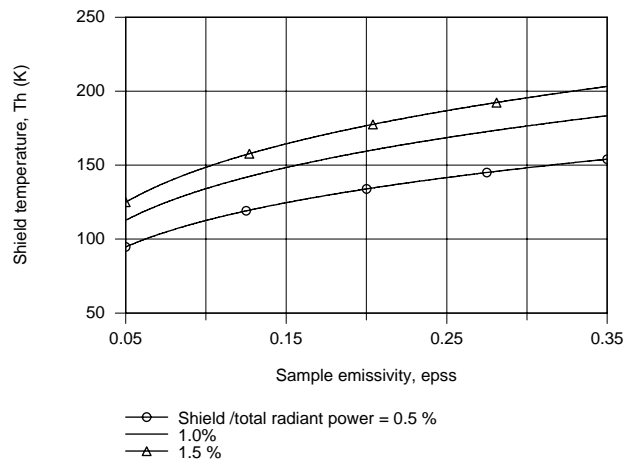

The requirement that the emitted radiation from the cold shield is 1% of the total radiation intercepted by the detector is expressed as

$$\frac{q_{sh-d}}{q_{tot}} = \frac{q_{sh-d}}{q_{sh-d} + q_{s-d}} = 0.01 \quad (3)$$

By evaluating Eq. (3) using Eqs. (1) and (3), find

$$T_{sh} = 134 \text{ K}$$

(b) Using the foregoing equations in the IHT workspace, the required shield temperature for  $q_{sh-d}/q_{tot} = 0.5, 1$  or  $1.5\%$  was computed and plotted as a function of the sample emissivity.

As the shield emission-to-total radiant power ratio decreases ( from 1.5 to 0.5% ), the required shield temperature decreases. The required shield temperature increases with increasing sample emissivity for a fixed ratio.

## PROBLEM 12.89

**KNOWN:** Wavelengths associated with a two-color pyrometer.

**FIND:** The ratio of intensities emitted by the surface at nominal wavelength of  $\lambda = 5 \mu\text{m}$  and  $\Delta\lambda = 0.1, 0.5$  and  $1 \mu\text{m}$ .

**ASSUMPTIONS:** Surface is hot relative to the surroundings so that reflection is negligible relative to emission.

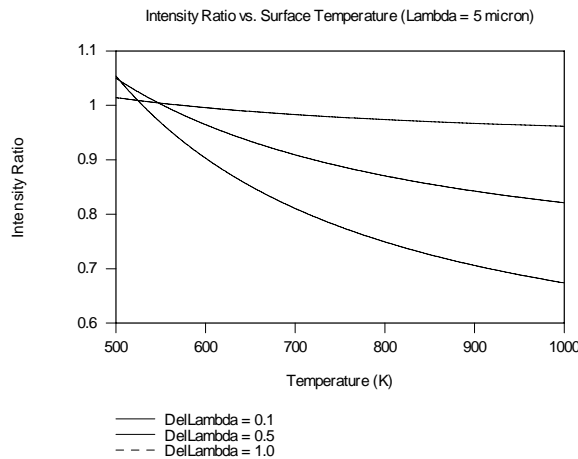

**ANALYSIS:** The spectral intensity emitted by the surface is

$$I_{\lambda,e} = \varepsilon_{\lambda} I_{\lambda,b}(\lambda, T) = \frac{\varepsilon_{\lambda} 2hc_o^2}{\lambda^5 [\exp(hc_o / \lambda kT) - 1]}$$

Assuming the spectral emissivity is independent of wavelength over  $\Delta\lambda$ , the intensity ratio, R, is

$$R = \frac{\lambda^5 [\exp(hc_o / \lambda kT) - 1]}{(\lambda + \Delta\lambda)^5 [\exp(hc_o / (\lambda + \Delta\lambda) kT) - 1]}$$

with  $h = 6.626 \times 10^{-34} \text{ J}\cdot\text{s}$ ,  $k = 1.381 \times 10^{-23} \text{ J/K}$ ,  $c_o = 2.998 \times 10^8 \text{ m/s}$ ,  $\lambda = 5 \mu\text{m}$  and  $\Delta\lambda = 0.1, 0.5$  and  $1.0 \mu\text{m}$ , the variation of R over the range  $500 \text{ K} \leq T \leq 1000 \text{ K}$  is shown below.

As  $\Delta\lambda$  increases, the ratio of intensities exhibits higher sensitivity to the surface temperature. However, a tradeoff exists since the assumption of uniform spectral emissivity over  $\Delta\lambda$  becomes less robust as the difference between  $\lambda_1$  and  $\lambda_2$  becomes large.

**COMMENTS:** (1) The pyrometer will also detect the reflection from the surface. If the surface reflectivity is large, or if the surface is cold relative to the surroundings, care must be made when interpreting the detector's output. (2) Care should be taken if the surface emissivity exhibits highly spectral behavior. (3) The intensity ratio is greater than unity at relatively low temperatures and less than unity at higher temperatures. Can you explain why?

### PROBLEM 12.90

**KNOWN:** Two wavelength values associated with a two-color pyrometer. Ratio of detected radiation from stainless steel.

**FIND:** Temperature of stainless steel.

**ASSUMPTIONS:** (1) Surface is hot relative to the surroundings so that reflection is negligible relative to emission, (2) Wien's law holds, (3) Emissivity does not vary greatly over the wavelength range associated with the pyrometer.

**ANALYSIS:** From Problem 12.27, Wien's law is

$$E_{\lambda,b} \approx \frac{C_1}{\lambda^5} \exp\left(-\frac{C_2}{\lambda T}\right)$$

The detected radiation flux is equal to the radiation flux emitted from the steel surface, since reflection has been assumed negligible. The ratio of intensities is equal to the ratio of emissive power (since  $I_\lambda = \pi E_\lambda$ ). Thus,

$$\frac{I_{\lambda_1}}{I_{\lambda_2}} = \frac{E_{\lambda_1}}{E_{\lambda_2}} = \frac{\varepsilon_1 E_{\lambda_1,b}}{\varepsilon_2 E_{\lambda_2,b}} = \frac{\lambda_2^5}{\lambda_1^5} \exp\left[-\frac{C_2}{T} \left(\frac{1}{\lambda_1} - \frac{1}{\lambda_2}\right)\right] = 2.15$$

where the assumption  $\varepsilon_1 \approx \varepsilon_2$  has been used. Solving for  $T$ ,

$$T = C_2 \frac{\left(\frac{1}{\lambda_2} - \frac{1}{\lambda_1}\right)}{\ln\left(2.15 \frac{\lambda_1^5}{\lambda_2^5}\right)} = 1.439 \times 10^4 \mu\text{m} \cdot \text{K} \frac{\left(\frac{1}{0.63 \mu\text{m}} - \frac{1}{0.65 \mu\text{m}}\right)}{\ln\left(2.15 \left(\frac{0.65 \mu\text{m}}{0.63 \mu\text{m}}\right)^5\right)} = 762 \text{ K} \quad <$$

**COMMENTS:** Comparing Eq. 12.30 to Wien's law, it can be seen that Wien's law is accurate provided that  $\exp(C_2/\lambda T) \gg 1$ . For the conditions of this problem,  $\exp(C_2/\lambda_1 T) = 4 \times 10^{12}$  and Wien's law is highly accurate.

## PROBLEM 12.91

**KNOWN:** Painted plate located inside a large enclosure being heated by an infrared lamp bank.

**FIND:** (a) Lamp irradiation required to maintain plot at  $T_s = 140^\circ\text{C}$  for the prescribed convection and enclosure irradiation conditions, (b) Compute and plot the lamp irradiation,  $G_{\text{lamp}}$ , required as a function of the plate temperature,  $T_s$ , for the range  $100 \leq T_s \leq 300^\circ\text{C}$  and for convection coefficients of  $h = 15, 20$  and  $30 \text{ W/m}^2\cdot\text{K}$ , and (c) Compute and plot the air stream temperature,  $T_\infty$ , required to maintain the plate at  $140^\circ\text{C}$  as a function of the convection coefficient  $h$  for the range  $10 \leq h \leq 30 \text{ W/m}^2\cdot\text{K}$  with a lamp irradiation  $G_{\text{lamp}} = 3000 \text{ W/m}^2$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) No losses on backside of plate.

**ANALYSIS:** (a) Perform an energy balance on the plate, per unit area,

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = 0 \quad (1)$$

$$\alpha_{\text{wall}} \cdot G_{\text{wall}} + \alpha_{\text{lamp}} G_{\text{lamp}} - q''_{\text{conv}} - E_s = 0 \quad (2)$$

where the emissive power of the surface and convective fluxes are

$$E_s = \epsilon_s E_b(T_s) = \epsilon_s \cdot \sigma T_s^4 \quad q''_{\text{conv}} = h(T_s - T_\infty) \quad (3,4)$$

Substituting values, find the lamp irradiation

$$0.7 \times 450 \text{ W/m}^2 + 0.6 \times G_{\text{lamp}} - 20 \text{ W/m}^2 \cdot \text{K} (413 - 300) \text{ K} - 0.8 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (413 \text{ K})^4 = 0 \quad (5)$$

$$G_{\text{lamp}} = 5441 \text{ W/m}^2 \quad \leftarrow$$

(b) Using the foregoing equations in the IHT workspace, the irradiation,  $G_{\text{lamp}}$ , required to maintain the plate temperature in the range  $100 \leq T_s \leq 300^\circ\text{C}$  for selected convection coefficients was computed. The results are plotted below.

Continued...

### PROBLEM 12.91 (Cont.)

As expected, to maintain the plate at higher temperatures, the lamp irradiation must be increased. At any plate operating temperature condition, the lamp irradiation must be increased if the convection coefficient increases. With forced convection (say,  $h \geq 20 \text{ W/m}^2\cdot\text{K}$ ) of the airstream at  $27^\circ\text{C}$ , excessive irradiation levels are required to maintain the plate above the cure temperature of  $140^\circ\text{C}$ .

(c) Using the IHT model developed for part (b), the airstream temperature,  $T_\infty$ , required to maintain the plate at  $T_s = 140^\circ\text{C}$  as a function of the convection coefficient with  $G_{\text{lamp}} = 3000 \text{ W/m}^2\cdot\text{K}$  was computed and the results are plotted below.

As the convection coefficient increases, for example by increasing the airstream velocity over the plate, the required air temperature must increase. Give a physical explanation for why this is so.

**COMMENTS:** (1) For a spectrally selective surface, we should expect the absorptivity to depend upon the spectral distribution of the source and  $\alpha \neq \varepsilon$ .

(2) Note the new terms used in this problem; use your Glossary, Section 12.10 to reinforce their meaning.

## PROBLEM 12.92

**KNOWN:** Small sample of reflectivity,  $\rho_\lambda$ , and diameter,  $D$ , is irradiated with an isothermal enclosure at  $T_f$ .

**FIND:** (a) Absorptivity,  $\alpha$ , of the sample with prescribed  $\rho_\lambda$ , (b) Emissivity,  $\varepsilon$ , of the sample, (c) Heat removed by coolant to the sample, (d) Explanation of why system provides a measure of  $\rho_\lambda$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Sample is diffuse and opaque, (2) Furnace is an isothermal enclosure with area much larger than the sample, (3) Aperture of furnace is small.

**ANALYSIS:** (a) The absorptivity,  $\alpha$ , follows from Eq. 12.48, where the irradiation on the sample is  $G = E_b(T_f)$  and  $\alpha_\lambda = 1 - \rho_\lambda$ .

$$\alpha = \int_0^\infty \alpha_\lambda G_\lambda d\lambda / G = \int_0^\infty (1 - \rho_\lambda) E_{\lambda,b}(\lambda, 1000\text{K}) d\lambda / E_b(1000\text{K})$$

$$\alpha = (1 - \rho_{\lambda,1}) F_{(0 \rightarrow \lambda_1)} + (1 - \rho_{\lambda,2}) [1 - F_{(0 \rightarrow \lambda_1)}]$$

Using Table 12.1 for  $\lambda_1 T_f = 4 \times 1000 = 4000 \mu\text{m}\cdot\text{K}$ ,  $F_{(0-\lambda)} = 0.481$  giving

$$\alpha = (1 - 0.2) \times 0.481 + (1 - 0.8) \times (1 - 0.481) = 0.49. \quad <$$

(b) The emissivity,  $\varepsilon$ , follows from Table 12.1 with  $\varepsilon_\lambda = \alpha_\lambda = 1 - \rho_\lambda$  since the sample is diffuse.

$$\varepsilon = E(T_s) / E_b(T_s) = \int_0^\infty \varepsilon_\lambda E_{\lambda,b}(\lambda, 300\text{K}) d\lambda / E_b(300\text{K})$$

$$\varepsilon = (1 - \rho_{\lambda,1}) F_{(0-\lambda_1)} + (1 - \rho_{\lambda,2}) [1 - F_{(0-\lambda_1)}]$$

Using Table 12.1 for  $\lambda_1 T_s = 4 \times 300 = 1200 \mu\text{m}\cdot\text{K}$ ,  $F_{(0-\lambda)} = 0.002$  giving

$$\varepsilon = (1 - 0.2) \times 0.002 + (1 - 0.8) \times (1 - 0.002) = 0.20.$$

(c) Performing an energy balance on the sample, the heat removal rate by the cooling water is

$$q_{\text{cool}} = A_s [\alpha G + q_{\text{conv}}'' - \varepsilon E_b(T_s)]$$

where

$$G = E_b(T_f) = E_b(1000\text{K})$$

$$q_{\text{conv}}'' = h(T_f - T_s) \quad A_s = \pi D^2 / 4$$

$$q_{\text{cool}} = (\pi/4)(0.03\text{m})^2 \left[ 0.49 \times 5.67 \times 10^{-8} \text{W/m}^2 \cdot \text{K}^4 \times (1000\text{K})^4 \right. \\ \left. + 10 \text{W/m}^2 \cdot \text{K} (1000 - 300) \text{K} - 0.20 \times 5.67 \times 10^{-8} \text{W/m}^2 \cdot \text{K}^4 \times (300\text{K})^4 \right] = 24.5 \text{W}. \quad <$$

(d) Assume that reflection makes the dominant contribution to the radiosity of the sample. When viewing in the direction A, the spectral radiant power is proportional to  $\rho_\lambda G_\lambda$ . In direction B, the spectral radiant power is proportional to  $E_{\lambda,b}(T_f)$ . Noting that  $G_\lambda = E_{\lambda,b}(T_f)$ , the ratio gives  $\rho_\lambda$ .

### PROBLEM 12.93

**KNOWN:** Small, opaque surface initially at 1200 K with prescribed  $\alpha_\lambda$  distribution placed in a large enclosure at 2400 K.

**FIND:** (a) Total, hemispherical absorptivity of the sample surface, (b) Total, hemispherical emissivity, (c)  $\alpha$  and  $\varepsilon$  after long time has elapsed, (d) Variation of sample temperature with time.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Surface is diffusely radiated. (2) Enclosure is much larger than surface and at a uniform temperature.

**PROPERTIES:** Table A.1, Tungsten ( $T \approx 1800$  K):  $\rho = 19,300$  kg/m<sup>3</sup>,  $c_p = 163$  J/kg·K,  $k \approx 102$  W/m·K.

**ANALYSIS:** (a) The total, hemispherical absorptivity follows from Eq. 12.52, where  $G_\lambda = E_{\lambda,b}(T_{\text{sur}})$ . That is, the irradiation corresponds to the spectral emissive power of a blackbody at the enclosure temperature and is independent of the enclosure emissivity.

$$\alpha = \int_0^\infty \alpha_\lambda G_\lambda d\lambda / \int_0^\infty G_\lambda d\lambda = \int_0^\infty \alpha_\lambda E_{\lambda,b}(\lambda, T_{\text{sur}}) d\lambda / E_b(T_{\text{sur}})$$

$$\alpha = \alpha_1 \int_0^{2\mu\text{m}} E_{\lambda,b}(\lambda, T_{\text{sur}}) d\lambda / \sigma T_{\text{sur}}^4 + \alpha_2 \int_{2\mu\text{m}}^\infty E_{\lambda,b}(\lambda, T_{\text{sur}}) d\lambda / \sigma T_{\text{sur}}^4$$

$$\alpha = \alpha_1 F_{(0 \rightarrow 2\mu\text{m})} + \alpha_2 [1 - F_{(0 \rightarrow 2\mu\text{m})}] = 0.1 \times 0.6076 + 0.8[1 - 0.6076] = 0.375 \quad <$$

where at  $\lambda T = 2 \times 2400 = 4800 \mu\text{m} \cdot \text{K}$ ,  $F_{(0 \rightarrow 2\mu\text{m})} = 0.6076$  from Table 12.1.

(b) The total, hemispherical emissivity follows from Eq. 12.43,

$$\varepsilon = \int_0^\infty \varepsilon_\lambda E_{\lambda,b}(\lambda, T_s) d\lambda / \int_0^\infty E_{\lambda,b}(\lambda, T_s) d\lambda$$

Since the surface is diffuse,  $\varepsilon_\lambda = \alpha_\lambda$  and the integral can be expressed as

$$\varepsilon = \alpha_1 \int_0^{2\mu\text{m}} E_{\lambda,b}(\lambda, T_s) d\lambda / \sigma T_s^4 + \alpha_2 \int_{2\mu\text{m}}^\infty E_{\lambda,b}(\lambda, T_s) d\lambda / \sigma T_s^4$$

$$\varepsilon = \alpha_1 F_{(0 \rightarrow 2\mu\text{m})} + \alpha_2 [1 - F_{(0 \rightarrow 2\mu\text{m})}] = 0.1 \times 0.1403 + 0.8[1 - 0.1403] = 0.702 \quad <$$

where at  $\lambda T = 2 \times 1200 = 2400 \mu\text{m} \cdot \text{K}$ , find  $F_{(0 \rightarrow 2\mu\text{m})} = 0.1403$  from Table 12.1.

(c) After a long period of time, the surface will be at the temperature of the enclosure. This condition of thermal equilibrium is described by Kirchoff's law, for which

$$\varepsilon = \alpha = 0.375. \quad <$$

### PROBLEM 12.93 (Cont.)

(d) Using the IHT *Lumped Capacitance Model*, the energy balance relation is of the form

$$\rho c_p \forall \frac{dT}{dt} = A_s [\alpha G - \varepsilon(T) E_b(T)]$$

where  $T = T_s$ ,  $\forall = \pi D^3/6$ ,  $A_s = \pi D^2$  and  $G = \sigma T_{\text{sur}}^4$ . Integrating over time in increments of  $\Delta t = 0.5\text{s}$  and using the *Radiation Toolpad* to determine  $\varepsilon(t)$ , the following results are obtained.

The temperature of the specimen increases rapidly with time and achieves a value of 2399 K within  $t \approx 47\text{s}$ . The emissivity decreases with increasing time, approaching the absorptivity as  $T$  approaches  $T_{\text{sur}}$ .

**COMMENTS:** (1) Recognize that  $\alpha$  always depends upon the spectral irradiation distribution, which, in this case, corresponds to emission from a blackbody at the temperature of the enclosure.

(2) With  $h_r = \varepsilon \sigma (T + T_{\text{sur}})(T^2 + T_{\text{sur}}^2) \approx 0.375 \sigma 4 T_{\text{sur}}^3 = 1176 \text{ W/m}^2 \cdot \text{K}$ ,  $\text{Bi} = h_r (r_o/3)/k = (1176 \text{ W/m}^2 \cdot \text{K}) 1.667 \times 10^{-3} \text{ m}/102 \text{ W/m} \cdot \text{K} = 0.0192 \ll 1$ , use of the lumped capacitance model is justified.

## PROBLEM 12.94

**KNOWN:** Diameter and initial temperature of copper rod. Wall and gas temperature.

**FIND:** (a) Expression for initial rate of change of rod temperature, (b) Initial rate for prescribed conditions, (c) Transient response of rod temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Applicability of lumped capacitance approximation, (2) Furnace approximates a blackbody cavity, (3) Thin film is diffuse and has negligible thermal resistance, (4) Properties of nitrogen approximate those of air (Part c).

**PROPERTIES:** Table A.1, copper ( $T = 300 \text{ K}$ ):  $c_p = 385 \text{ J/kg}\cdot\text{K}$ ,  $\rho = 8933 \text{ kg/m}^3$ ,  $k = 401 \text{ W/m}\cdot\text{K}$ .  
Table A.4, nitrogen ( $p = 1 \text{ atm}$ ,  $T_f = 900 \text{ K}$ ):  $\nu = 100.3 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\alpha = 139 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0597 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.721$ .

**ANALYSIS:** (a) Applying conservation of energy at an instant of time to a control surface about the cylinder,  $\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \dot{E}_{\text{st}}$ , where energy inflow is due to natural convection and radiation from the furnace wall and energy outflow is due to emission. Hence, for a unit cylinder length,

$$q_{\text{conv}} + q_{\text{rad,net}} = \frac{\rho \pi D^2}{4} c_p \frac{dT}{dt}$$

where

$$q_{\text{conv}} = \bar{h}(\pi D)(T_\infty - T)$$

$$q_{\text{rad,net}} = \pi D(\alpha G - \varepsilon E_b) = \pi D[\alpha E_b(T_w) - \varepsilon E_b(T)]$$

Hence, at  $t = 0$  ( $T = T_i$ ),

$$dT/dt|_i = (4/\rho c_p D) [\bar{h}(T_\infty - T_i) + \alpha E_b(T_w) - \varepsilon E_b(T_i)]$$

(b) With  $\text{Ra}_D = \frac{g\beta(T_\infty - T_i)D^3}{\alpha\nu} = \frac{9.8 \text{ m/s}^2 (1/900 \text{ K})(1200 \text{ K})(0.01 \text{ m})^3}{100.3 \times 139 \times 10^{-12} \text{ m}^4/\text{s}^2} = 937$ , the Churchill-Chu

correlation of Chapter 9 yields

$$\bar{\text{Nu}}_D = \left\{ 0.60 + \frac{0.387 \text{Ra}_D^{1/6}}{\left[ 1 + (0.559/\text{Pr})^{9/16} \right]^{8/27}} \right\}^2 = 2.58$$

$$\bar{h} = k \frac{\bar{\text{Nu}}_D}{D} = \frac{(0.0597 \text{ W/m}\cdot\text{K}) 2.58}{0.01 \text{ m}} = 15.4 \text{ W/m}^2\cdot\text{K}$$

With  $T = T_i = 300 \text{ K}$ ,  $\lambda T = 600 \mu\text{m}\cdot\text{K}$  yields  $F_{(0 \rightarrow \lambda)} = 0$ , in which case  $\varepsilon = \varepsilon_1 F_{(0 \rightarrow \lambda)} + \varepsilon_2 [1 - F_{(0 \rightarrow \lambda)}] = 0.4$ .

With  $T = T_w = 1500 \text{ K}$ ,  $\lambda T = 3000 \text{ K}$  yields  $F_{(0 \rightarrow \lambda)} = 0.273$ . Hence, with  $\alpha_\lambda = \varepsilon_\lambda$ ,  $\alpha = \varepsilon_1 F_{(0 \rightarrow \lambda)} + \varepsilon_2 [1 - F_{(0 \rightarrow \lambda)}] = 0.9(0.273) + 0.4(1 - 0.273) = 0.537$ . It follows that

Continued...

**PROBLEM 12.94 (Cont.)**

$$\left. \frac{dT}{dt} \right|_i = \frac{4}{8933 \frac{\text{kg}}{\text{m}^3} \left( 385 \frac{\text{J}}{\text{kg} \cdot \text{K}} \right) 0.01 \text{m}} \left[ 15.4 \frac{\text{W}}{\text{m}^2 \cdot \text{K}} (1500 - 300) \text{K} \right. \\ \left. + 0.537 \times 5.67 \times 10^{-4} \frac{\text{W}}{\text{m}^2 \cdot \text{K}^4} (1500 \text{K})^4 - 0.4 \times 5.67 \times 10^{-8} \frac{\text{W}}{\text{m}^2 \cdot \text{K}^4} (300 \text{K})^4 \right]$$

$$dT/dt)_i = 1.163 \times 10^{-4} \text{m}^2 \cdot \text{K}/\text{J} [18,480 + 154,140 - 180] \text{W}/\text{m}^2 = 20 \text{K/s} \quad <$$

Defining a pseudo radiation coefficient as  $h_r = (\alpha G - \epsilon E_b)/(T_w - T_i) = (153,960 \text{ W/m}^2)/1200 \text{ K} = 128.3 \text{ W/m}^2 \cdot \text{K}$ ,  $Bi = (h + h_r)(D/4)/k = 143.7 \text{ W/m}^2 \cdot \text{K} (0.0025 \text{ m})/401 \text{ W/m} \cdot \text{K} = 0.0009$ . Hence, the lumped capacitance approximation is appropriate.

(c) Using the IHT *Lumped Capacitance Model with the Correlations, Radiation and Properties* (copper and air) Toolpads, the transient response of the rod was computed for  $300 \leq T < 1200 \text{ K}$ , where the upper limit was determined by the temperature range of the copper property table.

The rate of change of the rod temperature,  $dT/dt$ , decreases with increasing temperature, in accordance with a reduction in the convective and *net* radiative heating rates. Note, however, that even at  $T \approx 1200 \text{ K}$ ,  $\alpha G$ , which is fixed, is large relative to  $q''_{\text{conv}}$  and  $\epsilon E_b$  and  $dT/dt$  is still significant.

## PROBLEM 12.95

**KNOWN:** Temperatures of furnace wall and top and bottom surfaces of a planar sample. Dimensions and emissivity of sample.

**FIND:** (a) Sample thermal conductivity, (b) Validity of assuming uniform bottom surface temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) One-dimensional conduction in sample, (3) Constant  $k$ , (4) Diffuse-gray surface, (5) Irradiation equal to blackbody emission at 1400K.

**PROPERTIES:** Table A-6, Water coolant (300K):  $c_{p,c} = 4179 \text{ J/kg}\cdot\text{K}$

**ANALYSIS:** (a) From energy balance at top surface,

$$\alpha G - E = q''_{\text{cond}} = k_s (T_s - T_c) / L$$

where  $E = \varepsilon_s \sigma T_s^4$ ,  $G = \sigma T_w^4$ ,  $\alpha = \varepsilon_s$  giving

$$\varepsilon_s \sigma T_w^4 - \varepsilon_s \sigma T_s^4 = k_s (T_s - T_c) / L.$$

Solving for the thermal conductivity and substituting numerical values, find

$$k_s = \frac{\varepsilon_s L \sigma}{T_s - T_c} (T_w^4 - T_s^4)$$

$$k_s = \frac{0.85 \times 0.015 \text{ m} \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4}{(1000 - 300) \text{ K}} \left[ (1400 \text{ K})^4 - (1000 \text{ K})^4 \right]$$

$$k_s = 2.93 \text{ W/m}\cdot\text{K}. \quad <$$

(b) Non-uniformity of bottom surface temperature depends on coolant temperature rise. From the energy balance

$$q = \dot{m}_c c_{p,c} \Delta T_c = (\alpha G - E) W^2$$

$$\Delta T_c = \frac{0.85 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left[ 1400^4 - 1000^4 \right] \text{ K}^4 (0.10 \text{ m})^2}{0.1 \text{ kg/s} \times 4179 \text{ J/kg}\cdot\text{K}}$$

$$\Delta T_c = 3.3 \text{ K}. \quad <$$

The variation in  $T_c$  ( $\sim 3\text{K}$ ) is small compared to  $(T_s - T_c) \approx 700\text{K}$ . Hence it is not large enough to introduce significant error in the  $k$  determination.

## PROBLEM 12.96

**KNOWN:** Thicknesses and thermal conductivities of a ceramic/metal composite. Emissivity of ceramic surface. Temperatures of vacuum chamber wall and substrate lower surface. Receiving area of radiation detector, distance of detector from sample, and sample surface area viewed by detector.

**FIND:** (a) Ceramic top surface temperature and heat flux, (b) Rate at which radiation emitted by the ceramic is intercepted by detector, (c) Effect of an interfacial (ceramic/substrate) contact resistance on sample top and bottom surface temperatures.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) One-dimensional, steady-state conduction in sample, (2) Constant properties, (3) Chamber forms a blackbody enclosure at  $T_w$ , (4) Ceramic surface is diffuse/gray, (5) Negligible interface contact resistance for part (a).

**PROPERTIES:** Ceramic:  $k_c = 6 \text{ W/m}\cdot\text{K}$ ,  $\epsilon_c = 0.8$ . Substrate:  $k_s = 25 \text{ W/m}\cdot\text{K}$ .

**ANALYSIS:** (a) From an energy balance at the exposed ceramic surface,  $q''_{\text{cond}} = q''_{\text{rad}}$ , or

$$\frac{T_1 - T_2}{(L_s/k_s) + (L_c/k_c)} = \epsilon_c \sigma (T_2^4 - T_w^4)$$

$$\frac{1500 \text{ K} - T_2}{\frac{0.008 \text{ m}}{25 \text{ W/m}\cdot\text{K}} + \frac{0.0005 \text{ m}}{6 \text{ W/m}\cdot\text{K}}} = 0.8 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (T_2^4 - 90^4) \text{ K}^4$$

$$3.72 \times 10^6 - 2479 T_2 = 4.54 \times 10^{-8} T_2^4 - 2.98$$

$$4.54 \times 10^{-8} T_2^4 + 2479 T_2 = 3.72 \times 10^6$$

Solving, we obtain

$$T_2 = 1425 \text{ K} \quad \angle$$

$$q''_h = \frac{T_1 - T_2}{(L_s/k_s) + (L_c/k_c)} = \frac{(1500 - 1425) \text{ K}}{4.033 \times 10^{-4} \text{ m}^2 \cdot \text{K/W}} = 1.87 \times 10^5 \text{ W/m}^2 \quad \angle$$

(b) Since the ceramic surface is diffuse, the total intensity of radiation emitted in all directions is  $I_e = \epsilon_c E_b(T_s)/\pi$ . Hence, the rate at which emitted radiation is intercepted by the detector is

$$q_{c(\text{em})-d} = I_e \Delta A_c \left( A_d / L_{s-d}^2 \right)$$

$$q_{c(\text{em})-d} = \frac{0.8 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (1425 \text{ K})^4}{\pi \text{ sr}} \times 10^{-4} \text{ m}^2 \times 10^{-5} \text{ sr} = 5.95 \times 10^{-5} \text{ W}$$

Continued...

### PROBLEM 12.96 (Cont.)

(c) With the development of an interfacial thermal contact resistance and fixed values of  $q_h''$  and  $T_w$ , (i)  $T_2$  remains the same (its value is determined by the requirement that  $q_h'' = \varepsilon_c \sigma (T_2^4 - T_w^4)$ ), while (ii)  $T_1$  increases (its value is determined by the requirement that  $q_h'' = (T_1 - T_2)/R_{\text{tot}}''$ , where  $R_{\text{tot}}'' = [(L_s/k_s) + R_{t,c}'' + (L_c/k_c)]$ ); if  $q_h''$  and  $T_2$  are fixed,  $T_1$  must increase with increasing  $R_{\text{tot}}''$ .

**COMMENTS:** The detector will also see radiation which is reflected from the ceramic. The corresponding radiation rate is  $q_{c(\text{reflection})-d} = \rho_c G_c \Delta A_c A_d / L_{s-d}^2 = 0.2 \sigma (90 \text{ K})^4 \times 10^{-4} \text{ m}^2 \times (10^{-5} \text{ sr}) = 7.44 \times 10^{-10} \text{ W}$ . Hence, reflection is negligible.

## PROBLEM 12.97

**KNOWN:** Wafer heated by ion beam source within large process-gas chamber with walls at uniform temperature; radiometer views a  $5 \times 5$  mm target on the wafer. Black panel mounted in place of wafer in a pre-production test of the equipment.

**FIND:** (a) Radiant power ( $\mu\text{W}$ ) received by the radiometer when the black panel temperature is  $T_{\text{bp}} = 800$  K and (b) Temperature of the wafer,  $T_{\text{w}}$ , when the ion beam source is adjusted so that the radiant power received by the radiometer is the same as that of part (a)

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Chamber represents large, isothermal surroundings, (3) Wafer is opaque, diffuse-gray, and (4) Target area  $\ll$  square of distance between target and radiometer objective.

**ANALYSIS:** (a) The radiant power leaving the black-panel target and reaching the radiometer as illustrated in the schematic below is

$$q_{\text{bp-rad}} = \left[ E_{\text{b, bp}}(T_{\text{bp}}) / \pi \right] A_{\text{t}} \cos \theta_{\text{t}} \cdot \Delta \omega_{\text{rad-t}} \quad (1)$$

where  $\theta_{\text{t}} = 0^\circ$  and the solid angle the radiometer subtends with respect to the target follows from Eq. 12.7,

$$\Delta \omega_{\text{rad-t}} = \frac{dA_{\text{n}}}{r^2} = \frac{(\pi D_{\text{o}}^2 / 4)}{r^2} = \frac{\pi (0.025 \text{ m})^2 / 4}{(0.500 \text{ m})^2} = 1.964 \times 10^{-3} \text{ sr}$$

With  $E_{\text{b, bp}} = \sigma T_{\text{bp}}^4$ , find

$$q_{\text{bp-rad}} = \left[ 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (800 \text{ K})^4 / \pi \text{ sr} \right] \\ \times (0.005 \text{ m})^2 \times \cos 30^\circ \times 1.964 \times 10^{-3} \text{ sr}$$

$$q_{\text{bp-rad}} = 314 \mu\text{W}$$

(a) Black panel,  $T_{\text{bp}} = 800$  K

(b) Wafer,  $\epsilon_{\text{w}} = 0.7$ ,  $T_{\text{w}} = ?$

Continued ...

### PROBLEM 12.97 (Cont.)

(b) With the wafer mounted, the ion beam source is adjusted until the radiometer receives the same radiant power as with part (a) for the black panel. The power reaching the radiometer is expressed in terms of the wafer radiosity,

$$q_{w-\text{rad}} = [J_w / \pi] A_t \cos \theta_t \cdot \Delta \omega_{\text{rad-t}} \quad (2)$$

Since  $q_{w-\text{rad}} = q_{\text{bp-rad}}$  (see Eq. (1)), recognize that

$$J_w = E_{\text{b, bp}}(T_{\text{bp}}) \quad (3)$$

where the radiosity is

$$J_w = \varepsilon_w E_{\text{b,w}}(T_w) + \rho_w G_w = \varepsilon_w E_{\text{b,w}}(T_w) + (1 - \varepsilon_w) E_{\text{b}}(T_{\text{ch}}) \quad (4)$$

and  $G_w$  is equal to the blackbody emissive power at  $T_{\text{ch}}$ . Using Eqs. (3) and (4) and substituting numerical values, find

$$\sigma T_{\text{bp}}^4 = \varepsilon_w \sigma T_w^4 + (1 - \varepsilon_w) \sigma T_{\text{ch}}^4$$

$$(800 \text{ K})^4 = 0.7 T_w^4 + 0.3(400 \text{ K})^4$$

$$T_w = 871 \text{ K} \quad <$$

**COMMENTS:** (1) Explain why  $T_w$  is higher than 800 K, the temperature of the black panel, when the radiometer receives the same radiant power for both situations.

(2) If the chamber walls were cold relative to the wafer, say near liquid nitrogen temperature,  $T_{\text{ch}} = 80 \text{ K}$ , and the test repeated with the same indicated radiometer power, is the wafer temperature higher or lower than 871 K?

(3) If the chamber walls were maintained at 800 K, and the test repeated with the same indicated radiometer power, what is the wafer temperature?

## PROBLEM 12.98

**KNOWN:** Spectral emissivity of fire brick wall used to construct brick oven. Magnitude and distribution of irradiation on wall. Temperature and heat transfer coefficient of gases adjacent to wall. Wall thickness and thermal conductivity.

**FIND:** Wall interior surface temperature if heat loss through wall is negligible. Wall interior surface temperature if wall is insulated and exterior surface temperature of insulation is 300 K.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Brick wall is opaque and diffuse, (2) Spectral distribution of irradiation reaching brick wall approximates that due to emission from a blackbody at 2000 K.

**PROPERTIES:** Fire brick wall (given in Example 12.10):  $\varepsilon_\lambda \approx 0.1$ ,  $\lambda < 1.5 \mu\text{m}$ ,  $\varepsilon_\lambda \approx 0.5$ ,  $1.5 \mu\text{m} \leq \lambda < 10 \mu\text{m}$ ,  $\varepsilon_\lambda \approx 0.8$ ,  $\lambda \geq 10 \mu\text{m}$ ;  $\alpha = 0.395$  (for irradiation with spectral distribution proportional to blackbody at 2000 K).

**ANALYSIS:** Neglecting heat transfer through the wall, an energy balance on the wall can be written,

$$\begin{aligned} \dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= \alpha G - E - q''_{\text{conv}} = 0 \\ \alpha G - E(T_s) - h(T_s - T_\infty) &= 0 \end{aligned} \quad (1)$$

From Example 12.10, we know that the absorptivity to irradiation having the spectral distribution of a blackbody at 2000 K is  $\alpha = 0.395$ . Now we must find the emissive power of the wall from Table 12.1 and Eq. 12.43,

$$E(T_s) = \varepsilon(T_s)E_b(T_s) = \int_0^\infty \varepsilon_\lambda(\lambda)E_{\lambda,b}(\lambda, T_s)d\lambda = I_1 + I_2 + I_3$$

where

$$I_1 = 0.1 \int_0^{1.5 \mu\text{m}} E_{\lambda,b}(\lambda, T_s)d\lambda = 0.1F_{(0 \rightarrow 1.5 \mu\text{m})}E_b(T_s)$$

$$I_2 = 0.5 \int_{1.5 \mu\text{m}}^{10 \mu\text{m}} E_{\lambda,b}(\lambda, T_s)d\lambda = 0.5F_{(1.5 \mu\text{m} \rightarrow 10 \mu\text{m})}E_b(T_s)$$

$$I_3 = 0.8 \int_{10 \mu\text{m}}^\infty E_{\lambda,b}(\lambda, T_s)d\lambda = 0.8F_{(10 \mu\text{m} \rightarrow \infty)}E_b(T_s)$$

Continued...

### PROBLEM 12.98 (Cont.)

Thus,

$$E(T_s) = \left[ 0.1F_{(0 \rightarrow 1.5\mu\text{m})} + 0.5(F_{(0 \rightarrow 10\mu\text{m})} - F_{(0 \rightarrow 1.5\mu\text{m})}) + 0.8(1 - F_{(0 \rightarrow 10\mu\text{m})}) \right] E_b(T_s) \quad (2)$$

Eqs. (1) and (2) are two equations in the two unknowns,  $T_s$  and  $E(T_s)$ , where each of the  $F$ 's also depends on  $T_s$  (from Table 12.1). A numerical solution is required. An *IHT* code to solve this problem is shown in the Comments section. The solution is

$$T_s = 796 \text{ K} \quad <$$

With conduction through the wall, the energy balance becomes

$$\begin{aligned} \dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= \alpha G - E - q_{\text{conv}}'' - q_{\text{cond}}'' = 0 \\ \alpha G - E(T_s) - h(T_s - T_{\infty}) - (T_s - T_{s,o})/R_{\text{tot}}'' &= 0 \end{aligned} \quad (3)$$

where

$$R_{\text{tot}}'' = L_b/k_b + L_i/k_i = 0.1 \text{ m}/1.0 \text{ W/m}\cdot\text{K} + 0.1 \text{ m}/0.05 \text{ W/m}\cdot\text{K} = 2.1 \text{ m}^2 \cdot \text{K}/\text{W}$$

Eqs. (2) and (3) can once again be solved using *IHT*, to find

$$T_s = 793 \text{ K} \quad <$$

**COMMENTS:** (1) If the conduction heat flux is included, the surface temperature drops by only 3 K. (2) The *IHT* code to solve the problem is shown below. Note that if Eq. (1) or (3) is used directly, the code does not converge to a solution for  $T_s$ . Instead, the code is set up to calculate a variable “qnet” that is the net heat flux at the surface, and  $T_s$  is varied until qnet is approximately zero.

```
//Energy balance on inner surface
/* To effect convergence, calculate qnet as a function of Ts, and "Explore" Ts to find value for which qnet = 0. */
qnet = alpha*G - E - h*(Ts - Tinf) - qcond
Ts = 500

//Calculate qcond. Select from two options below.
qcond = (Ts - Tso)/Rtot
//qcond = 0

//Calculate E(Ts).
lambda1 = 1.5
lambda2 = 10
/* The blackbody band emission factor, Figure 12.14 and Table 12.1, is */

```

## PROBLEM 12.99

**KNOWN:** Laser-materials-processing apparatus. Spectrally selective sample heated to the operating temperature  $T_s = 2000$  K by laser irradiation ( $0.5 \mu\text{m}$ ),  $G_{\text{laser}}$ , experiences convection with an inert gas and radiation exchange with the enclosure.

**FIND:** (a) Total emissivity of the sample,  $\epsilon$ ; (b) Total absorptivity of the sample,  $\alpha$ , for irradiation from the enclosure; (c) Laser irradiation required to maintain the sample at  $T_s = 2000$  K by performing an energy balance on the sample; (d) Sketch of the sample emissivity during the cool-down process when the laser and inert gas flow are deactivated; identify key features including the emissivity for the final condition ( $t \rightarrow \infty$ ); and (e) Time-to-cool the sample from the operating condition at  $T_s(0) = 2000$  K to a safe-to-touch temperature of  $T_s(t) = 40^\circ\text{C}$ ; use the lumped capacitance method and include the effects of convection with inert gas ( $T_\infty = 300$  K,  $h = 50$  W/m<sup>2</sup>·K) as well as radiation exchange  $T_{\text{enc}} = T_\infty$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Enclosure is isothermal and large compared to the sample, (2) Sample is opaque and diffuse, but spectrally selective, so that  $\epsilon_\lambda = \alpha_\lambda$ , (3) Sample is isothermal.

**PROPERTIES:** Sample (Given)  $\rho = 3900$  kg/m<sup>3</sup>,  $c_p = 760$  J/kg,  $k = 45$  W/m·K.

**ANALYSIS:** (a) The total emissivity of the sample,  $\epsilon$ , at  $T_s = 2000$  K follows from Eq. 12.43 which can be expressed in terms of the band emission factor,  $F_{(0-\lambda_1 T)}$  Eq. 12.34,

$$\epsilon = \epsilon_1 F_{(0-\lambda_1 T_s)} + \epsilon_2 [1 - F_{(0-\lambda_1 T_s)}] \quad (1)$$

$$\epsilon = 0.8 \times 0.7378 + 0.2 [1 - 0.7378] = 0.643 \quad <$$

where from Table 12.1, with  $\lambda_1 T_s = 3 \mu\text{m} \times 2000$  K = 6000  $\mu\text{m} \cdot \text{K}$ ,  $F_{(0-\lambda_1 T)} = 0.7378$ .

(b) The total absorptivity of the sample,  $\alpha$ , for irradiation from the enclosure at  $T_{\text{enc}} = 300$  K, is

$$\alpha = \epsilon_1 F_{(0-\lambda_1 T_{\text{enc}})} + \epsilon_2 [1 - F_{(0-\lambda_1 T_{\text{enc}})}] \quad (2)$$

$$\alpha = 0.8 \times 0 + 0.2 [1 - 0] = 0.200 \quad <$$

where, from Table 12.1, with  $\lambda_1 T_{\text{enc}} = 3 \mu\text{m} \times 300$  K = 900  $\mu\text{m} \cdot \text{K}$ ,  $F_{(0-\lambda_1 T)} = 0$ .

Continued...

### PROBLEM 12.99 (Cont.)

(c) The energy balance on the sample, on a per unit area basis, as shown in the schematic at the right is

$$\dot{E}_{in} - \dot{E}_{out} = 0$$

$$+\alpha_{las}G_{laser} + 2\alpha G - 2\varepsilon E_b(T_s) - q''_{cv} = 0$$

$$\alpha_{las}G_{laser} + 2\alpha\sigma T_{enc}^4 - 2\varepsilon\sigma T_s^4 - 2h(T_s - T_\infty) = 0 \quad (3)$$

Recognizing that  $\alpha_{las}(0.5 \mu\text{m}) = 0.8$ , and substituting numerical values find,

$$0.8 \times G_{laser} + 2 \times 0.200 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (300 \text{ K})^4$$

$$- 2 \times 0.643 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (2000 \text{ K})^4 - 2 \times 50 \text{ W/m}^2 \cdot \text{K} (2000 - 500) \text{ K} = 0$$

$$0.8 \times G_{laser} = \left[ -184.6 + 1.167 \times 10^6 + 1.500 \times 10^5 \right] \text{ W/m}^2$$

$$G_{laser} = 1646 \text{ kW/m}^2$$

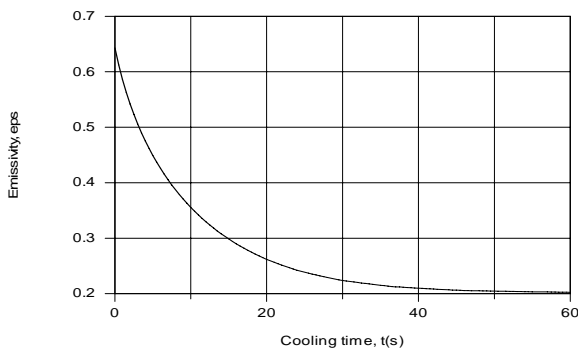

(d) During the cool-down process, the total emissivity  $\varepsilon$  will decrease as the temperature decreases,  $T_s(t)$ . In the limit,  $t \rightarrow \infty$ , the sample will reach that of the enclosure,  $T_s(\infty) = T_{enc}$  for which  $\varepsilon = \alpha = 0.200$ .

(e) Using the *IHT Lumped Capacitance Model* considering radiation exchange ( $T_{enc} = 300 \text{ K}$ ) and convection ( $T_\infty = 300 \text{ K}$ ,  $h = 50 \text{ W/m}^2 \cdot \text{K}$ ) and evaluating the emissivity using Eq. (1) with the *Radiation Tool, Band Emission Factors*, the temperature-time history was determined and the time-to-cool to  $T(t) = 40^\circ\text{C}$  was found as

$$t = 119 \text{ s}$$

**COMMENTS:** (1) From the IHT model used for part (e), the emissivity as a function of cooling time and sample temperature were computed and are plotted below. Compare these results to your sketch of part (c).

Continued...

## PROBLEM 12.99 (Cont.)

(2) The IHT workspace model to perform the lumped capacitance analysis with variable emissivity is shown below.

### // Lumped Capacitance Model - convection and emission/irradiation radiation processes:

```
/* Conservation of energy requirement on the control volume, CV. */
Edotin - Edotout = Edotst
Edotin = As * ( + Gabs)
Edotout = As * ( + q"cv + E )
Edotst = rho * vol * cp * Der(T,t)
T_C = T - 273
// Absorbed irradiation from large surroundings on CS
Gabs = alpha * G
G = sigma * Tsur^4
sigma = 5.67e-8 // Stefan-Boltzmann constant, W/m^2-K^4
// Emissive power of CS
E = eps * Eb
Eb = sigma * T^4
//sigma = 5.67e-8 // Stefan-Boltzmann constant, W/m^2-K^4
//Convection heat flux for control surface CS
q"cv = h * ( T - Tinf )
/* The independent variables for this system and their assigned numerical values are */
As = 2 * 1 // surface area, m^2; unit area, top and bottom surfaces
vol = 1 * w // vol, m^3
w = 0.001 // sample thickness, m
rho = 3900 // density, kg/m^3
cp = 760 // specific heat, J/kg-K
// Convection heat flux, CS
h = 50 // convection coefficient, W/m^2-K
Tinf = 300 // fluid temperature, K
// Emission, CS
//eps = 0.5 // emissivity; value used to test the model initially
// Irradiation from large surroundings, CS
alpha = 0.200 // absorptivity; from Part (b); remains constant during cool-down
Tsur = 300 // surroundings temperature, K
```

### // Radiation Tool - Band emission factor:

```
eps = eps1 * FL1T + eps2 * ( 1 - FL1T )
/* The blackbody band emission factor, Figure 12.12 and Table 12.1, is */
FL1T = F_lambda_T(lambda1,T) // Eq 12.34
// where units are lambda (micrometers, mum) and T (K)
lambda1 = 3 // wavelength, mum
eps1 = 0.8 // spectral emissivity; for lambda < lambda1
eps2 = 0.2 // spectral emissivity; for lambda > lambda1
```

## PROBLEM 12.100

**KNOWN:** Cross flow of air over a cylinder placed within a large furnace.

**FIND:** (a) Steady-state temperature of the cylinder when it is diffuse and gray with  $\varepsilon = 0.5$ , (b) Steady-state temperature when surface has spectral properties shown below, (c) Steady-state temperature of the diffuse, gray cylinder if air flow is parallel to the cylindrical axis, (d) Effect of air velocity on cylinder temperature for conditions of part (a).

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Cylinder is isothermal, (2) Furnace walls are isothermal and very large in area compared to the cylinder, (3) Steady-state conditions.

**PROPERTIES:** Table A.4, Air ( $T_f \approx 600$  K):  $\nu = 52.69 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 46.9 \times 10^{-3} \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.685$ .

**ANALYSIS:** (a) When the cylinder surface is gray and diffuse with  $\varepsilon = 0.5$ , the energy balance is of the form,  $q''_{\text{rad}} - q''_{\text{conv}} = 0$ . Hence,

$$\varepsilon \sigma (T_{\text{sur}}^4 - T_s^4) - \bar{h} (T_s - T_{\infty}) = 0.$$

The heat transfer coefficient,  $\bar{h}$ , can be estimated from the Churchill-Bernstein correlation of Chapter 7,

$$\overline{\text{Nu}}_D = (\bar{h} D/k) = 0.3 + \frac{0.62 \text{Re}_D^{1/2} \text{Pr}^{1/3}}{\left[1 + (0.4/\text{Pr})^{2/3}\right]^{1/4}} \left[1 + \left(\frac{\text{Re}_D}{282,000}\right)^{5/8}\right]^{4/5}$$

where  $\text{Re}_D = VD/\nu = 3 \text{ m/s} \times 30 \times 10^{-3} \text{ m} / 52.69 \times 10^{-6} \text{ m}^2/\text{s} = 1710$ . Hence,

$$\overline{\text{Nu}}_D = 20.8$$

$$\bar{h} = 20.8 \times 46.9 \times 10^{-3} \text{ W/m}\cdot\text{K} / 30 \times 10^{-3} \text{ m} = 32.5 \text{ W/m}^2\cdot\text{K}.$$

Using this value of  $\bar{h}$  in the energy balance expression, we obtain

$$0.5 \times 5.67 \times 10^{-8} (1000^4 - T_s^4) \text{ W/m}^2 - 32.5 \text{ W/m}^2\cdot\text{K} (T_s - 400) \text{ K} = 0$$

which yields  $T_s \approx 839$  K. <

(b) When the cylinder has the spectrally selective behavior, the energy balance is written as

$$\alpha G - \varepsilon E_b(T_s) - q''_{\text{conv}} = 0$$

where  $G = E_b(T_{\text{sur}})$ . With  $\alpha = \int_0^{\infty} \alpha_{\lambda} G_{\lambda} d\lambda / G$ ,

$$\alpha = 0.1 \times F_{(0 \rightarrow 3 \mu\text{m})} + 0.5 \times (1 - F_{(0 \rightarrow 3 \mu\text{m})}) = 0.1 \times 0.273 + 0.5(1 - 0.273) = 0.391$$

where, using Table 12.1 with  $\lambda T = 3 \times 1000 = 3000 \mu\text{m}\cdot\text{K}$ ,  $F_{(0 \rightarrow 3)} = 0.273$ . Assuming  $T_s$  is such that emission in the spectral region  $\lambda < 3 \mu\text{m}$  is negligible, the energy balance becomes

Continued...

### PROBLEM 12.100 (Cont.)

$$0.391 \times 5.67 \times 10^{-8} \times 1000^4 \text{ W/m}^2 - 0.5 \times 5.67 \times 10^{-8} \times T_s^4 \text{ W/m}^2 - 32.5 \text{ W/m}^2 \cdot \text{K} (T_s - 400) \text{ K} = 0$$

which yields  $T_s \approx 770 \text{ K}$ . <

Note that, for  $\lambda T = 3 \times 770 = 2310 \text{ } \mu\text{m}\cdot\text{K}$ ,  $F_{(0 \rightarrow \lambda)} \approx 0.11$ ; hence the assumption of  $\varepsilon = 0.5$  is acceptable.

Note that the value of  $\bar{h}$  based upon  $T_f = 600 \text{ K}$  is also acceptable.

(c) When the cylinder is diffuse-gray with air flow in the longitudinal direction, the characteristic length for convection is different. Assume conditions can be modeled as flow over a flat plate of  $L = 150 \text{ mm}$ .  
With

$$\text{Re}_L = VL/\nu = 3 \text{ m/s} \times 150 \times 10^{-3} \text{ m} / 52.69 \times 10^{-6} \text{ m}^2/\text{s} = 8540$$

$$\overline{\text{Nu}}_L = (\bar{h}L/k) = 0.664 \text{Re}_L^{1/2} \text{Pr}^{1/3} = 0.664(8540)^{1/2} 0.685^{1/3} = 54.1$$

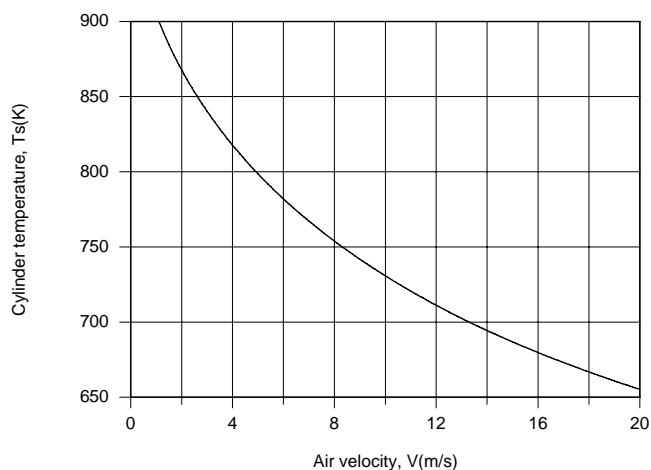

$$\bar{h} = 54.1 \times 0.0469 \text{ W/m} \cdot \text{K} / 0.150 \text{ m} = 16.9 \text{ W/m}^2 \cdot \text{K}.$$

The energy balance now becomes

$$0.5 \times 5.667 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (1000^4 - T_s^4) \text{ K}^4 - 16.9 \text{ W/m}^2 \cdot \text{K} (T_s - 400) \text{ K} = 0$$

which yields  $T_s \approx 850 \text{ K}$ . <

(b) Using the IHT *First Law Model* with the *Correlations and Properties* Toolpads, the effect of velocity may be determined and the results are as follows:

Since the convection coefficient increases with increasing  $V$  (from 18.5 to 90.6  $\text{W/m}^2 \cdot \text{K}$  for  $1 \leq V \leq 20 \text{ m/s}$ ), the cylinder temperature decreases, since a smaller value of  $(T_s - T_\infty)$  is needed to dissipate the absorbed irradiation by convection.

**COMMENTS:** The cylinder temperature exceeds the air temperature due to absorption of the incident radiation. The cylinder temperature would approach  $T_\infty$  as  $\bar{h} \rightarrow \infty$  and/or  $\alpha \rightarrow 0$ . If  $\alpha \rightarrow 0$  and  $\bar{h}$  has a small to moderate value, would  $T_s$  be larger than, equal to, or less than  $T_\infty$ ? Why?

## PROBLEM 12.101

**KNOWN:** Instrumentation pod, initially at  $87^\circ\text{C}$ , on a conveyor system passes through a large vacuum brazing furnace. Inner surface of pod surrounded by a mass of phase-change material (PCM). Outer surface with special diffuse, opaque coating of  $\epsilon_\lambda$ . Electronics in pod dissipate 50 W.

**FIND:** How long before all the PCM changes to the liquid state?

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Surface area of furnace walls much larger than that of pod, (2) No convection, (3) No heat transfer to pod from conveyor, (4) Pod coating is diffuse, opaque, (5) Initially pod internal temperature is uniform at  $T_{\text{pcm}} = 87^\circ\text{C}$  and remains so during time interval  $\Delta t_m$ , (6) Surface area provided is that exposed to walls.

**PROPERTIES:** Phase-change material, PCM (given): Fusion temperature,  $T_f = 87^\circ\text{C}$ ,  $h_{fg} = 25$  kJ/kg.

**ANALYSIS:** Perform an energy balance on the pod for an interval of time  $\Delta t_m$  which corresponds to the time for which the PCM changes from solid to liquid state,

$$E_{\text{in}} - E_{\text{out}} + E_{\text{gen}} = \Delta E$$

$$\left[ (\alpha G - \epsilon E_b) A_s + P_e \right] \Delta t_m = M h_{fg}$$

where  $P_e$  is the electrical power dissipation rate,  $M$  is the mass of PCM, and  $h_{fg}$  is the heat of fusion of PCM.

**Irradiation:**  $G = \sigma T_w^4 = 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (1200 \text{ K})^4 = 117,573 \text{ W/m}^2$

**Emissive power:**  $E_b = \sigma T_m^4 = \sigma (87 + 273)^4 = 952 \text{ W/m}^2$

**Emissivity:**  $\epsilon = \epsilon_1 F_{(0-\lambda T)} + \epsilon_2 (1 - F_{(0-\lambda T)})$   $\lambda T = 5 \times 360 = 1800 \mu\text{m} \cdot \text{K}$   
 $\epsilon = 0.05 \times 0.0393 + 0.9 (1 - 0.0393)$   $F_{0-\lambda T} = 0.0393$  (Table 12.1)  
 $\epsilon = 0.867$

**Absorptivity:**  $\alpha = \alpha_1 F_{(0-\lambda T)} + \alpha_2 (1 - F_{(0-\lambda T)})$   $\lambda T = 5 \times 1200 = 6000 \mu\text{m} \cdot \text{K}$   
 $\alpha = 0.05 \times 0.7378 + 0.9 (1 - 0.7378)$   $F_{0-\lambda T} = 0.7378$  (Table 12.1)  
 $\alpha = 0.273$

Substituting numerical values into the energy balance, find,

$$\left[ (0.273 \times 117,573 - 0.867 \times 952) \text{ W/m}^2 \times 0.040 \text{ m}^2 + 50 \text{ W} \right] \Delta t_m = 1.6 \text{ kg} \times 25 \times 10^3 \text{ J/kg}$$

$$\Delta t_m = 32.5 \text{ s} = 0.54 \text{ min.}$$

<

## PROBLEM 12.102

**KNOWN:** Temperatures of furnace and surroundings separated by ceramic plate. Maximum allowable temperature and spectral absorptivity of plate.

**FIND:** (a) Minimum value of air-side convection coefficient,  $h_o$ , (b) Effect of  $h_o$  on plate temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Diffuse surface, (2) Negligible temperature gradients in plate, (3) Negligible inside convection, (4) Furnace and surroundings act as blackbodies.

**ANALYSIS:** (a) From a surface energy balance on the plate,  $\alpha_w G_w + \alpha_{sur} G_{sur} = 2E + q''_{conv}$ . Hence,

$$\alpha_w \sigma T_w^4 + \alpha_{sur} \sigma T_{sur}^4 = 2\epsilon \sigma T_s^4 + h_o (T_s - T_\infty).$$

$$h_o = \frac{\alpha_w \sigma T_w^4 + \alpha_{sur} \sigma T_{sur}^4 - 2\epsilon \sigma T_s^4}{(T_s - T_\infty)}$$

Evaluating the absorptivities and emissivity,

$$\alpha_w = \int_0^\infty \alpha_\lambda G_\lambda d\lambda / G = \int_0^\infty \alpha_\lambda E_{\lambda b}(T_w) / E_b(T_w) d\lambda = 0.3F_{(0-3\mu m)} + 0.8[1 - F_{(0-3\mu m)}]$$

With  $\lambda T_w = 3 \mu m \times 2400 \text{ K} = 7200 \mu m \cdot \text{K}$ , Table 12.1  $\rightarrow F_{(0-3\mu m)} = 0.819$ . Hence,

$$\alpha_w = 0.3 \times 0.819 + 0.8(1 - 0.819) = 0.391$$

Since  $T_{sur} = 300 \text{ K}$ , irradiation from the surroundings is at wavelengths well above  $3 \mu m$ . Hence,

$$\alpha_{sur} = \int_0^\infty \alpha_\lambda E_{\lambda b}(T_{sur}) / E_b(T_{sur}) d\lambda \approx 0.800.$$

The emissivity is  $\epsilon = \int_0^\infty \epsilon_\lambda E_{\lambda b}(T_s) / E_b(T_s) d\lambda = 0.3F_{(0-3\mu m)} + 0.8[1 - F_{(0-3\mu m)}]$ . With

$\lambda T_s = 5400 \mu m \cdot \text{K}$ , Table 12.1  $\rightarrow F_{(0-3\mu m)} = 0.680$ . Hence,  $\epsilon = 0.3 \times 0.68 + 0.8(1 - 0.68) = 0.460$ .

For the maximum allowable value of  $T_s = 1800 \text{ K}$ , it follows that

$$h_o = \frac{0.391 \times 5.67 \times 10^{-8} (2400)^4 + 0.8 \times 5.67 \times 10^{-8} (300)^4 - 2 \times 0.46 \times 5.67 \times 10^{-8} (1800)^4}{(1800 - 300)}$$

$$h_o = \frac{7.335 \times 10^5 + 3.674 \times 10^2 - 5.476 \times 10^5}{1500} = 126 \text{ W/m}^2 \cdot \text{K}.$$

(b) Using the IHT *First Law Model* with the *Radiation Toolpad*, parametric calculations were performed to determine the effect of  $h_o$ .

Continued...

### PROBLEM 12.102 (Cont.)

With increasing  $h_o$ , and hence enhanced convection heat transfer at the outer surface, the plate temperature is reduced.

**COMMENTS:** (1) The surface is not gray. (2) The required value of  $h_o \geq 126 \text{ W/m}^2 \cdot \text{K}$  is well within the range of air cooling.

### PROBLEM 12.103

**KNOWN:** Spectral radiative properties of thin coating applied to long circular copper rods of prescribed diameter and initial temperature. Wall and atmosphere conditions of furnace in which rods are inserted.

**FIND:** (a) Emissivity and absorptivity of the coated rods when their temperature is  $T_s = 300$  K, (b) Initial rate of change of their temperature,  $dT_s/dt$ , (c) Emissivity and absorptivity when they reach steady-state temperature, and (d) Time required for the rods, initially at  $T_s = 300$  K, to reach 1000 K.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Rod temperature is uniform, (2) Nitrogen is quiescent, (3) Constant properties, (4) Diffuse, opaque surface coating, (5) Furnace walls form a blackbody cavity about the cylinders,  $G = E_b(T_f)$ , (6) Negligible end effects.

**PROPERTIES:** Table A.1, Copper (300 K):  $\rho = 8933$  kg/m<sup>3</sup>,  $c_p = 385$  J/kg·K,  $k = 401$  W/m·K; Table A.4, Nitrogen ( $T_f = 800$  K, 1 atm):  $\nu = 82.9 \times 10^{-6}$  m<sup>2</sup>/s,  $k = 0.0548$  W/m·K,  $\alpha = 116 \times 10^{-6}$  m<sup>2</sup>/s,  $Pr = 0.715$ ,  $\beta = (T_f)^{-1} = 1.25 \times 10^{-3}$  K<sup>-1</sup>.

**ANALYSIS:** (a) The total emissivity of the copper rod,  $\epsilon$ , at  $T_s = 300$  K follows from Eq. 12.43 which can be expressed in terms of the band emission factor,  $F(0 - \lambda T)$ , Eq. 12.34,

$$\epsilon = \epsilon_1 F(0 - \lambda_1 T_s) + \epsilon_2 [1 - F(0 - \lambda_1 T_s)] \quad (1)$$

$$\epsilon = 0.4 \times 0.0021 + 0.8 [1 - 0.0021] = 0.799 \quad <$$

where, from Table 12.1, with  $\lambda_1 T_s = 4 \mu\text{m} \times 300 \text{ K} = 1200 \mu\text{m}\cdot\text{K}$ ,  $F(0 - \lambda T) = 0.0021$ . The total absorptivity,  $\alpha$ , for irradiation for the furnace walls at  $T_f = 1300$  K, is

$$\alpha = \epsilon_1 F(0 - \lambda_1 T_f) + \epsilon_2 [1 - F(0 - \lambda_1 T_f)] \quad (2)$$

$$\alpha = 0.4 \times 0.6590 + 0.8 [1 - 0.6590] = 0.536 \quad <$$

where, from Table 12.1, with  $\lambda_1 T_f = 4 \mu\text{m} \times 1300 \text{ K} = 5200 \text{ K}$ ,  $F(0 - \lambda T) = 0.6590$ .

(b) From an energy balance on a control volume about the rod,

$$\dot{E}_{st} = \rho c_p \left( \pi D^2 / 4 \right) L (dT/dt) = \dot{E}_{in} - \dot{E}_{out} = \pi DL [\alpha G + \bar{h} (T_\infty - T_s) - E]$$

$$dT_s/dt = 4 \left[ \alpha G + \bar{h} (T_\infty - T_s) - \epsilon \sigma T_s^4 \right] / \rho c_p D. \quad (3)$$

With

$$Ra_D = \frac{g \beta (T_\infty - T_s) D^3}{\nu \alpha} = \frac{9.8 \text{ m}^2/\text{s} (1.25 \times 10^{-3} \text{ K}^{-1}) 1000 \text{ K} (0.01 \text{ m})^3}{82.9 \times 10^{-6} \text{ m}^2/\text{s} \times 116 \times 10^{-6} \text{ m}^2/\text{s}} = 1274 \quad (4)$$

The Churchill-Chu correlation of Chapter 9 gives

Continued...

### PROBLEM 12.103 (Cont.)

$$\bar{h} = \frac{0.0548}{0.01 \text{ m}} \left\{ 0.60 + \frac{0.387(1274)^{1/6}}{\left[ 1 + (0.559/0.715)^{9/16} \right]^{8/27}} \right\}^2 = 15.1 \text{ W/m}^2 \cdot \text{K} \quad (5)$$

With values of  $\varepsilon$  and  $\alpha$  from part (a), the rate of temperature change with time is

$$dT_s/dt = \frac{4 \left[ 0.53 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times (1300 \text{ K})^4 + 15.1 \text{ W/m}^2 \cdot \text{K} \times 1000 \text{ K} - 0.8 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K} \times (300 \text{ K})^4 \right]}{8933 \text{ kg/m}^3 \times 385 \text{ J/kg} \cdot \text{K} \times 0.01 \text{ m}}$$

$$dT_s/dt = 1.16 \times 10^{-4} [85,829 + 15,100 - 3767] \text{ K/s} = 11.7 \text{ K/s} . \quad <$$

(c) Under steady-state conditions,  $T_s = T_\infty = T_f = 1300 \text{ K}$ . For this situation,  $\varepsilon = \alpha$ , hence

$$\varepsilon = \alpha = 0.536 \quad <$$

(d) The time required for the rods, initially at  $T_s(0) = 300 \text{ K}$ , to reach  $1000 \text{ K}$  can be determined using the lumped capacitance method. Using the *IHT Lumped Capacitance Model*, considering convection, irradiation and emission processes; the *Correlations Tool, Free Convection, Horizontal Cylinder*; *Radiation Tool, Band Emission Fractions*; and a user-generated *Lookup Table Function* for the nitrogen thermophysical properties, find

$$T_s(t_0) = 1000 \text{ K} \quad t_0 = 81.8 \text{ s} \quad <$$

**COMMENTS:** (1) To determine the validity of the lumped capacitance method to this heating process, evaluate the approximate Biot number,  $Bi = \bar{h}D/k = 15 \text{ W/m}^2 \cdot \text{K} \times 0.010 \text{ m}/401 \text{ W/m} \cdot \text{K} = 0.0004$ . Since  $Bi \ll 0.1$ , the method is appropriate.

(2) The IHT workspace with the model used for part (c) is shown below.

```
// Lumped Capacitance Model - irradiation, emission, convection
/* Conservation of energy requirement on the control volume, CV. */
Edotin - Edotout = Edotst
Edotin = As * ( + Gabs)
Edotout = As * ( + q"cv + E )
Edotst = rho * vol * cp * Der(Ts,t)
//Convection heat flux for control surface CS
q"cv = h * ( Ts - Tinf )
// Emissive power of CS
E = eps * Eb
Eb = sigma * Ts^4
sigma = 5.67e-8 // Stefan-Boltzmann constant, W/m^2.K^4
// Absorbed irradiation from large surroundings on CS
Gabs = alpha * G
G = sigma * Tf^4
/* The independent variables for this system and their assigned numerical values are */
As = pi * D * 1 // surface area, m^2
vol = pi * D^2 / 4 * 1 // vol, m^3
rho = 8933 // density, kg/m^3
cp = 433 // specific heat, J/kg.K; evaluated at 800 K
// Convection heat flux, CS
//h = // convection coefficient, W/m^2.K
Tinf = 1300 // fluid temperature, K
// Emission, CS
//eps = // emissivity
// Irradiation from large surroundings, CS
//alpha = // absorptivity
Tf = 1300 // surroundings temperature, K
```

### PROBLEM 12.104

**KNOWN:** Large combination convection-radiation oven heating a cylindrical product of a prescribed spectral emissivity.

**FIND:** (a) Initial heat transfer rate to the product when first placed in oven at 300 K, (b) Steady-state temperature of the product, (c) Time to achieve a temperature within 50°C of the steady-state temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Cylinder is opaque-diffuse, (2) Oven walls are very large compared to the product, (3) Cylinder end effects are negligible, (4)  $\epsilon_\lambda$  is dependent of temperature.

**PROPERTIES:** Table A-4, Air ( $T_f = 525$  K, 1 atm):  $\nu = 42.2 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0423 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.684$ ; ( $T_f = 850$  K (assumed), 1 atm):  $\nu = 93.8 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0596 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.716$ .

**ANALYSIS:** (a) The net heat rate to the product is  $q_{\text{net}} = A_s(q''_{\text{conv}} + \alpha G - \epsilon E_b)$ , or

$$q_{\text{net}} = \pi DL[\bar{h}(T_\infty - T) + \alpha G - \epsilon \sigma T^4] \quad (1)$$

Evaluating properties at  $T_f = 525$  K,  $\text{Re}_D = VD/\nu = 5 \text{ m/s} \times 0.025 \text{ m} / 42.2 \times 10^{-6} \text{ m}^2/\text{s} = 2960$ , and the Churchill-Bernstein correlation of Chapter 7 yields

$$\overline{\text{Nu}}_D = \frac{\bar{h}D}{k} = 0.3 + \frac{0.62 \text{Re}_D^{1/2} \text{Pr}^{1/3}}{[1 + (0.4/\text{Pr})^{2/3}]^{1/4}} \left[ 1 + \left( \frac{\text{Re}_D}{282,000} \right)^{5/8} \right]^{4/5} = 27.5$$

Hence,

$$\bar{h} = \frac{0.0423 \text{ W/m}\cdot\text{K}}{0.025 \text{ m}} \times 27.5 = 46.5 \text{ W/m}^2 \cdot \text{K}.$$

The total, hemispherical emissivity of the diffuse, spectrally selective surface follows from Eq. 12.43,

$\epsilon = \int_0^\infty \epsilon_\lambda(\lambda, T_s) E_{\lambda, b} / \sigma T_s^4 = \epsilon_1 F_{(0 \rightarrow 4 \mu\text{m})} + \epsilon_2 (1 - F_{(0 \rightarrow 4 \mu\text{m})})$ , where  $\lambda T = 4 \mu\text{m} \times 300 \text{ K} = 1200 \mu\text{m}\cdot\text{K}$  and  $F_{(0 \rightarrow \lambda T)} = 0.002$  (Table 12.1). Hence,  $\epsilon = 0.8 \times 0.002 + 0.2 (1 - 0.002) = 0.201$ .

The absorptivity is for irradiation from the oven walls which, because they are large and isothermal, behave as a black surface at 1000 K. From Eq. 12.52, with  $G_\lambda = E_{\lambda, b}(\lambda, 1000 \text{ K})$  and  $\alpha_\lambda = \epsilon_\lambda$ ,

$$\alpha = \epsilon_1 F_{(0 \rightarrow 4 \mu\text{m})} + \epsilon_2 (1 - F_{(0 \rightarrow 4 \mu\text{m})}) = 0.8 \times 0.481 + 0.2(1 - 0.481) = 0.489$$

where, for  $\lambda T = 4 \times 1000 = 4000 \mu\text{m}\cdot\text{K}$  from Table 12.1,  $F_{(0 \rightarrow \lambda T)} = 0.481$ . From Eq. (1) the net initial

heat rate is  $q_{\text{net}} = \pi \times 0.025 \text{ m} \times 0.2 \text{ m} [46.5 \text{ W/m}^2 \cdot \text{K} (750 - 300) \text{ K} + 0.489 \sigma (1000)^4 \text{ K}^4 - 0.201 \sigma (300 \text{ K})^4]$

Continued...

### PROBLEM 12.104 (Cont.)

$$q = 763 \text{ W.}$$

&lt;

(b) For the steady-state condition, the net heat rate will be zero, and the energy balance yields,

$$0 = \bar{h}(T_\infty - T) + \alpha G - \varepsilon \sigma T^4 \quad (2)$$

Evaluating properties at an assumed film temperature of  $T_f = 850 \text{ K}$ ,  $Re_D = VD/\nu = 5 \text{ m/s} \times 0.025 \text{ m} / 93.8 \times 10^{-6} \text{ m}^2/\text{s} = 1333$ , and the Churchill-Bernstein correlation yields  $\overline{Nu}_D = 18.6$ . Hence,  $\bar{h} = 18.6 (0.0596 \text{ W/m} \cdot \text{K}) / 0.025 \text{ m} = 44.3 \text{ W/m}^2 \cdot \text{K}$ . Since irradiation from the oven walls is fixed, the absorptivity is unchanged, in which case  $\alpha = 0.489$ . However, the emissivity depends on the product temperature. Assuming  $T = 950 \text{ K}$ , we obtain

$$\varepsilon = \varepsilon_1 F_{(0 \rightarrow 4 \mu\text{m})} + \varepsilon_2 (1 - F_{(0 \rightarrow 4 \mu\text{m})}) = 0.8 \times 0.443 + 0.2(1 - 0.443) = 0.466$$

where for  $\lambda T = 4 \times 950 = 3800 \mu\text{m} \cdot \text{K}$ ,  $F_{0-\lambda T} = 0.443$ , from Table 12.1. Substituting values into Eq. (2) with  $\sigma = 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4$ ,

$$0 = 44.3 (750 - T) + 0.489 \sigma (1000 \text{ K})^4 - 0.466 \sigma T^4.$$

A trial-and-error solution yields  $T \approx 930 \text{ K}$ .

&lt;

(c) Using the IHT *Lumped Capacitance Model* with the *Correlations, Properties* (for copper and air) and *Radiation Toolpads*, the transient response of the cylinder was computed and the time to reach  $T = 880 \text{ K}$  is

$$t \approx 537 \text{ s.}$$

&lt;

**COMMENTS:** Note that  $\bar{h}$  is relatively insensitive to  $T$ , while  $\varepsilon$  is not. At  $T = 930 \text{ K}$ ,  $\varepsilon = 0.456$ .

## PROBLEM 12.105

**KNOWN:** Workpiece, initially at 25°C, to be annealed at a temperature above 725°C for a period of 5 minutes and then cooled; furnace wall temperature and convection conditions; cooling surroundings and convection conditions.

**FIND:** (a) Emissivity and absorptivity of the workpiece at 25°C when it is placed in the furnace, (b) Net heat rate per unit area into the workpiece for this initial condition; change in temperature with time,  $dT/dt$ , for the workpiece; (c) Calculate the time for the workpiece to cool from 750°C to a safe-to-touch temperature of 40°C if the cool surroundings and cooling air temperature are 25°C and the convection coefficient is 100 W/m<sup>2</sup>·K.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Workpiece is opaque and diffuse, (2) Spectral emissivity is independent of temperature, and (3) Furnace and cooling environment are large isothermal surroundings.

**ANALYSIS:** (a) Using Eqs. 12.43 and 12.52,  $\epsilon$  and  $\alpha$  can be determined using band-emission factors, Eq. 12.34 and 12.35.

*Emissivity, workpiece at 25°C*

$$\begin{aligned}\epsilon &= \epsilon_{\lambda 1} \cdot F_{(0-\lambda T)} + \epsilon_{\lambda 2} (1 - F_{(0-\lambda T)}) \\ \epsilon &= 0.3 \times 1.6 \times 10^{-5} + 0.8 \times (1 - 1.6 \times 10^{-5}) = 0.8\end{aligned} \quad <$$

where  $F_{(0-\lambda T)}$  is determined from Table 12.1 with  $\lambda T = 2.5 \mu\text{m} \times 298 \text{ K} = 745 \mu\text{m}\cdot\text{K}$ .

*Absorptivity, furnace temperature  $T_f = 750^\circ\text{C}$*

$$\begin{aligned}\alpha &= \epsilon_{\lambda 1} \cdot F_{(0-\lambda, T)} + \epsilon_{\lambda 2} \cdot (1 - F_{(0-\lambda, T)}) \\ \alpha &= 0.3 \times 0.174 + 0.8 \times (1 - 0.174) = 0.713\end{aligned} \quad <$$

where  $F_{(0-\lambda T)}$  is determined with  $\lambda T = 2.5 \mu\text{m} \times 1023 \text{ K} = 2557.5 \mu\text{m}\cdot\text{K}$ .

(b) For the initial condition,  $T(0) = T_i$ , the energy balance shown schematically below is written in terms of the net heat rate  $\dot{in}$ ,

Continued ...

**PROBLEM 12.105 (Cont.)**

$$\dot{E}_{\text{in}}'' - \dot{E}_{\text{out}}'' = \dot{E}_{\text{st}}'' \quad \text{and} \quad q_{\text{net,in}}'' = \dot{E}_{\text{in}}'' - \dot{E}_{\text{out}}''$$

$$q_{\text{net,in}}'' = 2[q_{\text{cv}}'' - \varepsilon E_b(T_i) + \alpha E_b(T_f)]$$

where  $G = E_b(T_f)$ . Substituting numerical values,

$$q_{\text{net,in}}'' = 2 \left[ h(T_\infty - T_i) - \varepsilon \sigma T_i^4 + \alpha \sigma T_f^4 \right]$$

$$q_{\text{net,in}}'' = 2 \left[ 100 \text{ W/m}^2 \cdot \text{K} (750 - 25) \text{ K} - 0.8 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (298 \text{ K})^4 + 0.713 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (1023 \text{ K})^4 \right]$$

$$q_{\text{net,in}}'' = 2 \times 116.4 \text{ kW/m}^2 = 233 \text{ kW/m}^2 \quad <$$

Considering the energy storage term,

$$\dot{E}_{\text{st}}'' = \rho c L \left( \frac{dT}{dt} \right)_i = q_{\text{net,in}}''$$

$$\left( \frac{dT}{dt} \right)_i = \frac{q_{\text{net,in}}''}{\rho c L} = \frac{233 \text{ kW/m}^2}{2700 \text{ kg/m}^3 \times 885 \text{ J/kg} \cdot \text{K} \times 0.010 \text{ m}} = 9.75 \text{ K/s} \quad <$$

(c) The energy balance of Part (b), using the lumped capacitance method with the *IHT DER* ( $T, t$ ) function, has the form,

$$2 \left[ h(T_\infty - T) - \varepsilon \sigma T^4 + \alpha \sigma T_f^4 \right] = \rho c L \text{ DER}(T, t)$$

Continued ...

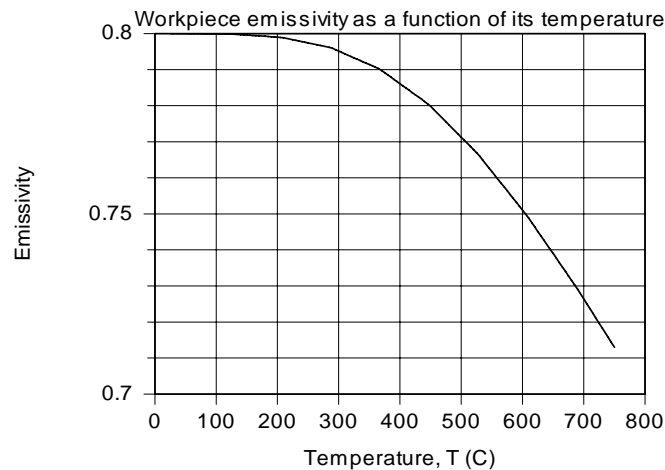

## PROBLEM 12.105 (Cont.)

The time to cool the workpiece from 750°C to the safe-to-touch temperature of 40°C can be determined using the *IHT* code in the Comments. The cooling conditions are  $T_\infty = 25^\circ\text{C}$  and  $h = 100 \text{ W/m}^2\cdot\text{K}$  with  $T_{\text{sur}} = 25^\circ\text{C}$ . The emissivity is still evaluated as in the Comments, but the absorptivity, which depends upon the surrounding temperature, is  $\alpha = 0.80$ . From the results in the *IHT* workspace, find

$$T(t_c) = 40^\circ\text{C} \quad \text{when} \quad t_c = 413 \text{ s} \quad \leftarrow$$

**COMMENTS:** (1) With the relation for  $\varepsilon$  of Part (a) in the *IHT* workspace, and using the *Radiation | Band Emission* tool,  $\varepsilon$  as a function of workpiece temperature is calculated and plotted below.

As expected,  $\varepsilon$  decreases with increasing  $T$ , and when  $T = T_f = 750^\circ\text{C}$ ,  $\varepsilon = \alpha = 0.713$ . Why is that so?

(2) The *IHT* code to obtain the heating time, including emissivity as a function of the workpiece temperature, Part (b), is shown below, complete except for the input variables.

```
/* Analysis. The radiative properties and net heat flux in are calculated when the workpiece is
just inserted into the furnace. The workpiece experiences emission, absorbed irradiation and
convection processes. See Help | Solver | Intrinsic Functions for information on DER(T, t). */

## PROBLEM 12.106

**KNOWN:** For the semiconductor silicon, the spectral distribution of absorptivity,  $\alpha_\lambda$ , at selected temperatures. High-intensity, tungsten halogen lamps having spectral distribution approximating that of a blackbody at 2800 K.

**FIND:** (a) 1%-limits of the spectral band that includes 98% of the blackbody radiation corresponding to the spectral distribution of the lamps; spectral region for which you need to know the spectral absorptivity; (b) Sketch the variation of the total absorptivity as a function of silicon temperature; explain key features; (c) Calculate the total absorptivity at 400, 600 and 900°C for the lamp irradiation; explain results and the temperature dependence; Calculate the total emissivity of the wafer at 600 and 900°C; explain results and the temperature dependence; and (d) Irradiation on the upper surface required to maintain the wafer at 600°C in a vacuum chamber with walls at 20°C. Use the *Look-up Table* and *Integral Functions of IHT* to perform the necessary integrations.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Silicon is a diffuse emitter, (2) Chamber is large, isothermal surroundings for the wafer, (3) Wafer is isothermal.

**ANALYSIS:** (a) From Eqs. 12.28 and 12.29, using Table 12.1 for the band emission factors,  $F_{(0-\lambda T)}$ , equal to 0.01 and 0.99 are:

$$F_{(0 \rightarrow \lambda_1 T)} = 0.01 \text{ at } \lambda_1 \cdot T = 1437 \mu\text{m} \cdot \text{K}$$

$$F_{(0 \rightarrow \lambda_2 T)} = 0.99 \text{ at } \lambda_2 \cdot T = 23,324 \mu\text{m} \cdot \text{K}$$

So that we have  $\lambda_1$  and  $\lambda_2$  limits for several temperatures, the following values are tabulated.

T(°C)	T(K)	$\lambda_1(\mu\text{m})$	$\lambda_2(\mu\text{m})$
-	2800	0.51	8.33
400	673	2.14	34.7
600	873	1.65	26.7
900	1173	1.23	19.9

For the 2800 K blackbody lamp irradiation, we need to know the spectral absorptivity over the spectral range 0.51 to 8.33  $\mu\text{m}$  in order to include 98% of the radiation.

(b) The spectral absorptivity is calculated from Eq. 12.52 in which the spectral distribution of the lamp irradiation  $G_\lambda$  is proportional to the blackbody spectral emissive power  $E_{\lambda,b}(\lambda, T)$  at the temperature of lamps,  $T_\ell = 2800 \text{ K}$ .

$$\alpha_\ell = \frac{\int_0^\infty \alpha_\lambda G_\lambda d\lambda}{\int_0^\infty G_\lambda d\lambda} = \frac{\int_0^\infty \alpha_\lambda E_{\lambda,b}(\lambda, 2800 \text{ K})}{\sigma T_\ell^4}$$

Continued ...

### PROBLEM 12.106 (Cont.)

For 2800 K, the peak of the blackbody curve is at 1  $\mu\text{m}$ ; the limits of integration for 98% coverage are 0.5 to 8.3  $\mu\text{m}$  according to part (a) results. Note that  $\alpha_\lambda$  increases at all wavelengths with temperature, until around 900°C where the behavior is gray. Hence, we'd expect the total absorptivity of the wafer for lamp irradiation to appear as shown in the graph below.

At 900°C, since the wafer is gray, we expect  $\alpha_\ell = \alpha_\lambda \approx 0.68$ . Near room temperature, since  $\alpha_\lambda \approx 0$  beyond the band edge,  $\alpha_\ell$  is dependent upon  $\alpha_\lambda$  in the spectral region below and slightly beyond the peak. From the blackbody tables, the band emission fraction to the short-wavelength side of the peak is 0.25. Hence, estimate  $\alpha_\ell \approx 0.68 \times 0.25 = 0.17$  at these low temperatures. The increase of  $\alpha_\ell$  with temperature is at first moderate, since the longer wavelength region is less significant than is the shorter region. As temperature increases, the  $\alpha_\lambda$  closer to the peak begin to change more noticeably, explaining the greater dependence of  $\alpha_\ell$  on temperature.

(c) The integration of part (b) can be performed numerically using the *IHT INTEGRAL* function and specifying the spectral absorptivity in a *Lookup Table* file (\*.lut). The code is shown in the Comments (1) and the results are:

$T_w(^{\circ}\text{C})$	400	600	900	
$\alpha_\ell$	0.30	0.59	0.68	<

The total emissivity can be calculated from Eq. 12.36, recognizing that  $\varepsilon_\lambda = \alpha_\lambda$  and that for silicon temperatures of 600 and 900°C, the 1% limits for the spectral integration are 1.65 - 26.7  $\mu\text{m}$  and 1.23 - 19.9  $\mu\text{m}$ , respectively. The integration is performed in the same manner as described above; see Comments (2).

$T(^{\circ}\text{C})$	600	900	
$\varepsilon$	0.66	0.68	<

As the silicon temperature increases, the peak of the corresponding blackbody emissive power shifts to shorter wavelengths. In general, this will reduce  $\varepsilon$ . However, this reduction is offset by the dependence of  $\varepsilon_\lambda$  on temperature, which is quite strong. As the temperature increases,  $\varepsilon_\lambda$  increases significantly.

(d) From an energy balance on the silicon wafer with irradiation on the upper surface as shown in the schematic below, calculate the irradiation required to maintain the wafer at 600°C.

$$\dot{E}_{\text{in}}'' - \dot{E}_{\text{out}}'' = 0 \qquad \alpha_\ell G_\ell - 2[\varepsilon E_b(T_w) - \alpha_{\text{sur}} E_b(T_{\text{sur}})] = 0$$

Recognize that  $\alpha_{\text{sur}}$  corresponds to the spectral distribution of  $E_{\lambda,b}(T_{\text{sur}})$ ; that is, upon  $\alpha_\lambda$  for long wavelengths ( $\lambda_{\text{max}} \approx 10 \mu\text{m}$ ). We assume  $\alpha_{\text{sur}} \approx 0.1$ , and with  $T_{\text{sur}} = 20^{\circ}\text{C}$ , find

```

(2) The *IHT* code to obtain the total emissivity for a wafer temperature of  $600^{\circ}\text{C}$  has the same organization as for obtaining the total absorptivity. We perform the integration, however, with the blackbody spectral emissivity evaluated at the wafer temperature (rather than the lamp temperature). The same look-up file for the spectral absorptivity created in the *IHT* code above can be used.

## PROBLEM 12.107

**KNOWN:** Solar irradiation of  $1100 \text{ W/m}^2$  incident on a flat roof surface of prescribed solar absorptivity and emissivity; air temperature and convection heat transfer coefficient.

**FIND:** (a) Roof surface temperature, (b) Effect of absorptivity, emissivity and convection coefficient on temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Back-side of plate is perfectly insulated, (3) Negligible irradiation to plate by atmospheric (sky) emission.

**ANALYSIS:** (a) Performing a surface energy balance on the exposed side of the plate,

$$\alpha_S G_S - q''_{\text{conv}} - \epsilon E_b(T_s) = 0 \quad \alpha_S G_S - \bar{h}(T_s - T_\infty) - \epsilon \sigma T_s^4 = 0$$

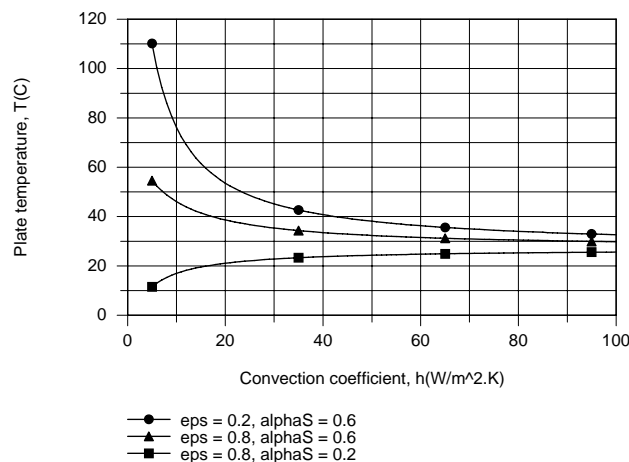

Substituting numerical values and using absolute temperatures,

$$0.6 \times 1100 \frac{\text{W}}{\text{m}^2} - 25 \frac{\text{W}}{\text{m}^2 \cdot \text{K}} (T_s - 300) \text{K} - 0.2 (5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4) T_s^4 = 0$$

Regrouping,  $8160 = 25T_s + 1.1340 \times 10^{-8} T_s^4$ , and performing a trial-and-error solution,

$$T_s = 321.5 \text{ K} = 48.5^\circ\text{C}.$$

(b) Using the IHT *First Law Model* for a plane wall, the following results were obtained.

Irrespective of the value of  $\bar{h}$ ,  $T$  decreases with increasing  $\epsilon$  (due to increased emission) and decreasing  $\alpha_S$  (due to reduced absorption of solar energy). For moderate to large  $\alpha_S$  and/or small  $\epsilon$  (net radiation transfer to the surface)  $T$  decreases with increasing  $\bar{h}$  due to enhanced cooling by convection. However, for small  $\alpha_S$  and large  $\epsilon$ , emission exceeds absorption, dictating convection heat transfer to the surface and hence  $T < T_\infty$ . With increasing  $\bar{h}$ ,  $T \rightarrow T_\infty$ , irrespective of the values of  $\alpha_S$  and  $\epsilon$ .

**COMMENTS:** To minimize the roof temperature, the value of  $\epsilon/\alpha_S$  should be maximized.

## PROBLEM 12.108

**KNOWN:** Solar flux above Earth's atmosphere. Distance of Earth, Venus, and Mars from the sun. Measured average temperatures of planets.

**FIND:** Planet temperatures neglecting atmospheric radiation effects and assuming gray behavior. Planet most affected by radiation transfer through its atmosphere.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Planets are at constant distance from sun, (3) Atmosphere has no effect on radiation heat transfer, (4) Planets have gray surfaces, (5) Negligible radiation from space.

**ANALYSIS:** The energy balance for each planet is between absorbed solar radiation and emitted radiation. The appropriate area for the intercepted solar radiation is the projected area  $A_p = \pi R^2$ , where  $R$  is the planet's radius, thus

$$q_{\text{rad,abs}} = \alpha G_s A_p$$

Radiation is emitted from the entire surface area of the planet,  $A_s = 4\pi R^2$ , therefore the emitted radiation is

$$q_{\text{rad,emit}} = \varepsilon \sigma T_s^4 A_s$$

The energy balance becomes

$$\begin{aligned} q_{\text{rad,abs}} - q_{\text{rad,emit}} &= 0 \\ \alpha G_s \pi R^2 - \varepsilon \sigma T_s^4 4\pi R^2 &= 0 \end{aligned}$$

With gray surface behavior,  $\alpha = \varepsilon$ , we find

$$T_s = \left( \frac{G_s}{4\sigma} \right)^{1/4}$$

The solar irradiation is different for each planet because they are at different distances from the sun. At a distance  $R_s$  from the sun, the solar radiation  $q_{\text{solar}}$  passes through the spherical area  $4\pi R_s^2$ , resulting in a solar heat flux

$$G_s = q_{\text{solar}} / 4\pi R_s^2$$

Continued...

### PROBLEM 12.108 (Cont.)

Thus, knowing the solar irradiation for Earth,  $G_{S,E}$ , we can find the solar irradiation for Venus and Mars:

$$G_{S,V} = G_{S,E} R_{S,E}^2 / R_{S,V}^2 = 1368 \text{ W/m}^2 \times (1.50 \times 10^{11} \text{ m})^2 / (1.08 \times 10^{11} \text{ m})^2 = 2640 \text{ W/m}^2$$

$$G_{S,M} = G_{S,E} R_{S,E}^2 / R_{S,M}^2 = 1368 \text{ W/m}^2 \times (1.50 \times 10^{11} \text{ m})^2 / (2.30 \times 10^{11} \text{ m})^2 = 580 \text{ W/m}^2$$

Finally, the planet temperatures can be calculated:

$$T_{s,E} = \left( \frac{G_{S,E}}{4\sigma} \right)^{1/4} = \left( \frac{1368 \text{ W/m}^2}{4 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4} \right)^{1/4} = 279 \text{ K} \quad <$$

Similarly,

$$T_{s,V} = 329 \text{ K}, \quad T_{s,M} = 225 \text{ K} \quad <$$

The calculated temperatures are compared with the measured average temperatures in the chart:

Planet	$L_{S-p}$ , m	$\bar{T}_p$ , K	$T_{\text{calc}}$ , K
Venus	$1.08 \times 10^{11}$	735	329
Earth	$1.50 \times 10^{11}$	287	279
Mars	$2.30 \times 10^{11}$	227	225

The biggest discrepancy is for Venus, which has a very dense atmosphere and significant radiation absorption, emission and scattering phenomena. <

## PROBLEM 12.109

**KNOWN:** Cavity with window whose outer surface experiences convection and radiation.

**FIND:** Temperature of the window and power required to maintain cavity at prescribed temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Cavity behaves as a blackbody, (3) Solar spectral distribution is that of a blackbody at 5800K, (4) Window is isothermal, (5) Negligible convection on lower surface of window.

**PROPERTIES:** Window material:  $0.2 \leq \lambda \leq 4 \mu\text{m}$ ,  $\tau_\lambda = 0.9$ ,  $\rho_\lambda = 0$ , hence  $\alpha_\lambda = 1 - \tau_\lambda = 0.1$ ;  $4 \mu\text{m} < \lambda$ ,  $\tau_\lambda = 0$ ,  $\alpha = \varepsilon = 0.95$ , diffuse-gray, opaque.

**ANALYSIS:** To determine the window temperature, perform an energy balance on the window,

$$\begin{aligned} \dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= 0 \\ [\alpha_{\text{sur}} G_{\text{sur}} + \alpha_S G_S - \varepsilon E_b - q''_{\text{conv}}]_{\text{upper}} + [\alpha_c G_c - \varepsilon E_b(T)]_{\text{lower}} &= 0. \end{aligned} \quad (1)$$

Calculate the absorptivities for various irradiation conditions using Eq. 12.52,

$$\alpha = \int_0^\infty \alpha_\lambda G_\lambda d\lambda / \int_0^\infty G_\lambda d\lambda \quad (2)$$

where  $G(\lambda)$  is the spectral distribution of the irradiation.

*Surroundings,  $\alpha_{\text{sur}}$ :*  $G_{\text{sur}} = E_b(T_{\text{sur}}) = \sigma T_{\text{sur}}^4$

$$\alpha_{\text{sur}} = 0.1 [F_{(0 \rightarrow 4\mu\text{m})} - F_{(0 \rightarrow 0.2\mu\text{m})}] + 0.95 [1 - F_{(0 \rightarrow 4\mu\text{m})}]$$

where from Table 12.1, with  $T = T_{\text{sur}} = (25 + 273)\text{K} = 298\text{K}$ ,

$$\lambda T = 0.2\mu\text{m} \times 298\text{K} = 59.6\mu\text{m} \cdot \text{K}, \quad F_{(0-\lambda T)} = 0.000$$

$$\lambda T = 4\mu\text{m} \times 298\text{K} = 1192\mu\text{m} \cdot \text{K}, \quad F_{(0-\lambda T)} = 0.002$$

$$\alpha_{\text{sur}} = 0.1 [0.002 - 0.000] + 0.95 [1 - 0.002] = 0.948. \quad (3)$$

*Solar,  $\alpha_S$ :*  $G_S \sim E_b(5800\text{K})$

$$\alpha_S = 0.1 [F_{(0 \rightarrow 4\mu\text{m})} - F_{(0 \rightarrow 0.2\mu\text{m})}] + 0.95 [1 - F_{(0 \rightarrow 4\mu\text{m})}]$$

where from Table 12.1, with  $T = 5800\text{K}$ ,

$$\lambda T = 0.2\mu\text{m} \times 5800\text{K} = 1160\mu\text{m} \cdot \text{K}, \quad F_{(0-\lambda T)} = 0.002$$

$$\lambda T = 4\mu\text{m} \times 5800\text{K} = 23,200\mu\text{m} \cdot \text{K}, \quad F_{(0-\lambda T)} = 0.990$$

$$\alpha_S = 0.1 [0.990 - 0.002] + 0.95 [1 - 0.990] = 0.108. \quad (4)$$

Continued ...

**PROBLEM 12.109 (Cont.)**

Cavity,  $\alpha_c$ :  $G_c = E_b(T_c) = \sigma T_c^4$

$$\alpha_c = 0.1 \left[ F_{(0 \rightarrow 4\mu\text{m})} - F_{(0 \rightarrow 0.2\mu\text{m})} \right] + 0.95 \left[ 1 - F_{(0 \rightarrow 4\mu\text{m})} \right]$$

where from Table 12.1 with  $T_c = 250^\circ\text{C} = 523\text{K}$ ,

$$\lambda T = 0.2\mu\text{m} \times 523\text{K} = 104.6\mu\text{m} \cdot \text{K}, \quad F_{0 \rightarrow \lambda T} = 0.000$$

$$\lambda T = 4\mu\text{m} \times 523\text{K} = 2092\mu\text{m} \cdot \text{K} \quad F_{0 \rightarrow \lambda T} = 0.082$$

$$\alpha_c = 0.1[0.082 - 0.000] + 0.95[1 - 0.082] = 0.880. \quad (5)$$

To determine the *emissivity* of the window, we need to know its temperature. However, we know that  $T$  will be less than  $T_c$  and the long wavelength behavior will dominate. That is,

$$\varepsilon \approx \varepsilon_\lambda (\lambda > 4\mu\text{m}) = 0.95. \quad (6)$$

With these radiative properties now known, the energy equation, Eq. (1) can now be evaluated using  $q_{\text{conv}}'' = h(T - T_\infty)$  with all temperatures in kelvin units.

$$0.948 \times \sigma (298\text{K})^4 + 0.108 \times 800 \text{ W/m}^2 - 0.95 \times \sigma T^4 - 10 \text{ W/m}^2 \cdot \text{K} (T - 298\text{K}) + 0.880 \sigma (523\text{K})^4 - 0.95 \times \sigma T^4 = 0$$

$$1.077 \times 10^{-7} T^4 + 10T - 7223 = 0.$$

Using a trial-and-error approach, find the window temperature as

$$T = 413\text{K} = 139^\circ\text{C}.$$

To determine the power required to maintain the cavity at  $T_c = 250^\circ\text{C}$ , perform an energy balance on the cavity.

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = 0$$

$$q_p + A_c [\rho E_b(T_c) + \tau_s G_s + \varepsilon E_b(T) - E_b(T_c)] = 0.$$

For simplicity, we have assumed the window opaque to irradiation from the surroundings. It follows that

$$\tau_s = 1 - \rho_s - \alpha_s = 1 - 0 - 0.108 = 0.892$$

$$\rho = 1 - \alpha = 1 - \varepsilon = 1 - 0.95 = 0.05.$$

Hence, the power required to maintain the cavity, when  $A_c = (\pi/4)D^2$ , is

$$q_p = A_c \left[ \sigma T_c^4 - \rho \sigma T_c^4 - \tau_s G_s - \varepsilon \sigma T^4 \right]$$

$$q_p = \frac{\pi}{4} (0.050\text{m})^2 \left[ \sigma (523\text{K})^4 - 0.05 \sigma (523\text{K})^4 - 0.892 \times 800 \text{ W/m}^2 - 0.95 \sigma (412\text{K})^4 \right]$$

$$q_p = 3.47\text{W}.$$

**COMMENTS:** Note that the assumed value of  $\varepsilon = 0.95$  is not fully satisfied. With  $T = 412\text{K}$ , we would expect  $\varepsilon = 0.929$ . Hence, an iteration may be appropriate.

### PROBLEM 12.110

**KNOWN:** Features of an evacuated tube solar collector.

**FIND:** Ideal surface spectral characteristics.

**SCHEMATIC:**

**ANALYSIS:** The outer tube should be transparent to the incident solar radiation, which is concentrated in the spectral region  $\lambda \leq 3\mu\text{m}$ , but it should be opaque and highly reflective to radiation emitted by the outer surface of the inner tube, which is concentrated in the spectral region above  $3\mu\text{m}$ . Accordingly, ideal spectral characteristics for the outer tube are

Note that large  $\rho_\lambda$  is desirable for the outer, as well as the inner, surface of the outer tube. If the surface is diffuse, a large value of  $\rho_\lambda$  yields a small value of  $\epsilon_\lambda = \alpha_\lambda = 1 - \rho_\lambda$ . Hence losses due to emission from the outer surface to the surroundings would be negligible.

The opaque outer surface of the inner tube should absorb all of the incident solar radiation ( $\lambda \leq 3\mu\text{m}$ ) and emit little or no radiation, which would be in the spectral region  $\lambda > 3\mu\text{m}$ . Accordingly, assuming diffuse surface behavior, ideal spectral characteristics are:

## PROBLEM 12.111

**KNOWN:** Plate exposed to solar flux with prescribed solar absorptivity and emissivity; convection and surrounding conditions also prescribed.

**FIND:** Steady-state temperature of the plate.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Plate is small compared to surroundings, (3) Backside of plate is perfectly insulated, (4) Diffuse behavior.

**ANALYSIS:** Perform a surface energy balance on the top surface of the plate.

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = 0$$

$$\alpha_S G_S + \alpha G_{\text{sur}} - q''_{\text{conv}} - \varepsilon E_b(T_S) = 0$$

Note that the effect of the surroundings is to provide an irradiation,  $G_{\text{sur}}$ , on the plate; since the spectral distribution of  $G_{\text{sur}}$  and  $E_{\lambda,b}(T_S)$  are nearly the same, according to Kirchoff's law,  $\alpha = \varepsilon$ .

Recognizing that  $G_{\text{sur}} = \sigma T_{\text{sur}}^4$  and using Newton's law of cooling, the energy balance is

$$\alpha_S G_S + \varepsilon \sigma T_{\text{sur}}^4 - \bar{h}(T_S - T_{\infty}) - \varepsilon \cdot \sigma T_S^4 = 0.$$

Substituting numerical values,

$$\begin{aligned} 0.9 \times 900 \text{ W/m}^2 + 0.1 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K} \times (17 + 273)^4 \text{ K}^4 \\ - 20 \text{ W/m}^2 \cdot \text{K} (T_S - 290) \text{ K} - 0.1 \left( 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \right) T_S^4 = 0 \\ 6650 \text{ W/m}^2 = 20 T_S + 5.67 \times 10^{-9} T_S^4. \end{aligned}$$

From a trial-and-error solution, find

$$T_S = 329.2 \text{ K.} \quad \leftarrow$$

**COMMENTS:** (1) When performing an analysis with both convection and radiation processes present, all temperatures must be expressed in absolute units (K).

(2) Note also that the terms  $\alpha G_{\text{sur}} - \varepsilon E_b(T_S)$  could be expressed as a radiation exchange term, written as

$$q''_{\text{rad}} = q/A = \varepsilon \sigma (T_{\text{sur}}^4 - T_S^4).$$

The conditions for application of this relation were met and are namely: surroundings much larger than surface, diffuse surface, and spectral distributions of irradiation and emission are similar (or the surface is gray).

## PROBLEM 12.112

**KNOWN:** Directional distribution of  $\alpha_\theta$  for a horizontal, opaque, gray surface exposed to direct and diffuse irradiation.

**FIND:** (a) Absorptivity to direct radiation at  $45^\circ$  and to diffuse radiation, and (b) Equilibrium temperature for specified direct and diffuse irradiation components.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Opaque, gray surface behavior, (3) Negligible convection at top surface and perfectly insulated back surface.

**ANALYSIS:** (a) From knowledge of  $\alpha_\theta(\theta)$  – see graph above – it is evident that the absorptivity of the surface to the direct radiation ( $45^\circ$ ) is

$$\alpha_{\text{dir}} = \alpha_\theta(45^\circ) = 0.8. \quad <$$

The absorptivity to the diffuse radiation is the hemispherical absorptivity given by Eq. 12.50. Dropping the  $\lambda$  subscript,

$$\alpha_{\text{dir}} = 2 \int_0^{\pi/2} \alpha_\theta(\theta) \cos \theta \sin \theta \, d\theta \quad (1)$$

$$\alpha_{\text{dir}} = 2 \left[ 0.8 \frac{\sin^2 \theta}{2} \Big|_0^{\pi/3} + 0.1 \frac{\sin^2 \theta}{2} \Big|_{\pi/3}^{\pi/2} \right]$$

$$\alpha_{\text{dir}} = 0.625. \quad <$$

(b) Performing a surface energy balance,

$$\dot{E}_{\text{in}}'' - \dot{E}_{\text{out}}'' = 0$$

$$\alpha_{\text{dir}} G_{\text{dir}} + \alpha_{\text{dif}} G_{\text{dif}} - \varepsilon \sigma T_s^4 = 0. \quad (2)$$

The total, hemispherical emissivity may be obtained from Eq. 12.42 where again the subscript may be deleted. Since this equation is of precisely the same form as Eq. 12.50 – see Eq. (1) above – and since  $\alpha_\theta = \varepsilon_\theta$ , it follows that

$$\varepsilon = \alpha_{\text{dif}} = 0.625$$

and from Eq. (2), find

$$T_s^4 = \frac{(0.8 \times 600 + 0.625 \times 100) \text{ W/m}^2}{0.625 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4} = 1.53 \times 10^{10} \text{ K}^4, \quad T_s = 352 \text{ K}. \quad <$$

**COMMENTS:** In assuming *gray* surface behavior, spectral effects are not present, and total and spectral properties are identical. However, the surface is *not diffuse* and hence hemispherical and directional properties differ.

### PROBLEM 12.113

**KNOWN:** Plate temperature and spectral and directional dependence of its absorptivity. Direction and magnitude of solar flux.

**FIND:** (a) Expression for total absorptivity, (b) Expression for total emissivity, (c) Net radiant flux, (d) Effect of cut-off wavelength associated with directional dependence of the absorptivity.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Diffuse component of solar flux is negligible, (2) Spectral distribution of solar radiation may be approximated as that from a blackbody at 5800 K, (3) Properties are independent of azimuthal angle  $\phi$ .

**ANALYSIS:** (a) For  $\lambda < \lambda_c$  and  $\theta = 45^\circ$ ,  $\alpha_\lambda = \alpha_1 \cos\theta = 0.707 \alpha_1$ . From Eq. 12.53 the total absorptivity is then

$$\alpha_S = 0.707 \alpha_1 \left\{ \frac{\int_0^{\lambda_c} E_{\lambda,b}(\lambda, 5800 \text{ K}) d\lambda}{E_b} \right\} + \alpha_2 \left\{ \frac{\int_{\lambda_c}^{\infty} E_{\lambda,b}(\lambda, 5800 \text{ K}) d\lambda}{E_b} \right\}$$

$$\alpha_S = 0.707 \alpha_1 F_{(0 \rightarrow \lambda_c)} + \alpha_2 [1 - F_{(0 \rightarrow \lambda_c)}] \quad <$$

For the prescribed value of  $\lambda_c$ ,  $\lambda_c T = 11,600 \mu\text{m}\cdot\text{K}$  and, from Table 12.1,  $F_{(0 \rightarrow \lambda_c)} = 0.941$ . Hence,

$$\alpha_S = 0.707 \times 0.93 \times 0.941 + 0.25(1 - 0.941) = 0.619 + 0.015 = 0.634 \quad <$$

(b) With  $\varepsilon_{\lambda,\theta} = \alpha_{\lambda,\theta}$ , Eq 12.42 may be used to obtain  $\varepsilon_\lambda$  for  $\lambda < \lambda_c$ .

$$\varepsilon_\lambda(\lambda, T) = 2\alpha_1 \int_0^{\pi/2} \cos^2 \theta \sin \theta d\theta = -2\alpha_1 \frac{\cos^3 \theta}{3} \Big|_0^{\pi/2} = \frac{2}{3} \alpha_1$$

From Eq. 12.43,

$$\varepsilon = 0.667 \alpha_1 \frac{\int_0^{\lambda_c} E_{\lambda,b}(\lambda, T_p) d\lambda}{E_b} + \alpha_2 \frac{\int_{\lambda_c}^{\infty} E_{\lambda,b}(\lambda, T_p) d\lambda}{E_b}$$

$$\varepsilon = 0.667 \alpha_1 F_{(0 \rightarrow \lambda_c)} + \alpha_2 [1 - F_{(0 \rightarrow \lambda_c)}] \quad <$$

For  $\lambda_c = 2 \mu\text{m}$  and  $T_p = 333 \text{ K}$ ,  $\lambda_c T = 666 \mu\text{m}\cdot\text{K}$  and, from Table 12.1,  $F_{(0 \rightarrow \lambda_c)} = 0$ . Hence,

$$\varepsilon = \alpha_2 = 0.25 \quad <$$

Continued ...

**PROBLEM 12.113 (Cont.)**

$$(c) \quad q''_{\text{net}} = \alpha_S q''_S - \varepsilon \sigma T_p^4 = 634 \text{ W/m}^2 - 0.25 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (333 \text{ K})^4$$

$$q''_{\text{net}} = 460 \text{ W/m}^2$$

<

(d) Using the foregoing model with the Radiation/Band Emission Factor option of *IHT*, the following results were obtained for  $\alpha_S$  and  $\varepsilon$ . The absorptivity increases with increasing  $\lambda_c$ , as more of the incident solar radiation falls within the region of  $\alpha_1 > \alpha_2$ . Note, however, the limit at  $\lambda \approx 3 \mu\text{m}$ , beyond which there is little change in  $\alpha_S$ . The emissivity also increases with increasing  $\lambda_c$ , as more of the emitted radiation is at wavelengths for which  $\varepsilon_1 = \alpha_1 > \varepsilon_2 = \alpha_2$ . However, the surface temperature is low, and even for  $\lambda_c = 5 \mu\text{m}$ , there is little emission at  $\lambda < \lambda_c$ . Hence,  $\varepsilon$  only increases from 0.25 to 0.26 as  $\lambda_c$  increases from 0.7 to 5.0  $\mu\text{m}$ .

The net heat flux increases from  $276 \text{ W/m}^2$  at  $\lambda_c = 2 \mu\text{m}$  to a maximum of  $477 \text{ W/m}^2$  at  $\lambda_c = 4.2 \mu\text{m}$  and then decreases to  $474 \text{ W/m}^2$  at  $\lambda_c = 5 \mu\text{m}$ . The existence of a maximum is due to the upper limit on the value of  $\alpha_S$  and the increase in  $\varepsilon$  with  $\lambda_c$ .

**COMMENTS:** Spectrally and directionally selective coatings may be used to enhance the performance of solar collectors.

### PROBLEM 12.114

**KNOWN:** Spectral distribution of  $\alpha_\lambda$  for two roof coatings.

**FIND:** Preferred coating for summer and winter use. Ideal spectral distribution of  $\alpha_\lambda$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Opaque, diffuse surface behavior, (2) Negligible convection effects and heat transfer from bottom of roof, negligible atmospheric irradiation, (3) Steady-state conditions.

**ANALYSIS:** From an energy balance on the roof surface

$$\varepsilon \sigma T_s^4 = \alpha_S G_S.$$

Hence

$$T_s = \left( \frac{\alpha_S G_S}{\varepsilon \sigma} \right)^{1/4}.$$

Solar irradiation is concentrated in the spectral region  $\lambda < 4\mu\text{m}$ , while surface emission is concentrated in the region  $\lambda > 4\mu\text{m}$ . Hence, with  $\alpha_\lambda = \varepsilon_\lambda$

$$\text{Coating A:} \quad \alpha_S \approx 0.8, \quad \varepsilon \approx 0.8$$

$$\text{Coating B:} \quad \alpha_S \approx 0.6, \quad \varepsilon \approx 0.2.$$

Since  $(\alpha_S/\varepsilon)_A = 1 < (\alpha_S/\varepsilon)_B = 3$ , Coating A would result in the lower roof temperature and is preferred for summer use. In contrast, Coating B is preferred for winter use. The ideal coating is one which minimizes  $(\alpha_S/\varepsilon)$  in the summer and maximizes it in the winter.

## PROBLEM 12.115

**KNOWN:** Shallow pan of water exposed to night desert air and sky conditions.

**FIND:** Whether water will freeze.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Bottom of pan is well insulated, (3) Water surface is diffuse-gray, (4) Sky provides blackbody irradiation,  $G_{\text{atm}} = \sigma T_{\text{sky}}^4$ .

**PROPERTIES:** Table A-11, Water (300 K):  $\epsilon = 0.96$ .

**ANALYSIS:** To estimate the water surface temperature for these conditions, begin by performing an energy balance on the pan of water considering convection and radiation processes.

$$\begin{aligned}\dot{E}_{\text{in}}'' - \dot{E}_{\text{out}}'' &= 0 \\ \alpha G_{\text{atm}} - \epsilon E_b - \bar{h}(T_s - T_\infty) &= 0 \\ \epsilon \sigma (T_{\text{sky}}^4 - T_s^4) - \bar{h}(T_s - T_\infty) &= 0.\end{aligned}$$

Note that, from Eq. 12.73,  $G_{\text{atm}} = \sigma T_{\text{sky}}^4$  and from Assumption 3,  $\alpha = \epsilon$ . Substituting numerical values, with all temperatures in kelvin units, the energy balance is

$$\begin{aligned}0.96 \times 5.67 \times 10^{-8} \frac{\text{W}}{\text{m}^2 \cdot \text{K}^4} \left[ (-40 + 273)^4 - T_s^4 \right] \text{K}^4 - 5 \frac{\text{W}}{\text{m}^2 \cdot \text{K}} \left[ T_s - (20 + 273) \right] \text{K} &= 0 \\ 5.443 \times 10^{-8} \left[ 233^4 - T_s^4 \right] - 5 \left[ T_s - 293 \right] &= 0.\end{aligned}$$

Using a trial-and-error approach, find the water surface temperature,

$$T_s = 268.5 \text{ K.} \quad <$$

Since  $T_s < 273 \text{ K}$ , it follows that the water surface will freeze under the prescribed air and sky conditions.

**COMMENTS:** If the heat transfer coefficient were to increase as a consequence of wind, freezing might not occur. Verify that for the given  $T_\infty$  and  $T_{\text{sky}}$ , that if  $\bar{h}$  increases by more than 40%, freezing cannot occur.

## PROBLEM 12.116

**KNOWN:** Environmental conditions associated with a corn leaf, evaporative fluxes in rural and urban settings due to differences in ambient CO<sub>2</sub> concentrations, absorptivity and emissivity values.

**FIND:** Leaf temperature for high (urban) and low (rural) ambient CO<sub>2</sub> concentrations.

**SCHEMATIC:**

**PROPERTIES:** (Given)  $h_{fg} = 2400 \text{ kJ/kg}$ .

**ASSUMPTIONS:** (1) Steady state conditions, (2) Ground and sky represent large surroundings, (3) Negligible irradiation from other leaves, (4)  $\alpha = \varepsilon$  for radiation at long wavelengths, (5) Evaporation flux on top and bottom of leaf.

**ANALYSIS:** Performing an energy balance on the leaf on a per unit area basis,

$$\alpha_s G_s + \alpha_{\text{sky}} \sigma T_{\text{sky}}^4 + \alpha_{\text{grd}} \sigma T_{\text{grd}}^4 = 2h(T - T_{\infty}) + 2\varepsilon \sigma T^4 + 2n''_{\text{H}_2\text{O}} h_{fg}$$

Substituting values for the lower CO<sub>2</sub> environment, high evaporation rate (rural) case,

$$\begin{aligned} &0.76 \times 600 \text{ W/m}^2 + 0.97 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times (273 + 0)^4 \text{ K}^4 + 0.97 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times (273 + 20)^4 \text{ K}^4 \\ &= \\ &2 \times 35 \text{ W/m}^2 \cdot \text{K} \times [T - (273 + 25)] \text{ K} \\ &+ 2 \times 0.97 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times (T)^4 \text{ K}^4 + 2 \times 50 \times 10^{-6} \text{ kg/m}^2 \cdot \text{s} \times 2400 \times 10^3 \text{ J/kg} \end{aligned}$$

which yields  $T = 298.7 \text{ K} = 25.7^\circ\text{C}$  <

Substituting  $n''_{\text{H}_2\text{O}} = 5 \times 10^{-6} \text{ kg/s}$  for the low evaporation (urban) case yields  $T = 301.4 \text{ K} = 28.4^\circ\text{C}$  <

**COMMENTS:** (1) Carbon dioxide levels in urban areas can easily be more than three times greater than in rural communities due to, primarily, fossil fuel combustion corresponding to high traffic density. The sensitivity of the leaf temperature to the local CO<sub>2</sub> concentration is significant. (2) Reduced leaf evaporation rates associated with the higher CO<sub>2</sub> concentration makes corn and other so-called C4 photosynthesis plants more drought-tolerant in urban areas. See, for example, Wall et al., "Elevated Atmospheric CO<sub>2</sub> Improved Sorghum Plant Water Status by Ameliorating the Adverse Effects of Drought," *New Phytologist*, Vol. 152, pp. 231 – 248, 2001. (3) Higher rates of respiratory ailments in urban versus rural communities have been attributed to increased pollen production by plants such as ragweed in cities. The increased pollen production is associated with the increased drought tolerance of ragweed due to elevated CO<sub>2</sub> levels. See L.H. Ziska et al., "Cities as Harbingers of Climate Change: Common Ragweed, Urbanization, and Public Health," *Journal of Allergy and Clinical Immunology*, Vol. 111, pp. 290 - 295, 2003.

## PROBLEM 12.117

**KNOWN:** Thermal conductivity, spectral absorptivity and inner and outer surface conditions for wall of central solar receiver.

**FIND:** Minimum wall thickness needed to prevent thermal failure. Collector efficiency.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Outer surface is opaque and diffuse, (3) Spectral distribution of solar radiation corresponds to blackbody emission at 5800 K.

**ANALYSIS:** From an energy balance at the outer surface,  $\dot{E}_{in} = \dot{E}_{out}$ ,

$$\alpha_S q_S'' + \alpha_{sur} G_{sur} = \varepsilon \sigma T_{s,o}^4 + h_o (T_{s,o} - T_{\infty,o}) + \frac{T_{s,o} - T_{\infty,i}}{(L/k) + (1/h_i)}$$

Since radiation from the surroundings is in the far infrared,  $\alpha_{sur} = 0.2$ . From Table 12.1,  $\lambda T = (3 \mu m \times 5800 \text{ K}) = 17,400 \mu m \cdot K$ , find  $F_{(0 \rightarrow 3 \mu m)} = 0.979$ . Hence,

$$\alpha_s = \frac{\int_0^{\infty} \alpha_\lambda E_{\lambda,b}(5800 \text{ K}) d\lambda}{E_b} = \alpha_1 F_{(0 \rightarrow 3 \mu m)} + \alpha_2 F_{(3 \rightarrow \infty)} = 0.9(0.979) + 0.2(0.021) = 0.885.$$

From Table 12.1,  $\lambda T = (3 \mu m \times 1000 \text{ K}) = 3000 \mu m \cdot K$ , find  $F_{(0 \rightarrow 3 \mu m)} = 0.273$ . Hence,

$$\varepsilon_s = \frac{\int_0^{\infty} \varepsilon_\lambda E_{\lambda,b}(1000 \text{ K}) d\lambda}{E_b} = \varepsilon_1 F_{(0 \rightarrow 3)} + \varepsilon_2 F_{(3 \rightarrow \infty)} = 0.9(0.273) + 0.2(0.727) = 0.391.$$

Substituting numerical values in the energy balance, find

$$0.885 \left( 80,000 \text{ W/m}^2 \right) + 0.2 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (300 \text{ K})^4 = 0.391 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (1000 \text{ K})^4 + 25 \text{ W/m}^2 \cdot \text{K} (700 \text{ K}) + (300 \text{ K}) \left[ (L/15 \text{ W/m} \cdot \text{K}) + (1/1000 \text{ W/m}^2 \cdot \text{K}) \right]$$

$$L = 0.129 \text{ m.} \quad <$$

The corresponding collector efficiency is

$$\eta = \frac{q_{use}''}{q_S''} = \left[ \frac{T_{s,o} - T_{\infty,i}}{(L/k) + (1/h_i)} \right] / q_S''$$

$$\eta = \left[ \frac{300 \text{ K}}{(0.129 \text{ m}/15 \text{ W/m} \cdot \text{K}) + (0.001 \text{ m}^2 \cdot \text{K}/\text{W})} \right] / 80,000 \text{ W/m}^2 = 0.391 \text{ or } 39.1\%. \quad <$$

**COMMENTS:** The collector efficiency could be increased and the outer surface temperature reduced by decreasing the value of L.

## PROBLEM 12.118

**KNOWN:** Dimensions, spectral absorptivity, and temperature of solar receiver. Solar irradiation and ambient temperature.

**FIND:** (a) Rate of energy collection  $q$  and collector efficiency  $\eta$ , (b) Effect of receiver temperature on  $q$  and  $\eta$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, (2) Uniform irradiation, (3) Opaque, diffuse surface.

**PROPERTIES:** Table A.4, air ( $T_f = 550$  K):  $\nu = 45.6 \times 10^{-6}$  m<sup>2</sup>/s,  $k = 0.0439$  W/m·K,  $\alpha = 66.7 \times 10^{-6}$  m<sup>2</sup>/s,  $Pr = 0.683$ .

**ANALYSIS:** (a) The rate of heat transfer to the receiver is  $q = A_s (\alpha_S G_S - E - q''_{conv})$ , or

$$q = \pi DL \left[ \alpha_S G_S - \varepsilon \sigma T_s^4 - \bar{h} (T_s - T_\infty) \right]$$

For  $\lambda T = 3 \mu\text{m} \times 5800 \text{ K} = 17,400$ ,  $F_{(0 \rightarrow \lambda)} = 0.979$ . Hence,

$$\alpha_S = \alpha_1 F_{(0 \rightarrow \lambda)} + \alpha_2 (1 - F_{(0 \rightarrow \lambda)}) = 0.9 \times 0.979 + 0.2(0.021) = 0.885$$

For  $\lambda T = 3 \mu\text{m} \times 800 \text{ K} = 2400 \mu\text{m} \cdot \text{K}$ ,  $F_{(0 \rightarrow \lambda)} = 0.140$ . Hence,

$$\varepsilon = \varepsilon_1 F_{(0 \rightarrow \lambda)} + \varepsilon_2 (1 - F_{(0 \rightarrow \lambda)}) = 0.9 \times 0.140 + 0.2(0.860) = 0.298.$$

With  $Ra_L = g\beta(T_s - T_\infty)L^3/\alpha\nu = 9.8 \text{ m/s}^2(1/550 \text{ K})(500 \text{ K})(12 \text{ m})^3/66.7 \times 10^{-6} \text{ m}^2/\text{s} \times 45.6 \times 10^{-6} \text{ m}^2/\text{s} = 5.06 \times 10^{12}$ , Eq. 9.26 yields

$$\overline{Nu}_L = \left\{ 0.825 + \frac{0.387 Ra_L^{1/6}}{\left[ 1 + (0.492/Pr)^{9/16} \right]^{8/27}} \right\}^2 = 1867$$

$$\bar{h} = \overline{Nu}_L \frac{k}{L} = 1867 \frac{0.0439 \text{ W/m} \cdot \text{K}}{12 \text{ m}} = 6.83 \text{ W/m}^2 \cdot \text{K}$$

Hence,

$$q = \pi (7 \text{ m} \times 12 \text{ m}) \left[ 0.885 \times 80,000 \text{ W/m}^2 - 0.298 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (800 \text{ K})^4 - 6.83 \text{ W/m}^2 \cdot \text{K} (500 \text{ K}) \right]$$

$$q = 263.9 \text{ m}^2 (70,800 - 6,920 - 3415) \text{ W/m}^2 = 1.60 \times 10^7 \text{ W} \quad <$$

The collector efficiency is  $\eta = q/A_s G_S$ . Hence

$$\eta = \frac{1.60 \times 10^7 \text{ W}}{263.9 \text{ m}^2 (80,000 \text{ W/m}^2)} = 0.758 \quad <$$

Continued ...

### PROBLEM 12.118 (Cont.)

(b) The IHT *Correlations, Properties* and *Radiation* Toolpads were used to obtain the following results.

Losses due to emission and convection increase with increasing  $T_s$ , thereby reducing  $q$  and  $\eta$ .

**COMMENTS:** The increase in radiation emission is due to the increase in  $T_s$ , as well as to the effect of  $T_s$  on  $\epsilon$ , which increases from 0.228 to 0.391 as  $T_s$  increases from 600 to 1000 K.

## PROBLEM 12.119

**KNOWN:** Flat plate exposed to night sky and in ambient air at  $T_{\text{air}} = 15^\circ\text{C}$  with a relative humidity of 70%. Radiation from the atmosphere or sky estimated as a fraction of the blackbody radiation corresponding to the near-ground air temperature,  $G_{\text{sky}} = \epsilon_{\text{sky}} \sigma T_{\text{air}}$ , and for a clear night,  $\epsilon_{\text{sky}} = 0.741 + 0.0062 T_{\text{dp}}$  where  $T_{\text{dp}}$  is the dew point temperature ( $^\circ\text{C}$ ). Convection coefficient estimated by correlation,  $\bar{h} (\text{W} / \text{m}^2 \cdot \text{K}) = 1.25 \Delta T^{1/3}$  where  $\Delta T$  is the plate-to-air temperature difference (K).

**FIND:** Whether dew will form on the plate if the surface is (a) clean metal with  $\epsilon_m = 0.23$  and (b) painted with  $\epsilon_p = 0.85$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Surfaces are diffuse, gray, and (3) Backside of plate is well insulated.

**PROPERTIES:** *Psychrometric charts* (Air),  $T_{\text{dp}} = 9.4^\circ\text{C}$  for dry bulb temperature  $15^\circ\text{C}$  and relative humidity 70%.

**ANALYSIS:** From the schematic above, the energy balance on the plate is

$$\dot{E}_{\text{in}}'' - \dot{E}_{\text{out}}'' = 0$$

$$\alpha_{\text{sky}} G_{\text{atm}} + q_{\text{cv}}'' - \epsilon E_b(T_s) = 0$$

$$\epsilon \left[ \left( 0.741 + 0.0062 T_{\text{dp}} (^\circ\text{C}) \right) \sigma T_{\text{air}}^4 \right] + 1.25 (T_{\text{air}} - T_s)^{4/3} \text{ W} / \text{m}^2 - \epsilon \sigma T_s^4 \text{ W} / \text{m}^2 = 0$$

where  $G_{\text{atm}} = \epsilon_{\text{sky}} \sigma T_{\text{air}}$ ,  $\epsilon_{\text{sky}} = 0.741 + 0.062 T_{\text{dp}} (^\circ\text{C})$ ;  $T_{\text{dp}}$  has units ( $^\circ\text{C}$ ); and, other temperatures in kelvins. Since the surface is diffuse-gray,  $\alpha_{\text{sky}} = \epsilon$ .

(a) *Clean metallic surface*,  $\epsilon_m = 0.23$

$$0.23 \left[ \left( 0.741 + 0.0062 T_{\text{dp}} (^\circ\text{C}) \right) \sigma (15 + 273)^4 \text{ K}^4 \right] + 1.25 (289 - T_{\text{s,m}})^{4/3} \text{ W} / \text{m}^2 - 0.23 \sigma T_{\text{s,m}}^4 \text{ W} / \text{m}^2 = 0$$

$$T_{\text{s,m}} = 282.7 \text{ K} = 9.7^\circ\text{C} \quad <$$

(b) *Painted surface*,  $\epsilon_p = 0.85$   $T_{\text{s,p}} = 278.5 \text{ K} = 5.5^\circ\text{C}$  <

**COMMENTS:** For the painted surface,  $\epsilon_p = 0.85$ , find that  $T_s < T_{\text{dp}}$ , so we expect dew formation. For the clean, metallic surface,  $T_s > T_{\text{dp}}$ , so we do not expect dew formation.

## PROBLEM 12.120

**KNOWN:** Glass sheet, used on greenhouse roof, is subjected to solar flux,  $G_S$ , atmospheric emission,  $G_{atm}$ , and interior surface emission,  $G_i$ , as well as to convection processes.

**FIND:** (a) Appropriate energy balance for a unit area of the glass, (b) Temperature of the greenhouse ambient air,  $T_{\infty,i}$ , for prescribed conditions.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Glass is at a uniform temperature,  $T_g$ , (2) Steady-state conditions.

**PROPERTIES:** Glass:  $\tau_\lambda = 1$  for  $\lambda \leq 1\mu\text{m}$ ;  $\tau_\lambda = 0$  and  $\alpha_\lambda = 1$  for  $\lambda > 1\mu\text{m}$ .

**ANALYSIS:** (a) Performing an energy balance on the glass sheet with  $\dot{E}_{in} - \dot{E}_{out} = 0$  and considering two convection processes, emission and three absorbed irradiation terms, find

$$\alpha_S G_S + \alpha_{atm} G_{atm} + h_o (T_{\infty,o} - T_g) + \alpha_i G_i + h_i (T_{\infty,i} - T_g) - 2\varepsilon \sigma T_g^4 = 0 \quad (1)$$

where

$\alpha_S =$  solar absorptivity for absorption of  $G_{\lambda,S} \sim E_{\lambda,b}(\lambda, 5800\text{K})$

$\alpha_{atm} = \alpha_i =$  absorptivity of long wavelength irradiation ( $\lambda \gg 1\mu\text{m}$ )  $\approx 1$

$\varepsilon = \alpha_\lambda$  for  $\lambda \gg 1\mu\text{m}$ , emissivity for long wavelength emission  $\approx 1$

(b) For the prescribed conditions,  $T_{\infty,i}$  can be evaluated from Eq. (1). As noted above,  $\alpha_{atm} = \alpha_i = 1$  and  $\varepsilon = 1$ . The solar absorptivity of the glass follows from Eq. 12.53 where  $G_{\lambda,S} \sim E_{\lambda,b}(\lambda, 5800\text{K})$ ,

$$\alpha_S = \int_0^\infty \alpha_\lambda G_{\lambda,S} d\lambda / G_S = \int_0^\infty \alpha_\lambda E_{\lambda,b}(\lambda, 5800\text{K}) d\lambda / E_b(5800\text{K})$$

$$\alpha_S = \alpha_1 F_{(0 \rightarrow 1\mu\text{m})} + \alpha_2 [1 - F_{(0 \rightarrow 1\mu\text{m})}] = 0 \times 0.720 + 1.0 [1 - 0.720] = 0.28.$$

Note that from Table 12.1 for  $\lambda T = 1\mu\text{m} \times 5800\text{K} = 5800\mu\text{m}\cdot\text{K}$ ,  $F_{(0-\lambda)} = 0.720$ . Substituting numerical values into Eq. (1),

$$0.28 \times 1100 \text{ W/m}^2 + 1 \times 250 \text{ W/m}^2 + 55 \text{ W/m}^2 \cdot \text{K} (24 - 27) \text{ K} + 1 \times 440 \text{ W/m}^2 + 10 \text{ W/m}^2 \cdot \text{K} (T_{\infty,i} - 27) \text{ K} - 2 \times 1 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K} (27 + 273)^4 \text{ K}^4 = 0$$

find that

$$T_{\infty,i} = 35.5^\circ\text{C}.$$

<

## PROBLEM 12.121

**KNOWN:** Plate temperature and spectral absorptivity of coating.

**FIND:** (a) Solar irradiation, (b) Effect of solar irradiation on plate temperature, total absorptivity, and total emissivity.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, (2) Opaque, diffuse surface, (3) Isothermal plate, (4) Negligible radiation from surroundings.

**ANALYSIS:** (a) Performing an energy balance on the plate,  $2\alpha_S G_S - 2E = 0$  and

$$\alpha_S G_S - \varepsilon \sigma T^4 = 0$$

For  $\lambda T = 4.5 \mu\text{m} \times 2000 \text{K} = 9000 \mu\text{m}\cdot\text{K}$ , Table 12.1 yields  $F_{(0 \rightarrow \lambda)} = 0.890$ . Hence,

$$\varepsilon = \varepsilon_1 F_{(0 \rightarrow \lambda)} + \varepsilon_2 (1 - F_{(0 \rightarrow \lambda)}) = 0.95 \times 0.890 + 0.03(1 - 0.890) = 0.849$$

For  $\lambda T = 4.5 \mu\text{m} \times 5800 \text{K} = 26,100$ ,  $F_{(0 \rightarrow \lambda)} = 0.993$ . Hence,

$$\alpha_S = \alpha_1 F_{(0 \rightarrow \lambda)} + \alpha_2 (1 - F_{(0 \rightarrow \lambda)}) = 0.95 \times 0.993 + 0.03 \times 0.007 = 0.944$$

Hence,

$$G_S = (\varepsilon / \alpha_S) \sigma T^4 = (0.849 / 0.944) 5.67 \times 10^{-8} \text{W/m}^2 \cdot \text{K}^4 (2000 \text{K})^4 = 8.16 \times 10^5 \text{W/m}^2 <$$

(b) Using the IHT *First Law Model* and the *Radiation Toolpad*, the following results were obtained.

The required solar irradiation increases with  $T$  to the fourth power. Since  $\alpha_S$  is determined by the spectral distribution of solar radiation, its value is fixed. However, with increasing  $T$ , the spectral distribution of emission is shifted to lower wavelengths, thereby increasing the value of  $\varepsilon$ .

## PROBLEM 12.122

**KNOWN:** Dimensions and construction of truck roof. Roof interior surface temperature. Truck speed, ambient air temperature, and solar irradiation.

**FIND:** (a) Preferred roof coating, (b) Roof surface temperature, (c) Heat load through roof, (d) Effect of velocity on surface temperature and heat load.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Turbulent boundary layer development over entire roof, (2) Constant properties, (3) Negligible atmospheric (sky) irradiation, (4) Negligible contact resistance.

**PROPERTIES:** Table A.4, Air ( $T_{s,o} \approx 300$  K, 1 atm):  $\nu = 15 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.026 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.71$ .

**ANALYSIS:** (a) To minimize heat transfer through the roof, minimize solar absorption relative to surface emission. Hence, use zinc oxide white for which  $\alpha_S = 0.16$  and  $\varepsilon = 0.93$ . (Table A.12) <

(b) Performing an energy balance on the outer surface of the roof,  $\alpha_S G_S + q''_{\text{conv}} - E - q''_{\text{cond}} = 0$ , it follows that

$$\alpha_S G_S + \bar{h}(T_{\infty} - T_{s,o}) = \varepsilon \sigma T_{s,o}^4 + (k/t)(T_{s,o} - T_{s,i})$$

where it is assumed that convection is from the air to the roof. With an analysis based upon the content of Chapter 7

$$\text{Re}_L = \frac{VL}{\nu} = \frac{30 \text{ m/s}(5 \text{ m})}{15 \times 10^{-6} \text{ m}^2/\text{s}} = 10^7$$

$$\overline{\text{Nu}}_L = 0.037 \text{Re}_L^{4/5} \text{Pr}^{1/3} = 0.037(10^7)^{4/5} (0.71)^{1/3} = 13,141$$

$$\bar{h} = \overline{\text{Nu}}_L (k/L) = 13,141(0.026 \text{ W/m}\cdot\text{K}/5 \text{ m}) = 68.3 \text{ W/m}^2\cdot\text{K}.$$

Substituting numerical values in the energy balance and solving by trial-and-error, we obtain

$$T_{s,o} = 295.2 \text{ K}. \quad <$$

(c) The heat load through the roof is

$$q = (kA_S/t)(T_{s,o} - T_{s,i}) = (0.05 \text{ W/m}\cdot\text{K} \times 10 \text{ m}^2 / 0.025 \text{ m}) 35.2 \text{ K} = 704 \text{ W}. \quad <$$

(d) Using the IHT *First Law Model* with the *Correlations* and *Properties* Toolpads, the following results are obtained.

Continued...

### PROBLEM 12.122 (Cont.)

The surface temperature and heat load decrease with decreasing  $V$  due to a reduction in the convection heat transfer coefficient and hence convection heat transfer from the air.

**COMMENTS:** The heat load would increase with increasing  $\alpha_s/\epsilon$ .

### PROBLEM 12.123

**KNOWN:** Sky, ground, and ambient air temperatures. Grape of prescribed diameter and properties.

**FIND:** (a) General expression for rate of change of grape temperature, (b) Whether grapes will freeze in quiescent air, (c) Whether grapes will freeze for a prescribed air speed.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible temperature gradients in grape, (2) Uniform blackbody irradiation over top and bottom hemispheres, (3) Properties of grape are those of water at 273 K, (4) Properties of air are constant at values for  $T_\infty$ , (5) Negligible buoyancy for  $V = 1$  m/s.

**PROPERTIES:** Table A-6, Water (273 K):  $c_p = 4217$  J/kg·K,  $\rho = 1000$  kg/m<sup>3</sup>; Table A-4, Air (273 K, 1 atm):  $\nu = 13.49 \times 10^{-6}$  m<sup>2</sup>/s,  $k = 0.0241$  W/m·K,  $\alpha = 18.9 \times 10^{-6}$  m<sup>2</sup>/s,  $Pr = 0.714$ ,  $\beta = 3.66 \times 10^{-3}$  K<sup>-1</sup>.

**ANALYSIS:** (a) Performing an energy balance for a control surface about the grape,

$$\frac{dE_{st}}{dt} = \rho_g \frac{\pi D^3}{6} c_{p,g} \frac{dT_g}{dt} = \bar{h} \pi D^2 (T_\infty - T_g) + \frac{\pi D^2}{2} (G_{ea} + G_{atm}) - E \pi D^2.$$

where  $G_{atm} = \sigma T_{sky}^4$ . Hence, the rate of temperature change with time is

$$\frac{dT_g}{dt} = \frac{6}{\rho_g c_{p,g} D} \left[ \bar{h} (T_\infty - T_g) + \sigma \left( \frac{T_{ea}^4 + T_{sky}^4}{2} - \epsilon_g T_g^4 \right) \right]. \quad <$$

(b) The grape freezes if  $dT_g/dt < 0$  when  $T_g = T_{fp} = 268$  K. With

$$Ra_D = \frac{g \beta (T_\infty - T_g) D^3}{\alpha \nu} = \frac{9.8 \text{ m/s}^2 (3.66 \times 10^{-3} \text{ K}^{-1}) 5 \text{ K} (0.015 \text{ m})^3}{18.9 \times 10^{-6} \times 13.49 \times 10^{-6} \text{ m}^4/\text{s}^2} = 2374$$

using Eq. 9.35 find

$$\bar{Nu}_D = 2 + \frac{0.589 (2374)^{1/4}}{\left[ 1 + (0.469 / Pr)^{9/16} \right]^{4/9}} = 5.17$$

$$\bar{h} = (k/D) \bar{Nu}_D = [(0.0241 \text{ W/m} \cdot \text{K}) / (0.015 \text{ m})] 5.17 = 8.31 \text{ W/m}^2 \cdot \text{K}.$$

Hence, the rate of temperature change is

$$\frac{dT_g}{dt} = \frac{6}{(1000 \text{ kg/m}^3) 4217 \text{ J/kg} \cdot \text{K} (0.015 \text{ m})} \left[ 8.31 \text{ W/m}^2 \cdot \text{K} (5 \text{ K}) + 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left[ \frac{(273^4 + 235^4)}{2} - 268^4 \right] \text{K}^4 \right]$$

Continued ...

**PROBLEM 12.123 (Cont.)**

$$\frac{dT_g}{dt} = 9.49 \times 10^{-5} \text{ K} \cdot \text{m}^2 / \text{J} [41.55 - 48.56] \text{ W} / \text{m}^2 = -6.66 \times 10^{-4} \text{ K} / \text{s} \quad <$$

and since  $dT_g/dt < 0$ , the grape *will freeze*.

(c) For  $V = 1 \text{ m/s}$ ,

$$\text{Re}_D = \frac{VD}{\nu} = \frac{1 \text{ m/s}(0.015 \text{ m})}{13.49 \times 10^{-6} \text{ m}^2 / \text{s}} = 1112.$$

Hence with  $(\mu/\mu_s)^{1/4} = 1$  and from an analysis based upon the content of Chapter 7,

$$\overline{\text{Nu}}_D = 2 + \left( 0.4 \text{Re}_D^{1/2} + 0.06 \text{Re}_D^{2/3} \right) \text{Pr}^{0.4} = 19.3$$

$$\bar{h} = \overline{\text{Nu}}_D \frac{k}{D} = 21.8 \frac{0.0241}{0.015} = 31 \text{ W} / \text{m}^2 \cdot \text{K}.$$

Hence the rate of temperature change with time is

$$\frac{dT_g}{dt} = 9.49 \times 10^{-5} \text{ K} \cdot \text{m}^2 / \text{J} \left[ 31 \text{ W} / \text{m}^2 \cdot \text{K} (5 \text{ K}) - 48.56 \text{ W} / \text{m}^2 \right] = -0.016 \text{ K} / \text{s}$$

and since  $dT_g/dt < 0$  and  $\left| dT_g/dt \right|_c > \left| dT_g/dt \right|_b$ , the grape *will freeze sooner than in part (b)*. <

**COMMENTS:** With  $\text{Gr}_D = \text{Ra}_D/\text{Pr} = 3325$  and  $\text{Gr}_D/\text{Re}_D^2 = 0.0027$ , the assumption of negligible buoyancy for  $V = 1 \text{ m/s}$  is reasonable.

## PROBLEM 12.124

**KNOWN:** Metal disk exposed to environmental conditions and placed in good contact with the earth.

**FIND:** (a) Fraction of direct solar irradiation absorbed, (b) Emissivity of the disk, (c) Average free convection coefficient of the disk upper surface, (d) Steady-state temperature of the disk (confirm the value 340 K).

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Disk is diffuse, (3) Disk is isothermal, (4) Negligible contact resistance between disk and earth, (5) Solar irradiance has spectral distribution of  $E_{\lambda,b}(\lambda, 5800 \text{ K})$ .

**PROPERTIES:** Table A-4, Air (1 atm,  $T_f = (T_s + T_\infty)/2 = (340 + 300) \text{ K}/2 = 320 \text{ K}$ ):  $\nu = 17.90 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0278 \text{ W/m}\cdot\text{K}$ ,  $\alpha = 25.5 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.704$ .

**ANALYSIS:** (a) The solar absorptivity follows from Eq. 12.53 with  $G_{\lambda,S} \propto E_{\lambda,b}(\lambda, 5800 \text{ K})$ , and  $\alpha_\lambda = \varepsilon_\lambda$ , since the disk surface is diffuse.

$$\alpha_S = \int_0^\infty \alpha_\lambda E_{\lambda,b}(\lambda, 5800 \text{ K}) / E_b(5800 \text{ K})$$

$$\alpha_S = \varepsilon_1 F_{(0 \rightarrow 1 \mu\text{m})} + \varepsilon_2 (1 - F_{(0 \rightarrow 1 \mu\text{m})}).$$

From Table 12.1 with

$$\lambda T = 1 \mu\text{m} \times 5800 \text{ K} = 5800 \mu\text{m}\cdot\text{K} \quad \text{find} \quad F_{(0 \rightarrow \lambda T)} = 0.720$$

giving

$$\alpha_S = 0.9 \times 0.720 + 0.2(1 - 0.720) = 0.704. \quad \leftarrow$$

Note this value is appropriate for diffuse or direct solar irradiation since the surface is diffuse.

(b) The emissivity of the disk depends upon the surface temperature  $T_s$  which we believe to be 340 K. (See part (d)). From Eq. 12.43,

$$\varepsilon = \int_0^\infty \varepsilon_\lambda E_{\lambda,b}(\lambda, T_s) / E_b(T_s)$$

$$\varepsilon = \varepsilon_1 F_{(0 \rightarrow 1 \mu\text{m})} + \varepsilon_2 (1 - F_{(0 \rightarrow 1 \mu\text{m})})$$

Continued ...

**PROBLEM 12.124 (Cont.)**

From Table 12.1 with

$$\lambda T = 1 \mu\text{m} \times 340 \text{ K} = 340 \mu\text{m} \cdot \text{K} \quad \text{find} \quad F_{(0 \rightarrow \lambda T)} = 0.000$$

giving

$$\varepsilon = 0.9 \times 0.000 + 0.2(1 - 0.000) = 0.20. \quad <$$

(c) The disk is a hot surface facing upwards for which the free convection correlation of Eq. 9.30 is appropriate. Evaluating properties at  $T_f = (T_s + T_\infty)/2 = 320 \text{ K}$ ,

$$\text{Ra}_L = g\beta\Delta TL^3 / \nu\alpha \quad \text{where} \quad L = A_s / P = D/4$$

$$\text{Ra}_L = 9.8 \text{ m/s}^2 (1/320 \text{ K})(340 - 300) \text{ K} (0.4 \text{ m}/4)^3 / 17.90 \times 10^{-6} \text{ m}^2/\text{s} \times 25.5 \times 10^{-6} \text{ m}^2/\text{s} = 2.684 \times 10^6$$

$$\overline{\text{Nu}}_L = \bar{h}L/k = 0.54 \text{Ra}_L^{1/4} \quad 10^4 \leq \text{Ra}_L \leq 10^7$$

$$\bar{h} = 0.0278 \text{ W/m} \cdot \text{K} / (0.4 \text{ m}/4) \times 0.54 (3.042 \times 10^6)^{1/4} = 6.07 \text{ W/m}^2 \cdot \text{K}. \quad <$$

(d) To determine the steady-state temperature, perform an energy balance on the disk.

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \dot{E}_{\text{st}}$$

$$(\alpha_S G_{S,d} + \alpha G_{\text{atm}} - \varepsilon E_b - q''_{\text{conv}}) A_s - q_{\text{cond}} = 0.$$

Since  $G_{\text{atm}}$  is predominately long wavelength radiation, it follows that  $\alpha = \varepsilon$ . The conduction heat rate between the disk and the earth is

$$q_{\text{cond}} = kS(T_s - T_{\text{ea}}) = k(2D)(T_s - T_{\text{ea}})$$

where  $S$ , the conduction shape factor, is that of an isothermal disk on a semi-infinite medium, Table 4.1. Substituting numerical values, with  $A_s = \pi D^2/4$ ,

$$\left[ 0.704 \times 745 \text{ W/m}^2 + 0.20\sigma(280 \text{ K})^4 - 0.20\sigma T_s^4 - 6.07 \text{ W/m}^2 \cdot \text{K} (T_s - 300 \text{ K}) \right] \pi (0.4 \text{ m})^2 / 4 - 0.52 \text{ W/m} \cdot \text{K} (2 \times 0.4 \text{ m})(T_s - 280 \text{ K}) = 0$$

$$65.908 \text{ W} + 8.759 \text{ W} - 1.425 \times 10^{-9} T_s^4 - 0.763(T_s - 300) - 0.416(T_s - 280) = 0.$$

By trial-and-error, find

$$T_s \approx 340 \text{ K}. \quad <$$

so indeed the assumed value of 340 K was proper.

**COMMENTS:** Note why it is not necessary for this situation to distinguish between direct and diffuse irradiation. Why does  $\alpha_{\text{sky}} = \varepsilon$ ?

## PROBLEM 12.125

**KNOWN:** Shed roof of weathered galvanized sheet metal exposed to solar insolation on a cool, clear spring day with ambient air at  $-10^\circ\text{C}$  and convection coefficient estimated by the empirical correlation  $\bar{h} = 1.0 \Delta T^{1/3}$  ( $\text{W}/\text{m}^2 \cdot \text{K}$  with temperature units of kelvins).

**FIND:** Temperature of the roof,  $T_s$ , (a) assuming the backside is well insulated, and (b) assuming the backside is exposed to ambient air with the same convection coefficient relation and experiences radiation exchange with the ground, also at the ambient air temperature. Comment on whether the roof will be a comfortable place for the neighborhood cat to snooze for these conditions.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) The roof surface is diffuse, spectrally selective, (3) Sheet metal is thin with negligible thermal resistance, and (3) Roof is a small object compared to the large isothermal surroundings represented by the sky and the ground.

**ANALYSIS:** (a) For the backside-insulated condition, the energy balance, represented schematically below, is

$$\begin{aligned} \dot{E}''_{\text{in}} - \dot{E}''_{\text{out}} &= 0 \\ \alpha_{\text{sky}} E_b(T_{\text{sky}}) + \alpha_S G_S - q''_{\text{cv}} - \varepsilon E_b(T_s) &= 0 \\ \alpha_{\text{sky}} \sigma T_{\text{sky}}^4 + \alpha_S G_S - 1.0(T_s - T_\infty)^{4/3} - \varepsilon \sigma T_s^4 &= 0 \end{aligned}$$

With  $\alpha_{\text{sky}} = \varepsilon$  (see Comment 2) and  $\sigma = 5.67 \times 10^{-8} \text{ W}/\text{m}^2 \cdot \text{K}^4$ , find  $T_s$ .

$$0.65 \sigma (233 \text{ K})^4 \text{ W}/\text{m}^2 + 0.8 \times 600 \text{ W}/\text{m}^2 - 1.0(T_s - 283 \text{ K})^{4/3} \text{ W}/\text{m}^2 - 0.65 \sigma T_s^4 = 0$$

$$T_s = 328.2 \text{ K} = 55.2^\circ\text{C} \quad <$$

Continued ...

### PROBLEM 12.125 (Cont.)

(b) With the backside exposed to convection with the ambient air and radiation exchange with the ground, the energy balance, represented schematically above, is

$$\alpha_{\text{sky}} E_b(T_{\text{sky}}) + \alpha_{\text{grd}} E_b(T_{\text{grd}}) + \alpha_S G_S - 2q''_{\text{cv}} - 2\varepsilon E_b(T_s) = 0$$

Substituting numerical values, recognizing that  $T_{\text{grd}} = T_{\infty}$ , and  $\alpha_{\text{grd}} = \varepsilon$  (see Comment 2), find  $T_s$ .

$$0.65 \sigma (233 \text{ K})^4 \text{ W/m}^2 + 0.65 \sigma (283 \text{ K})^4 \text{ W/m}^2 + 0.8 \times 600 \text{ W/m}^2 \\ - 2 \times 1.0 (T_s - 283 \text{ K})^{4/3} \text{ W/m}^2 - 2 \times 0.65 \sigma T_s^4 = 0$$

$$T_s = 308.9 \text{ K} = 35.9^\circ\text{C}$$

<

**COMMENTS:** (1) For the insulated-backside condition, the cat would find the roof too hot remembering that  $43^\circ\text{C}$  represents a safe-to-touch temperature. For the exposed-backside condition, the cat would find the roof comfortable, certainly compared to an area not exposed to the solar insolation (that is, exposed only to the ambient air through convection).

(2) For this spectrally selective surface, the absorptivity for the sky irradiation is equal to the emissivity,  $\alpha_{\text{sky}} = \varepsilon$ , since the sky irradiation and surface emission have the same approximate spectral regions. The same reasoning applies for the absorptivity of the ground irradiation,  $\alpha_{\text{grd}} = \varepsilon$ .

## PROBLEM 12.126

**KNOWN:** Amplifier operating and environmental conditions.

**FIND:** (a) Power generation when  $T_s = 58^\circ\text{C}$  with diffuse coating  $\varepsilon = 0.5$ , (b) Diffuse coating from among three (A, B, C) which will give greatest reduction in  $T_s$ , and (c) Surface temperature for the conditions with coating chosen in part (b).

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Environmental conditions remain the same with all surface coatings, (2) Coatings A, B, C are opaque, diffuse.

**ANALYSIS:** (a) Performing an energy balance on the amplifier's exposed surface,

$\dot{E}_{in} - \dot{E}_{out} = 0$ , we find

$$P_e + A_s [\alpha_S G_S + \alpha_{atm} G_{atm} - \varepsilon E_b - q''_{conv}] = 0$$

$$P_e = A_s \left[ \varepsilon \sigma T_s^4 + h(T_s - T_\infty) - \alpha_S G_S - \alpha_{atm} \sigma T_{sky}^4 \right]$$

$$P_e = 0.13 \times 0.13 \text{ m}^2 \left[ 0.5 \times \sigma (331)^4 + 15(331 - 300) - 0.5 \times 800 - 0.5 \times \sigma (253)^4 \right] \text{ W/m}^2$$

$$P_e = 0.0169 \text{ m}^2 [0.5 \times 680.6 + 465 - 0.5 \times 800 - 0.5 \times 232.3] \text{ W/m}^2 = 4.887 \text{ W.} \quad <$$

(b) From above, recognize that we seek a coating with low  $\alpha_S$  and high  $\varepsilon$  to decrease  $T_s$ . Further, recognize that  $\alpha_S$  is determined by values of  $\alpha_\lambda = \varepsilon_\lambda$  for  $\lambda < 3 \mu\text{m}$  and  $\varepsilon$  by values of  $\varepsilon_\lambda$  for  $\lambda > 3 \mu\text{m}$ . Find approximate values as

Coating	A	B	C
$\varepsilon$	0.5	0.3	0.6
$\alpha_S$	0.8	0.3	0.2
$\alpha_S/\varepsilon$	1.6	1	0.333

Note also that  $\alpha_{atm} \approx \varepsilon$ . We conclude that coating C is likely to give the lowest  $T_s$  since its  $\alpha_S/\varepsilon$  is substantially lower than for B and C. While  $\alpha_{atm}$  for C is twice that of B, because  $G_{atm}$  is nearly 25% that of  $G_S$ , we expect coating C to give the lowest  $T_s$ .

(c) With the values of  $\alpha_S$ ,  $\alpha_{atm}$  and  $\varepsilon$  for coating C from part (b), rewrite the energy balance as

$$P_e / A_s + \alpha_S G_S + \alpha_{atm} \sigma T_{sky}^4 - \varepsilon \sigma T_s^4 - h(T_s - T_\infty) = 0$$

$$4.887 \text{ W}/(0.13 \text{ m})^2 + 0.2 \times 800 \text{ W/m}^2 + 0.6 \times 232.3 \text{ W/m}^2 - 0.6 \times \sigma T_s^4 - 15(T_s - 300) = 0$$

Using trial-and-error, find  $T_s = 316.5 \text{ K} = 43.5^\circ\text{C}$ . <

**COMMENTS:** (1) Using coatings A and B, find  $T_s = 71$  and  $54^\circ\text{C}$ , respectively. (2) For more precise values of  $\alpha_S$ ,  $\alpha_{sky}$  and  $\varepsilon$ , use  $T_s = 43.5^\circ\text{C}$ . For example, at  $\lambda T_s = 3 \times (43.5 + 273) = 950 \mu\text{m}\cdot\text{K}$ ,  $F_{0-\lambda T} = 0.000$  while at  $\lambda T_{solar} = 3 \times 5800 = 17,400 \mu\text{m}\cdot\text{K}$ ,  $F_{0-\lambda T} \approx 0.98$ ; we conclude little effect will be seen.

## PROBLEM 12.127

**KNOWN:** Opaque, spectrally-selective horizontal plate with electrical heater on backside is exposed to convection, solar irradiation and sky irradiation.

**FIND:** Electrical power required to maintain plate at 60°C.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Plate is opaque, diffuse and uniform, (2) No heat lost out the backside of heater.

**ANALYSIS:** From an energy balance on the plate-heater system, per unit area basis,

$$\begin{aligned} \dot{E}_{in}'' - \dot{E}_{out}'' &= 0 \\ q_{elec}'' + \alpha_S G_S + \alpha G_{atm} \\ -\varepsilon E_b(T_s) - q_{conv}'' &= 0 \end{aligned}$$

where  $G_{atm} = \sigma T_{sky}^4$ ,  $E_b = \sigma T_s^4$ , and  $q_{conv}'' = h(T_s - T_\infty)$ . The solar absorptivity is

$$\alpha_S = \int_0^\infty \alpha_\lambda G_{\lambda,S} d\lambda / \int_0^\infty G_{\lambda,S} d\lambda = \int_0^\infty \alpha_\lambda E_{\lambda,b}(\lambda, 5800 \text{ K}) d\lambda / \int_0^\infty E_{\lambda,b}(\lambda, 5800 \text{ K}) d\lambda$$

where  $G_{\lambda,S} \sim E_{\lambda,b}(\lambda, 5800 \text{ K})$ . Noting that  $\alpha_\lambda = 1 - \rho_\lambda$ ,

$$\alpha_S = (1 - 0.2)F_{(0-2\mu\text{m})} + (1 - 0.7)(1 - F_{(0-2\mu\text{m})})$$

where at  $\lambda T = 2 \mu\text{m} \times 5800 \text{ K} = 11,600 \mu\text{m}\cdot\text{K}$ , find from Table 12.1,  $F_{(0-\lambda T)} = 0.941$ ,

$$\alpha_S = 0.80 \times 0.941 + 0.3(1 - 0.941) = 0.771.$$

The total, hemispherical emissivity is

$$\varepsilon = (1 - 0.2)F_{(0-2\mu\text{m})} + (1 - 0.7)(1 - F_{(0-2\mu\text{m})}).$$

At  $\lambda T = 2 \mu\text{m} \times 333 \text{ K} = 666 \text{ K}$ , find  $F_{(0-\lambda T)} \approx 0.000$ ; hence  $\varepsilon = 0.30$ . The total, hemispherical absorptivity for sky irradiation is  $\alpha = \varepsilon = 0.30$  since the surface is gray for this emission and irradiation process. Substituting numerical values,

$$q_{elec}'' = \varepsilon \sigma T_s^4 + h(T_s - T_\infty) - \alpha_S G_S - \alpha \sigma T_{sky}^4$$

$$q_{elec}'' = 0.30 \times \sigma (333 \text{ K})^4 + 10 \text{ W/m}^2 \cdot \text{K} (60 - 20)^\circ\text{C} - 0.771 \times 600 \text{ W/m}^2 - 0.30 \times \sigma (233 \text{ K})^4$$

$$q_{elec}'' = 209.2 \text{ W/m}^2 + 400.0 \text{ W/m}^2 - 462.6 \text{ W/m}^2 - 50.1 \text{ W/m}^2 = 96.5 \text{ W/m}^2. \quad <$$

**COMMENTS:** (1) Note carefully why  $\alpha_{sky} = \varepsilon$  for the sky irradiation.

## PROBLEM 12.128

**KNOWN:** Chord length and spectral emissivity of wing. Ambient air temperature, sky temperature and solar irradiation for ground and in-flight conditions. Flight speed.

**FIND:** Temperature of top surface of wing for (a) ground and (b) in-flight conditions.

**ASSUMPTIONS:** (1) Steady-state, (2) Negligible heat transfer from back of wing surface, (3) Diffuse surface behavior, (4) Negligible solar radiation for  $\lambda > 3 \mu\text{m}$  ( $\alpha_S = \alpha_{\lambda \leq 3 \mu\text{m}} = \epsilon_{\lambda \leq 3 \mu\text{m}} = 0.6$ ), (5) Negligible sky radiation and surface emission for  $\lambda \leq 3 \mu\text{m}$  ( $\alpha_{\text{sky}} = \alpha_{\lambda > 3 \mu\text{m}} = \epsilon_{\lambda > 3 \mu\text{m}} = 0.3 = \epsilon$ ), (6) Quiescent air for ground condition, (7) Air foil may be approximated as a flat plate, (8) Negligible viscous heating in boundary layer for in-flight condition, (9) The wing span  $W$  is much larger than the chord length  $L_c$ , (10) In-flight transition Reynolds number is  $5 \times 10^5$ .

**PROPERTIES:** Part (a). Table A-4, air ( $T_f \approx 325 \text{ K}$ ):  $\nu = 1.84 \times 10^{-5} \text{ m}^2/\text{s}$ ,  $\alpha = 2.62 \times 10^{-5} \text{ m}^2/\text{s}$ ,  $k = 0.0282 \text{ W/m}\cdot\text{K}$ ,  $\beta = 0.00307$ . Part (b). Given:  $\rho = 0.470 \text{ kg/m}^3$ ,  $\mu = 1.50 \times 10^{-5} \text{ N}\cdot\text{s/m}^2$ ,  $k = 0.021 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.72$ .

**ANALYSIS:** For both ground and in-flight conditions, a surface energy balance yields

$$\alpha_{\text{sky}} G_{\text{sky}} + \alpha_S G_S = \epsilon \sigma T_s^4 + \bar{h} (T_s - T_\infty) \quad (1)$$

where  $\alpha_{\text{sky}} = \epsilon = 0.3$ , and  $\alpha_S = 0.6$ .

(a) For the ground condition,  $\bar{h}$  may be evaluated from Eq. 9.30 or 9.31, where  $L = A_s/P = L_c \times W/2$  ( $L_c + W$ )  $\approx L_c/2 = 2 \text{ m}$  and  $\text{Ra}_L = g\beta(T_s - T_\infty)L^3/\nu\alpha$ . Using the *IHT* software to solve Eq. (1) and accounting for the effect of temperature-dependent properties, the surface temperature is

$$T_s = 350.6 \text{ K} = 77.6^\circ\text{C} \quad \leftarrow$$

where  $\text{Ra}_L = 2.52 \times 10^{10}$  and  $\bar{h} = 6.2 \text{ W/m}^2\cdot\text{K}$ . Heat transfer from the surface by emission and convection is  $257.0$  and  $313.6 \text{ W/m}^2$ , respectively.

(b) For the in-flight condition,  $\text{Re}_L = \rho u_\infty L_c / \mu = 0.470 \text{ kg/m}^3 \times 200 \text{ m/s} \times 4 \text{ m} / 1.50 \times 10^{-5} \text{ N}\cdot\text{s/m}^2 = 2.51 \times 10^7$ . For mixed, laminar/turbulent boundary layer conditions (Chapter 7) and a transition Reynolds number of  $\text{Re}_{x,c} = 5 \times 10^5$ .

$$\overline{\text{Nu}}_L = \left( 0.037 \text{Re}_L^{4/5} - 871 \right) \text{Pr}^{1/3} = 26,800$$

$$\bar{h} = \frac{k}{L} \overline{\text{Nu}}_L = \frac{0.021 \text{ W/m}\cdot\text{K} \times 26,800}{4 \text{ m}} = 141 \text{ W/m}^2\cdot\text{K}$$

Substituting into Eq. (1), a trial-and-error solution yields

$$T_s = 237.7 \text{ K} = -35.3^\circ\text{C} \quad \leftarrow$$

Heat transfer from the surface by emission and convection is now  $54.3$  and  $657.6 \text{ W/m}^2$ , respectively.

**COMMENTS:** The temperature of the wing is strongly influenced by the convection heat transfer coefficient, and the large coefficient associated with flight yields a surface temperature that is within  $5^\circ\text{C}$  of the air temperature.

## PROBLEM 12.129

**KNOWN:** Spectrally selective and gray surfaces in earth orbit are exposed to solar irradiation,  $G_S$ , in a direction  $30^\circ$  from the normal to the surfaces.

**FIND:** Equilibrium temperature of each plate.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Plates are at uniform temperature, (2) Surroundings are at 0K, (3) Steady-state conditions, (4) Solar irradiation has spectral distribution of  $E_{\lambda,b}(\lambda, 5800\text{K})$ , (5) Back side of plate is insulated.

**ANALYSIS:** Noting that the solar irradiation is directional (at  $30^\circ$  from the normal), the radiation balance has the form

$$\alpha_S G_S \cos \theta - \varepsilon E_b(T_S) = 0. \quad (1)$$

Using  $E_b(T_S) = \sigma T_S^4$  and solving for  $T_S$ , find

$$T_S = \left[ (\alpha_S / \varepsilon) (G_S \cos \theta / \sigma) \right]^{1/4}. \quad (2)$$

For the *gray surface*,  $\alpha_S = \varepsilon = \alpha_\lambda$  and the temperature is independent of the magnitude of the absorptivity.

$$T_S = \left( \frac{0.95}{0.95} \times \frac{1368 \text{ W/m}^2 \times \cos 30^\circ}{5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4} \right)^{1/4} = 380 \text{ K.} \quad <$$

For the *selective surface*,  $\alpha_S = 0.95$  since nearly all the solar spectral power is in the region  $\lambda < 3\mu\text{m}$ . The value of  $\varepsilon$  depends upon the surface temperature  $T_S$  and would be determined by the relation.

$$\varepsilon = 0.95 F_{(0 \rightarrow \lambda T_S)} + 0.05 \left[ 1 - F_{(0 \rightarrow \lambda T_S)} \right] \quad (3)$$

where  $\lambda = 3\mu\text{m}$  and  $T_S$  is as yet unknown. To find  $T_S$ , a trial-and-error procedure as follows will be used: (1) assume a value of  $T_S$ , (2) using Eq. (3), calculate  $\varepsilon$  with the aid of Table 12.1 evaluating  $F_{(0 \rightarrow \lambda T)}$  at  $\lambda T_S = 3\mu\text{m} \cdot T_S$ , (3) with this value of  $\varepsilon$ , calculate  $T_S$  from Eq. (2) and compare with assumed value of  $T_S$ . The results of the iterations are:

$T_S(\text{K})$ , assumed value	633	700	666	650	655
$\varepsilon$ , from Eq. (3)	0.098	0.125	0.110	0.104	0.106
$T_S(\text{K})$ , from Eq. (2)	656	629	650	659	656

Hence, for the coating,  $T_S \approx 656\text{K}$ . <

**COMMENTS:** Note the role of the ratio  $\alpha_s/\varepsilon$  in determining the equilibrium temperature of an isolated plate exposed to solar irradiation in space. This is an important property of the surface in spacecraft thermal design and analysis.

## PROBLEM 12.130

**KNOWN:** Spectral distribution of coating on satellite surface. Irradiation from earth and sun.

**FIND:** (a) Steady-state temperature of satellite on dark side of earth, (b) Steady-state temperature on bright side.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Opaque, diffuse-gray surface behavior, (3) Spectral distributions of earth and solar emission may be approximated as those of blackbodies at 280K and 5800K, respectively, (4) Satellite temperature is less than 500K.

**ANALYSIS:** Performing an energy balance on the satellite,

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = 0$$

$$\alpha_E G_E \left( \pi D^2 / 4 \right) + \alpha_S G_S \left( \pi D^2 / 4 \right) - \varepsilon \sigma T_s^4 \left( \pi D^2 \right) = 0$$

$$T_s = \left( \frac{\alpha_E G_E + \alpha_S G_S}{4 \varepsilon \sigma} \right)^{1/4}.$$

From Table 12.1, with 98% of radiation below  $3 \mu\text{m}$  for  $\lambda T = 17,400 \mu\text{m} \cdot \text{K}$ ,

$$\alpha_S \cong 0.6.$$

With 98% of radiation above  $3 \mu\text{m}$  for  $\lambda T = 3 \mu\text{m} \times 500\text{K} = 1500 \mu\text{m} \cdot \text{K}$ ,

$$\varepsilon \approx 0.3 \quad \alpha_E \approx 0.3.$$

(a) On *dark* side,

$$T_s = \left( \frac{\alpha_E G_E}{4 \varepsilon \sigma} \right)^{1/4} = \left( \frac{0.3 \times 340 \text{ W/m}^2}{4 \times 0.3 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4} \right)^{1/4}$$

$$T_s = 197 \text{ K.} \quad <$$

(b) On *bright* side,

$$T_s = \left( \frac{\alpha_E G_E + \alpha_S G_S}{4 \varepsilon \sigma} \right)^{1/4} = \left( \frac{0.3 \times 340 \text{ W/m}^2 + 0.6 \times 1368 \text{ W/m}^2}{4 \times 0.3 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4} \right)^{1/4}$$

$$T_s = 341 \text{ K.} \quad <$$

### PROBLEM 12.131

**KNOWN:** Radiative properties and operating conditions of a space radiator.

**FIND:** Equilibrium temperature of the radiator.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Negligible irradiation due to earth emission.

**ANALYSIS:** From a surface energy balance,  $\dot{E}''_{in} - \dot{E}''_{out} = 0$ .

$$q''_{dis} + \alpha_S G_S - E = 0.$$

Hence

$$T_s = \left( \frac{q''_{dis} + \alpha_S G_S}{\epsilon \sigma} \right)^{1/4}$$

$$T_s = \left( \frac{1500 \text{ W/m}^2 + 0.5 \times 1000 \text{ W/m}^2}{0.95 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4} \right)^{1/4}$$

or

$$T_s = 439 \text{ K.} \quad <$$

**COMMENTS:** *Passive* thermal control of spacecraft is practiced by using surface coatings with desirable values of  $\alpha_S$  and  $\epsilon$ .

## PROBLEM 12.132

**KNOWN:** Spherical satellite exposed to solar irradiation of  $1368 \text{ W/m}^2$ ; surface is to be coated with a checker pattern of evaporated aluminum film, (fraction,  $F$ ) and white zinc-oxide paint ( $1 - F$ ).

**FIND:** The fraction  $F$  for the checker pattern required to maintain the satellite at  $300 \text{ K}$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Satellite is isothermal, and (3) No internal power dissipation.

**ANALYSIS:** Perform an energy balance on the satellite, as illustrated in the schematic, identifying absorbed solar irradiation on the projected area,  $A_p$ , and emission from the spherical area  $A_s$ .

$$\dot{E}_{\text{in}} + \dot{E}_{\text{out}} = 0$$

$$\left( F \cdot \alpha_{S,f} + (1-F) \cdot \alpha_{S,p} \right) G_S A_p - \left( F \cdot \varepsilon_f + (1-F) \cdot \varepsilon_p \right) E_b (T_s) A_s = 0$$

where  $A_p = \pi D^2 / 4$ ,  $A_s = \pi D^2$ ,  $E_b = \sigma T^4$  and  $\sigma = 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4$ . Substituting numerical values, find  $F$ .

$$\frac{\left[ F \times 0.09 + (1-F) \times 0.22 \right] \times 1368 \text{ W/m}^2}{4} - \left[ F \times 0.03 + (1-F) \times 0.85 \times \sigma \times (300\text{K})^4 \right] = 0$$

$$F = 0.94$$

<

**COMMENTS:** (1) If the thermal control engineer desired to maintain the spacecraft at  $325 \text{ K}$ , would the fraction  $F$  (aluminum film) be increased or decreased? Verify your opinion with a calculation.

(2) If the internal power dissipation per unit surface area is  $150 \text{ W/m}^2$ , what fraction  $F$  will maintain the satellite at  $300 \text{ K}$ ?

### PROBLEM 12.133

**KNOWN:** Inner and outer radii, spectral reflectivity, and thickness of an annular fin. Base temperature and solar irradiation.

**FIND:** (a) Rate of heat dissipation if  $\eta_f = 1$ , (b) Differential equation governing radial temperature distribution in fin if  $\eta_f < 1$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, (2) One-dimensional radial conduction, (3) Adiabatic tip and bottom surface, (4) Opaque, diffuse surface ( $\alpha_\lambda = 1 - \rho_\lambda$ ,  $\varepsilon_\lambda = \alpha_\lambda$ ).

**ANALYSIS:** (a) If  $\eta_f = 1$ ,  $T(r) = T_b = 400$  K across the entire fin and

$$q_f = [\varepsilon E_b(T_b) - \alpha_S G_S] \pi r_o^2$$

With  $\lambda T = 2 \mu\text{m} \times 5800 \text{ K} = 11,600 \mu\text{m}\cdot\text{K}$ ,  $F_{(0 \rightarrow 2\mu\text{m})} = 0.941$ . Hence  $\alpha_S = \alpha_1 F_{(0 \rightarrow 2\mu\text{m})} +$

$\alpha_2 [1 - F_{(0 \rightarrow 2\mu\text{m})}] = 0.2 \times 0.941 + 0.9 \times 0.059 = 0.241$ . With  $\lambda T = 2 \mu\text{m} \times 400 \text{ K} = 800 \mu\text{m}\cdot\text{K}$ ,

$F_{(0 \rightarrow 2\mu\text{m})} = 0$  and  $\varepsilon = 0.9$ . Hence, for  $G_S = 0$ ,

$$q_f = 0.9 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (400 \text{ K})^4 \pi (0.5 \text{ m})^2 = 1026 \text{ W} \quad <$$

and for  $G_S = 1000 \text{ W/m}^2$ ,

$$q_f = 1026 \text{ W} - 0.241 (1000 \text{ W/m}^2) \pi (0.5 \text{ m})^2 = (1026 - 189) \text{ W} = 837 \text{ W} \quad <$$

(b) Performing an energy balance on a differential element extending from  $r$  to  $r+dr$ , we obtain

$$q_r + \alpha_S G_S (2\pi r dr) - q_{r+dr} - E (2\pi r dr) = 0$$

where

$$q_r = -k (dT/dr) 2\pi r t \quad \text{and} \quad q_{r+dr} = q_r + (dq_r/dr) dr.$$

Hence,

$$\alpha_S G_S (2\pi r dr) - d[-k (dT/dr) 2\pi r t] dr - E (2\pi r dr) = 0$$

$$2\pi r t k \frac{d^2 T}{dr^2} + 2\pi t k \frac{dT}{dr} + \alpha_S G_S 2\pi r - E 2\pi r = 0$$

$$k t \left( \frac{d^2 T}{dr^2} + \frac{1}{r} \frac{dT}{dr} \right) + \alpha_S G_S - \varepsilon \sigma T^4 = 0 \quad <$$

**COMMENTS:** The radiator should be constructed of a light weight, high thermal conductivity material (aluminum).

## PROBLEM 12.134

**KNOWN:** Rectangular plate, with prescribed geometry and thermal properties, for use as a radiator in a spacecraft application. Radiator exposed to solar radiation on upper surface, and to deep space on both surfaces.

**FIND:** Using a computer-based, finite-difference method with a space increment of 0.1 m, find the tip temperature,  $T_L$ , and rate of heat rejection,  $q_f$ , when the base temperature is maintained at  $80^\circ\text{C}$  for the cases: (a) when exposed to the sun, (b) on the dark side of the earth, not exposed to the sun; and (c) when the thermal conductivity is extremely large. Compare the case (c) results with those obtained from a hand calculation assuming the radiator is at a uniform temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (b) Plate-radiator behaves as an extended surface with one-dimensional conduction, and (c) Radiating tip condition.

**ANALYSIS:** The finite-difference network with 10 nodes and a space increment  $\Delta x = 0.1$  m is shown in the schematic below. The finite-difference equations (FDEs) are derived for an interior node (nodes 01 - 09) and the tip node (10). The energy balances are represented also in the schematic below where  $q_a$  and  $q_b$  represent conduction heat rates,  $q_S$  represents the absorbed solar radiation, and  $q_{rad}$  represents the radiation exchange with outer space.

**Finite-difference network, energy balances**

*Interior node 04*

$$\begin{aligned} \dot{E}_{in} - \dot{E}_{out} &= 0 \\ q_a + q_b + q_S + q_{rad} &= 0 \\ kA_c (T_{03} - T_{04}) / \Delta x + kA_c (T_{05} - T_{04}) / \Delta x \\ &+ \alpha_S G_S (P/2)\Delta x + \varepsilon P \Delta x \sigma (T_{sur}^4 - T_{04}^4) = 0 \end{aligned}$$

where  $P = 2W$  and  $A_c = W \cdot t$ .

*Tip node 10*

$$\begin{aligned} q_a + q_S + q_{rad,1} + q_{rad,2} &= 0 \\ kA_c (T_{09} - T_{10}) / \Delta x + \alpha_S G_S (P/2) (\Delta x / 2) \\ &+ \varepsilon A_c \sigma (T_{sur}^4 - T_{10}^4) + \varepsilon P (\Delta x / 2) \sigma (T_{sur}^4 - T_{04}^4) = 0 \end{aligned}$$

Continued ...

### PROBLEM 12.134 (Cont.)

Heat rejection,  $q_f$ . From an energy balance on the base node 00,

$$q_f + q_{01} + q_S + q_{\text{rad}} = 0$$

$$q_f + kA_c (T_{01} - T_{00}) / \Delta x + \alpha_S G_S (P/2) (\Delta x/2) + \varepsilon P (\Delta x/2) \sigma (T_{\text{sur}}^4 - T_{00}^4) = 0$$

The foregoing nodal equations and the heat rate expression were entered into the *IHT* workspace to obtain solutions for the three cases. See Comment 2 for the *IHT* code, and Comment 1 for code validation remarks.

Case	$k(\text{W/m}\cdot\text{K})$	$G_S(\text{W/m}^2)$	$T_L(^{\circ}\text{C})$	$q_f(\text{W})$	
a	300	1368	30.9	2746	<
b	300	0	-7.6	4720	<
c	$1 \times 10^{10}$	0	80.0	9565	<

Case (c) using the *IHT* code with  $k = 1 \times 10^{10}$  W/m·K corresponds to the condition of the plate at the uniform temperature of the base; that is  $T(x) = T_b$ . For this condition, the heat rejection from the upper and lower surfaces and the tip area can be calculated as

$$q_{f,u} = \varepsilon \sigma (T_b^4 - T_{\text{sur}}^4) [P \cdot L + A_c]$$

$$q_{f,u} = 0.9 \sigma [(80 + 273)^4 - 4^4] \text{W/m}^2 [12 + 6 \times 0.012] \text{m}^2$$

$$= 9674 \text{ W}$$

Note that the heat rejection rate for the uniform plate is in excellent agreement with the result of the FDE analysis when the thermal conductivity is made extremely large. We have confidence that the code is properly handling the conduction and radiation processes; but, we have not exercised the portion of the code dealing with the absorbed irradiation. What analytical solution/model could you use to validate this portion of the code?

**COMMENTS:** (1) The *IHT* code with the 10-nodal FDEs for the temperature distribution and the heat rejection rate is as follows.

#### **//Properties and dimensions**

```

W = 6 //m
t = 12/1000 //m
k = 300 //thermal conductivity (W/m-K)
eps = 0.90 //emissivity
absS = 0.45 //solar absorptivity
//Conditions
Tsur = 4 // (K)
T00 = 80 + 273 // (K)
GS = 1368 // (W/m^2)
Ac = t*W //cross sectional area (m^2)
P = 2*W //perimeter (m)
deltax = 0.1 // (m)
sigma=5.67e-8
    
```

Continued...

## PROBLEM 12.134 (Cont.)

### //Interior nodes, 01 to 09

$$k \cdot \text{Ac} \cdot (T_{00} - T_{01}) / \text{deltax} + k \cdot \text{Ac} \cdot (T_{02} - T_{01}) / \text{deltax} + \text{absS} \cdot \text{GS} \cdot P / 2 \cdot \text{deltax} + \text{eps} \cdot P \cdot \text{deltax} \cdot \text{sigma} \cdot (T_{\text{sur}}^4 - T_{01}^4) = 0$$

$$k \cdot \text{Ac} \cdot (T_{01} - T_{02}) / \text{deltax} + k \cdot \text{Ac} \cdot (T_{03} - T_{02}) / \text{deltax} + \text{absS} \cdot \text{GS} \cdot P / 2 \cdot \text{deltax} + \text{eps} \cdot P \cdot \text{deltax} \cdot \text{sigma} \cdot (T_{\text{sur}}^4 - T_{02}^4) = 0$$

$$k \cdot \text{Ac} \cdot (T_{02} - T_{03}) / \text{deltax} + k \cdot \text{Ac} \cdot (T_{04} - T_{03}) / \text{deltax} + \text{absS} \cdot \text{GS} \cdot P / 2 \cdot \text{deltax} + \text{eps} \cdot P \cdot \text{deltax} \cdot \text{sigma} \cdot (T_{\text{sur}}^4 - T_{03}^4) = 0$$

$$k \cdot \text{Ac} \cdot (T_{03} - T_{04}) / \text{deltax} + k \cdot \text{Ac} \cdot (T_{05} - T_{04}) / \text{deltax} + \text{absS} \cdot \text{GS} \cdot P / 2 \cdot \text{deltax} + \text{eps} \cdot P \cdot \text{deltax} \cdot \text{sigma} \cdot (T_{\text{sur}}^4 - T_{04}^4) = 0$$

$$k \cdot \text{Ac} \cdot (T_{04} - T_{05}) / \text{deltax} + k \cdot \text{Ac} \cdot (T_{06} - T_{05}) / \text{deltax} + \text{absS} \cdot \text{GS} \cdot P / 2 \cdot \text{deltax} + \text{eps} \cdot P \cdot \text{deltax} \cdot \text{sigma} \cdot (T_{\text{sur}}^4 - T_{05}^4) = 0$$

$$k \cdot \text{Ac} \cdot (T_{05} - T_{06}) / \text{deltax} + k \cdot \text{Ac} \cdot (T_{07} - T_{06}) / \text{deltax} + \text{absS} \cdot \text{GS} \cdot P / 2 \cdot \text{deltax} + \text{eps} \cdot P \cdot \text{deltax} \cdot \text{sigma} \cdot (T_{\text{sur}}^4 - T_{06}^4) = 0$$

$$k \cdot \text{Ac} \cdot (T_{06} - T_{07}) / \text{deltax} + k \cdot \text{Ac} \cdot (T_{08} - T_{07}) / \text{deltax} + \text{absS} \cdot \text{GS} \cdot P / 2 \cdot \text{deltax} + \text{eps} \cdot P \cdot \text{deltax} \cdot \text{sigma} \cdot (T_{\text{sur}}^4 - T_{07}^4) = 0$$

$$k \cdot \text{Ac} \cdot (T_{07} - T_{08}) / \text{deltax} + k \cdot \text{Ac} \cdot (T_{09} - T_{08}) / \text{deltax} + \text{absS} \cdot \text{GS} \cdot P / 2 \cdot \text{deltax} + \text{eps} \cdot P \cdot \text{deltax} \cdot \text{sigma} \cdot (T_{\text{sur}}^4 - T_{08}^4) = 0$$

$$k \cdot \text{Ac} \cdot (T_{08} - T_{09}) / \text{deltax} + k \cdot \text{Ac} \cdot (T_{10} - T_{09}) / \text{deltax} + \text{absS} \cdot \text{GS} \cdot P / 2 \cdot \text{deltax} + \text{eps} \cdot P \cdot \text{deltax} \cdot \text{sigma} \cdot (T_{\text{sur}}^4 - T_{09}^4) = 0$$

### //Tip node, 10

$$//k \cdot \text{Ac} \cdot (T_{09} - T_{10}) / \text{deltax} + \text{absS} \cdot \text{GS} \cdot (P/2) \cdot (\text{deltax}/2) + \text{eps} \cdot (P \cdot \text{deltax}/2 + \text{Ac}) \cdot \text{sigma} \cdot (T_{\text{sur}}^4 - T_{10}^4) = 0$$

$$\text{TLC} = T_{10} - 273$$

### //Rejection heat rate, energy balance on base node

$$q_f + k \cdot \text{Ac} \cdot (T_{01} - T_{00}) / \text{deltax} + \text{absS} \cdot \text{GS} \cdot (P/2) \cdot (\text{deltax}/2) + \text{eps} \cdot (P \cdot \text{deltax}/2) \cdot \text{sigma} \cdot (T_{\text{sur}}^4 - T_{00}^4) = 0$$

### //Check

$$q_{fu} = \text{eps} \cdot \text{sigma} \cdot ((80 + 273)^4 - 4^4) \cdot (P \cdot 1 + \text{Ac})$$

(2) To determine the validity of the one-dimensional, extended surface analysis, calculate the Biot number estimating the linearized radiation coefficient based upon the uniform plate condition,  $T_b = 80^\circ\text{C}$ .

$$\text{Bi} = h_{\text{rad}} (t/2) / k$$

$$h_{\text{rad}} = \varepsilon \sigma (T_b + T_{\text{sur}}) (T_b^2 + T_{\text{sur}}^2) \approx \varepsilon \sigma T_b^3 = 2.25 \text{ W} / \text{m}^2 \cdot \text{K}$$

$$\text{Bi} = 2.25 \text{ W} / \text{m}^2 \cdot \text{K} (0.012 \text{ m} / 2) / 300 \text{ W} / \text{m} \cdot \text{K} = 4.5 \times 10^{-5}$$

Since  $\text{Bi} \ll 0.1$ , the assumption of one-dimensional conduction is appropriate.

## PROBLEM 12.135

**KNOWN:** Directional absorptivity of a plate exposed to solar radiation on one side.

**FIND:** (a) Ratio of normal absorptivity to hemispherical emissivity, (b) Equilibrium temperature of plate at  $0^\circ$  and  $75^\circ$  orientation relative to sun's rays.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Surface is gray, (2) Properties are independent of  $\phi$ .

**ANALYSIS:** (a) From the prescribed  $\alpha_\theta(\theta)$ ,  $\alpha_n = 0.9$ . Since the surface is gray,  $\varepsilon_\theta = \alpha_\theta$ . Hence from Eq. 12.42, which applies for total as well as spectral properties.

$$\varepsilon = 2 \int_0^{\pi/2} \varepsilon_\theta \cos \theta \sin \theta d\theta = 2 \left[ 0.9 \frac{\sin^2 \theta}{2} \Big|_0^{\pi/3} + 0.1 \frac{\sin^2 \theta}{2} \Big|_{\pi/3}^{\pi/2} \right]$$

$$\varepsilon = 2 \left[ 0.9(0.375) + 0.1(0.5 - 0.375) \right] = 0.70.$$

Hence

$$\frac{\alpha_n}{\varepsilon} = \frac{0.9}{0.7} = 1.286.$$

(b) Performing an energy balance on the plate,

$$\alpha_\theta q_s'' \cos \theta - 2 \varepsilon \sigma T_s^4 = 0$$

or

$$T_s = \left[ \frac{\alpha_\theta q_s'' \cos \theta}{2 \varepsilon \sigma} \right]^{1/4}.$$

Hence for  $\theta = 0^\circ$ ,  $\alpha_\theta = 0.9$  and  $\cos \theta = 1$ ,

$$T_s = \left[ \frac{0.9}{2 \times 0.7 \times 5.67 \times 10^{-8}} \times 1368 \right]^{1/4} = 353\text{K.} \quad <$$

For  $\theta = 75^\circ$ ,  $\alpha_\theta = 0.1$  and  $\cos \theta = 0.259$

$$T_s = \left[ \frac{0.1}{2 \times 0.7 \times 5.67 \times 10^{-8}} \times 1368 \times 0.259 \right]^{1/4} = 145\text{K.} \quad <$$

**COMMENTS:** Since the surface is not diffuse, its absorptivity depends on the directional distribution of the incident radiation.

### PROBLEM 12.136

**KNOWN:** Transmissivity of cover plate and spectral absorptivity of absorber plate for a solar collector.

**FIND:** Absorption rate for prescribed solar flux and preferred absorber plate coating.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Solar irradiation of absorber plate retains spectral distribution of blackbody at 5800K, (2) Coatings are diffuse.

**ANALYSIS:** At the absorber plate we wish to maximize solar radiation absorption and minimize losses due to emission. The solar radiation is concentrated in the spectral region  $\lambda < 4\mu\text{m}$ , and for a representative plate temperature of  $T \leq 350\text{K}$ , emission from the plate is concentrated in the spectral region  $\lambda > 4\mu\text{m}$ . Hence,

*Coating A is vastly superior.* <

With  $G_{\lambda,S} \sim E_{\lambda,b}(5800\text{K})$ , it follows from Eq. 12.53

$$\alpha_A \approx 0.85 F_{(0-4\mu\text{m})} + 0.05 F_{(4\mu\text{m}-\infty)}.$$

From Table 12.1,  $\lambda T = 4\mu\text{m} \times 5800\text{K} = 23,200\mu\text{m}\cdot\text{K}$ ,

$$F_{(0-4\mu\text{m})} \approx 0.99.$$

Hence

$$\alpha_A = 0.85(0.99) + 0.05(1 - 0.99) \approx 0.85.$$

With  $G_S = 1000 \text{ W/m}^2$  and  $\tau = 0.84$  (Ex. 12.9), the absorbed solar flux is

$$G_{S,\text{abs}} = \alpha_A (\tau G_S) = 0.85 (0.84 \times 1000 \text{ W/m}^2)$$

$$G_{S,\text{abs}} = 714 \text{ W/m}^2. <$$

**COMMENTS:** Since the absorber plate emits in the infrared ( $\lambda > 4\mu\text{m}$ ), its emissivity is  $\epsilon_A \approx 0.05$ . Hence  $(\alpha/\epsilon)_A = 17$ . A large value of  $\alpha/\epsilon$  is desirable for solar absorbers.

## PROBLEM 12.137

**KNOWN:** Irradiation of satellite from earth and sun. Two emissivities associated with the satellite.

**FIND:** (a) Steady-state satellite temperature when satellite is on bright side of earth for  $\alpha_E/\alpha_s > 1$  and  $\alpha_E/\alpha_s < 1$ , (b) Steady-state satellite temperature when satellite is on dark side of earth for  $\alpha_E/\alpha_s > 1$  and  $\alpha_E/\alpha_s < 1$ , (c) Scheme to minimize temperature variations of the satellite.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Opaque, diffuse gray behavior.

**ANALYSIS:** Performing an energy balance on the satellite, it follows that  $\dot{E}_{in} = \dot{E}_{out}$  or

$$\alpha_E G_E (\pi D^2 / 4) + \alpha_s G_s (\pi D^2 / 4) - \epsilon_E \sigma T_{sat}^4 (\pi D^2 / 2) - \epsilon_s \sigma T_{sat}^4 (\pi D^2 / 2) = 0$$

or

$$T_{sat} = \left[ \frac{\alpha_E G_E + \alpha_s G_s}{2(\epsilon_E + \epsilon_s) \sigma} \right]^{1/4}$$

(a) Bright Side of Earth ( $G_s = 1368 \text{ W/m}^2$ ).

For  $\alpha_E = \epsilon_E = \alpha_2 = 0.3$ ,  $\alpha_s = \epsilon_s = \alpha_1 = 0.6$ ,

$$T_{sat} = \left[ \frac{0.3 \times 340 \text{ W/m}^2 + 0.6 \times 1353 \text{ W/m}^2}{2 \times (0.3 + 0.6) \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4} \right]^{1/4} = 308 \text{ K} \quad <$$

For  $\alpha_E = \epsilon_E = \alpha_1 = 0.6$ ,  $\alpha_s = \epsilon_s = \alpha_2 = 0.3$ ,

$$T_{sat} = \left[ \frac{0.6 \times 340 \text{ W/m}^2 + 0.3 \times 1353 \text{ W/m}^2}{2 \times (0.6 + 0.3) \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4} \right]^{1/4} = 279 \text{ K} \quad <$$

(b) Dark Side of Earth ( $G_s = 0 \text{ W/m}^2$ ).

For  $\alpha_E = \epsilon_E = \alpha_1 = 0.6$ ,  $\alpha_s = \epsilon_s = \alpha_2 = 0.3$ ,

Continued...

**PROBLEM 12.137 (Cont.)**

$$T_{\text{sat}} = \left[ \frac{0.6 \times 340 \text{ W/m}^2}{2 \times (0.6 + 0.3) \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4} \right]^{1/4} = 211 \text{ K} \quad <$$

For  $\alpha_E = \varepsilon_E = \alpha_2 = 0.3$ ,  $\alpha_s = \varepsilon_s = \alpha_1 = 0.6$ ,

$$T_{\text{sat}} = \left[ \frac{0.3 \times 340 \text{ W/m}^2}{2 \times (0.3 + 0.6) \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4} \right]^{1/4} = 178 \text{ K} \quad <$$

(c) To minimize the temperature variations of the satellite, we would have the high emissivity coating always facing earth.

**COMMENTS:** If the entire satellite were covered with either coating, the temperatures on the bright and dark sides of earth would be  $T_s = 294 \text{ K}$  and  $197 \text{ K}$ , respectively. Use of the two emissivity coatings reduces temperature variations from  $294 \text{ K} - 197 \text{ K} = 97 \text{ K}$  to  $278 \text{ K} - 211 \text{ K} = 67 \text{ K}$ .

## PROBLEM 12.138

**KNOWN:** Space capsule fired from earth orbit platform in direction of sun.

**FIND:** (a) Differential equation predicting capsule temperature as a function of time, (b) Position of capsule relative to sun when it reaches its destruction temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Capsule behaves as lumped capacitance system, (2) Capsule surface is black, (3) Temperature of surroundings approximates absolute zero, (4) Capsule velocity is constant.

**ANALYSIS:** (a) To find the temperature as a function of time, perform an energy balance on the capsule considering absorbed solar irradiation and emission,

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \dot{E}_{\text{st}} \quad G_S \cdot \pi R^2 - \sigma T^4 \cdot 4\pi R^2 = \rho c (4/3) \pi R^3 (dT/dt). \quad (1)$$

Note the use of the projected capsule area ( $\pi R^2$ ) and the surface area ( $4\pi R^2$ ). The solar irradiation will increase with decreasing radius (distance toward the sun) as

$$G_S(r) = G_{S,e} (r_e / r)^2 = G_{S,e} (r_e / (r_e - Vt))^2 = G_{S,e} (1 / (1 - Vt / r_e))^2 \quad (2)$$

where  $r_e$  is the distance of earth orbit from the sun and  $r = r_e - Vt$ . Hence, Eq. (1) becomes

$$\frac{dT}{dt} = \frac{3}{\rho c R} \left[ \frac{G_{S,e}}{4(1 - Vt / r_e)^2} - \sigma T^4 \right].$$

The rate of temperature change is

$$\frac{dT}{dt} = \frac{3}{(4 \times 10^6 \text{ J/m}^3 \cdot \text{K} \times 1.5 \text{ m})} \left[ \frac{1368 \text{ W/m}^2}{4(1 - 16 \times 10^3 \text{ m/s} \times t / 1.5 \times 10^{11} \text{ m})^2} - \sigma T^4 \right]$$

$$\frac{dT}{dt} = 1.691 \times 10^{-4} (1 - 1.067 \times 10^{-7} t)^{-2} - 2.835 \times 10^{-14} T^4$$

where  $T[\text{K}]$  and  $t(\text{s})$ . For the initial condition,  $t = 0$ , with  $T = 20^\circ\text{C} = 293\text{K}$ ,

$$\frac{dT}{dt}(0) = -3.9 \times 10^{-5} \text{ K/s.} \quad \leftarrow$$

That is, the capsule will cool for a period of time and then begin to heat.

(b) The differential equation cannot be explicitly solved for temperature as a function of time. Using a numerical method with a time increment of  $\Delta t = 5 \times 10^5 \text{ s}$ , find

$$T(t) = 150^\circ\text{C} = 423 \text{ K} \quad \text{at} \quad t \approx 5.5 \times 10^6 \text{ s.} \quad \leftarrow$$

Note that in this period of time the capsule traveled  $(r_e - r) = Vt = 16 \times 10^3 \text{ m/s} \times 5.5 \times 10^6 = 1.472 \times 10^{10} \text{ m}$ . That is,  $r = 1.353 \times 10^{11} \text{ m}$ .

## PROBLEM 12.139

**KNOWN:** Solar irradiation of coated aluminum. Spectral absorptivities above and below cutoff wavelength. Cutoff wavelength under normal conditions.

**FIND:** (a) Equilibrium temperature for normal conditions with  $\lambda_c = 0.15 \mu\text{m}$ . (b) Value of  $\lambda_c$  that will maximize surface temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady state conditions. (2) Solar irradiation approximated as that from a blackbody at  $T = 5800 \text{ K}$ .

**ANALYSIS:** (a) For the control surface shown in the schematic  $\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$  or  $G_s = J$  or  $\alpha_s G_s = \varepsilon \sigma T_s^4$ . Therefore,

$$T_s = \left[ \frac{\alpha_s G_s}{\varepsilon \sigma} \right]^{1/4} \quad (1)$$

The solar irradiation is approximated as that of a blackbody at  $5800 \text{ K}$ . From Table 12.1,  $F_{(0-\lambda_c)} = F_{(0-0.15\mu\text{m})} \approx 0$ . Therefore,

$$\alpha_s = \alpha_{\lambda,1} F_{(0-\lambda_c)} + \alpha_{\lambda,2} [1 - F_{(0-\lambda_c)}] = 0.98 \times 0 + 0.05 \times [1 - 0] = 0.05$$

The surface emissivity may be expressed as  $\varepsilon = \alpha_{\lambda,1} F_{(0-\lambda_c \cdot T_s)} + \alpha_{\lambda,2} [1 - F_{(0-\lambda_c \cdot T_s)}]$  (2)

where the variable  $F_{(0-\lambda_c \cdot T_s)}$  is the fraction of blackbody radiation in the band between  $0 \mu\text{m} \cdot \text{K}$  and  $\lambda_c T_s$ . Combining Equations 1 and 2 yields

Continued...

### PROBLEM 12.139 (Cont.)

$$T_s = \left[ \frac{0.05 \times 1368 \text{ W/m}^2}{\left\{ 0.98 \times F_{(0-\lambda_c, T_s)} + 0.05 \times [1 - F_{(0-\lambda_c, T_s)}] \right\} \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4} \right]^{1/4}$$

which may be solved by trial-and-error (since  $F_{(0-\lambda_c, T_s)}$  is a function of  $T_s$ ) to yield  $T_s = 394.1 \text{ K}$ . <

Equations 1 and 2 may be solved by trial-and-error to yield a maximum surface temperature of  $T_s = 797 \text{ K}$  at a cutoff wavelength of  $\lambda_c = 1.50 \mu\text{m}$ . <

**COMMENTS:** (1) The small value of  $\lambda_c$  that exists under normal conditions, coupled with the relatively low surface temperature, yields a surface emissivity of 0.05. (2) The emissivity and absorptivity associated with the surface temperature of  $T_s = 797 \text{ K}$  are  $\varepsilon = 0.052$  and  $\alpha = 0.869$ , respectively. (3) The variation of the surface temperature with the cutoff wavelength is shown in the plot below. Manipulation of the cutoff wavelength is an effective approach for achieving desired thermal performance.

## PROBLEM 12.140

**KNOWN:** Irradiation from the sun and earth on a spherical satellite. Spectral absorptivities of the satellite surface below and above a cutoff wavelength.

**FIND:** (a) Cutoff wavelength to minimize satellite temperature on bright side of earth, corresponding satellite temperature on dark side of earth, (b) Cutoff wavelength to maximize satellite temperature on dark side of earth, corresponding satellite temperature on bright side of earth.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Opaque, diffuse satellite surface.

**ANALYSIS:** Performing an energy balance on the satellite, it follows that  $\dot{E}_{in} = \dot{E}_{out}$  or

$$\alpha_E G_E (\pi D^2 / 4) + \alpha_s G_s (\pi D^2 / 4) - \epsilon \sigma T_s^4 (\pi D^2) = 0$$

or

$$T_s = \left[ \frac{\alpha_E G_E + \alpha_s G_s}{4 \epsilon \sigma} \right]^{1/4} \quad (1)$$

(a) Bright Side of Earth, Minimize  $T_s$ .

For earth irradiation being approximated as that of a blackbody at 280 K,

$$\alpha_E = \alpha_{\lambda,1} F_{(0-\lambda_c, 280K)} + \alpha_{\lambda,2} [1 - F_{(0-\lambda_c, 280K)}] \quad (2)$$

For solar irradiation being approximated as that of a blackbody at 5800K,

$$\alpha_s = \alpha_{\lambda,1} F_{(0-\lambda_c, 5800K)} + \alpha_{\lambda,2} [1 - F_{(0-\lambda_c, 5800K)}] \quad (3)$$

The satellite emissivity is, with  $\epsilon_\lambda = \alpha_\lambda$ ,  $\epsilon = \alpha_{\lambda,1} F_{(0-\lambda_c, T_s)} + \alpha_{\lambda,2} [1 - F_{(0-\lambda_c, T_s)}]$  (4)

Equations 1 through 4 may be solved using various  $\lambda_c$  yielding a minimum satellite temperature of  $T_s = 295 \text{ K}$  for  $\lambda_c = 0$  or  $\infty$ .

<  
Continued...

## PROBLEM 12.140 (Cont.)

(a) Dark Side of Earth, Maximize  $T_s$ .

For the satellite on the dark side of earth with a spectrally-selective coating, Equation 1 becomes

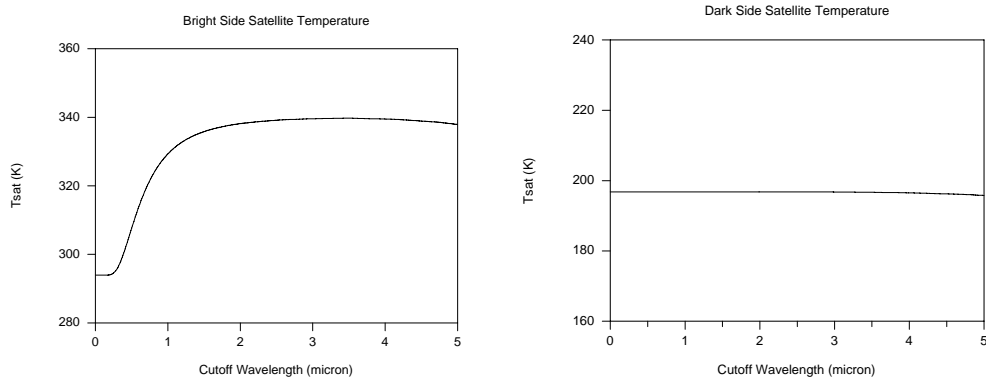

$$T_s = \left[ \frac{\alpha_E G_E}{4\epsilon\sigma} \right]^{1/4} \quad (5)$$

Equations 2 through 5 may be solved using various  $\lambda_c$ , yielding a maximum satellite temperature of  $T_s = 205 \text{ K}$  at  $\lambda_c = 13.57 \text{ }\mu\text{m}$ . <

The corresponding values of  $\alpha_E$ ,  $\alpha_s$  and  $\epsilon$  are 0.4330, 0.5999 and 0.3672, respectively.

When the satellite is on the bright side with  $\lambda_c = 13.57 \text{ }\mu\text{m}$ , the satellite temperature may be found by solving Equations 1 through 4 yielding a temperature of  $T_s = 310.4 \text{ K}$ . The corresponding values of  $\alpha_E$ ,  $\alpha_s$  and  $\epsilon$  are 0.4330, 0.5999 and 0.4554, respectively. <

**COMMENT:** In part (a) of the problem the satellite temperature is very sensitive to the cutoff wavelength of  $\lambda_c = 0$  when the satellite is on the bright side of earth. This is because of the presence of a significant amount of solar irradiation at relatively short wavelengths.

For part (b) of the problem, the dark side satellite temperature is relatively insensitive to the cutoff wavelength because of the similar spectral distributions of the earth irradiation and the satellite emission. In contrast, however, the temperature of the satellite on the bright side of earth is much more sensitive to the cutoff wavelength because of the presence of significant irradiation from the sun at short wavelengths.

## PROBLEM 12.141

**KNOWN:** Solar panel mounted on a spacecraft of area  $1 \text{ m}^2$  having a solar-to-electrical power conversion efficiency of 12% with specified radiative properties.

**FIND:** (a) Steady-state temperature of the solar panel and electrical power produced with solar irradiation of  $1500 \text{ W/m}^2$ , (b) Steady-state temperature if the panel were a thin plate (no solar cells) with the same radiative properties and for the same prescribed conditions, and (c) Temperature of the solar panel 1500 s after the spacecraft is eclipsed by a planet; thermal capacity of the panel per unit area is  $9000 \text{ J/m}^2 \cdot \text{K}$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Solar panel and thin plate are isothermal, (2) Solar irradiation is normal to the panel upper surface, and (3) Panel has unobstructed view of deep space at 0 K.

**ANALYSIS:** (a) The energy balance on the solar panel is represented in the schematic below and has the form

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = 0$$

$$\alpha_S G_S \cdot A_p - (\varepsilon_a + \varepsilon_b) E_b(T_{\text{sp}}) \cdot A_p - P_{\text{elec}} = 0 \quad (1)$$

where  $E_b(T) = \sigma T^4$ ,  $\sigma = 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4$ , and the electrical power produced is

$$P_{\text{elec}} = e \cdot G_S \cdot A_p \quad (2)$$

$$P_{\text{elec}} = 0.12 \times 1500 \text{ W/m}^2 \times 1 \text{ m}^2 = 180 \text{ W} \quad <$$

Substituting numerical values into Eq. (1), find

$$0.8 \times 1500 \text{ W/m}^2 \times 1 \text{ m}^2 - (0.8 + 0.7) \sigma T_{\text{sp}}^4 \times 1 \text{ m}^2 - 180 \text{ W} = 0$$

$$T_{\text{sp}} = 330.9 \text{ K} = 57.9^\circ \text{C} \quad <$$

(b) The energy balance for the thin plate shown in the schematic above follows from Eq. (1) with  $P_{\text{elec}} = 0$  yielding

$$0.8 \times 1500 \text{ W/m}^2 \times 1 \text{ m}^2 - (0.8 + 0.7) \sigma T_p^4 \times 1 \text{ m}^2 = 0 \quad (3)$$

$$T_p = 344.7 \text{ K} = 71.7^\circ \text{C} \quad <$$

Continued ...

### PROBLEM 12.141 (Cont.)

(c) Using the lumped capacitance method, the energy balance on the solar panel as illustrated in the schematic below has the form

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \dot{E}_{\text{st}}$$

$$-(\varepsilon_a + \varepsilon_b) \sigma T_{\text{sp}}^4 \cdot A_p = TC'' \cdot A_p \frac{dT_{\text{sp}}}{dt} \quad (4)$$

where the thermal capacity per unit area is  $TC'' = (Mc / A_p) = 9000 \text{ J} / \text{m}^2 \cdot \text{K}$ .

Eq. 5.18 provides the solution to this differential equation in terms of  $t = t(T_i, T_{\text{sp}})$ . Alternatively, use Eq. (4) in the *IHT* workspace (see Comment 4 below) to find

$$T_{\text{sp}}(1500 \text{ s}) = 242.6 \text{ K} = -30.4^\circ \text{C} \quad <$$

**COMMENTS:** (1) For part (a), the energy balance could be written as

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} + \dot{E}_{\text{g}} = 0$$

where the energy generation term represents the *conversion process from thermal energy to electrical energy*. That is,

$$\dot{E}_{\text{g}} = -e \cdot G_S \cdot A_p$$

(2) The steady-state temperature for the thin plate, part (b), is higher than for the solar panel, part (a). This is to be expected since, for the solar panel, some of the absorbed solar irradiation (thermal energy) is converted to electrical power.

(3) To justify use of the lumped capacitance method for the transient analysis, we need to know the effective thermal conductivity or internal thermal resistance of the solar panel.

(4) Selected portions of the *IHT* code using the *Models Lumped | Capacitance* tool to perform the transient analysis based upon Eq. (4) are shown below.

```
// Energy balance, Model | Lumped Capacitance
/* Conservation of energy requirement on the control volume, CV. */
Edotin - Edotout = Edotst
Edotin = 0
Edotout = Ap * (+q"rad)
Edostat = rhovolcp * Ap * Der(T,t)
// rhovolcp = rho * vol * cp // thermal capacitance per unit area, J/m^2-K

// Radiation exchange between Cs and large surroundings
q"rad = (eps_a + eps_b) * sigma * (T^4 - Tsur^4)
sigma = 5.67e-8 // Stefan-Boltzmann constant, W/m^2-K^4

// Initial condition
// Ti = 57.93 + 273 = 330.9 // From part (a), steady-state condition
T_C = T - 273
```

(5) The solar flux exceeds the solar constant value of  $1368 \text{ W/m}^2$ . Hence the spacecraft is closer to the sun than is earth.

## PROBLEM 12.142

**KNOWN:** Effective sky temperature and convection heat transfer coefficient associated with a thin layer of water.

**FIND:** Lowest air temperature for which the water will not freeze (without and with evaporation).

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Bottom of water is adiabatic, (3) Heat and mass transfer analogy is applicable, (4) Air is dry.

**PROPERTIES:** Table A-4, Air (273 K, 1 atm):  $\rho = 1.287 \text{ kg/m}^3$ ,  $c_p = 1.01 \text{ kJ/kg}\cdot\text{K}$ ,  $\nu = 13.49 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.72$ ; Table A-6, Saturated vapor ( $T_s = 273 \text{ K}$ ):  $\rho_A = 4.8 \times 10^{-3} \text{ kg/m}^3$ ,  $h_{fg} = 2502 \text{ kJ/kg}$ ; Table A-8, Vapor-air (298 K):  $D_{AB} \approx 0.36 \times 10^{-4} \text{ m}^2/\text{s}$ ,  $\text{Sc} = \nu/D_{AB} = 0.52$ .

**ANALYSIS:** Without evaporation, the surface heat loss by radiation must be balanced by heat gain due to convection. An energy balance gives

$$q''_{\text{conv}} = q''_{\text{rad}} \quad \text{or} \quad h(T_\infty - T_s) = \epsilon_s \sigma (T_s^4 - T_{\text{sky}}^4).$$

At freezing,  $T_s = 273 \text{ K}$ . Hence

$$T_\infty = T_s + \frac{\epsilon_s \sigma}{h} (T_s^4 - T_{\text{sky}}^4) = 273 \text{ K} + \frac{5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4}{25 \text{ W/m}^2 \cdot \text{K}} [274^4 - 243^4] \text{ K}^4 = 4.69^\circ\text{C}. \quad <$$

With evaporation, the surface energy balance is now

$$q''_{\text{conv}} = q''_{\text{evap}} + q''_{\text{rad}} \quad \text{or} \quad h(T_\infty - T_s) = h_m [\rho_{A,\text{sat}}(T_s) - \rho_{A,\infty}] h_{fg} + \epsilon_s \sigma (T_s^4 - T_{\text{sky}}^4).$$

$$T_\infty = T_s + \frac{h_m}{h} \rho_{A,\text{sat}}(T_s) h_{fg} + \frac{\epsilon_s \sigma}{h} (T_s^4 - T_{\text{sky}}^4).$$

Substituting from Eq. 6.60, with  $n \approx 0.33$ ,

$$\begin{aligned} h_m / h &= \left( \rho c_p \text{Le}^{0.67} \right)^{-1} = \left[ \rho c_p (\text{Sc} / \text{Pr})^{0.67} \right]^{-1} \\ &= \left[ 1.287 \text{ kg/m}^3 \times 1010 \text{ J/kg}\cdot\text{K} (0.52 / 0.72)^{0.67} \right]^{-1} \\ &= 9.57 \times 10^{-4} \text{ m}^3 \cdot \text{K} / \text{J}, \end{aligned}$$

$$T_\infty = 273 \text{ K} + 9.57 \times 10^{-4} \text{ m}^3 \cdot \text{K} / \text{J} \times 4.8 \times 10^{-3} \text{ kg/m}^3 \times 2.5 \times 10^6 \text{ J/kg} + 4.69 \text{ K} = 16.2^\circ\text{C}. \quad <$$

**COMMENTS:** The existence of clear, cold skies and dry air will allow water to freeze for ambient air temperatures well above  $0^\circ\text{C}$  (due to radiative and evaporative cooling effects, respectively). The lowest air temperature for which the water will not freeze increases with decreasing  $\phi_\infty$ , decreasing  $T_{\text{sky}}$  and decreasing  $h$ .

### PROBLEM 12.143

**KNOWN:** Temperature and environmental conditions associated with a shallow layer of water.

**FIND:** Whether water temperature will increase or decrease with time.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Water layer is well mixed (uniform temperature), (2) All non-reflected radiation is absorbed by water, (3) Bottom is adiabatic, (4) Heat and mass transfer analogy is applicable, (5) Perfect gas behavior for water vapor.

**PROPERTIES:** Table A-4, Air ( $T = 300 \text{ K}$ , 1 atm):  $\rho_a = 1.161 \text{ kg/m}^3$ ,  $c_{p,a} = 1007 \text{ J/kg}\cdot\text{K}$ ,  $\text{Pr} = 0.707$ ; Table A-6, Water ( $T = 300 \text{ K}$ , 1 atm):  $\rho_w = 997 \text{ kg/m}^3$ ,  $c_{p,w} = 4179 \text{ J/kg}\cdot\text{K}$ ; Vapor ( $T = 300 \text{ K}$ , 1 atm):  $\rho_{A,\text{sat}} = 0.0256 \text{ kg/m}^3$ ,  $h_{fg} = 2.438 \times 10^6 \text{ J/kg}$ ; Table A-8, Water vapor-air ( $T = 300 \text{ K}$ , 1 atm):  $D_{AB} \approx 0.26 \times 10^{-4} \text{ m}^2/\text{s}$ ; with  $v_a = 15.89 \times 10^{-6} \text{ m}^2/\text{s}$  from Table A-4,  $\text{Sc} = v_a/D_{AB} = 0.61$ .

**ANALYSIS:** Performing an energy balance on a control volume about the water,

$$\dot{E}_{st} = (G_{S,\text{abs}} + G_{A,\text{abs}} - E - q''_{\text{evap}})A$$

$$\frac{d(\rho_w c_{p,w} L A T_w)}{dt} = \left[ (1 - \rho_s) G_S + (1 - \rho_A) G_A - \epsilon \sigma T_w^4 - h_m h_{fg} (\rho_{A,\text{sat}} - \rho_{A,\infty}) \right] A$$

or, with  $T_\infty = T_w$ ,  $\rho_{A,\infty} = \phi_\infty \rho_{A,\text{sat}}$  and

$$\rho_w c_{p,w} L \frac{dT_w}{dt} = (1 - \rho_s) G_S + (1 - \rho_A) G_A - \epsilon \sigma T_w^4 - h_m h_{fg} (1 - \phi_\infty) \rho_{A,\text{sat}}$$

From Eq. 6.60, with a value of  $n = 1/3$ ,

$$h_m = \frac{h}{\rho_a c_{p,a} \text{Le}^{1-n}} = \frac{h}{\rho_a c_{p,a} (\text{Sc}/\text{Pr})^{1-n}} = \frac{25 \text{ W/m}^2 \cdot \text{K} (0.707)^{2/3}}{1.161 \text{ kg/m}^3 \times 1007 \text{ J/kg} \cdot \text{K} (0.61)^{2/3}} = 0.0236 \text{ m/s}.$$

Hence

$$\rho_w c_{p,w} L \frac{dT_w}{dt} = (1 - 0.3) 600 + (1 - 0) 300 - 0.97 \times 5.67 \times 10^{-8} (300)^4 - 0.0236 \times 2.438 \times 10^6 (1 - 0.5) 0.0256$$

$$\rho_w c_{p,w} L \frac{dT_w}{dt} = (420 + 300 - 445 - 736) \text{ W/m}^2 = -461 \text{ W/m}^2.$$

Hence the water will *cool*. <

**COMMENTS:** (1) Since  $T_w = T_\infty$  for the prescribed conditions, there is no convection of sensible energy. However, as the water cools, there will be convection heat transfer from the air. (2) If  $L = 1 \text{ m}$ ,  $(dT_w/dt) = -461/(997 \times 4179 \times 1) = -1.11 \times 10^{-4} \text{ K/s}$ .

## PROBLEM 12.144

**KNOWN:** Environmental conditions for a metal roof with and without a water film.

**FIND:** Roof surface temperature (a) without the film, (b) with the film.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Diffuse-gray surface behavior in the infrared (for the metal,  $\alpha_{\text{sky}} = \varepsilon = 0.3$ ; for the water,  $\alpha_{\text{sky}} = \varepsilon = 0.9$ ), (3) Adiabatic roof bottom, (4) Perfect gas behavior for vapor.

**PROPERTIES:** Table A-4, Air ( $T \approx 300$  K):  $\rho = 1.16$  kg/m<sup>3</sup>,  $c_p = 1007$  J/kg·K,  $\alpha = 22.5 \times 10^{-6}$  m<sup>2</sup>/s; Table A-6, Water vapor ( $T \approx 303$  K):  $v_g = 32.4$  m<sup>3</sup>/kg or  $\rho_{A,\text{sat}} = 0.031$  kg/m<sup>3</sup>; Table A-8, Water vapor-air ( $T = 298$  K):  $D_{AB} = 0.26 \times 10^{-4}$  m<sup>2</sup>/s.

**ANALYSIS:** (a) From an energy balance on the metal roof

$$\begin{aligned} \alpha_S G_S + \alpha_{\text{sky}} G_{\text{atm}} &= E + q''_{\text{conv}} \\ 0.5(700 \text{ W/m}^2) + 0.3 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (263 \text{ K})^4 \\ &= 0.3 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (T_S^4) + 20 \text{ W/m}^2 \cdot \text{K} (T_S - 303 \text{ K}) \\ 431 \text{ W/m}^2 &= 1.70 \times 10^{-8} T_S^4 + 20(T_S - 303). \end{aligned} \quad <$$

From a trial-and-error solution,  $T_S = 316.1$  K = 43.1°C.

(b) From an energy balance on the water film,

$$\begin{aligned} \alpha_S G_S + \alpha_{\text{sky}} G_{\text{atm}} &= E + q''_{\text{conv}} + q''_{\text{evap}} \\ 0.8(700 \text{ W/m}^2) + 0.9 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (263 \text{ K})^4 &= 0.9 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (T_S^4) \\ &+ 20 \text{ W/m}^2 \cdot \text{K} (T_S - 303) + h_m (\rho_{A,\text{sat}}(T_S) - 0.65 \times 0.031 \text{ kg/m}^3) h_{\text{fg}}. \end{aligned}$$

From Eq. 6.60, assuming  $n = 0.33$ ,

$$\begin{aligned} h_m &= \frac{h}{\rho c_p \text{Le}^{0.67}} = \\ \frac{h}{\rho c_p (\alpha / D_{AB})^{0.67}} &= \frac{20 \text{ W/m}^2 \cdot \text{K}}{1.16 \text{ kg/m}^3 \times 1007 \text{ J/kg} \cdot \text{K} (0.225 \times 10^{-4} / 0.260 \times 10^{-4})^{0.67}} = 0.019 \text{ m/s}. \end{aligned}$$

$$804 \text{ W/m}^2 = 5.10 \times 10^{-8} T_S^4 + 20(T_S - 303) + 0.019 [\rho_{A,\text{sat}}(T_S) - 0.020] h_{\text{fg}}.$$

From a trial-and-error solution, obtaining  $\rho_{A,\text{sat}}(T_S)$  and  $h_{\text{fg}}$  from Table A-6 for each assumed value of  $T_S$ , it follows that

$$T_S = 302.2 \text{ K} = 29.2^\circ\text{C}. \quad <$$

**COMMENTS:** (1) The film is an effective coolant, reducing  $T_S$  by 13.9°C. (2) With the film  $E \approx 425$  W/m<sup>2</sup>,  $q''_{\text{conv}} \approx -16$  W/m<sup>2</sup> and  $q''_{\text{evap}} \approx 428$  W/m<sup>2</sup>.

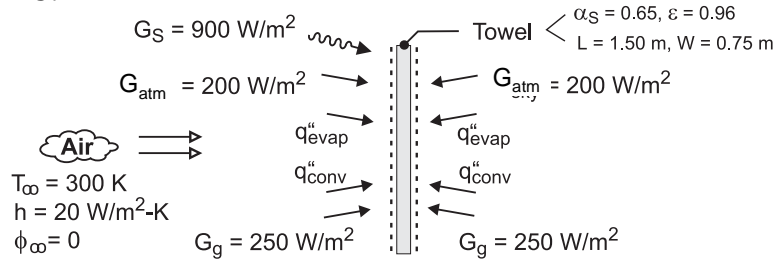

## PROBLEM 12.145

**KNOWN:** Solar, sky and ground irradiation of a wet towel. Towel dimensions, emissivity and solar absorptivity. Temperature, relative humidity and convection heat transfer coefficient associated with air flow over the towel.

**FIND:** Temperature of towel and evaporation rate.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, (2) Diffuse-gray surface behavior of towel in the infrared ( $\alpha_{\text{sky}} = \alpha_g = \epsilon = 0.96$ ), (3) Perfect gas behavior for vapor.

**PROPERTIES:** Table A-4, Air ( $T \approx 300$  K):  $\rho = 1.16$  kg/m<sup>3</sup>,  $c_p = 1007$  J/kg·K,  $\alpha = 0.225 \times 10^{-4}$  m<sup>2</sup>/s; Table A-6, Water vapor ( $T_\infty = 300$  K):  $\rho_{A,\text{sat}} = 0.0256$  kg/m<sup>3</sup>; Table A-8, Water vapor/air ( $T = 298$  K):  $D_{AB} = 0.26 \times 10^{-4}$  m<sup>2</sup>/s.

**ANALYSIS:** From an energy balance on the towel, it follows that

$$\begin{aligned} \alpha_S G_S + 2\alpha_{\text{sky}} G_{\text{atm}} + 2\alpha_g G_g &= 2E + 2q''_{\text{evap}} + 2q''_{\text{conv}} \\ 0.65 \times 900 \text{ W/m}^2 + 2 \times 0.96 \times 200 \text{ W/m}^2 + 2 \times 0.96 \times 250 \text{ W/m}^2 &= 2 \times 0.96 \sigma T_s^4 + 2n''_A h_{fg} + 2h(T_s - T_\infty) \end{aligned} \quad (1)$$

where  $n''_A = h_m [\rho_{A,\text{sat}}(T_s) - \phi_\infty \rho_{A,\text{sat}}(T_\infty)]$

From the heat and mass transfer analogy, Eq. 6.60, with an assumed exponent of  $n = 1/3$ ,

$$h_m = \frac{h}{\rho c_p (\alpha / D_{AB})^{2/3}} = \frac{20 \text{ W/m}^2 \cdot \text{K}}{1.16 \text{ kg/m}^3 (1007 \text{ J/kg} \cdot \text{K}) \left( \frac{0.225}{0.260} \right)^{2/3}} = 0.0189 \text{ m/s}$$

From a trial-and-error solution, we find that for  $T_s = 298$  K,  $\rho_{A,\text{sat}} = 0.0226$  kg/m<sup>3</sup>,  $h_{fg} = 2.442 \times 10^6$  J/kg and  $n''_A = 1.380 \times 10^{-4}$  kg/s·m<sup>2</sup>. Substituting into Eq. (1),

$$\begin{aligned} (585 + 384 + 480) \text{ W/m}^2 &= 2 \times 0.96 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (298 \text{ K})^4 \\ &+ 2 \times 1.380 \times 10^{-4} \text{ kg/s} \cdot \text{m}^2 \times 2.442 \times 10^6 \text{ J/kg} \\ &+ 2 \times 20 \text{ W/m}^2 \cdot \text{K} (-2 \text{ K}) \\ 1449 \text{ W/m}^2 &= (859 + 674 - 80) \text{ W/m}^2 = 1453 \text{ W/m}^2 \end{aligned}$$

The equality is satisfied to a good approximation, in which case

$$T_s \approx 298 \text{ K} = 25^\circ\text{C} \quad <$$

$$\text{and } n_A = 2 A_s n''_A = 2(1.50 \times 0.75) \text{ m}^2 (1.38 \times 10^{-4} \text{ kg/s} \cdot \text{m}^2) = 3.11 \times 10^{-4} \text{ kg/s} \quad <$$

**COMMENTS:** Note that the temperature of the air exceeds that of the towel, in which case convection heat transfer is to the towel. Reduction of the towel's temperature below that of the air is due to the evaporative cooling effect.

## PROBLEM 12.146

**KNOWN:** Wet paper towel experiencing forced convection heat and mass transfer and irradiation from radiant lamps. Prescribed convection parameters including wet and dry bulb temperature of the air stream,  $T_{wb}$  and  $T_{\infty}$ , average heat and mass transfer coefficients,  $\bar{h}$  and  $\bar{h}_m$ . Towel temperature  $T_s$ .

**FIND:** (a) Vapor densities,  $\rho_{A,s}$  and  $\rho_{A,\infty}$ ; the evaporation rate  $n_A$  (kg/s); and the net rate of radiation transfer to the towel  $q_{rad}$  (W); and (b) Emissive power  $E$ , the irradiation  $G$ , and the radiosity  $J$ , using the results from part (a).

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Negligible heat loss from the bottom side of the towel, (3) Uniform irradiation on the towel, and (4) Water surface is diffuse, gray.

**PROPERTIES:** Table A.6, Water ( $T_s = 310$  K):  $h_{fg} = 2414$  kJ/kg.

**ANALYSIS:** (a) Since  $T_{wb} = T_{\infty}$ , the free stream contains water vapor at its saturation condition. The water vapor at the surface is saturated since it is in equilibrium with the liquid in the towel. From Table A.6,

$T$ (K)	$v_g$ ( $m^3/kg$ )	$\rho_g$ ( $kg/m^3$ )
$T_{\infty} = 290$	69.7	$\rho_{A,\infty} = 1.435 \times 10^{-2}$
$T_s = 310$	22.93	$\rho_{A,s} = 4.361 \times 10^{-2}$

Using the mass transfer convection rate equation, the water evaporation rate from the towel is

$$n_A = \bar{h}_m A_s (\rho_{A,s} - \rho_{A,\infty}) = 0.027 \text{ m/s} (0.0925 \text{ m})^2 (4.361 - 1.435) \times 10^{-2} \text{ kg/m}^3 = 6.76 \times 10^{-6} \text{ kg/s} <$$

To determine the net radiation heat rate  $q_{rad}''$ , perform an energy balance on the water film,

$$\dot{E}_{in} - \dot{E}_{out} = 0 \quad q_{rad} - q_{cv} - q_{evap} = 0$$

$$q_{rad} = q_{cv} + q_{evap} = \bar{h}_s A_s (T_s - T_{\infty}) + n_A h_{fg}$$

and substituting numerical values find

$$q_{rad} = 28.7 \text{ W/m}^2 \cdot \text{K} (0.0925 \text{ m})^2 (310 - 290) \text{ K} + 6.76 \times 10^{-6} \text{ kg/s} \times 2414 \times 10^3 \text{ J/kg}$$

$$q_{rad} = (4.91 + 16.32) \text{ W} = 21.2 \text{ W} <$$

(b) The radiation parameters for the towel surface are now evaluated. The emissive power is

$$E = \epsilon E_b (T_s) = \epsilon \sigma T_s^4 = 0.96 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (310 \text{ K})^4 = 502.7 \text{ W/m}^2 <$$

To determine the irradiation  $G$ , recognize that the net radiation heat rate can be expressed as,

$$q_{rad} = (\alpha G - E) A_s \quad 21.2 \text{ W} = (0.96 G - 502.7) \text{ W/m}^2 \times (0.0925 \text{ m})^2 \quad G = 3105 \text{ W/m}^2 <$$

where  $\alpha = \epsilon$  since the water surface is diffuse, gray. From the definition of the radiosity,

$$J = E + \rho G = [502.7 + (1 - 0.96) \times 3105] \text{ W/m}^2 = 626.9 \text{ W/m}^2 <$$

where  $\rho = 1 - \alpha = 1 - \epsilon$ .

**COMMENTS:** An alternate method to evaluate  $J$  is to recognize that  $q_{rad}'' = G - J$ .

### PROBLEM 13.1

**KNOWN:** Various geometric shapes involving two areas  $A_1$  and  $A_2$ .

**FIND:** Shape factors,  $F_{12}$  and  $F_{21}$ , for each configuration.

**ASSUMPTIONS:** Surfaces are diffuse.

**ANALYSIS:** The analysis is not to make use of tables or charts. The approach involves use of the reciprocity relation, Eq. 13.3, and summation rule, Eq. 13.4. Recognize that reciprocity applies to two surfaces; summation applies to an enclosure. Certain shape factors will be identified by inspection. Note  $L$  is the length normal to page.

(a) Long duct (L):

By inspection,  $F_{12} = 1.0$  <

By reciprocity,  $F_{21} = \frac{A_1}{A_2} F_{12} = \frac{2RL}{(3/4) \cdot 2\pi RL} \times 1.0 = \frac{4}{3\pi} = 0.424$  <

(b) Small sphere,  $A_1$ , under concentric hemisphere,  $A_2$ , where  $A_2 = 2A_1$

Summation rule  $F_{11} + F_{12} + F_{13} = 1$

But  $F_{12} = F_{13}$  by symmetry, hence  $F_{12} = 0.50$  <

By reciprocity,  $F_{21} = \frac{A_1}{A_2} F_{12} = \frac{A_1}{2A_1} \times 0.5 = 0.25$ . <

(c) Long duct (L):

By inspection,  $F_{12} = 1.0$

By reciprocity,  $F_{21} = \frac{A_1}{A_2} F_{12} = \frac{2RL}{\pi RL} \times 1.0 = \frac{2}{\pi} = 0.637$  <

Summation rule,  $F_{22} = 1 - F_{21} = 1 - 0.64 = 0.363$ . <

(d) Long inclined plates (L):

Summation rule,  $F_{11} + F_{12} + F_{13} = 1$

But  $F_{12} = F_{13}$  by symmetry, hence  $F_{12} = 0.50$  <

By reciprocity,  $F_{21} = \frac{A_1}{A_2} F_{12} = \frac{20L}{10(2)^{1/2} L} \times 0.5 = 0.707$ . <

(e) Sphere lying on infinite plane

Summation rule,  $F_{11} + F_{12} + F_{13} = 1$

But  $F_{12} = F_{13}$  by symmetry, hence  $F_{12} = 0.5$  <

By reciprocity,  $F_{21} = \frac{A_1}{A_2} F_{12} \rightarrow 0$  since  $A_2 \rightarrow \infty$ . <

Continued ...

**PROBLEM 13.1 (Cont.)**

(f) Hemisphere over a disc of diameter  $D/2$ ; find also  $F_{22}$  and  $F_{23}$ .

By inspection,  $F_{12} = 1.0$

Summation rule for surface  $A_3$  is written as

$$F_{31} + F_{32} + F_{33} = 1. \quad \text{Hence, } F_{32} = 1.0.$$

By reciprocity, 
$$F_{23} = \frac{A_3}{A_2} F_{32}$$

$$F_{23} = \left\{ \left[ \frac{\pi D^2}{4} - \frac{\pi (D/2)^2}{4} \right] / \frac{\pi D^2}{2} \right\} 1.0 = 0.375.$$

By reciprocity, 
$$F_{21} = \frac{A_1}{A_2} F_{12} = \left\{ \frac{\pi \left[ \frac{D}{2} \right]^2}{4} / \frac{\pi D^2}{2} \right\} \times 1.0 = 0.125.$$

Summation rule for  $A_2$ , 
$$F_{21} + F_{22} + F_{23} = 1 \quad \text{or}$$

$$F_{22} = 1 - F_{21} - F_{23} = 1 - 0.125 - 0.375 = 0.5.$$

Note that by inspection you can deduce  $F_{22} = 0.5$

(g) Long open channel (L):

Summation rule for  $A_1$

$$F_{11} + F_{12} + F_{13} = 0$$

but  $F_{12} = F_{13}$  by symmetry, hence  $F_{12} = 0.50$ .

By reciprocity, 
$$F_{21} = \frac{A_1}{A_2} F_{12} = \frac{2 \times L}{(2\pi L) / 4 \times L} = \frac{4}{\pi} \times 0.50 = 0.637.$$

**COMMENTS:** (1) Note that the summation rule is applied to an enclosure. To complete the enclosure, it was necessary in several cases to define a third surface which was shown by dashed lines.

(2) Recognize that the solutions follow a systematic procedure; in many instances it is possible to deduce a shape factor by inspection.

### PROBLEM 13.2

**KNOWN:** Geometry of semi-circular, rectangular and V grooves.

**FIND:** (a) View factors of grooves with respect to surroundings, (b) View factor for sides of V groove, (c) View factor for sides of rectangular groove.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Diffuse surfaces, (2) Negligible end effects, “long grooves”.

**ANALYSIS:** (a) Consider a unit length of each groove and represent the surroundings by a hypothetical surface (dashed line).

*Semi-Circular Groove:*

$$F_{21} = 1; \quad F_{12} = \frac{A_2}{A_1} F_{21} = \frac{W}{(\pi W/2)} \times 1$$

$$F_{12} = 2/\pi. \quad <$$

*Rectangular Groove:*

$$F_{4(1,2,3)} = 1; \quad F_{(1,2,3)4} = \frac{A_4}{A_1 + A_2 + A_3} F_{4(1,2,3)} = \frac{W}{H + W + H} \times 1$$

$$F_{(1,2,3)4} = W/(W + 2H). \quad <$$

*V Groove:*

$$F_{3(1,2)} = 1; \quad F_{(1,2)3} = \frac{A_3}{A_1 + A_2} F_{3(1,2)} = \frac{W}{\frac{W/2}{\sin \theta} + \frac{W/2}{\sin \theta}}$$

$$F_{(1,2)3} = \sin \theta.$$

(b) From Eqs. 13.3 and 13.4,  $F_{12} = 1 - F_{13} = 1 - \frac{A_3}{A_1} F_{31}.$

From Symmetry,  $F_{31} = 1/2.$

Hence,  $F_{12} = 1 - \frac{W}{(W/2)/\sin \theta} \times \frac{1}{2}$  or  $F_{12} = 1 - \sin \theta. \quad <$

(c) From Fig. 13.4, with  $X/L = H/W = 2$  and  $Y/L \rightarrow \infty,$

$$F_{12} \approx 0.62. \quad <$$

**COMMENTS:** (1) Note that for the V groove,  $F_{13} = F_{23} = F_{(1,2)3} = \sin \theta,$  (2) In part (c), Fig. 13.4 could also be used with  $Y/L = 2$  and  $X/L = \infty.$  However, obtaining the limit of  $F_{ij}$  as  $X/L \rightarrow \infty$  from the figure is somewhat uncertain.

### PROBLEM 13.3

**KNOWN:** Two arrangements (a) circular disk and coaxial, ring shaped disk, and (b) circular disk and coaxial, right-circular cone.

**FIND:** Derive expressions for the view factor  $F_{12}$  for the arrangements (a) and (b) in terms of the areas  $A_1$  and  $A_2$ , and any appropriate hypothetical surface area, as well as the view factor for coaxial parallel disks (Table 13.2, Figure 13.5). For the disk-cone arrangement, sketch the variation of  $F_{12}$  with  $\theta$  for  $0 \leq \theta \leq \pi/2$ , and explain the key features.

**SCHEMATIC:**

**ASSUMPTIONS:** Diffuse surfaces with uniform radiosities.

**ANALYSIS:** (a) Define the hypothetical surface  $A_3$ , a co-planar disk inside the ring of  $A_1$ . Using the additive view factor relation, Eq. 13.5,

$$A_{(1,3)} F_{(1,3)} = A_1 F_{12} + A_3 F_{32}$$

$$F_{12} = \frac{1}{A_1} \left[ A_{(1,3)} F_{(1,3)} - A_3 F_{32} \right] \quad <$$

where the parenthesis denote a composite surface. All the  $F_{ij}$  on the right-hand side can be evaluated using Fig. 13.5.

(b) Define the hypothetical surface  $A_3$ , the disk at the bottom of the cone. The radiant power leaving  $A_2$  that is intercepted by  $A_1$  can be expressed as

$$F_{21} = F_{23} \quad (1)$$

That is, the same power also intercepts the disk at the bottom of the cone,  $A_3$ . From reciprocity,

$$A_1 F_{12} = A_2 F_{21} \quad (2)$$

and using Eq. (1),

$$F_{12} = \frac{A_2}{A_1} F_{23} \quad <$$

The variation of  $F_{12}$  as a function of  $\theta$  is shown below for the disk-cone arrangement. In the limit when  $\theta \rightarrow \pi/2$ , the cone approaches a disk of area  $A_3$ . That is,

$$F_{12} (\theta \rightarrow \pi/2) = F_{13}$$

When  $\theta \rightarrow 0$ , the cone area  $A_2$  diminishes so that

$$F_{12} (\theta \rightarrow 0) = 0$$

### PROBLEM 13.4

**KNOWN:** Right circular cone and right-circular cylinder of same diameter  $D$  and length  $L$  positioned coaxially a distance  $L_o$  from the circular disk  $A_1$ ; hypothetical area corresponding to the openings identified as  $A_3$ .

**FIND:** (a) Show that  $F_{21} = (A_1/A_2) F_{13}$  and  $F_{22} = 1 - (A_3/A_2)$ , where  $F_{13}$  is the view factor between two, coaxial parallel disks (Table 13.2), for both arrangements, (b) Calculate  $F_{21}$  and  $F_{22}$  for  $L = L_o = 50$  mm and  $D_1 = D_3 = 50$  mm; compare magnitudes and explain similarities and differences, and (c) Magnitudes of  $F_{21}$  and  $F_{22}$  as  $L$  increases and all other parameters remain the same; sketch and explain key features of their variation with  $L$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Diffuse surfaces with uniform radiosities, and (2) Inner base and lateral surfaces of the cylinder treated as a single surface,  $A_2$ .

**ANALYSIS:** (a) For both configurations,

$$F_{13} = F_{12} \tag{1}$$

since the radiant power leaving  $A_1$  that is intercepted by  $A_3$  is likewise intercepted by  $A_2$ . Applying reciprocity between  $A_1$  and  $A_2$ ,

$$A_1 F_{12} = A_2 F_{21} \tag{2}$$

Substituting from Eq. (1), into Eq. (2), solving for  $F_{21}$ , find

$$F_{21} = (A_1 / A_2) F_{12} = (A_1 / A_2) F_{13} \tag{3}$$

Treating the cone and cylinder as two-surface enclosures, the summation rule for  $A_2$  is

$$F_{22} + F_{23} = 1 \tag{3}$$

Apply reciprocity between  $A_2$  and  $A_3$ , solve Eq. (3) to find

$$F_{22} = 1 - F_{23} = 1 - (A_3 / A_2) F_{32}$$

and since  $F_{32} = 1$ , find

$$F_{22} = 1 - A_3 / A_2 \tag{3}$$

Continued ...

### PROBLEM 13.4 (Cont.)

(b) For the specified values of  $L$ ,  $L_o$ ,  $D_1$  and  $D_2$ , the view factors are calculated and tabulated below. Relations for the areas are:

$$\text{Disk-cone:} \quad A_1 = \pi D_1^2 / 4 \quad A_2 = \pi D_3 / 2 \left( L^2 + (D_3 / 2)^2 \right)^{1/2} \quad A_3 = \pi D_3^2 / 4$$

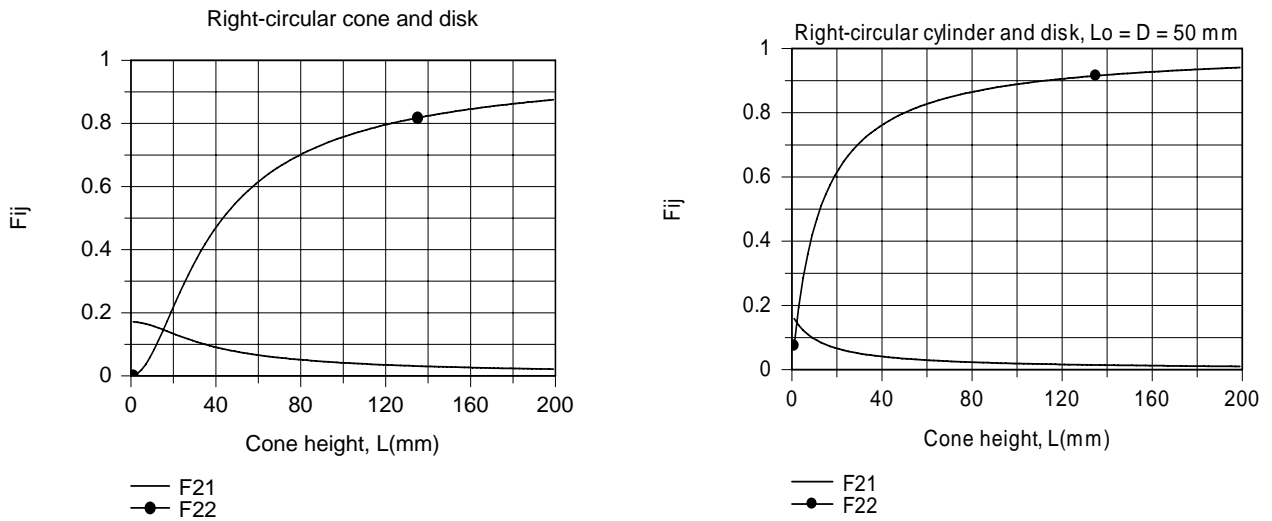

$$\text{Disk-cylinder:} \quad A_1 = \pi D_1^2 / 4 \quad A_2 = \pi D_3^2 / 4 + \pi D_3 L \quad A_3 = \pi D_3^2 / 4$$

The view factor  $F_{13}$  is evaluated from Table 13.2, coaxial parallel disks (Fig. 13.5); find  $F_{13} = 0.1716$ .

	$F_{21}$	$F_{22}$
<i>Disk-cone</i>	0.0767	0.553
<i>Disk-cylinder</i>	0.0343	0.800

It follows that  $F_{21}$  is greater for the disk-cone (a) than for the cylinder-cone (b). That is, for (a), surface  $A_2$  sees more of  $A_1$  and less of itself than for (b). Notice that  $F_{22}$  is greater for (b) than (a); this is a consequence of  $A_{2,b} > A_{2,a}$ .

(c) Using the foregoing equations in the IHT workspace, the variation of the view factors  $F_{21}$  and  $F_{22}$  with  $L$  were calculated and are graphed below.

Note that for both configurations, when  $L = 0$ , find that  $F_{21} = F_{13} = 0.1716$ , the value obtained for coaxial parallel disks. As  $L$  increases, find that  $F_{22} \rightarrow 1$ ; that is, the interior of both the cone and cylinder see mostly each other. Notice that the changes in both  $F_{21}$  and  $F_{22}$  with increasing  $L$  are greater for the disk-cylinder;  $F_{21}$  decreases while  $F_{22}$  increases.

**COMMENTS:** From the results of part (b), why isn't the sum of  $F_{21}$  and  $F_{22}$  equal to unity?

### PROBLEM 13.5

**KNOWN:** Two parallel, coaxial, ring-shaped disks.

**FIND:** Show that the view factor  $F_{12}$  can be expressed as

$$F_{12} = \frac{1}{A_1} \left\{ A_{(1,3)} F_{(1,3)(2,4)} - A_3 F_{3(2,4)} - A_4 (F_{4(1,3)} - F_{43}) \right\}$$

where all the  $F_{ij}$  on the right-hand side of the equation can be evaluated from Figure 13.5 (see Table 13.2) for coaxial parallel disks.

**SCHEMATIC:**

**ASSUMPTIONS:** Diffuse surfaces with uniform radiosities.

**ANALYSIS:** Using the additive rule, Eq. 13.5, where the parenthesis denote a composite surface,

$$F_{1(2,4)} = F_{12} + F_{14}$$

$$F_{12} = F_{1(2,4)} - F_{14} \quad (1)$$

*Relation for  $F_{1(2,4)}$ :* Using the additive rule

$$A_{(1,3)} F_{(1,3)(2,4)} = A_1 F_{1(2,4)} + A_3 F_{3(2,4)} \quad (2)$$

where the check mark denotes a  $F_{ij}$  that can be evaluated using Fig. 13.5 for coaxial parallel disks.

*Relation for  $F_{14}$ :* Apply reciprocity

$$A_1 F_{14} = A_4 F_{41} \quad (3)$$

and using the additive rule involving  $F_{41}$ ,

$$A_1 F_{14} = A_4 \left[ F_{4(1,3)} - F_{43} \right] \quad (4)$$

*Relation for  $F_{12}$ :* Substituting Eqs. (2) and (4) into Eq. (1),

$$F_{12} = \frac{1}{A_1} \left\{ A_{(1,3)} F_{(1,3)(2,4)} - A_3 F_{3(2,4)} - A_4 (F_{4(1,3)} - F_{43}) \right\} \quad <$$

**COMMENTS:** (1) The  $F_{ij}$  on the right-hand side can be evaluated using Fig. 13.5.

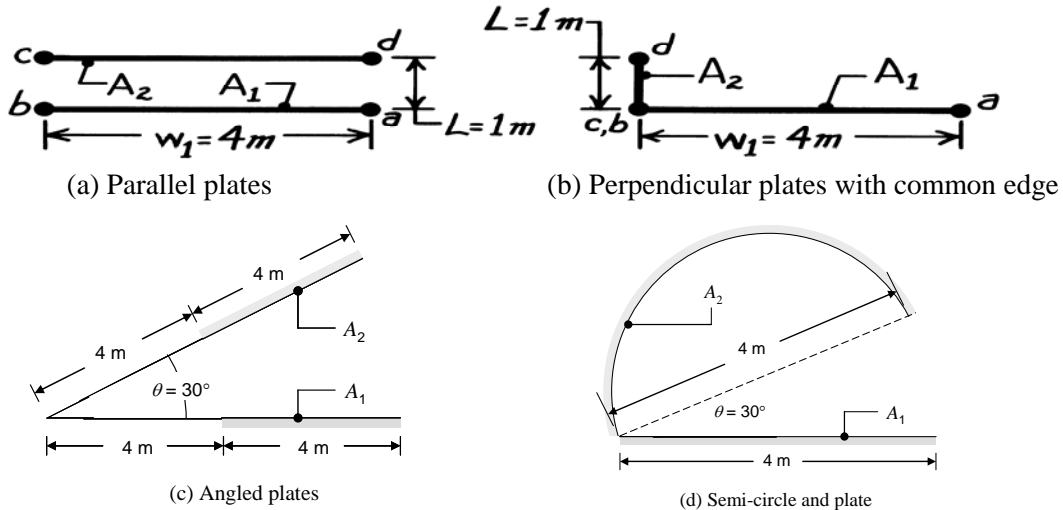

(2) To check the validity of the result, substitute numerical values and test the behavior at special limits. For example, as  $A_3, A_4 \rightarrow 0$ , the expression reduces to the identity  $F_{12} \equiv F_{12}$ .

### PROBLEM 13.6

**KNOWN:** Dimensions of four geometrical arrangements.

**FIND:** View factors using “crossed-strings” method; compare with appropriate graphs and analytical expressions.

**SCHEMATIC:**

**ASSUMPTIONS:** Plates infinite in extent in direction normal to page.

**ANALYSIS:** The crossed-strings method is applicable to surfaces of infinite extent in one direction having an unobstructed view of one another.

$$F_{12} = (1/2w_1)[(ac + bd) - (ad + bc)].$$

(a) *Parallel plates:* From the schematic, the edge and diagonal distances are

$$ac = bd = (w_1^2 + L^2)^{1/2} \quad bc = ad = L.$$

With  $w_1$  as the width of the plate, find

$$F_{12} = \frac{1}{2w_1} \left[ 2(w_1^2 + L^2)^{1/2} - 2(L) \right] = \frac{1}{2 \times 4 \text{ m}} \left[ 2(4^2 + 1^2)^{1/2} \text{ m} - 2(1 \text{ m}) \right] = 0.781. \quad <$$

Using Fig. 13.4 with  $X/L = 4/1 = 4$  and  $Y/L = \infty$ , find  $F_{12} \approx 0.80$ . Also, using the first relation of Table 13.1,

$$F_{ij} = \left\{ \left[ (W_i + W_j)^2 + 4 \right]^{1/2} - \left[ (W_i - W_j)^2 + 4 \right]^{1/2} \right\} / 2W_i$$

where  $w_i = w_j = w_1$  and  $W = w/L = 4/1 = 4$ , find

$$F_{12} = \left\{ \left[ (4+4)^2 + 4 \right]^{1/2} - \left[ (4-4)^2 + 4 \right]^{1/2} \right\} / 2 \times 4 = 0.781.$$

Continued...

### PROBLEM 13.6 (Cont.)

(b) *Perpendicular plates* with a common edge: From the schematic, the edge and diagonal distances are

$$ac = w_1 \quad bd = L \quad ad = \left( w_1^2 + L^2 \right)^{1/2} \quad bc = 0.$$

With  $w_1$  as the width of the horizontal plates, find

$$F_{12} = (1/2w_1) \left[ 2(w_1 + L) - \left( \left( w_1^2 + L^2 \right)^{1/2} + 0 \right) \right]$$

$$F_{12} = (1/2 \times 4 \text{ m}) \left[ (4 + 1) \text{ m} - \left( \left( 4^2 + 1^2 \right)^{1/2} \text{ m} + 0 \right) \right] = 0.110. \quad <$$

From the third relation of Table 13.1, with  $w_i = w_1 = 4 \text{ m}$  and  $w_j = L = 1 \text{ m}$ , find

$$F_{ij} = \left\{ 1 + \left( w_j / w_i \right) - \left[ 1 + \left( w_j / w_i \right)^2 \right]^{1/2} \right\} / 2$$

$$F_{12} = \left\{ 1 + (1/4) - \left[ 1 + (1/4)^2 \right]^{1/2} \right\} / 2 = 0.110.$$

(c) *Plates at an angle to one another.* From the schematic below, the edge and diagonal distances can be calculated as follows:

$$h = 4 \sin 30^\circ, \quad w = 8 - 4 \cos 30^\circ, \quad ac = \sqrt{h^2 + w^2} = 4.96 \text{ m}$$

$$\text{By symmetry, } bd = ac = 4.96 \text{ m}$$

$$bc = 2(4 \sin 15^\circ) = 2.07 \text{ m}$$

$$ad = 2(8 \sin 15^\circ) = 4.14 \text{ m}$$

We find

$$F_{12} = (1/8) \left[ (4.96 + 4.96) - (4.14 + 2.07) \right] = 0.463. \quad <$$

The same result can be found using the second and fourth view factors in Table 13.1, along with Equations 13.5 and 13.6.

From Eq. 13.5 with  $i = 3$  and  $j$  representing the combination (24),

$$F_{3-(24)} = F_{32} + F_{34}.$$

Then from Table 13.1 4<sup>th</sup> entry,

$$F_{3-(24)} = (w_3 + w_{24} - bd) / 2w_3 = (4 + 8 - 4.96) / 8 = 0.880$$

Continued...

### PROBLEM 13.6 (Cont.)

From Table 13.1, 2<sup>nd</sup> entry,  $F_{34} = 1 - \sin(30^\circ/2) = 0.741$ . Thus  $F_{32} = 0.880 - 0.741 = 0.139$ . Using Eq. 13.5 again, with  $i$  representing the combination of (13) and  $j$  representing the combination (24),

$$F_{(13)-(24)} = F_{(13)-2} + F_{(13)-4}$$

$F_{(13)-4}$  can be found using reciprocity, namely  $F_{(13)-4} = A_4 F_{4-(13)} / A_{13} = A_4 F_{3-(24)} / A_{13} = 0.5 F_{3-(24)} = 0.440$ . Then from Table 13.1, 2<sup>nd</sup> entry, it can be seen that  $F_{(13)-(24)} = F_{34} = 0.741$ . Thus,

$$F_{(13)-2} = F_{(13)-(24)} - F_{(13)-4} = 0.301$$

Finally, from Eq. 13.6, with  $i = 2$  and  $j$  representing the combination (13),

$$A_{13} F_{(13)-2} = A_1 F_{12} + A_3 F_{32}$$

Therefore,

$$F_{12} = (A_{13} F_{(13)-2} - A_3 F_{32}) / A_1 = (8 \times 0.301 - 4 \times 0.139) / 4 = 0.463.$$

(d) *Semi-circle and plate at angle to each other.*

The edge and diagonal distances are

$$ac = 8 \text{ m}, bc = 0 \text{ m}, ad = 2(8 \sin 15^\circ) = 4.14 \text{ m}, bd = 8 \text{ m}$$

We find

$$F_{12} = (1/16)[(8+8) - (4.14+0)] = 0.741.$$

<

The same result can be found using view factor relations in Table 13.1. Since radiation traveling from 1 to 2 must pass through 3,  $F_{12} = F_{13}$ . From Table 13.1, 2<sup>nd</sup> entry,

$$F_{12} = 1 - \sin(30^\circ/2) = 0.741$$

**COMMENTS:** (1) Hottel's method can be a significant time-saver. (2) The application of Hottel's method to cases where the view is obstructed between the two surfaces is discussed in Siegel, R., J.R. Howell, and M.P. Menguc, *Thermal Radiation Heat Transfer*, 5<sup>th</sup> ed., CRC Press, Taylor & Francis Group, New York, 2010 and in Modest, M.F., *Radiative Heat Transfer*, 2<sup>nd</sup> ed., Academic Press, San Diego, 2003.

### PROBLEM 13.7

**KNOWN:** Right-circular cylinder of diameter  $D$ , length  $L$  and the areas  $A_1$ ,  $A_2$ , and  $A_3$  representing the base, inner lateral and top surfaces, respectively.

**FIND:** (a) Show that the view factor between the base of the cylinder and the inner lateral surface has the form

$$F_{12} = 2 H \left[ \left(1 + H^2\right)^{1/2} - H \right]$$

where  $H = L/D$ , and (b) Show that the view factor for the inner lateral surface to itself has the form

$$F_{22} = 1 + H - \left(1 + H^2\right)^{1/2}$$

**SCHEMATIC:**

**ASSUMPTIONS:** Diffuse surfaces with uniform radiosities.

**ANALYSIS:** (a) *Relation for  $F_{12}$ , base-to-inner lateral surface.* Apply the summation rule to  $A_1$ , noting that  $F_{11} = 0$

$$F_{11} + F_{12} + F_{13} = 1$$

$$F_{12} = 1 - F_{13} \tag{1}$$

From Table 13.2, Fig. 13.5, with  $i = 1, j = 3$ ,

$$F_{13} = \frac{1}{2} \left\{ S - \left[ S^2 - 4(D_3 / D_1)^2 \right]^{1/2} \right\} \tag{2}$$

$$S = 1 + \frac{1 + R_3^2}{R_1^2} = \frac{1}{R^2} + 2 = 4 H^2 + 2 \tag{3}$$

where  $R_1 = R_3 = R = D/2L$  and  $H = L/D$ . Combining Eqs. (2) and (3) with Eq. (1), find after some manipulation

Continued ...

**PROBLEM 13.7 (Cont.)**

$$F_{12} = 1 - \frac{1}{2} \left\{ 4H^2 + 2 - \left[ (4H^2 + 2)^2 - 4 \right]^{1/2} \right\}$$
$$F_{12} = 2H \left[ (1 + H^2)^{1/2} - H \right] \quad (4)$$

(b) *Relation for  $F_{22}$ , inner lateral surface.* Apply summation rule on  $A_2$ , recognizing that  $F_{23} = F_{21}$ ,

$$F_{21} + F_{22} + F_{23} = 1 \quad F_{22} = 1 - 2F_{21} \quad (5)$$

Apply reciprocity between  $A_1$  and  $A_2$ ,

$$F_{21} = (A_1 / A_2) F_{12} \quad (6)$$

and substituting into Eq. (5), and using area expressions

$$F_{22} = 1 - 2 \frac{A_1}{A_2} F_{12} = 1 - 2 \frac{D}{4L} F_{12} = 1 - \frac{1}{2H} F_{12} \quad (7)$$

where  $A_1 = \pi D^2/4$  and  $A_2 = \pi DL$ .

Substituting from Eq. (4) for  $F_{12}$ , find

$$F_{22} = 1 - \frac{1}{2H} 2H \left[ (1 + H^2)^{1/2} - H \right] = 1 + H - (1 + H^2)^{1/2} \quad <$$

### PROBLEM 13.8

**KNOWN:** Arrangement of plane parallel rectangles.

**FIND:** Show that the view factor between  $A_1$  and  $A_2$  can be expressed as

$$F_{12} = \frac{1}{2 A_1} \left[ A_{(1,4)} F_{(1,4)(2,3)} - A_1 F_{13} - A_4 F_{42} \right]$$

where all  $F_{ij}$  on the right-hand side of the equation can be evaluated from Fig. 13.4 (see Table 13.2) for aligned parallel rectangles.

**SCHEMATIC:**

**ASSUMPTIONS:** Diffuse surfaces with uniform radiosity.

**ANALYSIS:** Using the additive rule where the parenthesis denote a composite surface,

$$A_{(1,4)} F_{(1,4)(2,3)}^* = A_1 F_{13}^* + A_1 F_{12} + A_4 F_{43} + A_4 F_{42}^* \quad (1)$$

where the asterisk (\*) denotes that the  $F_{ij}$  can be evaluated using the relation of Figure 13.4. Now, find suitable relation for  $F_{43}$ . By symmetry,

$$F_{43} = F_{21} \quad (2)$$

and from reciprocity between  $A_1$  and  $A_2$ ,

$$F_{21} = \frac{A_1}{A_2} F_{12} \quad (3)$$

Multiply Eq. (2) by  $A_4$  and substitute Eq. (3), with  $A_4 = A_2$ ,

$$A_4 F_{43} = A_4 F_{21} = A_4 \frac{A_1}{A_2} F_{12} = A_1 F_{12} \quad (4)$$

Substituting for  $A_4 F_{43}$  from Eq. (4) into Eq. (1), and rearranging,

$$F_{12} = \frac{1}{2 A_1} \left[ A_{(1,4)} F_{(1,4)(2,3)}^* - A_1 F_{13}^* - A_4 F_{42}^* \right] \quad <$$

### PROBLEM 13.9

**KNOWN:** Two perpendicular rectangles not having a common edge.

**FIND:** (a) Shape factor,  $F_{12}$ , and (b) Compute and plot  $F_{12}$  as a function of  $Z_b$  for  $0.05 \leq Z_b \leq 0.4$  m; compare results with the view factor obtained from the two-dimensional relation for perpendicular plates with a common edge, Table 13.1.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) All surfaces are diffuse, (2) Plane formed by  $A_1 + A_3$  is perpendicular to plane of  $A_2$ .

**ANALYSIS:** (a) Introducing the hypothetical surface  $A_3$ , we can write

$$F_{2(3,1)} = F_{23} + F_{21} \quad (1)$$

Using Fig. 13.6, applicable to perpendicular rectangles with a common edge, find

$$F_{23} = 0.19: \quad \text{with } Y = 0.3, \quad X = 0.5, \quad Z = Z_a - Z_b = 0.2, \quad \text{and } \frac{Y}{X} = \frac{0.3}{0.5} = 0.6, \quad \frac{Z}{X} = \frac{0.2}{0.5} = 0.4$$

$$F_{2(3,1)} = 0.25: \quad \text{with } Y = 0.3, \quad X = 0.5, \quad Z_a = 0.4, \quad \text{and } \frac{Y}{X} = \frac{0.3}{0.5} = 0.6, \quad \frac{Z}{X} = \frac{0.4}{0.5} = 0.8$$

Hence from Eq. (1)

$$F_{21} = F_{2(3,1)} - F_{23} = 0.25 - 0.19 = 0.06$$

By reciprocity,

$$F_{12} = \frac{A_2}{A_1} F_{21} = \frac{0.5 \times 0.3 \text{ m}^2}{0.5 \times 0.2 \text{ m}^2} \times 0.06 = 0.09 \quad (2) <$$

(b) Using the *IHT Tool – View Factors for Perpendicular Rectangles with a Common Edge* and Eqs. (1,2) above,  $F_{12}$  was computed as a function of  $Z_b$ . Also shown on the plot below is the view factor  $F_{(3,1)2}$  for the limiting case  $Z_b \rightarrow Z_a$ .

### PROBLEM 13.10

**KNOWN:** Arrangement of perpendicular surfaces without a common edge.

**FIND:** (a) A relation for the view factor  $F_{14}$  and (b) The value of  $F_{14}$  for prescribed dimensions.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Diffuse surfaces.

**ANALYSIS:** (a) To determine  $F_{14}$ , it is convenient to define the hypothetical surfaces  $A_2$  and  $A_3$ . From Eq. 13.6,

$$(A_1 + A_2)F_{(1,2)(3,4)} = A_1 F_{1(3,4)} + A_2 F_{2(3,4)}$$

where  $F_{(1,2)(3,4)}$  and  $F_{2(3,4)}$  may be obtained from Fig. 13.6. Substituting for  $A_1 F_{1(3,4)}$  from Eq. 13.5 and combining expressions, find

$$A_1 F_{1(3,4)} = A_1 F_{13} + A_1 F_{14}$$

$$F_{14} = \frac{1}{A_1} \left[ (A_1 + A_2)F_{(1,2)(3,4)} - A_1 F_{13} - A_2 F_{2(3,4)} \right].$$

Substituting for  $A_1 F_{13}$  from Eq. 13.6, which may be expressed as

$$(A_1 + A_2)F_{(1,2)3} = A_1 F_{13} + A_2 F_{23}.$$

The desired relation is then

$$F_{14} = \frac{1}{A_1} \left[ (A_1 + A_2)F_{(1,2)(3,4)} + A_2 F_{23} - (A_1 + A_2)F_{(1,2)3} - A_2 F_{2(3,4)} \right]. \quad <$$

(b) For the prescribed dimensions and using Fig. 13.6, find these view factors:

*Surfaces (1,2)(3,4)*       $(Y/X) = \frac{L_1 + L_2}{W} = 1, \quad (Z/X) = \frac{L_3 + L_4}{W} = 1.45, \quad F_{(1,2)(3,4)} = 0.22$

*Surfaces 23*       $(Y/X) = \frac{L_2}{W} = 0.5, \quad (Z/X) = \frac{L_3}{W} = 1, \quad F_{23} = 0.28$

*Surfaces (1,2)3*       $(Y/X) = \frac{L_1 + L_2}{W} = 1, \quad (Z/X) = \frac{L_3}{W} = 1, \quad F_{(1,2)3} = 0.20$

*Surfaces 2(3,4)*       $(Y/X) = \frac{L_2}{W} = 0.5, \quad (Z/X) = \frac{L_3 + L_4}{W} = 1.5, \quad F_{2(3,4)} = 0.31$

Using the relation above, find

$$F_{14} = \frac{1}{(WL_1)} \left[ (WL_1 + WL_2)0.22 + (WL_2)0.28 - (WL_1 + WL_2)0.20 - (WL_2)0.31 \right]$$

$$F_{14} = [2(0.22) + 1(0.28) - 2(0.20) - 1(0.31)] = 0.01. \quad <$$

### PROBLEM 13.11

**KNOWN:** Arrangements of rectangles.

**FIND:** The shape factors,  $F_{12}$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Diffuse surface behavior.

**ANALYSIS:** (a) Define the hypothetical surfaces shown in the sketch as  $A_3$  and  $A_4$ . From the additive view factor rule, Eq. 13.6, we can write

$$A_{(1,3)} \sqrt{F_{(1,3)}(2,4)} = A_1 F_{12} + A_1 F_{14} + A_3 F_{32} + A_3 F_{34} \quad (1)$$

Note carefully which factors can be evaluated from Fig. 13.6 for perpendicular rectangles with a common edge. (See  $\surd$ ). It follows from symmetry that

$$A_1 F_{12} = A_4 F_{43}. \quad (2)$$

Using reciprocity,

$$A_4 F_{43} = A_3 F_{34}, \quad \text{then} \quad A_1 F_{12} = A_3 F_{34}. \quad (3)$$

Solving Eq. (1) for  $F_{12}$  and substituting Eq. (3) for  $A_3 F_{34}$ , find that

$$F_{12} = \frac{1}{2A_1} \left[ A_{(1,3)} F_{(1,3)}(2,4) - A_1 F_{14} - A_3 F_{32} \right]. \quad (4)$$

Evaluate the view factors from Fig. 13.6:

$F_{ij}$	Y/X	Z/X	$F_{ij}$
(1,3) (2,4)	$\frac{6}{9} = 0.67$	$\frac{6}{9} = 0.67$	0.23
14	$\frac{6}{6} = 1$	$\frac{6}{6} = 1$	0.20
32	$\frac{6}{3} = 2$	$\frac{6}{3} = 2$	0.14

Substituting numerical values into Eq. (4) yields

$$F_{12} = \frac{1}{2 \times (6 \times 6) \text{ m}^2} \left[ (6 \times 9) \text{ m}^2 \times 0.23 - (6 \times 6) \text{ m}^2 \times 0.20 - (6 \times 3) \text{ m}^2 \times 0.14 \right]$$

$$F_{12} = 0.038.$$

<

Continued ...

**PROBLEM 13.11 (Cont.)**

(b) Define the hypothetical surface  $A_3$  and divide  $A_2$  into two sections,  $A_{2A}$  and  $A_{2B}$ . From the additive view factor rule, Eq. 13.6, we can write

$$A_{1,3} F_{(1,3)2} = A_1 F_{12} + A_3 F_{3(2A)} + A_3 F_{3(2B)}. \quad (5)$$

Note that the view factors checked can be evaluated from Fig. 13.4 for aligned, parallel rectangles. To evaluate  $F_{3(2A)}$ , we first recognize a relationship involving  $F_{(2A)1}$  will eventually be required. Using the additive rule again,

$$A_{2A} F_{(2A)(1,3)} = A_{2A} F_{(2A)1} + A_{2A} F_{(2A)3}. \quad (6)$$

Note that from symmetry considerations,

$$A_{2A} F_{(2A)(1,3)} = A_1 F_{12} \quad (7)$$

and using reciprocity, Eq. 13.3, note that

$$A_{2A} F_{2A3} = A_3 F_{3(2A)}. \quad (8)$$

Substituting for  $A_3 F_{3(2A)}$  from Eq. (8), Eq. (5) becomes

$$A_{(1,3)} F_{(1,3)2} = A_1 F_{12} + A_{2A} F_{(2A)3} + A_3 F_{3(2B)}.$$

Substituting for  $A_{2A} F_{(2A)3}$  from Eq. (6) using also Eq. (7) for  $A_{2A} F_{(2A)(1,3)}$  find that

$$A_{(1,3)} F_{(1,3)2} = A_1 F_{12} + \left( A_1 F_{12} - A_{2A} F_{(2A)1} \right) + A_3 F_{3(2B)} \quad (9)$$

and solving for  $F_{12}$ , noting that  $A_1 = A_{2A}$  and  $A_{(1,3)} = A_2$

$$F_{12} = \frac{1}{2A_1} \left[ A_2 F_{(1,3)2} + A_{2A} F_{(2A)1} - A_3 F_{3(2B)} \right]. \quad (10)$$

Evaluate the view factors from Fig. 13.4:

$F_{ij}$	X/L	Y/L	$F_{ij}$
(1,3) 2	$\frac{1}{1} = 1$	$\frac{1.5}{1} = 1.5$	0.25
(2A)1	$\frac{1}{1} = 1$	$\frac{0.5}{1} = 0.5$	0.11
3(2B)	$\frac{1}{1} = 1$	$\frac{1}{1} = 1$	0.20

Substituting numerical values into Eq. (10) yields

$$F_{12} = \frac{1}{2(0.5 \times 1) \text{m}^2} \left[ (1.5 \times 1.0) \text{m}^2 \times 0.25 + (0.5 \times 1) \text{m}^2 \times 0.11 - (1 \times 1) \text{m}^2 \times 0.20 \right]$$

$$F_{12} = 0.23.$$

<

## PROBLEM 13.12

**KNOWN:** Parallel plate geometry.

**FIND:** (a) The view factor  $F_{12}$  using the results of Figure 13.4, (b)  $F_{12}$  using the first case of Table 13.1, (c)  $F_{12}$  using Hottel's crossed-string method, (d)  $F_{12}$  using the second case of Table 13.1, (e)  $F_{12}$  for  $w = L = 2$  m using Figure 13.4.

**SCHEMATIC:**

**ASSUMPTIONS:** (a) Two-dimensional system, (b) Diffuse, gray surfaces.

**ANALYSIS:** (a) Using Figure 13.4,  $X/L = 1\text{m}/1\text{m} = 1$ ,  $Y/L \rightarrow \infty$ ,  $F_{12} = 0.41$  <

(b) For case 1 of Table 13.1,  $W_1 = W_2 = 1\text{m}/1\text{m} = 1$  and

$$F_{12} = \frac{\left[2^2 + 4\right]^{1/2} - 4^{1/2}}{2} = 0.414 \quad <$$

(c) From Problem 13.6,

$$F_{12} = \frac{1}{2 \times 1 \text{ m}} \left[ 2 \times \frac{1 \text{ m}}{\cos(45^\circ)} - 2 \text{ m} \right] = 0.414 \quad <$$

(d) For case 2 of Table 13.1,  $w = 1\text{m}$ ,  $\alpha = 90^\circ$ ,  $F_{13} = 1 - \sin(45^\circ) = 0.293$ . By symmetry,  $F_{14} = 0.293$  and by the summation rule,

$$F_{12} = 1 - F_{13} - F_{14} = 1 - 2 \times 0.293 = 0.414 \quad <$$

(e) Using Figure 13.4,  $X/L = 2\text{m}/2\text{m} = 1$ ,  $Y/L \rightarrow \infty$ ,  $F_{12} = 0.41$  <

**COMMENTS:** For most radiation heat transfer problems involving enclosures composed of diffuse gray surfaces, there are many alternative approaches that may be used to determine the appropriate view factors. It is highly unlikely that the view factors will be evaluated the same way by different individuals when solving a radiation heat transfer problem.

### PROBLEM 13.13

**KNOWN:** Parallel plates of infinite extent (1,2) having aligned opposite edges.

**FIND:** View factor  $F_{12}$  by using (a) appropriate view factor relations and results for opposing parallel plates and (b) Hottel's string method described in Problem 13.6.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Parallel planes of infinite extent normal to page and (2) Diffuse surfaces with uniform radiosity.

**ANALYSIS:** From symmetry consideration ( $F_{12} = F_{14}$ ) and Eq. 13.5, it follows that

$$F_{12} = (1/2) [F_{1(2,3,4)} - F_{13}]$$

where  $A_3$  and  $A_4$  have been defined for convenience in the analysis. Each of these view factors can be evaluated by the first relation of Table 13.1 for parallel plates with midlines connected perpendicularly.

$$F_{13}: \quad W_1 = w_1 / L = 2$$

$$W_2 = w_2 / L = 2$$

$$F_{13} = \frac{\left[ (W_1 + W_2)^2 + 4 \right]^{1/2} - \left[ (W_2 - W_1)^2 + 4 \right]^{1/2}}{2W_1} = \frac{\left[ (2+2)^2 + 4 \right]^{1/2} - \left[ (2-2)^2 + 4 \right]^{1/2}}{2 \times 2} = 0.618$$

$$F_{1(2,3,4)}: \quad W_1 = w_1 / L = 2$$

$$W_{(2,3,4)} = 3w_2 / L = 6$$

$$F_{1(2,3,4)} = \frac{\left[ (2+6)^2 + 4 \right]^{1/2} - \left[ (6-2)^2 + 4 \right]^{1/2}}{2 \times 2} = 0.944.$$

Hence, find  $F_{12} = (1/2) [0.944 - 0.618] = 0.163.$

(b) Using Hottel's string method,

$$F_{12} = (1/2w_1) [(ac + bd) - (ad + bc)]$$

$$ac = (1 + 4^2)^{1/2} = 4.123$$

$$bd = 1$$

$$ad = (1^2 + 2^2)^{1/2} = 2.236$$

$$bc = ad = 2.236$$

and substituting numerical values find

$$F_{12} = (1/2 \times 2) [(4.123 + 1) - (2.236 + 2.236)] = 0.163.$$

**COMMENTS:** Remember that Hottel's string method is applicable only to surfaces that are of infinite extent in one direction and have unobstructed views of one another.

### PROBLEM 13.14

**KNOWN:** Two small diffuse surfaces,  $A_1$  and  $A_2$ , on the inside of a spherical enclosure of radius  $R$ .

**FIND:** Expression for the view factor  $F_{12}$  in terms of  $A_2$  and  $R$  by two methods: (a) Beginning with the expression  $F_{ij} = q_{ij}/A_i J_i$  and (b) Using the view factor integral, Eq. 13.1.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Surfaces  $A_1$  and  $A_2$  are diffuse and (2)  $A_1$  and  $A_2 \ll R^2$ .

**ANALYSIS:** (a) The view factor is defined as the fraction of radiation leaving  $A_i$  which is intercepted by surface  $j$  and, from Section 13.1.1, can be expressed as

$$F_{ij} = \frac{q_{ij}}{A_i J_i} \quad (1)$$

From Eq. 12.11, the radiation leaving intercepted by  $A_1$  and  $A_2$  on the spherical surface is

$$q_{1 \rightarrow 2} = (J_1 / \pi) \cdot A_1 \cos \theta_1 \cdot \omega_{2-1} \quad (2)$$

where the solid angle  $A_2$  subtends with respect to  $A_1$  is

$$\omega_{2-1} = \frac{A_{2,n}}{r^2} = \frac{A_2 \cos \theta_2}{r^2} \quad (3)$$

From the schematic above,

$$\cos \theta_1 = \cos \theta_2 \quad r = 2R \cos \theta_1 \quad (4,5)$$

Hence, the view factor is

$$F_{ij} = \frac{(J_1 / \pi) A_1 \cos \theta_1 \cdot A_2 \cos \theta_2 / 4R^2 \cos \theta_1}{A_1 J_1} = \frac{A_2}{4\pi R^2} \quad <$$

(b) The view factor integral, Eq. 13.1, for the small areas  $A_1$  and  $A_2$  is

$$F_{12} = \frac{1}{A_1} \int_{A_1} \int_{A_2} \frac{\cos \theta_1 \cos \theta_2}{\pi r^2} dA_1 dA_2 = \frac{\cos \theta_1 \cos \theta_2 A_2}{\pi r^2}$$

and from Eqs. (4,5) above,

$$F_{12} = \frac{A_2}{4\pi R^2} \quad <$$

**COMMENTS:** Recognize the importance of the second assumption. We require that  $A_1, A_2 \ll R^2$  so that the areas can be considered as of differential extent,  $A_1 = dA_1$ , and  $A_2 = dA_2$ . It may be shown, however, that due to the unique geometry of a sphere,  $F_{12} = A_2/(4\pi R^2)$  even when the areas are not small. See M.F. Modest, Radiation Heat Transfer, 2nd edition, Academic Press, San Diego, 2003.

### PROBLEM 13.15

**KNOWN:** Disk  $A_1$ , located coaxially, but tilted  $30^\circ$  of the normal, from the diffuse-gray, ring-shaped disk  $A_2$ . Surroundings at 400 K.

**FIND:** Irradiation on  $A_1$ ,  $G_1$ , due to the radiation from  $A_2$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1)  $A_2$  is diffuse-gray surface, (2) Uniform radiosity over  $A_2$ , (3) The surroundings are large with respect to  $A_1$  and  $A_2$ .

**ANALYSIS:** The irradiation on  $A_1$  is

$$G_1 = q_{21} / A_1 = (F_{21} \cdot J_2 A_2) / A_1 \quad (1)$$

where  $J_2$  is the radiosity from  $A_2$  evaluated as

$$J_2 = \epsilon_2 E_{b,2} + \rho_2 G_2 = \epsilon_2 \sigma T_2^4 + (1 - \epsilon_2) \sigma T_{sur}^4$$

$$J_2 = 0.7 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (600 \text{ K})^4 + (1 - 0.7) 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (400 \text{ K})^4$$

$$J_2 = 5144 + 436 = 5580 \text{ W/m}^2. \quad (2)$$

Using the view factor relation of Eq. 13.8, evaluate view factors between  $A_1'$ , the normal projection of  $A_1$ , and  $A_3$  as

$$F_{1'3} = \frac{D_1^2}{D_1^2 + 4L^2} = \frac{(0.004 \text{ m})^2}{(0.004 \text{ m})^2 + 4(1 \text{ m})^2} = 4.00 \times 10^{-6}$$

and between  $A_1'$  and  $(A_2 + A_3)$  as

$$F_{1'(23)} = \frac{D_o^2}{D_o^2 + 4L^2} = \frac{(0.012)^2}{(0.012)^2 + 4(1 \text{ m})^2} = 3.60 \times 10^{-5}$$

giving  $F_{1'2} = F_{1'(23)} - F_{1'3} = 3.60 \times 10^{-5} - 4.00 \times 10^{-6} = 3.20 \times 10^{-5}$ .

From the reciprocity relation it follows that

$$F_{21'} = A_1' F_{1'2} / A_2 = (A_1 \cos \theta_1 / A_2) F_{1'2} = 3.20 \times 10^{-5} \cos \theta_1 (A_1 / A_2). \quad (3)$$

By inspection we note that all the radiation striking  $A_1'$  will also intercept  $A_1$ ; that is

$$F_{21} = F_{21'}. \quad (4)$$

Hence, substituting for Eqs. (3) and (4) for  $F_{21}$  into Eq. (1), find

$$G_1 = \left( 3.20 \times 10^{-5} \cos \theta_1 (A_1 / A_2) \times J_2 \times A_2 \right) / A_1 = 3.20 \times 10^{-5} \cos \theta_1 \cdot J_2 \quad (5)$$

$$G_1 = 3.20 \times 10^{-5} \cos(30^\circ) \times 5580 \text{ W/m}^2 = 27.7 \text{ } \mu\text{W/m}^2. \quad <$$

**COMMENTS:** (1) Note from Eq. (5) that  $G_1 \sim \cos \theta_1$  such that  $G_1$  is a maximum when  $A_1$  is normal to disk  $A_2$ .

### PROBLEM 13.16

**KNOWN:** Heat flux gage positioned normal to a blackbody furnace. Cover of furnace is at 350 K while surroundings are at 300 K.

**FIND:** (a) Irradiation on gage,  $G_g$ , considering only emission from the furnace aperture and (b) Irradiation considering radiation from the cover *and* aperture.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Furnace aperture approximates blackbody, (2) Shield is opaque, diffuse and gray with uniform temperature, (3) Shield has uniform radiosity, (4)  $A_g \ll R^2$ , so that  $\omega_{g-f} = A_g/R^2$ , (5) Surroundings are large, uniform at 300 K.

**ANALYSIS:** (a) The irradiation on the gage due *only* to aperture emission is

$$G_g = q_{f-g} / A_g = (I_{e,f} \cdot A_f \cos \theta_f \cdot \omega_{g-f}) / A_g = \frac{\sigma T_f^4}{\pi} \cdot A_f \cdot \frac{A_g}{R^2} / A_g$$

$$G_g = \frac{\sigma T_f^4}{\pi R^2} A_f = \frac{5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (1000 \text{ K})^4}{\pi (1 \text{ m})^2} \times (\pi/4) (0.005 \text{ m})^2 = 354.4 \text{ mW/m}^2. \quad <$$

(b) The irradiation on the gage due to radiation from the *aperture* (a) and *cover* (c) is

$$G_g = G_{g,a} + \frac{F_{c-g} \cdot J_c A_c}{A_g}$$

where  $F_{c-g}$  and the cover radiosity are

$$F_{c-g} = F_{g-c} \left( A_g / A_c \right) \approx \frac{D_c^2}{4R^2 + D_c^2} \cdot \frac{A_g}{A_c} \quad J_c = \epsilon_c E_b(T_c) + \rho_c G_c$$

but  $G_c = E_b(T_{sur})$  and  $\rho_c = 1 - \alpha_c = 1 - \epsilon_c$ ,  $J_c = \epsilon_c \sigma T_c^4 + (1 - \epsilon_c) \sigma T_{sur}^4 = (170.2 + 387.4) \text{ W/m}^2$ . Hence, the irradiation is

$$G_g = G_{g,a} + \frac{1}{A_g} \left( \frac{D_c^2}{4R^2 + D_c^2} \cdot \frac{A_g}{A_c} \right) \left[ \epsilon_c \sigma T_c^4 + (1 - \epsilon_c) \sigma T_{sur}^4 \right] A_c$$

$$G_g = 354.4 \text{ mW/m}^2 + \left( \frac{0.10^2}{4 \times 1^2 + 0.10^2} \right) \left[ 0.2 \times \sigma (350)^4 + (1 - 0.2) \times \sigma (300)^4 \right] \text{ W/m}^2$$

$$G_g = 354.4 \text{ mW/m}^2 + 424.4 \text{ mW/m}^2 + 916.2 \text{ mW/m}^2 = 1,695 \text{ mW/m}^2.$$

**COMMENTS:** (1) Note we have assumed  $A_f \ll A_c$  so that effect of the aperture is negligible. (2) In part (b), the irradiation due to radiosity from the shield can be written also as  $G_{g,c} = q_{c-g}/A_g = (J_c/\pi) \cdot A_c \cdot \omega_{g-c}/A_g$  where  $\omega_{g-c} = A_g/R^2$ . This is an excellent approximation since  $A_c \ll R^2$ .

### PROBLEM 13.17

**KNOWN:** Temperature and diameters of a circular ice rink and a hemispherical dome.

**FIND:** Net rate of heat transfer to the ice due to radiation exchange with the dome.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Blackbody behavior for dome and ice. (2) Surfaces have uniform irradiation and radiosity.

**ANALYSIS:** From Eq. 13.13,

$$q_{21} = A_2 F_{21} \sigma (T_2^4 - T_1^4)$$

From reciprocity,  $A_2 F_{21} = A_1 F_{12} = \left( \pi D_1^2 / 4 \right) 1$

$$A_2 F_{21} = (\pi / 4) (25 \text{ m})^2 1 = 491 \text{ m}^2.$$

Hence

$$q_{21} = 491 \text{ m}^2 \left( 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \right) \left[ (288 \text{ K})^4 - (273 \text{ K})^4 \right]$$

$$q_{21} = 3.69 \times 10^4 \text{ W.} \quad <$$

**COMMENTS:** (1) If the air temperature,  $T_\infty$ , exceeds  $T_1$ , there will also be heat transfer by convection to the ice. The radiation and convection transfer to the ice determine the heat load which must be handled by the cooling system. (2) Because they are isothermal and black, the two surfaces have uniform radiosity. Do you expect them each to be uniformly irradiated? Would non-uniform irradiation of either surface affect the answer?

### PROBLEM 13.18

**KNOWN:** Surface temperature of a semi-circular drying oven.

**FIND:** Drying rate per unit length of oven.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Blackbody behavior for furnace wall and water, (2) Convection effects are negligible and bottom is insulated, (3) Uniform surface irradiation and radiosity.

**PROPERTIES:** Table A-6, Water (325 K):  $h_{fg} = 2.378 \times 10^6 \text{ J/kg}$ .

**ANALYSIS:** Applying a surface energy balance,

$$q_{12} = q_{\text{evap}} = \dot{m} h_{fg}$$

where it is assumed that the net radiation heat transfer to the water is balanced by the evaporative heat loss. From Eq. 13.13,

$$q_{12} = A_1 F_{12} \sigma (T_1^4 - T_2^4).$$

From inspection and the reciprocity relation,

$$F_{12} = \frac{A_2}{A_1} F_{21} = \frac{D \cdot L}{(\pi D/2) \cdot L} \times 1 = 0.637.$$

Hence

$$\dot{m}' = \frac{\dot{m}}{L} = \frac{\pi D}{2} F_{12} \sigma \frac{(T_1^4 - T_2^4)}{h_{fg}}$$

$$\dot{m}' = \frac{\pi(1 \text{ m})}{2} \times 0.637 \times 5.67 \times 10^{-8} \frac{\text{W}}{\text{m}^2 \cdot \text{K}^4} \frac{(1200 \text{ K})^4 - (325 \text{ K})^4}{2.378 \times 10^6 \text{ J/kg}}$$

or

$$\dot{m}' = 0.0492 \text{ kg/s} \cdot \text{m.}$$

<

**COMMENTS:** (1) Air flow through the oven is needed to remove the water vapor. The water surface temperature,  $T_2$ , is determined by a balance between radiation heat transfer to the water and the convection of latent and sensible energy from the water. (2) Because the surfaces are black and isothermal, they have uniform radiosity.

### PROBLEM 13.19

**KNOWN:** Arrangement of three black surfaces with prescribed geometries and surface temperatures.

**FIND:** (a) View factor  $F_{13}$ , (b) Net radiation heat transfer from  $A_1$  to  $A_3$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Interior surfaces behave as blackbodies, (2)  $A_2 \gg A_1$ , (3) Surfaces are uniformly irradiated and have uniform radiosities.

**ANALYSIS:** (a) Define the enclosure as the interior of the cylindrical form and identify  $A_4$ . Applying the view factor summation rule, Eq. 13.4,

$$F_{11} + F_{12} + F_{13} + F_{14} = 1. \quad (1)$$

Note that  $F_{11} = 0$  and  $F_{14} = 0$ . From Eq. 13.8,

$$F_{12} = \frac{D^2}{D^2 + 4L^2} = \frac{(3\text{m})^2}{(3\text{m})^2 + 4(2\text{m})^2} = 0.36. \quad (2)$$

From Eqs. (1) and (2),

$$F_{13} = 1 - F_{12} = 1 - 0.36 = 0.64. \quad <$$

(b) From Eq. 13.13,

$$q_{13} = A_1 F_{13} \sigma (T_1^4 - T_3^4)$$

$$q_{13} = 0.05\text{m}^2 \times 0.64 \times 5.67 \times 10^{-8} \text{W/m}^2 \cdot \text{K}^4 (1000^4 - 500^4) \text{K}^4 = 1700 \text{W}. \quad <$$

**COMMENTS:** (1) Note that the summation rule, Eq. 13.4, applies to an enclosure; that is, the total region above the surface must be considered. (2) Because the surfaces are black and isothermal, their radiosities are uniform. Is the irradiation of each surface uniform?

### PROBLEM 13.20

**KNOWN:** Furnace diameter and temperature. Dimensions and temperature of suspended part.

**FIND:** Net rate of radiation transfer per unit length to the part.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) All surfaces may be approximated as blackbodies. (2) Uniform surface irradiation and radiosity.

**ANALYSIS:** From symmetry considerations, it is convenient to treat the system as a three-surface enclosure consisting of the inner surfaces of the vee (1), the outer surfaces of the vee (2) and the furnace wall (3). The net rate of radiation heat transfer to the part is then

$$q'_{w,p} = A'_3 F_{31} \sigma (T_w^4 - T_p^4) + A'_3 F_{32} \sigma (T_w^4 - T_p^4)$$

From reciprocity,

$$A'_3 F_{31} = A'_1 F_{13} = 2L \times 0.5 = 1\text{ m}$$

where surface 3 may be represented by the dashed line and, from symmetry,  $F_{13} = 0.5$ . Also,

$$A'_3 F_{32} = A'_2 F_{23} = 2L \times 1 = 2\text{ m}$$

Hence,

$$q'_{w,p} = (1+2)\text{ m} \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (1000^4 - 300^4) \text{ K}^4 = 1.69 \times 10^5 \text{ W/m} <$$

**COMMENTS:** (1) With all surfaces approximated as blackbodies, the result is independent of the tube diameter. (2) Note that  $F_{11} = 0.5$ . (3) Because the surfaces are approximated as blackbodies and are isothermal they have uniform radiosity. The irradiation of the surfaces is, however, non-uniform. Will this affect the answer?

### PROBLEM 13.21

**KNOWN:** Coaxial, parallel black plates with surroundings. Lower plate ( $A_2$ ) maintained at prescribed temperature  $T_2$  while electrical power is supplied to upper plate ( $A_1$ ).

**FIND:** Temperature of the upper plate  $T_1$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Plates are black surfaces of uniform temperature. (2) Backside of heater on  $A_1$  insulated. (3) Uniform surface irradiation and radiosity.

**ANALYSIS:** The net radiation heat rate leaving  $A_i$  is

$$P_e = \sum_{j=1}^N q_{ij} = A_1 F_{12} \sigma (T_1^4 - T_2^4) + A_1 F_{13} \sigma (T_1^4 - T_3^4)$$

$$P_e = A_1 \sigma \left[ F_{12} (T_1^4 - T_2^4) + F_{13} (T_1^4 - T_{sur}^4) \right] \quad (1)$$

From Fig. 13.5 for coaxial disks (see Table 13.2),

$$R_1 = r_1 / L = 0.10 \text{ m} / 0.20 \text{ m} = 0.5 \qquad R_2 = r_2 / L = 0.20 \text{ m} / 0.20 \text{ m} = 1.0$$

$$S = 1 + \frac{1 + R_2^2}{R_1^2} = 1 + \frac{1 + 1^2}{(0.5)^2} = 9.0$$

$$F_{12} = \frac{1}{2} \left\{ S - \left[ S^2 - 4(r_2 / r_1)^2 \right]^{1/2} \right\} = \frac{1}{2} \left\{ 9 - \left[ 9^2 - 4(0.2/0.1)^2 \right]^{1/2} \right\} = 0.469.$$

From the summation rule for the enclosure  $A_1$ ,  $A_2$  and  $A_3$  where the last area represents the surroundings with  $T_3 = T_{sur}$ ,  $F_{12} + F_{13} = 1$  and  $F_{13} = 1 - F_{12} = 1 - 0.469 = 0.531$ .

Substituting numerical values into Eq. (1), with  $A_1 = \pi D_1^2 / 4 = 3.142 \times 10^{-2} \text{ m}^2$ ,

$$17.5 \text{ W} = 3.142 \times 10^{-2} \text{ m}^2 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left[ 0.469 (T_1^4 - 500^4) \text{K}^4 \right. \\ \left. + 0.531 (T_1^4 - 300^4) \text{K}^4 \right]$$

$$9.823 \times 10^9 = 0.469 (T_1^4 - 500^4) + 0.531 (T_1^4 - 300^4)$$

we find that  $T_1 = 456 \text{ K}$ .

<

**COMMENTS:** (1) Note that if the upper plate were adiabatic,  $T_1 = 427 \text{ K}$ . (2) Would you expect the surfaces to experience uniform irradiation? If the heater were constructed of a low thermal conductivity material, temperature gradients would likely develop in the radial direction. If this were the case, the heater surface would no longer be isothermal, and would no longer have a uniform radiosity. A more detailed analysis involving more radiation surface might be warranted in practice.

### PROBLEM 13.22

**KNOWN:** Dimensions and separation distance of coaxial, parallel black plates. Temperatures of lower plate and surroundings. Electrical power supplied to upper plate.

**FIND:** Temperature of the upper plate for circular and square plates and dependence on separation distance.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Plates are black surfaces of uniform temperature. (2) Backside of heater on  $A_1$  insulated. (3) Surfaces have uniform irradiation and radiosity.

**ANALYSIS:** The net radiation heat rate leaving  $A_1$  is

$$P_e = \sum_{j=1}^N q_{ij} = A_1 F_{12} \sigma (T_1^4 - T_2^4) + A_1 F_{13} \sigma (T_1^4 - T_{\text{sur}}^4)$$

$$P_e = A_1 \sigma \left[ F_{12} (T_1^4 - T_2^4) + F_{13} (T_1^4 - T_{\text{sur}}^4) \right] \quad (1)$$

From Table 13.2 for coaxial disks (or Fig. 13.5),

$$R_1 = R_2 = r / L = 0.10 \text{ m} / 0.20 \text{ m} = 0.5$$

$$S = 1 + \frac{1 + R_2^2}{R_1^2} = 1 + \frac{1 + (0.5)^2}{(0.5)^2} = 6$$

$$F_{12} = \frac{1}{2} \left\{ S - \left[ S^2 - 4(r_2 / r_1)^2 \right]^{1/2} \right\} = \frac{1}{2} \left\{ 6 - \left[ 6^2 - 4 \right]^{1/2} \right\} = 0.172.$$

From the summation rule for the enclosure  $A_1$ ,  $A_2$ , and  $A_3$  where the last area represents the surroundings with  $T_3 = T_{\text{sur}}$ ,

$$F_{12} + F_{13} = 1 \quad F_{13} = 1 - F_{12} = 1 - 0.172 = 0.828.$$

From Eq. (1), with  $A_1 = \pi D_1^2 / 4 = 3.142 \times 10^{-2} \text{ m}^2$ ,

$$T_1 = \left[ \frac{\left( \frac{P_e}{A_1 \sigma} + F_{12} T_2^4 + F_{13} T_{\text{sur}}^4 \right)}{F_{12} + F_{13}} \right]^{1/4} \quad (2)$$

Continued...

**PROBLEM 13.22 (Cont.)**

$$T_1 = \left[ \frac{\left( \frac{17.5 \text{ W}}{3.142 \times 10^{-2} \text{ m}^2 \times 5.67 \times 10^{-8} \text{ W / m}^2 \cdot \text{K}^4} + 0.172 \times 500^4 \text{ K}^4 + 0.828 \times 300^4 \text{ K}^4 \right)}{1} \right]^{1/4}$$

$$T_1 = 406 \text{ K.}$$

<

For the coaxial squares,  $X = (\pi/4)^{1/2} D = 0.177 \text{ m}$ . Then  $F_{12}$  is found from Table 13.2 for aligned rectangles (or Fig. 13.4),

$$\bar{X} = \bar{Y} = X / L = 0.177 \text{ m} / 0.20 \text{ m} = 0.886$$

$$F_{12} = \frac{2}{\pi \bar{X}^2} \left\{ \ln \left[ \frac{(1 + \bar{X}^2)^2}{1 + 2\bar{X}^2} \right]^{1/2} + 2\bar{X}(1 + \bar{X}^2)^{1/2} \tan^{-1} \left[ \frac{\bar{X}}{(1 + \bar{X}^2)^{1/2}} \right] - 2\bar{X} \tan^{-1} \bar{X} \right\} = 0.170.$$

Then,

$$F_{12} + F_{13} = 1 \quad F_{13} = 1 - F_{12} = 1 - 0.170 = 0.830.$$

Finally, from Eq. (2)

$$T_1 = \left[ \frac{\left( \frac{17.5 \text{ W}}{3.142 \times 10^{-2} \text{ m}^2 \times 5.67 \times 10^{-8} \text{ W / m}^2 \cdot \text{K}^4} + 0.170 \times 500^4 \text{ K}^4 + 0.830 \times 300^4 \text{ K}^4 \right)}{1} \right]^{1/4}$$

$$T_1 = 406 \text{ K.}$$

<

Continued...

### PROBLEM 13.22 (Cont.)

Results were generated for  $0 < L \leq 1$  m using IHT and are shown below. The results for the circular disks and aligned squares are plotted together and are virtually indistinguishable.

<

**COMMENTS:** (1) For either geometry, as the plates approach one another the cooling effect of the surroundings vanishes, and the temperature of plate 1 adjusts to adhere to an energy balance between the power supplied by the heater and the heat loss to plate 2 at 500 K. That is,  $P_e = A_1 \sigma (T_1^4 - T_2^4)$ , resulting in  $T_1 = 519$  K. (2) As the plates become far apart, the effect of plate 2 on plate 1 vanishes. The temperature of plate 1 adjusts to adhere to an energy balance between the power supplied by the heater and the heat loss to the cool surroundings. That is,  $P_e = A_1 \sigma (T_1^4 - T_2^4)$ , resulting in  $T_1 = 366$  K. (3) The shape factors for the two geometries are nearly the same and therefore the temperature of plate 1 is almost the same for either geometry. (4) The surfaces are not uniformly irradiated. If the heater were constructed of low thermal conductivity material, it may experience a spatial temperature distribution. As such, it would no longer be isothermal and would no longer have a uniform radiosity. A more detailed analysis involving many radiation surfaces may be warranted in practice.

### PROBLEM 13.23

**KNOWN:** Tubular heater radiates like blackbody at 1000 K.

**FIND:** (a) Radiant power from the heater surface,  $A_s$ , intercepted by a disc,  $A_1$ , at a prescribed location  $q_{s \rightarrow 1}$ ; irradiation on the disk,  $G_1$ ; and (b) Compute and plot  $q_{s \rightarrow 1}$  and  $G_1$  as a function of the separation distance  $L_1$  for the range  $0 \leq L_1 \leq 200$  mm for disk diameters  $D_1 = 25$ , and 50 and 100 mm.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Heater surface behaves as blackbody with uniform temperature. (2) Surfaces have uniform radiosity and irradiation.

**ANALYSIS:** (a) The radiant power leaving the inner surface of the tubular heater that is intercepted by the disk is

$$q_{2 \rightarrow 1} = (A_2 E_{b2}) F_{21} \quad (1)$$

where the heater is surface 2 and the disk is surface 1. It follows from the reciprocity rule, Eq. 13.3, that

$$F_{21} = \frac{A_1}{A_2} F_{12}. \quad (2)$$

Define now the hypothetical disks,  $A_3$  and  $A_4$ , located at the ends of the tubular heater. By inspection, it follows that

$$F_{14} = F_{12} + F_{13} \quad \text{or} \quad F_{12} = F_{14} - F_{13} \quad (3)$$

where  $F_{14}$  and  $F_{13}$  may be determined from Fig. 13.5. Substituting numerical values, with  $D_3 = D_4 = D_2$ ,

$$F_{13} = 0.08 \quad \text{with} \quad \frac{L}{r_i} = \frac{L_1 + L_2}{D_1/2} = \frac{200}{50/2} = 8 \quad \frac{r_j}{L} = \frac{D_3/2}{L_1 + L_2} = \frac{100/2}{200} = 0.25$$

$$F_{14} = 0.20 \quad \text{with} \quad \frac{L}{r_i} = \frac{L_1}{D_1/2} = \frac{100}{50/2} = 4 \quad \frac{r_j}{L} = \frac{D_4/2}{L_1} = \frac{100/2}{100} = 0.5$$

Substituting Eq. (3) into Eq. (2) and then into Eq. (1), the result is

$$q_{2 \rightarrow 1} = A_1 (F_{14} - F_{13}) E_{b2}$$

$$q_{2 \rightarrow 1} = \left[ \pi (50 \times 10^{-3})^2 / 4 \right] (0.20 - 0.08) \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (1000 \text{ K})^4 = 13.4 \text{ W} \quad <$$

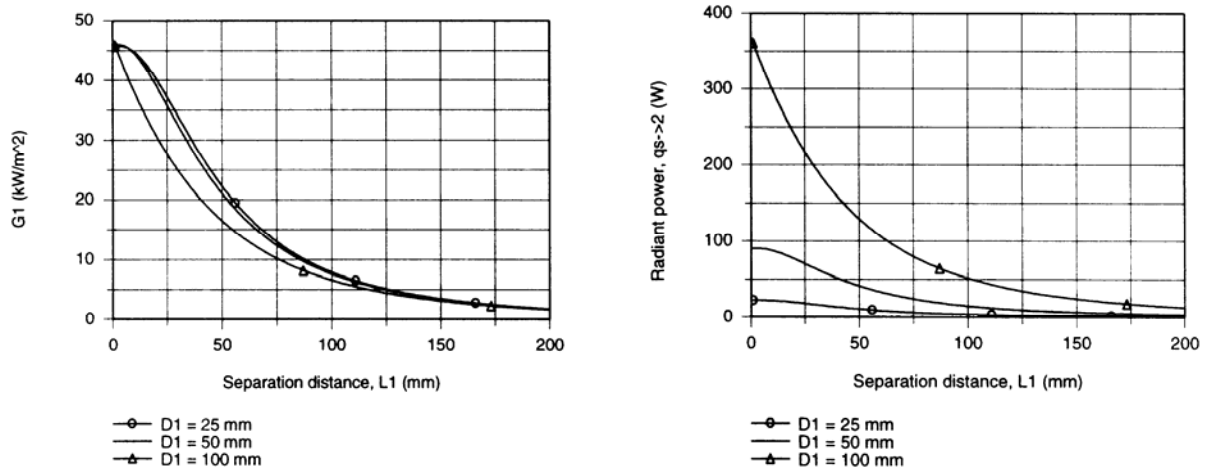

where  $E_{b2} = \sigma T_s^4$ . The irradiation  $G_1$  originating from emission leaving the heater surface is

$$G_1 = \frac{q_{s \rightarrow 1}}{A_1} = \frac{13.4 \text{ W}}{\pi (0.050 \text{ m})^2 / 4} = 6825 \text{ W/m}^2. \quad (4) <$$

Continued ...

### PROBLEM 13.23 (Cont.)

(b) Using the foregoing equations in *IHT* along with the *Radiation Tool-View Factors* for *Coaxial Parallel Disks*,  $G_1$  and  $q_{s \rightarrow 1}$  were computed as a function of  $L_1$  for selected values of  $D_1$ . The results are plotted below.

In the upper left-hand plot,  $G_1$  decreases with increasing separation distance. For a given separation distance, the irradiation decreases with increasing diameter. With values of  $D_1 = 25$  and  $50$  mm, the irradiation values are only slightly different, which diminishes as  $L_1$  increases. In the upper right-hand plot, the radiant power from the heater surface reaching the disk,  $q_{s \rightarrow 2}$ , decreases with increasing  $L_1$  and decreasing  $D_1$ . Note that while  $G_1$  is nearly the same for  $D_1 = 25$  and  $50$  mm, their respective  $q_{s \rightarrow 2}$  values are quite different. Why is this so?

Comment. Since the tube surface is assumed to be black and isothermal, it will have uniform radiosity distributions. However, its irradiation is not uniform. Will the nonuniformity of the irradiation affect the answer?

### PROBLEM 13.24

**KNOWN:** Circular plate ( $A_1$ ) maintained at 600 K positioned coaxially with a conical shape ( $A_2$ ) whose backside is insulated. Plate and cone are black surfaces and located in large, insulated enclosure at 300 K.

**FIND:** (a) Temperature of the conical surface  $T_2$  and (b) Electric power required to maintain plate at 600 K.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Plate and cone are black, (3) Cone behaves as insulated, reradiating surface, (4) Surroundings are large compared to plate and cone, (5) Uniform irradiation and radiosity.

**ANALYSIS:** (a) Recognizing that the plate, cone, and surroundings form a three-(black) surface enclosure, perform a radiation balance on the cone.

$$q_2 = 0 = q_{23} + q_{21} = A_2 F_{23} \sigma (T_2^4 - T_3^4) + A_2 F_{21} \sigma (T_2^4 - T_1^4)$$

where the view factor  $F_{21}$  can be determined from the *coaxial parallel disks* relation (Table 13.2 or Fig. 13.5) with  $R_i = r_i/L = 250/500 = 0.5$ ,  $R_j = 0.5$ ,  $S = 1 + (1 + R_j^2)/R_i^2 = 1 + (1 + 0.5^2)/0.5^2 = 6.00$ , and noting  $F_{2'1} = F_{21}$ ,

$$F_{21} = 0.5 \left\{ S - \left[ S^2 - 4 \left( r_j / r_i \right)^2 \right]^{1/2} \right\} = 0.5 \left\{ 6 - \left[ 6^2 - 4 (0.5 / 0.5)^2 \right]^{1/2} \right\} = 0.172.$$

For the enclosure, the summation rule provides,  $F_{2'3} = 1 - F_{2'1} = 1 - 0.172 = 0.828$ . Hence,

$$0.828 (T_2^4 - 300^4) = 0 + 0.172 (T_2^4 - 600^4)$$

$$T_2 = 413 \text{ K.} \quad <$$

(b) The power required to maintain the plate at  $T_2$  follows from a radiation balance,

$$q_1 = q_{12} + q_{13} = A_1 F_{12} \sigma (T_1^4 - T_2^4) + A_1 F_{13} \sigma (T_1^4 - T_3^4)$$

where  $F_{12} = A_2' F_{2'1} / A_1 = F_{21} = 0.172$  and  $F_{13} = 1 - F_{12} = 0.828$ ,

$$q_1 = (\pi 0.5^2 / 4) \text{ m}^2 \sigma \left[ 0.172 (600^4 - 413^4) \text{ K}^4 + 0.828 (600^4 - 300^4) \text{ K}^4 \right]$$

$$q_1 = 1312 \text{ W.} \quad <$$

**Comment:** Because the surfaces are black and isothermal, they each are characterized by a uniform radiosity. Will the non-uniformity of the irradiation of the surfaces affect the answer?

### PROBLEM 13.25

**KNOWN:** Conical and cylindrical furnaces ( $A_2$ ) as illustrated and dimensioned in Problem 13.4 supplied with power of 50 W. Workpiece ( $A_1$ ) with insulated backside located in large room at 300 K.

**FIND:** Temperature of the workpiece,  $T_1$ , and the temperature of the inner surfaces of the furnaces,  $T_2$ . Use expressions for the view factors  $F_{21}$  and  $F_{22}$  given in the statement for Problem 13.4.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Diffuse, black surfaces with uniform radiosities, (2) Backside of workpiece is perfectly insulated, (3) Inner base and lateral surfaces of the cylindrical furnace treated as single surface, (4) Negligible convection heat transfer, (5) Room behaves as large, isothermal surroundings.

**ANALYSIS:** Considering the furnace surface ( $A_2$ ), the workpiece ( $A_1$ ) and the surroundings ( $A_s$ ) as an enclosure, the net radiation transfer from  $A_1$  and  $A_2$  follows from Eq. 13.13,

$$\text{Workpiece} \quad q_1 = 0 = A_1 F_{12} (E_{b1} - E_{b2}) + A_1 F_{1s} (E_{b1} - E_{bs}) \quad (1)$$

$$\text{Furnace} \quad q_2 = 50 \text{ W} = A_2 F_{21} (E_{b2} - E_{b1}) + A_2 F_{2s} (E_{b2} - E_{bs}) \quad (2)$$

where  $E_b = \sigma T^4$  and  $\sigma = 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4$ . From summation rules on  $A_1$  and  $A_2$ , the view factors  $F_{1s}$  and  $F_{2s}$  can be evaluated. Using reciprocity,  $F_{12}$  can be evaluated.

$$F_{1s} = 1 - F_{12} \quad F_{2s} = 1 - F_{21} - F_{22} \quad F_{12} = (A_2 / A_1) F_{21}$$

The expressions for  $F_{21}$  and  $F_{22}$  are provided in the schematic. With  $A_1 = \pi D_1^2 / 4$  the  $A_2$  are:

$$\text{Cone: } A_2 = \pi D_3 / 2 \left( L^2 + (D_3 / 2)^2 \right)^{1/2} \quad \text{Cylinder: } A_2 = \pi D_3^2 / 4 + \pi D_3 L$$

Examine Eqs (1) and (2) and recognize that there are two unknowns,  $T_1$  and  $T_2$ , and the equations must be solved simultaneously. Using the foregoing equations in the *IHT* workspace, the results are

$$T_1 = 544 \text{ K} \quad T_2 = 828 \text{ K} \quad \leftarrow$$

**COMMENTS:** (1) From the *IHT* analysis, the relevant view factors are:  $F_{12} = 0.1716$ ;  $F_{1s} = 0.8284$ ; *Cone:*  $F_{21} = 0.07673$ ,  $F_{22} = 0.5528$ ; *Cylinder:*  $F_{21} = 0.03431$ ,  $F_{22} = 0.80$ . (2) That both furnace configurations provided identical results may not, at first, be intuitively obvious. Since both furnaces ( $A_2$ ) are black, they can be represented by the hypothetical black area  $A_3$  (the opening of the furnaces). As such, the analysis is for an enclosure with the workpiece ( $A_1$ ), the furnace represented by the disk  $A_3$  (at  $T_2$ ), and the surroundings. As an exercise, perform this analysis to confirm the above results. (3) Since the surfaces are assumed to be black and isothermal, their radiosities are uniform. The irradiation of the surfaces is not uniform. This may lead to non-uniform temperature distributions in the workpiece in a real application.

### PROBLEM 13.26

**KNOWN:** Furnace constructed in three sections: insulated circular (2) and cylindrical (3) sections, as well as, an intermediate cylindrical section (1) with imbedded electrical resistance heaters. Cylindrical sections (1,3) are of equal length.

**FIND:** (a) Electrical power required to maintain the heated section at  $T_1 = 1000$  K if all the surfaces are black, (b) Temperatures of the insulated sections,  $T_2$  and  $T_3$ , and (c) Compute and plot  $q_1$ ,  $T_2$  and  $T_3$  as functions of the length-to-diameter ratio, with  $1 \leq L/D \leq 5$  and  $D = 100$  mm.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) All surfaces are black, (2) Areas (1, 2, 3) are isothermal. (3) Uniform surface radiosity and irradiation.

**ANALYSIS:** (a) To complete the enclosure representing the furnace, define the hypothetical surface  $A_4$  as the opening at 0 K with unity emissivity. For each of the enclosure surfaces 1, 2, and 3, the energy balances following Eq. 13.13 are

$$q_1 = A_1 F_{12} (E_{b1} - E_{b2}) + A_1 F_{13} (E_{b1} - E_{b3}) + A_1 F_{14} (E_{b1} - E_{b4}) \quad (1)$$

$$0 = A_2 F_{21} (E_{b2} - E_{b1}) + A_2 F_{23} (E_{b2} - E_{b3}) + A_2 F_{24} (E_{b2} - E_{b4}) \quad (2)$$

$$0 = A_3 F_{31} (E_{b3} - E_{b1}) + A_3 F_{32} (E_{b3} - E_{b2}) + A_3 F_{34} (E_{b3} - E_{b4}) \quad (3)$$

where the emissive powers are

$$E_{b1} = \sigma T_1^4 \quad E_{b2} = \sigma T_2^4 \quad E_{b3} = \sigma T_3^4 \quad E_{b4} = 0 \quad (4-7)$$

For this four surface enclosure, there are  $N^2 = 16$  view factors and  $N(N-1)/2 = 4 \times 3/2 = 6$  must be directly determined (by inspection or formulas) and the remainder can be evaluated from the summation rule and reciprocity relation. By inspection,

$$F_{22} = 0 \quad F_{44} = 0 \quad (8,9)$$

From the coaxial parallel disk relation, Table 13.2, find  $F_{24}$

$$S = 1 + \frac{1 + R_4^2}{R_2^2} = 1 + \frac{1 + (0.250)^2}{(0.250)^2} = 18.00$$

$$R_2 = r_2 / L = 0.050 \text{ m} / 0.200 \text{ m} = 0.250 \quad R_4 = r_4 / L = 0.250$$

$$F_{24} = 0.5 \left\{ S - \left[ S^2 - 4(r_4 / r_2)^2 \right]^{1/2} \right\}$$

$$F_{24} = 0.5 \left\{ 18.00 - \left[ 18.00^2 - 4(1)^2 \right]^{1/2} \right\} = 0.0557 \quad (10)$$

Consider the three-surface enclosure 1-2-2' and find  $F_{11}$  as beginning with the summation rule,

Continued ...

**PROBLEM 13.26 (Cont.)**

$$F_{11} = 1 - F_{12} - F_{12'} \quad (11)$$

where, from symmetry,  $F_{12} = F_{12'}$ , and using reciprocity,

$$F_{12} = A_2 F_{21} / A_1 = \left( \pi D^2 / 4 \right) F_{23} / (\pi D L / 2) = D F_{21} / 2L \quad (12)$$

and from the summation rule on  $A_2$

$$F_{21} = 1 - F_{22'} = 1 - 0.172 = 0.828, \quad (13)$$

Using the coaxial parallel disk relation, Table 13.2, to find  $F_{22'}$ ,

$$S = 1 + \frac{1 + R_2^2}{R_2^2} = 1 + \frac{1 + 0.50^2}{0.50^2} = 6.000$$

$$R_2 = r_2 / L = 0.050 \text{ m} / (0.200 / 2 \text{ m}) = 0.500 \quad R_2' = 0.500$$

$$F_{22'} = 0.5 \left\{ S - \left[ S^2 - 4(r_2' / r_2)^2 \right]^{1/2} \right\}$$

$$F_{22'} = 0.5 \left\{ 6 - \left[ 6^2 - 4(1)^2 \right]^{1/2} \right\} = 0.1716$$

Evaluating  $F_{12}$  from Eq. (12), find

$$F_{12} = 0.100 \text{ m} \times 0.828 / 2 \times 0.200 \text{ m} = 0.2071$$

and evaluating  $F_{11}$  from Eq. (11), find

$$F_{11} = 1 - 2 \times F_{12} = 1 - 2 \times 0.207 = 0.586$$

From symmetry, recognize that  $F_{33} = F_{11}$  and  $F_{43} = F_{21}$ . To this point we have directly determined six view factors (underlined in the matrix below) and the remaining  $F_{ij}$  can be evaluated from the summation rules and appropriate reciprocity relations. The view factors written in matrix form,  $[F_{ij}]$  are.

<u>0.5858</u>	<u>0.2071</u>	0.1781	0.02896
<u>0.8284</u>	<u>0</u>	0.1158	<u>0.05573</u>
0.1781	0.02896	0.5858	0.2071
0.1158	0.05573	0.8284	<u>0</u>

Knowing all the required view factors, the energy balances and the emissive powers, Eqs. (4-6), can be solved simultaneously to obtain:

$q_1 = 255 \text{ W}$	$E_{b2} = 5.02 \times 10^4 \text{ W/m}^2$	$E_{b3} = 2.79 \times 10^4 \text{ W/m}^2$	<
$T_2 = 970 \text{ K}$	$T_3 = 837.5 \text{ K}$		<

Continued ...

### PROBLEM 13.26 (Cont.)

(b) Using the energy balances, Eqs. (1-3), along with the *IHT Radiation Tool, View Factors, Coaxial parallel disks*, a model was developed to calculate  $q_1$ ,  $T_2$ , and  $T_3$  as a function of length  $L$  for fixed diameter  $D = 100$  m. The results are plotted below.

For fixed diameter, as the overall length increases, the power required to maintain the heated section at  $T_1 = 1000$  K decreases. This follows since the furnace opening area is a smaller fraction of the enclosure surface area as  $L$  increases. As  $L$  increases, the bottom surface temperature  $T_2$  increases as  $L$  increases and, in the limit, will approach that of the heated section,  $T_1 = 1000$  K. As  $L$  increases, the temperature of the insulated cylindrical section,  $T_3$ , increases, but only slightly. The limiting value occurs when  $E_{b3} = 0.5 \times E_{b1}$  for which  $T_3 \rightarrow 840$  K. Why is that so?

COMMENT: If the electrical heating is uniformly distributed, the temperature of the heated section will not be uniform. In practice, a more detailed analysis involving more radiation surfaces might be warranted.

### PROBLEM 13.27

**KNOWN:** Dimensions and temperature of a rectangular fin array radiating to deep space.

**FIND:** Expression for rate of radiation transfer per unit length from a unit section of the array.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Surfaces may be approximated as blackbodies, (2) Surfaces are isothermal, (3) Length of array (normal to page) is much larger than  $W$  and  $L$ .

**ANALYSIS:** Deep space may be represented by the hypothetical surface  $A'_3$ , which acts as a blackbody at absolute zero temperature. The net rate of radiation heat transfer to this surface is therefore equivalent to the rate of heat rejection by a unit section of the array.

$$q'_3 = A'_1 F_{13} \sigma (T_1^4 - T_3^4) + A'_2 F_{23} \sigma (T_2^4 - T_3^4)$$

With  $A'_2 F_{23} = A'_3 F_{32} = A'_1 F_{12}$ ,  $T_1 = T_2 = T$  and  $T_3 = 0$ ,

$$q'_3 = A'_1 (F_{13} + F_{12}) \sigma T^4 = W \sigma T^4$$

<

Radiation from a unit section of the array corresponds to emission from the base. Hence, if blackbody behavior can, indeed, be maintained, the fins do nothing to enhance heat rejection.

**COMMENTS:** (1) The foregoing result should come as no surprise since the surfaces of the unit section form an isothermal blackbody cavity for which emission is proportional to the area of the opening. (2) Because surfaces 1 and 2 have the same temperature, the problem could be treated as a two-surface enclosure consisting of the combined (1, 2) and 3. It follows that  $q'_3 = q'_{(1,2)3} = A'_{(1,2)}$

$F_{(1,2)3} \sigma T^4 = A'_3 F_{3(1,2)} \sigma T^4 = W \sigma T^4$ , (3) If blackbody behavior cannot be achieved ( $\epsilon_1, \epsilon_2 < 1$ ), enhancement would be afforded by the fins.

### PROBLEM 13.28

**KNOWN:** Geometry of furnace. Total power. Heat flux is uniform. Temperature of surroundings.

**FIND:** Temperature of four surfaces.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Interior surfaces behave as blackbodies with uniform temperature, radiosity, and irradiation. (2) Heat transfer by convection is negligible. (3) Backs of electrically-heated surfaces are adiabatic.

**ANALYSIS:** With a total heat loss of  $q = 1522$  W, the heat flux is

$$q'' = \frac{q}{\pi D^2 / 4 + \pi DL} = \frac{1522 \text{ W}}{\pi(0.05 \text{ m})^2 / 4 + \pi \times 0.05 \text{ m} \times 0.15 \text{ m}} = 59,630 \text{ W/m}^2$$

The view factors from the surroundings to the furnace surfaces were found in Example 13.3, but it will be a little easier here to work with the view factors from the furnace surfaces to the surroundings:

$$F_{15} = \frac{A_5 F_{51}}{A_1} = F_{51} = 0.0263$$

$$F_{25} = \frac{A_5 F_{52}}{A_2} = \frac{(\pi D^2 / 4) F_{52}}{\pi DL / 3} = \frac{3D}{4L} F_{52} = \frac{3 \times 0.05 \text{ m}}{4 \times 0.15 \text{ m}} 0.0294 = 0.00735$$

$$F_{35} = \frac{A_5 F_{53}}{A_3} = \frac{3D}{4L} F_{53} = \frac{3 \times 0.05 \text{ m}}{4 \times 0.15 \text{ m}} 0.1163 = 0.0291$$

$$F_{45} = \frac{A_5 F_{54}}{A_4} = \frac{3D}{4L} F_{54} = \frac{3 \times 0.05 \text{ m}}{4 \times 0.15 \text{ m}} 0.828 = 0.207$$

Continued...

### PROBLEM 13.28 (Cont.)

As in Example 13.3, the electric power delivered to each surface balances the corresponding radiation loss. Equations (1)-(4) from Example 13.3 can be solved for the temperatures of each surface.

Recognizing that  $q_1/A_1 = q_2/A_2 = q_3/A_3 = q_4/A_4 = q''$ , we find

$$T_1 = \left( \frac{q_1}{A_1 F_{15} \sigma} + T_5^4 \right)^{1/4} = \left( \frac{q''}{F_{15} \sigma} + T_5^4 \right)^{1/4} = \left( \frac{59,630 \text{ W/m}^2}{0.0263 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4} + 300^4 \text{ K}^4 \right)^{1/4} = 2515 \text{ K} <$$

$$T_2 = \left( \frac{q''}{F_{25} \sigma} + T_5^4 \right)^{1/4} = \left( \frac{59,630 \text{ W/m}^2}{0.00735 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4} + 300^4 \text{ K}^4 \right)^{1/4} = 3459 \text{ K} <$$

$$T_3 = \left( \frac{q''}{F_{35} \sigma} + T_5^4 \right)^{1/4} = \left( \frac{59,630 \text{ W/m}^2}{0.0291 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4} + 300^4 \text{ K}^4 \right)^{1/4} = 2452 \text{ K} <$$

$$T_4 = \left( \frac{q''}{F_{45} \sigma} + T_5^4 \right)^{1/4} = \left( \frac{59,630 \text{ W/m}^2}{0.207 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4} + 300^4 \text{ K}^4 \right)^{1/4} = 1502 \text{ K} <$$

**COMMENTS:** (1) The hottest surface is surface 2, which has the smallest view factor from itself to the surroundings. (2) The large variation in temperature between the four surfaces suggests that the actual temperature of *each* surface would also vary substantially, invalidating the assumptions of uniform radiosity and irradiation. A more accurate analysis could be performed by following the methodology of Comment 3 of Example 13.3.

### PROBLEM 13.29

**KNOWN:** Dimensions and temperatures of side and bottom walls in a cylindrical cavity.

**FIND:** Emissive power of the cavity.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Blackbody behavior for surfaces 1 and 2. (2) Uniform surface radiosity and irradiation distributions.

**ANALYSIS:** The emissive power is defined as

$$E = q_3 / A_3$$

where

$$q_3 = A_1 F_{13} E_{b1} + A_2 F_{23} E_{b2}.$$

From symmetry,  $F_{23} = F_{21}$ , and from reciprocity,  $F_{21} = (A_1/A_2) F_{12}$ . With  $F_{12} = 1 - F_{13}$ , it follows that

$$q_3 = A_1 F_{13} E_{b1} + A_1 (1 - F_{13}) E_{b2} = A_1 E_{b2} + A_1 F_{13} (E_{b1} - E_{b2}).$$

Hence, with  $A_1 = A_3$ ,

$$E = \frac{q_3}{A_3} = E_{b2} + F_{13} (E_{b1} - E_{b2}) = \sigma T_2^4 + F_{13} \sigma (T_1^4 - T_2^4).$$

From Fig. 13.5, with  $(L/r_i) = 4$  and  $(r_j/L) = 0.25$ ,  $F_{13} \approx 0.05$ . Hence

$$E = 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (700^4) \text{K}^4 + 0.05 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (1000^4 - 700^4) \text{K}^4$$

$$E = 1.36 \times 10^4 \text{ W/m}^2 + 0.22 \times 10^4 \text{ W/m}^2$$

$$E = 1.58 \times 10^4 \text{ W/m}^2.$$

<

**COMMENT:** (1) The surfaces will not experience uniform irradiation. Will this affect the answer?

### PROBLEM 13.30

**KNOWN:** Aligned, parallel discs with prescribed geometry and orientation.

**FIND:** Net radiative heat exchange between the discs.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Surfaces behave as blackbodies, (2)  $A_1 \ll A_2$ .

**ANALYSIS:** From Eq. 13.13

$$q_{12} = A_1 F_{12} \sigma (T_1^4 - T_2^4).$$

The view factor can be determined from Eq. 13.8 which is appropriate for a small disc, aligned and parallel to a much larger disc.

$$F_{ij} = \frac{D_j^2}{D_j^2 + 4L^2}$$

where  $D_j$  is the diameter of the larger disk and  $L$  is the distance of separation. It follows that

$$F_{12} = F_{1o} - F_{1i} = 0.00990 - 0.00559 = 0.00431$$

where

$$F_{1o} = D_o^4 / (D_o^2 + 4L^2) = 0.2^2 \text{ m}^2 / (0.2^2 \text{ m}^2 + 4 \times 1 \text{ m}^2) = 0.00990$$

$$F_{1i} = D_i / (D_i^2 + 4L^2) = 0.15^2 \text{ m}^2 / (0.15^2 \text{ m}^2 + 4 \times 1 \text{ m}^2) = 0.00559.$$

The net radiation exchange is then

$$q_{12} = \frac{\pi (0.03 \text{ m})^2}{4} \times 0.00431 \times 5.67 \times 10^{-8} \frac{\text{W}}{\text{m}^2 \cdot \text{K}^4} (500^4 - 1000^4) \text{ K}^4 = -0.162 \text{ W}.$$

**COMMENTS:**  $F_{12}$  can be approximated using solid angle concepts if  $D_o \ll L$ . That is, the view factor for  $A_1$  to  $A_o$  (whose diameter is  $D_o$ ) is

$$F_{1o} \approx \frac{\omega_{o-1}}{\pi} = \frac{A_o / L^2}{\pi} = \frac{\pi D_o^2}{4\pi L^2} = \frac{D_o^2}{4L^2}.$$

Numerically,  $F_{1o} = 0.0100$  and it follows  $F_{1i} \approx D_i^2 / 4L^2 = 0.00563$ . This gives  $F_{12} = 0.00437$ . An analytical expression can be obtained from Example 13.1 by replacing the lower limit of integration by  $D_i/2$ , giving

$$F_{12} = L^2 \left[ -1 / (D_o^2 / 4 + L^2) + 1 / (D_i^2 / 4 + L^2) \right] = 0.00431.$$

### PROBLEM 13.31

**KNOWN:** Two black, plane discs, one being solid, the other ring-shaped.

**FIND:** Net radiative heat exchange between the two surfaces.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Discs are parallel and coaxial, (2) Discs are black, diffuse surfaces, (3) Convection effects are not being considered.

**ANALYSIS:** From Eq. 13.13

$$q_{12} = A_1 F_{12} \sigma (T_1^4 - T_2^4)$$

The view factor  $F_{12}$  can be determined from Fig. 13.5 after some manipulation. Define these two hypothetical surfaces;

$$A_3 = \frac{\pi D_o^2}{4}, \text{ located co-planar with } A_2, \text{ but a solid surface}$$

$$A_4 = \frac{\pi D_i^2}{4}, \text{ located co-planar with } A_2, \text{ representing the missing center.}$$

From view factor relations and Fig. 13.5, it follows that

$$F_{12} = F_{13} - F_{14} = 0.62 - 0.20 = 0.42$$

$$F_{14}: \quad \frac{r_j}{L} = \frac{40/2}{20} = 1, \quad \frac{L}{r_i} = \frac{20}{80/2} = 0.5, \quad F_{14} = 0.20$$

$$F_{13}: \quad \frac{r_j}{L} = \frac{80/2}{20} = 2, \quad \frac{L}{r_i} = \frac{20}{80/2} = 0.5, \quad F_{13} = 0.62.$$

Hence

$$q_{12} = \left( \pi 0.80^2 / 4 \right) \text{m}^2 \times 0.42 \times 5.67 \times 10^{-8} \text{W/m}^2 \cdot \text{K}^4 \left( 300^4 - 1000^4 \right) \text{K}^4$$

$$q_{12} = -11.87 \text{ kW.} \quad \leftarrow$$

Assuming negligible radiation exchange with the surroundings, the negative sign implies that  $q_1 = -11.87 \text{ kW}$  and  $q_2 = +11.87 \text{ kW}$ .

### PROBLEM 13.32

**KNOWN:** Radiometer viewing a small target area (1),  $A_1$ , with a solid angle  $\omega = 0.0008$  sr. Target has an area  $A_1 = 0.004 \text{ m}^2$  and is diffuse, gray with emissivity  $\varepsilon = 0.8$ . The target is heated by a ring-shaped disc heater (2) which is black and operates at  $T_2 = 1000 \text{ K}$ .

**FIND:** (a) Expression for the radiant power leaving the target which is collected by the radiometer in terms of the target radiosity,  $J_1$ , and relevant geometric parameters; (b) Expression for the target radiosity in terms of its irradiation, emissive power and appropriate radiative properties; (c) Expression for the irradiation on the target,  $G_1$ , due to emission from the heater in terms of the heater emissive power, the heater area and an appropriate view factor; numerically evaluate  $G_1$ ; and (d) Determine the radiant power collected by the radiometer using the foregoing expressions and results.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Target is diffuse, gray, (2) Target area is small compared to the square of the separation distance between the sample and the radiometer, and (3) Negligible irradiation from the surroundings onto the target area.

**ANALYSIS:** (a) From Eq. 12.27 with  $I_1 = I_{1,e+r} = J_1/\pi$ , the radiant power leaving the target collected by the radiometer is, from Eq. 12.11

$$q_{1 \rightarrow \text{rad}} = \frac{J_1}{\pi} A_1 \cos \theta_1 \omega_{\text{rad}-1} \quad < \quad (1)$$

where  $\theta_1 = 0^\circ$  and  $\omega_{\text{rad}-1}$  is the solid angle the radiometer subtends with respect to the target area.

(b) From Eq. 12.4, the radiosity is the sum of the emissive power plus the reflected irradiation.

$$J_1 = E_1 + \rho G_1 = \varepsilon E_{b,1} + (1 - \varepsilon) G_1 \quad < \quad (2)$$

where  $E_{b1} = \sigma T_1^4$  and  $\rho = 1 - \varepsilon$  since the target is diffuse, gray ( $\alpha = \varepsilon$ ).

(c) The irradiation onto  $G_1$  due to emission from the heater area  $A_2$  is

$$G_1 = \frac{q_{2 \rightarrow 1}}{A_1}$$

where  $q_{2 \rightarrow 1}$  is the radiant power leaving  $A_2$  which is intercepted by  $A_1$  and can be written as

$$q_{2 \rightarrow 1} = A_2 F_{21} E_{b2} \quad (3)$$

where  $E_{b2} = \sigma T_2^4$ .  $F_{21}$  is the fraction of radiant power leaving  $A_2$  which is intercepted by  $A_1$ . The view factor  $F_{12}$  can be written as

Continued ...

### PROBLEM 13.32 (Cont.)

$$F_{12} = F_{1-o} - F_{1-i} \qquad F_{12} = 0.5 - 0.2 = 0.3$$

where from Eq. 13.8,

$$F_{1-o} = \frac{D_o^2}{D_o^2 + 4L^2} = \frac{0.5^2}{0.5^2 + 4(0.25)^2} = 0.5 \qquad (3)$$

$$F_{1-i} = \frac{D_i^2}{D_i^2 + 4L^2} = \frac{0.25^2}{0.25^2 + 4(0.25)^2} = 0.2$$

and from the reciprocity rule,

$$F_{21} = \frac{A_1 F_{12}}{A_2} = \frac{0.0004 \text{ m}^2 \times 0.3}{\pi/4 (0.5^2 - 0.25^2) \text{ m}^2} = 0.000815$$

Substituting numerical values into Eq. (3), find

$$G_1 = \frac{\pi/4 (0.5^2 - 0.25^2) \text{ m}^2 \times 0.000815 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (1000 \text{ K})^4}{0.0004 \text{ m}^2}$$

$$G_1 = 17,013 \text{ W/m}^2 \qquad <$$

(d) Substituting numerical values into Eq. (1), the radiant power leaving the target collected by the radiometer is

$$q_{1 \rightarrow \text{rad}} = (6238 \text{ W/m}^2 / \pi \text{ sr}) \times 0.0004 \text{ m}^2 \times 1 \times 0.0008 \text{ sr} = 635 \mu\text{W} \qquad <$$

where the radiosity,  $J_1$ , is evaluated using Eq. (2) and  $G_1$ .

$$J_1 = 0.8 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times (500 \text{ K})^4 + (1 - 0.8) \times 17,013 \text{ W/m}^2$$

$$J_1 = (2835 + 3403) \text{ W/m}^2 = 6238 \text{ W/m}^2 \qquad <$$

**COMMENTS:** (1) Note that the emitted and reflected irradiation components of the radiosity,  $J_1$ , are of the same magnitude.

(2) Suppose the surroundings were at room temperature,  $T_{\text{sur}} = 300 \text{ K}$ . Would the reflected irradiation due to the surroundings contribute significantly to the radiant power collected by the radiometer? Justify your conclusion.

### PROBLEM 13.33

**KNOWN:** Thin-walled, black conical cavity with opening  $D = 10$  mm and depth of  $L = 12$  mm that is well insulated from its surroundings. Temperature of meter housing and surroundings is  $25.0^\circ\text{C}$ .

**FIND:** Radiant flux of laser beam,  $G_o$  ( $\text{W}/\text{m}^2$ ), incident on the cavity when the fine-wire thermocouple indicates a temperature rise of  $10.1^\circ\text{C}$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Cavity surface is black and perfectly insulated from its mounting material in the meter, (2) Negligible convection heat transfer from the cavity surface, and (3) Surroundings are large, isothermal.

**ANALYSIS:** Perform an energy balance on the walls of the cavity considering absorption of the laser irradiation, absorption from the surroundings and emission.

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = 0$$

$$A_o G_o + A_o G_{\text{sur}} - A_o E_b(T_c) = 0$$

where  $A_o = \pi D^2/4$  represents the opening of the cavity. All of the radiation entering or leaving the cavity passes through this hypothetical surface. Hence, we can treat the cavity as a black disk at  $T_c$ . Since  $G_{\text{sur}} = E_b(T_{\text{sur}})$ , and  $E_b = \sigma T^4$  with  $\sigma = 5.67 \times 10^{-8} \text{ W}/\text{m}^2 \cdot \text{K}^4$ , the energy balance has the form

$$G_o + \sigma(25.0 + 273)^4 \text{ K}^4 - \sigma(25.0 + 10.1 + 273)^4 \text{ K}^4 = 0$$

$$G_o = 63.8 \text{ W}/\text{m}^2$$

<

### PROBLEM 13.34

**KNOWN:** Electrically heated sample maintained at  $T_s = 500$  K with diffuse, spectrally selective coating. Sample is irradiated by a furnace located coaxial to the sample at a prescribed distance. Furnace has isothermal walls at  $T_f = 3000$  K with  $\epsilon_f = 0.7$  and an aperture of 25 mm diameter. Sample experiences convection with ambient air at  $T_\infty = 300$  K and  $h = 20$  W/m<sup>2</sup>·K. The surroundings of the sample are large with a uniform temperature  $T_{sur} = 300$  K. A radiation detector sensitive to only power in the spectral region 3 to 5  $\mu$ m is positioned at a prescribed location relative to the sample.

**FIND:** (a) Electrical power,  $P_e$ , required to maintain the sample at  $T_s = 500$  K, and (b) Radiant power incident on the detector within the spectral region 3 to 5  $\mu$ m considering both emission and reflected irradiation from the sample.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state condition, (2) Furnace is large, isothermal enclosure with small aperture and radiates as a blackbody, (3) Sample coating is diffuse, spectrally selective, (4) Sample and detector areas are small compared to their separation distance squared, (5) Surroundings are large, isothermal.

**ANALYSIS:** (a) Perform an energy balance on the sample mount, which experiences electrical power dissipation, convection with ambient air, absorbed irradiation from the furnace, absorbed irradiation from the surroundings and emission,

$$\dot{E}_{in} - \dot{E}_{out} = 0$$

$$P_e + [-h(T_s - T_\infty) + \alpha_f G_f + \alpha_{sur} G_{sur} - \epsilon E_b(T_s)] A_s = 0 \quad (1)$$

where  $E_b(T_s) = \sigma T_s^4$  and  $A_s = \pi D_s^2 / 4$ .

*Irradiations on the sample:* The irradiation from the furnace aperture onto the sample can be written as

$$G_f = \frac{q_{f \rightarrow s}}{A_s} = \frac{A_f F_{fs} E_{b,f}}{A_s} = \frac{A_f F_{fs} \sigma T_f^4}{A_s} \quad (2)$$

where  $A_f = \pi D_f^2 / 4$  and  $A_s = \pi D_s^2 / 4$ . The view factor between the furnace aperture and sample follows from the relation for coaxial parallel disks, Table 13.2,

$$R_f = r_f / L_{sf} = 0.0125 \text{ m} / 0.750 \text{ m} = 0.01667$$

$$R_s = r_s / L_{sf} = 0.0100 \text{ m} / 0.750 \text{ m} = 0.01333$$

$$S = 1 + \frac{1 + R_s^2}{R_f^2} = 1 + \frac{1 + 0.01333^2}{0.01667^2} = 3600.2$$

Continued ...

**PROBLEM 13.34 (Cont.)**

$$F_{\text{sf}} = 0.5 \left\{ S - \left[ S^2 - 4(r_s / r_f)^2 \right]^{1/2} \right\} = 0.5 \left\{ 3600 - \left[ 3600^2 - 4(0.05 / 0.0625)^2 \right]^{1/2} \right\} = 0.000178$$

Hence the irradiation from the furnace is

$$G_f = \frac{\pi (0.025 \text{ m})^2 / 4 \times 0.000178 \times 5.67 \times 10^{-8} \text{ W / m}^2 \cdot \text{K}^4 (3000 \text{ K})^4}{\pi (0.020^2 \text{ m}^2 / 4)} = 1277 \text{ W / m}^2$$

The irradiation from the surroundings which are large compared to the sample is

$$G_{\text{sur}} = \sigma T_{\text{sur}}^4 = 5.67 \times 10^{-8} \text{ W / m}^2 \cdot \text{K} (300 \text{ K})^4 = 459 \text{ W / m}^2$$

*Emissivity of the Sample:* The total hemispherical emissivity in terms of the spectral distribution can be written following Eq. 12.43 and Eq. 12.34,

$$\varepsilon = \int_0^\infty \varepsilon_\lambda E_{\lambda, \text{b}}(T_s) d\lambda / \sigma T^4 = \varepsilon_1 F_{(0-\lambda_1 T_s)} + \varepsilon_2 \left[ 1 - F_{(0-\lambda_1 T_s)} \right]$$

$$\varepsilon = 0.8 \times 0.066728 + 0.2 [1 - 0.066728] = 0.240$$

where, from Table 12.1, with  $\lambda_1 T_s = 4 \mu\text{m} \times 500 \text{ K} = 2000 \mu\text{m} \cdot \text{K}$ ,  $F_{(0-\lambda T)} = 0.066728$ .

*Absorptivity of the Sample:* The total hemispherical absorptivity due to irradiation from the furnace follows from Eq. 12.52 and Eq. 12.34,

$$\alpha_f = \varepsilon_1 F_{(0-\lambda_1 T_f)} + \varepsilon_2 \left[ 1 - F_{(0-\lambda_1 T_f)} \right] = 0.8 \times 0.945098 + 0.2 [1 - 0.945098] = 0.767$$

where, from Table 12.1, with  $\lambda_1 T_f = 4 \mu\text{m} \times 3000 \text{ K} = 12,000 \mu\text{m} \cdot \text{K}$ ,  $F_{(0-\lambda T)} = 0.945098$ . The total hemispherical absorptivity due to irradiation from the surroundings is

$$\alpha_{\text{sur}} = \varepsilon_1 F_{(0-\lambda_1 T_{\text{sur}})} + \varepsilon_2 \left[ 1 - F_{(0-\lambda_1 T_{\text{sur}})} \right] = 0.8 \times 0.00234 + 0.2 [1 - 0.00234] = 0.201$$

where, from Table 12.1, with  $\lambda_1 T_{\text{sur}} = 4 \mu\text{m} \times 300 \text{ K} = 1200 \mu\text{m} \cdot \text{K}$ ,  $F_{(0-\lambda T)} = 0.00234$ .

*Evaluating the Energy Balance:* Substituting numerical values into Eq. (1),

$$P_e = \left[ +20 \text{ W / m}^2 \cdot \text{K} (500 - 300) \text{ K} - 0.767 \times 1277 \text{ W / m}^2 \right.$$

$$\left. - 0.201 \times 459 \text{ W / m}^2 + 0.240 \times 5.67 \times 10^{-8} \text{ W / m}^2 \cdot \text{K}^4 (500 \text{ K})^4 \right] \times 4 / \left( \pi \times (0.02 \text{ m})^2 \right)$$

$$P_e = 1.256 \text{ W} - 0.308 \text{ W} - 0.029 \text{ W} + 0.267 \text{ W} = 1.19 \text{ W} \quad <$$

(b) The radiant power leaving the sample which is incident on the detector and within the spectral region,  $\Delta\lambda = 3$  to  $5 \mu\text{m}$ , follows from Eq. 12.11 with Eq. 12.34,

$$q_{\text{s-d}, \Delta\lambda} = \left[ E_{\text{s}, \Delta\lambda} + G_{\text{f}, \text{ref}, \Delta\lambda} + G_{\text{sur}, \text{ref}, \Delta\lambda} \right] (1/\pi) A_s \cos \theta_s \cdot A_d \cos \theta_d / L_{\text{sd}}^2$$

where  $\theta_s = 45^\circ$  and  $\theta_d = 0^\circ$ . The *emitted* component is

$$E_{\text{s}, \Delta\lambda} = \int_3^{5 \mu\text{m}} \varepsilon_\lambda E_{\lambda, \text{b}}(T_s)$$

$$E_{\text{s}, \Delta\lambda} = \left\{ \varepsilon_1 \left[ F_{(0-4 \mu\text{m}, T_s)} - F_{(0-3 \mu\text{m}, T_s)} \right] + \varepsilon_2 \left[ F_{(0-5 \mu\text{m}, T_s)} - F_{(0-4 \mu\text{m}, T_s)} \right] \right\} \sigma T_s^4$$

Continued ...

**PROBLEM 13.34 (Cont.)**

$$E_{s,\Delta\lambda} = \{0.8[0.066728 - 0.013754] + 0.2[0.16169 - 0.066728]\} \sigma (500\text{K})^4 = 217.5 \text{ W/m}^2$$

where, from Table 12.1,  $F_{(0-3\mu\text{m}, T_s)} = 0.013754$  at  $\lambda T = 3\mu\text{m} \times 500 \text{ K} = 1500 \mu\text{m}\cdot\text{K}$ ;

$F_{(0-4\mu\text{m}, T_s)} = 0.066728$  at  $\lambda = 4\mu\text{m} \times 500 \text{ K} = 2000 \mu\text{m}\cdot\text{K}$ ; and  $F_{(0-5\mu\text{m}, T_s)} = 0.16169$  at  $\lambda T = 5\mu\text{m} \times 500 \text{ K} = 2500 \mu\text{m}\cdot\text{K}$ .

The *reflected irradiation from the furnace* component is

$$G_{f,\text{ref},\Delta\lambda} = \int_3^{5\mu\text{m}} (1 - \varepsilon_\lambda) G_{f,\lambda} d\lambda$$

where  $G_{f,\lambda} \approx E_{\lambda,b}(T_f)$ , using band emission factors,

$$G_{f,\text{ref},\Delta\lambda} = \left\{ (1 - \varepsilon_1) \left[ F_{(0-4\mu\text{m}, T_f)} - F_{(0-3\mu\text{m}, T_f)} \right] + (1 - \varepsilon_2) \left[ F_{(0-5\mu\text{m}, T_f)} - F_{(0-4\mu\text{m}, T_f)} \right] \right\} G_f$$

$$G_{f,\text{ref},\Delta\lambda} = \{0.2[0.9451 - 0.8900] + 0.8[0.9700 - 0.9451]\} 1277 \text{ W/m}^2 = 39.51 \text{ W/m}^2$$

where, from Table 12.1,  $F_{(0-3\mu\text{m}, T_f)} = 0.8900$  at  $\lambda T_f = 3\mu\text{m} \times 3000 \text{ K} = 9000 \mu\text{m}\cdot\text{K}$ ;

$F_{(0-4\mu\text{m}, T_f)} = 0.9451$  at  $\lambda T_f = 4\mu\text{m} \times 3000 \text{ K} = 12,000 \mu\text{m}\cdot\text{K}$ ; and,  $F_{(0-5\mu\text{m}, T_f)} = 0.9700$  at  $\lambda T_f = 5\mu\text{m} \times 3000 \text{ K} = 15,000 \mu\text{m}\cdot\text{K}$ .

The *reflected irradiation from the surroundings* component is

$$G_{\text{sur},\text{ref},\Delta\lambda} = \int_3^{5\mu\text{m}} (1 - \varepsilon_\lambda) G_{\text{ref},\lambda} d\lambda$$

where  $G_{\text{ref},\lambda} \approx E_\lambda(T_{\text{sur}})$ , using band emission factors,

$$G_{\text{sur},\text{ref},\Delta\lambda} = \left\{ (1 - \varepsilon_1) \left[ F_{(0-4\mu\text{m}, T_{\text{sur}})} - F_{(0-3\mu\text{m}, T_{\text{sur}})} \right] + (1 - \varepsilon_2) \left[ F_{(0-5\mu\text{m}, T_{\text{sur}})} - F_{(0-4\mu\text{m}, T_{\text{sur}})} \right] \right\} G_{\text{sur}}$$

$$G_{\text{sur},\text{ref},\Delta\lambda} = \{0.2[0.002134 - 0.0001685] - 0.8[0.013754 - 0.002134]\} 459 \text{ W/m}^2 = 4.44 \text{ W/m}^2$$

where, from Table 12.1,  $F_{(0-3\mu\text{m}, T_{\text{sur}})} = 0.0001685$  at  $\lambda T_{\text{sur}} = 3\mu\text{m} \times 300 \text{ K} = 900 \mu\text{m}\cdot\text{K}$ ;

$F_{(0-4\mu\text{m}, T_{\text{sur}})} = 0.002134$  at  $\lambda T_{\text{sur}} = 4\mu\text{m} \times 300 \text{ K} = 1200 \mu\text{m}\cdot\text{K}$ ; and  $F_{(0-5\mu\text{m}, T_{\text{sur}})} = 0.013754$  at

$\lambda T_{\text{sur}} = 5\mu\text{m} \times 300 \text{ K} = 1500 \mu\text{m}\cdot\text{K}$ . Returning to Eq. (3), find

$$q_{\text{sd},\Delta\lambda} = [217.5 + 39.51 + 4.44] \text{ W/m}^2 (1/\pi) \left[ \pi (0.020 \text{ m})^2 / 4 \right] \cos 45^\circ \times 8 \times 10^{-5} \text{ m}^2 \times \cos 0^\circ / (1 \text{ m})^2 = 1.48 \mu\text{W} <$$

**COMMENTS:** (1) Note that  $F_{fs}$  is small, since  $A_f, A_s \ll L_{sf}^2$ . As such, we could have evaluated  $q_{f \rightarrow s}$  using Eq. 12.6 and found

$$G_f = \frac{E_{b,f} / \pi A_f \left( A_s / L_{sf}^2 \right)}{A_s} = 1276 \text{ W/m}^2$$

(2) Recognize in the analysis for part (b), Eq. (3), the role of the band emission factors in calculating the fraction of total radiant power for the emitted and reflected irradiation components.

### PROBLEM 13.35

**KNOWN:** Water-cooled heat flux gage exposed to radiant source, convection process and surroundings.

**FIND:** (a) Net radiation exchange between heater and gage, (b) Net transfer of radiation to the gage per unit area of the gage, (c) Net heat transfer to the gage per unit area of gage, (d) Heat flux indicated by gage described in Problem 3.98.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Heater and gage are parallel, coaxial discs having blackbody behavior, (2)  $A_g \ll A_h$ , (3) Surroundings are large compared to  $A_h$  and  $A_g$ .

**ANALYSIS:** (a) The net radiation exchange between the heater and the gage, both with blackbody behavior, is

$$q_{h-g} = A_h F_{hg} \sigma (T_h^4 - T_g^4) = A_g F_{gh} \sigma (T_h^4 - T_g^4).$$

Note the use of reciprocity, Eq. 13.3, for the view factors. From Eq. 13.8,

$$F_{gh} = D_h^2 / (4L^2 + D_h^2) = (0.2\text{m})^2 / (4 \times 0.5^2 \text{m}^2 + 0.2^2 \text{m}^2) = 0.0385.$$

$$q_{h-g} = (\pi 0.01^2 \text{m}^2 / 4) \times 0.0385 \times 5.67 \times 10^{-8} \text{W} / \text{m}^2 \cdot \text{K}^4 [800^4 - 290^4] \text{K}^4 = 69.0 \text{ mW}. \quad <$$

(b) The net radiation *to* the gage per unit area will involve exchange with the heater and the surroundings.

$$q''_{\text{net,rad}} = -q_g / A_g = q_{h-g} / A_g + q_{\text{sur-g}} / A_g.$$

The net exchange with the surroundings is

$$q_{\text{sur-g}} = A_{\text{sur}} F_{\text{sur-g}} \sigma (T_{\text{sur}}^4 - T_g^4) = A_g F_{g-\text{sur}} \sigma (T_{\text{sur}}^4 - T_g^4).$$

$$q''_{\text{net,rad}} = \frac{69.0 \times 10^{-3} \text{W}}{\pi (0.01 \text{m})^2 / 4} + (1 - 0.0385) 5.67 \times 10^{-8} \text{W} / \text{m}^2 \cdot \text{K}^4 (300^4 - 290^4) \text{K}^4 = 934.5 \text{ W} / \text{m}^2. \quad <$$

(c) The net heat transfer rate to the gage per unit area of the gage follows from the surface energy balance

$$q''_{\text{net,in}} = q''_{\text{net,rad}} + q''_{\text{conv}}$$

$$q''_{\text{net,in}} = 934.5 \text{ W} / \text{m}^2 + 15 \text{ W} / \text{m}^2 \cdot \text{K} (300 - 290) \text{K}$$

$$q''_{\text{net,in}} = 1085 \text{ W} / \text{m}^2. \quad <$$

(d) The heat flux gage described in Problem 3.98 would experience a net heat flux to the surface of  $1085 \text{ W} / \text{m}^2$ . The irradiation to the gage from the heater is  $G_g = q_{h \rightarrow g} / A_g = F_{gh} \sigma T_h^4 = 894 \text{ W} / \text{m}^2$ . Since the gage responds to net heat flux, there would be a systematic error in sensing irradiation from the heater.

### PROBLEM 13.36

**KNOWN:** Long cylindrical heating element located a given distance above an insulated wall exposed to cool surroundings. Diameter and temperature of heating element. Surroundings temperature.

**FIND:** (a) Maximum temperature attained by wall. (b) Plot the wall temperature over the range  $-100 \text{ mm} \leq x \leq 100 \text{ mm}$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Insulated wall, (3) Negligible conduction in wall, (4) All surfaces are black.

**ANALYSIS:** (a) We begin with a general analysis for the temperature at any point  $x$ . Consider an elemental area  $dA_o$  at point  $x$ . Since the wall is insulated and conduction is negligible, the net radiation leaving  $dA_o$  is zero. From Eq. 13.14 (divided by  $A_i$ ),

$$q''_o = q''_{o,h} + q''_{o,sur} = F_{o,h} \sigma (T_o^4 - T_h^4) + F_{o,sur} \sigma (T_o^4 - T_{sur}^4) = 0 \quad (1)$$

where  $F_{o,sur} = 1 - F_{o,h}$  and  $F_{o,h}$  can be found from the relation for a cylinder and parallel rectangle, Table 13.1, with  $s_2 = x$  and  $s_1 = s_2 + \delta$ , in the limit as  $\delta \rightarrow 0$ . From a Taylor series expansion,

$$\lim_{\delta \rightarrow 0} \tan^{-1} \left( \frac{s_2 + \delta}{L} \right) = \tan^{-1} \left( \frac{s_2}{L} \right) + \frac{\delta/L}{1 + (s_2/L)^2}$$

Thus,

$$F_{o,h} = \frac{r}{s_1 - s_2} \left[ \tan^{-1} \frac{s_1}{L} - \tan^{-1} \frac{s_2}{L} \right] = \frac{r}{\delta} \left[ \frac{\delta/L}{1 + (s_2/L)^2} \right] = \frac{r/L}{1 + (x/L)^2} \quad (2)$$

Rearranging Eq. (1) and substituting numerical values, find

$$T_o = \left[ F_{o,h} T_h^4 + (1 - F_{o,h}) T_{sur}^4 \right]^{1/4} \quad (3)$$

The maximum value of  $T_o$  will occur at  $x = 0$ , where  $F_{o,h} = r/L = 10/40 = 0.25$ . Thus,

$$T_{o,max} = \left[ 0.25(700 \text{ K})^4 + (1 - 0.25)(300 \text{ K})^4 \right]^{1/4} = 507 \text{ K} <$$

(b) Eq. (3) can be evaluated with Eq. (2) for  $F_{o,h}$ , over the range  $-100 \text{ mm} \leq x \leq 100 \text{ mm}$ . The results are shown below.

Continued...

### PROBLEM 13.36 (Cont.)

**COMMENTS:** (1) Note the importance of the assumptions that the wall is insulated and conduction is negligible. (2) In calculating  $F_{o,h}$  we are finding the view factor for a small area or point. As an alternative to using a Taylor series expansion, the value can be found by evaluating the view factor from the equation in Table 13.1 for progressively smaller values of  $s_1 - s_2$  until the value converges.

### PROBLEM 13.37

**KNOWN:** Diameter and pitch of in-line tubes occupying evacuated space between parallel plates of prescribed temperature. Temperature and flowrate  $\dot{m}$  of water through the tubes.

**FIND:** (a) Tube surface temperature  $T_s$  for  $\dot{m} = 0.20$  kg/s, (b) Effect of  $\dot{m}$  on  $T_s$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Surfaces behave as blackbodies, (2) Negligible tube wall conduction resistance, (3) Fully-developed tube flow.

**PROPERTIES:** Table A-6, water ( $T_m = 300$  K):  $\mu = 855 \times 10^{-6}$  N·s/m<sup>2</sup>,  $k = 0.613$  W/m·K,  $Pr = 5.83$ .

**ANALYSIS:** (a) Performing an energy balance on a single tube, it follows that  $q_{ps} = q_{conv}$ , or

$$A_p F_{ps} \sigma (T_p^4 - T_s^4) = h A_s (T_s - T_m)$$

From Table 13.1 and  $D/S = 0.75$ , the view factor is

$$F_{ps} = 1 - \left[ 1 - \left( \frac{D}{S} \right)^2 \right]^{1/2} + \left( \frac{D}{S} \right) \tan^{-1} \left( \frac{S^2 - D^2}{D^2} \right)^{1/2} = 0.881$$

With  $Re_D = 4\dot{m} / \pi D \mu = 4(0.20 \text{ kg/s}) / \pi(0.015 \text{ m}) 855 \times 10^{-6} \text{ N} \cdot \text{s} / \text{m}^2 = 19,856$ , fully-developed turbulent flow may be assumed, in which case Eq. 8.60 yields

$$h = \frac{k}{D} \left( 0.023 Re_D^{4/5} Pr^{0.4} \right) = \frac{0.613 \text{ W/m} \cdot \text{K}}{0.015 \text{ m}} (0.023)(19,856)^{4/5} (5.83)^{0.4} = 5220 \text{ W/m}^2 \cdot \text{K}$$

Hence, with  $(A_p/A_s) = 2S/\pi D = 0.849$ ,

$$T_s - T_m = \frac{F_{ps} \sigma}{h} \frac{A_p}{A_s} (T_p^4 - T_s^4) = \frac{0.881 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4}{5220 \text{ W/m}^2 \cdot \text{K}} (0.849) (T_p^4 - T_s^4)$$

With  $T_m = 300$  K and  $T_p = 1000$  K, a trial-and-error solution yields

$$T_s = 308 \text{ K}$$

(b) Using the *Correlations and Radiation* Toolpads of *IHT* to evaluate the convection coefficient and view factor, respectively, the following results were obtained.

The decrease in  $T_s$  with increasing  $\dot{m}$  is due to an increase in  $h$  and hence a reduction in the convection resistance.

**COMMENTS:** Due to the large value of  $h$ ,  $T_s \ll T_p$ .

### PROBLEM 13.38

**KNOWN:** Insulated wall exposed to a row of regularly spaced cylindrical heating elements.

**FIND:** Required operating temperature of the heating elements for the prescribed conditions.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Upper and lower walls are isothermal and infinite, (2) Lower wall is insulated, (3) All surfaces are black, (4) Steady-state conditions.

**ANALYSIS:** Perform an energy balance on the insulated wall considering convection and radiation.

$$\dot{E}_{in}'' - \dot{E}_{out}'' = -q_1'' - q_{conv}'' = 0$$

where  $q_1''$  is the net radiation leaving the insulated wall per unit area. We know that

$$q_1'' = q_{1e}'' + q_{12}'' = F_{1e}\sigma(T_1^4 - T_e^4) + F_{12}\sigma(T_1^4 - T_2^4)$$

where  $F_{12} = 1 - F_{1e}$ . Using Newton's law of cooling for  $q_{conv}''$  solve for  $T_e$ .

$$T_e^4 = \left[ T_1^4 + \frac{(1 - F_{1e})}{F_{1e}} (T_1^4 - T_2^4) \right] + \frac{h}{\sigma F_{1e}} (T_1 - T_\infty).$$

The view factor between the insulated wall and the tube row follows from the relation for an infinite plane and row of cylinders, Table 13.1,

$$F_{1e} = 1 - \left[ 1 - \left( \frac{D}{S} \right)^2 \right]^{1/2} + \left( \frac{D}{S} \right) \tan^{-1} \left( \frac{s^2 - D^2}{D^2} \right)^{1/2}$$

$$F_{1e} = 1 - \left[ 1 - \left( \frac{10}{20} \right)^2 \right]^{1/2} + \left( \frac{10}{20} \right) \tan^{-1} \left( \frac{20^2 - 10^2}{10^2} \right)^{1/2} = 0.658.$$

Substituting numerical values, find

$$T_e^4 = \left[ (500 \text{ K})^4 + \frac{1 - 0.658}{0.658} (500^4 - 300^4) \text{ K}^4 \right] + \frac{200 \text{ W/m}^2 \cdot \text{K}}{5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4} \times \frac{1}{0.658} (500 - 450) \text{ K}$$

$$T_e = 774 \text{ K.} \quad <$$

**COMMENTS:** Always express temperatures in kelvins when considering convection and radiation terms in an energy balance. Why is  $F_{1e}$  independent of the distance between the row of tubes and the wall?

### PROBLEM 13.39

**KNOWN:** Surface radiative properties, diameter and initial temperature of a copper rod placed in an evacuated oven of prescribed surface temperature.

**FIND:** (a) Initial heating rate, (b) Time  $t_h$  required to heat rod to 1000 K, (c) Effect of convection on heating time.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Copper may be treated as a lumped capacitance, (b) Radiation exchange between rod and oven may be approximated as blackbody exchange.

**PROPERTIES:** Table A-1, Copper (300 K):  $\rho = 8933 \text{ kg/m}^3$ ,  $c_p = 385 \text{ J/kg}\cdot\text{K}$ ,  $k = 401 \text{ W/m}\cdot\text{K}$ .

**ANALYSIS:** (a) Performing an energy balance on a unit length of the rod,  $\dot{E}_{\text{in}} = \dot{E}_{\text{st}}$ , or

$$q = Mc_p \frac{dT}{dt} = \rho \left( \frac{\pi D^2}{4} \times 1 \right) c_p \frac{dT}{dt}$$

Neglecting convection,  $q = q_{\text{rad}} = A_2 F_{21} \sigma (T_{\text{sur}}^4 - T^4) = A_1 F_{12} \sigma (T_{\text{sur}}^4 - T^4)$ , where  $A_1 = \pi D \times 1$  and  $F_{12} = 1$ . It follows that

$$\frac{dT}{dt} = \frac{\sigma \pi D (T_{\text{sur}}^4 - T^4)}{\rho (\pi D^2 / 4) c_p} = \frac{4\sigma (T_{\text{sur}}^4 - T^4)}{\rho D c_p} \quad (1)$$

$$\left. \frac{dT}{dt} \right|_i = \frac{4 \left[ (1650 \text{ K})^4 - (300 \text{ K})^4 \right] 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4}{8933 \text{ kg/m}^3 (0.01 \text{ m}) 385 \text{ J/kg}\cdot\text{K}} = 48.8 \text{ K/s.} \quad <$$

(b) Using the *IHT Lumped Capacitance Model* to numerically integrate Eq. (2), we obtain

$$t_s = 15.0 \text{ s} \quad <$$

(c) With convection,  $q = q_{\text{rad}} + q_{\text{conv}} = A_1 F_{12} \sigma (T_{\text{sur}}^4 - T^4) + hA_1 (T_{\infty} - T)$ , and the energy balance becomes

$$\frac{dT}{dt} = \frac{4\sigma (T_{\text{sur}}^4 - T^4)}{\rho D c_p} + \frac{4h(T_{\infty} - T)}{\rho D c_p}$$

Performing the numerical integration for the three values of  $h$ , we obtain

$h \text{ (W/m}^2\cdot\text{K)}$ :	10	100	500
$t_h \text{ (s)}$ :	14.6	12.0	6.8

**COMMENTS:** With an initial value of  $h_{\text{rad},i} = \sigma (T_{\text{sur}}^4 - T^4) / (T_{\text{sur}} - T) = 311 \text{ W/m}^2\cdot\text{K}$ ,  $Bi = h_{\text{rad}} (D/4) / k = 0.002$  and the lumped capacitance assumption is justified for parts (a) and (b). With  $h = 500 \text{ W/m}^2\cdot\text{K}$  and  $h + h_{\text{r},i} = 811 \text{ W/m}\cdot\text{K}$  in part (c),  $Bi = 0.005$  and the lumped capacitance approximation is also valid.

### PROBLEM 13.40

**KNOWN:** Long, inclined black surfaces maintained at prescribed temperatures.

**FIND:** (a) Net radiation exchange between the two surfaces per unit length, (b) Net radiation transfer to surface  $A_2$  with black, insulated surface positioned as shown below; determine temperature of this surface.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Surfaces behave as blackbodies, (2) Surfaces are very long in direction normal to page.

**ANALYSIS:** (a) The net radiation exchange between two black surfaces is

$$q_{12} = A_1 F_{12} \sigma (T_1^4 - T_2^4)$$

Noting that  $A_1 = \text{width} \times \text{length}$  ( $\ell$ ) and that from symmetry,  $F_{12} = 0.5$ , find

$$q'_{12} = \frac{q_{12}}{\ell} = 0.1 \text{ m} \times 0.5 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (1000^4 - 800^4) \text{ K}^4 = 1680 \text{ W/m.} \quad <$$

(b) From Eq. 13.14,

$$q'_3 = \frac{q_3}{\ell} = \frac{A_3}{\ell} F_{31} \sigma (T_3^4 - T_1^4) + \frac{A_3}{\ell} F_{32} \sigma (T_3^4 - T_2^4) = 0$$

Since  $F_{31} = F_{32}$ ,  $T_3 = \left[ \frac{(T_1^4 + T_2^4)}{2} \right]^{1/4} = \left[ \frac{(1000^4 + 800^4)}{2} \right]^{1/4} \text{ K} = 916 \text{ K.} \quad <$

Also from Eq. 13.14,

$$q'_2 = \frac{q_2}{\ell} = \frac{A_2}{\ell} F_{21} \sigma (T_2^4 - T_1^4) + \frac{A_2}{\ell} F_{23} \sigma (T_2^4 - T_3^4) \quad <$$

$$= 0.1 \times 0.5 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times (2 \times 800^4 - 1000^4 - 916^4) \text{ K}^4 = -2508 \text{ W/m}$$

### PROBLEM 13.41

**KNOWN:** Position of long cylindrical-shaped product conveyed in an oven with non-uniform wall temperatures. Product diameter, temperature of surroundings and panel heaters.

**FIND:** (a) Radiation incident upon the product, per unit length at product locations  $x = 0.5$  m and  $x = 1.0$  m for  $\alpha = 0$ , (b) Radiation incident upon the product, per unit length, at product locations of  $x = 0.5$  m and  $x = 1.0$  m for  $\alpha = \pi/15$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Two-dimensional system, (2) Steady-state conditions, (3) Blackbody behavior, (4) Large surroundings.

**ANALYSIS:**

Consider the cylinder and parallel rectangle arrangement of Table 13.1. We note that

$$F_{ij} = \frac{r}{s_1 - s_2} \left[ \tan^{-1} \frac{s_1}{L} - \tan^{-1} \frac{s_2}{L} \right]$$

and by reciprocity

$$F_{ji} = \frac{A_i F_{ij}}{A_j} = \frac{(s_1 - s_2) F_{ij}}{2\pi r}$$

Therefore,

$$F_{ji} = \frac{1}{2\pi} \left[ \tan^{-1} \frac{s_1}{L} + \tan^{-1} \frac{s_2}{L} \right] \quad (1)$$

Continued...

**PROBLEM 13.41 (Cont.)**

(a) For  $\alpha = 0$ ,

$$F_{13a} = \frac{1}{2\pi} \left[ \tan^{-1} \left( \frac{a}{x} \right) - \tan^{-1} \left( \frac{-(b-a)}{x} \right) \right]$$

where  $s_1 = a$  and  $s_2 = -(b - a)$ . For  $x = 0.5$  m,

$$F_{13a} = \frac{1}{2\pi} \left[ \tan^{-1} \left( \frac{0.02}{0.5} \right) - \tan^{-1} \left( \frac{-(0.04 - 0.02)}{0.5} \right) \right] = 0.0127$$

For  $x = 1.0$  m,

$$F_{13a} = \frac{1}{2\pi} \left[ \tan^{-1} \left( \frac{0.02}{1.0} \right) - \tan^{-1} \left( \frac{-(0.04 - 0.02)}{1.0} \right) \right] = 0.0064$$

Since  $A_{3b} = 0$  for  $\alpha = 0$ ,  $F_{13b} = 0$ .

For  $F_{13c}$  we note that  $s_1 = a$  and  $s_2 = -(b - a)$ . Therefore,

$$F_{13c} = \frac{1}{2\pi} \left[ \tan^{-1} \left( \frac{a}{L-x} \right) - \tan^{-1} \left( \frac{-(b-a)}{L-x} \right) \right]$$

For  $x = 0.5$  m,

$$F_{13c} = \frac{1}{2\pi} \left[ \tan^{-1} \left( \frac{0.02}{1.5} \right) - \tan^{-1} \left( \frac{-(0.04 - 0.02)}{1.5} \right) \right] = 0.0042$$

For  $x = 1.0$  m,

$$F_{13c} = \frac{1}{2\pi} \left[ \tan^{-1} \left( \frac{0.02}{1.0} \right) - \tan^{-1} \left( \frac{-(0.04 - 0.02)}{1.0} \right) \right] = 0.0064$$

Noting that  $F_{13} = F_{13a} + F_{13b} + F_{13c}$ , we find for  $x = 0.5$  m,  $F_{13} = 0.0127 + 0 + 0.0042 = 0.0169$ .

Likewise for  $x = 1.0$  m,  $F_{13} = 0.0064 + 0 + 0.0064 = 0.0128$ . The radiation incident upon the product is  $q_{in} = q_{21} + q_{31} = A_2 F_{21} \sigma T_1^4 + A_3 F_{31} \sigma T_3^4$ . Noting that  $A_2 F_{21} = A_1 F_{12} = A_1 (1 - F_{13})$  and  $A_1 = \pi DL$ , the preceding expression becomes

$$q_{in}' = q_{in} / L = \pi D \sigma \left[ T_2^4 (1 - F_{13}) + T_3^4 F_{13} \right] \quad (2)$$

For  $x = 0.5$  m,

Continued...

**PROBLEM 13.41 (Cont.)**

$$q'_{\text{in}} = \pi \times 0.01\text{m} \times 5.67 \times 10^{-8} \frac{\text{W}}{\text{m}^2 \cdot \text{K}^4} \times \left[ (500\text{K})^4 \times (1 - 0.0169) + (300\text{K})^4 \times 0.0169 \right] = 109.7 \text{ W/m} <$$

For  $x = 1.0 \text{ m}$ ,

$$q'_{\text{in}} = \pi \times 0.01\text{m} \times 5.67 \times 10^{-8} \frac{\text{W}}{\text{m}^2 \cdot \text{K}^4} \times \left[ (500\text{K})^4 \times (1 - 0.0128) + (300\text{K})^4 \times 0.0128 \right] = 110.1 \text{ W/m} <$$

(b) For  $\alpha = \pi/15$ ,

$$F_{13a} = \frac{1}{2\pi} \left[ \tan^{-1} \left( \frac{a + \gamma}{x} \right) - \tan^{-1} \left( \frac{-(b-a)}{x} \right) \right]$$

where  $\gamma = L \sin \alpha$ ,  $s_1 = a + L \sin \alpha$  and  $s_2 = -(b-a)$ .

For  $x = 0.5 \text{ m}$ ,

$$F_{13a} = \frac{1}{2\pi} \left[ \tan^{-1} \left( \frac{0.02 + 2 \sin(\pi/15)}{0.5} \right) - \tan^{-1} \left( \frac{-(0.04 - 0.02)}{0.5} \right) \right] = 0.1205$$

Likewise, for  $x = 1.0 \text{ m}$ ,  $F_{13a} = 0.0686$ .

From Eq. (1),

$$F_{13b} = \frac{1}{2\pi} \left[ \tan^{-1} \left( \frac{x}{a + \gamma} \right) - \tan^{-1} \left( \frac{\beta}{a + \gamma} \right) \right]$$

where  $\beta = L(1 - \cos \alpha)$ .

For  $x = 0.5 \text{ m}$ ,

$$F_{13b} = \frac{1}{2\pi} \left[ \tan^{-1} \left( \frac{0.5}{0.02 + 2 \sin(\pi/15)} \right) - \tan^{-1} \left( \frac{0.5 - 2(1 - \cos(\pi/15))}{0.02 + 2 \sin(\pi/15)} \right) \right] = 0.0072$$

Likewise, for  $x = 1.0 \text{ m}$ ,  $F_{13b} = 0.0026$ . The values of  $F_{13c}$  are the same as in part (a).

For  $x = 0.5 \text{ m}$ ,  $F_{13} = F_{13a} + F_{13b} + F_{13c} = 0.1205 + 0.0072 + 0.0042 = 0.1319$ . Likewise, for  $x = 1.0 \text{ m}$ ,  $F_{13} = 0.0686 + 0.0026 + 0.0064 = 0.0776$ .

Using Eq. (2) for  $x = 0.5 \text{ m}$ ,

$$q'_{\text{in}} = \pi \times 0.01\text{m} \times 5.67 \times 10^{-8} \frac{\text{W}}{\text{m}^2 \cdot \text{K}^4} \times \left[ (500\text{K})^4 (1 - 0.1319) + (300\text{K})^4 \times 0.1319 \right] = 98.5 \text{ W/m} <$$

Continued...

### PROBLEM 13.41 (Cont.)

Likewise for  $x = 1.0$  m,

$$q'_{\text{in}} = \pi \times 0.01\text{m} \times 5.67 \times 10^{-8} \frac{\text{W}}{\text{m}^2 \cdot \text{K}^4} \times \left[ (500\text{K})^4 (1 - 0.0776) + (300\text{K})^4 \times 0.0776 \right] = 103.8\text{W/m} \quad <$$

**COMMENTS:** (1) For the  $\alpha = 0$  case, the irradiation of the product at  $x = 0.5$  m is 99.6 % of the irradiation at  $x = 1$  m, where the irradiation is maximized. The influence of the oven openings is very small in the central portion of the oven. (2) Modifying the tilt angle of the upper panel heater is effective in controlling the radiative heating of the product. However, convection heating and/or cooling of the product will also be affected by the change in the oven geometry.

## PROBLEM 13.42

**KNOWN:** Two horizontal, very large parallel plates with prescribed surface conditions and temperatures.

**FIND:** (a) Irradiation to the top plate,  $G_1$ , (b) Radiosity of the top plate,  $J_1$ , (c) Radiosity of the lower plate,  $J_2$ , (d) Net radiative exchange between the plates per unit area of the plates.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Plates are sufficiently large to form a two surface enclosure and (2) Surfaces are diffuse-gray and have uniform radiation and radiosity distributions.

**ANALYSIS:** (a) The irradiation to the upper plate is defined as the radiant flux incident on that surface. The irradiation to the upper plate  $G_1$  is comprised of flux emitted by surface 2 and reflected flux emitted by surface 1.

$$G_1 = \varepsilon_2 E_{b2} + \rho_2 E_{b1} = \varepsilon_2 \sigma T_2^4 + (1 - \varepsilon_2) \sigma T_1^4$$

$$G_1 = 0.8 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (500 \text{ K})^4 + (1 - 0.8) \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (1000 \text{ K})^4$$

$$G_1 = 2835 \text{ W/m}^2 + 11,340 \text{ W/m}^2 = 14,175 \text{ W/m}^2. \quad <$$

(b) The radiosity is defined as the radiant flux leaving the surface by emission and reflection. For the blackbody surface 1, it follows that

$$J_1 = E_{b1} = \sigma T_1^4 = 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (1000 \text{ K})^4 = 56,700 \text{ W/m}^2. \quad <$$

(c) The radiosity of surface 2 is then,

$$J_2 = \varepsilon_2 E_{b2} + \rho_2 G_2.$$

Since the upper plate is a blackbody, it follows that  $G_2 = E_{b1}$  and

$$J_2 = \varepsilon_2 E_{b1} + \rho_2 E_{b1} = \varepsilon_2 \sigma T_2^4 + 1(1 - \varepsilon_2) \sigma T_1^4 = 14,175 \text{ W/m}^2. \quad <$$

Note that  $J_2 = G_1$ . That is, the radiant flux leaving surface 2 ( $J_2$ ) is incident upon surface 1 ( $G_1$ ).

(d) The net radiation heat exchange per unit area can be found by three relations.

$$q_1'' = J_1 - G_1 = (56,700 - 14,175) \text{ W/m}^2 = 42,525 \text{ W/m}^2$$

$$q_{12}'' = J_1 - J_2 = (56,700 - 14,175) \text{ W/m}^2 = 42,525 \text{ W/m}^2 \quad <$$

The exchange relation, Eq. 13.24, is also appropriate with  $\varepsilon_1 = 1$ ,

$$q_1'' = -q_2'' = q_{12}''$$

$$q_1'' = \varepsilon_2 \sigma (T_1^4 - T_2^4) = 0.8 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (1000^4 - 500^4) \text{ K}^4 = 42,525 \text{ W/m}^2.$$

**COMMENT:** Since the plates are large, the assumption of uniform irradiation and radiosity distributions is excellent.

### PROBLEM 13.43

**KNOWN:** Dimensions and temperature of a flat-bottomed hole.

**FIND:** (a) Radiant power leaving the opening, (b) Effective emissivity of the cavity,  $\epsilon_e$ , (c) Limit of  $\epsilon_e$  as depth of hole increases.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Hypothetical surface  $A_2$  is a blackbody at 0 K, (2) Cavity surface is isothermal, opaque and diffuse-gray with uniform radiosity and irradiation distributions.

**ANALYSIS:** Approximating  $A_2$  as a blackbody at 0 K implies that all of the radiation incident on  $A_2$  from the cavity results (directly or indirectly) from emission by the walls and escapes to the surroundings. It follows that for  $A_2$ ,  $\epsilon_2 = 1$  and  $J_2 = E_{b2} = 0$ .

(a) From the thermal circuit, the rate of radiation loss through the hole ( $A_2$ ) is

$$q_1 = (E_{b1} - E_{b2}) / \left[ \frac{1 - \epsilon_1}{\epsilon_1 A_1} + \frac{1}{A_1 F_{12}} + \frac{1 - \epsilon_2}{\epsilon_2 A_2} \right]. \quad (1)$$

Noting that  $F_{21} = 1$  and  $A_1 F_{12} = A_2 F_{21}$ , also that

$$A_1 = \pi D^2 / 4 + \pi D L = \pi D (D / 4 + L) = \pi (0.006 \text{ m}) (0.006 \text{ m} / 4 + 0.024 \text{ m}) = 4.807 \times 10^{-4} \text{ m}^2$$

$$A_2 = \pi D^2 / 4 = \pi (0.006 \text{ m})^2 / 4 = 2.827 \times 10^{-5} \text{ m}^2.$$

Substituting numerical values with  $E_b = \sigma T^4$ , find

$$q_1 = 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (1000^4 - 0) \text{ K}^4 / \left[ \frac{1 - 0.8}{0.8 \times 4.807 \times 10^{-4} \text{ m}^2} + \frac{1}{2.827 \times 10^{-5} \text{ m}^2} + 0 \right]$$

$$q_1 = 1.580 \text{ W}. \quad <$$

(b) The effective emissivity,  $\epsilon_e$ , of the cavity is defined as the ratio of the radiant power leaving the cavity to that from a blackbody having the same area of the cavity opening and at the temperature of the inner surfaces of the cavity. For the cavity above,

$$\epsilon_e = \frac{q_1}{A_2 \sigma T_1^4}$$

$$\epsilon_e = 1.580 \text{ W} / 2.827 \times 10^{-5} \text{ m}^2 (5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4) (1000 \text{ K})^4 = 0.986. \quad <$$

(c) As the depth of the hole increases, the term  $(1 - \epsilon_1) / \epsilon_1 A_1$  goes to zero such that the remaining term in the denominator of Eq. (1) is  $1 / A_1 F_{12} = 1 / A_2 F_{21}$ . That is, as  $L$  increases,  $q_1 \rightarrow A_2 F_{21} E_{b1}$ . This implies that  $\epsilon_e \rightarrow 1$  as  $L$  increases. For  $L/D = 10$ , one would expect  $\epsilon_e = 0.999$  or better.

## PROBLEM 13.44

**KNOWN:** Temperatures and emissivity of glass surfaces.

**FIND:** Heat flux through the window for case 1:  $\varepsilon_1 = \varepsilon_2 = 0.95$ , case 2:  $\varepsilon_1 = \varepsilon_2 = 0.05$ , and case 3:  $\varepsilon_1 = 0.05$ ,  $\varepsilon_2 = 0.95$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Diffuse-gray surfaces with uniform radiosity and irradiation distributions, (2) Infinite parallel glass surfaces.

**ANALYSIS:** For case 1, the net radiation heat flux between the glass sheets is

$$q_{rad}'' = \frac{\sigma(T_1^4 - T_2^4)}{\frac{1}{\varepsilon_1} + \frac{1}{\varepsilon_2} - 1} = \frac{5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (293\text{K}^4 - 263\text{K}^4)}{\frac{1}{0.95} + \frac{1}{0.95} - 1} = 133 \text{ W/m}^2 \quad <$$

Likewise, for case 2:  $\varepsilon_1 = \varepsilon_2 = 0.05$ ,  $q_{rad}'' = 3.76 \text{ W/m}^2$ , <

and for case 3:  $\varepsilon_1 = 0.05$ ,  $\varepsilon_2 = 0.95$ ,  $q_{rad}'' = 7.31 \text{ W/m}^2$ . <

**COMMENTS:** The reduction associated with case 2 is  $[(133 - 3.76)/133] \times 100 = 97\%$  while the reduction associated with case 3 is 94.5%. Both cases 2 and 3 provide a significant reduction in the heat flux relative to the uncoated glass of case 1. The decision to specify single- or double-surface coating depends on the cost of applying the low-emissivity coating.

### PROBLEM 13.45

**KNOWN:** Long V-groove machined in an isothermal block.

**FIND:** Radiant flux leaving the groove to the surroundings and effective emissivity.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Groove surface is diffuse-gray with uniform irradiation and radiosity distributions, (2) Groove is infinitely long, (3) Block is isothermal.

**ANALYSIS:** Define the hypothetical surface  $A_2$  with  $T_2 = 0$  K. The net radiation leaving  $A_1$ ,  $q_1$ , will pass to the surroundings. From the two surface enclosure analysis, Eq. 13.23,

$$q_1 = -q_2 = \frac{\sigma(T_1^4 - T_2^4)}{\frac{1 - \epsilon_1}{\epsilon_1 A_1} + \frac{1}{A_1 F_{12}} + \frac{1 - \epsilon_2}{\epsilon_2 A_2}}$$

Recognize that  $\epsilon_2 = 1$  and that from reciprocity,  $A_1 F_{12} = A_2 F_{21}$  where  $F_{21} = 1$ . Hence,

$$\frac{q_1}{A_2} = \frac{\sigma(T_1^4 - T_2^4)}{\frac{1 - \epsilon_1}{\epsilon_1} \frac{A_2}{A_1} + 1}$$

With  $A_2/A_1 = 2\ell \tan 20^\circ / (2\ell / \cos 20^\circ) = \sin 20^\circ$ , find

$$q_1'' = \frac{5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (1000^4 - 0) \text{ K}^4}{\frac{(1 - 0.6)}{0.6} \times \sin 20^\circ + 1} = 46.17 \text{ kW/m}^2. \quad <$$

The effective emissivity of the groove follows from the definition given in Problem 13.43 as the ratio of the radiant power leaving the cavity to that from a blackbody having the area of the cavity opening and at the same temperature as the cavity surface. For the present situation,

$$\epsilon_e = \frac{q_1''}{E_b(T_1)} = \frac{q_1''}{\sigma T_1^4} = \frac{46.17 \times 10^3 \text{ W/m}^2}{5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (1000 \text{ K})^4} = 0.814. \quad <$$

**COMMENTS:** (1) Note the use of the hypothetical surface defined as black at 0 K. This surface does not emit and absorbs all radiation on it; hence, is the radiant power to the surroundings. (2) Neither the irradiation or radiosity distributions are uniform. How will this affect your predictions?

### PROBLEM 13.46

**KNOWN:** Approximate wave geometry, hemispherical emissivity of water,  $\epsilon = 0.96$ .

**FIND:** (a) Effective emissivity of the water surface for  $\alpha = 3\pi/4$ , (b) Plot of the effective emissivity normalized by the hemispherical emissivity of water,  $\epsilon_{\text{eff}}/\epsilon$ , over the range  $\pi/2 \leq \alpha \leq \pi$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Two-dimensional system, (2) Diffuse, gray surfaces.

**ANALYSIS:** (a) The effective emissivity is defined by the relation

$$\epsilon_{\text{eff}} A_2 \sigma (T_1^4 - T_{\text{sur}}^4) = q_{12} = \frac{\sigma (T_1^4 - T_{\text{sur}}^4)}{\frac{1 - \epsilon_1}{\epsilon_1 A_1} + \frac{1}{A_1 F_{12}}}$$

From the schematic we see that  $A_2/A_1 = \sin(\alpha/2)$  and  $F_{21} = 1$ . Therefore,  $F_{12} = A_2 F_{21}/A_1 = \sin(\alpha/2)$  and the expression for the effective emissivity is

$$\epsilon_{\text{eff}} = \frac{1}{\frac{A_2(1 - \epsilon_1)}{\epsilon_1 A_1} + \frac{A_2}{A_1 F_{12}}} = \frac{1}{\frac{\sin(\alpha/2)(1 - \epsilon_1)}{\epsilon_1} + 1} = \frac{1}{\frac{\sin(3\pi/8)(1 - 0.96)}{0.96} + 1} = 0.963 \quad <$$

(b) The dependence of the normalized effective emissivity to the wave angle is shown in the plot below.

Continued...

### PROBLEM 13.46 (Cont.)

Comment: Although water exhibits nearly black behavior, and the sensitivity of the effective emissivity to the wave structure is small, the heat balance of the earth could be affected by approximately 1% depending on the sea roughness. These types of difficult-to-measure effects have led to debate on issues related to earth's energy balance.

### PROBLEM 13.47

**KNOWN:** Cavities formed by a cone, cylinder, and sphere having the same opening size ( $d$ ) and major dimension ( $L$ ) with prescribed wall emissivity.

**FIND:** (a) View factor between the inner surface of each cavity and the opening of the cavity; (b) Effective emissivity of each cavity as defined in Problem 13.43, if the walls are diffuse-gray with  $\varepsilon_w$ ; and (c) Compute and plot  $\varepsilon_e$  as a function of the major dimension-to-opening size ratio,  $L/d$ , over the range from 1 to 10 for wall emissivities of  $\varepsilon_w = 0.5, 0.7, \text{ and } 0.9$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Diffuse-gray surfaces, (2) Uniform radiosity over the surfaces.

**ANALYSIS:** (a) Using the summation rule and reciprocity, determine the view factor  $F_{12}$  for each of the cavities considered as a two-surface enclosure.

*Cone:*  $F_{21} + F_{22} = F_{21} + 0 = 1 \quad F_{21} = 1$

$$F_{12} = A_2 F_{21} / A_1 = (\pi d^2 / 4) / (\pi d / 2) \left[ L^2 + (d/2)^2 \right]^{1/2} = (1/2) \left[ (L/d)^2 + 1/4 \right]^{-1/2} <$$

*Cylinder:*  $F_{21} = 1$

$$F_{12} = A_2 F_{21} / A_1 = A_2 / A_1 = (\pi d^2 / 4) / [\pi d L + \pi d^2 / 4] = (1 + 4L/d)^{-1} <$$

*Sphere:*  $F_{21} = 1$

$$F_{12} = A_2 F_{21} / A_1 = A_2 / A_1 = (\pi d^2 / 4) / [\pi D^2 - \pi d^2 / 4] = (4D^2 / d^2 - 1)^{-1} <$$

(b) The effective emissivity of the cavity is defined as

$$\varepsilon_{\text{eff}} = q_{12} / q_c$$

where  $q_c = A_2 \sigma T_1^4$  which presumes the opening is a black surface at  $T_1$  and for the two-surface enclosure,

$$q_{12} = \frac{\sigma (T_1^4 - T_2^4)}{(1 - \varepsilon_1) / \varepsilon_1 A_1 + 1 / A_1 F_{12} + (1 - \varepsilon_2) / \varepsilon_2 A_2} = \frac{A_1 \sigma T_1^4}{(1 - \varepsilon_1) / \varepsilon_1 + 1 / F_{12}}$$

since  $T_2 = 0\text{K}$  and  $\varepsilon_2 = 1$ . Hence, since  $A_2 / A_1 = F_{12}$  for all the cavities, with  $\varepsilon_1 = \varepsilon_w$

$$\varepsilon_{\text{eff}} = \frac{1 / F_{12}}{(1 - \varepsilon_w) / \varepsilon_w + 1 / F_{12}} = \frac{1}{F_{12} (1 - \varepsilon_w) / \varepsilon_w + 1}$$

*Cone:*  $\varepsilon_{\text{eff}} = 1 / \left\{ (1/2) \left[ (L/d)^2 + 1/4 \right]^{-1/2} (1 - \varepsilon_w) / \varepsilon_w + 1 \right\} \quad (1) <$

Continued ...

### PROBLEM 13.47 (Cont.)

Cylinder: 
$$\varepsilon_{\text{eff}} = 1 / \left\{ [1 + 4L/d]^{-1} (1 - \varepsilon_w) / \varepsilon_w + 1 \right\} \quad (2) <$$

Sphere: 
$$\varepsilon_{\text{eff}} = 1 / \left\{ [4D^2/d^2 - 1]^{-1} (1 - \varepsilon_w) / \varepsilon_w + 1 \right\} \quad (3) <$$

(c) Using the *IHT* Workspace with eqs. (1,2,3), the effective emissivity was computed as a function of  $L/d$  (cone, cylinder and sphere) for selected wall emissivities. The results are plotted below.

In Fig. 1,  $\varepsilon_{\text{eff}}$  is shown as a function of  $L/d$  for  $\varepsilon_w = 0.7$ . For larger  $L/d$ , the sphere has the highest  $\varepsilon_{\text{eff}}$  and the cone the lowest. Figures 2, 3 and 4 illustrate the  $\varepsilon_{\text{eff}}$  vs.  $L/d$  for each of the cavity types. As expected,  $\varepsilon_{\text{eff}}$  increases with increasing wall emissivity.

Note that for the spherical cavity, with  $L/d \geq 5$ ,  $\varepsilon_{\text{eff}} > 0.98$  even with  $\varepsilon_w$  as low as 0.5. This feature makes the use of spherical cavities for high performance radiometry applications attractive since  $\varepsilon_{\text{eff}}$  is not very sensitive to  $\varepsilon_w$ .

**COMMENTS:** In Fig. 1, comparing  $\varepsilon_{\text{eff}}$  for the three cavity types, can you give a physical explanation for the results?

### PROBLEM 13.48

**KNOWN:** Dimensions of attic. Emissivity of aluminum foil and of surfaces prior to application of the foil.

**FIND:** (a) Reduction of radiation heat transfer from the hot roof to the attic floor if foil is installed on the bottom of the roof, (b) Reduction in radiation heat load if foil is installed on the top of the attic floor, (c) Reduction if foiled is installed on both the attic floor and bottom of roof.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Diffuse-gray surfaces of uniform radiosity and irradiation, (2) Temperatures of surfaces are unaffected by surface treatment, (3) Two-dimensional configuration.

**ANALYSIS:** From Eqn. 13.23 we know that the ratio of the radiation heat load after installation of the foil to the radiation heat load prior to the installation of the foil is

$$R = \left[ \frac{1 - \epsilon_o}{\epsilon_o A_1} + \frac{1}{A_1 F_{12}} + \frac{1 - \epsilon_o}{\epsilon_o A_2} \right] \bigg/ \left[ \frac{1 - \epsilon_1}{\epsilon_1 A_1} + \frac{1}{A_1 F_{12}} + \frac{1 - \epsilon_2}{\epsilon_2 A_2} \right] \quad (1)$$

On a per-unit depth basis,  $A_1 = 10 \text{ m}^2$  and  $A_2 = 10 \text{ m}^2 / \cos(30^\circ) = 11.55 \text{ m}^2$ , while from inspection,  $F_{12} = 1$ .

(a)  $\epsilon_1 = 0.85$ ,  $\epsilon_2 = 0.07$ . Evaluation of Eqn. (1) yields  $R = 0.105$ . <

(b)  $\epsilon_1 = 0.07$ ,  $\epsilon_2 = 0.85$ . Evaluation of Eqn. (1) yields  $R = 0.092$ . <

(c)  $\epsilon_1 = \epsilon_2 = 0.07$ . Evaluation of Eqn. (1) yields  $R = 0.052$ . <

**COMMENTS:** (1) The reduction in the radiation heat load is least when the foil is installed on the bottom of the attic roof only. The surface formed by the attic roof is relatively large compared to Surface 1. As the roof becomes more steeply pitched,  $A_2$  will increase and will eventually form a large surroundings. Installing foil on the roof, as its area becomes much larger, will become more ineffective. (2) The reduction is most significant when both surfaces are covered with foil, as expected. (3) Over time, the foil installed on the floor may become covered with a layer of dust, reducing the effectiveness of the foil installation on that surface.

### PROBLEM 13.49

**KNOWN:** Long, thin-walled horizontal tube with radiation shield having an air gap of 10 mm. Emissivities and temperatures of surfaces are prescribed.

**FIND:** Radiant heat transfer from the tube per unit length.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Tube and shield are very long, (2) Surfaces at uniform temperatures, (3) Surfaces are diffuse-gray.

**ANALYSIS:** The long tube and shield form a two surface enclosure, and since the surfaces are diffuse-gray, the radiant heat transfer from the tube, according to Eq. 13.23, is

$$q_{12} = \frac{\sigma(T_1^4 - T_2^4)}{\frac{1 - \epsilon_1}{\epsilon_1 A_1} + \frac{1}{A_1 F_{12}} + \frac{1 - \epsilon_2}{\epsilon_2 A_2}} \quad (1)$$

By inspection,  $F_{12} = 1$ . Note that

$$A_1 = \pi D_1 \ell \quad \text{and} \quad A_2 = \pi D_2 \ell$$

where  $\ell$  is the length of the tube and shield. Dividing Eq. (1) by  $\ell$ , find the heat rate per unit length,

$$q'_{12} = \frac{q_{12}}{\ell} = \frac{5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K} \left[ (273 + 120)^4 - (273 + 35)^4 \right] \text{ K}^4}{\frac{1 - 0.8}{0.8 \pi (100 \times 10^{-3} \text{ m})} + \frac{1}{\pi (100 \times 10^{-3} \text{ m}) \times 1} + \frac{1 - 0.1}{0.1 \pi (120 \times 10^{-3} \text{ m})}}$$

$$q'_{12} = \frac{842.3 \text{ W/m}^2}{(0.7958 + 3.183 + 23.87) \text{ m}^{-1}} = 30.2 \text{ W/m.} \quad <$$

**COMMENTS:** Recognize that convective heat transfer would be important in this annular air gap. Suitable correlations to estimate the heat transfer coefficient are given in Chapter 9.

## PROBLEM 13.50

**KNOWN:** Dimensions and temperature of an anodized aluminum sheet radiating to deep space.

**FIND:** (a) Net radiation from both sides of a 200 mm × 200 mm sheet, (b) Net radiation from the sheet with 3-mm diameter holes spaced 5 mm apart, (c) Net radiation from the sheet with 3-mm, flat-bottomed diameter holes of depth 2 mm, spaced 5 mm apart, (d) Ratio of net heat transfer to sheet mass for the three configurations.

**SCHEMATIC:**

**ASSUMPTIONS:** Diffuse, gray behavior.

**PROPERTIES:** Table A.11, anodized aluminum: ( $T = 300 \text{ K}$ ):  $\varepsilon = 0.82$ . Table A.1 aluminum ( $T = 300 \text{ K}$ ):  $\rho = 2702 \text{ kg/m}^3$ .

**ANALYSIS:** (a) For 2 sides,

$$E = 2Lw\varepsilon\sigma T_s^4 = 2 \times 0.2 \text{ m} \times 0.2 \text{ m} \times 0.82 \times 5.67 \times 10^{-8} \frac{\text{W}}{\text{m}^2 \cdot \text{K}^4} \times (300 \text{ K})^4 = 30.13 \text{ W} <$$

(b) The number of holes is  $N = Lw/s^2$  where  $s = 5 \text{ mm}$  is the hole spacing. Therefore,  $N = (0.2 \text{ m} \times 0.2 \text{ m}) / (0.005 \text{ m})^2 = 1600$ . The sheet area occupied by holes is  $A_h = N\pi D^2/4 = 1600 \times \pi \times (0.003 \text{ m})^2/4 = 11.31 \times 10^{-3} \text{ m}^2$ . The emission from the entire sheet is  $E = NE_h + E_s$ .

The emission from the flat sheet area is  $E_s = 2(Lw - A_h)\varepsilon\sigma T_s^4$ , or

$$E_s = 2 \times (0.2 \text{ m} \times 0.2 \text{ m} - 11.31 \times 10^{-3} \text{ m}^2) \times 0.82 \times 5.67 \times 10^{-8} \frac{\text{W}}{\text{m}^2 \cdot \text{K}^4} \times (300 \text{ K})^4 = 21.61 \text{ W}$$

Now, consider one hole. From the coaxial parallel disk results of Table 13.2,

$$S = 1 + \frac{1 + 0.32}{0.32} = 13.11 \quad ; \quad F_{23} = \frac{1}{2} \left[ 13.11 - (13.11^2 - 4)^{1/2} \right] = 0.0762$$

From the summation rule and reciprocity,

Continued...

**PROBLEM 13.50 (Cont.)**

$F_{21} = 1 - F_{23}$  and  $F_{12} = (1 - F_{23})A_2/A_1 = (1 - F_{23})D/4t = (1 - 0.0762) \times 3/(4 \times 5) = 0.139$ .  
Therefore,  $F_{1-(23)} = 0.277$  and the emission from one hole is

$$E_h = \frac{\sigma T^4}{\frac{1 - \epsilon_1}{\epsilon_1 A_1} + \frac{1}{A_1 F_{1-(23)}}} = \frac{5.67 \times 10^{-8} \frac{\text{W}}{\text{m}^2 \cdot \text{K}^4} \times (300\text{K})^4}{\frac{1 - 0.82}{0.82 \times \pi \times 0.05\text{m} \times 0.03\text{m}} + \frac{1}{\pi \times 0.005\text{m} \times 0.003\text{m} \times 0.277}} = 5.65 \times 10^{-3} \text{ W}$$

Therefore,  $E = 21.61 \text{ W} + 1600 \times 5.65 \times 10^{-3} \text{ W} = 30.65 \text{ W}$

<

(c) We shall treat the sides and bottom of the cavity as one surface with  $F_{21} = 1$ . For one opening,

$$E_h = \frac{\sigma T^4}{\frac{1 - \epsilon_1}{\epsilon_1 A_1} + \frac{1}{A_1 F_{12}}} = \frac{\sigma T^4}{\frac{1 - \epsilon_1}{\epsilon_1 A_1} + \frac{1}{A_2 F_{21}}} = \frac{5.67 \times 10^{-8} \frac{\text{W}}{\text{m}^2 \cdot \text{K}^4}}{\frac{1 - 0.82}{0.82 \times (\pi \times 0.003\text{m} \times 0.002\text{m} + \pi \times (0.003\text{m})^2 / 4)} + \frac{1}{\pi \times [(0.003\text{m})^2 / 4] \times 1}}$$

$E_h = 3.063 \times 10^{-3} \text{ W}$ . Therefore for both sides of the sheet,

$E = 21.61 \text{ W} + 1600 \times 2 \times 3.063 \times 10^{-3} \text{ W} = 31.41 \text{ W}$

<

(d) The mass of the sheet in part (a) is  $M_a = Lwt\rho = 0.2\text{m} \times 0.2\text{m} \times 0.005\text{m} \times 2702 \text{ kg/m}^3 = 0.540 \text{ kg}$ . For part (b),  $M_b = (Lwt - N\pi D^2 t/4)\rho = (0.2\text{m} \times 0.2\text{m} \times 0.005\text{m} - 1600 \times \pi \times (0.003\text{m})^2 \times 0.005\text{m}/4) \times 2702 \text{ kg/m}^3 = 0.387 \text{ kg}$ . For part (c),  $M_c = (Lwt - N\pi D^2(t - w)/4)\rho = (0.2\text{m} \times 0.2\text{m} \times 0.005\text{m} - 1600 \times \pi \times (0.003\text{m})^2 \times (0.004\text{m})/4) \times 2702 \text{ kg/m}^3 = 0.418 \text{ kg}$ .

Therefore, the ratios of the net radiation heat transfer to mass,  $R$ , for the three parts of the problem are:

Part (a):  $R = E/M_a = 30.13 \text{ W}/0.540 \text{ kg} = 55.8 \text{ W/kg}$ .

Part (b):  $R = E/M_b = 30.65 \text{ W}/0.387 \text{ kg} = 79.2 \text{ W/kg}$ .

Part (c):  $R = E/M_c = 31.41 \text{ W}/0.418 \text{ kg} = 75.1 \text{ W/kg}$ .

<

**COMMENTS:** (1) Boring holes in the sheet results in increased heat transfer rates and reduced mass. If a specific heat loss is required, the size of the sheets with the bored holes could be reduced slightly, leading to reduction in the mass of the bored aluminum sheet. (2) Holes that are bored completely through the sheet may lead to large conduction resistance along the sheet and, in turn, spatial temperature variations on the aluminum sheet. Since the two alternative designs involving holes are characterized by nearly the same emission-to-mass ratio, the third option might be preferred.

### PROBLEM 13.51

**KNOWN:** Temperature, emissivity and dimensions of a rectangular fin array radiating to deep space.

**FIND:** (a) Rate of radiation transfer per unit length from a unit section to space, (b) Effect of emissivity on heat rejection.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Diffuse/gray surface behavior, (2) Length of array (normal to page) is much larger than  $W$  and  $L$ , (3) Isothermal surfaces.

**ANALYSIS:** (a) Since the sides and base of the U-section have the same temperature and emissivity, they can be treated as a single surface and the U-section becomes a two-surface enclosure. Deep space may be represented by the hypothetical surface  $A'_3$ , which acts as a blackbody at absolute zero temperature. From Eq. 13.23, with  $T_1 = T_2 = T$  and  $\varepsilon_1 = \varepsilon_2 = \varepsilon$ ,

$$q'_{(1,2)3} = \frac{\sigma(T^4 - T_3^4)}{\frac{1-\varepsilon}{\varepsilon A'_{(1,2)}} + \frac{1}{A'_{(1,2)} F_{(1,2)3}} + \frac{1-\varepsilon}{\varepsilon A'_3}}$$

where  $A'_{(1,2)} = 2L + W$ ,  $A'_3 = W$ ,  $A'_{(1,2)} F_{(1,2)3} = A'_3 F_{3(1,2)} = W$ . Hence,

$$q'_{(1,2)3} = \frac{\sigma T^4}{\frac{1-\varepsilon}{\varepsilon(2L+W)} + \frac{1}{W} + \frac{1-\varepsilon}{\varepsilon W}}$$

$$q'_{(1,2)3} = \frac{5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (325 \text{ K})^4}{\frac{1-0.70}{0.70(0.275\text{m})} + \frac{1}{0.025\text{m}} + 0} = 15.2 \text{ W/m} \quad <$$

(b) For  $\varepsilon = 0.7$  emission from the base of the U-section is  $q'_b = \varepsilon A'_1 \sigma T^4 = 0.7 \times 0.025\text{m} \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (325 \text{ K})^4 = 11.1 \text{ W/m}$ . The effect of  $\varepsilon$  on  $q'_{(1,2)3}$  and  $q'_b$  is shown as follows.

Continued ...

**PROBLEM 13.51 (Cont.)**

The effect of the fins on heat transfer enhancement increases with decreasing emissivity.

**COMMENTS:** Note that, if the surfaces behaved as blackbodies ( $\epsilon_1 = \epsilon_2 = 1.0$ ), the U-section becomes a blackbody cavity for which heat rejection is simply  $A'_3 E_b(T) = q'_b$ . Hence, it is no surprise that the  $q'_b \rightarrow q'_{(1,2)3}$  as  $\epsilon \rightarrow 1$  in the foregoing figure. For  $\epsilon = 1$ , no enhancement is provided by the fins.

### PROBLEM 13.52

**KNOWN:** Power dissipation of electronic device and thermal resistance associated with attachment to inner wall of a cubical container. Emissivity of outer surface of container and wall temperature of service bay.

**FIND:** Temperatures of cubical container and device.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, (2) Device and container are isothermal, (3) Heat transfer from the container is exclusively by radiation exchange with bay (small surface in a large enclosure), (4) Container surface may be approximated as diffuse/gray.

**ANALYSIS:** From Eq. 13.27

$$P_e = q = \sigma (6W^2) \epsilon_c (T_{s,c}^4 - T_{sur}^4)$$

$$T_{s,c} = \left[ \frac{q}{\sigma (6W^2) \epsilon_c} + T_{sur}^4 \right]^{1/4}$$

$$T_{s,c} = \left[ \frac{50 \text{ W}}{5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times 6(0.12 \text{ m})^2 \times 0.8} + (150 \text{ K})^4 \right]^{1/4} = 339.4 \text{ K} = 66.4^\circ\text{C} \quad <$$

With  $q = (T_d - T_{s,c}) / R_t$ ,

$$T_d = q R_t + T_{s,c} = 50 \text{ W} \times 0.1 \text{ K/W} + 66.4^\circ\text{C} = 71.4^\circ\text{C} \quad <$$

**COMMENTS:** If the temperature of the device is too large to insure reliable operation, it may be reduced by increasing  $\epsilon_c$  or  $W$ .

### PROBLEM 13.53

**KNOWN:** Long electrical conductor with known heat dissipation is cooled by a concentric tube arrangement.

**FIND:** Surface temperature of the conductor.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Surfaces are diffuse-gray, (2) Conductor and cooling tube are concentric and very long, (3) Space between surfaces is evacuated.

**ANALYSIS:** The heat transfer by radiation exchange between the conductor and the concentric, cooled cylinder is given by Eq. 13.25. For a unit length,

$$q'_{12} = \frac{q_{12}}{\ell} = \sigma \cdot 2\pi r_1 \left( T_1^4 - T_2^4 \right) / \left[ \frac{1}{\epsilon_1} + \frac{1 - \epsilon_2}{\epsilon_2} \left( \frac{r_1}{r_2} \right) \right] \quad (1)$$

where  $A_1 = 2\pi r_1 \cdot \ell$ . Solving for  $T_1$  and substituting numerical values, find

$$T_1 = \left\{ T_2^4 + \frac{q'_{12}}{\sigma \cdot 2\pi r_1} \left[ \frac{1}{\epsilon_1} + \frac{1 - \epsilon_2}{\epsilon_2} \left( \frac{r_1}{r_2} \right) \right] \right\}^{1/4}$$

$$T_1 = \left\{ (27 + 273)^4 \text{ K}^4 + \frac{6 \text{ W/m}}{5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times 2\pi (0.005\text{m})} \left[ \frac{1}{0.6} + \frac{1 - 0.9}{0.9} \left( \frac{5}{25} \right) \right] \right\}^{1/4}$$

$$T_1 = \left\{ (300 \text{ K})^4 + 3.368 \times 10^9 \text{ K}^4 [1.667 + 0.00222] \right\}^{1/4} \quad (2)$$

$$T_1 = 342.3 \text{ K} = 69^\circ\text{C}.$$

<

**COMMENTS:** (1) Note that Eq. (1) implies that  $F_{12} = 1$ . From Eq. (2) by comparison of the second term in the brackets involving  $\epsilon_2$ , note that the influence of  $\epsilon_2$  is small. This follows since  $r_1 \ll r_2$ .

### PROBLEM 13.54

**KNOWN:** Temperatures and emissivities of spherical surfaces which form an enclosure.

**FIND:** Evaporation rate of oxygen stored in inner container.

**SCHEMATIC:**

**PROPERTIES:** Oxygen (given):  $h_{fg} = 2.13 \times 10^5 \text{ J/kg}$ .

**ASSUMPTIONS:** (1) Opaque, diffuse-gray surfaces, (2) Evacuated space between surfaces, (3) Negligible heat transfer along vent and support assembly.

**ANALYSIS:** From an energy balance on the inner container, the net radiation heat transfer to the container may be equated to the evaporative heat loss

$$q_{oi} = \dot{m}h_{fg}$$

Substituting from Eq. 13.26, where  $q_{oi} = -q_{io}$  and  $F_{iio} = 1$

$$\dot{m} = \frac{-\sigma(\pi D_i^2)(T_i^4 - T_o^4)}{h_{fg} \left[ \frac{1}{\varepsilon_i} + \frac{1 - \varepsilon_o}{\varepsilon_o} \left( \frac{r_i}{r_o} \right)^2 \right]}$$

$$\dot{m} = \frac{-5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times \pi (0.8 \text{ m})^2 (95^4 - 280^4) \text{ K}^4}{2.13 \times 10^5 \text{ J/kg} \left[ \frac{1}{0.05} + \frac{0.95}{0.05} \left( \frac{0.4}{0.6} \right)^2 \right]}$$

$$\dot{m} = 1.14 \times 10^{-4} \text{ kg/s.}$$

<

**COMMENTS:** This loss could be reduced by insulating the outer surface of the outer container and/or by inserting a radiation shield between the containers.

### PROBLEM 13.55

**KNOWN:** Emissivities, diameters and temperatures of concentric spheres.

**FIND:** (a) Radiation transfer rate for black surfaces. (b) Radiation transfer rate for diffuse-gray surfaces, (c) Effects of increasing the diameter and assuming blackbody behavior for the outer sphere. (d) Effect of emissivities on net radiation exchange.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Blackbody or diffuse-gray surface behavior.

**ANALYSIS:** (a) Assuming blackbody behavior, it follows that  $q_{ij} = A_i F_{ij} (J_i - J_j)$  where  $J_i = \sigma T_i^4$  and  $J_j = \sigma T_j^4$ . Therefore,

$$q_{12} = A_1 F_{12} \sigma (T_1^4 - T_2^4) = \pi (0.8 \text{ m})^2 (1) 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 [(400 \text{ K})^4 - (300 \text{ K})^4] = 1995 \text{ W.} <$$

(b) For diffuse-gray surface behavior, it follows from Eq. 13.26

$$q_{12} = \frac{\sigma A_1 (T_1^4 - T_2^4)}{\frac{1}{\epsilon_1} + \frac{1 - \epsilon_2}{\epsilon_2} \left(\frac{r_1}{r_2}\right)^2} = \frac{5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \pi (0.8 \text{ m})^2 [400^4 - 300^4] \text{ K}^4}{\frac{1}{0.5} + \frac{1 - 0.05}{0.05} \left(\frac{0.4}{0.6}\right)^2} = 191 \text{ W.} <$$

(c) With  $D_2 = 20 \text{ m}$ , it follows that

$$q_{12} = \frac{5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K} \pi (0.8 \text{ m})^2 [(400 \text{ K})^4 - (300 \text{ K})^4]}{\frac{1}{0.5} + \frac{1 - 0.05}{0.05} \left(\frac{0.4}{10}\right)^2} = 983 \text{ W.} <$$

With  $\epsilon_2 = 1$ , instead of 0.05, Eq. 13.21 reduces

$$q_{12} = \sigma A_1 \epsilon_1 (T_1^4 - T_2^4) = 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \pi (0.8 \text{ m})^2 0.5 [(400 \text{ K})^4 - (300 \text{ K})^4] = 998 \text{ W.} <$$

Continued ...

### PROBLEM 13.55 (Cont.)

(d) Using the *IHT Radiation* Tool Pad, the following results were obtained

Net radiation exchange increases with  $\epsilon_1$  and  $\epsilon_2$ , and the trends are due to increases in emission from and absorption by surfaces 1 and 2, respectively.

**COMMENTS:** From part (c) it is evident that the actual surface emissivity of a *large* enclosure has a small effect on radiation exchange with small surfaces in the enclosure. Working with  $\epsilon_2 = 1.0$  instead of  $\epsilon_2 = 0.05$ , the value of  $q_{12}$  is increased by only  $(998 - 983)/983 = 1.5\%$ . In contrast, from the results of (d) it is evident that the surface emissivity  $\epsilon_2$  of a *small* enclosure has a large effect on radiation exchange with interior objects, which increases with increasing  $\epsilon_1$ .

### PROBLEM 13.56

**KNOWN:** Two radiation shields positioned in the evacuated space between two infinite, parallel planes.

**FIND:** Steady-state temperature of the shields.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) All surfaces are diffuse-gray and (2) All surfaces are parallel and of infinite extent.

**ANALYSIS:** The planes and shields can be represented by a thermal circuit from which it follows that

$$q_1'' = -q_2'' = \frac{\sigma(T_1^4 - T_2^4)}{R_1'' + R_2'' + R_3''} = \frac{\sigma(T_1^4 - T_{s1}^4)}{R_1''} = \frac{\sigma(T_{s1}^4 - T_{s2}^4)}{R_2''} = \frac{\sigma(T_{s2}^4 - T_2^4)}{R_3''}.$$

Since all the emissivities involved are equal,  $R_1'' = \frac{A_1}{A_1 F_{12}} = 1 = R_2'' = R_3''$ , so that

$$T_{s1}^4 = T_1^4 - \frac{R_1''}{R_1'' + R_2'' + R_3''} (T_1^4 - T_2^4) = T_1^4 - (1/3)(T_1^4 - T_2^4)$$

$$T_{s1}^4 = (600 \text{ K})^4 - (1/3)(600^4 - 325^4) \text{ K}^4 \quad T_{s1} = 548 \text{ K} \quad <$$

$$T_{s2}^4 = T_2^4 + \frac{R_3''}{R_1'' + R_2'' + R_3''} (T_1^4 - T_2^4) = T_2^4 + (1/3)(T_1^4 - T_2^4)$$

$$T_{s2}^4 = (325 \text{ K})^4 + (1/3)(600^4 - 325^4) \text{ K}^4 \quad T_{s2} = 474 \text{ K} \quad <$$

### PROBLEM 13.57

**KNOWN:** Two large, infinite parallel plates that are diffuse-gray with temperatures and emissivities of  $T_1$  and  $\varepsilon_1$  and  $T_2$  and  $\varepsilon_2$ .

**FIND:** Show that the ratio of the radiation transfer rate with multiple shields,  $N$ , of emissivity  $\varepsilon_s$  to that with no shields,  $N = 0$ , is

$$\frac{q_{12,N}}{q_{12,0}} = \frac{[1/\varepsilon_1 + 1/\varepsilon_2 - 1]}{[1/\varepsilon_1 + 1/\varepsilon_2 - 1] + N[2/\varepsilon_s - 1]}$$

where  $q_{12,N}$  and  $q_{12,0}$  represent the radiation heat rate with  $N$  and  $N = 0$  shields, respectively.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Plane infinite planes with diffuse-gray surfaces and uniform radiosities, and (2) Shield has negligible thermal conduction resistance.

**ANALYSIS:** Representing the parallel plates by the resistance network shown above for the “no-shield” condition,  $N = 0$ , with  $F_{12} = 1$ , the heat rate per unit area follows from Eq. 13.24 (see also Fig. 13.11) as

$$q''_{12,0} = \frac{E_{b1} - E_{b2}}{1/\varepsilon_1 + 1/\varepsilon_2 - 1} \quad (1)$$

With the addition of each shield as shown in the schematic above, three resistance elements are added to the network: two surface resistances,  $(1 - \varepsilon_s)/\varepsilon_s$ , and one space resistance,  $1/F_{ij} = 1$ . Hence, for the “ $N$  - shield” condition,

$$q''_{12,N} = \frac{E_{b1} - E_{b2}}{[1/\varepsilon_1 + 1/\varepsilon_2 - 1] + N[2(1 - \varepsilon_s)/\varepsilon_s + 1]} \quad (2)$$

The ratio of the heat rates is obtained by dividing Eq. (2) by Eq. (1),

$$\frac{q''_{12,N}}{q_{12,0}} = \frac{[1/\varepsilon_1 + 1/\varepsilon_2 - 1]}{[1/\varepsilon_1 + 1/\varepsilon_2 - 1] + N[2/\varepsilon_s - 1]} \quad <$$

**COMMENTS:** Can you derive an expression to determine the temperature difference across pairs of the  $N$ -shields?

### PROBLEM 13.58

**KNOWN:** Emissivities of two large, parallel surfaces.

**FIND:** Heat shield emissivity needed to reduce radiation transfer by a factor of 10.

**SCHEMATIC:**

**ASSUMPTIONS:** (a) Diffuse-gray surface behavior, (b) Negligible conduction resistance for shield, (c) Same emissivity on opposite sides of shield.

**ANALYSIS:** For this arrangement,  $F_{13} = F_{32} = 1$ .

Without (wo) the shield, it follows from Eq. 13.24,

$$(q_{12})_{wo} = \frac{A_1 \sigma (T_1^4 - T_2^4)}{\frac{1}{\epsilon_1} + \frac{1}{\epsilon_2} - 1}$$

With (w) the shield it follows from Eq. 13.28,

$$(q_{12})_w = \frac{A_1 \sigma (T_1^4 - T_2^4)}{\frac{1}{\epsilon_1} + \frac{1}{\epsilon_2} + \frac{2}{\epsilon_3} - 2}$$

Hence, the heat rate ratio is

$$\frac{(q_{12})_w}{(q_{12})_{wo}} = 0.1 = \frac{\frac{1}{\epsilon_1} + \frac{1}{\epsilon_2} - 1}{\frac{1}{\epsilon_1} + \frac{1}{\epsilon_2} + \frac{2}{\epsilon_3} - 2} = \frac{\frac{1}{0.8} + \frac{1}{0.8} - 1}{\frac{1}{0.8} + \frac{1}{0.8} + \frac{2}{\epsilon_3} - 2}$$

Solving, find

$$\epsilon_3 = 0.138.$$

<

**COMMENTS:** The foregoing result is independent of  $T_1$  and  $T_2$ . It is only necessary that the temperatures be maintained at fixed values, irrespective of whether or not the shield is in place.

### PROBLEM 13.59

**KNOWN:** Surface emissivities of a radiation shield inserted between parallel plates of prescribed temperatures and emissivities.

**FIND:** (a) Effect of shield orientation on radiation transfer, (b) Effect of shield orientation on shield temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Diffuse-gray surface behavior, (2) Shield is isothermal.

**ANALYSIS:** (a) On a unit area basis, the network representation of the system is

Hence the total radiation resistance,

$$R = \frac{1-\varepsilon_1}{\varepsilon_1} + 1 + \frac{1-\varepsilon_s}{\varepsilon_s} + \frac{1-2\varepsilon_s}{2\varepsilon_s} + 1 + \frac{1-\varepsilon_2}{\varepsilon_2}$$

is independent of orientation. Since  $q = (E_{b1} - E_{b2})/R$ , the heat transfer rate is independent of orientation.

(b) Considering that portion of the circuit between  $E_{b1}$  and  $E_{b,s}$ , it follows that

$$q = \frac{E_{b1} - E_{b,s}}{\frac{1-\varepsilon_1}{\varepsilon_1} + 1 + f(\varepsilon_s)}, \text{ where } f(\varepsilon_s) = \frac{1-\varepsilon_s}{\varepsilon_s} \text{ or } \frac{1-2\varepsilon_s}{2\varepsilon_s}.$$

Hence,

$$E_{b,s} = E_{b1} - \left[ \frac{1-\varepsilon_1}{\varepsilon_1} + 1 + f(\varepsilon_s) \right] q.$$

It follows that, since  $E_{b,s}$  increases with decreasing  $f(\varepsilon_s)$  and  $(1-2\varepsilon_s)/2\varepsilon_s < (1-\varepsilon_s)/\varepsilon_s$ ,  $E_{b,s}$  is larger when the high emissivity ( $2\varepsilon_s$ ) side faces plate 1. Hence  $T_s$  is larger for case (b). <

### PROBLEM 13.60

**KNOWN:** End of propellant tank with radiation shield is subjected to solar irradiation in space environment.

**FIND:** (a) Temperature of the shield,  $T_s$ , and (b) Heat flux to the tank,  $q_1''$  ( $\text{W}/\text{m}^2$ ).

**SCHEMATIC:**

**ASSUMPTIONS:** (1) All surfaces are diffuse-gray, (2) View factor between shield and tank is unity,  $F_{st} = 1$ , (3) Space surroundings are black at 0 K, (4) Resistance of shield for conduction is negligible.

**ANALYSIS:** (a) Perform a radiation balance on the shield. From the schematic,

$$\alpha_S G_S - \epsilon_1 E_b(T_s) - q''_{st} = 0 \quad (1)$$

where  $q''_{st}$  is the net heat exchange between the shield and the tank. Considering these two surfaces as large, parallel planes, from Eq. 13.24,

$$q''_{st} = \sigma (T_s^4 - T_t^4) / [1/\epsilon_2 + 1/\epsilon_1 - 1]. \quad (2)$$

Substituting  $q''_{st}$  from Eq. (2) into Eq. (1), find

$$\alpha_S G_S - \epsilon_1 \sigma T_s^4 - \sigma (T_s^4 - T_t^4) / [1/\epsilon_2 + 1/\epsilon_1 - 1] = 0.$$

Solving for  $T_s$ , find

$$T_s = \left[ \frac{\alpha_S G_S + \sigma T_t^4 / [1/\epsilon_2 + 1/\epsilon_1 - 1]}{\sigma (\epsilon_1 + 1 / [1/\epsilon_2 + 1/\epsilon_1 - 1])} \right]^{1/4}.$$

Since the shield is diffuse-gray,  $\alpha_S = \epsilon_1$  and then

$$T_s = \left[ \frac{0.05 \times 1250 \text{ W/m}^2 + \sigma (100)^4 \text{ K}^4 / [1/0.05 + 1/0.1 - 1]}{\sigma (0.05 + 1 / [1/0.05 + 1/0.1 - 1])} \right]^{1/4} = 338 \text{ K.} \quad <$$

(b) The heat flux to the tank can be determined from Eq. (2),

$$q''_{st} = 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (338^4 - 100^4) \text{ K}^4 / [1/0.05 + 1/0.1 - 1] = 25.3 \text{ W/m}^2. \quad <$$

### PROBLEM 13.61

**KNOWN:** Black panel at 77 K in large vacuum chamber at 300 K with radiation shield having  $\epsilon = 0.05$ .

**FIND:** Net heat transfer by radiation to the panel.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Chamber is large compared to shield, (2) Shape factor between shield and plate is unity, (3) Shield is diffuse-gray, (4) Shield is thin, negligible thermal conduction resistance.

**ANALYSIS:** The arrangement lends itself to a network representation following Figs. 13.10 and 13.11.

Noting that  $F_{2s} = F_{s1} = 1$ , and that  $A_2 F_{2s} = A_s F_{s1}$ , the heat rate is

$$q_1 = (E_{b2} - E_{b1}) / \Sigma R_i = \sigma (T_2^4 - T_1^4) / \left[ \frac{1}{A_s} + 2 \left( \frac{1 - \epsilon_s}{\epsilon_s A_s} \right) + \frac{1}{A_s} \right].$$

Recognizing that  $A_s = A_1$  and multiplying numerator and denominator by  $A_1$  gives

$$q_1 = A_1 \sigma (T_2^4 - T_1^4) \left[ 2 + 2 \left( \frac{1 - \epsilon_s}{\epsilon_s} \right) \right].$$

Substituting numerical values, find

$$q_1 = \frac{\pi (0.1)^2 \text{ m}^2}{4} \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (300^4 - 77^4) \text{ K}^4 / \left[ 2 + 2 \left( \frac{1 - 0.05}{0.05} \right) \right]$$

$$q_1 = 89.8 \text{ mW.} \quad \leftarrow$$

**COMMENTS:** In using the network representation, be sure to designate direction of the net heat rate. In this situation, we have shown  $q_1$  as the net rate *into* the surface  $A_1$ . The temperature of the shield,  $T_s = 253 \text{ K}$ , follows from the relation

$$q_1 = (E_{bs} - E_{b1}) / \left[ \frac{1 - \epsilon_s}{\epsilon_s A_s} + \frac{1}{A_1 F_{s1}} \right].$$

### PROBLEM 13.62

**KNOWN:** Dense cryogenic piping array located close to furnace wall.

**FIND:** Number of radiation shields,  $N$ , to be installed such that the temperature of the shield closest to the array,  $T_{s,N}$ , is less than  $30^\circ\text{C}$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) The ice-covered dense piping array approximates a plane surface, (2) Piping array and furnace wall can be represented by infinite parallel plates, (3) Surfaces are diffuse-gray, and (4) Convection effects are negligible.

**ANALYSIS:** Treating the piping array and furnace wall as infinite parallel plates, the net heat rate by radiation exchange with  $N$  shields of identical emissivity,  $\epsilon_s$ , on both sides follows from extending the network of Fig. 13.12 to account for the resistances of  $N$  shields. (See Problem 13.57) For each shield added, two surface resistances and one space resistance are added,

$$q_{fp} = \frac{\sigma(T_f^4 - T_p^4)A_f}{\left[1/\epsilon_f + 1/\epsilon_p - 1\right] + N\left[2/\epsilon_s - 1\right]} \quad (1)$$

where  $\sigma = 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4$ . The requirement that the  $N$ -th shield (next to the piping array) has a temperature  $T_{s,N} \leq 30^\circ\text{C}$  will be satisfied when

$$q_{fp} \leq \frac{\sigma(T_{s,N}^4 - T_p^4)A_f}{\left[1/\epsilon_s + 1/\epsilon_p - 1\right]} \quad (2)$$

Using the foregoing equations in the *IHT* workspace, find that  $T_{s,N} = 30^\circ\text{C}$  when  $N = 8.60$ . So that  $T_{s,N}$  is less than  $30^\circ\text{C}$ , the number of shields required is

$$N = 9$$

<

**COMMENTS:** Note that when  $N = 0$ , Eq. (1) reduces to the case of two parallel plates. Show for the case with one shield,  $N = 1$ , that Eq. (1) is identical to Eq. 13.28.

### PROBLEM 13.63

**KNOWN:** Concentric tube arrangement with diffuse-gray surfaces.

**FIND:** (a) Heat gain by the cryogenic fluid per unit length of the inner tube (W/m), (b) Change in heat gain if diffuse-gray shield with  $\epsilon_s = 0.02$  is inserted midway between inner and outer surfaces.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Surfaces are diffuse-gray, (2) Space between tubes is evacuated.

**ANALYSIS:** (a) For the *no shield* case, the thermal circuit is shown at right. It follows that the net heat gain per unit tube length is

$$-q'_1 = \frac{q_{oi}}{L} = (E_{bo} - E_{bi}) / \left[ \frac{1 - \epsilon_o}{\epsilon \pi D_o} + \frac{1}{\pi D_i F_{i0}} + \frac{1 - \epsilon_i}{\epsilon_i \pi D_i} \right]$$

where  $A = \pi DL$ . Note that  $F_{i0} = 1$  and  $E_b = \sigma T^4$  giving

$$-q'_1 = 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left( 300^4 - 77^4 \right) \text{ K}^4 / \left[ \frac{1 - 0.05}{0.05 \pi \times 50 \times 10^{-3}} + \frac{1}{\pi 20 \times 10^{-3} \times 1} + \frac{1 - 0.02}{0.02 \pi \times 20 \times 10^{-3}} \right] \text{ m}^{-1}$$

$$-q'_1 = 457 \text{ W/m}^2 / [121.0 + 15.9 + 779.8] \text{ m}^{-1} = 0.501 \text{ W/m.} \quad <$$

(b) For the *with shield* case, the thermal circuit will include three additional resistances.

From the network, it follows that  $-q_i = (E_{bo} - E_{bi}) / \Sigma R_t$ . With  $F_{is} = F_{so} = 1$ , find

$$-q'_1 = 457 \text{ W/m}^2 / \left[ 121.0 + \frac{1}{\pi 35 \times 10^{-3} \times 1} + \frac{2(1 - 0.02)}{0.02 \pi 35 \times 10^{-3}} + 15.9 + 779.8 \right] \text{ m}^{-1}$$

$$-q'_1 = 457 \text{ W/m}^2 / [121.0 + 9.1 + 891.3 + 15.9 + 779.8] \text{ m}^{-1} = 0.251 \text{ W/m.}$$

The change (percentage) in heat gain per unit length of the tube as a result of inserting the radiation shield is

$$\frac{q'_{i,s} - q'_{i,ns}}{q'_{i,ns}} \times 100 = \frac{(0.251 - 0.501) \text{ W/m}}{0.501 \text{ W/m}} \times 100 = -49\%. \quad <$$

### PROBLEM 13.64

**KNOWN:** Heated tube with radiation shield whose exterior surface is exposed to convection and radiation processes.

**FIND:** Operating temperature for the tube under the prescribed conditions.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) No convection in space between tube and shield, (3) Surroundings are large compared to the shield and are isothermal, (4) Tube and shield are infinitely long, (5) Surfaces are diffuse-gray, (6) Shield is isothermal.

**ANALYSIS:** Perform an energy balance on the shield.

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = 0$$

$$q_{12} - q_{\text{conv}} - q_{\text{rad}} = 0$$

where  $q_{12}$  is the net radiation exchange between the tube and inner surface of the shield, which from Eq. 13.25 is,

$$-q_{12} = \frac{A_1 \sigma (T_1^4 - T_2^4)}{\frac{1}{\epsilon_1} + \frac{1 - \epsilon_{2,i}}{\epsilon_{2,i}} \frac{D_1}{D_2}}$$

Using appropriate rate equations for  $q_{\text{conv}}$  and  $q_{\text{rad}}$ , the energy balance is

$$\frac{A_1 \sigma (T_1^4 - T_2^4)}{1 + \frac{1 - \epsilon_{2,i}}{\epsilon_{2,i}} \frac{D_1}{D_2}} - h A_2 (T_2 - T_\infty) - \epsilon_{2,o} A_2 \sigma (T_2^4 - T_{\text{sur}}^4) = 0$$

where  $\epsilon_1 = 1$ . Substituting numerical values, with  $A_1/A_2 = D_1/D_2$ , and solving for  $T_1$ ,

$$\frac{(20/60) \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (T_1^4 - 315^4) \text{ K}^4}{1 + (1 - 0.01/0.01)(20/60)} - 10 \text{ W/m}^2 \cdot \text{K} (315 - 300) \text{ K} - 0.1 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (315^4 - 290^4) \text{ K}^4 = 0$$

$$T_1 = 745 \text{ K} = 472^\circ\text{C}.$$

<

**COMMENTS:** Note that all temperatures are expressed in kelvins. This is a necessary practice when dealing with radiation and convection modes.

### PROBLEM 13.65

**KNOWN:** Cylindrical-shaped, three surface enclosure with lateral surface insulated.

**FIND:** Temperatures of the lower plate  $T_1$  and insulated side surface  $T_3$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Surfaces have uniform radiosity or emissive power, (2) Upper and insulated surfaces are diffuse-gray, (3) Negligible convection.

**ANALYSIS:** Find the temperature of the lower plate  $T_1$  from Eq. 13.30

$$q_1 = \frac{\sigma(T_1^4 - T_2^4)}{(1 - \varepsilon_1) / \varepsilon_1 A_1 + \left[ A_1 F_{12} + \left[ (1 / A_1 F_{13}) + (1 / A_2 F_{23}) \right]^{-1} \right]^{-1} + (1 - \varepsilon_2) / \varepsilon_2 A_2} \quad (1)$$

From Table 13.2 for parallel coaxial disks,

$$R_1 = r_1 / L = 0.1 / 0.2 = 0.5$$

$$R_2 = r_2 / L = 0.1 / 0.2 = 0.5$$

$$S = 1 + \left( 1 + R_2^2 \right) / R_1^2 = 1 + \left( 1 + 0.5^2 \right) / 0.5^2 = 6.0$$

$$F_{12} = 1/2 \left\{ S - \left[ S^2 - 4(r_2 / r_1)^2 \right]^{1/2} \right\} = 1/2 \left\{ 6 - \left[ 6^2 - 4(0.5/0.5)^2 \right]^{1/2} \right\} = 0.172.$$

Using the summation rule for the enclosure,  $F_{13} = 1 - F_{12} = 1 - 0.172 = 0.828$ , and from symmetry,  $F_{23} = F_{13}$ . With  $A_1 = A_2 = \pi D^2 / 4 = \pi(0.2 \text{ m})^2 / 4 = 0.03142 \text{ m}^2$  and substituting numerical values into Eq. (1), obtain

$$10,000 \text{ W} = \frac{0.03142 \text{ m}^2 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left( T_1^4 - 473^4 \right) \text{ K}^4}{0 + \left[ 0.172 + \left[ (1 / 0.828) + (1 / 0.172) \right]^{-1} \right]^{-1} + (1 - 0.8) / 0.8}$$

$$10,000 = 4.540 \times 10^9 \left( T_1^4 - 473^4 \right) \quad T_1 = 1225 \text{ K.} \quad <$$

The temperature of the insulated side surface can be determined from the radiation balance, Eq. 13.31, with  $A_1 = A_2$ ,

$$\frac{J_1 - J_3}{1 / F_{13}} - \frac{J_3 - J_2}{1 / F_{23}} = 0 \quad (2)$$

where  $J_1 = \sigma T_1^4$  and  $J_2$  can be evaluated from Eq. 13.19,

Continued ...

**PROBLEM 13.65 (Cont.)**

$$q_2 = \frac{E_{b2} - J_2}{(1 - \varepsilon_2) / \varepsilon_2 A_2} \quad -10,000 \text{ W} = \frac{5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (473 \text{ K})^4 - J_2}{(1 - 0.8) / (0.8 \times 0.03142 \text{ m}^2)}$$

find  $J_2 = 82,405 \text{ W/m}^2$ . Substituting numerical values into Eq. (2),

$$\frac{5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (1225 \text{ K})^4 - J_3}{1/0.172} - \frac{J_3 - 82,405 \text{ W/m}^2}{1/0.172} = 0$$

find  $J_3 = 105,043 \text{ W/m}^2$ . Hence, for this insulated, re-radiating (adiabatic) surface,

$$E_{b3} = \sigma T_3^4 = 105,043 \text{ W/m}^2$$

$$T_3 = 1167 \text{ K.}$$

<

### PROBLEM 13.66

**KNOWN:** Furnace in the form of a truncated conical section, floor (1) maintained at  $T_1 = 1000 \text{ K}$  by providing a heat flux  $q''_{1,\text{in}} = 2200 \text{ W/m}^2$ ; lateral wall (3) perfectly insulated; radiative properties of all surfaces specified.

**FIND:** (a) Temperature of the upper surface,  $T_2$ , and of the lateral wall  $T_3$ , and (b)  $T_2$  and  $T_3$  if all the furnace surfaces are black instead of diffuse-gray, with all other conditions remain unchanged.

Explain effect of  $\varepsilon_2$  on your results.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Furnace is a three-surface, diffuse-gray enclosure, (2) Surfaces have uniform radiosities, (3) Lateral surface is adiabatic, and (4) Negligible convection effects.

**ANALYSIS:** For the three-surface enclosure, write the radiation surface energy balances, Eq. 13.21, to find the radiosities of the three surfaces.

$$\frac{E_{b,1} - J_1}{(1 - \varepsilon_1) / \varepsilon_1 A_1} = \frac{J_1 - J_2}{1/A_1 F_{12}} + \frac{J_1 - J_3}{1/A_1 F_{13}} \quad (1)$$

$$\frac{E_{b,2} - J_2}{(1 - \varepsilon_2) / \varepsilon_2 A_2} = \frac{J_2 - J_1}{1/A_2 F_{21}} + \frac{J_2 - J_3}{1/A_2 F_{23}} \quad (2)$$

$$\frac{E_{b,3} - J_3}{(1 - \varepsilon_3) / \varepsilon_3 A_3} = \frac{J_3 - J_1}{1/A_3 F_{31}} + \frac{J_3 - J_2}{1/A_3 F_{32}} \quad (3)$$

where the blackbody emissive powers are of the form  $E_b = \sigma T^4$  with  $\sigma = 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4$ . From Eq. 13.19, the net radiation leaving  $A_1$  is

$$q_1 = \frac{E_{b,1} - J_1}{(1 - \varepsilon_1) / \varepsilon_1 A_1} \quad (4)$$

$$q_1 = q''_{1,\text{in}} \cdot A_1 = 2200 \text{ W/m}^2 \times \pi(0.040 \text{ m})^2 / 4 = 2.76 \text{ W}$$

Continued ...

### PROBLEM 13.66 (Cont.)

Since the lateral surface is adiabatic,

$$q_3 = \frac{E_{b,3} - J_3}{(1 - \varepsilon_3) / \varepsilon_3 A_3} = 0 \quad (5)$$

from which we recognize  $E_{b,3} = J_3$ , but will find that as an outcome of the analysis. For the enclosure,  $N = 3$ , there are  $N^2 = 9$  view factors, for which  $N(N - 1)/2 = 3$  must be directly determined.

Calculations for the  $F_{ij}$  are summarized in Comments.

With the foregoing five relations, we can determine the five unknowns:  $J_1$ ,  $J_2$ ,  $J_3$ ,  $E_{b,2}$ , and  $E_{b,3}$ . The temperatures  $T_2$  and  $T_3$  will be evaluated from the relation  $E_b = \sigma T^4$ . Using this analysis approach with the relations in the *IHT* workspace, the results for (a) the diffuse-gray surfaces and (b) black surfaces are tabulated below. <

	$J_1$ (kW/m <sup>2</sup> )	$J_2$ (kW/m <sup>2</sup> )	$J_3$ (kW/m <sup>2</sup> )	$T_2$ (K)	$T_3$ (K)
(a) Diffuse-gray	55.76	45.30	53.48	896	986
(b) Black	56.70	46.24	54.42	950	990

**COMMENTS:** (1) From the tabulated results, it follows that the temperatures of the lateral and top surfaces will be higher when the surfaces are black, rather than diffuse-gray as specified.

(2) From Eq. (5) for the net heat radiation leaving the lateral surface,  $A_3$ , the rate is zero since the wall is adiabatic. The consequences are that the blackbody emissive power and the radiosity are equal, and that the emissivity of the surface has no effect in the analysis. That is, this surface emits and absorbs at the same rate; the net is zero.

(3) For the enclosure,  $N = 3$ , there are  $N^2 = 9$  view factors, for which

$$N(N - 1)/2 = 3 \times 2 / 2 = 3$$

must be directly determined. We used the *IHT Tools | Radiation | View Factors Relations* model that sets up the summation rules and reciprocity relations for the  $N$  surfaces. The user is required to specify the 3  $F_{ij}$  that must be determined directly; by inspection,  $F_{11} = F_{22} = 0$ ; and  $F_{12}$  can be evaluated using the parallel coaxial disk relation, Table 13.2 (Fig. 13.5). This model is also provided in *IHT* to simplify the calculation task. The results of the view factor analysis are:

$$F_{12} = 0.03348 \qquad F_{13} = 0.9665$$

$$F_{21} = 0.1339 \qquad F_{23} = 0.8661$$

(4) An alternative method of solution for part (a) is to treat the enclosure of part (a) as described in Section 13.3.5. For part (b), the black enclosure analysis is described in Section 13.2. We chose to use the direct approach, Section 13.3.2, to develop a general 3-surface enclosure code in *IHT* that can also handle black surfaces (caution: use  $\varepsilon = 0.999$ , not 1.000).

### PROBLEM 13.67

**KNOWN:** Parallel, aligned discs located in a large room; one disk is insulated, the other is at a prescribed temperature.

**FIND:** Temperature of the insulated disc.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Surfaces are diffuse-gray, (2) Surroundings are large, with uniform temperature, behaving as a blackbody, (3) Negligible convection.

**ANALYSIS:** From an energy balance on surface  $A_2$ ,

$$q_2 = 0 = \frac{J_2 - J_1}{1/A_2 F_{21}} + \frac{J_2 - J_3}{1/A_2 F_{23}}. \quad (1)$$

Note that  $q_2 = 0$  since the surface is adiabatic. Since  $A_3$  is a blackbody,  $J_3 = E_{b3} = \sigma T_3^4$ ; since  $A_2$  is adiabatic,  $J_2 = E_{b2} = \sigma T_2^4$ . From Fig. 13.5 and the summation rule for surface  $A_1$ , find

$$F_{12} = 0.62 \text{ with } \frac{r_j}{L} = \frac{0.2}{0.1} = 2 \text{ and } \frac{L}{r_i} = \frac{0.1}{0.2} = 0.5, \quad F_{13} = 1 - F_{12} = 1 - 0.62 = 0.38.$$

Hence, Eq. (1) with  $J_3 = 5.67 \times 10^{-8} \times 300^4 \text{ W/m}^2$  becomes

$$\frac{J_2 - J_1}{1/A_2 \times 0.62} + \frac{J_2 - 459.3 \text{ W/m}^2}{1/A_2 \times 0.38} = 0 \quad -0.62J_1 + 1.00J_2 = 174.5 \quad (2,3)$$

The radiation balance on surface  $A_1$  with  $E_{b3} = 5.67 \times 10^{-8} \times 500^4 \text{ W/m}^2$  becomes

$$\frac{E_{b1} - J_1}{(1 - \epsilon_1)/\epsilon_1 A_1} = \frac{J_1 - J_2}{1/A_1 F_{12}} + \frac{J_1 - J_3}{1/A_1 F_{13}} \quad (4)$$

$$\frac{3543.8 - J_1}{(1 - 0.6)/0.6 A_1} = \frac{J_1 - J_2}{1/A_1 \times 0.62} + \frac{J_1 - 459.3}{1/A_1 \times 0.38} \quad 2.50J_1 - 0.62J_2 = 5490.2 \quad (5,6)$$

Solve Eqs. (3) and (6) to find  $J_2 = 1815 \text{ W/m}^2$  and since  $E_{b2} = J_2$ ,

$$T_2 = \left( \frac{E_{b2}}{\sigma} \right)^{1/4} = \left( \frac{1815 \text{ W/m}^2}{5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4} \right)^{1/4} = 423 \text{ K.} \quad <$$

**COMMENTS:** A network representation would help to visualize the exchange relations. However, it is useful to approach the problem by recognizing there are two unknowns in the problem:  $J_1$  and  $J_2$ ; hence two radiation balances must be written. Note also the significance of  $J_2 = E_{b2}$  and  $J_3 = E_{b3}$ .

### PROBLEM 13.68

**KNOWN:** Thermal conditions in oven used to cure strip coatings.

**FIND:** Electrical power requirement.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Diffuse-gray surfaces, (2) Furnace wall is reradiating, (3) Negligible end effects.

**ANALYSIS:** The net radiant power leaving the heater surface per unit length is

$$q'_1 = \frac{E_{b1} - E_{b2}}{\frac{1 - \epsilon_1}{\epsilon_1 A'_1} + \frac{1}{A'_1 F_{12} + \left[ \frac{1}{A_1 F_{1R}} + \frac{1}{A_2 F_{2R}} \right]^{-1}} + \frac{1 - \epsilon_2}{\epsilon_2 A'_2}}$$

where  $A'_1 = \pi D = \pi(0.02 \text{ m}) = 0.0628 \text{ m}$  and  $A'_2 = 2(s_1 - s_2) = 0.08 \text{ m}$ . The view factor between the heater and one of the strips is

$$F_{21} = \frac{D/2}{s_1 - s_2} \left[ \tan^{-1} \frac{s_1}{L} - \tan^{-1} \frac{s_2}{L} \right] = \frac{0.01}{0.04} \left[ \tan^{-1} \frac{0.06}{0.08} - \tan^{-1} \frac{0.02}{0.08} \right] = 0.10$$

and using the view factor relations find

$$A'_1 F_{12} = A'_2 F_{21} = 0.08 \text{ m} \times 0.10 = 0.008 \text{ m} \qquad F_{12} = (0.080 / 0.0628) 0.10 = 0.127$$

$$F_{1R} = 1 - F_{12} = 1 - 0.127 = 0.873 \qquad F_{2R} = 1 - F_{21} = 1 - 0.10 = 0.90.$$

Hence, with  $E_b = \sigma T^4$ ,

$$q'_1 = \frac{5.67 \times 10^{-8} \left[ (1700)^4 - (600)^4 \right]}{\frac{1 - 0.9}{0.9 \times 0.0628} + \frac{1}{0.008 + \left[ 1 / (0.0628 \times 0.873) + 1 / (0.08 \times 0.90) \right]^{-1}} + \frac{1 - 0.4}{0.4 \times 0.08}}$$

$$q'_1 = \frac{4.66 \times 10^5}{1.77 + 25.56 + 18.75} = 10,100 \text{ W/m.} \quad \leftarrow$$

**COMMENTS:** The radiosities for  $A_1$  and  $A_2$  follow from Eq. 13.19,

$$J_1 = E_{b1} - (1 - \epsilon_1) q'_1 / \epsilon_1 A'_1 = 4.56 \times 10^5 \text{ W/m}^2$$

$$J_2 = E_{b2} + (1 - \epsilon_2) q'_1 / \epsilon_2 A'_2 = 1.97 \times 10^5 \text{ W/m}^2.$$

From Eq. 13.31, find  $J_R$  and hence  $T_R$  as

$$0.0628 \times 0.873 (J_1 - J_R) - 0.08 \times 0.90 (J_R - J_2) = 0$$

$$J_R = 3.08 \times 10^5 \text{ W/m}^2 = \sigma T_R^4 \qquad T_R = 1527 \text{ K.}$$

### PROBLEM 13.69

**KNOWN:** Dimensions, temperature and emissivity of cylindrical product. Temperature and emissivity of infrared panel heater.

**FIND:** (a) Radiative flux delivered to the product and panel heat flux for a spacing of  $s = 100$  mm and a product length of  $L = 1$  m, (b) Plot of the heat flux experienced by the product, and the panel heater heat flux over the range  $50 \text{ mm} \leq s \leq 250$  mm.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Diffuse-gray surfaces, (2) Negligible convection heat transfer.

**ANALYSIS:** (a) For the unit cell indicated in the schematic,  $A_1 = A_3 = A_R = s$  and  $A_2 = \pi D$ . From Eq. 13.30,

$$q_1 = -q_2 = \frac{E_{b1} - E_{b2}}{\frac{1 - \epsilon_1}{\epsilon_1 A_1} + \frac{1}{A_1 F_{12} + [(1/A_1 F_{1R}) + (1/A_2 F_{2R})]^{-1}} + \frac{1 - \epsilon_2}{\epsilon_2 A_2}}$$

Substituting the Stefan-Boltzmann equation and expressions for the unit surface areas, and dividing by  $A_2$  and using reciprocity in the form  $A_2 F_{2R} = A_R F_{R2}$ , the preceding expression may be written as

$$q_2'' = \frac{\sigma T_2^4 - \sigma T_1^4}{\frac{(1 - \epsilon_1)\pi D}{\epsilon_1 s} + \frac{\pi D}{s F_{12} + [(1/s F_{1R}) + (1/s F_{R2})]^{-1}} + \frac{1 - \epsilon_2}{\epsilon_2}} \quad (1)$$

The view factors are evaluated using the expression given in Table 13.1,

$$F_{R2} = F_{12} = 1 - \left[ 1 - \left( \frac{50}{100} \right)^2 \right]^{1/2} + \left( \frac{50}{100} \right) \tan^{-1} \left[ \left( \frac{100^2 - 50^2}{50^2} \right)^{1/2} \right] = 0.657 \quad (2)$$

$$\text{and } F_{1R} = 1 - F_{12} = 1 - 0.657 = 0.343. \quad (3)$$

Substituting into Eq. 1 yields

Continued...

### PROBLEM 13.69 (Cont.)

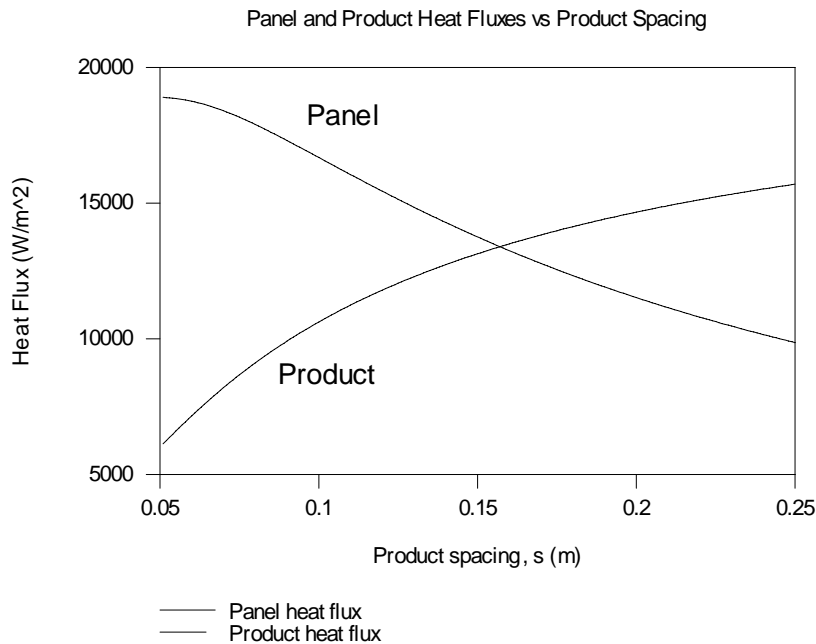

$$q_2'' = \frac{5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times (300\text{K}^4 - 800\text{K}^4)}{\frac{(1-0.85) \times \pi \times 0.05\text{m}}{0.85 \times 0.10\text{m}} + \frac{\pi \times 0.05\text{m}}{0.10\text{m} \times 0.657 + [(1/0.10\text{m} \times 0.343) + (1/0.10\text{m} \times 0.657)]^{-1}} + \frac{1-0.92}{0.92}}$$

$$= -10,616 \text{ W/m}^2 \quad <$$

The panel heat flux is found by noting that

$$q_1 = -q_2 = q_1'' s L = -q_2'' \pi D L \quad \text{or} \quad q_1'' = -q_2'' \frac{\pi D}{s} = 10,616 \frac{\text{W}}{\text{m}^2} \times \frac{\pi \times 0.05\text{m}}{0.10\text{m}} = 16,680 \frac{\text{W}}{\text{m}^2} \quad <$$

(b) Using IHT, the radiation heat flux *from* the panel and the radiation heat flux *to* the product, as a function of the product spacing,  $s$ , is shown below. This was obtained by solving Eqs. 1 – 3 simultaneously. At small product spacing, the heat flux from the panel must be large in order to deliver radiation to the larger product surface area per unit width of the oven. At large product spacing, the product heat flux becomes large as more of the product is exposed to direct irradiation from the panel.

**COMMENTS:** (1) The product may be heated by a batch or a continuous process. (2) For a batch process, the product temperature would increase with time, with a faster increase in temperature associated with large product spacing. Of course, a smaller amount of total mass would be processed per unit time as the spacing is increased. Would an optimal product spacing, to maximize the product that is produced per unit time, exist? (3) For a continuous process, for example, if the product were placed on a reradiating conveyor tray, individual product would be heated faster at larger product spacing, but the amount of product that could be processed per unit time decreases with increased product spacing (for a given conveyor speed). Hence, a tradeoff would exist during continuous processing between the increased heating and decreased productivity as the product spacing is increased. Would an optimal product spacing, to maximize product throughput, exist?

### PROBLEM 13.70

**KNOWN:** Surface temperature and emissivity of molten alloy and distance of surface from top of container. Container diameter.

**FIND:** Net rate of radiation heat transfer from surface of melt.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Opaque, diffuse, gray behavior for surface of melt, (2) Large surroundings may be represented by a hypothetical surface of temperature  $T = T_{\text{sur}}$  and  $\varepsilon = 1$ , (3) Negligible convection at exposed side wall, (4) Adiabatic side wall.

**ANALYSIS:** With negligible convection at an adiabatic side wall, the surface may be treated as reradiating. Hence, from Eq. 13.30, with  $A_1 = A_2$ ,

$$q_1 = \frac{A_1(E_{b1} - E_{b2})}{\frac{1 - \varepsilon_1}{\varepsilon_1} + \frac{1}{F_{12} + [(1/F_{1R}) + (1/F_{2R})]^{-1}} + \frac{1 - \varepsilon_2}{\varepsilon_2}}$$

With  $R_i = R_j = (D/2)/L = 1.25$  and  $S = \left[1 + \left(1 + R_j^2\right)/R_i^2\right] = 2.640$ , Table 13.2 yields

$$F_{12} = \frac{1}{2} \left\{ S - \left[ S^2 - 4(r_2/r_1)^2 \right]^{1/2} \right\} = 0.458$$

Hence,

$$F_{1R} = F_{2R} = 1 - F_{12} = 0.542 \text{ and}$$

$$q_1 = \frac{\pi(0.25\text{m})^2 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (900^4 - 300^4) \text{ K}^4}{\frac{1 - 0.55}{0.55} + \frac{1}{0.458 + (3.69)^{-1}} + 0} = 3295 \text{ W} \quad <$$

### PROBLEM 13.71

**KNOWN:** Long hemi-cylindrical shaped furnace comprised of three zones.

**FIND:** (a) Heat rate per unit length of the furnace which must be supplied by the gas burners and (b) Temperature of the insulating brick.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Surfaces are opaque, diffuse-gray or black, (2) Surfaces have uniform temperatures and radiositities, (3) Surface 3 is perfectly insulated, (4) Negligible convection, (5) Steady-state conditions.

**ANALYSIS:** (a) From an energy balance on the ceramic plate, the power required by the burner is  $q'_{\text{burners}} = q'_1$ , the net radiation leaving  $A_1$ ; hence

$$q'_1 = A_1 F_{12} (J_1 - J_2) + A_1 F_{13} (J_1 - J_3) = 0 + A_1 F_{13} (J_1 - J_3) \quad (1)$$

since  $F_{12} = 0$ . Note that  $J_2 = E_{b2} = \sigma T_2^4$  and that  $J_1$  and  $J_3$  are unknown. Hence, we need to write two radiation balances.

$$A_1: \quad \frac{E_{b1} - J_1}{(1 - \epsilon_1) / \epsilon_1 A_1} = q'_1 = 0 + A_1 F_{13} (J_1 - J_3) \quad (2)$$

$$A_3: \quad 0 = A_3 F_{31} (J_3 - J_1) + A_3 F_{32} (J_3 - E_{b2})$$

$$J_3 = \frac{J_1 + E_{b2}}{2} \quad (3)$$

since  $F_{31} = F_{23}$ . Substituting Eq. (3) into (2), find

$$(371,589 - J_1) / (1 - 0.85) / 0.85 = 1 [J_1 - (J_1 + 3,544) / 2]$$

$$J_1 = 341,748 \text{ W/m}^2 \quad J_3 = 172,646 \text{ W/m}^2$$

using  $E_{b1} = \sigma T_1^4 = 371,589 \text{ W/m}^2$  and  $E_{b2} = \sigma T_2^4 = 3544 \text{ W/m}^2$ . Substituting into Eq. (1), find

$$q'_1 = 1 \text{ m} \times 1 (341,748 - 172,646) \text{ W/m}^2 = 169 \text{ kW/m}. \quad <$$

(b) The temperature of the insulating brick, acting as a reradiating surface, is

$$J_3 = E_{b3} = \sigma T_3^4$$

$$T_3 = (J_3 / \sigma)^{1/4} = (172,646 \text{ W/m}^2 / 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4)^{1/4} = 1320 \text{ K}. \quad <$$

## PROBLEM 13.72

**KNOWN:** Steam producing still heated by radiation.

**FIND:** (a) Factor by which the vapor production could be increased if the cylindrical side of the heater were insulated rather than open to the surroundings, and (b) Compute and plot the net heat rate of radiation transfer to the still, as a function of the separation distance  $L$  for the range  $15 \leq L \leq 100$  mm for heater temperatures of 600, 800, 1000°C considering the cylindrical sides to be insulated.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Still and heater surfaces are black, (2) Surroundings are isothermal and large compared to still heater surfaces, (3) Insulation is diffuse-gray, (4) Negligible convection.

**ANALYSIS:** (a) The vapor production will be proportional to the net radiation exchange to the still. For the case when the sides are open (o) to the surroundings, the net radiation exchange leaving  $A_2$  is from Eq. 13.14.

$$q_{2,o} = q_{21} + q_{2s} = A_2 F_{21} \sigma (T_2^4 - T_1^4) + A_2 F_{2s} \sigma (T_2^4 - T_{sur}^4)$$

where  $F_{2s} = 1 - F_{21}$  and  $F_{21}$  follows from Fig. 13.5 with  $L/r_1 = 100/100 = 1$ ,  $r_2/L = 100/100 = 1$ .

$$F_{21} = 0.38$$

With  $A_2 = \pi D^2 / 4$ , find

$$q_{2,o} = \frac{\pi (0.200 \text{ m})^2}{4} \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left\{ 0.38 (373^4 - 1273^4) + (1 - 0.38) (373^4 - 300^4) \right\}$$

$$q_{2,o} = -1752 \text{ W.} \quad \text{without insulation} \quad \leftarrow$$

With the cylindrical side insulated (i), a three-surface, re-radiating enclosure is formed. Eq. 13.30 can be used to evaluate  $q_{2,i}$  and with  $\varepsilon_2 = \varepsilon_1 = 1$ , the relation is

$$q_{2,i} = \frac{\sigma (T_2^4 - T_1^4)^4}{\frac{1}{A_1 F_{12} + [(1/A_1 F_{1R}) + (1/A_2 F_{2R})]^{-1}}} = A_1 \left\{ F_{12} + [1/F_{1R} + 1/F_{2R}]^{-1} \right\} \sigma (T_2^4 - T_1^4)$$

Recall  $F_{12} = 0.38$  and  $F_{1R} = 1 - F_{12} = 1 - 0.38 = 0.62$ , giving

$$q_{2,i} = \frac{\pi (0.200 \text{ m})^2}{4} \left\{ 0.38 + [1/0.62 + 1/0.62]^{-1} \right\} 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K} (373^4 - 1273^4) \text{ K}^4$$

$$q_{2,i} = -3204 \text{ W.} \quad \text{with insulation} \quad \leftarrow$$

Continued ...

### PROBLEM 13.72 (Cont.)

Hence, the vapor production rate is increased by a factor

$$\frac{q_2)_{\text{insul}}}{q_2)_{\text{open}}} = \frac{3204 \text{ W}}{1752 \text{ W}} = 1.83$$

That is, the vapor production is increased by 83%. <

(b) The *IHT Radiation Tool – Radiation Exchange Analysis* for the *Three-Surface Enclosure* with a *reradiating surface* can be used directly to compute the net heat rate to the still,  $q_1 = q_2$ , as a function of the separation distance  $L$  for selected heater temperatures  $T_1$ . The results are plotted below.

Note that the heat rate for all values of  $T_1$  decreases as expected with increasing separation distances, but not markedly. For any separation distance, increasing the heater temperature greatly influences the heat rate. For example, at  $L = 50$  mm, increasing  $T_1$  from 600 to 800 K, causes a nearly 6 fold increase in the heat rate. But increasing  $T_1$  from 800 to 1000 K causes only a 2 fold increase in the heat rate.

**COMMENTS:** When assigning the emissivity variables ( $\epsilon_1, \epsilon_2, \epsilon_3$ ) in the *IHT* model mentioned above, set  $\epsilon = 0.999$ , rather than 1.0, to avoid a “division by zero” error message. You could also call up the *Radiation Tool, View Factor Coaxial Parallel Disk* to calculate  $F_{12}$ .

### PROBLEM 13.73

**KNOWN:** Furnace with cylindrical heater and re-radiating, insulated walls.

**FIND:** (a) Power required to maintain steady-state conditions, (b) Temperature of wall area.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Surfaces are diffuse-gray, (2) Furnace is of length  $\ell$  where  $\ell \gg w$ , (3) Convection is negligible, (4)  $A_1 \ll A_2$ .

**ANALYSIS:** (a) Consider the furnace as a three surface enclosure with the walls,  $A_R$ , represented as a re-radiating surface. The power that must be supplied to the heater is determined by Eq. 13.30.

$$q_1 = \frac{\sigma(T_1^4 - T_2^4)}{(1 - \epsilon_1) / \epsilon_1 A_1 + \left[ A_1 F_{12} + \left[ (1 / A_1 F_{1R}) + (1 / A_2 F_{2R}) \right]^{-1} \right]^{-1} + (1 - \epsilon_2) / \epsilon_2 A_2}$$

Note that  $A_1 = \pi d \ell$  and  $A_2 = w \ell$ . By inspection and the summation rule, find  $F_{12} = 60^\circ / 360^\circ = 0.167$ ,  $F_{1R} = 1 - F_{12} = 1 - 0.167 = 0.833$ , and  $F_{2R} \approx 1$ . With  $q'_1 = q_1 / \ell$ ,

$$q'_1 = \frac{5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (1500^4 - 500^4) \text{ K}^4}{0 + \left[ \pi (10 \times 10^{-3}) \text{ m} \times 0.167 + \left[ (1 / \pi (10 \times 10^{-3}) \text{ m}) \times 0.833 + (1 / 1 \text{ m} \times 1) \right]^{-1} \right]^{-1} + (1 - 0.6) / 0.6 \times 1 \text{ m}}$$

$$q'_1 = 8518 \text{ W/m.} \quad <$$

(b) To determine the wall temperature, apply the radiation balance, Eq. 13.31,

$$\frac{J_1 - J_R}{(1 / A_1 F_{1R})} = \frac{J_R - J_2}{(1 / A_2 F_{2R})} \quad \text{or} \quad \frac{J_1 - J_R}{(1 / \pi 10 \times 10^{-3} \text{ m} \times 0.833)} = \frac{J_R - J_2}{(1 / 1 \text{ m} \times 1)}$$

$$J_R = \sigma T_R^4 = (J_1 + 38.21 J_2) / 39.21. \quad (1)$$

Since  $A_1$  is a blackbody,  $J_1 = E_{b1} = \sigma T_1^4$ . To determine  $J_2$ , use Eq. 13.19. Noting that  $q'_1 = -q'_2$ , find

$$q_2 = (E_{b2} - J_2) / (1 - \epsilon_2) / \epsilon_2 A_2 \quad \text{or} \quad J_2 = E_{b2} - q_2 (1 - \epsilon_2) / \epsilon_2 A_2$$

$$J_2 = 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (500 \text{ K})^4 - \frac{(-8518 \text{ W/m})(1 - 0.6)}{0.6(1 \text{ m})} = 9222 \text{ W/m}^2.$$

Substituting this value for  $J_2$  into Eq. (1), the wall temperature can be calculated.

$$J_R = \left( 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (1500 \text{ K})^4 + 38.21 \times 9222 \text{ W/m}^2 \right) / 39.21 = 16,308 \text{ W/m}^2$$

$$T_R = (J_R / \sigma)^{1/4} = \left( 16,308 \text{ W/m}^2 / 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \right)^{1/4} = 732 \text{ K.} \quad <$$

**COMMENTS:** Considering the entire wall as a single re-radiating surface may be a poor assumption since  $J_R$  is not likely to be uniform over this large an area. It would be appropriate to consider several isothermal zones for improved accuracy.

### PROBLEM 13.74

**KNOWN:** Dimensions, temperature and emissivity of radiant heating tubes, temperature and emissivity of heated material, location of reradiating surface.

**FIND:** Net radiative heat flux to the heated material.

**ASSUMPTIONS:** Diffuse, gray behavior.

**ANALYSIS:** Treating the tubes as a single surface, the heat transfer rate from Surface 1 to Surface 2 is given by

$$q_1 = -q_2 = \frac{E_{b1} - E_{b2}}{\frac{1 - \epsilon_1}{\epsilon_1 A_1} + \frac{1}{A_1 F_{12} + \left[ \left( \frac{1}{A_1 F_{1R}} \right) + \left( \frac{1}{A_2 F_{2R}} \right) \right]^{-1}} + \frac{1 - \epsilon_2}{\epsilon_2 A_2}}$$

Utilizing the reciprocity relationship, incorporating the Stefan-Boltzmann law, and dividing by area  $A_2$ ,

$$q_1'' = -q_2'' = \frac{\sigma(T_1^4 - T_2^4)}{\frac{(1 - \epsilon_1)A_2}{\epsilon_1 A_1} + \frac{A_2}{A_2 F_{21} + \left[ \left( \frac{1}{A_R F_{R1}} \right) + \left( \frac{1}{A_2 F_{2R}} \right) \right]^{-1}} + \frac{1 - \epsilon_2}{\epsilon_2 A_2}} \quad (1)$$

From Table 13.1 for the infinite plane and row of cylinders,

$$F_{12} = 1 - \left[ 1 - \left( \frac{D}{s} \right)^2 \right]^{1/2} + \left( \frac{D}{s} \right) \tan^{-1} \left[ \left( \frac{s^2 - D^2}{D^2} \right)^{1/2} \right]$$

$$F_{21} = 1 - \left[ 1 - \left( \frac{0.02}{0.05} \right)^2 \right]^{1/2} + \left( \frac{0.02}{0.05} \right) \tan^{-1} \left[ \left( \frac{0.05^2 - 0.02^2}{0.02^2} \right)^{1/2} \right] = 0.5472 = F_{R1}$$

Therefore,  $F_{2R} = 1 - 0.5472 = 0.4528$ .

Continued...

### PROBLEM 13.74 (Cont.)

For a unit cell as shown in the schematic,  $A_2 = s$ ,  $A_1 = \pi D$ , and  $A_R = s$ . Therefore Eq. (1) is written as,

$$q_1'' = -q_2'' = \frac{\sigma(T_1^4 - T_2^4)}{\frac{(1 - \epsilon_1)s}{\epsilon_1 \pi D} + \frac{s}{sF_{21} + [(1/sF_{R1}) + (1/sF_{2R})]^{-1}} + \frac{(1 - \epsilon_2)}{\epsilon_2}}$$

or

$$q_1'' = -q_2'' = \frac{5.67 \times 10^{-8} \frac{\text{W}}{\text{m}^2 \cdot \text{K}^4} [(1000\text{K})^4 - (500\text{K})^4]}{\frac{(1 - 0.87) \times 0.05}{0.87 \times \pi \times 0.02} + \frac{0.05}{0.05 \times 0.5472 + [(1/0.05 \times 0.5472) + (1/0.05 \times 0.4528)]^{-1}} + \frac{(1 - 0.26)}{0.26}}$$

$$q_1'' = -q_2'' = 12,590 \text{ W/m}^2$$

<

**COMMENT:** The heat flux is independent of the separation distance between the heater and the material. Does this make sense to you?

### PROBLEM 13.75

**KNOWN:** Very long, triangular duct with walls that are diffuse-gray.

**FIND:** (a) Net radiation transfer from surface  $A_1$  per unit length of duct, (b) The temperature of the insulated surface, (c) Influence of  $\epsilon_3$  on the results; comment on exactness of results.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Surfaces are diffuse-gray, (2) Duct is very long; end effects negligible.

**ANALYSIS:** (a) The duct approximates a three-surface enclosure for which the third surface ( $A_3$ ) is re-radiating. Using Eq. 13.30 with  $A_3 = A_R$ , the net exchange is

$$q_1 = -q_2 = \frac{E_{b1} - E_{b2}}{\frac{(1-\epsilon_1)}{\epsilon_1 A_1} + \frac{1}{A_1 F_{12} + (1/A_1 F_{1R} + 1/A_2 F_{2R})^{-1}} + \frac{(1-\epsilon_2)}{\epsilon_2 A_2}} \quad (1)$$

From symmetry,  $F_{12} = F_{1R} = F_{2R} = 0.5$ . With  $A_1 = A_2 = w \cdot \ell$ , where  $\ell$  is the length normal to the page and  $w = 1$  m,

$$q'_1 = q_1 / \ell = (q_1 / A_1) w$$

$$q'_1 = \frac{(56,700 - 13,614) \text{ W/m}^2 \times 1 \text{ m}}{\frac{(1-0.33)}{0.33} + \frac{1}{0.5 + (1/0.5 + 1/0.5)^{-1}} + \frac{(1-0.5)}{0.5}} = 9874 \text{ W/m.} \quad <$$

(b) From a radiation balance on  $A_R$ ,

$$q_R = q_3 = 0 = \frac{E_{b3} - J_1}{(A_3 F_{31})^{-1}} + \frac{E_{b3} - J_2}{(A_3 F_{32})^{-1}} \quad \text{or} \quad E_{b3} = \frac{J_1 + J_2}{2} \quad (2)$$

To evaluate  $J_1$  and  $J_2$ , use Eq. 13.19,

$$J_i = E_{b,i} - \frac{q_i (1-\epsilon_i)}{A_i \epsilon_i} \begin{cases} J_1 = 56,700 - (9874) \frac{1-0.33}{0.33} = 36,653 \text{ W/m}^2 \\ J_2 = 13,614 - (-9874) \frac{1-0.5}{0.5} = 23,488 \text{ W/m}^2 \end{cases}$$

From Eq. (2), now find

$$T_3 = (E_{b3} / \sigma)^{1/4} = ([J_1 + J_2] / 2\sigma)^{1/4} = \left( \frac{(36,653 + 23,488) \text{ W/m}^2}{2(5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4)} \right)^{1/4} = 853 \text{ K.} \quad <$$

(c) Since  $A_3$  is adiabatic or re-radiating,  $J_3 = E_{b3}$ . Therefore, the value of  $\epsilon_3$  is of no influence on the radiation exchange or on  $T_3$ . In using Eq. (1), we require uniform radiosity over the surfaces. This requirement is not met near the corners. For best results we should subdivide the areas such that they represent regions of uniform radiosity. Of course, the analysis then becomes much more complicated.

### PROBLEM 13.76

**KNOWN:** Dimensions for aligned rectangular heater and coated plate. Temperatures of heater, plate and large surroundings.

**FIND:** (a) Electric power required to operate heater, (b) Heater power required if reradiating sidewalls are added, (c) Effect of coating emissivity and electric power.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, (2) Blackbody behavior for surfaces and surroundings (Parts (a) and (b)).

**ANALYSIS:** (a) For  $\epsilon_1 = \epsilon_2 = 1$ , the net radiation leaving  $A_1$  is

$$q_{\text{elec}} = q_1 = A_1 F_{12} \sigma (T_1^4 - T_2^4) + A_1 F_{1\text{sur}} \sigma (T_1^4 - T_{\text{sur}}^4).$$

From Fig. 13.4, with  $Y/L = 1/0.5 = 2$  and  $X/L = 2/0.5 = 4$ , the view factors are  $F_{12} \approx 0.5$  and  $F_{\text{sur}} \approx 1 - 0.5 = 0.5$ . Hence,

$$q_{\text{elec}} = (2\text{m}^2) 0.5 \times 5.67 \times 10^{-8} \text{W/m}^2 \cdot \text{K}^4 \left[ (700 \text{K})^4 - (400 \text{K})^4 \right] \\ + (2\text{m}^2) 0.5 \times 5.67 \times 10^{-8} \text{W/m}^2 \cdot \text{K}^4 \left[ (700 \text{K})^4 - (300 \text{K})^4 \right] = (12,162 + 13,154) \text{W} = 25,316 \text{W}. <$$

(b) With the reradiating walls, the net radiation leaving  $A_1$  is  $q_{\text{elec}} = q_1 = q_{12}$ . From Eq. 13.30 with  $\epsilon_1 = \epsilon_2 = 1$  and  $A_1 = A_2$ ,

$$q_{\text{elec}} = A_1 \sigma (T_1^4 - T_2^4) \left\{ F_{12} + [(1/F_{1R}) + (1/F_{2R})]^{-1} \right\} \\ q_{\text{elec}} = (2\text{m}^2) 5.67 \times 10^{-8} \text{W/m}^2 \cdot \text{K}^4 \left[ (700 \text{K})^4 - (400 \text{K})^4 \right] \times \left\{ 0.5 + [(1/0.5) + (1/0.5)]^{-1} \right\}$$

$$q_{\text{elec}} = 18,243 \text{W}. <$$

(c) Separately using the *IHT Radiation Tool Pad* for a three-surface enclosure, with one surface reradiating, and to perform a radiation exchange analysis for a three-surface enclosure, with one surface corresponding to large surroundings, the following results were obtained.

Continued ...

### PROBLEM 13.76 (Cont.)

In both cases, the required heater power decreases with decreasing  $\epsilon_2$ , and the trend is attributed to a reduction in  $\alpha_2 = \epsilon_2$  and hence to a reduction in the rate at which radiant energy must be absorbed by the surface to maintain the prescribed temperature.

**COMMENTS:** With the reradiating walls in part (b), it follows from Eq. 13.31 that

$$J_R = E_{bR} = (J_1 + J_2) / 2 = (E_{b1} + E_{b2}) / 2.$$

Hence,  $T_R = 604$  K. The reduction in  $q_{elec}$  resulting from use of the walls is due to the enhancement of radiation to the heater, which, in turn, is due to the presence of the high temperature walls.

### PROBLEM 13.77

**KNOWN:** Configuration and operating conditions of a furnace. Initial temperature and emissivity of steel plate to be treated.

**FIND:** (a) Heater temperature, (b) Sidewall temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Opaque, diffuse-gray surface behavior, (3) Negligible convection, (4) Sidewalls are re-radiating.

**ANALYSIS:** (a) From Eq. 13.30

$$q_1 = \frac{E_{b1} - E_{b2}}{\frac{1 - \epsilon_1}{\epsilon_1 A_1} + \frac{1}{A_1 F_{12} + \left[ (A_1 F_{1R})^{-1} + (A_2 F_{2R})^{-1} \right]^{-1}} + \frac{1 - \epsilon_2}{\epsilon_2 A_2}} = 1.5 \times 10^5 \text{ W}$$

Note that  $A_1 = A_2 = 4 \text{ m}^2$  and  $E_{b2} = \sigma T_2^4 = 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (300 \text{ K})^4 = 459 \text{ W/m}^2$ . From Fig. 13.4, with  $X/L = Y/L = 1$ ,  $F_{12} = 0.2$ ; hence  $F_{1R} = 1 - F_{12} = 0.8$ , and  $F_{2R} = F_{1R} = 0.8$ . With  $(1 - \epsilon_1)/\epsilon_1 = 0.25$  and  $(1 - \epsilon_2)/\epsilon_2 = 1.5$ , find

$$\frac{1.5 \times 10^5 \text{ W}}{4 \text{ m}^2} = \frac{E_{b1} - 459 \text{ W/m}^2}{0.25 + \frac{1}{0.2 + [1.25 + 1.25]^{-1}} + 1.5} = \frac{E_{b1} - 459 \text{ W/m}^2}{3.417}$$

$$E_{b1} = 1.28 \times 10^5 \text{ W/m}^2 + 459 \text{ W/m}^2 = 1.29 \times 10^5 \text{ W/m}^2 = \sigma T_1^4$$

$$T_1 = \left( 1.29 \times 10^5 \text{ W/m}^2 / 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \right)^{1/4} = 1228 \text{ K}.$$

(b) From Eq. 13.31, it follows that, with  $A_1 F_{1R} = A_2 F_{2R}$ ,

$$J_R = \sigma T_R^4 = (J_1 + J_2) / 2$$

$$\text{From Eq. 13.19, } J_1 = E_{b1} - \frac{(1 - \epsilon_1)}{\epsilon_1 A_1} q_1 = 1.29 \times 10^5 \text{ W/m}^2 - \frac{0.2 \times 1.5 \times 10^5 \text{ W}}{0.8 \times 4 \text{ m}^2}$$

$$J_1 = 1.196 \times 10^5 \text{ W/m}^2.$$

With  $q_2 = q_1 = -1.5 \times 10^5 \text{ W}$ ,

$$J_2 = E_{b2} - \frac{(1 - \epsilon_2)}{\epsilon_2 A_2} q_2 = 459 \text{ W/m}^2 + \frac{0.6}{0.4 \times 4 \text{ m}^2} 1.5 \times 10^5 \text{ W} = 5.67 \times 10^4 \text{ W/m}^2$$

$$T_R = \left( \frac{1.196 \times 10^5 \text{ W/m}^2 + 5.67 \times 10^4 \text{ W/m}^2}{2 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4} \right)^{1/4} = 1117 \text{ K}.$$

**COMMENTS:** (1) The above results are approximate, since the process is actually transient. (2)  $T_1$  and  $T_R$  will increase with time as  $T_2$  increases.

### PROBLEM 13.78

**KNOWN:** Dimensions, surface radiative properties, and operating conditions of an electrical furnace.

**FIND:** (a) Equivalent radiation circuit, (b) Furnace power requirement and temperature of a heated plate.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Opaque, diffuse-gray surfaces, (3) Negligible plate temperature gradients, (4) Back surfaces of heater are adiabatic, (5) Convection effects are negligible.

**ANALYSIS:** (a) Since there is symmetry about the plate, only one-half (top or bottom) of the system need be considered. Moreover, the plate must be adiabatic, thereby playing the role of a re-radiating surface.

(b) Note that  $A_1 = A_3 = 4 \text{ m}^2$  and  $A_2 = (0.5 \text{ m} \times 2 \text{ m})4 = 4 \text{ m}^2$ . From Fig. 13.4, with  $X/L = Y/L = 4$ ,  $F_{13} = 0.62$ . Hence

$$F_{12} = 1 - F_{13} = 0.38, \quad \text{and} \quad F_{32} = F_{12} = 0.38.$$

It follows that

$$A_1 F_{12} = 4(0.38) = 1.52 \text{ m}^2$$

$$A_1 F_{13} = 4(0.62) = 2.48 \text{ m}^2, \quad (1 - \epsilon_1) / \epsilon_1 A_1 = 0.1 / 3.6 \text{ m}^2 = 0.0278 \text{ m}^{-2}$$

$$A_3 F_{32} = 4(0.38) = 1.52 \text{ m}^2, \quad (1 - \epsilon_2) / \epsilon_2 A_2 = 0.7 / 1.2 \text{ m}^2 = 0.583 \text{ m}^{-2}.$$

Also,

$$E_{b1} = \sigma T_1^4 = 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (800 \text{ K})^4 = 23,224 \text{ W/m}^2,$$

$$E_{b2} = \sigma T_2^4 = 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (400 \text{ K})^4 = 1452 \text{ W/m}^2.$$

The system forms a three-surface enclosure, with one surface re-radiating. Hence the net radiation transfer from a single heater is, from Eq. 13.30,

$$q_1 = \frac{E_{b1} - E_{b2}}{\frac{1 - \epsilon_1}{\epsilon_1 A_1} + \frac{1}{A_1 F_{12} + [1/A_1 F_{13} + 1/A_3 F_{32}]^{-1}} + \frac{1 - \epsilon_2}{\epsilon_2 A_2}}$$

Continued ...

**PROBLEM 13.78 (Cont.)**

$$q_1 = \frac{(23,224 - 1452) \text{ W/m}^2}{(0.0278 + 0.4061 + 0.583) \text{ m}^{-2}} = 21.4 \text{ kW.}$$

The furnace power requirement is therefore  $q_{\text{elec}} = 2q_1 = 43.8 \text{ kW}$ , with

<

$$q_1 = \frac{E_{b1} - J_1}{(1 - \varepsilon_1) / \varepsilon_1 A_1}.$$

where

$$J_1 = E_{b1} - q_1 \frac{1 - \varepsilon_1}{\varepsilon_1 A_1} = 23,224 \text{ W/m}^2 - 21,400 \text{ W} \times 0.0278 \text{ m}^{-2}$$

$$J_1 = 22,679 \text{ W/m}^2.$$

Also,

$$J_2 = E_{b2} - q_2 \frac{1 - \varepsilon_2}{\varepsilon_2 A_2} = 1,452 \text{ W/m}^2 - (-21,400 \text{ W}) \times 0.583 \text{ m}^{-2}$$

$$J_2 = 13,928 \text{ W/m}^2.$$

From Eq. 13.31,

$$\frac{J_1 - J_3}{1/A_1 F_{13}} = \frac{J_3 - J_2}{1/A_3 F_{32}}$$

$$\frac{J_1 - J_3}{J_3 - J_2} = \frac{A_3 F_{32}}{A_1 F_{13}} = \frac{1.52}{2.48} = 0.613$$

$$1.613 J_3 = J_1 + 0.613 J_2 = 22,629 + 8537 = 31,166 \text{ W/m}^2$$

$$J_3 = 19,321 \text{ W/m}^2$$

Since  $J_3 = E_{b3}$ ,

$$T_3 = (E_{b3} / \sigma)^{1/4} = (19,321 / 5.67 \times 10^{-8})^{1/4} = 764 \text{ K.}$$

<

**COMMENTS:** (1) To reduce  $q_{\text{elec}}$ , the sidewall temperature  $T_2$ , should be increased by insulating it from the surroundings. (2) The problem must be solved by simultaneously determining  $J_1$ ,  $J_2$  and  $J_3$  from the radiation balances of the form

$$\frac{E_{b1} - J_1}{(1 - \varepsilon_1) / \varepsilon_1 A_1} = A_1 F_{12} (J_1 - J_2) + A_1 F_{13} (J_1 - J_3)$$

$$\frac{E_{b2} - J_2}{(1 - \varepsilon_2) / \varepsilon_2 A_2} = A_2 F_{21} (J_2 - J_1) + A_2 F_{23} (J_2 - J_3)$$

$$0 = A_1 F_{13} (J_3 - J_1) + A_2 F_{23} (J_3 - J_2).$$

### PROBLEM 13.79

**KNOWN:** Geometry and surface temperatures and emissivities of a solar collector.

**FIND:** Net rate of radiation transfer to cover plate due to exchange with the absorber plates.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Isothermal surfaces with uniform radiosity, (2) Absorber plates behave as blackbodies, (3) Cover plate is diffuse-gray and opaque to thermal radiation exchange with absorber plates, (4) Duct end effects are negligible.

**ANALYSIS:** Applying Eq. 13.21 to the cover plate, it follows that

$$E_{b1} - J_1 = \frac{1 - \varepsilon_1}{\varepsilon_1 A_1} \sum_{j=1}^N \frac{J_1 - J_j}{(A_1 F_{1j})^{-1}} = \frac{1 - \varepsilon_1}{\varepsilon_1 A_1} [A_1 F_{12} (J_1 - J_2) + A_1 F_{13} (J_1 - J_3)].$$

From symmetry,  $F_{12} = F_{13} = 0.5$ . Also,  $J_2 = E_{b2}$  and  $J_3 = E_{b3}$ . Hence

$$E_{b1} - J_1 = 0.0556(2J_1 - E_{b2} - E_{b3})$$

or with  $E_b = \sigma T^4$ ,

$$1.111J_1 = E_{b1} + 0.0556(E_{b2} + E_{b3})$$

$$1.111J_1 = 5.67 \times 10^{-8} (298)^4 \text{ W/m}^2 + 0.0556 \left( 5.67 \times 10^{-8} \right) \left[ (333)^4 + (343)^4 \right] \text{ W/m}^2$$

$$J_1 = 476.64 \text{ W/m}^2$$

From Eq. 13.19 the net rate of radiation transfer *from* the cover plate is then

$$q_1 = \frac{E_{b1} - J_1}{(1 - \varepsilon_1) / \varepsilon_1 A_1} = \frac{5.67 \times 10^{-8} (298)^4 - 476.64}{(1 - 0.9) / 0.9(\ell)} = (-265.5\ell) \text{ W.}$$

The net rate of radiation transfer *to* the cover plate per unit length is then

$$q'_1 = (q_1 / \ell) = 266 \text{ W/m.} \quad <$$

**COMMENTS:** Solar radiation effects are not relevant to the foregoing problem. All such radiation transmitted by the cover plate is completely absorbed by the absorber plate.

### PROBLEM 13.80

**KNOWN:** Dimensions of cylinder and piston, mass of air contained in the cylinder, emissivity of surfaces, bottom surface temperature and surroundings temperature, density of piston material.

**FIND:** Distance between bottom of piston and bottom of cylinder and temperature of the piston for  $T_1 = 300, 450$  and  $600$  K.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Diffuse-gray surfaces with uniform radiosity and irradiation, (2) Negligible convection heat transfer, (3) Ideal gas behavior, (4) Frictionless, isothermal piston, (5) Air temperature is average of bottom surface temperature and piston temperature, (6) Low thermal conductivity material is re-radiating.

**ANALYSIS:** The position and temperature of the piston are governed by energy and force balances that are applied to a control volume surrounding the piston.

Treating the air as an ideal gas,

$$P_a V_a = M_a (\mathcal{R} / \mathcal{M}) \bar{T}_a \quad (1)$$

where  $\bar{T}_a = (T_p + T_1) / 2$ . The force balance yields

$$p_a = M_p g + p_{atm} = \rho_p (\pi D_p^2 / 4) \delta g + p_{atm} \quad (2)$$

At steady state,

$$q_t = q_b \quad (3)$$

Continued...

### PROBLEM 13.80 (Cont.)

where the heat rates are determined by evaluating the radiation heat transfer in two enclosures; one enclosure formed by three surfaces below the piston (bottom of cylinder, bottom of piston and reradiating side wall) and the second enclosure formed by three surfaces above the piston (top of piston, hypothetical surface at the top of the cylinder and reradiating side wall).

Using Eq. 13.30 for the bottom enclosure,

$$q_b = \frac{E_{b1} - E_{bp}}{\frac{1 - \varepsilon_1}{\varepsilon_1 A_1} + \frac{1}{A_1 F_{1-p} + \left[ \left( 1/A_1 F_{1-Rb} \right) + \left( 1/A_p F_{p-Rb} \right) \right]^{-1}} + \frac{1 - \varepsilon_p}{\varepsilon_p A_p}} \quad (4)$$

while for the top enclosure,

$$q_t = \frac{E_{bp} - E_{bsur}}{\frac{1 - \varepsilon_p}{\varepsilon_p A_p} + \frac{1}{A_p F_{p-sur} + \left[ \left( 1/A_p F_{p-Rt} \right) + \left( 1/A_{sur} F_{sur-p} \right) \right]^{-1}} + \frac{1 - \varepsilon_{sur}}{\varepsilon_{sur} A_{sur}}} \quad (5)$$

The three emissive powers are

$$E_{b1} = \sigma T_1^4; \quad E_{bp} = \sigma T_p^4; \quad E_{bsur} = \sigma T_{sur}^4 \quad (6a,b,c)$$

The surface areas are

$$A_1 = A_p = A_{sur} = \pi D_p^2 / 4 \quad (7a,b,c)$$

while the gas volume is

$$V = (\pi D_p^2 / 4) L_b \quad (8)$$

The universal gas constant is  $\mathcal{R} = 8315 \text{ J/kmol}\cdot\text{K}$  and the molecular weight of the air is  $\mathcal{M} = 28.97 \text{ kg/kmol}$ .

View factors for use in Eqs. 4 and 5 are evaluated using the expressions for coaxial parallel disks in Table 13.2. For the bottom enclosure,

$$\begin{aligned} R_{ib} = R_{jb} = D/(2L_b), \quad S_b = 1 + (1 + R_{jb}^2)/R_{ib}^2, \quad F_{1-p} = 0.5(S_b - [S_b^2 - 4]^{1/2}), \\ F_{1-Rb} = 1 - F_{1-p}, \quad F_{p-Rb} = F_{1-Rb}. \end{aligned} \quad (9a,b,c,d,e,f)$$

For the top enclosure,

$$\begin{aligned} R_{it} = R_{jt} = D/(2L_t), \quad S_t = 1 + (1 + R_{jt}^2)/R_{it}^2, \quad F_{p-sur} = 0.5(S_t - [S_t^2 - 4]^{1/2}), \\ F_{p-Rt} = 1 - F_{p-sur}, \quad F_{sur-p} = F_{p-sur} \end{aligned} \quad (10a,b,c,d,e,f)$$

The lengths are related by

Continued...

### PROBLEM 13.80 (Cont.)

$$L_b + L_t + \delta = L \quad (11)$$

Simultaneous solution of Eqs. 1 through 11 yields the following results, presented in tabular form.

Input Variable		Results		View Factors					
$T_1$ (K)	$L_b$ (mm)	$T_p$ (K)	$q_b$ (W)	$F_{l-Rb}$	$F_{l-p}$	$F_{p-Rb}$	$F_{p-Rt}$	$F_{p-sur}$	$F_{sur-p}$
300	0.033	300	0	-	-	-	-	-	-
450	0.045	389.2	0.32	0.804	0.196	0.804	0.799	0.201	0.201
600	0.059	488	1.26	0.865	0.135	0.865	0.691	0.309	0.309

**COMMENTS:** As the temperature of the bottom surface increases, the gas temperature increases leading to expansion of the air and increased  $L_b$ . To solve Eqs. 1 through 11 requires a potentially tedious trial-and-error solution. The tedium is reduced significantly by using IHT. One approach is to guess values of  $L_b$  (or  $L_t$ ) and solve the equations until  $q_b = q_t$ . In doing so, one discovers that multiple solutions exist, but the second solution is unrealistic since piston temperatures are outside the range  $T_1 > T_p > T_{sur}$ .

### PROBLEM 13.81

**KNOWN:** Cylindrical peep-hole of diameter  $D$  through a furnace wall of thickness  $L$ . Temperatures prescribed for the furnace interior and surroundings outside the furnace.

**FIND:** Heat loss by radiation through the peep-hole.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Furnace interior and exterior surroundings are large, isothermal surroundings for the peep-hole openings, (3) Furnace refractory wall is adiabatic and diffuse-gray with uniform radiosity.

**ANALYSIS:** The open-ends of the cylindrical peep-hole ( $A_1$  and  $A_2$ ) and the cylindrical lateral surface of the refractory material ( $A_R$ ) form a diffuse-gray, three-surface enclosure. The hypothetical areas  $A_1$  and  $A_2$  behave as black surfaces at the respective temperatures of the large surroundings to which they are exposed. Since  $A_R$  is adiabatic, it behaves as a re-radiating surface, and its emissivity has no effect on the analysis. From Eq. 13.30, the net radiation leaving  $A_1$  passes through the enclosure into the outer surroundings.

$$q_1 = -q_2 = \frac{E_{b1} - E_{b2}}{\frac{1 - \varepsilon_1}{\varepsilon_1 A_1} + \frac{1}{A_1 F_{12} + [(1/A_1 F_{1R}) + (1/A_2 F_{2R})]^{-1}} + \frac{1 - \varepsilon_2}{\varepsilon_2 A_2}}$$

Since  $\varepsilon_1 = \varepsilon_2 = 1$ , and with  $E_b = \sigma T^4$  where  $\sigma = 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4$ ,

$$q_1 = \left\{ A_1 F_{12} + [(1/A_1 F_{1R}) + (1/A_2 F_{2R})]^{-1} \right\} \sigma (T_1^4 - T_2^4)$$

where  $A_1 = A_2 = \pi D^2/4$ . The view factor  $F_{12}$  can be determined from Table 13.2 (Fig. 13.5) for the coaxial parallel disks ( $R_1 = R_2 = 125/(2 \times 250) = 0.25$  and  $S = 17.063$ ) as

$$F_{12} = 0.05573$$

From the summation rule on  $A_1$ , with  $F_{11} = 0$ ,

$$F_{11} + F_{12} + F_{1R} = 1$$

$$F_{1R} = 1 - F_{12} = 1 - 0.05573 = 0.9443$$

and from symmetry of the enclosure,

$$F_{2R} = F_{1R} = 0.9443$$

Substituting numerical values into the rate equation, find the heat loss by radiation through the peep-hole to the exterior surroundings as

$$q_{\text{loss}} = q_1 = 1046 \text{ W}$$

<

**COMMENTS:** If you held your hand 50 mm from the exterior opening of the peep-hole, how would that feel? It is standard, safe practice to use optical protection when viewing the interiors of high temperature furnaces as used in petrochemical, metals processing and power generation operations.

### PROBLEM 13.82

**KNOWN:** Composite wall comprised of two large plates separated by sheets of refractory insulation of thermal conductivity  $k = 0.05 \text{ W/m}\cdot\text{K}$ ; gaps between the sheets of width  $w = 10 \text{ mm}$ , located at  $1\text{-m}$  spacing, allow radiation transfer between the plates.

**FIND:** (a) Heat loss by radiation through the gap per unit length of the composite wall (normal to the page), and (b) fraction of the total heat loss through the wall that is due to radiation transfer through the gap.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Surfaces are diffuse-gray with uniform radiosities, (3) Refractory insulation surface in the gap is adiabatic, and (4) Heat flow through the wall is one-dimensional between the plates in the direction of the gap centerline, (5) Negligible contact resistance, (6) Negligible free convection in gap.

**PROPERTIES:** Air ( $T = 490 \text{ K}$ ):  $k = 0.040 \text{ W/m}\cdot\text{K}$ .

**ANALYSIS:** (a) The gap of thickness  $w$  and infinite extent normal to the page can be represented by a diffuse-gray, three-surface enclosure formed by the plates  $A_1$  and  $A_2$  and the refractory walls,  $A_R$ . Since  $A_R$  is adiabatic, it behaves as a re-radiating surface, and its emissivity has no effect on the analysis. From Eq. 13.30, the net radiation leaving the plate  $A_1$  passes through the gap into plate  $A_2$ .

$$q_1 = -q_2 = \frac{E_{b1} - E_{b2}}{\frac{1 - \varepsilon_1}{\varepsilon_1 A_1} + \frac{1}{A_1 F_{12} + \left[ \left( \frac{1}{A_1 F_{1R}} \right) + \left( \frac{1}{A_2 F_{2R}} \right) \right]^{-1}} + \frac{1 - \varepsilon_2}{\varepsilon_2 A_2}}$$

where  $E_b = \sigma T^4$  with  $\sigma = 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4$  and  $A_1 = A_2 = w \cdot \ell$ , but making  $\ell = 1 \text{ m}$  to obtain  $q'_1$  ( $\text{W/m}$ ).

The view factor  $F_{12}$  can be determined from Table 13.2 (Fig. 13.4) for aligned parallel rectangles where  $\bar{X} = X/L = \infty$  since  $X \rightarrow \infty$  and  $\bar{Y} = Y/L = W/L = 10/50 = 0.2$  giving

$$F_{12} = 0.09902$$

From the summation rule on  $A_1$ , with  $F_{11} = 0$ ,

$$F_{11} + F_{12} + F_{1R} = 1 \qquad F_{1R} = 1 - F_{12} = 1 - 0.09902 = 0.901$$

and from symmetry of the enclosure,

Continued ...

### PROBLEM 13.82 (Cont.)

$$F_{2R} = F_{1R} = 0.901.$$

Substituting numerical values into the rate equation, find the heat loss through the gap due to radiation as

$$q'_{\text{rad}} = q'_1 = 37 \text{ W/m} \quad <$$

(b) The conduction heat rate per unit length (normal to the page) for a 1 - m section is

$$q'_{\text{cond}} = q'_{\text{cond, ins}} + q'_{\text{cond, air}} = 0.05 \text{ W/m} \cdot \text{K} \times (1 \text{ m} - 0.1 \text{ m}) \frac{(400 - 35) \text{ K}}{0.050 \text{ mm}} \\ + 0.04 \text{ W/m} \cdot \text{K} \times 0.01 \text{ m} \frac{(400 - 35) \text{ K}}{0.050 \text{ mm}}$$

$$q'_{\text{cond}} = 361.4 \text{ W/m} + 2.92 \text{ W/m} = 364 \text{ W/m}$$

The fraction of the total heat transfer through the 1 - m section due to radiation is

$$\frac{q'_{\text{rad}}}{q'_{\text{tot}}} = \frac{q'_{\text{rad}}}{q'_{\text{cond}} + q'_{\text{rad}}} = \frac{37}{364 + 37} = 9.2\% \quad <$$

We conclude that if the installation process for the sheet insulation can be accomplished with a smaller gap, there is an opportunity to reduce the cost of operating the furnace.

### PROBLEM 13.83

**KNOWN:** Diameter, temperature and emissivity of a heated disk. Diameter and emissivity of a hemispherical radiation shield. View factor of shield with respect to a coaxial disk of prescribed diameter, emissivity and temperature.

**FIND:** (a) Equivalent circuit, (b) Net heat rate from the hot disk.

**SCHEMA:**

**ASSUMPTIONS:** (1) Surfaces may be approximated as diffuse/gray, (2) Surface 4 is reradiating, (3) Negligible convection.

**ANALYSIS:** (a) The equivalent circuit is shown in the schematic. Since surface 4 is treated as reradiating, the net transfer of radiation from surface 1 is equal to the net transfer of radiation to surface 3 ( $q_1 = -q_3$ ).

(b) From the thermal circuit, the desired heat rate may be expressed as

$$q_1 = \frac{E_{b1} - E_{b3}}{\frac{1-\epsilon_1}{\epsilon_1 A_1} + \frac{1}{A_1 F_{12}} + \frac{2(1-\epsilon_2)}{\epsilon_2 A_2} + \left[ A_2 F_{23} + \frac{1}{\frac{1}{A_2 F_{24}} + \frac{1}{A_3 F_{34}}} \right]^{-1} + \frac{1-\epsilon_3}{\epsilon_3 A_3}}$$

where  $A_1 = A_3 = \pi D_1^2 / 4 = \pi(0.05 \text{ m})^2 / 4 = 1.963 \times 10^{-3} \text{ m}^2$ ,  $A_2 = \pi D_1^2 / 2 = 2A_1 = 3.925 \times 10^{-3} \text{ m}^2$ ,  $F_{12} = 1$ , and  $F_{24} = 1 - F_{23} = 0.7$ . With  $F_{34} = 1 - F_{32} = 1 - F_{23}(A_2/A_3) = 1 - 0.3(2) = 0.4$ , it follows that

Continued ...

**PROBLEM 13.83 (Cont.)**

$$q_1 = \frac{A_1 \sigma (T_1^4 - T_3^4)}{\frac{1-\varepsilon_1}{\varepsilon_1} + \frac{1}{F_{12}} + \frac{2(1-\varepsilon_2)}{\varepsilon_2} \frac{A_1}{A_2} + \left[ \frac{A_2}{A_1} F_{23} + \frac{1}{\frac{A_1}{A_2 F_{24}} + \frac{A_1}{A_3 F_{34}}} \right]^{-1} + \frac{1-\varepsilon_3}{\varepsilon_3}}$$

$$q_1 = \frac{A_1 \sigma (T_1^4 - T_3^4)}{0.667 + 1 + 49 + \left[ 0.6 + \frac{1}{\frac{1}{1.4} + \frac{1}{0.4}} \right]^{-1} + 1.5} = \frac{A_1 \sigma (T_1^4 - T_3^4)}{0.667 + 1 + 49 + 1.098 + 1.5}$$

$$q_1 = 0.0188 \left( 1.963 \times 10^{-3} \text{ m}^2 \right) 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left( 900^4 - 400^4 \right) \text{ K}^4$$

$$q_1 = 1.32 \text{ W}$$

<

**COMMENTS:** Radiation transfer from 1 to 3 is impeded and enhanced, respectively, by the radiation shield and the reradiating walls. However, the dominant contribution to the total radiative resistance is made by the shield.

### PROBLEM 13.84

**KNOWN:** Cylindrical cavity with prescribed geometry, wall emissivity, and temperature. Temperature of surroundings.

**FIND:** (a) Net radiation heat transfer from the cavity treating the bottom and sidewall as one surface. (b) Net radiation heat transfer from the cavity treating the bottom and sidewall as two separate surfaces.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Cavity interior surfaces are diffuse-gray, (2) Surroundings are much larger than the cavity opening  $A_3$ .

**ANALYSIS:** (a) We begin by finding the relevant areas and view factors.

$$A_1 = A_3 = \pi D^2 / 4 = 7.85 \times 10^{-3} \text{ m}^2$$

$$A_2 = \pi DL = 1.57 \times 10^{-2} \text{ m}^2$$

$$A_c = A_1 + A_2 = 2.36 \times 10^{-2} \text{ m}^2$$

From Table 13.2, Coaxial Parallel Disks, with  $r_1/L = 0.050/0.050 = 1$  and  $r_3/L = 1$ , find

$$F_{13} = F_{31} = 0.382$$

Then,  $F_{32} = F_{12} = 1 - F_{13} = 0.618$

$$F_{21} = F_{23} = A_1 F_{12} / A_2 = 0.309$$

The shape factor from the combined surfaces 1 and 2 to the surroundings is

$$F_{c-s} = F_{12-3} = A_3 F_{3-12} / A_{12} = 7.85 \times 10^{-3} \text{ m}^2 \times 1 / 2.36 \times 10^{-2} \text{ m}^2 = 0.333$$

The combined surface  $A_c$  exchanges radiation with the large surroundings. The net radiation heat transfer from the cavity is given by Eq. 13.23 with  $A_2$  in that equation representing the surroundings, such that  $A_2 \rightarrow \infty$ , and the equation reduces to

$$q_A = \frac{\sigma (T_c^4 - T_{sur}^4) A_c}{\frac{1 - \epsilon_c}{\epsilon_c} + \frac{1}{F_{c-s}}} = \frac{5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (1500^4 - 300^4) \text{ K}^4 \times 2.36 \times 10^{-2} \text{ m}^2}{\frac{1 - 0.6}{0.6} + \frac{1}{0.333}}$$

$$q_A = 1842 \text{ W} \quad \leftarrow$$

(b) Considering surfaces 1 and 2 separately, the heat transfer from the cavity to the surroundings can be found as the heat transfer reaching hypothetical surface 3 (the cavity opening), that is,  $q_B = -q_3$ , which from Eq. 13.20 is,

$$q_3 = A_3 F_{31} (J_3 - J_1) + A_3 F_{32} (J_3 - J_2). \quad (1)$$

Continued...

### PROBLEM 13.84 (Cont.)

As noted in Example 13.4, openings of enclosures that exchange radiation with large surroundings may be treated as hypothetical, nonreflecting black surfaces ( $\epsilon_3 = 1$ ) whose temperature is equal to that of the surroundings,  $T_3 = T_{\text{sur}}$ . With  $\epsilon_3 = 1$ ,  $J_3 = E_{b3}$ . However,  $J_1$  and  $J_2$  are unknown and must be obtained from the radiation balances, Eq. 13.21,

$$\frac{E_{b1} - J_1}{(1 - \epsilon_1)/\epsilon_1 A_1} = \sum_{j=1}^N \frac{J_1 - J_j}{(A_1 F_{1j})^{-1}} \quad (2)$$

Note also,  $E_{b1} = E_{b2} = \sigma T_1^4 = \sigma (1500\text{K})^4 = 287,044 \text{ W/m}^2$  and  $J_3 = E_{b3} = \sigma T_3^4 = 459.3 \text{ W/m}^2$ .

$$\begin{aligned} A_1: \quad \frac{E_{b1} - J_1}{(1 - \epsilon_1)/\epsilon_1 A_1} &= \frac{J_1 - J_2}{(A_1 F_{12})^{-1}} + \frac{J_1 - J_3}{(A_1 F_{13})^{-1}} \\ \frac{287,044 - J_1}{(1 - 0.6)/0.6} &= \frac{J_1 - J_2}{(0.618)^{-1}} + \frac{J_1 - 459.3}{(0.382)^{-1}} \quad 2.5J_1 - 0.618J_2 = 430,741 \end{aligned} \quad (3)$$

$$\begin{aligned} A_2: \quad \frac{E_{b2} - J_2}{(1 - \epsilon_2)/\epsilon_2 A_2} &= \frac{J_2 - J_1}{(A_2 F_{21})^{-1}} + \frac{J_2 - J_3}{(A_2 F_{23})^{-1}} \\ \frac{287,044 - J_2}{(1 - 0.6)/0.6} &= \frac{J_2 - J_1}{(0.309)^{-1}} + \frac{J_2 - 459.3}{(0.309)^{-1}} \quad -0.309J_1 + 2.118J_2 = 430,708 \end{aligned} \quad (4)$$

Solving Eqs. (3) and (4) simultaneously, find  $J_1 = 230,491 \text{ W/m}^2$  and  $J_2 = 234,654 \text{ W/m}^2$ , and from Eq. (1), find

$$q_B = 7.854 \times 10^{-3} \text{ m}^2 [0.382(459.3 - 230,491) + 0.618(459.3 - 234,654)] \text{ W/m}^2$$

$$q_B = 1840 \text{ W} \quad \leftarrow$$

(c) The equations for shape factors were entered into the *IHT* workspace, along with Eqs. (1), (3), and (4). The resulting plot is shown below.

Continued...

### PROBLEM 13.84 (Cont.)

**COMMENTS:** The difference between the two different methods for calculating heat transfer rates is less than 1% over the entire range of  $L$ . When we treat the sides and bottom as one surface, we are assuming that the radiosity is the same for these two surfaces. This is exactly true when the shape factor between each of those surfaces and the environment is the same, as it is for  $L$  around 0.075 m (see below). But from the graphs we see that even when the shape factors and radiosities are not very close for the two surfaces, the net heat transfer rate can still be accurately approximated by treating both surfaces as one.

### PROBLEM 13.85

**KNOWN:** Circular furnace with prescribed temperatures and emissivities of the lateral and end surfaces.

**FIND:** Net radiative heat transfer from each surface.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Surfaces are isothermal and diffuse-gray.

**ANALYSIS:** To calculate the net radiation heat transfer from each surface, we need to determine its radiosity. First, evaluate terms that will be required.

$$\begin{aligned}
 E_{b1} &= \sigma T_1^4 = 1452 \text{ W/m}^2 & A_1 &= A_2 = \pi D^2 / 4 = 0.07069 \text{ m}^2 & F_{12} &= F_{21} = 0.17 \\
 E_{b2} &= \sigma T_2^4 = 3544 \text{ W/m}^2 & A_3 &= \pi DL = 0.2827 \text{ m}^2 & F_{23} &= F_{13} = 0.83 \\
 E_{b3} &= \sigma T_3^4 = 23,224 \text{ W/m}^2
 \end{aligned}$$

The view factor  $F_{12}$  results from Fig. 13.5 with  $L/r_1 = 2$  and  $r_1/L = 0.5$ . The radiation balances using Eq. 13.21, omitting units for convenience, are:

$$\begin{aligned}
 A_1: \quad \frac{1452 - J_1}{(1 - 0.4)} &= 0.07069 \times 0.17 (J_1 - J_2) + 0.07069 \times 0.83 (J_1 - J_3) \\
 &= 0.4 \times 0.07069 \\
 &\quad -2.500J_1 + 0.2550J_2 + 1.2450J_3 = -1452 \quad (1)
 \end{aligned}$$

$$\begin{aligned}
 A_2: \quad \frac{3544 - J_2}{(1 - 0.5)} &= 0.07069 \times 0.17 (J_2 - J_1) + 0.07069 \times 0.83 (J_2 - J_3) \\
 &= 0.5 \times 0.07069 \\
 &\quad -0.1700J_1 - 2.0000J_2 + 0.8300J_3 = -3544 \quad (2)
 \end{aligned}$$

$$\begin{aligned}
 A_3: \quad \frac{23,224 - J_3}{(1 - 0.8)} &= 0.07069 \times 0.83 (J_3 - J_1) + 0.07069 \times 0.83 (J_3 - J_2) \\
 &= 0.8 \times 0.2827 \\
 &\quad 0.05189J_1 + 0.05189J_2 - 1.1037J_3 = -23,224 \quad (3)
 \end{aligned}$$

Solving Eqs. (1) – (3) simultaneously, find

$$J_1 = 12,877 \text{ W/m}^2 \quad J_2 = 12,086 \text{ W/m}^2 \quad J_3 = 22,216 \text{ W/m}^2.$$

Using Eq. 13.20, the net radiation heat transfer for each surface follows:

$$q_i = \sum_{j=1}^N A_i F_{ij} (J_i - J_j)$$

$$A_1: \quad q_1 = 0.07069 \times 0.17 (12,877 - 12,086) \text{ W} + 0.07069 \times 0.83 (12,877 - 22,216) \text{ W} = -538 \text{ W} <$$

$$A_2: \quad q_2 = 0.07069 \times 0.17 (12,086 - 12,877) \text{ W} + 0.07069 \times 0.83 (12,086 - 22,216) \text{ W} = -603 \text{ W} <$$

$$A_3: \quad q_3 = 0.07069 \times 0.83 (22,216 - 12,877) \text{ W} + 0.07069 \times 0.83 (22,216 - 12,086) \text{ W} = 1141 \text{ W} <$$

**COMMENTS:** Note that  $\sum q_i = 0$ . Also, note that  $J_2 < J_1$  despite the fact that  $T_2 > T_1$ ; note the role emissivity plays in explaining this.

### PROBLEM 13.86

**KNOWN:** Temperatures of two large parallel plates and desired radiation heat flux between them.

**FIND:** (a) If plate emissivities are uniform and equal, show that required emissivity is 0.5. (b) If plates are painted with checkerboard patterns having two different emissivities with an average value of 0.5, will heat flux be the desired value?

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Surfaces are diffuse, (2) Plates are effectively infinite (no radiation exchange with surroundings), (3) Plate temperatures are uniform.

**ANALYSIS:** (a) The heat flux between two infinite parallel plates is given by Eq. 13.24. With  $\epsilon_1 = \epsilon_2 = 0.5$ , we find

$$q''_{12} = \frac{\sigma(T_1^4 - T_2^4)}{2/\epsilon - 1} = \frac{5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (400^4 - 300^4) \text{K}^4}{2/0.5 - 1} = 331 \text{ W/m}^2 \quad (1)$$

Thus, to a very close approximation, the required emissivity of the plates is 0.5. <

(b) With the checkerboard pattern, we can identify four different surfaces: the high emissivity region on the top surface (1h), the low emissivity region on the top surface (1 $\ell$ ), the high emissivity region on the bottom surface (2h), and the low emissivity region on the bottom surface (2 $\ell$ ). The view factors can be found by inspection. The view factor between a region on the top plate and a region on the bottom plate is 0.5, that is,

$$\begin{aligned} F_{1h-2h} &= 0.5, & F_{1h-2\ell} &= 0.5, & F_{1\ell-2h} &= 0.5, & F_{1\ell-2\ell} &= 0.5 \\ F_{2h-1h} &= 0.5, & F_{2h-1\ell} &= 0.5, & F_{2\ell-2h} &= 0.5, & F_{2\ell-2\ell} &= 0.5 \end{aligned}$$

and all other view factors (from a region on one plate to a region on the same plate) are zero. We proceed to write Eq. 13.21 at all four surfaces, recognizing that all regions have the same area,

Continued...

**PROBLEM 13.86 (Cont.)**

$$\frac{E_{b1} - J_{1h}}{(1 - \varepsilon_h)/\varepsilon_h} = \frac{J_{1h} - J_{2h}}{1/0.5} + \frac{J_{1h} - J_{2\ell}}{1/0.5}$$

$$\frac{E_{b1} - J_{1\ell}}{(1 - \varepsilon_\ell)/\varepsilon_\ell} = \frac{J_{1\ell} - J_{2h}}{1/0.5} + \frac{J_{1\ell} - J_{2\ell}}{1/0.5}$$

$$\frac{E_{b2} - J_{2h}}{(1 - \varepsilon_h)/\varepsilon_h} = \frac{J_{2h} - J_{1h}}{1/0.5} + \frac{J_{2h} - J_{1\ell}}{1/0.5}$$

$$\frac{E_{b2} - J_{2\ell}}{(1 - \varepsilon_\ell)/\varepsilon_\ell} = \frac{J_{2\ell} - J_{1h}}{1/0.5} + \frac{J_{2\ell} - J_{1\ell}}{1/0.5}$$

Proceeding with the algebra required to solve these four simultaneous equations results in

$$J_{1h} = \varepsilon_h E_{b1} + \frac{1 - \varepsilon_h}{2 - \bar{\varepsilon}} [E_{b2} + (1 - \bar{\varepsilon})E_{b1}]$$

$$J_{1\ell} = \varepsilon_\ell E_{b1} + \frac{1 - \varepsilon_\ell}{2 - \bar{\varepsilon}} [E_{b2} + (1 - \bar{\varepsilon})E_{b1}]$$

$$J_{2h} = \varepsilon_h E_{b2} + \frac{1 - \varepsilon_h}{2 - \bar{\varepsilon}} [E_{b1} + (1 - \bar{\varepsilon})E_{b2}]$$

$$J_{2\ell} = \varepsilon_\ell E_{b2} + \frac{1 - \varepsilon_\ell}{2 - \bar{\varepsilon}} [E_{b1} + (1 - \bar{\varepsilon})E_{b2}]$$

where  $\bar{\varepsilon} = (\varepsilon_1 + \varepsilon_2)/2$ . Then the net radiation heat flux between the two plates can be expressed as,  $q''_{\text{net}} = (q''_{1h}A_h + q''_{1\ell}A_\ell)/A_{\text{tot}} = 0.5(q''_{1h} + q''_{1\ell})$ , and making use of Eq. 13.20 for the heat fluxes, we find,

$$\begin{aligned} q''_{\text{net}} &= 0.5 \{ [0.5(J_{1h} - J_{2h}) + 0.5(J_{1h} - J_{2\ell})] + [0.5(J_{1\ell} - J_{2h}) + 0.5(J_{1\ell} - J_{2\ell})] \} \\ &= 0.5 [(J_{1h} + J_{1\ell}) - (J_{2h} + J_{2\ell})] \end{aligned}$$

After much manipulation, this reduces to

$$q''_{\text{net}} = \frac{E_{b1} - E_{b2}}{2/\bar{\varepsilon} - 1} \quad (2)$$

Comparing Eqs. (1) and (2), we see that the checkerboard pattern with an average emissivity  $\bar{\varepsilon}$  will result in the same heat flux as uniform emissivity plates with emissivity  $\varepsilon = \bar{\varepsilon}$ .

With average emissivity of 0.5, the checkerboard pattern will yield the desired heat flux. <

**COMMENTS:** An alternative to this tedious algebraic proof would be to use *IHT* to solve the four surface enclosure problem and show numerically that average emissivities of 0.5 yield the desired heat flux.

## PROBLEM 13.87

**KNOWN:** Temperature of large enclosure. Areas and emissivity of two convex objects in enclosure, and view factor between them. Power supplied to object 2. Temperature of object 1.

**FIND:** Heating or cooling rate for object 1. Temperature of object 2.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Objects are gray and diffuse, (3) Large enclosure behaves as blackbody, (4) Each surface experiences uniform irradiation and radiosity.

**ANALYSIS:** We are given  $F_{12} = 0.2$ . Since object 1 is convex, it does not see itself, and  $F_{13} = 1 - F_{12} = 0.8$ . The areas of the two objects are the same, therefore from reciprocity  $F_{21} = F_{12} = 0.2$ . Finally, since object 2 is convex,  $F_{23} = 1 - F_{21} = 0.8$ .

The enclosure is assumed to be large enough to behave as a blackbody, therefore:

$$J_3 = E_{b3} = \sigma T_3^4 = 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times 300^4 \text{ K}^4 = 459.3 \text{ W/m}^2$$

Equation 13.21 can be written at surface 1 where the temperature is known:

$$\frac{E_{b1} - J_1}{(1 - \epsilon_1) / \epsilon_1 A_1} = \frac{J_1 - J_2}{1 / A_1 F_{12}} + \frac{J_1 - J_3}{1 / A_1 F_{13}} \quad (1)$$

The power is known at surface 2,  $q_2 = 400 \text{ W}$ , so we write Equation 13.22:

$$q_2 = \frac{J_2 - J_1}{1 / A_2 F_{21}} + \frac{J_2 - J_3}{1 / A_2 F_{23}} \quad (2)$$

Substituting values into Eqs. (1) and (2) gives

$$\begin{aligned} 0.05 \text{ m}^2 (E_{b1} - J_1) &= 0.04 \text{ m}^2 (J_1 - J_2) + 0.16 \text{ m}^2 (J_1 - J_3) \\ 400 \text{ W} &= 0.04 \text{ m}^2 (J_2 - J_1) + 0.16 \text{ m}^2 (J_2 - J_3) \end{aligned}$$

where  $E_{b1} = \sigma T_1^4 = 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times 200^4 \text{ K}^4 = 90.72 \text{ W/m}^2$  and  $J_3$  is given above. Solving these two simultaneous equations yields

Continued...

### PROBLEM 13.87 (Cont.)

$$J_1 = 713.7 \text{ W/m}^2, J_2 = 2510 \text{ W/m}^2$$

The net rate of radiation leaving object 1 is given by Equation 13.19:

$$q_1 = \frac{E_{b1} - J_1}{(1 - \varepsilon_1) / \varepsilon_1 A_1} = 0.05 \text{ m}^2 (90.72 \text{ W/m}^2 - 713.7 \text{ W/m}^2) = -31.1 \text{ W} \quad <$$

There is a net rate of radiation heat transfer *to* object 1 of 31.1 W, which must be *removed* from object 1 by the coolant. <

The temperature of object 2 can be found by solving Equation 13.19 for  $E_{b2}$ :

$$E_{b2} = J_2 + q_2 \frac{1 - \varepsilon_2}{\varepsilon_2 A_2} = 2510 \text{ W/m}^2 + 400 \text{ W} \frac{1 - 0.2}{0.2 \times 0.2 \text{ m}^2} = 10,510 \text{ W/m}^2$$

Then with  $E_{b2} = \sigma T_2^4$  we find  $T_2 = 656 \text{ K}$ . <

**COMMENTS:** (1) If the objects were concave, additional information would have to be known about their shapes in order to determine the appropriate view factors. (2) The objects would clearly experience non-uniform irradiation and radiosity. A more detailed analysis would need to be performed in order to determine whether the non-uniform radiation fluxes would affect the answers. As for concave objects, a more detailed analysis of the convex objects would necessitate information regarding the shape of the objects. (3) The coolant must have a freezing point less than 200 K.

### PROBLEM 13.88

**KNOWN:** Four surface enclosure with all sides of equal area; temperatures of three surfaces are specified while the fourth is re-radiating.

**FIND:** Temperature of the re-radiating surface  $A_4$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Surfaces are diffuse-gray, (2) Surfaces have uniform radiosities.

**ANALYSIS:** To determine the temperature of the re-radiating surface  $A_4$ , it is necessary to recognize that  $J_4 = E_{b4} = \sigma T_4^4$  and that the  $J_i$  ( $i = 1$  to 4) values must be evaluated by simultaneously solving four radiation balances of the form, Eq. 13.21,

$$\frac{E_{bi} - J_i}{(1 - \epsilon_i) / \epsilon_i A_i} = \sum_{j=1}^N \frac{J_i - J_j}{(A_i F_{ij})^{-1}}$$

For simplicity, set  $A_1 = A_2 = A_3 = A_4 = 1 \text{ m}^2$  and from symmetry, it follows that all view factors will be  $F_{ij} = 1/3$ . The necessary emissive powers are of the form  $E_{bi} = \sigma T_i^4$ .

$$E_{b1} = \sigma(700 \text{ K})^4 = 13,614 \text{ W/m}^2, \quad E_{b2} = \sigma(500 \text{ K})^4 = 3544 \text{ W/m}^2, \quad E_{b3} = \sigma(300 \text{ K})^4 = 459 \text{ W/m}^2.$$

The radiation balances are:

$$A_1: \frac{13,614 - J_1}{(1 - 0.7) / 0.7} = \frac{1}{3}(J_1 - J_2) + \frac{1}{3}(J_1 - J_3) + \frac{1}{3}(J_1 - J_4); -1.42857J_1 + 0.14826J_2 + 0.14826J_3 + 0.14826J_4 = -13,614$$

$$A_2: \frac{3544 - J_2}{(1 - 0.5) / 0.5} = \frac{1}{3}(J_2 - J_1) + \frac{1}{3}(J_2 - J_3) + \frac{1}{3}(J_2 - J_4) \quad 0.33333J_1 - 2.00000J_2 + 0.33333J_3 + 0.33333J_4 = -3544$$

$$A_3: \frac{459 - J_3}{(1 - 0.3) / 0.3} = \frac{1}{3}(J_3 - J_1) + \frac{1}{3}(J_3 - J_2) + \frac{1}{3}(J_3 - J_4) \quad 0.77778J_1 + 0.77778J_2 - 3.33333J_3 + 0.77778J_4 = -459$$

$$A_4: \quad 0 = \frac{1}{3}(J_4 - J_1) + \frac{1}{3}(J_4 - J_2) + \frac{1}{3}(J_4 - J_3) \quad 0.33333J_1 + 0.33333J_2 + 0.33333J_3 - 1.00000J_4 = 0$$

Solving this system of equations simultaneously, find

$$J_1 = 11,572 \text{ W/m}^2, \quad J_2 = 6031 \text{ W/m}^2, \quad J_3 = 6088 \text{ W/m}^2, \quad J_4 = 7897 \text{ W/m}^2.$$

Since the radiosity and emissive power of the re-radiating surface are equal,

$$T_4^4 = J_4 / \sigma$$

$$T_4 = \left( 7897 \text{ W/m}^2 / 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \right)^{1/4} = 611 \text{ K.} \quad <$$

**COMMENTS:** Note the values of the radiosities; are their relative values what you would have expected? Is the value of  $T_4$  reasonable?

### PROBLEM 13.89

**KNOWN:** A room with electrical heaters embedded in ceiling and floor; one wall is exposed to the outdoor environment while the other three walls are to be considered as insulated.

**FIND:** Net radiation heat transfer from each surface.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Diffuse-gray surfaces, (2) Surfaces are isothermal and irradiated uniformly, (3) Negligible convection effects, (4)  $A_5 = A_{5A} + A_{5B}$ .

**ANALYSIS:** To determine the net radiation heat transfer from each surface, find the surface radiosities using Eq. 13.20.

$$q_i = \sum_{j=1}^5 A_i F_{ij} (J_i - J_j) \quad (1)$$

To determine the value of  $J_i$ , energy balances must be written for each of the five surfaces. For surfaces 1, 2, and 3, the form is given by Eq. 13.21.

$$\frac{E_{bi} - J_i}{(1 - \epsilon_i) / \epsilon_i A_i} = \sum_{j=1}^5 \frac{J_i - J_j}{(A_i F_{ij})^{-1}} \quad i = 1, 2, \text{ and } 3. \quad (2)$$

For the insulated or adiabatic surfaces, Eq. 13.22 is appropriate with  $q_i = 0$ ; that is

$$q_i = \sum_{j=1}^N \frac{J_i - J_j}{(A_i F_{ij})^{-1}} = 0 \quad i = 4 \text{ and } 5. \quad (3)$$

In order to write the energy balances by Eq. (2) and (3), we will need to know view factors. Using Fig. 13.4 (parallel rectangles) or Fig. 13.5 (perpendicular rectangles) find:

$$\begin{aligned} F_{12} = F_{21} = 0.39 & & X/L = 10/4 = 2.5, & & Y/L = 6/4 = 1.5 \\ F_{13} = F_{14} = 0.19 & & Z/X = 4/10 = 0.4, & & Y/X = 6/10 = 0.6 \\ F_{34} = F_{43} = 0.19 & & X/L = 10/6 = 1.66, & & Y/L = 4/6 = 0.67 \\ F_{24} = F_{13} = 0.19 & & Z/X = 4/10 = 0.4, & & Y/X = 6/10 = 0.6 \end{aligned}$$

Note the use of symmetry in the above relations. Using reciprocity, find,

$$\begin{aligned} F_{32} = \frac{A_2}{A_3} F_{23} = \frac{A_2}{A_3} F_{13} = \frac{60}{40} \times 0.19 = 0.285; & & F_{31} = \frac{A_1}{A_3} F_{13} = \frac{60}{40} \times 0.19 = 0.285 \\ F_{51} = \frac{A_1}{A_5} F_{15} = \frac{60}{48} \times 0.23 = 0.288; & & F_{53} = \frac{A_3}{A_5} F_{35} = \frac{40}{48} \times 0.25 = 0.208. \end{aligned}$$

From the summation view factor relation,

$$\begin{aligned} F_{15} = 1 - F_{12} - F_{13} - F_{14} = 1 - 0.39 - 0.19 - 0.19 = 0.23 \\ F_{35} = 1 - F_{31} - F_{32} - F_{34} = 1 - 0.285 - 0.285 - 0.19 = 0.24 \end{aligned}$$

Continued ...

### PROBLEM 13.89 (Cont.)

Using Eq. (2), now write the energy balances for surfaces 1, 2, and 3. (Note  $E_b = \sigma T^4$ ).

$$\frac{544.2 - J_1}{1 - 0.8/0.8 \times 60} = \frac{J_1 - J_2}{1/60 \times 0.39} + \frac{J_1 - J_3}{1/60 \times 0.19} + \frac{J_1 - J_4}{1/60 \times 0.19} + \frac{J_1 - J_5}{1/60 \times 0.23}$$

$$-1.2500J_1 + 0.0975J_2 + 0.0475J_3 + 0.570J_5 = -544.2 \quad (4)$$

$$\frac{617.2 - J_2}{1 - 0.9/0.9 \times 60} = \frac{J_2 - J_1}{1/60 \times 0.39} + \frac{J_2 - J_3}{1/60 \times 0.19} + \frac{J_2 - J_4}{1/60 \times 0.19} + \frac{J_2 - J_5}{1/60 \times 0.23}$$

$$+0.0433J_1 - 1.111J_2 + 0.02111J_3 + 0.02111J_4 + 0.02556J_5 = -617.2 \quad (5)$$

$$\frac{390.1 - J_3}{1 - 0.7/0.7 \times 40} = \frac{J_3 - J_1}{1/40 \times 0.285} + \frac{J_3 - J_2}{1/40 \times 0.285} + \frac{J_3 - J_4}{1/40 \times 0.19} + \frac{J_3 - J_5}{1/40 \times 0.24}$$

$$+0.1221J_1 + 0.1221J_2 - 1.4284J_3 + 0.08143J_4 + 0.1028J_5 = -390.1 \quad (6)$$

Using Eq. (3), now write the energy balances for surfaces 4 and 5 noting  $q_4 = q_5 = 0$ .

$$0 = \frac{J_4 - J_1}{1/40 \times 0.285} + \frac{J_4 - J_2}{1/40 \times 0.285} + \frac{J_4 - J_3}{1/40 \times 0.19} + \frac{J_4 - J_5}{1/40 \times 0.24}$$

$$0.285J_1 + 0.285J_2 + 0.19J_3 - 1.0J_4 + 0.24J_5 = 0 \quad (7)$$

$$0 = \frac{J_5 - J_1}{1/48 \times 0.288} + \frac{J_5 - J_2}{1/48 \times 0.288} + \frac{J_5 - J_3}{1/48 \times 0.208} + \frac{J_5 - J_4}{1/48 \times 0.208}$$

$$0.288J_1 + 0.288J_2 + 0.208J_3 + 0.208J_4 - 0.992J_5 = 0 \quad (8)$$

Note that Eqs. (4) – (8) represent a set of simultaneous equations which can be written in matrix notation. That is,  $[A][J] = [C]$  with

$$A = \begin{bmatrix} -1.250 & 0.0975 & 0.0475 & 0.0475 & 0.0575 \\ 0.0433 & -1.111 & 0.02111 & 0.02111 & 0.02556 \\ 0.1221 & 0.1221 & -1.4284 & 0.08143 & 0.1028 \\ 0.285 & 0.285 & 0.190 & -1.000 & 0.240 \\ 0.288 & 0.288 & 0.208 & 0.208 & -0.992 \end{bmatrix} \quad C = \begin{bmatrix} -544.2 \\ -617.2 \\ -390.1 \\ 0 \\ 0 \end{bmatrix} \quad J = \begin{bmatrix} 545.1 \\ 607.9 \\ 441.5 \\ 542.3 \\ 541.0 \end{bmatrix} \quad \text{W/m}^2$$

where the  $J_i$  were found using IHT. The net radiation heat transfer from each of the surfaces can now be evaluated using Eq. (1).

$$q_1 = A_1 F_{12}(J_1 - J_2) + A_1 F_{13}(J_1 - J_3) + A_1 F_{14}(J_1 - J_4) + A_1 F_{15}(J_1 - J_5)$$

$$q_1 = 60 \text{ m}^2 [0.39(545.1 - 607.9)$$

$$+ 0.19(545.1 - 441.5) + 0.19(545.1 - 542.3) + 0.23(545.1 - 541.0)] \text{ W/m}^2 = -200 \text{ W} <$$

$$q_2 = 60 \text{ m}^2 [0.39(607.9 - 545.1)$$

$$+ 0.19(607.9 - 441.5) + 0.19(607.9 - 542.3) + 0.23(607.9 - 541.0)] \text{ W/m}^2 = 5037 \text{ W} <$$

$$q_3 = 40 \text{ m}^2 [0.285(441.5 - 545.1) + 0.285(441.5 - 607.9)$$

$$+ 0.19(441.5 - 542.3) + 0.24(441.5 - 541.0)] \text{ W/m}^2 = -4,799 \text{ W} <$$

Since  $A_4$  and  $A_5$  are insulated (adiabatic),  $q_4 = q_5 = 0$ . <

**COMMENTS:** (1) Note that the sum of  $q_1 + q_2 + q_3 = +38 \text{ W}$ ; this indicates a precision of less than 1% resulted from the solution of the equations. (2) The net radiation for the ceiling,  $A_1$ , is into the surface. Recognize that the embedded heaters function to offset heat losses to the room air by convection.

### PROBLEM 13.90

**KNOWN:** Cylindrical furnace of diameter  $D = 90$  mm and overall length  $L = 180$  mm. Heating elements maintain the refractory lining ( $\varepsilon = 0.8$ ) of section (1),  $L_1 = 135$  mm, at  $T_1 = 800^\circ\text{C}$ . The bottom (2) and upper (3) sections are refractory lined, but are insulated. Furnace operates in a spacecraft environment.

**FIND:** Power required to maintain the furnace operating conditions with the surroundings at  $23^\circ\text{C}$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) All surfaces are diffuse gray, (2) Uniform radiosity over the sections 1, 2, and 3, and (3) Negligible convection effects.

**ANALYSIS:** By defining the furnace opening as the hypothetical area  $A_4$ , the furnace can be represented as a four-surface enclosure as illustrated above. The power required to maintain  $A_1$  at  $T_1$  is  $q_1$ , the net radiation leaving  $A_1$ . To obtain  $q_1$  following the methodology of Section 13.3.2, we must determine the radiosity at all surfaces by simultaneously solving the radiation energy balance equations for each surface which will be of the form, Eqs. 13.20 or 13.21.

$$q_1 = \frac{E_{b1} - J_1}{(1 - \varepsilon_1) / \varepsilon_1 A_1} = \sum_{j=1}^N \frac{J_j - J_1}{1 / A_1 F_{1j}} \quad (1,2)$$

Since  $\varepsilon_4 = 1$ ,  $J_4 = E_{b4}$ , so we only need to perform three energy balances, for  $A_1$ ,  $A_2$ , and  $A_3$ , respectively

$$A_1: \quad \frac{E_{b1} - J_1}{(1 - \varepsilon_1) / \varepsilon_1 A_1} = \frac{J_1 - J_2}{1 / A_1 F_{12}} + \frac{J_1 - J_3}{1 / A_1 F_{13}} + \frac{J_1 - J_4}{1 / A_1 F_{14}} \quad (3)$$

$$A_2: \quad 0 = \frac{J_2 - J_1}{1 / A_2 F_{21}} + \frac{J_2 - J_3}{1 / A_2 F_{23}} + \frac{J_2 - J_4}{1 / A_2 F_{24}} \quad (4)$$

$$A_3: \quad 0 = \frac{J_3 - J_1}{1 / A_3 F_{31}} + \frac{J_3 - J_2}{1 / A_3 F_{32}} + \frac{J_3 - J_4}{1 / A_3 F_{34}} \quad (5)$$

Note that  $q_2 = q_3 = 0$  since the surfaces are insulated (adiabatic). Recognize that in the above equation set, there are three equations and three unknowns:  $J_1$ ,  $J_2$ , and  $J_3$ . From knowledge of  $J_1$ ,  $q_1$  can be determined using Eq. (1). Next we need to evaluate the view factors. There are  $N^2 = 4^2 = 16$  view factors and  $N(N - 1) / 2 = 6$  must be independently evaluated, while the remaining can be determined by the summation rule and appropriate reciprocity relations. The six independently determined  $F_{ij}$  are:

By inspection: (1)  $F_{22} = 0$                       (2)  $F_{44} = 0$

Coaxial parallel disks: From Fig. 13.5 or Table 13.5,

Continued ...

**PROBLEM 13.90 (Cont.)**

$$F_{24} = 0.5 \left\{ S - \left[ S^2 - 4(r_4 / r_2)^2 \right]^{1/2} \right\}$$

$$(3) \quad F_{24} = 0.5 \left\{ 18 - \left[ 18^2 - 4(1)^2 \right]^{1/2} \right\} = 0.05573$$

$$S = 1 + \frac{1 + R_4^2}{R_2^2} = 1 + \frac{1 + 0.250^2}{0.250^2} = 18.00 \quad R_2 = r_2 / L = 45 / 180 = 0.250 \quad R_4 = r_4 / L = 0.250$$

Enclosure 1-2-2': from the summation rule for A<sub>2</sub>,

$$(4) \quad F_{21} = 1 - F_{22'} = 1 - 0.09167 = 0.9083$$

where F<sub>22'</sub> can be evaluated from the coaxial parallel disk relation, Table 13.5. For these surfaces, R<sub>2</sub> = r<sub>2</sub>/L<sub>1</sub> = 45/135 = 0.333, R<sub>2'</sub> = r<sub>2</sub>/L<sub>1</sub> = 0.333, and S = 11.00. From the summation rule for A<sub>1</sub>,

$$(5) \quad F_{11} = 1 - F_{12} - F_{12'} = 1 - 0.1514 - 0.1514 = 0.6972$$

and by symmetry F<sub>12</sub> = F<sub>12'</sub> and using reciprocity

$$F_{12} = A_2 F_{21} / A_1 = [\pi(0.090\text{m})(2/4)] \times 0.9083 / \pi \times 0.090\text{m} \times 0.135\text{m} = 0.1514$$

Enclosure 2'-3-4: from the summation rule for A<sub>4</sub>,

$$(6) \quad F_{43} = 1 - F_{42'} - F_{44} = 1 - 0.3820 - 0 = 0.6180$$

where F<sub>44</sub> = 0 and using the coaxial parallel disk relation from Table 13.5, with R<sub>4</sub> = r<sub>4</sub>/L<sub>2</sub> = 45/45 = 1, R<sub>2'</sub> = r<sub>2</sub>/L<sub>2</sub> = 1, and S = 3.

The View Factors: Using summation rules and appropriate reciprocity relations, the remaining 10 view factors can be evaluated. Written in matrix form, the F<sub>ij</sub> are

0.6972*	0.1514	0.09704	0.05438	
0.9083*	0*	0.03597	0.05573*	
0.2911		0.017980.3819		0.3090
0.3262		0.055730.6180*	0*	

The F<sub>ij</sub> shown with an asterisk were independently determined.

From knowledge of the relevant view factors, the energy balances, Eqs. (3, 4, 5), can be solved simultaneously to obtain the radiosities,

$$J_1 = 73,084 \text{ W/m}^2 \quad J_2 = 67,723 \text{ W/m}^2 \quad J_3 = 36,609 \text{ W/m}^2$$

The net heat rate leaving A<sub>1</sub> can be evaluated using Eq. (1) written as

$$q_1 = \frac{E_{b1} - J_1}{(1 - \varepsilon_1) / \varepsilon_1 A_1} = \frac{(75,159 - 73,084) \text{ W/m}^2}{(1 - 0.8) / 0.8 \times 0.03817 \text{ m}^2} = 317 \text{ W} \quad <$$

where E<sub>b1</sub> = σT<sub>1</sub><sup>4</sup> = σ(800 + 273K)<sup>4</sup> = 75,159 W/m<sup>2</sup> and A<sub>1</sub> = πDL<sub>1</sub> = π × 0.090m × 0.135m = 0.03817 m<sup>2</sup>.

**COMMENTS:** (1) Recognize the importance of defining the furnace opening as the hypothetical area A<sub>4</sub> which completes the four-surface enclosure representing the furnace. The temperature of A<sub>4</sub> is that of the surroundings and its emissivity is unity since it absorbs all radiation incident on it. (2) To obtain the view factor matrix, we used the *IHT Tool, Radiation, View Factor Relations*, which permits you to specify the independently determined F<sub>ij</sub> and the tool will calculate the remaining ones.

### PROBLEM 13.91

**KNOWN:** Dimensions of furnace. Emissivity of surfaces. Temperatures of furnace walls and surroundings.

**FIND:** Rate of radiation heat transfer to surroundings.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Surfaces are gray and diffuse, (2) Surroundings behave as blackbody, (3) Outer surface of furnace is adiabatic, (4) Each identified surface has uniform irradiation and radiosity.

**ANALYSIS:** The surrounding room is assumed to be large enough to behave as a blackbody, therefore:

$$J_3 = E_{b3} = \sigma T_3^4 = 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times (20 + 273)^4 \text{ K}^4 = 417.9 \text{ W/m}^2$$

The temperature of the oven surfaces is known, therefore we can write Equation 13.21 for surfaces 1 and 2.

$$\frac{E_{b1} - J_1}{(1 - \epsilon_1) / \epsilon_1 A_1} = \frac{J_1 - J_2}{1 / A_1 F_{12}} + \frac{J_1 - J_3}{1 / A_1 F_{13}} \quad (1)$$

$$\frac{E_{b2} - J_2}{(1 - \epsilon_2) / \epsilon_2 A_2} = \frac{J_2 - J_1}{1 / A_2 F_{21}} + \frac{J_2 - J_3}{1 / A_2 F_{23}} \quad (2)$$

The view factor from the oven door (1) to the interior walls of the furnace (2) is the same as from the oven door to the furnace opening. From Table 13.2, 3<sup>rd</sup> entry, with  $X = Y = Z = 1\text{ m}$ , we find  $H = W = 1$  and  $F_{12} = 0.2$ . Then  $F_{13} = 1 - F_{12} = 0.8$ . From reciprocity,  $F_{21} = A_1 F_{12} / A_2 = F_{12} / 5 = 0.04$ .

The view factor from the interior of the furnace (2) to the surroundings (3) can be found from the following reasoning. The radiation which leaves the interior and reaches either the oven door or the surroundings must have passed through the opening, so it will be useful to know the view factor  $F_{2o}$ , where subscript  $o$  represents the opening. We know that  $F_{o2} = 1$ , therefore from reciprocity,  $F_{2o} = A_o F_{o2} / A_2 = 1/5 = 0.2$ . The radiation that leaves through the opening must go either to the oven door or the surroundings, therefore  $F_{2o} = F_{21} + F_{23}$ . Finally then,  $F_{23} = F_{2o} - F_{21} = 0.16$ . Substituting numbers into Eqs. (1) and (2) gives

Continued...

### PROBLEM 13.91 (Cont.)

$$5.67 \text{ m}^2(E_{b1} - J_1) = 0.2 \text{ m}^2(J_1 - J_2) + 0.8 \text{ m}^2(J_1 - 417.9 \text{ W/m}^2)$$

$$28.3 \text{ m}^2(E_{b2} - J_2) = 0.2 \text{ m}^2(J_2 - J_1) + 0.8 \text{ m}^2(J_2 - 417.9 \text{ W/m}^2)$$

where  $E_{b1} = E_{b2} = \sigma T_1^4 = 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times (375 + 273)^4 \text{ K}^4 = 9997 \text{ W/m}^2$ . Solving these two simultaneous equations yields

$$J_1 = 8840 \text{ W/m}^2, J_2 = 9728 \text{ W/m}^2$$

Then the radiation heat transfer to the room can be found by summing the contributions from surfaces 1 and 2:

$$\begin{aligned} q_{\text{room}} = -q_3 &= A_1 F_{13}(J_1 - J_3) + A_2 F_{23}(J_2 - J_3) \\ &= 0.8 \text{ m}^2(8840 \text{ W/m}^2 - 417.9 \text{ W/m}^2) + 0.8 \text{ m}^2(9728 \text{ W/m}^2 - 417.9 \text{ W/m}^2) = 1.42 \times 10^4 \text{ W} < \end{aligned}$$

**COMMENTS:** Subdividing the surfaces into smaller regions in order to more closely satisfy the assumption of uniform irradiation and radiosity would provide a more accurate answer.

## PROBLEM 13.92

**KNOWN:** Observation cabin located in a hot-strip mill directly over the line; cabin floor (f) exposed to steel strip (ss) at  $T_{ss} = 920^\circ\text{C}$  and to mill surroundings at  $T_{sur} = 80^\circ\text{C}$ .

**FIND:** Coolant system heat removal rate required to maintain the cabin floor at  $T_f = 50^\circ\text{C}$  for the following conditions: (a) when the floor is directly exposed to the steel strip and (b) when a radiation shield (s)  $\varepsilon_s = 0.10$  is installed between the floor and the strip.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Cabin floor (f) or shield (s), steel strip (ss), and mill surroundings (sur) form a three-surface, diffuse-gray enclosure, (2) Surfaces with uniform radiosities, (3) Mill surroundings are isothermal, black, (4) Floor-shield configuration treated as infinite parallel planes, and (5) Negligible convection heat transfer to the cabin floor.

**ANALYSIS:** A gray-diffuse, three-surface enclosure is formed by the cabin floor (f) (or radiation shield, s), steel strip (ss), and the mill surroundings (sur). The heat removal rate required to maintain the cabin floor at  $T_f = 50^\circ\text{C}$  is equal to  $-q_f$  (or,  $-q_s$ ), where  $q_f$  or  $q_s$  is the net radiation leaving the floor or shield. The schematic below represents the details of the surface energy balance on the floor and shield for the conditions *without the shield* (floor exposed) and *with the shield* (floor shielded from strip).

(a) Without shield

(b) With shield

(a) *Without the shield.* Radiation surface energy balances, Eq. 13.21, are written for the floor (f) and steel strip (ss) surfaces to determine their radiosities.

$$\frac{E_{b,f} - J_f}{(1 - \varepsilon_f) / \varepsilon_f A_f} = \frac{J_f - J_{ss}}{1 / A_f F_{f-ss}} + \frac{J_f - E_{b,sur}}{1 / A_f F_{f-sur}} \quad (1)$$

$$\frac{E_{b,ss} - J_{ss}}{(1 - \varepsilon_{ss}) / \varepsilon_{ss} A_{ss}} = \frac{J_{ss} - J_f}{1 / A_{ss} F_{ss-f}} + \frac{J_{ss} - E_{b,sur}}{1 / A_{ss} F_{ss-sur}} \quad (2)$$

Since the surroundings (sur) are black,  $J_{sur} = E_{b,sur}$ . The blackbody emissive powers are expressed as  $E_b = \sigma T^4$  where  $\sigma = 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4$ . The net radiation leaving the floor, Eq. 13.20, is

$$q_f = A_f F_{f-ss} (J_f - J_{ss}) + A_f F_{f-sur} (J_f - E_{b,sur}) \quad (3)$$

Continued ...

### PROBLEM 13.92 (Cont.)

The required view factors for the analysis are contained in the summation rule for the areas  $A_f$  and  $A_{ss}$ ,

$$F_{f-ss} + F_{f-sur} = 1 \qquad F_{ss-f} + F_{ss-sur} = 1 \qquad (4,5)$$

$F_{f-ss}$  can be evaluated from Fig. 13.4 (Table 13.2) for the aligned parallel rectangles geometry. By symmetry,  $F_{ss-f} = F_{f-ss}$ , and with the summation rule, all the view factors are determined. Using the foregoing relations in the *IHT* workspace, the following results were obtained:

$$F_{f-ss} = 0.1864 \qquad J_f = 7959 \text{ W/m}^2$$

$$F_{f-sur} = 0.8136 \qquad J_{ss} = 97.96 \text{ kW/m}^2$$

and the heat removal rate required of the coolant system (cs) is

$$q_{cs} = -q_f = 41.3 \text{ kW} \qquad <$$

(b) *With the shield.* Radiation surface energy balances are written for the shield (s) and steel strip (ss) to determine their radiosities.

$$\frac{E_{b,s} - J_s}{(1 - \varepsilon_s) / \varepsilon_s A_s} = \frac{J_s - J_{ss}}{1 / A_s F_{s-ss}} + \frac{J_s - E_{b,sur}}{1 / A_s F_{s-sur}} \qquad (6)$$

$$\frac{E_{b,ss} - J_{ss}}{(1 - \varepsilon_{ss}) / \varepsilon_{ss} A_{ss}} = \frac{J_{ss} - J_s}{1 / A_{ss} F_{ss-s}} + \frac{J_{ss} - E_{b,sur}}{1 / A_{ss} F_{ss-sur}} \qquad (7)$$

The net radiation leaving the shield is

$$q_s = A_{ss} F_{ss-s} (J_{ss} - J_s) + A_{ss} F_{ss-sur} (J_{ss} - E_{b,sur}) \qquad (8)$$

Since the temperature of the shield is unknown, an additional relation is required. The heat transfer from the shield (s) to the floor (f) - the coolant heat removal rate - is

$$-q_s = \frac{\sigma (T_s^4 - T_f^4) A_s}{1 - 1 / \varepsilon_s - 1 / \varepsilon_f} \qquad (9)$$

where the floor-shield configuration is that of infinite parallel planes, Eq. 13.24. Using the foregoing relations in the *IHT* workspace, with appropriate view factors from part (a), the following results were obtained

$$J_s = 18.13 \text{ kW/m}^2 \qquad J_{ss} = 98.20 \text{ kW/m}^2 \qquad T_s = 377^\circ\text{C}$$

and the heat removal rate required of the coolant system is

$$q_{cs} = -q_s = 6.55 \text{ kW} \qquad <$$

**COMMENTS:** The effect of the shield is to reduce the coolant system heat rate by a factor of nearly seven. Maintaining the integrity of the reflecting shield ( $\varepsilon_s = 0.10$ ) operating at nearly  $400^\circ\text{C}$  in the mill environment to prevent corrosion or oxidation may be necessary.

### PROBLEM 13.93

**KNOWN:** Dimensions of furnace and sphere. Emissivity of surfaces. Power supplied to floor of furnace. Temperature of other five walls. Sphere temperature.

**FIND:** (a) View factors  $F_{12}$ ,  $F_{13}$ ,  $F_{21}$ ,  $F_{31}$ ,  $F_{23}$ ,  $F_{32}$ , and  $F_{33}$ . (b) Temperature of floor. Net rate of radiation heat transfer leaving sphere. Whether the sphere is under steady-state conditions.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Surfaces are gray and diffuse, (2) Each identified surface has uniform irradiation and radiosity, (3) Outer surface of furnace floor is insulated and all power supplied to heater leaves as radiation into furnace (no storage), (4) Convection can be neglected.

**ANALYSIS:** (a) Due to symmetry, the view factor from the sphere to each of the six furnace walls must be equal, therefore  $F_{12} = 1/6$  and  $F_{13} = 5/6$ . <

From reciprocity,

$$F_{21} = \frac{A_1 F_{12}}{A_2} = \frac{\pi (0.03 \text{ m})^2}{6 \times (0.1 \text{ m})^2} = 0.0471 \quad <$$

$$F_{31} = \frac{A_1 F_{13}}{A_3} = \frac{5\pi (0.03 \text{ m})^2}{6 \times 5 \times (0.1 \text{ m})^2} = 0.0471 \quad <$$

Since surface 2 does not see itself,  $F_{21} + F_{23} = 1$ , therefore  $F_{23} = 1 - F_{21} = 0.953$ . <

From reciprocity,

$$F_{32} = \frac{A_2 F_{23}}{A_3} = \frac{(0.1 \text{ m})^2 \times 0.953}{5 \times (0.1 \text{ m})^2} = 0.191 \quad <$$

Finally,  $F_{33} = 1 - F_{31} - F_{32} = 0.762$ . <

(b) Equation 13.21 can be written at surfaces 1 and 3 where temperature is known:

$$\frac{E_{b1} - J_1}{(1 - \epsilon_1) / \epsilon_1 A_1} = \frac{J_1 - J_2}{1 / A_1 F_{12}} + \frac{J_1 - J_3}{1 / A_1 F_{13}} \quad (1)$$

Continued...

**PROBLEM 13.93 (Cont.)**

$$\frac{E_{b3} - J_3}{(1 - \varepsilon_3) / \varepsilon_3 A_3} = \frac{J_3 - J_1}{1 / A_3 F_{31}} + \frac{J_3 - J_2}{1 / A_3 F_{32}} \quad (2)$$

The power is known at surface 2,  $q_2 = P = 400 \text{ W}$ , so we write Equation 13.22:

$$q_2 = \frac{J_2 - J_1}{1 / A_2 F_{21}} + \frac{J_2 - J_3}{1 / A_2 F_{23}} \quad (3)$$

Substituting numbers into Eqs. (1) – (3) gives

$$\begin{aligned} 0.00189 \text{ m}^2 (E_{b1} - J_1) &= 0.000471 \text{ m}^2 (J_1 - J_2) + 0.00236 \text{ m}^2 (J_1 - J_3) \\ 0.0333 \text{ m}^2 (E_{b3} - J_3) &= 0.00236 \text{ m}^2 (J_3 - J_1) + 0.00953 \text{ m}^2 (J_3 - J_2) \\ 400 \text{ W} &= 0.000471 \text{ m}^2 (J_2 - J_1) + 0.00953 \text{ m}^2 (J_2 - J_3) \end{aligned}$$

where  $E_{b1} = \sigma T_1^4 = 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times (420)^4 \text{ K}^4 = 1764 \text{ W/m}^2$  and  $E_{b3} = \sigma T_3^4 = 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times (400)^4 \text{ K}^4 = 1452 \text{ W/m}^2$ . Solving these three simultaneous equations yields

$$J_1 = 1.24 \times 10^4 \text{ W/m}^2, J_2 = 5.28 \times 10^4 \text{ W/m}^2, J_3 = 1.29 \times 10^4 \text{ W/m}^2$$

The temperature of the floor can be found by solving Equation 13.19 for  $E_{b2}$ :

$$E_{b2} = J_2 + q_2 \frac{1 - \varepsilon_2}{\varepsilon_2 A_2} = 5.28 \times 10^4 \text{ W/m}^2 + 400 \text{ W} \frac{1 - 0.4}{0.4 \times (0.1 \text{ m})^2} = 1.128 \times 10^5 \text{ W/m}^2$$

Then with  $E_{b2} = \sigma T_2^4$  we find  $T_2 = 1188 \text{ K}$ . <

The net rate of radiation leaving the sphere surface 1 is given by Equation 13.19:

$$q_1 = \frac{E_{b1} - J_1}{(1 - \varepsilon_1) / \varepsilon_1 A_1} = 0.00189 \text{ m}^2 (1764 \text{ W/m}^2 - 1.24 \times 10^4 \text{ W/m}^2) = -20 \text{ W} \quad <$$

Since this is negative, heat is reaching the sphere at the rate of 20 W.

Since the sphere is not being heated or cooled by any mechanism other than radiation, at steady-state the net radiation heat transfer rate must be zero. Since it is not zero, it is not at steady-state. <

**COMMENTS:** (1) The bottom surface is very hot. (2) The irradiation and radiosity distributions on the spherical object are highly non-uniform. A more accurate treatment would include the effects of this non-uniformity by considering many additional radiation surfaces, as well as possible spatial temperature distributions within the spherical object. (3) The net heat radiation leaving surface 1 is relatively small and could be of the same magnitude as any convection effects.

### PROBLEM 13.94

**KNOWN:** Opaque, diffuse-gray plate with  $\epsilon_1 = 0.8$  is at  $T_1 = 400$  K at a particular instant. The bottom surface of the plate is subjected to radiative exchange with a furnace. The top surface is subjected to ambient air and large surroundings.

**FIND:** (a) Net radiative heat transfer to the bottom surface of the plate for  $T_1 = 400$  K, (b) Change in temperature of the plate with time,  $dT_1/dt$ , and (c) Compute and plot  $dT_1/dt$  as a function of  $T_1$  for the range  $350 \leq T_1 \leq 900$  K; determine the steady-state temperature of the plate.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Plate is opaque, diffuse-gray and isothermal, (2) Furnace bottom behaves as a blackbody while sides are perfectly insulated, (3) Surroundings are large compared to the plate and behave as a blackbody.

**ANALYSIS:** (a) Recognize that the plate ( $A_1$ ), furnace bottom ( $A_2$ ) and furnace side walls ( $A_R$ ) form a three-surface enclosure with one surface being re-radiating. The net radiative heat transfer *leaving*  $A_1$  follows from Eq. 13.30 written as

$$q_1 = \frac{E_{b1} - E_{b2}}{\frac{1 - \epsilon_1}{\epsilon_1 A_1} + \frac{1}{A_1 F_{12} + (1/A_1 F_{1R} + 1/A_2 F_{2R})^{-1}} + \frac{1 - \epsilon_2}{\epsilon_2 A_2}} \quad (1)$$

From Fig. 13.4 with  $X/L = 0.2/0.2 = 1$  and  $Y/L = 0.2/0.2 = 1$ , it follows that  $F_{12} = 0.2$  and  $F_{1R} = 1 - F_{12} = 1 - 0.2 = 0.8$ . Hence, with  $F_{1R} = F_{2R}$  (by symmetry) and  $\epsilon_2 = 1$ .

$$q_1 = \frac{5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (400^4 - 1000^4) \text{ K}^4}{\frac{1 - 0.8}{0.8 \times 0.04 \text{ m}^2} + \frac{1}{0.04 \text{ m}^2 \times 0.20 + (2/0.04 \text{ m}^2 \times 0.8)^{-1}}} = -1153 \text{ W} <$$

It follows the net radiative exchange to the plate is,  $q_{\text{rad},f} = 1153$  W.

(b) Perform now an energy balance on the plate written as

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \dot{E}_{\text{st}}$$

$$q_{\text{rad},f} - q_{\text{conv}} - q_{\text{rad},\text{sur}} = Mc_p \frac{dT_1}{dt}$$

$$q_{\text{rad},f} - hA_1(T_1 - T_\infty) - \epsilon_1 A_1 \sigma (T_1^4 - T_{\text{sur}}^4) = Mc_p \frac{dT_1}{dt}. \quad (2)$$

Substituting numerical values and rearranging to obtain  $dT/dt$ , find

Continued ...

### PROBLEM 13.94 (Cont.)

$$\frac{dT_1}{dt} = \frac{1}{2 \text{ kg} \times 900 \text{ J/kg} \cdot \text{K}} \left[ +1153 \text{ W} - 25 \text{ W/m}^2 \cdot \text{K} \times 0.04 \text{ m}^2 (400 - 300) \text{ K} - 0.8 \times 0.04 \text{ m}^2 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (400^4 - 300^4) \text{ K}^4 \right] <$$

$$\frac{dT_1}{dt} = 0.57 \text{ K/s.}$$

(c) With Eqs. (1) and (2) in the *IHT* workspace,  $dT_1/dt$  was computed and plotted as a function of  $T_1$ .

When  $T_1 = 400 \text{ K}$ , the condition of part (b), we found  $dT_1/dt = 0.57 \text{ K/s}$  which indicates the plate temperature is increasing with time. For  $T_1 = 900 \text{ K}$ ,  $dT_1/dt$  is a negative value indicating the plate temperature will decrease with time. The steady-state condition corresponds to  $dT_1/dt = 0$  for which

$$T_{1,ss} = 715 \text{ K} <$$

**COMMENTS:** Using the *IHT Radiation Tools – Radiation Exchange Analysis, Three Surface Enclosure with Re-radiating Surface and View Factors, Aligned Parallel Rectangle* – the above analysis can be performed. A copy of the workspace follows:

// Energy Balance on the Plate, Equation 2:

$$M \cdot c_p \cdot dTdt = -q_1 - h \cdot A_1 \cdot (T_1 - T_{inf}) - \epsilon_{ps1} \cdot A_1 \cdot \sigma \cdot (T_1^4 - T_{sur}^4)$$

/\* Radiation Tool – Radiation Exchange Analysis,

Three-Surface Enclosure with Reradiating Surface: \*/

/\* For the three-surface enclosure A1, A2 and the reradiating surface AR, the net rate of radiation transfer from the surface A1 to surface A2 is \*/

$$q_1 = (E_{b1} - E_{b2}) / \left( \frac{1 - \epsilon_{ps1}}{\epsilon_{ps1} \cdot A_1} + 1 / (A_1 \cdot F_{12} + 1 / (1 / (A_1 \cdot F_{1R}) + 1 / (A_2 \cdot F_{2R}))) \right) + (1 - \epsilon_{ps2}) / (\epsilon_{ps2} \cdot A_2) // \text{ Eq 13.30}$$

/\* The net rate of radiation transfer from surface A2 to surface A1 is \*/

$$q_2 = -q_1$$

/\* From a radiation energy balance on AR, \*/

$$(J_R - J_1) / (1 / (A_R \cdot F_{R1})) + (J_R - J_2) / (1 / (A_R \cdot F_{R2})) = 0 // \text{ Eq 13.31}$$

/\* where the radiosities J1 and J2 are determined from the radiation rate equations expressed in terms of the surface resistances, Eq 13.22 \*/

$$q_1 = (E_{b1} - J_1) / \left( \frac{1 - \epsilon_{ps1}}{\epsilon_{ps1} \cdot A_1} \right)$$

$$q_2 = (E_{b2} - J_2) / \left( \frac{1 - \epsilon_{ps2}}{\epsilon_{ps2} \cdot A_2} \right)$$

// The blackbody emissive powers for A1 and A2 are

$$E_{b1} = \sigma \cdot T_1^4$$

$$E_{b2} = \sigma \cdot T_2^4$$

// For the reradiating surface,

$$J_R = E_{bR}$$

Continued ...

## PROBLEM 13.94 (Cont.)

$E_bR = \sigma \cdot TR^4$   
 $\sigma = 5.67E-8$  // Stefan-Boltzmann constant,  $W/m^2 \cdot K^4$

### // Radiation Tool – View Factor:

 $T_{sur} = 300$  // Surroundings temperature, K

### PROBLEM 13.95

**KNOWN:** Tool for processing silicon wafer within a vacuum chamber with cooled walls. Thin wafer is radiatively coupled on its back side to a chuck which is electrically heated. The top side is irradiated by an ion beam flux and experiences convection with the process gas and radioactive exchange with the ion-beam *grid* control surface and the chamber walls.

**FIND:** (a) Show control surfaces and all relevant processes on a schematic of the wafer, and (b) Perform an energy balance on the wafer and determine the chuck temperature  $T_c$  required to maintain the prescribed conditions.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Wafer is diffuse, gray, (3) Separation distance between the wafer and chuck is much smaller than the wafer and chuck diameters, (4) Negligible convection in the gap between the wafer and chuck; convection occurs on the wafer top surface with the process gas, (5) Surfaces forming the three-surface enclosure – wafer ( $\epsilon_w = 0.8$ ), grid ( $\epsilon_g = 1$ ), and chamber walls ( $\epsilon_c = 1$ ) have uniform radiosity and are diffuse, gray, and (6) the chuck surface is black.

**ANALYSIS:** (a) The wafer is shown schematically above in relation to the key components of the tool: the ion beam generator, the grid which is used to control the ion beam flux,  $q''_{ib}$ , the chuck which aids in controlling the wafer temperature and the process gas flowing over the wafer top surface. The schematic below shows the control surfaces on the top and back surfaces of the wafer along with the relevant thermal processes:  $q_{cv}$ , convection between the wafer and process gas;  $q_a$ , applied heat source due to absorption of the ion beam flux,  $q''_{ib}$ ;  $q_{1,top}$ , net radiation leaving the top surface of the wafer (1) which is part of the three-surface enclosure – grid (2) and chamber walls (3), and;  $q_{1,bac}$ , net radiation leaving the backside of the wafer (w) which is part of a two-surface enclosure formed with the chuck (c).

Continued ...

### PROBLEM 13.95 (Cont.)

(b) Referring to the schematic and the identified thermal processes, the energy balance on the wafer has the form,

$$\begin{aligned}\dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= 0 \\ -q_{\text{cv}} + q_{\text{a}} - q_{1,\text{bac}} - q_{1,\text{top}} &= 0\end{aligned}\quad (1)$$

where each of the processes are evaluated as follows:

*Convection with the process gas:* with  $A_{\text{w}} = \pi D^2 / 4 = \pi (0.200\text{m})^2 / 4 = 0.03142\text{m}^2$ ,

$$q_{\text{cv}} = hA_{\text{w}} (T_{\text{w}} - T_{\text{g}}) = 10\text{ W/m}^2 \times 0.03142\text{m}^2 \times (700 - 500)\text{K} = 62.84\text{ W} \quad (2)$$

*Applied heat source – ion beam:*

$$q_{\text{a}} = q_{\text{ib}}'' A_{\text{w}} = 600\text{ W/m}^2 \times 0.03142\text{m}^2 = 18.85\text{ W} \quad (3)$$

*Net radiation heat rate, back side; enclosure (w,c):* for the two-surface enclosure comprised of the back side of the wafer (w) and the chuck, (c), Eq. 13.24, yields

$$\begin{aligned}q_{1,\text{bac}} &= \frac{\sigma (T_{\text{w}}^4 - T_{\text{c}}^4) A_{\text{w}}}{1/\varepsilon_{\text{w}}} \\ q_{1,\text{bac}} &= \frac{0.03142\text{m}^2 \times \sigma (700^4 - T_{\text{c}}^4)\text{K}^4}{1/0.6} = 1.069 \times 10^{-9} (700^4 - T_{\text{c}}^4)\end{aligned}\quad (4)$$

*Net radiation heat rate, top surface; enclosure (1, 2, 3):* from the surface energy balance on  $A_1$ , Eq. 13.19.

$$q_{1,\text{top}} = \frac{E_{\text{b1}} - J_1}{(1 - \varepsilon_1) / \varepsilon_1 A_1} \quad (5)$$

where  $\varepsilon_1 = \varepsilon_{\text{w}}$ ,  $A_1 = A_{\text{w}}$ ,  $E_{\text{b1}} = \sigma T_1^4$  and the radiosity can be evaluated by an enclosure analysis following the methodology of Section 13.3.2. From the energy balance, Eq. 13.21,

$$\frac{E_{\text{b1}} - J_1}{(1 - \varepsilon_1) / \varepsilon_1 A_1} = \frac{J_1 - J_2}{1/A_1 F_{12}} + \frac{J_1 - J_3}{1/A_1 F_{13}} \quad (6)$$

where  $J_2 = E_{\text{b2}} = \sigma T_{\text{g}}^4$  and  $J_3 = E_{\text{b3}} = \sigma T_{\text{vc}}^4$  since both surfaces are black ( $\varepsilon_{\text{g}} = \varepsilon_{\text{vc}} = 1$ ). The view factor  $F_{12}$  can be computed from the relation for coaxial parallel disks, Table 13.5.

$$\begin{aligned}F_{12} &= 0.5 \left\{ S - \left[ S^2 - 4(r_2/r_1)^2 \right]^{1/2} \right\} = 0.5 \left\{ 6.0 - \left[ 6.0^2 - 4(1)^2 \right]^{1/2} \right\} = 0.1716 \\ S &= 1 + \frac{1 + R_2^2}{R_1^2} = 1 + \frac{1 + 0.5^2}{0.5^2} = 6.00\end{aligned}$$

Continued ...

**PROBLEM 13.95 (Cont.)**

$$R_1 = r_1 / L = 100 / 200 = 0.5$$

$$R_4 = r_4 / L = 0.5$$

The view factor  $F_{13}$  follows from the summation rule applied to  $A_1$ ,

$$F_{13} = 1 - F_{12} = 1 - 0.1716 = 0.8284$$

Substituting numerical values into Eq. (6), with  $T_1 = T_w = 700$  K,  $T_2 = T_g = 500$  K, and  $T_3 = T_{vc} = 300$  K, find  $J_1$ ,

$$\frac{\sigma T_1^4 - J_1}{(1 - \varepsilon_1) / \varepsilon_1 A_1} = \frac{J_1 - \sigma T_g^4}{1 / F_{12}} + \frac{J_1 - \sigma T_{vc}^4}{1 / F_{13}} \quad (7)$$

$$J_1 = 8564 \text{ W/m}^2$$

Using Eq. (5), find  $q_{1,\text{top}}$  with  $E_{b2} = \sigma T_w^4 = 13,614 \text{ W/m}^2$  and  $A_1 = A_w$ ,

$$q_{1,\text{top}} = \frac{(13,614 - 8564) \text{ W/m}^2}{(1 - 0.6) / (0.6 \times 0.03142 \text{ m}^2)} = 238 \text{ W}$$

Evaluating  $T_c$  from the energy balance on the wafer, Eq. (1), and substituting appropriate expressions for each of the processes, find

$$-62.84 \text{ W/m}^2 + 18.85 \text{ W} - 1.069 \times 10^{-9} (700^4 - T_c^4) - 238 \text{ W} = 0$$

$$T_c = 842.5 \text{ K}$$

&lt;

From Eq. (4), with  $T_c = 815$  K, the electrical power required to maintain the chuck is

$$P_c = -q_{1,\text{bac}} = 1.069 \times 10^{-9} (842.5^4 - 700^4) = 282 \text{ W}$$

**COMMENTS:** Recognize that the method of analysis is centered about an energy balance on the wafer. Identifying the processes and representing them on the energy balance schematic, as described in Chapter 1, is a vital step in developing the strategy for a solution.

## PROBLEM 13.96

**KNOWN:** Dimensions and temperatures of rotating and stationary disks, air gap spacing between disks, rotational speed. Ambient and surroundings temperatures. Correlation for the local Nusselt number. Initial painted surfaces and emissivity of exposed base metal on the rotating disk.

**FIND:** Total power dissipated from the top surface of the rotating disk for painted and unpainted conditions.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Constant properties, (3) Diffuse-gray surfaces with uniform radiosity and irradiation distributions, (4) Large surroundings.

**PROPERTIES:** Table A.4, air ( $T = (80^\circ\text{C} + 20^\circ\text{C})/2 = 50^\circ\text{C} \approx 323\text{K}$ ):  $\nu = 18.20 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0280 \text{ W/m}\cdot\text{K}$ . Table A.11, Parsons black paint,  $\varepsilon = 0.98$ .

**ANALYSIS:** From Problem 6.17,  $Nu_r = \frac{h(r)r_o}{k} = 70(1 + e^{-140G})Re_{r_o}^{-0.456}Re_r^{0.478}$ .

Since  $Re_r = \Omega r^2 / \nu$ , the local heat transfer coefficient is

$$h(r) = k \left[ 70(1 + e^{-140G}) \left( \frac{\Omega r_o^2}{\nu} \right)^{-0.456} \left( \frac{\Omega}{\nu} \right)^{0.478} \right] r^{-0.044}$$

The average heat transfer coefficient may be evaluated from

$$\bar{h} = \frac{1}{A_s} \int_{A_s} h(r) dA_s = \frac{2\pi k}{\pi r_o^2} \left[ 70(1 + e^{-140G}) \left( \frac{\Omega r_o^2}{\nu} \right)^{-0.456} \left( \frac{\Omega}{\nu} \right)^{0.478} \right] \int_0^{r_o} r \times r^{-0.044} dr$$

or

$$\bar{h} = \frac{1.022k}{r_o^2} \left[ 70(1 + e^{-140G}) \left( \frac{\Omega r_o^2}{\nu} \right)^{-0.456} \left( \frac{\Omega}{\nu} \right)^{0.478} \right] r_o^{1.956}$$

Continued...

### PROBLEM 13.96 (Cont.)

Substituting values,

$$\bar{h} = \frac{1.022 \times 0.0280 \text{ W/m}^2 \cdot \text{K}}{(0.100 \text{ m})^2} \times \left[ 70 \left( 1 + e^{-140 \times 0.02} \right) \left( \frac{150 \text{ rad/s} \times (0.100 \text{ m})^2}{18.20 \times 10^{-6} \text{ m}^2/\text{s}} \right)^{-0.456} \left( \frac{150 \text{ rad/s}}{18.20 \times 10^{-6} \text{ m}^2/\text{s}} \right)^{0.478} \right] (0.100 \text{ m})^{1.956}$$

or

$$\bar{h} = 27.26 \text{ W/m}^2 \cdot \text{K}$$

The convective heat flux from the top surface of the disk is

$$q''_{\text{conv}} = \bar{h}(T_s - T_d) = 27.26 \text{ W/m}^2 \cdot \text{K} \times (80 - 20)^\circ\text{C} = 1636 \text{ W/m}^2$$

and the convective heat rate is

$$q_{\text{conv}} = q'' \pi r_o^2 = 1636 \text{ W/m}^2 \times \pi \times (0.10 \text{ m})^2 = 51.38 \text{ W}$$

The radiation heat transfer from the rotating disk may be determined by use of Eq. 13.21.

Surfaces 1 and 2:

$$\frac{\sigma T_1^4 - J_1}{(1 - \varepsilon_1)/\varepsilon_1 A_1} = \frac{J_1 - J_2}{1/A_1 F_{12}} + \frac{J_1 - J_3}{1/A_1 F_{13}} \quad ; \quad \frac{\sigma T_2^4 - J_2}{(1 - \varepsilon_2)/\varepsilon_2 A_2} = \frac{J_2 - J_1}{1/A_1 F_{12}} + \frac{J_2 - J_3}{1/A_2 F_{23}} \quad (1,2)$$

while for black Surface 3,  $J_3 = \sigma T_3^4 = 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times (20 + 273 \text{ K})^4 = 417.8 \text{ W/m}^2$ . Using the result for coaxial parallel disks in Table 13.2,  $R_1 = R_2 = r_o/g = 100 \text{ mm}/2 \text{ mm} = 50$ ,  $S = 1 + 2501/2500 = 2.0004$ , and

$$F_{12} = \frac{1}{2} \left\{ 2.0004 - \left[ 2.0004^2 - 4 \right]^{1/2} \right\} = 0.9802 \quad ; \quad F_{13} = 1 - F_{12} = 1 - 0.9802 = 0.0198$$

while  $A_1 = A_2 = \pi r_o^2 = \pi \times (0.100 \text{ m})^2 = 0.0314 \text{ m}^2$ . Substituting values of the view factors, areas, emissivities and  $J_3$  into Equations (1) and (2), and solving simultaneously yields

$$\varepsilon_1 = 0.98: J_1 = 871.3 \text{ W/m}^2, J_2 = 426.8 \text{ W/m}^2 \quad ; \quad \varepsilon_1 = 0.10: J_1 = 464.9 \text{ W/m}^2, J_2 = 417.9 \text{ W/m}^2$$

From Eq. 13.19,

$$q_{1,\text{rad},0.98} = \frac{\sigma T_1^4 - J_1}{(1 - \varepsilon_1)/\varepsilon_1 A_1} = \frac{5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times (80 + 273 \text{ K})^4 - 871.3 \text{ W/m}^2}{(1 - 0.98)/(0.98 \times 0.0314 \text{ m}^2)} = 13.97 \text{ W}$$

Continued...

### PROBLEM 13.96 (Cont.)

and

$$q_{1,\text{rad},0.10} = \frac{\sigma T_1^4 - J_1}{(1 - \varepsilon_1)/\varepsilon_1 A_1} = \frac{5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times (80 + 273 \text{ K})^4 - 464.9 \text{ W/m}^2}{(1 - 0.10)/(0.10 \times 0.0314 \text{ m}^2)} = 1.45 \text{ W}$$

The total power dissipated from the top surface of the rotating disk is:

$$\varepsilon_1 = 0.98: q = q_{\text{conv}} + q_{1,\text{rad},0.98} = 51.38 \text{ W} + 13.97 \text{ W} = 65.35 \text{ W} \quad <$$

$$\varepsilon_1 = 0.10: q = q_{\text{conv}} + q_{1,\text{rad},0.10} = 51.38 \text{ W} + 1.45 \text{ W} = 52.83 \text{ W} \quad <$$

**COMMENTS:** (1) The influence of the black surroundings is small since the view factors from the disks to the surroundings are small, the stationary disk temperature is the same as that of the surroundings, and the emissivity of the stationary disk is close to unity. Use of the result for infinite parallel surfaces (Equation 13.24) yields heat rates of 13.95 and 1.45 W for the high and low emissivity cases, respectively. (2) See Pelle and Harmand, "Heat Transfer Measurements in an Opened Rotor-Stator System Air-Gap," *Experimental Thermal and Fluid Science*, 'Vol. 31, pp. 165 – 180, 2007, for additional discussion.

## PROBLEM 13.97

**KNOWN:** Ice rink with prescribed ice, rink air, wall, ceiling and outdoor air conditions.

**FIND:** (a) Temperature of the ceiling,  $T_c$ , having an emissivity of 0.05 (highly reflective panels) or 0.94 (painted panels); determine whether condensation will occur for either or both ceiling panel types if the relative humidity of the rink air is 70%, and (b) Calculate and plot the ceiling temperature as a function of ceiling insulation thickness for  $0.1 \leq t \leq 1$  m, identify conditions for which condensation will occur on the ceiling.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Rink comprised of the ice, walls and ceiling approximates a three-surface, diffuse-gray enclosure, (2) Surfaces have uniform radiosities, (3) Ice surface and walls are black, (4) Panels are diffuse-gray, and (5) Thermal resistance for convection on the outdoor side of the ceiling is negligible compared to the conduction thermal resistance of the ceiling insulation.

**PROPERTIES:** *Psychrometric chart* (Atmospheric pressure; dry bulb temperature,  $T_{db} = T_{\infty,i} = 15^\circ\text{C}$ ; relative humidity,  $\text{RH} = 70\%$ ): Dew point temperature,  $T_{dp} = 9.4^\circ\text{C}$ .

**ANALYSIS:** The energy balance on the ceiling illustrated in the schematic below has the form

$$\begin{aligned} \dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= 0 \\ -q_o - q_{\text{conv},c} - q_{\text{rad},c} &= 0 \end{aligned} \quad (1)$$

where the rate equations for each process are

$$q_o = (T_c - T_{\infty,o}) / R_{\text{cond}} \quad R_{\text{cond}} = t / kA_c \quad (2,3)$$

$$q_{\text{conv},c} = h A_c (T_c - T_{\infty,i}) \quad (4)$$

$$q_{\text{rad},c} = \varepsilon E_b (T_c) A_c - \alpha A_w F_{wc} E_b (T_w) - \alpha A_i F_{ic} E_b (T_i) \quad (5)$$

The blackbody emissive powers are  $E_b = \sigma T^4$  where  $\sigma = 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4$ . Since the ceiling panels are diffuse-gray,  $\alpha = \varepsilon$ . The view factors required of Eq. (5): determine  $F_{ic}$  (ice to ceiling) from Table 13.2 (Fig. 13.5) for parallel, coaxial disks

$$F_{ic} = 0.672$$

and  $F_{wc}$  (wall to ceiling) from the summation rule on the ice (i) and the reciprocity rule,

$$F_{ic} + F_{iw} = 1 \quad F_{iw} = F_{cw} \text{ (symmetry)}$$

$$F_{cw} = 1 - F_{ic}$$

$$F_{wc} = (A_c / A_w) F_{cw} = (A_c / A_w) (1 - F_{ic}) = 0.410$$

Continued ...

### PROBLEM 13.97 (Cont.)

where  $A_c = \pi D^2/4$  and  $A_w = \pi DL$ .

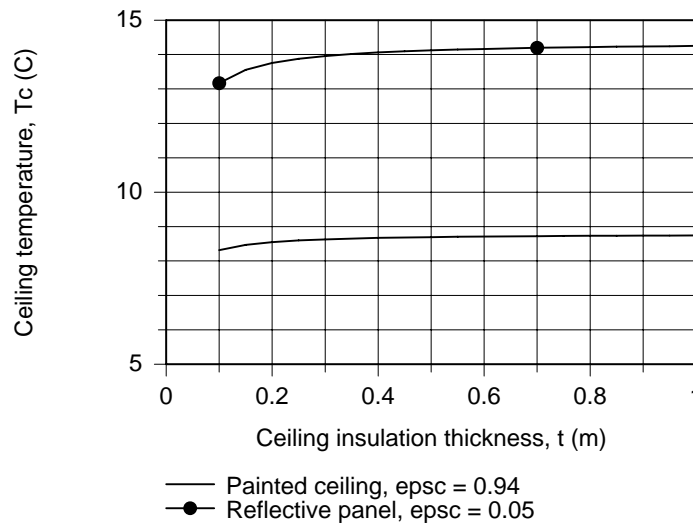

Using the foregoing energy balance, Eq. (1), and the rate equations, Eqs. (2-5), the ceiling temperature is calculated using radiative properties for the two panel types,

Ceiling panel	$\varepsilon$	$T_c$ (°C)		
Reflective	0.05	14.0		
Paint	0.94	8.6	$T_c < T_{dp}$	<

Condensation will occur on the painted panel since  $T_c < T_{dp}$ .

(b) The equations required of the analysis above were solved using *IHT*. The analysis is extended to calculate the ceiling temperatures for a range of insulation thickness and the results plotted below.

For the reflective panel ( $\varepsilon = 0.05$ ), the ceiling surface temperature is considerably above the dew point. Therefore, condensation will not occur for the range of insulation thickness shown. For the painted panel ( $\varepsilon = 0.94$ ), the ceiling surface temperature is always below the dew point. We expect condensation to occur for the range of insulation thickness shown.

**COMMENTS:** From the analysis, recognize that the radiative exchange between the ice and the ceiling is the dominant process for influencing the ceiling temperature. With the reflective panel, the rate is reduced nearly 20 times that with the painted panel. With the painted panel ceiling, for most of the conditions likely to exist in the rink, condensation will occur.

### PROBLEM 13.98

**KNOWN:** Diameter, temperature and emissivity of boiler tube. Thermal conductivity and emissivity of ash deposit. Convection coefficient and temperature of gas flow over the tube. Temperature of surroundings.

**FIND:** (a) Rate of heat transfer to tube without ash deposit, (b) Rate of heat transfer with an ash deposit of diameter  $D_d = 0.06$  m, (c) Effect of deposit diameter and convection coefficient on heat rate and contributions due to convection and radiation.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Diffuse/gray surface behavior, (2) Surroundings form a large enclosure about the tube and may be approximated as a blackbody, (3) One-dimensional conduction in ash, (4) Steady-state.

**ANALYSIS:** (a) Without an ash deposit, the heat rate per unit tube length may be calculated directly.

$$q' = \bar{h}\pi D_t (T_\infty - T_t) + \varepsilon_t \sigma \pi D_t (T_{sur}^4 - T_t^4)$$

$$q' = 100 \text{ W/m}^2 \cdot \text{K} (\pi) 0.05 \text{ m} (1800 - 600) \text{ K} + 0.8 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (\pi) (0.05 \text{ m}) (1500^4 - 600^4) \text{ K}^4$$

$$q' = (18,850 + 35,150) \text{ W/m} = 54,000 \text{ W/m} \quad <$$

(b) Performing an energy balance for a control surface about the outer surface of the ash deposit,

$$q'_{conv} + q'_{rad} = q'_{cond}, \text{ or}$$

$$\bar{h}\pi D_d (T_\infty - T_d) + \varepsilon_d \sigma \pi D_d (T_{sur}^4 - T_d^4) = \frac{2\pi k (T_d - T_t)}{\ln(D_d/D_t)}$$

Hence, canceling  $\pi$  and considering an ash deposit for which  $D_d = 0.06$  m,

$$\begin{aligned} 100 \text{ W/m}^2 \cdot \text{K} (0.06 \text{ m}) (1800 - T_d) \text{ K} + 0.9 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (0.06 \text{ m}) (1500^4 - T_d^4) \text{ K}^4 \\ = \frac{2(1 \text{ W/m} \cdot \text{K})(T_d - 600) \text{ K}}{\ln(0.06/0.05)} \end{aligned}$$

A trial-and-error, or *IHT* solution yields  $T_d \approx 1346$  K, from which it follows that

$$q' = \bar{h}\pi D_d (T_\infty - T_d) + \varepsilon_d \sigma \pi D_d (T_{sur}^4 - T_d^4)$$

$$q' = 100 \text{ W/m}^2 \cdot \text{K} (\pi) 0.06 \text{ m} (1800 - 1346) \text{ K} + 0.9 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (\pi) 0.06 \text{ m} (1500^4 - 1346^4) \text{ K}^4$$

Continued ...

### PROBLEM 13.98 (Cont.)

$$q' = (8560 + 17,140) \text{ W/m} = 25,700 \text{ W/m}$$

<

(c) The foregoing energy balance was entered into the *IHT* workspace and parametric calculations were performed to explore the effects of  $\bar{h}$  and  $D_d$  on the heat rates.

For  $D_d = 0.06$  m and  $10 \leq \bar{h} \leq 1000$  W/m<sup>2</sup>·K, the heat rate to the tube,  $q'_{\text{cond}}$ , as well as the contribution due to convection,  $q'_{\text{conv}}$ , increase with increasing  $\bar{h}$ . However, because the outer surface temperature  $T_d$  also increases with  $\bar{h}$ , the contribution due to radiation decreases and becomes negative (heat transfer from the surface) when  $T_d$  exceeds 1500 K at  $\bar{h} = 540$  W/m<sup>2</sup>·K. Both the convection and radiation heat rates, and hence the conduction heat rate, increase with decreasing  $D_d$ , as  $T_d$  decreases and approaches  $T_t = 600$  K. However, even for  $D_d = 0.051$  m (a deposit thickness of 0.5 mm),  $T_d = 773$  K and the ash provides a significant resistance to heat transfer.

**COMMENTS:** Boiler operation in an energy efficient manner dictates that ash deposits be removed periodically.

## PROBLEM 13.99

**KNOWN:** Two large parallel plates, separation distance and temperature of top plate. Gap between plates is filled with atmospheric pressure air, and heat flux from the bottom plate.

**FIND:** (a) Temperature of the bottom plate and the ratio of the convective to radiative heat fluxes for  $\varepsilon_1 = \varepsilon_2 = 0.5$ , (b) Temperature of the bottom plate and the ratio of the convective to radiative heat fluxes for  $\varepsilon_1 = \varepsilon_2 = 0.25$  and  $0.75$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) One-dimensional heat transfer, (2) Steady-state conditions, (3) Constant properties, (4) Diffuse, gray surfaces, (5) Ideal gas behavior.

**PROPERTIES:** Table A.4, air ( $\bar{T} = 350 \text{ K}$ ):  $k = 0.030 \text{ W/m}\cdot\text{K}$ ,  $\alpha = 2.99 \times 10^{-5} \text{ m}^2/\text{s}$ ,  $\nu = 2.092 \times 10^{-5} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.70$ .

**ANALYSIS:** (a) The heat flux is composed of radiation and convection components,

$$q'' = q''_{\text{rad}} + q''_{\text{conv}} \quad (1)$$

where

$$q''_{\text{rad}} = \frac{\sigma(T_1^4 - T_2^4)}{\frac{1}{\varepsilon_1} + \frac{1}{\varepsilon_2} - 1} \quad (2)$$

and

$$q''_{\text{conv}} = \bar{h}(T_1 - T_2) \quad (3)$$

We evaluate  $\bar{h}$  by using the Globe and Dropkin correlation of Chapter 9,

$$\bar{h} = \frac{k}{L} \left[ 0.069 \text{Ra}_L^{1/3} \text{Pr}^{0.074} \right] \quad (4)$$

where

Continued...

**PROBLEM 13.99 (Cont.)**

$$Ra_L = \frac{g\beta(T_1 - T_2)L^3}{\nu\alpha} \quad (5)$$

Combining Eqs. (1) through (5) yields

$$q'' = \frac{\sigma(T_1^4 - T_2^4)}{\frac{1}{\epsilon_1} + \frac{1}{\epsilon_2} - 1} + \left[ 0.069k \left( \frac{g\beta(T_1 - T_2)}{\nu\alpha} \right)^{1/3} Pr^{0.074} \right] (T_1 - T_2) \quad (6)$$

or

$$250 \text{ W/m}^2 = \frac{5.67 \times 10^{-8} \frac{\text{W}}{\text{m}^2 \cdot \text{K}^4} \times [T_1^4 - (330\text{K})^4]}{\frac{1}{0.5} + \frac{1}{0.5} - 1} + \left[ 0.069 \times 0.030 \frac{\text{W}}{\text{m} \cdot \text{K}} \left( \frac{9.81 \frac{\text{m}}{\text{s}^2} \times \frac{1}{350\text{K}} \times (T_1 - 330)\text{K}}{2.092 \times 10^{-5} \frac{\text{m}^2}{\text{s}} \times 2.99 \times 10^{-5} \frac{\text{m}^2}{\text{s}}} \right)^{1/3} \times 0.70^{0.074} \right] \times (T_1 - 330)\text{K} \quad (7)$$

Equation (7) may be solved iteratively or with *IHT* to yield  $T_1 = 373 \text{ K}$ . <

In addition,

$$Ra_L = \frac{9.8 \frac{\text{m}}{\text{s}^2} \times \frac{1}{350\text{K}} \times (373 - 330)\text{K} \times (0.1\text{m})^3}{2.092 \times 10^{-5} \frac{\text{m}^2}{\text{s}} \times 2.99 \times 10^{-5} \frac{\text{m}^2}{\text{s}}} = 1.93 \times 10^6$$

and

$$h = \frac{0.030 \frac{\text{W}}{\text{m} \cdot \text{K}}}{0.10\text{m}} \left[ 0.069 \times (1.93 \times 10^6)^{1/3} \times 0.70^{0.074} \right] = 2.51 \frac{\text{W}}{\text{m}^2 \cdot \text{K}}$$

$$q''_{\text{conv}} = 2.52 \frac{\text{W}}{\text{m}^2 \cdot \text{K}} \times (373 - 300)\text{K} = 108 \frac{\text{W}}{\text{m}^2}$$

$$q''_{\text{rad}} = q'' - q''_{\text{conv}} = 250 \frac{\text{W}}{\text{m}^2} - 108 \frac{\text{W}}{\text{m}^2} = 142 \frac{\text{W}}{\text{m}^2}; \quad \frac{q''_{\text{conv}}}{q''_{\text{rad}}} = \frac{108}{142} = 0.76 \quad <$$

Continued...

### PROBLEM 13.99 (Cont.)

(b) Substituting  $\varepsilon_1 = \varepsilon_2 = 0.25$  into Eq. (6) yields

$$T_1 = 388.4 \text{ K}, Ra_L = 2.6 \times 10^6, \bar{h} = 2.78 \text{ W/m}^2\cdot\text{K}, q_{\text{conv}}'' = 162 \text{ W/m}^2, q_{\text{rad}}'' = 88 \text{ W/m}^2,$$
$$\frac{q_{\text{conv}}''}{q_{\text{rad}}''} = \frac{162}{88} = 1.84 \quad <$$

(c) Substituting  $\varepsilon_1 = \varepsilon_2 = 0.75$  into Eq. (6) yields

$$T_1 = 361.6 \text{ K}, Ra_L = 1.4 \times 10^6, \bar{h} = 2.26 \text{ W/m}^2\cdot\text{K}, q_{\text{conv}}'' = 72 \text{ W/m}^2, q_{\text{rad}}'' = 178 \text{ W/m}^2,$$
$$\frac{q_{\text{conv}}''}{q_{\text{rad}}''} = \frac{72}{178} = 0.40 \quad <$$

**COMMENT:** Note the increase in the temperature difference between the plates as the emissivity is reduced. Both the radiation and convection heat fluxes are highly sensitive to the plate emissivity.

### PROBLEM 13.100

**KNOWN:** Dimensions, emissivities and temperatures of heated and cooled surfaces at opposite ends of a cylindrical cavity. External conditions.

**FIND:** Required heater power and outside convection coefficient.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Opaque, diffuse-gray surfaces, (3) Negligible convection within cavity, (4) Isothermal disk and heater surfaces, (5) One-dimensional conduction in base, (6) Negligible contact resistance between heater and base, (7) Sidewall is reradiating.

**ANALYSIS:** The equivalent circuit is

From an energy balance on the heater surface,  $q_{1,\text{elec}} = q_{1,\text{cond}} + q_{1,\text{rad}}$ ,

$$q_{1,\text{elec}} = k_b \left( \frac{\pi D^2}{4} \right) \frac{T_1 - T_b}{L_b} + \frac{\sigma (T_1^4 - T_2^4)}{\frac{1 - \epsilon_1}{\epsilon_1 A_1} + \frac{1}{A_1 F_{12} + [(1/A_1 F_{1R}) + (1/A_2 F_{2R})]^{-1}} + \frac{1 - \epsilon_{2,i}}{\epsilon_{2,i} A_2}}$$

where  $A_1 = A_2 = \pi D^2/4 = \pi(0.12 \text{ m})^2/4 = 0.0113 \text{ m}^2$  and from Fig. 13.5, with  $L_c/r_1 = 3.33$  and  $r_2/L_c = 0.3$  find  $F_{12} = F_{21} = 0.077$ ; hence,  $F_{1R} = F_{2R} = 0.923$ . The required heater power is

$$q_{1,\text{elec}} = 20 \text{ W/m} \cdot \text{K} \times 0.0113 \text{ m}^2 \frac{(800 - 300) \text{ K}}{0.025 \text{ m}} + \frac{0.0113 \text{ m}^2 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (800^4 - 400^4) \text{ K}^4}{\frac{1 - 0.9}{0.9} + \frac{1}{0.077 + [(1/0.923) + (1/0.923)]^{-1}} + \frac{1 - 0.5}{0.5}}$$

$$q_{1,\text{elec}} = 4521 \text{ W} + 82.9 \text{ W} = 4604 \text{ W} \quad <$$

An energy balance for the disk yields,  $q_{\text{rad},2} = q_{\text{rad},1} = h_o A_2 (T_2 - T_\infty) + \epsilon_{2,o} A_2 \sigma (T_2^4 - T_{\text{sur}}^4)$ ,

$$h_o = \frac{82.9 \text{ W} - 0.9 \times 0.0113 \text{ m}^2 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (400^4 - 300^4) \text{ K}^4}{0.0113 \text{ m}^2 \times 100 \text{ K}} = 64 \text{ W/m}^2 \cdot \text{K} \quad <$$

**COMMENTS:** Conduction through the ceramic base represents an enormous system loss. The base should be insulated to greatly reduce this loss and hence the electric power input.

## PROBLEM 13.101

**KNOWN:** Emissivity of glass sheets. Inside and outside temperatures and convection heat transfer coefficients. Type of gas within gap.

**FIND:** Heat flux through the window for case 1:  $\varepsilon_1 = \varepsilon_2 = 0.95$ , case 2:  $\varepsilon_1 = \varepsilon_2 = 0.05$ , and case 3:  $\varepsilon_1 = 0.05$ ,  $\varepsilon_2 = 0.95$ , with either air or argon between the glass sheets.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Diffuse-gray surfaces, (2) Infinite parallel glass surfaces, (3) Negligible radiation on exterior surfaces, (4) Negligible natural convection in gap.

**PROPERTIES:** Table A.4, Air (300 K):  $k = 0.0263$  W/m·K. Table A.3, Plate Glass (300 K):  $k = 1.4$  W/m·K.

**ANALYSIS:** The thermal resistance network is shown below.

The thermal resistances are as follows.

$$\begin{aligned}
 R''_{t,conv,o} &= 1/h_o = 1/(25 \text{ W/m}^2 \cdot \text{K}) = 0.040 \text{ m}^2 \cdot \text{K/W} \\
 R''_{t,cond,gl} &= t/k_g = 0.006 \text{ m}/(1.4 \text{ W/m} \cdot \text{K}) = 0.0043 \text{ m}^2 \cdot \text{K/W} \\
 R''_{t,cond,gs} &= L/k_{gs} = 0.005 \text{ m}/(0.0263 \text{ W/m} \cdot \text{K}) = 0.190 \text{ m}^2 \cdot \text{K/W} \quad (\text{for air}) \\
 R''_{t,cond,gs} &= L/k_{gs} = 0.005 \text{ m}/(0.0177 \text{ W/m} \cdot \text{K}) = 0.282 \text{ m}^2 \cdot \text{K/W} \quad (\text{for argon}) \\
 R''_{t,conv,i} &= 1/h_i = 1/(7.7 \text{ W/m}^2 \cdot \text{K}) = 0.130 \text{ m}^2 \cdot \text{K/W} \\
 R''_{t,rad} &= \frac{1/\varepsilon_1 + 1/\varepsilon_2 - 1}{\sigma(T_1^2 + T_2^2)(T_1 + T_2)} \quad (1)
 \end{aligned}$$

Note that the radiation thermal resistance of Eq. 1 depends on the interior surface temperatures,  $T_1$  and  $T_2$ . To avoid a tedious iterative procedure, IHT is used to solve three coupled algebraic equations that may be derived by equating the heat flux from  $T_i$  to  $T_1$ , from  $T_1$  to  $T_2$ , and from  $T_2$  to  $T_o$ .

Continued...

**PROBLEM 13.101 (Cont.)**

$$\text{From } T_i \text{ to } T_1: \quad q'' = (T_i - T_1) / (R_{t,conv,i}'' + R_{t,cond,gl}'') \quad (2)$$

$$\text{From } T_1 \text{ to } T_2: \quad q'' = (T_1 - T_2) \left[ \frac{1}{R_{t,rad}''} + \frac{1}{R_{t,cond,gs}''} \right] \quad (3)$$

$$\text{From } T_2 \text{ to } T_o: \quad q'' = (T_2 - T_o) / (R_{t,cond,gl}'' + R_{t,conv,o}'') \quad (4)$$

Solving Eqs. (2) through (3) simultaneously, using the resistance values and expressions provided above, yields the following results.

Gas	$\varepsilon_1$	$\varepsilon_2$	$q''$ (W/m <sup>2</sup> )
air	0.95	0.95	106
	0.05	0.05	82.3
	0.05	0.95	83.2
argon	0.95	0.95	97.5
	0.05	0.05	66.5
	0.05	0.95	67.7

<

**COMMENTS:** (1) Switching the gas from air to argon reduces the heat flux in all cases. (2) Applying a low-emissivity coating to the glass reduces the heat flux in all cases. However, coating the interior surfaces of both glass sheets provides little benefit beyond that of coating one surface only. (3) If the gap between the glass sheets could be evacuated so that conduction in the gas becomes negligible, the heat flux through the window would be reduced significantly, to values of 72.6 and 6.98 and 3.67 W/m<sup>2</sup> for the cases 1, 2 and 3, respectively. (4) Natural convection in the gap was ignored. Is this a good assumption? (5) Radiation at the external surfaces of the glass sheets was ignored. Is this a good assumption?

## PROBLEM 13.102

**KNOWN:** Electrical conductors in the form of parallel plates having one edge mounted to a ceramic insulated base. Plates exposed to large, isothermal surroundings,  $T_{sur}$ . Operating temperature is  $T_1 = 500$  K.

**FIND:** (a) Electrical power dissipated in a conductor plate per unit length,  $q'_1$ , considering only radiative exchange with the surroundings; temperature of the ceramic insulated base  $T_2$ ; and, (b)  $q'_1$  and  $T_2$  when the surfaces experience convection with an air stream at  $T_\infty = 300$  K and a convection coefficient of  $h = 24$  W/m<sup>2</sup>·K.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Conductor surfaces are diffuse, gray, (2) Conductor and ceramic insulated base surfaces have uniform temperatures and radiosities, (3) Surroundings are large, isothermal.

**ANALYSIS:** (a) Define the opening between the conductivities as the hypothetical area  $A_3$  at the temperature of the surroundings,  $T_{sur}$ , with an emissivity  $\epsilon_3 = 1$  since all the radiation incident on the area will be absorbed. The conductor (1)-base (2)-opening (3) form a three surface enclosure with one surface reradiating (2). From Eq. 13.30, the net radiation leaving the conductor surface  $A_1$  is

$$q_1 = \frac{E_{b1} - E_{b3}}{\frac{1 - \epsilon_1}{\epsilon_1 A_1} + \frac{1}{A_1 F_{13} + [(1/A_1 F_{12}) + (1/A_3 F_{32})]^{-1}} + \frac{1 - \epsilon_3}{\epsilon_3 A_3}} \quad (1)$$

where  $E_{b1} = \sigma T_1^4$  and  $E_{b3} = \sigma T_3^4 = J_3 = 5.67 \times 10^{-8}$  W/m<sup>2</sup>·K<sup>4</sup>  $\times (300 \text{ K})^4 = 459$  W/m<sup>2</sup>. The view factors are evaluated as follows:

$F_{32}$ : use the relation for two aligned parallel rectangles, Table 13.2 or Fig. 13.4,

$$\bar{X} = X/L = w/L = 10/40 = 0.25 \quad \bar{Y} = Y/L = \infty$$

$$F_{32} = 0.1231$$

$F_{13}$ : applying reciprocity between  $A_1$  and  $A_3$ , where  $A_1 = 2L\ell = 2 \times 0.040 \text{ m} \ell = 0.080 \ell$  and  $A_3 = w\ell = 0.010 \ell$  and  $\ell$  is the length of the conductors normal to the page,  $\ell \gg L$  or  $w$ ,

$$F_{13} = \frac{A_3 F_{31}}{A_1} = 0.010 \ell \times 0.8769 / 0.080 \ell = 0.1096$$

where  $F_{31}$  can be obtained by using the summation rule on  $A_3$ ,

$$F_{31} = 1 - F_{32} = 1 - 0.1231 = 0.8769$$

$F_{12}$ : by symmetry

$$F_{12} = F_{13} = 0.1096$$

Continued ...

### PROBLEM 13.102 (Cont.)

Substituting numerical values into Eq. (1), the net radiation leaving the conductor is

$$q_1 = \frac{5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (500^4 - 300^4) \text{ K}^4}{\frac{1-0.8}{0.8 \times 0.080 \ell} + \frac{1}{0.080 \ell \times 0.1096 + [(1/0.080 \ell \times 0.1096) + (1/0.010 \ell \times 0.123)]^{-1}} + 0}$$

$$q'_1 = q_1 / \ell = \frac{(3544 - 459.3) \text{ W}}{3.1250 + 101.557 + 0} = 29.5 \text{ W/m} \quad <$$

From Eq. 13.19,

$$J_1 = -q'_1 \left[ \frac{1 - \epsilon_1}{\epsilon_1 2L} \right] + \sigma T_1^4$$

$$= -29.5 \text{ W/m}^2 \left[ \frac{1 - 0.8}{0.8 \times 2 \times 0.04 \text{ m}} \right] + 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times (500 \text{ K})^4$$

$$= 3452 \text{ W/m}^2$$

and from Eq. 13.31,

$$J_2 = \frac{J_1 A_1 F_{12} + J_3 A_3 F_{32}}{A_1 F_{12} + A_3 F_{32}} = \frac{3452 \times 2 \times 0.040 \times 0.1096 + 459 \times 0.010 \times 0.1231}{2 \times 0.040 \times 0.1096 + 0.010 \times 0.1231} = 3060 \text{ W/m}^2$$

which yields

$$T_2 = \left( \frac{J_2}{\sigma} \right)^{1/4} = \left( \frac{3060 \text{ W/m}^2}{5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4} \right)^{1/4} = 482 \text{ K} \quad <$$

(b) Consider now convection processes occurring at the conductor (1) and base (2) surfaces, and perform energy balances as illustrated in the schematic below.

*Surface 1:* The heat rate from the conductor includes convection and the net radiation heat rates,

$$q_{in} = q_{cv,1} + q_1 = h A_1 (T_1 - T_\infty) + \frac{E_{b1} - J_1}{(1 - \epsilon_1) / \epsilon_1 A_1} \quad (2)$$

Continued...

### PROBLEM 13.102 (Cont.)

and the radiosity  $J_1$  can be determined from the radiation energy balance, Eq. 13.15,

$$\frac{E_{b1} - J_1}{(1 - \varepsilon_1) / \varepsilon_1 A_1} = \frac{J_1 - J_2}{1 / A_1 F_{12}} + \frac{J_1 - J_3}{1 / A_1 F_{13}} \quad (3)$$

where  $J_3 = E_{b3} = \sigma T_3^4$  since  $A_3$  is black.

*Surface 2:* Since the surface is insulated (adiabatic), the energy balance has the form

$$0 = q_{cv,2} + q_2 = hA_2(T_2 - T_\infty) + \frac{E_{b2} - J_2}{1 - \varepsilon_2 / \varepsilon_2 A_2} \quad (4)$$

and the radiosity  $J_2$  can be determined from the radiation energy balance, Eq. 13.21,

$$\frac{E_{b2} - J_2}{(1 - \varepsilon_2) / \varepsilon_2 A_2} = \frac{J_2 - J_1}{1 / A_2 F_{21}} + \frac{J_2 - J_3}{1 / A_2 F_{23}} \quad (5)$$

There are 4 equations, Eqs. (2-5), with 4 unknowns:  $J_1$ ,  $J_2$ ,  $T_2$  and  $q_1$ . Substituting numerical values, the simultaneous solution to the set yields

$$J_1 = 3417 \text{ W/m}^2 \quad J_2 = 1745 \text{ W/m}^2 \quad T_2 = 352 \text{ K} \quad q'_{in} = 441 \text{ W/m} \quad <$$

**COMMENTS:** (1) The effect of convection is substantial, increasing the heat removal rate from 29.5 W to 441 W for the combined modes. (2) With the convection process, the current carrying capacity of the conductors can be increased. Another advantage is that, with the presence of convection, the ceramic base operates at a cooler temperature: 352 K vs. 482 K.

### PROBLEM 13.103

**KNOWN:** Surface temperature and spectral radiative properties. Temperature of ambient air. Solar irradiation or temperature of shield.

**FIND:** (a) Convection heat transfer coefficient when surface is exposed to solar radiation, (b) Temperature of shield needed to maintain prescribed surface temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Surface is diffuse ( $\alpha_\lambda = \epsilon_\lambda$ ), (2) Bottom of surface is adiabatic, (3) Atmospheric irradiation is negligible, (4) With shield, convection coefficient is unchanged and radiation losses at ends are negligible (two-surface enclosure).

**ANALYSIS:** (a) From a surface energy balance,

$$\alpha_S G_S = \epsilon_S \sigma T_S^4 + h(T_S - T_\infty).$$

Emission occurs mostly at long wavelengths, hence  $\epsilon_S = \alpha_2 = 0.3$ . However,

$$\alpha_S = \frac{\int_0^\infty \alpha_\lambda E_{\lambda,b}(\lambda, 5800 \text{ K}) d\lambda}{E_b} = \alpha_1 F_{(0-1\mu\text{m})} + \alpha_2 F_{(1-\infty)}$$

and from Table 12.1 at  $\lambda T = 5800 \mu\text{m}\cdot\text{K}$ ,  $F_{(0-1\mu\text{m})} = 0.720$  and hence,  $F_{(1-\infty)} = 0.280$  giving  $\alpha = 0.9 \times 0.72 + 0.3 \times 0.280 = 0.732$ .

Hence

$$h = \frac{\alpha_S G_S - \epsilon_S \sigma T_S^4}{T_S - T_\infty} = \frac{0.732(1200 \text{ W/m}^2) - 0.3 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (320 \text{ K})^4}{20 \text{ K}}$$

$$h = 35 \text{ W/m}^2 \cdot \text{K}. \quad <$$

(b) Since the plate emits mostly at long wavelengths,  $\alpha_s = \epsilon_s = 0.3$ . Hence radiation exchange is between two diffuse-gray surfaces.

$$q''_{ps} = \frac{\sigma(T_p^4 - T_s^4)}{1/\epsilon_p + 1/\epsilon_s - 1} = q''_{\text{conv}} = h(T_s - T_\infty)$$

$$T_p^4 = (h/\sigma)(T_s - T_\infty)(1/\epsilon_p + 1/\epsilon_s - 1) + T_s^4$$

$$T_p^4 = \frac{35 \text{ W/m}^2 \cdot \text{K}(20 \text{ K})}{5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4} \left( \frac{1}{0.8} + \frac{1}{0.3} - 1 \right) + (320 \text{ K})^4 \quad T_p = 484 \text{ K}. \quad <$$

**COMMENTS:** For  $T_p = 484 \text{ K}$  and  $\lambda = 1 \mu\text{m}$ ,  $\lambda T = 484 \mu\text{m}\cdot\text{K}$  and  $F_{(0-\lambda)} = 0.000$ . Hence assumption of  $\alpha_s = 0.3$  is excellent.

### PROBLEM 13.104

**KNOWN:** Long uniform rod with volumetric energy generation positioned coaxially within a larger circular tube maintained at 500°C.

**FIND:** (a) Center  $T_1(0)$  and surface  $T_{1s}$  temperatures of the rod for evacuated space, (b)  $T_1(0)$  and  $T_{1s}$  for airspace, (c) Effect of tube diameter and emissivity on  $T_1(0)$  and  $T_{1s}$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) All surfaces are diffuse-gray.

**PROPERTIES:** Table A-4, Air ( $\bar{T} = 780$  K):  $\nu = 81.5 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0563 \text{ W/m}\cdot\text{K}$ ,  $\alpha = 115.6 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\beta = 0.00128 \text{ K}^{-1}$ ,  $\text{Pr} = 0.706$ .

**ANALYSIS:** (a) The net heat exchange by radiation between the rod and the tube is

$$q'_{12} = \frac{\sigma(T_1^4 - T_2^4)}{(1 - \epsilon_1)/\epsilon_1 \pi D_1 + 1/\pi D_1 F_{12} + (1 - \epsilon_2)/\epsilon_2 \pi D_2} \quad (1)$$

and, from an energy balance on the rod,  $-\dot{E}'_{\text{out}} + \dot{E}'_{\text{gen}} = 0$ , or

$$q'_{12} = \dot{q}(\pi D_1^2 / 4). \quad (2)$$

Combining Eqs. (1) and (2) and substituting numerical values, with  $F_{12} = 1$ , we obtain

$$\begin{aligned} \dot{q} &= \frac{4}{D_1} \left[ \frac{\sigma(T_1^4 - T_2^4)}{(1 - \epsilon_1)/\epsilon_1 + 1 + [(1 - \epsilon_2)/\epsilon_2](D_1/D_2)} \right] \\ 20 \times 10^3 \frac{\text{W}}{\text{m}^3} &= \frac{4}{0.050 \text{ m}} \left[ \frac{5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (T_{1s}^4 - 773^4) \text{ K}^4}{(1 - 0.2)/0.2 + 1 + [(1 - 0.2)/0.2](0.050/0.060)} \right] \\ &= 54.4 \times 10^{-8} (T_{1s}^4 - 773^4) \text{ W/m}^3 \end{aligned}$$

$$T_{1s} = 792 \text{ K.} \quad <$$

From Eq. 3.53, the rod center temperature is

$$\begin{aligned} T_1(0) &= \frac{\dot{q}(D_1/2)^2}{4k} + T_{1s} \\ T_1(0) &\approx \frac{20 \times 10^3 \text{ W/m}^3 (0.050 \text{ m}/2)^2}{4 \times 15 \text{ W/m}\cdot\text{K}} + 792 \text{ K} = 0.21 \text{ K} + 792 \text{ K} = 792.2 \text{ K.} \quad < \end{aligned}$$

(b) The convection heat rate is given by Eqs. 9.58 through 9.60. The length scale is  $L_c = 2[\ln(0.06/0.05)]^{4/3} / (0.025 \text{ m}^{-3/5} + 0.030 \text{ m}^{-3/5})^{5/3} = 0.0018 \text{ m}$ . Assuming a maximum possible value of  $(T_{s1} - T_2) = 19 \text{ K}$ ,  $\text{Ra}_c = g\beta(T_{s1} - T_2)L_c^3/\nu\alpha = 9.8 \text{ m/s}^2(0.00128 \text{ K}^{-1})19 \text{ K}(0.0018 \text{ m})^3/(81.5 \times 10^{-6} \text{ m}^2/\text{s} \times 115.6 \times 10^{-6} \text{ m}^2/\text{s}) = 0.142$  and  $k_{\text{eff}}/k = 0.386 \times [0.706/(0.861 + 0.706)]^{1/4} (0.142)^{1/4} = 0.194$ . Since  $k_{\text{eff}}/k$  is predicted to be less than unity, conduction occurs within the gap.

Continued ...

### PROBLEM 13.104 (Cont.)

Hence, from Eq. 3.32,

$$q'_{\text{cond}} = \frac{2\pi k(T_{1s} - T_2)}{\ln(r_2/r_1)} = \frac{2\pi(0.0563 \text{ W/m}\cdot\text{K})(T_{1s} - 773) \text{ K}}{\ln(30/25)} = 1.94(T_{1s} - 773)$$

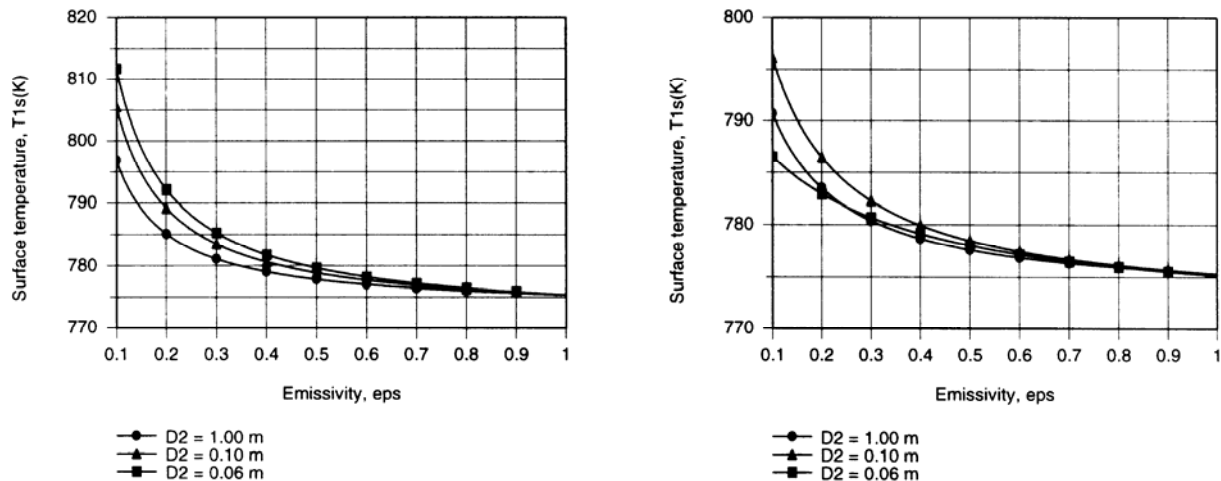

The energy balance then becomes  $\dot{q}(\pi D_1^2/4) = q'_{12} + q'_{\text{cond}}$ , or

$$\dot{q} = \left(4/\pi D_1^2\right)(q'_{12} + q'_{\text{cond}})$$

$$2 \times 10^4 = \left[54.4 \times 10^{-8} (T_{1s}^4 - 773^4) + 988(T_{1s} - 773)\right]$$

$$T_{1s} = 783 \text{ K} \qquad T_1(0) = 783.2 \text{ K} \qquad <$$

(c) Entering the foregoing model and the prescribed properties of air into the *IHT* workspace, the parametric calculations were performed for  $D_2 = 0.06 \text{ m}$  and  $D_2 = 0.10 \text{ m}$ . For  $D_2 = 1.0 \text{ m}$ ,  $Ra_c^* > 100$  and heat transfer across the airspace is by free convection, instead of conduction. In this case, convection was evaluated by entering Eqs. 9.58 – 9.60 into the workspace. The results are plotted as follows.

The first graph corresponds to the evacuated space, and the surface temperature decreases with increasing  $\epsilon_1 = \epsilon_2$ , as well as with  $D_2$ . The increased emissivities enhance the effectiveness of emission at surface 1 and absorption at surface 2, both which have the effect of reducing  $T_{1s}$ . Similarly, with increasing  $D_2$ , more of the radiation emitted from surface 1 is ultimately absorbed at 2 (less of the radiation reflected by surface 2 is intercepted by 1). The second graph reveals the expected effect of a reduction in  $T_{1s}$  with inclusion of conduction or convection heat transfer across the air. For small emissivities ( $\epsilon_1 = \epsilon_2 < 0.2$ ), conduction across the air is significant relative to radiation, and the small conduction resistance corresponding to  $D_2 = 0.06 \text{ m}$  yields the smallest value of  $T_{1s}$ . However, with increasing  $\epsilon$ , conduction/convection effects diminish relative to radiation and the trend reverts to one of decreasing  $T_{1s}$  with increasing  $D_2$ .

**COMMENTS:** For this situation, the temperature variation *within* the rod is small and independent of surface conditions.

### PROBLEM 13.105

**KNOWN:** Side wall and gas temperatures for adjoining semi-cylindrical ducts. Gas flow convection coefficients.

**FIND:** (a) Temperature of intervening wall, (b) Verification of gas temperature on one side.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) All duct surfaces may be approximated as blackbodies, (2) Fully developed conditions, (3) Negligible temperature difference across intervening wall, (4) Gases are nonparticipating media.

**ANALYSIS:** (a) Applying an energy balance to a control surface about the wall yields

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

Assuming  $T_{g,1} > T_w > T_{g,2}$ , it follows that

$$q_{\text{rad}(1 \rightarrow w)} + q_{\text{conv}(g1 \rightarrow w)} = q_{\text{rad}(w \rightarrow 2)} + q_{\text{conv}(w \rightarrow g2)}$$

$$A_1 F_{1w} \sigma (T_1^4 - T_w^4) + h A_w (T_{g,1} - T_w) = A_w F_{w2} \sigma (T_w^4 - T_2^4) + h A_w (T_w - T_{g,2})$$

and with

$$A_1 F_{1w} = A_w F_{w1} = A_w F_{w2} = A_w$$

and substituting numerical values,

$$2\sigma T_w^4 + 2hT_w = \sigma (T_1^4 + T_2^4) + h(T_{g,1} + T_{g,2})$$

$$11.34 \times 10^{-8} T_w^4 + 10T_w = 13,900.$$

which yields

$$T_w \approx 526 \text{ K.} \quad \leftarrow$$

(b) Applying an energy balance to a control surface about the hot gas (g1) yields

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$hA_1 (T_1 - T_{g1}) = hA_w (T_{g1} - T_w)$$

or

$$T_1 - T_{g1} = [D / (\pi D / 2)] (T_{g1} - T_w)$$

$$29^\circ\text{C} = 29^\circ\text{C.} \quad \leftarrow$$

**COMMENTS:** Since there is no change in any of the temperatures in the axial direction, this scheme simply provides for energy transfer from side wall 1 to side wall 2.

### PROBLEM 13.106

**KNOWN:** Dimensions of stainless steel pillar and nominal glass temperatures. Contact resistance between pillar and glass. Emissivity of inner glass surfaces. Unit area dimensions.

**FIND:** Ratio of conduction to radiation heat transfer through a unit area.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Constant properties, (3) Diffuse-gray surfaces, (4) Two-dimensional conduction, (5) Pillar does not affect radiation heat transfer ( $D/W \ll 1$ ), (6) Radiation heat transfer does not affect conduction in low-emissivity stainless steel pillar.

**PROPERTIES:** Table A.1, AISI 302 stainless steel (300 K):  $k_p = 15.1 \text{ W/m}\cdot\text{K}$ . Table A.3, plate glass (300 K):  $k_g = 1.4 \text{ W/m}\cdot\text{K}$ .

**ANALYSIS:** The conduction and radiation processes are decoupled. Conduction through the pillar results in a depression of the glass temperature in the immediate vicinity of the pillar. This is associated with a constriction resistance within each glass sheet. Therefore, the resistance network consists of two constriction resistances, two contact resistances, and a conduction resistance through the pillar as shown below.

Using the shape factor for Case 10 of Table 4.1(a), the resistances are:

$$R_{t,\text{cons}} = 1/(Sk_g) = 1/(2Dk_g) = 1/(2 \times 0.15 \times 10^{-3} \text{ m} \times 1.4 \text{ W/m}\cdot\text{K}) = 2381 \text{ K/W}$$

$$R_{t,c} = R_{t,c}'' / A_p = 1.5 \times 10^{-6} \text{ m}^2 \cdot \text{K/W} / \left[ \pi \times (0.15 \times 10^{-3} \text{ m})^2 / 4 \right] = 84.88 \text{ K/W}$$

$$R_{t,\text{cond}} = L/k_p A_p = L/k_p \left( \pi D_p^2 / 4 \right) = 0.4 \times 10^{-3} \text{ m} / \left[ 15.1 \text{ W/m}\cdot\text{K} \times \pi \times (0.15 \times 10^{-3} \text{ m})^2 / 4 \right] = 1500 \text{ K/W}$$

Therefore, the total resistance is

$$R_{\text{tot}} = 2(R_{t,\text{cons}} + R_{t,c}) + R_{t,\text{cond}} = 2 \times (2381 \text{ K/W} + 84.88 \text{ K/W}) + 1500 \text{ K/W} = 6430 \text{ K/W}$$

and the conduction through an individual pillar is

$$q_{\text{cond}} = (T_1 - T_2)/R_{\text{tot}} = [20 - (-10)^\circ\text{C}] / [6430 \text{ K/W}] = 4.66 \times 10^{-3} \text{ W} = 4.66 \text{ mW}$$

Continued...

### PROBLEM 13.106 (Cont.)

For  $W = 10$  mm, net radiation heat rate between the glass sheets through the unit area is

$$q_{\text{rad},10} = \frac{W^2 \sigma (T_1^4 - T_2^4)}{\frac{1}{\varepsilon_1} + \frac{1}{\varepsilon_2} - 1} = \frac{(0.01 \text{ m})^2 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (293\text{K}^4 - 263\text{K}^4)}{\frac{1}{0.95} + \frac{1}{0.05} - 1} = 0.73 \times 10^{-3} \text{ W} = 0.73 \text{ mW}$$

Similarly, for  $W = 20$  and  $30$  mm,  $q_{\text{rad},20} = 2.9 \text{ mW}$  ;  $q_{\text{rad},30} = 6.6 \text{ mW}$ . Therefore, the ratio of conduction to radiation through a unit area is

$$R = 6.38, 1.59, \text{ and } 0.709 \quad <$$

for  $W = 10, 20$  and  $30$  mm, respectively.

**COMMENTS:** (1) Although the pillars are small, they account for a large amount of the total heat transfer through the window, especially for small values of  $W$ . (2) The radiation and conduction effects become coupled in the immediate vicinity of the pillar. (3) Temperature differences also exist across the glass sheets, however these differences are relatively small. For  $W = 10$  mm, and for a glass sheet thickness of  $t = 6$  mm, the temperature difference across one sheet of glass may be estimated to be  $\Delta T = (q_{\text{rad},10} + q_{\text{cond}})t / (k_g W^2) = (0.73 \times 10^{-3} \text{ W} + 4.66 \times 10^{-3} \text{ W}) \times 0.006 \text{ m} / (1.4 \text{ W/m}\cdot\text{K} \times 0.01 \text{ m} \times 0.01 \text{ m}) = 0.23 \text{ K}$ . (4) Heat transfer through the window can be reduced by increasing the pillar length. However, practical limitations exist since sealing the edges of the window in order to maintain a high vacuum becomes more difficult as  $L$  increases. (5) See Manz, Brunner and Wullschleger, "Triple Vacuum Glazing: Heat Transfer and Basic Design Constraints," *Solar Energy*, Vol. 80, pp. 1632-1642, 2006 for more information.

### PROBLEM 13.107

**KNOWN:** Temperature, dimensions and arrangement of heating elements between two large parallel plates, one insulated and the other of prescribed temperature. Convection coefficients associated with elements and bottom surface.

**FIND:** (a) Temperature of gas enclosed by plates, (b) Element electric power requirement, (c) Rate of heat transfer to  $1 \text{ m} \times 1 \text{ m}$  section of panel.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Diffuse-gray surfaces, (2) Negligible end effects since the surfaces form an enclosure, (3) Gas is nonparticipating, (4) Surface 3 is reradiating with negligible conduction and convection.

**ANALYSIS:** (a) Performing an energy balance for a unit control surface about the gas space,

$$\dot{E}_{in} - \dot{E}_{out} = 0.$$

$$\bar{h}_1 \pi D (T_1 - T_m) - \bar{h}_2 s (T_m - T_2) = 0$$

$$T_m = \frac{\bar{h}_1 \pi D T_1 + \bar{h}_2 s T_2}{\bar{h}_1 \pi D + \bar{h}_2 s} = \frac{10 \text{ W/m}^2 \cdot \text{K} \pi (0.025 \text{ m}) 600 \text{ K} + 2 \text{ W/m}^2 \cdot \text{K} (0.05 \text{ m}) 400 \text{ K}}{10 \text{ W/m}^2 \cdot \text{K} \pi (0.025 \text{ m}) + 2 \text{ W/m}^2 \cdot \text{K} (0.05 \text{ m})}$$

$$T_m = 577 \text{ K.}$$

(b) The equivalent thermal circuit is

The energy balance on surface 1 is

$$q'_{1,elec} = q'_{1,conv} + q'_{1,rad}$$

where  $q'_{1,rad}$  can be evaluated by considering a unit cell of the form

$$A'_1 = \pi D = \pi (0.025 \text{ m}) = 0.0785 \text{ m}^2$$

$$A'_2 = A'_3 = s = 0.05 \text{ m}^2$$

Continued ...

**PROBLEM 13.107 (Cont.)**

The view factors are:

$$F_{21} = 1 - \left[ 1 - (D/s)^2 \right]^{1/2} + (D/s) \tan^{-1} \left[ \left( s^2 - D^2 \right) / D^2 \right]^{1/2}$$

$$F_{21} = 1 - \left[ 1 - 0.25 \right]^{1/2} + 0.5 \tan^{-1} (4 - 1)^{1/2} = 0.658 = F_{31}$$

$$F_{23} = 1 - F_{21} = 0.342 = F_{32}.$$

For the unit cell,

$$A'_2 F_{21} = s F_{21} = 0.05 \text{ m} \times 0.658 = 0.0329 \text{ m} = A'_1 F_{12} = A'_3 F_{31} = A'_1 F_{13}$$

$$A'_2 F_{23} = s F_{23} = 0.05 \text{ m} \times 0.342 = 0.0171 \text{ m} = A'_3 F_{32}.$$

Hence,

$$q'_{1,\text{rad}} = \frac{E_{b1} - E_{b2}}{R'_{\text{equiv}} + (1 - \varepsilon_2) / \varepsilon_2 A'_2}$$

$$R'_{\text{equiv}} = A'_1 F_{12} + \frac{1}{1/A'_1 F_{13} + 1/A'_2 F_{23}} = \left( 0.0329 + \frac{1}{(0.0329)^{-1} + (0.0171)^{-1}} \right) \text{ m}$$

$$R'_{\text{equiv}} = 22.6 \text{ m}^{-1}.$$

Hence

$$q'_{1,\text{rad}} = \frac{5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (600^4 - 400^4) \text{ K}^4}{[22.6 + (1 - 0.5) / 0.5 \times 0.05] \text{ m}^{-1}} = 138.3 \text{ W/m}$$

$$q'_{1,\text{conv}} = \bar{h}_1 \pi D (T_1 - T_m) = 10 \text{ W/m}^2 \cdot \text{K} \pi (0.025 \text{ m}) (600 - 577) \text{ K} = 17.8 \text{ W/m}$$

$$q'_{1,\text{elec}} = (138.3 + 17.8) \text{ W/m} = 156 \text{ W/m}. \quad <$$

(c) Since all energy added via the heating elements must be transferred to surface 2,

$$q'_2 = q'_1.$$

Hence, since there are 20 elements in a 1 m wide strip,

$$q_2(1\text{m} \times 1\text{m}) = 20 \times q'_{1,\text{elec}} = 3120 \text{ W}. \quad <$$

**COMMENTS:** The bottom panel would have to be cooled (from below) by a heat sink which could dissipate  $3120 \text{ W/m}^2$ .

### PROBLEM 13.108

**KNOWN:** Two large parallel plates, temperature of each plate. Bare plate and paint emissivities, thickness of paint layers.

**FIND:** (a) Radiation heat flux across the gap for  $\epsilon_1 = \epsilon_2 = \epsilon_s = 0.85$ , (b) Radiation heat flux across the gap for  $\epsilon_1 = \epsilon_2 = \epsilon_p = 0.98$ , (c) Radiation heat flux across the gap when the paint layer thickness is  $L = 2$  mm and paint thermal conductivity is  $k = 0.21$  W/m·K, (d) Plot of the radiation heat flux across the gap as a function of the surface emissivity over the range  $0.05 \leq \epsilon_s \leq 0.95$ . Show the heat flux of the painted surface with thin and thick paint layers on the same graph.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) One-dimensional heat transfer, (2) Diffuse, gray surfaces, (3) Negligible contact resistance between the plate and the paint.

**PROPERTIES:** Paint (given):  $k = 0.21$  W/m·K.

**ANALYSIS:** (a) The radiation heat flux across the gap is

$$q_{\text{rad}}'' = \frac{\sigma(T_1^4 - T_2^4)}{\frac{1}{\epsilon_1} + \frac{1}{\epsilon_2} - 1} = \frac{5.67 \times 10^{-8} \frac{\text{W}}{\text{m}^2 \cdot \text{K}^4} \times (350^4 - 300^4) \text{K}^4}{\frac{1}{0.85} + \frac{1}{0.85} - 1} = 289.4 \frac{\text{W}}{\text{m}^2} \quad (1) <$$

(b) With  $\epsilon_1 = \epsilon_2 = \epsilon_p = 0.98$ ,

$$q_{\text{rad}}'' = \frac{5.67 \times 10^{-8} \frac{\text{W}}{\text{m}^2 \cdot \text{K}^4} \times (350^4 - 300^4) \text{K}^4}{\frac{1}{0.98} + \frac{1}{0.98} - 1} = 376.2 \frac{\text{W}}{\text{m}^2} <$$

(c) After painting both surfaces, the thermal resistance network is

Continued...

### PROBLEM 13.108 (Cont.)

$$q'' = \frac{k_p}{L_p}(T_1 - T_{s,1}) = \frac{0.21 \frac{\text{W}}{\text{m} \cdot \text{K}}}{2 \times 10^{-3} \text{ m}}(350\text{K} - T_{s,1}) \quad (2)$$

$$q'' = \frac{\sigma(T_{s,1}^4 - T_{s,2}^4)}{\frac{1}{\varepsilon_p} + \frac{1}{\varepsilon_p} - 1} = \frac{5.67 \times 10^{-8} \frac{\text{W}}{\text{m}^2 \cdot \text{K}^4}}{\frac{1}{0.98} + \frac{1}{0.98} - 1} \quad (3)$$

$$q'' = \frac{k_p}{L_p}(T_{s,2} - T_2) = \frac{0.21 \frac{\text{W}}{\text{m} \cdot \text{K}}}{2 \times 10^{-3} \text{ m}}(T_{s,2} - 300\text{K}) \quad (4)$$

Solving Eqs. (2) through (4) simultaneously yields

$$T_{s,1} = 346.9 \text{ K}, T_{s,2} = 303.1 \text{ K}, q'' = q''_{\text{rad}} = q''_{\text{cond}} = 328.7 \frac{\text{W}}{\text{m}^2} \quad <$$

(d) Solving Eq. (1) over the range  $0.05 \leq \varepsilon \leq 0.95$  yields the following.

**COMMENTS:** (1) The paint is effective in increasing radiation heat transfer across the gap for all but very high emissivity bare surfaces. (2) Thick paint layers will result in significant thermal conduction resistances which, in turn, reduce heat transfer across the gap. (3) Use of paints is usually restricted to relatively low temperatures. (4) Thermal contact resistances may be large if flaking or peeling of the paint becomes significant.

### PROBLEM 13.109

**KNOWN:** Ceiling temperature of furnace. Thickness, thermal conductivity, and/or emissivities of alternative thermal insulation systems. Convection coefficient at outer surface and temperature of surroundings.

**FIND:** (a) Mathematical model for each system, (b) Temperature of outer surface  $T_{s,o}$  and heat loss  $q''$  for each system and prescribed conditions, (c) Effect of emissivity on  $T_{s,o}$  and  $q''$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, (2) Diffuse/gray surfaces, (3) Surroundings form a large enclosure about the furnace, (4) Radiation in air space corresponds to a two-surface enclosure of large parallel plates.

**PROPERTIES:** Table A-4, air ( $T_f = 730$  K):  $k = 0.055$  W/m·K,  $\alpha = 1.09 \times 10^{-4}$  m<sup>2</sup>/s,  $\nu = 7.62 \times 10^{-5}$  m<sup>2</sup>/s,  $\beta = 0.001335$  K<sup>-1</sup>, Pr = 0.702.

**ANALYSIS:** (a) To obtain  $T_{s,o}$  and  $q''$ , an energy balance must be performed at the outer surface of the shield.

*Insulation:*  $q''_{\text{cond}} = q''_{\text{conv},o} + q''_{\text{rad},o} = q''$

$$k \frac{(T_{s,i} - T_{s,o})}{L} = h_o (T_{s,o} - T_\infty) + \epsilon_o \sigma (T_{s,o}^4 - T_{\text{sur}}^4)$$

*Air Space:*  $q''_{\text{conv},i} + q''_{\text{rad},i} = q''_{\text{conv},o} + q''_{\text{rad},o} = q''$

$$h_i (T_{s,i} - T_{s,o}) + \frac{\sigma (T_{s,i}^4 - T_{s,o}^4)}{\frac{1}{\epsilon_i} + \frac{1}{\epsilon_o} - 1} = h_o (T_{s,o} - T_\infty) + \epsilon_o \sigma (T_{s,o}^4 - T_{\text{sur}}^4)$$

where Eq. 13.24 has been used to evaluate  $q''_{\text{rad},i}$  and  $h_i$  is given by Eq. 9.49

$$\overline{\text{Nu}}_L = \frac{h_i L}{k} = 0.069 \text{Ra}_L^{1/3} \text{Pr}^{0.074}$$

(b) For the prescribed conditions ( $\epsilon_i = \epsilon_o = 0.5$ ), the following results were obtained.

*Insulation:* The energy equation becomes

$$\frac{0.09 \text{ W/m} \cdot \text{K} (900 - T_{s,o}) \text{ K}}{0.025 \text{ m}} = 25 \text{ W/m}^2 \cdot \text{K} (T_{s,o} - 300) \text{ K} + 0.5 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (T_{s,o}^4 - 300^4) \text{ K}^4$$

Continued ...

### PROBLEM 13.109 (Cont.)

and a trial-and-error solution yields

$$T_{s,o} = 366 \text{ K} \quad q'' = 1920 \text{ W/m}^2 \quad \leftarrow$$

*Air-Space:* The energy equation becomes

$$\begin{aligned} h_i (900 - T_{s,o}) \text{ K} + \frac{5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (900^4 - T_{s,o}^4) \text{ K}^4}{3} \\ = 25 \text{ W/m}^2 \cdot \text{K} (T_{s,o} - 300) \text{ K} + 0.5 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (T_{s,o}^4 - 300^4) \text{ K}^4 \end{aligned}$$

where

$$h_i = \frac{0.055 \text{ W/m} \cdot \text{K}}{0.025 \text{ m}} 0.069 \text{ Ra}_L^{1/3} \text{ Pr}^{0.074} \quad (1)$$

and  $\text{Ra}_L = g\beta(T_{s,i} - T_{s,o})L^3/\alpha\nu$ . A trial-and-error solution, which includes reevaluation of the air properties, yields

$$T_{s,o} = 598 \text{ K} \quad q'' = 10,849 \text{ W/m}^2 \quad \leftarrow$$

The inner and outer heat fluxes are  $q''_{\text{conv},i} = 867 \text{ W/m}^2$ ,  $q''_{\text{rad},i} = 9982 \text{ W/m}^2$ ,  $q''_{\text{conv},o} = 7452 \text{ W/m}^2$ , and  $q''_{\text{rad},o} = 3397 \text{ W/m}^2$ .

(c) Entering the foregoing models into the *IHT* workspace, the following results were generated.

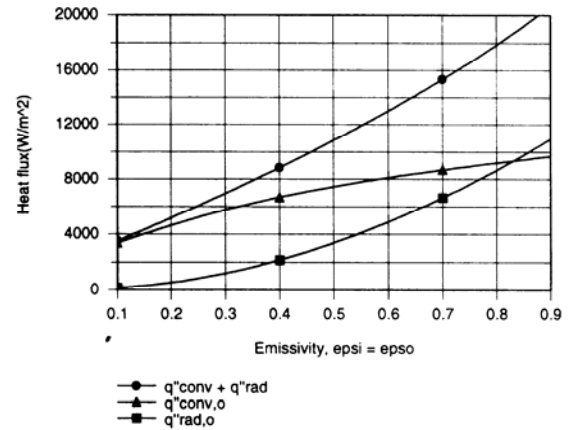

*Insulation:*

Continued ...

### PROBLEM 13.109 (Cont.)

As expected, the outer surface temperature decreases with increasing  $\epsilon_o$ . However, the reduction in  $T_{s,o}$  is not large since heat transfer from the outer surface is dominated by convection.

In this case  $T_{s,o}$  increases with increasing  $\epsilon_o = \epsilon_i$  and the effect is significant. The effect is due to an increase in radiative transfer from the inner surface, with  $q''_{rad,i} = q''_{conv,i} = 1750 \text{ W/m}^2$  for  $\epsilon_o = \epsilon_i = 0.1$  and  $q''_{rad,i} = 20,100 \text{ W/m}^2 \gg q''_{conv,i} = 523 \text{ W/m}^2$  for  $\epsilon_o = \epsilon_i = 0.9$ . With the increase in  $T_{s,o}$ , the total heat flux increases, along with the relative contribution of radiation ( $q''_{rad,o}$ ) to heat transfer from the outer surface.

**COMMENTS:** (1) With no insulation or radiation shield and  $\epsilon_i = 0.5$ , radiation and convection heat fluxes from the ceiling are  $18,370$  and  $15,000 \text{ W/m}^2$ , respectively. Hence, a significant reduction in the heat loss results from use of the insulation or the shield, although the insulation is clearly more effective.

(2) Rayleigh numbers associated with free convection in the air space are well below the lower limit of applicability of Eq. (1). Hence, the correlation was used outside its designated range, and the error associated with evaluating  $h_j$  may be large.

(3) The *IHT* solver had difficulty achieving convergence in the first calculation performed for the radiation shield, since the energy balance involves two nonlinear terms due to radiation and one due to convection. To obtain a solution, a fixed value of  $Ra_L$  was prescribed for Eq. (1), while a second value of  $Ra_{L,2} \equiv g\beta(T_{s,i} - T_{s,o})L^3/\alpha\nu$  was computed from the solution. The prescribed value of  $Ra_L$  was replaced by the value of  $Ra_{L,2}$  and the calculations were repeated until  $Ra_{L,2} = Ra_L$ .

### PROBLEM 13.110

**KNOWN:** Dimensions of a composite insulation consisting of honeycomb core sandwiched between solid slabs.

**FIND:** Total thermal resistance.

**SCHEMATIC:** Because of the repetitive nature of the honeycomb core, the cell sidewalls will be adiabatic. That is, there is no lateral heat transfer from cell to cell, and it suffices to consider the heat transfer across a single cell.

**ASSUMPTIONS:** (1) One-dimensional, steady-state conditions, (2) Equivalent conditions for each cell, (3) Constant properties, (4) Diffuse, gray surface behavior.

**PROPERTIES:** Table A-3, Particle board (low density):  $k_1 = 0.078 \text{ W/m}\cdot\text{K}$ ; Particle board (high density):  $k_2 = 0.170 \text{ W/m}\cdot\text{K}$ ; For both board materials,  $\varepsilon = 0.85$ ; Table A-4, Air ( $\bar{T} \approx 7.5^\circ\text{C}$ , 1 atm):  $\nu = 14.15 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0247 \text{ W/m}\cdot\text{K}$ ,  $\alpha = 19.9 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.71$ ,  $\beta = 3.57 \times 10^{-3} \text{ K}^{-1}$ .

**ANALYSIS:** The total resistance of the composite is determined by conduction, convection and radiation processes occurring within the honeycomb and by conduction across the inner and outer slabs. The corresponding thermal circuit is shown.

The total resistance of the composite and equivalent resistance for the honeycomb are

$$R = R_{\text{cond},i} + R_{\text{eq}} + R_{\text{cond},o} \quad R_{\text{eq}}^{-1} = \left( R_{\text{cond}}^{-1} + R_{\text{conv}}^{-1} + R_{\text{rad}}^{-1} \right)_{\text{hc}}$$

The component resistances may be evaluated as follows. The inner and outer slabs are plane walls, for which the thermal resistance is given by Eq. 3.6. Hence, since  $L_1 = L_3$  and the slabs are constructed from low-density particle board.

$$R_{\text{cond},i} = R_{\text{cond},o} = \frac{L_1}{k_1 W^2} = \frac{0.0125 \text{ m}}{0.078 \text{ W/m}\cdot\text{K} (0.01 \text{ m})^2} = 1603 \text{ K/W.}$$

Similarly, applying Eq. 3.6 to the side walls of the cell

$$\begin{aligned} R_{\text{cond},\text{hc}} &= \frac{L_2}{k_2 \left[ W^2 - (W-t)^2 \right]} = \frac{L_2}{k_2 (2Wt - t^2)} \\ &= \frac{0.050 \text{ m}}{0.170 \text{ W/m}\cdot\text{K} \left[ 2 \times 0.01 \text{ m} \times 0.002 \text{ m} - (0.002 \text{ m})^2 \right]} = 8170 \text{ K/W.} \end{aligned}$$

Continued ...

### PROBLEM 13.110 (Cont.)

From Eq. 3.9 the convection resistance associated with the cellular airspace may be expressed as

$$R_{\text{conv, hc}} = 1/h(W-t)^2.$$

The cell forms an enclosure that may be classified as a horizontal cavity heated from below, and the appropriate form of the Rayleigh number is  $Ra_L = g\beta(T_1 - T_2)L_2^3/\alpha\nu$ . To evaluate this parameter, however, it is necessary to *assume* a value of the cell temperature difference. As a first approximation,  $T_1 - T_2 = 15^\circ\text{C} - (-5^\circ\text{C}) = 20^\circ\text{C}$ ,

$$Ra_L = \frac{9.8 \text{ m/s}^2 \left(3.57 \times 10^{-3} \text{ K}^{-1}\right) (20 \text{ K}) (0.05 \text{ m})^3}{19.9 \times 10^{-6} \text{ m}^2/\text{s} \times 14.15 \times 10^{-6} \text{ m}^2/\text{s}} = 3.11 \times 10^5.$$

Applying Eq. 9.49 as a first approximation, it follows that

$$h = (k/L_2) \left[ 0.069 Ra_L^{1/3} Pr^{0.074} \right] = \frac{0.0247 \text{ W/m} \cdot \text{K}}{0.05 \text{ m}} \left[ 0.069 \left(3.11 \times 10^5\right)^{1/3} (0.71)^{0.074} \right] = 2.25 \text{ W/m}^2 \cdot \text{K}.$$

The convection resistance is then

$$R_{\text{conv, hc}} = \frac{1}{2.25 \text{ W/m}^2 \cdot \text{K} (0.01 \text{ m} - 0.002 \text{ m})^2} = 6944 \text{ K/W}.$$

The resistance to heat transfer by radiation may be obtained by first noting that the cell forms a three-surface enclosure for which the sidewalls are reradiating. The net radiation heat transfer between the end surfaces of the cell is then given by Eq. 13.30. With  $\varepsilon_1 = \varepsilon_2 = \varepsilon$  and  $A_1 = A_2 = (W-t)^2$ , the equation reduces to

$$q_{\text{rad}} = \frac{(W-t)^2 \sigma (T_1^4 - T_2^4)}{2(1/\varepsilon - 1) + \left[ F_{12} + \left[ (F_{1R} + F_{2R}) / F_{1R} F_{2R} \right] \right]^{-1}}.$$

However, with  $F_{1R} = F_{2R} = (1 - F_{12})$ , it follows that

$$q_{\text{rad}} = \frac{(W-t)^2 \sigma (T_1^4 - T_2^4)}{2\left(\frac{1}{\varepsilon} - 1\right) + \left[ F_{12} + \frac{(1 - F_{12})^2}{2(1 - F_{12})} \right]^{-1}} = \frac{(W-t)^2 \sigma (T_1^4 - T_2^4)}{2\left(\frac{1}{\varepsilon} - 1\right) + \frac{2}{1 + F_{12}}}.$$

The view factor  $F_{12}$  may be obtained from Fig. 13.4, where

$$\frac{X}{L} = \frac{Y}{L} = \frac{W-t}{L_2} = \frac{10 \text{ mm} - 2 \text{ mm}}{50 \text{ mm}} = 0.16.$$

Hence,  $F_{12} \approx 0.01$ . Defining the radiation resistance as

$$R_{\text{rad, hc}} = \frac{T_1 - T_2}{q_{\text{rad}}}$$

it follows that

Continued ...

**PROBLEM 13.110 (Cont.)**

$$R_{\text{rad,hc}} = \frac{2(1/\varepsilon - 1) + 2/(1 + F_{12})}{(W - t)^2 \sigma (T_1^2 + T_2^2)(T_1 + T_2)}$$

where  $(T_1^4 - T_2^4) = (T_1^2 + T_2^2)(T_1 + T_2)(T_1 - T_2)$ . Accordingly,

$$R_{\text{rad,hc}} = \frac{\left[ 2\left(\frac{1}{0.85} - 1\right) + \frac{2}{1 + 0.01} \right]}{(0.01 \text{ m} - 0.002 \text{ m})^2 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left[ (288 \text{ K})^2 + (268 \text{ K})^2 \right] (288 + 268) \text{ K}}$$

where, again, it is *assumed* that  $T_1 = 15^\circ\text{C}$  and  $T_2 = -5^\circ\text{C}$ . From the above expression, it follows that

$$R_{\text{rad,hc}} = \frac{0.353 + 1.980}{3.123 \times 10^{-4}} = 7471 \text{ K/W}.$$

In summary the component resistances are

$$R_{\text{cond,i}} = R_{\text{cond,o}} = 1603 \text{ K/W}$$

$$R_{\text{cond,hc}} = 8170 \text{ K/W}$$

$$R_{\text{conv,hc}} = 6944 \text{ K/W}$$

$$R_{\text{rad,hc}} = 7471 \text{ K/W}.$$

The equivalent resistance is then

$$R_{\text{eq}} = \left( \frac{1}{8170} + \frac{1}{6944} + \frac{1}{7471} \right)^{-1} = 2498 \text{ K/W}$$

and the total resistance is

$$R = 1603 + 2498 + 1603 = 5704 \text{ K/W}.$$

<

**COMMENTS:** (1) The solution is iterative, since values of  $T_1$  and  $T_2$  were assumed to calculate  $R_{\text{conv,hc}}$  and  $R_{\text{rad,hc}}$ . To check the validity of the assumed values, we first obtain the heat transfer rate  $q$  from the expression

$$q = \frac{T_{s,1} - T_{s,2}}{R} = \frac{25^\circ\text{C} - (-10^\circ\text{C})}{5704 \text{ K/W}} = 6.14 \times 10^{-3} \text{ W}.$$

Hence

$$T_1 = T_{s,i} - qR_{\text{cond,i}} = 25^\circ\text{C} - 6.14 \times 10^{-3} \text{ W} \times 1603 \text{ K/W} = 15.2^\circ\text{C}$$

$$T_2 = T_{s,o} + qR_{\text{cond,o}} = -10^\circ\text{C} + 6.14 \times 10^{-3} \text{ W} \times 1603 \text{ K/W} = -0.2^\circ\text{C}.$$

Using these values of  $T_1$  and  $T_2$ ,  $R_{\text{conv,hc}}$  and  $R_{\text{rad,hc}}$  should be recomputed and the process repeated until satisfactory agreement is obtained between the initial and computed values of  $T_1$  and  $T_2$ .

(2) The resistance of a section of low density particle board 75 mm thick ( $L_1 + L_2 + L_3$ ) of area  $W^2$  is 9615 K/W, which exceeds the total resistance of the composite by approximately 70%. Accordingly, use of the honeycomb structure offers no advantages as an insulating material. Its effectiveness as an insulator could be improved ( $R_{\text{eq}}$  increased) by reducing the wall thickness  $t$  to increase  $R_{\text{cond}}$ , evacuating the cell to increase  $R_{\text{conv}}$ , and/or decreasing  $\varepsilon$  to increase  $R_{\text{rad}}$ . A significant increase in  $R_{\text{rad,hc}}$  could be achieved by aluminizing the top and bottom surfaces of the cell.

### PROBLEM 13.111

**KNOWN:** Dimensions and surface conditions of a cylindrical thermos bottle filled with hot coffee and lying horizontally.

**FIND:** Heat loss.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Negligible heat loss from ends (long infinite cylinders), (3) Diffuse-gray surface behavior.

**PROPERTIES:** Table A-4, Air ( $T_f = (T_1 + T_2)/2 = 328$  K, 1 atm):  $k = 0.0284$  W/m·K,  $\nu = 23.74 \times 10^{-6}$  m<sup>2</sup>/s,  $\alpha = 26.6 \times 10^{-6}$  m<sup>2</sup>/s,  $Pr = 0.703$ ,  $\beta = 3.05 \times 10^{-3}$  K<sup>-1</sup>.

**ANALYSIS:** The heat transfer across the air space is

$$q = q_{\text{rad}} + q_{\text{conv}}$$

From Eq. 13.25 for concentric cylinders

$$q_{\text{rad}} = \frac{\sigma(\pi D_1 L)(T_1^4 - T_2^4)}{\frac{1}{\epsilon_1} + \frac{1 - \epsilon_2}{\epsilon_2} \left(\frac{r_1}{r_2}\right)} = \frac{5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \pi (0.07 \times 0.3) \text{ m}^2 (348^4 - 308^4) \text{ K}^4}{4 + 3(0.035/0.04)}$$

$$q_{\text{rad}} = 3.20 \text{ W}$$

The convection heat rate is given by Eqs. 9.58 through 9.60. The length scale is  $L_c = 2[\ln(0.08/0.07)]^{4/3}/(0.035 \text{ m}^{-3/5} + 0.040 \text{ m}^{-3/5})^{5/3} = 0.0016$  m. The Rayleigh number is

$$Ra_c = \frac{g\beta(T_1 - T_2)L_c^3}{\nu\alpha} = \frac{9.8 \text{ m/s}^2 (3.05 \times 10^{-3} \text{ K}^{-1})(40 \text{ K})(0.0016 \text{ m})^3}{26.6 \times 10^{-6} \text{ m}^2/\text{s} \times 23.74 \times 10^{-6} \text{ m}^2/\text{s}} = 7.85$$

From Eq. 9.59,

$$k_{\text{eff}}/k = 0.386 \left( \frac{Pr}{0.861 + Pr} \right)^{1/4} Ra_c^{1/4} = 0.386 \left( \frac{0.703}{0.861 + 0.703} \right)^{1/4} 7.85^{1/4} = 0.529$$

Since  $k_{\text{eff}}/k$  is predicted to be less than unity, conduction occurs in the gap. From Eq. 3.32

$$q_{\text{cond}} = \frac{2\pi Lk(T_1 - T_2)}{\ln(r_2/r_1)} = \frac{2\pi \times 0.3 \text{ m} \times 0.0284 \text{ W/m} \cdot \text{K} (75 - 35) \text{ K}}{\ln(0.04/0.035)} = 16.04 \text{ W}$$

Hence the total heat loss is

$$q = q_{\text{rad}} + q_{\text{cond}} = 19.24 \text{ W}$$

<

**COMMENTS:** (1) End effects could be considered in a more detailed analysis, (2) Conduction losses could be eliminated by evacuating the annulus.

### PROBLEM 13.112

**KNOWN:** Temperatures and emissivity of window panes and critical Rayleigh number for onset of convection in air space.

**FIND:** (a) The conduction heat flux across the air gap for the optimal spacing, (b) The total heat flux for uncoated panes, (c) The total heat flux if one or both of the panes has a low-emissivity coating.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Critical Rayleigh number is  $Ra_{L,c} = 2000$ , (2) Constant properties, (3) Radiation exchange between large (infinite), parallel, diffuse-gray surfaces.

**PROPERTIES:** Table A-4, air [ $T = (T_1 + T_2)/2 = 1^\circ\text{C} = 274\text{ K}$ ]:  $\nu = 13.6 \times 10^{-6}\text{ m}^2/\text{s}$ ,  $k = 0.0242\text{ W/m}\cdot\text{K}$ ,  $\alpha = 19.1 \times 10^{-6}\text{ m}^2/\text{s}$ ,  $\beta = 0.00365\text{ K}^{-1}$ .

**ANALYSIS:** (a) With  $Ra_{L,c} = g\beta(T_1 - T_2)L_{op}^3 / \alpha\nu$

$$L_{op} = \left[ \frac{\alpha\nu Ra_{L,c}}{g\beta(T_1 - T_2)} \right]^{1/3} = \left[ \frac{19.1 \times 13.6 \times 10^{-12}\text{ m}^4/\text{s}^2 \times 2000}{9.8\text{ m/s}^2 (0.00365\text{ K}^{-1}) 42^\circ\text{C}} \right]^{1/3} = 0.0070\text{ m}$$

The conduction heat flux is then

$$q''_{cond} = k(T_1 - T_2)/L_{op} = 0.0242\text{ W/m}\cdot\text{K}(42^\circ\text{C})/0.0070\text{ m} = 145.2\text{ W/m}^2 <$$

(b) For conventional glass ( $\varepsilon_g = 0.90$ ), Eq. 13.24 yields,

$$q''_{rad} = \frac{\sigma(T_1^4 - T_2^4)}{\frac{2}{\varepsilon_g} - 1} = \frac{5.67 \times 10^{-8}\text{ W/m}^2 \cdot \text{K}^4 (295^4 - 253^4)\text{ K}^4}{1.222} = 161.3\text{ W/m}^2$$

and the total heat flux is

$$q''_{tot} = q''_{cond} + q''_{rad} = 306.5\text{ W/m}^2 <$$

(c) With only one surface coated,

$$q''_{rad} = \frac{5.67 \times 10^{-8}\text{ W/m}^2 \cdot \text{K}^4 (295^4 - 253^4)}{\frac{1}{0.90} + \frac{1}{0.10} - 1} = 19.5\text{ W/m}^2$$

Continued ...

**PROBLEM 13.112 (Cont.)**

$$q''_{\text{tot}} = 164.7 \text{ W/m}^2$$

<

With both surfaces coated,

$$q''_{\text{rad}} = \frac{5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (295^4 - 253^4)}{\frac{1}{0.10} + \frac{1}{0.10} - 1} = 10.4 \text{ W/m}^2$$

$$q''_{\text{tot}} = 155.6 \text{ W/m}^2$$

<

**COMMENTS:** Without any coating, radiation makes a large contribution (53%) to the total heat loss. With one coated pane, there is a significant reduction (46%) in the total heat loss. However, the benefit of coating both panes is marginal, with only an additional 3% reduction in the total heat loss.

### PROBLEM 13.113

**KNOWN:** Dimensions and emissivity of double pane window. Thickness of air gap. Temperatures of room and ambient air and the related surroundings.

**FIND:** (a) Temperatures of glass panes and rate of heat transfer through window, (b) Heat rate if gap is evacuated. Heat rate if special coating is applied to window.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, (2) Negligible glass pane thermal resistance, (3) Constant properties, (4) Diffuse-gray surface behavior, (5) Radiation exchange between interior window surfaces may be approximated as exchange between infinite parallel plates, (6) Interior and exterior surroundings are very large.

**PROPERTIES:** Table A-4, Air ( $p = 1$  atm). Obtained from using *IHT* to solve for conditions of Part (a):  $T_{f,i} = 287.4$  K:  $\nu_i = 14.8 \times 10^{-6}$  m<sup>2</sup>/s,  $k_i = 0.0253$  W/m·K,  $\alpha_i = 20.8 \times 10^{-6}$  m<sup>2</sup>/s,  $Pr_i = 0.71$ ,  $\beta_i = 0.00348$  K<sup>-1</sup>.  $\bar{T} = (T_{s,i} + T_{s,o})/2 = 273.7$  K:  $\nu = 13.6 \times 10^{-6}$  m<sup>2</sup>/s,  $k = 0.0242$  W/m·K,  $\alpha = 19.0 \times 10^{-6}$  m<sup>2</sup>/s,  $Pr = 0.71$ ,  $\beta = 0.00365$  K<sup>-1</sup>.  $T_{f,o} = 259.3$  K:  $\nu_o = 12.3 \times 10^{-6}$  m<sup>2</sup>/s,  $k_o = 0.023$  W/m·K,  $\alpha_o = 17.1 \times 10^{-6}$  m<sup>2</sup>/s,  $Pr_o = 0.72$ ,  $\beta_o = 0.00386$  K<sup>-1</sup>.

**ANALYSIS:** (a) The heat flux through the window may be expressed as

$$q'' = q''_{\text{rad},i} + q''_{\text{conv},i} = \epsilon_g \sigma (T_{\text{sur},i}^4 - T_{s,i}^4) + \bar{h}_i (T_{\infty,i} - T_{s,i}) \quad (1)$$

$$q'' = q''_{\text{rad},\text{gap}} + q''_{\text{conv},\text{gap}} = \frac{\sigma (T_{s,i}^4 - T_{s,o}^4)}{\frac{1}{\epsilon_g} + \frac{1}{\epsilon_g} - 1} + \bar{h}_{\text{gap}} (T_{s,i} - T_{s,o}) \quad (2)$$

$$q'' = q''_{\text{rad},o} + q''_{\text{conv},o} = \epsilon_g \sigma (T_{s,o}^4 - T_{\text{sur},o}^4) + \bar{h}_o (T_{s,o} - T_{\infty,o}) \quad (3)$$

where radiation exchange between the window panes is determined from Eq. 13.24. The inner and outer convection coefficients,  $\bar{h}_i$  and  $\bar{h}_o$ , are determined from Eq. 9.26, and  $\bar{h}_{\text{gap}}$  is obtained from Eq. 9.52.

The foregoing equations may be solved for the three unknowns ( $q''$ ,  $T_{s,i}$ ,  $T_{s,o}$ ). Using the *IHT* software to effect the solution, we obtain

$$T_{s,i} = 281.8 \text{ K} = 8.8^\circ\text{C}$$

<

Continued ...

**PROBLEM 13.113 (Cont.)**

$$T_{s,o} = 265.6 \text{ K} = -7.4^\circ\text{C} \quad <$$

$$q = 91.3 \text{ W} \quad <$$

(b) If the air space is evacuated ( $\bar{h}_g = 0$ ), we obtain

$$T_{s,i} = 283.6 \text{ K} = 10.6^\circ\text{C} \quad <$$

$$T_{s,o} = 263.8 \text{ K} = 9.2^\circ\text{C} \quad <$$

$$q = 75.5 \text{ W} \quad <$$

If the space is not evacuated but the coating is applied to inner surfaces of the window panes,

$$T_{s,i} = 285.9 \text{ K} = 12.9^\circ\text{C} \quad <$$

$$T_{s,o} = 261.3 \text{ K} = -11.7^\circ\text{C} \quad <$$

$$q = 55.9 \text{ W} \quad <$$

If the space is evacuated and the coating is applied,

$$T_{s,i} = 291.7 \text{ K} = 18.7^\circ\text{C} \quad <$$

$$T_{s,o} = 254.7 \text{ K} = -18.3^\circ\text{C} \quad <$$

$$q = 9.0 \text{ W} \quad <$$

**COMMENTS:** (1) For the conditions of part (a), the convection and radiation heat fluxes are comparable at the inner and outer surfaces of the window, but because of the comparatively small convection coefficient, the radiation flux is approximately twice the convection flux across the air gap. (2) As the resistance across the air gap is progressively increased (evacuated, coated, evacuated and coated), the temperatures of the inner and outer panes increase and decrease, respectively, and the heat loss decreases. (3) Clearly, there are significant energy savings associated with evacuation of the gap and application of the coating. (4) In all cases, solutions were obtained using the temperature-dependent properties of air provided by the software. The property values listed in the **PROPERTIES** section of this solution pertain to the conditions of part (a).

### PROBLEM 13.114

**KNOWN:** Absorber and cover plate temperatures and spectral absorptivities for a flat plate solar collector. Collector orientation and solar flux.

**FIND:** (a) Rate of solar radiation absorption per unit area, (b) Heat loss per unit area.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Adiabatic sides and bottom, (3) Cover is transparent to solar radiation, (4) Sun emits as a blackbody at 5800 K, (5) Cover and absorber plates are diffuse-gray to long wave radiation, (6) Negligible end effects, (7)  $L \ll$  width and length.

**PROPERTIES:** Table A-4, Air ( $T = T_a + T_c$ )/2 = 321.5 K, 1 atm):  $\nu = 18.05 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0279 \text{ W/m}\cdot\text{K}$ ,  $\alpha = 25.7 \times 10^{-6} \text{ m}^2/\text{s}$ .

**ANALYSIS:** (a) The absorbed solar irradiation is

$$G_{S,\text{abs}} = \alpha_{S,a} G_S$$

where

$$G_S = q_s'' \cos 30^\circ = 900 \times 0.866 = 779.4 \text{ W/m}^2$$

$$\alpha_{S,a} = \frac{\int_0^\infty \alpha_{\lambda,a} G_{\lambda,S} d\lambda}{G_S} = \frac{\int_0^\infty \alpha_{\lambda,a} E_{\lambda,b}(5800 \text{ K}) d\lambda}{E_b(5800 \text{ K})}$$

$$\alpha_{S,a} = \alpha_{\lambda,a,1} F_{(0 \rightarrow 2 \mu\text{m})} + \alpha_{\lambda,a,2} F_{(2 \rightarrow \infty)}$$

For  $\lambda T = 2 \mu\text{m} \times 5800 \text{ K} = 11,600 \mu\text{m}\cdot\text{K}$  from Table 12.1,  $F_{(0 \rightarrow 2\lambda T)} = 0.941$ , find

$$\alpha_{S,a} = 0.9 \times 0.941 + 0.2 \times (1 - 0.941) = 0.859.$$

Hence

$$G_{S,\text{abs}} = 0.859 \times 779.4 = 669 \text{ W/m}^2. \quad \leftarrow$$

(b) The heat loss per unit area from the collector is

$$q_{\text{loss}}'' = q_{\text{conv}}'' + q_{\text{rad}}''$$

The convection heat flux is

$$q_{\text{conv}}'' = \bar{h} (T_a - T_c)$$

Continued ...

**PROBLEM 13.114 (Cont.)**

and with

$$\text{Ra}_L = \frac{g\beta(T_a - T_c)L^3}{\alpha\nu}$$

$$\text{Ra}_L = \frac{9.8 \text{ m/s}^2 \times (321.5 \text{ K})^{-1} (343 - 300) \text{ K} (0.02 \text{ m})^3}{18.05 \times 10^{-6} \text{ m}^2/\text{s} \times 25.7 \times 10^{-6} \text{ m}^2/\text{s}} = 22,604$$

find from Eq. 9.54 with

$$H/L > 12, \tau < \tau^*, \cos \tau = 0.5, \text{Ra}_L \cos \tau = 11,302$$

$$\overline{\text{Nu}}_L = 1 + 1.44 \left[ 1 - \frac{1708}{11,302} \right] \left[ 1 - \frac{1708(\sin 108^\circ)^{1.6}}{11,302} \right] + \left[ \left( \frac{11,302}{5830} \right)^{1/3} - 1 \right]$$

$$\bar{h} = \overline{\text{Nu}}_L \frac{k}{L} = 2.30 \times \frac{0.0279 \text{ W/m} \cdot \text{K}}{0.02 \text{ m}} = 3.21 \text{ W/m}^2 \cdot \text{K}.$$

Hence, the convective heat flux is

$$q''_{\text{conv}} = 3.21 \text{ W/m}^2 \cdot \text{K} (343 - 300) \text{ K} = 138.0 \text{ W/m}^2.$$

The radiative exchange can be determined from Eq. 13.24 treating the cover and absorber plates as a two-surface enclosure,

$$q''_{\text{rad}} = \frac{\sigma(T_a^4 - T_c^4)}{1/\epsilon_a + 1/\epsilon_c - 1} = \frac{5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left[ (343 \text{ K})^4 - (300 \text{ K})^4 \right]}{1/0.2 + 1/0.75 - 1}$$

$$q''_{\text{rad}} = 61.1 \text{ W/m}^2.$$

Hence, the total heat loss per unit area from the collector

$$q''_{\text{loss}} = (138.0 + 61.1) = 199 \text{ W/m}^2. \quad \leftarrow$$

**COMMENTS:** (1) Non-solar components of radiation transfer are concentrated at long wavelength for which  $\alpha_a = \epsilon_a = 0.2$  and  $\alpha_c = \epsilon_c = 0.75$ .

(2) The collector efficiency is

$$\eta = \frac{669.3 - 199.1}{669.3} \times 100 = 70\%.$$

This value is uncharacteristically high due to specification of nearly optimum  $\alpha_a(\lambda)$  for absorber.

### PROBLEM 13.115

**KNOWN:** Diameters and temperatures of a heated tube and a radiation shield.

**FIND:** (a) Total heat loss per unit length of tube, (b) Effect of shield diameter on heat rate.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Opaque, diffuse-gray surfaces, (2) Negligible end effects.

**PROPERTIES:** Table A-4, Air ( $T_f = 77.5^\circ\text{C} \approx 350 \text{ K}$ ):  $k = 0.030 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.70$ ,  $\nu = 20.92 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\alpha = 29.9 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\beta = 0.00286 \text{ K}^{-1}$ .

**ANALYSIS:** (a) Heat loss from the tube is by radiation and free convection

$$q' = q'_{\text{rad}} + q'_{\text{conv}}$$

From Eq. 13.25

$$q'_{\text{rad}} = \frac{\sigma(\pi D_i)(T_i^4 - T_o^4)}{\frac{1}{\epsilon_i} + \frac{1 - \epsilon_o}{\epsilon_o} \left(\frac{r_i}{r_o}\right)}$$

or

$$q'_{\text{rad}} = \frac{5.67 \times 10^{-8} \frac{\text{W}}{\text{m}^2 \cdot \text{K}^4} (\pi \times 0.1 \text{ m}) (393^4 - 308^4) \text{ K}^4}{\frac{1}{0.8} + \frac{0.9}{0.1} \left(\frac{0.05}{0.06}\right)} = 30.2 \frac{\text{W}}{\text{m}}$$

The convection heat rate is given by Eqs. 9.58 through 9.60. The length scale is  $L_c = 2[\ln(0.12/0.10)]^{4/3}/(0.05 \text{ m}^{-3/5} + 0.05 \text{ m}^{-3/5})^{5/3} = 0.0036 \text{ m}$ . The Rayleigh number is  $\text{Ra}_c = g\beta(T_i - T_o)L_c^3/\nu\alpha = 9.8 \text{ m/s}^2(0.00286 \text{ K}^{-1})(120 - 35) \text{ K}(0.0036 \text{ m})^3/(20.92 \times 10^{-6} \text{ m}^2/\text{s} \times 29.9 \times 10^{-6} \text{ m}^2/\text{s}) = 171.6$ . Also,  $k_{\text{eff}}/k = 0.386 \times [0.700/(0.861 + 0.700)]^{1/4}(171.6)^{1/4} = 1.14$ . Therefore,  $k_{\text{eff}} = 1.14 \times 0.030 \text{ W/m}\cdot\text{K} = 0.0343 \text{ W/m}\cdot\text{K}$ . From Eq. 9.58,

$$q'_{\text{conv}} \frac{2\pi k_{\text{eff}}(T_i - T_o)}{\ln(D_i/D_o)} = \frac{2 \times \pi \times 0.0343 \text{ W/m}\cdot\text{K} \times (120 - 35) \text{ K}}{\ln(0.12/0.10)} = 100.5 \text{ W/m}$$

$$q' = (30.2 + 100.5) \frac{\text{W}}{\text{m}} = 130.7 \frac{\text{W}}{\text{m}}$$

Continued...

### PROBLEM 13.115 (Cont.)

(b) As shown below, both convection and radiation, and hence the total heat rate, increase with increasing shield diameter. In the limit as  $D_o \rightarrow \infty$ , the radiation rate approaches that corresponding to net transfer between a small surface and large surroundings at  $T_o$ . The rate is independent of  $\varepsilon$ .

**COMMENTS:** Designation of a shield temperature is arbitrary. The temperature depends on the nature of the environment external to the shield.

### PROBLEM 13.116

**KNOWN:** Diameters of heated tube and radiation shield. Tube surface temperature and temperature of ambient air and surroundings.

**FIND:** Temperature of radiation shield and heat loss per unit length of tube.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Opaque, diffuse-gray surfaces, (2) Negligible end effects, (3) Large surroundings, (4) Quiescent air, (5) Steady-state.

**PROPERTIES:** Determined from use of *IHT* software for iterative solution. Air,  $(T_i + T_o)/2 = 362.7$  K:  $\nu_i = 2.23 \times 10^{-5} \text{ m}^2/\text{s}$ ,  $k_i = 0.031 \text{ W/m}\cdot\text{K}$ ,  $\alpha_i = 3.20 \times 10^{-5} \text{ m}^2/\text{s}$ ,  $\beta_i = 0.00276 \text{ K}^{-1}$ ,  $\text{Pr}_i = 0.698$ . Air,  $T_f = 312.7$  K:  $\nu_o = 1.72 \times 10^{-5} \text{ m}^2/\text{s}$ ,  $k_o = 0.027 \text{ W/m}\cdot\text{K}$ ,  $\alpha_o = 2.44 \times 10^{-5} \text{ m}^2/\text{s}$ ,  $\beta_o = 0.0032 \text{ K}^{-1}$ ,  $\text{Pr}_o = 0.705$ .

**ANALYSIS:** From an energy balance on the radiation shield,  $q'_i = q'_o$  or  $q'_{\text{rad},i} + q'_{\text{conv},i} = q'_{\text{rad},o} + q'_{\text{conv},o}$ . Evaluating the inner and outer radiation rates from Eqs. 13.25 and 13.27, respectively, and the convection heat rate in the air gap from Eq. 9.58,

$$\frac{\sigma \pi D_i (T_i^4 - T_o^4)}{\frac{1}{\varepsilon_i} + \frac{1 - \varepsilon_o}{\varepsilon_o} \left( \frac{D_i}{D_o} \right)} + \frac{2\pi k_{\text{eff}} (T_i - T_o)}{\ln(D_o/D_i)} = \sigma \pi D_o \varepsilon_o (T_o^4 - T_{\text{sur}}^4) + \pi D_o \bar{h}_o (T_o - T_\infty)$$

The convection heat rate is given by Eqs. 9.58 through 9.60. The length scale is  $L_c = 2[\ln(0.12/0.10)]^{4/3}/(0.05 \text{ m}^{-3/5} + 0.05 \text{ m}^{-3/5})^{5/3} = 0.0036 \text{ m}$ . The Rayleigh number is  $\text{Ra}_c = g\beta_i(T_i - T_o)L_c^3/\nu_i\alpha_i = 9.8 \text{ m/s}^2(0.00276 \text{ K}^{-1})(120 - T_o) \text{ K} (0.0036 \text{ m})^3/(22.3 \times 10^{-6} \text{ m}^2/\text{s} \times 32.0 \times 10^{-6} \text{ m}^2/\text{s})$ . Also,  $k_{\text{eff}}/k = 0.386 \times k_i \times [\text{Pr}_i/(0.861 + \text{Pr}_i)]^{1/4}(\text{Ra}_c)^{1/4} = 1.14$ . From Eq. 9.34, the convection coefficient on the outer surface of the shield is

$$\bar{h}_o = \frac{k_o}{D_o} \left\{ 0.60 + \frac{0.387 \text{ Ra}_D^{1/6}}{\left[ 1 + (0.559/\text{Pr}_o)^{9/16} \right]^{8/27}} \right\}^2$$

The solution to the energy balance is obtained using the *IHT* software, and the result is

$$T_o = 332.5 \text{ K} = 59.5^\circ\text{C} \quad <$$

The corresponding value of the heat loss is

$$q'_i = 88.7 \text{ W/m} \quad <$$

Continued...

### PROBLEM 13.116 (Cont.)

**COMMENTS:** (1) The radiation and convection heat rates are  $q'_{\text{rad},i} = 23.7 \text{ W/m}$ ,  $q'_{\text{rad},o} = 10.4 \text{ W/m}$ ,  $q'_{\text{conv},i} = 65.0 \text{ W/m}$ , and  $q'_{\text{conv},o} = 78.3 \text{ W/m}$ . Convection is clearly the dominant mode of heat transfer. (2) With a value of  $T_o = 59.5^\circ\text{C} > 35^\circ\text{C}$ , the heat loss is reduced (88.7 W/m compared to 130.7 W/m if the shield is at  $35^\circ\text{C}$ ).

### PROBLEM 13.117

**KNOWN:** Dimensions and inclination angle of a flat-plate solar collector. Absorber and cover plate temperatures and emissivities.

**FIND:** (a) Rate of heat transfer by free convection and radiation, (b) Effect of the absorber plate temperature on the heat rates.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Diffuse-gray, opaque surface behavior.

**PROPERTIES:** Table A-4, air ( $\bar{T} = (T_1 + T_2)/2 = 323 \text{ K}$ ):  $\nu = 18.2 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.028 \text{ W/m}\cdot\text{K}$ ,  $\alpha = 25.9 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.704$ ,  $\beta = 0.0031 \text{ K}^{-1}$ .

**ANALYSIS:** (a) The convection heat rate is

$$q_{\text{conv}} = \bar{h}A(T_1 - T_2)$$

where  $A = wH = 4 \text{ m}^2$  and, with  $H/L > 12$  and  $\tau < \tau^* = 70 \text{ deg}$ ,  $\bar{h}$  is given by Eq. 9.54. With a Rayleigh number of

$$\text{Ra}_L = \frac{g\beta(T_1 - T_2)L^3}{\alpha\nu} = \frac{9.8 \text{ m/s}^2 (0.0031 \text{ K}^{-1})(40^\circ\text{C})(0.03 \text{ m})^3}{25.9 \times 10^{-6} \text{ m}^2/\text{s} \times 18.2 \times 10^{-6} \text{ m}^2/\text{s}} = 69,600$$

$$\overline{\text{Nu}}_L = 1 + 1.44 \left[ 1 - \frac{1708}{0.5(69,600)} \right] \left[ 1 - \frac{1708(0.923)}{0.5(69,600)} \right] + \left[ \left( \frac{0.5 \times 69,600}{5830} \right)^{1/3} - 1 \right]$$

$$\overline{\text{Nu}}_L = 1 + 1.44[0.951][0.955] + 0.814 = 3.12$$

$$\bar{h} = (k/L)\overline{\text{Nu}}_L = (0.028 \text{ W/m}\cdot\text{K}/0.03 \text{ m})3.12 = 2.91 \text{ W/m}^2\cdot\text{K}$$

$$q_{\text{conv}} = 2.91 \text{ W/m}^2\cdot\text{K} (4 \text{ m}^2)(70 - 30)^\circ\text{C} = 466 \text{ W} \quad <$$

The net rate of radiation exchange is given by Eq. 13.24.

$$q = \frac{A\sigma(T_1^4 - T_2^4)}{\frac{1}{\epsilon_1} + \frac{1}{\epsilon_2} - 1} = \frac{(4 \text{ m}^2)5.67 \times 10^{-8} \text{ W/m}^2\cdot\text{K}^4(343^4 - 303^4)}{\frac{1}{0.96} + \frac{1}{0.92} - 1} = 1088 \text{ W} \quad <$$

(b) The effect of the absorber plate temperature was determined by entering Eq. 9.54 into the *IHT* workspace and using the *Properties* and *Radiation* Toolpads.

Continued ...

### PROBLEM 13.117 (Cont.)

As expected, the convection and radiation losses increase with increasing  $T_1$ , with the  $T^4$  dependence providing a more pronounced increase for the radiation.

**COMMENTS:** To minimize heat losses, it is obviously desirable to operate the absorber plate at the lowest possible temperature. However, requirements for the outlet temperature of the working fluid may dictate operation at a low flow rate and hence an elevated plate temperature.

## PROBLEM 13.118

**KNOWN:** Disk heated by an electric furnace on its lower surface and exposed to an environment on its upper surface.

**FIND:** (a) Net heat transfer to (or from) the disk  $q_{\text{net,d}}$  when  $T_d = 400$  K and (b) Compute and plot  $q_{\text{net,d}}$  as a function of disk temperature for the range  $300 \leq T_d \leq 500$  K; determine steady-state temperature of the disk.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Disk is isothermal; negligible thermal resistance, (3) Surroundings are isothermal and large compared to the disk, (4) Non-black surfaces are gray-diffuse, (5) Furnace-disk forms a 3-surface enclosure, (6) Negligible convection in furnace, (7) Ambient air is quiescent.

**PROPERTIES:** Table A-4, Air ( $T_f = (T_d + T_\infty)/2 = 350$  K, 1 atm):  $\nu = 20.92 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.30 \text{ W/m}\cdot\text{K}$ ,  $\alpha = 29.9 \times 10^{-6} \text{ m}^2/\text{s}$ .

**ANALYSIS:** (a) Perform an energy balance on the disk identifying:  $q_{\text{rad}}$  as the net radiation exchange between the disk and surroundings;  $q_{\text{conv}}$  as the convection heat transfer; and  $q_3$  as the net radiation leaving the disk within the 3-surface enclosure.

$$q_{\text{net,d}} = \dot{E}_{\text{in}} - \dot{E}_{\text{out}} = -q_{\text{rad}} - q_{\text{conv}} - q_3 \quad (1)$$

*Radiation exchange with surroundings:* The rate equation is of the form

$$q_{\text{rad}} = \varepsilon_{d,2} A_d \sigma (T_d^4 - T_{\text{sur}}^4) \quad (2)$$

$$q_{\text{rad}} = 0.8 (\pi/4) (0.400 \text{ m})^2 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (400^4 - 300^4) \text{ K}^4 = 99.8 \text{ W}.$$

*Free convection:* The rate equation is of the form

$$q_{\text{conv}} = \bar{h} A_d (T_d - T_\infty) \quad (3)$$

where  $\bar{h}$  can be estimated by an appropriate convection correlation. Find first,

$$\text{Ra}_L = g \beta \Delta T L^3 / \nu \alpha \quad (4)$$

$$\text{Ra}_L = 9.8 \text{ m/s}^2 (1/350 \text{ K}) (400 - 300) \text{ K} (0.400 \text{ m}/4)^3 / 20.92 \times 10^{-6} \text{ m}^2/\text{s}^2 \times 29.9 \times 10^{-6} \text{ m}^2/\text{s}$$

$$\text{Ra}_L = 4.476 \times 10^6$$

where  $L = A_c/P = D/4$ . For the upper surface of a heated plate for which  $10^4 \leq \text{Ra}_L \leq 10^7$ , Eq. 9.30 is the appropriate correlation,

Continued ...

**PROBLEM 13.118 (Cont.)**

$$\overline{\text{Nu}}_L = \overline{h}L/k = 0.54 \text{Ra}_L^{1/4} \quad (5)$$

$$\overline{h} = 0.030 \text{ W/m} \cdot \text{K} / (0.400 \text{ m} / 4) \times 0.54 \left( 4.476 \times 10^6 \right)^{1/4} = 7.45 \text{ W/m}^2 \cdot \text{K}$$

Hence, from Eq. (3),

$$q_{\text{conv}} = 7.45 \text{ W/m}^2 \cdot \text{K} (\pi/4) (0.400 \text{ m})^2 (400 - 300) \text{ K} = 93.6 \text{ W}.$$

*Furnace-disk enclosure:* From Eq. 13.20, the net radiation leaving the disk is

$$q_3 = \frac{J_3 - J_1}{(A_3 F_{31})^{-1}} + \frac{J_3 - J_2}{(A_3 F_{32})^{-1}} = A_3 [F_{31} (J_3 - J_1) + F_{32} (J_3 - J_2)]. \quad (6)$$

The view factor  $F_{32}$  can be evaluated from the *coaxial parallel disks* relation of Table 13.1 or from Fig. 13.5.

$$R_i = r_i / L = 200 \text{ mm} / 200 \text{ mm} = 1,$$

$$R_j = r_j / L = 1,$$

$$S = 1 + \left( 1 + R_j^2 \right) / R_i^2 = 1 + \left( 1 + 1^2 \right) 1^2 = 3$$

$$F_{31} = 1/2 \left\{ S - \left[ S^2 - 4 \left( r_j / r_i \right)^2 \right]^{1/2} \right\} = 1/2 \left\{ 3 - \left[ 3^2 - 4(1)^2 \right]^{1/2} \right\} = 0.382. \quad (7)$$

From summation rule,  $F_{32} = 1 - F_{33} - F_{31} = 0.618$  with  $F_{33} = 0$ . Since surfaces  $A_2$  and  $A_3$  are black,

$$J_2 = E_{b2} = \sigma T_2^4 = \sigma (500 \text{ K})^4 = 3544 \text{ W/m}^2$$

$$J_3 = E_{b3} = \sigma T_3^4 = \sigma (400 \text{ K})^4 = 1452 \text{ W/m}^2.$$

To determine  $J_1$ , use Eq. 13.21, the radiation balance equation for  $A_1$ , noting that  $F_{12} = F_{32}$  and  $F_{13} = F_{31}$ ,

$$\begin{aligned} \frac{E_{b1} - J_1}{(1 - \varepsilon_1) / \varepsilon_1 A_1} &= \frac{J_1 - J_2}{(A_1 F_{12})^{-1}} + \frac{J_1 - J_3}{(A_1 F_{13})^{-1}} \\ \frac{3544 - J_1}{(1 - 0.6) / 0.6} &= \frac{J_1 - 3544}{(0.618)^{-1}} + \frac{J_1 - 1452}{(0.382)^{-1}} \quad J_1 = 3226 \text{ W/m}^2. \end{aligned} \quad (8)$$

Substituting numerical values in Eq. (6), find

$$q_3 = (\pi/4) (0.400 \text{ m})^2 \left[ 0.382 (1452 - 3226) \text{ W/m}^2 + 0.618 (1452 - 3544) \text{ W/m}^2 \right] = -248 \text{ W}.$$

Returning to the overall energy balance, Eq. (1), the net heat transfer to the disk is

$$q_{\text{net,d}} = -99.8 \text{ W} - 93.6 \text{ W} - (-248 \text{ W}) = +54.6 \text{ W} \quad <$$

That is, there is a net heat transfer rate *into* the disk.

(b) Using the energy balance, Eq. (1), and the rate equation, Eqs. (2) and (3) with the *IHT Radiation Tool, Radiation, Exchange Analysis, Radiation surface energy balances* and the *Correlation Tool, Free Convection, Horizontal Plate (Hot surface up)*, the analysis was performed to obtain  $q_{\text{net,d}}$  as a function of  $T_d$ . The results are plotted below.

The steady-state condition occurs when  $q_{\text{net,d}} = 0$  for which

$$T_d = 413 \text{ K} \quad <$$

Continued ...

## PROBLEM 13.118 (Cont.)

**COMMENTS:** The *IHT* workspace for the foregoing analysis is shown below.

**// Radiation Tool - Three Surface Enclosure, Furnace Disk Enclosure:**

```

/* The net heat rate leaving A1 in terms of the surface resistance is */
q1 = (Eb1 - J1) / ((1 - eps1) / (eps1 * A1)) // Eq 13.19
/* The net heat rate leaving A1 in terms of the net exchanges between enclosure surfaces is */
q1 = q12 + q13
/* where the net exchange rates expressed in terms of the space resistances are, Eq 13.20 */
q12 = (J1 - J2) / (1 / (A1 * F12))
q13 = (J1 - J3) / (1 / (A1 * F13))
/* The net heat rate leaving A2 in terms of the surface resistance is */
q2 = (Eb2 - J2) / ((1 - eps2) / (eps2 * A2)) // Eq 13.19
/* The net heat rate leaving A2 in terms of the net exchanges between enclosure surfaces is */
q2 = q21 + q23
/* where the net exchange rates expressed in terms of the space resistances are Eq 13.20 */
q21 = (J2 - J1) / (1 / (A2 * F21))
q23 = (J2 - J3) / (1 / (A2 * F23))
/* The net heat rate leaving A3 in terms of the surface resistance is */
q3 = (Eb3 - J3) / ((1 - eps3) / (eps3 * A3)) // Eq 13.19
/* The net heat rate leaving A3 in terms of the net exchanges between enclosure surfaces is */
q3 = q31 + q32
/* where the net exchange rates expressed in terms of the space resistances are, Eq 13.20 */
q31 = (J3 - J1) / (1 / (A3 * F31))
q32 = (J3 - J2) / (1 / (A3 * F32))

```

**// Emissive Powers:**

```

Eb1 = sigma * T1^4
Eb2 = sigma * T2^4
Eb3 = sigma * T3^4
sigma = 5.67e-8 // Stefan-Boltzmann constant, W/m^2.K^4

```

**// Radiation Tool - View Factor:**

```

/* The view factor, F12, for coaxial parallel disks, is */
F13 = 0.5 * (S - sqrt(S^2 - 4*(r3 / r1)^2))
// where
R1 = r1 / L
R3 = r3 / L
S = 1 + (1 + R3^2) / R1^2
// See Table 13.2 for schematic of this three-dimensional geometry.

```

**// Other View Factors and Areas Required:**

```

F12 = 1 - F13 // Summation rule, A1
F21 = A1 * F12 / A2 // Reciprocity rule
F23 = F21 // Symmetry condition
F31 = F13 // Symmetry condition
F32 = F12 // Symmetry condition
A1 = pi * r1^2 // Surface area, m^2
A2 = pi * r1 * L // Surface area, m^2
A3 = pi * r3^2 // Surface area, m^2

```

**// Overall plate energy balance, Eqs (1,2,3):**

```

qnet = - qrad - qcv - q3
qrad = eps32 * A3 * sigma * (T3^4 - Tsur^4)
qcv = hLbar * A3 * (T3 - Tinf)

```

```

### PROBLEM 13.119

**KNOWN:** Radiation shield facing hot wall at  $T_w = 400$  K is backed by an insulating material of known thermal conductivity and thickness which is exposed to ambient air and surroundings at 300 K.

**FIND:** (a) Heat loss per unit area from the hot wall, (b) Radiosity of the shield, and (c) Perform a parameter sensitivity analysis on the insulation system considering effects of shield reflectivity  $\rho_s$ , insulation thermal conductivity  $k$ , overall coefficient  $h$ , on the heat loss from the hot wall.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Wall is black surface of uniform temperature, (2) Shield and wall behave as parallel infinite plates, (3) Negligible convection in region between shield and wall, (4) Shield is diffuse-gray and very thin, (5) Prescribed coefficient  $h = 10$  W/m<sup>2</sup>·K is for convection and radiation.

**ANALYSIS:** (a) Perform an energy balance on the shield to obtain

$$q''_{w-s} = q''_{cond}$$

But the insulating material and the convection process at the exposed surface can be represented by a thermal circuit.

In equation form, using Eq.13.24 for the wall and shield,

$$q''_{w-s} = \frac{\sigma(T_w^4 - T_s^4)}{1/\varepsilon_w + 1/\varepsilon_s - 1} = \frac{T_s - T_\infty}{L/k + 1/h} \quad (1,2)$$

$$\frac{\sigma(400^4 - T_s^4)}{1 + 1/0.05 - 1} = \frac{(T_s - 300) \text{ K}}{(0.025/0.016 + 1/10) \text{ m}^2 \cdot \text{K/W}}$$

$$T_s = 350 \text{ K.}$$

where  $\varepsilon_s = 1 - \rho_s$ . Hence,

$$q''_{w-s} = \frac{(350 - 300) \text{ K}}{(0.025/0.016 + 1/10) \text{ m}^2 \cdot \text{K/W}} = 30 \text{ W/m}^2. \quad <$$

(b) Using the Eqs. (1) and (2) in the *IHT* workspace,  $q''_{w-s}$  can be computed and plotted for selected ranges of the insulation system variables,  $\rho_s$ ,  $k$ , and  $h$ . Intuitively we know that  $q''_{w-s}$  will decrease with increasing  $\rho_s$ , decreasing  $k$  and decreasing  $h$ . We chose to generate the following family of curves plotting  $q''_{w-s}$  vs.  $k$  for selected values of  $\rho_s$  and  $h$ .

Continued ...

**PROBLEM 13.119 (Cont.)**

Considering the base condition with variable  $k$ , reducing  $k$  by a factor of 3, the heat loss is reduced by a factor of 2. The effect of changing  $h$  (4 to  $24 \text{ W/m}^2\cdot\text{K}$ ) has little influence on the heat loss.

However, the effect of shield reflectivity change is very significant. With  $\rho_s = 0.98$ , probably the upper limit of a practical reflector-type shield, the heat loss is reduced by a factor of two. To improve the performance of the insulation system, it is most advantageous to increase  $\rho_s$  and decrease  $k$ .

### PROBLEM 13.120

**KNOWN:** Diameter and surface temperature of a fire tube. Gas flow rate and temperature. Emissivity of tube and partition.

**FIND:** (a) Heat transfer per unit tube length,  $q'$ , without the partition, (b) Partition temperature,  $T_p$ , and heat rate with the partition, (c) Effect of flow rate and emissivity on  $q'$  and  $T_p$ . Effect of emissivity on radiative and convective contributions to  $q'$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Fully-developed flow in duct, (2) Diffuse/gray surface behavior, (3) Negligible gas radiation.

**PROPERTIES:** Table A-4, air ( $T_{m,g} = 900$  K):  $\mu = 398 \times 10^{-7}$  N·s/m<sup>2</sup>,  $k = 0.062$  W/m·K,  $Pr = 0.72$ ; air ( $T_s = 385$  K):  $\mu = 224 \times 10^{-7}$  N·s/m<sup>2</sup>.

**ANALYSIS:** (a) Without the partition, heat transfer to the tube wall is only by convection. With  $\dot{m}_g = 0.05$  kg/s and  $Re_D = 4 \dot{m}_g / \pi D \mu = 4(0.05 \text{ kg/s}) / \pi (0.07 \text{ m}) 398 \times 10^{-7} \text{ N·s/m}^2 = 22,850$ , the flow is turbulent. From Eq. 8.61,

$$Nu_D = 0.027 Re_D^{4/5} Pr^{1/3} (\mu / \mu_s)^{0.14} = 0.027 (22,850)^{4/5} (0.72)^{1/3} (398 / 224)^{0.14} = 80.5$$

$$h = \frac{k}{D} Nu_D = \frac{0.062 \text{ W/m·K}}{0.07 \text{ m}} 80.5 = 71.3 \text{ W/m}^2 \cdot \text{K}$$

$$q' = h \pi D (T_{m,g} - T_s) = 71.3 \text{ W/m}^2 \cdot \text{K} (\pi) (0.07 \text{ m}) (900 - 385) = 8075 \text{ W/m} \quad <$$

(b) The temperature of the partition is determined from an energy balance which equates net radiation exchange with the tube wall to convection from the gas. Hence,  $q''_{rad} = q''_{conv}$ , where from Eq. 13.23,

$$q''_{rad} = \frac{\sigma (T_p^4 - T_s^4)}{\frac{1 - \epsilon_p}{\epsilon_p} + \frac{1}{F_{ps}} + \frac{1 - \epsilon_s}{\epsilon_s} \frac{A_p}{A_s}}$$

where  $F_{12} = 1$  and  $A_p/A_s = D/(\pi D/2) = 2/\pi = 0.637$ . The flow is now in a noncircular duct for which  $D_h = 4A_c/P = 4(\pi D^2/8)/(\pi D/2 + D) = \pi D/(\pi + 2) = 0.611 D = 0.0428$  m and  $\dot{m}_{1/2} = \dot{m}_g / 2 = 0.025$  kg/s. Hence,  $Re_D = \dot{m}_{1/2} D_h / A_c \mu = \dot{m}_{1/2} D_h / (\pi D^2/8) \mu = 8(0.025 \text{ kg/s}) (0.0428 \text{ m}) / \pi (0.07 \text{ m})^2 398 \times 10^{-7} \text{ N·s/m}^2 = 13,970$  and

$$Nu_D = 0.027 (13,970)^{4/5} (0.72)^{1/3} (398 / 224)^{0.14} = 54.3$$

$$h = \frac{k}{D_h} Nu_D = \frac{0.062 \text{ W/m·K}}{0.0428 \text{ m}} 54.3 = 78.7 \text{ W/m}^2 \cdot \text{K}$$

Continued ...

**PROBLEM 13.120 (Cont.)**

Hence, with  $\varepsilon_s = \varepsilon_p = 0.5$  and  $q''_{\text{conv}} = h(T_{\text{m,g}} - T_p)$ ,

$$\frac{5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (T_p^4 - 385^4) \text{ K}^4}{1 + 1 + 0.637} = 78.7 \text{ W/m}^2 \cdot \text{K} (900 - T_p) \text{ K}$$

$$21.5 \times 10^{-8} T_p^4 + 78.7 T_p - 71,302 = 0$$

Which may be solved to yield

$$T_p = 796 \text{ K}$$

The heat rate to one-half of the tube is then

$$q'_{1/2} = q'_{\text{ps}} + q'_{\text{conv}} = \frac{D\sigma(T_p^4 - T_s^4)}{\frac{1 - \varepsilon_p}{\varepsilon_p} + \frac{1}{F_{\text{ps}}} + \frac{1 - \varepsilon_s}{\varepsilon_s} \frac{A_p}{A_s}} + h(\pi D/2)(T_{\text{m,g}} - T_s)$$

$$q'_{1/2} = \frac{0.07 \text{ m} (5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4) (796.4^4 - 385^4) \text{ K}^4}{2.637} + 78.7 \text{ W/m}^2 \cdot \text{K} (0.110 \text{ m}) (900 - 385) \text{ K}$$

$$q'_{1/2} = 572 \text{ W/m} + 4458 \text{ W/m} = 5030 \text{ W/m}$$

The heat rate for the entire tube is

$$q' = 2q'_{1/2} = 10,060 \text{ W/m}$$

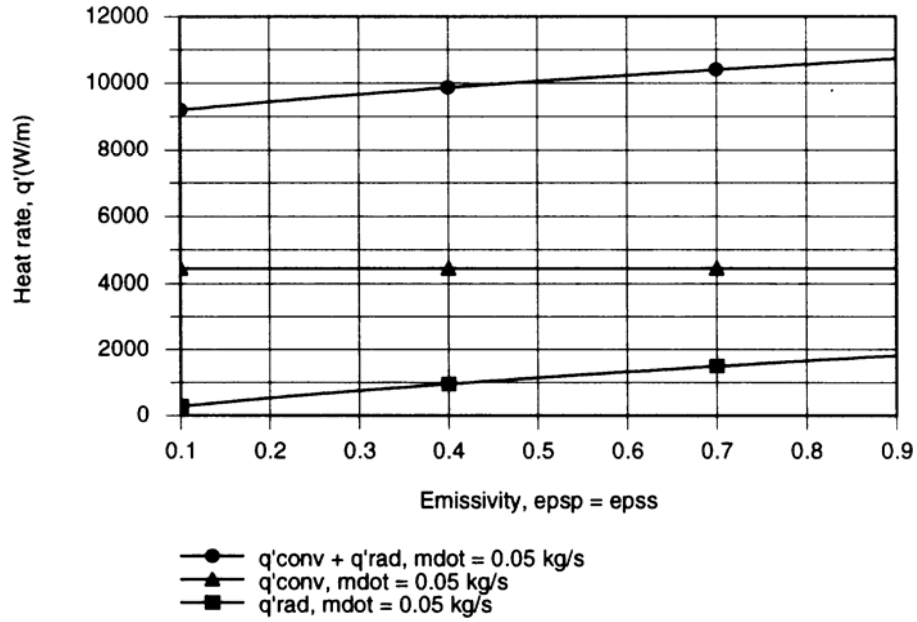

(c) The foregoing model was entered into the *IHT* workspace, and parametric calculations were performed to obtain the following results.

Radiation transfer from the partition increases with increasing  $\varepsilon_p = \varepsilon_s$ , thereby reducing  $T_p$  while increasing  $q'$ . Since  $h$  increases with increasing  $\dot{m}$ ,  $T_p$  and  $q'$  also increase with  $\dot{m}$ .

Continued ...

### PROBLEM 13.120 (Cont.)

Although the radiative contribution to the heat rate increases with increasing  $\epsilon_p = \epsilon_s$ , it still remains small relative to convection.

**COMMENTS:** Contrasting the heat rate predicted for part (b) with that for part (a), it is clear that use of the partition enhances heat transfer to the tube. However, the effect is due primarily to an increase in  $h$  and secondarily to the addition of radiation.

### PROBLEM 13.121

**KNOWN:** Dimensions of horizontal air space separating plates of known temperature. Emissivity of end plates and interleaving aluminum sheets.

**FIND:** (a) Neglecting conduction or convection in the air, determine the heat flux through the system, (b) Neglecting convection and radiation, determine the heat flux through the system, (c) Heat flux through the system accounting for conduction and radiation, (d) Determine whether natural convection is negligible in part (c).

**SCHEMATIC:**

**ASSUMPTIONS:** (1) One-dimensional heat transfer, (2) Diffuse, gray surfaces, (3) Constant properties in each gap, (4) Negligible natural convection.

**PROPERTIES:** Air: Properties evaluated using IHT.

**ANALYSIS:** (a) The radiation heat flux across each of the five gaps is

$$q''_{\text{rad},1-2} = \frac{\sigma(T_1^4 - T_2^4)}{\frac{1}{\varepsilon_1} + \frac{1}{\varepsilon_2} - 1} = \frac{5.67 \times 10^{-8} \frac{\text{W}}{\text{m}^2 \cdot \text{K}^4} [(473\text{K})^4 - T_2^4]}{\frac{1}{0.85} + \frac{1}{0.07} - 1} \quad (1)$$

$$q''_{\text{rad},2-3} = \frac{\sigma(T_2^4 - T_3^4)}{\frac{1}{\varepsilon_2} + \frac{1}{\varepsilon_3} - 1} = \frac{5.67 \times 10^{-8} \frac{\text{W}}{\text{m}^2 \cdot \text{K}^4} [T_2^4 - T_3^4]}{\frac{1}{0.07} + \frac{1}{0.07} - 1} \quad (2)$$

$$q''_{\text{rad},3-4} = \frac{\sigma(T_3^4 - T_4^4)}{\frac{1}{\varepsilon_3} + \frac{1}{\varepsilon_4} - 1} = \frac{5.67 \times 10^{-8} \frac{\text{W}}{\text{m}^2 \cdot \text{K}^4} [T_3^4 - T_4^4]}{\frac{1}{0.07} + \frac{1}{0.07} - 1} \quad (3)$$

Continued...

**PROBLEM 13.121 (Cont.)**

$$q_{\text{rad},4-5}'' = \frac{\sigma(T_4^4 - T_5^4)}{\frac{1}{\epsilon_4} + \frac{1}{\epsilon_5} - 1} = \frac{5.67 \times 10^{-8} \frac{\text{W}}{\text{m}^2 \cdot \text{K}^4} [T_4^4 - T_5^4]}{\frac{1}{0.07} + \frac{1}{0.07} - 1} \quad (4)$$

$$q_{\text{rad},5-6}'' = \frac{\sigma(T_5^4 - T_6^4)}{\frac{1}{\epsilon_5} + \frac{1}{\epsilon_6} - 1} = \frac{5.67 \times 10^{-8} \frac{\text{W}}{\text{m}^2 \cdot \text{K}^4} [T_5^4 - (325\text{K})^4]}{\frac{1}{0.07} + \frac{1}{0.85} - 1} \quad (5)$$

where

$$q_{\text{rad}}'' = q_{\text{rad},1-2}'' = q_{\text{rad},2-3}'' = q_{\text{rad},3-4}'' = q_{\text{rad},4-5}'' = q_{\text{rad},5-6}'' \quad (6)$$

Solving Eqns. (1) through (6) simultaneously yields

$$T_2 = 460.5 \text{ K}, T_3 = 433.5 \text{ K}, T_4 = 400.1 \text{ K}, T_5 = 355.4 \text{ K}, q_{\text{rad}}'' = 19.89 \text{ W/m}^2 \quad <$$

(b) The conduction heat flux across each of the five gaps is

$$q_{\text{cond}}'' = \frac{k_A}{L}(T_1 - T_2) \quad (7)$$

where  $k_A$  is the thermal conductivity of air evaluated at  $\bar{T}_A = (T_1 + T_2)/2$ . Likewise,

$$q_{\text{cond},2-3}'' = \frac{k_B}{L}(T_2 - T_3); \quad k_B = k_{\text{air}} \left( (T_2 + T_3)/2 \right) \quad (8)$$

$$q_{\text{cond},3-4}'' = \frac{k_C}{L}(T_3 - T_4); \quad k_C = k_{\text{air}} \left( (T_3 + T_4)/2 \right) \quad (9)$$

$$q_{\text{cond},4-5}'' = \frac{k_D}{L}(T_4 - T_5); \quad k_D = k_{\text{air}} \left( (T_4 + T_5)/2 \right) \quad (10)$$

$$q_{\text{cond},5-6}'' = \frac{k_E}{L}(T_5 - T_6); \quad k_E = k_{\text{air}} \left( (T_5 + T_6)/2 \right) \quad (11)$$

where

$$q_{\text{cond}}'' = q_{\text{cond},1-2}'' = q_{\text{cond},2-3}'' = q_{\text{cond},3-4}'' = q_{\text{cond},4-5}'' = q_{\text{cond},5-6}'' \quad (12)$$

Continued...

### PROBLEM 13.121 (Cont.)

Solving Eqns. (7) through (12) simultaneously and using IHT to evaluate  $k_A$ ,  $k_B$ ,  $k_C$ ,  $k_D$  and  $k_E$  yields

$$T_2 = 446.5 \text{ K}, T_3 = 418.6 \text{ K}, T_4 = 389.1 \text{ K}, T_5 = 357.4 \text{ K}, q''_{\text{cond}} = 100.6 \text{ W/m}^2 \quad <$$

(c) For each gap,  $q'' = q''_{\text{cond}} + q''_{\text{rad}}$ . Hence,

$$q''_{1-2} = q''_{\text{rad},1-2} + q''_{\text{cond},1-2} \quad (13)$$

$$q''_{2-3} = q''_{\text{rad},2-3} + q''_{\text{cond},2-3} \quad (14)$$

$$q''_{3-4} = q''_{\text{rad},3-4} + q''_{\text{cond},3-4} \quad (15)$$

$$q''_{4-5} = q''_{\text{rad},4-5} + q''_{\text{cond},4-5} \quad (16)$$

$$q''_{5-6} = q''_{\text{rad},5-6} + q''_{\text{cond},5-6} \quad (17)$$

$$\text{where } q'' = q''_{1-2} = q''_{2-3} = q''_{3-4} = q''_{4-5} = q''_{5-6} \quad (18)$$

Solving Eqns. (1) through (5), (8) through (11), and (13) through (18) simultaneously and using IHT to evaluate  $k_A$ ,  $k_B$ ,  $k_C$ ,  $k_D$  and  $k_E$  yields

$$T_2 = 450.2 \text{ K}, T_3 = 421.9 \text{ K}, T_4 = 391.2 \text{ K}, T_5 = 357.4 \text{ K}, q'' = 122.1 \text{ W/m}^2 \quad <$$

(d) The Rayleigh number for gap A is

$$\text{Ra}_{L,A} = \frac{g\beta(T_1 - T_2)L^3}{\nu\alpha}$$

where  $T_1 = 473 \text{ K}$  and  $T_2 = 450.2 \text{ K}$ . Therefore,  $\bar{T} = (473\text{K} + 450.2\text{K})/2 = 461.1\text{K}$ . Hence,

$$\beta = \frac{1}{\bar{T}} = \frac{1}{461.1\text{K}}, \nu = 3.381 \times 10^{-5} \frac{\text{m}^2}{\text{s}} \text{ and } \alpha = 4.931 \times 10^{-5} \frac{\text{m}^2}{\text{s}}$$

from which

$$\text{Ra}_{L,A} = \frac{9.81 \frac{\text{m}}{\text{s}^2} \frac{1}{461.1\text{K}} \times (473\text{K} - 450.2\text{K}) \times 0.01\text{m}^3}{3.381 \times 10^{-5} \frac{\text{m}^2}{\text{s}} \times 4.931 \times 10^{-5} \frac{\text{m}^2}{\text{s}}} = 289.2$$

Continued...

### PROBLEM 13.121 (Cont.)

Repeating the calculation for the remaining gaps yields

$$Ra_{L,B} = 463, Ra_{L,C} = 690, Ra_{L,D} = 1104, Ra_{L,E} = 1747.$$

The largest Rayleigh number is slightly higher than the critical value of 1703. Therefore, natural convection in the gaps is negligible. <

**COMMENTS:** (1) Ignoring the presence of the air will result in an estimated heat flux that is only 16% of the actual value. One must carefully account for conduction or convection effects in radiation problems, in particular when the radiation occurs in conjunction with low emissivity surfaces. (2) The heat flux for combined radiation and conduction exceeds the sum of the individual components acting alone. This is due to the non-linear effects brought about by the fourth-power dependence of the radiation heat flux upon temperature and property variations. (3) The foil temperatures vary for the three simulations. Can you explain why different temperatures exist for the three cases?

IHT code for solution of part (c) is shown below.

```
T1 = 200 + 273
T6 = 50 + 273
emiss1 = 0.85
emiss6 = 0.85
emiss2 = 0.07
emiss3 = emiss2
emiss4 = emiss3
emiss5 = emiss4
sigma=5.67*10^-8

// Air property functions : From Table A.4
// Units: T(K); 1 atm pressure

k12 = k_T("Air",T12) // Thermal conductivity, W/m-K
k23 = k_T("Air",T23) // Thermal conductivity, W/m-K
k34 = k_T("Air",T34) // Thermal conductivity, W/m-K
k45 = k_T("Air",T45) // Thermal conductivity, W/m-K
k56 = k_T("Air",T56) // Thermal conductivity, W/m-K
T12 = (T1 + T2)/2
T23 = (T2 + T3)/2
T34 = (T3 + T4)/2
T45 = (T4 + T5)/2
T56 = (T5 + T6)/2

L = 0.01

//March through the gaps

qrad12 = sigma*(T1^4-T2^4)/(1/emiss1+1/emiss2-1)
qcon12 = k12*(T1-T2)/L
qtot = qrad12+qcon12

qrad23 = sigma*(T2^4-T3^4)/(1/emiss2+1/emiss3-1)
qcon23 = k23*(T2-T3)/L
qtot = qrad23+qcon23
```

Continued...

### PROBLEM 13.121 (Cont.)

$$\begin{aligned}q_{\text{rad}34} &= \sigma(T_3^4 - T_4^4) / (1/\epsilon_{\text{miss}3} + 1/\epsilon_{\text{miss}4} - 1) \\q_{\text{con}34} &= k_{34}(T_3 - T_4)/L \\q_{\text{tot}} &= q_{\text{rad}34} + q_{\text{con}34}\end{aligned}$$

$$\begin{aligned}q_{\text{rad}45} &= \sigma(T_4^4 - T_5^4) / (1/\epsilon_{\text{miss}4} + 1/\epsilon_{\text{miss}5} - 1) \\q_{\text{con}45} &= k_{45}(T_4 - T_5)/L \\q_{\text{tot}} &= q_{\text{rad}45} + q_{\text{con}45}\end{aligned}$$

$$\begin{aligned}q_{\text{rad}56} &= \sigma(T_5^4 - T_6^4) / (1/\epsilon_{\text{miss}5} + 1/\epsilon_{\text{miss}6} - 1) \\q_{\text{con}56} &= k_{56}(T_5 - T_6)/L \\q_{\text{tot}} &= q_{\text{rad}56} + q_{\text{con}56}\end{aligned}$$

//Note that one must input initial temperatures of around 350 K for all values, or else the system of equations will not converge.

### PROBLEM 13.122

**KNOWN:** Diameters, temperatures, and emissivities of concentric spheres.

**FIND:** Rate at which nitrogen is vented from the inner sphere. Effect of radiative properties on evaporation rate.

**SCHEMATIC:**

**ASSUMPTIONS:** Diffuse-gray surfaces.

**PROPERTIES:** Liquid nitrogen (given):  $h_{fg} = 2 \times 10^5 \text{ J/kg}$ ; *Table A-4*, Helium ( $\bar{T} = (T_i + T_o)/2 = 180 \text{ K}$ , 1 atm):  $\nu = 51.3 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.107 \text{ W/m}\cdot\text{K}$ ,  $\alpha = 76.2 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.673$ ,  $\beta = 0.00556 \text{ K}^{-1}$ .

**ANALYSIS:** (a) Performing an energy balance for a control surface about the liquid nitrogen, it follows that  $q = q_{\text{conv}} + q_{\text{rad}} = \dot{m}h_{fg}$ . The convection heat rate is given by Eqs. 9.61 through 9.63.

$$L_s = \frac{\left(\frac{1}{r_i} - \frac{1}{r_o}\right)^{4/3}}{2^{1/3} \left(r_i^{-7/5} + r_o^{-7/5}\right)^{5/3}} = \frac{\left(\frac{1}{0.5\text{m}} - \frac{1}{0.55\text{m}}\right)^{4/3}}{2^{1/3} \left(0.5\text{m}^{-7/5} + 0.55\text{m}^{-7/5}\right)^{5/3}} = 0.0057\text{m}$$

The Rayleigh number is

$$\text{Ra}_s = \left| \frac{g\beta(T_i - T_o)L_s^3}{\nu\alpha} \right| = \left| \frac{9.8\text{m/s}^2(0.00556\text{K}^{-1})(77 - 283)\text{K}(0.0057\text{m})^3}{51.3 \times 10^{-6}\text{m}^2/\text{s} \times 76.2 \times 10^{-6}\text{m}^2/\text{s}} \right| = 529$$

From Eq. 9.62,

$$\frac{k_{\text{eff}}}{k} = 0.74 \left( \frac{\text{Pr}}{0.861 + \text{Pr}} \right)^{1/4} \text{Ra}_s^{1/4} = 0.74 \left( \frac{0.673}{0.861 + 0.673} \right)^{1/4} 529^{1/4} = 2.89$$

Therefore,  $k_{\text{eff}} = 2.89 \times 0.107 \text{ W/m}\cdot\text{K} = 0.309 \text{ W/m}\cdot\text{K}$ . From Eq. 9.61,

$$q_{\text{conv}} = \frac{4\pi k_{\text{eff}}(T_i - T_o)}{(1/r_i) - (1/r_o)} = \frac{4 \times \pi \times 0.309 \text{ W/m}\cdot\text{K} \times (206\text{K})}{(1/0.5\text{m}) - (1/0.55\text{m})} = 4399\text{W}$$

Continued...

### PROBLEM 13.122 (Cont.)

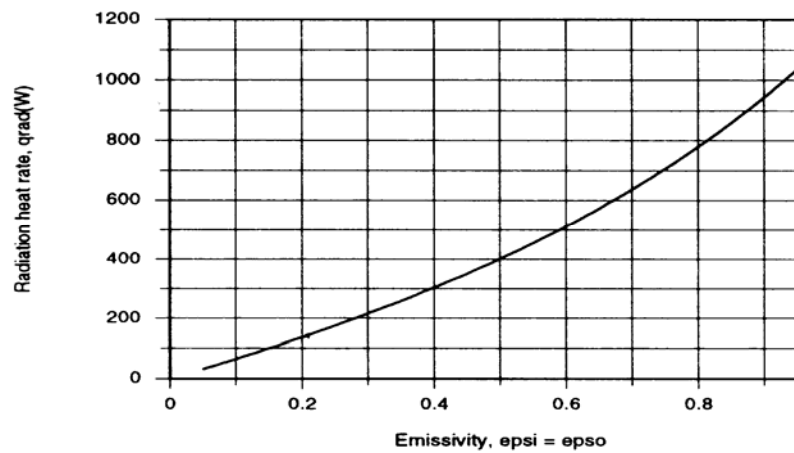

From Table 13.21,

$$q_{\text{rad}} = q_{\text{oi}} = \frac{\sigma \pi D_1^2 (T_o^4 - T_1^4)}{1/\epsilon_i + ((1 - \epsilon_o)/\epsilon_o)(D_i/D_o)^2}$$

$$= \frac{(5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4) \pi (1 \text{ m})^2 (283^4 - 77^4) \text{ K}^4}{1/0.3 + (0.7/0.3)(1/1.1)^2} = 216 \text{ W.}$$

Hence,  $\dot{m} = q/h_{\text{fg}} = (4399 + 216) \text{ W} / 2 \times 10^5 \text{ J/kg} = 0.023 \text{ kg/s.}$  <

With the cavity evacuated, *IHT* was used to compute the radiation heat rate as a function of  $\epsilon_i = \epsilon_o$ .

Clearly, significant advantage is associated with reducing the emissivities and  $q_{\text{rad}} = 31.8 \text{ W}$  for  $\epsilon_i = \epsilon_o = 0.05$ .

**COMMENTS:** The convection heat rate is too large. It could be reduced by replacing He with a gas of smaller  $k$ , a cryogenic insulator (Table A.3), or a vacuum. Radiation effects are second order for small values of the emissivity.

### PROBLEM 13.123

**KNOWN:** Dimensions, emissivity and upper temperature limit of coated panel. Arrangement and power dissipation of a radiant heater. Temperature of surroundings.

**FIND:** (a) Minimum panel-heater separation, neglecting convection, (b) Minimum panel-heater separation, including convection.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Top and bottom surfaces of heater and panel, respectively, are adiabatic, (2) Bottom and top surfaces of heater and panel, respectively are diffuse-gray, (3) Surroundings form a large enclosure about the heater-panel arrangement, (4) Steady-state conditions, (5) Heater power is dissipated entirely as radiation (negligible convection), (6) Air is quiescent and convection from panel may be approximated as free convection from a horizontal surface, (7) Air is at atmospheric pressure.

**PROPERTIES:** Table A-4, Air ( $T_f = (400 + 298)/2 \approx 350$  K, 1 atm):  $\nu = 20.9 \times 10^{-6}$  m<sup>2</sup>/s,  $k = 0.03$  W/m·K,  $Pr = 0.700$ ,  $\alpha = 29.9 \times 10^{-6}$  m<sup>2</sup>/s,  $\beta = 2.86 \times 10^{-3}$  K<sup>-1</sup>.

**ANALYSIS:** (a) Neglecting convection effects, the panel constitutes a floating potential for which the net radiative transfer must be zero. That is, the panel behaves as a re-radiating surface for which  $E_{b2} = J_2$ . Hence

$$q_1 = \frac{J_1 - E_{b2}}{1/A_1 F_{12}} + \frac{J_1 - E_{b3}}{1/A_1 F_{13}} \quad (1)$$

and evaluating terms

$$E_{b2} = \sigma T_2^4 = 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (400 \text{ K})^4 = 1452 \text{ W/m}^2$$

$$E_{b3} = \sigma T_3^4 = 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (298 \text{ K})^4 = 447 \text{ W/m}^2$$

$$F_{13} = 1 - F_{12} \quad A_1 = 25 \text{ m}^2$$

find that

$$\frac{75,000 \text{ W}}{25 \text{ m}^2} = \frac{J_1 - 1452}{1/F_{12}} + \frac{J_1 - 447}{1/(1 - F_{12})}$$

$$3000 \text{ W/m}^2 = F_{12} (J_1 - 1452) + (J_1 - 447) - F_{12} (J_1 - 447)$$

$$J_1 = 3447 + 1005 F_{12}. \quad (2)$$

Performing a radiation balance on the panel yields

$$\frac{J_1 - E_{b2}}{1/A_1 F_{12}} = \frac{E_{b2} - E_{b3}}{1/A_2 F_{23}}.$$

Continued ...

**PROBLEM 13.123 (Cont.)**

With  $A_1 = A_2$  and  $F_{23} = 1 - F_{12}$

$$F_1 (J_1 - 1452) = (1 - F_{12})(1452 - 447)$$

or

$$447F_{12} = F_{12}J_1 - 1005. \quad (3)$$

Substituting for  $J_1$  from Eq. (2), find

$$447F_{12} = F_{12} (3447 + 1005F_{12}) - 1005$$

$$1005F_{12}^2 + 3000F_{12} - 1005 = 0$$

$$F_{12} = 0.30.$$

Hence from Fig. 13.4, with  $X/L = Y/L$  and  $F_{ij} = 0.3$ ,

$$X/L \approx 1.45$$

$$L \approx 5 \text{ m} / 1.45 = 3.45 \text{ m.} \quad <$$

(b) Accounting for convection from the panel, the net radiation transfer is no longer zero at this surface and  $E_{b2} \neq J_2$ . It then follows that

$$q_1 = \frac{J_1 - J_2}{1/A_1 F_{12}} + \frac{J_1 - E_{b3}}{1/A_1 F_{13}} \quad (4)$$

where, from an energy balance on the panel,

$$\frac{J_2 - E_{b2}}{(1 - \varepsilon_2)/\varepsilon_2 A_2} = q_{\text{conv},2} = \bar{h} A_2 (T_2 - T_\infty). \quad (5)$$

With  $L \equiv A_s/P = 25 \text{ m}^2/20 \text{ m} = 1.25 \text{ m}$ ,

$$\text{Ra}_L = \frac{g\beta(T_s - T_\infty)L^3}{\nu\alpha} = \frac{9.8 \text{ m/s}^2 (2.86 \times 10^{-3} \text{ K}^{-1})(102 \text{ K})(1.25 \text{ m})^3}{(20.9 \times 29.9) 10^{-12} \text{ m}^4/\text{s}^2} = 8.94 \times 10^9.$$

Hence, from Eq. 9.31

$$\overline{\text{Nu}}_L = 0.15 \text{Ra}_L^{1/3} = 0.15 (8.94 \times 10^9)^{1/3} = 311$$

$$\bar{h} = 311 \text{ k/L} = 311 \frac{0.03 \text{ W/m} \cdot \text{K}}{1.25 \text{ m}} = 7.46 \text{ W/m}^2 \cdot \text{K}$$

$$q''_{\text{conv},2} = 7.46 \text{ W/m}^2 \cdot \text{K} (102 \text{ K}) = 761 \text{ W/m}^2.$$

From Eq. (5)

$$J_2 = E_{b2} + \frac{1 - \varepsilon_2}{\varepsilon_2} q''_{\text{conv},2} = 1452 + \frac{0.7}{0.3} 761 = 3228 \text{ W/m}^2.$$

Continued ...

### PROBLEM 13.123 (Cont.)

From Eq. (4),

$$\frac{75,000}{25} = \frac{J_1 - 3228}{1/F_{12}} + \frac{J_1 - 447}{1/(1 - F_{12})}$$

$$3000 = F_{12}(J_1 - 3228) + J_1 - 447 - F_{12}(J_1 - 447)$$

$$J_1 = 3447 + 2781F_{12}. \quad (6)$$

From an energy balance on the panel,

$$\frac{J_1 - J_2}{1/A_1 F_{12}} + \frac{E_{b3} - J_2}{1/A_2 F_{23}} = \frac{J_2 - E_{b2}}{(1 - \varepsilon_2)/\varepsilon_2 A_2} = q_{\text{conv},2}$$

$$F_{12}(J_1 - 3228) + (1 - F_{12})(447 - 3228) = 761$$

$$F_{12}J_1 - 447F_{12} = 3542.$$

Substituting from Eq. (6),

$$F_{12}(3447 + 2781F_{12}) - 447F_{12} = 3542$$

$$2781F_{12}^2 + 3000F_{12} - 3542 = 0$$

$$F_{12} = 0.71.$$

Hence from Fig. 13.4, with  $X/L = Y/L$  and  $F_{ij} = 0.71$ ,

$$X/L = 5.7$$

$$L \approx 5 \text{ m} / 5.7 = 0.88 \text{ m}. \quad <$$

**COMMENTS:** (1) The results are independent of the heater surface radiative properties. (2) Convection at the heater surface would reduce the heat rate  $q_1$  available for radiation exchange and hence reduce the value of  $L$ .

### PROBLEM 13.124

**KNOWN:** Diameter and emissivity of rod heater. Diameter and position of reflector. Width, emissivity, temperature and position of coated panel. Temperature of air and large surroundings.

**FIND:** (a) Equivalent thermal circuit, (b) System of equations for determining heater and reflector temperatures. Values of temperatures for prescribed conditions, (c) Electrical power needed to operate heater.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Diffuse-gray surfaces, (3) Large surroundings act as blackbody, (4) Surfaces are infinitely long (negligible end effects), (5) Air is quiescent, (6) Negligible convection at reflector, (7) Reflector and panel are perfectly insulated.

**PROPERTIES:** Table A-4, Air ( $T_f = 350$  K, 1 atm):  $k = 0.03$  W/m·K,  $\nu = 20.9 \times 10^{-6}$  m<sup>2</sup>/s,  $\alpha = 29.9 \times 10^{-6}$  m<sup>2</sup>/s, Pr = 0.70; ( $T_f = (1295 + 300)/2 = 800$  K):  $k = 0.0573$  W/m·K,  $\nu = 84.9 \times 10^{-6}$  m<sup>2</sup>/s,  $\alpha = 120 \times 10^{-6}$  m<sup>2</sup>/s.

**ANALYSIS:** (a) We have assumed blackbody behavior for  $A_1$  and  $A_4$ ; hence,  $J = E_b$ . Also,  $A_2$  is insulated and has negligible convection; hence  $q = 0$  and  $J_2 = E_{b2}$ . The equivalent thermal circuit is:

(b) Performing surface energy balances at 1, 2 and 3:

$$q_1 - q_{\text{conv},1} = \frac{E_{b1} - E_{b2}}{1/A_1 F_{12}} + \frac{E_{b1} - J_3}{1/A_1 F_{13}} + \frac{E_{b1} - E_{b4}}{1/A_1 F_{14}} \quad (1)$$

$$0 = \frac{E_{b1} - E_{b2}}{1/A_2 F_{21}} + \frac{J_3 - E_{b2}}{1/A_2 F_{23}} + \frac{E_{b4} - E_{b2}}{1/A_2 F_{24}} \quad (2)$$

$$\frac{J_3 - E_{b3}}{(1 - \epsilon_3)/\epsilon_3 A_3} = \frac{E_{b1} - J_3}{1/A_3 F_{31}} + \frac{E_{b2} - J_3}{1/A_3 F_{32}} + \frac{E_{b4} - J_3}{1/A_3 F_{34}} \quad (3a)$$

where

$$\frac{J_3 - E_{b3}}{(1 - \epsilon_3)/\epsilon_3 A_3} = q_{\text{conv},3} \quad (3b)$$

Continued ...

### PROBLEM 13.124 (Cont.)

Solution procedure with  $E_{b3}$  and  $E_{b4}$  known: Evaluate  $q_{\text{conv},3}$  and use Eq. (3b) to obtain  $J_3$ ; Solve Eqs. (2) and (3a) simultaneously for  $E_{b1}$  and  $E_{b2}$  and hence  $T_1$  and  $T_2$ ; Evaluate  $q_{\text{conv},1}$  and use Eq. (1) to obtain  $q_1$ .

For *free convection* from a heated, horizontal plate using Eqs. 9.29, 9.25, and 9.31:

$$L_c = \frac{A_s}{P} = \frac{(W \times L)}{(2L + 2W)} \approx \frac{W}{2} = 0.5 \text{ m}$$

$$\text{Ra}_L = \frac{g\beta(T_3 - T_\infty)L_c^3}{\alpha\nu} = \frac{9.8 \text{ m/s}^2 (350 \text{ K})^{-1} (100 \text{ K})(0.5 \text{ m})^3}{20.9 \times 29.9 \times 10^{-12} \text{ m}^4/\text{s}^2} = 5.6 \times 10^8$$

$$\overline{\text{Nu}}_L = 0.15 \text{Ra}_L^{1/3} = 0.15 (5.6 \times 10^8)^{1/3} = 123.6$$

$$\overline{h}_3 = \frac{k}{L_c} \overline{\text{Nu}}_L = \frac{0.03 \text{ W/m} \cdot \text{K} \times 123.6}{0.5 \text{ m}} = 7.42 \text{ W/m}^2 \cdot \text{K}.$$

$$q''_{\text{conv},3} = \overline{h}_3 (T_3 - T_\infty) = 742 \text{ W/m}^2.$$

Hence, with

$$E_{b3} = \sigma T_3^4 = 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (400 \text{ K})^4 = 1451 \text{ W/m}^2$$

using Eq. (3b) find

$$J_3 = E_{b3} + \frac{1 - \varepsilon_3}{\varepsilon_3 A_3} q_{\text{conv},3} = (1451 + [0.3/0.7]742) = 1769 \text{ W/m}^2.$$

*View Factors:* From symmetry, it follows that  $F_{12} = 0.5$ . With  $\theta = \tan^{-1}(W/2)/H = \tan^{-1}(0.5) = 26.57^\circ$ , it follows that

$$F_{13} = 2\theta/360 = 0.148.$$

From summation and reciprocity relations,

$$F_{14} = 1 - F_{12} - F_{13} = 0.352$$

$$F_{21} = (A_1/A_2)F_{12} = (2D_1/D_2)F_{12} = 0.02 \times 0.5 = 0.01$$

$$F_{23} = (A_3/A_2)F_{32} = (2/\pi)(F_{32}' - F_{31}).$$

For  $X/L = 1$ ,  $Y/L \approx \infty$ , find from Fig. 13.4 that  $F_{32}' \approx 0.42$ . Also find,

$$F_{31} = (A_1/A_3)F_{13} = (\pi \times 0.01/1)0.148 = 0.00465 \approx 0.005$$

$$F_{23} = (2/\pi)(0.42 - 0.005) = 0.264$$

$$F_{22} \approx 1 - F_{22}' = 1 - (A_2'/A_2)F_{22}' = 1 - (2/\pi) = 0.363$$

$$F_{24} = 1 - F_{21} - F_{22} - F_{23} = 0.363$$

Continued ...

**PROBLEM 13.124 (Cont.)**

$$F_{31} = 0.005, \quad F_{32} = 0.415$$

$$F_{34} = 1 - F_{32}' = 1 - 0.42 = 0.58.$$

With  $E_{b4} = \sigma T_4^4 = 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (300 \text{ K})^4 = 459 \text{ W/m}^2$ ,

$$\begin{aligned} \text{Eq. (3a)} \rightarrow 0.005(E_{b1} - 1769) + 0.415(E_{b2} - 1769) + 0.58(459 - 1769) &= 742 \\ 0.005E_{b1} + 0.415E_{b2} &= 2245 \end{aligned} \quad (4)$$

$$\begin{aligned} \text{Eq. (2)} \rightarrow 0.01(E_{b1} - E_{b2}) + 0.264(1769 - E_{b2}) + 0.363(459 - E_{b2}) &= 0 \\ 0.01E_{b1} - 0.637E_{b2} + 633.6 &= 0. \end{aligned} \quad (5)$$

Hence, manipulating Eqs. (4) and (5), find

$$E_{b2} = 0.0157E_{b1} + 994.7$$

$$0.005E_{b1} + (0.415)(0.0157E_{b1} + 994.7) = 2245.$$

$$E_{b1} = 159,322 \text{ W/m}^2 \quad T_1 = (E_{b1}/\sigma)^{1/4} = 1295 \text{ K} \quad <$$

$$E_{b2} = 0.0157(159,322) + 994.7 = 3496 \text{ W/m}^2 \quad T_2 = (E_{b2}/\sigma)^{1/4} = 498 \text{ K}. \quad <$$

(c) With  $T_1 = 1295 \text{ K}$ , then  $T_f = (1295 + 300)/2 \approx 800 \text{ K}$ , and using Eq. 9.33

$$Ra_D = \frac{g\beta(T_1 - T_\infty)D_1^3}{\alpha\nu} = \frac{9.8 \text{ m/s}^2 (1/800 \text{ K})(1295 - 300) \text{ K} (0.01 \text{ m})^3}{120 \times 84.9 \times 10^{-12} \text{ m}^4/\text{s}^2} = 1196$$

$$\overline{Nu}_D = 0.85Ra_D^{0.188} = 0.85(1196)^{0.188} = 3.22$$

$$\overline{h}_1 = (k/D_1)\overline{Nu}_D = (0.0573/0.01) \times 3.22 = 18.5 \text{ W/m}^2 \cdot \text{K}.$$

The convection heat flux is

$$q''_{\text{conv},1} = \overline{h}_1(T_1 - T_\infty) = 18.5(1295 - 300) = 18,407 \text{ W/m}^2,$$

Using Eq. (1), find

$$q''_1 = q''_{\text{conv},1} + F_{12}(E_{b1} - E_{b2}) + F_{13}(E_{b1} - J_3) + F_{14}(E_{b1} - E_{b4})$$

$$\begin{aligned} q''_1 &= 18,407 + 0.5(159,322 - 3496) \\ &\quad + 0.148(159,322 - 1769) + 0.352(159,322 - 459) \end{aligned}$$

$$q''_1 = 18,407 + (77,913 + 23,314 + 55,920)$$

$$q''_1 = 18,407 + 236,381 = 254,788 \text{ W/m}^2$$

$$q'_1 = \pi D_1 q''_1 = \pi(0.01)254,788 = 8000 \text{ W/m}. \quad <$$

**COMMENTS:** Although convection represents less than 8% of the net radiant transfer from the heater, it is equal to the net radiant transfer to the panel. Since the reflector is a reradiating surface, results are independent of its emissivity.

### PROBLEM 13.125

**KNOWN:** Temperature, power dissipation and emissivity of a cylindrical heat source. Surface emissivities of a parabolic reflector. Temperature of air and surroundings.

**FIND:** (a) Radiation circuit, (b) Net radiation transfer from the heater, (c) Net radiation transfer from the heater to the surroundings, (d) Temperature of reflector.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Heater and reflector are in quiescent and infinite air, (3) Surroundings are infinitely large, (4) Reflector is thin (isothermal), (5) Diffuse-gray surfaces.

**PROPERTIES:** Table A-4, Air ( $T_f = 750$  K, 1 atm):  $\nu = 76.37 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0549 \text{ W/m}\cdot\text{K}$ ,  $\alpha = 109 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.702$ .

**ANALYSIS:** (a) The thermal circuit is

(b) Energy transfer from the heater is by radiation and free convection. Hence,

$$P'_1 = q'_1 + q'_{1,\text{conv}}$$

where

$$q'_{1,\text{conv}} = \bar{h}\pi D_1 (T_1 - T_\infty)$$

and

$$\text{Ra}_D = \frac{g\beta(T_1 - T_\infty)D^3}{\nu\alpha} = \frac{9.8 \text{ m/s}^2 (750 \text{ K})^{-1} (900 \text{ K})(0.005 \text{ m})^3}{76.37 \times 109 \times 10^{-12} \text{ m}^4/\text{s}^2} = 176.6.$$

Using the Churchill and Chu correlation of Chapter 9, find

$$\bar{\text{Nu}}_D = \left\{ 0.6 + \frac{0.387 \text{Ra}_D^{1/6}}{\left[ 1 + (0.559/\text{Pr})^{9/16} \right]^{8/27}} \right\}^2 = \left\{ 0.6 + \frac{0.387(176.6)^{1/6}}{\left[ 1 + (0.559/0.702)^{9/16} \right]^{8/27}} \right\}^2 = 1.85$$

$$\bar{h} = \bar{\text{Nu}}_D (k/D) = 1.85(0.0549 \text{ W/m}\cdot\text{K}/0.005 \text{ m}) = 20.3 \text{ W/m}^2 \cdot \text{K}.$$

Continued ...

**PROBLEM 13.125 (Cont.)**

Hence,

$$q'_{1,\text{conv}} = 20.3 \text{ W/m}^2 \cdot \text{K} \pi (0.005 \text{ m})(1200 - 300) \text{ K} = 287 \text{ W/m}$$

$$q'_1 = 1500 \text{ W/m} - 287 \text{ W/m} = 1213 \text{ W/m} \quad <$$

(c) The net radiative heat transfer from the heater to the surroundings is

$$q'_{1(\text{sur})} = A'_1 F_{1\text{sur}} (J_1 - J_{\text{sur}}).$$

The view factor is

$$F_{1\text{sur}} = (135/360) = 0.375$$

and the radiosities are

$$J_{\text{sur}} = \sigma T_{\text{sur}}^4 = 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (300 \text{ K})^4 = 459 \text{ W/m}^2$$

$$J_1 = E_{b1} - q'_1 (1 - \varepsilon_1) \varepsilon_1 A'_1 = 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (1200 \text{ K})^4 - 1213 \text{ W/m} [0.2/0.8\pi(0.005 \text{ m})]$$

$$J_1 = 98,268 \text{ W/m}^2.$$

Hence

$$q'_{1(\text{sur})} = \pi (0.005 \text{ m}) 0.375 (98,268 - 459) \text{ W/m}^2 = 576 \text{ W/m} \quad <$$

(d) Perform an energy balance on the reflector,

$$q'_{2i} = q'_{2o} + q'_{2,\text{conv}}$$

$$\frac{J_{2i} - E_{b2}}{(1 - \varepsilon_{2i})/\varepsilon_{2i}A'_2} = \frac{E_{b2} - J_{\text{sur}}}{(1 - \varepsilon_{2o})/\varepsilon_{2o}A'_2 + 1/A'_2 F_{2o(\text{sur})}} + 2\bar{h}_2 A'_2 (T_2 - T_\infty).$$

The radiosity of the reflector is

$$J_{2i} = J_1 - \frac{q'_{1(2i)}}{A'_1 F_{1(2i)}} = 98,268 \text{ W/m}^2 - \frac{(1213 - 576) \text{ W/m}}{\pi (0.005 \text{ m})(225/360)}$$

$$J_{2i} = 33,384 \text{ W/m}^2.$$

Hence

$$\frac{33,384 - 5.67 \times 10^{-8} (T_2^4)}{(0.9/0.1 \times 0.2 \text{ m})} = \frac{5.67 \times 10^{-8} (T_2^4) - 459}{(0.2/0.8 \times 0.2 \text{ m}) + (1/0.2 \text{ m} \times 1)} + 2 \times 0.4 (T_2 - 300)$$

$$741.9 - 0.126 \times 10^{-8} T_2^4 = 0.907 \times 10^{-8} T_2^4 - 73.4 + 0.8 T_2 - 240$$

$$1.033 \times 10^{-8} T_2^4 + 0.8 T_2 = 1005$$

which may be solved to yield

$$T_2 = 502 \text{ K} \quad <$$

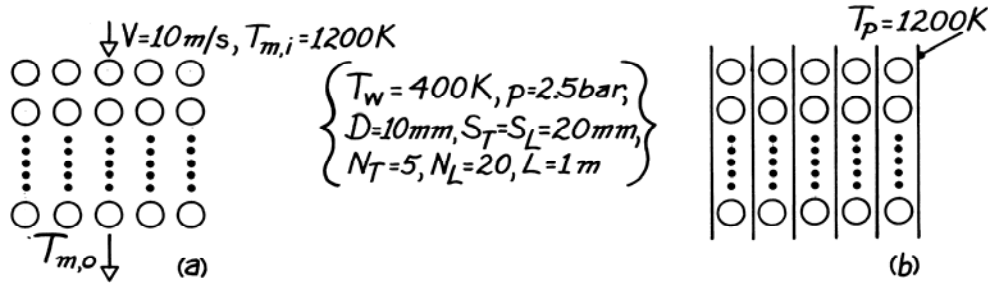

**COMMENTS:** Choice of small  $\varepsilon_{2i}$  and large  $\varepsilon_{2o}$  insures that most of the radiation from heater is reflected to surroundings and reflector temperature remains low.

### PROBLEM 13.126

**KNOWN:** Geometrical conditions associated with tube array. Tube wall temperature and pressure of water flowing through tubes. Gas inlet velocity and temperature when heat is transferred from products of combustion in cross-flow, or temperature of electrically heated plates when heat is transferred by radiation from the plates.

**FIND:** (a) Steam production rate for gas flow without heated plates, (b) Steam production rate with heated plates and no gas flow, (c) Effects of inserting unheated plates with gas flow.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Negligible gas radiation, (3) Tube and plate surfaces may be approximated as blackbodies, (4) Gas outlet temperature is 600 K.

**PROPERTIES:** Table A-4, Air ( $\bar{T} = 900$  K, 1 atm):  $\rho = 0.387$  kg/m<sup>3</sup>,  $c_p = 1121$  J/kg·K,  $\nu = 102.9 \times 10^{-6}$  m<sup>2</sup>/s,  $k = 0.062$  W/m·K,  $Pr = 0.720$ ; (T = 400 K):  $Pr = 0.686$ ; (T = 1200 K):  $\rho = 0.29$  kg/m<sup>3</sup>; Table A-6, Sat. water (2.5 bars):  $h_{fg} = 2.18 \times 10^6$  J/kg.

**ANALYSIS:** (a) With

$$V_{\max} = [S_T / (S_T - D)] V = 20 \text{ m/s}$$

$$Re_D = \frac{V_{\max} D}{\nu} = \frac{20 \text{ m/s} (0.01 \text{ m})}{102.9 \times 10^{-6} \text{ m}^2/\text{s}} = 1944$$

and from the Zukauskas correlation of Chapter 7 with  $C_1 = 0.27$  and  $m = 0.63$ ,

$$\bar{Nu}_D = 0.27 (1944)^{0.63} (0.720)^{0.36} (0.720/0.686)^{1/4} = 28.7$$

$$\bar{h} = 0.062 \text{ W/m} \cdot \text{K} \times 28.7 / 0.01 \text{ m} = 178 \text{ W/m}^2 \cdot \text{K}.$$

The outlet temperature may be evaluated from

$$\frac{T_s - T_{m,o}}{T_s - T_{m,i}} = \exp\left(-\frac{\bar{h}A}{\dot{m}c_p}\right) = \exp\left(-\frac{\bar{h}N\pi D}{\rho V N_T S_T c_p}\right)$$

$$\frac{400 - T_{m,o}}{400 - 1200} = \exp\left(-\frac{178 \text{ W/m}^2 \cdot \text{K} \times 100 \times \pi \times 0.01 \text{ m}}{0.29 \text{ kg/m}^3 \times 10 \text{ m/s} \times 5 \times 0.02 \text{ m} \times 1121 \text{ J/kg} \cdot \text{K}}\right)$$

$$T_{m,o} = 543 \text{ K}.$$

Continued ...

**PROBLEM 13.126 (Cont.)**

With

$$\Delta T_{\ell m} = \frac{(T_s - T_{m,i}) - (T_s - T_{m,o})}{\ln[(T_s - T_{m,i}) / (T_s - T_{m,o})]} = \frac{-800 - (-143)}{\ln(800/143)} = -382 \text{ K}$$

find

$$q = \bar{h} A \Delta T_{\ell m} = 178 \text{ W/m}^2 \cdot \text{K} (100) \pi (0.01 \text{ m}) 1 \text{ m} (-382 \text{ K})$$

$$q = -214 \text{ kW.}$$

If the water enters and leaves as saturated liquid and vapor, respectively, it follows that  $-q = \dot{m} h_{fg}$ , hence

$$\dot{m} = \frac{214,000 \text{ W}}{2.18 \times 10^6 \text{ J/kg}} = 0.098 \text{ kg/s.} \quad <$$

(b) The radiation exchange between the plates and tube walls is

$$q = \left[ A_p F_{ps} \sigma (T_p^4 - T_s^4) \right] \cdot 2 \cdot N_T$$

where the factor of 2 is due to radiation transfer from two plates. The view factor and area are

$$F_{ps} = 1 - \left[ 1 - (D/S)^2 \right]^{1/2} + (D/S) \tan^{-1} \left[ \left( S^2 - D^2 \right) / D^2 \right]^{1/2}$$

$$F_{ps} = 1 - 0.866 + 0.5 \tan^{-1} 1.732 = 1 - 0.866 + 0.524$$

$$F_{ps} = 0.658$$

$$A_p = N_L \cdot S_L \cdot 1 \text{ m} = 20 \times 0.02 \text{ m} \times 1 \text{ m} = 0.40 \text{ m}^2.$$

Hence,

$$q = 5 \times \left[ 0.80 \text{ m}^2 \times 0.658 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (1200^4 - 400^4) \text{ K}^4 \right]$$

$$q = 305,440 \text{ W}$$

and the steam production rate is

$$\dot{m} = \frac{305,440 \text{ W}}{2.18 \times 10^6 \text{ J/kg}} = 0.140 \text{ kg/s.} \quad <$$

(c) The plate temperature is determined by an energy balance for which convection to the plate from the gas is equal to net radiation transfer from the plate to the tube. Conditions are complicated by the fact that the gas transfers energy to both the plate and the tubes, and its decay is not governed by a simple exponential. Insertion of the plates enhances heat transfer to the tubes and thereby increases the steam generation rate. However, for the prescribed conditions, the effect would be small, since in case (a), the heat transfer is already  $\approx 80\%$  of the maximum possible transfer.

### PROBLEM 13.127

**KNOWN:** Temperature and emissivity of ceramic plate which is separated from a glass plate of equivalent height and width by an air space. Temperature of air and surroundings on opposite side of glass. Spectral radiative properties of glass.

**FIND:** (a) Transmissivity of glass, (b) Glass temperature  $T_g$  and total heat rate  $q_h$ , (c) Effect of external forced convection on  $T_g$  and  $q_h$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Spectral distribution of emission from ceramic approximates that of a blackbody, (2) Glass surface is diffuse, (3) Atmospheric air in cavity and ambient, (4) Cavity may be approximated as a two-surface enclosure with infinite parallel plates, (5) Glass is isothermal.

**PROPERTIES:** Table A-4, air ( $p = 1$  atm): Evaluated at  $\bar{T} = (T_c + T_g)/2$  and  $T_f = (T_g + T_\infty)/2$  using *IHT Properties Toolpad*.

**ANALYSIS:** (a) The total transmissivity of the glass is

$$\tau = \frac{\int_0^\infty \tau_\lambda E_{\lambda,b} d\lambda}{E_b} = \int_{\lambda_1=0.4\mu\text{m}}^{\lambda_2=1.6\mu\text{m}} (E_{\lambda,b} / E_b) d\lambda = F_{(0 \rightarrow \lambda_2)} - F_{(0 \rightarrow \lambda_1)}$$

With  $\lambda_2 T = 1600 \mu\text{m}\cdot\text{K}$  and  $\lambda_1 T = 400 \mu\text{m}\cdot\text{K}$ , respectively, Table 12.1 yields  $F_{(0 \rightarrow \lambda_2)} = 0.0197$  and  $F_{(0 \rightarrow \lambda_1)} = 0.0$ . Hence,

$$\tau = 0.0197$$

With so little transmission of radiation from the ceramic, the glass plate may be assumed to be opaque to a good approximation. Since more than 98% of the incident radiation is at wavelengths exceeding  $1.6 \mu\text{m}$ , for which  $\alpha_\lambda = 0.9$ ,  $\alpha_g \approx 0.9$ . Also, since  $T_g < T_c$ , nearly 100% of emission from the glass is at  $\lambda > 1.6 \mu\text{m}$ , for which  $\epsilon_\lambda = \alpha_\lambda = 0.9$ ,  $\epsilon_g = 0.9$  and the glass may be approximated as a gray surface.

(b) The glass temperature may be obtained from an energy balance of the form  $q''_{\text{conv},i} + q''_{\text{rad},i} = q''_{\text{conv},o} + q''_{\text{rad},o}$ . Using Eqs. 13.24 and 13.27 to evaluate  $q''_{\text{rad},i}$  and  $q''_{\text{rad},o}$ , respectively, it follows that

$$\bar{h}_i (T_c - T_g) + \frac{\sigma (T_c^4 - T_g^4)}{\frac{1}{\epsilon_c} + \frac{1}{\epsilon_g} - 1} = \bar{h}_o (T_g - T_\infty) + \epsilon_g \sigma (T_g^4 - T_{\text{sur}}^4)$$

Continued ...

### PROBLEM 13.127 (Cont.)

where, assuming  $10^4 \leq Ra_L \leq 10^7$ ,  $\bar{h}_i$  and  $\bar{h}_o$  are given by Eqs. 9.52 and 9.26, respectively,

$$\bar{h}_i = 0.42 \frac{k_i}{L} Ra_L^{1/4} Pr_i^{0.012} (H/L)^{-0.3}$$

$$\bar{h}_o = \frac{k_o}{H} \left\{ 0.825 + \frac{0.387 Ra_H^{1/6}}{\left[ 1 + (0.492 / Pr_o)^{9/16} \right]^{8/27}} \right\}^2$$

with  $Ra_L = g\beta_i (T_c - T_g)L^3/\nu_i\alpha_i$  and  $Ra_H = g\beta_o (T_g - T_\infty) H^3/\nu_o\alpha_o$ . Entering the energy balance into the *IHT* workspace and using the *Correlations*, *Properties* and *Radiation* Toolpads to evaluate the convection and radiation terms, the following result is obtained.

$$T_g = 825 \text{ K} \quad \leftarrow$$

The corresponding value of  $q_h$  is

$$q_h = 108 \text{ kW} \quad \leftarrow$$

where  $q_{\text{conv},i} = 3216 \text{ W}$ ,  $q_{\text{rad},i} = 104.7 \text{ kW}$ ,  $q_{\text{conv},o} = 15,190 \text{ W}$  and  $q_{\text{rad},o} = 92.8 \text{ kW}$ . The convection coefficients are  $\bar{h}_i = 4.6 \text{ W/m}^2 \cdot \text{K}$  and  $\bar{h}_o = 7.2 \text{ W/m}^2 \cdot \text{K}$ .

(c) For the prescribed range of  $\bar{h}_o$ , *IHT* was used to generate the following results.

With increasing  $\bar{h}_o$ , the glass is cooled more effectively and  $T_g$  must decrease. With decreasing  $T_g$ ,  $q_{\text{conv},i}$ ,  $q_{\text{rad},i}$  and hence  $q_h$  must increase. Note that radiation makes the dominant contribution to heat transfer across the airspace. Although  $q_{\text{rad},o}$  decreases with decreasing  $T_g$ , the increase in  $q_{\text{conv},o}$  exceeds the reduction in  $q_{\text{rad},o}$ .

### PROBLEM 13.128

**KNOWN:** Spectral distribution of the absorption coefficient of pure solid silicon.

**FIND:** (a) The total absorption coefficient for pure solid silicon subject to irradiation from a source at the melting point temperature of silicon. (b) Estimates of the total transmissivity, total absorptivity and total emissivity of a  $L = 150 \mu\text{m}$  thick silicon sheet.

**ASSUMPTIONS:** (1) Irradiation from large surroundings, (2) Kirchoff's law assumed to be valid.

**PROPERTIES:** Table A-1, Silicon:  $T_f = 1685 \text{ K}$ .

**ANALYSIS:** Treating the irradiation from the large surroundings as black, we have

$$\begin{aligned} \kappa &= \frac{\int_0^\infty \kappa_\lambda G_\lambda(\lambda) d\lambda}{G} \approx \frac{\int_0^\infty \kappa_\lambda(\lambda) E_{\lambda,b}(\lambda, 1685 \text{ K}) d\lambda}{\int_0^\infty E_{\lambda,b}(\lambda, 1685 \text{ K}) d\lambda} \\ &= \kappa_{\lambda,1} F_{(0 \rightarrow 0.4 \mu\text{m})} + \kappa_{\lambda,2} F_{(0.4 \rightarrow 8 \mu\text{m})} + \kappa_{\lambda,3} F_{(8 \rightarrow 25 \mu\text{m})} + \kappa_{\lambda,4} F_{(25 \mu\text{m} \rightarrow \infty)} \end{aligned}$$

From Table 12.2,  $F_{(0 \rightarrow 0.4 \mu\text{m} \cdot 1685\text{K})} \approx 0$ ,  $F_{(0.4 \mu\text{m} \cdot 1685\text{K} \rightarrow 8 \mu\text{m} \cdot 1685\text{K})} = 0.955$ ,  $F_{(8 \mu\text{m} \cdot 1685\text{K} \rightarrow 15 \mu\text{m} \cdot 1685\text{K})} = 0.998 - 0.955 = 0.043$ ,  $F_{(15 \mu\text{m} \cdot 1685\text{K} \rightarrow \infty)} = 1 - 0.998 = 0.002$ . Therefore,

$$\kappa = (10^8 \text{ m}^{-1} \times 0) + (0 \text{ m}^{-1} \times 0.955) + (10^2 \text{ m}^{-1} \times 0.043) + (0 \text{ m}^{-1} \times 0.002) = 4.3 \text{ m}^{-1} \quad <$$

(b) The spectral transmissivity is  $\tau_\lambda = e^{-\kappa_\lambda L}$  which, for  $L = 150 \mu\text{m}$ , gives  $\tau_{\lambda,1} = 0$ ,  $\tau_{\lambda,2} = 1$ ,  $\tau_{\lambda,3} = 0.985$ ,  $\tau_{\lambda,4} = 1$ . Hence,

$$\tau = (0 \times 0) + (1 \times 0.955) + (0.985 \times 0.043) + (1 \times 0.002) = 0.999 \quad <$$

The total absorptivity is  $\alpha = 1 - \tau = 0.001$ , and the total emissivity is  $\varepsilon = \alpha = 0.001$ . <

**COMMENTS:** (1) Solid silicon is almost perfectly transparent to irradiation emanating from high temperature sources. It is a serious error to treat the solid material as opaque. (2) Liquid silicon can, however, be considered to be opaque, except for extremely small thicknesses. (3) *Dopants* are often added to silicon for semiconductor applications in order to tailor the electrical properties of the material. The presence of dopants can significantly increase the spectral absorption coefficients over the entire spectral range.

### PROBLEM 13.129

**KNOWN:** Conditions associated with a spherical furnace cavity.

**FIND:** Cooling rate needed to maintain furnace wall at a prescribed temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, (2) Blackbody behavior for furnace wall, (3)  $N_2$  is non-radiating.

**ANALYSIS:** From an energy balance on a unit surface area of the furnace wall, the cooling rate per unit area must equal the absorbed irradiation from the gas ( $E_g$ ) minus the portion of the wall's emissive power absorbed by the gas

$$q_c'' = E_g - \alpha_g E_b(T_s)$$

$$q_c'' = \varepsilon_g \sigma T_g^4 - \alpha_g \sigma T_s^4$$

Hence, for the entire furnace wall,

$$q_c = A_s \sigma (\varepsilon_g T_g^4 - \alpha_g T_s^4)$$

The gas emissivity,  $\varepsilon_g$ , follows from the mean beam length of Table 13.4

$$L_e = 0.65D = 0.65 \times 0.5 \text{ m} = 0.325 \text{ m} = 1.066 \text{ ft.}$$

$$p_c L_e = 0.25 \text{ atm} \times 1.066 \text{ ft} = 0.267 \text{ ft} - \text{atm}$$

and from Fig. 13.18, find  $\varepsilon_g = \varepsilon_c = 0.09$ . From Eq. 13.42,

$$\alpha_g = \alpha_c = C_c \left( \frac{T_g}{T_s} \right)^{0.45} \times \varepsilon_c (T_s, p_c L_e [T_s / T_g])$$

With  $C_c = 1$  from Fig. 13.19,

$$\alpha_g = 1(1400/500)^{0.45} \times \varepsilon_c (500\text{K}, 0.095 \text{ ft} - \text{atm})$$

where, from Fig. 13.18,

$$\varepsilon_c (500\text{K}, 0.095 \text{ ft} - \text{atm}) = 0.067$$

Hence

$$\alpha_g = 1(1400/500)^{0.45} \times 0.067 = 0.106$$

and the heat rate is

$$q_c = \pi (0.5 \text{ m})^2 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 [0.09(1400 \text{ K})^4 - 0.106(500 \text{ K})^4]$$

$$q_c = 15.1 \text{ kW.}$$

<

### PROBLEM 13.130

**KNOWN:** Diameter and gas pressure, temperature and composition associated with a gas turbine combustion chamber.

**FIND:** Net radiative heat flux between the gas and the chamber surface.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Blackbody behavior for chamber surface, (3) Remaining species are non-radiating, (4) Chamber may be approximated as an infinitely long tube.

**ANALYSIS:** From Eq. 13.40 the net rate of radiation transfer to the surface is

$$q_{\text{net}} = A_s \sigma \left( \epsilon_g T_g^4 - \alpha_g T_s^4 \right) \quad \text{or} \quad q'_{\text{net}} = \pi D \sigma \left( \epsilon_g T_g^4 - \alpha_g T_s^4 \right)$$

with  $A_s = \pi DL$ . From Table 13.4,  $L_e = 0.95D = 0.95 \times 0.4 \text{ m} = 0.380 \text{ m} = 1.25 \text{ ft}$ . Hence,  $p_w L_e = p_c L_e = 0.152 \text{ atm} \times 1.25 \text{ ft} = 0.187 \text{ atm-ft}$ .

$$\text{Fig. 13.16 } (T_g = 1273 \text{ K}), \rightarrow \epsilon_w \approx 0.069.$$

$$\text{Fig. 13.18 } (T_g = 1273 \text{ K}), \rightarrow \epsilon_c \approx 0.085.$$

$$\text{Fig. 13.20 } (p_w / (p_c + p_w) = 0.5, L_c (p_w + p_c) = 0.375 \text{ ft-atm}, T_g \geq 930^\circ\text{C}), \rightarrow \Delta\epsilon \geq 0.01.$$

From Eq. 13.38,

$$\epsilon_g = \epsilon_w + \epsilon_c - \Delta\epsilon = 0.069 + 0.085 - 0.01 \approx 0.144.$$

From Eq. 13.41 for the water vapor,

$$\alpha_w = C_w \left( T_g / T_s \right)^{0.45} \times \epsilon_w \left( T_s, p_w L_c \left[ T_s / T_g \right] \right)$$

where from Fig. 13.16 (773 K, 0.114 ft-atm),  $\rightarrow \epsilon_w \approx 0.083$ ,

$$\alpha_w = 1(1273/773)^{0.45} \times 0.083 = 0.104.$$

From Eq. 13.42, using Fig. 13.18 (773 K, 0.114 ft-atm),  $\rightarrow \epsilon_c \approx 0.08$ ,

$$\alpha_c = 1(1273/773)^{0.45} \times 0.08 = 0.100.$$

From Fig. 13.20, the correction factor for water vapor at carbon dioxide mixture,

$$\left( p_w / (p_c + p_w) = 0.1, L_e (p_w + p_c) = 0.375, T_g \approx 540^\circ\text{C} \right), \rightarrow \Delta\alpha \approx 0.004$$

and using Eq. 13.43

$$\alpha_g = \alpha_w + \alpha_c - \Delta\alpha = 0.104 + 0.100 - 0.004 \approx 0.200.$$

Hence, the heat rate is

$$q'_{\text{net}} = \pi (0.4 \text{ m}) 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left[ 0.144 (1273)^4 - 0.200 (773)^4 \right] = 21.9 \text{ kW/m.} <$$

### PROBLEM 13.131

**KNOWN:** Pressure, temperature and composition of flue gas in a long duct of prescribed diameter.

**FIND:** Net radiative flux to the duct surface.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Duct surface behaves as a blackbody, (3) Other gases are non-radiating, (4) Flue may be approximated as an infinitely long tube.

**ANALYSIS:** With  $A_s = \pi DL$ , it follows from Eq. 13.40 that

$$q'_{\text{net}} = \pi D \sigma \left( \epsilon_g T_g^4 - \alpha_g T_s^4 \right)$$

From Table 13.4,  $L_e = 0.95D = 0.95 \times 1 \text{ m} = 0.95 \text{ m} = 3.12 \text{ ft}$ . Hence

$$p_w L_e = 0.12 \text{ atm} \times 3.12 \text{ m} = 0.312 \text{ atm-ft}$$

$$p_c L_e = 0.05 \text{ atm} \times 3.12 \text{ m} = 0.156 \text{ atm-ft}$$

With  $T_g = 1400 \text{ K}$ , Fig. 13.16  $\rightarrow \epsilon_w = 0.083$ ; Fig. 13.18  $\rightarrow \epsilon_c = 0.072$ . With  $p_w/(p_c + p_w) = 0.67$ ,  $L_e(p_w + p_c) = 0.468 \text{ atm-ft}$ ,  $T_g \geq 930^\circ\text{C}$ , Fig. 13.20  $\rightarrow \Delta\epsilon = 0.01$ . Hence from Eq. 13.38,

$$\epsilon_g = \epsilon_w + \epsilon_c - \Delta\epsilon = 0.083 + 0.072 - 0.01 = 0.145.$$

From Eq. 13.41,

$$\alpha_w = C_w \left( T_g / T_s \right)^{0.45} \times \epsilon_w \left( T_s, p_w L_e \left[ T_s / T_g \right] \right)$$

$$\alpha_w = 1 \left( 1400 / 400 \right)^{0.45} \times \epsilon_w \text{ Fig. 13.16} \rightarrow \epsilon_w \left( 400 \text{ K}, 0.0891 \text{ atm-ft} \right) = 0.1$$

$$\alpha_w = 0.176.$$

From Eq. 13.42,

$$\alpha_c = C_c \left( T_g / T_s \right)^{0.45} \times \epsilon_c \left( T_s, p_c L_e T_s / T_g \right)$$

$$\alpha_c = 1 \left( 1400 / 400 \right)^{0.45} \times \epsilon_c \text{ Fig. 13.18} \rightarrow \epsilon_c \left( 400 \text{ K}, 0.0891 \text{ atm-ft} \right) = 0.053$$

$$\alpha_c = 0.093.$$

With  $p_w/(p_c + p_w) = 0.67$ ,  $L_e(p_w + p_c) = 0.468 \text{ atm-ft}$ ,  $T_g \approx 125^\circ\text{C}$ , Fig. 13.20 gives  $\Delta\alpha \approx 0.003$ .

Hence from Eq. 13.43,

$$\alpha_g = \alpha_w + \alpha_c - \Delta\alpha = 0.176 + 0.093 - 0.003 = 0.266.$$

The heat rate per unit length is

$$q'_{\text{net}} = \pi (1 \text{ m}) 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left[ 0.145 (1400 \text{ K})^4 - 0.266 (400 \text{ K})^4 \right]$$

$$q'_{\text{net}} = 98 \text{ kW/m}.$$

<

### PROBLEM 13.132

**KNOWN:** Gas mixture of prescribed temperature, pressure and composition between large parallel plates of prescribed separation.

**FIND:** Net radiation flux to the plates.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Furnace wall behaves as a blackbody, (3)  $\text{O}_2$  and  $\text{N}_2$  are non-radiating, (4) Negligible end effects.

**ANALYSIS:** The net radiative flux to a plate is

$$q''_{s,1} = G_s - E_s = \varepsilon_g \sigma T_g^4 - (1 - \tau_g) \sigma T_s^4$$

where  $G_s = \varepsilon_g \sigma T_g^4 + \tau_g E_s$ ,  $E_s = \sigma T_s^4$  and  $\tau_g = 1 - \alpha_g(T_s)$ . From Table 13.4,  $L_e = 1.8L = 1.8 \times 0.75\text{ m} = 1.35\text{ m} = 4.43\text{ ft}$ . Hence  $p_w L_e = p_c L_e = 1.33\text{ atm-ft}$ . From Figs. 3.16 and 3.18 find  $\varepsilon_w \approx 0.22$  and  $\varepsilon_c \approx 0.16$  for  $p = 1\text{ atm}$ . With  $(p_w + p)/2 = 1.15\text{ atm}$ , Fig. 13.17 yields  $C_w \approx 1.40$  and from Fig. 13.19,  $C_c \approx 1.08$ . Hence, the gas emissivities are

$$\varepsilon_w = C_w \varepsilon_w(1\text{ atm}) \approx 1.40 \times 0.22 = 0.31 \quad \varepsilon_c = C_c \varepsilon_c(1\text{ atm}) \approx 1.08 \times 0.16 = 0.17.$$

From Fig. 13.20 with  $p_w/(p_c + p_w) = 0.5$ ,  $L_e(p_c + p_w) = 2.66\text{ atm-ft}$  and  $T_g > 930^\circ\text{C}$ ,  $\Delta\varepsilon \approx 0.047$ . Hence, from Eq. 13.38,

$$\varepsilon_g = \varepsilon_w + \varepsilon_c - \Delta\varepsilon \approx 0.31 + 0.17 - 0.047 \approx 0.43.$$

To evaluate  $\alpha_g$  at  $T_s$ , use Eq. 13.43 with

$$\alpha_w = C_w \left( T_g / T_s \right)^{0.45} \varepsilon_w \left( T_s, p_w L_e T_s / T_g \right) = C_w (1300/500)^{0.45} \varepsilon_w(500, 0.51)$$

$$\alpha_w \approx 1.40 (1300/500)^{0.45} 0.22 = 0.47$$

$$\alpha_c = C_c (1300/500)^{0.45} \varepsilon_c(500, 0.51) \approx 1.08 (1300/500)^{0.45} 0.11 = 0.18.$$

From Fig. 13.20, with  $T_g \approx 125^\circ\text{C}$  and  $L_e(p_w + p_c) = 2.66\text{ atm-ft}$ ,  $\Delta\alpha = \Delta\varepsilon \approx 0.024$ . Hence

$$\alpha_g = \alpha_w + \alpha_c - \Delta\alpha \approx 0.47 + 0.18 - 0.024 \approx 0.63 \quad \text{and} \quad \tau_g = 1 - \alpha_g \approx 0.37.$$

Hence, the heat flux from Eq. (1) is

$$q''_{s,1} = 0.43 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (1300\text{ K})^4 - 0.63 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (500\text{ K})^4$$

$$q''_{s,1} \approx 67.4 \text{ kW/m}^2.$$

The net radiative flux to both plates is then  $q''_{s,2} \approx 134.8 \text{ kW/m}^2$ . <

### PROBLEM 13.133

**KNOWN:** Flow rate, temperature, pressure and composition of exhaust gas in pipe of prescribed diameter. Velocity and temperature of external coolant.

**FIND:** Pipe wall temperature and heat flux.

**SCHEMATIC:**

**ASSUMPTIONS:** (1)  $L/D \gg 1$  (infinitely long pipe), (2) Negligible axial gradient for gas temperature, (3) Gas is in fully developed flow, (4) Gas thermophysical properties are those of air, (5) Negligible pipe wall thermal resistance, (6) Negligible pipe wall emission.

**PROPERTIES:** Table A-4: Air ( $T_m = 2000 \text{ K}$ , 1 atm):  $\rho = 0.174 \text{ kg/m}^3$ ,  $\mu = 689 \times 10^{-7} \text{ kg/m}\cdot\text{s}$ ,  $k = 0.137 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.672$ ; Table A-6: Water ( $T_\infty = 300 \text{ K}$ ):  $\rho = 997 \text{ kg/m}^3$ ,  $\mu = 855 \times 10^{-6} \text{ kg/s}\cdot\text{m}$ ,  $k = 0.613 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 5.83$ .

**ANALYSIS:** Performing an energy balance for a control surface about the pipe wall,

$$q_r'' + q_{c,i}'' = q_{c,o}''$$

$$\epsilon_g \sigma T_g^4 + h_i (T_m - T_s) = \bar{h}_o (T_s - T_\infty)$$

The gas emissivity is

$$\epsilon_g = \epsilon_w + \epsilon_c - \Delta\epsilon$$

where

$$L_e = 0.95D = 0.238 \text{ m} = 0.799 \text{ ft}$$

$$p_c L_e = p_w L_e = 0.1 \text{ atm} \times 0.238 \text{ m} = 0.0238 \text{ atm}\cdot\text{m} = 0.0779 \text{ atm}\cdot\text{ft}$$

and from Fig. 13.16  $\rightarrow \epsilon_w \approx 0.017$ ; Fig. 13.18  $\rightarrow \epsilon_c \approx 0.031$ ; Fig. 13.20  $\rightarrow \Delta\epsilon \approx 0.001$ . Hence  $\epsilon_g = 0.047$ . Estimating the *internal flow convection coefficient*, find

$$\text{Re}_D = \frac{4 \dot{m}}{\pi D \mu} = \frac{4 \times 0.25 \text{ kg/s}}{\pi (0.25 \text{ m}) 689 \times 10^{-7} \text{ kg/m}\cdot\text{s}} = 18,480$$

and for turbulent flow, we may use the Dittus-Boelter correlation of Chapter 8,

$$\text{Nu}_D = 0.023 \text{Re}_D^{4/5} \text{Pr}^{0.3} = 0.023 (18,480)^{4/5} (0.672)^{0.3} = 52.9$$

$$h_i = \text{Nu}_D \frac{k}{D} = 52.9 \frac{0.137 \text{ W/m}\cdot\text{K}}{0.25 \text{ m}} = 29.0 \text{ W/m}^2\cdot\text{K}$$

Continued ...

### PROBLEM 13.133 (Cont.)

Estimating the *external convection coefficient*, find

$$\text{Re}_D = \frac{\rho V D}{\mu} = \frac{997 \text{ kg/m}^3 \times 0.3 \text{ m/s} \times 0.25 \text{ m}}{855 \times 10^{-6} \text{ kg/s} \cdot \text{m}} = 87,456.$$

Hence, using the Zukauskas correlation of Chapter 7,

$$\overline{\text{Nu}}_D = 0.26 \text{Re}_D^{0.6} \text{Pr}^{0.37} (\text{Pr}/\text{Pr}_s)^{1/4}.$$

Assuming  $\text{Pr}/\text{Pr}_s \approx 1$ ,

$$\overline{\text{Nu}}_D = 0.26(87,456)^{0.6} (5.83)^{0.37} = 461$$

$$\bar{h}_o = \overline{\text{Nu}}_D (k/D) = 461(0.613 \text{ W/m} \cdot \text{K} / 0.25 \text{ m}) = 1129 \text{ W/m}^2 \cdot \text{K}.$$

Substituting numerical values in the energy balance, find

$$\begin{aligned} 0.047 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (2000 \text{ K})^4 + 29 \text{ W/m}^2 \cdot \text{K} (2000 - T_s) \text{ K} \\ = 1129 \text{ W/m}^2 \cdot \text{K} (T_s - 300) \text{ K} \end{aligned}$$

$$T_s = 380 \text{ K.} \quad <$$

The heat flux due to convection is

$$q''_{c,i} = h_i (T_m - T_s) = 29 \text{ W/m}^2 \cdot \text{K} (2000 - 379.4) \text{ K} = 46,997 \text{ W/m}^2$$

and the total heat flux is

$$q''_s = q''_r + q''_{c,i} = 42,638 + 46,997 = 89,640 \text{ W/m}^2. \quad <$$

**COMMENTS:** Contributions of gas radiation and convection to the wall heat flux are approximately the same. Small value of  $T_s$  justifies neglecting emission from the pipe wall to the gas.  $\text{Pr}_s = 1.62$  for  $T_s = 380 \rightarrow (\text{Pr}/\text{Pr}_s)^{1/4} = 1.38$ . Hence the value of  $\bar{h}_o$  should be corrected. The value would  $\uparrow$ , and  $T_s$  would  $\downarrow$ .

### PROBLEM 13.134

**KNOWN:** Flow rate, temperature, pressure and composition of combustion gas that is subsequently mixed with saturated steam of known flow rate.

**FIND:** Gas emission to a pipe wall with and without steam injection.

**ASSUMPTIONS:** (1) Gas thermophysical properties and molecular weight same as air, (2) ideal gas mixture.

**ANALYSIS:** The mass flow rate without steam injection is  $\dot{m}_1 = 0.25 \text{ kg/s}$ . The mass flow rate of water vapor in the original mixture is  $\dot{m}_1 m_{w1}$  where  $m_{w1}$  is the mass fraction of water vapor,

$$\begin{aligned} m_{w1} &= p_{w1} \mathcal{M}_w / p \mathcal{M}_{\text{air}} \\ &= 0.1 \text{ atm} \times 18 \text{ kg/kmol} / (1 \text{ atm} \times 29 \text{ kg/kmol}) \\ &= 0.0621 \end{aligned}$$

Thus the mass flow rate of the injected steam is

$$\dot{m}_s = 0.5 \dot{m}_1 m_{w1} = 0.5 \times 0.25 \text{ kg/s} \times 0.0621 = 0.00776 \text{ kg/s}$$

and the total mass flow rate after injection is  $\dot{m}_2 = \dot{m}_1 + \dot{m}_s = 0.2578 \text{ kg/s}$ . Treating the gases as ideal with properties of air, an energy balance on the mixing of the combustion products and injected steam yields

$$\dot{m}_1 T_{g1} + \dot{m}_w T_{w1} = \dot{m}_2 T_g ; T_g = \frac{\dot{m}_1 T_{g1} + \dot{m}_w T_{w1}}{\dot{m}_2} = \frac{0.25 \text{ kg/s} \times 2000 \text{ K} + 0.0076 \text{ kg/s} \times 373 \text{ K}}{0.2578 \text{ kg/s}} = 1951 \text{ K}$$

The gas emissivity is  $\varepsilon_g = \varepsilon_w + \varepsilon_c - \Delta\varepsilon$  where  $L_e = 0.95 D = 0.238 \text{ m} = 0.799 \text{ ft}$ . The partial pressures of the gases are obtained by accounting for the additional water vapor in the pipe relative to Problem 13.133.

$$p_{w2} = x_{w2} p = \frac{x_{w1} + 0.5x_{w1}}{1 + 0.5x_{w1}} p = \frac{0.15}{1.05} p = 0.143 \text{ atm}$$

where  $x_{w2}$  is the mole fraction of water in the final mixture. Similarly,

$$p_{c2} = \frac{x_{c1}}{1 + 0.5x_{w1}} p = \frac{0.1}{1.05} p = 0.0952 \text{ atm}$$

The products of the partial pressures and mean beam lengths are therefore

$$p_c L_e = 0.095 \text{ atm} \times 0.799 \text{ ft} = 0.076 \text{ atm-ft} ; p_w L_e = 0.143 \text{ atm} \times 0.799 \text{ ft} = 0.114 \text{ atm-ft}$$

From Fig. 13.15,  $\varepsilon_w \approx 0.025$ . From Fig. 13.17,  $\varepsilon_c \approx 0.034$ . From Fig. 13.19,  $\Delta\varepsilon \approx 0.002$ . Hence,  $\varepsilon_g = 0.025 + 0.034 - 0.002 = 0.057$  and the emission from the gas to the pipe wall is

$$E_g = \varepsilon_g \sigma T_g^4 = 0.057 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times (1951 \text{ K})^4 = 46,800 \text{ W/m}^2 \quad <$$

Continued...

### PROBLEM 13.134 (Cont.)

Without injection, the partial pressures are  $p_w = p_c = 0.1$  atm and the partial pressure – mean beam length products are  $p_c L_e = p_w L_e = 0.10$  atm  $\times$  0.799 ft = 0.080 atm-ft yielding from Fig. 13.15,  $\varepsilon_w \approx 0.017$ . From Fig. 13.17,  $\varepsilon_c \approx 0.031$ . From Fig. 13.19,  $\Delta\varepsilon \approx 0.001$ . Hence,  $\varepsilon_g = 0.047$  and the emission from the gas to the pipe wall is

$$E_g = \varepsilon_g \sigma T_g^4 = 0.047 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times (2000 \text{ K})^4 = 42,600 \text{ W/m}^2 \quad <$$

**COMMENTS:** (1) The gas emissivity is increased significantly with steam injection, but the temperature of the hot gas is reduced due to mixing with the relatively cool steam. The net effect is a modest increase in radiation heat flux to the pipe surface. Injection of a greater amount of steam results in even higher gas emissivities, but the effect is offset by even lower gas temperatures. (2) Injection of *liquid* water would further reduce the gas temperature as the latent heat of vaporization of the water is accounted for. (3) The results are highly dependent upon the accuracy with which one can read the figures in the text. (4) Water vapor properties are taken to be the same as those of air. (5) A more detailed analysis would be appropriate if the scheme were to be considered seriously.

### PROBLEM 13.135

**KNOWN:** Flowrate, composition and temperature of flue gas passing through inner tube of an annular waste heat boiler. Boiler dimensions. Steam pressure.

**FIND:** Rate at which saturated liquid can be converted to saturated vapor,  $\dot{m}_s$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Inner wall is thin and steam side convection coefficient is very large; hence  $T_s = T_{\text{sat}}(2.455 \text{ bar})$ , (2) For calculation of gas radiation, inner tube is assumed infinitely long and gas is approximated as isothermal at  $T_g$ .

**PROPERTIES:** Flue gas (given):  $\mu = 530 \times 10^{-7} \text{ kg/s}\cdot\text{m}$ ,  $k = 0.091 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.70$ ; Table A-6, Saturated water (2.455 bar):  $T_s = 400 \text{ K}$ ,  $h_{fg} = 2183 \text{ kJ/kg}$ .

**ANALYSIS:** The steam generation rate is

$$\dot{m}_s = q / h_{fg} = (q_{\text{conv}} + q_{\text{rad}}) / h_{fg}$$

where

$$q_{\text{rad}} = A_s \sigma (\epsilon_g T_g^4 - \alpha_g T_s^4)$$

with

$$\epsilon_g = \epsilon_w + \epsilon_c - \Delta\epsilon \quad \alpha_g = \alpha_w + \alpha_c - \Delta\alpha.$$

From Table 13.4, find  $L_e = 0.95D = 0.95 \text{ m} = 3.117 \text{ ft}$ . Hence

$$p_w L_e = 0.2 \text{ atm} \times 3.117 \text{ ft} = 0.623 \text{ ft}\cdot\text{atm}$$

$$p_c L_e = 0.1 \text{ atm} \times 3.117 \text{ ft} = 0.312 \text{ ft}\cdot\text{atm}.$$

From Fig. 13.16, find  $\epsilon_w \approx 0.13$  and Fig. 13.18 find  $\epsilon_c \approx 0.095$ . With  $p_w/(p_c + p_w) = 0.67$  and  $L_e(p_w + p_c) = 0.935 \text{ ft}\cdot\text{atm}$ , from Fig. 13.20 find  $\Delta\epsilon \approx 0.036 \approx \Delta\alpha$ . Hence  $\epsilon_g \approx 0.13 + 0.095 - 0.036 = 0.189$ .

Also, with  $p_w L_e (T_s/T_g) = 0.2 \text{ atm} \times 0.95 \text{ m} (400/1400) = 0.178 \text{ ft}\cdot\text{atm}$  and  $T_s = 400 \text{ K}$ , Fig. 13.16 yields  $\epsilon_w \approx 0.14$ . With  $p_c L_e (T_s/T_g) = 0.1 \text{ atm} \times 0.95 \text{ m} (400/1400) = 0.089 \text{ ft}\cdot\text{atm}$  and  $T_s = 400 \text{ K}$ , Fig. 13.18 yields  $\epsilon_c \approx 0.067$ . Hence

$$\alpha_w = (T_g/T_s)^{0.45} \epsilon_w (T_s, p_w L_e T_s/T_g)$$

$$\alpha_w = (1400/400)^{0.45} 0.14 = 0.246$$

and

$$\alpha_c = (T_g/T_s)^{0.65} \epsilon_c (T_s, p_c L_e T_s/T_g)$$

Continued ...

**PROBLEM 13.135 (Cont.)**

$$\alpha_c = (1400/400)^{0.65} 0.067 = 0.151$$

$$\alpha_g = 0.246 + 0.151 - 0.036 = 0.361.$$

Hence

$$q_{\text{rad}} = \pi(1 \text{ m})7 \text{ m} \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left[ 0.189(1400 \text{ K})^4 - 0.361(400 \text{ K})^4 \right]$$

$$q_{\text{rad}} = (905.3 - 11.5) \text{ kW} = 893.8 \text{ kW}.$$

For convection,

$$q_{\text{conv}} = \bar{h}\pi DL(T_g - T_s)$$

with

$$\text{Re}_D = \frac{4\dot{m}}{\pi D\mu} = \frac{4 \times 2 \text{ kg/s}}{\pi \times 1 \text{ m} \times 530 \times 10^{-7} \text{ kg/s} \cdot \text{m}} = 48,047$$

and assuming fully developed turbulent flow throughout the tube, the Dittus-Boelter correlation of Chapter 8 gives

$$\overline{\text{Nu}}_D = 0.023 \text{Re}_D^{4/5} \text{Pr}^{0.3} = 0.023(48,047)^{4/5} (0.70)^{0.3} = 115$$

$$\bar{h} = (k/D)\overline{\text{Nu}}_D = (0.091 \text{ W/m} \cdot \text{K}/1 \text{ m})115 = 10.5 \text{ W/m}^2 \cdot \text{K}.$$

Hence

$$q_{\text{conv}} = 10.5 \text{ W/m}^2 \cdot \text{K} \pi(1 \text{ m})7 \text{ m}(1400 - 400) \text{ K} = 230.1 \text{ kW}$$

and the vapor production rate is

$$\dot{m}_s = \frac{q}{h_{fg}} = \frac{(893.8 + 230.1) \text{ kW}}{2183 \text{ kJ/kg}} = \frac{1123.9 \text{ kW}}{2183 \text{ kJ/kg}}$$

$$\dot{m}_s = 0.515 \text{ kg/s}.$$

<

**COMMENTS:** (1) Heat transfer is dominated by radiation, which is typical of heat recovery devices having a large gas volume. (2) A more detailed analysis would account for radiation exchange involving the ends (upstream and downstream) of the inner tube. (3) Using a representative specific heat of  $c_p = 1.2 \text{ kJ/kg} \cdot \text{K}$ , the temperature drop of the gas passing through the tube would be  $\Delta T_g = 1123.9 \text{ kW}/(2 \text{ kg/s} \times 1.2 \text{ kJ/kg} \cdot \text{K}) = 468 \text{ K}$ .

### PROBLEM 13.136

**KNOWN:** Wet newsprint moving through a drying oven.

**FIND:** Required evaporation rate, air velocity and oven temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Negligible freestream turbulence, (3) Heat and mass transfer analogy applicable, (4) Oven and newsprint surfaces are diffuse gray, (5) Oven end effects negligible.

**PROPERTIES:** Table A-6, Water vapor (300 K, 1 atm):  $\rho_{\text{sat}} = 1/v_g = 0.0256 \text{ kg/m}^3$ ,  $h_{\text{fg}} = 2438 \text{ kJ/kg}$ ; Table A-4, Air (300 K, 1 atm):  $\nu = 15.89 \times 10^{-6} \text{ m}^2/\text{s}$ ; Table A-8, Water vapor-air (300 K, 1 atm):  $D_{\text{AB}} = 0.26 \times 10^{-4} \text{ m}^2/\text{s}$ ,  $S_c = \nu/D_{\text{AB}} = 0.611$ .

**ANALYSIS:** The evaporation rate required to completely dry the newsprint having a water content of  $m''_{\text{A}} = 0.02 \text{ kg/m}^2$  as it enters the oven ( $x = L$ ) follows from a species balance on the newsprint.

$$\dot{M}_{\text{A},\text{in}} - \dot{M}_{\text{A},\text{out}} = \dot{M}_{\text{st}}$$

$$\dot{M}_{\text{L}} - \dot{M}_0 - \dot{M}_{\text{A},\text{s}} = 0.$$

The rate at which moisture enters in the newsprint is

$$\dot{M}_{\text{L}} = m''_{\text{A}} VW$$

hence,

$$\dot{M}_{\text{A},\text{s}} = m''_{\text{A}} VW = 0.02 \text{ kg/m}^2 \times 0.2 \text{ m/s} \times 1 \text{ m} = 4 \times 10^{-3} \text{ kg/s.} \quad <$$

The required velocity of the airstream through the oven,  $u_{\infty}$ , can be determined from a convection analysis. From the rate equation,

$$\dot{M}_{\text{A},\text{s}} = \bar{h}_m WL (\rho_{\text{A},\text{s}} - \rho_{\text{A},\infty}) = \bar{h}_m WL \rho_{\text{A},\text{sat}} (1 - \phi_{\infty})$$

$$\bar{h}_m = \dot{M}_{\text{A},\text{s}} / WL \rho_{\text{A},\text{sat}} (1 - \phi_{\infty})$$

$$\bar{h}_m = 4 \times 10^{-3} \text{ kg/s} / 1 \text{ m} \times 20 \text{ m} \times 0.0256 \text{ kg/m}^3 (1 - 0.2) = 9.77 \times 10^{-3} \text{ m/s.}$$

Now determine what flow velocity is required to produce such a coefficient. Assume flow over a flat plate with

$$\overline{\text{Sh}}_{\text{L}} = \bar{h}_m L / D_{\text{AB}} = 9.77 \times 10^{-3} \text{ m/s} \times 20 \text{ m} / 0.26 \times 10^{-4} \text{ m}^2/\text{s} = 7515$$

Continued ...

**PROBLEM 13.136 (Cont.)**

and, from Section 7.2.1 for laminar flow

$$\text{Re}_L = \left[ \overline{\text{Sh}}_L / 0.664 \text{Sc}^{1/3} \right]^2 = \left[ 7515 / 0.664 (0.611)^{1/3} \right]^2 = 1.78 \times 10^8.$$

However, since  $\text{Re}_L > \text{Re}_{Lc} = 5 \times 10^5$ , the flow must be turbulent. Using the correlation for mixed laminar and turbulent flow conditions from Section 7.2.3, find

$$\text{Re}_L^{4/5} = \left[ \overline{\text{Sh}}_L / \text{Sc}^{1/3} + 871 \right] / 0.037$$

$$\text{Re}_L^{4/5} = \left[ 7515 / (0.611)^{1/3} + 871 \right] / 0.037$$

$$\text{Re}_L = 5.95 \times 10^6$$

noting  $\text{Re}_L > \text{Re}_{Lc}$ . Recognize that  $u_\infty^*$  is the velocity relative to the newspaper,

$$u_\infty^* = \text{Re}_L \nu / L = 5.95 \times 10^6 \times 15.89 \times 10^{-6} \text{ m}^2 / \text{s} / 20 \text{ m} = 4.73 \text{ m/s}.$$

The air velocity relative to the oven will be,

$$u_\infty = u_\infty^* - V = (4.73 - 0.2) \text{ m/s} = 4.53 \text{ m/s}.$$

The temperature required of the oven surface follows from an energy balance on the newspaper. Find

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = 0$$

$$q_{\text{rad}} - q_{\text{evap}} = 0$$

where

$$q_{\text{evap}} = \dot{M}_{A,s} h_{fg} = 4.0 \times 10^{-3} \text{ kg/s} \times 2438 \times 10^3 \text{ J/kg} = 9752 \text{ W}$$

and the radiation exchange is that for a two surface enclosure, Eq. 13.23,

$$q_{\text{rad}} = \frac{\sigma (T_1^4 - T_2^4)}{(1 - \epsilon_1) / \epsilon_1 A_1 + 1 / A_1 F_{12} + (1 - \epsilon_2) / \epsilon_2 A_2}.$$

Evaluate,

$$A_1 = \pi / 2 \text{ WL}, \quad A_2 = \text{WL}, \quad F_{21} = 1, \quad \text{and} \quad A_1 F_{12} = A_2 F_{21} = \text{WL}$$

hence, with  $\epsilon_1 = 0.8$ ,

$$q_{\text{rad}} = \sigma \text{WL} (T_1^4 - T_2^4) / [(1/2\pi) + 1]$$

$$T_1^4 = T_2^4 + q_{\text{rad}} [(1/2\pi) + 1] / \sigma \text{WL}$$

$$T_1^4 = (300 \text{ K})^4 + 9752 \text{ W} [(1/2\pi + 1)] / 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times 1 \text{ m} \times 20 \text{ m}$$

$$T_1 = 367 \text{ K}.$$

**COMMENTS:** Note that there is no convection heat transfer since  $T_\infty = T_s = 300 \text{ K}$ .

### PROBLEM 13.137

**KNOWN:** Configuration of grain dryer. Emissivities of grain bed and heater surface. Temperature of grain.

**FIND:** (a) Temperature of heater required for specified drying rate, (b) Convection mass transfer coefficient required to sustain evaporation, (c) Validity of assuming negligible convection heat transfer.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Diffuse/gray surfaces, (2) Oven wall is a reradiating surface, (3) Negligible convection heat transfer, (4) Applicability of heat/mass transfer analogy, (5) Air is dry.

**PROPERTIES:** Table A-6, saturated water ( $T = 330 \text{ K}$ ):  $v_g = 8.82 \text{ m}^3/\text{kg}$ ,  $h_{fg} = 2.366 \times 10^6 \text{ J/kg}$ . Table A-4, air (assume  $T \approx 300 \text{ K}$ ):  $\rho = 1.614 \text{ kg/m}^3$ ,  $c_p = 1007 \text{ J/kg}\cdot\text{K}$ ,  $\alpha = 22.5 \times 10^{-6} \text{ m}^2/\text{s}$ . Table A-8,  $\text{H}_2\text{O}(\text{v}) - \text{air}$  ( $T = 298 \text{ K}$ ):  $D_{AB} = 0.26 \times 10^{-4} \text{ m}^2/\text{s}$ .

**ANALYSIS:** (a) Neglecting convection, the energy required for evaporation must be supplied by net radiation transfer from the heater plate to the grain bed. Hence,

$$q'_{\text{rad}} = \dot{m}'_{\text{evap}} h_{fg} = (2.5 \text{ kg/h}\cdot\text{m}) \left( 2.366 \times 10^6 \text{ J/kg} \right) / 3600 \text{ s/h} = 1643 \text{ W/m}$$

where  $q'_{\text{rad}}$  is given by Eq. 13.30. With  $A'_p = A'_g \equiv A'$ ,

$$q'_{\text{rad}} = \frac{A' (E_{bp} - E_{bg})}{\frac{1 - \epsilon_p}{\epsilon_p} + \frac{1}{F_{pg} + \left[ \left( \frac{1}{F_{pR}} \right) + \left( \frac{1}{F_{gR}} \right) \right]^{-1}}} + \frac{1 - \epsilon_g}{\epsilon_g}$$

where  $A' = R = 1 \text{ m}$ ,  $F_{pg} = 0$  and  $F_{pR} = F_{gR} = 1$ . Hence,

$$q'_{\text{rad}} = \frac{\sigma (T_p^4 - 320^4)}{0.25 + 2 + 0.111} = 2.40 \times 10^{-8} (T_p^4 - 320^4) = 1643 \text{ W/m}$$

$$2.40 \times 10^{-8} T_p^4 - 2518 = 1643$$

$$T_p = 530 \text{ K}$$

<

(b) The evaporation rate is given by Eq. 6.12, and with  $A'_s = 1 \text{ m}$ ,  $n'_A = \dot{m}'_{\text{evap}}$ , and  $\rho_{A,\infty} = 0$ ,

Continued ...

**PROBLEM 13.137 (Cont.)**

$$h_m = \frac{n'_A}{A'_s \rho_{A,s}} = \frac{n'_A v_g}{A'_s} = \frac{2.5 \text{ kg/h} \cdot \text{m}}{1 \text{ m}} \times \frac{1}{3600 \text{ s}} \times 8.82 \frac{\text{m}^3}{\text{kg}} = 6.13 \times 10^{-3} \text{ m/s}$$

<

(c) From the heat and mass transfer analogy, Eq. 6.60,

$$h = h_m \rho c_p \text{Le}^{2/3}$$

where  $\text{Le} = \alpha/D_{AB} = 22.5/26.0 = 0.865$ . Hence

$$h = 6.13 \times 10^{-3} \text{ m/s} (1.161 \text{ kg/m}^3) 1007 \text{ J/kg} \cdot \text{K} (0.865)^{2/3} = 6.5 \text{ W/m}^2 \cdot \text{K}.$$

The corresponding convection heat transfer rate is

$$q'_{\text{conv}} = hA'(T_g - T_\infty) = 6.5 \text{ W/m}^2 \cdot \text{K} (1 \text{ m}) (330 - 300) \text{ K} = 195 \text{ W/m}$$

Since  $q'_{\text{conv}} \ll q'_{\text{rad}}$ , the assumption of negligible convection heat transfer is reasonable.

### PROBLEM 13.138

**KNOWN:** Diameters of coaxial cylindrical drum and heater. Heater emissivity. Temperature and emissivity of pellets covering bottom half of drum. Convection mass transfer coefficient associated with flow of dry air over the pellets.

**FIND:** (a) Evaporation rate per unit length of drum, (b) Surface temperatures of heater and top half of drum.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, (2) Negligible heat transfer from ends of drum, (3) Diffuse-gray surface behavior, (4) Negligible heat loss from the drum to the surroundings, (5) Negligible convection heat transfer from interior surfaces of the drum, (6) Pellet surface area corresponds to that of bottom half of drum.

**PROPERTIES** Table A-6, sat. water ( $T = 325 \text{ K}$ ):  $\rho_{A,\text{sat}} = v_g^{-1} = 0.0904 \text{ kg/m}^3$ ,  $h_{fg} = 2378 \text{ kJ/kg}$ .

**ANALYSIS:** (a) The evaporation rate is

$$n'_A = h_m (\pi D_d / 2) [\rho_{A,\text{sat}} (T_p) - \rho_{A,\infty}]$$

$$n'_A = 0.024 \text{ m/s} (\pi \times 1 \text{ m} / 2) \times 0.0904 \text{ kg/m}^3 = 0.00341 \text{ kg/s} \cdot \text{m} \quad <$$

(b) From an energy balance on the surface of the pellets,

$$q'_p = q'_{\text{evap}} = n'_A h_{fg} = 0.00341 \text{ kg/s} \cdot \text{m} \times 2.378 \times 10^6 \text{ J/kg} = 8109 \text{ W/m} \quad <$$

where  $q'_p$  may be determined from analysis of radiation transfer in a three surface enclosure. Since the top half of the enclosure may be treated as reradiating, net radiation transfer to the pellets may be obtained from Eq. 13.30, which takes the form

$$q'_p = \frac{E_{bh} - E_{bp}}{\frac{1 - \varepsilon_h}{\varepsilon_h A'_h} + \frac{1}{A'_h F_{hp} + \left[ (1/A'_h F_{hd}) + (1/A'_p F_{pd}) \right]^{-1}} + \frac{1 - \varepsilon_p}{\varepsilon_p A'_p}}$$

where  $F_{hp} = F_{hd} = 0.5$ ,  $A'_h = \pi D_h$  and  $A'_p = \pi D_d / 2$ .

The view factor  $F_{pd}$  may be obtained from the summation rule,

$$F_{pd} = 1 - F_{ph} - F_{pp}$$

Continued ...

**PROBLEM 13.138 (Cont.)**

where  $F_{ph} = A'_h F_{hp} / A'_p = (\pi D_h \times 0.5) / (\pi D_d / 2) = 0.10$  and

$$F_{pp} = 1 - (2/\pi) \left\{ \left[ 1 - (0.1)^2 \right]^{1/2} + 0.1 \sin^{-1}(0.1) \right\} = 0.360$$

Hence,  $F_{pd} = 1 - 0.10 - 0.360 = 0.540$ , and the expression for the heat rate yields

$$8109 \text{ W/m} = \frac{E_{bh} - \sigma(325 \text{ K})^4}{\frac{0.25}{\pi \times 0.1\text{m}} + \frac{1}{\pi \left\{ 0.1\text{m} \times 0.5 + \left[ (0.1\text{m} \times 0.5)^{-1} + (0.5\text{m} \times 0.54)^{-1} \right]^{-1} \right\}} + \frac{0.053}{\pi \times 0.5\text{m}}}$$

$$E_{bh} = \sigma T_h^4 = 35,359 \text{ W/m}^2$$

$$T_h = 889 \text{ K} \quad <$$

Applying Eq. 13.19 to surfaces h and p,

$$J_h = E_{bh} - q'_h (1 - \varepsilon_h) / \varepsilon_h A'_h = 35,359 \text{ W/m}^2 - 6,453 \text{ W/m}^2 = 28,906 \text{ W/m}^2$$

$$J_p = E_{bp} + q'_p (1 - \varepsilon_p) / \varepsilon_p A'_p = 633 \text{ W/m}^2 + 272 \text{ W/m}^2 = 905 \text{ W/m}^2$$

Hence, from

$$\frac{J_h - J_d}{(A'_h F_{hd})^{-1}} - \frac{J_d - J_p}{(A'_p F_{pd})^{-1}} = 0$$

$$\frac{28,906 \text{ W/m}^2 - J_d}{(\pi \times 0.1\text{m} \times 0.5)^{-1}} - \frac{J_d - 905 \text{ W/m}^2}{(\pi \times 0.5\text{m} \times 0.54)^{-1}} = 0$$

$$J_d = \sigma T_d^4 = 24,530 \text{ W/m}^2$$

$$T_d = 811 \text{ K} \quad <$$

**COMMENTS:** The required value of  $T_h$  could be reduced by increasing  $D_h$ , although care must be taken to prevent contact of the plastic with the heater.

### PROBLEM 14.1

**KNOWN:** Mixture of O<sub>2</sub> and N<sub>2</sub> with partial pressures in the ratio 0.21 to 0.79.

**FIND:** Mass fraction of each species in the mixture.

**SCHEMATIC:**

$$\frac{p_{O_2}}{p_{N_2}} = \frac{0.21}{0.79}$$

$$\mathcal{M}_{O_2} = 32 \text{ kg/kmol}$$

$$\mathcal{M}_{N_2} = 28 \text{ kg/kmol}$$

**ASSUMPTIONS:** (1) Perfect gas behavior.

**ANALYSIS:** From the definition of the mass fraction,

$$m_i = \frac{\rho_i}{\rho} = \frac{\rho_i}{\sum \rho_i}$$

Hence, with

$$\rho_i = \frac{p_i}{R_i T} = \frac{p_i}{(\mathcal{R}/\mathcal{M}_i)T} = \frac{\mathcal{M}_i p_i}{\mathcal{R}T}$$

Hence

$$m_i = \frac{\mathcal{M}_i p_i / \mathcal{R}T}{\sum \mathcal{M}_i p_i / \mathcal{R}T}$$

or, canceling terms and dividing numerator and denominator by the total pressure  $p$ ,

$$m_i = \frac{\mathcal{M}_i x_i}{\sum \mathcal{M}_i x_i}$$

With the mole fractions as

$$x_{O_2} = p_{O_2} / p = \frac{0.21}{0.21 + 0.79} = 0.21$$

$$x_{N_2} = p_{N_2} / p = 0.79,$$

find the mass fractions as

$$m_{O_2} = \frac{32 \times 0.21}{32 \times 0.21 + 28 \times 0.79} = 0.233 \quad <$$

$$m_{N_2} = 1 - m_{O_2} = 0.767. \quad <$$

## PROBLEM 14.2

**KNOWN:** Mole fraction (or mass fraction) and molecular weight of each species in a mixture of  $n$  species. Equal mole fractions (or mass fractions) of  $O_2$ ,  $N_2$  and  $CO_2$  in a mixture.

**FIND:**

**SCHEMATIC:**

$$x_{O_2} = x_{N_2} = x_{CO_2} = 0.333$$

or

$$m_{O_2} = m_{N_2} = m_{CO_2} = 0.333$$

$$\mathcal{M}_{CO_2} = 44$$

$$\mathcal{M}_{O_2} = 32, \mathcal{M}_{N_2} = 28$$

**ASSUMPTIONS:** (1) Perfect gas behavior.

**ANALYSIS:** (a) With

$$m_i = \frac{\rho_i}{\rho} = \frac{\rho_i}{\sum_i \rho_i} = \frac{p_i / R_i T}{\sum_i p_i / R_i T} = \frac{p_i \mathcal{M}_i / \mathcal{R} T}{\sum_i p_i \mathcal{M}_i / \mathcal{R} T}$$

and dividing numerator and denominator by the total pressure  $p$ ,

$$m_i = \frac{\mathcal{M}_i x_i}{\sum_i \mathcal{M}_i x_i} \quad <$$

Similarly,

$$x_i = \frac{p_i}{\sum_i p_i} = \frac{\rho_i R_i T}{\sum_i \rho_i R_i T} = \frac{(\rho_i / \mathcal{M}_i) \mathcal{R} T}{\sum_i (\rho_i / \mathcal{M}_i) \mathcal{R} T}$$

or, dividing numerator and denominator by the total density  $\rho$

$$x_i = \frac{m_i / \mathcal{M}_i}{\sum_i m_i / \mathcal{M}_i} \quad <$$

(b) With

$$\mathcal{M}_{O_2} x_{O_2} + \mathcal{M}_{N_2} x_{N_2} + \mathcal{M}_{CO_2} x_{CO_2} = 32 \times 0.333 + 28 \times 0.333 + 44 \times 0.333 = 34.6$$

$$m_{O_2} = 0.31, \quad m_{N_2} = 0.27, \quad m_{CO_2} = 0.42. \quad <$$

With

$$m_{O_2} / \mathcal{M}_{O_2} + m_{N_2} / \mathcal{M}_{N_2} + m_{CO_2} / \mathcal{M}_{CO_2} = 0.333 / 32 + 0.333 / 28 + 0.333 / 44$$

$$m_{O_2} = 2.987 \times 10^{-2}.$$

find

$$x_{O_2} = 0.35, \quad x_{N_2} = 0.40, \quad x_{CO_2} = 0.25. \quad <$$

### PROBLEM 14.3

**KNOWN:** Partial pressures and temperature for a mixture of CO<sub>2</sub> and N<sub>2</sub>.

**FIND:** Molar concentration, mass density, mole fraction and mass fraction of each species.

**SCHEMATIC:**

A hand-drawn schematic consisting of a cloud-like shape with a stippled border. Inside the cloud, the text reads:  $p_A = p_B = 1 \text{ bar}$  and  $T = 298 \text{ K}$ .

$$A \rightarrow \text{CO}_2, \mathcal{M}_A = 44 \text{ kg/kmol}$$

$$B \rightarrow \text{N}_2, \mathcal{M}_B = 28 \text{ kg/kmol}$$

**ASSUMPTIONS:** (1) Perfect gas behavior.

**ANALYSIS:** From the equation of state for an ideal gas,

$$C_i = \frac{p_i}{\mathcal{R}T}$$

Hence, with  $p_A = p_B$ ,

$$C_A = C_B = \frac{1 \text{ bar}}{8.314 \times 10^{-2} \text{ m}^3 \cdot \text{bar/kmol} \cdot \text{K} \times 298 \text{ K}}$$

$$C_A = C_B = 0.040 \text{ kmol/m}^3. \quad <$$

With  $\rho_i = \mathcal{M}_i C_i$ , it follows that

$$\rho_A = 44 \text{ kg/kmol} \times 0.04 \text{ kmol/m}^3 = 1.78 \text{ kg/m}^3 \quad <$$

$$\rho_B = 28 \text{ kg/kmol} \times 0.04 \text{ kmol/m}^3 = 1.13 \text{ kg/m}^3. \quad <$$

Also, with

$$x_i = C_i / \sum_i C_i$$

find

$$x_A = x_B = 0.04 / 0.08 = 0.5 \quad <$$

and with

$$m_i = \rho_i / \sum \rho_i$$

find

$$m_A = 1.78 / (1.78 + 1.13) = 0.61 \quad <$$

$$m_B = 1.13 / (1.78 + 1.13) = 0.39. \quad <$$

### PROBLEM 14.4

**KNOWN:** He-Xe mixture containing 0.75 mole fraction of He at 300 K and 1 atm.

**FIND:** Mass fraction of He and mixture mass density, molar concentration, and molecular weight. Mass of coolant in 10 liters.

**SCHEMATIC:**

**ASSUMPTIONS:** Ideal gas mixture.

**PROPERTIES:**  $\mathcal{M}_{\text{He}} = 4 \text{ kg/kmol}$ ,  $\mathcal{M}_{\text{Xe}} = 131.3 \text{ kg/kmol}$

**ANALYSIS:** The molar concentration of the mixture can be found directly from the ideal gas law, in the form

$$C = \frac{p}{\mathcal{R}T} = \frac{1 \text{ atm}}{8.205 \times 10^{-2} \text{ m}^3 \cdot \text{atm/kmol} \cdot \text{K} \times 300 \text{ K}} = 0.0406 \text{ kmol/m}^3 \quad <$$

The mass density of one component in a mixture can be related to the mole fraction by combining Eqs. 14.11 and 14.1 to yield

$$\rho_i = \mathcal{M}_i x_i C$$

For He this results in

$$\rho_{\text{He}} = 4 \text{ kg/kmol} \times 0.75 \times 0.0406 \text{ kmol/m}^3 = 0.1219 \text{ kg/m}^3$$

Then the total mass density can be found by summing the species mass densities,

$$\rho = \sum_i \rho_i = C \sum_i \mathcal{M}_i x_i = 0.0406 [4 \text{ kg/kmol} \times 0.75 + 131.3 \text{ kg/kmol} \times 0.25]$$
$$\rho = 1.455 \text{ kg/m}^3 \quad <$$

Thus the helium mass fraction is

$$m_{\text{He}} = \frac{\rho_{\text{He}}}{\rho} = \frac{0.1219 \text{ kg/m}^3}{1.455 \text{ kg/m}^3} = 0.0837 \quad <$$

Finally, the molecular weight of the mixture can be found from

Continued...

**PROBLEM 14.4 (Cont.)**

$$\mathcal{M} = \frac{\rho}{C} = \frac{1.455 \text{ kg/m}^3}{0.0406 \text{ kmol/m}^3} = 35.8 \text{ kg/kmol} \quad <$$

Finally, the mass corresponding to a 10 liter cooling system capacity would be

$$M = \rho V = 1.455 \text{ kg/m}^3 \times 10 \text{ liters} \times 10^{-3} \text{ m}^3/\text{liter} = 0.0146 \text{ kg} \quad <$$

**COMMENTS:** (1) As you may recall from thermodynamics, the molar concentration of an ideal gas is a function only of pressure and temperature, independent of the species. (2) The mass fraction of helium is much less than its mole fraction because its molecular weight is so much less than that of xenon.

### PROBLEM 14.5

**KNOWN:** Mass diffusion coefficients of two binary mixtures at a given temperature, 298 K.

**FIND:** Mass diffusion coefficients at a different temperature,  $T = 350$  K.

**ASSUMPTIONS:** (a) Ideal gas behavior, (b) Mixtures at 1 atm total pressure.

**PROPERTIES:** Table A-8, Ammonia-air binary mixture (298 K),  $D_{AB} = 0.28 \times 10^{-4} \text{ m}^2/\text{s}$ ;  
Hydrogen-air binary mixture (298 K),  $D_{AB} = 0.41 \times 10^{-4} \text{ m}^2/\text{s}$ .

**ANALYSIS:** According to treatment of Section 14.1.4, assuming ideal gas behavior,

$$D_{AB} \sim T^{3/2}$$

where  $T$  is in kelvin units. It follows then, that for

$$\text{NH}_3 - \text{Air}: \quad D_{AB}(350 \text{ K}) = 0.28 \times 10^{-4} \text{ m}^2/\text{s} (350 \text{ K}/298 \text{ K})^{3/2}$$

$$D_{AB}(350 \text{ K}) = 0.36 \times 10^{-4} \text{ m}^2/\text{s} \quad <$$

$$\text{H}_2 - \text{Air}: \quad D_{AB}(350 \text{ K}) = 0.41 \times 10^{-4} \text{ m}^2/\text{s} (350/298)^{3/2}$$

$$D_{AB}(350 \text{ K}) = 0.52 \times 10^{-4} \text{ m}^2/\text{s} \quad <$$

**COMMENTS:** Since the  $\text{H}_2$  molecule is smaller than the  $\text{NH}_3$  molecule, it follows that

$$D_{\text{H}_2-\text{Air}} > D_{\text{NH}_3-\text{Air}}$$

as indeed the numerical data indicate.

## PROBLEM 14.6

**KNOWN:** Pressure and temperature. Substance A and Substance B.

**FIND:** Plot of  $D_{AB}$  versus  $\mathcal{M}_A$  for  $\text{NH}_3$ ,  $\text{H}_2\text{O}$ ,  $\text{CO}_2$ ,  $\text{H}_2$ ,  $\text{O}_2$ , acetone, benzene and naphthalene in air.

**ASSUMPTIONS:** Ideal gas behavior.

<b>PROPERTIES:</b>	<u>Substance A (<math>T, p</math>)</u>	<u><math>D_{AB}^*</math> (<math>\text{m}^2/\text{s}</math>)</u>	<u><math>\mathcal{M}_A</math> (kg/kmol)</u>
	$\text{NH}_3$ (298 K, 1 atm)	$0.28 \times 10^{-4}$	17.03 **
	$\text{H}_2\text{O}$ (298 K, 1 atm)	$0.26 \times 10^{-4}$	18.02 **
	$\text{CO}_2$ (298 K, 1 atm)	$0.16 \times 10^{-4}$	44.01 **
	$\text{H}_2$ (298 K, 1 atm)	$0.41 \times 10^{-4}$	2.016 **
	$\text{O}_2$ (298 K, 1 atm)	$0.21 \times 10^{-4}$	32.00 **
	Acetone (273 K, 1 atm)	$0.11 \times 10^{-4}$	58.08 ***
	Benzene (298 K, 1 atm)	$0.88 \times 10^{-5}$	78.11 *****
	Naphthalene (300 K, 1 atm)	$0.62 \times 10^{-5}$	128.16 *****

\* Table A.8

\*\* Table A.4

\*\*\* J.R. Howell and R.O. Buckius, *Fundamentals of Engineering Thermodynamics*, 2<sup>nd</sup> ed., McGraw-Hill, 1992.

\*\*\*\* M.J. Moran and H.N. Shapiro, *Fundamentals of Engineering Thermodynamics*, 6<sup>th</sup> ed., John Wiley and Sons, Hoboken, 2008.

\*\*\*\*\* Problem 6.63

**ANALYSIS:** The mass diffusivity values must be corrected to account for the temperature and pressure dependence. From Table A.8,  $D_{AB} \propto p^{-1}T^{3/2}$  and the corrected mass diffusivity for  $\text{NH}_3$  is

$$D_{ABc} = 0.28 \times 10^{-4} \text{ m}^2/\text{s} \times (1 \text{ atm} / 1.5 \text{ atm}) \times (320 \text{ K} / 298 \text{ K})^{3/2} = 0.21 \times 10^{-4} \text{ m}^2/\text{s}$$

Repeating the calculation for the other substances yields the following.

<u>Substance A</u>	<u><math>D_{ABc}</math> (<math>\text{m}^2/\text{s}</math>)</u>
$\text{NH}_3$	$0.21 \times 10^{-4}$
$\text{H}_2\text{O}$	$0.19 \times 10^{-4}$
$\text{CO}_2$	$0.12 \times 10^{-4}$
$\text{H}_2$	$0.30 \times 10^{-4}$
$\text{O}_2$	$0.16 \times 10^{-4}$
Acetone	$0.93 \times 10^{-5}$
Benzene	$0.65 \times 10^{-5}$
Naphthalene	$0.46 \times 10^{-5}$

A plot of the corrected mass diffusivities versus molecular weight of Substance A follows.

Continued...

### PROBLEM 14.6 (Cont.)

According to kinetic theory, the mass diffusivity decreases with increasing molecular weight. This behavior is readily evident in the plot, and therefore the kinetic theory is consistent with measured values. <

**COMMENTS:** Small molecules can diffuse through the host medium more readily than large molecules.

## PROBLEM 14.7

**KNOWN:** The inner and outer surfaces of an iron cylinder of 100-mm length are exposed to a carburizing gas (mixtures of CO and CO<sub>2</sub>). Observed experimental data on the variation of the carbon composition (weight carbon, %) in the iron at 1000°C as a function of radius. Carbon flow rate under steady-state conditions.

**FIND:** (a) Beginning with Fick's law, show that  $d\rho_c / d(\ln(r))$  is a constant if the diffusion coefficient,  $D_{C-Fe}$ , is a constant; sketch of the carbon mass density,  $\rho_c(r)$ , as function of  $\ln(r)$  for such a diffusion process; (b) Create a graph for the experimental data and determine whether  $D_{C-Fe}$  for this diffusion process is constant, increases or decreases with increasing mass density; and (c) Using the experimental data, calculate and tabulate  $D_{C-Fe}$  for selected carbon compositions over the range of the experiment.

**SCHEMATIC:**

**PROPERTIES:** Iron (1000°C).  $\rho = 7730 \text{ kg/m}^3$ . Experimental observations of carbon composition

r (mm)	4.49	4.66	4.79	4.91	5.16	5.27	5.40	5.53
Wt. C (%)	1.42	1.32	1.20	1.09	0.82	0.65	0.46	0.28

**ASSUMPTIONS:** (1) Steady-state conditions, (2) One-dimensional, radial diffusion in a stationary medium, and (3) Uniform total concentration.

**ANALYSIS:** (a) For the one-dimensional, radial (cylindrical) coordinate system, Fick's law is

$$j_A = -D_{AB} A_r \frac{d\rho_A}{dr} \quad (1)$$

where  $A_r = 2\pi rL$ . For steady-state conditions,  $j_A$  is constant, and if  $D_{AB}$  is constant, the product

$$r \frac{d\rho_A}{dr} = C_1 \quad (2)$$

must be a constant. Using the differential relation  $dr/r = d(\ln r)$ , it follows that

$$\frac{d\rho_A}{d(\ln r)} = C_1 \quad (3)$$

so that on a  $\ln(r)$  plot,  $\rho_A$  is a straight line. See the graph below for this behavior.

Continued ...

### PROBLEM 14.7 (Cont.)

(b) To determine whether  $D_{C-Fe}$  is a constant for the experimental diffusion process, the data are represented on a  $\ln(r)$  coordinate.

Since the plot is not linear,  $D_{C-Fe}$  is not a constant. From the treatment of part (a), if  $D_{AB}$  is not a constant, then

$$D_{AB} \frac{d\rho_A}{d(\ln r)} = C_2$$

must be constant. We conclude that  $D_{C-Fe}$  will be lower at the radial position where the gradient is higher. Hence, we expect  $D_{C-Fe}$  to increase with increasing carbon content.

(c) From a plot of Wt - %C vs.  $r$  (not shown), the mass fraction gradient is determined at three locations and Fick's law is used to calculate the diffusion coefficient,

$$j_c = -\rho \cdot A_r \cdot D_{C-Fe} \frac{\Delta (\text{Wt} - \% \text{ C})}{\Delta r}$$

where the mass flow rate is

$$j_c = 3.6 \times 10^{-3} \text{ kg} / 100 \text{ h} (3600 \text{ s} / \text{h}) = 1 \times 10^{-8} \text{ kg} / \text{s}$$

and  $\rho = 7730 \text{ kg} / \text{m}^3$ , density of iron. The results of this analysis yield,

Wt - C (%)	$r$ (mm)	$\Delta \text{Wt-C} / \Delta r$ (%/mm)	$D_{C-Fe} \times 10^{11}$ ( $\text{m}^2 / \text{s}$ )
1.32	4.66	-0.679	6.51
0.955	5.04	-1.08	3.79
0.37	5.47	-1.385	2.72

### PROBLEM 14.8

**KNOWN:** Air is enclosed at uniform pressure in a vertical, cylindrical container whose top and bottom surfaces are maintained at different temperatures.

**FIND:** (a) Conditions in air when bottom surface is colder than top surface, (b) Conditions when bottom surface is hotter than top surface.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Uniform pressure, (2) Perfect gas behavior.

**ANALYSIS:** (a) If  $T_1 > T_2$ , the axial temperature gradient ( $dT/dx$ ) will result in an axial density gradient. However, since  $d\rho/dx < 0$  there will be no buoyancy driven, convective motion of the mixture.

There will also be axial species density gradients,  $d\rho_{O_2}/dx$  and  $d\rho_{N_2}/dx$ . However, there is no gradient associated with the mass fractions ( $dm_{O_2}/dx = 0$ ,  $dm_{N_2}/dx = 0$ ). Hence, from Fick's law, Eq. 14.12, there is *no* mass transfer by diffusion.

(b) If  $T_1 < T_2$ ,  $d\rho/dx > 0$  and there may be a buoyancy driven, convective motion of the mixture. However,  $dm_{O_2}/dx = 0$  and  $dm_{N_2}/dx = 0$ , and there is still *no* mass transfer. Hence, although there is motion of each species with the convective motion of the mixture, there is *no relative motion* between species.

**COMMENTS:** The commonly used special case of Fick's law,

$$j_A = -D_{AB} \frac{d\rho_A}{dx}$$

would be inappropriate for this problem since  $\rho$  is not uniform. If applied, this special case indicates that mass transfer would occur, thereby providing an incorrect result.

### PROBLEM 14.9

**KNOWN:** Dimensions of rubber stopper in medicine jar. Molar concentration of medicine vapor at top and bottom surfaces. Mass diffusivity of medicine vapor in rubber.

**FIND:** Rate at which medicine vapor exits through the stopper.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Glass neck is impermeable to medicine vapor, thus there is negligible mass loss out of slanted surface, (2) One-dimensional mass diffusion, (3) Steady state, (4) Constant properties, (5) No chemical reaction.

**PROPERTIES:** Medicine vapor-rubber (given):  $D_{AB} = 0.2 \times 10^{-9} \text{ m}^2/\text{s}$ .

**ANALYSIS:** The analysis follows the “alternative conduction analysis” approach. For one-dimensional diffusion in the  $x$ -direction, Fick’s Law in molar form, Eq. 14.13, reduces to

$$J_A^* = -CD_{AB} \frac{dx_A}{dx} = -D_{AB} \frac{dC_A}{dx} \quad (1)$$

where the total concentration,  $C$ , has been assumed constant. The transfer rate of species A through the entire stopper cross-section,  $N_A$ , can be expressed as  $N_A = J_A^* A_c$ , where  $A_c$  is the cross-sectional area. For steady-state, one-dimensional diffusion with no chemical reaction, the species transfer rate must be constant. We multiply Eq. (1) by  $A_c$ , separate variables, and integrate between the top and bottom of the stopper, as follows

$$N_A = J_A^* A_c = -D_{AB} A_c \frac{dC_A}{dx}$$

$$N_A \int_0^L \frac{dx}{A_c} = -D_{AB} \int_{x_{A1}}^{x_{A2}} dC_A = D_{AB} (C_{A1} - C_{A2}) = D_{AB} C_{A1} \quad (2)$$

The cross-sectional area is given by

$$A_c = \pi R^2, \text{ where } R = R_1 + (R_2 - R_1)x/L$$

Continued...

### PROBLEM 14.9 (Cont.)

Thus  $dx = LdR/(R_2 - R_1)$ , and Eq. (2) becomes

$$N_A \int_{R_1}^{R_2} \frac{dR}{\pi R^2} \frac{L}{R_2 - R_1} = D_{AB} C_{A1}$$
$$\frac{N_A}{\pi} \left( \frac{1}{R_1} - \frac{1}{R_2} \right) \frac{L}{R_2 - R_1} = D_{AB} C_{A1}$$

Thus

$$N_A = \frac{\pi D_{AB} C_{A1} R_1 R_2}{L}$$
$$= \frac{\pi \times 0.2 \times 10^{-9} \text{ m}^2 / \text{s} \times 2 \times 10^{-3} \text{ kmol} / \text{m}^3 \times 0.005 \text{ m} \times 0.01 \text{ m}}{0.02 \text{ m}}$$

$$N_A = 3.14 \times 10^{-15} \text{ kmol} / \text{s}$$

<

**COMMENTS:** (1) The assumption of constant concentration,  $C$ , is excellent because the “mixture” of rubber and medicine vapor would be dominated by the rubber. (2) Using the properties of water for the medicine, we can estimate how much the liquid would be depleted per year. The molar loss in one year is  $3.14 \times 10^{-15} \text{ kmol} / \text{s} \times 3.15 \times 10^7 \text{ s} / \text{yr} = 9.9 \times 10^{-8} \text{ kmol} / \text{yr}$ . If the molecular weight is  $18 \text{ kg} / \text{kmol}$ , the loss would be  $1.8 \times 10^{-6} \text{ kg} / \text{yr}$ . If the liquid density is  $1000 \text{ kg} / \text{m}^3$ , the volume loss would be  $1.8 \times 10^{-9} \text{ m}^3 / \text{yr}$ . For a bottle cross-sectional area of  $2 \times 10^{-3} \text{ m}^2$ , the liquid level would drop by less than  $1 \text{ } \mu\text{m}$  per year.

## PROBLEM 14.10

**KNOWN:** Evaporation of liquid A into a column containing vapor A and B. Species B cannot be absorbed in liquid A.

**FIND:** The relationship between the ratio of the molar-average velocity to the species velocity of species A to the mole fraction of species A.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady, one-dimensional diffusion, (2) No chemical reactions.

**ANALYSIS:** From Section 14.2.2, we know that  $N''_{B,x} = 0$ . From Eq. 14.27,

$$N''_{A,x} = C_A v_{A,x} \quad \text{and} \quad N''_{B,x} = C_B v_{B,x} = 0 \quad \text{or} \quad v_{B,x} = 0 \quad (1)$$

From Eq. 14.29,

$$v_x^* = X_A v_{A,x} \quad (2)$$

Therefore

$$\frac{v_x^*}{v_{A,x}} = X_A \quad <$$

The relationship is shown in the graph below.

### PROBLEM 14.10 (Cont.)

**COMMENTS:** (1) When the mole fraction of Species A is small and Species B is not in motion, the molar-average velocity is dominated by Species B and is negligible compared to the non-zero species velocity of A. In other words, the vapor in the column can be treated as a stationary medium since, although Species A is in motion, there is very little species A present. (2) When the mole fraction of Species A is large, there is very little Species B present, and the velocity of the mixture is dominated by the velocity of Species A. Hence, the velocity ratio approaches unity as mixture becomes dominated by Species A.

### PROBLEM 14.11

**KNOWN:** Water in an open pan exposed to prescribed ambient conditions.

**FIND:** Evaporation rate considering (a) diffusion only and (b) convective effects.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) One-dimensional diffusion, (3) Constant properties, (4) Uniform T and p, (5) Perfect gas behavior.

**PROPERTIES:** Table A-8, Water vapor-air ( $T = 300 \text{ K}$ , 1 atm),  $D_{AB} = 0.26 \times 10^{-4} \text{ m}^2/\text{s}$ ; Table A-6, Water vapor ( $T = 300 \text{ K}$ , 1 atm),  $p_{\text{sat}} = 0.03531 \text{ bar}$ ,  $v_g = 39.13 \text{ m}^3/\text{kg}$ .

**ANALYSIS:** (a) The evaporation rate considering only diffusion follows from Eq. 14.32 simplified for a stationary medium. That is,

$$N_{A,x} = N''_{A,x} \cdot A = -D_{AB} A \frac{dC_A}{dx}.$$

Recognizing that  $\phi \equiv p_A/p_{A,\text{sat}} = C_A/C_{A,\text{sat}}$ , the rate is expressed as

$$N_{A,x} = -D_{AB} A \frac{C_{A,\infty} - C_{A,s}}{L} = \frac{D_{AB} A}{L} C_{A,\text{sat}} (1 - \phi_\infty)$$

$$N_{A,x} = \frac{0.26 \times 10^{-4} \text{ m}^2/\text{s} (\pi/4) (0.2 \text{ m})^2}{80 \times 10^{-3} \text{ m}} \frac{1}{39.13 \text{ m}^3/\text{kg} \times 18 \text{ kg}/\text{kmol}} (1 - 0.25) = 1.087 \times 10^{-8} \text{ kmol}/\text{s}$$

where  $C_{A,s} = 1/(v_g \mathcal{M}_A)$  with  $\mathcal{M}_A = 18 \text{ kg}/\text{kmol}$ .

(b) The evaporation rate considering convective effects using Eq. 14.40 is

$$N_{A,x} = N''_{A,x} \cdot A = \frac{CD_{AB}A}{L} \ln \frac{1 - x_{A,L}}{1 - x_{A,0}}.$$

Using the perfect gas law, the total concentration of the mixture is

$$C = p/\mathcal{R}T = 1.0133 \text{ bar} / (8.314 \times 10^{-2} \text{ m}^3 \cdot \text{bar}/\text{kmol} \cdot \text{K} \times 300 \text{ K}) = 0.04063 \text{ kmol}/\text{m}^3$$

where  $p = 1 \text{ atm} = 1.0133 \text{ bar}$ . The mole fractions at  $x = 0$  and  $x = L$  are

$$x_{A,0} = \frac{p_{A,s}}{p} = \frac{0.03531 \text{ bar}}{1.0133 \text{ bar}} = 0.0348 \quad x_{A,L} = \phi_\infty x_{A,0} = 0.0087.$$

Hence

$$N_{A,x} = \frac{0.04063 \text{ kmol}/\text{m}^3 \times 0.26 \times 10^{-4} \text{ m}^2/\text{s} (\pi/4) (0.2 \text{ m})^2}{80 \times 10^{-3} \text{ m}} \ln \frac{1 - 0.0087}{1 - 0.0348} = 1.107 \times 10^{-8} \text{ kmol}/\text{s} \quad <$$

**COMMENTS:** For this situation, the advective effect is very small but does tend to increase (by 1.5%) the evaporation rate as expected.

## PROBLEM 14.12

**KNOWN:** Spherical droplet of liquid A and radius  $r_o$  evaporating into stagnant gas B.

**FIND:** Evaporation rate of species A in terms of  $p_{A,sat}$ , partial pressure  $p_A(r)$ , the total pressure  $p$  and other pertinent parameters.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) One-dimensional, radial, species diffusion, (3) Constant properties, including total concentration, (4) Droplet and mixer air at uniform pressure and temperature, (5) Perfect gas behavior.

**ANALYSIS:** From Eq. 14.32 for a radial spherical coordinate system, the evaporation rate of liquid A into a binary gas mixture A + B is

$$N_{A,r} = -D_{AB}A_r \frac{dC_A}{dr} + \frac{C_A}{C} N_{A,r}$$

where  $A_r = 4\pi r^2$  and  $N_{A,r} = N_A$ , a constant,

$$N_A \left( 1 - \frac{C_A}{C} \right) = -D_{AB} \cdot 4\pi r^2 \cdot \frac{dC_A}{dr}$$

From perfect gas behavior,  $C_A = p_A / \mathfrak{R}T$  and  $C = p / \mathfrak{R}T$ ,

$$N_A (p - p_A) = -D_{AB} \cdot 4\pi r^2 \cdot \frac{p}{\mathfrak{R}T} \frac{dp_A}{dr}$$

Separating variables, setting definite limits, and integrating

$$-N_A \frac{\mathfrak{R}T}{p} \frac{1}{4\pi D_{AB}} \int_{r_o}^r \frac{dr}{r^2} = \int_{p_{A,r_o}}^{p_{A,r}} \frac{dp_A}{p - p_A}$$

find that

$$N_A = 4\pi r_o D_{AB} \frac{p}{\mathfrak{R}T} \frac{1}{1 - r_o/r} \ln \frac{p - p_A(r)}{p - p_{A,o}} \quad <$$

where  $p_{A,o} = p_A(r_o) = p_{A,sat}$ , the saturation pressure of liquid A at temperature T.

**COMMENTS:** Compare the method of solution and result with the content of Section 14.2.2, Evaporation in a Column.

### PROBLEM 14.13

**KNOWN:** Clean surface with pure steam has condensate rate of  $0.020 \text{ kg/m}^2 \cdot \text{s}$  for the prescribed conditions. With the presence of stagnant air in the steam, the condensate surface drops from  $28^\circ\text{C}$  to  $24^\circ\text{C}$  and the condensate rate is halved.

**FIND:** Partial pressure of air in the air-steam mixture as a function of distance from the condensate film.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Constant properties including pressure in air-steam mixture, (3) Perfect gas behavior.

**PROPERTIES:** Table A-6, Water vapor:  $p_{\text{sat}}(28^\circ\text{C} = 301 \text{ K}) = 0.03767 \text{ bar}$ ;  $p_{\text{sat}}(24^\circ\text{C} = 297 \text{ K}) = 0.02983 \text{ bar}$ ; Table A-8, Water-air (298 K, 1 bar):  $D_{\text{AB}} = 0.26 \times 10^{-4} \text{ m}^2/\text{s}$ .

**ANALYSIS:** The partial pressure distribution of the air as a function of distance  $y$  can be found from the species (A) rate expression, Eq. 14.40,

$$N''_{\text{A},y} = (CD_{\text{AB}}/y) \ln\left(\frac{1-x_{\text{A},y}}{1-x_{\text{A},0}}\right).$$

With  $C = p/\mathcal{R}T$ ,  $x_{\text{B},y} = 1 - x_{\text{A},y}$  and  $x_{\text{B},0} = 1 - x_{\text{A},0}$ , recognizing that  $x_{\text{B}} = p_{\text{B}}/p$ , find

$$p_{\text{B}}(y) = p_{\text{B},0} \cdot \exp\left(N''_{\text{A},y} \frac{\mathcal{R}T}{pD_{\text{AB}}} y\right)$$

$$p_{\text{B},0} = p - p_{\text{A},0} = p_{\text{sat}}(28^\circ\text{C}) - p_{\text{sat}}(24^\circ\text{C}) = (0.03767 - 0.02983) \text{ bar} = 0.00784 \text{ bar}.$$

With  $N''_{\text{A},y} = -(0.020/2) \text{ kg/m}^2 \cdot \text{s} / 29 \text{ kg/kmol} = 3.45 \times 10^{-4} \text{ kmol/m}^2 \cdot \text{s}$ ,

$$p_{\text{B}}(y) = 0.0784 \text{ bar} \times \exp\left(3.45 \times 10^{-4} \text{ kmol/m}^2 \cdot \text{s} \frac{8.314 \times 10^{-2} \text{ m}^3 \cdot \text{bar/kmol} \cdot \text{K} \times 299 \text{ K}}{0.03767 \text{ bar} \times 6.902 \times 10^{-4} \text{ m}^2/\text{s}} y\right)$$

$$p_{\text{B}}(y) = 784 \text{ kPa} \times \exp(-0.330y)$$

with  $p_{\text{B}}$  in [kPa] and  $y$  in [mm], where  $T = 26^\circ\text{C} = 299 \text{ K}$ , the average temperature of the air-steam mixture, and  $D_{\text{AB}} \approx p^{-1} T^{3/2} = 0.26 \times 10^{-4} \text{ m}^2/\text{s} (1/0.03767) (299/298)^{3/2} = 6.902 \times 10^{-4} \text{ m}^2/\text{s}$ .

Selected values for the pressure are shown below and the distribution is shown above:

$y$ (mm)	0	5	10	15
$p_{\text{B}}(y)$ (kPa)	784	151	29.0	5.6

**COMMENTS:** To minimize inert gas effects, the usual practice is to pass vapor over the surfaces so that the inerts are eventually collected near the outlet region of the condenser. Our estimate shows that the effective region to be swept is approximately 10 mm thick.

## PROBLEM 14.14

**KNOWN:** Column containing liquid phase of water (A) evaporates into the air (B) flowing over the mouth of the column.

**FIND:** Evaporation rate of water ( $\text{kg}/\text{h}\cdot\text{m}^2$ ) using the known value of the binary diffusion coefficient for the water vapor - air mixture.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, one-dimensional diffusion in the column, (2) Constant properties, (3) Uniform temperature and pressure throughout the column, (4) Water vapor exhibits ideal gas behavior, and (5) Negligible water vapor in the chamber air.

**PROPERTIES:** Table A-6, water ( $T = 320 \text{ K}$ ):  $p_{\text{sat}} = 0.1053 \text{ bar}$ ; Table A-8, water vapor-air (0.25 atm, 320 K): Since  $D_{AB} \sim p^{-1} T^{3/2}$  find

$$D_{AB} = 0.26 \times 10^{-4} \text{ m}^2 / \text{s} (1.00 / 0.25) (320 / 298)^{3/2} = 1.157 \times 10^{-4} \text{ m}^2 / \text{s}$$

**ANALYSIS:** From Eq. 14.40, the molar flow rate per unit area is

$$N''_{A,x} = \frac{C D_{AB}}{L} \ln \frac{1 - x_{A,L}}{1 - x_{A,0}}$$

where  $C$  is the mixture concentration determined from the ideal gas law as

$$C = \frac{p}{\mathcal{R}T} = \frac{0.25 \text{ atm}}{8.205 \times 10^{-2} \text{ m}^3 \cdot \text{atm}/\text{kmol} \cdot \text{K} \times 320 \text{ K}} = 0.009397 \text{ kmol}/\text{m}^3$$

where  $\mathcal{R} = 8.205 \times 10^{-2} \text{ m}^3 \cdot \text{atm}/\text{kmol} \cdot \text{K}$ . The mole fractions at  $x = 0$  and  $x = L$  are

$$x_{A,L} = 0 \quad (\text{no water vapor in air above column})$$

$$x_{A,0} = p_A / p = 0.1053 / 0.25 = 0.4212$$

where  $p_A$  is the saturation pressure for water at  $T = 320 \text{ K}$ . Substituting numerical values

$$N''_{A,x} = \frac{0.009397 \text{ kmol} / \text{m}^3 \times 1.157 \times 10^{-4} \text{ m}^2 / \text{s}}{0.150 \text{ m}} \ln \frac{(1-0)}{(1-0.4212)}$$

$$N''_{A,x} = 3.964 \times 10^{-6} \text{ kmol} / \text{m}^2 \cdot \text{s}$$

or, on a mass basis,

$$m''_{A,x} = N''_{A,x} \mathcal{M}_A$$

$$m''_{A,x} = 3.964 \times 10^{-6} \text{ kmol} / \text{m}^2 \cdot \text{s} \times 3600 \text{ s} / \text{h} \times 18 \text{ kg} / \text{kmol}$$

$$m''_{A,x} = 0.257 \text{ kg} / \text{m}^2 \cdot \text{h}$$

<

### PROBLEM 14.15

**KNOWN:** Molar concentrations of helium at the inner and outer surfaces of a plastic membrane. Diffusion coefficient and membrane thickness.

**FIND:** Molar diffusion flux.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) One-dimensional diffusion in a plane wall, (3) Stationary medium, (4) Uniform  $C = C_A + C_B$ .

**ANALYSIS:** The molar flux may be obtained from Eq. 14.54,

$$N''_{A,x} = \frac{D_{AB}}{L} (C_{A,1} - C_{A,2}) = \frac{10^{-9} \text{ m}^2/\text{s}}{0.001 \text{ m}} (0.02 - 0.005) \text{ kmol/m}^3$$

$$N''_{A,x} = 1.5 \times 10^{-8} \text{ kmol/s} \cdot \text{m}^2.$$

<

**COMMENTS:** The mass flux is

$$n''_{A,x} = \mathcal{M}_A N''_{A,x} = 4 \text{ kg/kmol} \times 1.5 \times 10^{-8} \text{ kmol/s} \cdot \text{m}^2 = 6 \times 10^{-8} \text{ kg/s} \cdot \text{m}^2.$$

### PROBLEM 14.16

**KNOWN:** Three-dimensional diffusion of species A in a stationary medium with chemical reactions.

**FIND:** Derive molar form of diffusion equation.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Uniform total molar concentration, (2) Stationary medium.

**ANALYSIS:** The derivation parallels that of Section 14.4.2, except that Eq. 14.43 is applied on a molar basis. That is,

$$N_{A,x} + N_{A,y} + N_{A,z} + \dot{N}_{A,g} - N_{A,x+dx} - N_{A,y+dy} - N_{A,z+dz} = \dot{N}_{A,st}$$

With

$$N_{A,x+dx} = N_{A,x} + \frac{\partial N_{A,x}}{\partial x} dx, \quad N_{A,y+dy} = \dots$$

$$N_{A,x} = -D_{AB} (dydz) \frac{\partial C_A}{\partial x}, \quad N_{A,y} = \dots$$

$$\dot{N}_{A,g} = \dot{N}_A (dxdydz), \quad \dot{N}_{A,st} = \frac{\partial C_A}{\partial t} dxdydz$$

It follows that

$$\frac{\partial}{\partial x} \left( D_{AB} \frac{\partial C_A}{\partial x} \right) + \frac{\partial}{\partial y} \left( D_{AB} \frac{\partial C_A}{\partial y} \right) + \frac{\partial}{\partial z} \left( D_{AB} \frac{\partial C_A}{\partial z} \right) + \dot{N}_A = \frac{\partial C_A}{\partial t}. \quad <$$

**COMMENTS:** If  $D_{AB}$  is constant, the foregoing result reduces to Eq. 14.48b.

### PROBLEM 14.17

**KNOWN:** Gas (A) diffuses through a cylindrical tube wall (B) and experiences chemical reactions at a volumetric rate,  $\dot{N}_A$ .

**FIND:** Differential equation which governs molar concentration of gas in plastic.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) One-dimensional radial diffusion, (2) Uniform total molar concentration, (3) Stationary medium.

**ANALYSIS:** Dividing the species conservation requirement, Eq. 14.43, by the molecular weight,  $\mathcal{M}_A$ , and applying it to a differential control volume of unit length normal to the page,

$$N_{A,r} + \dot{N}_{A,g} - N_{A,r+dr} = \dot{N}_{A,st}$$

where

$$N_{A,r} = (2\pi r \cdot 1) N''_{A,r} = -2\pi r D_{AB} \frac{\partial C_A}{\partial r}$$

$$N_{A,r+dr} = N_{A,r} + \frac{\partial N_{A,r}}{\partial r} dr$$

$$\dot{N}_{A,g} = -\dot{N}_A (2\pi r \cdot dr \cdot 1) \qquad \dot{N}_{A,st} = \frac{\partial [C_A (2\pi r dr \cdot 1)]}{\partial t}$$

Hence

$$-\dot{N}_A (2\pi r dr) + 2\pi D_{AB} \frac{\partial}{\partial r} \left( r \frac{\partial C_A}{\partial r} \right) dr = 2\pi r dr \frac{\partial C_A}{\partial t}$$

or

$$\frac{D_{AB}}{r} \frac{\partial}{\partial r} \left( r \frac{\partial C_A}{\partial r} \right) - \dot{N}_A = \frac{\partial C_A}{\partial t} \qquad <$$

**COMMENTS:** (1) The minus sign in the generation term is necessitated by the fact that the reactions deplete the concentration of species A.

(2) From knowledge of  $\dot{N}_A (r, t)$ , the foregoing equation could be solved for  $C_A (r, t)$ .

(3) Note the agreement between the above result and the one-dimensional form of Eq. 14.49 for uniform C.

### PROBLEM 14.18

**KNOWN:** One-dimensional, radial diffusion of species A in a stationary, spherical medium with chemical reactions.

**FIND:** Derive appropriate form of diffusion equation.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) One-dimensional, radial diffusion, (2) Uniform total molar concentration, (3) Stationary medium.

**ANALYSIS:** Dividing the species conservation requirement, Eq. 14.43, by the molecular weight,  $\mathcal{M}_A$ , and applying it to the differential control volume, it follows that

$$N_{A,r} + \dot{N}_{A,g} - N_{A,r+dr} = \dot{N}_{A,st}$$

where

$$N_{A,r} = -D_{AB} 4\pi r^2 \frac{\partial C_A}{\partial r}$$

$$N_{A,r+dr} = N_{A,r} + \frac{\partial N_{A,r}}{\partial r} dr$$

$$\dot{N}_{A,g} = \dot{N}_A (4\pi r^2 dr), \quad \dot{N}_{A,st} = \frac{\partial [C_A (4\pi r^2 dr)]}{\partial t}$$

Hence

$$\dot{N}_A (4\pi r^2 dr) + 4\pi \frac{\partial}{\partial r} \left( D_{AB} r^2 \frac{\partial C_A}{\partial r} \right) dr = 4\pi r^2 \frac{\partial C_A}{\partial t} dr$$

or

$$\frac{1}{r^2} \frac{\partial}{\partial r} \left( D_{AB} r^2 \frac{\partial C_A}{\partial r} \right) + \dot{N}_A = \frac{\partial C_A}{\partial t}. \quad <$$

**COMMENTS:** Equation 14.50 reduces to the foregoing result if C is independent of r and variations in  $\phi$  and  $\theta$  are negligible.

### PROBLEM 14.19

**KNOWN:** Pressure and temperature of hydrogen stored in a spherical steel tank of prescribed diameter and thickness.

**FIND:** (a) Initial rate of hydrogen mass loss from the tank, (b) Initial rate of pressure drop in the tank.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) One-dimensional species diffusion in a stationary medium, (2) Uniform total molar concentration,  $C$ , (3) No chemical reactions.

**ANALYSIS:** (a) From Table 14.1

$$N_{A,r} = \frac{C_{A,o} - C_{A,L}}{R_{m,dif}} = \frac{C_{A,o}}{(1/4\pi D_{AB})(1/r_i - 1/r_o)}$$

$$N_{A,r} = \frac{4\pi(0.3 \times 10^{-12} \text{ m}^2/\text{s})1.5 \text{ kmol/m}^3}{(1/0.05 \text{ m} - 1/0.052 \text{ m})} = 7.35 \times 10^{-12} \text{ kmol/s}$$

or

$$n_{A,r} = M_A N_{A,r} = 2 \text{ kg/kmol} \times 7.35 \times 10^{-12} \text{ kmol/s} = 14.7 \times 10^{-12} \text{ kg/s.} \quad <$$

(b) Applying a species balance to a control volume about the hydrogen,

$$\dot{M}_{A,st} = -\dot{M}_{A,out} = -n_{A,r}$$

$$\dot{M}_{A,st} = \frac{d(\rho_A V)}{dt} = \frac{\pi D^3}{6} \frac{d\rho_A}{dt} = \frac{\pi D^3}{6R_A T} \frac{dp_A}{dt} = \frac{\pi D^3 M_A}{6RT} \frac{dp_A}{dt}$$

Hence

$$\frac{dp_A}{dt} = -\frac{6RT}{\pi D^3 M_A} n_{A,r} = -\frac{6(0.08314 \text{ m}^3 \cdot \text{bar/kmol} \cdot \text{K})(300 \text{ K})}{\pi(0.1 \text{ m})^3 2 \text{ kg/kmol}} \times 14.7 \times 10^{-12} \text{ kg/s}$$

$$\frac{dp_A}{dt} = -3.50 \times 10^{-7} \text{ bar/s.} \quad <$$

**COMMENTS:** If the spherical shell is approximated as a plane wall,  $N_{a,x} = D_{AB}(C_{A,o}) \pi D^2/L = 7.07 \times 10^{-12} \text{ kmol/s}$ . This result is 4% lower than that associated with the spherical shell calculation.

## PROBLEM 14.20

**KNOWN:** Temperature of atmospheric air and water. Percentage by volume of oxygen in the air.

**FIND:** (a) Mole and mass fractions of water at the air and water sides of the interface, (b) Mole and mass fractions of oxygen in the air and water.

**SCHEMATIC:**

$$M_w = 18, M_{air} = 29$$

**ASSUMPTIONS:** (1) Perfect gas behavior for air and water vapor, (2) Thermodynamic equilibrium at liquid/vapor interface, (3) Dilute concentration of oxygen and other gases in water, (4) Molecular weight of air is independent of vapor concentration.

**PROPERTIES:** Table A-6, Saturated water ( $T = 290 \text{ K}$ ):  $p_{\text{vap}} = 0.01917 \text{ bars}$ . Table A-9,  $\text{O}_2/\text{water}$ ,  $H = 37,600 \text{ bars}$ .

**ANALYSIS:** (a) Assuming ideal gas behavior,  $p_{w,\text{vap}} = (N_{w,\text{vap}}/V) \mathcal{R}T$  and  $p = (N/V) \mathcal{R}T$ , in which case

$$x_{w,\text{vap}} = (p_{w,\text{vap}} / p_{\text{air}}) = (0.01917 / 1.0133) = 0.0189 \quad <$$

With  $m_{w,\text{vap}} = (\rho_{w,\text{vap}}/\rho_{\text{air}}) = (C_{w,\text{vap}} M_w / C_{\text{air}} M_{\text{air}}) = x_{w,\text{vap}} (M_w / M_{\text{air}})$ . Hence,

$$m_{w,\text{vap}} = 0.0189 (18/29) = 0.0120 \quad <$$

Assuming negligible gas phase concentrations in the liquid,

$$x_{w,\text{liq}} = m_{w,\text{liq}} = 1 \quad <$$

(b) Since the partial volume of a gaseous species is proportional to the number of moles of the species, its mole fraction is equivalent to its volume fraction. Hence on the air side of the interface

$$x_{\text{O}_2,\text{air}} = 0.205 \quad <$$

$$m_{\text{O}_2,\text{air}} = x_{\text{O}_2,\text{air}} (M_{\text{O}_2} / M_{\text{air}}) = 0.205 (32/29) = 0.226 \quad <$$

The mole fraction of  $\text{O}_2$  in the water is

$$x_{\text{O}_2,\text{liq}} = p_{\text{O}_2,\text{air}} / H = 0.208 \text{ bars} / 37,600 \text{ bars} = 5.53 \times 10^{-6} \quad <$$

where  $p_{\text{O}_2,\text{air}} = x_{\text{O}_2,\text{air}} p_{\text{atm}} = 0.205 \times 1.0133 \text{ bars} = 0.208 \text{ bars}$ . The mass fraction of  $\text{O}_2$  in the water is

$$m_{\text{O}_2,\text{liq}} = x_{\text{O}_2,\text{liq}} (M_{\text{O}_2} / M_w) = 5.53 \times 10^{-6} (32/18) = 9.83 \times 10^{-6} \quad <$$

**COMMENTS:** There is a large discontinuity in the oxygen content between the air and water sides of the interface. Despite the low concentration of oxygen in the water, it is sufficient to support the life of aquatic organisms.

### PROBLEM 14.21

**KNOWN:** Pressure and temperature of hydrogen inside and outside of a circular tube. Diffusivity and solubility of hydrogen in tube wall of prescribed thickness and diameter.

**FIND:** Rate of hydrogen transfer through tube per unit length.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady diffusion in radial direction, (2) Uniform total molar concentration in wall, (3) No chemical reactions, (4) Stationary medium.

**ANALYSIS:** The mass transfer rate per unit tube length is

$$N'_{A,r} = \frac{C_A(r_1) - C_A(r_2)}{\ln(r_2/r_1) / 2\pi D_{AB}}$$

where from Eq. 14.62,  $C_{A,s} = S p_a$ ,

$$C_A(r_1) = S p_{A,1} = 160 \text{ kmol/m}^3 \cdot \text{atm} \times 2 \text{ atm} = 320 \text{ kmol/m}^3$$

$$C_A(r_2) = S p_{A,2} = 160 \text{ kmol/m}^3 \cdot \text{atm} \times 0.1 \text{ atm} = 16 \text{ kmol/m}^3.$$

Hence,

$$N'_{A,r} = \frac{(320 - 16) \text{ kmol/m}^3}{\ln(20.5/20) / 2\pi \times 1.8 \times 10^{-11} \text{ m}^2/\text{s}} = \frac{304 \text{ kmol/m}^3}{2.18 \times 10^8 \text{ s/m}^2}$$

$$N'_{A,r} = 1.39 \times 10^{-6} \text{ kmol/s} \cdot \text{m}.$$

<

**COMMENTS:** If the wall were assumed to be plane,

$$R'_{m,dif} = \frac{L}{D_{AB}\pi D} = \frac{5 \times 10^{-4} \text{ m}}{1.8 \times 10^{-11} \text{ m}^2/\text{s} \pi (0.04 \text{ m})} = 2.21 \times 10^8 \text{ s/m}^2$$

which is close to the value of  $2.18 \times 10^8 \text{ s/m}^2$  for the cylindrical wall.

### PROBLEM 14.22

**KNOWN:** Oxygen pressures on opposite sides of a rubber membrane.

**FIND:** (a) Molar diffusion flux of O<sub>2</sub>, (b) Molar concentrations of O<sub>2</sub> outside the rubber.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) One-dimensional, steady-state conditions, (2) Stationary medium of uniform total molar concentration,  $C = C_A + C_B$ , (3) Perfect gas behavior.

**PROPERTIES:** Table A-8, Oxygen-rubber (298 K):  $D_{AB} = 0.21 \times 10^{-9} \text{ m}^2/\text{s}$ ; Table A-10, Oxygen-rubber (298 K):  $S = 3.12 \times 10^{-3} \text{ kmol/m}^3 \cdot \text{bar}$ .

**ANALYSIS:** (a) For the assumed conditions

$$N''_{A,x} = J''_{A,x} = -D_{AB} \frac{dC_A}{dx} = D_{AB} \frac{C_A(0) - C_A(L)}{L}$$

From Eq. 14.62,

$$C_A(0) = S p_{A,1} = 6.24 \times 10^{-3} \text{ kmol/m}^3$$

$$C_A(L) = S p_{A,2} = 3.12 \times 10^{-3} \text{ kmol/m}^3$$

Hence

$$N''_{A,x} = 0.21 \times 10^{-9} \text{ m}^2/\text{s} \frac{(6.24 \times 10^{-3} - 3.12 \times 10^{-3}) \text{ kmol/m}^3}{0.0005 \text{ m}}$$

$$N''_{A,x} = 1.31 \times 10^{-9} \text{ kmol/s} \cdot \text{m}^2 \quad <$$

(b) From the perfect gas law

$$C_{A,1} = \frac{p_{A,1}}{\mathcal{R}T} = \frac{2 \text{ bar}}{(0.08314 \text{ m}^3 \cdot \text{bar}/\text{kmol} \cdot \text{K}) 298 \text{ K}} = 0.0807 \text{ kmol/m}^3 \quad <$$

$$C_{A,2} = 0.5 C_{A,1} = 0.0404 \text{ kmol/m}^3 \quad <$$

**COMMENTS:** Recognize that the molar concentrations outside the membrane differ from those within the membrane; that is,  $C_{A,1} \neq C_A(0)$  and  $C_{A,2} \neq C_A(L)$ .

### PROBLEM 14.23

**KNOWN:** Water vapor is transferred through dry wall by diffusion.

**FIND:** The mass diffusion rate through a  $0.01 \times 3 \times 5$  m wall.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) One-dimensional species diffusion, (3) Homogeneous medium, (4) Constant properties, (5) Uniform total molar concentration, (6) Stationary medium with  $x_A \ll 1$ , (7) Negligible condensation in the dry wall.

**ANALYSIS:** From Eq. 14.42,

$$N''_{A,x} = -CD_{AB} \frac{dx_A}{dx} = -D_{AB} \frac{dC_A}{dx} = D_{AB} \frac{C_{A,1} - C_{A,2}}{L}.$$

From Eq. 14.62

$$C_{A,1} = Sp_{A,1} = 0.15 \times 10^{-3} \text{ kmol/m}^3$$

$$C_{A,2} = Sp_{A,2} = 0 \text{ kmol/m}^3.$$

Hence

$$N''_A = 10^{-9} \text{ m}^2/\text{s} \times \frac{0.15 \times 10^{-3} \text{ kmol/m}^3}{0.01 \text{ m}} = 0.15 \times 10^{-10} \text{ kmol/s} \cdot \text{m}^2.$$

Therefore

$$n_A = \mathcal{M}_A (A \cdot N''_A) = 18 \text{ kg/kmol} \times 15 \text{ m}^2 \times 0.15 \times 10^{-10} \text{ kmol/s} \cdot \text{m}^2$$

or

$$n_A = 4.05 \times 10^{-9} \text{ kg/s.}$$

<

### PROBLEM 14.24

**KNOWN:** Pressure and temperature of helium in a glass cylinder of 100 mm inside diameter and 5 mm thickness.

**FIND:** Mass rate of helium loss per unit length.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) One-dimensional radial diffusion through cylinder wall, (3) Negligible end losses, (4) Stationary medium, (5) Uniform total molar concentration, (6) Negligible helium concentration outside cylinder.

**PROPERTIES:** Table A-8, He-SiO<sub>2</sub> (298 K):  $D_{AB} \approx 0.4 \times 10^{-13} \text{ m}^2/\text{s}$ ; Table A-10, He-SiO<sub>2</sub> (298 K):  $S \approx 0.45 \times 10^{-3} \text{ kmol}/\text{m}^3 \cdot \text{bar}$ .

**ANALYSIS:** From Table 14.1,

$$N'_{A,r} = \frac{C_{A,S1} - C_{A,S2}}{\ln(r_2/r_1)/2\pi D_{AB}}$$

where, from Eq. 14.62,  $C_{A,S} = Sp_A$ . Hence

$$C_{A,S1} = Sp_{A,1} = 0.45 \times 10^{-3} \text{ kmol}/\text{m}^3 \cdot \text{bar} \times 4 \text{ bar} = 1.8 \times 10^{-3} \text{ kmol}/\text{m}^3$$

$$C_{A,S2} = Sp_{A,2} = 0.$$

Hence

$$N'_{A,r} = \frac{1.8 \times 10^{-3} \text{ kmol}/\text{m}^3}{\ln(0.055/0.050)/2\pi(0.4 \times 10^{-13} \text{ m}^2/\text{s})}$$

$$N'_{A,r} = 4.75 \times 10^{-15} \text{ kmol}/\text{s} \cdot \text{m}.$$

The mass loss is then

$$n'_{A,r} = \mathcal{M}_A N'_{A,r} = 4 \text{ kg}/\text{kmol} \times 4.75 \times 10^{-15} \text{ kmol}/\text{s} \cdot \text{m}$$

$$n'_{A,r} = 1.90 \times 10^{-14} \text{ kg}/\text{s} \cdot \text{m}.$$

<

### PROBLEM 14.25

**KNOWN:** Temperature and pressure of helium stored in a spherical pyrex container of prescribed diameter and wall thickness.

**FIND:** Mass rate of helium loss.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Helium loss by one-dimensional diffusion in radial direction through the pyrex, (3)  $C = C_A + C_B$  is independent of  $r$ , and  $x_A \ll 1$ , (4) Stationary medium.

**PROPERTIES:** Table A-8, He-SiO<sub>2</sub> (293 K):  $D_{AB} = 0.4 \times 10^{-13} \text{ m}^2/\text{s}$ ; Table A-10, He-SiO<sub>2</sub> (293 K):  $S = 0.45 \times 10^{-3} \text{ kmol/m}^3 \cdot \text{bar}$ .

**ANALYSIS:** From Table 14.1, the molar diffusion rate may be expressed as

$$N_{A,r} = \frac{C_{A,S1} - C_{A,S2}}{R_{m,dif}}$$

where

$$R_{m,dif} = \frac{1}{4\pi D_{AB}} \left( \frac{1}{r_1} - \frac{1}{r_2} \right) = \frac{1}{4\pi (0.4 \times 10^{-13} \text{ m}^2/\text{s})} \left( \frac{1}{0.1 \text{ m}} - \frac{1}{0.11 \text{ m}} \right) = 1.81 \times 10^{12} \text{ s/m}^3$$

with

$$C_{A,S1} = S p_A = 0.45 \times 10^{-3} \text{ kmol/m}^3 \cdot \text{bar} \times 4 \text{ bar} = 1.80 \times 10^{-3} \text{ kmol/m}^3$$

$$C_{A,S2} = 0$$

find

$$N_{A,r} = \frac{1.80 \times 10^{-3} \text{ kmol/m}^3}{1.81 \times 10^{12} \text{ s/m}^3} = 10^{-15} \text{ kmol/s.}$$

Hence

$$n_{A,r} = \mathcal{M}_A N_{A,r} = 4 \text{ kg/mol} \times 10^{-15} \text{ kmol/s} = 4 \times 10^{-15} \text{ kg/s.} \quad <$$

**COMMENTS:** Since  $r_1 \approx r_2$ , the spherical shell could have been approximated as a plane wall with  $L = 0.01 \text{ m}$  and  $A \approx 4\pi r_m^2 = 0.139 \text{ m}^2$ . From Table 14.1,

$$R_{m,dif} = \frac{L}{D_{AB} A} = \frac{0.01 \text{ m}}{(0.4 \times 10^{-13} \text{ m}^2/\text{s})(0.137 \text{ m}^2)} = 1.8 \times 10^{12} \text{ s/m}^3 \text{ and}$$

$$N_{A,x} = \frac{C_{A,S1} - C_{A,S2}}{R_{m,dif}} = \frac{1.80 \times 10^{-3} \text{ kmol/m}^3}{1.8 \times 10^{12} \text{ s/m}^3} = 10^{-15} \text{ kmol/s.}$$

Hence the approximation is excellent.

## PROBLEM 14.26

**KNOWN:** Thickness of polymer packaging material, temperature and humidity conditions in gas on either side of the material.

**FIND:** (a) Solubility of the packaging material, (b) Total water vapor transfer rate for a material that has 10% of the diffusivity of the material in Example 14.3, (c) Total water vapor transfer rate for a material that has 10% the solubility of the material in Example 14.3, (d) Total water vapor transfer rate after coating the exterior surface with a thin film to reduce its solubility by a factor of 9, leaving the interior surface untreated.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Constant properties and steady-state conditions, (2) Stationary medium.

**PROPERTIES:** Table A.6, water ( $T = 295 \text{ K}$ ):  $p_{\text{sat}} = 0.02617 \text{ bars}$ .

**ANALYSIS:**

(a) For the exterior Surface 1,  $p_A(x=0) = \phi_1 p_{A,\text{sat}} = 0.9 \times 0.02617 \text{ bars} = 0.02355 \text{ bars}$ . For the interior Surface 2,  $p_A(x=L) = \phi_2 p_{A,\text{sat}} = 0.1 \times 0.02617 \text{ bars} = 0.002617 \text{ bars}$ . From Example 14.3,  $C_{A,s2} = C_{A,s}(x=L) = 0.5 \times 10^{-3} \text{ kmol/m}^3$  so that

$$S = \frac{C_{A,s2}}{p_A(x=L)} = \frac{0.5 \times 10^{-3} \text{ kmol/m}^3}{0.002617 \text{ bar}} = 191 \times 10^{-3} \frac{\text{kmol}}{\text{m}^3 \text{bar}} \quad <$$

(b) From Example 14.3,  $N_{A,x,p} = 0.32 \times 10^{-15} \text{ kmol/s}$ . If the diffusivity is reduced to 10% of its original value,

$$N_{A,x} = 0.1 N_{A,x,p} = 0.1 \times 0.32 \times 10^{-15} \text{ kmol/s} = 0.32 \times 10^{-16} \text{ kmol/s} \quad <$$

Continued...

### PROBLEM 14.26 (Cont.)

(c) If the solubility is reduced to 10% of its original value at both surfaces,  $C_{A,s1} = 0.5 \times 10^{-4} \text{ kmol/m}^3$  and  $C_{A,s2} = 4.5 \times 10^{-4} \text{ kmol/m}^3$ . Hence,

$$N_{A,x} = 0.1N_{A,x,p} = 0.32 \times 10^{-16} \text{ kmol/s} \quad <$$

(d) If the solubility of exterior Surface 1 is reduced by a factor of 9,  $C_{A,s1} = C_{A,s1,p}/9 = 4.5 \times 10^{-3} \text{ kmol/m}^3/9 = 0.5 \times 10^{-3} \text{ kmol/m}^3 = C_{A,s2}$ . Hence,

$$C_{A,s1} - C_{A,s2} = 0 \text{ and } N_{A,x} = 0 \quad <$$

**COMMENT:** (1) The same value of the solubility may be found in part (a) by considering conditions at Surface 1. (2) By manipulating the solubilities of the surfaces independently, one may eliminate concentration gradients in the material and, in turn, completely eliminate water vapor transfer by diffusion. Materials that have properties designed to change through their thickness in order to promote desired behavior are known as *functionally-graded* materials.

## PROBLEM 14.27

**KNOWN:** Dimensions of sphere containing a pharmaceutical product. Mass loss of sphere over specified time period, mass diffusivity, external conditions.

**FIND:** The value of the partition coefficient,  $K$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Constant properties and steady-state conditions, (2) Stationary medium.

**PROPERTIES:** Pharmaceutical product (given):  $\rho_p = 1250 \text{ kg/m}^3$ ,  $D_{AB} = 0.2 \times 10^{-11} \text{ m}^2/\text{s}$ ,

**ANALYSIS:** By the definition of the partition coefficient provided in the problem statement,

$\rho_{p,1} = K\rho_p$  and  $\rho_{p,2} = K\rho_{p,\infty}$ . The mass transfer rate through the polymer is found using the one-dimensional species diffusion resistance approach

$$n_{p,r} = \frac{\rho_{p,1} - \rho_{p,2}}{R_{m,dif}} = \frac{K\rho_p}{\frac{1}{4\pi D_{AB}} \left( \frac{1}{r_1} - \frac{1}{r_2} \right)} = \frac{\Delta M}{\Delta t}$$

Hence,

$$K = \frac{\Delta M}{\Delta t \rho_p} \left[ \frac{1}{4\pi D_{AB}} \left( \frac{1}{r_1} - \frac{1}{r_2} \right) \right]$$

$$= \frac{8.2 \times 10^{-6} \text{ kg}}{7 \text{ days} \times 24 \text{ h/day} \times 3600 \text{ s/h} \times 1250 \text{ kg/m}^3} \times \left[ \frac{1}{4\pi \times 0.2 \times 10^{-11} \text{ m}^2/\text{s}} \left( \frac{2}{5 \times 10^{-3} \text{ m}} - \frac{2}{5.1 \times 10^{-3} \text{ m}} \right) \right]$$

$$= 0.0034$$

<

## PROBLEM 14.28

**KNOWN:** Dimensions of  $N = 100$  closed-end palladium tubes. Hydrogen ( $H_2$ ) pressures and temperature on either side of tube wall. Mass diffusivity of atomic hydrogen (H) through the palladium, and Sievert's constant.

**FIND:** Hourly production rate of pure hydrogen ( $H_2$ ).

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Constant properties and steady-state conditions, (2) Stationary medium.

**PROPERTIES:** Hydrogen (H) in palladium, given:  $D_{AB} = 7 \times 10^{-9} \text{ m}^2/\text{s}$ .

**ANALYSIS:** The concentration of atomic hydrogen (H) on the outer and inner surfaces of the tube are

$$C_{H,o} = 1.4 \frac{\text{kmol}}{\text{m}^3 \text{bar}^{1/2}} \times (0.85 \times 15 \text{ bar})^{1/2} = 5.00 \text{ kmol/m}^3$$

and

$$C_{H,i} = 1.4 \frac{\text{kmol}}{\text{m}^3 \text{bar}^{1/2}} \times (6 \text{ bar})^{1/2} = 3.43 \text{ kmol/m}^3$$

The one-dimensional species diffusion resistances for the wall and end of one tube are

$$R_{m,dif,w} = \frac{\ln(r_2/r_1)}{2\pi L D_{AB}} = \frac{\ln[(0.8 \times 10^{-3} \text{ m} + 75 \times 10^{-6} \text{ m})/0.8 \times 10^{-3} \text{ m}]}{2\pi \times 80 \times 10^{-3} \text{ m} \times 7 \times 10^{-9} \text{ m}^2/\text{s}} = 25.5 \times 10^6 \text{ s/m}^3$$

and

$$R_{m,dif,e} = \frac{t}{D_{AB} A_c} = \frac{75 \times 10^{-6} \text{ m}}{7 \times 10^{-9} \text{ m}^2/\text{s} \times \pi \times (0.8 \times 10^{-3} \text{ m})^2} = 5.33 \times 10^9 \text{ s/m}^3$$

The molar transfer rate of atomic hydrogen (H) in one tube is therefore

Continued...

### PROBLEM 14.28 (Cont.)

$$N_H = \frac{(5.00 - 3.43) \frac{\text{kmol}}{\text{m}^3}}{25.5 \times 10^6 \frac{\text{s}}{\text{m}^3}} + \frac{(5.00 - 3.43) \frac{\text{kmol}}{\text{m}^3}}{5.33 \times 10^9 \frac{\text{s}}{\text{m}^3}} = 61.9 \times 10^{-9} \frac{\text{kmol}}{\text{s}}$$

The molar transfer rate of molecular hydrogen ( $\text{H}_2$ ) is therefore  $N_{\text{H}_2} = 0.5N_H = 30.95 \text{ kmol/s}$

The total production rate,  $N_{\text{H}_2,t}$ , in kg/h is

$$N_{\text{H}_2,t} = N_{\text{H}_2} \times \mathcal{M}_{\text{H}_2} \times N \times t = 30.95 \text{ kmol/s} \times 2 \text{ kg/kmol} \times 3600 \text{ s/h} \times 100 \text{ tubes} = 0.022 \text{ kg/h} \quad <$$

**Comments:** (1) The concentrations of hydrogen ( $\text{H}_2$ ) in the gas streams are  $0.25 \text{ kmol/m}^3$  and  $0.12 \text{ kmol/m}^3$ , respectively. (2) Palladium and other nanostructured materials, such as carbon nanotubes, can store very high concentrations of hydrogen within their atomic matrix.

### PROBLEM 14.29

**KNOWN:** Conditions of the exhaust gas passing over a catalytic surface for the removal of NO.

**FIND:** (a) Mole fraction of NO at the catalytic surface, (b) NO removal rate.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) One-dimensional species diffusion through the film, (3) Effects of bulk motion on NO transfer in the film are negligible (stationary medium), (4) No homogeneous reactions of NO within the film, (5) Constant properties, including the total molar concentration,  $C$ , throughout the film.

**ANALYSIS:** Subject to the above assumptions, the transfer of species A (NO) is governed by diffusion in a stationary medium, and the desired results are obtained from Eqs. 14.69 and 14.70.

Hence

$$\frac{x_{A,s}}{x_{A,L}} = \frac{1}{1 + (Lk_1''/D_{AB})} \quad x_{A,s} = \frac{0.15}{1 + 0.001 \text{ m} \times 0.05 \text{ m/s} / 10^{-4} \text{ m}^2/\text{s}} = 0.10. <$$

Also

$$N_{A,s}'' = -\frac{k_1'' C x_{A,L}}{1 + (Lk_1''/D_{AB})}$$

where, from the equation of state for a perfect gas,

$$C = \frac{p}{RT} = \frac{1.2 \text{ bar}}{8.314 \times 10^{-2} \text{ m}^3 \cdot \text{bar} / \text{kmol} \cdot \text{K} \times 773 \text{ K}} = 0.0187 \text{ kmol} / \text{m}^3.$$

Hence

$$N_{A,s}'' = -\frac{0.05 \text{ m/s} \times 0.0187 \text{ kmol} / \text{m}^3 \times 0.15}{1 + (0.001 \text{ m} \times 0.05 \text{ m/s} / 10^{-4} \text{ m}^2/\text{s})} = -9.35 \times 10^{-5} \text{ kmol} / \text{s} \cdot \text{m}^2$$

or

$$n_{A,s}'' = \mathcal{M}_A N_{A,s}'' = 30 \text{ kg} / \text{kmol} \left( -9.35 \times 10^{-5} \text{ kmol} / \text{s} \cdot \text{m}^2 \right) = -2.80 \times 10^{-3} \text{ kg} / \text{s} \cdot \text{m}^2.$$

The molar rate of NO removal for the entire surface is then

$$N_{A,s} = N_{A,s}'' A = -9.35 \times 10^{-5} \text{ kmol} / \text{s} \cdot \text{m}^2 \times 0.02 \text{ m}^2 = -1.87 \times 10^{-6} \text{ kmol} / \text{s}$$

or

$$n_{A,s} = -5.61 \times 10^{-5} \text{ kg} / \text{s}. <$$

**COMMENTS:** Because bulk motion is likely to contribute significantly to NO transfer within the film, the above results should be viewed as a first approximation.

### PROBLEM 14.30

**KNOWN:** Radius of coal pellets burning in oxygen atmosphere of prescribed pressure and temperature.

**FIND:** Oxygen molar consumption rate.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) One-dimensional diffusion in  $r$ , (2) Steady-state conditions, (3) Constant properties, (4) Perfect gas behavior, (5) Uniform  $C$  and  $T$ , (6) Stationary medium.

**ANALYSIS:** From Equation 14.57,

$$\frac{d}{dr} \left( r^2 \frac{dC_A}{dr} \right) = 0$$

$$dC_A / dr = C_1 / r^2 \quad \text{or} \quad C_A = -C_1 / r + C_2.$$

The boundary conditions at  $r \rightarrow \infty$  and  $r = r_0$  are, respectively,

$$C_A(\infty) = C \rightarrow C_2 = C$$

$$\dot{N}_A'' = N_A''(r_0) = -CD_{AB} \left. \frac{dx_A}{dr} \right|_{r_0} = -D_{AB} \left. \frac{dC_A}{dr} \right|_{r_0}$$

Hence

$$-k_1''(-C_1/r_0 + C) = -D_{AB}C_1/r_0^2$$

$$k_1''(C_1/r_0) + D_{AB}(C_1/r_0^2) = k_1''C \quad \text{or} \quad C_1 = \frac{k_1''C}{(k_1''/r_0) + (D_{AB}/r_0^2)}.$$

The oxygen molar consumption rate is

$$N_A''(r_0) = -D_{AB} \left. \frac{dC_A}{dr} \right|_{r_0} = -D_{AB} \frac{k_1''C}{k_1''r_0 + D_{AB}}$$

where 
$$C = \frac{p}{\mathcal{R}T} = \frac{1 \text{ atm}}{(8.205 \times 10^{-2} \text{ m}^3 \cdot \text{atm} / \text{kmol} \cdot \text{K}) 1450 \text{ K}} = 8.405 \times 10^{-3} \text{ kmol} / \text{m}^3.$$

Hence,

$$N_A''(r_0) = -1.71 \times 10^{-4} \text{ m}^2 / \text{s} \frac{0.1 \text{ m} / \text{s} \times 8.405 \times 10^{-3} \text{ kmol} / \text{m}^3}{(10^{-4} + 1.71 \times 10^{-4}) \text{ m}^2 / \text{s}} = -5.30 \times 10^{-4} \text{ kmol} / \text{s} \cdot \text{m}^2$$

$$N_A(r_0) = 4\pi r_0^2 N_A''(r_0) = 4\pi (0.001 \text{ m})^2 \times 5.30 \times 10^{-4} \text{ kmol} / \text{s} \cdot \text{m}^2$$

$$N_A(r_0) = 6.66 \times 10^{-9} \text{ kmol} / \text{s}. \quad \leftarrow$$

**COMMENTS:** The  $O_2$  consumption rate would increase with increasing  $k_1''$  and approach a limiting *finite* value as  $k_1''$  approaches infinity.

### PROBLEM 14.31

**KNOWN:** Pore geometry in a catalytic reactor. Concentration of reacting species at pore opening and order of catalytic reaction.

**FIND:** (a) Differential equation which determines concentration of reacting species, (b) Distribution of reacting species concentration along the pore.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) One-dimensional diffusion in x direction, (3) Stationary medium, (4) Uniform total molar concentration, (5) Stationary medium.

**ANALYSIS:** (a) Apply the species conservation requirement to the differential control volume,  $N_{A,x} - k_1'' C_A (\pi D) dx - N_{A,x+dx} = 0$ , where

$$N_{A,x+dx} = N_{A,x} + (dN_{A,x} / dx) dx$$

and from Fick's law

$$N_{A,x} = \left( -CD_{AB} \frac{dx_A}{dx} \right) \frac{\pi D^2}{4} = -\frac{\pi D^2}{4} D_{AB} \frac{dC_A}{dx}.$$

Hence

$$-\frac{dN_A}{dx} dx - k_1'' C_A (\pi D) dx = \frac{\pi D^2}{4} D_{AB} \frac{d^2 C_A}{dx^2} - k_1'' C_A (\pi D) dx = 0$$

$$\frac{d^2 C_A}{dx^2} - \frac{4k_1''}{DD_{AB}} C_A = 0. \quad \leftarrow$$

(b) A solution to the above equation is readily obtained by recognizing that it is of exactly the same form as the energy equation for an extended surface of uniform cross section. Hence for boundary conditions of the form

$$C_A(0) = C_{A,0}, \quad -D_{AB} (dC_A / dx)_{x=L} = k_1'' C_A(L)$$

the solution must be analogous to that obtained for a fin with a convection tip condition. With the analogous quantities

$$C_A \leftrightarrow \theta \equiv T - T_\infty, \quad m \equiv (4k_1'' / DD_{AB})^{1/2} \leftrightarrow (4h / Dk)^{1/2}$$

$$D_{AB} \leftrightarrow k, \quad k_1'' \leftrightarrow h$$

the solution is, by analogy to Eq. 3.75

$$C_A(x) = \frac{\cosh m(L-x) + (k_1'' / mD_{AB}) \sinh m(L-x)}{\cosh mL + (k_1'' / mD_{AB}) \sinh mL}. \quad \leftarrow$$

**COMMENTS:** The total pore reaction rate is  $-D_{AB}(\pi D^2/4) (dC_A/dx)_{x=0}$ , which can be inferred by applying the analogy to Eq. 3.76.

## PROBLEM 14.32

**KNOWN:** Pressure, temperature and mole fraction of CO in auto exhaust. Diffusion coefficient for CO in gas mixture. Film thickness and reaction rate coefficient for catalytic surface.

**FIND:** (a) Mole fraction of CO at catalytic surface and CO removal rate, (b) Effect of reaction rate coefficient on removal rate.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, (2) One-dimensional species diffusion in film, (3) Negligible effect of advection in film (stationary medium), (4) Constant total molar concentration and diffusion coefficient in film.

**ANALYSIS:** From Eq. (14.69) the surface molar concentration is

$$x_A(0) = \frac{x_{A,L}}{1 + (Lk_1''/D_{AB})} = \frac{0.0012}{1 + (0.01\text{m} \times 0.005 \text{ m/s} / 10^{-4} \text{ m}^2/\text{s})} = 0.0008 \quad <$$

With  $C = p/\mathcal{R}T = 1.2 \text{ bar} / (8.314 \times 10^{-2} \text{ m}^3 \cdot \text{bar}/\text{kmol} \cdot \text{K} \times 773 \text{ K}) = 0.0187 \text{ kmol}/\text{m}^3$ , Eq. (14.70) yields a CO molar flux, and hence a CO removal rate, of

$$N_{A,s}'' = -N_A''(0) = \frac{k_1'' C x_{A,L}}{1 + (Lk_1''/D_{AB})}$$

$$N_{A,s}'' = \frac{0.005 \text{ m/s} \times 0.0187 \text{ kmol}/\text{m}^3 \times 0.0012}{1 + (0.01\text{m} \times 0.005 \text{ m/s} / 10^{-4} \text{ m}^2/\text{s})} = 7.48 \times 10^{-8} \text{ kmol}/\text{s} \cdot \text{m}^2 \quad <$$

If the process is diffusion limited,  $Lk_1''/D_{AB} \gg 1$  and

$$N_{A,s}'' = \frac{C D_{AB} x_{A,L}}{L} = \frac{0.0187 \text{ kmol}/\text{m}^3 \times 10^{-4} \text{ m}^2/\text{s} \times 0.0012}{0.01\text{m}} = 2.24 \times 10^{-7} \text{ kmol}/\text{s} \cdot \text{m}^2 \quad <$$

**COMMENTS:** If the process is reaction limited,  $N_{A,s}'' \rightarrow 0$  as  $k_1'' \rightarrow 0$ .

### PROBLEM 14.33

**KNOWN:** Mass flow rate of gas containing palladium (species A), which flows through a tube and deposits into pores of tube wall. Inlet mass concentration of palladium. Mass transfer coefficient between gas and tube surface. Deposition rate is proportional to mass concentration of palladium at tube surface.

**FIND:** (a) Expression for variation of mean species density of palladium with  $x$ . Expression for local deposition rate for tube of diameter  $D$ . (b) Ratio of deposition rates at  $x = L$  and  $x = 0$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady state, (2) Constant properties, (3) Constant mass flow rate, (4) Negligible leakage of gas through porous walls.

**ANALYSIS:** (a) Section 8.9 develops the variation of mean species density,  $\rho_{A,m}$ , for the case in which the surface species concentration,  $\rho_{A,s}$ , is uniform. Here, however, the surface concentration will vary as the mean species density decreases with  $x$ . Under steady-state conditions, the mass flux of palladium reaching the surface must equal the mass flux of palladium depositing into the pores. Referring to Equation 8.82, where  $n''_{A,s}$  is the mass flux *from* the surface,

$$n''_{A,s} = h_m(\rho_{A,s} - \rho_{A,m}) = -k_1 \rho_{A,s}$$

Solving for the surface concentration yields  $\rho_{A,s} = h_m \rho_{A,m} / (h_m + k_1)$ . Then substituting this into either expression for  $n''_{A,s}$  yields

$$n''_{A,s} = -U_m \rho_{A,m}, \quad U_m^{-1} = 1/h_m + 1/k_1$$

Comparing this result with Equation 8.82, we see that they are analogous if we replace  $h_m$  with  $U_m$  and  $\rho_{A,s}$  with 0. Applying the same analogy to Equation 8.86, the distribution of the mean species density is

$$\frac{\rho_{A,m}(x)}{\rho_{A,m,i}} = \exp\left(-\frac{U_m \rho P}{\dot{m}} x\right) \quad (1) \quad <$$

where  $P$  is the perimeter,  $P = \pi D$ . Note that we could have found this same result by expressing mass species conservation for species A. Noting that the rate at which species A is carried downstream by the flow is  $\dot{m} \rho_{A,m} / \rho$ , and assuming  $\rho$  to be constant, we have

Continued...

**PROBLEM 14.33 (Cont.)**

$$\frac{\dot{m}}{\rho} \frac{d\rho_{A,m}}{dx} = n''_{A,s} P = -U_m P \rho_{A,m}$$

Integrating with respect to  $x$  and applying the inlet condition yields the same result as Equation (1).

The local deposition rate is

$$-n''_{A,s} = U_m \rho_{A,m} = U_m \rho_{A,m,i} \exp\left(-\frac{U_m P}{\dot{m}} x\right) = U_m \rho_{A,m,i} \exp\left(-B \frac{x}{L}\right) \quad (2) \quad <$$

where  $B = U_m P L / \dot{m}$ .

(b) The ratio of deposition rates at  $x = L$  and  $x = 0$  is

$$\text{ratio of deposition rates} = \exp(-B) \quad <$$

**COMMENT:** From Eq. (2), the deposition rate decreases exponentially with distance  $x$ . Therefore, as the tube length increases, the deposit thickness at the outlet end will become thinner, and the variation in deposit thickness between the inlet and outlet will increase.

### PROBLEM 14.34

**KNOWN:** Radius of a spherical organism and molar concentration of oxygen at surface. Diffusion and reaction rate coefficients.

**FIND:** (a) Radial distribution of O<sub>2</sub> concentration, (b) Rate of O<sub>2</sub> consumption, (c) Molar concentration at r = 0.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, one-dimensional diffusion, (2) Stationary medium, (3) Uniform total molar concentration, (4) Constant properties ( $k_0$ ,  $D_{AB}$ ).

**ANALYSIS:** (a) For the prescribed conditions and assumptions, Eq. (14.50) reduces to

$$\frac{D_{AB}}{r^2} \frac{d}{dr} \left( r^2 \frac{dC_A}{dr} \right) - k_0 = 0$$

$$r^2 \frac{dC_A}{dr} = \frac{k_0 r^3}{3D_{AB}} + C_1$$

$$C_A = \frac{k_0 r^2}{6D_{AB}} - \frac{C_1}{r} + C_2$$

With the requirement that  $C_A(r)$  remain finite at  $r = 0$ ,  $C_1 = 0$ . With  $C_A(r_o) = C_{A,o}$

$$C_2 = C_{A,o} - \frac{k_0 r_o^2}{6D_{AB}}$$

$$C_A = C_{A,o} - (k_0 / 6D_{AB}) (r_o^2 - r^2) \quad <$$

Because  $C_A$  cannot be less than zero at any location within the organism, the right-hand side of the foregoing equation must always exceed zero, thereby placing limits on the value of  $C_{A,o}$ . The smallest possible value of  $C_{A,o}$  is determined from the requirement that  $C_A(0) \geq 0$ , in which case

$$C_{A,o} \geq (k_0 r_o^2 / 6D_{AB}) \quad <$$

(b) Since oxygen consumption occurs at a uniform volumetric rate of  $k_0$ , the total respiration rate is  $\dot{R} = \forall k_0$ , or

$$\dot{R} = (4/3) \pi r_o^3 k_0 \quad <$$

Continued ...

### PROBLEM 14.34 (Cont.)

(c) With  $r = 0$ ,

$$C_A(0) = C_{A,o} - k_0 r_0^2 / 6D_{AB}$$

$$C_A(0) = 5 \times 10^{-5} \text{ kmol/m}^3 - 1.2 \times 10^{-4} \text{ kmol/s} \cdot \text{m}^3 \left(10^{-4} \text{ m}\right)^2 / 6 \times 10^{-8} \text{ m}^2/\text{s}$$

$$C_A(0) = 3 \times 10^{-5} \text{ kmol/m}^3 \quad <$$

**COMMENTS:** (1) The minimum value of  $C_{A,o}$  for which a physically realistic solution is possible is  $C_{A,o} = k_0 r_0^2 / 6D_{AB} = 2 \times 10^{-5} \text{ kmol/m}^3$ .

(2) The total respiration rate may also be obtained by applying Fick's law at  $r = r_0$ , in which case  $\dot{R} = -N_A(r_0) = +D_{AB} \left(4\pi r_0^2\right) dC_A/dr|_{r=r_0} = D_{AB} \left(4\pi r_0^2\right) (k_0 / 6D_{AB}) 2r_0 = (4/3)\pi r_0^3 k_0$ .  
The result agrees with that of part (b).

### PROBLEM 14.35

**KNOWN:** Radius of a spherical organism and molar concentration of oxygen at its surface. Diffusion and reaction rate coefficients.

**FIND:** (a) Radial distribution of O<sub>2</sub> concentration, (b) Expression for rate of O<sub>2</sub> consumption, (c) Molar concentration at r = 0 and rate of oxygen consumption for prescribed conditions.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, one-dimensional diffusion, (2) Stationary medium, (3) Uniform total molar concentration, (4) Constant properties ( $k_1$ ,  $D_{AB}$ ).

**ANALYSIS:** (a) For the prescribed conditions and assumptions, Eq. (14.50) reduces to

$$\frac{1}{r^2} \frac{d}{dr} \left( D_{AB} r^2 \frac{dC_A}{dr} \right) - k_1 C_A = 0$$

With  $y \equiv r C_A$ ,  $dC_A/dr = (1/r) dy/dr - y/r^2$  and

$$\frac{1}{r^2} \frac{d}{dr} \left( D_{AB} r^2 \frac{dC_A}{dr} \right) = \frac{D_{AB}}{r^2} \frac{d}{dr} \left( r \frac{dy}{dr} - y \right) = \frac{D_{AB}}{r^2} \left( r \frac{d^2y}{dr^2} \right)$$

The species equation is then

$$\frac{d^2y}{dr^2} - \frac{k_1}{D_{AB}} y = 0$$

The general solution is of the form

$$y = C_1 \sinh(k_1/D_{AB})^{1/2} r + C_2 \cosh(k_1/D_{AB})^{1/2} r$$

or

$$C_A = \frac{C_1}{r} \sinh(k_1/D_{AB})^{1/2} r + \frac{C_2}{r} \cosh(k_1/D_{AB})^{1/2} r$$

Because  $C_A$  must remain finite at  $r = 0$ ,  $C_2 = 0$ . Hence, with  $C_A(r_o) = C_{A,o}$ ,

$$C_1 = \frac{C_{A,o} r_o}{\sinh(k_1/D_{AB})^{1/2} r_o}$$

and

Continued ...

**PROBLEM 14.35 (Cont.)**

$$C_A = C_{A,o} \left( \frac{r_0}{r} \right) \frac{\sinh(k_1/D_{AB})^{1/2} r}{\sinh(k_1/D_{AB})^{1/2} r_0} \quad <$$

(b) The total O<sub>2</sub> consumption rate corresponds to the rate of diffusion at the surface of the organism.

$$\dot{R} = -N_A(r_0) = +D_{AB} \left( 4\pi r_0^2 \right) dC_A / dr \Big|_{r_0}$$

$$\dot{R} = 4\pi r_0^2 D_{AB} C_{A,o} r_0 \left[ -\frac{1}{r_0^2} + \frac{1}{r_0} (k_1/D_{AB})^{1/2} \cot(k_1/D_{AB})^{1/2} r_0 \right]$$

$$\dot{R} = 4\pi r_0 D_{AB} C_{A,o} (\alpha \coth \alpha - 1) \quad <$$

where  $\alpha \equiv \left( k_1 r_0^2 / D_{AB} \right)^{1/2}$ .

(c) For the prescribed conditions,  $(k_1/D_{AB})^{1/2} = (20 \text{ s}^{-1} \div 10^{-8} \text{ m}^2/\text{s})^{1/2} = 44,720 \text{ m}^{-1}$  and  $\alpha = 4.472$ .

$$C_A = \frac{5 \times 10^{-5} \text{ kmol/m}^3 \times 10^{-4} \text{ m}}{\sinh(4.472)} \times \frac{\sinh(k_1/D_{AB})^{1/2} r}{r} = 1.136 \times 10^{-10} \frac{\text{kmol}}{\text{m}^3} \times \frac{\sinh(k_1/D_{AB})^{1/2} r}{r}$$

In the limit of  $r \rightarrow 0$ , the foregoing expression yields

$$C_A(r \rightarrow 0) = 5.11 \times 10^{-6} \text{ kmol/m}^3 \quad <$$

$$\begin{aligned} \dot{R} &= 4\pi \times 10^{-4} \text{ m} \times 10^{-8} \text{ m}^2/\text{s} \times 5 \times 10^{-5} \text{ kmol/m}^3 (4.472 \coth 4.472 - 1) \\ &= 2.18 \times 10^{-15} \text{ kmol/s} \end{aligned}$$

**COMMENTS:** The total respiration rate may also be obtained by integrating the volumetric rate of consumption over the volume of the organism. That is,  $\dot{R} = -\int \dot{N}_A dV = \int_0^{r_0} k_1 C_A(r) 4\pi r^2 dr$ .

### PROBLEM 14.36

**KNOWN:** Combustion at constant temperature and pressure of a hydrogen-oxygen mixture adjacent to a metal wall according to the reaction  $2\text{H}_2 + \text{O}_2 \rightarrow 2\text{H}_2\text{O}$ . Molar concentrations of hydrogen, oxygen, and water vapor are  $0.10$ ,  $0.10$  and  $0.20 \text{ kmol/m}^3$ , respectively. Generation rate of water vapor is  $0.96 \times 10^{-2} \text{ kmol/m}^3 \cdot \text{s}$ .

**FIND:** (a) Expression for  $C_{\text{H}_2}$  as function of distance from wall, plot qualitatively, (b)  $C_{\text{H}_2}$  at the wall, (c) Sketch also curves for  $C_{\text{O}_2}(x)$  and  $C_{\text{H}_2\text{O}}(x)$ , and (d) Molar flux of water at  $x = 10 \text{ mm}$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) One-dimensional diffusion, (3) Stationary medium, (4) Constant properties including pressure and temperature.

**PROPERTIES:** Species binary diffusion coefficient (given, for  $\text{H}_2$ ,  $\text{O}_2$  and  $\text{H}_2\text{O}$ ):  $D_{\text{AB}} = 0.6 \times 10^{-5} \text{ m}^2/\text{s}$ .

**ANALYSIS:** (a) The species conservation equation, Eq. 14.48b, and its general solution are

$$\frac{d^2 C_A}{dx^2} + \frac{\dot{N}_A}{D_{\text{AB}}} = 0 \quad C_A(x) = -\frac{\dot{N}_A}{2D_{\text{AB}}} x^2 + C_1 x + C_2. \quad (1,2)$$

The boundary condition at the wall must be  $dC_A(0)/dx = 0$ , such that  $C_1 = 0$ . For the species hydrogen, evaluate  $C_2$  from knowledge of  $C_{\text{H}_2}(10 \text{ mm}) = 0.10 \text{ kmol/m}^3$  and  $\dot{N}_{\text{H}_2} = -\dot{N}_{\text{H}_2\text{O}}$ , according to the chemical reaction. Hence,

$$0.10 \text{ kmol/m}^3 = -\frac{(-0.96 \times 10^{-2} \text{ kmol/m}^3 \cdot \text{s})}{2 \times 0.6 \times 10^{-5} \text{ m}^2/\text{s}} (0.010 \text{ m})^2 + 0 + C_2$$

$$C_2 = 0.02 \text{ kmol/m}^3.$$

Hence, the hydrogen species concentration distribution is

$$C_{\text{H}_2}(x) = -\frac{\dot{N}_{\text{H}_2}}{2D_{\text{AB}}} x^2 + 0.02 = 800x^2 + 0.02 \quad <$$

which is parabolic with zero slope at the wall; see sketch above.

(b) The value of  $C_{\text{H}_2}$  at the wall is,

$$C_{\text{H}_2}(0) = (0 + 0.02) \text{ kmol/m}^3 = 0.02 \text{ kmol/m}^3. \quad <$$

Continued ...

**PROBLEM 14.36 (Cont.)**

(c) The concentration distribution for water vapor species will be of the same form,

$$C_{\text{H}_2\text{O}}(x) = -\frac{\dot{N}_{\text{H}_2\text{O}}}{2D_{\text{AB}}}x^2 + C_1x + C_2 \quad (3)$$

With  $C_1 = 0$  for the wall condition, find  $C_2$  from  $C_{\text{H}_2\text{O}}(10 \text{ mm})$ ,

$$0.20 \text{ kmol/m}^3 = -\frac{(0.96 \times 10^{-2} \text{ kmol/m}^3)}{2 \times 0.6 \times 10^{-5} \text{ m}^2/\text{s}}(0.010 \text{ m})^2 + C_2 \quad C_2 = 0.28 \text{ kmol/m}^3.$$

Hence,  $C_{\text{H}_2\text{O}}$  at the wall is,

$$C_{\text{H}_2\text{O}}(0) = 0 + 0 + C_2 = 0.28 \text{ kmol/m}^3$$

and its distribution appears as above. Recognizing that  $\dot{N}_{\text{O}_2} = -0.5\dot{N}_{\text{H}_2\text{O}}$ , by the same analysis, find

$$C_{\text{O}_2}(0) = 0.06 \text{ kmol/m}^3$$

and its shape, also parabolic with zero slope at the wall is shown above.

(d) The molar flux of water vapor at  $x = 10 \text{ mm}$  is given by Fick's law

$$N''_{\text{H}_2\text{O},x} = -D_{\text{AB}} \frac{dC_{\text{H}_2\text{O}}}{dx}$$

and using the concentration distribution of Eq. (3), find

$$N''_{\text{H}_2\text{O},x} = -D_{\text{AB}} \frac{d}{dx} \left( -\frac{\dot{N}_{\text{H}_2\text{O}}}{2D_{\text{AB}}}x^2 \right) = +\dot{N}_{\text{H}_2\text{O}}x$$

and evaluation at the location  $x = 10 \text{ mm}$ , the species flux is

$$N''_{\text{H}_2\text{O},x}(10 \text{ mm}) = +(0.96 \times 10^{-2} \text{ kmol/m}^3 \cdot \text{s}) \times 0.010 \text{ m} = 9.60 \times 10^{-5} \text{ kmol/m}^2 \cdot \text{s} \quad <$$

**COMMENTS:** Note that the generation rate of water vapor is a positive quantity. Whereas for  $\text{H}_2$  and  $\text{O}_2$ , species are consumed and hence  $\dot{N}_{\text{H}_2}$  and  $\dot{N}_{\text{O}_2}$  are negative. According to the chemical reaction one mole of  $\text{H}_2$  and 0.5 mole of  $\text{O}_2$  are consumed to generate one mole of  $\text{H}_2\text{O}$ . Therefore,  $\dot{N}_{\text{H}_2} = -\dot{N}_{\text{H}_2\text{O}}$  and  $\dot{N}_{\text{O}_2} = -0.5 \dot{N}_{\text{H}_2\text{O}}$ .

### PROBLEM 14.37

**KNOWN:** Molar concentrations of oxygen at inner and outer surfaces of lung tissue. Volumetric rate of oxygen consumption within the tissue.

**FIND:** (a) Variation of oxygen molar concentration with position in the tissue, (b) Rate of oxygen transfer to the blood per unit tissue surface area.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) One-dimensional species transfer by diffusion through a plane wall, (3) Homogeneous, stationary medium with uniform total molar concentration and constant diffusion coefficient.

**ANALYSIS:** (a) From Eq. 14.71 the appropriate form of the species diffusion equation is

$$D_{AB} \frac{d^2 C_A}{dx^2} - k_o = 0.$$

Integrating,

$$dC_A / dx = (k_o / D_{AB})x + C_1 \quad C_A = \frac{k_o}{2D_{AB}}x^2 + C_1x + C_2.$$

With  $C_A = C_A(0)$  at  $x = 0$  and  $C_A = C_A(L)$  at  $x = L$ ,

$$C_2 = C_A(0) \quad C_1 = \frac{C_A(L) - C_A(0)}{L} - \frac{k_o L}{2D_{AB}}.$$

Hence

$$C_A(x) = \frac{k_o}{2D_{AB}}x(x-L) + [C_A(L) - C_A(0)]\frac{x}{L} + C_A(0). \quad <$$

(b) The oxygen assimilation rate per unit area is

$$N''_{A,x}(L) = -D_{AB} \left( \frac{dC_A}{dx} \right)_{x=L}$$

$$N''_{A,x}(L) = -D_{AB} \left( \frac{k_o L}{D_{AB}} - \frac{k_o L}{2D_{AB}} \right) - \frac{D_{AB}}{L} [C_A(L) - C_A(0)]$$

$$N''_{A,x} = -\frac{k_o L}{2} + \frac{D_{AB}}{L} [C_A(0) - C_A(L)]. \quad <$$

**COMMENTS:** The above model provides a highly approximate and simplified treatment of a complicated problem. The lung tissue is actually heterogeneous and conditions are transient.

### PROBLEM 14.38

**KNOWN:** Ground level flux of  $\text{NO}_2$  in a stagnant urban atmosphere.

**FIND:** (a) Vertical distribution of  $\text{NO}_2$  molar concentration, (b) Critical ground level flux of  $\text{NO}_2$ ,  $N''_{A,0,\text{crit}}$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) One-dimensional diffusion in a stationary medium, (3) Total molar concentration  $C$  is uniform, (4) Perfect gas behavior.

**ANALYSIS:** (a) For the prescribed conditions the molar concentration of  $\text{NO}_2$  is given by Eq. 14.73, subject to the following boundary conditions.

$$C_A(\infty) = 0, \quad \left. \frac{dC_A}{dx} \right|_{x=0} = -\frac{N''_{A,0}}{D_{AB}}.$$

From the first condition,  $C_1 = 0$ . From the second condition,

$$-mC_2 = -N''_{A,0}/D_{AB}.$$

Hence

$$C_A(x) = \frac{N''_{A,0}}{mD_{AB}} e^{-mx} \quad <$$

where  $m = (k_1/D_{AB})^{1/2}$ .

(b) At ground level,  $C_A(0) = \frac{N''_{A,0}}{mD_{AB}}$ . Hence, from the perfect gas law,

$$P_A(0) = C_A(0) \mathcal{R}T = \frac{\mathcal{R}T N''_{A,0}}{mD_{AB}}.$$

Hence, with  $m = (0.03/0.15 \times 10^{-4})^{1/2} \text{ m}^{-1} = 44.7 \text{ m}^{-1}$ .

$$N''_{A,0,\text{crit}} = \frac{mD_{AB}P_A(0)_{\text{crit}}}{\mathcal{R}T} = \frac{44.7 \text{ m}^{-1} \times 0.15 \times 10^{-4} \text{ m}^2/\text{s} \times 2 \times 10^{-6} \text{ bar}}{8.314 \times 10^{-2} \text{ m}^3 \cdot \text{bar}/\text{kmol} \cdot \text{K} \times 300 \text{ K}}$$

$$N''_{A,0,\text{crit}} = 5.38 \times 10^{-11} \text{ kmol}/\text{s} \cdot \text{m}^2. \quad <$$

**COMMENTS:** Because the dispersion of pollutants in the atmosphere is governed strongly by convection effects, the above model should be viewed as a first approximation which describes a worst case condition.

### PROBLEM 14.39

**KNOWN:** Ground level flux of NO<sub>2</sub> in a stagnant urban atmosphere.

**FIND:** (a) Governing differential equation and boundary conditions for the molar concentration of NO<sub>2</sub>, (b) Concentration of NO<sub>2</sub> at ground level three hours after the beginning of emissions.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) One-dimensional diffusion in a stationary medium, (2) Uniform total molar concentration, (3) Constant properties.

**ANALYSIS:** (a) Applying the species conservation requirement, Eq. 14.43, on a molar basis to a unit area of the control volume,

$$N''_{A,x} - (k_1 C_A) dx - N''_{A,x+dx} = \frac{\partial C_A}{\partial t} dx.$$

With  $N''_{A,x+dx} = N''_{A,x} + (\partial N''_{A,x} / \partial x) dx$  and  $N''_{A,x} = -D_{AB} (\partial C_A / \partial x)$ , it follows that

$$D_{AB} \frac{\partial^2 C_A}{\partial x^2} - k_1 C_A = \frac{\partial C_A}{\partial t}. \quad <$$

Initial Condition:  $C_A(x, 0) = 0. \quad <$

Boundary Conditions:  $-D_{AB} \left. \frac{\partial C_A}{\partial x} \right|_{x=0} = N''_{A,0}, \quad C_A(\infty, t) = 0. \quad <$

(b) The present problem is analogous to Case (2) of Fig. 5.7 for heat conduction in a semi-infinite medium. Hence by analogy to Eq. 5.62, with  $k \leftrightarrow D_{AB}$  and  $\alpha \leftrightarrow D_{AB}$ ,

$$C_A(x, t) = 2N''_{A,0} \left( \frac{t}{\pi D_{AB}} \right)^{1/2} \exp\left(-\frac{x^2}{4D_{AB}t}\right) - \frac{N''_{A,0} x}{D_{AB}} \operatorname{erfc}\left(\frac{x}{2(D_{AB}t)^{1/2}}\right)$$

At ground level ( $x = 0$ ) and 3h,

$$C_A(0, 3h) = 2N''_{A,0} \left( \frac{t}{\pi D_{AB}} \right)^{1/2}$$

$$C_A(0, 3h) = 2 \left( 3 \times 10^{-11} \text{ kmol/s} \cdot \text{m}^2 \right) \left( 10,800 \text{ s} / \pi \times 0.15 \times 10^{-4} \text{ m}^2 / \text{s} \right)^{1/2} = 9.08 \times 10^{-7} \text{ kmol/m}^3. \quad <$$

**COMMENTS:** The concentration decays rapidly to zero with increasing  $x$ , and at  $x = 100$  m it is, for all practical purposes, equal to zero.

### PROBLEM 14.40

**KNOWN:** Initial concentration of hydrogen in a sheet of prescribed thickness. Surface concentrations for time  $t > 0$ .

**FIND:** Time required for density of hydrogen to reach prescribed value at midplane of sheet.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) One-dimensional diffusion in  $x$ , (2) Constant  $D_{AB}$ , (3) No internal chemical reactions, (4) Uniform total molar concentration, (5) Stationary medium.

**ANALYSIS:** The mass transfer Biot number is  $Bi_m = h_m L / D_{AB} \rightarrow \infty$ . Hence,  $Bi_m^{-1} = 0$ . By analogy to Equation 5.44, the approximate solution, it follows that

$$\gamma_o^* \approx C_1 \exp\left(-\zeta_1^2 Fo_m\right) = \frac{C_A - C_{A,s}}{C_{A,i} - C_{A,s}} = \frac{0.6 - 0.0}{3.0 - 0.0} = 0.2$$

Using values of  $\zeta_1 = 1.57$  and  $C_1 = 1.27$  from Table 5.1, it follows that

$$1.27 \exp\left[-(1.57)^2 Fo_m\right] = 0.2$$

from which

$$Fo_m = 0.75$$

Hence,  $t_f = 0.75(0.02\text{m})^2 / 9 \times 10^{-7} \text{ m}^2/\text{s} = 333 \text{ s}$

<

**COMMENT:**  $Fo_m > 0.2$ . Hence, the approximate, one-term solution is valid.

### PROBLEM 14.41

**KNOWN:** Radius and temperature of air bubble in water.

**FIND:** Time to reach 99% of saturated vapor concentration at center.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) One-dimensional radial diffusion of vapor in air, (2) Constant properties, (3) Air is initially dry, (4) Stationary medium.

**PROPERTIES:** Table A-8, Water vapor-air (300 K):  $D_{AB} = 0.26 \times 10^{-4} \text{ m}^2/\text{s}$ .

**ANALYSIS:** If the one-term approximation to the infinite series solution (Eq. 5.53),

$$\theta_0^* = C_1 \exp(-\zeta_1^2 \text{Fo})$$

is used, it follows that,

$$\gamma_o^* \approx C_1 \exp(-\zeta_1^2 \text{Fo}_m) = \frac{C_A - C_{A,s}}{C_{A,i} - C_{A,s}} = \frac{0.99 - 1}{0.0 - 1} = 0.01.$$

Using values of  $C_1 = 2.0$  and  $\zeta_1 = 3.1415$  for  $\text{Bi}_m \rightarrow \infty$ , it follows that

$$0.01 = 2.0 \exp\left[-(3.1415)^2 \text{Fo}_m\right] \quad \text{or} \quad \text{Fo}_m = 0.54$$

Hence,  $t = \text{Fo}_m D^2 / D_{AB} = 0.54(0.001\text{m})^2 / 0.26 \times 10^{-4} \text{ m}^2/\text{s} = 0.02 \text{ s}$

<

**COMMENT:** Since  $\text{Fo} > 0.2$ , the approximate solution is valid.

## PROBLEM 14.42

**KNOWN:** Radius and temperature of air bubble.

**FIND:** (a) Time to reach 95% of the maximum average water vapor concentration, (b) Time to reach 50% of the maximum average water vapor concentration.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) One-dimensional radial diffusion of vapor in air, (2) Constant properties, (3) Air is initially dry, (4) Stationary medium.

**PROPERTIES:** Table A.8, Water vapor-air (300 K):  $D_{AB} = 0.26 \times 10^{-4} \text{ m}^2/\text{s}$ .

**ANALYSIS:** (a) We may employ the one-term approximation to the infinite series solution (Eq. 5.55)

$$\frac{Q}{Q_o} = 1 - \frac{3\theta_o^*}{\zeta_1^3} [\sin(\zeta_1) - \zeta_1 \cos(\zeta_1)] \quad ; \quad \theta_o^* = C_1 \exp(-\zeta_1^2 Fo)$$

By analogy, the preceding equations may be written as

$$\frac{\bar{C}_A}{\bar{C}_{A,\max}} = 1 - \frac{3\gamma_o^*}{\zeta_1^3} [\sin(\zeta_1) - \zeta_1 \cos(\zeta_1)] \quad ; \quad \gamma_o^* = \frac{C_A - C_{A,s}}{C_{A,i} - C_{A,s}} = C_1 \exp(-\zeta_1^2 Fo_m)$$

Using values of  $C_1 = 2.000$  and  $\zeta_1 = 3.1415$  from Table 5.1 for  $Bi_m \rightarrow \infty$ , it follows that

$$\frac{\bar{C}_A}{\bar{C}_{A,\max}} = 0.95 = 1 - \frac{3\gamma_o^*}{3.1415^3} [\sin(3.1415) - 3.1415 \cos(3.1415)] \quad ;$$

$$\gamma_o^* = \frac{C_A - C_{A,s}}{C_{A,i} - C_{A,s}} = 2.0 \exp(-3.1415^2 Fo_m)$$

Solving the two equations yields  $\gamma_o^* = 0.1645$ ,  $Fo_m = 0.2531$ . Since  $Fo_m > 0.2$ , the approximate solution is valid. Hence,

$$t = Fo_m r_o^2 / D_{AB} = 0.2531(0.001\text{m})^2 / 0.26 \times 10^{-4} \text{ m}^2 / \text{s} = 9.7 \times 10^{-3} \text{ s} = 9.7 \text{ ms} \quad <$$

(b) The time associated with an average water vapor concentration of 50% is expected to be significantly shorter than in part (a). Hence,  $Fo_m$  may be less than 0.2 and the one-term approximation to the exact solution may not be valid. Therefore, we employ the approximate solution of Section 5.8 and apply the analogy between heat and mass transfer.

Continued...

### PROBLEM 14.42 (Cont.)

From Table 5.2a for  $Fo < 0.2$ ,

$$q_s^* = \frac{q_s'' r_o}{k(T_s - T_i)} = \frac{1}{\sqrt{\pi Fo}} - 1 \quad ; \quad Fo = \frac{\alpha t}{r_o^2}$$

Substituting the expression for  $Fo$  into the first equation yields

$$q_s'' = \frac{k(T_s - T_i)}{r_o} \left[ \frac{r_o}{\sqrt{\pi \alpha}} t^{-1/2} - 1 \right]$$

We desire an expression for  $Q/Q_o$ . Hence,

$$\frac{Q}{Q_o} = \frac{4\pi r_o^2 \int_{t=0}^t q_s'' dt}{(4/3)\pi r_o^3 \rho c (T_s - T_i)} = \frac{3\alpha}{r_o^2} \int_{t=0}^t \left( \frac{r_o}{\sqrt{\pi \alpha}} t^{-1/2} - 1 \right) dt$$

or

$$\begin{aligned} \frac{Q}{Q_o} &= \frac{3\alpha}{r_o^2} \left[ \frac{2r_o}{\sqrt{\pi \alpha}} t^{1/2} - t \right] \\ &= 3 \left[ \frac{2}{\sqrt{\pi}} \sqrt{Fo} - Fo \right] \end{aligned}$$

Applying the analogy between heat and mass transfer,

$$\frac{\bar{C}_A}{\bar{C}_{A,\max}} = 0.50 = 3 \left[ \frac{2}{\sqrt{\pi}} \sqrt{Fo_m} - Fo_m \right]$$

from which  $Fo_m = 0.0305$ . Hence,

$$t = Fo_m r_o^2 / D_{AB} = 0.0305 (0.001 \text{ m})^2 / 0.26 \times 10^{-4} \text{ m}^2 / \text{s} = 1.17 \times 10^{-3} \text{ s} = 1.17 \text{ ms} \quad <$$

**COMMENTS:** (1) Use of the approximate solution of Section 5.8 is not valid for part (a) since its use yields  $Fo_m = 0.366$ , which does not satisfy the criterion  $Fo_m < 0.2$ . (2) Use of the one-term approximation to the exact solution for part (b) yields a mass transfer Fourier number of  $Fo_m = 0.0198$ , which does not satisfy the criterion  $Fo_m > 0.2$ .

### PROBLEM 14.43

**KNOWN:** Initial carbon content and prescribed surface content for heated steel.

**FIND:** Time required for carbon mole fraction to reach 0.01 at a distance of 1 mm from the surface.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steel may be approximated as a semi-infinite medium, (2) One-dimensional diffusion in  $x$ , (3) Isothermal conditions, (4) No internal chemical reactions, (5) Uniform total molar concentration, (6) Stationary medium.

**ANALYSIS:** Conditions within the steel are governed by the species diffusion equation of the form

$$\frac{\partial^2 C_A}{\partial x^2} = \frac{1}{D_{AB}} \frac{\partial C_A}{\partial t}$$

or, in molar form,

$$\frac{\partial^2 x_A}{\partial x^2} = \frac{1}{D_{AB}} \frac{\partial x_A}{\partial t}$$

The initial and boundary conditions are of the form

$$x_A(x, 0) = 0.001$$

$$x_A(0, t) = x_{A,s} = 0.02 \quad x_A(\infty, t) = 0.001.$$

The problem is analogous to that of heat transfer in a semi-infinite medium with constant surface temperature, and by analogy to Eq. 5.60, the solution is

$$\frac{x_A(x, t) - x_{A,s}}{x_{A,i} - x_{A,s}} = \operatorname{erf}\left(\frac{x}{2(D_{AB}t)^{1/2}}\right)$$

where

$$D_{AB} = 2 \times 10^{-5} \exp[-17,000/1273] = 3.17 \times 10^{-11} \text{ m}^2/\text{s}.$$

Hence

$$\frac{0.01 - 0.02}{0.001 - 0.02} = 0.526 = \operatorname{erf}\left(\frac{0.001 \text{ m}}{2(3.17 \times 10^{-11} t)^{1/2}}\right)$$

where  $\operatorname{erf} w = 0.526 \rightarrow w \approx 0.51$ ,

$$0.51 = 0.001/2(3.17 \times 10^{-11} t)^{1/2} \quad \text{or} \quad t = 30,321 \text{ s} = 8.42 \text{ h. } <$$

## PROBLEM 14.44

**KNOWN:** Thick plate of pure iron at 1000°C subjected to a carburizing process with sudden exposure to a carbon concentration  $C_{C,s}$  at the surface.

**FIND:** (a) Consider the heat transfer analog to the carburization process; sketch the mass and heat transfer systems; explain correspondence between variables; provide analytical solutions to the mass and heat transfer situation; (b) Determine the carbon concentration ratio,  $C_C(x, t)/C_{C,s}$ , at a depth of 1 mm after 1 hour of carburization; and (c) From the analogy, show that the time dependence of the mass flux of carbon into the plate can be expressed as  $n_C'' = \rho_{C,s} (D_{C-Fe} / \pi t)^{1/2}$ ; also, obtain an expression for the mass of carbon per unit area entering the iron plate over the time period  $t$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) One-dimensional transient diffusion, (2) Thick plate approximates a semi-infinite medium for the transient mass and heat transfer processes, and (3) Constant properties, (4) Stationary medium.

**ANALYSIS:** (a) The analogy between the carburizing mass transfer process in the plate and the heat transfer process is illustrated in the schematic above. The basis for the mass - heat transfer analogy stems from the similarity of the conservation of species and energy equations (Eqs. 14.77 and 5.29, respectively), the general solution to the equations, and their initial and boundary conditions. For both processes, the plate is a semi-infinite medium with initial distributions,  $C_C(x, t \leq 0) = C_{C,i} = 0$  and  $T(x, t \leq 0) = T_i$ , suddenly subjected to a surface potential,  $C_C(0, t > 0) = C_{C,s}$  and  $T(0, t > 0) = T_s$ . The heat transfer situation corresponds to Case 1, Figure 5.7, from which the following relations were obtained.

**Heat transfer**  
Distributions

$$\frac{T(x, t) - T_s}{T_i - T_s} = \operatorname{erf}\left(\frac{x}{2\sqrt{\alpha t}}\right)$$

**Mass transfer**

$$\frac{C_c(x, t) - C_{c,s}}{0 - C_{c,s}} = \operatorname{erf}\left(\frac{x}{2\sqrt{D_{C-Fe}t}}\right)$$

or

$$\frac{C_c(x, t)}{C_{c,s}} = \operatorname{erfc}\left(\frac{x}{2\sqrt{D_{C-Fe}t}}\right)$$

Fluxes

$$q_s''(t) = \frac{k(T_s - T_i)}{\sqrt{\pi \alpha t}}$$

$$n_{C,s}''(t) = \frac{D_{C-Fe}(\rho_{C,s})}{\sqrt{\pi D_{C-Fe}t}}$$

Continued ...

### PROBLEM 14.44 (Cont.)

(b) Using the concentration distribution expression above, with  $L = 1 \text{ mm}$ ,  $t = 1 \text{ h}$  and  $D_{\text{C-Fe}} = 3 \times 10^{-11} \text{ m}^2/\text{s}$ , find the concentration ratio,

$$\frac{C_C(1 \text{ mm}, 1 \text{ h})}{C_{\text{C},s}} = \text{erfc} \left( \frac{0.001 \text{ m}}{2(3 \times 10^{-11} \text{ m}^2/\text{s} \times 3600 \text{ s})^{1/2}} \right) = 0.0314 \quad <$$

(c) From the species flux expression above, the mass flux of carbon can be written as

$$\dot{n}_{\text{C},s} = \rho_{\text{C},s} (D_{\text{C-Fe}}/\pi t)^{1/2} \quad <$$

The mass per unit area entering the plate over the time period follows from the integration of the rate expression

$$m_{\text{C}}(t) = \int_0^t \dot{n}_{\text{C},s} dt = \rho_{\text{C},s} (D_{\text{C-Fe}}/\pi)^{1/2} \int_0^t t^{-1/2} dt = 2 \rho_{\text{C},s} (D_{\text{C-Fe}} t/\pi)^{1/2} \quad <$$

## PROBLEM 14.45

**KNOWN:** Radius of pharmaceutical product, density of the active ingredient, partition coefficient, and binary diffusion coefficient of the active ingredient in the gastrointestinal tract.

**FIND:** (a) Dosage delivered over 5 hours from a  $D = 6$  mm diameter tablet, (b) Dosage delivered over 5 hours from  $N = 200$  small, spherical tablets of the same mass.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) One-dimensional radial diffusion of active ingredient, (2) Constant properties, (3) Stationary medium, (4) Constant sphere radius.

**PROPERTIES:** Given:  $D_{AB} = 0.40 \times 10^{-10} \text{ m}^2/\text{s}$ ,  $K = 3 \times 10^{-2}$ .

**ANALYSIS:** (a) The approximate solution of Chapter 5 for external conduction from an isothermal sphere and the heat-mass transfer analogy will be used. From Table 5.2a,

$$q^*(Fo) = \frac{1}{\sqrt{\pi Fo}} + 1 \quad \text{or,} \quad \frac{q_s'' r_o}{k(T_s - T_\infty)} = \frac{r_o}{\sqrt{\pi \alpha t}} + 1 \quad (1,2)$$

By analogy, Eq. 2 may be written as

$$\frac{n_{A, s}'' r_o}{D_{AB}(\rho_{A, s} - \rho_{A, \infty})} = \frac{r_o}{\sqrt{\pi D_{AB} t}} + 1 \quad (3)$$

Rearranging,

$$n_{A, s}'' = \frac{\sqrt{D_{AB} / \pi} (\rho_{A, s} - \rho_{A, \infty})}{\sqrt{t}} + \frac{D_{AB} (\rho_{A, s} - \rho_{A, \infty})}{r_o}$$

For  $\rho_{A, \infty} = 0$ , the dosage (for  $A_s = 4\pi r_o^2$ ) is

$$D = \int_0^t 4\pi r_o^2 n_{A, s}'' dt = \int_0^t 4\pi r_o^2 \left[ \sqrt{D_{AB} / \pi} (\rho_{A, s}) t^{-1/2} + \frac{D_{AB} (\rho_{A, s})}{r_o} \right] dt$$

With  $\rho_{A, s} = K\rho_A$ , the preceding expression yields

$$D = 4\pi r_o K \rho_A \left[ 2r_o \sqrt{D_{AB} / \pi} t^{1/2} + D_{AB} t \right] \quad (4)$$

Continued...

### PROBLEM 14.45 (Cont.)

Substituting the appropriate values into Eq. 4 results in

$$D = 4\pi \times 3 \times 10^{-3} \text{ m} \times 3 \times 10^{-2} \times 15 \text{ kg/m}^3 \times \left[ \frac{2 \times 3 \times 10^{-3} \text{ m} \sqrt{0.4 \times 10^{-10} \text{ m}^2 / \text{s} \times 18000 \text{ s} / \pi}}{+0.4 \times 10^{-10} \text{ m}^2 / \text{s} \times 18000 \text{ s}} \right]$$

$$D = 60.9 \times 10^{-9} \text{ kg} = 60.9 \times 10^{-6} \text{ g} = 60.9 \text{ } \mu\text{g} \quad <$$

(b) For the same initial mass and  $N = 200$  tablets,

$$\frac{4}{3} \pi r_{o,1}^3 = \frac{N4}{3} \pi r_{o,N}^3 \quad \text{or} \quad r_{o,N} = r_{o,1} / N^{1/3} = 3 \times 10^{-3} \text{ m} / 200^{1/3} = 0.513 \text{ mm}$$

The dosage is  $D = ND_1$  where  $D_1$  is the dosage for one tablet. Hence,

$$D = ND_1 = 200 \times 4\pi \times 0.513 \times 10^{-3} \text{ m} \times 3 \times 10^{-2} \times 15 \text{ kg/m}^3 \times \left[ \frac{2 \times 0.513 \times 10^{-3} \text{ m} \sqrt{0.4 \times 10^{-10} \text{ m}^2 / \text{s} \times 18000 \text{ s} / \pi}}{+0.4 \times 10^{-10} \text{ m}^2 / \text{s} \times 18000 \text{ s}} \right]$$

$$D = 703 \times 10^{-9} \text{ kg} = 703 \times 10^{-6} \text{ g} = 703 \text{ } \mu\text{g} \quad <$$

**COMMENTS:** (1) The dosage is controlled by the tablet size. In this example, the medication dosage is increased by over an order of magnitude by replacing the single tablet with the encapsulated, smaller diameter spherical tablets. (2) The initial mass of the medication is  $M = 4/3 \rho \pi r_o^3 = 4/3 \times 15 \text{ kg/m}^3 \times \pi \times (3 \times 10^{-3} \text{ m})^3 = 1.696 \times 10^{-6} \text{ kg} = 1.696 \times 10^{-3} \text{ g} = 1.696 \text{ mg} = 1696 \text{ } \mu\text{g}$ . For the smaller tablets, the mass of medication left after 5 hours is  $1696 \text{ } \mu\text{g} - 703 \text{ } \mu\text{g} = 993 \text{ } \mu\text{g}$ . Hence, the tablet radius after 5 hours is  $r_{5h} = 0.513 \text{ mm} \times (993/1696)^{1/3} = 0.429 \text{ mm}$ . The assumption of a constant radius is marginally valid.

### PROBLEM 14.46

**KNOWN:** Thickness, initial condition and bottom surface condition of a water layer.

**FIND:** (a) Time to reach 25% of saturation at top, (b) Amount of salt transfer in that time, (c) Final concentration of salt solution at top and bottom.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) One-dimensional diffusion, (2) Uniform total mass density, (3) Constant  $D_{AB}$ , (4) Stationary medium.

**ANALYSIS:** (a) With constant  $\rho$  and  $D_{AB}$  and no homogeneous chemical reactions, Eq. 14.47b reduces to

$$\frac{\partial^2 \rho_A}{\partial x^2} = \frac{1}{D_{AB}} \frac{\partial \rho_A}{\partial t}.$$

with the origin of coordinates placed at the top of the layer, the dimensionless mass density is

$$\gamma^*(x^*, Fo_m) = \frac{\gamma}{\gamma_i} = \frac{\rho_A - \rho_{A,s}}{\rho_{A,i} - \rho_{A,s}} = 1 - \frac{\rho_A}{\rho_{A,s}}$$

Hence,  $\gamma^*(0, Fo_{m,1}) = 1 - 0.25 = 0.75$ . The initial condition is  $\gamma^*(x^*, 0) = 1$ , and the boundary conditions are

$$\left. \frac{\partial \gamma^*}{\partial x^*} \right|_{x^*=0} = 0 \quad \gamma^*(1, Fo_m) = 0$$

where the condition at  $x^* = 1$  corresponds to  $Bi_m = \infty$ . Hence, the mass transfer problem is analogous to the heat transfer problem governed by Eq. 5.38 through 5.40. Assuming applicability of a one-term approximation ( $Fo_m > 0.2$ ), the solution is analogous to Eq. 5.43.

$$\gamma^* = C_1 \exp(-\zeta_1^2 Fo_m) \cos(\zeta_1 x^*).$$

With  $Bi_m = \infty$ ,  $\zeta_1 = \pi/2 = 1.571$  rad and, from Table 5.1,  $C_1 \approx 1.273$ . Hence, for  $x^* = 0$ ,

$$0.75 = 1.273 \exp\left[-(1.571)^2 Fo_{m,1}\right]$$

$$Fo_{m,1} = -\ln(0.75/1.274)/(1.571)^2 = 0.214.$$

Hence,

$$t_1 = \frac{L^2}{D_{AB}} Fo_{m,1} = \frac{(1 \text{ m})^2}{1.2 \times 10^{-9} \text{ m}^2/\text{s}} 0.214 = 1.79 \times 10^8 \text{ s} = 2071 \text{ days.} \quad <$$

Continued ...

**PROBLEM 14.46 (Cont.)**

(b) The change in the salt mass within the water is

$$\Delta M_A = M_A(t_1) - M_{A,i} = \int (\rho_A - \rho_{A,i}) dV = A \int_0^L \rho_A dx$$

Hence,

$$\Delta M_A'' = \rho_{A,s} \int_0^L (\rho_A / \rho_{A,s}) dx$$

$$\Delta M_A'' = \rho_{A,s} L \int_0^1 (1 - \gamma^*) dx^*$$

$$\Delta M_A'' = \rho_{A,s} L \int_0^1 \left[ 1 - C_1 \exp(-\zeta_1^2 Fo_{m,1}) \cos(\zeta_1 x^*) \right] dx^*$$

$$\Delta M_A'' = \rho_{A,s} L \left[ 1 - C_1 \exp(-\zeta_1^2 Fo_{m,1}) \sin \zeta_1 / \zeta_1 \right].$$

Substituting numerical values,

$$\Delta M_A'' = 380 \text{ kg/m}^3 (1 \text{ m}) \left[ 1 - \frac{1.274 \exp[-(1.571)^2 0.214] 1}{1.571 \text{ rad}} \right]$$

$$\Delta M_A'' = 198.3 \text{ kg/m}^2. \quad <$$

(c) Steady-state conditions correspond to a uniform mass density in the water. Hence,

$$\rho_A(0, \infty) = \rho_A(L, \infty) = \Delta M_A'' / L = 198.3 \text{ kg/m}^3. \quad <$$

**COMMENTS:** (1) The assumption of constant  $\rho$  is weak, since the density of salt water depends strongly on the salt composition.

(2) The requirement of  $Fo_m > 0.2$  for the one-term approximation to be valid is barely satisfied.

## PROBLEM 14.47

**KNOWN:** Temperature distribution expression for a semi-infinite medium, initially at a uniform temperature, that is suddenly exposed to an instantaneous amount of energy,  $Q''_0$  ( $\text{J}/\text{m}^2$ ).

Analogous situation of a silicon (Si) wafer with a  $1\text{-}\mu\text{m}$  layer of phosphorous (P) that is placed in a furnace suddenly initiating diffusion of P into Si.

**FIND:** (a) Explain the correspondence between the variables in the analogous temperature and concentration distribution expressions, and (b) Determine the mole fraction of P at a depth of  $0.1\ \mu\text{m}$  in the Si after 30 s.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) One-dimensional, transient diffusion, (2) Wafer approximates a semi-infinite medium, (3) Uniform properties, and (4) Diffusion process for Si and P is initiated when the wafer reaches the elevated temperature as a consequence of the large temperature dependence of the diffusion coefficient, (5) Stationary medium.

**PROPERTIES:** Given in statement:  $D_{\text{P-Si}} = 1.2 \times 10^{-17}\ \text{m}^2/\text{s}$ ; Mass densities of Si and P: 2000 and  $2300\ \text{kg}/\text{m}^3$ ; Molecular weights of Si and P: 30.97 and 28.09 kg/kmol.

**ANALYSIS:** (a) For the thermal process illustrated in the schematic, the temperature distribution is

$$T(x, t) - T_i = \frac{Q''_0}{\rho c (\pi \alpha t)^{1/2}} \exp(-x^2 / 4 \alpha t) \quad (\text{HT})$$

where  $T_i$  is the initial, uniform temperature of the medium. For the mass transfer process, the P concentration has the form

$$C_{\text{P}}(x, t) = \frac{M_{\text{P},0}^{\text{P}}}{(\pi D_{\text{P-Si}} t)^{1/2}} \exp(-x^2 / 4 D_{\text{P-Si}} t) \quad (\text{MT})$$

where  $M_{\text{P},0}^{\text{P}}$  is the molar area density ( $\text{kmol}/\text{m}^2$ ) of P represented by the film of concentration  $C_{\text{P}}$  and thickness  $d_0$ .

The correspondence between mass and heat transfer variables in the equations HT and MT involves the following conditions. The LHS represents the increase with time of the temperature or concentration above the initial uniform distribution. The initial concentration is zero, so only the  $C_{\text{P}}(x, t)$  appears. On the RHS note the correspondence of the terms in the exponential parenthesis and in the denominator. The thermal diffusivity and diffusion coefficient are directly analogous; this can be seen by comparing the MT and HT diffusion equations, Eq. 2.21 and 14.77. The terms  $Q''_0 / \rho c$  and  $M_{\text{P},0}^{\text{P}}$  for HT and MT represent the energy and mass instantaneously appearing at the surface. The product  $\rho c$  is the thermal capacity per unit area and appears in the storage term of the HT diffusion equation. For MT, the “capacity” term is the volume itself.

### PROBLEM 14.47 (Cont.)

(b) The molar area density ( $\text{kmol}/\text{m}^2$ ) of P associated with the film of thickness  $d_o = 1 \mu\text{m}$  and concentration  $C_{P,o}$  is

$$M_{P,o}^{\#} = C_{P,o} \cdot d_o = (\rho_P / M_P) d_o$$

$$M_{P,o}^{\#} = (2000 \text{ kg} / \text{m}^3 / 30.97 \text{ kmol} / \text{kg}) \times 1 \times 10^{-6} \text{ m}$$

$$M_{P,o}^{\#} = 6.458 \times 10^{-5} \text{ kmol} / \text{m}^2$$

Substituting numerical values into the MT equation, find

$$C_p(0.1 \mu\text{m}, 30 \text{ s}) = \frac{6.458 \times 10^{-5} \text{ kmol}/\text{m}^2}{(\pi \times 1.2 \times 10^{-17} \text{ m}^2/\text{s} \times 30 \text{ s})^{1/2}} \exp\left[-(0.1 \times 10^{-6} \text{ m})^2 / (4 \times 1.2 \times 10^{-17} \text{ m}^2/\text{s} \times 30 \text{ s})\right]$$

$$C_p = 1.85 \text{ kmol}/\text{m}^3$$

The mole fraction of P in the Si wafer is

$$x_P = C_P / C_{Si} = C_P / (\rho_{Si} / \mathcal{M}_{Si})$$

$$x_P = 1.85 \text{ kmol}/\text{m}^3 / (2300 \text{ kg}/\text{m}^3 / 28.09 \text{ kmol}/\text{kg})$$

$$x_P = 0.023$$

<

## PROBLEM 14.48

**KNOWN:** Carbon dioxide concentration at water surface and reaction rate constant.

**FIND:** (a) Differential equation which governs variation with position and time of CO<sub>2</sub> concentration in water, (b) Appropriate boundary conditions and solution for a deep body of water with negligible chemical reactions.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) One-dimensional diffusion in  $x$ , (2) Constant properties, including total density  $\rho$ , (3) Water is stagnant, (4) Stationary medium.

**ANALYSIS:** (a) From Eq. 14.47b, it follows that, for the prescribed conditions,

$$D_{AB} \frac{\partial^2 \rho_A}{\partial x^2} - k_1 \rho_A = \frac{\partial \rho_A}{\partial t}. \quad <$$

The first term on the left-hand side represents the *net* transport of CO<sub>2</sub> into a differential control volume by diffusion. The second term represents the rate of CO<sub>2</sub> consumption due to chemical reactions. The term on the right-hand side represents the rate of increase of CO<sub>2</sub> storage within the control volume.

(b) For a deep body of water, appropriate boundary conditions are

$$\rho_A(0, t) = \rho_{A,0}$$

$$\rho_A(\infty, t) = 0$$

and, with negligible chemical reactions, the species diffusion equation reduces to

$$\frac{\partial^2 \rho_A}{\partial x^2} = \frac{1}{D_{AB}} \frac{\partial \rho_A}{\partial t}.$$

With an initial condition,  $\rho_A(x, 0) \equiv \rho_{A,i} = 0$ , the problem is analogous to that involving heat transfer in a semi-infinite medium with constant surface temperature. By analogy to Eq. 5.60, the species concentration is then

$$\frac{\rho_A(x, t) - \rho_{A,0}}{-\rho_{A,0}} = \operatorname{erf} \left( \frac{x}{2(D_{AB}t)^{1/2}} \right)$$

$$\rho_A(x, t) = \rho_{A,0} \operatorname{erfc} \left( \frac{x}{2(D_{AB}t)^{1/2}} \right). \quad <$$

### PROBLEM 14.49

**KNOWN:** Solubility and diffusivity of oxygen ( $O_2$ ) in polycarbonate. Distance of thin reacting film of polymer from DVD surface. Initial  $O_2$  distribution. Critical concentration needed to start reaction in the thin film.

**FIND:** Elapsed time before reaction begins in the thin film.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Constant properties and steady-state conditions, (2) Stationary medium. (3) Presence of thin, reacting film does not affect the diffusion process, (4) Semi-infinite media.

**PROPERTIES:** Oxygen ( $O_2$ ) in polycarbonate, given:  $D_{AB} = 6.5 \times 10^{-12} \text{ m}^2/\text{s}$ ,  $S = 8.9 \times 10^{-3} \text{ kmol}/\text{m}^3 \cdot \text{bar}$ .

**ANALYSIS:**

The mole fraction of oxygen in air is 0.21. Therefore, the partial pressure of  $O_2$  in the atmosphere is

$$P_{O_2} = 0.21 \text{ atm} \times 1.0133 \frac{\text{bar}}{\text{atm}} = 0.213 \text{ bar}$$

and the surface concentration is

$$C_s = C(x=0) = SP_{O_2} = 8.9 \times 10^{-3} \frac{\text{kmol}}{\text{m}^3 \cdot \text{bar}} \times 0.213 \text{ bar} = 1.89 \times 10^{-3} \frac{\text{kmol}}{\text{m}^3}$$

Incorporating the heat and mass transfer analogy and using Eq. 5.60,

$$\frac{C(x,t) - C_s}{C_i - C_s} = \text{erf} \left( \frac{x}{2\sqrt{D_{AB}t}} \right) = \frac{5 \times 10^{-5} \frac{\text{kmol}}{\text{m}^3} - 1.89 \times 10^{-3} \frac{\text{kmol}}{\text{m}^3}}{0 - 1.89 \times 10^{-3} \frac{\text{kmol}}{\text{m}^3}} = \text{erf} \left( \frac{0.5 \times 10^{-3} \text{ m}}{2\sqrt{6.5 \times 10^{-12} \frac{\text{m}^2}{\text{s}} \times t}} \right)$$

which yields

$$t = 3940 \text{ s}$$

<

**COMMENT:** The thin film will convert  $O_2$  to a product of the reaction. A more detailed analysis would include the effects of  $O_2$  conversion on the process.

### PROBLEM 14.50

**KNOWN:** DVD with reacting polymer throughout, undergoing first-order homogeneous reaction between polymer and oxygen, with reaction rate proportional to oxygen molar concentration.

**FIND:** (a) Governing equations and boundary and initial conditions for oxygen molar concentration. (b) Expression for volume-averaged molar concentration of product of reaction.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Constant properties, (2) One-dimensional mass diffusion with heterogeneous chemical reaction. (3) Reaction rate is proportional to molar concentration of oxygen.

**ANALYSIS:** (a) From Eq. 14.48b for one-dimensional diffusion of species A (oxygen),

$$\frac{\partial C_A}{\partial t} = D_{AB} \frac{\partial^2 C_A}{\partial x^2} + \dot{N}_A$$

For a first-order reaction that consumes oxygen, we can write  $\dot{N}_A = -k_1 C_A$ . Thus,

$$\frac{\partial C_A}{\partial t} = D_{AB} \frac{\partial^2 C_A}{\partial x^2} - k_1 C_A \quad <$$

The boundary conditions express symmetry about the midplane and relate the molar concentration at the surface to the partial pressure of oxygen in the environment,  $p_A$ .

$$\left. \frac{\partial C_A}{\partial x} \right|_{x=0} = 0, \quad C_A(L, t) = S p_A \quad <$$

The initial condition expresses that there is no oxygen initially in the DVD before the pouch is opened, that is,

$$C_A(x, 0) = 0 \quad <$$

(b) Since each mole of oxygen that reacts with the polymer results in  $p$  moles of product, we can write the following expression for the rate of generation of product:  $\dot{N}_{\text{prod}} = -p \dot{N}_A = p k_1 C_A$ .

Continued...

**PROBLEM 14.50 (Cont.)**

The volume-averaged molar concentration of product is just the rate of generation integrated over time and averaged over the volume. Thus,

$$\bar{C}_{\text{prod}} = \frac{1}{V} \int_V \int_0^t \dot{N}_{\text{prod}} dt dV = \frac{1}{2AL} \int_{-L}^L \int_0^t \dot{N}_{\text{prod}} dt (A dx) = \frac{1}{L} \int_0^L \int_0^t pk_1 C_A dt dx$$
$$\bar{C}_{\text{prod}} = \frac{pk_1}{L} \int_0^L \int_0^t C_A(x, t) dt dx \quad <$$

## PROBLEM 14.51

**KNOWN:** Sheet material has high, uniform concentration of hydrogen at the end of a process, and is then subjected to an air stream with a specified, low concentration of hydrogen. Mass transfer parameters specified include: convection mass transfer coefficient,  $h_m$ , and the mass diffusivity and solubility of hydrogen (A) in the sheet material (B),  $D_{AB}$  and  $S_{AB}$ , respectively.

**FIND:** (a) The final mass density of hydrogen in the material if the sheet is exposed to the air stream for a very long time,  $\rho_{A,f}$ , (b) Identify and evaluate the parameter that can be used to determine whether the transient mass diffusion process in the sheet can be characterized by a uniform concentration at any time; *Hint:* this situation is analogous to the lumped capacitance method for a transient heat transfer process; (c) Determine the time required to reduce the hydrogen concentration to twice the limiting value calculated in part (a).

**SCHEMATIC:**

**ASSUMPTIONS:** (1) One-dimensional diffusion, (2) Stationary medium, (3) Constant properties, (4) Uniform temperature in air stream and material, and (5) Ideal gas behavior.

**ANALYSIS:** (a) The final content of  $\text{H}_2$  in the material will depend upon the solubility of  $\text{H}_2$  (A) in the material (B) and its partial pressure in the free stream. From Eq. 14.62,

$$C_{A,f} = S_{AB} p_{A,\infty} = 160 \text{ kmol/m}^3 \cdot \text{atm} \times 0.1 \text{ atm} = 16 \text{ kmol/m}^3$$

$$\rho_f = \mathcal{M}_A C_{A,f} = 2 \text{ kg/kmol} \times 16 \text{ kmol/m}^3 = 32 \text{ kg/m}^3 \quad \leftarrow$$

(b) The parameters associated with transient diffusion in the material follow from the analogous treatment of Section 5.2 (Fig. 5.3) and are represented in the schematic.

In the material, from Fick's law, the diffusive flux is

$$N''_{A,dif} = D_{AB} (C_{A,1} - C_{A,2}) / L \quad (1)$$

At the surface,  $x = L$ , the rate equation, Eq. 6.8, convective flux of species A is

$$N''_{A,conv} = h_m (C_{A,s} - C_{A,\infty})$$

Continued ...

**PROBLEM 14.51 (Cont.)**

and substituting the ideal gas law, Eq. 14.9, and introducing the solubility relation, Eq. 14.62,

$$N''_{A,\text{conv}} = \frac{h_m}{S_{AB} \mathcal{R} T_\infty} (S_{AB} p_{A,s} - S_{AB} p_{A,\infty})$$

$$N''_{A,\text{conv}} = \frac{h_m}{S_{AB} \mathcal{R} T_\infty} (C_{2,s} - C_{A,\infty}) \quad (2)$$

where  $C_{A,\infty} = C_{A,f}$ , the final concentration in the material after exposure to the air stream a long time. Considering a surface species flux balance, as shown in the schematic above, with the rate equations (1) and (2),

$$\frac{D_{AB} (C_{A,1} - C_{A,2})}{L} = \frac{h_m}{S_{AB} \mathcal{R} T_\infty} (C_{A,s} - C_{A,f})$$

$$\frac{C_{A,1} - C_{A,2}}{C_{A,s} - C_{A,f}} = \frac{h_m / S_{AB} \mathcal{R} T_\infty}{D_{AB} / L} = \frac{R''_{m,\text{dif}}}{R''_{m,\text{conv}}} = \text{Bi}_m \quad (3)$$

and introducing resistances to species transfer by diffusion and convection. Recognize from the analogy to heat transfer, Eq. 5.10 and Table 14.2, that when  $\text{Bi}_m < 0.1$ , the concentration can be characterized as uniform during the transient process. That is, the diffusion resistance is negligible compared to the convection resistance,

$$\text{Bi}_m = \frac{h_m L}{S_{AB} R_u T_\infty D_{AB}} < 0.1 \quad (4)$$

$$\text{Bi}_m = \frac{(1.5 \text{ m/h} \times 3600 \text{ s/h}) \times 0.003 \text{ m}}{160 \text{ kmol/m}^3 \cdot \text{atm} \times 8.205 \times 10^{-2} \text{ m}^3 \cdot \text{atm/kmol} \cdot \text{K} \times 555 \text{ K} \times 2.68 \times 10^{-8} \text{ m}^2/\text{s}}$$

$$\text{Bi}_m = 6.60 \times 10^{-3} < 0.1$$

Hence, the mass transfer process can be treated as a nearly uniform concentration situation. From conservation of species on the material with uniform concentration,

$$-N''_{A,\text{conv}} = \dot{N}''_{A,\text{st}}$$

$$-\frac{h_m}{S_{AB} \mathcal{R} T_\infty} (C_A - C_{A,f}) = L \frac{dC_A}{dt}$$

Integrating, with the initial condition  $C_A(0) = C_{A,i}$ , find

$$\frac{C_A - C_{A,f}}{C_{A,i} - C_{A,f}} = \exp\left(-\frac{h_m t}{L S_{AB} \mathcal{R} T_\infty}\right) \quad (5) <$$

Continued .....

### PROBLEM 14.51 (Cont.)

which is similar to the analogous heat transfer relation for the lumped capacitance analysis, Eq. 5.6.

(c) The time,  $t_o$ , required for the material to reach a concentration twice that of the limiting value,  $C_A(T_o) = 2 C_{A,f}$ , can be calculated from Eq. (5).

$$\frac{(2-1) \times 16 \text{ kmol/m}^3}{(320-16) \text{ kmol/m}^3} = \exp\left(-\frac{1.5 \text{ m/h} \times t_o}{0.003 \text{ m} \times 160 \text{ kmol/m}^3 \cdot \text{atm} \times 8.205 \times 10^{-2} \text{ m}^3 \cdot \text{atm/kmol} \cdot \text{K} \times 555 \text{ K}}\right)$$

$$t_o = 42.9 \text{ h}$$

<

## PROBLEM 14.52

**KNOWN:** Hydrogen-removal process described in Problem 14.51, but under conditions for which the mass diffusivity of hydrogen gas (A) in the sheet (B) is  $D_{AB} = 1.8 \times 10^{-11} \text{ m}^2/\text{s}$  (instead of  $2.6 \times 10^{-8} \text{ m}^2/\text{s}$ ). With a smaller  $D_{AB}$ , a uniform concentration condition may no longer be assumed to exist in the material during the removal process.

**FIND:** (a) The final mass density of hydrogen in the material if the sheet is exposed to the air stream for a very long time,  $\rho_{A,f}$ , (b) Identify and evaluate the parameters that describe the transient mass transfer process in the sheet; *Hint:* this situation is analogous to that of transient heat conduction in a plane wall; (c) Assuming a uniform concentration in the sheet at any time during the removal process, determine the time required to reach twice the limiting mass density calculated in part (a); (d) Using the analogy developed in part (b), determine the time required to reduce the hydrogen concentration to twice the limiting value calculated in part (a); Compare the result with that from part (c).

**SCHEMATIC:**

**ASSUMPTIONS:** (1) One-dimensional diffusion, (2) Stationary medium, (3) Constant properties, (4) Uniform temperature in air stream and material, and (5) Ideal gas behavior.

**ANALYSIS:** (a) The final content of  $\text{H}_2$  in the material will depend upon the solubility of  $\text{H}_2$  (A) in the material (B) at its partial pressure in the free stream. From Eq. 14.62,

$$C_{A,f} = S_{AB} p_{A,\infty} = 160 \text{ kmol/m}^3 \cdot \text{atm} \times 0.1 \text{ atm} = 16 \text{ kmol/m}^3$$

$$\rho_f = M_A C_{A,f} = 2 \text{ kg/kmol} \times 16 \text{ kmol/m}^3 = 32 \text{ kg/m}^3 \quad <$$

(b) For the plane wall shown in the schematic below, the heat and mass transfer conservation equations and their initial and boundary conditions are

*Heat transfer*

$$\frac{\partial T}{\partial t} = \alpha \frac{\partial^2 T}{\partial x^2}$$

$$T(x,0) = T_i$$

$$\frac{\partial T}{\partial x}(0,t) = 0$$

$$-k \frac{\partial T}{\partial x}(L,t) = h[T(L,t) - T_\infty]$$

*Mass (Species A) transfer*

$$\frac{\partial C_A}{\partial t} = D_{AB} \frac{\partial^2 C_A}{\partial x^2}$$

$$C_A(x,0) = C_{A,i}$$

$$\frac{\partial C_A}{\partial x}(0,t) = 0$$

$$-D_{AB} \frac{\partial C_A}{\partial x}(L,t) = \frac{h_m}{S_{AB} \mathcal{R} T} [C_A(x,t) - C_f]$$

Continued ...

**PROBLEM 14.52 (Cont.)**

The derivation for the species transport surface boundary condition is developed in the solution for Problem 14.51. The solution to the mass transfer problem is identical to the analogous heat transfer problem provided the transport coefficients are represented as

$$\frac{h}{k} \Leftrightarrow \frac{h_m / S_{AB} \mathcal{R} T}{D_{AB}} \quad (1)$$

(c) The uniform concentration transient diffusion process is analogous to the heat transfer lumped-capacitance process. From the solution of Problem 14.51, the time to reach twice the limiting concentration,  $C_A(t_0) = 2 C_{A,f}$ , can be calculated as

$$\frac{C_A(t_0) - C_{A,f}}{C_{A,i} - C_{A,f}} = \exp\left(-\frac{h_m t_0}{L S_{AB} \mathcal{R} T}\right) \quad (2)$$

$$t_0 = 42.9 \text{ hour}$$

<

For the present situation, the mass transfer Biot number is

$$Bi_m = \frac{h_m L}{S_{AB} \mathcal{R} T D_{AB}}$$

$$Bi_m = \frac{(1.5 \text{ m/h} / 3600 \text{ s/h}) \times 0.003 \text{ m}}{160 \text{ kmol/m}^3 \cdot \text{atm} \times 8.205 \times 10^{-2} \text{ m}^3 \cdot \text{atm/kmol} \cdot \text{K} \times 555 \text{ K} \times 1.8 \times 10^{-11} \text{ m}^2/\text{s}}$$

$$Bi_m = 9.5 \gg 0.1$$

and hence the concentration of A within B is not uniform

(d) Invoking the analogy with the heat transfer situation, we can use the one-term series solution, Eq. 5.43, with  $Bi_m \Leftrightarrow Bi$  and

$$Fo_m \Leftrightarrow Fo \quad Fo_m = \frac{D_{AB} t}{L^2} \quad (3)$$

Continued ...

### PROBLEM 14.52 (Cont.)

With  $Bi_m = 9.5$ , find  $\zeta_1 = 1.4219$  rad and  $C_1 = 1.2609$  from Table 5.1, so that Eq. 5.44 becomes

$$\frac{C_A(t_o) - C_{A,f}}{C_{A,i} - C_{A,f}} = C_1 \exp(-\zeta_1^2 Fo_m)$$

$$\frac{(2-1) \times 16 \text{ kmol/m}^3}{(320-16) \text{ kmol/m}^3} = 1.2609 \exp(-1.4219^2 Fo_m)$$

$$Fo_m = \frac{1.8 \times 10^{-11} \text{ m}^2/\text{s} \times t_o}{(0.003 \text{ m})^2} = 1.571$$

$$t_o = 218 \text{ h}$$

<

**COMMENTS:** (1) Since  $Bi_m = 9.5$ , the uniform concentration assumption is not valid, and we expect the analysis to provide a longer time estimate to reach  $C_A(t_o) = 2 C_{A,f}$ .

(2) Note that the uniform concentration analysis model of part (c) does not include  $D_{AB}$ . Why is this so?

### PROBLEM 14.53

**KNOWN:** Dimensions of polymer sheet. Temperature and relative humidity of environment. Increase in mass of sheet over 24 and 48 hour periods.

**FIND:** Solubility and mass diffusivity of water vapor in polymer, assuming mass diffusivity is greater than  $7 \times 10^{-13} \text{ m}^2/\text{s}$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Constant properties, (2) One-dimensional mass diffusion, (3) Mass gain is solely due to water vapor diffusing into the sheet.

**PROPERTIES:** Table A.6, saturated water ( $T = 300 \text{ K}$ ),  $p_{A,\text{sat}} = 0.03531 \text{ bars}$ ,  $\mathcal{M}_A = 18 \text{ kg/kmol}$ .

**ANALYSIS:** The process of diffusion of water vapor (A) in the polymer (B) sheet is governed by Eq. 14.77 with boundary and initial conditions given by Eqs. 14.78 through 14.80. These equations can be cast in nondimensional form as in Eqs. 14.83 through 14.86, and the analogy with Eqs. 5.37 through 5.40 is apparent (for  $\text{Bi} \rightarrow \infty$ ), with the analogous quantities defined in Table 14.2.

Since the mass gained by the polymer sheet is known, it is more convenient to work the problem in mass terms. Making use of Eq. 14.1, we recognize that  $\gamma^*$  defined in Eq. 14.81 can be written in the alternative form,

$$\gamma^* = \frac{C_A - C_{A,s}}{C_{A,i} - C_{A,s}} = \frac{\rho_A - \rho_{A,s}}{\rho_{A,i} - \rho_{A,s}} \quad (1)$$

Here  $\rho_{A,i} = 0$  since the sheet is initially dry, and  $\rho_{A,s} = \mathcal{M}_A C_{A,s} = \mathcal{M}_A S p_{A,\infty}$ , or

$$\rho_{A,s} = \mathcal{M}_A S \phi p_{A,\text{sat}} \quad (2)$$

where  $S$  is the solubility (see Eq. 14.62).

The mass gained by the polymer sheet is then analogous to the energy transfer,  $Q$ , in the heat transfer problem. Specifically, for the mass loss, we can write a sequence of equations analogous to Eqs. 5.46 through 5.48,

Continued...

**PROBLEM 14.53 (Cont.)**

$$\text{Mass loss} = \Delta M_A = -[M_A(t) - M_A(0)] = -\int [\rho_A(x, t) - \rho_{A,i}] dV$$

$$\Delta M_{A,0} \equiv V(\rho_{A,i} - \rho_{A,s})$$

and

$$\frac{\Delta M_A}{\Delta M_{A,0}} = -\int \frac{[\rho_A(x, t) - \rho_{A,i}]}{\rho_{A,i} - \rho_{A,s}} \frac{dV}{V} = \frac{1}{V} \int (1 - \gamma^*) dV$$

If  $Fo_m > 0.2$ , the solution can be approximated by the first term in the series, and the result for the mass loss would be analogous to Eq. 5.49. To determine if the first term approximation can be used, we estimate the mass transfer Fourier number with knowledge that the mass diffusivity is greater than  $7 \times 10^{-13} \text{ m}^2/\text{s}$ ,

$$Fo_m = D_{AB}t/L^2, \quad Fo_m > 7 \times 10^{-13} \text{ m}^2/\text{s} \times 24 \text{ h} \times 3600 \text{ s/h} / (0.0005 \text{ m})^2 = 0.24$$

Thus the one-term approximation is valid and by analogy to Eqs. 5.49 and 5.44, the nondimensional mass loss is given by

$$\frac{\Delta M_A}{\Delta M_{A,0}} = 1 - \frac{\sin \zeta_1}{\zeta_1} C_1 \exp(-\zeta_1^2 Fo_m) \quad (3)$$

or

$$\frac{-\Delta M_A}{\rho_{A,s} V} = 1 - \frac{\sin \zeta_1}{\zeta_1} C_1 \exp(-\zeta_1^2 \frac{D_{AB}}{L^2} t) \quad (4)$$

From Table 5.1 for  $Bi \rightarrow \infty$ , we find  $\zeta_1 = 1.5707 = \pi/2$  and  $C_1 = 1.2733$ . The quantity  $-\Delta M_A$  is the mass gain at the two stated times. The unknowns to be determined are  $D_{AB}$  and  $S$ , which appears in  $\rho_{A,s}$  (see Eq. (2)). From Eq. (4) evaluated at the two times, we have two simultaneous equations which can be solved for the unknowns  $D_{AB}$  and  $\rho_{A,s}$ , namely

$$\frac{0.012 \times 10^{-6} \text{ kg}}{\rho_{A,s} \times 10^{-5} \text{ kg/m}^3} = 1 - \frac{\sin \pi/2}{\pi/2} 1.2733 \exp\left(-\frac{\pi^2}{4} \frac{D_{AB}}{(0.0005 \text{ m})^2} 24 \text{ h} \times 3600 \text{ s/h}\right)$$

$$\frac{0.016 \times 10^{-6} \text{ kg}}{\rho_{A,s} \times 10^{-5} \text{ kg/m}^3} = 1 - \frac{\sin \pi/2}{\pi/2} 1.2733 \exp\left(-\frac{\pi^2}{4} \frac{D_{AB}}{(0.0005 \text{ m})^2} 48 \text{ h} \times 3600 \text{ s/h}\right)$$

There are two solutions to these two equations,

$$D_{AB} = 1.92 \times 10^{-13} \text{ m}^2/\text{s}, \quad \rho_{A,s} = 0.003848 \text{ kg/m}^3$$

or

$$D_{AB} = 8.5 \times 10^{-13} \text{ m}^2/\text{s}, \quad \rho_{A,s} = 0.001976 \text{ kg/m}^3$$

Continued...

### PROBLEM 14.53 (Cont.)

Since we expect  $D_{AB}$  to be greater than  $7 \times 10^{-13} \text{ m}^2/\text{s}$ , we choose the second solution. Thus,

$$D_{AB} = 8.5 \times 10^{-13} \text{ m}^2/\text{s} \quad <$$

$$S = \rho_{A,S} / \mathcal{M}_A \phi_{A,\text{sat}} = 0.001976 \text{ kg/m}^3 / (18 \text{ kg/kmol} \times 0.95 \times 0.03531 \text{ bars})$$

$$S = 3.3 \times 10^{-3} \text{ kmol/m}^3 \cdot \text{bar} \quad <$$

**COMMENTS:** The system of equations has two solutions, but one of them would yield a mass diffusivity less than  $7 \times 10^{-13} \text{ m}^2/\text{s}$ , and is therefore rejected. That solution also has  $Fo_m < 0.2$ , so the solution is not valid. It does raise the question of whether there is another solution for which  $Fo_m < 0.2$ . If the problem is solved correctly for  $Fo_m < 0.2$ , it can be determined that there is no other solution.

### PROBLEM 14.54

**KNOWN:** Diameter of optical fiber sensor in a hydrogen chamber. Pressure of hydrogen (species A) in environment. Mass diffusivity and solubility for hydrogen in glass fiber (species B).

**FIND:** (a) Average hydrogen concentration in fiber after 100 hours of operation. Change in refractive index, given that  $\Delta n = (1.6 \times 10^{-3} \text{ m}^3/\text{kmol}) \times \bar{C}$ . (b) Average hydrogen concentration and change in refractive index after 1 and 10 hours of operation.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Constant properties, (2) One-dimensional mass diffusion.

**PROPERTIES:** Hydrogen in vitreous silica fiber (given):  $D_{AB} = 2.88 \times 10^{-15} \text{ m}^2/\text{s}$ ,  $S = 4.15 \times 10^{-3} \text{ kmol}/\text{m}^3 \cdot \text{bar}$ .

**ANALYSIS:** (a) This is a problem of transient mass diffusion in a cylinder, analogous to transient conduction in a cylinder. We begin by calculating the mass transfer Fourier number,

$$Fo_m = D_{AB}t/r_0^2 = 2.88 \times 10^{-15} \text{ m}^2/\text{s} \times 100 \text{ h} \times 3600 \text{ s/h} / (50 \times 10^{-6} \text{ m})^2 = 0.415$$

With  $Fo_m > 0.2$ , we can use the first-term approximation to the series solution. The average hydrogen concentration can be found by analogy with the nondimensional energy transfer  $Q/Q_0$  defined in Eq. 5.48, with reference to Table 14.3 for the analogous quantities. We define

$$\frac{\Delta M_A}{\Delta M_{A,0}} \equiv \int \frac{-(C_A(x,t) - C_{A,i})}{C_{A,i} - C_{A,s}} \frac{dV}{V} = \frac{1}{V} \int (1 - \gamma^*) dV \quad (1)$$

Here the surface concentration,  $C_{A,s}$ , is used in place of the environment temperature,  $T_\infty$ , because this is a problem of specified surface concentration, modeled by allowing  $Bi_m \rightarrow \infty$ . By analogy with Eq. 5.54,

$$\frac{\Delta M_A}{\Delta M_{A,0}} = 1 - \frac{2\gamma_0^*}{\zeta_1} J_1(\zeta_1)$$

where from Eq. 5.52c, the centerline value of the nondimensional molar concentration is  $\gamma_0^* = C_1 \exp(-\zeta_1^2 Fo_m)$ . From Table 5.1,  $\zeta_1 = 2.4050$ ,  $C_1 = 1.6018$ , so  $\gamma_0^* = 0.145$ . From Table B.4,  $J_1(2.4050) \approx 0.52$ . Thus,

Continued...

**PROBLEM 14.54 (Cont.)**

$$\frac{\Delta M_A}{\Delta M_{A,0}} = 1 - \frac{2 \times 0.145}{2.4050} \times 0.52 = 0.937$$

Referring back to Eq. (1), we can determine the average hydrogen concentration,

$$\bar{C}_A = \int C_A(x, t) \frac{dV}{V} = C_{A,i} + \frac{\Delta M_A}{\Delta M_{A,0}} (C_{A,s} - C_{A,i})$$

where  $C_{A,i} = 0$  since the fiber initially contains no hydrogen, and  $C_{A,s} = Sp_A = 4.15 \times 10^{-3} \text{ kmol/m}^3 \cdot \text{bar} \times 20 \text{ bars} = 0.0830 \text{ kmol/m}^3$ . Thus,

$$\bar{C}_A = 0 + 0.937(0.0830 \text{ kmol/m}^3 - 0) = 0.0778 \text{ kmol/m}^3 \quad <$$

The change in refractive index is then

$$\Delta n = 1.6 \times 10^{-3} \text{ m}^3/\text{kmol} \times 0.0778 \text{ kmol/m}^3 = 1.24 \times 10^{-4}$$

(b) For the shorter times, the Fourier number is no longer larger than 0.2, and we must use a different approach. We could use the exact infinite series solution, but it is easier to use the solutions provided in Table 5.2a, which are appropriate for uniform surface concentration. For an infinite cylinder, with  $L_c = r_0$ ,

$$q^* = q_s'' r_0 / k(T_s - T_i)$$

The analogous quantity is

$$N_A^* = N_{A,s}'' r_0 / D_{AB}(C_{A,s} - C_{A,i})$$

With knowledge of the molar flux at the surface,  $N_{A,s}''$ , the average hydrogen concentration can be found as follows. We multiply the flux by the surface area and integrate over time to find how much hydrogen has entered the fiber. Then we divide by the volume to find the average concentration. That is,

$$\bar{C}_A = \int_0^t N_{A,s}'' dt \times \frac{2\pi r_0}{\pi r_0^2} = \frac{2}{r_0} \int_0^t N_{A,s}'' dt$$

Now from Table 5.2a for the interior case, infinite cylinder, with  $Fo_m < 0.2$ ,

$$N_A^* = N_{A,s}'' r_0 / D_{AB}(C_{A,s} - C_{A,i}) = \frac{1}{\sqrt{\pi Fo_m}} - 0.50 - 0.65 Fo_m$$

Thus, we have

Continued...

**PROBLEM 14.54 (Cont.)**

$$\begin{aligned}\bar{C}_A &= \frac{2}{r_0} \int_0^t N''_{A,s} dt = \frac{2}{r_0^2} D_{AB} (C_{A,s} - C_{A,i}) \int_0^t \left( \frac{1}{\sqrt{\pi Fo_m}} - 0.50 - 0.65 Fo_m \right) dt \\ &= 2(C_{A,s} - C_{A,i}) \int_0^{Fo_m} \left( \frac{1}{\sqrt{\pi Fo_m}} - 0.50 - 0.65 Fo_m \right) dFo_m \\ &= 2(C_{A,s} - C_{A,i}) \left( \frac{2Fo_m^{1/2}}{\sqrt{\pi}} - 0.50 Fo_m - \frac{0.65}{2} Fo_m^2 \right)\end{aligned}$$

At 1 hour and 10 hours,  $Fo_m = 0.00415$  and  $0.0415$ , respectively. Then with  $C_{A,s} = 0.0830$  kmol/m<sup>3</sup> and  $C_{A,i} = 0$ , we find,

$$\text{For } t = 1 \text{ hr, } \bar{C}_A = 0.0117 \text{ kmol/m}^3, \quad \Delta n = 1.9 \times 10^{-5} \quad <$$

$$\text{For } t = 10 \text{ hr, } \bar{C}_A = 0.0346 \text{ kmol/m}^3, \quad \Delta n = 5.5 \times 10^{-5} \quad <$$

**COMMENTS:** (1) Hydrogen diffusion into glass optical fibers is highly undesirable because of the effects described in the problem statement. Hermetic coatings are typically applied to the fibers to prevent diffusion of hydrogen and other unwanted species into the glass. (2) At  $t = 100$

hours,  $\gamma_0^* = \frac{C_A(0,t) - C_{A,s}}{C_{A,i} - C_{A,s}} = 0.145$ . This tells us that the centerline concentration is within

14.5% of reaching the surface concentration. At the same time, the *average* molar concentration is 93.7% of the surface concentration, i.e. within 6.3% of reaching the surface concentration. This is because of the radial geometry, which has greater volume near the surface than near the centerline.

## PROBLEM 14.55

**KNOWN:** Diameters of glass optical fiber and acrylate polymer coating. Mass diffusivity of water vapor in the acrylate.

**FIND:** Whether microcracking would occur within several hot and humid days.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) One-dimensional mass diffusion. (2) Use of acrylate properties throughout the cylinder is sufficient for estimating the diffusion process in order to answer the question.

**PROPERTIES:** Water vapor in acrylate polymer (given):  $D_{AB} = 5.5 \times 10^{-13} \text{ m}^2/\text{s}$ .

**ANALYSIS:** We arbitrarily begin by considering a two-day period. Then the mass transfer Fourier number is,

$$Fo_m = D_{AB}t/r_o^2 = 5.5 \times 10^{-13} \text{ m}^2/\text{s} \times 48 \text{ h} \times 3600 \text{ s/h} / (125 \times 10^{-6} \text{ m})^2 = 6.1$$

Since  $Fo_m > 0.2$ , we can use the one-term approximation, analogous to Eq. 5.49a. Referring to Table 14.3 for the analogies,

$$\gamma^* = \frac{C_A(r, t) - C_{A,s}}{C_{A,i} - C_{A,s}} = C_1 \exp(-\zeta_1^2 Fo_m) J_0(\zeta_1 r^*) \quad (1)$$

where from Table 5.1, as  $Bi \rightarrow \infty$ ,  $\zeta_1 = 2.4050$ ,  $C_1 = 1.6018$ . At the outer surface of the glass,  $r^* = 0.5$  and from Table B.4,  $J_0(2.4050 \times 0.5) \approx J_0(1.2) \approx 0.67$ . Thus

$$\gamma^* = 1.6018 \exp(-2.4050^2 \times 6.1) \times 0.67 = 5.6 \times 10^{-16}$$

Referring to the definition of  $\gamma^*$  in Eq. (1), we see that this very small value means that the concentration has essentially already reached the surface concentration. Therefore, careful storage of the optical fiber will not prevent microcracking, since within two days (probably much less), the water vapor has penetrated through the acrylate polymer coating. <

**COMMENTS:** (1) Equation 5.52 assumes uniform properties throughout the cylinder. Since the glass is impermeable to moisture, the build-up of moisture in the coating would be even more rapid than this equation predicts. (2) The time required for the concentration to be within 5% of the surface concentration ( $\gamma^* = 0.05$ ) is around four hours. (3) Development of *hermetic coatings* for use in fiber optic and other high technology applications is an ongoing area of research.

## PROBLEM 14.56

**KNOWN:** Mass of insect repellent applied to known area of skin. Convective mass transfer coefficient, partition coefficient at the ingredient – skin interface, mass diffusivity of the ingredient in the skin.

**FIND:** (a) Initial thickness of the active ingredient, (b) Duration of effective treatment, (c) Duration of effective treatment with use of reformulated repellent with a very small partition coefficient.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Constant properties and steady-state conditions, (2) Stationary medium. (3) Skin is semi-infinite medium.

**PROPERTIES:** Active Ingredient, given:  $\rho_A = 2000 \text{ kg/m}^3$ ,  $\mathcal{M}_A = 152 \text{ kg/kmol}$ ,  $p_{A,\text{sat}} = 1.2 \times 10^{-5} \text{ bars}$ ,  $K$  (active Ingredient-skin interface) = 0.05,  $D_{AB}$  (active ingredient in skin) =  $1 \times 10^{-13} \text{ m}^2/\text{s}$ .

**ANALYSIS:**

(a) For an active ingredient volume fraction of  $f = 0.25$ , the initial thickness of the active ingredient is

$$L(t=0) = \frac{fM}{\rho_A A} = \frac{0.25 \times 10 \times 10^{-3} \text{ kg}}{2000 \frac{\text{kg}}{\text{m}^3} \times 0.5 \text{ m}^2} = 2.5 \times 10^{-6} \text{ m} = 2.5 \mu\text{m} \quad <$$

(b) The duration of the effective treatment is associated with the complete depletion of the active ingredient through combined evaporation and absorption. For absorption of the ingredient into the skin, the analogy to Eq. 5.61 may be employed to provide

$$L(t=0) = \frac{1}{\rho_A} \left[ \int_0^t n''_{A,\text{conv}} dt + \int_0^t n''_{A,\text{dif}} dt \right] = \frac{1}{\rho_A} \left[ \int_0^t h_m (\rho_{A,s,c} - \rho_{A,\infty}) dt + \int_0^t \frac{\sqrt{D_{AB}}}{\sqrt{\pi t}} (\rho_{A,s,D} - \rho_{A,i}) dt \right]$$

Continued...

### PROBLEM 14.56 (Cont.)

Noting that  $\rho_{A,\infty} = \rho_{A,i} = 0$  and  $\rho_{A,s,D} = K\rho_A$ , the integrations may be carried out to yield

$$L(t=0) = \frac{1}{\rho_A} \left[ \bar{h}_m (\rho_{A,s,c}) t \right] + 2 \frac{\sqrt{D_{AB} K}}{\sqrt{\pi}} \sqrt{t}$$

The surface concentration of the active ingredient is

$$\rho_{A,s,c} = \frac{p_{A,\text{sat}}(T_s)}{(\mathcal{R}/M_A)T_s} = \frac{1.2 \times 10^{-5} \text{ bar}}{(8.314 \times 10^{-2} \text{ m}^3 \cdot \text{bar}/\text{kmol} \cdot \text{K}/152 \text{ kmol}/\text{kg}) \times (273 + 32)\text{K}} = 71.9 \times 10^{-6} \text{ kg}/\text{m}^3$$

Substituting the values of  $L(t=0)$ ,  $\rho_{A,s,c}$ , and the quantities given in the problem statement, the preceding equation may be solved to yield

$$t = 6130 \text{ s or } 1.7 \text{ h} \quad <$$

(c) Setting  $K = 0$ , the preceding equation may be solved again to yield

$$t = 13900 \text{ s or } 3.9 \text{ h} \quad <$$

**COMMENT:** In part (b), convective losses are 43% of the total loss, while losses due to diffusion into the skin are 57%.

### PROBLEM 4S.1

**KNOWN:** Long furnace of refractory brick with prescribed surface temperatures and material thermal conductivity.

**FIND:** Shape factor and heat transfer rate per unit length using the flux plot method

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Furnace length normal to page,  $\ell$ ,  $\gg$  cross-sectional dimensions, (2) Two-dimensional, steady-state conduction, (3) Constant properties.

**ANALYSIS:** Considering the cross-section, the cross-hatched area represents a symmetrical element. Hence, the heat rate for the entire furnace per unit length is

$$q' = \frac{q}{\ell} = 4 \frac{S}{\ell} k (T_1 - T_2) \quad (1)$$

where  $S$  is the shape factor for the symmetrical section. Selecting three temperature increments ( $N = 3$ ), construct the flux plot shown below.

From Equation 4S.7,  $S = \frac{M\ell}{N}$  or  $\frac{S}{\ell} = \frac{M}{N} = \frac{8.5}{3} = 2.83$  <

and from Equation (1),  $q' = 4 \times 2.83 \times 1.2 \frac{\text{W}}{\text{m} \cdot \text{K}} (600 - 60)^\circ \text{C} = 7.34 \text{ kW/m}$ . <

**COMMENTS:** The shape factor can also be estimated from the relations of Table 4.1. The symmetrical section consists of two plane walls (horizontal and vertical) with an adjoining edge. Using the appropriate relations, the numerical values are, in the same order,

$$S = \frac{0.75\text{m}}{0.5\text{m}} \ell + 0.54\ell + \frac{0.5\text{m}}{0.5\text{m}} \ell = 3.04\ell$$

Note that this result compares favorably with the flux plot result of  $2.83\ell$ .

### PROBLEM 4S.2

**KNOWN:** Hot pipe embedded eccentrically in a circular system having a prescribed thermal conductivity.

**FIND:** The shape factor and heat transfer per unit length for the prescribed surface temperatures.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Two-dimensional conduction, (2) Steady-state conditions, (3) Length  $l \gg$  diametrical dimensions.

**ANALYSIS:** Considering the cross-sectional view of the pipe system, the symmetrical section shown above is readily identified. Selecting four temperature increments ( $N = 4$ ), construct the flux plot shown below.

For the pipe system, the heat rate per unit length is

$$q' = \frac{q}{l} = kS(T_1 - T_2) = 0.5 \frac{\text{W}}{\text{m}\cdot\text{K}} \times 4.26(150 - 35)^\circ\text{C} = 245 \text{ W/m.} \quad <$$

**COMMENTS:** Note that in the lower, right-hand quadrant of the flux plot, the curvilinear squares are irregular. Further work is required to obtain an improved plot and, hence, obtain a more accurate estimate of the shape factor.

### PROBLEM 4S.3

**KNOWN:** Structural member with known thermal conductivity subjected to a temperature difference.

**FIND:** (a) Temperature at a prescribed point P, (b) Heat transfer per unit length of the strut, (c) Sketch the 25, 50 and 75°C isotherms, and (d) Same analysis on the shape but with adiabatic-isothermal boundary conditions reversed.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Two-dimensional conduction, (2) Steady-state conditions, (3) Constant properties.

**ANALYSIS:** (a) When constructing the flux plot, note that the line of symmetry which passes through the point P is an isotherm as shown above. It follows that

$$T(P) = (T_1 + T_2)/2 = (100 + 0)^\circ \text{C} / 2 = 50^\circ \text{C}. \quad \leftarrow$$

(b) The flux plot on the symmetrical section is now constructed to obtain the shape factor from which the heat rate is determined. That is, from Equation 4S.6 and 4S.7,

$$q = kS(T_1 - T_2) \quad \text{and} \quad S = M\ell/N. \quad (1,2)$$

From the plot of the symmetrical section,

$$S_0 = 4.2\ell/4 = 1.05\ell.$$

For the full section of the strut,

$$M = M_0 = 4.2$$

but  $N = 2N_0 = 8$ . Hence,

$$S = S_0/2 = 0.53\ell$$

and with  $q' = q/\ell$ , giving

$$q'/\ell = 75 \text{ W/m} \cdot \text{K} \times 0.53(100 - 0)^\circ \text{C} = 3975 \text{ W/m}. \quad \leftarrow$$

(c) The isotherms for  $T = 50, 75$  and  $100^\circ\text{C}$  are shown on the flux plot. The  $T = 25^\circ\text{C}$  isotherm is symmetric with the  $T = 75^\circ\text{C}$  isotherm.

(d) By reversing the adiabatic and isothermal boundary conditions, the two-dimensional shape appears as shown in the sketch below. The symmetrical element to be flux plotted is the same as for the strut, except the symmetry line is now an adiabat.

Continued...

**PROBLEM 4S.3 (Cont.)**

From the flux plot, find  $M_o = 3.4$  and  $N_o = 4$ , and from Equation (2)

$$S_o = M_o \ell / N_o = 3.4 \ell / 4 = 0.85 \ell \quad S = 2S_o = 1.70 \ell$$

and the heat rate per unit length from Equation (1) is

$$q' = 75 \text{ W/m} \cdot \text{K} \times 1.70 (100 - 0)^\circ \text{C} = 12,750 \text{ W/m} \quad <$$

From the flux plot, estimate that

$$T(P) \approx 40^\circ \text{C}. \quad <$$

**COMMENTS:** (1) By inspection of the shapes for parts (a) and (b), it is obvious that the heat rate for the latter will be greater. The calculations show the heat rate is greater by more than a factor of three.

(2) By comparing the flux plots for the two configurations, and corresponding roles of the adiabats and isotherms, would you expect the shape factor for parts (a) to be the reciprocal of part (b)?

**PROBLEM 4S.4**

**KNOWN:** Relative dimensions and surface thermal conditions of a V-grooved channel.

**FIND:** Flux plot and shape factor.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Two-dimensional conduction, (2) Steady-state conditions, (3) Constant properties.

**ANALYSIS:** With symmetry about the midplane, only one-half of the object need be considered as shown below.

Choosing 6 temperature increments ( $N = 6$ ), it follows from the plot that  $M \approx 7$ . Hence from Equation 4S.7, the shape factor for the half section is

$$S = \frac{M}{N} \ell = \frac{7}{6} \ell = 1.17\ell.$$

For the complete system, the shape factor is then

$$S = 2.34\ell.$$

<

## PROBLEM 4S.5

**KNOWN:** Long conduit of inner circular cross section and outer surfaces of square cross section.

**FIND:** Shape factor and heat rate for the two applications when outer surfaces are insulated or maintained at a uniform temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Two-dimensional, steady-state conduction, (2) Constant properties and (3) Conduit is very long.

**ANALYSIS:** The adiabatic symmetry lines for each of the applications is shown above. Using the flux plot methodology and selecting four temperature increments ( $N = 4$ ), the flux plots are as shown below.

For the symmetrical sections,  $S = 2S_o$ , where  $S_o = M \ell / N$  and the heat rate for each application is  $q = 2(S_o / \ell)k(T_1 - T_2)$ .

Application	M	N	$S_o / \ell$	$q'$ (W/m)	
A	10.3	4	2.58	11,588	<
B	6.2	4	1.55	6,975	<

**COMMENTS:** (1) For application A, most of the heat lanes leave the inner surface ( $T_1$ ) on the upper portion.

(2) For application B, most of the heat flow lanes leave the inner surface on the upper portion (that is, lanes 1-4). Because the lower, right-hand corner is insulated, the entire section experiences small heat flows (lane 6 + 0.2). Note the shapes of the isotherms near the right-hand, insulated boundary and that they intersect the boundary normally.

### PROBLEM 4S.6

**KNOWN:** Shape and surface conditions of a support column.

**FIND:** (a) Heat transfer rate per unit length. (b) Height of a rectangular bar of equivalent thermal resistance.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Negligible three-dimensional conduction effects, (3) Constant properties, (4) Adiabatic sides.

**PROPERTIES:** Table A-1, Steel, AISI 1010 (323K):  $k = 62.7 \text{ W/m}\cdot\text{K}$ .

**ANALYSIS:** (a) From the flux plot for the half section,  $M \approx 5$  and  $N \approx 8$ . Hence for the full section

$$S = 2 \frac{M\ell}{N} \approx 1.25\ell$$

$$q = Sk(T_1 - T_2)$$

$$q' \approx 1.25 \times 62.7 \frac{\text{W}}{\text{m}\cdot\text{K}} (100 - 0)^\circ\text{C}$$

$$q' \approx 7.8 \text{ kW/m.} \quad <$$

(b) The rectangular bar provides for one-dimensional heat transfer. Hence,

$$q = k A \frac{(T_1 - T_2)}{H} = k(0.3\ell) \frac{(T_1 - T_2)}{H}$$

Hence, 
$$H = \frac{0.3k(T_1 - T_2)}{q'} = \frac{0.3\text{m}(62.7 \text{ W/m}\cdot\text{K})(100^\circ\text{C})}{7800 \text{ W/m}} = 0.24\text{m.} \quad <$$

**COMMENTS:** The fact that  $H < 0.3\text{m}$  is consistent with the requirement that the thermal resistance of the trapezoidal column must be less than that of a rectangular bar of the same height and top width (because the width of the trapezoidal column increases with increasing distance,  $x$ , from the top). Hence, if the rectangular bar is to be of equivalent resistance, it must be of smaller height.

### PROBLEM 4S.7

**KNOWN:** Hollow prismatic bars fabricated from plain carbon steel, 1m in length with prescribed temperature difference.

**FIND:** Shape factors and heat rate per unit length.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Two-dimensional conduction, (3) Constant properties.

**PROPERTIES:** Table A-1, Steel, Plain Carbon (400K),  $k = 57 \text{ W/m}\cdot\text{K}$ .

**ANALYSIS:** Construct a flux plot on the symmetrical sections (shaded-regions) of each of the bars.

The shape factors for the symmetrical sections are,

$$S_{o,A} = \frac{M\ell}{N} = \frac{4}{4}\ell = 1\ell \quad S_{o,B} = \frac{M\ell}{N} = \frac{3.5}{4}\ell = 0.88\ell.$$

Since each of these sections is  $\frac{1}{4}$  of the bar cross-section, it follows that

$$S_A = 4 \times 1\ell = 4\ell \quad S_B = 4 \times 0.88\ell = 3.5\ell. \quad <$$

The heat rate per unit length is  $q' = q/\ell = k(S/\ell)(T_1 - T_2)$ ,

$$q'_A = 57 \frac{\text{W}}{\text{m}\cdot\text{K}} \times 4(500 - 300) \text{ K} = 45.6 \text{ kW/m} \quad <$$

$$q'_B = 57 \frac{\text{W}}{\text{m}\cdot\text{K}} \times 3.5(500 - 300) \text{ K} = 39.9 \text{ kW/m}. \quad <$$

## PROBLEM 4S.8

**KNOWN:** Two-dimensional, square shapes, 1 m to a side, maintained at uniform temperatures as prescribed, perfectly insulated elsewhere.

**FIND:** Using the flux plot method, estimate the heat rate per unit length normal to the page if the thermal conductivity is 50 W/m·K

**ASSUMPTIONS:** (1) Steady-state, two-dimensional conduction, (2) Constant properties.

**ANALYSIS:** Use the methodology of Section 4S.1 to construct the flux plots to obtain the shape factors from which the heat rates can be calculated. With Figure (a), begin at the lower-left side making the isotherms almost equally spaced, since the heat flow will only slightly spread toward the right. Start sketching the adiabats in the vicinity of the  $T_2$  surface. The dashed line represents the adiabat which separates the shape into two segments. Having recognized this feature, it was convenient to identify partial heat lanes. Figure (b) is less difficult to analyze since the isotherm intervals are nearly regular in the lower left-hand corner.

The shape factors are calculated from Equation 4S.7 and the heat rate from Equation 4S.6.

$$S' = \frac{M}{N} = \frac{0.5 + 3 + 0.5 + 0.5 + 0.2}{6}$$

$$S' = \frac{M}{N} = \frac{4.5}{5} = 0.90$$

$$S' = 0.70$$

$$q' = kS'(T_1 - T_2)$$

$$q' = kS'(T_1 - T_2)$$

$$q' = 50 \text{ W/m} \cdot \text{K} \times 0.70(100 - 0) \text{ K} = 3500 \text{ W/m} \quad q' = 50 \text{ W/m} \cdot \text{K} \times 0.90(100 - 0) \text{ K} = 4500 \text{ W/m} \quad <$$

**COMMENTS:** Using a finite-element package with a fine mesh, we determined heat rates of 4780 and 4575 W/m, respectively, for Figures (a) and (b). The estimate for the less difficult Figure (b) is within 2% of the numerical method result. For Figure (a), our flux plot result was 27% low.

### PROBLEM 5S.1

**KNOWN:** Configuration, initial temperature and charging conditions of a thermal energy storage unit.

**FIND:** Time required to achieve 75% of maximum possible energy storage and corresponding minimum and maximum temperatures.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) One-dimensional conduction, (2) Constant properties, (3) Negligible radiation exchange with surroundings.

**ANALYSIS:** For the system, find first

$$Bi = \frac{hL}{k} = \frac{100 \text{ W/m}^2 \cdot \text{K} \times 0.025 \text{ m}}{0.7 \text{ W/m} \cdot \text{K}} = 3.57$$

indicating that the lumped capacitance method cannot be used.

*Groeber chart, Fig. 5S.3:*  $Q/Q_o = 0.75$

$$\alpha = \frac{k}{\rho c} = \frac{0.7 \text{ W/m} \cdot \text{K}}{1900 \text{ kg/m}^3 \times 800 \text{ J/kg} \cdot \text{K}} = 4.605 \times 10^{-7} \text{ m}^2/\text{s}$$

$$Bi^2 Fo = \frac{h^2 \alpha t}{k^2} = \frac{(100 \text{ W/m}^2 \cdot \text{K})^2 \times (4.605 \times 10^{-7} \text{ m}^2/\text{s}) \times t(\text{s})}{(0.7 \text{ W/m} \cdot \text{K})^2} = 9.4 \times 10^{-3} t$$

Find  $Bi^2 Fo \approx 11$ , and substituting numerical values

$$t = 11/9.4 \times 10^{-3} = 1170 \text{ s.} \quad <$$

*Heisler chart, Fig. 5S.1:*  $T_{\min}$  is at  $x = 0$  and  $T_{\max}$  at  $x = L$ , with

$$Fo = \frac{\alpha t}{L^2} = \frac{4.605 \times 10^{-7} \text{ m}^2/\text{s} \times 1170 \text{ s}}{(0.025 \text{ m})^2} = 0.86 \quad Bi^{-1} = 0.28.$$

From Fig. 5S.1,  $\theta_o^* \approx 0.33$ . Hence,

$$T_o \approx T_{\infty} + 0.33(T_i - T_{\infty}) = 600^\circ \text{C} + 0.33(-575^\circ \text{C}) = 410^\circ \text{C} = T_{\min}. \quad <$$

From Fig. 5S.2,  $\theta/\theta_o \approx 0.33$  at  $x = L$ , for which

$$T_{x=L} \approx T_{\infty} + 0.33(T_o - T_{\infty}) = 600^\circ \text{C} + 0.33(-190)^\circ \text{C} = 537^\circ \text{C} = T_{\max}. \quad <$$

**COMMENTS:** Comparing masonry (m) with aluminum (Al), see Problem 5.16,  $(\rho c)_{Al} > (\rho c)_m$  and  $k_{Al} > k_m$ . Hence, the aluminum can store more energy and can be charged (or discharged) more quickly.

## PROBLEM 5S.2

**KNOWN:** Car windshield, initially at a uniform temperature of  $-20^{\circ}\text{C}$ , is suddenly exposed on its interior surface to the defrost system airstream at  $30^{\circ}\text{C}$ . The ice layer on the exterior surface acts as an insulating layer.

**FIND:** What airstream convection coefficient would allow the exterior surface to reach  $0^{\circ}\text{C}$  in 60 s?

**SCHEMATIC:**

**ASSUMPTIONS:** (1) One-dimensional, transient conduction in the windshield, (2) Constant properties, (3) Exterior surface is perfectly insulated.

**PROPERTIES:** Windshield (Given):  $\rho = 2200\text{ kg/m}^3$ ,  $c_p = 830\text{ J/kg}\cdot\text{K}$  and  $k = 1.2\text{ W/m}\cdot\text{K}$ .

**ANALYSIS:** For the prescribed conditions, from Equations 5.34 and 5.36,

$$\frac{\theta(0, 60\text{s})}{\theta_i} = \frac{\theta_o}{\theta_i} = \frac{T(0, 60\text{s}) - T_{\infty}}{T_i - T_{\infty}} = \frac{(0 - 30)^{\circ}\text{C}}{(-20 - 30)^{\circ}\text{C}} = 0.6$$

$$Fo = \frac{kt}{\rho cL^2} = \frac{1.2\text{ W/m}\cdot\text{K} \times 60}{2200\text{ kg/m}^3 \times 830\text{ J/kg}\cdot\text{K} \times (0.005\text{ m})^2} = 1.58$$

The single-term series approximation, Eq. 5.44, along with Table 5.1, requires an iterative solution to find an appropriate Biot number. Alternatively, the Heisler charts, Section 5S.1, Figure 5S.1, for the midplane temperature could be used to find

$$Bi^{-1} = k/hL = 2.5$$

$$h = 1.2\text{ W/m}\cdot\text{K} / 2.5 \times 0.005\text{ m} = 96\text{ W/m}^2\cdot\text{K} \quad <$$

**COMMENTS:** Using the *IHT, Transient Conduction, Plane Wall Model*, the convection coefficient can be determined by solving the model with an assumed  $h$  and then sweeping over a range of  $h$  until the  $T(0, 60\text{s})$  condition is satisfied. Since the model is based upon multiple terms of the series, the result of  $h = 99\text{ W/m}^2\cdot\text{K}$  is more precise than that found using the chart.

### PROBLEM 5S.3

**KNOWN:** Inlet and outlet temperatures of steel rods heat treated by passage through an oven.

**FIND:** Rod speed,  $V$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) One-dimensional radial conduction (axial conduction is negligible), (2) Constant properties, (3) Negligible radiation.

**PROPERTIES:** Table A-1, AISI 1010 Steel ( $\bar{T} \approx 600\text{K}$ ):  $k = 48.8 \text{ W/m}\cdot\text{K}$ ,  $\rho = 7832 \text{ kg/m}^3$ ,  $c_p = 559 \text{ J/kg}\cdot\text{K}$ ,  $\alpha = (k/\rho c_p) = 1.11 \times 10^{-5} \text{ m}^2/\text{s}$ .

**ANALYSIS:** The time needed to traverse the rod through the oven may be found from Figure 5S.4.

$$\theta_o^* = \frac{T_o - T_\infty}{T_i - T_\infty} = \frac{600 - 750}{50 - 750} = 0.214$$

$$\text{Bi}^{-1} = \frac{k}{h r_o} = \frac{48.8 \text{ W/m}\cdot\text{K}}{125 \text{ W/m}^2\cdot\text{K} (0.025\text{m})} = 15.6.$$

Hence,

$$\text{Fo} = \alpha t/r_o^2 \approx 12.2$$

$$t = 12.2(0.025\text{m})^2 / 1.11 \times 10^{-5} \text{ m}^2/\text{s} = 687 \text{ s}.$$

The rod velocity is

$$V = \frac{L}{t} = \frac{5\text{m}}{687\text{s}} = 0.0073 \text{ m/s}.$$

**COMMENTS:** (1) Since  $(h r_o/2)/k = 0.032$ , the lumped capacitance method could have been used. From Equation 5.5 it follows that  $t = 675 \text{ s}$ .

(2) Radiation effects decrease  $t$  and hence increase  $V$ , assuming there is net radiant transfer from the oven walls to the rod.

(3) Since  $\text{Fo} > 0.2$ , the approximate analytical solution may be used. With  $\text{Bi} = h r_o/k = 0.0641$ , Table 5.1 yields  $\zeta_1 = 0.3549 \text{ rad}$  and  $C_1 = 1.0158$ . Hence from Equation 5.52c

$$\text{Fo} = -\left(\zeta_1^2\right)^{-1} \ln \left[ \frac{\theta_o^*}{C_1} \right] = 12.4,$$

which is in good agreement with the graphical result.

### PROBLEM 5S.4

**KNOWN:** Hot dog with prescribed thermophysical properties, initially at  $6^\circ\text{C}$ , is immersed in boiling water.

**FIND:** Time required to bring centerline temperature to  $80^\circ\text{C}$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Hot dog can be treated as infinite cylinder, (2) Constant properties.

**ANALYSIS:** The Biot number, based upon Equation 5.10, is

$$\text{Bi} \equiv \frac{h L_c}{k} = \frac{h r_o / 2}{k} = \frac{100 \text{ W/m}^2 \cdot \text{K} (10 \times 10^{-3} \text{ m} / 2)}{0.52 \text{ W/m} \cdot \text{K}} = 0.96$$

Since  $\text{Bi} > 0.1$ , a lumped capacitance analysis is not appropriate. Using the Heisler chart, Figure 5S.4 with

$$\text{Bi} \equiv \frac{h r_o}{k} = \frac{100 \text{ W/m}^2 \cdot \text{K} \times 10 \times 10^{-3} \text{ m}}{0.52 \text{ W/m} \cdot \text{K}} = 1.92 \quad \text{or} \quad \text{Bi}^{-1} = 0.52$$

and 
$$\theta_o^* = \frac{\theta_o}{\theta_i} = \frac{T(0, t) - T_\infty}{T_i - T_\infty} = \frac{(80 - 100)^\circ\text{C}}{(6 - 100)^\circ\text{C}} = 0.21 \quad (1)$$

find 
$$\text{Fo} = t^* = \frac{\alpha t}{r_o^2} = 0.8 \quad t = \frac{r_o^2}{\alpha} \cdot \text{Fo} = \frac{(10 \times 10^{-3} \text{ m})^2}{1.764 \times 10^{-7} \text{ m}^2/\text{s}} \times 0.8 = 453.5 \text{ s} = 7.6 \text{ min} <$$

where 
$$\alpha = k / \rho c = 0.52 \text{ W/m} \cdot \text{K} / 880 \text{ kg/m}^3 \times 3350 \text{ J/kg} \cdot \text{K} = 1.764 \times 10^{-7} \text{ m}^2/\text{s}.$$

**COMMENTS:** (1) Note that  $L_c = r_o/2$  when evaluating the Biot number for the lumped capacitance analysis; however, in the Heisler charts,  $\text{Bi} \equiv h r_o/k$ .

(2) The surface temperature of the hot dog follows from use of Figure 5S.5 with  $r/r_o = 1$  and  $\text{Bi}^{-1} = 0.52$ ; find  $\theta(1, t)/\theta_o \approx 0.45$ . From Equation (1), note that  $\theta_o = 0.21 \theta_i$  giving

$$\theta(1, t) = T(r_o, t) - T_\infty = 0.45 \theta_o = 0.45 (0.21 [T_i - T_\infty]) = 0.45 \times 0.21 [6 - 100]^\circ\text{C} = -8.9^\circ\text{C}$$

$$T(r_o, t) = T_\infty - 8.9^\circ\text{C} = (100 - 8.9)^\circ\text{C} = 91.1^\circ\text{C}$$

(3) Since  $\text{Fo} \geq 0.2$ , the approximate solution for  $\theta^*$ , Equation 5.52, is valid. From Table 5.1 with  $\text{Bi} = 1.92$ , find that  $\zeta_1 = 1.3245$  rad and  $C_1 = 1.2334$ . Rearranging Equation 5.52 and substituting values,

$$\text{Fo} = -\frac{1}{\zeta_1^2} \ln \left( \theta_o^* / C_1 \right) = \frac{1}{(1.3245 \text{ rad})^2} \ln \left[ \frac{0.213}{1.2334} \right] = 1.00$$

This result leads to a value of  $t = 9.5$  min or 20% higher than that of the graphical method.

### PROBLEM 5S.5

**KNOWN:** Long bar of 70 mm diameter, initially at 90°C, is suddenly immersed in a water bath ( $T_\infty = 40^\circ\text{C}$ ,  $h = 20 \text{ W/m}^2\cdot\text{K}$ ).

**FIND:** (a) Time,  $t_f$ , that bar should remain in bath in order that, when removed and allowed to equilibrate while isolated from surroundings, it will have a uniform temperature  $T(r, \infty) = 55^\circ\text{C}$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) One-dimensional radial conduction, (2) Constant properties.

**PROPERTIES:** Bar (given):  $\rho = 2600 \text{ kg/m}^3$ ,  $c = 1030 \text{ J/kg}\cdot\text{K}$ ,  $k = 3.50 \text{ W/m}\cdot\text{K}$ ,  $\alpha = k/\rho c = 1.31 \times 10^{-6} \text{ m}^2/\text{s}$ .

**ANALYSIS:** Determine first whether conditions are space-wise isothermal

$$\text{Bi} = \frac{hL_c}{k} = \frac{h(r_o/2)}{k} = \frac{20 \text{ W/m}^2\cdot\text{K} \cdot (0.035 \text{ m}/2)}{3.50 \text{ W/m}\cdot\text{K}} = 0.10$$

and since  $\text{Bi} \geq 0.1$ , a Heisler solution is appropriate.

(a) Consider an overall energy balance on the bar during the time interval  $\Delta t = t_f$  (the time the bar is in the bath).

$$E_{\text{in}} - E_{\text{out}} = \Delta E$$

$$0 - Q = E_{\text{final}} - E_{\text{initial}} = Mc(T_f - T_\infty) - Mc(T_i - T_\infty)$$

$$-Q = Mc(T_f - T_\infty) - Q_o$$

$$\frac{Q}{Q_o} = 1 - \frac{T_f - T_\infty}{T_i - T_\infty} = 1 - \frac{(55 - 40)^\circ\text{C}}{(90 - 40)^\circ\text{C}} = 0.70$$

where  $Q_o$  is the initial energy in the bar (relative to  $T_\infty$ ; Equation 5.44). With  $\text{Bi} = hr_o/k = 0.20$  and  $Q/Q_o = 0.70$ , use Figure 5S.6 to find  $\text{Bi}^2\text{Fo} = 0.15$ ; hence  $\text{Fo} = 0.15/\text{Bi}^2 = 3.75$  and

$$t_f = \text{Fo} \cdot r_o^2 / \alpha = 3.75 (0.035 \text{ m})^2 / 1.31 \times 10^{-6} \text{ m}^2/\text{s} = 3507 \text{ s.} \quad <$$

(b) To determine  $T(r_o, t_f)$ , use Figures 5S.4 and 5S.5 for  $\theta(r_o, t)/\theta_i$  ( $\text{Fo} = 3.75$ ,  $\text{Bi}^{-1} = 5.0$ ) and  $\theta_o/\theta_i$  ( $\text{Bi}^{-1} = 5.0$ ,  $r/r_o = 1$ , respectively, to find

$$T(r_o, t_f) = T_\infty + \frac{\theta(r_o, t)}{\theta_o} \cdot \frac{\theta_o}{\theta_i} \cdot \theta_i = 40^\circ\text{C} + 0.25 \times 0.90 (90 - 40)^\circ\text{C} = 51^\circ\text{C.} \quad <$$

### PROBLEM 5S.6

**KNOWN:** An 80 mm sphere, initially at a uniform elevated temperature, is quenched in an oil bath with prescribed  $T_\infty$ ,  $h$ .

**FIND:** The center temperature of the sphere,  $T(0,t)$  at a certain time when the surface temperature is  $T(r_o,t) = 150^\circ\text{C}$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) One-dimensional radial conduction, (2) Initial uniform temperature within sphere, (3) Constant properties, (4)  $Fo \geq 0.2$ .

**ANALYSIS:** Check first to see if the sphere is spacewise isothermal.

$$Bi_c = \frac{hL_c}{k} = \frac{h(r_o/3)}{k} = \frac{1000 \text{ W/m}^2 \cdot \text{K} \times 0.040 \text{ m}/3}{50 \text{ W/m} \cdot \text{K}} = 0.26.$$

Since  $Bi_c > 0.1$ , lumped capacitance method is not appropriate. Recognize that when  $Fo \geq 0.2$ , the time dependence of the temperature at any point within the sphere will be the same as the center. Using the Heisler chart method, Figure 5S.8 provides the relation between  $T(r_o, t)$  and  $T(0, t)$ . Find first the Biot number,

$$Bi = \frac{hr_o}{k} = \frac{1000 \text{ W/m}^2 \cdot \text{K} \times 0.040 \text{ m}}{50 \text{ W/m} \cdot \text{K}} = 0.80.$$

With  $Bi^{-1} = 1/0.80 = 1.25$  and  $r/r_o = 1$ , read from Figure 5S.8,

$$\frac{\theta}{\theta_o} = \frac{T(r_o, t) - T_\infty}{T(0, t) - T_\infty} = 0.67.$$

It follows that

$$T(0, t) = T_\infty + \frac{1}{0.67} [T(r_o, t) - T_\infty] = 50^\circ\text{C} + \frac{1}{0.67} [150 - 50]^\circ\text{C} = 199^\circ\text{C}. \quad <$$

**COMMENTS:** (1) There is sufficient information to evaluate  $Fo$ ; hence, we require that the time be sufficiently long after the start of quenching for this solution to be appropriate.

(2) The approximate series solution could also be used to obtain  $T(0, t)$ . For  $Bi = 0.80$  from Table 5.1,  $\zeta_1 = 1.5044$  rad. Substituting numerical values,  $r^* = 1$ ,

$$\frac{\theta^*}{\theta_o^*} = \frac{T(r_o, t) - T_\infty}{T(0, t) - T_\infty} = \frac{1}{\zeta_1 r^*} \sin(\zeta_1 r^*) = \frac{1}{1.5044} \sin(1.5044 \text{ rad}) = 0.663.$$

It follows that  $T(0, t) = 201^\circ\text{C}$ .

**PROBLEM 5S.7**

**KNOWN:** Diameter and initial temperature of hailstone falling through warm air.

**FIND:** (a) Time,  $t_m$ , required for outer surface to reach melting point,  $T(r_o, t_m) = T_m = 0^\circ\text{C}$ ,  
 (b) Centerpoint temperature at that time, (c) Energy transferred to the stone.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) One-dimensional radial conduction, (2) Constant properties.

**PROPERTIES:** Table A-3, Ice (253K):  $\rho = 920 \text{ kg/m}^3$ ,  $k = 2.03 \text{ W/m}\cdot\text{K}$ ,  $c_p = 1945 \text{ J/kg}\cdot\text{K}$ ;  
 $\alpha = k/\rho c_p = 1.13 \times 10^{-6} \text{ m}^2/\text{s}$ .

**ANALYSIS:** (a) Calculate the lumped capacitance Biot number,

$$Bi = \frac{h(r_o/3)}{k} = \frac{250 \text{ W/m}^2 \cdot \text{K} (0.0025\text{m}/3)}{2.03 \text{ W/m}\cdot\text{K}} = 0.103.$$

Since  $Bi > 0.1$ , use the Heisler charts for which

$$\frac{\theta(r_o, t_m)}{\theta_i} = \frac{T(r_o, t_m) - T_\infty}{T_i - T_\infty} = \frac{0 - 5}{-30 - 5} = 0.143$$

$$Bi^{-1} = \frac{k}{hr_o} = \frac{2.03 \text{ W/m}\cdot\text{K}}{250 \text{ W/m}^2 \cdot \text{K} \times 0.0025\text{m}} = 3.25.$$

From Figure 5S.8, find  $\frac{\theta(r_o, t_m)}{\theta_o(t_m)} \approx 0.86$ .

It follows that  $\frac{\theta_o(t_m)}{\theta_i} = \frac{\theta(r_o, t_m)/\theta_i}{\theta(r_o, t_m)/\theta_o(t_m)} \approx \frac{0.143}{0.86} \approx 0.17$ .

From Figure 5S.7 find  $Fo \approx 2.1$ . Hence,

$$t_m \approx \frac{Fo r_o^2}{\alpha} = \frac{2.1(0.0025)^2}{1.13 \times 10^{-6} \text{ m}^2/\text{s}} = 12\text{s}. \quad <$$

(b) Since  $(\theta_o/\theta_i) \approx 0.17$ , find

$$T_o - T_\infty \approx 0.17(T_i - T_\infty) \approx 0.17(-30 - 5) \approx -6.0^\circ\text{C}$$

$$T_o(t_m) \approx -1.0^\circ\text{C}. \quad <$$

(c) With  $Bi^2 Fo = (1/3.25)^2 \times 2.1 = 0.2$ , from Figure 5S.9, find  $Q/Q_o \approx 0.82$ . From Equation 5.47,

$$Q_o = \rho V c_p \theta_i = (920 \text{ kg/m}^3) (\pi/6)(0.005\text{m})^3 1945 (\text{J/kg}\cdot\text{K})(-35\text{K}) = -4.10 \text{ J}$$

$$Q = 0.82 Q_o = 0.82(-4.10 \text{ J}) = -3.4 \text{ J}. \quad <$$

## PROBLEM 5S.8

**KNOWN:** Properties, initial temperature, and convection conditions associated with cooling of glass beads.

**FIND:** (a) Time required to achieve a prescribed center temperature, (b) Effect of convection coefficient on center and surface temperature histories.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) One-dimensional conduction in  $r$ , (2) Constant properties, (3) Negligible radiation, (4)  $Fo \geq 0.2$ .

**ANALYSIS:** (a) With  $h = 400\text{ W/m}^2\cdot\text{K}$ ,  $Bi \equiv h(r_o/3)/k = 400\text{ W/m}^2\cdot\text{K}(0.0005\text{ m})/1.4\text{ W/m}\cdot\text{K} = 0.143$  and the lumped capacitance method should not be used. Instead, use the Heisler charts for which

$$\theta_o = \frac{T(0, t) - T_\infty}{T_i - T_\infty} = \frac{80 - 15}{477 - 15} = 0.141$$

$$Bi^{-1} = \frac{k}{hr_o} = \frac{1.4\text{ W/m}\cdot\text{K}}{400\text{ W/m}^2\cdot\text{K} \times 0.0015\text{ m}} = 2.33.$$

From Figure 5S.7, find  $Fo \approx 1.8$ .

$$t \approx \frac{Fo r_o^2}{\alpha} = \frac{1.8(0.0015)^2}{\left[ 1.4\text{ W/m}\cdot\text{K} / (2200\text{ kg/m}^3 \times 800\text{ J/kg}\cdot\text{K}) \right]} = 5.1\text{ s.} \quad \leftarrow$$

From Figure 5S.8,  $\frac{\theta(r_o, t)}{\theta_o} \approx 0.82$ .

Hence, the corresponding surface temperature is

$$T(r_o, t) \approx T_\infty + 0.82(T_o - T_\infty) = 15\text{ }^\circ\text{C} + 0.82(80\text{ }^\circ\text{C} - 15\text{ }^\circ\text{C}) = 68.3\text{ }^\circ\text{C} \quad \leftarrow$$

(b) The effect of  $h$  on the surface and center temperatures was determined using the IHT *Transient Conduction Model* for a *Sphere*.

Continued...

### PROBLEM 5S.8 (Cont.)

The cooling rate increases with increasing  $h$ , particularly from 100 to 400  $\text{W/m}^2\cdot\text{K}$ . The temperature difference between the center and surface decreases with increasing  $t$  and, during the early stages of solidification, with decreasing  $h$ .

**COMMENTS:** Temperature gradients in the glass are largest during the early stages of solidification and increase with increasing  $h$ . Since thermal stresses increase with increasing temperature gradients, the propensity to induce defects due to crack formation in the glass increases with increasing  $h$ . Hence, there is a value of  $h$  above which product quality would suffer and the process should not be operated.

### PROBLEM 5S.9

**KNOWN:** Steel (plain carbon) billet of square cross-section initially at a uniform temperature of 30°C is placed in a soaking oven and subjected to a convection heating process with prescribed temperature and convection coefficient.

**FIND:** Time required for billet center temperature to reach 600°C.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Two-dimensional conduction in  $x_1$  and  $x_2$  directions, (2) Constant properties, (3) Heat transfer to billet is by convection only.

**PROPERTIES:** Table A-1, Steel, plain carbon ( $T = (30+600)^\circ\text{C}/2 = 588\text{K} \approx 600\text{K}$ ):  $\rho = 7854 \text{ kg/m}^3$ ,  $c_p = 559 \text{ J/kg}\cdot\text{K}$ ,  $k = 48.0 \text{ W/m}\cdot\text{K}$ ,  $\alpha = k/\rho c_p = 1.093 \times 10^{-5} \text{ m}^2/\text{s}$ .

**ANALYSIS:** The billet corresponds to Case (e), Figure 5S.11 (infinite rectangular bar). Hence, the temperature distribution is of the form

$$\theta^*(x_1, x_2, t) = P(x_1, t) \times P(x_2, t)$$

where  $P(x, t)$  denotes the distribution corresponding to the plane wall. Because of symmetry in the  $x_1$  and  $x_2$  directions, the  $P$  functions are identical. Hence,

$$\frac{\theta(0,0,t)}{\theta_i} = \left[ \frac{\theta_o(0,t)}{\theta_i} \right]_{\text{Plane wall}}^2 \quad \text{where} \quad \begin{cases} \theta = T - T_\infty \\ \theta_i = T_i - T_\infty \\ \theta_o = T(0,t) - T_\infty \end{cases} \quad \text{and } L = 0.15\text{m}.$$

Substituting numerical values, find

$$\frac{\theta_o(0,t)}{\theta_i} = \left[ \frac{T(0,0,t) - T_\infty}{T_i - T_\infty} \right]^{1/2} = \left[ \frac{(600 - 750)^\circ\text{C}}{(30 - 750)^\circ\text{C}} \right]^{1/2} = 0.46.$$

Consider now the Heisler chart for the plane wall, Figure 5S.1. For the values

$$\theta_o^* = \frac{\theta_o}{\theta_i} \approx 0.46 \quad \text{Bi}^{-1} = \frac{k}{hL} = \frac{48.0 \text{ W/m}\cdot\text{K}}{100 \text{ W/m}^2\cdot\text{K} \times 0.15\text{m}} = 3.2$$

find

$$t^* = \text{Fo} = \frac{\alpha t}{L^2} \approx 3.2.$$

Hence,

$$t = \frac{3.2 L^2}{\alpha} = \frac{3.2 (0.15 \text{ m})^2}{1.093 \times 10^{-5} \text{ m}^2/\text{s}} = 6587 \text{ s} = 1.83 \text{ h}.$$

<

### PROBLEM 5S.10

**KNOWN:** Initial temperature of fire clay brick which is cooled by convection.

**FIND:** Center and corner temperatures after 50 minutes of cooling.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Homogeneous medium with constant properties, (2) Negligible radiation effects.

**PROPERTIES:** Table A-3, Fire clay brick (900K):  $\rho = 2050 \text{ kg/m}^3$ ,  $k = 1.0 \text{ W/m}\cdot\text{K}$ ,  $c_p = 960 \text{ J/kg}\cdot\text{K}$ .  $\alpha = 0.51 \times 10^{-6} \text{ m}^2/\text{s}$ .

**ANALYSIS:** From Figure 5S.11, the center temperature is given by

$$\frac{T(0,0,0,t) - T_\infty}{T_i - T_\infty} = P_1(0,t) \times P_2(0,t) \times P_3(0,t)$$

where  $P_1$ ,  $P_2$  and  $P_3$  must be obtained from Figure 5S.1.

$$L_1 = 0.03\text{m}: \quad Bi_1 = \frac{h L_1}{k} = 1.50 \quad Fo_1 = \frac{\alpha t}{L_1^2} = 1.70$$

$$L_2 = 0.045\text{m}: \quad Bi_2 = \frac{h L_2}{k} = 2.25 \quad Fo_2 = \frac{\alpha t}{L_2^2} = 0.756$$

$$L_3 = 0.10\text{m}: \quad Bi_3 = \frac{h L_3}{k} = 5.0 \quad Fo_3 = \frac{\alpha t}{L_3^2} = 0.153$$

Hence from Figure 5S.1,

$$P_1(0,t) \approx 0.22 \quad P_2(0,t) \approx 0.50 \quad P_3(0,t) \approx 0.85.$$

Hence, 
$$\frac{T(0,0,0,t) - T_\infty}{T_i - T_\infty} \approx 0.22 \times 0.50 \times 0.85 = 0.094$$

and the center temperature is

$$T(0,0,0,t) \approx 0.094(1600 - 313)\text{K} + 313 \text{ K} = 434 \text{ K}.$$

<

Continued ...

### PROBLEM 5S.10 (Cont.)

The corner temperature is given by

$$\frac{T(L_1, L_2, L_3, t) - T_\infty}{T_i - T_\infty} = P(L_1, t) \times P(L_2, t) \times P(L_3, t)$$

where

$$P(L_1, t) = \frac{\theta(L_1, t)}{\theta_o} \cdot P_1(0, t), \text{ etc.}$$

and similar forms can be written for  $L_2$  and  $L_3$ . From Figure 5S.2,

$$\frac{\theta(L_1, t)}{\theta_o} \approx 0.55 \quad \frac{\theta(L_2, t)}{\theta_o} \approx 0.43 \quad \frac{\theta(L_3, t)}{\theta_o} \approx 0.25.$$

Hence,

$$\begin{aligned} P(L_1, t) &\approx 0.55 \times 0.22 = 0.12 \\ P(L_2, t) &\approx 0.43 \times 0.50 = 0.22 \\ P(L_3, t) &\approx 0.85 \times 0.25 = 0.21 \end{aligned}$$

and

$$\frac{T(L_1, L_2, L_3, t) - T_\infty}{T_i - T_\infty} \approx 0.12 \times 0.22 \times 0.21 = 0.0056$$

or

$$T(L_1, L_2, L_3, t) \approx 0.0056(1600 - 313) \text{ K} + 313 \text{ K.}$$

The corner temperature is then

$$T(L_1, L_2, L_3, t) \approx 320 \text{ K.}$$

<

**COMMENTS:** (1) The foregoing temperatures are overpredicted by ignoring radiation, which is significant during the early portion of the transient.

(2) Note that, if the time required to reach a certain temperature were to be determined, an iterative approach would have to be used. The foregoing procedure would be used to compute the temperature for an assumed value of the time, and the calculation would be repeated until the specified temperature were obtained.

### PROBLEM 5S.11

**KNOWN:** Cylindrical copper pin, 100 mm long  $\times$  50 mm diameter, initially at 20°C; end faces are subjected to intense heating, suddenly raising them to 500°C; at the same time, the cylindrical surface is subjected to a convective heating process ( $T_\infty, h$ ).

**FIND:** (a) Temperature at center point of cylinder after a time of 8 seconds from sudden application of heat, (b) Consider parameters governing transient diffusion and justify simplifying assumptions that could be applied to this problem.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Two-dimensional conduction, (2) Constant properties and convection heat transfer coefficient.

**PROPERTIES:** Table A-1, Copper, pure ( $\bar{T} \approx (500 + 20)^\circ \text{C} / 2 \approx 500\text{K}$ ):  $\rho = 8933 \text{ kg/m}^3$ ,  $c = 407$

$\text{J/kg}\cdot\text{K}$ ,  $k = 386 \text{ W/m}\cdot\text{K}$ ,  $\alpha = k/\rho c = 386 \text{ W/m}\cdot\text{K} / 8933 \text{ kg/m}^3 \times 407 \text{ J/kg}\cdot\text{K} = 1.064 \times 10^{-4} \text{ m}^2/\text{s}$ .

**ANALYSIS:** (1) The pin can be treated as a two-dimensional system comprised of an infinite cylinder whose surface is exposed to a convection process ( $T_\infty, h$ ) and of a plane wall whose surfaces are maintained at a constant temperature ( $T_e$ ). This configuration corresponds to the short cylinder, Case (i) of Figure 5S.11,

$$\frac{\theta(r, x, t)}{\theta_i} = C(r, t) \times P(x, t). \quad (1)$$

For the infinite cylinder, using Figure 5S.4, with

$$\text{Bi} = \frac{hr_o}{k} = \frac{100 \text{ W/m}^2 \cdot \text{K} (25 \times 10^{-3} \text{ m})}{386 \text{ W/m}\cdot\text{K}} = 6.47 \times 10^{-3} \quad \text{and} \quad \text{Fo} = \frac{\alpha t}{r_o^2} = \frac{1.064 \times 10^{-4} \frac{\text{m}^2}{\text{s}} \times 8 \text{ s}}{(25 \times 10^{-3} \text{ m})^2} = 1.36,$$

$$\text{find} \quad C(0, 8\text{s}) = \left. \frac{\theta(0, 8\text{s})}{\theta_i} \right]_{\text{cyl}} \approx 1. \quad (2)$$

For the infinite plane wall, using Figure 5S.1, with

$$\text{Bi} = \frac{hL}{k} \rightarrow \infty \quad \text{or} \quad \text{Bi}^{-1} \rightarrow 0 \quad \text{and} \quad \text{Fo} = \frac{\alpha t}{L^2} = \frac{1.064 \times 10^{-4} \text{ m}^2/\text{s} \times 8 \text{ s}}{(50 \times 10^{-3} \text{ m})^2} = 0.34,$$

$$\text{find} \quad P(0, 8\text{s}) = \left. \frac{\theta(0, 8\text{s})}{\theta_i} \right]_{\text{wall}} \approx 0.5. \quad (3)$$

Combining Equations (2) and (3) with Eq. (1), find  $\frac{\theta(0, 0, 8\text{s})}{\theta_i} = \frac{T(0, 0, 8\text{s}) - T_\infty}{T_i - T_\infty} \approx 1 \times 0.5 = 0.5$

$$T(0, 0, 8\text{s}) = T_\infty + 0.5(T_i - T_\infty) = 500 + 0.5(20 - 500) = 260^\circ \text{C}. \quad <$$

(b) The parameters controlling transient conduction with convective boundary conditions are the Biot and Fourier numbers. Since  $\text{Bi} \ll 0.1$  for the cylindrical shape, we can assume radial gradients are negligible. That is, we need only consider conduction in the x-direction.

### PROBLEM 5S.12

**KNOWN:** Cylindrical-shaped meat roast weighing 2.25 kg, initially at 6°C, is placed in an oven and subjected to convection heating with prescribed ( $T_\infty, h$ ).

**FIND:** Time required for the center to reach a done temperature of 80°C.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Two-dimensional conduction in  $x$  and  $r$  directions, (2) Uniform and constant properties, (3) Properties approximated as those of water.

**PROPERTIES:** Table A-6, Water, liquid ( $\bar{T} = (80 + 6)^\circ\text{C}/2 \approx 315\text{K}$ ):  $\rho = 1/v_f = 1/1.009 \times 10^{-3} \text{ m}^3/\text{kg} = 991.1 \text{ kg/m}^3$ ,  $c_{p,f} = 4179 \text{ J/kg}\cdot\text{K}$ ,  $k = 0.634 \text{ W/m}\cdot\text{K}$ ,  $\alpha = k/\rho c = 1.531 \times 10^{-7} \text{ m}^2/\text{s}$ .

**ANALYSIS:** The dimensions of the roast are determined from the requirement  $r_o = L$  and knowledge of its weight and density,

$$M = \rho V = \rho \cdot 2L \cdot \pi r_o^2 \quad \text{or} \quad r_o = L = \left[ \frac{M}{2\pi\rho} \right]^{1/3} = \left[ \frac{2.25 \text{ kg}}{2\pi \cdot 991.1 \text{ kg/m}^3} \right]^{1/3} = 0.0712 \text{ m}. \quad (1)$$

The roast corresponds to Case (i), Figure 5S.11, and the temperature distribution may be expressed as the product of one-dimensional solutions,  $\frac{T(x,r,t) - T_\infty}{T_i - T_\infty} = P(x,t) \times C(r,t)$ , where

$P(x,t)$  and  $C(r,t)$  are defined by Equations 5S.2 and 5S.3, respectively. For the center of the cylinder,

$$\frac{T(0,0,t) - T_\infty}{T_i - T_\infty} = \frac{(80 - 175)^\circ\text{C}}{(6 - 175)^\circ\text{C}} = 0.56. \quad (2)$$

In terms of the product solutions,

$$\frac{T(0,0,t) - T_\infty}{T_i - T_\infty} = 0.56 = \left[ \frac{T(0,t) - T_\infty}{T_i - T_\infty} \right]_{\text{wall}} \times \left[ \frac{T(0,t) - T_\infty}{T_i - T_\infty} \right]_{\text{cylinder}} \quad (3)$$

For each of these shapes, we need to find values of  $\theta_o/\theta_i$  such that their product satisfies Equation (3). For both shapes,

$$\text{Bi} = \frac{h r_o}{k} = \frac{hL}{k} = \frac{15 \text{ W/m}^2 \cdot \text{K} \times 0.0712 \text{ m}}{0.634 \text{ W/m} \cdot \text{K}} = 1.68 \quad \text{or} \quad \text{Bi}^{-1} \approx 0.6$$

$$\text{Fo} = \alpha t/r_o^2 = \alpha t/L^2 = 1.53 \times 10^{-7} \text{ m}^2/\text{s} \times t / (0.0712 \text{ m})^2 = 3.020 \times 10^{-5} t.$$

Continued ...

**PROBLEM 5S.12 (Cont.)**

A trial-and-error solution is necessary. Begin by assuming a value of  $Fo$ ; obtain the respective  $\theta_o/\theta_i$  values from Figures 5S.1 and 5S.4; test whether their product satisfies Equation (3).

Two trials are shown as follows:

<i>Trial</i>	$Fo$	$t(\text{hrs})$	$\theta_o/\theta_i)_{\text{wall}}$	$\theta_o/\theta_i)_{\text{cyl}}$	$\left. \frac{\theta_o}{\theta_i} \right]_{\text{w}} \times \left. \frac{\theta_o}{\theta_i} \right]_{\text{cyl}}$
1	0.4	3.68	0.72	0.50	0.36
2	0.3	2.75	0.78	0.68	0.53

For Trial 2, the product of 0.53 agrees closely with the value of 0.56 from Equation (2). Hence, it will take approximately  $2 \frac{3}{4}$  hours to roast the meat.

### PROBLEM 5S.13

**KNOWN:** A long alumina rod, initially at a uniform temperature of 850 K, is suddenly exposed to a cooler fluid.

**FIND:** Temperature of the rod after 30 s, at an exposed end,  $T(0,0,t)$ , and at an axial distance 6mm from the end,  $T(0,6\text{ mm},t)$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Two-dimensional conduction in  $(r,x)$  directions, (2) Constant properties, (3) Convection coefficient is same on end and cylindrical surfaces.

**PROPERTIES:** Table A-2, Alumina, polycrystalline aluminum oxide (assume  $\bar{T} \approx (850 + 600)\text{K}/2 = 725\text{K}$ ):  $\rho = 3970\text{ kg/m}^3$ ,  $c = 1154\text{ J/kg}\cdot\text{K}$ ,  $k = 12.4\text{ W/m}\cdot\text{K}$ .

**ANALYSIS:** First, check if system behaves as a lumped capacitance. Find

$$Bi = \frac{hL_c}{k} = \frac{h(r_o/2)}{k} = \frac{500\text{ W/m}\cdot\text{K}(0.010\text{m}/2)}{12.4\text{ W/m}\cdot\text{K}} = 0.202.$$

Since  $Bi > 0.1$ , rod does not behave as spacewise isothermal object. Hence, treat rod as a semi-infinite cylinder, the multi-dimensional system Case (f), Figure 5S.11.

The product solution can be written as

$$\theta^*(r,x,t) = \frac{\theta(r,x,t)}{\theta_i} = \frac{\theta(r,t)}{\theta_i} \times \frac{\theta(x,t)}{\theta_i} = C(r^*,t^*) \times S(x^*,t^*)$$

*Infinite cylinder, C*( $r^*,t^*$ ). Using the Heisler charts with  $r^* = r = 0$  and

$$Bi^{-1} = \left[ \frac{h r_o}{k} \right]^{-1} = \left[ \frac{500\text{ W/m}^2 \cdot \text{K} \times 0.01\text{m}}{12.4\text{ W/m}\cdot\text{K}} \right]^{-1} = 2.48.$$

Evaluate  $\alpha = k/\rho c = 2.71 \times 10^{-6}\text{ m}^2/\text{s}$ , find  $Fo = \alpha t/r_o^2 = 2.71 \times 10^{-6}\text{ m}^2/\text{s} \times 30\text{s}/(0.01\text{m})^2 = 0.812$ . From the Heisler chart, Figure 5S.4, with  $Bi^{-1} = 2.48$  and  $Fo = 0.812$ , read  $C(0,t^*) = \theta(0,t)/\theta_i = 0.61$ .

Continued ...

**PROBLEM 5S.13 (Cont.)**

*Semi-infinite medium, S(x\*,t\*).* Recognize this as Case (3), Figure 5.7. From Equation 5.63, note that the LHS needs to be transformed as follows,

$$\frac{T - T_i}{T_\infty - T_i} = 1 - \frac{T - T_\infty}{T_i - T_\infty} \quad S(x,t) = \frac{T - T_\infty}{T_i - T_\infty}.$$

Thus,

$$S(x,t) = 1 - \left\{ \operatorname{erfc} \left[ \frac{x}{2(\alpha t)^{1/2}} \right] - \left[ \exp \left[ \frac{hx}{k} + \frac{h^2 \alpha t}{k^2} \right] \right] \left[ \operatorname{erfc} \left[ \frac{x}{2(\alpha t)^{1/2}} + \frac{h(\alpha t)^{1/2}}{k} \right] \right] \right\}.$$

Evaluating this expression at the surface ( $x = 0$ ) and 6 mm from the exposed end, find

$$S(0,30s) = 1 - \left\{ \operatorname{erfc}(0) - \left[ \exp \left[ 0 + \frac{(500 \text{ W/m}^2 \cdot \text{K})^2 \cdot 2.71 \times 10^{-6} \text{ m}^2 / \text{s} \times 30\text{s}}{(12.4 \text{ W/m} \cdot \text{K})^2} \right] \right] \left[ \operatorname{erfc} \left[ 0 + \frac{500 \text{ W/m}^2 \cdot \text{K} (2.71 \times 10^{-6} \text{ m}^2 / \text{s} \times 30\text{s})^{1/2}}{12.4 \text{ W/m} \cdot \text{K}} \right] \right] \right\}$$

$$S(0,30s) = 1 - \left\{ 1 - \left[ \exp(0.1322) \right] \left[ \operatorname{erfc}(0.3636) \right] \right\} = 0.693.$$

Note that Table B.2 was used to evaluate the complementary error function,  $\operatorname{erfc}(w)$ .

$$S(6\text{mm},30s) = 1 - \left\{ \operatorname{erfc} \left[ \frac{0.006\text{m}}{2(2.71 \times 10^{-6} \text{ m}^2 / \text{s} \times 30\text{s})^{1/2}} \right] - \left[ \exp \left[ \frac{500 \text{ W/m}^2 \cdot \text{K} \times 0.006\text{m}}{12.4 \text{ W/m} \cdot \text{K}} + 0.1322 \right] \right] \left[ \operatorname{erfc}(0.3327 + 0.3636) \right] \right\} = 0.835.$$

The product solution can now be evaluated for each location. At (0,0),

$$\theta^*(0,0,t) = \frac{T(0,0,30s) - T_\infty}{T_i - T_\infty} = C(0,t^*) \times S(0,t^*) = 0.61 \times 0.693 = 0.423.$$

Hence,  $T(0,0,30s) = T_\infty + 0.423(T_i - T_\infty) = 350\text{K} + 0.423(850 - 350)\text{K} = 561 \text{ K.} <$

At (0,6mm),

$$\theta^*(0,6\text{mm},t) = C(0,t^*) \times S(6\text{mm},t^*) = 0.61 \times 0.835 = 0.509$$

$$T(0,6\text{mm},30s) = 604 \text{ K.} <$$

**COMMENTS:** Note that the temperature at which the properties were evaluated was a good estimate.

### PROBLEM 5S.14

**KNOWN:** Stainless steel cylinder of Example 5S.1, 80-mm diameter by 60-mm length, initially at 600 K, suddenly quenched in an oil bath at 300 K with  $h = 500 \text{ W/m}^2 \cdot \text{K}$ . Use the *Transient Conduction, Plane Wall and Cylinder models of IHT* to obtain the following solutions.

**FIND:** (a) Calculate the temperatures  $T(r,x,t)$  after 3 min: at the cylinder center,  $T(0, 0, 3 \text{ min})$ , at the center of a circular face,  $T(0, L, 3 \text{ min})$ , and at the midheight of the side,  $T(r_o, 0, 3 \text{ min})$ ; compare your results with those in the example; (b) Calculate and plot temperature histories at the cylinder center,  $T(0, 0, t)$ , the mid-height of the side,  $T(r_o, 0, t)$ , for  $0 \leq t \leq 10 \text{ min}$ ; comment on the gradients and what effect they might have on phase transformations and thermal stresses; and (c) For  $0 \leq t \leq 10 \text{ min}$ , calculate and plot the temperature histories at the cylinder center,  $T(0, 0, t)$ , for convection coefficients of 500 and  $1000 \text{ W/m}^2 \cdot \text{K}$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Two-dimensional conduction in  $r$ - and  $x$ -coordinates, (2) Constant properties.

**PROPERTIES:** Stainless steel (*Example 5S.1*):  $\rho = 7900 \text{ kg/m}^3$ ,  $c = 526 \text{ J/kg} \cdot \text{K}$ ,  $k = 17.4 \text{ W/m} \cdot \text{K}$ .

**ANALYSIS:** The following results were obtained using the *Transient Conduction models for the Plane Wall and Cylinder of IHT*. Salient portions of the code are provided in the Comments.

(a) Following the methodology for a product solution outlined in Example 5S.1, the following results were obtained at  $t = t_0 = 3 \text{ min}$

$(r, x, t)$	$P(x, t)$	$C(r, t)$	$T(r, x, t)$ -IHT (K)	$T(r, x, t)$ -Ex (K)
$0, 0, t_0$	0.6357	0.5388	402.7	405
$0, L, t_0$	0.4365	0.5388	370.5	372
$r_o, 0, t_0$	0.6357	0.3273	362.4	365

Continued ...

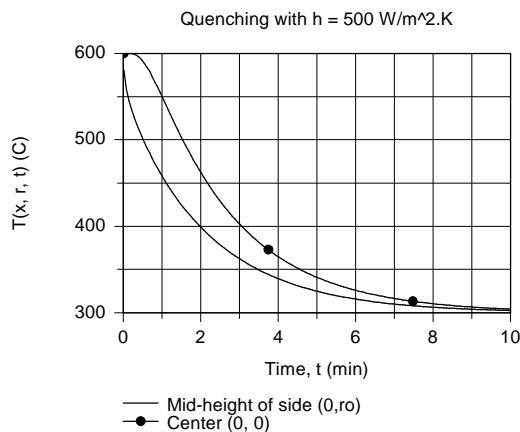

## PROBLEM 5S.14 (Cont.)

The temperatures from the one-term series calculations of the Example 5S.1 are systematically higher than those resulting from the *IHT* multiple-term series model, which is the more accurate method.

(b) The temperature histories for the center and mid-height of the side locations are shown in the graph below. Note that at early times, the temperature difference between these locations, and hence the gradient, is large. Large differences could cause variations in microstructure and hence, mechanical properties, as well as induce residual thermal stresses.

(c) Effect of doubling the convection coefficient is to increase the quenching rate, but much less than by a factor of two as can be seen in the graph below.

**COMMENTS:** From *IHT* menu for *Transient Conduction* | *Plane Wall* and *Cylinder*, the models were combined to solve the product solution. Key portions of the code, less the input variables, are copied below.

**// Plane wall temperature distribution**

```
// The temperature distribution is
T_xtP = T_xt_trans("Plane Wall",xstar,FoP,BiP,Ti,Tinf) // Eq 5.42
// The dimensionless parameters are
xstar = x / L
BiP = h * L / k // Eq 5.9
FoP = alpha * t / L^2 // Eq 5.33
alpha = k / (rho * cp)
// Dimensionless representation, P(x,t)
P_xt = (T_xtP - Tinf) / (Ti - Tinf)
```

**// Cylinder temperature distribution**

```
// The temperature distribution T(r,t) is
T_rtC = T_xt_trans("Cylinder",rstar,FoC,BiC,Ti,Tinf) // Eq 5.50
// The dimensionless parameters are
rstar = r / ro
BiC = h * ro / k
FoC = alpha * t / ro^2
// Dimensionless representation, C(r,t)
C_rt = (T_rtC - Tinf) / (Ti - Tinf)
```

**// Product solution temperature distribution**

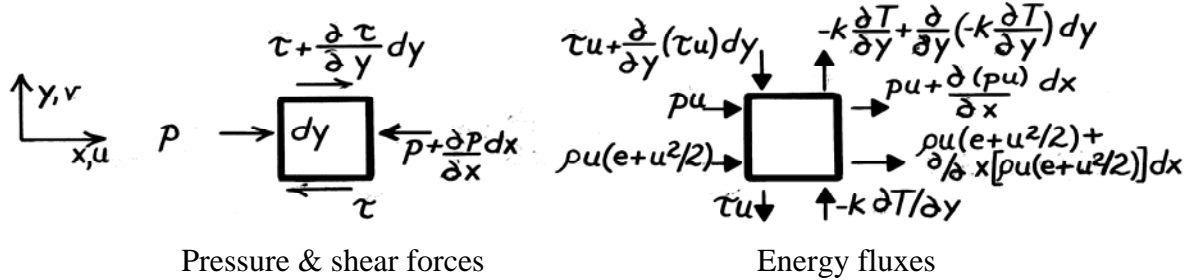

```
(T_xrt - Tinf) / (Ti - Tinf) = P_xt * C_rt
```

## PROBLEM 6S.1

**KNOWN:** Two-dimensional flow conditions for which  $v = 0$  and  $T = T(y)$ .

**FIND:** (a) Verify that  $u = u(y)$ , (b) Derive the x-momentum equation, (c) Derive the energy equation.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Incompressible fluid with constant properties, (3) Negligible body forces, (4)  $v = 0$ , (5)  $T = T(y)$  or  $\partial T / \partial x = 0$ , (6) Thermal energy generation occurs only by viscous dissipation.

**ANALYSIS:** (a) From the mass continuity equation, it follows from the prescribed conditions that  $\partial u / \partial x = 0$ . Hence  $u = u(y)$ .

(b) From Newton's second law of motion,  $\Sigma F_x = (\text{Rate of increase of fluid momentum})_x$ ,

$$\left[ p - \left[ p + \frac{\partial p}{\partial x} dx \right] \right] dy \cdot 1 + \left[ -\tau + \left[ \tau + \frac{\partial \tau}{\partial y} dy \right] \right] dx \cdot 1 = \left\{ (\rho u)u + \frac{\partial}{\partial x} [(\rho u)u] dx \right\} dy \cdot 1 - (\rho u)u dy \cdot 1$$

Hence, with  $\tau = \mu(\partial u / \partial y)$ , it follows that

$$-\frac{\partial p}{\partial x} + \frac{\partial \tau}{\partial y} = \frac{\partial}{\partial x} [(\rho u)u] = 0 \quad \frac{\partial p}{\partial x} = \mu \frac{\partial^2 u}{\partial y^2}. \quad <$$

(c) From the conservation of energy requirement and the prescribed conditions, it follows that

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = 0, \text{ or}$$

$$\left[ pu + \rho u \left( e + u^2 / 2 \right) \right] dy \cdot 1 + \left[ -k \frac{\partial T}{\partial y} + \tau u + \frac{\partial (\tau u)}{\partial y} dy \right] dx \cdot 1 - \left\{ pu + \frac{\partial}{\partial x} (pu) dx + \rho u \left( e + u^2 / 2 \right) + \frac{\partial}{\partial x} \left[ \rho u \left( e + u^2 / 2 \right) \right] dx \right\} dy \cdot 1 - \left[ \tau u - k \frac{\partial T}{\partial y} + \frac{\partial}{\partial y} \left[ -k \frac{\partial T}{\partial y} \right] dy \right] dx \cdot 1 = 0$$

or, 
$$\frac{\partial (\tau u)}{\partial y} - \frac{\partial}{\partial x} (pu) - \frac{\partial}{\partial x} \left[ \rho u \left( e + u^2 / 2 \right) \right] + \frac{\partial}{\partial y} \left[ k \frac{\partial T}{\partial y} \right] = 0$$

$$\tau \frac{\partial u}{\partial y} + u \frac{\partial \tau}{\partial y} - u \frac{\partial p}{\partial x} + k \frac{\partial^2 T}{\partial y^2} = 0.$$

Noting that the second and third terms cancel from the momentum equation,

$$\mu \left[ \frac{\partial u}{\partial y} \right]^2 + k \left[ \frac{\partial^2 T}{\partial y^2} \right] = 0. \quad <$$

## PROBLEM 6S.2

**KNOWN:** Oil properties, journal and bearing temperatures, and journal speed for a lightly loaded journal bearing.

**FIND:** Maximum oil temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Incompressible fluid with constant properties, (3) Clearance is much less than journal radius and flow is Couette.

**ANALYSIS:** The temperature distribution corresponds to the result obtained in the text Example on Couette flow,

$$T(y) = T_0 + \frac{\mu}{2k} U^2 \left[ \frac{y}{L} - \left[ \frac{y}{L} \right]^2 \right].$$

The position of maximum temperature is obtained from

$$\frac{dT}{dy} = 0 = \frac{\mu}{2k} U^2 \left[ \frac{1}{L} - \frac{2y}{L^2} \right]$$

or,  $y = L/2$ .

The temperature is a maximum at this point since  $d^2T/dy^2 < 0$ . Hence,

$$T_{\max} = T(L/2) = T_0 + \frac{\mu}{2k} U^2 \left[ \frac{1}{2} - \frac{1}{4} \right] = T_0 + \frac{\mu U^2}{8k}$$

$$T_{\max} = 40^\circ\text{C} + \frac{10^{-2} \text{ kg/s} \cdot \text{m} (10 \text{ m/s})^2}{8 \times 0.15 \text{ W/m} \cdot \text{K}}$$

$$T_{\max} = 40.83^\circ\text{C}.$$

<

**COMMENTS:** Note that  $T_{\max}$  increases with increasing  $\mu$  and  $U$ , decreases with increasing  $k$ , and is independent of  $L$ .

### PROBLEM 6S.3

**KNOWN:** Diameter, clearance, rotational speed and fluid properties of a lightly loaded journal bearing. Temperature of bearing.

**FIND:** (a) Temperature distribution in the fluid, (b) Rate of heat transfer from bearing and operating power.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Incompressible fluid with constant properties, (3) Couette flow.

**PROPERTIES:** Oil (Given):  $\rho = 800 \text{ kg/m}^3$ ,  $\nu = 10^{-5} \text{ m}^2/\text{s}$ ,  $k = 0.13 \text{ W/m}\cdot\text{K}$ ;  $\mu = \rho\nu = 8 \times 10^{-3} \text{ kg/s}\cdot\text{m}$ .

**ANALYSIS:** (a) For Couette flow, the velocity distribution is linear,  $u(y) = U(y/L)$ , and the energy equation and general form of the temperature distribution are

$$k \frac{d^2 T}{dy^2} = -\mu \left[ \frac{du}{dy} \right]^2 = -\mu \left[ \frac{U}{L} \right]^2 \quad T = -\frac{\mu}{2k} \left[ \frac{U}{L} \right]^2 y^2 + \frac{C_1}{k} y + C_2.$$

Considering the boundary conditions  $dT/dy|_{y=L} = 0$  and  $T(0) = T_0$ , find  $C_2 = T_0$  and  $C_1 = \mu U^2/L$ . Hence,

$$T = T_0 + \left( \mu U^2 \right) / k \left[ \left( y/L \right) - 1/2 \left( y/L \right)^2 \right]. \quad <$$

(b) Applying Fourier's law at  $y = 0$ , the rate of heat transfer per unit length to the bearing is

$$q' = -k (\pi D) \left. \frac{dT}{dy} \right|_{y=0} = -(\pi D) \frac{\mu U^2}{L} = -(\pi \times 75 \times 10^{-3} \text{ m}) \frac{8 \times 10^{-3} \text{ kg/s}\cdot\text{m} (14.14 \text{ m/s})^2}{0.25 \times 10^{-3} \text{ m}} = -1507.5 \text{ W/m}$$

where the velocity is determined as

$$U = (D/2) \omega = 0.0375 \text{ m} \times 3600 \text{ rev/min} (2\pi \text{ rad/rev}) / (60 \text{ s/min}) = 14.14 \text{ m/s}.$$

The journal power requirement is

$$P' = F'_{(y=L)} U = \tau_{s(y=L)} \cdot \pi D \cdot U$$

$$P' = 452.5 \text{ kg/s}^2 \cdot \text{m} \left( \pi \times 75 \times 10^{-3} \text{ m} \right) 14.14 \text{ m/s} = 1507.5 \text{ kg}\cdot\text{m/s}^3 = 1507.5 \text{ W/m} \quad <$$

where the shear stress at  $y = L$  is

$$\tau_{s(y=L)} = \mu \left( \partial u / \partial y \right)_{y=L} = \mu \frac{U}{L} = 8 \times 10^{-3} \text{ kg/s}\cdot\text{m} \left[ \frac{14.14 \text{ m/s}}{0.25 \times 10^{-3} \text{ m}} \right] = 452.5 \text{ kg/s}^2 \cdot \text{m}.$$

**COMMENTS:** Note that  $q' = P'$ , which is consistent with the energy conservation requirement.

## PROBLEM 6S.4

**KNOWN:** Conditions associated with the Couette flow of air or water.

**FIND:** (a) Force and power requirements per unit surface area, (b) Viscous dissipation, (c) Maximum fluid temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Fully-developed Couette flow, (2) Incompressible fluid with constant properties.

**PROPERTIES:** Table A-4, Air (300K):  $\mu = 184.6 \times 10^{-7} \text{ N}\cdot\text{s}/\text{m}^2$ ,  $k = 26.3 \times 10^{-3} \text{ W}/\text{m}\cdot\text{K}$ ; Table A-6, Water (300K):  $\mu = 855 \times 10^{-6} \text{ N}\cdot\text{s}/\text{m}^2$ ,  $k = 0.613 \text{ W}/\text{m}\cdot\text{K}$ .

**ANALYSIS:** (a) The force per unit area is associated with the shear stress. Hence, with the linear velocity profile for Couette flow,  $\tau = \mu(du/dy) = \mu(U/L)$ .

$$\text{Air:} \quad \tau_{\text{air}} = 184.6 \times 10^{-7} \text{ N}\cdot\text{s}/\text{m}^2 \times \frac{200 \text{ m/s}}{0.005 \text{ m}} = 0.738 \text{ N}/\text{m}^2 \quad <$$

$$\text{Water:} \quad \tau_{\text{water}} = 855 \times 10^{-6} \text{ N}\cdot\text{s}/\text{m}^2 \times \frac{200 \text{ m/s}}{0.005 \text{ m}} = 34.2 \text{ N}/\text{m}^2.$$

With the required power given by  $P/A = \tau \cdot U$ ,

$$\text{Air:} \quad (P/A)_{\text{air}} = (0.738 \text{ N}/\text{m}^2) 200 \text{ m/s} = 147.6 \text{ W}/\text{m}^2 \quad <$$

$$\text{Water:} \quad (P/A)_{\text{water}} = (34.2 \text{ N}/\text{m}^2) 200 \text{ m/s} = 6840 \text{ W}/\text{m}^2.$$

(b) The viscous dissipation is  $\mu\Phi = \mu(du/dy)^2 = \mu(U/L)^2$ . Hence,

$$\text{Air:} \quad (\mu\Phi)_{\text{air}} = 184.6 \times 10^{-7} \frac{\text{N}\cdot\text{s}}{\text{m}^2} \left[ \frac{200 \text{ m/s}}{0.005 \text{ m}} \right]^2 = 2.95 \times 10^4 \text{ W}/\text{m}^3 \quad <$$

$$\text{Water:} \quad (\mu\Phi)_{\text{water}} = 855 \times 10^{-6} \frac{\text{N}\cdot\text{s}}{\text{m}^2} \left[ \frac{200 \text{ m/s}}{0.005 \text{ m}} \right]^2 = 1.37 \times 10^6 \text{ W}/\text{m}^3.$$

(c) From the solution to Part 4 of Example 6S.1, the location of the maximum temperature corresponds to  $y_{\text{max}} = L/2$ . Hence,  $T_{\text{max}} = T_0 + \mu U^2 / 8k$  and

$$\text{Air:} \quad (T_{\text{max}})_{\text{air}} = 27^\circ\text{C} + \frac{184.6 \times 10^{-7} \text{ N}\cdot\text{s}/\text{m}^2 (200 \text{ m/s})^2}{8 \times 0.0263 \text{ W}/\text{m}\cdot\text{K}} = 30.5^\circ\text{C} \quad <$$

$$\text{Water:} \quad (T_{\text{max}})_{\text{water}} = 27^\circ\text{C} + \frac{855 \times 10^{-6} \text{ N}\cdot\text{s}/\text{m}^2 (200 \text{ m/s})^2}{8 \times 0.613 \text{ W}/\text{m}\cdot\text{K}} = 34.0^\circ\text{C}.$$

**COMMENTS:** (1) The viscous dissipation associated with the entire fluid layer,  $\mu\Phi(LA)$ , must equal the power,  $P$ . (2) Although  $(\mu\Phi)_{\text{water}} \gg (\mu\Phi)_{\text{air}}$ ,  $k_{\text{water}} \gg k_{\text{air}}$ . Hence,

$$T_{\text{max,water}} \approx T_{\text{max,air}}.$$

### PROBLEM 6S.5

**KNOWN:** Velocity and temperature difference of plates maintaining Couette flow. Mean temperature of air, water or oil between the plates.

**FIND:** (a) Pr·Ec product for each fluid, (b) Pr·Ec product for air with plate at sonic velocity.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Couette flow, (3) Air is at 1 atm.

**PROPERTIES:** Table A-4, Air (300K, 1atm),  $c_p = 1007\text{ J/kg}\cdot\text{K}$ ,  $\text{Pr} = 0.707$ ,  $\gamma = 1.4$ ,  $R = 287.02\text{ J/kg}\cdot\text{K}$ ; Table A-6, Water (300K):  $c_p = 4179\text{ J/kg}\cdot\text{K}$ ,  $\text{Pr} = 5.83$ ; Table A-5, Engine oil (300K),  $c_p = 1909\text{ J/kg}\cdot\text{K}$ ,  $\text{Pr} = 6400$ .

**ANALYSIS:** The product of the Prandtl and Eckert numbers is dimensionless,

$$\text{Pr} \cdot \text{Ec} = \text{Pr} \frac{U^2}{c_p \Delta T} \left( \frac{\text{m}^2/\text{s}^2}{(\text{J/kg}\cdot\text{K})\text{K}} \right) \left( \frac{\text{m}^2/\text{s}^2}{(\text{kg}\cdot\text{m}^2/\text{s}^2)/\text{kg}} \right)$$

Substituting numerical values, find

	<i>Air</i>	<i>Water</i>	<i>Oil</i>	
Pr·Ec	0.0028	0.0056	13.41	<

(b) For an ideal gas, the speed of sound is

$$c = (\gamma R T)^{1/2}$$

where R, the gas constant for air, is  $R_u/M = 8.315\text{ kJ/kmol}\cdot\text{K}/(28.97\text{ kg/kmol}) = 287.02\text{ J/kg}\cdot\text{K}$ . Hence, at 300K for air,

$$U = c = (1.4 \times 287.02\text{ J/kg}\cdot\text{K} \times 300\text{K})^{1/2} = 347.2\text{ m/s}.$$

For sonic velocities, it follows that

$$\text{Pr} \cdot \text{Ec} = 0.707 \frac{(347.2\text{ m/s})^2}{1007\text{ J/kg}\cdot\text{K} \times 25\text{K}} = 3.38. \quad <$$

**COMMENTS:** From the above results it follows that viscous dissipation effects must be considered in the high speed flow of gases and in oil flows at moderate speeds. For Pr·Ec to be less than 0.1 in air with  $\Delta T = 25^\circ\text{C}$ , U should be  $\lesssim 60\text{ m/s}$ .

### PROBLEM 6S.6

**KNOWN:** Couette flow with moving plate isothermal and stationary plate insulated.

**FIND:** Temperature of stationary plate and heat flux at the moving plate.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Incompressible fluid with constant properties, (3) Couette flow.

**ANALYSIS:** The energy equation is given by

$$0 = k \left[ \frac{\partial^2 T}{\partial y^2} \right] + \mu \left[ \frac{\partial u}{\partial y} \right]^2$$

Integrating twice find the general form of the temperature distribution,

$$\frac{\partial^2 T}{\partial y^2} = -\frac{\mu}{k} \left[ \frac{U}{L} \right]^2 \quad \frac{\partial T}{\partial y} = -\frac{\mu}{k} \left[ \frac{U}{L} \right]^2 y + C_1$$

$$T(y) = -\frac{\mu}{2k} \left[ \frac{U}{L} \right]^2 y^2 + C_1 y + C_2.$$

Consider the boundary conditions to evaluate the constants,

$$\left. \frac{\partial T}{\partial y} \right|_{y=0} = 0 \rightarrow C_1 = 0 \quad \text{and} \quad T(L) = T_L \rightarrow C_2 = T_L + \frac{\mu}{2k} U^2.$$

Hence, the temperature distribution is

$$T(y) = T_L + \left[ \frac{\mu U^2}{2k} \right] \left[ 1 - \left[ \frac{y}{L} \right]^2 \right].$$

The temperature of the lower plate ( $y = 0$ ) is

$$T(0) = T_L + \left[ \frac{\mu U^2}{2k} \right]. \quad <$$

The heat flux to the upper plate ( $y = L$ ) is

$$q''(L) = -k \left. \frac{\partial T}{\partial y} \right|_{y=L} = \frac{\mu U^2}{L}. \quad <$$

**COMMENTS:** The heat flux at the top surface may also be obtained by integrating the viscous dissipation over the fluid layer height. For a control volume about a unit area of the fluid layer,

$$\dot{E}_g'' = \dot{E}_{\text{out}}'' \quad \int_0^L \mu \left[ \frac{\partial u}{\partial y} \right]^2 dy = q''(L) \quad q''(L) = \frac{\mu U^2}{L}.$$

## PROBLEM 6S.7

**KNOWN:** Couette flow with heat transfer. Lower (insulated) plate moves with speed  $U$  and upper plate is stationary with prescribed thermal conductivity and thickness. Outer surface of upper plate maintained at constant temperature,  $T_{sp} = 40^\circ\text{C}$ .

**FIND:** (a) On  $T$ - $y$  coordinates, sketch the temperature distribution in the oil and the stationary plate, and (b) An expression for the temperature at the lower surface of the oil film,  $T(0) = T_o$ , in terms of the plate speed  $U$ , the stationary plate parameters ( $T_{sp}$ ,  $k_{sp}$ ,  $L_{sp}$ ) and the oil parameters ( $\mu$ ,  $k_o$ ,  $L_o$ ). Determine this temperature for the prescribed conditions.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Fully developed Couette flow and (3) Incompressible fluid with constant properties.

**ANALYSIS:** (a) The temperature distribution is shown above with these key features: linear in plate, parabolic in oil film, discontinuity in slope at plate-oil interface, and zero gradient at lower plate surface.

(b) From Example 6S.1, the general solution to the conservation equations for the temperature distribution in the oil film is

$$T_o(y) = -Ay^2 + C_3y + C_4 \quad \text{where} \quad A = \frac{\mu}{2k_o} \left( \frac{U}{L_o} \right)^2$$

and the boundary conditions are,

$$\text{At } y = 0, \text{ insulated boundary} \quad \left. \frac{dT_o}{dy} \right|_{y=0} = 0; \quad C_3 = 0$$

$$\text{At } y = L_o, \text{ heat fluxes in oil and plate are equal,} \quad q_o''(L_o) = q_{sp}''(L_o)$$

Continued...

**PROBLEM 6S.7 (Cont.)**

$$-k_o \left. \frac{dT_o}{dy} \right|_{y=L_o} = \frac{T_o(L_o) - T_{sp}}{R_{sp}} \quad \left\{ \begin{array}{l} \left. \frac{dT_o}{dy} \right|_{y=L_o} = -2AL_o \\ R_{sp} = L_{sp}/k_{sp} \end{array} \right. \quad T_o(L_o) = -AL_o^2 + C_4$$

$$C_4 = T_{sp} + AL_o^2 \left[ 1 + 2 \frac{k_o}{L_o} \frac{L_{sp}}{k_{sp}} \right]$$

Hence, the temperature distribution at the lower surface is

$$T_o(0) = -A \cdot 0 + C_4$$

$$T_o(0) = T_{sp} + \frac{\mu}{2k_o} U^2 \left[ 1 + 2 \frac{k_o}{L_o} \frac{L_{sp}}{k_{sp}} \right] \quad <$$

Substituting numerical values, find

$$T_o(0) = 40^\circ\text{C} + \frac{0.799 \text{ N}\cdot\text{s}/\text{m}^2}{2 \times 0.145 \text{ W}/\text{m}\cdot\text{K}} (5 \text{ m/s})^2 \left[ 1 + 2 \frac{0.145}{5} \times \frac{3}{1.5} \right] = 116.9^\circ\text{C} \quad <$$

**COMMENTS:** (1) Give a physical explanation about why the maximum temperature occurs at the lower surface.

(2) Sketch the temperature distribution if the upper plate moved with a speed  $U$  while the lower plate is stationary and all other conditions remain the same.

## PROBLEM 6S.8

**KNOWN:** Shaft of diameter 100 mm rotating at 9000 rpm in a journal bearing of 70 mm length. Uniform gap of 1 mm separates the shaft and bearing filled with lubricant. Outer surface of bearing is water-cooled and maintained at  $T_{wc} = 30^\circ\text{C}$ .

**FIND:** (a) Viscous dissipation in the lubricant,  $\mu\Phi(\text{W}/\text{m}^3)$ , (b) Heat transfer rate from the lubricant, assuming no heat lost through the shaft, and (c) Temperatures of the bearing and shaft,  $T_b$  and  $T_s$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Fully developed Couette flow, (3) Incompressible fluid with constant properties, and (4) Negligible heat lost through the shaft.

**ANALYSIS:** (a) The viscous dissipation,  $\mu\Phi$ , Eq. 6S.20, for Couette flow from Example 6S.1, is

$$\mu\Phi = \mu \left( \frac{du}{dy} \right)^2 = \mu \left( \frac{U}{L} \right)^2 = 0.03 \text{ N}\cdot\text{s}/\text{m}^2 \left( \frac{47.1 \text{ m/s}}{0.001 \text{ m}} \right)^2 = 6.656 \times 10^7 \text{ W}/\text{m}^3 \quad <$$

where the velocity distribution is linear and the tangential velocity of the shaft is

$$U = \pi DN = \pi (0.100 \text{ m}) \times 9000 \text{ rpm} \times (\text{min}/60\text{s}) = 47.1 \text{ m/s}.$$

(b) The heat transfer rate from the lubricant volume  $\forall$  through the bearing is

$$q = \mu\Phi \cdot \forall = \mu\Phi (\pi D \cdot L \cdot \ell) = 6.65 \times 10^7 \text{ W}/\text{m}^3 (\pi \times 0.100 \text{ m} \times 0.001 \text{ m} \times 0.070 \text{ m}) = 1462 \text{ W} \quad <$$

where  $\ell = 70 \text{ mm}$  is the length of the bearing normal to the page.

Continued...

### PROBLEM 6S.8 (Cont.)

(c) From Fourier's law, the heat rate through the bearing material of inner and outer diameters,  $D_i$  and  $D_o$ , and thermal conductivity  $k_b$  is, from Eq. (3.32),

$$q_r = \frac{2\pi\ell k_b (T_b - T_{wc})}{\ln(D_o/D_i)}$$

$$T_b = T_{wc} + \frac{q_r \ln(D_o/D_i)}{2\pi\ell k_b}$$

$$T_b = 30^\circ\text{C} + \frac{1462\text{ W} \ln(200/100)}{2\pi \times 0.070\text{ m} \times 45\text{ W/m}\cdot\text{K}} = 81.2^\circ\text{C} \quad <$$

To determine the temperature of the shaft,  $T(0) = T_s$ , first the temperature distribution must be found beginning with the general solution, Example 6S.1,

$$T(y) = -\frac{\mu}{2k} \left(\frac{U}{L}\right)^2 y^2 + C_3 y + C_4$$

The boundary conditions are, at  $y = 0$ , the surface is adiabatic

$$\left. \frac{dT}{dy} \right|_{y=0} = 0 \quad C_3 = 0$$

and at  $y = L$ , the temperature is that of the bearing,  $T_b$

$$T(L) = T_b = -\frac{\mu}{2k} \left(\frac{U}{L}\right)^2 L^2 + 0 + C_4 \quad C_4 = T_b + \frac{\mu}{2k} U^2$$

Hence, the temperature distribution is

$$T(y) = T_b + \frac{\mu}{2k} U^2 \left(1 - \frac{y^2}{L^2}\right)$$

and the temperature at the shaft,  $y = 0$ , is

$$T_s = T(0) = T_b + \frac{\mu}{2k} U^2 = 81.3^\circ\text{C} + \frac{0.03\text{ N}\cdot\text{s}/\text{m}^2}{2 \times 0.15\text{ W/m}\cdot\text{K}} (47.1\text{ m/s})^2 = 303^\circ\text{C} \quad <$$

## PROBLEM 6S.9

**KNOWN:** Couette flow with heat transfer.

**FIND:** (a) Dimensionless form of temperature distribution, (b) Conditions for which top plate is adiabatic, (c) Expression for heat transfer to lower plate when top plate is adiabatic.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) incompressible fluid with constant properties, (3) Negligible body forces, (4) Couette flow.

**ANALYSIS:** (a) From Example 6.4, the temperature distribution is

$$T = T_0 + \frac{\mu}{2k} U^2 \left[ \frac{y}{L} - \left( \frac{y}{L} \right)^2 \right] + (T_L - T_0) \frac{y}{L}$$

$$\frac{T - T_0}{T_L - T_0} = \frac{\mu U^2}{2k(T_L - T_0)} \left[ \frac{y}{L} - \left( \frac{y}{L} \right)^2 \right] + \frac{y}{L}$$

or, with

$$\theta \equiv (T - T_0)/(T_L - T_0), \quad \eta \equiv y/L,$$

$$\text{Pr} \equiv c_p \mu / k, \quad \text{Ec} \equiv U^2 / c_p (T_L - T_0)$$

$$\theta = \frac{\text{Pr} \cdot \text{Ec}}{2} (\eta - \eta^2) + \eta = \eta \left[ 1 + \frac{1}{2} \text{Pr} \cdot \text{Ec} (1 - \eta) \right] \quad (1) <$$

(b) For there to be zero heat transfer at the top plate,  $(dT/dy)_{y=L} = 0$ . Hence,  $(d\theta/d\eta)_{\eta=1} = 0$ .

$$\left. \frac{d\theta}{d\eta} \right|_{\eta=1} = \frac{\text{Pr} \cdot \text{Ec}}{2} (1 - 2\eta) \Big|_{\eta=1} + 1 = -\frac{\text{Pr} \cdot \text{Ec}}{2} + 1 = 0$$

There is no heat transfer at the top plate if,

$$\text{Ec} \cdot \text{Pr} = 2. \quad (2) <$$

(c) The heat transfer rate to the lower plate (per unit area) is

$$q_0'' = -k \left. \frac{dT}{dy} \right|_{y=0} = -k \frac{(T_L - T_0)}{L} \left. \frac{d\theta}{d\eta} \right|_{\eta=0}$$

$$q_0'' = -k \frac{T_L - T_0}{L} \left[ \frac{\text{Pr} \cdot \text{Ec}}{2} (1 - 2\eta) \Big|_{\eta=0} + 1 \right]$$

$$q_0'' = -k \frac{T_L - T_0}{L} \left( \frac{\text{Pr} \cdot \text{Ec}}{2} + 1 \right) = -2k (T_L - T_0) / L \quad <$$

Continued...

### PROBLEM 6S.9 (Cont.)

(d) Using Eq. (1), the dimensionless temperature distribution is plotted as a function of dimensionless distance,  $\eta = y/L$ . When  $Pr \cdot Ec = 0$ , there is no dissipation and the temperature distribution is linear, so that heat transfer is by conduction only. As  $Pr \cdot Ec$  increases, viscous dissipation becomes more important. When  $Pr \cdot Ec = 2$ , heat transfer to the upper plate is zero. When  $Pr \cdot Ec > 2$ , the heat rate is out of the oil film at both surfaces.

## PROBLEM 6S.10

**KNOWN:** Steady, incompressible, laminar flow between infinite parallel plates at different temperatures.

**FIND:** (a) Form of continuity equation, (b) Form of momentum equations and velocity profile. Relationship of pressure gradient to maximum velocity, (c) Form of energy equation and temperature distribution. Heat flux at top surface.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Two-dimensional flow (no variations in  $z$ ) between infinite, parallel plates, (2) Negligible body forces, (3) No internal energy generation, (4) Incompressible fluid with constant properties.

**ANALYSIS:** (a) For two-dimensional, steady conditions, the continuity equation is

$$\frac{\partial(\rho u)}{\partial x} + \frac{\partial(\rho v)}{\partial y} = 0.$$

Hence, for an incompressible fluid (constant  $\rho$ ) in parallel flow ( $v = 0$ ),

$$\frac{\partial u}{\partial x} = 0. \quad <$$

The flow is fully developed in the sense that, irrespective of  $y$ ,  $u$  is independent of  $x$ .

(b) With the above result and the prescribed conditions, the momentum equations reduce to

$$0 = -\frac{\partial p}{\partial x} + \mu \frac{\partial^2 u}{\partial y^2} \quad 0 = -\frac{\partial p}{\partial y} \quad <$$

Since  $p$  is independent of  $y$ ,  $\partial p / \partial x = dp / dx$  is independent of  $y$  and

$$\mu \frac{\partial^2 u}{\partial y^2} = \mu \frac{d^2 u}{dy^2} = \frac{dp}{dx}.$$

Since the left-hand side can, at most, depend only on  $y$  and the right-hand side is independent of  $y$ , both sides must equal the same constant  $C$ . That is,

$$\mu \frac{d^2 u}{dy^2} = C.$$

Hence, the velocity distribution has the form

$$u(y) = \frac{C}{2\mu} y^2 + C_1 y + C_2.$$

Using the boundary conditions to evaluate the constants,

$$u(0) = 0 \quad \rightarrow \quad C_2 = 0 \quad \text{and} \quad u(L) = 0 \quad \rightarrow \quad C_1 = -CL/2\mu.$$

Continued .....

**PROBLEM 6S.10 (Cont.)**

The velocity profile is  $u(y) = \frac{C}{2\mu}(y^2 - Ly)$ .

The profile is symmetric about the midplane, in which case the maximum velocity exists at  $y = L/2$ . Hence,

$$u(L/2) = u_{\max} = \frac{C}{2\mu} \left[ -\frac{L^2}{4} \right] \quad \text{or} \quad u_{\max} = -\frac{L^2}{8\mu} \frac{dp}{dx}. \quad <$$

(c) For fully developed thermal conditions,  $(\partial T/\partial x) = 0$  and temperature depends only on  $y$ . Hence with  $v = 0$ ,  $\partial u/\partial x = 0$ , and the prescribed assumptions, the energy equation becomes

$$\rho u \frac{\partial i}{\partial x} = k \frac{d^2 T}{dy^2} + u \frac{dp}{dx} + \mu \left[ \frac{du}{dy} \right]^2.$$

With  $i = e + p/\rho$ ,  $\frac{\partial i}{\partial x} = \frac{\partial e}{\partial x} + \frac{1}{\rho} \frac{dp}{dx}$  where  $\frac{\partial e}{\partial x} = \frac{\partial e}{\partial T} \frac{\partial T}{\partial x} + \frac{\partial e}{\partial \rho} \frac{\partial \rho}{\partial x} = 0$ .

Hence, the energy equation becomes  $0 = k \frac{d^2 T}{dy^2} + \mu \left[ \frac{du}{dy} \right]^2$ . <

With  $du/dy = (C/2\mu)(2y - L)$ , it follows that

$$\frac{d^2 T}{dy^2} = -\frac{C^2}{4k\mu} (4y^2 - 4Ly + L^2).$$

Integrating twice,

$$T(y) = -\frac{C^2}{4k\mu} \left[ \frac{y^4}{3} - \frac{2Ly^3}{3} + \frac{L^2 y^2}{2} \right] + C_3 y + C_4$$

Using the boundary conditions to evaluate the constants,

$$T(0) = T_2 \quad \rightarrow \quad C_4 = T_2 \quad \text{and} \quad T(L) = T_1 \quad \rightarrow \quad C_3 = \frac{C^2 L^3}{24k\mu} + \frac{(T_1 - T_2)}{L}.$$

Hence,  $T(y) = T_2 + \left[ \frac{y}{L} \right] (T_1 - T_2) - \frac{C^2}{4k\mu} \left[ \frac{y^4}{3} - \frac{2Ly^3}{3} + \frac{L^2 y^2}{2} - \frac{L^3 y}{6} \right]$ . <

From Fourier's law,

$$q''(L) = -k \left. \frac{\partial T}{\partial y} \right|_{y=L} = \frac{k}{L} (T_2 - T_1) + \frac{C^2}{4\mu} \left[ \frac{4}{3} L^3 - 2L^3 + L^3 - \frac{L^3}{6} \right]$$

$$q''(L) = \frac{k}{L} (T_2 - T_1) + \frac{C^2 L^3}{24\mu}. \quad <$$

**COMMENTS:** The third and second terms on the right-hand sides of the temperature distribution and heat flux, respectively, represents the effects of viscous dissipation. If  $C$  is large (due to large  $\mu$  or  $u_{\max}$ ), viscous dissipation is significant. If  $C$  is small, conduction effects dominate.

## PROBLEM 6S.11

**KNOWN:** Steady, incompressible flow of binary mixture between infinite parallel plates with different species concentrations.

**FIND:** Form of species continuity equation and concentration distribution. Species flux at upper surface.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Two-dimensional flow, (2) No chemical reactions, (3) Constant properties.

**ANALYSIS:** For fully developed conditions,  $\partial C_A / \partial x = 0$ . Hence with  $v = 0$ , the species conservation equation reduces to

$$\frac{d^2 C_A}{dy^2} = 0. \quad <$$

Integrating twice, the general form of the species concentration distribution is

$$C_A(y) = C_1 y + C_2.$$

Using appropriate boundary conditions and evaluating the constants,

$$\begin{aligned} C_A(0) = C_{A,2} &\rightarrow C_2 = C_{A,2} \\ C_A(L) = C_{A,1} &\rightarrow C_1 = (C_{A,1} - C_{A,2})/L, \end{aligned}$$

the concentration distribution is

$$C_A(y) = C_{A,2} + (y/L) (C_{A,1} - C_{A,2}). \quad <$$

From Fick's law, the species flux is

$$\begin{aligned} N_A''(L) &= -D_{AB} \left. \frac{dC_A}{dy} \right|_{y=L} \\ N_A''(L) &= \frac{D_{AB}}{L} (C_{A,2} - C_{A,1}). \quad < \end{aligned}$$

**COMMENTS:** An analogy between heat and mass transfer exists if viscous dissipation is negligible. The energy equation is then  $d^2 T / dy^2 = 0$ . Hence, both heat and species transfer are influenced only by diffusion. Expressions for  $T(y)$  and  $q''(L)$  are analogous to those for  $C_A(y)$  and  $N_A''(L)$ .

## PROBLEM 6S.12

**KNOWN:** Flow conditions between two parallel plates, across which vapor transfer occurs.

**FIND:** (a) Variation of vapor molar concentration between the plates and mass rate of water production per unit area, (b) Heat required to sustain the process.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Fully developed, incompressible flow with constant properties, (3) Negligible body forces, (4) No chemical reactions, (5) All work interactions, including viscous dissipation, are negligible.

**ANALYSIS:** (a) The flow will be fully developed in terms of the vapor concentration field, as well as the velocity and temperature fields. Hence

$$\frac{\partial C_A}{\partial x} = 0 \quad \text{or} \quad C_A(x, y) = C_A(y).$$

Also, with  $\partial C_A / \partial t = 0$ ,  $\dot{N}_A = 0$ ,  $v = 0$  and constant  $D_{AB}$ , the species conservation equation reduces to

$$\frac{d^2 C_A}{dy^2} = 0.$$

Separating and integrating twice,

$$C_A(y) = C_1(y) + C_2.$$

Applying the boundary conditions,

$$\begin{aligned} C_A(0) = C_{A,0} &\quad \rightarrow \quad C_2 = C_{A,0} \\ C_A(L) = C_{A,L} &\quad \rightarrow \quad C_{A,L} = C_1 L + C_2 \quad \quad C_1 = -\frac{C_{A,0} - C_{A,L}}{L} \end{aligned}$$

find the species concentration distribution,

$$C_A(y) = C_{A,0} - (C_{A,0} - C_{A,L}) (y/L). \quad <$$

From Fick's law, Eq. 6.7, the species transfer rate is

$$N_A'' = N_{A,s}'' = -D_{AB} \left. \frac{\partial C_A}{\partial y} \right]_{y=0} = D_{AB} \frac{C_{A,0} - C_{A,L}}{L}.$$

Continued .....

**PROBLEM 6S.12 (Cont.)**

Multiplying by the molecular weight of water vapor,  $\mathcal{M}_A$ , the mass rate of water production per unit area is

$$n''_A = \mathcal{M}_A N''_A = \mathcal{M}_A D_{AB} \frac{C_{A,0} - C_{A,L}}{L}. \quad <$$

(b) Heat must be supplied to the bottom surface in an amount equal to the latent and sensible heat transfer from the surface,

$$q'' = q''_{\text{lat}} + q''_{\text{sen}}$$

$$q'' = n''_{A,s} h_{fg} + \left[ -k \frac{dT}{dy} \right]_{y=0}.$$

The temperature distribution may be obtained by solving the energy equation, which, for the prescribed conditions, reduces to

$$\frac{d^2T}{dy^2} = 0.$$

Separating and integrating twice,

$$T(y) = C_1 y + C_2.$$

Applying the boundary conditions,

$$\begin{aligned} T(0) = T_0 &\quad \rightarrow \quad C_2 = T_0 \\ T(L) = T_L &\quad \rightarrow \quad C_1 = (T_1 - T_0)/L \end{aligned}$$

find the temperature distribution,

$$T(y) = T_0 - (T_0 - T_L) y/L.$$

Hence,

$$\left[ -k \frac{dT}{dy} \right]_{y=0} = k \frac{(T_0 - T_L)}{L}.$$

Accordingly,

$$q'' = \mathcal{M}_A D_{AB} \frac{C_{A,0} - C_{A,L}}{L} h_{fg} + k \frac{(T_0 - T_L)}{L}. \quad <$$

**COMMENTS:** Despite the existence of the flow, species and energy transfer across the air are uninfluenced by advection and transfer is only by diffusion. If the flow were not fully developed, advection would have a significant influence on the species concentration and temperature fields and hence on the rate of species and energy transfer. The foregoing results would, of course, apply in the case of no air flow. The physical condition is an example of Poiseuille flow with heat and mass transfer.

### PROBLEM 6S.13

**KNOWN:** The conservation equations, Eqs. 6S.24 and 6S.31.

**FIND:** (a) Describe physical significance of terms in these equations, (b) Identify approximations and special conditions used to reduce these equations to the boundary layer equations, Eqs. 6.29 and 6.30, (c) Identify the conditions under which these two boundary layer equations have the same form and, hence, an analogy will exist.

**ANALYSIS:** (a) The energy conservation equation, Eq. 6S.24, has the form

$$\rho u \frac{\partial i}{\partial x} + \rho v \frac{\partial i}{\partial y} = \frac{\partial}{\partial x} \left[ k \frac{\partial T}{\partial x} \right] + \frac{\partial}{\partial y} \left[ k \frac{\partial T}{\partial y} \right] + \left[ u \frac{\partial p}{\partial x} + v \frac{\partial p}{\partial y} \right] + \mu \Phi + \dot{q}.$$

1a
1b
2a
2b
3
4
5

The terms, as identified, have the following physical significance:

1. Change of enthalpy (thermal + flow work) advected in x and y directions, <
2. Change of conduction flux in x and y directions,
3. Work done by static pressure forces,
4. Work done by viscous stresses,
5. Rate of energy generation.

The species mass conservation equation for a constant total concentration has the form

$$u \frac{\partial C_A}{\partial x} + v \frac{\partial C_A}{\partial y} = \frac{\partial}{\partial x} \left[ D_{AB} \frac{\partial C_A}{\partial x} \right] + \frac{\partial}{\partial y} \left[ D_{AB} \frac{\partial C_A}{\partial y} \right] + \dot{N}_A$$

1a
1b
2a
2b
3

1. Change in species transport due to advection in x and y directions, <
2. Change in species transport by diffusion in x and y directions, and
3. Rate of species generation.

(b) The special conditions used to reduce the above equations to the boundary layer equations are: *constant properties, incompressible flow, non-reacting species* ( $\dot{N}_A = 0$ ), *without internal heat generation* ( $\dot{q} = 0$ ), *species diffusion has negligible effect on the thermal boundary layer,  $u(\partial p / \partial x)$  is negligible.* The approximations are,

Velocity boundary layer  $\left\{ u \gg v \quad \frac{\partial u}{\partial y} \gg \frac{\partial u}{\partial x}, \frac{\partial v}{\partial y}, \frac{\partial v}{\partial x} \right.$

Thermal b.1.:  $\left\{ \frac{\partial T}{\partial y} \gg \frac{\partial T}{\partial x} \right.$       Concentration b.1.:  $\left\{ \frac{\partial C_A}{\partial y} \gg \frac{\partial C_A}{\partial x} \right.$

The resulting simplified boundary layer equations are

$$u \frac{\partial T}{\partial x} + v \frac{\partial T}{\partial y} = \alpha \frac{\partial^2 T}{\partial y^2} + \frac{v}{c} \left[ \frac{\partial u}{\partial y} \right]^2 \quad u \frac{\partial C_A}{\partial x} + v \frac{\partial C_A}{\partial y} = D_{AB} \frac{\partial^2 C_A}{\partial y^2}$$

1a
1b
2a
3
1c
1d
2b
<

where the terms are: 1. Advective transport, 2. Diffusion, and 3. Viscous dissipation.

(c) When viscous dissipation effects are negligible, the two boundary layer equations have identical form. If the boundary conditions for each equation are of the same form, an analogy between heat and mass (species) transfer exists.

### PROBLEM 6S.14

**KNOWN:** Thickness and inclination of a liquid film. Mass density of gas in solution at free surface of liquid.

**FIND:** (a) Liquid momentum equation and velocity distribution for the x-direction. Maximum velocity, (b) Continuity equation and density distribution of the gas in the liquid, (c) Expression for the local Sherwood number, (d) Total gas absorption rate for the film, (e) Mass rate of NH<sub>3</sub> removal by a water film for prescribed conditions.

**SCHEMATIC:**

NH<sub>3</sub> (A) – Water (B)  
 $L = 2\text{m}$   
 $\delta = 1\text{mm}$   
 $D = 0.05\text{m}$   
 $W = \pi D = 0.157\text{m}$   
 $\rho_{A,0} = 25\text{kg/m}^3$   
 $D_{AB} = 2 \times 10^{-9}\text{m}^2/\text{s}$   
 $\phi = 0^\circ$

**ASSUMPTIONS:** (1) Steady-state conditions, (2) The film is in fully developed, laminar flow, (3) Negligible shear stress at the liquid-gas interface, (4) Constant properties, (5) Negligible gas concentration at  $x = 0$  and  $y = \delta$ , (6) No chemical reactions in the liquid, (7) Total mass density is constant, (8) Liquid may be approximated as semi-infinite to gas transport.

**PROPERTIES:** Table A-6, Water, liquid (300K):  $\rho_f = 1/v_f = 997\text{kg/m}^3$ ,  $\mu = 855 \times 10^{-6}\text{N}\cdot\text{s/m}^2$ ,  $\nu = \mu/\rho_f = 0.855 \times 10^{-6}\text{m}^2/\text{s}$ .

**ANALYSIS:** (a) For fully developed flow ( $v = w = 0$ ,  $\partial u/\partial x = 0$ ), the x-momentum equation is  
 $0 = \partial \tau_{yx} / \partial y + X$  where  $\tau_{yx} = \mu(\partial u / \partial y)$  and  $X = (\rho g) \cos \phi$ .

That is, the momentum equation reduces to a balance between gravitational and shear forces. Hence,

$$\mu \left( \partial^2 u / \partial y^2 \right) = -(\rho g) \cos \phi.$$

Integrating,  $\partial u / \partial y = -(g \cos \phi / \nu) y + C_1$        $u = -(g \cos \phi / 2\nu) y^2 + C_1 y + C_2$ .

Applying the boundary conditions,

$$\left. \partial u / \partial y \right|_{y=0} = 0 \quad \rightarrow \quad C_1 = 0$$

$$u(\delta) = 0 \quad \rightarrow \quad C_2 = g \cos \phi \frac{\delta^2}{2\nu}.$$

Hence, 
$$u = \frac{g \cos \phi}{2\nu} (\delta^2 - y^2) = \frac{g \cos \phi \delta^2}{2\nu} \left[ 1 - (y/\delta)^2 \right] \quad <$$

and the maximum velocity exists at  $y = 0$ ,

$$u_{\max} = u(0) = (g \cos \phi \delta^2) / 2\nu. \quad <$$

(b) Species transport within the liquid is influenced by diffusion in the y-direction and advection in the x-direction. Hence, the species continuity equation with  $u$  assumed equal to  $u_{\max}$  throughout the region of gas penetration is

Continued .....

**PROBLEM 6S.14 (Cont.)**

$$u \frac{\partial \rho_A}{\partial x} = D_{AB} \frac{\partial^2 \rho_A}{\partial y^2} \quad \frac{\partial^2 \rho_A}{\partial y^2} = \frac{u_{\max}}{D_{AB}} \frac{\partial \rho_A}{\partial x}$$

Appropriate boundary conditions are:  $\rho_A(x,0) = \rho_{A,o}$  and  $\rho_A(x,\infty) = 0$  and the entrance condition is:  $\rho_A(0,y) = 0$ . The problem is therefore analogous to transient conduction in a semi-infinite medium due to a sudden change in surface temperature. From Section 5.7, the solution is then

$$\frac{\rho_A - \rho_{A,o}}{0 - \rho_{A,o}} = \operatorname{erf} \frac{y}{2(D_{AB}x/u_{\max})^{1/2}} \quad \rho_A = \rho_{A,o} \operatorname{erfc} \frac{y}{2(D_{AB}x/u_{\max})^{1/2}} <$$

(c) The Sherwood number is defined as

$$\operatorname{Sh}_x = \frac{h_{m,x} x}{D_{AB}} \quad \text{where} \quad h_{m,x} \equiv \frac{n''_{A,x}}{\rho_{A,o}} = \frac{-D_{AB} \partial \rho_A / \partial y|_{y=0}}{\rho_{A,o}}$$

$$\left. \frac{\partial \rho_A}{\partial y} \right|_{y=0} = -\rho_{A,o} \frac{2}{(\pi)^{1/2}} \exp \left[ -\frac{y^2 u_{\max}}{4 D_{AB} x} \right] \frac{1}{2(D_{AB}x/u_{\max})^{1/2}} \bigg|_{y=0} = -\rho_{A,o} \left[ \frac{u_{\max}}{\pi D_{AB} x} \right]^{1/2}$$

Hence,

$$h_{m,x} = \left[ \frac{u_{\max} D_{AB}}{\pi x} \right]^{1/2} \quad \operatorname{Sh}_x = \frac{1}{(\pi)^{1/2}} \left[ \frac{u_{\max} x}{D_{AB}} \right]^{1/2} = \frac{1}{(\pi)^{1/2}} \left[ \frac{u_{\max} x}{\nu} \right]^{1/2} \left[ \frac{\nu}{D_{AB}} \right]^{1/2}$$

and with  $\operatorname{Re}_x \equiv u_{\max} x/\nu$ ,

$$\operatorname{Sh}_x = \left[ 1/(\pi)^{1/2} \right] \operatorname{Re}_x^{1/2} \operatorname{Sc}^{1/2} = 0.564 \operatorname{Re}_x^{1/2} \operatorname{Sc}^{1/2} <$$

(d) The total gas absorption rate may be expressed as

$$n_A = \bar{h}_{m,x} (W \cdot L) \rho_{A,o}$$

where the average mass transfer convection coefficient is

$$\bar{h}_{m,x} = \frac{1}{L} \int_0^L h_{m,x} dx = \frac{1}{L} \left[ \frac{u_{\max} D_{AB}}{\pi} \right]^{1/2} \int_0^L \frac{dx}{x^{1/2}} = \left[ \frac{4u_{\max} D_{AB}}{\pi L} \right]^{1/2}$$

Hence, the absorption rate per unit width is

$$n_A / W = (4u_{\max} D_{AB} L / \pi)^{1/2} \rho_{A,o} <$$

(e) From the foregoing results, it follows that the ammonia absorption rate is

$$n_A = \left[ \frac{4u_{\max} D_{AB} L}{\pi} \right]^{1/2} W \rho_{A,o} = \left[ \frac{4 g \cos \phi \delta^2 D_{AB} L}{2\pi \nu} \right]^{1/2} W \rho_{A,o}$$

Substituting numerical values,

$$n_A = \left[ \frac{4 \times 9.8 \text{ m/s}^2 \times 1 \times (10^{-3} \text{ m})^2 (2 \times 10^{-9} \text{ m}^2/\text{s}) 2\text{m}}{2\pi \times 0.855 \times 10^{-6} \text{ m}^2/\text{s}} \right]^{1/2} (0.157 \text{ m}) 25 \text{ kg/m}^3 = 6.71 \times 10^{-4} \text{ kg/s} <$$

**COMMENTS:** Note that  $\rho_{A,o} \neq \rho_{A,\infty}$ , where  $\rho_{A,\infty}$  is the mass density of the gas phase. The value of  $\rho_{A,o}$  depends upon the pressure of the gas and the solubility of the gas in the liquid.

## PROBLEM 11S.1

**KNOWN:** Operating conditions and surface area of a finned-tube, cross-flow exchanger.

**FIND:** Overall heat transfer coefficient.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat loss to surroundings, (2) Constant properties, (3) Exhaust gas properties are those of air.

**PROPERTIES:** Table A-6, Water ( $\bar{T}_m = 87^\circ\text{C}$ ):  $\bar{c}_p = 4203 \text{ J/kg}\cdot\text{K}$ ; Table A-4, Air ( $T_m \approx 275^\circ\text{C}$ ):  $\bar{c}_p = 1040 \text{ J/kg}\cdot\text{K}$ .

**ANALYSIS:** From the energy balance equations

$$q = \dot{m}_c c_{p,c} (T_{c,o} - T_{c,i}) = 0.5 \text{ kg/s} \times 4203 \text{ J/kg}\cdot\text{K} (150 - 25)^\circ\text{C} = 2.63 \times 10^5 \text{ W}$$

$$T_{h,o} = T_{h,i} - \frac{q}{\dot{m}_h c_{p,h}} = 325^\circ\text{C} - \frac{2.63 \times 10^5 \text{ W}}{2 \text{ kg/s} \times 1040 \text{ J/kg}\cdot\text{K}} = 198.6^\circ\text{C}.$$

Hence

$$U = q / A \Delta T_{\ell m} \quad \text{where} \quad \Delta T_{\ell m} = F \Delta T_{\ell m, \text{CF}}.$$

From Fig. 11S.3, with

$$P = \frac{t_o - t_i}{T_i - t_i} = \frac{150 - 25}{325 - 25} = 0.42, \quad R = \frac{T_i - T_o}{t_o - t_i} = \frac{325 - 198.6}{150 - 25} = 1.01, \quad F = 0.94$$

$$\Delta T_{\ell m, \text{CF}} = \frac{(325 - 150) - (198.6 - 25)}{\ln \frac{325 - 150}{198.6 - 25}} = 174.3^\circ\text{C}.$$

Hence

$$U = \frac{q}{A F \Delta T_{\ell m, \text{CF}}} = \frac{2.63 \times 10^5 \text{ W}}{10 \text{ m}^2 \times 0.94 \times 174.3^\circ\text{C}} = 160 \text{ W/m}^2 \cdot \text{K}. \quad <$$

**COMMENTS:** From the  $\varepsilon$ -NTU method,  $C_c = 2102 \text{ W/K}$ ,  $C_h = 2080 \text{ W/K}$ ,  $(C_{\min}/C_{\max}) \approx 1$ ,  $q_{\max} = 6.24 \times 10^5 \text{ W}$  and  $\varepsilon = 0.42$ . Hence, from Fig. 11.14,  $\text{NTU} \approx 0.75$  and  $U \approx 156 \text{ W/m}^2 \cdot \text{K}$ .

## PROBLEM 11S.2

**KNOWN:** Heat exchanger with two shell passes and eight tube passes having an area  $925\text{m}^2$ ;  $45,500\text{ kg/h}$  water is heated from  $80^\circ\text{C}$  to  $150^\circ\text{C}$ ; hot exhaust gases enter at  $350^\circ\text{C}$  and exit at  $175^\circ\text{C}$ .

**FIND:** Overall heat transfer coefficient.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible losses to surroundings, (2) Negligible kinetic and potential energy changes, (3) Constant properties, (4) Exhaust gas properties are approximated as those of atmospheric air.

**PROPERTIES:** Table A-6, Water ( $\bar{T}_c = (80 + 150)^\circ\text{C} / 2 = 388\text{K}$ ):  $c_c = c_{p,f} = 4236\text{ J/kg}\cdot\text{K}$ .

**ANALYSIS:** The overall heat transfer coefficient follows from Eqs. 11.9 and 11S.1 written in the form

$$U = q / AF\Delta T_{\ell m,CF}$$

where  $F$  is the correction factor for the HXer configuration, Fig. 11S.2, and  $\Delta T_{\ell m,CF}$  is the log mean temperature difference (CF), Eqs. 11.15 and 11.16. From Fig. 11S.2, find

$$R = \frac{T_{h,i} - T_{h,o}}{T_{c,o} - T_{c,i}} = \frac{(350 - 175)^\circ\text{C}}{(150 - 80)^\circ\text{C}} = 2.5 \quad P = \frac{T_{c,o} - T_{c,i}}{T_{h,i} - T_{c,i}} = \frac{(150 - 80)^\circ\text{C}}{(350 - 80)^\circ\text{C}} = 0.26$$

find  $F \approx 0.97$ . The log-mean temperature difference, Eqs. 11.15 and 11.17, is

$$\Delta T_{\ell m,CF} = \frac{\Delta T_1 - \Delta T_2}{\ln(\Delta T_1 / \Delta T_2)} = \frac{(350 - 150)^\circ\text{C} - (175 - 80)^\circ\text{C}}{\ln[(350 - 150) / (175 - 80)]} = 141.1^\circ\text{C}.$$

From an overall energy balance on the cold fluid (water), the heat rate is

$$q = \dot{m}_c c_c (T_{c,o} - T_{c,i})$$

$$q = 45,500\text{ kg/h} \times 1\text{h} / 3600\text{s} \times 4236\text{ J/kg}\cdot\text{K} (150 - 80)^\circ\text{C} = 3.748 \times 10^6\text{ W}.$$

Substituting values with  $A = 925\text{ m}^2$ , find

$$U = 3.748 \times 10^6\text{ W} / 925\text{m}^2 \times 0.97 \times 141.1\text{K} = 29.6\text{ W/m}^2 \cdot \text{K}.$$

<

**COMMENTS:** Compare the above result with representative values for air-water exchangers, as given in Table 11.2. Note that in this exchanger, two shells with eight tube passes, the correction factor effect is very small, since  $F = 0.97$ .

### PROBLEM 11S.3

**KNOWN:** A shell and tube Hxer (two shells, four tube passes) heats 10,000 kg/h of pressurized water from 35°C to 120°C with 5,000 kg/h water entering at 300°C.

**FIND:** Required heat transfer area,  $A_S$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat loss to surroundings, (2) Constant properties.

**PROPERTIES:** Table A-6, Water ( $\bar{T}_c = 350$  K):  $c_p = 4195$  J/kg·K; Table A-6, Water (Assume  $T_{h,o} \approx 150^\circ\text{C}$ ,  $\bar{T}_h \approx 500$  K):  $c_p = 4660$  J/kg·K.

**ANALYSIS:** The rate equation, Eq. 11.14, can be written in the form

$$A_S = q / U \Delta T_{\ell m} \quad (1)$$

and from Eq. 11S.1,

$$\Delta T_{\ell m} = F \Delta T_{\ell m, CF} \quad \text{where} \quad \Delta T_{\ell m, CF} = \frac{\Delta T_1 - \Delta T_2}{\ln(\Delta T_1 / \Delta T_2)}. \quad (2,3)$$

From an energy balance on the cold fluid, the heat rate is

$$q = \dot{m}_c c_{p,c} (T_{c,o} - T_{c,i}) = \frac{10,000 \text{ kg/h}}{3600 \text{ s/h}} \times 4195 \frac{\text{J}}{\text{kg} \cdot \text{K}} (120 - 35) \text{ K} = 9.905 \times 10^5 \text{ W}.$$

From an energy balance on the hot fluid, the outlet temperature is

$$T_{h,o} = T_{h,i} - q / \dot{m}_h c_{p,h} = 300^\circ\text{C} - 9.905 \times 10^5 \text{ W} / \frac{5000 \text{ kg}}{3600 \text{ s}} \times 4660 \frac{\text{J}}{\text{kg} \cdot \text{K}} = 147^\circ\text{C}.$$

From Fig. 11S.2, determine  $F$  from values of  $P$  and  $R$ , where  $P = (120 - 35)^\circ\text{C} / (300 - 35)^\circ\text{C} = 0.32$ ,  $R = (300 - 147)^\circ\text{C} / (120 - 35)^\circ\text{C} = 1.8$ , and  $F \approx 0.97$ . The log-mean temperature difference based upon a CF arrangement follows from Eq. (3); find

$$\Delta T_{\ell m} = [(300 - 120) - (147 - 35)] \text{ K} / \ln \frac{(300 - 120)}{(147 - 35)} = 143.3 \text{ K}.$$

$$A_S = 9.905 \times 10^5 \text{ W} / 1500 \text{ W/m}^2 \cdot \text{K} \times 0.97 \times 143.3 \text{ K} = 4.75 \text{ m}^2 \quad <$$

**COMMENTS:** (1) Check  $\bar{T}_h \approx 500$  K used in property determination;  $\bar{T}_h = (300 + 147)^\circ\text{C} / 2 = 497$  K.

(2) Using the NTU- $\varepsilon$  method, determine first the capacity rate ratio,  $C_{\min} / C_{\max} = 0.56$ . Then

$$\varepsilon \equiv \frac{q}{q_{\max}} = \frac{C_{\max} (T_{c,o} - T_{c,i})}{C_{\min} (T_{h,i} - T_{c,i})} = \frac{1}{0.56} \times \frac{(120 - 35)^\circ\text{C}}{(300 - 35)^\circ\text{C}} = 0.57.$$

From Fig. 11.13, find that  $\text{NTU} = AU / C_{\min} \approx 1.1$  giving  $A_S = 4.7 \text{ m}^2$ .

### PROBLEM 11S.4

**KNOWN:** The shell and tube Hxer (two shells, four tube passes) of Problem 11.14, known to have an area  $4.75\text{m}^2$ , provides  $95^\circ\text{C}$  water at the cold outlet (rather than  $120^\circ\text{C}$ ) after several years of operation. Flow rates and inlet temperatures of the fluids remain the same.

**FIND:** The fouling factor,  $R_f$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat loss to surroundings, (2) Constant properties, (3) Thermal resistance for the clean condition is  $R_t'' = (1500\text{ W/m}^2 \cdot \text{K})^{-1}$ .

**PROPERTIES:** Table A-6, Water ( $\bar{T}_c \approx 338\text{ K}$ ):  $c_p = 4187\text{ J/kg} \cdot \text{K}$ ; Table A-6, Water (Assume  $T_{h,o} \approx 190^\circ\text{C}$ ,  $\bar{T}_h \approx 520\text{ K}$ ):  $c_p = 4840\text{ J/kg} \cdot \text{K}$ .

**ANALYSIS:** The overall heat transfer coefficient can be expressed as

$$U = 1/(R_t'' + R_f'') \quad \text{or} \quad R_f'' = 1/U - R_t'' \quad (1)$$

where  $R_t''$  is the thermal resistance for the clean condition and  $R_f''$ , the fouling factor, represents the additional resistance due to fouling of the surface. The rate equation, Eq. 11.14 with Eq. 11S.1, has the form,

$$U = q/A_s F \Delta T_{lm,CF} \quad \Delta T_{lm,CF} = (\Delta T_1 - \Delta T_2)/\ln(\Delta T_1/\Delta T_2). \quad (2)$$

From energy balances on the cold and hot fluids, find

$$q = \dot{m}_c c_{p,c} (T_{c,o} - T_{c,i}) = (10,000/3600\text{ kg/s}) 4187\text{ J/kg} \cdot \text{K} (95 - 35)\text{ K} = 6.978 \times 10^5\text{ W}$$

$$T_{h,o} = T_{h,i} - q/\dot{m}_h c_{p,h} = 300^\circ\text{C} - 6.978 \times 10^5\text{ W}/(5000/3600\text{ kg/s} \times 4840\text{ J/kg} \cdot \text{K}) = 196.2^\circ\text{C}.$$

The factor,  $F$ , follows from values of  $P$  and  $R$  as given by Fig. 11S.2 with

$$P = (95 - 35)/(300 - 35) = 0.23 \quad R = (300 - 196)/(120 - 35) = 1.22$$

giving  $F \approx 1$ . Based upon CF arrangement,

$$\Delta T_{lm,CF} = [(300 - 95) - (196 - 35)]^\circ\text{C}/\ln[(300 - 95)/(196 - 35)] = 182\text{ K}.$$

Using Eq. (2), find now the overall heat transfer coefficient as

$$U = 6.978 \times 10^5\text{ W}/4.75\text{m}^2 \times 1 \times 182\text{ K} = 806\text{ W/m}^2 \cdot \text{K}.$$

From Eq. (1), the fouling factor is

$$R_f'' = \frac{1}{806\text{ W/m}^2 \cdot \text{K}} - \frac{1}{1500\text{ W/m}^2 \cdot \text{K}} = 5.74 \times 10^{-4}\text{ m}^2 \cdot \text{K/W}. \quad \leftarrow$$

**COMMENTS:** Note that the effect of fouling is to nearly double ( $U_{\text{clean}}/U_{\text{fouled}} = 1500/806 \approx 1.9$ ) the resistance to heat transfer. Note also the assumption for  $T_{h,o}$  used for property evaluation is satisfactory.

## PROBLEM 11S.5

**KNOWN:** Flow rates and inlet temperatures for automobile radiator configured as a cross-flow heat exchanger with both fluids unmixed. Overall heat transfer coefficient.

**FIND:** (a) Area required to achieve hot fluid (water) outlet temperature,  $T_{h,o} = 330$  K, and (b) Outlet temperatures,  $T_{h,o}$  and  $T_{c,o}$ , as a function of the overall coefficient for the range,  $200 \leq U \leq 400$  W/m<sup>2</sup>·K with the surface area  $A$  found in part (a) with all other heat transfer conditions remaining the same as for part (a).

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat loss to surrounding, (2) Constant properties.

**PROPERTIES:** Table A.6, Water ( $\bar{T}_h = 365$  K):  $c_{p,h} = 4209$  J/kg·K; Table A.4, Air ( $\bar{T}_c \approx 310$  K):  $c_{p,c} = 1007$  J/kg·K.

**ANALYSIS:** (a) The required heat transfer rate is

$$q = \dot{m}_h c_{p,h} (T_{h,i} - T_{h,o}) = 0.05 \text{ kg/s} (4209 \text{ J/kg} \cdot \text{K}) 70 \text{ K} = 14,732 \text{ W}.$$

and from an energy balance on the cold fluid,

$$T_{c,o} = T_{c,i} + q / \dot{m}_c c_{p,c} = 300 \text{ K} + 14,732 \text{ W} / (0.75 \text{ kg/s} \times 1007 \text{ J/kg} \cdot \text{K}) = 319.5 \text{ K}$$

We will use Eq. 11.14 with Eq. 11S.1. From Fig. 11S.3, with  $P = (T_{c,o} - T_{c,i}) / (T_{h,i} - T_{c,i}) = 0.20$  and  $R = (T_{h,i} - T_{h,o}) / (T_{c,o} - T_{c,i}) = 3.6$ , we find  $F \approx 0.95$ . Then,

$$\Delta T_{lm,CF} = \frac{(T_{h,i} - T_{c,o}) - (T_{h,o} - T_{c,i})}{\ln(T_{h,i} - T_{c,o}) / (T_{h,o} - T_{c,i})} = 51.2 \text{ K}$$

Thus

$$A = q / U F \Delta T_{lm,CF} = 14,732 \text{ W} / 200 \text{ W/m}^2 \cdot \text{K} \times 0.95 \times 51.2 \text{ K} = 1.5 \text{ m}^2 \quad <$$

(b) To solve this “performance” problem using the log mean temperature difference method is very cumbersome. It requires solving the following equations for the two unknown outlet temperatures (and  $q$ ), where  $F$  is also a function of the two outlet temperatures,

$$q = \dot{m}_c c_{p,c} (T_{c,o} - T_{c,i}) \quad (1)$$

$$q = \dot{m}_h c_{p,h} (T_{h,i} - T_{h,o}) \quad (2)$$

$$q = U A F \Delta T_{lm,CF} \quad \Delta T_{lm,CF} = \frac{(T_{h,i} - T_{c,o}) - (T_{h,o} - T_{c,i})}{\ln(T_{h,i} - T_{c,o}) / (T_{h,o} - T_{c,i})} \quad (3,4)$$

Continued...

## PROBLEM 11S.5 (Cont.)

One rational approach is to work backward. For a specified value of  $q$ , Eqs. (1) and (2) can be used to solve for the outlet temperatures. Then  $F$  and  $\Delta T_{lm,CF}$  can be determined, and  $U$  can be found from Eq. (3). In this way, we can generate the following plot.

With a higher  $U$ , the outlet temperature of the hot fluid (water) decreases. A benefit is enhanced heat removal from the engine block and a cooler operating temperature. If it is desired to cool the engine with water at 330 K, the heat exchanger surface area and, hence its volume in the engine component could be reduced.

**COMMENT:** This problem is much easier to solve using the  $\epsilon$ -NTU method, as shown in this IHT model.

```

// Heat Exchanger Tool - Cross-flow with both fluids unmixed:
// For the cross-flow, single-pass heat exchanger with both fluids unmixed,
eps = 1 - exp((1 / Cr) * (NTU^0.22) * (exp(-Cr * NTU^0.78) - 1)) // Eq 11.32
// where the heat-capacity ratio is
Cr = Cmin / Cmax
// and the number of transfer units, NTU, is
NTU = U * A / Cmin // Eq 11.24
// The effectiveness is defined as
eps = q / qmax
qmax = Cmin * (Thi - Tci) // Eq 11.18, 11.19
// See Tables 11.3 and 11.4 and Fig 11.14
// Overall Energy Balances on Fluids:
q = mdoth * cph * (Thi - Tho)
q = mdotc * cpc * (Tco - Tci)
// Assigned Variables:
Cmin = Ch // Capacity rate, minimum fluid, W/K
Ch = mdoth * cph // Capacity rate, hot fluid, W/K
mdoth = 0.05 // Flow rate, hot fluid, kg/s
Thi = 400 // Inlet temperature, hot fluid, K
Tho = 330 // Outlet temperature, hot fluid, K; specified for part (a)
Cmax = Cc // Capacity rate, maximum fluid, W/K
Cc = mdotc * cpc // Capacity rate, cold fluid, W/K
mdotc = 0.75 // Flow rate, cold fluid, kg/s
Tci = 300 // Inlet temperature, cold fluid, K
U = 200 // Overall coefficient, W/m^2.K

// Properties Tool - Water (h)
// Water property functions :T dependence, From Table A.6
// Units: T(K), p(bars);
xh = 0 // Quality (0=sat liquid or 1=sat vapor)
rho_h = rho_Tx("Water",Tmh,xh) // Density, kg/m^3
cph = cp_Tx("Water",Tmh,xh) // Specific heat, J/kg.K
Tmh = Tfluid_avg(Thi,Tho)

// Properties Tool - Air(c)
// Air property functions : From Table A.4
// Units: T(K); 1 atm pressure
rho_c = rho_T("Air",Tmc) // Density, kg/m^3
cpc = cp_T("Air",Tmc) // Specific heat, J/kg.K
Tmc = Tfluid_avg(Tci,Tco)
    
```

## PROBLEM 11S.6

**KNOWN:** Single pass, cross-flow heat exchanger with hot exhaust gases (mixed) to heat water (unmixed)

**FIND:** Required surface area.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat loss to surroundings, (2) Negligible kinetic and potential energy changes, (3) Exhaust gas properties assumed to be those of air.

**PROPERTIES:** Table A-6, Water ( $\bar{T}_c = (80 + 30)^\circ\text{C}/2 = 328\text{ K}$ ):  $c_p = 4184\text{ J/kg}\cdot\text{K}$ ; Table A-4, Air (1 atm,  $\bar{T}_h = (100 + 225)^\circ\text{C}/2 = 436\text{ K}$ ):  $c_p = 1019\text{ J/kg}\cdot\text{K}$ .

**ANALYSIS:** The rate equation for the heat exchanger follows from Eqs. 11.14 and 11S.1. The area is given as

$$A = q / U\Delta T_{\ell m} = q / UF\Delta T_{\ell m,CF} \quad (1)$$

where  $F$  is determined from Fig. 11S.4 using

$$P = \frac{80 - 30}{225 - 30} = 0.26 \quad \text{and} \quad R = \frac{225 - 100}{80 - 30} = 2.50 \quad \text{giving} \quad F \approx 0.92. \quad (2)$$

From an energy balance on the cold fluid, find

$$q = \dot{m}_c c_c (T_{c,o} - T_{c,i}) = 3 \frac{\text{kg}}{\text{s}} \times 4184 \frac{\text{J}}{\text{kg}\cdot\text{K}} (80 - 30)\text{K} = 627,600\text{ W}. \quad (3)$$

From Eq. 11.15, the LMTD for counter-flow conditions is

$$\Delta T_{\ell m,CF} = \frac{\Delta T_1 - \Delta T_2}{\ln(\Delta T_1 / \Delta T_2)} = \frac{(225 - 80) - (100 - 30)}{\ln(145/70)}^\circ\text{C} = 103.0^\circ\text{C}. \quad (4)$$

Substituting numerical values resulting from Eqs. (2-4) into Eq. (1), find the required surface area to be

$$A = 627,600\text{ W} / 200\text{ W/m}^2 \cdot \text{K} \times 0.92 \times 103.0\text{K} = 33.1\text{m}^2. \quad <$$

**COMMENTS:** Note that the properties of the exhaust gases were not needed in this method of analysis. If the  $\varepsilon$ -NTU method were used, find first  $C_h/C_c = 0.40$  with  $C_{\min} = C_h = 5021\text{ W/K}$ . From Eqs. 11.18 and 11.19, with  $C_h = C_{\min}$ ,  $\varepsilon = q/q_{\max} = (T_{h,i} - T_{h,o}) / (T_{h,i} - T_{c,i}) = (225 - 100) / (225 - 30) = 0.64$ . Using Fig. 11.15 with  $C_{\min}/C_{\max} = 0.4$  and  $\varepsilon = 0.64$ , find  $\text{NTU} = UA/C_{\min} \approx 1.4$ . Hence,

$$A = \text{NTU} \cdot C_{\min} / U \approx 1.4 \times 5021\text{ W/K} / 200\text{ W/m}^2 \cdot \text{K} = 35.2\text{m}^2.$$

Note agreement with above result.

## PROBLEM 11S.7

**KNOWN:** Conditions of oil and water for heat exchanger, one shell with 4 tube passes.

**FIND:** Length of exchanger tubes per pass,  $L$ ; and (b) Compute and plot the effectiveness,  $\epsilon$ , fluid outlet temperatures,  $T_{h,o}$  and  $T_{c,o}$ , and water-side convection coefficient,  $h_c$ , as a function of the water flow rate for  $5000 \leq \dot{m}_c \leq 15,000$  kg/h for the tube length found in part (a) with all other conditions remaining the same.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat loss to surroundings, (2) Constant properties, (3) Fully-developed flow in tubes.

**PROPERTIES:** Table A-1, Brass (400 K):  $k = 137$  W/m·K; Table A-5, Water (323 K):  $\rho = 998.1$  kg/m<sup>3</sup>,  $k = 0.643$  W/m·K,  $c_p = 4182$  J/kg·K,  $\mu = 548 \times 10^{-6}$  N·s/m<sup>2</sup>,  $Pr = 3.56$ .

**ANALYSIS:** (a) From an energy balance on the water, the heat rate required is

$$q = \dot{m}_c c_c (T_{c,o} - T_{c,i}) = 10,000 / 3600 \text{ kg/s} \times 4182 \text{ J/kg} \cdot \text{K} (84 - 16)^\circ \text{C} = 789,933 \text{ W}. \quad (1)$$

The required tube length may be obtained from Eqs. 11.14 and 11.15,

$$q = U_o A_o F \Delta T_{\ell m, CF} \quad (2)$$

$$\Delta T_{\ell m, CF} = \left[ (160 - 84)^\circ \text{C} - (94 - 16)^\circ \text{C} \right] / \ln \left( (160 - 84) / (94 - 16) \right) = 77.0^\circ \text{C}.$$

From Fig. 11S.1,  $F = 0.86$  using  $P = (84 - 16) / (160 - 16) = 0.47$  and  $R = (160 - 94) / (84 - 16) = 0.97$ . From Eq. 11.5,

$$U_o = \left[ \frac{1}{h_o} + \frac{r_o}{k} \ln \frac{r_o}{r_i} + \frac{r_o}{r_i} \frac{1}{h_i} \right]^{-1}$$

where  $h_i$  must be estimated from the appropriate correlation. With  $N = 11$ , the number of tubes,

$$Re_D = \frac{4\dot{m}/N}{\pi D \mu} = \frac{4 \times (10,000/3600) \text{ kg/s} / (11)}{\pi \times 22.9 \times 10^{-3} \text{ m} \times 548 \times 10^{-6} \text{ N} \cdot \text{s/m}^2} = 25,621.$$

For fully developed turbulent flow, the Dittus-Boelter correlation with  $n = 0.4$  yields

$$Nu_D = h_i D / k = 0.023 Re_D^{0.8} Pr^{0.4} = 0.023 (25,621)^{0.8} (3.56)^{0.4} = 128.6$$

$$h_i = Nu_D (k/D) = 128.6 \times 0.643 \text{ W/m} \cdot \text{K} / (22.9 \times 10^{-3} \text{ m}) = 3610 \text{ W/m}^2 \cdot \text{K}.$$

Continued...

**PROBLEM 11S.7 (Cont.)**

$$U_o = \left[ \frac{1}{400 \text{ W/m}^2 \cdot \text{K}} + \frac{25.4 \times 10^{-3} \text{ m}}{2 \times 137 \text{ W/m} \cdot \text{K}} \ln \frac{25.4}{22.9} + \frac{25.4}{22.9} \times \frac{1}{3610 \text{ W/m}^2 \cdot \text{K}} \right]^{-1} = 355 \text{ W/m}^2 \cdot \text{K} .$$

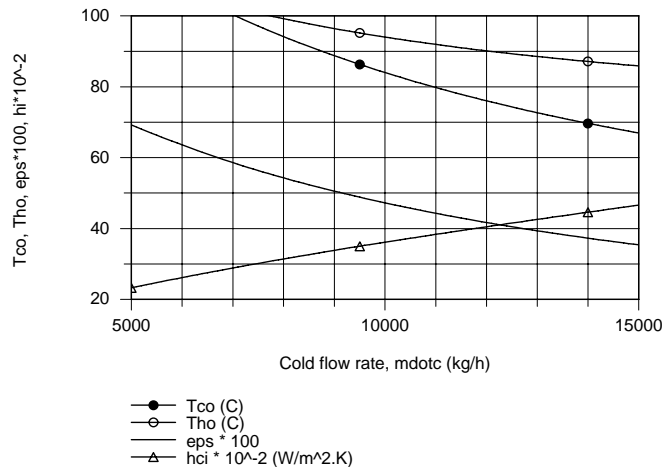

Returning now to Eq. (2), find  $A_o$ , then the length,

$$A_o = \pi D_o L \times \text{No. of Passes} \times \text{No. of Tubes} = \pi \times 25.4 \times 10^{-3} \text{ m} \times 4 \times 11 L = 3.511 L$$

$$L = 789,933 \text{ W} / 3.511 \text{ m} \times 355 \text{ W/m}^2 \cdot \text{K} \times 0.86 \times 77.0^\circ \text{ C} = 9.6 \text{ m}$$

<

(b) Using the *IHT Heat Exchanger Tool, Shell and Tube, One-shell pass and N tube passes*, the *Correlation Tool, Forced Convection, Internal Flow for Turbulent, fully developed condition*, and the *Properties Tool for Water*, a model was developed using the effectiveness - NTU method to compute and plot  $T_{c,o}$ ,  $T_{h,o}$ ,  $\epsilon$ , and  $h_i$  as a function of  $\dot{m}_c$ .

In order to avoid a boiling condition in the cold fluid, the cold flow rate should not be less than 8000 kg/h. As expected,  $T_{c,o}$  and  $T_{h,o}$  decrease and the internal convection coefficient increases nearly linearly with increasing flow rate. The effectiveness increases with increasing flow rate since the overall convection coefficient is increasing.

**COMMENTS:** (1) The thermal resistance of the brass tubes is negligible. Since  $L/D_i = 400$ , fully-developed conditions are reasonable.

(2) In the analysis of part (b), you have to specify the capacity rate for the hot fluid in order to solve the model. From the analysis of part (a) using the model, we found  $L = 9.56 \text{ m}$  and  $C_h = 11,974 \text{ W/K}$ .

## PROBLEM 11S.8

**KNOWN:** Power output and efficiency of an ocean energy conversion system. Temperatures and overall heat transfer coefficient of shell-and-tube evaporator.

**FIND:** (a) Evaporator area, (b) Water flow rate.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat loss to surroundings, (2) Constant properties.

**PROPERTIES:** Table A-6, Water ( $\bar{T}_m = 296 \text{ K}$ ):  $c_p = 4181 \text{ J/kg} \cdot \text{K}$ .

**ANALYSIS:** (a) The efficiency is

$$\eta = \frac{\dot{W}}{q} = \frac{2 \text{ MW}}{q} = 0.03.$$

Hence the required heat transfer rate is

$$q = \frac{2 \text{ MW}}{0.03} = 66.7 \text{ MW}.$$

Also

$$\Delta T_{\ell m, CF} = \frac{(300 - 290) - (292 - 290)^\circ \text{C}}{\ln \frac{300 - 290}{292 - 290}} = 5^\circ \text{C}$$

and, with  $P = 0$  and  $R = \infty$ , from Fig. 11S.1 it follows that  $F = 1$ . Hence

$$A = \frac{q}{UF\Delta T_{\ell m, CF}} = \frac{6.67 \times 10^7 \text{ W}}{1200 \text{ W/m}^2 \cdot \text{K} \times 1 \times 5^\circ \text{C}}$$

$$A = 11,100 \text{ m}^2. \quad <$$

(b) The water flow rate through the evaporator is

$$\dot{m}_h = \frac{q}{c_{p,h}(T_{h,i} - T_{h,o})} = \frac{6.67 \times 10^7 \text{ W}}{4181 \text{ J/kg} \cdot \text{K} (300 - 292)}$$

$$\dot{m}_h = 1994 \text{ kg/s}. \quad <$$

**COMMENTS:** (1) From the  $\epsilon$ -NTU method,  $(C_{\min}/C_{\max}) = 0$ ,  $q_{\max} = 8.34 \times 10^7 \text{ W}$ ,  $\epsilon = 0.80$  and from Fig. 11.12,  $\text{NTU} \approx 1.65$ , giving  $A = 11,500 \text{ m}^2$ . (2) The required heat exchanger size is enormous due to the small temperature differences involved.

## PROBLEM 11S.9

**KNOWN:** Shell-and-tube heat exchanger with one shell pass and 20 tube passes.

**FIND:** Average convection coefficient for the outer tube surface.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat loss to surroundings, (2) Constant properties, (3) Type of oil not specified, (4) Thermal resistance of tubes negligible; no fouling.

**PROPERTIES:** Table A-6, Water, liquid ( $\bar{T}_h = 330$  K):  $c_p = 4184$  J/kg·K,  $k = 0.650$  W/m·K,  $\mu = 489 \times 10^{-6}$  N·s/m<sup>2</sup>,  $Pr = 3.15$ .

**ANALYSIS:** To find the average coefficient for the outer tube surface,  $h_o$ , we need to evaluate  $h_i$  for the internal tube flow and  $U$ , the overall coefficient. From Eq. 11.5,

$$\frac{1}{UA} = \frac{1}{h_i A_i} + \frac{1}{h_o A_o} = \frac{1}{N_t \pi L} \left[ \frac{1}{h_i D_i} + \frac{1}{h_o D_o} \right]$$

where  $N_t$  is the total number of tubes. Solving for  $h_o$ ,

$$h_o = D_o^{-1} \left[ (UA)^{-1} N_t \pi L - 1/h_i D_i \right]^{-1}. \quad (1)$$

Evaluate  $h_i$  from an appropriate correlation; begin by calculating the Reynolds number.

$$Re_{D,i} = \frac{4 \dot{m}_h}{\pi D_i \mu} = \frac{4 \times 0.2 \text{ kg/s}}{\pi (0.020 \text{ m}) 489 \times 10^{-6} \text{ N} \cdot \text{s/m}^2} = 26,038.$$

Hence, flow is turbulent and since  $L \gg D_i$ , the flow is likely to be fully developed. Use the Dittus-Boelter correlation with  $n = 0.3$  since  $T_s < T_m$ ,  $Nu_D = 0.023 Re_D^{4/5} Pr^{0.3}$

$$h_i = \frac{k}{D} Nu_D = \frac{0.650 \text{ W/m} \cdot \text{K}}{0.020 \text{ m}} \times 0.023 (26,038)^{4/5} (3.15)^{0.3} = 3594 \text{ W/m}^2 \cdot \text{K}. \quad (2)$$

To evaluate  $UA$ , we need to employ the rate equation, written as

$$UA = q / F \Delta T_{\ell m, CF} \quad (3)$$

where  $q = \dot{m}_h c_{p,h} (T_{h,i} - T_{h,o}) = 0.2 \text{ kg/s} \times 4184 \text{ J/kg} \cdot \text{K} (87 - 27)^\circ\text{C} = 50,208 \text{ W}$  and  $\Delta T_{\ell m, CF} = [\Delta T_1 - \Delta T_2] / \ln (\Delta T_1 / \Delta T_2) = [(87 - 37) - (27 - 7)]^\circ\text{C} / \ln [(87 - 37) / (27 - 7)] = 32.7^\circ\text{C}$ . Find  $F \approx 0.5$  using Fig. 11S.1 with  $P = (27 - 87) / (7 - 87) = 0.75$  and  $R = (7 - 37) / (27 - 87) = 0.50$ . Substituting numerical values in Eqs. (3) and (1), find

$$UA = 50,208 \text{ W} / 0.5 \times 32.7^\circ\text{C} = 3071 \text{ W/K} \quad (4)$$

$$h_o = (0.024 \text{ m})^{-1} \left[ (3071 \text{ W/K})^{-1} \times 20 \times \pi \times 3 \text{ m} - 1 / 3594 \text{ W/m}^2 \cdot \text{K} \times 0.020 \text{ m} \right]^{-1} = 878 \text{ W/m}^2 \cdot \text{K}. <$$

**COMMENTS:** Using the  $\epsilon$ -NTU method: find  $C_h$  and  $C_c$  to obtain  $C_r = 0.5$  and  $\epsilon = 0.75$ . From Eq. 11.30b,c find  $NTU = 3.44$  and  $UA = 2881 \text{ W/K}$ .

### PROBLEM 11S.10

**KNOWN:** Flow rates and inlet temperatures of exhaust gases and combustion air used in a cross-flow (one fluid mixed) heat exchanger. Overall heat transfer coefficient. Desired air outlet temperature.

**FIND:** Required heat exchanger surface area.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Negligible heat loss to surroundings, (3) Constant properties, (4) Gas properties are those of air.

**PROPERTIES:** Table A-4, Air ( $\bar{T}_m \approx 700$  K, 1 atm):  $c_p = 1075$  J/kg·K.

**ANALYSIS:** From Eqs. 11.6 and 11.7,

$$T_{h,o} = T_{h,i} - \frac{\dot{m}_c c_{p,c}}{\dot{m}_h c_{p,h}} (T_{c,o} - T_{c,i}) = 1100\text{K} - \frac{10 \text{ kg/s}}{15 \text{ kg/s}} (850 - 300)\text{K} = 733\text{K}.$$

From Eqs. 11.15, 11.17 and 11S.1,

$$\Delta T_{lm} = F \frac{(T_{h,i} - T_{c,o}) - (T_{h,o} - T_{c,i})}{\ln \left[ \frac{(T_{h,i} - T_{c,o})}{(T_{h,o} - T_{c,i})} \right]} = F \frac{250 - 433}{\ln(250/433)} = F \times 333\text{K}.$$

From Fig. 11S.4, with  $R = (300 - 850)/(733 - 1100) = 1.50$  and  $P = (733 - 1100)/(300 - 1100) = 0.46$ ,  $F \approx 0.73$ . With

$$q = \dot{m}_h c_{p,h} (T_{h,i} - T_{h,o}) = 15 \text{ kg/s} \times 1075 \text{ J/kg} \cdot \text{K} (367\text{K}) = 5.92 \times 10^6 \text{ W}$$

it follows from Eq. 11.14 that

$$A = \frac{5.92 \times 10^6 \text{ W}}{100 \text{ W/m}^2 \cdot \text{K} \times 0.73(333\text{K})} = 243 \text{ m}^2. \quad <$$

**COMMENTS:** Using the effectiveness-NTU method, from Eq. 11.21

$$\varepsilon = \frac{T_{c,o} - T_{c,i}}{T_{h,i} - T_{c,i}} = \frac{(850 - 300)\text{K}}{(1100 - 300)\text{K}} = 0.688.$$

Hence, with  $C_{\text{mixed}}/C_{\text{unmixed}} = C_c/C_h = 0.67$ , Fig. 11.15 gives  $\text{NTU} \approx 2.3$ . From Eq. 11.24,

$$A = \text{NTU} \frac{C_{\min}}{U} \approx 2.3 \frac{10 \text{ kg/s} \times 1075 \text{ J/kg} \cdot \text{K}}{100 \text{ W/m}^2 \cdot \text{K}} \approx 247 \text{ m}^2.$$

### PROBLEM 11S.11

**KNOWN:** Flow rate, specific heat and inlet temperature of gas in cross-flow heat exchanger. Flow rate and temperature of water which enters as saturated liquid and leaves as saturated vapor. Number of tubes, tube diameter and overall heat transfer coefficient.

**FIND:** Required tube length.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat loss to surroundings, (2) Constant gas specific heat.

**PROPERTIES:** Table A-6, Saturated Water, ( $T = 450 \text{ K}$ ):  $h_{fg} = 2.024 \times 10^6 \text{ J/kg}$ .

**ANALYSIS:** The heat transfer rate can be found from considering the cold fluid,

$$q = \dot{m}_c h_{fg} = 3 \text{ kg/s} \times 2.024 \times 10^6 \text{ J/kg} = 6.072 \times 10^6 \text{ W}$$

Then an energy balance on the hot fluid yields

$$T_{h,o} = T_{h,i} - q/\dot{m}_h c_{p,h} = 1400 \text{ K} - 6.072 \times 10^6 \text{ W}/10 \text{ kg/s} \times 1120 \text{ J/kg} \cdot \text{K} = 857.9 \text{ K}$$

From Eqs. 11.15 and 11.17,

$$\Delta T_{lm,CF} = \frac{(T_{h,i} - T_{c,o}) - (T_{h,o} - T_{c,i})}{\ln \left[ \frac{(T_{h,i} - T_{c,o})}{(T_{h,o} - T_{c,i})} \right]} = \frac{(1400 - 450) \text{ K} - (857.9 - 450) \text{ K}}{\ln \left[ \frac{(1400 - 450) \text{ K}}{(857.9 - 450) \text{ K}} \right]} = 641 \text{ K}$$

From Fig. 11S.4, with  $P = (T_{c,o} - T_{c,i})/(T_{h,i} - T_{c,i}) = 0$ , find  $F = 1$ , thus

$$A_o = q/U\Delta T_{lm,CF} = 6.072 \times 10^6 \text{ W}/50 \text{ W/m}^2 \cdot \text{K} \times 641 \text{ K} = 189 \text{ m}^2$$

$$L = A_o/N\pi D_o = 189 \text{ m}^2/500 \times \pi \times 0.025 \text{ m} = 4.8 \text{ m}$$

<

## PROBLEM 11S.12

**KNOWN:** Compact heat exchanger (see Example 11S.2) after extended use has prescribed fouling factors on water and gas sides.

**FIND:** Gas-side overall heat transfer coefficient.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Heat transfer coefficients on the inside and outside (cold- and hot-sides) are the same as for the unfouled condition, (2) Temperature effectiveness of the finned hot side surface is the same as for the unfouled condition.

**ANALYSIS:** The overall heat transfer coefficient follows from Eq. 11.1 as

$$\frac{1}{U_h A_h} = \frac{1}{(\eta_o h A)_c} + \frac{R''_{f,c}}{(\eta_o A)_c} + R_w + \frac{R''_{f,h}}{(\eta_o A)_h} + \frac{1}{(\eta_o h A)_h}$$

where  $R_w$  and  $R''_f$  are the wall resistance and fouling factors, respectively. Multiply both sides by  $A_h$  and recognizing that  $\eta_{o,c} = 1$ , obtain

$$\frac{1}{U_h} = \frac{1}{h_c (A_c/A_h)} + \frac{R''_{f,c}}{(A_c/A_h)} + A_h R_w + \frac{R''_{f,h}}{\eta_{o,h}} + \frac{1}{\eta_o h_h}$$

Substitute numerical values from Example 11S.2 results ( $h_h$ ,  $\eta_{o,h}$ ,  $A_h R_w$ ,  $A_c/A_h$ ) and those from the problem statement ( $R''_{f,h}$ ,  $R''_{f,c}$ ,  $h_c$ ) to find,

$$\frac{1}{U_h} = \frac{1}{1500 \text{ W}/\text{m}^2 \cdot \text{K} (0.143)} + \frac{0.0005 \text{ m}^2 \cdot \text{K}/\text{W}}{(0.143)} + 3.51 \times 10^{-5} \text{ m}^2 \cdot \text{K}/\text{W} + \frac{0.001 \text{ m}^2 \cdot \text{K}/\text{W}}{0.91} + \frac{1}{0.91 \times 190 \text{ W}/\text{m}^2 \cdot \text{K}}$$

$$\frac{1}{U_h} = \left( 4.662 \times 10^{-3} + 3.497 \times 10^{-3} + 3.51 \times 10^{-5} + 1.099 \times 10^{-3} + 6.005 \times 10^{-3} \right) \text{ m}^2 \cdot \text{K}/\text{W}$$

$$U_h = 66.3 \text{ W}/\text{m}^2 \cdot \text{K}.$$

<

**COMMENTS:** For the unfouled condition, we found  $U_h = 100 \text{ W}/\text{m}^2 \cdot \text{K}$  from Example 11S.2. Note that the thermal resistance of the tube-fin material is negligible and that fouling has a significant effect, reducing  $U_h$  by 34%.

### PROBLEM 11S.13

**KNOWN:** Compact heat exchanger with prescribed core geometry and operating parameters.

**FIND:** Required heat exchanger volume; number of tubes in the longitudinal and transverse directions,  $N_L$  and  $N_T$ ; required tube length.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat loss to surroundings, (2) Single pass operation, (3) Gas properties are those of air.

**PROPERTIES:** Table A-6, Water ( $\bar{T}_c = 325 \text{ K}$ ):  $\rho = 987.2 \text{ kg/m}^3$ ,  $c_p = 4182 \text{ J/kg} \cdot \text{K}$ ; Table A-4, Air (Assume  $T_{h,o} \approx 400 \text{ K}$ ,  $\bar{T}_h \approx 550 \text{ K}$ , 1 atm):  $c_p = 1040 \text{ J/kg} \cdot \text{K}$ .

**ANALYSIS:** To find the Hxer volume, first find  $A_h$  using the  $\epsilon$ -NTU method. By definition,

$$V = A_h / \alpha \quad \text{and} \quad A_h = \text{NTU} \cdot C_{\min} / U_h. \quad (1,2)$$

Find the capacity rates,  $q$ ,  $q_{\max}$  and  $\epsilon$ :

$$C_c = \dot{m}_c c_{p,c} = 2 \text{ kg/s} \times 4182 \text{ J/kg} \cdot \text{K} = 8364 \text{ W/K}$$

$$C_h = \dot{m}_h c_{p,h} = 1.25 \text{ kg/s} \times 1040 \text{ J/kg} \cdot \text{K} = 1300 \text{ W/K} \leftarrow C_{\min}$$

Hence,

$$C_r = \frac{C_{\min}}{C_{\max}} = 0.155.$$

It follows that

$$\epsilon = \frac{q}{q_{\max}} = \frac{C_c (T_{c,o} - T_{c,i})}{C_{\min} (T_{h,i} - T_{c,i})} = \frac{8364 \text{ W/K} (350 - 300) \text{ K}}{1300 \text{ W/K} (700 - 300) \text{ K}} = 0.804.$$

With  $\epsilon = 0.804$  and  $C_r = 0.155$ , find  $\text{NTU} \approx 1.7$  from Fig. 11.14 for a single-pass, cross flow Hxer with both fluids unmixed. Using Eqs. (2) and (1), find

$$A_h = 1.7 \times 1300 \text{ W/K} / 100 \text{ W/m}^2 \cdot \text{K} = 22.1 \text{ m}^2$$

$$V = 22.1 \text{ m}^2 / 269 \text{ m}^2/\text{m}^3 = 0.082 \text{ m}^3.$$

Continued .....

**PROBLEM 11S.13 (Cont.)**

To determine the number of tubes in the longitudinal direction, consider the tubular arrangement in the sketch. The Hxer volume can be written as

$$V = A_{fr} \times \ell_L \quad (3)$$

where

$$\ell_L = (N_L - 1)\ell + D_f \quad (4)$$

and  $N_L$  is the number of tubes in the longitudinal direction. Combining Eqs. (3) and (4) and substituting numerical values, find

$$N_L = (V / A_{fr} - D_f) / \ell + 1 \quad (5)$$

where  $D_f$  is the overall diameter of the finned tube, and

$$N_L = (0.082 \text{ m}^3 / 0.20 \text{ m}^2 - 0.0285 \text{ m}) / 0.0343 + 1 = 12.1 \approx 13. \quad <$$

To determine the number of tubes in the transverse direction, compare the overall water flow rate  $\dot{m}_c$  with that for a single tube,  $\dot{m}_t$ . That is,

$$\dot{m}_t = \rho_c A_t V_i \quad (6)$$

where  $A_t$  is the tube inner cross-sectional area  $(\pi D_i^2 / 4)$  and  $V_i$  the internal velocity. Hence,

$$N = \dot{m}_c / \dot{m}_t = (2 \text{ kg/s}) / 987.2 \text{ kg/m}^3 \times \frac{\pi}{4} (0.0138 \text{ m})^2 \times 0.100 \text{ m/s} = 135.4 \approx 135.$$

The total number of tubes required,  $N$ , is 135; the number in the transverse direction is

$$N_T = N / N_L = 135 / 13 = 10.4 \approx 11. \quad <$$

To determine the water tube length, recognize that the total area ( $A_h$ ), less that of the finned surfaces ( $A_f$ ), will be that of the water tube surface area. That is,

$$A_h - A_f = \pi D_o \ell_T \cdot N.$$

From specification of the core geometry, we know  $A_f / A_h = 0.830$ ; solve for  $\ell_T$  to obtain

$$\ell_T = A_h (1 - A_f / A_h) / \pi D_o \cdot N \quad (7)$$

$$\ell_T = 22.1 \text{ m}^2 (1 - 0.830) / \pi (0.0164 \text{ m}) \times 135 = 0.54 \text{ m}. \quad <$$

**COMMENTS:** In summary we find that

Total number of tubes, $N$ ( $N_T \times N_L$ )	143
Tubes in longitudinal direction, $N_L$	13
Tubes in transverse direction, $N_T$	11

with a total surface area of  $22.1 \text{ m}^2$ . The length of the exchanger is

Length in longitudinal direction, $\ell_L$	0.41 m
Length in transverse direction, $\ell_T$	0.54 m.

### PROBLEM 11S.14

**KNOWN:** Compact heat exchanger geometry, gas-side flow rate and inlet temperature, water-side convection coefficient, water flow rate, and water inlet and outlet temperatures.

**FIND:** Gas-side overall heat transfer coefficient. Required heat exchanger volume.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Gas has properties of atmospheric air at an assumed mean temperature of 700 K, (2) Negligible fouling, (3) Negligible heat exchange with the surroundings.

**PROPERTIES:** Table A-1, aluminum ( $T \approx 300$  K):  $k = 237$  W/m·K. Table A-4, air ( $p = 1$  atm,  $\bar{T} = 700$  K):  $c_p = 1075$  J/kg·K,  $\mu = 338.8 \times 10^{-7}$  N·s/m<sup>2</sup>,  $Pr = 0.695$ . Table A-6, water ( $\bar{T} = 330$  K):  $c_p = 4184$  J/kg·K.

**ANALYSIS:** For the prescribed heat exchanger core,

$$\frac{1}{U_h} = \frac{1}{h_c (A_c / A_h)} + A_h R_w + \frac{1}{\eta_{o,h} h_h}$$

where

$$\frac{A_c}{A_h} \approx \frac{D_i}{D_o} \left( 1 - \frac{A_{f,h}}{A_h} \right) = \frac{8.2}{10.2} (1 - 0.913) = 0.070$$

The product of  $A_h$  and the wall conduction resistance is

$$A_h R_w = \frac{\ln(D_o / D_i)}{2\pi k L / A_h} = \frac{D_i \ln(D_o / D_i)}{2k(A_c / A_h)} = \frac{0.0082\text{m} \times \ln(10.2/8.2)}{2 \times 237 \text{ W/m} \cdot \text{K} (0.070)} = 5.39 \times 10^{-5} \text{ m}^2 \cdot \text{K/W}$$

With a gas-side mass velocity of  $G = \dot{m}_h / \sigma A_{fr} = 1.25 \text{ kg/s} / 0.534 \times 0.20 \text{ m}^2 = 11.7 \text{ kg/s} \cdot \text{m}^2$ ,

$$Re = \frac{G D_h}{\mu} = \frac{11.7 \text{ kg/s} \cdot \text{m}^2 \times 0.00363\text{m}}{338.8 \times 10^{-7} \text{ N} \cdot \text{s/m}^2} = 1254$$

and Fig. 11S.6 yields  $j_H \approx 0.0096$ . Hence,

$$h_h \approx \frac{0.0096 G c_p}{Pr^{2/3}} = \frac{0.0096 (11.7 \text{ kg/s} \cdot \text{m}^2) (1075 \text{ J/kg} \cdot \text{K})}{(0.695)^{2/3}} = 154 \text{ W/m}^2 \cdot \text{K}$$

Continued .....

**PROBLEM 11S.14 (Cont.)**

With  $r_{2c} = r_2 + t/2 = 15.8 \text{ mm} + 0.330 \text{ mm}/2 = 15.97 \text{ mm}$ ,  $r_{2c}/r_1 = 15.97/5.1 = 3.13$ ,  $L = r_2 - r_1 = 10.7 \text{ mm}$ ,  $L_c = L + t/2 = 10.87 \text{ mm} = 0.0109 \text{ m}$ ,  $A_p = L_c t = 3.59 \times 10^{-6} \text{ m}^2$ , and  $L_c^{3/2} (h_h/kA_p)^{1/2} = 0.484$ , Fig. 3.20 yields  $\eta_f \approx 0.77$ . Hence,

$$\eta_{o,h} = 1 - \frac{A_f}{A} (1 - \eta_f) = 1 - 0.913(1 - 0.77) = 0.790$$

$$U_h^{-1} = \left(1500 \text{ W/m}^2 \cdot \text{K} \times 0.07\right)^{-1} + 5.39 \times 10^{-5} \text{ m}^2 \cdot \text{K/W} + \left(0.79 \times 154 \text{ W/m}^2 \cdot \text{K}\right)^{-1} = 0.0183 \text{ m}^2 \cdot \text{K/W}$$

$$U_h = 56.2 \text{ W/m}^2 \cdot \text{K} \quad <$$

With  $q = C_c (T_{c,o} - T_{c,i}) = 4184 \text{ W/K} \times 80 \text{ K} = 3.35 \times 10^5 \text{ W}$ ,  $q_{\max} = C_{\min} (T_{h,i} - T_{c,i}) = 1344 \text{ W/K} \times 535 \text{ K} = 7.19 \times 10^5 \text{ W}$ ,  $\epsilon = 0.466$  and  $C_r = 0.321$ . From Figure 11.14, we then obtain  $\text{NTU} \approx 0.65$ . The required gas-side surface area is then

$$A_h = \frac{\text{NTU} \times C_{\min}}{U_h} = \frac{0.65 \times 1344 \text{ W/K}}{56.2 \text{ W/m}^2 \cdot \text{K}} = 15.5 \text{ m}^2$$

With  $\alpha = 587 \text{ m}^2/\text{m}^3$ , the required volume is

$$V = \frac{A_h}{\alpha} = \frac{15.5 \text{ m}^2}{587 \text{ m}^2/\text{m}^3} = 0.026 \text{ m}^3 \quad <$$

**COMMENTS:** (1) Although  $U_h$  is small and  $A_h$  larger for the continuous fins than for the circular fins of Example 11.6, the much larger value of  $\alpha$  renders the volume requirement smaller.

(2) The heat exchanger length is  $L = V/A_{fr} = 0.132 \text{ m}$ , and the number of tube rows is

$$N_L \approx \frac{L}{S_L} + 1 = 7$$

(3) The hypothetical fin radius ( $r_2 = 15.8 \text{ mm}$ ) was estimated to be the arithmetic mean of one-half the center-to-center spacing between one tube and its six neighbors.

### PROBLEM 11S.15

**KNOWN:** Cooling coil geometry. Air flow rate and inlet and outlet temperatures. Refrigerant-134a pressure and convection coefficient.

**FIND:** Required number of tube rows.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible fouling, (2) Constant properties, (3) Negligible heat loss to surroundings.

**PROPERTIES:** Table A-4, Air ( $\bar{T}_h = 300$  K, 1 atm):  $c_p = 1007$  J/kg·K,  $\mu = 184.6 \times 10^{-7}$  N·s/m<sup>2</sup>,  $k = 0.0263$  W/m·K,  $Pr = 0.707$ ; Table A-5, Sat. R-134a (1 atm):  $T_{sat} = T_c = 247$  K,  $h_{fg} = 217$  kJ/kg.

**ANALYSIS:** The required number of tube rows is

$$N_L = (L - D_f) / S_L + 1$$

where

$$L = V / A_{fr} \quad V = A_h / \alpha \quad A_h = NTU (C_{min} / U_h)$$

$$1 / U_h = 1 / h_c (A_c / A_h) + A_h R_w + 1 / \eta_{o,h} h_h.$$

From Ex. 11S.2,  $(A_c / A_h) = 0.143$  and  $A_h R_w = 3.51 \times 10^{-5}$  m<sup>2</sup>·K/W. With

$$G = \frac{\dot{m}_h}{\sigma A_{fr}} = \frac{1.50 \text{ kg/s}}{0.449 \times 0.16 \text{ m}^2} = 20.9 \text{ kg/s} \cdot \text{m}^2$$

$$Re = \frac{GD_h}{\mu} = \frac{20.9 \text{ kg/s} \cdot \text{m}^2 \times 6.68 \times 10^{-3} \text{ m}}{184.6 \times 10^{-7} \text{ N} \cdot \text{s/m}^2} = 7563$$

and Fig. 11S.5 gives  $j_H \approx 0.0068$ . Hence,

$$h_h = j_h \frac{Gc_p}{Pr^{2/3}} = 0.0068 \frac{20.9 \text{ kg/s} \cdot \text{m}^2 \times 1007 \text{ J/kg} \cdot \text{K}}{(0.707)^{2/3}} = 180 \text{ W/m}^2 \cdot \text{K}.$$

With  $L_c = 6.18$  mm and  $A_p = 1.57 \times 10^{-6}$  m<sup>2</sup> from Ex. 11S.5,  $L_c^{3/2} (h_h / kA_p)^{1/2} = 0.338$  and, from Fig. 3.20,  $\eta_f \approx 0.89$  for  $r_{2c}/r_1 = 1.75$ . Hence, as in Ex. 11S.5,  $\eta_{o,h} = 0.91$  and

$$1 / U_h = 1 / (5000 \text{ W/m}^2 \cdot \text{K}) 0.143 + 3.51 \times 10^{-5} \text{ m}^2 \cdot \text{K/W} + 1 / (0.91 \times 180 \text{ W/m}^2 \cdot \text{K})$$

$$U_h = 133 \text{ W/m}^2 \cdot \text{K}.$$

Continued .....

### PROBLEM 11S.15 (Cont.)

With  $C_{\min}/C_{\max} = 0$  and  $C_{\min} = \dot{m}_h c_{p,h} = 1511 \text{ W/K}$ ,

$$\varepsilon = \frac{q}{q_{\max}} = \frac{C_h (T_{h,i} - T_{h,o})}{C_h (T_{h,i} - T_{c,i})} = \frac{20 \text{ K}}{67 \text{ K}} = 0.317$$

$$\text{NTU} = -\ln(1 - \varepsilon) = 0.382$$

and

$$A_h = \text{NTU} \frac{C_{\min}}{U_h} = 0.382 \frac{1511 \text{ W/K}}{133 \text{ W/m}^2 \cdot \text{K}} = 4.34 \text{ m}^2.$$

Hence,

$$L = \frac{A_h}{\alpha A_{\text{fr}}} = \frac{4.34 \text{ m}^2}{(269 \text{ m}^2/\text{m}^3) 0.16 \text{ m}^2} = 0.101 \text{ m}$$

and

$$N_L = \frac{L - D_f}{S_L} + 1 = \frac{0.0723}{0.0343 \text{ m}} + 1 = 3.1.$$

Hence, three or more rows must be used. <

**COMMENTS:** For the prescribed operating conditions, the heat rate would be

$$q = C_h (T_{h,i} - T_{h,o}) = 1511 \text{ W/K} (20 \text{ K}) = 30,220 \text{ W}.$$

If R-134a enters the tubes as saturated liquid, a flow rate of at least

$$\dot{m}_c = \frac{q}{h_{\text{fg}}} = \frac{30,220 \text{ W}}{217,000 \text{ J/kg}} = 0.139 \text{ kg/s}$$

would be needed to maintain saturated conditions in the tubes.

### PROBLEM 11S.16

**KNOWN:** Cooling coil geometry. Air flow rate and inlet temperature. R-134a pressure and convection coefficient.

**FIND:** Air outlet temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible fouling, (2) Constant properties, (3) Negligible heat loss to surroundings.

**PROPERTIES:** Table A-4, Air ( $\bar{T}_h \approx 300 \text{ K}$ , 1 atm):  $c_p = 1007 \text{ J/kg} \cdot \text{K}$ ,  $\mu = 184.6 \times 10^{-7} \text{ N} \cdot \text{s/m}^2$ ,  $k = 0.0263 \text{ W/m} \cdot \text{K}$ ,  $Pr = 0.707$ ; Table A-5, Sat. R-134a (1 atm):  $T_{\text{sat}} = T_c = 247 \text{ K}$ ,  $h_{fg} = 217 \text{ kJ/kg}$ .

**ANALYSIS:** To obtain the air outlet temperature, we must first obtain the heat rate from the  $\epsilon$ -NTU method. To find  $A_h$ , first find the heat exchanger length,

$$L \approx (N_L - 1)S_L + D_f = 3(0.0343 \text{ m}) + 0.0285 \text{ m} = 0.131 \text{ m}.$$

Hence,

$$V = A_{fr}L = 0.16 \text{ m}^2 (0.131 \text{ m}) = 0.021 \text{ m}^3$$

$$A_h = \alpha V = (269 \text{ m}^2 / \text{m}^3) 0.021 \text{ m}^3 = 5.65 \text{ m}^2.$$

The overall coefficient is

$$\frac{1}{U_h} = \frac{1}{h_c (A_c / A_h)} + A_h R_w + \frac{1}{\eta_{o,h} h_h}$$

where Ex. 11S.2 yields  $(A_c / A_h) = 0.143$  and  $A_h R_w = 3.51 \times 10^{-5} \text{ m}^2 \cdot \text{K/W}$ . With

$$G = \frac{\dot{m}_h}{\sigma A_{fr}} = \frac{1.50 \text{ kg/s}}{0.449 \times 0.16 \text{ m}^2} = 20.9 \text{ kg/s} \cdot \text{m}^2$$

$$Re = \frac{GD_h}{\mu} = \frac{20.9 \text{ kg/s} \cdot \text{m}^2 \times 6.68 \times 10^{-3} \text{ m}}{184.6 \times 10^{-7} \text{ N} \cdot \text{s/m}^2} = 7563.$$

Fig. 11S.5 gives  $j_H \approx 0.0068$ . Hence,

$$h_h = j_h \frac{Gc_p}{Pr^{2/3}} = 0.0068 \frac{20.9 \text{ kg/s} \cdot \text{m}^2 \times 1007 \text{ J/kg} \cdot \text{K}}{(0.707)^{2/3}}$$

$$h_h = 180 \text{ W/m}^2 \cdot \text{K}.$$

Continued .....

### PROBLEM 11S.16 (Cont.)

With  $L_c = 6.18 \text{ mm}$  and  $A_p = 1.57 \times 10^{-6} \text{ m}^2$  from Ex. 11S.2,  $L_c^{3/2} (h_h / kA_p)^{1/2} = 0.338$  and, from Fig. 3.20,  $\eta_f \approx 0.89$  for  $r_{2c}/r_1 = 1.75$ . Hence, as in Ex. 11S.2,  $\eta_{o,h} = 0.91$  and

$$\frac{1}{U_h} = \frac{1}{(5000 \text{ W/m}^2 \cdot \text{K})0.143} + 3.51 \times 10^{-5} \text{ m}^2 \cdot \text{K/W} + \frac{1}{0.91(180 \text{ W/m}^2 \cdot \text{K})}$$

$$U_h = 133 \text{ W/m}^2 \cdot \text{K}.$$

With

$$C_{\min} = C_h = \dot{m}_h c_{p,h} = 1.5 \text{ kg/s}(1007 \text{ J/kg} \cdot \text{K}) = 1511 \text{ W/K}$$

$$NTU = \frac{U_h A_h}{C_{\min}} = \frac{133 \text{ W/m}^2 \cdot \text{K} \times 5.65 \text{ m}^2}{1511 \text{ W/K}} = 0.497.$$

With  $C_{\min}/C_{\max} = 0$ , Eq. 11.35a yields

$$\varepsilon = 1 - \exp(-NTU) = 1 - \exp(-0.497) = 0.392.$$

Hence,

$$q = \varepsilon q_{\max} = \varepsilon C_{\min} (T_{h,i} - T_{c,i}) = 0.392(1511 \text{ W/K})63 \text{ K}$$

$$q = 37,200 \text{ W}.$$

The air outlet temperature is

$$T_{h,o} = T_{h,i} - \frac{q}{C_h} = 310 \text{ K} - \frac{37,200 \text{ W}}{1511 \text{ W/K}} = 285 \text{ K}.$$

<

**COMMENTS:** If R-134a enters the tubes as saturated liquid, a flow rate of at least

$$\dot{m}_c = \frac{q}{h_{fg}} = \frac{37,200 \text{ W}}{217,000 \text{ J/kg}} = 0.171 \text{ kg/s}$$

would be needed to maintain saturated conditions in the tubes.

### PROBLEM 11S.17

**KNOWN:** Cooling coil geometry. Gas flow rate and inlet temperature. Water pressure, flow rate and convection coefficient.

**FIND:** Required number of tube rows.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible fouling, (2) Constant properties, (3) Negligible heat loss to surroundings.

**PROPERTIES:** Table A-4, Air ( $\bar{T}_h \approx 725$  K, 1 atm):  $c_p = 1081$  J/kg·K,  $\mu = 346.7 \times 10^{-7}$  N·s/m<sup>2</sup>,  $k = 0.0536$  W/m·K,  $Pr = 0.698$ ; Table A-6, Sat. water (2.455 bar):  $T_{\text{sat}} = T_c = 400$  K,  $h_{fg} = 2183$  kJ/kg.

**ANALYSIS:** The required number of tube rows is

$$N_L = \frac{L - D_f}{S_L} + 1$$

where

$$L = \frac{V}{A_{fr}} \quad V = \frac{A_h}{\alpha} \quad A_h = NTU \frac{C_{\min}}{U_h}$$

$$\frac{1}{U_h} = \frac{1}{h_c (A_c / A_h)} + A_h R_w + \frac{1}{\eta_{o,h} h_h}$$

From Ex. 11S.2,  $(A_c / A_h) \approx 0.143$  and

$$A_h R_w = \frac{D_i \ln(D_o / D_i)}{2k (A_c / A_h)} = \frac{(0.0138 \text{ m}) \ln(16.4 / 13.8)}{2(15 \text{ W/m} \cdot \text{K})(0.143)} = 5.55 \times 10^{-4} \text{ m}^2 \cdot \text{K/W}$$

With

$$G = \frac{\dot{m}_h}{\sigma A_{fr}} = \frac{3.0 \text{ kg/s}}{0.449 \times 0.36 \text{ m}^2} = 18.6 \text{ kg/s} \cdot \text{m}^2$$

$$Re = \frac{GD_h}{\mu} = \frac{18.6 \text{ kg/s} \cdot \text{m}^2 \times 6.68 \times 10^{-3} \text{ m}}{346.7 \times 10^{-7} \text{ N} \cdot \text{s/m}^2} = 3576$$

and Fig. 11.16S.5 gives  $j_h \approx 0.009$ . Hence,

$$h_h = j_h \frac{Gc_p}{Pr^{2/3}} = 0.009 \frac{18.6 \text{ kg/s} \cdot \text{m}^2 \times 1081 \text{ J/kg} \cdot \text{K}}{(0.698)^{2/3}} = 230 \text{ W/m}^2 \cdot \text{K}$$

Continued .....

**PROBLEM 11S.17 (Cont.)**

With  $r_{2c}/r_1 = 1.75$ ,  $L_c = 6.18$  mm and  $A_p = 1.57 \times 10^{-6} \text{ m}^2$  from Ex. 11.6,  $L_c^{3/2} (h_h/kA_p)^{1/2} = 1.52$  and Fig. 3.20 gives  $\eta_f \approx 0.40$ . Hence,

$$\eta_{o,h} = 1 - \frac{A_f}{A} (1 - \eta_f) = 1 - 0.83(1 - 0.4) = 0.50.$$

Hence,

$$\frac{1}{U_h} = \frac{1}{(10^4 \text{ W/m}^2 \cdot \text{K})0.143} + 5.55 \times 10^{-4} \text{ m}^2 \cdot \text{K/W} + \frac{1}{0.50(230 \text{ W/m}^2 \cdot \text{K})}$$

$$U_h = 100.5 \text{ W/m}^2 \cdot \text{K}.$$

With

$$q = \dot{m}_c h_{fg} = 0.5 \text{ kg/s} (2.183 \times 10^6 \text{ J/kg}) = 1.092 \times 10^6 \text{ W}$$

$$C_{\min} = C_h = 3.0 \text{ kg/s} (1081 \text{ J/kg} \cdot \text{K}) = 3243 \text{ W/K}$$

$$q_{\max} = C_{\min} (T_{h,i} - T_{c,i}) = 3243 \text{ W/K} (500 \text{ K}) = 1.622 \times 10^6 \text{ W}$$

find

$$\varepsilon = \frac{q}{q_{\max}} = \frac{1.092 \times 10^6 \text{ W}}{1.622 \times 10^6 \text{ W}} = 0.674.$$

From Eq. 11.35b

$$NTU = -\ln(1 - \varepsilon) = -\ln(1 - 0.674) = 1.121.$$

Hence,

$$A_h = NTU \frac{C_{\min}}{U_h} = 1.121 \frac{3243 \text{ W/K}}{100.5 \text{ W/m}^2 \cdot \text{K}} = 36.17 \text{ m}^2$$

$$L = \frac{A_h}{A_{fr} \alpha} = \frac{36.17 \text{ m}^2}{0.36 \text{ m}^2 (269 \text{ m}^2/\text{m}^3)} = 0.373 \text{ m}$$

$$N_L = \frac{L - D_f}{S_L} + 1 = \frac{373 - 28.5}{34.3} + 1 = 11.06 \approx 11. \quad <$$

**COMMENTS:** The gas outlet temperature is

$$T_{h,o} = T_{h,i} - \frac{q}{C_{\min}} = 900 \text{ K} - \frac{1.092 \times 10^6 \text{ W}}{3243 \text{ W/K}} = 564 \text{ K}.$$

Hence  $\bar{T}_h = (900 \text{ K} + 564 \text{ K})/2 = 732 \text{ K}$  is in good agreement with the assumed value.

## PROBLEM 11S.18

**KNOWN:** Cooling coil geometry. Gas flow rate and inlet temperature. Water pressure and convection coefficient.

**FIND:** Gas outlet temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible fouling, (2) Constant properties, (3) Negligible heat loss to surroundings.

**PROPERTIES:** Table A-4, Air ( $\bar{T}_h \approx 725$  K, 1 atm):  $c_p = 1081$  J/kg·K,  $\mu = 346.7 \times 10^{-7}$  N·s/m<sup>2</sup>,  $k = 0.0536$  W/m·K,  $Pr = 0.698$ ; Table A-6, Sat. water (2.455 bar):  $T_{\text{sat}} = T_c = 400$  K,  $h_{fg} = 2183$  kJ/kg.

**ANALYSIS:** To obtain  $T_{h,o}$ , first obtain  $q$  from the  $\epsilon$ -NTU method. To determine NTU,  $A_h$  must be found from knowledge of  $L$ .

$$L \approx (N_L - 1)S_L + D_f = 10(0.0343 \text{ m}) + 0.0285 \text{ m} = 0.372 \text{ m}.$$

Hence,

$$V = A_{fr}L = 0.36 \text{ m}^2 (0.372 \text{ m}) = 0.134 \text{ m}^3$$

$$A_h = \alpha V = (269 \text{ m}^2 / \text{m}^3) 0.134 \text{ m}^3 = 36.05 \text{ m}^2.$$

The overall coefficient is

$$\frac{1}{U_h} = \frac{1}{h_c (A_c / A_h)} + A_h R_w + \frac{1}{\eta_{o,h} h_h}.$$

From Ex. 11S.2,  $(A_c / A_h) \approx 0.143$  and

$$A_h R_w = \frac{D_i \ln(D_o / D_i)}{2k(A_c / A_h)} = \frac{(0.0138 \text{ m}) \ln(16.4 / 13.8)}{2(15 \text{ W/m} \cdot \text{K})(0.143)} = 5.55 \times 10^{-4} \text{ m}^2 \cdot \text{K} / \text{W}.$$

With

$$G = \frac{\dot{m}_h}{\sigma A_{fr}} = \frac{3.0 \text{ kg/s}}{0.449 \times 0.36 \text{ m}^2} = 18.6 \text{ kg/s} \cdot \text{m}^2$$

$$Re = \frac{GD_h}{\mu} = \frac{18.6 \text{ kg/s} \cdot \text{m}^2 \times 6.68 \times 10^{-3} \text{ m}}{346.7 \times 10^{-7} \text{ N} \cdot \text{s/m}^2} = 3576$$

and Fig. 11S.5 gives  $j_H \approx 0.009$ . Hence,

Continued .....

**PROBLEM 11S.18 (Cont.)**

$$h_h = j_h \frac{Gc_p}{Pr^{2/3}} = 0.009 \frac{18.6 \text{ kg/s} \cdot \text{m}^2 \times 1081 \text{ J/kg} \cdot \text{K}}{(0.698)^{2/3}}$$

$$h_h = 230 \text{ W/m}^2 \cdot \text{K}.$$

With  $r_{2c}/r_1 = 1.75$ ,  $L_c = 6.18 \text{ mm}$  and  $A_p = 1.57 \times 10^{-6} \text{ m}^2$  from Ex. 11.6,  $L_c^{3/2} (h_h / kA_p)^{1/2} = 1.52$  and Fig. 3.20 gives  $\eta_f \approx 0.40$ . Hence,

$$\eta_{o,h} = 1 - \frac{A_f}{A} (1 - \eta_f) = 1 - 0.83(1 - 0.4) = 0.50.$$

Hence,

$$\frac{1}{U_h} = \frac{1}{(10^4 \text{ W/m}^2 \cdot \text{K})0.143} + 5.55 \times 10^{-4} \text{ m}^2 \cdot \text{K/W} + \frac{1}{0.50(230 \text{ W/m}^2 \cdot \text{K})}$$

$$U_h = 100.5 \text{ W/m}^2 \cdot \text{K}.$$

With

$$C_{\min} = C_h = 3 \text{ kg/s}(1081 \text{ J/kg} \cdot \text{K}) = 3243 \text{ W/K}$$

$$NTU = \frac{U_h A_h}{C_{\min}} = \frac{100.5 \text{ W/m}^2 \cdot \text{K} (36.05 \text{ m}^2)}{3243 \text{ W/K}} = 1.117.$$

Since  $C_{\min}/C_{\max} = 0$ , Eq. 11.35a gives

$$\varepsilon = 1 - \exp(-NTU) = 1 - \exp(-1.117) = 0.673.$$

Hence,

$$q = \varepsilon C_{\min} (T_{h,i} - T_{c,i}) = 0.673(3243 \text{ W/K})(500 \text{ K}) = 1.091 \times 10^6 \text{ W}$$

and

$$T_{h,o} = T_{h,i} - \frac{q}{C_{\min}} = 900 \text{ K} - \frac{1.091 \times 10^6 \text{ W}}{3243 \text{ W/K}} = 564 \text{ K}.$$

<

**COMMENTS:** (1) The assumption of  $\bar{T}_h = 725 \text{ K}$  is good.

(2) If water enters the tubes as saturated liquid, a flow rate of at least

$$\dot{m}_c = \frac{q}{h_{fg}} = \frac{1.091 \times 10^6 \text{ W}}{2.183 \times 10^6 \text{ J/kg}} = 0.50 \text{ kg/s}$$

would be need to maintain saturated conditions in the tubes.
