**PROPERTIES:** Table A-6, Water vapor:  $p_{A,\text{sat}}(21.1^\circ\text{C}) = 0.02512 \text{ bar}$ ,  $p_{A,\text{sat}}(37.8^\circ\text{C}) = 0.06603 \text{ bar}$ ,  $h_{fg}(21.1^\circ\text{C}) = 2451 \text{ kJ/kg}$ ; Table A-4, Air ( $T_{\text{am}} = [T_{\text{WB}} + T_{\text{DB}}]/2 \cong 300\text{K}$ , 1 atm):  $\alpha = 22.5 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $c_p = 1007 \text{ J/kg}\cdot\text{K}$ ,  $\rho = 1.15 \text{ kg/m}^3$ ; Table A-8, Air-water vapor (298K):  $D_{AB} = 0.26 \times 10^{-4} \text{ m}^2/\text{s}$ .

**ANALYSIS:** (a) Carrier's equation has the form

$$p_v = p_{\text{gw}} - \frac{(p - p_{\text{gw}})(T_{\text{DB}} - T_{\text{WB}})}{1810 - T_{\text{WB}}}$$

where  $p_v$  = partial pressure of vapor in air stream, bar

$p_{\text{gw}}$  = sat. pressure at  $T_{\text{WB}} = 21.1^\circ\text{C}$ , 0.02512 bar

$p$  = total pressure of mixture, 1.033 bar

$T_{\text{DB}}$  = dry bulb temperature,  $37.8^\circ\text{C}$

$T_{\text{WB}}$  = wet bulb temperature,  $21.1^\circ\text{C}$ .

Hence,

$$p_v = 0.02512 \text{ bar} - \frac{(1.033 - 0.02512) \text{ bar} \times (37.8 - 21.1)^\circ\text{C}}{1810 - (21.1 + 273.1) \text{ K}} = 0.0142 \text{ bar.}$$

The relative humidity,  $\phi$ , is then

$$\phi \equiv \frac{p_A}{p_{A,\text{sat}}} = \frac{p_v}{p_A(37.8^\circ\text{C})} = \frac{0.0142 \text{ bar}}{0.06603 \text{ bar}} = 0.214. \quad <$$

(b) Using a psychrometric chart

$$\left. \begin{array}{l} T_{\text{WB}} = 21.1^\circ\text{C} = 70^\circ\text{F} \\ T_{\text{DB}} = 37.8^\circ\text{C} = 100^\circ\text{F} \end{array} \right\} \phi \approx 0.225 \quad <$$

$$p_v = \phi p_{\text{sat}} = 0.225 \times 0.06603 \text{ bar} = 0.0149 \text{ bar.} \quad <$$

Continued ...

**PROBLEM 6.78 (Cont.)**

(c) An application of the heat-mass transfer analogy is the process of evaporative cooling which occurs when air flows over water. The change in temperature is estimated by Eq. 6.65.

$$T_{\infty} - T_s = \frac{\mathcal{M}_A h_{fg}}{\mathcal{R} \rho c_p L e^{2/3}} \left[ \frac{p_{A,sat}(T_s)}{T_s} - \frac{p_{A,\infty}}{T_{\infty}} \right]$$

or

$$(37.8 - 21.1)\text{K} = \frac{(18\text{kg/kmol} \times 2451 \times 10^3 \text{J/kg})}{8.314 \times 10^{-2} \text{m}^3 \text{bar/kmol} \cdot \text{K} \times 1.16 \text{kg/m}^3 \times 1007 \text{J/kg} \cdot \text{K} \times \left( \frac{22.5 \times 10^{-6} \text{m}^2/\text{s}}{0.26 \times 10^{-4} \text{m}^2/\text{s}} \right)^{2/3}} \times \left[ \frac{0.02512 \text{bar}}{(273 + 21.1)\text{K}} + \frac{p_{A,\infty}}{(273 + 37.8)\text{K}} \right]$$

Thus,  $p_{A,\infty} = 0.016 \text{ bar}$

and

$$\phi = p_A/p_{A,sat} = p_v/p_{A,sat} = 0.016 \text{ bar}/0.06603 \text{ bar} = 0.242 \quad <$$

**COMMENTS:** The following table compares results from the two calculation methods.

	<i>Carrier's Eq.</i>	<i>Psychrometric Chart</i>
$p_v$ (bar)	0.0142	0.016
$\phi$	0.214	0.242

$$\% \text{ Difference: } \frac{0.242 - 0.214}{0.214} \times 100 = 13.1\%$$

## PROBLEM 6.79

**KNOWN:** Initial temperature and droplet diameter of water mist. Expression for Nusselt number. Temperature and relative humidity of air stream.

**FIND:** (a) Initial convection heat transfer rate, evaporative heat loss rate, and rate of change of droplet temperature, (b) Steady-state droplet temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) The properties of the air-water vapor mixture can be approximated by pure air properties, (2) Air properties and  $D_{AB}$  evaluated at  $T_{am} = (T_s + T_\infty)/2$ .

**PROPERTIES:** Table A-4, Air ( $T = 294$  K):  $k = 0.0258$  W/m·K; Table A-8, H<sub>2</sub>O in Air ( $T = 294$  K):  $D_{AB} = 0.26 \times 10^{-4}$  m<sup>2</sup>/s  $(294/298)^{3/2} = 0.255 \times 10^{-4}$  m<sup>2</sup>/s; Table A-6, Water ( $T = 283$  K):  $\rho_{A,sat}(T_s) = 1/111.8$  m<sup>3</sup>/kg = 0.00894 kg/m<sup>3</sup>,  $h_{fg} = 2478$  kJ/kg,  $\rho_w = 1000$  kg/m<sup>3</sup>,  $c_{p,w} = 4193$  J/kg·K; ( $T = 305$  K):  $\rho_{A,sat}(T_\infty) = 1/29.74$  m<sup>3</sup>/kg = 0.0336 kg/m<sup>3</sup>.

**ANALYSIS:** (a) The convection heat transfer coefficient is

$$\bar{h} = \overline{Nu}_{Dk} / D = 2k / D = 2 \times 0.0258 \text{ W/m} \cdot \text{K} / 100 \times 10^{-6} \text{ m} = 516 \text{ W/m}^2 \cdot \text{K}$$

At the initial time, when the droplet temperature is  $T_i = 10^\circ\text{C}$ , the convection heat transfer rate to the droplet is given by

$$q_{\text{conv}} = \bar{h}A_s(T_\infty - T_i) = 516 \text{ W/m}^2 \cdot \text{K} \times \pi(100 \times 10^{-6} \text{ m})^2 \times (32 - 10)^\circ\text{C} = 357 \times 10^{-6} \text{ W} \quad <$$

Referring to Eq. 6.59, since  $Nu$  is independent of  $Pr$ ,  $n = 0$ , and we have

$$Nu = Sh = 2 \quad \text{or} \quad \bar{h}_m = 2D_{AB} / D = 2 \times 0.255 \times 10^{-4} \text{ m}^2/\text{s} / 100 \times 10^{-6} \text{ m} = 0.510 \text{ m/s}$$

Thus the rate of evaporative heat loss can be expressed as

$$q_{\text{evap}} = \dot{m}_{\text{evap}} h_{fg} = \bar{h}_m A_s (\rho_{A,s} - \rho_{A,\infty}) h_{fg}$$

For  $\phi_\infty = 0.20$ ,  $\rho_{A,\infty} = \phi_\infty \rho_{A,sat}(T_\infty) = 0.2 \times 0.0336 \text{ kg/m}^3 = 0.00672 \text{ kg/m}^3$ . Thus,

$$\begin{aligned} q_{\text{evap}} &= \dot{m}_{\text{evap}} h_{fg} = \bar{h}_m A_s (\rho_{A,s} - \rho_{A,\infty}) h_{fg} \\ &= 0.510 \text{ m/s} \times \pi(100 \times 10^{-6} \text{ m})^2 \times (0.00894 - 0.00672) \text{ kg/m}^3 \times 2478 \times 10^3 \text{ J/kg} \\ &= 88.1 \times 10^{-6} \text{ W} \end{aligned} \quad <$$

Continued...

### PROBLEM 6.79 (Cont.)

Similarly, for  $\phi_\infty = 0.95$ ,  $\rho_{A,\infty} = \phi_\infty \rho_{A,\text{sat}}(T_\infty) = 0.95 \times 0.0336 \text{ kg/m}^3 = 0.0319 \text{ kg/m}^3$

$$q_{\text{evap}} = -912 \times 10^{-6} \text{ W} \quad <$$

The rate of change of temperature of the droplet can be found from an energy balance on the droplet:

$$(\rho c_p V)_w \frac{dT}{dt} = q_{\text{conv}} - q_{\text{evap}}$$

For  $\phi_\infty = 0.20$ ,

$$\frac{dT}{dt} = \frac{q_{\text{conv}} - q_{\text{evap}}}{(\rho c_p V)_w} = \frac{(357 - 88.1) \times 10^{-6} \text{ W}}{1000 \text{ kg/m}^3 \times 4193 \text{ J/kg} \cdot \text{K} \times \pi \times (100 \times 10^{-6} \text{ m})^3 / 6} = 122 \text{ K/s} <$$

And for  $\phi_\infty = 0.95$ ,

$$\frac{dT}{dt} = \frac{q_{\text{conv}} - q_{\text{evap}}}{(\rho c_p V)_w} = \frac{(357 + 912) \times 10^{-6} \text{ W}}{1000 \text{ kg/m}^3 \times 4193 \text{ J/kg} \cdot \text{K} \times \pi \times (100 \times 10^{-6} \text{ m})^3 / 6} = 578 \text{ K/s} <$$

For  $\phi_\infty = 0.20$ , the evaporative heat loss is positive; the droplet is evaporating. Convection from the warm air is warming the droplet, while evaporation is cooling it. The net effect is to warm the droplet. For  $\phi_\infty = 0.95$ , the evaporative heat loss is negative; water from the humid environment is condensing on the droplet. Both convection and condensation cause warming of the droplet, so the rate of temperature increase is higher in this case. Eventually, the droplet will become warm enough so that condensation ceases and evaporation will begin. <

(b) At steady-state, an energy balance requires  $q_{\text{conv}} = q_{\text{evap}}$ . Eq. 6.64 applies, with  $\bar{h}_m / \bar{h} = D_{AB} / k$ . Thus, the following implicit equation must be solved for  $T_s$ :

$$T_\infty - T_s = h_{fg} \frac{D_{AB}}{k} [\rho_{A,\text{sat}}(T_s) - \rho_{A,\infty}]$$

where the properties  $D_{AB}$  and  $k$  should be evaluated at  $T_{\text{am}} = (T_s + T_\infty)/2$ , and  $h_{fg}$  should be evaluated at  $T_s$ . This equation is most easily solved in IHT, which yields

$$T_s = 289 \text{ K for } \phi_\infty = 0.20 \quad <$$

$$T_s = 304 \text{ K for } \phi_\infty = 0.95 \quad <$$

**COMMENTS:** (1) As expected, the steady-state droplet temperature is lower for the low humidity conditions. (2) The steady-state temperature does not depend on the droplet diameter because the areas for convection and evaporation are the same and the heat and mass transfer coefficients have the same dependence on diameter. (3) Based on the initial rate of temperature increase, it appears that the droplet will take less than 1 s to reach its steady-state temperature. A complete analysis of the transient problem shows that the steady-state temperature is reached in approximately 0.17 and 0.15 s for the  $\phi_\infty = 0.20$  and 0.95 cases, respectively. In this time period, the change in diameter of the droplet is less than 1% in both cases. Of course, the droplet will eventually evaporate.

## PROBLEM 6.80

**KNOWN:** Wet and dry bulb temperatures.

**FIND:** Relative humidity of air.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Perfect gas behavior for vapor, (2) Steady-state conditions, (3) Negligible radiation, (4) Negligible conduction along thermometer.

**PROPERTIES:** Table A-4, Air (308K, 1 atm):  $\rho = 1.135 \text{ kg/m}^3$ ,  $c_p = 1007 \text{ J/kg}\cdot\text{K}$ ,  $\alpha = 23.7 \times 10^{-6} \text{ m}^2/\text{s}$ ; Table A-6, Saturated water vapor (298K):  $v_g = 44.25 \text{ m}^3/\text{kg}$ ,  $h_{fg} = 2443 \text{ kJ/kg}$ ; (318K):  $v_g = 15.52 \text{ m}^3/\text{kg}$ ; Table A-8, Air-vapor (1 atm, 298K):  $D_{AB} = 0.26 \times 10^{-4} \text{ m}^2/\text{s}$ ,  $D_{AB}$  (308K) =  $0.26 \times 10^{-4} \text{ m}^2/\text{s} \times (308/298)^{3/2} = 0.27 \times 10^{-4} \text{ m}^2/\text{s}$ ,  $Le = \alpha/D_{AB} = 0.88$ .

**ANALYSIS:** From an energy balance on the wick, Eq. 6.64 follows from Eq. 6.61. Dividing Eq. 6.64 by  $\rho_{A,\text{sat}}(T_\infty)$ ,

$$\frac{T_\infty - T_s}{\rho_{A,\text{sat}}(T_\infty)} = h_{fg} \left[ \frac{h_m}{h} \right] \left[ \frac{\rho_{A,\text{sat}}(T_s)}{\rho_{A,\text{sat}}(T_\infty)} - \frac{\rho_{A,\infty}}{\rho_{A,\text{sat}}(T_\infty)} \right].$$

With  $[\rho_{A,\infty} / \rho_{A,\text{sat}}(T_\infty)] \approx \phi_\infty$  for a perfect gas and  $h/h_m$  given by Eq. 6.60,

$$\phi_\infty = \frac{\rho_{A,\text{sat}}(T_s)}{\rho_{A,\text{sat}}(T_\infty)} - \frac{\rho c_p Le^{2/3}}{\rho_{A,\text{sat}}(T_\infty) h_{fg}} (T_\infty - T_s).$$

Using the property values, evaluate

$$\frac{\rho_{A,\text{sat}}(T_s)}{\rho_{A,\text{sat}}(T_\infty)} = \frac{v_g(T_\infty)}{v_g(T_s)} = \frac{15.52}{44.25} = 0.351$$

$$\rho_{A,\text{sat}}(T_\infty) = (15.52 \text{ m}^3/\text{kg})^{-1} = 0.064 \text{ kg/m}^3.$$

Hence,

$$\phi_\infty = 0.351 - \frac{1.135 \text{ kg/m}^3 (1007 \text{ J/kg}\cdot\text{K})(0.88)^{2/3}}{0.064 \text{ kg/m}^3 (2.443 \times 10^6 \text{ J/kg})} (45 - 25) \text{ K}$$

$$\phi_\infty = 0.351 - 0.133 = 0.218.$$

<

**COMMENTS:** Note that latent heat must be evaluated at the surface temperature (evaporation occurs at the surface).

## PROBLEM 6.81

**KNOWN:** Heat transfer correlation for a contoured surface heated from below while experiencing air flow across it. Flow conditions and steady-state temperature when surface experiences evaporation from a thin water film.

**FIND:** (a) Heat transfer coefficient and convection heat rate, (b) Mass transfer coefficient and evaporation rate (kg/h) of the water, (c) Rate at which heat must be supplied to surface for these conditions.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Heat-mass transfer analogy applies, (3) Correlation requires properties evaluated at  $T_f = (T_s + T_\infty)/2$ .

**PROPERTIES:** Table A-4, Air ( $T_f = (T_s + T_\infty)/2 = (290 + 310)K/2 = 300$  K, 1 atm):  $\nu = 15.89 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0263 \text{ W/m}\cdot\text{K}$ ,  $Pr = 0.707$ ; Table A-8, Air-water mixture (300 K, 1 atm):  $D_{AB} = 0.26 \times 10^{-4} \text{ m}^2/\text{s}$ ; Table A-6, Sat. water ( $T_s = 310$  K):  $\rho_{A,\text{sat}} = 1/v_g = 1/22.93 \text{ m}^3/\text{kg} = 0.04361 \text{ kg/m}^3$ ,  $h_{fg} = 2414 \text{ kJ/kg}$ .

**ANALYSIS:** (a) To characterize the flow, evaluate  $Re_L$  at  $T_f$

$$Re_L = \frac{VL}{\nu} = \frac{10 \text{ m/s} \times 1 \text{ m}}{15.89 \times 10^{-6} \text{ m}^2/\text{s}} = 6.293 \times 10^5$$

and substituting into the prescribed correlation for this surface, find

$$\overline{Nu}_L = 0.43 \left( 6.293 \times 10^5 \right)^{0.58} (0.707)^{0.4} = 864.1$$

$$\overline{h}_L = \frac{\overline{Nu}_L \cdot k}{L} = \frac{864.1 \times 0.0263 \text{ W/m}\cdot\text{K}}{1 \text{ m}} = 22.7 \text{ W/m}^2 \cdot \text{K} \quad <$$

Hence, the convection heat rate is

$$q_{\text{conv}} = \overline{h}_L A_s (T_s - T_\infty)$$

$$q_{\text{conv}} = 22.7 \text{ W/m}^2 \cdot \text{K} \times 1 \text{ m}^2 (310 - 290) \text{ K} = 454 \text{ W} \quad <$$

(b) Invoking the heat-mass transfer analogy

$$\overline{Sh}_L = \frac{\overline{h}_m L}{D_{AB}} = 0.43 Re_L^{0.58} Sc^{0.4}$$

where

$$Sc = \frac{\nu}{D_{AB}} = \frac{15.89 \times 10^{-6} \text{ m}^2/\text{s}}{0.26 \times 10^{-4} \text{ m}^2/\text{s}} = 0.611$$

and  $\nu$  is evaluated at  $T_f$ . Substituting numerical values, find

Continued ...

**PROBLEM 6.81 (Cont.)**

$$\overline{Sh}_L = 0.43 \left( 6.293 \times 10^5 \right)^{0.58} (0.611)^{0.4} = 815.2$$

$$\overline{h}_m = \frac{\overline{Sh}_L \cdot D_{AB}}{L} = \frac{815.2 \times 0.26 \times 10^{-4} \text{ m}^2/\text{s}}{1 \text{ m}} = 2.12 \times 10^{-2} \text{ m/s.} \quad <$$

The evaporation rate, with  $\rho_{A,s} = \rho_{A,\text{sat}}(T_s)$ , is

$$\begin{aligned} \dot{m} &= \overline{h}_m A_s (\rho_{A,s} - \rho_{A,\infty}) \\ \dot{m} &= 2.12 \times 10^{-2} \text{ m/s} \times 1 \text{ m}^2 (0.04361 - 0) \text{ kg/m}^3 \end{aligned}$$

$$\dot{m} = 9.243 \times 10^{-4} \text{ kg/s} = 3.32 \text{ kg/h.} \quad <$$

(c) The rate at which heat must be supplied to the plate to maintain these conditions follows from an energy balance.

$$\begin{aligned} \dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= 0 \\ q_{\text{in}} - q_{\text{conv}} - q_{\text{evap}} &= 0 \end{aligned}$$

where  $q_{\text{in}}$  is the heat supplied to sustain the losses by convection and evaporation.

$$\begin{aligned} q_{\text{in}} &= q_{\text{conv}} + q_{\text{evap}} \\ q_{\text{in}} &= \overline{h}_L A_s (T_s - T_{\infty}) + \dot{m} h_{fg} \\ q_{\text{in}} &= 454 \text{ W} + 9.243 \times 10^{-4} \text{ kg/s} \times 2414 \times 10^3 \text{ J/kg} \end{aligned}$$

$$q_{\text{in}} = (254 + 2231) \text{ W} = 2685 \text{ W.} \quad <$$

**COMMENTS:** Note that the loss from the surface by evaporation is nearly 5 times that due to convection.

## PROBLEM 6.82

**KNOWN:** Thickness, temperature and evaporative flux of a water layer. Temperature of air flow and surroundings.

**FIND:** (a) Convection mass transfer coefficient and time to completely evaporate the water, (b) Convection heat transfer coefficient, (c) Heater power requirement per surface area, (d) Temperature of dry surface if heater power is maintained.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, (2) Applicability of heat and mass transfer analogy with  $n = 1/3$ , (3) Radiation exchange at surface of water may be approximated as exchange between a small surface and large surroundings, (4) Air is dry ( $\rho_{A,\infty} = 0$ ), (5) Negligible heat transfer from unwetted surface of the plate.

**PROPERTIES:** Table A-6, Water ( $T_w = 340\text{K}$ ):  $\rho_f = 979 \text{ kg/m}^3$ ,  $\rho_{A,\text{sat}} = v_g^{-1} = 0.174 \text{ kg/m}^3$ ,  $h_{fg} = 2342 \text{ kJ/kg}$ . Prescribed, Air:  $\rho = 1.08 \text{ kg/m}^3$ ,  $c_p = 1008 \text{ J/kg}\cdot\text{K}$ ,  $k = 0.028 \text{ W/m}\cdot\text{K}$ . Vapor/Air:  $D_{AB} = 0.29 \times 10^{-4} \text{ m}^2/\text{s}$ . Water:  $\epsilon_w = 0.95$ . Plate:  $\epsilon_p = 0.60$ .

**ANALYSIS:** (a) The convection mass transfer coefficient may be determined from the rate equation  $n''_A = h_m (\rho_{A,s} - \rho_{A,\infty})$ , where  $\rho_{A,s} = \rho_{A,\text{sat}}(T_w)$  and  $\rho_{A,\infty} = 0$ . Hence,

$$h_m = \frac{n''_A}{\rho_{A,\text{sat}}} = \frac{0.03 \text{ kg/s}\cdot\text{m}^2}{0.174 \text{ kg/m}^3} = 0.172 \text{ m/s} \quad <$$

The time required to completely evaporate the water is obtained from a mass balance of the form  $-n''_A = \rho_f d\delta/dt$ , in which case

$$\rho_f \int_{\delta_i}^0 d\delta = -n''_A \int_0^t dt$$

$$t = \frac{\rho_f \delta_i}{n''_A} = \frac{979 \text{ kg/m}^3 (0.002 \text{ m})}{0.03 \text{ kg/s}\cdot\text{m}^2} = 65.3 \text{ s} \quad <$$

(b) With  $n = 1/3$  and  $Le = \alpha/D_{AB} = k/\rho c_p D_{AB} = 0.028 \text{ W/m}\cdot\text{K}/(1.08 \text{ kg/m}^3 \times 1008 \text{ J/kg}\cdot\text{K} \times 0.29 \times 10^{-4} \text{ m}^2/\text{s}) = 0.887$ , the heat and mass transfer analogy yields

$$h = \frac{k h_m}{D_{AB} Le^{1/3}} = \frac{0.028 \text{ W/m}\cdot\text{K} (0.172 \text{ m/s})}{0.29 \times 10^{-4} \text{ m}^2/\text{s} (0.887)^{1/3}} = 173 \text{ W/m}^2\cdot\text{K} \quad <$$

The electrical power requirement per unit area corresponds to the rate of heat loss from the water. Hence,

Continued ...

**PROBLEM 6.82 (Cont.)**

$$P''_{\text{elec}} = q''_{\text{evap}} + q''_{\text{conv}} + q''_{\text{rad}} = n''_A h_{fg} + h(T_w - T_\infty) + \varepsilon_w \sigma (T_w^4 - T_{\text{sur}}^4)$$

$$P''_{\text{elec}} = 0.03 \text{ kg/s} \cdot \text{m}^2 \left( 2.342 \times 10^6 \text{ J/kg} \right) + 173 \text{ W/m}^2 \cdot \text{K} (40\text{K}) + 0.95 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left( 340^4 - 300^4 \right)$$

$$P''_{\text{elec}} = 70,260 \text{ W/m}^2 + 6920 \text{ W/m}^2 + 284 \text{ W/m}^2 = 77,464 \text{ W/m}^2 \quad <$$

(c) After complete evaporation, the steady-state temperature of the plate is determined from the requirement that

$$P''_{\text{elec}} = h(T_p - T_\infty) + \varepsilon_p \sigma (T_p^4 - T_{\text{sur}}^4)$$

$$77,464 \text{ W/m}^2 = 173 \text{ W/m}^2 \cdot \text{K} (T_p - 300) + 0.60 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (T_p^4 - 300^4)$$

$$T_p = 702\text{K} = 429^\circ\text{C} \quad <$$

**COMMENTS:** The evaporative heat flux is the dominant contributor to heat transfer from the water layer, with convection of sensible energy being an order of magnitude smaller and radiation exchange being negligible. Without evaporation (a dry surface), convection dominates and is approximately an order of magnitude larger than radiation.

### PROBLEM 6.83

**KNOWN:** Heater power required to maintain water film at prescribed temperature in dry ambient air and evaporation rate.

**FIND:** (a) Average mass transfer convection coefficient  $\bar{h}_m$ , (b) Average heat transfer convection coefficient  $\bar{h}$ , (c) Whether values of  $\bar{h}_m$  and  $\bar{h}$  satisfy the heat-mass analogy, and (d) Effect on evaporation rate and disc temperature if relative humidity of the ambient air were increased from 0 to 0.5 but with heater power maintained at the same value.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Water film and disc are at same temperature; (2) Mass and heat transfer coefficient are independent of ambient air relative humidity, (3) Constant properties.

**PROPERTIES:** Table A-6, Saturated water (305 K):  $v_g = 29.74 \text{ m}^3/\text{kg}$ ,  $h_{fg} = 2426 \times 10^3 \text{ J/kg}$ ; Table A-4, Air ( $\bar{T} = 300 \text{ K}$ , 1 atm):  $k = 0.0263 \text{ W/m}\cdot\text{K}$ ,  $\alpha = 22.5 \times 10^{-6} \text{ m}^2/\text{s}$ , Table A-8, Air-water vapor (300 K, 1 atm):  $D_{AB} = 0.26 \times 10^{-4} \text{ m}^2/\text{s}$ .

**ANALYSIS:** (a) Using the mass transfer convection rate equation,

$$n_A = \bar{h}_m A_s (\rho_{A,s} - \rho_{A,\infty}) = \bar{h}_m A_s \rho_{A,\text{sat}} (1 - \phi_\infty)$$

and evaluating  $\rho_{A,s} = \rho_{A,\text{sat}}(305 \text{ K}) = 1/v_g(305 \text{ K})$  with  $\phi_\infty \sim \rho_{A,\infty} = 0$ , find

$$\bar{h}_m = \frac{n_A}{A_s (\rho_{A,s} - \rho_{A,\infty})}$$

$$\bar{h}_m = \frac{2.55 \times 10^{-4} \text{ kg/hr} / (3600 \text{ s/hr})}{\left( \pi (0.020 \text{ m})^2 / 4 \right) (1/29.74 - 0) \text{ kg/m}^3} = 6.71 \times 10^{-3} \text{ m/s.} \quad <$$

(b) Perform an overall energy balance on the disc,

$$q = q_{\text{conv}} + q_{\text{evap}} = \bar{h} A_s (T_s - T_\infty) + n_A h_{fg}$$

and substituting numerical values with  $h_{fg}$  evaluated at  $T_s$ , find  $\bar{h}$ :

$$200 \times 10^{-3} \text{ W} = \bar{h} \pi (0.020 \text{ m})^2 / 4 (305 - 295) \text{ K} + 7.083 \times 10^{-8} \text{ kg/s} \times 2426 \times 10^3 \text{ J/kg}$$

$$\bar{h} = 8.97 \text{ W/m}^2 \cdot \text{K.} \quad <$$

Continued ...

**PROBLEM 6.83 (Cont.)**

(c) The heat-mass transfer analogy, Eq. 6.67, requires that

$$\frac{\bar{h}}{h_m} \stackrel{?}{=} \frac{k}{D_{AB}} \left( \frac{D_{AB}}{\alpha} \right)^{1/3}.$$

Evaluating  $k$  and  $D_{AB}$  at  $\bar{T} = (T_s + T_\infty)/2 = 300 \text{ K}$  and substituting numerical values,

$$\frac{8.97 \text{ W/m}^2 \cdot \text{K}}{6.71 \times 10^{-3} \text{ m/s}} = 1337 \neq \frac{0.0263 \text{ W/m} \cdot \text{K}}{0.26 \times 10^{-4} \text{ m}^2/\text{s}} \left( \frac{0.26 \times 10^{-4} \text{ m}^2/\text{s}}{22.5 \times 10^{-6} \text{ m}^2/\text{s}} \right)^{1/3} = 1061$$

Since the equality is not satisfied, we conclude that, for this situation, the analogy is only approximately met ( $\approx 30\%$ ).

(d) If  $\phi_\infty = 0.5$  instead of 0.0 and  $q$  is unchanged,  $n_A$  will decrease by nearly a factor of two, as will  $n_A h_{fg} = q_{\text{evap}}$ . Hence, since  $q_{\text{conv}}$  must increase and  $\bar{h}$  remains nearly constant,  $T_s - T_\infty$  must increase. Hence,  $T_s$  will increase.

**COMMENTS:** Note that in part (d), with an increase in  $T_s$ ,  $h_{fg}$  decreases, but only slightly, and  $\rho_{A,\text{sat}}$  increases. From a trial-and-error solution assuming constant values for  $\bar{h}_m$  and  $h$ , the disc temperature is 315 K for  $\phi_\infty = 0.5$ .

### PROBLEM 6.84

**KNOWN:** Power-time history required to completely evaporate a droplet of fixed diameter maintained at 37°C.

**FIND:** (a) Average mass transfer convection coefficient when droplet, heater and dry ambient air are at 37°C and (b) Energy required to evaporate droplet if the dry ambient air temperature is 27°C.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Wetted surface area of droplet is of fixed diameter  $D$ , (2) Heat-mass transfer analogy is applicable, (3) Heater controlled to operate at constant temperature,  $T_s = 37^\circ\text{C}$ , (4) Mass of droplet same for part (a) and (b), (5) Mass transfer coefficients for parts (a) and (b) are the same.

**PROPERTIES:** Table A-6, Saturated water ( $37^\circ\text{C} = 310\text{ K}$ ):  $h_{fg} = 2414\text{ kJ/kg}$ ,  $\rho_{A,\text{sat}} = 1/v_g = 1/22.93 = 0.04361\text{ kg/m}^3$ ; Table A-8, Air-water vapor ( $T_s = 37^\circ\text{C} = 310\text{ K}$ , 1 atm):  $D_{AB} = 0.26 \times 10^{-6}\text{ m}^2/\text{s} (310/298)^{3/2} = 0.276 \times 10^{-6}\text{ m}^2/\text{s}$ ; Table A-4, Air ( $\bar{T} = (27 + 37)^\circ\text{C}/2 = 305\text{ K}$ , 1 atm):  $\rho = 1.1448\text{ kg/m}^3$ ,  $c_p = 1008\text{ J/kg}\cdot\text{K}$ ,  $\nu = 16.39 \times 10^{-6}\text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.706$ .

**ANALYSIS:** (a) For the isothermal conditions ( $37^\circ\text{C}$ ), the electrical energy  $Q$  required to evaporate the droplet during the interval of time  $\Delta t = t_e$  follows from the area under the  $P$ - $t$  curve above,

$$Q = \int_0^{t_e} P dt = \left[ 20 \times 10^{-3}\text{ W} \times (50 \times 60)\text{ s} + 0.5 \times 20 \times 10^{-3}\text{ W} (100 - 50) \times 60\text{ s} \right]$$

$$Q = 90\text{ J.}$$

From an overall energy balance during the interval of time  $\Delta t = t_e$ , the mass loss due to evaporation is

$$Q = M h_{fg} \quad \text{or} \quad M = Q/h_{fg}$$

$$M = 90\text{ J} / 2414 \times 10^3\text{ J/kg} = 3.728 \times 10^{-5}\text{ kg.}$$

To obtain the average mass transfer coefficient, write the rate equation for an interval of time  $\Delta t = t_e$ ,

$$M = \dot{m} \cdot t_e = \bar{h}_m A_s (\rho_{A,s} - \rho_{A,\infty}) \cdot t_e = \bar{h}_m A_s \rho_{A,s} (1 - \phi_\infty) \cdot t_e$$

Substituting numerical values with  $\phi_\infty = 0$ , find

$$3.278 \times 10^{-5}\text{ kg} = \bar{h}_m \left( \pi (0.004\text{ m})^2 / 4 \right) 0.04361\text{ kg/m}^3 \times (100 \times 60)\text{ s}$$

Continued ...

**PROBLEM 6.84 (Cont.)**

$$\bar{h}_m = 0.0113 \text{ m/s.} \quad <$$

(b) The energy required to evaporate the droplet of mass  $M = 3.728 \times 10^{-5} \text{ kg}$  follows from an overall energy balance,

$$Q = Mh_{fg} + \bar{h}A_s(T_s - T_\infty)$$

where  $\bar{h}$  is obtained from the heat-mass transfer analogy, Eq. 6.60, using  $n = 1/3$ ,

$$\frac{\bar{h}}{h_m} = \frac{k}{D_{AB}Le^n} = \rho c_p Le^{2/3}$$

where

$$Sc = \frac{\nu}{D_{AB}} = \frac{16.39 \times 10^{-6} \text{ m}^2/\text{s}}{0.276 \times 10^{-4} \text{ m}^2/\text{s}} = 0.594$$
$$Le = \frac{Sc}{Pr} = \frac{0.594}{0.706} = 0.841.$$

Hence,

$$\bar{h} = 0.0113 \text{ m/s} \times 1.1448 \text{ kg/m}^3 \times 1008 \text{ J/kg} \cdot \text{K} (0.841)^{2/3} = 11.62 \text{ W/m}^2 \cdot \text{K}.$$

and the energy requirement is

$$Q = 3.728 \times 10^{-5} \text{ kg} \times 2414 \text{ kJ/kg} + 11.62 \text{ W/m}^2 \cdot \text{K} \left( \pi (0.004 \text{ m})^2 / 4 \right) (37 - 27)^\circ \text{C}$$

$$Q = (90.00 + 0.00145) \text{ J} = 90 \text{ J.} \quad <$$

The energy required to meet the convection heat loss is very small compared to that required to sustain the evaporative loss.

## PROBLEM 6.85

**KNOWN:** Initial plate temperature  $T_p(0)$  and saturated air temperature ( $T_\infty$ ) in a dishwasher at the start of the dry cycle. Thermal mass per unit area of the plate  $Mc/A_s = 1600 \text{ J/m}^2 \cdot \text{K}$ .

**FIND:** (a) Differential equation to predict plate temperature as a function of time during the dry cycle and (b) Rate of change in plate temperature at the start of the dry cycle assuming the average convection heat transfer coefficient is  $3.5 \text{ W/m}^2 \cdot \text{K}$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Plate is spacewise isothermal, (2) Negligible thermal resistance of water film on plate, (3) Heat-mass transfer analogy applies.

**PROPERTIES:** Table A-4, Air ( $\bar{T} = (55 + 65)^\circ\text{C}/2 = 333 \text{ K}$ , 1 atm):  $\rho = 1.0516 \text{ kg/m}^3$ ,  $c_p = 1008 \text{ J/kg} \cdot \text{K}$ ,  $Pr = 0.703$ ,  $\nu = 19.24 \times 10^{-6} \text{ m}^2/\text{s}$ ; Table A-6, Saturated water vapor, ( $T_s = 65^\circ\text{C} = 338 \text{ K}$ ):  $\rho_{A,s} = 1/v_g = 0.1592 \text{ kg/m}^3$ ,  $h_{fg} = 2347 \text{ kJ/kg}$ ; ( $T_s = 55^\circ\text{C} = 328 \text{ K}$ ):  $\rho_{A,\infty} = 1/v_g = 0.1029 \text{ kg/m}^3$ ; Table A-8, Air-water vapor ( $T_s = 65^\circ\text{C} = 338 \text{ K}$ , 1 atm):  $D_{AB} = 0.26 \times 10^{-4} \text{ m}^2/\text{s}$  ( $338/298$ ) $^{3/2} = 0.314 \times 10^{-4} \text{ m}^2/\text{s}$ .

**ANALYSIS:** (a) Perform an energy balance on a rate basis on the plate,

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \dot{E}_{\text{st}} \quad q''_{\text{conv}} - q''_{\text{evap}} = (Mc/A_s)(dT_p/dt).$$

Using the rate equations for the heat and mass transfer fluxes, find

$$\bar{h}[T_\infty - T_p(t)] - \bar{h}_m[\rho_{A,s}(T_s) - \rho_{A,\infty}(T_\infty)]h_{fg} = (Mc/A_s)(dT/dt). \quad <$$

(b) To evaluate the change in plate temperature at  $t = 0$ , the start of the drying process when  $T_p(0) = 65^\circ\text{C}$  and  $T_\infty = 55^\circ\text{C}$ , evaluate  $\bar{h}_m$  from knowledge of  $\bar{h} = 3.5 \text{ W/m}^2 \cdot \text{K}$  using the heat-mass transfer analogy, Eq. 6.60, with  $n = 1/3$ ,

$$\frac{\bar{h}}{\bar{h}_m} = \rho c_p Le^{2/3} = \rho c_p \left( \frac{Sc}{Pr} \right)^{2/3} = \rho c_p \left( \frac{\nu/D_{AB}}{Pr} \right)^{2/3}$$

and evaluating thermophysical properties at their appropriate temperatures, find

$$\frac{3.5 \text{ W/m}^2 \cdot \text{K}}{\bar{h}_m} = 1.0516 \text{ kg/m}^3 \times 1008 \text{ J/kg} \cdot \text{K} \left( \frac{19.24 \times 10^{-6} \text{ m}^2/\text{s} / 0.314 \times 10^{-4} \text{ m}^2/\text{s}}{0.703} \right)^{2/3} \quad \bar{h}_m = 3.619 \times 10^{-3} \text{ m/s}.$$

Substituting numerical values into the conservation expression of part (a), find

$$3.5 \text{ W/m}^2 \cdot \text{K} (55 - 65)^\circ\text{C} - 3.619 \times 10^{-3} \text{ m/s} (0.1592 - 0.1029) \text{ kg/m}^3 \times 2347 \times 10^3 \text{ J/kg} = 1600 \text{ J/m}^2 \cdot \text{K} (dT_p/dt)$$

$$dT_p/dt = -[35.0 + 478.2] \text{ W/m}^2 \cdot \text{K} / 1600 \text{ J/m}^2 \cdot \text{K} = -0.32 \text{ K/s}. \quad <$$

**COMMENTS:** This rate of temperature change will not be sustained for long, since, as the plate cools, the rate of evaporation (which dominates the cooling process) will diminish.

## PROBLEM 7.1

**KNOWN:** Temperature and velocity of fluids in parallel flow over a flat plate.

**FIND:** (a) Velocity and thermal boundary layer thicknesses at a prescribed distance from the leading edge, and (b) For each fluid plot the boundary layer thicknesses as a function of distance.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Transition Reynolds number is  $5 \times 10^5$ .

**PROPERTIES:** Table A.4, Air (300 K, 1 atm):  $\nu = 15.89 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.707$ ; Table A.6, Water (300 K):  $\nu = \mu/\rho = 855 \times 10^{-6} \text{ N}\cdot\text{s}/\text{m}^2/997 \text{ kg}/\text{m}^3 = 0.858 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 5.83$ ; Table A.5, Engine Oil (300 K):  $\nu = 550 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 6400$ ; Table A.5, Mercury (300 K):  $\nu = 0.113 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.0248$ .

**ANALYSIS:** (a) If the flow is laminar, the following expressions may be used to compute  $\delta$  and  $\delta_t$ , respectively,

$$\delta = \frac{5x}{\text{Re}_x^{1/2}} \quad \delta_t = \frac{\delta}{\text{Pr}^{1/3}}$$

where

$$\text{Re}_x = \frac{u_\infty x}{\nu} = \frac{1 \text{ m/s}(0.04 \text{ m})}{\nu} = \frac{0.04 \text{ m}^2/\text{s}}{\nu}$$

Fluid	$\text{Re}_x$	$\delta$ (mm)	$\delta_t$ (mm)	<
Air	2517	3.99	4.48	
Water	$4.66 \times 10^4$	0.93	0.52	
Oil	72.7	23.5	1.27	
Mercury	$3.54 \times 10^5$	0.34	1.17	

(b) Using IHT with the foregoing equations, the boundary layer thicknesses are plotted as a function of distance from the leading edge,  $x$ .

**COMMENTS:** (1) Note that  $\delta \approx \delta_t$  for air,  $\delta > \delta_t$  for water,  $\delta \gg \delta_t$  for oil, and  $\delta < \delta_t$  for mercury. As expected, the boundary layer thicknesses increase with increasing distance from the leading edge.

(2) The value of  $\delta_t$  for mercury should be viewed as a rough approximation since the expression for  $\delta/\delta_t$  was derived subject to the approximation that  $\text{Pr} > 0.6$ .

## PROBLEM 7.2

**KNOWN:** Temperature and velocity of engine oil. Temperature and length of flat plate.

**FIND:** (a) Velocity and thermal boundary layer thickness at trailing edge, (b) Heat flux and surface shear stress at trailing edge, (c) Total drag force and heat transfer per unit plate width, and (d) Plot the boundary layer thickness and local values of the shear stress, convection coefficient, and heat flux as a function of  $x$  for  $0 \leq x \leq 1$  m.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Critical Reynolds number is  $5 \times 10^5$ , (2) Flow over top and bottom surfaces.

**PROPERTIES:** Table A.5, Engine Oil ( $T_f = 333$  K):  $\rho = 864$  kg/m<sup>3</sup>,  $\nu = 86.1 \times 10^{-6}$  m<sup>2</sup>/s,  $k = 0.140$  W/m·K,  $Pr = 1081$ .

**ANALYSIS:** (a) Calculate the Reynolds number to determine nature of the flow,

$$Re_L = \frac{u_\infty L}{\nu} = \frac{0.1 \text{ m/s} \times 1 \text{ m}}{86.1 \times 10^{-6} \text{ m}^2/\text{s}} = 1161$$

Hence the flow is laminar at  $x = L$ . From Eqs. 7.19 and 7.24,

$$\delta = 5L Re_L^{-1/2} = 5(1 \text{ m})(1161)^{-1/2} = 0.147 \text{ m} \quad <$$

$$\delta_t = \delta Pr^{-1/3} = 0.147 \text{ m}(1081)^{-1/3} = 0.0143 \text{ m} \quad <$$

(b) The local convection coefficient, Eq. 7.23, and heat flux at  $x = L$  are

$$h_L = \frac{k}{L} 0.332 Re_L^{1/2} Pr^{1/3} = \frac{0.140 \text{ W/m} \cdot \text{K}}{1 \text{ m}} 0.332 (1161)^{1/2} (1081)^{1/3} = 16.25 \text{ W/m}^2 \cdot \text{K}$$

$$q''_x = h_L (T_s - T_\infty) = 16.25 \text{ W/m}^2 \cdot \text{K} (20 - 100)^\circ \text{C} = -1300 \text{ W/m}^2 \quad <$$

Also, the local shear stress is, from Eq. 7.20,

$$\tau_{s,L} = \frac{\rho u_\infty^2}{2} 0.664 Re_L^{-1/2} = \frac{864 \text{ kg/m}^3}{2} (0.1 \text{ m/s})^2 0.664 (1161)^{-1/2}$$

$$\tau_{s,L} = 0.0842 \text{ kg/m} \cdot \text{s}^2 = 0.0842 \text{ N/m}^2 \quad <$$

(c) With the drag force per unit width given by  $D' = 2L \bar{\tau}_{s,L}$  where the factor of 2 is included to account for both sides of the plate, it follows from Eq. 7.29 that

$$D' = 2L \left( \frac{\rho u_\infty^2}{2} \right) 1.328 Re_L^{-1/2} = (1 \text{ m}) 864 \text{ kg/m}^3 (0.1 \text{ m/s})^2 1.328 (1161)^{-1/2} = 0.337 \text{ N/m} \quad <$$

For laminar flow, the average value  $\bar{h}_L$  over the distance 0 to  $L$  is twice the local value,  $h_L$ ,

$$\bar{h}_L = 2h_L = 32.5 \text{ W/m}^2 \cdot \text{K}$$

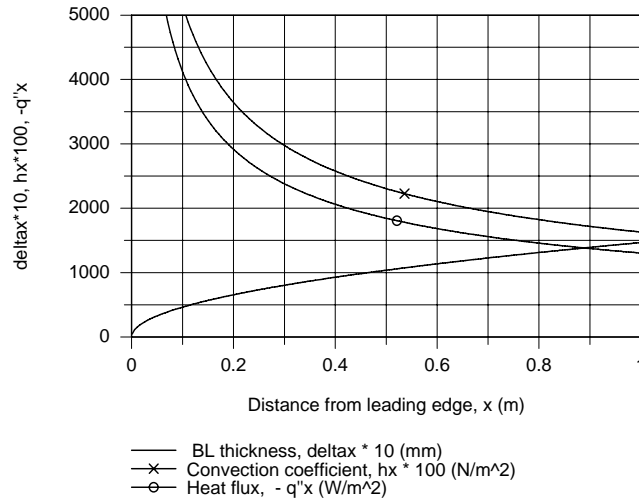

The total heat transfer rate per unit width of the plate is

$$q' = 2L \bar{h}_L (T_s - T_\infty) = 2(1 \text{ m}) 32.5 \text{ W/m}^2 \cdot \text{K} (20 - 100)^\circ \text{C} = -5200 \text{ W/m} \quad <$$

Continued...

## PROBLEM 7.2 (Cont.)

(c) Using IHT with the foregoing equations, the boundary layer thickness, and local values of the convection coefficient and heat flux were calculated and plotted as a function of  $x$ .

**COMMENTS:** (1) Note that since  $Pr \gg 1$ ,  $\delta \gg \delta_t$ . That is, for the high Prandtl liquids, the velocity boundary layer will be much thicker than the thermal boundary layer.

(2) A copy of the *IHT Workspace* used to generate the above plot is shown below.

```

// Boundary layer thickness, delta
delta = 5 * x * Rex ^-0.5
delta_mm = delta * 1000
delta_plot = delta_mm * 10      // Scaling parameter for convenience in plotting

// Convection coefficient and heat flux, q''x
q''x = hx * (Ts - Tinf)
Nux = 0.332 * Rex^0.5 * Pr^(1/3)
Nux = hx * x / k
hx_plot = 100 * hx              // Scaling parameter for convenience in plotting
q''x_plot = (-1) * q''x        // Scaling parameter for convenience in plotting

// Reynolds number
Rex = uinf * x / nu

// Properties Tool: Engine oil
// Engine Oil property functions : From Table A.5
// Units: T(K)
rho = rho_T("Engine Oil",Tf)    // Density, kg/m^3
cp = cp_T("Engine Oil",Tf)     // Specific heat, J/kg-K
nu = nu_T("Engine Oil",Tf)     // Kinematic viscosity, m^2/s
k = k_T("Engine Oil",Tf)       // Thermal conductivity, W/m-K
Pr = Pr_T("Engine Oil",Tf)     // Prandtl number

// Assigned variables
Tf = (Ts + Tinf) / 2            // Film temperature, K
Tinf = 100 + 273                // Freestream temperature, K
Ts = 20 + 273                  // Surface temperature, K
uinf = 0.1                      // Freestream velocity, m/s
x = 1                          // Plate length, m

```

### PROBLEM 7.3

**KNOWN:** Velocity and temperature of air in parallel flow over a flat plate.

**FIND:** (a) Velocity boundary layer thickness at selected stations. Distance at which boundary layers merge for plates separated by  $H = 3$  mm. (b) Surface shear stress and  $v(\delta)$  at selected stations.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady flow, (2) Boundary layer approximations are valid, (3) Flow is laminar.

**PROPERTIES:** Table A-4, Air (300 K, 1 atm):  $\rho = 1.161 \text{ kg/m}^3$ ,  $\nu = 15.89 \times 10^{-6} \text{ m}^2/\text{s}$ .

**ANALYSIS:** (a) For laminar flow,

$$\delta = \frac{5x}{\text{Re}_x^{1/2}} = \frac{5}{(u_\infty/\nu)^{1/2}} x^{1/2} = \frac{5x^{1/2}}{(25 \text{ m/s}/15.89 \times 10^{-6} \text{ m}^2/\text{s})^{1/2}} = 3.99 \times 10^{-3} x^{1/2}.$$

$x$ (m)	0.001	0.01	0.1
$\delta$ (mm)	0.126	0.399	1.262

Boundary layer merger occurs at  $x = x_m$  when  $\delta = 1.5$  mm. Hence

$$x_m^{1/2} = \frac{0.0015 \text{ m}}{3.99 \times 10^{-3} \text{ m}^{1/2}} = 0.376 \text{ m}^{1/2} \quad x_m = 141 \text{ mm.} \quad <$$

(b) The shear stress is

$$\tau_{s,x} = 0.664 \frac{\rho u_\infty^2 / 2}{\text{Re}_x^{1/2}} = 0.664 \frac{\rho u_\infty^2 / 2}{(u_\infty/\nu)^{1/2} x^{1/2}} = \frac{0.664 \times 1.161 \text{ kg/m}^3 (25 \text{ m/s})^2 / 2}{(25 \text{ m/s}/15.89 \times 10^{-6} \text{ m}^2/\text{s})^{1/2} x^{1/2}} = \frac{0.192}{x^{1/2}} \left( \text{N/m}^2 \right).$$

$x$ (m)	0.001	0.01	0.1
$\tau_{s,x}$ ( $\text{N/m}^2$ )	6.07	1.92	0.61

The velocity distribution in the boundary layer is  $v = (1/2) (\nu u_\infty / x)^{1/2} (\eta df/d\eta - f)$ . At  $y = \delta$ ,  $\eta \approx 5.0$ ,  $f \approx 3.24$ ,  $df/d\eta \approx 0.991$ .

$$v = \frac{0.5}{x^{1/2}} \left( 15.89 \times 10^{-6} \text{ m}^2/\text{s} \times 25 \text{ m/s} \right)^{1/2} (5.0 \times 0.991 - 3.24) = \left( 0.0167 / x^{1/2} \right) \text{ m/s.}$$

$x$ (m)	0.001	0.01	0.1
$v$ (m/s)	0.528	0.167	0.053

**COMMENTS:** (1)  $v \ll u_\infty$  and  $\delta \ll x$  are consistent with BL approximations. Note,  $v \rightarrow \infty$  as  $x \rightarrow 0$  and approximations breakdown very close to the leading edge. (2) Since  $\text{Re}_{x_m} = 2.22 \times 10^5$ , laminar BL model is valid. (3) Above expressions are approximations for flow between parallel plates, since  $du_\infty/dx > 0$  and  $dp/dx < 0$ .

## PROBLEM 7.4

**KNOWN:** Liquid metal in parallel flow over a flat plate.

**FIND:** An expression for the local Nusselt number.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady, incompressible flow, (2)  $\delta \ll \delta_t$ , hence  $u(y) \approx u_\infty$ , (3) Boundary layer approximations are valid, (4) Constant properties.

**ANALYSIS:** The boundary layer energy equation is

$$u \frac{\partial T}{\partial x} + v \frac{\partial T}{\partial y} = \alpha \frac{\partial^2 T}{\partial y^2}.$$

Assuming  $u(y) = u_\infty$ , it follows that  $v = 0$  and the energy equation becomes

$$u_\infty \frac{\partial T}{\partial x} = \alpha \frac{\partial^2 T}{\partial y^2} \quad \text{or} \quad \frac{\partial T}{\partial x} = \frac{\alpha}{u_\infty} \frac{\partial^2 T}{\partial y^2}.$$

*Boundary Conditions:*  $T(x,0) = T_s$ ,  $T(x,\infty) = T_\infty$ .

*Initial Condition:*  $T(0,y) = T_\infty$ .

The differential equation is analogous to that for transient one-dimensional conduction in a plane wall, and the conditions are analogous to those of Fig. 5.7, Case (1). Hence the solution is given by Eqs.

5.60 and 5.61. Substituting  $y$  for  $x$ ,  $x$  for  $t$ ,  $T_\infty$  for  $T_i$ , and  $\alpha/u_\infty$  for  $\alpha$ , the boundary layer temperature and the surface heat flux become

$$\frac{T(x,y) - T_s}{T_\infty - T_s} = \text{erf} \left[ \frac{y}{2(\alpha x/u_\infty)^{1/2}} \right]$$

$$q_s'' = \frac{k(T_s - T_\infty)}{(\pi \alpha x/u_\infty)^{1/2}}.$$

Hence, with 
$$\text{Nu}_x \equiv \frac{h x}{k} = \frac{q_s'' x}{(T_s - T_\infty) k}$$

find 
$$\text{Nu}_x = \frac{x}{(\pi \alpha x/u_\infty)^{1/2}} = \frac{(x u_\infty)^{1/2}}{\pi^{1/2} (k/\rho c_p)^{1/2}} = \frac{1}{\pi^{1/2}} \left[ \frac{\rho u_\infty x}{\mu} \cdot \frac{c_p \mu}{k} \right]^{1/2}$$

$$\text{Nu}_x = 0.564 (\text{Re}_x \text{Pr})^{1/2} = 0.564 \text{Pe}^{1/2} \quad <$$

where  $\text{Pe} = \text{Re} \cdot \text{Pr}$  is the Peclet number.

**COMMENTS:** Because  $k$  is very large, axial conduction effects may not be negligible. That is, the  $\alpha \frac{\partial^2 T}{\partial x^2}$  term of the energy equation may be important.

## PROBLEM 7.5

**KNOWN:** Form of velocity profile for flow over a flat plate.

**FIND:** (a) Expression for profile in terms of  $u_\infty$  and  $\delta$ , (b) Expression for  $\delta(x)$ , (c) Expression for  $C_{f,x}$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady state conditions, (2) Constant properties, (3) Incompressible flow, (4) Boundary layer approximations are valid.

**ANALYSIS:** (a) From the boundary conditions

$$u(x, 0) = 0 \rightarrow C_1 = 0 \quad \text{and} \quad u(x, \delta) = u_\infty \rightarrow C_2 = u_\infty / \delta.$$

Hence,  $u = u_\infty (y/\delta)$ . <

(b) From the momentum integral equation for a flat plate

$$\begin{aligned} \frac{d}{dx} \int_0^\delta (u_\infty - u) u \, dy &= \tau_s / \rho \\ u_\infty^2 \frac{d}{dx} \int_0^\delta \left(1 - \frac{u}{u_\infty}\right) \frac{u}{u_\infty} \, dy &= \left. \frac{\mu}{\rho} \frac{\partial u}{\partial y} \right|_{y=0} = \frac{\nu u_\infty}{\delta} \\ u_\infty^2 \frac{d}{dx} \int_0^\delta \left(1 - \frac{y}{\delta}\right) \frac{y}{\delta} \, dy &= \frac{\nu u_\infty}{\delta} \\ u_\infty^2 \frac{d}{dx} \left[ \left( \frac{y^2}{2\delta} - \frac{y^3}{3\delta^2} \right) \Big|_0^\delta \right] &= \frac{\mu u_\infty}{\delta} \quad \text{or} \quad \frac{u_\infty}{6} \frac{d\delta}{dx} = \frac{\nu}{\delta}. \end{aligned}$$

Separating and integrating, find

$$\int_0^\delta \delta \, d\delta = \frac{6\nu}{u_\infty} \int_0^x dx \quad \delta = \left( \frac{12 \nu x}{u_\infty} \right)^{1/2} = 3.46 x \left( \frac{\nu}{u_\infty x} \right)^{1/2} = 3.46 x \text{Re}_x^{-1/2}. \quad <$$

(c) The shear stress at the wall is

$$\tau_s = \left. \mu \frac{\partial u}{\partial y} \right|_{y=0} = \mu \frac{u_\infty}{\delta} = \frac{\mu u_\infty}{3.46 x} \text{Re}_x^{1/2}$$

and the friction coefficient is

$$C_{f,x} = \frac{\tau_s}{\rho u_\infty^2 / 2} = \frac{\mu}{\rho u_\infty x} \frac{2}{3.46} \text{Re}_x^{1/2} = 0.578 \text{Re}_x^{-1/2}. \quad <$$

**COMMENTS:** The foregoing results underpredict those associated with the exact solution  $(\delta = 4.96 x \text{Re}_x^{-1/2}, C_{f,x} = 0.664 \text{Re}_x^{-1/2})$  and the cubic profile  $(\delta = 4.64 x \text{Re}_x^{-1/2}, C_{f,x} = 0.646 \text{Re}_x^{-1/2})$ .

### PROBLEM 7.6

**KNOWN:** Velocity and temperature profiles and shear stress-boundary layer thickness relation for turbulent flow over a flat plate.

**FIND:** (a) Expressions for hydrodynamic boundary layer thickness and average friction coefficient, (b) Expressions for local and average Nusselt numbers.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady flow, (2) Constant properties, (3) Fully turbulent boundary layer, (4) Incompressible flow, (5) Isothermal plate, (6) Negligible viscous dissipation, (7)  $\delta \approx \delta_t$ .

**ANALYSIS:** (a) The momentum integral equation is

$$\rho u_\infty^2 \frac{d}{dx} \int_0^\delta \left(1 - \frac{u}{u_\infty}\right) \frac{u}{u_\infty} dy = \tau_s.$$

Substituting the expression for the wall shear stress

$$\rho u_\infty^2 \frac{d}{dx} \int_0^\delta \left[1 - \left(\frac{y}{\delta}\right)^{1/7}\right] \left(\frac{y}{\delta}\right)^{1/7} dy = 0.0228 \rho u_\infty^2 \left(\frac{u_\infty \delta}{\nu}\right)^{-1/4}$$

$$\frac{d}{dx} \int_0^\delta \left[\left(\frac{y}{\delta}\right)^{1/7} - \left(\frac{y}{\delta}\right)^{2/7}\right] dy = \frac{d}{dx} \left[\frac{7}{8} \frac{y^{8/7}}{\delta^{1/7}} - \frac{7}{9} \frac{y^{9/7}}{\delta^{2/7}}\right] \Big|_0^\delta$$

$$\frac{d}{dx} \left(\frac{7}{8} \delta - \frac{7}{9} \delta\right) = 0.0228 \left(\frac{u_\infty \delta}{\nu}\right)^{-1/4}$$

$$\frac{7}{72} \frac{d\delta}{dx} = 0.0228 \left(\frac{\nu}{u_\infty}\right)^{1/4} \delta^{-1/4} \quad \frac{7}{72} \int_0^\delta \delta^{1/4} d\delta = 0.0228 \left(\frac{\nu}{u_\infty}\right)^{1/4} \int_0^x dx$$

$$\frac{7}{72} \times \frac{4}{5} \delta^{5/4} = 0.0228 \left(\frac{\nu}{u_\infty}\right)^{1/4} x, \quad \delta = 0.376 \left(\frac{\nu}{u_\infty}\right)^{1/5} x^{4/5}, \quad \frac{\delta}{x} = 0.376 \text{Re}_x^{-1/5}. <$$

Knowing  $\delta$ , it follows

$$\tau_s = 0.0228 \rho u_\infty^2 \left(\frac{u_\infty}{\nu}\right)^{-1/4} \left[0.376 x \text{Re}_x^{-1/5}\right]^{-1/4}$$

$$C_{f,x} = \frac{\tau_s}{\rho u_\infty^2 / 2} = 0.0456 \left[0.376 \frac{u_\infty}{\nu} \left(\frac{u_\infty}{\nu}\right)^{-1/5} x x^{-1/5}\right]^{-1/4} = 0.0582 \text{Re}_x^{-1/5}.$$

Continued ...

### PROBLEM 7.6 (Cont.)

The average friction coefficient is then

$$\bar{C}_{f,x} = \frac{1}{x} \int_0^x C_{f,x} dx = \frac{1}{x} 0.0582 \left( \frac{u_\infty}{\nu} \right)^{-1/5} \int_0^x x^{-1/5} dx$$

$$\bar{C}_{f,x} = \frac{1}{x} 0.0582 \left( \frac{u_\infty}{\nu} \right)^{-1/5} x^{4/5} \left( \frac{5}{4} \right) = 0.073 \text{Re}_x^{-1/5}. \quad <$$

(b) The energy integral equation for turbulent flow is

$$\frac{d}{dx} \int_0^{\delta_t} u(T_\infty - T) dy = \frac{q_s''}{\rho c_p} = -\frac{h}{\rho c_p} (T_s - T_\infty).$$

Hence,

$$u_\infty \frac{d}{dx} \int_0^{\delta_t} \frac{u}{u_\infty} \frac{T - T_\infty}{T_s - T_\infty} dy = u_\infty \frac{d}{dx} \int_0^{\delta_t} (y/\delta)^{1/7} \left[ 1 - (y/\delta_t)^{1/7} \right] dy = \frac{h}{\rho c_p}$$

$$u_\infty \frac{d}{dx} \left[ \frac{7}{8} \frac{\delta_t^{8/7}}{\delta^{1/7}} - \frac{7}{9} \frac{\delta_t^{8/7}}{\delta^{1/7}} \right] = \frac{h}{\rho c_p}$$

or, with  $\xi \equiv \delta_t / \delta$ ,

$$u_\infty \frac{d}{dx} \left[ \frac{7}{8} \delta \xi^{8/7} - \frac{7}{9} \delta \xi^{8/7} \right] = \frac{h}{\rho c_p} \quad u_\infty \frac{d}{dx} \left[ \frac{7}{72} \delta \xi^{8/7} \right] = \frac{h}{\rho c_p}.$$

Hence, with  $\xi \approx 1$  and  $\delta/x = 0.376 \text{Re}_x^{-1/5}$ ,

$$\frac{7}{72} u_\infty (0.376) \left( \frac{u_\infty}{\nu} \right)^{-1/5} \frac{d(x^{4/5})}{dx} = \frac{h}{\rho c_p}$$

$$h = 0.0292 \rho c_p u_\infty \text{Re}_x^{-1/5} = 0.0292 \frac{k}{x} \frac{\nu}{\alpha} \frac{u_\infty x}{\nu} \text{Re}_x^{-1/5}$$

$$\text{Nu}_x = \frac{hx}{k} = 0.0292 \text{Re}_x^{4/5} \text{Pr}. \quad <$$

Hence,

$$\bar{h}_x = \frac{1}{x} \int_0^x h dx = \frac{0.0292 \text{Pr}}{x} k \left( \frac{u_\infty}{\nu} \right)^{4/5} \int_0^x x^{-1/5} dx = 0.0292 \frac{k}{x} \text{Pr} \left( \frac{u_\infty x}{\nu} \right)^{4/5} \frac{5}{4}$$

$$\bar{\text{Nu}}_x = \frac{\bar{h}_x x}{k} = 0.037 \text{Re}_x^{4/5} \text{Pr}. \quad <$$

**COMMENTS:** (1) The foregoing results are in excellent agreement with empirical correlations, except that use of  $\text{Pr}^{1/3}$  instead of  $\text{Pr}$ , would be more appropriate. This result arose because of the assumption  $\delta \approx \delta_t$ , which is only valid for  $\text{Pr} \approx 1$ .

(2) Note that the 1/7 profile breaks down at the surface. For example,

$$\left. \frac{\partial(u/u_\infty)}{\partial y} \right)_{y=0} = \frac{1}{7} \delta^{-1/7} y^{-6/7} = \infty$$

or  $\tau_s = \infty$ . Despite this unrealistic characteristic of the profile, its use with integral methods provides excellent results.

## PROBLEM 7.7

**KNOWN:** Parallel flow over a flat plate and two locations representing a short span  $x_1$  to  $x_2$  where  $(x_2 - x_1) \ll L$ .

**FIND:** Three different expressions for the average heat transfer coefficient over the short span  $x_1$  to  $x_2$ ,  $\bar{h}_{1-2}$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Parallel flow over a flat plate.

**ANALYSIS:** The heat rate per unit width for the span can be written as

$$q'_{1-2} = \bar{h}_{1-2} (x_2 - x_1) (T_s - T_\infty) \quad (1)$$

where  $\bar{h}_{1-2}$  is the average heat transfer coefficient over the span and can be evaluated in either of the following three ways:

(a) *Local coefficient at  $\bar{x} = (x_1 + x_2)/2$ .* If the span is very short, it is reasonable to assume that

$$\bar{h}_{1-2} \approx h_{\bar{x}} \quad (2)$$

where  $h_{\bar{x}}$  is the local convection coefficient at the mid-point of the span.

(b) *Local coefficients at  $x_1$  and  $x_2$ .* If the span is very short it is reasonable to assume that  $\bar{h}_{1-2}$  is the average of the local values at the ends of the span,

$$\bar{h}_{1-2} \approx [h_{x1} + h_{x2}] / 2. \quad (3)$$

(c) *Average coefficients for  $x_1$  and  $x_2$ .* The heat rate for the span can also be written as

$$q'_{1-2} = q'_{0-2} - q'_{0-1} \quad (4)$$

where the rate  $q'_{0-x}$  denotes the heat rate for the plate over the distance from 0 to  $x$ . In terms of heat transfer coefficients, find

$$\begin{aligned} \bar{h}_{1-2} \cdot (x_2 - x_1) &= \bar{h}_2 \cdot x_2 - \bar{h}_1 \cdot x_1 \\ \bar{h}_{1-2} &= \bar{h}_2 \frac{x_2}{x_2 - x_1} - \bar{h}_1 \frac{x_1}{x_2 - x_1} \end{aligned} \quad (5)$$

where  $\bar{h}_1$  and  $\bar{h}_2$  are the average coefficients from 0 to  $x_1$  and  $x_2$ , respectively.

**COMMENTS:** Eqs. (2) and (3) are approximate and work better when the span is small and the flow is turbulent rather than laminar ( $h_x \sim x^{-0.2}$  vs  $h_x \sim x^{-0.5}$ ). Of course, we require that  $x_c < x_1, x_2$  or  $x_c > x_1, x_2$ ; that is, the approximations are inappropriate around the transition region. Eq. (5) is an exact relationship, which applies under any conditions.

## PROBLEM 7.8

**KNOWN:** Flat plate comprised of rectangular modules of surface temperature  $T_s$ , thickness  $a$  and length  $b$  cooled by air at  $25^\circ\text{C}$  and a velocity of  $30\text{ m/s}$ . Prescribed thermophysical properties of the module material.

**FIND:** (a) Required power generation for the module positioned  $700\text{ mm}$  from the leading edge of the plate and (b) Maximum temperature in this module.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Laminar flow at leading edge of plate, (2) Transition Reynolds number of  $5 \times 10^5$ , (3) Heat transfer is one-dimensional in  $y$ -direction within each module, (4)  $\dot{q}$  is uniform within module, (5) Negligible radiation heat transfer.

**PROPERTIES:** Module material (given):  $k = 5.2\text{ W/m}\cdot\text{K}$ ,  $c_p = 320\text{ J/kg}\cdot\text{K}$ ,  $\rho = 2300\text{ kg/m}^3$ ; Table A-4, Air ( $\bar{T}_f = (T_s + T_\infty)/2 = 360\text{ K}$ ,  $1\text{ atm}$ ):  $k = 0.0308\text{ W/m}\cdot\text{K}$ ,  $\nu = 22.02 \times 10^{-6}\text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.698$ .

**ANALYSIS:** (a) The module power generation follows from an energy balance on the module surface,

$$q''_{\text{conv}} = q''_{\text{gen}}$$

$$\bar{h}(T_s - T_\infty) = \dot{q} \cdot a \quad \text{or} \quad \dot{q} = \frac{\bar{h}(T_s - T_\infty)}{a}.$$

To select a convection correlation for estimating  $\bar{h}$ , first find the Reynolds numbers at  $x = L$ .

$$\text{Re}_L = \frac{u_\infty L}{\nu} = \frac{30\text{ m/s} \times 0.70\text{ m}}{22.02 \times 10^{-6}\text{ m}^2/\text{s}} = 9.537 \times 10^5.$$

Since the flow is turbulent over the module, the approximation  $\bar{h} \approx h_x(L + b/2)$  is appropriate, with

$$\text{Re}_{L+b/2} = \frac{30\text{ m/s} \times (0.700 + 0.050/2)\text{ m}}{22.02 \times 10^{-6}\text{ m}^2/\text{s}} = 9.877 \times 10^5.$$

Using the turbulent flow correlation with  $x = L + b/2 = 0.725\text{ m}$ ,

$$\text{Nu}_x = \frac{h_x x}{k} = 0.0296 \text{Re}_x^{4/5} \text{Pr}^{1/3}$$

$$\text{Nu}_x = 0.0296 (9.877 \times 10^5)^{4/5} (0.698)^{1/3} = 1640$$

$$\bar{h} \approx h_x = \frac{\text{Nu}_x k}{x} = \frac{1640 \times 0.0308\text{ W/m}\cdot\text{K}}{0.725} = 69.7\text{ W/m}^2 \cdot \text{K}.$$

Continued ...

**PROBLEM 7.8 (Cont.)**

Hence,

$$\dot{q} = \frac{69.7 \text{ W/m}^2 \cdot \text{K} (150 - 25) \text{ K}}{0.010 \text{ m}} = 8.713 \times 10^5 \text{ W/m}^3. \quad <$$

(b) The maximum temperature within the module occurs at the surface next to the insulation ( $y = 0$ ). For one-dimensional conduction with thermal energy generation, use Eq. 3.42 to obtain

$$T(0) = \frac{\dot{q}a^2}{2k} + T_s = \frac{8.713 \times 10^5 \text{ W/m}^3 \times (0.010 \text{ m})^2}{2 \times 5.2 \text{ W/m} \cdot \text{K}} + 150^\circ \text{C} = 158.4^\circ \text{C}. \quad <$$

**COMMENTS:** An alternative approach for estimating the average heat transfer coefficient for the module follows from the relation

$$q_{\text{module}} = q_{0 \rightarrow L+b} - q_{0 \rightarrow L}$$

$$\bar{h} \cdot b = \bar{h}_{L+b} \cdot (L+b) - \bar{h}_L \cdot L \quad \text{or} \quad \bar{h} = \bar{h}_{L+b} \frac{L+b}{b} - \bar{h}_L \frac{L}{b}.$$

Recognizing that laminar and turbulent flow conditions exist, the appropriate correlation is

$$\overline{\text{Nu}}_x = \left( 0.037 \text{Re}_x^{4/5} - 871 \right) \text{Pr}^{1/3}$$

With  $x = L + b$  and  $x = L$ , find

$$\bar{h}_{L+b} = 54.79 \text{ W/m}^2 \cdot \text{K} \quad \text{and} \quad \bar{h}_L = 53.73 \text{ W/m}^2 \cdot \text{K}.$$

Hence,

$$\bar{h} = \left[ 54.79 \frac{0.750}{0.050} - 53.73 \frac{0.700}{0.05} \right] \text{ W/m}^2 \cdot \text{K} = 69.7 \text{ W/m}^2 \cdot \text{K}.$$

which is in excellent agreement with the approximate result employed in part (a).

## PROBLEM 7.9

**KNOWN:** Dimensions and surface temperature of electrically heated strips. Temperature and velocity of air in parallel flow.

**FIND:** (a) Rate of convection heat transfer from first, fifth and tenth strips as well as from all the strips, (b) For air velocities of 2, 5 and 10 m/s, determine the convection heat rates for all the locations of part (a), and (c) Repeat the calculations of part (b), but under conditions for which the flow is fully turbulent over the entire array of strips.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Top surface is smooth, (2) Bottom surface is adiabatic, (3) Critical Reynolds number is  $5 \times 10^5$ , (4) Negligible radiation.

**PROPERTIES:** Table A.4, Air ( $T_f = 535$  K, 1 atm):  $\nu = 43.54 \times 10^{-6}$  m<sup>2</sup>/s,  $k = 0.0429$  W/m·K,  $Pr = 0.683$ .

**ANALYSIS:** (a) The location of transition is determined from

$$x_c = 5 \times 10^5 \frac{\nu}{u_\infty} = 5 \times 10^5 \frac{43.54 \times 10^{-6} \text{ m}^2/\text{s}}{2 \text{ m/s}} = 10.9 \text{ m}$$

Since  $x_c \gg L = 0.25$  m, the air flow is laminar over the entire heater. For the *first* strip,  $q_1 = \bar{h}_1 (\Delta L \times w)(T_s - T_\infty)$  where  $\bar{h}_1$  is obtained from

$$\bar{h}_1 = \frac{k}{\Delta L} 0.664 \text{Re}_x^{1/2} \text{Pr}^{1/3}$$

$$\bar{h}_1 = \frac{0.0429 \text{ W/m} \cdot \text{K}}{0.01 \text{ m}} \times 0.664 \left( \frac{2 \text{ m/s} \times 0.01 \text{ m}}{43.54 \times 10^{-6} \text{ m}^2/\text{s}} \right)^{1/2} (0.683)^{1/3} = 53.8 \text{ W/m}^2 \cdot \text{K}$$

$$q_1 = 53.8 \text{ W/m}^2 \cdot \text{K} (0.01 \text{ m} \times 0.2 \text{ m}) (500 - 25)^\circ \text{C} = 51.1 \text{ W} \quad <$$

For the *fifth* strip,  $q_5 = q_{0-5} - q_{0-4}$ ,

$$q_5 = h_{0-5} (5\Delta L \times w)(T_s - T_\infty) - \bar{h}_{0-4} (4\Delta L \times w)(T_s - T_\infty)$$

$$q_5 = (5\bar{h}_{0-5} - 4\bar{h}_{0-4})(\Delta L \times w)(T_s - T_\infty)$$

Hence, with  $x_5 = 5\Delta L = 0.05$  m and  $x_4 = 4\Delta L = 0.04$  m, it follows that  $\bar{h}_{0-5} = 24.1$  W/m<sup>2</sup>·K and  $\bar{h}_{0-4} = 26.9$  W/m<sup>2</sup>·K and

$$q_5 = (5 \times 24.1 - 4 \times 26.9) \text{ W/m}^2 \cdot \text{K} (0.01 \times 0.2) \text{ m}^2 (500 - 25) \text{ K} = 12.2 \text{ W} \quad <$$

Similarly, where  $\bar{h}_{0-10} = 17.00$  W/m<sup>2</sup>·K and  $\bar{h}_{0-9} = 17.92$  W/m<sup>2</sup>·K.

$$q_{10} = (10\bar{h}_{0-10} - 9\bar{h}_{0-9})(\Delta L \times w)(T_s - T_\infty)$$

$$q_{10} = (10 \times 17.00 - 9 \times 17.92) \text{ W/m}^2 \cdot \text{K} (0.01 \times 0.2) \text{ m}^2 (500 - 25) \text{ K} = 8.3 \text{ W} \quad <$$

Continued...

### PROBLEM 7.9 (Cont.)

For the entire heater,

$$\bar{h}_{0-25} = \frac{k}{L} 0.664 \text{Re}_L^{1/2} \text{Pr}^{1/3} = \frac{0.0429}{0.25} \times 0.664 \left( \frac{2 \times 0.25}{43.54 \times 10^{-6}} \right)^{1/2} (0.683)^{1/3} = 10.75 \text{ W/m}^2 \cdot \text{K}$$

and the heat rate over all 25 strips is

$$q_{0-25} = \bar{h}_{0-25} (L \times w) (T_s - T_\infty) = 10.75 \text{ W/m}^2 \cdot \text{K} (0.25 \times 0.2) \text{ m}^2 (500 - 25)^\circ \text{C} = 255.3 \text{ W} <$$

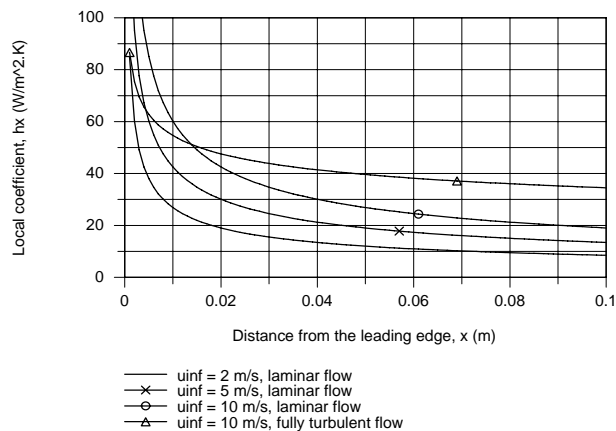

(b,c) Using the *IHT Correlations Tool, External Flow*, for *Laminar or Mixed Flow Conditions*, and following the same method of solution as above, the heat rates for the first, fifth, tenth and all the strips were calculated for air velocities of 2, 5 and 10 m/s. To evaluate the heat rates for fully turbulent conditions, the analysis was performed setting  $\text{Re}_{x,c} = 1 \times 10^6$ . The results are tabulated below.

Flow conditions	$u_\infty$ (m/s)	$q_1$ (W)	$q_5$ (W)	$q_{10}$ (W)	$q_{0-25}$ (W)
Laminar	2	51.1	12.1	8.3	256
	5	80.9	19.1	13.1	404
	10	114	27.0	18.6	572
Fully turbulent	2	17.9	10.6	9.1	235
	5	37.3	22.1	19.0	490
	10	64.9	38.5	33.1	853

**COMMENTS:** (1) An alternative approach to evaluating the heat loss from a single strip, for example, strip 5, would take the form  $q_5 = \bar{h}_5 (\Delta L \times w) (T_s - T_\infty)$ , where  $h_5 \approx h_{x=4.5\Delta L}$  or  $\bar{h}_5 \approx (h_{x=5\Delta L} + h_{x=4\Delta L})/2$ .

(2) From the tabulated results, note that for both flow conditions, the heat rate for each strip and the entire heater, increases with increasing air velocity. For both flow conditions and for any specified velocity, the strip heat rates decrease with increasing distance from the leading edge.

(3) To more fully appreciate the effects due to laminar vs. turbulent flow conditions and air velocity, it is useful to examine the local coefficient as a function of distance from the leading edge. How would you use the results plotted below to explain heat rate behavior evident in the summary table above?

### PROBLEM 7.10

**KNOWN:** Speed and temperature of atmospheric air flowing over a flat plate of prescribed length and temperature.

**FIND:** Rate of heat transfer corresponding to  $Re_{x,c} = 10^5$ ,  $5 \times 10^5$  and  $10^6$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Flow over top and bottom surfaces.

**PROPERTIES:** Table A-4, Air ( $T_f = 348\text{K}$ , 1 atm):  $\rho = 1.00\text{ kg/m}^3$ ,  $\nu = 20.72 \times 10^{-6}\text{ m}^2/\text{s}$ ,  $k = 0.0299\text{ W/m}\cdot\text{K}$ ,  $Pr = 0.700$ .

**ANALYSIS:** With

$$Re_L = \frac{u_\infty L}{\nu} = \frac{25\text{ m/s} \times 1\text{ m}}{20.72 \times 10^{-6}\text{ m}^2/\text{s}} = 1.21 \times 10^6$$

the flow becomes turbulent for each of the three values of  $Re_{x,c}$ . Hence,

$$\overline{Nu}_L = \left(0.037 Re_L^{4/5} - A\right) Pr^{1/3}$$

$$A = 0.037 Re_{x,c}^{4/5} - 0.664 Re_{x,c}^{1/2}$$

$Re_{x,c}$	$10^5$	$5 \times 10^5$	$10^6$
A	160	871	1671
$\overline{Nu}_L$	2267	1635	926
$\overline{h}_L$ ( $\text{W/m}^2 \cdot \text{K}$ )	67.8	48.9	27.7
$q'$ ( $\text{W/m}$ )	13,560	9780	5530

where  $q' = 2 \overline{h}_L L (T_s - T_\infty)$  is the total heat loss per unit width of plate.

**COMMENTS:** Note that  $\overline{h}_L$  decreases with increasing  $Re_{x,c}$ , as more of the surface becomes covered with a laminar boundary layer.

## PROBLEM 7.11

**KNOWN:** Length of isothermal flat plate in parallel flow,  $L$ .

**FIND:** Expression for the average heat transfer coefficients for  $N$  plates each of length  $L_N = L/N$  to the average coefficient for the single plate.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Laminar flow, (2) Constant properties.

**ANALYSIS:** For the single plate, Equation 7.30 applies

$$\overline{Nu}_L = \frac{\bar{h}_{L,1} L}{k} = 0.664 Re_L^{1/2} Pr^{1/3} \quad \text{or} \quad \bar{h}_{L,1} = (k/L) 0.664 Re_L^{1/2} Pr^{1/3} \quad (1)$$

For the multiple plates,

$$\overline{Nu}_{L,N} = \frac{\bar{h}_{L,N} L_N}{k} = 0.664 Re_{L_N}^{1/2} Pr^{1/3} \quad \text{where} \quad L_N = L/N \quad \text{and} \quad Re_{L_N} = Re_L/N \quad (2a, b, c)$$

Combining Equations 2a, 2b and 2c yields

$$\bar{h}_{L,N} = \frac{kN}{L} 0.664 (Re_L/N)^{1/2} Pr^{1/3} \quad (3)$$

Dividing Equation 3 by Equation 1 yields

$$\bar{h}_{L,N} / \bar{h}_{L,1} = N^{1/2} \quad <$$

**COMMENTS:** (1) By breaking the single plate into shorter segments, the average boundary layer thickness is reduced, resulting in an increase of the average heat transfer coefficient. This is an effective strategy for heat transfer *enhancement*. (2) If the boundary layer over the single plate is not completely laminar, breaking it into shorter segments may or may not result in an increase in the average heat transfer coefficient since the turbulent section of the boundary layer over the single plate may be eliminated. (3) The relationship for completely turbulent flow is  $\bar{h}_{L,N} / \bar{h}_L = N^{1/5}$ , revealing less sensitivity to the plate length than for laminar conditions.

## PROBLEM 7.12

**KNOWN:** Length of isothermal flat plate in parallel flow,  $L$ .

**FIND:** Expression for the average heat transfer coefficients for  $N$  plates each of length  $L_N = L/N$  to the average heat transfer coefficient for the single plate.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Turbulent flow, (2) Constant properties.

**ANALYSIS:** Since  $Re_{x,c} = 0$ , Equation 7.39 yields  $A = 0$ . Therefore, for the single plate,

$$\overline{Nu}_L = \frac{\bar{h}_{L,1}L}{k} = 0.036Re_L^{4/5}Pr^{1/3} \quad \text{or} \quad \bar{h}_{L,1} = (k/L)0.036Re_L^{4/5}Pr^{1/3} \quad (1)$$

For the multiple plates,

$$\overline{Nu}_{L,N} = \frac{\bar{h}_{L,N}L_N}{k} = 0.037Re_{L_N}^{4/5}Pr^{1/3} \quad \text{where} \quad L_N = L/N \quad \text{and} \quad Re_{L_N} = Re_L/N \quad (2a, b, c)$$

Combining Equations 2a, 2b and 2c yields

$$\bar{h}_{L,N} = \frac{kN}{L}0.037(Re_L/N)^{4/5}Pr^{1/3} \quad (3)$$

Dividing Equation 3 by Equation 1 yields

$$\bar{h}_{L,N} / \bar{h}_{L,1} = N^{1/5} \quad <$$

**COMMENTS:** (1) By breaking the single plate into shorter segments, the average boundary layer thickness is reduced, resulting in a slight increase of the average heat transfer coefficient. Hence, breaking the plate into shorter lengths results in modest heat transfer *enhancement*. (2) The relationship for laminar flow is  $\bar{h}_{L,N} / \bar{h}_L = N^{1/2}$ , revealing more sensitivity to the plate length for laminar conditions.

### PROBLEM 7.13

**KNOWN:** Dimensions and surface temperatures of a flat plate. Velocity and temperature of air and water flow parallel to the plate.

**FIND:** (a) Average convective heat transfer coefficient, convective heat transfer rate, and drag force when  $L = 2$  m,  $w = 2$  m. (b) Average convective heat transfer coefficient, convective heat transfer rate, and drag force when  $L = 0.1$  m,  $w = 0.1$  m.

**SCHEMATIC:**

(a) Air

(b) Water

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Boundary layer assumptions are valid, (3) Constant properties, (4) Transition Reynolds number is  $5 \times 10^5$ .

**PROPERTIES:** Using *IHT*, Air ( $p = 1$  atm,  $T_f = 35^\circ\text{C} = 308$  K):  $Pr = 0.706$ ,  $k = 26.9 \times 10^{-3}$  W/m·K,  $\nu = 1.669 \times 10^{-5}$  m<sup>2</sup>/s,  $\rho = 1.135$  kg/m<sup>3</sup>. Air ( $p = 1$  atm,  $T_f = 50^\circ\text{C} = 323$  K):  $Pr = 0.704$ ,  $k = 28.0 \times 10^{-3}$  W/m·K,  $\nu = 1.82 \times 10^{-5}$  m<sup>2</sup>/s,  $\rho = 1.085$  kg/m<sup>3</sup>. Water ( $T_f = 308$  K):  $Pr = 4.85$ ,  $k = 0.625$  W/m·K,  $\nu = 7.291 \times 10^{-7}$  m<sup>2</sup>/s,  $\rho = 994$  kg/m<sup>3</sup>. Water ( $T_f = 323$  K):  $Pr = 3.56$ ,  $k = 0.643$  W/m·K,  $\nu = 5.543 \times 10^{-7}$  m<sup>2</sup>/s,  $\rho = 988$  kg/m<sup>3</sup>.

**ANALYSIS:**

(a) We begin by calculating the Reynolds numbers for the two different surface temperatures:

$$Re_{L1} = \frac{u_\infty L}{\nu_1} = \frac{5 \text{ m/s} \times 2 \text{ m}}{1.669 \times 10^{-5} \text{ m}^2/\text{s}} = 5.99 \times 10^5$$

$$Re_{L2} = \frac{u_\infty L}{\nu_2} = \frac{5 \text{ m/s} \times 2 \text{ m}}{1.82 \times 10^{-5} \text{ m}^2/\text{s}} = 5.49 \times 10^5$$

Therefore, in both cases the flow is turbulent at the end of the plate and the conditions in the boundary layer are “mixed.”

The average drag coefficient can be calculated from Equation 7.40. For the first case,

$$\begin{aligned} \bar{C}_{f,L1} &= 0.074 Re_{L1}^{-1/5} - 1742 Re_{L1}^{-1} \\ &= 0.074(5.99 \times 10^5)^{-1/5} - 1742(5.99 \times 10^5)^{-1} = 2.27 \times 10^{-3} \end{aligned}$$

Then

$$\begin{aligned} F_{D1} &= \bar{C}_{f,L1} \frac{1}{2} \rho u_\infty^2 A_s \\ &= 2.27 \times 10^{-3} \times \frac{1}{2} \times 1.135 \text{ kg/m}^3 \times (5 \text{ m/s})^2 \times 8 \text{ m}^2 = 0.257 \text{ N} \\ &= 0.257 \text{ N} \end{aligned}$$

<

Continued...

### PROBLEM 7.13 (Cont.)

The average Nusselt number is calculated from Equation 7.38, with  $A = 871$  for a transition Reynolds number of  $5 \times 10^5$ .

$$\begin{aligned}\overline{Nu}_{L1} &= (0.037 Re_L^{4/5} - 871) Pr^{1/3} \\ &= \left[ 0.037(5.99 \times 10^5)^{4/5} - 871 \right] (0.706)^{1/3} = 604.\end{aligned}$$

Then

$$\overline{h}_{L1} = \overline{Nu}_{L1} k / L = 604 \times 26.9 \times 10^{-3} \text{ W/m} \cdot \text{K} / 2 \text{ m} = 8.13 \text{ W/m}^2 \cdot \text{K} \quad <$$

and

$$q_1 = \overline{h}_{L1} A_s (T_s - T_\infty) = 8.13 \text{ W/m}^2 \cdot \text{K} \times 8 \text{ m}^2 \times (50^\circ\text{C} - 20^\circ\text{C}) = 1950 \text{ W} \quad <$$

Similarly for  $T_s = 80^\circ\text{C}$  we find

$$F_{D2} = 0.227 \text{ N}, \quad \overline{h}_{L2} = 7.16 \text{ W/m}^2 \cdot \text{K}, \quad q_2 = 3440 \text{ W} \quad <$$

(b) Repeating the calculations for water

$$Re_{L1} = \frac{u_\infty L}{\nu} = \frac{5 \text{ m/s} \times 0.1 \text{ m}}{7.291 \times 10^{-7} \text{ m}^2/\text{s}} = 6.86 \times 10^5$$

$$Re_{L2} = 9.02 \times 10^5$$

The flow is turbulent at the end of the plate in both cases.

$$\overline{C}_{f,L1} = 0.074(6.86 \times 10^5)^{-1/5} - 1742(6.86 \times 10^5)^{-1} = 2.49 \times 10^{-3}$$

$$F_{D1} = 2.49 \times 10^{-3} \times 1/2 \times 994 \text{ kg/m}^3 \times (5 \text{ m/s})^2 \times 0.02 \text{ m}^2 = 0.620 \text{ N} \quad <$$

$$\overline{Nu}_L = \left[ 0.037(6.86 \times 10^5)^{4/5} - 871 \right] (4.85)^{1/3} = 1450$$

$$\overline{h}_{L1} = 1450 \times 0.625 \text{ W/m} \cdot \text{K} / 0.1 \text{ m} = 9050 \text{ W/m}^2 \cdot \text{K} \quad <$$

$$q_1 = 9050 \text{ W/m}^2 \cdot \text{K} \times 0.02 \text{ m}^2 \times (50^\circ\text{C} - 20^\circ\text{C}) = 5430 \text{ W} \quad <$$

For the higher surface temperature,

$$F_{D2} = 0.700 \text{ N}, \quad \overline{h}_{L2} = 12,600 \text{ W/m}^2 \cdot \text{K}, \quad q_2 = 15,100 \text{ W} \quad <$$

**COMMENTS:** (1) For air, kinematic viscosity increases with increasing temperature. This decreases the Reynolds number which causes the transition to turbulence to move downstream, thereby decreasing the drag force and average heat transfer coefficient. The heat transfer rate increases for the higher surface temperature, however, because of the greater temperature difference between the surface and air. (2) For water, kinematic viscosity decreases with increasing temperature, causing the opposite trends as for air. The heat transfer rate increases dramatically for the higher surface temperature because of the increases in both the heat transfer coefficient and temperature difference. (3) Even though the water flows over a plate that is 400 times smaller, the drag force and heat transfer rate are larger than for air because of the smaller viscosity and greater density, thermal conductivity, and Prandtl number. The discrepancy is particularly great for the heat transfer rate. (4) The problem highlights the importance of carefully accounting for the temperature dependence of thermal properties.

## PROBLEM 7.14

**KNOWN:** Velocity and temperature of water in parallel flow over a flat plate of 1-m length.

**FIND:** (a) Calculate and plot the variation of the local convection coefficient,  $h_x(x)$ , with distance for flow conditions corresponding to transition Reynolds numbers of  $5 \times 10^5$ ,  $3 \times 10^5$  and 0 (fully turbulent), (b) Plot the variation of the average convection coefficient,  $\bar{h}_x(x)$ , for the three flow conditions of part (a), and (c) Determine the average convection coefficients for the entire plate,  $\bar{h}_L$ , for the three flow conditions of part (a).

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Constant surface temperature, and (3) Critical Reynolds depends upon prescribed flow conditions.

**PROPERTIES:** Table A.6, Water (300 K):  $\rho = 997 \text{ kg/m}^3$ ,  $\mu = 855 \times 10^{-6} \text{ N}\cdot\text{s/m}^2$ ,  $\nu = \mu/\rho = 0.858 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.613 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 583$ .

**ANALYSIS:** (a) The Reynolds number for the plate ( $L = 1 \text{ m}$ ) is

$$\text{Re}_L = \frac{u_\infty L}{\nu} = \frac{2 \text{ m/s} \times 1 \text{ m}}{0.858 \times 10^{-6} \text{ m}^2/\text{s}} = 2.33 \times 10^6.$$

and the boundary layer is mixed with  $\text{Re}_{x,c} = 5 \times 10^5$ ,

$$x_c = L \left( \text{Re}_{x,c} / \text{Re}_L \right) = 1 \text{ m} \frac{5 \times 10^5}{2.33 \times 10^6} = 0.215 \text{ m}$$

Using the *IHT Correlation Tool, External Flow, Local coefficients for Laminar or Turbulent Flow*,  $h_x(x)$  was evaluated and plotted with critical Reynolds numbers of  $5 \times 10^5$ ,  $3.0 \times 10^5$  and 0 (fully turbulent). Note the location of the laminar-turbulent transition for the first two flow conditions.

Continued...

## PROBLEM 7.14 (Cont.)

(b) Using the *IHT Correlation Tool, External Flow, Average coefficient for Laminar or Mixed Flow*,  $\bar{h}_x(x)$  was evaluated and plotted for the three flow conditions. Note that the change in  $\bar{h}_x(x)$  at the critical length,  $x_c$ , is rather gradual, compared to the abrupt change for the local coefficient,  $h_x(x)$ .

(c) The average convection coefficients for the plate can be determined from the above plot since  $\bar{h}_L = \bar{h}_x(L)$ . The values for the three flow conditions are

$$\bar{h}_L = 4110, 4490 \text{ and } 5072 \text{ W/m}^2 \cdot \text{K}$$

**COMMENTS:** A copy of the *IHT Workspace* used to generate the above plot is shown below.

**/\* Method of Solution:** Use the Correlation Tools, External Flow, Flat Plate, for (i) Local, laminar or turbulent flow and (ii) Average, laminar or mixed flow, to evaluate the local and average convection coefficients as a function of position on the plate. In each of these tools, the value of the critical Reynolds number,  $R_{ex,c}$ , can be set corresponding to the special flow conditions. \*/

### PROBLEM 7.15

**KNOWN:** Two plates of length  $L$  and  $2L$  experience parallel flow with a critical Reynolds number of  $5 \times 10^5$ .

**FIND:** Reynolds numbers for which the total heat transfer rate is independent of orientation.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Plate temperatures and flow conditions are equivalent.

**ANALYSIS:** The total heat transfer rate would be the same ( $q_L = q_{2L}$ ), if the convection coefficients were equal,  $\bar{h}_L = \bar{h}_{2L}$ . Conditions for which such an equality is possible may be inferred from a sketch of  $\bar{h}_L$  versus  $Re_L$ .

For laminar flow ( $Re_L < Re_{x,c}$ ),  $\bar{h}_L \propto L^{-1/2}$ , and for mixed laminar and turbulent flow ( $Re_L > Re_{x,c}$ ),  $\bar{h}_L = C_1 L^{-1/5} - C_2 L^{-1}$ . Hence  $\bar{h}_L$  varies with  $Re_L$  as shown, and two possibilities are suggested.

*Case (a):* Laminar flow exists on the shorter plate, while mixed flow conditions exist on the longer plate.

*Case (b):* Mixed boundary layer conditions exist on both plates.

In both cases, it is required that

$$\bar{h}_L = \bar{h}_{2L} \quad \text{and} \quad Re_{2L} = 2 Re_L.$$

Continued ...

### PROBLEM 7.15 (Cont.)

Case (a): From expressions for  $\bar{h}_L$  in laminar and mixed flow

$$0.664 \frac{k}{L} \text{Re}_L^{1/2} \text{Pr}^{1/3} = \frac{k}{2L} (0.037 \text{Re}_{2L}^{4/5} - 871) \text{Pr}^{1/3}$$
$$0.664 \text{Re}_L^{1/2} = 0.032 \text{Re}_L^{4/5} - 435.$$

Since  $\text{Re}_L < 5 \times 10^5$  and  $\text{Re}_{2L} = 2 \text{Re}_L > 5 \times 10^5$ , the required value of  $\text{Re}_L$  may be narrowed to the range

$$2.5 \times 10^5 < \text{Re}_L < 5 \times 10^5.$$

From a trial-and-error solution, it follows that

$$\text{Re}_L \approx 3.2 \times 10^5. \quad <$$

Case (b): For mixed flow on both plates

$$\frac{k}{L} (0.037 \text{Re}_L^{4/5} - 871) \text{Pr}^{1/3} = \frac{k}{2L} (0.037 \text{Re}_{2L}^{4/5} - 871) \text{Pr}^{1/3}$$

or

$$0.037 \text{Re}_L^{4/5} - 871 = 0.032 \text{Re}_L^{4/5} - 435$$
$$0.005 \text{Re}_L^{4/5} = 436$$

$$\text{Re}_L \approx 1.50 \times 10^6. \quad <$$

**COMMENTS:** (1) Note that it is impossible to satisfy the requirement that  $\bar{h}_L = \bar{h}_{2L}$  if  $\text{Re}_L < 0.25 \times 10^5$  (laminar flow for both plates).

(2) The results are independent of the nature of the fluid.

## PROBLEM 7.16

**KNOWN:** Dimensions of and heat generation rate in thin membrane. Velocity and temperature of air flow parallel to membrane. Air streams above and below membrane are in same, opposite, or orthogonal directions.

**FIND:** (a) Minimum and maximum local membrane temperatures. Flow configuration that minimizes the membrane temperature. (b) Plot the surface temperature distribution for flow in the same and opposite directions. Find configuration that minimizes spatial temperature gradients.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Boundary layer assumptions hold, (3) Constant properties, (4) Solutions are bounded by constant surface temperature and constant heat flux cases for the opposite and orthogonal flow configurations.

**PROPERTIES:** Table A-4, Air ( $T_f \approx 323$  K):  $\nu = 18.20 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0280 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.704$ .

**ANALYSIS:**

(a) We begin by calculating the Reynolds number

$$\text{Re}_L = \frac{u_\infty L}{\nu} = \frac{2 \text{ m/s} \times 0.15 \text{ m}}{18.20 \times 10^{-6} \text{ m}^2/\text{s}} = 1.65 \times 10^4$$

Therefore, the flow is laminar.

(a) Top and bottom flows in same direction.

By symmetry, the heat flux from the membrane to the air is  $50 \text{ W/m}^2$  everywhere for the top and bottom air flows. Since the heat flux is uniform, the local Nusselt number is given by Equation 7.45,

$$\text{Nu}_x = 0.453 \text{Re}_x^{1/2} \text{Pr}^{1/3}$$

Thus  $h_x = c_q x^{-1/2}$

where

$$\begin{aligned} c_q &= 0.453(u_\infty/\nu)^{1/2} \text{Pr}^{1/3} k \\ &= 0.453(2 \text{ m/s}/18.2 \times 10^{-6} \text{ m}^2/\text{s})^{1/2} \times (0.704)^{1/3} \times 0.028 \text{ W/m}\cdot\text{K} = 3.74 \text{ W/m}^{3/2} \cdot \text{K} \end{aligned}$$

Then  $q_s'' = h_x(T_s - T_\infty)$  and  $T_s - T_\infty = \frac{q_s''}{h_x} = \frac{q_s''}{c_q} x^{1/2}$  (1)

Continued...

### PROBLEM 7.16 (Cont.)

Clearly the minimum temperature occurs at  $x = 0$  and is

$$T_{\min} = T_{\infty} = 25^{\circ}\text{C} \quad <$$

The maximum temperature occurs at  $x = L$  and is

$$T_{\max} = 25^{\circ}\text{C} + 50 \text{ W/m}^2 \times (0.15 \text{ m})^{1/2} / 3.74 \text{ W/m}^{3/2} \cdot \text{K} = 30.2^{\circ}\text{C} \quad <$$

(ii) Top and bottom flows in opposite direction.

The heat flux entering each of the top and bottom flows will no longer be uniform. Near  $x = 0$ , where the top flow first encounters the plate, the heat transfer coefficient on the top surface is theoretically infinite, and all the generated heat will enter the top flow. The opposite situation will occur at  $x = L$ .

We bound the solution by considering Nusselt number correlations for uniform surface temperature and uniform surface heat flux, Equations 7.23 and 7.45. In both cases, the heat transfer coefficient varies as  $x^{-1/2}$ , where  $x$  is the distance from the leading edge, thus for the top and bottom,

$$h_{x,t} = cx^{-1/2}, \quad h_{x,b} = c(L-x)^{-1/2}$$

And all of the generated heat is removed by the top and bottom flows:

$$\dot{q}'' = (h_{x,t} + h_{x,b})(T_s - T_{\infty})$$

$$\text{Thus } T_s - T_{\infty} = \frac{\dot{q}''}{h_{x,t} + h_{x,b}} = \frac{\dot{q}''}{c[x^{-1/2} + (L-x)^{-1/2}]} \quad (2)$$

The minimum temperature occurs at  $x = 0$  or  $x = L$ , and is

$$T_{\min} = T_{\infty} = 25^{\circ}\text{C} \quad <$$

The maximum temperature occurs where the denominator is minimum:

$$\frac{d}{dx} [x^{-1/2} + (L-x)^{-1/2}] = 0$$

$$-\frac{1}{2}x^{-3/2} + \frac{1}{2}(L-x)^{-3/2} = 0$$

$$x = L - x$$

$$x = L/2$$

At that location

$$T_{\max} = T_{\infty} + \frac{\dot{q}''}{c2(L/2)^{-1/2}}$$

For uniform surface temperature,

$$c_T = 0.332(u_{\infty}/\nu)^{1/2} \text{Pr}^{1/3} k$$

$$= 0.332(2 \text{ m/s}/18.2 \times 10^{-6} \text{ m}^2/\text{s})^{1/2} \times (0.704)^{1/3} \times 0.0280 \text{ W/m} \cdot \text{K} = 2.74 \text{ W/m}^{3/2} \cdot \text{K}$$

$$\text{And } T_{\max} = 25^{\circ}\text{C} + \frac{100 \text{ W/m}^2}{2.74 \text{ W/m}^{3/2} \cdot \text{K} \times 2 \times (0.15 \text{ m}/2)^{-1/2}} = 30.0^{\circ}\text{C}$$

Continued...

### PROBLEM 7.16 (Cont.)

For uniform surface heat flux, we previously found  $c_q = 3.74 \text{ W/m}^{3/2}\cdot\text{K}$ , thus,  $T_{\max} = 28.7^\circ\text{C}$ .

Therefore, for the opposite flow case,  $28.7^\circ\text{C} \leq T_{\max} \leq 30.0^\circ\text{C}$

(iii) Top and bottom flows in orthogonal directions.

Here the heat transfer coefficients are given by

$$h_{x,t} = cx^{-1/2}, \quad h_{y,b} = cy^{-1/2}$$

And  $\dot{q}'' = c(x^{-1/2} + y^{-1/2})(T_s - T_\infty)$

$$\text{So } T_s - T_\infty = \frac{\dot{q}''}{c(x^{-1/2} + y^{-1/2})}$$

The temperature will be minimum along  $x = 0$  or  $y = 0$ , where

$$T_{\min} = T_\infty = 25^\circ\text{C}$$

The temperature will be maximum along  $x = y = L$ , where

$$T_{\max} = T_\infty + \frac{\dot{q}''}{c \cdot 2 L^{-1/2}}$$

The values of  $c$  are the same as previously, therefore we find  $30.2^\circ\text{C} \leq T_{\max} \leq 32.1^\circ\text{C}$

The surface temperature is minimized when the air streams are in opposite directions, because a small heat transfer coefficient on the top is paired with a large heat transfer coefficient on the bottom, and vice versa.

(b) *IHT* was used to plot Equation (1) and (2) for  $c = c_T$  or  $c_q$ . The result is shown below.

The spatial temperature gradients are somewhat less for the opposite flow case.

**COMMENTS:** To correctly treat the convective heat transfer would require a coupled numerical solution of the thermal energy equation for both boundary layers simultaneously.

### PROBLEM 7.17

**KNOWN:** Temperature, pressure and Reynolds number for air flow over a flat plate of uniform surface temperature.

**FIND:** (a) Rate of heat transfer from the plate, (b) Rate of heat transfer if air velocity is doubled and pressure is increased to 10 atm.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Uniform surface temperature, (3) Negligible radiation, (4)  $Re_{x_c} = 5 \times 10^5$ .

**PROPERTIES:** Table A-4, Air ( $T_f = 348\text{K}$ , 1 atm):  $k = 0.0299 \text{ W/m}\cdot\text{K}$ ,  $Pr = 0.70$ .

**ANALYSIS:** (a) The heat rate is

$$q = \bar{h}_L (w \times L) (T_s - T_\infty).$$

Since the flow is laminar over the entire plate for  $Re_L = 4 \times 10^4$ , it follows that

$$\overline{Nu}_L = \frac{\bar{h}_L L}{k} = 0.664 Re_L^{1/2} Pr^{1/3} = 0.664 (40,000)^{1/2} (0.70)^{1/3} = 117.9.$$

Hence 
$$\bar{h}_L = 117.9 \frac{k}{L} = 117.9 \frac{0.0299 \text{ W/m}\cdot\text{K}}{0.2 \text{ m}} = 17.6 \text{ W/m}^2 \cdot \text{K}$$

and 
$$q = 17.6 \frac{\text{W}}{\text{m}^2 \cdot \text{K}} (0.1 \text{ m} \times 0.2 \text{ m}) (100 - 50)^\circ \text{C} = 17.6 \text{ W.} \quad <$$

(b) With  $p_2 = 10 p_1$ , it follows that  $\rho_2 = 10 \rho_1$  and  $v_2 = v_1/10$ . Hence

$$Re_{L,2} = \left( \frac{u_\infty L}{\nu} \right)_2 = 2 \times 10 \left( \frac{u_\infty L}{\nu} \right)_1 = 20 Re_{L,1} = 8 \times 10^5$$

and mixed boundary layer conditions exist on the plate. Hence

$$\overline{Nu}_L = \frac{\bar{h}_L L}{k} = \left( 0.037 Re_L^{4/5} - 871 \right) Pr^{1/3} = \left[ 0.037 \times (8 \times 10^5)^{4/5} - 871 \right] (0.70)^{1/3}$$

$$\overline{Nu}_L = 961.$$

Hence, 
$$\bar{h}_L = 961 \frac{0.0299 \text{ W/m}\cdot\text{K}}{0.2 \text{ m}} = 143.6 \text{ W/m}^2 \cdot \text{K}$$

$$q = 143.6 \frac{\text{W}}{\text{m}^2 \cdot \text{K}} (0.1 \text{ m} \times 0.2 \text{ m}) (100 - 50)^\circ \text{C} = 143.6 \text{ W.} \quad <$$

**COMMENTS:** Note that, in calculating  $Re_{L,2}$ , ideal gas behavior has been assumed. It has also been assumed that  $k$ ,  $\mu$  and  $Pr$  are independent of pressure over the range considered.

## PROBLEM 7.18

**KNOWN:** Solar cell material dimensions and properties, solar-to-electrical conversion efficiency dependence on silicon temperature, solar irradiation and location where the irradiation is absorbed, air velocity and temperature.

**FIND:** (a) Electrical power produced and silicon temperature for a  $L = 1$  m long,  $w = 0.1$  m wide solar cell with  $G = 700$   $\text{W/m}^2$  with tripped boundary layer, (b) Same as Part (a) but with  $L = 0.1$  m,  $w = 1$  m, (c) Plot of the electrical power produced and the silicon temperature for air velocities in the range  $0 \leq u_m \leq 10$  m/s for the  $L = 0.1$  m configuration.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Constant properties, (3) One-dimensional heat transfer, (4) Tripped and turbulent boundary layer, (5) Large surroundings, (6) Negligible contact resistances.

**PROPERTIES:** Table A.4, air (assume  $T_f = 308$  K,  $p = 1$  atm):  $k = 0.0269$   $\text{W/m}\cdot\text{K}$ ,  $\nu = 1.669 \times 10^{-5}$   $\text{m}^2/\text{s}$ ,  $\text{Pr} = 0.706$ .

**ANALYSIS:**

(a) We begin by drawing the thermal circuit for the problem, recognizing that there is no heat transfer downward from the thin silicon layer.

Continued...

**PROBLEM 7.18 (Cont.)**

The thermal resistances are

$$R_{t,g} = L_g/k_gA = 3 \times 10^{-3} \text{ m}/(1.4 \text{ W/m} \cdot \text{K} \times 1 \text{ m} \times 0.1 \text{ m}) = 21.43 \times 10^{-3} \text{ K/W}$$

$$R_{t,a} = L_a/k_aA = 0.1 \times 10^{-3} \text{ m}/(145 \text{ W/m} \cdot \text{K} \times 1 \text{ m} \times 0.1 \text{ m}) = 6.897 \times 10^{-6} \text{ K/W}$$

$$h_{\text{rad}} = \varepsilon_g \sigma (T_1 + T_{\text{sur}})(T_1^2 + T_{\text{sur}}^2)$$

$$R_{t,\text{rad}} = \frac{1}{0.9 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times (T_1 + 295 \text{ K}) \times (T_1^2 + (295 \text{ K})^2) \times 1 \text{ m} \times 0.1 \text{ m}} \quad (1)$$

For the tripped boundary layer,

$$\text{Re}_L = \frac{u_m L}{\nu} = \frac{4 \text{ m/s} \times 1 \text{ m}}{1.669 \times 10^{-5} \text{ m}^2/\text{s}} = 239.7 \times 10^3$$

From Equation 7.38

$$\overline{\text{Nu}}_L = 0.037 \text{Re}_L^{4/5} \text{Pr}^{1/3} = 0.037 \times [239.7 \times 10^3]^{0.8} \times 0.706^{1/3} = 662.8$$

$$\bar{h} = \overline{\text{Nu}}_L k/L = 662.8 \times 0.0269 \text{ W/m} \cdot \text{K}/1 \text{ m} = 17.82 \text{ W/m}^2 \cdot \text{K}$$

$$R_{t,\text{conv}} = 1/\bar{h}A = \frac{1}{17.82 \text{ W/m}^2 \cdot \text{K} \times 1 \text{ m} \times 0.1 \text{ m}} = 561.2 \times 10^{-3} \text{ K/W}$$

From the thermal circuit,

$$0.83 \text{ GA} (1 - \eta) = (T_3 - T_1)/(R_{t,g} + R_{t,a}) \quad \text{or} \quad T_3 - T_1 = (R_{t,g} + R_{t,a}) 0.83 \text{ GA} (1 - \eta)$$

$$T_3 - T_1 = (21.43 \times 10^{-3} \text{ K/W} + 6.897 \times 10^{-6} \text{ K/W}) \times 0.83 \times 700 \text{ W/m}^2 \times 1 \text{ m} \times 0.1 \text{ m} \times (1 - \eta)$$

$$T_3 - T_1 = 1.245(1 - \eta) \quad (2)$$

We also note from the thermal circuit,

Continued...

**PROBLEM 7.18 (Cont.)**

$$0.83GA(1 - \eta) + 0.1G = (T_1 - T_{\text{sur}})/R_{t,\text{rad}} + (T_1 - T_{\infty})/R_{t,\text{conv}}$$

Since  $T_{\infty} = T_{\text{sur}}$

$$0.83GA(1 - \eta) + 0.1G = (T_1 - T_{\text{sur}}) \left[ \frac{1}{R_{t,\text{rad}}} + \frac{1}{R_{t,\text{conv}}} \right]$$

$$T_1 - T_{\text{sur}} = \frac{0.83GA(1 - \eta) + 0.1GA}{\left[ \frac{1}{R_{t,\text{rad}}} + \frac{1}{R_{t,\text{conv}}} \right]}$$

$$T_1 - T_{\text{sur}} = \frac{0.83 \times 700 \text{ W/m}^2 \times 1 \text{ m} \times 0.1 \text{ m} \times (1 - \eta) + 0.1 \times 700 \text{ W/m}^2 \times 1 \text{ m} \times 0.1 \text{ m}}{\left[ \frac{1}{R_{t,\text{rad}}} + 1.7819 \text{ W/K} \right]}$$

$$T_1 - T_{\text{sur}} = \frac{58.1 \text{ W} (1 - \eta) + 7 \text{ W}}{\left[ \frac{1}{R_{t,\text{rad}}} + 1.7819 \text{ W/K} \right]} \quad (3)$$

$$\text{where } \eta = 0.28 - 0.001^\circ\text{C}^{-1} \times (T_3 - 273)^\circ\text{C} \quad (4)$$

Equations (1) – (4) may be solved simultaneously to yield

$$\eta = 0.2353, T_3 = T_{\text{si}} = 44.7^\circ\text{C}, T_1 = 43.7^\circ\text{C}, R_{t,\text{rad}} = 1.71 \text{ K/W} \quad <$$

$$\text{The electric power is } P = 0.83GA\eta = 0.83 \times 700 \text{ W/m}^2 \times 1 \text{ m} \times 0.1 \text{ m} \times 0.2353 = 13.67 \text{ W} \quad <$$

(b) For the tripped boundary layer

$$\text{Re}_L = \frac{u_m L}{\nu} = \frac{4/\text{ms} \times 0.1 \text{ m}}{1.669 \times 10^{-5} \text{ m}^2/\text{s}} = 239.7 \times 10^2$$

From Equation 7.38

$$\overline{\text{Nu}}_L = 0.037 \text{Re}^{4/5} \text{Pr}^{1/3} = 0.037 \times \left[ 239.7 \times 10^2 \right]^{0.8} \times 0.706^{1/3} = 105$$

$$\bar{h} = \overline{\text{Nu}}_L k/L = 105 \times 0.0269 \text{ W/m} \cdot \text{K} / 1 \text{ m} = 28.25 \text{ W/m}^2 \cdot \text{K}$$

$$R_{t,\text{conv}} = 1/\bar{h}A = \frac{1}{28.25 \text{ W/m}^2 \cdot \text{K} \times 1 \text{ m} \times 0.1 \text{ m}} = 354.0 \times 10^{-3} \text{ K/W}$$

Proceeding as in Part (a) we find

$$\eta = 0.242, T_3 = T_{\text{si}} = 38.0^\circ\text{C}, T_1 = 37.1^\circ\text{C}, R_{t,\text{rad}} = 1.768 \text{ K/W}, P = 14.06 \text{ W} \quad <$$

(c) Solving Equations 1 through 4 over the velocity range  $0 \leq u_m \leq 10 \text{ m/s}$  yields the following behavior

Continued...

### PROBLEM 7.18 (Cont.)

**COMMENTS:** (1) Changing the orientation of the solar panel to the  $L = 0.1$  m configuration reduces the temperature of the silicon semiconductor significantly. The influence of the orientation on the electric power would be more pronounced for warmer air temperatures. (2) Decreasing the air velocity results in significantly diminished power output. At very low cross flow velocities, natural convection would become significant and would lead to slightly improved power output relative to that predicted here. (3) Film temperatures for Parts (a) and (b) are  $31.9$  °C and  $28.6$  °C, respectively. The assumed value of the film temperature is good.

## PROBLEM 7.19

**KNOWN:** Dimensions of a photovoltaic cell, cooling air velocity and temperature, size of concentrating lens, photovoltaic construction and properties.

**FIND:** (a) The electric power output and silicon temperature of a system consisting of a 400 mm × 400 mm concentrating lens and a 100 mm × 100 mm photovoltaic cell, (b) Variation of the electric power output and silicon temperature for 100 mm ≤  $L_{\text{lens}}$  ≤ 600 mm.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Constant properties, (3) One-dimensional heat transfer, (4) Tripped and turbulent boundary layer, (5) Large surroundings, (6) Negligible contact resistances.

**PROPERTIES:** Given, Glass:  $k_g = 1.4 \text{ W/m}\cdot\text{K}$ ,  $\varepsilon_g = 0.90$ , Adhesive:  $k_a = 145 \text{ W/m}\cdot\text{K}$ , Solder,  $k_s = 50 \text{ W/m}\cdot\text{K}$ , Aluminum nitride:  $k_{an} = 120 \text{ W/m}\cdot\text{K}$ , Table A.4, air (assume  $T_f = 70^\circ\text{C}$ ):  $k = 0.02948 \text{ W/m}\cdot\text{K}$ ,  $\nu = 2.022 \times 10^{-5} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.701$ .

**ANALYSIS:**

(a) We begin by drawing the thermal circuit,

Continued...

**PROBLEM 7.19 (Cont.)**

The thermal resistances are

$$R_{t,g} = L_g / (k_g A) = 3 \times 10^{-3} \text{ m} / (1.4 \text{ W/m} \cdot \text{K} \times 0.1 \text{ m} \times 0.1 \text{ m}) = 0.2143 \text{ K/W}$$

$$R_{t,a} = L_a / (k_a A) = 0.1 \times 10^{-3} \text{ m} / (145 \text{ W/m} \cdot \text{K} \times 0.1 \text{ m} \times 0.1 \text{ m}) = 6.897 \times 10^{-5} \text{ K/W}$$

$$R_{t,s} = L_s / (k_s A) = 0.1 \times 10^{-3} \text{ m} / (50 \text{ W/m} \cdot \text{K} \times 0.1 \text{ m} \times 0.1 \text{ m}) = 200 \times 10^{-6} \text{ K/W}$$

$$R_{t,an} = L_{an} / (k_{an} A) = 2 \times 10^{-3} \text{ m} / (120 \text{ W/m} \cdot \text{K} \times 0.1 \text{ m} \times 0.1 \text{ m}) = 1.67 \times 10^{-3} \text{ K/W}$$

$$h_{\text{rad,tp}} = \epsilon_g \sigma (T_1 + T_{\text{sur}})(T_1^2 + T_{\text{sur}}^2)$$

$$R_{t,\text{rad,tp}} = \frac{1}{0.9 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times (T_1 + 298 \text{ K}) \times (T_1^2 + (298 \text{ K})^2)} \quad (1)$$

$$h_{\text{rad,b}} = \epsilon_b \sigma (T_5 + T_{\text{sur}})(T_5^2 + T_{\text{sur}}^2)$$

$$R_{t,\text{rad,b}} = \frac{1}{0.95 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times (T_5 + 298 \text{ K}) \times (T_5^2 + (298 \text{ K})^2)} \quad (2)$$

For the top and bottom tripped boundary layers,

$$\text{Re}_L = \frac{u_\infty L}{\nu} = \frac{5 \text{ m/s} \times 0.1 \text{ m}}{2.022 \times 10^{-5} \text{ m}^2/\text{s}} = 24.73 \times 10^3$$

From Equation 7.38

Continued...

**PROBLEM 7.19 (Cont.)**

$$\overline{Nu}_L = 0.037Re_L^{4/5}Pr^{1/3} = 0.037 \times [24.73 \times 10^3]^{0.8} \times 0.701^{1/3} = 107.5$$

$$\bar{h} = \overline{Nu}_L k/L = \frac{107.5 \times 0.02948 \text{ W/m} \cdot \text{K}}{0.1 \text{ m}} = 31.69 \text{ W/m}^2 \cdot \text{K}$$

$$R_{t,conv} = 1/\bar{h}A = \frac{1}{(31.69 \text{ W/m}^2 \cdot \text{K} \times 0.1 \text{ m} \times 0.1 \text{ m})} = 3.155 \text{ K/W}$$

From the thermal circuit,

$$\begin{aligned} 0.83G_c A (1 - \eta) &= 0.83G (L_{\text{lens}}/L)^2 A (1 - \eta) = q_t + q_b \\ 0.83 \times 700 \text{ W/m}^2 \times 4^2 \times 0.1 \text{ m} \times 0.1 \text{ m} \times (1 - \eta) &= q_t + q_b \\ 9296 \text{ W} &= (q_t + q_b)/(1 - \eta) \end{aligned} \quad (3)$$

where

$$q_t = (T_3 - T_1)/(R_{t,a} + R_{t,g}) = (T_3 - T_1)/0.2144 \text{ K/W} \quad (4)$$

and

$$\begin{aligned} q_b &= (T_1 - T_{\text{sur}})/R_{t,rad,tp} + (T_1 - T_{\infty})/R_{t,conv} \\ &= (T_1 - 298 \text{ K})/R_{t,rad,tp} + (T_1 - 298 \text{ K})/3.155 \text{ K/W} \end{aligned} \quad (5)$$

Likewise

$$q_b = (T_3 - T_5)/(R_{t,s} + R_{t,an}) = (T_3 - T_5)/1.87 \times 10^{-3} \text{ K/W} \quad (6)$$

and

$$\begin{aligned} q_b &= (T_5 - T_{\text{sur}})/R_{t,rad,b} + (T_5 - T_{\infty})/R_{t,conv} \\ &= (T_5 - 298 \text{ K})/R_{t,rad,b} + (T_5 - 298 \text{ K})/3.155 \text{ K/W} \end{aligned} \quad (7)$$

The solar-to-electrical conversion efficiency is

$$\eta = 0.28 - 0.001^\circ\text{C}^{-1} \times (T_3 - 273)^\circ\text{C} \quad (8)$$

Equations (1) through (8) may be solved simultaneously to yield

$$\begin{aligned} T_{si} = T_3 - 273 &= 125.9^\circ\text{C}, \eta = 0.1541, T_1 = 390.9 \text{ K}, T_5 = 398.8 \text{ K}, \\ R_{t,rad,tp} &= 11.78 \text{ K/W}, R_{t,rad,b} = 10.75 \text{ K/W}, q_t = 37.32 \text{ W}, q_b = 41.32 \text{ W}. \end{aligned}$$

The electric power produced is

$$\begin{aligned} P &= 0.83G (L_{\text{lens}}/L)^2 A \eta \\ &= 0.83 \times 700 \text{ W/m}^2 \times 4^2 \times 0.1 \text{ m} \times 0.1 \text{ m} \times 0.1541 = 14.33 \text{ W} \end{aligned}$$

<  
Continued...

### PROBLEM 7.19 (Cont.)

(b) The *IHT* Software may be used to investigate the sensitivity of the silicon temperature and the electric power produced in response to the concentrating lense size. Results are shown below. <

**COMMENTS:** (1) The electric power output is highly sensitive to the size of the concentrating lens. The concentrated irradiation continually increases as the concentrator is made larger until, eventually, the silicon temperature becomes very high and the solar-to-electrical conversion efficiency becomes small. (2) The electric power could be increased if heat sinks and/or liquid cooling could be applied to the solar cell, keeping the silicon temperature low and the conversion efficiency relatively high. (3) The assumed film temperature is a good estimate since  $T_{f,fp} = 71.4$  °C and  $T_{f,bot} = 75.4$  °C.

## PROBLEM 7.20

**KNOWN:** Material properties, inner surface temperature and dimensions of roof of refrigerated truck compartment. Truck speed and ambient temperature. Solar irradiation.

**FIND:** (a) Outer surface temperature of roof and rate of heat transfer to compartment, (b) Effect of changing radiative properties of outer surface, (c) Effect of eliminating insulation.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible irradiation from the sky, (2) Turbulent flow over entire outer surface, (3) Average convection coefficient may be used to estimate average surface temperature, (4) Constant properties.

**PROPERTIES:** Table A-4, air ( $p = 1 \text{ atm}$ ,  $T_f \approx 300\text{K}$ ):  $\nu = 15.89 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0263 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.707$ .

**ANALYSIS:** (a) From an energy balance for the outer surface,

$$\alpha_S G_S + q_{\text{conv}}'' - E = q_{\text{cond}}'' = \frac{T_{s,o} - T_{s,i}}{R_{\text{tot}}''}$$

$$\alpha_S G_S + \bar{h}(T_{\infty} - T_{s,o}) - \varepsilon \sigma T_{s,o}^4 = \frac{T_{s,o} - T_{s,i}}{2R_p'' + R_i''}$$

where  $R_p'' = (t_1/k_p) = 2.78 \times 10^{-5} \text{ m}^2 \cdot \text{K}/\text{W}$ ,  $R_i'' = (t_2/k_i) = 1.923 \text{ m}^2 \cdot \text{K}/\text{W}$ , and with  $\text{Re}_L = u_{\infty} L / \nu = 29.2 \text{ m/s} \times 10 \text{ m} / 15.89 \times 10^{-6} \text{ m}^2/\text{s} = 1.84 \times 10^7$ ,

$$\bar{h} = \frac{k}{L} 0.037 \text{Re}_L^{4/5} \text{Pr}^{1/3} = \frac{0.0263 \text{ W/m}\cdot\text{K}}{10 \text{ m}} 0.037 (1.84 \times 10^7)^{4/5} (0.707)^{1/3} = 56.2 \text{ W/m}^2 \cdot \text{K}$$

Hence,

$$0.5 \left( 750 \text{ W/m}^2 \cdot \text{K} \right) + 56.2 \text{ W/m}^2 \cdot \text{K} (305 - T_{s,o}) - 0.5 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 T_{s,o}^4 = \frac{T_{s,o} - 263\text{K}}{\left( 5.56 \times 10^{-5} + 1.923 \right) \text{ m}^2 \cdot \text{K}/\text{W}}$$

Solving, we obtain

$$T_{s,o} = 306.8\text{K} = 33.8^\circ\text{C} \quad <$$

Hence, the heat load is

$$q = (W \cdot L) q_{\text{cond}}'' = (3.5 \text{ m} \times 10 \text{ m}) \frac{(33.8 + 10)^\circ\text{C}}{1.923 \text{ m}^2 \cdot \text{K}/\text{W}} = 797 \text{ W} \quad <$$

(b) With the special surface finish ( $\alpha_S = 0.15$ ,  $\varepsilon = 0.8$ ),

Continued ...

**PROBLEM 7.20 (Cont.)**

$$T_{s,o} = 300.1\text{K} = 27.1^\circ\text{C} \quad <$$

$$q = 675.3\text{W} \quad <$$

(c) Without the insulation ( $t_2 = 0$ ) and with  $\alpha_s = \varepsilon = 0.5$ ,

$$T_{s,o} = 263.1\text{K} = -9.9^\circ\text{C} \quad <$$

$$q = 90,630\text{W} \quad <$$

**COMMENTS:** (1) Use of the special surface finish reduces the solar input, while increasing radiation emission from the surface. The cumulative effect is to reduce the heat load by 15%. (2) The thermal resistance of the aluminum panels is negligible, and without the insulation, the heat load is *enormous*.

### PROBLEM 7.21

**KNOWN:** Surface characteristics of a flat plate in an air stream.

**FIND:** Orientation which minimizes convection heat transfer.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Surface B is sufficiently rough to trip the boundary layer when in the upstream position (Configuration 2).

**PROPERTIES:** Table A-4, Air ( $T_f = 333\text{ K}$ , 1 atm):  $\nu = 19.2 \times 10^{-6}\text{ m}^2/\text{s}$ ,  $k = 28.7 \times 10^{-3}\text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.7$ .

**ANALYSIS:** Since Configuration (2) results in a turbulent boundary layer over the entire surface, the lowest heat transfer is associated with Configuration (1). Find

$$\text{Re}_L = \frac{u_\infty L}{\nu} = \frac{20\text{ m/s} \times 1\text{ m}}{19.2 \times 10^{-6}\text{ m}^2/\text{s}} = 1.04 \times 10^6.$$

Hence in Configuration (1), transition will occur just before the rough surface ( $x_c = 0.48\text{ m}$ ). Note that

$$\begin{aligned} \overline{\text{Nu}}_{L,1} &= \left[ 0.037 \left( 1.04 \times 10^6 \right)^{4/5} - 871 \right] 0.7^{1/3} = 1366 \\ \overline{\text{Nu}}_{L,2} &= 0.037 \left( 1.04 \times 10^6 \right)^{4/5} (0.7)^{1/3} = 2139 > \overline{\text{Nu}}_{L,1}. \end{aligned}$$

For Configuration (1):

$$\frac{\overline{h}_{L,1} L}{k} = \overline{\text{Nu}}_{L,1} = 1366.$$

Hence

$$\overline{h}_{L,1} = 1366 \left( 28.7 \times 10^{-3}\text{ W/m}\cdot\text{K} \right) / 1\text{ m} = 39.2\text{ W/m}^2 \cdot \text{K}$$

and

$$q_1 = \overline{h}_{L,1} A (T_s - T_\infty) = 39.2\text{ W/m}^2 \cdot \text{K} (0.5\text{ m} \times 1\text{ m}) (100 - 20)\text{ K}$$

$$q_1 = 1568\text{ W}.$$

<

## PROBLEM 7.22

**KNOWN:** Dimensions and orientation of a flat plate placed in atmospheric airstream, airstream velocity and temperature, plate temperature.

**FIND:** The average convection coefficient for the entire surface.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Constant properties, (3) Boundary layer on rough plate is tripped at leading edge, (4) Transition occurs at  $Re_{x,c} = 500,000$ .

**PROPERTIES:** Table A.4, air ( $T_f = 60^\circ\text{C} = 333\text{K}$ ,  $p = 1\text{ atm}$ ):  $\nu = 19.24 \times 10^{-6}\text{ m}^2/\text{s}$ ,  $Pr = 0.702$ ,  $k = 0.0288\text{ W/m}\cdot\text{K}$ .

**ANALYSIS:** For both the smooth and rough sections of the plate,

$$Re_L = \frac{u_\infty L}{\nu} = \frac{20\text{ m/s} \times 0.5\text{ m}}{19.24 \times 10^{-6}\text{ m}^2/\text{s}} = 520,000$$

Therefore, flow over portion A of the plate is nearly all laminar except near the trailing edge.

For portion A, Eq. 7.38 yields

$$\bar{h}_A = \frac{k}{L} \left[ 0.037 Re_L^{4/5} - 871 \right] Pr^{1/3} = \frac{0.0288\text{ W/m}\cdot\text{K}}{0.5\text{ m}} \left[ 0.037 \times 520,000^{4/5} - 871 \right] 0.702^{1/3} = 26.2\text{ W/m}^2 \cdot \text{K}$$

For portion B, Eq. 7.38 yields

$$\bar{h}_B = \frac{k}{L} \left[ 0.037 Re_L^{4/5} \right] Pr^{1/3} = \frac{0.0288\text{ W/m}\cdot\text{K}}{0.5\text{ m}} \left[ 0.037 \times 520,000^{4/5} \right] 0.702^{1/3} = 70.8\text{ W/m}^2 \cdot \text{K}$$

Therefore, for the entire plate consisting of half portion A and half portion B,

$$\bar{h} = \frac{\bar{h}_A + \bar{h}_B}{2} = 48.5\text{ W/m}^2 \cdot \text{K} \quad <$$

**COMMENTS:** (1) The value of the average coefficient for orientations 1 and 2 of Problem 7.21 are  $\bar{h}_1 = 39.2\text{ W/m}^2 \cdot \text{K}$  and  $\bar{h}_2 = 61.4\text{ W/m}^2 \cdot \text{K}$ , respectively. The average heat transfer coefficient found here is approximately midway between the values associated with the other two orientations. This is coincidental, since the nature of the flow is very different for the three different orientations. (2) In reality, boundary layer development *cannot* proceed on the smooth and rough parts of the plate independent of the other part of the plate, as implied in the solution above. Rather, there will be an intermediate region that will be characterized by complex flow and heat transfer phenomena. The solution should be viewed as a first approximation of actual heat transfer conditions.

### PROBLEM 7.23

**KNOWN:** Design of an anemometer comprised of a thin metallic strip supported by stiff rods serving as electrodes for passage of heating current. Fine-wire thermocouple on trailing edge of strip.

**FIND:** (a) Relationship between electrical power dissipation per unit width of the strip in the transverse direction,  $P'$  (mW/mm), and airstream velocity  $u_\infty$  when maintained at constant strip temperature,  $T_s$ ; show the relationship graphically; (b) The uncertainty in the airstream velocity if the accuracy with which the strip temperature can be measured and maintained constant is  $\pm 0.2^\circ\text{C}$ ; (c) Relationship between strip temperature and airstream velocity  $u_\infty$  when the strip is provided with a constant power,  $P' = 30$  mW/mm; show the relationship graphically. Also, find the uncertainty in the airstream velocity if the accuracy with which the strip temperature can be measured is  $\pm 0.2^\circ\text{C}$ ; (d) Compare features associated with each of the operating modes.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Constant properties, (3) Strip has uniform temperature in the midspan region of the strip, (4) Negligible conduction in the transverse direction in the midspan region, and (5) Airstream over strip approximates parallel flow over two sides of a smooth flat plate.

**ANALYSIS:** (a) In the midspan region of uniform temperature  $T_s$  with no conduction in the transverse direction, all the dissipated electrical power is transferred by convection to the airstream,

$$P' = 2\bar{h}_L L (T_s - T_\infty) \quad (1)$$

where  $P'$  is the power per unit width (transverse direction). Using the *IHT Correlation Tool for External Flow-Flat Plate* the power as a function of airstream velocity was determined and is plotted below. The IHT tool uses the flat plate correlation, Eq. 7.30 since the flow is laminar over this velocity range.

Continued...

### PROBLEM 7.23 (Cont.)

(b) By differentiation of Eq. (1), the relative uncertainties of the convection coefficient and strip temperature are, assuming the power remains constant,

$$\frac{\Delta \bar{h}_L}{\bar{h}} = - \frac{\Delta T_s}{T_s - T_\infty} \quad (2)$$

Since the flow was laminar for the range of airstream velocities, Eq. 7.30,

$$\bar{h}_L \sim u_\infty^{1/2} \quad \text{or} \quad \frac{\Delta \bar{h}_L}{\bar{h}_L} = 0.5 \frac{\Delta u_\infty}{u_\infty} \quad (3)$$

Hence, the relative uncertainty in the air velocity due to uncertainty in  $T_s$ ,  $\Delta T_s = \pm 0.2^\circ \text{C}$

$$\frac{\Delta u_\infty}{u_\infty} = 2 \frac{\Delta T_s}{T_s - T_\infty} = 2 \frac{\pm 0.2^\circ \text{C}}{(35 - 25)^\circ \text{C}} = \pm 4\% \quad (4) \leftarrow$$

(c) Using the IHT workspace setting  $P' = 30 \text{ mW/mm}$ , the strip temperature  $T_s$  as a function of the airstream velocity was determined and plotted. Note that the slope of the  $T_s$  vs.  $u_\infty$  curve is steep for low velocities and relatively flat for high velocities. That is, the technique is more sensitive at lower velocities. Using Eq. (4), but with  $T_s$  dependent upon  $u_\infty$ , the relative uncertainty in  $u_\infty$  can be determined.

(d) For the constant power mode of operation, part (a), the uncertainty in  $u_\infty$  due to uncertainty in temperature measurement was found as 4%, independent of the magnitude  $u_\infty$ . For the constant-temperature mode of operation, the uncertainty in  $u_\infty$  is less than 4% for velocities less than 30 m/s, with a value of 1% around 2 m/s. However, in the upper velocity range, the error increases to 5%.

## PROBLEM 7.24

**KNOWN:** Plate dimensions and initial temperature. Velocity and temperature of air in parallel flow over plates.

**FIND:** Initial rate of heat transfer from plate. Rate of change of plate temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible radiation, (2) Negligible effect of conveyor velocity on boundary layer development, (3) Plates are isothermal, (4) Negligible heat transfer from sides of plate, (5)

$Re_{x,c} = 5 \times 10^5$ , (6) Constant properties.

**PROPERTIES:** Table A-1, AISI 1010 steel (573K):  $k_p = 49.2 \text{ W/m}\cdot\text{K}$ ,  $c = 549 \text{ J/kg}\cdot\text{K}$ ,  $\rho = 7832 \text{ kg/m}^3$ . Table A-4, Air ( $p = 1 \text{ atm}$ ,  $T_f = 433\text{K}$ ):  $\nu = 30.4 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0361 \text{ W/m}\cdot\text{K}$ ,  $Pr = 0.688$ .

**ANALYSIS:** The initial rate of heat transfer from a plate is

$$q = 2 \bar{h} A_s (T_i - T_\infty) = 2 \bar{h} L^2 (T_i - T_\infty)$$

With  $Re_L = u_\infty L / \nu = 10 \text{ m/s} \times 1 \text{ m} / 30.4 \times 10^{-6} \text{ m}^2/\text{s} = 3.29 \times 10^5$ , flow is laminar over the entire surface and

$$\overline{Nu}_L = 0.664 Re_L^{1/2} Pr^{1/3} = 0.664 (3.29 \times 10^5)^{1/2} (0.688)^{1/3} = 336$$

$$\bar{h} = (k/L) \overline{Nu}_L = (0.0361 \text{ W/m}\cdot\text{K} / 1 \text{ m}) 336 = 12.1 \text{ W/m}^2 \cdot \text{K}$$

Hence,

$$q = 2 \times 12.1 \text{ W/m}^2 \cdot \text{K} (1 \text{ m})^2 (300 - 20)^\circ\text{C} = 6780 \text{ W} \quad <$$

Performing an energy balance at an instant of time for a control surface about the plate,  $-\dot{E}_{\text{out}} = \dot{E}_{\text{st}}$ , we obtain,

$$\rho \delta L^2 c \left. \frac{dT}{dt} \right|_i = -\bar{h} 2L^2 (T_i - T_\infty)$$

$$\left. \frac{dT}{dt} \right|_i = -\frac{2(12.1 \text{ W/m}^2 \cdot \text{K})(300 - 20)^\circ\text{C}}{7832 \text{ kg/m}^3 \times 0.006 \text{ m} \times 549 \text{ J/kg}\cdot\text{K}} = -0.26^\circ\text{C/s} \quad <$$

**COMMENTS:** (1) With  $Bi = \bar{h}(\delta/2)/k_p = 7.4 \times 10^{-4}$ , use of the lumped capacitance method is appropriate. (2) Despite the large plate temperature and the small convection coefficient, if adjoining plates are in close proximity, radiation exchange with the surroundings will be small and the assumption of negligible radiation is justifiable.

## PROBLEM 7.25

**KNOWN:** Prevailing wind with prescribed speed blows past ten window panels, each of 1-m length, on a penthouse tower.

**FIND:** (a) Average convection coefficient for the first, third and tenth window panels when the wind speed is 5 m/s; evaluate thermophysical properties at 300 K, but determine suitability when ambient air temperature is in the range  $-15 \leq T_\infty \leq 38^\circ\text{C}$ ; (b) Compute and plot the average coefficients for the same panels with wind speeds for the range  $5 \leq u_\infty \leq 100$  km/h; explain features and relative magnitudes.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Constant properties, (3) Wind over panels approximates parallel flow over a smooth flat plate, and (4) Transition Reynolds number is  $Re_{x,c} = 5 \times 10^5$ .

**PROPERTIES:** Table A.4, Air ( $T_f = 300$  K, 1 atm):  $\nu = 15.89 \times 10^{-6}$  m<sup>2</sup>/s,  $k = 26.3 \times 10^{-3}$  W/m·K,  $Pr = 0.707$ .

**ANALYSIS:** (a) The average convection coefficients for the first, third and tenth panels are

$$\bar{h}_1 \quad \bar{h}_{2-3} = \frac{\bar{h}_3 x_3 - \bar{h}_2 x_2}{x_3 - x_2} \quad \bar{h}_{9-10} = \frac{\bar{h}_{10} x_{10} - \bar{h}_9 x_9}{x_{10} - x_9} \quad (1,2,3)$$

where  $\bar{h}_2 = \bar{h}_2(x_2)$ , etc. If  $Re_{x,c} = 5 \times 10^5$ , with properties evaluated at  $T_f = 300$  K, transition occurs at

$$x_c = \frac{\nu}{u_\infty} Re_{x,c} = \frac{15.89 \times 10^{-6} \text{ m}^2/\text{s}}{5 \text{ m/s}} \times 5 \times 10^5 = 1.59 \text{ m}$$

The flow over the first panel is laminar, and  $\bar{h}_1$  can be estimated using Eq. (7.30).

$$\overline{Nu}_{x1} = \frac{\bar{h}_1 x_1}{k} = 0.664 Re_x^{1/2} Pr^{1/3}$$

$$\bar{h}_1 = (0.0263 \text{ W/m} \cdot \text{K} \times 0.664/\text{lm}) \left( 5 \text{ m/s} \times 1\text{m} / 15.89 \times 10^{-6} \text{ m}^2/\text{s} \right)^{1/2} (0.707)^{1/3} = 8.73 \text{ W/m}^2 \cdot \text{K} <$$

The flow over the third and tenth panels is mixed, and  $\bar{h}_2$ ,  $\bar{h}_3$ ,  $\bar{h}_9$  and  $\bar{h}_{10}$  can be estimated using Eq. (7.41). For the third panel with  $x_3 = 3$  m and  $x_2 = 2$  m,

$$\overline{Nu}_{x3} = \frac{\bar{h}_3 x_3}{k} = \left( 0.037 Re_x^{4/5} - 871 \right) Pr^{1/3}$$

$$\bar{h}_3 = (0.0263 \text{ W/m} \cdot \text{K}/3\text{m}) \times \left[ 0.037 \left( 5 \text{ m/s} \times 3\text{m} / 15.89 \times 10^{-6} \text{ m}^2/\text{s} \right)^{4/5} - 871 \right] (0.707)^{1/3} = 10.6 \text{ W/m}^2 \cdot \text{K}$$

Continued...

**PROBLEM 7.25 (Cont.)**

$$\bar{h}_2 = (0.0263 \text{ W/m} \cdot \text{K}/2\text{m}) \times \left[ 0.037 \left( 5 \text{ m/s} \times 2\text{m} / 15.89 \times 10^{-6} \text{ m}^2/\text{s} \right)^{4/5} - 871 \right] (0.707)^{1/3} = 8.68 \text{ W/m}^2 \cdot \text{K}$$

From Eq. (2),

$$\bar{h}_{2-3} = \frac{10.61 \text{ W/m}^2 \cdot \text{K} \times 3\text{m} - 8.68 \text{ W/m}^2 \cdot \text{K} \times 2\text{m}}{(3-2)\text{m}} = 14.5 \text{ W/m}^2 \cdot \text{K} \quad <$$

Following the same procedure for the tenth panel, find  $\bar{h}_{10} = 11.64 \text{ W/m}^2 \cdot \text{K}$  and  $\bar{h}_9 = 11.71 \text{ W/m}^2 \cdot \text{K}$ , and

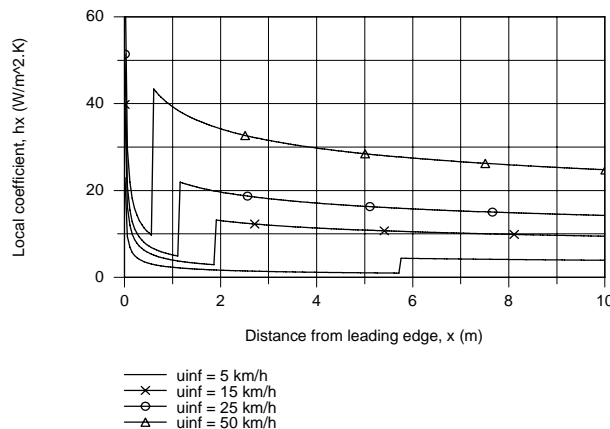

$$\bar{h}_{9-10} = 11.1 \text{ W/m}^2 \cdot \text{K} \quad <$$

Assuming that the window panel temperature will always be close to room temperature,  $T_s = 23^\circ\text{C} = 296 \text{ K}$ . If  $T_\infty$  ranges from  $-15$  to  $38^\circ\text{C}$ , the film temperature,  $T_f = (T_s + T_\infty)/2$ , will vary from  $275$  to  $310 \text{ K}$ . We'll explore the effect of  $T_f$  subsequently.

(b) Using the *IHT Tool, Correlations, External Flow, Flat Plate*, results were obtained for the average coefficients  $\bar{h}$ . Using Eqs. (2) and (3), average coefficients for the panels as a function of wind speed were computed and plotted.

**COMMENTS:** (1) The behavior of the panel average coefficients as a function of wind speed can be explained from the behavior of the local coefficient as a function of distance for difference velocities as plotted below.

Continued...

### PROBLEM 7.25 (Cont.)

For low wind speeds, transition occurs near the mid-panel, making  $\bar{h}_1$  and  $\bar{h}_{9-10}$  nearly equal and very high because of leading-edge and turbulence effects, respectively. As the wind speed increases, transition occurs closer to the leading edge. Notice how  $\bar{h}_{2-3}$  increases rather abruptly, subsequently becoming greater than  $\bar{h}_{9-10}$ . The abrupt increase in  $\bar{h}_1$  around 30 km/h is a consequence of transition occurring with  $x < 1$  m.

(2) Using the IHT code developed for the foregoing analysis with  $u_\infty = 5$  m/s, the effect of  $T_f$  is tabulated below

$T_f$ (K)	275	300	310
$\bar{h}_1$ (W/m <sup>2</sup> ·K)	8.72	8.73	8.70
$\bar{h}_{2-3}$ (W/m <sup>2</sup> ·K)	15.1	14.5	14.2
$\bar{h}_{9-10}$ (W/m <sup>2</sup> ·K)	11.6	11.1	10.8

The overall effect of  $T_f$  on estimates for the average panel coefficient is slight, less than 5%.

## PROBLEM 7.26

**KNOWN:** Length and surface temperature of a rectangular fin.

**FIND:** (a) Heat removal per unit width,  $q'$ , when air at a prescribed temperature and velocity is in parallel, turbulent flow over the fin, and (b) Calculate and plot  $q'$  for motorcycle speeds ranging from 10 to 100 km/h.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Negligible radiation, (3) Turbulent flow over entire surface.

**PROPERTIES:** Table A.4, Air (412 K, 1 atm):  $\nu = 27.85 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0346 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.69$ .

**ANALYSIS:** (a) The heat loss per unit width is

$$q' = 2 \times [\bar{h}_L L (T_s - T_\infty)]$$

where  $\bar{h}$  is obtained from the correlation, Eq. 7.38 but with turbulent flow over the entire surface,

$$\overline{\text{Nu}}_L = 0.037 \text{Re}_L^{4/5} \text{Pr}^{1/3} = 0.037 \left[ \frac{80 \text{ km/h} \times 1000 \text{ m/km} \times 1/3600 \text{ h/s} \times 0.15 \text{ m}}{27.85 \times 10^{-6} \text{ m}^2/\text{s}} \right]^{4/5} (0.69)^{1/3} = 378$$

Hence,

$$\bar{h}_L = \frac{k}{L} \overline{\text{Nu}}_L = \frac{0.0346 \text{ W/m}\cdot\text{K}}{0.15 \text{ m}} 378 = 87 \text{ W/m}^2 \cdot \text{K}$$

$$q' = 2 \times [87 \text{ W/m}^2 \cdot \text{K} \times 0.15 \text{ m} (523 - 300) \text{ K}] = 5826 \text{ W/m}.$$

<

(b) Using the foregoing equations in the IHT Workspace,  $q'$  as a function of speed was calculated and is plotted as shown.

**COMMENTS:** (1) Radiation emission from the fin is not negligible. With an assumed emissivity of  $\varepsilon = 1$ , the rate of emission per unit width at 80 km/h would be  $q' = (\sigma T_s^4) 2L = 1273 \text{ W/m}$ . If the fin received negligible radiation from its surroundings, its loss by radiation would then be approximately 20% of that by convection.

(2) From the correlation and heat rate expression, it follows that  $q' \sim u_\infty^{4/5}$ . That is,  $q'$  vs.  $u_\infty$  is nearly linear as evident from the above plot.

## PROBLEM 7.27

**KNOWN:** Wall of a metal building experiences a 10 mph (4.47 m/s) breeze with air temperature of 90°F (32.2°C) and solar insolation of 400 W/m<sup>2</sup>. The length of the wall in the wind direction is 10 m and the emissivity is 0.93.

**FIND:** Estimate the average wall temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) The solar absorptivity of the wall is unity, (3) Sky irradiation is negligible, (4) Wall is isothermal at the average temperature  $T_s$ , (5) Flow is fully turbulent over the wall, and (6) Negligible heat transfer into the building.

**PROPERTIES:** Table A-4, Air (assume  $T_f = 305$  K, 1 atm):  $\nu = 16.27 \times 10^{-6}$  m<sup>2</sup>/s,  $k = 0.02658$  W/m·K,  $Pr = 0.707$ .

**ANALYSIS:** Perform an energy balance on the wall surface considering convection, absorbed irradiation and emission. On a per unit width basis,

$$\begin{aligned} \dot{E}'_{in} - \dot{E}'_{out} &= 0 \\ -q'_{cv} + (\alpha_S G_S - E_s)L &= 0 \\ -\bar{h}_L L (T_s - T_\infty) + (\alpha_S G_S - \epsilon \sigma T_s^4)L &= 0 \end{aligned} \quad (1)$$

The average convection coefficient is estimated using Eq. 7.41 assuming fully turbulent flow over the length of the wall in the direction of the breeze.

$$\overline{Nu}_L = \frac{\bar{h}_L L}{k} = 0.037 Re_L^{4/5} Pr^{1/3} \quad (2)$$

$$Re_L = u_\infty L / \nu = 4.47 \text{ m/s} \times 10 \text{ m} / 16.27 \times 10^{-6} \text{ m}^2/\text{s} = 2.748 \times 10^6$$

$$\bar{h}_L = (0.02658 \text{ W/m} \cdot \text{K} / 10 \text{ m}) \times 0.037 \left( 2.748 \times 10^6 \right)^{4/5} (0.707)^{1/3} = 12.4 \text{ W/m}^2 \cdot \text{K}$$

Substituting numerical values into Eq. (1), find  $T_s$ .

$$\begin{aligned} -12.4 \text{ W/m}^2 \times 10 \text{ m} [T_s - (32.2 + 273)] \text{ K} \\ + \left[ 1.0 \times 400 \text{ W/m}^2 - 0.93 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 T_s^4 \right] \times 10 \text{ m} = 0 \end{aligned}$$

$$T_s = 302.2 \text{ K} = 29^\circ\text{C} \quad <$$

**COMMENTS:** (1) The properties for the correlation should be evaluated at  $T_f = (T_s + T_\infty)/2 = 304$  K. The assumption of 305 K was reasonable.

(2) Is the heat transfer by the emission process significant? Would application of a low emissive coating be effective in reducing the wall temperature, assuming  $\alpha_S$  remained unchanged? Or, should a low solar absorbing coating be considered?

## PROBLEM 7.28

**KNOWN:** Velocity, initial temperature, and dimensions of aluminum strip on a production line. Velocity and temperature of air in counter flow over top surface of strip.

**FIND:** (a) Differential equation governing temperature distribution along the strip and expression for outlet temperature, (b) Value of outlet temperature for prescribed conditions.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible variation of sheet temperature across its thickness, (2) Negligible effect of conduction along length ( $x$ ) of sheet, (3) Negligible radiation, (4) Turbulent flow over entire top surface, (5) Negligible effect of sheet velocity on boundary layer development, (6) Negligible heat transfer from bottom surface and sides, (7) Constant properties.

**PROPERTIES:** Table A-1, Aluminum, 2024-T6 ( $\bar{T}_{AL} \approx 500\text{K}$ ):  $\rho = 2770\text{ kg/m}^3$ ,  $c_p = 983\text{ J/kg}\cdot\text{K}$ ,  $k = 186\text{ W/m}\cdot\text{K}$ . Table A-4, Air ( $p = 1\text{ atm}$ ,  $T_f \approx 400\text{K}$ ):  $\nu = 26.4 \times 10^{-6}\text{ m}^2/\text{s}$ ,  $k = 0.0338\text{ W/m}\cdot\text{K}$ ,  $Pr = 0.69$

**ANALYSIS:** (a) Applying conservation of energy to a stationary control surface, through which the sheet moves, steady-state conditions exist and  $\dot{E}_{in} - \dot{E}_{out} = 0$ . Hence, with *inflow* due to *advection* and *outflow* due to *advection* and *convection*,

$$\begin{aligned} \rho V A_c c_p (T + dT) - \rho V A_c c_p T - dq &= 0 \\ + \rho V \delta W c_p dT - h_x (dx \cdot W) (T - T_\infty) &= 0 \\ \frac{dT}{dx} &= + \frac{h_x}{\rho V \delta c_p} (T - T_\infty) \end{aligned} \quad (1) <$$

Alternatively, if the control surface is fixed to the sheet, conditions are transient and the energy balance is of the form,  $-\dot{E}_{out} = \dot{E}_{st}$ , or

$$\begin{aligned} -h_x (dx \cdot W) (T - T_\infty) &= \rho (dx \cdot W \cdot \delta) c_p \frac{dT}{dt} \\ \frac{dT}{dt} &= - \frac{h_x}{\rho \delta c_p} (T - T_\infty) \end{aligned}$$

Dividing the left- and right-hand sides of the equation by  $dx/dt$  and  $dx/dt = -V$ , respectively, equation (1) is obtained. The equation may be integrated from  $x = 0$  to  $x = L$  to obtain

$$\int_{T_o}^{T_i} \frac{dT}{T - T_\infty} = \frac{L}{\rho V \delta c_p} \left[ \frac{1}{L} \int_0^L h_x dx \right]$$

Continued ...

**PROBLEM 7.28 (Cont.)**

where  $h_x = (k/x)0.0296 \text{Re}_x^{4/5} \text{Pr}^{1/3}$  and the bracketed term on the right-hand side of the equation reduces to  $\bar{h}_L = (k/L)0.037 \text{Re}_L^{4/5} \text{Pr}^{1/3}$ .

Hence,

$$\ln\left(\frac{T_i - T_\infty}{T_o - T_\infty}\right) = \frac{L \bar{h}_L}{\rho V \delta c_p}$$

$$\frac{T_o - T_\infty}{T_i - T_\infty} = \exp\left(-\frac{L \bar{h}_L}{\rho V \delta c_p}\right) \quad <$$

(b) For the prescribed conditions,  $\text{Re}_L \approx u_\infty L / \nu = 20 \text{ m/s} \times 5 \text{ m} / 26.4 \times 10^{-6} \text{ m}^2/\text{s} = 3.79 \times 10^6$  and

$$\bar{h}_L = \left(\frac{0.0338 \text{ W/m}\cdot\text{K}}{5 \text{ m}}\right) 0.037 \left(3.79 \times 10^6\right)^{4/5} (0.69)^{1/3} = 40.5 \text{ W/m}^2 \cdot \text{K}$$

$$T_o = 20^\circ\text{C} + (280^\circ\text{C}) \exp\left(-\frac{5 \text{ m} \times 40.5 \text{ W/m}^2 \cdot \text{K}}{2770 \text{ kg/m}^3 \times 0.1 \text{ m/s} \times 0.002 \text{ m} \times 983 \text{ J/kg}\cdot\text{K}}\right) = 213^\circ\text{C} \quad <$$

**COMMENTS:** (1) With  $T_o = 213^\circ\text{C}$ ,  $\bar{T}_{\text{Al}} = 530\text{K}$  and  $T_f = 411\text{K}$  are close to values used to determine the material properties, and iteration is not needed. (2) For a representative emissivity of  $\varepsilon = 0.2$  and  $T_{\text{sur}} = T_\infty$ , the maximum value of the radiation coefficient is

$h_r = \varepsilon \sigma (T_i + T_{\text{sur}})(T_i^2 + T_{\text{sur}}^2) = 4.1 \text{ W/m}^2 \cdot \text{K} \ll \bar{h}_L$ . Hence, the assumption of negligible radiation is appropriate.

## PROBLEM 7.29

**KNOWN:** Dimensions of aluminum heat sink. Temperature and velocity of coolant (water) flow through the heat sink. Power dissipation of electronic package attached to the heat sink.

**FIND:** Base temperature of heat sink.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Average convection coefficient associated with flow over fin surfaces may be approximated as that for a flat plate in parallel flow, (2) All of the electric power is dissipated by the heat sink, (3) Transition Reynolds number of  $Re_{x,c} = 5 \times 10^5$ , (4) Constant properties. (5) Water temperature is nearly constant as it flows through the array.

**PROPERTIES:** Given. Aluminum:  $k_{hs} = 180 \text{ W/m}\cdot\text{K}$ . Water:  $k_w = 0.62 \text{ W/m}\cdot\text{K}$ ,  $\nu = 7.73 \times 10^{-7} \text{ m}^2/\text{s}$ ,  $Pr = 5.2$ .

**ANALYSIS:** From the thermal circuit,

$$q = P_{elec} = \frac{T_b - T_{\infty}}{R_b + R_{t,o}}$$

where  $R_b = L_b / k_{hs} (w_1 \times w_2) = 0.01 \text{ m} / 180 \text{ W/m}\cdot\text{K} (0.10 \text{ m})^2 = 5.56 \times 10^{-3} \text{ K/W}$  and, from Eqs. 3.107 and 3.108,

$$R_{t,o} = \left\{ \bar{h} A_t \left[ 1 - \frac{NA_f}{A_t} (1 - \eta_f) \right] \right\}^{-1}$$

The fin and total surface area of the array are  $A_f = 2w_2 (L_f + t/2) = 0.2 \text{ m} (0.055 \text{ m}) = 0.011 \text{ m}^2$  and  $A_t = NA_f + A_b = NA_f + (N-1)(S-t)w_2 = 6(0.011 \text{ m}^2) + 5(0.008 \text{ m})0.1 \text{ m} = (0.066 + 0.004) = 0.070 \text{ m}^2$ .

With  $Re_{w_2} = u_{\infty} w_2 / \nu = 3 \text{ m/s} \times 0.10 \text{ m} / 7.73 \times 10^{-7} \text{ m}^2/\text{s} = 3.88 \times 10^5$ , laminar flow may be assumed over the entire surface. Hence

$$\bar{h} = \left( \frac{k_w}{w_2} \right) 0.664 Re_{w_2}^{1/2} Pr^{1/3} = \left( \frac{0.62 \text{ W/m}\cdot\text{K}}{0.10 \text{ m}} \right) 0.664 (3.88 \times 10^5)^{1/2} (5.2)^{1/3} = 4443 \text{ W/m}^2 \cdot \text{K}$$

With  $m = (2\bar{h}/k_{hs}t)^{1/2} = (2 \times 4443 \text{ W/m}^2 \cdot \text{K} / 180 \text{ W/m}\cdot\text{K} \times 0.01 \text{ m})^{1/2} = 70.3 \text{ m}^{-1}$ ,  $mL_c = 70.3 \text{ m}^{-1} (0.055 \text{ m}) = 3.86$  and  $\tanh mL_c = 0.9991$ , Eq. 3.94 yields

$$\eta_f = \frac{\tanh mL_c}{mL_c} = \frac{0.9991}{3.86} = 0.259$$

Continued ...

### PROBLEM 7.29 (Cont.)

Hence,

$$R_{t,o} = \left\{ 4443 \text{ W/m}^2 \cdot \text{K} \times 0.070 \text{ m}^2 \left[ 1 - \frac{0.066 \text{ m}^2}{0.070 \text{ m}^2} (1 - 0.259) \right] \right\}^{-1} = 0.0107 \text{ K/W} \quad <$$

and

$$T_b = T_\infty + P_{\text{elec}} (R_b + R_{t,o}) = 17^\circ\text{C} + 1800 \text{ W} (5.56 \times 10^{-3} + 0.0107) \text{ K/W} = 46.2^\circ\text{C} \quad <$$

**COMMENTS:** (1) The boundary layer thickness at the trailing edge of the fin is

$\delta = 5w_2 / (\text{Re}_{w_2})^{1/2} = 0.80 \text{ mm} \ll (S - t)$ . Hence, the assumption of parallel flow over a flat plate is reasonable. (2) If a finned heat sink is not employed and heat transfer is simply by convection from the  $w_2 \times w_2$  base surface, the corresponding convection resistance would be  $0.0225 \text{ K/W}$ , which is only twice the resistance associated with the fin array. The small enhancement by the array is attributable to the large value of  $\bar{h}$  and the correspondingly small value of  $\eta_f$ . Were a fluid such as air or a dielectric liquid used as the coolant, the much smaller thermal conductivity would yield a smaller  $\bar{h}$ , a larger  $\eta_f$  and hence a larger effectiveness for the array. (3) The water outlet temperature may be calculated based the energy balance,  $q = \dot{m} c_p (T_{m,o} - T_{m,i})$  or  $T_{m,o} = 17^\circ\text{C} + 1800 \text{ W} / (5 \times 0.008 \text{ m} \times 0.05 \text{ m} \times 3 \text{ m/s} \times 995 \text{ kg/m}^3 \times 4178 \text{ J/kg}\cdot\text{K}) = 17.07^\circ\text{C}$  where there are  $N = 5$  channels. (The density and specific heat are evaluated at  $\text{Pr} = 5.2$ .) The assumption of constant water mean temperature is excellent. (4) If the increase in the water temperature was significant, an approach described in Chapter 11 would be needed to analyze the problem. See Problem 11.90.

### PROBLEM 7.30

**KNOWN:** Dimensions of a photovoltaic cell, material and dimensions of a finned heat sink, solar irradiation and dimensions of concentrating lens, velocity and temperature of dielectric liquid.

**FIND:** (a) Electric power produced and silicon temperature for a square concentrating lens with the heat sink in place, (b) Electric power and silicon temperature without the heat sink, (c) Electric power and silicon temperature for  $100 \text{ mm} \leq L_{\text{lens}} \leq 3000 \text{ mm}$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Constant properties, (3) One-dimensional heat transfer, (4) Average convection coefficient associated with flow over fin surfaces may be approximated as that for a flat plate in parallel flow, (5) Transition Reynolds number of  $Re_{x,c} = 5 \times 10^5$ , (6) Negligible convection off of the top of the solar cell, (7), No radiation to or through the dielectric liquid, (8) Negligible increase in dielectric fluid temperature as it flows through the array.

**PROPERTIES:** Given: Aluminum:  $k_{hs} = 180 \text{ W/m}\cdot\text{K}$ , Dielectric liquid:  $k_d = 0.064 \text{ W/m}\cdot\text{K}$ ,  $\nu = 10^{-6} \text{ m}^2/\text{s}$ ,  $\rho = 1400 \text{ kg/m}^3$ ,  $c_p = 1300 \text{ J/kg}\cdot\text{K}$ ,  $Pr = 25$ , Glass:  $k_g = 1.4 \text{ W/m}\cdot\text{K}$ , Adhesive:  $k_a = 145 \text{ W/m}\cdot\text{K}$ , Solder:  $k_s = 50 \text{ W/m}\cdot\text{K}$ , Aluminum Nitride:  $k_{an} = 120 \text{ W/m}\cdot\text{K}$ .

**ANALYSIS:** (a) The base resistance is

$$R_b = L_b/k_{hs}(w_1 \times w_2) = \frac{0.01\text{m}}{180 \text{ W/m}\cdot\text{K}(0.10\text{m})^2} = 5.56 \times 10^{-3} \text{ K/W}$$

and, from Equations 3.107 and 3.108

$$R_{t,o} = \left\{ \bar{h}A_t \left[ 1 - \frac{NA_f}{A_t}(1 - \eta_f) \right] \right\}^{-1}$$

The fin and total surface areas of the array are

$$A_f = 2w_2(L_f + t/2) = 0.20\text{m} \times (0.055\text{m}) = 0.0110 \text{ m}^2 \text{ and}$$

$$A_t = NA_f + A_b = NA_f + (N - 1)(S - t)w_2$$

$$= 6(0.0110 \text{ m}^2) + 5(0.008 \text{ m})(0.100 \text{ m}) = 0.0660 \text{ m}^2 + 0.0040 \text{ m}^2 = 0.071 \text{ m}^2$$

Continued...

### PROBLEM 7.30 (Cont.)

with  $Re_{w_2} = u_\infty w_2 / \nu = 3 \text{ m/s} \times 0.10 \text{ m} / 10^{-6} \text{ m}^2/\text{s} = 3.00 \times 10^5$ , laminar flow may be assumed over the entire surface. Hence

$$\begin{aligned} \bar{h} &= \left( \frac{k_w}{w_2} \right) 0.664 Re_{w_2}^{1/2} Pr^{1/3} \\ &= \left( \frac{0.064 \text{ W/m} \cdot \text{K}}{0.10 \text{ m}} \right) 0.664 (3.00 \times 10^5)^{1/2} (25)^{1/3} = 681 \text{ W/m}^2 \cdot \text{K} \end{aligned}$$

with  $m = (2\bar{h}/k_{hs}t)^{1/2} = \left[ 362 \text{ W/m}^2 / (180 \text{ W/m} \cdot \text{K} \times 0.01 \text{ m}) \right]^{1/2} = 27.50 \text{ m}^{-1}$   
 $mL_c = 27.50 \text{ m}^{-1} (0.055 \text{ m}) = 1.51$  and  $\tanh mL_c = 0.907$  Equation 3.94 yields  
 $\eta_f = \frac{\tanh mL_c}{mL_c} = \frac{0.907}{1.51} = 0.600$

Hence,

$$R_{t,o} = \left\{ 681 \text{ W/m}^2 \cdot \text{K} \times 0.070 \text{ m}^2 \left[ 1 - \frac{0.066 \text{ m}^2}{0.070 \text{ m}^2} (0.400) \right] \right\}^{-1} = 33.70 \times 10^{-3} \text{ K/W}$$

The conduction resistances are

$$R_{t,g} = \frac{L_g}{k_g A} = 3 \times 10^{-3} \text{ m} / (1.4 \text{ W/m} \cdot \text{K} \times 0.1 \text{ m} \times 0.1 \text{ m}) = 0.2143 \text{ K/W}$$

$$R_{t,a} = \frac{L_a}{k_a A} = 0.1 \times 10^{-3} \text{ m} / (145 \text{ W/m} \cdot \text{K} \times 0.1 \text{ m} \times 0.1 \text{ m}) = 6.897 \times 10^{-5} \text{ K/W}$$

$$R_{t,s} = \frac{L_s}{k_s A} = 0.1 \times 10^{-3} \text{ m} / (50 \text{ W/m} \cdot \text{K} \times 0.1 \text{ m} \times 0.1 \text{ m}) = 200 \times 10^{-6} \text{ K/W}$$

$$R_{t,an} = \frac{L_{an}}{k_{an} A} = 2 \times 10^{-3} \text{ m} / (120 \text{ W/m} \cdot \text{K} \times 0.1 \text{ m} \times 0.1 \text{ m}) = 1.67 \times 10^{-3} \text{ K/W}$$

$$R_{t,c} = \frac{R''_{t,c}}{A} = 0.5 \times 10^{-4} \text{ m}^2 \cdot \text{K/W} / (0.1 \text{ m} \times 0.1 \text{ m}) = 5.0 \times 10^{-3} \text{ K/W}$$

$$h_{\text{rad,top}} = \varepsilon_g \sigma (T_1 + T_{\text{sur}})(T_1^2 + T_{\text{sur}}^2)$$

$$R_{t,\text{rad,top}} = 1 / 0.9 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times (T_1 + 298 \text{ K}) \times (T_1^2 + (298 \text{ K})^2) \quad (1)$$

The thermal circuit is

Continued...

### PROBLEM 7.30 (Cont.)

where  $G_c = G(L_{\text{lens}}/w_1)^2$

From the thermal circuit,

$$\begin{aligned} 0.83G (L_{\text{lens}}/w_1)^2 (w_1 \times w_2)(1 - \eta) &= q_{\text{top}} + q_{\text{bot}} \\ 0.83 \times 700 \text{ W/m}^2 (4)^2 (0.1 \text{ m} \times 0.1 \text{ m})(1 - \eta) &= q_{\text{top}} - q_{\text{bot}} \\ 92.96 \text{ W}(1 - \eta) &= q_{\text{top}} + q_{\text{bot}} \end{aligned} \quad (2)$$

$$\begin{aligned} q_{\text{top}} &= (T_3 - T_{\text{sur}}) / (R_{t,a} + R_{t,g} + R_{t,\text{rad,top}}) \\ &= (T_{\text{si}} - 298 \text{ K}) / \left( 6.897 \times 10^{-5} \text{ K/W} + 0.2143 \text{ K/W} + R_{t,\text{rad,top}} \right) \\ &= (T_{\text{si}} - 298 \text{ K}) / (0.2143 \text{ K/W} + R_{t,\text{rad,top}}) \end{aligned} \quad (3)$$

$$\begin{aligned} q_{\text{bot}} &= (T_3 - T_{\infty}) / (R_{t,o} + R_{t,c} + R_{t,\text{an}} + R_{t,s}) \\ &= (T_{\text{si}} - 298 \text{ K}) / \left( 33.70 \times 10^{-3} \text{ K/W} + 5.0 \times 10^{-3} \text{ K/W} + 1.67 \times 10^{-3} \text{ K/W} + 0.20 \times 10^{-3} \text{ K/W} \right) \\ &= (T_{\text{si}} - 298 \text{ K}) / (40.57 \times 10^{-3} \text{ K/W}) \end{aligned} \quad (4)$$

From the problem statement

$$\eta = 0.28 - 0.001^\circ\text{C}^{-1}(T_{\text{si}} - 273)^\circ\text{C} \quad (5)$$

Solving Equations (1) through (5) simultaneously yields

$$T_{\text{si}} = 28.2^\circ\text{C}, \quad \eta = 0.252 \quad <$$

The electric power is

$$P = 0.83G(L_{\text{lens}}/w_1)^2(w_1 \times w_2)(\eta) \quad (6)$$

$$P = 0.83 \times 700 \text{ W/m}^2 (4)^2 (0.1 \text{ m} \times 0.1 \text{ m})(0.252) = 23.4 \text{ W} \quad <$$

(b) Substituting  $L_{\text{lens}} = 1500 \text{ mm}$  in Equations 2 and 6 yields

$$T_{\text{si}} = 72.6^\circ\text{C}, \quad P = 271 \text{ W} \quad <$$

with the heat sink in place. For no heat sink we also substitute

$$R_{t,c} = 0 \text{ and } R_{t,o} = R_{t,\text{conv}} = 1/\bar{h}w_1^2 = 1/681 \text{ W/m}^2\cdot\text{K}(0.1\text{m})^2 = 146.8 \times 10^{-3} \text{ K/W}$$

into Equation 4 and solving Equations (1) through (5) simultaneously yields

### PROBLEM 7.30 (Cont.)

$T_{si} = 200^\circ\text{C}$ ,  $P = 105\text{ W}$

(c) The variation of the silicon temperature and electric power with the heat sink in place is shown in the accompanying graphs.

Continued...

### PROBLEM 7.30 (Cont.)

**COMMENTS:** (1) In Problem 7.19, we see that, for air cooling and  $L_{\text{lens}} = 400 \text{ mm}$ ,  $T_{\text{si}} = 126 \text{ }^\circ\text{C}$ ,  $P = 14.3 \text{ W}$ . Use of liquid cooling increases the electrical power output to  $23.4 \text{ W}$ , or 64 percent. In Problem 7.19 we see the maximum power output to be about  $15 \text{ W}$ . With liquid cooling and the heat sink, maximum power output increases to about  $420 \text{ W}$ , or 2800%. (2) The electric power is highly sensitive to the size of the concentrator. Initially, the power output increases as the concentrated irradiation increases, but as the silicon temperature increases the efficiency drops, driving the power output down. (3) The boundary layer thickness at the trailing edge of the fin is  $\delta = 5w_2/\text{Re}_{w_2}^{1/2} = 0.91 \text{ mm} \ll (S - t)$ . Also, since  $\text{Pr} > 1$ ,  $\delta_t < \delta$ . Hence, the assumption of parallel flow over a flat plate is reasonable. (4) The dielectric fluid outlet temperature may be calculated based the energy balance,  $q_{\text{bot}} = (T_{\text{si}} - 298 \text{ K})/(40.57 \times 10^{-3} \text{ K/W}) = 79 \text{ W} = \dot{m} c_p (T_{m,o} - T_{m,i})$  or  $T_{m,o} = 25^\circ\text{C} + 79 \text{ W}/(5 \times 0.008\text{m} \times 0.05\text{m} \times 3 \text{ m/s} \times 1400 \text{ kg/m}^3 \times 1300 \text{ J/kg}\cdot\text{K}) = 25.007^\circ\text{C}$  where there are  $N = 5$  channels. The assumption of constant dielectric mean temperature is excellent. (5) If the increase in the dielectric fluid temperature was significant, an approach described in Chapter 11 would be needed to analyze the problem. (6) Solar irradiation values can be nearly  $1100 \text{ W/m}^2$  in clear environments. How do you think the maximum electric power will change when the solar irradiation is increased? You may want to re-work the solution to the problem to find the surprising result.

### PROBLEM 7.31

**KNOWN:** Velocity, initial temperature, properties and dimensions of steel strip on a production line. Velocity and temperature of air in cross flow over top and bottom surfaces of strip. Temperature of surroundings.

**FIND:** (a) Differential equation governing temperature distribution along the strip, (b) Exact solution for negligible radiation and corresponding value of outlet temperature for prescribed conditions, (c) Effect of radiation on outlet temperature, and parametric effect of sheet velocity on temperature distribution.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible variation of sheet temperature across its width and thickness, (2) Negligible effect of conduction along length ( $x$ ) of sheet, (3) Constant properties, (4) Radiation exchange between small surface (both sides of sheet) and large surroundings, (5) Turbulent flow over top and bottom surfaces of sheet, (6) Motion of sheet has a negligible effect on the convection coefficient, ( $V \ll u_\infty$ ), (7) Negligible heat transfer from sides of sheet.

**PROPERTIES:** Prescribed. Steel:  $\rho = 7850 \text{ kg/m}^3$ ,  $c_p = 620 \text{ J/kg} \cdot \text{K}$ ,  $\varepsilon = 0.70$ . Air:  $k = 0.044 \text{ W/m} \cdot \text{K}$ ,  $\nu = 4.5 \times 10^{-5} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.68$ .

**ANALYSIS:** (a) Applying conservation of energy to a stationary differential control surface, through which the sheet passes, conditions are steady and  $\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = 0$ . Hence, with *inflow* due to *advection* and *outflow* due to *advection, convection* and *radiation*

$$\begin{aligned} \rho V A_c c_p T - \rho V A_c c_p (T + dT) - 2 dq &= 0 \\ -\rho V \delta W c_p dT - 2(W dx) \left[ \bar{h}_W (T - T_\infty) + \varepsilon \sigma (T^4 - T_{\text{sur}}^4) \right] &= 0 \\ \frac{dT}{dx} &= -\frac{2}{\rho V \delta c_p} \left[ \bar{h}_W (T - T_\infty) + \varepsilon \sigma (T^4 - T_{\text{sur}}^4) \right] \end{aligned} \quad (1) <$$

Alternatively, if the control surface is fixed to the sheet, conditions are transient and the energy balance is of the form,  $-\dot{E}_{\text{out}} = \dot{E}_{\text{st}}$ , or

$$\begin{aligned} -2(W dx) \left[ \bar{h}_W (T - T_\infty) + \varepsilon \sigma (T^4 - T_{\text{sur}}^4) \right] &= \rho (W \delta dx) c_p \frac{dT}{dt} \\ \frac{dT}{dt} &= -\frac{2}{\rho \delta c_p} \left[ \bar{h}_W (T - T_\infty) + \varepsilon \sigma (T^4 - T_{\text{sur}}^4) \right] \end{aligned}$$

Dividing the left- and right-hand sides of the equation by  $dx/dt$  and  $V = dx/dt$ , respectively, Eq. (1) is obtained.

(b) Neglecting radiation, separating variables and integrating, Eq. (1) becomes

$$\int_{T_i}^T \frac{dT}{T - T_\infty} = -\frac{2 \bar{h}_W}{\rho V \delta c_p} \int_0^x dx$$

Continued ...

**PROBLEM 7.31 (Cont.)**

$$\ln\left(\frac{T - T_\infty}{T_i - T_\infty}\right) = -\frac{2\bar{h}_W x}{\rho V \delta c_p}$$

$$T = T_\infty + (T_i - T_\infty) \exp\left(-\frac{2\bar{h}_W x}{\rho V \delta c_p}\right) \quad (2) <$$

With  $Re_W = u_\infty W / \nu = 20 \text{ m/s} \times 1\text{m} / 4 \times 10^{-5} \text{ m}^2/\text{s} = 5 \times 10^5$ , the correlation for turbulent flow over a flat plate yields

$$\overline{Nu}_W = 0.037 Re_W^{4/5} Pr^{1/3} = 0.037 (5 \times 10^5)^{4/5} (0.68)^{1/3} = 1179$$

$$\bar{h}_W = \frac{k}{W} \overline{Nu}_W = \frac{0.044 \text{ W/m} \cdot \text{K}}{1\text{m}} 1179 = 51.9 \text{ W/m}^2 \cdot \text{K}$$

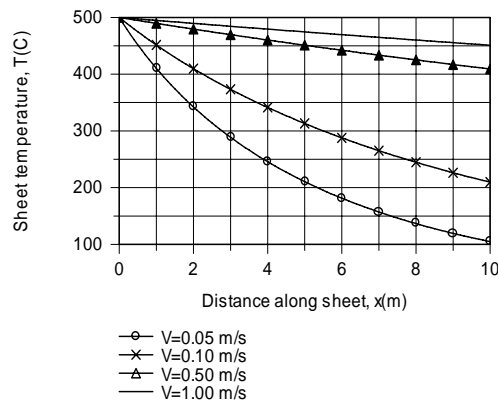

Hence, applying Eq. (2) at  $x = L = 10\text{m}$ ,

$$T_o = 20^\circ\text{C} + (480^\circ\text{C}) \exp\left(-\frac{2 \times 51.9 \text{ W/m}^2 \cdot \text{K} \times 10\text{m}}{7850 \text{ kg/m}^3 \times 0.1 \text{ m/s} \times 0.003 \text{ m} \times 620 \text{ J/kg} \cdot \text{K}}\right) = 256^\circ\text{C} <$$

(c) Using the DER function of IHT, Eq. (1) may be numerically integrated from  $x = 0$  to  $x = L = 10\text{m}$  to obtain

$$T_o = 210^\circ\text{C} <$$

Contrasting this result with that of Part (b), it is clear that radiation makes a discernable contribution to cooling of the sheet. IHT was also used to determine the effect of the sheet velocity on the temperature distribution.

The sheet velocity has a significant influence on the temperature distribution. The temperature decay decreases with increasing  $V$  due to the increasing effect of advection on energy transfer in the  $x$  direction.

**COMMENTS:** (1) A critical parameter in the production process is the *coiling temperature*, that is, the temperature at which the wire may be safely coiled for subsequent storage or shipment. The larger the production rate ( $V$ ), the longer the cooling distance needed to achieve a desired coiling temperature. (2) Cooling may be enhanced by increasing the cross stream velocity  $u_\infty$ .

### PROBLEM 7.32

**KNOWN:** Length, thickness, speed and temperature of steel strip.

**FIND:** Rate of change of strip temperature 1 m from leading edge and at trailing edge. Location of minimum cooling rate.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Constant properties, (2) Negligible radiation, (3) Negligible longitudinal conduction in strip, (4) Critical Reynolds number is  $5 \times 10^5$ .

**PROPERTIES:** Steel (given):  $\rho = 7900 \text{ kg/m}^3$ ,  $c_p = 640 \text{ J/kg}\cdot\text{K}$ . Table A-4, Air ( $\bar{T} = 750\text{K}$ , 1 atm):  $\nu = 76.4 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0549 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.702$ .

**ANALYSIS:** Performing an energy balance for a control mass of unit surface area  $A_s$  riding with the strip,

$$-\dot{E}_{\text{out}} = dE_{\text{st}}/dt$$

$$-2h_x A_s (T - T_\infty) = \rho \delta A_s c_p (dT/dt)$$

$$dT/dt = \frac{-2h_x (T - T_\infty)}{\rho \delta c_p} = -\frac{2(900\text{K})h_x}{7900 \text{ kg/m}^3 (0.003 \text{ m}) 640 \text{ J/kg}\cdot\text{K}} = -0.119h_x \text{ (K/s)}.$$

$$\text{At } x = 1 \text{ m, } \text{Re}_x = \frac{Vx}{\nu} = \frac{20 \text{ m/s}(1\text{m})}{76.4 \times 10^{-6} \text{ m}^2/\text{s}} = 2.62 \times 10^5 < \text{Re}_{x,c}. \text{ Hence,}$$

$$h_x = (k/x) 0.332 \text{Re}_x^{1/2} \text{Pr}^{1/3} = \frac{0.0549 \text{ W/m}\cdot\text{K}}{1 \text{ m}} (0.332) (2.62 \times 10^5)^{1/2} (0.702)^{1/3} = 8.29 \text{ W/m}^2 \cdot \text{K}$$

$$\text{and at } x = 1 \text{ m, } dT/dt = -0.987 \text{ K/s.} \quad <$$

At the trailing edge,  $\text{Re}_x = 2.62 \times 10^7 > \text{Re}_{x,c}$ . Hence

$$h_x = (k/x) 0.0296 \text{Re}_x^{4/5} \text{Pr}^{1/3} = \frac{0.0549 \text{ W/m}\cdot\text{K}}{100 \text{ m}} (0.0296) (2.62 \times 10^7)^{4/5} (0.702)^{1/3} = 12.4 \text{ W/m}^2 \cdot \text{K}$$

$$\text{and at } x = 100 \text{ m, } dT/dt = -1.47 \text{ K/s.} \quad <$$

The minimum cooling rate occurs just before transition; hence, for  $\text{Re}_{x,c} = 5 \times 10^5$

$$x_c = 5 \times 10^5 (\nu/V) = \frac{5 \times 10^5 \times 76.4 \times 10^{-6} \text{ m}^2/\text{s}}{20 \text{ m/s}} = 1.91 \text{ m} \quad <$$

**COMMENTS:** The cooling rates are very low and would remain low even if radiation were considered. For this reason, hot strip metals are quenched by water and not by air.

### PROBLEM 7.33

**KNOWN:** Thin metallic strip with thermocouple at trailing edge is used as an anemometer. Laminar flow.

**FIND:** (a) Calibration equations for constant surface temperature and constant heat flux conditions. (b) Percentage error in using the wrong calibration. (c) Location of thermocouple for which calibration is insensitive to thermal boundary condition.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Boundary layer assumptions hold, (3) Laminar flow, (4) Constant properties.

**ANALYSIS:**

(a) For constant surface temperature

$$\overline{Nu}_L = 0.664 Re_L^{1/2} Pr^{1/3}$$

Therefore

$$\overline{h}_L = 0.664 Re_L^{1/2} Pr^{1/3} k/L$$

and 
$$P' = 2\overline{h}_L L (T_s - T_\infty) = 2 (0.664) \left(\frac{u_\infty L}{\nu}\right)^{1/2} Pr^{1/3} (T_s - T_\infty)$$

Solving for  $u_\infty$ , the calibration for constant  $T_s$  is:

$$u_\infty = \left\{ P' / \left[ 2 (0.664) Pr^{1/3} k (T_s - T_\infty) \right] \right\}^2 \left( \frac{\nu}{L} \right) \quad (1) <$$

For constant heat flux, we consider the local heat transfer coefficient at the end of the strip.

$$Nu_L = 0.453 Re_L^{1/2} Pr^{1/3}$$

$$h_L = 0.453 Re_L^{1/2} Pr^{1/3} k/L$$

Accounting for heat loss from both surfaces,

$$P' = 2q_s''L$$

The uniform heat flux can be related to the conditions at  $x = L$ :

$$q_s'' = h_L (T_{s,L} - T_\infty)$$

Thus

$$P' = 2h_L L (T_{s,L} - T_\infty) = 2 (0.453) \left(\frac{u_\infty L}{\nu}\right)^{1/2} Pr^{1/3} k (T_{s,L} - T_\infty)$$

Continued...

### PROBLEM 7.33 (Cont.)

Solving for  $u_\infty$ , the calibration for constant  $q_s''$  is:

$$u_\infty = \left\{ P' / \left[ 2 (0.453) \text{Pr}^{1/3} k (T_{s,L} - T_\infty) \right] \right\}^2 \left( \frac{\nu}{L} \right) \quad (2) <$$

(b) Since the true situation is uniform heat flux, the true velocity is found from Equation (2). However the predicted velocity is incorrectly calculated from Equation (1). Thus

$$\frac{u_{\infty, \text{pred.}}}{u_{\infty, \text{true}}} = \left( \frac{0.453}{0.664} \right)^2 = 0.47 \quad <$$

The velocity is underpredicted by more than half, or 53%.

(c) For constant surface heat flux, the local surface temperature is given by

$$T_{s,q}(x) - T_\infty = q_s'' / h_x = \frac{P'/2L}{0.453 \text{Re}_x^{1/2} \text{Pr}^{1/3} k/x}$$

where the  $q$  subscript on  $T_s$  indicates that it is for the constant heat flux case. This should be equal to the surface temperature for the constant  $T_s$  case, namely

$$T_{s,T} - T_\infty = P'/2L \bar{h}_L = \frac{P'/2L}{0.664 \text{Re}_L^{1/2} \text{Pr}^{1/3} k/L}$$

Equating  $T_{s,q}$  and  $T_{s,T}$  and solving for  $x$  yields

$$\begin{aligned} 0.453x^{-1/2} &= 0.664L^{-1/2} \\ (x/L) &= \left( \frac{0.453}{0.664} \right)^2 = 0.47 \quad < \end{aligned}$$

Thus, if the thermocouple is placed approximately at the midpoint of the strip it will be insensitive to the type of thermal boundary condition experienced by the strip.

## PROBLEM 7.34

**KNOWN:** Dimensions of flat plate in parallel flow. Plate and fluid temperatures, fluid velocities.

**FIND:** Average heat transfer coefficient, convection heat transfer rate, drag force for (a) water flowing at a velocity of 0.5 m/s, (b) nanofluid of Example 2.2 at a velocity of 0.5 m/s, (c) water at a velocity of 2.5 m/s, (d) nanofluid at a velocity of 2.5 m/s.

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Constant properties,  $Re_{x,c} = 5 \times 10^5$ .

**PROPERTIES:** Table A.4, water (300 K):  $\rho_{bf} = 997 \text{ kg/m}^3$ ,  $\nu_{bf} = 857 \times 10^{-9} \text{ m}^2/\text{s}$ ,  $k_{bf} = 0.613 \text{ W/m}\cdot\text{K}$ ,  $Pr_{bf} = 5.83$ . Example 2.2, nanofluid (300 K):  $\rho_{nf} = 1146 \text{ kg/m}^3$ ,  $\mu_{nf} = 962 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\nu_{nf} = \mu_{nf}/\rho_{nf} = 839 \times 10^{-9} \text{ m}^2/\text{s}$ ,  $k_{nf} = 0.705 \text{ W/m}\cdot\text{K}$ ,  $\alpha_{nf} = 171 \times 10^{-9} \text{ m}^2/\text{s}$ ,  $Pr_{nf} = \nu_{nf}/\alpha_{nf} = 4.91$ .

**ANALYSIS:** (a) For water flowing over the plate at  $u_m = 0.5 \text{ m/s}$ ,

$$Re_L = \frac{u_\infty L}{\nu_{bf}} = \frac{0.5 \text{ m/s} \times 0.2 \text{ m}}{857 \times 10^{-9} \text{ m}^2/\text{s}} = 117 \times 10^3$$

Since  $Re_L < Re_{x,c}$  the flow is laminar and Eq. 7.30 yields

$$\bar{h}_L = \frac{k_{bf}}{L} \left[ 0.664 Re_L^{1/2} \right] Pr_{bf}^{1/3} = \frac{0.613 \text{ W/m}\cdot\text{K}}{0.2 \text{ m}} \left[ 0.664 \times 117,000^{1/2} \right] 5.83^{1/3} = 1253 \text{ W/m}^2\cdot\text{K} \quad <$$

and the convection heat transfer rate from the top of the plate is

$$q = wL\bar{h}_L(T_s - T_\infty) = 1 \text{ m} \times 0.2 \text{ m} \times 1253 \text{ W/m}^2\cdot\text{K} \cdot \text{K} \times (32 - 22)^\circ\text{C} = 2500 \text{ W} = 2.51 \text{ kW} \quad <$$

The drag force on the plate is

$$\begin{aligned} F &= \bar{\tau}_{s,L} wL = \frac{\bar{C}_f \rho_{bf} u_\infty^2}{2} wL \\ &= \frac{1.328 \rho_{bf} u_\infty^2}{2\sqrt{Re_L}} wL = \frac{1.328 \times 997 \text{ kg/m}^3 \times (0.5 \text{ m/s})^2}{2\sqrt{117 \times 10^3}} \times 1 \text{ m} \times 0.2 \text{ m} \\ &= 0.097 \text{ N} \quad < \end{aligned}$$

where Equation 7.29 has been used to determine the average friction coefficient.

Continued...

### PROBLEM 7.34 (Cont.)

(b) For the nanofluid flowing over the plate at  $u_m = 0.5$  m/s,

$$Re_L = \frac{u_\infty L}{\nu_{nf}} = \frac{0.5 \text{ m/s} \times 0.2 \text{ m}}{839 \times 10^{-9} \text{ m}^2/\text{s}} = 119 \times 10^3$$

The flow is laminar and Eq. 7.30 yields

$$\bar{h}_L = \frac{k_{nf}}{L} \left[ 0.664 Re_L^{1/2} \right] Pr_{nf}^{1/3} = \frac{0.705 \text{ W/m} \cdot \text{K}}{0.2 \text{ m}} \left[ 0.664 \times 119,000^{1/2} \right] 4.91^{1/3} = 1372 \text{ W/m}^2 \cdot \text{K} \quad <$$

and the convection heat transfer rate from the top of the plate is

$$q = wL\bar{h}_L(T_s - T_\infty) = 1 \text{ m} \times 0.2 \text{ m} \times 1372 \text{ W/m}^2 \cdot \text{K} (32 - 22)^\circ\text{C} = 2740 \text{ W} = 2.74 \text{ kW} \quad <$$

The drag force on the plate is

$$\begin{aligned} F &= \bar{\tau}_{s,L} wL = \frac{\bar{C}_f \rho_{nf} u_\infty^2}{2} wL \\ &= \frac{1.328 \rho_{nf} u_\infty^2}{2\sqrt{Re_L}} wL = \frac{1.328 \times 1146 \text{ kg/m}^3 \times (0.5 \text{ m/s})^2}{2\sqrt{119 \times 10^3}} \times 1 \text{ m} \times 0.2 \text{ m} \\ &= 0.110 \text{ N} \end{aligned} \quad <$$

(c) For water flowing over the plate at  $u_m = 2.5$  m/s,

$$Re_L = \frac{u_\infty L}{\nu_{bf}} = \frac{2.5 \text{ m/s} \times 0.2 \text{ m}}{857 \times 10^{-9} \text{ m}^2/\text{s}} = 5.83 \times 10^5$$

Therefore, the flow at the end of the plate is turbulent and Eq. 7.30 yields

$$\begin{aligned} \bar{h}_L &= \frac{k_{bf}}{L} \left[ 0.037 Re_L^{4/5} - 871 \right] Pr_{bf}^{1/3} \\ &= \frac{0.613 \text{ W/m} \cdot \text{K}}{0.2 \text{ m}} \left[ 0.037 (5.83 \times 10^5)^{4/5} - 871 \right] 5.83^{1/3} = 3562 \text{ W/m}^2 \cdot \text{K} \end{aligned} \quad <$$

and the convection heat transfer rate from the top of the plate is

$$q = wL\bar{h}_L(T_s - T_\infty) = 1 \text{ m} \times 0.2 \text{ m} \times 3562 \text{ W/m}^2 \cdot \text{K} (32 - 22)^\circ\text{C} = 7120 \text{ W} = 7.12 \text{ kW} \quad <$$

The drag force on the plate is

Continued...

### PROBLEM 7.34 (Cont.)

$$\begin{aligned} F &= \bar{\tau}_{s,L} wL = \bar{C}_f \frac{\rho_{\text{bf}} u_{\infty}^2}{2} wL \\ &= \left( 0.074 Re_L^{-1/5} - \frac{2 \times 871}{Re_L} \right) \frac{\rho_{\text{bf}} u_{\infty}^2}{2} wL \\ &= \left( 0.074 \times (5.83 \times 10^5)^{-1/5} - \frac{2 \times 871}{5.83 \times 10^5} \right) \frac{997 \text{ kg/m}^3 \times (2.5 \text{ m})^2}{2} \times 1 \text{ m} \times 0.2 \text{ m} \\ &= 1.379 \text{ N} \end{aligned} \quad <$$

where Equation 7.40 has been used to determine the average friction coefficient.

(d) For the nanofluid flowing over the plate at  $u_m = 2.5 \text{ m/s}$ ,  $Re_L = 5.96 \times 10^5$ ,  $\bar{h}_L = 4024 \text{ W/m}^2 \cdot \text{K}$ ,  $q = 8050 \text{ W} = 8.05 \text{ kW}$ , and  $F = 1.615 \text{ N}$ . <

**COMMENTS:** (1) The convection heat transfer rate is greater for the nanofluid than for the base fluid (water). For the laminar case, the nanofluid convection heat transfer rate is 9.5% larger when the nanofluid is used. For the turbulent flow case the convection heat transfer rate is 13% higher for the nanofluid. The higher efficacy of the nanofluid in the turbulent flow case is associated with its larger Reynolds number,  $Re_{L,\text{nf}} > Re_{L,\text{bf}}$ . Hence more of the plate experiences turbulent flow when the nanofluid is used. (2) The drag force is always greater when the nanofluid is used. For the laminar flow case, the drag force is 13.6% larger when the nanofluid is used, while for the turbulent flow case the drag force associated with the nanofluid is 17.1% larger than for the base fluid. Larger drag forces are expected due to the larger viscosity associated with the nanofluid. (c) For many cases involving nanofluids, a tradeoff exists between potentially increasing the heat transfer rates, but at a cost of experiencing larger friction losses.

### PROBLEM 7.35

**KNOWN:** Operating power of electrical components attached to one side of copper plate. Contact resistance. Velocity and temperature of water flow on opposite side.

**FIND:** (a) Plate temperature, (b) Component temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Constant properties, (3) Negligible heat loss from sides and bottom, (4) Turbulent flow throughout.

**PROPERTIES:** Water (given):  $\nu = 0.96 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.620 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 5.2$ .

**ANALYSIS:** (a) From the convection rate equation,

$$T_s = T_\infty + q/\bar{h}A$$

where  $q = Nq_c = 2500 \text{ W}$  and  $A = L^2 = 0.04 \text{ m}^2$ . The convection coefficient is given by the turbulent flow correlation

$$\bar{h} = \overline{\text{Nu}}_L (k/L) = 0.037 \text{Re}_L^{4/5} \text{Pr}^{1/3} (k/L)$$

where

$$\text{Re}_L = (u_\infty L / \nu) = (2 \text{ m/s} \times 0.2 \text{ m}) / 0.96 \times 10^{-6} \text{ m}^2/\text{s} = 4.17 \times 10^5$$

and hence

$$\bar{h} = 0.037 \left( 4.17 \times 10^5 \right)^{4/5} (5.2)^{1/3} (0.62 \text{ W/m}\cdot\text{K} / 0.2 \text{ m}) = 6228 \text{ W/m}^2 \cdot \text{K}.$$

The plate temperature is then

$$T_s = 17^\circ\text{C} + 2500 \text{ W} / \left( 6228 \text{ W/m}^2 \cdot \text{K} \right) (0.20 \text{ m})^2 = 27^\circ\text{C}. \quad <$$

(b) For an individual component, a rate equation involving the component's contact resistance can be used to find its temperature,

$$q_c = (T_c - T_s) / R_{t,c} = (T_c - T_s) / (R''_{t,c} / A_c)$$

$$T_c = T_s + q_c R''_{t,c} / A_c = 27^\circ\text{C} + 25 \text{ W} \left( 2 \times 10^{-4} \text{ m}^2 \cdot \text{K/W} \right) / 10^{-4} \text{ m}^2$$

$$T_c = 77^\circ\text{C}. \quad <$$

**COMMENTS:** With  $\text{Re}_L = 4.17 \times 10^5$ , the boundary layer would be laminar over the entire plate without the boundary layer trip, causing  $T_s$  and  $T_c$  to be appreciably larger.

### PROBLEM 7.36

**KNOWN:** Air at 27°C with velocity of 10 m/s flows turbulently over a series of electronic devices, each having dimensions of 4 mm × 4 mm and dissipating 40 mW.

**FIND:** (a) Surface temperature  $T_s$  of the fourth device located 15 mm from the leading edge, (b) Compute and plot the surface temperatures of the first four devices for the range  $5 \leq u_\infty \leq 15$  m/s, and (c) Minimum free stream velocity  $u_\infty$  if the surface temperature of the hottest device is not to exceed 80°C.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Turbulent flow, (2) Heat from devices leaving through top surface by convection only, (3) Device surface is isothermal, and (4) The average coefficient for the devices is equal to the local value at the mid position, i.e.  $\bar{h}_4 = h_x(L)$ .

**PROPERTIES:** Table A.4, Air (assume  $T_s = 330$  K,  $\bar{T} = (T_s + T_\infty)/2 = 315$  K, 1 atm):  $k = 0.0274$  W/m·K,  $\nu = 17.40 \times 10^{-6}$  m<sup>2</sup>/s,  $\alpha = 24.7 \times 10^{-6}$  m<sup>2</sup>/s,  $Pr = 0.705$ .

**ANALYSIS:** (a) From Newton's law of cooling,

$$T_s = T_\infty + q_{conv} / \bar{h}_4 A_s \quad (1)$$

where  $\bar{h}_4$  is the average heat transfer coefficient over the 4th device. Since flow is turbulent, it is reasonable and convenient to assume that

$$\bar{h}_4 = h_x(L = 15 \text{ mm}). \quad (2)$$

To estimate  $h_x$ , use the turbulent correlation evaluating thermophysical properties at  $\bar{T}_f = 315$  K (assume  $T_s = 330$  K),

$$Nu_x = 0.0296 Re_x^{4/5} Pr^{1/3}$$

where

$$Re_x = \frac{u_\infty L}{\nu} = \frac{10 \text{ m/s} \times 0.015 \text{ m}}{17.4 \times 10^{-6} \text{ m}^2/\text{s}} = 8621$$

giving

$$Nu_x = \frac{h_x L}{k} = 0.0296 (8621)^{4/5} (0.705)^{1/3} = 37.1$$

$$\bar{h}_4 = h_x = \frac{Nu_x k}{L} = \frac{37.1 \times 0.0274 \text{ W/m} \cdot \text{K}}{0.015 \text{ m}} = 67.8 \text{ W/m}^2 \cdot \text{K}$$

Hence, with  $A_s = 4 \text{ mm} \times 4 \text{ mm}$ , the surface temperature is

$$T_s = 300 \text{ K} + \frac{40 \times 10^{-3} \text{ W}}{67.8 \text{ W/m}^2 \cdot \text{K} \times (4 \times 10^{-3} \text{ m})^2} = 337 \text{ K} = 64^\circ \text{C}. \quad <$$

Continued...

### PROBLEM 7.36 (Cont.)

(b) The surface temperature for each of the four devices ( $i = 1, 2, 3, 4$ ) follows from Eq. (1),

$$T_{s,i} = T_{\infty} + q_{\text{conv}} / \bar{h}_i A_s \quad (3)$$

For devices 2, 3 and 4,  $\bar{h}_i$  is evaluated as the local coefficient at the mid-positions, Eq. (2),  $x_2 = 6.5$  mm,  $x_3 = 10.75$  mm and  $x_4 = 15$  mm. For device 1,  $\bar{h}_1$  is the average value 0 to  $x_1$ , where evaluated  $x_1 = L_1 = 4.25$  mm. Using Eq. (3) in the *IHT Workspace* along with the *Correlations Tool, External Flow, Local Coefficient for Laminar or Turbulent Flow*, the surface temperatures  $T_{s,i}$  are determined as a function of the free stream velocity.

(c) Using the *Explore* option on the *Plot Window* associated with the IHT code of part (b), the minimum free stream velocity of

$$u_{\infty} = 6.6 \text{ m/s}$$

<

will maintain device 4, the hottest of the devices, at a temperature  $T_{s,4} = 80^{\circ}\text{C}$ .

**COMMENTS:** (1) Note that the thermophysical properties were evaluated at a reasonable assumed film temperature in part (a).

(2) From the  $T_{s,i}$  vs.  $u_{\infty}$  plots, note that, as expected, the surface temperatures of the devices increase with distance from the leading edge.

## PROBLEM 7.37

**KNOWN:** Length of isothermal flat plate in parallel flow,  $L$ .

**FIND:** Expression for the Reynolds number associated with the location of a trip wire to maximize heat transfer,  $Re_{x,c,opt}$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Constant properties.

**ANALYSIS:** From Equations 7.38 and 7.39

$$\overline{Nu}_L = \left(0.037 Re_L^{4/5} - A\right) Pr^{1/3} \quad \text{where} \quad A = 0.037 Re_{x,c}^{4/5} - 0.664 Re_{x,c}^{1/2} \quad (1a, b)$$

To maximize the average Nusselt number, it is necessary to minimize the value of  $A$ . Taking the derivative of  $A$  with respect to  $Re_{x,c}$  results in

$$\frac{dA}{dRe_{x,c}} = 0.037 \left(\frac{4}{5}\right) (Re_{x,c})^{-1/5} - 0.664 \left(\frac{1}{2}\right) (Re_{x,c})^{-1/2}$$

Setting  $dA/dRe_{x,c}$  equal to zero yields

$$Re_{x,c,opt}^{-1/5} Re_{x,c,opt}^{1/2} = \frac{0.664(1/2)}{0.037(4/5)} = 11.216$$

or  $Re_{x,c,opt} = 11.216^{(1/0.3)} = 3158$  <

**COMMENTS:** Substituting  $Re_{x,c,opt} = 3158$  into Equation 1b yields  $A_{opt} = -14$ . Since  $A = 0$  corresponds to tripping the boundary layer at the leading edge of the plate, and  $A = 871$  corresponds to a critical Reynolds number of  $Re_{x,c} = 5 \times 10^5$ , we know that placing the trip wire at an  $x$  location corresponding to  $Re_{x,c,opt} = 3158$  must maximize heat transfer from the plate (as opposed to minimizing heat transfer from the plate).

### PROBLEM 7.38

**KNOWN:** Convection correlation for irregular surface due to electronic elements mounted on a circuit board experiencing forced air cooling with prescribed temperature and velocity

**FIND:** Surface temperature when heat dissipation rate is 30 mW for chip of prescribed area located a specific distance from the leading edge.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Situation approximates parallel flow over a flat plate with prescribed correlation, (2) Heat rate is from top surface of chip.

**PROPERTIES:** Table A-4, Air (assume  $T_s \approx 45^\circ\text{C}$ , then  $\bar{T} = (45 + 25)^\circ\text{C}/2 \approx 310\text{ K}$ , 1 atm):  $k = 0.027\text{ W/m}\cdot\text{K}$ ,  $\nu = 16.90 \times 10^{-6}\text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.706$ .

**ANALYSIS:** For the chip upper surface, the heat rate is

$$q_{\text{chip}} = \bar{h}_{\text{chip}} A_s (T_s - T_\infty) \quad \text{or} \quad T_s = T_\infty + q_{\text{chip}} / \bar{h}_{\text{chip}} A_s$$

Assuming the average convection coefficient over the chip length to be equal to the local value at the center of the chip ( $x = x_0$ ),  $\bar{h}_{\text{chip}} \approx h_x(x_0)$ , where

$$\text{Nu}_x = 0.04 \text{Re}_x^{0.85} \text{Pr}^{0.33}$$

$$\text{Nu}_x = 0.04 \left( 10\text{ m/s} \times 0.120\text{ m} / 16.90 \times 10^{-6}\text{ m}^2/\text{s} \right)^{0.85} (0.706)^{0.33} = 473.4$$

$$h_x = \frac{\text{Nu}_x k}{x_0} = \frac{473.4 \times 0.027\text{ W/m}\cdot\text{K}}{0.120\text{ m}} = 107\text{ W/m}^2 \cdot \text{K}$$

Hence,

$$T_s = 25^\circ\text{C} + 30 \times 10^{-3}\text{ W} / 107\text{ W/m}^2 \cdot \text{K} \times \left( 4 \times 10^{-3}\text{ m} \right)^2 = (25 + 17.5)^\circ\text{C} = 42.5^\circ\text{C}. <$$

**COMMENTS:** (1) Note that the assumed value of  $\bar{T}$  used to evaluate the thermophysical properties was reasonable. (2) We could have evaluated  $\bar{h}_{\text{chip}}$  by two other approaches. In one case the average coefficient is approximated as the arithmetic mean of local values at the leading and trailing edges of the chip.

$$\bar{h}_{\text{chip}} \approx [h_{x2}(x_2) + h_{x1}(x_1)] / 2 = 107\text{ W/m}^2 \cdot \text{K}.$$

The exact approach is of the form

$$\bar{h}_{\text{chip}} \cdot \ell = \bar{h}_{x2} \cdot x_2 - \bar{h}_{x1} \cdot x_1$$

Recognizing that  $h_x \sim x^{-0.15}$ , it follows that

$$\bar{h}_x = \frac{1}{x} \int_0^x h_x \cdot dx = 1.176 h_x$$

and  $\bar{h}_{\text{chip}} = 108\text{ W/m}^2 \cdot \text{K}$ . Why do results for the two approximate methods and the exact method compare so favorably?

### PROBLEM 7.39

**KNOWN:** Air at atmospheric pressure and a temperature of 25°C in parallel flow at a velocity of 5 m/s over a 1-m long flat plate with a uniform heat flux of 1250 W/m<sup>2</sup>.

**FIND:** (a) Plate surface temperature,  $T_s(L)$ , and local convection coefficient,  $h_x(L)$ , at the trailing edge,  $x = L$ , (b) Average temperature of the plate surface,  $\bar{T}_s$ , (c) Plot the variation of the plate surface temperature,  $T_s(x)$ , and the convection coefficient,  $h_x(x)$ , with distance on the same graph; explain key features of these distributions.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Flow is fully turbulent, and (3) Constant properties.

**PROPERTIES:** Table A-4, Air (assume  $T_f = 325$  K, 1 atm):  $\nu = 18.76 \times 10^{-6}$  m<sup>2</sup>/s;  $k = 0.0284$  W/m·K;  $Pr = 0.703$ .

**ANALYSIS:** (a) At the trailing edge,  $x = L$ , the convection rate equation is

$$q_s'' = q_{cv}'' = h_x(L) [T_s(L) - T_\infty] \quad (1)$$

where the local convection coefficient, assuming turbulent flow, follows from Eq. 7.46.

$$Nu_x = \frac{h_x x}{k} = 0.0308 Re_x^{4/5} Pr^{1/3} \quad (2)$$

With  $x = L = 1$  m, find

$$Re_x = u_\infty L / \nu = 5 \text{ m/s} \times 1 \text{ m} / 18.76 \times 10^{-6} \text{ m}^2/\text{s} = 2.67 \times 10^5$$

$$h_x(L) = (0.0284 \text{ W/m} \cdot \text{K} / 1 \text{ m}) \times 0.0308 \left( 2.67 \times 10^5 \right)^{4/5} (0.703)^{1/3} = 17.1 \text{ W/m}^2 \cdot \text{K}$$

Substituting numerical values into Eq. (1),

$$T_s(L) = 25^\circ\text{C} + 1250 \text{ W/m}^2 / 17.1 \text{ W/m}^2 \cdot \text{K} = 98.3^\circ\text{C} \quad <$$

(b) The average surface temperature  $\bar{T}_s$  follows from the expression

$$\bar{T}_s - T_\infty = \frac{1}{L} \int_0^L (T_s - T_\infty) dx = \frac{q_s''}{L} \int_0^L \frac{x}{k Nu_x} dx \quad (3)$$

where  $Nu_x$  is given by Eq. (2). Using the *Integral* function in *IHT* as described in Comment (3) find

$$\bar{T}_s = 86.1^\circ\text{C}. \quad <$$

(c) The variation of the plate surface temperature  $T_s(x)$  and convection coefficient,  $h_x(x)$ , shown in the graph are calculated using Eqs. (1) and (2).

Continued ...

### PROBLEM 7.39 (Cont.)

**COMMENTS:** (1) The properties for the correlation should be evaluated at  $T_f = (\bar{T}_s + T_\infty)/2$ .

From the foregoing analyses,  $T_f = (86.1 + 25)^\circ/2 = 55.5^\circ\text{C} = 329\text{ K}$ . Hence, the assumed value of 325 K was reasonable.

(2) The IHT code, excluding the input variables and air property functions, used to evaluate the integral of Eq. (3) and generate the graphs in part (c) is shown below.

```
/* Programming note: when using the INTEGRAL function, the value of the independent variable
must not be specified as an input variable. If done so, this error message will appear:
"Redefinition of a constant variable." */
```

```
// Turbulent flow correlation, Eq. 7.45, local values
```

```
Nu_x = 0.0308 * Re_x^0.8 * Pr^0.333
```

```
Nu_x = h_x * x / k
```

```
Re_x = uinf * x / nu
```

```
// Plate temperatures
```

```
// Local
```

```
Ts_x = Tinf + q"s / h_x
```

```
// Average
```

```
Ts_avg - Tinf = q"s / L * INTEGRAL (y,x)
```

```
delT_avg = Ts_avg - Tinf
```

```
y = x / (k * Nu_x)
```

## PROBLEM 7.40

**KNOWN:** Experimental apparatus providing nearly uniform airstream over a flat *test plate*. Temperature history of the pre-heated plate for airstream velocities of 3 and 9 m/s were fitted to a fourth-order polynomial.

**FIND:** (a) Convection coefficient for the two cases assuming the plate behaves as a spacewise isothermal object and (b) Coefficients C and m for a correlation of the form  $\overline{Nu}_L = C Re^m Pr^{1/3}$ ; compare result with a standard-plate correlation and comment on the goodness of the comparison; explain any differences.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Airstream over the *test plate* approximates parallel flow over a flat plate, (2) Plate is spacewise isothermal, (3) Negligible radiation exchange between plate and surroundings, (4) Constant properties, and (5) Negligible heat loss from the bottom surface or edges of the test plate.

**PROPERTIES:** Table A.4, Air ( $T_f = (T_s + T_\infty)/2 \approx 310$  K, 1 atm):  $k_a = 0.0269$  W/m·K,  $\nu = 1.669 \times 10^{-5}$  m<sup>2</sup>/s,  $Pr = 0.706$ . Test plate (Given):  $\rho = 2770$  kg/m<sup>3</sup>,  $c_p = 875$  J/kg·K,  $k = 177$  W/m·K.

**ANALYSIS:** (a) Using the lumped-capacitance method, the energy balance on the plate is

$$-\bar{h}_L A_s [T_s(t) - T_\infty] = \rho V c_p \frac{dT}{dt} \quad (1)$$

and the average convection coefficient can be determined from the temperature history,  $T_s(t)$ ,

$$\bar{h}_L = \frac{\rho V c_p}{A_s} \frac{(dT/dt)}{T_s(t) - T_\infty} \quad (2)$$

where the temperature-time derivative is

$$\frac{dT_s}{dt} = b + 2ct + 3dt^2 + 4et^3 \quad (3)$$

The temperature time history plotted below shows the experimental behavior of the observed data.

Continued...

### PROBLEM 7.40 (Cont.)

Consider now the integrated form of the energy balance, Eq. (5.6), expressed as

$$\ln \frac{T_s(t) - T_\infty}{T_i - T_\infty} = - \left( \frac{\bar{h}_L A_s}{\rho V c} \right) t \quad (4)$$

If we were to plot the LHS vs  $t$ , the slope of the curve would be proportional to  $\bar{h}_L$ . Using IHT, plots were generated of  $\bar{h}_L$  vs.  $T_s$ , Eq. (1), and  $\ln \left[ (T_s(t) - T_\infty) / (T_i - T_\infty) \right]$  vs.  $t$ , Eq. (4). From the latter plot, recognize that the regions where the slope is constant corresponds to early times ( $\leq 100$ s when  $u_\infty = 3$  m/s and  $\leq 50$ s when  $u_\infty = 5$  m/s).

Selecting two elapsed times at which to evaluate  $\bar{h}_L$ , the following results were obtained

$u_\infty$ (m/s)	$t$ (s)	$T_s(t)$ , ( $^\circ\text{C}$ )	$\bar{h}_L$ ( $\text{W}/\text{m}^2 \cdot \text{K}$ )	$\overline{\text{Nu}}_L$	$\text{Re}_L$
3	100	44.77	30.81	152.4	$2.39 \times 10^4$
9	50	45.80	56.7	280.4	$7.17 \times 10^4$

where the dimensionless parameters are evaluated as

$$\overline{\text{Nu}}_L = \frac{\bar{h}_L L}{k_a} \quad \text{Re}_L = \frac{u_\infty L}{\nu} \quad (5,6)$$

where  $k_a$ ,  $\nu$  are thermophysical properties of the airstream.

(b) Using the above pairs of  $\overline{\text{Nu}}_L$  and  $\text{Re}_L$ ,  $C$  and  $m$  in the correlation can be evaluated,

$$\overline{\text{Nu}}_L = C \text{Re}_L^m \text{Pr}^{1/3} \quad (7)$$

$$152.4 = C(2.39 \times 10^4)^m (0.706)^{1/3}$$

$$280.4 = C(7.17 \times 10^4)^m (0.706)^{1/3}$$

Solving, find

$$C = 0.633 \quad m = 0.555 \quad (8,9) <$$

Continued...

### PROBLEM 7.40 (Cont.)

The plot below compares the experimental correlation ( $C = 0.633$ ,  $m = 0.555$ ) with those for laminar flow ( $C = 0.664$ ,  $m = 0.5$ ) and fully turbulent flow ( $C = 0.037$ ,  $m = 0.8$ ). The experimental correlation yields  $\overline{Nu}_L$  values which are 25% higher than for the correlation. The most likely explanation for this unexpected trend is that the airstream reaching the plate is not parallel, but with a slight impingement effect and/or the flow is very highly turbulent at the leading edge.

**COMMENTS:** (1) A more extensive analysis of the experimental observations would involve determining  $\overline{Nu}_L$  for the full range of elapsed time (rather than at two selected times) and using a fitting routine to determine values for  $C$  and  $m$ .

## PROBLEM 7.41

**KNOWN:** Conditions for airflow over isothermal plate with optional unheated starting length.

**FIND:** (a) local coefficient,  $h_x$ , at leading and trailing edges with and without an unheated starting length,  $\xi = 1$  m.

**SCHEMATIC:**

**PROPERTIES:** Table A.4, Air ( $T_f = 325$  K, 1 atm):  $\nu = 18.4 \times 10^{-6}$  m<sup>2</sup>/s, Pr = 0.703,  $k = 0.0282$  W/m·K.

**ANALYSIS:** (a) The Reynolds number at  $\xi = 1$  m is

$$Re_\xi = \frac{u_\infty \xi}{\nu} = \frac{2 \text{ m/s} \times 1 \text{ m}}{18.4 \times 10^{-6} \text{ m}^2/\text{s}} = 1.087 \times 10^5$$

If  $Re_{x,c} = 5 \times 10^5$ , flow is laminar over the entire plate (with or without the starting length). In general,

$$Nu_x = \frac{0.332 Re_x^{1/2} Pr^{1/3}}{\left[1 - (\xi/x)^{3/4}\right]^{1/3}} \quad (1)$$

$$h_x = \frac{(0.332k Pr^{1/3}) Re_x^{1/2}}{x \left[1 - (\xi/x)^{3/4}\right]^{1/3}} = 0.00832 \text{ W/m} \cdot \text{K} \frac{Re_x^{1/2}}{x \left[1 - (\xi/x)^{3/4}\right]^{1/3}}$$

*With Unheated Starting Length:* Leading edge ( $x = 1$  m):  $Re_x = Re_\xi$ ,  $\xi/x = 1$ ,  $h_x = \infty$  <

Trailing Edge ( $x = 2$  m):  $Re_x = 2 Re_\xi = 2.17 \times 10^5$ ,  $\xi/x = 0.5$

$$h_x = 0.00832 \text{ W/m} \cdot \text{K} \frac{(2.17 \times 10^5)^{1/2}}{2 \text{ m} \left[1 - (0.5)^{3/4}\right]^{1/3}} = 2.61 \text{ W/m}^2 \cdot \text{K} \quad <$$

*Without Unheated Starting Length:* Leading edge ( $x = 0$ ):  $h_x = \infty$  <

Trailing edge ( $x = 1$  m):  $Re_x = 1.087 \times 10^5$

$$h_x = 0.00832 \text{ W/m} \cdot \text{K} \frac{(1.087 \times 10^5)^{1/2}}{1 \text{ m}} = 2.74 \text{ W/m}^2 \cdot \text{K} \quad <$$

(b) The average convection coefficient  $\bar{h}_L$  for the two cases in the schematic are, from Eq. 6.14,

Continued...

### PROBLEM 7.41 (Cont.)

$$\bar{h}_L = \frac{1}{L} \int_0^L h_x(x) dx \quad (2)$$

where L is the x location at the end of the heated section. Substituting Eq. (1) into Eq. (2) and numerically integrating, the results are tabulated below:

$\xi$ (m)	$h_x(L)$ (W/m <sup>2</sup> ·K)	$\bar{h}_L$ (W/m <sup>2</sup> ·K)
0	2.74	5.41
1	2.61	4.22

(c) The variation of the local convection coefficient over the plate, with and without the unheated starting length, using Eq. (1) is shown below. The abscissa is  $x - \xi$ .

**COMMENTS:** (1) When the velocity and thermal boundary layers grow simultaneously (*without starting length*), we expect the local and average coefficients to be larger than when the velocity boundary layer is thicker (*with starting length*).

(2) When  $\xi = 0$ ,  $\bar{h}_L = 2h_L$ , when  $\xi = 1$ ,  $\bar{h}_L < 2h_L$ . From Eq. (7.44),  $\bar{h}_L = 4.25 \text{ W/m}^2 \cdot \text{K}$ .

(3) The numerical integration of Eq. (2) was performed using the INTEGRAL (f,x) operation in IHT as shown in the Workspace below.

**// Average Coefficient:**

```
hbarL = 1 / (L - zeta) * INTEGRAL (hx,x)
```

**// Local Coefficient With Unheated Starting Length:**

```
hx = (k / x) * 0.332 * Rex^0.5 * Pr^0.3333 / (1 - (zeta / x)^(3/4))^(1/3)
Rex = uinf * x / nu
```

**// Properties Tool - Air:**

```
// Air property functions : From Table A.4
// Units: T(K); 1 atm pressure
nu = nu_T("Air",Tf) // Kinematic viscosity, m^2/s
k = k_T("Air",Tf) // Thermal conductivity, W/m-K
Pr = Pr_T("Air",Tf) // Prandtl number
Tf = 325 // Film temperature, K
```

**// Assigned Variables:**

```
uinf = 2 // Airstream velocity, m/s
x = 1 // Distance from leading edge, m
L = 2 // Full length of plate, m
zeta = 1 // Starting length, m
xzeta = x - zeta // Difference
```

## PROBLEM 7.42

**KNOWN:** Dimensions of thin fuel cell in parallel flow. Ambient and surroundings temperatures, fuel cell emissivity, desired fuel cell operating temperature. Fuel cell thermal generation rate.

**FIND:** Minimum velocity needed to sustain desired fuel cell temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Negligible temperature variations inside the fuel cell, (3) Large surroundings, (4) Insulated fuel cell edges, (5) Negligible energy entering or leaving the fuel cell due to gas or liquid flows, (6), Constant properties, (7) Isothermal fuel cell, (8) Trip wire causes laminar-to-turbulent transition.

**PROPERTIES:** Table A.4, air ( $T_f = (77^\circ\text{C} + 27^\circ\text{C})/2 = 52^\circ\text{C} = 325\text{K}$ ,  $p = 1\text{ atm}$ ):  $\nu = 18.4 \times 10^{-6}\text{ m}^2/\text{s}$ ,  $Pr = 0.704$ ,  $k = 0.0282\text{ W/m}\cdot\text{K}$ .

**ANALYSIS:** An energy balance on the control volume yields  $\dot{E}_g = q_{\text{rad}} + q_{\text{cv}}$  or

$$\begin{aligned} q_{\text{cv}} &= \dot{E}_g - 2LW\varepsilon\sigma(T_c^4 - T_{\text{sur}}^4) \\ &= 11\text{W} - 2 \times (50 \times 10^{-3}\text{m})^2 \times 0.85 \times 5.67 \times 10^{-8}\text{W/m}^2 \cdot \text{K}^4 \times \left[ (273 + 77\text{K})^4 - (273 + 27\text{K})^4 \right] \\ &= 9.34\text{W} \end{aligned}$$

Applying Newton's law of cooling yields

$$\bar{h} = \frac{q_{\text{cv}}}{2LW(T_c - T_\infty)} = \frac{9.34\text{W}}{2 \times (50 \times 10^{-3}\text{m})^2 \times (77 - 27)^\circ\text{C}} = 37.4\text{W/m}^2 \cdot \text{K}$$

Since the flow may transition at the location of the trip wire, Eqs. (7.38) and (7.39) may be applied, yielding

$$\bar{h} = \frac{0.0282\text{W/m}\cdot\text{K}}{0.050\text{m}} \left( 0.037Re_L^{4/5} - 0.037Re_{x,c}^{4/5} + 0.664Re_{x,c}^{1/2} \right) 0.704^{1/3} = 37.4\text{W/m}^2 \cdot \text{K}$$

where  $Re_L = VL/\nu = V \times 0.050\text{m}/18.4 \times 10^{-6}\text{m}^2/\text{s}$  and  $Re_{x,c} = Vx_c/\nu = Vx_c/18.4 \times 10^{-6}\text{m}^2/\text{s}$

The preceding three equations may be solved for the free stream velocity,  $V$ , for various trip wire locations,  $x_c$ . The results are shown in the following graph. From the graph, we note that the minimum air velocity is approximately  $V_{\text{min}} = 3.84\text{ m/s}$  with a trip wire location of  $x_c = 15\text{ mm}$ .

<  
Continued...

### PROBLEM 7.42 (Cont.)

**COMMENTS:** (1) The optimal trip wire location takes advantage of the very high local Nusselt numbers associated with very thin laminar boundary layers near the leading edge of the fuel cell. Once the local Nusselt numbers within the laminar section begin to decrease, the flow is tripped to take advantage of the increased local Nusselt numbers of turbulent boundary layers. Hence, an optimum trip wire location exists. (2) The *maximum* Reynolds number based upon the fuel cell length and a maximum velocity of approximately  $V_{\max} = 4.65 \text{ m/s}$  is  $Re_{\max,L} = 4.65 \text{ m/s} \times 0.050 \text{ m} / 18.4 \times 10^{-6} \text{ m}^2/\text{s} = 12,630$ . This is far below the typical transition Reynolds number of 500,000, and the flow will be laminar if it is not tripped into a turbulent condition. (3) The reduction in the air velocity associated with placement of the trip wires is significant and will result in substantially reduced power requirements to operate the cooling fan.

### PROBLEM 7.43

**KNOWN:** Cover plate dimensions and temperature for flat plate solar collector. Air flow conditions.

**FIND:** (a) Heat loss with simultaneous velocity and thermal boundary layer development, (b) Heat loss with unheated starting length.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Negligible radiation, (3) Boundary layer is not disturbed by roof-plate interface, (4)  $Re_{x,c} = 5 \times 10^5$ .

**PROPERTIES:** Table A-4, Air ( $T_f = 285.5\text{K}$ , 1 atm):  $\nu = 14.6 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0251 \text{ W/m}\cdot\text{K}$ ,  $Pr = 0.71$ .

**ANALYSIS:** (a) The Reynolds number for the plate of  $L = 1\text{ m}$  is

$$Re_L = \frac{u_\infty L}{\nu} = \frac{2 \text{ m/s} \times 1 \text{ m}}{14.6 \times 10^{-6} \text{ m}^2/\text{s}} = 1.37 \times 10^5 < Re_{x,c}$$

For laminar flow

$$\overline{Nu}_L = 0.664 Re_L^{1/2} Pr^{1/3} = 0.664 (1.37 \times 10^5)^{1/2} (0.71)^{1/3} = 219.2$$

$$q = \frac{k}{L} \overline{Nu}_L A_s (T_s - T_\infty) = \frac{0.0251 \text{ W/m}\cdot\text{K}}{1 \text{ m}} 219.2 (2 \text{ m}^2) 5^\circ\text{C} = 55 \text{ W.} \quad <$$

(b) The Reynolds number for the roof and collector of length  $L = 3\text{ m}$  is

$$Re_L = \frac{2 \text{ m/s} \times 3 \text{ m}}{14.6 \times 10^{-6} \text{ m}^2/\text{s}} = 4.11 \times 10^5 < Re_{x,c}$$

Hence, laminar boundary layer conditions exist throughout and the heat rate is

$$q = \int_{\xi}^L q'' dA = (T_s - T_\infty) 0.332 \left( \frac{u_\infty}{\nu} \right)^{1/2} Pr^{1/3} kW \int_{\xi}^L \frac{x^{-1/2} dx}{\left[ 1 - (\xi/x)^{3/4} \right]^{1/3}}$$

$$q = (5^\circ\text{C}) 0.332 \left( \frac{2 \text{ m/s}}{14.6 \times 10^{-6} \text{ m}^2/\text{s}} \right)^{1/2} (0.71)^{1/3} 0.0251 \frac{\text{W}}{\text{m}\cdot\text{K}} 2 \text{ m} \int_{\xi}^L \frac{x^{-1/2} dx}{\left[ 1 - (\xi/x)^{3/4} \right]^{1/3}}$$

Using a numerical technique to evaluate the integral,

$$q = 27.50 \int_2^3 \frac{x^{-1/2} dx}{\left[ 1 - (2.0/x)^{3/4} \right]^{1/3}} = 27.50 \times 1.417 = 39 \text{ W} \quad <$$

**COMMENTS:** Values of  $\bar{h}$  with and without the unheated starting length are 3.9 and 5.5  $\text{W/m}^2\cdot\text{K}$ . Prior development of the velocity boundary layer decreases  $\bar{h}$ .

### PROBLEM 7.44

**KNOWN:** Surface dimensions for an array of 10 silicon chips. Maximum allowable chip temperature. Air flow conditions.

**FIND:** Maximum allowable chip electrical power (a) without and (b) with a turbulence promoter at the leading edge.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Film temperature of 52°C, (3) Negligible radiation, (4) Negligible heat loss through insulation, (5) Uniform heat flux at chip interface with air, (6)

$$Re_{x,c} = 5 \times 10^5.$$

**PROPERTIES:** Table A-4, Air ( $T_f = 325\text{K}$ , 1 atm):  $\nu = 18.4 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0282 \text{ W/m}\cdot\text{K}$ ,  $Pr = 0.703$ .

**ANALYSIS:**  $Re_L = u_\infty L / \nu = 40 \text{ m/s} \times 0.1 \text{ m} / 18.4 \times 10^{-6} \text{ m}^2/\text{s} = 2.174 \times 10^5$ . Hence, flow is laminar over all chips without the promoter.

(a) For *laminar flow*, the minimum  $h_x$  exists on the last chip. Approximating the average coefficient for Chip 10 as the local coefficient at  $x = 95 \text{ mm}$ ,  $\bar{h}_{10} = h_x = 0.095 \text{ m}$ .

$$\bar{h}_{10} = 0.453 \frac{k}{x} Re_x^{1/2} Pr^{1/3}$$

$$Re_x = \frac{u_\infty x}{\nu} = \frac{40 \text{ m/s} \times 0.095 \text{ m}}{18.4 \times 10^{-6} \text{ m}^2/\text{s}} = 2.065 \times 10^5$$

$$\bar{h}_{10} = 0.453 \frac{0.0282 \text{ W/m}\cdot\text{K}}{0.095} \left(2.065 \times 10^5\right)^{1/2} (0.703)^{1/3} = 54.3 \text{ W/m}^2 \cdot \text{K}$$

$$q_{10} = \bar{h}_{10} A (T_s - T_\infty) = 54.3 \frac{\text{W}}{\text{m}^2 \cdot \text{K}} (0.01 \text{ m})^2 (80 - 24)^\circ \text{C} = 0.30 \text{ W}.$$

Hence, if all chips are to dissipate the same power and  $T_s$  is not to exceed 80°C.

$$q_{\max} = 0.30 \text{ W}. \quad <$$

(b) For *turbulent flow*,

$$\bar{h}_{10} = 0.0308 \frac{k}{x} Re_x^{4/5} Pr^{1/3} = 0.0308 \frac{0.0282 \text{ W/m}\cdot\text{K}}{0.095 \text{ m}} \left(2.065 \times 10^5\right)^{4/5} (0.703)^{1/3} = 145 \text{ W/m}^2 \cdot \text{K}$$

$$q_{10} = \bar{h}_{10} A (T_s - T_\infty) = 145 \frac{\text{W}}{\text{m}^2 \cdot \text{K}} (0.01 \text{ m})^2 (80 - 24)^\circ \text{C} = 0.81 \text{ W}.$$

Hence,  $q_{\max} = 0.81 \text{ W}.$  <

**COMMENTS:** It is far better to orient array normal to the air flow. Since  $\bar{h}_1 > \bar{h}_{10}$ , more heat could be dissipated per chip, and the same heat could be dissipated from each chip.

### PROBLEM 7.45

**KNOWN:** Dimensions and maximum allowable temperature of a silicon chip. Air flow conditions.

**FIND:** Maximum allowable power with or without unheated starting length.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2)  $T_f = 52^\circ\text{C}$ , (3) Negligible radiation, (4) Negligible heat loss through insulation, (5) Uniform heat flux at chip-air interface, (6)  $\text{Re}_{x,c} = 5 \times 10^5$ .

**PROPERTIES:** Table A-4, Air ( $T_f = 325\text{K}$ , 1 atm):  $\nu = 18.41 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0282 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.703$ .

**ANALYSIS:** For uniform heat flux, maximum  $T_s$  corresponds to minimum  $h_x$ . Without unheated starting length,

$$\text{Re}_L = \frac{u_\infty L}{\nu} = \frac{20 \text{ m/s} \times 0.01 \text{ m}}{18.41 \times 10^{-6} \text{ m}^2/\text{s}} = 10,864.$$

With the unheated starting length,  $L = 0.03 \text{ m}$ ,  $\text{Re}_L = 32,591$ . Hence, the flow is laminar in both cases and the minimum  $h_x$  occurs at the trailing edge ( $x = L$ ).

Without unheated starting length,

$$h_L = \frac{k}{L} 0.453 \text{Re}_L^{1/2} \text{Pr}^{1/3} = \frac{0.0282 \text{ W/m}\cdot\text{K}}{0.01 \text{ m}} 0.453 (10,864)^{1/2} (0.703)^{1/3}$$

$$h_L = 118 \text{ W/m}^2 \cdot \text{K}$$

$$q''(L) = h_L (T_s - T_\infty) = 118 \text{ W/m}^2 \cdot \text{K} (80 - 24)^\circ\text{C} = 6630 \text{ W/m}^2$$

$$q_{\max} = A_s q'' = (10^{-2} \text{ m})^2 6630 \text{ W/m}^2 = 0.66 \text{ W.} \quad <$$

With the unheated starting length,

$$h_L = \frac{k}{L} 0.453 \frac{\text{Re}_L^{1/2} \text{Pr}^{1/3}}{\left[1 - (\xi/L)^{3/4}\right]^{1/3}} = \frac{0.0282 \text{ W/m}\cdot\text{K}}{0.03 \text{ m}} 0.453 \frac{(32,591)^{1/2} (0.703)^{1/3}}{\left[1 - (0.02/0.03)^{3/4}\right]^{1/3}}$$

$$h_L = 107 \text{ W/m}^2 \cdot \text{K}$$

$$q''(L) = h_L (T_s - T_\infty) = 107 \text{ W/m}^2 \cdot \text{K} (80 - 24)^\circ\text{C} = 6013 \text{ W/m}^2$$

$$q_{\max} = A_s q'' = 10^{-4} \text{ m}^2 \times 6013 \text{ W/m}^2 = 0.60 \text{ W.} \quad <$$

**COMMENTS:** Prior velocity boundary layer development on the unheated starting section decreases  $h_x$ , although the effect diminishes with increasing  $x$ .

## PROBLEM 7.46

**KNOWN:** Cylinder diameter and surface temperature. Temperature and velocity of fluids in cross flow.

**FIND:** (a) Rate of heat transfer per unit length for the fluids: atmospheric air and saturated water, and engine oil, for velocity  $V = 5$  m/s, using the Churchill-Bernstein correlation, and (b) Compute and plot  $q'$  as a function of the fluid velocity  $0.5 \leq V \leq 10$  m/s.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Uniform cylinder surface temperature.

**PROPERTIES:** Table A.4, Air ( $T_f = 308$  K, 1 atm):  $\nu = 16.69 \times 10^{-6}$  m<sup>2</sup>/s,  $k = 0.0269$  W/m·K,  $Pr = 0.706$ ; Table A.6, Saturated Water ( $T_f = 308$  K):  $\rho = 994$  kg/m<sup>3</sup>,  $\mu = 725 \times 10^{-6}$  N·s/m<sup>2</sup>,  $k = 0.625$  W/m·K,  $Pr = 4.85$ ; Table A.5, Engine Oil ( $T_f = 308$  K):  $\nu = 340 \times 10^{-6}$  m<sup>2</sup>/s,  $k = 0.145$  W/m·K,  $Pr = 4000$ .

**ANALYSIS:** (a) For each fluid, calculate the Reynolds number and use the Churchill-Bernstein correlation, Eq. 7.54,

$$\overline{Nu}_D = \frac{\bar{h}D}{k} = 0.3 + \frac{0.62 Re_D^{1/2} Pr^{1/3}}{\left[1 + (0.4/Pr)^{2/3}\right]^{1/4}} \left[1 + \left(\frac{Re_D}{282,000}\right)^{5/8}\right]^{4/5}$$

*Fluid: Atmospheric Air*

$$Re_D = \frac{VD}{\nu} = \frac{(5 \text{ m/s})0.01 \text{ m}}{16.69 \times 10^{-6} \text{ m}^2/\text{s}} = 2996$$

$$\overline{Nu}_D = 0.3 + \frac{0.62(2996)^{1/2} (0.706)^{1/3}}{\left[1 + (0.4/0.706)^{2/3}\right]^{1/4}} \left[1 + \left(\frac{2996}{282,000}\right)^{5/8}\right]^{4/5} = 28.1$$

$$\bar{h} = \frac{k}{D} \overline{Nu}_D = \frac{0.0269 \text{ W/m}\cdot\text{K}}{0.01 \text{ m}} 28.1 = 75.5 \text{ W/m}^2 \cdot \text{K}$$

$$q' = \bar{h}\pi D(T_s - T_\infty) = 75.5 \text{ W/m}^2 \cdot \text{K} \pi (0.01 \text{ m})(50 - 20)^\circ \text{C} = 71.1 \text{ W/m} \quad <$$

*Fluid: Saturated Water*

$$Re_D = \frac{VD}{\nu} = \frac{(5 \text{ m/s})0.01 \text{ m}}{725 \times 10^{-6} \text{ N}\cdot\text{s/m}^2 / 994 \text{ kg/m}^3} = 68,552$$

$$\overline{Nu}_D = 0.3 + \frac{0.62(68,552)^{1/2} (4.85)^{1/3}}{\left[1 + (0.4/4.85)^{2/3}\right]^{1/4}} \left[1 + \left(\frac{68,552}{282,000}\right)^{5/8}\right]^{4/5} = 347$$

Continued...

**PROBLEM 7.46 (Cont.)**

$$\bar{h} = \frac{k}{D} \overline{\text{Nu}}_D = \frac{0.625 \text{ W/m} \cdot \text{K}}{0.01 \text{ m}} 347 = 21,690 \text{ W/m}^2 \cdot \text{K} \quad q' = 20,438 \text{ W/m} \quad <$$

Fluid: Engine Oil

$$\text{Re}_D = \frac{VD}{\nu} = \frac{(5 \text{ m/s})0.01 \text{ m}}{340 \times 10^{-6} \text{ m}^2/\text{s}} = 147$$

$$\overline{\text{Nu}}_D = 0.3 + \frac{0.62(147)^{1/2} (4000)^{1/3}}{\left[1 + (0.4/4000)^{2/3}\right]^{1/4}} \left[1 + \left(\frac{147}{282,000}\right)^{5/8}\right]^{4/5} = 120$$

$$\bar{h} = \frac{k}{D} \overline{\text{Nu}}_D = \frac{0.145 \text{ W/m} \cdot \text{K}}{0.01 \text{ m}} 120 = 1740 \text{ W/m}^2 \cdot \text{K} \quad q' = 1639 \text{ W/m} \quad <$$

(b) Using the *IHT Correlations Tool, External Flow, Cylinder*, along with the *Properties Tool* for each of the fluids, the heat rates,  $q'$ , were calculated for the range  $0.5 \leq V \leq 10 \text{ m/s}$ . Note the  $q'$  scale multipliers for the air and oil fluids which permit easy comparison of the three curves.

**COMMENTS:** (1) Note the inapplicability of the Zukauskas relation, Eq. 7.53, since  $\text{Pr}_{\text{oil}} > 500$ .

(2) In the plot above, recognize that the heat rate for the water is more than 10 times that with oil and 300 times that with air. How do changes in the velocity affect the heat rates for each of the fluids?

### PROBLEM 7.47

**KNOWN:** Conditions associated with air in cross flow over a pipe.

**FIND:** (a) Drag force per unit length of pipe, (b) Heat transfer per unit length of pipe.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Uniform cylinder surface temperature, (3) Negligible radiation effects.

**PROPERTIES:** Table A-4, Air ( $T_f = 335 \text{ K}$ , 1 atm):  $\nu = 19.31 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\rho = 1.048 \text{ kg/m}^3$ ,  $k = 0.0288 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.702$ .

**ANALYSIS:** (a) From the definition of the drag coefficient with  $A_f = DL$ , find

$$F_D = C_D A_f \frac{\rho V^2}{2}$$

$$F_D' = C_D D \frac{\rho V^2}{2}$$

With

$$\text{Re}_D = \frac{VD}{\nu} = \frac{15 \text{ m/s} \times (0.025 \text{ m})}{19.31 \times 10^{-6} \text{ m}^2/\text{s}} = 1.942 \times 10^4$$

from Fig. 7.9,  $C_D \approx 1.1$ . Hence

$$F_D = 1.1(0.025 \text{ m}) 1.048 \text{ kg/m}^3 (15 \text{ m/s})^2 / 2 = 3.24 \text{ N/m.} \quad <$$

(b) Using Hilpert's relation, with  $C = 0.193$  and  $m = 0.618$  from Table 7.2,

$$\bar{h} = \frac{k}{D} C \text{Re}_D^m \text{Pr}^{1/3} = \frac{0.0288 \text{ W/m}\cdot\text{K}}{0.025 \text{ m}} \times 0.193 (1.942 \times 10^4)^{0.618} (0.702)^{1/3}$$

$$\bar{h} = 88 \text{ W/m}^2 \cdot \text{K}.$$

Hence, the heat rate per unit length is

$$q' = \bar{h}(\pi D) (T_s - T_\infty) = 88 \text{ W/m}^2 \cdot \text{K} (\pi \times 0.025 \text{ m}) (100 - 25)^\circ\text{C} = 520 \text{ W/m.} \quad <$$

**COMMENTS:** Using the Zukauskas correlation and evaluating properties at  $T_\infty$  ( $\nu = 15.71 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0261 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.707$ ), but with  $\text{Pr}_s = 0.695$  at  $T_s$ ,

$$\bar{h} = \frac{0.0261}{0.025} 0.26 \left( \frac{15 \times 0.025}{15.71 \times 10^{-6}} \right)^{0.6} (0.707)^{0.37} (0.707/0.695)^{1/4} = 102 \text{ W/m}^2 \cdot \text{K}.$$

This result agrees with that obtained from Hilpert's relation to within the uncertainty normally associated with convection correlations.

## PROBLEM 7.48

**KNOWN:** Dimensions of a vertical copper tube experiencing crossflow. Air velocity and temperature, water temperature inside the tube.

**FIND:** (a) The heat loss per unit mass from the water (W/kg) when the pipe is full. (b) The heat loss from the water (W/kg) when the pipe is half full.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Constant properties, (3) Tube behaves as an infinite fin, (4) Water is well-mixed, (5) One-dimensional heat transfer, (6) Inside copper wall temperature at water temperature, (7) Negligible heat transfer to/from the gas above the liquid water, (8) Negligible radiation.

**PROPERTIES:** Table A.4, air assumed: ( $T_f = (0^\circ\text{C} - 20^\circ\text{C})/2 = -10^\circ\text{C} \approx 263\text{K}$ ,  $p = 1\text{ atm}$ ):  $\nu = 12.6 \times 10^{-6}\text{ m}^2/\text{s}$ ,  $Pr = 0.717$ ,  $k = 0.0233\text{ W/m}\cdot\text{K}$ . Table A.1, copper: ( $T = 300\text{ K}$ ):  $k_{\text{CU}} = 401\text{ W/m}\cdot\text{K}$ . Table A.6, water ( $T = 273\text{ K}$ ),  $\rho = 1000\text{ kg/m}^3$ .

**ANALYSIS:** For either case, the average convection coefficient about the tube must be evaluated. The Reynolds number, based upon the outer diameter  $D_o = 20\text{ mm} + 4\text{ mm} = 24\text{ mm}$  is  $Re_D = VD_o/\nu = 3\text{ m/s} \times 24 \times 10^{-3}\text{ m}/12.6 \times 10^{-6}\text{ m}^2/\text{s} = 5714$ . Using Eq. 7.54, the average heat transfer coefficient about the exterior of the tube is

$$h = \frac{0.0233\text{ W/m}\cdot\text{K}}{24 \times 10^{-3}\text{ m}} \left\{ 0.3 + \frac{0.62(5714^{1/2})0.717^{1/3}}{\left[1 + (0.4/0.717)^{2/3}\right]^{1/4}} \left[ 1 + \left(\frac{5714}{282,000}\right)^{5/8} \right]^{4/5} \right\} = 38.56\text{ W/m}^2\cdot\text{K}$$

(a) From Eq. 3.34 heat loss from the water is

$$q = 1\text{ m} \times \frac{(0 - (-20)^\circ\text{C})}{\frac{\ln(24/20)}{2\pi \times 401\text{ W/m}\cdot\text{K}} + \frac{1}{\pi \times 24 \times 10^{-3}\text{ m} \times 38.56\text{ W/m}^2\cdot\text{K}}} = 58\text{ W}$$

while the mass of water is  $M = \pi(D_i^2/4)L\rho = \pi \times (20 \times 10^{-3}\text{ m})^2/4 \times 1\text{ m} \times 1000\text{ kg/m}^3 = 0.314\text{ kg}$ . Hence, the heat loss per unit mass of water is

$$q_M = q/M = 58\text{ W}/0.314\text{ kg} = 185\text{ W/kg.} \quad \leftarrow$$

Continued...

### PROBLEM 7.48 (Cont.)

(b) When the tube is half full, the upper half of the tube will act as a fin. The total heat loss per unit mass will be  $q_M = q_{M1} + q_{M2}$  where  $q_{M1}$  is the radial heat loss that is the same as in part (a) and  $q_{M2}$  is the heat loss to the upper half of the copper tubing, which serves as a fin. From part (a)  $q_{M1} = 185$  W/kg. Assuming an infinite fin and recognizing that the cross-sectional area is associated with the inner and outer diameters of the tubing,

$$\begin{aligned} q_{M2} &= \sqrt{hPkA_c} \theta_b / M \\ &= \sqrt{38.56 \text{ W/m}^2 \cdot \text{K} \times \pi \times 24 \times 10^{-3} \text{ m} \times 401 \text{ W/m} \cdot \text{K} \times \pi \left( (24 \times 10^{-3} \text{ m})^2 - (20 \times 10^{-3} \text{ m})^2 \right) / 4} \\ &\quad \times (0 - (-20))^\circ\text{C} / 0.157 \text{ kg} \\ &= 51.3 \text{ W/kg} \end{aligned}$$

Therefore,  $q_M = 185 \text{ W/kg} + 51.3 \text{ W/kg} = 236 \text{ W/kg}$  <

**COMMENTS:** (1) The fin effect is significant, and the water in the half-full tube will freeze before the water in the full tube. (2) The temperature distribution in the copper tubing above the water level in the half-full tubing is  $\theta/\theta_b = \exp^{-mx}$  where  $x$  is a local coordinate with origin at the water level. For this problem,

$$\begin{aligned} m &= \sqrt{hP/kA_c} = \sqrt{4hD_o/k(D_o^2 - D_i^2)} \\ &= \sqrt{4 \times 38.56 \text{ W/m}^2 \cdot \text{K} \times 24 \times 10^{-3} \text{ m} / 401 \text{ W/m} \cdot \text{K} \left( (24 \times 10^{-3} \text{ m})^2 - (20 \times 10^{-3} \text{ m})^2 \right)} = 7.24 \text{ m}^{-1}. \end{aligned}$$

Therefore, over a 0.5 m length above the water surface for part (b), the temperature decreases to  $T(x = 0.5 \text{ m}) = -20^\circ\text{C} + (20^\circ\text{C})\exp(-7.24 \text{ m}^{-1} \times 0.5 \text{ m}) = -19.5^\circ\text{C}$ . The assumption of an infinitely long fin is reasonable.

### PROBLEM 7.49

**KNOWN:** Initial temperature, power dissipation, diameter, and properties of heating element. Velocity and temperature of air in cross flow.

**FIND:** (a) Steady-state temperature, (b) Time to come within 10°C of steady-state temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Uniform heater temperature, (2) Negligible radiation.

**PROPERTIES:** Table A.4, air (assume  $T_f \approx 450$  K):  $\nu = 32.39 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0373 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.686$ .

**ANALYSIS:** (a) Performing an energy balance for steady-state conditions, we obtain

$$q'_{\text{conv}} = \bar{h}(\pi D)(T - T_{\infty}) = P'_{\text{elec}} = 1000 \text{ W/m}$$

With

$$\text{Re}_D = \frac{VD}{\nu} = \frac{(10 \text{ m/s})0.01 \text{ m}}{32.39 \times 10^{-6} \text{ m}^2/\text{s}} = 3,087$$

the Churchill and Bernstein correlation, Eq. 7.54, yields

$$\bar{\text{Nu}}_D = 0.3 + \frac{0.62 \text{Re}_D^{1/2} \text{Pr}^{1/3}}{\left[1 + (0.4/\text{Pr})^{2/3}\right]^{1/4}} \left[1 + \left(\frac{\text{Re}_D}{282,000}\right)^{5/8}\right]^{4/5}$$

$$\bar{\text{Nu}}_D = 0.3 + \frac{0.62(3087)^{1/2} (0.686)^{1/3}}{\left[1 + (0.4/0.686)^{2/3}\right]^{1/4}} \left[1 + \left(\frac{3087}{282,000}\right)^{5/8}\right]^{4/5} = 28.2$$

$$\bar{h} = \frac{k}{D} \bar{\text{Nu}}_D = \frac{0.0373 \text{ W/m}\cdot\text{K}}{0.010 \text{ m}} 28.2 = 105.2 \text{ W/m}^2 \cdot \text{K}$$

Hence, the steady-state temperature is

$$T = T_{\infty} + \frac{P'_{\text{elec}}}{\pi D \bar{h}} = 300 \text{ K} + \frac{1000 \text{ W/m}}{\pi(0.01 \text{ m})105.2 \text{ W/m}^2 \cdot \text{K}} = 603 \text{ K} \quad <$$

(b) With  $\text{Bi} = \bar{h}r_0/k = 105.2 \text{ W/m}^2 \cdot \text{K}(0.005 \text{ m})/240 \text{ W/m}\cdot\text{K} = 0.0022$ , a lumped capacitance analysis may be performed. The time response of the heater is given by Eq. 5.25, which, for  $T_i = T_{\infty}$ , reduces to

$$T = T_{\infty} + (b/a)[1 - \exp(-at)]$$

Continued...

### PROBLEM 7.49 (Cont.)

where  $a = 4\bar{h}/D\rho c_p = (4 \times 105.2 \text{ W/m}^2 \cdot \text{K}) / (0.01 \text{ m} \times 2700 \text{ kg/m}^3 \times 900 \text{ J/kg} \cdot \text{K}) = 0.0173 \text{ s}^{-1}$  and  $b/a = P'_{\text{elec}}/\pi D\bar{h} = 1000 \text{ W/m} / \pi (0.01 \text{ m} \times 105.2 \text{ W/m}^2 \cdot \text{K}) = 302.6 \text{ K}$ . Hence,

$$[1 - \exp(-0.0173t)] = \frac{(593 - 300)\text{K}}{302.6\text{K}} = 0.968$$

$$t \approx 200\text{s}$$

&lt;

**COMMENTS:** (1) For  $T = 603 \text{ K}$  and a representative emissivity of  $\varepsilon = 0.8$ , net radiation exchange between the heater and surroundings at  $T_{\text{sur}} = T_{\infty} = 300 \text{ K}$  would be  $q'_{\text{rad}} = \varepsilon\sigma(\pi D)(T^4 - T_{\text{sur}}^4) = 0.8 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (\pi \times 0.01 \text{ m})(603^4 - 300^4)\text{K}^4 = 177 \text{ W/m}$ . Hence, although small, radiation exchange is not negligible. The effects of radiation are considered in Problem 7.50.

(2) The assumed value of  $T_f$  is very close to the actual value, rendering the selected air properties accurate.

## PROBLEM 7.50

**KNOWN:** Initial temperature, power dissipation, diameter, and properties of a heating element. Velocity and temperature of air in cross flow. Temperature of surroundings.

**FIND:** (a) Steady-state temperature, (b) Time to come within 10°C of steady-state temperature, (c) Variation of power dissipation required to maintain a fixed heater temperature of 275°C over a range of velocities.

**SCHEMATIC:**

**ASSUMPTIONS:** Uniform heater surface temperature.

**ANALYSIS:** (a) Performing an energy balance for steady-state conditions, we obtain

$$q'_{conv} + q'_{rad} = P'_{elec}$$

$$\bar{h}(\pi D)(T - T_{\infty}) + \varepsilon\sigma(\pi D)(T^4 - T_{sur}^4) = P'_{elec}$$

$$(\pi \times 0.01 \text{ m}) \left[ \bar{h}(T - 300) \text{ K} + 0.8(5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4)(T^4 - 300^4) \text{ K}^4 \right] = 1000 \text{ W/m}$$

Using the *IHT Energy Balance Model* for an *Isothermal Solid Cylinder* with the *Correlations Tool Pad* for a *Cylinder in Crossflow* and the *Properties Tool Pad* for *Air*, we obtain

$$T = 562.4 \text{ K} \quad \leftarrow$$

where  $\bar{h} = 105.4 \text{ W/m}^2 \cdot \text{K}$ ,  $h_r = 15.9 \text{ W/m}^2 \cdot \text{K}$ ,  $q'_{conv} = 868.8 \text{ W/m}$ , and  $q'_{rad} = 131.2 \text{ W/m}$ .

(b) With  $Bi = (\bar{h} + h_r)r_0/k = (121.3 \text{ W/m}^2 \cdot \text{K})0.005 \text{ m}/240 \text{ W/m} \cdot \text{K} = 0.0025$ , the transient behavior may be analyzed using the lumped capacitance method. Using the *IHT Lumped Capacitance Model* to perform the numerical integration, the following temperature histories were obtained.

Continued...

### PROBLEM 7.50 (Cont.)

The agreement between predictions with and without radiation for  $t < 50$ s implies negligible radiation. However, as the heater temperature increases with time, radiation becomes significant, yielding a reduced heater temperature. Steady-state temperatures correspond to 562.4 K and 602.8 K, with and without radiation, respectively. The time required for the heater to reach 552.4 K (with radiation) is  $t \approx 155$ s.

(c) If the heater temperature is to be maintained at a fixed value in the face of velocity excursions, provision must be made for adjusting the heater power. Using the *Explore* and *Graph* options of IHT with the model of part (a), the following results were obtained.

For  $T = 275^\circ\text{C} = 548$  K, the controller would compensate for velocity reductions from 10 to 5 m/s by reducing the power from approximately 935 to 690 W/m.

**COMMENTS:** Although convection heat transfer substantially exceeds radiation heat transfer, radiation is not negligible and should be included in the analysis. If it is neglected,  $T = 603$  K would be predicted for  $P'_{\text{elec}} = 1000$  W/m, in contrast to 562 K from the results of part (a).

## PROBLEM 7.51

**KNOWN:** Geometry and dimensions of three pin fins. Velocity and temperature of air in cross flow.

**FIND:** Which fin has the largest heat transfer rate.

**SCHEMATIC:**

$V = 10 \text{ m/s}$  for all cases

**ASSUMPTIONS:** (1) Steady-state, (2) Constant properties, (3) Fins can be treated as infinitely long, (4) Presence of fin base doesn't affect heat transfer coefficients.

**PROPERTIES:** Table A-4 Air ( $T = 350 \text{ K}$ ):  $\nu_a = 20.92 \times 10^{-6} \text{ m}^2/\text{s}$

**ANALYSIS:** For infinitely long fins, the fin heat transfer rate is given by Equation 3.85:

$$q_f = \sqrt{hPkA_c} \theta_b$$

In every case, the heat transfer coefficient is found from a correlation of the form,  $\overline{Nu}_D = CRe_D^m Pr^{1/3}$ , thus

$$q_f = \sqrt{\frac{k_a}{D} CRe_D^m Pr_a^{1/3} PkA_c} \theta_b$$

where subscript  $a$  refers to air properties. Since each fin has the same cross-sectional area, the parameters that vary from one configuration to another are  $D$ ,  $C$ ,  $Re_D$ ,  $m$ , and  $P$ . Thus, it is sufficient to examine the combination parameter  $CRe_D^m P / D$  to determine which fin has the largest heat transfer rate.

The cross-sectional area of the circular cylinder is  $A_c = \pi D^2/4$ . Thus the dimension of the square,  $D_s$ , is  $D_s = A_c^{1/2} = \pi^{1/2} D / 2 = \pi^{1/2} (15 \text{ mm}) / 2 = 13.3 \text{ mm}$ . The dimension of the diamond is the same, however  $D_d$  is defined differently. Referring to Table 7.3,  $D_d = 2^{1/2} D_s = 2^{1/2} (13.3 \text{ mm}) = 18.8 \text{ mm}$ . The perimeters are  $P_c = \pi D = 47.1 \text{ mm}$  for the circular cylinder and  $P_s = P_d = 4D_s = 53.2 \text{ mm}$  for both the square and diamond configurations.

The Reynolds number can be calculated from  $Re = VD/\nu_a$ , then  $C$  and  $m$  can be found from Tables 7.2 and 7.3 for the different configurations. The results are tabulated below for all three configurations. A line has been included to represent the heat transfer coefficient, which is proportional to  $CRe_D^m / D$ .

Continued...

### PROBLEM 7.51 (Cont.)

	Configuration A (circular)	Configuration B (square)	Configuration C (diamond)
$D$ (mm)	15	13.3	18.8
$P$ (mm)	47.1	53.2	53.2
$Re_D = VD/\nu_a$	7,170	6,358	8,987
$C$	0.193	0.158	0.304
$m$	0.618	0.66	0.59
$Cre_D^m / D$ ( $m^{-1}$ ) $\sim h$	3106	3846	3478
$Cre_D^m P / D \sim q_f$	146	205	185

For fins of equal mass, the square fin configuration has the largest heat transfer rate.

<

**COMMENTS:** (1) For the same cross-sectional area, the square and diamond configurations have larger perimeters than the circular cylinder, which contributes to the larger heat transfer rate. (2) For the same cross-sectional area, the square and diamond configurations have larger heat transfer coefficients, which also contributes to the larger heat transfer rates.

## PROBLEM 7.52

**KNOWN:** Pin fin of 10 mm diameter dissipates 30 W by forced convection in cross-flow of air with  $Re_D = 4000$ .

**FIND:** Fin heat rate if diameter is doubled while all conditions remain the same.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Pin behaves as infinitely long fin, (2) Conditions of flow, as well as base and air temperatures, remain the same for both situations, (3) Negligible radiation heat transfer.

**ANALYSIS:** For an infinitely long pin fin, the fin heat rate is

$$q_f = q_{conv} = (\bar{h} P k A_c)^{1/2} \theta_b$$

where  $P = \pi D$  and  $A_c = \pi D^2/4$ . Hence,

$$q_{conv} \sim (\bar{h} \cdot D \cdot D^2)^{1/2}.$$

For forced convection cross-flow over a cylinder, an appropriate correlation for estimating the dependence of  $\bar{h}$  on the diameter is

$$\overline{Nu}_D = \frac{\bar{h} D}{k} = C Re_D^m Pr^{1/3} = C \left( \frac{VD}{\nu} \right)^m Pr^{1/3}.$$

From Table 7.2 for  $Re_D = 4000$ , find  $m = 0.466$  and

$$\bar{h} \sim D^{-1} (D)^{0.466} = D^{-0.534}.$$

It follows that

$$q_{conv} \sim (D^{-0.534} \cdot D \cdot D^2)^{1/2} = D^{1.23}.$$

Hence, with  $q_1 \rightarrow D_1$  (10 mm) and  $q_2 \rightarrow D_2$  (20 mm), find

$$q_2 = q_1 \left( \frac{D_2}{D_1} \right)^{1.23} = 30 \text{ W} \left( \frac{20}{10} \right)^{1.23} = 70.4 \text{ W.} \quad <$$

**COMMENTS:** The effect of doubling the diameter, with all other conditions remaining the same, is to increase the fin heat rate by a factor of 2.35. The effect is nearly linear, with enhancements due to the increase in surface and cross-sectional areas ( $D^{1.5}$ ) exceeding the attenuation due to a decrease in the heat transfer coefficient ( $D^{-0.267}$ ). Note that, with increasing Reynolds number, the exponent  $m$  increases and there is greater heat transfer enhancement due to increasing the diameter.

## PROBLEM 7.53

**KNOWN:** Pin fin installed on a surface with prescribed heat rate and temperature.

**FIND:** (a) Maximum heat removal rate possible, (b) Length of the fin, (c) Effectiveness,  $\varepsilon_f$ , (d) Percentage increase in heat rate from surface due to fin.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Conditions over  $A_s$  are uniform for both situations, (3) Conditions over fin length are uniform, (4) Flow over pin fin approximates cross-flow.

**PROPERTIES:** Table A-4, Air ( $T_f = (T_\infty + T_s)/2 = (27 + 127)^\circ\text{C}/2 = 350\text{ K}$ ):  $\nu = 20.92 \times 10^{-6}\text{ m}^2/\text{s}$ ,  $k = 30.0 \times 10^{-3}\text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.700$ . Table A-1, SS AISI304 ( $\bar{T} = T_f = 350\text{ K}$ ):  $k = 15.8\text{ W/m}\cdot\text{K}$ .

**ANALYSIS:** (a) Maximum heat rate from fin occurs when fin is infinitely long,

$$q_f = M = (\bar{h}PkA_c)^{1/2} \theta_b \quad (1)$$

from Eq. 3.85. Estimate convection heat transfer coefficient for cross-flow over cylinder,

$$\text{Re}_D = \frac{VD}{\nu} = 5\text{ m/s} \times 0.005\text{ m} / 20.92 \times 10^{-6}\text{ m}^2/\text{s} = 1195.$$

Using the Hilpert correlation, Eq. 7.52, with Table 7.2, find

$$\bar{h} = \frac{k}{D} \text{CRe}_D^m \text{Pr} = (0.030\text{ W/m}\cdot\text{K} / 0.005\text{ m}) 0.683 (1195)^{0.466} (0.700)^{1/3} = 98.9\text{ W/m}^2\cdot\text{K}$$

From Eq. (1), with  $P = \pi D$ ,  $A_c = \pi D^2/4$ , and  $\theta_b = T_s - T_\infty$ , find

$$q_f = \left( 98.9\text{ W/m}^2\cdot\text{K} \times \pi (0.005\text{ m}) \times 15.8\text{ W/m}\cdot\text{K} \times \pi (0.005\text{ m})^2 / 4 \right)^{1/2} (127 - 27)\text{ K} = 2.20\text{ W}. <$$

(b) From Example 3.9,  $L \approx L_\infty = 2.65(kA_c/hP)^{1/2}$ . Hence,

$$L \approx L_\infty = 2.65 \left[ 15.8\text{ W/m}\cdot\text{K} \times \pi (0.005\text{ m})^2 / 4 / 98.9\text{ W/m}^2\cdot\text{K} \times \pi (0.005\text{ m}) \right]^{1/2} = 37.4\text{ mm}. <$$

(c) From Eq. 3.86, with  $h_s$  used for the base area  $A_s$ , the effectiveness is

$$\varepsilon_f = \frac{q_f}{h_s A_{c,b} \theta_b} = \frac{q_f}{q_{w0}} \frac{A_s}{A_{c,b}} = \frac{2.2\text{ W}}{0.5\text{ W}} \cdot \frac{(0.020 \times 0.020)\text{ m}^2}{\pi (0.005\text{ m})^2 / 4} = 89.6 <$$

where  $h_s = q_{w0} / A_s \theta_b$ .

(d) The percentage increase in heat rate with the installed fin (w) is

$$\frac{q_w - q_{w0}}{q_{w0}} \times 100 = \left( \left[ q_f + h_s \left( A_s - \pi D^2 / 4 \right) (T_s - T_\infty) \right] - q_{w0} \right) \times 100 / q_{w0}$$

$$\Delta q/q = \left\{ \left[ 2.2\text{ W} + 12.5\text{ W/m}^2\cdot\text{K} \left( [0.02\text{ m}]^2 - (\pi/4)(0.005\text{ m})^2 \right) 100\text{ K} - 0.5\text{ W} \right] \times 100 / 0.5\text{ W} \right\}$$

$$\Delta q/q = 435\%. <$$

## PROBLEM 7.54

**KNOWN:** Dimensions of chip and pin fin. Chip temperature. Free stream velocity and temperature of air coolant.

**FIND:** (a) Average pin convection coefficient, (b) Pin heat transfer rate, (c) Total heat rate, (d) Effect of velocity and pin diameter on total heat rate.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) One-dimensional conduction in pin, (3) Constant properties, (4) Convection coefficients on pin surface (tip and side) and chip surface correspond to single cylinder in cross flow, (5) Negligible radiation.

**PROPERTIES:** Table A.1, Copper (350 K):  $k = 399 \text{ W/m}\cdot\text{K}$ ; Table A.4, Air ( $T_f \approx 325 \text{ K}$ , 1 atm):  $\nu = 18.41 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0282 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.704$ .

**ANALYSIS:** (a) With  $V = 10 \text{ m/s}$  and  $D = 0.002 \text{ m}$ ,

$$\text{Re}_D = \frac{VD}{\nu} = \frac{10 \text{ m/s} \times 0.002 \text{ m}}{18.41 \times 10^{-6} \text{ m}^2/\text{s}} = 1087$$

Using the Churchill and Bernstein correlations, Eq. (7.54),

$$\overline{\text{Nu}}_D = 0.3 + \frac{0.62 \text{Re}_D^{1/2} \text{Pr}^{1/3}}{\left[1 + (0.4/\text{Pr})^{2/3}\right]^{1/4}} \left[1 + \left(\frac{\text{Re}_D}{282,000}\right)^{5/8}\right]^{4/5} = 16.7$$

$$\bar{h} = (\overline{\text{Nu}}_D k / D) = (16.7 \times 0.0282 \text{ W/m}\cdot\text{K} / 0.002 \text{ m}) = 235 \text{ W/m}^2 \cdot \text{K} \quad <$$

(b) For the fin with tip convection and

$$M = \left(\bar{h} \pi D k \pi D^2 / 4\right)^{1/2} \theta_b = (\pi/2) \left[235 \text{ W/m}^2 \cdot \text{K} (0.002 \text{ m})^3 399 \text{ W/m}\cdot\text{K}\right]^{1/2} 50 \text{ K} = 2.15 \text{ W}$$

$$m = (\bar{h} P / k A_c)^{1/2} = \left(4 \times 235 \text{ W/m}^2 \cdot \text{K} / 399 \text{ W/m}\cdot\text{K} \times 0.002 \text{ m}\right)^{1/2} = 34.3 \text{ m}^{-1}$$

$$mL = 34.3 \text{ m}^{-1} (0.012 \text{ m}) = 0.412$$

$$(\bar{h} / mk) = \left(235 \text{ W/m}^2 \cdot \text{K} / 34.3 \text{ m}^{-1} \times 399 \text{ W/m}\cdot\text{K}\right) = 0.0172.$$

The fin heat rate is

$$q_f = M \frac{\sinh mL + (\bar{h} / mk) \cosh mL}{\cosh mL + (\bar{h} / mk) \sinh mL} = 0.868 \text{ W} \quad <$$

Continued...

### PROBLEM 7.54 (Cont.)

(c) The total heat rate is that from the base and through the fin,

$$q = q_b + q_f = \bar{h} \left( W^2 - \pi D^2 / 4 \right) \theta_b + q_f = (0.151 + 0.868) W = 1.019 W .$$

<

(d) Using the IHT Extended Surface Model for a Pin Fin with the Correlations Tool Pad for a Cylinder in crossflow and Properties Tool Pad for Air, the following results were generated.

Clearly, there is significant benefit associated with increasing  $V$  which increases the convection coefficient and the total heat rate. Although the convection coefficient decreases with increasing  $D$ , the increase in the total heat transfer surface area is sufficient to yield an increase in  $q$  with increasing  $D$ . The maximum heat rate is  $q = 2.77 \text{ W}$  for  $V = 40 \text{ m/s}$  and  $D = 4 \text{ mm}$ .

**COMMENTS:** Radiation effects should be negligible, although tip and base convection coefficients will differ from those calculated in parts (a) and (d).

## PROBLEM 7.55

**KNOWN:** Diameter, resistivity, thermal conductivity and emissivity of Nichrome wire. Electrical current. Temperature of air flow and surroundings. Velocity of air flow.

**FIND:** (a) Surface and centerline temperatures of the wire, (b) Effect of flow velocity and electric current on temperatures.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, (2) Radiation exchange with large surroundings, (3) Constant Nichrome properties, (4) Uniform surface temperature.

**PROPERTIES:** Prescribed, Nichrome:  $k = 25 \text{ W/m}\cdot\text{K}$ ,  $\rho_e = 10^{-6} \Omega\cdot\text{m}$ ,  $\varepsilon = 0.2$ . *Table A-4*, air ( $T_f \approx 800\text{K}$ :  $k_a = 0.057 \text{ W/m}\cdot\text{K}$ ,  $\nu = 8.5 \times 10^{-5} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.71$ ).

**ANALYSIS:** (a) The surface temperature may be obtained from Eq. 3.60, with  $\bar{h} = \bar{h}_c + h_r$  and

$$\dot{q} = I^2 R_e / \forall = I^2 \rho_e / A_c^2 = I^2 \rho_e / (\pi D^2 / 4)^2 = 1.013 \times 10^9 \text{ W/m}^3.$$

$$T_s = T_\infty + \frac{\dot{q}(D/2)}{2(\bar{h}_c + h_r)} \quad (1)$$

The convection coefficient is obtained from the Churchill and Bernstein correlation

$$\bar{h}_c = \frac{k_a}{D} \left\{ 0.3 + \frac{0.62 \text{Re}_D^{1/2} \text{Pr}^{1/3}}{\left[1 + (0.4/\text{Pr})^{2/3}\right]^{1/4}} \left[1 + \left(\frac{\text{Re}_D}{282,000}\right)^{5/8}\right]^{4/5} \right\} = 230 \text{ W/m}^2 \cdot \text{K}$$

where  $\text{Re}_D = VD/\nu = 58.8$ , and the radiation coefficient is obtained from Eq. 1.9

$$h_r = \varepsilon \sigma (T_s + T_{\text{sur}}) (T_s^2 + T_{\text{sur}}^2) \quad (2)$$

From an iterative solution of Eqs. (1) and (2), we obtain

$$T_s \approx 1285\text{K} = 1012^\circ\text{C} \quad <$$

From Eq. 3.58, the centerline temperature is

$$T_o = \frac{\dot{q}(D/2)^2}{4k} + T_s = \frac{1.013 \times 10^9 \text{ W/m}^3 (0.0005\text{m})^2}{100 \text{ W/m}\cdot\text{K}} + 1012^\circ\text{C} \approx 1014^\circ\text{C} \quad <$$

The centerline temperature is only approximately  $2^\circ\text{C}$  larger than the surface temperature, and the wire may be assumed to be isothermal.

Continued ...

### PROBLEM 7.55 (Cont.)

(b) Over the range  $1 \leq V < 100$  m/s for  $I = 25$  A,  $\bar{h}_c$  varies from approximately  $114 \text{ W/m}^2 \cdot \text{K}$  to  $1050 \text{ W/m}^2 \cdot \text{K}$ , while  $h_r$  varies from approximately  $69 \text{ W/m}^2 \cdot \text{K}$  to  $4 \text{ W/m}^2 \cdot \text{K}$ . The effect on the surface temperature is shown below.

Maximum and minimum values of  $T_s = 1433^\circ\text{C}$  and  $T_s = 290^\circ\text{C}$  are associated with the smallest and largest velocities respectively, while the difference between the centerline and surface temperatures remains at  $(T_o - T_s) \approx 2^\circ\text{C}$ .

For  $V = 5$  m/s, the effect on  $T_s$  of varying the current over the range from 1 to 30 A is shown below.

From a value of  $T_s \approx 52^\circ\text{C}$  at 1 A,  $T_s$  increases to  $1320^\circ\text{C}$  at 30 A. Over this range the temperature difference  $(T_o - T_s)$  increases from approximately  $0.01^\circ\text{C}$  to  $3^\circ\text{C}$ .

**COMMENTS:** (1) The radiation coefficient for the conditions of Part (a) is  $h_r = 32 \text{ W/m}^2 \cdot \text{K}$ , which is approximately 1/8 of the total coefficient  $\bar{h}$ . Hence, except for small values of  $V$  less than approximately 5 m/s, radiation is negligible compared with convection. (2) The small wire diameter and large thermal conductivity are responsible for maintaining nearly isothermal conditions within the wire. (3) The calculations of Part (b) were performed using the IHT solver with the function  $T_f = T_{\text{fluid\_avg}}(T_s, T_{\text{inf}})$  used to account for the effect of temperature on the air properties.

## PROBLEM 7.56

**KNOWN:** Diameter, thickness and thermal conductivity of steel pipe. Temperature of water flow in pipe. Temperature and velocity of air in cross flow over pipe. Cost of producing hot water.

**FIND:** (a) Cost of daily heat loss from an uninsulated pipe, (b) Savings associated with insulating the pipe.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, (2) Negligible convection resistance for water flow, (3) Negligible contact resistance between insulation and pipe, (4) Negligible radiation.

**PROPERTIES:** Table A-4, air ( $p = 1 \text{ atm}$ ,  $T_f \approx 300 \text{ K}$ ):  $k_a = 0.0263 \text{ W/m}\cdot\text{K}$ .

$$\nu = 15.89 \times 10^{-6} \text{ m}^2/\text{s}, \text{ Pr} = 0.707.$$

**ANALYSIS:** (a) With  $\text{Re}_D = VD_o/\nu = 3 \text{ m/s} \times 0.1 \text{ m} / 15.89 \times 10^{-6} \text{ m}^2/\text{s} = 18,880$ , application of the Churchill-Bernstein correlation yields

$$\overline{\text{Nu}}_D = 0.3 + \frac{0.62(18,880)^{1/2} (0.707)^{1/3}}{\left[1 + (0.4/0.707)^{2/3}\right]^{1/4}} \left[1 + \left(\frac{18,880}{282,000}\right)^{5/8}\right]^{4/5} = 76.6$$

$$\bar{h} = \frac{k_a}{D_o} \overline{\text{Nu}}_D = \frac{0.0263 \text{ W/m}\cdot\text{K}}{0.1 \text{ m}} 76.6 = 20.1 \text{ W/m}^2\cdot\text{K}$$

Without the insulation, the total thermal resistance and heat loss per length of pipe are then

$$\begin{aligned} R'_{\text{tot}(\text{wo})} &= \frac{\ln(D_o/D_i)}{2\pi k_p} + \frac{1}{\pi D_o \bar{h}} = \frac{\ln(100/84)}{2\pi \times 60 \text{ W/m}\cdot\text{K}} + \frac{1}{\pi (0.1 \text{ m}) 20.1 \text{ W/m}^2\cdot\text{K}} \\ &= (4.63 \times 10^{-4} + 0.158) \text{ m}\cdot\text{K/W} = 0.159 \text{ m}\cdot\text{K/W} \end{aligned}$$

$$q'_{\text{wo}} = \frac{T - T_\infty}{R'_{\text{tot}(\text{wo})}} = \frac{55^\circ\text{C}}{0.159 \text{ m}\cdot\text{K/W}} = 346 \text{ W/m} = 0.346 \text{ kW/m}$$

The corresponding daily energy loss is

$$Q'_{\text{wo}} = 0.346 \text{ kW/m} \times 24 \text{ h/d} = 8.3 \text{ kW}\cdot\text{h/m}\cdot\text{d}$$

and the associated cost is

$$C'_{\text{wo}} = (8.3 \text{ kW}\cdot\text{h/m}\cdot\text{d})(\$0.05/\text{kW}\cdot\text{h}) = \$0.415/\text{m}\cdot\text{d}$$

<

(b) The conduction resistance of the insulation is

Continued ...

**PROBLEM 7.56 (Cont.)**

$$R'_{\text{cnd}} = \frac{\ln(D_o/D_i)}{2\pi k_i} = \frac{\ln(120/100)}{2\pi(0.026 \text{ W/m}\cdot\text{K})} = 1.116 \text{ m}\cdot\text{K/W}$$

Using the Churchill-Bernstein correlation with an outside diameter of  $D_o = 0.12\text{m}$ ,  $Re_D = 22,660$ ,  $\overline{Nu}_D = 83.9$  and  $\overline{h} = 18.4 \text{ W/m}^2\cdot\text{K}$ . The convection resistance is then

$$R'_{\text{cnv}} = \frac{1}{\pi D_o \overline{h}} = \frac{1}{\pi(0.12\text{m})18.4 \text{ W/m}^2\cdot\text{K}} = 0.144 \text{ m}\cdot\text{K/W}$$

and the total resistance is

$$R'_{\text{tot}(w)} = \left(4.63 \times 10^{-4} + 1.116 + 0.144\right) \text{ m}\cdot\text{K/W} = 1.261 \text{ m}\cdot\text{K/W}$$

The heat loss and cost are then

$$q'_w = \frac{T - T_\infty}{R'_{\text{tot}(w)}} = \frac{55^\circ\text{C}}{1.261 \text{ m}\cdot\text{K/W}} = 43.6 \text{ W/m} = 0.0436 \text{ kW/m}$$

$$C'_w = 0.0436 \text{ kW/m} \times 24 \text{ h/d} \times \$0.05/\text{kW}\cdot\text{h} = \$0.052/\text{m}\cdot\text{d}$$

The daily savings is then

$$S' = C'_{w0} - C'_w = \$0.363/\text{m}\cdot\text{d} \quad \leftarrow$$

**COMMENTS:** (1) The savings are significant, and the pipe should be insulated. (2) Assuming a negligible temperature drop across the pipe wall, a pipe emissivity of  $\epsilon_p = 0.6$  and surroundings at  $T_{\text{sur}} = 268\text{K}$ , the radiation coefficient associated with the uninsulated pipe is  $h_r = \epsilon\sigma(T + T_{\text{sur}})(T^2 + T_{\text{sur}}^2) = 0.6 \times 5.67 \times 10^{-8} \text{ W/m}^2\cdot\text{K}^4 (591\text{K}) (323^2 + 268^2) \text{ K}^2 = 3.5 \text{ W/m}^2\cdot\text{K}$ . Accordingly, radiation increases the heat loss estimate of Part (a) by approximately 17%.

## PROBLEM 7.57

**KNOWN:** Dimension and initial temperature of long aluminum rods of square cross-section. Velocity and temperature of air in cross flow. Rod emissivity and surroundings temperature.

**FIND:** Which orientation of the rod relative to the cross flow should be used to minimize the time needed for the rods to reach a temperature of 60°C. Required cooling time for preferred configuration.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Constant properties.

**PROPERTIES:** Table A-4, Air ( $T = 400$  K):  $\nu = 26.41 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0338 \text{ W/m}\cdot\text{K}$ ,  $Pr = 0.690$ .  
Table A-1, Pure aluminum ( $T = 500$  K):  $\rho_s = 2702 \text{ kg/m}^3$ ,  $c_{p,s} = 991 \text{ J/kg}\cdot\text{K}$ ,  $k_s = 235 \text{ W/m}\cdot\text{K}$ .

**ANALYSIS:** The heat transfer coefficient can be calculated from Equation 7.52, with the dimension  $D$  defined differently for the two configurations, as shown in Table 7.3. When the air flows perpendicular to a face of the rod,

$D = d = 0.025 \text{ m}$ ,  $Re_D = VD/\nu = 8 \text{ m/s} \times 0.025 \text{ m}/26.41 \times 10^{-6} \text{ m}^2/\text{s} = 7573$ , and from Table 7.3,  $C = 0.158$  and  $m = 0.66$ . Thus,

$$\bar{h} = \frac{k}{D} C Re_D^m Pr^{1/3} = \frac{0.0338 \text{ W/m}\cdot\text{K}}{0.025 \text{ m}} 0.158 (7573)^{0.66} (0.69)^{1/3} = 68.6 \text{ W/m}^2 \cdot \text{K}$$

When the rod is rotated so that it presents an edge to the flow,  $D = 2^{1/2}d = 2^{1/2} \times 0.025 \text{ m} = 0.0354 \text{ m}$ ,  $Re_D = VD/\nu = 8 \text{ m/s} \times 0.0354 \text{ m}/26.41 \times 10^{-6} \text{ m}^2/\text{s} = 10,710$ , and from Table 7.3,  $C = 0.304$  and  $m = 0.59$ . Thus,

$$\bar{h} = \frac{k}{D} C Re_D^m Pr^{1/3} = \frac{0.0338 \text{ W/m}\cdot\text{K}}{0.0354 \text{ m}} 0.304 (10,710)^{0.59} (0.69)^{1/3} = 61.2 \text{ W/m}^2 \cdot \text{K}$$

Radiation will affect both rods in the same way, therefore the rod with the larger value of convection heat transfer coefficient will cool faster. The rod should be oriented with a face perpendicular to the flow in order to minimize the cooling time. <

The importance of radiation can be estimated by calculating the radiation heat flux at the initial time,  $q_{\text{rad}}'' = \epsilon \sigma (T_s^4 - T_{\text{sur}}^4) = 0.1 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times [(673 \text{ K})^4 - (293 \text{ K})^4] = 1120 \text{ W/m}^2$ . The initial convection heat transfer flux is  $q_{\text{conv}}'' = \bar{h} (T_s - T_{\infty}) = 68.6 \text{ W/m}^2 \cdot \text{K} \times (400^\circ\text{C} - 30^\circ\text{C}) = 25,380 \text{ W/m}^2$ . Since the radiation heat transfer rate is only around 4% initially, and will decrease in relative importance with time, radiation can be neglected in a calculation of the cooling time.

Continued...

### PROBLEM 7.57 (Cont.)

The cooling process can be modeled using the lumped capacitance approximation, provided the Biot number is small. Using a characteristic length of  $L = V/A_s = d/4 = 0.00625$  m, the Biot number is

$$Bi = \frac{\bar{h}L}{k} = \frac{68.6 \text{ W/m}^2 \cdot \text{K} \times 0.00625 \text{ m}}{235 \text{ W/m} \cdot \text{K}} = 0.0018$$

Therefore, the lumped capacitance approximation is valid and the cooling time is given by Equation 5.5,

$$t = \frac{\rho Vc}{hA_s} \ln \frac{\theta_i}{\theta} = \frac{\rho dc}{4\bar{h}} \ln \frac{T_i - T_\infty}{T - T_\infty} = \frac{2702 \text{ kg/m}^3 \times 0.025 \text{ m} \times 991 \text{ J/kg} \cdot \text{K}}{4 \times 68.6 \text{ W/m}^2 \cdot \text{K}} \ln \left( \frac{400 - 30}{60 - 30} \right) = 613 \text{ s} <$$

**COMMENTS:** *IHT* was used to solve this problem including the effect of radiation. The required cooling time, including radiation, is 601 s. Inclusion of radiation has a minor effect on the cooling time, as expected.

### PROBLEM 7.58

**KNOWN:** Temperature and heat dissipation in a wire of diameter  $D$ .

**FIND:** (a) Expression for flow velocity over wire, (b) Velocity of airstream for prescribed conditions.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Uniform wire temperature, (3) Negligible radiation.

**PROPERTIES:** Table A-4, Air ( $T_\infty = 298 \text{ K}$ , 1 atm):  $\nu = 15.8 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0262 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.71$ ; ( $T_s = 313 \text{ K}$ , 1 atm):  $\text{Pr} = 0.705$ .

**ANALYSIS:** (a) The rate of heat transfer per unit cylinder length is

$$q' = (q/L) = \bar{h}(\pi D) (T_s - T_\infty)$$

where, from the Zhukauskas relation, with  $\text{Pr} \approx \text{Pr}_s$ ,

$$\bar{h} = \frac{k}{D} C \text{Re}_D^m \text{Pr}^n = \frac{k}{D} C \left( \frac{VD}{\nu} \right)^m \text{Pr}^n$$

Hence,

$$V = \left[ \frac{q'}{(k/D) C \text{Pr}^n (\pi D) (T_s - T_\infty)} \right]^{1/m} \left( \frac{\nu}{D} \right). \quad <$$

(b) Assuming ( $10^3 < \text{Re}_D < 2 \times 10^5$ ),  $C = 0.26$ ,  $m = 0.6$  from Table 7.4. Hence,

$$V = \left[ \frac{35 \text{ W/m}}{0.0262 \text{ W/m}\cdot\text{K} \times 0.26 (0.71)^{0.37} \pi (40 - 25)^\circ\text{C}} \right]^{1/0.6} \left( \frac{15.8 \times 10^{-6} \text{ m}^2/\text{s}}{5 \times 10^{-4} \text{ m}} \right)$$

$$V = 97 \text{ m/s}. \quad <$$

To verify the assumption of the Reynolds number range, calculate

$$\text{Re}_D = \frac{VD}{\nu} = \frac{97 \text{ m/s} (5 \times 10^{-4} \text{ m})}{15.8 \times 10^{-6} \text{ m}^2/\text{s}} = 3074.$$

Hence the assumption was correct.

**COMMENTS:** The major uncertainty associated with using this method to determine  $V$  is that associated with use of the correlation for  $\bar{\text{Nu}}_D$ .

## PROBLEM 7.59

**KNOWN:** Platinum wire maintained at a constant temperature in an airstream to be used for determining air velocity changes.

**FIND:** (a) Relationship between fractional changes in current to maintain constant wire temperature and fractional changes in air velocity and (b) Current required when air velocity is 10 m/s.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Cross-flow of air on wire with  $40 < Re_D < 1000$ , (3) Radiation effects negligible, (4) Wire is isothermal.

**PROPERTIES:** Platinum wire (given): Electrical resistivity,  $\rho_e = 17.1 \times 10^{-5}$  Ohm-m; *Table A-4*, Air ( $T_\infty = 27^\circ\text{C} = 300$  K, 1 atm):  $\nu = 15.89 \times 10^{-6}$  m<sup>2</sup>/s,  $k = 0.0263$  W/m-K,  $Pr = 0.707$ ; ( $T_s = 77^\circ\text{C} = 350$  K, 1 atm):  $Pr_s = 0.700$ .

**ANALYSIS:** (a) From an energy balance on a unit length of the platinum wire,

$$q'_{\text{elec}} - q'_{\text{conv}} = I^2 R'_e - \bar{h}P(T_s - T_\infty) = 0 \quad (1)$$

where the electrical resistance per unit length is  $R'_e = \rho_e / A_c$ ,  $P = \pi D$ , and  $A_c = \pi D^2 / 4$ . Hence,

$$I = \left[ \frac{\bar{h}P A_c}{\rho_e} (T_s - T_\infty) \right]^{1/2} = \left[ \frac{\pi^2 \bar{h} D^3}{4 \rho_e} (T_s - T_\infty) \right]^{1/2} \quad (2)$$

For the range  $40 < Re_D < 1000$ , using the Zhukauskas correlation for cross-flow over a cylinder with  $C = 0.51$  and  $m = 0.5$ ,

$$\overline{Nu}_D = \frac{\bar{h}D}{k} = 0.51 Re_D^{0.5} Pr^{0.37} \left( \frac{Pr}{Pr_s} \right)^{1/4} = 0.51 \left( \frac{VD}{\nu} \right)^{0.5} Pr^{0.37} \left( \frac{Pr}{Pr_s} \right)^{1/4} \quad (3)$$

note that  $\bar{h} \sim V^{0.5}$ , which, when substituted into Eq. (2) yields

$$I \sim \bar{h}^{1/2} = \left( V^{0.5} \right)^{1/2} = V^{1/4}.$$

Differentiating the proportionality and dividing the result by the proportionality, it follows that

$$\frac{\Delta I}{I} \approx \frac{1}{4} \frac{\Delta V}{V}. \quad (4) \quad <$$

(b) For air at  $T_\infty = 27^\circ\text{C}$  and  $V = 10$  m/s, the current required to maintain the wire of  $D = 0.5$  mm at  $T_s = 77^\circ\text{C}$  follows from Eq. (2) with  $\bar{h}$  evaluated by Eq. (3)

Continued ...

**PROBLEM 7.59 (Cont.)**

$$\bar{h} = \frac{0.0263 \text{ W/m} \cdot \text{K}}{0.0005 \text{ m}} \times 0.51 \left( \frac{10 \text{ m/s} \times 0.0005 \text{ m}}{15.89 \times 10^{-6} \text{ m}^2/\text{s}} \right)^{0.5} (0.707)^{0.37} \left( \frac{0.707}{0.700} \right)^{1/4}$$
$$\bar{h} = 420 \text{ W/m}^2 \cdot \text{K}$$

where  $\text{Re}_D = 315$ . Hence the required current is

$$I = \left[ \frac{\pi^2 \times 420 \text{ W/m}^2 \cdot \text{K} (0.0005 \text{ m})^3}{4 \times 17.1 \times 10^{-5} \Omega \cdot \text{m}} (77 - 27) \text{ K} \right]^{1/2} = 195 \text{ mA}. \quad (5)$$

**COMMENTS:** (1) To measure 1% fractional velocity change, a 0.25% fractional change in current must be measured according to Eq. (4). From Eq. (5), this implies that  $\Delta I = 0.0025I = 0.0025 \times 195 \text{ mA} = 488 \mu\text{A}$ . An electronic circuit with such measurement sensitivity requires care in its design.

(2) Instruments built on this principle to measure air velocities are called *hot-wire anemometers*. Generally, the wire diameters are much smaller (3 to 30  $\mu\text{m}$  vs 500  $\mu\text{m}$  of this problem) in order to have faster response times.

(3) What effect would the presence of radiation exchange between the wire and its surroundings have?

## PROBLEM 7.60

**KNOWN:** Hot film sensor on a quartz rod maintained at  $T_s = 50^\circ\text{C}$ .

**FIND:** (a) Compute and plot the convection coefficient as a function of velocity for water,  $0.5 \leq V_w \leq 5$  m/s, and air,  $1 \leq V_a \leq 20$  m/s with  $T_\infty = 20^\circ\text{C}$  and (b) Suitability of using the hot film sensor for the two fluids based upon Biot number considerations.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Cross-flow over a smooth cylinder, (2) Steady-state conditions, (3) Uniform surface temperature.

**PROPERTIES:** Table A.6, Water ( $T_f = 308$  K, sat liquid); Table A.4, Air ( $T_f = 308$  K, 1 atm).

**ANALYSIS:** (a) Using the *IHT Tool, Correlations, Cylinder*, along with the *Properties Tool* for Air and Water, results were obtained for the convection coefficients as a function of velocity.

(b) The Biot number,  $hD/2k$ , is the ratio of the internal to external thermal resistances. When  $Bi \gg 1$ , the thin film is thermally coupled well to the fluid. When  $Bi \leq 1$ , significant power from the heater is dissipated axially by conduction in the rod. The Biot numbers for the fluids as a function of velocity are shown below.

We conclude that the sensor is well suited for use with water, but not so for use with air.

Continued...

## PROBLEM 7.60 (Cont.)

**COMMENTS:** A copy of the IHT workspace developed to generate the above plots is shown below.

**// Problem 7.60**

**// Correlation Tool: External Flow, Cylinder**

/\* Correlation description: External cross flow (EF) over cylinder (CY), average coefficient,  $ReD^*Pr > 0.2$ , Churchill-Bernstein correlation, Eq 7.57. See Table 7.7. \*/

**// Air flow (a)**

$Nu_{Dbar} = Nu_{D\_bar\_EF\_CY}(ReDa, Pra)$  // Eq 7.54

$Nu_{Dbar} = h_{Dbar} * D / k_a$

$ReDa = Va * D / \nu_a$

// Evaluate properties at the film temperature,  $T_{fa}$ .

$T_f = (T_{inf} + T_s) / 2$

$Bi_a = h_{Dbar} * D / (2 * k)$  // Biot number

**// Properties Tool: Air**

// Air property functions : From Table A.4

// Units: T(K); 1 atm pressure

$\nu_a = \nu_{T}(\text{"Air"}, T_f)$  // Kinematic viscosity,  $m^2/s$

$k_a = k_{T}(\text{"Air"}, T_f)$  // Thermal conductivity, W/m-K

$Pra = Pr_{T}(\text{"Air"}, T_f)$  // Prandtl number

**// Water flow (w)**

$Nu_{Dbarw} = Nu_{D\_bar\_EF\_CY}(ReDw, Prw)$  // Eq 7.54

$Nu_{Dbarw} = h_{Dbarw} * D / k_w$

$ReDw = Vw * D / \nu_w$

// Evaluate properties at the film temperature,  $T_{fw}$ .

//  $T_{fw} = (T_{infw} + T_{sw}) / 2$

$Bi_w = h_{Dbarw} * D / (2 * k)$  // Biot number

**// Properties Tool: Water**

// Water property functions : T dependence, From Table A.6

$\nu_w = \nu_{Tx}(\text{"Water"}, T_f, xf)$  // Kinematic viscosity,  $m^2/s$

$k_w = k_{Tx}(\text{"Water"}, T_f, xf)$  // Thermal conductivity, W/m-K

$Prw = Pr_{Tx}(\text{"Water"}, T_f, xf)$  // Prandtl number

**// Assigned Variables:**

$Va = 1$  // Air velocity, m/s; range 1 to 20 m/s

$Vw = 0.5$  // Water velocity, m/s; range 0.5 to 5 m/s

$k = 1.4$  // Thermal conductivity, W/m.K; quartz rod

$D = 0.0015$  // Diameter, m

$T_s = 30 + 273$  // Surface temperature, K

$T_{inf} = 20 + 273$  // Fluid temperature, K

**/\* Solve, Explore and Graph:** After solving, separate Explore sweeps for  $1 \leq Va \leq 20$  and  $0.5 \leq Vw \leq 5$  m/s were performed saving results in different Data Sets. Four separate plot windows were generated. \*/

## PROBLEM 7.61

**KNOWN:** Diameter, temperature and heat flux of a hot-film sensor. Fluid temperature. Thickness and thermal conductivity of deposit.

**FIND:** (a) Fluid velocity, (b) Heat flux if sensor is coated by a deposit.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, (2) Constant properties, (3) Thickness of hot film sensor is negligible, (4) Applicability of Churchill-Bernstein correlation for uniform surface heat flux, (5)  $Re_D \ll 282,000$ , (6) Deposit may be approximated as a plane layer.

**PROPERTIES:** Table A-6, water ( $T_f = 292.5\text{K}$ ):  $k = 0.602\text{ W/m}\cdot\text{K}$ ,  $\nu = 1.02 \times 10^{-6}\text{ m}^2/\text{s}$ ,  $Pr = 7.09$ .

**ANALYSIS:** (a) With  $Re_D \ll 282,000$  and  $\bar{h} = q''_{hf} / (T_{s,hf} - T_\infty)$ , Eq. (7.54) reduces to

$$\overline{Nu}_D = \frac{q''_{hf} D}{k(T_{s,hf} - T_\infty)} \approx 0.3 + \frac{0.62 Re_D^{1/2} Pr^{1/3}}{\left[1 + (0.4/Pr)^{2/3}\right]^{1/4}} \quad (1)$$

Substituting for  $D$ ,  $(T_{s,hf} - T_\infty)$ ,  $k$  and  $Pr$ ,

$$4.98 \times 10^{-4} q''_{hf} \approx 0.3 + 1.15 Re_D^{1/2}$$

or, with  $Re_D^{1/2} = (D/\nu)^{1/2} V^{1/2} = 38.3 V^{1/2}$ ,

$$4.98 \times 10^{-4} q''_{hf} \approx 0.3 + 44.1 V^{1/2} \quad (2)$$

Substituting for  $q''_{hf}$ ,

$$V = 0.20\text{ m/s} \quad <$$

(b) For a fixed value of  $T_{s,hf}$ , the thermal resistance of the deposit reduces  $q''_{hf}$ . From the thermal circuit.

$$q''_{hf} = \frac{T_{s,hf} - T_\infty}{(1/\bar{h}) + (\delta/k_d)}$$

Using Eq. (1) to evaluate  $\bar{h}$ ,

Continued ...

**PROBLEM 7.61 (Cont.)**

$$\bar{h} \approx \frac{k}{(D + \delta)} \left\{ 0.3 + \frac{0.62 \text{Re}_D^{1/2} \text{Pr}^{1/3}}{\left[ 1 + (0.4/\text{Pr})^{2/3} \right]^{1/4}} \right\}$$

where, with  $V = 0.20$  m/s,  $\text{Re}_D = V(D + \delta)/\nu = 314$ , we obtain

$$\bar{h} \approx \frac{0.602 \text{ W/m} \cdot \text{K}}{0.0016 \text{ m}} \{20.7\} = 7,780 \text{ W/m}^2 \cdot \text{K}$$

Hence, 
$$q''_{\text{hf}} = \frac{5^\circ\text{C}}{\left( 1.285 \times 10^{-4} + 0.5 \times 10^{-4} \right) \text{ m}^2 \cdot \text{K/W}} = 2.80 \times 10^4 \text{ W/m}^2 <$$

With the foregoing heat flux applied to the sensor and use of the model for Part (a), the sensor would indicate a velocity predicted from Eq. (2), or

$$V = \left[ \left( 4.98 \times 10^{-4} \times 2.80 \times 10^4 - 0.3 \right) / 44.1 \right]^2 = 0.096 \text{ m/s}$$

The error in the velocity measurement is therefore

$$\% \text{ Error} \equiv \frac{V_{(a)} - V_{(b)}}{V_{(a)}} (100\%) = \frac{0.20 - 0.096}{0.20} \times 100 = 52\% <$$

**COMMENTS:** (1) The accuracy of the hot-film sensor is strongly influenced by the deposit, and in any such application it is important to maintain a clean surface. (2) The Reynolds numbers are much less than 282,000 and assumption 5 is valid.

## PROBLEM 7.62

**KNOWN:** Dimensions of a flat plate in parallel flow. Plate and air temperatures and air velocity. Dimensions of a horizontal cylinder.

**FIND:** Convective heat loss from top and bottom of the flat plate and from the cylinder.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Constant properties.

**PROPERTIES:** Table A.4, air ( $T_f = (80^\circ\text{C} + 25^\circ\text{C})/2 = 52.5^\circ\text{C} \approx 325\text{K}$ ,  $p = 1\text{ atm}$ ):  $\nu = 18.4 \times 10^{-6}\text{ m}^2/\text{s}$ ,  $Pr = 0.704$ ,  $k = 0.0282\text{ W/m}\cdot\text{K}$ .

**ANALYSIS:** For the plate,

$$Re_L = \frac{u_\infty L}{\nu} = \frac{3\text{ m/s} \times 25 \times 10^{-3}\text{ m}}{18.4 \times 10^{-6}\text{ m}^2/\text{s}} = 4076$$

Therefore, the flow is laminar and Eq. 7.30 yields

$$\bar{h} = \frac{k}{L} \left[ 0.664 Re_L^{1/2} \right] Pr^{1/3} = \frac{0.0282\text{ W/m}\cdot\text{K}}{25 \times 10^{-3}\text{ m}} \left[ 0.664 \times 4076^{1/2} \right] 0.704^{1/3} = 42.5\text{ W/m}^2 \cdot \text{K}$$

and the convective heat transfer rate from the top and bottom of the flat plate is

$$q = 2wLh(T_s - T_\infty) = 2 \times 50 \times 10^{-3}\text{ m} \times 25 \times 10^{-3}\text{ m} \times 42.5\text{ W/m}^2 \cdot \text{K} (80 - 25)^\circ\text{C} = 5.84\text{ W} \quad \leftarrow$$

For the cylinder,  $D = \sqrt{\frac{4}{\pi} tL} = \sqrt{\frac{4}{\pi} \times 1 \times 10^{-3}\text{ m} \times 25 \times 10^{-3}\text{ m}} = 0.00564\text{ m} = 5.64\text{ mm}$  and

$$Re_D = \frac{VD}{\nu} = \frac{3\text{ m/s} \times 5.64 \times 10^{-3}\text{ m}}{18.4 \times 10^{-6}\text{ m}^2/\text{s}} = 920$$

Equation 7.54 yields

$$\begin{aligned} \bar{Nu}_D &= 0.3 + \frac{0.62 Re_D^{1/2} Pr^{1/3}}{\left[ 1 + (0.4/Pr)^{2/3} \right]^{1/4}} \left[ 1 + \left( \frac{Re_D}{282,000} \right)^{5/8} \right]^{4/5} \\ &= 0.3 + \frac{0.62 \times 920^{1/2} \times 0.704^{1/3}}{\left[ 1 + (0.4/0.704)^{2/3} \right]^{1/4}} \left[ 1 + \left( \frac{920}{282,000} \right)^{5/8} \right]^{4/5} = 15.3 \end{aligned}$$

### PROBLEM 7.62 (Cont.)

and 
$$\bar{h} = \frac{\overline{Nu_D} k}{D} = \frac{15.3 \times 0.0282 \text{ W/m} \cdot \text{K}}{5.64 \times 10^{-3} \text{ m}} = 76.5 \text{ W/m}^2 \cdot \text{K}$$

Therefore, the heat transfer rate from the cylinder is,

$$q = \pi D L_c \bar{h} (T_s - T_\infty) = \pi \times 5.64 \times 10^{-3} \text{ m} \times 50 \times 10^{-3} \text{ m} \times 76.52 \text{ W/m}^2 \cdot \text{K} (80 - 25)^\circ \text{C} = 3.73 \text{ W} \quad <$$

**COMMENTS:** (1) The heat transfer coefficient associated with the cylinder is 80% greater than that associated with the flat plate. However, for the same volume, the exposed surface area of the cylinder is 65% smaller than that of the flat plate, resulting in an overall smaller heat transfer rate for the cylinder. (2) A trial-and-error solution reveals that a larger cylinder of diameter  $D = 13.6$  mm is necessary to transfer the same amount of energy by convection as the flat plate.

## PROBLEM 7.63

**KNOWN:** Dimensions of a rectangular fin in parallel flow. Circular pin fin of same cross-sectional area.

**FIND:** (a) Fin heat transfer rate for both fins. (b) Diameter of cylindrical fin needed to produce the same fin heat transfer rate as for the rectangular fin.

**SCHEMATIC:**

Cross-sectional views of the rectangular fin (left) and the cylindrical fin (right).  $T_b = 85^\circ\text{C}$ .

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Constant properties, (3) Infinite fins, (4) Uniform heat transfer coefficients, equal to the average values.

**PROPERTIES:** Table A.4, air ( $T_f = (85^\circ\text{C} + 20^\circ\text{C})/2 = 52.5^\circ\text{C} \approx 325\text{K}$ ,  $p = 1\text{ atm}$ ):  $\nu = 18.4 \times 10^{-6}\text{ m}^2/\text{s}$ ,  $Pr = 0.704$ ,  $k = 0.0282\text{ W/m}\cdot\text{K}$ .

**ANALYSIS:** (a) For the rectangular fin,

$$Re_w = \frac{u_\infty w}{\nu} = \frac{5\text{ m/s} \times 20 \times 10^{-3}\text{ m}}{18.4 \times 10^{-6}\text{ m}^2/\text{s}} = 5435$$

Therefore, the flow is laminar and Eq. 7.30 yields

$$\bar{h} = \frac{k}{w} \left[ 0.664 Re_w^{1/2} \right] Pr^{1/3} = \frac{0.0282\text{ W/m}\cdot\text{K}}{20 \times 10^{-3}\text{ m}} \left[ 0.664 \times 5435^{1/2} \right] 0.704^{1/3} = 61.4\text{ W/m}^2 \cdot \text{K}$$

The periphery of the fin is  $P = 2(w + t) = 2 \times (20 \times 10^{-3}\text{ m} + 1 \times 10^{-3}\text{ m}) = 42 \times 10^{-3}\text{ m}$  and the cross-sectional area is  $A_c = wt = 20 \times 10^{-3}\text{ m} \times 1 \times 10^{-3}\text{ m} = 20 \times 10^{-6}\text{ m}^2$ . Evaluating the fin parameter  $M$  yields

$$M = \sqrt{hPkA_c} \theta_b = \sqrt{61.4\text{ W/m}^2 \cdot \text{K} \times 42 \times 10^{-3}\text{ m} \times 237\text{ W/m}\cdot\text{K} \times 20 \times 10^{-6}\text{ m}^2} \times (85 - 20)^\circ\text{C} = 7.19\text{ W}$$

For an infinite fin,

$$q_f = M = 7.19\text{ W} \quad \leftarrow$$

For the cylindrical fin,  $D = \sqrt{\frac{4}{\pi} tw} = \sqrt{\frac{4}{\pi} \times 1 \times 10^{-3}\text{ m} \times 20 \times 10^{-3}\text{ m}} = 0.00505\text{ m} = 5.05\text{ mm}$  and

$$Re_D = \frac{VD}{\nu} = \frac{5\text{ m/s} \times 5.05 \times 10^{-3}\text{ m}}{18.4 \times 10^{-6}\text{ m}^2/\text{s}} = 1372$$

Continued...

### PROBLEM 7.63 (Cont.)

Equation 7.54 yields

$$\begin{aligned}\overline{Nu}_D &= 0.3 + \frac{0.62 Re_D^{1/2} Pr^{1/3}}{\left[1 + (0.4/Pr)^{2/3}\right]^{1/4}} \left[1 + \left(\frac{Re_D}{282,000}\right)^{5/8}\right]^{4/5} \\ &= 0.3 + \frac{0.62 \times 1372^{1/2} \times 0.704^{1/3}}{\left[1 + (0.4/0.704)^{2/3}\right]^{1/4}} \left[1 + \left(\frac{1372}{282,000}\right)^{5/8}\right]^{4/5} = 18.7\end{aligned}$$

and 
$$\bar{h} = \frac{\overline{Nu}_D k}{D} = \frac{18.7 \times 0.0282 \text{ W/m} \cdot \text{K}}{5.05 \times 10^{-3} \text{ m}} = 104.4 \text{ W/m}^2 \cdot \text{K}$$

The periphery of the fin is  $P = \pi D = \pi \times 5.05 \times 10^{-3} \text{ m} = 15.9 \times 10^{-3} \text{ m}$  and the cross-sectional area is  $A_c = 20 \times 10^{-6} \text{ m}^2$ . Evaluating the fin parameter  $M$  yields

$$M = \sqrt{h P k A_c} \theta_b = \sqrt{104.4 \text{ W/m}^2 \cdot \text{K} \times 15.9 \times 10^{-3} \text{ m} \times 237 \text{ W/m} \cdot \text{K} \times 20 \times 10^{-6} \text{ m}^2} \times (85 - 20)^\circ\text{C} = 5.77 \text{ W}$$

For an infinite fin,

$$q_f = M = 5.77 \text{ W} \quad <$$

The rectangular fin heat rate is 25% greater than that of the cylindrical fin. <

(b) A trial-and-error solution shows that a cylinder diameter of  $D = 6.02 \text{ mm}$  is necessary to transfer the same amount of heat as the rectangular fin. <

**COMMENTS:** (1) The Reynolds number and heat transfer coefficient associated with part (b) are 1636 and  $96.0 \text{ W/m}^2 \cdot \text{K}$ , respectively. (2) The ratio of the mass of the cylinder in part (b) to that of the cylinder in part (a) is  $r = (D_b^2 / D_a^2) = (6.02 / 5.05)^2 = 1.42$ . Good thermal design, such as use of the rectangular fin rather than the cylindrical fin, can help conserve both natural resources and energy that is used to produce the aluminum.

## PROBLEM 7.64

**KNOWN:** Temperature sensor of 12.5 mm diameter experiences cross-flow of water at 80°C and velocity,  $0.005 < V < 0.20$  m/s. Sensor temperature may vary over the range  $20 < T_s < 80^\circ\text{C}$ .

**FIND:** Expression for convection heat transfer coefficient as a function of  $T_s$  and  $V$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Sensor-water flow approximates a cylinder in cross-flow, (3) Prandtl number varies linearly with temperature over the range of interest.

**PROPERTIES:** Table A-6, Sat. water ( $T_\infty = 80^\circ\text{C} = 353$  K):  $k = 0.670$  W/m·K,  $\nu = \mu v_f = 352 \times 10^{-6}$  N·s/m<sup>2</sup>  $\times 1.029 \times 10^{-3}$  m<sup>3</sup>/kg =  $3.621 \times 10^{-7}$  m<sup>2</sup>/s;  $Pr_s$  values for  $20 \leq T_s \leq 80^\circ\text{C}$ :

T (K)	293	300	325	350	353
Pr	7.00	5.83	3.42	2.29	2.20

**ANALYSIS:** Using the Zhukauskus correlation for the range  $40 < Re_D < 4000$  with  $C = 0.51$  and  $m = 0.5$ ,

$$\overline{Nu}_D = \frac{\bar{h}D}{k} = 0.51 Re_D^{0.5} Pr^{0.37} \left( \frac{Pr}{Pr_s} \right)^{1/4}$$

with  $Re_D = VD/\nu$ , the thermophysical properties of interest are  $k$ ,  $\nu$  and  $Pr$ , which are evaluated at  $T_\infty = 80^\circ\text{C}$ , and  $Pr_s$  which varies markedly with  $T_s$  for the range  $20 < T_s < 80^\circ\text{C}$ . Assuming  $Pr_s$  to vary linearly with  $T_s$  and using the extreme values to find the relation,

$$Pr_s = 7.00 + \frac{(2.20 - 7.00)}{(353 - 293) \text{ K}} (T_s - 293) \text{ K} = 7.00 - 0.0800(T_s - 293)$$

where the units of  $T_s$  are [K]. Substituting numerical values, find

$$\bar{h}(T_s) = \frac{0.670 \text{ W/m}\cdot\text{K}}{0.0125 \text{ m}} 0.51 \left( \frac{V \times 0.0125 \text{ m}}{3.621 \times 10^{-7} \text{ m}^2/\text{s}} \right)^{0.5} (2.20)^{0.37} \left( \frac{2.20}{7.00 - 0.080(T_s - 293)} \right)^{1/4}$$

$$\bar{h}(T_s) = 6800V^{0.5} [3.182 - 0.0364(T_s - 293)]^{-1/4} \quad <$$

**COMMENTS:** (1) From the  $Pr_s$  vs  $T_s$  graph above, a linear fit is seen to be poor for this temperature range. However, because the  $Pr_s$  dependence is to the  $1/4$  power, the discrepancy may be acceptable.

## PROBLEM 7.65

**KNOWN:** Diameter, electrical resistance and current for a high tension line. Velocity and temperature of ambient air.

**FIND:** (a) Surface and (b) Centerline temperatures of the wire, (c) Effect of air velocity on surface temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Constant properties, (3) One-dimensional radial conduction.

**PROPERTIES:** Table A.4, Air ( $T_f \approx 300$  K, 1 atm):  $\nu = 15.89 \times 10^{-6}$  m<sup>2</sup>/s,  $k = 0.0263$  W/m·K,  $Pr = 0.707$ ; Table A.1, Copper ( $T \approx 300$  K):  $k = 400$  W/m·K.

**ANALYSIS:** (a) Applying conservation of energy to a control volume of unit length,

$$\dot{E}'_g = I^2 R'_e = q' = \bar{h} \pi D (T_s - T_\infty)$$

With

$$Re_D = \frac{VD}{\nu} = \frac{10 \text{ m/s}(0.025 \text{ m})}{15.89 \times 10^{-6} \text{ m}^2/\text{s}} = 15,733$$

the Churchill and Bernstein correlation, yields

$$\overline{Nu}_D = 0.3 + \frac{0.62 Re_D^{1/2} Pr^{1/3}}{\left[1 + (0.4/Pr)^{2/3}\right]^{1/4}} \left[1 + \left(\frac{Re_D}{282,000}\right)^{5/8}\right]^{4/5} = 69.0$$

Hence,

$$\bar{h} = \overline{Nu}_D \frac{k}{D} = 69.0 \frac{0.0263 \text{ W/m} \cdot \text{K}}{0.025 \text{ m}} = 72.6 \text{ W/m}^2 \cdot \text{K}$$

and

$$T_s = T_\infty + \frac{I^2 R'_e}{\bar{h} \pi D} = 10^\circ \text{C} + \frac{(1000 \text{ A})^2 10^{-4} \Omega/\text{m}}{(72.6 \text{ W/m}^2 \cdot \text{K}) \pi (0.025 \text{ m})} = 10^\circ \text{C} + 17.6^\circ \text{C} = 27.6^\circ \text{C} \quad <$$

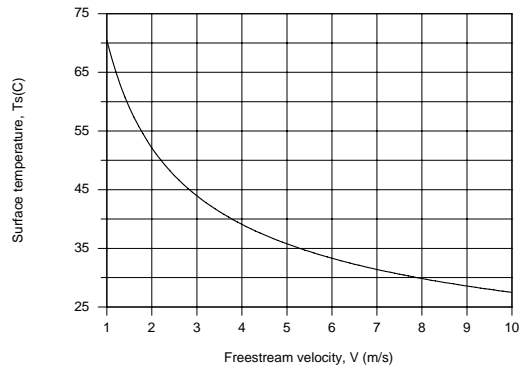

(b) With  $\dot{q} = \dot{E}'_g / (\pi D^2 / 4) = 4(1000 \text{ A})^2 (10^{-4} \Omega/\text{m}) / \pi (0.025 \text{ m})^2 = 2.04 \times 10^5 \text{ W/m}^3$ , Equation 3.58 yields

$$T(0) = \frac{\dot{q} r_0^2}{4k} + T_s = \frac{2.041 \times 10^5 \text{ W/m}^3 (0.0125 \text{ m})^2}{1600 \text{ W/m} \cdot \text{K}} + 27.6^\circ \text{C} = 0.02^\circ \text{C} + 27.6^\circ \text{C} \approx 27.6^\circ \text{C} \quad <$$

Continued...

### PROBLEM 7.65 (Cont.)

(c) The effect of  $V$  on the surface temperature was determined using the *Correlations and Properties* Tool Pads of IHT.

The effect is significant, with a surface temperature of  $T_s \approx 70^\circ\text{C}$  corresponding to  $V = 1$  m/s. For velocities of 1 and 10 m/s, respectively, convection coefficients are 21.1 and 72.8  $\text{W/m}^2\cdot\text{K}$  and film temperatures are 313.2 and 291.7 K.

**COMMENTS:** The small values of  $\dot{q}$  and  $r_o$  and the large value of  $k$  render the wire approximately isothermal.

## PROBLEM 7.66

**KNOWN:** Aluminum transmission line with a diameter of 20 mm having an electrical resistance of  $R' = 2.636 \times 10^{-4}$  ohm/m carrying a current of 700 A subjected to severe cross winds. To reduce potential fire hazard when adjacent lines make contact and spark, insulation is to be applied.

**FIND:** (a) The bare conductor temperature when the air temperature is  $20^\circ\text{C}$  and the line is subjected to cross flow with a velocity of 10 m/s; (b) The conductor temperature for the same conditions, but with an insulation covering of 2 mm thickness and thermal conductivity of  $0.15 \text{ W/m}\cdot\text{K}$ ; and (c) Plot the conductor temperatures of the bare and insulated conductors for wind velocities in the range of 2 to 20 m/s. Comment on the features of the curves and the effect that wind velocity has on the conductor operating temperatures.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Uniform surface temperatures, (3) Negligible solar irradiation and radiation exchange, and (4) Constant properties.

**PROPERTIES:** Table A-4, Air ( $T_f = (T_s + T_\infty)/2$ , 1 atm): evaluated using the *IHT Properties* library with a *Correlation* function; see Comment 2.

**ANALYSIS:** (a) For the *bare* conductor the energy balance per unit length is

$$\begin{aligned} \dot{E}'_{\text{in}} - \dot{E}'_{\text{out}} + \dot{E}'_{\text{gen}} &= 0 \\ 0 - q'_{\text{cv}} + \dot{q} A_c &= 0 \end{aligned} \quad (1)$$

where the cross-sectional area of the conductor is  $A_c = \pi D^2/4$  and the generation rate is

$$\dot{q} = I^2 R'_e / A_c = (700 \text{ A})^2 \times 2.636 \times 10^{-4} \Omega / \text{m} / \left( \pi (0.020 \text{ m})^2 / 4 \right) \quad (2)$$

$$\dot{q} = 4.111 \times 10^5 \text{ W/m}^3$$

The convection rate equation can be expressed as

$$q'_{\text{cv}} = (T_{\text{c,bare}} - T_\infty) / R'_t \quad R'_t = 1 / (\bar{h}_D \times \pi D) \quad (3,4)$$

and the convection coefficient is estimated using the Churchill-Bernstein correlation, Eq. 7.54, with  $\text{Re}_D = VD/\nu$ ,

$$\overline{\text{Nu}}_L = \frac{\bar{h}_D D}{k} = 0.3 + \frac{0.62 \text{Re}_D^{1/2} \text{Pr}^{1/3}}{\left[ 1 + (0.4/\text{Pr})^{2/3} \right]^{1/4}} \left[ 1 + \left( \frac{\text{Re}_D}{282,000} \right)^{5/8} \right]^{4/5} \quad (4)$$

(b) For the conductor *with insulation* thickness  $t = 2$  mm, the energy balance per unit length is

$$\begin{aligned} \dot{E}'_{\text{in}} - \dot{E}'_{\text{out}} + \dot{E}'_{\text{gen}} &= 0 \\ 0 - (T_{\text{c,ins}} - T_\infty) / R'_t + I^2 R'_e / A_c &= 0 \end{aligned} \quad (5)$$

Continued ...

### PROBLEM 7.66 (Cont.)

where  $R'_t$  is the sum of the insulation conduction and convection process thermal resistances,

$$R'_t = \ln[(D+2t)/D]/(2\pi k) + 1/[\bar{h}_{D+2t}\pi(D+2t)] \quad (6)$$

The results of the analysis using *IHT* are tabulated below.

Condition	V (m/s)	D (mm)	Re <sub>D</sub>	$\bar{Nu}_D$	$\bar{h}_D$ (W/m <sup>2</sup> ·K)	R' <sub>t</sub> (m·K/W)	T <sub>c</sub> (°C)
bare	10	20	$1.214 \times 10^4$	59.6	79.6	0.1998	45.8
insulated	10	24	$1.468 \times 10^4$	66.3	73.6	0.3736	68.3

(c) Using the *IHT* code with the foregoing relations, the conductor temperatures  $T_{c,base}$  and  $T_{c,ins}$  for the bare and insulated conditions are calculated and plotted for the wind velocity range of 2 to 20 m/s.

**COMMENTS:** (1) The effect of the 2-mm thickness insulation is to increase the conductor operating temperature by  $(68.3 - 46.1)^\circ\text{C} = 22^\circ\text{C}$ . While we didn't account for an increase in the electrical resistivity with increasing temperature, the adverse effect is to increase the  $I^2R$  loss, which represents a loss of revenue to the power provider. From the graph, note that the conductor temperature increases markedly with decreasing wind velocity, and the effect of insulation is still around  $+20^\circ\text{C}$ .

(2) Because of the tediousness of hand calculations required in using the convection correlation without fore-knowledge of  $T_f$  at which to evaluate properties, we used the *IHT Correlation* function treating  $T_f$  as one of the unknowns in the system of equations. Salient portions of the *IHT* code and property values are provided below.

## PROBLEM 7.66 (Cont.)

### // Forced convection, cross flow, cylinder

NuDbar = NuD\_bar\_EF\_CY(ReD,Pr) // Eq 7.54

NuDbar = hDbar \* Do / k

ReD = V \* Do / nu // Outer diameter; bare or with insulation

// Evaluate properties at the film temperature, Tf.

Tf = Tfluid\_avg (Tinf,Ts) // Ts is the outer surface temperature

/\* Correlation description: External cross flow (EF) over cylinder (CY), average coefficient, ReD\*Pr>0.2, Churchill-Bernstein correlation, Eq 7.54. See Table 7.9. \*/

### // Air property functions : From Table A.4

// Units: T(K); 1 atm pressure

nu = nu\_T("Air",Tf) // Kinematic viscosity, m<sup>2</sup>/s

k = k\_T("Air",Tf) // Thermal conductivity, W/m·K

Pr = Pr\_T("Air",Tf) // Prandtl number

(3) Is the temperature gradient within the conductor significant?

### PROBLEM 7.67

**KNOWN:** Velocities and temperatures of two air streams separated by a wall. Dimensions of an aluminum pin fin inserted through the wall. Distance it extends into the upper fluid.

**FIND:** (a) Heat transfer rate between the fluids via the pin fin, when it extends 50 mm into the upper fluid. (b) Heat transfer rate as a function of the distance it extends into the upper fluid.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Velocity is uniform – decreased velocity near wall can be neglected, (2) For the purpose of evaluating properties, the fin temperature is equal to the average of the two fluid temperatures,  $T_s = 25^\circ\text{C}$ .

**PROPERTIES:** Table A-4, Air 1 ( $T_{f1} = 17.5^\circ\text{C} \cong 290.5 \text{ K}$ ):  $\nu_1 = 1.504 \times 10^{-5} \text{ m}^2/\text{s}$ ,  $k_1 = 0.02554 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr}_1 = 0.710$ . Air 2 ( $T_{f2} = 32.5^\circ\text{C} \cong 305.5 \text{ K}$ ):  $\nu_2 = 1.644 \times 10^{-5} \text{ m}^2/\text{s}$ ,  $k_2 = 0.02671 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr}_2 = 0.706$ . Table A-1, Aluminum 2024 ( $T_s = 25^\circ\text{C} \approx 300 \text{ K}$ ):  $k = 177 \text{ W/m}\cdot\text{K}$ .

**ANALYSIS:**

(a) The heat transfer coefficients between the air and the fin are analyzed as flow past a cylinder using the Churchill-Bernstein correlation:

$$\text{Re}_{D1} = \frac{V_1 D}{\nu_1} = \frac{10 \text{ m/s} \times 0.005 \text{ m}}{1.504 \times 10^{-5} \text{ m}^2/\text{s}} = 3320$$

$$\text{Re}_{D2} = \frac{V_2 D}{\nu_2} = \frac{3 \text{ m/s} \times 0.005 \text{ m}}{1.644 \times 10^{-5} \text{ m}^2/\text{s}} = 912.$$

From Equation 7.54,

$$\text{Nu}_{D1} = 0.3 + \frac{0.62 \text{Re}_{D1}^{1/2} \text{Pr}_1^{1/3}}{\left[1 + (0.4/\text{Pr}_1)^{2/3}\right]^{1/4}} \left[1 + \left(\frac{\text{Re}_{D1}}{282,000}\right)^{5/8}\right]^{4/5}$$

$$= 0.3 + \frac{0.62 \times (3320)^{1/2} \times (0.710)^{1/3}}{\left[1 + (0.4/0.710)^{2/3}\right]^{1/4}} \left[1 + \left(\frac{3320}{282,000}\right)^{5/8}\right]^{4/5} = 29.7$$

and 
$$h_1 = \frac{\text{Nu}_{D1} k_1}{D} = \frac{29.7 \times 0.02554 \text{ W/m}\cdot\text{K}}{0.005 \text{ m}} = 152 \text{ W/m}^2 \cdot \text{K}$$

Continued...

### PROBLEM 7.67 (Cont.)

Similarly,  $Nu_{D2} = 15.3$ ,  $h_2 = 81.5 \text{ W/m}^2\cdot\text{K}$ .

Next we analyze heat transfer along the rod as if it were two fins joined at their base – the location where the fin passes through the wall. Thus, using the corrected fin length approach, Equation 3.88,

$$\begin{aligned} q_1 &= M_1 \tanh m_1 L_{c1} \\ q_2 &= M_2 \tanh m_2 L_{c2} \end{aligned}$$

where

$$\begin{aligned} M_i &= \sqrt{h_i P k A_c} \theta_{bi} = \sqrt{h_i D k} \frac{\pi D}{2} (T_b - T_{\infty i}) \\ m_i &= \sqrt{h_i P / k A_c} = 2\sqrt{h_i / k D} \end{aligned}$$

and  $L_{ci} = L_i + D/4$ . In this expression,  $L_1 = d$  and  $L_2 = L - d$ . Finally, since heat leaving one rod enters the other,

$$\begin{aligned} q_1 &= -q_2 \\ \sqrt{h_1 D k} \frac{\pi D}{2} (T_b - T_{\infty 1}) \tanh m_1 L_{c1} &= -\sqrt{h_2 D k} \frac{\pi D}{2} (T_b - T_{\infty 2}) \tanh m_2 L_{c2} \end{aligned}$$

Solving for  $T_b$ :

$$T_b = \frac{\sqrt{h_1} T_{\infty 1} \tanh(m_1 L_{c1}) + \sqrt{h_2} T_{\infty 2} \tanh(m_2 L_{c2})}{\sqrt{h_1} \tanh(m_1 L_{c1}) + \sqrt{h_2} \tanh(m_2 L_{c2})} \quad (1)$$

We calculate

$$m_1 = 2\sqrt{h_1 / k D} = 2\sqrt{152 \text{ W/m}^2 \cdot \text{K} / (177 \text{ W/m} \cdot \text{K} \times 0.005 \text{ m})} = 26.2 \text{ m}^{-1}$$

and similarly,  $m_2 = 19.2 \text{ m}^{-1}$ . Also,  $L_{c1} = L_{c2} = d + D/4 = 0.05 \text{ m} + 0.005 \text{ m}/4 = 0.05125 \text{ m}$ .

Thus

$$\begin{aligned} T_b &= \frac{\left[ \sqrt{152 \text{ W/m}^2 \cdot \text{K}} \times 10^\circ\text{C} \times \tanh(26.2 \text{ m}^{-1} \times 0.05125 \text{ m}) \right. \\ &\quad \left. + \sqrt{81.5 \text{ W/m}^2 \cdot \text{K}} \times 40^\circ\text{C} \times \tanh(19.2 \text{ m}^{-1} \times 0.05125 \text{ m}) \right]}{\left[ \sqrt{152 \text{ W/m}^2 \cdot \text{K}} \times \tanh(26.2 \text{ m}^{-1} \times 0.05125 \text{ m}) \right. \\ &\quad \left. + \sqrt{81.5 \text{ W/m}^2 \cdot \text{K}} \times \tanh(19.2 \text{ m}^{-1} \times 0.05125 \text{ m}) \right]} = 21.6^\circ\text{C} \end{aligned}$$

Finally

$$\begin{aligned} q &= q_1 = -q_2 = \sqrt{h_1 D k} \frac{\pi D}{2} (T_b - T_{\infty 1}) \tanh(m_1 L_{c1}) \quad (2) \\ &= \sqrt{152 \text{ W/m}^2 \cdot \text{K} \times 0.005 \text{ m} \times 177 \text{ W/m} \cdot \text{K}} \times \frac{\pi(0.005 \text{ m})}{2} \\ &\quad \times (21.6^\circ\text{C} - 10^\circ\text{C}) \tanh(26.2 \text{ m}^{-1} \times 0.05125 \text{ m}) \\ &= 0.924 \text{ W} \end{aligned}$$

<

### PROBLEM 7.67 (Cont.)

(b) With  $L_{c1} = d + D/4$  and  $L_{c2} = L - d + D/4$ , we vary  $d$  in the range  $0 \leq d \leq 0.1$  m and solve Equations (1) and (2). The results for  $q$  are plotted below.

We see that there is an optimal insertion distance,  $d \cong 40$  mm. A longer fin length ( $\approx 60$  mm) is needed in fluid 2 to compensate for its smaller heat transfer coefficient.

COMMENTS: It is of interest to compare the heat transfer between the two fluids via the fin to the heat transfer through the wall. In Chapter 8 we will see how to calculate heat transfer coefficients for flow in a channel. Assuming that the channel widths are both approximately 50 mm, the heat transfer coefficients between the fluid and the wall are roughly  $40 \text{ W/m}^2\cdot\text{K}$  and  $10 \text{ W/m}^2\cdot\text{K}$  for the faster and slower streams, respectively. Then  $q'' = \frac{T_2 - T_1}{1/h_1 + 1/h_2} \cong 240 \text{ W/m}^2$ . A wall area of  $4 \times 10^{-3} \text{ m}^2$ , for example a 60 mm-square area, would be required to transfer the same amount of heat as the fin (in part a), 0.924 W.

## PROBLEM 7.68

**KNOWN:** Diameter and surface temperature of an uninsulated steam pipe. Velocity and temperature of air in cross flow.

**FIND:** (a) Heat loss per unit length, (b) Effect of insulation thickness on heat loss.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Uniform surface temperature, (3) Negligible radiation.

**PROPERTIES:** Table A.4, Air ( $T_f \approx 350$  K, 1 atm):  $\nu = 20.9 \times 10^{-6}$  m<sup>2</sup>/s,  $k = 0.030$  W/m·K,  $Pr = 0.70$ .

**ANALYSIS:** (a) Without the insulation, the heat loss per unit length is

$$q' = \bar{h} \pi D (T_{s,i} - T_{\infty})$$

where  $\bar{h}$  may be obtained from the Churchill-Bernstein relation. With

$$Re_D = \frac{VD}{\nu} = \frac{5 \text{ m/s} \times 0.5 \text{ m}}{20.9 \times 10^{-6} \text{ m}^2/\text{s}} = 1.196 \times 10^5$$

$$\overline{Nu}_D = 0.3 + \frac{0.62 Re_D^{1/2} Pr^{1/3}}{\left[1 + (0.4/Pr)^{2/3}\right]^{1/4}} \left[1 + \left(\frac{Re_D}{282,000}\right)^{5/8}\right]^{4/5} = 242$$

$$\bar{h} = \overline{Nu}_D \frac{k}{D} = 242 \frac{0.030 \text{ W/m} \cdot \text{K}}{0.5 \text{ m}} = 14.5 \text{ W/m}^2 \cdot \text{K}$$

The heat rate is then

$$q' = 14.5 \text{ W/m}^2 \cdot \text{K} \pi (0.5 \text{ m}) (150 - (-10))^\circ \text{C} = 3644 \text{ W/m}.$$

<

(b) With the insulation, the heat loss may be expressed as

$$q' = U_i \pi D (T_{s,i} - T_{\infty})$$

where, from Eq. 3.36,

$$U_i = \left[ \frac{(D/2)}{k_i} \ln \bar{r} + \frac{1}{\bar{r}h} \right]^{-1}$$

and  $\bar{r} \equiv (D/2 + \delta)/(D/2)$ . The outer diameter,  $D_o = D + 2\delta$ , as well as the film temperature,  $T_f = (T_{s,o} + T_{\infty})/2$ , must now be used to evaluate the convection coefficient, where

Continued...

### PROBLEM 7.68 (Cont.)

$$\frac{T_{s,i} - T_{s,o}}{T_{s,i} - T_{\infty}} = \frac{R'_{\text{cond}}}{R'_{\text{tot}}} = \frac{(\ln \bar{r})/k_i}{(\ln \bar{r})/k_i + 1/(D/2)\bar{h}}$$

Using the IHT *Correlations and Properties* Tool Pads to evaluate  $\bar{h}$ , the following results were obtained.

The insulation is extremely effective, with a thickness of only 10 mm yielding a 7-fold reduction in heat loss and decreasing the outer surface temperature from 150 to 10°C. For  $\delta = 50$  mm,  $U_i = 0.56 \text{ W/m}^2 \cdot \text{K}$ ,  $q' = 140 \text{ W/m}$  and  $T_{s,o} = -5.2^\circ\text{C}$ .

**COMMENTS:** The dominant contribution to the total thermal resistance is made by the insulation.

### PROBLEM 7.69

**KNOWN:** Dimensions and thermal conductivity of a thermocouple well. Temperatures at well tip and base. Air velocity.

**FIND:** Air temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Constant properties, (3) One-dimensional conduction along well, (4) Uniform convection coefficient, (5) Negligible radiation.

**PROPERTIES:** Steel (given):  $k = 35 \text{ W/m}\cdot\text{K}$ ; Air (given):  $\rho = 0.774 \text{ kg/m}^3$ ,  $\mu = 251 \times 10^{-7} \text{ N}\cdot\text{s/m}^2$ ,  $k = 0.0373 \text{ W/m}\cdot\text{K}$ ,  $Pr = 0.686$ .

**ANALYSIS:** Applying Equation 3.75 at the well tip ( $x = L$ ), where  $T = T_1$ ,

$$\frac{T_1 - T_\infty}{T_2 - T_\infty} = \left[ \cosh mL + (\bar{h}/mk) \sinh mL \right]^{-1}$$

$$m = (\bar{h}P/kA_c)^{1/2} \quad P = \pi D_o = \pi(0.010 \text{ m}) = 0.0314 \text{ m}$$

$$A_c = (\pi/4)(D_o^2 - D_i^2) = (\pi/4)(0.010^2 - 0.005^2) \text{ m}^2 = 5.89 \times 10^{-5} \text{ m}^2.$$

$$\text{With } Re_D = \frac{\rho V D}{\mu} = \frac{0.774 \text{ kg/m}^3 (3 \text{ m/s}) 0.01 \text{ m}}{251 \times 10^{-7} \text{ N}\cdot\text{s/m}^2} = 925$$

$C = 0.51$ ,  $m = 0.5$ ,  $n = 0.37$  and the Zhukauskas correlation yields

$$\overline{Nu}_D = 0.51 Re_D^{0.5} Pr^{0.37} (Pr/Pr_s)^{1/4} \approx 0.51 (925)^{0.5} (0.686)^{0.37} \times 1 = 13.5$$

$$\bar{h} = \overline{Nu}_D \frac{k}{D_o} = 13.5 \frac{0.0373 \text{ W/m}\cdot\text{K}}{0.01 \text{ m}} = 50.4 \text{ W/m}^2 \cdot \text{K}.$$

Hence

$$m = \left[ \frac{(50.4 \text{ W/m}^2 \cdot \text{K}) 0.0314 \text{ m}}{(35 \text{ W/m}\cdot\text{K}) 5.89 \times 10^{-5} \text{ m}^2} \right]^{1/2} = 27.7 \text{ m}^{-1} \quad mL = (27.7 \text{ m}^{-1}) 0.15 \text{ m} = 4.15.$$

With

$$(\bar{h}/mk) = (50.4 \text{ W/m}^2 \cdot \text{K}) / (27.7 \text{ m}^{-1}) (35 \text{ W/m}\cdot\text{K}) = 0.0519$$

$$\text{find } \frac{T_1 - T_\infty}{T_2 - T_\infty} = [31.9 + (0.0519) 31.8]^{-1} = 0.0298 \quad T_\infty = 452.2 \text{ K.} \quad <$$

**COMMENTS:** Heat conduction along the wall to the base at 375 K is balanced by convection from the air.

## PROBLEM 7.70

**KNOWN:** Mercury-in-glass thermometer mounted on duct wall used to measure air temperature.

**FIND:** (a) Relationship for the immersion error,  $\Delta T_i = T(L) - T_\infty$  as a function of air velocity, thermometer diameter and length, (b) Length of insertion if  $\Delta T_i$  is not to exceed  $0.25^\circ\text{C}$  when the air velocity is 10 m/s, (c) For the length of part (b), calculate and plot  $\Delta T_i$  as a function of air velocity for 2 to 20 m/s, and (d) For a given insertion length, will  $\Delta T_i$  increase or decrease with thermometer diameter increase; is  $\Delta T_i$  more sensitive to diameter or velocity changes?

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Thermometer approximates a one-dimensional (glass) fin with an *adiabatic* tip, (3) Convection coefficient is uniform over length of thermometer.

**PROPERTIES:** Table A.3, Glass (300 K):  $k_g = 1.4 \text{ W/m}\cdot\text{K}$ ; Table A.4, Air ( $T_f = (15 + 77)^\circ\text{C}/2 \approx 320 \text{ K}$ , 1 atm):  $k = 0.0278 \text{ W/m}\cdot\text{K}$ ,  $\nu = 17.90 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.704$ .

**ANALYSIS:** (a) From the analysis of a one-dimensional fin, see Table 3.4,

$$\frac{T_L - T_\infty}{T_b - T_\infty} = \frac{1}{\cosh(mL)} \quad m^2 = \frac{\bar{h}P}{k_g A_c} = \frac{4\bar{h}}{k_g D} \quad (1)$$

where  $P = \pi D$  and  $A_c = \pi D^2/4$ . Hence, the immersion error is

$$\Delta T_i = T(L) - T_\infty = (T_b - T_\infty) / \cosh(mL). \quad (2)$$

Using the Hilpert correlation for the circular cylinder in cross flow,

$$\bar{h} = \frac{k}{D} C \text{Re}_D^m \text{Pr}^{1/3} = \frac{k}{D} C \left( \frac{VD}{\nu} \right)^m \text{Pr}^{1/3} = \frac{k \text{Pr}^{1/3}}{\nu^m} \cdot C \cdot V^m \cdot D^{m-1} \quad (3)$$

$$\bar{h} = N \cdot V^m \cdot D^{m-1} \quad \text{where} \quad N = \frac{k \text{Pr}^{1/3}}{\nu^m} C \quad (4,5)$$

Substituting into Eq. (2), the immersion error is

$$\Delta T_i(V, D, L) = (T_b - T_\infty) / \cosh \left\{ \left[ \left( 4/k_g \right) N \cdot V^m \cdot D^{m-2} \right]^{1/2} L \right\} \quad (6) <$$

where  $k_g$  is the thermal conductivity of the glass thermometer.

(b) When the air velocity is 10 m/s, find

$$\text{Re}_D = \frac{VD}{\nu} = \frac{10 \text{ m/s} \times 0.004 \text{ m}}{17.9 \times 10^{-6} \text{ m}^2/\text{s}^2} = 2235$$

Continued...

### PROBLEM 7.70 (Cont.)

with  $C = 0.683$  and  $m = 0.466$  from Table 7.2 for the range  $40 < Re_D < 4000$ . From Eqs. (5) and (6),

$$N = \frac{0.0278 \text{ W/m} \cdot \text{K} (0.704)^{1/3}}{(17.9 \times 10^{-6} \text{ m/s}^2)^{0.466}} \times 0.683 = 2.753$$

$$\Delta T_i = (15 - 77) \text{ K} / \cosh \left\{ \left[ \frac{4}{1.4 \text{ W/m} \cdot \text{K}} \times 2.753 (10 \text{ m/s})^{0.466} (0.004 \text{ m})^{0.466-2} \right]^{1/2} L \right\}$$

and when  $\Delta T_i = -0.25^\circ\text{C}$ , find

$$L = 18.7 \text{ mm} \quad \leftarrow$$

(c) For the air velocity range 2 to 20 m/s, find  $447 \leq Re_D \leq 4470$  for which the previous values of  $C$  and  $m$  of the Hilpert correlation are appropriate. Hence, the immersion error for an insertion length of  $L = 18.7$  mm, part (b), find

$$\Delta T_i = (15 - 77) \text{ K} / \cosh \left\{ \left[ \frac{4}{1.4 \text{ W/m} \cdot \text{K}} \times 2.753 \times V^{0.466} (0.004 \text{ m}) - 1.534 \right]^{1/2} 0.0187 \right\}$$

$$\Delta T_i = -62^\circ\text{C} / \cosh \left( 3.629 V^{0.233} \right) \quad \leftarrow$$

where the units of  $V$  are [m/s]. Entering the above equation into the IHT Workspace the plot shown below was generated.

V(m/s)	$\Delta T_i$ ( $^\circ\text{C}$ )
2	-1.74
5	-0.63
10	-0.25
15	-0.14
20	-0.08

(d) For a given insertion length, the immersion error will *increase* if the diameter of the thermometer were *increased*. This follows from Eq. (6) written as

$$\Delta T_i \sim 1 / \cosh \left( A \cdot D^{(m-2)/2} \right) \quad (7)$$

where  $A$  is a constant depending on variables other than  $D$ . For a given insertion length and air velocity, from Eq. (6)

$$\Delta T_i \sim 1 / \cosh \left( B \cdot V^{m/2} \right) \quad (8)$$

where  $B$  is a constant. From Eq. (7) we see  $\Delta T_i$  relates to change in *diameter* as  $D^{-0.767}$  and to change in *velocity* as  $V^{0.233}$ . That is, to reduce the immersion error decrease  $D$  and increase  $V$  (both cause  $\bar{h}$  to increase!). Based upon the exponents of each parameter, however, diameter change is the more influential.

## PROBLEM 7.71

**KNOWN:** Long coated plastic, 20-mm diameter rod, initially at a uniform temperature of  $T_i = 25^\circ\text{C}$ , is suddenly exposed to the cross-flow of air at  $T_\infty = 350^\circ\text{C}$  and  $V = 50\text{ m/s}$ .

**FIND:** (a) Time for the surface of the rod to reach  $175^\circ\text{C}$ , the temperature above which the special coating cures, and (b) Compute and plot the time-to-reach  $175^\circ\text{C}$  as a function of air velocity for  $5 \leq V \leq 50\text{ m/s}$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (a) One-dimensional, transient conduction in the rod, (2) Constant properties, and (3) Evaluate thermophysical properties at  $T_f = [(T_s + T_i)/2 + T_\infty]/2 = [(175 + 25)/2 + 350]^\circ\text{C}/2 = 225^\circ\text{C} = 500\text{ K}$ .

**PROPERTIES:** Rod (Given):  $\rho = 2200\text{ kg/m}^3$ ,  $c = 800\text{ J/kg}\cdot\text{K}$ ,  $k = 1\text{ W/m}\cdot\text{K}$ ,  $\alpha = k/\rho c = 5.68 \times 10^{-7}\text{ m}^2/\text{s}$ ; Table A.4, Air ( $T_f \approx 500\text{ K}$ , 1 atm):  $\nu = 38.79 \times 10^{-6}\text{ m}^2/\text{s}$ ,  $k = 0.0407\text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.684$ .

**ANALYSIS:** (a) To determine whether the lumped capacitance method is valid, determine the Biot number

$$\text{Bi}_{lc} = \frac{\bar{h}(r_o/2)}{k} \quad (1)$$

The convection coefficient can be estimated using the Churchill-Bernstein correlation, Eq. 7.54,

$$\overline{\text{Nu}}_D = \frac{\bar{h}D}{k} = 0.3 + \frac{0.62 \text{Re}_D^{1/2} \text{Pr}^{1/3}}{\left[1 + (0.4/\text{Pr})^{2/3}\right]^{1/4}} \left[1 + \left(\frac{\text{Re}_D}{282,000}\right)^{5/8}\right]^{4/5}$$

$$\text{Re}_D = \frac{VD}{\nu} = 50\text{ m/s} \times 0.020\text{ m} / 38.79 \times 10^{-6}\text{ m}^2/\text{s} = 25,780$$

$$\bar{h} = \frac{0.0407\text{ W/m}\cdot\text{K}}{0.020\text{ m}} \left\{ 0.3 + \frac{0.62(25,780)^{1/2} (0.684)^{1/3}}{\left[1 + (0.4/0.684)^{2/3}\right]^{1/4}} \left[1 + \left(\frac{25,780}{282,000}\right)^{5/8}\right]^{4/5} \right\} = 184\text{ W/m}^2\cdot\text{K} \quad (2)$$

Substituting for  $\bar{h}$  from Eq. (2) into Eq. (1), find

$$\text{Bi}_{lc} = 184\text{ W/m}^2\cdot\text{K} (0.010\text{ m}/2) / 1\text{ W/m}\cdot\text{K} = 0.92 \quad \gg 0.1$$

Hence, the lumped capacitance method is inappropriate. Using the one-term series approximation, Eqs. 5.52 with Table 5.1,

$$\theta^* = C_1 \exp(-\zeta_1^2 \text{Fo}) J_0(\zeta_1 r^*) \quad r^* = r/r_o = 1$$

$$\theta^* = \frac{T(r_o, t) - T_\infty}{T_i - T_\infty} = \frac{(175 - 350)^\circ\text{C}}{(25 - 350)^\circ\text{C}} = 0.54$$

$$\text{Bi} = \bar{h}r_o/k = 1.84 \quad \zeta_1 = 1.546\text{ rad} \quad C_1 = 1.318$$

Continued...

**PROBLEM 7.71 (Cont.)**

$$0.54 = 1.318 \exp[-(1.546 \text{ rad})^2 \text{Fo}] J_0(1.546 \times 1)$$

Using Table B.4 to evaluate  $J_0(1.546) = 0.4859$ , find  $\text{Fo} = 0.0725$  where

$$\text{Fo} = \frac{\alpha t_o}{r_o^2} = \frac{5.68 \times 10^{-7} \text{ m}^2/\text{s} \times t_o}{(0.010 \text{ m})^2} = 5.68 \times 10^{-3} t_o \quad (6)$$

$$t_o = 12.8 \text{ s}$$

<

(b) Using the *IHT Model, Transient Conduction, Cylinder*, and the *Tool, Correlations, External Flow, Cylinder*, results for the time-to-reach a surface temperature of 175°C as a function of air velocity  $V$  are plotted below.

**COMMENTS:** (1) Using the *IHT Tool, Correlations, External Flow, Cylinder*, the effect of the film temperature  $T_f$  on the estimated convection coefficient with  $V = 50 \text{ m/s}$  can be readily evaluated.

$T_f$ (K)	460	500	623
$\bar{h}$ ( $\text{W}/\text{m}^2 \cdot \text{K}$ )	187	184	176

At early times,  $\bar{h} = 184 \text{ W}/\text{m}^2 \cdot \text{K}$  is a good estimate, while as the cylinder temperature approaches the airstream temperature, the effect starts to be noticeable (10% decrease).

(2) The IHT analysis performed for part (b) was developed in two parts. Using a known value for  $\bar{h}$ , the *Transient Conduction, Cylinder Model* was tested. Separately, the *Correlation Tools* was assembled and tested. Then, the two files were merged to give the workspace for determining the time-to-reach 175°C as a function of velocity  $V$ .

## PROBLEM 7.72

**KNOWN:** Velocity, diameter, initial temperature and properties of extruded wire. Temperature and velocity of air. Temperature of surroundings.

**FIND:** (a) Differential equation for temperature distribution  $T(x)$ , (b) Exact solution for negligible radiation and corresponding value of temperature at prescribed length of wire, (c) Effect of radiation on temperature of wire at prescribed length. Effect of wire velocity and emissivity on temperature distribution.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible variation of wire temperature in radial direction, (2) Negligible effect of axial conduction along the wire, (3) Constant properties, (4) Radiation exchange between small surface and large enclosure, (5) Motion of wire has a negligible effect on the convection coefficient ( $V_e \ll V$ ).

**PROPERTIES:** Prescribed. Copper:  $\rho = 8900 \text{ kg/m}^3$ ,  $c_p = 400 \text{ J/kg} \cdot \text{K}$ ,  $\varepsilon = 0.55$ . Air:  
 $k = 0.037 \text{ W/m} \cdot \text{K}$ ,  $\nu = 3 \times 10^{-5} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.69$ .

**ANALYSIS:** (a) Applying conservation of energy to a stationary control surface, through which the wire moves, steady-state conditions exist and  $\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = 0$ . Hence, with *inflow* due to *advection* and *outflow* due to *advection*, *convection* and *radiation*,

$$\begin{aligned} \rho V_e A_c c_p T - \rho V_e A_c c_p (T + dT) - dq_{\text{conv}} - dq_{\text{rad}} &= 0 \\ -\rho V_e \left( \pi D^2 / 4 \right) c_p dT - \pi D dx \left[ \bar{h} (T - T_\infty) + \varepsilon \sigma (T^4 - T_{\text{sur}}^4) \right] &= 0 \\ \frac{dT}{dx} = -\frac{4}{\rho V_e D c_p} \left[ \bar{h} (T - T_\infty) + \varepsilon \sigma (T^4 - T_{\text{sur}}^4) \right] &\quad (1) \end{aligned}$$

Alternatively, if the control surface is fixed to the wire, conditions are transient and the energy balance is of the form,  $-\dot{E}_{\text{out}} = \dot{E}_{\text{st}}$ , or

$$\begin{aligned} -\pi D dx \left[ \bar{h} (T - T_\infty) + \varepsilon \sigma (T^4 - T_{\text{sur}}^4) \right] &= \rho \left( \frac{\pi D^2}{4} dx \right) c_p \frac{dT}{dt} \\ \frac{dT}{dt} = -\frac{4}{\rho D c_p} \left[ \bar{h} (T - T_\infty) + \varepsilon \sigma (T^4 - T_{\text{sur}}^4) \right] &\end{aligned}$$

Dividing the left- and right-hand sides of the equation by  $dx/dt$  and  $V_e = dx/dt$ , respectively, Eq. (1) is obtained.

(b) Neglecting radiation, separating variables and integrating, Eq. (1) becomes

$$\int_{T_1}^T \frac{dT}{T - T_\infty} = -\frac{4\bar{h}}{\rho V_e D c_p} \int_0^x dx$$

Continued ...

**PROBLEM 7.72 (Cont.)**

$$\ln\left(\frac{T - T_\infty}{T_i - T_\infty}\right) = -\frac{4\bar{h}x}{\rho V_e D c_p}$$

$$T = T_\infty + (T_i - T_\infty) \exp\left(-\frac{4\bar{h}x}{\rho V_e D c_p}\right) \quad (2) \quad <$$

With  $Re_D = VD/\nu = 5 \text{ m/s} \times 0.005 \text{ m} / 3 \times 10^{-5} \text{ m}^2/\text{s} = 833$ , the Churchill-Bernstein correlation yields

$$\overline{Nu}_D = 0.3 + \frac{0.62(833)^{1/2} (0.69)^{1/3}}{\left[1 + (0.4/0.69)^{2/3}\right]^{1/4}} \left[1 + \left(\frac{833}{282,000}\right)^{5/8}\right]^{4/5} = 14.4$$

$$\bar{h} = \frac{k}{D} \overline{Nu}_D = \frac{0.037 \text{ W/m}\cdot\text{K}}{0.005 \text{ m}} 14.4 = 107 \text{ W/m}^2 \cdot \text{K}$$

Hence, applying Eq. (2) at  $x = L$ ,

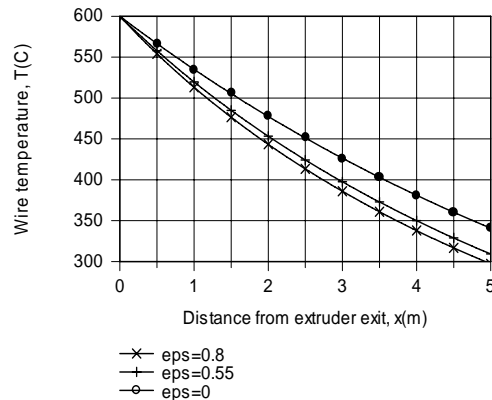

$$T_o = 25^\circ\text{C} + (575^\circ\text{C}) \exp\left(-\frac{4 \times 107 \text{ W/m}^2 \cdot \text{K} \times 5 \text{ m}}{8900 \text{ kg/m}^3 \times 0.2 \text{ m/s} \times 0.005 \text{ m} \times 400 \text{ J/kg}\cdot\text{K}}\right)$$

$$T_o = 340^\circ\text{C} \quad <$$

(c) Using the DER function of IHT, Eq. (1) may be numerically integrated from  $x = 0$  to  $x = L = 5.0 \text{ m}$  to obtain

$$T_o = 309^\circ\text{C} \quad <$$

Hence, radiation makes a discernable contribution to cooling of the wire. IHT was also used to obtain the following distributions.

The speed with which the wire is drawn from the extruder has a significant influence on the temperature distribution. The temperature decay decreases with increasing  $V_e$  due to the increasing effect of advection on energy transfer in the  $x$  direction. The effect of the surface emissivity is less pronounced, although, as expected, the temperature decay becomes more pronounced with increasing  $\epsilon$ .

**COMMENTS:** (1) A critical parameter in wire extrusion processes is the *coiling temperature*, that is, the temperature at which the wire may be safely coiled for subsequent storage or shipment. The larger the production rate ( $V_e$ ), the longer the cooling distance needed to achieve a desired coiling temperature. (2) Cooling may be enhanced by increasing the cross-flow velocity, and the specific effect of  $V$  may also be explored.

### PROBLEM 7.73

**KNOWN:** Experimental apparatus comprised of a flat plate subjected to an airstream in parallel flow. Electrical patch heater on backside dissipates 15.5 W for all conditions. Pin fins fabricated from brass with prescribed diameter and length can be firmly attached to the plate. Fin tip and base temperatures observed for five different configurations (N, number of fins).

**FIND:** (a) The thermal resistance between the plate and airstream for the five configurations, (b) Model of the plate-fin system using appropriate convection correlations to predict the thermal resistances for the five configurations; compare predictions and observations; explain differences, and (b) Predict thermal resistances when the airstream velocity is doubled.

**SCHEMATIC:**

Experimental observations:	N	$T_{tip}$ (°C)	$T_s$ (°C)
	0	--	70.2
	1	40.6	67.4
	2	39.5	64.7
	5	36.4	57.4
	8	34.2	52.1

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Negligible effect of flow interactions between pins, (3) Negligible radiation exchange with surroundings, (4) All heater power is transferred to airstream, and (5) Constant properties.

**PROPERTIES:** *Table A.4*, Air ( $T_f = 310$  K, 1 atm):  $k = 0.0270$  W/m·K,  $\nu = 1.69 \times 10^{-5}$  m<sup>2</sup>/s, Pr = 0.706; *Table A.1*, Brass ( $T = 300$  K):  $k = 110$  W/m·K.

**ANALYSIS:** (a) The thermal resistance between the plate and the airstream is defined as

$$R_{tot} = \frac{T_s - T_\infty}{q} \quad (1)$$

The heat rate is 15.5 W for all configurations and using  $T_s$  values from the above table with  $T_\infty = 20^\circ\text{C}$ , find

Continued...

**PROBLEM 7.73 (Cont.)**

N	0	1	2	5	8
R <sub>tot</sub> (K/W)	3.24	3.06	2.88	2.41	2.07

<

(b) The thermal resistance of the plate-fin system can be expressed as

$$R_{\text{tot}} = [1/R_{\text{base}} + N/R_{\text{fin}}]^{-1} \quad (2)$$

where the thermal resistance of the exposed portion of the base, A<sub>b</sub>, is

$$R_{\text{base}} = \frac{1}{\bar{h}_b A_b} \quad (3)$$

$$A_b = A_s - N A_c \quad (4)$$

where A<sub>c</sub> is the cross-sectional area of a fin and A<sub>s</sub> is the plate surface area. Approximating the airstream over the plate as parallel flow over a plate, use the *IHT Correlation Tool, External Flow, Flat Plate* assuming the flow is turbulent by the leading edge, to find

$$\bar{h}_b = 51 \text{ W/m}^2 \cdot \text{K}.$$

From the experimental observation with no fins (N = 0), the convection coefficient was measured as

$$\bar{h}_{b,\text{exp}} = \frac{q}{A_s (T_s - T_\infty)} = \frac{15.5 \text{ W}}{(0.0259 \text{ m})^2 (70.2 - 20)^\circ \text{C}} = 460 \text{ W/m}^2 \cdot \text{K}$$

Since the predicted coefficient is nearly an order of magnitude lower, we chose to use the experimental value in our subsequent analyses to predict overall system thermal resistance.

Approximating the airstream over a pin fin as cross-flow over a cylinder, use the *IHT Correlation Tool, External Flow, Cylinder* to find

$$\bar{h}_{\text{fin}} = 118 \text{ W/m}^2 \cdot \text{K}.$$

Using the *IHT Extended Surface Model for the Rectangular Pin Fin (Temperature Distribution and Heat Rate)* with a convection tip condition, the following fin thermal resistance was found as

$$R_{\text{fin}} = 25.4 \text{ K/W}$$

Using the foregoing values for R<sub>fin</sub> and  $\bar{h}_b$ , the thermal resistances of the plate-fin system are tabulated below.

N	0	1	2	4	8
R <sub>base</sub> (K/W)	3.241	3.331	3.426	3.746	4.133
R <sub>fin</sub> (K/W)	--	25.4	12.7	5.08	3.18
R <sub>tot</sub> (K/W)	3.24	2.95	2.70	2.16	1.80

<

By comparison with the experimental results of part (a), note that we assured agreement for the N = 0 condition by using the measured rather than estimated (correlation) convection coefficient. The predicted thermal resistances are systematically lower than the experimental values, with the worst case (N = 8) being 13% lower.

Continued...

### PROBLEM 7.73 (Cont.)

(c) The effect of doubling the velocity, from  $u_\infty = 6$  to  $12$  m/s, will cause the fin convection coefficient to increase from  $\bar{h}_{\text{fin}} = 118$  to  $169$  W/m<sup>2</sup>·K. For the base convection coefficient, we'll assume the flow is fully turbulent so that  $\bar{h} \sim (u_\infty)^{0.8}$  according to Eq. 7.38, hence

$$\bar{h}_b(12 \text{ m/s}) = \bar{h}_b(6 \text{ m/s}) \left( \frac{12}{6} \right)^{0.8} = 460 \text{ W/m}^2 \cdot \text{K} (2)^{0.8} = 800 \text{ W/m}^2 \cdot \text{K}$$

Using the same procedure as above, find

N	0	1	2	4	8
$R_{\text{base}}$ (K/W)	1.863	1.915	1.970	2.154	2.376
$R_{\text{fin}}$ (K/W)	--	18.96	9.480	4.740	2.370
$R_{\text{tot}}$ (K/W)	1.86	1.74	1.63	1.48	1.19

The effect of doubling the airstream velocity is to reduce the thermal resistance by approximately 35%.

### PROBLEM 7.74

**KNOWN:** Temperature and velocity of air flow over a sphere of prescribed surface temperature and diameter.

**FIND:** (a) Drag force, (b) Heat transfer rate with air velocity of 25 m/s; and (c) Compute and plot the heat rate as a function of air velocity for the range  $1 \leq V \leq 25$  m/s.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Uniform surface temperature, (3) Negligible radiation exchange with surroundings.

**PROPERTIES:** Table A.4, Air ( $T_\infty = 298$  K, 1 atm):  $\mu = 184 \times 10^{-7}$  N·s/m<sup>2</sup>;  $\nu = 15.71 \times 10^{-6}$  m<sup>2</sup>/s,  $k = 0.0261$  W/m·K,  $Pr = 0.71$ ; ( $T_s = 348$  K):  $\mu = 208 \times 10^{-7}$  N·s/m<sup>2</sup>; ( $T_f = 323$  K):  $\nu = 18.2 \times 10^{-6}$  m<sup>2</sup>/s,  $\rho = 1.085$  kg/m<sup>3</sup>.

**ANALYSIS:** (a) Working with properties evaluated at  $T_f$

$$Re_D = \frac{VD}{\nu} = \frac{25 \text{ m/s}(0.01 \text{ m})}{18.2 \times 10^{-6} \text{ m}^2/\text{s}} = 1.37 \times 10^4$$

and from Fig. 7.9, find  $C_D \approx 0.4$ . Hence

$$F_D = C_D \left( \pi D^2 / 4 \right) \left( \rho V^2 / 2 \right) = 0.4 (\pi / 4) (0.01 \text{ m})^2 1.085 \text{ kg/m}^3 (25 \text{ m/s})^2 / 2 = 0.011 \text{ N} <$$

(b) With

$$Re_D = \frac{VD}{\nu} = \frac{25 \text{ m/s}(0.01 \text{ m})}{15.71 \times 10^{-6} \text{ m}^2/\text{s}} = 1.59 \times 10^4$$

it follows from the Whitaker relation that

$$\begin{aligned} \overline{Nu}_D &= 2 + \left[ 0.4 Re_D^{1/2} + 0.06 Re_D^{2/3} \right] Pr^{0.4} \left( \frac{\mu}{\mu_s} \right)^{1/4} \\ \overline{Nu}_D &= 2 + \left[ 0.4 (1.59 \times 10^4)^{1/2} + 0.06 (1.59 \times 10^4)^{2/3} \right] (0.71)^{0.4} \left( \frac{184}{208} \right)^{1/4} = 76.7 \end{aligned}$$

Hence, the convection coefficient and convection heat rate are

$$\bar{h} = \overline{Nu}_D \frac{k}{D} = 76.7 \frac{0.0261 \text{ W/m} \cdot \text{K}}{0.01 \text{ m}} = 200 \text{ W/m}^2 \cdot \text{K}$$

$$q = \bar{h} \pi D^2 (T_s - T_\infty) = 200 \text{ W/m}^2 \cdot \text{K} \times \pi (0.01 \text{ m})^2 (75 - 25)^\circ \text{C} = 3.14 \text{ W} <$$

Continued...

## PROBLEM 7.74 (Cont.)

(c) Using the *IHT Correlation Tool, External Flow, Sphere*, the average coefficient and heat rate were calculated and are plotted below.

**COMMENTS:** (1) A copy of the IHT Workspace used to generate the above plot is shown below.

**// Correlation Tool - External Flow, Sphere:**

NuDbar = NuL\_bar\_EF\_SP(ReD,Pr,mu,mus) // Eq 7.56

NuDbar = hbar \* D / k

ReD = V \* D / nu

/\* Evaluate properties at Tinf and the surface temperature, Ts. \*/

/\* Correlation description: External flow (EF) over a sphere (SP), average coefficient,  $3.5 < \text{ReD} < 7.6 \times 10^4$ ,  $0.71 < \text{Pr} < 380$ ,  $1.0 < (\mu/\mu_s) < 3.2$ , Whitaker correlation, Eq 7.56. See Table 7.7. \*/

**// Properties Tool - Air:**

// Air property functions : From Table A.4

// Units: T(K); 1 atm pressure

mu = mu\_T("Air",Tinf) // Viscosity, N·s/m<sup>2</sup>

mus = mu\_T("Air",Ts) // Viscosity, N·s/m<sup>2</sup>

nu = nu\_T("Air",Tinf) // Kinematic viscosity, m<sup>2</sup>/s

k = k\_T("Air",Tinf) // Thermal conductivity, W/m·K

Pr = Pr\_T("Air",Tinf) // Prandtl number

**// Heat Rate Equation:**

q = hbar \* pi \* D<sup>2</sup> \* (Ts - Tinf)

**// Assigned Variables:**

D = 0.01 // Sphere diameter, m

Ts = 75 + 273 // Surface temperature, K

V = 25 // Airstream velocity, m/s

Tinf = 25 + 273 // Airstream temperature, K

## PROBLEM 7.75

**KNOWN:** Sphere with a diameter of 20 mm and a surface temperature of 60°C that is immersed in a fluid at a temperature of 30°C with a velocity of 2.5 m/s.

**FIND:** The drag force and the heat rate when the fluid is (a) water and (b) air at atmospheric pressure. Explain why the results for the two fluids are so different.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Flow over a smooth sphere, (2) Constant properties.

**PROPERTIES:** Table A-6, Water ( $T_\infty = 30^\circ\text{C} = 303\text{ K}$ ):  $\mu = 8.034 \times 10^{-4}\text{ N}\cdot\text{s}/\text{m}^2$ ,  $\nu = 8.068 \times 10^{-7}\text{ m}^2/\text{s}$ ,  $k = 0.6172\text{ W}/\text{m}\cdot\text{K}$ ,  $\text{Pr} = 5.45$ ; Water ( $T_s = 333\text{ K}$ ):  $\mu_s = 4.674 \times 10^{-4}\text{ N}\cdot\text{s}/\text{m}^2$ ; Table A-4, Air ( $T_\infty = 30^\circ\text{C} = 303\text{ K}$ , 1 atm):  $\mu = 1.86 \times 10^{-5}\text{ N}\cdot\text{s}/\text{m}^2$ ,  $\nu = 1.619 \times 10^{-5}\text{ m}^2/\text{s}$ ,  $k = 0.0265\text{ W}/\text{m}\cdot\text{K}$ ,  $\text{Pr} = 0.707$ ; Air ( $T_\infty = 333\text{ K}$ ):  $\mu_s = 2.002 \times 10^{-5}\text{ N}\cdot\text{s}/\text{m}^2$ .

**ANALYSIS:** The drag force,  $F_D$ , for the sphere is determined from the drag coefficient, Eq. 7.50,

$$C_D = \frac{F_D}{A_f \left( \rho V^2 / 2 \right)}$$

where  $A_f = \pi D^2 / 4$  is the frontal area.  $C_D$  is a function of the Reynolds number  $\text{Re}_D = VD / \nu$  as represented in Figure 7.9. For the convection rate equation,

$$q = \bar{h}_D A_s (T_s - T_\infty)$$

where  $A_s = \pi D^2$  is the surface area and the convection coefficient is estimated using the Whitaker correlation, Eq. 7.56,

$$\bar{\text{Nu}}_D = 2 + \left[ 0.4 \text{Re}_D^{1/2} + 0.06 \text{Re}_D^{2/3} \right] \text{Pr}^{0.4} (\mu / \mu_s)^{1/4}$$

where all properties except  $\mu_s$  are evaluated at  $T_\infty$ . For convenience we will evaluate properties required for the drag force at  $T_\infty$ . The results of the analyses for the two fluids are tabulated below.

Fluid	$\text{Re}_D$	$C_D$	$F_D$ (N)	$\bar{\text{Nu}}_D$	$\bar{h}_D$ ( $\text{W}/\text{m}^2 \cdot \text{K}$ )	$q$ (W)
water	$6.198 \times 10^4$	0.5	0.489	439	13,540	510
air	$3.088 \times 10^3$	0.4	$0.452 \times 10^{-3}$	31.9	42.3	1.59

The frontal and surface areas, respectively, are  $A_f = 3.142 \times 10^{-4}\text{ m}^2$  and  $A_s = 1.257 \times 10^{-3}\text{ m}^2$ .

**COMMENTS:** The Reynolds number is the ratio of inertia to viscous forces. We associate higher viscous shear and heat transfer with larger Reynolds numbers. The drag force also depends upon the fluid density, which further explains why  $F_D$  for water is much larger, by a factor of 1000, than for air.

$\text{Nu}_D$  is dependent upon  $\text{Re}_D^n$  where  $n$  is  $1/2$  to  $2/3$ , and represents the dimensionless temperature gradient at the surface. Since the thermal conductivity of water is nearly 20 times that of air, we expect a significant difference between  $\bar{h}_D$  and  $q$  for the two fluids.

## PROBLEM 7.76

**KNOWN:** Diameter, properties and initial temperature of niobium sphere. Velocity and temperature of nitrogen. Temperature of surroundings.

**FIND:** (a) Time for sphere to cool to prescribed temperature if radiation is neglected, (b) Cooling time if radiation is considered. Effect of flow velocity.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Lumped capacitance method is valid, (2) Constant properties, (3) Radiation exchange with large surroundings.

**PROPERTIES:** Table A-4, nitrogen ( $T_\infty = 298\text{K}$ ):  $\mu = 177 \times 10^{-7} \text{ N}\cdot\text{s}/\text{m}^2$ ,  $\nu = 15.7 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0257 \text{ W}/\text{m}\cdot\text{K}$ ,  $\text{Pr} = 0.716$ . Table A-4, nitrogen ( $\bar{T}_s = 873\text{K}$ ):  $\mu_s = 368 \times 10^{-7} \text{ N}\cdot\text{s}/\text{m}^2$ .

**ANALYSIS:** (a) Neglecting radiation, the cooling time may be determined from Eq. (5.5),

$$t = \frac{\rho(\pi D^3/6)c}{\bar{h}\pi D^2} \ln \frac{\theta_i}{\theta} = \frac{\rho c D}{6\bar{h}} \ln \frac{T_i - T_\infty}{T_f - T_\infty}$$

The convection coefficient is obtained from the Whitaker correlation with  $\text{Re}_D = \text{VD}/\nu$   
 $= 5 \text{ m}/\text{s} \times 0.01 \text{ m} / 15.7 \times 10^{-6} \text{ m}^2/\text{s} = 3185$ . Hence,

$$\bar{\text{Nu}}_D = (\bar{h}D/k) = 2 + \left( 0.4 \text{Re}_D^{1/2} + 0.06 \text{Re}_D^{2/3} \right) \text{Pr}^{0.4} (\mu/\mu_s)^{1/4}$$

$$\bar{h} = \frac{0.0257 \text{ W}/\text{m}\cdot\text{K}}{0.01 \text{ m}} \left\{ 2 + \left[ 0.4(3185)^{1/2} + 0.06(3185)^{2/3} \right] (0.716)^{0.4} \left( \frac{177}{368} \right)^{0.25} \right\} = 71.8 \text{ W}/\text{m}^2\cdot\text{K}$$

$$t = \frac{8600 \text{ kg}/\text{m}^3 \times 290 \text{ J}/\text{kg}\cdot\text{K} \times 0.01 \text{ m}}{6 \times 71.8 \text{ W}/\text{m}^2\cdot\text{K}} \ln \frac{(900 - 25)}{(300 - 25)} = 67 \text{ s} \quad <$$

(b) If the effect of radiation is considered, the cooling time can be obtained by integrating Eq. (5.15).

With  $A_s/V = \pi D^2 / (\pi D^3/6) = 6/D$ , the appropriate form of the equation is

$$\frac{dT}{dt} = -\frac{6}{\rho c D} \left[ \bar{h}(T - T_\infty) + \varepsilon \sigma (T^4 - T_{\text{sur}}^4) \right]$$

Using the DER function of IHT to integrate this equation over the limits from  $T_i = 1173 \text{ K}$  to  $T_f = 573 \text{ K}$ , we obtain

$$t = 48 \text{ s} \quad <$$

Continued ...

### PROBLEM 7.76 (Cont.)

For  $V = 1.0$  and  $25.0$  m/s, the cooling times are  $t \approx 80$  and  $24$  s, respectively. Temperature histories for the three velocities are shown below.

**COMMENTS:** The cooling time is significantly affected by the flow velocity.

## PROBLEM 7.77

**KNOWN:** An underwater instrument pod having a spherical shape with a diameter of 85 mm dissipating 300 W.

**FIND:** Estimate the surface temperature of the pod for these conditions: (a) when submersed in a bay where the water temperature is 15°C and the current is 1 m/s, and (b) after being hauled out of the water *without deactivating the power* and suspended in the ambient where the air temperature is 15°C and the wind speed is 3 m/s.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Flow over a smooth sphere, (3) Uniform surface temperatures, (4) Negligible radiation heat transfer for air (a) condition, and (5) Constant properties.

**PROPERTIES:** Table A-6, Water ( $T_\infty = 15^\circ\text{C} = 288\text{ K}$ ):  $\mu = 0.001053\text{ N}\cdot\text{s}/\text{m}^2$ ,  $\nu = 1.139 \times 10^{-6}\text{ m}^2/\text{s}$ ,  $k = 0.5948\text{ W}/\text{m}\cdot\text{K}$ ,  $\text{Pr} = 8.06$ ; Table A-4, Air ( $T_\infty = 288\text{ K}$ , 1 atm):  $\mu = 1.788 \times 10^{-5}\text{ N}\cdot\text{s}/\text{m}^2$ ,  $\nu = 1.482 \times 10^{-5}\text{ m}^2/\text{s}$ ,  $k = 0.02534\text{ W}/\text{m}\cdot\text{K}$ ,  $\text{Pr} = 0.710$ ; Air ( $T_s = 945\text{ K}$ ):  $\mu_s = 4.099 \times 10^{-5}\text{ N}\cdot\text{s}/\text{m}^2$ .

**ANALYSIS:** The energy balance for the submersed-in-water (w) and suspended-in-air (a) conditions are represented in the schematics above and have the form

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} + \dot{E}_{\text{gen}} = -q_{\text{cv}} + P_e = 0 \quad (1)$$

$$-\bar{h}_D A_s (T_s - T_\infty) + P_e = 0$$

where  $A_s = \pi D^2$  and  $\bar{h}_D$  is estimated using the Whitaker correlation, Eq. 7.56,

$$\bar{\text{Nu}}_D = 2 + \left[ 0.4 \text{Re}_D^{1/2} + 0.06 \text{Re}_D^{2/3} \right] \text{Pr}^{0.4} (\mu/\mu_s)^{1/4} \quad (2)$$

where all properties except  $\mu_s$  are evaluated at  $T_\infty$ . The results are tabulated below.

Condition	$\text{Re}_D$	$\bar{\text{Nu}}_D$	$\bar{h}_D$ ( $\text{W}/\text{m}^2\cdot\text{K}$ )	$T_s$ ( $^\circ\text{C}$ )
(w) water	$7.465 \times 10^4$	499	3491	18.8
(a) air	$1.72 \times 10^4$	67.5	20.1	672

**COMMENTS:** (1) While submersed and dissipating 300 W, the pod is safely operating at a temperature slightly above that of the water. When hauled from the water and suspended in air, the pod temperature increases to a destruction temperature (672°C). The pod gets smoked!

(2) The assumption that  $\mu/\mu_s \approx 1$  is appropriate for the water (w) condition. For the air (a) condition,  $\mu/\mu_s = 0.436$  and the final term of the correlation is significant. Recognize that radiation exchange with the surroundings for the air condition should be considered for an improved estimate.

Continued ...

## PROBLEM 7.77 (Cont.)

(3) Why such a difference in  $T_s$  for the water (w) and air (a) conditions? From the results table note that the  $Re_D$ ,  $Nu_D$ , and  $\bar{h}_D$  are, respectively, 4x, 7x and 170x times larger for water compared to air. Water, because of its thermophysical properties which drive the magnitude of  $\bar{h}_D$ , is a much better coolant than air for similar flow conditions.

**/\* Comment:** Because  $T_s$  is much larger than  $T_{inf}$  for the in-air operation, the ratio of  $\mu / \mu_s$  exceeds the limits for the correlation. Hence, a warning message comes with the IHT solution. \*/

### **/\* Results - operation in air**

## PROBLEM 7.78

**KNOWN:** Method to manufacture small diameter lead solder balls. Properties of  $D = 130 \mu\text{m}$  diameter particles ejected into nitrogen gas at  $V = 2 \text{ m/s}$ . Nitrogen temperature and pressure, initial particle temperature. Piezoelectric device oscillation frequency.

**FIND:** (a) Terminal velocity of the droplets and distance traveled when a droplet completely solidifies, (b) Separation distance between droplets and pot size needed to produce solder balls continuously for one week.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible radiation heat transfer, (2) lumped capacitance thermal response.

**PROPERTIES:** Table A.4, Nitrogen: ( $T_f \approx (T_i + T_\infty)/2 = (225^\circ\text{C} + 30^\circ\text{C})/2 = 127.5^\circ\text{C} \approx 400 \text{ K}$ ):  $\rho = 0.8425 \text{ kg/m}^3$ ,  $\nu = 26.16 \times 10^{-6} \text{ m}^2/\text{s}$ . ( $\bar{T}_s = (225^\circ\text{C} + 183^\circ\text{C})/2 = 205^\circ\text{C} = 477 \text{ K}$ ):  $\mu_s = 248 \times 10^{-7} \text{ N}\cdot\text{s/m}^2$ . ( $T_\infty = 30^\circ\text{C} = 303 \text{ K}$ ):  $\rho = 1.1233 \text{ kg/m}^3$ ,  $\nu = 15.86 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0259 \text{ W/m}\cdot\text{K}$ ,  $\mu = 178 \times 10^{-7} \text{ N}\cdot\text{s/m}^2$ ,  $\text{Pr} = 0.716$ .

**ANALYSIS:**

(a) A force balance on the particle yields

$$F_D = mg = \pi(D_p/2)^2 C_D \rho_f V^2/2 = \frac{4}{3} \pi (D_p/2)^3 \rho_p g$$

Which may be rearranged to yield

$$C_D = \frac{4}{3} D_p (\rho_p / \rho_f) g / V^2$$

$$C_D = \frac{4}{3} \times 130 \times 10^{-6} \text{ m} \times (8230/0.8425) \times 9.8 \text{ m/s}^2 / V^2$$

$$C_D = (16.59 \text{ m}^2 / \text{s}^2) / V^2 \tag{1}$$

and

Continued...

### PROBLEM 7.78 (Cont.)

$$\text{Re}_D = \frac{VD_p}{\nu} = V \times 130 \times 10^{-6} \text{ m} / 26.16 \times 10^{-6} \text{ m}^2/\text{s}$$

$$\text{Re}_D = (4.97 \text{ s/m}) \times V \quad (2)$$

Equations 1 and 2 may be solved for  $C_D$  and  $\text{Re}_D$  for any value of  $V$ . The resulting values of  $C_D$  and  $\text{Re}_D$  must be consistent with the results of Figure 7.9.

A trial-and-error solution yields  $V = 2.03 \text{ m/s}$ ,  $C_D = 4.03$ ,  $\text{Re}_D = 10.09$  from solution of Equations 1 and 2. From Figure 7.9, at  $\text{Re}_D = 10$ ,  $C_D = 4$ . Therefore  $V \approx 2 \text{ m/s}$ . <

We note that the terminal velocity is identical to the injection velocity. Hence, the particles travel at constant velocity. The particle cooling process occurs in two steps.

Step One: Particle cooling to  $T_f = 183^\circ\text{C}$ .

With nitrogen properties evaluated at  $T_\infty = 30^\circ\text{C}$ , the Reynolds number is

$$\text{Re}_D = \frac{2 \text{ m/s} \times 130 \times 10^{-6} \text{ m}}{15.86 \times 10^{-6} \text{ m}^2/\text{s}} = 16.39$$

The Whitaker correlation yields

$$\overline{\text{Nu}}_D = 2 + \left[ 0.4\sqrt{16.39} + 0.06 \times 16.39^{2/3} \right] \times 0.716^{0.4} \times \left( \frac{178}{248} \right)^{1/4} = 3.62$$

Therefore

$$\overline{h}_D = \overline{\text{Nu}}_D k / D_p = 3.62 \times 0.0259 \text{ W/m} \cdot \text{K} / 130 \times 10^{-6} \text{ m} = 721 \text{ W/m}^2 \cdot \text{K}$$

Using Equation 5.6 with  $A_s = 4\pi(D/2)^2 = 4 \times \pi \times (130 \times 10^{-6} \text{ m}/2)^2 = 53.1 \times 10^{-9} \text{ m}^2$ ,

$$\forall = (4/3) \pi (D/2)^3 = (4/3) \times \pi \times (130 \times 10^{-6} \text{ m}/2)^3 = 1.15 \times 10^{-12} \text{ m}^3,$$

$$\frac{T - T_\infty}{T_i - T_\infty} = \frac{183 - 30}{225 - 30} = 0.785 = \exp \left[ - \left( \frac{721 \text{ W/m}^2 \cdot \text{K} \times 53.1 \times 10^{-9} \text{ m}^2}{8230 \text{ kg/m}^3 \times 1.15 \times 10^{-12} \text{ m}^3 \times 240 \text{ J/kg} \cdot \text{K}} \right) \times t_1 \right]$$

from which

$$t_1 = 14.3 \times 10^{-3} \text{ s}$$

Step Two: Particle solidification at  $T_f = 183^\circ\text{C}$ .

An energy balance on the particle during solidification yields

$$\dot{E}_{\text{st}} + \dot{E}_{\text{out}} = 0$$

or

$$-\forall \rho_p h_{\text{sf}} - h A_s (T_f - T_\infty) t_2$$

or

$$t_2 = \frac{1.15 \times 10^{-12} \text{ m}^3 \times 8230 \text{ kg/m}^3 \times 42,000 \text{ J/kg}}{721 \text{ W/m}^2 \cdot \text{K} \times 53.1 \times 10^{-9} \text{ m}^2 \times (183 - 30)^\circ\text{C}} = 67.6 \times 10^{-3} \text{ s}$$

Therefore, the time to completely solidify is

Continued...

### PROBLEM 7.78 (Cont.)

$$T = t_1 + t_2 = 14.3 \times 10^{-3} \text{ s} + 67.6 \times 10^{-3} \text{ s} = 82 \times 10^{-3} \text{ s}$$

and the distance traveled is  $L = 2 \text{ m/s} \times 0.082 \text{ s} = 0.163 \text{ m}$

&lt;

(b) The distance that one particle travels is

$$L = (2 \text{ m/s}) / (1800 \text{ s}^{-1}) = 1.11 \text{ mm}$$

&lt;

The required pot size for one week of operation is

$$\forall_{\text{pot}} = 1.15 \times 10^{-12} \text{ m}^3/\text{particle} \times 1800 \text{ particles/s} \times 7 \text{ days} \times 24 \text{ h/day} \times 3600 \text{ s/h}$$

$$\forall_{\text{pot}} = 1.25 \times 10^{-3} \text{ m}^3$$

&lt;

**COMMENTS:** (1) The Biot number associated with the cooling of the particle is  $Bi = h(D_p/6)/k_p = 721 \text{ W/m}^2 \cdot \text{K} \times (130 \times 10^{-6} \text{ m/s}) / (38 \text{ W/m} \cdot \text{K}) = 0.0004 \ll 0.1$ . Therefore, the lumped capacitance assumption is valid. (2) The maximum possible radiation heat transfer coefficient is associated with the initial particle temperature and an emissivity of unity. Assuming a surroundings temperature of  $30^\circ\text{C} = 303 \text{ K}$ , we find a radiation heat transfer coefficient of  $h_r = 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times (498 + 303) \text{ K} \times (498^2 + 303^2) \text{ K}^2 = 15 \text{ W/m}^2 \cdot \text{K}$ . Therefore, radiation heat transfer is negligible. (3) The terminal velocity of the very small spherical particle is relatively low. This is because the surface area to weight ratio of a sphere is inversely proportional to the sphere diameter. As the sphere becomes small, drag forces become relatively large at relatively low velocities.

## PROBLEM 7.79

**KNOWN:** A spherical workpiece of pure copper with a diameter of 15 mm and emissivity of 0.5 is suspended in a large furnace with walls at a uniform temperature of 600°C. The air flow over the workpiece has a temperature of 900°C with a velocity of 7.5 m/s.

**FIND:** (a) The steady-state temperature of the workpiece; (b) Estimate the time required for the workpiece to reach within 5°C of the steady-state temperature if its initial, uniform temperature is 25°C; (c) Estimate the steady-state temperature of the workpiece if the air velocity is doubled with all other conditions remaining the same; also, determine the time required for the workpiece to reach within 5°C of this value. Plot on the same graph the workpiece temperature histories for the two air velocity conditions.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Flow over a smooth sphere, (2) Sphere behaves as spacewise isothermal object; lumped capacitance method is valid, (3) Sphere is small object in large, isothermal surroundings, and (4) Constant properties.

**PROPERTIES:** Table A-4, Air ( $T_\infty = 1173$  K, 1 atm):  $\mu = 4.665 \times 10^{-5}$  N·s/m<sup>2</sup>,  $\nu = 0.0001572$  m<sup>2</sup>/s,  $k = 0.075$  W/m·K,  $Pr = 0.728$ ; Air ( $T_s = 1010$  K, 1 atm):  $\mu_s = 4.268 \times 10^{-5}$  N·s/m<sup>2</sup>.

**ANALYSIS:** (a) The steady-state temperature is determined from the energy balance on the sphere as represented in the schematic above.

$$\begin{aligned} \dot{E}_{\text{in}} - \dot{E}_{\text{out}} + \dot{E}_{\text{gen}} &= 0 & -q_{\text{cv}} - q_{\text{rad}} + 0 &= 0 \\ -\bar{h}_D A_s (T_s - T_\infty) - \varepsilon A_s \sigma (T_s^4 - T_{\text{sur}}^4) &= 0 \end{aligned} \quad (1)$$

where  $A_s = \pi D^2/4$ . The convection coefficient can be estimated using the Whitaker correlation, Eq. 7.56, where all properties except  $\mu_s$  are evaluated at  $T_\infty$ . Assume  $T_s = 737^\circ\text{C} = 1010$  K to evaluate  $\mu_s$ .

$$\bar{Nu}_D = 2 + \left[ 0.4 Re_D^{1/2} + 0.06 Re_D^{2/3} \right] Pr^{0.4} (\mu/\mu_s)^{1/4} \quad (2)$$

See the table below for results of the correlation calculations. From the energy balance, canceling out  $A_s$ , with numerical values, find  $T_s$ .

$$-79.8 \text{ W/m}^2 \cdot \text{K} (T_s - 1173) \text{ K} - 0.5 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (T_s^4 - 873^4) \text{ K}^4 = 0$$

$$T_s = 1010 \text{ K} = 737^\circ\text{C}. \quad \leftarrow$$

(b) The time required for the sphere initially at  $T_i = 25^\circ\text{C}$  to reach within 5°C of the steady-state temperature can be determined from the energy balance for the transient condition.

Continued ...

**PROBLEM 7.79 (Cont.)**

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} + \dot{E}_{\text{gen}} = \dot{E}_{\text{st}}$$

$$-\bar{h}_D A_s (T_s - T_\infty) - \varepsilon A_s \sigma (T_s^4 - T_{\text{sur}}^4) = \rho c \left( \pi D^3 / 6 \right) \frac{dT}{dt} \quad (3)$$

Recognize that  $\bar{h}_D$  is not constant, but depends upon  $T_s(t)$ . Using *IHT* to perform the integration, evaluate  $\bar{h}_D$ , and provide pure copper properties  $\rho$  and  $c$  as a function of  $T_s$ , the time  $t_o$  for  $T(t_o) = (737 - 5)^\circ\text{C} = 732^\circ\text{C}$  is

$$t_o = 274 \text{ s} \quad \leftarrow$$

See Comments 1 and 2 for details on the *IHT* calculation method.

(c) Use Eq. (1) and (2) to find the steady-state temperature when the air velocity is doubled,  $V = 2 \times 7.5 \text{ m/s} = 15 \text{ m/s}$ . The results are tabulated below along with those from part (a).

Part	V (m/s)	Re <sub>D</sub>	$\bar{\text{Nu}}_D$	$\bar{h}_D$ (W/m <sup>2</sup> ·K)	T <sub>s</sub> (°C)
a	7.5	715.6	15.96	79.8	737
b	15	1431	22.42	112.1	760

As expected, increasing the air velocity will cause the sphere temperature to increase toward  $T_\infty$ . Note that  $\bar{h}_D$  increases by a factor of 1.4 as the air velocity is doubled. From correlation Eq. (2) note that  $\bar{h}_D$  is approximately proportional to  $V^n$  where  $n$  is in the range 1/2 to 2/3. Using the *IHT* code for the lumped capacitance analysis, the time for  $T(t_o) = (760 - 5)^\circ\text{C} = 755^\circ\text{C}$  is

$$t_o = 230 \text{ s} \quad \leftarrow$$

The temperature histories for the two air velocity conditions are calculated using the foregoing transient analyses in the *IHT* workspace.

Continued ...

## PROBLEM 7.79 (Cont.)

**COMMENTS:** (1) The portion of the *IHT* code for performing the energy balance and evaluating the convection correlation function using the properties function follows.

```
// Convection correlation, sphere
NuDbar = NuL_bar_EF_SP(ReD,Pr,mu,mus) // Eq 7.56
NuDbar = hbar * D / k
ReD = V * D / nu
/* All properties except mus are evaluated at Tinf. */
/* Correlation description: External flow (EF) over a sphere (SP), average coefficient,
3.5<ReD<7.6x10^4, 0.71<Pr<380, 1.0<(mu/mus)<3.2, Whitaker correlation, Eq 7.56. See Table 7.9. */

// Energy balance, steady-state temperature
-hbar * As * (Ts - Tinf) - eps * sigma * (Ts^4 - Tsur^4) * As = 0
As = pi * D^2
sigma = 5.67e-8

// Air property functions : From Table A.4
// Units: T(K); 1 atm pressure
mu = mu_T("Air",Tinf) // Viscosity, N-s/m^2
mus = mu_T("Air",Ts) // Viscosity, N-s/m^2
nu = nu_T("Air",Tinf) // Kinematic viscosity, m^2/s
k = k_T("Air",Tinf) // Thermal conductivity, W/m-K
Pr = Pr_T("Air",Tinf) // Prandtl number

// Input variables
D = 0.015
eps = 0.5
V = 7.5
Tinf = 900 + 273
Tsur = 600 + 273
```

(2) Two modifications can be made to the code above to perform the lumped capacitance method for the transient analysis: (a) include the storage term in the energy balance and (b) provide the properties function for copper. The initial condition,  $T_i = 288$  K, is entered as the initial condition when the solver performs the integration.

```
// Energy balance, steady-state; equilibrium temperature
-hbar * As * (Ts - Tinf) - eps * sigma * (Ts^4 - Tfur^4) * As = M * ccu * der(Ts,t)
As = pi * D^2
sigma = 5.67e-8
M = rhocu * pi * D^3 / 6

// Copper (pure) property functions : From Table A.1
// Units: T(K)
rhocu = rho_300K("Copper") // Density, kg/m^3
kcu = k_T("Copper",Ts) // Thermal conductivity, W/m-K
ccu = cp_T("Copper",Ts) // Specific heat, J/kg-K
```

(3) Show that the lumped capacitance method is valid for this application.

### PROBLEM 7.80

**KNOWN:** Diameter and initial and final temperatures of copper spheres quenched in a water bath.

**FIND:** (a) Terminal velocity in the bath, (b) Tank height.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Sphere descends at terminal velocity, (2) Uniform, but time varying surface, temperature.

**PROPERTIES:** Table A-1, Copper (350K):  $\rho = 8933 \text{ kg/m}^3$ ,  $k = 398 \text{ W/m}\cdot\text{K}$ ,  $c_p = 387 \text{ J/kg}\cdot\text{K}$ ;  
 Table A-6, Water ( $T_\infty = 280 \text{ K}$ ):  $\rho = 1000 \text{ kg/m}^3$ ,  $\mu = 1422 \times 10^{-6} \text{ N}\cdot\text{s/m}^2$ ,  $k = 0.582 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 10.26$ ; ( $T_s \approx 340 \text{ K}$ ):  $\mu_s = 420 \times 10^{-5} \text{ N}\cdot\text{s/m}^2$ .

**ANALYSIS:** A force balance gives  $C_D \left( \frac{\pi D^2}{4} \right) \rho V^2 / 2 = (\rho_{cu} - \rho) g \pi D^3 / 6$ ,

$$C_D V^2 = \frac{4D}{3} \frac{\rho_{cu} - \rho}{\rho} g = \frac{4 \times 0.02 \text{ m}}{3} \cdot \frac{8933 - 1000}{1000} 9.8 \text{ m/s}^2 = 2.07 \text{ m}^2/\text{s}^2.$$

An iterative solution is needed, where  $C_D$  is obtained from Figure 7.9 with  $\text{Re}_D = VD/\nu = 0.02 \text{ m} / (1.42 \times 10^{-6} \text{ m}^2/\text{s}) = 14,085$ . Convergence is achieved with

$$V \approx 2.1 \text{ m/s} \quad <$$

for which  $\text{Re}_D = 29,580$  and  $C_D \approx 0.46$ . Using the Whitaker expression

$$\overline{\text{Nu}}_D = 2 + \left( 0.4 \times 29,850^{1/2} + 0.06 \times 29,850^{2/3} \right) (10.26)^{0.4} (1422/420)^{1/4} = 439$$

$$\bar{h} = \overline{\text{Nu}}_D k/D = 439 \times 0.582 \text{ W/m}\cdot\text{K} / 0.02 \text{ m} = 12,775 \text{ W/m}^2 \cdot \text{K}.$$

To determine applicability of lumped capacitance method, find  $\text{Bi} = \bar{h}(r_o/3)/k_{cu} = 12,775$

$\text{W/m}^2 \cdot \text{K} (0.01 \text{ m}/3) / 398 \text{ W/m}\cdot\text{K} = 0.11$ . Applicability is marginal. Using Eq. 5.53c,

$\theta_o^* = C_1 \exp(-\xi_1^2 \text{Fo})$  and from Table 5.1 at  $\text{Bi}_i = \bar{h} r_o/k = 0.32$ ,  $C_1 = 1.0937$ ,  $\xi_1 = 0.9472$ . Substituting into the preceding equation yields

$$0.5 = 1.0937 \exp(-0.9472^2 \text{Fo}) \text{ from which}$$

$$\text{Fo} = 0.87 = \alpha t_f / r_o^2$$

With  $\alpha_{cu} = k/\rho c_p = 398 \text{ W/m}\cdot\text{K} / (8933 \text{ kg/m}^3) (387 \text{ J/kg}\cdot\text{K}) = 1.15 \times 10^{-4} \text{ m}^2/\text{s}$ , find

$$t_f = 0.87 (0.01 \text{ m})^2 / 1.15 \times 10^{-4} \text{ m}^2/\text{s} = 0.76 \text{ s}.$$

Required tank height is

$$H = t_f \cdot V = 0.76 \text{ s} \times 2.1 \text{ m/s} = 1.6 \text{ m}. \quad <$$

**COMMENTS:** Note that the terminal velocity is not reached immediately. Reduced  $V$  implies reduced  $\bar{h}$  and increased  $t_f$ . The Fourier number,  $\text{Fo}$ , is greater than 0.2. Hence, use of Eq. 5.53c is justified.

### PROBLEM 7.81

**KNOWN:** Diameter and initial and final temperatures of copper spheres quenched in an oil bath.

**FIND:** (a) Terminal velocity in bath, (b) Bath height.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Sphere descends at terminal velocity, (2) Uniform, but time varying, surface temperature.

**PROPERTIES:** Table A-1, Copper (350K):  $\rho_{\text{Cu}} = 8933 \text{ kg/m}^3$ ,  $k = 398 \text{ W/m}\cdot\text{K}$ ,  $c_p = 387 \text{ J/kg}\cdot\text{K}$ ;  
Table A-5, Oil ( $T_\infty = 300\text{K}$ ):  $\rho = 884 \text{ kg/m}^3$ ,  $\mu = 0.486 \text{ N}\cdot\text{s/m}^2$ ,  $k = 0.145 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 6400$ ; ( $T_s \approx 340\text{K}$ ):  $\mu = 0.0531 \text{ N}\cdot\text{s/m}^2$ .

**ANALYSIS:** (a) Force balance gives  $C_D (\pi D^2 / 4) \rho V^2 / 2 = (\rho_{\text{Cu}} - \rho) g \pi D^3 / 6$ ,

$$C_D V^2 = \frac{4D}{3} \frac{\rho_{\text{Cu}} - \rho}{\rho} g = \frac{4 \times 0.02 \text{ m}}{3} \frac{8933 - 884}{884} 9.8 \frac{\text{m}}{\text{s}^2} = 2.38 \text{ m}^2 / \text{s}^2.$$

An iterative solution is needed, where  $C_D$  is obtained from Fig. 7.9 with

$$\text{Re}_D = \frac{VD}{\nu} = \frac{0.02 \text{ m} (V)}{(0.486/884) \text{ m}^2 / \text{s}} = 36.4 V (\text{m/s}).$$

Convergence is achieved for  $V \approx 1.1 \text{ m/s}$  <

for which  $\text{Re}_D = 40$  and  $C_D \approx 1.97$ . Using the Whitaker expression

$$\begin{aligned} \overline{\text{Nu}}_D &= 2 + \left( 0.4 \text{Re}_D^{1/2} + 0.06 \text{Re}_D^{2/3} \right) \text{Pr}^{0.4} (\mu / \mu_s)^{1/4} \\ \overline{\text{Nu}}_D &= 2 + \left( 0.4 \times 40^{1/2} + 0.06 \times 40^{2/3} \right) (6400)^{0.4} (0.486 / 0.0531)^{1/4} = 189.2 \\ \bar{h} &= \overline{\text{Nu}}_D k / D = 189.2 \times 0.145 / 0.02 = 1357 \text{ W/m}^2 \cdot \text{K}. \end{aligned}$$

To determine applicability of the lumped capacitance method, find  $\text{Bi} = \bar{h} (r_o / 3) / k_{\text{Cu}} =$

$1357 \text{ W/m}^2 \cdot \text{K} (0.01 \text{ m} / 3) / 398 \text{ W/m}\cdot\text{K} = 0.011$ . Hence lumped capacitance method can be used; from Eq. 5.5,

$$\begin{aligned} t_f &= \frac{(\rho c)_{\text{Cu}} \pi D^3 / 6}{\bar{h} \pi D^2} \ln \frac{T_i - T_\infty}{T_f - T_\infty} \\ t_f &= \frac{8933 \text{ kg/m}^3 \times 387 \text{ J/kg}\cdot\text{K} \times 0.02 \text{ m}}{1357 \text{ W/m}^2 \cdot \text{K}} \ln \frac{60}{20} = 9.33 \text{ s}. \end{aligned}$$

Required tank height is  $H = t_f \cdot V = 9.33 \text{ s} \times 1.1 \text{ m/s} = 10.3 \text{ m}$ . <

**COMMENTS:** (1) Whitaker correlation has been used well beyond its limits ( $\text{Pr} \gg 380$ ). Hence estimate of  $\bar{h}$  is uncertain. (2) Since terminal velocity is not reached immediately,

$\bar{h} < 1357 \text{ W/m}^2 \cdot \text{K}$  and  $t_f > 9.33 \text{ s}$ .

## PROBLEM 7.82

**KNOWN:** Velocity of plasma jet and initial particle velocity in a plasma spray coating process.  
Distance from particle injection to impact.

**FIND:** (a) Particle velocity and distance of travel as a function of time. Time-in-flight and particle impact velocity, (b) Convection heat transfer coefficient and time required to heat particle to melting point and to subsequently melt it.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Applicability of Stokes' law, (2) Constant particle and plasma properties, (3) Negligible influence of viscosity ratio in Whitaker correlation, (4) Negligible radiation effects, (5) Validity of lumped capacitance approximation.

**ANALYSIS:** (a) From Eqs. 7.50 and 7.55,

$$C_D \equiv \frac{F_D}{A_f (\rho \bar{V}^2 / 2)} = \frac{24}{\text{Re}_D} = \frac{24}{\rho \bar{V} D_p / \mu}$$

where  $\bar{V} \equiv V - V_p$  is the relative velocity and  $A_f = \pi D_p^2 / 4$ . Hence, the drag force on the particle is

$$F_D = 3\pi\mu D_p \bar{V} = m_p (dV_p / dt) = -m_p (d\bar{V} / dt)$$

Separating variables and integrating from the nozzle exit, where  $V_p = 0$ ,  $\bar{V} = V$  and  $t = 0$ ,

$$\int_V \frac{d\bar{V}}{\bar{V}} = -\frac{3\pi\mu D_p}{m_p} \int_0^t dt$$

$$\ln \frac{\bar{V}}{V} = -\frac{3\pi\mu D_p t}{m_p}$$

$$\bar{V} = V \exp(-3\pi\mu D_p t / m_p) = V - V_p$$

Hence,

$$V_p(t) = V \left[ 1 - \exp(-3\pi\mu D_p t / m_p) \right]$$

With  $V_p = dx_p / dt$ , it follows that

$$\int_0^L dx_p = \int_0^{t_f} V \left[ 1 - \exp(-3\pi\mu D_p t / m_p) \right] dt$$

Continued... <

**PROBLEM 7.82 (Cont.)**

$$L = Vt_f - \frac{Vm_p}{3\pi\mu D_p} \left[ 1 - \exp(-3\pi\mu D_p t_f / m_p) \right] \quad <$$

Substituting the prescribed values of  $D_p$ ,  $L$ ,  $V$  and the material properties, the foregoing equations yield

$$V_p = 166.7 \text{ m/s} \quad t_f = 0.0011 \text{ s} \quad <$$

(b) Assuming an average value of  $\bar{V} = 315 \text{ m/s}$ , the Reynolds number is

$$Re_D = \frac{315 \text{ m/s} \times 50 \times 10^{-6} \text{ m}}{5.6 \times 10^{-3} \text{ m}^2/\text{s}} = 2.81$$

From the Whitaker correlation,

$$\bar{Nu}_D = 2 + \left( 0.4 Re_D^{1/2} + 0.06 Re_D^{2/3} \right) Pr^{0.4}$$

$$\bar{Nu}_D = 2 + \left( 0.4 \times 2.81^{1/2} + 0.06 \times 2.81^{2/3} \right) (0.60)^{0.4} = 2.64$$

$$\bar{h} = 2.64 k / D_p = 2.64 (0.671 \text{ W/m} \cdot \text{K}) / 50 \times 10^{-6} \text{ m} = 35,400 \text{ W/m}^2 \cdot \text{K} \quad <$$

The two-step melting process involves (i) the time  $t_1$  to heat the particle to its melting point and (ii) the time  $t_2$  required to achieve complete melting. Hence,  $t_m = t_1 + t_2$ , where from Eq. 5.5,

$$t_1 = \frac{\rho_p D_p c_p}{6\bar{h}} \ln \frac{T_i - T_\infty}{T_{mp} - T_\infty}$$

$$t_1 = \frac{3970 \text{ kg/m}^3 (50 \times 10^{-6} \text{ m}) 1560 \text{ J/kg} \cdot \text{K}}{6 (35,400 \text{ W/m}^2 \cdot \text{K})} \ln \frac{(300 - 10,000)}{(2318 - 10,000)} = 3.4 \times 10^{-4} \text{ s}$$

Performing an energy balance for the second step, we obtain

$$\int_{t_1}^{t_m} q_{conv} dt = \Delta E_{st} = \rho_p \forall h_{sf}$$

Hence,

$$t_2 = \frac{\rho_p D_p}{6\bar{h}} \frac{h_{sf}}{(T_\infty - T_{mp})} = \frac{3970 \text{ kg/m}^3 (50 \times 10^{-6} \text{ m})}{6 (35,400 \text{ W/m}^2 \cdot \text{K})} \times \frac{3.577 \times 10^6 \text{ J/kg}}{(10,000 - 2318) \text{ K}} = 4.4 \times 10^{-4} \text{ s}$$

Hence,

$$t_m = (3.4 \times 10^{-4} + 4.4 \times 10^{-4}) \text{ s} = 7.8 \times 10^{-4} \text{ s} \quad <$$

and the prescribed value of  $L$  is sufficient to insure complete melting before impact.

**COMMENTS:** (1) Since  $Bi = (\bar{h} r_p / 3) / k_p \approx 0.03$ , use of the lumped capacitance approach is appropriate.

(2) With  $Re_D = 2.81$ , conditions are slightly outside the ranges associated with Stokes' law.

### PROBLEM 7.83

**KNOWN:** Diameter, velocity, initial temperature and melting point of molten aluminum droplets. Temperature of helium atmosphere.

**FIND:** Maximum allowable separation between droplet injector and substrate.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Lumped capacitance approximation is valid, (2) Constant properties, (3) Negligible radiation.

**PROPERTIES:** Table A-4, Helium ( $T_\infty = 300 \text{ K}$ ):  $\nu = 122 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\mu = 199 \times 10^{-7} \text{ N}\cdot\text{s}/\text{m}^2$ ,  $k = 0.152 \text{ W}/\text{m}\cdot\text{K}$ ,  $\text{Pr} = 0.68$ . Helium ( $T_s \approx 1000 \text{ K}$ ):  $\mu_s = 446 \times 10^{-7} \text{ N}\cdot\text{s}/\text{m}^2$ . Given, Aluminum:  $\rho = 2500 \text{ kg}/\text{m}^3$ ,  $c = 1200 \text{ J}/\text{kg}\cdot\text{K}$ ,  $k = 200 \text{ W}/\text{m}\cdot\text{K}$ .

**ANALYSIS:** With  $\text{Re}_D = VD/\nu = 3 \text{ m/s} (5 \times 10^{-4} \text{ m}) / 122 \times 10^{-6} \text{ m}^2/\text{s} = 12.3$ , the Whitaker correlation yields

$$\bar{h} = \frac{k}{D} \left[ 2 + \left( 0.4 \text{Re}_D^{1/2} + 0.06 \text{Re}_D^{2/3} \right) \text{Pr}^{0.4} \left( \mu / \mu_s \right)^{1/4} \right]$$

$$\bar{h} = \frac{0.152 \text{ W}/\text{m}\cdot\text{K}}{0.0005 \text{ m}} \left\{ 2 + \left[ 0.4 (12.3)^{1/2} + 0.06 (12.3)^{2/3} \right] (0.68)^{0.4} \left( \frac{199}{446} \right)^{1/4} \right\} = 975 \text{ W}/\text{m}^2 \cdot \text{K}$$

The *time-of-flight* for the droplet to cool from 1100K to 933K may be obtained from Eq. 5.5.

$$t = \frac{\rho \forall c}{\bar{h} A_s} \ln \frac{\theta_i}{\theta} = \frac{\rho c D}{6 \bar{h}} \ln \frac{T_i - T_\infty}{T_f - T_\infty}$$

$$t = \frac{(2500 \text{ kg}/\text{m}^3) 1200 \text{ J}/\text{kg}\cdot\text{K} (0.0005 \text{ m})}{6 \times 975 \text{ W}/\text{m}^2 \cdot \text{K}} \ln \left( \frac{800}{633} \right) = 0.06 \text{ s}$$

The maximum separation is therefore

$$L = V \times t = 3 \text{ m/s} \times 0.06 \text{ s} = 0.18 \text{ m} = 180 \text{ mm} \quad \leftarrow$$

**COMMENTS:** (1) With  $\text{Bi} = \bar{h} (D/6) / k = 4 \times 10^{-4}$ , the lumped capacitance approximation is excellent. (2) With the surroundings assumed to be at  $T_{\text{sur}} = T_\infty$  and a representative emissivity of  $\varepsilon = 0.1$  for molten aluminum,  $h_r \leq \varepsilon \sigma (T_i + T_\infty) (T_i^2 + T_\infty^2) \approx 10 \text{ W}/\text{m}^2 \cdot \text{K} \ll \bar{h} = 975 \text{ W}/\text{m}^2 \cdot \text{K}$ . Hence, radiation is, in fact, negligible. (3) Note that, for liquid metals especially, surfaces can quickly become oxidized. The oxidation layer restricts surface motion and the droplet can behave like a solid sphere. Thus we have used the Whitaker correlation in lieu of the Ranz-Marshall correlation.

## PROBLEM 7.84

**KNOWN:** Method to manufacture small diameter droplets. Properties of  $D = 75 \mu\text{m}$  diameter particles ejected into air. Air temperature and pressure, initial particle temperature. Desired temperature of drop upon impact of a substrate.

**FIND:** (a) Terminal velocity of the droplets, (b) Separation distance between droplet injection location and substrate so that the droplets impact the substrate at  $T_2 = 120^\circ\text{C}$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible radiation heat transfer, (2) lumped capacitance thermal response, (3) Negligible microscale heat transfer effects.

**PROPERTIES:** Table A.4, air: ( $T_f \approx [(T_i + T_2)/2 + T_\infty]/2 = [(150^\circ\text{C} + 120^\circ\text{C})/2 + 25^\circ\text{C}]/2 = 80^\circ\text{C} \approx 353\text{ K}$ ):  $\rho = 0.9876\text{ kg/m}^3$ ,  $\nu = 21.25 \times 10^{-6}\text{ m}^2/\text{s}$ ,  $k = 0.03023\text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.6994$ . ( $\bar{T}_s = (150^\circ\text{C} + 120^\circ\text{C})/2 = 135^\circ\text{C} = 408\text{ K}$ ):  $\mu_s = 2.334 \times 10^{-5}\text{ N}\cdot\text{s/m}^2$ . ( $T_\infty = 25^\circ\text{C} = 298\text{ K}$ ):  $\nu = 15.71 \times 10^{-6}\text{ m}^2/\text{s}$ ,  $k = 0.02614\text{ W/m}\cdot\text{K}$ ,  $\mu = 1.836 \times 10^{-5}\text{ N}\cdot\text{s/m}^2$ ,  $\text{Pr} = 0.7075$ .

**ANALYSIS:**

(a) A force balance on the particle yields

$$\forall \rho_p g = C_D A_f (\rho V^2 / 2) \quad (1)$$

where  $\forall = \frac{4}{3} \pi (D_p/2)^3 = \frac{4}{3} \times \pi \times (75 \times 10^{-6}\text{ m}/2)^3 = 220.9 \times 10^{-15}\text{ m}^3$

$$A_f = \pi (D_p/2)^2 = \pi \times (75 \times 10^{-6}\text{ m}/2)^2 = 4.42 \times 10^{-9}\text{ m}^2$$

We also know

$$\text{Re}_D = \frac{V D_p}{\nu} = \frac{V \times 75 \times 10^{-6}\text{ m}}{21.25 \times 10^{-6}\text{ m}^2/\text{s}} = 3.53(\text{s/m}) \times V \quad (2)$$

The correct velocity will yield values of  $C_D$  and  $\text{Re}_D$  that are consistent with Figure 7.9. A trial-and-error solution yields (using properties at  $\bar{T}_f$ )

$$V \approx 0.30\text{ m/s}, \text{Re}_D = 1.06, C_D = 24.2 \quad (C_D \text{ from Figure 7.8} \approx 25) \quad <$$

(b) Using the Whitaker correlation with properties evaluated at  $T_\infty$ ,

$$\text{Re}_D = 0.3\text{ m/s} \times 75 \times 10^{-6}\text{ m} / 1.571 \times 10^{-5}\text{ m}^2/\text{s} = 1.43$$

Therefore,

Continued...

### PROBLEM 7.84 (Cont.)

$$\overline{\text{Nu}}_D = 2 + \left[ 0.4\sqrt{1.43} + 0.06 \times 1.43^{2/3} \right] \times 0.7075^{0.4} \times \left( \frac{1.836}{2.334} \right)^{1/4} = 2.45$$

$$\bar{h}_D = \overline{\text{Nu}}_D k / D_p = 2.45 \times 0.02614 \text{ W/m} \cdot \text{K} / 75 \times 10^{-6} \text{ m} = 854 \text{ W/m}^2 \cdot \text{K}$$

Using Equation 5.6 with  $A_s = 4 \times \pi \times (75 \times 10^{-6} \text{ m}/2)^2 = 17.7 \times 10^{-9} \text{ m}^2$ ,

$$\frac{T_2 - T_\infty}{T_1 - T_\infty} = \frac{120 - 25}{150 - 25} = 0.76 = \exp \left[ - \left( \frac{854 \text{ W/m}^2 \cdot \text{K} \times 17.7 \times 10^{-9} \text{ m}^2}{2200 \text{ kg/m}^3 \times 220.9 \times 10^{-15} \text{ m}^3 \times 700 \text{ J/kg} \cdot \text{K}} \right) \times t \right]$$

yielding  $t = 6.20 \times 10^{-3} \text{ s} = 6.2 \text{ ms}$ . The separation distance,  $L$ , is therefore

$$L = 0.30 \text{ m/s} \times 6.2 \times 10^{-3} \text{ s} = 1.86 \times 10^{-3} \text{ m} = 1.86 \text{ mm}$$

<

**COMMENTS:** (1) The maximum possible radiation heat transfer coefficient is associated with the initial particle temperature and an emissivity of unity. Assuming a surroundings temperature of  $25^\circ\text{C} = 298 \text{ K}$ , we find a radiation heat transfer coefficient of  $h_r = 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times (423 + 298) \text{ K} \times (423^2 + 298^2) \text{ K}^2 = 11 \text{ W/m}^2 \cdot \text{K}$ . Therefore, radiation heat transfer is negligible. (2) The terminal velocity of the very small spherical particle is very low. This is because the surface area to weight ratio of a sphere is inversely proportional to the sphere diameter. As the sphere becomes small, drag forces become relatively large at relatively low velocities. (3) The Whitaker correlation has been extrapolated outside of its recommended range of application. However, we know that the limiting value of the average Nusselt number is two. (4) The sphere is very small and the density of the sphere is relatively low. The lumped capacitance assumption is likely to be valid.

## PROBLEM 7.85

**KNOWN:** Velocity and temperature of combustion gases. Diameter and emissivity of thermocouple junction. Combustor temperature.

**FIND:** (a) Time to achieve 98% of maximum thermocouple temperature rise, (b) Steady-state thermocouple temperature, (c) Effect of gas velocity and thermocouple emissivity on measurement error.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Validity of lumped capacitance analysis, (2) Constant properties, (3) Negligible conduction through lead wires, (4) Radiation exchange between small surface and a large enclosure (parts b and c).

**PROPERTIES:** Thermocouple (given):  $0.1 \leq \varepsilon \leq 1.0$ ,  $k = 100 \text{ W/m}\cdot\text{K}$ ,  $c = 385 \text{ J/kg}\cdot\text{K}$ ,  $\rho = 8920 \text{ kg/m}^3$ ; Gases (given):  $k = 0.05 \text{ W/m}\cdot\text{K}$ ,  $\nu = 50 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.69$ .

**ANALYSIS:** (a) If the lumped capacitance analysis may be used, it follows from Equation 5.5 that

$$t = \frac{\rho V c}{h A_s} \ln \frac{T_i - T_\infty}{T - T_\infty} = \frac{D \rho c}{6 h} \ln(50).$$

Neglecting the viscosity ratio correlation for variable property effects, use of  $V = 5 \text{ m/s}$  with the Whitaker correlation yields

$$\overline{\text{Nu}}_D = (\overline{h}D/k) = 2 + \left(0.4 \text{Re}_D^{1/2} + 0.06 \text{Re}_D^{2/3}\right) \text{Pr}^{0.4} \quad \text{Re}_D = \frac{VD}{\nu} = \frac{5 \text{ m/s}(0.001 \text{ m})}{50 \times 10^{-6} \text{ m}^2/\text{s}} = 100$$

$$\overline{h} = \frac{0.05 \text{ W/m}\cdot\text{K}}{0.001 \text{ m}} \left[ 2 + \left(0.4(100)^{1/2} + 0.06(100)^{2/3}\right) (0.69)^{0.4} \right] = 328 \text{ W/m}^2 \cdot \text{K}$$

Since  $\text{Bi} = \overline{h}(r_o/3)/k = 5.5 \times 10^{-4}$ , the lumped capacitance method may be used. Hence,

$$t = \frac{0.001 \text{ m} \left(8920 \text{ kg/m}^3\right) 385 \text{ J/kg}\cdot\text{K}}{6 \times 328 \text{ W/m}^2 \cdot \text{K}} \ln(50) = 6.83 \text{ s} \quad \leftarrow$$

(b) Performing an energy balance on the junction and evaluating radiation exchange,  $q_{\text{conv}} = q_{\text{rad}}$ . Hence, with  $\varepsilon = 0.5$ ,

$$\overline{h} A_s (T_\infty - T) = \varepsilon A_s \sigma (T^4 - T_c^4)$$

$$(1000 - T) \text{ K} = \frac{0.5 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4}{328 \text{ W/m}^2 \cdot \text{K}} \left[ T^4 - (400)^4 \right] \text{ K}^4.$$

$$T = 936 \text{ K} \quad \leftarrow$$

(c) Using the *IHT First Law Model for a Solid Sphere* with the appropriate *Correlation* for external flow from the Tool Pad, parametric calculations were performed to determine the effects of  $V$  and  $\varepsilon_g$ , and the following results were obtained.

Continued...

### PROBLEM 7.85 (Cont.)

Since the temperature recorded by the thermocouple junction increases with increasing  $V$  and decreasing  $\epsilon$ , the measurement error,  $T_\infty - T$ , decreases with increasing  $V$  and decreasing  $\epsilon$ . The error is due to net radiative transfer from the junction (which depresses  $T$ ) and hence should decrease with decreasing  $\epsilon$ . For a prescribed heat loss, the temperature difference ( $T_\infty - T$ ) decreases with decreasing convection resistance, and hence with increasing  $h(V)$ .

**COMMENTS:** To infer the actual gas temperature (1000 K) from the measured result (936 K), correction would have to be made for radiation exchange with the cold surroundings.

## PROBLEM 7.86

**KNOWN:** Diameter, emissivity and temperature of a thermocouple junction exposed to hot gases flowing through a duct of prescribed surface temperature.

**FIND:** (a) Relative magnitudes of gas and thermocouple temperatures if the duct surface temperature is less than the gas temperature, (b) Gas temperature for prescribed conditions, (c) Effect of Velocity and emissivity on measurement error.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Junction is diffuse-gray, (3) Duct forms a large enclosure about the junction, (4) Negligible heat transfer by conduction through the thermocouple leads, (5) Gas properties are those of atmospheric air.

**PROPERTIES:** Table A-4, Air ( $T_g \approx 650$  K, 1 atm):  $\nu = 60.21 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0497 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.690$ ,  $\mu = 322.5 \times 10^{-7} \text{ N}\cdot\text{s}/\text{m}^2$ ; Air ( $T_j = 593$  K, 1 atm):  $\mu = 304 \times 10^{-7} \text{ N}\cdot\text{s}/\text{m}^2$ .

**ANALYSIS:** (a) From an energy balance on the thermocouple junction,  $q_{\text{conv}} = q_{\text{rad}}$ . Hence,

$$\bar{h}A(T_g - T_j) = \varepsilon\sigma A(T_j^4 - T_s^4) \quad \text{or} \quad T_g - T_j = \frac{\varepsilon}{h}\sigma(T_j^4 - T_s^4).$$

If  $T_s < T_j$ , it follows that  $T_j < T_g$ . <

(b) Neglecting the variable property correction,  $(\mu/\mu_s)^{1/4} = (322.5/304)^{1/4} = 1.01 \approx 1.00$ , and using

$$\text{Re}_D = \frac{VD}{\nu} = \frac{3 \text{ m/s}(0.002 \text{ m})}{60.21 \times 10^{-6} \text{ m}^2/\text{s}} = 100$$

the Whitaker correlation for a sphere gives

$$\bar{h} = \frac{0.0497 \text{ W/m}\cdot\text{K}}{0.002 \text{ m}} \left\{ 2 + \left[ 0.4(100)^{1/2} + 0.06(100)^{2/3} \right] (0.69)^{0.4} \right\} = 163 \text{ W/m}^2 \cdot \text{K}.$$

Hence

$$(T_g - 593 \text{ K}) = \frac{0.6}{163 \text{ W/m}^2 \cdot \text{K}} 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left[ (593 \text{ K})^4 - (448 \text{ K})^4 \right] = 17 \text{ K}$$

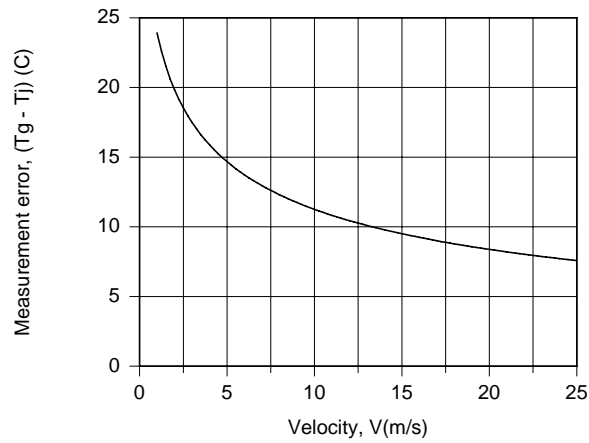

$$T_g = 610 \text{ K} = 337^\circ\text{C}. \quad \text{<}$$

(c) With  $T_g$  fixed at 610 K, the IHT *First Law* Model was used with the *Correlations* and *Properties* Tool Pads to compute the measurement error as a function of  $V$  and  $\varepsilon$ .

Continued...

### PROBLEM 7.86 (Cont.)

Since the convection resistance decreases with increasing  $V$ , the junction temperature will approach the gas temperature and the measurement error will decrease. Since the depression in the junction temperature is due to radiation losses from the junction to the duct wall, a reduction in  $\epsilon$  will reduce the measurement error.

**COMMENTS:** In part (b), calculations could be improved by evaluating properties at 610 K (instead of 650 K).

### PROBLEM 7.87

**KNOWN:** Diameter and emissivity of a thermocouple junction exposed to hot gases of prescribed velocity and temperature flowing through a duct of prescribed surface temperature.

**FIND:** (a) Thermocouple reading for gas at atmospheric pressure, (b) Thermocouple reading when gas pressure is doubled.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Junction is diffuse-gray, (3) Duct forms a large enclosure about junction, (4) Negligible heat loss by conduction through thermocouple leads, (5) Gas properties are those of air, (6) Perfect gas behavior.

**PROPERTIES:** Table A-4, Air ( $T_g = 773\text{ K}$ , 1 atm):  $\nu = 80.5 \times 10^{-6}\text{ m}^2/\text{s}$ ,  $k = 0.0561\text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.705$ .

**ANALYSIS:** (a) Performing an energy balance on the junction

$$q_{\text{conv}} = q_{\text{rad}}$$

$(g \rightarrow j) \quad (j \rightarrow s)$

$$\bar{h}A(T_g - T_j) = \epsilon\sigma A(T_j^4 - T_s^4).$$

Neglecting the variable property correction,  $(\mu/\mu_s)^{1/4}$ , and using

$$\text{Re}_D = \frac{VD}{\nu} = \frac{3\text{ m/s} \times 0.002\text{ m}}{80.5 \times 10^{-6}\text{ m}^2/\text{s}} = 74.5$$

the Whitaker correlation for a sphere gives,

$$\bar{h} = \frac{0.0561\text{ W/m}\cdot\text{K}}{0.002\text{ m}} \left\{ 2 + \left[ 0.4(74.5)^{1/2} + 0.06(74.5)^{2/3} \right] (0.705)^{0.4} \right\} = 166\text{ W/m}^2\cdot\text{K}.$$

$$166(773 - T_j) = 0.6 \times 5.67 \times 10^{-8} \left[ T_j^4 - (473)^4 \right]$$

and from a trial-and-error solution,

$$T_j \approx 726\text{ K.} \quad <$$

(b) Assuming all properties other than  $\nu$  to remain constant with a change in pressure,  $\uparrow p$  by 2 will  $\downarrow \nu$  by 2 and hence  $\uparrow \text{Re}_D$  by 2, giving  $\text{Re}_D = 149$ . Hence

$$\bar{h} = \frac{0.0561}{0.002} \left\{ 2 + \left[ 0.4(149)^{1/2} + 0.06(149)^{2/3} \right] (0.705)^{0.4} \right\} = 216\text{ W/m}^2\cdot\text{K}.$$

$$216(773 - T_j) = 0.6 \times 5.67 \times 10^{-8} \left[ T_j^4 - (473)^4 \right]$$

and from a trial-and-error solution

$$T_j \approx 735\text{ K.} \quad <$$

**COMMENTS:** The thermocouple error will  $\downarrow$  with  $\uparrow h$ , which  $\uparrow$  with  $\uparrow p$ .

## PROBLEM 7.88

**KNOWN:** Initial temperature, dimensions and properties of chip and solder connectors. Velocity, temperature and properties of liquid.

**FIND:** (a) Ratio of time constants (chip-to-solder), (b) Chip-to-solder temperature difference after 0.25s of heating.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Solder balls and chips are spatially isothermal, (2) Negligible heat transfer from sides of chip, (3) Top and bottom surfaces of chip act as flat plates in turbulent parallel flow, (4) Heat transfer from solder balls may be approximated as that from an isolated sphere, (5) Constant properties.

**PROPERTIES:** Given. Dielectric liquid:  $k = 0.064 \text{ W/m}\cdot\text{K}$ ,  $\nu = 10^{-6} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 25$ ; Silicon chip:  $k = 150 \text{ W/m}\cdot\text{K}$ ,  $\rho = 2300 \text{ kg/m}^3$ ,  $c_p = 700 \text{ J/kg}\cdot\text{K}$ ; Solder ball:  $k = 40 \text{ W/m}\cdot\text{K}$ ,  $\rho = 10,000 \text{ kg/m}^3$ ,  $c_p = 150 \text{ J/kg}\cdot\text{K}$ .

**ANALYSIS:** (a) From Eq. 5.7, the thermal time constant is  $\tau_t = (\rho \nabla c / \bar{h} A_s)$ . Hence,

$$\frac{\tau_{t,\text{ch}}}{\tau_{t,\text{sld}}} = \frac{(\rho c)_{\text{ch}} (L^2 t)}{2 \bar{h}_{\text{ch}} L^2} \frac{\bar{h}_{\text{sld}} (\pi D^2)}{(\rho c)_{\text{sld}} (\pi D^3 / 6)} = 3 \frac{t}{D} \frac{(\rho c)_{\text{ch}} \bar{h}_{\text{sld}}}{(\rho c)_{\text{sld}} \bar{h}_{\text{ch}}}$$

The convection coefficient for the chip may be obtained from Eq. 7.38 with  $A = 0$ , with  $\text{Re}_L = VL/\nu = 0.2 \text{ m/s} \times 0.01 \text{ m} / 10^{-6} \text{ m}^2/\text{s} = 2000$ .

$$\bar{h}_{\text{ch}} = \frac{0.064 \text{ W/m}\cdot\text{K}}{0.01 \text{ m}} (0.037) (2000)^{4/5} (25)^{1/3} = 302 \text{ W/m}^2\cdot\text{K}$$

The convection coefficient for the solder may be obtained from Eq. 7.56, with  $\text{Re}_D = VD/\nu = 0.2 \text{ m/s} \times 0.001 \text{ m} / 10^{-6} \text{ m}^2/\text{s} = 200$ . Neglecting the effect of the viscosity ratio,

$$\bar{h}_{\text{sld}} = \frac{0.064 \text{ W/m}\cdot\text{K}}{0.001 \text{ m}} \left\{ 2 + \left[ 0.4 (200)^{1/2} + 0.06 (200)^{2/3} \right] (25)^{0.4} \right\} = 1916 \text{ W/m}^2\cdot\text{K}$$

Hence, 
$$\frac{\tau_{t,\text{ch}}}{\tau_{t,\text{sld}}} = 3 \left( \frac{2300 \text{ kg/m}^3 \times 700 \text{ J/kg}\cdot\text{K}}{10,000 \text{ kg/m}^3 \times 150 \text{ J/kg}\cdot\text{K}} \right) \frac{1916 \text{ W/m}^2\cdot\text{K}}{302 \text{ W/m}^2\cdot\text{K}} = 20.4 <$$

Hence, the solder responds much more quickly to the convective heating.

(b) From Eq. 5.6, the chip-to-solder temperature difference may be expressed as

Continued ...

**PROBLEM 7.88 (Cont.)**

$$T_{\text{ch}} - T_{\text{sld}} = (T_i - T_\infty) \left\{ \exp \left[ - \left( \frac{2\bar{h}}{\rho c t} \right)_{\text{ch}} t \right] - \exp \left[ - \left( \frac{6\bar{h}}{\rho c D} \right)_{\text{sld}} t \right] \right\}$$

$$T_{\text{ch}} - T_{\text{sld}} = 60^\circ\text{C} \left\{ \exp \left[ - \frac{604 \text{ W/m}^2 \cdot \text{K}}{1610 \text{ J/m}^2 \cdot \text{K}} 0.25 \text{ s} \right] - \exp \left[ - \frac{11,496 \text{ W/m}^2 \cdot \text{K}}{1500 \text{ J/m}^2 \cdot \text{K}} 0.25 \text{ s} \right] \right\}$$

$$T_{\text{ch}} - T_{\text{sld}} = 60^\circ\text{C} \{0.910 - 0.147\} = 45.8^\circ\text{C} \quad <$$

**COMMENTS:** (1) The foregoing process is used to subject soldered chip connections (a major reliability issue) to rapid and intense thermal stresses. (2) Some heat transfer by conduction will occur between the chip and solder balls, thereby reducing the temperature difference and thermal stress. (3) Constriction of flow between the chip and substrate will reduce  $\bar{h}_{\text{sld}}$ , as well as  $\bar{h}_{\text{ch}}$  at the lower surface of the chip, relative to values predicted by the correlations. The corresponding time constants would be increased accordingly. (4) With  $\text{Bi}_{\text{ch}} = \bar{h}_{\text{ch}} (t/2) / k_{\text{chip}} = 0.001 \ll 1$  and  $\text{Bi}_{\text{sld}} = \bar{h}_{\text{sld}} (D/6) / k_{\text{sld}} = 0.008 \ll 1$ , the lumped capacitance analysis is appropriate for both components.

### PROBLEM 7.89

**KNOWN:** Conditions associated with Example 7.7, but with reduced longitudinal and transverse pitches.

**FIND:** (a) Air side convection coefficient, (b) Tube bundle pressure drop, (c) Heat rate.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Uniform tube surface temperature, (3) Negligible radiation and incompressible flow.

**PROPERTIES:** Table A-4, Atmospheric air ( $T_\infty = 288$  K):  $\rho = 1.217$  kg/m<sup>3</sup>,  $\nu = 14.82 \times 10^{-6}$  m<sup>2</sup>/s,  $k = 0.0253$  W/m·K,  $Pr = 0.71$ ,  $c_p = 100.7$  J/kg·K; ( $T_s = 343$  K):  $Pr = 0.701$ .

**ANALYSIS:** (a) From the tube pitches, find

$$S_D = \left[ S_L^2 + (S_T/2)^2 \right]^{1/2} = \left[ (20.5)^2 + (10.25)^2 \right]^{1/2} = 22.91 \text{ mm}$$

$$(S_T + D)/2 = (20.5 + 16.4)/2 = 18.45 \text{ mm.}$$

Hence, the maximum velocity occurs on the transverse plane, and

$$V_{\max} = \frac{S_T}{S_T - D} V = \frac{20.5 \text{ mm}}{(20.5 - 16.4) \text{ mm}} 6 \text{ m/s} = 30 \text{ m/s.}$$

With 
$$Re_{D,\max} = \frac{V_{\max} D}{\nu} = \frac{30 \text{ m/s} (0.0164 \text{ m})}{14.82 \times 10^{-6} \text{ m}^2/\text{s}} = 3.32 \times 10^4$$

and  $(S_T/S_L) = 1 < 2$ , it follows from Table 7.5 that

$$C_1 = 0.35 \quad m = 0.60.$$

Hence, from the Zukauskas correlation and Table 7.6 ( $C_2 = 0.95$ ),

$$\overline{Nu}_D = (0.95) 0.35 Re_{D,\max}^{0.6} Pr^{0.36} (Pr/Pr_s)^{1/4}$$

$$\overline{Nu}_D = (0.95) 0.35 (3.32 \times 10^4)^{0.6} (0.71)^{0.36} (0.71/0.701)^{1/4} = 152$$

$$\bar{h} = \overline{Nu}_D \frac{k}{D} = 152 \times \frac{0.0253 \text{ W/m} \cdot \text{K}}{0.0164 \text{ m}} = 234 \text{ W/m}^2 \cdot \text{K.} \quad <$$

(b) From the Zukauskas relation

$$\Delta p = N_L \chi \left( \frac{\rho V_{\max}^2}{2} \right) f.$$

With  $Re_{D,\max} = 3.32 \times 10^4$ ,  $P_T = (S_T/D) = 1.25$  and  $(P_T/P_L) = 1$ , it follows from Fig. 7.15 that  $\chi \approx 1.02$  and  $f \approx 0.38$ .

Continued ...

### PROBLEM 7.89 (Cont.)

Hence

$$\Delta p = 7 \times 1.02 \frac{1.217 \text{ kg/m}^3 (30 \text{ m/s})^2}{2} 0.38 = 1490 \text{ N/m}^2$$

$$\Delta p = 0.0149 \text{ bar.}$$

<

(c) The air outlet temperature is obtained from

$$T_s - T_o = (T_s - T_i) \exp\left(-\frac{\pi D N \bar{h}}{\rho V N_t S_t c_p}\right)$$

$$T_s - T_o = 55^\circ \text{C} \exp\left(\frac{-\pi (0.0164 \text{ m}) 56 (234 \text{ W/m}^2 \cdot \text{K})}{1.217 \text{ kg/m}^3 \times 6 \text{ m/s} \times 8 \times 0.0205 \text{ m} \times 1007 \text{ J/kg} \cdot \text{K}}\right)$$

$$T_s - T_o = 31.4^\circ \text{C}$$

$$T_o = 38.5^\circ \text{C.}$$

<

The log mean temperature difference is

$$\Delta T_{\ell m} = \frac{\Delta T_i - \Delta T_o}{\ln(\Delta T_i / \Delta T_o)} = \frac{(55 - 31.4)^\circ \text{C}}{\ln(55/31.4)} = 42.1^\circ \text{C}$$

$$q' = N \bar{h} \pi D \Delta T_{\ell m} = 56 (234 \text{ W/m}^2 \cdot \text{K}) \pi (0.0164 \text{ m}) 42.1^\circ \text{C}$$

$$q' = 28.4 \text{ kW/m.}$$

<

**COMMENTS:** Making the tube bank more compact has the desired effect of increasing the convection coefficient and therefore the heat transfer rate. However, it has the adverse effect of increasing the pressure drop and hence the fan power requirement. Note that the convection coefficient increases by a factor of  $(234/135.6) = 1.73$ , while the pressure drop increases by a factor of  $(1490/246) = 6.1$ . This disparity is a consequence of the fact that  $\bar{h} \sim V_{\max}^{0.6}$ , while  $\Delta p \sim V_{\max}^2$ .

Hence any increase in  $V_{\max}$ , which would result from a more closely spaced arrangement, would more adversely affect  $\Delta p$  than favorably affect  $\bar{h}$ .

### PROBLEM 7.90

**KNOWN:** Surface temperature and geometry of a tube bank. Velocity and temperature of air in cross flow.

**FIND:** (a) Total heat transfer, (b) Air flow pressure drop.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Negligible radiation and incompressible flow, (3) Uniform surface temperature.

**PROPERTIES:** Table A-4, Atmospheric air ( $T_\infty = 298$  K):  $\nu = 15.8 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0263 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.707$ ,  $c_p = 1007 \text{ J/kg}\cdot\text{K}$ ,  $\rho = 1.17 \text{ kg/m}^3$ ; ( $T_s = 373$  K):  $\text{Pr} = 0.695$ .

**ANALYSIS:** (a) The total heat transfer rate is

$$q = \bar{h} N \pi D L \frac{(T_s - T_i) - (T_s - T_o)}{\ln[(T_s - T_i)/(T_s - T_o)]} = \bar{h} N \pi D L \Delta T_{\ell m}$$

$$\text{With } V_{\max} = \frac{S_T}{S_T - D} V = \frac{15 \text{ mm}}{5 \text{ mm}} 5 \text{ m/s} = 15 \text{ m/s}, \text{Re}_{D, \max} = \frac{15 \text{ m/s}(0.01 \text{ m})}{15.8 \times 10^{-6} \text{ m}^2/\text{s}} = 9494. \quad \text{Tables 7.5}$$

and 7.6 give  $C_1 = 0.27$ ,  $m = 0.63$  and  $C_2 \approx 0.99$ . Hence, from the Zukauskas correlation

$$\bar{\text{Nu}}_D = 0.99 \times 0.27 (9494)^{0.63} (0.707)^{0.36} (0.707/0.695)^{1/4} = 75.9$$

$$\bar{h} = \bar{\text{Nu}}_D k/D = 75.9 \times 0.0263 \text{ W/m}\cdot\text{K}/0.01 \text{ m} = 200 \text{ W/m}^2 \cdot \text{K}$$

$$T_s - T_o = (T_s - T_i) \exp\left(-\frac{\pi D N \bar{h}}{\rho V N_T S_T c_p}\right) = 75^\circ\text{C} \exp\left(-\frac{\pi \times 0.01 \text{ m} \times 196 \times 200 \text{ W/m}^2 \cdot \text{K}}{1.17 \text{ kg/m}^3 \times 5 \text{ m/s} \times 14 \times 0.015 \text{ m} \times 1007 \text{ J/kg}\cdot\text{K}}\right)$$

$$T_s - T_o = 27.7^\circ\text{C}.$$

Hence

$$q = 200 \text{ W/m}^2 \cdot \text{K} \times 196 \pi (0.01 \text{ m}) 1 \text{ m} \frac{75^\circ\text{C} - 27.7^\circ\text{C}}{\ln(75/27.7)} = 58.5 \text{ kW}. \quad <$$

(b) With  $\text{Re}_{D, \max} = 9494$ ,  $(P_T - 1)/(P_L - 1) = 1$ , Fig. 7.14 yields  $f \approx 0.32$  and  $\chi = 1$ . Hence,

$$\Delta p = N \chi \left( \rho V_{\max}^2 / 2 \right) f = 14 \times 1 \left( \frac{1.17 \text{ kg/m}^3 (15 \text{ m/s})^2}{2} \right) 0.32$$

$$\Delta p = 590 \text{ N/m}^2 = 5.9 \times 10^{-3} \text{ bar}.$$

**COMMENTS:** The heat transfer rate would have been substantially overestimated (93.3 kW) if the inlet temperature difference ( $T_s - T_i$ ) had been used in lieu of the log-mean temperature difference.

## PROBLEM 7.91

**KNOWN:** Surface temperature and geometry of a tube bank. Inlet velocity and inlet and outlet temperatures of air in cross flow over the tubes.

**FIND:** Number of tube rows needed to achieve the prescribed outlet temperature and corresponding pressure drop of air.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, (2) Negligible temperature drop across tube wall and uniform outer surface temperature, (3) Constant properties, (4)  $C_2 \approx 1$ , (5) Negligible radiation and incompressible flow.

**PROPERTIES:** Table A-4, Atmospheric air. ( $\bar{T} = (T_i + T_o)/2 = 323\text{K}$ ):  $\rho = 1.085\text{ kg/m}^3$ ,

$c_p = 1007\text{ J/kg}\cdot\text{K}$ ,  $\nu = 18.2 \times 10^{-6}\text{ m}^2/\text{s}$ ,  $k = 0.028\text{ W/m}\cdot\text{K}$ ,  $Pr = 0.707$ ; ( $T_i = 298\text{K}$ ):  $\rho = 1.17\text{ kg/m}^3$ ; ( $T_s = 373\text{K}$ ):  $Pr_s = 0.695$ .

**ANALYSIS:** The temperature difference ( $T_s - T$ ) decreases exponentially in the flow direction, and at the outlet

$$\frac{T_s - T_o}{T_s - T_i} = \exp\left(-\frac{\pi D N_L \bar{h}}{\rho V S_T c_p}\right)$$

where  $N_L = N/N_T$ . Hence,

$$N_L = -\frac{\rho V S_T c_p}{\pi D \bar{h}} \ln\left(\frac{T_s - T_o}{T_s - T_i}\right) \quad (1)$$

With  $V_{\max} = [S_T / (S_T - D)]V = 15\text{ m/s}$ ,  $Re_{D,\max} = V_{\max} D / \nu = 8240$ . Hence, with  $S_T / S_L = 1 > 0.7$ ,  $C_1 = 0.27$  and  $m = 0.63$  from Table 7.5, and the Zukauskas correlation yields

$$\overline{Nu}_D = C_1 C_2 Re_{D,\max}^m Pr^{0.36} \left(\frac{Pr}{Pr_s}\right)^{1/4} = 0.27 \times 1 (8240)^{0.63} (0.707)^{0.36} (0.707/0.695)^{1/4} = 70.1$$

$$\bar{h} = \frac{k}{D} \overline{Nu}_D = \frac{0.028\text{ W/m}\cdot\text{K}}{0.01\text{ m}} 70.1 = 196.3\text{ W/m}^2\cdot\text{K}$$

Hence,

$$N_L = -\frac{1.17\text{ kg/m}^3 (5\text{ m/s}) 0.015\text{ m} (1007\text{ J/kg}\cdot\text{K})}{\pi (0.01\text{ m}) 196.3\text{ W/m}^2\cdot\text{K}} \ln\left(\frac{25}{75}\right) = 15.7$$

and 16 tube rows should be used

$$N_L = 16$$

<

With  $Re_{D,\max} = 8240$ ,  $P_L = 1.5$  and  $(P_T - 1)/(P_L - 1) = 1$ ,  $f \approx 0.35$  and  $\chi = 1$  from Fig. 7.14. Hence,

$$\Delta p \approx N_L \chi \left(\frac{\rho V_{\max}^2}{2}\right) f = 16 \left[\frac{1.085\text{ kg/m}^3 \times (15\text{ m/s})^2}{2}\right] 0.35 = 684\text{ N/m}^2 \quad <$$

**COMMENTS:** (1) With  $C_2 = 0.99$  for  $N_L = 16$  from Table 7.8, assumption 4 is appropriate. (2) Note use of the density evaluated at  $T_i = 298\text{K}$  in Eq. (1).

## PROBLEM 7.92

**KNOWN:** Geometry, surface temperature, and air flow conditions associated with a tube bank.

**FIND:** Rate of heat transfer per unit length.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Negligible radiation effects and incompressible flow, (3) Gas properties are approximately those of air.

**PROPERTIES:** Table A-4, Air (300K, 1 atm):  $Pr = 0.707$ ; Table A-4, Air (700K, 1 atm):  $\nu = 68.1 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0524 \text{ W/m}\cdot\text{K}$ ,  $Pr = 0.695$ ,  $\rho = 0.498 \text{ kg/m}^3$ ,  $c_p = 1075 \text{ J/kg}\cdot\text{K}$ .

**ANALYSIS:** The rate of heat transfer per unit length of tubes is

$$q' = \bar{h}N\pi D \Delta T_{\ell m} = \bar{h}N\pi D \frac{(T_s - T_i) - (T_s - T_o)}{\ln[(T_s - T_i)/(T_s - T_o)]}$$

$$\text{With } V_{\max} = \frac{S_T}{S_T - D} V = \frac{20}{10} 5 \text{ m/s} = 10 \text{ m/s}, \text{Re}_{D,\max} = \frac{V_{\max} D}{\nu} = \frac{10 \text{ m/s} \times 0.01 \text{ m}}{68.1 \times 10^{-6} \text{ m}^2/\text{s}} = 1468.$$

Tables 7.5 and 7.6 give  $C_1 = 0.27$ ,  $m = 0.63$  and  $C_2 = 0.97$ . Hence from the Zukauskas correlation,

$$\overline{Nu}_D = C_1 C_2 \text{Re}_{D,\max}^m Pr^{0.36} (Pr/Pr_s)^{1/4} = 0.26(1468)^{0.63} (0.695)^{0.36} (0.695/0.707)^{1/4}$$

$$\overline{Nu}_D = 22.4 \quad \bar{h} = \frac{k}{D} \overline{Nu}_D = 0.0524 \text{ W/m}\cdot\text{K} \times 22.4/0.01 \text{ m} = 117 \text{ W/m}^2 \cdot \text{K}.$$

Hence,

$$(T_s - T_o) = (T_s - T_i) \exp\left(-\frac{\pi DN \bar{h}}{\rho V N_T S_T c_p}\right) = -400 \text{ K} \exp\left(-\frac{\pi \times 0.01 \text{ m} \times 500 \times 117 \text{ W/m}^2 \cdot \text{K}}{0.498 \text{ kg/m}^3 (5 \text{ m/s}) 50 (0.02 \text{ m}) 1075 \text{ J/kg}\cdot\text{K}}\right)$$

$$T_s - T_o = -201.3 \text{ K}$$

and the heat rate is

$$q' = \left(117 \text{ W/m}^2 \cdot \text{K}\right) 500 \pi (0.01 \text{ m}) \frac{(-400 + 201.3) \text{ K}}{\ln[(-400)/(-201.3)]} = -532 \text{ kW/m} \quad <$$

**COMMENTS:** (1) There is a significant decrease in the gas temperature as it passes through the tube bank. Hence, the heat rate would have been substantially overestimated (- 768 kW) if the inlet temperature difference had been used in lieu of the log-mean temperature difference. (2) The negative sign implies heat transfer to the water. (3) If the temperature of the water increases substantially, the assumption of uniform  $T_s$  becomes poor. The extent to which the water temperature increases depends on the water flow rate.

## PROBLEM 7.93

**KNOWN:** An air duct heater consists of an aligned arrangement of electrical heating elements with  $S_L = S_T = 24$  mm,  $N_L = 3$  and  $N_T = 4$ . Atmospheric air with an upstream velocity of 12 m/s and temperature of 25°C moves in cross flow over the elements with a diameter of 12 mm and length of 250 mm maintained at a surface temperature of 350°C.

**FIND:** (a) The total heat transfer to the air and the temperature of the air leaving the duct heater, (b) The pressure drop across the element bank and the fan power requirement, (c) Compare the average convection coefficient obtained in part (a) with the value for an isolated (single) element; explain the relative difference between the results; (d) What effect would increasing the longitudinal and transverse pitches to 30 mm have on the exit temperature of the air, the total heat rate, and the pressure drop?

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Negligible radiation effects, (3) Negligible effect of change in air temperature across tube bank on air properties.

**PROPERTIES:** Table A-4, Air ( $T_i = 298$ , 1 atm):  $\rho = 1.171$  kg/m<sup>3</sup>,  $c_p = 1007$  J/kg·K; Air ( $T_m = (T_i + T_o)/2 = 309$  K, 1 atm):  $\rho = 1.130$  kg/m<sup>3</sup>,  $c_p = 1007$  J/kg·K,  $\mu = 1.89 \times 10^{-5}$  N·s/m<sup>2</sup>,  $k = 0.02699$  W/m·K,  $Pr = 0.7057$ ; Air ( $T_s = 623$  K, 1 atm):  $Pr_s = 0.687$ ; Air ( $T_f = (T_i + T_o)/2 = 461$  K, 1 atm):  $\nu = 3.373 \times 10^{-5}$  m<sup>2</sup>/s,  $k = 0.03801$  W/m·K,  $Pr = 0.686$ .

**ANALYSIS:** (a) The total heat transfer to the air is determined from the rate equation

$$q = N(\bar{h}_D \pi D \Delta T_{\ell m}) \quad (1)$$

where the log mean temperature difference is

$$\Delta T_{\ell m} = \frac{T_s - T_i}{T_s - T_o} \ln \frac{(T_s - T_i)}{(T_s - T_o)} \quad (2)$$

and from the overall energy balance,

$$\frac{T_s - T_o}{T_s - T_i} = \exp\left(\frac{\pi D N \bar{h}_D}{\rho V N_T S_T c_p}\right) \quad (3)$$

The properties  $\rho$  and  $c_p$  in Eq. (3) are evaluated at the inlet temperature  $T_i$ . The average convection coefficient using the Zukauskus correlation,

$$\overline{Nu}_D = \frac{\bar{h}_D}{k} = C Re_{D,\max}^m Pr^{0.36} (Pr/Pr_s)^{1/4} \quad (4)$$

where  $C_1 = 0.27$ ,  $m = 0.63$  are determined from Table 7.5 for the *aligned* configuration with  $S_T/S_L = 1 > 0.7$  and  $10^3 < Re_{D,\max} \leq 10^5$ . All properties except  $Pr_s$  are evaluated at the arithmetic mean temperature  $T_m = (T_i + T_o)/2$ . The maximum Reynolds number is

Continued ...

**PROBLEM 7.93 (Cont.)**

$$\text{Re}_{D,\max} = \rho V_{\max} D / \mu \quad (5)$$

where for the *aligned* arrangement, the maximum velocity occurs at the transverse plane

$$V_{\max} = \frac{S_T}{S_T - D} V \quad (6)$$

The results of the analyses for  $S_T = S_L = 24 \text{ mm}$  are tabulated below.

$V_{\max}$ (m/s)	$\text{Re}_{D,\max}$	$\overline{\text{Nu}}_D$	$\overline{h}_D$ (W/m <sup>2</sup> ·K)	$\Delta T_{\ell m}$ (°C)	$q$ (W)	$T_o$ (°C)
24	1.723×10 <sup>4</sup>	96.2	216	314	7671	47.6

<

(b) The pressure drop across the tube bundle is

$$\Delta p = N_L \chi \left( \rho V_{\max}^2 / 2 \right) f \quad (7)$$

where the friction factor,  $f$ , and correction factor,  $\chi$ , are determined from Fig. 7.14 using  $\text{Re}_{D,\max} = 1.723 \times 10^4$ ,

$$f = 0.2 \quad \chi = 1$$

Substituting numerical values,

$$\Delta p = 3 \times 1 \left[ 1.171 \text{ kg/m}^3 \times (24 \text{ m/s})^2 / 2 \right] \times 0.2$$

$$\Delta p = 195 \text{ N/m}^2 \quad <$$

The fan power requirement is

$$P = \dot{V} \Delta p = V N_T S_T L \Delta p \quad (8)$$

$$P = 12 \text{ m/s} \times 4 \times 0.024 \text{ m} \times 0.250 \text{ m} \times 195 \text{ N/m}^2$$

$$P = 56 \text{ W} \quad <$$

where  $\dot{V}$  is the volumetric flow rate. For this calculation,  $\rho$  in Eq. (7) was evaluated at  $T_m$ .

(c) For a single element in cross flow, the average convection coefficient can be estimated using the Churchill-Bernstein correlation,

$$\overline{\text{Nu}}_D = \frac{\overline{h}_D D}{k} = 0.3 + \frac{0.62 \text{ Re}_D^{1/2} \text{ Pr}^{1/3}}{\left[ 1 + (0.4/\text{Pr})^{2/3} \right]^{1/4}} \left[ 1 + \left( \frac{\text{Re}_D}{282,000} \right)^{5/8} \right]^{4/5} \quad (9)$$

where all properties are evaluated at the film temperature,  $T_f = (T_i + T_o)/2$ . The results of the calculations are

$$\text{Re}_{D,1} = 4269 \quad \overline{\text{Nu}}_{D,1} = 33.4 \quad \overline{h}_{D,1} = 106 \text{ W/m}^2 \cdot \text{K} \quad <$$

Continued ...

### PROBLEM 7.93 (Cont.)

For the isolated element,  $\bar{h}_{D,1} = 106 \text{ W/m}^2 \cdot \text{K}$ , compared to the average value for the array,  $\bar{h}_D = 216 \text{ W/m}^2 \cdot \text{K}$ . Because the first row of the array acts as a turbulence grid, the heat transfer coefficient for the second and third rows will be larger than for the first row. Here, the array value is twice that for the isolated element.

(d) The effect of increasing the longitudinal and transverse pitches to 30 mm, should be to reduce the outlet temperature, heat rate, and pressure drop. The effect can be explained by recognizing that the maximum Reynolds number will be decreased, which in turn will result in lower values for the convection coefficient and pressure drop. Repeating the calculations of part (a) for  $S_L = S_T = 30 \text{ mm}$ , find

$V_{\max}$ (m/s)	$Re_{D,\max}$	$\overline{Nu}_D$	$\bar{h}_D$ (W/m <sup>2</sup> ·K)	$\Delta T_{\ell m}$ (°C)	$q$ (W)	$T_o$ (°C)
12	$1.46 \times 10^4$	86.7	193	317	6925	41.3

and part (b) for the pressure drop and fan power, find

$$f = 0.18 \qquad \chi = 1 \qquad \Delta p = 122 \text{ N/m}^2 \qquad P = 44 \text{ W}$$

## PROBLEM 7.94

**KNOWN:** Surface temperature and geometry of a tube bank. Velocity and temperature of air in cross-flow.

**FIND:** (a) Air outlet temperature, (b) Pressure drop and fan power requirements.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Negligible radiation, (3) Air pressure is approximately one atmosphere, (4) Uniform surface temperature.

**PROPERTIES:** Table A-4, Air (300 K, 1 atm):  $\rho = 1.1614 \text{ kg/m}^3$ ,  $c_p = 1007 \text{ J/kg}\cdot\text{K}$ ,  $\nu = 15.89 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0263 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.707$ ; (373K):  $\text{Pr} = 0.695$ .

**ANALYSIS:** (a) The air temperature increases exponentially, with

$$T_o = T_s - (T_s - T_i) \exp\left(-\frac{\pi D N \bar{h}}{\rho V N_T S_T c_p}\right).$$

$$\text{With } V_{\max} = \frac{S_T}{S_T - D} V = \frac{60}{30} 15 \frac{\text{m}}{\text{s}} = 30 \frac{\text{m}}{\text{s}}; \text{Re}_{D,\max} = \frac{30 \text{ m/s} \times 0.03 \text{ m}}{15.89 \times 10^{-6} \text{ m}^2/\text{s}} = 56,639.$$

Tables 7.5 and 7.6 give  $C_1 = 0.27$ ,  $m = 0.63$  and  $C_2 = 0.97$ . Hence from the Zukauskas correlation,

$$\bar{\text{Nu}}_D = 0.27(0.97)(56,639)^{0.63}(0.707)^{0.36}(0.707/0.695)^{1/4} = 229$$

$$\bar{h} = \bar{\text{Nu}}_D k/D = 229 \times 0.0263 \text{ W/m}\cdot\text{K}/0.03 \text{ m} = 201 \text{ W/m}^2 \cdot \text{K}.$$

Hence,

$$T_o = 373\text{K} - (373 - 300)\text{K} \exp\left(-\frac{\pi \times 0.03 \text{ m} \times 70 \times 201 \text{ W/m}^2 \cdot \text{K}}{1.1614 \text{ kg/m}^3 \times 15 \text{ m/s} \times 7 \times 0.06 \text{ m} \times 1007 \text{ J/kg}\cdot\text{K}}\right)$$

$$T_o = 373\text{K} - 73\text{K} \times 0.835 = 312\text{K} = 39^\circ\text{C}. \quad <$$

(b) With  $\text{Re}_{D,\max} = 5.66 \times 10^4$ ,  $P_L = 2$ ,  $(P_T - 1)/(P_L - 1) = 1$ , Fig. 7.14 yields  $f \approx 0.19$  and  $\chi = 1$ .

Hence,

$$\Delta p = N_L \chi \left(\frac{\rho V_{\max}^2}{2}\right) f = 10 \left(\frac{1.1614 \text{ kg/m}^3 \times (30 \text{ m/s})^2}{2}\right) 0.19 = 993 \text{ N/m}^2 = 0.00993 \text{ bar}. \quad <$$

The fan power requirement is

$$P = \dot{m}_a \Delta p / \rho = \rho V N_T S_T L \Delta p / \rho = 15 \text{ m/s} \times 7 \times 0.06 \text{ m} \times 1 \text{ m} \times 993 \text{ N/m}^2 = 6.26 \text{ kW}. \quad <$$

**COMMENTS:** The heat rate is

$$q = \dot{m}_a c_p (T_o - T_i) = \rho V N_T S_T L c_p (T_o - T_i)$$

$$q = 1.1614 \text{ kg/m}^3 \times 15 \text{ m/s} \times 7 \times 0.06 \text{ m} \times 1 \text{ m} \times 1007 \text{ J/kg}\cdot\text{K} (312 - 300) \text{ K} = 88.4 \text{ kW}.$$

## PROBLEM 7.95

**KNOWN:** Surface temperature and geometry of tube bank. Velocity and temperature of air in cross-flow.

**FIND:** (a) Air outlet temperature, (b) Pressure drop and fan power requirements.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Negligible radiation, (3) Air pressure approximately one atmosphere, (4) Uniform surface temperature.

**PROPERTIES:** Table A.4, air (300K, 1 atm):  $\nu = 15.89 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $Pr = 0.707$ ,  $k = 0.0263 \text{ W/m}\cdot\text{K}$ ,  $\rho = 1.1614 \text{ kg/m}^3$ ,  $c_p = 1007 \text{ J/kg}\cdot\text{K}$ ; (373 K):  $Pr_s = 0.695$ .

**ANALYSIS:** (a) The outlet air temperature may be found from

$$T_o = T_s - (T_s - T_i) \exp\left(-\frac{\pi DN \bar{h}}{\rho V N_T S_T c_p}\right)$$

$$\text{With } V_{\max} = \frac{S_T}{S_T - D} V = \frac{60}{30} \times 10.5 \text{ m/s} = 21 \text{ m/s}; \quad Re_{D,\max} = \frac{21 \text{ m/s} \times 0.03 \text{ m}}{15.89 \times 10^{-6} \text{ m}^2/\text{s}} = 39,648$$

Tables 7.5 and 7.6 give  $C_1 = 0.27$ ,  $m = 0.63$  and  $C_2 = 0.95$ . From the Zukauskas correlation,

$$\bar{Nu}_D = 0.27 \times 0.95 \times 39,648^{0.63} (0.707)^{0.36} (0.707/0.695)^{1/4} = 179.3$$

$$\bar{h} = \bar{Nu}_D k / D = 179.3 \times 0.0263 \text{ W/m}\cdot\text{K} / 0.03 \text{ m} = 157 \text{ W/m}^2 \cdot \text{K}$$

and therefore,

$$T_o = 373 \text{ K} - 73 \text{ K} \exp\left(-\frac{\pi \times 0.03 \text{ m} \times 70 \times 157 \text{ W/m}^2 \cdot \text{K}}{1.1614 \text{ kg/m}^3 \times 10.5 \text{ m/s} \times 10 \times 0.06 \text{ m} \times 1007 \text{ J/kg}\cdot\text{K}}\right)$$

<

$$= 373 \text{ K} - 73 \text{ K} \times 0.869 = 310 \text{ K} = 37^\circ\text{C}$$

(b) With  $Re_{D,\max} = 39,648$ ,  $P_L = P_T = 2$ ,  $(P_T - 1)/(P_L - 1) = 1$ , Fig. 7.14 yields  $f \approx 0.20$  and  $\chi = 1$ . Therefore,

$$\Delta p = N_L \chi \left(\frac{\rho V_{\max}^2}{2}\right) f = 7 \left(\frac{1.1614 \text{ kg/m}^3 \times (21 \text{ m/s})^2}{2}\right) 0.20 = 359 \text{ N/m}^2$$

and the fan power requirement is

Continued...

### PROBLEM 7.95 (Cont.)

$$P = \dot{m}_a \Delta p / \rho = V N_T S_T L \Delta p = 10.5 \text{ m/s} \times 10 \times 0.06 \text{ m} \times 1 \text{ m} \times 359 \text{ N/m}^2 = 2.26 \text{ kW} \quad <$$

**COMMENTS:** Note that the mass flow rate here is the same as in Problem 7.94. In Problem 7.94, for  $N_L = 7$  and  $N_T = 10$ , the outlet temperature, pressure drop, and fan power requirements are  $T_o = 39^\circ\text{C}$ ,  $\Delta p = 993 \text{ N/m}^2$ , and  $P = 6.26 \text{ kW}$ , respectively. Placing the tube bundle with fewer tubes in the streamwise direction ( $N_L/N_T < 1$ ) results in a higher overall heat transfer rate (lower air outlet temperature) since the downstream tubes experience a larger temperature difference between the tube wall and the flowing air. In addition, a significantly lower pressure drop and pumping power is needed. However, the cross-sectional area of the duct within which the tube bundle is placed must be increased, and therefore capital cost of installation would be higher, for the  $N_L/N_T < 1$  case.

## PROBLEM 7.96

**KNOWN:** Characteristics of pin fin array used to enhance cooling of electronic components. Velocity and temperature of coolant air.

**FIND:** (a) Average convection coefficient for array, (b) Total heat rate and air outlet temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Negligible radiation, (3) One-dimensional conduction in pins, (4) Uniform plate temperature, (5) Plates have a negligible effect on flow over pins, (6) Uniform convection coefficient over all surfaces, corresponding to average coefficient for flow over a tube bank.

**PROPERTIES:** Air (300 K, 1 atm):  $\rho = 1.1614 \text{ kg/m}^3$ ,  $\text{Pr} = 0.707$ ,  $c_p = 1007 \text{ J/kg}\cdot\text{K}$ ,  $\mu = 184.6 \times 10^{-7} \text{ kg/s}\cdot\text{m}$ ,  $k = 0.0263 \text{ W/m}\cdot\text{K}$ . Aluminum (given):  $k = 240 \text{ W/m}\cdot\text{K}$ .

**ANALYSIS:** (a) From the Zukauskas relation

$$\overline{\text{Nu}}_D = C \text{Re}_{D,\text{max}}^m \text{Pr}^{0.36} (\text{Pr}_\infty / \text{Pr}_s)^{1/4}$$

$$(\text{Pr}_\infty / \text{Pr}_s)^{1/4} \approx 1 \quad V_{\text{max}} = \frac{S_T}{S_T - D} V = \frac{4}{4 - 2} 10 \text{ m/s} = 20 \text{ m/s}$$

$$\text{Re}_{D,\text{max}} = \frac{1.164 \text{ kg/m}^3 \times 20 \text{ m/s} \times 0.002 \text{ m}}{184.6 \times 10^{-7} \text{ kg/s}\cdot\text{m}} = 2517$$

From Table 7.5 find  $C_1 = 0.27$  and  $m = 0.63$ , hence

$$\overline{\text{Nu}}_D = 0.27 (2517)^{0.63} (0.707)^{0.36} = 33.1$$

$$\bar{h} = \overline{\text{Nu}}_D \frac{k}{D} = 33.1 \times \frac{0.0263 \text{ W/m}\cdot\text{K}}{0.002 \text{ m}} = 435 \text{ W/m}^2 \cdot \text{K} \quad <$$

(b) If  $T_s = 350 \text{ K}$  is taken to be the temperature of all of the heat transfer surfaces, correction must be made for the actual temperature drop along the pins. This is done by introducing the overall surface efficiency  $\eta_o$  and replacing  $\bar{h}A$  by  $\bar{h}A_t \eta_o$ . Hence, to obtain the air outlet temperature, we use

$$\frac{T_s - T_o}{T_s - T_i} = \exp\left(-\frac{\bar{h}A_t \eta_o}{\dot{m}c_p}\right)$$

where

Continued ...

**PROBLEM 7.96 (Cont.)**

$$A_t = N(\pi DL) + 2W^2 - 2N(\pi D^2/4)$$

$$A_t = 625(\pi \times 0.002 \text{ m} \times 0.1 \text{ m}) + 2(0.1 \text{ m})^2 - 2 \times 625\pi(0.002 \text{ m})^2/4 = 0.409 \text{ m}^2$$

Also  $\eta_o = 1 - \frac{A_f}{A_t}(1 - \eta_f)$  where  $\eta_f$  is given by Eq. (3.91). With symmetry about the

midplane of the pin,  $q_f = M \tanh(mL/2)$ . Hence

$$\eta_f = \frac{q}{q_{\max}} = \frac{(\bar{h}\pi D k \pi D^2/4)^{1/2} \theta_b \tanh(mL/2)}{\bar{h}\pi D(L/2)\theta_b} = \frac{\tanh(mL/2)}{(\bar{h}/kD)^{1/2} L}$$

or, with  $m = \left[ \bar{h}\pi D / (k\pi D^2/4) \right]^{1/2} = 2(\bar{h}/kD)^{1/2}$ ,

$$\eta_f = \frac{\tanh(mL/2)}{mL/2}$$

$$m = 2 \left( \frac{435 \text{ W/m}^2 \cdot \text{K}}{240 \text{ W/m} \cdot \text{K} \times 0.002 \text{ m}} \right)^{1/2} = 60.2 \text{ m}^{-1}$$

$$mL/2 = 60.2 \text{ m}^{-1} \times 0.05 \text{ m} = 3.01 \quad \text{and} \quad \tanh(mL/2) = 0.995$$

$$\eta_f = \frac{0.995}{3.01} = 0.331.$$

$$\text{Hence, } \eta_o = 1 - \frac{625 \times \pi(0.002 \text{ m})(0.1 \text{ m})}{0.409 \text{ m}^2} (1 - 0.331) = 0.357$$

$$\dot{m} = \rho V L N_T S_T = 1.1614 \text{ kg/m}^3 (10 \text{ m/s}) 0.1 \text{ m} (25) (0.004 \text{ m}) = 0.116 \text{ kg/s}.$$

Now evaluating the air outlet temperature,

$$\frac{T_s - T_o}{T_s - T_i} = \exp\left( - \frac{435 \text{ W/m}^2 \cdot \text{K} \times 0.409 \text{ m}^2 \times 0.357}{0.116 \text{ kg/s} \times 1007 \text{ J/kg} \cdot \text{K}} \right) = 0.581$$

$$T_o = T_s - 0.581(T_s - T_i) = 350 \text{ K} - 0.581(50 \text{ K})$$

$$T_o = 321 \text{ K.} \quad \leftarrow$$

The total heat rate is

$$q = \dot{m} c_p (T_o - T_i) = 0.116 \text{ kg/s} (1007 \text{ J/kg} \cdot \text{K}) 21 \text{ K} = 2453 \text{ W.} \quad \leftarrow$$

**COMMENTS:** (1) The average surface heat flux which can be dissipated by the electronic components is  $q/2W^2 = 122,650 \text{ W/m}^2$ , or  $12.3 \text{ W/cm}^2$ . (2) To check the numerical results, compute

$$\Delta T_{\ell m} = \frac{\Delta T_o - \Delta T_i}{\ln(\Delta T_o / \Delta T_i)} = \frac{29 \text{ K} - 50 \text{ K}}{\ln(29/50)} = 38.6 \text{ K}$$

$$\text{Hence } q = \bar{h} A_t \eta_o \Delta T_{\ell m} = 435 \text{ W/m}^2 \cdot \text{K} \times 0.409 \text{ m}^2 \times 0.357 \times 38.6 \text{ K} = 2449 \text{ W}.$$

## PROBLEM 7.97

**KNOWN:** Dimensions and properties of chip, board and pin fin assembly. Convection conditions for chip and board surface. Maximum allowable chip temperature.

**FIND:** Effect of design and operating conditions on maximum chip power dissipation.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Uniform chip temperature, (2) One-dimensional conduction in pins, (3) Insulated pin tips, (4) Negligible radiation, (5) Uniform convection coefficient over pin and base surfaces.

**PROPERTIES:** Table A.1, copper ( $T \approx 340$  K):  $k_p = 397$  W/m·K. Table A.4, air: properties evaluated using IHT Properties Tool Pad.

**ANALYSIS:** The chip heat rate may be expressed as

$$q_c = \frac{A_c (T_c - T_\infty)}{\left[ R''_{t,c} + (L_b/k_b) + (1/h_b) \right]} + q_t$$

where  $A_c = W^2$  and  $q_t$  is the total heat rate for the fin array. This heat rate must account for the variation of the air temperature across the array. Hence, the appropriate driving potential is

$\Delta T_{lm} = [(T_c - T_i) - (T_c - T_o)] / \ln [(T_c - T_i) / (T_c - T_o)]$ . However, the total surface area must account for the finite pin length and the exposed base (prime) surface. Hence, from Eqs. 3.106 and 3.107, with  $\Delta T_{lm}$  replacing  $\theta_b$ ,

$$q_t = \bar{h} A_t \eta_o \Delta T_{lm}$$

where  $A_t = N^2 A_f + A_b$ ,  $A_b = A_c - N^2 A_{p,c}$ ,  $A_{p,c} = \pi D_p^2 / 4$  and

$$\eta_o = 1 - \frac{N^2 A_f}{A_t} (1 - \eta_f)$$

For an adiabatic tip, Eq. 3.100 yields

$$\eta_f = \frac{\tanh mL_p}{mL_p}$$

where  $m = (4\bar{h}/k_p D_p)^{1/2}$ . The air outlet temperature is given by the expression

$$\frac{T_c - T_o}{T_c - T_i} = \exp \left( - \frac{\bar{h} A_t \eta_o}{\dot{m} c_p} \right)$$

Continued...

### PROBLEM 7.97 (Cont.)

where  $\dot{m} = \rho V W L_p$  and  $\bar{h}$  is obtained from the Zukauskas correlation,

$$\overline{Nu}_D = C_1 C_2 Re_{D,\max}^m Pr^{0.36} (Pr/Pr_s)^{1/4}$$

The foregoing model, including the convection correlation, was entered from the keyboard into the workspace of IHT and used with the *Properties* Tool Pad to perform the following parametric calculations.

Remaining within the limit  $ND_p \leq 9$  mm, there is clearly considerable benefit associated with increasing  $N$  from 4 to 6 for  $D_p = 1.5$  mm or with increasing  $D_p$  from 1.5 to 2.25 mm for  $N = 4$ . However, the best configuration corresponds to  $N = 6$  and  $D_p = 1.5$  mm (a larger number of smaller diameter pins), for which both  $A_t$  and  $\bar{h}$  are approximately 50% and 20% larger than values associated with  $N = 4$  and  $D_p = 2.25$  mm. The peak heat rate is  $q_c = 64.5$  W for  $V = 10$  m/s,  $N = 6$ , and  $D_p = 1.5$  mm.

**COMMENTS:** (1) The heat rate through the board is only  $q_b = 0.295$  W and hence a negligible portion of the total heat rate. (2) Values of  $C = 0.27$  and  $m = 0.63$  were used for the entire range of conditions. However,  $Re_{D,\max}$  was less than 1000 in the mid to low range of  $V$ , for which the correlation was therefore used outside its prescribed limits and the results are somewhat approximate. (3) Using the IHT solver, the model was implemented in three stages, beginning with (i) the correlation and the Properties Tool Pad and sequentially adding (ii) expressions for  $q_t$  and  $(T_c - T_o)/(T_c - T_i)$  without  $\eta_o$ , and (iii) inclusion of  $\eta_o$  in the model. Results computed from one calculation were loaded as initial guesses for the next calculation.

## PROBLEM 7.98

**KNOWN:** Tube geometry and flow conditions for steam condenser. Surface temperature and pressure of saturated steam.

**FIND:** (a) Coolant outlet temperature, (b) Heat and condensation rates, (c) Effects of reducing longitudinal pitch and change in velocity.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, (2) Negligible radiation, (3) Negligible effect of temperature change on air properties, (parts a and b), (4) Applicability of convection correlation outside designated range.

**PROPERTIES:** Table A.4, air ( $T_i = 300$  K):  $\rho = 1.16$  kg/m<sup>3</sup>,  $c_p = 1007$  J/kg·K,  $\nu = 15.89 \times 10^{-6}$  m<sup>2</sup>/s,  $k = 0.0263$  W/m·K,  $Pr = 0.707$ . ( $T_s = 390$  K):  $Pr = 0.692$ . Table A.6, saturated water at 2.455 bars:  $h_{fg} = 2.183 \times 10^6$  J/kg.

**ANALYSIS:** (a) From Section 7.6,

$$T_o = T_s - (T_s - T_i) \exp\left(-\frac{\pi D N \bar{h}}{\rho V N_T S_T c_p}\right)$$

With

$$V_{\max} = \frac{S_T}{S_T - D} V = \frac{30}{10} 4 \text{ m/s} = 12 \text{ m/s}$$

$$Re_{D,\max} = \frac{V_{\max} D}{\nu} = \frac{12 \text{ m/s} (0.02 \text{ m})}{15.89 \times 10^{-6} \text{ m}^2/\text{s}} = 15,104$$

Using the Zhukauskas correlation outside its designated range ( $S_T/S_L = 0.5$ ), Table 7.5 yields  $C_1 = 0.27$  and  $m = 0.63$ . Hence, with  $C_2 = 1$ ,

$$\bar{Nu}_D = C_1 Re_{D,\max}^m Pr^{0.36} (Pr/Pr_s)^{1/4} = 0.27 (15,104)^{0.63} (0.707)^{0.36} \left(\frac{0.707}{0.692}\right)^{1/4} = 103$$

$$\bar{h} = \bar{Nu}_D (k/D) = 103 (0.0263 \text{ W/m} \cdot \text{K} / 0.02 \text{ m}) = 135 \text{ W/m}^2 \cdot \text{K}$$

$$T_o = 390 \text{ K} - (90 \text{ K}) \exp\left[-\frac{\pi (0.02 \text{ m}) 400 \left(135 \text{ W/m}^2 \cdot \text{K}\right)}{1.16 \text{ kg/m}^3 (4 \text{ m/s}) 20 (0.03 \text{ m}) 1007 \text{ J/kg} \cdot \text{K}}\right] = 363 \text{ K} \quad <$$

(b) With  $q = q' L$ ,

Continued...

### PROBLEM 7.98 (Cont.)

$$q = N(\bar{h}\pi DL\Delta T_{lm})$$

where

$$\Delta T_{lm} = \frac{(T_s - T_i) - (T_s - T_o)}{\ln\left(\frac{T_s - T_i}{T_s - T_o}\right)} = \frac{(90 - 27) \text{ K}}{\ln\left(\frac{90}{27}\right)} = 52.3 \text{ K}$$

$$\text{Hence } q = 400\left(135 \text{ W/m}^2 \cdot \text{K}\right)\pi(0.02 \text{ m})2 \text{ m}(52.3 \text{ K}) = 355 \text{ kW} \quad <$$

The condensation rate is

$$\dot{m}_{\text{cond}} = \frac{q}{h_{fg}} = \frac{3.55 \times 10^5 \text{ W}}{2.183 \times 10^6 \text{ J/kg}} = 0.163 \text{ kg/s} \quad <$$

(c) For  $S_L = 0.03 \text{ m}$ ,  $N_L = 40$  and  $N = 800$ , using IHT with the foregoing model and the Properties Tool Pad to evaluate air properties at  $(T_i + T_o)/2$ , we obtain

$$T_o = 383.6 \text{ K}, \quad \Delta T_{lm} = 31.6 \text{ C}, \quad q = 414 \text{ kW}, \quad \dot{m}_{\text{cond}} = 0.190 \text{ kg/s} \quad <$$

As expected,  $q$  and  $\dot{m}_{\text{cond}}$  increase with increasing  $N_L$ . However, due to a corresponding increase in  $T_o$ , and hence a reduction in  $\Delta T_{lm}$ , the increase is not commensurate with the two-fold increase in surface area for the tube bank.

The effect of velocity is shown below.

The heat rate, and hence condensation rate, is strongly affected by velocity, because in addition to increasing  $\bar{h}$ , an increase in  $V$  decreases  $T_o$ , and hence increases  $\Delta T_{lm}$ .

**COMMENTS:** (1) The calculations of part (a) should be repeated with air properties evaluated at  $(T_i + T_o)/2$ . (2) the condensation rate could be increased significantly by using a water-cooled (larger  $\bar{h}$ ), rather than an air-cooled, condenser.

## PROBLEM 7.99

**KNOWN:** Temperature of single round air jet.

**FIND:** Minimum jet diameter for which Equation 7.71 can be applied.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, (2) Constant properties, (3) Air is ideal gas, (4) Flow is incompressible for  $Ma < 0.3$ .

**PROPERTIES:** Table A-4, Air ( $T = 273$  K):  $c_p = 1006.5$  J/kg·K,  $\nu = 13.5 \times 10^{-6}$  m<sup>2</sup>/s; ( $T = 773$  K):  $c_p = 1092.5$  J/kg·K,  $\nu = 80.3 \times 10^{-6}$  m<sup>2</sup>/s.

**ANALYSIS:** (a) Equation 7.71 is restricted to the Reynolds range:

$$2000 \leq Re \leq 400,000$$

With  $Re = VD/\nu$ , this restricts  $VD$ , but does not limit  $D$  directly. Therefore there must be another constraint, namely the flow must be incompressible, which is valid for  $Ma = V/a < 0.3$ , where  $a$  is the speed of sound. The Mach number constraint implies  $V < 0.3a$ , which in turn means that  $Re < 0.3aD/\nu$ . Incorporating the lower Reynolds number limit provides a minimum bound on  $D$ , namely

$$2000 \leq Re < \frac{0.3aD}{\nu}$$

$$D \geq 2000 \frac{\nu}{0.3a}$$

Also, the gas constant for air is  $R \equiv \mathcal{R}/\mathcal{M} = 8315$  J/kmol·K/28.97 kg/kmol = 287 J/kg.

(a) At  $T = 273$  K,  $c_v \equiv c_p - R = 1006.5$  J/kg·K - 287 J/kg·K = 719.5 J/kg·K. The ratio of specific heats is therefore  $\gamma = c_p/c_v = 1006.5$  J/kg·K/719.5 J/kg·K = 1.40 and the speed of sound is  $a = \sqrt{\gamma RT} = \sqrt{1.40 \times 287$  J/kg·K  $\times$  273 K = 331 m/s. Hence the minimum diameter jet is given by

$$D \geq 2000 \frac{13.5 \times 10^{-6} \text{ m}^2/\text{s}}{0.3 \times 331 \text{ m/s}} = 2.7 \times 10^{-4} \text{ m} = 0.27 \text{ mm} \quad <$$

(b) For  $T = 773$  K,  $c_v \equiv c_p - R = 1092.5$  J/kg·K - 287 J/kg·K = 805.5 J/kg·K. The ratio of specific heats is therefore  $\gamma = c_p/c_v = 1092.5$  J/kg·K/805.5 J/kg·K = 1.36 and the speed of sound is  $a = \sqrt{\gamma RT} = \sqrt{1.36 \times 287$  J/kg·K  $\times$  773 K = 549 m/s. Hence the minimum diameter jet is given by

$$D \geq 2000 \frac{80.3 \times 10^{-6} \text{ m}^2/\text{s}}{0.3 \times 549 \text{ m/s}} = 0.00098 \text{ m} = 0.98 \text{ mm} \quad <$$

**COMMENTS:** If jet diameters smaller than these limits are to be used, alternative approaches would need to be taken to estimate the corresponding convection heat transfer rates.

### PROBLEM 7.100

**KNOWN:** Geometry of air jet impingement on a transistor. Jet temperature and velocity. Maximum allowable transistor temperature.

**FIND:** Maximum allowable operating power.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Isothermal surface, (3) Bell-shaped nozzle, (4) All of the transistor power is dissipated to the jet.

**PROPERTIES:** Table A-4, Air ( $T_f = 323 \text{ K}$ , 1 atm):  $\nu = 18.2 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.028 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.704$ .

**ANALYSIS:** The maximum power or heat transfer rate by convection is

$$P_{\max} = q_{\max} = \bar{h} \left( \pi D_t^2 / 4 \right) (T_s - T_e)_{\max}$$

For a single round nozzle,

$$\frac{\bar{Nu}}{\text{Pr}^{0.42}} = G(A_r, H/D) F_1(\text{Re})$$

where  $A_r = D^2/4r^2 = 0.04$  and

$$G = Z A_r^{1/2} \frac{1 - 2.2 A_r^{1/2}}{1 + 0.2(H/D - 6) A_r^{1/2}} = 2(0.04)^{1/2} \frac{1 - 2.2(0.04)^{1/2}}{1 + 0.2(5 - 6)(0.04)^{1/2}} = 0.233$$

With

$$\text{Re} = \frac{V_e D}{\nu} = \frac{(20 \text{ m/s}) 0.002 \text{ m}}{18.2 \times 10^{-6} \text{ m}^2/\text{s}} = 2198$$

$$F_1 = 2\text{Re}^{1/2} \left( 1 + 0.005\text{Re}^{0.55} \right)^{1/2} = 2(2198)^{1/2} \left[ 1 + 0.005(2198)^{0.55} \right]^{1/2} = 108.7$$

$$\text{Hence } \bar{h} = \frac{k}{D} G F_1 \text{Pr}^{0.42} = \frac{0.028 \text{ W/m}\cdot\text{K}}{0.002 \text{ m}} (0.233)(108.7)(0.704)^{0.42} = 306 \text{ W/m}^2 \cdot \text{K}$$

$$\text{Hence } P_{\max} = \left( 306 \text{ W/m}^2 \cdot \text{K} \right) \left( \pi / 4 \right) (0.01 \text{ m})^2 (70^\circ\text{C}) = 1.68 \text{ W.} \quad <$$

**COMMENTS:** (1) All conditions required for use of the correlation are satisfied.

(2) Power dissipation may be enhanced by allowing for heat loss through the side and base of the transistor.

## PROBLEM 7.101

**KNOWN:** Dimensions of heated plate and slot jet array. Jet exit temperature and velocity. Initial plate temperature.

**FIND:** Initial plate cooling rate.

**SCHEMATIC:**

**ASSUMPTIONS:** (a) Negligible variation in  $h$  along plate, (b) Negligible heat loss from back surface of plate, (c) Negligible radiation from front surface of plate.

**PROPERTIES:** Table A-1, AISI 304 Stainless steel (1200 K):  $k = 28.0 \text{ W/m}\cdot\text{K}$ ,  $c_p = 640 \text{ J/kg}\cdot\text{K}$ ,  $\rho = 7900 \text{ kg/m}^3$ ; Table A-4, Air ( $\bar{T}_f = 800 \text{ K}$ ):  $\nu = 84.9 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0573 \text{ W/m}\cdot\text{K}$ ,  $Pr = 0.709$ .

**ANALYSIS:** Performing an energy balance on a control surface about the plate,

$$-q_{\text{conv}} = -\bar{h}A_s(T_i - T_e) = \dot{E}_{\text{st}} = \rho(A_s t)c_p \left(\frac{dT}{dt}\right)_i \quad \left(\frac{dT}{dt}\right)_i = -\frac{\bar{h}(T_i - T_e)}{\rho c_p t}$$

For an array of slot nozzles,

$$\frac{\bar{Nu}}{Pr^{0.42}} = \frac{2}{3} A_{r,o}^{3/4} \left[ \frac{2Re}{A_r / A_{r,o} + A_{r,o} / A_r} \right]^{2/3}$$

where  $A_r = W/S = 0.1$

$$A_{r,o} = \left\{ 60 + 4 \left[ \left( \frac{H}{2W} \right) - 2 \right]^2 \right\}^{-1/2} = \left\{ 60 + 4(64) \right\}^{-1/2} = 0.0563$$

$$Re = \frac{V_e(2W)}{\nu} = \frac{30 \text{ m/s}(0.02 \text{ m})}{84.9 \times 10^{-6} \text{ m}^2/\text{s}} = 7067$$

$$\bar{h} = \frac{0.0573 \text{ W/m}\cdot\text{K}}{0.02 \text{ m}} \frac{2}{3} (0.0563)^{3/4} \left[ \frac{2 \times 7067}{1.776 + 0.563} \right]^{2/3} = 73.2 \text{ W/m}^2 \cdot \text{K}$$

Hence,

$$\left(\frac{dT}{dt}\right)_i = -\frac{73.2 \text{ W/m}^2 \cdot \text{K}(800 \text{ K})}{(7900 \text{ kg/m}^3)(640 \text{ J/kg}\cdot\text{K})(0.008 \text{ m})} = -1.45 \text{ K/s} \quad \leftarrow$$

**COMMENTS:** (1)  $Bi = \bar{h}t/k = (73.2 \text{ W/m}^2 \cdot \text{K})(0.008 \text{ m})/28 \text{ W/m}\cdot\text{K} = 0.02$  and use of the lumped capacitance method is justified.

(2) Radiation may be significant.

(3) Conditions required for use of the correlation are satisfied.

## PROBLEM 7.102

**KNOWN:** Dimensions and material of a cryogenic probe. Temperature and velocity of nitrogen at jet exit. Cancerous tissue thermal conductivity and temperature far from the probe.

**FIND:** (a) Skin surface temperature under probe.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Constant properties, (3) Negligible contact resistance between skin and probe, (4) Incompressible flow, (5) Due to wall confinement, jet can be modeled as if it were one in an array.

**PROPERTIES:** Table A-4, Nitrogen ( $T \approx 100$  K):  $k = 9.58 \times 10^{-3}$  W/m·K,  $\nu = 2.00 \times 10^{-6}$  m<sup>2</sup>/s,  $Pr = 0.768$ . Table A-1, AISI 302 Stainless Steel ( $T \approx 300$  K):  $k_p = 15.1$  W/m·K.

**ANALYSIS:** (a) The Reynolds number is

$$Re = \frac{V_e D}{\nu} = \frac{20 \text{ m/s} \times 0.002 \text{ m}}{2.00 \times 10^{-6} \text{ m}^2/\text{s}} = 2 \times 10^4$$

The jet behaves as if it were in a staggered array, with the probe walls behaving as if they were the symmetry planes between jets (see Figure 7.18c). Thus  $S = D_o - 2t = 11$  mm and

$$A_r = \pi D_e^2 / 2\sqrt{3}S^2 = \pi(0.002 \text{ m})^2 / 2\sqrt{3}(0.011 \text{ m})^2 = 0.030 \text{ m}^2$$

Furthermore,  $H/D_e = 2.5$ . Based on all of these values, the correlation for an array of round nozzles is valid. From Equations 7.72 and 7.74,

$$G = 2A_r^{1/2} \frac{1 - 2.2A_r^{1/2}}{1 + 0.2(H/D_e - 6)A_r^{1/2}} = 2(0.030 \text{ m}^2)^{1/2} \frac{1 - 2.2(0.030 \text{ m}^2)^{1/2}}{1 + 0.2(2.5 - 6)(0.030 \text{ m}^2)^{1/2}} = 0.244$$

$$K = \left[ 1 + \left( \frac{H/D_e}{0.6/A_r^{1/2}} \right)^6 \right]^{-0.05} = \left[ 1 + \left( \frac{2.5}{0.6/(0.030 \text{ m})^{1/2}} \right)^6 \right]^{-0.05} = 0.993$$

Thus from Equation 7.73,

Continued...

**PROBLEM 7.102 (Cont.)**

$$\overline{Nu} = 0.5KGR e^{2/3} Pr^{0.42} = 0.5 \times 0.993 \times 0.244 \times (2 \times 10^4)^{2/3} (0.768)^{0.42} = 79.9$$

and

$$\overline{h} = \overline{Nu} k / D_e = 79.9 \times 9.58 \times 10^{-3} \text{ W/m} \cdot \text{K} / 0.002 \text{ m} = 383 \text{ W/m}^2 \cdot \text{K}$$

Next, consider the heat transfer from the cancerous tissue at  $T_c$  to the probe surface, through the probe wall, and from the wall to the jet. The heat transfer rate can be written by considering a sum of thermal resistances, as follows:

$$q = \frac{T_c - T_e}{R_c + R_p + R_{\text{jet}}}$$

In this expression,

$R_c$  is the resistance associated with the semi-infinite cancerous tissue having a disk of diameter  $D_o$  at temperature  $T_s$ , as in Table 4.1, Case 10:

$$R_c = 1/2D_o k_c = 1/(2 \times 0.015 \text{ m} \times 0.2 \text{ W/m} \cdot \text{K}) = 167 \text{ K/W}$$

$R_p$  represents conduction through the probe wall:

$$R_p = t/(k_p \pi D_o^2 / 4) = 0.002 \text{ m} \times 4/(15.1 \text{ W/m} \cdot \text{K} \times \pi \times 0.015^2 \text{ m}^2) = 0.750 \text{ K/W}$$

$$R_{\text{jet}} = 1/(\overline{h} \pi D_o^2 / 4) = 4/(383 \text{ W/m}^2 \cdot \text{K} \times \pi \times 0.015^2 \text{ m}^2) = 14.8 \text{ K/W}$$

The heat transfer rate is

$$q = \frac{(310 - 100)\text{K}}{(167 + 0.75 + 14.8)\text{K} / \text{W}} = 1.15 \text{ W}$$

and  $q = (T_c - T_s)/R_c$ , so that

$$T_s = T_c - qR_c = 310 \text{ K} - 1.15 \text{ W} \times 167 \text{ K} / \text{W} = 118 \text{ K} \quad <$$

**COMMENTS:** (1) The assumption of incompressible flow can be checked as follows. For nitrogen, the gas constant is  $R \equiv \mathcal{R}/M = 8315 \text{ J/kmol} \cdot \text{K} / 28 \text{ kg/kmol} = 297 \text{ J/kg}$ . At 100 K,  $c_v = c_p - R = 1070 \text{ J/kg} \cdot \text{K} - 297 \text{ J/kg} \cdot \text{K} = 773 \text{ J/kg} \cdot \text{K}$ . The ratio of specific heats is therefore  $\gamma = c_p/c_v = 1070 \text{ J/kg} \cdot \text{K} / 773 \text{ J/kg} \cdot \text{K} = 1.38$  and the speed of sound is  $a = \sqrt{1.38 \times 297 \text{ J/kg} \cdot \text{K} \times 100 \text{ K}} = 203 \text{ m/s}$ . Hence the Mach number is  $Ma = V/a = 20 \text{ m/s} / 203 \text{ m/s} = 0.1$ , and the flow may be treated as incompressible.

### PROBLEM 7.103

**KNOWN:** Air at 10 m/s and 15°C is available for cooling hot plastic plate. An array of slotted nozzles with prescribed width, pitch and nozzle-to-plate separation.

**FIND:** (a) Improvement in cooling rate achieved using the slotted nozzle arrangement in place of turbulent air in parallel flow over the plate, (b) Change in heat rates if air velocities were doubled, (c) Air mass rate requirement for the slotted nozzle arrangement.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) For parallel flow over plate, flow is turbulent, (3) Negligible radiation effects.

**PROPERTIES:** Table A-4, Air ( $T_f = (140 + 15)^\circ\text{C}/2 = 350\text{ K}$ , 1 atm):  $\rho = 0.995\text{ kg/m}^3$ ,  $\nu = 20.92 \times 10^{-6}\text{ m}^2/\text{s}$ ,  $k = 30.3 \times 10^{-3}\text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.700$ .

**ANALYSIS:** (a) For turbulent flow over the *plate* of length  $L$  with

$$\text{Re}_L = \frac{u_\infty L}{\nu} = \frac{10\text{ m/s} \times 0.5\text{ m}}{20.92 \times 10^{-6}\text{ m}^2/\text{s}} = 2.390 \times 10^5$$

using the turbulent flow correlation, find

$$\overline{\text{Nu}}_L = \frac{\bar{h}L}{k} = 0.037\text{Re}_L^{4/5}\text{Pr}^{1/3} = 0.037(2.390 \times 10^5)^{4/5}(0.700)^{1/3} = 659.6$$

$$\bar{h} = \overline{\text{Nu}}_L k/L = 659.6 \times 0.030\text{ W/m}\cdot\text{K}/0.5\text{ m} = 39.6\text{ W/m}^2\cdot\text{K}.$$

For an array of *slot nozzles*,

$$\overline{\text{Nu}} = \frac{\bar{h}D}{k} = \frac{2}{3}\text{Ar}_{r,o}^{3/4} \left[ \frac{2\text{Re}}{\text{Ar}_r/\text{Ar}_{r,o} + \text{Ar}_{r,o}/\text{Ar}_r} \right]^{2/3} \text{Pr}^{0.42}$$

where 
$$\text{Re} = \frac{V_e D_h}{\nu} = \frac{10\text{ m/s}(2 \times 0.004\text{ m})}{20.92 \times 10^{-6}\text{ m}^2/\text{s}} = 3824$$

$$\text{Ar}_{r,o} = \left\{ 60 + 4 \left[ \left( \frac{H}{2W} \right) - 2 \right]^2 \right\}^{-1/2} = \left\{ 60 + 4 \left[ \frac{40}{2 \times 4} - 2 \right]^2 \right\}^{-1/2} = 0.1021$$

$$\text{Ar}_r = W/S = 4\text{ mm}/56\text{ mm} = 0.0714$$

$$\overline{\text{Nu}} = \frac{2}{3}(0.1021)^{3/4} \left[ \frac{2 \times 3824}{0.0714/0.1021 + 0.1021/0.0714} \right]^{2/3} (0.700)^{0.42} = 24.3$$

$$\bar{h} = \overline{\text{Nu}}k/D_h = 24.3 \times 0.030\text{ W/m}\cdot\text{K}/2 \times 0.004\text{ m} = 91.1\text{ W/m}^2\cdot\text{K}.$$

Continued ...

### PROBLEM 7.103 (Cont.)

The improvement in heat rate with the slot nozzles (sn) over the flat plate (fp) is

$$\frac{q''_{\text{sn}}}{q''_{\text{fp}}} = \frac{\bar{h}_{\text{sn}}}{\bar{h}_{\text{fp}}} = \frac{91.1 \text{ W/m}^2 \cdot \text{K}}{39.6 \text{ W/m}^2 \cdot \text{K}} = 2.3. \quad <$$

(b) If the air velocities were doubled for each arrangement in part (a), the heat transfer coefficients are affected as

$$\bar{h}_{\text{sn}} \sim \text{Re}^{2/3} \quad \bar{h}_{\text{fp}} \sim \text{Re}^{4/5}.$$

Hence

$$\frac{\bar{h}_{\text{sn}}}{\bar{h}_{\text{fp}}} = 2.3 \left( \frac{2^{2/3}}{2^{4/5}} \right) = 2.1. \quad <$$

That is, comparative advantage of the slot nozzle over the flat plate decreases with increasing velocity.

(c) The mass rate of air flow through the array of slot nozzles is

$$\dot{m} = \rho N A_{c,e} = 0.995 \text{ kg/m}^3 \times 9 (0.5 \text{ m} \times 0.004 \text{ m}) 10 \text{ m/s} = 0.179 \text{ kg/s}$$

where the number of slots is determined as

$$N \approx L/S = 0.5 \text{ m} / 0.056 \text{ m} = 8.9 \approx 9. \quad <$$

**COMMENTS:** Note, for the slot nozzle, the hydraulic diameter is  $D_h = 2W$  and the relative nozzle area ( $A_{c,e}/A_{\text{cell}}$ ) is  $A_r = W/S$ .

## PROBLEM 7.104

**KNOWN:** Air jet velocity and temperature of 10 m/s and 15°C, respectively, for cooling hot plastic plate..

**FIND:** Design of optimal round nozzle array. Compare cooling rate with results for a slot nozzle array and flow over a flat plate. Discuss features associated with these three methods relevant to selecting one for this application.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Negligible radiation effects.

**PROPERTIES:** Table A-4, Air ( $T_f = (140 + 15)^\circ\text{C}/2 = 350\text{ K}$ , 1 atm):  $\rho = 0.995\text{ kg/m}^3$ ,  $\nu = 20.92 \times 10^{-6}\text{ m}^2/\text{s}$ ,  $k = 30.0 \times 10^{-3}\text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.700$ .

**ANALYSIS:** To design an *optimal array* of round nozzles, we require that  $D_{h,op} \approx 0.2H$  and  $S_{op} \approx 1.4H$ . Choose  $H = 40\text{ mm}$ , the nozzle-to-plate separation, hence

$$D_{h,op} = D = 0.2 \times 40\text{ mm} = 8\text{ mm} \quad S_{op} = 1.4 \times 40\text{ mm} = 56\text{ mm}.$$

For an array of round nozzles,

$$\overline{\text{Nu}} = K(A_r, H/D) \cdot G(A_r, H/D) \cdot F_2(\text{Re}) \cdot \text{Pr}^{0.42}$$

where for an *in-line* array, see Fig. 7.18,

$$A_r = \frac{\pi D^2}{4S^2} = \frac{\pi (8\text{ mm})^2}{4(56\text{ mm})^2} = 0.0160$$

$$K = \left[ 1 + \left( \frac{H/D}{0.6/A_r^{1/2}} \right)^6 \right]^{-0.05} = \left[ 1 + \left( \frac{40/8}{0.6/0.0160^{1/2}} \right)^6 \right]^{-0.05} = 0.9577$$

$$G = 2A_r^{1/2} \frac{1 - 2.2A_r}{1 + 0.2(H/D - 6)A_r^{1/2}} = 2 \times 0.0160^{1/2} \frac{1 - 2.2 \times 0.0160}{1 + 0.2(40/8 - 6)0.0160^{1/2}}$$

$$G = 0.2504$$

$$F_2 = 0.5\text{Re}^{2/3} = 0.5 \left( \frac{10\text{ m/s} \times 0.008\text{ m}}{20.92 \times 10^{-6}\text{ m}^2/\text{s}} \right)^{2/3} = 122.2.$$

The average heat transfer coefficient for the *optimal in-line* (op, il) array of round nozzles is,

$$\overline{h}_{op,il} = \overline{\text{Nu}} k/D_{h,op} = \frac{0.030\text{ W/m}\cdot\text{K}}{0.008\text{ m}} \times 0.9577 \times 0.2504 \times 122.2 (0.700)^{0.42}$$

$$\overline{h}_{op,il} = 94.6\text{ W/m}^2 \cdot \text{K}.$$

Continued ...

### PROBLEM 7.104 (Cont.)

If an *optimal staggered* (op,s) array were used, see Fig. 7.18, with

$$A_r = \frac{\pi D^2}{2(3)^{1/2} S^2} = \frac{\pi \times (8 \text{ mm})^2}{2(3)^{1/2} (56 \text{ mm})^2} = 0.0185$$

find  $K = 0.9447$ ,  $G = 0.2632$ ,  $F_2 = 122.2$  and  $\bar{h}_{\text{op,s}} = 100.0 \text{ W/m}^2 \cdot \text{K}$ .

Using the previous results for *parallel flow* (pf) and the *slot nozzle* (sn) array, the heat rates, which are proportional to the average convection coefficients, can be compared.

Arrangement	Flat plate (fp)	Slot nozzle (sn)	Optimal round nozzle (op) In-line (il)	Staggered (s)
$\bar{h}$ , $\text{W/m}^2 \cdot \text{K}$	39.6	91.1	94.6	100.0
$\bar{h}/h_{\text{fp}}$	1.0	2.30	2.39	2.53
$\dot{m}$ , kg/s	---	0.199	0.040	0.046

For these flow conditions, we conclude that there is only slightly improved performance associated with using the round nozzles. As expected, the *staggered* array is better than the *in-line* arrangement, since the former has a higher area ratio ( $A_r$ ). The air flow requirements for the round nozzle arrays are

$$\dot{m} = \rho N A_{c,e} V_e = \rho (A_s / A_{\text{cell}}) A_{c,e} V_e = \rho A_r A_s V_e$$

where  $N = A_s / A_{\text{cell}}$  is the number of nozzles and  $A_s$  is the area of the plate to be cooled. Substituting numerical values, find

$$\dot{m}_{\text{op,il}} = 0.995 \text{ kg/m}^3 \times 0.0160 (0.5 \times 0.5 \text{ m}^2) \times 10 \text{ m/s} = 0.040 \text{ kg/s}$$

$$\dot{m}_{\text{op,s}} = 0.995 \text{ kg/m}^3 \times 0.0185 (0.5 \times 0.5 \text{ m}^2) \times 10 \text{ m/s} = 0.046 \text{ kg/s}.$$

For this application, selection of a nozzle arrangement should be based upon air flow requirements (round nozzles have considerable advantage) and costs associated with fabrication of the arrays (slot nozzle may be easier to form from sheet metal).

## PROBLEM 7.105

**KNOWN:** Exit diameter of plasma generator and radius of jet impingement surface. Temperature and velocity of plasma jet. Temperature of impingement surface. Droplet deposition rate.

**FIND:** Rate of heat transfer to substrate due to convection and release of latent heat.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Negligible radiation, (3) Negligible sensible energy change due to cooling of droplets to  $T_s$ .

**ANALYSIS:** The total heat rate to the substrate is due to convection from the jet and release of the latent heat of fusion due to solidification,  $q = q_{\text{conv}} + q_{\text{lat}}$ . With  $Re = V_e D / \nu = (400 \text{ m/s})0.01 \text{ m} / 5.6 \times 10^{-3} \text{ m}^2/\text{s} = 714$ ,  $A_r = D^2 / 4r^2 = 0.04$ , and  $H/D = 10$ ,  $F_1 = 2Re^{1/2}(1 + 0.005 Re^{0.55})^{1/2} = 58.2$  and  $G =$

$2A_r^{1/2}(1 - 2.2A_r^{1/2}) / [1 + 0.2(H/D - 6)A_r^{1/2}] = 0.193$ , the correlation for a single round nozzle (Section 7.7) yields

$$\overline{Nu} = GF_1 Pr^{0.42} = 0.193(58.2)(0.60^{0.42}) = 9.07$$

$$\bar{h} = \overline{Nu}(k/D) = 9.07(0.671 \text{ W/m} \cdot \text{K} / 0.01 \text{ m}) = 609 \text{ W/m}^2 \cdot \text{K}$$

Hence,

$$q = \bar{h}A_s(T_e - T_s) = 609 \text{ W/m}^2 \cdot \text{K} \times \pi(0.025 \text{ m})^2(10,000 - 300) \text{ K} = 11,600 \text{ W} \quad <$$

The release of latent heat is

$$q_{\text{lat}} = A_s \dot{m}_p'' h_{sf} = \pi(0.025 \text{ m})^2 (0.02 \text{ kg/s} \cdot \text{m}^2) 3.577 \times 10^6 \text{ J/kg} = 140 \text{ W} \quad <$$

**COMMENTS:** (1) The large plasma temperature renders heat transfer due to droplet deposition negligible compared to convection from the plasma. (2) Note that  $Re = 714$  is outside the range of applicability of the correlation, which has therefore been used as an approximation to actual conditions.

## PROBLEM 7.106

**KNOWN:** A round nozzle with a diameter of 1 mm located a distance of 2 mm from the surface mount area with a diameter of 2.5 mm; air jet has a velocity of 70 m/s and a temperature of 500°C.

**FIND:** (a) Estimate the average convection coefficient over the area of the surface mount, (b) Estimate the time required for the surface mount region on the PCB, modeled as a semi-infinite medium initially at 25°C, to reach 183°C; (c) Calculate and plot the surface temperature of the surface mount region for air jet temperatures of 500, 600 and 700°C as a function time for  $0 \leq t \leq 150$  s. Comment on the outcome of your study, the appropriateness of the assumptions, and the feasibility of using the jet for a soldering application.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Air jet is a single round nozzle, (2) Uniform temperature over the PCB surface, and (3) Surface mount region can be modeled as a one-dimensional semiinfinite medium.

**PROPERTIES:** Table A-4, Air ( $T_f = 536$  K, 1 atm):  $\nu = 4.36 \times 10^{-5}$  m<sup>2</sup>/s,  $k = .0497$  W/m·K,  $Pr = 0.6833$ ; Solder (given):  $\rho = 8333$  kg/m<sup>3</sup>,  $c_p = 188$  J/kg·K, and  $k = 51$  W/m·K; eutectic temperature,  $T_{sol} = 183^\circ\text{C}$ ; PCB (given): glass transition temperature,  $T_{gl} = 250^\circ\text{C}$ .

**ANALYSIS:** For a single round nozzle, from the correlation of Eqs. 7.71 and 7.72, estimate the convection coefficient,

$$\frac{\overline{Nu}}{Pr^{0.42}} = G \left( \frac{r}{D}, \frac{H}{D} \right) F_1(Re) \quad \overline{Nu} = \frac{\overline{h}D}{k} \quad (1,2)$$

where

$$F_1 = 2Re^{1/2} \left( 1 + 0.005 Re^{0.55} \right)^{1/2} \quad (3)$$

$$G = 2 A_r^{1/2} \frac{1 - 2.2 A_r^{1/2}}{1 + 0.2(H/D - 6) A_r^{1/2}} \quad (4)$$

$$A_r = D^2 / 4r_o^2 \quad (5)$$

The Reynolds number is based on the jet diameter and velocity at the nozzle,

$$Re_D = V_e D / \nu \quad (6)$$

and  $r_o$  is the radius of the region over which the average coefficient is being evaluated. The thermophysical properties are evaluated at the film temperature,  $T_f = (T_e + T_i)/2$ . The results of the calculation are tabulated below.

Continued ...

### PROBLEM 7.106 (Cont.)

Re	$F_1$	G	$A_F$	$\overline{Nu}$	$\overline{h}$ (W/m <sup>2</sup> ·K)	<
1605	91.01	0.1412	0.16	10.95	470.5	

Consider the surface mount region as a semi-infinite medium, with solder properties, initially at a uniform temperature of 25°C, that experiences sudden exposure to the convection process with the air jet at a temperature  $T_\infty = 500^\circ\text{C}$  and the convection coefficient as found in part (a). The surface temperature,  $T(0,t)$ , is determined from Case 3, Fig. 5.7 and Eq. 5.63,

$$\frac{T(0,t) - T_i}{T_\infty - T_i} = 1 - \exp\left(-\frac{h^2 \alpha t}{k^2}\right) \times \text{erfc}\left(\frac{h(\alpha t)^{1/2}}{k}\right) \quad (7)$$

where  $\alpha = k/\rho c_p$ . With  $T_i = 25^\circ\text{C}$  and  $T_\infty = T_e$ , by trial-and-error, or by using the appropriate *IHT* model, find

$$T(0, t_0) = 183^\circ\text{C} \qquad t_0 = 40.1 \text{ s} \qquad <$$

(c) Using the foregoing relations in *IHT*, the surface temperature  $T(0,t)$  is calculated and plotted for jet air temperatures of 400, 500 and 600°C for  $0 \leq t \leq 40$  s.

The effect of increasing the jet air temperature is to reduce the time for the surface temperature to reach the solder temperature of 183°C. With the 700°C air jet, it takes about 14 s to reach the solder temperature, and the glass transition temperature is achieved in 35 s. The analysis represents a first-order model giving approximate results only. While the estimates for the average convection coefficients are reasonable, modeling the surface mount region as a semi-infinite medium is an over simplification. The region is of limited extent on the PCB, which is thin and also a poor approximation to an infinite medium. However, the model has provided insight into the conditions under which an air jet could be used for a soldering operation.

**COMMENTS:** (1) Note that for our application, the round nozzle correlation of part (a) exceeds the ranges of validity.

(2) The jet convection coefficient is not strongly dependent upon the air temperature. Values for 500, 600, and 700°C, respectively, are 464, 471, and 458 W/m<sup>2</sup>·K.

## PROBLEM 7.107

**KNOWN:** Diameter and properties of aluminum spheres used in packed bed. Porosity of bed and velocity and temperature of inlet air.

**FIND:** Time for sphere to acquire 90% of maximum possible thermal energy.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat transfer to or from a sphere by radiation or conduction due to contact with other spheres, (2) Validity of lumped capacitance method, (3) Constant properties.

**PROPERTIES:** Prescribed, Aluminum:  $\rho = 2700 \text{ kg/m}^3$ ,  $c = 950 \text{ J/kg}\cdot\text{K}$ ,  $k = 240 \text{ W/m}\cdot\text{K}$ . *Table A-4*, Air (573K):  $\rho_a = 0.609 \text{ kg/m}^3$ ,  $c_{p,a} = 1045 \text{ J/kg}\cdot\text{K}$ ,  $\nu = 48.8 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k_a = 0.0453 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.684$ .

**ANALYSIS:** From Eqs. 5.7 and 5.8a, achievement of 90% of the maximum possible thermal energy storage corresponds to

$$\frac{Q}{\rho c \nabla \theta_i} = 0.9 = 1 - \exp\left(-\frac{t}{\tau_t}\right) = 1 - \exp\left(-\frac{\bar{h} A_s t}{\rho \nabla c}\right)$$

where the convection coefficient is given by

$$\varepsilon j_H = \varepsilon \bar{\text{St}} \text{Pr}^{2/3} = \varepsilon \frac{\bar{h}}{\rho_a V c_{p,a}} \text{Pr}^{2/3} = 2.06 \text{Re}_D^{-0.575}$$

With  $\text{Re}_D = VD/\nu = 1 \text{ m/s} \times 0.075 \text{ m} / 48.8 \times 10^{-6} \text{ m}^2/\text{s} = 1537$ ,

$$\bar{h} = \frac{2.06 \times 0.609 \text{ kg/m}^3 \times 1 \text{ m/s} \times 1045 \text{ J/kg}\cdot\text{K}}{0.4 (0.684)^{2/3} (1537)^{0.575}} = 62.1 \text{ W/m}^2 \cdot \text{K}$$

Hence, with  $A_s/\nabla = 6/D$ ,

$$t = -\frac{\rho c D}{6\bar{h}} \ln(0.1) = \frac{2700 \text{ kg/m}^3 \times 950 \text{ J/kg}\cdot\text{K} \times 0.075 \text{ m} \times 2.30}{6 \times 62.1 \text{ W/m}^2 \cdot \text{K}} = 1189 \text{ s} \quad <$$

**COMMENTS:** (1) With  $\text{Bi} = \bar{h}(D/6)/k = 0.003$ , the spheres are spatially isothermal and the lumped capacitance approximation is excellent. (2) Before the packed bed becomes fully charged, the temperature of the air decreases as it passes through the bed. Hence, the time required for a sphere to reach a prescribed state of thermal energy storage increases with increasing distance from the bed inlet.

### PROBLEM 7.108

**KNOWN:** Overall dimensions of a packed bed of rocks. Rock diameter and thermophysical properties. Initial temperature of rock and bed porosity. Flow rate and upstream temperature of atmospheric air passing through the pile.

**FIND:** Rate of heat transfer to pile.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Rocks are spherical and at a uniform temperature, (2) Steady-state conditions.

**PROPERTIES:** Table A-4, Atmospheric air ( $T_\infty = 363\text{K}$ ):  $\nu = 22.35 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.031 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.70$ ,  $\rho = 0.963 \text{ kg/m}^3$ ,  $c_p = 1010 \text{ J/kg}\cdot\text{K}$ .

**ANALYSIS:** The heat transfer rate may be expressed as  $q = \bar{h}A_{p,t}\Delta T_{\ell m}$  where the total surface area of the rocks is

$$A_{p,t} = V_r \frac{\pi D_r^2}{\pi D_r^3/6} = (1-\varepsilon) \left( \frac{\pi D_b^2}{4} L_b \right) \frac{6}{D_r} = (1-0.42) \left( \pi (1 \text{ m})^2 \times 2 \text{ m}/4 \right) 6/0.03 \text{ m} = 182.2 \text{ m}^2.$$

The upstream velocity and Reynolds number are

$$V = \frac{\dot{m}_a}{\rho \pi D_b^2/4} = \frac{4 \times 1 \text{ kg/s}}{(0.963 \text{ kg/m}^3) \pi 1 \text{ m}^2} = 1.32 \text{ m/s} \quad \text{Re}_D = \frac{VD_r}{\nu} = \frac{1.32 \text{ m/s} \times 0.03 \text{ m}}{22.35 \times 10^{-6} \text{ m}^2/\text{s}} = 1772.$$

From Section 7.8, it follows that

$$\varepsilon \bar{h} = \varepsilon \bar{St} \text{Pr}^{2/3} = \varepsilon \frac{\bar{h}}{\rho V c_p} \text{Pr}^{2/3} = 2.06 \text{Re}_D^{-0.575}$$

$$\bar{h} = \frac{2.06}{\varepsilon} \rho V c_p \text{Re}_D^{-0.575} \text{Pr}^{-2/3}$$

$$\bar{h} = \frac{2.06}{0.42} 0.963 \text{ kg/m}^3 \times 1.32 \text{ m/s} \times 1010 \text{ J/kg}\cdot\text{K} (1772)^{-0.575} (0.70)^{-2/3} = 108 \text{ W/m}^2 \cdot \text{K}.$$

The appropriate form of the mean temperature difference,  $\Delta T_{\ell m}$ , may be obtained by performing an energy balance on a differential control volume about the rock. That is,

$$\dot{m}_a c_p T_a - \dot{m}_a c_p (T_a + dT_a) - dq_r = 0$$

where  $dq_r = \bar{h}A'_{p,t} dx (T_a - T_s)$  and  $A'_{p,t}$  is the rock surface area per unit length of bed. Hence

$$\dot{m}_a c_p dT_a = -\bar{h}A'_{p,t} dx (T_a - T_s) \quad \frac{dT_a}{dx} = -\frac{\bar{h}A'_{p,t}}{\dot{m}_a c_p} (T_a - T_s).$$

Continued ...

### PROBLEM 7.108 (Cont.)

Integrating between inlet and outlet, it follows that

$$\ln(T_a - T_s) \Big|_i^o = -\frac{\bar{h}A'_{p,t}}{\dot{m}_a c_p} L_b = -\frac{\bar{h}A_{p,t}}{\dot{m}_a c_p} \quad \ln \frac{T_{a,o} - T_s}{T_{a,i} - T_s} = -\frac{\bar{h}A_{p,t}}{\dot{m}_a c_p}$$

With  $q = \dot{m}_a c_p (T_{a,i} - T_{a,o}) = \dot{m}_a c_p [(T_{a,i} - T_s) - (T_{a,o} - T_s)]$

it follows that

$$q = \bar{h}A_{p,t} \frac{(T_{a,i} - T_s) - (T_{a,o} - T_s)}{\ln[(T_{a,i} - T_s)/(T_{a,o} - T_s)]} = \bar{h}A_{p,t} \Delta T_{lm}$$

where 
$$\Delta T_{lm} = \frac{(T_{a,i} - T_s) - (T_{a,o} - T_s)}{\ln[(T_{a,i} - T_s)/(T_{a,o} - T_s)]}$$

The air outlet temperature may be obtained from the requirement

$$\frac{T_{a,o} - T_s}{T_{a,i} - T_s} = \exp\left(-\frac{\bar{h}A_{p,t}}{\dot{m}_a c_p}\right) = \exp\left(-\frac{108 \text{ W/m}^2 \cdot \text{K} \times 182.2 \text{ m}^2}{1 \text{ kg/s} \times 1010 \text{ J/kg} \cdot \text{K}}\right) = 3.46 \times 10^{-9}$$

$$T_{a,o} = 25^\circ \text{C} + 65^\circ \text{C} (3.46 \times 10^{-9}) = 25^\circ \text{C} + 2.25 \times 10^{-7} \text{ }^\circ \text{C}$$

$$T_{a,o} \approx T_s = 25^\circ \text{C}.$$

Hence 
$$\Delta T_{lm} = \frac{65^\circ \text{C} - 2.25 \times 10^{-7} \text{ }^\circ \text{C}}{\ln(65^\circ \text{C} / 2.25 \times 10^{-7} \text{ }^\circ \text{C})} = 3.34^\circ \text{C}$$

and 
$$q = 108 \text{ W/m}^2 \cdot \text{K} (182.2 \text{ m}^2) 3.34^\circ \text{C} = 65.7 \text{ kW}.$$

**COMMENTS:** (1) The above result may be checked from the requirement that  $q =$

$$\dot{m}_a c_p (T_{a,i} - T_{a,o}) = 1 \text{ kg/s} \times 1010 \text{ J/kg} \cdot \text{K} \times 65^\circ \text{C} = 65.7 \text{ kW}.$$

(2) The heat rate would be *grossly* overpredicted by using a rate equation of the form

$$q = \bar{h}A_{p,t} (T_{a,i} - T_s).$$

(3) The foregoing results are reasonable during the early stages of the heating process; however  $q$  would decrease with increasing time as the temperature of the rock increases. The axial temperature distribution of the rock in the pile would be as shown for different times.

### PROBLEM 7.109

**KNOWN:** Dimensions of a pebble bed nuclear reactor. Dimensions of core and cladding of pellets. Porosity of the reactor and helium properties, inlet temperature, and upstream velocity. Graphite properties. Correlation for convective heat transfer from the spherical pellets in the packed bed.

**FIND:** (a) Mean helium outlet temperature and amount of thermal energy generated per pellet for an overall thermal energy transfer rate of  $q = 125 \text{ MW}$ , (b) Maximum internal temperature of the hottest pellet.

**SCHEMATIC:**

Helium

$V = 3.2 \text{ m/s}$ ,  $T_i = 450^\circ\text{C}$ ,  $P = 40 \text{ bars}$

$c_p = 5193 \text{ J/kg}\cdot\text{K}$ ,  $k = 0.3355 \text{ W/m}\cdot\text{K}$ ,  $\rho = 2.1676 \text{ kg/m}^3$ ,  $\mu = 4.214 \times 10^{-5} \text{ kg/s}\cdot\text{m}$

$Pr = 0.654$

$$\varepsilon \bar{j}_H = 2.876 Re_D^{-1} + 0.3023 Re_D^{-0.35}$$

**ASSUMPTIONS:** (1) Negligible radiation heat transfer, (2) One-dimensional heat transfer, (3) Uniform volumetric thermal generation inside the core, (4) Negligible contact resistance between core and cladding.

**ANALYSIS:**

(a) From the simplified steady-flow thermal energy equation of Chapter 1 we may write

$$q = \dot{m} c_p (T_o - T_i) = \rho A V c_p (T_o - T_i)$$

Thus

$$T_o = T_i + q / \rho A V c_p$$

$$= 450^\circ\text{C} + 125 \times 10^6 \text{ W} / \left( 2.1676 \text{ kg/m}^3 \times \pi \times (0.3 \text{ m}/2)^2 \times 3.2 \text{ m/s} \times 5193 \text{ J/k}\cdot\text{K} \right)$$

$$T_o = 941^\circ\text{C}$$

<

The number of pellets in the chamber is

Continued....

**PROBLEM 7.109 (Cont.)**

$$N = (1 - \varepsilon)(\pi)(D/2)^2 \times L / \left[ \frac{4}{3} \pi \left[ (D_p + 2\delta)/2 \right]^3 \right]$$

$$N = (1 - 0.4) \times (1.5\text{m})^2 \times 10 \text{ m} / \left( \frac{4}{3} \times \left[ (50 \times 10^{-3} \text{ m} + 10 \times 10^{-3} \text{ m})/2 \right]^3 \right)$$

$$N = 375,000$$

The energy generated per pellet is

$$\dot{E}_g = q/N = 125 \times 10^6 \text{ W} / 375,000 = 333 \text{ W}$$

<

(b) The Reynolds number based on the pellet diameter is

$$\text{Re}_D = \frac{\rho V (D_p + 2\delta)}{\mu} = \frac{2.1676 \text{ kg/m}^3 \times 3.2 \text{ m/s} \times (50 \times 10^{-6} \text{ m} + 10 \times 10^{-6} \text{ m})}{4.214 \times 10^{-5} \text{ kg/s} \cdot \text{m}}$$

$$\text{Re}_D = 9876$$

From the problem statement we know

$$\bar{\varepsilon}_{\text{h}} = \varepsilon \frac{\bar{h}}{\rho V c_p} \text{Pr}^{2/3} = \frac{2.876}{\text{Re}_D} + \frac{0.3023}{\text{Re}_D^{0.35}}$$

or

$$\bar{h} = \frac{\rho V c_p}{\varepsilon \text{Pr}^{2/3}} \left[ \frac{2.876}{\text{Re}_D} + \frac{0.3023}{\text{Re}_D^{0.35}} \right]$$

$$\bar{h} = \frac{2.1676 \text{ kg/m}^3 \times 3.2 \text{ m/s} \times 5193 \text{ J/kg} \cdot \text{K}}{0.4 \times (0.654)^{2/3}} \times \left[ \frac{2.876}{9876} + \frac{0.3023}{9876^{0.35}} \right] = 1480 \text{ W/m}^2 \cdot \text{K}$$

A sphere at the exit of the chamber will be adjacent to the highest helium temperature and will be, in turn, the hottest. An energy balance about the single sphere yields

$$q = \bar{h}A(T_s - T_\infty) \quad \text{or} \quad T_s = T_\infty + \frac{q}{\bar{h}A} = T_o + \frac{\dot{E}_g}{\bar{h}\pi(D_p + 2\delta)^2}$$

$$T_s = 941^\circ\text{C} + \frac{333 \text{ W}}{1480 \text{ W/m}^2 \cdot \text{K} \times \pi \times (50 \times 10^{-3} \text{ m} + 10 \times 10^{-3} \text{ m})^2}$$

$$T_s = 960.9^\circ\text{C}$$

The temperature at the inner surface of the cladding may be found using Equation 3.40

$$q_r = \frac{4\pi k(T_{s,1} - T_s)}{\frac{1}{(D_p/2)} - \frac{1}{(D_p/2 + \delta)}}$$

$$T_{s,1} = T_s + q \left[ \frac{1}{(D_p/2)} - \frac{1}{(D_p/2 + \delta)} \right] / 4\pi k$$

Continued....

**PROBLEM 7.109 (Cont.)**

$$T_{s,1} = 960.9^\circ\text{C} + 333 \text{ W} \times \left[ \frac{1}{25 \times 10^{-3} \text{ m}} - \frac{1}{(25 \times 10^{-3} \text{ m} + 5 \times 10^{-3} \text{ m})} \right] / (4\pi \times 2 \text{ W/m} \cdot \text{K})$$

$$T_{s,1} = 1049.2^\circ\text{C}$$

The maximum temperature occurs at the center of the sphere at the exit plane. Beginning with the heat equation for the pellet, find

$$\frac{d}{dr} \left( r^2 \frac{dT}{dr} \right) = - \frac{\dot{q}}{k} r^2$$

$$r^2 \frac{dT}{dr} = - \frac{\dot{q}}{3k} r^3 + C_1$$

$$T(r) = - \frac{\dot{q}}{6k} r^2 - \frac{C_1}{r} + C_2$$

Applying boundary conditions,

$$\text{at } r = 0, \quad dT/dr|_{r=0} = 0 \rightarrow C_1 = 0$$

$$\text{at } r = r_p = D_p/2, \quad T(r_p) = T_{s,1} \rightarrow C_2 = T_{s,1} + \frac{\dot{q}}{6k} r_p^2$$

$$T(r) = T_{s,1} + \frac{\dot{q}}{6k} (r_p^2 - r^2)$$

$$T(0) = T_{s,1} + \frac{\dot{q} D_p^2}{24k}$$

For  $\dot{q} = \dot{E}_g / \nabla = \dot{E}_g / \left[ \frac{4}{3} \pi (D_p/2)^3 \right]$

$$\dot{q} = 333 \text{ W} / \left[ \frac{4}{3} \times \pi \times (50 \times 10^{-3} \text{ m}/2)^3 \right]$$

$$\dot{q} = 5.09 \times 10^6 \text{ W/m}^3$$

$$T(0) = 1049.2^\circ\text{C} + \frac{5.09 \times 10^6 \text{ W/m}^3 \times (50 \times 10^{-3} \text{ m})^2}{24 \times 2 \text{ W/m} \cdot \text{K}} = 1314^\circ\text{C} \quad <$$

**COMMENTS:** (1) The maximum temperature is below the temperature associated with reduction in the thermal energy generation. (2) Helium is an excellent choice for the working fluid due to its high thermal conductivity and extremely small *nuclear cross section* (Helium does not absorb gamma radiation. Therefore the helium that exists the chamber can be fed directly to a turbine as opposed to transferring thermal energy from the helium to a second working fluid.)

## PROBLEM 7.110

**KNOWN:** Diameter and properties of phase-change material. Dimensions of cylindrical vessel and porosity of packed bed. Inlet temperature and velocity of air.

**FIND:** (a) Outlet temperature of air and rate of melting, (b) Effect of inlet velocity and capsule diameter on outlet temperature, (c) Location at which complete melting of PCM is first to occur and subsequent variation of outlet temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible thickness (and thermal resistance) of capsule shell, (2) All capsules are at  $T_{mp}$ , (3) Constant properties, (4) Negligible heat transfer from surroundings to vessel.

**PROPERTIES:** Prescribed, PCM:  $T_{mp} = 4^\circ\text{C}$ ,  $\rho = 1200 \text{ kg/m}^3$ ,  $h_{sf} = 165 \text{ kJ/kg}$ . *Table A-4*, Air (Assume  $(T_i + T_o)/2 = 17^\circ\text{C} = 290\text{K}$ ):  $\rho_a = 1.208 \text{ kg/m}^3$ ,  $c_p = 1007 \text{ J/kg}\cdot\text{K}$ ,  $\nu = 15.00 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.71$ .

**ANALYSIS:** (a) For a packed bed the outlet temperature is given by

$$T_o = T_{mp} - (T_{mp} - T_i) \exp\left(-\frac{\bar{h} A_{p,t}}{\rho_a V A_{c,b} c_p}\right)$$

where  $A_{c,b} = \pi D_v^2 / 4 = \pi (0.40\text{m})^2 / 4 = 0.126\text{m}^2$  and  $A_{p,t} = (1 - \varepsilon)(\nabla_v / \nabla_c)(\pi D_c^2) = (1 - \varepsilon)(1.5 \pi L_v D_v^2 / D_c) = 0.5(1.5 \pi \times 0.4\text{m}^3 / 0.05\text{m}) = 3.02\text{m}^2$ . With  $\text{Re}_D = VD_c / \nu = 1\text{m/s} \times 0.05\text{m} / 15.00 \times 10^{-6} \text{ m}^2/\text{s} = 3333$ , the convection correlation for a packed bed yields

$$\varepsilon \bar{j}_H = \varepsilon \bar{\text{St}} \text{Pr}^{2/3} = \varepsilon \frac{\bar{h}}{\rho_a V c_p} \text{Pr}^{2/3} = 2.06 \text{Re}_D^{-0.575}$$

$$\bar{h} = \frac{2.06 \rho_a V c_p}{\varepsilon \text{Pr}^{2/3} \text{Re}_D^{0.575}} = \frac{2.06 \times 1.208 \text{ kg/m}^3 \times 1\text{m/s} \times 1007 \text{ J/kg}\cdot\text{K}}{0.5(0.71)^{2/3} (3333)^{0.575}} = 59.4 \text{ W/m}^2 \cdot \text{K}$$

Hence, 
$$T_o = 4^\circ\text{C} + (21^\circ\text{C}) \exp\left(-\frac{59.4 \text{ W/m}^2 \cdot \text{K} \times 3.02\text{m}^2}{1.208 \text{ kg/m}^3 \times 1\text{m/s} \times 0.126\text{m}^2 \times 1007 \text{ J/kg}\cdot\text{K}}\right) = 10.5^\circ\text{C} <$$

The rate at which PCM in the vessel changes from the solid to liquid state,  $\dot{M}$  (kg/s), may be obtained from an energy balance that equates the total rate of heat transfer to the capsules to the rate of increase in latent energy of the PCM. That is

$$q = \frac{d}{dt}(M h_{sf}) = h_{sf} \dot{M}$$

Continued ...

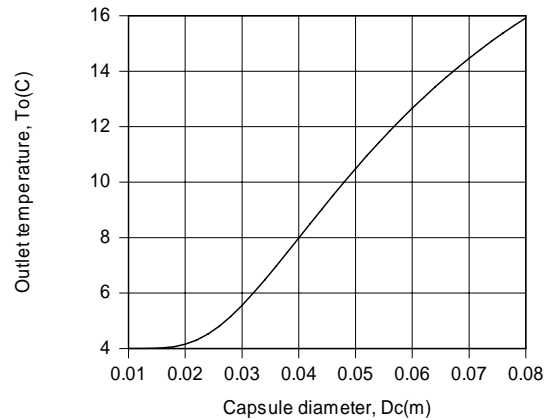

### PROBLEM 7.110 (Cont.)

where  $M$  is the total mass of PCM and

$$q = -\bar{h} A_{p,t} \frac{(T_{mp} - T_i) - (T_{mp} - T_o)}{\ln\left(\frac{T_{mp} - T_i}{T_{mp} - T_o}\right)} = -59.4 \text{ W/m}^2 \cdot \text{K} \times 3.02 \text{ m}^2 \frac{-14.5^\circ\text{C}}{\ln\left(\frac{-21}{-6.5}\right)} = 2220 \text{ W}$$

Hence,  $\dot{M} = q / h_{sf} = 2220 \text{ W} / 165,000 \text{ J/kg} = 0.0134 \text{ kg/s}$  <

(b) The effect of the inlet velocity and capsule diameter are shown below.

Despite the reduction in  $\bar{h}$  with decreasing  $V$ , the reduction in the mass flow rate of air through the vessel and the corresponding increase in the residence time of air in the vessel allow it to more closely achieve thermal equilibrium with the capsules before it leaves the vessel. Hence,  $T_o$  decreases with decreasing  $V$ , approaching  $T_{mp}$  in the limit  $V \rightarrow 0$ . Of course, the production of chilled air in kg/s decreases accordingly. With decreasing capsule diameter, there is an increase in the number of capsules in the vessel and in the total surface area  $A_{p,t}$  for heat transfer from the air. Hence, the heat rate increases with decreasing  $D_c$  and the outlet temperature of the air decreases.

(c) Because the temperature of the air decreases as it moves through the vessel, heat rates to the capsules are largest and smallest at the entrance and exit, respectively, of the vessel. Hence, complete melting will first occur in capsules at the entrance. After complete melting begins to occur in the capsules, progressing downstream with increasing time, heat transfer from the air will increase the temperatures of the capsules, thereby decreasing the heat rate. With decreasing heat rate, the outlet temperature will increase, approaching the inlet temperature after melting has occurred in all capsules and they achieve thermal equilibrium with the inlet air.

**COMMENTS:** (1) The estimate of  $T_o$  used to evaluate the properties of air was good, and iteration of the solution is not necessary. (2) The total mass of phase change material in the vessel is  $M = N_c$

$$\rho \nabla_c = [(1 - \varepsilon) \nabla_v / \nabla_c] \rho \nabla_c = (1 - \varepsilon) \rho L_v \left( \pi D_v^2 / 4 \right) = (\pi / 4) 0.5 \times 1200 \text{ kg/m}^3 (0.4 \text{ m})^3 = 30.2 \text{ kg.}$$

At the maximum possible melting rate of  $\dot{M} = 0.0134 \text{ kg/s}$ , it would therefore take  $2250 \text{ s} = 37.5 \text{ min}$  to melt all of the PCM in the vessel. Why would it, in fact, take longer to melt all of the PCM?

## PROBLEM 7.111

**KNOWN:** Diameter and properties of phase-change material. Dimensions of cylindrical vessel and porosity of packed bed. Inlet temperature and velocity of air.

**FIND:** (a) Outlet temperature of air and rate of melting for  $\varepsilon = 0.3$  and length reduced to compensate, (b) Outlet temperature of air and rate of melting for  $\varepsilon = 0.3$  and diameter reduced to compensate. Which geometry is preferred.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible thickness (and thermal resistance) of capsule shell, (2) All capsules are at  $T_{mp}$ , (3) Constant properties, (4) Negligible heat transfer from surroundings to vessel.

**PROPERTIES:** Prescribed, PCM:  $T_{mp} = 4^\circ\text{C}$ ,  $\rho = 1200 \text{ kg/m}^3$ ,  $h_{sf} = 165 \text{ kJ/kg}$ . *Table A-4*, Air (Assume  $(T_i + T_o)/2 = 17^\circ\text{C} = 290\text{K}$ ):  $\rho_a = 1.208 \text{ kg/m}^3$ ,  $c_p = 1007 \text{ J/kg}\cdot\text{K}$ ,  $\nu = 15.00 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $Pr = 0.71$ .

**ANALYSIS:** (a) The new length of the vessel is determined from the fact that the same mass, or volume, of capsules is now compressed to give a porosity of 0.3 instead of 0.5. We can relate the total capsule volume,  $\forall_c$ , to the vessel volume,  $\forall_v = \pi D_v^2 L_v$ , as follows.

$$\forall_c = (1 - \varepsilon_{old}) \forall_{v,old} = (1 - \varepsilon_{new}) \forall_{v,new} \quad (1)$$

Thus,

$$L_{v,new} = \frac{(1 - \varepsilon_{old})}{(1 - \varepsilon_{new})} L_{v,old} = \frac{0.5}{0.7} 0.4 \text{ m} = 0.286 \text{ m}$$

For a packed bed the outlet temperature is given by

$$T_o = T_{mp} - (T_{mp} - T_i) \exp\left(-\frac{\bar{h} A_{p,t}}{\rho_a \forall A_{c,b} c_p}\right) \quad (2)$$

where  $A_{c,b} = \pi D_v^2 / 4 = \pi (0.40 \text{ m})^2 / 4 = 0.126 \text{ m}^2$  and  $A_{p,t} = (1 - \varepsilon)(\forall_v / \forall_c)(\pi D_c^2) = (1 - \varepsilon)(1.5 \pi L_v D_v^2 / D_c) = 0.7(1.5 \pi \times 0.286 \text{ m} \times 0.4^2 \text{ m}^2 / 0.05 \text{ m}) = 3.02 \text{ m}^2$ . With  $Re_D = VD_c / \nu = 1 \text{ m/s} \times 0.05 \text{ m} / 15.00 \times 10^{-6} \text{ m}^2/\text{s} = 3333$ , the convection correlation for a packed bed yields

Continued ...

**PROBLEM 7.111 (Cont.)**

$$\varepsilon \bar{j}_H = \varepsilon \bar{St} Pr^{2/3} = \varepsilon \frac{\bar{h}}{\rho_a V c_p} Pr^{2/3} = 2.06 Re_D^{-0.575}$$

$$\bar{h} = \frac{2.06 \rho_a V c_p}{\varepsilon Pr^{2/3} Re_D^{0.575}} = \frac{2.06 \times 1.208 \text{ kg/m}^3 \times 1 \text{ m/s} \times 1007 \text{ J/kg} \cdot \text{K}}{0.3(0.71)^{2/3} (3333)^{0.575}} = 99.0 \text{ W/m}^2 \cdot \text{K}$$

Hence,  $T_o = 4^\circ\text{C} + (21^\circ\text{C}) \exp\left(-\frac{99.0 \text{ W/m}^2 \cdot \text{K} \times 3.02 \text{ m}^2}{1.208 \text{ kg/m}^3 \times 1 \text{ m/s} \times 0.126 \text{ m}^2 \times 1007 \text{ J/kg} \cdot \text{K}}\right) = 7.0^\circ\text{C} <$

The rate at which PCM in the vessel changes from the solid to liquid state,  $\dot{M}$  (kg/s), may be obtained from an energy balance that equates the total rate of heat transfer to the capsules to the rate of increase in latent energy of the PCM. That is

$$q = \frac{d}{dt}(M h_{sf}) = h_{sf} \dot{M}$$

where  $M$  is the total mass of PCM and

$$q = -\bar{h} A_{p,t} \frac{(T_{mp} - T_i) - (T_{mp} - T_o)}{\ln\left(\frac{T_{mp} - T_i}{T_{mp} - T_o}\right)} = -99.0 \text{ W/m}^2 \cdot \text{K} \times 3.02 \text{ m}^2 \frac{-18^\circ\text{C}}{\ln\left(\frac{-21}{-3.0}\right)} = 2770 \text{ W}$$

Hence,  $\dot{M} = q / h_{sf} = 2770 \text{ W} / 165,000 \text{ J/kg} = 0.0168 \text{ kg/s} <$

(b) The new vessel diameter is found from Eq. (1) to be

$$D_{v,new} = \sqrt{\frac{(1 - \varepsilon_{old})}{(1 - \varepsilon_{new})}} D_{v,old} = \sqrt{\frac{0.5}{0.7}} 0.4 \text{ m} = 0.338 \text{ m}$$

Since the mass flow rate of air is unchanged, the velocity must be increased to compensate for the reduced diameter, thus

$$V_{new} = V_{old} D_{v,old}^2 / D_{v,new}^2 = 1 \text{ m/s} (0.4 \text{ m} / 0.338 \text{ m})^2 = 1.40 \text{ m/s}$$

Repeating all of the calculations, we find

$$A_{c,b} = \pi D_v^2 / 4 = \pi (0.338 \text{ m})^2 / 4 = 0.0897 \text{ m}^2, \quad A_{p,t} = 3.02 \text{ m}^2 \text{ (unchanged)}, \quad Re_D = 4667,$$

$$\bar{h} = 114 \text{ W/m}^2 \cdot \text{K}, \text{ and}$$

$$T_o = 6.2^\circ\text{C} <$$

Continued ...

### PROBLEM 7.111 (Cont.)

Then  $q = 2870 \text{ W}$  and

$$\dot{M} = 0.0173 \text{ kg/s} \quad <$$

This configuration results in a lower air outlet temperature and an increased PCM melting rate. <

**COMMENTS:** (1) The estimate of  $T_o$  used to evaluate the properties of air was reasonably good, and iteration of the solution is not necessary. (2) Compared to Problem 7.110 which had  $\varepsilon = 0.5$ , both of these configurations yield a higher heat transfer coefficient and result in a lower outlet temperature and are therefore preferable from the heat transfer point-of-view. However, a more thorough design would also consider the pressure drop and pumping power requirements for the various configurations. Which configuration do you expect to have the lowest pumping power requirement? (3) By reducing the vessel diameter in part (b), the velocity and Reynolds number increase, thereby increasing the heat transfer coefficient. This yields a lower outlet temperature compared to part (a).

## PROBLEM 7.112

**KNOWN:** Diameter and properties of phase-change material. Dimensions of cylindrical vessel and porosity of packed bed. Inlet temperature and velocity of air.

**FIND:** (a) Outlet temperature of air and rate of freezing, (b) Effect of inlet velocity and capsule diameter on outlet temperature, (c) Location at which complete melting of PCM is first to occur and subsequent variation of outlet temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible thickness (and thermal resistance) of capsule shell, (2) All capsules are at  $T_{mp}$ , (3) Constant properties, (4) Negligible heat transfer from vessel to surroundings.

**PROPERTIES:** Prescribed, PCM:  $T_{mp} = 50^\circ\text{C}$ ,  $\rho = 900 \text{ kg/m}^3$ ,  $h_{sf} = 200 \text{ kJ/kg}$ . *Table A-4*, Air (Assume  $(T_i + T_o)/2 = 30^\circ\text{C} = 303\text{K}$ ):  $\rho_a = 1.151 \text{ kg/m}^3$ ,  $c_p = 1007 \text{ J/kg}\cdot\text{K}$ ,  $\nu = 16.2 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.707$ .

**ANALYSIS:** (a) For a packed bed the outlet temperature is given by

$$T_o = T_{mp} - (T_{mp} - T_i) \exp\left(-\frac{\bar{h} A_{p,t}}{\rho_a V A_{c,b} c_p}\right)$$

where  $A_{c,b} = \pi D_v^2 / 4 = 0.126 \text{ m}^2$  and  $A_{p,t} = (1 - \varepsilon)(\nabla_v / \nabla_c) \pi D_c^2 = 3.02 \text{ m}^2$ . With  $\text{Re}_D = VD_c / \nu = 3086$ , the convection correlation for a packed bed yields

$$\varepsilon \bar{h} = \varepsilon \bar{\text{St}} \text{Pr}^{2/3} = \varepsilon \frac{\bar{h}}{\rho_a V c_p} \text{Pr}^{2/3} = 2.06 \text{Re}_D^{-0.575}$$

$$\bar{h} = \frac{2.06 \rho_a V c_p}{\varepsilon \text{Pr}^{2/3} \text{Re}_D^{0.575}} = \frac{2.06 \times 1.151 \text{ kg/m}^3 \times 1 \text{ m/s} \times 1007 \text{ J/kg}\cdot\text{K}}{0.5 (0.707)^{2/3} (3086)^{0.575}} = 59.1 \text{ W/m}^2 \cdot \text{K}$$

Hence,

$$T_o = 50^\circ\text{C} - (30^\circ\text{C}) \exp\left(-\frac{59.1 \text{ W/m}^2 \cdot \text{K} \times 3.02 \text{ m}^2}{1.151 \text{ kg/m}^3 \times 1 \text{ m/s} \times 0.126 \text{ m}^2 \times 1007 \text{ J/kg}\cdot\text{K}}\right) = 41.2^\circ\text{C} <$$

The rate at which PCM in the vessel solidifies,  $\dot{M}$  (kg/s), may be obtained from an energy balance that equates the total rate of heat transfer from the capsules to the rate at which the latent energy of the PCM decreases. That is,

$$q = \frac{d}{dt}(M h_{s,f}) = h_{sf} \dot{M}$$

where  $M$  is the total mass of PCM and

Continued ...

**PROBLEM 7.112 (Cont.)**

$$q = \bar{h} A_{p,t} \frac{(T_{mp} - T_i) - (T_{mp} - T_o)}{\ln\left(\frac{T_{mp} - T_i}{T_{mp} - T_o}\right)} = 59.1 \text{ W/m}^2 \cdot \text{K} \times 3.02 \text{ m}^2 \frac{21.2^\circ\text{C}}{\ln\left(\frac{30}{8.8}\right)} = 3085 \text{ W}$$

Hence,  $\dot{M} = q / h_{sf} = 3085 \text{ W} / 200,000 \text{ J/kg} = 0.0154 \text{ kg/s}$

<

(b) The effect of  $V$  and  $D_c$  are shown below

Despite the reduction in  $\bar{h}$  with decreasing  $V$ , the reduction in the mass flow rate of air in the vessel and the corresponding increase in the residence time of air in the vessel allow it to more closely reach thermal equilibrium with the capsules before it leaves the vessel. Hence,  $T_o$  increases with decreasing  $V$ , approaching  $T_{mp}$  in the limit  $V \rightarrow 0$ . Of course, the production of warm air in kg/s decreases accordingly. With decreasing capsule diameter, there is an increase in the number of capsules in the vessel and in the total surface area  $A_{p,t}$  for heat transfer to the air. Hence, the heat rate and the air outlet temperature increase with decreasing  $D_c$ .

(c) Because the air temperature increases as it moves through the vessel, heat rates from the capsules are largest and smallest at the entrance and exit, respectively, of the vessel. Hence, complete freezing will first occur in capsules at the entrance. After complete freezing begins to occur in the capsules, progressing downstream with increasing time, heat transfer to the air will decrease the temperatures of the capsules, thereby decreasing the heat rate. With decreasing heat rate, the outlet temperature will decrease, approaching the inlet temperature after freezing has occurred in all capsules and they achieve thermal equilibrium with the inlet air.

**COMMENTS:** (1) The estimate of  $T_o$  used to evaluate the properties of air was good, and iteration of the solution is not necessary. (2) The total mass of phase change material in the vessel is  $M = N_c \rho \forall_c = [(1 - \varepsilon) \forall_v / \forall_c] \rho \forall_c = (1 - \varepsilon) \rho L_v \left( \pi D_v^2 / 4 \right) = 22.6 \text{ kg}$ . At the maximum possible melting rate of  $\dot{M} = 0.0154 \text{ kg/s}$ , it would therefore take  $1470 \text{ s} = 24.5 \text{ min}$  to freeze all of the PCM in the vessel. Why would it, in fact, take longer to freeze all of the PCM?

### PROBLEM 7.113

**KNOWN:** Dimensions, particle diameter, and porosity of bronze foam sheet. Temperature of upper and lower surfaces of foam. Velocity and inlet temperature of air flowing through foam.

**FIND:** (a) Convection heat transfer rate to air assuming foam is at uniform temperature  $T_s$ . Whether actual heat transfer rate would be greater, less, or the same. (b) Convection heat transfer rate to air treating foam as an extended surface with one-dimensional conduction in the  $x$ -direction. Whether actual heat transfer rate would be greater, less, or the same. Effective perimeter and effective thermal conductivity of the foam.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) One-dimensional heat transfer, (3) Constant properties, (4) Foam behaves as packed bed in part (a), (5) Foam behaves as extended surface in part (b), (6) Negligible radiation transfer.

**PROPERTIES:** Table A-1, Commercial bronze ( $T \approx 325$  K):  $k_b = 52$  W/m·K. Table A-4, Air ( $T \approx 325$  K):  $\rho = 1.0782$  kg/m<sup>3</sup>,  $c_p = 1008$  J/kg·K,  $k = 0.0282$  W/m·K,  $\nu = 18.41 \times 10^{-6}$  m<sup>2</sup>/s,  $Pr = 0.704$ .

**ANALYSIS:** (a) The heat transfer coefficient can be found from Equation 7.81:

$$\varepsilon \bar{j}_H = \varepsilon \frac{\bar{h}}{\rho c_p V} Pr^{2/3} = 2.06 Re_D^{-0.575}$$

where  $Re_D = VD/\nu = 10 \text{ m/s} \times 0.0006 \text{ m} / 18.41 \times 10^{-6} \text{ m}^2/\text{s} = 326$

$$\begin{aligned} \bar{h} &= \frac{2.06 \rho c_p V}{\varepsilon} Re_D^{-0.575} Pr^{-2/3} \\ &= \frac{2.06 \times 1.0782 \text{ kg/m}^3 \times 1008 \text{ J/kg} \cdot \text{K} \times 10 \text{ m/s}}{0.25} (326)^{-0.575} (0.704)^{-2/3} = 4060 \text{ W/m}^2 \cdot \text{K} \end{aligned}$$

The surface area can be found as follows, where  $N$  = number of particles:

$$\begin{aligned} V_p &= N\pi D^3/6 = (1 - \varepsilon)V_{\text{tot}} = (1 - \varepsilon)WtL \text{ and} \\ A_{p,t} &= N\pi D^2 = 6(1 - \varepsilon)WtL/D = \frac{6 \times 0.75 \times 0.04 \text{ m} \times 0.01 \text{ m} \times 0.04 \text{ m}}{0.0006 \text{ m}} = 0.12 \text{ m}^2 \end{aligned}$$

The outlet air temperature is given by Equation 7.83:

$$T_o = T_s - (T_s - T_i) \exp\left(\frac{-\bar{h}A_{p,t}}{\rho V A_{c,b} c_p}\right)$$

Continued...

**PROBLEM 7.113 (Cont.)**

$$= 80^{\circ}\text{C} - 60^{\circ}\text{C} \exp\left(\frac{-4060 \text{ W/m}^2 \cdot \text{K} \times 0.12 \text{ m}^2}{1.0782 \text{ kg/m}^3 \times 10 \text{ m/s} \times (0.04 \text{ m})^2 \times 1008 \text{ J/kg} \cdot \text{K}}\right) = 80^{\circ}\text{C}$$

From Equation 7.82, or equivalently from an energy balance on the air,

$$q = \dot{m}c_p(T_o - T_i) = \rho VA_{c,b}c_p(T_o - T_i) \\ = 1.0782 \text{ kg/m}^3 \times 10 \text{ m/s} \times (0.04 \text{ m})^2 \times 1008 \text{ J/kg} \cdot \text{K} \times (80 - 20)^{\circ}\text{C} = 1043 \text{ W} \quad <$$

We would expect the actual convection heat transfer rate to be less because the foam has a conduction resistance and there are temperature gradients in the foam, primarily in the  $x$ -direction. Thus, near the center of the cross-section, the foam temperature will be reduced and so will the heat transfer rate.

(b) For a slice of the foam of length  $dx$ , the surface area of foam in contact with the air is  $dA_s = A_{p,t}dx/L$ . Thus,

$$dq_{\text{conv}} = \frac{\bar{h}A_{p,t}dx}{L}(T(x) - T_{\infty})$$

By analogy with  $dq_{\text{conv}} = hPdx(T(x) - T_{\infty})$  for a solid fin, we find

$$P_{\text{eff}} = \frac{A_{p,t}}{L} = \frac{0.12 \text{ m}^2}{0.04 \text{ m}} = 3.0 \text{ m} \quad <$$

From Equation 3.25 with  $k_s = k_b$ ,

$$k_{\text{eff}} = \left[ \frac{k_f + 2k_b - 2\varepsilon(k_b - k_f)}{k_f + 2k_b + \varepsilon(k_b - k_f)} \right] k_b \\ = \left[ \frac{(0.0282 + 2 \times 52 - 2 \times 0.25 \times (52 - 0.0282)) \text{ W/m} \cdot \text{K}}{(0.0282 + 2 \times 52 + 0.25 \times (52 - 0.0282)) \text{ W/m} \cdot \text{K}} \right] \times 52 \text{ W/m} \cdot \text{K} = 34.7 \text{ W/m} \cdot \text{K} \quad <$$

Due to symmetry, the foam sheet can be treated as a fin of length  $L/2$  with an insulated fin tip. From Equation 3.81,

$$q_f = 2\sqrt{\bar{h}P_{\text{eff}}k_{\text{eff}}A_{c,f}}(T_s - T_i) \tanh(mL/2)$$

where the factor of 2 accounts for both halves of the foam, each of length  $L/2$ ,  $A_{c,f}$  is the fin cross-sectional area,  $A_{c,f} = Wt = 0.04 \text{ m} \times 0.01 \text{ m} = 4 \times 10^{-4} \text{ m}^2$ , and

$$m = \sqrt{\bar{h}P_{\text{eff}}/k_{\text{eff}}A_{c,f}} = \sqrt{4060 \text{ W/m}^2 \cdot \text{K} \times 3 \text{ m}/(34.7 \text{ W/m} \cdot \text{K} \times 4 \times 10^{-4} \text{ m}^2)} = 937 \text{ m}^{-1}$$

Continued...

### PROBLEM 7.113 (Cont.)

Thus,

$$\begin{aligned}q_f &= 2\sqrt{4060 \text{ W/m}^2 \cdot \text{K} \times 3 \text{ m} \times 34.7 \text{ W/m} \cdot \text{K} \times 4 \times 10^{-4} \text{ m}^2 (80 - 20)^\circ\text{C} \tanh(933 \text{ m}^{-1} \times 0.02 \text{ m})} \\ &= 1560 \text{ W} \end{aligned} \quad <$$

We would expect the actual rate of heat transfer to be less because the air temperature increases as it flows through the foam. This is not accounted for in the extended surface analysis, and if it were to be accounted for, we would have a smaller driving overall temperature difference through most of the foam, reducing  $q_f$ . <

**COMMENTS:** (1) The results *suggest* that the foam might be an effective heat transfer medium. The heat transfer rates are quite high. However, the actual heat transfer rate will be lower than calculated here because of the *simultaneous* conduction resistance in the foam *and* increase in the air temperature as it passes through the foam. (2) In Problem 11.93, this problem is solved accounting for both the variation of air temperature in the flow direction and the variation of foam temperature in the  $x$ -direction. By accounting for both effects, you will learn that the heat transfer rates calculated here significantly overestimate the actual heat transfer rate.

### PROBLEM 7.114

**KNOWN:** Flow of air over a flat, smooth wet plate.

**FIND:** (a) Average mass transfer coefficient,  $\bar{h}_m$ , (b) Water vapor mass loss rate,  $n_A$  (kg/s).

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Heat-mass transfer analogy applies, (3)  $Re_{x,c} = 5 \times 10^5$ .

**PROPERTIES:** Table A-4, Air (300K):  $\nu = 15.89 \times 10^{-6}\text{ m}^2/\text{s}$ ,  $Pr = 0.707$ ; Table A-8, Water vapor-air (300K, 1 atm):  $D_{AB} = 0.26 \times 10^{-4}\text{ m}^2/\text{s}$ ,  $Sc = \nu/D_{AB} = 0.611$ ; Table A-6, Water vapor (300K):  $\rho_{A,sat} = 1/v_g = 0.0256\text{ kg/m}^3$ .

**ANALYSIS:** (a) The Reynolds number for the plate,  $x = L$ , is

$$Re_L = \frac{u_\infty L}{\nu} = \frac{35\text{ m/s} \times 0.5\text{ m}}{15.89 \times 10^{-6}\text{ m}^2/\text{s}} = 1.10 \times 10^6.$$

Hence flow is mixed and the appropriate flat plate convection correlation is given by Eq. 7.41,

$$\overline{Sh}_L = \frac{\bar{h}_m L}{D_{AB}} = (0.037 Re_L^{4/5} - 871) Sc^{1/3} = \left( 0.037 [1.10 \times 10^6]^{0.8} - 871 \right) 0.611^{0.33}$$

giving

$$\overline{Sh}_L = 1399 \quad \bar{h}_m = \frac{1399 \times 0.26 \times 10^{-4}\text{ m}^2/\text{s}}{0.5\text{ m}} = 0.0728\text{ m/s}. \quad <$$

(b) The evaporative mass loss rate is

$$n_A = \bar{h}_m A_s (\rho_{A,s} - \rho_{A,\infty})$$

where  $A_s = L \cdot w$ ,  $\rho_{A,\infty} = 0$  (dry air) and  $\rho_{A,s} = \rho_{A,sat}$ . Hence,

$$n_A = 0.0728\text{ m/s} \times (0.5 \times 3)\text{ m}^2 (0.0256 - 0)\text{ kg/m}^3 = 0.0028\text{ kg/s}. \quad <$$

## PROBLEM 7.115

**KNOWN:** Air flow conditions over a wetted flat plate of known length and temperature.

**FIND:** (a) Heat loss and evaporation rate, per unit plate width,  $q'$  and  $n'_A$ , respectively, (b) Compute and plot  $q'$  and  $n'_A$  for a range of water temperatures  $300 \leq T_s \leq 350$  K with air velocities of 10, 20 and 35 m/s, and (c) Water temperature  $T_s$  at which the heat loss will be zero for the air velocities and temperatures of part (b).

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Heat and mass transfer analogy is applicable, (2) Constant properties, (3)  $Re_{x,c} = 5 \times 10^5$ .

**PROPERTIES:** Table A.4, Air ( $T = 300$  K, 1 atm):  $\nu = 15.89 \times 10^{-6} \text{ m}^2/\text{s}$ ; Table A.6, Water (300 K):  $v_g = 39.13 \text{ m}^3/\text{kg}$ ,  $h_{fg} = 2438 \text{ kJ/kg}$ ; Table A.8, Water-air (298 K, 1 atm):  $D_{AB} = 0.26 \times 10^{-4} \text{ m}^2/\text{s}$ ,  $Sc = 0.61$ .

**ANALYSIS:** (a) The heat loss from the plate is due only to the transfer of latent heat. Per unit width of the plate,

$$q' = n'_A h_{fg} \quad (1)$$

$$n'_A = \bar{h}_m L [\rho_{A,\text{sat}}(T_s) - \rho_{A,\infty}] = \bar{h}_m L \rho_{A,\text{sat}}(T_s) \quad (2)$$

With

$$Re_L = \frac{u_\infty L}{\nu} = \frac{35 \text{ m/s} \times 0.5 \text{ m}}{15.89 \times 10^{-6} \text{ m}^2/\text{s}} = 1.10 \times 10^6$$

mixed boundary layer condition exists and the appropriate correlation is Eq. 7.41 with  $A = 871$ ,

$$\bar{Sh}_L = (0.037 Re_L^{4/5} - 871) Sc^{1/3} = \left[ 0.037 (1.10 \times 10^6)^{4/5} - 871 \right] (0.61)^{1/3} \quad (3)$$

giving  $\bar{Sh}_L = 1398$  and

$$\bar{h}_m = \bar{Sh}_L \frac{D_{AB}}{L} = 1398 \frac{0.26 \times 10^{-4} \text{ m}^2/\text{s}}{0.5 \text{ m}} = 0.0727 \text{ m/s}.$$

with  $\rho_{A,\text{sat}}(T_s) = v_g^{-1} = 0.0256 \text{ kg/m}^3$ ,

$$n'_A = 0.0727 \text{ m/s} (0.5 \text{ m}) (0.0256 \text{ kg/m}^3) = 9.29 \times 10^{-4} \text{ kg/s} \cdot \text{m} \quad <$$

Hence, the evaporative heat loss per unit plate width is

$$q' = n'_A h_{fg} = 9.29 \times 10^{-4} \text{ kg/s} \cdot \text{m} (2.438 \times 10^6 \text{ J/kg}) = 2265 \text{ W/m} \quad <$$

Continued...

### PROBLEM 7.115 (Cont.)

Heat would have to be applied to the plate in the amount of 2265 W/m to maintain its temperature at 300 K with the evaporative heat loss.

(b) When  $T_s$  and  $T_\infty$  are different, convection heat transfer will also occur, and the heat loss from the water surface is

$$q'_{\text{loss}} = q'_{\text{conv}} + q'_{\text{evap}} = \bar{h}L(T_s - T_\infty) + n'_A h_{fg} \quad (4)$$

Invoking the heat-mass analogy, Eq. 6.60 with  $n = 1/3$ ,

$$\bar{h}/\bar{h}_m = \rho c (\alpha/D_{AB})^{2/3} \quad (5)$$

where  $\bar{h}_m$  and  $n'_A$  are evaluated using Eqs. (3) and (2), respectively. Using the foregoing relations in the *IHT Workspace*, but evaluating  $\bar{h}$  (rather than  $\bar{h}_m$ ) with the *Correlations Tool, External Flow*, for the *Average coefficient for Laminar or Mixed Flow*,  $q'_{\text{loss}}$  was evaluated as a function of  $u_\infty$  with  $T_\infty = 300$  K.

(c) To determine the water temperature  $T_s$  at which the heat loss is zero, the foregoing IHT model was run with  $q'_{\text{loss}} = 0$  with the result that, for all velocities,

$$T_s = 281 \text{ K}$$

<

**COMMENTS:** Why is the result for part (c) independent of the air velocity?

## PROBLEM 7.116

**KNOWN:** Flow over a heated flat plate coated with a volatile substance.

**FIND:** Electric power required to maintain surface at  $T_s = 134^\circ\text{C}$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Heat-mass transfer analogy is applicable, (3) Transition occurs at  $Re_{xc} = 5 \times 10^5$ , (4) Perfect gas behavior of vapor A, (5) Upstream air is dry,  $\rho_{A,\infty} = 0$ .

**PROPERTIES:** Table A-4, Air ( $T_f = (134 + 20)^\circ\text{C}/2 = 350\text{ K}$ , 1 atm):  $\nu = 20.92 \times 10^{-6}\text{ m}^2/\text{s}$ ,  $k = 0.030\text{ W/m}\cdot\text{K}$ ,  $Pr = 0.700$ ; Substance A (given):  $M_A = 150\text{ kg/kmol}$ ,  $p_{A,\text{sat}}(134^\circ\text{C}) = 0.12\text{ atm}$ ,  $D_{AB} = 7.75 \times 10^{-7}\text{ m}^2/\text{s}$ ,  $h_{fg} = 5.44 \times 10^6\text{ J/kg}$ .

**ANALYSIS:** From an overall energy balance on the plate, the power required to maintain  $T_s$  is

$$q_{\text{elec}} = q_{\text{conv}} + q_{\text{evap}} = \bar{h}_L A_s (T_s - T_\infty) + \bar{h}_{m,L} A_s (\rho_{A,s} - \rho_{A,\infty}) h_{fg}. \quad (1)$$

To estimate  $\bar{h}_L$ , first determine  $Re_L$ ,

$$Re_L = u_\infty L / \nu = 8\text{ m/s} \times 4\text{ m} / 20.92 \times 10^{-6}\text{ m}^2/\text{s} = 1.530 \times 10^6.$$

Hence the flow is mixed and the appropriate correlation:

$$\bar{Nu}_L = \bar{h}_L L / k = \left( 0.037 Re_L^{4/5} - 871 \right) Pr^{1/3}$$

$$\bar{h}_L = (0.030\text{ W/m}\cdot\text{K}/4\text{ m}) \left( 0.037 (1.530 \times 10^6)^{4/5} - 871 \right) (0.700)^{1/3} = 16.0\text{ W/m}^2 \cdot \text{K}.$$

To estimate  $\bar{h}_{m,L}$ , invoke the heat-mass analogy, with  $Sc = \nu_B / D_{AB}$ ,

$$\bar{h}_{m,L} = \bar{h}_L \frac{D_{AB}}{k} \left( \frac{Sc}{Pr} \right)^{1/3} = 16.0 \frac{\text{W}}{\text{m}^2 \cdot \text{K}} \left( \frac{7.75 \times 10^{-7}\text{ m}^2/\text{s}}{0.030\text{ W/m}\cdot\text{K}} \right) \left( \frac{20.92 \times 10^{-6}\text{ m}^2/\text{s}}{7.75 \times 10^{-7}\text{ m}^2/\text{s}} / 0.700 \right)^{1/3} = 0.00140 \frac{\text{m}}{\text{s}}.$$

The density of species A at the surface,  $\rho_{A,s}(T_s)$ , follows from the perfect gas law,

$$\rho_{A,s} = p_{A,s} / \frac{\mathcal{R}}{M_A} T_s = 0.12\text{ atm} / \frac{8.205 \times 10^{-2}\text{ m}^3 \cdot \text{atm/kmol} \cdot \text{K}}{150\text{ kg/kmol}} \cdot (134 + 273)\text{ K} = 0.539 \frac{\text{kg}}{\text{m}^3}.$$

Using values calculated for  $\bar{h}_L$ ,  $\bar{h}_{m,L}$  and  $\rho_{A,s}$  in Eq. (1), find

$$q_{\text{elec}} = (4\text{ m} \times 0.25\text{ m}) \left[ 16.0 \frac{\text{W}}{\text{m}^2 \cdot \text{K}} (134 - 20)^\circ\text{C} + 0.00140 \frac{\text{m}}{\text{s}} (0.539 - 0) \frac{\text{kg}}{\text{m}^3} \times 5.44 \times 10^6 \frac{\text{J}}{\text{kg}} \right]$$

$$q_{\text{elec}} = 1.0\text{ m}^2 [1,824 + 4,105]\text{ W/m}^2 = 5.93\text{ kW}. \quad <$$

**COMMENTS:** For these conditions, nearly 70% of the heat loss is by evaporation.

## PROBLEM 7.117

**KNOWN:** Flow of dry air over a water-saturated plate for prescribed flow conditions and mixed temperature.

**FIND:** (a) Mass rate of evaporation per unit plate width,  $n'_A$  ( $\text{kg}/\text{s} \cdot \text{m}$ ), and (b) Calculate and plot  $n'_A$  as a function of velocity for the range  $1 \leq u_\infty \leq 25$  m/s for air and water temperatures of  $T_s = T_\infty = 300$ , 325, and 350 K.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Water surface is smooth, (2) Heat and mass transfer analogy is applicable, (3)  $Re_{x,c} = 5 \times 10^5$ .

**PROPERTIES:** Table A.6, Water vapor ( $T_s = 350 \text{ K}, 1 \text{ atm}$ ):  $\rho_{A,s} = 1/v_g = 1/3.846 \text{ m}^3/\text{kg} = 0.2600 \text{ kg}/\text{m}^3$ ; Table A.4, Air ( $T_f = T_\infty = 350 \text{ K}, 1 \text{ atm}$ ):  $\nu = 20.92 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\alpha = 29.9 \times 10^{-6} \text{ m}^2/\text{s}$ ; Table A.8, Air-water ( $T_f = T_\infty = 350 \text{ K}, 1 \text{ atm}$ ):  $D_{AB} = 0.26 \times 10^{-4} \text{ m}^2/\text{s}$  ( $350 \text{ K}/298 \text{ K}$ )<sup>3/2</sup> =  $0.331 \times 10^{-4} \text{ m}^2/\text{s}$ .

**ANALYSIS:** (a) Determine the nature of the air flow by calculating  $Re_L$ . With  $L = 1 \text{ m}$ ,

$$Re_L = \frac{u_\infty L}{\nu} = \frac{25 \text{ m/s} \times 1 \text{ m}}{20.92 \times 10^{-6} \text{ m}^2/\text{s}} = 1.195 \times 10^6. \quad (1)$$

Since  $Re_L > 5 \times 10^5$ , it follows that the flow is mixed, and with Eq. 7.41 with  $A = 871$ , using  $Sc = \nu/D_{AB}$ ,

$$\overline{Sh}_L = \frac{\bar{h}_m L}{D_{AB}} = \left( 0.037 Re_L^{4/5} - 871 \right) Sc^{1/3}. \quad (2)$$

$$\overline{Sh}_L = \left( 0.037 \left[ 1.195 \times 10^6 \right]^{4/5} - 871 \right) \left( \frac{20.92 \times 10^{-6} \text{ m}^2/\text{s}}{0.331 \times 10^{-4} \text{ m}^2/\text{s}} \right)^{1/3} = 1563$$

The average mass transfer coefficient for the entire plate is

$$\bar{h}_m = \overline{Sh}_L \frac{D_{AB}}{L} = 1563 \frac{0.331 \times 10^{-4} \text{ m}^2/\text{s}}{1 \text{ m}} = 0.0517 \text{ m/s}.$$

The mass rate of water evaporation per unit plate width is

$$n'_A = \bar{h}_m L (\rho_{A,s} - \rho_{A,\infty}) = 0.0517 \text{ m/s} \times 1 \text{ m} (0.260 - 0) \text{ kg}/\text{m}^3 = 0.0135 \text{ kg}/\text{s} \cdot \text{m} \quad <$$

(b) Using Eq. (1) and (3) in the IHT Workspace with the *Correlations Tool, External Flow, Flat Plate, Average coefficient for Laminar or Mixed Flow*, replacing heat transfer with mass transfer parameters, the evaporation rate as a function of a velocity for selected air-water velocities was calculated and is plotted below.

Continued...

### PROBLEM 7.117 (Cont.)

**COMMENTS:** (1) Note carefully the use of the heat-mass transfer analogy, recognizing that air is species B.

(2) How do you explain the abrupt slope changes in the evaporation rate as a function of velocity in the above plot?

## PROBLEM 7.118

**KNOWN:** Temperature of water bath used to dissipate heat from 100 integrated circuits. Air flow conditions.

**FIND:** Heat dissipation per circuit.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Heat and mass transfer analogy is applicable, (2) Vapor may be approximated as a perfect gas, (3) Turbulent boundary layer over entire surface, (4) All heat loss is across air-water interface.

**PROPERTIES:** Table A-4, Air (325 K, 1 atm):  $\nu = 18.4 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0282 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.704$ ; Table A-8, Air-vapor (325 K, 1 atm):  $D_{AB} = 0.26 \times 10^{-4} \text{ m}^2/\text{s}$ ; Table A-6, Saturated water vapor ( $T_b = 350 \text{ K}$ ):  $\rho_g = 0.260 \text{ kg/m}^3$ ,  $h_{fg} = 2.32 \times 10^6 \text{ J/kg}$ ; ( $T_\infty = 300 \text{ K}$ ):  $\rho_g = 0.026 \text{ kg/m}^3$ .

**ANALYSIS:** The heat rate is

$$q_1 = \frac{q}{N} = \frac{L^2}{N} \left[ q'' + n''_A h_{fg} (T_b) \right].$$

Evaluate the heat and mass transfer convection coefficients with

$$\text{Re}_L = \frac{u_\infty L}{\nu} = \frac{10 \text{ m/s} \times 0.1 \text{ m}}{18.4 \times 10^{-6} \text{ m}^2/\text{s}} = 54,348$$

$$\bar{h} = (k/L) 0.037 \text{Re}_L^{4/5} \text{Pr}^{1/3} = (0.0282 \text{ W/m}\cdot\text{K}/0.1 \text{ m}) 0.037 (54,348)^{4/5} (0.704)^{1/3} = 57 \text{ W/m}^2 \cdot \text{K}$$

$$\bar{h}_m = (D_{AB}/L) 0.037 \text{Re}_L^{4/5} \text{Sc}^{1/3} = (0.296 \times 10^{-4} \text{ m}^2/\text{s}/0.1 \text{ m}) 0.037 (54,348)^{4/5} (0.622)^{1/3} = 0.0574 \text{ m/s}.$$

The convection heat transfer rate is

$$q'' = \bar{h} (T_b - T_\infty) = 57 \text{ W/m}^2 \cdot \text{K} (350 - 300) \text{ K} = 2850 \text{ W/m}^2$$

and the evaporative cooling rate is

$$n''_A h_{fg} = \bar{h}_m \left[ \rho_{A,\text{sat}} (T_b) - \phi_\infty \rho_{A,\text{sat}} (T_\infty) \right] h_{fg} (T_b)$$

$$n''_A h_{fg} = 0.0574 \text{ m/s} [0.260 - 0.5 \times 0.026] \text{ kg/m}^3 \times 2.32 \times 10^6 \text{ J/kg} = 32,890 \text{ W/m}^2$$

Hence

$$q_1 = \frac{(0.1 \text{ m})^2}{100} (2850 + 32,890) \text{ W/m}^2 = 3.57 \text{ W}.$$

<

**COMMENTS:** Heat loss due to evaporative cooling is approximately an order of magnitude larger than that due to the convection of sensible energy.

## PROBLEM 7.119

**KNOWN:** Dry air flows at 300 K over water-filled trays, each 222 mm long, with velocity of 15 m/s while radiant heaters maintain the surface temperature at 330 K.

**FIND:** (a) Evaporative flux ( $\text{kg/s}\cdot\text{m}^2$ ) at a distance 1 m from leading edge, (b) Radiant flux at this distance required to maintain water temperature at 330 K, (c) Evaporation rate from the tray at location  $L = 1 \text{ m}$ ,  $\dot{n}'_A$  ( $\text{kg/s}\cdot\text{m}$ ) and (d) Irradiation which should be applied to each of the first four trays such that their rates are identical to that found in part (c).

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Heat-mass transfer analogy applicable, (3) Water vapor behaves as perfect gas, (4) All incident radiant power absorbed by water, (5) Critical Reynolds number is  $5 \times 10^5$ .

**PROPERTIES:** Table A.4, Air ( $T_f = 315 \text{ K}$ , 1 atm):  $\nu = 17.40 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0274 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.705$ ; Table A.8, Water vapor-air ( $T_f = 315 \text{ K}$ ):  $D_{AB} = 0.26 \times 10^{-4} \text{ m}^2/\text{s}$  ( $315/298$ )<sup>3/2</sup> =  $0.28 \times 10^{-4} \text{ m}^2/\text{s}$ ,  $\text{Sc} = \nu/D_{AB} = 0.616$ ; Table A.6, Saturated water vapor ( $T_s = 330 \text{ K}$ ):  $\rho_{A,\text{sat}} = 1/\nu_g = 0.1134 \text{ kg/m}^3$ ,  $h_{fg} = 2366 \text{ kJ/kg}$ .

**ANALYSIS:** (a) The evaporative flux of water vapor (A) at location  $x$  is

$$\dot{n}'_{A,x} = h_{m,x} (\rho_{A,s} - \rho_{A,\infty}) = h_{m,x} [\rho_{A,\text{sat}}(T_s) - \phi_\infty \rho_{A,\text{sat}}(T_\infty)] \quad (1)$$

Evaluate  $\text{Re}_x$  to determine the nature of the flow and then select the proper correlation.

$$\text{Re}_x = \frac{u_\infty x}{\nu} = 15 \text{ m/s} \times 1 \text{ m} / 17.40 \times 10^{-6} \text{ m}^2/\text{s} = 8.621 \times 10^5.$$

Hence, the flow is turbulent, and invoking the heat-mass analogy with Eq. 7.37,

$$\text{Sh}_x = \frac{h_{m,x}}{D_{AB}} = 0.0296 \text{Re}_x^{4/5} \text{Sc}^{1/3}$$

$$h_m = \frac{0.28 \times 10^{-4} \text{ m}^2/\text{s}}{1 \text{ m}} \times 0.0296 (8.621 \times 10^5)^{4/5} (0.616)^{1/3} = 3.952 \times 10^{-2} \text{ m/s}.$$

Hence, the evaporative flux at  $x = 1 \text{ m}$  is

$$\dot{n}'_{A,x} = 3.952 \times 10^{-2} \text{ m/s} (0.1134 \text{ kg/m}^3 - 0) = 4.48 \times 10^{-3} \text{ kg/s}\cdot\text{m}^2 \quad (2) <$$

(b) From an energy balance on the differential element at  $x = 1 \text{ m}$ ,

$$q''_{\text{rad}} = q''_{\text{conv}} + q''_{\text{evap}} = h_x (T_s - T_\infty) + \dot{n}'_{A,x} h_{fg} \quad (3)$$

Continued...

**PROBLEM 7.119 (Cont.)**

To estimate  $h_x$ , invoke the heat-mass analogy using the correlation, Eq. 7.37,

$$\text{Nu}_x / \text{Sh}_x = (\text{Pr}/\text{Sc})^{1/3} \quad \text{or} \quad h_x = h_{m,x} k / D_{AB} (\text{Pr}/\text{Sc})^{1/3} \quad (4)$$

$$h_x = 3.95 \times 10^{-2} \text{ kg/s} \cdot \text{m}^2 \left( 0.0274 \text{ W/m} \cdot \text{K} / 0.28 \times 10^{-4} \text{ m}^2/\text{s} \right) (0.705/0.616)^{1/3} = 40.45 \text{ W/m}^2 \cdot \text{K}$$

Hence, the required radiant flux is

$$q''_{\text{rad}} = 40.45 \text{ W/m}^2 \cdot \text{K} (330 - 300) \text{ K} + 4.48 \times 10^{-3} \text{ kg/s} \cdot \text{m}^2 \times 2366 \times 10^3 \text{ J/kg}$$

$$q''_{\text{rad}} = 1,214 \text{ W/m}^2 + 10,600 \text{ W/m}^2 = 11,813 \text{ W/m}^2 \quad <$$

(c) The flow is turbulent over tray 5 having its mid-length at  $x = 1 \text{ m}$ , so that it is reasonable to assume,

$$\bar{h}_5 \approx h_x (1 \text{ m}) \quad (5)$$

so that the evaporation rate can be determined from the evaporative flux as,

$$n'_A = n''_{A,x} \Delta L = 4.48 \times 10^{-3} \text{ kg/s} \cdot \text{m}^2 \times 0.222 \text{ m} = 9.95 \times 10^{-4} \text{ kg/s} \cdot \text{m} \quad <$$

(d) For tray 5, following the form of Eq. (3), the energy balance is

$$q''_{\text{rad},5} \Delta L = \bar{h}_5 \Delta L (T_{s,5} - T_\infty) + n'_{A,5} h_{fg} \quad (6)$$

and the evaporation rate for the tray is

$$n'_{A,5} = \bar{h}_{m,5} \Delta L (\rho_{A,s} - 0) \quad (7)$$

While  $\bar{h}_5$  and  $\bar{h}_{m,5}$  represent tray averages, Eq. (4) is still applicable. Using the *IHT Correlation Tool, External Flow, Average coefficient for Laminar, or Mixed Flow*,  $\bar{h}_5$  is evaluated as

$$\bar{h}_5 = \left[ \bar{h}_x (1.10 \text{ m}) L_5 - \bar{h}_x (0.880 \text{ m}) L_4 \right] / \Delta L \quad (8)$$

where  $\Delta L = L_5 - L_4 = 0.22 \text{ m}$ . The same relations can be applied to trays 2, 3 and 4. For tray 1,  $\bar{h}_1 = \bar{h} (0.22 \text{ m}) \cdot L_1$ , where  $L_1 = \Delta L$ . With Eqs. (3, 6, 7 and 8) in the IHT Workspace, along with the *Correlations* and *Properties Tools*, the following results were obtained with the requirement that the evaporation rate for each tray is equal at  $n'_{A,5} = 10.01 \times 10^{-4} \text{ kg/s} \cdot \text{m}$ .

Tray	1	2	3	4	5
$T_s$	342.7	357	348.1	329	330
$q''_{\text{rad}}$	11,920	11,150	11,400	11,950	11,920

**COMMENTS:** (1) Note carefully at which temperatures the thermophysical properties are evaluated.

(2) Recognize that in part (d), if we require equal evaporation rates for each tray,  $n'_{A,5}$ , the water temperature,  $T_s$ , and radiant flux,  $q''_{\text{rad}}$ , for each tray must be different since the convection coefficients  $\bar{h}_x$  and  $\bar{h}_{m,x}$  are different for each of the trays. How do you explain the changes in  $T_s$ ? Which tray has the highest  $\bar{h}$ ? The lowest  $\bar{h}$ ?

(3) For tray 5, using Eq. (5) we found  $\bar{h}_5 = 40.45 \text{ W/m}^2 \cdot \text{K}$ ; using the more accurate formulation, Eq. (8), the result is  $40.49 \text{ W/m}^2 \cdot \text{K}$ . If the flow were laminar or mixed over the tray, Eq. (5) would be inappropriate.

## PROBLEM 7.120

**KNOWN:** Irradiation on sequential water-filled trays of prescribed length and width. Temperature and velocity of airflow over the trays.

**FIND:** Rate of water loss from first, third and fourth trays and temperature of water in each tray.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Uniform irradiation of each container, (3) Complete absorption of irradiation by water, (4) Negligible heat transfer between containers and from bottom of containers, (5) Validity of heat-mass transfer analogy, (6) Applicability of convection correlations for an isothermal surface, (7)  $Re_{x,c} = 5 \times 10^5$ .

**PROPERTIES:** Table A.4, air (1 atm, assume  $T_f = 315$  K):  $\nu = 17.4 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0274 \text{ W/m}\cdot\text{K}$ ,  $Pr = 0.705$ . Table A.8, vapor/air (1 atm, 315 K):  $D_{AB} = 0.26 \times 10^{-4} \text{ m}^2/\text{s}$  ( $315/298$ )<sup>3/2</sup> =  $0.28 \times 10^{-4} \text{ m}^2/\text{s}$ ,  $Sc = \nu/D_{AB} = 0.616$ .

**ANALYSIS:** The temperature of each tray is determined by a balance between the absorbed radiation and the convection and evaporative losses. Hence,

$$G = q''_{\text{conv}} + q''_{\text{evap}} = \bar{h}(T_s - T_\infty) + \bar{h}_m \rho_{A,\text{sat}} h_{fg}$$

where, assuming an exponent of  $n = 1/3$ , the heat-mass transfer analogy yields

$$\bar{h}_m = (D_{AB}/k)(Sc/Pr)^{1/3} \bar{h} = (0.26 \times 10^{-4} \text{ m}^2/\text{s}/0.0274 \text{ W/m}\cdot\text{K})(0.616/0.705)^{1/3} \bar{h} = (9.07 \times 10^{-4} \text{ m}^3 \cdot \text{K}/\text{W} \cdot \text{s}) \bar{h}$$

Hence,

$$G = \bar{h} \left[ (T_s - T_\infty) + 9.07 \times 10^{-4} \rho_{A,\text{sat}} h_{fg} \right]$$

With  $Re_N = u_\infty N \Delta x / \nu = 15 \text{ m/s}(N \times 0.25 \text{ m})/17.4 \times 10^{-6} \text{ m}^2/\text{s} = (2.155 \times 10^5)N$ , the flow is laminar for  $N = 1, 2$  with transition to turbulence occurring for  $N = 3$ .

For tray 1,

$$\begin{aligned} \bar{h} &= (k/\Delta x) 0.664 Re_1^{1/2} Pr^{1/3} \\ &= (0.0274 \text{ W/m}\cdot\text{K}/0.25 \text{ m}) 0.664 (2.155 \times 10^5)^{1/2} (0.705)^{1/3} = 30.1 \text{ W/m}^2 \cdot \text{K} \end{aligned}$$

For tray 4, with  $x = 0.875 \text{ m}$  ( $N = 7/2$ ),

$$\begin{aligned} \bar{h}_4 &\approx (k/x) 0.0296 Re_{7/2}^{4/5} Pr^{1/3} \\ &= (0.0274 \text{ W/m}\cdot\text{K}/0.875 \text{ m}) 0.0296 (7.543 \times 10^5)^{4/5} (0.705)^{1/3} = 41.5 \text{ W/m}^2 \cdot \text{K} \end{aligned}$$

Continued...

**PROBLEM 7.120 (Cont.)**

For tray 3,  $\bar{h}_3 = (\bar{h}_{1-3}L_3 - \bar{h}_{1-2}L_2) / \Delta x$ , where

$$\begin{aligned}\bar{h}_{1-3}L_3 &= k \left( 0.037 \text{Re}_3^{4/5} - 871 \right) \text{Pr}^{1/3} \\ &= 0.0274 \text{ W/m} \cdot \text{K} (0.037 \times 44,510 - 871) (0.705)^{1/3} = 18.9 \text{ W/m} \cdot \text{K}\end{aligned}$$

$$\begin{aligned}\bar{h}_{1-2}L_2 &= k \left( 0.664 \text{Re}_2^{1/2} \text{Pr}^{1/3} \right) \\ &= 0.0274 \text{ W/m} \cdot \text{K} (0.664 \times 656.5) (0.705)^{1/3} = 10.6 \text{ W/m} \cdot \text{K}\end{aligned}$$

$$\bar{h}_3 = (18.9 - 10.6) \text{ W/m} \cdot \text{K} / 0.25 \text{ m} = 33.1 \text{ W/m}^2 \cdot \text{K}$$

For tray 1, the energy balance yields

$$10^4 \text{ W/m}^2 = 30.1 \text{ W/m}^2 \cdot \text{K} \left[ (T_s - T_\infty) + 9.07 \times 10^{-4} \rho_{A,\text{sat}} h_{\text{fg}} \right]$$

Since  $\rho_{A,\text{sat}}$  depends strongly on  $T_s$ , the solution to this equation must be obtained by trial-and-error, with  $\rho_{A,\text{sat}}$  (and  $h_{\text{fg}}$ ) determined from Table A.6. The solution yields

$$T_{s,1} \approx 334.7 \text{ K} \quad <$$

Similarly, for trays 3 and 4

$$T_{s,3} \approx 332.8 \text{ K} \quad T_{s,4} \approx 327.1 \text{ K} \quad <$$

The evaporation rate for tray N is

$$\dot{m}_{\text{evap}} = \bar{h}_m \rho_{A,\text{sat}} (W \Delta x) = 2.27 \times 10^{-4} \bar{h} \rho_{A,\text{sat}}$$

from which it follows that

$$\dot{m}_{\text{evap},1} \approx 9.5 \times 10^{-4} \text{ kg/s}, \quad \dot{m}_{\text{evap},3} \approx 9.5 \times 10^{-4} \text{ kg/s}, \quad \dot{m}_{\text{evap},4} \approx 9.3 \times 10^{-4} \text{ kg/s} \quad <$$

**COMMENTS:** (1) The largest convection coefficient is associated with the tray for which the entire flow is turbulent. (2) The temperature of the water varies inversely with the average convection coefficient for its tray.

## PROBLEM 7.121

**KNOWN:** Apparatus as described in Problem 7.40 providing a nearly uniform airstream over a flat *test plate* to experimentally determine the heat and mass transfer coefficients. Temperature history of the preheated plate for airstream velocities of 3 and 9 m/s were fitted to a fourth-order polynomial for determining the heat transfer coefficient. Water mass loss observations from a water-saturated paper over the plate and its surface temperature for determining the heat transfer coefficient.

**FIND:** (a) From the temperature-time history, determine the heat transfer coefficients and evaluate the constants  $C$  and  $m$  for a correlation of the form  $\overline{Nu}_L = C Re^m Pr^{1/3}$ ; compare results with a standard-plate correlation and comment on the goodness of the comparison; explain any differences; (b) From the water mass loss observations, determine the mass transfer coefficients for the two flow conditions; evaluate the constants  $C$  and  $m$  for a correlation of the form  $\overline{Sh}_L = C Re^m Sc^{1/3}$ ; and (c) Using the heat-mass analogy, compare the experimental results with each other and against standard correlations; comment on the goodness of the comparison; explain any differences.

**SCHEMATIC:**

(a) Heat transfer experiment

Temperature Observations		
$u_\infty$ (m/s)	3	9
$\Delta t$ (s)	300	160
$a$ ( $^\circ\text{C}$ )	56.87	57.00
$b$ ( $^\circ\text{C/s}$ )	-0.1472	-0.2641
$c$ ( $^\circ\text{C/s}^2$ )	$3 \times 10^{-4}$	$9 \times 10^{-4}$
$d$ ( $^\circ\text{C/s}^3$ )	$-4 \times 10^{-7}$	$-2 \times 10^{-6}$
$e$ ( $^\circ\text{C/s}^4$ )	$2 \times 10^{-10}$	$1 \times 10^{-9}$

(b) Mass transfer experiment

Mass Loss Observations				
$V$	$\overline{T}_s$	$m(t)$	$m(t + \Delta t)$	$\Delta t$
(m/s)	( $^\circ\text{C}$ )	(g)	(g)	(s)
3	15.3	55.62	54.45	475
9	16.0	55.60	54.50	240

**ASSUMPTIONS:** (1) Airstream over the test plate approximates parallel flow over a flat plate, (2) Plate is spacewise isothermal, (3) Negligible radiation exchange between plate and surroundings, (4) Constant properties, and (5) Negligible heat loss from the bottom surface or edges of the test plate.

**PROPERTIES:** *Heat transfer coefficient, Table A.4, Air* ( $T_f = (\overline{T}_s + T_\infty)/2 = 310 \text{ K}$ , 1 atm):  $k_a = 0.0269 \text{ W/m}\cdot\text{K}$ ,  $\nu = 1.669 \times 10^{-5} \text{ m}^2/\text{s}$ ,  $Pr = 0.706$ . *Test plate (Given):*  $\rho = 2770 \text{ kg/m}^3$ ,  $c_p = 875 \text{ J/kg}\cdot\text{K}$ ,  $k = 177 \text{ W/m}\cdot\text{K}$ . *Mass transfer coefficient: Table A.6, Water vapor* ( $\overline{T}_s = 15.3^\circ\text{C} = 288.3 \text{ K}$ ):  $\rho_{A,\text{sat}} = 1/v_g = 79.81 \text{ m}^3/\text{kg} = 0.01253 \text{ kg/m}^3$ ; *Table A.6, Water vapor* ( $\overline{T}_s = 16.0^\circ\text{C} = 289 \text{ K}$ ):  $\rho_{A,\text{sat}} = 0.01322 \text{ kg/m}^3$ ; *Table A.6, Water vapor* ( $T_{\text{inf}} = 27^\circ\text{C} = 300 \text{ K}$ ):  $\rho_{A,\text{sat}} = 0.02556 \text{ kg/m}^3$ ; *Table A.8, Water vapor-air* [ $T_f = (\overline{T}_s + T_\infty)/2 \approx 295 \text{ K}$ ]:  $D_{AB} = 0.26 \times 10^{-4} \text{ m}^2/\text{s} (295/298)^{1.5} = 0.256 \times 10^{-4} \text{ m}^2/\text{s}$ .

**ANALYSIS:** (a) Using the lumped-capacitance method, the energy balance on the plate is

$$-\overline{h}_L A_s [T_s(t) - T_\infty] = \rho V c_p \frac{dT}{dt} \quad (1)$$

Continued...

### PROBLEM 7.121 (Cont.)

and the average convection coefficient can be determined from the temperature history,  $T_s(t)$ ,

$$\bar{h}_L = \frac{\rho V c_p}{A_s} \frac{(dT/dt)}{T_s(t) - T_\infty} \quad (2)$$

where the temperature-time derivative is

$$\frac{dT_s}{dt} = b + 2ct + 3dt^2 + 4et^3 \quad (3)$$

The temperature time history plotted below shows the experimental behavior of the observed data.

Consider now the integrated form of the energy balance, Eq. (5.6), expressed as

$$\ln \frac{T_s(t) - T_\infty}{T_i - T_\infty} = - \left( \frac{\bar{h}_L A_s}{\rho V c} \right) t \quad (4)$$

If we were to plot the LHS vs  $t$ , the slope of the curve would be proportional to  $\bar{h}_L$ . Using IHT, plots were generated of  $\bar{h}_L$  vs.  $T_s$ , Eq. (1), and  $\ln \left[ (T_s(t) - T_\infty) / (T_i - T_\infty) \right]$  vs.  $t$ , Eq. (4). From the latter plot, recognize that the regions where the slope is constant corresponds to early times ( $\leq 100$ s when  $u_\infty = 3$  m/s and  $\leq 50$ s when  $u_\infty = 5$  m/s).

Continued...

### PROBLEM 7.121 (Cont.)

Selecting two elapsed times at which to evaluate  $\bar{h}_L$ , the following results were obtained

$u_\infty$ (m/s)	$t$ (s)	$T_s$ (t), ( $^\circ\text{C}$ )	$\bar{h}_L$ ( $\text{W}/\text{m}^2\cdot\text{K}$ )	$\overline{\text{Nu}}_L$	$\text{Re}_L$
3	100	44.77	30.81	152.4	$2.39 \times 10^4$
9	50	45.80	56.7	280.4	$7.17 \times 10^4$

where the dimensionless parameters are evaluated as

$$\overline{\text{Nu}}_L = \frac{\bar{h}_L L}{k_a} \quad \text{Re}_L = \frac{u_\infty L}{\nu} \quad (5,6)$$

where  $k_a$ ,  $\nu$  are thermophysical properties of the airstream.

(b) Using the above pairs of  $\overline{\text{Nu}}_L$  and  $\text{Re}_L$ ,  $C$  and  $m$  in the correlation can be evaluated,

$$\overline{\text{Nu}}_L = C \text{Re}_L^m \text{Pr}^{1/3} \quad (7)$$

$$152.4 = C(2.39 \times 10^4)^m (0.706)^{1/3} \quad 280.4 = C(7.17 \times 10^4)^m (0.706)^{1/3}$$

Solving, find  $C = 0.633$   $m = 0.555$  (8,9) <

The plot below compares the experimental correlation ( $C = 0.633$ ,  $m = 0.555$ ) with those for laminar flow ( $C = 0.664$ ,  $m = 0.5$ ) and fully turbulent flow ( $C = 0.037$ ,  $m = 0.8$ ). The experimental correlation yields  $\overline{\text{Nu}}_L$  values which are 25% higher than for the correlation. The most likely explanation for this unexpected trend is that the airstream reaching the plate is not parallel, but with a slight impingement effect and/or the flow is very highly turbulent at the leading edge.

(b) From the convection mass transfer rate equation,

$$n_A = \bar{h}_{m,L} A_s (\rho_{A,s} - \rho_{A,\infty}) \quad (10)$$

where the evaporation rate can be determined from the paper mass and time interval observations,

$$n_A = \frac{[m(t + \Delta t) - m(t)]}{\Delta t} \quad (11)$$

and the species densities,  $\rho_{A,s}$  and  $\rho_{A,\infty}$ , correspond to  $\rho_{A,\text{sat}}(\bar{T}_s)$  and  $\phi_\infty \rho_{A,\text{sat}}(T_\infty)$ , respectively.

Using the ASHRAE psychrometric chart (1 atm) with  $T_{\text{wb}} = 13^\circ\text{C}$  and  $T_{\text{db}} = 27^\circ\text{C}$ , find the relative humidity as  $\phi_\infty = 0.17$ . The correlation dimensionless parameters are evaluated as

$$\overline{\text{Sh}}_L = \frac{\bar{h}_{m,L} L}{D_{AB}} \quad \text{Re}_L = \frac{u_\infty L}{\nu} \quad \text{Sc} = \frac{\nu}{D_{AB}} \quad (12,13,14)$$

Continued...

**PROBLEM 7.121 (Cont.)**

where all the properties are evaluated at  $T_f = (\bar{T}_S + T_\infty)/2$ . The results of the analyses are summarized in the following table.

$u_\infty$	$n_A$	$\bar{h}_{m,L}$	$\bar{Sh}_L$	$Re_L$	$Sc$
(m/s)	kg/s	(m/s)			
3	$2.463 \times 10^{-6}$	0.0168	87.58	$2.594 \times 10^4$	0.603
9	$4.583 \times 10^{-6}$	0.0288	150	$7.767 \times 10^4$	0.603

Using the two sets of tabulated values for  $\bar{Sh}_L$ ,  $Re_L$  and  $Sc$  and the standard correlation of the form,

$$\bar{Sh}_L = C Re_L^m Sc^{1/3} \tag{15}$$

$$87.58 = C (2.594 \times 10^4)^m (0.603)^{1/3} \qquad 150 = C (7.767 \times 10^4)^m (0.603)^{1/3}$$

solve simultaneously to find  $C = 0.711$   $m = 0.490$  (16,17)

From the heat-mass analogy, we expect the constants  $C$  and  $m$  in Eq. (7) for heat transfer and in Eq. (13) for mass transfer to be the same. From the two experiments, we found

	$C$	$m$
Heat transfer	0.633	0.555
Mass transfer	0.711	0.490

In the plot below, the parameters  $\bar{Sh}_L/Sc^{1/3}$  or  $\bar{Nu}_L/Pr^{1/3}$  are plotted against  $Re_L$  using Eq. (15) or (7). Note that the curves are nearly parallel on the log-log axes since their “ $m$ ” constants are of similar value. The mass transfer results are, however, nearly 50% higher than those for heat transfer. We have no way to explain this systematic difference without more information on the apparatus, observation procedures and repeated observations. However, overall the results support the general form of the heat-mass analogy.

## PROBLEM 7.122

**KNOWN:** Dry air at prescribed temperature and velocity flowing over a wetted plate of length 500 mm and width 150 mm. Imbedded electrical heater maintains the surface at  $T_s = 20^\circ\text{C}$ .

**FIND:** (a) Water evaporation rate (kg/h) and electrical power  $P_e$  (W) required to maintain steady-state conditions, and (b) The temperature of the plate after all the water has evaporated, for the same airstream conditions and heater power of part (a).

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Constant properties and (3) Heat-mass transfer analogy is applicable.

**PROPERTIES:** Table A.4, Air ( $T_f = (T_s + T_\infty)/2 = 300\text{ K}$ , 1 atm):  $\rho = 1.16\text{ kg/m}^3$ ,  $c_p = 1007\text{ J/kg}\cdot\text{K}$ ,  $k = 0.0263\text{ W/m}\cdot\text{K}$ ,  $\nu = 15.94 \times 10^{-6}\text{ m}^2/\text{s}$ ,  $\alpha = 2.257 \times 10^{-5}\text{ m}^2/\text{s}$ , Table A.6, Water ( $T_s = 20^\circ\text{C} = 293\text{ K}$ ):  $\rho_{A,s} = 1/\nu_g = 1/59.04 = 0.0169\text{ kg/m}^3$ ,  $h_{fg} = 2454\text{ kJ/K}$ ; Table A.8, Water-air ( $T_f = 300\text{ K}$ ):  $D_{AB} = 0.26 \times 10^{-4}\text{ m}^2/\text{s}$ .

**ANALYSIS:** (a) Perform an energy balance on the plate,

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = 0 \quad P_e - q_{\text{conv}} - q_{\text{evap}} = 0 \quad (1)$$

where the convection and evaporation rate equations are,

$$q_{\text{conv}} = \bar{h}_L A_s (T_s - T_\infty) \quad (2)$$

$$q_{\text{evap}} = n_A h_{fg} = \bar{h}_m A_s (\rho_{A,s} - \rho_{A,\infty}) h_{fg} \quad (3)$$

The Reynolds number for the plate length  $L$  is

$$\text{Re}_L = \frac{u_\infty L}{\nu} = \frac{20\text{ m/s} \times 0.50\text{ m}}{15.94 \times 10^{-6}\text{ m}^2/\text{s}} = 6.274 \times 10^5$$

so that the flow is mixed and Eq. 7.38 is appropriate to estimate  $\bar{h}_L$ ,

$$\begin{aligned} \overline{\text{Nu}}_L &= \frac{\bar{h}_L L}{k} = \left(0.037 \text{Re}_D^{4/5} - 871\right) \text{Pr}^{1/3} \\ \bar{h}_L &= \frac{0.0263\text{ W/m}\cdot\text{K}}{0.5\text{ m}} \left(0.037 \left[6.274 \times 10^5\right]^{4/5} - 871\right) (0.707)^{1/3} = 34.5\text{ W/m}^2\cdot\text{K} \end{aligned}$$

Invoking the heat-mass analogy, Chapter 6, with  $n = 1/3$

$$\frac{\bar{h}_L}{\bar{h}_m} = \rho c_p \left(\frac{\alpha}{D_{AB}}\right)^{-2/3} = 1.16\text{ kg/m}^3 \times 1007\text{ J/kg}\cdot\text{K} \left(\frac{2.257 \times 10^{-5}\text{ m}^2/\text{s}}{0.26 \times 10^{-4}\text{ m}^2/\text{s}}\right)^{-2/3} = 1284\text{ J/m}^3\cdot\text{K}$$

Continued...

**PROBLEM 7.122 (Cont.)**

$$\bar{h}_m = 34.5 \text{ W/m}^2 \cdot \text{K} / 1284 \text{ J/m}^3 \cdot \text{K} = 0.0269 \text{ m/s}$$

Substituting numerical values, the energy balance, Eq. (1), with  $A_s = 0.5 \text{ m} \times 0.15 \text{ m} = 0.075 \text{ m}^2$ ,

$$P_e - 34.5 \text{ W/m}^2 \cdot \text{K} \times 0.075 \text{ m}^2 (20 - 35) \text{ K} \\ - 0.0269 \text{ m/s} \times 0.075 \text{ m}^2 (0.0169 - 0) \text{ kg/m}^3 \times 2454 \times 10^3 \text{ J/kg} \cdot \text{K} = 0$$

$$P_e = -38.8 \text{ W} + 83.7 = 44.9 \text{ W}$$

<

The evaporation rate is

$$n_A = \bar{h}_m A_s (\rho_{A,s} - \rho_{A,\infty}) = 0.0269 \text{ m/s} \times 0.075 \text{ m}^2 \times 0.0169 \text{ kg/m}^3 \times 3600 \text{ s/h} = 0.123 \text{ kg/h}$$

<

(b) When the plate is dry, the energy balance is

$$P_e = \bar{h}_L A_s (T_s - T_\infty)$$

and with  $P_e$  and  $\bar{h}_L$  as determined in part (a),

$$T_s = T_\infty + P_e / \bar{h}_L A_s = 35^\circ \text{C} + 44.9 \text{ W} / 34.5 \text{ W/m}^2 \cdot \text{K} \times 0.075 \text{ m}^2 = 52.3^\circ \text{C}$$

<

**COMMENTS:** Using *IHT Correlations Tool, External Flow, Flat Plate*, the calculation of part (b) was performed using the proper film temperature,  $T_f = 318 \text{ K}$ , to find  $\bar{h}_L = 32.7 \text{ W/m}^2 \cdot \text{K}$  and  $T_s = 53.3^\circ \text{C}$ .

### PROBLEM 7.123

**KNOWN:** Convection mass transfer with turbulent flow over a flat plate (van roof).

**FIND:** (a) Location on van that will dry last, (b) Evaporation rate at trailing edge,  $\text{kg/s}\cdot\text{m}^2$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Turbulent flow over entire plate (van top), (2) Heat-mass transfer analogy is applicable, (3) Perfect gas behavior for water vapor (A).

**PROPERTIES:** Table A-4, Air (300 K, 1 atm):  $\nu = 15.89 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0263 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.707$ ; Table A-8, Air-water vapor (25°C):  $D_{AB} = 0.26 \times 10^{-4} \text{ m}^2/\text{s}$ ; Table A-6, Saturated water vapor (300K):  $\rho_{A,\text{sat}} = \nu_g^{-1} = 0.0256 \text{ kg/m}^3$ .

**ANALYSIS:** (a) The mass transfer coefficient,  $h_m(x)$ , will be largest at  $x = 0$  and smallest at  $x = L$  for turbulent flow conditions. Hence, the trailing edge will dry last.

(b) The evaporation rate on a per unit area basis, at the trailing edge where  $x = L$ , is given by the rate equation,

$$n''_A = h_{m,L} (\rho_{A,s} - \rho_{A,\infty}) = h_{m,L} \rho_{A,\text{sat}} (1 - \phi_\infty)$$

For turbulent flow the appropriate correlation for estimating  $h_{m,L}$  is of the form

$$\text{Sh}_x = h_{m,x} x / D_{AB} = 0.0296 \text{Re}_x^{4/5} \text{Sc}^{1/3}.$$

Substituting numerical values,

$$\text{Re}_L = \frac{u_\infty L}{\nu_B} = \frac{90 \times 10^3 \text{ m/h}}{3600 \text{ s/h}} \times 6 \text{ m} / 15.89 \times 10^{-6} \text{ m}^2/\text{s} = 9.44 \times 10^6$$

$$\text{Sc} = \frac{\nu_B}{D_{AB}} = 15.89 \times 10^{-6} \text{ m}^2/\text{s} / 0.26 \times 10^{-4} \text{ m}^2/\text{s} = 0.611$$

$$h_{m,L} = \left( 0.26 \times 10^{-4} \text{ m}^2/\text{s} / 6 \text{ m} \right) \times 0.0296 \left( 9.44 \times 10^6 \right)^{4/5} (0.611)^{1/3} = 0.0414 \text{ m/s}.$$

Hence, the evaporation flux (rate per unit area) is

$$n''_A = 0.0414 \text{ m/s} \times 0.0256 \text{ kg/m}^3 (1 - 0.8) = 2.12 \times 10^{-4} \text{ kg/s}\cdot\text{m}^2. \quad <$$

**COMMENTS:** Recognize how the heat-mass analogy is utilized and the appropriate correlation selected from Table 7.7.

### PROBLEM 7.124

**KNOWN:** Length and thickness of a layer of benzene. Velocity and temperature of air in parallel flow over the layer.

**FIND:** Time required for complete evaporation.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Smooth liquid surface and negligible free-stream turbulence, (3) Heat and mass transfer analogy is applicable, (4) Negligible benzene vapor concentration in free-stream air, (5) Isothermal conditions at  $25^\circ\text{C}$ .

**PROPERTIES:** Table A-4, Air ( $25^\circ\text{C}$ , 1 atm):  $\nu = 15.7 \times 10^{-6} \text{ m}^2/\text{s}$ ; Table A-8, Benzene-air, ( $25^\circ\text{C}$ , 1 atm):  $D_{AB} = 0.88 \times 10^{-5} \text{ m}^2/\text{s}$ ,  $Sc = 1.78$ .

**ANALYSIS:** Applying conservation of mass to a control volume about the liquid,

$$\frac{dM}{dt} = \frac{d(\rho_l V)}{dt} = -n_A.$$

For a unit width,  $V = L \cdot \delta$ . Hence

$$\rho_l L \frac{d\delta}{dt} = -n'_A = -\bar{h}_m L (\rho_{A,\text{sat}} - \rho_{A,\infty})$$

and integrating

$$\int_{\delta_i}^0 d\delta = -\frac{\bar{h}_m}{\rho_l} \rho_{A,\text{sat}} \int_0^t dt$$

$$t = \frac{\delta_i \rho_l}{\bar{h}_m \rho_{A,\text{sat}}}.$$

With  $Re_L = \frac{u_\infty L}{\nu} = \frac{1 \text{ m/s} \times 2 \text{ m}}{15.7 \times 10^{-6} \text{ m}^2/\text{s}} = 1.27 \times 10^5,$

the flow is laminar throughout and from Eq. 7.31,

$$\bar{h}_m = \frac{D_{AB}}{L} 0.664 Re_L^{1/2} Sc^{1/3} = \frac{0.88 \times 10^{-5} \text{ m}^2/\text{s}}{2 \text{ m}} \times 0.664 (1.27 \times 10^5)^{1/2} (1.78)^{1/3}$$

$$\bar{h}_m = 1.26 \times 10^{-3} \text{ m/s}$$

and

$$t = \frac{0.001 \text{ m} (900 \text{ kg/m}^3)}{(1.26 \times 10^{-3} \text{ m/s}) (0.417 \text{ kg/m}^3)} = 1713 \text{ s} = 28.6 \text{ min.}$$

<

### PROBLEM 7.125

**KNOWN:** Parallel air flow over a series of water-filled trays.

**FIND:** Power required to maintain each of the first three trays at 300K.

**SCHEMATIC:**

**ASSUMPTIONS:** (a) Steady-state conditions, (2) Heat-mass transfer analogy applicable, (3) Perfect gas behavior for water vapor, (4)  $Re_{x,c} = 5 \times 10^5$ .

**PROPERTIES:** Table A-4, Air (300 K, 1 atm):  $\nu = \nu_B = 15.89 \times 10^{-6} \text{ m}^2/\text{s}$ ; Table A-8, Water vapor-air (300K):  $D_{AB} = 0.26 \times 10^{-4} \text{ m}^2/\text{s}$ ,  $Sc = \nu_B/D_{AB} = 0.611$ ; Table A-6, Saturated water vapor (300K):  $\rho_{A,sat} = \nu_g^{-1} = 0.02556 \text{ kg/m}^3$ ,  $h_{fg} = 2438 \text{ kJ/kg}$ .

**ANALYSIS:** Since  $T_s = T_\infty$ , there is no convective heat transfer, hence,

$$q_{\text{tray}} = \dot{m}_{\text{tray}} h_{fg} = \bar{h}_m \cdot A_s \cdot \rho_{A,sat} (1 - \phi_\infty) h_{fg} \quad (1)$$

where

$\phi_\infty \equiv \rho_{A,\infty} / \rho_{A,sat}$  and  $\rho_{A,s} = \rho_{A,sat}(T_s)$ . Calculate the Reynolds number at  $x_3$ ,

$$Re_{x3} = u_\infty x_3 / \nu_B = 12 \text{ m/s} \times 1.5 \text{ m} / 15.89 \times 10^{-6} \text{ m}^2/\text{s} = 1.133 \times 10^6$$

finding that transition occurs at  $x = 0.662 \text{ m}$ , a location on tray 2. The average mass transfer coefficients  $\bar{h}_m$  and heat rates for each tray are as follows:

*Tray 1:* The flow is laminar and the appropriate correlation for  $\bar{h}_{m,1}$  and heat rate are

$$\overline{Sh}_{x1} = \bar{h}_{m,1} x_1 / D_{AB} = 0.664 Re_{x1}^{1/2} Sc^{1/3}$$

$$\bar{h}_{m,1} = \left( 0.26 \times 10^{-4} \text{ m}^2/\text{s} / 0.5 \text{ m} \right) \times 0.664 \left( \frac{12 \text{ m/s} \times 0.5 \text{ m}}{15.89 \times 10^{-6} \text{ m}^2/\text{s}} \right)^{1/2} (0.611)^{1/3} = 1.800 \times 10^{-2} \text{ m/s}$$

$$q'_1 = 1.800 \times 10^{-2} \text{ m/s} \times 0.5 \text{ m} \times 0.02556 \text{ kg/m}^3 (1 - 0.40) \times 2438 \times 10^3 \text{ J/kg} = 337 \text{ W/m.} \quad <$$

*Tray 2:* Since transition occurs over the span of tray 2, the rate equation has the form

$$q'_2 = \left[ x_2 \bar{h}_{m,0-2} - x_1 \bar{h}_{m,0-1} \right] \rho_{A,sat} (1 - \phi_\infty) h_{fg}. \quad (2)$$

Continued ....

### PROBLEM 7.125 (Cont.)

Note that  $\bar{h}_{m,0-1} = \bar{h}_{m,1}$  from above and that  $\bar{h}_{m,0-2}$  is evaluated using the correlation

$$\overline{Sh}_x = \left(0.037 Re_x^{4/5} - 871\right) Sc^{1/3}$$

$$\bar{h}_{m,0-2} = 2.193 \times 10^{-2} \text{ m/s} \quad q'_2 = 483 \text{ W/m.} \quad <$$

*Tray 3:* The rate equation is of the same form as Eq. (2). Alternatively, an approximation can be used,

$$q'_3 = h_m(\bar{x}) (x_3 - x_2) \rho_{A,sat} (1 - \phi_\infty) h_{fg}$$

where  $h_m(\bar{x})$  is the *local* value at the midspan,  $\bar{x} = (x_2 + x_3)/2$ . Using

$$\overline{Sh}_x = 0.0296 Re_x^{4/5} Sc^{1/3}$$

and substituting numerical values, find

$$h_m(\bar{x}) = 3.148 \times 10^{-2} \text{ m/s} \quad q'_3 = 589 \text{ W/m.} \quad <$$

### PROBLEM 7.126

**KNOWN:** Air and surface conditions for a drying process in which photographic plates are aligned in the direction of the air flow.

**FIND:** (a) Variation of local mass transfer convection coefficient, (b) Drying rate for fastest drying plate, (c) Heat addition needed to maintain the plate temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Heat and mass transfer analogy is applicable, (2) Critical Reynolds number is  $Re_{x,c} = 5 \times 10^5$ , (3) Radiation effects are negligible.

**PROPERTIES:** Table A-4, Air ( $50^\circ\text{C} = 323\text{K}$ ):  $\nu = 18.2 \times 10^{-6} \text{ m}^2/\text{s}$ ; Table A-6, Water vapor ( $50^\circ\text{C} = 323\text{K}$ ):  $\rho_{A,\text{sat}} = 0.082 \text{ kg/m}^3$ ,  $h_{fg} = 2383 \text{ kJ/kg}$ ; Table A-8, Water vapor-air ( $25^\circ\text{C} = 298\text{K}$ )  $D_{AB} = 0.26 \times 10^{-4} \text{ m}^2/\text{s}$ ; since  $D_{AB} \propto T^{3/2}$ ,  $D_{AB}(50^\circ\text{C} = 323\text{K}) = 0.26 \times 10^{-4} (323/298)^{3/2} = 0.29 \times 10^{-4} \text{ m}^2/\text{s}$ ,  $Sc = \nu/D_{AB} = 0.62$ .

**ANALYSIS:** (a) With  $Re_{x,c} = u_\infty x_c / \nu = 5 \times 10^5$ , the point of transition is

$$x_c = \frac{5 \times 10^5 (18.2 \times 10^{-6} \text{ m}^2/\text{s})}{9.1 \text{ m/s}} = 1 \text{ m}$$

and the variation of the local mass transfer coefficient is as shown below

(b) The largest evaporation will be associated with either the first plate or the fifth plate. For the *first* plate,

$$n_{A,1} = \bar{h}_{m,1} A_{s,1} (\rho_{A,s} - \rho_{A,\infty})$$

where  $\rho_{A,\infty} = 0$  since the upstream air is dry. Since the boundary layer is laminar over the entire plate, with

$$Re_{x,1} = (9.1 \text{ m/s}) (0.25 \text{ m}) / (18.2 \times 10^{-6} \text{ m}^2/\text{s}) = 1.25 \times 10^5$$

Continued ...

**PROBLEM 7.126 (Cont.)**

Eq. 7.31 may be used to obtain

$$\bar{h}_{m,1} = \left( \frac{D_{AB}}{x_1} \right) 0.664 \text{Re}_{x,1}^{1/2} \text{Sc}^{1/3} = \left( \frac{0.29 \times 10^{-4} \text{ m}^2/\text{s}}{0.25 \text{ m}} \right) 0.664 \left( 1.25 \times 10^5 \right)^{1/2} (0.62)^{1/3}$$

$$\bar{h}_{m,1} = 0.0232 \text{ m/s.}$$

Hence  $n_{A,1} = 0.0232 \text{ m/s} (0.25 \text{ m} \times 1 \text{ m}) (0.082 \text{ kg/m}^3) = 4.72 \times 10^{-4} \text{ kg/s} \cdot \text{m}.$

For the *fifth* plate,

$$n_{A,5} = n_{A,0-5} - n_{A,0-4} = \left[ (\bar{h}_m A_s)_{0-5} - (\bar{h}_m A_s)_{0-4} \right] (\rho_{A,s} - \rho_{A,\infty}).$$

With  $\text{Re}_{x,5} = 6.25 \times 10^5$ , Eq. 7.41 gives

$$\bar{h}_{m,0-5} = \left( \frac{D_{AB}}{x_5} \right) \left[ 0.037 \text{Re}_{x,5}^{4/5} - 871 \right] \text{Sc}^{1/3}$$

$$\bar{h}_{m,0-5} = \left( \frac{0.29 \times 10^{-4} \text{ m}^2/\text{s}}{1.25 \text{ m}} \right) \left[ 0.037 (6.25 \times 10^5)^{4/5} - 871 \right] (0.62)^{1/3}$$

$$\bar{h}_{m,0-5} = 0.0145 \text{ m/s.}$$

With  $\text{Re}_{x,4} = 5 \times 10^5$ , Eq. 7.31 gives

$$\bar{h}_{m,0-4} = \left( \frac{D_{AB}}{x_4} \right) 0.664 \text{Re}_{x,4}^{1/4} \text{Sc}^{1/3}$$

$$\bar{h}_{m,0-4} = \left( \frac{0.29 \times 10^{-4} \text{ m}^2/\text{s}}{1 \text{ m}} \right) \left[ 0.664 (5 \times 10^5)^{1/2} (0.62)^{1/3} \right]$$

$$\bar{h}_{m,0-4} = 0.0116 \text{ m/s.}$$

Hence,

$$n_{A,5} = [0.0145 \text{ m/s} \times 1.25 \text{ m} \times 1 \text{ m} - 0.0116 \text{ m/s} \times 1 \text{ m} \times 1 \text{ m}] (0.082 \text{ kg/m}^3)$$

$$n_{A,5} = 5.35 \times 10^{-4} \text{ kg/s} \cdot \text{m.} \quad <$$

Hence the evaporation rate is largest for Plate 5.

(c) Heat would have to be supplied to each plate at a rate which is equal to the evaporative cooling rate in order to maintain the prescribed temperature. Hence

$$q_5 = n_{A,5} h_{fg} = 5.35 \times 10^{-4} \text{ kg/s} \cdot \text{m} \times 2.383 \times 10^6 \text{ J/kg} = 1.275 \text{ kW/m.} \quad <$$

**COMMENTS:** The large value of  $q_5$  is a consequence of the significant evaporative cooling effect.

### PROBLEM 7.127

**KNOWN:** Dimensions and temperature of a cooling pond. Conditions of air flow.

**FIND:** Daily make-up water requirement.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Turbulent boundary layer over the entire surface, (3) Heat and mass transfer analogy is applicable.

**PROPERTIES:** Table A-4, Air ( $T = 300\text{K}$ , 1 atm):  $\nu = 15.89 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0263 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.707$ ; Table A-6, Water vapor (300K):  $\rho_{A,\text{sat}} = \nu_g^{-1} = 0.0256 \text{ kg/m}^3$ ; Table A-8, Water vapor-air (300K):  $D_{AB} = 0.26 \times 10^{-4} \text{ m}^2/\text{s}$ ,  $\text{Sc} = \nu/D_{AB} = 0.61$ .

**ANALYSIS:** The make-up water requirement must equal the daily water loss due to evaporation,

$$\Delta M = \dot{m}_{\text{evap}} \Delta t = \bar{h}_m (W \cdot L) \left[ \rho_{A,\text{sat}}(T_s) - \phi_\infty \rho_{A,\text{sat}}(T_\infty) \right] \cdot \Delta t.$$

From Eq. 7.41 with  $A = 0$ ,  $\bar{\text{Sh}}_L = 0.037 \text{ Re}_L^{4/5} \text{ Sc}^{1/3}$ , with

$$\text{Re}_L = \frac{u_\infty L}{\nu} = \frac{2 \text{ m/s} \times 1000 \text{ m}}{15.89 \times 10^{-6} \text{ m}^2/\text{s}} = 1.26 \times 10^8$$

$$\bar{\text{Sh}}_L = 0.037 \left( 1.26 \times 10^8 \right)^{4/5} (0.61)^{1/3} = 9.48 \times 10^4$$

$$\bar{h}_{m,L} = \frac{D_{AB} \bar{\text{Sh}}_L}{L} = \frac{0.26 \times 10^{-4} \text{ m}^2/\text{s} \times 9.48 \times 10^4}{1000 \text{ m}}$$

$$\bar{h}_{m,L} = 2.47 \times 10^{-3} \text{ m/s}.$$

Hence, the make-up water requirement is

$$\Delta M = 2.47 \times 10^{-3} \text{ m/s} (500 \text{ m} \times 1000 \text{ m}) 0.0256 \text{ kg/m}^3 (24 \text{ h} \times 3600 \text{ s/h})$$

$$\Delta M = 2.73 \times 10^6 \text{ kg/day}.$$

<

## PROBLEM 7.128

**KNOWN:** Dimensions and initial temperature of plate covered by liquid film. Properties of liquid. Velocity and temperature of air flow over the plates.

**FIND:** Initial rate of heat transfer from plate and rate of change of plate temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible effect of conveyor velocity on boundary layer development, (2) Plates are isothermal and at same temperature as liquid film, (3) Negligible heat transfer from sides of plate, (4) Smooth air-liquid interface, (5) Applicability of heat/mass transfer analogy, (6) Negligible solvent vapor in free stream, (7)  $Re_{x,c} = 5 \times 10^5$ , (8) Constant properties.

**PROPERTIES:** Table A-1, AISI 1010 steel (313K):  $c = 441 \text{ J/kg}\cdot\text{K}$ ,  $\rho = 7832 \text{ kg/m}^3$ . Table A-4,

Air ( $p = 1 \text{ atm}$ ,  $T_f = 303\text{K}$ ):  $\nu = 16.2 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0265 \text{ W/m}\cdot\text{K}$ ,  $Pr = 0.707$ . Prescribed: Solvent:  $\rho_{A,\text{sat}} = 0.75 \text{ kg/m}^3$ ,  $D_{AB} = 10^{-5} \text{ m}^2/\text{s}$ ,  $h_{fg} = 9 \times 10^5 \text{ J/kg}$ .

**SOLUTION:** The initial rate of heat transfer from the plate is due to both convection and evaporation.

$$q = q_{\text{conv}} + q_{\text{evap}} = \bar{h} A_s (T_i - T_\infty) + n_A h_{fg} = \bar{h} A_s (T_i - T_\infty) + \bar{h}_m A_s \rho_{A,\text{sat}} h_{fg}$$

With  $Re_L = u_\infty L / \nu = 1 \text{ m/s} \times 1 \text{ m} / 16.2 \times 10^{-6} \text{ m}^2/\text{s} = 6.17 \times 10^4$ , flow is laminar over the entire surface. Hence,

$$\bar{Nu}_L = 0.664 Re_L^{1/2} Pr^{1/3} = 0.664 (6.17 \times 10^4)^{1/2} (0.707)^{1/3} = 147$$

$$\bar{h} = (k/L) \bar{Nu}_L = (0.0265 \text{ W/m}\cdot\text{K} / 1 \text{ m}) 147 = 3.9 \text{ W/m}^2 \cdot \text{K}$$

Also, with  $Sc = \nu / D_{AB} = 16.2 \times 10^{-6} \text{ m}^2/\text{s} / 10^{-5} \text{ m}^2/\text{s} = 1.62$ ,

$$\bar{Sh}_L = 0.664 Re_L^{1/2} Sc^{1/3} = 0.664 (6.17 \times 10^4)^{1/2} (1.62)^{1/3} = 194$$

$$\bar{h}_m = (D_{AB}/L) \bar{Sh}_L = (10^{-5} \text{ m}^2/\text{s} / 1 \text{ m}) 194 = 0.00194 \text{ m/s}$$

Hence, with  $A_s = 2 L^2 = 2 \text{ m}^2$ ,

$$q = 2 \text{ m}^2 \left[ 3.9 \text{ W/m}^2 \cdot \text{K} (20^\circ\text{C}) + 0.00194 \text{ m/s} \times 0.75 \text{ kg/m}^3 \times 9 \times 10^5 \text{ J/kg} \right] = 156 \text{ W} + 2619 \text{ W} = 2775 \text{ W} <$$

Performing an energy balance at an instant of time for a control surface about the plate,  $-\dot{E}_{\text{out}} = \dot{E}_{\text{st}}$ , we obtain (Eq. 5.2),

$$\left. \frac{dT}{dt} \right|_i = -\frac{q}{\rho \delta L^2 c} = -\frac{2775 \text{ W}}{7832 \text{ kg/m}^3 \times 0.006 \text{ m} (1 \text{ m})^2 441 \text{ J/kg}\cdot\text{K}} = -0.13^\circ\text{C/s} <$$

**COMMENTS:** (1) Heat transfer by evaporation exceeds that due to convection by more than an order of magnitude, (2) The total heat rate is small enough to render the lumped capacitance approximation excellent.

### PROBLEM 7.129

**KNOWN:** Dimensions of round jet array. Jet exit velocity and temperature. Temperature of paper.

**FIND:** Drying rate per unit surface area.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Applicability of heat and mass transfer analogy. (2) Paper motion has a negligible effect on convection ( $u \ll V_e$ ), (3) Air is dry.

**PROPERTIES:** Table A-4, Air (300K, 1 atm):  $\nu = 15.89 \times 10^{-6} \text{ m}^2/\text{s}$ ; Table A-6, Saturated water (300K):  $\rho_{A,\text{sat}} = \nu_g^{-1} = 0.0256 \text{ kg/m}^3$ ; Table A-8, water vapor-air (300K):  $D_{AB} = 0.26 \times 10^{-4} \text{ m}^2/\text{s}$ ,  $Sc = 0.61$ .

**ANALYSIS:** The average mass evaporation flux is

$$n''_A = \bar{h}_m (\rho_{A,s} - \rho_{A,e}) = \bar{h}_m \rho_{A,s}$$

For an array of round nozzles,

$$\bar{Sh} = 0.5 K G Re^{2/3} Sc^{0.42}$$

where  $Re = V_e D / \nu = 20 \text{ m/s} \times 0.02 \text{ m} / 15.89 \times 10^{-6} \text{ m}^2/\text{s} = 25,170$  and, with  $H/D = 10$  and

$$A_r = \pi D^2 / 4S^2 = 0.0314,$$

$$K = \left[ 1 + \left( \frac{H/D}{0.6/A_r^{1/2}} \right)^6 \right]^{-0.05} = \left[ 1 + \left( \frac{10}{3.39} \right)^6 \right]^{-0.05} = 0.723$$

$$G = 2A_r^{1/2} \frac{1 - 2.2A_r^{1/2}}{1 + 0.2(H/D - 6)A_r^{1/2}} = 0.354 \frac{1 - 0.390}{1 + 0.2(4)0.177} = 0.189$$

Hence,

$$\bar{h}_m = \frac{D_{AB}}{D} \bar{Sh} = \frac{0.26 \times 10^{-4} \text{ m}^2/\text{s}}{0.02 \text{ m}} \left[ 0.5 \times 0.723 \times 0.189 (25,170)^{2/3} (0.61)^{0.42} \right] = 0.062 \text{ m/s}$$

The average evaporative flux is then

$$n''_A = 0.062 \text{ m/s} (0.0256 \text{ kg/m}^3) = 0.0016 \text{ kg/s} \cdot \text{m}^2 \quad <$$

**COMMENTS:** Note that, for maximum evaporation, the ratio  $D/H = 0.1$  is less than the optimum of  $(D/H)_{\text{op}} \approx 0.2$ , as is  $S/H = 0.5$  less than  $(S/H)_{\text{op}} \approx 1.4$ . If  $H$  is reduced by a factor of 2 and  $S$  is increased by 40%, a near optimal condition could be achieved.

## PROBLEM 7.130

**KNOWN:** Paper mill process using radiant heat for drying.

**FIND:** (a) Evaporative flux at a distance 1 m from roll edge; corresponding irradiation,  $G$  ( $\text{W}/\text{m}^2$ ), required to maintain surface at  $T_s = 300$  K, and (b) Compute and plot variations of  $h_{m,x}(x)$ ,  $N''_A(x)$ , and  $G(x)$  for the range  $0 \leq x \leq 1$  m when the velocity and temperature are increased to 10 m/s and 340 K, respectively.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Heat-mass transfer analogy, (3) Paper slurry (water-fiber mixture) has water properties, (4) Water vapor behaves as perfect gas, (5) All irradiation absorbed by slurry, (6) Negligible emission from the slurry, (7)  $Re_{x,c} = 5 \times 10^5$ .

**PROPERTIES:** Table A.4, Air ( $T_f = 315$  K, 1 atm):  $\nu = 17.40 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0274 \text{ W}/\text{m}\cdot\text{K}$ ,  $Pr = 0.705$ ; Table A.8, Water vapor-air ( $T_f = 315$  K):  $D_{AB} = 0.26 \times 10^{-4} \text{ m}^2/\text{s}$  ( $315/298$ )<sup>3/2</sup> =  $0.28 \times 10^{-4} \text{ m}^2/\text{s}$ ,  $Sc = \nu_B/D_{AB} = 0.616$ ; Table A.6, Saturated water vapor ( $T_s = 330$  K):  $\rho_{A,sat} = 1/\nu_g = 0.1134 \text{ kg}/\text{m}^3$ ,  $h_{fg} = 2366 \text{ kJ}/\text{kg}$ .

**ANALYSIS:** (a) Recognize that the drying process can be modeled as flow over a flat plate with heat and mass transfer. For a unit area at  $x = 1$  m,

$$n''_{A,x} = h_{m,x} (\rho_{A,s} - \rho_{A,\infty}) = h_{m,x} [\rho_{A,sat}(T_s) - \phi_\infty \rho_{A,sat}(T_\infty)] \quad (1)$$

Evaluate  $Re_x$  to determine the nature of flow, select a correlation to estimate  $h_{m,x}$ ,

$$Re_x = u_\infty x / \nu_B = (5 \text{ m/s} \times 1 \text{ m}) / (17.40 \times 10^{-6} \text{ m}^2/\text{s}) = 2.874 \times 10^5.$$

Since  $Re_x < 5 \times 10^5$ , the flow is laminar. Invoking the heat-mass analogy,

$$Sh_x = \frac{h_{m,x} x}{D_{AB}} = 0.332 Re_x^{1/2} Sc^{1/3} \quad (2)$$

$$h_{m,x} = (0.28 \times 10^{-4} \text{ m}^2/\text{s} / 1 \text{ m}) \times 0.332 (2.874 \times 10^5)^{1/2} (0.616)^{1/3} = 4.24 \times 10^{-3} \text{ m/s}.$$

Hence, the evaporative flux at  $x = 1$  m is

$$n''_{A,x} = 4.24 \times 10^{-3} \text{ m/s} (0.1134 \text{ kg}/\text{m}^3 - 0) = 4.81 \times 10^{-4} \text{ kg}/\text{s} \cdot \text{m}^2 <$$

From an energy balance on the differential element at  $x = 1$  m (see above),

$$G = q''_{conv} + q''_{evap} = h_x (T_s - T_\infty) + n''_{A,x} h_{fg}. \quad (3)$$

Continued...

### PROBLEM 7.130 (Cont.)

To estimate  $h_x$ , invoke the heat-mass transfer analogy using the correlation of Eq. (2),

$$h_x = h_{m,x} \frac{k}{D_{AB}} \left( \frac{Pr}{Sc} \right)^{1/3} = 4.24 \times 10^{-3} \text{ m/s} \left( \frac{0.0274 \text{ W/m} \cdot \text{K}}{0.28 \times 10^{-4} \text{ m}^2/\text{s}} \right) \left( \frac{0.705}{0.616} \right)^{1/3} = 4.34 \text{ W/m}^2 \cdot \text{K} \quad (4)$$

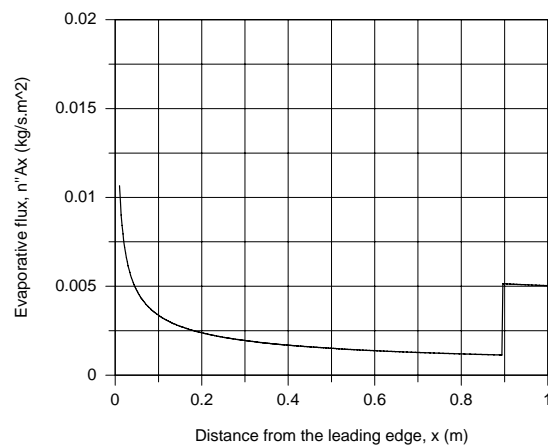

Hence, from Eq. (3), the radiant power required to maintain the slurry at  $T_s = 330 \text{ K}$  is

$$G = 4.34 \text{ W/m}^2 \cdot \text{K} (330 - 300) \text{ K} + 4.81 \times 10^{-4} \text{ kg/s} \cdot \text{m}^2 \times 2366 \times 10^3 \text{ J/kg}$$

$$G = (130 + 1138) \text{ W/m}^2 = 1268 \text{ W/m}^2 .$$

<

(b) Equations (1), (3) and (4) were entered into the *IHT Workspace*. The *Correlations Tool, External Flow, Local coefficients for Laminar or Turbulent Flow* was used to estimate the heat transfer convection coefficient. The results for  $h_{m,x}(x)$ ,  $n''_{A,x}(x)$  and  $G(x)$  were evaluated, and are plotted below for  $T_s = 340 \text{ K}$  and  $u_\infty = 10 \text{ m/s}$ .

**COMMENTS:** (1) The abrupt change in the parameter plots occurs at the transition,  $x_c = 0.9 \text{ m}$ .

### PROBLEM 7.131

**KNOWN:** Geometry and air flow conditions for a water storage channel.

**FIND:** (a) Evaporation rate, (b) Expression for rate of change of water layer depth and time required for complete evaporation.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Smooth water surface and negligible free stream turbulence, (3) Heat and mass transfer analogy is applicable, (4)  $Re_{x,c} = 5 \times 10^5$ , (5) Perfect gas behavior for water vapor.

**PROPERTIES:** Table A-4 Air ( $25^\circ\text{C} = 298\text{K}$ ):  $\nu = 15.71 \times 10^{-6} \text{ m}^2/\text{s}$ ; Table A-6, Water ( $25^\circ\text{C} = 298\text{K}$ ):  $\rho_{A,sat} = \nu_g^{-1} = 0.0226 \text{ kg/m}^3$ ,  $\rho_f = \nu_f^{-1} = 997 \text{ kg/m}^3$ ; Table A-8, Water vapor-air ( $25^\circ\text{C} = 298\text{K}$ ):  $D_{AB} = 0.26 \times 10^{-4} \text{ m}^2/\text{s}$ ,  $Sc = \nu/D_{AB} = 0.60$ .

**ANALYSIS:** (a) The evaporation rate is  $n_A = \bar{h}_m A_s (\rho_{A,sat} - \rho_{A,\infty}) = \bar{h}_m (w \times L) \rho_{A,sat} (1 - \phi_\infty)$ . With

$$Re_L = u_\infty L / \nu = 5 \text{ m/s} \times 25 \text{ m} / 15.71 \times 10^{-6} \text{ m}^2/\text{s} = 7.96 \times 10^6$$

$$\text{Eq. 7.42 yields } \bar{Sh}_L = \left[ 0.037 (7.96 \times 10^6)^{4/5} - 871 \right] (0.6)^{1/3} = 9616$$

$$\bar{h}_m = 9616 D_{AB} / L = 9616 \times 0.26 \times 10^{-4} \text{ m}^2/\text{s} / (25 \text{ m}) = 0.010 \text{ m/s.}$$

With  $w = 2z = 2\text{ m}$ ,

$$n_A = 0.01 \text{ m/s} (2\text{ m} \times 25\text{ m}) 0.0226 \text{ kg/m}^3 (0.5) = 0.00565 \text{ kg/s} = 20.3 \text{ kg/h.} \quad <$$

(b) Performing a mass balance on a control volume about the water,

$$-n_A = \dot{m}_{A,st} = \frac{d}{dt} (\rho_f V) \quad -\bar{h}_m (2zL) \rho_{A,sat} (1 - \phi_\infty) = \frac{d}{dt} (\rho_f z^2 L)$$

$$\frac{dz}{dt} = -\bar{h}_m \frac{\rho_{A,sat}}{\rho_f} (1 - \phi_\infty).$$

$$\text{Integrating, } \int_z^0 dz = -\bar{h}_m \frac{\rho_{A,sat}}{\rho_f} (1 - \phi_\infty) \int_0^t dt$$

$$t = \frac{z \rho_f}{\bar{h}_m \rho_{A,sat}} \frac{1}{1 - \phi_\infty} = \frac{1 \text{ m} \times 997 \text{ kg/m}^3}{0.01 \text{ m/s} \times 0.0226 \text{ kg/m}^3 (1 - 0.5)} = 8.82 \times 10^6 \text{ s} = 2451 \text{ h} = 102 \text{ d.} \quad <$$

**COMMENTS:** Although the evaporation rate decreases with increasing time due to decreasing  $A_s$ ,  $dz/dt$  remains constant and the water depth decreases linearly.

### PROBLEM 7.132

**KNOWN:** Mass change for a given time period of a solid naphthalene cylinder subjected to cross flow of air for prescribed conditions.

**FIND:** (a) Mass transfer coefficient,  $\bar{h}_m$ , based upon experimental observations and (b)  $\bar{h}_m$  based upon appropriate correlation.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Negligible naphthalene vapor in free stream, (3) Heat-mass transfer analogy applies.

**PROPERTIES:** Table A-4, Air (299K, 1 atm):  $\nu = 15.80 \times 10^{-6} \text{ m}^2/\text{s}$ ; Table A-6, Naphthalene vapor-air (298K, 1 atm):  $D_{AB} = 0.62 \times 10^{-5} \text{ m}^2/\text{s}$ ; Naphthalene (given):  $\mathcal{M} = 128.16 \text{ kg/kmol}$ ,  $p_{\text{sat}} = p \times 10^E$  where  $E = 8.67 - (3766/T)$  with  $p[\text{bar}]$  and  $T[\text{K}]$ .

**ANALYSIS:** (a) The rate equation for the sublimation of naphthalene vapor from the solid naphthalene can be written in terms of the mass transfer coefficient.

$$\bar{h}_m = \frac{n_A}{A_s (\rho_{A,s} - \rho_{A,\infty})} \quad (1)$$

where  $A_s = \pi D \ell$ . From the mass loss and time observations

$$n_A = \frac{\Delta m}{\Delta t} = \frac{0.35 \times 10^{-3} \text{ kg}}{39 \times 60 \text{ s}} = 1.50 \times 10^{-7} \text{ kg/s.}$$

The saturation density of the vapor at the solid surface,  $\rho_{A,s}$ , can be determined from the perfect gas relation,

$$\rho_{A,s} = C_{A,s} \mathcal{M}_A = \frac{p_{\text{sat}}(T_s)}{(\mathcal{R}/\mathcal{M}_A) T_s} \quad (2)$$

The saturation pressure,  $p_{\text{sat}}$ , is given by

$$p_{\text{sat}} = p \times 10^E \quad (3)$$

where  $E = 8.67 - (3766/T) = 8.67 - (3766/299\text{K}) = -3.925$

$$p = 750.6 \text{ mm Hg} \times \frac{1 \text{ N/m}^2}{2.953 \times 10^{-4} \text{ in Hg}} \times \frac{1 \text{ in}}{25.4 \text{ mm}} \times \frac{1 \text{ bar}}{1 \times 10^5 \text{ N/m}^2} = 1.001 \text{ bar}$$

or 
$$p_{\text{sat}} = 1.001 \text{ bar} \times 10^{-3.925} = 1.190 \times 10^{-4} \text{ bar.}$$

Continued ...

### PROBLEM 7.132 (Cont.)

Substituting into Eq. (2),

$$\rho_{A,s} = 1.190 \times 10^{-4} \text{ bar} / \frac{8.314 \times 10^{-2} \text{ m}^3 \cdot \text{bar/kmol} \cdot \text{K}}{128.16 \text{ kg/kmol}} \times 299 \text{ K} = 6.135 \times 10^{-4} \text{ kg/m}^3.$$

Using the parameters required for Eq. (1), the mass transfer coefficient is

$$\bar{h}_m = \frac{1.50 \times 10^{-7} \text{ kg/s}}{\pi (18.4 \times 10^{-3} \text{ m}) (88.9 \times 10^{-3} \text{ m})} [6.135 \times 10^{-4} - 0] \text{ kg/m}^3$$

$$\bar{h}_m = 4.76 \times 10^{-2} \text{ m/s.} \quad <$$

(b) Invoking the heat-mass transfer analogy and assuming a Prandtl number ratio of unity, Eq. 7.53 can be used to estimate  $\bar{h}_m$ ,

$$\overline{\text{Sh}}_D = \frac{\bar{h}_m D}{D_{AB}} = C \text{Re}_D^m \text{Sc}^n.$$

With

$$\text{Re}_D = \frac{VD}{\nu} = 12 \text{ m/s} (18.4 \times 10^{-3} \text{ m}) / 15.80 \times 10^{-6} \text{ m}^2/\text{s} = 13,975$$

it follows from Table 7.4 that  $C = 0.26$  and  $m = 0.6$ . With

$$\text{Sc} = \nu/D_{AB} = 15.80 \times 10^{-6} \text{ m}^2/\text{s} / 0.62 \times 10^{-5} \text{ m}^2/\text{s} = 2.55$$

$$n = 0.37 \text{ and}$$

$$\overline{\text{Sh}}_D = 0.26 (13,975)^{0.6} (2.55)^{0.37} = 112.9$$

and

$$\bar{h}_m = \overline{\text{Sh}}_D \frac{D_{AB}}{D} = 112.9 \times \frac{0.62 \times 10^{-5} \text{ m}^2/\text{s}}{18.4 \times 10^{-3} \text{ m}} = 3.80 \times 10^{-2} \text{ m/s.} \quad <$$

**COMMENTS:** The result from the correlation is 20% less than the experimental result. This may be considered reasonable in view of the uncertainties associated with the observations and the approximate nature of the correlation.

### PROBLEM 7.133

**KNOWN:** Flow of dry air over a cylindrical medium saturated with water.

**FIND:** (a) Mass rate of water vapor evaporated per unit length  $n'_A$ , when water-air is at 300 K, (b) Briefly explain change in mass rate if temperatures are at 325 K.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Heat-mass transfer analogy.

**PROPERTIES:** Table A.4, Air (300 K, 1 atm):  $\nu = 15.89 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.707$ ; Air (325 K, 1 atm):  $\nu = 18.41 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.703$ ; Table A.8, Water vapor-air (300 K):  $D_{AB} = 0.26 \times 10^{-4} \text{ m}^2/\text{s}$ ; Table A.6, Water vapor (300 K, 1 atm):  $\rho_{A,\text{sat}} = (\nu_g)^{-1} = (39.13 \text{ m}^3/\text{kg})^{-1} = 0.0256 \text{ kg/m}^3$ ; Water vapor (325 K, 1 atm):  $\rho_{A,\text{sat}} = (\nu_g)^{-1} = (11.06 \text{ m}^3/\text{kg})^{-1} = 0.0904 \text{ kg/m}^3$ .

**ANALYSIS:** (a) For cross-flow over a cylinder, Eq. 7.52,

$$\overline{\text{Sh}}_D = C \text{Re}^m \text{Sc}^{1/3} \quad (1)$$

where  $m, n$  are taken from Table 7.2. Calculate the Reynolds number,  $\text{Re}_D = VD/\nu = 15 \text{ m/s} \times 0.04 \text{ m} / 15.89 \times 10^{-6} \text{ m}^2/\text{s} = 37,760$ . With  $C = 0.193$ ,  $m = 0.618$ , and  $\text{Sc} \equiv \nu/D_{AB}$ ,

$$\overline{\text{Sh}}_D = \frac{\bar{h}_m D}{D_{AB}} = 0.193 (37,760)^{0.618} \left[ 15.89 \times 10^{-6} \text{ m}^2/\text{s} / 0.26 \times 10^{-4} \text{ m}^2/\text{s} \right]^{1/3} = 110.4 \quad (2)$$

$$\bar{h}_m = \overline{\text{Sh}}_D D_{AB} / D = 110.4 \times 0.26 \times 10^{-4} \text{ m}^2/\text{s} / 0.04 \text{ m} = 0.0717 \text{ m/s}$$

The evaporation rate, with  $A_s = \pi D \cdot \ell$ , is

$$n_A = \bar{h}_m A_s (\rho_{A,s} - \rho_{A,\infty}) \quad n'_A = n_A / \ell = \bar{h}_m \pi D (\rho_{A,s} - \rho_{A,\infty}) \quad (3)$$

$$n'_A = 0.0717 \text{ m/s} (\pi \times 0.04 \text{ m}) (0.0256 - 0) \text{ kg/m}^3 = 2.31 \times 10^{-4} \text{ kg/s} \cdot \text{m} \quad <$$

(b) The foregoing equations were entered into the *IHT Workspace*, and using the *Properties Tools* for air and water vapor thermophysical properties, the evaporation rate  $n'_A$  was calculated as a function of air-water temperatures ( $T_s = T_{\text{inf}}$ ).

Continued...

## PROBLEM 7.133 (Cont.)

As expected, the evaporation rate increased with increasing temperature markedly. For a 50 K increase, the evaporation rate increased by a factor of approximately 12.

**COMMENTS:** (1) What parameters cause this high sensitivity of  $n'_A$  to  $T_s$ ? From the IHT analysis, we observed only modest changes in  $D_{AB}$  ( $0.26$  to  $0.33 \times 10^{-4}$  m<sup>2</sup>/s) and  $\bar{h}_m$  ( $0.07273$  to  $0.0779$  m/s) over the range 300 to 350 K. The density of water vapor,  $\rho_{A,s}$ , however, is highly temperature dependent as can be seen by examining the steam tables, Table A.6. Find  $\rho_{A,s}$  (300 K) =  $0.02556$  kg/m<sup>3</sup> while  $\rho_{A,s}$  (350 K) =  $0.260$  kg/m<sup>3</sup>, which accounts for more than a factor of 10 change.

(2) A copy of the IHT Workspace used to perform the analysis is shown below.

```
// The Mass Transfer Rate Equation:
n'A = hmbars * pi * D * (rhoAs - 0) // Eq (3)
n'A_plot = 1e4 * n'A // Scale change for plotting

// Mass Transfer Coefficient Correlation:
ShDbar = C * ReD^m * Sc^(1/3) // Eq (1,2)
ShDbar = hmbars * D / DAB
C = 0.193 // Table 7.2, 4000 <= ReD <= 40000
m = 0.618
ReD = uinf * D / nu
Sc = nu / DAB

// Properties Tool - Water Vapor:
// Water property functions :T dependence, From Table A.6
// Units: T(K), p(bars);
xs = 1 // Quality (0=sat liquid or 1=sat vapor)
rhoAs = rho_Tx("Water",Ts,xs) // Density, kg/m^3

// Properties Tool - Air:
// Air property functions : From Table A.4
// Units: T(K); 1 atm pressure
nu = nu_T("Air",Tf) // Kinematic viscosity, m^2/s

// Properties, Table A.8, Water Vapor - Air:
DAB = 0.26e-4 * (Tf / 298)^1.5 // Table A.8
Tf = (Ts + Tinf) / 2

// Assigned Variables:
Ts = 300 // Surface temperature, K
D = 0.040 // Diameter, m
uinf = 15 // Airstream velocity, m/s
Tinf = Ts // Airstream temperature, K
```

**PROBLEM 7.134**

**KNOWN:** Dry air at prescribed temperature and velocity flowing over a long, wetted cylinder of diameter 20 mm. Embedded electrical heater maintains the surface at  $T_s = 20^\circ\text{C}$ .

**FIND:** (a) Water evaporation rate per unit length (kg/h-m) and electrical power per unit length  $P'_e$  (W/m) required to maintain steady-state conditions, and (b) The temperature of the cylinder after all the water has evaporated for the same airstream conditions and heater power of part (a).

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Constant properties and (3) Heat-mass transfer analogy is applicable.

**PROPERTIES:** Table A.4, Air ( $T_f = (T_s + T_\infty)/2 = 300\text{ K}$ , 1 atm):  $\rho = 1.16\text{ kg/m}^3$ ,  $c_p = 1007\text{ J/kg}\cdot\text{K}$ ,  $k = 0.0263\text{ W/m}\cdot\text{K}$ ,  $\nu = 15.94 \times 10^{-6}\text{ m}^2/\text{s}$ ,  $\alpha = 2.257 \times 10^{-5}\text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.707$ . Table A.6, Water ( $T_s = 20^\circ\text{C} = 293\text{ K}$ ):  $\rho_{A,s} = 1/\nu_g = 1/59.04 = 0.0169\text{ kg/m}^3$ ,  $h_{fg} = 2454\text{ kJ/K}$ ; Table A.8, Water-air ( $T_f = 300\text{ K}$ ):  $D_{AB} = 0.26 \times 10^{-4}\text{ m}^2/\text{s}$ .

**ANALYSIS:** (a) Perform an energy balance on the cylinder,

$$\dot{E}_{in} - \dot{E}_{out} = 0 \quad P'_e - q'_{conv} - q'_{evap} = 0 \quad (1)$$

where the convection and evaporation rate equations are,

$$q'_{conv} = \bar{h}_D \pi D (T_s - T_\infty) \quad (2)$$

$$q_{evap} = n_A h_{fg} = \bar{h}_m \pi D (\rho_{A,s} - \rho_{A,\infty}) h_{fg} \quad (3)$$

The convection coefficient can be estimated from the Churchill-Bernstein correlation, Eq. 7.54,

$$\bar{Nu}_D = 0.3 + \frac{0.62 \text{Re}_D^{1/2} \text{Pr}^{1/3}}{\left[1 + (0.4/\text{Pr})^{2/3}\right]^{1/4}} \left[1 + \left(\frac{\text{Re}_D}{282,000}\right)^{5/8}\right]^{4/5}$$

$$\text{Re}_D = \frac{VD}{\nu} = \frac{15\text{ m/s} \times 0.020\text{ m}}{15.94 \times 10^{-6}\text{ m}^2/\text{s}} = 18,821$$

$$\bar{Nu}_D = 0.3 + \frac{0.62(18,821)^{1/2} (0.707)^{1/3}}{\left[1 + (0.4/0.707)^{2/3}\right]^{1/4}} \left[1 + \left(\frac{18,821}{282,000}\right)^{5/8}\right]^{4/5} = 76.5$$

$$\bar{h}_D = \frac{k}{D} \bar{Nu}_D = \frac{0.0263\text{ W/m}\cdot\text{K}}{0.020\text{ m}} \times 76.5 = 101\text{ W/m}^2\cdot\text{K}$$

Continued...

**PROBLEM 7.134 (Cont.)**

Invoking the heat-mass analogy, Chapter 6, with  $n = 1/3$

$$\frac{\bar{h}_D}{\bar{h}_m} = \rho c_p \left( \frac{\alpha}{D_{AB}} \right)^{2/3} = 1.16 \text{ kg/m}^3 \times 1007 \text{ J/kg} \cdot \text{K} \left( \frac{2.257 \times 10^{-5} \text{ m}^2/\text{s}}{0.26 \times 10^{-4} \text{ m}^2/\text{s}} \right)^{2/3} = 1063 \text{ J/m}^3 \cdot \text{K}$$

$$\bar{h}_m = 101 \text{ W/m}^2 \cdot \text{K} / 1063 \text{ J/m}^3 \cdot \text{K} = 0.095 \text{ m/s}$$

Substituting numerical values, the energy balance, Eq. (1),

$$P_e - 101 \text{ W/m}^2 \cdot \text{K} \times \pi \times 0.020 \text{ m} (20 - 35) \text{ K} \\ - 0.095 \text{ m/s} \times \pi \times 0.020 \text{ m} (0.0169 - 0) \text{ kg/m}^3 \times 2454 \times 10^3 \text{ J/kg} \cdot \text{K} = 0$$

$$P_e = -95.1 \text{ W/m} + 247 \text{ W/m} = 152 \text{ W/m} \quad <$$

The evaporation rate is

$$n_A = \bar{h}_m \pi D (\rho_{A,s} - \rho_{A,\infty}) = 0.095 \text{ m/s} \pi \times 0.020 \text{ m} (0.0169 - 0) \text{ kg/m}^3 = 0.362 \text{ kg/h} \cdot \text{m} \quad <$$

(b) When the cylinder is dry, the energy balance is

$$P'_e = \bar{h}_D \pi D (T_s - T_\infty)$$

$$T_s = T_\infty + P'_e / \bar{h}_D \pi D = 35^\circ \text{C} + 152 \text{ W/m} / \left( 101 \text{ W/m}^2 \cdot \text{K} \pi \times 0.020 \text{ m} \right) = 58.9^\circ \text{C} \quad <$$

**COMMENTS:** Using *IHT Correlations Tool, External Flow, Cylinder*, the calculation of part (b) was performed using the proper film temperature,  $T_f = 316.8 \text{ K}$ , to find  $\bar{h}_D = 99.4 \text{ W/m}^2 \cdot \text{K}$  and  $T_s = 52.6^\circ \text{C}$ .

## PROBLEM 7.135

**KNOWN:** Dry air at prescribed temperature and velocity flows over a rod covered with a thin porous coating saturated with water. The ends of the rod are attached to heat sinks maintained at a constant temperature.

**FIND:** Temperature at the midspan of the rod and evaporation rate from the surface using a steady-state, finite-difference analysis. Validate your code, without the evaporation process, by comparing the temperature distribution with the analytical solution of a fin.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) One-dimensional conduction in rod, (3) Constant properties, and (4) Heat-mass transfer analogy is applicable.

**PROPERTIES:** Table A.4, Air ( $\bar{T}_f$ , see Eq. (2); 1 atm):  $\rho$ ,  $c_p$ ,  $k$ ,  $\alpha$ , Pr; Table A.6, Water ( $T_m = T_{\text{sat},m}$ , 1 atm):  $\rho_{A,\text{sat}} = 1/v_g$ ,  $h_{fg}$ ; Table A.8, Water Vapor-Air ( $\bar{T}_f$ , 1 atm):  $D_{AB} = D_{AB}(298 \text{ K}) \times (\bar{T}_f / 298)^{1.5}$ .

**ANALYSIS:** As suggested, the 10-node network shown above represents the half-length of the system. Performing an energy balance on the control volume about the  $m$ -th node, the finite-difference equation for the system is derived.

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = 0$$

$$q_a - q_{\text{evap}} + q_b + q_c = 0$$

$$kA_c \frac{T_{m+1} - T_m}{\Delta x} - n_{A,m} h_{fg,m} + \bar{h} P \Delta x (T_\infty - T_m) + kA_c \frac{T_{m-1} - T_m}{\Delta x} = 0 \quad (1)$$

where the cross-sectional area and perimeter are  $A_c = \pi D^2/4$  and  $P = \pi D$ , respectively. The average heat transfer coefficient  $\bar{h}$  can be evaluated using the Churchill-Bernstein correlation, Eq. 7.54, evaluating thermophysical properties at an average film temperature for the system,

$$\bar{T}_f = [(T_1 + T_b)/2 + T_\infty]/2 \quad (2)$$

The evaporation rate from Eq. (1) can be expressed as

$$n_{A,m} = \bar{h}_{D,m} P \Delta x (\rho_{A,s,m} - 0) \quad (3)$$

where  $\bar{h}_{D,m}$  can be determined from the heat-mass analogy, Eq. 6.60, with  $n = 1/3$ ,

$$\frac{\bar{h}}{\bar{h}_m} = \rho c_p \left( \frac{\alpha}{D_{AB}} \right)^{-2/3} \quad (4)$$

Continued...

## PROBLEM 7.135 (Cont.)

where all properties are evaluated at  $\bar{T}_f$ . The density of water vapor,  $\rho_{A,s,m}$ , as well as the heat of vaporization,  $h_{fg,m}$ , must be evaluated at the nodal temperature  $T_m$ .

Using the *IHT Correlation Tool, External Flow, Cylinder*, an estimate of  $\bar{h}_D = 101 \text{ W/m}^2\cdot\text{K}$  was obtained with  $\bar{T}_f = 298.5 \text{ K}$  (based upon assumed value of  $T_1 = 27^\circ\text{C}$ ). From the analogy, Eq. (4), find that  $\bar{h}_{D,m} = 0.0772 \text{ m/s}$ . Using the *IHT Workspace*, the finite-difference equations, Eq. (1), were entered and the temperature distribution (K, Case 1) determined as tabulated below. Using this same code with  $\bar{h}_{D,m} = 1.0 \times 10^{-10} \text{ m/s}$ , the temperature distribution (K, Case 2) was obtained. The results compared identically with the analytical solution for a fin with an adiabatic tip using the *IHT Model, Extended Surface, Rectangular Pin Fin*.

Case	$T_1$	$T_2$	$T_3$	$T_4$	$T_5$	$T_6$	$T_7$	$T_8$	$T_9$	$T_{10}$	$T_b$
1	287	287.2	287.6	288.3	289.4	290.9	292.9	295.4	298.6	302.7	308
2	300.3	300.4	300.6	300.9	301.4	302.1	302.8	303.8	305	306.4	308

The evaporation rate obtained by summing rates from each nodal element including node b is

$$n_{A,\text{tot}} = 1.08 \times 10^{-5} \text{ kg/s}$$

**COMMENTS:** A copy of the *IHT Workspace* used to perform the above analysis is shown below.

```
// Nodal finite-difference equations (Only Nodes 1, 2 and 10 shown):

```

### PROBLEM 7.136

**KNOWN:** The dimensions of a cylinder which approximates the human body.

**FIND:** (a) Heat loss by forced convection to ambient air, (b) Total heat loss when a water film covers the surface.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Direct contact between skin and air (no clothing), (2) Negligible radiation effects, (3) Heat and mass transfer analogy is applicable, (4) Water vapor is an ideal gas.

**PROPERTIES:** Table A-6, Water (30°C = 303 K):  $\rho_{A,\text{sat}} = v_g^{-1} = 0.0336 \text{ kg/m}^3$ ,  $h_{fg} = 2431 \text{ kJ/kg}$ ;  
 Water (20°C = 293K):  $\rho_{A,\text{sat}} = 0.017 \text{ kg/m}^3$ ; Table A-4, Air: ( $T_\infty = 20^\circ\text{C} = 293\text{K}$ ):  $\nu = 15.27 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 25.7 \times 10^{-3} \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.71$ ; Table A-8, Water vapor-air (300K):  $D_{AB} = 26 \times 10^{-6} \text{ m}^2/\text{s}$ ,  
 $\text{Sc} = \nu/D_{AB} = 0.59$ .

**ANALYSIS:** (a) The heat rate is

$$q = \bar{h}(\pi DL) (T_s - T_\infty).$$

With

$$\text{Re}_D = \frac{VD}{\nu} = \frac{(10 \text{ m/s})(0.3 \text{ m})}{15.27 \times 10^{-6} \text{ m}^2/\text{s}} = 1.96 \times 10^5$$

obtain  $\bar{h}$  from Eq. 7.53, where  $n = 0.37$  and, from Table 7.4,  $C = 0.26$  and  $m = 0.6$ ,

$$\overline{\text{Nu}}_D = 0.6 \left( 1.96 \times 10^5 \right)^{0.6} (0.71)^{0.37} (0.71/0.71)^{0.25} = 343.$$

$$\text{Hence } \bar{h} = \overline{\text{Nu}}_D \frac{k}{D} = 343 \times \frac{25.7 \times 10^{-3} \text{ W/m}\cdot\text{K}}{0.3 \text{ m}} = 29.4 \text{ W/m}^2 \cdot \text{K}$$

$$\text{and } q = 29.4 \text{ W/m}^2 \cdot \text{K} (\pi \times 0.3 \text{ m} \times 1.75 \text{ m}) (30 - 20)^\circ\text{C} = 485 \text{ W.} \quad \leftarrow$$

(b) The total heat loss with the water film includes latent, as well as sensible, contributions and may be expressed as

$$q = \bar{h}(\pi DL) (T_s - T_\infty) + \dot{n}_A h_{fg}$$

$$\text{where } \dot{n}_A = \bar{h}_m (\pi DL) \left[ \rho_{A,\text{sat}}(T_s) - \rho_{A,\infty} \right]$$

$$\rho_{A,\text{sat}}(T_s) = 0.0336 \text{ kg/m}^3 \quad \rho_{A,\infty} \approx \phi \rho_{A,\text{sat}}(T_\infty) = 0.6(0.017) = 0.010 \text{ kg/m}^3.$$

Continued ...

### PROBLEM 7.136 (Cont.)

The convection mass transfer coefficient may be obtained by expressing the mass transfer analog of Eq. 7.53. Neglecting the Pr ratio, the analogous form is

$$\begin{aligned}\overline{Sh}_D &= 0.26 Re_D^{0.6} Sc^{0.37} \\ \overline{Sh}_D &= 0.26 \left(1.96 \times 10^5\right)^{0.6} (0.59)^{0.37} = 320.\end{aligned}$$

Hence

$$\bar{h}_m = 320 \frac{D_{AB}}{D} = \frac{320 \times 0.26 \times 10^{-4} \text{ m}^2/\text{s}}{0.3 \text{ m}} = 0.028 \text{ m/s}.$$

The evaporation rate is then

$$\begin{aligned}\dot{n}_A &= 0.028 \text{ m/s} (\pi \times 0.3 \text{ m} \times 1.75 \text{ m}) [0.0336 - 0.010] \text{ kg/m}^3 \\ \dot{n}_A &= 1.09 \times 10^{-3} \text{ kg/s}.\end{aligned}$$

Hence,

$$q = 485 \text{ W} + 1.09 \times 10^{-3} \text{ kg/s} \times 2.431 \times 10^6 \text{ J/kg}$$

$$q = 485 \text{ W} + 2650 \text{ W} = 3135 \text{ W}.$$

<

**COMMENTS:** The evaporative (latent) heat loss dominates over the sensible heat loss. Its effect is often felt when stepping out of a swimming pool or other body of water.

### PROBLEM 7.137

**KNOWN:** Horizontal tube exposed to transverse stream of dry air.

**FIND:** Equation to determine heat transfer enhancement due to wetting. Evaluate enhancement for prescribed conditions.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Heat-mass transfer analogy applicable, (3) Water vapor behaves as perfect gas.

**PROPERTIES:** Table A-4, Air (310K, 1 atm):  $\rho = 1.1281 \text{ kg/m}^3$ ,  $c_p = 1007.4 \text{ J/kg}$ ,  $\nu = 16.90 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.706$ ; Table A-8, Air-water vapor mixture (310K):  $D_{AB} \approx 0.26 \times 10^{-4} \text{ m}^2/\text{s}$ ,  $\text{Sc} = \nu_B/D_{AB} = 0.650$ ; Table A-6, Saturated water vapor (320K):  $\rho_{A,\text{sat}} = 1/\nu_g = 0.07153 \text{ kg/m}^3$ ,  $h_{fg} = 2390 \text{ kJ/kg}$ .

**ANALYSIS:** The enhancement due to wetting can be expressed as the ratio of the wet-to-dry cylinder heat fluxes.

$$\frac{q''_w}{q''_d} = \frac{q''_{\text{conv}} + q''_{\text{evap}}}{q''_{\text{conv}}} = 1 + \frac{q''_{\text{evap}}}{q''_{\text{conv}}}$$

where

$$q''_{\text{conv}} = \bar{h}(T_s - T_\infty) \quad q''_{\text{evap}} = \dot{m}''_A h_{fg} = \bar{h}_m (\rho_{A,s} - \rho_{A,\infty}) h_{fg} = \bar{h}_m \rho_{A,\text{sat}} h_{fg}$$

Invoking the heat-mass transfer analogy, using Eq. 6.60, find

$$\frac{\bar{h}}{\bar{h}_m} = (\rho c_p)_B \text{Le}^{1-n} = (\rho c_p)_B (\text{Sc}/\text{Pr})^{2/3}$$

assuming  $n = 1/3$  with  $\rho_{A,\infty} = 0$ , find

$$\frac{q''_w}{q''_d} = 1 + \left[ (\rho c_p)_B (\text{Sc}/\text{Pr})^{2/3} \right]^{-1} \frac{\rho_{A,\text{sat}} h_{fg}}{(T_s - T_\infty)} \quad <$$

Substituting numerical values, the enhancement is

$$\frac{q''_w}{q''_d} = 1 + \left[ \left( 1.1281 \frac{\text{kg}}{\text{m}^3} \times 1007.4 \frac{\text{J}}{\text{kg}} \right) \left( \frac{0.650}{0.706} \right)^{2/3} \right]^{-1} \frac{0.07153 \text{ kg/m}^3 \times 2390 \times 10^3 \text{ J/kg}}{(320 - 300) \text{ K}} = 9.0 \quad <$$

**COMMENTS:** For the prescribed conditions, the effect of wetting is to enhance the heat transfer by nearly an order of magnitude. Will the enhancement increase or decrease with increasing  $T_s$ ?

## PROBLEM 7.138

**KNOWN:** Moisture-soaked paper is cylindrical form maintained at given temperature by imbedded heaters. Dry air at prescribed velocity and temperature in cross flow over cylinder.

**FIND:** (a) Required electrical power and the evaporation rate per unit length,  $q'_{\text{evap}}$  and  $n'_A$ , respectively, and (b) Calculate and plot  $q'$  and  $n'_A$  as a function of dry air velocity  $5 \leq V \leq 20$  m/s and paper temperatures of 65, 70 and 75°C.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Heat-mass transfer analogy applicable, (3) Negligible radiation effects.

**PROPERTIES:** Table A.4, Air ( $T_\infty = 20^\circ\text{C} = 293$  K, 1 atm):  $\rho = 1.1941$  kg/m<sup>3</sup>,  $c_p = 1007$  J/kg·K,  $k = 25.7 \times 10^{-3}$  W/m·K,  $\nu = 15.26 \times 10^{-6}$  m<sup>2</sup>/s,  $\text{Pr} = 0.709$ ; ( $T_s = 70^\circ\text{C} = 343$  K):  $\text{Pr}_s = 0.701$ ; Table A.6, Sat. water vapor ( $T_s = 70^\circ\text{C} = 343$  K):  $\rho_{A,s} = 1/\nu_g = 0.196$  kg/m<sup>3</sup>,  $h_{fg} = 2334 \times 10^3$  J/kg; Table A.8, Air-water vapor mixture ( $\bar{T}_f = (T_\infty + T_s)/2 = 318$  K, 1 atm):  $D_{AB} = 0.26 \times 10^{-4}$  m<sup>2</sup>/s  $(318/298)^{3/2} = 0.29 \times 10^{-4}$  m<sup>2</sup>/s.

**ANALYSIS:** (a) From an energy balance on the cylinder on a per unit length basis,

$$q'_{\text{elec}} = q'_{\text{conv}} + q'_{\text{evap}} \quad q'_{\text{elec}} = \pi D \left[ \bar{h} (T_s - T_\infty) + \bar{h}_m (\rho_{A,s} - \rho_{A,\infty}) h_{fg} \right] \quad (1)$$

where  $\rho_{A,\infty} = 0$ , the freestream air is dry, and  $\rho_{A,s} = \rho_{A,\text{sat}}(T_s)$ . To estimate  $\bar{h}$ , find

$$\text{Re}_D = \frac{VD}{\nu} = \frac{10 \text{ m/s} \times 0.15 \text{ m}}{15.26 \times 10^{-6} \text{ m}^2/\text{s}} = 98,296 \quad (2)$$

and using the Zhukauskus correlation, from Table 7.4:  $C = 0.26$ ,  $m = 0.6$ , and  $n = 0.37$ ,

$$\overline{\text{Nu}}_D = \frac{\bar{h}D}{k} = 0.26 \text{Re}^{0.6} \text{Pr}^{0.37} (\text{Pr}/\text{Pr}_s)^{0.25} \quad (3)$$

$$\bar{h} = \frac{0.0257 \text{ W/m} \cdot \text{K}}{0.15 \text{ m}} \times 0.26 (98,296)^{0.6} (0.709)^{0.37} (0.709/0.701)^{0.25} = 38.9 \text{ W/m}^2 \cdot \text{K}.$$

Using the heat-mass analogy with  $n = 1/3$ , find

$$\bar{h}/\bar{h}_m = (\rho c_p)_B (\text{Sc}/\text{Pr})^{2/3} = (\rho c_p)_B (\nu/D_{AB}/\text{Pr})^{2/3} \quad (4)$$

$$\bar{h}_m = 38.9 \text{ W/m}^2 \cdot \text{K} / \left( 1.1941 \text{ kg/m}^3 \times 1007 \text{ J/kg} \cdot \text{K} \right) \left[ \frac{15.26 \times 10^{-6} \text{ m}^2/\text{s} / 0.29 \times 10^{-4} \text{ m}^2/\text{s}}{0.709} \right]^{2/3}$$

$$\bar{h}_m = 0.03946 \text{ m/s}.$$

Hence, the electric power requirement is

$$q'_{\text{elec}} = \pi \times 0.15 \text{ m} \left[ 38.9 \text{ W/m}^2 \cdot \text{K} (70 - 20) \text{ K} + 0.03946 \text{ m/s} (0.196 - 0) \text{ kg/m}^3 \times 2334 \times 10^3 \text{ J/kg} \right]$$

Continued...

### PROBLEM 7.138 (Cont.)

$$q'_{\text{elec}} = (917 + 8507) \text{ W/m} = 9424 \text{ W/m} \quad (5) <$$

(b) The foregoing equations were entered into the IHT Workspace, and using the *Properties Tools*, for air and water vapor required thermophysical properties, the required electrical power,  $q'$ , and evaporation rate,  $n'_A$ , were calculated as a function of dry air velocity for selected water temperatures.

**COMMENTS:** (1) Note at which temperatures the thermophysical properties are evaluated.

(2) From Equation (5), note that the evaporation heat rate far exceeds that due to convection.

(3) From the plots, note that both  $q'_{\text{elec}}$  and  $n'_A$  are nearly proportional to air velocity, and increase with increasing water temperature.

## PROBLEM 7.139

**KNOWN:** Dry- and wet-bulb temperatures associated with a moist airflow through a large diameter duct of prescribed surface temperature.

**FIND:** Temperature and relative humidity of airflow.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Conduction along the thermometers is negligible, (3) Duct wall forms a large enclosure about the thermometers.

**PROPERTIES:** Table A-4, Air (318K, 1 atm):  $\nu = 17.7 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0276 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.70$ ; Table A-4, Air (298K, 1 atm):  $\nu = 15.7 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0261 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.71$ ; Table A-6, Saturated water vapor (298K):  $\nu_g = 44.3 \text{ m}^3/\text{kg}$ ,  $h_{fg} = 2442 \text{ kJ/kg}$ ; Saturated water vapor (318.5K):  $\nu_g = 15.5 \text{ m}^3/\text{kg}$ ; Table A-8, Water vapor-air (298K):  $D_{AB} = 0.26 \times 10^{-4} \text{ m}^2/\text{s}$ ,  $\text{Sc} = 0.60$ .

**ANALYSIS:** *Dry-bulb Thermometer:* Since  $T_{db} > T_s$ , there is net radiation transfer from the surface of the dry-bulb thermometer to the duct wall. Hence to maintain steady-state conditions, the thermometer temperature must be less than that of the air ( $T_{db} < T_\infty$ ) to allow for convection heat transfer from the air. Hence, from application of a surface energy balance to the thermometer,  $q_{\text{conv}} = q_{\text{rad}}$ , or,

$$\bar{h}A_{\text{db}}(T_\infty - T_{\text{db}}) = \varepsilon_g A_{\text{db}} \sigma (T_{\text{db}}^4 - T_s^4).$$

The air temperature is then

$$T_\infty = T_{\text{db}} + \left( \varepsilon_g \sigma / \bar{h} \right) (T_{\text{db}}^4 - T_s^4) \quad (1)$$

where  $\bar{h}$  may be obtained from Eq. 7.53.

*Wet-bulb Temperature:* The relative humidity may be obtained by performing an energy balance on the wet-bulb thermometer. In this case convection heat transfer to the wick is balanced by evaporative and radiative heat losses from the wick,

$$\begin{aligned} q_{\text{conv}} &= q_{\text{evap}} + q_{\text{rad}} & q_{\text{evap}} &= n''_A A_{\text{wb}} h_{fg} = \bar{h}_m \left[ \rho_{A,\text{sat}}(T_{\text{wb}}) - \phi_\infty \rho_{A,\text{sat}}(T_\infty) \right] A_{\text{wb}} h_{fg} \\ \bar{h} A_{\text{wb}} (T_\infty - T_{\text{wb}}) &= \bar{h}_m \left[ \rho_{A,\text{sat}}(T_{\text{wb}}) - \phi_\infty \rho_{A,\text{sat}}(T_\infty) \right] A_{\text{wb}} h_{fg} + \varepsilon_w A_{\text{wb}} \sigma (T_{\text{wb}}^4 - T_s^4) \\ \phi_\infty &= \left\{ \rho_{A,\text{sat}}(T_{\text{wb}}) + \left[ \varepsilon_w \sigma (T_{\text{wb}}^4 - T_s^4) - \bar{h} (T_\infty - T_{\text{wb}}) \right] / h_{fg} \bar{h}_m \right\} / \rho_{A,\text{sat}}(T_\infty) \quad (2) \end{aligned}$$

where  $\bar{h}_m$  may be determined from the mass transfer analog of Eq. 7.53.

Continued ...

### PROBLEM 7.139 (Cont.)

*Convection Calculations:* For the prescribed conditions, the Reynolds number associated with the dry-bulb thermometer is

$$\text{Re}_{D(\text{db})} = VD_{\text{db}} / \nu = 5 \text{ m/s} \times 0.003 \text{ m} / 17.7 \times 10^{-6} \text{ m}^2/\text{s} = 847.$$

Approximating the Prandtl number ratio as unity, from Eq. 7.53 and Table 7.4,

$$\overline{\text{Nu}}_{D(\text{db})} = C \text{Re}_{D(\text{db})}^m \text{Pr}^n = 0.51(847)^{0.5} (0.70)^{0.37} = 13.01$$

$$\bar{h} = 13.01 \frac{k}{D_{\text{db}}} = 13.01 \frac{0.0276 \text{ W/m} \cdot \text{K}}{0.003 \text{ m}} = 120 \text{ W/m}^2 \cdot \text{K}.$$

From Eq. (1) the air temperature is

$$T_{\infty} = 45^{\circ}\text{C} + \frac{0.95 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4}{120 \text{ W/m}^2 \cdot \text{K}} (318^4 - 308^4) \text{ K}^4 = 45^{\circ}\text{C} + 0.55^{\circ}\text{C} = 45.6^{\circ}\text{C}. \quad <$$

The relative humidity may now be obtained from Eq. (2). The Reynolds number associated with the wet-bulb thermometer is

$$\text{Re}_{D(\text{wb})} = VD_{\text{wb}} / \nu = 5 \text{ m/s} \times 0.004 \text{ m} / 15.7 \times 10^{-6} \text{ m}^2/\text{s} = 1274.$$

From Eq. 7.53 and Table 7.4, it follows that

$$\overline{\text{Nu}}_{D(\text{wb})} = 0.26(1274)^{0.6} (0.71)^{0.37} = 16.71$$

$$\bar{h} = 16.71 \frac{k}{D_{\text{wb}}} = 16.71 \frac{0.0261 \text{ W/m} \cdot \text{K}}{0.004 \text{ m}} = 109 \text{ W/m}^2 \cdot \text{K}.$$

Using the mass transfer analog of Eq. 7.53, it also follows that

$$\overline{\text{Sh}}_{D(\text{wb})} = 0.26 \text{Re}_{D(\text{wb})}^{0.6} \text{Sc}^{0.37} = 0.26(1274)^{0.6} (0.6)^{0.37} = 15.7$$

$$\bar{h}_m = 15.7 \frac{D_{\text{AB}}}{D_{\text{wb}}} = \frac{15.7 \times 0.26 \times 10^{-4} \text{ m}^2/\text{s}}{0.004 \text{ m}} = 0.102 \text{ m/s}.$$

Also,  $\rho_{\text{A,sat}}(T_{\text{wb}}) = v_g (298 \text{ K})^{-1} = (44.3 \text{ m}^3/\text{kg})^{-1} = 0.0226 \text{ kg/m}^3$

$$\rho_{\text{A,sat}}(T_{\infty}) = v_g (318.5 \text{ K})^{-1} = (15.5 \text{ m}^3/\text{kg})^{-1} = 0.0645 \text{ kg/m}^3.$$

Hence the relative humidity is, from Eq. (2)

$$\phi_{\infty} = \left( 0.0226 \text{ kg/m}^3 + \frac{[0.95 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (298^4 - 308^4) \text{ K}^4 - 109 \text{ W/m}^2 \cdot \text{K} (45.55 - 25) \text{ K}]}{(2.442 \times 10^6 \text{ J/kg})(0.102 \text{ m/s})} \right) / 0.0645 \text{ kg/m}^3$$

$$\phi_{\infty} = 0.21 \quad <$$

**COMMENTS:** (1) The effect of radiation exchange between the duct wall and the thermometers is small. For this reason  $T_{\infty} = T_{\text{db}}$ . (2) The evaporative heat loss is significant due to the small value of  $\phi_{\infty}$ , causing  $T_{\text{wb}}$  to be significantly less than  $T_{\infty}$ .

### PROBLEM 7.140

**KNOWN:** Velocity, diameter and temperature of a spherical droplet. Conditions of surroundings.

**FIND:** (a) Expressions for droplet evaporation and cooling rates, (b) Evaporation and cooling rates for prescribed conditions.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible temperature gradients in the drop, (2) Heat and mass transfer analogy is applicable, (3) Perfect gas behavior for vapor.

**PROPERTIES:** Table A-4, Air ( $T_\infty = 298\text{K}$ , 1 atm):  $\nu = 15.71 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0261 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.71$ ; Table A-6, Water ( $T = 40^\circ\text{C}$ ):  $\rho_{A,\text{sat}} = 0.050 \text{ kg/m}^3$ ,  $h_{fg} = 2407 \text{ kJ/kg}$ ,  $\rho_\ell = 992 \text{ kg/m}^3$ ,  $c_{p,\ell} = 4179 \text{ J/kg}\cdot\text{K}$ ; ( $T_\infty = 25^\circ\text{C}$ ):  $\rho_{A,\text{sat}} = 0.023 \text{ kg/m}^3$ ; Table A-8, Water vapor-air (298K):  $D_{AB} = 0.26 \times 10^{-4} \text{ m}^2/\text{s}$ .

**ANALYSIS:** (a) The evaporation rate is given by

$$\dot{m}_{\text{evap}} = \bar{h}_m A_s (\rho_{A,s} - \rho_{A,\infty}) = \bar{h}_m \pi D^2 [\rho_{A,\text{sat}}(T) - \phi_\infty \rho_{A,\text{sat}}(T_\infty)]. \quad <$$

The cooling rate is obtained from an energy balance performed for a control surface about the droplet,

$$\dot{E}_{\text{st}} = -\dot{q}_{\text{out}} = -(\dot{q}_{\text{conv}} + \dot{q}_{\text{rad}} + \dot{q}_{\text{evap}})$$

$$\text{or} \quad \frac{d}{dt} \left( \rho_\ell \frac{\pi D^3}{6} c_{p,\ell} T \right) = -A_s \left[ \bar{h} (T_s - T_\infty) + \varepsilon \sigma (T_s^4 - T_{\text{sur}}^4) + \dot{m}_{\text{evap}}'' h_{fg} \right].$$

With  $A_s = \pi D^2$ , it follows that

$$\frac{dT}{dt} = -\frac{6}{\rho_\ell c_{p,\ell} D} \left[ \bar{h} (T_s - T_\infty) + \varepsilon \sigma (T_s^4 - T_{\text{sur}}^4) + \dot{m}_{\text{evap}}'' h_{fg} \right]. \quad <$$

(b) To obtain  $\bar{h}_m$ , the mass transfer analog of the Ranz-Marshall correlation gives

$$\bar{\text{Sh}}_D = 2 + 0.6 \text{Re}_D^{1/2} \text{Sc}^{1/3}$$

where

$$\text{Re}_D = \frac{VD}{\nu} = \frac{7 \text{ m/s} \times 0.003 \text{ m}}{15.71 \times 10^{-6} \text{ m}^2/\text{s}} = 1337, \quad \text{Sc} = \frac{\nu}{D_{AB}} = \frac{15.71 \times 10^{-6}}{26 \times 10^{-6}} = 0.60.$$

Continued ...

**PROBLEM 7.140 (Cont.)**

Hence

$$\overline{Sh}_D = 2 + 0.6(1337)^{1/2} (0.6)^{1/3} = 20.5$$

$$\bar{h}_m = \overline{Sh}_D \frac{D_{AB}}{D} = 20.5 \frac{0.26 \times 10^{-4} \text{ m}^2/\text{s}}{0.003 \text{ m}} = 0.18 \text{ m/s}$$

$$\dot{m}_{\text{evap}} = 0.18 \text{ m/s} \pi (0.003 \text{ m})^2 [0.05 - 0.6 \times 0.023] \text{ kg/m}^3 = 1.82 \times 10^{-7} \text{ kg/s.} \quad <$$

The evaporative heat flux is then

$$q''_{\text{evap}} = \frac{q_{\text{evap}}}{A_s} = \frac{\dot{m}_{\text{evap}} h_{fg}}{\pi D^2} = \frac{1.82 \times 10^{-7} \text{ kg/s} (2.407 \times 10^6 \text{ J/kg})}{\pi (0.003 \text{ m})^2}$$

$$q''_{\text{evap}} = 15,494 \text{ W/m}^2.$$

Using the heat transfer correlation, the Nusselt number is

$$\overline{Nu}_D = 2 + 0.6 Re_D^{1/2} Pr^{1/3} = 2 + 0.6(1337)^{1/2} (0.71)^{1/3} = 21.58.$$

Hence 
$$\bar{h} = \overline{Nu}_D \frac{k}{D} = 21.58 \frac{0.0261 \text{ W/m} \cdot \text{K}}{0.003 \text{ m}} = 188 \text{ W/m}^2 \cdot \text{K}$$

and the sensible heat flux is

$$q''_{\text{conv}} = \bar{h} (T - T_\infty) = 188 \text{ W/m}^2 \cdot \text{K} (40 - 25)^\circ \text{C}$$

$$q''_{\text{conv}} = 2815 \text{ W/m}^2.$$

The net radiative flux is

$$q''_{\text{rad}} = \varepsilon \sigma (T^4 - T_{\text{sur}}^4) = 0.95 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 [313^4 - 288^4] \text{ K}^4$$

$$q''_{\text{rad}} = 146 \text{ W/m}^2 \cdot \text{K}.$$

Hence 
$$\frac{dT}{dt} = - \frac{6}{992 \text{ kg/m}^3 \times 4179 \text{ J/kg} \cdot \text{K} (0.003 \text{ m})} (2815 + 146 + 15,494) \text{ W/m}^2$$

$$\frac{dT}{dt} = -8.9 \text{ K/s.} \quad <$$

**COMMENTS:** (1) Evaporative cooling provides the dominant heat loss from the drop. (2) To test the validity of assuming negligible temperature gradients in the drop, calculate

$$Bi \approx \frac{h_{\text{eff}} (r_o/3)}{k_\ell}, \quad \text{where } h_{\text{eff}} \equiv \frac{q''_{\text{tot}}}{T - T_\infty} = \frac{18,455}{25} = 738 \text{ W/m}^2 \cdot \text{K}.$$

From Table A-6,  $k_\ell = 0.631 \text{ W/m} \cdot \text{K}$ , hence

$$Bi \approx \frac{738 \text{ W/m}^2 \cdot \text{K} (0.0005 \text{ m})}{0.631 \text{ W/m} \cdot \text{K}} = 0.58.$$

Hence, although suspect, the assumption is not totally unreasonable.

## PROBLEM 7.141

**KNOWN:** Cranberries with an average diameter of 15 mm rolling over a fine screen. Thickness of the water film is 0.2 mm.

**FIND:** Time required to dry the berries exposed to heated air with a velocity of 2 m/s and temperature of 30°C.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Air stream is dry, (3) Water film on the berries is also at 30°C, (4) Convection process is uniform over the exposed surface, and (5) Heat-mass analogy is applicable.

**PROPERTIES:** Table A-6, Water ( $T_f = 30^\circ\text{C} = 303 \text{ K}$ ):  $\rho_{A,f} = 995.8 \text{ kg/m}^3$ ,  $\rho_{A,g} = 0.02985 \text{ kg/m}^3$ ; Table A-8, Water-air ( $T_f = 303 \text{ K}$ , 1 atm):  $D_{AB} = 0.26 \times 10^{-4} \text{ m}^2/\text{s} (303/298)^{1.5} = 2.67 \times 10^{-5} \text{ m}^2/\text{s}$ ; Table A-4, Air ( $T_f = 303 \text{ K}$ , 1 atm):  $\mu = \mu_s = 1.86 \times 10^{-5} \text{ N}\cdot\text{s/m}^2$ ,  $\nu = 1.619 \times 10^{-5} \text{ m}^2/\text{s}$ ,  $\alpha = 2.294 \times 10^{-5} \text{ m}^2/\text{s}$ ,  $k = 0.02652 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.707$ .

**ANALYSIS:** The evaporation rate of water from the berry surface is given by the rate equation,

$$n = \bar{h}_m A_s (\rho_{A,s} - \rho_{A,\infty}) \quad (1)$$

where  $A_s = \pi D^2$  and  $\bar{h}_m$  is determined using the heat-mass analogy, Eq. 6.60,

$$\frac{\bar{h}}{\bar{h}_m} = \frac{k}{D_{AB}} \text{Le}^{-n} \quad (2)$$

where  $\text{Le} = \alpha/D_{AB}$  and typically  $n = 1/3$ . The heat transfer coefficient  $\bar{h}$  is estimated with the Whitaker correlation, Eq. 7.56,

$$\overline{\text{Nu}}_D = \frac{\bar{h}D}{k} = 2 + \left[ 0.4 \text{Re}_D^{1/2} + 0.06 \text{Re}_D^{2/3} \right] \text{Pr}^{0.4} (\mu/\mu_s)^{1/4} \quad (3)$$

Substituting numerical values, find

$$\text{Re}_D = \frac{VD}{\nu} = \frac{2 \text{ m/s} \times 0.015 \text{ m}}{1.619 \times 10^{-5} \text{ m}^2/\text{s}} = 1853$$

$$\text{Nu}_D = 2 + \left[ 0.4(1853)^{1/2} + 0.06(1853)^{2/3} \right] \times (0.707)^{0.4} \times 1 = 24.9$$

$$\bar{h} = 24.9 \times 0.02652 \text{ W/m}\cdot\text{K} / 0.015 \text{ m} = 44.0 \text{ W/m}^2\cdot\text{K}$$

and using the heat-mass analogy,

$$\bar{h}_m = 44.0 \text{ W/m}^2\cdot\text{K} \times \left( 2.67 \times 10^{-5} \text{ m}^2/\text{s} / 0.02652 \text{ W/m}\cdot\text{K} \right) \times (0.861)^{1/3}$$

$$\bar{h}_m = 0.0420 \text{ m/s}$$

Continued ...

### PROBLEM 7.141 (Cont.)

where

$$\text{Le} = \alpha / D_{AB} = 2.294 \times 10^{-5} \text{ m}^2 / \text{s} / 2.667 \times 10^{-5} \text{ m}^2 / \text{s} = 0.861$$

Using Eq. (1), the evaporation rate is

$$\dot{n} = 0.0420 \text{ m/s} \times \left( \pi (0.015 \text{ m})^2 \right) (0.02985 - 0) \text{ kg/m}^3 = 8.87 \times 10^{-7} \text{ kg/s}$$

The time,  $t_o$ , required to evaporate the water film of thickness  $\delta = 0.2 \text{ mm}$  is

$$\dot{n} t_o = M_{\text{film}} = \rho_{A,\ell} \left( \pi D^2 \right) \delta$$

$$t_o = 995.8 \text{ kg/m}^3 \left( \pi \times (0.015 \text{ m})^2 \right) \times 0.0002 \text{ m} / 8.87 \times 10^{-7} \text{ kg/s}$$

$$t_o = 159 \text{ s}$$

<

### PROBLEM 7.142

**KNOWN:** Spherical droplet at prescribed temperature and velocity falling in still, hotter dry air.

**FIND:** Instantaneous rate of evaporation.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Heat-mass transfer analogy applicable.

**PROPERTIES:** Table A-4, Air ( $T_\infty = 100^\circ\text{C} = 373\text{K}$ , 1 atm):  $\rho = 0.9380\text{ kg/m}^3$ ,  $c_p = 1011\text{ J/kg}\cdot\text{K}$ ,  $k = 0.0317\text{ W/m}\cdot\text{K}$ ,  $\nu = 23.45 \times 10^{-6}\text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.695$ ; Table A-6, Sat. water ( $T_s = 60^\circ\text{C} = 333\text{K}$ ):  $\rho_\ell = 1/\nu_\ell = 983\text{ kg/m}^3$ ,  $\rho_{A,s} = 1/\nu_f = 0.129\text{ kg/m}^3$ ; Table A-8, Air-water vapor mixture ( $T_\infty = 373\text{K}$ , 1 atm):  $D_{AB} = 0.267 \times 10^{-4}\text{ m}^2/\text{s} (373/298)^{3/2} = 0.36 \times 10^{-4}\text{ m}^2/\text{s}$ .

**ANALYSIS:** The instantaneous evaporation rate is

$$\dot{n}_A = \bar{h}_m A_s (\rho_{A,s} - \rho_{A,\infty})$$

where  $A_s = \pi D^2$ ,  $\rho_{A,\infty} = 0$  and  $\rho_{A,s} = \rho_{A,\text{sat}}(T_s)$ . To estimate  $\bar{h}_m$  use the Whitaker correlation, written in terms of mass transfer parameters and with  $\mu/\mu_s \approx 1$ ,

$$\overline{\text{Sh}}_D = \frac{\bar{h}_m D}{D_{AB}} = 2 + \left( 0.4 \text{Re}_D^{1/2} + 0.06 \text{Re}_D^{2/3} \right) \text{Sc}^{0.4}$$

$$\bar{h}_m = \frac{0.36 \times 10^{-4}\text{ m}^2/\text{s}}{0.0005\text{ m}} \left[ 2 + \left( 0.4(45.8)^{1/2} + 0.06(45.8)^{2/3} \right) \times 0.651^{0.4} \right] = 0.355\text{ m/s}$$

where 
$$\text{Re}_D = \frac{VD}{\nu} = \frac{2.15\text{ m/s} \times 0.0005\text{ m}}{23.45 \times 10^{-6}\text{ m}^2/\text{s}} = 45.8$$

$$\text{Sc} = \nu/D_{AB} = 23.45 \times 10^{-6}\text{ m}^2/\text{s} / 0.36 \times 10^{-4}\text{ m}^2/\text{s} = 0.651.$$

Hence, the evaporation rate is

$$\dot{n}_A = 0.355\text{ m/s} \times \pi (0.0005\text{ m})^2 (0.129 - 0)\text{ kg/m}^3 = 3.60 \times 10^{-8}\text{ kg/s.} \quad <$$

**COMMENTS:** If this evaporation rate were to remain constant with time, the droplet of mass  $M$  would be completely evaporated in

$$\Delta t = M/\dot{n}_A = \frac{\rho_\ell (\pi D^3 / 6)}{\dot{n}_A} = \frac{983\text{ kg/m}^3 (\pi (0.0005\text{ m})^3 / 6)}{3.60 \times 10^{-8}\text{ kg/s}} = 1.8\text{ s.}$$

To determine whether the droplet temperature will increase or decrease with time, it is necessary to compare convective heat and evaporation rates. Hence it is not clear whether the time to completely evaporate will be less or greater than 1.8 s.

### PROBLEM 7.143

**KNOWN:** Diameter, velocity and surface vapor concentration of alcohol droplet falling in quiescent air. Latent heat of vaporization and diffusion coefficient. Air temperature.

**FIND:** Droplet surface temperature

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Applicability of heat and mass transfer analogy, (3) Negligible radiation, (4) Negligible vapor concentration in air ( $\rho_{A,\infty} = 0$ ).

**PROPERTIES:** Table A.4, air ( $T_\infty = 300$  K):  $\nu = 15.89 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0263 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.707$ .

**ANALYSIS:** Application of a surface energy balance yields

$$q''_{\text{evap}} = q''_{\text{conv}}$$

$$\bar{h}_m (\rho_{A,s} - \rho_{A,\infty}) h_{fg} = \bar{h} (T_\infty - T_s)$$

$$T_s = T_\infty - \frac{\bar{h}_m}{\bar{h}} \rho_{A,s} h_{fg}$$

With  $\text{Re}_D = VD/\nu = 1.8 \text{ m/s} \times 5 \times 10^{-4} \text{ m} / 15.89 \times 10^{-6} \text{ m}^2/\text{s} = 56.6$  and  $\text{Sc} = \nu/D_{AB} = 1.59$ , the Ranz-Marshall correlation yields

$$\overline{\text{Nu}}_D = 2 + 0.6 \text{Re}_D^{1/2} \text{Pr}^{1/3} = 2 + 0.6(56.6)^{1/2} (0.707)^{1/3} = 6.02$$

$$\overline{\text{Sh}}_D = 2 + 0.6 \text{Re}_D^{1/2} \text{Sc}^{1/3} = 2 + 0.6(56.6)^{1/2} (1.59)^{1/3} = 7.27$$

With  $\bar{h}_m/\bar{h} = \overline{\text{Sh}}_D (D_{AB}/D) / \overline{\text{Nu}}_D (k/D)$ ,

$$\frac{\bar{h}_m}{\bar{h}} = \frac{\overline{\text{Sh}}_D (D_{AB})}{\overline{\text{Nu}}_D (k)} = \frac{7.27 \times 10^{-5} \text{ m}^2/\text{s}}{6.02 \times 0.0263 \text{ W/m}\cdot\text{K}} = 4.59 \times 10^{-4} \text{ m}^3 \cdot \text{K}/\text{J}$$

Hence,

$$T_s = 300 \text{ K} - 4.59 \times 10^{-4} \text{ m}^3 \cdot \text{K}/\text{J} \left( 0.0573 \text{ kg}/\text{m}^3 \right) \left( 8.42 \times 10^5 \text{ J}/\text{kg} \right) = 277.9 \text{ K} \quad <$$

**COMMENTS:** The large vapor density,  $\rho_{A,s}$ , renders the *evaporative cooling* effect significant.

## PROBLEM 7.144

**KNOWN:** Diameter and density of liver cells, diameter of droplets.

**FIND:** (a) Terminal velocity of the droplets when each droplet contains one liver cell, (b) Time of flight of a droplet containing one liver cell if the distance between injector and scaffold is  $L = 4$  mm, (c) Initial evaporation rate from the droplet, (d) Comparison of the mass variation due to evaporation to variation due to liver cell populations ranging from one to five per droplet.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Constant properties, (2) Negligible evaporative cooling, (3) Stokes' law is valid,  $C_D = 24/Re_D$ , (4) Neglect mass of displaced air in force balance, (5) Evaporation rate is unaffected by change in droplet diameter, (6) Negligible microscale mass transfer effects.

**PROPERTIES:** Table A.4, air: ( $T = 25$  °C = 298 K):  $\rho = 1.171$  kg/m<sup>3</sup>,  $\nu = 15.71 \times 10^{-6}$  m<sup>2</sup>/s, Table A.6, liquid water: ( $T = 25$  °C = 298 K):  $\rho = 997.4$  kg/m<sup>3</sup>, Table A.6, water vapor: ( $T = 25$  °C = 298 K):  $v_g = 44.25$  m<sup>3</sup>/kg. Table A.8, water vapor in air: ( $T = 25$  °C = 298 K):  $D_{AB} = 0.26 \times 10^{-4}$  m<sup>2</sup>/s.

**ANALYSIS:**

(a) At terminal velocity, the force balance is

$$Mg = C_D A_f (\rho V^2 / 2) \quad (1)$$

The mass of the particle,  $M$ , is

$$M = \nabla_{lc} \rho_{lc} + (\nabla_p - \nabla_{lc}) \rho_p \quad (2)$$

The volume of the droplet is  $\nabla_p = \frac{4}{3} \pi \times (25 \times 10^{-6} \text{ m})^3 = 6.54 \times 10^{-14} \text{ m}^3$  while the volume of a

liver cell is  $\nabla_{lc} = \frac{4}{3} \pi \times (10 \times 10^{-6} \text{ m})^3 = 4.12 \times 10^{-15} \text{ m}^3$  and the frontal area is

$$A_f = \pi \times (25 \times 10^{-6} \text{ m})^2 = 1.963 \times 10^{-9} \text{ m}^2.$$

The mass is therefore

$$M = 4.12 \times 10^{-15} \text{ m}^3 \times 2400 \text{ kg/m}^3 + (6.54 \times 10^{-14} \text{ m}^3 - 4.12 \times 10^{-15} \text{ m}^3) \times 997.4 \text{ kg/m}^3$$

$$M = 7.10 \times 10^{-11} \text{ kg} \quad (3)$$

Note that  $C_D = 24/Re_D = 24 \nu / VD_p$  (4)

Continued....

### PROBLEM 7.144 (Cont.)

Combining Equations 1, 2 and 3 yields

$$V = \frac{M_g D_p}{12\nu A_f \rho} = \frac{7.10 \times 10^{-11} \text{ kg} \times 9.8 \text{ m/s}^2 \times 50 \times 10^{-6} \text{ m}}{12 \times 15.71 \times 10^{-6} \text{ m}^2/\text{s} \times 1.963 \times 10^{-9} \text{ m}^2 \times 1.171 \text{ kg/m}^3}$$

$$V = 0.080 \text{ m/s} \quad <$$

The volume fraction of liver cells in the slurry is

$$f = \nabla_{lc} / \nabla_p = 4.12 \times 10^{-15} \text{ m}^3 / 6.54 \times 10^{-14} \text{ m}^3 = 0.063 \quad <$$

(b) The time of flight is

$$t = L/V = 4 \times 10^{-3} \text{ m} / 0.080 \text{ m/s} = 50 \times 10^{-3} \text{ s} = 50 \text{ ms} \quad <$$

(c) With  $Sc = \nu/D_{AB} = 1.571 \times 10^{-5} \text{ m}^2/\text{s} / 0.26 \times 10^{-4} \text{ m}^2/\text{s} = 0.604$ , the heat and mass transfer analogy may be applied to Whitaker's correlation to yield

$$\bar{h}_D = \frac{D_{AB}}{D_p} \left\{ 2 + \left[ 0.4\sqrt{Re_D} + 0.06(Re_D)^{2/3} \right] Pr^{0.4} \right\}$$

The Reynolds number is  $Re_D = VD_p/\nu = 0.08 \text{ m/s} \times 50 \times 10^{-6} \text{ m} / 15.71 \times 10^{-6} \text{ m}^2/\text{s} = 0.255$ .

Hence,

$$\bar{h}_D = \frac{0.26 \times 10^{-4} \text{ m}^2/\text{s}}{50 \times 10^{-6} \text{ m}} \left\{ 2 + \left[ 0.4\sqrt{0.255} + 0.06(0.255)^{2/3} \right] 0.604^{0.4} \right\}$$

$$\bar{h}_D = 1.14 \text{ m/s}$$

The initial evaporation rate is

$$n_A = \bar{h}_D A (\rho_{A,sat} - \phi \rho_{A,sat})$$

$$n_A = 1.14 \text{ m/s} \times \pi \times (50 \times 10^{-6} \text{ m})^2 \times \left[ \frac{1}{44.25} - \frac{0.5}{44.25} \right] \frac{\text{kg}}{\text{m}^3} = 1.01 \times 10^{-10} \text{ kg/s} \quad <$$

(d) The sensitivity may be estimated by comparing the change in mass due to evaporation to the difference in mass due to liver cell loading.

Evaporation

$$\Delta M = n_A t = 1.01 \times 10^{-10} \text{ kg/s} \times 50 \times 10^{-3} \text{ s} = 5.05 \times 10^{-12} \text{ kg} \quad <$$

Loading

The droplet mass with 3 liver cells is

$$M_3 = 3 \times 4.12 \times 10^{-15} \text{ m}^3 \times 2400 \text{ kg/m}^3 + (6.54 \times 10^{-14} \text{ m}^3 - 3 \times 4.12 \times 10^{-15} \text{ m}^3) \times 997.4 \text{ kg/m}^3$$

$$M_3 = 8.26 \times 10^{-11} \text{ kg}$$

The change in mass relative to one liver cell in the droplet is

$$\Delta M = M_3 - M_1 = 8.26 \times 10^{-11} \text{ kg} - 7.10 \times 10^{-11} \text{ kg} = 1.16 \times 10^{-11} \text{ kg} \quad <$$

The change in mass is more sensitive to variations in the number of liver cells than to evaporation.

**COMMENTS:** (1) Inspection of Figure 7.9 shows that Stokes' law is valid at  $Re_D = 0.255$ .

## PROBLEM 7.145

**KNOWN:** Dimension and approximate shape of E. coli bacterium. Binary diffusivity, nutrient value, propulsion efficiency and concentration difference from free stream water-based solution to bacterium shell.

**FIND:** Estimate the maximum E. coli speed in body diameters per second.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible capability of bacterium to store energy, (2) Constant properties, (3) Steady-state, (4) Stokes' law is valid, that is  $C_D = 24/Re_D$ , (5) Negligible microscale mass transfer effects.

**PROPERTIES:** Table A.6, water ( $T = 37\text{ }^\circ\text{C} = 310\text{ K}$ ):  $\rho = 993\text{ kg/m}^3$ ,  $\nu = 6.999 \times 10^{-7}\text{ m}^2/\text{s}$ ,  $Pr = 0.701$ .

**ANALYSIS:** For the spherical bacterium shell

$$Re_D = VD/\nu = (V \times 2 \times 10^{-6}\text{ m}) / (6.999 \times 10^{-7}\text{ m}^2/\text{s}) = 2.858\text{ (s/m)} \times V \quad (1)$$

The power required to propel the bacterium is

$$P = F_D V = \frac{C_D A_f \rho V^2}{2} V = \frac{C_D \pi D^2 \rho V^3}{8} \quad (2)$$

assuming  $C_D = \frac{24}{Re_D} = \frac{24}{2.858\text{ (s/m)} V}$

We may combine Equations 1 and 2 to yield

$$\begin{aligned} P &= \frac{24}{2.858} \frac{\pi D^2 \rho V^2}{8} = \frac{3}{2.858\text{ s/m}} \times \pi \times (2 \times 10^{-6}\text{ m})^2 \times 993\text{ kg/m}^3 \times V^2 \\ &= 13.1 \times 10^{-9}\text{ W s}^2/\text{m}^2 (V)^2 \end{aligned}$$

For  $\eta = 0.5$ , the energy to be delivered from the water-based solution to the bacterium is

$$E = P/\eta = 26.2 \times 10^{-9}\text{ W s}^2/\text{m}^2 (V)^2 \quad (3)$$

The energy supplied to the bacterium is

$$E = \bar{h}_m A \mathcal{N} \Delta C = \bar{h}_m \rho D^2 \mathcal{N} \Delta C / 4$$

$$E = \bar{h}_m \pi (2 \times 10^{-6}\text{ m})^2 \times 16,000\text{ kJ/kg} \times 860 \times 10^{-12}\text{ kg/m}^3 / 4$$

Continued...

### PROBLEM 7.145 (Cont.)

$$E = 43.23 \times 10^{-18} \text{ Ws/m} \times \bar{h}_m \quad (4)$$

Applying the heat and mass transfer analogy to the Whitaker correlation yields

$$\overline{\text{Sh}}_D = \frac{\bar{h}_m D}{D_{AB}} = 2 + (0.4\sqrt{\text{Re}_D} + 0.06 \text{Re}_D^{2/3}) \text{Sc}^{0.4} \left(\frac{1}{1}\right)$$

$$\text{where } \text{Sc} = \nu/D_{AB} = 6.999 \times 10^{-7} \text{ m}^2/\text{s} / (0.7 \times 10^{-9} \text{ m}^2/\text{s}) = 1000$$

Therefore

$$\bar{h}_m = \frac{0.7 \times 10^{-9} \text{ m}^2/\text{s}}{2 \times 10^{-6} \text{ m}} \left[ 2 + \left( 0.4\sqrt{2.858 \text{ s/m} \times V} + 0.06(2.858 \text{ s/m} \times V)^{2/3} \right) \times 1000^{0.4} \right] \quad (5)$$

Combining Equations (3) through (5) and solving for V yields

$$V = 70 \times 10^{-6} \text{ m/s} = 70 \text{ } \mu\text{m/s}$$

$$\text{or } V = 70 \text{ } \mu\text{m/s} \times 1 \text{ body diameter} / 2 \text{ } \mu\text{m} = 35 \text{ body diameters/s} \quad \leftarrow$$

**COMMENTS:** (1) The maximum Reynolds number is  $\text{Re}_D = VD/\nu = 70 \times 10^{-6} \text{ m/s} \times 2 \times 10^{-6} \text{ m} / 6.999 \times 10^{-7} \text{ m}^2/\text{s} = 200 \times 10^{-6}$ . The Whitaker correlation is extrapolated outside of its range of application and provides a Sherwood number of 2.093 and a mass transfer coefficient of  $732 \times 10^{-6} \text{ m/s}$ . Using a Sherwood number of two, one would calculate a mass transfer coefficient of  $700 \times 10^{-6} \text{ m/s}$ . Using the limiting value of the Sherwood number would change the answer by less than 5%. (2) The small Reynolds number validates the application of Stokes' law. (3) It is hypothesized that the direction of rotation of the flagellum (clockwise or counterclockwise) is driven by the spatial concentration gradient in the solution. The direction of rotation changes with the solutions' nutrient concentration gradient in a manner that consistently "steers" the bacterium into more fertile feeding grounds. (4) The bacterium splits into multiple bacteria when it is stationary. Presumably, the energy needed to split the bacterium is available since no power is needed to propel the E. coli during splitting.

## PROBLEM 7.146

**KNOWN:** Humidity and temperature of air entering heater; temperature of air leaving heater. Diameter, temperature and relative velocity of injected droplets.

**FIND:** Droplet evaporation rate.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible change in droplet diameter due to evaporation, (2) Negligible cooling of droplet due to evaporation, (3) Applicability of heat/mass transfer analogy, (4) Ideal gas behavior for vapor.

**PROPERTIES:** Table A.4, air ( $T_\infty = T_o = 320 \text{ K}$ ):  $\nu = 17.90 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0278 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.705$ . Table A.6, saturated water ( $T_i = 290 \text{ K}$ ):  $p_{\text{sat}} = 0.01917 \text{ bars}$ ; ( $T_o = 320 \text{ K}$ ):  $p_{\text{sat}} = 0.1053 \text{ bars}$ ,  $\nu_g = 13.98 \text{ m}^3/\text{kg}$ . Table A.8,  $\text{H}_2\text{O}/\text{air}$  ( $T = 320 \text{ K}$ ):  $D_{\text{AB}} = 0.26 \times 10^{-4} \text{ m}^2/\text{s}$  ( $320/298$ ) $^{3/2} = 0.289 \times 10^{-4} \text{ m}^2/\text{s}$ .

**ANALYSIS:** Due to an increase in temperature, the air leaves the heater with a smaller relative humidity. With  $\phi_i = 0.7$  and  $p_{\text{sat},i} = 0.01917 \text{ bars}$ , the vapor pressure at the heater inlet is  $p_i = \phi_i p_{\text{sat},i} = 0.7(0.01917 \text{ bars}) = 0.0134 \text{ bars}$ . Since the vapor pressure doesn't change with passage through the heater,

$$\phi_o = \frac{p_i}{p_{\text{sat},o}} = \frac{0.0134 \text{ bars}}{0.1053 \text{ bars}} = 0.127$$

The vapor density associated with air flow around the droplets is therefore

$$\rho_{\text{A},\infty} = \phi_o \rho_{\text{A},\text{sat}}(T_o) = \phi_o \nu_g(T_o)^{-1} = 0.127 \times 0.0715 \text{ kg/m}^3 = 0.0091 \text{ kg/m}^3$$

The droplet evaporation rate is

$$\dot{m}_{\text{evap}} = \bar{h}_m A_s [\rho_{\text{A},\text{sat}}(T_s) - \rho_{\text{A},\infty}]$$

where  $\bar{h}_m$  may be obtained from the mass transfer analog to the Whitaker correlation. With  $\text{Re}_D = VD/\nu = 15 \text{ m/s} \times 0.001 \text{ m}/17.9 \times 10^{-6} \text{ m}^2/\text{s} = 838$ ,  $\text{Sc} = \nu/D_{\text{AB}} = 17.9 \times 10^{-6} \text{ m}^2/\text{s}/28.9 \times 10^{-6} \text{ m}^2/\text{s} = 0.62$ , and  $\mu/\mu_s = 1$ ,

$$\bar{\text{Sh}}_D = 2 + \left(0.4 \text{Re}_D^{1/2} + 0.06 \text{Re}_D^{2/3}\right) \text{Sc}^{0.4} = 2 + \left[0.4(838)^{1/2} + 0.06(838)^{2/3}\right] (0.62)^{0.4} = 16.0$$

$$\bar{h}_m = \bar{\text{Sh}}_D (D_{\text{AB}}/D) = 16 \left(0.289 \times 10^{-4} \text{ m}^2/\text{s}/0.001 \text{ m}\right) = 0.462 \text{ m/s}$$

$$\dot{m}_{\text{evap}} = (0.462 \text{ m/s}) \pi (0.001 \text{ m})^2 (0.0715 - 0.0091) \text{ kg/m}^3 = 9.06 \times 10^{-8} \text{ kg/s} \quad <$$

**COMMENTS:** The energy required for evaporation must be supplied by convection heat transfer from the heated air to the droplet. Hence, in actuality, the droplet temperature  $T_s$  must be less than that of the freestream air,  $T_\infty$ , which in turn will decrease from the value  $T_o$  at the heater outlet.

### PROBLEM 7.147

**KNOWN:** Diameter and temperature of sphere wetted with kerosene. Air flow conditions.

**FIND:** (a) Minimum kerosene flow rate, (b) Air temperature required to maintain wetted surface at 300K.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Sphere mount has a negligible influence on the flow field and hence on  $\bar{h}$ , (3) Negligible kerosene vapor concentration in free stream.

**PROPERTIES:** Table A-4, Air (300K):  $\nu = 15.89 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0263 \text{ W/m}\cdot\text{K}$ ,  $\rho = 1.161 \text{ kg/m}^3$ ,  $Pr = 0.707$ ; Kerosene (given):  $\rho_{A,\text{sat}} = 0.015 \text{ kg/m}^3$ ,  $h_{fg} = 300 \text{ kJ/kg}$ ; Kerosene vapor-air (given):  $D_{AB} = 10^{-5} \text{ m}^2/\text{s}$ .

**ANALYSIS:** (a) The kerosene flowrate is  $\dot{n}_A = \bar{h}_m A (\rho_{A,\text{sat}} - \rho_{A,\infty})$ . Using the mass transfer analog of Eq. 7.56 and neglecting the viscosity ratio,

$$\overline{Sh}_D = 2 + \left( 0.4 Re_D^{1/2} + 0.06 Re_D^{2/3} \right) Sc^{0.4}$$

with  $Re_D = \frac{VD}{\nu} = \frac{15 \text{ m/s} \times 0.001 \text{ m}}{15.89 \times 10^{-6} \text{ m}^2/\text{s}} = 944$      $Sc = \frac{\nu}{D_{AB}} = \frac{15.89 \times 10^{-6}}{10 \times 10^{-6}} = 1.59$

$$\overline{Sh}_D = 2 + \left( 0.4 \times 944^{1/2} + 0.06 \times 944^{2/3} \right) (1.59)^{0.4} = 23.7$$

$$\bar{h}_m = \overline{Sh}_D D_{AB} / D = 23.7 \times 10^{-5} \text{ m}^2/\text{s} / 0.001 \text{ m} = 0.237 \text{ m/s}$$

$$\dot{n}_A = 0.237 \text{ m/s} \pi (10^{-3} \text{ m})^2 0.015 \text{ kg/m}^3 = 1.12 \times 10^{-8} \text{ kg/s.} \quad <$$

(b) An energy balance on the sphere yields  $\dot{n}_A h_{fg} = \bar{h} A (T_\infty - T_s)$ . Using the Whitaker correlation and neglecting the viscosity ratio,

$$\overline{Nu}_D = 2 + \left( 0.4 \times 944^{1/2} + 0.06 \times 944^{2/3} \right) (0.707)^{0.4} = 17.72$$

$$\bar{h} = \overline{Nu}_D k / D = 17.72 \times 0.0263 \text{ W/m}\cdot\text{K} / 0.001 \text{ m} = 466 \text{ W/m}^2 \cdot \text{K}$$

$$T_\infty = T_s + \frac{\dot{n}_A h_{fg}}{\bar{h} \pi D^2} = 300 \text{ K} + \frac{1.12 \times 10^{-8} \text{ kg/s} \times 3 \times 10^5 \text{ J/kg}}{466 \text{ W/m}^2 \cdot \text{K} \times \pi (0.001 \text{ m})^2}$$

$$T_\infty = 300 \text{ K} + 2.3 \text{ K} = 302.3 \text{ K} \quad <$$

or  $T_\infty - T_s = 2.3 \text{ K}$ .

**COMMENTS:** The small temperature excess (2.3K) is due to comparatively small values of  $\rho_{A,\text{sat}}$  and  $h_{fg}$  for kerosene.

### PROBLEM 7.148

**KNOWN:** Geometry and surface temperature of a tube bank with or without wetted surfaces. Temperature, velocity and flowrate associated with air in cross flow.

**FIND:** (a) Ratio of air cooling with water film to that without film, (b) Air outlet temperature and specific humidity for prescribed conditions.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Heat and mass transfer analogy is applicable, (3) Air is dry, (4) Heat and mass transfer driving potentials are  $T_{a,i} - T_s$  and  $\rho_{A,sat}(T_s)$ , (5) Vapor has negligible effect on flowrate.

**PROPERTIES:** Table A-4, Air (assume  $\bar{T}_a \approx 305\text{K}$ ):  $\rho = 1.1448 \text{ kg/m}^3$ ,  $c_p = 1007 \text{ J/kg}\cdot\text{K}$ ,  $\nu = 16.39 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0267 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.706$ ,  $\alpha = 23.2 \times 10^{-6} \text{ m}^2/\text{s}$ ; Table A-6, Water vapor ( $T_s = 10^\circ\text{C}$ ):  $\nu_g = 111.8 \text{ m}^2/\text{kg}$ ,  $\rho_{A,sat} = 8.94 \times 10^{-3} \text{ kg/m}^3$ ,  $h_{fg} = 2.478 \times 10^6 \text{ J/kg}$ ; Table A-8, Water vapor-air ( $T_f \approx 298\text{K}$ ):  $D_{AB} = 0.26 \times 10^{-4} \text{ m}^2/\text{s}$ ,  $\text{Sc} = (\nu/D_{AB}) = 0.630$ .

**ANALYSIS:** (a) The rate of heat loss from the air may be expressed as

$$q = \dot{m}_a c_{p,a} (T_{a,i} - T_{a,o})$$

in which case, the amount of air cooling is

$$(T_{a,i} - T_{a,o}) = \frac{q}{\dot{m}_a c_{p,a}} \quad (1)$$

Without the water film,  $q_{wo} \approx \bar{h}A(T_{a,i} - T_s)$  (2)

With the film,  $q_w \approx \bar{h}A(T_{a,i} - T_s) + \dot{m}_{\text{evap}} h_{fg}$

$$q_w \approx \bar{h}A(T_{a,i} - T_s) + \bar{h}_m A (\rho_{A,sat} - \rho_{A,\infty}) h_{fg} \quad (3)$$

where  $\rho_{A,\infty} = 0$ . Hence

$$\frac{(T_{a,i} - T_{a,o})_w}{(T_{a,i} - T_{a,o})_{wo}} \approx 1 + \frac{\bar{h}_m \rho_{A,sat} h_{fg}}{\bar{h} (T_{a,i} - T_s)}$$

or substituting from Eq. 6.60, with  $\text{Le} = \alpha/D_{AB}$  and a value of  $n = 0.33$ ,

$$\frac{(T_{a,i} - T_{a,o})_w}{(T_{a,i} - T_{a,o})_{wo}} \approx 1 + \frac{(D_{AB}/\alpha)^{0.67}}{\rho c_p} \frac{\rho_{A,sat} h_{fg}}{(T_{a,i} - T_s)} \quad <$$

Continued ...

### PROBLEM 7.148 (Cont.)

For the prescribed conditions,

$$\frac{(T_{a,i} - T_{a,o})_w}{(T_{a,i} - T_{a,o})_{wo}} \approx 1 + \frac{\left(\frac{0.26 \times 10^{-4} \text{ m}^2/\text{s}}{0.232 \times 10^{-4} \text{ m}^2/\text{s}}\right)^{0.67}}{1.145 \text{ kg/m}^3 \times 1007 \text{ J/kg} \cdot \text{K}} \times \frac{8.94 \times 10^{-3} \text{ kg/m}^3 \times 2.478 \times 10^6 \text{ J/kg}}{(35 - 10)^\circ \text{C}} \approx 1.83. \quad <$$

(b)  $T_{a,o}$  may be obtained from Eq. (1), where  $q$  is approximated by Eq. (2) or Eq. (3). With  $S_D = 26.83 \text{ mm} > (S_T + D)/2 = 16$ ,  $V_{\max}$  is at the transverse plane. Hence

$$V_{\max} = \frac{S_T}{S_T - D} V = \frac{24}{16} \times 3 \text{ m/s} = 4.5 \text{ m/s} \quad \text{Re}_{D,\max} = \frac{4.5 \text{ m/s} \times 0.008 \text{ m}}{16.39 \times 10^{-6} \text{ m}^2/\text{s}} = 2196.$$

From Tables 7.5 and 7.6,  $C_1 = 0.35$ ,  $m = 0.60$ ,  $C_2 = 0.98$  and the Zukauskas relation gives

$$\overline{\text{Nu}}_D = 0.35(0.98)(2196)^{0.6} (0.706)^{0.36} = 30.6$$

where  $(\text{Pr}/\text{Pr}_s)^{1/4}$  is 1.00. Hence

$$\bar{h} = \overline{\text{Nu}}_D k/D = 30.6(0.0267 \text{ W/m} \cdot \text{K})/0.008 \text{ m} = 102 \text{ W/m}^2 \cdot \text{K}.$$

$$\text{Also } \bar{h}_m = \bar{h} \frac{(D_{AB}/\alpha)^{0.67}}{\rho c_p} = 102 \frac{\text{W}}{\text{m}^2 \cdot \text{K}} \frac{(0.26/0.232)^{0.67}}{1.145 \text{ kg/m}^3 \times 1007 \text{ J/kg} \cdot \text{K}} = 0.0956 \text{ m/s}.$$

Hence

$$q_{\text{conv}} \approx \bar{h}A(T_{a,i} - T_s) = 102 \text{ W/m}^2 \cdot \text{K} \times \pi(0.008 \text{ m})0.5 \text{ m} \times 60(35 - 10)^\circ \text{C} = 1923 \text{ W}$$

$$q_{\text{evap}} = n_A h_{fg} = \bar{h}_m A \rho_{A,\text{sat}} h_{fg}$$

$$q_{\text{evap}} = 0.0956 \text{ m/s} \times \pi(0.008 \text{ m})0.5 \text{ m} \times 60(8.94 \times 10^{-3} \text{ kg/m}^3)2.478 \times 10^6 \text{ J/kg}$$

$$q_{\text{evap}} \approx 1597 \text{ W}.$$

With water film,

$$T_{a,o} = T_{a,i} - \frac{q_{\text{conv}} + q_{\text{evap}}}{\dot{m}_a c_{p,a}} \approx 35^\circ \text{C} - \frac{(1923 + 1597) \text{ W}}{0.5 \text{ kg/s} \times 1007 \text{ J/kg} \cdot \text{K}} = 28.0^\circ \text{C}. \quad <$$

The specific humidity of the outlet air is

$$\omega_o = \frac{n_A}{\dot{m}_a} = \frac{\bar{h}_m 60\pi DL \rho_{A,\text{sat}}}{\dot{m}_a} = \frac{0.0956 \text{ m/s}(60\pi)(0.008 \text{ m})0.5 \text{ m}(8.94 \times 10^{-3} \text{ kg/m}^3)}{0.5 \text{ kg/s}} = 0.00129. \quad <$$

**COMMENTS:** (1) Enhancement of air cooling by evaporation is significant ( $T_{a,o} = T_{a,i} - q_{\text{conv}}/\dot{m}_a c_{p,a} \approx 31.1^\circ \text{C}$  without the film). (2) Small value of  $\omega_o$  justifies neglecting effect of evaporation on  $\dot{m}_a$ . (3)  $q_{\text{conv}}$  has been overestimated by using  $(T_{a,i} - T_s)$  as the driving potential for convection heat transfer. A more accurate determination involves  $\Delta T_{\ell m}$  rather than  $(T_{a,i} - T_s)$ . (4) Apparently the air properties were evaluated at an appropriate  $\bar{T}_a$ .

### PROBLEM 7.149

**KNOWN:** Dimensions of slot jet array. Jet exit velocity and temperature. Temperature of paper.

**FIND:** Drying rate per unit surface area.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Applicability of heat and mass transfer analogy, (2) Paper motion has negligible effect on convection ( $U \ll V_e$ ).

**PROPERTIES:** Table A-4, Air (300 K, 1 atm):  $\nu = 15.89 \times 10^{-6} \text{ m}^2/\text{s}$ ; Table A-6, Saturated water (300 K):  $\rho_{A,\text{sat}} = \nu_g^{-1} = 0.0256 \text{ kg/m}^3$ ; Table A-8, Water vapor-air (300 K):  $D_{AB} = 0.26 \times 10^{-4} \text{ m}^2/\text{s}$ ,  $Sc = 0.61$ .

**ANALYSIS:** The mass evaporation flux is

$$n_A'' = \bar{h}_m (\rho_{A,s} - \rho_{A,e}) = \bar{h}_m \rho_{A,\text{sat}}$$

For an array of slot nozzles,

$$\frac{\bar{Sh}}{Sc^{0.42}} = \frac{2}{3} A_{r,o}^{3/4} \left( \frac{2 Re}{A_r / A_{r,o} + A_{r,o} / A_r} \right)^{2/3}$$

where

$$A_r = W/S = 0.1$$

$$A_{r,o} = \left\{ 60 + 4 \left[ \left( \frac{H}{2W} \right) - 2 \right]^2 \right\}^{-1/2} = \{ 60 + 4(64) \}^{-1/2} = 0.0563$$

$$Re = \frac{V_e (2W)}{\nu} = \frac{20 \text{ m/s} (0.02 \text{ m})}{15.89 \times 10^{-6} \text{ m}^2/\text{s}} = 25,173.$$

Hence

$$\frac{\bar{Sh}}{Sc^{0.42}} = 0.667 (0.0563)^{3/4} \left( \frac{50,346}{1.776 + 0.563} \right)^{2/3} = 59.6$$

$$\bar{h}_m = \frac{D_{AB}}{2W} 59.6 Sc^{0.42} = \frac{0.26 \times 10^{-4} \text{ m}^2/\text{s}}{0.02 \text{ m}} 59.6 (0.61)^{0.42} = 0.063 \text{ m/s}.$$

The evaporative flux is then

$$n_A'' = 0.063 \text{ m/s} (0.0256 \text{ kg/m}^3) = 0.0016 \text{ kg/s} \cdot \text{m}^2. \quad \leftarrow$$

**COMMENTS:** The mass fraction of water vapor to air leaving the sides of the dryer is

$n_A'' (S \times L) / \rho_{\text{air}} V_e (W \times L) = 7 \times 10^{-4}$ . Hence, the assumption of dry air throughout the dryer is reasonable.

### PROBLEM 8.1

**KNOWN:** Flowrate and temperature of water in fully developed flow through a tube of prescribed diameter.

**FIND:** Maximum velocity and pressure gradient.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Isothermal flow, (3) Horizontal tube.

**PROPERTIES:** Table A-6, Water (300 K):  $\rho = 998 \text{ kg/m}^3$ ,  $\mu = 855 \times 10^{-6} \text{ N}\cdot\text{s/m}^2$ .

**ANALYSIS:** From Eq. 8.6,

$$\text{Re}_D = \frac{4\dot{m}}{\pi D \mu} = \frac{4 \times 0.01 \text{ kg/s}}{\pi (0.025 \text{ m}) 855 \times 10^{-6} \text{ kg/m}\cdot\text{s}} = 596.$$

Hence the flow is laminar and the velocity profile is given by Eq. 8.15,

$$\frac{u(r)}{u_m} = 2 \left[ 1 - (r/r_0)^2 \right].$$

The maximum velocity is therefore at  $r = 0$ , the centerline, where

$$u(0) = 2 u_m.$$

From Eq. 8.5

$$u_m = \frac{\dot{m}}{\rho \pi D^2 / 4} = \frac{4 \times 0.01 \text{ kg/s}}{998 \text{ kg/m}^3 \times \pi (0.025 \text{ m})^2} = 0.020 \text{ m/s},$$

hence

$$u(0) = 0.041 \text{ m/s}.$$

Combining Eqs. 8.16 and 8.19, the pressure gradient is

$$\frac{dp}{dx} = -\frac{64}{\text{Re}_D} \frac{\rho u_m^2}{2D}$$

$$\frac{dp}{dx} = -\frac{64}{596} \times \frac{998 \text{ kg/m}^3 (0.020 \text{ m/s})^2}{2 \times 0.025 \text{ m}} = -0.86 \text{ kg/m}^2 \cdot \text{s}^2$$

$$\frac{dp}{dx} = -0.86 \text{ N/m}^2 \cdot \text{m} = -0.86 \times 10^{-5} \text{ bar/m}.$$

<

## PROBLEM 8.2

**KNOWN:** Temperature and mean velocity of water flow through a cast iron pipe of prescribed length and diameter.

**FIND:** Pressure drop.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Fully developed flow, (3) Constant properties.

**PROPERTIES:** Table A-6, Water (300 K):  $\rho = 997\text{ kg/m}^3$ ,  $\mu = 855 \times 10^{-6}\text{ N}\cdot\text{s/m}^2$ .

**ANALYSIS:** From Eq. 8.22, the pressure drop is

$$\Delta p = f \frac{\rho u_m^2}{2D} L.$$

With

$$\text{Re}_D = \frac{\rho u_m D}{\mu} = \frac{997\text{ kg/m}^3 \times 0.2\text{ m/s} \times 0.15\text{ m}}{855 \times 10^{-6}\text{ N}\cdot\text{s/m}^2} = 3.50 \times 10^4$$

the flow is turbulent and with  $e = 2.6 \times 10^{-4}\text{ m}$  for cast iron (see Fig. 8.3), it follows that  $e/D = 1.73 \times 10^{-3}$  and from Eq. 8.20 (or Fig. 8.3)

$$\frac{1}{\sqrt{f}} = -2.0 \log \left[ \frac{e/D}{3.7} + \frac{2.51}{\text{Re}_D \sqrt{f}} \right] \quad f = 0.027$$

Hence,

$$\Delta p = 0.027 \frac{997\text{ kg/m}^3 (0.2\text{ m/s})^2}{2 \times 0.15\text{ m}} (600\text{ m})$$

$$\Delta p = 2154\text{ kg/s}^2 \cdot \text{m} = 2154\text{ N/m}^2$$

$$\Delta p = 0.0215\text{ bar.} \quad \leftarrow$$

**COMMENTS:** For the prescribed geometry,  $L/D = (600/0.15) = 4000 \gg (x_{fd,h}/D)_{\text{turb}} \approx 10$ , and the assumption of fully developed flow throughout the pipe is justified.

### PROBLEM 8.3

**KNOWN:** Temperature and velocity of water flow in a pipe of prescribed dimensions.

**FIND:** Pressure drop and pump power requirement for (a) a smooth pipe, (b) a cast iron pipe with a clean surface, and (c) smooth pipe for a range of mean velocities 0.05 to 1.5 m/s.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady, fully developed flow.

**PROPERTIES:** Table A.6, Water (300 K):  $\rho = 997 \text{ kg/m}^3$ ,  $\mu = 855 \times 10^{-6} \text{ N}\cdot\text{s/m}^2$ ,  $\nu = \mu/\rho = 8.576 \times 10^{-7} \text{ m}^2/\text{s}$ .

**ANALYSIS:** From Eq. 8.22a and 8.22b, the pressure drop and pump power requirement are

$$\Delta p = f \frac{\rho u_m^2}{2D} L \quad P = \Delta p \dot{V} = \Delta p \left( \pi D^2 / 4 \right) u_m \quad (1,2)$$

The friction factor,  $f$ , may be determined from Figure 8.3 or Eq. 8.20 for different relative roughness,  $e/D$ , surfaces or from Eq. 8.21 for the smooth condition,  $3000 \leq \text{Re}_D \leq 5 \times 10^6$ ,

$$f = \left( 0.790 \ln(\text{Re}_D) - 1.64 \right)^{-2} \quad (3)$$

where the Reynolds number is

$$\text{Re}_D = \frac{u_m D}{\nu} = \frac{1 \text{ m/s} \times 0.25 \text{ m}}{8.576 \times 10^{-7} \text{ m}^2/\text{s}} = 2.915 \times 10^5 \quad (4)$$

(a) *Smooth surface:* from Eqs. (3), (1) and (2),

$$f = \left( 0.790 \ln(2.915 \times 10^5) - 1.64 \right)^{-2} = 0.01451$$

$$\Delta p = 0.01451 \left( 997 \text{ kg/m}^3 \times 1 \text{ m}^2/\text{s}^2 / 2 \times 0.25 \text{ m} \right) 1000 \text{ m} = 2.89 \times 10^4 \text{ kg/s}^2 \cdot \text{m} = 0.289 \text{ bar} <$$

$$P = 2.89 \times 10^4 \text{ N/m}^2 \left( \pi \times 0.25^2 \text{ m}^2 / 4 \right) 1 \text{ m/s} = 1418 \text{ N} \cdot \text{m/s} = 1.42 \text{ kW} <$$

(b) *Cast iron clean surface:* with  $e = 260 \mu\text{m}$ , the relative roughness is  $e/D = 260 \times 10^{-6} \text{ m} / 0.25 \text{ m} = 1.04 \times 10^{-3}$ . From Figure 8.3 or Eq. 8.20 with  $\text{Re}_D = 2.92 \times 10^5$ , find  $f = 0.021$ . Hence,

$$\Delta p = 0.402 \text{ bar} \quad P = 1.97 \text{ kW} <$$

(c) *Smooth surface:* Using IHT with the expressions of part (a), the pressure drop and pump power requirement as a function of mean velocity,  $u_m$ , for the range  $0.05 \leq u_m \leq 1.5 \text{ m/s}$  are computed and plotted below.

Continued...

## PROBLEM 8.4

**KNOWN:** Number, diameter and length of tubes and flow rate for an engine oil cooler.

**FIND:** Pressure drop and pump power (a) for flow rate of 24 kg/s and (b) as a function of flow rate for the range  $10 \leq \dot{m} \leq 30$  kg/s.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Fully developed flow throughout the tubes.

**PROPERTIES:** Table A.5, Engine oil (300 K):  $\rho = 884$  kg/m<sup>3</sup>,  $\mu = 0.486$  kg/s·m.

**ANALYSIS:** (a) Considering flow through a single tube, find

$$\text{Re}_D = \frac{4\dot{m}}{\pi D \mu} = \frac{4(24 \text{ kg/s})}{25\pi(0.010 \text{ m})0.486 \text{ kg/s}\cdot\text{m}} = 251.5 \quad (1)$$

Hence, the flow is laminar and from Equation 8.19,

$$f = \frac{64}{\text{Re}_D} = \frac{64}{251.5} = 0.2545. \quad (2)$$

With

$$u_m = \frac{\dot{m}_1}{\rho(\pi D^2/4)} = \frac{(24/25) \text{ kg/s}(4)}{(884 \text{ kg/m}^3)\pi(0.010 \text{ m})^2} = 13.8 \text{ m/s} \quad (3)$$

Equation 8.22a yields

$$\Delta p = f \frac{\rho u_m^2}{2D} L = 0.2545 \frac{(884 \text{ kg/m}^3)(13.8 \text{ m/s})^2}{2(0.010 \text{ m})} 2.5 \text{ m} = 5.38 \times 10^6 \text{ N/m}^2 = 53.8 \text{ bar} \quad (4) \ll$$

The pump power requirement from Equation 8.22b,

$$P = \Delta p \cdot \dot{V} = \Delta p \cdot \frac{\dot{m}}{\rho} = 5.38 \times 10^6 \text{ N/m}^2 \frac{24 \text{ kg/s}}{884 \text{ kg/m}^3} = 1.459 \times 10^5 \text{ N}\cdot\text{m/s} = 146 \text{ kW}. \quad (5) \ll$$

(b) Using IHT with the expressions of part (a), the pressure drop and pump power requirement as a function of flow rate,  $\dot{m}$ , for the range  $10 \leq \dot{m} \leq 30$  kg/s are computed and plotted below.

Continued...

## PROBLEM 8.4 (Cont.)

In the plot above, note that the pressure drop is linear with the flow rate since, from Eq. (2), the friction factor is inversely dependent upon mean velocity. The pump power, however, is quadratic with the flow rate.

**COMMENTS:** (1) If there is a hydrodynamic entry region, the average friction factor for the entire tube length would exceed the fully developed value, thereby increasing  $\Delta p$  and  $P$ .

(2) The *IHT Workspace* used to generate the graphical results follows.

```

/* Results: base case, part (a)

```

## PROBLEM 8.5

**KNOWN:** The x-momentum equation for fully developed laminar flow in a parallel-plate channel

$$\frac{dp}{dx} = \text{constant} = \mu \frac{d^2u}{dy^2}$$

**FIND:** Following the same approach as for the circular tube in Section 8.1: (a) Show that the velocity profile,  $u(y)$ , is parabolic of the form

$$u(y) = \frac{3}{2} u_m \left[ 1 - \frac{y^2}{(a/2)^2} \right]$$

where  $u_m$  is the mean velocity expressed as

$$u_m = \frac{a^2}{12\mu} \left( -\frac{dP}{dx} \right)$$

and  $-dp/dx = \Delta p/L$  where  $\Delta p$  is the pressure drop across the channel of length  $L$ ; (b) Write the expression defining the friction factor,  $f$ , using the hydraulic diameter as the characteristic length,  $D_h$ ; What is the hydraulic diameter for the parallel-plate channel? (c) The friction factor is estimated from the expression  $f = C/Re_{D_h}$  where  $C$  depends upon the flow cross-section as shown in Table 8.1;

What is the coefficient  $C$  for the parallel-plate channel ( $b/a \rightarrow \infty$ )? (d) Calculate the mean air velocity and the Reynolds number for air at atmospheric pressure and 300 K in a parallel-plate channel with separation of 5 mm and length of 100 mm subjected to a pressure drop of  $\Delta p = 3.75 \text{ N/m}^2$ ; Is the assumption of fully developed flow reasonable for this application? If not, what effect does this have on the estimate for  $u_m$ ?

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Fully developed laminar flow, (2) Parallel-plate channel,  $a \ll b$ .

**PROPERTIES:** Table A-4, Air (300 K, 1 atm):  $\mu = 184.6 \times 10^{-7} \text{ N}\cdot\text{s/m}^2$ ,  $\nu = 15.89 \times 10^{-6} \text{ m}^2/\text{s}$ .

**ANALYSIS:** (a) The x-momentum equation for fully developed laminar flow is

$$\mu \left( \frac{d^2u}{dy^2} \right) = \frac{dp}{dx} = \text{constant} \quad (1)$$

Since the longitudinal pressure gradient is constant, separate variables and integrate twice,

$$\frac{d}{dy} \left( \frac{du}{dy} \right) = \frac{1}{\mu} \left( \frac{dp}{dx} \right) \quad \frac{du}{dy} = \frac{1}{\mu} \left( \frac{dp}{dx} \right) y + C_1$$

$$u = \frac{1}{2\mu} \left( \frac{dp}{dx} \right) y^2 + C_1 y + C_2$$

Continued ...

### PROBLEM 8.5 (Cont.)

The integration constants are determined from the boundary conditions,

$$\left. \frac{du}{dy} \right|_{y=0} = 0 \quad u(a/2) = 0$$

to find

$$C_1 = 0 \quad C_2 = -\frac{1}{2\mu} \left( \frac{dp}{dx} \right) (a/2)^2$$

giving

$$u(y) = -\frac{(a/2)^2}{2\mu} \left( \frac{dp}{dx} \right) \left[ 1 - \frac{y^2}{(a/2)^2} \right] \quad (2)$$

The mean velocity is

$$u_m = \frac{2}{a} \int_0^{a/2} u(y) dy = -\frac{2}{a} \frac{(a/2)^2}{2\mu} \left( \frac{dp}{dx} \right) \left[ y - \frac{y^3/3}{(a/2)^2} \right]_0^{a/2}$$

$$u_m = \frac{a^2}{12\mu} \left( -\frac{dp}{dx} \right) \quad (3)$$

Substituting Eq. (3) for  $dp/dx$  into Eq. (2) find the velocity distribution in terms of the mean velocity

$$u(y) = \frac{3}{2} u_m \left[ 1 - \frac{y^2}{(a/2)^2} \right] \quad < \quad (4)$$

(b) The friction factor follows from its definition, Eq. 8.16,

$$f = \frac{-(dp/dx) D_h}{\rho \cdot u_m^2 / 2} \quad (5)$$

where the hydraulic diameter for the channel using Eq. 8.66 is

$$D_h = \frac{4 \cdot A_c}{P} = \frac{4(a \times b)}{2(a+b)} = 2a \quad < \quad (6)$$

since  $a \ll b$ .

(c) Substituting for the pressure gradient, Eq. (3), and rearranging, find using Eq. (6),

$$f = \frac{u_m}{a^2 / 12\mu} \frac{D_h}{\rho u_m^2 / 2} = \frac{96}{u_m D_h / \nu} = \frac{96}{\text{Re}_{D_h}} \quad < \quad (7)$$

where the Reynolds number is

$$\text{Re}_{D_h} = u_m D_h / \nu \quad (8)$$

Continued ...

### PROBLEM 8.5 (Cont.)

This result is in agreement with Table 8.1 for the cross-section with  $b/a \rightarrow \infty$  where

$$C = 96.$$

<

(d) For the conditions shown in the schematic, with air properties evaluated at 300 K, using Eqs. (3) and (8), find

$$u_m = \frac{(0.005\text{m})^2}{12 \times 184.6 \times 10^{-7} \text{ N} \cdot \text{s} / \text{m}^2} \left( \frac{3.75 \text{ N} / \text{m}^2}{0.200\text{m}} \right) = 2.12 \text{ m/s}$$

$$\text{Re}_D = \frac{2.12 \text{ m/s} \times 2 \times 0.005 \text{ m}}{15.89 \times 10^{-6} \text{ m}^2 / \text{s}} = 1332$$

The flow is laminar since  $\text{Re}_{Dh} < 2300$ , and from Eq. 8.3, the laminar entry length is

$$\left( \frac{x_{fd,h}}{D_h} \right)_{\text{lam}} = 0.05 \text{Re}_{Dh}$$

$$x_{fd,h} = 2 \times 0.005 \text{ m} \times 0.05 \times 1332 = 0.67 \text{ m}$$

We conclude that the flow is not fully developed, and the friction factor in the entry region will be higher than for fully developed conditions. Hence, for the same pressure drop, the mean velocity will be less than our estimate.

## PROBLEM 8.6

**KNOWN:** Water, engine oil and NaK flowing in a 20 mm diameter tube, temperature of the fluids.

**FIND:** (a) The mean velocity as well as hydrodynamic and thermal entrance lengths, for a flow rate of 0.01 kg/s and mean temperature of 366 K, (b) The mass flow rate as well as hydrodynamic and thermal entrance lengths for water and oil at a mean velocity of 0.02 m/s at mean temperatures of 300 and 400 K.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Constant properties.

**PROPERTIES:**

Liquid	T(K)	Table	$\rho(\text{kg/m}^3)$	$\mu(\text{N}\cdot\text{s/m}^2)$	$\nu(\text{m}^2/\text{s})$	Pr
Water	300	A.6	997	$855 \times 10^{-6}$	-	5.83
	366	A.6	963	$303 \times 10^{-6}$	-	1.89
	400	A.6	937	$217 \times 10^{-6}$	-	1.34
Oil	300	A.5	884	$48.6 \times 10^{-2}$	-	6400
	366	A.5	844	$2.12 \times 10^{-2}$	-	338
	400	A.5	825	$0.874 \times 10^{-2}$	-	152
NaK	366	A.7	849	-	$5.797 \times 10^{-7}$	0.019

**ANALYSIS:** (a) The mean velocity is given by

$$u_m = \dot{m} / \rho A_c = 0.01 \text{ kg/s} / [\rho \pi (0.020 \text{ m})^2 / 4] = 31.8 \text{ kg/s} \cdot \text{m}^2 / \rho \quad (1)$$

The Reynolds number is

$$\text{Re}_D = \frac{4\dot{m}}{\pi D \mu} = \frac{4 \times 0.01 \text{ kg/s}}{\pi (0.020 \text{ m}) \mu} = \frac{0.636 \text{ kg/s} \cdot \text{m}}{\mu} \quad (2)$$

The hydrodynamic entrance length is

$$\begin{aligned} x_{fd,h} &= 0.05 \text{Re}_D D = 0.05 \times \frac{0.636 \text{ kg/s} \cdot \text{m}}{\mu} \times (0.020 \text{ m}) \\ &= \frac{636 \times 10^{-6} \text{ kg/s} \cdot \text{m}}{\mu} \end{aligned} \quad (3)$$

Continued...

**PROBLEM 8.6 (Cont.)**

The thermal entrance length is

$$\begin{aligned}
 x_{fd,t} &= 0.05Re_D DPr = x_{fd,h} Pr \\
 &= \frac{636 \times 10^{-6} \text{ kg/s} \cdot \text{m}}{\mu} Pr
 \end{aligned}
 \tag{4}$$

Solving Equations (1), (3) and (4) yields

Liquid	$u_m$ (m/s)	$x_{fd,h}$ (m)	$x_{fd,t}$ (m)
water	0.033	2.1	3.97
engine oil	0.038	0.030	10.1
NaK	0.037	1.3	0.025

where, for the NaK,  $\mu$  is found from the definition

$$\mu = \nu\rho = 5.797 \times 10^{-7} \text{ m}^2/\text{s} \times 849 \text{ kg/m}^3 = 492 \times 10^{-6} \text{ N} \cdot \text{s/m}^2$$

(b) The mass flow rate is given by

$$\dot{m} = \rho A_c u_m = \frac{0.02 \text{ m/s} \times \pi \times (0.020 \text{ m})^2}{4} \rho = 6.28 \times 10^{-6} \frac{\text{m}^3}{\text{s}} \rho \tag{5}$$

The Reynolds number is

$$Re_D = \frac{4\dot{m}}{\pi D\mu} = \frac{4 \times 6.28 \times 10^{-6} \text{ m}^3/\text{s} \times \rho}{\pi(0.020 \text{ m})\mu} = 400 \times 10^{-6} \text{ m}^2/\text{s} \times (\rho/\mu) \tag{6}$$

The hydrodynamic entrance length is

$$\begin{aligned}
 x_{fd,h} &= 0.05Re_D D = 0.05 \times 400 \times 10^{-6} \text{ m}^2/\text{s} \times 0.02 \text{ m} (\rho/\mu) \\
 x_{fd,h} &= 400 \times 10^{-9} \text{ m}^3/\text{s} (\rho/\mu)
 \end{aligned}
 \tag{7}$$

The thermal entrance length is

$$x_{fd,t} = x_{fd,h} Pr = 400 \times 10^{-9} \text{ m}^3/\text{s} (\rho/\mu) Pr \tag{8}$$

Solving Equations (5), (7) and (8) yields

Liquid	T (k)	$\dot{m}$ (kg/s)	$x_{fd,h}$ (m)	$x_{fd,t}$ (m)
Water	300	0.0063	0.464	2.72
Water	400	0.0059	1.72	2.30
Engine Oil	300	0.0056	$7.27 \times 10^{-4}$	4.65
Engine Oil	400	0.0052	$37.7 \times 10^{-3}$	5.74

**COMMENTS:** (1) As the momentum and thermal diffusivities approach similar values ( $Pr \rightarrow 1$ )  $x_{fd,h}/x_{fd,t} \rightarrow 1$ . (2) Note the variation of  $x_{fd,h}/x_{fd,t}$  with  $Pr$  for large and small values of the Prandtl number. (c) The Reynolds number associated with the oil is very small. Buoyancy forces are likely to be significant and may induce secondary fluid motion which, in turn, may increase the convection heat transfer coefficients. We will treat buoyancy effects in Chapter 9.

## PROBLEM 8.7

**KNOWN:** Velocity and temperature profiles for laminar flow in a tube of radius  $r_o = 10$  mm.

**FIND:** Mean (or bulk) temperature,  $T_m$ , at this axial position.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Laminar incompressible flow, (2) Constant properties.

**ANALYSIS:** The prescribed velocity and temperature profiles, (m/s and K, respectively) are

$$u(r) = 0.1 [1 - (r/r_o)^2] \quad T(r) = 344.8 + 75.0 (r/r_o)^2 - 18.8 (r/r_o)^4 \quad (1,2)$$

For incompressible flow with constant  $c_v$  in a circular tube, from Eq. 8.26, the mean temperature and  $u_m$ , the mean velocity, from Eq. 8.8 are, respectively,

$$T_m = \frac{2}{u_m r_o^2} \int_0^{r_o} u(r) \cdot T(r) \cdot r \cdot dr \quad u_m = \frac{2}{r_o^2} \int_0^{r_o} u(r) \cdot r \cdot dr \quad (3,4)$$

Substituting the velocity profile, Eq. (1), into Eq. (4) and integrating, find

$$u_m = \frac{2}{r_o^2} \int_0^{r_o} 0.1 [1 - (r/r_o)^2] (r/r_o) d(r/r_o) = 2 \left\{ 0.1 \left[ \frac{1}{2} (r/r_o)^2 - \frac{1}{4} (r/r_o)^4 \right] \right\}_0^1 = 0.05 \text{ m/s}$$

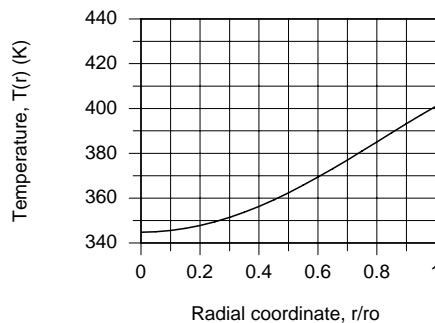

Substituting the profiles and  $u_m$  into Eq. (3), find

$$T_m = \frac{2}{(0.05 \text{ m/s}) r_o^2} \int_0^{r_o} \left\{ 0.1 [1 - (r/r_o)^2] \right\} \left\{ 344.8 + 75.0 (r/r_o)^2 - 18.8 (r/r_o)^4 \right\} \cdot (r/r_o) \cdot d(r/r_o)$$

$$T_m = 4 \int_0^1 \left\{ [344.8 (r/r_o) + 75.0 (r/r_o)^3 - 18.8 (r/r_o)^5] - [344.8 (r/r_o)^3 + 75.0 (r/r_o)^5 - 18.8 (r/r_o)^7] \right\} d(r/r_o)$$

$$T_m = 4 \{ [172.40 + 18.75 - 3.13] - [86.20 + 12.50 - 2.35] \} = 367 \text{ K} \quad <$$

The velocity and temperature profiles appear as shown below. Do the values of  $u_m$  and  $T_m$  found above compare with their respective profiles as you thought? Is the fluid being heated or cooled?

## PROBLEM 8.8

**KNOWN:** Velocity and temperature profiles for laminar flow in a parallel plate channel.

**FIND:** Mean velocity,  $u_m$ , and mean (or bulk) temperature,  $T_m$ , at this axial position. Plot the velocity and temperature distributions. Comment on whether values of  $u_m$  and  $T_m$  appear reasonable.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Laminar incompressible flow, (2) Constant properties.

**ANALYSIS:** The prescribed velocity and temperature profiles (m/s and °C, respectively) are

$$u(y) = 0.75 \left[ 1 - (y/y_o)^2 \right] \quad T(y) = 5.0 + 95.66(y/y_o)^2 - 47.83(y/y_o)^4 \quad (1,2)$$

The mean velocity,  $u_m$ , follows from its definition, Eq. 8.7,

$$\dot{m} = \rho A_c u_m = \rho \int_{A_c} u(y) \cdot dA_c$$

where the flow cross-sectional area is  $dA_c = 1 \cdot dy$ , and  $A_c = 2y_o$ ,

$$u_m = \frac{1}{A_c} \int_{A_c} u(y) \cdot dy = \frac{1}{2y_o} \int_{-y_o}^{+y_o} u(y) dy \quad (3)$$

$$u_m = \frac{1}{2y_o} \cdot y_o \int_{-1}^{+1} 0.75 \left[ 1 - (y/y_o)^2 \right] d(y/y_o)$$

$$u_m = 1/2 \left\{ 0.75 \left[ (y/y_o) - 1/3 (y/y_o)^3 \right] \right\}_{-1}^{+1}$$

$$u_m = 1/2 \times 0.75 \{ [1 - 1/3] - [-1 + 1/3] \} = 1/2 \times 0.75 \times 4/3 = 2/3 \times 0.75 = 0.50 \text{ m/s} \quad <$$

The mean temperature,  $T_m$ , follows from its definition, Eq. 8.25,

$$\dot{E}_t = \dot{m} c_v T_m \quad \text{where} \quad \dot{m} = \rho A_c u_m$$

$$\rho A_c u_m c_p T_m = \rho c_p \int_{A_c} u(y) \cdot T(y) dA_c$$

Hence, substituting velocity and temperature profiles,

$$T_m = \frac{1}{u_m A_c} \int_{-y_o}^{+y_o} u(y) \cdot T(y) dy \quad (4)$$

$$T_m = \frac{1}{(0.5 \text{ m/s}) 2y_o} y_o \int_{-1}^{+1} \left\{ 0.75 \left[ 1 - (y/y_o)^2 \right] \right\} \left\{ 5.0 + 95.66(y/y_o)^2 - 47.83(y/y_o)^4 \right\} d(y/y_o)$$

$$T_m = \frac{0.75}{0.5 \times 2} \left\{ \left[ 5(y/y_o) + 31.89(y/y_o)^3 - 9.57(y/y_o)^5 \right] - \left[ 1.67(y/y_o)^3 + 19.13(y/y_o)^5 - 6.83(y/y_o)^7 \right] \right\}_{-1}^{+1}$$

$$T_m = \frac{0.75}{0.5 \times 2} \{ [27.32 - 13.97] - [-27.32 - (-13.97)] \} = 20.0^\circ \text{C} \quad <$$

Continued...

### PROBLEM 8.8 (Cont.)

The velocity and temperature profiles along with the  $u_m$  and  $T_m$  values are plotted below.

For the velocity profile, the mean velocity is  $2/3$  that of the centerline velocity,  $u_m = 2u(0)/3$ . Note that the areas above and below the  $u_m$  line appear to be equal. Considering the temperature profile, we'd expect the mean temperature to be closer to the centerline temperature since the velocity profile weights the integral toward the centerline.

**COMMENTS:** The integrations required to obtain  $u_m$  and  $T_m$ , Eqs. (3) and (4), could also be performed using the intrinsic function *INTEGRAL* ( $y,x$ ) in the *IHT Workspace*.

## PROBLEM 8.9

**KNOWN:** Flow rate and properties of oil flowing in pipe. Dimensions of pipe.

**FIND:** Pressure drop, flow work, temperature rise caused by flow work.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, (2) Incompressible flow, (3) Negligible kinetic and potential energy changes, (4) No work *other than* flow work.

**ANALYSIS:** We begin by determining whether the flow is laminar or turbulent. From Equation 8.6

$$Re_d = \frac{4\dot{m}}{\pi D \mu} = \frac{4 \times 500 \text{ kg/s}}{\pi \times 1.2 \text{ m} \times 0.765 \text{ N}\cdot\text{s/m}^2} = 693$$

and the flow is laminar. The friction factor is given by Equation 8.19,

$$f = 64/Re_D$$

and the pressure drop by Equation 8.22a,

$$\Delta p = f \frac{\rho u_m^2}{2D} (x_2 - x_1) = 32 \frac{\rho u_m^2}{D Re_D} L$$

where  $u_m$  can be found from  $\dot{m} = \rho u_m A_c$  :

$$u_m = \frac{\dot{m}}{\rho A_c} = \frac{\dot{m}}{\rho \pi D^2/4} = \frac{4 \times 500 \text{ kg/s}}{900 \text{ kg/m}^3 \times \pi \times (1.2 \text{ m})^2} = 0.491 \text{ m/s}$$

Thus

$$p_{in} - p_{out} = \Delta p = \frac{32 \times 900 \text{ kg/m}^3 \times (0.491 \text{ m/s})^2 \times 100,000 \text{ m}}{1.2 \text{ m} \times 693} = 8.4 \times 10^5 \text{ Pa}$$

$$\Delta p = 0.84 \text{ MPa} \quad <$$

The flow work is then found from its definition (see discussion leading to Equation 1.11d),

$$\begin{aligned} \dot{W}_{flow} &= \frac{\dot{m}}{\rho} (p_{in} - p_{out}) = 500 \text{ kg/s} \times 0.84 \text{ MPa} / 900 \text{ kg/m}^3 \\ &= 0.46 \text{ MW} \quad < \end{aligned}$$

Finally, with reference to Equation 1.12d, the portion of the temperature rise due to flow work is given by

$$\begin{aligned} \dot{m} c_p \Delta T_{flow} &= \frac{\dot{m}}{\rho} (p_{in} - p_{out}) = \dot{W}_{flow} \\ \Delta T_{flow} &= \dot{W}_{flow} / \dot{m} c_p = 0.46 \text{ MW} / (500 \text{ kg/s} \times 2000 \text{ J/kg}\cdot\text{K}) \\ &= 0.46^\circ\text{C} \quad < \end{aligned}$$

**COMMENTS:** Despite the long length of pipeline and high viscosity of the oil, which results in a large pressure drop, the temperature rise due to the flow work is quite small.

## PROBLEM 8.10

**KNOWN:** Thermal energy equation describing laminar, fully developed flow in a circular pipe with viscous dissipation.

**FIND:** (a) Left hand side of equation integrated over the pipe volume, (b) viscous dissipation term integrated over the same volume, (c) temperature rise caused by viscous dissipation.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, (2) Laminar, (3) Fully-developed.

**ANALYSIS:** (a) The thermal energy equation is given as

$$\rho c_p u \frac{\partial T}{\partial x} = \frac{k}{r} \frac{\partial}{\partial r} \left( r \frac{\partial T}{\partial r} \right) + \mu \left( \frac{du}{dr} \right)^2$$

where  $u$  is given by Equation 8.15,

$$u = 2 u_m \left[ 1 - (r/r_0)^2 \right]$$

Integrating the advection term on the left-hand side over a section of the pipe of length  $L$ , we have

$$\begin{aligned} \text{Adv.} &= \int_0^L \int_{A_c} \rho c_p u \frac{\partial T}{\partial x} dA_c dx \\ &= \int_0^L \frac{d}{dx} \left[ \int_{A_c} \rho c_p u T dA_c \right] dx \end{aligned}$$

From Equation 8.25, the term in square brackets is  $\dot{m} c_p T_m$ , thus

$$\text{Adv.} = \int_0^L \dot{m} c_p \frac{dT_m}{dx} dx = \dot{m} c_p (T_{m,o} - T_{m,i}) \quad <$$

which coincides with the right-hand side of Equation 8.34.

(b) Integrating the viscous dissipation term, we have

$$\begin{aligned} \text{Visc. Diss.} &= \int_0^L \int_{A_c} \mu \left( \frac{du}{dr} \right)^2 dA_c dx \\ &= \int_0^L 2 \pi \mu \int_0^{r_0} \left( \frac{du}{dr} \right)^2 r dr dx \\ &= 2 \pi \mu L \int_0^{r_0} 16 u_m^2 \frac{r^2}{r_0^4} r dr \\ &= 32 \pi \mu L u_m^2 \frac{r^2}{4 r_0^4} \Big|_0^{r_0} = 8 \pi \mu L u_m^2 \quad < \end{aligned}$$

Continued...

### PROBLEM 8.10 (Cont.)

(c) Using the values from Problem 8.9,

$$\dot{m} c_p \Delta T_{v.d.} = 8 \pi \mu L u_m^2$$

$$\Delta T_{v.d.} = 8 \pi \mu L u_m^2 / \dot{m} c_p$$

where  $u_m = \dot{m} / \rho A_c$ . Thus

$$\Delta T_{v.d.} = \frac{8 \pi \mu L \dot{m}}{\rho^2 c_p A_c^2}$$

$$= \frac{8\pi \times 0.765 \text{ N}\cdot\text{s/m}^2 \times 100,000 \text{ m} \times 500 \text{ kg/s}}{\left[ (900 \text{ kg/m}^3)^2 \times 2000 \text{ J/kg}\cdot\text{K} \times (\pi \times (1.2 \text{ m})^2/4)^2 \right]}$$

$$= 0.46^\circ\text{C}$$

<

**COMMENTS:** (1) Even in the case of a long pipe with a highly viscous fluid, the temperature rise due to viscous dissipation is quite small. (2) The temperature rise due to viscous dissipation is identical to the temperature rise due to flow work in Problem 8.9. This is no coincidence. In fully-developed pipe flow, there is a balance between the viscous forces (friction) and the pressure drop needed to overcome them. As a result, viscous dissipation exactly equals the work done by the pressure forces (flow work). Conservation of energy can be expressed in a form that includes flow work (for example, Equation 1.12d) or in a form that includes viscous dissipation (for example, Equation 6.29), and in the case of fully-developed pipe flow they are equal.

## PROBLEM 8.11

**KNOWN:** Mass flow rate in a circular tube, tube length and diameter, thermal conditions.

**FIND:** (a) Expression for  $(T_s(x=L) - T_{m,i})/q$  for constant heat flux conditions, (b)  $(T_s - T_{m,i})/q$  for constant surface temperature conditions.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Constant properties.

**ANALYSIS** (a) From Newton's law of cooling,

$$T_s(x=L) - T_m(x=L) = q'' / h \quad (1)$$

and from an energy balance on the entire tube,

$$T_m(x=L) = T_{m,i} + q / \dot{m}c_p \quad (2)$$

Combining Eqs. (1) and (2) and noting that  $q = q''\pi DL$  yields

$$\frac{T_s(x=L) - T_{m,i}}{q} = \frac{1}{\pi DLh} + \frac{1}{\dot{m}c_p}$$

Substituting the expression for the local Nusselt number,  $Nu_D = hD/k$  gives

$$\frac{T_s(x=L) - T_{m,i}}{q} = \frac{1}{Nu_D \pi Lk} + \frac{1}{\dot{m}c_p} \quad <$$

(b) From Eq. (8.41b)

$$\frac{T_s - T_m(x=L)}{T_s - T_{m,i}} = \exp\left(-\frac{\pi D \bar{h} L}{\dot{m}c_p}\right) \quad (3)$$

Combining Eqs. (2) and (3) yields

$$1 - \frac{q / \dot{m}c_p}{(T_s - T_{m,i})} = \exp\left(-\frac{\pi D \bar{h} L}{\dot{m}c_p}\right)$$

Continued...

### PROBLEM 8.11 (Cont.)

which may be rearranged to yield

$$\frac{q}{(T_s - T_{m,i})} = \dot{m}c_p \left[ 1 - \exp\left(-\frac{\pi D \bar{h} L}{\dot{m}c_p}\right) \right]$$

or

$$\frac{(T_s - T_{m,i})}{q} = \frac{1}{\dot{m}c_p \left[ 1 - \exp\left(-\frac{\pi \overline{Nu}_D k L}{\dot{m}c_p}\right) \right]} \quad <$$

**COMMENTS:** (1) The ratio on the LHS is a *figure of merit* that, in many applications, is sought to be minimized. (2) The two terms on the RHS of the final expression for the constant heat flux case may be thought of as thermal resistances. The first term on the RHS is a thermal resistance associated with heat transfer between the fluid and the tube wall at the tube exit, and the second term is associated with the increase in temperature between the tube inlet and the tube exit. (3) As the argument of the exponential term increases in magnitude for the constant surface temperature expression, the mean outlet temperature approaches the surface temperature value (see Eq. 3), and the figure of merit expression reduces to Eq. (2).

## PROBLEM 8.12

**KNOWN:** Internal flow with prescribed wall heat flux as a function of distance.

**FIND:** (a) Beginning with a properly defined differential control volume, the temperature distribution,  $T_m(x)$ , (b) Outlet temperature,  $T_{m,o}$ , (c) Sketch  $T_m(x)$ , and  $T_s(x)$  for fully developed *and* developing flow conditions, and (d) Value of uniform wall flux  $q_s''$  (instead of  $q_s' = ax$ ) providing same outlet temperature as found in part (a); sketch  $T_m(x)$  and  $T_s(x)$  for this heating condition.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Constant properties, (3) Incompressible liquid with negligible viscous dissipation.

**PROPERTIES:** Table A.6, Water (300 K):  $c_p = 4.179 \text{ kJ/kg}\cdot\text{K}$ .

**ANALYSIS:** (a) Applying energy conservation to the control volume above,

$$dq_{\text{conv}} = \dot{m} c_p dT_m \quad (1)$$

where  $T_m(x)$  is the mean temperature at any cross-section and  $dq_{\text{conv}} = q' \cdot dx$ . Hence,

$$ax = \dot{m} c_p \frac{dT_m}{dx} \quad (2)$$

Separating and integrating with proper limits gives

$$a \int_{x=0}^x x dx = \dot{m} c_p \int_{T_{m,i}}^{T_m(x)} dT_m \quad T_m(x) = T_{m,i} + \frac{ax^2}{2\dot{m}c_p} \quad (3,4) <$$

(b) To find the outlet temperature, let  $x = L$ , then

$$T_m(L) = T_{m,o} = T_{m,i} + aL^2/2\dot{m}c_p \quad (5)$$

Solving for  $T_{m,o}$ , we find

$$T_{m,o} = 27^\circ\text{C} + \frac{20 \text{ W/m}^2 (30 \text{ m}^2)}{2(450 \text{ kg/h}/(3600 \text{ s/h})) \times 4179 \text{ J/kg}\cdot\text{K}} = 27^\circ\text{C} + 17.2^\circ\text{C} = 44.2^\circ\text{C} \quad <$$

(c) For *linear wall heating*,  $q_s' = ax$ , the fluid temperature distribution along the length of the tube is quadratic as prescribed by Eq. (4). From the convection rate equation,

$$q_s' = h(x) \cdot \pi D (T_s(x) - T_m(x)) \quad (6)$$

For fully developed flow conditions,  $h(x) = h$  is a constant; hence,  $T_s(x) - T_m(x)$  increases linearly with  $x$ . For developing conditions,  $h(x)$  will decrease with increasing distance along the tube eventually achieving the fully developed value.

Continued...

**PROBLEM 8.12 (Cont.)**

(d) For *uniform wall heat flux heating*, the overall energy balance on the tube yields

$$q = q_s'' \pi D L = \dot{m} c_p (T_{m,o} - T_{m,i})$$

Requiring that  $T_{m,o} = 44.2^\circ\text{C}$  from part (a), find

$$q_s'' = \frac{(450/3600) \text{ kg/s} \times 4179 \text{ J/kg} \cdot \text{K} (44.2 - 27) \text{ K}}{\pi D \times 30 \text{ m}} = 95.3/D \text{ W/m}^2$$

<

where  $D$  is the diameter (m) of the tube which, when specified, would permit determining the required heat flux,  $q_s''$ . For uniform heating, Section 8.3.2, we know that  $T_m(x)$  will be linear with distance.  $T_s(x)$  will also be linear for fully developed conditions and appear as shown below when the flow is developing.

**COMMENTS:** (1) Note that  $c_p$  should be evaluated at  $T_m = (27 + 44)^\circ\text{C}/2 = 309 \text{ K}$ .

(2) Why did we show  $T_s(0) = T_m(0)$  for both types of history when the flow was developing?

(3) Why must  $T_m(x)$  be linear with distance in the case of uniform wall flux heating?

### PROBLEM 8.13

**KNOWN:** Internal flow with constant surface heat flux,  $q_s''$ .

**FIND:** (a) Qualitative temperature distributions,  $T(x)$ , under developing and fully-developed flow, (b) Exit mean temperature for both situations.

**SCHEMATIC:**

**ASSUMPTIONS:** (a) Steady-state conditions, (b) Constant properties, (c) Incompressible flow with negligible viscous dissipation.

**ANALYSIS:** Based upon the analysis leading to Eq. 8.39, note for the case of constant surface heat flux conditions,

$$\frac{dT_m}{dx} = \text{constant.}$$

Hence, regardless of whether the hydrodynamic or thermal boundary layer is fully developed, it follows that

$T_m(x)$  is linear and

$T_{m,2}$  will be the same for all flow conditions. <

The surface heat flux can also be written, using Eq. 8.27, as

$$q_s'' = h[T_s(x) - T_m(x)].$$

Under fully-developed flow and thermal conditions,  $h = h_{fd}$  is a constant. When flow is developing  $h > h_{fd}$ . Hence, the temperature distributions appear as below.

<

### PROBLEM 8.14

**KNOWN:** Geometry and coolant flow conditions associated with a nuclear fuel rod. Axial variation of heat generation within the rod.

**FIND:** (a) Axial variation of local heat flux and total heat transfer rate, (b) Axial variation of mean coolant temperature, (c) Axial variation of rod surface temperature and location of maximum temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Constant fluid properties, (3) Uniform surface convection coefficient, (4) Negligible axial conduction in rod and fluid, (5) Incompressible liquid with negligible viscous dissipation, (6) Outer surface is adiabatic.

**ANALYSIS:** (a) Performing an energy balance for a control volume about the rod,

$$\dot{E}_{in} - \dot{E}_{out} + \dot{E}_g = 0 \quad -dq + \dot{E}_g = 0$$

or

$$-q''(\pi D dx) + \dot{q}_o \sin(\pi x/L) \left(\pi D^2/4\right) dx = 0 \quad q'' = \dot{q}_o (D/4) \sin(\pi x/L). \quad <$$

The total heat transfer rate is then

$$q = \int_0^L q'' \pi D dx = \left(\pi D^2/4\right) \dot{q}_o \int_0^L \sin(\pi x/L) dx$$

$$q = \frac{\pi D^2}{4} \dot{q}_o \left( -\frac{L}{\pi} \cos \frac{\pi x}{L} \right) \Big|_0^L = \frac{D^2 \dot{q}_o L}{4} (1+1)$$

$$q = \frac{D^2 L}{2} \dot{q}_o. \quad (1) <$$

(b) Performing an energy balance for a control volume about the coolant,

$$\dot{m} c_p T_m + dq = \dot{m} c_p (T_m + dT_m) = 0.$$

Hence

$$\dot{m} c_p dT_m = dq = (\pi D dx) q''$$

$$\frac{dT_m}{dx} = \frac{\pi D}{\dot{m} c_p} \frac{\dot{q}_o D}{4} \sin\left(\frac{\pi x}{L}\right).$$

Continued ...

**PROBLEM 8.14 (Cont.)**

Integrating,

$$T_m(x) - T_{m,i} = \frac{\pi D^2}{4} \frac{\dot{q}_o}{\dot{m} c_p} \int_0^x \sin \frac{\pi x}{L} dx$$

$$T_m(x) = T_{m,i} + \frac{L D^2}{4} \frac{\dot{q}_o}{\dot{m} c_p} \left[ 1 - \cos \frac{\pi x}{L} \right] \quad (2) <$$

(c) From Newton's law of cooling,

$$q'' = h(T_s - T_m).$$

Hence

$$T_s = \frac{q''}{h} + T_m$$

$$T_s = \frac{\dot{q}_o D}{4h} \sin \frac{\pi x}{L} + T_{m,i} + \frac{L D^2}{4} \frac{\dot{q}_o}{\dot{m} c_p} \left[ 1 - \cos \frac{\pi x}{L} \right]. \quad <$$

To determine the location of the maximum surface temperature, evaluate

$$\frac{dT_s}{dx} = 0 = \frac{\dot{q}_o D \pi}{4hL} \cos \frac{\pi x}{L} + \frac{L D^2}{4} \frac{\dot{q}_o}{\dot{m} c_p} \frac{\pi}{L} \sin \frac{\pi x}{L}$$

or

$$\frac{1}{hL} \cos \frac{\pi x}{L} + \frac{D}{\dot{m} c_p} \sin \frac{\pi x}{L} = 0.$$

Hence

$$\tan \frac{\pi x}{L} = -\frac{\dot{m} c_p}{D h L}$$

$$x = \frac{L}{\pi} \tan^{-1} \left( -\frac{\dot{m} c_p}{D h L} \right) = x_{\max}. \quad <$$

**COMMENTS:** Note from Eq. (2) that

$$T_{m,o} = T_m(L) = T_{m,i} + \frac{L D^2 \dot{q}_o}{2 \dot{m} c_p}$$

which is equivalent to the result obtained by combining Eq. (1) and Eq. 8.34.

## PROBLEM 8.15

**KNOWN:** Laminar boundary layer development in a tube entrance.

**FIND:** (a) Expression for  $Nu_D$  in terms of  $Gz_D^{-1}$  and  $Pr$ . Plot of  $Nu_D$  versus  $Gz_D^{-1}$  for  $Pr = 0.7$ . (b) Expression for  $\overline{Nu}_D$  in terms of  $Gz_D^{-1}$  and  $Pr$ . Comparison to combined entrance length correlation in the limit of small  $x$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Constant properties. (2) Laminar conditions.

**ANALYSIS:** (a) From Equation 7.23, the Nusselt number based upon the streamwise coordinate  $x$  is

$$Nu_x = \frac{hx}{k} = 0.332 Re_x^{1/2} Pr^{1/3} \quad (1)$$

Multiplying both sides of Equation 1 by  $D/x$  and substituting  $Re_x = Re_D x/D$  yields

$$Nu_D = \frac{hD}{k} = 0.332 \left[ Re_x \left( \frac{x}{D} \right) \right]^{1/2} \left[ \frac{D}{x} \right] Pr^{1/3} = 0.332 \left[ Re_x \left( \frac{D}{x} \right) \right]^{1/2} Pr^{1/3} \quad (2)$$

Substituting  $Gz_D^{-1} = (x/D)/(Re_D Pr)$  into Equation 2 and noting that  $Pr^{1/3} = Pr^{1/2} \cdot Pr^{-1/6}$  yields

$$Nu_D = 0.332 [Gz_D^{-1}]^{-1/2} Pr^{-1/6} \quad <$$

The expression for the local Nusselt number,  $Nu_D$  with  $Pr = 0.7$  is plotted below.

Continued...

**PROBLEM 8.15 (Cont.)**

(b) Equation 7.30 gives the following for the average Nusselt number:

$$\overline{Nu}_x = \frac{\bar{h}_x x}{k} = 0.664 Re_x^{1/2} Pr^{1/3}$$

Following the same steps as in part (a), this can be rewritten as

$$\overline{Nu}_D = 0.664 [Gz_D^{-1}]^{-1/2} Pr^{-1/6} \quad (3)$$

The average Nusselt number for the combined entrance length is given as

$$\overline{Nu}_D = \frac{\frac{3.66}{\tanh\left[2.264 Gz_D^{-1/3} + 1.7 Gz_D^{-2/3}\right]} + 0.0499 Gz_D \tanh\left(Gz_D^{-1}\right)}{\tanh\left(2.432 Pr^{1/6} Gz_D^{-1/6}\right)}$$

In the limit of small  $x$ ,  $Gz_D^{-1}$  is also small. Furthermore,  $Gz_D^{-2/3} \ll Gz_D^{-1/3}$ . Noting that  $\tanh(\varepsilon) \rightarrow \varepsilon$  as  $\varepsilon \rightarrow 0$ , we find

$$\begin{aligned} \overline{Nu}_D &= \frac{\frac{3.66}{\tanh\left[2.264 Gz_D^{-1/3} + 1.7 Gz_D^{-2/3}\right]} + 0.0499 Gz_D \tanh\left(Gz_D^{-1}\right)}{\tanh\left(2.432 Pr^{1/6} Gz_D^{-1/6}\right)} \\ &\rightarrow \frac{\frac{3.66}{2.264 Gz_D^{-1/3}} + 0.0499 Gz_D Gz_D^{-1}}{2.432 Pr^{1/6} Gz_D^{-1/6}} \rightarrow \frac{3.66}{2.264 \times 2.432 Gz_D^{-1/6} Gz_D^{-1/3} Pr^{1/6}} = 0.665 [Gz_D^{-1}]^{-1/2} Pr^{-1/6} \end{aligned}$$

This is in excellent agreement with Eq. (3).

Continued...

### PROBLEM 8.15 (Cont.)

**COMMENT:** The combined thermal entrance length solution and the boundary layer solution based upon the results of Chapter 7 exhibit asymptotic behavior at small inverse Graetz numbers. Small values of  $Gz_D^{-1}$  correspond to the locations where the boundary layer is very thin.

### PROBLEM 8.16

**KNOWN:** Axial variation of surface heat flux for flow through a tube.

**FIND:** Axial variation of fluid and surface temperatures.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Convection coefficient is independent of \$x\$, (2) Applicability of Eq. 8.34.

**ANALYSIS:** Since Equation 8.37 is applicable,

$$\frac{dT_m}{dx} = \frac{q_s'' P}{\dot{m} c_p} = \frac{(\pi D) q_{s,m}'' \sin(\pi x/L)}{\dot{m} c_p}$$

Separating variables and integrating from \$x = 0\$

$$\int_{T_{m,i}}^{T_{m,o}} dT_m = \frac{\pi D q_{s,m}''}{\dot{m} c_p} \int_0^x \sin \frac{\pi x}{L} dx$$

$$T_m(x) - T_{m,i} = -\frac{LD q_{s,m}''}{\dot{m} c_p} \cos \frac{\pi x}{L} \Big|_0^x$$

$$T_m(x) = T_{m,i} + \frac{LD q_{s,m}''}{\dot{m} c_p} (1 - \cos \pi x/L). \quad <$$

From Newton's law of cooling, Eq. 8.27,

$$T_s(x) = (q_s''/h) + T_m(x)$$

$$T_s(x) = \frac{q_{s,m}''}{h} \sin \frac{\pi x}{L} + T_{m,i} + \frac{LD q_{s,m}''}{\dot{m} c_p} (1 - \cos \pi x/L). \quad <$$

**COMMENTS:** For the prescribed surface condition, the flow is not fully developed. Hence, the assumption of constant \$h\$ should be viewed as a first approximation.

### PROBLEM 8.17

**KNOWN:** Surface heat flux for air flow through a rectangular channel.

**FIND:** (a) Differential equation describing variation in air mean temperature, (b) Air outlet temperature for prescribed conditions.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Ideal gas with negligible viscous dissipation and pressure variation, (2) No heat loss through bottom of channel, (3) Uniform heat flux at top of channel.

**PROPERTIES:** Table A-4, Air ( $T \approx 50^\circ\text{C}$ , 1 atm):  $c_p = 1008 \text{ J/kg}\cdot\text{K}$ .

**ANALYSIS:** (a) For the differential control volume about the air,

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\dot{m} c_p T_m + q_o'' (w \cdot dx) = \dot{m} c_p (T_m + dT_m)$$

$$\frac{dT_m}{dx} = \frac{q_o'' \cdot w}{\dot{m} c_p}$$

Separating and integrating between the limits of  $x = 0$  and  $x$ , find

$$T_m(x) = T_{m,i} + \frac{q_o'' (w \cdot x)}{\dot{m} c_p}$$

$$T_{m,o} = T_{m,i} + \frac{q_o'' (w \cdot L)}{\dot{m} c_p} \quad <$$

(b) Substituting numerical values, the air outlet temperature is

$$T_{m,o} = 40^\circ\text{C} + \frac{(700 \text{ W/m}^2) (1 \times 3) \text{ m}^2}{0.1 \text{ kg/s} (1008 \text{ J/kg}\cdot\text{K})}$$

$$T_{m,o} = 60.8^\circ\text{C} \quad <$$

**COMMENTS:** Due to increasing heat loss with increasing  $T_m$ , the net flux  $q_o''$  will actually decrease slightly with increasing  $x$ .

## PROBLEM 8.18

**KNOWN:** Air inlet conditions and heat transfer coefficient for a circular tube of prescribed geometry. Surface heat flux.

**FIND:** (a) Tube heat transfer rate,  $q$ , air outlet temperature,  $T_{m,o}$ , and surface inlet and outlet temperatures,  $T_{s,i}$  and  $T_{s,o}$ , for a uniform surface heat flux,  $q''_s$ . Air mean and surface temperature distributions. (b) Values of  $q$ ,  $T_{m,o}$ ,  $T_{s,i}$  and  $T_{s,o}$  for a linearly varying surface heat flux  $q''_s = 500x$  (m). Air mean and surface temperature distributions, (c) For each type of heating process (a & b), compute and plot the mean fluid and surface temperatures,  $T_m(x)$  and  $T_s(x)$ , respectively, as a function of distance; What is effect of four-fold increase in convection coefficient, and (d) For each type of heating process, heat fluxes required to achieve an outlet temperature of  $T_{m,o} = 125^\circ\text{C}$ ; Plot temperatures.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Fully developed conditions in the tube, (2) Applicability of Eq. 8.34, (3) Heat transfer coefficient is the same for both heating conditions.

**PROPERTIES:** Table A.4, Air (for an assumed value of  $T_{m,o} = 100^\circ\text{C}$ ,  $\bar{T}_m = (T_{m,i} + T_{m,o})/2 = 60^\circ\text{C} = 333 \text{ K}$ ):  $c_p = 1.008 \text{ kJ/kg}\cdot\text{K}$ .

**ANALYSIS:** (a) With constant heat flux, from Eq. 8.38,

$$q = q''_s (\pi DL) = 1000 \text{ W/m}^2 (\pi \times 0.05 \text{ m} \times 3 \text{ m}) = 471 \text{ W} . \quad (1)$$

From the overall energy balance, Eq. 8.34,

$$T_{m,o} = T_{m,i} + \frac{q}{\dot{m}c_p} = 20^\circ\text{C} + \frac{471 \text{ W}}{0.005 \text{ kg/s} \times 1008 \text{ J/kg}\cdot\text{K}} = 113.5^\circ\text{C} \quad (2) <$$

From the convection rate equation, it follows that

$$T_{s,i} = T_{m,i} + \frac{q''_s}{h} = 20^\circ\text{C} + \frac{1000 \text{ W/m}^2}{25 \text{ W/m}^2\cdot\text{K}} = 60^\circ\text{C} \quad (3) <$$

$$T_{s,o} = T_{m,o} + q''_s/h = 113.5^\circ\text{C} + 40^\circ\text{C} = 153.5^\circ\text{C} \quad <$$

From Eq. 8.39,  $(dT_m/dx)$  is a constant, as is  $(dT_s/dx)$  for constant  $h$  from Eq. 8.30. In the more realistic case for which  $h$  decreases with  $x$  in the entry region,  $(dT_m/dx)$  is still constant but  $(dT_s/dx)$  decreases with increasing  $x$ . See the plot below.

(b) From Eq. 8.37,

$$\frac{dT_m}{dx} = \frac{500x (\pi D)}{\dot{m}c_p} = \frac{500x \text{ W/m}^2 (\pi \times 0.05 \text{ m})}{0.005 \text{ kg/s} \times 1008 \text{ J/kg}\cdot\text{K}} = 15.6x \text{ K/m} . \quad (4)$$

Continued...

### PROBLEM 8.18 (Cont.)

Integrating from  $x = 0$  to  $L$  it follows that

$$T_{m,o} = T_{m,i} + 15.6 \int_0^3 x dx = 20^\circ\text{C} + 15.6 \frac{x^2}{2} \Big|_0^3 = 20^\circ\text{C} + 70.2^\circ\text{C} = 90.2^\circ\text{C}. \quad (5) <$$

The heat rate is

$$q = \int q_s'' dA_s = 500(\pi \times 0.05 \text{ m}) \int_0^3 x dx = 78.5 \frac{x^2}{2} \Big|_0^3 = 353 \text{ W} <$$

From Eq. 8.27 it then follows that

$$T_s = T_m + q_s''/h = T_{m,i} + 15.6 \frac{x^2}{2} + \frac{500}{25} x = 20^\circ\text{C} + 7.8x^2 + 20x \quad (6)$$

Hence, at the inlet ( $x = 0$ ) and outlet ( $x = L$ ),

$$T_{s,i} = T_{m,i} = 20^\circ\text{C} \quad \text{and} \quad T_{s,o} = 150.2^\circ\text{C} <$$

Note that  $(dT_s/dx)$  and  $(dT_m/dx)$  both increase linearly with  $x$ , but  $(dT_s/dx) > (dT_m/dx)$ .

(c) The foregoing relations can be used to determine  $T_m(x)$  and  $T_s(x)$  for the two heating conditions:

*Uniform surface flux,  $q_s''$ ; Eqs. (1-3),*

$$T_m(x) = T_{m,i} + q_s'' \pi D x / \dot{m} c_p \quad T_s(x) = T_m(x) + q_s''/h \quad (7,8)$$

*Linear surface heat flux,  $q_s'' = a_o x$ ,  $a_o = 500 \text{ W/m}^3$ ; Eqs. (4-6),*

$$T_m(x) = T_{m,i} + \left( a_o \pi D / 2 \dot{m} c_p \right) x^2 \quad T_s(x) = T_m(x) + a_o x / h \quad (9, 10)$$

Using Eqs. (7-10) in IHT, the mean fluid and surface temperatures as a function of distance are evaluated and plotted below. The calculations were repeated with the coefficient increased four-fold,  $h = 4 \times 25 = 100 \text{ W/m}^2 \cdot \text{K}$ . As expected, the fluid temperature remained unchanged, but the surface temperatures decreased since the thermal resistance between the surface and fluid decreased.

(d) The foregoing set of equations, Eqs. (7-10), in the IHT model can be used to determine the required heat fluxes for the two heating conditions to achieve  $T_{m,o} = 125^\circ\text{C}$ . The results with  $h = 25 \text{ W/m}^2 \cdot \text{K}$  are:

$$\text{Uniform flux: } q_s'' = 1123 \text{ W/m}^2 \quad \text{Linear flux: } q_s'' = 748.7x \text{ W/m}^2 <$$

Continued...

### PROBLEM 8.18 (Cont.)

The temperature distributions resulting from these heat fluxes are plotted below. The heat rate for both heating processes is 529 W.

**COMMENTS:** Note that the assumed value for  $T_{m,o}$  (100°C) in determining the specific heat of the air was reasonable.

## PROBLEM 8.19

**KNOWN:** Tube length, diameter and surface temperature. Mass flow rate and inlet temperature of fluid.

**FIND:** (a) Heat transfer rate if the fluid is water. (b) Heat transfer rate for the nanofluid of Example 2.2.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Constant properties, (2) Negligible viscous dissipation.

**PROPERTIES:** Table A.4, water (300 K):  $\mu_{\text{bf}} = 855 \times 10^{-6}\text{ m}^2/\text{s}$ ,  $k_{\text{bf}} = 0.613\text{ W/m}\cdot\text{K}$ ,  $c_{p,\text{bf}} = 4179\text{ J/kg}\cdot\text{K}$ ,  $Pr_{\text{bf}} = 5.83$ . Example 2.2, nanofluid (300 K):  $\rho_{\text{nf}} = 1146\text{ kg/m}^3$ ,  $\mu_{\text{nf}} = 962 \times 10^{-6}\text{ m}^2/\text{s}$ ,  $\nu_{\text{nf}} = \mu_{\text{nf}}/\rho_{\text{nf}} = 839 \times 10^{-9}\text{ m}^2/\text{s}$ ,  $k_{\text{nf}} = 0.705\text{ W/m}\cdot\text{K}$ ,  $c_{p,\text{nf}} = 3587\text{ J/kg}\cdot\text{K}$ ,  $\alpha_{\text{nf}} = 171 \times 10^{-9}\text{ m}^2/\text{s}$ ,  $Pr_{\text{nf}} = \nu_{\text{nf}}/\alpha_{\text{nf}} = 4.91$ .

**ANALYSIS:** (a) The Reynolds number is

$$Re_D = 4\dot{m} / \pi D \mu_{\text{bf}} = 4 \times 0.015\text{ kg/s} / \left[ \pi \times 0.015\text{ m} \times 855 \times 10^{-6}\text{ m}^2/\text{s} \right] = 1489$$

Therefore the flow is laminar. The hydrodynamic and thermal entry lengths are

$$x_{fd,h} = 0.05DRe_D = 0.05 \times 0.015\text{ m} \times 1489 = 1.12\text{ m}$$

$$x_{fd,t} = 0.05DRe_DPr_{\text{bf}} = 0.05 \times 0.015\text{ m} \times 1489 \times 5.83 = 6.51\text{ m}$$

Since the tube length is  $L = 6\text{ m}$ , the temperature is still developing. The hydrodynamic entry length is less than the tube length, but perhaps not sufficiently shorter to consider the velocity to be fully developed through the entire tube. With  $Pr_{\text{bf}} > 5$ , the Hausen correlation, Equation 8.57, could be used as an approximation. However the nanofluid Prandtl number is less than 5. To compare the two fluids on an equal basis, we will use the combined entry correlation, Equation 8.58, for both. With  $G_{z,D} = (D/L)Re_DPr_{\text{bf}} = (0.015\text{ m}/6\text{ m}) \times 1489 \times 5.83 = 21.7$ , Equation 8.58 is

$$\overline{Nu}_D = \frac{\frac{3.66}{\tanh\left[2.264 \times 21.7^{-1/3} + 1.7 \times 21.7^{-2/3}\right]} + 0.0499 \times 21.7 \times \tanh\left(21.7^{-1}\right)}{\tanh\left(2.432 \times 5.83^{1/6} \times 21.7^{-1/6}\right)} = 4.98$$

Therefore  $\bar{h} = \overline{Nu}_D k_{\text{bf}} / D = 4.98 \times 0.613\text{ W/m}\cdot\text{K} / 0.015\text{ m} = 203\text{ W/m}^2\cdot\text{K}$ . From Equation 8.41b

Continued...

### PROBLEM 8.19 (Cont.)

$$\begin{aligned} T_{m,o} &= T_s - (T_s - T_{m,i}) \exp\left(-\frac{\pi DL \bar{h}}{\dot{m} c_{p,\text{bf}}}\right) \\ &= 30^\circ\text{C} - 10^\circ\text{C} \exp\left(-\frac{\pi \times 0.015 \text{ m} \times 6 \text{ m}}{0.015 \text{ kg/s} \times 4179 \text{ J/kg} \cdot \text{K}} 203 \text{ W/m}^2 \cdot \text{K}\right) = 26.0^\circ\text{C} \end{aligned}$$

Therefore the heat transfer rate to the water is

$$q = \dot{m} c_{p,\text{bf}} (T_{m,o} - T_{m,i}) = 0.015 \text{ kg/s} \times 4179 \text{ J/kg} \cdot \text{K} \times (26.0^\circ\text{C} - 20^\circ\text{C}) = 376 \text{ W} \quad <$$

(b) The preceding calculations may be repeated for the nanofluid. The results are:

$$Re_D = 1324, x_{fd,h} = 0.99 \text{ m}, x_{fd,t} = 4.87 \text{ m}$$

The combined entry solution is again appropriate. The remaining results are:

$$G_{zD} = 16.2, \overline{Nu}_D = 4.68, \bar{h} = 220 \text{ W/m}^2 \cdot \text{K}, T_{m,o} = 26.9^\circ\text{C}, \text{ and } q = 369 \text{ W} \quad <$$

**COMMENTS:** (1) The nanofluid of Example 2.2 is water containing  $\text{Al}_2\text{O}_3$  nanoparticles. The thermal conductivity of the nanofluid is 15% greater than that of the base fluid (water). In addition, the convection heat transfer coefficient of the nanofluid is 8% greater than that of the water, and the temperature increase of the nanofluid is 15% higher than for the water. *However, less heat is transferred to the nanofluid than to the water.* This is because the nanofluid suffers from a reduced specific heat relative to the pure water. Any claim that a nanofluid is a better heat transfer medium than its corresponding base fluid because of its larger thermal conductivity is suspect. In this problem, the pure water is the preferred heat transfer fluid if the objective is to maximize the heat transfer rate. In addition, the nanofluid is more costly to produce, and because of its larger viscosity, would suffer from larger pressure drops and higher pumping costs. (2) Use of the Hausen correlation, Equation 8.57 yields  $q = 366 \text{ W}$  and  $362 \text{ W}$  for the water and nanofluid, respectively. Hence, the predictions of the Hausen correlation are within 3% of the predictions using the correlation of Baehr and Stephan. Use of the Hausen correlation also predicts less heat transfer for the nanofluid than for the pure water.

## PROBLEM 8.20

**KNOWN:** Water at prescribed temperature and flow rate enters a 0.25 m diameter, black thin-walled tube of 8-m length, which passes through a large furnace whose walls and air are at a temperature of  $T_{\text{fur}} = T_{\infty} = 700 \text{ K}$ . The convection coefficients for the internal water flow and external furnace air are  $300 \text{ W/m}^2\cdot\text{K}$  and  $50 \text{ W/m}^2\cdot\text{K}$ , respectively.

**FIND:** (a) An expression for the linearized radiation coefficient for the radiation exchange process between the outer surface of the pipe and the furnace walls; represent the tube by an average temperature and explain how to calculate this value, and (b) determine the outlet temperature of the water,  $T_{\text{O}}$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions; (2) Tube is small object with large, isothermal surroundings; (3) Furnace air and walls are at the same temperature; (4) Tube is thin-walled with black surface; and (5) Incompressible liquid with negligible viscous dissipation.

**PROPERTIES:** Table A-6, Water ( $T_m = (T_{m,i} + T_{m,o})/2 = 304 \text{ K}$ ):  $c_p = 4178 \text{ J/kg}\cdot\text{K}$ .

**ANALYSIS:** (a) The linearized radiation coefficient follows from Eq. 1.9 with  $\epsilon = 1$ ,

$$\bar{h}_{\text{rad}} = \sigma (\bar{T}_t + T_{\text{fur}}) (\bar{T}_t^2 + T_{\text{fur}}^2)$$

where  $\bar{T}_t$  represents the average tube wall surface temperature, which can be evaluated from an energy balance on the tube as represented by the thermal circuit above.

$$T_m = (T_{m,i} + T_{m,o}) / 2$$

$$R_{\text{tot}} = R_{\text{cv},i} + \frac{1}{1/R_{\text{cv},o} + 1/R_{\text{rad}}}$$

$$\frac{T_m - \bar{T}_t}{R_{\text{cv},i}} = (\bar{T}_t - T_{\text{fur}}) (1/R_{\text{cv},o} + 1/R_{\text{rad}})$$

The thermal resistances, with  $A_s = PL = \pi DL$ , are

$$R_{\text{cv},i} = 1/h_i A_s$$

$$R_{\text{cv},o} = 1/h_o A_s$$

$$R_{\text{rad}} = 1/\bar{h}_{\text{rad}} A_s$$

(b) The outlet temperature can be calculated using the energy balance relation, Eq. 8.45b, with  $T_{\text{fur}} = T_{\infty}$ ,

$$\frac{T_{\infty} - T_{m,o}}{T_{\infty} - T_{m,i}} = \exp\left(-\frac{1}{\dot{m} c_p R_{\text{tot}}}\right)$$

where  $c_p$  is evaluated at  $T_m$ . Using *IHT*, the following results were obtained.

$$R_{\text{cv},i} = 5.31 \times 10^{-4} \text{ K/W} \quad R_{\text{cv},o} = 3.18 \times 10^{-3} \text{ K/W} \quad R_{\text{rad}} = 3.96 \times 10^{-3} \text{ K/W}$$

$$T_m = 304 \text{ K} \quad \bar{T}_t = 396 \text{ K} \quad T_{m,o} = 308 \text{ K} \quad <$$

**COMMENTS:** Since  $T_{\infty} = T_{\text{fur}}$ , it was possible to use Eq. 8.45b with  $R_{\text{tot}}$ . How would you write the energy balance relation if  $T_{\infty} \neq T_{\text{fur}}$ ?

## PROBLEM 8.21

**KNOWN:** Laminar, slug flow in a circular tube with uniform surface heat flux.

**FIND:** Temperature distribution and Nusselt number.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady, incompressible flow, with negligible viscous dissipation, (2) Constant properties, (3) Fully developed, laminar flow, (4) Uniform surface heat flux.

**ANALYSIS:** With  $v = 0$  for fully developed flow and  $\partial T / \partial x = dT_m / dx = \text{const}$ , from Eqs. 8.32 and 8.39, the energy equation, Eq. 8.48, reduces to

$$u_0 \frac{dT_m}{dx} = \frac{\alpha}{r} \frac{\partial}{\partial r} \left( r \frac{\partial T}{\partial r} \right).$$

Integrating twice, it follows that

$$T(r) = \frac{u_0}{\alpha} \frac{dT_m}{dx} \frac{r^2}{4} + C_1 \ln(r) + C_2.$$

Since  $T(0)$  must remain finite,  $C_1 = 0$ . Hence, with  $T(r_0) = T_s$

$$C_2 = T_s - \frac{u_0}{\alpha} \frac{dT_m}{dx} \frac{r_0^2}{4} \quad T(r) = T_s - \frac{u_0}{4\alpha} \frac{dT_m}{dx} (r_0^2 - r^2). \quad <$$

From Eq. 8.26, with  $u_m = u_0$ ,

$$\begin{aligned} T_m &= \frac{2}{r_0^2} \int_0^{r_0} T r \, dr = \frac{2}{r_0^2} \int_0^{r_0} \left[ T_s r - \frac{u_0}{4\alpha} \frac{dT_m}{dx} (r_0^2 - r^2) \right] dr \\ T_m &= \frac{2}{r_0^2} \left[ T_s \frac{r_0^2}{2} - \frac{u_0}{4\alpha} \frac{dT_m}{dx} \left( \frac{r_0^4}{2} - \frac{r_0^4}{4} \right) \right] = T_s - \frac{u_0 r_0^2}{8\alpha} \frac{dT_m}{dx}. \end{aligned}$$

From Eq. 8.27 and Fourier's law,

$$h = \frac{q_s''}{T_s - T_m} = \frac{k \frac{\partial T}{\partial r} \Big|_{r_0}}{T_s - T_m}$$

hence,

$$h = \frac{k \left( \frac{u_0 r_0}{2\alpha} \right) \frac{dT_m}{dx}}{\frac{u_0 r_0^2}{8\alpha} \frac{dT_m}{dx}} = \frac{4k}{r_0} = \frac{8k}{D} \quad \overline{\text{Nu}}_D = \frac{hD}{k} = 8. \quad <$$

### PROBLEM 8.22

**KNOWN:** Heat transfer between fluid flow over a tube and flow through the tube.

**FIND:** Axial variation of mean temperature for inner flow.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Applicability of Eq. 8.34, (2) Negligible axial conduction, (3) Constant  $c_p$ , (4) Uniform  $T_\infty$ .

**ANALYSIS:** From Eq. 8.36,

$$dq = \dot{m} c_p dT_m$$

with

$$dq = U dA (T_\infty - T_m) = UP (T_\infty - T_m) dx.$$

The overall heat transfer coefficient may be defined in terms of the inner or outer surface area, with

$$U_i P_i = U_o P_o.$$

For the inner surface, from Eq. 3.36,

$$U_i = \left[ \frac{1}{h_i} + \frac{r_i}{k} \ln \frac{r_o}{r_i} + \frac{r_i}{r_o} \frac{1}{h_o} \right]^{-1}.$$

Hence,

$$\frac{dT_m}{T_\infty - T_m} = + \frac{UP}{\dot{m} c_p} dx$$

or, with  $\Delta T \equiv T_\infty - T_m$ ,

$$\int_{\Delta T_i}^{\Delta T_o} \frac{d(\Delta T)}{\Delta T} = - \frac{P}{\dot{m} c_p} \int_0^L U dx.$$

Hence,

$$\ln \frac{\Delta T_o}{\Delta T_i} = - \frac{PL}{\dot{m} c_p} \left( \frac{1}{L} \int_0^L U dx \right)$$

$$\frac{T_\infty - T_{m,o}}{T_\infty - T_{m,i}} = \exp \left( - \frac{PL}{\dot{m} c_p} \bar{U} \right).$$

<

**COMMENTS:** The development and results parallel those for a constant surface temperature, with  $\bar{U}$  and  $T_\infty$  replacing  $\bar{h}$  and  $T_s$ .

## PROBLEM 8.23

**KNOWN:** Thin-walled tube experiences sinusoidal heat flux distribution on the wall.

**FIND:** (a) Total rate of heat transfer from the tube to the fluid,  $q$ , (b) Fluid outlet temperature,  $T_{m,o}$ , (c) Axial distribution of the wall temperature  $T_s(x)$  and (d) Magnitude and position of the highest wall temperature, and (e) For prescribed conditions, calculate and plot the mean fluid and surface temperatures,  $T_m(x)$  and  $T_s(x)$ , respectively, as a function of distance along the tube; identify features of the distributions; explore the effect of  $\pm 25\%$  changes in the convection coefficient on the distributions.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Applicability of Eq. 8.34, (3) Turbulent, fully developed flow.

**ANALYSIS:** (a) The total rate of heat transfer from the tube to the fluid is

$$q = \int_0^L q_s'' P dx = q_o'' \pi D \int_0^L \sin(\pi x/L) dx = q_o'' \pi D (L/\pi) [-\cos(\pi x/L)]_0^L = 2DLq_o'' \quad (1) <$$

(b) The fluid outlet temperature follows from the overall energy balance with knowledge of the total heat rate,

$$q = \dot{m}c_p (T_{m,o} - T_{m,i}) = 2DLq_o'' \quad T_{m,o} = T_{m,i} + (2DLq_o''/\dot{m}c_p) \quad (2) <$$

(c) The axial distribution of the wall temperature can be determined from the rate equation

$$q_s'' = h [T_s(x) - T_m(x)] \quad T_{s,x} = T_{m,x}(x) + q_s''/h \quad (3)$$

where, by combining expressions of parts (a) and (b),  $T_{m,x}(x)$  is

$$\int_0^x q_s'' P dx = \dot{m}c_p (T_{m,x} - T_{m,i})$$

$$T_{m,x} = T_{m,i} + \frac{q_o'' \pi D}{\dot{m}c_p} \int_0^x \sin(\pi x/L) dx = T_{m,i} + \frac{DLq_o''}{\dot{m}c_p} [1 - \cos(\pi x/L)] \quad (4)$$

Hence, substituting Eq. (4) into (3), find

$$T_s(x) = T_{m,i} + \frac{DLq_o''}{\dot{m}c_p} [1 - \cos(\pi x/L)] + \frac{q_o''}{h} \sin(\pi x/L) \quad (5) <$$

(d) To determine the location of the maximum wall temperature  $x'$  where  $T_x(x') = T_{s,max}$ , set

$$\frac{dT_s(x)}{dx} = 0 = \frac{d}{dx} \left\{ \frac{DLq_o''}{\dot{m}c_p} [1 - \cos(\pi x/L)] + \frac{q_o''}{h} \sin(\pi x/L) \right\}$$

$$\frac{DLq_o''}{\dot{m}c_p} \cdot \frac{\pi}{L} \cdot \sin(\pi x'/L) + \frac{q_o''}{h} \cdot \frac{\pi}{L} \cdot \cos(\pi x'/L) = 0 \quad \tan(\pi x'/L) = -\frac{q_o''/h}{DLq_o''/\dot{m}c_p} = -\frac{\dot{m}c_p}{DLh}$$

Continued...

**PROBLEM 8.23 (Cont.)**

$$x' = \frac{L}{\pi} \tan^{-1}(-\dot{m}c_p/DLh) \quad (6) <$$

At this location, the wall temperature is

$$T_{s,\max} = T_s(x') = T_{m,i} + \frac{DLq_o''}{\dot{m}c_p} [1 - \cos(\pi x'/L)] + \frac{q_o''}{h} \sin(\pi x'/L) \quad (7) <$$

(e) Consider the prescribed conditions for which to compute and plot  $T_m(x)$  and  $T_s(x)$ ,

$D = 40 \text{ mm}$	$\dot{m} = 0.025 \text{ kg/s}$	$h = 1000 \text{ W/m}^2\text{K}$	$q_o'' = 10,000 \text{ W/m}^2$
$L = 4 \text{ m}$	$c_p = 4180 \text{ J/kg}\cdot\text{K}$	$T_{m,i} = 25^\circ\text{C}$	

Using Eqs. (4) and (5) in IHT, the results are plotted below.

The effect of a lower convection coefficient is to increase the wall temperature. The position of the maximum temperature,  $T_{s,\max}$ , moves away from the tube exit with decreasing convection coefficient.

**COMMENTS:** (1) Because the flow is fully developed and turbulent, assuming  $h$  is constant along the entire length of the tube is reasonable.

(2) To determine whether the  $T_x(x)$  distribution has a maximum (rather than a minimum), you should evaluate  $d^2T_s(x)/dx^2$  to show the value is indeed negative.

## PROBLEM 8.24

**KNOWN:** Water is heated in a tube having a wall flux that is dependent upon the wall temperature.

**FIND:** (a) Beginning with a properly defined differential control volume in the tube, derive expressions that can be used to obtain the temperatures for the water and the wall surface as a function of distance from the inlet,  $T_m(x)$  and  $T_s(x)$ , respectively; (b) Using a numerical integration scheme, calculate and plot the temperature distributions,  $T_m(x)$  and  $T_s(x)$ , on the same graph. Identify and comment on the main features of the distributions; and (c) Calculate the total heat transfer rate to the water.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Fully developed flow and thermal conditions, (3) No losses to the outer surface of the tube, (3) Constant properties, and (4) Incompressible liquid with negligible viscous dissipation .

**PROPERTIES:** Table A-6, Water ( $\bar{T}_m = (T_{m,i} + T_{m,o})/2 = 300 \text{ K}$ ):  $c_p = 4179 \text{ J/kg}\cdot\text{K}$

**ANALYSIS:** (a) The properly defined control volume of perimeter  $P = \pi D$  shown in the above schematic follows from Fig. 8.6. The energy balance on the CV includes advection, convection at the inner tube surface, and the heat flux dissipated in the tube wall. (See Eq. 8.37).

$$\dot{m} c_p \frac{dT_m}{dx} = q_s''(x) P = h P [T_s(x) - T_m(x)] \quad (1,2)$$

where  $q_s''(x)$  is dependent upon  $T_s(x)$  according to the relation

$$q_s''(x) = q_{s,o}'' [1 + \alpha(T_s(x) - T_{ref})] \quad (3)$$

(b) Eqs. (1 and 2) with Eq. (3) can be solved by numerical integration using the Der function in *IHT* as shown in Comment 1. The temperature distributions for the water and wall surface are plotted below.

Continued ...

### PROBLEM 8.24 (Cont.)

(c) The total heat transfer to the water can be evaluated from an overall energy balance on the water,

$$q = \dot{m} c_p (T_{m,o} - T_{m,i}) \quad (4)$$

$$q = 0.1 \text{ kg/s} \times 4179 \text{ J/kg} \cdot \text{K} (34.4 - 20) \text{ K} = 6018 \text{ W} \quad <$$

Alternatively, the heat rate can be evaluated by integration of the heat flux from the tube surface over the length of the tube,

$$q = \int_0^L q_s''(x) P dx \quad (5)$$

where  $q_s''(x)$  is given by Eq. (3), and  $T_s(x)$  and  $T_m(x)$  are determined from the differential form of the energy equation, Eqs. (1) and (2). The result as shown in the *IHT* code below is 6005 W.

**COMMENTS:** (1) Note that  $T_m(x)$  increases with distance greater than linearly, as expected since  $q_s''(x)$  does. Also as expected, the difference,  $T_s(x) - T_m(x)$ , likewise increases with distance greater than linearly.

(2) In the foregoing analysis,  $c_p$  is evaluated at the mean fluid temperature  $T_m = (T_{m,i} + T_{m,o})/2$ .

(3) The *IHT* code representing the foregoing equations to calculate and plot the temperature distribution and to calculate the total heat rate to the water is shown below.

```

## PROBLEM 8.25

**KNOWN:** Inlet temperature and flowrate of oil flowing through a tube of prescribed surface temperature and geometry.

**FIND:** (a) Oil outlet temperature and total heat transfer rate, and (b) Effect of flowrate.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible temperature drop across tube wall, (2) Incompressible liquid with negligible viscous dissipation.

**PROPERTIES:** Table A.5, Engine oil (assume  $T_{m,o} = 140^\circ\text{C}$ , hence  $\bar{T}_m = 80^\circ\text{C} = 353 \text{ K}$ ):  $\rho = 852 \text{ kg/m}^3$ ,  $\nu = 37.5 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 138 \times 10^{-3} \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 490$ ,  $\mu = \rho \cdot \nu = 0.032 \text{ kg/m}\cdot\text{s}$ ,  $c_p = 2131 \text{ J/kg}\cdot\text{K}$ .

**ANALYSIS:** (a) For constant surface temperature the oil outlet temperature may be obtained from Eq. 8.41b. Hence

$$T_{m,o} = T_s - (T_s - T_{m,i}) \exp\left(-\frac{\pi D L \bar{h}}{\dot{m} c_p}\right)$$

To determine  $\bar{h}$ , first calculate  $\text{Re}_D$  from Eq. 8.6,

$$\text{Re}_D = \frac{4\dot{m}}{\pi D \mu} = \frac{4(0.5 \text{ kg/s})}{\pi(0.05 \text{ m})(0.032 \text{ kg/m}\cdot\text{s})} = 398$$

Hence the flow is laminar. Moreover, from Eq. 8.23 the thermal entry length is

$$x_{fd,t} \approx 0.05 D \text{Re}_D \text{Pr} = 0.05(0.05 \text{ m})(398)(490) = 486 \text{ m}.$$

Since  $L = 25 \text{ m}$  the flow is far from being thermally fully developed. Since  $\text{Pr} > 5$ ,  $\bar{h}$  may be determined from Eq. 8.57

$$\overline{\text{Nu}}_D = 3.66 + \frac{0.0668 \text{Gz}_D}{1 + 0.04 \text{Gz}_D^{2/3}}.$$

With  $\text{Gz}_D = (D/L)\text{Re}_D\text{Pr} = (0.05/25)398 \times 490 = 390$ , it follows that

$$\overline{\text{Nu}}_D = 3.66 + \frac{26}{1 + 2.14} = 11.95.$$

Hence,  $\bar{h} = \overline{\text{Nu}}_D \frac{k}{D} = 11.95 \frac{0.138 \text{ W/m}\cdot\text{K}}{0.05 \text{ m}} = 33 \text{ W/m}^2 \cdot \text{K}$  and it follows that

Continued...

### PROBLEM 8.25 (Cont.)

$$T_{m,o} = 150^\circ\text{C} - (150^\circ\text{C} - 20^\circ\text{C}) \exp\left[-\frac{\pi(0.05\text{ m})(25\text{ m})}{0.5\text{ kg/s} \times 2131\text{ J/kg}\cdot\text{K}} \times 33\text{ W/m}^2\cdot\text{K}\right]$$

$$T_{m,o} = 35^\circ\text{C}.$$

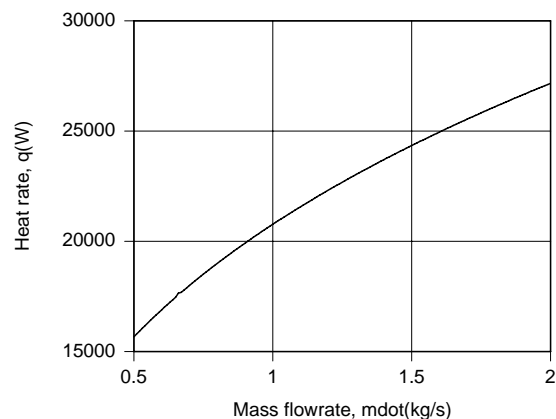

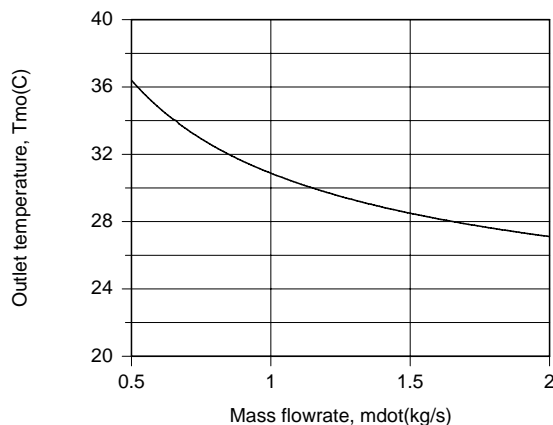

From the overall energy balance, Eq. 8.34, it follows that

$$q = \dot{m}c_p(T_{m,o} - T_{m,i}) = 0.5\text{ kg/s} \times 2131\text{ J/kg}\cdot\text{K} \times (35 - 20)^\circ\text{C}$$

$$q = 15,980\text{ W}.$$

The value of  $T_{m,o}$  has been grossly overestimated in evaluating the properties. The properties should be re-evaluated at  $\bar{T} = (20 + 35)/2 = 27^\circ\text{C}$  and the calculations repeated. Iteration should continue until satisfactory convergence is achieved between the calculated and assumed values of  $T_{m,o}$ . Following such a procedure, one would obtain  $T_{m,o} = 36.4^\circ\text{C}$ ,  $Re_D = 27.8$ ,  $\bar{h} = 32.8\text{ W/m}^2\cdot\text{K}$ , and  $q = 15,660\text{ W}$ . The small effect of reevaluating the properties is attributed to the compensating effects on  $Re_D$  (a large decrease) and  $Pr$  (a large increase).

(b) The effect of flowrate on  $T_{m,o}$  and  $q$  was determined by using the appropriate IHT *Correlations* and *Properties* Toolpads.

The heat rate increases with increasing  $\dot{m}$  due to the corresponding increase in  $Re_D$  and hence  $\bar{h}$ . However, the increase is not proportional to  $\dot{m}$ , causing  $(T_{m,o} - T_{m,i}) = q/\dot{m}c_p$ , and hence  $T_{m,o}$  to decrease with increasing  $\dot{m}$ . The maximum heat rate corresponds to the maximum flowrate ( $\dot{m} = 0.20\text{ kg/s}$ ).

**COMMENTS:** Note that significant error would be introduced by assuming fully developed thermal conditions and  $\overline{Nu}_D = 3.66$ . The flow remains well within the laminar region over the entire range of  $\dot{m}$ .

## PROBLEM 8.26

**KNOWN:** Inlet temperature and flowrate of oil moving through a tube of prescribed diameter and surface temperature.

**FIND:** (a) Oil outlet temperature  $T_{m,o}$  for two tube lengths, 5 m and 100 m, and log mean and arithmetic mean temperature differences, (b) Effect of  $L$  on  $T_{m,o}$  and  $\overline{Nu}_D$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Incompressible liquid with negligible viscous dissipation, (3) Constant properties.

**PROPERTIES:** Table A.4, Oil (330 K):  $c_p = 2035 \text{ J/kg}\cdot\text{K}$ ,  $\mu = 0.0836 \text{ N}\cdot\text{s/m}^2$ ,  $k = 0.141 \text{ W/m}\cdot\text{K}$ ,  $Pr = 1205$ .

**ANALYSIS:** (a) Using Eqs. 8.41b and 8.6

$$T_{m,o} = T_s - (T_s - T_{m,i}) \exp\left(-\frac{\pi DL \bar{h}}{\dot{m} c_p}\right)$$

$$Re_D = \frac{4\dot{m}}{\pi D \mu} = \frac{4 \times 0.5 \text{ kg/s}}{\pi \times 0.025 \text{ m} \times 0.0836 \text{ N}\cdot\text{s/m}^2} = 304.6$$

With  $x_{fd,h} = 0.05DRe_D = 0.4 \text{ m}$ , it is reasonable to assume the flow is hydrodynamically fully developed. However, with  $x_{fd,t} = x_{fd,h}Pr = 495 \text{ m}$ , the flow is thermally developing. Since thermal entry length effects will be significant and  $Pr > 5$ , use Eq. 8.57 with Eq. 8.56 for the Graetz number:

$$\bar{h} = \frac{k}{D} \left[ 3.66 + \frac{0.0688(D/L)Re_D Pr}{1 + 0.04[(D/L)Re_D Pr]^{2/3}} \right] = \frac{0.141 \text{ W/m}\cdot\text{K}}{0.025 \text{ m}} \left[ 3.66 + \frac{2.45 \times 10^4 D/L}{1 + 205(D/L)^{2/3}} \right]$$

For  $L = 5 \text{ m}$ ,  $\bar{h} = 5.64(3.66 + 17.51) = 119 \text{ W/m}^2 \cdot \text{K}$ , hence

$$T_{m,o} = 100^\circ\text{C} - (75^\circ\text{C}) \exp\left(-\frac{\pi \times 0.025 \text{ m} \times 5 \text{ m} \times 119 \text{ W/m}^2 \cdot \text{K}}{0.5 \text{ kg/s} \times 2035 \text{ J/kg}\cdot\text{K}}\right) = 28.4^\circ\text{C} \quad <$$

For  $L = 100 \text{ m}$ ,  $\bar{h} = 5.64(3.66 + 3.38) = 40 \text{ W/m}^2 \cdot \text{K}$ ,  $T_{m,o} = 44.9^\circ\text{C}$ . <

Also, for  $L = 5 \text{ m}$ ,

$$\Delta T_{\ell m} = \frac{\Delta T_o - \Delta T_i}{\ln(\Delta T_o / \Delta T_i)} = \frac{71.6 - 75}{\ln(71.6/75)} = 73.3^\circ\text{C} \quad \Delta T_{am} = (\Delta T_o + \Delta T_i)/2 = 73.3^\circ\text{C} \quad <$$

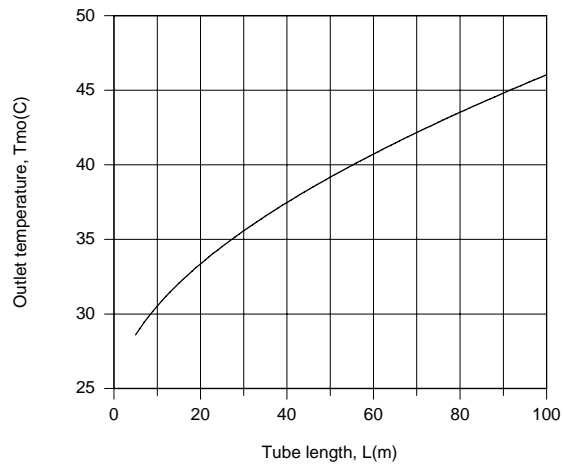

For  $L = 100 \text{ m}$ ,  $\Delta T_{\ell m} = 64.5^\circ\text{C}$ ,  $\Delta T_{am} = 65.1^\circ\text{C}$  <

(b) The effect of tube length on the outlet temperature and Nusselt number was determined by using the *Correlations and Properties* Toolpads of IHT.

Continued...

### PROBLEM 8.26 (Cont.)

The outlet temperature approaches the surface temperature with increasing  $L$ , but even for  $L = 100$  m,  $T_{m,o}$  is well below  $T_s$ . Although  $\overline{Nu}_D$  decays with increasing  $L$ , it is still well above the fully developed value of  $Nu_{D,fd} = 3.66$ .

**COMMENTS:** (1) The average, mean temperature,  $\overline{T}_m = 330$  K, was significantly overestimated in part (a). The accuracy may be improved by evaluating the properties at a lower temperature. (2) Use of  $\Delta T_{am}$  instead of  $\Delta T_{\ell m}$  is reasonable for small to moderate values of  $(T_{m,i} - T_{m,o})$ . For large values of  $(T_{m,i} - T_{m,o})$ ,  $\Delta T_{\ell m}$  should be used.

### PROBLEM 8.27

**KNOWN:** Inlet and outlet temperatures and velocity of fluid flow in tube. Tube diameter and length.

**FIND:** Surface heat flux and temperatures at  $x = 0.5$  and  $10$  m.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Constant properties, (3) Negligible heat loss to surroundings, (4) Incompressible liquid with negligible viscous dissipation, (5) Negligible axial conduction.

**PROPERTIES:** Pharmaceutical (given):  $\rho = 1000 \text{ kg/m}^3$ ,  $c_p = 4000 \text{ J/kg}\cdot\text{K}$ ,  $\mu = 2 \times 10^{-3} \text{ kg/s}\cdot\text{m}$ ,  $k = 0.80 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 10$ .

**ANALYSIS:** With

$$\dot{m} = \rho VA = 1000 \text{ kg/m}^3 (0.2 \text{ m/s}) \pi (0.0127 \text{ m})^2 / 4 = 0.0253 \text{ kg/s}$$

Eq. 8.34 yields

$$q = \dot{m} c_p (T_{m,o} - T_{m,i}) = 0.0253 \text{ kg/s} (4000 \text{ J/kg}\cdot\text{K}) 50 \text{ K} = 5060 \text{ W}.$$

The required heat flux is then

$$q_s'' = q/A_s = 5060 \text{ W} / \pi (0.0127 \text{ m}) 10 \text{ m} = 12,682 \text{ W/m}^2. \quad <$$

With

$$\text{Re}_D = \rho VD / \mu = 1000 \text{ kg/m}^3 (0.2 \text{ m/s}) 0.0127 \text{ m} / 2 \times 10^{-3} \text{ kg/s}\cdot\text{m} = 1270$$

the flow is laminar and Eq. 8.23 yields

$$x_{fd,t} = 0.05 \text{Re}_D \text{Pr} D = 0.05 (1270) 10 (0.0127 \text{ m}) = 8.06 \text{ m}.$$

Hence, with fully developed hydrodynamic and thermal conditions at  $x = 10$  m, Eq. 8.53 yields

$$h(10 \text{ m}) = \text{Nu}_{D,fd} (k/D) = 4.36 (0.80 \text{ W/m}\cdot\text{K} / 0.0127 \text{ m}) = 274.6 \text{ W/m}^2 \cdot \text{K}.$$

Hence, from Newton's law of cooling,

$$T_{s,o} = T_{m,o} + (q_s'' / h) = 75^\circ\text{C} + (12,682 \text{ W/m}^2 / 274.6 \text{ W/m}^2 \cdot \text{K}) = 121^\circ\text{C}. \quad <$$

At  $x = 0.5$  m,  $(x/D) / (\text{Re}_D \text{Pr}) = 0.0031$  and Figure 8.10 yields  $\text{Nu}_D \approx 8$  for a thermal entry region with uniform surface heat flux. Hence,  $h(0.5 \text{ m}) = 503.9 \text{ W/m}^2 \cdot \text{K}$  and, since  $T_m$  increases linearly with  $x$ ,  $T_m(x = 0.5 \text{ m}) = T_{m,i} + (T_{m,o} - T_{m,i}) (x/L) = 27.5^\circ\text{C}$ . It follows that

$$T_s(x = 0.5 \text{ m}) \approx 27.5^\circ\text{C} + (12,682 \text{ W/m}^2 / 503.9 \text{ W/m}^2 \cdot \text{K}) = 52.7^\circ\text{C}. \quad <$$

## PROBLEM 8.28

**KNOWN:** Oil at 75°C enters a single-tube preheater of 10-mm diameter and 5-m length; tube surface maintained at 175°C by swirling combustion gases.

**FIND:** Determine the flow rate and heat transfer rate when the outlet temperature is 100°C.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Laminar flow, (2) Tube wall is isothermal, (3) Incompressible liquid with negligible viscous dissipation, (4) Constant properties.

**PROPERTIES:** Table A-5, Engine oil, new ( $T_m = (T_{m,i} + T_{m,o})/2 = 361 \text{ K}$ ):  $\rho = 847.5 \text{ kg/m}^3$ ,  $c_p = 2163 \text{ J/kg}\cdot\text{K}$ ,  $\nu = 2.931 \times 10^{-5} \text{ m}^2/\text{s}$ ,  $k = 0.1379 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 390.2$ ,  $\mu = 0.0245$ .

**ANALYSIS:** The overall energy balance, Eq. 8.34, and rate equation, Eq. 8.41b, are

$$q = \dot{m} c_p (T_{m,o} - T_{m,i}) \quad (1)$$

$$\frac{T_s - T_{m,o}}{T_s - T_{m,i}} = \exp\left(-\frac{PL\bar{h}}{\dot{m} c_p}\right) \quad (2)$$

Not knowing the flow rate  $\dot{m}$ , the Reynolds number cannot be calculated. Assume that the flow is laminar. Since  $\text{Pr} > 5$ , the average convection coefficient can be estimated using the Hausen correlation, Eq. 8.57, with Eq. 8.56 for the Graetz number:

$$\overline{\text{Nu}}_D = 3.66 + \frac{0.0668(D/L) \text{Re}_D \text{Pr}}{1 + 0.04[(D/L) \text{Re}_D \text{Pr}]^{2/3}} \quad (3)$$

where all properties are evaluated at  $T_m = (T_{m,i} + T_{m,o})/2$ . The Reynolds number follows from Eq. 8.6,

$$\text{Re}_D = 4\dot{m} / \pi D \mu \quad (4)$$

A tedious trial-and-error solution is avoided by using *IHT* to solve the system of equations with the following result:

$\text{Re}_D$	$\overline{\text{Nu}}_D$	$\bar{h}_D \text{ (W/m}^2\cdot\text{K)}$	$q \text{ (W)}$	$\dot{m} \text{ (kg/h)}$	
130	7.25	100	1360	90	<

Note that the flow is laminar, and evaluating  $x_{fd,t}$  using Eq. 8.23, find  $x_{fd,t} = 25 \text{ m}$ , so the flow is not thermally fully developed.

**COMMENT:** Use of the Baehr and Stephan correlation for the combined entry problem yields the identical values. Hence it may also be used.

## PROBLEM 8.29

**KNOWN:** Oil flow rate. Pipe diameter. Inlet, outlet, and pipe surface temperatures.

**FIND:** Length of tube required to achieve desired outlet temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, (2) Incompressible flow, (3) Negligible viscous dissipation.

**PROPERTIES:** Table A-5, Engine oil ( $T_i = 45^\circ\text{C} = 318\text{ K}$ ):  $\mu_i = 16.3 \times 10^{-2}\text{ N}\cdot\text{s}/\text{m}^2$ ; ( $T_o = 80^\circ\text{C} = 353\text{ K}$ ):  $\mu_o = 3.25 \times 10^{-2}\text{ N}\cdot\text{s}/\text{m}^2$ .

**ANALYSIS:** We begin by calculating the Reynolds numbers at the inlet and outlet, from Equation 8.6,

$$\text{Re}_{Di} = \frac{4 \dot{m}}{\pi D \mu_i} = \frac{4 \times 1 \text{ kg/s}}{\pi \times 0.005 \text{ m} \times 16.3 \times 10^{-2} \text{ N}\cdot\text{s}/\text{m}^2} = 1560$$

$$\text{Re}_{Do} = \frac{4 \times 1 \text{ kg/s}}{\pi \times 0.005 \text{ m} \times 3.25 \times 10^{-2} \text{ N}\cdot\text{s}/\text{m}^2} = 7840$$

Therefore the flow is laminar at the inlet and turbulent at the outlet. The transition occurs when  $\text{Re}_D = 2300$ , that is, where

$$\mu = \frac{4 \dot{m}}{\pi D 2300} = \frac{4 \times 1 \text{ kg/s}}{\pi \times 0.005 \text{ m} \times 2300} = 11.1 \times 10^{-2} \text{ N}\cdot\text{s}/\text{m}^2$$

From Table A-5, this occurs at a transition temperature of  $T_{m,t} = 325\text{ K} = 52^\circ\text{C}$ . Now we proceed to analyze separately the heat transfer in the laminar and turbulent regions.

Laminar Region. The mean temperature in the laminar region is  $\bar{T}_{m1} = (45^\circ\text{C} + 52^\circ\text{C})/2 = 48.5^\circ\text{C} = 321.5\text{ K}$ . The properties are  $c_{p1} = 1999\text{ J}/\text{kg}\cdot\text{K}$ ,  $\mu_1 = 13.2 \times 10^{-2}\text{ N}\cdot\text{s}/\text{m}^2$ ,  $k_1 = 0.143\text{ W}/\text{m}\cdot\text{K}$ ,  $\text{Pr}_1 = 1851$ . We recalculate the Reynolds number,

$$\text{Re}_{D1} = \frac{4 \dot{m}}{\pi D \mu_1} = \frac{4 \times 1 \text{ kg/s}}{\pi \times 0.005 \text{ m} \times 13.2 \times 10^{-2} \text{ N}\cdot\text{s}/\text{m}^2} = 1930$$

The hydrodynamic and thermal entry lengths are given by

$$x_{fd,h} = 0.05 \text{ Re}_{Di} D = 0.05 \times 1930 \times 0.005 \text{ m} = 0.48 \text{ m}$$

$$x_{fd,t} = x_{fd,h} \cdot \text{Pr}_1 = 0.48 \text{ m} \times 1851 = 890 \text{ m}$$

Based on this information, we assume the flow is hydrodynamically developed but thermally developing, and use Equations 8.56 and 8.57 for the Nusselt number (with  $\text{Pr} > 5$ ),

$$\overline{\text{Nu}}_{D1} = \overline{h}_1 D / k_1 = 3.66 + \frac{0.0668 (D/L_1) \text{Re}_{D1} \text{Pr}_1}{1 + 0.04 [(D/L_1) \text{Re}_{D1} \text{Pr}_1]^{2/3}} \quad (1)$$

where  $L_1$  is the length of the laminar region, which is as yet unknown. We can also use Equation 8.42 for the mean temperature variation:

$$\frac{T_s - T_{m,t}}{T_s - T_i} = \exp\left(-\frac{\pi D L_1 \overline{h}_1}{\dot{m} c_{p1}}\right)$$

Continued...

### PROBLEM 8.29 (Cont.)

Solving for  $\bar{h}_1 L_1$ , we have

$$\begin{aligned}\bar{h}_1 L_1 &= -\frac{\dot{m} c_{p1}}{\pi D} \ln\left(\frac{T_s - T_{m,t}}{T_s - T_i}\right) = -\frac{1 \text{ kg/s} \times 1999 \text{ J/kg} \cdot \text{K}}{\pi \times 0.005 \text{ m}} \ln\left(\frac{150^\circ\text{C} - 52^\circ\text{C}}{150^\circ\text{C} - 45^\circ\text{C}}\right) \\ &= 8780 \text{ W/m} \cdot \text{K}\end{aligned}\quad (2)$$

We can solve by iterating between Equations (1) and (2). Beginning with the estimate  $\bar{Nu}_{D1} = 3.66$ , we find  $\bar{h}_1 = 3.66 \text{ k}_1/D = 105 \text{ W/m}^2 \cdot \text{K}$ . From Equation (2),  $L_1 = 84 \text{ m}$ . Then from Equation (1),  $\bar{Nu}_{D1} = 22.3$  and  $\bar{h}_1 = 639 \text{ W/m}^2 \cdot \text{K}$ . Continuing the iterations, we find  $\bar{Nu}_{D1} = 16.9$ ,  $\bar{h}_1 = 484 \text{ W/m}^2 \cdot \text{K}$ , and  $L_1 = 18.1 \text{ m}$ .

Turbulent Range. The mean temperature in the turbulent region is  $\bar{T}_{m2} = (52^\circ\text{C} + 80^\circ\text{C})/2 = 66^\circ\text{C} = 339 \text{ K}$ . The properties are  $c_{p2} = 2072 \text{ J/kg} \cdot \text{K}$ ,  $\mu_2 = 5.62 \times 10^{-2} \text{ N} \cdot \text{s/m}^2$ ,  $k_2 = 0.139 \text{ W/m} \cdot \text{K}$ ,  $Pr_2 = 834$ . Thus

$$Re_{D2} = \frac{4 \dot{m}}{\pi D \mu_2} = 4530$$

We assume the flow is fully-developed hydrodynamically and thermally and use Equation 8.62,

$$Nu_{D2} = \frac{(f/8)(Re_{D2} - 1000) Pr_2}{1 + 12.7 (f/8)^{1/2} (Pr_2^{2/3} - 1)}$$

where from Equation 8.21,

$$f = (0.790 \ln Re_{D2} - 1.64)^{-2} = (0.790 \ln(4530) - 1.64)^{-2} = 0.0398$$

Thus

$$Nu_{D2} = \frac{(0.0398/8)(4530 - 1000) 834}{1 + 12.7 (0.0398/8)^{1/2} (834^{2/3} - 1)} = 184$$

and  $h_2 = Nu_{D2} k_2 / D = 5120 \text{ W/m}^2 \cdot \text{K}$ . Then the required length  $L_2$  can be found from Equation 8.42, expressed between the transition point and the outlet,

$$\begin{aligned}\frac{T_s - T_o}{T_s - T_{m,t}} &= \exp\left(-\frac{\pi D L_2 \bar{h}_2}{\dot{m} c_{p2}}\right) \\ L_2 &= -\frac{\dot{m} c_{p2}}{\pi D \bar{h}_2} \ln\left(\frac{T_s - T_o}{T_s - T_{m,t}}\right) = -\frac{1 \text{ kg/s} \times 2072 \text{ J/kg} \cdot \text{K}}{\pi \times 0.005 \text{ m} \times 5120 \text{ W/m}^2 \cdot \text{K}} \ln\left(\frac{150^\circ\text{C} - 80^\circ\text{C}}{150^\circ\text{C} - 52^\circ\text{C}}\right) \\ &= 8.7 \text{ m}\end{aligned}$$

The total required length is  $L = L_1 + L_2 = 26.8 \text{ m}$ . <

**COMMENTS:** (1) If we had simply calculated the properties based on the mean temperature of  $\bar{T}_m = (45^\circ\text{C} + 80^\circ\text{C})/2 = 62.5^\circ\text{C} = 335.5 \text{ K}$ , we would have found  $Re_D = 3810$ . Assuming the flow to be turbulent throughout would have resulted in a higher average Nusselt number,  $\bar{Nu}_D = 159$ , and correspondingly lower total length,  $L = 11.9 \text{ m}$ . The variation of properties with temperature can be very important for some fluids such as oils. (2) If the oil were being cooled by exposure to a cooler wall, the Reynolds number could decrease from a turbulent to a laminar value. The flow would likely not completely “relaminarize,” and the heat transfer in the section for which  $Re_D < 2300$  would fall between the values calculated using laminar and turbulent Nusselt number correlations.

### PROBLEM 8.30

**KNOWN:** Diameter and length of tube, air flow rate, air temperature and pressure at the tube inlet. Surface temperature at the tube exit.

**FIND:** (a) The heat transfer rate of the problem. (b) Conditions at the tube exit for reduced tube length. (c) Conditions at the tube exit for increased air flow rate.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Constant properties, (3) Negligible viscous dissipation.

**PROPERTIES:** Table A.4, Air ( $\bar{T}_m \approx 400$  K,  $p = 1$  atm):  $\mu = 230.1 \times 10^{-7}$  N·s/m<sup>2</sup>,  $Pr = 0.690$ ,  $k = 0.0338$  W/m·K,  $c_p = 1014$  J/kg·K.

**ANALYSIS:** (a) We begin by calculating the Reynolds number

$$Re_D = \frac{4\dot{m}}{\pi D \mu} = \frac{4 \times 135 \times 10^{-6} \text{ kg/s}}{\pi \times 0.005 \text{ m} \times 230.1 \times 10^{-7} \text{ N} \cdot \text{s/m}^2} = 1494$$

Therefore, the flow is laminar. The hydrodynamic and thermal entrance lengths are

$$x_{fd,h} = 0.05 D Re_D = 0.05 \times 0.005 \text{ m} \times 1494 = 0.37 \text{ m}$$

$$x_{fd,t} = x_{fd,h} Pr = 0.37 \text{ m} \times 0.690 = 0.26 \text{ m}$$

Therefore, the flow is fully-developed at the tube exit. For fully-developed laminar flow with constant heat flux conditions, the Nusselt number is  $Nu_D = 4.36$ . Therefore, the local heat transfer coefficient at the tube exit is

$$h = 4.36k / D = 4.36 \times 0.0338 \text{ W/m} \cdot \text{K} / 0.005 \text{ m} = 29.47 \text{ W/m}^2 \cdot \text{K}$$

Two independent expressions for the heat flux may be written based upon application of Newton's law of cooling at the tube exit and an overall energy balance.

$$q'' = h(T_{s,o} - T_{m,o}) \quad ; \quad q'' = \frac{\dot{m}c_p(T_{m,o} - T_{m,i})}{\pi DL} \quad (1, 2)$$

Equating Eqs. (1) and (2) yields

Continued...

**PROBLEM 8.30 (Cont.)**

$$\begin{aligned}
 T_{m,o} &= \left[ hT_{s,o} + \frac{\dot{m}c_p}{\pi DL} T_{m,i} \right] / \left[ \frac{\dot{m}c_p}{\pi DL} + h \right] \\
 &= \frac{\left[ 29.47 \text{ W/m}^2 \cdot \text{K} \times 160^\circ\text{C} + \frac{135 \times 10^{-6} \text{ kg/s} \times 1014 \text{ J/kg} \cdot \text{K}}{\pi \times 0.005 \text{ m} \times 2 \text{ m}} \times 100^\circ\text{C} \right]}{\left[ \frac{135 \times 10^{-6} \text{ kg/s} \times 1014 \text{ J/kg} \cdot \text{K}}{\pi \times 0.005 \text{ m} \times 2 \text{ m}} + 29.47 \text{ W/m}^2 \cdot \text{K} \right]} \\
 &= 152.3^\circ\text{C}
 \end{aligned}$$

Hence, the heat rate is

$$q = \dot{m}c_p(T_{m,o} - T_{m,i}) = 135 \times 10^{-6} \text{ kg/s} \times 1014 \text{ J/kg} \cdot \text{K} \times 52.3^\circ\text{C} = 7.16 \text{ W} \quad <$$

(b) If  $L = 0.2 \text{ m}$ , conditions at  $x = L$  are not fully developed and the value of the heat transfer coefficient at the tube exit would exceed that of part (a).

(c) If the flow rate is increased by an order of magnitude, the Reynolds number will increase to  $Re_D = 14,940$ , and the flow will be turbulent at the tube exit. Since  $L/D = 2 \text{ m} / 0.005 \text{ m} = 400$ , the turbulent flow at the tube exit will also be fully developed. The heat transfer coefficient at the tube exit would exceed that of part (a).

**COMMENTS:** In part (b), the local heat transfer coefficient would exceed  $h = 29.47 \text{ W/m}^2$  at the tube exit and could be estimated using Fig. 8.10a. Specifically, for  $Gz^{-1} = (x/D)/(Re_D Pr) = (0.2 \text{ m} / 0.005 \text{ m}) / (1494 \times 0.690) = 0.039$ ,  $Nu_D \approx 4.6$ . Hence,  $h = 29.47 \text{ W/m}^2 \times (4.6/4.36) = 31.1 \text{ W/m}^2 \cdot \text{K}$ . In part (c), the local heat transfer coefficient would exceed  $h = 29.47 \text{ W/m}^2$  and could be evaluated using the Dittus-Boelter correlation. Specifically,  $Nu_D = 0.023 \times (14,940)^{4/5} \times 0.690^{0.4} = 43.3$ . Hence,  $h = 29.47 \text{ W/m}^2 \times (43.3/4.36) = 292.7 \text{ W/m}^2 \cdot \text{K}$ . For  $T_{s,o}$  to remain the same, the heat rate associated with either part (b) or part (c) would have to exceed that of part (a).

### PROBLEM 8.31

**KNOWN:** Thermal conductivity and inner and outer diameters of plastic pipe. Volumetric flow rate and inlet and outlet temperatures of air flow through pipe. Convection coefficient and temperature of water.

**FIND:** Pipe length and fan power requirement.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, (2) Negligible heat transfer from air in vertical legs of pipe, (3) Ideal gas with negligible viscous dissipation and pressure variation, (4) Smooth interior surface, (5) Constant properties.

**PROPERTIES:** Table A-4, Air ( $T_{m,i} = 29^\circ\text{C}$ ):  $\rho_1 = 1.155 \text{ kg/m}^3$ . Air ( $\bar{T}_m = 25^\circ\text{C}$ ):  $c_p = 1007 \text{ J/kg}\cdot\text{K}$ ,  $\mu = 183.6 \times 10^{-7} \text{ N}\cdot\text{s/m}^2$ ,  $k_a = 0.0261 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.707$ .

**ANALYSIS:** From Eq. (8.45a)

$$\frac{T_\infty - T_{m,o}}{T_\infty - T_{m,i}} = \exp\left(-\frac{\bar{U}A_s}{\dot{m}c_p}\right)$$

where, from Eqs. (3.34) and (3.35),  $(\bar{U}A_s)^{-1} = R_{\text{tot}} = \frac{1}{h_i\pi D_i L} + \frac{\ln(D_o/D_i)}{2\pi Lk} + \frac{1}{h_o\pi D_o L}$

With  $\dot{m} = \rho_1 \dot{V}_i = 0.0289 \text{ kg/s}$  and  $\text{Re}_D = 4\dot{m}/\pi D_i \mu = 13,350$ , flow in the pipe is turbulent. Assuming fully developed flow throughout the pipe, and from Eq. (8.60),

$$\bar{h}_i = \frac{k_a}{D_i} 0.023 \text{Re}_D^{4/5} \text{Pr}^{0.3} = \frac{0.0261 \text{ W/m}\cdot\text{K} \times 0.023}{0.15 \text{ m}} (13,350)^{4/5} (0.707)^{0.3} = 7.20 \text{ W/m}^2 \cdot \text{K}$$

$$(\bar{U}A_s)^{-1} = \frac{1}{L} \left( \frac{1}{7.21 \text{ W/m}^2 \cdot \text{K} \times \pi \times 0.15 \text{ m}} + \frac{\ln(0.17/0.15)}{2\pi \times 0.15 \text{ W/m}\cdot\text{K}} + \frac{1}{1500 \text{ W/m}^2 \cdot \text{K} \times \pi \times 0.17 \text{ m}} \right)$$

$$\bar{U}A_s = \frac{L}{(0.294 + 0.133 + 0.001)} = 2.335 L \text{ W/K}$$

$$\frac{T_\infty - T_{m,o}}{T_\infty - T_{m,i}} = \frac{17 - 21}{17 - 29} = 0.333 = \exp\left(-\frac{2.335 L}{0.0289 \text{ kg/s} \times 1007 \text{ J/kg}\cdot\text{K}}\right) = \exp(-0.0802L)$$

$$L = -\frac{\ln(0.333)}{0.0802} = 13.7 \text{ m} \quad \leftarrow$$

From Eqs. (8.22a) and (8.22b) and with  $u_{m,i} = \dot{V}_i / (\pi D_i^2 / 4) = 1.415 \text{ m/s}$ , the fan power is

$$P = (\Delta p) \dot{V} \approx f \frac{\rho_1 u_{m,i}^2}{2D_i} L \dot{V}_i = 0.0291 \frac{1.155 \text{ kg/m}^3 (1.415 \text{ m/s})^2}{2(0.15 \text{ m})} 13.7 \text{ m} \times 0.025 \text{ m}^3/\text{s} = 0.077 \text{ W} \quad \leftarrow$$

where  $f = (0.790 \ln \text{Re}_D - 1.64)^{-2} = 0.0291$  from Eq. (8.21).

**COMMENTS:** (1) With  $L/D_i = 91$ , the assumption of fully developed flow throughout the pipe is justified. (2) The fan power requirement is small, and the process is economical. (3) The resistance to heat transfer associated with convection at the outer surface is negligible.

### PROBLEM 8.32

**KNOWN:** Inlet temperature, flow rate and properties of hot fluid. Initial temperature, volume and properties of pharmaceutical. Heat transfer coefficient at outer surface and dimensions of coil.

**FIND:** (a) Expressions for  $T_c(t)$  and  $T_{h,o}(t)$ , (b) Plots of  $T_c(t)$  and  $T_{h,o}(t)$  for prescribed conditions. Effect of flow rate on time for pharmaceutical to reach a prescribed temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Constant properties, (2) Negligible heat loss from vessel to surroundings, (3) Pharmaceutical is isothermal, (4) Negligible work due to stirring, (5) Negligible thermal energy generation (or absorption) due to chemical reactions associated with the batch process, (6) Hot fluid is an incompressible liquid with negligible viscous dissipation, (7) Negligible tube wall conduction resistance.

**ANALYSIS:** (a) Performing an energy balance for a control surface about the stirred liquid, it follows that

$$\frac{dU_c}{dt} = \frac{d}{dt}(\rho_c V_c c_{v,c} T_c) = \rho_c V_c c_{v,c} \frac{dT_c}{dt} = q(t) \quad (1)$$

where,  $q(t) = \dot{m}_h c_{p,h} (T_{h,i} - T_{h,o}) \quad (2)$

or,  $q(t) = UA_s \Delta T_{lm} \quad (3a)$

where

$$\Delta T_{lm} = \frac{(T_{h,i} - T_c) - (T_{h,o} - T_c)}{\ln\left(\frac{T_{h,i} - T_c}{T_{h,o} - T_c}\right)} = \frac{(T_{h,i} - T_{h,o})}{\ln\left(\frac{T_{h,i} - T_c}{T_{h,o} - T_c}\right)} \quad (3b)$$

Substituting (3b) into (3a) and equating to (2),

$$\dot{m}_h c_{p,h} (T_{h,i} - T_{h,o}) = UA_s \frac{(T_{h,i} - T_{h,o})}{\ln\left(\frac{T_{h,i} - T_c}{T_{h,o} - T_c}\right)}$$

Hence,  $\ln\left(\frac{T_{h,i} - T_c}{T_{h,o} - T_c}\right) = \frac{UA_s}{\dot{m}_h c_{p,h}}$

or,  $T_{h,o}(t) = T_c + (T_{h,i} - T_c) \exp(-UA_s / \dot{m}_h c_{p,h}) \quad (4) <$

Substituting Eqs. (2) and (4) into Eq. (1),

Continued ...

**PROBLEM 8.32 (Cont.)**

$$\rho_c V_c c_{v,c} \frac{dT_c}{dt} = \dot{m}_h c_{p,h} \left[ T_{h,i} - T_c - (T_{h,i} - T_c) \exp(-UA_s / \dot{m}_h c_{p,h}) \right]$$

$$\frac{dT_c}{dt} = \frac{\dot{m}_h c_{p,h} (T_{h,i} - T_c)}{\rho_c V_c c_{v,c}} \left[ 1 - \exp(-UA_s / \dot{m}_h c_{p,h}) \right]$$

$$-\int_{T_{c,i}}^{T_c(t)} \frac{dT_c}{(T_c - T_{h,i})} = \frac{\dot{m}_h c_{p,h}}{\rho_c V_c c_{v,c}} \left[ 1 - \exp(-UA_s / \dot{m}_h c_{p,h}) \right] \int_0^t dt$$

$$-\ln \left( \frac{T_c - T_{h,i}}{T_{c,i} - T_{h,i}} \right) = \frac{\dot{m}_h c_{p,h}}{\rho_c V_c c_{v,c}} \left[ 1 - \exp(-UA_s / \dot{m}_h c_{p,h}) \right] t$$

$$T_c(t) = T_{h,i} - (T_{h,i} - T_{c,i}) \exp \left\{ - \frac{\dot{m}_h c_{p,h} \left[ 1 - \exp(-UA_s / \dot{m}_h c_{p,h}) \right] t}{\rho_c V_c c_{v,c}} \right\} \quad (5) <$$

Eq. (5) may be used to determine  $T_c(t)$  and the result used with (4) to determine  $T_{h,o}(t)$ .

(b) To evaluate the temperature histories, the overall heat transfer coefficient,  $U = (h_o^{-1} + h_i^{-1})^{-1}$ , must first be determined. With  $Re_D = 4 \dot{m} / \pi D \mu = 4 \times 2.4 \text{ kg/s} / \pi (0.05 \text{ m}) 0.002 \text{ N} \cdot \text{s/m}^2 = 30,600$ , the flow is turbulent and

$$h_i = \frac{k}{D} Nu_D = \frac{0.260 \text{ W/m} \cdot \text{K}}{0.05 \text{ m}} \left[ 0.023 (30,600)^{4/5} (20)^{0.3} \right] = 1140 \text{ W/m}^2 \cdot \text{K}$$

Hence,  $U = \left[ (1000)^{-1} + (1140)^{-1} \right]^{-1} \text{ W/m}^2 \cdot \text{K} = 532 \text{ W/m}^2 \cdot \text{K}$ . As shown below, the temperature of the pharmaceuticals increases with time due to heat transfer from the hot fluid, approaching the inlet temperature of the hot fluid (and its maximum possible temperature of 200°C) at  $t = 3600\text{s}$ .

Continued ...

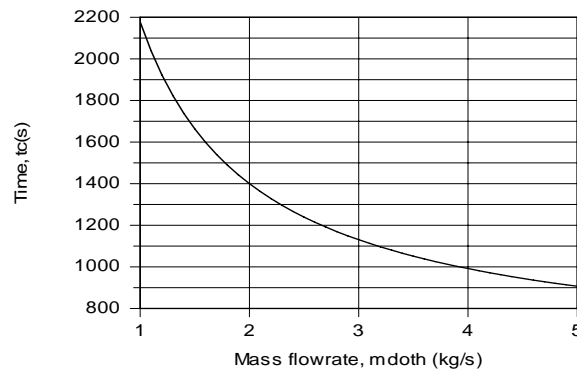

### PROBLEM 8.32 (Cont.)

With increasing  $T_c$ , the rate of heat transfer from the hot fluid decreases (from  $4.49 \times 10^5$  W at  $t = 0$  to 6760 W at 3600s), in which case  $T_{h,o}$  increases (from  $125.2^\circ\text{C}$  at  $t = 0$  to  $198.9^\circ\text{C}$  at 3600s). The time required for the pharmaceuticals to reach a temperature of  $T_c = 160^\circ\text{C}$  is

$$t_c = 1266\text{s}$$

&lt;

With increasing  $\dot{m}_h$ , the overall heat transfer coefficient increases due to increasing  $h_i$  and the hot fluid maintains a higher temperature as it flows through the tube. Both effects enhance heat transfer to the pharmaceutical, thereby reducing the time to reach  $160^\circ\text{C}$  from 2178s for  $\dot{m}_h = 1$  kg/s to 906s at 5 kg/s.

For  $1 \leq \dot{m}_h \leq 5$  kg/s,  $12,700 \leq \text{Re}_D \leq 63,700$  and  $565 \leq h_i \leq 2050$  W/m<sup>2</sup>·K.

**COMMENTS:** (1) Although design changes involving the length and diameter of the coil can be used to alter the heating rate, process control parameters are limited to  $T_{h,i}$  and  $\dot{m}_h$ . (2) Coiling the tube can increase the inside heat transfer coefficient, as will be seen in Section 8.7.

### PROBLEM 8.33

**KNOWN:** Diameter and surface temperature of ten tubes in an ice bath. Inlet temperature and flowrate per tube. Volume ( $\nabla$ ) of container and initial volume fraction,  $f_{v,i}$ , of ice.

**FIND:** (a) Tube length required to achieve a prescribed air outlet temperature  $T_{m,o}$  and time to completely melt the ice, (b) Effect of mass flowrate on  $T_{m,o}$  and suitable design and operating conditions.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, (2) Ideal gas with negligible viscous dissipation and pressure variation, (3) Constant properties, (4) Fully developed flow throughout each tube, (5) Negligible tube wall thermal resistance.

**PROPERTIES:** Table A.4, air (assume  $\bar{T}_m = 292$  K):  $c_p = 1007$  J/kg·K,  $\mu = 180.6 \times 10^{-7}$  N·s/m<sup>2</sup>,  $k = 0.0257$  W/m·K,  $Pr = 0.709$ ; Ice:  $\rho = 920$  kg/m<sup>3</sup>,  $h_{sf} = 3.34 \times 10^5$  J/kg.

**ANALYSIS:** (a) With  $Re_D = 4 \dot{m} / \pi D \mu = 4(0.01 \text{ kg/s}) / \pi(0.05 \text{ m})180.6 \times 10^{-7} \text{ N·s/m}^2 = 14,100$  for  $\dot{m} = 0.01$  kg/s, the flow is turbulent, and from Eq. 8.60,

$$\overline{Nu}_D = Nu_D = 0.023 Re_D^{0.8} Pr^{0.3} = 0.023(14,100)^{0.8} (0.709)^{0.3} = 43.3$$

$$\bar{h} = \overline{Nu}_D (k/D) = 43.3(0.0257 \text{ W/m} \cdot \text{K} / 0.05 \text{ m}) = 22.2 \text{ W/m}^2 \cdot \text{K}$$

With  $T_{m,o} = 14^\circ\text{C}$ , the tube length may be obtained from Eq. 8.41b,

$$\frac{T_s - T_{m,o}}{T_s - T_{m,i}} = \frac{-14}{-24} = \exp\left(-\frac{\pi DL \bar{h}}{\dot{m} c_p}\right) = \exp\left[-\frac{\pi(0.05 \text{ m})(22.2 \text{ W/m}^2 \cdot \text{K})L}{0.01 \text{ kg/s}(1007 \text{ J/kg} \cdot \text{K})}\right]$$

$$L = 1.56 \text{ m} \quad \leftarrow$$

The time required to completely melt the ice may be obtained from an energy balance of the form,

$$(-q)t = f_{v,i} \nabla (\rho h_{sf})$$

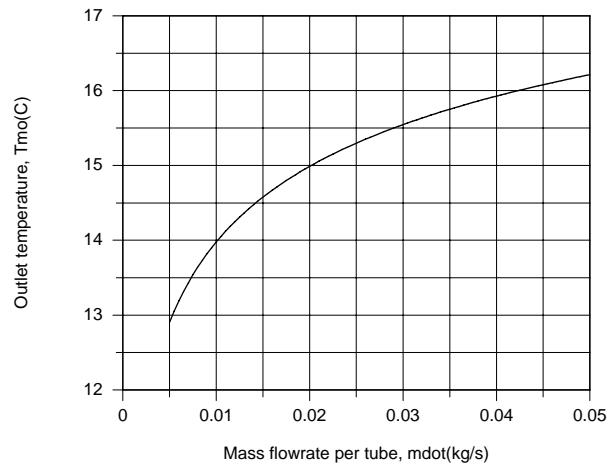

where  $q = N \dot{m} c_p (T_{m,i} - T_{m,o}) = 10(0.01 \text{ kg/s})1007 \text{ J/kg} \cdot \text{K}(10 \text{ K}) = 1007 \text{ W}$ . Hence,

$$t = \frac{0.8(10 \text{ m}^3)(920 \text{ kg/m}^3)3.34 \times 10^5 \text{ J/kg}}{1007 \text{ W}} = 2.44 \times 10^6 \text{ s} = 28.3 \text{ days} \quad \leftarrow$$

(b) Using the appropriate IHT Correlations and Properties Tool Pads, the following results were obtained.

### PROBLEM 8.33 (Cont.)

Although heat extraction from the air passing through each tube increases with increasing flowrate, the increase is not in proportion to the change in  $\dot{m}$  and the temperature difference ( $T_{m,i} - T_{m,o}$ ) decreases. If 0.05 kg/s of air is routed through a single tube, the outlet temperature of  $T_{m,o} = 16.2^\circ\text{C}$  slightly exceeds the desired value of  $16^\circ\text{C}$ . The prescribed value could be achieved by slightly increasing the tube length. However, in the interest of reducing pressure drop requirements, it would be better to operate at a lower flowrate per tube. If, for example, air is routed through four of the tubes at 0.01 kg/s per tube and the discharge is mixed with 0.01 kg/s of the available air at  $24^\circ\text{C}$ , the desired result would be achieved.

**COMMENTS:** Since the flow is turbulent and  $L/D = 31$ , the assumption of fully developed flow throughout a tube is marginal and the foregoing analysis overestimates the discharge temperature.

## PROBLEM 8.34

**KNOWN:** Initial food temperature and mass flow rate. Length of heating and cooling sections in a food sterilizer. Diameter of sterilizer tube. Time-at-temperature constraint, and constraint on local maximum food temperature.

**FIND:** (a) Heat flux in the heating section. (b) Maximum local product temperature and its location. (c) Minimum required sterilizing section length. (d) Sketch of the axial distributions of the mean, surface, and centerline food temperatures from entrance to exit of sterilizer.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Constant properties, (3) Negligible viscous dissipation.

**PROPERTIES:** Table A.6, Water ( $\bar{T}_m = 330 \text{ K}$ ,  $p = 1 \text{ atm}$ ):  $\mu = 489 \times 10^{-6} \text{ N}\cdot\text{s}/\text{m}^2$ ,  $Pr = 3.15$ ,  $k = 0.65 \text{ W}/\text{m}\cdot\text{K}$ ,  $c_p = 4184 \text{ J}/\text{kg}\cdot\text{K}$ ,  $\rho = 984 \text{ kg}/\text{m}^3$ .

**ANALYSIS:** (a) An energy balance applied to the heating section yields

$$q = q''A = q''\pi DL_h = \dot{m}c_p(T_{m,o,h} - T_{m,i,h})$$

which may be rearranged to provide the expression

$$q'' = \frac{\dot{m}c_p(T_{m,o,h} - T_{m,i,h})}{\pi DL_h} = \frac{1 \text{ kg/s} \times 4184 \text{ J}/\text{kg}\cdot\text{K} \times (90 - 20)^\circ\text{C}}{\pi \times 0.04 \text{ m} \times 5 \text{ m}} = 466,000 \text{ W}/\text{m}^2 = 466 \text{ kW}/\text{m}^2 <$$

(b) The maximum local product temperature occurs at the tube wall at the end of the heating section. The Reynolds number is

$$Re_D = \frac{4\dot{m}}{\pi D\mu} = \frac{4 \times 1 \text{ kg/s}}{\pi \times 0.04 \text{ m} \times 489 \times 10^{-6} \text{ N}\cdot\text{s}/\text{m}^2} = 65,090$$

Hence, the flow is turbulent. Since  $L_h/D = 5 \text{ m}/0.04 \text{ m} = 125$ , the flow is fully-developed. Using the Dittus-Boelter correlation,

$$h = \frac{k}{D} \left[ 0.023 Re_D^{4/5} Pr^{0.4} \right] = \frac{0.65 \text{ W}/\text{m}\cdot\text{K}}{0.04 \text{ m}} \left[ 0.023 \times 65,090^{4/5} \times 3.15^{0.4} \right] = 4190 \text{ W}/\text{m}^2 \cdot \text{K}$$

From Newton's law of cooling,

$$T_s(x = L_h = 5 \text{ m}) = T_{m,o,h} + \frac{q''}{h} = 90^\circ\text{C} + \frac{466,000 \text{ W}/\text{m}^2}{4190 \text{ W}/\text{m}^2 \cdot \text{K}} = 201^\circ\text{C} <$$

Continued...

### PROBLEM 8.34 (Cont.)

The second constraint is satisfied. <

(c) The minimum length of the sterilizing section is

$$L_s = u_m t_s = \frac{4\dot{m}}{\rho\pi D^2} t_s = \frac{4 \times 1 \text{ kg/s}}{984 \text{ kg/m}^3 \times \pi \times (0.04 \text{ m})^2} \times 10 \text{ s} = 8.1\text{m} <$$

(d) The axial distributions of the mean, surface, and centerline temperatures are shown below.

Important features of the temperature distribution are as follows.

$0 \leq x \leq x_{fd,t}$ : Near the tube entrance, the heat transfer coefficient is theoretically infinite, and all three temperatures are nearly the same value.

$x_{fd,t} \leq x \leq L_h$ : The flow is fully-developed; the shape of the radial temperature distribution does not change down the tube length. Therefore, the three temperature distributions are parallel.

$L_h \leq x \leq L_h + L_s$ : The heat transfer coefficient is zero. However, temperature differences exist in the fluid, with warm temperatures adjacent to the tube wall and cool temperatures near the centerline of the tube. As the flow progresses down the insulated sterilizing section, the temperatures equilibrate by way of diffusion and turbulent mixing. The equilibration takes place over a distance approximately equal to  $x_{fd,t}$ .

Continued...

### PROBLEM 8.34 (Cont.)

$L_h + L_s \leq x \leq L_h + L_s + L_c$ : The fluid is cooled. Hence, the warmest temperature fluid is at the centerline, and the coolest fluid is adjacent to the tube wall. Since the fluid is cooled by exposure of the tube to the environment, the cooling rate is expected to be smaller than the heating rate in the heating section. Hence, the radial temperature differences in the cooling section are smaller than the radial temperature differences in the heating section.

**COMMENTS:** (1) The velocity of the fluid at the centerline exceeds velocities at any other radial location. Hence, the fluid at the centerline of the tube will not satisfy the time-at-temperature criterion. Therefore, use of a coiled tube or other heat transfer enhancement devices (Section 8.7) would be appropriate in this application. (2) The insulation thickness in the sterilizing section should be much greater than the critical insulation thickness.

### PROBLEM 8.35

**KNOWN:** Flow rate, inlet temperature and desired outlet temperature of water passing through a tube of prescribed diameter and surface temperature.

**FIND:** (a) Required tube length,  $L$ , for prescribed conditions, (b) Required length using tube diameters over the range  $30 \leq D \leq 50$  mm with flow rates  $\dot{m} = 1, 2$  and  $3$  kg/s; represent this design information graphically, and (c) Pressure gradient as a function of tube diameter for the three flow rates assuming the tube wall is smooth.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Incompressible liquid with negligible viscous dissipation, (3) Constant properties.

**PROPERTIES:** Table A.6, Water ( $\bar{T}_m = 323$  K):  $c_p = 4181$  J/kg·K,  $\mu = 547 \times 10^{-6}$  N·s/m<sup>2</sup>,  $k = 0.643$  W/m·K,  $Pr = 3.56$ .

**ANALYSIS:** (a) From Eq. 8.6, the Reynolds number is

$$Re_D = \frac{4\dot{m}}{\pi D \mu} = \frac{4 \times 2 \text{ kg/s}}{\pi (0.04 \text{ m}) 547 \times 10^{-6} \text{ N} \cdot \text{s/m}^2} = 1.16 \times 10^5. \quad (1)$$

Hence the flow is turbulent, and assuming fully developed conditions throughout the tube, it follows from the Dittus-Boelter correlation, Eq. 8.60,

$$\bar{h} = \frac{k}{D} 0.023 Re_D^{4/5} Pr^{0.4} = \frac{0.643 \text{ W/m} \cdot \text{K}}{0.04 \text{ m}} 0.023 (1.16 \times 10^5)^{4/5} (3.56)^{0.4} = 6919 \text{ W/m}^2 \cdot \text{K} \quad (2)$$

From Eq. 8.41a, we then obtain

$$L = \frac{-\dot{m} c_p \ln(\Delta T_o / \Delta T_i)}{\pi D \bar{h}} = - \frac{2 \text{ kg/s} (4181 \text{ J/kg} \cdot \text{K}) \ln(25^\circ \text{C} / 75^\circ \text{C})}{\pi (0.04 \text{ m}) 6919 \text{ W/m}^2 \cdot \text{K}} = 10.6 \text{ m}. \quad <$$

(b) Using the *IHT Correlations Tool, Internal Flow*, for fully developed *Turbulent Flow*, along with appropriate energy balance and rate equations, the required length  $L$  as a function of flow rate is computed and plotted on the right.

Continued...

### PROBLEM 8.35 (Cont.)

(c) From Eq. 8.22a the pressure drop is

$$\frac{\Delta p}{\Delta x} = f \frac{\rho u_m^2}{2D} \quad (4)$$

The friction factor,  $f$ , for the smooth surface condition, Eq. 8.21 with  $3000 \leq Re_D \leq 5 \times 10^6$ , is

$$f = (0.790 \ln(Re_D) - 1.64)^{-2} \quad (5)$$

Using IHT with these equations and Eq. (1), the pressure gradient as a function of diameter for the selected flow rates is computed and plotted on the right.

**COMMENTS:** (1) Since  $L/D = (10.6/0.040) = 265$ , the assumption of fully developed conditions throughout is justified.

(2) The IHT Workspace used to generate the graphical results are shown below.

```

// Rate Equation Tool - Tube Flow with Constant Surface Temperature:
/* For flow through a tube with a uniform wall temperature, Fig 8.7b, the
overall energy balance and heat rate equations are */
q = mdot*cp*(Tmo - Tmi) // Heat rate, W; Eq 8.34

f = ( 0.790 * ln (ReD) - 1.64 ) ^ -2
    
```

### PROBLEM 8.36

**KNOWN:** Diameters and thermal conductivity of steel pipe. Temperature and velocity of water flow in pipe. Temperature and velocity of air in cross flow over pipe. Cost of producing hot water.

**FIND:** Daily cost of heat loss per unit length of pipe.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady state, (2) Constant properties, (3) Negligible radiation from outer surface, (4) Fully-developed flow in pipe.

**PROPERTIES:** Table A-4, air ( $p = 1 \text{ atm}$ ,  $T_f \approx 300 \text{ K}$ ):  $k_a = 0.0263 \text{ W/m}\cdot\text{K}$ ,  $\nu_a = 15.89 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\text{Pr}_a = 0.707$ . Table A-6, water ( $T_m = 323 \text{ K}$ ):  $\rho_w = 988 \text{ kg/m}^3$ ,  $\mu_w = 548 \times 10^{-6} \text{ N}\cdot\text{s/m}^2$ ,  $k_w = 0.643 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr}_w = 3.56$ .

**ANALYSIS:** The heat loss per unit length of pipe is

$$q' = \frac{T_m - T_\infty}{R'_{\text{cnv},w} + R'_{\text{cnd}} + R'_{\text{cnv},a}} = \frac{T_m - T_\infty}{(h_w \pi D_i)^{-1} + \frac{\ln(D_o/D_i)}{2\pi k_p} + (h_a \pi D_o)^{-1}}$$

With  $\text{Re}_{D,w} = \rho_w u_m D_i / \mu_w = 988 \text{ kg/m}^3 \times 0.5 \text{ m/s} \times 0.084 \text{ m} / 548 \times 10^{-6} \text{ N}\cdot\text{s/m}^2 = 75,700$ , flow is turbulent, and for fully developed conditions, the Dittus-Boelter correlation yields

$$h_w = \frac{k_w}{D_i} 0.023 \text{Re}_{D,w}^{0.8} \text{Pr}_w^{0.3} = 0.023 \frac{0.643 \text{ W/m}\cdot\text{K}}{0.084 \text{ m}} (75,700)^{0.8} (3.56)^{0.3} = 2060 \text{ W/m}^2 \cdot \text{K}$$

With  $\text{Re}_{D,a} = VD_o / \nu_a = 3 \text{ m/s} \times (0.1 \text{ m}) / 15.89 \times 10^{-6} \text{ m}^2/\text{s} = 18,880$ , the Churchill-Bernstein correlation yields

$$h_a = \bar{h} = \frac{k_a}{D_o} \left\{ 0.3 + \frac{0.62 \text{Re}_{D,a}^{1/2} \text{Pr}_a^{1/3}}{\left[ 1 + (0.4/\text{Pr}_a)^{2/3} \right]^{1/4}} \left[ 1 + \left( \frac{\text{Re}_{D,w}}{282,000} \right)^{5/8} \right]^{4/5} \right\} = 20.1 \text{ W/m}^2 \cdot \text{K}$$

Hence,

$$q' = \frac{50^\circ\text{C} - (-5^\circ\text{C})}{\left( 1.84 \times 10^{-3} + 0.46 \times 10^{-3} + 158.36 \times 10^{-3} \right) \text{ K/W}} = 342 \text{ W/m} = 0.342 \text{ kW/m}$$

The daily energy loss is then  $Q' = 0.346 \text{ kW/m} \times 24 \text{ h/d} = 8.22 \text{ kW}\cdot\text{h/d}\cdot\text{m}$

and the associated cost is  $C' = (8.22 \text{ kW}\cdot\text{h/d}\cdot\text{m})(\$0.05/\text{kW}\cdot\text{h}) = \$0.411/\text{m}\cdot\text{d} <$

**COMMENTS:** Because  $R'_{\text{cnv},a} \gg R'_{\text{cnv},w}$ , the convection resistance for the water side of the pipe could have been neglected, with negligible error. The implication is that the temperature of the pipe's inner surface closely approximates that of the water. If  $R'_{\text{cnv},w}$  is neglected, the heat loss is

$$q' = 346 \text{ W/m}.$$

### PROBLEM 8.37

**KNOWN:** Inner and outer diameter of a steel pipe insulated on the outside and experiencing uniform heat generation. Flow rate and inlet temperature of water flowing through the pipe.

**FIND:** (a) Pipe length required to achieve desired outlet temperature, (b) Location and value of maximum pipe temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Constant properties, (3) Incompressible liquid with negligible viscous dissipation, (4) One-dimensional radial conduction in pipe wall, (5) Outer surface is adiabatic.

**PROPERTIES:** Table A-1, Stainless steel 316 ( $T \approx 400\text{K}$ ):  $k = 15 \text{ W/m}\cdot\text{K}$ ; Table A-6, Water ( $\bar{T}_m = 303\text{K}$ ):  $c_p = 4178 \text{ J/kg}\cdot\text{K}$ ,  $k = 0.617 \text{ W/m}\cdot\text{K}$ ,  $\mu = 803 \times 10^{-6} \text{ N}\cdot\text{s/m}^2$ ,  $\text{Pr} = 5.45$ .

**ANALYSIS:** (a) Performing an energy balance for a control volume about the inner tube, it follows that

$$\dot{m} c_p (T_{m,o} - T_{m,i}) = \dot{q} = \dot{q} (\pi/4) (D_o^2 - D_i^2) L$$

$$L = \frac{\dot{m} c_p (T_{m,o} - T_{m,i})}{\dot{q} (\pi/4) (D_o^2 - D_i^2)} = \frac{(0.1 \text{ kg/s}) 4178 (\text{J/kg}\cdot\text{K}) 20^\circ\text{C}}{10^6 \text{ W/m}^3 (\pi/4) [(0.04\text{m})^2 - (0.02\text{m})^2]}$$

$$L = 8.87\text{m.} \quad \leftarrow$$

(b) The maximum wall temperature exists at the pipe exit ( $x = L$ ) and the insulated surface ( $r = r_o$ ). From Eq. 3.56, the radial temperature distribution in the wall is of the form

$$T(r) = -\frac{\dot{q}}{4k} r^2 + C_1 \ln r + C_2.$$

Considering the boundary conditions;

$$r = r_o: \left. \frac{dT}{dr} \right|_{r=r_o} = 0 = -\frac{\dot{q}}{2k} r_o + \frac{C_1}{r_o} \quad C_1 = \frac{\dot{q} r_o^2}{2k}$$

Continued ...

**PROBLEM 8.37 (Cont.)**

$$r = r_i : \quad T(r_i) = T_s = -\frac{\dot{q}}{4k} r_i^2 + \frac{\dot{q} r_o^2}{2k} \ln r_i + C_2 \quad C_2 = \frac{\dot{q}}{4k} r_i^2 - \frac{\dot{q} r_o^2}{2k} \ln r_i + T_s.$$

The temperature distribution and the maximum wall temperature ( $r = r_o$ ) are

$$T(r) = -\frac{\dot{q}}{4k} (r^2 - r_i^2) + \frac{\dot{q} r_o^2}{2k} \ln \frac{r}{r_i} + T_s$$

$$T_{w,\max} = T(r_o) = -\frac{\dot{q}}{4k} (r_o^2 - r_i^2) + \frac{\dot{q} r_o^2}{2k} \ln \frac{r_o}{r_i} + T_s$$

where  $T_s$ , the inner surface temperature of the wall at the exit, follows from

$$q_s'' = \frac{\dot{q}(\pi/4) (D_o^2 - D_i^2)L}{\pi D_i L} = \frac{\dot{q}(D_o^2 - D_i^2)}{4 D_i} = h(T_s - T_{m,o})$$

where  $h$  is the local convection coefficient at the exit. With

$$Re_D = \frac{4 \dot{m}}{\pi D_i \mu} = \frac{4 \times 0.1 \text{ kg/s}}{\pi (0.02 \text{ m}) 803 \times 10^{-6} \text{ N} \cdot \text{s/m}^2} = 7928$$

the flow is turbulent and, with  $(L/D_i) = (8.87 \text{ m}/0.02 \text{ m}) = 444 \gg (x_{fd}/D) \approx 10$ , it is also fully developed. Hence, from the Gnielinski correlation, Eq. 8.62,

$$h = \frac{k}{D_i} \left[ \frac{(f/8)(Re_D - 1000) Pr}{1 + 12.7(f/8)^{1/2} (Pr^{2/3} - 1)} \right]$$

$$= \frac{0.617 \text{ W/m} \cdot \text{K}}{0.02 \text{ m}} \left[ \frac{(0.033618)(7928 - 1000)5.45}{1 + 12.7(0.033618)^{1/2} (5.45^{2/3} - 1)} \right] = 1796 \text{ W/m}^2 \cdot \text{K}$$

where from Eq. 8.21,  $f = (0.790 \ln Re_D - 1.64)^{-2} = 0.0336$ . Hence, the inner surface temperature of the wall at the exit is

$$T_s = \frac{\dot{q}(D_o^2 - D_i^2)}{4 h D_i} + T_{m,o} = \frac{10^6 \text{ W/m}^3 [(0.04 \text{ m})^2 - (0.02 \text{ m})^2]}{4 \times 1796 \text{ W/m}^2 \cdot \text{K} (0.02 \text{ m})} + 40^\circ \text{C} = 48.4^\circ \text{C}$$

$$\text{and } T_{w,\max} = -\frac{10^6 \text{ W/m}^3}{4 \times 15 \text{ W/m} \cdot \text{K}} \left[ (0.02 \text{ m})^2 - (0.01 \text{ m})^2 \right]$$

$$+ \frac{10^6 \text{ W/m}^3 (0.02 \text{ m})^2}{2 \times 15 \text{ W/m} \cdot \text{K}} \ln \frac{0.02}{0.01} + 48.4^\circ \text{C} = 52.6^\circ \text{C}. \quad <$$

**COMMENTS:** The physical situation corresponds to a uniform surface heat flux, and  $T_m$  increases linearly with  $x$ . In the fully developed region,  $T_s$  also increases linearly with  $x$ .

### PROBLEM 8.38

**KNOWN:** Inlet temperature, pressure and flow rate of air. Tube diameter and length. Pressure of saturated steam.

**FIND:** Outlet temperature and pressure of air. Mass rate of steam condensation.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, (2) Outer surface of annulus is adiabatic, (3) Ideal gas with negligible viscous dissipation and pressure variation, (4) Fully-developed flow throughout the tube, (5) Smooth tube surface, (6) Constant properties.

**PROPERTIES:** Table A-4, air ( $\bar{T}_m \approx 325$  K,  $p = 5$  atm):  $\rho = 5 \times \rho(1 \text{ atm}) = 5.391 \text{ kg/m}^3$ ,

$c_p = 1008 \text{ J/kg} \cdot \text{K}$ ,  $\mu = 196.4 \times 10^{-7} \text{ N} \cdot \text{s/m}^2$ ,  $k = 0.0281 \text{ W/m} \cdot \text{K}$ ,  $Pr = 0.703$ . Table A-6, sat. steam ( $p = 2.455$  bars):  $T_s = 400$  K,  $h_{fg} = 2183 \text{ kJ/kg}$ .

**ANALYSIS:** With a uniform surface temperature, the air outlet temperature is

$$T_{m,o} = T_s - (T_s - T_{m,i}) \exp\left(-\frac{\pi D_i L \bar{h}}{\dot{m} c_p}\right)$$

With  $Re_D = 4\dot{m}/\pi D_i \mu = 0.12 \text{ kg/s} / \pi (0.05 \text{ m}) 196.4 \times 10^{-7} \text{ kg/s} \cdot \text{m} = 38,980$ , the flow is turbulent, and the Dittus-Boelter correlation yields

$$\bar{h} \approx h_{fd} = \left(\frac{k}{D_i}\right) 0.023 Re_D^{4/5} Pr^{0.4} = \left(\frac{0.0281 \text{ W/m} \cdot \text{K}}{0.05 \text{ m}}\right) 0.023 (38,980)^{4/5} (0.703)^{0.4} = 52.8 \text{ W/m}^2 \cdot \text{K}$$

$$T_{m,o} = 127^\circ\text{C} - (110^\circ\text{C}) \exp\left(-\frac{\pi \times 0.05 \text{ m} \times 5 \text{ m} \times 52.8 \text{ W/m}^2 \cdot \text{K}}{0.03 \text{ kg/s} \times 1008 \text{ J/kg} \cdot \text{K}}\right) = 99^\circ\text{C} \quad <$$

The pressure drop is  $\Delta p = f \left(\rho u_m^2 / 2 D_i\right) L$ , where, with  $A_c = \pi D_i^2 / 4 = 1.963 \times 10^{-3} \text{ m}^2$ ,  $u_m = \dot{m} / \rho A_c = 2.83 \text{ m/s}$ , and with  $Re_D = 38,980$ , Eq. 8.21 gives  $f = [0.790 \ln(Re_D) - 1.64]^{-2} = 0.022$ . Hence,

$$\Delta p = 0.022 \times 5.391 \text{ kg/m}^3 \frac{(2.83 \text{ m/s})^2 5 \text{ m}}{2 \times 0.05 \text{ m}} = 47.5 \text{ N/m}^2 = 4.7 \times 10^{-4} \text{ atm} \quad <$$

The rate of heat transfer to the air is

$$q = \dot{m} c_p (T_{m,o} - T_{m,i}) = 0.03 \text{ kg/s} \times 1008 \text{ J/kg} \cdot \text{K} (82^\circ\text{C}) = 2480 \text{ W}$$

and the rate of condensation is then

$$\dot{m}_c = \frac{q}{h_{fg}} = \frac{2480 \text{ W}}{2.183 \times 10^6 \text{ J/kg}} = 1.14 \times 10^{-3} \text{ kg/s} \quad <$$

**COMMENTS:** (1) With  $\bar{T}_m = (T_{m,i} + T_{m,o}) / 2 = 331 \text{ K}$ , the initial estimate of 325 K is reasonable and iteration is not necessary. (2) For a steam flow rate of 0.01 kg/s, approximately 10% of the outflow would be in the form of saturated liquid, (3) With  $L/D_i = 100$ , it is reasonable to assume fully developed flow throughout the tube.

## PROBLEM 8.39

**KNOWN:** Fully-developed conditions for laminar or turbulent flow characterized by a fixed mass flow rate. Constant surface temperature conditions with  $T_s < T_m$ .

**FIND:** Determine whether a small or large diameter tube will be more effective in minimizing heat loss from the flowing fluid.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Fully-developed, (2) Constant properties, (3) Negligible viscous dissipation.

**ANALYSIS:** The heat loss rate per unit tube length is

$$q' = \pi D h (T_s - T_m) \quad \text{where } h = Nu_D k / D$$

Combining the preceding equations yields

$$q' = \pi Nu_D k (T_s - T_m) \quad (1)$$

### Laminar Conditions

For laminar conditions,  $Nu_D = 3.66$ . Substituting this expression into Eq. (1) yields

$$q' = 3.66 \pi k (T_s - T_m)$$

and the heat loss rate is independent of the tube diameter. <

### Turbulent Conditions

For turbulent flow, we may substitute the Dittus-Boelter correlation,  $Nu_D = 0.023 Re_D^{4/5} Pr^{0.3}$  with  $Re_D = (4\dot{m} / \pi D \mu)$  into Eq. (1) to find

$$q' = \pi (0.023) \left( \frac{4\dot{m}}{\pi \mu} \right)^{4/5} D^{-4/5} Pr^{0.3} k (T_s - T_m)$$

Hence, to minimize the heat loss, a large diameter tube is preferred. <

**COMMENTS:** The large diameter tube will result in reduced heat loss, but will be more expensive relative to a small diameter tube. If the cool surface temperature is induced by heat losses to the environment, a more effective approach to minimize heat loss would be to insulate the exterior of the tube.

## PROBLEM 8.40

**KNOWN:** Dimensions and thermal conductivity of concrete duct. Convection conditions of ambient air. Flow rate and inlet temperature of water flow through duct.

**FIND:** (a) Outlet temperature, (b) Pressure drop and pump power requirement, (c) Effect of flow rate and pipe diameter on outlet temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, (2) Fully developed flow throughout duct, (3) Negligible pipe wall conduction resistance, (4) Water is incompressible liquid with negligible viscous dissipation, (5) Constant properties.

**PROPERTIES:** Table A-6, water ( $\bar{T}_m \approx 360 \text{ K}$ ):  $\rho = 967 \text{ kg/m}^3$ ,  $c_p = 4203 \text{ J/kg} \cdot \text{K}$ ,  $\mu = 324 \times 10^{-6} \text{ N} \cdot \text{s/m}^2$ ,  $k_w = 0.674 \text{ W/m} \cdot \text{K}$ ,  $\text{Pr} = 2.02$ .

**ANALYSIS:** (a) The outlet temperature is given by

$$T_{m,o} = T_\infty + (T_{m,i} - T_\infty) \exp(-UA / \dot{m} c_p)$$

where

$$UA = (R_{\text{tot}})^{-1} = (R_{\text{conv,w}} + R_{\text{cnd}} + R_{\text{conv,a}})^{-1}$$

From Table 4.1, Case 6,

$$R_{\text{cnd}} = \frac{\ln(1.08 w / D)}{2\pi k L} = \frac{\ln(1.08 \times 0.30 \text{ m} / 0.15 \text{ m})}{2\pi (1.4 \text{ W/m} \cdot \text{K}) 100 \text{ m}} = 8.75 \times 10^{-4} \text{ K/W}$$

$$R_{\text{conv,a}} = (4 w L h)^{-1} = (4 \times 0.30 \text{ m} \times 100 \text{ m} \times 25 \text{ W/m}^2 \cdot \text{K})^{-1} = 3.33 \times 10^{-4} \text{ K/W}$$

With  $\text{Re}_D = 4 \dot{m} / \pi D \mu = (4 \times 2 \text{ kg/s}) / (\pi \times 0.15 \text{ m} \times 324 \times 10^{-6} \text{ N} \cdot \text{s/m}^2) = 52,400$ ,

$$\bar{h}_w \approx h_{\text{fd}} = \frac{k_w}{D} 0.023 \text{Re}_D^{4/5} \text{Pr}^{0.3} = \frac{0.674 \text{ W/m} \cdot \text{K} \times 0.023}{0.15 \text{ m}} (52,400)^{4/5} (2.02)^{0.3} = 761 \text{ W/m}^2 \cdot \text{K}$$

$$R_{\text{conv,w}} = (\pi D L \bar{h}_w)^{-1} = (\pi \times 0.15 \text{ m} \times 100 \text{ m} \times 761 \text{ W/m}^2 \cdot \text{K})^{-1} = 2.79 \times 10^{-5} \text{ K/W}$$

$$UA = \left[ (2.79 \times 10^{-5} + 8.75 \times 10^{-4} + 3.33 \times 10^{-4}) \text{ K/W} \right]^{-1} = 809 \text{ W/K}$$

$$T_{m,o} = 0^\circ\text{C} + 90^\circ\text{C} \exp\left(-\frac{809 \text{ W/K}}{2 \text{ kg/s} \times 4203 \text{ J/kg} \cdot \text{K}}\right) = 81.7^\circ\text{C}$$

<

Continued ...

### PROBLEM 8.40 (Cont.)

(b) From Eq. 8.21,  $f = [0.790 \ln(\text{Re}_D) - 1.64]^{-2} = 0.0207$  and  $u_m = \dot{m} / \rho \pi D^2 / 4 = 0.117 \text{ m/s}$ ,

$$\Delta p = f \frac{\rho u_m^2}{2D} L = 0.0207 \frac{967 \text{ kg/m}^3 (0.117 \text{ m/s})^2}{2 \times 0.15 \text{ m}} 100 \text{ m} = 91 \text{ N/m}^2 = 9.1 \times 10^{-4} \text{ bars} \quad <$$

With  $\dot{V} = \dot{m} / \rho = 2.07 \times 10^{-3} \text{ m}^3/\text{s}$ , the pump power requirement is

$$P = \Delta p \dot{V} = (91 \text{ N/m}^2) 2.07 \times 10^{-3} \text{ m}^3/\text{s} = 0.19 \text{ W} \quad <$$

(c) The effects of varying the flowrate and duct diameter were assessed using the IHT software, and results are shown below.

Although  $R_{\text{cnv},w}$ , and hence  $R_{\text{tot}}$ , decreases with increasing  $\dot{m}$ , thereby increasing  $UA$ , the effect is significantly less than that of  $\dot{m}$  to the first power, causing the exponential term,  $\exp(-UA / \dot{m} c_p)$ , to approach unity and  $T_{m,o}$  to approach  $T_{m,i}$ . The effect can alternatively be attributed to a reduction in the residence time of the water in the pipe ( $u_m$  increases with increasing  $\dot{m}$  for fixed  $D$ ). With increasing  $D$  for fixed  $\dot{m}$  and  $w$ ,  $T_{m,o}$  decreases due to an increase in the residence time, as well as a reduction in the conduction resistance,  $R_{\text{cnd}}$ .

**COMMENTS:** (1) Use of  $\bar{T}_m = 360 \text{ K}$  to evaluate properties of the water for Parts (a) and (b) is reasonable, and iteration is not necessary. (2) The pressure drop and pump power requirement are small.

### PROBLEM 8.41

**KNOWN:** Water flow through a thick-walled tube immersed in a well stirred, hot reaction tank maintained at 85°C; conduction thermal resistance of the tube wall based upon the inner surface area is  $R''_{cd} = 0.002 \text{ m}^2 \cdot \text{K} / \text{W}$ .

**FIND:** (a) The outlet temperature of the process fluid,  $T_{m,o}$ ; assume, and then justify, fully developed flow and thermal conditions within the tube; and (b) Do you expect  $T_{m,o}$  to increase or decrease if the combined entry condition exists within the tube? Estimate the outlet temperature of the process fluid for this condition.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Flow is fully developed, part (a), (2) Constant properties, (3) Incompressible liquid with negligible viscous dissipation, and (4) Constant wall temperature heating, with  $T_s \approx T_{\infty}$  because of small thermal resistance associated with well-stirred reaction fluid.

**PROPERTIES:** Table A-6, Water ( $T_m = (T_{m,o} + T_{m,i})/2 = 315 \text{ K}$ ):  $c_p = 4179 \text{ J/kg}\cdot\text{K}$ ,  $\mu = 6.31 \times 10^{-4} \text{ N}\cdot\text{s/m}^2$ ,  $k = 0.634 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 4.16$ .

**ANALYSIS:** (a) The outlet temperature is determined from the rate equation, Eq. 8.45a, written as

$$\frac{T_s - T_{m,o}}{T_s - T_{m,i}} = \exp\left(-\frac{\bar{U}A_s}{\dot{m}c_p}\right) \quad (1)$$

where the overall coefficient, based upon the inner surface area of the tube is expressed in terms of the convection and conduction thermal resistances,

$$\frac{1}{\bar{U}} = \frac{1}{h} + R''_{cd,i} \quad (2)$$

To estimate  $\bar{h}$ , begin by characterizing the flow

$$\text{Re}_D = 4\dot{m}/\pi D\mu \quad (3)$$

$$\text{Re}_D = 4(33/3600 \text{ kg/s})/\pi \times 0.012 \text{ m} \times 6.31 \times 10^{-4} \text{ N}\cdot\text{s/m}^2 = 1540$$

Consider the flow as laminar, and assuming fully developed conditions, estimate  $\bar{h}$  with the correlation of Eq. 8.55,

$$\bar{\text{Nu}}_D = \bar{h}D/k = 3.66 \quad (4)$$

$$\bar{h} = 3.66 \times 0.634 \text{ W/m}\cdot\text{K} / 0.012 \text{ m} = 193 \text{ W/m}^2 \cdot \text{K}$$

From Eq. (2),

$$\bar{U} = \left[1/193 \text{ W/m}^2 \cdot \text{K} + 0.002 \text{ m}^2 \cdot \text{K/W}\right]^{-1} = 139 \text{ W/m}^2 \cdot \text{K}$$

and from Eq. (1), with  $A_s = \pi DL$ , calculate  $T_{m,o}$ .

Continued ...

**PROBLEM 8.41 (Cont.)**

$$\frac{85 - T_{m,o}}{85 - 20} = \exp\left(-\frac{139 \text{ W/m}^2 \cdot \text{K} \times \pi \times 0.012 \text{ m} \times 8 \text{ m}}{33/3600 \text{ kg/s} \times 4179 \text{ J/kg} \cdot \text{K}}\right)$$

$$T_{m,o} = 63^\circ\text{C} \quad \leftarrow$$

Fully developed flow and thermal conditions are justified if the tube length is much greater than the fully developed lengths  $x_{fd,h}$  and  $x_{fd,t}$ . From Eqs. 8.3 and 8.23,

$$\begin{aligned} x_{fd,h} &= 0.05 \text{ Re}_D D = 0.05 \times 1540 \times 0.012 \text{ m} = 0.92 \text{ m} \\ x_{fd,t} &= x_{fd,h} \text{ Pr} = 0.92 \text{ m} \times 4.16 = 3.8 \text{ m} \end{aligned}$$

That is, while fully developed velocity conditions may be justifiable, the length is only twice that required to reach *thermally* fully developed conditions.

(b) We expect the calculated outlet temperature to be larger if the combined entrance effect exists, since the average heat transfer coefficient would be larger relative to that associated with fully-developed conditions. ←

Considering combined entry length conditions, estimate the convection coefficient using the Baehr and Stephan correlation, Eq. 8.58, where from Eq. 8.56,  $Gz_D = (D/L)\text{Re}_D\text{Pr} = (0.012 \text{ m}/8 \text{ m}) \times 1540 \times 4.16 = 9.61$ :

$$\begin{aligned} \overline{\text{Nu}}_D &= \frac{\bar{h}D}{k} = \frac{\frac{3.66}{\tanh[2.264Gz_D^{-1/3} + 1.7Gz_D^{-2/3}]} + 0.0499Gz_D \tanh(Gz_D^{-1})}{\tanh(2.432 \text{ Pr}^{1/6} Gz_D^{-1/6})} \quad (5) \\ \bar{h} &= \frac{0.634 \text{ W/m} \cdot \text{K}}{0.012 \text{ m}} \left( \frac{\frac{3.66}{\tanh[2.264 \times 9.61^{-1/3} + 1.7 \times 9.61^{-2/3}]} + 0.0499 \times 9.61 \tanh(9.61^{-1})}{\tanh(2.432 \times 4.16^{1/6} \times 9.61^{-1/6})} \right) = 225 \text{ W/m}^2 \cdot \text{K} \end{aligned}$$

which is a 17% increase over the fully developed analysis result. Using the foregoing relations, find

$$U = 155 \text{ W/m}^2 \cdot \text{K}$$

$$T_{m,o} = 65.9^\circ\text{C} \quad \leftarrow$$

**COMMENTS:** (1) The thermophysical properties for the fully developed correlation should be evaluated at the mean fluid temperature  $T_m = (T_{m,o} + T_{m,i})/2 = 316 \text{ K}$ . This is very close to the assumed value of 315 K. (2) For the Baehr and Stephan correlation, the properties are also evaluated at  $T_m$ . (3) For this case where the tube length is about twice  $x_{fd,t}$ , the average heat transfer coefficient is larger than the fully developed value, as we would expect. (4) The thermal entry length correlation due to Hausen yields  $\bar{h} = 222 \text{ W/m}^2 \cdot \text{K}$ , close to the combined entry length value. This is not surprising, considering that the Prandtl number of 4.16 is close to meeting the  $\text{Pr} > 5$  condition for the Hausen correlation to be valid.

## PROBLEM 8.42

**KNOWN:** Flow rate and temperature of atmospheric air entering a duct of prescribed diameter, length and surface temperature.

**FIND:** (a) Air outlet temperature and duct heat loss for the prescribed conditions and (b) Calculate and plot  $q$  and  $\Delta p$  for the range of diameters,  $0.1 \leq D \leq 0.2$  m, maintaining the total surface area,  $A_s = \pi DL$ , at the same value as part (a). Explain the trade off between the heat transfer rate and pressure drop.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Constant properties, (3) Ideal gas with negligible viscous dissipation and pressure variation, (4) Uniform surface temperature, (5) Fully developed flow conditions.

**PROPERTIES:** Table A.4, Air ( $\bar{T}_m \approx 310 \text{ K}$ , 1 atm):  $\rho = 1.128 \text{ kg/m}^3$ ,  $c_p = 1007 \text{ J/kg}\cdot\text{K}$ ,  $\mu = 189 \times 10^{-7} \text{ N}\cdot\text{s/m}^2$ ,  $k = 0.027 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.706$ .

**ANALYSIS:** (a) With

$$\text{Re}_D = \frac{4\dot{m}}{\pi D \mu} = \frac{4 \times 0.04 \text{ kg/s}}{\pi (0.15 \text{ m}) 189 \times 10^{-7} \text{ N}\cdot\text{s/m}^2} = 17,965$$

the flow is turbulent. Assuming fully developed conditions throughout the tube, it follows from the Dittus-Boelter correlation, Eq. 8.60, that

$$\bar{h} = \frac{k}{D} 0.023 \text{Re}_D^{4/5} \text{Pr}^{0.3} = \frac{0.027 \text{ W/m}\cdot\text{K}}{0.15 \text{ m}} 0.023 (17,965)^{4/5} (0.706)^{0.3} = 9.44 \text{ W/m}^2 \cdot \text{K}.$$

Hence, from the energy balance relation, Eq. 8.41b,

$$T_{m,o} = T_s - (T_s - T_{m,i}) \exp\left(-\frac{\pi DL \bar{h}}{\dot{m} c_p}\right)$$

$$T_{m,o} = 15^\circ\text{C} + 45^\circ\text{C} \exp\left(-\frac{\pi (0.15 \text{ m}) 10 \text{ m} (9.44 \text{ W/m}^2 \cdot \text{K})}{0.04 \text{ kg/s} (1007 \text{ J/kg}\cdot\text{K})}\right) = 29.9^\circ\text{C} \quad <$$

From the overall energy balance, Eq. 8.34, it follows that

$$q = \dot{m} c_p (T_{m,o} - T_{m,i}) = 0.04 \text{ kg/s} \times 1007 \text{ J/kg}\cdot\text{K} (29.9 - 60)^\circ\text{C} = -1212 \text{ W} . \quad <$$

From Eq. 8.22a, the pressure drop is

$$\Delta p = f \frac{\rho u_m^2}{2D} L$$

Continued...

### PROBLEM 8.42 (Cont.)

and for the smooth surface conditions, Eq. 8.21 can be used to evaluate the friction factor,

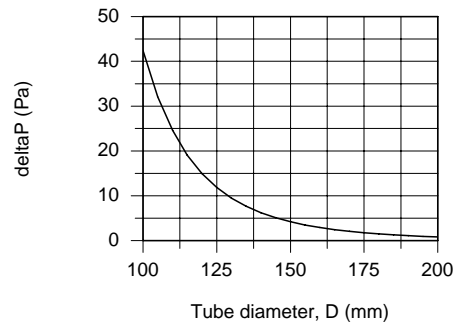

$$f = (0.790 \ln(\text{Re}_D) - 1.64)^{-2} = (0.790 \ln(17,965) - 1.64)^{-2} = 0.0269$$

Hence, the pressure drop is

$$\Delta p = 0.0269 \frac{1.128 \text{ kg/m}^3 (2.0 \text{ m/s})^2}{2 \times 0.15 \text{ m}} \times 10 \text{ m} = 4.03 \text{ N/m}^2$$

where  $u_m = \dot{m} / \rho A_c = 0.04 \text{ kg/s} / 1.128 \text{ kg/m}^3 \times (\pi 0.15^2 \text{ m}^2 / 4) = 2.0 \text{ m/s}$ .

(b) For the prescribed conditions of part (a),  $A_s = \pi DL = \pi(0.15 \text{ m}) \times 10 \text{ m} = 4.712 \text{ m}^2$ , using the *IHT Correlations Tool, Internal Flow* for fully developed *Turbulent Flow* along with the energy balance equation, rate equation and pressure drop equations used above, the heat rate  $q$  and  $\Delta p$  are calculated and plotted below.

From above, as  $D$  increases,  $L$  decreases so that  $A_s$  remains unchanged. The decrease in heat rate with increasing diameter is nearly linear, while the pressure drop decreases markedly. This is the trade off: increased heat rate requires a more significant increase in pressure drop, and hence fan blower power requirements.

**COMMENTS:** (1) To check the calculations, compute  $q$  from Eq. 8.43, where  $\Delta T_{\ell m}$  is given by Eq. 8.44. It follows that  $\Delta T_{\ell m} = -27.1^\circ\text{C}$  and  $q = -1206 \text{ W}$ . The small difference in results may be attributed to round-off error.

(2) For part (a), a slight improvement in accuracy may be obtained by evaluating the properties at  $\bar{T}_m = 318 \text{ K}$ :  $\bar{h} = 9.42 \text{ W/m}^2\cdot\text{K}$ ,  $T_{m,o} = 303 \text{ K} = 30^\circ\text{C}$ ,  $q = -1211 \text{ W}$ ,  $f = 0.0271$  and  $\Delta p = 4.20 \text{ N/m}^2$ .

## PROBLEM 8.43

**KNOWN:** Flow rate of NaK, NaK inlet and outlet temperatures, tube wall temperature, tube diameter.

**FIND:** Tube length, and local convective flux at the tube exit.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Constant properties, (2) Negligible viscous dissipation, (3) Fully developed flow.

**PROPERTIES:** Table A.7 NaK (45%/55%);  $\bar{T}_m = (332\text{K} + 400\text{K})/2 = 366\text{K}$ :  $\rho = 887 \text{ kg/m}^3$ ,  $k = 25.6 \text{ W/m}\cdot\text{K}$ ,  $\nu = 6.52 \times 10^{-7} \text{ m}^2/\text{s}$ ,  $Pr = 0.026$ ,  $c_p = 1130 \text{ J/kg}\cdot\text{K}$ .

**ANALYSIS:** The Reynolds number is

$$Re_D = 4\dot{m} / \pi D \nu \rho = 4 \times 1 \text{ kg/s} / \left[ \pi \times 0.05 \text{ m} \times 6.52 \times 10^{-7} \text{ m}^2/\text{s} \times 887 \text{ kg/m}^3 \right] = 44,000$$

and the flow is turbulent. The Peclet number is  $Pe_D = Re_D Pr = 44,000 \times 0.026 = 1145$ . Therefore, we may use Eq. 8.65 if the flow is fully developed. Hence,

$$h = \frac{k}{D} \left( 5.0 + 0.025 Pe_D^{0.8} \right) = \frac{25.6 \text{ W/m}\cdot\text{K}}{0.05 \text{ m}} \times \left( 5.0 + 0.025 \times 1145^{0.8} \right) = 6140 \text{ W/m}^2 \cdot \text{K}$$

The required tube length is, from Eq. 8.41a,

$$L = -\frac{\dot{m} c_p}{\pi D h} \ln \frac{\Delta T_o}{\Delta T_i} = -\frac{1 \text{ kg/s} \times 1130 \text{ J/kg}\cdot\text{K}}{\pi \times 0.05 \text{ m} \times 6140 \text{ W/m}^2 \cdot \text{K}} \ln \left( \frac{50}{118} \right) = 1 \text{ m} \quad <$$

The local convective heat flux at  $x = L = 1 \text{ m}$  is

$$q'' = h(T_s - T_{m,o}) = 6140 \text{ W/m}^2 \cdot \text{K} \times (450 - 400) \text{ K} = 30,700 \text{ W/m}^2 \quad <$$

**COMMENTS:** The dimensionless tube length is  $L/D = 1\text{m}/0.05\text{m} = 20$ . The flow is therefore fully developed, and use of Eq. 8.65 is appropriate.

## PROBLEM 8.44

**KNOWN:** Duct diameter and length. Thermal conductivity of insulation. Gas inlet temperature and velocity and minimum allowable outlet temperature. Temperature and velocity of air in cross flow.

**FIND:** Minimum allowable insulation thickness.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Combustion gases are ideal with negligible viscous dissipation and pressure variation, (2) Fully developed flow throughout duct, (3) Negligible duct wall conduction resistance, (4) Negligible effect of insulation thickness on outer convection coefficient and thermal resistance, (5) Properties of gas may be approximated as those of air.

**PROPERTIES:** Table A-4, air ( $p = 1 \text{ atm}$ ).  $T_{m,i} = 1600 \text{ K}$ : ( $\rho_i = 0.218 \text{ kg/m}^3$ ).  $\bar{T}_m = (T_{m,i} + T_{m,o})/2 = 1500 \text{ K}$ : ( $\rho = 0.232 \text{ kg/m}^3$ ,  $c_p = 1230 \text{ J/kg}\cdot\text{K}$ ,  $\mu = 557 \times 10^{-7} \text{ N}\cdot\text{s/m}^2$ ,  $k = 0.100 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.685$ ).  $T_f \approx 300 \text{ K}$  (assumed): ( $\nu = 15.89 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0263 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.707$ ).

**ANALYSIS:** From Eqs. (8.45a) and (3.19),

$$\frac{T_\infty - T_{m,o}}{T_\infty - T_{m,i}} = \frac{-1150 \text{ K}}{-1350 \text{ K}} = 0.852 = \exp\left(-\frac{\bar{U}A_s}{\dot{m}c_p}\right) = \exp\left(-\frac{1}{R_{\text{tot}}\dot{m}c_p}\right)$$

Hence, with  $\dot{m} = (\rho u_m A_c)_i = 0.218 \text{ kg/m}^3 \times 10 \text{ m/s} \times \pi(1\text{m})^2/4 = 1.712 \text{ kg/s}$ ,

$$R_{\text{tot}} = -\left[\dot{m}c_p \ln(0.852)\right]^{-1} = -\left[1.712 \text{ kg/s} \times 1230 \text{ J/kg}\cdot\text{K} \times (-0.160)\right]^{-1} = 2.96 \times 10^{-3} \text{ K/W}$$

The total thermal resistance is

$$R_{\text{tot}} = R_{\text{conv},i} + R_{\text{cond,ins}} + R_{\text{conv},o} = (h_i \pi D_i L)^{-1} + \frac{\ln(D_o/D_i)}{2\pi k_{\text{ins}} L} + (h_o \pi D_o L)^{-1} \quad (1)$$

With  $\text{Re}_{D,i} = 4\dot{m}/\pi D_i \mu = (4 \times 1.712 \text{ kg/s})/(\pi \times 1\text{m} \times 557 \times 10^{-7} \text{ N}\cdot\text{s/m}^2) = 39,130$ , the Dittus-Boelter correlation yields

$$h_i = \left(\frac{k}{D}\right) 0.023 \text{Re}_D^{4/5} \text{Pr}^{0.3} = \left(\frac{0.100 \text{ W/m}\cdot\text{K}}{1\text{m}}\right) 0.023 (39,130)^{4/5} (0.685)^{0.3} = 9.69 \text{ W/m}^2 \cdot \text{K}$$

The internal resistance is then

$$R_{\text{conv},i} = (h_i \pi D_i L)^{-1} = \left(9.69 \text{ W/m}^2 \cdot \text{K} \times \pi \times 1\text{m} \times 100\text{m}\right)^{-1} = 3.28 \times 10^{-4} \text{ K/W}$$

With  $\text{Re}_D \approx VD_i/\nu = 15 \text{ m/s} \times 1\text{m}/15.89 \times 10^{-6} \text{ m}^2/\text{s} = 9.44 \times 10^5$ , the Churchill-Bernstein correlation yields

Continued ...

**PROBLEM 8.44 (Cont.)**

$$h_o \approx \left(\frac{k}{D}\right) \left\{ 0.3 + \frac{0.62 \text{Re}_D^{1/2} \text{Pr}^{1/3}}{\left[1 + (0.4/\text{Pr})^{2/3}\right]^{1/4}} \left[1 + \left(\frac{\text{Re}_D}{282,000}\right)^{5/8}\right]^{4/5} \right\} = 30.9 \text{ W/m}^2 \cdot \text{K}$$

$$R_{\text{conv},o} \approx (h_o \pi D_i L)^{-1} = (30.9 \text{ W/m}^2 \cdot \text{K} \times \pi \times 1\text{m} \times 100\text{m})^{-1} = 1.03 \times 10^{-4} \text{ K/W}$$

Hence, from Eq. (1)

$$\frac{\ln(D_o/D_i)}{2\pi k_{\text{ins}} L} = (2.96 \times 10^{-3} - 3.33 \times 10^{-4} - 1.03 \times 10^{-4}) \text{ K/W} = 2.53 \times 10^{-3} \text{ K/W}$$

$$D_o = D_i \exp(2\pi k_{\text{ins}} L \times 2.53 \times 10^{-3} \text{ K/W}) = 1\text{m} \times \exp(1.59 \times 10^{-2} \text{ K/W} \times 0.125 \text{ W/m} \cdot \text{K} \times 100\text{m}) = 1.22\text{m}$$

Hence, the minimum insulation thickness is

$$t_{\text{min}} = (D_o - D_i)/2 = 0.11\text{m} \quad <$$

**COMMENTS:** With  $D_o = 1.22\text{m}$ , use of  $D_i = 1\text{m}$  to evaluate the outer convection coefficient and thermal resistance is a reasonable approximation. However, improved accuracy may be obtained by using the calculated value of  $D_o$  to determine conditions at the outer surface and iterating on the solution.

### PROBLEM 8.45

**KNOWN:** Flow rate, inlet temperature and desired outlet temperature of liquid mercury flowing through a tube of prescribed diameter and surface temperature.

**FIND:** Required tube length and error associated with use of a correlation for moderate to large Pr fluids.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Constant properties, (3) Incompressible liquid with negligible viscous dissipation, (4) Fully developed flow.

**PROPERTIES:** Table A-5, Mercury ( $\bar{T}_m = 350\text{K}$ ):  $c_p = 137.7\text{ J/kg}\cdot\text{K}$ ,  $\mu = 0.1309 \times 10^{-2}\text{ N}\cdot\text{s/m}^2$ ,  $k = 9.18\text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.0196$ .

**ANALYSIS:** The Reynolds and Peclet numbers are

$$\text{Re}_D = \frac{4\dot{m}}{\pi D\mu} = \frac{4 \times 0.5\text{ kg/s}}{\pi (0.05\text{ m}) 0.1309 \times 10^{-2}\text{ N}\cdot\text{s/m}^2} = 9727$$

$$\text{Pe}_D = \text{Re}_D \text{Pr} = 9727 (0.0196) = 191.$$

Hence, assuming fully developed turbulent flow throughout the tube, it follows from Eq. 8.65 that

$$\bar{h} = \frac{k}{D} \left( 5.0 + 0.025 \text{Pe}_D^{0.8} \right) = \frac{9.18\text{ W/m}\cdot\text{K}}{0.05\text{ m}} \left( 5.0 + 0.025 \times 191^{0.8} \right) = 1224\text{ W/m}^2\cdot\text{K}.$$

From Eq. 8.41a, it follows that

$$L = -\frac{\dot{m} c_p}{\pi Dh} \ln \frac{\Delta T_o}{\Delta T_i} = -\frac{(0.5\text{ kg/s}) 137.7\text{ J/kg}\cdot\text{K}}{\pi (0.05\text{ m}) 1224\text{ W/m}^2\cdot\text{K}} \ln \frac{450 - 400}{450 - 300} = 0.39\text{ m}. \quad <$$

If the Dittus-Boelter correlation, Eq. 8.60, is used in place of Eq. 8.65,

$$\bar{h} = \frac{k}{D} 0.023 \text{Re}_D^{4/5} \text{Pr}^{0.4} = \frac{9.18\text{ W/m}^2\cdot\text{K}}{0.05\text{ m}} 0.023 (9727)^{4/5} (0.0196)^{0.4} = 1358\text{ W/m}^2\cdot\text{K}$$

and the required tube length is

$$L = -\frac{\dot{m} c_p}{\pi Dh} \ln \frac{\Delta T_o}{\Delta T_i} = -\frac{(0.5\text{ kg/s}) 137.7\text{ J/kg}\cdot\text{K}}{\pi (0.05\text{ m}) 1358\text{ W/m}^2\cdot\text{K}} \ln \frac{450 - 400}{450 - 300} = 0.35\text{ m}. \quad <$$

**COMMENTS:** (1) Such good agreement between results does not occur in general. For example, if  $\text{Re}_D = 2 \times 10^4$ ,  $\bar{h} = 1463$  from Eq. 8.65 and 2417 from Eq. 8.60. Large errors are usually associated with using conventional (moderate to large Pr) correlations with liquid metals. (2) The Dittus-Boelter correlation is recommended for  $\text{Re}_D \geq 10,000$ , which is not quite satisfied here.

### PROBLEM 8.46

**KNOWN:** Surface temperature and diameter of a tube. Velocity and temperature of air in cross flow. Velocity and temperature of air in fully developed internal flow.

**FIND:** Convection heat flux associated with the external and internal flows.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Uniform cylinder surface temperature, (3) Fully developed internal flow, (4) For internal flow, air is an ideal gas with negligible viscous dissipation and pressure variations.

**PROPERTIES:** Table A-4, Air (336 K):  $\nu = 19.51 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0290 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.702$ .

**ANALYSIS:** For the *external* and *internal* flows,

$$\text{Re}_D = \frac{VD}{\nu} = \frac{u_m D}{\nu} = \frac{30 \text{ m/s} \times 0.05 \text{ m}}{19.71 \times 10^{-6} \text{ m}^2/\text{s}} = 7.69 \times 10^4.$$

From the Churchill-Bernstein relation for the *external* flow,

$$\begin{aligned} \overline{\text{Nu}}_D &= 0.3 + \frac{0.62 \text{Re}_D^{1/2} \text{Pr}^{1/3}}{\left[1 + (0.4/\text{Pr})^{2/3}\right]^{1/4}} \left[1 + \left(\frac{\text{Re}_D}{282,000}\right)^{5/8}\right]^{4/5} \\ &= 0.3 + \frac{0.62(7.69 \times 10^4)^{1/2} 0.702^{1/3}}{\left[1 + (0.4/0.702)^{2/3}\right]^{1/4}} \left[1 + \left(\frac{7.69 \times 10^4}{282,000}\right)^{5/8}\right]^{4/5} = 180 \end{aligned}$$

Hence, the convection coefficient and heat flux are

$$\bar{h} = \frac{k}{D} \overline{\text{Nu}}_D = \frac{0.0290 \text{ W/m}\cdot\text{K}}{0.05 \text{ m}} \times 180 = 104 \text{ W/m}^2 \cdot \text{K}$$

$$q'' = h(T_s - T_\infty) = 104 \text{ W/m}^2 \cdot \text{K} (100 - 25)^\circ\text{C} = 7840 \text{ W/m}^2. \quad \leftarrow$$

Using the Dittus-Boelter correlation, Eq. 8.60, for the *internal* flow, which is turbulent,

$$\overline{\text{Nu}}_D = 0.023 \text{Re}_D^{4/5} \text{Pr}^{0.4} = 0.023 (7.69 \times 10^4)^{4/5} (0.702)^{0.4} = 162$$

$$\bar{h} = \frac{k}{D} \overline{\text{Nu}}_D = \frac{0.0290 \text{ W/m}\cdot\text{K}}{0.05 \text{ m}} \times 162 = 94 \text{ W/m}^2 \cdot \text{K}$$

Continued...

**PROBLEM 8.46 (Cont.)**

and the heat flux is

$$q'' = h(T_s - T_m) = 94 \text{ W/m}^2 \cdot \text{K} (100 - 25)^\circ \text{C} = 7040 \text{ W/m}^2. \quad <$$

**COMMENT:** Convection effects associated with the two flow conditions are comparable.

### PROBLEM 8.47

**KNOWN:** Length and diameter of tube submerged in paraffin of prescribed dimensions. Inlet temperature and flow rate of water flowing through tube.

**FIND:** (a) Outlet temperature, heat rate, and time required for complete melting, and (b) Effect of flowrate on operating conditions.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible KE/PE and flow work changes for water, (2) Constant water properties, (3) Negligible tube wall conduction resistance, (4) Negligible convection resistance in melt ( $T_s = T_\infty = T_{mp}$ ), (5) Fully developed flow, (6) No heat loss to the surroundings.

**PROPERTIES:** Water (given):  $c_p = 4.185 \text{ kJ/kg}\cdot\text{K}$ ,  $k = 0.653 \text{ W/m}\cdot\text{K}$ ,  $\mu = 467 \times 10^{-6} \text{ kg/s}\cdot\text{m}$ ,  $\text{Pr} = 2.99$ ; Paraffin (given):  $T_{mp} = 27.4^\circ\text{C}$ ,  $h_{sf} = 244 \text{ kJ/kg}$ ,  $\rho = 770 \text{ kg/m}^3$ .

**ANALYSIS:** (a) From Eq. 8.41b,  $\frac{T_\infty - T_{m,o}}{T_\infty - T_{m,i}} = \exp\left(-\frac{\pi D L \bar{h}}{\dot{m} c_p}\right)$ . With  $\text{Re}_D = \frac{4\dot{m}}{\pi D \mu} =$

$\frac{4 \times 0.1 \text{ kg/s}}{\pi \times 0.025 \text{ m} \times 467 \times 10^{-6} \text{ kg/s}\cdot\text{m}} = 10,906$ , the flow is turbulent. Assuming fully developed conditions,

$$h = \frac{\text{Nu}_D k}{D} = \frac{k}{D} 0.023 \text{Re}_D^{4/5} \text{Pr}^{0.3} = \frac{0.653 \text{ W/m}\cdot\text{K}}{0.025 \text{ m}} 0.023 (10,906)^{4/5} (2.99)^{0.3} = 1418 \text{ W/m}^2\cdot\text{K}$$

$$T_{m,o} = 27.4^\circ\text{C} - (27.4 - 60)^\circ\text{C} \exp\left(-\frac{\pi \times 0.025 \text{ m} \times 3 \text{ m}}{0.1 \text{ kg/s} \times 4185 \text{ J/kg}\cdot\text{K}} 1418 \text{ W/m}^2\cdot\text{K}\right) = 42.17^\circ\text{C} <$$

From the overall energy balance,

$$q = \dot{m} c_p (T_{m,i} - T_{m,o}) = 0.1 \text{ kg/s} \times 4185 \text{ J/kg}\cdot\text{K} (60 - 42.17)^\circ\text{C} = 7500 \text{ W} <$$

Applying an energy balance to a control volume about the paraffin,  $E_{in} = \Delta E_{st}$ , the time  $t_m$  required to melt the paraffin is

$$q t_m = \rho V h_{sf} = \rho L \left( W H - \pi D^2 / 4 \right) h_{sf}$$

$$t_m = \frac{770 \text{ kg/m}^3 \times 3 \text{ m} \left( 0.25 \times 0.25 \text{ m}^2 - \pi (0.025 \text{ m})^2 / 4 \right)}{7500 \text{ W}} 2.44 \times 10^5 \text{ J/kg} = 4660 \text{ s} = 1.29 \text{ h} <$$

Continued...

### PROBLEM 8.47 (Cont.)

(b) The effect of  $\dot{m}$  on  $q$  and  $T_{m,o}$  was determined by accessing the *Correlations* Toolpad of IHT, and the results are plotted as follows.

Although  $q$  increases with increasing  $\dot{m}$  due to the attendant increase in  $Re_D$ , and therefore  $\bar{h}$ , the increase is not linearly proportional to the change in  $\dot{m}$ . Hence, from the overall energy balance,  $q = \dot{m} c_p (T_{m,i} - T_{m,o})$ , there is a reduction in  $(T_{m,i} - T_{m,o})$ , which corresponds to an increase in  $T_{m,o}$ . With the increase in  $q$ , there is a reduction in  $t_m$ , and for  $\dot{m} = 0.5 \text{ kg/s}$ ,

$$t_m = 1167 \text{ s} = 0.324 \text{ h}$$

<

**COMMENTS:** Heat transfer from the water to the paraffin is also affected by free convection in the melt region around the tube. The effect is to decrease  $U$ , increase  $T_s$ , and decrease  $q$  with increasing time. The actual time to achieve complete melting would exceed values computed in the foregoing analysis.

## PROBLEM 8.48

**KNOWN:** Diameter and length of circular tube, liquid water flow rate, liquid water entrance temperatures and tube surface temperatures.

**FIND:** Water outlet temperatures for (a)  $T_{m,i} = 500 \text{ K}$ ,  $T_s = 510 \text{ K}$  and (b)  $T_{m,i} = 300 \text{ K}$ ,  $T_s = 310 \text{ K}$ . (c) Discuss whether the flow is laminar or turbulent for  $T_{m,i} = 300 \text{ K}$ ,  $T_s = 647 \text{ K}$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Constant properties in parts (a) and (b), (3) Negligible viscous dissipation.

**PROPERTIES:** Table A.6, liquid water ( $\bar{T}_m = 505 \text{ K}$ , assumed):  $\mu = 115.5 \times 10^{-6} \text{ N}\cdot\text{s}/\text{m}^2$ ,  $Pr = 0.855$ ,  $k = 0.635 \text{ W}/\text{m}\cdot\text{K}$ ,  $c_p = 4700 \text{ J}/\text{kg}\cdot\text{K}$ . Liquid water ( $\bar{T}_m = 305 \text{ K}$ , assumed):  $\mu = 769 \times 10^{-6} \text{ N}\cdot\text{s}/\text{m}^2$ ,  $Pr = 5.20$ ,  $k = 0.620 \text{ W}/\text{m}\cdot\text{K}$ ,  $c_p = 4178 \text{ J}/\text{kg}\cdot\text{K}$ .

**ANALYSIS:** (a) We begin by calculating the Reynolds number

$$Re_D = \frac{4\dot{m}}{\pi D \mu} = \frac{4 \times 0.1 \text{ kg/s}}{\pi \times 0.1 \text{ m} \times 115.5 \times 10^{-6} \text{ N}\cdot\text{s}/\text{m}^2} = 11,014$$

Therefore, the flow is in a fully turbulent condition. Since  $L/D = 6\text{m}/0.1\text{m} = 60$ , we conclude that entrance effects are not important. We may use Dittus-Boelter (Eq. 8.60) to determine the average heat transfer coefficient and the mean outlet temperature may be found from Eq. (8.41b).

$$\bar{h} = \frac{k}{D} \left[ 0.023 Re_D^{4/5} Pr^{0.4} \right] = \frac{0.635 \text{ W}/\text{m}\cdot\text{K}}{0.1 \text{ m}} \left[ 0.023 \times 11,014^{4/5} 0.855^{0.4} \right] = 235 \text{ W}/\text{m}^2 \cdot \text{K}$$

$$\begin{aligned} T_{m,o} &= T_s - (T_s - T_{m,i}) \exp\left(-\frac{PL}{\dot{m}c_p} \bar{h}\right) \\ &= 510 \text{ K} - 10 \text{ K} \times \exp\left(-\frac{\pi \times 0.1 \text{ m} \times 6 \text{ m}}{0.1 \text{ kg/s} \times 4700 \text{ J}/\text{kg}\cdot\text{K}} 235 \text{ W}/\text{m}^2 \cdot \text{K}\right) = 506.1 \text{ K} \end{aligned}$$

(b) The Reynolds number is

$$Re_D = \frac{4\dot{m}}{\pi D \mu} = \frac{4 \times 0.1 \text{ kg/s}}{\pi \times 0.1 \text{ m} \times 769 \times 10^{-6} \text{ N}\cdot\text{s}/\text{m}^2} = 1655$$

Continued...

### PROBLEM 8.48 (Cont.)

Therefore, the flow is laminar. The thermal entrance length is  $x_{fd,t} = 0.05 \times D \times Re_D \times Pr = 0.05 \times 0.1 \text{ m} \times 1655 \times 5.20 = 43.0 \text{ m} > L$ . Therefore, we expect entrance effects to be significant. With  $Pr > 5$ , we may use Eq. (8.57) with Eq. (8.56) for the Graetz number, to estimate the value of  $\bar{h}$ .

$$h = \frac{k}{D} \left\{ 3.66 + \frac{0.0668(D/L)Re_D Pr}{1 + 0.04[(D/L)Re_D Pr]^{2/3}} \right\}$$

$$= \frac{0.620 \text{ W/m} \cdot \text{K}}{0.1 \text{ m}} \left\{ 3.66 + \frac{0.0668(0.1 \text{ m}/6 \text{ m}) \times 1655 \times 5.20}{1 + 0.04[(0.1 \text{ m}/6.0 \text{ m}) \times 1655 \times 5.20]^{2/3}} \right\} = 51.0 \text{ W/m}^2 \cdot \text{K}$$

Using Eq. (8.41b)

$$T_{m,o} = T_s - (T_s - T_{m,i}) \exp\left(-\frac{PL}{\dot{m}c_p} \bar{h}\right)$$

$$= 310 \text{ K} - 10 \text{ K} \times \exp\left(-\frac{\pi \times 0.1 \text{ m} \times 6 \text{ m}}{0.1 \text{ kg/s} \times 4178 \text{ J/kg} \cdot \text{K}} 51 \text{ W/m}^2 \cdot \text{K}\right) = 302.1 \text{ K} \quad <$$

(c) The temperature variations within the water are very large. Therefore, properties are expected to vary significantly from location to location. Near the entrance of the tube, average temperatures will be low, and the flow is expected to be laminar. However, as the boundary layer regions grow, higher temperatures will exist in a greater portion of the liquid and viscosities may drop to very low values. Hence, the flow may trip into turbulent conditions at a location between the tube entrance and the tube exit. The assumption of constant properties under the conditions of part (c) may not be appropriate.

**COMMENTS:** Even though entrance effects are important for the laminar flow conditions of part (b), the heat transfer coefficient is small relative to that associated with the turbulent conditions of part (a).

### PROBLEM 8.49

**KNOWN:** Diameter, length and surface temperature of condenser tubes. Water velocity and inlet temperature.

**FIND:** (a) Water outlet temperature evaluating properties at  $T_m = 300$  K, (b) Repeat calculations using properties evaluated at the appropriate temperature,  $\bar{T}_m = (T_{m,i} + T_{m,o})/2$ , and (c) Coolant mean velocities for the range  $4 \leq L \leq 7$  m which provide the same  $T_{m,o}$  as found in part (b).

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible tube wall conduction resistance, (2) Incompressible liquid with negligible viscous dissipation.

**PROPERTIES:** Table A.6, Water ( $\bar{T}_m = 300$  K):  $\rho = 997$  kg/m<sup>3</sup>,  $c_p = 4179$  J/kg·K,  $\mu = 855 \times 10^{-6}$  kg/s·m,  $k = 0.613$  W/m·K,  $Pr = 5.83$ .

**ANALYSIS:** (a) From Equation 8.41b

$$T_{m,o} = T_s - (T_s - T_{m,i}) \exp \left[ - \left( \pi DL / \dot{m} c_p \right) \bar{h} \right].$$

and evaluating properties at  $\bar{T}_m = 300$  K, find

$$Re_D = \frac{\rho u_m D}{\mu} = \frac{997 \text{ kg/m}^3 (1 \text{ m/s}) (0.0254 \text{ m})}{855 \times 10^{-6} \text{ kg/s} \cdot \text{m}} = 29,618$$

The flow is turbulent, and since  $L/D = 197$ , it is reasonable to assume fully developed flow throughout the tube. Hence,  $\bar{h} \approx h_{fd}$ . From the Dittus-Boelter equation,

$$Nu_D = 0.023 Re_D^{4/5} Pr^{0.4} = 0.023 (29,618)^{4/5} (5.83)^{0.4} = 176$$

$$\bar{h} = Nu_D (k/D) = 176 (0.613 \text{ W/m} \cdot \text{K} / 0.0254 \text{ m}) = 4248 \text{ W/m}^2 \cdot \text{K}.$$

With

$$\dot{m} = \rho u_m \left( \pi D^2 / 4 \right) = (\pi/4) 997 \text{ kg/m}^3 (1 \text{ m/s}) (0.0254 \text{ m})^2 = 0.505 \text{ kg/s}.$$

Equation 8.41b yields

$$T_{m,o} = 350 \text{ K} - (60 \text{ K}) \exp \left[ - \frac{\pi (0.0254 \text{ m}) 5 \text{ m} (4248 \text{ W/m}^2 \cdot \text{K})}{0.505 \text{ kg/s} (4179 \text{ J/kg} \cdot \text{K})} \right] = 323 \text{ K} = 50^\circ \text{C} \quad <$$

(b) Using the *IHT Correlations Tool, Internal Flow*, for fully developed *Turbulent Flow*, along with the energy balance and rate equations above, the calculation of part (a) is repeated with  $\bar{T}_m = (T_{m,i} + T_{m,o})/2$  giving these results:

$$\bar{T}_m = 307.3 \text{ K} \quad T_{m,o} = 51.7^\circ \text{C} = 324.7 \text{ K} \quad <$$

(c) Using the IHT model developed for the part (b) analysis, the coolant mean velocity,  $u_m$ , as a function of tube length  $L$  with  $T_{m,o} = 51.7^\circ \text{C}$  is calculated and the results plotted below.

Continued...

### PROBLEM 8.49 (Cont.)

**COMMENTS:** (1) Using  $\bar{T}_m = 300$  K vs.  $\bar{T}_m = (T_{m,i} + T_{m,o})/2 = 307$  K for this application resulted in a difference of  $T_{m,o} = 50^\circ\text{C}$  vs.  $T_{m,o} = 51.7^\circ\text{C}$ . While the difference is only  $1.7^\circ\text{C}$ , it is good practice to use the proper value for  $\bar{T}_m$ .

(2) Note that  $u_m$  must be increased markedly with increasing length in order that  $T_{m,o}$  remain fixed.

## PROBLEM 8.50

**KNOWN:** Gas turbine vane approximated as a tube of prescribed diameter and length maintained at a known surface temperature. Air inlet temperature and flowrate.

**FIND:** (a) Outlet temperature of the air coolant for the prescribed conditions and (b) Compute and plot the air outlet temperature  $T_{m,o}$  as a function of flow rate,  $0.1 \leq \dot{m} \leq 0.6$  kg/h. Compare this result with those for vanes having passage diameters of 2 and 4 mm.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Ideal gas with negligible viscous dissipation and pressure variation.

**PROPERTIES:** Table A.4, Air (assume  $\bar{T}_m = 780$  K, 1 atm):  $c_p = 1094$  J/kg·K,  $k = 0.0563$  W/m·K,  $\mu = 363.7 \times 10^{-7}$  N·s/m<sup>2</sup>,  $Pr = 0.706$ .

**ANALYSIS:** (a) For constant wall temperature heating, from Eq. 8.41b,

$$\frac{T_s - T_{m,o}}{T_s - T_{m,i}} = \exp\left(-\frac{PL\bar{h}}{\dot{m}c_p}\right) \quad (1)$$

where  $P = \pi D$ . For flow in a circular passage,

$$Re_D = \frac{4\dot{m}}{\pi D\mu} = \frac{4 \times 0.18 \text{ kg/h} (1/3600 \text{ s/h})}{\pi (0.003 \text{ m}) 363.7 \times 10^{-7} \text{ N}\cdot\text{s}/\text{m}^2} = 584. \quad (2)$$

The flow is laminar, and from Eq. 8.3,  $x_{fd,h} = 0.05 Re_D D = 88$  mm. Thus, the flow is in the combined entry length. From Eq. 8.56,  $Gz_D = (D/L) Re_D Pr = 16.5$  and from Eq. 8.58,

$$\overline{Nu}_D = \frac{\bar{h}D}{k} = \frac{3.66}{\tanh[2.264 Gz_D^{-1/3} + 1.7 Gz_D^{-2/3}]} + \frac{0.0499 Gz_D \tanh(Gz_D^{-1})}{\tanh(2.432 Pr^{1/6} Gz_D^{-1/6})} \quad (3)$$

$$\bar{h} = \frac{0.0563 \text{ W/m}\cdot\text{K}}{0.003 \text{ m}} \left( \frac{\frac{3.66}{\tanh[2.264 \times 16.5^{-1/3} + 1.7 \times 16.5^{-2/3}]} + 0.0499 \times 16.5 \tanh(16.5^{-1})}{\tanh(2.432 \times 0.706^{1/6} \times 16.5^{-1/6})} \right) = 95.0 \text{ W/m}^2 \cdot \text{K}$$

Hence, the air outlet temperature is

$$\frac{650 - T_{m,o}}{(650 - 427)^\circ \text{C}} = \exp\left(-\frac{\pi (0.003 \text{ m}) \times 0.075 \text{ m} \times 95.0 \text{ W/m}^2 \cdot \text{K}}{(0.18/3600) \text{ kg/s} \times 1094 \text{ J/kg}\cdot\text{K}}\right)$$

$$T_{m,o} = 585^\circ \text{C}$$

<

Continued...

### PROBLEM 8.50 (Cont.)

(b) Using the *IHT Correlations Tool, Internal Flow, for Laminar Flow with combined entry length*, along with the energy balance and rate equations above, the outlet temperature  $T_{m,o}$  was calculated as a function of flow rate for diameters of  $D = 2, 3$  and  $4$  mm. The plot below shows that  $T_{m,o}$  decreases strongly with increasing flow rate, but is independent of passage diameter.

**COMMENTS:** (1) Based upon the calculation for  $T_{m,o} = 585^\circ\text{C}$ ,  $\bar{T}_m = 779$  K which is in good agreement with our assumption to evaluate the thermophysical properties. (2) Why is  $T_{m,o}$  independent of  $D$ ? Since  $Re_D$  varies inversely with  $D$ ,  $Gz_D$  is independent of  $D$ , and so is  $Nu_D$ . From Eq. (3), note that  $\bar{h}$  is inversely proportional to  $D$ ,  $\bar{h} \sim D^{-1}$ . From Eq. (1), note that on the right-hand side the product  $P \cdot \bar{h}$  will be independent of  $D$ . Hence,  $T_{m,o}$  will depend only on the mass flow rate. This is, of course, a consequence of the laminar flow condition and will not be the same for turbulent flow.

## PROBLEM 8.51

**KNOWN:** Gas-cooled nuclear reactor tube of 20 mm diameter and 780 mm length with helium heated from 600 K to 1000 K at  $8 \times 10^{-3}$  kg/s.

**FIND:** (a) Uniform tube wall temperature required to heat the helium, (b) Outlet temperature and required flow rate to achieve same removal rate and wall temperature if the coolant gas is air.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Ideal gas with negligible viscous dissipation and pressure variation, (3) Fully developed conditions.

**PROPERTIES:** Table A-4, Helium ( $\bar{T}_m = 800\text{K}$ , 1 atm):  $\rho = 0.06272 \text{ kg/m}^3$ ,  $c_p = 5193 \text{ J/kg}\cdot\text{K}$ ,  $k = 0.304 \text{ W/m}\cdot\text{K}$ ,  $\mu = 382 \times 10^{-7} \text{ N}\cdot\text{s/m}^2$ ,  $\nu = 6.39 \times 10^{-4} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.654$ ; Air ( $\bar{T}_m = 800\text{K}$ , 1 atm):  $\rho = 0.4354 \text{ kg/m}^3$ ,  $c_p = 1099 \text{ J/kg}\cdot\text{K}$ ,  $k = 57.3 \times 10^{-3} \text{ W/m}\cdot\text{K}$ ,  $\nu = 84.93 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.709$ .

**ANALYSIS:** (a) For helium and a constant wall temperature, from Eq. 8.41b,

$$\frac{T_s - T_{m,o}}{T_s - T_{m,i}} = \exp\left(-\frac{PL\bar{h}}{\dot{m} c_p}\right)$$

where  $P = \pi D$ . For the circular tube,

$$\text{Re}_D = \frac{4\dot{m}}{\pi D\mu} = \frac{4 \times 8 \times 10^{-3} \text{ kg/s}}{\pi \times 0.020 \text{ m} \times 382 \times 10^{-7} \text{ N}\cdot\text{s/m}^2} = 1.333 \times 10^4$$

and using the Dittus-Boelter correlation for turbulent, fully developed flow,

$$\text{Nu} = 0.023 \text{Re}_D^{4/5} \text{Pr}^{0.4} = 0.023 (1.333 \times 10^4)^{4/5} (0.654)^{0.4} = 38.7$$

$$h = \text{Nu} \cdot k/D = 38.7 \times 0.304 \text{ W/m}\cdot\text{K} / 0.02 \text{ m} = 588 \text{ W/m}^2 \cdot \text{K}.$$

Hence, the surface temperature is

$$\frac{T_s - 1000 \text{ K}}{T_s - 600 \text{ K}} = \exp\left[-\frac{\pi (0.020 \text{ m}) \times 0.780 \text{ m} \times 588 \text{ W/m}^2 \cdot \text{K}}{8 \times 10^{-3} \text{ kg/s} \times 5193 \text{ J/kg}\cdot\text{K}}\right] = 0.500$$

$$T_s = 1400 \text{ K}.$$

The heat rate with helium coolant is

$$q = \dot{m} c_p (T_{m,o} - T_{m,i}) = 8 \times 10^{-3} \text{ kg/s} \times 5193 \text{ J/kg}\cdot\text{K} (1000 - 600) \text{ K} = 16.62 \text{ kW}.$$

Continued ...

**PROBLEM 8.51 (Cont.)**

(b) For the same heat removal rate ( $q$ ) and wall temperature ( $T_s$ ) with air supplied at  $T_{m,i}$ , the relevant relations are

$$q = 16,620 \text{ W} = \dot{m}_a c_p (T_{m,o} - T_{m,i}) \quad (1)$$

$$\frac{T_s - T_{m,o}}{T_s - T_{m,i}} = \exp\left[-\frac{PL\bar{h}_a}{\dot{m}_a c_p}\right] \quad (2)$$

$$\text{Re} = \frac{4\dot{m}_a}{\pi D\mu} \quad \frac{\bar{h}D}{k} = 0.023 \text{Re}_D^{4/5} \text{Pr}^{0.4} \quad (3,4)$$

where  $T_{m,o}$  and  $\dot{m}$  are unknown. An iterative solution is required: assume a value of  $T_{m,o}$  and find  $\dot{m}$  from Eq. (1); use  $\dot{m}$  in Eqs. (3) and (4) to find  $\bar{h}$  and then Eq. (2) to evaluate  $T_{m,o}$ ; compare results and iterate. Using thermophysical properties of air evaluated at  $\bar{T}_m = 800\text{K}$ , the above relations, written in the order they would be used in the iteration, become

$$\dot{m}_a = \frac{15.1}{T_{m,o} - 600} \quad (5)$$

$$\bar{h}_a = 5600\dot{m}_a^{4/5} \quad (6)$$

$$T_{m,o} = 1400 \text{ K} - 800 \text{ K} \times \exp\left[-4.459 \times 10^{-5} (\bar{h}_a / \dot{m}_a)\right] \quad (7)$$

Results of the iterative solution are

Trial	$T_{m,o}$ (K) (Assumed)	$\dot{m}$ (kg/s) Eq. (5)	$\bar{h}_a$ ( $\text{W}/\text{m}^2 \cdot \text{K}$ ) Eq. (6)	$T_{m,o}$ (K) Eq. (7)
1	1000	$3.781 \times 10^{-2}$	407	905
2	950	$4.321 \times 10^{-2}$	453	899
3	900	$5.041 \times 10^{-2}$	513	891
4	890	$5.215 \times 10^{-2}$	527	890

Hence, we find

$$\dot{m}_a = 5.22 \times 10^{-2} \text{ kg/s} \quad T_{m,o} = 890 \text{ K.} \quad \leftarrow$$

**COMMENTS:** To achieve the same cooling rate with air, the required mass rate is 6.5 times that obtained with helium.

### PROBLEM 8.52

**KNOWN:** Air at prescribed inlet temperature and mean velocity heated by condensing steam on its outer surface.

**FIND:** (a) Air outlet temperature, pressure drop and heat transfer rate and (b) Effect on parameters of part (a) if pressure were doubled.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Negligible kinetic and potential energy changes, (3) Thermal resistance of tube wall and condensate film are negligible.

**PROPERTIES:** Table A-4, Air (assume  $\bar{T}_m = 450$  K, 1 atm = 101.3 kPa):  $\rho = 0.7740$  kg/m<sup>3</sup>,  $c_p = 1021$  J/kg·K,  $\mu = 250.7 \times 10^{-7}$  N·s/m<sup>2</sup>,  $k = 0.0373$  W/m·K,  $Pr = \mu c_p / k = 0.686$ . Note that only  $\rho$  is pressure dependent; i.e.,  $\rho \propto p$ ; Table A-6, Saturated water (20 bar):  $T_{sat} = T_s = 485$  K.

**ANALYSIS:** (a) For constant wall temperature heating, from Eq. 8.41b,

$$\frac{T_s - T_{m,o}}{T_s - T_{m,i}} = \exp\left(-\frac{PL}{\dot{m} c_p} \bar{h}_i\right)$$

where  $P = \pi D$ . For the air flow, find the mass rate and Reynolds number,

$$\dot{m} = \rho A_c u_m = 0.7740 \text{ kg/m}^3 (200 \text{ kPa}/101.3 \text{ kPa}) \left(\pi (0.025 \text{ m})^2 / 4\right) \times 6 \text{ m/s}$$

$$\dot{m} = 4.501 \times 10^{-3} \text{ kg/s.}$$

$$Re_D = \frac{4\dot{m}}{\mu \pi D} = \frac{4 \times 4.501 \times 10^{-3} \text{ kg/s}}{250.7 \times 10^{-7} \text{ N}\cdot\text{s/m}^2 \times \pi (0.025 \text{ m})} = 9.143 \times 10^3.$$

Using the Dittus-Boelter correlation for fully-developed turbulent flow,

$$Nu_D = 0.023 Re^{4/5} Pr^{0.4} = 0.023 (9.143 \times 10^3)^{4/5} (0.682)^{0.4} = 29.12$$

$$h_i = Nu \cdot k / D = 29.12 \times 0.0373 \text{ W/m}\cdot\text{K} / 0.025 \text{ m} = 43.4 \text{ W/m}^2 \cdot \text{K}.$$

Hence, the outlet temperature is

$$\frac{212 - T_{m,o}}{(212 - 150)^\circ \text{C}} = \exp\left[-\frac{\pi (0.025 \text{ m}) \times 2 \text{ m} \times 43.4 \text{ W/m}^2 \cdot \text{K}}{4.501 \times 10^{-3} \text{ kg/s} \times 1021 \text{ J/kg}\cdot\text{K}}\right]$$

$$T_{m,o} = 198^\circ \text{C.}$$

<

Continued ...

**PROBLEM 8.52 (Cont.)**

The pressure drop follows from Eqs. 8.21 and 8.22,

$$f = (0.790 \ln(\text{Re}_D) - 1.64)^{-2} = \left(0.790 \ln(9.143 \times 10^3) - 1.64\right)^{-2} = 0.0323$$

$$\Delta p = f \frac{\rho u_m^2}{2D} L$$

$$\Delta p = 0.0323 \frac{0.7740 \text{ kg/m}^3 (200/101.3) (6 \text{ m/s})^2 \times 2 \text{ m}}{2 \times 0.025 \text{ m}} = 71.1 \text{ N/m}^2. \quad <$$

The heat transfer rate is

$$q = \dot{m} c_p (T_{m,o} - T_{m,i}) = 4.501 \times 10^{-3} \text{ kg/s} \times 1021 \text{ J/kg} \cdot \text{K} (198 - 150) \text{ K} = 221 \text{ W}. \quad <$$

(b) If the pressure were doubled, we can see from the above relations that  $\dot{m} \propto p$  hence

$$\dot{m} = 2\dot{m}_o$$

$$\text{Re}_D = 2\text{Re}_{D,o},$$

since

$$h_i \propto (\text{Re})^{4/5} \rightarrow (h_i / h_{i,o}) = 2^{4/5},$$

$$h_i = 1.74 h_{i,o}.$$

It follows that  $T_{m,o} = 195^\circ\text{C}$ , so that the effect on temperature is slight. However, the pressure drop increases by the factor 1.68 and the heat rate by the factor 1.88. In summary:

Parameter	p = 200 kPa Part (a)	p = 400 kPa Part (b)	Increase, %
$\dot{m}$ , kg/s $\times 10^3$	4.501	9.002	100
$h_i$ , W/m <sup>2</sup> ·K	43.4	75.6	74
$T_{m,o} - T_{m,i}$ , °C	48	45	-6
$\Delta p$ , N/m <sup>2</sup>	71.1	119	68
q, W	221	415	88

**COMMENTS:** (1) Note that  $\bar{T}_m = (198 + 150)^\circ\text{C}/2 = 447 \text{ K}$  agrees well with the assumed value (450 K) used to evaluate the thermophysical properties.

### PROBLEM 8.53

**KNOWN:** Diameter, length and surface temperature of tubes used to heat ambient air. Flow rate and inlet temperature of air.

**FIND:** (a) Air outlet temperature and heat rate per tube, (b) Effect of flow rate on outlet temperature. Design and operating conditions suitable for providing 1 kg/s of air at 75°C.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, (2) Ideal gas with negligible viscous dissipation and pressure variation, (3) Negligible tube wall thermal resistance.

**PROPERTIES:** Table A.4, air (assume  $\bar{T}_m = 330$  K):  $c_p = 1008$  J/kg·K,  $\mu = 198.8 \times 10^{-7}$  N·s/m<sup>2</sup>,  $k = 0.0285$  W/m·K, Pr = 0.703.

**ANALYSIS:** (a) For  $\dot{m} = 0.01$  kg/s,  $Re_D = 4\dot{m}/\pi D\mu = 0.04$  kg/s/ $\pi(0.05$  m) $198.8 \times 10^{-7}$  N·s/m<sup>2</sup> = 12,810. Hence, the flow is turbulent. If fully developed flow is assumed throughout the tube, the Dittus-Boelter correlation may be used to obtain the average Nusselt number.

$$\bar{Nu}_D \approx Nu_D = 0.023 Re_D^{4/5} Pr^{0.4} = 0.023(12,810)^{0.8} (0.703)^{0.4} = 38.6$$

Hence,  $\bar{h} = \bar{Nu}_D (k/D) = 38.6(0.0285$  W/m·K/ $0.05$  m) =  $22.0$  W/m<sup>2</sup>·K

From Eq. 8.41b,

$$\frac{T_s - T_{m,o}}{T_s - T_{m,i}} = \exp\left(-\frac{\pi DL\bar{h}}{\dot{m}c_p}\right) = \exp\left(-\frac{\pi \times 0.05 \text{ m} \times 5 \text{ m} \times 22 \text{ W/m}^2 \cdot \text{K}}{0.01 \text{ kg/s} \times 1008 \text{ J/kg} \cdot \text{K}}\right) = 0.180$$

$$T_{m,o} = T_s - 0.180(T_s - T_{m,i}) = 100^\circ\text{C} - 0.180(80^\circ\text{C}) = 85.6^\circ\text{C} \quad <$$

Hence,  $q = \dot{m}c_p(T_{m,o} - T_{m,i}) = 0.01$  kg/s( $1008$  J/kg·K) $65.6$  K =  $661$  W <

(b) The effect of flow rate on the outlet temperature was determined by using the IHT *Correlations and Properties* Toolpads.

Continued...

### PROBLEM 8.53 (Cont.)

Although  $\bar{h}$  and hence the heat rate increase with increasing  $\dot{m}$ , the increase in  $q$  is not linearly proportional to the increase in  $\dot{m}$  and  $T_{m,o}$  decreases with increasing  $\dot{m}$ .

A flow rate of  $\dot{m} = 0.05 \text{ kg/s}$  is not large enough to provide the desired outlet temperature of  $75^\circ\text{C}$ , and to achieve this value, a flow rate of  $0.0678 \text{ kg/s}$  would be needed. At such a flow rate,  $N = 1 \text{ kg/s} / 0.0678 \text{ kg/s} = 14.75 \approx 15$  tubes would be needed to satisfy the process air requirement. Alternatively, a lower flow rate could be supplied to a larger number of tubes and the discharge mixed with ambient air to satisfy the desired conditions. Requirements of this option are that

$$N\dot{m} + \dot{m}_{\text{amb}} = 1 \text{ kg/s}$$

$$(N\dot{m} + \dot{m}_{\text{amb}})c_p(T_{m,o} - T_{m,i}) = 1 \text{ kg/s} \times 1008 \text{ J/kg} \cdot \text{K} (75 - 20) \text{ K} = 55,400 \text{ W}$$

where  $\dot{m}$  is the flow rate per tube. Using a larger number of tubes with a smaller flow rate per tube would reduce flow pressure losses and hence provide for reduced operating costs.

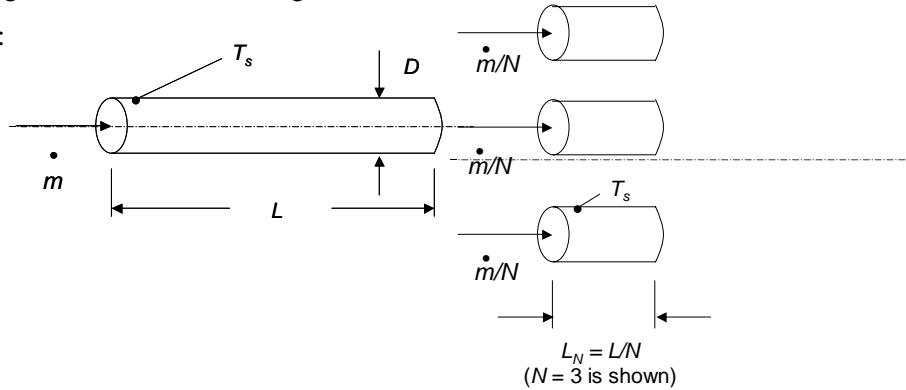

**COMMENTS:** With  $L/D = 5 \text{ m} / 0.05 \text{ m} = 100$ , the assumption of fully developed conditions throughout the tube is reasonable.

## PROBLEM 8.54

**KNOWN:** Length of a tube with constant surface temperature and a combined entrance length,  $L < x_{fd,t}$ .

**FIND:** Expression for the ratio of the average heat transfer coefficient for  $N$  tubes each of length  $L_N = L/N$  to the average coefficient for the single tube.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Combined entrance conditions, (2) Constant properties, (3) Negligible viscous dissipation.

**PROPERTIES:** Given:  $Pr = 4$ .

**ANALYSIS:** The Nusselt number for the combined entrance problem with  $0.1 < Pr < 5$  is given by Equation 8.58 and is seen to be a function of the Graetz number,  $Gz_D = DRe_DPr/L$ , and the Prandtl number,  $Pr$ . For multiple tubes, each of length  $L_N = L/N$  with a flowrate of  $\dot{m}_N = \dot{m} / N$ , observe that  $Re_{D,N} = Re_{D,1}/N$ , resulting in

$$Gz_{D,N} = DRe_{D,N}Pr/L_N = DRe_{D,1}Pr/L = Gz_{D,1}$$

Since the Graetz number is unchanged, and  $Pr$  has been specified as constant, the Nusselt number is unchanged. With  $h = Nu_D k/D$ ,

$$\bar{h}_{D,N} / \bar{h}_{D,1} = 1 \quad <$$

**COMMENTS:** (1) Breaking the tube into shorter lengths has no impact on the overall heat transfer rate. Shortening the tube will, in general, tend to increase the average heat transfer coefficient, but this effect is offset by reduction of the flow rate in each of the shorter tubes. The scheme would not result in any heat transfer *enhancement*. (2) The same result holds for the thermal entrance problem, since the Nusselt number is also a function only of  $Gz_D$ .

## PROBLEM 8.55

**KNOWN:** Configuration of microchannel heat sink.

**FIND:** (a) Expressions for longitudinal distributions of fluid mean and surface temperatures, (b) Coolant and channel surface temperature distributions for prescribed conditions, (c) Effect of heat sink design and operating conditions on the chip heat flux for a prescribed maximum allowable surface temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, (2) Incompressible liquid with negligible viscous dissipation, (3) All of the chip power dissipation is transferred to the coolant, with a uniform surface heat flux,  $q''_s$ , (4) Laminar, fully developed flow, (5) Constant properties.

**PROPERTIES:** Table A.6, Water (assume  $\bar{T}_m = T_{m,i} = 290$  K):  $c_p = 4184$  J/kg·K,  $\mu = 1080 \times 10^{-6}$  N·s/m<sup>2</sup>,  $k = 0.598$  W/m·K,  $Pr = 7.56$ .

**ANALYSIS:** (a) The number of channels passing through the heat sink is  $N = L/S = L/C_1D$ , and conservation of energy dictates that

$$q''_c L^2 = N(\pi DL)q''_s = \pi L^2 q''_s / C_1$$

which yields

$$q''_s = \frac{C_1 q''_c}{\pi} \quad (1)$$

With the mass flowrate per channel designated as  $\dot{m}_1 = \dot{m}/N$ , Eqs. 8.40 and 8.27 yield

$$T_m(x) = T_{m,i} + \frac{q''_s \pi D}{\dot{m}_1 c_p} x = T_{m,i} + \frac{L q''_c}{\dot{m} c_p} x \quad (2) <$$

$$T_s(x) = T_m(x) + \frac{q''_s}{h} = T_m(x) + \frac{C_1 q''_c}{\pi h} \quad (3) <$$

where, for laminar, fully developed flow with uniform  $q''_s$ , Eq. 8.53 yields  $h = 4.36$  k/D.

(b) With  $L = 12$  mm,  $D = 1$  mm,  $C_1 = 2$  and  $\dot{m} = 0.01$  kg/s, it follows that  $S = 2$  mm,  $N = 6$  and  $Re_D = 4\dot{m}_1/\pi D\mu = 4(0.01 \text{ kg/s})/6\pi(0.001 \text{ m})1.08 \times 10^{-3} \text{ N}\cdot\text{s}/\text{m}^2 = 1965$ . Hence, the flow is laminar, as assumed, and  $h = 4.36(0.598 \text{ W/m}\cdot\text{K}/0.001 \text{ m}) = 2607 \text{ W/m}^2\cdot\text{K}$ . From Eqs. (2) and (3) the outlet mean and surface temperatures are

$$T_{m,o} = 290 \text{ K} + \frac{(0.012 \text{ m})^2 20 \times 10^4 \text{ W}/\text{m}^2}{0.01 \text{ kg/s}(4184 \text{ J/kg}\cdot\text{K})} = 290.7 \text{ K} = 17.7^\circ \text{C}$$

$$T_{s,o} = T_{m,o} + \frac{2}{\pi} \times \frac{20 \times 10^4 \text{ W}/\text{m}^2}{2607 \text{ W}/\text{m}^2\cdot\text{K}} = 339.5 \text{ K} = 66.5^\circ \text{C}$$

Continued...

## PROBLEM 8.55 (Cont.)

The axial temperature distributions are as follows

The flowrate is sufficiently large (and the convection coefficient sufficiently low) to render the increase in  $T_m$  and  $T_s$  with increasing  $x$  extremely small.

(c) The desired constraint of  $T_{s,max} \leq 50^\circ\text{C}$  is not met by the foregoing conditions. An obvious and logical approach to achieving improved performance would involve increasing  $\dot{m}_1$  such that turbulent flow is maintained in each channel. A value of  $\dot{m}_1 > 0.002 \text{ kg/s}$  would provide  $Re_D > 2300$  for  $D = 0.001$ . Using Eq. 8.60 with  $n = 0.4$  to evaluate  $Nu_D$  and accessing the Correlations Toolpad of IHT to explore the effect of variations in  $\dot{m}_1$  for different combinations of  $D$  and  $C_1$ , the following results were obtained.

We first note that a significant increase in  $q_c''$  may be obtained by operating the channels in turbulent flow. In addition, there is an obvious advantage to reducing  $C_1$ , thereby increasing the number of channels for a fixed channel diameter. The biggest enhancement is associated with reducing the channel diameter, which significantly increases the convection coefficient, as well as the number of channels for fixed  $C_1$ . For  $\dot{m}_1 = 0.005 \text{ kg/s}$ ,  $h$  increases from  $32,400$  to  $81,600 \text{ W/m}^2\cdot\text{K}$  with decreasing  $D$  from  $1.0$  to  $0.6 \text{ mm}$ . However, for fixed  $\dot{m}_1$ , the mean velocity in a channel increases with decreasing  $D$  and care must be taken to maintain the flow pressure drop within acceptable limits.

**COMMENTS:** Although the distribution computed for  $T_m(x)$  in part (b) is correct, the distribution for  $T_s(x)$  represents an upper limit to actual conditions due to the assumption of fully developed flow throughout the channel.

## PROBLEM 8.56

**KNOWN:** Cold plate geometry and temperature. Inlet temperature and flow rate of water. Number of circuit boards and temperature and velocity of air in parallel flow over boards.

**FIND:** (a) Heat dissipation by cold plates, (b) Heat dissipation by air flow.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Isothermal cold plate, (2) All heated generated by circuit boards is dissipated by cold plates (Part (a)), (3) Circuit boards may be represented as isothermal at an average surface temperature, (4) Air flow over circuit boards approximates that over a flat plate in parallel flow, (5) Steady operation, (6) Constant properties, (7) Water is incompressible liquid with negligible viscous dissipation.

**PROPERTIES:** Table A-6, Water ( $\bar{T}_m \approx 290\text{K}$ ):  $c_p = 4184\text{ J/kg}\cdot\text{K}$ ,  $\mu = 1080 \times 10^{-6}\text{ N}\cdot\text{s/m}^2$ ,  $k = 0.598\text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 7.56$ . Table A-4, Air ( $p = 1\text{ atm}$ ,  $T_f = 300\text{K}$ ):  $\nu = 15.89 \times 10^{-6}\text{ m}^2/\text{s}$ ,  $k = 0.0263\text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.707$ .

**ANALYSIS:** (a) With  $\text{Re}_D = 4\dot{m}_1 / \pi D \mu = 4 \times 0.2\text{ kg/s} / \pi \times 0.01\text{m} \times 1080 \times 10^{-6}\text{ N}\cdot\text{s/m}^2 = 23,600$ , the flow is turbulent, and from Eq. (8.60),

$$h = \frac{k}{D} \text{Nu}_D = 0.023 \frac{k}{D} \text{Re}_D^{4/5} \text{Pr}^{0.4} = \frac{0.023 \times 0.598\text{ W/m}\cdot\text{K}}{0.01\text{m}} (23,600)^{4/5} (7.56)^{0.4} = 9,730\text{ W/m}^2\cdot\text{K}$$

With  $H/D = 0.75/0.01 = 75$ , it is reasonable to assume fully developed flow throughout the tube. Hence, from Eqs. (8.41b) and (8.34)

$$\frac{T_{s,cp} - T_{m,o}}{T_{s,cp} - T_{m,i}} = \exp\left(-\frac{\pi D H}{\dot{m}_1 c_p} h\right) = \exp\left(-\frac{\pi \times 0.01\text{m} \times 0.75\text{m} \times 9730\text{ W/m}^2\cdot\text{K}}{0.2\text{ kg/s} \times 4184\text{ J/kg}\cdot\text{K}}\right) = 0.760$$

$$T_{m,o} = T_{s,cp} - 0.76(T_{s,cp} - T_{m,i}) = 13^\circ\text{C}$$

$$q_1 = \dot{m}_1 c_p (T_{m,o} - T_{m,i}) = 0.2\text{ kg/s} \times 4184\text{ J/kg}\cdot\text{K} \times 6^\circ\text{C} = 5021\text{ W}$$

With a total of  $2N = 20$  passages, the total heat dissipation is

$$q = 2Nq_1 = 20 \times 5021\text{ W} = 100\text{ kW} \quad <$$

(b) For the air flow,  $\text{Re}_D = u_\infty L / \nu = 10\text{ m/s} \times 0.60\text{m} / 15.89 \times 10^{-6}\text{ m}^2/\text{s} = 378,000$ , and the flow is laminar. From Eq. (7.30),

$$\bar{h} = \frac{k}{L} \text{Nu}_L = 0.664 \frac{k}{L} \text{Re}_L^{1/2} \text{Pr}^{1/3} = \frac{0.664 \times 0.0263\text{ W/m}\cdot\text{K}}{0.60\text{m}} (378,000)^{1/2} (0.707)^{1/3} = 15.9\text{ W/m}^2\cdot\text{K}$$

Heat dissipation to the air from both sides of 10 circuit boards is then

$$q = 2N_{cb} \bar{h} (WL) (T_{s,cb} - T_\infty) = 20 \times 15.9\text{ W/m}^2\cdot\text{K} \times 0.21\text{m}^2 \times 40^\circ\text{C} = 2,670\text{ W} \quad <$$

**COMMENTS:** The cooling capacity of the cold plates far exceeds that of the air flow. However, the challenge would be one of efficiently transferring such a large amount of energy to the cold plates without incurring excessive temperatures on the circuit boards.

### PROBLEM 8.57

**KNOWN:** Flow rate and temperature of Refrigerant-134a passing through a Teflon tube of prescribed inner and outer diameter. Velocity and temperature of air in cross flow over tube.

**FIND:** Heat transfer per unit tube length.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) One-dimensional radial conduction, (3) Constant properties, (4) Fully developed flow.

**PROPERTIES:** Table A-4, Air ( $T = 300$  K, 1 atm):  $\nu = 15.89 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0263 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.707$ ; Table A-5, R-134a ( $T = 240$  K):  $\mu = 4.202 \times 10^{-4} \text{ N}\cdot\text{s/m}^2$ ,  $k = 0.1073 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 5.0$ ; Table A-3, Teflon ( $T \approx 300$  K):  $k = 0.35 \text{ W/m}\cdot\text{K}$ .

**ANALYSIS:** Considering the thermal circuit shown above, the heat rate is

$$q' = \frac{T_\infty - T_m}{\left(1/\bar{h}_o \pi D_o\right) + \left[\ln(D_o/D_i)/2\pi k\right] + \left(1/h_i \pi D_i\right)}$$

$$\text{Re}_{D,i} = \frac{4 \dot{m}}{\pi D_i \mu} = \frac{0.4 \text{ kg/s}}{\pi (0.025 \text{ m}) 4.202 \times 10^{-4} \text{ N}\cdot\text{s/m}^2} = 12,120$$

and the flow is turbulent. Hence, from the Dittus-Boelter correlation

$$h_i = \frac{k}{D_i} 0.023 \text{Re}_{D,i}^{4/5} \text{Pr}^{0.4} = \frac{0.1073 \text{ W/m}\cdot\text{K}}{0.025 \text{ m}} 0.023 (12,120)^{4/5} (5)^{0.4} = 347 \text{ W/m}^2 \cdot \text{K}$$

$$\text{With } \text{Re}_{D,o} = \frac{VD_o}{\nu} = \frac{(25 \text{ m/s}) 0.028 \text{ m}}{15.89 \times 10^{-6} \text{ m}^2/\text{s}} = 4.405 \times 10^4$$

it follows from Eq. 7.53 and Table 7.4 that

$$\bar{h}_o = \frac{k}{D} 0.26 \text{Re}_{D,o}^{0.6} \text{Pr}^{0.37} = \frac{0.0263 \text{ W/m}\cdot\text{K}}{0.028 \text{ m}} 0.26 \left(4.405 \times 10^4\right)^{0.6} (0.707)^{0.37} = 131 \text{ W/m}^2 \cdot \text{K}$$

Hence

$$q' = \frac{T_\infty - T_m}{\left(131 \text{ W/m}^2 \cdot \text{K} \pi 0.028 \text{ m}\right)^{-1} + \ln(28/25)/2\pi (0.350 \text{ W/m}\cdot\text{K}) + \left(347 \text{ W/m}^2 \cdot \text{K} \pi 0.025 \text{ m}\right)^{-1}}$$

$$q' = \frac{(300 - 240) \text{ K}}{(0.087 + 0.052 + 0.037) \text{ K}\cdot\text{m/W}} = 343 \text{ W/m} \quad \leftarrow$$

**COMMENTS:** The three thermal resistances are comparable. Note that  $T_{s,o} = T_\infty - q'/h_o \pi D_o = 300 \text{ K} - 343 \text{ W/m}/131 \text{ W/m}^2 \cdot \text{K} \pi 0.028 \text{ m} = 270 \text{ K}$ .

### PROBLEM 8.58

**KNOWN:** Oil flowing slowly through a long, thin-walled pipe suspended in a room.

**FIND:** Heat loss per unit length of the pipe,  $q'_{conv}$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Tube wall thermal resistance negligible, (3) Fully developed flow, (4) Radiation exchange between pipe and room negligible.

**PROPERTIES:** Table A-5, Unused engine oil ( $T_m = 150^\circ\text{C} = 423\text{K}$ ):  $k = 0.133 \text{ W/m}\cdot\text{K}$ .

**ANALYSIS:** The rate equation, for a unit length of the pipe, can be written as

$$q'_{conv} = \frac{(T_m - T_\infty)}{R'_t}$$

where the thermal resistance is comprised of two elements,

$$R'_t = \frac{1}{h_i \pi D} + \frac{1}{h_o \pi D} = \frac{1}{\pi D} \left( \frac{1}{h_i} + \frac{1}{h_o} \right).$$

The convection coefficient for internal flow,  $h_i$ , must be estimated from an appropriate correlation. From practical considerations, we recognize that the oil flow rate cannot be large enough to achieve turbulent flow conditions. Hence, the flow is *laminar*, and if the pipe is very long, the flow will be *fully developed*. The appropriate correlation is

$$\text{Nu}_D = \frac{h_i D}{k} = 3.66$$

$$h_i = \text{Nu}_D k/D = 3.66 \times 0.133 \frac{\text{W}}{\text{m}\cdot\text{K}} / 0.030 \text{ m} = 16.2 \text{ W/m}^2 \cdot \text{K}.$$

The heat rate per unit length of the pipe is

$$q'_{conv} = \frac{(150 - 20)^\circ\text{C}}{\frac{1}{\pi(0.030\text{m})} \left( \frac{1}{16.2} + \frac{1}{11} \right) \frac{\text{m}^2 \cdot \text{K}}{\text{W}}} = 80.3 \text{ W/m.} \quad <$$

**COMMENTS:** This problem requires making a judgment that the oil flow will be laminar rather than turbulent. Why is this a reasonable assumption? Recognize that the correlation applies to a constant surface temperature condition.

## PROBLEM 8.59

**KNOWN:** Thin-walled, tall stack discharging exhaust gases from an oven into the environment.

**FIND:** (a) Outlet gas and stack surface temperatures,  $T_{m,o}$  and  $T_{s,o}$ , and (b) Effect of wind temperature and velocity on  $T_{m,o}$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Wall thermal resistance negligible, (3) Exhaust gas properties approximated as those of atmospheric air, (4) Radiative exchange with surroundings negligible, (5) Ideal gas with negligible viscous dissipation and pressure variation, (6) Fully developed flow, (7) Constant properties.

**PROPERTIES:** *Table A.4*, air (assume  $T_{m,o} = 773$  K,  $\bar{T}_m = 823$  K, 1 atm):  $c_p = 1104$  J/kg·K,  $\mu = 376.4 \times 10^{-7}$  N·s/m<sup>2</sup>,  $k = 0.0584$  W/m·K,  $Pr = 0.712$ ; *Table A.4*, air (assume  $T_s = 523$  K,  $T_\infty = 4^\circ\text{C} = 277$  K,  $T_f = 400$  K, 1 atm):  $\nu = 26.41 \times 10^{-6}$  m<sup>2</sup>/s,  $k = 0.0338$  W/m·K,  $Pr = 0.690$ .

**ANALYSIS:** (a) From Eq. 8.45a,

$$T_{m,o} = T_\infty - (T_\infty - T_{m,i}) \exp\left[-\frac{PL}{\dot{m}c_p} \bar{U}\right] \quad U = 1 / \left( \frac{1}{h_i} + \frac{1}{h_o} \right) \quad (1,2)$$

where  $h_i$  and  $h_o$  are average coefficients for internal and external flow, respectively.

*Internal flow:* With a Reynolds number of

$$Re_{D_i} = \frac{4\dot{m}}{\pi D \mu} = \frac{4 \times 0.5 \text{ kg/s}}{\pi \times 0.5 \text{ m} \times 376.4 \times 10^{-7} \text{ N}\cdot\text{s}/\text{m}^2} = 33,827 \quad (3)$$

the flow is turbulent. Considering the flow to be fully developed throughout the stack ( $L/D = 12$ ) and with  $T_s < T_m$ , the Dittus-Boelter correlation has the form

$$Nu_D = \frac{h_i D}{k} = 0.023 Re_{D_i}^{4/5} Pr^{0.3} \quad (4)$$

$$h_i = \frac{58.4 \times 10^{-3} \text{ W}/\text{m}\cdot\text{K}}{0.5 \text{ m}} \times 0.023 (33,827)^{4/5} (0.712)^{0.3} = 10.2 \text{ W}/\text{m}^2 \cdot \text{K}.$$

*External flow:* Working with the Churchill/Bernstein correlation, the Reynolds and Nusselt numbers are

$$Re_{D_o} = \frac{VD}{\nu} = \frac{5 \text{ m/s} \times 0.5 \text{ m}}{26.41 \times 10^{-6} \text{ m}^2/\text{s}} = 94,660 \quad (5)$$

Continued...

**PROBLEM 8.59 (Cont.)**

$$\overline{Nu}_D = 0.3 + \frac{0.62 Re_D^{1/2} Pr^{1/3}}{\left[1 + (0.4/Pr)^{2/3}\right]^{1/4}} \left[1 + \left(\frac{Re_D}{282,000}\right)^{5/8}\right]^{4/5} = 205$$

Hence,

$$h_o = (0.0338 \text{ W/m} \cdot \text{K} / 0.5 \text{ m}) \times 205 = 13.9 \text{ W/m}^2 \cdot \text{K} \quad (6)$$

The outlet gas temperature is then

$$T_{m,o} = 4^\circ\text{C} - (4 - 600)^\circ\text{C} \exp\left[-\frac{\pi \times 0.5 \text{ m} \times 6 \text{ m}}{0.5 \text{ kg/s} \times 1104 \text{ J/kg} \cdot \text{K}} \left(\frac{1}{1/10.2 + 1/13.9} \text{ W/m}^2 \cdot \text{K}\right)\right] = 543^\circ\text{C} \quad <$$

The outlet stack surface temperature can be determined from a local surface energy balance of the form,  $h_i(T_{m,o} - T_{s,o}) = h_o(T_{s,o} - T_\infty)$ , which yields

$$T_{s,o} = \frac{h_i T_{m,o} + h_o T_\infty}{h_i + h_o} = \frac{(10.2 \times 543 + 13.9 \times 4) \text{ W/m}^2}{(10.2 + 13.9) \text{ W/m}^2 \cdot \text{K}} = 232^\circ\text{C} \quad <$$

(b) Using the Correlations and Properties Toolpads of IHT, with a surface temperature of  $T_s = 523 \text{ K}$  assumed solely for the purpose of evaluating properties associated with airflow over the cylinder, the following results were generated.

Due to the elevated temperatures of the gas, the variation in ambient temperature has only a small effect on the gas exit temperature. However, the effect of the freestream velocity is more pronounced.

Discharge temperatures of approximately 530 and 560°C would be representative of cold/windy and warm/still atmospheric conditions, respectively.

**COMMENTS:** If there are constituents in the discharge gas flow that condense or precipitate out at temperatures below  $T_{s,o}$ , this operating condition should be avoided.

### PROBLEM 8.60

**KNOWN:** Hot fluid passing through a thin-walled tube with coolant in cross flow over the tube. Fluid flow rate and inlet and outlet temperatures.

**FIND:** Outlet temperature,  $T_{m,o}$ , if the flow rate is increased by a factor of 2 with all other conditions the same.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Hot fluid is incompressible with negligible viscous dissipation, (3) Constant properties, (4) Fully developed flow and thermal conditions, (5) Convection coefficients,  $\bar{h}_o$  and  $\bar{h}_i$ , independent of temperature, and (6) Negligible wall thermal resistance.

**PROPERTIES:** Hot fluid (Given):  $\rho = 1079 \text{ kg/m}^3$ ,  $c_p = 2637 \text{ J/kg}\cdot\text{K}$ ,  $\mu = 0.0034 \text{ N}\cdot\text{s/m}^2$ ,  $k = 0.261 \text{ W/m}\cdot\text{K}$ .

**ANALYSIS:** For conditions prescribed in the Schematic, Eq. 8.45a can be used to evaluate the overall convection coefficient with  $P = \pi D$ ,

$$\frac{T_{\infty} - T_{m,o}}{T_{\infty} - T_{m,i}} = \exp\left(-\frac{PL}{\dot{m}_o c_p} \bar{U}\right) \quad (1)$$

$$\frac{(25 - 78)^\circ\text{C}}{(25 - 85)^\circ\text{C}} = \exp\left(-\frac{\pi \times 0.010 \text{ m} \times 1 \text{ m}}{(18/3600) \text{ kg/s} \times 2637 \text{ J/kg}\cdot\text{K}} \bar{U}\right)$$

$$U = 52.1 \text{ W/m}^2 \cdot \text{K}$$

The overall coefficient can be expressed in terms of the inside and outside coefficients,

$$U = (1/\bar{h}_i + 1/\bar{h}_o)^{-1} \quad (2)$$

Characterize the internal flow with the Reynolds number, Eq. 8.6,

$$\text{Re}_D = \frac{4\dot{m}_o}{\pi D \mu} = \frac{4 \times (18/3600) \text{ kg/s}}{\pi \times 0.010 \text{ m} \times 0.0034 \text{ N}\cdot\text{s/m}^2} = 187$$

and since the flow is laminar, and assumed to be fully developed,  $\bar{h}_i$  will not change when the flow rate is doubled. That is,  $U = 52.1 \text{ W/m}^2\cdot\text{K}$  when  $\dot{m} = 2\dot{m}_o$ . Using Eq. (1) again, but with  $T_{m,o}$  unknown,

$$\frac{(25 - T_{m,o})^\circ\text{C}}{(25 - 85)^\circ\text{C}} = \exp\left(-\frac{\pi \times 0.010 \text{ m} \times 1 \text{ m}}{2(18/3600) \text{ kg/s} \times 2637 \text{ J/kg}\cdot\text{K}} \times 52.1 \text{ W/m}^2 \cdot \text{K}\right)$$

$$T_{m,o} = 81.4^\circ\text{C} \quad <$$

**COMMENTS:** Examine the assumptions and explain why they were necessary in order to affect the solution.

## PROBLEM 8.61

**KNOWN:** Thin walled tube of prescribed diameter and length. Water inlet temperature and flow rate.

**FIND:** (a) Outlet temperature of the water when the tube surface is maintained at a uniform temperature  $T_s = 27^\circ\text{C}$  assuming  $\bar{T}_m = 300\text{ K}$  for evaluating water properties, (b) Outlet temperature of the water when the tube is heated by cross flow of air with  $V = 10\text{ m/s}$  and  $T_\infty = 100^\circ\text{C}$  assuming  $\bar{T}_f = 350\text{ K}$  for evaluating air properties, and (c) Outlet temperature of the water for the conditions of part (b) using properly evaluated properties.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Incompressible liquid with negligible viscous dissipation and negligible axial conduction, (3) Fully developed flow and thermal conditions for internal flow, and (4) Negligible tube wall thermal resistance.

**PROPERTIES:** Table A.6, Water ( $\bar{T}_m = 300\text{ K}$ ):  $\rho = 997\text{ kg/m}^3$ ,  $c_p = 4179\text{ J/kg}\cdot\text{K}$ ,  $\mu = 855 \times 10^{-6}\text{ N}\cdot\text{s/m}^2$ ,  $k = 0.613\text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 5.83$ ; Table A.4, Air ( $\bar{T}_f = 350\text{ K}$ , 1 atm):  $\nu = 20.92 \times 10^{-6}\text{ m}^2/\text{s}$ ,  $k = 0.030\text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.700$ .

**ANALYSIS:** (a) For the constant wall temperature cooling process,  $T_s = 27^\circ\text{C}$ , the water outlet temperature can be determined from Eq. 8.41b, with  $P = \pi D$ ,

$$\frac{T_s - T_{m,o}}{T_s - T_{m,i}} = \exp\left(-\frac{PL}{\dot{m}c_p} \bar{h}_i\right) \quad (1)$$

To estimate the convection coefficient, characterize the flow evaluating properties at  $\bar{T}_m = 300\text{ K}$

$$\text{Re}_D = \frac{4\dot{m}}{\pi D \mu} = \frac{4 \times 0.2\text{ kg/s}}{\pi \times 0.010\text{ m} \times 855 \times 10^{-6}\text{ N}\cdot\text{s/m}^2} = 29,783$$

Hence, the flow is turbulent and assuming fully developed ( $L/D = 200$ ), and using the Dittus-Boelter correlation, Eq. 8.60, find  $\bar{h}_i$ ,

$$\text{Nu}_D = \frac{\bar{h}_i D}{k} = 0.023 \text{Re}_D^{0.8} \text{Pr}^{0.3} \quad \bar{h}_i = \frac{0.613\text{ W/m}\cdot\text{K}}{0.010\text{ m}} 0.023 (29,783)^{0.8} (5.83)^{0.3} = 9080\text{ W/m}^2\cdot\text{K} \quad (2)$$

Substituting this value for  $\bar{h}_i$  into Eq. (1), find

$$\frac{(27 - T_{m,o})}{(27 - 47)^\circ\text{C}} = \exp\left(-\frac{\pi \times 0.010\text{ m} \times 2\text{ m}}{0.2\text{ kg/s} \times 4179\text{ J/kg}\cdot\text{K}} \times 9080\text{ W/m}^2\cdot\text{K}\right) \quad T_{m,o} = 37.1^\circ\text{C} <$$

(b) For the air heating process,  $T_\infty = 100^\circ\text{C}$ , the water outlet temperature follows from Eq. 8.45a,

$$\frac{T_\infty - T_{m,o}}{T_\infty - T_{m,i}} = \exp\left(-\frac{\pi DL}{\dot{m}c_p} \bar{U}\right) \quad (3)$$

Continued...

**PROBLEM 8.61 (Cont.)**

where the overall coefficient is  $\bar{U} = (1/\bar{h}_i + 1/\bar{h}_o)$  (4)

To estimate  $\bar{h}_o$ , use the Churchill-Bernstein correlation, Eq. 7.54, for cross flow over a cylinder using properties evaluated at  $\bar{T}_f = 350$  K.

$$Re_D = \frac{VD}{\nu} = \frac{10 \text{ m/s} \times 0.010 \text{ m}}{20.92 \times 10^{-6} \text{ m}^2/\text{s}} = 4780 \quad (5)$$

$$\bar{Nu}_D = 0.3 + \frac{0.62 Re_D^{1/2} Pr^{1/3}}{\left[1 + (0.4/Pr)^{2/3}\right]^{1/4}} \left[1 + \left(\frac{Re_D}{282,000}\right)^{5/8}\right]^{4/5} \quad (6)$$

$$\bar{Nu}_D = 0.3 + \frac{0.62(4780)^{1/2} (0.700)^{1/3}}{\left[1 + (0.4/0.700)^{2/3}\right]^{1/4}} \left[1 + \left(\frac{4780}{282,000}\right)^{5/8}\right]^{4/5} = 35.76$$

$$\bar{h}_o = \frac{\bar{Nu}_D k}{D} = \frac{0.030 \text{ W/m} \cdot \text{K}}{0.010 \text{ m}} \times 35.76 = 107 \text{ W/m}^2 \cdot \text{K}$$

The value of  $\bar{h}_i$  can be recalculated for heating conditions:

$$Nu_D = \frac{\bar{h}_i D}{k} = 0.023 Re_D^{0.8} Pr^{0.4} \quad \bar{h}_i = \frac{0.613 \text{ W/m} \cdot \text{K}}{0.010 \text{ m}} 0.023 (29,783)^{0.8} (5.83)^{0.4} = 10,800 \text{ W/m}^2 \cdot \text{K}$$

Next, find  $\bar{U}$  then  $T_{m,o}$ ,

$$\bar{U} = (1/10,800 + 1/107)^{-1} \text{ W/m}^2 \cdot \text{K} = 106 \text{ W/m}^2 \cdot \text{K}$$

$$\frac{100 - T_{m,o}}{(100 - 47)^\circ \text{C}} = \exp\left(-\frac{\pi \times 0.010 \text{ m} \times 2 \text{ m}}{0.2 \text{ kg/s} \times 4179 \text{ J/kg} \cdot \text{K}} \times 106 \text{ W/m}^2 \cdot \text{K}\right) \quad T_{m,o} = 47.4^\circ \text{C} <$$

(c) Using the *IHT Correlation Tools for Internal Flow (Turbulent Flow)* and *External Flow (over a Cylinder)* the analyses of part (b) were performed considering the appropriate temperatures to evaluate the thermophysical properties. For internal and external flow, respectively,

$$\bar{T}_m = (T_{m,i} + T_{m,o})/2 \quad \bar{T}_f = (\bar{T}_s + T_\infty)/2 \quad (7,8)$$

where the average tube wall temperature is evaluated from the thermal circuit,

$$\frac{\bar{T}_m - \bar{T}_s}{1/\bar{h}_i} = \frac{\bar{T}_s - T_\infty}{1/\bar{h}_o} \quad (9)$$

The results of the analyses are summarized in the table along with the results from parts (a) and (b),

Condition	$\bar{T}_m$ (K)	$\bar{h}_i$ (W/m <sup>2</sup> ·K)	$\bar{T}_f$ (K)	$\bar{h}_o$ (W/m <sup>2</sup> ·K)	$\bar{U}$ (W/m <sup>2</sup> ·K)	$T_{m,o}$ (°C)
$T_s = 27^\circ \text{C}$	300	9080	---	---	---	37.1°C
$T_\infty = 100^\circ \text{C}, T_f = 350^\circ \text{C}$	300	10,800	350	107	106	47.4°C
Exact solution	320	13,000	347	107.3	106.3	47.4°C

Continued...

**PROBLEM 8.61 (Cont.)**

Note that since  $\bar{h}_o \ll \bar{h}_i$ ,  $\bar{U}$  is controlled by the value of  $\bar{h}_o$  which was evaluated near 350 K for both parts (b) and (c). Hence, it follows that  $T_{m,o}$  is not very sensitive to  $\bar{h}_i$  which, as seen above, is sensitive to the value of  $\bar{T}_m$ .

## PROBLEM 8.62

**KNOWN:** Diameter of tube through which water of prescribed flow rate and inlet and outlet temperatures flows. Temperature of fluid in cross flow over the tube.

**FIND:** (a) Required tube length for air in cross flow at prescribed velocity, (b) Required tube length for water in cross flow at a prescribed velocity.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, (2) Constant properties, (3) Negligible tube wall conduction resistance, (4) Water is incompressible liquid with negligible viscous dissipation.

**PROPERTIES:** Table A.6, water ( $\bar{T}_m = 50^\circ\text{C} = 323\text{ K}$ ):  $c_p = 4181\text{ J/kg}\cdot\text{K}$ ,  $\mu = 548 \times 10^{-6}\text{ N}\cdot\text{s/m}^2$ ,  $k = 0.643\text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 3.56$ . Table A.4, air (assume  $T_f = 300\text{ K}$ ):  $\nu = 15.89 \times 10^{-6}\text{ m}^2/\text{s}$ ,  $k = 0.0263\text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.707$ . Table A.6, water (assume  $T_f = 300\text{ K}$ ):  $\nu = 0.858 \times 10^{-6}\text{ m}^2/\text{s}$ ,  $k = 0.613\text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 5.83$ .

**ANALYSIS:** The required heat rate may be determined from the overall energy balance,

$$q = \dot{m}c_p(T_{m,i} - T_{m,o}) = 0.215\text{ kg/s}(4181\text{ J/kg}\cdot\text{K})40^\circ\text{C} = 35,960\text{ W}$$

and the required tube length may be determined from the rate equation, Eq. 8.46a,

$$L = \frac{q}{U\pi D\Delta T_{\ell m}}$$

where

$$\Delta T_{\ell m} = \frac{(T_{m,i} - T_\infty) - (T_{m,o} - T_\infty)}{\ln\left(\frac{T_{m,i} - T_\infty}{T_{m,o} - T_\infty}\right)} = 30.8^\circ\text{C} \quad \text{and} \quad 1/U = 1/h_i + 1/h_o.$$

With

$$\text{Re}_{D_i} = 4\dot{m}/\pi D\mu = 0.860\text{ kg/s}/\pi(0.05\text{ m})548 \times 10^{-6}\text{ N}\cdot\text{s/m}^2 = 9991$$

the flow is turbulent and, assuming fully developed flow throughout the tube, the inside convection coefficient is determined from Eq. 8.62

$$\text{Nu}_{D_i} = \frac{(f/8)(\text{Re}_{D_i} - 1000)\text{Pr}}{1 + 12.7(f/8)^{1/2}(\text{Pr}^{2/3} - 1)} = \frac{(0.0315/8)(9991 - 1000)3.56}{1 + 12.7(0.0315/8)^{1/2}(3.56^{2/3} - 1)} = 61.1$$

where  $f = (0.79 \ln \text{Re}_{D_i} + 1.64)^{-2} = 0.0315$

$$h_i = \text{Nu}_{D_i} k/D = 61.1(0.643\text{ W/m}\cdot\text{K})/0.05\text{ m} = 786\text{ W/m}^2\cdot\text{K}$$

Continued...

### PROBLEM 8.62 (Cont.)

(a) For air in cross flow at 20 m/s,  $Re_{D_o} = VD/v = 20 \text{ m/s}(0.05 \text{ m})/15.89 \times 10^{-6} \text{ m}^2/\text{s} = 62,933$ . From the Churchill/Bernstein correlation, it follows that

$$Nu_{D_o} = 0.3 + \frac{0.62 Re_{D_o}^{1/2} Pr^{1/3}}{\left[1 + (0.4/Pr)^{2/3}\right]^{1/4}} \left[1 + \left(\frac{Re_{D_o}}{282,000}\right)^{5/8}\right]^{4/5} = 158.7$$

$$h_o = Nu_{D_o} k/D = 158.7(0.0263 \text{ W/m} \cdot \text{K})/0.05 \text{ m} = 83.5 \text{ W/m}^2 \cdot \text{K}$$

Hence,  $U = (1/h_i + 1/h_o)^{-1} = 75.5 \text{ W/m}^2 \cdot \text{K}$  and

$$L = \frac{35,960 \text{ W}}{\left(75.5 \text{ W/m}^2 \cdot \text{K}\right) \pi (0.05 \text{ m}) 30.8^\circ \text{C}} = 98.5 \text{ m} \quad <$$

(b) For water in cross flow at 2 m/s,  $Re_{D_o} = 2 \text{ m/s}(0.05 \text{ m})/0.858 \times 10^{-6} \text{ m}^2/\text{s} = 116,550$ , and the correlation yields  $Nu_{D_o} = 527.3$ . Hence,

$$h_o = Nu_{D_o} k/D = 527.3(0.613 \text{ W/m} \cdot \text{K})/0.05 \text{ m} = 6,465 \text{ W/m}^2 \cdot \text{K}$$

$$U = (1/h_i + 1/h_o)^{-1} = 701 \text{ W/m}^2 \cdot \text{K}$$

Hence,

$$L = \frac{35,960 \text{ W}}{\left(701 \text{ W/m}^2 \cdot \text{K}\right) \pi (0.05 \text{ m}) 30.8^\circ \text{C}} = 10.6 \text{ m} \quad <$$

**COMMENTS:** The foregoing results clearly indicate the superiority of water (relative to air) as a heat transfer fluid. Note the dominant contribution made by the smaller convection coefficient to the value of  $U$  in each of the two cases.

## PROBLEM 8.63

**KNOWN:** Length, diameter, insulation characteristics and burial depth of a pipe. Ground surface temperature. Inlet temperature, flow rate and properties of oil flowing through pipe.

**FIND:** (a) An expression for the oil outlet temperature, (b) Oil outlet temperature and pipe heat transfer rate for prescribed conditions, and (c) Design information for trade off between burial depth of pipe ( $z$ ) and pipe insulation thickness ( $t$ ) on the heat loss.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Constant properties, (3) Two-dimensional conduction in soil, (4) Negligible pipe wall thermal resistance, (5) Total resistance to heat loss is independent of  $x$ , (6) Oil is incompressible liquid with negligible viscous dissipation.

**PROPERTIES:** Oil (given):  $\rho_o = 900 \text{ kg/m}^3$ ,  $c_{p,o} = 2000 \text{ J/kg}\cdot\text{K}$ ,  $\nu_o = 8.5 \times 10^{-4} \text{ m}^2/\text{s}$ ,  $k_o = 0.140 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr}_o = 10^4$ ; Soil (given):  $k_s = 0.50 \text{ W/m}\cdot\text{K}$ ; Insulation (given):  $k_i = 0.05 \text{ W/m}\cdot\text{K}$ .

**ANALYSIS:** (a) From Eq. 8.36 for a differential control volume in the oil and the rate equation

$$dq_{\text{conv}} = \dot{m}_o c_{p,o} dT_m = dq = (T_s - T_m) / R_{\text{tot}} \quad (1)$$

where the total resistance is expressed as

$$R_{\text{tot}} = R_{\text{conv}} + R_{\text{cond},i} + R_{\text{cond},s} = (\bar{h}\pi D dx)^{-1} + \frac{\ln(D_o/D_i)}{2\pi k_i dx} + \frac{1}{k_s S}$$

$$R_{\text{tot}} = \left( \frac{1}{\bar{h}\pi D_i} + \frac{\ln(D_o/D_i)}{2\pi k_i} + \frac{\cosh^{-1}(2z/D_o)}{2\pi k_s} \right) / dx = R'_{\text{tot}} / dx \quad (2)$$

where, from Table 4.1,

$$S = 2\pi dx / \cosh^{-1}(2z/D_o) \quad (3)$$

It follows that

$$\frac{(T_s - T_m) dx}{R'_{\text{tot}}} = \dot{m}_o c_{p,o} dT_m \quad \frac{dT_m}{T_s - T_m} = \frac{dx}{\dot{m}_o c_{p,o} R'_{\text{tot}}}$$

Integrating between inlet and outlet conditions

$$\int_{T_{m,i}}^{T_{m,o}} \frac{dT_m}{T_m - T_s} = - \int_0^L \frac{dx}{\dot{m}_o c_{p,o} R'_{\text{tot}}}$$

Assuming  $R'_{\text{tot}}$  to be independent of  $x$  and integrating,

$$\frac{T_{m,o} - T_s}{T_{m,i} - T_s} = \exp\left( - \frac{L}{\dot{m}_o c_{p,o} R'_{\text{tot}}} \right). \quad (3) <$$

Continued...

### PROBLEM 8.63 (Cont.)

(b) To calculate  $T_{m,o}$  for the prescribed conditions, begin by evaluating  $\bar{h}$ , where

$$Re_D = \frac{4\dot{m}_o}{\pi D_i \rho_o \nu_o} = \frac{4 \times 500 \text{ kg/s}}{\pi (1.2 \text{ m}) 900 \text{ kg/m}^3 \times 8.5 \times 10^{-4} \text{ m}^2/\text{s}} = 694 \quad (4)$$

Hence, the flow is laminar, and with  $Pr_o > 5$ , the Hausen correlation is appropriate,

$$\overline{Nu}_D = 3.66 + \frac{0.0668 Gz_D}{1 + 0.04 Gz_D^{2/3}} \quad (5)$$

$$Gz_D = (D_i/L) Re_D Pr = \left( \frac{1.2}{10^5} \right) (694) 10^4 = 83.3 \quad \overline{Nu}_D = 6.82$$

$$\bar{h} = \frac{k}{D_i} 6.82 = \frac{0.14 \text{ W/m} \cdot \text{K}}{1.2 \text{ m}} 6.82 = 0.80 \text{ W/m}^2 \cdot \text{K}$$

From Eq. (2), the overall thermal resistance is

$$R'_{tot} = \frac{1}{0.8 \text{ W/m}^2 \cdot \text{K} \pi (1.2 \text{ m})} + \frac{\ln(1.5/1.2)}{2\pi (0.05 \text{ W/m} \cdot \text{K})} + \frac{\cosh^{-1}(4)}{2\pi (0.5 \text{ W/m} \cdot \text{K})}$$

$$R'_{tot} = (0.33 + 0.71 + 0.66) \text{ K} \cdot \text{m/W} = 1.70 \text{ K} \cdot \text{m/W}$$

and the oil outlet temperature can be calculated as

$$\frac{T_{m,o} - T_s}{T_{m,i} - T_s} = \exp\left(-\frac{10^5 \text{ m}}{500 \text{ kg/s} \times 2000 \text{ J/kg} \cdot \text{K} \times 1.7 \text{ K} \cdot \text{m/W}}\right) = 0.943$$

$$T_{m,o} = 110.9^\circ\text{C} \quad <$$

The total rate of heat transfer *from* the pipeline is then

$$q = \dot{m}_o c_{p,o} (T_{m,i} - T_{m,o}) \quad (6)$$

$$q = 500 \text{ kg/s} \times 2000 \text{ J/kg} \cdot \text{K} (120 - 110.9)^\circ\text{C} = 9.1 \times 10^6 \text{ W}. \quad <$$

(c) Using the *IHT Workspace* with the foregoing equations, an analysis was performed to determine the heat loss,  $q$ , as a function of burial depth for the range,  $1 \leq z \leq 6 \text{ m}$ , for thicknesses of insulation which are -25%, +25%, +50% and 100% that of the base case,  $t = r_o - r_i = 150 \text{ mm}$ .

Continued...

### PROBLEM 8.63 (Cont.)

From this information, the operations manager can compare the costs associated with burial depth and insulation thickness with respect to acceptable heat loss.

**COMMENTS:** (1) Since the thermal entry region is very long,  $x_{fd,t} \approx 0.05DR_{eD}Pr = 4.16 \times 10^5$  m,  $h_x$  will be changing with  $x$  throughout the pipe. A more accurate solution would therefore be one in which Eq. (1) is integrated numerically, in a step-by-step fashion. For example, the integration could involve a step width of  $\Delta x = 10^3$  m, with  $h$  and  $R'_t$  evaluated at each step.

(2) The three contributions to the total thermal resistance are comparable.

(3) In IHT 3.0, the inverse hyperbolic cosine function is “`invcosh`,” so the shape factor can be found as:

```
// Shape factor:  
S = 2 * pi / invcosh(arg)  
arg = 2*z/Do  
z = 3  
Do = 1.5
```

Note that the argument of a function must be calculated separately in IHT. That is, we cannot use `invcosh(2*z/Do)`.

## PROBLEM 8.64

**KNOWN:** Length, diameter, insulation characteristics and burial depth of pipe. Ground surface temperature. Inlet temperature, minimum allowable exit temperature, flow rate and properties of oil flow through pipe.

**FIND:** Effect of soil thermal conductivity and flowrate on heat rate and outlet temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Constant properties, (3) Two-dimensional conduction in soil, (4) Negligible pipe wall thermal resistance, (5) Total resistance to heat loss is independent of  $x$ , (6) Oil is incompressible liquid with negligible viscous dissipation.

**PROPERTIES:** Oil (given):  $\rho_o = 900 \text{ kg/m}^3$ ,  $c_{p,o} = 2000 \text{ J/kg}\cdot\text{K}$ ,  $\nu_o = 8.5 \times 10^{-4} \text{ m}^2/\text{s}$ ,  $k_o = 0.140 \text{ W/m}\cdot\text{K}$ ,  $Pr_o = 10^4$ .

**ANALYSIS:** From the analysis of Problem 8.63, the outlet temperature may be computed from the expression

$$\frac{T_{m,o} - T_s}{T_{m,i} - T_s} = \exp\left(-\frac{L}{\dot{m}c_{p,o}R'_{\text{tot}}}\right)$$

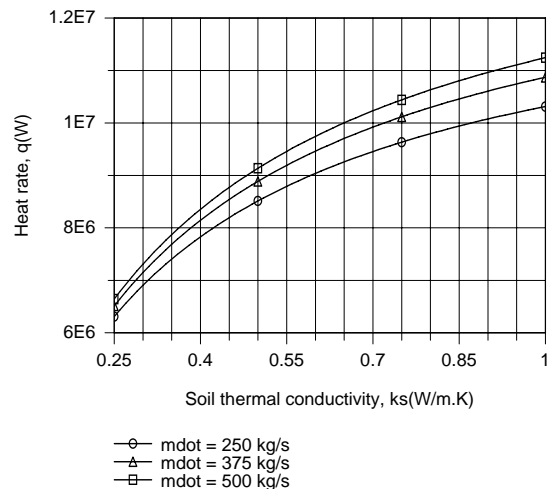

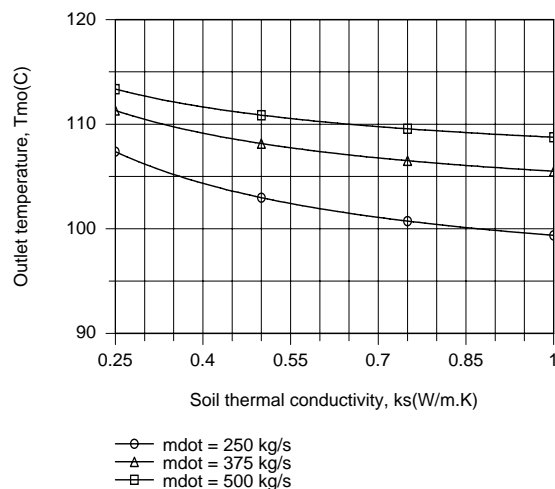

where

$$R'_{\text{tot}} = \frac{1}{\bar{h}\pi D_i} + \frac{\ln(D_o/D_i)}{2\pi k_i} + \frac{\cosh^{-1}(2z/D_o)}{2\pi k_s}$$

and  $\bar{h}$  is determined from Eq. 8.57. The heat rate may then be obtained from the overall energy balance

$$q = \dot{m}c_p(T_{m,i} - T_{m,o})$$

Using the *Correlations* Toolpad of IHT to perform the parametric calculations, the following results were obtained.

Continued...

### PROBLEM 8.64 (Cont.)

Due to a reduction in the thermal conduction resistance of the soil with increasing  $k_s$ , there is a corresponding increase in the heat rate  $q$  from the pipe and a reduction in the oil outlet temperature. The heat rate also increases with increasing  $\dot{m}$  (due to an increase in  $\bar{h}$  and hence a decrease in the convection resistance), but the increase lags that of the flow rate, causing the outlet temperature to increase with increasing  $\dot{m}$ . Conditions for which  $T_{m,o} \geq 110^\circ\text{C}$  cannot be achieved for  $\dot{m} = 250 \text{ kg/s}$ , but can be achieved for  $k_s \leq 0.33 \text{ W/m}\cdot\text{K}$  and  $k_s \leq 0.65 \text{ W/m}\cdot\text{K}$  for  $\dot{m} = 375 \text{ kg/s}$  and  $500 \text{ kg/s}$ , respectively. The worst case condition corresponds to the smallest value of  $\dot{m}$  and the largest value of  $k_s$ .

Measures to maintain  $T_{m,o} \geq 110^\circ\text{C}$  could include increasing the burial depth, increasing the insulation thickness, and/or using an insulation of lower thermal conductivity.

**COMMENTS:** The thermophysical properties of oil depend strongly on temperature, and a more accurate solution would account for the effect of variations in  $\bar{T}_m$  on the properties.

### PROBLEM 8.65

**KNOWN:** Water flow rate and inlet temperature for a thin-walled tube of prescribed length and diameter.

**FIND:** Water outlet temperature for each of the following conditions: (a) Tube surface maintained at 27°C, (b) Insulation applied and outer surface maintained at 27°C, (c) Insulation applied and outer surface exposed to ambient air at 27°C.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Fully developed flow throughout the tube, (3) Negligible tube wall conduction resistance, (4) Negligible contact resistance between tube wall and insulation, (5) Uniform outside convection coefficient.

**PROPERTIES:** Assume water cools to  $T_{m,o} = 27^\circ\text{C}$  with no insulation but that cooling is negligible ( $T_{m,o} = 97^\circ\text{C}$ ) with insulation. *Table A-4*, Water ( $\bar{T}_m = 335\text{K}$ ):  $c_p = 4186\text{ J/kg}\cdot\text{K}$ ,  $\mu = 453 \times 10^{-6}\text{ N}\cdot\text{s/m}^2$ ,  $k = 0.656\text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 2.88$ ; *Table A-4*, Water ( $T_{m,i} = 370\text{K}$ ):  $c_p = 4214\text{ J/kg}\cdot\text{K}$ ,  $\mu = 289 \times 10^{-6}\text{ N}\cdot\text{s/m}^2$ ,  $k = 0.679\text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 1.80$ .

**ANALYSIS:** For each of the three cases, heat is transferred from the warm water to a surface (or the air) which is at a fixed temperature ( $27^\circ\text{C}$ ). Accordingly, an expression of the form given by Eq. 8.41b may be used to determine the outlet temperature of the water, so long as the appropriate heat transfer coefficient is used. In particular, each of the cases can be described by Eq. 8.45a.

$$\frac{\Delta T_o}{\Delta T_i} = \exp\left(-\frac{\bar{U}A_s}{\dot{m}c_p}\right)$$

Referring to the thermal circuit associated with heat transfer from the water,

and the  $UA$  product may be evaluated as

$$UA = (\sum R_t)^{-1}.$$

(a) For the first case:  $T_{s,i} = 27^\circ\text{C}$     $\Delta T_i = T_{m,i} - T_{s,i} = 70^\circ\text{C}$     $UA = h_i \pi D_i L$ .

$$\text{Re}_D = \frac{4\dot{m}}{\pi D_i \mu} = \frac{4 \times 0.015\text{ kg/s}}{\pi (0.003\text{ m}) 453 \times 10^{-6}\text{ N}\cdot\text{s/m}^2} = 14,053.$$

Continued ...

**PROBLEM 8.65 (Cont.)**

From Eq. 8.60,

$$h_i = \frac{k}{D_i} 0.023 \text{Re}_D^{4/5} \text{Pr}^{0.30} = \frac{0.656 \text{ W/m} \cdot \text{K}}{0.003\text{m}} (0.023) (14,053)^{4/5} (2.88)^{0.3} = 14,373 \text{ W/m}^2 \cdot \text{K}.$$

$$\Delta T_o = \Delta T_i \exp \left( -\frac{h_i \pi D_i L}{\dot{m} c_p} \right) = 70^\circ \text{C} \exp \left( -\frac{14,373 \frac{\text{W}}{\text{m}^2 \cdot \text{K}} \pi \times 0.003\text{m} \times 1\text{m}}{0.015 \text{ kg/s} \times 4186 \text{ J/kg} \cdot \text{K}} \right) = 8.1^\circ \text{C}$$

$$T_{m,o} = \Delta T_o + T_{s,i} = 8.1^\circ \text{C} + 27^\circ \text{C} = 35.1^\circ \text{C}. \quad <$$

(b) For the second case:  $T_{s,o} = 27^\circ \text{C}$  with

$$\Delta T_i = T_{m,i} - T_{s,o} = 70^\circ \text{C} \quad UA = \left[ (1/h_i \pi D_i L) + \ln(D_o/D_i)/2\pi \text{ kL} \right]^{-1}.$$

$$\text{With } \text{Re}_D = \frac{4 \dot{m}}{\pi D_i \mu} = \frac{4 \times 0.015 \text{ kg/s}}{\pi (0.003\text{m}) 289 \times 10^{-6} \text{ N} \cdot \text{s/m}^2} = 22,028$$

$$h_i = \frac{k}{D_i} 0.023 \text{Re}_D^{4/5} \text{Pr}^{0.3} = \frac{0.679 \text{ W/m} \cdot \text{K}}{0.003\text{m}} (0.023) (22,028)^{4/5} (1.80)^{0.3} = 18,511 \text{ W/m}^2 \cdot \text{K}.$$

It follows that

$$UA = \left[ \frac{1}{18,511 \pi \times 0.003} + \frac{\ln(0.004/0.003)}{2\pi(0.05)} \right]^{-1} = \left[ 5.73 \times 10^{-3} + 0.916 \right]^{-1} = 1.085 \text{ W/K}$$

and the outlet temperature is

$$\Delta T_o = 70^\circ \text{C} \exp \left( -\frac{1.085 \text{ W/K}}{0.015 \text{ kg/s} \times 4214 \text{ J/kg} \cdot \text{K}} \right) = 68.8^\circ \text{C}$$

$$T_{m,o} = \Delta T_o + T_{s,o} = 68.8^\circ \text{C} + 27^\circ \text{C} = 95.8^\circ \text{C}. \quad <$$

(c) For the third case:  $T_\infty = 27^\circ \text{C}$ ,  $\Delta T_i = T_{m,i} - T_\infty = 70^\circ \text{C}$  and

$$UA = \left[ (1/h_i \pi D_i L) + \ln(D_o/D_i)/2\pi \text{ kL} + (1/h_o \pi D_o L) \right]^{-1}$$

$$UA = \left[ 5.73 \times 10^{-3} + 0.916 + \frac{1}{5\pi(0.004)} \right]^{-1} = \left[ 5.73 \times 10^{-3} + 0.916 + 15.92 \right]^{-1} = 0.0594 \text{ W/K}$$

$$\Delta T_o = 70^\circ \text{C} \exp \left( -\frac{0.0594 \text{ W/K}}{0.015 \text{ kg/s} \times 4214 \text{ J/kg} \cdot \text{K}} \right) = 69.9^\circ \text{C}$$

$$T_{m,o} = \Delta T_o + T_\infty = 69.9^\circ \text{C} + 27^\circ \text{C} = 96.9^\circ \text{C}. \quad <$$

**COMMENTS:** Note that  $R_{\text{conv},o} \gg R_{\text{cond,insul}} \gg R_{\text{conv},i}$ ,

## PROBLEM 8.66

**KNOWN:** Dimensions of circular tube, applied constant heat flux, inlet temperature, mass flow rate, and expression for nanofluid viscosity.

**FIND:** Tube wall temperature at the tube exit for pure water and for a water-Al<sub>2</sub>O<sub>3</sub> nanofluid.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Constant properties.

**PROPERTIES:** Table A.4, water (300 K):  $\mu_{\text{bf}} = 855 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k_{\text{bf}} = 0.613 \text{ W/m}\cdot\text{K}$ ,  $c_{p,\text{bf}} = 4179 \text{ J/kg}\cdot\text{K}$ ,  $Pr_{\text{bf}} = 5.83$ . Example 2.2, nanofluid (300 K):  $\mu_{\text{nf}} = 962 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k_{\text{nf}} = 0.705 \text{ W/m}\cdot\text{K}$ ,  $c_{p,\text{nf}} = 3587 \text{ J/kg}\cdot\text{K}$ ,  $Pr_{\text{nf}} = \mu_{\text{nf}} c_{p,\text{nf}} / k_{\text{nf}} = 4.91$ .

**ANALYSIS:** The Reynolds number for the pure water

is  $Re_D = 4\dot{m} / \pi D \mu_{\text{bf}} = [4 \times (0.1/1000 \text{ kg/s})] / (\pi \times 0.0002 \text{ m} \times 855 \times 10^{-6} \text{ N}\cdot\text{s/m}^2) = 745$  and the flow is laminar. Similarly, the Reynolds number for the nanofluid is  $Re_{D,\text{nf}} = 662$ . The hydrodynamic entrance length for the pure water is  $x_{fd,h} = 0.05 Re_D D = 0.05 \times 745 \times 0.2/1000 \text{ m} = 7.45 \times 10^{-3} \text{ m} = 7.45 \text{ mm}$  and the flow at the tube exit is hydrodynamically fully developed. Similarly, the hydrodynamic entrance length for the nanofluid is  $x_{fd,h,\text{nf}} = 6.62 \times 10^{-3} \text{ m} = 6.62 \text{ mm}$  and the flow at the tube exit is also hydrodynamically fully developed. For the pure water, the thermal entrance length is  $x_{fd,t} = x_{fd,h} Pr_{\text{bf}} = 7.45 \text{ mm} \times 5.83 = 43.4 \text{ mm}$ , while for the nanofluid  $x_{fd,t,\text{nf}} = x_{fd,h,\text{nf}} Pr_{\text{nf}} = 6.62 \text{ mm} \times 4.91 = 32.5 \text{ mm}$  and the flow is also thermally fully-developed at the tube exit for both fluids.

For constant heat flux conditions, the local Nusselt number in the fully-developed region is  $Nu_D = 4.36$ . Therefore, the local heat transfer coefficient at the tube exit is:

$$\text{Pure fluid: } h_{\text{bf}} = Nu_D k_{\text{bf}} / D = 4.36 \times 0.613 \text{ W/m}\cdot\text{K} / (0.2/1000 \text{ m}) = 13,360 \text{ W/m}^2\cdot\text{K}.$$

$$\text{Nanofluid: } h_{\text{nf}} = Nu_D k_{\text{nf}} / D = 4.36 \times 0.705 \text{ W/m}\cdot\text{K} / (0.2/1000 \text{ m}) = 15,370 \text{ W/m}^2\cdot\text{K}.$$

Applying Eq. (8.40) to the pure fluid yields

$$T_{m,o} = T_{m,i} + \frac{q'' \pi D}{\dot{m} c_{p,\text{bf}}} L = 29^\circ\text{C} + \frac{20,000 \text{ W/m}^2 \pi (0.2/1000 \text{ m})}{(0.1/1000 \text{ kg/s}) \times (4179 \text{ J/kg}\cdot\text{K})} 0.1 \text{ m} = 29^\circ\text{C} + 3.00^\circ\text{C} = 32.00^\circ\text{C}$$

whereas applying Eq. (8.40) to the nanofluid results in

$$T_{m,o,\text{nf}} = T_{m,i} + \frac{q'' \pi D}{\dot{m} c_{p,\text{nf}}} L = 29^\circ\text{C} + \frac{20,000 \text{ W/m}^2 \pi (0.2/1000 \text{ m})}{(0.1/1000 \text{ kg/s}) \times (3587 \text{ J/kg}\cdot\text{K})} 0.1 \text{ m} = 29^\circ\text{C} + 3.50^\circ\text{C} = 32.50^\circ\text{C}$$

Continued...

### PROBLEM 8.66 (Cont.)

From Eq. (8.27) the wall temperature at the outlet of the tube carrying the pure water is,

$$T_s(x=L) = T_{m,o} + q'' / h_{bf} = 32.00^\circ\text{C} + 20,000\text{W/m}^2 / 13,360 \text{ W/m}^2 \cdot \text{K} = 32^\circ\text{C} + 1.50^\circ\text{C} = 33.50^\circ\text{C} <$$

Similarly for the nanofluid,

$$\begin{aligned} T_{s,nf}(x=L) &= T_{m,o,nf} + q'' / h_{nf} < \\ &= 32.50^\circ\text{C} + 20,000\text{W/m}^2 / 15,370 \text{ W/m}^2 \cdot \text{K} = 32.50^\circ\text{C} + 1.30^\circ\text{C} = 33.80^\circ\text{C} \end{aligned}$$

**COMMENTS:** Although the nanofluid provides a larger thermal conductivity and, in turn, a larger convective heat transfer coefficient relative to the pure water, the wall temperature at the tube outlet with the nanofluid exceeds that of the wall temperature using pure water. This is due to the reduction of the specific heat upon addition of the nanoparticles to the pure water and the associated increase in the outlet mean temperature. Hence, careful consideration of the flow conditions must be made in order to determine whether wall temperatures will decrease or increase with use of the nanofluid.

## PROBLEM 8.67

**KNOWN:** Dimensions of circular tube, applied constant heat flux, inlet temperature, mass flow rate.

**FIND:** Tube wall temperature at the tube exit for pure water and for a water-Al<sub>2</sub>O<sub>3</sub> nanofluid.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Constant properties.

**PROPERTIES:** Table A.4, water (300 K):  $\mu_{bf} = 855 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k_{bf} = 0.613 \text{ W/m}\cdot\text{K}$ ,  $c_{p,bf} = 4179 \text{ J/kg}\cdot\text{K}$ ,  $Pr_{bf} = 5.83$ . Example 2.2, nanofluid (300 K):  $\mu_{nf} = 962 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k_{nf} = 0.705 \text{ W/m}\cdot\text{K}$ ,  $c_{p,nf} = 3587 \text{ J/kg}\cdot\text{K}$ ,  $Pr_{nf} = 4.91$ .

**ANALYSIS:** The Reynolds number for the pure water

is  $Re_D = 4\dot{m} / \pi D \mu_{bf} = [4 \times (10/1000 \text{ kg/s})] / (\pi \times 0.002 \text{ m} \times 855 \times 10^{-6} \text{ N}\cdot\text{s/m}^2) = 7450$  and the flow is turbulent. Similarly, the Reynolds number for the nanofluid is  $Re_{D,nf} = 6620$ . Since  $L/D = 100/2 = 50$ , the flow is fully-developed at the tube exit for both fluids.

The local Nusselt number is evaluated using the Gnielinski correlation. For pure water, Eq. (8.21) yields,  $f_{bf} = (0.790 \ln(7450) - 1.64)^{-2} = 0.0342$  while for the nanofluid,  $f_{nf} = (0.790 \ln(6620) - 1.64)^{-2} = 0.0355$ . The Gnielinski correlation yields, for the pure fluid

$$Nu_{D,bf} = \frac{(0.0342/8)(7450 - 1000)5.83}{1 + 12.7(0.0342/8)^{1/2}(5.83^{2/3} - 1)} = 56.24$$

while for the nanofluid,

$$Nu_{D,nf} = \frac{(0.0355/8)(6620 - 1000)4.91}{1 + 12.7(0.0355/8)^{1/2}(4.91^{2/3} - 1)} = 47.08$$

Hence,  $h_{bf} = Nu_{D,bf} k_{bf} / D = 56.24(0.613 \text{ W/m}\cdot\text{K}) / 0.002 \text{ m} = 17,240 \text{ W/m}^2\cdot\text{K}$  and  $h_{nf} = Nu_{D,bf} k_{nf} / D = 47.08(0.705 \text{ W/m}\cdot\text{K}) / 0.002 \text{ m} = 16,600 \text{ W/m}^2\cdot\text{K}$ .

Applying Eq. (8.40) to the pure fluid yields

$$T_{m,o} = T_{m,i} + \frac{q'' \pi D}{\dot{m} c_{p,bf}} L = 29^\circ\text{C} + \frac{200,000 \text{ W/m}^2 \pi (2/1000 \text{ m})}{(10/1000 \text{ kg/s}) \times (4179 \text{ J/kg}\cdot\text{K})} 0.1 \text{ m} = 29^\circ\text{C} + 3.00^\circ\text{C} = 32.00^\circ\text{C}$$

whereas applying Eq. (8.40) to the nanofluid results in

Continued...

### PROBLEM 8.67 (Cont.)

$$T_{m,o,nf} = T_{m,i} + \frac{q''\pi D}{\dot{m}c_{p,nf}}L = 29^\circ\text{C} + \frac{200,000 \text{ W/m}^2\pi(2/1000 \text{ m})}{(10/1000 \text{ kg/s})\times(3587 \text{ J/kg}\cdot\text{K})}0.1 \text{ m} = 29^\circ\text{C} + 3.50^\circ\text{C} = 32.50^\circ\text{C}$$

From Eq. (8.27) the wall temperature at the outlet of the tube carrying the pure water is,

$$\begin{aligned} T_s(x=L) &= T_{m,o} + q''/h_{bf} \\ &= 32.00^\circ\text{C} + 200,000\text{W/m}^2 / 17,240 \text{ W/m}^2 \cdot \text{K} = 32.00^\circ\text{C} + 11.61^\circ\text{C} = 43.61^\circ\text{C} \end{aligned} \quad <$$

Similarly for the nanofluid,

$$\begin{aligned} T_{s,nf}(x=L) &= T_{m,o,nf} + q''/h_{nf} \\ &= 32.50^\circ\text{C} + 200,000\text{W/m}^2 / 16,600 \text{ W/m}^2 \cdot \text{K} = 32.50^\circ\text{C} + 12.05^\circ\text{C} = 44.55^\circ\text{C} \end{aligned} \quad <$$

**COMMENT:** The nanofluid provides a larger thermal conductivity but a smaller convective heat transfer coefficient relative to the pure water. If the objective is to minimize the wall temperature at the outlet of the tube, the nanofluid is *not* the appropriate selection. The wall temperature at the tube outlet may be greater than, less than, or equal to the wall temperature associated with use of pure water, depending on the tube geometry and flow rate.

## PROBLEM 8.68

**KNOWN:** Reaction vessel with process fluid at 75°C cooled by water at 27°C and 0.12 kg/s through 15 mm tube. High convection coefficient on outside of tube ( $3000 \text{ W/m}^2 \cdot \text{K}$ ) created by vigorous stirring.

**FIND:** (a) Maximum heat transfer rate if outlet temperature of water cannot exceed  $T_{m,o} = 47^\circ\text{C}$ , and (b) Required tube length.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Incompressible liquid with negligible viscous dissipation, (3) Negligible thermal resistance of tube wall.

**PROPERTIES:** Table A-6, Water ( $\bar{T}_m = (47 + 27)^\circ\text{C}/2 = 310\text{K}$ ):  $\rho = 1/\nu_f = 993.1 \text{ kg/m}^3$ ,  $c_p = 4178 \text{ J/kg}\cdot\text{K}$ ,  $\mu = 695 \times 10^{-6} \text{ N}\cdot\text{s/m}^2$ ,  $k = 0.628 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 4.62$ .

**ANALYSIS:** (a) From an overall energy balance on the tube with  $T_{m,o} = 47^\circ\text{C}$ ,

$$q_{\max} = \dot{m} c_p (T_{m,o} - T_{m,i}) = 0.12 \text{ kg/s} \times 4178 \text{ J/kg}\cdot\text{K} (47 - 27)^\circ\text{C} = 10,027 \text{ W} \quad <$$

(b) For the constant surface temperature heating condition, from Eq. 8.45a,

$$\frac{T_\infty - T_{m,o}}{T_\infty - T_{m,i}} = \exp\left(-\frac{PL}{\dot{m} c_p} \bar{U}\right) \quad \text{where} \quad 1/U = 1/\bar{h}_o + 1/\bar{h}_i.$$

For internal flow in the tube, find

$$\text{Re}_D = \frac{4\dot{m}}{\pi D \mu} = \frac{4 \times 0.12 \text{ kg/s}}{\pi \times 0.015 \text{ m} \times 695 \times 10^{-6} \text{ N}\cdot\text{s/m}^2} = 14,656$$

and the flow is turbulent. Assuming fully developed flow, use the Dittus-Boelter correlation with  $n = 0.4$  (heating),

$$\text{Nu}_D = h_i D/k = 0.023 \text{Re}_D^{4/5} \text{Pr}^{0.4}$$

$$h_i = [0.628 \text{ W/m}\cdot\text{K}/0.015 \text{ m}] \times 0.023 (14,656)^{4/5} (4.62)^{0.4} = 3822 \text{ W/m}^2 \cdot \text{K}.$$

Hence,  $1/U = [1/3000 + 1/3822] \text{ m}^2 \cdot \text{K/W}$  or  $U = 1680 \text{ W/m}^2 \cdot \text{K}$ . From the energy balance relation with  $P = \pi D$ , find

$$\frac{(75 - 47)^\circ\text{C}}{(75 - 27)^\circ\text{C}} = \exp\left(-\frac{\pi (0.015 \text{ m}) L \times 1680 \text{ W/m}^2 \cdot \text{K}}{0.12 \text{ kg/s} \times 4178 \text{ J/kg}\cdot\text{K}}\right) \quad L = 3.4 \text{ m} \quad <$$

**COMMENTS:** Note that  $L/D = 227$  and the fully developed flow assumption is appropriate.

## PROBLEM 8.69

**KNOWN:** Water flowing through a tube heated by cross flow of a hot gas. Required to heat water from 15 to 35°C with a flow rate of 0.2 kg/s.

**FIND:** Design graphs to demonstrate acceptable combinations of tube diameter ( $D = 20, 30$  or  $40$  mm), tube length ( $L = 3, 4$  or  $6$  m) and hot gas velocity ( $20 \leq V \leq 40$  m/s) and temperature ( $T_\infty = 250, 375$  or  $500^\circ\text{C}$ ).

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Water is incompressible liquid with negligible viscous dissipation, (3) Fully developed flow and thermal conditions for internal flow, (4) Properties of the hot gas are those of atmospheric air, and (5) Negligible tube wall thermal resistance.

**PROPERTIES:** Table A.6, Water ( $\bar{T}_m = (15 + 35)^\circ\text{C}/2 = 298\text{K}$ ); Table A.4, Air ( $\bar{T}_f = (\bar{T}_s + T_\infty)/2$ , 1 atm).

**ANALYSIS:** *Method of Analysis:* The tube having internal flow of water with cross flow of hot gas can be analyzed by the energy balance relation, Eq. 8.45a

$$\frac{T_\infty - T_{m,o}}{T_\infty - T_{m,i}} = \exp\left(-\frac{(\pi DL)}{\dot{m}c_p} \bar{U}\right) \quad (1)$$

where the overall coefficient  $\bar{U}$  is

$$\bar{U} = \left(1/\bar{h}_i + 1/\bar{h}_o\right)^{-1} \quad (2)$$

*Estimation of the internal flow coefficient,  $\bar{h}_i$ :* Evaluating water properties at the average mean fluid temperature

$$\bar{T}_m = (T_{m,i} + T_{m,o})/2, \quad (3)$$

characterize the flow with the Reynolds number,

$$\text{Re}_{D,i} = \frac{4\dot{m}}{(\pi D\mu)} \quad (4)$$

and assuming the flow to be both turbulent and fully developed ( $L/D > 3\text{m}/0.07\text{m} = 42$ ), use the Dittus-Boelter correlation, Eq. 8.60, to evaluate  $\bar{h}_i$ ,

Continued...

**PROBLEM 8.69 (Cont.)**

$$\overline{\text{Nu}}_{D,i} = \frac{\overline{h}_i D}{k_i} = 0.023 \text{Re}_{D,i}^{0.8} \text{Pr}^{0.4} \quad (5)$$

Estimation of the external flow coefficient,  $\overline{h}_o$ : Evaluating gas (air) properties at the average film temperature

$$\overline{T}_f = (\overline{T}_s + T_\infty)/2 \quad (6)$$

where  $\overline{T}_s$  is the average tube wall temperature (see Eq. (9)), characterize the flow

$$\text{Re}_{D,o} = \frac{VD}{\nu} \quad (7)$$

and use the Churchill-Bernstein correlation, Eq. 7.54, for cross-flow over a cylinder,

$$\text{Nu}_{D,o} = \frac{\overline{h}_o D}{k_o} = 0.3 + \frac{0.62 \text{Re}_{D,o}^{1/2} \text{Pr}_o^{1/3}}{\left[1 + (0.4/\text{Pr}_o)^{2/3}\right]^{1/4}} \left[1 + \left(\frac{\text{Re}_{D,o}}{282,000}\right)^{5/8}\right]^{4/5} \quad (8)$$

The average tube wall temperature,  $\overline{T}_s$ , follows from the thermal circuit

$$\frac{\overline{T}_m - \overline{T}_s}{1/\overline{h}_i} = \frac{\overline{T}_s - T_\infty}{1/\overline{h}_o} \quad (9)$$

*The IHT Workspace:* Using the *Correlation Tools for Internal Flow (Turbulent flow)*, and *External Flow (Flow over a Cylinder)* and *Properties for Air and Water*, along with the appropriate energy balances and rate equations, the heater-tube system can be analyzed.

*The Design Strategy:* We have chosen to generate the design information in the following manner: for a specified gas temperature,  $T_\infty$ , plot the required length  $L$  (limiting the scale to  $3 \leq L \leq 6\text{m}$ ) as a function of gas velocity  $V$  ( $20 \leq V \leq 40\text{ m/s}$ ) for tube diameters of  $D = 20, 30$  and  $40\text{ mm}$ . Three design graphs corresponding to  $T_\infty = 250, 375$  and  $500^\circ\text{C}$  were generated and are shown on the next page.

**COMMENTS:** (1) The collection of design graphs will allow the contractor to select appropriate combinations of tube  $D$  and  $L$  and gas stream parameters ( $T_\infty$  and  $V$ ) to achieve the required water heating.

(2) Note from the design graphs that with  $T_\infty = 250^\circ\text{C}$ , the required heating of the water can be achieved only with a 40-mm diameter by 6 m length tube with gas velocities greater than 32 m/s. This configuration represents a worst case condition of largest tube parameters and highest gas velocity.

(3) Which operating conditions,  $T_\infty = 375$  or  $500^\circ\text{C}$ , provides the contractor with more options in selecting combinations of tube parameters and gas velocities? What are the trade-offs in operating at 375 or  $500^\circ\text{C}$ ? Consider such features as tube life, tubing costs and fan requirements.

(4) The Reynolds numbers for the internal flow are approximately 7,100, 9,460 and 14,200 for the tube diameters of 20, 30 and 40 mm. For the larger tube sizes, the Reynolds numbers are below 10,000, the usual lower limit for turbulent flow. The Gnielinski correlation would be more accurate under these conditions.

Continued...

## PROBLEM 8.69 (Cont.)

### PROBLEM 8.70

**KNOWN:** Exhaust gases at 200°C and mass rate 0.03 kg/s enter tube of diameter 6 mm and length 20 m. Tube experiences cross-flow of autumn winds at 15°C and 5 m/s.

**FIND:** Average heat transfer coefficients for (a) exhaust gas inside tube and (b) air flowing across outside of tube, (c) Estimate overall coefficient and exhaust gas temperature at outlet of tube.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Ideal gas with negligible viscous dissipation and pressure variation, (3) Negligible tube wall resistance, (4) Exhaust gas properties are those of air, (5) Negligible radiation effects.

**PROPERTIES:** Table A-4, Air (assume  $T_{m,o} \approx 15^\circ\text{C}$ , hence  $\bar{T}_m = 380\text{ K}$ , 1 atm):  $c_p = 1012\text{ J/kg}\cdot\text{K}$ ,  $k = 0.0323\text{ W/m}\cdot\text{K}$ ,  $\mu = 221.6 \times 10^{-7}\text{ N}\cdot\text{s/m}^2$ ,  $\text{Pr} = 0.694$ ; Air ( $T_\infty = 15^\circ\text{C} = 288\text{ K}$ , 1 atm):  $k = 0.0253\text{ W/m}\cdot\text{K}$ ,  $\nu = 14.82 \times 10^{-6}\text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.710$ ; Air ( $\bar{T}_s \approx 90^\circ\text{C} = 363\text{ K}$ , 1 atm):  $\text{Pr} = 0.698$ .

**ANALYSIS:** (a) For the *internal flow* through the tube assuming a value for  $T_{m,o} = 15^\circ\text{C}$ , find

$$\text{Re}_D = \frac{4\dot{m}}{\pi D\mu} = \frac{4 \times 0.003\text{ kg/s}}{\pi \times 0.006\text{ m} \times 221.6 \times 10^{-7}\text{ N}\cdot\text{s/m}^2} = 2.873 \times 10^4.$$

Hence the flow is turbulent and, since  $L/D \gg 10$ , fully developed. Using the Dittus-Doelter correlation with  $n = 0.3$ ,

$$\text{Nu}_D = 0.023\text{Re}_D^{0.8}\text{Pr}^{0.3} = 0.023(2.873 \times 10^4)^{0.8}(0.694)^{0.3} = 76.0$$

$$h_i = \text{Nu} \cdot k/D = 76.0 \times 0.0323\text{ W/m}\cdot\text{K}/0.006\text{ m} = 409\text{ W/m}^2 \cdot \text{K}. \quad <$$

(b) For *cross-flow* over the circular tube, find using thermophysical properties at  $T_\infty$ ,

$$\text{Re}_D = \frac{VD}{\nu} = \frac{5\text{ m/s} \times 0.006\text{ m}}{14.82 \times 10^{-6}\text{ m}^2/\text{s}} = 2024$$

and using the Zukauskus correlation with  $C = 0.26$ ,  $m = 0.6$ , and  $n = 0.37$ ,

$$\text{Nu}_D = C\text{Re}_D^m\text{Pr}^n(\text{Pr}/\text{Pr}_s)^{1/4} = 0.26(2024)^{0.6}0.710^{0.37}(0.710/0.698)^{0.25} = 22.2$$

where  $\text{Pr}_s$  is evaluated at  $\bar{T}_s$ . Hence,

$$h_o = \text{Nu}_D \cdot k/D = 22.2 \times 0.0253\text{ W/m}\cdot\text{K}/0.006\text{ m} = 93.4\text{ W/m}^2 \cdot \text{K}. \quad <$$

Continued ...

**PROBLEM 8.70 (Cont.)**

(c) Assuming the thermal resistance of the tube wall is negligible,

$$\frac{1}{U} = \frac{1}{h_o} + \frac{1}{h_i} = \left( \frac{1}{93.4} + \frac{1}{409} \right) \text{m}^2 \cdot \text{K/W} \quad U = 76.1 \text{ W/m}^2 \cdot \text{K}. \quad <$$

The gas outlet temperature can be determined from the expression where  $P = \pi D$ .

$$\frac{T_\infty - T_{m,o}}{T_\infty - T_{m,i}} = \exp\left(-\frac{PUL}{\dot{m} c_p}\right) = \exp\left(-\frac{\pi \times 0.006 \text{ m} \times 76.1 \text{ W/m}^2 \cdot \text{K} \times 20 \text{ m}}{0.003 \text{ kg/s} \times 1012 \text{ J/kg} \cdot \text{K}}\right)$$

$$\frac{15 - T_{m,o}}{(15 - 200)^\circ \text{C}} = 7.9 \times 10^{-5}$$

$$T_{m,o} = 15^\circ \text{C}. \quad <$$

**COMMENTS:** (1) With  $T_{m,o} = 15^\circ \text{C}$ , find  $\bar{T}_m = 380 \text{ K}$ ; hence thermophysical properties for the internal flow correlation were evaluated at a reasonable temperature. Note that the gas is cooled from  $200^\circ \text{C}$  to the ambient air temperature,  $T_{m,o} = T_\infty$ , over the 20-m length!

(2) The average wall surface temperature,  $\bar{T}_s$ , follows from an energy balance on the wall surface,

$$\frac{\bar{T}_m - \bar{T}_s}{\bar{T}_s - T_{\text{inf}}} = \frac{h_i}{h_o}$$

and substituting numerical values, find  $\bar{T}_s = 90^\circ \text{C} = 363 \text{ K}$ , the value we assumed for evaluating  $Pr_s$ . Can you draw a thermal circuit to represent this energy balance relation?

(3) When using the Zukauskus correlation, it is reasonable to evaluate  $Pr_s$  at the  $\bar{T}_m$  for the first trial. For gases the assumption is a safe one, but for liquids, especially oils, additional trials will be required since the Prandtl number may be strongly dependent upon temperature.

## PROBLEM 8.71

**KNOWN:** Superheated steam passing through thin-walled pipe covered with insulation and suspended in a quiescent air.

**FIND:** Point along pipe surface where steam will begin condensing ( $x_1$ ).

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Steam is ideal gas with negligible viscous dissipation and pressure variation, (3) Steam properties may be approximated as those corresponding to saturated conditions.

**PROPERTIES:** Table A.6, Saturated steam ( $\bar{T}_m = (100 + 120)^\circ\text{C}/2 = 110^\circ\text{C} \approx 385 \text{ K}$ ):  $\rho_g = 0.876 \text{ kg/m}^3$ ,  $c_{p,g} = 2080 \text{ J/kg}\cdot\text{K}$ ,  $\mu_g = 12.49 \times 10^{-6} \text{ N}\cdot\text{s/m}^2$ ,  $k_g = 0.0258 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr}_g = 1.004$ .

**ANALYSIS:** From Eq. 8.45a, where  $T_{m,x}$  is the mean temperature at any distance  $x$ ,

$$\frac{T_\infty - T_{m,x}}{T_\infty - T_{m,i}} = \exp\left(-\frac{Px}{\dot{m}c_p} U\right) \quad (1)$$

The mass flow rate, with  $A_c = \pi D^2/4$ , is

$$\dot{m} = \rho_g A_c u_m = 0.876 \text{ kg/m}^3 \left( \pi (0.050 \text{ m})^2 / 4 \right) \times 10 \text{ m/s} = 0.0172 \text{ kg/s}$$

and for the internal flow,

$$\text{Re}_D = \frac{4\dot{m}}{\pi D \mu} = \frac{4 \times 0.0172 \text{ kg/s}}{\pi (0.050 \text{ m}) \times 12.49 \times 10^{-6} \text{ N}\cdot\text{s/m}^2} = 35,068.$$

Assuming the flow is fully developed, the Dittus-Boelter correlation yields

$$\text{Nu}_D = \frac{h_i D}{k} = 0.023 (35,068)^{4/5} (1.004)^{0.3} = 99.58$$

$$h_i = \frac{0.0258 \text{ W/m}\cdot\text{K}}{0.050 \text{ m}} \times 99.58 = 51.4 \text{ W/m}^2 \cdot \text{K}$$

Hence, from Eq. 3.36, the overall coefficient for the inner surface is

$$U_i = \left[ \frac{1}{h_i} + \frac{D_i \ln(D_o/D_i)}{2k} + \frac{D_i}{D_o} \frac{1}{h_o} \right]^{-1} = \left[ \frac{1}{51.4} + \frac{(0.050) \ln(0.100/0.050)}{2 \times 0.085} + \frac{0.050}{0.100} \frac{1}{10} \right]^{-1} \text{ W/m}^2 \cdot \text{K}$$

$$U_i = \left[ 1.946 \times 10^{-2} + 2.039 \times 10^{-1} + 5.000 \times 10^{-2} \right]^{-1} = 3.66 \text{ W/m}^2 \cdot \text{K}.$$

Continued...

### PROBLEM 8.71 (Cont.)

With condensation occurring when the surface temperature reaches  $100^\circ\text{C}$ , the corresponding value of  $T_m$  may be determined from the local ( $x = x_1$ ) requirement that  $U_i (\pi D_i) [T_m(x_1) - T_\infty]$

$= h_i (\pi D_i) [T_m(x_1) - T_s]$ . Hence,

$$T_m(x_1) = \frac{T_\infty - (h_i/U_i)T_s}{1 - (h_i/U_i)} = \frac{20 - (51.4/3.66)100^\circ\text{C}}{1 - (51.4/3.66)} = 106^\circ\text{C}$$

The distance at which the mean steam temperature is  $106^\circ\text{C}$  can then be estimated from Eq. (1), where  $P = \pi D_i$  and  $U = U_i$ ,

$$\frac{(20 - 106)^\circ\text{C}}{(20 - 120)^\circ\text{C}} = \exp\left(-\frac{\pi(0.050\text{ m})3.66\text{ W/m}^2 \cdot \text{K}(x_1)}{0.0172\text{ kg/s} \times 2080\text{ J/kg} \cdot \text{K}}\right)$$

$$x_1 = 9.3\text{ m}$$

<

**COMMENTS:** Note that condensation first occurs at the location for which the surface, and not the mean, temperature reaches  $100^\circ\text{C}$ .

## PROBLEM 8.72

**KNOWN:** Length and diameter of air conditioning duct. Inlet temperature of chilled air. Temperature and convection coefficient associated with outer air. Chilled air flowrate.

**FIND:** Chilled air exit temperature and heat flow rate.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Negligible tube wall conduction resistance, (3) Ideal gas with negligible viscous dissipation, pressure variation, and axial conduction.

**PROPERTIES:** Table A-4, Air (300 K, 1 atm):  $c_p = 1007 \text{ J/kg}\cdot\text{K}$ ,  $\mu = 184.6 \times 10^{-7} \text{ kg/s}\cdot\text{m}$ ,  $k = 0.0263 \text{ W/m}\cdot\text{K}$ ,  $Pr = 0.707$ .

**ANALYSIS:** The exit temperature may be obtained from Eq. 8.45a, where

$$\bar{U} = \left( h_i^{-1} + h_o^{-1} \right)^{-1}$$

$$\text{With } Re_D = \left( 4\dot{m} / \pi D \mu \right) = \frac{4(0.05 \text{ kg/s})}{\pi(0.3 \text{ m})184.6 \times 10^{-7} \text{ kg/s}\cdot\text{m}} = 11,495$$

the flow is turbulent and, assuming fully developed conditions over the entire length, the Dittus-Boelter correlation yields

$$Nu_D = 0.023 Re_D^{4/5} Pr^{0.4} = 0.023(11,495)^{4/5} (0.707)^{0.4} = 35.5$$

$$h_i = Nu_D (k/D) = 35.5(0.0263 \text{ W/m}\cdot\text{K}/0.3 \text{ m}) = 3.11 \text{ W/m}^2 \cdot \text{K}$$

$$\text{and } \bar{U} = \left( 3.11^{-1} + 2.0^{-1} \right)^{-1} \left( \text{W/m}^2 \cdot \text{K} \right) = 1.22 \text{ W/m}^2 \cdot \text{K}.$$

$$\text{Eq. 8.45a yields } T_{m,o} = T_{\infty} - (T_{\infty} - T_{m,i}) \exp \left[ -(\pi DL / \dot{m} c_p) \bar{U} \right]$$

$$T_{m,o} = 37^{\circ}\text{C} - 30^{\circ}\text{C} \exp \left[ -\frac{\pi(0.3 \text{ m})15 \text{ m} \left( 1.22 \text{ W/m}^2 \cdot \text{K} \right)}{0.05 \text{ kg/s} (1007 \text{ J/kg}\cdot\text{K})} \right] = 15.7^{\circ}\text{C} \quad <$$

and the heat rate is

$$q = \dot{m} c_p (T_{m,o} - T_{m,i}) = 0.05 \text{ kg/s} (1007 \text{ J/kg}\cdot\text{K}) (8.7^{\circ}\text{C}) = 438 \text{ W}. \quad <$$

**COMMENTS:** (1) The temperature rise of the chilled air is excessive, and the outer surface of the duct should be insulated to reduce  $\bar{U}$  and thereby  $T_{m,o}$  and  $q$ . (2) The temperature selected for evaluating air properties was not very accurate. Air properties should be evaluated at  $\bar{T}_m = (T_{m,o} + T_{m,i}) / 2 \approx 285 \text{ K}$ .

### PROBLEM 8.73

**KNOWN:** Flow conditions associated with water passing through a pipe and air flowing over the pipe.

**FIND:** (a) Differential equation which determines the variation of the mixed-mean temperature of the water, (b) Heat transfer per unit length of pipe at the inlet and outlet temperature of the water.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible temperature drop across the pipe wall, (2) Negligible radiation exchange between outer surface of insulation and surroundings, (3) Fully developed flow throughout pipe, (4) Water is incompressible liquid with negligible viscous dissipation.

**PROPERTIES:** Table A-6, Water ( $T_{m,i} = 200^\circ\text{C}$ ):  $c_{p,w} = 4500 \text{ J/kg}\cdot\text{K}$ ,  $\mu_w = 134 \times 10^{-6} \text{ N}\cdot\text{s/m}^2$ ,  $k_w = 0.665 \text{ W/m}\cdot\text{K}$ ,  $Pr_w = 0.91$ ; Table A-4, Air ( $T_\infty = -10^\circ\text{C}$ ):  $\nu_a = 12.6 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k_a = 0.023 \text{ W/m}\cdot\text{K}$ ,  $Pr_a = 0.71$ ,  $Pr_s \approx 0.7$ .

**ANALYSIS:** (a) Following the development of Section 8.3.1 and applying Eq. 1.12e to a differential element in the water, we obtain

$$dq = -\dot{m} c_{p,w} dT_m$$

where 
$$dq = U_i dA_i (T_m - T_\infty) = U_i \pi D dx (T_m - T_\infty).$$

Substituting into the energy balance, it follows that

$$\frac{dT_m}{dx} = -\frac{U_i \pi D}{\dot{m} c_p} (T_m - T_\infty). \quad (1)$$

The overall heat transfer coefficient based on the inside surface area may be evaluated from Eq. 3.36 which, for the present conditions, reduces to

$$U_i = \frac{1}{\frac{1}{h_i} + \frac{D}{2k} \ln\left(\frac{D+2t}{D}\right) + \frac{D}{D+2t} \frac{1}{h_o}}. \quad (2)$$

For the *inner water flow*, Eq. 8.6 gives

$$Re_D = \frac{4 \dot{m}}{\pi D \mu_w} = \frac{4 \times 2 \text{ kg/s}}{\pi (1 \text{ m}) \times 134 \times 10^{-6} \text{ kg/s}\cdot\text{m}} = 19,004.$$

Continued ...

### PROBLEM 8.73 (Cont.)

Hence, the flow is turbulent. With the assumption of fully developed conditions, it follows from Eq. 8.60 that

$$h_i = \frac{k_w}{D} \times 0.023 \text{Re}_D^{4/5} \text{Pr}_w^{0.3}. \quad (3)$$

For the *external air flow*

$$\text{Re}_D = \frac{V(D+2t)}{\nu} = \frac{4 \text{ m/s}(1.3\text{m})}{12.6 \times 10^{-6} \text{ m}^2/\text{s}} = 4.13 \times 10^5.$$

Using Eq. 7.53 to obtain the outside convection coefficient,

$$h_o = \frac{k_a}{(D+2t)} \times 0.076 \text{Re}_D^{0.7} \text{Pr}_a^{0.37} (\text{Pr}_a / \text{Pr}_s)^{1/4}. \quad (4)$$

(b) The heat transfer per unit length of pipe at the inlet is

$$q' = \pi D U_i (T_{m,i} - T_\infty). \quad (5)$$

From Eqs. (3 and 4),

$$h_i = \frac{0.665 \text{ W/m} \cdot \text{K}}{1 \text{ m}} \times 0.023 (19,004)^{4/5} (0.91)^{0.3} = 39.4 \text{ W/m}^2 \cdot \text{K}$$

$$h_o = \frac{0.023 \text{ W/m} \cdot \text{K}}{(1.3 \text{ m})} \times 0.076 (4.13 \times 10^5)^{0.7} (0.71)^{0.37} (1)^{1/4} = 10.1 \text{ W/m}^2 \cdot \text{K}.$$

Hence, from Eq. (2)

$$U_i = \left[ \frac{1}{39.4 \text{ W/m}^2 \cdot \text{K}} + \frac{1 \text{ m}}{0.1 \text{ W/m} \cdot \text{K}} \ln\left(\frac{1.3}{1}\right) + \frac{1}{1.3} \times \frac{1}{10.1 \text{ W/m}^2 \cdot \text{K}} \right]^{-1} = 0.37 \text{ W/m}^2 \cdot \text{K}$$

and from Eq. (5)

$$q' = \pi (1 \text{ m}) (0.37 \text{ W/m}^2 \cdot \text{K}) (200 + 10)^\circ \text{C} = 244 \text{ W/m}. \quad <$$

Since  $U_i$  is a constant, independent of  $x$ , Eq. (1) may be integrated from  $x = 0$  to  $x = L$ . The result is Eq. 8.45a.

$$\frac{T_\infty - T_{m,o}}{T_\infty - T_{m,i}} = \exp\left(-\frac{\pi DL}{\dot{m} c_{p,w}} U_i\right) = \exp\left(-\frac{\pi \times 1 \text{ m} \times 500 \text{ m}}{2 \text{ kg/s} \times 4500 \text{ J/kg} \cdot \text{K}} \times 0.37 \text{ W/m}^2 \cdot \text{K}\right)$$

Hence 
$$\frac{T_\infty - T_{m,o}}{T_\infty - T_{m,i}} = 0.937.$$

$$T_{m,o} = T_\infty + 0.937(T_{m,i} - T_\infty) = 187^\circ \text{C}. \quad <$$

**COMMENTS:** The largest contribution to the denominator on the right-hand side of Eq. (2) is made by the conduction term (the insulation provides 96% of the total resistance to heat transfer). For this reason the assumption of fully developed conditions throughout the pipe has a negligible effect on the calculations. Since the reduction in  $T_m$  is small ( $13^\circ\text{C}$ ), little error is incurred by evaluating all properties of water at  $T_{m,i}$ .

## PROBLEM 8.74

**KNOWN:** Inner and outer radii and thermal conductivity of a Teflon tube. Flowrate and temperature of confined water. Heat flux at outer surface and temperature and convection coefficient of ambient air.

**FIND:** Fraction of heat transfer to water and temperature of tube outer surface.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Fully-developed flow, (3) One-dimensional conduction, (4) Negligible tape contact and conduction resistances.

**PROPERTIES:** Table A-6, Water ( $T_m = 290\text{K}$ ):  $\mu = 1080 \times 10^{-6} \text{ kg/s}\cdot\text{m}$ ,  $k = 0.598 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 7.56$ .

**ANALYSIS:** The outer surface temperature follows from a surface energy balance

$$(2\pi r_o L)q'' = \frac{T_{s,o} - T_\infty}{(h_o 2\pi r_o L)^{-1}} + \frac{T_{s,o} - T_m}{\left(\ln(r_o/r_i)/2\pi Lk\right) + (1/2\pi r_i L h_i)}$$

$$q'' = h_o (T_{s,o} - T_\infty) + \frac{T_{s,o} - T_m}{(r_o/k)\ln(r_o/r_i) + (r_o/r_i)/h_i}$$

With  $\text{Re}_D = 4 \dot{m}/(\pi D\mu) = 4(0.2\text{kg/s})/[\pi(0.02\text{ m})1080 \times 10^{-6} \text{ kg/s}\cdot\text{m}] = 11,789$

the flow is turbulent and Eq. 8.60 yields

$$h_i = (k/D_i)0.023\text{Re}_D^{4/5}\text{Pr}^{0.4} = (0.598 \text{ W/m}\cdot\text{K}/0.02 \text{ m})(0.023)(11,789)^{4/5}(7.56)^{0.4} = 2792 \text{ W/m}^2\cdot\text{K}.$$

Hence

$$2000 \text{ W/m}^2 = 25 \text{ W/m}^2\cdot\text{K}(T_{s,o} - 300\text{K}) + \frac{T_{s,o} - 290 \text{ K}}{(0.013 \text{ m}/0.35 \text{ W/m}\cdot\text{K})\ln(1.3) + (1.3)/(2792 \text{ W/m}^2\cdot\text{K})}$$

and solving for  $T_{s,o}$ ,  $T_{s,o} = 308.3 \text{ K}$ . <

The heat flux to the air is

$$q''_o = h_o (T_{s,o} - T_\infty) = 25 \text{ W/m}^2\cdot\text{K}(308.3 - 300) \text{ K} = 207.5 \text{ W/m}^2.$$

Hence,  $q''_i/q'' = (2000 - 207.5) \text{ W/m}^2/2000 \text{ W/m}^2 = 0.90$ . <

**COMMENTS:** The resistance to heat transfer by convection to the air substantially exceeds that due to conduction in the teflon and convection in the water. Hence, most of the heat is transferred to the water.

## PROBLEM 8.75

**KNOWN:** Temperature recorded by a thermocouple inserted in a stack containing flue gases with a prescribed flow rate. Diameters and emissivities of thermocouple tube and gas stack. Conditions associated with stack surroundings.

**FIND:** Equations for predicting thermocouple error and error associated with prescribed conditions.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Flue gas has properties of air at  $T_g \approx 327^\circ\text{C}$ , (3) Stack forms a large enclosure about the thermocouple tube and surroundings form a large enclosure around the stack, (4) Stack surface energy balance is unaffected by heat loss to tube, (5) Gas flow is fully developed, (6) Negligible conduction along thermocouple tube, (7) Stack wall is thin.

**PROPERTIES:** Table A-4, Air ( $T_g \approx 600\text{K}$ ,  $p_g = 1\text{ atm}$ ):  $\rho = 0.58\text{ kg/m}^3$ ,  $\mu = 305.8 \times 10^{-7}\text{ N}\cdot\text{s/m}^2$ ,  $\nu = 52.7 \times 10^{-6}\text{ m}^2/\text{s}$ ,  $k = 0.0469\text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.685$ .

**ANALYSIS:** Determination of the thermocouple error necessitates determining the gas temperature  $T_g$  and relating it to the thermocouple temperature  $T_t$ . From an energy balance applied to a control surface about the thermocouple,

$$q_{\text{conv}} = q_{\text{rad}} \quad \text{or} \quad h_t A_t (T_g - T_t) = \varepsilon_t \sigma A_t (T_t^4 - T_s^4).$$

$$\text{Hence} \quad T_g = T_t + \frac{\varepsilon_t \sigma}{h_t} (T_t^4 - T_s^4). \quad (1) <$$

However,  $T_s$  is unknown and must be determined from an energy balance on the stack wall.

$$q_{\text{conv},i} = q_{\text{conv},o} + q_{\text{rad}}$$

$$h_i A_s (T_g - T_s) = h_o A_s (T_s - T_\infty) + \varepsilon_s \sigma A_s (T_s^4 - T_{\text{sur}}^4)$$

$$\text{or} \quad T_g = T_s + \frac{h_o}{h_i} (T_s - T_\infty) + \frac{\varepsilon_s \sigma}{h_i} (T_s^4 - T_{\text{sur}}^4). \quad (2) <$$

$T_g$  and  $T_s$  may be determined by simultaneously solving Eqs. (1) and (2). For the prescribed conditions

$$\text{Re}_{D_t} = \frac{\rho V D_t}{\mu} = \frac{\rho (\dot{m}_g / \rho \pi D_s^2 / 4) D_t}{\mu} = \frac{4 \dot{m}_g D_t}{\pi \mu D_s^2} = \frac{4 \times 1\text{ kg/s} \times 0.01\text{ m}}{\pi \times 305.8 \times 10^{-7}\text{ N}\cdot\text{s/m}^2 (0.6\text{ m})^2} = 1157.$$

Continued ...

**PROBLEM 8.75 (Cont.)**

Assuming  $(Pr/Pr_s) = 1$ , it follows from the Zukauskus correlation

$$\overline{Nu}_D = 0.26 Re_{Dt}^{0.6} Pr^{0.37}$$

where  $C = 0.26$  and  $m = 0.6$  from Table 7.4. Hence

$$h_t = \frac{0.0469 \text{ W/m} \cdot \text{K}}{0.01 \text{ m}} (1157)^{0.6} (0.685)^{0.37} \times 0.26 = 73 \text{ W/m}^2 \cdot \text{K}.$$

Hence, from Eq. (1) 
$$T_g = 573 \text{ K} + \frac{0.8 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4}{73 \text{ W/m}^2 \cdot \text{K}} (573^4 - T_s^4) \text{ K}^4$$

$$T_g = 573 \text{ K} + 67 \text{ K} - 6.214 \times 10^{-10} T_s^4 = 640 - 6.214 \times 10^{-10} T_s^4. \quad (1a)$$

Also, 
$$Re_{Ds} = \frac{4 \dot{m}_g}{\pi D_s \mu} = \frac{4 \times 1 \text{ kg/s}}{\pi (0.6 \text{ m}) 305.8 \times 10^{-7} \text{ N} \cdot \text{s/m}^2} = 6.94 \times 10^4$$

and the gas flow is turbulent. Hence from the Dittus-Boelter correlation,

$$h_i = \frac{k}{D_s} 0.023 Re_{Ds}^{4/5} Pr^{0.3} = \frac{0.0469 \text{ W/m} \cdot \text{K}}{0.6 \text{ m}} \times 0.023 (6.94 \times 10^4)^{4/5} \times (0.685)^{0.3} = 12 \text{ W/m}^2 \cdot \text{K}.$$

Hence from Eq. (2)

$$T_g = T_s + \frac{25}{12} (T_s - 300 \text{ K}) + \frac{0.8 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4}{12 \text{ W/m}^2 \cdot \text{K}} [T_s^4 - 300^4] \text{ K}^4$$

$$T_g = T_s + 2.083 T_s - 625 \text{ K} + 3.78 \times 10^{-9} T_s^4 - 30.6 \text{ K} = -655.6 \text{ K} + 3.083 T_s + 3.78 \times 10^{-9} T_s^4. \quad (2a)$$

Solve Eqs. (1a) and (2a) by trial-and-error. Assume values for  $T_s$  and determine  $T_g$  from (1a) and (2a). Continue until values of  $T_g$  agree.

$T_s$ (K)	$T_g$ (K) $\rightarrow$ (1a)	$T_g$ (K) $\rightarrow$ (2a)
400	624	674
375	628	575
387	626	622
388	626	626

Hence  $T_s = 388 \text{ K}$ ,  $T_g = 626 \text{ K}$

and the thermocouple error is  $T_g - T_t = 626 \text{ K} - 573 \text{ K} = 53^\circ\text{C}$ . <

**COMMENTS:** The thermocouple error results from radiation exchange between the thermocouple tube and the cooler stack wall. Anything done to  $\uparrow T_s$  would  $\downarrow$  this error (e.g.,  $\downarrow h_o$  or  $\uparrow T_\infty$  and  $T_{sur}$ ). The error also  $\downarrow$  with  $\uparrow h_t$ . The error could be reduced by installing a radiation shield around the tube.

## PROBLEM 8.76

**KNOWN:** Platen heated by hot ethylene glycol flowing through tubing arrangement with spacing  $S$  soldered to lower surface. Top surface exposed to convection process.

**FIND:** Tube spacing  $S$  and heating fluid temperature  $T_m$  which will maintain the top surface at  $45 \pm 0.25^\circ\text{C}$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions; (2) Lower surface is insulated, all heat transfer from hot fluid is into platen; (3) Copper tube is thick-walled such that interface between solder and platen is isothermal; (4) Fully developed flow conditions in tube.

**PROPERTIES:** Table A.4, Ethylene glycol ( $T_m = 60^\circ\text{C}$ ):  $\mu = 0.00522 \text{ N}\cdot\text{s}/\text{m}^2$ ,  $k = 0.2603 \text{ W}/\text{m}\cdot\text{K}$ .

**ANALYSIS:** Begin the analysis by setting up a nodal mesh ( $9 \times 6$ ) to represent the platen experiencing convection on the top surface ( $T_\infty$ ,  $h$ ) while the two side boundaries are symmetry adiabats. On the lower surface, nodes 46 and 47 represent the isothermal platen-solder interface maintained at  $T_0$  by the hot fluid. The remaining nodes (49-54) are insulated on their lower boundary.

The heat rate supplied by the tube to the platen can be expressed as

$$q'_{cv} = 0.5h_o(\pi D_i)(T_m - T_0) \quad (1)$$

From energy balances about nodes 46 and 47, the heat rate into the platen by conduction can be expressed as

$$q'_{cd} = q'_a + q'_b + q'_c \quad (2)$$

$$q'_a = k(\Delta x/2)(T_{46} - T_{37})/\Delta y \quad (3)$$

Continued...

**PROBLEM 8.76 (Cont.)**

$$q'_b = k(\Delta x)(T_{47} - T_{38})/\Delta y \quad (4)$$

$$q'_c = k(\Delta y/2)(T_{47} - T_{48})/\Delta x \quad (5)$$

and we require that

$$q'_{cd} = q'_{cv} \quad (6)$$

The convection coefficient for internal flow can be estimated from a correlation assuming fully developed flow. First, characterize the flow with

$$Re_D = \frac{4\dot{m}}{\pi D_i \mu} = \frac{4 \times 0.06 \text{ kg/s}}{\pi (0.008 \text{ m}) 0.00522 \text{ N}\cdot\text{s/m}^2} = 1829$$

and since it is laminar,

$$Nu_D = \frac{h_o D_i}{k} = 3.66$$

$$h_o = 3.66 \times 0.2603 \text{ W/m}\cdot\text{K} / 0.008 \text{ m} = 119.1 \text{ W/m}\cdot\text{K}$$

where properties are evaluated at  $T_m$ . Using the *IHT Finite-Difference Tool for Two-Dimensional Steady-State Conditions* and the *Properties Tool for Ethylene Glycol*, along with the foregoing rate equations and energy balances, Eqs. (1-6), a model was developed to solve for the temperature distribution in the platen. In the solution, we determined what hot fluid temperature was required to maintain  $T_1 = 45^\circ\text{C}$ . Two trials were run. In the first, the nodal arrangement was as shown above ( $9 \times 6$ ) for which  $S/2 = (9 - 1)\Delta x = 42.67 \text{ mm}$  with  $\Delta x = 2D_i/3 = 5.33 \text{ mm}$  and  $\Delta y = w/5 = 5 \text{ mm}$ . In the second trial, we repositioned the right-hand symmetry adiabat to pass vertically through the nodes 6-51 so that now the nodal mesh is ( $6 \times 6$ ) and  $S/2 = (6 - 1)\Delta x = 26.65 \text{ mm}$  with  $\Delta x$  and  $\Delta y$  remaining the same. The results of the trials are tabulated below.

Trial	Mesh	$T_1$ ( $^\circ\text{C}$ )	$T_6$ ( $^\circ\text{C}$ )	$T_9$ ( $^\circ\text{C}$ )	$T_m$ ( $^\circ\text{C}$ )	$q'_{cv}$ (W/m)
1	$9 \times 6$	45.0	43.5	43.0	105	80.5
2	$6 \times 6$	45.0	44.5	---	85	52.6

From the trial 2 results, the surface temperature uniformity is  $(T_1 - T_6) = 0.5^\circ\text{C}$  which satisfies the  $\pm 0.25^\circ\text{C}$  requirement. So that suitable tube spacing and fluid temperature are

$$S = 53 \text{ mm}$$

$$T_m = 85^\circ\text{C}$$

<

**COMMENTS:** (1) Recognize that the grid spacing is quite coarse and good practice demands that we repeat the analysis decreasing the nodal spacing until no further changes are seen in  $T_m$ .

(2) In the first trial, note that  $T_m = 105^\circ\text{C}$  which of course, is not possible.

## PROBLEM 8.77

**KNOWN:** Features of tubing used in a ground source heat pump. Temperature of surrounding soil. Fluid inlet temperature and flowrate.

**FIND:** (a) Effect of tube length on outlet temperature, (b) Recommended tube length and the effect of variations in the flowrate.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Constant properties, (3) Negligible conduction resistance in soil, (4) Incompressible liquid with negligible viscous dissipation, (5) Fluid properties correspond to those of water.

**PROPERTIES:** Table A.6 (assume  $\bar{T}_m = 277 \text{ K}$ ):  $c_p = 4206 \text{ J/kg}\cdot\text{K}$ ,  $\mu = 1560 \times 10^{-6} \text{ N}\cdot\text{s/m}^2$ ,  $k = 0.577 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 11.44$ .

**ANALYSIS:** (a) For the prescribed conditions,  $\text{Re}_D = 4\dot{m}/\pi D_i \mu = 4(0.03 \text{ kg/s})/\pi(0.025 \text{ m})1560 \times 10^{-6} \text{ N}\cdot\text{s/m}^2 = 980$  and the flow is laminar. With  $\text{Pr} > 5$ , Eq. 8.57 may be used to determine the average convection coefficient, with Eq. 8.56 defining the Graetz number:

$$\overline{\text{Nu}}_D = 3.66 + \frac{0.0668(D/L)\text{Re}_D \text{Pr}}{1 + 0.04[(D/L)\text{Re}_D \text{Pr}]^{2/3}}$$

With  $T_s$  used in lieu of  $T_\infty$ , Eq. 8.45b may be used to determine  $T_{m,o}$ ,

$$\frac{T_s - T_{m,o}}{T_s - T_{m,i}} = \exp\left(-\frac{L}{\dot{m}c_p R'_{\text{tot}}}\right)$$

where  $R'_{\text{tot}}$  accounts for the convection and tube wall conduction resistances,

$$R'_{\text{tot}} = R'_{\text{cnv}} + R'_{\text{cnd}} = \left(1/\pi D_i \bar{h}\right) + \ln(D_o/D_i)/2\pi k_t$$

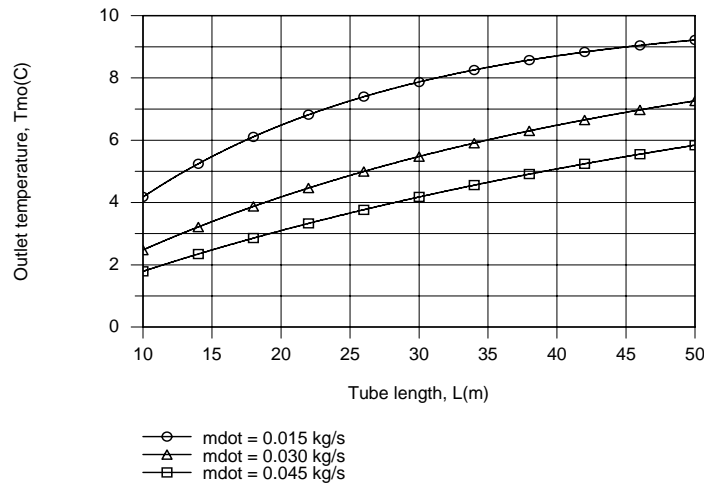

and

$$D_o = D_i + 2t = 41 \text{ mm}.$$

Using the *Correlations and Properties* Toolpads of IHT, the following results were obtained for the effect of the tube length  $L$  on  $T_{m,o}$ .

Continued...

### PROBLEM 8.77 (Cont.)

The longer the tube the larger the rate of heat extraction from the soil, and for  $\dot{m} = 0.030$  kg/s, the temperature rise of  $\Delta T = (T_{m,o} - T_{m,i}) \approx 7^\circ\text{C}$  is well below the maximum possible value of  $\Delta T_{\max} = 10^\circ\text{C}$ .

(b) The length should be *at least* 50 m long. If the flowrate were reduced by 50% ( $\dot{m} = 0.015$  kg/s), the corresponding temperature rise would be close to  $\Delta T_{\max}$  and  $L = 50$  m would be close to optimal. However, for the nominal flowrate and a 50% increase from the nominal, the length should exceed 50 m to recover more heat and provide a heat pump inlet temperature which is closer to the maximum possible value.

**COMMENTS:** In practice, the tube surface temperature would be less than  $10^\circ\text{C}$  (if the temperature of the soil well removed from the tube were at  $10^\circ\text{C}$ ), thereby reducing the heat extraction rate and  $T_{m,o}$ .

### PROBLEM 8.78

**KNOWN:** Effect of entry length on average Nusselt number for turbulent flow in a tube.

**FIND:** Ratio of average to fully developed Nusselt numbers for prescribed conditions.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Sharp edged inlet, (2) Combined entry region.

**ANALYSIS:** From Eq. 8.63,

$$\frac{\overline{Nu}_D}{Nu_{D,fd}} = 1 + \frac{C}{(x/D)^m}$$

and with  $C = 24Re_D^{-0.23}$  and  $m = 0.815 - 2.08 \times 10^{-6} Re_D$ ,

$$\frac{\overline{Nu}_D}{Nu_{D,fd}} = 1 + \frac{24Re_D^{-0.23}}{(x/D)^{(0.815 - 2.08 \times 10^{-6} Re_D)}}$$

It follows that

$\left(\overline{Nu}_D / Nu_{D,fd}\right)$	$Re_D$	$x/D$
1.463	$10^4$	10
1.116	$10^4$	60
1.420	$10^5$	10
1.142	$10^5$	60

**COMMENTS:** The assumption  $\overline{Nu}_D \approx Nu_{fd}$  for  $x/D = 10$  would result in underprediction of  $\overline{Nu}_D$  by approximately 45%. The underprediction is only approximately 10% for  $x/D = 60$ .

### PROBLEM 8.79

**KNOWN:** Fluid enters a thin-walled tube of 5-mm diameter and 2-m length with a flow rate of 0.04 kg/s and temperature of  $T_{m,i} = 85^\circ\text{C}$ ; tube surface temperature is maintained at  $T_s = 25^\circ\text{C}$ ; and, for this *base* operating condition, the outlet temperature is  $T_{m,o} = 31.1^\circ\text{C}$ .

**FIND:** The outlet temperature if the flow rate is doubled?

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Flow is fully developed and turbulent, (2) Fluid properties are independent of temperature, (3) Constant surface temperature cooling conditions, (4) Applicability of Eq. 8.34.

**ANALYSIS:** For the *base* operating condition (b), the rate equation, Eq. 8.41b, with  $C = \dot{m}c_p$ , the capacity rate, is

$$\frac{T_s - T_{m,o})_b}{T_s - T_{m,i}} = \exp\left(-\frac{PL\bar{h}_b}{C_b}\right) \quad (1)$$

Substituting numerical values, with  $P = \pi D$ , find the ratio,  $\bar{h}_b / C_b$ ,

$$\frac{25 - 31.1}{25 - 85} = \exp\left[-\pi \times 0.005 \text{ m} \times 2 \text{ m} \left(\bar{h}_b / C_b\right)\right]$$

$$\bar{h}_b / C_b = 72.77 \text{ m}^{-2}$$

For the *new* operating condition (n), the flow rate is doubled,  $C_n = 2C_b$ , and the convection coefficient scales according to the Dittus-Boelter relation, Eq. 8.60,

$$\bar{h} \propto \text{Re}_D^{0.8} \propto \dot{m}^{0.8}$$

$$\bar{h}_n = 2^{0.8}\bar{h}_b \text{ and } (\bar{h}_n / C_n) = (2^{0.8} / 2)(\bar{h}_b / C_b) \quad (2)$$

Using the rate equation for the new operating condition, find

$$\frac{T_s - T_{m,o})_n}{T_s - T_{m,i}} = \exp\left(-\frac{PL\bar{h}_n}{C_n}\right) = \exp\left[-PL \times 0.871(\bar{h}_b / C_b)\right] \quad (3)$$

$$\frac{25 - T_{m,o})_n}{25 - 85} = \exp\left[-\pi \times 0.005 \text{ m} \times 2 \text{ m} \times 0.871 \times 72.77 \text{ m}^{-2}\right]$$

$$T_{m,o})_n = 33.2^\circ\text{C} \quad <$$

### PROBLEM 8.80

**KNOWN:** Flow rate and inlet temperature of air passing through a rectangular duct of prescribed dimensions and surface heat flux.

**FIND:** Air and duct surface temperatures at outlet.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Uniform surface heat flux, (3) Constant properties, (4) Atmospheric pressure, (5) Fully developed conditions at duct exit, (6) Ideal gas with negligible viscous dissipation and pressure variation.

**PROPERTIES:** Table A-4, Air ( $\bar{T}_m \approx 300\text{K}$ , 1 atm):  $c_p = 1007\text{ J/kg}\cdot\text{K}$ ,  $\mu = 184.6 \times 10^{-7}\text{ N}\cdot\text{s/m}^2$ ,  $k = 0.0263\text{ W/m}\cdot\text{K}$ ,  $Pr = 0.707$ .

**ANALYSIS:** For this uniform heat flux condition, the heat rate is

$$q = q_s'' A_s = q_s'' [2(L \times W) + 2(L \times H)]$$

$$q = 600\text{ W/m}^2 [2(1\text{m} \times 0.016\text{m}) + 2(1\text{m} \times 0.004\text{m})] = 24\text{ W}.$$

From an overall energy balance

$$T_{m,o} = T_{m,i} + \frac{q}{\dot{m} c_p} = 300\text{K} + \frac{24\text{ W}}{3 \times 10^{-4}\text{ kg/s} \times 1007\text{ J/kg}\cdot\text{K}} = 379\text{ K} \quad <$$

The surface temperature at the outlet may be determined from Newton's law of cooling, where

$$T_{s,o} = T_{m,o} + q''/h.$$

From Eqs. 8.66 and 8.1

$$D_h = \frac{4 A_c}{P} = \frac{4(0.016\text{m} \times 0.004\text{m})}{2(0.016\text{m} + 0.004\text{m})} = 0.0064\text{ m}$$

$$Re_D = \frac{\rho u_m D_h}{\mu} = \frac{\dot{m} D_h}{A_c \mu} = \frac{3 \times 10^{-4}\text{ kg/s}(0.0064\text{m})}{64 \times 10^{-6}\text{ m}^2 (184.6 \times 10^{-7}\text{ N}\cdot\text{s/m}^2)} = 1625.$$

Hence the flow is laminar, and from Table 8.1

$$h = \frac{k}{D_h} 5.33 = \frac{0.0263\text{ W/m}\cdot\text{K}}{0.0064\text{ m}} 5.33 = 22\text{ W/m}^2 \cdot \text{K}$$

$$T_{s,o} = 379\text{ K} + \frac{600\text{ W/m}^2}{22\text{ W/m}^2 \cdot \text{K}} = 406\text{ K} \quad <$$

**COMMENTS:** The calculations should be repeated with properties evaluated at  $\bar{T}_m = 340\text{ K}$ . The change in  $T_{m,o}$  would be negligible, and  $T_{s,o}$  would decrease slightly.

## PROBLEM 8.81

**KNOWN:** Inlet temperature and mass flow rate of air flow. Geometry and dimensions of channels through a mold. Mold temperature.

**FIND:** (a) Heat transferred to the air for case A, (b) Heat transferred to the air for case B, and (c) pressure drop for both cases.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Flow is hydrodynamically and thermally fully developed, (2) Mold temperature is uniform. (3) Narrow fins between channels in case B are at the mold temperature.

**PROPERTIES:** Table A-4, Air ( $T \approx 310$  K assumed, 1 atm):  $\rho = 1.128$  kg/m<sup>3</sup>,  $c_p = 1007$  J/kg·K,  $\mu = 189.3 \times 10^{-7}$  N·s/m<sup>2</sup>,  $k = 0.027$  W/m·K.

**ANALYSIS:**

(a) The Reynolds number is

$$Re_D = \frac{4 \dot{m}}{\pi D \mu} = \frac{4 \times 30 \times 10^{-6} \text{ kg/s}}{\pi \times 0.01 \text{ m} \times 189.3 \times 10^{-7} \text{ N} \cdot \text{s/m}^2} = 202$$

Thus, the flow is laminar. Since it has also been assumed that the flow is fully developed and the mold temperature is uniform, the Nusselt number is

$$Nu_D = 3.66$$

Thus  $h = Nu_D k / D = 3.66 \times 0.027 \text{ W/m} \cdot \text{K} / 0.01 \text{ m} = 9.88 \text{ W/m}^2 \cdot \text{K}$ .

The outlet temperature can be found from Equation 8.41b,

$$\begin{aligned} T_{m,o} &= T_s + (T_{m,i} - T_s) \exp\left(-\frac{P L}{\dot{m} c_p} h\right) \\ &= 50^\circ\text{C} + (25^\circ\text{C} - 50^\circ\text{C}) \exp\left(-\frac{\pi \times 0.01 \text{ m} \times 0.1 \text{ m} \times 9.88 \text{ W/m}^2 \cdot \text{K}}{30 \times 10^{-6} \text{ kg/s} \times 1007 \text{ J/kg} \cdot \text{K}}\right) \\ &= 41.0^\circ\text{C} \end{aligned}$$

Thus

$$q = \dot{m} c_p (T_{m,o} - T_{m,i}) = 30 \times 10^{-6} \text{ kg/s} \times 1007 \text{ J/kg} \cdot \text{K} \times (41.0^\circ\text{C} - 25^\circ\text{C}) = 0.485 \text{ W} \quad \leftarrow$$

(b) We first determine the dimensions of the triangular channels from the requirement that the total area is the same as case A.

Continued...

**PROBLEM 8.81 (Cont.)**

$$\pi D^2/4 = 6a^2/2$$

$$a = \left(\frac{\pi}{12}\right)^{1/2} D = \left(\frac{\pi}{12}\right)^{1/2} \times 10 \text{ mm} = 5.1 \text{ mm}$$

and the flowrate in one channel is  $5 \times 10^{-6}$  kg/s.

The hydraulic diameter is  $D_h = 4A_c/P = 4(a^2/2)/3a = 2a/3 = 3.4\text{mm}$ .

The Reynolds number is

$$\text{Re}_D = \frac{4 \dot{m}}{\pi D_h \mu} = \frac{4 \times 5 \times 10^{-6} \text{ kg/s}}{\pi \times 0.0034 \text{ m} \times 189.3 \times 10^{-7} \text{ N}\cdot\text{s/m}^2} = 98.6$$

so the flow is laminar. From Table 8.1, the Nusselt number is  $\text{Nu}_D = 2.47$ , so

$$h = \text{Nu}_D k / D_h = 2.47 \times 0.027 \text{ W/m}\cdot\text{K} / 0.0034 \text{ m} = 19.6 \text{ W/m}^2\cdot\text{K}.$$

The outlet temperature is

$$\begin{aligned} T_{m,o} &= T_s + (T_{m,i} - T_s) \exp\left(-\frac{P L}{\dot{m} c_p} \bar{h}\right) \\ &= 50^\circ\text{C} + (25^\circ\text{C} - 50^\circ\text{C}) \exp\left(-\frac{3 \times 0.0051 \text{ m} \times 0.1 \text{ m} \times 19.0 \text{ W/m}^2 \cdot \text{K}}{5 \times 10^{-6} \text{ kg/s} \times 1007 \text{ J/kg}\cdot\text{K}}\right) \\ &= 49.9^\circ\text{C} \end{aligned}$$

Then using the total flowrate to account for all six channels,

$$\dot{q} = \dot{m} c_p (T_{m,o} - T_{m,i}) = 30 \times 10^{-6} \text{ kg/s} \times 1007 \text{ J/kg}\cdot\text{K} \times (49.9^\circ\text{C} - 25^\circ\text{C}) = 0.753 \text{ W} \quad <$$

(c) The friction factor for case A is  $f = 64/\text{Re}_D = 64/202 = 0.317$ . The pressure drop is, from Equation 8.22a,

$$\Delta p = f \frac{\rho u_m^2}{2D} L$$

with  $u_m = \dot{m} / \rho A_c = 30 \times 10^{-6} \text{ kg/s} / (1.128 \text{ kg/m}^3 \times \pi (0.01 \text{ m})^2 / 4) = 0.339 \text{ m/s}$ . Thus

$$\Delta p = 0.317 \times \frac{1.128 \text{ kg/m}^3 \times (0.339 \text{ m/s})^2}{2 \times 0.01 \text{ m}} \times 0.1 \text{ m} = 0.205 \text{ Pa} \quad <$$

For Case B, from Table 8.1,  $f = 53/\text{Re}_D = 53/98.6 = 0.538$ , and  $u_m = 0.339 \text{ m/s}$  as in Case A. Thus

$$\Delta p = f \frac{\rho u_m^2}{2D_h} L = 0.538 \times \frac{1.128 \text{ kg/m}^3 \times (0.339 \text{ m/s})^2}{2 \times 0.0034 \text{ m}} \times 0.1 \text{ m} = 1.02 \text{ Pa} \quad <$$

COMMENTS: (1) Segmenting the channel into six smaller sections increases the heat transfer by 55%, but at the expense of almost a five-fold increase in the pressure drop. (2) For the circular duct, the hydrodynamic entry length, is  $x_{fd,h} = 0.05 \text{ Re}_D D = 0.1 \text{ m}$ , so it is not fully developed as assumed. For the triangular duct,  $x_{fd,h} = 0.05 \text{ Re}_D D_h = 0.02 \text{ m}$ , so the assumption is more appropriate. The thermal development length is shorter, since  $\text{Pr} = 0.7$ .

## PROBLEM 8.82

**KNOWN:** Dimensions, surface temperature and thermal conductivity of a *cold plate*. Velocity, inlet temperature, and properties of coolant.

**FIND:** (a) Model for determining the heat rate  $q$  and outlet temperature,  $T_{m,o}$ . (b) Values of  $q$  and  $T_{m,o}$  for prescribed conditions.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Incompressible liquid with negligible viscous dissipation, (3) Constant properties, (4) Symmetry about the midplane (horizontal) of the cold plate and the midplane (vertical) of each cooling channel, (5) Negligible heat transfer at sidewalls of cold plate, (6) One-dimensional conduction from outer surface of cold plate to base surface of channel and within the channel side walls, which act as extended surfaces.

**PROPERTIES:** Water (prescribed):  $\rho = 984 \text{ kg/m}^3$ ,  $c_p = 4184 \text{ J/kg}\cdot\text{K}$ ,  $\mu = 489 \times 10^{-6} \text{ N}\cdot\text{s/m}^2$ ,  $k = 0.65 \text{ W/m}\cdot\text{K}$ ,  $Pr = 3.15$ .

**ANALYSIS:** (a) The outlet temperature,  $T_{m,o}$ , may be determined from the energy balance prescribed by Eq. 8.45b,

$$\frac{T_s - T_{m,o}}{T_s - T_{m,i}} = \exp\left(-\frac{1}{\dot{m}_1 c_p R_{\text{tot}}}\right)$$

where  $\dot{m}_1 = \rho u_m A_c$  is the flowrate for a single channel and  $R_{\text{tot}}$  is the total resistance to heat transfer between the cold plate surface and the coolant for a particular channel. This resistance may be determined from the symmetrical section shown schematically, which represents one-half of the cell associated with a full channel. With the number of channels (and cells) corresponding to  $N = W/S$ , there are  $2N = 2(W/S)$  symmetrical sections, and the total resistance  $R_{\text{tot}}$  of a cell is one-half that of a symmetrical section. Hence,  $R_{\text{tot}} = R_{\text{ss}}/2$ , where the resistance of the symmetrical section includes the effect of conduction through the outer wall of the cold plate and convection from the inner surfaces. Hence,

$$R_{\text{ss}} = \frac{(H-h)/2}{k_{cp}(SW)} + \frac{1}{\eta_o \bar{h} A_t}$$

where  $A_t = A_f + A_b = 2(h/2 \times W) + (w \times W)$ ,  $\bar{h}$  is the average convection coefficient for the channel flow, and  $\eta_o$  is the overall surface efficiency.

$$\eta_o = 1 - \frac{A_f}{A_t} (1 - \eta_f)$$

Continued...

### PROBLEM 8.82 (Cont.)

The efficiency  $\eta_f$  corresponds to that of a straight, rectangular fin with an adiabatic tip, Eq. 3.92, and  $L_c = w/2$ . With  $D_h = 4A_c/P = 4w^2/4w = w = 0.006\text{ m}$ ,  $Re_{D_h} = \rho u_m D_h/\mu = 984\text{ kg/m}^3 \times 2\text{ m/s} \times 0.006\text{ m}/489 \times 10^{-6}\text{ N}\cdot\text{s/m}^2 = 24,150$  and the channel flow is turbulent. Assuming fully-developed flow throughout the channel, the Dittus-Boelter correlation, Eq. 8.60, may therefore be used to evaluate  $\bar{h}$ , where

$$\overline{Nu}_D \approx Nu_{D,fd} = 0.023 Re_D^{4/5} Pr^{0.4}$$

The total heat rate for the cold plate may be expressed as

$$q = Nq_1 = N\dot{m}_1 c_p (T_{m,o} - T_{m,i})$$

(b) For the prescribed conditions,

$$\dot{m}_1 = \rho u_m A_c = 984\text{ kg/m}^3 (2\text{ m/s})(0.006\text{ m})^2 = 0.0708\text{ kg/s}$$

$$\overline{Nu}_D = 0.023(24,150)^{4/5} (3.15)^{0.4} = 116.8$$

$$\bar{h} = 116.8\text{ k/D}_h = 116.8(0.65\text{ W/m}\cdot\text{K})/(0.006\text{ m}) = 12,650\text{ W/m}^2\cdot\text{K}$$

$$A_f = 2(h/2 \times W) = 2(0.003\text{ m} \times 0.1\text{ m}) = 6 \times 10^{-4}\text{ m}^2$$

$$A_t = A_f + A_b = 6 \times 10^{-4}\text{ m}^2 + (0.006\text{ m} \times 0.1\text{ m}) = 1.2 \times 10^{-3}\text{ m}^2$$

With  $m = (\bar{h}P_f/k_{cp}A_{cf})^{1/2} = [\bar{h}(2\delta + 2W)/k_{cp}(\delta W)]^{1/2} = [12,650\text{ W/m}^2\cdot\text{K}(0.008 + 0.200)\text{m}/400\text{ W/m}\cdot\text{K}(0.004 \times 0.100)\text{m}^2]^{1/2} = 128.2\text{ m}^{-1}$ .

$$\eta_f = \frac{\tanh m(h/2)}{m(h/2)} = \frac{\tanh(128.2 \times 0.003)}{128.2 \times 0.003} = \frac{0.366}{0.385} = 0.952$$

$$\eta_o = 1 - 0.5(1 - 0.952) = 0.976$$

$$R_{ss} = \frac{(0.010 - 0.006)\text{m}/2}{400\text{ W/m}\cdot\text{K}(0.01\text{ m} \times 0.1\text{ m})} + \frac{1}{0.976(12650\text{ W/m}^2\cdot\text{K})1.2 \times 10^{-3}\text{ m}^2}$$

$$R_{ss} = (0.005 + 0.0675)\text{ K/W} = 0.0725\text{ K/W}$$

With  $R_{\text{tot}} = R_{ss}/2 = 0.0362\text{ K/W}$ ,

$$\frac{T_s - T_{m,o}}{T_s - T_{m,i}} = \exp\left(-\frac{1}{0.0708\text{ kg/s} \times 4184\text{ J/kg}\cdot\text{K} \times 0.0362\text{ K/W}}\right) = 0.911$$

$$T_{m,o} = T_s - 0.911(T_s - T_{m,i}) = 360\text{ K} - 0.911(360 - 300)\text{ K} = 305.3\text{ K} \quad <$$

The total heat rate is

$$q = N\dot{m}_1 c_p (T_{m,o} - T_{m,i}) = 10 \times 0.0708\text{ kg/s} \times 4184\text{ J/kg}\cdot\text{K} (305.3 - 300)\text{ K} = 15,700\text{ W} \quad <$$

**COMMENTS:** The prescribed properties correspond to a value of  $\bar{T}_m$  which significantly exceeds that obtained from the foregoing solution ( $\bar{T}_m = 302.6\text{ K}$ ). Hence, the calculations should be repeated using more appropriate thermophysical properties (see next problem). From Eq. 3.90, the effectiveness of the extended surface is

$$\varepsilon = R_{t,b}/R_{t,f} = (\bar{h}\delta W)^{-1}/(\bar{h}A_f\eta_f)^{-1} = (A_f\eta_f/\delta W) = (6 \times 10^{-4}\text{ m}^2 \times 0.954)/(0.004\text{ m} \times 0.10\text{ m}) = 1.43.$$

Hence, the ribs are only marginally effective in enhancing heat transfer to the coolant.

### PROBLEM 8.83

**KNOWN:** Geometry, surface temperature and thermal conductivity of a *cold plate*. Velocity and inlet temperature of coolant.

**FIND:** Effect of channel width on total heat rate.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Incompressible liquid with negligible viscous dissipation, (3) Constant properties, (4) Symmetry about midplane (horizontal) of the cold plate and the midplane (vertical) of each channel, (5) Negligible heat transfer at sidewalls of cold plate, (6) One-dimensional conduction from outer surface of cold plate to base surface of channel and within the channel side walls, which act as extended surfaces.

**PROPERTIES:** Water: Evaluated at  $\bar{T}_m$  using the *Properties* Toolpad of IHT.

**ANALYSIS:** The model developed for the preceding problem was entered into the workspace of IHT, with the Dittus-Boelter equation and exponential relation accessed from the *Correlations* Toolpad and modified to account for the hydraulic diameter and the total resistance to heat transfer. Calculations were performed for

- |         |  |
|---------|--|
| Case 1: | $w = 96\text{ mm}, N = 1, S = W = 100\text{ mm}$ |
| Case 2: | $w = 46\text{ mm}, N = 2, S = 50\text{ mm}$      |
| Case 3: | $w = 21\text{ mm}, N = 4, S = 25\text{ mm}$      |
| Case 4: | $w = 6\text{ mm}, N = 10, S = 10\text{ mm}$      |
| Case 5: | $w = 1\text{ mm}, N = 20, S = 5\text{ mm}$       |

and the results are tabulated as follows.

Case	N	$D_h$ (m)	$Re_D$	$\bar{h}$ ( $\text{W}/\text{m}^2 \cdot \text{K}$ )	$T_{m,o}$ (K)	q (W)
1	1	0.01129	26,920	8783	302.1	10,090
2	2	0.01062	25,310	8892	302.3	10,370
3	4	0.00933	22,340	9142	302.6	10,960
4	10	0.00600	14,630	10,070	304.3	12,950
5	20	0.00171	4760	13,740	317.2	17,160

It is clearly beneficial to increase the number of channels, with the total heat rate increasing by approximately a factor of 5 as N increases from 1 to 20. The heat rate may be increased further by increasing  $u_m$ , and hence the flowrate per channel, although an upper limit would be associated with the pressure drop, which would increase with decreasing  $D_h$ . Could additional heat transfer enhancement be achieved by altering the thickness  $\delta$  of the channel walls?

**COMMENTS:** (1) Note that results obtained for Case 4 differ from those of the preceding problem due to different fluid properties. In this case the properties were evaluated at the actual value of  $\bar{T}_m = 302.2\text{ K}$ , rather than at an assumed (significantly larger) value. (2) Note that the Dittus-Boelter correlation is applied outside its intended range for the Reynolds number of case 5. The Gnielinski correlation would be preferable.

### PROBLEM 8.84

**KNOWN:** Temperature and velocity of gas flow between parallel plates of prescribed surface temperature and separation. Thickness and location of plate insert.

**FIND:** Heat flux to the plates (a) without and (b) with the insert.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Negligible radiation, (3) Gas has properties of atmospheric air, (4) Plates are of infinite width  $W$ , (5) Fully developed flow.

**PROPERTIES:** Table A-4, Air (1 atm,  $T_m = 1000$  K):  $\rho = 0.348 \text{ kg/m}^3$ ,  $\mu = 424.4 \times 10^{-7} \text{ kg/s}\cdot\text{m}$ ,  $k = 0.0667 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.726$ .

**ANALYSIS:** (a) Based upon the hydraulic diameter  $D_h$ , the Reynolds number is

$$D_h = 4 A_c / P = 4(H \cdot W) / 2(H + W) = 2H = 80 \text{ mm}$$

$$\text{Re}_{D_h} = \frac{\rho u_m D_h}{\mu} = \frac{0.348 \text{ kg/m}^3 (60 \text{ m/s}) 0.08 \text{ m}}{424.4 \times 10^{-7} \text{ kg/s}\cdot\text{m}} = 39,360.$$

Since the flow is fully developed and turbulent, use the Dittus-Boelter correlation,

$$\text{Nu}_D = 0.023 \text{Re}_D^{4/5} \text{Pr}^{0.3} = 0.023(39,360)^{4/5} (0.726)^{0.3} = 99.1$$

$$h = \frac{k}{D_h} \text{Nu}_D = \frac{0.0667 \text{ W/m}\cdot\text{K}}{0.08 \text{ m}} 99.1 = 82.6 \text{ W/m}^2 \cdot \text{K}$$

$$q'' = h(T_m - T_s) = 82.6 \text{ W/m}^2 \cdot \text{K} (1000 - 350) \text{ K} = 53,700 \text{ W/m}^2. \quad <$$

(b) From continuity,

$$\dot{m} = (\rho u_m A)_a = (\rho u_m A)_b \quad u_m)_b = u_m)_a (\rho A)_a / (\rho A)_b = 60 \text{ m/s} (40/20) = 120 \text{ m/s}.$$

For each of the resulting channels,  $D_h = 0.02 \text{ m}$  and

$$\text{Re}_{D_h} = \frac{\rho u_m D_h}{\mu} = \frac{0.348 \text{ kg/m}^3 (120 \text{ m/s}) 0.02 \text{ m}}{424.4 \times 10^{-7} \text{ kg/s}\cdot\text{m}} = 19,680.$$

Since the flow is still turbulent,

$$\text{Nu}_D = 0.023(19,680)^{4/5} (0.726)^{0.3} = 56.9 \quad h = \frac{56.9(0.0667 \text{ W/m}\cdot\text{K})}{0.02 \text{ m}} = 189.8 \text{ W/m}^2 \cdot \text{K}$$

$$q'' = 189.8 \text{ W/m}^2 \cdot \text{K} (1000 - 350) \text{ K} = 123,400 \text{ W/m}^2. \quad <$$

**COMMENTS:** From the Dittus-Boelter equation,

$$h_b / h_a = (u_{m,b} / u_{m,a})^{0.8} (D_{h,a} / D_{h,b})^{0.2} = (2)^{0.8} (4)^{0.2} = 1.74 \times 1.32 = 2.30.$$

Hence, heat transfer enhancement due to the insert is primarily a result of the increase in  $u_m$  and secondarily a result of the decrease in  $D_h$ .

### PROBLEM 8.85

**KNOWN:** Temperature, pressure and flow rate of air entering a rectangular duct of prescribed dimensions and surface temperature.

**FIND:** Air outlet temperature and duct heat transfer rate.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Constant properties, (3) Uniform surface temperature, (4) Fully developed flow throughout, (5) Ideal gas with negligible viscous dissipation and pressure variation.

**PROPERTIES:** Table A-4, Air (assume  $T_m \approx 325\text{K}$ , 1 atm):  $c_p = 1008\text{ J/kg}\cdot\text{K}$ ,  $\mu = 196.4 \times 10^{-7}\text{ N}\cdot\text{s/m}^2$ ,  $k = 0.0282\text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.707$ .

**ANALYSIS:** From Eqs. 8.66 and 8.1,

$$D_h = \frac{4 A_c}{P} = \frac{4 \times (0.15 \times 0.075)\text{ m}^2}{2(0.15 + 0.075)\text{ m}} = 0.10\text{ m}$$

$$\text{Re}_D = \frac{\rho u_m D_h}{\mu} = \frac{\dot{m} D_h}{A_c \mu} = \frac{0.1\text{ kg/s}(0.1\text{ m})}{(0.15\text{ m} \times 0.075\text{ m})196.4 \times 10^{-7}\text{ N}\cdot\text{s/m}^2} = 45,260.$$

Hence the flow is turbulent, and from Eq. 8.60

$$h = \frac{k}{D_h} 0.023 \text{Re}_D^{4/5} \text{Pr}^{0.4} = \frac{0.0282\text{ W/m}\cdot\text{K}}{0.10\text{ m}} 0.023(45,260)^{4/5} (0.707)^{0.4} = 30\text{ W/m}^2\cdot\text{K}.$$

From Eq. 8.41b, with  $P = 2(W + H)$ ,

$$T_{m,o} = T_s - (T_s - T_{m,i}) \exp\left(-\frac{PL}{\dot{m} c_p} \bar{h}\right)$$

$$T_{m,o} = 400\text{ K} - (400 - 285)\text{ K} \exp\left[-\frac{2(0.15\text{ m} + 0.075\text{ m})2\text{ m}(30\text{ W/m}^2\cdot\text{K})}{0.1\text{ kg/s} \times 1008\text{ J/kg}\cdot\text{K}}\right]$$

$$T_{m,o} = 312\text{ K} \quad <$$

and from Eq. 8.34

$$q = \dot{m} c_p (T_{m,o} - T_{m,i}) = 0.1\text{ kg/s} \times 1008\text{ J/kg}\cdot\text{K} (312 - 285)\text{ K} = 2724\text{ W}. \quad <$$

**COMMENTS:** (1) The calculations may be checked by determining  $q$  from Eqs. 8.43 and 8.44. We obtain  $\Delta T_{\ell m} = 101^\circ\text{C}$  and  $q = 2724\text{ W}$ .

(2)  $\bar{T}_m$  has been over-estimated. The calculations should be repeated with properties evaluated at  $\bar{T}_m = 299\text{ K}$ .

## PROBLEM 8.86

**KNOWN:** Dimensions of semi-circular copper tubes in contact at plane surfaces. Thermal contact resistance. Tube flow conditions.

**FIND:** (a) Heat rate per unit tube length, and (b) The effect on the heat rate when the fluids are ethylene glycol, the exchanger tube is fabricated from an aluminum alloy, or the exchanger tube thickness is increased.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Constant properties, (3) Adiabatic outer surface, (4) Fully developed flow, (5) Negligible heat loss to surroundings.

**PROPERTIES:** Table A.1, Copper ( $T \approx 300$  K):  $k = 400$  W/m·K; Water (given):  $\mu = 800 \times 10^{-6}$  kg/s·m,  $k = 0.625$  W/m·K,  $Pr = 5.35$ .

**ANALYSIS:** (a,b) Heat transfer from the hot to cold fluids is *enhanced* by conduction through the semi-circular portions of the tube walls. The walls may be approximated as straight fins with an insulated tip, and the thermal circuit is shown below.

Note that, since each semi-circular surface is insulated on one side, surfaces may be combined to yield a *single* fin of thickness  $2t$  with convection on both sides. Also, due to the equivalent geometry and the assumption of constant properties, there is symmetry on opposite sides of the contact resistance. From the thermal circuit, the heat rate is

$$q' = \frac{T_{h,m} - T_{c,m}}{R'_{tot}} \quad (1)$$

For flow through the semi-circular tube,

$$\begin{aligned} Re_D &= \frac{\rho u_m D_h}{\mu} = \frac{\dot{m} D_h}{A_c \mu} = \frac{4 \dot{m} A_c}{A_c P \mu} = \frac{4 \dot{m}}{P \mu} = \frac{4 \dot{m}}{(2r_i + \pi r_i) \mu} \\ Re_D &= \frac{4 \times 0.2 \text{ kg/s}}{(2 + \pi) 0.02 \text{ m} \times 800 \times 10^{-6} \text{ kg/s} \cdot \text{m}} = 9725 \end{aligned} \quad (2)$$

the flow is turbulent. Using the Gnielinski correlation, since  $Re_D < 10,000$

$$Nu_D = \frac{(f/8)(Re_D - 1000) Pr}{1 + 12.7(f/8)^{1/2} (Pr^{2/3} - 1)} = 69.9 \quad (3)$$

Continued...

**PROBLEM 8.86 (Cont.)**

where  $f = (0.79 \ln(\text{Re}_D) - 1.64)^{-2} = 0.0317$

$$D_h = \frac{4A_c}{P} = \frac{4(\pi r_1^2/2)}{(\pi + 2)r_1} = \frac{2\pi}{\pi + 2} 0.02 \text{ m} = 0.0244 \text{ m} \quad (4)$$

$$h = \text{Nu}_D \frac{k}{D_h} = 69.9 \frac{0.625}{0.0244} = 1790 \text{ W/m}^2 \cdot \text{K} \quad (5)$$

Find now values for the thermal resistance of the circuit.

$$R'_{\text{conv}} = \frac{1}{2r_1 h} = \frac{1}{(0.04 \text{ m}) 1790 \text{ W/m}^2 \cdot \text{K}} = 0.0140 \text{ m} \cdot \text{K/W} \quad (6)$$

$$R'_{\text{fin}} = \frac{\theta_b}{q'_f} = \frac{1}{(hP'kA'_c)^{1/2} \tanh(hP/kA_c)L} \quad (7)$$

$$L = \pi r_1/2 = \pi(0.01 \text{ m}) = 0.0314 \text{ m} \quad A_c = 2t \cdot 1 \text{ m} = 0.006 \text{ m}^2 \quad P \approx 2.1 \text{ m} \quad (8,9,10)$$

$$(hP'kA'_c)^{1/2} = \left(1790 \text{ W/m}^2 \cdot \text{K} \times 2 \text{ m/m} \times 400 \text{ W/m} \cdot \text{K} \times 0.006 \text{ m}^2/\text{s}\right)^{1/2} = 92.7 \text{ W/K} \cdot \text{m}$$

$$(hP/kA_c)^{1/2} L = \left(1790 \text{ W/m}^2 \cdot \text{K} \times 2 \text{ m} / 400 \text{ W/m} \cdot \text{K} \times 0.006 \text{ m}^2\right)^{1/2} 0.0314 \text{ m} = 1.21$$

$$R'_{\text{fin}} = \frac{1}{92.7 \text{ W/m} \cdot \text{K} (0.838)} = 0.0129 \text{ m} \cdot \text{K/W} \quad (11)$$

$$R'_{\text{cond}} = \frac{t}{2kr_1} = \frac{0.003 \text{ m}}{2(400 \text{ W/m} \cdot \text{K})(0.02 \text{ m})} = 1.875 \times 10^{-4} \text{ m} \cdot \text{K/W} \quad (12)$$

$$R'_{t,c} = \frac{R''_{t,c}}{2r_1} = \frac{10^{-5} \text{ m}^2 \cdot \text{K/W}}{2(0.02 \text{ m})} = 2.5 \times 10^{-4} \text{ m} \cdot \text{K/W} \quad (13)$$

The equivalent resistance of the parallel circuit is

$$R'_{\text{eq}} = \left(R'_{\text{fin}}{}^{-1} + R'_{\text{conv}}{}^{-1}\right)^{-1} = \left(77.6 \text{ W/m} \cdot \text{K} + 71.5 \text{ W/m} \cdot \text{K}\right)^{-1} = 6.70 \times 10^{-3} \text{ m} \cdot \text{K/W} \quad (14)$$

Hence

$$R'_{\text{tot}} = 2\left(R'_{\text{eq}} + R'_{\text{cond}}\right) + R'_{t,c} \quad (15)$$

$$R'_{\text{tot}} = \left[2\left(6.70 \times 10^{-3} + 1.875 \times 10^{-4}\right) + 2.50 \times 10^{-4}\right] \text{ m} \cdot \text{K/W} = 0.0140 \text{ m} \cdot \text{K/W}$$

$$q' = \frac{(330 - 290) \text{ K}}{0.0140 \text{ m} \cdot \text{K/W}} = 2850 \text{ W/m} \cdot \text{K} \quad \leftarrow$$

(c) Using the *IHT Workspace* with the foregoing equations, analyses were performed and the results summarized in the table below. The “Conditions” are described below; the “Change” is relative to the base case condition.

Continued ...

### PROBLEM 8.86 (Cont.)

Condition*	$R'_{\text{conv}} \times 10^4$ (m·K/W)	$R'_{\text{fin}} \times 10^4$ (m·K/W)	$R'_{\text{cond}} \times 10^4$ (m·K/W)	$R'_{\text{tot}} \times 10^4$ (m·K/W)	$R'_{\text{eq}} \times 10^4$ (m·K/W)	$q'$ (W/m)	Change (%)
Base case	140	129	1.88	140	67.0	2850	--
Ethylene glycol	6550	4210	1.88	5130	2560	77.9	-97
Aluminum alloy	140	171	4.24	165	76.9	2430	-15
Thicker tube	140	120	2.50	136	64.4	2930	+2.8

\*Conditions: change from base case

Base case - water, copper ( $k = 400 \text{ W/m}\cdot\text{K}$ ),  $t = 3 \text{ mm}$

Ethylene glycol - ethylene glycol instead of water,  $Re_D = 727$ , laminar,  $Nu_D = 3.66$  estimated

Aluminum alloy - alloy ( $k = 177 \text{ W/m}\cdot\text{K}$ ) instead of copper

Thicker tube -  $t = 4 \text{ mm}$  instead of  $3 \text{ mm}$

As expected, using ethylene glycol as the working fluid would decrease the heat rate, especially because the flow becomes laminar. Note that  $R'_{\text{conv}}$  is the dominate resistance since the convection coefficient is considerably reduced compared to that with water. Using aluminum alloy, rather than copper, as the tube material reduces the heat rate by 14%. Conduction-convection (fin) in the tube wall is important as can be seen by examining the change in  $R'_{\text{fin}}$  relative to the base condition. Increasing the tube wall thickness for the copper tube exchanger from 3 to 4 mm had only a marginal positive effect on the heat rate.

**COMMENTS:** A more accurate calculation would account for the absence of symmetry about the contact plane. Evaluation of water properties at  $T_{h,m} = 330 \text{ K}$  and  $T_{c,m} = 290 \text{ K}$  yields  $h_h = 1930 \text{ W/m}^2\cdot\text{K}$  and  $h_c = 1470 \text{ W/m}^2\cdot\text{K}$ .

### PROBLEM 8.87

**KNOWN:** Rectangular channel with constant surface temperature. Aspect ratio.

**FIND:** Which aspect ratio channel provides the largest heat transfer rate. Whether this is greater than, equal to, or less than the heat transfer rate for a circular tube.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, (2) Incompressible flow, (3) Laminar, (4) Fully-developed.

**ANALYSIS:** The heat transfer rate is given by  $q_s = \dot{m}c_p(T_{m,o} - T_{m,i})$ , where from Eq. 8.41b with constant heat transfer coefficient,

$$T_{m,o} - T_{m,i} = (T_s - T_{m,i}) \left[ 1 - \exp\left(-\frac{hPL}{\dot{m}c_p}\right) \right]$$

Thus, the heat transfer rate increases with increasing values of

$$\frac{hPL}{\dot{m}c_p} = \frac{Nu_k PL}{\dot{m}c_p D_h} = \frac{Nu_k P^2 L}{4\dot{m}c_p A_c}$$

For fixed mass flow rate and length, and assuming the same properties, the relevant parameter that determines the heat transfer rate is therefore  $NuP^2/A_c$ . For a rectangular channel,  $P^2/A_c = 4(a+b)^2/ab = 4(1+b/a)^2/(b/a)$ , whereas for a circular tube,  $P^2/A_c = 4\pi$ . The table below compares values of  $NuP^2/A_c$  for the three different aspect ratio rectangular channels and a circular tube.

$b/a$	$Nu$	$P^2/A_c$	$NuP^2/A_c$
1.0	2.98	16	47.7
1.43	3.08	16.5	50.9
2.0	3.39	18	61.0
Circular tube	3.66	12.6	46.0

The rectangular channel with  $b/a = 2.0$  provides the largest heat transfer rate, which is larger than for a circular tube. <

**COMMENTS:** The Nusselt numbers for the rectangular channel are all less than 3.66 for the circular tube, but their convective heat transfer rates are larger than that of the circular tube because their  $P^2/A_c$  values are larger.

### PROBLEM 8.88

**KNOWN:** Heat exchanger to warm blood from a storage temperature  $10^\circ\text{C}$  to  $37^\circ$  at  $200\text{ ml/min}$ . Tubing has rectangular cross-section  $6.4\text{ mm} \times 1.6\text{ mm}$  sandwiched between plates maintained at  $40^\circ\text{C}$ .

**FIND:** (a) Length of tubing and (b) Assessment of assumptions to indicate whether analysis under- or over-estimates length.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Incompressible liquid with negligible viscous dissipation, (3) Blood flow is fully developed, (4) Blood has properties of water, and (5) Negligible tube wall and contact resistance.

**PROPERTIES:** Table A-6, Water ( $\bar{T}_m \approx 300\text{ K}$ ):  $c_{p,f} = 4179\text{ J/kg}\cdot\text{K}$ ,  $\rho_f = 1/v_f = 997\text{ kg/m}^3$ ,  $v_f = \mu_f/\nu_f = 8.58 \times 10^{-7}\text{ m}^2/\text{s}$ ,  $k = 0.613\text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 5.83$ .

**ANALYSIS:** (a) From an overall energy balance and the rate equation,

$$q = \dot{m} c_p (T_{m,o} - T_{m,i}) = \bar{h} A_s \Delta T_{\text{LMTD}} \quad (1)$$

where

$$\Delta T_{\text{LMTD}} = \frac{\Delta T_1 - \Delta T_2}{\ln(\Delta T_1 / \Delta T_2)} = \frac{(40 - 15) - (40 - 37)}{\ln(25/3)} = 11.7^\circ\text{C}.$$

To estimate  $\bar{h}$ , find the Reynolds number for the rectangular tube,

$$\text{Re}_D = \frac{u_m D_h}{\nu} = \frac{0.326\text{ m/s} \times 0.00256\text{ m}}{8.58 \times 10^{-7}\text{ m}^2/\text{s}} = 973$$

where

$$D_h = 4 A_c / P = 4(6.4\text{ mm} \times 1.6\text{ mm}) / 2(6.4 + 1.6)\text{ mm} = 2.56\text{ mm}$$

$$A_c = (6.4\text{ mm} \times 1.6\text{ mm}) = 1.024 \times 10^{-5}\text{ m}^2$$

$$u_m = \dot{m} / \rho A_c = \dot{V} / A_c = 200\text{ ml} / 60\text{ s} \left( 10^{-6}\text{ m}^3 / \text{ml} \right) / 1.024 \times 10^{-5}\text{ m}^2 = 0.326\text{ m/s}.$$

Hence the flow is laminar, but assuming fully developed flow with an isothermal surface from Table 8.1 with  $b/a = 6.4/1.6 = 4$ ,

$$\text{Nu}_D = \frac{h D_h}{k} = 4.44 \quad h = \frac{4.44 \times 0.613\text{ W/m}\cdot\text{K}}{0.00256\text{ m}} = 1063\text{ W/m}^2\cdot\text{K}.$$

Continued ...

### PROBLEM 8.88 (Cont.)

From Eq. (1) with

$$A_s = PL = 2(6.4 + 1.6) \times 10^{-3} \text{ m} \times L = 1.6 \times 10^{-2} L$$

$$\dot{m} = \rho A_c u_m = 997 \text{ kg/m}^3 \times 1.024 \times 10^{-5} \text{ m}^2 \times 0.326 \text{ m/s} = 3.328 \times 10^{-3} \text{ kg/s}$$

the length of the rectangular tubing can be found from Eq. (1) as

$$3.328 \times 10^{-3} \text{ kg/s} \times 4179 \text{ J/kg} \cdot \text{K} (37 - 10) \text{ K} = 1063 \text{ W/m}^2 \cdot \text{K} \times 1.6 \times 10^{-2} L \text{ m}^2 \times 11.7 \text{ K}$$

$$L = 1.9 \text{ m.}$$

<

(b) Consider these comments with regard to whether the analysis under- or over-estimates the length,

- ⇒ With  $x_{fd,h} \approx 0.05 D_h$ ,  $Re_D = 0.12 \text{ m}$  and  $x_{fd,t} = x_{fd,h}$ ,  $Pr = 0.73$ , the thermal development may not be negligible and would contribute to increasing heat transfer; the present analysis over predicts the length,
- ⇒ negligible tube wall resistance - depends upon materials of construction; if plastic, analysis under predicts length,
- ⇒ negligible thermal contact resistance between tube and heating plate - if present, analysis under predicts length.

### PROBLEM 8.89

**KNOWN:** Coolant flowing through a rectangular channel (gallery) within the body of a mold.

**FIND:** Convection coefficient when the coolant is process water or ethylene glycol.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Gallery can be approximated as a rectangular channel with a uniform surface temperature, (2) Fully developed flow conditions.

**PROPERTIES:** Table A.6, Water ( $\bar{T}_m = (140 + 15)^\circ\text{C}/2 = 350\text{ K}$ ):  $\rho = 974\text{ kg/m}^3$ ,  $\mu = 365 \times 10^{-6}\text{ N}\cdot\text{s/m}^2$ ,  $\nu = \mu/\rho = 3.749 \times 10^{-7}\text{ m}^2/\text{s}$ ,  $k = 0.668\text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 2.29$ ; Table A.5, Ethylene glycol ( $\bar{T}_m = 350\text{ K}$ ):  $\rho = 1079\text{ kg/m}^3$ ,  $\nu = 3.17 \times 10^{-6}\text{ m}^2/\text{s}$ ,  $k = 0.261\text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 34.6$ .

**ANALYSIS:** The characteristic length of the channel, the hydraulic diameter, Eq. 8.66, is  $D_h = 4A_c/P$  where  $A_c$  is the cross-sectional flow area and  $P$  is the wetted perimeter. For our channel,

$$D_h = \frac{4(a \times b)}{2(a + b)} = \frac{4 \times 0.090\text{ m} \times 0.0095\text{ m}}{2(0.090 + 0.0095)\text{ m}} = 0.0172\text{ m}$$

For the *water* coolant, from the continuity equation, find the Reynolds number to characterize the flow

$$u_m = \frac{\dot{V}}{A_c} = \frac{1.3 \times 10^{-3}\text{ m}^3/\text{s}}{0.090\text{ m} \times 0.0095\text{ m}} = 1.52\text{ m/s}$$

$$\text{Re}_{D_h} = \frac{u_m D_h}{\nu} = \frac{1.52\text{ m/s} \times 0.0172\text{ m}}{3.749 \times 10^{-7}\text{ m}^2/\text{s}} = 69,736$$

Since the flow is turbulent, and assuming fully developed conditions, use the Dittus-Boelter correlation, Eq. 8.60, to estimate the convection coefficient,

$$\text{Nu}_{D_h} = \frac{h D_h}{k} = 0.023 \text{Re}_{D_h}^{0.8} \text{Pr}^{0.4} = 0.023 (69,736)^{0.8} (2.29)^{0.4} = 240$$

$$h_w = \frac{0.668\text{ W/m}\cdot\text{K}}{0.0172\text{ m}} \times 240 = 9326\text{ W/m}^2\cdot\text{K} \quad <$$

Repeating the calculations using properties for the *ethylene glycol* coolant, find

$$\text{Re}_{D_h} = 8,247 \quad \text{Nu}_{D_h} = 128 \quad h_{eg} = 1957\text{ W/m}^2\cdot\text{K} \quad <$$

Continued...

### PROBLEM 8.89 (Cont.)

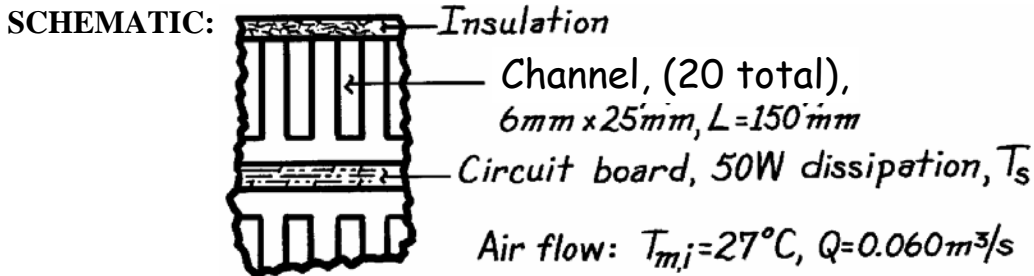

**COMMENTS:** (1) The convection coefficient for the *water* coolant is more than 4 times greater than that with the *ethylene glycol* coolant. The corrosion protection afforded by the latter coolant greatly compromises the thermal performance of the gallery. In such situations, it is useful to explore a compromise between corrosion protection and thermal performance by using an aqueous solution of ethylene glycol (50%-50%, for example).

(2) Recognize that for the ethylene glycol coolant calculation the Reynolds number is slightly below the lower limit of applicability of the Dittus-Boelter correlation, and the Gnielinski correlation would be more accurate.

### PROBLEM 8.90

**KNOWN:** Heat sink with 20 passages for air flow removes power dissipation from circuit board.

**FIND:** Operating temperature of the board and pressure drop across the sink.

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Ideal gas with negligible viscous dissipation and pressure variation, (3) Negligible thermal resistance between the circuit boards and air passages, (4) Sink surface and board are isothermal at  $T_s$ .

**PROPERTIES:** Table A-4, Air ( $\bar{T} \approx 310\text{ K}$ , 1 atm):  $\rho = 1.1281\text{ kg/m}^3$ ,  $c_p = 1008\text{ J/kg}\cdot\text{K}$ ,  $\nu = 16.89 \times 10^{-6}\text{ m}^2/\text{s}$ ,  $k = 0.0270\text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.706$ .

**ANALYSIS:** The air outlet temperature follows from Eq. 8.41b,

$$\frac{T_s - T_{m,o}}{T_s - T_{m,i}} = \exp\left(-\frac{PL\bar{h}}{\dot{m}c_p}\right).$$

The mass flow rate for both heat sinks is

$$\dot{m} = \rho\dot{V} = 1.1281\text{ kg/m}^3 \times 0.060\text{ m}^3/\text{s} = 6.77 \times 10^{-2}\text{ kg/s}$$

and the Reynolds number for a rectangular passage is

$$\text{Re}_D = \frac{u_m D_h}{\nu}$$

where  $D_h = 4A_c/P = 4(6\text{ mm} \times 25\text{ mm})/2(6 + 25)\text{ mm} = 9.68\text{ mm}$

$$u_m = \frac{\dot{m}/20}{\rho A_c} = \frac{6.77 \times 10^{-2}\text{ kg/s}/20}{1.1281\text{ kg/m}^3 (6 \times 25) \times 10^{-6}\text{ m}^2} = 20.0\text{ m/s}$$

giving  $\text{Re}_D = \frac{20.0\text{ m/s} \times 9.68 \times 10^{-3}\text{ m}}{16.89 \times 10^{-6}\text{ m}^2/\text{s}} = 11,460$ .

Assume the flow is turbulent and fully developed and using the Dittus-Boelter correlation find

$$\text{Nu}_D = 0.023\text{Re}^{4/5}\text{Pr}^{0.4} = 0.023(11,460)^{4/5}(0.706)^{0.4} = 35.4$$

$$h = \frac{\text{Nu} \cdot k}{D_h} = \frac{35.4 \times 0.027\text{ W/m}\cdot\text{K}}{0.00968\text{ m}} = 98.6\text{ W/m}^2 \cdot \text{K}.$$

Continued ...

### PROBLEM 8.90 (Cont.)

From an overall energy balance on the sink,

$$q = \dot{m} c_p (T_{m,o} - T_{m,i}) \quad T_{m,o} = T_{m,i} + q/\dot{m} c_p$$

$$T_{m,o} = 27^\circ\text{C} + 50 \text{ W}/6.77 \times 10^{-2} \text{ kg/s} \times 1008 \text{ J/kg} \cdot \text{K} = 27.73^\circ\text{C}$$

Hence, the operating temperature of the circuit board for these conditions is

$$\frac{T_s - 27.73}{T_s - 27} = \exp \left[ - \frac{2(6 + 25) \times 10^{-3} \text{ m} \times 0.150 \text{ m} \times 98.6 \text{ W/m}^2 \cdot \text{K}}{(6.77 \times 10^{-2} \text{ kg/s}/20) \times 1008 \text{ J/kg} \cdot \text{K}} \right]$$

$$T_s = 30.1^\circ\text{C}. \quad <$$

The pressure drop in the rectangular passage for the smooth surface condition follows from Eqs. 8.22 and 8.21

$$\Delta p = f \frac{\rho u_m^2 L}{D_h}$$

where

$$f = (0.790 \ln(\text{Re}_D) - 1.64)^{-2} = 0.032.$$

$$\Delta p = 0.0320 \frac{1.1281 \text{ kg/m}^3 (20.0 \text{ m/s})^2}{0.00968 \text{ m}} \times 0.150 \text{ m} = 224 \text{ N/m}^2. \quad <$$

**COMMENTS:** (1) The analysis has been simplified by assuming the channel is rectangular and all four sides experience heat transfer. Since the insulated surface is a small portion of the total passage surface area, the effect can't be very large. (2) The power required to move the air through the heat sink is  $P_{\text{elec}} = \dot{V} \Delta p = 0.060 \text{ m}^3/\text{s} \times 224 \text{ N/m}^2 = 13.4 \text{ W}$ . (3) The assumption  $\bar{T} \approx 310 \text{ K}$  for evaluating properties is an overestimate. The calculation could be repeated for  $\bar{T} = 300 \text{ K}$  for greater accuracy.

## PROBLEM 8.91

**KNOWN:** Channel formed between metallic blades dissipating heat by internal volumetric generation.

**FIND:** (a) The heat removal rate per blade for the prescribed thermal conditions and (b) Time required to slow a train of mass  $10^6$  kg from 120 km/h to 50 km/h.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions for channel blades and air flow, (2) The blades form a channel of rectangular ( $a \times b$ ) cross-section and length  $L$ , (3) Ideal gas with negligible viscous dissipation, pressure variation, and axial conduction, and (4) Fully developed flow conditions in the channel.

**PROPERTIES:** Table A.4, Air ( $\bar{T}_m \approx 350$  K, 1 atm):  $\rho = 0.995$  kg/m<sup>3</sup>,  $c_p = 1009$  J/kg · K,  $\nu = 20.92 \times 10^{-6}$  m<sup>2</sup>/s,  $k = 0.030$  W/m · K,  $Pr = 0.700$ .

**ANALYSIS:** (a) The heat removal rate by the air from a single channel (one blade) follows from an overall energy balance,

$$q = \dot{m}c_p(T_{m,o} - T_{m,i}) \quad (1)$$

where the outlet temperature can be determined from Eq. 8.41b,

$$\frac{T_s - T_{m,o}}{T_s - T_{m,i}} = \exp\left(-\frac{PL}{\dot{m}c_p}\bar{h}\right) \quad (2)$$

The hydraulic diameter,  $D_h$ , follows from Eq. 8.66,

$$D_h = \frac{4A_c}{P} = \frac{4(a \times b)}{2(a + b)} = \frac{4(0.220 \times 0.004) \text{ m}^2}{2(0.220 + 0.004) \text{ m}} = 0.0079 \text{ m} \quad (3)$$

Assuming  $\bar{T}_m = 350$  K, the Reynolds number is

$$Re_{D_h} = \frac{u_m D_h}{\nu} = \frac{50 \text{ m/s} \times 0.0079 \text{ m}}{20.92 \times 10^{-6} \text{ m}^2/\text{s}} = 18,779 \quad (4)$$

Using the Dittus-Boelter correlation, Eq. 8.60,

$$Nu_{D_h} = \frac{\bar{h}D_h}{k} = 0.023 Re_{D_h}^{0.8} Pr^{0.4} = 0.023(18,779)^{0.8} (0.700)^{0.4} = 52.37 \quad (5)$$

Continued...

**PROBLEM 8.91 (Cont.)**

$$\bar{h} = \frac{0.030 \text{ W/m} \cdot \text{K}}{0.0079 \text{ m}} \times 52.37 = 199 \text{ W/m}^2 \cdot \text{K}$$

Hence, the outlet temperature is

$$\frac{600 - T_{m,o}}{(600 - 25)^\circ \text{C}} = \exp\left(-\frac{2(0.220 + 0.004) \text{ m} \times 0.070 \text{ m}}{0.0438 \text{ kg/s} \times 1009 \text{ J/kg} \cdot \text{K}} 199 \text{ W/m}^2 \cdot \text{K}\right)$$

$$T_{m,o} = 100.7^\circ \text{C}$$

where

$$\dot{m} = \rho A_c u_m = 0.995 \text{ kg/m}^3 \times (0.220 \times 0.004) \text{ m}^2 \times 50 \text{ m/s} = 0.0438 \text{ kg/s}$$

and the rate of heat removal per blade, from Eq. (1), is

$$q = 0.0438 \text{ kg/s} \times 1009 \text{ J/kg} \cdot \text{K} (100.7 - 25)^\circ \text{C} = 3.346 \text{ kW} \quad <$$

(b) From an energy balance on the locomotive over an interval of time,  $\Delta t$ , the heat energy transferred to the air stream results in a change in kinetic energy of the train,

$$-E_{\text{out}} = \Delta E = KE_f - KE_i \quad (6)$$

$$-(q \times N) \times \Delta t = \frac{1}{2} M (V_f^2 - V_i^2)$$

$$-3346 \text{ W/blade} \times 2000 \text{ blades} \times \Delta t (\text{s}) = \frac{1}{2} \times 10^6 \text{ kg} \left[ \left( \frac{50,000}{3600} \right)^2 - \left( \frac{120,000}{3600} \right)^2 \right] \text{ m}^2/\text{s}^2$$

$$\Delta t = 69 \text{ s} \quad <$$

**COMMENTS:** (1) For the channel,  $L/D_h = 0.070 \text{ m}/0.0079 \text{ m} = 8.9 < 10$  so that the assumption of fully developed conditions may not be satisfied. Recognize that the flow at the channel entrance may be highly turbulent because of the upstream fan swirl and ducting.

(2) What benefits could be realized by increasing the heat transfer coefficient? Aside from increasing velocity, what design changes would you make to increase  $h$ ?

(3) Our assumption for  $\bar{T}_m = 350 \text{ K}$  at which to evaluate properties is reasonable considering  $T_m = (100.7 + 25)^\circ \text{C}/2 = 335 \text{ K}$ .

## PROBLEM 8.92

**KNOWN:** Printed-circuit board (PCB) with uniform temperature  $T_s$  cooled by laminar, fully developed flow in a parallel-plate channel. The air flow with an inlet temperature of  $T_{m,i}$  is driven by a pressure difference,  $\Delta p$ .

**FIND:** The average heat removal rate per unit area,  $\bar{q}_s''$  ( $\text{W}/\text{m}^2$ ), from the PCB.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Laminar, fully developed flow, (2) Upper and lower walls of the channel are insulated and of infinite extent in the transverse direction, (3) PCB has uniform surface temperature, (4) Constant properties, (5) Ideal gas with negligible viscous dissipation.

**PROPERTIES:** Table A-4, Air ( $T_m = 293 \text{ K}$ , 1 atm):  $\rho = 1.192 \text{ kg/m}^3$ ,  $c_p = 1007 \text{ J/kg}\cdot\text{K}$ ,  $\nu = 1.531 \times 10^{-5} \text{ m}^2/\text{s}$ ,  $k = 0.0258 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.709$ .

**ANALYSIS:** The energy equations for determining the heat rate from one surface of the board are Eqs. 8.34 and 8.41b

$$q = \dot{m} c_p (T_{m,o} - T_{m,i}) = \bar{q}_s'' A_s \quad (1)$$

$$\frac{T_s - T_{m,o}}{T_s - T_{m,i}} = \exp\left(-\frac{P_h L \bar{h}}{\dot{m} c_p}\right) \quad (2)$$

where  $A_s = Lw$  and  $P = w$ , since heat transfer is only from one surface, where  $w$  is the width in the transverse direction. For the fully developed flow condition, the velocity is estimated from the friction pressure drop relation, Eq. 8.22a,

$$\Delta p = f \left( \rho u_m^2 / 2 \right) (L / D_h) \quad (3)$$

where the hydraulic diameter for the channel cross section is

$$D_h = \frac{4 A_c}{P} = \frac{4(w a)}{2(w + a)} = 2a \quad a \ll w$$

The friction factor  $f$  from Table 8.1 for the cross section  $b/a = \infty$  is

$$f \cdot \text{Re}_{D_h} = 96 \quad (4)$$

where the Reynolds number is

$$\text{Re}_{D_h} = u_m D_h / \nu \quad (5)$$

Continued ...

### PROBLEM 8.92 (Cont.)

and the flow rate through one channel is

$$\dot{m} = \rho A_c u_m = \rho (wa) u_m \quad (6)$$

For fully developed laminar flow from Table 8.1.

$$\overline{Nu}_D = \bar{h} D_h / k = 4.86 \quad (7)$$

Substituting Eqs. (4) and (5) into Eq. (3) and solving for  $u_m$  yields

$$u_m = \Delta p D_h^2 / 48 \nu \rho L = 2 \text{ N/m}^2 \times (0.01 \text{ m})^2 / 48 \times 1.531 \times 10^{-5} \text{ m}^2/\text{s} \times 1.192 \text{ kg/m}^3 \times 0.15 \text{ m} = 1.52 \text{ m/s}$$
$$Re = u_m D_h / \nu = 1.52 \text{ m/s} \times 0.01 \text{ m} / 1.531 \times 10^{-5} \text{ m}^2/\text{s} = 994$$

Thus the flow is laminar, as assumed. From Eqs. (6), (7), and (2),  $\dot{m}/w = \rho u_m a = 1.192 \text{ kg/m}^3 \times 1.52 \text{ m/s} \times 0.005 \text{ m} = 0.00907 \text{ kg/s}\cdot\text{m}$ .  $\bar{h} = \overline{Nu}_D k / D_h = 4.86 \times 0.0258 \text{ W/m}\cdot\text{K} / 0.01 \text{ m} = 12.5 \text{ W/m}^2\cdot\text{K}$ .  $T_{m,o} = T_s - (T_s - T_{m,i}) \exp(-L \bar{h} / (\dot{m}/w) c_p) = 65^\circ\text{C} - 45^\circ\text{C} \exp(-0.15 \text{ m} \times 12.5 \text{ W/m}^2\cdot\text{K} / 0.00907 \text{ kg/s}\cdot\text{m} \times 1007 \text{ J/kg}\cdot\text{K}) = 28.4^\circ\text{C}$ .

From Eq. (1)

$$q' = \frac{\dot{m}}{w} c_p (T_{m,o} - T_{m,i}) = 0.00907 \text{ kg/m}\cdot\text{s} \times 1007 \text{ J/kg}\cdot\text{K} \times (28.4 - 20)^\circ\text{C} = 76.5 \text{ W/m} \quad <$$
$$q'' = q'/L = 510 \text{ W/m}^2$$

**COMMENTS:** (1) The thermophysical properties of the air are evaluated at the average mean temperature,  $\bar{T}_m = (T_{m,i} + T_{m,o})/2$ .

(2) The fully developed flow length,  $x_{fd,t}$ , for the channel follows from Eq. 8.23,

$$x_{fd,t} = D_h \times 0.05 Re_{D_h} Pr$$
$$x_{fd,t} = 2 \times 0.010 \text{ m} \times 0.05 \times 7954 \times 0.709 = 5.6 \text{ m}$$

Since  $L \ll x_{fd,t}$ , we conclude that the flow is not likely to be fully developed.

### PROBLEM 8.93

**KNOWN:** Surface thermal conditions and diameters associated with a concentric tube annulus. Water flow rate and inlet temperature.

**FIND:** (a) Length required to achieve desired outlet temperature, (b) Heat flux from inner tube at outlet.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Fully developed conditions throughout, (3) Adiabatic outer surface, (4) Uniform temperature at inner surface, (5) Constant properties, (6) Water is incompressible liquid with negligible viscous dissipation.

**PROPERTIES:** Table A-6, Water ( $\bar{T}_m = 320\text{K}$ ):  $c_p = 4180\text{ J/kg}\cdot\text{K}$ ,  $\mu = 577 \times 10^{-6}\text{ N}\cdot\text{s/m}^2$ ,  $k = 0.640\text{ W/m}\cdot\text{K}$ ,  $Pr = 3.77$ .

**ANALYSIS:** (a) From Eq. 8.41a,

$$L = -\frac{\dot{m} c_p}{Ph} \ln \frac{\Delta T_o}{\Delta T_i} = -\frac{\dot{m} c_p}{\pi D_i \bar{h}} \ln \frac{T_s - T_{m,o}}{T_s - T_{m,i}}$$

$$\text{With } Re_D = \frac{\rho u_m D_h}{\mu} = \frac{\dot{m} (D_o - D_i)}{(\pi/4) (D_o^2 - D_i^2) \mu} = \frac{4 \dot{m}}{\pi (D_o + D_i) \mu}$$

$$Re_D = \frac{4 \times 0.02\text{ kg/s}}{\pi (0.125\text{ m}) 577 \times 10^{-6}\text{ N}\cdot\text{s/m}^2} = 353$$

the flow is laminar. Hence, from Eq. 8.69 and Table 8.2,

$$\bar{h} = h_i = \frac{k}{D_h} Nu_i = \frac{0.64\text{ W/m}\cdot\text{K}}{(0.100 - 0.025)\text{ m}} 7.37 = 63\text{ W/m}^2\cdot\text{K}$$

$$\text{and } L = -\frac{0.02\text{ kg/s} (4180\text{ J/kg}\cdot\text{K})}{\pi (0.025\text{ m}) 63\text{ W/m}^2\cdot\text{K}} \ln \frac{(100 - 75)^\circ\text{C}}{(100 - 20)^\circ\text{C}} = 19.7\text{ m.} \quad <$$

(b) From Eq. 8.67

$$q_i''(L) = h_i (T_{s,i} - T_{m,o}) = 63 \frac{\text{W}}{\text{m}^2\cdot\text{K}} (100 - 75)^\circ\text{C} = 1575\text{ W/m}^2. \quad <$$

**COMMENTS:** The total heat rate to the water is

$$q = \dot{m} c_p (T_{m,o} - T_{m,i}) = 0.02\text{ kg/s} \times 4180\text{ J/kg}\cdot\text{K} (55^\circ\text{C}) = 4598\text{ W.}$$

### PROBLEM 8.94

**KNOWN:** Surface thermal conditions and diameters associated with a concentric tube annulus. Water flow rate and inlet temperature.

**FIND:** Length required to achieve desired outlet temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Fully developed conditions throughout, (3) Adiabatic outer surface, (4) Uniform temperature at inner surface, (5) Constant properties, (6) Incompressible liquid with negligible viscous dissipation.

**PROPERTIES:** Table A-6, Water ( $\bar{T}_m = 320\text{K}$ ):  $c_p = 4180\text{ J/kg}\cdot\text{K}$ ,  $\mu = 577 \times 10^{-6}\text{ N}\cdot\text{s/m}^2$ ,  $k = 0.640\text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 3.77$ .

**ANALYSIS:** From Eq. 8.41a,

$$L = -\frac{\dot{m} c_p}{P \bar{h}} \ln \frac{\Delta T_o}{\Delta T_i} = -\frac{\dot{m} c_p}{\pi D_i \bar{h}} \ln \frac{T_s - T_{m,o}}{T_s - T_{m,i}}$$

With

$$\text{Re}_D = \frac{\rho u_m D_h}{\mu} = \frac{\dot{m} (D_o - D_i)}{(\pi/4) (D_o^2 - D_i^2) \mu} = \frac{4 \dot{m}}{\pi (D_o + D_i) \mu}$$

$$\text{Re}_D = \frac{4 \times 0.30\text{ kg/s}}{\pi (0.125\text{ m}) 577 \times 10^{-6}\text{ N}\cdot\text{s/m}^2} = 5296$$

and the flow is turbulent. Hence, from Eq. 8.60,

$$\bar{h} = \frac{k}{D_h} \text{Nu}_D = 0.023 \frac{k}{D_h} \text{Re}_D^{4/5} \text{Pr}^{0.4}$$

$$\bar{h} = 0.023 \frac{0.640\text{ W/m}\cdot\text{K}}{0.075\text{ m}} (5296)^{4/5} (3.77)^{0.4} = 318\text{ W/m}^2\cdot\text{K}$$

and hence the required length is

$$L = -\frac{0.30\text{ kg/s} (4180\text{ J/kg}\cdot\text{K})}{\pi (0.025\text{ m}) 318\text{ W/m}^2\cdot\text{K}} \ln \frac{(100 - 75)^\circ\text{C}}{(100 - 20)^\circ\text{C}} = 58.4\text{ m.} \quad <$$

**COMMENTS:** (1) Increasing  $\dot{m}$  by a factor of 15 increases  $\text{Re}_D$  accordingly, and the flow is turbulent. However,  $\bar{h}$  increases by a factor of only 5 from the result of Problem 8.93, in which case the tube length must be a factor of 3 larger than that of Problem 8.93. (2) The Gnielinski correlation would be more accurate than the Dittus-Boelter correlation for the low (but turbulent) conditions suggested by the value of the Reynolds number.

### PROBLEM 8.95

**KNOWN:** Inner and outer tube surface conditions for an annulus.

**FIND:** (a) Velocity profile, (b) Temperature profile and expression for inner surface Nusselt number.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Laminar, fully developed flow, (3) Uniform heat flux at inner surface, (4) Adiabatic outer surface, (5) Constant properties, (6) Applicability of Eq. 8.34.

**ANALYSIS:** (a) From Section 8.1.3, the general solution to Eq. 8.12, which also applies to annular flow as represented in Figure 8.11, is

$$u(r) = \frac{1}{\mu} \left( \frac{dp}{dx} \right) \frac{r^2}{4} + C_1 \ln r + C_2.$$

Applying the boundary conditions,

$$u(r_i) = 0 \quad 0 = \frac{1}{\mu} \left( \frac{dp}{dx} \right) \frac{r_i^2}{4} + C_1 \ln r_i + C_2$$

$$u(r_o) = 0 \quad 0 = \frac{1}{\mu} \left( \frac{dp}{dx} \right) \frac{r_o^2}{4} + C_1 \ln r_o + C_2.$$

Hence,

$$C_1 = \frac{\frac{1}{\mu} \left( \frac{dp}{dx} \right) \left( \frac{r_o^2}{4} - \frac{r_i^2}{4} \right)}{\ln r_i / r_o} \quad C_2 = -\frac{1}{\mu} \left( \frac{dp}{dx} \right) \frac{r_o^2}{4} - \frac{1}{\mu} \left( \frac{dp}{dx} \right) \left( \frac{r_o^2}{4} - \frac{r_i^2}{4} \right) \frac{\ln r_o}{\ln (r_i / r_o)}$$

and the velocity distribution is

$$u(r) = \frac{1}{\mu} \left( \frac{dp}{dx} \right) \left( \frac{r^2}{4} - \frac{r_o^2}{4} \right) + \frac{1}{\mu} \left( \frac{dp}{dx} \right) \left( \frac{r_o^2}{4} - \frac{r_i^2}{4} \right) \frac{\ln r}{\ln (r_i / r_o)} - \frac{1}{\mu} \left( \frac{dp}{dx} \right) \left( \frac{r_o^2}{4} - \frac{r_i^2}{4} \right) \frac{\ln r_o}{\ln (r_i / r_o)}$$

$$u(r) = -\frac{r_o^2}{4\mu} \left( \frac{dp}{dx} \right) \left[ 1 - (r/r_o)^2 + \frac{(r_i/r_o)^2 - 1}{\ln (r_i / r_o)} \ln (r/r_o) \right]. \quad (1) <$$

(b) For fully developed conditions with uniform surface heat flux,

$$v = 0 \quad \partial T / \partial x = dT_m / dx = \text{const.}$$

Continued ...

**PROBLEM 8.95 (Cont.)**

Hence, from Eq. 8.48, which also applies for annular flow,

$$\frac{1}{r} \frac{\partial}{\partial r} \left( r \frac{\partial T}{\partial r} \right) = \frac{u}{\alpha} \frac{dT_m}{dx}$$

Substituting the velocity distribution, with

$$C_1 = -\frac{r_0^2}{4\mu} \left( \frac{dp}{dx} \right) \quad C_2 = \frac{(r_1/r_0)^2 - 1}{\ln(r_1/r_0)} \quad (2)$$

it follows that  $\frac{1}{r} \frac{\partial}{\partial r} \left( r \frac{\partial T}{\partial r} \right) = \frac{C_1}{\alpha} \frac{dT_m}{dx} \left[ 1 - (r/r_0)^2 + C_2 \ln(r/r_0) \right]$ .

$$r \frac{\partial T}{\partial r} = \frac{C_1}{\alpha} \frac{dT_m}{dx} \int \left[ r - \frac{r^3}{r_0^2} + C_2 r \ln \frac{r}{r_0} \right] dr + C_3$$

$$\frac{\partial T}{\partial r} = \frac{C_1}{\alpha} \frac{dT_m}{dx} \left[ \frac{r}{2} - \frac{r^3}{4r_0^2} + C_2 \left( \frac{r}{2} \ln \frac{r}{r_0} - \frac{r}{4} \right) \right] + \frac{C_3}{r}$$

and the temperature distribution is

$$T(r) = \frac{C_1}{\alpha} \frac{dT_m}{dx} \left[ \frac{r^2}{4} - \frac{r^4}{16r_0^2} + C_2 \left( \frac{r^2}{4} \ln \frac{r}{r_0} - \frac{r^2}{4} \right) \right] + C_3 \ln r + C_4. \quad (3) <$$

From the requirement that  $q_0'' = 0$ , it follows that  $\partial T / \partial r|_{r_0} = 0$ . Hence,

$$\frac{C_1}{\alpha} \frac{dT_m}{dx} \left[ \frac{r_0}{2} - \frac{r_0}{4} + C_2 \left( -\frac{r_0}{4} \right) \right] + \frac{C_3}{r_0} = 0$$

$$C_3 = \frac{C_1}{\alpha} \frac{dT_m}{dx} \frac{r_0^2}{4} (C_2 - 1). \quad (4) <$$

From the condition that  $T(r_1) = T_{s,i}$ , it follows that

$$C_4 = T_{s,i} - \frac{C_1}{\alpha} \frac{dT_m}{dx} \left[ \frac{r_1^2}{4} - \frac{r_1^4}{16r_0^2} + C_2 \left( \frac{r_1^2}{4} \ln \frac{r_1}{r_0} - \frac{r_1^2}{4} \right) \right] + C_3 \ln r_1. \quad (5) <$$

From Eqs. 8.67 and 8.69, the inner surface Nusselt number is

$$Nu_i = \frac{h_i D_h}{k} = \frac{q_i'' D_h}{k(T_{s,i} - T_m)}$$

where  $D_h = 2(r_0 - r_1)$ . To obtain a workable form of  $Nu_i$ , the mean temperature  $T_m$  must be evaluated.

This may be done by substituting Eqs. (1) and (3) into Eq. 8.26 and evaluating  $u_m$  by substituting Eq. (1) into Eq. 8.8. Since the integrations are long and tedious, they are not provided.

**COMMENTS:** From an energy balance performed for a differential control volume in the annular region,  $dT_m/dx = 2r_1 q_i'' / \rho c_p u_m (r_0^2 - r_1^2)$ .

## PROBLEM 8.96

**KNOWN:** Inlet temperature, pressure and flow rate of air. Annulus length and tube diameters. Pressure of saturated steam.

**FIND:** Outlet temperature and pressure drop of air. Mass rate of steam condensation.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, (2) Outer surface of annulus is adiabatic, (3) Air is ideal gas with negligible viscous dissipation and pressure variation, (4) Fully developed flow throughout annulus, (5) Smooth annulus surfaces, (6) Constant properties.

**PROPERTIES:** Table A-4, air ( $\bar{T}_m \approx 325$  K,  $p = 5$  atm):  $\rho = 5 \times \rho(1 \text{ atm}) = 5.391 \text{ kg/m}^3$ ,  $c_p = 1008 \text{ J/kg}\cdot\text{K}$ ,  $\mu = 196.4 \times 10^{-7} \text{ N}\cdot\text{s/m}^2$ ,  $k = 0.0281 \text{ W/m}\cdot\text{K}$ ,  $Pr = 0.703$ . Table A-6, sat. steam ( $p = 2.455$  bars):  $T_s = 400$  K,  $h_{fg} = 2183 \text{ kJ/kg}$ .

**ANALYSIS:** With a uniform surface temperature, the air outlet temperature is

$$T_{m,o} = T_s - (T_s - T_{m,i}) \exp\left(-\frac{\pi D_i L \bar{h}}{\dot{m} c_p}\right)$$

With  $A_c = \pi(D_o^2 - D_i^2)/4 = 1.355 \times 10^{-3} \text{ m}^2$ ,  $D_h = D_o - D_i = 0.015 \text{ m}$  and  $Re_D = \rho u_m D_h / \mu = \dot{m} D_h / A_c \mu = 16,900$ , the flow is turbulent and the Dittus-Boelter correlation yields

$$\bar{h} \approx h_{fd} = \left(\frac{k}{D_h}\right) 0.023 Re_D^{4/5} Pr^{0.4} = \left(\frac{0.0281 \text{ W/m}\cdot\text{K}}{0.015 \text{ m}}\right) 0.023 (16,900)^{4/5} (0.703)^{0.4} = 90.3 \text{ W/m}^2 \cdot \text{K}$$

$$T_{m,o} = 127^\circ\text{C} - (110^\circ\text{C}) \exp\left(-\frac{\pi \times 0.05 \text{ m} \times 5 \text{ m} \times 90.3 \text{ W/m}^2 \cdot \text{K}}{0.03 \text{ kg/s} \times 1008 \text{ J/kg}\cdot\text{K}}\right) = 116.5^\circ\text{C} <$$

The pressure drop is  $\Delta p = f \left(\rho u_m^2 / 2D_h\right) L$ , where, with  $u_m = \dot{m} / \rho A_c = 0.03 \text{ kg/s} /$

$\left(5.391 \text{ kg/m}^3 \times 1.355 \times 10^{-3} \text{ m}^2\right) = 4.11 \text{ m/s}$ , and with  $Re_D = 16,900$ , Eq. 8.21 yields  $f = [0.790 \ln(Re_D) - 1.64]^{-2} = 0.027$ . Hence,

$$\Delta p \approx 0.027 \times 5.391 \text{ kg/m}^3 \frac{(4.11 \text{ m/s})^2 5 \text{ m}}{2 \times 0.015 \text{ m}} = 415 \text{ N/m}^2 = 4.1 \times 10^{-3} \text{ atm} <$$

The rate of heat transfer to the air is

$$q = \dot{m} c_p (T_{m,o} - T_{m,i}) = 0.03 \text{ kg/s} \times 1008 \text{ J/kg}\cdot\text{K} (99.5^\circ\text{C}) = 3009 \text{ W}$$

and the rate of condensation is then

$$\dot{m}_c = \frac{q}{h_{fg}} = \frac{3009 \text{ W}}{2.183 \times 10^6 \text{ J/kg}} = 1.38 \times 10^{-3} \text{ kg/s} <$$

**COMMENTS:** (1) With  $\bar{T}_m = (T_{m,i} + T_{m,o}) / 2 = 340$  K, the initial estimate of 325 K is too low and an iterative solution should be obtained, (2) For a steam flow rate of 0.01 kg/s, approximately 14% of the outflow would be in the form of saturated liquid, (3) With  $L/D_h = 333$ , the assumption of fully developed flow throughout the tube is excellent.

### PROBLEM 8.97

**KNOWN:** Dimensions and surface thermal conditions for a concentric tube annulus. Water flow rate and inlet temperature.

**FIND:** (a) Tube length required to achieve desired outlet temperature, (b) Inner tube surface temperature at outlet.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Uniform heat flux at inner surface, (3) Adiabatic outer surface, (4) Fully developed flow at exit, (5) Constant properties, (6) Incompressible liquid with negligible viscous dissipation.

**PROPERTIES:** Table A-6, Water ( $\bar{T}_m = 328\text{K}$ ):  $c_p = 4183 \text{ J/kg}\cdot\text{K}$ ; ( $T_{m,o} = 358\text{K}$ ):  $\mu = 332 \times 10^{-6} \text{ N}\cdot\text{s/m}^2$ ,  $k = 0.673 \text{ W/m}\cdot\text{K}$ ,  $Pr = 2.07$ .

**ANALYSIS:** (a) From the overall energy balance, Eq. 8.34,

$$q = q_i' L = \dot{m} c_p (T_{m,o} - T_{m,i})$$

$$L = \frac{\dot{m} c_p (T_{m,o} - T_{m,i})}{q_i'} = \frac{(0.04 \text{ kg/s}) 4183 \text{ J/kg}\cdot\text{K} (85 - 25)^\circ\text{C}}{4000 \text{ W/m}} = 2.51 \text{ m.} \quad <$$

(b) From Eqs. 8.1 and 8.5,

$$Re_D = \frac{\rho u_m D_h}{\mu} = \frac{\dot{m} D_h}{A_c \mu} = \frac{\dot{m} (D_o - D_i)}{(\pi/4) (D_o^2 - D_i^2) \mu} = \frac{4 \dot{m}}{\pi (D_o + D_i) \mu}$$

$$Re_D = \frac{4 \times 0.04 \text{ kg/s}}{\pi (0.075 \text{ m}) 332 \times 10^{-6} \text{ kg/s}\cdot\text{m}} = 2045.$$

Hence the flow is laminar, and with  $D_i/D_o = 0.5$ , it follows from Eq. 8.72 and Table 8.3

$$Nu_i = Nu_{ij} = 6.24$$

$$h_i = 6.24 \frac{k}{D_h} = 6.24 \frac{0.673 \text{ W/m}\cdot\text{K}}{0.025 \text{ m}} = 168 \text{ W/m}^2 \cdot \text{K}.$$

From Eq. 8.67,

$$T_{s,i}(L) = T_{m,o} + \frac{q_i'}{h_i} = T_{m,o} + \frac{q_i' / \pi D_i}{h_i}$$

$$T_{s,i}(L) = 85^\circ\text{C} + \frac{4000 \text{ W/m}}{\pi (0.025 \text{ m}) 168 \text{ W/m}^2 \cdot \text{K}} = 388^\circ\text{C.} \quad <$$

**COMMENTS:** Unless the water is pressurized, local boiling would occur at the tube surface, causing  $h_i$  to be larger.

### PROBLEM 8.98

**KNOWN:** Heat rate per unit length at the inner surface of an annular recuperator of prescribed dimensions. Flow rate and inlet temperature of air passing through annular region.

**FIND:** (a) Temperature of air leaving the recuperator, (b) Inner pipe temperature at inlet and outlet and outer pipe temperature at inlet.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Constant properties, (3) Uniform heating of recuperator inner surface, (4) Adiabatic outer surface, (5) Air is ideal gas with negligible viscous dissipation and pressure variation, (6) Fully developed air flow throughout.

**PROPERTIES:** Table A-4, Air (given):  $c_p = 1030 \text{ J/kg}\cdot\text{K}$ ,  $\mu = 270 \times 10^{-7} \text{ N}\cdot\text{s/m}^2$ ,  $k = 0.041 \text{ W/m}\cdot\text{K}$ ,  $Pr = 0.68$ .

**ANALYSIS:** (a) From an energy balance on the air

$$q'_i L = \dot{m}_a c_{p,a} (T_{a,2} - T_{a,1})$$

$$T_{a,2} = T_{a,1} + \frac{q'_i L}{\dot{m}_a c_{p,a}} = 300 \text{ K} + \frac{1.25 \times 10^5 \text{ W/m} \times 7 \text{ m}}{2.1 \text{ kg/s} \times 1030 \text{ J/kg}\cdot\text{K}} = 704.5 \text{ K.} \quad <$$

(b) The surface temperatures may be evaluated from Eqs. 8.67 and 8.68 with

$$Re_D = \frac{\rho u_m D_h}{\mu} = \frac{\dot{m}_a (D_o - D_i)}{(\pi/4) (D_o^2 - D_i^2) \mu} = \frac{4 \dot{m}_a}{\pi (D_o + D_i) \mu} = \frac{4(2.1 \text{ kg/s})}{\pi(4.05 \text{ m}) 270 \times 10^{-7} \text{ N}\cdot\text{s/m}^2}$$

$$Re_D = 24,452$$

the flow is turbulent and from Eq. 8.60

$$h_i \approx h_o \approx \frac{k}{D_h} 0.023 Re_D^{4/5} Pr^{0.4} = \frac{0.041 \text{ W/m}\cdot\text{K}}{0.05 \text{ m}} 0.023 (24,452)^{4/5} (0.68)^{0.4} = 52 \text{ W/m}^2 \cdot \text{K.}$$

$$\text{With } q''_i = q'_i / \pi D_i = 1.25 \times 10^5 \text{ W/m} / \pi \times 2 \text{ m} = 19,900 \text{ W/m}^2$$

Eq. 8.67 gives

$$(T_{s,i} - T_m) = q''_i / h_i = 19,900 \text{ W/m}^2 / 52 \text{ W/m}^2 \cdot \text{K} = 383 \text{ K}$$

$$T_{s,i,1} = 683 \text{ K} \quad T_{s,i,2} = 1087 \text{ K.} \quad <$$

From Eq. 8.68, with  $q''_o = 0$ ,  $(T_{s,o} - T_m) = 0$ . Hence

$$T_{s,o,1} = T_{a,1} = 300 \text{ K.} \quad <$$

## PROBLEM 8.99

**KNOWN:** A concentric tube arrangement for removing heat generated from a biochemical reaction in a settling tank. Water is supplied to the annular region at rate of 0.2 kg/s.

**FIND:** (a) The inlet temperature of the supply water that will provide for an average tank surface temperature of 37°C; assume and then justify fully developed flow and thermal conditions; and (b) Sketch the water and surface temperatures along the flow direction for two cases: the fully developed conditions of part (a), and when entrance effects are important. Comment on the features of the temperature distributions, with particular attention to the longitudinal gradient on the tank surface. What change to the system or operating conditions would you make to reduce the gradient?

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Fully developed flow and thermal conditions, (2) Inner annulus surface has uniform heat flux, while outer surface is insulated, (3) Constant properties, (4) Incompressible liquid with negligible viscous dissipation.

**PROPERTIES:** Table A-6, Water ( $T_m = 304$  K):  $\rho = 995.6$  kg/m<sup>3</sup>,  $c_p = 4178$  J/kg·K,  $\nu = 7.987 \times 10^{-7}$  m<sup>2</sup>/s,  $k = 0.618$  W/m·K,  $Pr = 5.39$ .

**ANALYSIS:** (a) The overall energy balance on the fluid passing through the concentric tube is

$$q = \dot{m} c_p (T_{m,i} - T_{m,o}) \quad (1)$$

and from an energy balance on the reaction tank,

$$q = \dot{q} (\pi D_i^2 / 4) / L = 1 \times 10^5 \text{ W/m}^3 (\pi (0.08 \text{ m})^2 / 4) \times 1 \text{ m} = 503 \text{ W}. \quad (2)$$

The convection rate equation applied to the inner surface  $A_{s,i}$  is

$$q = \bar{h}_i A_{s,i} (\bar{T}_s - \bar{T}_m) = \bar{h}_i \pi D_i L (\bar{T}_s - \bar{T}_m) \quad (3)$$

where  $\bar{T}_s$  is the average inner surface temperature and

$$\bar{T}_m = (T_{m,i} + T_{m,o}) / 2. \quad (4)$$

To estimate  $\bar{h}$ , begin by characterizing the flow with

$$Re_{Dh} = u_m D_h / \nu \quad D_h = D_o - D_i \quad \dot{m} = \rho A_c u_m$$

where  $A_c = \pi (D_o^2 - D_i^2) / 4$ . Substituting numerical values find

$$Re_{Dh} = 1779$$

Assuming fully developed conditions for laminar flow through an annulus, it follows from Table 8.3 and Eq. 8.72 with  $D_i/D_o = 0.8$ ,

$$\bar{Nu}_i = \bar{h}_i D_h / k = 5.58 \quad \bar{h}_i = 172 \text{ W/m}^2 \cdot \text{K}$$

Continued ...

### PROBLEM 8.99 (Cont.)

Using Eq. (3) with  $\bar{h}_i$ , and  $\bar{T}_s = 37^\circ\text{C}$ , and  $q$  from Eq. (2), find

$$\bar{T}_m = 25.4^\circ\text{C}$$

From Eqs. (1) and (4), calculate

$$T_{m,i} = 25.1^\circ\text{C} \quad T_{m,o} = 25.7^\circ\text{C}$$

<

For this annulus, the thermal entry length from Eq. 8.23 is

$$x_{fd,t} = D_h \times 0.05 \text{ Re}_{Dh} \text{ Pr}$$

$$x_{fd,t} = (0.100 - 0.080) \text{ m} \times 0.05 \times 1779 \times 5.39 = 9.59 \text{ m}$$

Since  $L = 1 \text{ m}$ , we conclude that entry length effects are significant, and the fully developed flow assumption is approximate.

(b) Since the fluid is being heated by flow over a surface with uniform heat flux, the mean fluid temperature,  $T_m(x)$ , will increase linearly with longitudinal distance  $x$ . Assuming fully developed conditions, the surface temperature  $T_s(x)$  will likewise increase linearly with distance as shown in the schematic below. Note that the longitudinal temperature difference is about  $0.6^\circ\text{C}$ , and that the inlet mean temperature is  $25.1^\circ\text{C}$ .

Considering now entrance length effects, the convection coefficient is no longer uniform, and will be largest near the entrance, and larger than for the fully developed flow everywhere. Hence, we expect the surface temperature near the entrance to be closer to the mean fluid temperature than elsewhere. We also expect the average mean temperature of the fluid will be higher so that the average surface temperature,  $\bar{T}_s$ , remains at  $37^\circ\text{C}$ . However, the rise in temperature of the fluid ( $T_{m,o} - T_{m,i}$ ) will remain the same, about  $0.6^\circ\text{C}$ , since the heat removal rate is the same. Increasing the flow rate will tend to minimize the longitudinal gradient by reducing ( $T_{m,o} - T_{m,i}$ ) and increasing  $h(x)$ . The graph below illustrates the distinctive features of the fully developed flow and entrance length effects.

**COMMENTS:** The thermophysical properties required in the convection correlation and the energy equations should be evaluated at  $T_m = (T_{m,i} + T_{m,o})/2 \approx 298 \text{ K}$ .

## PROBLEM 8.100

**KNOWN:** Dimensions and thermal conductivity of plastic pipe. Volumetric flow rate and temperature of inlet air. Enhancement of inner convection coefficient and friction factor associated with coiled spring. Thermal resistance of coating on outer surface.

**FIND:** (a) Air outlet temperature and fan power requirement without coating and coiled spring, (b) Effect of coiled spring on air outlet temperature and fan power, (c) Effect of coating on outlet temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, (2) Negligible heat transfer from air in vertical pipe sections, (3) Air is ideal gas with negligible viscous dissipation and pressure variation, (4) Smooth interior surface without spring, (5) Negligible coating thickness, (6) Constant properties.

**PROPERTIES:** Table A-4, Air ( $T_{m,i} = 29^\circ\text{C}$ ):  $\rho_1 = 1.155 \text{ kg/m}^3$ . Air ( $\bar{T}_m \approx 25^\circ\text{C}$ ):  $c_p = 1007 \text{ J/kg}\cdot\text{K}$ ,  $\mu = 183.6 \times 10^{-7} \text{ N}\cdot\text{s/m}^2$ ,  $k_a = 0.0261 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.707$ .

**ANALYSIS:** (a) From Eq. (8.45a),

$$\frac{T_\infty - T_{m,o}}{T_\infty - T_{m,i}} = \exp\left(-\frac{\bar{U}A_s}{\dot{m}c_p}\right)$$

where, from Eqs. (3.36) and (3.37),

$$(\bar{U}A_s)^{-1} = R_{\text{tot}} = \frac{1}{h_i\pi D_i L} + \frac{\ln(D_o/D_i)}{2\pi Lk} + \frac{1}{h_o\pi D_o L}$$

With  $\dot{m} = \rho_1 \dot{V}_1 = 0.0289 \text{ kg/s}$  and  $\text{Re}_D = 4\dot{m}/\pi D_i \mu = 13,350$ , the pipe flow is turbulent. With  $L/D_i = 100$ , we may assume fully developed flow throughout the pipe, and from Eq. (8.60),

$$\bar{h}_i = \frac{k_a}{D_i} 0.023 \text{Re}_D^{4/5} \text{Pr}^{0.3} = \frac{0.0261 \text{ W/m}\cdot\text{K}}{0.15\text{m}} 0.023(13,350)^{4/5} (0.707)^{0.3} = 7.20 \text{ W/m}^2\cdot\text{K}$$

$$\text{Hence, } R_{\text{tot}} = \left( \frac{1}{7.20 \times \pi \times 0.15 \times 15} + \frac{\ln(0.17/0.15)}{2\pi \times 15 \times 0.15} + \frac{1}{1500 \times \pi \times 0.17 \times 15} \right) \frac{\text{K}}{\text{W}}$$

$$R_{\text{tot}} = (0.0196 + 0.0089 + 0.0001) \text{ K/W} = 0.0286 \text{ K/W}$$

Hence,  $\bar{U}A_s = R_{\text{tot}}^{-1} = 35.0 \text{ W/K}$  and

$$T_{m,o} = T_\infty + (T_{m,i} - T_\infty) \exp\left(-\frac{\bar{U}A_s}{\dot{m}c_p}\right) = 17^\circ\text{C} + (12^\circ\text{C}) \exp\left(-\frac{35.0 \text{ W/K}}{0.0289 \text{ kg/s} \times 1007 \text{ J/kg}\cdot\text{K}}\right) = 20.6^\circ\text{C} <$$

Continued ...

### PROBLEM 8.100 (Cont.)

From Eq. (8.21),  $f = [0.790 \ln(Re_D) - 1.64]^{-2} = 0.0291$ . Hence, from Eqs. (8.22a) and (8.22b), with  $u_{m,i} = \dot{V}_i / A_c = 1.415 \text{ m/s}$ ,

$$P \approx f \frac{\rho_i u_{m,i}^2}{2D_i} L \dot{V}_i = 0.0291 \frac{1.155 \text{ kg/m}^3 (1.415 \text{ m/s})^2}{2(0.15 \text{ m})} 15 \text{ m} \times 0.025 \text{ m}^3/\text{s} = 0.084 \text{ W} \quad <$$

(b) With  $h_{cp} = 2h_i = 14.4 \text{ W/m}^2 \cdot \text{K}$ , the inner convection resistance is reduced from  $0.0196 \text{ K/W}$  to  $0.0098 \text{ K/W}$  and hence the total resistance from  $0.0286 \text{ K/W}$  to  $0.0188 \text{ K/W}$ . It follows that  $\bar{U}A_s = 53.2 \text{ W/K}$  and

$$T_{m,o} = 18.9^\circ\text{C} \quad <$$

With  $f_{cp} = 1.5f$ ,

$$P = 0.126 \text{ W} \quad <$$

(c) With the coating of organic matter, there is an additional thermal resistance of the form  $R_{t,c} = R''_{t,c} / (\pi D_o L) = (0.05 \text{ m}^2 \cdot \text{K/W}) / (\pi \times 0.17 \text{ m} \times 15 \text{ m}) = 0.0062 \text{ K/W}$ . The total resistance is then  $R_{tot} = 0.0348 \text{ K/W}$  and  $\bar{U}A_s = 28.7 \text{ W/K}$ . Hence,

$$T_{m,o} = 21.5^\circ\text{C} \quad <$$

**COMMENTS:** (1) The fan power requirement is small, and the process is economical, with or without the coiled spring. (2) Heat transfer enhancement associated with the coiled spring is manifested by a 34% reduction in the total thermal resistance and a  $1.7^\circ\text{C}$  reduction in the outlet temperature. (3) *Fouling* of the outer surface increases the total resistance by 22% and the outlet temperature by  $0.9^\circ\text{C}$ . The penalty is not severe but could be ameliorated by periodic cleaning of the surface.

### PROBLEM 8.101

**KNOWN:** Inlet and desired outlet temperature of a pharmaceutical fluid flowing in a straight tube or coiled tube of known diameter. Inlet velocity and tube surface temperature.

**FIND:** (a) Length of straight tube needed to achieve the desired outlet temperature, (b) Length of coiled tube to achieve the desired outlet temperature, (c) Pressure drops associated with the straight and coiled tubes, (d) Steam condensation rate.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Constant properties, (2) Incompressible liquid and negligible viscous dissipation, (3) Steady-state conditions, (4) fully developed hydrodynamic conditions at the entrance.

**PROPERTIES:** Steam (Table A.6):  $h_{fg}(T = 100^\circ\text{C}) = 2257 \text{ kJ/kg}$ . Pharmaceutical (given):  $\rho = 1000 \text{ kg/m}^3$ ,  $c_p = 4000 \text{ J/kg}\cdot\text{K}$ ,  $\mu = 2 \times 10^{-3} \text{ kg/s}\cdot\text{m}$ ,  $k = 0.80 \text{ W/m}\cdot\text{K}$ ,  $Pr = 10$ .

**ANALYSIS:**

(a) From Problem 8.27,  $Re_D = \rho u_m D / \mu = 1270$  and the flow is laminar for both cases. Hence, augmentation is expected to occur in the coiled tube. For the straight tube case a, the Hausen correlation is written as

$$\overline{Nu}_D = \frac{\bar{h}D}{k} = 3.66 + \frac{0.0668 \times (D/L_s) Re_D Pr}{1 + 0.04 [(D/L_s) Re_D Pr]^{2/3}}$$

which may be rearranged to yield

Continued...

**PROBLEM 8.101 (Cont.)**

$$\bar{h} = \frac{k}{D} \left\{ 3.66 + \frac{0.0668 (D/L_s) \text{Re}_D \text{Pr}}{1 + 0.04 [(D/L_s) \text{Re}_D \text{Pr}]^{2/3}} \right\}$$

$$\bar{h} = \frac{0.80 \text{ W/mK}}{12.7 \times 10^{-3} \text{ m}} \left\{ 3.66 + \frac{0.0668(12.7 \times 10^{-3} \text{ m/L}_s) \times 1270 \times 10}{1 + 0.04 [(12.7 \times 10^{-3} \text{ m/L}_s) \times 1270 \times 10]^{2/3}} \right\} \quad (1)$$

From Problem 8.27  $\dot{m} = 0.0253 \text{ kg/s}$  and the tube perimeter is

$$P = \pi D = \pi \times 12.7 \times 10^{-3} \text{ m} = 39.9 \times 10^{-3} \text{ m}$$

Equation 8.41b may be written

$$\frac{100^\circ\text{C} - 75^\circ\text{C}}{100^\circ\text{C} - 25^\circ\text{C}} = \exp\left(-\frac{39.9 \times 10^{-3} \text{ m} \times L_s}{0.0253 \text{ kg/s} \times 4000 \text{ J/kg} \cdot \text{K}} \times \bar{h}\right) \quad (2)$$

Equations (1) and (2) may be solved simultaneously to yield

$$L_s = 9.77 \text{ m}, (\bar{h} = 286 \text{ W/m}^2 \cdot \text{K}) \quad <$$

(b) For the coiled tube,

$$\text{Re}_D(D/C)^{1/2} = 1270 \times (12.7/100)^{1/2} = 452.6$$

Therefore,  $C/D = 100/12.7 = 7.87 > 3$ , Equation 8.77 yields

$$a = \left(1 + \frac{957(C/D)}{\text{Re}_D^2 \text{Pr}}\right) = \left(1 + \frac{957 \times (100/12.7)}{1270^2 \times 10}\right) = 1.0005$$

$$b = 1 + \frac{0.477}{\text{Pr}} = 1 + \frac{0.477}{10} = 1.0477$$

Therefore Equation 8.76 becomes

$$\text{Nu}_D = \left[ \left(3.66 + \frac{4.343}{1.0005}\right)^3 + 1.158 \times \left(\frac{1270 \times (12.7/100)^{1/2}}{1.0477}\right)^{3/2} \right]^{1/3} = 22.18$$

Therefore,

$$h = \text{Nu}_D \frac{k}{D} = 22.18 \times \frac{0.80 \text{ W/m} \cdot \text{K}}{12.7 \times 10^{-3} \text{ m}} = 1397 \text{ W/m}^2 \cdot \text{K}$$

Equation 8.41b may be written

Continued...

**PROBLEM 8.101 (Cont.)**

$$\frac{100^\circ\text{C} - 75^\circ\text{C}}{100^\circ\text{C} - 25^\circ\text{C}} = \exp\left(-\frac{3.99 \times 10^{-3} \text{ m} \times L_c}{0.0253 \text{ kg/s} \times 4000 \text{ J/kg} \cdot \text{K}} \times 1397 \text{ W/m}^2 \cdot \text{K}\right)$$

or  $L_c = 2.00 \text{ m}$

The number of coil turns is  $N = \frac{L_c}{\pi C} = \frac{2.00 \text{ m}}{\pi \times 100 \times 10^{-3} \text{ m}} = 6.4$

The coil length is  $L_{cl} = NS = 6.4 \times 25 \times 10^{-3} \text{ m} = 159 \times 10^{-3} \text{ m} = 159 \text{ mm}$  <

(c) The flow is hydrodynamically fully-developed in the straight tube. From Equations 8.19 and 8.22a,

$$\Delta p_s = \frac{64}{\text{Re}_D} \frac{\rho u_m^2}{2D} L_s = \frac{64}{1270} \times \frac{1000 \text{ kg/m}^3 \times (0.2 \text{ m/s})^2}{2 \times 12.7 \times 10^{-3} \text{ m}} \times 9.77 \text{ m} = 775 \text{ N/m}^2$$
 <

For the coiled tube, Equation 8.75b is

$$f = \frac{7.2}{\text{Re}_D^{0.5}} (D/C)^{0.25} = \frac{7.2}{1270^{0.5}} \times \left(\frac{12.7}{100}\right)^{0.25} = 0.121$$

$$\Delta p_c = f \frac{\rho u_m^2}{2D} L_c = 0.121 \times \frac{1000 \text{ kg/m}^3 \times (0.2 \text{ m/s})^2}{2 \times 12.7 \times 10^{-3} \text{ m}} \times 2.00 \text{ m} = 379 \text{ N/m}^2$$
 <

(d) The steam condensation rate,  $\dot{m}_{st}$ , is

$$\dot{m}_{st} h_{fg} = \dot{m} c_p (T_{m,o} - T_{m,i}) = u_m \rho A c_p (T_{m,o} - T_{m,i})$$

or

$$\dot{m}_{st} = \frac{0.2 \text{ m/s} \times 1000 \text{ kg/m}^3 \times \pi \times (12.7 \times 10^{-3} \text{ m})^2 \times 4000 \text{ J/kg} \cdot \text{K} \times (75 - 25)^\circ\text{C}}{4 \times 2257 \times 10^3 \text{ J/kg}}$$

$$\dot{m}_{st} = 2.25 \times 10^{-3} \text{ kg/s}$$
 <

**COMMENTS:** (1) For the straight tube,  $x_{fd,t} = 0.05 \text{Re}_D \text{Pr} D = 0.05 \times 1270 \times 10 \times 12.7 \times 10^{-3} \text{ m} = 8 \text{ m}$ . The value of the entrance length for the coiled tube will be 20 to 50 percent shorter than for the straight tube or between approximately 4 and 6 m. The flow in the coiled tube is not fully developed, and actual heat transfer rates will exceed those predicted using Equation 8.76. (2) The coiled tube requires  $(2/9.77) \times 100 = 20$  percent of the tube length relative to the straight tube case. (3) The coil length is  $(0.159/9.77) \times 100 = 1.6$  percent that of the straight tube. (4) The pressure drop in the coiled tube is  $(379/775) \times 100 = 48$  percent that of the straight tube. (5) The coiled tube will induce secondary flow in the pharmaceutical, thereby reducing radial temperature gradients in the liquid.

## PROBLEM 8.102

**KNOWN:** Laminar flow within a tube of diameter  $D_o$ . Inner rod diameter,  $D_i$ . Mean fluid temperature,  $T_m$ , and tube wall temperature,  $T_{s,o}$ .

**FIND:** Ratio of heat transfer from the fluid to the tube wall for  $D_i/D_o = 0, 0.10, 0.25$  and  $0.50$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Fully developed, laminar flow, (2) Constant properties, (3) Negligible conduction in the rod.

**ANALYSIS:** A control volume analysis about the inner rod reveals that there is no heat transfer to or from the rod. Hence, it acts as an insulated surface. Equation 8.68 may be written for the tube where, from Equation 8.70  $h_o = Nu_o k / D_h = Nu_o k / (D_o - D_i)$ . Hence,

$$q_o'' = \frac{Nu_o k (T_{s,o} - T_m)}{D_o (1 - D_i / D_o)} \quad (1)$$

Without the rod,  $D_i/D_o = 0$  and  $Nu_o = 3.66$ , yielding

$$q_{o,wo}'' = \frac{Nu_o k (T_{s,o} - T_m)}{D_o} = \frac{3.66 k (T_{s,o} - T_m)}{D_o} \quad (2)$$

Hence,

$$q_o'' / q_{o,wo}'' = \frac{Nu_o}{3.66(1 - D_i / D_o)}$$

From Table 8.2,

$D_i/D_o$	$Nu_o$	$q_o'' / q_{o,wo}''$	<
0	3.66	1	
0.10	4.11	1.25	
0.25	4.23	1.54	
0.50	4.43	2.42	

**COMMENTS:** (1) The proposed scheme enhances the heat transfer between the fluid and the tube wall, (2) The fluid temperature will change as the fluid flows in the axial direction. If the rod is of relatively high thermal conductivity compared to the fluid, the rod will be at a nearly uniform temperature. Hence, the rod could no longer be considered an insulated surface, since it would cool the fluid in upstream locations, and heat the fluid further downstream for the case where the fluid enters the annular region at a temperature higher than that of the tube wall.

### PROBLEM 8.103

**KNOWN:** Tubing with ethylene glycol welded to transformer to remove dissipated power. Maximum allowable coolant temperature rise of 6°C.

**FIND:** Required coolant flow rate, tube length and lateral spacing of turns.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Constant properties, (2) Incompressible liquid and negligible viscous dissipation, (3) Steady-state conditions, (4) Negligible tube wall thermal resistance, (5) Fully-developed flow, (6) All heat dissipated by transformer is transferred to ethylene glycol.

**PROPERTIES:** Table A.5, ethylene glycol: ( $\bar{T}_m = 300$  K, assumed):  $k = 0.252$  W/m·K,  $c_p = 2415$  J/kg·K,  $\mu_f = 1.57 \times 10^{-2}$  N·s/m<sup>2</sup>,  $Pr = 1151$ .

**ANALYSIS:** From an overall energy balance, the required flow rate is

$$q = \dot{m}c_p(T_{m,o} - T_{m,i}) \quad \text{or} \quad \dot{m} = q/c_p(T_{m,o} - T_{m,i})$$

$$\dot{m} = 1000 \text{ W} / (2415 \text{ J/kg} \cdot \text{K} \times 6\text{K})$$

$$\dot{m} = 6.90 \times 10^{-2} \text{ kg/s}$$

<

From Equation 8.41a the length of tubing may be determined,

$$L = -\frac{\dot{m}c_p}{Ph} \ln\left(\frac{T_s - T_{m,o}}{T_s - T_{m,i}}\right)$$

where  $P = \pi D$ . For the tube flow, find

$$Re_D = \frac{4\dot{m}}{\pi D\mu} = \frac{4 \times 6.90 \times 10^{-2} \text{ kg/s}}{\pi \times 0.020 \text{ m} \times 1.57 \times 10^{-2} \text{ N} \cdot \text{S/m}^2} = 279.8$$

$$C/D = (D_t + D) = 250/20 = 12.5; \quad Re_D(D/C)^{1/2} = 279.8 \times (20/250)^{1/2} = 79.1$$

Equation 8.77 yields

Continued...

### PROBLEM 8.103 (Cont.)

$$a = \left( 1 + \frac{957 \times (250/20)}{(279.8)^2 \times 1151} \right) = 1.0001$$

$$b = 1 + \frac{0.477}{1151} = 1.0004$$

Therefore, Equation 8.76 is

$$\begin{aligned} \text{Nu}_D &= \left[ \left( 3.66 + \frac{4.343}{1.0001} \right)^3 + 1.158 \left( \frac{279.8 \times (20/250)^{1/2}}{1.0004} \right)^{3/2} \right]^{1/3} \\ &= 10.99 \end{aligned}$$

$$\bar{h} = h = \text{Nu}_D \frac{k}{D} = 10.99 \times 252 \times 10^{-3} \text{ W/m} \cdot \text{K} / 20 \times 10^{-3} \text{ m} = 138.5 \text{ W/m}^2 \cdot \text{K}$$

Equation 8.41a becomes

$$L = - \frac{6.90 \times 10^{-2} \text{ kg/s} \times 2415 \text{ J/kg} \cdot \text{K}}{\pi \times 0.02 \text{ m} \times 138.5 \text{ W/m}^2 \cdot \text{K}} \ln \left( \frac{(47 - 30)^\circ\text{C}}{(47 - 24)^\circ\text{C}} \right) = 5.79 \text{ m} \quad <$$

The number of turns of the tubing,  $N$ , is  $N = L/\pi D = 5.79 \text{ m} / \pi(0.025 \text{ m}) = 7.37$  and hence the spacing,  $S$ , is

$$S = H/N = 500 \text{ mm} / 7.37 = 67.8 \text{ mm} \quad <$$

**COMMENT:** (1) Coiling the tube results in a convective heat transfer coefficient that is  $10.99/3.66 = 3$  times larger than the fully-developed value for a straight tube. (2) For a straight tube, the thermal entrance length is  $x_{fd,t} = 0.05 \text{Re}_D \text{Pr}D = 0.05 \times 279.8 \times 1151 \times 0.02 \text{ m} = 322 \text{ m}$ . The flow will not be fully-developed, and care must be taken when using the predictions.

## PROBLEM 8.104

**KNOWN:** Geometry and dimensions of a tube with straight and coiled sections. Temperature and convection coefficient of coolant flowing outside the tube. Inlet temperature, mass flow rate, and properties of pharmaceutical fluid in tube.

**FIND:** (a) Outlet temperature of pharmaceutical, (b) Outlet temperature with inner heat transfer coefficient doubled in straight sections, (c) Effect of left- or right-handed spiral.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Tube wall thermal resistance is negligible. (2) Flow is fully-developed in coiled section. (3) Flow in last straight section is unaffected by swirl introduced in coiled section. (4) Constant properties.

**PROPERTIES:** Pharmaceutical fluid (given):  $\rho = 1200 \text{ kg/m}^3$ ,  $\mu = 4 \times 10^{-3} \text{ N}\cdot\text{s/m}^2$ ,  $c_p = 2000 \text{ J/kg}\cdot\text{K}$ ,  $k = 0.5 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = \mu c_p/k = 16$ .

**ANALYSIS:**

(a) The Reynolds number is

$$\text{Re}_D = \frac{4 \dot{m}}{\pi D \mu} = \frac{4 \times 0.005 \text{ kg/s}}{\pi \times 0.01 \text{ m} \times 4 \times 10^{-3} \text{ N}\cdot\text{s/m}^2} = 159$$

Thus the flow is laminar.

1<sup>st</sup> Straight Section. The development length in the straight section is

$$x_{fd,h} = 0.05 \text{ Re}_D D = 0.05 \times 159 \times 0.01 \text{ m} = 0.08 \text{ m}$$

$$x_{fd,t} = x_{fd,h} \cdot \text{Pr} = 0.08 \text{ m} \times 16 = 1.3 \text{ m}$$

The flow is thermally developing. With  $\text{Pr} > 5$ , we can use Equation 8.57 with Equation 8.56,

$$\overline{\text{Nu}}_D = 3.66 + \frac{0.0668 (D/L) \text{Re}_D \text{Pr}}{1 + 0.04 [(D/L) \text{Re}_D \text{Pr}]^{2/3}} = 7.29$$

Thus  $h_i = \overline{\text{Nu}}_D k/D = 7.29 \times 0.5 \text{ W/m}\cdot\text{K}/0.01 \text{ m} = 365 \text{ W/m}^2 \cdot \text{K}$ .

Continued...

### PROBLEM 8.104 (Cont.)

The mean temperature at the end of the first straight section can be found from Equation 8.45a,

$$T_{m,o1} = T_{\infty} + (T_{m,i} - T_{\infty}) \exp\left(-\frac{\bar{U}A_s}{\dot{m}c_p}\right)$$

where  $\bar{U} = [1/h_i + 1/h_o]^{-1} = [1/365 \text{ W/m}^2 \cdot \text{K} + 1/500 \text{ W/m}^2 \cdot \text{K}]^{-1} = 211 \text{ W/m}^2 \cdot \text{K}$ .

$$\text{Thus } T_{m,o1} = 20^\circ\text{C} + (90^\circ\text{C} - 20^\circ\text{C}) \exp\left(-\frac{211 \text{ W/m}^2 \cdot \text{K} \times \pi \times 0.01 \text{ m} \times 0.25 \text{ m}}{0.005 \text{ kg/s} \times 2000 \text{ J/kg} \cdot \text{K}}\right) = 79.3^\circ\text{C}$$

Coiled Section. The critical Reynolds number in the coiled section is given by Equation 8.74,

$$Re_{D,C,h} = Re_{D,C} [1 + 12(D/C)^{0.5}]$$

where  $Re_{D,C} = 2300$ . Since this must be greater than 2300, the flow in the coiled section, with  $Re_D = 159$ , is still laminar. The length of the coiled section is  $6.5 \pi C = 6.5 \pi (0.075 \text{ m}) = 1.53 \text{ m}$ . Since development lengths are 20 to 50% shorter in coiled tubes than in straight tubes the flow can be approximated as fully developed. The Nusselt number is given by Equation 8.76, with

$$a = \left[1 + \frac{957 (C/D)}{Re_D^2 Pr}\right] = \left[1 + \frac{957 (75 \text{ mm}/10 \text{ mm})}{(159)^2 \times 16}\right] = 1.018$$

and  $b = 1 + 0.477/Pr = 1 + 0.477/16 = 1.030$ . Note that  $Re_D (D/C)^{1/2} = 58$ , therefore the criteria for using Equations 8.76 and 8.77 are satisfied. Thus assuming  $\mu_s = \mu$ ,

$$\begin{aligned} Nu_D &= \left[ \left( 3.66 + \frac{4.343}{a} \right)^3 + 1.158 \left( \frac{Re_D (D/C)^{1/2}}{b} \right)^{3/2} \right]^{1/3} \\ &= \left[ \left( 3.66 + \frac{4.343}{1.018} \right)^3 + 1.158 \left( \frac{159 (10 \text{ mm}/75 \text{ mm})^{1/2}}{1.030} \right)^{3/2} \right]^{1/3} = 9.96 \end{aligned}$$

and  $h_i = Nu_D k/D = 498 \text{ W/m}^2 \cdot \text{K}$ .

Then  $\bar{U} = [1/h_i + 1/h_o]^{-1} = [1/498 \text{ W/m}^2 \cdot \text{K} + 1/500 \text{ W/m}^2 \cdot \text{K}]^{-1} = 250 \text{ W/m}^2 \cdot \text{K}$ .

The outlet temperature of the coiled section can be found from Equation 8.45a, with  $A_s = (\pi D)(6.5 \pi C) = 0.048 \text{ m}^2$ , and the inlet temperature is the outlet temperature of the straight section:

$$T_{m,o2} = T_{\infty} + (T_{m,o1} - T_{\infty}) \exp\left(-\frac{\bar{U}A_s}{\dot{m}c_p}\right)$$

$$T_{m,o2} = 20^\circ\text{C} + (79.3^\circ\text{C} - 20^\circ\text{C}) \exp\left(-\frac{250 \text{ W/m}^2 \cdot \text{K} \times 0.048 \text{ m}^2}{0.005 \text{ kg/s} \times 2000 \text{ J/kg} \cdot \text{K}}\right) = 37.9^\circ\text{C}$$

Continued...

### PROBLEM 8.104 (Cont.)

2<sup>nd</sup> Straight Section. The overall heat transfer coefficient would be the same as in the 1<sup>st</sup> straight section. The outlet temperature can be calculated from Equation 8.45a with the inlet temperature equal to the outlet temperature of the coiled section.

$$T_{m,03} = T_{\infty} + (T_{m,02} - T_{\infty}) \exp\left(-\frac{\bar{U}A_s}{\dot{m}c_p}\right)$$

$$T_{m,03} = 20^{\circ}\text{C} + (37.9^{\circ}\text{C} - 20^{\circ}\text{C}) \exp\left(-\frac{211 \text{ W/m}^2 \cdot \text{K} \times \pi \times 0.01 \text{ m} \times 0.25 \text{ m}^2}{0.005 \text{ kg/s} \times 2000 \text{ J/kg} \cdot \text{K}}\right)$$

$$T_{m,03} = 35.1^{\circ}\text{C}$$

&lt;

(b) Repeating the calculations with  $h_i$  in the straight sections doubled, in the 1<sup>st</sup> straight section:

$$\bar{U} = \left[1/730 \text{ W/m}^2 \cdot \text{K} + 1/500 \text{ W/m}^2 \cdot \text{K}\right]^{-1} = 297 \text{ W/m}^2 \cdot \text{K}$$

$$T_{m,01} = 75.4^{\circ}\text{C}$$

In the coiled section,  $\bar{U}$  is unchanged, and

$$T_{m,02} = 36.7^{\circ}\text{C}$$

In the 2<sup>nd</sup> straight section,  $\bar{U} = 297 \text{ W/m}^2 \cdot \text{K}$  and

$$T_{m,03} = 33.2^{\circ}\text{C}$$

(c) Yes, the orientation of the springs could have an effect, because they introduce swirl that interacts with the swirl introduced in the coiled section. However, the effect is probably small.

**COMMENTS:** The analysis is only approximate. In particular, the flow in the last section would be affected by the swirl introduced in the coiled section, which would in turn affect the heat transfer.

## PROBLEM 8.105

**KNOWN:** Pressurized water inlet temperature and total mass flow rate for mold cooling and heating. Water channel dimensions for conventional and conformally-cooled mold. Initial hot and cold mold temperatures, mold dimensions and mold properties.

**FIND:** (a) Initial heating rate of a cold (100°C) mold, initial cooling rate of a hot (200°C) mold for straight water channels with  $D = 50$  mm, (b) Initial heating rate of a cold (100°C) mold, initial cooling rate of a hot (200°C) mold for a conformally-cooled mold with water channels of diameter  $D = 50$  mm, (c) Surface areas of cooling/heating channels for both molds and determination of which mold will enable production of more parts per day.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Constant properties, (2) Incompressible liquid and negligible viscous dissipation, (3) Fully developed hydrodynamic conditions at the entrance, (4) Negligible part mass, (5) Water sufficiently pressurized to prevent boiling, (6) Negligible heat transfer in short straight sections of the channel for the conformally-cooled case.

**PROPERTIES:** Table A.6, water: ( $\bar{T}_m = 260^\circ\text{C}$ , assumed):  $k = 0.6038$  W/m·K,  $c_p = 4989$  J/kg·K,  $\mu = 103.1 \times 10^{-6}$  N·s/m<sup>2</sup>,  $Pr = 0.853$ . ( $\bar{T}_m = 40^\circ\text{C}$ , assumed):  $k = 0.6316$  W/m·K,  $c_p = 4179$  J/kg·K,  $\mu = 656.6 \times 10^{-6}$  N·s/m<sup>2</sup>,  $Pr = 4.344$ . ( $T_s = 200^\circ\text{C}$ ):  $\mu_s = 133.9 \times 10^{-6}$  N·s/m<sup>2</sup>.

Continued...

### PROBLEM 8.105 (Cont.)

**ANALYSIS:** (a) Heating,  $\overline{T}_m = 260^\circ\text{C}$ . The Reynolds number is

$$\text{Re}_D = \frac{4\dot{m}}{\pi D\mu} = \frac{(4 \times 0.01 \text{ kg/s})/5}{\pi \times 5 \times 10^{-3} \text{ m} \times 103.1 \times 10^{-6} \text{ N}\cdot\text{s}/\text{m}^2} = 4940$$

From the Gnielinski correlation, with  $f = (0.790 \ln \text{Re}_D - 1.64)^{-2} = (0.790 \ln 4940 - 1.64)^{-2} = 38.8 \times 10^{-3}$ ,

$$\text{Nu}_D = \frac{(f/8)(\text{Re}_D - 1000)\text{Pr}}{1 + 12.7(f/8)^{1/2}(\text{Pr}^{2/3} - 1)} = \frac{(38.8 \times 10^{-3}/8) \times (4940 - 1000) \times 0.853}{1 + 12.7(38.8 \times 10^{-3}/8)^{1/2}(0.853^{2/3} - 1)} = 17.89$$

Therefore,  $h_D = \text{Nu}_D k/D = 17.89 \times 0.6038 \text{ W/m}\cdot\text{K}/5 \times 10^{-3} \text{ m} = 2161 \text{ W/m}^2\cdot\text{K}$ . For  $P = \pi D = \pi \times 5 \times 10^{-3} \text{ m} = 15.7 \times 10^{-3} \text{ m}$ ,  $L = 60 \times 10^{-3} \text{ m}$ ,  $\dot{m} = 0.01 \text{ kg/s}/5 = 0.002 \text{ kg/s}$ , Equation 8.42 is written

$$\frac{100 - T_{m,o}}{100 - 275} = \exp\left(-\frac{15.7 \times 10^{-3} \text{ m} \times 60 \times 10^{-3} \text{ m} \times 2161 \text{ W/m}^2\cdot\text{K}}{0.002 \text{ kg/s} \times 4989 \text{ J/kg}\cdot\text{K}}\right)$$

from which  $T_{m,o} = 243^\circ\text{C}$ . Therefore,

$$q_w = \dot{m}c_p(T_{m,o} - T_{m,i}) = 0.002 \text{ kg/s} \times 4989 \text{ J/kg}\cdot\text{K} \times (243^\circ\text{C} - 275^\circ\text{C}) = 319 \text{ W/channel and, for}$$

$$\text{the entire mold, } q_h = -q_w \times M \times 2 = 319 \text{ W} \times 5 \times 2 = 3190 \text{ W} \quad <$$

Cooling,  $\overline{T}_m = 40^\circ\text{C}$ . The Reynolds number is

$$\text{Re}_D = \frac{4\dot{m}}{\pi D\mu} = \frac{(4 \times 0.01 \text{ kg/s})/5}{\pi \times 5 \times 10^{-3} \text{ m} \times 656.6 \times 10^{-6} \text{ N}\cdot\text{s}/\text{m}^2} = 776$$

Using Equation 8.56,

$$\text{Nu}_D = 3.66 + \frac{0.0668(D/L)\text{Re}_D\text{Pr}}{1 + 0.04[(D/L)\text{Re}_D\text{Pr}]^{2/3}} = 3.66 + \frac{0.0668(5/60) \times 776 \times 4.344}{1 + 0.04[(5/60) \times 776 \times 4.344]^{2/3}} = 10.57$$

Therefore,  $h_D = \text{Nu}_D k/D = 10.57 \times 0.6316 \text{ W/m}\cdot\text{K}/5 \times 10^{-3} \text{ m} = 1335 \text{ W/m}^2\cdot\text{K}$ . Equation 8.42 yields

$$\frac{200 - T_{m,o}}{100 - 25} = \exp\left(-\frac{15.7 \times 10^{-3} \text{ m} \times 60 \times 10^{-3} \text{ m} \times 1335 \text{ W/m}^2\cdot\text{K}}{0.002 \text{ kg/s} \times 4179 \text{ J/kg}\cdot\text{K}}\right)$$

from which  $T_{m,o} = 49.4^\circ\text{C}$ . Therefore,

$$q_w = \dot{m}c_p(T_{m,o} - T_{m,i}) = 0.002 \text{ kg/s} \times 4179 \text{ J/kg}\cdot\text{K} \times (49.4^\circ\text{C} - 25^\circ\text{C}) = 203.9 \text{ W/channel and, for}$$

$$\text{the entire mold, } q_c = -q_w \times M \times 2 = -203.9 \text{ W} \times 5 \times 2 = -2039 \text{ W} \quad <$$

Continued...

**PROBLEM 8.105 (Cont.)**

(b) Heating,  $\overline{T}_m = 260^\circ\text{C}$ . The critical Reynolds number is

$$\text{Re}_{D,c,h} = \text{Re}_{D,c} \left[ 1 + 12(D/C)^{0.5} \right] = 2300 \times \left[ 1 + 12(5/50)^{0.5} \right] = 11030. \text{ The actual}$$

Reynolds number is  $\text{Re}_D = \frac{4\dot{m}}{\pi D\mu} = \frac{4 \times 0.01 \text{ kg/s}}{\pi \times 5 \times 10^{-3} \text{ m} \times 103.1 \times 10^{-6} \text{ N}\cdot\text{s/m}^2} = 24700$  and the flow is turbulent. Using the Gnielinski correlation, with  $f = (0.790 \ln \text{Re}_D - 1.64)^{-2} = (0.790 \ln 24700 - 1.64)^{-2} = 24.8 \times 10^{-3}$ ,

$$\text{Nu}_D = \frac{(f/8)(\text{Re}_D - 1000)\text{Pr}}{1 + 12.7(f/8)^{1/2}(\text{Pr}^{2/3} - 1)} = \frac{(24.8 \times 10^{-3}/8) \times (24700 - 1000) \times 0.853}{1 + 12.7(24.8 \times 10^{-3}/8)^{1/2}(0.853^{2/3} - 1)} = 62.67$$

Therefore,  $h_D = \text{Nu}_D k/D = 62.67 \times 0.6038 \text{ W/m}\cdot\text{K}/5 \times 10^{-3} \text{ m} = 7570 \text{ W/m}^2\cdot\text{K}$ . For  $P = 15.7 \times 10^{-3} \text{ m}$ ,  $L = 2\pi C = 2 \times \pi \times 50 \times 10^{-3} \text{ m} = 0.314 \text{ m}$ , and  $\dot{m} = 0.01 \text{ kg/s}$ , Equation 8.42 is written as

$$\frac{100 - T_{m,o}}{100 - 275} = \exp\left(-\frac{15.7 \times 10^{-3} \text{ m} \times 0.314 \text{ m} \times 7570 \text{ W/m}^2\cdot\text{K}}{0.01 \text{ kg/s} \times 4989 \text{ J/kg}\cdot\text{K}}\right)$$

from which  $T_{m,o} = 182.8^\circ\text{C}$ . Then,  $q_h = 0.02 \text{ kg/s} \times 4989 \text{ J/kg}\cdot\text{K} \times (182.8^\circ\text{C} - 275^\circ\text{C}) = 9197 \text{ W} <$

Cooling,  $\overline{T}_m = 40^\circ\text{C}$ . The Reynolds number is

$$\text{Re}_D = \frac{4\dot{m}}{\pi D\mu} = \frac{(4 \times 0.01 \text{ kg/s})}{\pi \times 5 \times 10^{-3} \text{ m} \times 656.6 \times 10^{-6} \text{ N}\cdot\text{s/m}^2} = 3880$$

Since  $\text{Re}_D < \text{Re}_{D,c,h}$ , the flow is laminar and  $\text{Re}_D(D/C)^{1/2} = 3880 \times (5/50)^{1/2} = 1227$ . The values of a and b for use in Equation 8.77 are

$$a = \left( \frac{1 + 957(C/D)}{\text{Re}_D^2 \text{Pr}} \right) = \left( \frac{1 + 957 \times (50/5)}{3880^2 \times 4.344} \right) = 146 \times 10^{-3}; \quad b = 1 + \frac{0.477}{\text{Pr}} = -1 + \frac{0.477}{4.344} = 1.11$$

Equation 8.76 is rearranged to yield

$$h_D = \frac{0.6316 \text{ W/m}\cdot\text{K}}{5 \times 10^{-3} \text{ m}} \left[ \left( 3.66 + \frac{4.343}{146 \times 10^{-3}} \right)^3 + 1.158 \times \left( \frac{1227}{1.11} \right)^{3/2} \right]^{1/3} \left( \frac{656}{133.9} \right)^{0.14} = 6794 \text{ W/m}^2\cdot\text{K}$$

Equation 8.42 is written

Continued...

**PROBLEM 8.105 (Cont.)**

$$\frac{200 - T_{m,o}}{100 - 25} = \exp\left(-\frac{15.7 \times 10^{-3} \text{ m} \times 0.314 \text{ m} \times 6794 \text{ W/m}^2 \cdot \text{K}}{0.01 \text{ kg/s} \times 4179 \text{ J/kg} \cdot \text{K}}\right)$$

from which  $T_{m,o} = 121.5^\circ\text{C}$ . Therefore,

$$q_c = \dot{m}c_p(T_{m,o} - T_{m,i}) = 0.02 \text{ kg/s} \times 4179 \text{ J/kg} \cdot \text{K} \times (25^\circ\text{C} - 121.5^\circ\text{C}) = -8065 \text{ W}$$

<

(c) For the conventional mold,

$A_{cp} = 2M\pi DL = 2 \times 5 \times \pi \times 5 \times 10^{-3} \text{ m} \times 60 \times 10^{-3} \text{ m} = 9.42 \times 10^{-3} \text{ m}^2$ . For the conformally-cooled mold,  $A_{cc} = 2N\pi C\pi D = 2 \times 2 \times \pi^2 \times 50 \times 10^{-3} \text{ m} \times 5 \times 10^{-3} \text{ m} = 9.87 \times 10^{-3} \text{ m}^2$ .

The time rate of change of the mold temperature is

$$\frac{dT}{dt} = \frac{q}{V\rho C} = \frac{q}{(60 \times 10^{-3} \text{ m})^2 \times 40 \times 10^{-3} \text{ m} \times 7800 \text{ kg/m}^3 \times 450 \text{ J/kg} \cdot \text{K}} = \frac{q}{505.4 \text{ W} \cdot \text{s/K}}$$

The results are summarized in the following table.

Mold Type	q (W)	Flow Regime	dT/dt (K/s)
Conventional heating	3190	turbulent	6.51
Conventional cooling	-2039	laminar	4.03
Conformal heating	9197	turbulent	18.20
Conformal cooling	-8065	laminar enhanced	15.96

The conformally-cooled mold will increase production by a factor of 3 to 4 times, using the same cooling area.

**COMMENTS:** (1) The average mean temperature for heating is  $258.8^\circ\text{C}$  and  $230^\circ\text{C}$  for the conventional and conformally-cooled molds, respectively. The assumed average mean temperature ( $260^\circ\text{C}$ ) is very good for the conventional mold case. A more accurate solution would be obtained by re-calculating the answer for the conformally-cooled case based upon a better estimate of the average mean temperature. (2) The average mean temperature for cooling is  $37.2^\circ\text{C}$  and  $73.3^\circ\text{C}$  for the conventional and conformally-cooled molds, respectively. The assumed average mean temperature for cooling ( $40^\circ\text{C}$ ) is very good for the conventional mold case. A more accurate solution would be obtained by re-calculating the answer for the conformally-cooled case based upon a better estimate of the average mean temperature. (3) The conformally-cooled mold offers enhanced performance due to higher mean velocity in the case of heating, and enhanced laminar flow due to curvature in the case of cooling. (4) Equation 8.76 has been extended slightly beyond its range of recommended application. Care should be taken in using the predictions.

## PROBLEM 8.106

**KNOWN:** Inlet temperatures and flow rates of a pharmaceutical product and pressurized water, tube diameter, coil diameter and number of coils.

**FIND:** (a) The outlet temperature of the pharmaceutical product, (b) The variation of the pharmaceutical outlet temperature with the pressurized water flow rate.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Constant properties and steady-state conditions, (2) Incompressible liquid and negligible viscous dissipation, (3) Fully developed flow, (4) Negligible tube wall thermal resistance, (5) Negligible heat loss to surroundings and ambient.

**PROPERTIES:** Table A.6, water: ( $\bar{T}_m = 380 \text{ K}$ ):  $k = 0.683 \text{ W/m}\cdot\text{K}$ ,  $c_p = 4226 \text{ J/kg}\cdot\text{K}$ ,  $\mu = 260 \times 10^{-6} \text{ N}\cdot\text{s/m}^2$ ,  $Pr = 1.61$ ,  $\rho = 953.3 \text{ kg/m}^3$ . Pharmaceutical (given):  $k = 0.80 \text{ W/m}\cdot\text{K}$ ,  $c_p = 4000 \text{ J/kg}\cdot\text{K}$ ,  $\mu = 2 \times 10^{-3} \text{ kg/s}\cdot\text{m}$ ,  $Pr = 10$ ,  $\rho = 1000 \text{ kg/m}^3$ .

**ANALYSIS:** For the water,

$$\dot{m}_w = \frac{\rho u_w \pi D^2}{4} = \frac{953.3 \text{ kg/m}^3 \times 0.12 \text{ m/s} \times \pi \times (0.01 \text{ m})^2}{4} = 0.00899 \text{ kg/s}$$

$$Re_{D,w} = \frac{4\dot{m}_w}{\pi D \mu} = \frac{4 \times 0.00899 \text{ kg/s}}{\pi \times 0.01 \text{ m} \times 260 \times 10^{-6} \text{ kg/s}\cdot\text{m}} = 4400$$

For the pharmaceutical,

$$\dot{m}_p = \frac{\rho u_p \pi D^2}{4} = \frac{1000 \text{ kg/m}^3 \times 0.10 \text{ m/s} \times \pi \times (0.01 \text{ m})^2}{4} = 0.00785 \text{ kg/s}$$

Continued...

**PROBLEM 8.106 (Cont.)**

$$\text{Re}_{D,p} = \frac{4\dot{m}_p}{\pi D\mu} = \frac{4 \times 0.00785 \text{ kg/s}}{\pi \times 0.01 \text{ m} \times 2 \times 10^{-3} \text{ kg/s} \cdot \text{m}} = 500$$

The flow of the pharmaceutical is laminar ( $\text{Re}_{D,p} < 2300$ ). For the coiled tube,  $C = D_r + 2(D/2) = 40 \text{ mm} + 2 \times 5 \text{ mm} = 50 \text{ mm}$ . Using Equation 8.74,  $\text{Re}_{D,c,h,w} = 2300[1 + 12 \times (10/50)^{0.5}] = 14,640$ . Therefore, the flow of the pressurized water is laminar ( $\text{Re}_{D,w} = 4400 < 14,640$ ).

For the pharmaceutical product,  $\text{Re}_{D,p}(D/C)^{1/2} = 500 \times (10/50)^{1/2} = 223$ , while for the water  $\text{Re}_{D,w}(D/C)^{1/2} = 4400 \times (10/50)^{1/2} = 1967$ . For each tube,  $C/D = 50/10 = 5 > 3$ .

For the pharmaceutical product and water, the overall energy balances are

$$q = \dot{m}_p c_{p,p} (T_{p,o} - T_{p,i}) \quad ; \quad q = \dot{m}_w c_{p,w} (T_{w,i} - T_{w,o}) \quad (1,2)$$

For the pharmaceutical and water, Equation 8.42 is

$$\frac{T_s - T_{p,o}}{T_s - T_{p,i}} = \exp\left(-\frac{\pi DL}{\dot{m}_p c_{p,p}} \bar{h}_p\right) \quad ; \quad \frac{T_s - T_{w,o}}{T_s - T_{w,i}} = \exp\left(-\frac{\pi DL}{\dot{m}_w c_{p,w}} \bar{h}_w\right) \quad (3,4)$$

Once we determine  $\bar{h}_p$  and  $\bar{h}_w$ , we may solve Equations (1) through (4) simultaneously for four unknowns:  $q$ ,  $T_{p,o}$ ,  $T_{w,o}$  and  $T_s$ . We will use Equation 8.76, but be aware that we are using the correlation outside of its recommended range of applicability for the water. For the pharmaceutical product, Equation 8.77 yields

$$a = \left(1 + \frac{957 \times (50/10)}{(500)^2 \times 10}\right) = 1.002 \quad ; \quad b = 1 + \frac{0.477}{10} = 1.048$$

Therefore, Equation 8.76 becomes

$$\text{Nu}_{D,p} = \left[ \left(3.66 + \frac{4.343}{1.002}\right)^3 + 1.158 \left(\frac{500(10/50)^{1/2}}{1.048}\right)^{3/2} \right]^{1/3} = 16.03$$

Therefore,  $\bar{h}_p = \text{Nu}_{D,p} k_p / D = 16.03 \times 0.80 \text{ W/m} \cdot \text{K} / 0.01 \text{ m} = 1283 \text{ W/m}^2 \cdot \text{K}$ . For the pressurized water, Equation 8.77 yields

$$a = \left(1 + \frac{957 \times (50/10)}{(4400)^2 \times 1.61}\right) = 1.00 \quad ; \quad b = 1 + \frac{0.477}{1.61} = 1.296$$

Continued...

### PROBLEM 8.106 (Cont.)

Proceeding as before, we find  $Nu_{D,w} = 41.01$ ,  $\overline{h_w} = 2801 \text{ W/m}^2 \cdot \text{K}$ . The tube length is  $L = N \times \pi \times D_f = 20 \times \pi \times 0.05 \text{ m} = 3.14 \text{ m}$ . Substituting values into Equations (1) through (4) and solving simultaneously yields

$$q = 1736 \text{ W}, T_{p,o} = 80.25^\circ\text{C}, T_{w,o} = 81.28^\circ\text{C}, T_s = 81.25^\circ\text{C}$$

<

(b) The dependence of the pharmaceutical outlet temperature on the water velocity is shown in the graph below. Note that the pharmaceutical product's outlet temperature can be controlled accurately by modifying the water flow rate.

**COMMENTS:** (1) The pharmaceutical outlet temperature will be relatively uniform across the diameter of the tube due to mixing associated with secondary flow. (2) Although we have applied Equation 8.76 outside of its range of general applicability, the actual behavior is not expected to be significantly different than predicted. That is, we would still expect the pharmaceutical outlet temperature to be highly controllable by adjusting the water flow rate. Actual outlet temperatures could be easily measured and the water flow rate adjusted to provide the desired thermal response. (3) The average mean water temperature is  $\overline{T}_m = (T_{w,i} + T_{w,o})/2 = (127^\circ\text{C} + 81.3^\circ\text{C})/2 = 104^\circ\text{C} = 377 \text{ K}$ . The assumed mean temperature of 380 K is reasonable.

### PROBLEM 8.107

**KNOWN:** Chip and cooling channel dimensions. Channel flowrate and inlet temperature. Chip temperature.

**FIND:** Water outlet temperature and chip power.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Incompressible liquid with negligible viscous dissipation, (2) Uniform channel surface temperature, (3)  $\bar{T}_m = 300$  K, (4) Fully developed flow.

**PROPERTIES:** Table A-6, Water ( $\bar{T}_m = 300$  K):  $c_p = 4179$  J/kg·K,  $\mu = 855 \times 10^{-6}$  kg/s·m,  $k = 0.613$  W/m·K,  $Pr = 5.83$ .

**ANALYSIS:** Using the hydraulic diameter, find the Reynolds number,

$$D_h = \frac{4(H \times W)}{2(H + W)} = \frac{2(50 \times 200) \mu\text{m}^2}{250 \mu\text{m}} 10^{-6} \text{ m}/\mu\text{m} = 8 \times 10^{-5} \text{ m}$$

$$Re_D = \frac{\rho u_m D_h}{\mu} = \frac{\dot{m}_1 D_h}{A_c \mu} = \frac{10^{-4} \text{ kg/s} (8 \times 10^{-5} \text{ m})}{(50 \times 200) 10^{-12} \text{ m}^2 (855 \times 10^{-6} \text{ kg/s} \cdot \text{m})} = 936.$$

Hence, the flow is laminar and, from Table 8.1,  $Nu_D = 4.44$ , so that

$$h = Nu_D \frac{k}{D_h} = \frac{4.44(0.613 \text{ W/m} \cdot \text{K})}{8 \times 10^{-5} \text{ m}} = 34,022 \text{ W/m}^2 \cdot \text{K}.$$

With  $P = 2(H + W) = 2(250 \mu\text{m}) 10^{-6} \text{ m}/\mu\text{m} = 5 \times 10^{-4} \text{ m}$ , Eq. 8.41b yields

$$\frac{T_s - T_{m,o}}{T_s - T_{m,i}} = \frac{350\text{K} - T_{m,o}}{60 \text{ K}} = \exp\left(-\frac{PL}{\dot{m}_1 c_p} h\right) = \exp\left(-\frac{5 \times 10^{-6} \text{ m}^2 \times 34,022 \text{ W/m}^2 \cdot \text{K}}{10^{-4} \text{ kg/s} \times 4179 \text{ J/kg} \cdot \text{K}}\right)$$

$$T_{m,o} = 350\text{K} - 60 \text{ K} \exp(-0.407) = 310 \text{ K}. \quad <$$

Hence, from Eq. 8.34,

$$q = \dot{m} c_p (T_{m,o} - T_{m,i}) = N \dot{m}_1 c_p (T_{m,o} - T_{m,i}) = 50 \times 10^{-4} \text{ kg/s} (4179 \text{ J/kg} \cdot \text{K}) (20 \text{ K}) = 418 \text{ W}. \quad <$$

**COMMENTS:** (1) The chip heat flux of  $418 \text{ W/cm}^2$  is extremely large and the method provides a very efficient means of heat removal from high power chips. However, clogging of the microchannels is a potential problem which could seriously compromise reliability. (2)  $L/D_h = 125$  and  $0.05 Re_D Pr = 272$ . Hence, fully developed conditions are not realized and  $\bar{h} > 34,022$ . The actual power dissipation is therefore greater than 418 W.

## PROBLEM 8.108

**KNOWN:** Flow of an ideal gas through a small diameter tube.

**FIND:** Expression for the transition density, below which microscale effects become important. Value of the transition density for hydrogen, air and carbon dioxide.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Constant properties, (2) Ideal gas.

**PROPERTIES:** Figure 2.8 and Table A.4 ( $p = 1 \text{ atm}$ ,  $T = 300 \text{ K}$ ) Air:  $\mathcal{M} = 28.97 \text{ kmol/kg}$ ,  $d = 0.372 \text{ nm}$ ,  $\rho = 1.161 \text{ kg/m}^3$ ,  $\text{H}_2$ :  $\mathcal{M} = 2.016 \text{ kmol/kg}$ ,  $d = 0.274 \text{ nm}$ ,  $\rho = 0.0808 \text{ kg/m}^3$ ,  $\text{CO}_2$ :  $\mathcal{M} = 44.01 \text{ kmol/kg}$ ,  $d = 0.464 \text{ nm}$ ,  $\rho = 1.773 \text{ kg/m}^3$ .

**ANALYSIS:** From Eq. 2.11 the mean free path is

$$\lambda_{\text{mfp}} = \frac{k_B T}{\sqrt{2} \pi d^2 p}$$

and from the ideal gas equation of state,  $p = \rho \mathcal{R} T / \mathcal{M}$ . Microscale effects become important at  $\lambda_{\text{mfp}} / D \approx 0.01$ . Therefore,

$$\frac{\lambda_{\text{mfp}}}{D} = 0.01 = \frac{k_B \mathcal{M}}{\sqrt{2} \pi d^2 \rho_c \mathcal{R} D} \quad \text{or} \quad \rho_c = \frac{100 k_B \mathcal{M}}{\sqrt{2} \pi d^2 \mathcal{R} D}$$

<

For air,

$$\rho_{c,\text{Air}} = \frac{100 k_B \mathcal{M}}{\sqrt{2} \pi d^2 \mathcal{R} D} = \frac{100 \times 1.381 \times 10^{-23} \text{ J/K} \times 28.97 \text{ kmol/kg}}{\sqrt{2} \pi \times (0.372 \times 10^{-9} \text{ m})^2 \times 8315 \text{ J/kmol} \cdot \text{K} \times 10 \times 10^{-6} \text{ m}} = 0.783 \text{ kg/m}^3 \quad <$$

Repeating the calculation for hydrogen and  $\text{CO}_2$  yields

$$\rho_{c,\text{H}_2} = 0.100 \text{ kg/m}^3; \quad \rho_{c,\text{CO}_2} = 0.764 \text{ kg/m}^3. \quad <$$

The ratios of the transition to molecular density at  $p = 1 \text{ atm}$ ,  $T = 300 \text{ K}$ , for the three gases are:

Gas	Ratio
Air	$0.783/1.161 = 0.674$
$\text{H}_2$	$0.100/0.0808 = 1.24$
$\text{CO}_2$	$0.764/1.773 = 0.431$

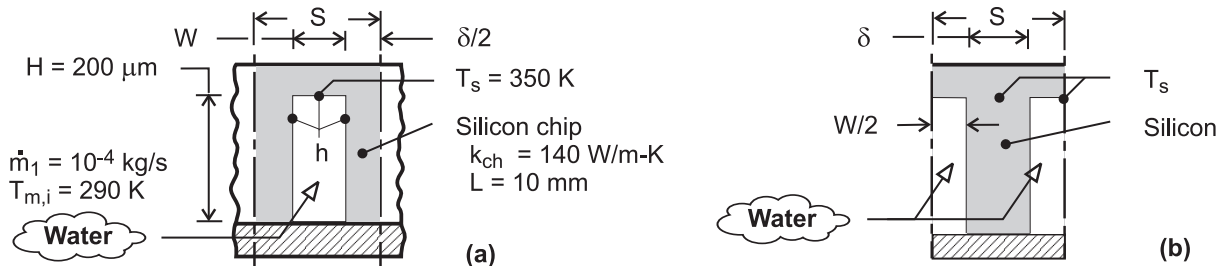

**COMMENT:** Microscale effects could be important, especially for hydrogen at atmospheric pressure and  $T = 300 \text{ K}$ .

## PROBLEM 8.109

**KNOWN:** Chip and cooling channel dimensions. Channel flow rate and inlet temperature. Temperature of chip at base of channel.

**FIND:** (a) Water outlet temperature and chip power, (b) Effect of channel width and pitch on power dissipation.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Incompressible liquid with negligible viscous dissipation, (2) Flow may be approximated as fully developed and channel walls as isothermal for purposes of estimating the convection coefficient, (3) One-dimensional conduction along channel side walls, (4) Adiabatic condition at end of side walls, (5) Heat dissipation is exclusively through fluid flow in channels, (6) Constant properties.

**PROPERTIES:** Table A-6, Water ( $\bar{T}_m = 300\text{K}$ ):  $c_p = 4179\text{ J/kg}\cdot\text{K}$ ,  $\mu = 855 \times 10^{-6}\text{ kg/s}\cdot\text{m}$ ,  $k = 0.613\text{ W/m}\cdot\text{K}$ ,  $Pr = 5.83$ .

**ANALYSIS:** (a) The channel sidewalls act as fins, and a *unit* channel/sidewall combination is shown in schematic (a), where the total number of unit cells corresponds to  $N = L/S$ . With  $N = 50$  and  $L = 10\text{ mm}$ ,  $S = 200\ \mu\text{m}$  and  $\delta = S - W = 150\ \mu\text{m}$ . Alternatively, the unit cell may be represented in terms of a single fin of thickness  $\delta$ , as shown in schematic (b). The thermal resistance of the unit cell may be obtained from the expression for a fin array, Eq. (3.108),  $R_{t,o} = (\eta_o h A_t)^{-1}$ , where  $A_t = A_f + A_b = L(2H + W) = 0.01\text{m}(4 \times 10^{-4} + 0.5 \times 10^{-4})\text{ m} = 4.5 \times 10^{-6}\text{ m}^2$ . With  $D_h = 4(H \times W)/2(H + W) = 4(2 \times 10^{-4}\text{ m} \times 0.5 \times 10^{-4}\text{ m})/2(2.5 \times 10^{-4}\text{ m}) = 8 \times 10^{-5}\text{ m}$ , the Reynolds number is  $Re_D = \rho u_m D_h/\mu = \dot{m}_1 D_h/A_c \mu = 10^{-4}\text{ kg/s} \times 8 \times 10^{-5}\text{ m}/(2 \times 10^{-4}\text{ m} \times 0.5 \times 10^{-4}\text{ m}) 855 \times 10^{-6}\text{ kg/s}\cdot\text{m} = 936$ . Hence, the flow is laminar, and assuming fully developed conditions throughout a channel with uniform surface temperature, Table 8.1 yields  $Nu_D = 4.44$ . Hence,

$$h = \frac{k}{D_h} Nu_D = \frac{0.613\text{ W/m}\cdot\text{K} \times 4.44}{8 \times 10^{-5}\text{ m}} = 34,022\text{ W/m}^2 \cdot \text{K}$$

With  $m = (2h/k_{ch}\delta)^{1/2} = (68,044\text{ W/m}^2 \cdot \text{K}/140\text{ W/m}\cdot\text{K} \times 1.5 \times 10^{-4}\text{ m})^{1/2} = 1800\text{ m}^{-1}$  and  $mH = 0.36$ , the fin efficiency is

$$\eta_f = \frac{\tanh mH}{mH} = \frac{0.345}{0.36} = 0.958$$

and the overall surface efficiency is

$$\eta_o = 1 - \frac{A_f}{A_t}(1 - \eta_f) = 1 - \frac{4.0 \times 10^{-6}}{4.5 \times 10^{-6}}(1 - 0.958) = 0.963$$

The thermal resistance of the unit cell is then

Continued ...

**PROBLEM 8.109 (Cont.)**

$$R_{t,o} = (\eta_o h A_t)^{-1} = \left(0.963 \times 34,022 \text{ W/m}^2 \cdot \text{K} \times 4.5 \times 10^{-6} \text{ m}^2\right)^{-1} = 6.78 \text{ K/W}$$

The outlet temperature follows from Eq. (8.45b),

$$T_{m,o} = T_s - (T_s - T_{m,i}) \exp\left(-\frac{1}{\dot{m}_1 c_p R_{t,o}}\right) = 350\text{K} - (60\text{K}) \times \exp\left(-\frac{1}{10^{-4} \text{ kg/s} \times 4179 \text{ J/kg} \cdot \text{K} \times 6.78 \text{ K/W}}\right) = 307.8\text{K} \quad <$$

The heat rate per channel is then

$$q_1 = \dot{m}_1 c_p (T_{m,o} - T_{m,i}) = 10^{-4} \text{ kg/s} \times 4179 \text{ J/kg} \cdot \text{K} (17.8\text{K}) = 7.46 \text{ W}$$

and the chip power dissipation is

$$q = Nq_1 = 50 \times 7.46 \text{ W} = 373 \text{ W} \quad <$$

(b) The foregoing result indicates significant heat transfer from the channel side walls due to the large value of  $\eta_f$ . If the pitch is reduced by a factor of 2 ( $S = 100 \mu\text{m}$ ), we obtain

$$S = 100 \mu\text{m}, W = 50 \mu\text{m}, \delta = 50 \mu\text{m}, N = 100: q_1 = 7.04 \text{ W}, q = 704 \text{ W} \quad <$$

Hence, although there is a reduction in  $\eta_f$  due to the reduction in  $\delta$  ( $\eta_f = 0.89$ ) and therefore a slight reduction in the value of  $q_1$ , the effect is more than compensated by the increase in the number of channels. Additional benefit may be derived by further reducing the pitch to whatever minimum value of  $\delta$  is imposed by manufacturing or structural limitations. There would also be an advantage to increasing the channel hydraulic diameter and or flowrate, such that turbulent flow is achieved with a correspondingly larger value of  $h$ .

**COMMENTS:** (1) Because electronic devices fail by contact with a polar fluid such as water, great care would have to be taken to hermetically seal the devices from the coolant channels. In lieu of water, a dielectric fluid could be used, thereby permitting contact between the fluid and the electronics. However, all such fluids, such as air, are less effective as coolants. (2) With  $L/D_h = 125$  and  $L/D_h)_{fd} \approx 0.05 \text{ Re}_D \text{ Pr} = 273$ , fully developed flow is not achieved and the value of  $h = h_{fd}$  underestimates the actual value of  $\bar{h}$  in the channel. The coefficient is also underestimated by using a Nusselt number that presumes heat transfer from all four (rather than three) surfaces of a channel.

## PROBLEM 8.110

**KNOWN:** Temperature and pressure of a gas flowing in a circular tube.

**FIND:** The critical tube diameter,  $D_c$ , below which incompressible turbulent flow cannot exist for (a) air (b)  $\text{CO}_2$ , and (c) He.

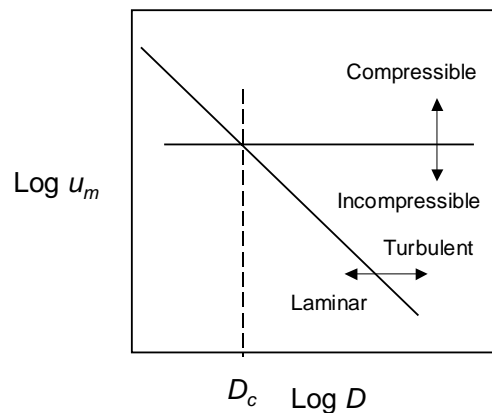

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Ideal gas behavior. (2) Fully-developed flow.

**PROPERTIES:** Table A.4 ( $T = 300 \text{ K}$ ): Air;  $c_p = 1007 \text{ J/kg}\cdot\text{K}$ ,  $\mu = 184.6 \times 10^{-7} \text{ N}\cdot\text{s/m}^2$ .  $\text{CO}_2$ ;  $c_p = 851 \text{ J/kg}\cdot\text{K}$ ,  $\mu = 149 \times 10^{-7} \text{ N}\cdot\text{s/m}^2$ . He;  $c_p = 5193 \text{ J/kg}\cdot\text{K}$ ,  $\mu = 199 \times 10^{-7} \text{ N}\cdot\text{s/m}^2$ . Figure 2.8: Air;  $\mathcal{M} = 28.97 \text{ kg/kmol}$ .  $\text{CO}_2$ ;  $\mathcal{M} = 44.01 \text{ kg/kmol}$  He;  $\mathcal{M} = 4.003 \text{ kg/kmol}$ .

**ANALYSIS:** The relationship  $Re_{D,c} = u_m D / \nu \approx 2300$  may be plotted on a *log-log* scale, as shown in the figure below. Laminar flow occurs to the left of the sloped line, while turbulent flow occurs to the right of the line. The critical Mach number  $Ma_c = u_m / a \approx 0.3$  is drawn as the horizontal line that separates regions of incompressible flow (below the line) and compressible flow (above the line). It is evident that below a critical diameter,  $D_c$ , turbulent incompressible flow and heat transfer cannot exist.

(a) From the ideal gas equation of state,

$$\rho = p/RT \quad (1)$$

and from Section 6.4.2 the speed of sound is

$$a = \sqrt{\gamma RT} \quad (2)$$

Continued...

### PROBLEM 8.110 (Cont.)

where  $\gamma \equiv c_p/c_v$  is the ratio of specific heats. The mean velocity may be related to the Mach number,  $Ma$ , and is

$$u_m = Ma \cdot a \quad (3)$$

Combining the preceding equations yields

$$Re = \frac{Ma \cdot p}{\mu} \sqrt{\frac{\gamma}{RT}} D \quad (4)$$

Specifying  $Re = Re_c$  and  $Ma = Ma_c$  leads to the following expression for the critical tube diameter

$$D_c = \frac{Re_c}{Ma_c} \sqrt{\frac{RT}{\gamma}} \frac{\mu}{p} \quad (5)$$

For air, the ideal gas constant, specific heat at constant volume, and ratio of specific heats are

$$R = \frac{\mathcal{R}}{\mathcal{M}} = \frac{8.315 \text{ kJ/kmol} \cdot \text{K}}{28.97 \text{ kg/kmol}} = 0.287 \frac{\text{kJ}}{\text{kg} \cdot \text{K}};$$

$$c_v = c_p - R = 1.007 \frac{\text{kJ}}{\text{kg} \cdot \text{K}} - 0.287 \frac{\text{kJ}}{\text{kg} \cdot \text{K}} = 0.720 \frac{\text{kJ}}{\text{kg} \cdot \text{K}}; \quad \gamma = \frac{c_p}{c_v} = \frac{1.007}{0.720} = 1.399$$

Therefore,

$$D_c = \frac{2300}{0.3} \sqrt{\frac{287 \text{ J/kg} \cdot \text{K} \times 300 \text{ K}}{1.399}} \times \frac{184.6 \times 10^{-7} \text{ N} \cdot \text{s/m}^2}{1.0133 \times 10^5 \text{ N/m}^2} = 346 \times 10^{-6} \text{ m} = 0.346 \text{ mm} \quad <$$

(b,c) The calculations may be repeated for CO<sub>2</sub> and He, yielding the following results.

Gas	$R$ (kJ/kg·K)	$c_v$ (kJ/kg·K)	$\gamma$	$D_c$ (mm)	
CO <sub>2</sub>	0.189	0.662	1.285	0.237	<
He	2.077	3.116	1.667	0.920	<

**COMMENTS:** (1) Below the critical diameter,  $D_c$ , the effects of compressibility must *always* be accounted for if the flow is turbulent, and are *often* important if the flow is laminar. Because the correlations of Chapter 8 do not account for the effects of compressibility, they may not be applied to situations where turbulence exists and the tube diameter is less than  $D_c$ . The correlations must be used with caution if the flow is laminar and  $D < D_c$  since compressibility effects might be important. (2) The critical diameter is moderately dependent on the specific gas of interest, for the three gases considered here.

## PROBLEM 8.111

**KNOWN:** Chip and cooling channel dimensions. Channel flow rate and inlet temperature. Temperature of chip at base of channel.

**FIND:** (a) Outlet temperature and chip power dissipation for dielectric liquid, (b) Outlet temperature and chip power dissipation for air.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Applicability of Eq. 8.34, (2) Flow may be approximated as fully developed and channel walls as isothermal for purposes of estimating the convection coefficient, (3) One-dimensional conduction along the channel side walls, (4) Adiabatic condition at end of side walls, (5) Heat dissipation is exclusively through fluid flow in channels, (6) Constant properties.

**PROPERTIES:** Prescribed. Dielectric liquid:  $c_p = 1050 \text{ J/kg}\cdot\text{K}$ ,  $k = 0.065 \text{ W/m}\cdot\text{K}$ ,  $\mu = 0.0012 \text{ N}\cdot\text{s/m}^2$ ,  $\text{Pr} = 15$ . Air:  $c_p = 1007 \text{ J/kg}\cdot\text{K}$ ,  $k = 0.0263 \text{ W/m}\cdot\text{K}$ ,  $\mu = 185 \times 10^{-7} \text{ N}\cdot\text{s/m}^2$ ,  $\text{Pr} = 0.707$ .

**ANALYSIS:** (a) The channel side walls act as fins, and a *unit* channel/sidewall combination is shown in schematic (a), where  $\delta = S - W = 150 \mu\text{m}$ . Alternatively, the unit cell may be represented in terms of a single fin of thickness  $\delta$ , as shown in schematic (b). The thermal resistance of the unit cell may be obtained from the expression for a fin array, Eq. (3.108),  $R_{t,o} = (\eta_o h A_t)^{-1}$ , where  $A_t = A_f + A_b = L (2H + W) = 4.5 \times 10^{-6} \text{ m}^2$ . With  $A_c = H \times W = 10^{-8} \text{ m}^2$  and  $D_h = 4 A_c / (2H + W) = 8 \times 10^{-5} \text{ m}$ , the Reynolds number is  $\text{Re}_D = \rho u_m D_h / \mu = \dot{m}_1 D_h / A_c \mu = 667$ . Hence, the flow is laminar, and assuming fully developed conditions throughout a channel with uniform surface temperature, Table 8.1 yields

$$\text{Nu}_D = 4.44. \text{ Hence, } h = \frac{k}{D_h} \text{Nu}_D = \frac{0.065 \text{ W/m}\cdot\text{K} \times 4.44}{8 \times 10^{-5} \text{ m}} = 3608 \text{ W/m}^2 \cdot \text{K}$$

With  $m = (2h/k_{ch}\delta)^{1/2} = 586 \text{ m}^{-1}$  and  $mH = 0.117$ , the fin efficiency is

$$\eta_f = \frac{\tanh mH}{mH} = \frac{0.1167}{0.117} = 0.995$$

and the overall surface efficiency is

$$\eta_o = 1 - \frac{A_f}{A_t} (1 - \eta_f) = 1 - \frac{4.0 \times 10^{-6}}{4.5 \times 10^{-6}} (1 - 0.995) = 0.996.$$

The thermal resistance of the unit cell is then

$$R_{t,o} = (\eta_o h A_t)^{-1} = \left( 0.996 \times 3608 \text{ W/m}^2 \cdot \text{K} \times 4.5 \times 10^{-6} \text{ m}^2 \right)^{-1} = 61.9 \text{ K/W}$$

The outlet temperature follows from Eq. (8.45b),

$$T_{m,o} = T_s - (T_s - T_{m,i}) \exp \left( -\frac{1}{\dot{m}_1 c_p R_{t,o}} \right) = 350 \text{ K}$$

Continued ...

**PROBLEM 8.111 (Cont.)**

$$-(60\text{K}) \exp\left(-\frac{1}{10^{-4} \text{ kg/s} \times 1050 \text{ J/kg} \cdot \text{K} \times 61.9 \text{ K/W}}\right) = 298.6\text{K} \quad <$$

The heat rate per channel is then

$$q_1 = \dot{m}_1 c_p (T_{m,o} - T_{m,i}) = 10^{-4} \text{ kg/s} \times 1050 \text{ J/kg} \cdot \text{K} \times 8.6 \text{ K} = 0.899 \text{ W}$$

and the chip power dissipation is

$$q = Nq_1 = 50 \times 0.899 \text{ W} = 45.0 \text{ W} \quad <$$

(b) With  $\dot{m}_1 = 10^{-6} \text{ kg/s}$ ,  $\text{Re}_D = \dot{m}_1 D_h / A_c \mu = 432$  and the flow is laminar. Hence, with  $\text{Nu}_D = 4.44$ ,

$$h = \frac{k}{D_h} \text{Nu}_D = \frac{0.0263 \text{ W/m} \cdot \text{K} \times 4.44}{8 \times 10^{-5} \text{ m}} = 1460 \text{ W/m}^2 \cdot \text{K}$$

With  $m = (2h/k_{ch}\delta)^{1/2} = 373 \text{ m}^{-1}$  and  $mH = 0.0746$ , the fin efficiency is

$$\eta_f = \frac{\tanh mH}{mH} = \frac{0.0744}{0.0746} = 0.998$$

and the overall surface efficiency is

$$\eta_o = 1 - \frac{A_f}{A_t} (1 - \eta_f) = 1 - \frac{4.0 \times 10^{-6}}{4.5 \times 10^{-6}} (1 - 0.998) = 0.998$$

Hence,  $R_{t,o} = (\eta_o h A_t)^{-1} = \left(0.998 \times 1460 \text{ W/m}^2 \cdot \text{K} \times 4.5 \times 10^{-6} \text{ m}^2\right)^{-1} = 153 \text{ K/W}$

The outlet temperature is then

$$T_{m,o} = T_s - (T_s - T_{m,i}) \exp\left(-\frac{1}{\dot{m}_1 c_p R_{t,o}}\right) = 350\text{K}$$

$$-(60\text{K}) \exp\left(-\frac{1}{10^{-6} \text{ kg/s} \times 1007 \text{ J/kg} \cdot \text{K} \times 153 \text{ K/W}}\right) = 349.9 \text{ K} \quad <$$

$$q_1 = \dot{m}_1 c_p (T_{m,o} - T_{m,i}) = 10^{-6} \text{ kg/s} \times 1007 \text{ J/kg} \cdot \text{K} \times 59.9 \text{ K} = 0.060 \text{ W}$$

$$q = Nq_1 = 3.02 \text{ W} \quad <$$

**COMMENTS:** (1) For laminar flow in the channels, there is a clear advantage to using the dielectric liquid instead of air. (2) The prescribed channel geometry is by no means optimized, and the number of fins should be increased by reducing  $S$ . Also, channel dimensions and/or flow rates could be increased to achieve turbulent flow and hence much larger values of  $h$ . (3) With  $L/D_h = 125$  and  $(L/D_h)_{fd} \approx 0.05 \text{ Re}_D \text{ Pr} = 500$  for the dielectric liquid, fully developed flow is not achieved and its assumption yields a conservative (under) estimate of the convection coefficient. The coefficient is also underestimated by using a Nusselt number that presumes heat transfer from all four (rather than three) surfaces of a channel.

## PROBLEM 8.112

**KNOWN:** Temperature and pressure of air flowing in a circular tube of known diameter. Thermal and momentum accommodation coefficients. Fully developed laminar flow with constant heat flux.

**FIND:** Graph of the Nusselt number versus tube diameter for  $1 \mu\text{m} \leq D \leq 1 \text{ mm}$  and (a)  $\alpha_t = 1$ ,  $\alpha_p = 1$ , (b)  $\alpha_t = 0.1$ ,  $\alpha_p = 0.1$ , (c)  $\alpha_t = 1$ ,  $\alpha_p = 0.1$  and (d)  $\alpha_t = 0.1$ ,  $\alpha_p = 1$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Ideal gas behavior. (2) Fully-developed laminar flow.

**PROPERTIES:** Table A.4 ( $T = 300 \text{ K}$ ): Air;  $c_p = 1007 \text{ J/kg}\cdot\text{K}$ ,  $Pr = 0.707$ . Figure 2.8: Air;  $\mathcal{M} = 28.97 \text{ kg/kmol}$ ,  $d = 0.372 \times 10^{-9} \text{ m}$ .

**ANALYSIS:** The ideal gas constant, specific heat at constant volume, and ratio of specific heats are:

$$R = \frac{\mathcal{R}}{\mathcal{M}} = \frac{8.315 \text{ kJ/kmol}\cdot\text{K}}{28.97 \text{ kg/kmol}} = 0.287 \frac{\text{kJ}}{\text{kg}\cdot\text{K}};$$

$$c_v = c_p - R = 1007 \frac{\text{kJ}}{\text{kg}\cdot\text{K}} - 0.287 \frac{\text{kJ}}{\text{kg}\cdot\text{K}} = 0.720 \frac{\text{kJ}}{\text{kg}\cdot\text{K}}; \quad \gamma = \frac{c_p}{c_v} = \frac{1.007}{0.720} = 1.399$$

From Equation 2.11 the mean free path of air is

$$\lambda_{\text{mfp}} = \frac{k_B T}{\sqrt{2} \pi d^2 p} = \frac{1.381 \times 10^{-23} \text{ J/K} \times 300 \text{ K}}{\sqrt{2} \pi (0.372 \times 10^{-9} \text{ m})^2 (1.0133 \times 10^5 \text{ N/m}^2)} = 66.5 \times 10^{-9} \text{ m} = 66.5 \text{ nm}$$

From Equation 8.78, the Nusselt number may be expressed as

$$Nu_D = \frac{hD}{k} = \frac{48}{11 - 6\zeta + \zeta^2 + 48\Gamma_t} \quad (1)$$

where

$$\Gamma_t = \frac{2 - \alpha_t}{\alpha_t} \frac{2\gamma}{\gamma + 1} \left[ \frac{\lambda_{\text{mfp}}}{PrD} \right] \quad (2)$$

Continued...

### PROBLEM 8.112 (Cont.)

$$\Gamma_p = \frac{2 - \alpha_p}{\alpha_p} \left[ \frac{\lambda_{\text{mf}}}{D} \right] \quad (3)$$

$$\zeta = \frac{8\Gamma_p}{(1 + 8\Gamma_p)} \quad (4)$$

Equations 1 through 4 may be combined to yield the following graph that shows the variation of the Nusselt number over the tube diameter range  $1 \mu\text{m} \leq D \leq 1000 \mu\text{m}$ .

The accommodation coefficients begin to influence the Nusselt number (and hence the convection heat transfer coefficient) at diameters less than approximately  $400 \mu\text{m}$ .

The Nusselt number is least sensitive to changes in the tube diameter for  $\alpha_i = \alpha_p = 1$ .

The Nusselt number can exceed 4.36 when the momentum accommodation coefficient is small and the thermal accommodation coefficient is large.

Small values of the thermal accommodation coefficient in conjunction with large values of the momentum accommodation coefficient result in the most significant reductions in the Nusselt number.

The Nusselt number can increase or decrease relative to the value associated with conventional flows, and the change in the Nusselt number can be quite large. Hence prediction of convection heat transfer coefficients in nano- and some microscale devices involving gas flow is typically subject to a high degree of uncertainty.

**Comment:** Thermal accommodation coefficients can be of very small value, as discussed in Chapter 3.

### PROBLEM 8.113

**KNOWN:** Arrangement of chips and cooling channels for a substrate. Contact and conduction resistances. Coolant velocity and inlet temperature.

**FIND:** (a) Coolant temperature rise, (b) Chip and substrate temperatures.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Constant properties, (2) Fully-developed flow, (3) Incompressible liquid with negligible viscous dissipation, (4) Heat transfer exclusively to water, (5) Steady-state conditions.

**PROPERTIES:** Water (given):  $\rho = 1000 \text{ kg/m}^3$ ,  $c_p = 4180 \text{ J/kg}\cdot\text{K}$ ,  $k = 0.610 \text{ W/m}\cdot\text{K}$ ,  $Pr = 5.8$ ,  $\mu = 855 \times 10^{-6} \text{ kg/s}\cdot\text{m}$ .

**ANALYSIS:** (a) For a single flow channel, the overall energy balance yields

$$T_{m,o} - T_{m,i} = \frac{q}{\dot{m} c_p} = \frac{N_L P}{\rho u_m A_c c_p} = \frac{10 \times 5 \text{ W}}{1000 \text{ kg/m}^3 (1 \text{ m/s}) (0.005 \text{ m})^2 4180 \text{ J/kg}\cdot\text{K}} = 0.48^\circ\text{C} \quad <$$

From the thermal circuit,

$$q = \frac{T_o - \bar{T}_m}{R_{t,c} + R_{cond} + R_{conv}} \quad R_{t,c} = R''_{t,c} / A_s = (0.5 \times 10^{-4} \text{ m}^2 \cdot \text{K/W}) / 10 (0.005 \text{ m})^2 = 0.2 \text{ K/W}.$$

With  $D_h = 4A_c/P = 4(0.005 \text{ m})^2 / 4(0.005 \text{ m}) = 0.005 \text{ m}$ ,

$$Re_D = \frac{\rho u_m D_h}{\mu} = \frac{1000 \text{ kg/m}^3 (1 \text{ m/s}) 0.005 \text{ m}}{855 \times 10^{-6} \text{ kg/s}\cdot\text{m}} = 5848.$$

With turbulent flow, the Gnielinski correlation yields

$$h = \frac{k}{D} \frac{(f/8)(Re_D - 1000) Pr}{1 + 12.7(f/8)^{1/2}(Pr^{2/3} - 1)} = \frac{0.61 \text{ W/m}\cdot\text{K}}{0.005 \text{ m}} \frac{(0.0368/8)(5848 - 1000) 5.8}{1 + 12.7(0.0368/8)^{1/2}(5.8^{2/3} - 1)} = 5406 \text{ W/m}^2 \cdot \text{K}$$

where  $f = (0.79 \ln Re_D - 1.64)^{-2} = 0.0368$ .

$$R_{conv} = (h A_s)^{-1} = (5406 \text{ W/m}^2 \cdot \text{K} \times 4 \times 0.005 \text{ m} \times 0.2 \text{ m})^{-1} = 0.046 \text{ K/W}.$$

Approximating  $T_m$  as  $(T_{m,i} + T_{m,o})/2 = 25.24^\circ\text{C}$ ,

$$\bar{T}_c = \bar{T}_m + q(R_{t,c} + R_{cond} + R_{conv}) = 25.24^\circ\text{C} + 50 \text{ W} (0.2 + 0.12 + 0.046) \text{ K/W} = 43.6^\circ\text{C} \quad <$$

Similarly, from the thermal circuits,

$$\bar{T}_s = \bar{T}_m + q \times R_{conv} = 25.24^\circ\text{C} + 50 \text{ W} \times 0.046 \text{ K/W} = 27.6^\circ\text{C} \quad <$$

**COMMENTS:** (1) Since the coolant temperature rise is less than  $0.5^\circ\text{C}$ , all chip temperatures will be within  $0.5^\circ\text{C}$  of each other. (2) The channel surface temperature may also be obtained from Eq. 8.41b, yielding the same result.

## PROBLEM 8.114

**KNOWN:** Temperature and pressure of a gas flowing in a circular tube of known diameter with constant surface heat flux. Thermal and momentum accommodation coefficients. Fully developed laminar flow.

**FIND:** Graph of the Nusselt number for tube diameters of  $1 \mu\text{m} \leq D \leq 1 \text{ mm}$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Ideal gas behavior. (2) Fully-developed laminar flow.

**PROPERTIES:** Table A.4 ( $T = 350 \text{ K}$ ): Air;  $c_p = 1009 \text{ J/kg}\cdot\text{K}$ ,  $k = 0.030 \text{ W/m}\cdot\text{K}$ ,  $Pr = 0.70$ . Figure 2.8: Air;  $\mathcal{M} = 28.97 \text{ kg/kmol}$ ,  $d = 0.372 \times 10^{-9} \text{ m}$ .

**ANALYSIS:** The ideal gas constant, specific heat at constant volume, and ratio of specific heats are:

$$R = \frac{\mathcal{R}}{\mathcal{M}} = \frac{8.315 \text{ kJ/kmol}\cdot\text{K}}{28.97 \text{ kg/kmol}} = 0.287 \frac{\text{kJ}}{\text{kg}\cdot\text{K}};$$

$$c_v = c_p - R = 1.009 \frac{\text{kJ}}{\text{kg}\cdot\text{K}} - 0.287 \frac{\text{kJ}}{\text{kg}\cdot\text{K}} = 0.722 \frac{\text{kJ}}{\text{kg}\cdot\text{K}}; \quad \gamma = \frac{c_p}{c_v} = \frac{1.009}{0.722} = 1.398$$

From Equation 2.11 the mean free path of air is

$$\lambda_{\text{mfp}} = \frac{k_B T}{\sqrt{2} \pi d^2 p} = \frac{1.381 \times 10^{-23} \text{ J/K} \times 350 \text{ K}}{\sqrt{2} \pi (0.372 \times 10^{-9} \text{ m})^2 (1.0133 \times 10^5 \text{ N/m}^2)} = 77.6 \times 10^{-9} \text{ m} = 77.6 \text{ nm}$$

From Equation 8.78 the Nusselt number may be expressed as

$$Nu_D = \frac{hD}{k} = \frac{48}{11 - 6\zeta + \zeta^2 + 48\Gamma_t} \quad (1)$$

where

Continued...

**PROBLEM 8.114 (Cont.)**

$$\Gamma_t = \frac{2 - \alpha_t}{\alpha_t} \frac{2\gamma}{\gamma + 1} \left[ \frac{\lambda_{\text{mf}}}{PrD} \right] = \frac{2 - 0.92}{0.92} \cdot \frac{2 \times 1.398}{1.398 + 1} \left[ \frac{77.6 \times 10^{-9} \text{ m}}{0.700D} \right] = \frac{152 \times 10^{-9} \text{ m}}{D} \quad (2)$$

$$\Gamma_p = \frac{2 - \alpha_p}{\alpha_p} \left[ \frac{\lambda_{\text{mf}}}{D} \right] = \frac{2 - 0.87}{0.87} \cdot \left[ \frac{77.6 \times 10^{-9} \text{ m}}{D} \right] = \frac{101 \times 10^{-9} \text{ m}}{D} \quad (3)$$

$$\zeta = \frac{8\Gamma_p}{(1 + 8\Gamma_p)} \quad (4)$$

Equations 1 through 4 may be combined to yield the following graph that shows the variation of the Nusselt number over the tube diameter range  $1 \mu\text{m} \leq D \leq 1000 \mu\text{m}$ .

**COMMENTS:** (1) The Nusselt number begins to be affected by the tube dimension at a tube diameter of  $D \approx 100 \mu\text{m}$ . (2) Equation 8.78 is associated with constant heat flux conditions. We would expect a similar reduction in Nusselt numbers for constant temperature wall conditions.

## PROBLEM 8.115

**KNOWN:** Inner diameter of microscale tube, wall thickness of tube, temperature of water inside the tube, and temperature of water in cross flow over the tube.

**FIND:** (a) Required tube length at  $Re_D = 2000$ , (b) Water outlet temperature, (c) Pressure drop associated with the flow of water inside the tube, (d) Height of water column needed to supply the required inlet pressure and time needed to collect 0.1 liter of water. Discuss measurement of outlet water temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Constant properties and steady-state conditions, (2) Incompressible liquid and negligible viscous dissipation, (3) Negligible microscale or nanoscale effects.

**PROPERTIES:** Table A.6, water: ( $\bar{T}_m = 305$  K):  $k = 0.620$  W/m·K,  $c_p = 4178$  J/kg·K,  $\mu = 769 \times 10^{-6}$  N·s/m<sup>2</sup>,  $Pr = 5.2$ ,  $\rho = 995$  kg/m<sup>3</sup>; ( $\bar{T} = 330$  K):  $k = 0.650$  W/m·K,  $c_p = 4194$  J/kg·K,  $\mu = 489 \times 10^{-6}$  N·s/m<sup>2</sup>,  $Pr = 3.15$ ,  $\rho = 984$  kg/m<sup>3</sup>. Table A.3 glass:  $k = 1.4$  W/m·K.

**ANALYSIS:** (a) At  $Re_D = 2000$ , Equation 8.3 yields  $x_{fd,h} = 0.05Re_DPrD = 0.05 \times 2000 \times 5.2 \times 50 \times 10^{-6}$  m =  $26 \times 10^{-3}$  m. Therefore,  $L = 2x_{fd,h} = 2 \times 26 \times 10^{-3}$  m =  $52 \times 10^{-3}$  m = 52 mm. <

(b) Equation 8.45a is

$$\frac{T_{\infty} - T_{m,o}}{T_{\infty} - T_{m,i}} = \exp\left(-\frac{\bar{U}A_s}{\dot{m}c_p}\right) \quad (1)$$

where we will use  $\bar{U} = \bar{U}_i$ ,  $A_s = A_{s,i}$ . Note that  $Re_D = 4\dot{m}/(\pi D\mu)$  so that  $\dot{m} = Re_D \pi D\mu / 4 = 2000 \times \pi \times 50 \times 10^{-6}$  m  $\times 769 \times 10^{-6}$  N·s/m<sup>2</sup>/4 =  $60.4 \times 10^{-6}$  kg/s. Therefore,  $u_m = \dot{m}/(\rho A_c) = 60.4 \times 10^{-6}$  kg/s  $\times 4 / (995$  kg/m<sup>3</sup>  $\times \pi \times (50 \times 10^{-6}$  m)<sup>2</sup>) = 31 m/s. From Equation 3.36,

Continued...

**PROBLEM 8.115 (Cont.)**

$$\bar{U}_i = \frac{1}{\frac{1}{h_i} + \frac{d/2}{k_g} \ln \left[ \frac{(d/2+t)}{d/2} \right] + \frac{d/2}{(d/2+t)} \frac{1}{h_o}} \quad (2)$$

$A_{s,i} = \pi dL = \pi \times 50 \times 10^{-6} \text{ m} \times 52 \times 10^{-3} \text{ m} = 8.17 \times 10^{-6} \text{ m}^2$ . From Equation 8.56,

$$\bar{Nu}_D = 3.66 + \frac{0.0668(50 \times 10^{-6} / 53 \times 10^{-3}) \times 2000 \times 5.3}{1 + 0.04 \left[ (50 \times 10^{-6} / 53 \times 10^{-3}) \times 2000 \times 5.3 \right]^{2/3}} = 4.371$$

and  $\bar{h}_D = h_i = \bar{Nu}_D \frac{k}{D} = 4.371 \times 0.620 \text{ W/m} \cdot \text{K} / 50 \times 10^{-6} \text{ m} = 54.2 \times 10^3 \text{ W/m}^2 \cdot \text{K}$ .

For the cross flow of water over the tube,  $Re_D = VD\rho/\mu = 2 \text{ m/s} \times (50 \times 10^{-6} \text{ m} + 2 \times 1 \times 10^{-3} \text{ m})(984 \text{ kg/m}^3)/489 \times 10^{-6} \text{ N}\cdot\text{s/m}^2 = 8253$ . From Equation 7.54,

$$\bar{Nu}_D = 0.3 + \frac{0.62(8253)^{1/2}(3.15)^{1/3}}{\left[ 1 + (0.4/3.15)^{2/3} \right]^{1/4}} \left[ 1 + \left( \frac{8253}{282,000} \right)^{5/8} \right]^{4/5} = 85.14$$

and

$$\bar{h}_D = h_o = \bar{Nu}_D k / (d + 2t) = 85.14 \times 0.65 \text{ W/m} \cdot \text{K} / (50 \times 10^{-6} \text{ m} + 2 \times 1 \times 10^{-3} \text{ m}) = 27.0 \times 10^3 \text{ W/m}^2 \cdot \text{K}$$

Therefore,

$$\bar{U}_i = \frac{1}{\left[ \frac{1}{54.2 \times 10^3 \text{ W/m} \cdot \text{K}} + \frac{50 \times 10^{-6} \text{ m}/2}{1.4 \text{ W/m} \cdot \text{K}} \ln \left[ \frac{(50 \times 10^{-6} \text{ m}/2 + 1 \times 10^{-3} \text{ m})}{50 \times 10^{-6} \text{ m}/2} \right] \right] + \frac{50 \times 10^{-6} \text{ m}/2}{(50 \times 10^{-6} \text{ m}/2 + 1 \times 10^{-3} \text{ m})} \times \frac{1}{27.0 \times 10^3 \text{ W/m}^2 \cdot \text{K}}} = 11.7 \times 10^3 \text{ W/m}^2 \cdot \text{K}$$

Equation (1) becomes

$$\frac{350\text{K} - T_{m,o}}{350\text{K} - 300\text{K}} = \exp \left( - \frac{11.7 \times 10^3 \text{ W/m}^2 \cdot \text{K} \times 8.17 \times 10^{-6} \text{ m}^2}{60.4 \times 10^{-6} \text{ kg/s} \cdot 4194 \text{ J/kg} \cdot \text{K}} \right)$$

or,  $T_{m,o} = 316 \text{ K}$

<  
Continued...

### PROBLEM 8.115 (Cont.)

(c) For laminar flow, Equation 8.19 yields  $f = 64/\text{Re}_D = 64/2000 = 32 \times 10^{-3}$ . Equation 8.22a yields

$$\Delta p = f \frac{\rho u_m^2}{2D} L = \frac{32 \times 10^{-3} \times 995 \text{ kg/m}^3 \times (31 \text{ m/s})^2 \times 52 \times 10^{-3} \text{ m}}{2(50 \times 10^{-6} \text{ m})} = 15.9 \times 10^6 \text{ Pa} \quad <$$

(d) The pressure generated by the water column must offset the pressure drop in the tube. Therefore,

$$\rho g H = \Delta p \quad \text{or} \quad H = \Delta p / \rho g = 15.9 \times 10^6 \text{ N/m}^2 / (995 \text{ kg/m}^3 \times 9.8 \text{ m/s}^2) = 1630 \text{ m} = 1.63 \text{ km} \quad <$$

The time required for a particular volume of water to flow through the system is

$$t = \frac{V\rho}{m} = \frac{0.1 \times \frac{1 \text{ m}^3}{1000 \text{ ml}} \times 995 \text{ kg/m}^3}{60.4 \times 10^{-6} \text{ kg/s}} = 1650 \text{ s} \quad <$$

**COMMENTS:** (1) Microscale experimentation is often very difficult to perform. In addition to the difficulty in measuring the water outlet temperature, establishing a constant flow rate with such a large inlet pressure would be very difficult. (2) Turbulent conditions in microscale systems are rare in nature, and are difficult to achieve experimentally. (3) The glass tube wall is relatively thick. Therefore, conduction in the axial direction is likely to be significant. (4) The average mean water temperature inside the tube is  $\bar{T}_m = (T_{m,i} + T_{m,o})/2 = (300 \text{ K} + 316 \text{ K})/2 = 308 \text{ K}$ . The assumed mean temperature of 305 K is good.

## PROBLEM 8.116

**KNOWN:** Temperature and pressure of air flowing in a circular tube or between parallel plates. Thermal and momentum accommodation coefficients.

**FIND:** Tube diameter  $D$  and plate spacing  $a$  that correspond to a 10 percent reduction in the Nusselt number.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Ideal gas behavior. (2) Fully-developed laminar flow.

**PROPERTIES:** Table A.4 ( $T = 350 \text{ K}$ ): Air;  $c_p = 1009 \text{ J/kg}\cdot\text{K}$ ,  $Pr = 0.70$ . Figure 2.8: Air;  $\mathcal{M} = 28.97 \text{ kg/kmol}$ ,  $d = 0.372 \times 10^{-9} \text{ m}$ .

**ANALYSIS:** The ideal gas constant, specific heat at constant volume, and ratio of specific heats are:

$$R = \frac{\mathcal{R}}{\mathcal{M}} = \frac{8.315 \text{ kJ/kmol}\cdot\text{K}}{28.97 \text{ kg/kmol}} = 0.287 \frac{\text{kJ}}{\text{kg}\cdot\text{K}};$$

$$c_v = c_p - R = 1.009 \frac{\text{kJ}}{\text{kg}\cdot\text{K}} - 0.287 \frac{\text{kJ}}{\text{kg}\cdot\text{K}} = 0.722 \frac{\text{kJ}}{\text{kg}\cdot\text{K}}; \quad \gamma = \frac{c_p}{c_v} = \frac{1.009}{0.722} = 1.398$$

From Equation 2.11 the mean free path of air is

$$\lambda_{\text{mfp}} = \frac{k_B T}{\sqrt{2} \pi d^2 p} = \frac{1.381 \times 10^{-23} \text{ J/K} \times 350 \text{ K}}{\sqrt{2} \pi (0.372 \times 10^{-9} \text{ m})^2 (1.0133 \times 10^5 \text{ N/m}^2)} = 77.6 \times 10^{-9} \text{ m} = 77.6 \text{ nm}$$

From Equation 8.78 the Nusselt number for the tube may be expressed as

$$Nu_D = \frac{48}{11 - 6\zeta + \zeta^2 + 48\Gamma_t} = 0.9 \times 4.36 = 3.92 \quad (1)$$

where

$$\Gamma_t = \frac{2 - \alpha_t}{\alpha_t} \frac{2\gamma}{\gamma + 1} \left[ \frac{\lambda_{\text{mfp}}}{PrD} \right] = \frac{2 - 0.92}{0.92} \cdot \frac{2 \times 1.398}{1.398 + 1} \left[ \frac{77.6 \times 10^{-9} \text{ m}}{0.700D} \right] = \frac{152 \times 10^{-9} \text{ m}}{D} \quad (2)$$

Continued...

**PROBLEM 8.116 (Cont.)**

$$\Gamma_p = \frac{2 - \alpha_p}{\alpha_p} \left[ \frac{\lambda_{\text{mfp}}}{D} \right] = \frac{2 - 0.87}{0.87} \cdot \left[ \frac{77.6 \times 10^{-9} \text{ m}}{D} \right] = \frac{101 \times 10^{-9} \text{ m}}{D} \quad (3)$$

$$\zeta = \frac{8\Gamma_p}{(1 + 8\Gamma_p)} \quad (4)$$

Equations 1 through 4 may be solved by trial-and-error to yield  $D = 2.94 \times 10^{-6} \text{ m} = 2.94 \text{ }\mu\text{m}$ . <

From Equation 8.79 the Nusselt number for the parallel plate configuration may be expressed as

$$Nu_D = \frac{140}{17 - 6\zeta + (2/3)\zeta^2 + 70\Gamma_t} = 0.9 \times 8.23 = 7.41 \quad (5)$$

where

$$\Gamma_t = \frac{2 - \alpha_t}{\alpha_t} \frac{2\gamma}{\gamma + 1} \left[ \frac{\lambda_{\text{mfp}}}{PrD_h} \right] = \frac{2 - 0.92}{0.92} \cdot \frac{2 \times 1.398}{1.398 + 1} \left[ \frac{77.6 \times 10^{-9} \text{ m}}{0.700D_h} \right] = \frac{152 \times 10^{-9} \text{ m}}{D_h} \quad (6)$$

$$\Gamma_p = \frac{2 - \alpha_p}{\alpha_p} \left[ \frac{\lambda_{\text{mfp}}}{D_h} \right] = \frac{2 - 0.87}{0.87} \cdot \left[ \frac{77.6 \times 10^{-9} \text{ m}}{D_h} \right] = \frac{101 \times 10^{-9} \text{ m}}{D_h} \quad (7)$$

$$\zeta = \frac{6\Gamma_p}{(1 + 6\Gamma_p)} \quad (8)$$

Equations 5 through 8 may be solved by trial-and-error to yield  $D_h = 3.97 \times 10^{-6} \text{ m} = 3.97 \text{ }\mu\text{m}$ . The plate spacing  $a = D_h/2 = 3.97 \text{ }\mu\text{m}/2 = 1.99 \text{ }\mu\text{m}$ . <

**COMMENTS:** The tube diameter and plate spacing required to reduce the Nusselt number by 10 percent are quite small. In situations involving characteristic dimensions that are not extremely small, the effect of the molecule-wall interaction can typically be neglected.

## PROBLEM 8.117

**KNOWN:** Diameters and length of three microchannels machined in a copper block. Inlet temperature of water flowing through the channels, copper block temperature, pressure difference from inlet to outlet of the channels.

**FIND:** (a) Mass flow rate and outlet temperature in each channel, (b) Average flow rate through each channel and average, mixed temperature of water collected from all three channels, (c) Comparison between average flow rates and average heat transfer rates based upon experiment to that calculated based upon a single microchannel diameter of 50  $\mu\text{m}$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Constant properties and steady-state conditions, (2) Incompressible liquid and negligible viscous dissipation, (3) Negligible microscale or nanoscale effects, (4) Negligible entrance or exit losses in the microchannels, (5) Fully developed flow for purposes of calculating the mass flow rate in each channel, (6) Isothermal copper block.

**PROPERTIES:** Table A.6, water: ( $\bar{T}_m = 305 \text{ K}$ ):  $k = 0.620 \text{ W/m}\cdot\text{K}$ ,  $c_p = 4178 \text{ J/kg}\cdot\text{K}$ ,  $\mu = 769 \times 10^{-6} \text{ N}\cdot\text{s/m}^2$ ,  $\nu = 7.728 \times 10^{-7} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 5.2$ ,  $\rho = 995 \text{ kg/m}^3$ .

**ANALYSIS:** (a) For the  $D = 50 \mu\text{m}$  channel, from Equation 8.22a,

$$\Delta p = f \rho u_m^2 L / 2D = f \times 995 \text{ kg/m}^3 \times u_m^2 \times 20 \times 10^{-3} \text{ m} / (2 \times 50 \times 10^{-6} \text{ m}) \quad (1)$$

where the friction factor may be evaluated using the Petukhov expression,

$$f = (0.790 \ln \text{Re}_D - 1.64)^{-2} \quad (2)$$

The Reynolds number may be expressed as

$$\text{Re}_D = \frac{u_m D}{\nu} = \frac{u_m \times 50 \times 10^{-6} \text{ m}}{7.728 \times 10^{-7} \text{ m}^2/\text{s}} \quad (3)$$

Continued...

### PROBLEM 8.117 (Cont.)

Simultaneous solution of Equations (1) through (3) yields, for the  $D = 50 \mu\text{m}$  channel,  $\text{Re}_D = 845$ ,  $u_m = 13.06 \text{ m/s}$ . The mass flow rate is

$$\dot{m} = \rho u_m \pi D^2 / 4 = 995 \text{ kg/m}^3 \times 13.06 \text{ m/s} \times \pi \times (50 \times 10^{-6} \text{ m})^2 / 4 = 2.55 \times 10^{-5} \text{ kg/s} \quad <$$

The thermal entrance length is  $x_{fd,t} = 0.05 \text{Re}_D \text{Pr}D = 0.05 \times 845 \times 5.2 \times 50 \times 10^{-6} \text{ m} = 11.0 \times 10^{-3} \text{ m} = 11.0 \text{ mm}$ . From the Hausen correlation,

$$\overline{\text{Nu}}_D = 3.66 + \frac{0.0668 \times (50 \times 10^{-6} \text{ m} / 20 \times 10^{-3} \text{ m}) \times 845 \times 5.2}{1 + 0.04 \times \left[ (50 \times 10^{-6} \text{ m} / 20 \times 10^{-3} \text{ m}) \times 845 \times 5.2 \right]^{2/3}} = 4.27$$

Hence,

$$\bar{h} = \frac{\overline{\text{Nu}}_D k}{D} = \frac{4.27 \times 0.62 \text{ W/m} \cdot \text{K}}{50 \times 10^{-6} \text{ m}} = 5.29 \times 10^4 \text{ W/m}^2 \cdot \text{K}$$

From Equation 8.42,

$$\begin{aligned} T_m(x=L) &= T_s - [T_s - T_{m,i}] \exp\left(-\frac{PL}{\dot{m}c_p} \bar{h}\right) \\ &= 310\text{K} - [310\text{K} - 300\text{K}] \exp\left(-\frac{\pi \times 50 \times 10^{-6} \text{ m}}{2.55 \times 10^{-5} \text{ kg/s} \times 4178 \text{ J/kg} \cdot \text{K}} \times 5.29 \times 10^4 \text{ W/m}^2 \cdot \text{K}\right) \\ &= 307.9\text{K} = 34.9^\circ\text{C} = T_{m,o} \end{aligned} \quad <$$

Results for the three different channels are shown in the table below. <

	<u><math>D = 45 \mu\text{m}</math> (case 1)</u>	<u><math>D = 50 \mu\text{m}</math> (case 2)</u>	<u><math>D = 55 \mu\text{m}</math> (case 3)</u>
$\text{Re}_D$	690	845	1012
$u_m$ (m/s)	11.85	13.06	14.23
$\dot{m}$ (kg/s)	$1.88 \times 10^{-5}$	$2.55 \times 10^{-5}$	$3.36 \times 10^{-5}$
$x_{fd,t}$ (mm)	8.1	11.0	14.5
$\overline{\text{Nu}}_D$	4.12	4.27	4.44
$\bar{h}$ ( $\text{W/m}^2 \cdot \text{K}$ )	$5.68 \times 10^4$	$5.29 \times 10^4$	$5.01 \times 10^4$
$T_{m,o}$ (K)	308.7	307.9	307.1

Continued...

### PROBLEM 8.117 (Cont.)

(b) The average mass flow rate is

$$\bar{m} = (\dot{m}_1 + \dot{m}_2 + \dot{m}_3)/3 = \left[ (1.88 \times 10^{-5} + 2.55 \times 10^{-5} + 3.36 \times 10^{-5}) \text{kg/s} \right] / 3 = 2.60 \times 10^{-5} \text{kg/s} \quad <$$

(c) The average, mixed outlet temperature is

$$\begin{aligned} T_{m,o} &= (\dot{m}_1 T_{m,o,1} + \dot{m}_2 T_{m,o,2} + \dot{m}_3 T_{m,o,3}) / (\dot{m}_1 + \dot{m}_2 + \dot{m}_3) \\ &= \frac{(1.88 \times 10^{-5} \text{kg/s} \times 308.7 \text{K} + 2.55 \times 10^{-5} \text{kg/s} \times 307.9 \text{K} + 3.36 \times 10^{-5} \text{kg/s} \times 307.1 \text{K})}{(1.88 \times 10^{-5} + 2.55 \times 10^{-5} + 3.36 \times 10^{-5}) \text{kg/s}} = 307.7 \text{K} \end{aligned}$$

(d) Equation 8.42 may be re-arranged to

$$\bar{h} = -\frac{\dot{m} c_p}{PL} \ln \left( \frac{T_s - T_{m,o}}{T_s - T_{m,L}} \right) = -\frac{2.60 \times 10^{-5} \text{kg/s} \times 4178 \text{J/kg} \cdot \text{K}}{\pi \times 50 \times 10^{-6} \text{m} \times 20 \times 10^{-3} \text{m}} \ln \left( \frac{310 - 307.7}{310 - 300} \right) = 50,800 \text{W/m}^2 \cdot \text{K}$$

Thus, the inferred value of the mass flow rate is 2% greater than the predicted value for a 50  $\mu\text{m}$  diameter channel. The inferred value of the convection coefficient (50,800 W/m<sup>2</sup>·K) is 4% less than the predicted value for a 50  $\mu\text{m}$  diameter channel. The experimenter must carefully assess his or her claims since the differences are small and might be attributed to variations in the channel dimensions that occur during their manufacture.

**COMMENTS:** (1) Experimentation at the microscale is challenging. Misinterpretation of the experimental results might occur unless the experimental system is designed very carefully. For example, the diameters of the channels might need to be measured after their manufacture. (2) When boring holes, the hole diameter is always greater than the diameter of the tool. If the experimentalist assumes that the actual hole size is the same as the tool size, what (inappropriate) conclusions might he or she make regarding possible microscale fluid flow and heat transfer effects when analyzing the measured results?

### PROBLEM 8.118

**KNOWN:** Air flow through a plastic tube in which evaporation occurs.

**FIND:** Convection mass transfer coefficient,  $h_m$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Constant properties, (3) Heat-mass transfer analogy applicable, (4) Fully-developed flow and mass transfer conditions.

**PROPERTIES:** Plastic-air (given, 400K):  $Sc = \nu/D_{AB} = 2.0$ ; Table A-4, Air (400K, 1 atm):  $\nu = 26.41 \times 10^{-6} \text{ m}^2/\text{s}$ .

**ANALYSIS:** For fully-developed flow and thermal conditions with laminar flow and a uniform surface temperature,

$$Nu_D = \frac{h D}{k} = 3.66$$

This situation is analogous to the evaporation of plastic vapor into the air stream with the inner surface remaining at a constant concentration of plastic vapor,  $C_{A,s}$ , along the length of the tube. Invoking the heat-mass transfer analogy,

$$Sh_D = \frac{h_m D}{D_{AB}} = 3.66.$$

Recognizing that  $Sc = \nu/D_{AB}$ ,

$$h_m = 3.66 \left( \frac{\nu}{Sc} \right) \frac{1}{D} = 3.66 \times \frac{26.4 \times 10^{-6} \text{ m}^2/\text{s}}{2.0} \times \frac{1}{2 \times 10^{-3} \text{ m}} = 2.42 \times 10^{-2} \text{ m/s.} \quad <$$

**COMMENTS:** (1) The heat-mass transfer analogy requires that the vapor (A) have a negligible effect on the flow. Hence, the flow is that of air (B) and  $\nu = \nu_B$ .

(2) Only the mixture property  $D_{AB}$  is required to characterize the plastic vapor for this evaporation process.

### PROBLEM 8.119

**KNOWN:** Air passing upward through a tube having a thin water film on its inside surface.

**FIND:** Convection mass transfer coefficient.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Constant properties, (3) Heat-mass analogy applicable, and (4) Fully developed flow and thermal conditions.

**PROPERTIES:** Table A.4, Air (300 K, 1 atm):  $\mu = 184.6 \times 10^{-7}\text{ N}\cdot\text{s}/\text{m}^2$ ,  $k = 0.0263\text{ W}/\text{m}\cdot\text{K}$ ; Table A.8, Water vapor-air (300 K, 1 atm):  $D_{AB} = 0.26 \times 10^{-4}\text{ m}^2/\text{s}$ .

**ANALYSIS:** Begin by characterizing the air flow with the Reynolds number,

$$\text{Re}_D = \frac{4\dot{m}}{\pi D \mu} = \frac{4 \times (3/3600)\text{ kg/s}}{\pi \times 0.030\text{ m} \times 184.6 \times 10^{-7}\text{ N/s}\cdot\text{m}^2} = 1916$$

Since the flow is laminar, and assuming fully developed flow and thermal conditions, Eq. 8.55 is appropriate for the uniform  $T_s$  wall condition,

$$\text{Nu}_D = \frac{hD}{k} = 3.66 \quad h = \frac{0.0263\text{ W}/\text{m}\cdot\text{K}}{0.030\text{ m}} \times 3.66 = 3.21\text{ W}/\text{m}^2\cdot\text{K}$$

Invoking the heat-mass analogy, for laminar flow conditions,

$$\text{Sh}_D = \frac{h_m D}{D_{AB}} = \text{Nu}_D$$

$$h_m = \frac{D_{AB}}{D} \text{Nu}_D = \frac{0.26 \times 10^{-4}\text{ m}^2/\text{s}}{0.030\text{ m}} \times 3.66 = 0.0032\text{ m/s} \quad \leftarrow$$

**COMMENTS:** (1) The heat-mass analogy requires that the water vapor (A) have negligible effect on the velocity boundary layer. It is important to recognize that the vapor is species (A) and the air species (B). Hence the flow is that of air (B) and hence  $\mu = \mu_B$ .

(2) Note only the mixture property  $D_{AB}$  is required to characterize the water vapor for this evaporation process.

### PROBLEM 8.120

**KNOWN:** Temperature and flow rate of air in a tube with a naphthalene coated inner surface.

**FIND:** Convection mass transfer coefficient under fully developed conditions and velocity and concentration entry lengths.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Heat and mass transfer analogy is applicable, (2) Uniform vapor concentration along inner surface.

**PROPERTIES:** Table A-4, Air (300 K, 1 atm):  $\mu = 184.6 \times 10^{-7} \text{ N}\cdot\text{s/m}^2$ ,  $\nu = 15.89 \times 10^{-6} \text{ m}^2/\text{s}$ ; Table A-8, Naphthalene-air (300K, 1 atm):  $D_{AB} = 6.2 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $Sc = \mu/D_{AB} = 2.56$ .

**ANALYSIS:** For air flow through the tube,

$$Re_D = \frac{4 \dot{m}}{\pi D \mu} = \frac{4 \times 0.04 \text{ kg/s}}{\pi (0.05 \text{ m}) 184.6 \times 10^{-7} \text{ N}\cdot\text{s/m}^2} = 55,178.$$

Hence the flow is turbulent and from Eq. 8.88,

$$Sh_D = 0.023 Re_D^{4/5} Sc^{0.4} = 0.023 (55,178)^{4/5} (2.56)^{0.4} = 208$$

$$h_m = \frac{D_{AB}}{D} Sh_D = \frac{6.2 \times 10^{-6} \text{ m}^2/\text{s}}{0.05 \text{ m}} 208 = 0.026 \text{ m/s.} \quad <$$

From Eq. 8.4, it follows that

$$10D \leq x_{fd,h} \approx x_{fd,c} \leq 60D$$

or

$$0.5 \text{ m} \leq x_{fd,h} \approx x_{fd,c} \leq 3 \text{ m.} \quad <$$

An entry length of 0.5 m is assumed.

**COMMENTS:** Note that the flow properties are taken to be those of the air, with the contribution of the naphthalene vapor assumed to be negligible.

## PROBLEM 8.121

**KNOWN:** Air flow over roughened section of tube constructed from naphthalene.

**FIND:** Mass and heat transfer convection coefficients associated with the roughened section; contrast these results with those for a smooth section.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Heat-mass transfer analogy applicable, (3) Negligible naphthalene vapor in airstream,  $\rho_{A,m} = 0$ , (4) Constant properties, (5) Naphthalene vapor behaves as perfect gas.

**PROPERTIES:** Table A-4, Air (300K, 1 atm):  $\nu = 15.89 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0263 \text{ W/m}\cdot\text{K}$ ,  $Pr = 0.707$ ; Table A-8, Naphthalene-air mixture (300K, 1 atm):  $D_{AB} = 0.62 \times 10^{-5} \text{ m}^2/\text{s}$ ,  $Sc = \nu_B/D_{AB} = 2.563$ ; Naphthalene (given, 300K):  $p_{\text{sat},A} = 1.31 \times 10^{-4} \text{ bar}$ ,  $M_A = 128.16 \text{ kg/kmol}$ .

**ANALYSIS:** Using the rate equation with the experimentally observed sublimation rate of naphthalene vapor, the average mass transfer coefficient for the section is

$$h_m = \dot{m}_A / (\pi DL) (\rho_{A,s} - \rho_{A,m})$$

$$\rho_{A,m} = 0 \quad \rho_{A,s} = \rho_{A,\text{sat}}(300\text{K}) = M_A p_{\text{sat},A} / \mathcal{R}T$$

$$\rho_{A,s} = 128.16 \text{ kg/kmol} \times \frac{1.31 \times 10^{-4} \text{ bar}}{8.314 \times 10^{-2} \text{ m}^3 \cdot \text{bar/kmol} \cdot \text{K} \times 300 \text{ K}} = 6.731 \times 10^{-4} \text{ kg/m}^3$$

$$h_m = \frac{0.010 \text{ kg}}{3 \times 3600 \text{ s}} / (\pi \times 0.075 \text{ m} \times 0.150 \text{ m}) (6.731 \times 10^{-4} - 0) \text{ kg/m}^3 = 3.89 \times 10^{-2} \text{ m/s} \quad <$$

Invoking the heat-mass transfer analogy, the associated heat transfer coefficient is

$$h = h_m \frac{k}{D_{AB}} \left( \frac{Pr}{Sc} \right)^{1/3} = 3.89 \times 10^{-2} \text{ m/s} \frac{0.0263 \text{ W/m}\cdot\text{K}}{0.62 \times 10^{-5} \text{ m}^2/\text{s}} \left( \frac{0.707}{2.563} \right)^{1/3} = 107 \text{ W/m}^2 \cdot \text{K} \quad <$$

The corresponding convection coefficients for a *smooth* section can be estimated using the Dittus-Boelter relation (the heating condition,  $n = 0.4$ , has been selected),

$$h = \frac{k}{D} 0.023 Re_D^{4/5} Pr^{0.4} = (0.0263 \text{ W/m}\cdot\text{K} / 0.075 \text{ m}) \times 0.023 (35,000)^{4/5} (0.707)^{0.4} = 30 \text{ W/m}^2 \cdot \text{K} \quad <$$

Using the analogous mass transfer relation, Eq. 8.88,

$$h_m = (D_{AB} / D) 0.023 Re_D^{4/5} Sc^{0.4} = (0.62 \times 10^{-5} \text{ m}^2/\text{s} / 0.075 \text{ m}) \times 0.023 (35,000)^{4/5} (2.563)^{0.4}$$

$$h_m = 1.20 \times 10^{-2} \text{ m/s} \quad <$$

**COMMENTS:** The effect of roughening is to increase the convection coefficients over the corresponding value for the smooth condition; in this case, by a factor of approximately 3.5.

## PROBLEM 8.122

**KNOWN:** Dry air with prescribed velocity and temperature flowing over a thin-walled tube with a water-saturated fibrous coating. Water passes at a prescribed rate through the tube to maintain an approximately uniform surface temperature  $T_s = 27^\circ\text{C}$ .

**FIND:** (a) Heat rate from the external surface of the tube considering heat and mass transfer processes and (b) For a flow rate of  $\dot{m} = 0.025 \text{ kg/s}$ , the inlet temperature,  $T_{m,i}$ , of the water that must be supplied to the tube.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Constant properties, (3) Heat-mass analogy applicable, and (4) Water in tube flow is incompressible with negligible viscous dissipation.

**PROPERTIES:** Table A.4, Air ( $\bar{T}_f = (T_s + T_\infty)/2 = 304 \text{ K}$ ):  $\rho = 1.148 \text{ kg/m}^3$ ,  $c_p = 1007 \text{ J/kg}\cdot\text{K}$ ,  $\nu = 16.29 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0266 \text{ W/m}\cdot\text{K}$ ,  $\alpha = 23.09 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.706$ ; Table A.6, Water ( $T_s = 300 \text{ K}$ ):  $\rho_{A,s} = 1/\nu_g = 0.02556 \text{ kg/m}^3$ ,  $h_{fg} = 2438 \text{ kJ/kg}$ ,  $\mu = 855 \times 10^{-6} \text{ N}\cdot\text{s/m}^2$ ; Table A.6, Water ( $\bar{T}_m = 305 \text{ K}$ ):  $\rho = 995 \text{ kg/m}^3$ ,  $c_p = 4178 \text{ J/kg}\cdot\text{K}$ ,  $\mu = 769 \times 10^{-6} \text{ N}\cdot\text{s/m}^2$ ,  $k = 0.620 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 5.20$ ; Table A.8, Water vapor-air ( $T_s = 300 \text{ K}$ ):  $D_{AB} = 0.26 \times 10^{-4} \text{ m}^2/\text{s}$ .

**ANALYSIS:** (a) On the Schematic above, the surface energy balance yields

$$q_{\text{out}} = q_{\text{conv}} + q_{\text{evap}} \quad (1)$$

and substituting the rate equations,

$$q_{\text{conv}} = \bar{h}_o A_s (T_s - T_\infty) \quad q_{\text{evap}} = n_A h_{fg} = \bar{h}_m A_s (\rho_{A,s} - \rho_{A,\infty}) h_{fg} \quad (2,3)$$

where  $\bar{h}_o$  can be estimated from an appropriate correlation and  $\bar{h}_m$  from the heat-mass analogy using  $\bar{h}_o$ .

*Estimation of the heat transfer coefficient,  $\bar{h}_o$ :* The Reynolds number, evaluated with properties at  $\bar{T}_f = (T_s + T_\infty)/2 = 304 \text{ K}$ , is

$$\text{Re}_{D,o} = \frac{VD}{\nu} = \frac{10 \text{ m/s} \times 0.020 \text{ m}}{1.629 \times 10^{-5} \text{ m}^2/\text{s}} = 12,277 \quad (4)$$

Using the Churchill-Bernstein correlation, Eq. 7.54, for cross flow over a cylinder, find  $\bar{h}_o$

$$\text{Nu}_{D,o} = 0.3 + \frac{0.62 \text{Re}_{D,o}^{1/2} \text{Pr}_o^{1/3}}{\left[1 + (0.4/\text{Pr}_o)^{2/3}\right]^{1/4}} \left[1 + \left(\frac{\text{Re}_{D,o}}{282,000}\right)^{5/8}\right]^{4/5} \quad (5)$$

Continued...

**PROBLEM 8.122 (Cont.)**

$$\text{Nu}_{D,o} = 0.3 + \frac{0.62(12,277)^{1/2} (0.706)^{1/3} \left[ 1 + \left( \frac{12,277}{282,000} \right)^{5/8} \right]^{4/5}}{\left[ 1 + (0.4/0.706)^{2/3} \right]^{1/4}}$$

$$\bar{h}_o = \frac{k}{D} \text{Nu}_{D,o} = \frac{0.0266 \text{ W/m} \cdot \text{K}}{0.020 \text{ m}} \times 60.1 = 80.0 \text{ W/m}^2 \cdot \text{K}$$

*The Heat-Mass Analogy:* From Eq. 6.60, with  $n = 1/3$ ,

$$\frac{\bar{h}_o}{\bar{h}_m} = \rho c_p \text{Le}^{2/3} = \rho c_p \left( \frac{\alpha}{D_{AB}} \right)^{2/3} \quad (6)$$

$$\bar{h}_m = 80.0 \text{ W/m}^2 \cdot \text{K} \left/ \left[ 1.148 \text{ kg/m}^3 \times 1007 \text{ J/kg} \cdot \text{K} \left( 23.09 \times 10^{-6} \text{ m}^2/\text{s} / 0.26 \times 10^{-4} \text{ m}^2/\text{s} \right)^{2/3} \right] \right. = 0.0749 \text{ m/s}$$

Hence, the heat rate leaving the tube surface from Eq. (1) is,

$$q_{\text{out}} = \left[ 80 \text{ W/m}^2 \cdot \text{K} (27 - 35)^\circ \text{C} + 0.0749 \text{ m/s} (0.02556 - 0) \text{ kg/m}^3 \times 2438 \times 10^3 \text{ J/kg} \right] (\pi \times 0.020 \text{ m} \times 0.200 \text{ m})$$

$$q_{\text{out}} = -8.04 \text{ W} + 58.65 = 50.6 \text{ W} \quad <$$

(b) For tube flow analysis, the heat rate and rate equations are

$$q = \dot{m} c_p (T_{m,o} - T_{m,i}) \quad \frac{T_s - T_{m,o}}{T_s - T_{m,i}} = \exp \left( - \frac{\pi D L}{\dot{m} c_p} \right) \bar{h}_i \quad (7,8)$$

where  $T_s = 27^\circ\text{C}$ , the uniform temperature of the tube surface, and  $q = -50.6 \text{ W}$  according to the analysis of part (a). To estimate  $\bar{h}_i$ , first characterize the flow,

$$\text{Re}_{D,i} = \frac{4\dot{m}}{\pi D \mu_i} = \frac{4 \times 0.025 \text{ kg/s}}{\pi \times 0.020 \text{ m} \times 769 \times 10^{-6} \text{ N} \cdot \text{s/m}^2} = 2070 \quad (9)$$

using properties evaluated at an assumed mean temperature,  $\bar{T}_m = 305 \text{ K}$  (slightly above  $T_s$ ). The flow is laminar, and with  $\text{Pr} > 5$ , the Hausen correlation, Eq. 8.57 applies, with  $\text{Gz}_D = (D/L)\text{Re}_D\text{Pr} = (0.02 \text{ m}/0.2 \text{ m}) \times 2070 \times 5.2 = 1076$ . Thus,

$$\overline{\text{Nu}}_{D,i} = \frac{\bar{h}_i D}{k} = 3.66 + \frac{0.0668 \text{ Gz}_D}{1 + 0.04 \text{ Gz}_D^{2/3}} = 3.66 + \frac{0.0668 \times 1076}{1 + 0.04(1076)^{2/3}} = 17.5$$

$$\bar{h}_i = \frac{k_i}{D} \overline{\text{Nu}}_{D,i} = \frac{0.620 \text{ W/m} \cdot \text{K}}{0.020 \text{ m}} \times 17.5 = 542 \text{ W/m}^2 \cdot \text{K}$$

Referring to Eqs. (7) and (8), recognize that there are two unknowns,  $T_{m,i}$  and  $T_{m,o}$ , as we have evaluated both  $q$  and  $\bar{h}_i$ . Using the IHT solver,

$$T_{m,i} = 307.7 \text{ K}, \quad T_{m,o} = 307.2 \text{ K} \quad <$$

### PROBLEM 8.123

**KNOWN:** Density and flow rate of gas through a tube with evaporation or sublimation at the tube surface.

**FIND:** (a) Longitudinal distribution of mean vapor density, (b) Total rate of vapor transfer.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady, incompressible flow, (2) Flow rate is independent of \$x\$, (3) Negligible chemical reactions, (4) Uniform perimeter \$P\$.

**ANALYSIS:** (a) Applying conservation of species to a differential control volume

$$\rho_{A,m} u_m A_c + dn_A = \left( \rho_{A,m} + \frac{d\rho_{A,m}}{dx} dx \right) u_m A_c$$

or, with  $u_m A_c = \dot{m}/\rho$  and  $dn_A = h_m P dx (\rho_{A,s} - \rho_{A,m})$ ,

$$\frac{\dot{m}}{\rho} \frac{d\rho_{A,m}}{dx} dx = h_m P dx (\rho_{A,s} - \rho_{A,m}).$$

Separating variables and integrating,

$$\int_{\rho_{A,m,i}}^{\rho_{A,m}} \frac{d\rho_{A,m}}{\rho_{A,s} - \rho_{A,m}} = \int_0^x \frac{\rho h_m P}{\dot{m}} dx = \frac{\rho P}{\dot{m}} \int_0^x h_m dx$$

$$\ell_n \frac{\rho_{A,s} - \rho_{A,m}}{\rho_{A,s} - \rho_{A,m,i}} = -\frac{\rho P x \bar{h}_m}{\dot{m}} \quad \text{or} \quad \frac{\rho_{A,s} - \rho_{A,m}(x)}{\rho_{A,s} - \rho_{A,m,i}} = \exp\left(-\frac{\rho P x \bar{h}_m}{\dot{m}}\right). \quad (1) <$$

(b) With  $\Delta\rho_A \equiv \rho_{A,s} - \rho_{A,m}$ ,

$$n_A = (\dot{m}/\rho) (\rho_{A,m,o} - \rho_{A,m,i}) = -(\dot{m}/\rho) (\Delta\rho_{A,o} - \Delta\rho_{A,i})$$

and from Eq. (1) with

$$-\frac{\dot{m}}{\rho} = P L \bar{h}_m / \ell_n \frac{\Delta\rho_{A,o}}{\Delta\rho_{A,i}}$$

it follows that

$$n_A = \bar{h}_m P L \frac{\Delta\rho_{A,o} - \Delta\rho_{A,i}}{\ell_n (\Delta\rho_{A,o} / \Delta\rho_{A,i})}. <$$

**COMMENTS:** Due to the addition of vapor,  $\dot{m}$  will actually increase with \$x\$. However, if the specific humidity of the saturated gas-vapor mixture is small (as is usually the case), the change in  $\dot{m}$  will be small.

### PROBLEM 8.124

**KNOWN:** Flow rate and temperature of air. Tube diameter and length. Presence of water film on tube inner surface.

**FIND:** (a) Vapor density at tube outlet, (b) Evaporation rate.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady, incompressible flow, (2) Constant flow rate, (3) Isothermal system (water film maintained at 25°C).

**PROPERTIES:** Table A-4, Air (1 atm, 298 K):  $\rho = 1.1707 \text{ kg/m}^3$ ,  $\mu = 183.6 \times 10^{-7} \text{ N}\cdot\text{s/m}^2$ ,  $\nu = 15.71 \times 10^{-6} \text{ m}^2/\text{s}$ ; Table A-6, Water vapor (298 K):  $\rho_{A,\text{sat}} = 1/v_g = (1/44.25 \text{ m}^3/\text{kg}) = 0.0226 \text{ kg/m}^3$ ; Table A-8, Air-vapor (298 K):  $D_{AB} = 26 \times 10^{-6} \text{ m}^2/\text{s}$ ;  $Sc = \nu/D_{AB} = 0.60$ .

**ANALYSIS:** (a) We begin by determining the whether the flow is laminar or turbulent.

$$Re_D = \frac{4 \dot{m}}{\pi D \mu} = \frac{4 \times 3 \times 10^{-4} \text{ kg/s}}{\pi (0.01 \text{ m}) 183.6 \times 10^{-7} \text{ N}\cdot\text{s/m}^2} = 2080.$$

Flow is laminar and from Eq. 8.3 and the mass transfer analogy to Eq. 8.23,

$$x_{fd,h} = 0.05 Re_D D = 0.05 \times 2080 \times 0.01 \text{ m} = 1.04 \text{ m}, \quad x_{fd,c} = x_{fd,h} Sc = 1.04 \text{ m} \times 0.60 = 0.62 \text{ m}$$

Thus this is a combined entry length situation and the mass transfer analogy to the Baehr and Stephan correlation, Eq. 8.58, is appropriate. By analogy to Eq. 8.57,  $Gz_{m,D} = (D/L) Re_D Sc = (0.01 \text{ m}/1 \text{ m}) \times 2080 \times 0.60 = 12.5$ , and

$$\begin{aligned} \overline{Sh}_D &= \frac{\overline{h}_m D}{D_{AB}} = \frac{3.66}{\tanh[2.264 Gz_{m,D}^{-1/3} + 1.7 Gz_{m,D}^{-2/3}]} + \frac{0.0499 Gz_{m,D} \tanh(Gz_{m,D}^{-1})}{\tanh(2.432 Sc^{1/6} Gz_{m,D}^{-1/6})} \\ &= \frac{3.66}{\tanh[2.264 \times 12.5^{-1/3} + 1.7 \times 12.5^{-2/3}]} + \frac{0.0499 \times 12.5 \tanh(12.5^{-1})}{\tanh(2.432 \times 0.60^{1/6} \times 12.5^{-1/6})} = 4.79 \end{aligned}$$

$$\overline{h}_m = \frac{\overline{Sh}_D D_{AB}}{D} = \frac{4.79 \times 26 \times 10^{-6} \text{ m}^2/\text{s}}{0.01 \text{ m}} = 0.0125 \text{ m/s}$$

From Equation 8.86,

$$\rho_{A,m,o} = \rho_{A,s} - (\rho_{A,s} - \rho_{A,m,i}) \exp\left(-\frac{\pi DL}{\dot{m}} \rho \overline{h}_m\right)$$

where  $\rho_{A,s} = \rho_{A,\text{sat}} = 0.0226 \text{ kg/m}^3$ . Thus,

Continued ...

**PROBLEM 8.124 (Cont.)**

$$\begin{aligned}\rho_{A,m,o} &= 0.0226 \text{ kg/m}^3 \\ &- \left(0.0226 \text{ kg/m}^3 - 0\right) \exp\left(-\frac{\pi \cdot 0.01 \text{ m} \times 1 \text{ m}}{3 \times 10^{-4} \text{ kg/s}} \times 1.1707 \text{ kg/m}^3 \times 0.0125 \text{ m/s}\right) < \\ &= 0.0177 \text{ kg/m}^3\end{aligned}$$

(b) The evaporation rate is

$$n_A = u_m A_c (\rho_{A,m,o} - \rho_{A,m,i}) = \frac{\dot{m}}{\rho} (\rho_{A,m,o}) = \frac{3 \times 10^{-4} \text{ kg/s}}{1.1707 \text{ kg/m}^3} \cdot 0.0177 \frac{\text{kg}}{\text{m}^3} = 4.54 \times 10^{-6} \text{ kg/s.} <$$

### PROBLEM 8.125

**KNOWN:** Flow rate and temperature of air in circular tube of prescribed diameter. Inner tube surface is wetted. Flow is fully developed and inlet air is dry.

**FIND:** Tube length required to reach 99% of saturation.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady, incompressible flow, (2) Constant flow rate, (3) Water film is also at 25°C.

**PROPERTIES:** Table A-4, Air (298 K, 1 atm):  $\rho = 1.17 \text{ kg/m}^3$ ,  $\mu = 183.6 \times 10^{-7} \text{ N}\cdot\text{s/m}^2$ ,  $\nu = 15.71 \times 10^{-6} \text{ m}^2/\text{s}$ ; Table A-6, Water vapor (298 K):  $\rho_{A,\text{sat}} = 1/v_g = (1/44.25 \text{ m}^3/\text{kg}) = 0.0226 \text{ kg/m}^3$ ; Table A-8, Air-vapor (298 K):  $D_{AB} = 26 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $Sc = \nu/D_{AB} = 0.60$ .

**ANALYSIS:** If  $\rho_{A,m,o} = 0.99 \rho_{A,s}$ , it follows from Equation 8.86 that

$$\frac{\rho_{A,s} - 0.99 \rho_{A,s}}{\rho_{A,s}} = 0.01 = \exp\left(-\frac{\pi DL \rho \bar{h}_m}{\dot{m}}\right).$$

With

$$Re_D = \frac{4 \dot{m}}{\pi D \mu} = \frac{4 \times 10^{-3} \text{ kg/s}}{\pi (0.01 \text{ m}) 183.6 \times 10^{-7} \text{ N}\cdot\text{s/m}^2} = 6935$$

the flow is turbulent and from Eq. 8.88

$$Sh_D = 0.023 Re_D^{4/5} Sc^{0.4} = 0.023 (6935)^{4/5} (0.60)^{0.4} = 22.2$$

$$\bar{h}_m = \frac{Sh_D D_{AB}}{D} = \frac{22.2 \times 26 \times 10^{-6} \text{ m}^2/\text{s}}{0.01 \text{ m}} = 0.0576 \text{ m/s}.$$

Hence

$$0.01 = \exp\left(-\frac{\pi \times 0.01 \text{ m} \times L \times 1.17 \text{ kg/m}^3}{10^{-3} \text{ kg/s}} 0.0576 \text{ m/s}\right)$$

$$0.01 = \exp(-2.12 L)$$

$$L = 2.2 \text{ m}.$$

<

**COMMENT:** With  $Re_D < 10,000$ , the mass transfer analog of the Gnielinski correlation would be preferable.

### PROBLEM 8.126

**KNOWN:** Flow rate and temperature of atmospheric air in circular tube of prescribed diameter. Flow is fully developed, and air is dry. Inner tube surface is wetted.

**FIND:** (a) Tube length required to reach 99% saturation, (b) Heat rate needed to maintain tube surface at air temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady, incompressible flow, (2) Constant flow rate.

**PROPERTIES:** Table A-4, Air (298 K, 1 atm):  $\rho = 1.17 \text{ kg/m}^3$ ,  $\mu = 183.6 \times 10^{-7} \text{ N}\cdot\text{s/m}^2$ ,  $\nu = 15.71 \times 10^{-6} \text{ m}^2/\text{s}$ ; Table A-6, Water vapor (298 K):  $\nu_g = 44.25 \text{ m}^3/\text{kg}$ ,  $\rho_{A,\text{sat}} = 1/\nu_g = 0.0226 \text{ kg/m}^3$ ,  $h_{fg} = 2443 \text{ kJ/kg}$ ; Table A-8, Air-vapor (298 K):  $D_{AB} = 26 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $Sc = \nu/D_{AB} = 0.60$ .

**ANALYSIS:** (a) If  $\rho_{A,m,o} = 0.99 \rho_{A,s}$ , it follows from Eq. 8.86 that

$$\frac{\rho_{A,s} - 0.99 \rho_{A,s}}{\rho_{A,s}} = 0.01 = \exp\left(-\frac{\pi DL \bar{h}_m}{\dot{m}}\right).$$

$$\text{With } Re_D = \frac{4 \dot{m}}{\pi D \mu} = \frac{4 \times 10^{-3} \text{ kg/s}}{\pi (0.02 \text{ m}) 183.6 \times 10^{-7} \text{ N}\cdot\text{s/m}^2} = 3467,$$

The flow is turbulent (weakly) and Eq. 8.88 yields

$$Sh_D = 0.023 Re_D^{4/5} Sc^{0.4} = 0.023 (3467)^{4/5} (0.60)^{0.4} = 12.7$$

$$h_m = \frac{Sh_D D_{AB}}{D} = \frac{12.7 \times 26 \times 10^{-6} \text{ m}^2/\text{s}}{0.02 \text{ m}} = 0.0166 \text{ m/s}.$$

Hence,

$$L = -\frac{\dot{m}}{\pi D \bar{h}_m} \ln(0.01) = -\frac{10^{-3} \text{ kg/s} \times \ln(0.01)}{\pi (0.02 \text{ m}) 1.17 \text{ kg/m}^3 (0.0166 \text{ m/s})} = 3.78 \text{ m}. \quad <$$

(b) The required heat rate is

$$q = n_A h_{fg} \quad n_A = \bar{h}_m \pi DL \frac{\Delta \rho_{A,o} - \Delta \rho_{A,i}}{\ln(\Delta \rho_{A,o} / \Delta \rho_{A,i})} \quad \text{with } \rho_{A,s} = \rho_{A,\text{sat}}$$

$$n_A = 0.0166 \text{ m/s} \times \pi (0.02 \text{ m}) 3.78 \text{ m} \frac{0.01 \rho_{A,s} - \rho_{A,s}}{\ln(0.01)}$$

$$n_A = -8.55 \times 10^{-4} \text{ m}^3/\text{s} \left( -0.99 \times 0.0226 \text{ kg/m}^3 \right) = 1.91 \times 10^{-5} \text{ kg/s}$$

$$q = n_A h_{fg} = 1.91 \times 10^{-5} \text{ kg/s} \times 2.443 \times 10^6 \text{ J/kg} = 46.7 \text{ W}. \quad <$$

**COMMENTS:** (1) The evaporation rate is low; hence the heat requirement is small. (2) The evaporation rate can also be calculated from

$n_A = \dot{m}(\rho_{A,o}/\rho - \rho_{A,i}/\rho) = \dot{m}/\rho(0.99\rho_{A,s}) = 1.91 \times 10^{-5} \text{ kg/s}$  which agrees with the preceding result.

### PROBLEM 8.127

**KNOWN:** Tube length, diameter and temperature. Air temperature and velocity. Saturation pressure of thin liquid film and properties of vapor.

**FIND:** (a) Partial pressure and mass fraction of vapor at tube exit, (b) Mass rate at which liquid is removed from the tube.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) System is isothermal at 300K, (2) Steady, incompressible flow, (3) Perfect gas behavior, (4) Mass flow rate is independent of  $x$ .

**PROPERTIES:** Table A-4, Air (300 K, 1 atm):  $\rho = 1.16 \text{ kg/m}^3$ ,  $\nu = 15.9 \times 10^{-6} \text{ m}^2/\text{s}$ . Prescribed, Vapor (300K):  $p_{A,sat} = 15 \text{ mm Hg}$ ,  $\mathcal{M}_A = 70 \text{ kg/kmol}$ ,  $D_{AB} = 10^{-5} \text{ m}^2/\text{s}$ .

**ANALYSIS:** (a) With the vapor assumed to behave as an ideal gas,  $p_A = C_A \Re T = \rho_A (\Re / \mathcal{M}_A) T$ , and isothermal conditions, the vapor pressure at the outlet may be obtained from the expression

$$\frac{p_{A,sat} - p_{A,o}}{p_{A,sat} - p_{A,i}} = \frac{\rho_{A,s} - \rho_{A,m,o}}{\rho_{A,s} - \rho_{A,m,i}} = \exp\left(-\frac{\rho \pi D L \bar{h}_m}{\dot{m}}\right)$$

where  $\dot{m} = \rho u_m A_c = 1.16 \text{ kg/m}^3 \times 0.5 \text{ m/s} \times \pi (0.05 \text{ m})^2 / 4 = 1.14 \times 10^{-3} \text{ kg/s}$ . With  $\text{Re}_D = u_m D / \nu = 0.5 \text{ m/s} \times 0.05 \text{ m} / 15.9 \times 10^{-6} \text{ m}^2/\text{s} = 1570$ , the flow is laminar. From Eq. 8.3 and the mass transfer analogy to Eq. 8.23, with  $\text{Sc} = \nu / D_{AB} = 1.59$ ,

$$x_{fd,h} = 0.05 \text{Re}_D D = 0.05 \times 1570 \times 0.05 \text{ m} = 3.93 \text{ m}, \quad x_{fd,c} = x_{fd,h} \text{Sc} = 3.93 \text{ m} \times 1.59 = 6.24 \text{ m}$$

Thus this is a combined entry length situation and the mass transfer analogy to the Baehr and Stephan correlation, Eq. 8.58, is appropriate. By analogy to Eq. 8.57,  $Gz_{m,D} = (D/L)\text{Re}_D \text{Sc} = (0.05 \text{ m}/5 \text{ m}) \times 1570 \times 1.59 = 25.0$ , and

$$\begin{aligned} \bar{Sh}_D = \frac{\bar{h}_m D}{D_{AB}} &= \frac{3.66}{\tanh[2.264 Gz_{m,D}^{-1/3} + 1.7 Gz_{m,D}^{-2/3}] + 0.0499 Gz_{m,D} \tanh(Gz_{m,D}^{-1})} \\ &= \frac{3.66}{\tanh(2.432 \text{Sc}^{1/6} Gz_{m,D}^{-1/6})} = \frac{3.66}{\tanh[2.264 \times 25.0^{-1/3} + 1.7 \times 25.0^{-2/3}] + 0.0499 \times 25.0 \tanh(25.0^{-1})} \\ &= \frac{3.66}{\tanh(2.432 \times 1.59^{1/6} \times 25.0^{-1/6})} = 5.41 \end{aligned}$$

$$\bar{h}_m = \frac{\bar{Sh}_D D_{AB}}{D} = 5.41 \times \frac{10^{-5} \text{ m}^2/\text{s}}{0.05 \text{ m}} = 1.08 \times 10^{-3} \text{ m/s}$$

Hence, with  $p_{A,i} = 0$

Continued ...

**PROBLEM 8.127 (Cont.)**

$$p_{A,o} = p_{A,sat} \left[ 1 - \exp\left(-\frac{\rho \pi D L \bar{h}_m}{\dot{m}}\right) \right] = 15 \text{ mm Hg} \left[ 1 - \exp\left(-\frac{1.16 \text{ kg/m}^3 \times \pi \times 0.05 \text{ m} \times 5 \text{ m} \times 1.08 \times 10^{-3} \text{ m/s}}{1.14 \times 10^{-3} \text{ kg/s}}\right) \right] = 8.7 \text{ mm Hg} <$$

The corresponding mass density of the vapor is

$$\rho_{A,m,o} = \frac{p_{A,o} \mathcal{M}_A}{\mathcal{R}T} = \frac{8.7 \text{ mm Hg} \times 70 \text{ kg/kmol}}{(760 \text{ mm Hg/atm})(0.082 \text{ m}^3 \cdot \text{atm/kmol} \cdot \text{K})300 \text{ K}} = 0.0326 \text{ kg/m}^3 <$$

(b) The evaporation rate is

$$n_A = u_m A_c (\rho_{A,m,o} - \rho_{A,m,i}) = 0.5 \text{ m/s} \times 1.96 \times 10^{-3} \text{ m}^2 \times 0.0326 \text{ kg/m}^3 = 3.20 \times 10^{-5} \text{ kg/s} <$$

**COMMENTS:** (1) Since the evaporation rate ( $n_A = 3.2 \times 10^{-5} \text{ kg/s}$ ) is much less than the air flow rate ( $\dot{m} = 1.14 \times 10^{-3} \text{ kg/s}$ ), the assumption of a fixed flow rate is reasonable. (2) The evaporation rate is also given by  $n_A = \bar{h}_m \pi D L \Delta \rho_{A,m} = -\bar{h}_m \pi D L \rho_{A,m,o} / \ln [(p_{A,sat} - p_{A,o})/p_{A,sat}] = 3.22 \times 10^{-5} \text{ kg/s}$ , which agrees with the calculation of part (b).

## PROBLEM 8.128

**KNOWN:** Air flow rate through trachea of diameter  $D$  and length  $L$ .

**FIND:** (a) Average mass transfer convection coefficient,  $\bar{h}_m$ , and (b) Rate of water loss per day (liter/day).

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Trachea can be approximated as a smooth tube with uniform surface temperature, (2) Laminar, fully developed flow, (3) Trachea inner surface is saturated with water at body temperature,  $T_s = 37^\circ\text{C}$ , (4) Negligible water vapor in air at 310 K during inhalation, and (5) Heat-mass analogy is applicable.

**PROPERTIES:** Table A-4, Air (310 K, 1 atm):  $\rho_B = 1.128 \text{ kg/m}^3$ ,  $\mu = 1.893 \times 10^{-5} \text{ N}\cdot\text{s/m}^2$ ; Table A-6, Water ( $T_s = 37^\circ\text{C} = 310 \text{ K}$ ):  $\rho_{A,f} = 993 \text{ kg/m}^3$ ,  $\rho_{A,g} = 0.04361 \text{ kg/m}^3$ ; Table A-8, Water-vapor air (310 K, 1 atm):  $D_{AB} = 0.26 \times 10^{-4} (310/298)^{3/2} = 2.76 \times 10^{-5} \text{ m}^2/\text{s}$ .

**ANALYSIS:** (a) Begin by characterizing the air (B) flow in the trachea modeled as a smooth tube,

$$\text{Re}_D = \frac{4\dot{m}}{\pi D \mu} = \frac{4\dot{V}_B \rho_B}{\pi D \mu}$$

$$\text{Re}_D = \frac{4 \times 10 \text{ liter/min} \times 10^{-3} \text{ m}^3/\text{liter} \times 1 \text{ min}/60\text{s} \times 1.128 \text{ kg/m}^3}{\pi \times 0.020 \text{ m} \times 1.893 \times 10^{-5} \text{ N}\cdot\text{s/m}^2} = 632$$

Hence, the flow is laminar, and for fully developed conditions and invoking the heat-mass analogy

$$\text{Nu}_D = \text{Sh}_D = 3.66 \quad \text{Sh} = \bar{h}_m D / D_{AB}$$

$$\bar{h}_m = 3.66 D_{AB} / D = 3.66 \times 2.76 \times 10^{-5} \text{ m}^2/\text{s} / 0.020 \text{ m} = 0.0050 \text{ m/s} \quad <$$

(b) The species (A) transfer rate equation, Eq. 8.83, has the form

$$n_A = \bar{h}_m A_s \Delta\rho_{A,\ell m}$$

$$\Delta\rho_{A,\ell m} = \frac{(\rho_{A,s} - \rho_{A,m,o}) - (\rho_{A,s} - \rho_{A,m,i})}{\ell m \left[ (\rho_{A,s} - \rho_{A,m,o}) / (\rho_{A,s} - \rho_{A,m,i}) \right]}$$

where the mean outlet species density,  $\rho_{A,m,o}$ , can be determined from Eq. 8.86

$$\frac{\rho_{A,s} - \rho_{A,m,o}}{\rho_{A,s} - \rho_{A,m,i}} = \exp\left(-\frac{\bar{h}_m \rho P L}{\dot{m}}\right)$$

where  $\dot{m} / \rho = u_m A_c = \dot{V}_B$ . Substituting numerical values with  $P = \pi D$ , find

$$\rho_{A,m,o} = 0.009233 \quad n_A = 1.54 \times 10^{-6} \text{ kg/s}$$

The volumetric rate of water loss on a daily basis, assuming a 12 hour inhalation period, is

$$\dot{V}_A = \left(1.54 \times 10^{-6} \text{ kg/s} / 993 \text{ kg/m}^3\right) \times 10^3 \text{ liter/m}^3 \times (3600 \text{ s/h} \times 24 \text{ h/day})$$

$$\dot{V}_A = 0.134 \text{ liter/day}$$

### PROBLEM 8.129

**KNOWN:** Air (species B) is in fully developed, laminar flow as it enters a circular tube wetted with liquid A (water). Tube length and diameter. Flow rate of air and system temperature.

**FIND:** (a) Governing differential equation for species transfer, (b) Heat transfer analog and an expression for  $\overline{Sh}_D$ , (c) General expression for  $\rho_{A,m,o}$ , (d) Value of  $\rho_{A,m,o}$  for prescribed conditions.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady, incompressible flow, (2) Flow rate is independent of  $x$ , (3) Laminar, fully developed flow (hydrodynamically), (4) Isothermal conditions, (5) Dry air at inlet.

**PROPERTIES:** Table A.4, Air (298 K, 1 atm):  $\rho = 1.1707 \text{ kg/m}^3$ ,  $\mu = 183.6 \times 10^{-7} \text{ N}\cdot\text{s/m}^2$ ,  $\nu = 15.71 \times 10^{-6} \text{ m}^2/\text{s}$ ; Table A.6, Water vapor (298 K):  $\rho_{A,sat} = 1/\nu_g = 0.0266 \text{ kg/m}^3$ ; Table A.8, Air-vapor (298 K):  $D_{AB} = 26 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $Sc = \nu/D_{AB} = 0.60$ .

**ANALYSIS:** (a) The governing differential equation may be inferred by analogy to Eq. 8.48. In this case, the dependent variable is the vapor mass density,  $\rho_A(x,r)$ , and the diffusivity is  $D_{AB}$ . It follows that

$$u \frac{\partial \rho_A}{\partial x} = \frac{D_{AB}}{r} \frac{\partial}{\partial r} \left( r \frac{\partial \rho_A}{\partial r} \right) \quad <$$

The entrance condition is

$$\rho_A(0, r) = 0 \quad <$$

and the boundary conditions are

$$\rho_A(r_o, x) = \rho_{A,s} \quad \rho_A|_{r=0} \text{ is finite} \quad <$$

(b) The foregoing conditions are analogous to those of the thermal entry length condition associated with Eq. 8.57. Invoking this analogy the average Sherwood number for laminar, fully developed flow is

$$\overline{Sh}_D = 3.66 + \frac{0.0668(D/L) Re_D Sc}{1 + 0.04[(D/L) Re_D Sc]^{2/3}} \quad <$$

where the mass transfer analogy to Eq. 8.56 was used for the Graetz number.

(c) Applying conservation of species to the differential control volume,

$$\rho_{A,m} u_m A_c + dn_A = \left( \rho_{A,m} + \frac{d\rho_{A,m}}{dx} dx \right) u_m A_c$$

or, with  $u_m A_c = \dot{m}/\rho$  and  $dn_A = h_m \pi D dx (\rho_{A,s} - \rho_{A,m})$

$$\frac{\dot{m}}{\rho} \frac{d\rho_{A,m}}{dx} dx = h_m \pi D dx (\rho_{A,s} - \rho_{A,m})$$

Continued...

**PROBLEM 8.129 (Cont.)**

$$\int_{\rho_{A,m,i}}^{\rho_{A,m}} \frac{d\rho_{A,m}}{\rho_{A,s} - \rho_{A,m}} = \int_0^x \frac{\rho\pi D h_m}{\dot{m}} dx$$

or

$$\frac{\rho_{A,s} - \rho_{A,m}(x)}{\rho_{A,s} - \rho_{A,m,i}} = \exp\left(-\frac{\rho\pi D x \bar{h}_m(x)}{\dot{m}}\right)$$

at  $x = L$ ,

$$\frac{\rho_{A,s} - \rho_{A,m,o}}{\rho_{A,s} - \rho_{A,m,i}} = \exp\left(-\frac{\rho\pi D L \bar{h}_m}{\dot{m}}\right) \quad <$$

(d) For the prescribed conditions,  $Re_D = 4\dot{m}/\pi D \mu = 4(2.5 \times 10^{-4} \text{ kg/s})/\pi(0.01 \text{ m})183.6 \times 10^{-7} \text{ N}\cdot\text{s}/\text{m}^2 = 1734$  and  $(D/L)Re_D Sc = (0.01 \text{ m}/1 \text{ m})1734(0.6) = 10.4$ . Hence,

$$\bar{Sh}_D = 3.66 + \frac{0.0668(10.4)}{1 + 0.04(10.4)^{2/3}} = 4.24$$

$$\bar{h}_m = \bar{Sh}_D (D_{AB}/D) = 4.24(26 \times 10^{-6} \text{ m}^2/\text{s}/0.01 \text{ m}) = 0.011 \text{ m/s}$$

Hence,

$$\frac{\rho_{A,s} - \rho_{A,m,o}}{\rho_{A,s} - \rho_{A,m,i}} = \exp\left(-\frac{1.1707 \text{ kg}/\text{m}^3 \times \pi \times 0.01 \text{ m} \times 1 \text{ m} \times 0.011 \text{ m/s}}{2.5 \times 10^{-4} \text{ kg/s}}\right) = 0.198$$

$$\rho_{A,m,o} = \rho_{A,s} - 0.198(\rho_{A,s} - \rho_{A,m,i}) = 0.0226 \text{ kg}/\text{m}^3 (1 - 0.198) = 0.0181 \text{ kg}/\text{m}^3 <$$

**COMMENTS:** Due to evaporation,  $\dot{m}$  actually increases with increasing  $x$ . However, the increase is small, and the assumption of fixed  $\dot{m}$  is good.

## PROBLEM 9.1

**KNOWN:** Thickness and thermal conductivity of plane wall. Fluid temperatures.

**FIND:** Expected minimum and maximum steady-state heat fluxes through the wall for (a) free convection in gases, (b) free convection in liquids, (c) forced convection in gases, (d) forced convection in liquids, and (e) convection with phase change.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Constant properties. (2) Steady state conditions. (3) Negligible radiation.

**ANALYSIS:** The thermal resistance network is

From Table 1.1 for free convection in gases, the minimum convective heat transfer coefficient is  $h = 2 \text{ W/m}^2\cdot\text{K}$ . Therefore, the corresponding heat flux is

$$q_x'' = \frac{T_{\infty,1} - T_{\infty,2}}{\frac{1}{h_1} + \frac{L}{k} + \frac{1}{h_2}} = \frac{200^\circ\text{C} - 100^\circ\text{C}}{\frac{1}{2 \text{ W/m}^2 \cdot \text{K}} + \frac{75 \times 10^{-3} \text{ m}}{5 \text{ W/m} \cdot \text{K}} + \frac{1}{2 \text{ W/m}^2 \cdot \text{K}}} = 98.5 \text{ W/m}^2$$

Proceeding in the same manner, we find the following results

Process	$h_{\min} \text{ (W/m}^2\cdot\text{K)}$	$h_{\max} \text{ (W/m}^2\cdot\text{K)}$	$q_{x,\min}''$	$q_{x,\max}''$	$q_{x,\max}'' / q_{x,\min}''$	
(a) Free convection, gas	2	25	98.5	1053	10.7	<
(b) Free convection, liquid	50	1000	1818	5882	3.23	<
(c) Forced convection, gas	25	250	1053	4348	4.12	<
(d) Forced convection, liquid	100	20,000	2857	6623	2.32	<
(e) Phase change	2500	100,000	6329	6658	1.05	<

**COMMENTS:** For either gases or liquids, the dependence of the heat flux on the range of convection coefficients associated with each type of convective heat transfer process, as quantified by the ratio  $q_{x,\max}'' / q_{x,\min}''$ , is strongest for free convection, and weakest for convection involving phase change. The temptation to attach less significance to free convection because the convection coefficients are small is to be resisted. Free convection poses large thermal resistance, and therefore can be the dominant factor in thermal engineering processes and design.

## PROBLEM 9.2

**KNOWN:** Tabulated values of density for water and definition of the volumetric thermal expansion coefficient,  $\beta$ .

**FIND:** Value of the volumetric expansion coefficient at 300K; compare with tabulated values.

**PROPERTIES:** *Table A-6, Water (300K):*  $\rho = 1/v_f = 1/1.003 \times 10^{-3} \text{ m}^3/\text{kg} = 997.0 \text{ kg/m}^3$ ,  $\beta = 276.1 \times 10^{-6} \text{ K}^{-1}$ ; (295K):  $\rho = 1/v_f = 1/1.002 \times 10^{-3} \text{ m}^3/\text{kg} = 998.0 \text{ kg/m}^3$ ; (305K):  $\rho = 1/v_f = 1/1.005 \times 10^{-3} \text{ m}^3/\text{kg} = 995.0 \text{ kg/m}^3$ .

**ANALYSIS:** The volumetric expansion coefficient is defined by Eq. 9.4 as

$$\beta = -\frac{1}{\rho} \left( \frac{\partial \rho}{\partial T} \right)_p.$$

The density change with temperature at constant pressure can be estimated as

$$\left( \frac{\partial \rho}{\partial T} \right)_p \approx \left( \frac{\rho_1 - \rho_2}{T_1 - T_2} \right)_p$$

where the subscripts (1,2) denote the property values just above and below, respectively, the condition for  $T = 300\text{K}$  denoted by the subscript (o). That is,

$$\beta_o \approx -\frac{1}{\rho_o} \left( \frac{\rho_1 - \rho_2}{T_1 - T_2} \right)_p.$$

Substituting numerical values, find

$$\beta_o \approx \frac{-1}{997.0 \text{ kg/m}^3} \frac{(995.0 - 998.0) \text{ kg/m}^3}{(305 - 295) \text{ K}} = 300.9 \times 10^{-6} \text{ K}^{-1}. \quad <$$

Compare this value with the tabulation,  $\beta = 276.1 \times 10^{-6} \text{ K}^{-1}$ , to find our estimate is 8.7% high.

**COMMENTS:** (1) The poor agreement between our estimate and the tabulated value is due to the poor precision with which the density change with temperature is estimated. The tabulated values of  $\beta$  were determined from accurate equation of state data.

(2) Note that  $\beta$  is negative for  $T < 275\text{K}$ . Why? What is the implication for free convection?

### PROBLEM 9.3

**KNOWN:** Relation for the Rayleigh number.

**FIND:** Rayleigh number for four fluids for prescribed conditions.

**SCHEMATIC:**

Quiescent  
fluid,  $T_\infty$   
 $\Delta T = 30^\circ\text{C}$   
 $L = 0.01\text{m}$

**ASSUMPTIONS:** (1) Perfect gas behavior for specified gases.

**PROPERTIES:** Table A-4, Air (400K, 1 atm):  $\nu = 26.41 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\alpha = 38.3 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\beta = 1/T = 1/400\text{K} = 2.50 \times 10^{-3} \text{ K}^{-1}$ ; Table A-4, Helium (400K, 1 atm):  $\nu = 199 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\alpha = 295 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\beta = 1/T = 2.50 \times 10^{-3} \text{ K}^{-1}$ ; Table A-5, Glycerin (12°C = 285K):  $\nu = 2830 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\alpha = 0.964 \times 10^{-7} \text{ m}^2/\text{s}$ ,  $\beta = 0.475 \times 10^{-3} \text{ K}^{-1}$ ; Table A-6, Water (37°C = 310K, sat. liq.):  $\nu = \mu_f \nu_f = 695 \times 10^{-6} \text{ N}\cdot\text{s}/\text{m}^2 \times 1.007 \times 10^{-3} \text{ m}^3/\text{kg} = 0.700 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\alpha = k_f \nu_f / c_{p,f} = 0.628 \text{ W}/\text{m}\cdot\text{K} \times 1.007 \times 10^{-3} \text{ m}^3/\text{kg} / 4178 \text{ J}/\text{kg}\cdot\text{K} = 0.151 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\beta_f = 361.9 \times 10^{-6} \text{ K}^{-1}$ .

**ANALYSIS:** The Rayleigh number, a dimensionless parameter used in free convection analysis, is defined as the product of the Grashof and Prandtl numbers.

$$\text{Ra}_L \equiv \text{Gr} \cdot \text{Pr} = \frac{g\beta\Delta T L^3}{\nu^2} \frac{\mu c_p}{k} = \frac{g\beta\Delta T L^3}{\nu^2} \frac{(\nu\rho)c_p}{k} = \frac{g\beta\Delta T L^3}{\nu\alpha}$$

where  $\alpha = k/\rho c_p$  and  $\nu = \mu/\rho$ . The numerical values for the four fluids follow:

*Air* (400K, 1 atm)

$$\text{Ra}_L = 9.8\text{m}/\text{s}^2 (1/400\text{K}) 30\text{K} (0.01\text{m})^3 / 26.41 \times 10^{-6} \text{ m}^2/\text{s} \times 38.3 \times 10^{-6} \text{ m}^2/\text{s} = 727 <$$

*Helium* (400K, 1 atm)

$$\text{Ra}_L = 9.8\text{m}/\text{s}^2 (1/400\text{K}) 30\text{K} (0.01\text{m})^3 / 199 \times 10^{-6} \text{ m}^2/\text{s} \times 295 \times 10^{-6} \text{ m}^2/\text{s} = 12.5 <$$

*Glycerin* (285K)

$$\text{Ra}_L = 9.8\text{m}/\text{s}^2 (0.475 \times 10^{-3} \text{ K}^{-1}) 30\text{K} (0.01\text{m})^3 / 2830 \times 10^{-6} \text{ m}^2/\text{s} \times 0.964 \times 10^{-7} \text{ m}^2/\text{s} = 512 <$$

*Water* (310K)

$$\text{Ra}_L = 9.8\text{m}/\text{s}^2 (0.362 \times 10^{-3} \text{ K}^{-1}) 30\text{K} (0.01\text{m})^3 / 0.700 \times 10^{-6} \text{ m}^2/\text{s} \times 0.151 \times 10^{-6} \text{ m}^2/\text{s} = 1.01 \times 10^6 <$$

**COMMENTS:** (1) Note the wide variation in values of Ra for the four fluids. A large value of Ra implies enhanced free convection, however, other properties affect the value of the heat transfer coefficient.

### PROBLEM 9.4

**KNOWN:** Form of the Nusselt number correlation for natural convection and fluid properties.

**FIND:** Expression for figure of merit  $F_N$  and values for air, water and a dielectric liquid.

**PROPERTIES:** Prescribed. Air:  $k = 0.026 \text{ W/m}\cdot\text{K}$ ,  $\beta = 0.0035 \text{ K}^{-1}$ ,  $\nu = 1.5 \times 10^{-5} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.70$ .

Water:  $k = 0.600 \text{ W/m}\cdot\text{K}$ ,  $\beta = 2.7 \times 10^{-4} \text{ K}^{-1}$ ,  $\nu = 10^{-6} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 5.0$ . Dielectric liquid:  $k = 0.064$

$\text{W/m}\cdot\text{K}$ ,  $\beta = 0.0014 \text{ K}^{-1}$ ,  $\nu = 10^{-6} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 25$

**ANALYSIS:** With  $\text{Nu}_L \sim \text{Ra}^n$ , the convection coefficient may be expressed as

$$h \sim \frac{k}{L} \left( \frac{g\beta\Delta T L^3}{\alpha\nu} \right)^n \sim \frac{(g\Delta T L^3)^n}{L} \left( \frac{k\beta^n}{\alpha^n \nu^n} \right)$$

The figure of merit is therefore

$$F_N = \frac{k\beta^n}{\alpha^n \nu^n} \quad <$$

and for the three fluids, with  $n = 0.33$  and  $\alpha = \nu / \text{Pr}$ ,

$$F_N \left( \text{W}\cdot\text{s}^{2/3} / \text{m}^{7/3} \cdot \text{K}^{4/3} \right) \quad \begin{array}{ccc} \text{Air} & \text{Water} & \text{Dielectric} \\ \hline 5.8 & 663 & 209 \end{array} \quad <$$

Water is clearly the superior heat transfer fluid, while air is the least effective.

**COMMENTS:** The figure of merit indicates that heat transfer is enhanced by fluids of large  $k$ , large  $\beta$  and small values of  $\alpha$  and  $\nu$ .

## PROBLEM 9.5

**KNOWN:** Temperature and pressure of air in a free convection application.

**FIND:** Figure of merit for  $T = 27^\circ\text{C}$  and  $P = 1, 10$  and  $100$  bar.

**ASSUMPTIONS:** (1) Ideal gas, (2) Thermal conductivity, dynamic viscosity and specific heat are independent of pressure.

**PROPERTIES:** Table A.4, air: ( $T_f = 300$  K,  $p = 1$  atm):  $k = 0.0263$  W/m·K,  $c_p = 1007$  J/kg·K,  $\nu = 15.89 \times 10^{-6}$  m<sup>2</sup>/s,  $\alpha = 22.5 \times 10^{-6}$  m<sup>2</sup>/s.

**ANALYSIS:** With  $\text{Nu}_L \approx \text{Ra}^n$ , the convection coefficient may be expressed as

$$h \approx \frac{k}{L} \left( \frac{g\beta\Delta TL^3}{\alpha\nu} \right)^n = \frac{(g\Delta TL^3)^n}{L} \left( \frac{k\beta^n}{\alpha^n\nu^n} \right)$$

and the figure of merit is  $F_N = \frac{k\beta^n}{\alpha^n\nu^n}$ .

For an ideal gas,  $\beta = 1/T$ . The thermal diffusivity is  $\alpha = k/\rho c_p$ . Since  $k$  and  $c_p$  are independent of pressure, and the density is proportional to pressure for an ideal gas,  $\alpha \propto 1/p$ . The kinematic viscosity is  $\nu = \mu/\rho$ . Therefore, for an ideal gas,  $\nu \propto 1/p$ . Thus, the properties and the figure of merit, using  $n = 0.33$ , at the three pressures are

$p = 1 \text{ bar} = 1 \times 10^5 \text{ N/m}^2$	$p = 10 \text{ bar}$	$p = 100 \text{ bar}$
$\beta = 1/300 \text{ K}^{-1}$	$\beta = 1/300 \text{ K}^{-1}$	$\beta = 1/300 \text{ K}^{-1}$
$k = 0.0263 \text{ W/m}\cdot\text{K}$	$k = 0.0263 \text{ W/m}\cdot\text{K}$	$k = 0.0263 \text{ W/m}\cdot\text{K}$
$\alpha = 22.5 \times 10^{-6} \text{ m}^2/\text{s} \times \left( \frac{1.0133}{1} \right)$	$\alpha = 22.5 \times 10^{-6} \text{ m}^2/\text{s} \times \left( \frac{1.0133}{10} \right)$	$\alpha = 22.5 \times 10^{-6} \text{ m}^2/\text{s} \times \left( \frac{1.0133}{100} \right)$
$= 2.28 \times 10^{-5} \text{ m}^2/\text{s}$	$= 2.28 \times 10^{-6} \text{ m}^2/\text{s}$	$= 2.28 \times 10^{-7} \text{ m}^2/\text{s}$
$\nu = 1.589 \times 10^{-5} \text{ m}^2/\text{s} \times \left( \frac{1.0133}{1} \right)$	$\nu = 1.589 \times 10^{-5} \text{ m}^2/\text{s} \times \left( \frac{1.0133}{10} \right)$	$\nu = 1.589 \times 10^{-5} \text{ m}^2/\text{s} \times \left( \frac{1.0133}{100} \right)$
$= 1.610 \times 10^{-5} \text{ m}^2/\text{s}$	$= 1.610 \times 10^{-6} \text{ m}^2/\text{s}$	$= 1.610 \times 10^{-7} \text{ m}^2/\text{s}$

Therefore, for  $P = 1$  bar,  $F_N = \frac{0.0263 \text{ W/m}\cdot\text{K} \times (1/300\text{K})^{0.33}}{(2.28 \times 10^{-5} \text{ m}^2/\text{s})^{0.33} \times (1.61 \times 10^{-5} \text{ m}^2/\text{s})^{0.33}} = 5.20$ . Similarly, for

$P = 10$  bar,  $F_N = 23.78$  while for  $P = 100$  bar,  $F_N = 108.7$ . <

**COMMENT:** The efficacy of natural convection cooling within sealed enclosures can be increased significantly by increasing the pressure of the gas.

## PROBLEM 9.6

**KNOWN:** Heat transfer rate by convection from a vertical surface, 1m high by 0.6m wide, to quiescent air that is 20K cooler.

**FIND:** Ratio of the heat transfer rate for the above case to that for a vertical surface that is 0.6m high by 1m wide with quiescent air that is 20K warmer.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Thermophysical properties independent of temperature; evaluate at 300K; (2) Negligible radiation exchange with surroundings, (3) Quiescent ambient air.

**PROPERTIES:** Table A-4, Air (300K, 1 atm):  $\nu = 15.89 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\alpha = 22.5 \times 10^{-6} \text{ m}^2/\text{s}$ .

**ANALYSIS:** The rate equation for convection between the plates and quiescent air is

$$q = \bar{h}_L A_S \Delta T \quad (1)$$

where  $\Delta T$  is either  $(T_s - T_\infty)$  or  $(T_\infty - T_s)$ ; for both cases,  $A_S = Lw$ . The desired heat transfer ratio is then

$$\frac{q_1}{q_2} = \frac{\bar{h}_{L1}}{\bar{h}_{L2}} \quad (2)$$

To determine the dependence of  $\bar{h}_L$  on geometry, first calculate the Rayleigh number,

$$\text{Ra}_L = g \beta \Delta T L^3 / \nu \alpha \quad (3)$$

and substituting property values at 300K, find,

$$\text{Case 1: } \text{Ra}_{L1} = 9.8 \text{ m/s}^2 (1/300\text{K}) 20\text{K} (1\text{m})^3 / 15.89 \times 10^{-6} \text{ m}^2/\text{s} \times 22.5 \times 10^{-6} \text{ m}^2/\text{s} = 1.82 \times 10^9$$

$$\text{Case 2: } \text{Ra}_{L2} = \text{Ra}_{L1} (L_2/L_1)^3 = 1.82 \times 10^4 (0.6\text{m}/1.0\text{m})^3 = 3.94 \times 10^8$$

Hence, Case 1 is turbulent and Case 2 is laminar. Using the correlation of Eq. 9.24,

$$\overline{\text{Nu}}_L = \frac{\bar{h}_L L}{k} = C (\text{Ra}_L)^n \quad \bar{h}_L = \frac{k}{L} C \text{Ra}_L^n \quad (4)$$

where for Case 1:  $C_1 = 0.10$ ,  $n_1 = 1/3$  and for Case 2:  $C_2 = 0.59$ ,  $n_2 = 1/4$ . Substituting Eq. (4) into the ratio of Eq. (2) with numerical values, find

$$\frac{q_1}{q_2} = \frac{(C_1/L_1) \text{Ra}_{L1}^{n_1}}{(C_2/L_2) \text{Ra}_{L2}^{n_2}} = \frac{(0.10/1\text{m}) (1.82 \times 10^9)^{1/3}}{(0.59/0.6\text{m}) (3.94 \times 10^8)^{1/4}} = 0.881 <$$

**COMMENTS:** Is this result to be expected? How do you explain this effect of plate orientation on the heat rates?

## PROBLEM 9.7

**KNOWN:** Large vertical plate with uniform surface temperature of 130°C suspended in quiescent air at 25°C and atmospheric pressure.

**FIND:** (a) Boundary layer thickness at 0.25 m from lower edge, (b) Maximum velocity in boundary layer at this location and position of maximum, (c) Heat transfer coefficient at this location, (d) Location where boundary layer becomes turbulent.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Isothermal, vertical surface in an extensive, quiescent medium, (2) Boundary layer assumptions valid.

**PROPERTIES:** Table A-4, Air ( $T_f = (T_s + T_\infty)/2 = 350\text{K}$ , 1 atm):  $\nu = 20.92 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.030 \text{ W/m}\cdot\text{K}$ ,  $Pr = 0.700$ .

**ANALYSIS:** (a) From the similarity solution results, Fig. 9.4 (see above right), the boundary layer thickness corresponds to a value of  $\eta \approx 5$ . From Eqs. 9.13 and 9.12,

$$y = \eta x (\text{Gr}_x / 4)^{-1/4} \quad (1)$$

$$\text{Gr}_x = g\beta(T_s - T_\infty)x^3 / \nu^2 = 9.8 \frac{\text{m}}{\text{s}^2} \times \frac{1}{350\text{K}} (130 - 25)\text{K} x^3 / \left(20.92 \times 10^{-6} \text{ m}^2/\text{s}\right)^2 = 6.718 \times 10^9 x^3 \quad (2)$$

$$y \approx 5(0.25\text{m}) \left(6.718 \times 10^9 (0.25)^3 / 4\right)^{-1/4} = 1.746 \times 10^{-2} \text{ m} = 17.5 \text{ mm}. \quad (3) <$$

(b) From the similarity solution shown above, the maximum velocity occurs at  $\eta \approx 1$  with  $f'(\eta) = 0.275$ . From Eq. 9.15, find

$$u = \frac{2\nu}{x} \text{Gr}_x^{1/2} f'(\eta) = \frac{2 \times 20.92 \times 10^{-6} \text{ m}^2/\text{s}}{0.25\text{m}} \left(6.718 \times 10^9 (0.25)^3\right)^{1/2} \times 0.275 = 0.47 \text{ m/s}. <$$

The maximum velocity occurs at a value of  $\eta = 1$ ; using Eq. (3), it follows that this corresponds to a position in the boundary layer given as

$$y_{\text{max}} = 1/5 (17.5 \text{ mm}) = 3.5 \text{ mm}. <$$

(c) From Eq. 9.19, the local heat transfer coefficient at  $x = 0.25 \text{ m}$  is

$$\text{Nu}_x = h_x x / k = (\text{Gr}_x / 4)^{1/4} g(Pr) = \left(6.718 \times 10^9 (0.25)^3 / 4\right)^{1/4} 0.50 = 35.7$$

$$h_x = \text{Nu}_x k / x = 35.7 \times 0.030 \text{ W/m}\cdot\text{K} / 0.25 \text{ m} = 4.3 \text{ W/m}^2 \cdot \text{K}. <$$

The value for  $g(Pr)$  is determined from Eq. 9.20 with  $Pr = 0.700$ .

(d) According to Eq. 9.23, the boundary layer becomes turbulent at  $x_c$  given as

$$\text{Ra}_{x,c} = \text{Gr}_{x,c} Pr \approx 10^9 \quad x_c \approx \left[10^9 / 6.718 \times 10^9 (0.700)\right]^{1/3} = 0.60 \text{ m}. <$$

**COMMENTS:** Note that  $\beta = 1/T_f$  is a suitable approximation for air.

## PROBLEM 9.8

**KNOWN:** Laminar free convection on a vertical plate.

**FIND:** Exact values of  $C$  from the similarity solution for  $Pr = 0.01, 1, 10$  and  $100$ .

**ASSUMPTIONS:** (1) Constant properties. (2) Steady state conditions. (3) Parameter  $n = 1/4$ .

**ANALYSIS:** The similarity solution for the average Nusselt number is

$$\overline{Nu}_L = \frac{4}{3} \left( \frac{Gr_L}{4} \right)^{1/4} \left[ \frac{0.75 Pr^{1/2}}{\left( 0.609 + 1.221 Pr^{1/2} + 1.238 Pr \right)^{1/4}} \right] \quad (1)$$

while the correlation for the average Nusselt number is expressed as

$$\overline{Nu}_L = C Ra_L^n = C (Gr_L \cdot Pr)^n = C (Gr_L \cdot Pr)^{1/4} \quad (2)$$

Equating the preceding two expressions yields

$$C = \frac{4}{3} \left( \frac{1}{4} \right)^{1/4} \left[ \frac{0.75 Pr^{1/4}}{\left( 0.609 + 1.221 Pr^{1/2} + 1.238 Pr \right)^{1/4}} \right] \quad (3)$$

Values of  $C$  may be determined by substituting  $Pr = 0.01, 1, 10$  and  $100$  into Equation 3.

$Pr$	$C$
0.01	0.241
1	0.534
10	0.621
100	0.654

**COMMENTS:** (1) The correlation should not be used for liquid metals (i.e. low  $Pr$  fluids). (2) The average value of  $C$  for  $Pr = 1, 10$  and  $100$  is  $0.60 \approx 0.59$ . Use of the correlation for  $Pr \geq 0.7$  results in an error of approximately 10% as compared to the similarity solution. (3) There are few if any fluids characterized by  $Pr \approx 0.1$ . Hence, this range of the Prandtl numbers is not included in the comparison, and is omitted from Figure 9.4.

## PROBLEM 9.9

**KNOWN:** Dimensions of vertical rectangular fins. Temperature of fins and quiescent air.

**FIND:** (a) Optimum fin spacing, (b) Rate of heat transfer from an array of fins at the optimal spacing.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Fins are isothermal, (2) Radiation effects are negligible, (3) Air is quiescent.

**PROPERTIES:** Table A-4, Air ( $T_f = 325\text{K}$ , 1 atm):  $\nu = 18.41 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0282 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.703$ .

**ANALYSIS:** (a) If fins are too close, boundary layers on adjoining surfaces will coalesce and heat transfer will decrease. If fins are too far apart, the surface area becomes too small and heat transfer decreases.  $S_{\text{op}} \approx \delta_{x=H}$ . From Fig. 9.4, the edge of boundary layer corresponds to

$$\eta = (\delta/H) (\text{Gr}_H/4)^{1/4} \approx 5.$$

$$\text{Hence, } \text{Gr}_H = \frac{g\beta(T_s - T_\infty)H^3}{\nu^2} = \frac{9.8 \text{ m/s}^2 (1/325\text{K}) 50\text{K} (0.15\text{m})^3}{(18.41 \times 10^{-6} \text{ m}^2/\text{s})^2} = 1.5 \times 10^7$$

$$\delta(H) = 5(0.15\text{m}) / \left(1.5 \times 10^7 / 4\right)^{1/4} = 0.017\text{m} = 17\text{mm} \quad S_{\text{op}} \approx 34\text{mm}. \quad <$$

(b) The number of fins  $N$  can be found as

$$N = W / (S_{\text{op}} + t) = 355 / 35.5 = 10$$

and the rate is  $q = 2 N \bar{h} (H \cdot L) (T_s - T_\infty)$ .

For laminar flow conditions

$$\overline{\text{Nu}}_H = 0.68 + 0.67 \text{ Ra}_L^{1/4} / \left[1 + (0.492/\text{Pr})^{9/16}\right]^{4/9}$$

$$\overline{\text{Nu}}_H = 0.68 + 0.67 \left(1.5 \times 10^7 \times 0.703\right)^{1/4} / \left[1 + (0.492/0.703)^{9/16}\right]^{4/9} = 30$$

$$\bar{h} = k \text{ Nu}_H / H = 0.0282 \text{ W/m}\cdot\text{K} (30) / 0.15 \text{ m} = 5.6 \text{ W/m}^2 \cdot \text{K}$$

$$q = 2(10) 5.6 \text{ W/m}^2 \cdot \text{K} (0.15\text{m} \times 0.02\text{m}) (350 - 300)\text{K} = 16.8 \text{ W}. \quad <$$

**COMMENTS:** Part (a) result is a conservative estimate of the optimum spacing. The increase in area resulting from a further reduction in  $S$  would more than compensate for the effect of fluid entrapment due to boundary layer merger. From a more rigorous treatment (see Section 9.7.1),  $S_{\text{op}} \approx 10 \text{ mm}$  is obtained for the prescribed conditions.

### PROBLEM 9.10

**KNOWN:** Thin, vertical plates of length 0.15m at 54°C being cooled in a water bath at 20°C.

**FIND:** Minimum spacing between plates such that no interference will occur between free-convection boundary layers.

**SCHEMATIC:**

**ASSUMPTIONS:** (a) Water in bath is quiescent, (b) Plates are at uniform temperature.

**PROPERTIES:** Table A-6, Water ( $T_f = (T_s + T_\infty)/2 = (54 + 20)^\circ\text{C}/2 = 310\text{K}$ ):  $\rho = 1/v_f = 993.05 \text{ kg/m}^3$ ,  $\mu = 695 \times 10^{-6} \text{ N}\cdot\text{s/m}^2$ ,  $\nu = \mu/\rho = 6.998 \times 10^{-7} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 4.62$ ,  $\beta = 361.9 \times 10^{-6} \text{ K}^{-1}$ .

**ANALYSIS:** The minimum separation distance will be twice the thickness of the boundary layer at the trailing edge where  $x = 0.15\text{m}$ . Assuming laminar, free convection boundary layer conditions, the similarity parameter,  $\eta$ , given by Eq. 9.13, is

$$\eta = \frac{y}{x} (\text{Gr}_x / 4)^{1/4}$$

where  $y$  is measured normal to the plate (see Fig. 9.3). According to Fig. 9.4, the boundary layer thickness occurs at a value  $\eta \approx 5$ .

It follows then that,

$$y_{bl} = \eta x (\text{Gr}_x / 4)^{-1/4}$$

$$\text{where } \text{Gr}_x = \frac{g \beta (T_s - T_\infty) x^3}{\nu^2}$$

$$\text{Gr}_x = 9.8 \text{ m/s}^2 \times 361.9 \times 10^{-6} \text{ K}^{-1} (54 - 20) \text{ K} \times (0.15 \text{ m})^3 / (6.998 \times 10^{-7} \text{ m}^2/\text{s})^2 = 8.310 \times 10^8. <$$

$$\text{Hence, } y_{bl} = 5 \times 0.15 \text{ m} \left( 8.310 \times 10^8 / 4 \right)^{-1/4} = 6.247 \times 10^{-3} \text{ m} = 6.3 \text{ mm}$$

and the minimum separation is

$$d = 2 y_{bl} = 2 \times 6.3 \text{ mm} = 12.6 \text{ mm}. <$$

**COMMENTS:** According to Eq. 9.23, the critical Grashof number for the onset of turbulent conditions in the boundary layer is  $\text{Gr}_{x,c} \text{Pr} \approx 10^9$ . For the conditions above,  $\text{Gr}_x \text{Pr} = 8.31 \times 10^8 \times 4.62 = 3.8 \times 10^9$ . We conclude that the boundary layer is indeed turbulent at  $x = 0.15\text{m}$  and our calculation is only an estimate which is likely to be low. Therefore, the plate separation should be greater than 12.6 mm.

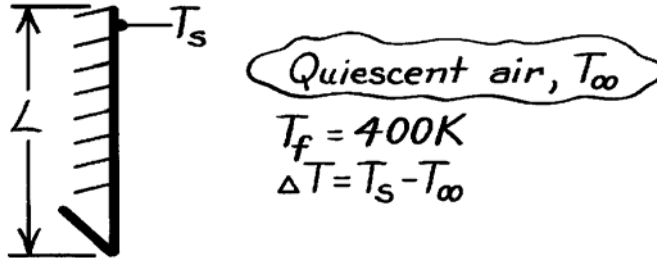

### PROBLEM 9.11

**KNOWN:** Vertical plate experiencing free convection with quiescent air at atmospheric pressure and film temperature 400 K.

**FIND:** Form of correlation for average heat transfer coefficient in terms of  $\Delta T$  and characteristic length.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Air is extensive, quiescent medium, (2) Perfect gas behavior.

**PROPERTIES:** Table A-6, Air ( $T_f = 400K$ , 1 atm):  $\nu = 26.41 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0338 \text{ W/m}\cdot\text{K}$ ,  $\alpha = 38.3 \times 10^{-6} \text{ m}^2/\text{s}$ .

**ANALYSIS:** Consider the correlation having the form of Eq. 9.24 with  $Ra_L$  defined by Eq. 9.25.

$$\overline{Nu}_L = \overline{h}_L L / k = C Ra_L^n \quad (1)$$

where

$$Ra_L = \frac{g\beta(T_s - T_{\infty})L^3}{\nu\alpha} = \frac{9.8 \text{ m/s}^2 (1/400 \text{ K})\Delta T \cdot L^3}{26.41 \times 10^{-6} \text{ m}^2/\text{s} \times 38.3 \times 10^{-6} \text{ m}^2/\text{s}} = 2.422 \times 10^7 \Delta T \cdot L^3. \quad (2)$$

Combining Eqs. (1) and (2),

$$\overline{h}_L = (k/L) C Ra_L^n = \frac{0.0338 \text{ W/m}\cdot\text{K}}{L} C \left( 2.422 \times 10^7 \Delta T L^3 \right)^n. \quad (3)$$

From Fig. 9.6, note that for laminar boundary layer conditions,  $10^4 < Ra_L < 10^9$ ,  $C = 0.59$  and  $n = 1/4$ . Using Eq. (3),

$$\overline{h} = 1.40 \left[ L^{-1} (\Delta T \cdot L^3)^{1/4} \right] = 1.40 \left( \frac{\Delta T}{L} \right)^{1/4} <$$

For turbulent conditions in the range  $10^9 < Ra_L < 10^{13}$ ,  $C = 0.10$  and  $n = 1/3$ . Using Eq. (3),

$$\overline{h}_L = 0.98 \left[ L^{-1} (\Delta T \cdot L^3)^{1/3} \right] = 0.98 \Delta T^{1/3}. <$$

**COMMENTS:** Note the dependence of the average heat transfer coefficient on  $\Delta T$  and  $L$  for laminar and turbulent conditions. The characteristic length  $L$  does not influence  $\overline{h}_L$  for turbulent conditions.

## PROBLEM 9.12

**KNOWN:** Temperature dependence of free convection coefficient,  $\bar{h} = C\Delta T^{1/4}$ , for a solid suddenly submerged in a quiescent fluid.

**FIND:** (a) Expression for cooling time,  $t_f$ , (b) Considering a plate of prescribed geometry and thermal conditions, the time required to reach  $80^\circ\text{C}$  using the appropriate correlation from Problem 9.11 and (c) Plot the temperature-time history obtained from part (b) and compare with results using a constant  $\bar{h}_0$  from an appropriate correlation based upon an average surface temperature  $\bar{T} = (T_i + T_f)/2$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Lumped capacitance approximation is valid, (2) Negligible radiation, (3) Constant properties.

**PROPERTIES:** Table A.1, Aluminum alloy 2024 ( $\bar{T} = (T_i + T_f)/2 \approx 400\text{ K}$ ):  $\rho = 2770\text{ kg/m}^3$ ,  $c_p = 925\text{ J/kg}\cdot\text{K}$ ,  $k = 186\text{ W/m}\cdot\text{K}$ ; Table A.4, Air ( $\bar{T}_{\text{film}} = 362\text{ K}$ ):  $\nu = 2.221 \times 10^{-5}\text{ m}^2/\text{s}$ ,  $k = 0.03069\text{ W/m}\cdot\text{K}$ ,  $\alpha = 3.187 \times 10^{-5}\text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.6976$ ,  $\beta = 1/\bar{T}_{\text{film}}$ .

**ANALYSIS:** (a) From Eq. 5.28,

$$\frac{\theta}{\theta_i} = \left[ \frac{n C A_s \theta_i^n}{\rho V c} t + 1 \right]^{-1/n} \quad (1)$$

where  $\theta = T - T_\infty$  and  $n = 1/4$ . Solving for  $t_f$ , the time at which  $T = T_f$ ,

$$t_f = \frac{4\rho V c}{C A_s (T_i - T_\infty)^{1/4}} \left[ \left( \frac{T_i - T_\infty}{T_f - T_\infty} \right)^{1/4} - 1 \right] \quad (2) <$$

(b) Considering the aluminum plate, initially at  $T(0) = 225^\circ\text{C}$ , and suddenly exposed to ambient air at  $T_\infty = 25^\circ\text{C}$ , from Problem 9.11 the convection coefficient has the form

$$\bar{h}_i = 1.40 \left( \frac{\Delta t}{L} \right)^{1/4} \quad \bar{h}_i = C \Delta T^{1/4}$$

where  $C = 1.40/L^{1/4} = 1.40/(0.150)^{1/4} = 2.2496\text{ W/m}^2 \cdot \text{K}^{3/4}$ . Using Eq. (2), find

Continued...

**PROBLEM 9.12 (Cont.)**

$$t_f = \frac{4 \times 2770 \text{ kg/m}^3 \left(0.150^2 \times 0.005\right) \text{m}^3 \times 925 \text{ J/kg} \cdot \text{K}}{2.2496 \text{ W/m}^2 \cdot \text{K}^{3/4} \times 2 \times (0.150 \text{ m})^2 (225 - 25)^{1/4} \text{ K}^{1/4}} \left[ \left( \frac{225 - 25}{80 - 25} \right)^{1/4} - 1 \right] = 1154 \text{ s}$$

(c) For the vertical plate, Eq. 9.27 is an appropriate correlation. Evaluating properties at

$$\bar{T}_{\text{film}} = (\bar{T}_s + T_\infty)/2 = ((T_i + T_f)/2 + T_\infty)/2 = 362 \text{ K}$$

where  $\bar{T}_s = 426 \text{ K}$ , the average plate temperature, find

$$\text{Ra}_L = \frac{g\beta(\bar{T}_s - T_\infty)L^3}{\nu\alpha} = \frac{9.8 \text{ m/s}^2 (1/362 \text{ K})(426 - 298) \text{ K} (0.150 \text{ m})^3}{2.221 \times 10^{-5} \text{ m}^2/\text{s} \times 3.187 \times 10^{-5} \text{ m}^2/\text{s}} = 1.652 \times 10^7$$

$$\bar{\text{Nu}}_L = 0.68 + \frac{0.670 \text{Ra}_L^{1/4}}{\left[1 + (0.492/\text{Pr})^{9/16}\right]^{4/9}} = 0.68 + \frac{0.670(1.652 \times 10^7)^{1/4}}{\left[1 + (0.492/0.6976)^{9/16}\right]^{4/9}} = 33.4$$

$$\bar{h}_o = \frac{k}{L} \bar{\text{Nu}}_L = \frac{0.03069 \text{ W/m} \cdot \text{K}}{0.150 \text{ m}} \times 33.4 = 6.83 \text{ W/m}^2 \cdot \text{K}$$

From Eq. 5.6, the temperature-time history with a constant convection coefficient is

$$T(t) = T_\infty + (T_i - T_\infty) \exp\left[-(\bar{h}_o A_s / \rho V c) t\right] \quad (3)$$

where  $A_s/V = 2L^2/(L \times L \times w) = 2/w = 400 \text{ m}^{-1}$ . The temperature-time histories for the  $h = \text{CaT}^{1/4}$  and  $\bar{h}_o$  analyses are shown in plot below.

**COMMENTS:** (1) The times to reach  $T(t_o) = 80^\circ \text{C}$  were 1154 and 1212s for the variable and constant coefficient analysis, respectively, a difference of 5%. For convenience, it is reasonable to evaluate the convection coefficient as described in part (b).

(2) Note that  $\text{Ra}_L < 10^9$  so indeed the expression selected from Problem 9.11 was the appropriate one.

(3) Recognize that if the emissivity of the plate were unity, the average linearized radiation coefficient using Eq. (1.9) is  $\bar{h}_{\text{rad}} = 11.0 \text{ W/m}^2 \cdot \text{K}$  and radiative exchange becomes an important process.

### PROBLEM 9.13

**KNOWN:** Square aluminum plate at 15°C suspended in quiescent air at 40°C.

**FIND:** Average heat transfer coefficient by two methods – using results of boundary layer similarity and results from an empirical correlation.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Uniform plate surface temperature, (2) Quiescent room air, (3) Surface radiation exchange with surroundings negligible, (4) Perfect gas behavior for air,  $\beta = 1/T_f$ .

**PROPERTIES:** Table A-4, Air ( $T_f = (T_s + T_\infty)/2 = (40 + 15)^\circ\text{C}/2 = 300\text{K}$ , 1 atm):  $\nu = 15.89 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0263 \text{ W/m}\cdot\text{K}$ ,  $\alpha = 22.5 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.707$ .

**ANALYSIS:** Calculate the Rayleigh number to determine the boundary layer flow conditions,

$$\text{Ra}_L = g \beta \Delta T L^3 / \nu \alpha$$

$$\text{Ra}_L = 9.8 \text{ m/s}^2 (1/300\text{K}) (40 - 15)^\circ\text{C} (0.2\text{m})^3 / (15.89 \times 10^{-6} \text{ m}^2/\text{s}) (22.5 \times 10^{-6} \text{ m}^2/\text{s}) = 1.827 \times 10^7$$

where  $\beta = 1/T_f$  and  $\Delta T = T_\infty - T_s$ . Since  $\text{Ra}_L < 10^9$ , the flow is laminar and the *similarity solution* of Section 9.4 is applicable. From Eqs. 9.21 and 9.20,

$$\overline{\text{Nu}}_L = \frac{\overline{h}_L L}{k} = \frac{4}{3} (\text{Gr}_L / 4)^{1/4} g(\text{Pr}) \quad \text{where } g(\text{Pr}) = \frac{0.75 \text{Pr}^{1/2}}{[0.609 + 1.221 \text{Pr}^{1/2} + 1.238 \text{Pr}]^{1/4}}$$

and substituting numerical values with  $\text{Gr}_L = \text{Ra}_L / \text{Pr}$ , find

$$g(\text{Pr}) = 0.75 (0.707)^{1/2} / [0.609 + 1.22 (0.707)^{1/2} + 1.238 \times 0.707]^{1/4} = 0.501$$

$$\overline{h}_L = \left( \frac{0.0263 \text{ W/m}\cdot\text{K}}{0.20\text{m}} \right) \times \frac{4}{3} \left( \frac{1.827 \times 10^7 / 0.707}{4} \right)^{1/4} \times 0.501 = 4.42 \text{ W/m}^2 \cdot \text{K} <$$

The appropriate empirical correlation for estimating  $\overline{h}_L$  is given by Eq. 9.27,

$$\overline{\text{Nu}}_L = \frac{\overline{h}_L L}{k} = 0.68 + \frac{0.670 \text{Ra}_L^{1/4}}{[1 + (0.492 / \text{Pr})^{9/16}]^{4/9}}$$

$$\overline{h}_L = (0.0263 \text{ W/m}\cdot\text{K} / 0.20\text{m}) \left[ 0.68 + 0.670 (1.827 \times 10^7)^{1/4} / [1 + (0.492 / 0.707)^{9/16}]^{4/9} \right]$$

$$\overline{h}_L = 4.51 \text{ W/m}^2 \cdot \text{K} <$$

**COMMENTS:** The agreement of  $\overline{h}_L$  calculated by these two methods is excellent. Using the Churchill-Chu correlation, Eq. 9.26, find  $\overline{h}_L = 4.87 \text{ W/m}\cdot\text{K}$ . This relation is not the most accurate for the laminar regime, but is suitable for both laminar and turbulent regions.

### PROBLEM 9.14

**KNOWN:** Aluminum plate (alloy 2024) at an initial uniform temperature of 227°C is suspended in a room where the ambient air and surroundings are at 27°C.

**FIND:** (a) Expression for time rate of change of the plate, (b) Initial rate of cooling (K/s) when plate temperature is 227°C, (c) Validity of assuming a uniform plate temperature, (d) Decay of plate temperature and the convection and radiation rates during cooldown.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Plate temperature is uniform, (2) Ambient air is quiescent and extensive, (3) Surroundings are large compared to plate.

**PROPERTIES:** Table A.1, Aluminum alloy 2024 ( $T = 500\text{ K}$ ):  $\rho = 2770\text{ kg/m}^3$ ,  $k = 186\text{ W/m}\cdot\text{K}$ ,  $c = 983\text{ J/kg}\cdot\text{K}$ ; Table A.4, Air ( $T_f = 400\text{ K}$ , 1 atm):  $\nu = 26.41 \times 10^{-6}\text{ m}^2/\text{s}$ ,  $k = 0.0388\text{ W/m}\cdot\text{K}$ ,  $\alpha = 38.3 \times 10^{-6}\text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.690$ .

**ANALYSIS:** (a) From an energy balance on the plate with free convection and radiation exchange,  $-\dot{E}_{\text{out}} = \dot{E}_{\text{st}}$ , we obtain

$$-\bar{h}_L 2A_s (T_s - T_\infty) - \varepsilon 2A_s \sigma (T_s^4 - T_{\text{sur}}^4) = \rho A_s t c \frac{dT}{dt} \quad \text{or} \quad \frac{dT}{dt} = \frac{-2}{\rho t c} \left[ \bar{h}_L (T_s - T_\infty) + \varepsilon \sigma (T_s^4 - T_{\text{sur}}^4) \right] <$$

where  $T_s$ , the plate temperature, is assumed to be uniform at any time.

(b) To evaluate  $(dT/dt)$ , estimate  $\bar{h}_L$ . First, find the Rayleigh number,

$$\text{Ra}_L = g\beta (T_s - T_\infty) L^3 / \nu\alpha = \frac{9.8\text{ m/s}^2 (1/400\text{ K})(227 - 27)\text{ K} \times (0.3\text{ m})^3}{26.41 \times 10^{-6}\text{ m}^2/\text{s} \times 38.3 \times 10^{-6}\text{ m}^2/\text{s}} = 1.308 \times 10^8.$$

Eq. 9.27 is appropriate; substituting numerical values, find

$$\overline{\text{Nu}}_L = 0.68 + \frac{0.670 \text{Ra}_L^{1/4}}{\left[1 + (0.492/\text{Pr})^{9/16}\right]^{4/9}} = 0.68 + \frac{0.670 (1.308 \times 10^8)^{1/4}}{\left[1 + (0.492/0.690)^{9/16}\right]^{4/9}} = 55.5$$

$$\bar{h}_L = \overline{\text{Nu}}_L k / L = 55.5 \times 0.0388\text{ W/m}\cdot\text{K} / 0.3\text{ m} = 6.25\text{ W/m}^2\cdot\text{K}$$

Continued...

**PROBLEM 9.14 (Cont.)**

$$\frac{dT}{dt} = \frac{-2}{2770 \text{ kg/m}^3 \times 0.015 \text{ m} \times 983 \text{ J/kg} \cdot \text{K}} \times \left[ 6.25 \text{ W/m}^2 \cdot \text{K} (227 - 27) \text{ K} + 0.25 \left( 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \right) (500^4 - 300^4) \text{ K}^4 \right] = -0.099 \text{ K/s} \quad <$$

(c) The uniform temperature assumption is justified if the Biot number criterion is satisfied. With  $L_c \equiv (V/2A_s) = (A_s \cdot t/2A_s) = (t/2)$  and  $\bar{h}_{\text{tot}} = \bar{h}_{\text{conv}} + \bar{h}_{\text{rad}}$ ,  $\text{Bi} = \bar{h}_{\text{tot}} (t/2)/k \leq 0.1$ . Using the linearized radiation coefficient relation, find

$$\bar{h}_{\text{rad}} = \varepsilon \sigma (T_s + T_{\text{sur}}) (T_s^2 + T_{\text{sur}}^2) = 0.25 \left( 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \right) (500 + 300) (500^2 + 300^2) \text{ K}^3 = 3.86 \text{ W/m}^2 \cdot \text{K}$$

Hence,  $\text{Bi} = (6.25 + 3.86) \text{ W/m}^2 \cdot \text{K} (0.015 \text{ m}/2) / 186 \text{ W/m} \cdot \text{K} = 4.07 \times 10^{-4}$ . Since  $\text{Bi} \ll 0.1$ , the assumption is appropriate.

(d) The temperature history of the plate was computed by combining the *Lumped Capacitance Model* of IHT with the appropriate *Correlations* and *Properties* Toolpads.

Due to the small values of  $\bar{h}_L$  and  $\bar{h}_{\text{rad}}$ , the plate cools slowly and does not reach 30°C until  $t \approx 14000\text{s} = 3.89\text{h}$ . The convection and radiation rates decrease rapidly with increasing  $t$  (decreasing  $T$ ), thereby decelerating the cooling process.

**COMMENTS:** The reduction in the convection rate with increasing time is due to a reduction in the thermal conductivity of air, as well as the values of  $\bar{h}_L$  and  $T$ .

## PROBLEM 9.15

**KNOWN:** Instantaneous temperature and time rate of temperature change of a vertical plate cooling in a room.

**FIND:** Average free convection coefficient for the prescribed conditions; compare with standard empirical correlation.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Uniform plate temperature, (2) Quiescent room air, (3) Large surroundings.

**PROPERTIES:** Table A-1, Aluminum alloy 2024 ( $T_s = 127^\circ\text{C} = 400\text{K}$ ):  $\rho = 2770\text{ kg/m}^3$ ,  $c_p = 925\text{ J/kg}\cdot\text{K}$ ; Table A-4, Air ( $T_f = (T_s + T_\infty)/2 = 350\text{K}$ , 1 atm):  $\nu = 20.92 \times 10^{-6}\text{ m}^2/\text{s}$ ,  $k = 0.030\text{ W/m}\cdot\text{K}$ ,  $\alpha = 29.9 \times 10^{-6}\text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.700$ .

**ANALYSIS:** From an energy balance on the plate considering free convection and radiation exchange,

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \dot{E}_{\text{st}}$$

$$-\bar{h}_L (2A_s)(T_s - T_\infty) - \varepsilon (2A_s)\sigma(T_s^4 - T_{\text{sur}}^4) = \rho A_s l c_p \frac{dT}{dt}.$$

Noting that the plate area is  $2A_s$ , solving for  $\bar{h}_L$ , and substituting numerical values, find

$$\bar{h}_L = \left[ -\rho l c_p \frac{dT}{dt} - 2\varepsilon\sigma(T_s^4 - T_{\text{sur}}^4) \right] / 2(T_s - T_\infty)$$

$$\bar{h}_L = \left[ -2770\text{ kg/m}^3 \times 0.015\text{ m} \times 925\text{ J/kg}\cdot\text{K} (-0.0465\text{ K/s}) - 2 \times 0.25 \times 5.67 \times 10^{-8}\text{ W/m}^2 \cdot \text{K}^4 (400^4 - 300^4)\text{ K}^4 \right] / 2(127 - 27)^\circ\text{C} = (8.936 - 2.455)\text{ W/m}^2 \cdot \text{K}$$

$$\bar{h}_L = 6.5\text{ W/m}^2 \cdot \text{K}. \quad <$$

To select an appropriate empirical correlation, first evaluate the Rayleigh number,

$$\text{Ra}_L = g\beta\Delta TL^3 / \nu\alpha$$

$$\text{Ra}_L = 9.8\text{ m/s}^2 (1/350\text{K})(127 - 27)\text{K} (0.3\text{m})^3 / (20.92 \times 10^{-6}\text{ m}^2/\text{s})(29.9 \times 10^{-6}\text{ m}^2/\text{s}) = 1.21 \times 10^8.$$

Since  $\text{Ra}_L < 10^9$ , the flow is laminar and Eq. 9.27 is applicable,

$$\overline{\text{Nu}}_L = \frac{\bar{h}_L L}{k} = 0.68 + \frac{0.670 \text{Ra}_L^{1/4}}{\left[ 1 + (0.492/\text{Pr})^{9/16} \right]^{4/9}}$$

$$\bar{h}_L = \left( \frac{0.030\text{ W/m}\cdot\text{K}}{0.3\text{m}} \right) \left\{ 0.68 + 0.670 (1.21 \times 10^8)^{1/4} / \left[ 1 + (0.492/0.700)^{9/16} \right]^{4/9} \right\} = 5.5\text{ W/m}^2 \cdot \text{K}. \quad <$$

**COMMENTS:** (1) The correlation estimate is 15% lower than the experimental result. (2) This transient method, useful for obtaining an average free convection coefficient for spacewise isothermal objects, requires  $\text{Bi} \leq 0.1$ .

## PROBLEM 9.16

**KNOWN:** Interior air and wall temperatures; wall height.

**FIND:** (a) Average heat transfer coefficient when  $T_\infty = 20^\circ\text{C}$  and  $T_s = 10^\circ\text{C}$ , (b) Average heat transfer coefficient when  $T_\infty = 27^\circ\text{C}$  and  $T_s = 37^\circ\text{C}$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (a) Wall is at a uniform temperature, (b) Room air is quiescent.

**PROPERTIES:** Table A-4, Air ( $T_f = 288\text{K}$ , 1 atm):  $\beta = 1/T_f = 3.472 \times 10^{-3} \text{ K}^{-1}$ ,  $\nu = 14.82 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0253 \text{ W/m}\cdot\text{K}$ ,  $\alpha = 20.9 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.710$ ; ( $T_f = 305\text{K}$ , 1 atm):  $\beta = 1/T_f = 3.279 \times 10^{-3} \text{ K}^{-1}$ ,  $\nu = 16.39 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0267 \text{ W/m}\cdot\text{K}$ ,  $\alpha = 23.2 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.706$ .

**ANALYSIS:** The appropriate correlation for the average heat transfer coefficient for free convection on a vertical wall is Eq. 9.26.

$$\overline{\text{Nu}}_L = \frac{\bar{h}L}{k} = \left\{ 0.825 + \frac{0.387 \text{Ra}_L^{0.1667}}{\left[ 1 + (0.492/\text{Pr})^{0.563} \right]^{0.296}} \right\}^2$$

where  $\text{Ra}_L = g \beta \Delta T L^3 / \nu \alpha$ , Eq. 9.25, with  $\Delta T = T_s - T_\infty$  or  $T_\infty - T_s$ .

(a) Substituting numerical values typical of *winter* conditions gives

$$\text{Ra}_L = \frac{9.8 \text{ m/s}^2 \times 3.472 \times 10^{-3} \text{ K}^{-1} (20 - 10) \text{ K} (2.5 \text{ m})^3}{14.82 \times 10^{-6} \text{ m}^2/\text{s} \times 20.96 \times 10^{-6} \text{ m}^2/\text{s}} = 1.711 \times 10^{10}$$

$$\overline{\text{Nu}}_L = \left\{ 0.825 + \frac{0.387 (1.711 \times 10^{10})^{0.1667}}{\left[ 1 + (0.492/0.710)^{0.563} \right]^{0.296}} \right\}^2 = 299.6.$$

Hence,  $\bar{h} = \overline{\text{Nu}}_L k/L = 299.6(0.0253 \text{ W/m}\cdot\text{K})/2.5 \text{ m} = 3.03 \text{ W/m}^2 \cdot \text{K}$ . <

(b) Substituting numerical values typical of *summer* conditions gives

$$\text{Ra}_L = \frac{9.8 \text{ m/s}^2 \times 3.279 \times 10^{-3} \text{ K}^{-1} (37 - 27) \text{ K} (2.5 \text{ m})^3}{23.2 \times 10^{-6} \text{ m}^2/\text{s} \times 16.39 \times 10^{-6} \text{ m}^2/\text{s}} = 1.320 \times 10^{10}$$

$$\overline{\text{Nu}}_L = \left\{ 0.825 + \frac{0.387 (1.320 \times 10^{10})^{0.1667}}{\left[ 1 + (0.492/0.706)^{0.563} \right]^{0.296}} \right\}^2 = 275.8.$$

Hence,  $\bar{h} = \overline{\text{Nu}}_L k/L = 275.8 \times 0.0267 \text{ W/m}\cdot\text{K}/2.5 \text{ m} = 2.94 \text{ W/m}^2 \cdot \text{K}$ . <

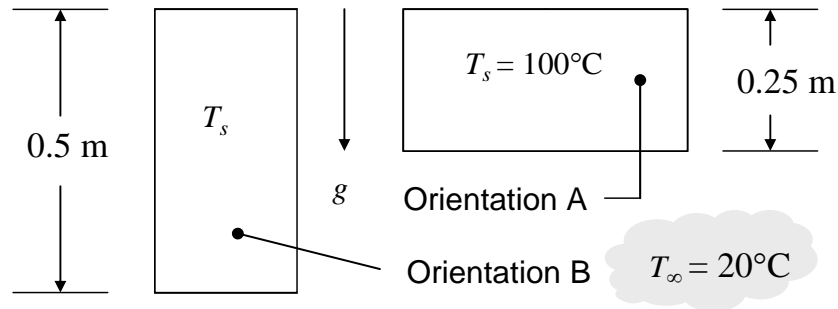

**COMMENTS:** There is a small influence due to  $T_f$  on  $\bar{h}$  for these conditions. We should expect radiation effects to be important with such low values of  $\bar{h}$ .

### PROBLEM 9.17

**KNOWN:** Dimensions of vertical plate. Plate and ambient temperatures.

**FIND:** Preferred orientation to minimize convective heat transfer and convective heat transfer rate for that orientation.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Constant properties, (3) Ideal gas, (4) Quiescent environment.

**PROPERTIES:** Table A.4, air ( $\bar{T} = 60^\circ\text{C} = 333\text{ K}$ ):  $\nu = 19.21 \times 10^{-6}\text{ m}^2/\text{s}$ ,  $\alpha = 27.4 \times 10^{-6}\text{ m}^2/\text{s}$ ,  $Pr = 0.702$ ,  $k = 0.0287\text{ W/m}\cdot\text{K}$ .

**ANALYSIS:** Note that the maximum value of the Rayleigh number is associated with Orientation B.

$$Ra_{\max} = \frac{g\beta(T_s - T_\infty)L^3}{\nu \cdot \alpha} = \frac{9.81\text{ m/s}^2 \times (1/333\text{ K}) \times (100 - 20)^\circ\text{C} \times (0.5\text{ m})^3}{19.21 \times 10^{-6}\text{ m}^2/\text{s} \times 27.4 \times 10^{-6}\text{ m}^2/\text{s}} = 560 \times 10^6$$

Since the maximum Rayleigh number is less than  $Ra_{x,c} = 10^9$ , flow conditions are laminar for both orientations. Hence, to minimize heat transfer from the plate, we wish to maximize the thickness of the boundary layer and therefore maximize the plate length in the vertical direction. Therefore, Orientation B is preferred. <

Selecting Eq. 9.27,

$$\begin{aligned} \bar{h} &= \frac{k}{L} \left\{ 0.68 + \frac{0.67 Ra_L^{1/4}}{\left[ 1 + (0.492/Pr)^{9/16} \right]^{4/9}} \right\} \\ &= \frac{0.0287\text{ W}/(\text{m}\cdot\text{K})}{0.5\text{ m}} \left\{ 0.68 + \frac{0.67 \times (560 \times 10^6)^{1/4}}{\left[ 1 + (0.492/0.702)^{9/16} \right]^{4/9}} \right\} = 4.57 \frac{\text{W}}{\text{m}^2 \cdot \text{K}} \end{aligned}$$

and

$$q = \bar{h}A(T_s - T_\infty) = 4.57\text{ W}/\text{m}^2 \cdot \text{K} \times (0.25\text{ m} \times 0.50\text{ m}) \times (100 - 20)^\circ\text{C} = 45.7\text{ W} \quad <$$

**COMMENTS:** 1. For Orientation A,  $Ra = 7 \times 10^7$ ,  $\bar{h} = 5.48\text{ W}/\text{m}^2 \cdot \text{K}$  and  $q = 54.8\text{ W}$ . Although the Rayleigh and Nusselt numbers are smaller for Orientation A, the length scale in the Nusselt number is half that of Orientation B, leading to an overall increase in the convection coefficient and heat transfer rate. 2. Radiation heat transfer will be significant.

## PROBLEM 9.18

**KNOWN:** During a winter day, the window of a patio door with a height of 1.8 m and width of 1.0 m shows a frost line near its base.

**FIND:** (a) Explain why the window would show a frost layer at the base of the window, rather than at the top, and (b) Estimate the heat loss through the window due to free convection and radiation. If the room has electric baseboard heating, estimate the daily cost of the window heat loss for this condition based upon the utility rate of 0.18 \$/kW·h.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Window has a uniform temperature, (3) Ambient air is quiescent, and (4) Room walls are isothermal and large compared to the window.

**PROPERTIES:** Table A-4, Air ( $T_f = (T_s + T_\infty)/2 = 280 \text{ K}$ , 1 atm):  $\nu = 14.11 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0247 \text{ W/m}\cdot\text{K}$ ,  $\alpha = 1.986 \times 10^{-5} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.710$ .

**ANALYSIS:** (a) For these winter conditions, a frost line could appear and it would be at the bottom of the window. The boundary layer is thinnest at the top of the window, and hence the heat flux from the warmer room is greater than compared to that at the bottom portion of the window where the boundary layer is thicker. Also, the air in the room may be stratified and cooler near the floor compared to near the ceiling.

(b) The heat loss from the room to the window having a uniform temperature  $T_s = 0^\circ\text{C}$  by convection and radiation is

$$q_{\text{loss}} = q_{\text{cv}} + q_{\text{rad}} \quad (1)$$

$$q_{\text{loss}} = A_s \left[ \bar{h}_L (T_\infty - T_s) + \varepsilon \sigma (T_{\text{sur}}^4 - T_s^4) \right] \quad (2)$$

The average convection coefficient is estimated from the Churchill-Chu correlation, Eq. 9.26, using properties evaluated at  $T_f = (T_s + T_\infty)/2$ .

$$\overline{\text{Nu}}_L = \frac{\bar{h}_L L}{k} = \left\{ 0.825 + \frac{0.387 \text{ Ra}_L^{1/6}}{\left[ 1 + (0.492/\text{Pr})^{9/16} \right]^{8/27}} \right\}^2 \quad (3)$$

$$\text{Ra}_L = g\beta T (T_\infty - T_s) L^3 / \nu\alpha \quad (4)$$

Substituting numerical values in the correlation expressions, find

$$\text{Ra}_L = 1.084 \times 10^{10} \quad \overline{\text{Nu}}_L = 258.9 \quad \bar{h}_L = 3.6 \text{ W/m}^2 \cdot \text{K}$$

Continued ...

### PROBLEM 9.18 (Cont.)

Using Eq. (2), the heat loss with  $\sigma = 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4$  is

$$q_{\text{loss}} = (1 \times 1.8) \text{ m}^2 \left[ 3.6 \text{ W/m}^2 \cdot \text{K} (15 \text{ K}) + 0.940 \sigma (288^4 - 273^4) \text{ K}^4 \right]$$

$$q_{\text{loss}} = (96.1 + 127.1) \text{ W} = 223 \text{ W}$$

The daily cost of the window heat loss for the given utility rate is

$$\text{cost} = q_{\text{loss}} \times (\text{utility rate}) \times 24 \text{ hours}$$

$$\text{cost} = 223 \text{ W} \times (10^{-3} \text{ kW/W}) \times 0.18 \text{ \$/kW} \cdot \text{h} \times 24 \text{ h}$$

$$\text{cost} = 0.96 \text{ \$/day}$$

<

**COMMENTS:** Note that the heat loss by radiation is 30% larger than by free convection.

### PROBLEM 9.19

**KNOWN:** Room and ambient air conditions for window glass.

**FIND:** Temperature of the glass and rate of heat loss.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Negligible temperature gradients in the glass, (3) Inner and outer surfaces exposed to large surroundings.

**PROPERTIES:** Table A.4, air ( $T_{f,i}$  and  $T_{f,o}$ ): Obtained from the IHT *Properties* Tool Pad.

**ANALYSIS:** Performing an energy balance on the window pane, it follows that  $\dot{E}_{in} = \dot{E}_{out}$ , or

$$\varepsilon\sigma(T_{sur,i}^4 - T^4) + \bar{h}_i(T_{\infty,i} - T) = \varepsilon\sigma(T^4 - T_{sur,o}^4) + \bar{h}_o(T - T_{\infty,o})$$

where  $\bar{h}_i$  and  $\bar{h}_o$  may be evaluated from Eq. 9.26.

$$\bar{Nu}_L = \left\{ 0.825 + \frac{0.387Ra_L^{1/6}}{\left[1 + (0.492/Pr)^{9/16}\right]^{8/27}} \right\}^2$$

Using the *First Law Model for an Isothermal Plane Wall* and the *Correlations and Properties* Tool Pads of IHT, the energy balance equation was formulated and solved to obtain

$$T = 273.8 \text{ K} \quad <$$

The heat rate is then  $q_i = q_o$ , or

$$q_i = L^2 \left[ \varepsilon\sigma(T_{sur,i}^4 - T^4) + \bar{h}_i(T_{\infty,i} - T) \right] = 174.8 \text{ W} \quad <$$

**COMMENTS:** The radiative and convective contributions to heat transfer at the inner and outer surfaces are  $q_{rad,i} = 99.04 \text{ W}$ ,  $q_{conv,i} = 75.73 \text{ W}$ ,  $q_{rad,o} = 86.54 \text{ W}$ , and  $q_{conv,o} = 88.23 \text{ W}$ , with corresponding convection coefficients of  $\bar{h}_i = 3.95 \text{ W/m}^2\cdot\text{K}$  and  $\bar{h}_o = 4.23 \text{ W/m}^2\cdot\text{K}$ . The heat loss could be reduced significantly by installing a double pane window.

## PROBLEM 9.20

**KNOWN:** Room and ambient air conditions for window glass. Thickness and thermal conductivity of glass.

**FIND:** Inner and outer surface temperatures and heat loss.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) One-dimensional conduction in the glass, (3) Inner and outer surfaces exposed to large surroundings.

**PROPERTIES:** Table A.4, air ( $T_{f,i}$  and  $T_{f,o}$ ): Obtained from the IHT *Properties* Tool Pad.

**ANALYSIS:** Performing energy balances at the inner and outer surfaces, we obtain, respectively,

$$\varepsilon\sigma(T_{sur,i}^4 - T_{s,i}^4) + \bar{h}_i(T_{\infty,i} - T_{s,i}) = (k_g/t_g)(T_{s,i} - T_{s,o}) \quad (1)$$

$$(k_g/t_g)(T_{s,i} - T_{s,o}) = \varepsilon\sigma(T_{s,o}^4 - T_{sur,o}^4) + \bar{h}_o(T_{s,o} - T_{\infty,o}) \quad (2)$$

where Eq. 9.26 may be used to evaluate  $\bar{h}_i$  and  $\bar{h}_o$

$$\bar{Nu}_L = \left\{ 0.825 + \frac{0.387Ra_L^{1/6}}{\left[1 + (0.492/Pr)^{9/16}\right]^{8/27}} \right\}^2$$

Using the *First Law Model for One-dimensional Conduction in a Plane Wall* and the *Correlations and Properties* Tool Pads of IHT, the energy balance equations were formulated and solved to obtain

$$T_{s,i} = 274.4 \text{ K} \quad T_{s,o} = 273.2 \text{ K} \quad <$$

from which the heat loss is

$$q = \frac{k_g L^2}{t_g} (T_{s,i} - T_{s,o}) = 168.8 \text{ W} \quad <$$

**COMMENTS:** By accounting for the thermal resistance of the glass, the heat loss is smaller (168.8 W) than that determined in the preceding problem (174.8 W) by assuming an isothermal pane.

## PROBLEM 9.21

**KNOWN:** Oven door with average surface temperature of 32°C in a room with ambient air at 22°C.

**FIND:** Heat loss to the room. Also, find effect on heat loss if emissivity of door is unity and the surroundings are at 22°C.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Ambient air is quiescent, (2) Surface radiation effects are negligible.

**PROPERTIES:** Table A-4, Air ( $T_f = 300\text{K}$ , 1 atm):  $\nu = 15.89 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0263 \text{ W/m}\cdot\text{K}$ ,  $\alpha = 22.5 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.707$ ,  $\beta = 1/T_f = 3.33 \times 10^{-3} \text{ K}^{-1}$ .

**ANALYSIS:** The heat rate from the oven door surface by convection to the ambient air is

$$q = \bar{h} A_s (T_s - T_\infty) \quad (1)$$

where  $\bar{h}$  can be estimated from the free-convection correlation for a vertical plate, Eq. 9.26,

$$\overline{\text{Nu}}_L = \frac{\bar{h}L}{k} = \left\{ 0.825 + \frac{0.387 \text{Ra}_L^{1/6}}{\left[ 1 + (0.492/\text{Pr})^{9/16} \right]^{8/27}} \right\}^2 \quad (2)$$

The Rayleigh number, Eq. 9.25, is

$$\text{Ra}_L = \frac{g\beta(T_s - T_\infty)L^3}{\nu\alpha} = \frac{9.8 \text{ m/s}^2 (1/300\text{K})(32 - 22)\text{K} \times 0.5^3 \text{ m}^3}{15.89 \times 10^{-6} \text{ m}^2/\text{s} \times 22.5 \times 10^{-6} \text{ m}^2/\text{s}} = 1.142 \times 10^8.$$

Substituting numerical values into Eq. (2), find

$$\overline{\text{Nu}}_L = \left\{ 0.825 + \frac{0.387 (1.142 \times 10^8)^{1/6}}{\left[ 1 + (0.492/0.707)^{9/16} \right]^{8/27}} \right\}^2 = 63.5$$

$$\bar{h}_L = \frac{k}{L} \overline{\text{Nu}}_L = \frac{0.0263 \text{ W/m}\cdot\text{K}}{0.5 \text{ m}} \times 63.5 = 3.34 \text{ W/m}^2 \cdot \text{K}.$$

The heat rate using Eq. (1) is

$$q = 3.34 \text{ W/m}^2 \cdot \text{K} \times (0.5 \times 0.7) \text{ m}^2 (32 - 22) \text{ K} = 11.7 \text{ W}. \quad <$$

Heat loss by radiation, assuming  $\varepsilon = 1$ , is

$$q_{\text{rad}} = \varepsilon A_s \sigma (T_s^4 - T_{\text{sur}}^4)$$

$$q_{\text{rad}} = 1(0.5 \times 0.7) \text{ m}^2 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left[ (273 + 32)^4 - (273 + 22)^4 \right] \text{ K}^4 = 21.4 \text{ W}. \quad <$$

Note that heat loss by radiation is nearly double that by free convection. Using Eq. (1.9), the radiation heat transfer coefficient is  $h_{\text{rad}} = 6.4 \text{ W/m}^2 \cdot \text{K}$ , which is twice the coefficient for the free convection process.

## PROBLEM 9.22

**KNOWN:** Dimensions of window pane with frost formation on inner surface. Temperature of room air and walls.

**FIND:** Heat loss through window.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, (2) Surface of frost is isothermal with  $T_s \approx 0^\circ\text{C}$ , (3) Radiation exchange is between a small surface (window) and a large enclosure (walls of room), (4) Room air is quiescent.

**PROPERTIES:** Table A-4, air ( $T_f = 9^\circ\text{C} = 282\text{ K}$ ):  $k = 0.0249\text{ W/m}\cdot\text{K}$ ,  $\nu = 14.3 \times 10^{-6}\text{ m}^2/\text{s}$ ,  $\alpha = 20.1 \times 10^{-6}\text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.712$ ,  $\beta = 3.55 \times 10^{-3}\text{ K}^{-1}$ .

**ANALYSIS:** Under steady-state conditions, the heat loss through the window corresponds to the rate of heat transfer to the frost by convection and radiation.

$$q = q_{\text{conv}} + q_{\text{rad}} = W \times L \left[ \bar{h} (T_\infty - T_s) + \varepsilon \sigma (T_{\text{sur}}^4 - T_s^4) \right]$$

$$\text{With } \text{Ra}_L = g\beta(T_\infty - T_s)L^3 / \alpha\nu = 9.8\text{ m/s}^2 \times 0.00355\text{ K}^{-1} \times 18\text{ K} (1\text{ m})^3 / (14.3 \times 20.1 \times 10^{-12}\text{ m}^4/\text{s}^2) \\ = 2.18 \times 10^9, \text{ Eq. (9.26) yields}$$

$$\bar{\text{Nu}}_L = \left\{ 0.825 + \frac{0.387 \text{Ra}_L^{1/6}}{\left[ 1 + (0.492/\text{Pr})^{9/16} \right]^{8/27}} \right\}^2 = 156.5$$

$$\bar{h} = \text{Nu}_L \frac{k}{L} = 156.5 \left( \frac{0.0249\text{ W/m}\cdot\text{K}}{1\text{ m}} \right) = 3.9\text{ W/m}^2 \cdot \text{K}$$

$$q = 1\text{ m}^2 \left[ 3.9\text{ W/m}^2 \cdot \text{K} (18\text{ K}) + 0.90 \times 5.67 \times 10^{-8}\text{ W/m}^2 \cdot \text{K}^4 (291^4 - 273^4) \right]$$

$$= 70.2\text{ W} + 82.5\text{ W} = 152.7\text{ W} \quad <$$

**COMMENTS:** (1) The thickness of the frost layer does not affect the heat loss, since the inner surface of the layer remains at  $T_s \approx 0^\circ\text{C}$ . However, the temperature of the glass/frost interface decreases with increasing thickness, from a value of  $0^\circ\text{C}$  for negligible thickness. (2) Since the thermal boundary layer thickness is zero at the top of the window and has its maximum value at the bottom, the temperature of the glass will actually be largest and smallest at the top and bottom, respectively. Hence, frost will first begin to form at the bottom.

## PROBLEM 9.23

**KNOWN:** Length of isothermal vertical plate,  $L$ .

**FIND:** Expression for the ratio of the average heat transfer coefficients for  $N$  plates each of length  $L_N = L/N$  to the average coefficient for the single plate.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Constant properties.

**ANALYSIS:** Equation 9.21 yields, for the single plate,

$$\overline{Nu}_L = \frac{\bar{h}L}{k} = \frac{4}{3} \left( \frac{Gr_L}{4} \right)^{1/4} g(Pr) \quad \text{or} \quad \bar{h}_{L,1} = \frac{4k}{3L} \left( \frac{Gr_L}{4} \right)^{1/4} g(Pr) \quad (1)$$

For multiple plates,

$$\overline{Nu}_{L,N} = \frac{\bar{h}_{L,N}L_N}{k} = \frac{4}{3} \left( \frac{Gr_{L,N}}{4} \right)^{1/4} g(Pr) \quad \text{where} \quad L_N = L/N \quad \text{and} \quad Gr_{L,N} = Gr_L/(N^3) \quad (2a, b, c)$$

Combining Equations 2a, 2b and 2c yields

$$\bar{h}_{L,N} = \frac{4Nk}{3L} \left( \frac{Gr_L}{4N^3} \right)^{1/4} g(Pr) \quad (3)$$

Dividing Equation 3 by Equation 1 yields

$$\bar{h}_{L,N} / \bar{h}_{L,1} = N \left( \frac{1}{N^3} \right)^{1/4} = N^{1/4} <$$

**COMMENTS:** (1) By breaking the single plate into shorter segments, the average boundary layer thickness is reduced, resulting in a modest increase in the average heat transfer coefficient and, in turn, the convective heat transfer from the plate. (2) The relationship for laminar *forced* convection for an isothermal plate in parallel flow is  $\bar{h}_{L,N} / \bar{h}_{L,1} = N^{1/2}$ , illustrating that, in general, enhancement of free convection heat transfer is more challenging than enhancement of forced convection. See Problem 7.11.

## PROBLEM 9.24

**KNOWN:** Plate dimensions, initial temperature, and final temperature. Air temperature.

**FIND:** (a) Initial cooling rate, (b) Time to reach prescribed final temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Plate is spacewise isothermal as it cools (lumped capacitance approximation), (2) Negligible heat transfer from minor sides of plate, (3) Thermal boundary layer development corresponds to that for an isolated plate (negligible interference between adjoining boundary layers). (4) Negligible radiation. (5) Constant properties.

**PROPERTIES:** Table A-1, AISI 1010 steel ( $\bar{T} = 473 \text{ K}$ ):  $\rho = 7832 \text{ kg/m}^3$ ,  $c = 513 \text{ J/kg}\cdot\text{K}$ . Table A-4, air ( $T_{f,i} = 433 \text{ K}$ ):  $\nu = 30.4 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0361 \text{ W/m}\cdot\text{K}$ ,  $\alpha = 44.2 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.687$ ,  $\beta = 0.0023 \text{ K}^{-1}$ .

**ANALYSIS:** (a) The initial rate of heat transfer is  $q_i = \bar{h} A_s (T_i - T_\infty)$ , where  $A_s \approx 2L^2 = 2 \text{ m}^2$ .

With  $\text{Ra}_{L,i} = g\beta(T_i - T_\infty)L^3/\alpha\nu = 9.8 \text{ m/s}^2 \times 0.0021 (280)1\text{m}^3/44.2 \times 10^{-6} \text{ m}^2/\text{s} \times 30.4 \times 10^{-6} \text{ m}^2/\text{s} = 4.72 \times 10^9$ , Eq. 9.26 yields

$$\bar{h} = \frac{0.0361 \text{ W/m}\cdot\text{K}}{1\text{m}} \left\{ 0.825 + \frac{0.387 \left( 4.72 \times 10^9 \right)^{1/6}}{\left[ 1 + \left( 0.492 / 0.687 \right)^{9/16} \right]^{8/27}} \right\}^2 = 7.16 \text{ W/m}^2 \cdot \text{K}$$

Hence,  $q_i = 7.16 \text{ W/m}^2 \cdot \text{K} \times 2\text{m}^2 \times 280^\circ\text{C} = 4010 \text{ W}$  <

(b) From an energy balance at an instant of time for a control surface about the plate,  $-q = \dot{E}_{st} = \rho L^2 \delta c dT/dt$ , the rate of change of the plate temperature is

$$\frac{dT}{dt} = -\frac{\bar{h} 2L^2 (T - T_\infty)}{\rho L^2 \delta c} = -\frac{2\bar{h}}{\rho \delta c} (T - T_\infty)$$

where the Rayleigh number, and hence  $\bar{h}$ , changes with time due to the change in the temperature of the plate. Integrating the foregoing equation with the DER function of IHT, the following results are obtained for the temperature history of the plate.

Continued ...

### PROBLEM 9.24 (Cont.)

The time for the plate to cool to 100°C is

$$t \approx 2365 \text{ s}$$

<

**COMMENTS:** (1) Although the plate temperature is comparatively large and radiation emission is significant relative to convection, much of the radiation leaving one plate is intercepted by the adjoining plate if the spacing between plates is small relative to their width. The net effect of radiation on the plate temperature would then be small. (2) Because of the increase in  $\beta$  and reductions in  $\nu$  and  $\alpha$  with increasing  $t$ , the Rayleigh number decreases only slightly as the plate cools from 300°C to 100°C (from  $4.72 \times 10^9$  to  $4.48 \times 10^9$ ), despite the significant reduction in  $(T - T_\infty)$ . The reduction in  $\bar{h}$  from 7.2 to 5.6  $\text{W/m}^2 \cdot \text{K}$  is principally due to a reduction in the thermal conductivity.

## PROBLEM 9.25

**KNOWN:** Thin-walled container with hot process fluid at 50°C placed in a quiescent, cold water bath at 10°C.

**FIND:** (a) Overall heat transfer coefficient,  $U$ , between the hot and cold fluids, and (b) Compute and plot  $U$  as a function of the hot process fluid temperature for the range  $20 \leq T_{\infty,h} \leq 50^\circ\text{C}$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Heat transfer at the surfaces approximated by free convection from a vertical plate, (3) Fluids are extensive and quiescent, (4) Hot process fluid thermophysical properties approximated as those of water, and (5) Negligible container wall thermal resistance.

**PROPERTIES:** *Table A.6*, Water (assume  $T_{f,h} = 310 \text{ K}$ ):  $\rho_h = 1/1.007 \times 10^{-3} = 993 \text{ kg/m}^3$ ,  $c_{p,h} = 4178 \text{ J/kg}\cdot\text{K}$ ,  $\nu_h = \mu_h/\rho_h = 695 \times 10^{-6} \text{ N}\cdot\text{s/m}^2/993 \text{ kg/m}^3 = 6.999 \times 10^{-7} \text{ m}^2/\text{s}$ ,  $k_h = 0.628 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr}_h = 4.62$ ,  $\alpha_h = k_h/\rho_h c_{p,h} = 1.514 \times 10^{-7} \text{ m}^2/\text{s}$ ,  $\beta_h = 361.9 \times 10^{-6} \text{ K}^{-1}$ ; *Table A.6*, Water (assume  $T_{f,c} = 295 \text{ K}$ ):  $\rho_c = 1/1.002 \times 10^{-3} = 998 \text{ kg/m}^3$ ,  $c_{p,c} = 4181 \text{ J/kg}\cdot\text{K}$ ,  $\nu_c = \mu_c/\rho_c = 959 \times 10^{-6} \text{ N}\cdot\text{s/m}^2/998 \text{ kg/m}^3 = 9.609 \times 10^{-7} \text{ m}^2/\text{s}$ ,  $k_c = 0.606 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr}_c = 6.62$ ,  $\alpha_c = k_c/\rho_c c_{p,c} = 1.452 \times 10^{-7} \text{ m}^2/\text{s}$ ,  $\beta_c = 227.5 \times 10^{-6} \text{ K}^{-1}$ .

**ANALYSIS:** (a) The overall heat transfer coefficient between the hot process fluid,  $T_{\infty,h}$ , and the cold water bath fluid,  $T_{\infty,c}$ , is

$$U = \left( \frac{1}{\bar{h}_h} + \frac{1}{\bar{h}_c} \right)^{-1} \quad (1)$$

where the average free convection coefficients can be estimated from the vertical plate correlation Eq. 9.26, with the Rayleigh number, Eq. 9.25,

$$\bar{Nu}_L = \left\{ 0.825 + \frac{0.387 \text{Ra}_L^{1/6}}{\left[ 1 + (0.492/\text{Pr})^{9/16} \right]^{8/27}} \right\}^2 \quad \text{Ra}_L = \frac{g\beta\Delta T L^3}{\nu\alpha} \quad (2,3)$$

To affect a solution, assume  $T_s = (T_{\infty,h} + T_{\infty,c})/2 = 30^\circ\text{C} = 303 \text{ K}$ , so that the hot and cold fluid film temperatures are  $T_{f,h} = 313 \text{ K} \approx 310 \text{ K}$  and  $T_{f,c} = 293 \text{ K} \approx 295 \text{ K}$ . From an energy balance across the container walls,

$$\bar{h}_h (T_{\infty,h} - T_s) = \bar{h}_c (T_s - T_{\infty,c}) \quad (4)$$

the surface temperature  $T_s$  can be determined. Evaluating the correlation parameters, find:

*Hot process fluid:*

$$\text{Ra}_{L,h} = \frac{9.8 \text{ m/s}^2 \times 361.9 \times 10^{-6} \text{ K}^{-1} (50 - 30) \text{ K} (0.200 \text{ m})^3}{6.999 \times 10^{-7} \text{ m}^2/\text{s} \times 1.514 \times 10^{-7} \text{ m}^2/\text{s}} = 5.357 \times 10^9$$

Continued...

**PROBLEM 9.25 (Cont.)**

$$\overline{Nu}_{L,h} = \left\{ 0.825 + \frac{0.387 \left( 5.357 \times 10^9 \right)^{1/6}}{\left[ 1 + \left( 0.492/4.62 \right)^{9/16} \right]^{8/27}} \right\}^2 = 251.5$$

$$\overline{h}_h = \overline{Nu}_{L,h} \frac{h_h}{L} = 251.5 \times 0.628 \text{ W/m}^2 \cdot \text{K} / 0.200 \text{ m} = 790 \text{ W/m}^2 \cdot \text{K}$$

Cold water bath:

$$Ra_{L,c} = \frac{9.8 \text{ m/s}^2 \times 227.5 \times 10^{-6} \text{ K}^{-1} (30 - 10) \text{ K} (0.200 \text{ m})^3}{9.609 \times 10^{-7} \text{ m}^2/\text{s} \times 1.452 \times 10^{-7} \text{ m}^2/\text{s}} = 2.557 \times 10^9$$

$$\overline{Nu}_{L,c} = \left\{ 0.825 + \frac{0.387 \left( 2.557 \times 10^9 \right)^{1/6}}{\left[ 1 + \left( 0.492/6.62 \right)^{9/16} \right]^{8/27}} \right\}^2 = 203.9$$

$$\overline{h}_c = 203.9 \times 0.606 \text{ W/m}^2 \cdot \text{K} / 0.200 \text{ m} = 618 \text{ W/m}^2 \cdot \text{K}$$

From Eq. (1) find

$$U = (1/790 + 1/618)^{-1} \text{ W/m}^2 \cdot \text{K} = 347 \text{ W/m}^2 \cdot \text{K}$$

Using Eq.(4), find the resulting surface temperature

$$790 \text{ W/m}^2 \cdot \text{K} (50 - T_s) \text{ K} = 618 \text{ W/m}^2 \cdot \text{K} (T_s - 10) \text{ K} \quad T_s = 32.4^\circ \text{C}$$

Which compares favorably with our assumed value of 30°C.

(b) Using the *IHT Correlations Tool, Free Convection, Vertical Plate* and following the foregoing approach, the overall coefficient was computed as a function of the hot fluid temperature and is plotted below. Note that  $U$  increases almost linearly with  $T_{\infty,h}$ .

**COMMENTS:** For the conditions of part (a), using the IHT model of part (b) with thermophysical properties evaluated at the proper film temperatures, find  $U = 352 \text{ W/m}^2 \cdot \text{K}$  with  $T_s = 32.4^\circ \text{C}$ . Our approximate solution was a good one.

(2) Because the set of equations for part (b) is quite stiff, when using the IHT model you should follow the suggestions in the IHT Example 9.2 including use of the intrinsic function Tfluid\_avg (T1,T2).

## PROBLEM 9.26

**KNOWN:** Size and emissivity of a vertical heated plate. Temperature of the ambient and surroundings.

**FIND:** (a) Electrical power to be supplied to the plate in order to achieve a plate temperature of  $T_s = 35^\circ\text{C}$  for  $\varepsilon = 0.95$ . Fraction of the plate exposed to turbulent conditions, (b) Steady-state plate temperature for  $\varepsilon = 0.05$  and fraction of the plate exposed to turbulent conditions.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Constant properties and steady-state conditions, (2) Large surroundings, (3) Isothermal plate, (4) Critical Rayleigh number of  $\text{Ra}_{x,c} = 10^9$ .

**PROPERTIES:** Table A.4, air: ( $T_f = 303\text{ K}$ ):  $k = 0.02652\text{ W/m}\cdot\text{K}$ ,  $\nu = 1.619 \times 10^{-5}\text{ m}^2/\text{s}$ ,  $\alpha = 2.294 \times 10^{-5}\text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.7066$ .

**ANALYSIS:** (a) The Rayleigh number is

$$\text{Ra}_L = \frac{g\beta\Delta T L^3}{\nu\alpha} = \frac{9.8\text{ m/s}^2 \times (1/303\text{ K}) \times 10^\circ\text{C} \times (1\text{ m})^3}{1.619 \times 10^{-5}\text{ m}^2/\text{s} \times 2.294 \times 10^{-5}\text{ m}^2/\text{s}} = 8.71 \times 10^8 \quad (1)$$

Since  $\text{Ra} < \text{Ra}_{x,c}$ , the boundary layer is completely laminar. The electric power required is

$$P = \dot{E}_g = q_{\text{conv}} + q_{\text{rad}} = \bar{h}A(T_s - T_\infty) + \varepsilon A\sigma(T_s^4 - T_{\text{sur}}^4) \quad (2)$$

The convection coefficient may be found from the Churchill and Chu correlation

$$\bar{\text{Nu}}_L = \left\{ 0.825 + \frac{0.387 \times (8.71 \times 10^8)^{1/6}}{\left[ 1 + (0.492/0.7066)^{9/16} \right]^{8/27}} \right\}^2 = 117.6 \quad (3)$$

Thus, the convection coefficient is

Continued...

**PROBLEM 9.26 (Cont.)**

$$\bar{h} = \overline{\text{Nu}}_L k / L = 117.6 \times 0.02652 \text{ W/m} \cdot \text{K} / 1\text{m} = 3.12 \text{ W/m}^2 \cdot \text{K}$$

Hence, Equation 2 is written

$$\begin{aligned} P &= 2 \times (1\text{m} \times 2\text{m}) \times 3.12 \text{ W/m}^2 \cdot \text{K} \times (35 - 25)^\circ\text{C} \\ &\quad + 0.95 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times (308^4 - 298^4) \text{K}^4 < \\ &= 124.8 \text{ W} + 239.8 \text{ W} = 364.2 \text{ W} \end{aligned}$$

(b) Equations 1, 2 and 3 may be solved simultaneously with the constraint that  $P = 364.6 \text{ W}$ . Property variations may be taken into account by using IHT. A simultaneous solution of Equations 1 through 3 yields

$$\text{Ra}_L = 1.71 \times 10^9, \overline{\text{Nu}}_L = 144.9, \bar{h} = 3.906 \text{ W/m}^2 \cdot \text{K}, T_s = 319.5 \text{ K} = 46.5^\circ\text{C} <$$

The length of the plate that is subjected to laminar conditions may be found from the definition of the Rayleigh number,  $\text{Ra}_L = g\beta\Delta T L^3 / \nu\alpha$  and the knowledge that  $T_f = (319.5 \text{ K} + 298 \text{ K})/2 = 308.8 \text{ K}$ .

$$L = \left( \frac{\text{Ra}_{x,c} \nu \alpha}{g\beta\Delta T} \right)^{1/3} = \left( \frac{10^9 \times 1.677 \times 10^{-5} \text{ m}^2/\text{s} \times 2.379 \times 10^{-5} \text{ m}^2/\text{s}}{9.8 \text{ m/s} \times (1/308.8 \text{ K}) \times (319.5 \text{ K} - 298 \text{ K})} \right)^{1/3} = 0.836 \text{ m} <$$

Therefore,  $1\text{m} - 0.836\text{m} = 0.164\text{m}$  or 16.4% of the plate is exposed to turbulent conditions.

**COMMENTS:** (1) In part (b), the convection and radiation heat rates are 335.9 W and 28.74 W, respectively. Convection dominates in part (b) while in part (a) radiation losses are significantly larger than convection losses. (2) Radiation exchange can fundamentally alter the nature of the flow in free convection systems. (3) The polished plate would slowly oxidize over time, causing *drift* in the experimentalist's measurements of the transition to turbulent flow. (4) The properties used in part (b) are evaluated at the film temperature of  $T_f = 308.8 \text{ K}$  and are  $k = 0.02695 \text{ W/m}\cdot\text{K}$ ,  $\nu = 1.677 \times 10^{-5} \text{ m}^2/\text{s}$ ,  $\alpha = 2.397 \times 10^{-5} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.7058$ .

## PROBLEM 9.27

**KNOWN:** Boundary conditions associated with a rear window experiencing uniform volumetric heating.

**FIND:** (a) Volumetric heating rate  $\dot{q}$  needed to maintain inner surface temperature at  $T_{s,i} = 15^\circ\text{C}$ , (b) Effects of  $T_{\infty,o}$ ,  $u_\infty$ , and  $T_{\infty,i}$  on  $\dot{q}$  and  $T_{s,o}$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, one-dimensional conditions, (2) Constant properties, (3) Uniform volumetric heating in window, (4) Convection heat transfer from interior surface of window to interior air may be approximated as free convection from a vertical plate, (5) Heat transfer from outer surface is due to forced convection over a flat plate in parallel flow.

**PROPERTIES:** Table A.3, Glass (300 K):  $k = 1.4 \text{ W/m}\cdot\text{K}$ ; Table A.4, Air ( $T_{f,i} = 12.5^\circ\text{C}$ , 1 atm):  $\nu = 14.6 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0251 \text{ W/m}\cdot\text{K}$ ,  $\alpha = 20.59 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\beta = (1/285.5) = 3.503 \times 10^{-3} \text{ K}^{-1}$ ,  $\text{Pr} = 0.711$ ; ( $T_{f,o} \approx 0^\circ\text{C}$ ):  $\nu = 13.49 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0241 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.714$ .

**ANALYSIS:** (a) The temperature distribution in the glass is governed by the appropriate form of the heat equation, Eq. 3.44, whose general solution is given by Eq. 3.45.

$$T(x) = -(\dot{q}/2k)x^2 + C_1x + C_2.$$

The constants of integration may be evaluated by applying appropriate boundary conditions at  $x = 0$ . In particular, with  $T(0) = T_{s,i}$ ,  $C_2 = T_{s,i}$ . Applying an energy balance to the inner surface,  $q''_{\text{cond}} = q''_{\text{conv},i}$

$$-k \left. \frac{dT}{dx} \right|_{x=0} = \bar{h}_i (T_{\infty,i} - T_{s,i}) \quad -k \left( -\frac{\dot{q}}{k}x + C_1 \right) \Big|_{x=0} = \bar{h}_i (T_{\infty,i} - T_{s,i})$$

$$C_1 = -(\bar{h}_i/k)(T_{\infty,i} - T_{s,i})$$

$$T(x) = -(\dot{q}/2k)x^2 - \frac{\bar{h}_i (T_{\infty,i} - T_{s,i})}{k}x + T_{s,i} \quad (1)$$

The required generation may then be obtained by formulating an energy balance at the outer surface, where  $q''_{\text{cond}} = q''_{\text{conv},o}$ . Using Eq. (1),

$$-k \left. \frac{dT}{dx} \right|_{x=L} = \bar{h}_o (T_{s,o} - T_{\infty,o}) \quad (2)$$

Continued...

**PROBLEM 9.27 (Cont.)**

$$-k \left. \frac{dT}{dx} \right|_{x=L} = -k \left( -\frac{\dot{q}L}{k} \right) + \bar{h}_i (T_{\infty,i} - T_{s,i}) = \dot{q}L + \bar{h}_i (T_{\infty,i} - T_{s,i}) \quad (3)$$

Substituting Eq. (3) into Eq. (2), the energy balance becomes

$$\dot{q}L = \bar{h}_o (T_{s,o} - T_{\infty,o}) + \bar{h}_i (T_{s,i} - T_{\infty,i}) \quad (4)$$

where  $T_{s,o}$  may be evaluated by applying Eq. (1) at  $x = L$ .

$$T_{s,o} = -\frac{\dot{q}L^2}{2k} - \frac{\bar{h}_i (T_{\infty,i} - T_{s,i})}{k} L + T_{s,i}. \quad (5)$$

The *inside* convection coefficient may be obtained from Eq. 9.26. With

$$Ra_H = \frac{g\beta (T_{s,i} - T_{\infty,i}) H^3}{\nu\alpha} = \frac{9.8 \text{ m/s}^2 (3.503 \times 10^{-3} \text{ K}^{-1}) (15 - 10) \text{ K} (0.5 \text{ m})^3}{14.60 \times 10^{-6} \text{ m}^2/\text{s} \times 20.59 \times 10^{-6} \text{ m}^2/\text{s}} = 7.137 \times 10^7,$$

$$\bar{Nu}_H = \left[ 0.825 + \frac{0.387 Ra_H^{1/6}}{\left[ 1 + (0.492/Pr)^{9/16} \right]^{8/27}} \right]^2 = \left[ 0.825 + \frac{0.387 (7.137 \times 10^7)^{1/6}}{\left[ 1 + (0.492/0.711)^{9/16} \right]^{8/27}} \right]^2 = 55.2$$

$$\bar{h}_i = \bar{Nu}_H \frac{k}{H} = \frac{55.2 \times 0.0251 \text{ W/m} \cdot \text{K}}{0.5 \text{ m}} = 2.77 \text{ W/m}^2 \cdot \text{K}$$

The *outside* convection coefficient may be obtained by first evaluating the Reynolds number. With

$$Re_H = \frac{u_{\infty} H}{\nu} = \frac{20 \text{ m/s} \times 0.5 \text{ m}}{13.49 \times 10^{-6} \text{ m}^2/\text{s}} = 7.413 \times 10^5$$

and with  $Re_{x,c} = 5 \times 10^5$ , mixed boundary layer conditions exist. Hence,

$$\bar{Nu}_H = (0.037 Re_H^{4/5} - 871) Pr^{1/3} = \left[ 0.037 (7.413 \times 10^5)^{4/5} - 871 \right] (0.714)^{1/3} = 864$$

$$\bar{h}_o = \bar{Nu}_H (k/H) = (864 \times 0.0241 \text{ W/m} \cdot \text{K}) / 0.5 \text{ m} = 41.6 \text{ W/m}^2 \cdot \text{K}.$$

Eq. (5) may now be expressed as

$$T_{s,o} = -\frac{\dot{q}(0.008 \text{ m})^2}{2(1.4 \text{ W/m} \cdot \text{K})} - \frac{2.77 \text{ W/m}^2 \cdot \text{K} (10 - 15) \text{ K}}{1.4 \text{ W/m} \cdot \text{K}} \times 0.008 \text{ m} + 288 \text{ K} = -2.286 \times 10^{-5} \dot{q} + 288.1 \text{ K}$$

$$\text{or, solving for } \dot{q}, \quad \dot{q} = -43,745 (T_{s,o} - 288.1) \quad (6)$$

and substituting into Eq. (4),

$$-43,745 (T_{s,o} - 288.1) (0.008 \text{ m}) = 41.6 \text{ W/m}^2 \cdot \text{K} (T_{s,o} - 263 \text{ K}) + 2.77 \text{ W/m}^2 \cdot \text{K} (288 \text{ K} - 283 \text{ K}).$$

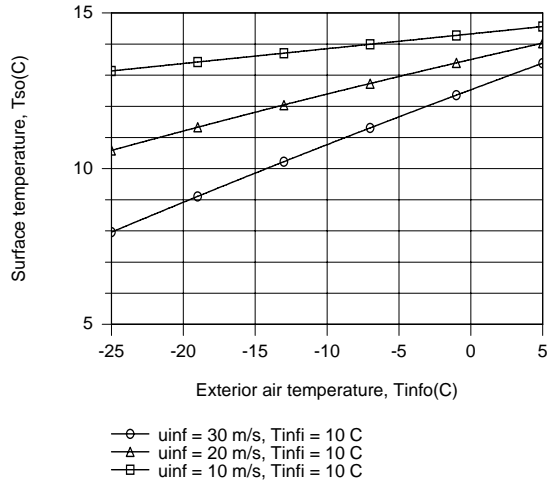

It follows that  $T_{s,o} = 285.4 \text{ K}$  in which case, from Eq. (6)

$$\dot{q} = 118 \text{ kW/m}^3. \quad \leftarrow$$

(b) The parametric calculations were performed using the *One-Dimensional, Steady-state Conduction* Model of IHT with the appropriate *Correlations* and *Properties* Tool Pads, and the results are as follows.

### PROBLEM 9.27 (Cont.)

For fixed  $T_{s,i}$  and  $T_{\infty,i}$ ,  $T_{s,o}$  and  $\dot{q}$  are strongly influenced by  $T_{\infty,o}$  and  $u_{\infty}$ , increasing and decreasing, respectively, with increasing  $T_{\infty,o}$  and decreasing and increasing, respectively with increasing  $u_{\infty}$ . For fixed  $T_{s,i}$  and  $u_{\infty}$ ,  $T_{s,o}$  and  $\dot{q}$  are independent of  $T_{\infty,i}$ , but increase and decrease, respectively, with increasing  $T_{\infty,o}$ .

**COMMENTS:** In lieu of performing a surface energy balance at  $x = L$ , Eq. (4) may also be obtained by applying an energy balance to a control volume about the entire window.

### PROBLEM 9.28

**KNOWN:** Vertical panel with uniform heat flux exposed to ambient air.

**FIND:** Allowable heat flux if maximum temperature is not to exceed a specified value,  $T_{max}$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Constant properties, (2) Radiative exchange with surroundings negligible.

**PROPERTIES:** Table A-4, Air ( $T_f = (T_{L/2} + T_\infty)/2 = (35.4 + 25)^\circ\text{C}/2 = 30.2^\circ\text{C} = 303\text{K}$ , 1 atm):  $\nu = 16.19 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 26.5 \times 10^{-3} \text{ W/m}\cdot\text{K}$ ,  $\alpha = 22.9 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.707$ .

**ANALYSIS:** Following the treatment of Section 9.6.1 for a vertical plate with uniform heat flux (constant  $q_s''$ ), the heat flux can be evaluated as

$$q_s'' = \bar{h} \Delta T_{L/2} \quad \text{where} \quad \Delta T_{L/2} = T_s(L/2) - T_\infty \quad (1,2)$$

and  $\bar{h}$  is evaluated using an appropriate correlation for a constant temperature vertical plate. From Eq. 9.28,

$$\Delta T_x \equiv T_x - T_\infty = 1.15(x/L)^{1/5} \Delta T_{L/2} \quad (3)$$

and recognizing that the maximum temperature will occur at the top edge,  $x = L$ , use Eq. (3) to find

$$\Delta T_{L/2} = (37 - 25)^\circ\text{C} / 1.15(1/1)^{1/5} = 10.4^\circ\text{C} \quad \text{or} \quad T_{L/2} = 35.4^\circ\text{C}.$$

Calculate now the Rayleigh number based upon  $\Delta T_{L/2}$ , with  $T_f = (T_{L/2} + T_\infty)/2 = 303\text{K}$ ,

$$\text{Ra}_L = \frac{g\beta\Delta T L^3}{\nu\alpha} \quad \text{where} \quad \Delta T = \Delta T_{L/2} \quad (4)$$

$$\text{Ra}_L = 9.8 \text{ m/s}^2 (1/303\text{K}) \times 10.4\text{K} (1\text{m})^3 / 16.19 \times 10^{-6} \text{ m}^2/\text{s} \times 22.9 \times 10^{-6} \text{ m}^2/\text{s} = 9.07 \times 10^8.$$

Since  $\text{Ra}_L < 10^9$ , the boundary layer flow is laminar; hence the correlation of Eq. 9.27 is appropriate,

$$\overline{\text{Nu}}_L = \frac{\bar{h}L}{k} = 0.68 + \frac{0.670 \text{ Ra}_L^{1/4}}{\left[1 + (0.492/\text{Pr})^{9/16}\right]^{4/9}} \quad (5)$$

$$\bar{h} = \left[ \frac{0.0265 \text{ W/m}\cdot\text{K}}{1\text{m}} \right] \left\{ 0.68 + \frac{0.670 (9.07 \times 10^8)^{1/4}}{\left[1 + (0.492/0.707)^{9/16}\right]^{4/9}} \right\} = 2.38 \text{ W/m}^2 \cdot \text{K}.$$

From Eqs. (1) and (2) with numerical values for  $\bar{h}$  and  $\Delta T_{L/2}$ , find

$$q_s'' = 2.38 \text{ W/m}^2 \cdot \text{K} \times 10.4^\circ\text{C} = 24.8 \text{ W/m}^2. \quad <$$

**COMMENTS:** Recognize that radiation exchange with the environment will be significant.

Assuming  $\bar{T}_s = T_{L/2}$ ,  $T_{\text{sur}} = T_\infty$  and  $\varepsilon = 1$ , find  $q_{\text{rad}}'' = \sigma (\bar{T}_s^4 - T_{\text{sur}}^4) = 66 \text{ W/m}^2$ .

### PROBLEM 9.29

**KNOWN:** Vertical circuit board dissipating 5W to ambient air.

**FIND:** (a) Maximum temperature of the board assuming uniform surface heat flux and (b) Temperature of the board for an isothermal surface condition.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Either uniform  $q_s''$  or  $T_s$  on the board, (2) Quiescent room air.

**PROPERTIES:** Table A-4, Air ( $T_f = (T_{L/2} + T_\infty)/2$  or  $(T_s + T_\infty)/2$ , 1 atm), values used in iterations:

Iteration	$T_f$ (K)	$\nu \cdot 10^6$ (m <sup>2</sup> /s)	$k \cdot 10^3$ (W/m·K)	$\alpha \cdot 10^6$ (m <sup>2</sup> /s)	Pr
1	312	17.10	27.2	24.3	0.705
2	324	18.30	28.1	26.1	0.704
3	319	17.80	27.7	25.3	0.704
4	320	17.90	27.8	25.4	0.704

**ANALYSIS:** (a) For the uniform heat flux case (see Section 9.6.1), the heat flux is

$$q_s'' = \bar{h} \Delta T_{L/2} \quad \text{where} \quad \Delta T_{L/2} = T_{L/2} - T_\infty \quad (1,2)$$

and  $q_s'' = q / A_s = 5 \text{ W} / (0.150 \text{ m})^2 = 222 \text{ W} / \text{m}^2$ .

The maximum temperature on the board will occur at  $x = L$  and from Eq. 9.28 is

$$\Delta T_x = 1.15 (x/L)^{1/5} \Delta T_{L/2} \quad (3)$$

$$T_L = T_{\max} = T_\infty + 1.15 \Delta T_{L/2}.$$

The average heat transfer coefficient  $\bar{h}$  is estimated from a vertical (uniform  $T_s$ ) plate correlation based upon the temperature difference  $\Delta T_{L/2}$ . Recognize that an iterative procedure is required: (i) assume a value of  $T_{L/2}$ , use Eq. (2) to find  $\Delta T_{L/2}$ ; (ii) evaluate the Rayleigh number

$$Ra_L = g \beta \Delta T_{L/2} L^3 / \nu \alpha \quad (4)$$

and select the appropriate correlation (either Eq. 9.26 or 9.27) to estimate  $\bar{h}$ ; (iii) use Eq. (1) with values of  $\bar{h}$  and  $\Delta T_{L/2}$  to find the calculated value of  $q_s''$ ; and (iv) repeat this procedure until the calculated value for  $q_s''$  is close to  $q_s'' = 222 \text{ W} / \text{m}^2$ , the required heat flux.

Continued ...

**PROBLEM 9.29 (Cont.)**

To evaluate properties for the correlation, use the film temperature,

$$T_f = (T_{L/2} + T_\infty) / 2. \quad (5)$$

Iteration #1: Assume  $T_{L/2} = 50^\circ\text{C}$  and from Eqs. (2) and (5) find

$$\Delta T_{L/2} = (50 - 27)^\circ\text{C} = 23^\circ\text{C} \quad T_f = (50 + 27)^\circ\text{C} / 2 = 312\text{K}.$$

From Eq. (4), with  $\beta = 1/T_f$ , the Rayleigh number is

$$\text{Ra}_L = 9.8\text{m/s}^2 (1/312\text{K}) \times 23^\circ\text{C} (0.150\text{m})^3 / \left(17.10 \times 10^{-6} \text{m}^2/\text{s}\right) \times \left(24.3 \times 10^{-6} \text{m}^2/\text{s}\right) = 5.868 \times 10^6.$$

Since  $\text{Ra}_L < 10^9$ , the flow is laminar and Eq. 9.27 is appropriate

$$\overline{\text{Nu}}_L = \frac{\bar{h}L}{k} = 0.68 + \frac{0.670 \text{Ra}_L^{1/4}}{\left[1 + (0.492/\text{Pr})^{9/16}\right]^{4/9}}$$

$$\bar{h}_L = \frac{0.0272 \text{W/m}\cdot\text{K}}{0.150\text{m}} \left\{ 0.68 + 0.670 \left(5.868 \times 10^6\right)^{1/4} / \left[1 + (0.492/0.705)^{9/16}\right]^{4/9} \right\} = 4.71 \text{W/m}^2 \cdot \text{K}.$$

Using Eq. (1), the calculated heat flux is

$$q_s'' = 4.71 \text{W/m}^2 \cdot \text{K} \times 23^\circ\text{C} = 108 \text{W/m}^2.$$

Since  $q_s'' < 222 \text{W/m}^2$ , the required value, another iteration with an increased estimate for  $T_{L/2}$  is warranted. Further iteration results are tabulated.

Iteration	$T_{L/2}(\text{C})$	$\Delta T_{L/2}(\text{C})$	$T_f(\text{K})$	$\text{Ra}_L$	$\bar{h}(\text{W/m}^2 \cdot \text{K})$	$q_s''(\text{W/m}^2)$
2	75	48	324	$1.026 \times 10^7$	5.57	268
3	65	38	319	$8.749 \times 10^6$	5.29	201
4	68	41	320	$9.321 \times 10^6$	5.39	221

After Iteration 4, close agreement between the calculated and required  $q_s''$  is achieved with

$T_{L/2} = 68^\circ\text{C}$ . From Eq. (3), the maximum board temperature is

$$T_L = T_{\text{max}} = 27^\circ\text{C} + 1.15(41)^\circ\text{C} = 74^\circ\text{C}. \quad <$$

(b) For the uniform temperature case, the procedure for estimation of the average heat transfer coefficient is the same. Hence,

$$T_s = T_{L/2} | q_s'' = 68^\circ\text{C}. \quad <$$

**COMMENTS:** In both cases,  $q = 5\text{W}$  and  $\bar{h} = 5.38 \text{W/m}^2$ . However, the temperature distributions for the two cases are quite different as shown on the sketch. For  $q_s'' = \text{constant}$ ,  $\Delta T_x \sim x^{1/5}$  according to Eq. 9.28.

### PROBLEM 9.30

**KNOWN:** Coolant flow rate and inlet and outlet temperatures. Dimensions and emissivity of channel side walls. Temperature of surroundings. Power dissipation.

**FIND:** (a) Temperature of sidewalls for  $\varepsilon_s = 0.15$ , (b) Temperature of sidewalls for  $\varepsilon_s = 0.90$ , (c) Sidewall temperatures with loss of coolant for  $\varepsilon_s = 0.15$  and  $\varepsilon_s = 0.90$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, (2) Negligible heat transfer from top and bottom surfaces of duct, (3) Isothermal side walls, (4) Large surroundings, (5) Coolant is incompressible liquid with negligible viscous dissipation, (6) Constant properties.

**PROPERTIES:** Table A-4, air ( $\bar{T}_m = 298 \text{ K}$ ):  $c_p = 1007 \text{ J/kg}\cdot\text{K}$ . Air properties required for the free convection calculations depend on  $T_s$  and were evaluated as part of the iterative solution obtained using the IHT software.

**ANALYSIS:** (a) The heat dissipated by the components is transferred by forced convection to the coolant ( $q_c$ ), as well as by natural convection ( $q_{\text{conv}}$ ) and radiation ( $q_{\text{rad}}$ ) to the ambient air and the surroundings. Hence,

$$q = q_c + q_{\text{conv}} + q_{\text{rad}} = 200 \text{ W} \quad (1)$$

$$q_c = \dot{m}c_p(T_{m,o} - T_{m,i}) = 0.015 \text{ kg/s} \times 1007 \text{ J/kg}\cdot\text{K} \times 10^\circ\text{C} = 151 \text{ W} \quad (2)$$

$$q_{\text{conv}} = 2\bar{h}A_s(T_s - T_\infty) \quad (3)$$

where  $A_s = H \times L = 0.32 \text{ m}^2$  and  $\bar{h}$  is obtained from Eq. 9.26, with  $Ra_H = g\beta(T_s - T_\infty)H^3 / \alpha\nu$ .

$$\bar{h} = \frac{k}{H} \left\{ 0.825 + \frac{0.387 Ra_H^{1/6}}{\left[ 1 + (0.492/Pr)^{9/16} \right]^{8/27}} \right\}^2 \quad (3a)$$

$$q_{\text{rad}} = 2A_s \varepsilon_s \sigma (T_s^4 - T_{\text{sur}}^4) \quad (4)$$

Substituting Eqs. (2) – (4) into (1) and solving using the IHT software with  $\varepsilon_s = 0.15$ , we obtain

$$T_s = 308.8 \text{ K} = 35.8^\circ\text{C} \quad <$$

The corresponding heat rates are  $q_{\text{conv}} = 39.6 \text{ W}$  and  $q_{\text{rad}} = 9.4 \text{ W}$ .

(b) For  $\varepsilon_s = 0.90$  and  $q_c = 151 \text{ W}$ , the solution to Eqs. (1) – (4) yields

Continued ...

**PROBLEM 9.30 (Cont.)**

$$T_s = 301.8 \text{ K} = 28.8^\circ\text{C} \quad <$$

with  $q_{\text{conv}} = 18.7 \text{ W}$  and  $q_{\text{rad}} = 30.3 \text{ W}$ . Hence, enhanced emission from the surface yields a lower operating temperature and heat transfer by radiation now exceeds that due to conduction.

(c) With loss of coolant flow, we can expect all of the heat to be dissipated from the sidewalls ( $q_c = 0$ ). Solving Eqs. (1), (3) and (4), we obtain

$$\varepsilon_s = 0.15: \quad T_s = 341.8 \text{ K} = 68.8^\circ\text{C} \quad <$$

$$q_{\text{conv}} = 165.9 \text{ W}, \quad q_{\text{rad}} = 34.1 \text{ W}$$

$$\varepsilon_s = 0.90: \quad T_s = 322.5 \text{ K} = 49.5^\circ\text{C} \quad <$$

$$q_{\text{conv}} = 87.6 \text{ W}, \quad q_{\text{rad}} = 112.4 \text{ W}$$

Since the temperature of the electronic components exceeds that of the sidewalls, the value of  $T_s = 68.8^\circ\text{C}$  corresponding to  $\varepsilon_s = 0.15$  may be unacceptable, in which case the high emissivity coating should be applied to the walls.

**COMMENTS:** For the foregoing cases the convection coefficient is in the range  $3.31 \leq \bar{h} \leq 5.31 \text{ W/m}^2 \cdot \text{K}$ , with the smallest value corresponding to ( $q_c = 151 \text{ W}$ ,  $\varepsilon_s = 0.90$ ) and the largest value to ( $q_c = 0$ ,  $\varepsilon_s = 0.15$ ). The radiation coefficient is in the range  $0.93 \leq h_{\text{rad}} \leq 5.96 \text{ W/m}^2 \cdot \text{K}$ , with the smallest value corresponding to ( $q_c = 151 \text{ W}$ ,  $\varepsilon_s = 0.15$ ) and the largest value to ( $q_c = 0$ ,  $\varepsilon_s = 0.90$ ).

### PROBLEM 9.31

**KNOWN:** Dimensions, interior surface temperature, and exterior surface emissivity of a refrigerator door. Temperature of ambient air and surroundings.

**FIND:** (a) Heat gain with no insulation, (b) Heat gain as a function of thickness for polystyrene insulation.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Negligible thermal resistance of steel and polypropylene sheets, (3) Negligible contact resistance between sheets and insulation, (4) One-dimensional conduction in insulation, (5) Quiescent air.

**PROPERTIES:** Table A.4, air ( $T_f = 288 \text{ K}$ ):  $\nu = 14.82 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\alpha = 20.92 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0253 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.71$ ,  $\beta = 0.00347 \text{ K}^{-1}$ .

**ANALYSIS:** (a) Without insulation,  $T_{s,o} = T_{s,i} = 278 \text{ K}$  and the heat gain is

$$q_{wo} = \bar{h}A_s(T_\infty - T_{s,i}) + \varepsilon\sigma A_s(T_{sur}^4 - T_{s,i}^4)$$

where  $A_s = HW = 0.65 \text{ m}^2$ . With a Rayleigh number of  $\text{Ra}_H = g\beta(T_\infty - T_{s,i})H^3/\alpha\nu = 9.8 \text{ m/s}^2(0.00347 \text{ K}^{-1})(20 \text{ K})(1)^3/(20.92 \times 10^{-6} \text{ m}^2/\text{s})(14.82 \times 10^{-6} \text{ m}^2/\text{s}) = 2.19 \times 10^9$ , Eq. 9.26 yields

$$\bar{\text{Nu}}_H = \left\{ 0.825 + \frac{0.387(2.19 \times 10^9)^{1/6}}{\left[1 + (0.492/0.71)^{9/16}\right]^{8/27}} \right\}^2 = 156.6$$

$$\bar{h} = \bar{\text{Nu}}_H(k/H) = 156.6(0.0253 \text{ W/m}\cdot\text{K}/1 \text{ m}) = 4.0 \text{ W/m}^2\cdot\text{K}$$

$$q_{wo} = 4.0 \text{ W/m}^2\cdot\text{K}(0.65 \text{ m}^2)(20 \text{ K}) + 0.6(5.67 \times 10^{-8} \text{ W/m}^2\cdot\text{K}^4)(0.65 \text{ m}^2)(298^4 - 278^4) \text{ K}^4$$

$$q_{wo} = (52.00 + 42.3) \text{ W} = 94.3 \text{ W} \quad \leftarrow$$

(b) With the insulation,  $T_{s,o}$  may be determined by performing an energy balance at the outer surface, where  $q''_{conv} + q''_{rad} = q''_{cond}$ , or

$$\bar{h}(T_\infty - T_{s,o}) + \varepsilon\sigma(T_{sur}^4 - T_{s,o}^4) = \frac{k_i}{L}(T_{s,o} - T_{s,i})$$

Using the *IHT First Law Model* for a *Nonisothermal Plane Wall* with the appropriate *Correlations* and *Properties* Tool Pads and evaluating the heat gain from

Continued...

### PROBLEM 9.31 (Cont.)

$$q_w = \frac{k_i A_s}{L} (T_{s,o} - T_{s,i})$$

the following results are obtained for the effect of  $L$  on  $T_{s,o}$  and  $q_w$ .

The outer surface temperature increases with increasing  $L$ , causing a reduction in the rate of heat transfer to the refrigerator compartment. For  $L = 0.025$  m,  $\bar{h} = 2.29$  W/m<sup>2</sup>·K,  $h_{\text{rad}} = 3.54$  W/m<sup>2</sup>·K,  $q_{\text{conv}} = 5.16$  W,  $q_{\text{rad}} = 7.99$  W,  $q_w = 13.15$  W, and  $T_{s,o} = 21.5^\circ\text{C}$ .

**COMMENTS:** The insulation is very effective in reducing the heat load, and there would be little value to increasing  $L$  beyond 25 mm.

### PROBLEM 9.32

**KNOWN:** Air receiving tank of height 2.5 m and diameter 0.75 m; inside air is at 3 atm and 100°C while outside ambient air is 25°C.

**FIND:** (a) Receiver wall temperature and heat transfer to the ambient air; assume receiver wall is  $T_s = 60^\circ\text{C}$  to facilitate use of the free convection correlations; (b) Whether film temperatures  $T_{f,i}$  and  $T_{f,o}$  were reasonable; if not, use an iteration procedure to find consistent values; and (c) Receiver wall temperatures,  $T_{s,i}$  and  $T_{s,o}$ , considering radiation exchange from the exterior surface ( $\epsilon_{s,o} = 0.85$ ) and thermal resistance of the wall (20 mm thick,  $k = 0.25\text{W/m}\cdot\text{K}$ ); represent the system by a thermal circuit.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Surface radiation effects are negligible, parts (a,b), (2) Losses from top and bottom of receiver are negligible, (3) Thermal resistance of receiver wall is negligible compared to free convection resistance, parts (a,b), (4) Interior and exterior air is quiescent and extensive.

**PROPERTIES:** Table A-4, Air (assume  $T_{f,o} = 315\text{ K}$ , 1 atm):  $\nu = 1.74 \times 10^{-5}\text{ m}^2/\text{s}$ ,  $k = 0.02741\text{ W/m}\cdot\text{K}$ ,  $\alpha = 2.472 \times 10^{-5}\text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.7049$ ; Table A-4, Air (assume  $T_{f,i} = 350\text{ K}$ , 3 atm):  $\nu = 2.092 \times 10^{-5}\text{ m}^2/\text{s}/3 = 6.973 \times 10^{-6}\text{ m}^2/\text{s}$ ,  $k = 0.030\text{ W/m}\cdot\text{K}$ ,  $\alpha = 2.990 \times 10^{-5}\text{ m}^2/\text{s}/3 = 9.967 \times 10^{-6}\text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.700$ . Note that the pressure effect is present for  $\nu$  and  $\alpha$  since  $\rho(1\text{ atm}) = 1/3\rho(3\text{ atm})$ ; other properties ( $c_p$ ,  $k$ ,  $\mu$ ) are assumed independent of pressure.

**ANALYSIS:** The heat transfer rate from the receiver follows from the thermal circuit,

$$q = \frac{\Delta T}{R_t} = \frac{T_{\infty,i} - T_{\infty,o}}{1/\bar{h}_o A_s + 1/\bar{h}_i A_s} = \frac{A_s (T_{\infty,i} - T_{\infty,o})}{1/\bar{h}_o + 1/\bar{h}_i} \quad (1)$$

where  $\bar{h}_o$  and  $\bar{h}_i$  must be estimated from free convection correlations. We must assume a value of  $T_s$  in order to obtain first estimates for  $\Delta T_o = T_s - T_{\infty,o}$  and  $\Delta T_i = T_{\infty,o} - T_s$  as well as  $T_{f,o}$  and  $T_{f,i}$ . Assume that  $T_s = 60^\circ\text{C}$ , then  $\Delta T_o = 60 - 25 = 35^\circ\text{C}$ ,  $T_{f,o} = 315\text{ K}$  and  $\Delta T_i = 100 - 60 = 40^\circ\text{C}$ , and  $T_{f,i} = 350\text{ K}$ .

$$\text{Ra}_{L,o} = \frac{g\beta\Delta T L^3}{\nu\alpha} = \frac{9.8\text{ m/s}^2 (1/315\text{ K}) \times 35\text{ K} (2.5\text{ m})^3}{1.74 \times 10^{-5}\text{ m}^2/\text{s} \times 2.472 \times 10^{-5}\text{ m}^2/\text{s}} = 3.952 \times 10^{10}$$

$$\text{Ra}_{L,i} = \frac{9.8\text{ m/s}^2 (1/350\text{ K}) \times 40\text{ K} (2.5\text{ m})^3}{6.973 \times 10^{-6}\text{ m}^2/\text{s} \times 9.967 \times 10^{-6}\text{ m}^2/\text{s}} = 2.518 \times 10^{11}$$

Approximating the receiver wall as a vertical plate, Eq. 9.26 yields

Continued...

**PROBLEM 9.32 (Cont.)**

$$\overline{\text{Nu}}_{L,o} = \left[ 0.825 + \frac{0.387 \text{Ra}_{L,o}^{1/6}}{\left[ 1 + (0.492/\text{Pr})^{9/16} \right]^{8/27}} \right]^2 = \left[ 0.825 + \frac{0.387 (3.952 \times 10^{10})^{1/6}}{\left[ 1 + (0.492/0.7049)^{9/16} \right]^{8/27}} \right]^2 = 390.0$$

$$\overline{\text{Nu}}_{L,i} = \frac{\bar{h}_{L,i} L}{k} = \left[ 0.825 + \frac{0.387 (2.518 \times 10^{11})^{1/6}}{\left[ 1 + (0.492/0.700)^{9/16} \right]^{8/27}} \right]^2 = 706.4$$

$$\bar{h}_{L,o} = \frac{0.02741 \text{ W/m} \cdot \text{K}}{2.5 \text{ m}} \times 390.0 = 4.27 \text{ W/m}^2 \cdot \text{K} \quad \bar{h}_{L,i} = \frac{0.030 \text{ W/m} \cdot \text{K}}{2.5 \text{ m}} \times 706.4 = 8.48 \text{ W/m}^2 \cdot \text{K}$$

From Eq. (1),

$$q = \pi \times 0.75 \text{ m} \times 2.5 \text{ m} (100 - 25) \text{ K} / \left[ \frac{1}{4.27} + \frac{1}{8.48} \right] \text{ m}^2 / \text{K} \cdot \text{W} = 1225 \text{ W} \quad <$$

Also,

$$T_s = T_{\infty,i} - q / \bar{h}_i A_s = 100^\circ \text{C} - 1225 \text{ W} / (8.48 \text{ W/m}^2 \cdot \text{K} \times \pi \times 0.75 \text{ m} \times 2.5 \text{ m}) = 74.9^\circ \text{C} <$$

(b) From the above result for  $T_s$ , the computed film temperatures are

$$T_{f,o} = 323 \text{ K} \quad T_{f,i} = 360 \text{ K}$$

as compared to assumed values of 315 and 350 K, respectively. Using *IHT Correlation Tools* for the *Free Convection, Vertical Plate*, and the thermal circuit representing Eq. (1) to find  $T_s$ , rather than using as assumed value,

$$\frac{T_{\infty,o} - T_s}{1/\bar{h}_o} = \frac{T_s - T_{\infty,o}}{1/\bar{h}_o}$$

we found

$$q = 1262 \text{ W} \quad T_s = 71.4^\circ \text{C} \quad <$$

with  $T_{f,o} = 321 \text{ K}$  and  $359 \text{ K}$ . The iteration only influenced the heat rate slightly.

(c) Considering effects due to thermal resistance of the tank wall and radiation exchange, the thermal resistance network representing the system is shown below.

Continued ...

### PROBLEM 9.32 (Cont.)

Using the *IHT Model, Thermal Network*, with the *Correlation Tool for Free Convection, Vertical Plate*, and *Properties Tool for Air*, a model was developed which incorporates all the foregoing equations of parts (a,b), but includes the thermal resistance of the wall, Table 3.3,

$$R_{\text{wall}} = \frac{\ln(D_i/D_o)}{2\pi Lk} \quad D_o = D_i + 2 \times t$$

The results of the analyses are tabulated below showing for comparison those from parts (a) and (b):

Part	$R_{\text{cv},i}$ (K/W)	$R_w$ (K/W)	$R_{\text{cv},o}$ (K/W)	$R_{\text{rad}}$ (K/W)	$T_{s,i}$ (°C)	$T_{s,o}$ (°C)	$q$ W
(a)	0.0200	0	0.0398	$\infty$	74.9*	74.9*	1255
(b)	0.0227	0	0.0367	$\infty$	71.4	71.4	1262
(c)	0.0219	0.0132	0.0419	0.0280	68.4	49.3	1445

\*Recall we assumed  $T_s = 60^\circ\text{C}$  in order to simplify the correlation calculation with fixed values of  $\Delta T_i$ ,  $\Delta T_o$  as well as  $T_{f,o}$ ,  $T_{f,i}$ .

**COMMENTS:** (1) In the table note the slight difference between results using assumed values for  $T_f$  and  $\Delta T$  in the correlations (part (a)) and the exact solution (part (b)).

(2) In the part (c) results, considering thermal resistance of the wall and the radiation exchange process, the net effect was to reduce the overall thermal resistance of the system and, hence, the heat rate increased.

(3) In the part (c) analysis, the *IHT Thermal Resistance Network* model was used to create the thermal circuit and generate the required energy balances. The convection resistances were determined from appropriate *Convection Correlation Tools*. The code was developed in two steps: (1) Solve the energy balance relations from the *Network* with assigned values for  $h_i$  and  $h_o$  to demonstrate that the energy relations were correct and then (2) Call in the *Convection Correlations* and solve with variable coefficients. Because this equation set is very stiff, we used the intrinsic heat transfer function *Tfluid\_avg* and followed these steps in the solution: Step (1): Assign constant values to the film temperatures,  $T_{fi}$  and  $T_{fo}$ , and to the temperature differences in the convection correlations,  $\Delta T_i$  and  $\Delta T_o$ ; and in the *Initial Guesses* table, restrain all thermal resistances to be positive (minimum value = 1e-20); *Solve*; Step (2): Allow the film temperatures to be unknowns but keep assigned variables for the temperature differences; use the *Load* option and *Solve*. Step (3): Repeat the previous step but allowing the temperature differences to be unknowns. Even though you get a "successful solve" message, repeat the *Load-Solve* sequence until you see no changes in key variables so that you are assured that the Solver has fully converged on the solution.

### PROBLEM 9.33

**KNOWN:** Dimensions and emissivity of cylindrical solar receiver. Incident solar flux. Temperature of ambient air.

**FIND:** (a) Heat loss and collection efficiency for a prescribed receiver temperature, (b) Effect of receiver temperature on heat losses and collector efficiency.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, (2) Ambient air is quiescent, (3) Incident solar flux is uniformly distributed over receiver surface, (4) All of the incident solar flux is absorbed by the receiver, (5) Negligible irradiation from the surroundings, (6) Uniform receiver surface temperature, (7) Curvature of cylinder has a negligible effect on boundary layer development, (8) Constant properties.

**PROPERTIES:** Table A-4, air ( $T_f = 550$  K):  $k = 0.0439$  W/m·K,  $\nu = 45.6 \times 10^{-6}$  m<sup>2</sup>/s,  $\alpha = 66.7 \times 10^{-6}$  m<sup>2</sup>/s,  $Pr = 0.683$ ,  $\beta = 1.82 \times 10^{-3}$  K<sup>-1</sup>.

**ANALYSIS:** (a) The total heat loss is

$$q = q_{\text{rad}} + q_{\text{conv}} = A_s \varepsilon \sigma T_s^4 + \bar{h} A_s (T_s - T_\infty)$$

With  $Ra_L = g\beta(T_s - T_\infty)L^3/\nu\alpha = 9.8 \text{ m/s}^2 (1.82 \times 10^{-3} \text{ K}^{-1}) 500\text{K} (12\text{m})^3 / (45.6 \times 66.7 \times 10^{-12} \text{ m}^4/\text{s}^2) = 5.07 \times 10^{12}$ , Eq. 9.26 yields

$$\bar{h} = \frac{k}{L} \left\{ 0.825 + \frac{0.387 Ra_L^{1/6}}{\left[ 1 + (0.492/Pr)^{9/16} \right]^{8/27}} \right\}^2 = \frac{0.0439 \text{ W/m}\cdot\text{K}}{12\text{m}} \{0.825 + 42.4\}^2 = 6.83 \text{ W/m}^2 \cdot \text{K}$$

Hence, with  $A_s = \pi DL = 264 \text{ m}^2$

$$q = 264 \text{ m}^2 \times 0.2 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (800 \text{ K})^4 + 264 \text{ m}^2 \times 6.83 \text{ W/m}^2 \cdot \text{K} (500 \text{ K})$$

$$q = q_{\text{rad}} + q_{\text{conv}} = 1.23 \times 10^6 \text{ W} + 9.01 \times 10^5 \text{ W} = 2.13 \times 10^6 \text{ W} \quad <$$

With  $A_s q_s'' = 2.64 \times 10^7 \text{ W}$ , the collector efficiency is

$$\eta = \left( \frac{A_s q_s'' - q}{A_s q_s''} \right) 100 = \frac{(2.64 \times 10^7 - 2.13 \times 10^6) \text{ W}}{2.64 \times 10^7 \text{ W}} (100) = 91.9\% \quad <$$

Continued ...

### PROBLEM 9.33 (Cont.)

(b) As shown below, because of its dependence on temperature to the fourth power,  $q_{\text{rad}}$  increases more significantly with increasing  $T_s$  than does  $q_{\text{conv}}$ , and the effect on the efficiency is pronounced.

**COMMENTS:** The collector efficiency is also reduced by the inability to have a perfectly absorbing receiver. Partial reflection of the incident solar flux will reduce the efficiency by at least several percent.

### PROBLEM 9.34

**KNOWN:** Transformer which dissipates 1000 W whose surface is to be maintained at 47°C in quiescent air and surroundings at 27°C.

**FIND:** Power removal (a) by free convection and radiation from lateral and upper horizontal surfaces and (b) with 30 vertical fins attached to lateral surface.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Fins are isothermal at lateral surface temperature,  $T_s$ , (2) Vertical fins and lateral surface behave as vertical plate, (3) Transformer has isothermal surfaces and loses heat only on top and side.

**PROPERTIES:** Table A-4, Air ( $T_f = (27+47)^\circ\text{C}/2 = 310\text{K}$ , 1 atm):  $\nu = 16.90 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 27.0 \times 10^{-3} \text{ W/m}\cdot\text{K}$ ,  $\alpha = 23.98 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.706$ ,  $\beta = 1/T_f$ .

**ANALYSIS:** (a) For the vertical lateral (lat) and top horizontal (top) surfaces, the heat loss by radiation and convection is

$$q = q_{\text{lat}} + q_{\text{top}} = (\bar{h}_{\text{lat}} + h_r) \pi D L (T_s - T_\infty) + (\bar{h}_{\text{top}} + h_r) \left( \pi^2 D / 4 \right) (T_s - T_\infty)$$

where, from Eq. 1.9, the linearized radiation coefficient is

$$h_r = \varepsilon \sigma (T_s + T_\infty) (T_s^2 + T_\infty^2)$$

$$h_r = 0.8 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (320 + 300) \text{ K} (320^2 + 300^2) \text{ K}^2 = 5.41 \text{ W/m}^2 \cdot \text{K}.$$

The free convection coefficient for the lateral and top surfaces is:

*Lateral-vertical plate:* Using Eq. 9.26 with

$$\text{Ra}_L = \frac{g \beta (T_s - T_\infty) H^3}{\nu \alpha} = \frac{9.8 \text{ m/s}^2 (1/310 \text{ K}) (47 - 27) \text{ K} (0.5 \text{ m})^3}{16.90 \times 10^{-6} \text{ m}^2/\text{s} \times 23.98 \times 10^{-6} \text{ m}^2/\text{s}} = 1.950 \times 10^8$$

$$\bar{\text{Nu}}_L = \left\{ 0.825 + \frac{0.387 \text{Ra}_L^{1/6}}{\left[ 1 + (0.492/\text{Pr})^{9/16} \right]^{8/27}} \right\}^2$$

$$\bar{\text{Nu}}_L = \left\{ 0.825 + \frac{0.387 (1.950 \times 10^8)^{1/6}}{\left[ 1 + (0.492/0.706)^{9/16} \right]^{8/27}} \right\}^2 = 74.5$$

$$\bar{h}_{\text{lat}} = \bar{\text{Nu}}_L \cdot k / H = 74.5 \times 0.027 \text{ W/m}\cdot\text{K} / 0.5 \text{ m} = 4.02 \text{ W/m}^2 \cdot \text{K}.$$

Continued ...

**PROBLEM 9.34 (Cont.)**

*Top-horizontal plate:* Using Eq. 9.30 with

$$L_c = A_s / P = \frac{\pi D^2 / 4}{\pi D} = D / 4 = 0.0575 \text{ m}$$

$$Ra_L = \frac{g\beta(T_s - T_\infty)L_c^3}{\nu\alpha} = \frac{9.8 \text{ m/s}^2 (1/310 \text{ K})(47 - 27) \text{ K} (0.0575 \text{ m})^3}{16.90 \times 10^{-6} \text{ m}^2/\text{s} \times 23.98 \times 10^{-6} \text{ m}^2/\text{s}} = 2.97 \times 10^5$$

$$\overline{Nu}_L = 0.54 Ra_L^{1/4} = 0.54 (2.97 \times 10^5)^{1/4} = 12.6$$

$$\overline{h}_{\text{top}} = \overline{Nu}_L \cdot k / L_c = 12.6 \times 0.027 \text{ W/m} \cdot \text{K} / 0.0575 \text{ m} = 5.92 \text{ W/m}^2 \cdot \text{K}.$$

Hence, the heat loss by convection and radiation is

$$q = (4.02 + 5.41) \text{ W/m}^2 \cdot \text{K} (\pi \times 0.23 \text{ m} \times 0.50 \text{ m})(47 - 27) \text{ K} \\ + (5.92 + 5.41) \text{ W/m}^2 \cdot \text{K} (\pi \times 0.23^2 \text{ m}^2 / 4)(47 - 27) \text{ K}$$

$$q = (68.2 + 4.50) \text{ W} = 72.7 \text{ W}. \quad \leftarrow$$

(b) The effect of adding the vertical fins is to increase the area of the lateral surface to

$$A_{\text{wf}} = [\pi DH - 30(t \cdot H)] + 30 \times 2(w \cdot H)$$

$$A_{\text{wf}} = [\pi 0.23 \text{ m} \times 0.50 \text{ m} - 30(0.005 \times 0.500) \text{ m}^2] + 30 \times 2(0.075 \times 0.500) \text{ m}^2$$

$$A_{\text{wf}} = [0.361 - 0.075] \text{ m}^2 + 2.25 \text{ m}^2 = 2.536 \text{ m}^2.$$

where  $t$  and  $w$  are the thickness and width of the fins, respectively. Hence, the heat loss is now

$$q = q_{\text{lat}} + q_{\text{top}} = (\overline{h}_{\text{lat}} + h_r) A_{\text{wf}} (T_s - T_\infty) + q_{\text{top}}$$

$$q = (4.02 + 5.41) \text{ W/m}^2 \times 2.536 \text{ m}^2 \times 20 \text{ K} + 4.50 \text{ W} = 483 \text{ W}. \quad \leftarrow$$

Adding the fins to the lateral surface increases the heat loss by a factor of more than six.

**COMMENTS:** Since the fins are not likely to have 100% efficiency, our estimate is optimistic. Further, since the fins see one another, as well as the lateral surface, the radiative heat loss is over predicted.

### PROBLEM 9.35

**KNOWN:** Surface temperature of a long duct and ambient air temperature.

**FIND:** Heat gain to the duct per unit length of the duct.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Surface radiation effects are negligible, (2) Ambient air is quiescent.

**PROPERTIES:** Table A-4, Air ( $T_f = (T_\infty + T_s)/2 \approx 300\text{K}$ , 1 atm):  $\nu = 15.89 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0263 \text{ W/m}\cdot\text{K}$ ,  $\alpha = 22.5 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.707$ ,  $\beta = 1/T_f$ .

**ANALYSIS:** The heat gain to the duct can be expressed as

$$q' = 2q'_s + q'_t + q'_b = (2\bar{h}_s \cdot H + \bar{h}_t \cdot W + \bar{h}_b \cdot W)(T_\infty - T_s). \quad (1)$$

Consider now correlations to estimate  $\bar{h}_s$ ,  $\bar{h}_t$ , and  $\bar{h}_b$ . From Eq. 9.25, for the sides with  $L \equiv H$ ,

$$\text{Ra}_L = \frac{g\beta(T_\infty - T_s)L^3}{\nu\alpha} = \frac{9.8 \text{ m/s}^2 (1/300\text{K})(35 - 10) \text{ K} \times (0.2 \text{ m})^3}{15.89 \times 10^{-6} \text{ m}^2/\text{s} \times 22.5 \times 10^{-6} \text{ m}^2/\text{s}} = 1.827 \times 10^7. \quad (2)$$

Eq. 9.27 is appropriate to estimate  $\bar{h}_s$ ,

$$\bar{\text{Nu}}_L = 0.68 + \frac{0.670 \text{Ra}_L^{1/4}}{\left[1 + (0.492/\text{Pr})^{9/16}\right]^{4/9}} = 0.68 + \frac{0.670(1.827 \times 10^7)^{1/4}}{\left[1 + (0.492/0.707)^{9/16}\right]^{4/9}} = 34.29$$

$$\bar{h}_s = \bar{\text{Nu}}_L \cdot k/L = 34.29 \times 0.0263 \text{ W/m}\cdot\text{K} / 0.2 \text{ m} = 4.51 \text{ W/m}^2 \cdot \text{K}. \quad (3)$$

For the top and bottom portions of the duct,  $L \equiv A_s/P \approx W/2$ , (see Eq. 9.29), find the Rayleigh number from Eq. (2) with  $L = 0.1 \text{ m}$ ,  $\text{Ra}_L = 2.284 \times 10^6$ . From the correlations, Eqs. 9.30 and 9.32 for the top and bottom surfaces, respectively, find

$$\bar{h}_t = \frac{k}{(W/2)} \times 0.54 \text{Ra}_L^{1/4} = \frac{0.0263 \text{ W/m}\cdot\text{K}}{0.1 \text{ m}} \times 0.54 (2.284 \times 10^6)^{1/4} = 5.52 \text{ W/m}^2 \cdot \text{K}. \quad (4)$$

$$\bar{h}_b = \frac{k}{(W/2)} \times 0.52 \text{Ra}_L^{1/5} = \frac{0.0263 \text{ W/m}\cdot\text{K}}{0.1 \text{ m}} \times 0.52 (2.284 \times 10^6)^{1/5} = 2.56 \text{ W/m}^2 \cdot \text{K}. \quad (5)$$

The heat rate, Eq. (1), can now be evaluated using the heat transfer coefficients estimated from Eqs. (3), (4), and (5).

$$q' = (2 \times 4.51 \text{ W/m}^2 \cdot \text{K} \times 0.2 \text{ m} + 5.52 \text{ W/m}^2 \cdot \text{K} \times 0.2 \text{ m} + 2.56 \text{ W/m}^2 \cdot \text{K} \times 0.2 \text{ m})(35 - 10) \text{ K}$$

$$q' = 85.5 \text{ W/m}. \quad \leftarrow$$

**COMMENTS:** Radiation surface effects will be significant in this situation. With knowledge of the duct emissivity and surroundings temperature, the radiation heat exchange could be estimated.

### PROBLEM 9.36

**KNOWN:** Inner surface temperature and dimensions of rectangular duct. Thermal conductivity, thickness and emissivity of insulation.

**FIND:** (a) Outer surface temperatures and heat losses from the walls, (b) Effect of insulation thickness on outer surface temperatures and heat losses.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Ambient air is quiescent, (2) One-dimensional conduction, (3) Steady-state.

**PROPERTIES:** Table A.4, air (obtained from *Properties* Tool Pad of IHT).

**ANALYSIS:** (a) The analysis follows that of Example 9.3, except the surface energy balance must now include the effect of radiation. Hence,  $q''_{cond} = q''_{conv} + q''_{rad}$ , in which case

$$(k_i/t)(T_{s,1} - T_{s,2}) = \bar{h}(T_{s,2} - T_{\infty}) + h_r(T_{s,2} - T_{sur})$$

where  $h_r = \varepsilon\sigma(T_{s,2} + T_{sur})(T_{s,2}^2 + T_{sur}^2)$ . Applying this expression to each of the top, bottom and side walls, with the appropriate correlation obtained from the *Correlations* Tool Pad of IHT, the following results are determined for  $t = 25$  mm.

*Sides:*  $T_{s,2} = 19.3^{\circ}\text{C}$ ,  $\bar{h} = 2.82 \text{ W/m}^2\cdot\text{K}$ ,  $h_{rad} = 5.54 \text{ W/m}^2\cdot\text{K}$

*Top:*  $T_{s,2} = 19.3^{\circ}\text{C}$ ,  $\bar{h} = 2.94 \text{ W/m}^2\cdot\text{K}$ ,  $h_{rad} = 5.54 \text{ W/m}^2\cdot\text{K}$  <

*Bottom:*  $T_{s,2} = 20.1^{\circ}\text{C}$ ,  $\bar{h} = 1.34 \text{ W/m}^2\cdot\text{K}$ ,  $h_{rad} = 5.56 \text{ W/m}^2\cdot\text{K}$

With  $q'' = q''_{cond}$ , the surface heat losses may also be evaluated, and we obtain

*Sides:*  $q' = 2Hq'' = 21.6 \text{ W/m}$ ; *Top:*  $q' = wq'' = 27.0 \text{ W/m}$ ; *Bottom:*  $q' = wq'' = 26.2 \text{ W/m}$  <

(b) For the top surface, the following results are obtained from the parametric calculations

Continued...

### PROBLEM 9.36 (Cont.)

**COMMENTS:** Contrasting the heat rates of part (a) with those predicted in Comment 1 of Example 9.3, it is evident that radiation is significant and increases the total heat loss from 57.6 W/m to 74.8 W/m. As shown in part (b), reductions in  $T_{s,o}$  and  $q'$  may be effected by increasing the insulation thickness above 0.025 W/m·K, although attendant benefits diminish with increasing  $t$ .

### PROBLEM 9.37

**KNOWN:** Electric heater at bottom of tank of 400mm diameter maintains surface at 70°C with engine oil at 5°C.

**FIND:** Power required to maintain 70°C surface temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Oil is quiescent, (2) Quasi-steady state conditions exist.

**PROPERTIES:** Table A-5, Engine Oil ( $T_f = (T_\infty + T_s)/2 = 310\text{K}$ ):  $\nu = 288 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.145 \text{ W/m}\cdot\text{K}$ ,  $\alpha = 0.847 \times 10^{-7} \text{ m}^2/\text{s}$ ,  $\beta = 0.70 \times 10^{-3} \text{ K}^{-1}$ .

**ANALYSIS:** The heat rate from the bottom heater surface to the oil is

$$q = \bar{h}A_s(T_s - T_\infty)$$

where  $\bar{h}$  is estimated from the appropriate correlation depending upon the Rayleigh number  $Ra_L$ , from Eq. 9.25, using the characteristic length,  $L$ , from Eq. 9.29,

$$L = \frac{A_s}{P} = \frac{\pi D^2/4}{\pi D} = \frac{D}{4} = \frac{0.4\text{m}}{4} = 0.1\text{m}.$$

The Rayleigh number is

$$Ra_L = \frac{g\beta(T_s - T_\infty)L^3}{\nu\alpha}$$

$$Ra_L = \frac{9.8\text{m/s}^2 \times 0.70 \times 10^{-3} \text{ K}^{-1} (70 - 5)\text{K} \times 0.1^3 \text{ m}^3}{288 \times 10^{-6} \text{ m}^2/\text{s} \times 0.847 \times 10^{-7} \text{ m}^2/\text{s}} = 1.828 \times 10^7.$$

The appropriate correlation is Eq. 9.31 giving

$$\overline{Nu}_L = \frac{\bar{h}L}{k} = 0.15 Ra_L^{1/3} = 0.15 (1.828 \times 10^7)^{1/3} = 39.5$$

$$\bar{h} = \frac{k}{L} \overline{Nu}_L = \frac{0.145 \text{ W/m}\cdot\text{K}}{0.1\text{m}} \times 39.5 = 57.3 \text{ W/m}^2 \cdot \text{K}.$$

The heat rate is then

$$q = 57.3 \text{ W/m}^2 \cdot \text{K} (\pi/4) (0.4\text{m})^2 (70 - 5)\text{K} = 468 \text{ W}.$$

<

**COMMENTS:** Note that the characteristic length is  $D/4$  and not  $D$ ; however,  $A_s$  is based upon  $D$ . Recognize that if the oil is being continuously heated by the plate,  $T_\infty$  could change. Hence, here we have analyzed a quasi-steady state condition.

### PROBLEM 9.38

**KNOWN:** Horizontal, straight fin fabricated from plain carbon steel with thickness 6 mm and length 100 mm; base temperature is 150°C and air temperature is 25°C.

**FIND:** (a) Fin heat rate per unit width,  $q'_f$ , assuming an average fin surface temperature  $\bar{T}_s = 125^\circ\text{C}$  for estimating free convection and linearized radiation coefficient; how sensitive is  $q'_f$  to the assumed value for  $\bar{T}_s$ ?; (b) Compute and plot the heat rate,  $q'_f$  as a function of emissivity  $0.05 \leq \epsilon \leq 0.95$ ; show also the fraction of the total heat rate due to radiation exchange.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Air is quiescent medium, (2) Surface radiation effects are negligible, (3) One dimensional conduction in fin, (4) Characteristic length,  $L_c = A_s/P = \ell L(2\ell + 2L) \approx L/2$ .

**PROPERTIES:** Plain carbon steel, Given ( $\bar{T}_{\text{fin}} \approx 125^\circ\text{C} \approx 400\text{K}$ ):  $k = 57\text{ W/m}\cdot\text{K}$ ,  $\epsilon = 0.5$ ; Table A-

4, Air ( $T_f = (\bar{T}_{\text{fin}} + T_\infty)/2 = (125 + 25)^\circ\text{C}/2 \approx 350\text{K}$ , 1 atm):  $\nu = 20.92 \times 10^{-6}\text{ m}^2/\text{s}$ ,  $\alpha = 29.9 \times 10^{-6}\text{ m}^2/\text{s}$ ,  $k = 0.030\text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.70$ ,  $\beta = 1/T_f$ .

**ANALYSIS:** (a) We estimate  $\bar{h}$  as the average of the values for a heated plate facing upward and a heated plate facing downward. See Table 9.2, Case 3(a) and (b). Begin by evaluating the Rayleigh number, using Eq. 9.29 for  $L_c$ .

$$\text{Ra}_L = \frac{g\beta(\bar{T}_{\text{fin}} - T_\infty)L_c^3}{\nu\alpha} = \frac{9.8\text{ m/s}^2(1/350\text{K})(125 - 25)\text{K} \times (0.1\text{ m}/2)^3}{20.92 \times 10^{-6}\text{ m}^2/\text{s} \times 29.9 \times 10^{-6}\text{ m}^2/\text{s}} = 5.595 \times 10^5$$

An average fin temperature of  $\bar{T}_{\text{fin}} \approx 125^\circ\text{C}$  has been assumed in evaluating properties and  $\text{Ra}_L$ . According to Table 9.2, Eqs. 9.30 and 9.32 are appropriate. For the *upper* fin surface, Eq. 9.30,

$$\overline{\text{Nu}}_L = \bar{h}L_c/k = 0.54\text{Ra}_L^{1/4} = 0.54(5.595 \times 10^5)^{1/4} = 14.77$$

$$\bar{h}_{\text{upper}} = \overline{\text{Nu}}_L k/L_c = 14.77 \times 0.030\text{ W/m}\cdot\text{K}/0.05\text{ m} = 8.86\text{ W/m}^2\cdot\text{K}.$$

For the *lower* fin surface, Eq. 9.32,

$$\overline{\text{Nu}}_L = \bar{h}L/k = 0.52\text{Ra}_L^{1/5} = 0.52(5.595 \times 10^5)^{1/5} = 7.34$$

$$\bar{h}_{\text{lower}} = \overline{\text{Nu}}_L k/L = 7.34 \times 0.030\text{ W/m}\cdot\text{K}/0.05\text{ m} = 4.40\text{ W/m}^2\cdot\text{K}.$$

The linearized radiation coefficient follows from Eq. 1.9

$$\bar{h}_r = \epsilon\sigma(\bar{T}_{\text{fin}} + T_{\text{sur}})(\bar{T}_{\text{fin}}^2 + T_{\text{sur}}^2)$$

$$\bar{h}_r = 0.5 \times 5.67 \times 10^{-8}\text{ W/m}^2\cdot\text{K}^4(398 + 298)(398^2 + 298^2)\text{K}^3 = 4.88\text{ W/m}^2\cdot\text{K}$$

Continued ...

**PROBLEM 9.38 (Cont.)**

Hence, the average heat transfer coefficient for the fin is

$$\bar{h} = (\bar{h}_{\text{upper}} + \bar{h}_{\text{lower}})/2 + \bar{h}_r = [(8.86 + 4.40)/2 + 4.88] \text{ W/m}^2 \cdot \text{K} = 11.51 \text{ W/m}^2 \cdot \text{K}$$

Assuming the fin tip is adiabatic, from Eq. 3.81,

$$q_f = M \tanh(mL)$$

$$M = (\bar{h} P k A_c)^{1/2} \theta_b = \left( 11.51 \text{ W/m}^2 \cdot \text{K} \times 2\ell \times 57 \text{ W/m} \cdot \text{K} \left( 6 \times 10^{-3} \text{ m} \times \ell \right) \right)^{1/2} (150 - 25) \text{ K} = 350.7 \text{ W}$$

$$m = (\bar{h} P / k A_c)^{1/2} = \left( 11.51 \text{ W/m}^2 \cdot \text{K} \times 2\ell / 57 \text{ W/m} \cdot \text{K} \left( 6 \times 10^{-3} \text{ m} \times \ell \right) \right)^{1/2} = 8.20 \text{ m}^{-1}$$

$$mL = 8.20 \text{ m}^{-1} \times 0.1 \text{ m} = 0.820$$

$$q'_f = q_f / \ell = 350.7 \text{ W/m} \times \tanh(0.820) = 237 \text{ W/m} .$$

<

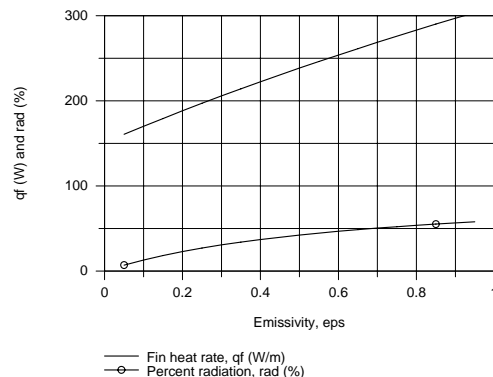

To determine how sensitive the estimate for  $\bar{h}$  is to the choice of the average fin surface temperature, the foregoing calculations were repeated using the *IHT Correlations Tool and Extended Surface Model* and the results are tabulated below; coefficients have units  $\text{W/m}^2 \cdot \text{K}$ ,

$\bar{T}_{\text{fin}} (\text{ }^\circ\text{C})$	125	135	145
$\bar{h}_{\text{lower}}$	4.40	4.49	4.56
$\bar{h}_{\text{upper}}$	8.87	9.05	9.21
$\bar{h}_r$	4.88	5.11	5.35
$\bar{h}$	11.5	11.9	12.2
$q' (\text{W/m})$	237	243	249

The temperature distribution for the  $\bar{T}_{\text{fin}} = 125^\circ\text{C}$  case is shown above. With  $\bar{T}_{\text{fin}} = 145^\circ\text{C}$ , the tip temperature is about  $2^\circ\text{C}$  higher. It appears that  $\bar{T}_{\text{fin}} = 125^\circ\text{C}$  was a reasonable choice. Note  $\bar{T}_{\text{fin}}$  is the value at the mid length.

(b) Using the IHT code developed for part (a), the fin heat rate,  $q_f$ , was plotted as a function of the emissivity. In this analysis, the convection and radiation coefficients were evaluated for an average fin temperature  $\bar{T}_{\text{fin}}$  evaluated at  $L/2$ . On the same plot we have also shown  $\text{rad} (\%) = (\bar{h}_r / \bar{h}) \times 100$ , which is the portion of the total heat rate due to radiation exchange.

### PROBLEM 9.39

**KNOWN:** Width and thickness of sample material. Rate of heat dissipation at bottom surface of sample and temperatures of top and bottom surfaces. Temperature of quiescent air and surroundings.

**FIND:** Thermal conductivity and emissivity of the sample.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, (2) One-dimensional conduction in sample, (3) Quiescent air, (4) Sample is small relative to surroundings, (5) All of the heater power dissipation is transferred through the sample, (6) Constant properties.

**PROPERTIES:** Table A-4, air ( $T_f = 335.5\text{K}$ ):  $\nu = 19.5 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0289 \text{ W/m}\cdot\text{K}$ ,  $\alpha = 27.8 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.703$ ,  $\beta = 0.00298 \text{ K}^{-1}$ .

**ANALYSIS:** The thermal conductivity is readily obtained by applying Fourier's law to the sample.

Hence, with  $q = P_{\text{elec}}$ ,

$$k = \frac{P_{\text{elec}} / W^2}{(T_1 - T_2) / L} = \frac{70 \text{ W} / (0.250\text{m})^2}{50^\circ\text{C} / 0.025\text{m}} = 0.560 \text{ W} / \text{m}\cdot\text{K} \quad <$$

The surface emissivity may be obtained by applying an energy balance to a control surface about the sample, in which case

$$P_{\text{elec}} = q_{\text{conv}} + q_{\text{rad}} = \left[ \bar{h}(T_2 - T_\infty) + \varepsilon\sigma(T_2^4 - T_{\text{sur}}^4) \right] W^2$$

$$\varepsilon = \frac{\left( P_{\text{elec}} / W^2 \right) - \bar{h}(T_2 - T_\infty)}{\sigma(T_2^4 - T_{\text{sur}}^4)}$$

With  $L = A_s/P = W^2/4W = W/4 = 0.0625\text{m}$ ,  $\text{Ra}_L = g\beta(T_2 - T_\infty)L^3/\nu\alpha = 9.86 \times 10^5$  and Eq. 9.30 yields

$$\bar{h} = \frac{\overline{\text{Nu}}_L k}{L} = \frac{k}{L} 0.54 \text{Ra}_L^{1/4} = \frac{0.0289 \text{ W} / \text{m}\cdot\text{K}}{0.0625\text{m}} 0.54 \left( 9.86 \times 10^5 \right)^{1/4} = 7.87 \text{ W} / \text{m}^2 \cdot \text{K} \quad <$$

Hence,

$$\varepsilon = \frac{70 \text{ W} / (0.250\text{m})^2 - 7.87 \text{ W} / \text{m}^2 \cdot \text{K} (75^\circ\text{C})}{5.67 \times 10^{-8} \text{ W} / \text{m}^2 \cdot \text{K}^4 \left( 373^4 - 298^4 \right) \text{K}^4} = 0.815 \quad <$$

**COMMENTS:** The uncertainty in the determination of  $\varepsilon$  is strongly influenced by uncertainties associated with using Eq. 9.30. If, for example,  $\bar{h}$  is overestimated by 10%, the actual value of  $\varepsilon$  would be 0.905.

### PROBLEM 9.40

**KNOWN:** Diameter, power dissipation, emissivity and temperature of gage(s). Air temperature (Cases A and B) and temperature of surroundings (Case A).

**FIND:** (a) Convection heat transfer coefficient (Case A), (b) Convection coefficient and temperature of surroundings (Case B).

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, (2) Quiescent air, (3) Net radiation exchange from surface of gage approximates that of a small surface in large surroundings, (4) All of the electrical power is dissipated by convection and radiation heat transfer from the surface(s) of the gage, (5) Negligible thickness of strip separating semi-circular disks of Part B, (6) Constant properties.

**PROPERTIES:** Table A-4, air ( $T_f = 320\text{K}$ ):  $\nu = 17.9 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\alpha = 25.5 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0278 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.704$ ,  $\beta = 0.00313 \text{ K}^{-1}$ .

**ANALYSIS:** (a) With  $q = q_{\text{conv}} + q_{\text{rad}} = P_{\text{elec}}$  and  $A_s = \pi D^2/4 = 0.0201 \text{ m}^2$ ,

$$\bar{h}_{\text{meas}} = \frac{P_{\text{elec}} - \varepsilon \sigma A_s (T^4 - T_{\text{sur}}^4)}{A_s (T - T_{\infty})} = \frac{10.8 \text{ W} - 0.8 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times 0.0201 \text{ m}^2 (340^4 - 300^4) \text{ K}^4}{0.0201 \text{ m}^2 (40 \text{ K})} = 7.46 \text{ W/m}^2 \cdot \text{K} <$$

With  $L = A_s/P = D/4 = 0.04 \text{ m}$  and  $\text{Ra}_L = g\beta(T - T_{\infty})L^3/\nu\alpha = 1.72 \times 10^5$ , Eq. 9.30 yields

$$\bar{h} = \frac{k}{L} 0.54 \text{Ra}_L^{1/4} = \frac{0.0278 \text{ W/m}\cdot\text{K} \times 0.54 (1.72 \times 10^5)^{1/4}}{0.04 \text{ m}} = 7.64 \text{ W/m}^2 \cdot \text{K} <$$

Agreement between the two values of  $\bar{h}$  is well within the uncertainty of the measurements.

(b) Since the semi-circular disks have the same temperature, each is characterized by the same convection coefficient and  $q_{\text{conv},1} = q_{\text{conv},2}$ . Hence, with

$$P_{\text{elec},1} = q_{\text{conv},1} + \varepsilon_1 \sigma (A_s/2) (T^4 - T_{\text{sur}}^4) \quad (1)$$

$$P_{\text{elec},2} = q_{\text{conv},2} + \varepsilon_2 \sigma (A_s/2) (T^4 - T_{\text{sur}}^4) \quad (2)$$

$$T_{\text{sur}} = \left[ T^4 - \frac{P_{\text{elec},1} - P_{\text{elec},2}}{(\varepsilon_1 - \varepsilon_2) \sigma (A_s/2)} \right]^{1/4} = \left[ (350)^4 - \frac{4.03 \text{ W}}{0.7 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times 0.01 \text{ m}^2} \right]^{1/4}$$

$$T_{\text{sur}} = 264 \text{ K} <$$

From Eq. (1), the convection coefficient is then

$$\bar{h}_{\text{meas}} = \frac{P_{\text{elec},1} - \varepsilon_1 \sigma (A_s/2) (T^4 - T_{\text{sur}}^4)}{(A_s/2) (T - T_{\infty})} = \frac{9.70 \text{ W} - 4.60 \text{ W}}{(0.01 \times 60) \text{ m}^2 \cdot \text{K}} = 8.49 \text{ W/m}^2 \cdot \text{K} <$$

With  $\text{Ra}_L = 2.58 \times 10^5$ , Eq. 9.30 yields

$$\bar{h} = \frac{k}{L} 0.54 \text{Ra}_L^{1/4} = \frac{0.0278 \text{ W/m}\cdot\text{K}}{0.04 \text{ m}} 0.54 (2.58 \times 10^5)^{1/4} = 8.46 \text{ W/m}^2 \cdot \text{K} <$$

Again, agreement between the two values of  $\bar{h}$  is well within the experimental uncertainty of the measurements.

**COMMENTS:** Because the semi-circular disks are at the same temperature, the characteristic length corresponds to that of the circular disk,  $L = D/4$ .

### PROBLEM 9.41

**KNOWN:** Horizontal, circular grill of 0.2m diameter with emissivity 0.9 is maintained at a uniform surface temperature of 130°C when ambient air and surroundings are at 24°C.

**FIND:** Electrical power required to maintain grill at prescribed surface temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Room air is quiescent, (2) Surroundings are large compared to grill surface.

**PROPERTIES:** Table A-4, Air ( $T_f = (T_\infty + T_s)/2 = (24 + 130)^\circ\text{C}/2 = 350\text{K}$ , 1 atm):

$$\nu = 20.92 \times 10^{-6} \text{ m}^2/\text{s}, k = 0.030 \text{ W/m}\cdot\text{K}, \alpha = 29.9 \times 10^{-6} \text{ m}^2/\text{s}, \beta = 1/T_f.$$

**ANALYSIS:** The heat loss from the grill is due to free convection with the ambient air and to radiation exchange with the surroundings.

$$q = A_s \left[ \bar{h} (T_s - T_\infty) + \varepsilon \sigma (T_s^4 - T_{\text{sur}}^4) \right] \quad (1)$$

Calculate  $Ra_L$  from Eq. 9.25,

$$Ra_L = g\beta (T_s - T_\infty) L_c^3 / \nu\alpha$$

where for a horizontal disc from Eq. 9.29,  $L_c = A_s/P = (\pi D^2/4)/\pi D = D/4$ . Substituting numerical values, find

$$Ra_L = \frac{9.8 \text{ m/s}^2 (1/350\text{K})(130 - 24)\text{K} (0.25\text{m}/4)^3}{20.92 \times 10^{-6} \text{ m}^2/\text{s} \times 29.9 \times 10^{-6} \text{ m}^2/\text{s}} = 1.158 \times 10^6.$$

Since the grill has a *hot upper surface*, Eq. 9.30 is the appropriate correlation,

$$\overline{Nu}_L = \bar{h}_L L_c / k = 0.54 Ra_L^{1/4} = 0.54 (1.158 \times 10^6)^{1/4} = 17.72$$

$$\bar{h}_L = \overline{Nu}_L k / L_c = 17.72 \times 0.030 \text{ W/m}\cdot\text{K} / (0.25\text{m}/4) = 8.50 \text{ W/m}^2 \cdot \text{K}. \quad (2)$$

Substituting from Eq. (2) for  $\bar{h}$  into Eq. (1), the heat loss or required electrical power,  $q_{\text{elec}}$ , is

$$q = \frac{\pi}{4} (0.25\text{m})^2 \left[ 8.50 \frac{\text{W}}{\text{m}^2 \cdot \text{K}} (130 - 24)\text{K} + 0.9 \times 5.67 \times 10^{-8} \frac{\text{W}}{\text{m}^2 \cdot \text{K}^4} \left( (130 + 273)^4 - (24 + 273)^4 \right) \text{K}^4 \right]$$

$$q = 44.2 \text{ W} + 46.0 \text{ W} = 90.2 \text{ W}. \quad <$$

**COMMENTS:** Note that for this situation, free convection and radiation modes are of equal importance. If the grill were highly polished such that  $\varepsilon \approx 0.1$ , the required power would be reduced by nearly 50%.

## PROBLEM 9.42

**KNOWN:** Power dissipation by a laptop computer CPU. Dimensions and emissivity of the laptop screen assembly. Thickness and thermal conductivity of plastic casing as well as thermal contact resistance between heat spreader and plastic casing. Temperature of the surroundings and of the ambient.

**FIND:** Temperature of the heat spreader and magnitudes of convection, radiation, conduction and contact resistances.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Constant properties and steady-state conditions, (2) Large surroundings, (3) Isothermal heat spreader, (4) Laptop screen can be treated as a suspended plate.

**PROPERTIES:** Table A.4, air: ( $T_f = 310 \text{ K}$  assumed):  $k = 0.02704 \text{ W/m}\cdot\text{K}$ ,  $\nu = 1.690 \times 10^{-5} \text{ m}^2/\text{s}$ ,  $\alpha = 2.398 \times 10^{-5} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.7056$ .

**ANALYSIS:** An energy balance on the control surface shown in the schematic yields

$$P = q_{\text{conv}} + q_{\text{rad}} = Lw \left[ \bar{h}(T_s - T_\infty) + \varepsilon\sigma(T_s^4 - T_{\text{sur}}^4) \right]$$

or

$$15\text{W} = 0.275\text{m} \times 0.175\text{m} \left[ \bar{h}(T_s - 298\text{K}) + 0.85 \times 5.67 \times 10^{-8} \text{W/m}^2 \cdot \text{K}^4 (T_s^4 - (298\text{K})^4) \right] \quad (1)$$

The convection coefficient can be found by using the Churchill and Chu correlation with  $g$  replaced by  $g \cos \theta$ . Hence,

$$\text{Ra}_L = \frac{g(\cos \theta)\beta(T_s - T_\infty)L^3}{\nu \cdot \alpha}$$

Continued...

**PROBLEM 9.42 (Cont.)**

$$Ra_L = \frac{9.8 \text{ m/s}^2 \times \cos 30^\circ \times (1/310 \text{ K}) \times (T_s - 298 \text{ K}) \times (0.175 \text{ m})^3}{1.690 \times 10^{-5} \text{ m}^2/\text{s} \times 2.398 \times 10^{-5} \text{ m}^2/\text{s}} \quad (2)$$

and

$$\bar{h} = \frac{0.02704 \text{ W/m} \cdot \text{K}}{0.175 \text{ m}} \times \left\{ 0.825 + \frac{0.387 \times Ra_L^{1/6}}{\left[ 1 + (0.492/0.7056)^{9/16} \right]^{8/27}} \right\}^2 \quad (3)$$

Simultaneous solution of Equations 1 through 3 yields

$$Ra_L = 1.048 \times 10^7, \bar{Nu}_L = 31.6, \bar{h} = 4.89 \text{ W/m}^2 \cdot \text{K}, T_s = 325.2 \text{ K} = 52.2^\circ \text{C}$$

The temperature of the heat spreader is

$$T_{hs} = T_s + \frac{P}{Lw} \left[ R_{t,c}'' + t/k \right] \text{ or}$$

$$T_{hs} = 52.2^\circ \text{C} + \frac{15 \text{ W}}{0.175 \text{ m} \times 0.275 \text{ m}} \left[ 2 \times 10^{-4} \frac{\text{m}^2 \cdot \text{K}}{\text{W}} + \frac{3 \times 10^{-3} \text{ m}}{0.21 \text{ W/m} \cdot \text{K}} \right] = 56.7^\circ \text{C} \quad <$$

Knowing  $A = Lw = 0.275 \text{ m} \times 0.175 \text{ m} = 4.81 \times 10^{-3} \text{ m}^2$ , the convection resistance is

$$R_{t,conv} = \frac{1}{hA} = \frac{1}{4.89 \text{ W/m}^2 \cdot \text{K} \times 4.81 \times 10^{-3} \text{ m}^2} = 4.30 \text{ K/W} \quad <$$

The radiation resistance, using

$$h_r = \varepsilon \sigma (T_s + T_{sur})(T_s^2 + T_{sur}^2)$$

$$= 0.85 \times 5.67 \times 10^{-8} (\text{W/m}^2 \cdot \text{K}^4) \times (325.2 \text{ K} + 298 \text{ K}) \times (325.2^2 + 298^2) \text{ K}^2 = 5.84 \text{ W/m}^2 \cdot \text{K}$$

is

$$R_{t,rad} = \frac{1}{h_r A} = \frac{1}{5.84 \text{ W/m}^2 \cdot \text{K} \times 4.81 \times 10^{-3} \text{ m}^2} = 3.56 \text{ K/W} \quad <$$

The conduction resistance is

$$R_{t,cond} = \frac{t}{kA} = \frac{3 \times 10^{-3} \text{ m}}{0.21 \text{ W/m} \cdot \text{K} \times 4.81 \times 10^{-3} \text{ m}^2} = 0.30 \text{ K/W} \quad <$$

Continued...

### PROBLEM 9.42 (Cont.)

The contact resistance is

$$R_{t,c} = \frac{R''_{t,c}}{A} = \frac{2 \times 10^{-4} \text{ m}^2 \cdot \text{K/W}}{4.81 \times 10^{-3} \text{ m}^2} = 4.2 \times 10^{-3} \text{ K/W} \quad <$$

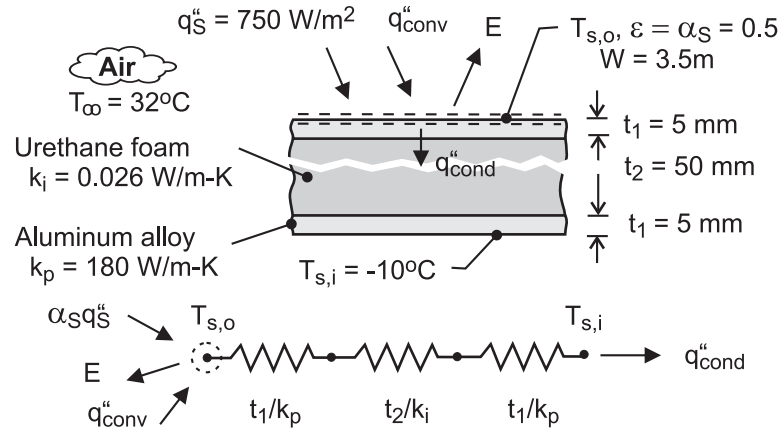

**COMMENTS:** (1) The actual film temperature is  $T_f = (23^\circ\text{C} + 52.2^\circ\text{C})/2 = 37.6^\circ\text{C} = 310.6 \text{ K}$ . The assumed value of the film temperature is excellent. (2) The convection and radiation resistances are large. The radiation resistance cannot be reduced significantly since the emissivity of the plastic is high. The convection resistance would vary as the laptop screen angle is changed.

### PROBLEM 9.43

**KNOWN:** Material properties, inner surface temperature and dimensions of roof of refrigerated truck compartment. Solar irradiation and ambient temperature.

**FIND:** Outer surface temperature of roof and rate of heat transfer to compartment.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible irradiation from the sky, (2)  $T_{s,o} > T_{\infty}$  (hot surface facing upward) and  $Ra_L > 10^7$ , (3) Constant properties.

**PROPERTIES:** Table A-4, air ( $p = 1 \text{ atm}$ ,  $T_f \approx 310 \text{ K}$ ):  $\nu = 16.9 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0270 \text{ W/m}\cdot\text{K}$ ,  $Pr = 0.706$ ,  $\alpha = \nu/Pr = 23.9 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\beta = 0.00323 \text{ K}^{-1}$ .

**ANALYSIS:** From an energy balance for the outer surface,

$$\alpha_S G_S - q_{\text{conv}}'' - E = q_{\text{cond}}'' = \frac{T_{s,o} - T_{s,i}}{R_{\text{tot}}''}$$

$$\alpha_S G_S - \bar{h}(T_{s,o} - T_{\infty}) - \varepsilon \sigma T_{s,o}^4 = \frac{T_{s,o} - T_{s,i}}{2R_p'' + R_i''}$$

where  $R_p'' = (t_1/k_p) = 2.78 \times 10^{-5} \text{ m}^2 \cdot \text{K}/\text{W}$  and  $R_i'' = (t_2/k_i) = 1.923 \text{ m}^2 \cdot \text{K}/\text{W}$ . For a hot surface facing upward and  $Ra_L = g\beta(T_{s,o} - T_{\infty})L^3/\alpha\nu > 10^7$ ,  $\bar{h}$  is obtained from Eq. 9.31. Hence, with cancellation of  $L$ ,

$$\begin{aligned} \bar{h} = \frac{k}{L} 0.15 Ra_L^{1/3} &= 0.15 \times 0.0270 \text{ W/m}\cdot\text{K} \left( \frac{9.8 \text{ m/s}^2 \times 0.00323 \text{ K}^{-1}}{16.9 \times 23.9 \times 10^{-12} \text{ m}^4/\text{s}^2} \right)^{1/3} (T_{s,o} - T_{\infty})^{1/3} \\ &= 1.73 \text{ W/m}^2 \cdot \text{K}^{4/3} (T_{s,o} - 305 \text{ K})^{1/3} \end{aligned}$$

Hence,

$$0.5 \left( 750 \text{ W/m}^2 \cdot \text{K} \right) - 1.73 \text{ W/m}^2 \cdot \text{K}^{4/3} (T_{s,o} - 305)^{4/3} - 0.5 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 T_{s,o}^4 = \frac{T_{s,o} - 263 \text{ K}}{(5.56 \times 10^{-5} + 1.923) \text{ m}^2 \cdot \text{K}/\text{W}}$$

Solving, we obtain  $T_{s,o} = 318.3 \text{ K} = 45.3^\circ\text{C}$  <

Hence, the heat load is  $q = (W \cdot L_t) q_{\text{cond}}'' = (3.5 \text{ m} \times 10 \text{ m}) \frac{(45.3 + 10)^\circ\text{C}}{1.923 \text{ m}^2 \cdot \text{K}/\text{W}} = 1007 \text{ W}$  <

**COMMENTS:** (1) The thermal resistance of the aluminum panels is negligible compared to that of the insulation. (2) The value of the convection coefficient is  $\bar{h} = 1.73(T_{s,o} - T_{\infty})^{1/3} = 4.10 \text{ W/m}^2 \cdot \text{K}$ .

## PROBLEM 9.44

**KNOWN:** Inner surface temperature and composition of a furnace roof. Emissivity of outer surface and temperature of surroundings.

**FIND:** (a) Heat loss through roof with no insulation, (b) Heat loss with insulation and inner surface temperature of insulation, and (c) Thickness of fire clay brick which would reduce the insulation temperature,  $T_{ins,i}$  to 1350 K.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) One-dimensional conduction through the composite wall, (3) Negligible contact resistance, (4) Constant properties.

**PROPERTIES:** Table A-4, Air ( $T_f \approx 400$  K, 1 atm):  $k = 0.0338$  W/m·K,  $\nu = 26.4 \times 10^{-6}$  m<sup>2</sup>/s,  $\alpha = 38.3 \times 10^{-6}$  m<sup>2</sup>/s,  $Pr = 0.69$ ,  $\beta = (400 \text{ K})^{-1} = 0.0025 \text{ K}^{-1}$ ; Table A-1, Steel 1010 (600 K):  $k = 48.8$  W/m·K; Table A-3 Alumina-Silica blanket (64 kg/m<sup>3</sup>, 750 K):  $k = 0.125$  W/m·K; Table A-3, Fire clay brick (1478 K):  $k = 1.8$  W/m·K.

**ANALYSIS:** (a) Without the insulation, the thermal circuit is

Performing an energy balance at the outer surface, it follows that

$$q_{\text{cond}} = q_{\text{conv}} + q_{\text{rad}} \quad \frac{T_{s,i} - T_{s,o}}{L_1/k_1A + L_3/k_3A} = hA(T_{s,o} - T_{\infty}) + \varepsilon\sigma A(T_{s,o}^4 - T_{\text{sur}}^4) \quad (1,2)$$

where the radiation term is evaluated from Eq. 1.7. The characteristic length associated with free convection from the roof is, from Eq. 9.29  $L = A_s/P = 16\text{m}^2/16\text{m} = 1\text{m}$ . From Eq. 9.25, with an assumed value for the film temperature,  $T_f = 400$  K,

$$Ra_L = \frac{g\beta(T_{s,o} - T_{\infty})L^3}{\nu\alpha} = \frac{9.8\text{m/s}^2(0.0025\text{K}^{-1})(T_{s,o} - T_{\infty})(1\text{m})^3}{26.4 \times 10^{-6}\text{m}^2/\text{s} \times 38.3 \times 10^{-6}\text{m}^2/\text{s}} = 2.42 \times 10^7 (T_{s,o} - T_{\infty})$$

Hence, from Eq. 9.31

$$h = \frac{k}{L} 0.15 Ra_L^{1/3} = \frac{0.0338\text{W/m}\cdot\text{K}}{1\text{m}} 0.15 (2.42 \times 10^7)^{1/3} (T_{s,o} - T_{\infty})^{1/3} = 1.47 (T_{s,o} - T_{\infty})^{1/3} \text{W/m}^2 \cdot \text{K}. (3)$$

Continued...

### PROBLEM 9.44 (Cont.)

The energy balance can now be written

$$\frac{(1700 - T_{s,o})K}{(0.08\text{m}/1.8\text{ W/m}\cdot\text{K} + 0.005\text{m}/48.8\text{ W/m}\cdot\text{K})} = 1.47(T_{s,o} - 298\text{ K})^{4/3} + 0.3 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 [T_{s,o}^4 - (298\text{ K})^4]$$

and from iteration, find  $T_{s,o} \approx 895\text{ K}$ . Hence,

$$q = 16\text{m}^2 \left\{ 1.47(895 - 298)^{4/3} \text{ W/m}^2 + 0.3 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 [(895\text{ K})^4 - (298\text{ K})^4] \right\}$$

$$q = 16\text{m}^2 \{ 7,389 + 10,780 \} \text{ W/m}^2 = 2.91 \times 10^5 \text{ W} . \quad <$$

(b) *With the insulation*, an additional conduction resistance is provided and the energy balance at the outer surface becomes

$$\frac{T_{s,i} - T_{s,o}}{L_1/k_1A + L_2/k_2A + L_3/k_3A} = hA(T_{s,o} - T_\infty) + \varepsilon\sigma A(T_{s,o}^4 - T_{\text{sur}}^4) \quad (4)$$

$$\frac{(1700 - T_{s,o})K}{(0.08\text{m}/1.8 + 0.02/0.125 + 0.005/48.8)\text{m}^2 \cdot \text{K/W}} = 1.47(T_{s,o} - 298\text{ K})^{4/3} + 0.3 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 [T_{s,o}^4 - (298\text{ K})^4]$$

From an iterative solution, it follows that  $T_{s,o} \approx 610\text{ K}$ . Hence,

$$q = 16\text{m}^2 \left\{ 1.47(610 - 298)^{4/3} \text{ W/m}^2 + 0.3 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 [(610\text{ K})^4 - (298\text{ K})^4] \right\}$$

$$q = 16\text{m}^2 \{ 3111 + 2221 \} \text{ W/m}^2 = 8.53 \times 10^4 \text{ W} . \quad <$$

The insulation inner surface temperature is given by

$$q = \frac{T_{s,i} - T_{\text{ins},i}}{L_1/k_1A} .$$

Hence

$$T_{\text{ins},i} = -q \frac{L_1}{k_1A} + T_{s,i} = -8.53 \times 10^4 \text{ W} \frac{0.08\text{ m}}{1.8\text{ W/m}\cdot\text{K} \times 16\text{m}^2} + 1700\text{ K} = 1463\text{ K} . \quad <$$

(c) To determine the required thickness  $L_1$  of the fire clay brick to reduce  $T_{\text{ins},i} = 1350\text{ K}$ , we keyed Eq. (4) into the IHT Workspace and found

$$L_1 = 0.13\text{ m} . \quad <$$

**COMMENTS:** (1) The accuracy of the calculations could be improved by re-evaluating thermophysical properties at more appropriate temperatures.

(2) Convection and radiation heat losses from the roof are comparable. The relative contribution of radiation increases with increasing  $T_{s,o}$ , and hence decreases with the addition of insulation.

(3) Note that with the insulation,  $T_{\text{ins},i} = 1463\text{ K}$  exceeds the melting point of aluminum (933 K). Hence, molten aluminum, which can seep through the refractory, would penetrate, and thereby degrade the insulation, under the specified conditions.

### PROBLEM 9.45

**KNOWN:** Diameter, thickness, emissivity and initial temperature of silicon wafer. Temperature of air and surrounding.

**FIND:** (a) Initial cooling rate, (b) Time required to achieve prescribed final temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat transfer from side of wafer, (2) Large surroundings, (3) Wafer may be treated as a lumped capacitance, (4) Constant properties, (5) Quiescent air.

**PROPERTIES:** Table A-1, Silicon ( $\bar{T} = 187^\circ\text{C} = 460\text{K}$ ):  $\rho = 2330 \text{ kg/m}^3$ ,  $c_p = 813 \text{ J/kg}\cdot\text{K}$ ,  $k = 87.8 \text{ W/m}\cdot\text{K}$ . Table A-4, Air ( $T_{f,i} = 175^\circ\text{C} = 448\text{K}$ ):  $\nu = 32.15 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0372 \text{ W/m}\cdot\text{K}$ ,  $\alpha = 46.8 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.686$ ,  $\beta = 0.00223 \text{ K}^{-1}$ .

**SOLUTION:** (a) Heat transfer is by natural convection and net radiation exchange from top and bottom surfaces. Hence, with  $A_s = \pi D^2/4 = 0.0177 \text{ m}^2$ ,

$$q = A_s \left[ (\bar{h}_t + \bar{h}_b)(T_i - T_\infty) + 2\epsilon\sigma(T_i^4 - T_{\text{sur}}^4) \right]$$

where the radiation flux is obtained from Eq. 1.7, and with  $L = A_s/P = 0.0375\text{m}$  and  $\text{Ra}_L = g\beta(T_i - T_\infty)L^3/\alpha\nu = 2.30 \times 10^5$ , the convection coefficients are obtained from Eqs. 9.30 and 9.32. Hence,

$$\bar{h}_t = \frac{k}{L} \left( 0.54 \text{Ra}_L^{1/4} \right) = \frac{0.0372 \text{ W/m}\cdot\text{K} \times 11.8}{0.0375\text{m}} = 11.7 \text{ W/m}^2\cdot\text{K}$$

$$\bar{h}_b = \frac{k}{L} \left( 0.52 \text{Ra}_L^{1/5} \right) = \frac{0.0372 \text{ W/m}\cdot\text{K} \times 6.14}{0.0375\text{m}} = 6.1 \text{ W/m}^2\cdot\text{K}$$

$$q = 0.0177 \text{ m}^2 \left[ (11.7 + 6.1) \text{ W/m}^2\cdot\text{K} (300\text{K}) + 2 \times 0.65 \times 5.67 \times 10^{-8} \text{ W/m}^2\cdot\text{K}^4 (598^4 - 298^4) \text{ K}^4 \right]$$

$$q = 0.0177 \text{ m}^2 \left[ (5350 + 8845) \text{ W/m}^2 \right] = 251 \text{ W} \quad <$$

(b) From the generalized lumped capacitance model, Eq. 5.15,

$$\rho c A_s \delta \frac{dT}{dt} = - \left[ (\bar{h}_t + \bar{h}_b)(T - T_\infty) + 2\epsilon\sigma(T^4 - T_{\text{sur}}^4) \right] A_s$$

$$\int_{T_i}^T dT = - \int_0^t \left[ \frac{(\bar{h}_t + \bar{h}_b)(T - T_\infty) + 2\epsilon\sigma(T^4 - T_{\text{sur}}^4)}{\rho c \delta} \right] dt$$

Continued .....

**PROBLEM 9.45 (Cont.)**

Using the DER function of IHT to perform the integration, thereby accounting for variations in  $\bar{h}_t$  and  $\bar{h}_b$  with T, the time  $t_f$  to reach a wafer temperature of 50°C is found to be

$$t_f (T = 323 \text{ K}) = 179 \text{ s}$$

<

As shown above, the rate at which the wafer temperature decays with increasing time decreases due to reductions in the convection and radiation heat fluxes. Initially, the surface radiative flux (top or bottom) exceeds the heat flux due to natural convection from the top surface, which is twice the flux due to natural convection from the bottom surface. However, because  $q''_{rad}$  and  $q''_{cnv}$  decay approximately as  $T^4$  and  $T^{5/4}$ , respectively, the reduction in  $q''_{rad}$  with decreasing T is more pronounced, and at  $t = 181\text{s}$ ,  $q''_{rad}$  is well below  $q''_{cnv,t}$  and only slightly larger than  $q''_{cnv,b}$ .

**COMMENTS:** With  $\bar{h}_{r,i} = \varepsilon\sigma(T_i + T_{sur})(T_i^2 + T_{sur}^2) = 14.7 \text{ W/m}^2 \cdot \text{K}$ , the largest cumulative coefficient of  $\bar{h}_{tot} = \bar{h}_{r,i} + \bar{h}_{t,i} = 26.4 \text{ W/m}^2 \cdot \text{K}$  corresponds to the top surface. If this coefficient is used to estimate a Biot number, it follows that  $Bi = \bar{h}_{tot}(\delta/2)/k = 1.5 \times 10^{-4} \ll 1$  and the lumped capacitance approximation is excellent.

## PROBLEM 9.46

**KNOWN:** Pyrex tile, initially at a uniform temperature  $T_i = 140^\circ\text{C}$ , experiences cooling by convection with ambient air and radiation exchange with surroundings.

**FIND:** (a) Time required for tile to reach the safe-to-touch temperature of  $T_f = 40^\circ\text{C}$  with free convection and radiation exchange; use  $\bar{T} = (T_i + T_f)/2$  to estimate the average free convection and linearized radiation coefficients; comment on how sensitive result is to this estimate, and (b) Time-to-cool if ambient air is blown in parallel flow over the tile with a velocity of 10 m/s.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Tile behaves as spacewise isothermal object, (2) Backside of tile is perfectly insulated, (3) Surroundings are large compared to the tile, (4) For forced convection situation, part (b), assume flow is fully turbulent.

**PROPERTIES:** Table A.3, Pyrex (300 K):  $\rho = 2225 \text{ kg/m}^3$ ,  $c_p = 835 \text{ J/kg}\cdot\text{K}$ ,  $k = 1.4 \text{ W/m}\cdot\text{K}$ ,  $\varepsilon = 0.80$  (given); Table A.4, Air ( $T_f = (\bar{T}_s + T_\infty)/2 = 330.5 \text{ K}$ , 1 atm):  $\nu = 18.96 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0286 \text{ W/m}\cdot\text{K}$ ,  $\alpha = 27.01 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.7027$ ,  $\beta = 1/T_f$ .

**ANALYSIS:** (a) For the lumped capacitance system with a constant coefficient, from Eq. 5.6,

$$\frac{T_s(t) - T_\infty}{T_i - T_\infty} = \exp\left[-\left(\frac{\bar{h}A_s}{\rho Vc}\right)t\right] \quad (1)$$

where  $\bar{h}$  is the combined coefficient for the convection and radiation processes,

$$\bar{h} = \bar{h}_{\text{cv}} + \bar{h}_{\text{rad}} \quad (2)$$

$$\text{and } A_s = L^2 \quad V = L^2d \quad (3,4)$$

The linearized radiation coefficient based upon the average temperature,  $\bar{T}_s$ , is

$$\bar{T}_s = (T_i + T_f)/2 = (140 + 40)^\circ\text{C}/2 = 90^\circ\text{C} = 363 \text{ K} \quad (5)$$

$$\bar{h}_{\text{rad}} = \varepsilon\sigma(\bar{T}_s + T_{\text{sur}})(\bar{T}_s^2 + T_{\text{sur}}^2) \quad (6)$$

$$\bar{h}_{\text{rad}} = 0.8 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (363 + 298)(363^2 + 298^2) \text{ K}^3 = 6.61 \text{ W/m}^2 \cdot \text{K}$$

The free convection coefficient can be estimated from the correlation for the flat plate, Eq. 9.30, with

$$\text{Ra}_L = \frac{g\beta\Delta TL^3}{\nu\alpha} \quad L = A_s/P = L^2/4L = 0.25L \quad (7,8)$$

Continued...

**PROBLEM 9.46 (Cont.)**

$$Ra_L = \frac{9.8 \text{ m/s}^2 (1/330 \text{ K})(363 - 298) \text{ K} (0.25 \times 0.200 \text{ m})^3}{18.96 \times 10^{-6} \text{ m}^2/\text{s} \times 27.01 \times 10^{-6} \text{ m}^2/\text{s}} = 4.712 \times 10^5$$

$$\overline{Nu}_L = 0.54 Ra_L^{1/4} = 0.54 (4.712 \times 10^5)^{1/4} = 14.18$$

$$\overline{h}_{cv} = \overline{Nu}_L k/L = 14.18 \times 0.0286 \text{ W/m} \cdot \text{K} / 0.25 \times 0.200 \text{ m} = 8.09 \text{ W/m}^2 \cdot \text{K}$$

From Eq. (2), it follows

$$\overline{h} = (6.61 + 8.09) \text{ W/m}^2 \cdot \text{K} = 14.7 \text{ W/m}^2 \cdot \text{K}$$

From Eq. (1), with  $A_s/V = 1/d$ , where  $d$  is the tile thickness, the time-to-cool is found as

$$\frac{40 - 25}{140 - 25} = \exp \left[ - \frac{14.7 \text{ W/m}^2 \cdot \text{K} \times t_f}{2225 \text{ kg/m}^3 \times 0.010 \text{ m} \times 835 \text{ J/kg} \cdot \text{K}} \right]$$

$$t_f = 2574 \text{ s} = 42.9 \text{ min} \quad \leftarrow$$

Using the *IHT Lumped Capacitance Model* with the *Correlations Tool, Free Convection, Flat Plate*, we can perform the analysis where both  $h_{cv}$  and  $h_{rad}$  are evaluated as a function of the tile temperature. The time-to-cool is

$$t_f = 2860 \text{ s} = 47.7 \text{ min} \quad \leftarrow$$

which is 10% higher than the approximate value.

(b) Considering parallel flow with a velocity,  $u_\infty = 10 \text{ m/s}$  over the tile, the Reynolds number is

$$Re_L = \frac{u_\infty L}{\nu} = \frac{10 \text{ m/s} \times 0.200 \text{ m}}{18.96 \times 10^{-6} \text{ m}^2/\text{s}} = 1.055 \times 10^5$$

but, assuming the flow is turbulent at the upstream edge, use Eq. 7.38 with  $A = 0$  to estimate  $\overline{h}_{cv}$ ,

$$\overline{Nu}_L = 0.037 Re_L^{4/5} Pr^{1/3} = 0.037 (1.055 \times 10^5)^{4/5} (0.7027)^{1/3} = 343.3$$

$$\overline{h}_{cv} = \overline{Nu}_L k/L = 343.3 \times 0.0286 \text{ W/m} \cdot \text{K} / 0.200 \text{ m} = 49.1 \text{ W/m}^2 \cdot \text{K}$$

Hence, using Eqs. (2) and (1), find

$$\overline{h} = 57.2 \text{ W/m}^2 \cdot \text{K} \quad t_f = 661 \text{ s} = 11.0 \text{ min} \quad \leftarrow$$

**COMMENTS:** (1) For the conditions of part (a),  $Bi = hd/k = 14.7 \text{ W/m}^2 \cdot \text{K} \times 0.01 \text{ m} / 1.4 \text{ W/m} \cdot \text{K} = 0.105$ . We conclude that the lumped capacitance analysis is marginally applicable. For the condition of part (b),  $Bi = 0.4$  and, hence, we need to consider spatial effects as explained in Section 5.4. If we considered spatial effects, would our estimates for the time-to-cool be greater or less than those from the foregoing analysis?

(2) For the conditions of part (a), the convection and radiation coefficients are shown in the plot below as a function of cooling time. Can you use this information to explain the relative magnitudes of the  $t_f$  estimates?

## PROBLEM 9.47

**KNOWN:** Stacked IC boards within a duct dissipating 500 W with prescribed air flow inlet temperature, flow rate, and internal convection coefficient. Outer surface has emissivity of 0.5 and is exposed to ambient air and large surroundings at 25°C.

**FIND:** Develop a model to estimate outlet temperature of the air,  $T_{m,o}$ , and the average surface temperature of the duct,  $\bar{T}_s$ , following these steps: (a) Estimate the average free convection for the outer surface,  $\bar{h}_o$ , assuming an average surface temperature of 37°C; (b) Estimate the average (linearized) radiation coefficient for the outer surface,  $\bar{h}_{rad}$ , assuming an average surface temperature of 37°C; (c) Perform an overall energy balance on the duct considering (i) advection of the air flow, (ii) dissipation of electrical power in the ICs, and (iii) heat transfer from the fluid to the ambient air and surroundings. Express the last process in terms of thermal resistances between the mean fluid temperature,  $\bar{T}_m$ , and the outer temperatures  $T_\infty$  and  $T_{sur}$ ; (d) Substituting numerical values into the expression of part (c), calculate  $T_{m,o}$  and  $\bar{T}_s$ ; comment on your results and the assumptions required to develop your model.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Air in duct is ideal gas with negligible viscous dissipation and pressure variation, (3) Constant properties, (4) Power dissipated in IC boards nearly uniform in longitudinal direction, (5) Ambient air is quiescent, and (5) Surroundings are isothermal and large relative to the duct.

**PROPERTIES:** Table A-4, Air ( $T_f = (\bar{T}_s + T_\infty)/2 = 304$  K):  $\nu = 1.629 \times 10^{-5}$  m<sup>2</sup>/s,  $\alpha = 2.309 \times 10^{-5}$  m<sup>2</sup>/s,  $k = 0.0266$  W/m·K,  $\beta = 0.003289$  K<sup>-1</sup>,  $Pr = 0.706$ ,  $\rho = 1.148$  kg/m<sup>3</sup>,  $c_p = 1007$  J/kg·K.

**ANALYSIS:** (a) *Average, free-convection coefficient over the duct.* Heat loss by free convection occurs on the vertical sides and horizontal top and bottom. The methodology for estimating the average coefficient assuming the average duct surface temperature  $\bar{T}_s = 37^\circ\text{C}$  follows that of Example 9.3. For the *vertical sides*, from Eq. 9.25 with  $L = H$ , find

$$Ra_L = \frac{g\beta(\bar{T}_s - T_\infty)H^3}{\nu\alpha}$$

$$Ra_L = \frac{9.8 \text{ m/s}^2 \times 0.003289 \text{ K}^{-1} (37 - 25) \text{ K} \times (0.150 \text{ m})^3}{1.629 \times 10^{-5} \text{ m}^2/\text{s} \times 2.309 \times 10^{-5} \text{ m}^2/\text{s}} = 3.47 \times 10^6$$

The free convection is laminar, and from Eq. 9.27,

$$\overline{Nu}_L = 0.68 + \frac{0.670 Ra_L^{1/4}}{\left[1 + (0.492/Pr)^{9/16}\right]^{4/9}}$$

Continued.....

**PROBLEM 9.47 (Cont.)**

$$\overline{\text{Nu}}_L = \frac{\bar{h}_v H}{k} = 0.68 + \frac{0.670 \times (3.47 \times 10^6)^{1/4}}{\left[1 + (0.492/0.706)^{9/16}\right]^{4/9}} = 22.9$$

$$\bar{h}_v = 4.05 \text{ W/m}^2 \cdot \text{K}$$

For the top and bottom surfaces,  $L_c = (A_s/P) = (w \times L)/(2w + 2L) = 0.0577 \text{ m}$ , hence,  $\text{Ra}_L = 1.974 \times 10^5$  and with Eqs. 9.30 and 9.32, respectively,

$$\text{Top surface:} \quad \overline{\text{Nu}}_L = \frac{\bar{h}_t L_c}{k} = 0.54 \text{ Ra}_L^{1/4}; \quad \bar{h}_t = 5.25 \text{ W/m}^2 \cdot \text{K}$$

$$\text{Bottom surface:} \quad \overline{\text{Nu}}_L = \frac{\bar{h}_b L_c}{k} = 0.52 \text{ Ra}_L^{1/5}; \quad \bar{h}_b = 2.75 \text{ W/m}^2 \cdot \text{K}$$

The average coefficient for the entire duct is

$$\bar{h}_{\text{cv},o} = (2\bar{h}_v + \bar{h}_t + \bar{h}_b)/4 = (2 \times 4.05 + 5.25 + 2.75) \text{ W/m}^2 \cdot \text{K}/4 = 4.03 \text{ W/m}^2 \cdot \text{K} \quad <$$

(b) *Average (linearized) radiation coefficient over the duct.* Heat loss by radiation exchange between the duct outer surface and the surroundings on the vertical sides and horizontal top and bottom. With  $\bar{T}_s = 37^\circ\text{C}$ , from Eq. 1.9,

$$\bar{h}_{\text{rad}} = \varepsilon \sigma (\bar{T}_s + T_{\text{sur}}) (\bar{T}_s^2 + T_{\text{sur}}^2)$$

$$\bar{h}_{\text{rad}} = 0.5 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (310 + 298) (310^2 + 298^2) \text{ K}^3 = 3.2 \text{ W/m}^2 \cdot \text{K} \quad <$$

(c) *Overall energy balance on the fluid in the duct.* The control volume is shown in the schematic below and the energy balance is

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} + \dot{E}_{\text{gen}} = 0$$

$$-q_{\text{adv}} + P_{\text{elec}} - q_{\text{out}} = 0 \quad (1)$$

The advection term has the form, with  $\dot{m} = \dot{V}\rho$ ,

$$q_{\text{adv}} = \dot{m} c_p (T_{m,o} - T_{m,i}) \quad (2)$$

and the heat rate  $q_{\text{out}}$  is represented by the thermal circuit shown below and has the form, with  $T_{\text{sur}} = T_\infty$ ,

$$q_{\text{out}} = \frac{\bar{T}_m - T_\infty}{R_{\text{cv},i} + (1/R_{\text{cv},o} + 1/R_{\text{rad}})^{-1}} \quad (3)$$

where  $\bar{T}_m$  is the average mean temperature of the fluid,  $(T_{m,i} + T_{m,o})/2$ . The thermal resistances are evaluated with  $A_s = 2(w + H)L = 0.3 \text{ m}^2$  as

$$R_{\text{cv},i} = 1/\bar{h}_i A_s \quad (4)$$

$$R_{\text{cv},o} = 1/\bar{h}_{\text{cv},o} A_s \quad (5)$$

$$R_{\text{rad}} = 1/\bar{h}_{\text{rad}} A_s \quad (6)$$

Continued ...

### PROBLEM 9.47 (Cont.)

Using this energy balance, the outlet temperature of the air can be calculated. From the thermal circuit, the average surface temperature can be calculated from the relation

$$q_{\text{out}} = (\bar{T}_m - \bar{T}_s) / R_{\text{cv},i} \quad (7)$$

(d) *Calculating  $T_{m,o}$  and  $\bar{T}_s$ .* Substituting numerical values into the expressions of Part (c), find

$$T_{m,o} = 45.7^\circ\text{C} \quad \bar{T}_s = 34.0^\circ\text{C} \quad <$$

The heat rates and thermal resistance results are

$$\begin{aligned} q_{\text{adv}} &= 480.5 \text{ W} & q_{\text{out}} &= 19.5 \text{ W} \\ R_{\text{cv},i} &= 0.0667 \text{ K/W} & R_{\text{cv},o} &= 0.827 \text{ K/W} & R_{\text{rad}} &= 1.05 \text{ K/W} \end{aligned}$$

**COMMENTS:** (1) We assumed  $\bar{T}_s = 37^\circ\text{C}$  for estimating  $\bar{h}_{\text{cv},o}$  and  $\bar{h}_{\text{rad}}$ , whereas from the energy balance we found the value was  $34.0^\circ\text{C}$ . Performing an iterative solution, with different assumed  $\bar{T}_s$  we would find that the results are not sensitive to the  $\bar{T}_s$  value, and that the foregoing results are satisfactory.

(2) From the results of Part (d) for the heat rates, note that about 4% of the electrical power is transferred from the duct outer surface. The present arrangement does not provide a practical means to cool the IC boards.

(3) Note that  $T_{m,i} < T_s < T_{m,o}$ . As such, we can't utilize the usual log-mean temperature (LMTD) expression, Eq. 8.44, in the rate equation for the internal flow analysis. It is for this reason we used the overall coefficient approach representing the heat transfer by the thermal circuit. The average surface temperature of the duct,  $\bar{T}_s$ , is only used for the purposes of estimating  $\bar{h}_{\text{cv},o}$  and  $\bar{h}_{\text{rad}}$ . We represented the effective temperature difference between the fluid and the ambient/surroundings as  $\bar{T}_m - T_\infty$ . Because the fluid temperature rise is not very large, this assumption is a reasonable one.

### PROBLEM 9.48

**KNOWN:** Parallel flow of air over a highly polished aluminum plate flat plate maintained at a uniform temperature  $T_s = 47^\circ\text{C}$  by a series of segmented heaters.

**FIND:** (a) Electrical power required to maintain the heater segment covering the section between  $x_1 = 0.2$  m and  $x_2 = 0.3$  m and (b) Temperature that the surface would reach if the air blower malfunctions and heat transfer occurs by free, rather than forced, convection.

**SCHEMATIC:**

**ASSUMPTIONS :** (1) Steady-state conditions, (2) Backside of plate is perfectly insulated, (3) Flow is turbulent over the entire length of plate, part (a), (4) Ambient air is extensive, quiescent at  $23^\circ\text{C}$  for part (b).

**PROPERTIES:** Table A.4, Air ( $T_f = (T_s + T_\infty)/2 = 308\text{K}$ ):  $\nu = 16.69 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.02689 \text{ W/m}\cdot\text{K}$ ,  $\alpha = 23.68 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.7059$ ,  $\beta = 1/T_f$ ; Table A.12, Aluminum, highly polished:  $\varepsilon = 0.03$ .

**ANALYSIS:** (a) The power required to maintain the segmented heater ( $x_1 - x_2$ ) is

$$P_e = \bar{h}_{x_1-x_2} (x_2 - x_1) w (T_s - T_\infty) \quad (1)$$

where  $\bar{h}_{x_1-x_2}$  is the average coefficient for the section between  $x_1$  and  $x_2$ , and can be approximated as the average of the local values at  $x_1$  and  $x_2$ ,

$$\bar{h}_{x_1-x_2} = (h(x_1) + h(x_2))/2 \quad (2)$$

Using Eq. 7.36 appropriate for fully turbulent flow, with  $\text{Re}_x = u_\infty x / \nu$ ,

$$\text{Nu}_{x_1} = 0.0296 \text{Re}_x^{4/5} \text{Pr}^{1/3}$$

$$\text{Nu}_{x_1} = 0.0296 \left( \frac{10 \text{ m/s} \times 0.2 \text{ m}}{16.69 \times 10^{-6} \text{ m}^2/\text{s}} \right)^{4/5} (0.7059)^{1/3} = 304.6$$

$$h_{x_1} = \text{Nu}_{x_1} k / x_1 = 304.6 \times 0.02689 \text{ W/m}\cdot\text{K} / 0.2 \text{ m} = 40.9 \text{ W/m}^2\cdot\text{K}$$

$$\text{Nu}_{x_2} = 421.3 \quad h_{x_2} = 37.8 \text{ W/m}^2\cdot\text{K}$$

Hence, from Eq (2) to obtain  $\bar{h}_{x_1-x_2}$  and Eq. (1) to obtain  $P_e$ ,

$$\bar{h}_{x_1-x_2} = (40.9 + 37.8) \text{ W/m}^2\cdot\text{K} / 2 = 39.4 \text{ W/m}^2\cdot\text{K}$$

$$P_e = 39.4 \text{ W/m}^2\cdot\text{K} (0.3 - 0.2) \text{ m} \times 0.2 \text{ m} (47 - 23)^\circ\text{C} = 18.9 \text{ W}$$

<

Continued...

**PROBLEM 9.48 (Cont.)**

(b) Without the airstream flow, the heater segment experiences free convection and radiation exchange with the surroundings,

$$P_e = \left[ \bar{h}_{cv} (T_s - T_\infty) + \varepsilon \sigma (T_s^4 - T_{sur}^4) \right] (x_2 - x_1) w \quad (3)$$

We will assume that the free convection coefficient,  $\bar{h}_{cv}$ , for the segment is the same as that for the entire plate. Using the correlation for a flat plate, Eq. 9.30, with

$$Ra_L = \frac{g\beta\Delta T L_c^3}{\nu\alpha} \quad L_c = \frac{A_s}{P} = \frac{0.2 \times 0.5 \text{ m}^2}{2(0.2 + 0.5) \text{ m}} = 0.0714 \text{ m}$$

and evaluating properties at  $T_f = 308 \text{ K}$ ,

$$Ra_L = \frac{9.8 \text{ m/s}^2 (1/308 \text{ K})(47 - 23)(0.0714 \text{ m})^3}{16.69 \times 10^{-6} \text{ m}^2/\text{s}^2 \times 23.68 \times 10^{-6} \text{ m}^2/\text{s}} = 7.033 \times 10^5$$

$$\overline{Nu}_L = 0.54 Ra_L^{1/4} = 0.54 (7.033 \times 10^5)^{1/4} = 15.64$$

$$\bar{h}_{cv} = \overline{Nu}_L k / L_c = 15.64 \times 0.02689 \text{ W/m} \cdot \text{K} / 0.0714 \text{ m} = 5.89 \text{ W/m}^2 \cdot \text{K}$$

Substituting numerical values into Eq. (3),

$$18.9 \text{ W} = \left[ 5.89 \text{ W/m}^2 \cdot \text{K} (T_s - 296) + 0.03 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (T_s^4 - 296^4) \right] (0.3 - 0.2) \text{ m} \times 0.2 \text{ m}$$

$$T_s = 447 \text{ K} = 174^\circ \text{C} \quad \leftarrow$$

**COMMENTS:** Recognize that in part (b), the assumed value for  $T_f = 308 \text{ K}$  is a poor approximation. Using the above relations in the IHT work space with the *Properties Tool*, find that  $T_s = 406 \text{ K} = 133^\circ \text{C}$  using the properly evaluated film temperature ( $T_f$ ) and temperature difference ( $\Delta T$ ) in the correlation. From this analysis,  $\bar{h}_{cv} = 8.29 \text{ W/m}^2 \cdot \text{K}$  and  $h_{rad} = 0.3 \text{ W/m}^2 \cdot \text{K}$ . Because of the low emissivity of the plate, the radiation exchange process is not significant.

### PROBLEM 9.49

**KNOWN:** Correlation for estimating the average free convection coefficient for the exterior surface of a long horizontal rectangular cylinder (duct) exposed to a quiescent fluid. Consider a horizontal 0.15 m-square duct with a surface temperature of 35°C passing through ambient air at 15°C.

**FIND:** (a) Calculate the average convection coefficient and the heat rate per unit length using the H-D correlation, (b) Calculate the average convection coefficient and the heat rate per unit length considering the duct as formed by vertical plates (sides) and horizontal plates (top and bottom), and (c) Using an appropriate correlation, calculate the average convection coefficient and the heat rate per unit length for a duct of circular cross-section having a diameter equal to the wetted perimeter of the rectangular duct of part (a). Do you expect the estimates for parts (b) and (c) to be lower or higher than those obtained with the H-D correlation? Explain the differences, if any.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Ambient air is quiescent, (3) Duct surface has uniform temperature.

**PROPERTIES:** Table A-4, air ( $T_f = (T_s + T_\infty)/2 = 298$  K, 1 atm):  $\nu = 1.571 \times 10^{-5}$  m<sup>2</sup>/s,  $k = 0.0261$  W/m·K,  $\alpha = 2.22 \times 10^{-5}$  m<sup>2</sup>/s,  $Pr = 0.708$ .

**ANALYSIS:** (a) The Hahn-Didion (H-D) correlation [ASHRAE Proceedings, Part 1, pp 262-67, 1972] has the form

$$\overline{Nu}_p = 0.55 Ra_p^{1/4} \left( \frac{H}{p} \right)^{1/8} \quad Ra_p \leq 10^7$$

where the characteristic length is the half-perimeter,  $p = (w + H)$ , and  $w$  and  $H$  are the horizontal width and vertical height, respectively, of the duct. The thermophysical properties are evaluated at the film temperature. Using *IHT*, with the correlation and thermophysical properties, the following results were obtained.

$Ra_p$	$\overline{Nu}_p$	$\overline{h}_p$ (W/m <sup>2</sup> ·K)	$q'_p$ (W/m)	<
$5.08 \times 10^7$	42.6	3.71	44.5	

where the heat rate per unit length of the duct is

$$q'_p = \overline{h}_p 2(H + w)(T_s - T_\infty).$$

(b) Treating the duct as a combination of horizontal (*top*: hot-side up and *bottom*: hot-side down) and two vertical plates (*v*) as considered in Example 9.3, the following results were obtained

$\overline{h}_t$	$\overline{h}_b$	$\overline{h}_v$	$\overline{h}_{hv}$	$q'_{hv}$	<
(W/m <sup>2</sup> ·K)	(W/m <sup>2</sup> ·K)	(W/m <sup>2</sup> ·K)	(W/m <sup>2</sup> ·K)	(W/m)	
5.62	2.81	4.78	4.50	54.0	

Continued...

### PROBLEM 9.49 (Cont.)

where the average coefficient and heat rate per unit length for the horizontal-vertical plate duct are

$$\bar{h}_{hv} = (\bar{h}_t + \bar{h}_b + 2\bar{h}_v) / 4$$

$$q'_{hv} = \bar{h}_{hv} 2(H + w)(T_s - T_\infty).$$

(c) Consider a circular duct having a wetted perimeter equal to that of the rectangular duct, for which the diameter is

$$\pi D = 2(H + w) \qquad D = 0.191 \text{ m}$$

Using the Churchill-Chu correlation, Eq. 9.34, the following results are obtained.

$Ra_D$	$\overline{Nu}_D$	$\bar{h}_D \left( W / m^2 \cdot K \right)$	$q'_D \left( W / m \right)$	
$1.31 \times 10^7$	30.6	4.19	50.3	<

where the heat rate per unit length for the circular duct is

$$q'_D = \pi D \bar{h}_D (T_s - T_\infty).$$

**COMMENTS:** (1) The H-D correlation, based upon experimental measurements, provided the lowest estimate for  $\bar{h}$  and  $q'$ . The circular duct analysis results are in closer agreement than are those for the horizontal-vertical plate duct.

(2) An explanation for the relative difference in  $\bar{h}$  and  $q'$  values can be drawn from consideration of the boundary layers and induced flows around the surfaces. Viewing the cross-section of the square duct, recognize that flow induced by the bottom surface flows around the vertical sides, joining the vertical plume formed on the top surface. The flow over the vertical sides is quite different than would occur if the vertical surface were modeled as an *isolated* vertical surface. Also, flow from the top surface is likewise modified by flow rising from the sides, and doesn't behave as an *isolated* horizontal surface. It follows that treating the duct as a combination of horizontal-vertical plates (hv results), each considered as *isolated*, would over estimate the average coefficient and heat rate.

(3) It follows that flow over the horizontal cylinder more closely approximates the situation of the square duct. However, the flow is more streamlined; thinnest along the bottom, and of increasing thickness as the flow rises and eventually breaks away from the upper surface. The edges of the duct disrupt the rising flow, lowering the convection coefficient. As such, we expect the horizontal cylinder results to be systematically higher than for the H-D correlation that accounts for the edges.

## PROBLEM 9.50

**KNOWN:** Dimensions, emissivity and operating temperatures of a wood burning stove. Temperature of ambient air and surroundings.

**FIND:** Rate of heat transfer.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, (2) Quiescent air, (3) Negligible heat transfer from pipe elbow, (4) Free convection from pipe corresponds to that from a vertical plate.

**PROPERTIES:** Table A.4, air ( $T_f = 400$  K):  $\nu = 26.41 \times 10^{-6}$  m<sup>2</sup>/s,  $k = 0.0338$  W/m·K,  $\alpha = 38.3 \times 10^{-6}$  m<sup>2</sup>/s,  $\beta = 0.0025$  K<sup>-1</sup>,  $Pr = 0.69$ . Table A.4, air ( $T_f = 350$  K):  $\nu = 20.92 \times 10^{-6}$  m<sup>2</sup>/s,  $k = 0.030$  W/m·K,  $\alpha = 29.9 \times 10^{-6}$  m<sup>2</sup>/s,  $Pr = 0.70$ ,  $\beta = 0.00286$  K<sup>-1</sup>.

**ANALYSIS:** Three distinct contributions to the heat rate are made by the 4 side walls, the top surface, and the pipe surface. Hence  $q_t = 4q_s + q_t + q_p$ , where each contribution includes transport due to convection and radiation.

$$q_s = \bar{h}_s L_s^2 (T_{s,s} - T_\infty) + h_{\text{rad},s} L_s^2 (T_{s,s} - T_{\text{sur}})$$

$$q_t = \bar{h}_t L_s^2 (T_{s,s} - T_\infty) + h_{\text{rad},s} L_s^2 (T_{s,s} - T_{\text{sur}})$$

$$q_p = \bar{h}_p (\pi D_p L_p) (T_{s,p} - T_\infty) + h_{\text{rad},p} (\pi D_p L_p) (T_{s,p} - T_{\text{sur}})$$

The radiation coefficients are

$$h_{\text{rad},s} = \varepsilon \sigma (T_{s,s} + T_{\text{sur}}) (T_{s,s}^2 + T_{\text{sur}}^2) = 12.3 \text{ W/m}^2 \cdot \text{K}$$

$$h_{\text{rad},p} = \varepsilon \sigma (T_{s,p} + T_{\text{sur}}) (T_{s,p}^2 + T_{\text{sur}}^2) = 7.9 \text{ W/m}^2 \cdot \text{K}$$

For the stove side walls,  $Ra_{L,s} = g\beta (T_{s,s} - T_\infty) L_s^3 / \alpha \nu = 4.84 \times 10^9$ . Similarly, with  $(A_s/P) = L_s^2 / 4L_s = 0.25$  m,  $Ra_{L,t} = 7.57 \times 10^7$  for the top surface, and with  $L_p = 2$  m,  $Ra_{L,p} = 3.59 \times 10^{10}$  for the stove pipe.

For the side walls and the pipe, the average convection coefficient may be determined from Eq. 9.26,

$$\bar{Nu}_L = \left\{ 0.825 + \frac{0.387 Ra_L^{1/6}}{\left[ 1 + (0.492/Pr)^{9/16} \right]^{8/27}} \right\}^2$$

Continued...

### PROBLEM 9.50 (Cont.)

which yields  $\overline{\text{Nu}}_{L,s} = 199.9$  and  $\overline{\text{Nu}}_{L,p} = 377.6$ . For the top surface, the average coefficient may be obtained from Eq. 9.31,

$$\overline{\text{Nu}}_L = 0.15\text{Ra}_L^{1/3}$$

which yields  $\overline{\text{Nu}}_{L,t} = 63.5$ . With  $\bar{h} = \overline{\text{Nu}}(k/L)$ , the convection coefficients are

$$\bar{h}_s = 6.8 \text{ W/m}^2 \cdot \text{K}, \quad \bar{h}_t = 8.6 \text{ W/m}^2 \cdot \text{K}, \quad \bar{h}_p = 5.7 \text{ W/m}^2 \cdot \text{K}$$

Hence,

$$q_s = (\bar{h}_s + h_{\text{rad},s})L_s^2(T_{s,s} - 300 \text{ K}) = 19.1 \text{ W/m}^2 \cdot \text{K} (1 \text{ m}^2)(200 \text{ K}) = 3820 \text{ W}$$

$$q_t = (\bar{h}_t + h_{\text{rad},s})L_s^2(T_{s,s} - 300 \text{ K}) = 20.9 \text{ W/m}^2 \cdot \text{K} (1 \text{ m}^2)(200 \text{ K}) = 4180 \text{ W}$$

$$q_p = (\bar{h}_p + h_{\text{rad},p})(\pi D_p L_p)(T_{s,p} - 300 \text{ K}) = 13.6 \text{ W/m}^2 \cdot \text{K} (\pi \times 0.25 \text{ m} \times 2 \text{ m})(100 \text{ K}) = 2140 \text{ W}$$

and the total heat rate is

$$q_{\text{tot}} = 4q_s + q_t + q_p = 21,600 \text{ W}$$

<

**COMMENTS:** The amount of heat transfer is significant, and the stove would be capable of maintaining comfortable conditions in a large, living space under harsh (cold) environmental conditions.

### PROBLEM 9.51

**KNOWN:** Plate,  $1\text{ m} \times 1\text{ m}$ , inclined at  $45^\circ$  from the vertical is exposed to a net radiation heat flux of  $300\text{ W/m}^2$ ; backside of plate is insulated and ambient air is at  $0^\circ\text{C}$ .

**FIND:** Temperature plate reaches for the prescribed conditions.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Net radiation heat flux ( $300\text{ W/m}^2$ ) includes exchange with surroundings, (2) Ambient air is quiescent, (3) No heat losses from backside of plate, (4) Steady-state conditions.

**PROPERTIES:** Table A-4, Air (assuming  $T_s = 84^\circ\text{C}$ ,  $T_f = (T_s + T_\infty)/2 = (84 + 0)^\circ\text{C}/2 = 315\text{ K}$ , 1 atm):  $\nu = 17.40 \times 10^{-6}\text{ m}^2/\text{s}$ ,  $k = 0.0274\text{ W/m}\cdot\text{K}$ ,  $\alpha = 24.7 \times 10^{-6}\text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.705$ ,  $\beta = 1/T_f$ .

**ANALYSIS:** From an energy balance on the plate, it follows that  $q''_{\text{rad}} = q''_{\text{conv}}$ . That is, the net radiation heat flux into the plate is equal to the free convection heat flux to the ambient air. The temperature of the surface can be expressed as

$$T_s = T_\infty + q''_{\text{rad}} / \bar{h}_L \quad (1)$$

where  $\bar{h}_L$  must be evaluated from an appropriate correlation. Since this is the *bottom surface of a heated inclined plate*, “ $g$ ” may be replaced by “ $g \cos \theta$ ”; hence using Eq. 9.25, find

$$\text{Ra}_L = \frac{g \cos \theta \beta (T_s - T_\infty) L^3}{\nu \alpha} = \frac{9.8\text{ m/s}^2 \times \cos 45^\circ (1/315\text{ K})(84 - 0)\text{ K} (1\text{ m})^3}{17.40 \times 10^{-6}\text{ m}^2/\text{s} \times 24.7 \times 10^{-6}\text{ m}^2/\text{s}} = 4.30 \times 10^9.$$

Since  $\text{Ra}_L > 10^9$ , conditions are turbulent and Eq. 9.26 is appropriate for estimating  $\overline{\text{Nu}}_L$

$$\overline{\text{Nu}}_L = \left\{ 0.825 + \frac{0.387 \text{Ra}_L^{1/6}}{\left[ 1 + (0.492/\text{Pr})^{9/16} \right]^{8/27}} \right\}^2 \quad (2)$$

$$\overline{\text{Nu}}_L = \left\{ 0.825 + \frac{0.387 (4.30 \times 10^9)^{1/6}}{\left[ 1 + (0.492/0.705)^{9/16} \right]^{8/27}} \right\}^2 = 193.2$$

$$\bar{h}_L = \overline{\text{Nu}}_L k / L = 193.2 \times 0.0274\text{ W/m}\cdot\text{K} / 1\text{ m} = 5.29\text{ W/m}^2\cdot\text{K}. \quad (3)$$

Substituting  $\bar{h}_L$  from Eq. (3) into Eq. (1), the plate temperature is

$$T_s = 0^\circ\text{C} + 300\text{ W/m}^2 / 5.29\text{ W/m}^2\cdot\text{K} = 57^\circ\text{C}. \quad <$$

**COMMENTS:** Note that the resulting value of  $T_s \approx 57^\circ\text{C}$  is substantially lower than the assumed value of  $84^\circ\text{C}$ . The calculation should be repeated with a new estimate of  $T_s$ , say,  $60^\circ\text{C}$ . An alternate approach is to write Eq. (2) in terms of  $T_s$ , the unknown surface temperature and then combine with Eq. (1) to obtain an expression which can be solved, by trial-and-error, for  $T_s$ .

## PROBLEM 9.52

**KNOWN:** Horizontal rod immersed in water maintained at a prescribed temperature.

**FIND:** Free convection heat transfer rate per unit length of the rod,  $q'_{\text{conv}}$

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Water is extensive, quiescent medium.

**PROPERTIES:** Table A-6, Water ( $T_f = (T_s + T_\infty)/2 = 310\text{K}$ ):  $\rho = 1/v_f = 993.0\text{ kg/m}^3$ ,  $\nu = \mu/\rho = 695 \times 10^{-6}\text{ N}\cdot\text{s/m}^2/993.0\text{ kg/m}^3 = 6.999 \times 10^{-7}\text{ m}^2/\text{s}$ ,  $\alpha = k/\rho c = 0.628\text{ W/m}\cdot\text{K}/993.0\text{ kg/m}^3 \times 4178\text{ J/kg}\cdot\text{K} = 1.514 \times 10^{-7}\text{ m}^2/\text{s}$ ,  $\text{Pr} = 4.62$ ,  $\beta = 361.9 \times 10^{-6}\text{ K}^{-1}$ .

**ANALYSIS:** The heat rate per unit length by free convection is given as

$$q'_{\text{conv}} = \bar{h}_D \cdot \pi D (T_s - T_\infty). \quad (1)$$

To estimate  $\bar{h}_D$ , first find the Rayleigh number, Eq. 9.25,

$$\text{Ra}_D = \frac{g \beta (T_s - T_\infty) D^3}{\nu \alpha} = \frac{9.8\text{ m/s}^2 (361.9 \times 10^{-6}\text{ K}^{-1}) (56 - 18)\text{ K} (0.005\text{ m})^3}{6.999 \times 10^{-7}\text{ m}^2/\text{s} \times 1.514 \times 10^{-7}\text{ m}^2/\text{s}} = 1.587 \times 10^5$$

and use Eq. 9.34 for a horizontal cylinder,

$$\bar{\text{Nu}}_D = \left\{ 0.60 + \frac{0.387 \text{Ra}_D^{1/6}}{\left[ 1 + (0.599/\text{Pr})^{9/16} \right]^{8/27}} \right\}^2$$

$$\bar{\text{Nu}}_D = \left\{ 0.60 + \frac{0.387 (1.587 \times 10^5)^{1/6}}{\left[ 1 + (0.599/4.62)^{9/16} \right]^{8/27}} \right\}^2 = 10.40$$

$$\bar{h}_D = \bar{\text{Nu}}_D k / D = 10.40 \times 0.628\text{ W/m}\cdot\text{K} / 0.005\text{ m} = 1306\text{ W/m}^2\cdot\text{K}. \quad (2)$$

Substituting for  $\bar{h}_D$  from Eq. (2) into Eq. (1),

$$q'_{\text{conv}} = 1306\text{ W/m}^2\cdot\text{K} \times \pi (0.005\text{ m}) (56 - 18)\text{ K} = 780\text{ W/m}. \quad <$$

**COMMENTS:** (1) Note the relatively large value of  $\bar{h}_D$ ; if the rod were immersed in air, the heat transfer coefficient would be close to  $5\text{ W/m}^2\cdot\text{K}$ .

(2) Eq. 9.33 with appropriate values of  $C$  and  $n$  from Table 9.1 could also be used to estimate  $\bar{h}_D$ . Find

$$\bar{\text{Nu}}_D = C \text{Ra}_D^n = 0.48 (1.587 \times 10^5)^{0.25} = 9.58$$

$$\bar{h}_D = \bar{\text{Nu}}_D k / D = 9.58 \times 0.628\text{ W/m}\cdot\text{K} / 0.005\text{ m} = 1203\text{ W/m}^2\cdot\text{K}.$$

By comparison with the result of Eq. (2), the disparity of the estimates is ~8%.

### PROBLEM 9.53

**KNOWN:** Horizontal, uninsulated steam pipe passing through a room.

**FIND:** Heat loss per unit length from the pipe.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Pipe surface is at uniform temperature, (2) Air is quiescent medium, (3) Surroundings are large compared to pipe.

**PROPERTIES:** Table A-4, Air ( $T_f = (T_s + T_\infty)/2 = 350 \text{ K}$ , 1 atm):  $\nu = 20.92 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.030 \text{ W/m}\cdot\text{K}$ ,  $\alpha = 29.9 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.700$ ,  $\beta = 1/T_f = 2.857 \times 10^{-3} \text{ K}^{-1}$ .

**ANALYSIS:** Recognizing that the heat loss from the pipe will be by free convection to the air and by radiation exchange with the surroundings, we can write

$$q' = q'_{\text{conv}} + q'_{\text{rad}} = \pi D \left[ \bar{h}_D (T_s - T_\infty) + \epsilon \sigma (T_s^4 - T_{\text{sur}}^4) \right]. \quad (1)$$

To estimate  $\bar{h}_D$ , first find  $\text{Ra}_L$ , Eq. 9.25, and then use the correlation for a horizontal cylinder, Eq. 9.34,

$$\text{Ra}_L = \frac{g \beta (T_s - T_\infty) D^3}{\nu \alpha} = \frac{9.8 \text{ m/s}^2 (1/350 \text{ K}) (400 - 300) \text{ K} (0.150 \text{ m})^3}{20.92 \times 10^{-6} \text{ m}^2/\text{s} \times 29.9 \times 10^{-6} \text{ m}^2/\text{s}} = 1.511 \times 10^7$$

$$\bar{\text{Nu}}_D = \left\{ 0.60 + \frac{0.387 \text{ Ra}_L^{1/6}}{\left[ 1 + (0.559/\text{Pr})^{9/16} \right]^{8/27}} \right\}^2$$

$$\bar{\text{Nu}}_D = \left\{ 0.60 + \frac{0.387 (1.511 \times 10^7)^{1/6}}{\left[ 1 + (0.559/0.700)^{9/16} \right]^{8/27}} \right\}^2 = 31.88$$

$$\bar{h}_D = \bar{\text{Nu}}_D \cdot k / D = 31.88 \times 0.030 \text{ W/m}\cdot\text{K} / 0.15 \text{ m} = 6.38 \text{ W/m}^2 \cdot \text{K}. \quad (2)$$

Substituting for  $\bar{h}_D$  from Eq. (2) into Eq. (1), find

$$q' = \pi (0.150 \text{ m}) \left[ 6.38 \text{ W/m}^2 \cdot \text{K} (400 - 300) \text{ K} + 0.85 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (400^4 - 300^4) \text{ K}^4 \right]$$

$$q' = 301 \text{ W/m} + 397 \text{ W/m} = 698 \text{ W/m}. \quad \leftarrow$$

**COMMENTS:** (1) Note that for this situation, heat transfer by radiation and free convection are of equal importance.

(2) Using Eq. 9.33 with constants  $C, n$  from Table 9.1, the estimate for  $\bar{h}_D$  is

$$\bar{\text{Nu}}_D = C \text{ Ra}_L^n = 0.125 (1.511 \times 10^7)^{0.333} = 30.73$$

$$\bar{h}_D = \bar{\text{Nu}}_D k / D = 30.73 \times 0.030 \text{ W/m}\cdot\text{K} / 0.150 \text{ m} = 6.15 \text{ W/m}^2 \cdot \text{K}.$$

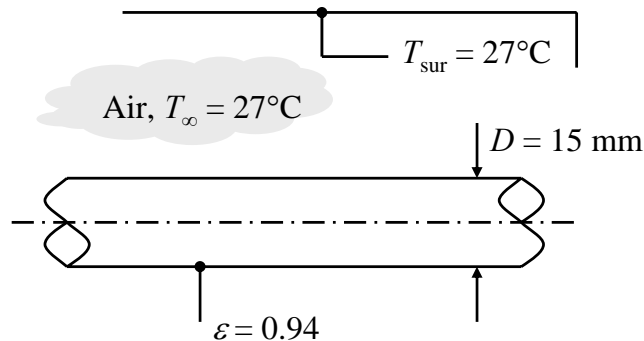

The agreement is within 4% of the Eq. 9.34 result.

## PROBLEM 9.54

**KNOWN:** Diameter and emissivity of horizontal glass cylinder. Temperature of air and surroundings.

**FIND:** Temperature at which lumped capacitance approximation may be applied.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) The quasi-steady approximation holds: the heat transfer coefficient can be evaluated based on steady-state conditions, (2) Air properties can be evaluated at 350 K, (3) Radiation is to large surroundings.

**PROPERTIES:** Table A-3, Glass ( $T = 300$  K):  $k_g = 1.4$  W/m·K; Table A-4, Air ( $T = 350$  K):  $\nu = 20.92 \times 10^{-6}$  m<sup>2</sup>/s,  $\alpha = 29.9 \times 10^{-6}$  m<sup>2</sup>/s,  $k = 30 \times 10^{-3}$  W/m·K,  $Pr = 0.700$ ,  $\beta = 1/T_s = 1/(350$  K) = 0.00286 K<sup>-1</sup>.

**ANALYSIS:** The largest heat transfer coefficient for which the lumped capacitance approximation is valid can be found from  $Bi = 0.1$ , where the characteristic length is the cylinder radius,  $r_o$ . In this case, the heat transfer coefficient should be the effective value that includes both convection and radiation,

$$h_{\text{eff}} = \bar{h} + h_r \quad (1)$$

Therefore, with  $Bi = h_{\text{eff}}D/k_g$ ,

$$h_{\text{eff}} = 0.2 \frac{k_g}{D} = 0.2 \frac{1.4 \text{ W/m} \cdot \text{K}}{0.015 \text{ m}} = 18.67 \text{ W/m}^2 \cdot \text{K} \quad (2)$$

The radiation heat transfer coefficient is given by

$$h_r = \varepsilon \sigma (T_s + T_{\text{sur}})(T_s^2 + T_{\text{sur}}^2) \quad (3)$$

The free convection heat transfer coefficient can be found from the Churchill-Chu correlation,

$$\overline{Nu}_D = \frac{\bar{h}D}{k} = \left\{ 0.60 + \frac{0.387 Ra_D^{1/6}}{\left[ 1 + (0.559 / Pr)^{9/16} \right]^{8/27}} \right\}^2 \quad (4)$$

Continued...

### PROBLEM 9.54 (Cont.)

where the Rayleigh number is:

$$Ra_D = \frac{g\beta(T_s - T_\infty)D^3}{\nu\alpha} \quad (5)$$

Equations (1)-(5) can be solved for the unknowns, including the surface temperature. This can easily be done using *IHT*, but it can also be solved by hand as follows. We begin by taking  $T_s = 400$  K for the purpose of estimating the radiation heat transfer coefficient of Eq. (3):

$$\begin{aligned} h_r &= \varepsilon\sigma(T_s + T_{\text{sur}})(T_s^2 + T_{\text{sur}}^2) \\ &= 0.94 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times (400 + 300)\text{K} \times (400^2 + 300^2)\text{K}^2 = 9.33 \text{ W/m}^2 \cdot \text{K} \end{aligned}$$

From Eqs. (1) and (2),  $\bar{h} = h_{\text{eff}} - h_r = (18.67 - 9.33) \text{ W/m}^2 \cdot \text{K} = 9.34 \text{ W/m}^2 \cdot \text{K}$  and

$$\overline{Nu}_D = \frac{\bar{h}D}{k} = \frac{9.34 \text{ W/m}^2 \cdot \text{K} \times 0.015 \text{ m}}{30 \times 10^{-3} \text{ W/m} \cdot \text{K}} = 4.67$$

Then Eq. (4) can be solved for  $Ra_D$ ,

$$\begin{aligned} Ra_D &= \left\{ \frac{1}{0.387} \left( \sqrt{\overline{Nu}_D} - 0.60 \right) \left[ 1 + (0.559/Pr)^{9/16} \right]^{8/27} \right\}^6 \\ &= \left\{ \frac{1}{0.387} \left( \sqrt{4.67} - 0.60 \right) \left[ 1 + (0.559/0.707)^{9/16} \right]^{8/27} \right\}^6 = 13,200 \end{aligned}$$

Eq. (5) can now be solved for  $T_s$ :

$$T_s = T_\infty + Ra_D \frac{\nu\alpha}{g\beta D^3} = 300 \text{ K} + 13,200 \times \frac{20.92 \times 10^{-6} \text{ m}^2/\text{s} \times 29.9 \times 10^{-6} \text{ m}^2/\text{s}}{9.8 \text{ m/s}^2 \times 0.00286 \text{ K}^{-1} \times (0.015 \text{ m})^3} = 388 \text{ K}$$

This is reasonably close to the initial assumption of  $T_s = 400$  K. Greater accuracy could be obtained by repeating the calculations with the new estimate of  $T_s$  and evaluating air properties at the film temperature. Repeated iterations converge on  $T_s = 395$  K, thus the lumped capacitance approximation is valid for  $T_s < 395$  K. <

**COMMENTS:** (1) Because of the relatively small thermal conductivity of glass, the effective heat transfer coefficient must be fairly small,  $18.67 \text{ W/m}^2 \cdot \text{K}$ , for the lumped capacitance approximation to be valid. (2) The conclusion that lumped capacitance is valid for  $T_s < 395$  K requires further evaluation. If the rod is initially hotter than 395 K, it would be subject to large spatial temperature gradients in the initial stages of cooling. When the temperature meets the Biot criterion, there would still be residual temperature gradients in the rod from the preceding cooling period, so the lumped capacitance method might never be applicable.

### PROBLEM 9.55

**KNOWN:** Dimensions and temperature of beer can in refrigerator compartment.

**FIND:** Orientation which maximizes cooling rate.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) End effects are negligible, (2) Compartment air is quiescent, (3) Constant properties.

**PROPERTIES:** Table A-4, Air ( $T_f = 288.5\text{K}$ , 1 atm):  $\nu = 14.87 \times 10^{-6} \text{m}^2/\text{s}$ ,  $k = 0.0254 \text{W/m}\cdot\text{K}$ ,  $\alpha = 21.0 \times 10^{-6} \text{m}^2/\text{s}$ ,  $\text{Pr} = 0.71$ ,  $\beta = 1/T_f = 3.47 \times 10^{-3} \text{K}^{-1}$ .

**ANALYSIS:** The ratio of cooling rates may be expressed as

$$\frac{q_v}{q_h} = \frac{\bar{h}_v \pi D L (T_s - T_{\infty})}{\bar{h}_h \pi D L (T_s - T_{\infty})} = \frac{\bar{h}_v}{\bar{h}_h}.$$

For the *vertical* surface, find

$$\text{Ra}_L = \frac{g\beta(T_s - T_{\infty})L^3}{\nu\alpha} = \frac{9.8 \text{m/s}^2 \times 3.47 \times 10^{-3} \text{K}^{-1} (23^{\circ}\text{C})}{(14.87 \times 10^{-6} \text{m}^2/\text{s})(21 \times 10^{-6} \text{m}^2/\text{s})} L^3 = 2.5 \times 10^9 L^3$$

$$\text{Ra}_L = 2.5 \times 10^9 (0.15)^3 = 8.44 \times 10^6,$$

and using the correlation of Eq. 9.26, 
$$\bar{\text{Nu}}_L = \left\{ 0.825 + \frac{0.387 (8.44 \times 10^6)^{1/6}}{[1 + (0.492/0.71)^{9/16}]^{8/27}} \right\}^2 = 29.7.$$

Hence 
$$\bar{h}_L = \bar{h}_v = \bar{\text{Nu}}_L \frac{k}{L} = 29.7 \frac{0.0254 \text{W/m}\cdot\text{K}}{0.15\text{m}} = 5.03 \text{W/m}^2 \cdot \text{K}.$$

For the *horizontal* surface, find 
$$\text{Ra}_D = \frac{g\beta(T_s - T_{\infty})D^3}{\nu\alpha} = 2.5 \times 10^9 (0.06)^3 = 5.4 \times 10^5$$

and using the correlation of Eq. 9.34, 
$$\bar{\text{Nu}}_D = \left\{ 0.60 + \frac{0.387 (5.4 \times 10^5)^{1/6}}{[1 + (0.559/0.71)^{9/16}]^{8/27}} \right\}^2 = 12.24$$

$$\bar{h}_D = \bar{h}_h = \bar{\text{Nu}}_D \frac{k}{D} = 12.24 \frac{0.0254 \text{W/m}\cdot\text{K}}{0.06\text{m}} = 5.18 \text{W/m}^2 \cdot \text{K}.$$

Hence 
$$\frac{q_v}{q_h} = \frac{5.03}{5.18} = 0.97.$$

<

**COMMENTS:** In view of the uncertainties associated with Eqs. 9.26 and 9.34 and the neglect of end effects, the above result is inconclusive. The cooling rates are approximately the same.

## PROBLEM 9.56

**KNOWN:** A long uninsulated steam line with a diameter of 89 mm and surface emissivity of 0.8 transports steam at 200°C and is exposed to atmospheric air and large surroundings at an equivalent temperature of 20°C.

**FIND:** (a) The heat loss per unit length for a calm day when the ambient air temperature is 20°C; (b) The heat loss on a breezy day when the wind speed is 8 m/s; and (c) For the conditions of part (a), calculate the heat loss with 20-mm thickness of insulation ( $k = 0.08 \text{ W/m}\cdot\text{K}$ ). Would the heat loss change significantly with an appreciable wind speed?

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Calm day corresponds to quiescent ambient conditions, (3) Breeze is in crossflow over the steam line, (4) Atmospheric air and large surroundings are at the same temperature; and (5) Emissivity of the insulation surface is 0.8.

**PROPERTIES:** Table A-4, Air ( $T_f = (T_s + T_{\infty})/2 = 383 \text{ K}$ , 1 atm):  $\nu = 2.454 \times 10^{-5} \text{ m}^2/\text{s}$ ,  $k = 0.03251 \text{ W/m}\cdot\text{K}$ ,  $\alpha = 3.544 \times 10^{-5} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.693$ .

**ANALYSIS:** (a) The heat loss per unit length from the pipe by convection and radiation exchange with the surroundings is

$$q'_b = q'_{cv} + q'_{rad}$$

$$q'_b = \bar{h}_D P_b (T_{s,b} - T_{\infty}) + \varepsilon P_b \sigma (T_{s,b}^4 - T_{\infty}^4) \quad P_b = \pi D_b \quad (1,2)$$

where  $D_b$  is the diameter of the bare pipe. Using the Churchill-Chu correlation, Eq. 9.34, for free convection from a horizontal cylinder, estimate  $\bar{h}_D$

$$\overline{\text{Nu}}_D = \frac{\bar{h}_D D_b}{k} = \left\{ 0.60 + \frac{0.387 \text{ Ra}_D^{1/6}}{\left[ 1 + (0.559/\text{Pr})^{9/16} \right]^{8/27}} \right\}^2 \quad (3)$$

where properties are evaluated at the film temperature,  $T_f = (T_s + T_{\infty})/2$  and

$$\text{Ra}_D = \frac{g\beta(T_s - T_{\infty})D_b^3}{\nu\alpha} \quad (4)$$

Substituting numerical values, find for the *bare* steam line

$\text{Ra}_D$	$\overline{\text{Nu}}_D$	$\bar{h}_D \text{ (W/m}^2\cdot\text{K)}$	$q'_{cv} \text{ (W/m)}$	$q'_{rad} \text{ (W/m)}$	$q'_b \text{ (W/m)}$	<
$3.73 \times 10^6$	21.1	7.71	388	541	929	

Continued ...

**PROBLEM 9.56 (Cont.)**

(b) For forced convection conditions with  $V = 8$  m/s, use the Churchill-Bernstein correlation, Eq. 7.54,

$$\overline{\text{Nu}}_D = \frac{\bar{h}_D D_b}{k} = 0.3 + \frac{0.62 \text{Re}_D^{1/2} \text{Pr}^{1/3}}{\left[1 + (0.4/\text{Pr})^{2/3}\right]^{1/4}} \left[1 + \left(\frac{\text{Re}_D}{282,000}\right)^{5/8}\right]^{4/5}$$

where  $\text{Re}_D = VD/v$ . Substituting numerical values, find

$\text{Re}_D$	$\overline{\text{Nu}}_D$	$\bar{h}_{D,b}$ (W/m <sup>2</sup> ·K)	$q'_{cv}$ (W/m)	$q'_{rad}$ (W/m)	$q'_b$ (W/m)
$2.90 \times 10^4$	97.7	35.7	1800	541	2340

(c) With 20-mm thickness insulation, and for the calm-day condition, the heat loss per unit length is

$$q'_{ins} = (T_{s,o} - T_\infty) / R'_{tot} \quad (1)$$

$$R'_t = R'_{ins} + [1/R'_{cv} + 1/R'_{rad}]^{-1} \quad (2)$$

where the thermal resistance of the insulation from Eq. 3.33 is

$$R'_{ins} = \ell \ln(D_o / D_b) / [2\pi k] \quad (3)$$

and the convection and radiation thermal resistances are

$$R'_{cv} = 1 / (\bar{h}_{D,o} \pi D_o) \quad (4)$$

$$R'_{rad} = 1 / (\bar{h}_{rad} \pi D_o) \quad \bar{h}_{rad,o} = \varepsilon \sigma (T_{s,o} + T_\infty) (T_{s,o}^2 + T_\infty^2) \quad (5,6)$$

The outer surface temperature of the insulation,  $T_{s,o}$ , can be determined by an energy balance on the *surface node* of the thermal circuit.

$$\frac{T_{s,b} - T_{s,o}}{R'_{ins}} = \frac{T_{s,o} - T_\infty}{[1/R'_{cv} + 1/R'_{rad}]^{-1}}$$

Substituting numerical values with  $D_{b,o} = 129$  mm, find the following results.

$R'_{ins} = 0.7384$ m·K/W	$\bar{h}_{D,o} = 5.30$ W/m <sup>2</sup> ·K
$R'_{cv} = 0.4655$ K/W	$\bar{h}_{rad} = 5.65$ W/m <sup>2</sup> ·K
$R'_{rad} = 0.4371$ K/W	$q'_{ins} = 187$ W/m
$T_{s,o} = 62.1^\circ\text{C}$	

Continued ...

### PROBLEM 9.56 (Cont.)

**COMMENTS:** (1) For the calm-day conditions, the heat loss by radiation exchange is 58% of the total loss. Using a reflective shield (say,  $\varepsilon = 0.1$ ) on the outer surface could reduce the heat loss by 50%.

(2) The effect of a 8-m/s breeze over the steam line is to increase the heat loss by more than a factor of two above that for a calm day. The heat loss by radiation exchange is approximately 25% of the total loss.

(3) The effect of the 20-mm thickness insulation is to reduce the heat loss to 20% the rate by free convection or to 9% the rate on the breezy day. From the results of part (c), note that the insulation resistance is nearly 3 times that due to the combination of the convection and radiation process thermal resistances. The effect of increased wind speed is to reduce  $R'_{cv}$ , but since  $R'_{ins}$  is the dominant resistance, the effect will not be very significant.

(4) The convection correlation models in *IHT* are especially useful for applications such as the present one to eliminate the tediousness of evaluating properties and performing the calculations. However, it is essential that you have experiences in hand calculations with the correlations before using the software.

### PROBLEM 9.57

**KNOWN:** Length and diameter of tube submerged in paraffin of prescribed dimensions. Properties of paraffin. Inlet temperature, flow rate and properties of water in the tube.

**FIND:** (a) Water outlet temperature, (b) Heat rate, (c) Time for complete melting.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Water is incompressible liquid with negligible viscous dissipation, (2) Constant properties for water and paraffin, (3) Negligible tube wall conduction resistance, (4) Free convection at outer surface associated with horizontal cylinder in an infinite quiescent medium, (5) Negligible heat loss to surroundings, (6) Fully developed flow in tube.

**PROPERTIES:** Water (given):  $c_p = 4185 \text{ J/kg}\cdot\text{K}$ ,  $k = 0.653 \text{ W/m}\cdot\text{K}$ ,  $\mu = 467 \times 10^{-6} \text{ kg/s}\cdot\text{m}$ ,  $\text{Pr} = 2.99$ ; Paraffin (given):  $T_{mp} = 27.4^\circ\text{C}$ ,  $h_{sf} = 244 \text{ kJ/kg}$ ,  $k = 0.15 \text{ W/m}\cdot\text{K}$ ,  $\beta = 8 \times 10^{-4} \text{ K}^{-1}$ ,  $\rho = 770 \text{ kg/m}^3$ ,  $\nu = 5 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\alpha = 8.85 \times 10^{-8} \text{ m}^2/\text{s}$ .

**ANALYSIS:** (a) The overall heat transfer coefficient is

$$\frac{1}{U} = \frac{1}{h_i} + \frac{1}{h_o}$$

To estimate  $h_i$ , find  $\text{Re}_D = \frac{4\dot{m}}{\pi D \mu} = \frac{4 \times 0.1 \text{ kg/s}}{\pi \times 0.025 \text{ m} \times 467 \times 10^{-6} \text{ kg/s}\cdot\text{m}} = 10,906$

and noting the flow is turbulent, use the Dittus-Boelter correlation

$$\text{Nu}_D = 0.023 \text{Re}_D^{4/5} \text{Pr}^{0.3} = 0.023(10,906)^{4/5} (2.99)^{0.3} = 54.3$$

$$h_i = \frac{\text{Nu}_D k}{D} = \frac{54.3 \times 0.653 \text{ W/m}\cdot\text{K}}{0.025 \text{ m}} = 1418 \text{ W/m}^2 \cdot \text{K}$$

To estimate  $h_o$ , find

$$\text{Ra}_D = \frac{g\beta(T_s - T_\infty)D^3}{\nu\alpha} = \frac{(9.8 \text{ m/s}^2)8 \times 10^{-4} \text{ K}^{-1}(55 - 27.4) \text{ K}(0.025 \text{ m})^3}{5 \times 10^{-6} \text{ m}^2/\text{s} \times 8.85 \times 10^{-8} \text{ m}^2/\text{s}}$$

$$\text{Ra}_D = 7.64 \times 10^6$$

and using the correlation of Eq. 9.34,  $\overline{\text{Nu}}_D = \left\{ 0.60 + \frac{0.387 \text{Ra}_D^{1/6}}{\left[ 1 + (0.559/\text{Pr})^{9/16} \right]^{8/27}} \right\}^2 = 35.0$

$$h_o = \overline{\text{Nu}}_D \frac{k}{D} = 35.0 \frac{0.15 \text{ W/m}\cdot\text{K}}{0.025 \text{ m}} = 210 \text{ W/m}^2 \cdot \text{K}$$

Alternatively, using the correlation of Eq. 9.33,

Continued ...

**PROBLEM 9.57 (Cont.)**

$$\text{Nu}_D = C\text{Ra}_D^n \text{ with } C = 0.48, n = 0.25 \quad \text{Nu}_D = 25.2$$

$$h_o = 25.2 \frac{0.15 \text{ W/m} \cdot \text{K}}{0.025 \text{ m}} = 151 \text{ W/m}^2 \cdot \text{K}.$$

The significant difference in  $h_o$  values for the two correlations may be due to difficulties associated with high Pr applications of one or both correlations. Continuing with the result from Eq. 9.34,

$$\frac{1}{\bar{U}} = \frac{1}{h_i} + \frac{1}{h_o} = \frac{1}{1418} + \frac{1}{210} = 5.467 \times 10^{-3} \text{ m}^2 \cdot \text{K} / \text{W}$$

$$\bar{U} = 183 \text{ W/m}^2 \cdot \text{K}.$$

Using Eq. 8.45a, find

$$\frac{T_\infty - T_{m,o}}{T_\infty - T_{m,i}} = \exp\left(-\frac{\pi D L \bar{U}}{\dot{m} c_p}\right) = \exp\left(-\frac{\pi \times 0.025 \text{ m} \times 3 \text{ m}}{0.1 \text{ kg/s} \times 4185 \text{ J/kg} \cdot \text{K}} 183 \frac{\text{W}}{\text{m}^2 \cdot \text{K}}\right)$$

$$T_{m,o} = T_\infty - (T_\infty - T_{m,i}) 0.902 = [27.4 - (27.4 - 60) 0.902]^\circ\text{C}$$

$$T_{m,o} = 56.8^\circ\text{C}. \quad <$$

(b) From an energy balance, the heat rate is

$$q = \dot{m} c_p (T_{m,i} - T_{m,o}) = 0.1 \text{ kg/s} \times 4185 \text{ J/kg} \cdot \text{K} (60 - 56.8) \text{ K} = 1335 \text{ W} \quad <$$

or using the rate equation,

$$q = \bar{U} A \Delta T_{\ell m} = 183 \text{ W/m}^2 \cdot \text{K} \pi (0.025 \text{ m}) 3 \text{ m} \frac{(60 - 27.4) \text{ K} - (56.8 - 27.4) \text{ K}}{\ln \frac{60 - 27.4}{56.8 - 27.4}}$$

$$q = 1335 \text{ W}.$$

(c) Applying an energy balance to a control volume about the paraffin,

$$E_{\text{in}} = \Delta E_{\text{st}}$$

$$q \cdot t = \rho V h_{\text{sf}} = \rho L \left[ WH - \pi D^2 / 4 \right] h_{\text{sf}}$$

$$t = \frac{770 \text{ kg/m}^3 \times 3 \text{ m}}{1335 \text{ W}} \left[ (0.25 \text{ m})^2 - \frac{\pi}{4} (0.025 \text{ m})^2 \right] 2.44 \times 10^5 \text{ J/kg}$$

$$t = 2.618 \times 10^4 \text{ s} = 7.27 \text{ h}. \quad <$$

**COMMENTS:** (1) The value of  $\bar{h}_o$  is overestimated by assuming an infinite quiescent medium. The fact that the paraffin is enclosed will increase the resistance due to free convection and hence decrease  $q$  and increase  $t$ .

(2) Using  $\bar{h}_o = 151 \text{ W/m}^2 \cdot \text{K}$  results in  $\bar{U} = 136 \text{ W/m}^2 \cdot \text{K}$ ,  $T_{m,o} = 57.6^\circ\text{C}$ ,  $q = 1009 \text{ W}$  and  $t = 9.62 \text{ h}$ .

### PROBLEM 9.58

**KNOWN:** Horizontal tube, 12.5mm diameter, with surface temperature 240°C located in room with an air temperature 20°C.

**FIND:** Heat transfer rate per unit length of tube due to convection.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Ambient air is quiescent, (2) Surface radiation effects are not considered.

**PROPERTIES:** Table A-4, Air ( $T_f = 400\text{K}$ , 1 atm):  $\nu = 26.41 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0338 \text{ W/m}\cdot\text{K}$ ,  $\alpha = 38.3 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.690$ ,  $\beta = 1/T_f = 2.5 \times 10^{-3} \text{ K}^{-1}$ .

**ANALYSIS:** The heat rate from the tube, per unit length of the tube, is

$$q' = \bar{h} \pi D (T_s - T_\infty)$$

where  $\bar{h}$  can be estimated from the correlation, Eq. 9.34,

$$\overline{\text{Nu}}_D = \left\{ 0.60 + \frac{0.387 \text{Ra}_D^{1/6}}{\left[ 1 + (0.559/\text{Pr})^{9/16} \right]^{8/27}} \right\}^2$$

From Eq. 9.25,

$$\text{Ra}_D = \frac{g\beta(T_s - T_\infty)D^3}{\nu\alpha} = \frac{9.8 \text{ m/s}^2 \times 2.5 \times 10^{-3} \text{ K}^{-1} (240 - 20) \text{ K} \times (12.5 \times 10^{-3} \text{ m})^3}{26.41 \times 10^{-6} \text{ m}^2/\text{s} \times 38.3 \times 10^{-6} \text{ m}^2/\text{s}} = 10,410.$$

$$\text{Hence, } \overline{\text{Nu}}_D = \left\{ 0.60 + \frac{0.387 (10,410)^{1/6}}{\left[ 1 + (0.559/0.690)^{9/16} \right]^{8/27}} \right\}^2 = 4.40$$

$$\bar{h} = \frac{k}{D} \overline{\text{Nu}}_D = \frac{0.0338 \text{ W/m}\cdot\text{K}}{12.5 \times 10^{-3} \text{ m}} \times 4.40 = 11.9 \text{ W/m}^2 \cdot \text{K}.$$

The heat rate is

$$q' = 11.9 \text{ W/m}^2 \cdot \text{K} \times \pi (12.5 \times 10^{-3} \text{ m}) (240 - 20) \text{ K} = 103 \text{ W/m}. \quad <$$

**COMMENTS:** Heat loss rate by radiation, assuming an emissivity of 1.0 for the surface, is

$$q'_{\text{rad}} = \varepsilon P \sigma (T_s^4 - T_\infty^4) = 1 \times \pi (12.5 \times 10^{-3} \text{ m}) \times 5.67 \times 10^{-8} \frac{\text{W}}{\text{m}^2 \cdot \text{K}^4} \left[ (240 + 273)^4 - (20 + 273)^4 \right] \text{ K}^4$$

$$q'_{\text{rad}} = 138 \text{ W/m}.$$

Note that  $P = \pi D$ . Note also this estimate assumes the surroundings are at ambient air temperature. In this instance,  $q'_{\text{rad}} > q'_{\text{conv}}$ .

## PROBLEM 9.59

**KNOWN:** Insulated steam tube exposed to atmospheric air and surroundings at 25°C.

**FIND:** (a) Heat transfer rate by free convection to the room, per unit length of the tube; effect on quality,  $x$ , at outlet of 30 m length of tube; (b) Effect of radiation on heat transfer and quality of outlet flow; (c) Effect of emissivity and insulation thickness on heat rate.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Ambient air is quiescent, (2) Negligible surface radiation (part a), (3) Tube wall resistance negligible.

**PROPERTIES:** Steam tables, steam (sat., 4 bar):  $i_f = 566$  kJ/kg,  $T_{sat} = 416$  K,  $i_g = 2727$  kJ/kg,  $i_{fg} = h_{fg} = 2160$  kJ/kg,  $v_g = 0.476$  m<sup>3</sup>/kg; Table A.3, magnesia, 85% (310 K):  $k_m = 0.051$  W/m·K; Table A.4, air (assume  $T_s = 60^\circ\text{C}$ ,  $T_f = (60 + 25)^\circ\text{C}/2 = 315$  K, 1 atm):  $\nu = 17.4 \times 10^{-6}$  m<sup>2</sup>/s,  $k = 0.0274$  W/m·K,  $\alpha = 24.7 \times 10^{-6}$  m<sup>2</sup>/s,  $Pr = 0.705$ ,  $T_f = 1/315$  K =  $3.17 \times 10^{-3}$  K<sup>-1</sup>.

**ANALYSIS:** (a) The heat rate per unit length of the tube (see sketch) is given as,

$$q' = \frac{T_i - T_\infty}{R'_t} \quad \text{where} \quad \frac{1}{R'_t} = \left[ \frac{1}{\bar{h}_o \pi D_3} + \frac{1}{2\pi k_m} \ln \frac{D_3}{D_2} + \frac{1}{\bar{h}_i \pi D_1} \right]^{-1} \quad (1,2)$$

To estimate  $\bar{h}_o$ , we have assumed  $T_s \approx 60^\circ\text{C}$  in order to calculate  $Ra_D$  from Eq. 9.25,

$$Ra_D = \frac{g\beta(T_s - T_\infty)D_3^3}{\nu\alpha} = \frac{9.8 \text{ m/s}^2 \times 3.17 \times 10^{-3} \text{ K}^{-1} (60 - 25) \text{ K} (0.115 \text{ m})^3}{17.4 \times 10^{-6} \text{ m}^2/\text{s} \times 24.7 \times 10^{-6} \text{ m}^2/\text{s}} = 3.85 \times 10^6.$$

The appropriate correlation is Eq. 9.34; find

$$\bar{Nu}_D = \left\{ 0.60 + \frac{0.387(Ra_D)^{1/6}}{\left[ 1 + (0.559/Pr)^{9/16} \right]^{8/27}} \right\}^2 = \left\{ 0.60 + \frac{0.387(3.85 \times 10^6)^{1/6}}{\left[ 1 + (0.559/0.705)^{9/16} \right]^{8/27}} \right\}^2 = 21.4$$

$$\bar{h}_o = \frac{k}{D_3} \bar{Nu}_D = \frac{0.0274 \text{ W/m} \cdot \text{K}}{0.115 \text{ m}} \times 21.4 = 5.09 \text{ W/m}^2 \cdot \text{K}.$$

Substituting numerical values into Eq. (2), find

$$\frac{1}{R'_t} = \left[ \frac{1}{5.09 \text{ W/m}^2 \cdot \text{K} \times \pi \times 0.115 \text{ m}} + \frac{1}{2\pi \times 0.051 \text{ W/m} \cdot \text{K}} \ln \frac{115}{65} + \frac{1}{11,000 \text{ W/m}^2 \cdot \text{K} \times \pi \times 0.055 \text{ m}} \right]^{-1} = 0.430 \text{ W/m} \cdot \text{K}$$

and from Eq. (1),  $q' = 0.430 \text{ W/m} \cdot \text{K} (416 - 298) \text{ K} = 50.8 \text{ W/m}$  <

Continued...

### PROBLEM 9.59 (Cont.)

We need to verify that the assumption of  $T_s = 60^\circ\text{C}$  is reasonable. From the thermal circuit,

$$T_s = T_\infty + q'/\bar{h}_o \pi D_3 = 25^\circ\text{C} + 50.8 \text{ W/m} / \left( 5.09 \text{ W/m}^2 \cdot \text{K} \times \pi \times 0.115 \text{ m} \right) = 53^\circ\text{C}.$$

Another calculation using  $T_s = 53^\circ\text{C}$  would be appropriate for a more precise result.

Assuming  $q'$  is constant, the enthalpy of the steam at the outlet ( $L = 30 \text{ m}$ ),  $i_2$ , is

$$i_2 = i_1 - q' \cdot L/\dot{m} = 2727 \text{ kJ/kg} - 50.8 \text{ W/m} \times 30 \text{ m} / 0.015 \text{ kg/s} = 2625 \text{ kJ/kg}$$

where  $\dot{m} = \rho_g A_c u_m$  with  $\rho_g = 1/v_g$  and  $A_c = \pi D_1^2/4$ . For negligible pressure drop,

$$x = (i_2 - i_f)/i_{fg} = (2625 - 566) \text{ kJ/kg} / (2160 \text{ kJ/kg}) = 0.953. \quad <$$

(b) With radiation, we first determine  $T_s$  by performing an energy balance at the outer surface, where

$$q'_i = q'_{\text{conv},o} + q'_{\text{rad}}$$

$$\frac{T_i - T_s}{R'_i} = \bar{h}_o \pi D_3 (T_s - T_\infty) + \pi D_3 \varepsilon \sigma (T_s^4 - T_{\text{sur}}^4)$$

and

$$R'_i = \frac{1}{h_i \pi D_1} + \frac{1}{2\pi k_m} \ln \frac{D_3}{D_2}$$

From knowledge of  $T_s$ ,  $q'_i = (T_i - T_s)/R'_i$  may then be determined. Using the *Correlations* and *Properties* Tool Pads of IHT to determine  $\bar{h}_o$  and the properties of air evaluated at  $T_f = (T_s + T_\infty)/2$ , the following results are obtained.

	Condition	$T_s$ ( $^\circ\text{C}$ )	$q'_i$ (W/m)	x	
	$\varepsilon = 0.8, D_3 = 115 \text{ mm}$	41.8	56.9	0.948	<
(c)	$\varepsilon = 0.8, D_3 = 165 \text{ mm}$	33.7	37.6	0.966	<
	$\varepsilon = 0.2, D_3 = 115 \text{ mm}$	49.4	52.6	0.952	<
	$\varepsilon = 0.2, D_3 = 165 \text{ mm}$	38.7	35.9	0.967	<

**COMMENTS:** Clearly, a significant reduction in heat loss may be realized by increasing the insulation thickness. Although  $T_s$ , and hence  $q'_{\text{conv},o}$ , increases with decreasing  $\varepsilon$ , the reduction in  $q'_{\text{rad}}$  is more than sufficient to reduce the heat loss.

### PROBLEM 9.60

**KNOWN:** Dissipation rate of an electrical cable suspended in air.

**FIND:** Surface temperature of the cable,  $T_s$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Quiescent air, (2) Cable in horizontal position, (3) Negligible radiation exchange.

**PROPERTIES:** Table A-4, Air ( $T_f = (T_s + T_\infty)/2 = 325\text{K}$ , based upon initial estimate for  $T_s$ , 1 atm):  
 $\nu = 18.41 \times 10^{-6}\ \text{m}^2/\text{s}$ ,  $k = 0.0282\ \text{W/m}\cdot\text{K}$ ,  $\alpha = 26.2 \times 10^{-6}\ \text{m}^2/\text{s}$ ,  $\text{Pr} = 0.704$ .

**ANALYSIS:** From the rate equation on a unit length basis, the surface temperature is

$$T_s = T_\infty + q' / \pi D \bar{h}$$

where  $\bar{h}$  is estimated by an appropriate correlation. Since such a calculation requires knowledge of  $T_s$ , an iteration procedure is required. Begin by assuming  $T_s = 77^\circ\text{C}$  and calculated  $\text{Ra}_D$ ,

$$\text{Ra}_D = g\beta\Delta T D^3 / \nu\alpha \quad \text{where } \Delta T = T_s - T_\infty \quad \text{and} \quad T_f = (T_s + T_\infty)/2 \quad (1,2,3)$$

For air,  $\beta = 1/T_f$ , and substituting numerical values,

$$\text{Ra}_D = 9.8 \frac{\text{m}}{\text{s}^2} (1/325\text{K})(77 - 27)\text{K} (0.025\text{m})^3 / 18.41 \times 10^{-6} \frac{\text{m}^2}{\text{s}} \times 26.2 \times 10^{-6} \frac{\text{m}^2}{\text{s}} = 4.884 \times 10^4.$$

Using the Churchill-Chu relation, find  $\bar{h}$ .

$$\overline{\text{Nu}}_D = \frac{\bar{h}D}{k} = \left\{ 0.60 + \frac{0.387 \text{Ra}_D^{1/6}}{\left[ 1 + (0.559/\text{Pr})^{9/16} \right]^{8/27}} \right\}^2 \quad (4)$$

$$\bar{h} = \frac{0.0282\ \text{W/m}\cdot\text{K}}{0.025\text{m}} \left\{ 0.60 + \frac{0.387 (4.884 \times 10^4)^{1/6}}{\left[ 1 + (0.559/0.704)^{9/16} \right]^{8/27}} \right\}^2 = 7.28\ \text{W/m}^2 \cdot \text{K}.$$

Substituting numerical values into Eq. (1), the calculated value for  $T_s$  is

$$T_s = 27^\circ\text{C} + (30\ \text{W/m}) / \pi \times 0.025\text{m} \times 7.28\ \text{W/m}^2 \cdot \text{K} = 79.5^\circ\text{C}.$$

This value is very close to the assumed value ( $77^\circ\text{C}$ ), but an iteration with a new value of  $79^\circ\text{C}$  is warranted. Using the same property values, find for this iteration:

$$\text{Ra}_D = 5.08 \times 10^4 \quad \bar{h} = 7.35\ \text{W/m}^2 \cdot \text{K} \quad T_s = 79^\circ\text{C}. \quad <$$

We conclude that  $T_s = 79^\circ\text{C}$  is a good estimate for the surface temperature.

**COMMENTS:** Recognize that radiative exchange is likely to be significant and would have the effect of reducing the estimate for  $T_s$ .

### PROBLEM 9.61

**KNOWN:** Dissipation rate of an immersion heater in a large tank of water.

**FIND:** Surface temperature in water and, if accidentally operated, in air.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Quiescent ambient fluid, (2) Negligible radiative exchange.

**PROPERTIES:** Table A-6, Water and Table A-4, Air:

	T(K)	$k \cdot 10^3$ (W/m·K)	$\nu \cdot 10^7$ ( $\mu/\rho, \text{m}^2/\text{s}$ )	$\alpha \cdot 10^7$ ( $k/\rho c_p, \text{m}^2/\text{s}$ )	Pr	$\beta \cdot 10^6$ ( $\text{K}^{-1}$ )
Water	315	634	6.25	1.531	4.16	400.4
Air	1500	100	2400	3500	0685	666.7

**ANALYSIS:** From the rate equation, the surface temperature,  $T_s$ , is

$$T_s = T_\infty + q / (\pi D L \bar{h}) \quad (1)$$

where  $\bar{h}$  is estimated by an appropriate correlation. Since such a calculation requires knowledge of  $T_s$ , an iteration procedure is required. Begin by assuming for *water* that  $T_s = 64^\circ\text{C}$  such that  $T_f = 315\text{K}$ . Calculate the Rayleigh number,

$$\text{Ra}_D = \frac{g\beta\Delta T D^3}{\nu\alpha} = \frac{9.8\text{m/s}^2 \times 400.4 \times 10^{-6} \text{K}^{-1} (64 - 20) \text{K} (0.010\text{m})^3}{6.25 \times 10^{-7} \text{m}^2/\text{s} \times 1.531 \times 10^{-7} \text{m}^2/\text{s}} = 1.804 \times 10^6. \quad (2)$$

Using the Churchill-Chu relation, find

$$\overline{\text{Nu}}_D = \frac{\bar{h}D}{k} = \left\{ 0.60 + \frac{0.387 \text{Ra}_D^{1/6}}{\left[ 1 + (0.559/\text{Pr})^{9/16} \right]^{8/27}} \right\}^2 \quad (3)$$

$$\bar{h} = \frac{0.634 \text{W/m}\cdot\text{K}}{0.01\text{m}} \left\{ 0.60 + \frac{0.387 (1.804 \times 10^6)^{1/6}}{\left[ 1 + (0.559/4.16)^{9/16} \right]^{8/27}} \right\}^2 = 1301 \text{W/m}^2 \cdot \text{K}.$$

Substituting numerical values into Eq. (1), the calculated value for  $T_s$  in *water* is

$$T_s = 20^\circ\text{C} + 550 \text{W} / \pi \times 0.010\text{m} \times 0.30\text{m} \times 1301 \text{W/m}^2 \cdot \text{K} = 64.8^\circ\text{C}. \quad <$$

Continued ...

### PROBLEM 9.61 (Cont.)

Our initial assumption of  $T_s = 64^\circ\text{C}$  is in excellent agreement with the calculated value.

With accidental operation in *air*, the heat transfer coefficient will be nearly a factor of 100 less.

Suppose  $\bar{h} \approx 25 \text{ W/m}^2 \cdot \text{K}$ , then from Eq. (1),  $T_s \approx 2360^\circ\text{C}$ . Very likely the heater will burn out.

Using air properties at  $T_f \approx 1500\text{K}$  and Eq. (2), find  $\text{Ra}_D = 1.815 \times 10^2$ . Using Eq. 9.33,

$\text{Nu}_D = C \text{Ra}_D^n$  with  $C = 0.85$  and  $n = 0.188$  from Table 9.1, find  $\bar{h} = 22.6 \text{ W/m}^2 \cdot \text{K}$ . Hence, our first estimate for the surface temperature in *air* was reasonable,

$$T_s \approx 2300^\circ\text{C}.$$

<

However, radiation exchange will be the dominant mode, and would reduce the estimate for  $T_s$ .

Generally such heaters could not withstand operating temperatures above  $1000^\circ\text{C}$  and safe operation in *air* is not possible.

## PROBLEM 9.62

**KNOWN:** Motor shaft of 20-mm diameter operating in ambient air at  $T_\infty = 27^\circ\text{C}$  with surface temperature  $T_s \leq 87^\circ\text{C}$ .

**FIND:** Convection coefficients and/or heat removal rates for different heat transfer processes: (a) For a rotating horizontal cylinder as a function of rotational speed 5000 to 15,000 rpm using the recommended correlation, (b) For free convection from a horizontal stationary shaft; investigate whether mixed free and forced convection effects for the range of rotational speeds in part (a) are significant using the recommended criterion; (c) For radiation exchange between the shaft having an emissivity of 0.8 and the surroundings also at ambient temperature,  $T_{\text{sur}} = T_\infty$ ; and (d) For cross flow of ambient air over the stationary shaft, required air velocities to remove the heat rates determined in part (a).

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Shaft is horizontal with isothermal surface.

**PROPERTIES:** Table A.4, Air ( $T_f = (T_s + T_\infty)/2 = 330\text{ K}$ , 1 atm):  $\nu = 18.91 \times 10^{-6}\text{ m}^2/\text{s}$ ,  $k = 0.02852\text{ W/m}\cdot\text{K}$ ,  $\alpha = 26.94 \times 10^{-6}\text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.7028$ ,  $\beta = 1/T_f$ .

**ANALYSIS:** (a) The recommended correlation for a horizontal rotating shaft is

$$\overline{\text{Nu}}_D = 0.133 \text{Re}_D^{2/3} \text{Pr}^{1/3} \quad \text{Re}_D < 4.3 \times 10^5 \quad 0.7 < \text{Pr} < 670$$

where the Reynolds number is

$$\text{Re}_D = \Omega D^2 / \nu$$

and  $\Omega$  (rad/s) is the rotational velocity. Evaluating properties at  $T_f = (T_s + T_\infty)/2$ , find for  $\omega = 5000$  rpm,

$$\text{Re}_D = (5000 \text{ rpm} \times 2\pi \text{ rad/rev} / 60 \text{ s/min}) (0.020 \text{ m})^2 / 18.91 \times 10^{-6} \text{ m}^2/\text{s} = 11,076$$

$$\overline{\text{Nu}}_D = 0.133 (11,076)^{2/3} (0.7028)^{1/3} = 58.75$$

$$\overline{h}_{D,\text{rot}} = \overline{\text{Nu}}_D k / D = 58.75 \times 0.02852 \text{ W/m}\cdot\text{K} / 0.020 \text{ m} = 83.8 \text{ W/m}^2 \cdot \text{K} \quad <$$

The heat rate per unit shaft length is

$$q'_{\text{rot}} = \overline{h}_{D,\text{rot}} (\pi D) (T_s - T_\infty) = 83.8 \text{ W/m}^2 \cdot \text{K} (\pi \times 0.020 \text{ m}) (87 - 27)^\circ\text{C} = 316 \text{ W/m} \quad <$$

The convection coefficient and heat rate as a function of rotational speed are shown in a plot below.

(b) For the stationary shaft condition, the free convection coefficient can be estimated from the Churchill-Chu correlation, Eq. (9.34) with

Continued...

**PROBLEM 9.62 (Cont.)**

$$Ra_D = \frac{g\beta\Delta TD^3}{\nu\alpha}$$

$$Ra_D = \frac{9.8 \text{ m/s}^2 (1/330\text{K})(87 - 27) \text{ K} (0.020\text{m})^3}{18.91 \times 10^{-6} \text{ m}^2/\text{s} \times 26.94 \times 10^{-6} \text{ m}^2/\text{s}} = 27,981$$

$$\overline{Nu}_D = \left\{ 0.60 + \frac{0.387 Ra_D^{1/6}}{\left[ 1 + (0.559/Pr)^{9/16} \right]^{8/27}} \right\}^2$$

$$\overline{Nu}_D = \left\{ 0.60 + \frac{0.387 (27,981)^{1/6}}{\left[ 1 + (0.559/0.7028)^{9/16} \right]^{8/27}} \right\}^2 = 5.61$$

$$\overline{h}_{D,fc} = \overline{Nu}_D k/D = 5.61 \times 0.02852 \text{ W/m} \cdot \text{K} / 0.020\text{m} = 8.00 \text{ W/m}^2 \cdot \text{K}$$

$$q'_{fc} = 8.00 \text{ W/m}^2 \cdot \text{K} (\pi \times 0.020\text{m})(87 - 27)^\circ \text{C} = 30.2 \text{ W/m}$$

<

Mixed free and forced convection effects may be significant if

$$Re_D < 4.7 \left( Gr_D^3 / Pr \right)^{0.137}$$

where  $Gr_D = Ra_D/Pr$ , find using results from above and in part (a) for  $\omega = 5000$  rpm,

$$11,076 \text{ ?} < 4.7 \left[ (27,981/0.7028)^3 / 0.7018 \right]^{0.137} = 383$$

We conclude that free convection effects are not significant for rotational speeds above 5000 rpm.

(c) Considering radiation exchange between the shaft and the surroundings,

$$h_{rad} = \varepsilon\sigma(T_s + T_{sur})(T_s^2 + T_{sur}^2)$$

$$h_{rad} = 0.8 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K} (360 + 300) (360^2 + 300^2) \text{ K}^3 = 6.57 \text{ W/m}^2 \cdot \text{K}$$

<

and the heat rate by radiation exchange is

$$q'_{rad} = h_{rad} (\pi D)(T_s - T_{sur})$$

$$q'_{rad} = 6.57 \text{ W/m}^2 \cdot \text{K} (\pi \times 0.020\text{m})(87 - 27) \text{ K} = 24.8 \text{ W/m}$$

<

(d) For cross flow of ambient air at a velocity  $V$  over the shaft, the convection coefficient can be estimated using the Churchill-Bernstein correlation, Eq. 7.54, with

$$Re_{D,cf} = \frac{VD}{\nu}$$

$$\overline{Nu}_{D,cf} = \overline{h}_{D,cf} D/k = 0.3 + \frac{0.62 Re_{D,cf}^{1/2} Pr^{1/3}}{\left[ 1 + (0.4/Pr)^{2/3} \right]^{1/4}} \left[ 1 + \left( \frac{Re_{D,cf}}{282,000} \right)^{5/8} \right]^{4/5}$$

Continued...

### PROBLEM 9.62 (Cont.)

From the plot below (left) for the rotating shaft condition of part (a),  $\bar{h}_{D,rot}$  vs. rpm, note that the convection coefficient varies from approximately 75 to 175  $W/m^2 \cdot K$ . Using the *IHT Correlations Tool, Forced Convection, Cylinder*, which is based upon the above relations, the range of air velocities  $V$  required to achieve  $\bar{h}_{D,cf}$  in the range 75 to 175  $W/m^2 \cdot K$  was computed and is plotted below (right).

Note that the air cross-flow velocities are quite substantial in order to remove similar heat rates for the rotating shaft condition.

**COMMENTS:** We conclude for the rotational speed and surface temperature conditions, free convection effects are not significant. Further, radiation exchange, part (c) result, is less than 10% of the convection heat loss for the lowest rotational speed condition.

### PROBLEM 9.63

**KNOWN:** Horizontal pin fin of 6-mm diameter and 60-mm length fabricated from plain carbon steel ( $k = 57 \text{ W/m}\cdot\text{K}$ ,  $\varepsilon = 0.5$ ). Fin base maintained at  $T_b = 150^\circ\text{C}$ . Ambient air and surroundings at  $25^\circ\text{C}$ .

**FIND:** Fin heat rate,  $q_f$ , by two methods: (a) Analytical solution using average fin surface temperature of  $\bar{T}_s = 125^\circ\text{C}$  to estimate the free convection and linearized radiation coefficients; comment on sensitivity of fin heat rate to choice of  $\bar{T}_s$ ; and, (b) Finite-difference method when coefficients are based upon local temperatures, rather than an average fin surface temperature; compare result of the two solution methods.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) One-dimensional conduction in the pin fin, (3) Ambient air is quiescent and extensive, (4) Surroundings are large compared to the pin fin, and (5) Fin tip is adiabatic.

**PROPERTIES:** Table A.4, Air ( $T_f = (\bar{T}_s + T_\infty)/2 = 348 \text{ K}$ ):  $\nu = 20.72 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.02985 \text{ W/m}\cdot\text{K}$ ,  $\alpha = 29.60 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.7003$ ,  $\beta = 1/T_f$ .

**ANALYSIS:** (a) The heat rate for the pin fin with an adiabatic tip condition is, Eq. 3.81,

$$q_f = M \tanh(mL) \quad (1)$$

$$M = (\bar{h}_{\text{tot}} P k A_c)^{1/2} \theta_b \quad m = (hP/kA_c)^{1/2} \quad (2,3)$$

$$P = \pi D \quad A_c = \pi D^2/4 \quad \theta_b = T_b - T_\infty \quad (4-6)$$

and the average coefficient is the sum of the convection and linearized radiation processes, respectively,

$$\bar{h}_{\text{tot}} = \bar{h}_{\text{fc}} + \bar{h}_{\text{rad}} \quad (7)$$

evaluated at  $\bar{T}_s = 125^\circ\text{C}$  with  $\bar{T}_f = (\bar{T}_s + T_\infty)/2 = 75^\circ\text{C} = 348 \text{ K}$ .

*Estimating  $\bar{h}_{\text{fc}}$ :* For the horizontal cylinder, Eq. 9.34, with

$$\text{Ra}_D = \frac{g\beta\Delta T D^3}{\nu\alpha}$$

Continued ...

**PROBLEM 9.63 (Cont.)**

$$Ra_D = \frac{9.8 \text{ m/s}^2 (1/348\text{K})(125 - 25)(0.006\text{m})^3}{20.72 \times 10^{-6} \text{ m}^2/\text{s} \times 29.60 \times 10^{-6} \text{ m}^2/\text{s}} = 991.79$$

$$\overline{Nu}_D = \left\{ 0.60 + \frac{0.387 Ra_D^{1/6}}{\left[ 1 + (0.559/Pr)^{9/16} \right]^{8/27}} \right\}^2$$

$$\overline{Nu}_D = \left\{ 0.60 + \frac{0.387 (991.79)^{1/6}}{\left[ 1 + (0.559/0.7003)^{9/16} \right]^{8/27}} \right\}^2 = 2.603$$

$$\overline{h}_{fc} = \overline{Nu}_D k/D = 2.603 \times 0.02985 \text{ W/m} \cdot \text{K} / 0.006\text{m} = 12.95 \text{ W/m}^2 \cdot \text{K}$$

Calculating  $\overline{h}_{rad}$ : The linearized radiation coefficient is

$$\overline{h}_{rad} = \varepsilon \sigma (\overline{T}_s + T_{sur}) (\overline{T}_s^2 + T_{sur}^2) \quad (8)$$

$$\overline{h}_{rad} = 0.5 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (398 + 298) (398^2 + 298^2) \text{ K}^3 = 4.88 \text{ W/m}^2 \cdot \text{K}$$

Substituting numerical values into Eqs. (1-7), find

$$q_{fin} = 2.04 \text{ W} \quad <$$

with  $\theta_b = 125 \text{ K}$ ,  $A_c = 2.827 \times 10^{-5} \text{ m}^2$ ,  $P = 0.01885 \text{ m}$ ,  $m = 14.44 \text{ m}^{-1}$ ,  $M = 2.909 \text{ W}$ , and  $\overline{h}_{tot} = 17.83 \text{ W/m}^2 \cdot \text{K}$ .

Using the *IHT Model, Extended Surfaces, Rectangular Pin Fin*, with the *Correlations Tool for Free Convection* and the *Properties Tool for Air*, the above analysis was repeated to obtain the following results.

$\overline{T}_s$ ( $^{\circ}\text{C}$ )	115	120	125	130	135
$q_f$ (W)	1.989	2.012	2.035	2.057	2.079
$(q_f - q_{f,o})/q_{f,o}$ (%)	-2.3	-1.1	0	+1.1	+2.2

The fin heat rate is not very sensitive to the choice of  $\overline{T}_s$  for the range  $T_s = 125 \pm 10 \text{ }^{\circ}\text{C}$ . For the base case condition, the fin tip temperature is  $T(L) = 114 \text{ }^{\circ}\text{C}$  so that  $\overline{T}_s \approx (T(L) + T_b)/2 = 132 \text{ }^{\circ}\text{C}$  would be consistent assumed value.

Continued ...

### PROBLEM 9.63 (Cont.)

(b) Using the *IHT Tool, Finite-Difference Equation, Steady-State, Extended Surfaces*, the temperature distribution was determined for a 15-node system from which the fin heat rate was determined. The local free convection and linearized radiation coefficients  $h_{\text{tot}} = h_{\text{fc}} + h_{\text{rad}}$ , were evaluated at local temperatures,  $T_m$ , using *IHT with the Correlations Tool, Free Convection, Horizontal Cylinder*, and the *Properties Tool for Air*, and Eq. (8). The local coefficient  $h_{\text{tot}}$  vs.  $T_s$  is nearly a linear function for the range  $114 \leq T_s \leq 150^\circ\text{C}$  so that it was reasonable to represent  $h_{\text{tot}}(T_s)$  as a *Lookup Table Function*. The fin heat rate follows from an energy balance on the base node, (see schematic next page)

$$q_f = q_a + q_b = (0.08949 + 1.879) \text{ W} = 1.97 \text{ W} \quad \leftarrow$$

$$q_a = h_b (P\Delta x/2)(T_b - T_\infty)$$

$$q_b = kA_c (T_b - T_1)/\Delta x$$

where  $T_b = 150^\circ\text{C}$ ,  $T_1 = 418.3 \text{ K} = 145.3^\circ\text{C}$ , and  $h_b = h_{\text{tot}}(T_b) = 18.99 \text{ W/m}^2 \cdot \text{K}$ .

Considering variable coefficients, the fin heat rate is -3.3% lower than for the analytical solution with the assumed  $\bar{T}_s = 125^\circ\text{C}$ .

**COMMENTS:** (1) To validate the FDE model for part (b), we compared the temperature distribution and fin heat rate using a constant  $h_{\text{tot}}$  with the analytical solution ( $\bar{T}_s = 125^\circ\text{C}$ ). The results were identical indicating that the 15-node mesh is sufficiently fine.

(2) The fin temperature distribution (K) for the IHT finite-difference model of part (b) is

$T_b$	T01	T02	T03	T04	T05	T06	T07
423	418.3	414.1	410.3	406.8	403.7	401	398.6
T08	T09	T10	T11	T12	T13	T14	T15
396.6	394.9	393.5	392.4	391.7	391.2	391	390.9

## PROBLEM 9.64

**KNOWN:** Diameter, thickness, emissivity and thermal conductivity of steel pipe. Temperature of water flow in pipe. Cost of producing hot water.

**FIND:** Cost of daily heat loss from an uninsulated pipe.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, (2) Negligible convection resistance for water flow, (3) Negligible radiation from pipe surroundings, (4) Quiescent air, (5) Constant properties.

**PROPERTIES:** Table A-4, air ( $p = 1 \text{ atm}$ ,  $T_f \approx 295 \text{ K}$ ):  $k_a = 0.0259 \text{ W/m}\cdot\text{K}$ .  $\nu = 15.45 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\alpha = 21.8 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.708$ ,  $\beta = 3.39 \times 10^{-3} \text{ K}^{-1}$ .

**ANALYSIS:** Performing an energy balance for a control surface about the outer surface,  $q'_{\text{cond}} = q'_{\text{conv}} + q'_{\text{rad}}$ , it follows that

$$\frac{T - T_{s,o}}{R'_{\text{cond}}} = \bar{h} \pi D_o (T_{s,o} - T_{\infty}) + \varepsilon_p \pi D_o \sigma T_{s,o}^4 \quad (1)$$

where  $R'_{\text{cond}} = \ln(D_o/D_i)/2\pi k_p = \ln(100/84)/2\pi(60 \text{ W/m}\cdot\text{K}) = 4.62 \times 10^{-4} \text{ m}\cdot\text{K/W}$ . The convection coefficient may be obtained from the Churchill and Chu correlation. Hence, with  $\text{Ra}_D = g\beta(T_{s,o} - T_{\infty}) D_o^3 / \alpha\nu = 9.8 \text{ m/s}^2 \times 3.39 \times 10^{-3} \text{ K}^{-1} (0.1 \text{ m})^3 (T_{s,o} - 268 \text{ K}) / (21.8 \times 15.45 \times 10^{-12} \text{ m}^4/\text{s}^2) = 98,637 (T_{s,o} - 268)$ ,

$$\bar{\text{Nu}}_D = \left\{ 0.60 + \frac{0.387 \text{ Ra}_D^{1/6}}{\left[ 1 + (0.559/\text{Pr})^{9/16} \right]^{8/27}} \right\}^2 = \left\{ 0.60 + 2.182 (T_{s,o} - 268)^{1/6} \right\}^2$$

$$\bar{h} = \frac{k_a}{D_o} \bar{\text{Nu}}_D = 0.259 \text{ W/m}^2 \cdot \text{K} \left\{ 0.60 + 2.182 (T_{s,o} - 268)^{1/6} \right\}^2$$

Substituting the foregoing expression for  $\bar{h}$ , as well as values of  $R'_{\text{cond}}$ ,  $D_o$ ,  $\varepsilon_p$  and  $\sigma$  into Eq. (1), an iterative solution yields  $T_{s,o} = 322.9 \text{ K} = 49.9^\circ\text{C}$

It follows that  $\bar{h} = 6.10 \text{ W/m}^2 \cdot \text{K}$ , and the heat loss per unit length of pipe is

$$q' = q'_{\text{conv}} + q'_{\text{rad}} = 6.10 \text{ W/m}^2 \cdot \text{K} (\pi \times 0.1 \text{ m}) 54.9 \text{ K} + 0.6 (\pi \times 0.1 \text{ m}) 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (322.9 \text{ K})^4 = (105.2 + 116.2) \text{ W/m} = 221.4 \text{ W/m}$$

The corresponding daily energy loss is  $Q' = 0.221 \text{ kW/m} \times 24 \text{ h/d} = 5.3 \text{ kW}\cdot\text{h/m}\cdot\text{d}$

and the associated cost is  $C' = (5.3 \text{ kW}\cdot\text{h/m}\cdot\text{d})(\$0.10/\text{kW}\cdot\text{h}) = \$0.53/\text{m}\cdot\text{d} <$

**COMMENTS:** (1) The heat loss is significant, and the pipe should be insulated. (2) The conduction resistance of the pipe wall is negligible relative to the combined convection and radiation resistance at the outer surface. Hence, the temperature of the outer surface is only slightly less than that of the water.

### PROBLEM 9.65

**KNOWN:** Insulated, horizontal pipe with aluminum foil having emissivity which varies from 0.12 to 0.36 during service. Pipe diameter is 300 mm and its surface temperature is 90°C.

**FIND:** Effect of emissivity degradation on heat loss with ambient air at 25°C and (a) quiescent conditions and (b) cross-wind velocity of 10 m/s.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Surroundings are large compared to pipe, (3) Pipe has uniform temperature.

**PROPERTIES:** Table A-4, Air ( $T_f = (90 + 25)^\circ\text{C}/2 = 330\text{K}$ , 1 atm):  $\nu = 18.9 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 28.5 \times 10^{-3} \text{ W/m}\cdot\text{K}$ ,  $\alpha = 26.9 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.703$ .

**ANALYSIS:** The heat loss per unit length from the pipe is

$$q' = \bar{h}P(T_s - T_\infty) + \epsilon\sigma P(T_s^4 - T_{sur}^4)$$

where  $P = \pi D$  and  $\bar{h}$  needs to be evaluated for the two ambient air conditions.

(a) *Quiescent air.* Treating the pipe as a horizontal cylinder, find

$$\text{Ra}_D = \frac{g\beta(T_s - T_\infty)D^3}{\nu\alpha} = \frac{9.8 \text{ m/s}^2 (1/330\text{K})(90 - 25)\text{K}(0.30 \text{ m})^3}{18.9 \times 10^{-6} \text{ m}^2/\text{s} \times 26.9 \times 10^{-6} \text{ m}^2/\text{s}} = 1.025 \times 10^8$$

and using the Churchill-Chu correlation for  $10^{-5} < \text{Ra}_D < 10^{12}$ .

$$\bar{\text{Nu}}_D = \left\{ 0.60 + \frac{0.387 \text{Ra}_D^{1/6}}{\left[ 1 + (0.559/\text{Pr})^{9/16} \right]^{8/27}} \right\}^2$$

$$\bar{\text{Nu}}_D = \left\{ 0.60 + \frac{0.387 (1.025 \times 10^8)^{1/6}}{\left[ 1 + (0.559/0.703)^{9/16} \right]^{8/27}} \right\}^2 = 56.93$$

$$\bar{h}_D = \bar{\text{Nu}}_D k / D = 56.93 \times 0.0285 \text{ W/m}\cdot\text{K} / 0.300 \text{ m} = 5.4 \text{ W/m}^2 \cdot \text{K}$$

Continued ...

**PROBLEM 9.65 (Cont.)**

Hence, the heat loss is

$$q' = 5.4 \text{ W/m}^2 \cdot \text{K} (\pi 0.30 \text{ m}) (90 - 25) \text{ K} + \varepsilon \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K} (\pi 0.30 \text{ m}) (363^4 - 298^4) \text{ K}^4$$

$$q' = 331 + 506\varepsilon \begin{cases} \varepsilon = 0.12 \rightarrow q' = (331 + 61) = 392 \text{ W/m} & < \\ \varepsilon = 0.36 \rightarrow q' = (331 + 182) = 513 \text{ W/m} & < \end{cases}$$

The radiation effect accounts for 16 and 35%, respectively, of the heat rate.

(b) *Cross-wind condition.* With a cross-wind, find

$$\text{Re}_D = \frac{VD}{\nu} = \frac{10 \text{ m/s} \times 0.30 \text{ m}}{18.9 \times 10^{-6} \text{ m}^2/\text{s}} = 1.587 \times 10^5$$

and using the Hilpert correlation where  $C = 0.027$  and  $m = 0.805$  from Table 7.2,

$$\overline{\text{Nu}}_D = C \text{Re}_D^m \text{Pr}^{1/3} = 0.027 (1.587 \times 10^5)^{0.805} (0.703)^{1/3} = 368.9$$

$$\overline{h}_D = \text{Nu}_D \cdot k / D = 368.9 \times 0.0285 \text{ W/m} \cdot \text{K} / 0.30 \text{ m} = 35 \text{ W/m}^2 \cdot \text{K}.$$

Recognizing that *combined* free and forced convection conditions may exist, from Eq. 9.64 with  $n = 4$ ,

$$\text{Nu}_m^4 = \text{Nu}_F^4 + \text{Nu}_N^4 \quad \overline{h}_m = (5.4^4 + 35^4)^{1/4} = 35 \text{ W/m}^2 \cdot \text{K}$$

we find forced convection dominates. Hence, the heat loss is

$$q' = 35 \text{ W/m}^2 \cdot \text{K} (\pi 0.30 \text{ m}) (90 - 25) \text{ K} + \varepsilon \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K} (\pi 0.30 \text{ m}) (393^4 - 298^4) \text{ K}^4$$

$$q' = 2144 + 853\varepsilon \begin{cases} \varepsilon = 0.12 \rightarrow q' = 2144 + 102 = 2246 \text{ W/m} & < \\ \varepsilon = 0.36 \rightarrow q' = 2144 + 307 = 2451 \text{ W/m} & < \end{cases}$$

The radiation effect accounts for 5 and 13%, respectively, of the heat rate.

**COMMENTS:** (1) For high velocity wind conditions, radiation losses are quite low and the degradation of the foil is not important. However, for low velocity and quiescent air conditions, radiation effects are significant and the degradation of the foil can account for a nearly 25% change in heat loss.

(2) The radiation coefficient is in the range  $0.83$  to  $2.48 \text{ W/m}^2 \cdot \text{K}$  for  $\varepsilon = 0.12$  and  $0.36$ , respectively. Compare these values with those for convection.

## PROBLEM 9.66

**KNOWN:** Diameter, emissivity, and power dissipation of cylindrical heater. Temperature of ambient air and surroundings.

**FIND:** Steady-state temperature of heater and time required to come within 10°C of this temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Air is quiescent, (2) Duct wall forms large surroundings about heater, (3) Heater may be approximated as a lumped capacitance.

**PROPERTIES:** Table A.4, air (Obtained from *Properties* Tool Pad of IHT).

**ANALYSIS:** Performing an energy balance on the heater, the final (steady-state) temperature may be obtained from the requirement that  $q' = q'_{conv} + q'_{rad}$ , or

$$q' = \bar{h}(\pi D)(T - T_{\infty}) + h_r(\pi D)(T - T_{sur})$$

where  $\bar{h}$  is obtained from Eq. 9.34 and  $h_r = \varepsilon\sigma(T + T_{sur})(T^2 + T_{sur}^2)$ . Using the *Correlations* Tool Pad of IHT to evaluate  $\bar{h}$ , this expression may be solved to obtain

$$T = 854 \text{ K} = 581^{\circ}\text{C} \quad \leftarrow$$

Under transient conditions, the energy balance is of the form,  $\dot{E}'_{st} = q' - q'_{conv} - q'_{rad}$ , or

$$\rho c_p \left( \frac{\pi D^2}{4} \right) dT/dt = q' - \bar{h}(\pi D)(T - T_{\infty}) - h_r(\pi D)(T - T_{sur})$$

Using the IHT *Lumped Capacitance* model with the *Correlations* Tool Pad, the above expression is integrated from  $t = 0$ , for which  $T_1 = 562.4 \text{ K}$ , to the time for which  $T = 844 \text{ K}$ . The integration yields

$$t = 183 \text{ s} \quad \leftarrow$$

The value of  $T_1 = 562.4 \text{ K}$  corresponds to the steady-state temperature for which the power dissipation is balanced by forced convection and radiation (see solution to Problem 7.50).

**COMMENTS:** The forced convection coefficient (Problems 7.49 and 7.50) of  $105 \text{ W/m}^2\cdot\text{K}$  is much larger than that associated with free convection for the steady-state conditions of this problem ( $14.6 \text{ W/m}^2\cdot\text{K}$ ). However, because of the correspondingly larger heater temperature, the radiation coefficient with free convection ( $42.9 \text{ W/m}^2\cdot\text{K}$ ) is much larger than that associated with forced convection ( $15.9 \text{ W/m}^2\cdot\text{K}$ ).

### PROBLEM 9.67

**KNOWN:** Cylindrical sensor of 12.5 mm diameter positioned horizontally in quiescent air at 27°C.

**FIND:** An expression for the free convection coefficient as a function of only  $\Delta T = T_s - T_\infty$  where  $T_s$  is the sensor temperature.

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Uniform temperature over cylindrically shaped sensor, (3) Ambient air extensive and quiescent.

**PROPERTIES:** Table A-4, Air ( $T_f$ , 1 atm):  $\beta = 1/T_f$  and

$T_s$ (°C)	$T_f$ (K)	$\nu \times 10^6$ m <sup>2</sup> /s	$\alpha \times 10^6$ m <sup>2</sup> /s	$k \times 10^3$ W/m·K	Pr
30	302	16.09	22.8	26.5	0.707
55	314	17.30	24.6	27.3	0.705
80	327	18.61	26.5	28.3	0.703

**ANALYSIS:** For the cylindrical sensor, using Eqs. 9.25 and 9.34,

$$Ra_D = \frac{g\beta\Delta TD^3}{\nu\alpha} \quad \overline{Nu}_D = \frac{\overline{h}_D D}{k} = \left\{ 0.60 + \frac{0.387 Ra_D^{1/6}}{\left[1 + (0.559/Pr)^{9/16}\right]^{8/27}} \right\}^2 \quad (1.2)$$

where properties are evaluated at  $T_f = (T_s + T_\infty)/2$ . With  $30 \leq T_s \leq 80^\circ\text{C}$  and  $T_\infty = 27^\circ\text{C}$ ,  $302 \leq T_f \leq 326$  K. Using properties evaluated at the mid-range of  $T_f$ ,  $\overline{T}_f = 314$  K, find

$$Ra_D = \frac{9.8 \text{ m/s}^2 (1/314 \text{ K}) \Delta T (0.0125 \text{ m})^3}{17.30 \times 10^{-6} \text{ m}^2/\text{s} \times 24.6 \times 10^{-6} \text{ m}^2/\text{s}} = 143.2 \Delta T$$

$$\overline{h}_D = \frac{0.0273 \text{ W/m}\cdot\text{K}}{0.0125 \text{ m}} \left\{ 0.60 + \frac{0.387 (143.2 \Delta T)^{1/6}}{\left[1 + (0.559/0.705)^{9/16}\right]^{8/27}} \right\}^2$$

$$\overline{h}_D = 2.184 \left\{ 0.60 + 0.734 \Delta T^{1/6} \right\}^2. \quad (3) <$$

**COMMENTS:** (1) The effect of using a fixed film temperature,  $\overline{T}_f = 314 \text{ K} = 41^\circ\text{C}$ , for the full range  $30 \leq T_s \leq 80^\circ\text{C}$  can be seen by comparing results from the approximate Eq. (3) and the correlation, Eq. (2), with the proper film temperature. The results are summarized in the table.

$T_s$ (°C)	$\Delta T = T_s - T_\infty$ (°C)	Correlation			Eq. (3)
		$Ra_D$	$\overline{Nu}_D$	$\overline{h}_D$ (W/m <sup>2</sup> ·K)	$\overline{h}_D$ (W/m <sup>2</sup> ·K)
30	3	518	2.281	4.83	4.80
55	28	4011	3.534	7.72	7.71

The approximate expression for  $\overline{h}_D$  is in excellent agreement with the correlation.

(2) In calculating heat rates it may be important to consider radiation exchange with the surroundings.

## PROBLEM 9.68

**KNOWN:** Thin-walled tube mounted horizontally in quiescent air and wrapped with an electrical tape passing hot fluid in an experimental loop.

**FIND:** (a) Heat flux  $q_e''$  from the heating tape required to prevent heat loss from the hot fluid when (a) neglecting and (b) including radiation exchange with the surroundings, (c) Effect of insulation on  $q_e''$  and convection/radiation rates.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Ambient air is quiescent and extensive, (3) Surroundings are large compared to the tube.

**PROPERTIES:** Table A.4, Air ( $T_f = (T_s + T_\infty)/2 = (45 + 15)^\circ\text{C}/2 = 303\text{ K}$ , 1 atm):  $\nu = 16.19 \times 10^{-6}\text{ m}^2/\text{s}$ ,  $\alpha = 22.9 \times 10^{-6}\text{ m}^2/\text{s}$ ,  $k = 26.5 \times 10^{-3}\text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.707$ ,  $\beta = 1/T_f$ .

**ANALYSIS:** (a,b) To prevent heat losses from the hot fluid, the heating tape temperature must be maintained at  $T_m$ ; hence  $T_{s,i} = T_m$ . From a surface energy balance,

$$q_e'' = q_{\text{conv}}'' + q_{\text{rad}}'' = (\bar{h}_{D_i} + h_r)(T_{s,i} - T_\infty)$$

where the linearized radiation coefficient, Eq. 1.9, is  $h_r = \epsilon\sigma(T_{s,i} + T_\infty)(T_{s,i}^2 + T_\infty^2)$ , or

$$h_r = 0.95 \times 5.67 \times 10^{-8}\text{ W/m}^2 \cdot \text{K}^4 (318 + 288)(318^2 + 288^2)\text{ K}^3 = 6.01\text{ W/m}^2 \cdot \text{K}.$$

*Neglecting radiation:* For the horizontal cylinder, Eq. 9.34 yields

$$\text{Ra}_D = \frac{g\beta(T_{s,i} - T_\infty)D_i^3}{\nu\alpha} = \frac{9.8\text{ m/s}^2 (1/303\text{ K})(45 - 15)\text{ K}(0.020\text{ m})^3}{16.19 \times 10^{-6}\text{ m}^2/\text{s} \times 22.9 \times 10^{-6}\text{ m}^2/\text{s}} = 20,900$$

$$\overline{\text{Nu}}_D = \frac{\bar{h}_{D_i} D_i}{k} = \left\{ 0.60 + \frac{0.387\text{Ra}_D^{1/6}}{\left[1 + (0.559/\text{Pr})^{9/16}\right]^{8/27}} \right\}^2$$

Continued ...

**PROBLEM 9.68 (Cont.)**

$$\bar{h}_{D_i} = \frac{0.0265 \text{ W/m} \cdot \text{K}}{0.020 \text{ m}} \left\{ 0.60 + \frac{0.386(20,900)^{1/6}}{\left[ 1 + (0.559/0.707)^{9/16} \right]^{8/27}} \right\}^2 = 6.90 \text{ W/m}^2 \cdot \text{K}$$

Hence, neglecting radiation, the required heat flux is

$$q_e'' = 6.90 \text{ W/m}^2 \cdot \text{K} (45 - 15) \text{ K} = 207 \text{ W/m}^2 \cdot \text{K} \quad <$$

*Considering radiation:* The required heat flux considering radiation is

$$q_e'' = (6.90 + 6.01) \text{ W/m}^2 \cdot \text{K} (45 - 15) \text{ K} = 387 \text{ W/m}^2 \cdot \text{K} \quad <$$

(c) With insulation, the surface energy balance must be modified to account for an increase in the outer diameter from  $D_i$  to  $D_o = D_i + 2t$  and for the attendant thermal resistance associated with conduction across the insulation. From an energy balance at the inner surface of the insulation,

$$q_e'' (\pi D_i) = q'_{\text{cond}} = \frac{2\pi k_i (T_m - T_{s,o})}{\ln(D_o/D_i)}$$

and from an energy balance at the outer surface,

$$q'_{\text{cond}} = q'_{\text{conv}} + q'_{\text{rad}} = \pi D_o (\bar{h}_{D_o} + h_r) (T_{s,o} - T_\infty)$$

The foregoing expressions may be used to determine  $T_{s,o}$  and  $q_e''$  as a function of  $t$ , with the IHT

*Correlations and Properties* Tool Pads used to evaluate  $\bar{h}_{D_o}$ . The desired results are plotted as follows.

By adding 20 mm of insulation, the required power dissipation is reduced by a factor of approximately 3. Convection and radiation heat rates at the outer surface are comparable.

**COMMENTS:** Over the range of insulation thickness,  $T_{s,o}$  decreases from 45°C to 20°C, while  $\bar{h}_{D_o}$  and  $h_r$  decrease from 6.9 to 3.5 W/m<sup>2</sup>·K and from 3.8 to 3.3 W/m<sup>2</sup>·K, respectively.

## PROBLEM 9.69

**KNOWN:** A billet of stainless steel AISI 316 with a diameter of 150 mm and length 500 mm emerges from a heat treatment process at 200°C and is placed into an unstirred oil bath maintained at 20°C.

**FIND:** (a) Determine whether it is advisable to position the billet in the bath with its centerline horizontal or vertical in order to decrease to the cooling time, and (b) Estimate the time for the billet to cool to 30°C for the better positioning arrangement.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions for part (a), (2) Oil bath approximates a quiescent fluid, (3) Consider only convection from the lateral surface of the cylindrical billet; and (4) For part (b), the billet has a uniform initial temperature.

**PROPERTIES:** Table A-5, Engine oil ( $T_f = (T_s + T_\infty)/2$ ): see Comment 1. Table A-1, AISI 316 (400 K):  $\rho = 8238 \text{ kg/m}^3$ ,  $c_p = 468 \text{ J/kg}\cdot\text{K}$ ,  $k = 15 \text{ W/m}\cdot\text{K}$ .

**ANALYSIS:** (a) For the purpose of determining whether the horizontal or vertical position is preferred for faster cooling, consider only free convection from the lateral surface. The heat loss from the lateral surface follows from the rate equation

$$q = \bar{h} A_s (T_s - T_\infty)$$

*Vertical position.* The lateral surface of the cylindrical billet can be considered as a vertical surface of height  $L$ , width  $P = \pi D$ , and area  $A_s = PL$ . The Churchill-Chu correlation, Eq. 9.26, is appropriate to estimate  $\bar{h}_L$ ,

$$\overline{\text{Nu}}_L = \frac{\bar{h}_L L}{k} = \left\{ 0.825 + \frac{0.387 \text{Ra}_L^{1/6}}{\left[ 1 + (0.492/\text{Pr})^{9/16} \right]^{8/27}} \right\}^2$$

$$\text{Ra}_L = \frac{g\beta(T_s - T_\infty)L^3}{\nu\alpha}$$

with properties evaluated at  $T_f = (T_s + T_\infty)/2$ .

*Horizontal position.* In this position, the billet is considered as a long horizontal cylinder of diameter  $D$  for which the Churchill-Chu correlation of Eq. 9.34 is appropriate to estimate  $\bar{h}_D$ ,

$$\overline{\text{Nu}}_L = \frac{\bar{h}_D D}{k} = \left\{ 0.60 + \frac{0.387 \text{Ra}_D^{1/6}}{\left[ 1 + (0.559/\text{Pr})^{9/16} \right]^{8/27}} \right\}^2$$

Continued ...

**PROBLEM 9.69 (Cont.)**

$$Ra_D = \frac{g\beta(T_s - T_\infty)D^3}{\nu\alpha}$$

with properties evaluated at  $T_f$ . The heat transfer area is also  $A_s = PL$ .

Using the foregoing relations in *IHT* with the thermophysical properties library as shown in Comment 1, the analysis results are tabulated below.

$Ra_L = 1.36 \times 10^{11}$	$\overline{Nu}_L = 801$	$\overline{h}_L = 218 \text{ W/m}^2 \cdot \text{K}$	(vertical)
$Ra_D = 3.67 \times 10^9$	$\overline{Nu}_D = 245$	$\overline{h}_D = 221 \text{ W/m}^2 \cdot \text{K}$	(horizontal)

Recognize that the orientation has a small effect on the convection coefficient for these conditions, but we'll select the horizontal orientation as the preferred one.

(b) Evaluate first the Biot number to determine if the lumped capacitance method is valid.

$$Bi = \frac{\overline{h}_D (D_o/2)}{k} = \frac{221 \text{ W/m}^2 \cdot \text{K} (0.150 \text{ m}/2)}{15 \text{ W/m} \cdot \text{K}} = 1.1$$

Since  $Bi \gg 0.1$ , the spatial effects are important and we should use the one-term series approximation for the infinite cylinder, Eq. 5.52. Since  $\overline{h}_D$  will decrease as the billet cools, we need to estimate an average value for the cooling process from 200°C to 30°C. Based upon the analysis summarized in Comment 1, use  $\overline{h}_D = 119 \text{ W/m}^2 \cdot \text{K}$ . Using the transient model for the infinite cylinder in *IHT*, (see Comment 2) find for  $T(r_o, t_o) = 30^\circ\text{C}$ ,

$$t_o = 3845 \text{ s} = 1.1 \text{ h}$$

<

**COMMENTS:** (1) The *IHT* code using the convection correlation functions to estimate the coefficients is shown below. This same code was used to calculate  $\overline{h}_D$  for the range  $30 \leq T_s \leq 200^\circ\text{C}$  and determine that an average value for the cooling period of part (b) is  $119 \text{ W/m}^2 \cdot \text{K}$ .

$Bi = h * ro / k$

$Fo = \alpha * t / ro^2$

$\alpha = k / (\rho * cp)$

### PROBLEM 9.70

**KNOWN:** Diameter, initial temperature and emissivity of long steel rod. Temperature of air and surroundings.

**FIND:** (a) Average surface convection coefficient, (b) Effective radiation coefficient, (c,d) Maximum allowable conveyor time.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible effect of forced convection, (2) Constant properties, (3) Large surroundings, (4) Quiescent air.

**PROPERTIES:** Stainless steel (given):  $k = 25 \text{ W/m}\cdot\text{K}$ ,  $\alpha = 5.2 \times 10^{-6} \text{ m}^2/\text{s}$ ; Table A.4, Air ( $T_f = 650 \text{ K}$ , 1 atm):  $\nu = 6.02 \times 10^{-5} \text{ m}^2/\text{s}$ ,  $\alpha = 8.73 \times 10^{-5} \text{ m}^2/\text{s}$ ,  $k = 0.0497 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.69$ .

**ANALYSIS:** (a) For free convection from a horizontal cylinder,

$$\text{Ra}_D = \frac{g\beta(T_s - T_{\infty})D^3}{\alpha\nu} = \frac{9.8 \text{ m/s}^2 (1/650 \text{ K})(1000 - 300) \text{ K} (0.05 \text{ m})^3}{6.02 \times 8.73 \times 10^{-10} \text{ m}^4/\text{s}^2} = 2.51 \times 10^5$$

The Churchill and Chu correlation yields

$$\overline{\text{Nu}}_D = \left\{ 0.60 + \frac{0.387 \text{Ra}_D^{1/6}}{\left[ 1 + (0.559/\text{Pr})^{9/16} \right]^{8/27}} \right\}^2 = \left\{ 0.60 + \frac{0.387 (2.51 \times 10^5)^{1/6}}{\left[ 1 + (0.559/0.69)^{9/16} \right]^{8/27}} \right\}^2 = 9.9$$

$$\bar{h} = \overline{\text{Nu}}_D k/D = 9.9 (0.0497 \text{ W/m}\cdot\text{K}) / 0.05 \text{ m} = 9.84 \text{ W/m}^2 \cdot \text{K} \quad <$$

(b) The radiation heat transfer coefficient is

$$h_r = \epsilon\sigma(T_s + T_{\text{sur}})(T_s^2 + T_{\text{sur}}^2) = 0.4 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (1000 + 300) \text{ K} \left[ (1000)^2 + (300)^2 \right] \text{ K}^2 = 32.1 \text{ W/m}^2 \cdot \text{K} \quad <$$

(c) For the long stainless steel rod and the initial values of  $\bar{h}$  and  $h_r$ ,

$$\text{Bi} = (\bar{h} + h_r)(r_o/2)/k = 42.0 \text{ W/m}^2 \cdot \text{K} \times 0.0125 \text{ m} / 25 \text{ W/m}\cdot\text{K} = 0.021.$$

Hence, the lumped capacitance method can be used.

$$\frac{T - T_{\infty}}{T_i - T_{\infty}} = \frac{600 \text{ K}}{700 \text{ K}} = \exp(-\text{Bi} \cdot \text{Fo}) = \exp(-0.021\text{Fo})$$

Continued...

**PROBLEM 9.70 (Cont.)**

$$Fo = 7.34 = \alpha t / (r_o/2)^2 = 0.0333t$$

$$t = 221 \text{ s.}$$

<

(d) Using the IHT *Lumped Capacitance* Model with the *Correlations* and *Properties* Tool Pads, a more accurate estimate of the maximum allowable transit time may be obtained by evaluating the numerical integration,

$$\int_0^t dt = -\frac{\rho c_p D}{4} \int_{1000\text{K}}^{900\text{K}} \frac{dT}{(\bar{h} + h_r)(T - T_\infty)}$$

where  $\rho c_p = k/\alpha = 4.81 \times 10^6 \text{ J/K} \cdot \text{m}^3$ . The integration yields

$$t = 245 \text{ s}$$

<

At this time, the convection and radiation coefficients are  $\bar{h} = 9.75$  and  $h_r = 24.5 \text{ W/m}^2 \cdot \text{K}$ , respectively.

**COMMENTS:** Since  $\bar{h}$  and  $h_r$  decrease with increasing time, the maximum allowable conveyor time is underestimated by the result of part (c).

## PROBLEM 9.71

**KNOWN:** Velocity and temperature of air flowing through a duct of prescribed diameter. Temperature of duct surroundings. Thickness, thermal conductivity and emissivity of applied insulation.

**FIND:** (a) Duct surface temperature and heat loss per unit length with no insulation, (b) Surface temperatures and heat loss with insulation.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Fully-developed internal flow, (3) Negligible duct wall resistance, (4) Duct outer surface is diffuse-gray, (5) Outside air is quiescent, (6) Pressure of inside and outside air is atmospheric.

**PROPERTIES:** Table A.4, Air ( $T_m = 70^\circ\text{C}$ ):  $\nu = 20.22 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.70$ ,  $k = 0.0295 \text{ W/m}\cdot\text{K}$ ; Table A.4, Air ( $T_f \approx 27^\circ\text{C}$ ):  $\nu = 15.89 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.707$ ,  $k = 0.0263 \text{ W/m}\cdot\text{K}$ ,  $\alpha = 22.5 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\beta = 0.00333 \text{ K}^{-1}$ .

**ANALYSIS:** (a) Performing an energy balance on the duct wall with no insulation ( $T_{s,i} = T_{s,o}$ ),

$$q'_{\text{conv},i} = q'_{\text{conv},o} + q'_{\text{rad},o} \quad h_i (\pi D_i) (T_m - T_{s,i}) = h_o (\pi D_i) (T_{s,i} - T_\infty) + \epsilon_i \sigma (\pi D_i) (T_{s,i}^4 - T_{\text{sur}}^4)$$

with  $\text{Re}_{D,i} = u_m D_i / \nu = 3 \text{ m/s} \times 0.15 \text{ m} / (20.22 \times 10^{-6} \text{ m}^2/\text{s}) = 2.23 \times 10^4$ , the internal flow is turbulent, and from the Dittus-Boelter correlation,

$$h_i = \frac{k}{D_i} 0.023 \text{Re}_{D,i}^{4/5} \text{Pr}^{0.3} = \frac{0.0295 \text{ W/m}\cdot\text{K}}{0.15 \text{ m}} 0.023 (2.23 \times 10^4)^{4/5} (0.7)^{0.3} = 12.2 \text{ W/m}^2 \cdot \text{K}.$$

For free convection, the Rayleigh number is

$$\text{Ra}_{D,i} = \frac{g\beta(T_{s,i} - T_\infty)D_i^3}{\nu\alpha} = \frac{9.8 \text{ m/s}^2 (0.0033)(T_{s,i} - 273)(0.15)^3 \text{ m}^3}{15.89 \times 10^{-6} \text{ m}^2/\text{s} \times 22.5 \times 10^{-6} \text{ m}^2/\text{s}} = 3.08 \times 10^5 (T_{s,i} - T_\infty)$$

and from Eq. 9.34,

$$\bar{h}_o = \frac{k}{D_i} \left[ 0.60 + \frac{0.387 \text{Ra}_{D,i}^{1/6}}{\left[ 1 + (0.559/\text{Pr})^{9/16} \right]^{8/27}} \right]^2 = \frac{0.0263}{0.15} \left[ 0.60 + \frac{0.387 \left[ 3.08 \times 10^5 (T_{s,i} - T_\infty) \right]^{1/6}}{\left[ 1 + (0.559/0.707)^{9/16} \right]^{8/27}} \right]^2$$

Continued...

**PROBLEM 9.71 (Cont.)**

$$\bar{h}_o = 0.175 \left[ 0.60 + 2.64 (T_{s,i} - T_\infty)^{1/6} \right]^2$$

Hence

$$12.2(343 - T_{s,i}) = 0.175 \left\{ 0.60 + 2.64 (T_{s,i} - 273)^{1/6} \right\}^2 (T_{s,i} - 273) + 0.5 \times 5.67 \times 10^{-8} \left[ T_{s,i}^4 - (273)^4 \right]$$

A trial-and-error solution gives  $T_{s,i} \approx 314.7 \text{ K} \approx 41.7^\circ \text{C}$  <

The heat loss per unit length is then

$$q' = q'_{\text{conv},i} \approx 12.2(\pi \times 0.15)(70 - 42) \approx 163 \text{ W/m.}$$
 <

(b) Performing energy balances at the inner and outer surfaces, we obtain, respectively,

$$q'_{\text{conv},i} = q'_{\text{cond}}$$

or,

$$\bar{h}_i (\pi D_i) (T_m - T_{s,i}) = \frac{2\pi k_s (T_{s,i} - T_{s,o})}{\ln(D_o/D_i)}$$

and,

$$q'_{\text{cond}} = q'_{\text{conv},o} + q'_{\text{rad},o}$$

or,

$$\frac{2\pi k_s (T_{s,i} - T_{s,o})}{\ln(D_o/D_i)} = \bar{h}_o (\pi D_o) (T_s - T_\infty) + \varepsilon_o \sigma (\pi D_o) (T_{s,o}^4 - T_{\text{sur}}^4)$$

Using the IHT workspace with the *Correlations* and *Properties* Tool Pads to solve the energy balances for the unknown surface temperatures, we obtain

$$T_{s,i} = 60.8^\circ \text{C} \quad T_{s,o} = 12.5^\circ \text{C}$$
 <

With the heat loss per unit length again evaluated from the inside convection process, we obtain

$$q' = q'_{\text{conv},i} = 52.8 \text{ W/m}$$
 <

**COMMENTS:** For part (a), the outside convection coefficient is  $\bar{h}_o = 5.4 \text{ W/m}^2 \cdot \text{K} < h_i$ . The outside heat transfer rates are  $q'_{\text{conv},o} \approx 106 \text{ W/m}$  and  $q'_{\text{rad},o} \approx 57 \text{ W/m}$ . For part (b),  $\bar{h}_o = 3.74 \text{ W/m}^2 \cdot \text{K}$ ,  $q'_{\text{conv},o} = 29.4 \text{ W/m}$ , and  $q'_{\text{rad},o} = 23.3 \text{ W/m}$ . Although  $T_{s,i}$  increases with addition of the insulation, there is a substantial reduction in  $T_{s,o}$  and hence the heat loss.

## PROBLEM 9.72

**KNOWN:** Biological fluid with prescribed flow rate and inlet temperature flowing through a coiled, thin-walled, 5-mm diameter tube submerged in a large water bath maintained at 50°C.

**FIND:** (a) Length of tube and number of coils required to provide an exit temperature of  $T_{m,o} = 38^\circ\text{C}$ , and (b) Variations expected in  $T_{m,o}$  for a  $\pm 10\%$  change in the mass flow rate for the tube length determined in part (a).

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Coiled tube approximates a horizontal tube experiencing free convection in a quiescent, extensive medium (water bath), (3) Biological fluid has thermophysical properties of water, (4) Negligible tube wall thermal resistance, (5) Biological fluid flow is incompressible with negligible viscous dissipation, and (6) Flow in tube is fully developed.

**PROPERTIES:** *Table A.4* Water - cold side ( $T_{m,c} = (T_{m,i} + T_{m,o}) / 2 = 304.5 \text{ K}$ ):  $c_{p,c} = 4178 \text{ J/kg}\cdot\text{K}$ ,  $\mu_c = 7.776 \times 10^{-4} \text{ N}\cdot\text{s/m}^2$ ,  $k_c = 0.6193 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr}_c = 5.263$ ; *Table A.4*, Water - hot side

( $\bar{T}_f = (T_s + T_\infty) / 2 = 315.7 \text{ K}$ , see comment 1):  $k_h = 0.635 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr}_h = 4.11$ ,  $\nu_h = 6.294 \times 10^{-7} \text{ m}^2/\text{s}$ ,  $\alpha_h = 1.533 \times 10^{-7} \text{ m}^2/\text{s}$ ,  $\beta_h = 4.054 \times 10^{-4} \text{ K}^{-1}$ ; Water ( $T_s = 308.4 \text{ K}$ ):  $\mu_s = 7.28 \times 10^{-4} \text{ N}\cdot\text{s/m}^2$ .

**ANALYSIS:** (a) Following the treatment of Section 8.3.3, the coil experiences internal flow of the cold biological fluid (c) and free convection with the external hot fluid (h). From Eq. 8.45a, we can solve for  $\bar{U}A_s$ ,

$$\bar{U}A_s = -\dot{m}c_{p,c} \ln \left( \frac{T_\infty - T_{m,o}}{T_\infty - T_{m,i}} \right) = -0.02 \text{ kg/s} \times 4178 \text{ J/kg}\cdot\text{K} \times \ln \left( \frac{50 - 38}{50 - 25} \right) = 61.3 \text{ W/K}$$

with  $A_s = \pi DL$  and for the overall coefficient  $\bar{U} = (1/\bar{h}_c + 1/\bar{h}_h)^{-1}$ ,  $\bar{h}_c$  and  $\bar{h}_h$  are the average convection coefficients for internal flow and external free convection, respectively.

*Internal flow,  $\bar{h}_c$ :* To characterize the flow, calculate the Reynolds number,

$$\text{Re}_{D,c} = \frac{4\dot{m}}{\pi D \mu_c} = \frac{4 \times 0.02 \text{ kg/s}}{\pi \times 0.005 \text{ m} \times 777.6 \times 10^{-6} \text{ N}\cdot\text{s/m}^2} = 6550$$

evaluating properties at  $\bar{T}_m = (T_{m,i} + T_{m,o}) / 2 = (25 + 38)^\circ\text{C} / 2 = 31.5^\circ\text{C} = 304.5\text{K}$ . Note that transition to turbulence occurs at a higher Reynolds number in a coiled tube flow, as given by Eq. 8.74,

$$\text{Re}_{D,c,cr} = \text{Re}_{D,cr} \left[ 1 + 12(D/D_c)^{0.5} \right] = 2300 \times \left[ 1 + 12(0.005 \text{ m}/0.2 \text{ m})^{0.5} \right] = 6664$$

Therefore the flow is laminar and the Nusselt number is given by Eq. 8.76 with Eqs. 8.77.

Continued...

**PROBLEM 9.72 (Cont.)**

$$\overline{\text{Nu}}_{D,c} = \left[ \left( 3.66 + \frac{4.343}{a} \right)^3 + 1.158 \left( \frac{\text{Re}_{D,c} (D/D_c)^{0.5}}{b} \right)^{1.5} \right]^{1/3} \left( \frac{\mu_c}{\mu_s} \right)^{0.14}$$

where

$$a = \left( 1 + \frac{957 (D_c/D)}{\text{Re}_{D,c}^2 \text{Pr}_c} \right) \quad b = 1 + \frac{0.477}{\text{Pr}_c}$$

Substituting numerical values yields  $\overline{\text{Nu}}_{D,c} = 32.8$ , therefore

$$\bar{h}_c = \overline{\text{Nu}}_{D,c} k_c / D = 32.8 \times 0.6193 \text{ W/m} \cdot \text{K} / 0.005 \text{ m} = 4065 \text{ W/m}^2 \cdot \text{K}$$

External free convection,  $\bar{h}_h$  : For the horizontal tube, Eq. 9.34,

$$\overline{\text{Nu}}_{D,h} = \frac{\bar{h}_h D}{k_h} = \left\{ 0.60 + \frac{0.387 \text{Ra}_D^{1/4}}{\left[ 1 + (0.559/\text{Pr})^{9/16} \right]^{8/27}} \right\}^2 \quad (1)$$

with

$$\text{Ra}_{D,h} = \frac{g \beta_h (\bar{T}_s - T_\infty) D^3}{\nu_h \alpha_h} \quad (2)$$

where  $\bar{T}_s$  is the average tube wall temperature determined from the thermal circuit for which

$$\bar{h}_c (\bar{T}_m - \bar{T}_s) = \bar{h}_h (\bar{T}_s - T_\infty) \quad (3)$$

and the average film temperature at which to evaluate properties is

$$\bar{T}_f = (\bar{T}_s + T_\infty) / 2 \quad (4)$$

We need to guess a value for  $\bar{T}_s$  and iterate the solution of the system of equations (1-4) and property evaluation until all the equations are satisfied. See Comments 1 and 2.

*Results of the analysis:* Using the foregoing relations in IHT (see Comment 2) the following results were obtained

$$\bar{T}_s = 308.4 \text{ K}, \quad \bar{T}_f = 315.7 \text{ K}, \quad \text{Ra}_D = 7.53 \times 10^4, \quad \bar{h}_h = 1078 \text{ W/m}^2 \cdot \text{K}$$

Then

$$\bar{U} = (1/\bar{h}_c + 1/\bar{h}_h)^{-1} = (1/4065 \text{ W/m}^2 \cdot \text{K} + 1/1078 \text{ W/m}^2 \cdot \text{K})^{-1} = 852 \text{ W/m}^2 \cdot \text{K}$$

$$L = \bar{U} A_s / \bar{U} \pi D = 61.3 \text{ W/K} / 852 \text{ W/m}^2 \cdot \text{K} \times \pi \times 0.005 \text{ m} = 4.58 \text{ m}$$

<

Continued...

**PROBLEM 9.72(Cont.)**

From knowledge of the tube length with the diameter of the coil  $D_c = 200$  mm, the number of coils required is

$$N = \frac{L}{\pi D_c} = \frac{4.58 \text{ m}}{\pi \times 0.200 \text{ m}} = 7.3 \approx 7$$

<

(b) With the length fixed at  $L = 4.58$  m, we can backsolve the foregoing IHT workspace model to find what effect a  $\pm 10\%$  change in the mass flow rate has on the outlet temperature,  $T_{m,o}$ . The results of the analysis are tabulated below.

$\dot{m}$ (kg/s)	0.018	0.02	0.022
$T_{m,o}$ ( $^{\circ}\text{C}$ )	38.8	38.0	37.3

That is, a  $\pm 10\%$  change in the flow rate causes less than a  $\pm 1^{\circ}\text{C}$  change in the outlet temperature. While this change seems quite small, the effect on biological processes can be significant.

**COMMENTS:** (1) For the hot fluid, the Properties section shows the relevant thermophysical properties evaluated at the proper average (rather than a guess value for the film temperature). (2) For the tube  $L/D = 4.58 \text{ m}/0.005 \text{ m} = 916$  which is substantially greater than the entrance length criterion,  $0.05\text{Re}_D = 0.05 \times 6550 = 328$ . Hence, the assumption of fully developed internal flow is justified, especially since the entrance length is shorter in a coiled tube. (3) We are slightly outside of the range for Eq. 8.76, since  $\text{Re}_{D,c}(D/C)^{1/2} = 1036 > 1000$ , but it should give a reasonable estimate. (4) The IHT model for the system can be constructed beginning with the *Rate Equation Tools, Tube Flow, Constant Surface Temperature* along with the *Correlation Tools for Free Convection, Horizontal Cylinder* and the *Properties Tool* for the hot and cold fluids (water). The correlation for the internal flow in a coiled tube must be keyed in by hand. The full set of equations is extensive and very stiff. Review of the IHT Example 8.6 would be helpful in understanding how to organize the complete model.

### PROBLEM 9.73

**KNOWN:** Volume, thermophysical properties, and initial and final temperatures of a pharmaceutical. Diameter and length of submerged tubing. Pressure of saturated steam flowing through the tubing.

**FIND:** (a) Initial rate of heat transfer to the pharmaceutical, (b) Time required to heat the pharmaceutical to 70°C and the amount of steam condensed during the process.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Pharmaceutical may be approximated as an infinite, quiescent fluid of uniform, but time-varying temperature, (2) Free convection heat transfer from the coil may be approximated as that from a heated, horizontal cylinder, (3) Negligible thermal resistance of condensing steam and tube wall, (4) Negligible heat transfer from tank to surroundings, (5) Constant properties.

**PROPERTIES:** Table A-4, Saturated water (2.455 bars):  $T_{\text{sat}} = 400\text{K} = 127^\circ\text{C}$ ,  $h_{\text{fg}} = 2.183 \times 10^6$  J/kg. Pharmaceutical: See schematic.

**ANALYSIS:** (a) The initial rate of heat transfer is  $q = \bar{h}A_s(T_s - T_i)$ , where  $A_s = \pi DL = 0.707 \text{ m}^2$  and  $\bar{h}$  is obtained from Eq. 9.34. With  $\alpha = \nu/\text{Pr} = 4.0 \times 10^{-7} \text{ m}^2/\text{s}$  and  $\text{Ra}_D = g\beta(T_s - T_i) D^3/\alpha\nu = 9.8 \text{ m/s}^2 (0.002 \text{ K}^{-1}) (102\text{K}) (0.015\text{m})^3/16 \times 10^{-13} \text{ m}^4/\text{s}^2 = 4.22 \times 10^6$ ,

$$\bar{\text{Nu}}_D = \left\{ 0.60 + \frac{0.387 \text{Ra}_D^{1/6}}{\left[ 1 + (0.559/\text{Pr})^{9/16} \right]^{8/27}} \right\}^2 = \left\{ 0.60 + \frac{0.387 (4.22 \times 10^6)^{1/6}}{\left[ 1 + (0.559/10)^{9/16} \right]^{8/27}} \right\}^2 = 27.7$$

Hence,  $\bar{h} = \text{Nu}_D k / D = 27.7 \times 0.250 \text{ W/m} \cdot \text{K} / 0.015\text{m} = 462 \text{ W/m}^2 \cdot \text{K}$

and  $q = \bar{h}A_s(T_s - T_i) = 462 \text{ W/m}^2 \cdot \text{K} \times 0.707 \text{ m}^2 (102^\circ\text{C}) = 33,300 \text{ W} <$

(b) Performing an energy balance at an instant of time for a control surface about the liquid,

$$\frac{d(\rho V c T)}{dt} = q(t) = \bar{h}(t) A_s (T_s - T(t))$$

where the Rayleigh number, and hence  $\bar{h}$ , changes with time due to the change in the temperature of the liquid. Integrating the foregoing equation using the DER function of IHT, the following results are obtained for the variation of  $T$  and  $\bar{h}$  with  $t$ .

Continued ...

**PROBLEM 9.73 (Cont.)**

The time at which the liquid reaches 70°C is

$$t_f \approx 855 \text{ s}$$

<

The temperature increases at a decreasing rate due to the corresponding reduction in  $(T_s - T)$ , and hence reductions in  $Ra_D$ ,  $\bar{h}$  and  $q$ . The Rayleigh number decreases from  $4.22 \times 10^6$  to  $2.16 \times 10^6$ , while the heat rate decreases from 33,300 to 14,000 W. The convection coefficient decreases approximately as  $(T_s - T)^{1/3}$ , while  $q \sim (T_s - T)^{4/3}$ . The latent energy released by the condensed steam corresponds to the increase in thermal energy of the pharmaceutical. Hence,  $m_c h_{fg} = \rho \forall c (T_f - T_i)$ , and

$$m_c = \frac{\rho \forall c (T_f - T_i)}{h_{fg}} = \frac{1100 \text{ kg/m}^3 \times 0.2 \text{ m}^3 \times 2000 \text{ J/kg} \cdot \text{K} \times 45^\circ\text{C}}{2.183 \times 10^6 \text{ J/kg}} = 9.07 \text{ kg}$$

<

**COMMENTS:** (1) Over such a large temperature range, the fluid properties are likely to vary significantly, particularly  $\nu$  and Pr. A more accurate solution could therefore be performed if the temperature dependence of the properties were known. (2) Condensation of the steam is a significant process expense, which is linked to the equipment (capital) and energy (operating) costs associated with steam production.

## PROBLEM 9.74

**KNOWN:** Fin of uniform cross section subjected to prescribed conditions.

**FIND:** Tip temperature and fin effectiveness based upon (a) *average* values for free convection and radiation coefficients and (b) *local* values using a numerical method of solution.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Surroundings are isothermal and large compared to the fin, (3) One-dimensional conduction in fin, (4) Constant fin properties, (5) Tip of fin is insulated, (6) Fin surface is diffuse-gray.

**PROPERTIES:** Table A-4, Air ( $T_f = 325$  K, 1 atm):  $\nu = 18.41 \times 10^{-6}$  m<sup>2</sup>/s,  $k = 0.0282$  W/m·K,  $\alpha = 26.2 \times 10^{-6}$  m<sup>2</sup>/s,  $Pr = 0.704$ ,  $\beta = 1/T_f = 3.077 \times 10^{-3}$  K<sup>-1</sup>; Table A-1, Steel AISI 316 ( $\bar{T}_s = 350$  K):  $k = 14.3$  W/m·K.

**ANALYSIS:** (a) *Average value*  $\bar{h}_c$  and  $\bar{h}_r$ : From Table 3.4 for a fin of constant cross section with an insulated tip and constant heat transfer coefficient  $\bar{h}$ , the tip temperature ( $x = L$ ) is given by Eq. 3.80,

$$\theta_L = \theta_b \frac{\cosh m(L-x)}{\cosh mL} = \theta_b / \cosh(mL) \quad m = (\bar{h}P/kA_c)^{1/2} \quad (1,2)$$

where  $\theta_L = T_L - T_\infty$  and  $\theta_b = T_b - T_\infty$ . For this situation, the average heat transfer coefficient is

$$\bar{h} = \bar{h}_c + \bar{h}_r \quad (3)$$

and is evaluated at the average temperature of the fin. The fin effectiveness  $\varepsilon_f$  follows from Eqs. 3.81 and 3.86

$$\varepsilon_f \equiv q_f / \bar{h}A_{c,b}\theta_b, \quad q_f = M \cdot \tanh(mL), \quad M = (\bar{h}PkA_c)^{1/2} \theta_b. \quad (4,5,6)$$

To estimate the coefficients, assume a value of  $\bar{T}_s$ ; the lowest  $\bar{T}_s$  occurs when the tip reaches  $T_\infty$ . That is,

$$\bar{T}_s = (\bar{T}_\infty + T_b) / 2 = (27 + 125)^\circ \text{C} / 2 = 76^\circ \text{C} \approx 350 \text{ K}$$

$$T_f = (\bar{T}_s + T_\infty) / 2 = 325 \text{ K}.$$

The free convection coefficient can be estimated from Eq. 9.33,

$$\overline{Nu}_D = \frac{\bar{h}_c D}{k} = C Ra_D^n \quad (7)$$

$$Ra_D = \frac{g\beta\Delta T D^3}{\nu\alpha} = \frac{9.8 \text{ m/s}^2 \times 3.077 \times 10^{-3} \text{ K}^{-1} (350 - 300) \text{ K} (0.006 \text{ m})^3}{18.41 \times 10^{-6} \text{ m}^2/\text{s} \times 26.2 \times 10^{-6} \text{ m}^2/\text{s}} = 675$$

and from Table 9.1 with  $10^2 < Ra_L < 10^4$ ,  $C = 0.850$  and  $n = 0.188$ . Hence

Continued...

**PROBLEM 9.74 (Cont.)**

$$\bar{h}_c = \frac{0.0282 \text{ W/m} \cdot \text{K}}{0.006 \text{ m}} \times 0.850 (675)^{0.188} = 13.6 \text{ W/m}^2 \cdot \text{K}. \quad (8)$$

The radiation coefficient is estimated from Eq. 1.9,

$$\begin{aligned} \bar{h}_r &= \varepsilon \sigma (\bar{T}_s + T_{\text{sur}}) (\bar{T}_s^2 + T_{\text{sur}}^2) \\ \bar{h}_r &= 0.6 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (350 + 300) (350^2 + 300^2) \text{ K}^3 = 4.7 \text{ W/m}^2 \cdot \text{K} \end{aligned} \quad (9)$$

Hence, the average coefficient, Eq. (3), is

$$\bar{h} = (13.6 + 4.7) \text{ W/m}^2 \cdot \text{K} = 18.3 \text{ W/m}^2 \cdot \text{K}.$$

Evaluate the fin parameters, Eq. (2) and (6) with

$$\begin{aligned} P &= \pi D = \pi \times 0.006 \text{ m} = 1.885 \times 10^{-2} \text{ m} & A_c &= \pi D^2/4 = \pi (0.006 \text{ m})^2/4 = 2.827 \times 10^{-5} \text{ m}^2 \\ m &= \left( 18.3 \text{ W/m}^2 \cdot \text{K} \times 1.885 \times 10^{-2} \text{ m} / 14.3 \text{ W/m} \cdot \text{K} \times 2.827 \times 10^{-5} \text{ m}^2 \right)^{1/2} = 29.21 \text{ m}^{-1} \\ M &= \left( 18.3 \text{ W/m}^2 \cdot \text{K} \times 1.885 \times 10^{-2} \text{ m} \times 14.3 \text{ W/m} \cdot \text{K} \times 2.827 \times 10^{-5} \text{ m}^2 \right)^{1/2} (125 - 27) \text{ K} = 1.157 \text{ W}. \end{aligned}$$

From Eq. (1), the tip temperature is

$$\theta_L = T_L - T_b = (125 - 27) \text{ K} / \cosh(29.21 \text{ m}^{-1} \times 0.050 \text{ m}) = 43.2 \text{ K} \quad T_L = 70.2^\circ \text{C} = 343 \text{ K}. <$$

Note this value of  $T_L$  provides for  $\bar{T}_s \approx 370 \text{ K}$ ; so we underestimated  $\bar{T}_s$ . For best results, an iteration is warranted. The fin effectiveness, Eqs. (4) and (5), is

$$\begin{aligned} q_f &= 1.157 \text{ W} \tanh(29.21 \text{ m}^{-1} \times 0.050 \text{ m}) = 1.039 \text{ W} \\ \varepsilon_f &= 1.039 \text{ W} / 18.3 \text{ W/m}^2 \cdot \text{K} \times 2.827 \times 10^{-5} \text{ m}^2 (125 - 27) \text{ K} = 20.5. < \end{aligned}$$

(b) *Local values  $h_c$  and  $h_r$ :* Consider the nodal arrangement for using a numerical method to find the tip temperature  $T_L$ , the heat rate  $q_f$ , and the fin effectiveness  $\varepsilon$ .

From an energy balance on a control volume about node m, the finite-difference equation is of the form

$$T_m = \left[ T_{m+1} + T_{m-1} + (h_c + h_r) (4\Delta x^2/kD) T_\infty \right] / \left[ 2 + (h_r + h_c) (4\Delta x^2/kD) \right]. \quad (10)$$

The local coefficient  $h_c$  follows from Eq. (3), with Eq. 9.33, yielding

$$\begin{aligned} h_c &= \frac{k}{D} \text{CRa}_D^n \\ h_c &= \frac{0.0282 \text{ W/m} \cdot \text{K}}{0.006 \text{ m}} \times 0.850 \left( 675 \left[ \Delta T / (350 - 300) \right] \right)^{0.188} = 6.517 (T_m - 300)^{0.188}. \end{aligned} \quad (11)$$

The local coefficient  $h_r$  follows from Eq. (9),

$$h_r = 0.6 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (T_m + 300) (T_m^2 + 300^2) \quad \text{Continued...}$$

**PROBLEM 9.74 (Cont.)**

$$h_r = 3.402 \times 10^{-8} (T_m + 300) (T_m^2 + 300^2). \quad (12)$$

The 20-node system of finite-difference equations based upon Eq. (10) with the variable coefficients  $h_c$  and  $h_r$  prescribed Eqs. (11) and (12), respectively, can be solved simultaneously using IHT or another approach. The temperature distribution is

Node	$T_m$ (K)	Node	$T_m$ (K)	Node	$T_m$ (K)	Node	$T_m$ (K)
1	391.70	6	367.61	11	353.02	16	345.49
2	385.95	7	364.03	12	351.00	17	344.70
3	380.70	8	360.81	13	349.25	18	344.15
4	375.92	9	357.91	14	347.75	19	343.82
5	371.56	10	355.32	15	346.50	20	343.71

From these results the tip temperature is

$$T_L = T_{fd} = 343.7 \text{ K} = 70.7^\circ \text{ C}.$$

<

The fin heat rate follows from an energy balance for the control surface about node b.

$$q_f = q_{conv} + q_{cond}$$

$$q_f = h_b P \frac{\Delta x}{2} (T_b - T_\infty) + k A_c \frac{T_b - T_1}{\Delta x}$$

where  $h_b$  follows from Eqs. (11) and (12), with  $T_b = 125^\circ \text{ C} = 398 \text{ K}$ ,

$$h_b = 6.517 (398 - 300)^{0.188} + 3.402 \times 10^{-8} (398 + 300) (398^2 + 300^2) = 21.33 \text{ W/m}^2 \cdot \text{K}$$

$$q_f = 21.33 \text{ W/m}^2 \cdot \text{K} \times 1.855 \times 10^{-2} \text{ m} (0.0025 \text{ m}/2) (398 - 300) \text{ K}$$

$$+ 14.3 \text{ W/m} \cdot \text{K} \times 2.827 \times 10^{-5} \text{ m}^2 \frac{(398 - 391.70) \text{ K}}{0.0025 \text{ m}} = (0.049 + 1.018) \text{ W} = 1.067 \text{ W}.$$

The effectiveness follows from Eq. (4)

$$\varepsilon_f = 1.067 \text{ W} / 21.33 \text{ W/m}^2 \cdot \text{K} \times 2.827 \times 10^{-5} \text{ m}^2 (125 - 27) \text{ K} = 18.1$$

**COMMENTS:** (1) The results by the two methods of solution compare as follows:

Coefficients	$T(L)$ ,K	$q_f$ (W)	$\varepsilon_f$
average	343.1	1.039	20.5
local	343.7	1.067	18.1

The temperature predictions are in excellent agreement and the heat rates very close, within 4%.

(2) To obtain the finite-different equation for node  $n = 20$ , use Eq. (10) but consider the adiabatic surface as a symmetry plane.

### PROBLEM 9.75

**KNOWN:** Horizontal tubes of different shapes each of the same cross-sectional area transporting a hot fluid in quiescent air. Lienhard correlation for immersed bodies.

**FIND:** Tube shape which has the minimum heat loss to the ambient air by free convection.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Ambient air is quiescent, (2) Negligible heat loss by radiation, (3) All shapes have the same cross-sectional area and uniform surface temperature.

**PROPERTIES:** Table A-4, Air ( $T_f \approx 300\text{K}$ , 1 atm):  $\nu = 15.89 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\alpha = 22.5 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0263 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.707$ ,  $\beta = 1/T_f$ .

**ANALYSIS:** The Lienhard correlation approximates the laminar convection coefficient for an immersed body on which the boundary layer does not separate from the surface by  $\overline{\text{Nu}}_\ell = (\overline{h}\ell)/k = 0.52\text{Ra}_\ell^{1/4}$ , where the characteristic length,  $\ell$ , is the length of travel of the fluid in the boundary layer across the shape surface. The heat loss per unit length from any shape is  $q' = \overline{h}P(T_s - T_\infty)$ . For the shapes,

$$\text{Ra}_\ell = \frac{g\beta\Delta T\ell^3}{\nu\alpha} = \frac{9.8 \text{ m/s}^2 (1/300 \text{ K})(35 - 25) \text{ K} \ell^3 \text{ m}^3}{15.89 \times 10^{-6} \text{ m}^2/\text{s} \times 22.5 \times 10^{-6} \text{ m}^2/\text{s}} = 9.137 \times 10^8 \ell^3$$

$$\overline{h}_\ell = (0.0263 \text{ W/m}\cdot\text{K} / \ell) 0.52 \left( 9.137 \times 10^8 \ell^3 \right)^{1/4} = 2.378 \ell^{-1/4}$$

For the shapes,  $\ell$  is half the total wetted perimeter  $P$ . Evaluating  $\overline{h}_\ell$  and  $q'$ , find

Shape	$P$ (mm)	$\ell$ (mm)	$\overline{h}_\ell$ ( $\text{W/m}^2 \cdot \text{K}$ )	$q'$ ( $\text{W/m}$ )
1	$2 \times 40 + 2 \times 10 = 100$	50	5.03	5.03
2	$4 \times 20 = 80$	40	5.32	4.26
3	$4 \times 20 = 80$	40	5.32	4.26
4	$\pi \times 22.56 = 70.9$	35.4	5.48	3.89

Hence, it follows that shape 4 has the minimum heat loss. <

**COMMENTS:** Using the Lienhard correlation for a sphere of  $D = 22.56 \text{ mm}$ , find  $\ell = 35.4 \text{ mm}$ , the same as for a cylinder, namely,  $h_4 = 5.48 \text{ W/m}^2 \cdot \text{K}$ . Using the Churchill correlation, Eq. 9.35, find  $\overline{h} = 7.69 \text{ W/m}^2 \cdot \text{K}$ . Hence, the approximation for the sphere is 29% low. For a cylinder, using Eq. 9.34, find  $\overline{h} = 5.15 \text{ W/m}^2 \cdot \text{K}$ . The approximation for the cylinder is 6% high.

## PROBLEM 9.76

**KNOWN:** Sphere of 2-mm diameter immersed in a fluid at 300 K.

**FIND:** (a) The conduction limit of heat transfer from the sphere to the quiescent, extensive fluid,  $Nu_{D,cond} = 2$ ; (b) Considering free convection, surface temperature at which the Nusselt number is twice that of the conduction limit for the fluids air and water; and (c) Considering forced convection, fluid velocity at which the Nusselt number is twice that of the conduction limit for the fluids air and water.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Sphere is isothermal, (2) For part (a), fluid is stationary, and (3) For part (b), fluid is quiescent, extensive.

**ANALYSIS:** (a) Following the hint provided in the problem statement, the thermal resistance of a hollow sphere, Eq. 3.40 of inner and outer radii,  $r_1$  and  $r_2$ , respectively, and thermal conductivity  $k$ , is

$$R_{t,cond} = \frac{1}{4\pi k} \left( \frac{1}{r_1} - \frac{1}{r_2} \right) \quad (1)$$

and as  $r_2 \rightarrow \infty$ , that is the medium is extensive

$$R_{t,cond} = \frac{1}{4\pi k r_1} = \frac{1}{2\pi k D} \quad (2)$$

The Nusselt number can be expressed as

$$Nu = \frac{hD}{k} \quad (3)$$

and the conduction resistance in terms of a convection coefficient is

$$R_{t,cond} = \frac{1}{hA_s} = \frac{1}{h\pi D^2} \quad (4)$$

Combining Eqs. (3) and (4)

$$Nu_{D,cond} = \frac{\left(1/R_{t,cond}\pi D^2\right)D}{k} = \frac{\left[1/(1/2\pi k D)\left(\pi D^2\right)\right]D}{k} = 2 \quad <$$

(b) For free convection, the recommended correlation, Eq. 9.35, is

$$\overline{Nu}_D = 2 + \frac{0.589 Ra_D^{1/4}}{\left[1 + (0.469/Pr)^{9/16}\right]^{4/9}}$$

Continued...

**PROBLEM 9.76 (Cont.)**

$$Ra_D = \frac{g\beta\Delta T D^3}{\nu\alpha} \quad \Delta T = T_s - T_\infty$$

where properties are evaluated at  $T_f = (T_s + T_\infty) / 2$ . What value of  $T_s$  is required for  $\overline{Nu}_D = 4$  for the fluids air and water? Using the *IHT Correlations Tool, Free Convection, Sphere* and the *Properties Tool* for *Air* and *Water*, find

*Air:*  $\overline{Nu} \leq 3.1$  for all  $T_s > 300$  <

*Water:*  $T_s = 301.1\text{K}$  <

(c) For forced convection, the recommended correlation, Eq. 7.56, is

$$\overline{Nu}_D = 2 + \left(0.4 Re_D^{1/2} + 0.06 Re_D^{2/3}\right) Pr^{0.4} (\mu/\mu_s)^{1/4}$$

$$Re_D = VD/\nu$$

where properties are evaluated at  $T_\infty$ , except for  $\mu_s$  evaluated at  $T_s$ . What value of  $V$  is required for  $\overline{Nu}_D = 4$  if the fluids are air and water? Using the *IHT Correlations Tool, Forced Convection, Sphere* and the *Properties Tool* for *Air* and *Water*, find (evaluating all properties at 300 K)

*Air:*  $V = 0.17 \text{ m/s}$       *Water:*  $V = 0.00185 \text{ m/s}$  <

**COMMENTS:** (1) For water,  $\overline{Nu}_D = 2 \times \overline{Nu}_{D,\text{cond}}$  can be achieved by  $\Delta T \approx 1$  for free convection and with very low velocity,  $V < 0.002 \text{ m/s}$ , for forced convection.

(2) For air,  $\overline{Nu}_D = 2 \times \overline{Nu}_{D,\text{cond}}$  can be achieved in forced convection with low velocities,  $V < 0.2 \text{ m/s}$ . In free convection,  $\overline{Nu}_D$  increases with increasing  $T_s$  and reaches a maximum,  $\overline{Nu}_{D,\text{max}} = 3.1$ , around 450 K. Why is this so? Hint: Plot  $Ra_D$  as a function of  $T_s$  and examine the role of  $\beta$  and  $\Delta T$  as a function of  $T_s$ .

### PROBLEM 9.77

**KNOWN:** Sphere with embedded electrical heater is maintained at a uniform surface temperature when suspended in various media.

**FIND:** Required electrical power for these media: (a) atmospheric air, (b) water, (c) ethylene glycol.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible surface radiation effects, (2) Extensive and quiescent media.

**PROPERTIES:** Evaluated at  $T_f = (T_s + T_\infty)/2 = 330\text{K}$ :

	$\nu \cdot 10^6, \text{m}^2/\text{s}$	$k \cdot 10^3, \text{W/m}\cdot\text{K}$	$\alpha \cdot 10^6, \text{m}^2/\text{s}$	Pr	$\beta \cdot 10^3, \text{K}^{-1}$
Table A-4, Air (1 atm)	18.91	28.5	26.9	0.711	3.03
Table A-6, Water	0.497	650	0.158	3.15	0.504
Table A-5, Ethylene glycol	5.15	260	0.0936	55.0	0.65

**ANALYSIS:** The electrical power ( $P_e$ ) required to offset convection heat transfer is

$$q_{\text{conv}} = \bar{h} A_s (T_s - T_\infty) = \pi \bar{h} D^2 (T_s - T_\infty). \quad (1)$$

The free convection heat transfer coefficient for the sphere can be estimated from Eq. 9.35 using Eq. 9.25 to evaluate  $Ra_D$ .

$$\bar{Nu}_D = 2 + \frac{0.589 Ra_D^{1/4}}{\left[1 + (0.469/Pr)^{9/16}\right]^{4/9}} \begin{cases} Pr \geq 0.7 \\ Ra_D \leq 10^{11} \end{cases} \quad Ra_D = \frac{g \beta \Delta T D^3}{\nu \alpha}. \quad (2,3)$$

(a) For air

$$Ra_D = \frac{9.8 \text{m/s}^2 \left(3.03 \times 10^{-3} \text{K}^{-1}\right) (94 - 20) \text{K} (0.025 \text{m})^3}{18.91 \times 10^{-6} \text{m}^2/\text{s} \times 26.9 \times 10^{-6} \text{m}^2/\text{s}} = 6.750 \times 10^4$$

$$\bar{h}_D = \frac{k}{D} \bar{Nu}_D = \frac{0.0285 \text{W/m}\cdot\text{K}}{0.025 \text{m}} \left\{ 2 + \frac{0.589 \left(6.750 \times 10^4\right)^{1/4}}{\left[1 + (0.469/0.711)^{9/16}\right]^{4/9}} \right\} = 10.6 \text{W/m}^2 \cdot \text{K}$$

$$q_{\text{conv}} = \pi \times 10.6 \text{W/m}^2 \cdot \text{K} (0.025 \text{m})^2 (94 - 20) \text{K} = 1.55 \text{W}.$$

Continued ...

**PROBLEM 9.77 (Cont.)**

(b,c) Summary of the calculations above and for water and ethylene glycol:

Fluid	$Ra_D$	$\bar{h}_D \left( W / m^2 \cdot K \right)$	$q(W)$	
Air	$6.750 \times 10^4$	10.6	1.55	<
Water	$7.273 \times 10^7$	1299	187	<
Ethylene glycol	$15.82 \times 10^6$	393	57.0	<

**COMMENTS:** Note large differences in the coefficients and heat rates for the fluids.

## PROBLEM 9.78

**KNOWN:** Temperatures and spacing of vertical, isothermal plates.

**FIND:** (a) Shape of velocity distribution, (b) Forms of mass, momentum and energy equations for laminar flow, (c) Expression for the temperature distribution, (d) Vertical pressure gradient, (e) Expression for the velocity distribution.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Laminar, incompressible, fully-developed flow, (2) Constant properties, (3) Negligible viscous dissipation, (4) Boussinesq approximation.

**ANALYSIS:** (a) For the prescribed conditions, there must be buoyancy driven ascending and descending flows along the surfaces corresponding to  $T_{s,1}$  and  $T_{s,2}$ , respectively (see schematic). However, conservation of mass dictates equivalent rates of *upflow* and *downflow* and, assuming constant properties, inverse symmetry of the velocity distribution about the midplane.

(b) For fully-developed flow, which is achieved for *long* plates,  $v_x = 0$  and the continuity equation yields

$$\frac{\partial v_z}{\partial z} = 0 \quad <$$

With both surface temperatures independent of  $z$ , the fully-developed temperature distribution will also have  $\partial T / \partial z = 0$ . Hence, there is no net transfer of momentum or energy by advection, and the corresponding equations are, respectively,

$$0 = -\left(\frac{dp}{dz}\right) + \mu \left(\frac{d^2 v_z}{dx^2}\right) - \rho(g/g_c) \quad <$$

$$0 = (dT^2/dx^2) \quad <$$

(c) Integrating the energy equation twice, we obtain

$$T = C_1 x + C_2$$

and applying the boundary conditions,  $T(-L) = T_{s,1}$  and  $T(L) = T_{s,2}$ , it follows that  $C_1 = -(T_{s,1} - T_{s,2})/2L$  and  $C_2 = (T_{s,1} + T_{s,2})/2 \equiv T_m$ , in which case,

$$\frac{T - T_m}{T_{s,1} - T_{s,2}} = -\frac{x}{2L} \quad <$$

Continued...

### PROBLEM 9.78 (Cont.)

(d) From hydrostatic considerations and the assumption of a constant density  $\rho_m$ , the balance between the gravitational and net pressure forces may be expressed as  $dp/dz = -\rho_m(g/g_c)$ . The momentum equation is then of the form

$$0 = \mu \left( d^2 v_z / dx^2 \right) - (\rho - \rho_m) (g/g_c)$$

or, invoking the Boussinesq approximation,  $\rho - \rho_m \approx -\beta \rho_m (T - T_m)$ ,

$$d^2 v_z / dx^2 = -(\beta \rho_m / \mu) (g/g_c) (T - T_m)$$

or, from the known temperature distribution,

$$d^2 v_z / dx^2 = (\beta \rho_m / 2\mu) (g/g_c) (T_{s,1} - T_{s,2}) (x/L) \quad <$$

(e) Integrating the foregoing expression, we obtain

$$dv_z / dx = (\beta \rho_m / 4\mu) (g/g_c) (T_{s,1} - T_{s,2}) \left( x^2 / L \right) + C_1$$

$$v_z = (\beta \rho_m / 12\mu) (g/g_c) (T_{s,1} - T_{s,2}) \left( x^3 / L \right) + C_1 x + C_2$$

Applying the boundary conditions  $v_z(-L) = v_z(L) = 0$ , it follows that  $C_1 = -(\beta \rho_m / 12\mu) (g/g_c) (T_{s,1} - T_{s,2}) L$  and  $C_2 = 0$ . Hence,

$$v_z = \left( \beta \rho_m L^2 / 12\mu \right) (g/g_c) (T_{s,1} - T_{s,2}) \left[ \left( x^3 / L^3 \right) - (x/L) \right] \quad <$$

**COMMENTS:** The validity of assuming fully-developed conditions improves with increasing plate length and would be satisfied precisely for infinite plates.

### PROBLEM 9.79

**KNOWN:** Dimensions of vertical rectangular fins. Temperature of fins and quiescent air.

**FIND:** Optimum fin spacing and corresponding fin heat transfer rate.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Isothermal fins, (2) Negligible radiation, (3) Quiescent air, (4) Negligible heat transfer from fin tips, (5) Negligible radiation.

**PROPERTIES:** Table A-4, Air ( $T_f = 325\text{K}$ , 1 atm):  $\nu = 18.41 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0282 \text{ W/m}\cdot\text{K}$ ,  $\alpha = 26.1 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.703$ .

**ANALYSIS:** From Table 9.3

$$S_{\text{opt}} = 2.71 \left( \text{Ra}_S / S^3 H \right)^{-1/4} = 2.71 \left[ \frac{g\beta(T_s - T_\infty)}{\alpha\nu H} \right]^{-1/4}$$

$$S_{\text{opt}} = 2.71 \left[ \frac{9.8 \text{ m/s}^2 (325 \text{ K})^{-1} (50 \text{ K})}{26.1 \times 10^{-6} \text{ m}^2/\text{s} \times 18.4 \times 10^{-6} \text{ m}^2/\text{s} \times 0.15 \text{ m}} \right]^{-1/4} = 7.12 \text{ mm} \quad <$$

From Eq. 9.45 and Table 9.3

$$\overline{\text{Nu}}_S = \left[ \frac{576}{(\text{Ra}_S S/L)^2} + \frac{2.87}{(\text{Ra}_S S/L)^{1/2}} \right]^{-1/2}$$

$$\text{Ra}_S (S/L) = \frac{g\beta(T_s - T_\infty) S^4}{\alpha\nu H} = \frac{9.8 \text{ m/s}^2 (325 \text{ K})^{-1} (50 \text{ K}) (7.12 \times 10^{-3} \text{ m})^4}{25.4 \times 10^{-6} \text{ m}^2/\text{s} \times 18.4 \times 10^{-6} \text{ m}^2/\text{s} \times 0.15 \text{ m}}$$

$$\text{Ra}_S (S/L) = 53.2$$

$$\overline{\text{Nu}}_S = \left[ \frac{576}{(53.2)^2} + \frac{2.87}{(53.2)^{1/2}} \right]^{-1/2} = [0.204 + 0.393]^{-1/2} = 1.29$$

$$\bar{h} = \overline{\text{Nu}}_S k / S = 1.29 (0.0282 \text{ W/m}\cdot\text{K} / 0.00712 \text{ m}) = 5.13 \text{ W/m}^2 \cdot \text{K}$$

With  $N = W/(t + S) = (355 \text{ mm}) / (8.62 \times 10^{-3} \text{ m}) = 41.2 \approx 41$ ,

$$q = 2N\bar{h}(L \times H)(T_s - T_\infty) = 82 (5.13 \text{ W/m}^2 \cdot \text{K}) (0.02 \text{ m} \times 0.15 \text{ m}) 50 \text{ K}$$

$$q = 63.1 \text{ W} \quad <$$

**COMMENTS:**  $S_{\text{opt}} = 7.12 \text{ mm}$  is considerably less than the value of 34 mm predicted from previous considerations. Hence, the corresponding value of  $q = 63.1 \text{ W}$  is considerably larger than that of the previous prediction.

### PROBLEM 9.80

**KNOWN:** Length, width and spacing of vertical circuit boards. Maximum allowable board temperature.

**FIND:** Maximum allowable power dissipation per board.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Circuit boards are flat with uniform heat flux at each surface, (2) Negligible radiation.

**PROPERTIES:** Table A-4, Air ( $\bar{T} = 320\text{K}$ , 1 atm):  $\nu = 17.9 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0278 \text{ W/m}\cdot\text{K}$ ,  $\alpha = 25.5 \times 10^{-6} \text{ m}^2/\text{s}$ .

**ANALYSIS:** From Eqs. 9.41 and 9.46 and Table 9.3,

$$\frac{q_s''}{T_{s,L} - T_{\infty}} \frac{S}{k} = \left[ \frac{48}{\text{Ra}_S^* S/L} + \frac{2.51}{(\text{Ra}_S^* S/L)^{2/5}} \right]^{-1/2}$$

where 
$$\text{Ra}_S^* \frac{S}{L} = \frac{g\beta q_s'' S^5}{k\alpha\nu L} = \frac{9.8 \text{ m/s}^2 (320 \text{ K})^{-1} (0.025 \text{ m})^5 q_s''}{0.0278 \text{ W/m}\cdot\text{K} (25.5 \times 10^{-6} \text{ m}^2/\text{s}) (17.9 \times 10^{-6} \text{ m}^2/\text{s}) 0.4 \text{ m}}$$

$$\text{Ra}_S^* \frac{S}{L} = 58.9 q_s''$$

and 
$$\frac{q_s''}{T_{s,L} - T_{\infty}} \frac{S}{k} = \frac{0.025 \text{ m} \cdot q_s''}{(60 \text{ K}) 0.0278 \text{ W/m}\cdot\text{K}} = 0.015 q_s''.$$

Hence, 
$$0.015 q_s'' = \left[ \frac{0.815}{q_s''} + \frac{0.492}{(q_s'')^{0.4}} \right]^{-1/2}.$$

A trial-and-error solution yields

$$q_s'' = 287 \text{ W/m}^2.$$

Hence, 
$$q = 2A_s q_s'' = 2(0.4 \text{ m})^2 (287 \text{ W/m}^2) = 91.8 \text{ W.} \quad <$$

**COMMENTS:** Larger heat rates may be achieved by using a fan to superimpose a forced flow on the buoyancy driven flow.

## PROBLEM 9.81

**KNOWN:** Dimensions of window and gap between window and insulation. Temperature of window and surrounding air.

**FIND:** (a) Heat loss through the window and associated weekly cost, (b) Heat loss through window as a function of gap spacing.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible radiation heat loss. (2) Insulation creates adiabatic condition.

**PROPERTIES:** Table A-4, Air (assumed  $\bar{T} = 7^\circ\text{C} = 280\text{ K}$ ):  $\nu = 14.11 \times 10^{-6}\text{ m}^2/\text{s}$ ,  $k = 0.0247\text{ W/m}\cdot\text{K}$ ,  $\alpha = 19.9 \times 10^{-6}\text{ m}^2/\text{s}$ ,  $\beta = 1/\bar{T} = 0.0036\text{ K}^{-1}$ .

**ANALYSIS:**

(a) This is a case of free convection in a vertical parallel plate channel. The window can be approximated as isothermal and the insulation can be modeled as adiabatic. Therefore we can use Equation 9.45 to find the average Nusselt number, with  $C_1 = 144$ ,  $C_2 = 2.87$  in Table 9.3. We begin by calculating the Rayleigh number from Equation 9.38:

$$Ra_S = \frac{g \beta |T_s - T_\infty| S^3}{\alpha \nu} \quad (1)$$

$$Ra_S = \frac{9.8\text{ m/s}^2 \times 0.0036\text{ K}^{-1} \times |0^\circ\text{C} - 15^\circ\text{C}| \times (0.005\text{ m})^3}{19.9 \times 10^{-6}\text{ m}^2/\text{s} \times 14.11 \times 10^{-6}\text{ m}^2/\text{s}} = 234$$

Then

$$\bar{Nus} = \left[ \frac{C_1}{(Ra_S S/L)^2} + \frac{C_2}{(Ra_S S/L)^{1/2}} \right]^{-1/2} \quad (2)$$

$$\bar{Nus} = \left[ \frac{144}{(234 \times 0.005\text{ m}/1.8\text{ m})^2} + \frac{2.87}{(234 \times 0.005\text{ m}/1.8\text{ m})^{1/2}} \right]^{-1/2} = 0.0538$$

From Equation 9.37 (noting that heat transfer is in the direction from the air to the surface)

$$\begin{aligned} q &= \bar{Nus} k A (T_\infty - T_s)/S \\ &= 0.0538 \times 0.0247\text{ W/m}\cdot\text{K} \times 1.8\text{ m}^2 (15^\circ\text{C} - 0^\circ\text{C})/0.005\text{ m} \\ &= 7.2\text{ W} \end{aligned} \quad (3)$$

Then the weekly cost is

$$\text{Cost} = 7.2\text{ W} \times 0.18 \times 10^{-3}\text{ \$/W}\cdot\text{h} \times 24\text{ h/day} \times 7\text{ days}$$

$$\text{Cost} = \$0.22$$

Continued...

### PROBLEM 9.81 (Cont.)

(b) Solving Equations (1), (2), and (3) for  $1 \text{ mm} \leq S \leq 20 \text{ mm}$ , the following graph can be generated.

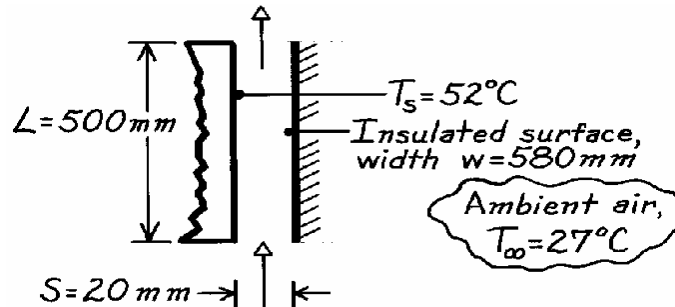

**COMMENTS:** (1) Despite the poor workmanship there is a significant cost savings. (2) With  $Ra_S S/L = 0.65 < 10$  in part (a), we could have used the fully developed results, Equation 9.40. However this equation is not valid for  $Ra_S S \gtrsim 10$ , which corresponds to  $S \gtrsim 10 \text{ mm}$ .

## PROBLEM 9.82

**KNOWN:** Vertical air vent in front door of dishwasher with prescribed width and height. Spacing between isothermal and insulated surface of 20 mm.

**FIND:** (a) Heat loss from the tub surface and (b) Effect on heat rate of changing spacing by  $\pm 10$  mm.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Vent forms vertical parallel isothermal/adiabatic plates, (3) Ambient air is quiescent.

**PROPERTIES:** Table A-4, ( $T_f = (T_s + T_\infty)/2 = 312.5\text{K}$ , 1 atm):  $\nu = 17.15 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\alpha = 24.4 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 27.2 \times 10^{-3} \text{ W/m}\cdot\text{K}$ ,  $\beta = 1/T_f$ .

**ANALYSIS:** The vent arrangement forms two vertical plates, one is isothermal,  $T_s$ , and the other is adiabatic ( $q'' = 0$ ). The heat loss can be estimated from Eq. 9.37 with the correlation of Eq. 9.45

using  $C_1 = 144$  and  $C_2 = 2.87$  from Table 9.3:

$$Ra_S = \frac{g\beta(T_s - T_\infty)S^3}{\nu\alpha} = \frac{9.8 \text{ m/s}^2 (1/312.5 \text{ K})(52 - 27) \text{ K} (0.020 \text{ m})^3}{17.15 \times 10^{-6} \text{ m}^2/\text{s} \times 24.4 \times 10^{-6} \text{ m}^2/\text{s}} = 14,988$$

$$q = A_s (T_s - T_\infty) \frac{k}{S} \left[ \frac{C_1}{(Ra_S S/L)^2} + \frac{C_2}{(Ra_S S/L)^{1/2}} \right]^{-1/2} = (0.500 \times 0.580) \text{ m}^2 \times$$

$$(52 - 27) \text{ K} \frac{0.0272 \text{ W/m}\cdot\text{K}}{0.020 \text{ m}} \left[ \frac{C_1}{(Ra_S S/L)^2} + \frac{C_2}{(Ra_S S/L)^{1/2}} \right]^{-1/2} = 28.8 \text{ W.} \quad <$$

(b) To determine the effect of the spacing at  $S = 30$  and  $10$  mm, we need only repeat the above calculations with these results

S (mm)	$Ra_S$	q (W)	
10	1874	26.1	<
30	50,585	28.8	<

Since it would be desirable to minimize heat losses from the tub, based upon these calculations, you would recommend a decrease in the spacing.

**COMMENTS:** For this situation, according to Table 9.3, the spacing corresponding to the maximum heat transfer rate is  $S_{\max} = (S_{\max}/S_{\text{opt}}) \times 2.15(Ra_S/S^3 L)^{-1/4} = 14.5 \text{ mm}$ . Find  $q_{\max} = 28.5 \text{ W}$ . Note that the heat rate is not very sensitive to spacing for these conditions.

### PROBLEM 9.83

**KNOWN:** Dimensions, spacing and temperature of plates in a vertical array. Ambient air temperature. Total width of the array.

**FIND:** Optimal plate spacing for maximum heat transfer from the array and corresponding number of plates and heat transfer.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, (2) Negligible plate thickness, (3) Constant properties.

**PROPERTIES:** Table A-4, air ( $p = 1 \text{ atm}$ ,  $\bar{T} = 320 \text{ K}$ ):  $\nu = 17.9 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0278 \text{ W/m}\cdot\text{K}$ ,  $\alpha = 25.5 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.704$ ,  $\beta = 0.00313 \text{ K}^{-1}$ .

**ANALYSIS:** With  $\text{Ra}_S/S^3L = g\beta(T_s - T_\infty)/\alpha\nu L = (9.8 \text{ m/s}^2 \times 0.00313 \text{ K}^{-1} \times 55^\circ\text{C}) / (25.5 \times 17.9 \times 10^{-12} \text{ m}^4/\text{s}^2 \times 0.3 \text{ m}) = 1.232 \times 10^{10} \text{ m}^{-4}$ , from Table 9.3, the spacing which maximizes heat transfer for the array is

$$S_{opt} = \frac{2.71}{(\text{Ra}_S/S^3L)^{1/4}} = \frac{2.71}{(1.232 \times 10^{10} \text{ m}^{-4})^{1/4}} = 8.13 \times 10^{-3} \text{ m} = 8.13 \text{ mm} \quad <$$

With the requirement that  $(N - 1) S_{opt} \leq W_{ar}$ , it follows that  $N \leq 1 + 150 \text{ mm}/8.13 \text{ mm} = 19.4$ , in which case

$$N = 19 \quad <$$

The corresponding heat rate is  $q = N(2WL)\bar{h}(T_s - T_\infty)$ , where, from Eq. 9.45 and Table 9.3,

$$\bar{h} = \frac{k}{S} \overline{\text{Nu}}_S = \frac{k}{S} \left[ \frac{576}{(\text{Ra}_S S/L)^2} + \frac{2.87}{(\text{Ra}_S S/L)^{1/2}} \right]^{1/2}$$

With  $\text{Ra}_S S/L = (\text{Ra}_S/S^3L)S^4 = 1.232 \times 10^{10} \text{ m}^{-4} \times (0.00813 \text{ m})^4 = 53.7$ ,

$$\bar{h} = \frac{0.0278 \text{ W/m}\cdot\text{K}}{0.00813 \text{ m}} \left[ \frac{576}{(53.7)^2} + \frac{2.87}{(53.7)^{1/2}} \right] = 3.42(0.200 + 0.392) = 2.02 \text{ W/m}^2 \cdot \text{K}$$

$$q = 19(2 \times 0.3 \text{ m} \times 0.3 \text{ m}) 2.02 \text{ W/m}^2 \cdot \text{K} \times 55^\circ\text{C} = 380 \text{ W} \quad <$$

**COMMENTS:** It would be difficult to fabricate heater plates of thickness  $\delta \ll S_{opt}$ . Hence, subject to the constraint imposed on  $W_{ar}$ ,  $N$  would be reduced, where  $N \leq 1 + W_{ar}/(S_{opt} + \delta)$ .

## PROBLEM 9.84

**KNOWN:** A bank of drying ovens is mounted on a rack in a room with an ambient temperature of 27°C; the cubical ovens are 500 mm to a side and the spacing between the ovens is 15 mm.

**FIND:** (a) Estimate the heat loss from the facing side of an oven when its surface temperature is 47°C, and (b) Explore the effect of the spacing dimension on the heat loss. At what spacing is the heat loss a maximum? Describe the boundary layer behavior for this condition. Can this condition be analyzed by treating the oven side-surface as an isolated vertical plate?

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Adjacent oven sides form a vertical channel with symmetrically heated plates, (3) Room air is quiescent, and channel sides are open to the room air, and (4) Constant properties.

**PROPERTIES:** Table A-4, Air ( $T_f = (T_s + T_\infty)/2 = 310$  K, 1 atm):  $\nu = 1.69 \times 10^{-5}$  m<sup>2</sup>/s,  $k = 0.0270$  W/m·K,  $\alpha = 2.40 \times 10^{-5}$  m<sup>2</sup>/s,  $Pr = 0.706$ ,  $\beta = 1/T_f$ .

**ANALYSIS:** (a) For the isothermal plate channel, Eq. 9.45 with Eqs. 9.37 and 9.38, allow for calculation of the heat transfer from a plate to the ambient air.

$$\overline{Nu}_S = \left[ \frac{C_1}{(Ra_S S/L)^2} + \frac{C_2}{(Ra_S S/L)^{1/2}} \right]^{-1/2} \quad (1)$$

$$\overline{Nu}_S = \frac{q/A}{T_s - T_\infty} \frac{S}{k} \quad (2)$$

$$Ra_S = \frac{g\beta(T_s - T_\infty)S^3}{\alpha\nu} \quad (3)$$

where, from Table 9.3, for the *symmetrical isothermal plates*,  $C_1 = 576$  and  $C_2 = 2.87$ . Properties are evaluated at the film temperature  $T_f$ . Substituting numerical values, evaluate the correlation parameters and the heat rate.

$$Ra_S = \frac{9.8 \text{ m/s}^2 (1/310 \text{ K})(47 - 27) \text{ K} (0.015 \text{ m})^3}{2.40 \times 10^{-5} \text{ m}^2/\text{s} \times 1.69 \times 10^{-5} \text{ m}^2/\text{s}} = 5267$$

$$\overline{Nu}_S = \left[ \frac{576}{(5267 \times 0.015 \text{ m}/0.50 \text{ m})^2} + \frac{2.87}{(5267 \times 0.015 \text{ m}/0.050 \text{ m})^{1/2}} \right]^{-1/2} = 1.994$$

$$1.994 = \frac{q/(0.50 \times 0.50) \text{ m}^2}{(47 - 27) \text{ K}} \frac{0.015 \text{ m}}{0.0270 \text{ W/m} \cdot \text{K}} \quad q = 18.0 \text{ W} \quad <$$

Continued ...

### PROBLEM 9.84 (Cont.)

(b) Using the foregoing relations in *IHT*, the heat rate is calculated for a range of spacing  $S$ .

Note that the heat rate increases with increasing spacing up to about  $S = 20$  mm. This implies that for  $S > 20$  mm, the side wall of the oven behaves as an *isolated vertical plate*. From the treatment of the vertical channel, Section 9.7.1, the spacing to provide maximum heat rate from a plate occurs at  $S_{\max}$  which, from Table 9.3, is evaluated by

$$S_{\max} = 1.71 S_{\text{opt}} = 0.01964 \text{ m} = 19.6 \text{ mm}$$

$$S_{\text{opt}} = 2.71 \left( \text{Ra}_S / S^3 L \right)^{-1/4} = 0.01147 \text{ m}$$

For the condition  $S = S_{\max}$ , the spacing is sufficient that the boundary layers on the plates do not overlap.

**COMMENTS:** Using the Churchill-Chu correlation, Eq. 9.26, for the isolated vertical plate, where the characteristic dimension is the height  $L$ , find  $q = 20.2 \text{ W}$  ( $\text{Ra}_L = 1.951 \times 10^8$  and  $\bar{h}_L = 4.03 \text{ W/m}^2 \cdot \text{K}$ ). This value is slightly larger than that from the channel correlation when  $S > S_{\max}$ , but a good approximation.

### PROBLEM 9.85

**KNOWN:** Inclination angle of parallel plate solar collector. Plate spacing. Absorber plate and inlet temperature.

**FIND:** Rate of heat transfer to collector fluid.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Flow in collector corresponds to buoyancy driven flow between parallel plates with quiescent fluids at the inlet and outlet, (2) Constant properties.

**PROPERTIES:** Table A-6, Water ( $\bar{T} = 320\text{K}$ ):  $\rho = 989\text{ kg/m}^3$ ,  $c_p = 4180\text{ J/kg}\cdot\text{K}$ ,  $\mu = 577 \times 10^{-6}\text{ kg/s}\cdot\text{m}$ ,  $k = 0.640\text{ W/m}\cdot\text{K}$ ,  $\beta = 436.7 \times 10^{-6}\text{ K}^{-1}$ .

**ANALYSIS:** With

$$\alpha = \frac{k}{\rho c_p} = \frac{0.640\text{ W/m}\cdot\text{K}}{989\text{ kg/m}^3 (4180\text{ J/kg}\cdot\text{K})} = 1.55 \times 10^{-7}\text{ m}^2/\text{s}$$

$$\nu = (\mu / \rho) = (577 \times 10^{-6}\text{ kg/s}\cdot\text{m}) / 989\text{ kg/m}^3 = 5.83 \times 10^{-7}\text{ m}^2/\text{s}$$

find

$$\text{Ra}_S \frac{S}{L} = \frac{g\beta(T_s - T_\infty)S^4}{\alpha\nu L} = \frac{9.8\text{ m/s}^2 (436.7 \times 10^{-6}\text{ K}^{-1})(40\text{ K})(0.015\text{ m})^4}{(1.55 \times 10^{-7}\text{ m}^2/\text{s})(5.83 \times 10^{-7}\text{ m}^2/\text{s})1.5\text{ m}}$$

$$\text{Ra}_S \frac{S}{L} = 6.39 \times 10^4.$$

Since  $\text{Ra}_S(S/L) > 200$ , Eq. 9.47 may be used,

$$\overline{\text{Nu}}_S = 0.645 [\text{Ra}_S(S/L)]^{1/4} = 0.645 (6.39 \times 10^4)^{1/4} = 10.3$$

$$\bar{h} = \overline{\text{Nu}}_S \frac{k}{S} = 10.3 (0.64\text{ W/m}\cdot\text{K} / 0.015\text{ m}) = 438\text{ W/m}^2\cdot\text{K}.$$

Hence the heat rate is

$$q = \bar{h}A(T_s - T_\infty) = 438\text{ W/m}^2\cdot\text{K} (1.5\text{ m})(67 - 27)\text{ K} = 26,300\text{ W/m}.$$

<

**COMMENTS:** Such a large heat rate would necessitate use of a concentrating solar collector for which the normal solar flux would be significantly amplified.

## PROBLEM 9.86

**KNOWN:** Critical Rayleigh number for onset of convection in vertical cavity filled with atmospheric air. Temperatures of opposing surfaces.

**FIND:** Maximum allowable spacing for heat transfer by conduction across the air. Effect of surface temperature and air pressure.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Critical Rayleigh number is  $Ra_{L,c} = 2000$ , (2) Constant properties.

**PROPERTIES:** Table A-4, air [ $T = (T_1 + T_2)/2 = 1^\circ\text{C} = 274\text{K}$ ]:  $\nu = 13.6 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0242 \text{ W/m}\cdot\text{K}$ ,  $\alpha = 19.1 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\beta = 0.00365 \text{ K}^{-1}$ .

**ANALYSIS:** With  $Ra_{L,c} = g \beta (T_1 - T_2) L_c^3 / \alpha \nu$ ,

$$L_c = \left[ \frac{\alpha \nu Ra_{L,c}}{g \beta (T_1 - T_2)} \right]^{1/3} = \left[ \frac{19.1 \times 13.6 \times 10^{-12} \text{ m}^4 / \text{s}^2 \times 2000}{9.8 \text{ m/s}^2 \times 0.00365 \text{ K}^{-1} \times 42^\circ\text{C}} \right]^{1/3} = 0.007 \text{ m} = 7 \text{ mm} \quad <$$

The critical value of the spacing, and hence the corresponding thermal resistance of the air space, increases with a decreasing temperature difference,  $T_1 - T_2$ , and decreasing air pressure. With  $\nu = \mu/\rho$  and  $\alpha \equiv k/\rho c_p$ , both quantities increase with decreasing  $p$ , since  $\rho$  decreases while  $\mu$ ,  $k$  and  $c_p$  are approximately unchanged.

**COMMENTS:** (1) For the prescribed conditions and  $L_c = 7 \text{ mm}$ , the conduction heat flux across the air space is  $q'' = k (T_1 - T_2) / L_c = 0.0242 \text{ W/m}\cdot\text{K} \times 42^\circ\text{C} / 0.007 \text{ m} = 145 \text{ W/m}^2$ , (2) With triple pane construction, the conduction heat loss could be reduced by a factor of approximately two, (3) Heat loss is also associated with radiation exchange between the panes.

### PROBLEM 9.87

**KNOWN:** Temperatures and dimensions of a window-storm window combination.

**FIND:** Rate of heat loss by free convection.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Both glass plates are of uniform temperature with insulated interconnecting walls and (2) Negligible radiation exchange.

**PROPERTIES:** Table A-4, Air (278K, 1 atm):  $\nu = 13.93 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0245 \text{ W/m}\cdot\text{K}$ ,  $\alpha = 19.6 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.71$ ,  $\beta = 0.00360 \text{ K}^{-1}$ .

**ANALYSIS:** For the vertical cavity,

$$\text{Ra}_L = \frac{g\beta(T_1 - T_2)L^3}{\alpha\nu} = \frac{9.8 \text{ m/s}^2 (0.00360 \text{ K}^{-1})(30^\circ\text{C})(0.06\text{m})^3}{19.6 \times 10^{-6} \text{ m}^2/\text{s} \times 13.93 \times 10^{-6} \text{ m}^2/\text{s}}$$

$$\text{Ra}_L = 8.37 \times 10^5.$$

With  $(H/L) = 20$ , Eq. 9.52 may be used as a first approximation for  $\text{Pr} = 0.71$ ,

$$\overline{\text{Nu}}_L = 0.42 \text{Ra}_L^{1/4} \text{Pr}^{0.012} (H/L)^{-0.3} = 0.42 (8.37 \times 10^5)^{1/4} (0.71)^{0.012} (20)^{-0.3}$$

$$\overline{\text{Nu}}_L = 5.2$$

$$\bar{h} = \overline{\text{Nu}}_L \frac{k}{L} = 5.2 \frac{0.0245 \text{ W/m}\cdot\text{K}}{0.06\text{m}} = 2.1 \text{ W/m}^2 \cdot \text{K}.$$

The heat loss by free convection is then

$$q = \bar{h} A (T_1 - T_2)$$

$$q = 2.1 \text{ W/m}^2 \cdot \text{K} (1.2\text{m} \times 0.8\text{m}) (30^\circ\text{C}) = 61 \text{ W}.$$

<

**COMMENTS:** In such an application, radiation losses should also be considered, and infiltration effects could render heat loss by free convection significant.

## PROBLEM 9.88

**KNOWN:** Dimensions of horizontal rectangular duct and radiation shield. Temperatures of duct and shield walls.

**FIND:** Convection heat loss per unit length.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, (2) Uniform duct and shield wall temperatures, (3) Constant properties, (4) Convection occurs in four distinct rectangular regions, (4) Convection is two-dimensional.

**PROPERTIES:** Table A-4, Air ( $T = 303 \text{ K}$ ):  $\nu = 16.19 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\alpha = 22.94 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 26.5 \times 10^{-3} \text{ W/m} \cdot \text{K}$ ,  $Pr = 0.707$ ,  $\beta = 1/T = 0.0033 \text{ K}^{-1}$ .

**ANALYSIS:** Within the vertical portions of the enclosure, motion will occur in the vertical direction and will likely extend from the bottom to the top of the shield wall. Thus, the aspect ratio for the vertical regions is  $(H + 2t)/t = 0.42/0.06 = 7$ . The Rayleigh number based on the enclosure width,  $t$ , is

$$Ra_t = \frac{g\beta(T_1 - T_2)t^3}{\nu\alpha} = \frac{9.8 \text{ m/s}^2 \times 0.0033 \text{ K}^{-1} \times (40 - 20)^\circ\text{C} \times (0.06 \text{ m})^3}{16.19 \times 10^{-6} \text{ m}^2/\text{s} \times 22.94 \times 10^{-6} \text{ m}^2/\text{s}} = 3.76 \times 10^5$$

Therefore, Eq. 9.50 holds, and yields

$$\overline{Nu}_t = 0.22 \left( \frac{Pr}{0.2 + Pr} Ra_t \right)^{0.28} \left( \frac{H + 2t}{t} \right)^{-1/4} = 0.22 \left( \frac{0.707}{0.2 + 0.707} 3.76 \times 10^5 \right)^{0.28} (7)^{-1/4} = 4.59$$

and

$$\overline{h}_{\text{vert}} = \overline{Nu}_t k / t = 4.59 \times 26.5 \times 10^{-3} \text{ W/m} \cdot \text{K} / 0.06 \text{ m} = 2.03 \text{ W/m}^2 \cdot \text{K}$$

The two horizontal regions differ from one another. The bottom region is heated from above. There is therefore no air motion and  $\overline{Nu}_t = 1$ , which yields

$$\overline{h}_{\text{bot}} = \overline{Nu}_{t,\text{bot}} k / t = 1 \times 26.5 \times 10^{-3} \text{ W/m} \cdot \text{K} / 0.06 \text{ m} = 0.442 \text{ W/m}^2 \cdot \text{K}$$

The top region is heated from below and the Rayleigh number exceeds the critical value for convection to occur,  $Ra_{t,\text{crit}} = 1708$ . From Eq. 9.49,

Continued...

**PROBLEM 9.88 (Cont.)**

$$\overline{Nu}_{t,\text{top}} = 0.069 Ra_t^{1/3} Pr^{0.074} = 4.85$$

and

$$\overline{h}_{\text{top}} = \overline{Nu}_{t,\text{top}} k / t = 4.85 \times 26.5 \times 10^{-3} \text{ W/m} \cdot \text{K} / 0.06 \text{ m} = 2.15 \text{ W/m}^2 \cdot \text{K}$$

Finally, the convection heat loss per unit length is

$$\begin{aligned} q'_{\text{conv}} &= \left[ 2\overline{h}_{\text{vert}} (H + 2t) + (\overline{h}_{\text{bot}} + \overline{h}_{\text{top}}) W \right] (T_1 - T_2) \\ &= \left[ 2 \times 2.03 \text{ W/m}^2 \cdot \text{K} (0.42 \text{ m}) + (0.442 + 2.15) \text{ W/m}^2 \cdot \text{K} \times 0.8 \text{ m} \right] (40 - 20)^\circ\text{C} = 75.5 \text{ W/m} \quad < \end{aligned}$$

**COMMENTS:** (1) The identified rectangular regions do not satisfy the adiabatic end condition. (2) Presumably the shield would have a small emissivity to reduce radiation. However, if both surfaces have an emissivity of one, radiation across the enclosure is given by  $q'_{\text{rad}} = \sigma [2W + 2H] (T_1^4 - T_2^4)$   
 $= 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times [2 \times 0.8 \text{ m} + 2 \times 0.3 \text{ m}] \times (313^4 - 293^4) \text{ K}^4 = 278 \text{ W/m}$ . Radiation can be more significant than free convection.

### PROBLEM 9.89

**KNOWN:** Absorber plate and cover plate temperatures and geometry for a flat plate solar collector.

**FIND:** Heat flux due to free convection.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Aspect ratio,  $H/L$ , is greater than 12.

**PROPERTIES:** Table A-4, Air (325K, 1 atm):  $\nu = 18.4 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.028 \text{ W/m}\cdot\text{K}$ ,  $\alpha = 26.2 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.703$ ,  $\beta = 3.08 \times 10^{-3} \text{ K}^{-1}$ .

**ANALYSIS:** For the inclined enclosure,

$$\text{Ra}_L = \frac{g \beta (T_1 - T_2) L^3}{\alpha \nu} = \frac{9.8 \text{ m/s}^2 (3.08 \times 10^{-3} \text{ K}^{-1}) (70 - 35)^\circ\text{C} (0.05 \text{ m})^3}{(26.2 \times 10^{-6} \text{ m}^2/\text{s}) (18.4 \times 10^{-6} \text{ m}^2/\text{s})}$$

$$\text{Ra}_L = 2.74 \times 10^5.$$

With  $\tau < \tau^* = 70^\circ$ , Table 9.4,

$$\overline{\text{Nu}}_L = 1 + 1.44 \left[ 1 - \frac{1708}{\text{Ra}_L \cos \tau} \right]^{\bullet} \left[ 1 - \frac{1708 (\sin 1.8\tau)^{1.6}}{\text{Ra}_L \cos \tau} \right] + \left[ \left( \frac{\text{Ra}_L \cos \tau}{5830} \right)^{1/3} - 1 \right]^{\bullet}$$

$$\overline{\text{Nu}}_L = 1 + 1.44(0.99)(0.99) + 1.86 = 4.28$$

$$\bar{h} = \overline{\text{Nu}}_L \frac{k}{L} = 4.28 \frac{0.028 \text{ W/m}\cdot\text{K}}{0.05 \text{ m}} = 2.4 \text{ W/m}^2 \cdot \text{K}.$$

Hence, the heat flux is

$$q'' = h(T_1 - T_2) = 2.4 \text{ W/m}^2 \cdot \text{K} (70 - 35)^\circ\text{C}$$

$$q'' = 84 \text{ W/m}^2.$$

<

**COMMENTS:** Radiation exchange between the absorber and cover plates will also contribute to heat loss from the collector.

### PROBLEM 9.90

**KNOWN:** Dimensions and properties of paraffin slab, initial liquid layer thickness. Temperature of the hot surface.

**FIND:** (a) Amount of paraffin melted over a period of 5 hours in response to bottom heating, (b) Amount of energy used to melt the paraffin and amount of energy needed to raise the average temperature of the liquid paraffin, (c) Amount of paraffin melted over a period of 5 hours with top heating.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Constant properties, (2) Neglect change of sensible energy of the liquid, (3) One-dimensional heat transfer.

**PROPERTIES:** Given, see schematic.

**ANALYSIS:** (a) Neglecting the change in the sensible energy, the mass melted is

$$M = E/h_{sf} = q'' At/h_{sf} = \bar{h}A(T_s - T_{mp})t/h_{sf}$$

Using the Globe and Dropkin correlation,

$$h = 0.069k \left[ \frac{g\beta(T_s - T_{mp})}{\nu\alpha} \right]^{1/3} \text{Pr}^{0.074}$$

Combining the equations gives

$$M = 0.15 \text{ W/m}\cdot\text{K} \times 0.069 \times \left[ \frac{9.8 \text{ m/s}^2 \times 8 \times 10^{-4} \text{ K}^{-1} \times (50 - 27.4)^\circ\text{C}}{5 \times 10^{-6} \text{ m}^2/\text{s} \times 8.85 \times 10^{-8} \text{ m}^2/\text{s}} \right]^{1/3} \times \left[ \frac{5 \times 10^{-6} \text{ m}^2/\text{s}}{8.85 \times 10^{-8} \text{ m}^2/\text{s}} \right]^{0.074}$$

$$\times \frac{2.5 \text{ m}^2 \times (50 - 27.4)^\circ\text{C} \times 5 \text{ h} \times 3600 \text{ s/h}}{244 \times 10^3 \text{ J/kg}}$$

$$= 429 \text{ kg} \quad <$$

(b) The energy consumed to melt the paraffin is

Continued...

**PROBLEM 9.90 (Cont.)**

$$E_m = Mh_{sf} = 429\text{kg} \times 244 \times 10^3 \text{J/kg} = 105 \times 10^6 \text{J} \quad <$$

The energy associated with raising the temperature to  $\bar{T} = (50^\circ\text{C} + 27.4^\circ\text{C})/2 = 38.7^\circ\text{C}$  is

$$\begin{aligned} E_s &= Mc_p(\bar{T} - T_{mp}) = M(k/\rho\alpha)(\bar{T} - T_{mp}) \\ &= 429\text{kg} \times \left( \frac{0.15\text{W/m}\cdot\text{K}}{770\text{kg/m}^3 \cdot 8.85 \times 10^{-8} \text{m}^2/\text{s}} \right) \times (38.7 - 27.4^\circ\text{C}) = 10.7 \times 10^6 \text{J} \end{aligned}$$

The ratio of the change of sensible energy to energy absorbed in the phase change is

$$E_s/E_m = 10.7 \times 10^6 \text{J} / 105 \times 10^6 \text{J} = 0.102 \quad <$$

(c) The liquid layer is heated from above. Heat transfer in the liquid phase is by conduction. The temperature distribution in the liquid is linear if the change in sensible energy of the liquid is neglected. Hence, an energy balance on the control surface shown in the schematic yields

$$q'' = k \frac{(T_s - T_{mp})}{s} = \rho h_{sf} \frac{ds}{dt}$$

Separating variables and integrating

$$\frac{k(T_s - T_{mp})}{\rho h_{sf}} \int_{t=0}^t dt = \int_{s_i}^{s(t)} s ds \quad \text{or} \quad s(t) = \sqrt{\frac{2k(T_s - T_{mp})t}{\rho h_{sf}} + s_i^2}$$

Therefore,

$$s(t = 5\text{h}) = \sqrt{\frac{2 \times 0.15\text{W/m}\cdot\text{K} \times (50 - 27.4)^\circ\text{C} \times 5\text{h} \times 3600\text{s/h}}{770\text{kg/m}^3 \times 244 \times 10^3 \text{J/kg}} + (0.01\text{m})^2}$$

$$= 27 \times 10^{-3} \text{m} = 27 \text{mm}$$

$$M = A\rho[s(t = 5\text{h}) - s_i] = 2.5\text{m}^2 \times 770\text{kg/m}^3 \times (27 \times 10^{-3}\text{m} - 10 \times 10^{-3}\text{m}) = 33.4\text{kg} \quad <$$

**COMMENTS:** (1) For the bottom heated case at  $t = 5$  h, the solid-liquid interface is located at  $M/\rho A + s_i = 429 \text{kg}/(770 \text{kg/m}^3 \times 2.5 \text{m}^2) + 0.01 \text{m} = 0.233 \text{m}$ . The Rayleigh numbers associated with the bottom heating case range from  $Ra_s = g\beta(T_s - T_{mp})s_i^3/\nu\alpha = 9.8\text{m/s}^2 \times 8 \times 10^{-4} \text{K}^{-1} \times (50 - 27.4)^\circ\text{C} \times (0.01\text{m})^3 / (5 \times 10^{-6} \text{m}^2/\text{s} \times 8.85 \times 10^{-8} \text{m}^2/\text{s}) = 4 \times 10^5$  to  $5 \times 10^9$  at  $t = 5$  h. Hence, use of the Globe and Dropkin correlation is justified. (2) The ratio of the change in sensible energy to the absorption of latent energy is referred to as the liquid phase Stefan number. Since the liquid phase Stefan number is much less than unity, it is reasonable to neglect the change of sensible energy of the liquid phase when calculating the melting rate or solid-liquid interface location.

### PROBLEM 9.91

**KNOWN:** Rectangular cavity of two parallel, 0.5m square plates with insulated inter-connecting sides and with prescribed separation distance and surface temperatures.

**FIND:** Heat flux between surfaces for three orientations of the cavity: (a) Vertical  $\tau = 90^\circ$ , (b) Horizontal with  $\tau = 0^\circ$ , and (c) Horizontal with  $\tau = 180^\circ$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Radiation exchange is negligible, (2) Air is at atmospheric pressure.

**PROPERTIES:** Table A-4, Air ( $T_f = (T_1 + T_2)/2 = 300\text{K}$ , 1 atm):  $\nu = 15.89 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0263 \text{ W/m}\cdot\text{K}$ ,  $\alpha = 22.5 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.707$ ,  $\beta = 1/T_f = 3.333 \times 10^{-3} \text{ K}^{-1}$ .

**ANALYSIS:** The convective heat flux between the two cavity plates is

$$q''_{\text{conv}} = \bar{h}(T_1 - T_2)$$

where  $\bar{h}$  is estimated from the appropriate enclosure correlation which will depend upon the Rayleigh number. From Eq. 9.25, find

$$\text{Ra}_L = \frac{g\beta(T_1 - T_2)L^3}{\nu\alpha} = \frac{9.8 \text{ m/s}^2 \times 3.333 \times 10^{-3} \text{ K}^{-1} (325 - 275) \text{ K} (0.05 \text{ m})^3}{15.89 \times 10^{-6} \text{ m}^2/\text{s} \times 22.5 \times 10^{-6} \text{ m}^2/\text{s}} = 5.710 \times 10^5.$$

Note that  $H/L = 0.5/0.05 = 10$ , a factor which is important in selecting correlations.

(a) With  $\tau = 90^\circ$ , for a vertical cavity, Eq. 9.50, is appropriate,

$$\overline{\text{Nu}}_L = 0.22 \left( \frac{\text{Pr}}{0.2 + \text{Pr}} \text{Ra}_L \right)^{0.28} \left( \frac{H}{L} \right)^{-1/4} = 0.22 \left( \frac{0.707}{0.2 + 0.707} \times 5.71 \times 10^5 \right)^{0.28} (10)^{-1/4} = 4.72$$

$$\bar{h}_L = \frac{k}{L} \overline{\text{Nu}}_L = \frac{0.0263 \text{ W/m}\cdot\text{K}}{0.05 \text{ m}} \times 4.72 = 2.48 \text{ W/m}^2 \cdot \text{K}$$

$$q''_{\text{conv}} = 2.48 \text{ W/m}^2 \cdot \text{K} (325 - 275) \text{ K} = 124 \text{ W/m}^2. \quad <$$

(b) With  $\tau = 0^\circ$  for a horizontal cavity heated from below, Eq. 9.49 is appropriate.

$$\bar{h} = \frac{k}{L} \overline{\text{Nu}}_L = 0.069 \frac{k}{L} \text{Ra}_L^{1/3} \text{Pr}^{0.074} = 0.069 \frac{0.0263 \text{ W/m}\cdot\text{K}}{0.05 \text{ m}} (5.710 \times 10^5)^{1/3} (0.707)^{0.074}$$

$$\bar{h} = 2.92 \text{ W/m}^2 \cdot \text{K}$$

$$q''_{\text{conv}} = 2.92 \text{ W/m}^2 \cdot \text{K} (325 - 275) \text{ K} = 146 \text{ W/m}^2. \quad <$$

(c) For  $\tau = 180^\circ$  corresponding to the horizontal orientation with the heated plate on the top, heat transfer will be by conduction. That is,

$$\overline{\text{Nu}}_L = 1 \quad \text{or} \quad \bar{h}_L = \overline{\text{Nu}}_L \cdot \frac{k}{L} = 1 \times 0.0263 \text{ W/m}\cdot\text{K} / (0.05 \text{ m}) = 0.526 \text{ W/m}^2 \cdot \text{K}.$$

$$q''_{\text{conv}} = 0.526 \text{ W/m}^2 \cdot \text{K} (325 - 275) \text{ K} = 26.3 \text{ W/m}^2. \quad <$$

**COMMENTS:** Compare the heat fluxes for the various orientations and explain physically their relative magnitudes.

## PROBLEM 9.92

**KNOWN:** Horizontal flat roof and vertical wall sections of same dimensions exposed to identical temperature differences.

**FIND:** (a) Ratio of convection heat rate for horizontal section to that of the vertical section and (b) Effect of inserting a baffle at the mid-height of the vertical wall section on the convection heat rate.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Ends of sections and baffle adiabatic, (2) Steady-state conditions.

**PROPERTIES:** Table A-4, Air ( $\bar{T} = (T_1 + T_2)/2 = 277\text{K}$ , 1 atm):  $\nu = 13.84 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0245 \text{ W/m}\cdot\text{K}$ ,  $\alpha = 19.5 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.713$ .

**ANALYSIS:** (a) The ratio of the convection heat rates is

$$\frac{q_{\text{hor}}}{q_{\text{vert}}} = \frac{\bar{h}_{\text{hor}} A_s \Delta T}{\bar{h}_{\text{vert}} A_s \Delta T} = \frac{\bar{h}_{\text{hor}}}{\bar{h}_{\text{vert}}} \quad (1)$$

To estimate coefficients, recognizing both sections have the same characteristic length,  $L = 0.1 \text{ m}$ , with  $\text{Ra}_L = g\beta\Delta T L^3 / \nu\alpha$  find

$$\text{Ra}_L = \frac{9.8 \text{ m/s}^2 \times (1/277\text{K})(18 - (-10))\text{K}(0.1\text{m})^3}{13.84 \times 10^{-6} \text{ m}^2/\text{s} \times 19.5 \times 10^{-6} \text{ m}^2/\text{s}} = 3.67 \times 10^6$$

The appropriate correlations for the sections are Eqs. 9.49 and 9.52 (with  $H/L = 30$ ),

$$\overline{\text{Nu}}_L \Big|_{\text{hor}} = 0.069 \text{Ra}_L^{1/3} \text{Pr}^{0.074} \quad \overline{\text{Nu}}_L \Big|_{\text{vert}} = 0.42 \text{Ra}_L^{1/4} \text{Pr}^{0.012} (H/L)^{-0.3} \quad (3,4)$$

Using Eqs. (3) and (4), the ratio of Eq. (1) becomes,

$$\frac{q_{\text{hor}}}{q_{\text{vert}}} = \frac{0.069 \text{Ra}_L^{1/3} \text{Pr}^{0.074}}{0.42 \text{Ra}_L^{1/4} \text{Pr}^{0.012} (H/L)^{-0.3}} = \frac{0.069 (3.67 \times 10^6)^{1/3} (0.713)^{0.074}}{0.42 (3.67 \times 10^6)^{1/4} (0.713)^{0.012} (30)^{-0.3}} = 1.57. \quad <$$

(b) The effect of the baffle in the vertical wall section is to reduce  $H/L$  from 30 to 15. Using Eq. 9.52, it follows,

$$\frac{q_{\text{baf}}}{q} = \frac{\bar{h}_{\text{baf}}}{\bar{h}} = \frac{(H/L)_{\text{baf}}^{-0.3}}{(H/L)^{-0.3}} = \left(\frac{15}{30}\right)^{-0.3} = 1.23. \quad <$$

That is, the effect of the baffle is to increase the convection heat rate.

**COMMENTS:** (1) Note that the heat rate for the horizontal section is 57% larger than that for the vertical section for the same  $(T_1 - T_2)$ . This indicates the importance of heat losses from the ceiling or roofs in house construction. (2) Recognize that for Eq. 9.52, the  $\text{Pr} > 1$  requirement is not completely satisfied. (3) What is the physical explanation for the result of part (b)?

### PROBLEM 9.93

**KNOWN:** Dimensions of horizontal air space separating plates of known temperature.

**FIND:** (a) Convective heat flux for a 50 mm gap, hot and cold plate temperatures of  $T_h = 200^\circ\text{C}$  and  $T_c = 50^\circ\text{C}$ , respectively, (b) Minimum number of thin aluminum sheets needed to suppress convection, (c) Conduction heat flux with the sheets in place.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Constant properties, (2) Steady-state conditions, (3) Foil sheets have negligible conduction resistance and negligible thickness.

**PROPERTIES:** Table A.4, air: ( $T_f = (200^\circ\text{C} + 50^\circ\text{C})/2 = 125^\circ\text{C}$ ):  $k = 0.03365 \text{ W/m}\cdot\text{K}$ ,  $\nu = 2.619 \times 10^{-5} \text{ m}^2/\text{s}$ ,  $\alpha = 3.796 \times 10^{-5} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.6904$ .

**ANALYSIS:** (a) The Rayleigh number is

$$\begin{aligned} \text{Ra} &= g\beta(T_h - T_c)L^3 / \nu \cdot \alpha \\ &= 9.8 \text{ m/s}^2 \times \frac{1}{(125 + 273) \text{ K}} \times (200 - 50)^\circ\text{C} \times (0.05 \text{ m})^3 / (2.619 \times 10^{-5} \text{ m}^2/\text{s} \times 3.796 \times 10^{-5} \text{ m}^2/\text{s}) \\ &= 4.64 \times 10^5 \end{aligned}$$

Using the Globe and Dropkin correlation,

$$\begin{aligned} \bar{h}_L &= 0.069(k/L)\text{Ra}^{1/3} \text{Pr}^{0.074} = 0.069 \times (0.03365 \text{ W/m}\cdot\text{K} / 5 \times 10^{-3} \text{ m}) \times (4.64 \times 10^5)^{1/3} \times (0.6904)^{0.074} \\ &= 3.50 \text{ W/m}^2\cdot\text{K} \end{aligned}$$

Therefore,  $q_{\text{conv}}'' = 3.50 \text{ W/m}^2 \cdot \text{K} \times (200 - 50)^\circ\text{C} = 525 \text{ W/m}^2$  <

(b) For  $\text{Ra}_{L_g} < 1708$ , there will be no convection in an air layer. The number of gaps is  $N_g = N + 1$ . The gap width is  $L_g = L/(N + 1)$  and, as a first estimate, the temperature difference across each gap is  $\Delta T_g = (T_h - T_c)/(N + 1)$ . We require  $1708 > \text{Ra}_{L_g}$ , or

Continued...

**PROBLEM 9.93 (Cont.)**

$$\frac{g\beta[(T_h - T_c)(N + 1)][L/(N + 1)]^3}{\nu \cdot \alpha} < 1708$$

or

$$\frac{9.8\text{m/s}^2 \times [1/(273 + 125)]\text{K}^{-1} \times [(200 - 50)^\circ\text{C}/(N + 1)] \times [0.05\text{m}/(N + 1)]^3}{2.619 \times 10^{-5}\text{m}^2/\text{s} \times 3.796 \times 10^{-5}\text{m}^2/\text{s}} < 1708$$

from which we may determine  $N > 3.06$ . Therefore, we specify  $N = 4$ . <

(c) Neglecting the thickness and thermal resistance of the foil sheets,

$$q''_{\text{cond}} = k(T_h - T_c)/L = 0.03365\text{W/m} \cdot \text{K} \times (200 - 50)^\circ\text{C}/0.05\text{m} = 101\text{W/m}^2 \quad <$$

**COMMENTS:** (1) Installation of the foils results in a  $100 - 101/525 = 81\%$  reduction in heat transfer across the large gap. (2) Because of the temperature dependence of the thermophysical properties, we should check to make sure the Rayleigh numbers associated with the top and bottom gaps do not exceed 1708. Assuming  $\Delta T_g = (T_h - T_c)/(N + 1) = 150^\circ\text{C}/(5) = 30^\circ\text{C}$  and evaluating properties at the average gap temperatures of  $65^\circ\text{C}$  and  $185^\circ\text{C}$ , respectively, we find  $Ra_{L,g} = 1569$  for the top gap and 394 for the bottom gap. We therefore conclude that convection is in fact suppressed in all the gaps. (3) A more accurate handling of the thermophysical property variation would account for the temperature variation of the thermal conductivity in each gap and, in turn, the variation in the temperatures of the individual foil sheets. Equating the conduction heat transfer through each gap and evaluating the thermal conductivity for each gap at the average air temperature in the gap, one finds (using an iterative procedure or IHT) foil temperatures of (top to bottom):  $T_1 = 84.3^\circ\text{C}$ ,  $T_2 = 116.1^\circ\text{C}$ ,  $T_3 = 145.7^\circ\text{C}$  and  $T_4 = 173.6^\circ\text{C}$ . Values of  $Ra_{L,g}$  are 1742 and 340 for the top and bottom gaps, respectively. Hence, with 4 foils, the top gap will experience very weak convection and a conservative specification would call for installation of  $N = 5$  foils. (4) As will become evident in Chapter 13, the foils will also reduce radiation heat transfer across the gap.

### PROBLEM 9.94

**KNOWN:** Double-glazed window of variable spacing  $L$  between panes filled with either air or carbon dioxide.

**FIND:** Heat transfer across window for variable spacing when filled with either gas. Consider these conditions (outside,  $T_1$ ; inside,  $T_2$ ): winter ( $-10, 20^\circ\text{C}$ ) and summer ( $35^\circ\text{C}, 25^\circ\text{C}$ ).

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Radiation exchange is negligible, (3) Gases are at atmospheric pressure, (4) Perfect gas behavior.

**PROPERTIES:** Table A-4: Winter,  $\bar{T} = (-10 + 20)^\circ\text{C} / 2 = 288\text{ K}$ , Summer,  $\bar{T} = (35 + 25)^\circ\text{C} / 2 = 303\text{ K}$  :

Gas (1 atm)	$\bar{T}$ (K)	$\alpha$ ( $\text{m}^2/\text{s} \times 10^6$ )	$\nu$ ( $\text{m}^2/\text{s} \times 10^6$ )	$k \times 10^3$ (W/m·K)
Air	288	20.5	14.82	24.9
Air	303	22.9	16.19	26.5
CO <sub>2</sub>	288	10.2	7.78	15.74
CO <sub>2</sub>	303	11.2	8.55	16.78

**ANALYSIS:** The heat flux by convection across the window is

$$q'' = h(T_1 - T_2)$$

where the convection coefficient is estimated from the correlation of Eq. 9.53 for large aspect ratios  $10 < H/L < 40$ , for which  $\bar{h}$  is independent of  $L$ ,

$$\overline{\text{Nu}}_L = \bar{h}L/k = 0.046\text{Ra}_L^{1/3}.$$

Substituting numerical values for winter (w) and summer (s) conditions,

$$\text{Ra}_{L,w,\text{air}} = \frac{9.8\text{ m/s}^2 (1/288\text{ K})(20 - (-10))\text{ KL}^3}{20.5 \times 10^{-6}\text{ m}^2/\text{s} \times 14.82 \times 10^{-6}\text{ m}^2/\text{s}} = 3.360 \times 10^9 \text{ L}^3$$

$$\text{Ra}_{L,s,\text{air}} = 8.724 \times 10^8 \text{ L}^3 \quad \text{Ra}_{L,w,\text{CO}_2} = 1.286 \times 10^{10} \text{ L}^3 \quad \text{Ra}_{L,s,\text{CO}_2} = 3.378 \times 10^9 \text{ L}^3$$

the heat transfer coefficients are

$$\bar{h}_{w,\text{air}} = (0.0249\text{ W/m}\cdot\text{K/L}) \times 0.046 \left( 3.360 \times 10^9 \text{ L}^3 \right)^{1/3} = 1.72\text{ W/m}^2\cdot\text{K}$$

$$h_{s,\text{air}} = 1.16\text{ W/m}^2\cdot\text{K} \quad h_{w,\text{CO}_2} = 1.70\text{ W/m}^2\cdot\text{K} \quad h_{s,\text{CO}_2} = 1.16\text{ W/m}^2\cdot\text{K}.$$

Thus,

$$q''_{w,\text{air}} = 51.5\text{ W/m}^2 \quad q''_{s,\text{air}} = 11.6\text{ W/m}^2 \quad q''_{w,\text{CO}_2} = 50.9\text{ W/m}^2 \quad q''_{s,\text{CO}_2} = 11.6\text{ W/m}^2.$$

**COMMENTS:** (1) The correlation is valid for  $10^6 < \text{Ra}_L < 10^9$ . As an example, for a spacing  $L = 10$  mm, the Rayleigh number would be less than  $10^6$  in all four cases, and Eq. 9.52 should be used instead. However, note that  $H/L = 150$ , which is out of the range of validity of both correlations. (2) For this particular case, the smaller  $k$  for CO<sub>2</sub> is almost exactly offset by the smaller  $\alpha$  and  $\nu$  which lead to larger  $\text{Ra}_L$ , and there is very little difference between the results for air and CO<sub>2</sub>.

## PROBLEM 9.95

**KNOWN:** Dimensions of double pane window. Thickness of air gap. Temperatures of room and ambient air.

**FIND:** (a) Temperatures of glass panes and heat rate through window, (b) Resistance of glass pane relative to smallest convection resistance.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, (2) Negligible glass pane thermal resistance, (3) Constant properties.

**PROPERTIES:** Table A-3, Plate glass:  $k_p = 1.4 \text{ W/m}\cdot\text{K}$ . Table A-4, Air ( $p = 1 \text{ atm}$ ).  $T_{f,i} = 287.6\text{K}$ :  $\nu_i = 14.8 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k_i = 0.0253 \text{ W/m}\cdot\text{K}$ ,  $\alpha_i = 20.9 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\text{Pr}_i = 0.710$ ,  $\beta_i = 0.00348 \text{ K}^{-1}$ .  $\bar{T} = (T_{s,i} + T_{s,o})/2 = 272.8\text{K}$ :  $\nu = 13.49 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0241 \text{ W/m}\cdot\text{K}$ ,  $\alpha = 18.9 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.714$ ,  $\beta = 0.00367 \text{ K}^{-1}$ .  $T_{f,o} = 258.2\text{K}$ :  $\nu_o = 12.2 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k_o = 0.0230 \text{ W/m}\cdot\text{K}$ ,  $\alpha = 17.0 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.718$ ,  $\beta_o = 0.00387 \text{ K}^{-1}$ .

**ANALYSIS:** (a) The heat rate may be expressed as

$$q = q_o = \bar{h}_o H^2 (T_{s,o} - T_{\infty,o}) \quad (1)$$

$$q = q_g = \bar{h}_g H^2 (T_{s,i} - T_{s,o}) \quad (2)$$

$$q = q_i = \bar{h}_i H^2 (T_{\infty,i} - T_{s,i}) \quad (3)$$

where  $\bar{h}_o$  and  $\bar{h}_i$  may be obtained from Eq. (9.26),

$$\bar{\text{Nu}}_H = \left\{ 0.825 + \frac{0.387 \text{Ra}_H^{1/6}}{\left[ 1 + (0.492/\text{Pr})^{9/16} \right]^{8/27}} \right\}^2$$

with  $\text{Ra}_H = g\beta_o (T_{s,o} - T_{\infty,o}) H^3 / \alpha_o \nu_o$  and  $\text{Ra}_H = g\beta_i (T_{\infty,i} - T_{s,i}) H^3 / \alpha_i \nu_i$ , respectively. Assuming  $10^4 < \text{Ra}_L < 10^7$ ,  $\bar{h}_g$  is obtained from

$$\bar{\text{Nu}}_L = 0.42 \text{Ra}_L^{1/4} \text{Pr}^{0.012} (H/L)^{-0.3}$$

where  $\text{Ra}_L = g\beta (T_{s,i} - T_{s,o}) L^3 / \alpha \nu$ . A simultaneous solution to Eqs. (1) – (3) for the three unknowns yields

Continued ...

**PROBLEM 9.95 (Cont.)**

$$T_{s,i} = 9.1^\circ\text{C}, \quad T_{s,o} = -9.6^\circ\text{C}, \quad q = 35.7 \text{ W} \quad <$$

where  $\bar{h}_i = 3.29 \text{ W/m}^2 \cdot \text{K}$ ,  $\bar{h}_o = 3.45 \text{ W/m}^2 \cdot \text{K}$  and  $\bar{h}_g = 1.90 \text{ W/m}^2 \cdot \text{K}$ .

(b) The unit conduction resistance of a glass pane is  $R''_{\text{cond}} = L_p / k_p = 0.00429 \text{ m}^2 \cdot \text{K/W}$ , and the smallest convection resistance is  $R''_{\text{conv},o} = (1/\bar{h}_o) = 0.290 \text{ m}^2 \cdot \text{K/W}$ . Hence,

$$R''_{\text{cond}} \ll R''_{\text{conv},\text{min}} \quad <$$

and it is reasonable to neglect the thermal resistance of the glass.

**COMMENTS:** (1) Assuming a heat flux of  $35.7 \text{ W/m}^2$  through a glass pane, the corresponding temperature difference across the pane is  $\Delta T = q''(L_p / k_p) = 0.15^\circ\text{C}$ . Hence, the assumption of an isothermal pane is good. (2) Equations (1) – (3) were solved using the IHT workspace and the temperature-dependent air properties provided by the software. The property values provided in the PROPERTIES section of this solution were obtained from the software.

## PROBLEM 9.96

**KNOWN:** Top surface of an oven maintained at 60°C.

**FIND:** (a) Reduction in heat transfer from the surface by installation of a cover plate with specified air gap; temperature of the cover plate, (b) Effect of cover plate spacing.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Oven surface at  $T_1 = T_s$  for both cases, (3) Negligible radiative exchange with surroundings and across air gap.

**PROPERTIES:** Table A.4, Air ( $T_f = (T_s + T_\infty)/2 = 315 \text{ K}$ , 1 atm):  $\nu = 17.40 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0274 \text{ W/m}\cdot\text{K}$ ,  $\alpha = 24.7 \times 10^{-6} \text{ m}^2/\text{s}$ ; Table A.4, Air ( $\bar{T} = (T_1 + T_2)/2$  and  $T_{f2} = (T_2 + T_\infty)/2$ ): Properties obtained from *Correlations Toolpad* of IHT.

**ANALYSIS:** (a) The convective heat loss from the exposed top surface of the oven is  $q_s = \bar{h} A_s (T_s - T_\infty)$ . With  $L = A_s/P = (0.5 \text{ m})^2/(4 \times 0.5 \text{ m}) = 0.125 \text{ m}$ ,

$$Ra_L = \frac{g\beta\Delta T L^3}{\nu\alpha} = \frac{9.8 \text{ m/s}^2 (1/315 \text{ K})(60 - 23)^\circ \text{C} (0.125 \text{ m})^3}{17.40 \times 10^{-6} \text{ m}^2/\text{s} \times 24.7 \times 10^{-6} \text{ m}^2/\text{s}^2} = 5.231 \times 10^6.$$

The appropriate correlation for a heated plate facing upwards, Eq. 9.30, is

$$\overline{Nu}_L = \frac{\bar{h}L}{k} = 0.54 Ra_L^{1/4} \quad 10^4 \leq Ra_L \leq 10^7$$

$$\bar{h} = \left( \frac{0.0274 \text{ W/m}\cdot\text{K}}{0.125 \text{ m}} \right) \times 0.54 (5.231 \times 10^6)^{1/4} = 5.66 \text{ W/m}^2 \cdot \text{K}$$

Hence, the heat rate for the exposed surface is

$$q_s = 5.66 \text{ W/m}^2 \cdot \text{K} (0.5 \text{ m})^2 (60 - 23)^\circ \text{C} = 52.4 \text{ W} .$$

With the cover plate, the surface temperature ( $T_s = T_2$ ) is unknown and must be obtained by performing an energy balance at the top surface.

Continued...

### PROBLEM 9.96 (Cont.)

Equating heat flow across the gap to that from the top surface,  $q_g = q_{cp}$ . Hence, for a unit surface area,

$$\bar{h}_g (T_1 - T_2) = \bar{h}_{cp} (T_2 - T_\infty)$$

where  $\bar{h}_{cp}$  is obtained from Eq. 9.30 and  $\bar{h}_g$  is evaluated from Eq. 9.49.

$$\overline{Nu}_L = \frac{\bar{h}_g L}{k} = 0.069 Ra_L^{1/3} Pr^{0.074}$$

Entering this expression from the keyboard and Eq. 9.30 from the *Correlations* Toolpad, with the *Properties* Toolpad used to evaluate air properties at  $\bar{T}$  and  $T_{fs}$ , IHT was used with  $L = 0.05$  m to obtain

$$T_2 = 35.4^\circ\text{C} \qquad q_{cp} = 13.5 \text{ W} \qquad <$$

where  $\bar{h}_g = 2.2 \text{ W/m}^2 \cdot \text{K}$  and  $\bar{h}_{cp} = 4.4 \text{ W/m}^2 \cdot \text{K}$ . Hence, the effect of installing the cover plate creating the enclosure is to reduce the heat loss by

$$\frac{q_s - q_{cp}}{q_s} \times 100 = \frac{52.4 - 13.5}{52.4} \times 100 = 74\% . \qquad <$$

Note, however, that for  $L = 0.05$  m,  $Ra_L = 2.05 \times 10^5$  is slightly less than the lower limit of applicability for Eq. 9.49.

(b) If we use the foregoing model to evaluate  $T_2$  and  $q_{cp}$  for  $0.005 \leq L \leq 0.05$  m, we find that there is no effect. This seemingly unusual result is a consequence of the fact that, in Eq. 9.49,  $\overline{Nu}_L \propto Ra_L^{1/3}$ , in which case  $\bar{h}_g$  is independent of  $L$ . However,  $Ra_L$  and  $Nu_L$  do decrease with decreasing  $L$ , eventually approaching conditions for which transport across the airspace is determined by conduction and not convection. If transport is by conduction, the heat rate must be determined from Fourier's law, for which  $q_g'' = (k/L)(T_1 - T_2)$  and the equivalent, *pseudo*, Nusselt number is  $\overline{Nu}_L = \bar{h}L/k = 1$ . If this expression is used to determine  $\bar{h}_g$  in the energy balance,  $q_{cp}$  increases with decreasing  $L$ . The results would only apply if there is negligible advection in the airspace and hence for Rayleigh numbers less than 1708, which corresponds to  $L \approx 10.5$  mm. For this value of  $L$ ,  $q_{cp} = 15.4$  W exceeds that previously determined for  $L = 50$  mm. Hence, there is little variation in  $q_{cp}$  over the range  $10.5 < L < 50$  mm. However,  $q_{cp}$  increases with decreasing  $L$  below 10.5 mm, achieving a value of 24.2 W for  $L = 5$  mm. Hence, a value of  $L$  slightly larger than 10.5 mm could be considered an optimum.

**COMMENTS:** Radiation exchange across the cavity and with the surroundings is likely to be significant and should be considered in a more detailed analysis.

## PROBLEM 9.97

**KNOWN:** Dimensions of air space between windows, dimensions of individual blinds. Temperatures of windows.

**FIND:** Convection heat transfer rates between windows when the blinds are in the open and closed positions, respectively. Explanation of the small effect of the closed blinds on the convective heat transfer rate.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Constant properties, (2) Steady-state conditions, (3) Isothermal windows, (4) Blinds are adiabatic, (5) Neglect presence of the blind when in the closed position.

**PROPERTIES:** Table A.4, air: ( $T_f = 273 \text{ K}$ ):  $k = 0.02414 \text{ W/m}\cdot\text{K}$ ,  $\nu = 1.349 \times 10^{-5} \text{ m}^2/\text{s}$ ,  $\alpha = 1.894 \times 10^{-5} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.714$ .

**ANALYSIS:**

Case A, Open Position The aspect ratio of a typical cell is  $H_o/L = 25/25 = 1$ . The Rayleigh number is

$$\text{Ra} = g\beta \frac{(T_{s,o} - T_{s,i})L^3}{\nu\alpha} = 9.8 \text{ m/s}^2 \times (1/273) \text{ K}^{-1} \times \frac{(20 - (-20))^\circ\text{C} \times (0.025 \text{ m})^3}{1.349 \times 10^{-5} \text{ m}^2/\text{s} \times 1.894 \times 10^{-5} \text{ m}^2/\text{s}} = 87.81 \times 10^3$$

and  $(\text{RaPr})/(0.2 + \text{Pr}) = (87.81 \times 10^3 \times 0.714)/(0.2 + 0.714) = 68,600$ . Therefore, Equation 9.51 may be used, resulting in

$$\overline{\text{Nu}}_L = 0.18 \left[ \frac{0.714}{(0.2 + 0.714)} \times 87.81 \times 10^3 \right]^{0.29} = 4.55 \quad \text{and}$$

$$\overline{h}_L = \overline{\text{Nu}}_L k / L = 4.55 \times 0.02414 \text{ W/m}\cdot\text{K} / 0.025 \text{ m} = 4.39 \text{ W/m}^2 \cdot \text{K}$$

The same value of the convection heat transfer coefficient exists for each cell. Hence,

Continued...

### PROBLEM 9.97 (Cont.)

$$q_{\text{conv}} = 4.39 \text{ W/m}^2 \cdot \text{K} \times 0.5 \text{ m} \times 0.5 \text{ m} \times (20^\circ\text{C} - (-20^\circ\text{C})) = 43.9 \text{ W} \quad <$$

Case B, Closed Position The aspect ratio of the cavity is  $H_c/L = 0.5 \text{ m}/0.025 \text{ m} = 20$ . The Rayleigh number is  $87.81 \times 10^3$ , as before. Therefore, select Equation 9.52, resulting in

$$\overline{\text{Nu}}_L = 0.42 \times (87.81 \times 10^3)^{1/4} \times (0.714)^{0.012} \times (20)^{-3} = 2.931$$

$$\bar{h}_L = \overline{\text{Nu}}_L k / L = 2.931 \times 0.02414 \text{ W/m} \cdot \text{K} / 0.025 \text{ m} = 2.83 \text{ W/m}^2 \cdot \text{K} \quad \text{Hence,}$$

$$q_{\text{conv}} = 2.83 \text{ W/m}^2 \cdot \text{K} \times 0.5 \text{ m} \times 0.5 \text{ m} \times (20^\circ\text{C} - (-20^\circ\text{C})) = 28.3 \text{ W} \quad <$$

The closed blinds may be neglected if the core of the air layer is nearly stagnant. <

**COMMENTS:** (1) Equation 9.52 has been extrapolated slightly outside of its range of application with respect to the suggested Prandtl number limits. (2) In the open blind case, recirculating flow will exist in each small square sub-enclosure, yielding larger values of the convection coefficient relative to the closed blind case. (3) The blind material will have a higher thermal conductivity than air, and the open blinds will serve as extended surfaces, further increasing heat loss through the window. Since the blinds will participate in the heat transfer when in the open position, treating the top and bottom surfaces of the small square sub-enclosures is an aggressive assumption. (4) Net radiation transfer between the two window surfaces will be greater for the open blind case.

## PROBLEM 9.98

**KNOWN:** Dimensions and surface temperatures of a flat-plate solar collector.

**FIND:** (a) Heat loss across collector cavity, (b) Effect of plate spacing on the heat loss.

**SCHEMATIC:**

**ASSUMPTIONS:** Negligible radiation.

**PROPERTIES:** Table A.4, Air ( $\bar{T} = (T_1 + T_2)/2 = 323 \text{ K}$ ):  $\nu = 18.2 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.028 \text{ W/m}\cdot\text{K}$ ,  $\alpha = 25.9 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\beta = 0.0031 \text{ K}^{-1}$ .

**ANALYSIS:** (a) Since  $H/L = 2 \text{ m}/0.03 \text{ m} = 66.7 > 12$ ,  $\tau < \tau^*$  and Eq. 9.54 may be used to evaluate the convection coefficient associated with the air space. Hence,  $q = \bar{h} A_s (T_1 - T_2)$ , where  $\bar{h} = (k/L) \overline{\text{Nu}}_L$  and

$$\overline{\text{Nu}}_L = 1 + 1.44 \left[ 1 - \frac{1708}{\text{Ra}_L \cos \tau} \right] \cdot \left[ 1 - \frac{1708 (\sin 1.8\tau)^{1.6}}{\text{Ra}_L \cos \tau} \right] + \left[ \left( \frac{\text{Ra}_L \cos \tau}{5830} \right)^{1/3} - 1 \right]$$

For  $L = 30 \text{ mm}$ , the Rayleigh number is

$$\text{Ra}_L = \frac{g\beta(T_1 - T_2)L^3}{\alpha\nu} = \frac{9.8 \text{ m/s}^2 (0.0031 \text{ K}^{-1})(40^\circ \text{C})(0.03 \text{ m})^3}{25.9 \times 10^{-6} \text{ m}^2/\text{s} \times 18.2 \times 10^{-6} \text{ m}^2/\text{s}} = 6.96 \times 10^4$$

and  $\text{Ra}_L \cos \tau = 3.48 \times 10^4$ . It follows that  $\overline{\text{Nu}}_L = 3.12$  and  $\bar{h} = (0.028 \text{ W/m}\cdot\text{K}/0.03 \text{ m})3.12 = 2.91 \text{ W/m}^2\cdot\text{K}$ . Hence,

$$q = 2.91 \text{ W/m}^2\cdot\text{K} (4 \text{ m}^2) (40^\circ \text{C}) = 466 \text{ W} \quad \leftarrow$$

(b) The foregoing model was entered into the workspace of IHT, and results of the calculations are plotted as follows.

Continued...

### PROBLEM 9.98 (Cont.)

The plots are influenced by the fact that the third and second terms on the right-hand side of the correlation are set to zero at  $L \approx 0.017$  m and  $L \approx 0.011$  m, respectively. For the range of conditions, minima in the heat loss of  $q \approx 410$  W and  $q = 397$  W are achieved at  $L \approx 0.012$  m and  $L = 0.05$  m, respectively. Operation at  $L \approx 0.02$  m corresponds to a maximum and is clearly undesirable, as is operation at  $L < 0.011$  m, for which conditions are conduction dominated.

**COMMENTS:** Because the convection coefficient is low, radiation effects would be significant.

## PROBLEM 9.99

**KNOWN:** Cylindrical 120-mm diameter radiation shield of Example 9.5 installed concentric with a 100-mm diameter tube carrying steam; spacing provides for an air gap of  $L = 10$  mm.

**FIND:** (a) Heat loss per unit length of the tube by convection when a second shield of diameter 140 mm is installed; compare the result to that for the single shield calculation of the example; and (b) The heat loss per unit length if the gap dimension is made  $L = 15$  mm (rather than 10 mm). Do you expect the heat loss to increase or decrease?

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, and (b) Constant properties.

**PROPERTIES:** Table A-4, Air ( $T_f = (T_s + T_\infty)/2 = 350$  K, 1 atm):  $\nu = 20.92 \times 10^{-6}$  m<sup>2</sup>/s,  $k = 0.030$  W/m·K,  $Pr = 0.700$ .

**ANALYSIS:** (a) The thermal circuit representing the tube with two concentric cylindrical radiation shields having gap spacings  $L = 10$  mm is shown above. The heat loss per unit length by convection is

$$q' = \frac{T_i - T_2}{R'_{g1} + R'_{g2}} = \frac{T_i - T_1}{R'_{g1}} \quad (1)$$

where the  $R'_g$  represents the thermal resistance of the annular gap (spacing). From Eqs. 9.58, 59 and 60, find

$$R'_g = \frac{\ln(D_o/D_i)}{2\pi k_{\text{eff}}} \quad (2)$$

$$\frac{k_{\text{eff}}}{k} = 0.386 \left( \frac{Pr}{0.861 + Pr} \right)^{1/4} (Ra_c)^{1/4} \quad (3)$$

$$Ra_c = g\beta(T_o - T_i)L_c^3 / \alpha\nu \quad (4)$$

where  $L_c = \frac{2[\ln(r_o/r_i)]^{4/3}}{(r_i^{-3/5} + r_o^{-3/5})^{5/3}}$

where the properties are evaluated at the average temperature of the bounding surfaces,  $T_f = (T_i + T_o)/2$ . Recognize that the above system of equations needs to be solved iteratively by initial guess values of  $T_1$ , or solved simultaneously using equation-solving software with a properties library. The results are tabulated below.

Continued ...

### PROBLEM 9.99 (Cont.)

(b) Using the foregoing relations, the analyses can be repeated with  $L = 15$  mm, so that  $D_i = 130$  mm and  $D_2 = 160$  mm. The results are tabulated below along with those from Example 9.5 for the single-shield configuration.

Shields	L(mm)	$R'_{g1}$ (m·K/W)	$R'_{g2}$ (m·K/W)	$R'_{tot}$ (m·K/W)	$T_1$ (°C)	$q'$ (W/m)
1	10	0.7658	---	0.76	---	100
2	10	1.008	0.8855	1.89	74.8	44.9
2	15	0.9751	0.8224	1.80	73.9	47.3

**COMMENTS:** (1) The effect of adding the second shield is to more than double the thermal resistance of the shields to convection heat transfer.

(2) The effect of gap increase from 10 to 15 mm for the two-shield configuration is slight. Increasing  $L$  allows for greater circulation in the annular space, thereby reducing the thermal resistance.

(3) Note the difference in thermal resistances for the annular spaces  $R'_{g1}$  of the one-and two-shield configurations with  $L = 10$  mm. Why are they so different (0.7658 vs. 1.008 m·K/W, respectively)?

(4) See Example 9.5 for details on how to evaluate the properties for use with the correlation.

## PROBLEM 9.100

**KNOWN:** Concentric cylinders or concentric spheres of uniform inner and outer surface temperatures.

**FIND:** Expressions for the critical Rayleigh numbers,  $Ra_{c,crit}$  and  $Ra_{s,crit}$  below which  $k_{eff}$  is minimized. Evaluate  $Ra_{c,crit}$  and  $Ra_{s,crit}$  for air, water, and glycerin at a mean temperature of 300 K. Comment on the convection heat transfer rate associated with  $Ra_{c,crit}$  and  $Ra_{s,crit}$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Constant properties.

**PROPERTIES:** Table A.4, air (300 K):  $Pr = 0.707$ . Table A.6 water (300 K):  $Pr = 5.83$ . Table A.5 glycerin (300 K):  $Pr = 6780$ .

**ANALYSIS:** When heat transfer across the gap is conduction-dominated,  $k_{eff} = k$ . When convection becomes significant,  $k_{eff}/k > 1$ . Hence, the minimum heat transfer rate occurs when  $k_{eff}/k = 1$ .

Concentric Cylinders: (Equation 9.59)

$$\frac{k_{eff}}{k} = 1 = 0.386 \left( \frac{Pr}{0.861 + Pr} \right)^{1/4} Ra_{c,crit}^{1/4} \quad \text{or} \quad Ra_{c,crit} = \left[ \frac{1}{0.386} \left( \frac{0.861 + Pr}{Pr} \right)^{1/4} \right]^4 = 45.0 \left( \frac{0.861 + Pr}{Pr} \right) <$$

Concentric Spheres: (Equation 9.62)

$$\frac{k_{eff}}{k} = 1 = 0.74 \left( \frac{Pr}{0.861 + Pr} \right)^{1/4} Ra_{s,crit}^{1/4} \quad \text{or} \quad Ra_{s,crit} = \left[ \frac{1}{0.74} \left( \frac{0.861 + Pr}{Pr} \right)^{1/4} \right]^4 = 3.33 \left( \frac{0.861 + Pr}{Pr} \right) <$$

For the three fluids of interest the critical Rayleigh numbers,  $Ra_{c,crit}$  and  $Ra_{s,crit}$  are:

	Concentric Cylinders, $Ra_{c,crit}$	Concentric Spheres, $Ra_{s,crit}$	<
Air	100	7.39	
Water	51.6	3.82	
Glycerin	45.0	3.33	

For specified inner and outer surface temperatures and inner surface radius, the heat transfer rates vary with the outer surface radius as shown in the figure on the following page. For Rayleigh numbers exceeding  $Ra_{c,crit}$  or  $Ra_{s,crit}$  the heat transfer rate increases as free convection becomes more vigorous. For Rayleigh numbers less than  $Ra_{c,crit}$  or  $Ra_{s,crit}$  conduction occurs within the fluid and the conduction heat transfer rate increases as the gap between the surfaces becomes small. Hence conditions associated with  $Ra_{c,crit}$  or  $Ra_{s,crit}$  correspond to the minimum heat transfer rate.

Continued...

### PROBLEM 9.100 (Cont.)

**COMMENTS:** (1) For glycerin, both correlations have been extrapolated slightly beyond the recommended upper limit of the Prandtl number. (2) The critical Rayleigh numbers for the cylinder are substantially larger than those for the sphere. This reflects the fact that, for a given  $r_o/r_i$  ratio, the concentric sphere arrangement has a lower surface area to gas volume ratio than the concentric cylinder arrangement. Hence, the fluid is less constrained by the no-slip boundary conditions of the solid surfaces in the concentric sphere geometry.

### PROBLEM 9.101

**KNOWN:** Operating conditions of a concentric tube solar collector.

**FIND:** Convection heat transfer per unit length across air space between tubes.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Long tubes.

**PROPERTIES:** Table A-4, Air ( $T = 50^\circ\text{C}$ , 1 atm):  $\nu = 18.2 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.028 \text{ W/m}\cdot\text{K}$ ,  $\alpha = 25.9 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.71$ ,  $\beta = 0.0031 \text{ K}^{-1}$ .

**ANALYSIS:** The length scale in  $\text{Ra}_c$  is given by Eq. 9.60,

$$L_c = \frac{2[\ln(r_o/r_i)]^{4/3}}{(r_i^{-3/5} + r_o^{-3/5})^{5/3}} = \frac{2[\ln(0.075/0.05)]^{4/3}}{[(0.075 \text{ m})^{-3/5} + (0.05 \text{ m})^{-3/5}]^{5/3}} = 0.0114 \text{ m}$$

Then

$$\text{Ra}_c = \frac{g\beta(T_s - T_\infty)L_c^3}{\nu\alpha} = \frac{9.8 \text{ m/s}^2 \times 0.0031 \text{ K}^{-1} (70 - 30)^\circ\text{C} (0.0114 \text{ m})^3}{18.2 \times 10^{-6} \text{ m}^2/\text{s} \times 25.9 \times 10^{-6} \text{ m}^2/\text{s}} = 3860$$

Next, Eq. 9.59 may be used, in which case

$$k_{\text{eff}} = 0.386k \left( \frac{\text{Pr}}{0.861 + \text{Pr}} \right)^{1/4} (\text{Ra}_c)^{1/4}$$

$$k_{\text{eff}} = 0.386(0.028 \text{ W/m}\cdot\text{K}) \left( \frac{0.71}{0.861 + 0.71} \right)^{1/4} (3860)^{1/4} = 0.07 \text{ W/m}\cdot\text{K}.$$

From Eq. 9.58, it then follows that

$$q' = \frac{2\pi k_{\text{eff}}}{\ln(r_o/r_i)} (T_i - T_o) = \frac{2\pi(0.07 \text{ W/m}\cdot\text{K})}{\ln(0.15/0.10)} (70 - 30)^\circ\text{C} = 43.4 \text{ W/m}. \quad <$$

**COMMENTS:** An additional heat loss is related to thermal radiation exchange between the inner and outer surfaces.

## PROBLEM 9.102

**KNOWN:** Concentric cylinders. Radius of inner cylinder. Temperature of inner cylinder and ambient temperature.

**FIND:** Outer diameter for minimizing heat loss. Comparison of the heat loss to the situation with no outer cylinder.

**ASSUMPTIONS:** (1) Constant properties, (2) Negligible radiation heat transfer, (3) Steady state, (4) Isothermal and thin outer cylinder, (5) Quiescent environment.

**PROPERTIES:** Table A.4, air ( $50^\circ\text{C} = 323 \text{ K}$ ):  $k = 0.028 \text{ W/m}\cdot\text{K}$ ,  $\alpha = 2.59 \times 10^{-5} \text{ m}^2/\text{s}$ ,  $\nu = 1.82 \times 10^{-5} \text{ m}^2/\text{s}$ ,  $\beta = 0.003096 \text{ K}^{-1}$ ,  $Pr = 0.704$ .

**ANALYSIS:** Neither the radius of the outer cylinder nor the temperature of the outer cylinder is specified. Therefore, an iterative process must be used in order to solve for the optimal radius of the outer cylinder and its temperature. Furthermore, it is not known whether the fluid motion in the annulus is vigorous enough to produce an effective thermal conductivity that is greater than unity. Hence, the analysis will be carried out based upon the assumption of either conduction or convection occurring in the gap; the actual situation corresponds to the larger heat transfer rate per unit length.

For the exterior of the outer cylinder,  $q'_o = h_o 2\pi r_o (T_o - T_\infty) = h_o 2\pi r_o (T_o - 30^\circ\text{C})$  (1)

and the Churchill and Chu correlation may be used to evaluate  $h_o$ ,

$$h_o = \frac{0.028 \text{ W/m}\cdot\text{K}}{2r_o} \left\{ 0.60 + \frac{0.387 Ra_D^{1/6}}{\left[ 1 + (0.559/0.704)^{9/16} \right]^{8/27}} \right\}^2 \quad (2)$$

where

$$Ra_D = \frac{g\beta(T_o - T_\infty)(2r_o)^3}{\nu\alpha} = \frac{9.81 \text{ m/s}^2 \cdot 0.003096 \text{ K}^{-1} (T_o - 30^\circ\text{C})(2r_o)^3}{1.82 \times 10^{-5} \text{ m}^2/\text{s} \times 2.59 \times 10^{-5} \text{ m}^2/\text{s}} \quad (3)$$

For the annular region between the cylinders,

$$q'_i = \frac{2\pi k_{\text{eff}}(T_i - T_o)}{\ln(r_o/r_i)} = \frac{2\pi k_{\text{eff}}(70^\circ\text{C} - T_o)}{\ln(r_o/0.020 \text{ m})} \quad (4)$$

where the Raithby and Hollands formulation may be used to determine the value of  $k_{\text{eff}}$ ,

Continued...

### PROBLEM 9.102 (Cont.)

$$k_{\text{eff}} = 0.386k \left( \frac{Pr}{0.861 + Pr} \right)^{1/4} Ra_c^{1/4} = 0.386 \times 0.028 \text{ W/m} \cdot \text{K} \left( \frac{0.704}{0.861 + 0.704} \right) Ra_c^{1/4} \quad (5)$$

The characteristic length in the Rayleigh number is

$$L_c = \frac{2[\ln(r_o/r_i)]^{4/3}}{(r_i^{-3/5} + r_o^{-3/5})^{5/3}} = \frac{2[\ln(r_o/0.020 \text{ m})]^{4/3}}{((0.020 \text{ m})^{-3/5} + r_o^{-3/5})^{5/3}} \quad (6)$$

and 
$$Ra_c = g\beta(T_i - T_o)L_c^3/\nu\alpha. \quad (7)$$

From the surface energy balance shown in the schematic,

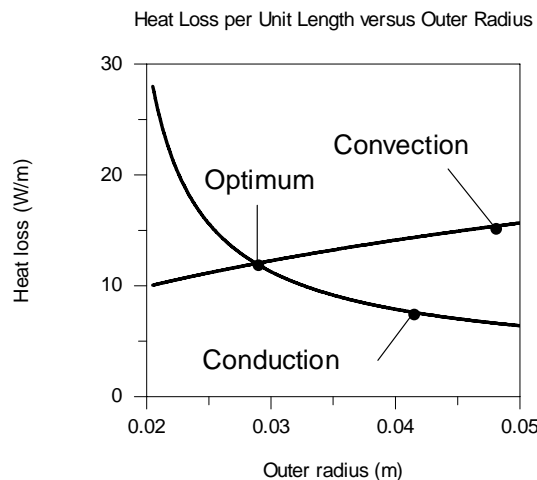

$$q'_i = q'_o \quad (8)$$

Equations 1 through 8 include 9 unknowns,  $q'_i$ ,  $q'_o$ ,  $L_c$ ,  $r_o$ ,  $T_o$ ,  $k_{\text{eff}}$ ,  $Ra_D$ ,  $Ra_c$ , and  $h_o$ . IHT was used to solve these equations simultaneously over a range of  $r_o$ , and the results are plotted below.

For small gap widths, it is expected that augmentation of heat transfer rates due to free convection in the annulus will be small. For these cases,

$$k_{\text{eff}} = k = 0.028 \text{ W/m} \cdot \text{K} \quad (8)$$

Equations 1 through 4, 7 and 8 may be solved simultaneously for  $q'_i$ ,  $q'_o$ ,  $r_o$ ,  $T_o$  and  $h_o$ . IHT was used to solve the equations, and to plot the results shown below.

Heat losses are calculated based upon the two assumptions of (i) convection in the annulus and (ii) conduction in the annulus. The actual heat loss sensitivity to the outer cylinder radius follows the conduction curve until the optimum point is reached, then follows the convection curve after the optimal outer radius. From IHT it is determined that the optimal outer radius is

$$r_{o,\text{opt}} = 0.0289 \text{ m} = 28.9 \text{ mm}, \text{ yielding a heat transfer rate of } q' = 11.99 \text{ W/m.} \quad \leftarrow$$

Continued...

## PROBLEM 9.102 (Cont.)

Without the outer cylinder, the heat loss is determined by the Raithby and Hollands formula with

$$Ra_D = \frac{g\beta(T_i - T_\infty)(2r_i)^3}{\nu\alpha} = \frac{9.81 \text{ m/s}^2 \cdot 0.003096 \text{ K}^{-1} (70^\circ\text{C} - 30^\circ\text{C})(0.040\text{m})^3}{1.82 \times 10^{-5} \text{ m}^2/\text{s} \times 2.59 \times 10^{-5} \text{ m}^2/\text{s}} = 165 \times 10^3$$

Hence,

$$h = \frac{0.028 \text{ W/m} \cdot \text{K}}{0.040 \text{ m}} \left\{ 0.060 + \frac{0.387 (165 \times 10^3)^{1/6}}{\left[ 1 + (0.559/0.707)^{9/16} \right]^{8/27}} \right\}^2 = 4.16 \text{ W/m}^2 \cdot \text{K}$$

and  $q' = 2\pi r_i h (T_i - T_\infty) = 2\pi \times 0.02 \text{ m} \times 4.16 \text{ W/m}^2 \cdot \text{K} \times (70^\circ\text{C} - 30^\circ\text{C}) = 20.9 \text{ W/m}$ . <

The scheme reduces the convective heat transfer loss by  $[(20.9 - 12)/20.9] \times 100 = 43 \%$ . The scheme is somewhat effective.

**COMMENTS:** (1) For the outer cylinder of optimal radius, the surface temperature is  $T_o = 44.9^\circ\text{C}$ . The Rayleigh number for the outer cylinder is  $1.9 \times 10^5$ . (2) The IHT code is shown below.

```

qcd = hDcd*pi*D*(Tocd - Tinf) //External convection heat transfer per unit length (with conduction in annulus), W/m
```

## PROBLEM 9.103

**KNOWN:** Dimensions and heat generation rate associated with horizontally-oriented lithium ion battery. Size of annulus filled with liquid paraffin. Properties and fusion temperature of the paraffin.

**FIND:** (a) Battery surface temperature when  $r_o = 19$  mm, (b) Rate at which  $r_o$  is increasing with time, (c) Plot of battery surface temperature versus  $r_o$  for  $15 \text{ mm} \leq r_o \leq 30 \text{ mm}$  and explanation of relative insensitivity of battery temperature to size of the annulus.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Constant properties and steady-state conditions, (2) Solid paraffin at melting point temperature.

**PROPERTIES:** Given, see schematic.

**ANALYSIS:** (a) The length scale used in the Rayleigh number is given by Equation 9.60.

$$L_c = \frac{2[\ln(r_o/r_i)]^{4/3}}{(r_i^{-3/5} + r_o^{-3/5})^{5/3}} = \frac{2[\ln(19/9)]^{4/3}}{\left[(9 \times 10^{-3} \text{ m})^{-3/5} + (19 \times 10^{-3} \text{ m})^{-3/5}\right]^{5/3}} = 5.36 \times 10^{-3} \text{ m}$$

The Rayleigh number is

$$\begin{aligned} \text{Ra}_c &= \frac{g\beta(T_s - T_{\text{mp}})L_c^3}{\nu \cdot \alpha} = \frac{9.8 \text{ m/s}^2 \times 8 \times 10^{-4} \text{ K}^{-1} \times (T_s - 27.4)^\circ\text{C} \times (5.36 \times 10^{-3} \text{ m})^3}{5 \times 10^{-6} \text{ m}^2/\text{s} \times 8.85 \times 10^{-8} \text{ m}^2/\text{s}} \quad (1) \\ &= 2728 \text{ K}^{-1} \times (T_s - 27.4^\circ\text{C}) \end{aligned}$$

The Prandtl number is  $\text{Pr} = \nu/\alpha = 5 \times 10^{-6} \text{ m}^2/\text{s} / 8.85 \times 10^{-8} \text{ m}^2/\text{s} = 56.5$ , and the effective thermal conductivity is given by Equation 9.59,

Continued...

**PROBLEM 9.103 (Cont.)**

$$k_{\text{eff}} = 0.386k \left( \frac{\text{Pr}}{0.861 + \text{Pr}} \right)^{1/4} \text{Ra}_c^{1/4} = 0.386 \times 0.15 \text{ W/m} \cdot \text{K} \times \left( \frac{56.5}{0.861 + 565} \right)^{1/4} \text{Ra}_c^{1/4}$$

$$k_{\text{eff}} = 0.0577 \text{ Ra}_c^{1/4} \quad (2)$$

The effective thermal conductivity may also be expressed in terms of Equation 9.58,

$$k_{\text{eff}} = \frac{\dot{E}_g \ln(r_o/r_i)}{2\pi L(T_s - T_{\text{mp}})} = \frac{1 \text{ W} \times \ln(19/9)}{2\pi \times 65 \times 10^{-3} \text{ m} \times (T_s - 27.4^\circ\text{C})} = \frac{1.829 \text{ W/m}}{(T_s - 27.4^\circ\text{C})} \quad (3)$$

Equations 1, 2 and 3 may be solved simultaneously to yield

$$\text{Ra}_c = 8901, k_{\text{eff}} = 0.5603 \text{ W/m} \cdot \text{K}, T_s = 30.7^\circ\text{C}. \quad <$$

(b) An energy balance on the control surface shown in the schematic yields

$$q_{\text{conv}} = \dot{E}_g = A \rho h_{\text{sf}} dr_o / dt$$

or

$$\begin{aligned} \frac{dr_o}{dt} &= \frac{\dot{E}_g}{2\pi r_o L \rho h_{\text{sf}}} = \frac{1 \text{ W}}{2 \times \pi \times 19 \times 10^{-3} \text{ m} \times 65 \times 10^{-3} \text{ m} \times 770 \text{ kg/m}^3 \times 244 \times 10^3 \text{ J/kg}} < \\ &= 685 \times 10^{-9} \text{ m/s} = 0.685 \mu\text{m/s} \end{aligned}$$

(c) Equations 1 through 3 may be re-solved for various outer radii of the annular region. As evident, the battery surface temperature is very insensitive to the size of the annular region. If heat transfer in the annulus were conduction-dominated, one would expect the battery surface temperature to *increase* as the annulus becomes larger. The opposite trend is evident here.

Continued...

### PROBLEM 9.103 (Cont.)

As the annulus becomes larger, fluid velocities associated with free convection increase and the effective thermal conductivity is expected to increase as well. The ratio of the effective thermal conductivity to the bulk thermal conductivity of the paraffin and its sensitivity to the size of the annulus is shown in the plot below. The enhanced fluid motion associated with the larger enclosures increases the effective thermal conductivity of the fluid significantly. Hence, both the numerator and denominator of Equation 9.58 increase with increasing size of the annular region, yielding relatively constant battery surface temperatures.

### PROBLEM 9.104

**KNOWN:** Temperatures of concentric spheres and diameter of inner sphere.

**FIND:** Outer sphere diameter required so that convection heat transfer is same as for inner sphere in a large, quiescent environment at 20°C.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, (2) Uniform sphere surface temperatures, (3) Constant properties.

**PROPERTIES:** Table A-4, Air ( $T = 308 \text{ K}$ ):  $\nu = 16.69 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\alpha = 23.68 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 26.9 \times 10^{-3} \text{ W/m} \cdot \text{K}$ ,  $Pr = 0.706$ ,  $\beta = 1/T = 0.00325 \text{ K}^{-1}$ .

**ANALYSIS:** For the single inner sphere in a large quiescent enclosure, the Rayleigh number based on inner diameter is

$$Ra_D = \frac{g\beta(T_i - T_\infty)D_i^3}{\nu\alpha} = \frac{9.8 \text{ m/s}^2 \times 0.00325 \text{ K}^{-1} \times (50 - 20)^\circ\text{C} \times (0.05 \text{ m})^3}{16.69 \times 10^{-6} \text{ m}^2/\text{s} \times 23.68 \times 10^{-6} \text{ m}^2/\text{s}} = 3.02 \times 10^5$$

Eq. 9.35 holds, and yields

$$\overline{Nu}_D = 2 + \frac{0.589 Ra_D^{1/4}}{[1 + (0.469 / Pr)^{9/16}]^{4/9}} = 12.7$$

and

$$q_1 = \bar{h}\pi D_i^2(T_i - T_\infty) = \overline{Nu}_D k \pi D_i(T_i - T_\infty) = 12.7 \times 26.9 \times 10^{-3} \text{ W/m} \cdot \text{K} \times \pi \times 0.05 \text{ m} \times (50 - 20)^\circ\text{C} = 1.60 \text{ W}$$

For the concentric spheres, the Rayleigh number is based on the length scale given by Eq. 9.63,

$$Ra_s = \frac{g\beta(T_i - T_o)}{\nu\alpha} \frac{(1/r_i - 1/r_o)^4}{2(r_i^{-7/5} + r_o^{-7/5})^5} \quad (1)$$

Substituting this into Eq. 9.62 and substituting Eq. 9.62 in Eq. 9.61 yields

Continued...

**PROBLEM 9.104 (Cont.)**

$$\begin{aligned}
 q_2 &= 4\pi k(T_i - T_o)0.74 \left( \frac{Pr}{0.861 + Pr} \right)^{1/4} \left( \frac{g\beta(T_i - T_o)}{\nu\alpha} \right)^{1/4} \frac{1}{2^{1/4}(r_i^{-7/5} + r_o^{-7/5})^{5/4}} \quad (2) \\
 &= 4\pi \times 26.9 \times 10^{-3} \text{ W/m} \cdot \text{K} \times (50 - 20)^\circ\text{C} \times 0.74 \times \left( \frac{0.706}{0.861 + 0.706} \right)^{1/4} \\
 &\quad \times \left( \frac{9.8 \text{ m/s}^2 \times 0.00325 \text{ K}^{-1} \times (50 - 20)^\circ\text{C}}{16.69 \times 10^{-6} \text{ m}^2/\text{s} \times 23.68 \times 10^{-6} \text{ m}^2/\text{s}} \right)^{1/4} \frac{1}{2^{1/4}(r_i^{-7/5} + r_o^{-7/5})^{5/4}} \\
 &= 1146 \text{ W/m}^{7/4} \frac{1}{(r_i^{-7/5} + r_o^{-7/5})^{5/4}}
 \end{aligned}$$

Setting  $q_2 = q_1 = 1.60 \text{ W}$ , and solving for  $r_o$  yields

$$r_o = \left[ \left( \frac{1146 \text{ W/m}^{7/4}}{1.60 \text{ W}} \right)^{4/5} - r_i^{-7/5} \right]^{-5/7} = \left[ \left( \frac{1146 \text{ W/m}^{7/4}}{1.60 \text{ W}} \right)^{4/5} - (0.025 \text{ m})^{-7/5} \right]^{-5/7} = 0.130 \text{ m}$$

Thus the required diameter of the outer cylinder is

$$D_o = 260 \text{ mm} \quad <$$

From Eq. (1),  $Ra_s = 5000$ , so the correlation for concentric spheres is within its range of applicability.

**COMMENTS:** It is of interest whether the concentric sphere correlation approaches the single sphere limit as  $r_o \rightarrow \infty$ . From Eq. (2) above, it can be seen that  $q_2$  reaches an asymptote. This can be rephrased in terms of a heat transfer coefficient for concentric spheres,  $h_2$ , defined such that  $q_2 = h_2 \pi D_i^2 (T_i - T_o)$ . The corresponding Nusselt number,  $\overline{Nu}_D = h_2 D_i / k$ , is then

$$\overline{Nu}_D = \frac{0.74 Ra_D^{1/4}}{(1 + 0.861 / Pr)^{1/4}}$$

This has the same asymptotic Rayleigh number dependence as Eq. 9.35 (as long as the leading 2 is negligible), but not the same Prandtl number dependence. When researchers fit experimental data to a correlating equation, they must make a judgment as to whether it is appropriate, based on the range of their experimental data, to impose the correct limiting behavior.

### PROBLEM 9.105

**KNOWN:** Annulus formed by two concentric, horizontal tubes with prescribed diameters and surface temperatures is filled with nitrogen at 5 atm.

**FIND:** Convective heat transfer rate per unit length of the tubes.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Thermophysical properties  $k$ ,  $\mu$ , and  $Pr$ , are independent of pressure, (2) Density is proportional to pressure, (3) Perfect gas behavior.

**PROPERTIES:** Table A-4, Nitrogen ( $\bar{T} = (T_i + T_o)/2 = 350\text{K}$ , 5 atm):  $k = 0.0293\text{ W/m}\cdot\text{K}$ ,  $\mu = 200 \times 10^{-7}\text{ N}\cdot\text{s/m}^2$ ,  $\rho(5\text{ atm}) = 5\rho(1\text{ atm}) = 5 \times 0.9625\text{ kg/m}^3 = 4.813\text{ kg/m}^3$ ,  $Pr = 0.711$ ,  $\nu = \mu/\rho = 4.155 \times 10^{-6}\text{ m}^2/\text{s}$ ,  $\alpha = k/\rho c = 0.0293\text{ W/m}\cdot\text{K}/(4.813\text{ kg/m}^3 \times 1042\text{ J/kg}\cdot\text{K}) = 5.842 \times 10^{-6}\text{ m}^2/\text{s}$ .

**ANALYSIS:** The length scale in  $Ra_c$  is given by Eq. 9.60,

$$L_c = \frac{2[\ln(r_o/r_i)]^{4/3}}{(r_i^{-3/5} + r_o^{-3/5})^{5/3}} = \frac{2[\ln(125/100)]^{4/3}}{[(0.1\text{ m})^{-3/5} + (0.125\text{ m})^{-3/5}]^{5/3}} = 0.0095\text{ m}$$

Then

$$Ra_c = \frac{g\beta(T_s - T_\infty)L_c^3}{\nu\alpha} = \frac{9.8\text{ m/s}^2 \times (1/350\text{ K}) (400 - 300)\text{K} (0.0095\text{ m})^3}{4.155 \times 10^{-6}\text{ m}^2/\text{s} \times 5.842 \times 10^{-6}\text{ m}^2/\text{s}} = 98,800$$

The effective thermal conductivity is found from Eq. 9.59,

$$\frac{k_{\text{eff}}}{k} = 0.386 \left( \frac{Pr}{0.861 + Pr} \right)^{1/4} Ra_c^{1/4}$$

$$\frac{k_{\text{eff}}}{k} = 0.386 \left( \frac{0.711}{0.861 + 0.711} \right)^{1/4} (98,800)^{1/4} = 5.61.$$

Hence, the heat rate, Eq. (1), becomes

$$q' = \frac{2\pi \times 5.61 \times 0.0293\text{ W/m}\cdot\text{K}}{\ln(125/100)} (400 - 300)\text{K} = 463\text{ W/m}. \quad <$$

**COMMENTS:** Note that the heat loss by convection is nearly six times that for conduction. Radiation transfer is likely to be important for this situation. The effect of nitrogen pressure is to decrease  $\nu$  which in turn increases  $Ra_L$ ; that is, free convection heat transfer will increase with increase in pressure.

### PROBLEM 9.106

**KNOWN:** Diameter of cylindrical enclosure housing solid PCM. Diameter and temperature of heated inner concentric cylinder. Initial PCM temperature.

**FIND:** Time to melt half of PCM.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) The quasi-steady approximation holds: the heat transfer coefficient can be evaluated based on steady-state conditions, (2) Constant properties, (3) The sensible energy associated with the portion of PCM above its melting temperature is negligible.

**PROPERTIES:** From Problems 8.47 and 9.57, PCM:  $T_m = 27.4^\circ\text{C}$ ,  $h_{sf} = 244 \text{ kJ/kg}$ ,  $\rho = 770 \text{ kg/m}^3$ ,  $k = 0.15 \text{ W/m} \cdot \text{K}$ ,  $\beta = 8 \times 10^{-4} \text{ K}^{-1}$ ,  $\nu = 5 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\alpha = 8.85 \times 10^{-8} \text{ m}^2/\text{s}$ ,  $Pr = \nu/\alpha = 56.5$ ,  $c_p = k/\rho\alpha = 2200 \text{ J/kg} \cdot \text{K}$ .

**ANALYSIS:** The molten PCM occupies the region between the heater radius,  $r_i$ , and the solid-liquid interface,  $r_o$ . The latter radius is a function of time. According to the quasi-steady approximation, the convection heat transfer rate can be found from Eqs. 9.58, 9.59, and 9.60 using the instantaneous value of  $r_o$ . Combining these equations yields the convection heat transfer rate per unit length:

$$q' = 2\pi k(T_i - T_o)0.386 \left( \frac{Pr}{0.861 + Pr} \right)^{1/4} \left( \frac{g\beta(T_i - T_o)}{\nu\alpha} \right)^{1/4} \frac{2^{3/4}}{(r_i^{-3/5} + r_o^{-3/5})^{5/4}} = \frac{A}{(r_i^{-3/5} + r_o^{-3/5})^{5/4}} \quad (1)$$

where  $T_o = T_m = 27.4^\circ\text{C}$  and  $T_i = T_h = 50^\circ\text{C}$ . The constant  $A$  is defined by the above equation and has the value  $A = 1.10 \times 10^4 \text{ W/m}^{7/4}$ . The rate at which heat reaches the solid-liquid interface is equal to the rate of change of mass of molten PCM (kg/s) multiplied by the latent heat of fusion, thus

$$q' = \frac{dm'}{dt} h_{sf} = \frac{d}{dt} (\rho\pi(r_o^2 - r_i^2)) h_{sf} = 2\pi r_o \rho h_{sf} \frac{dr_o}{dt} \quad (2)$$

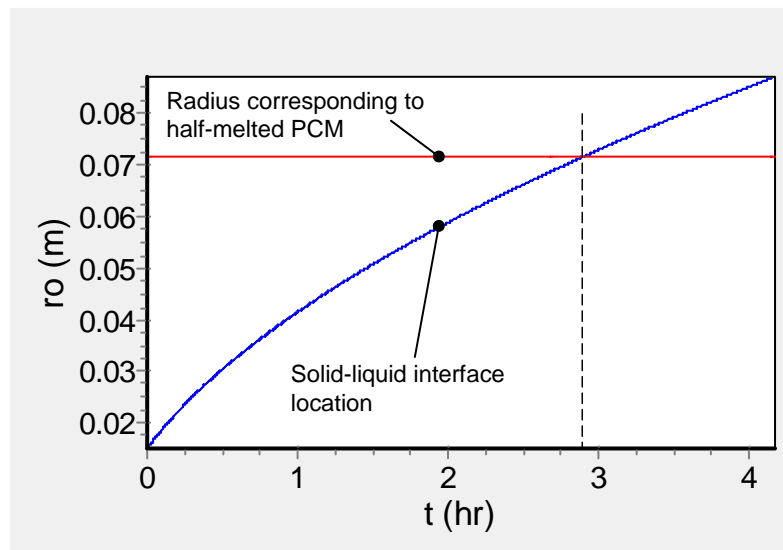

Combining Eqs. (1) and (2) yields a differential equation for  $r_o(t)$ :

$$\frac{dr_o}{dt} = \frac{A / 2\pi\rho h_{sf}}{r_o (r_i^{-3/5} + r_o^{-3/5})^{5/4}}$$

The criterion that half the PCM has been melted is satisfied when  $\pi(r_{o,\text{final}}^2 - r_i^2) = \frac{1}{2}\pi(r_e^2 - r_i^2)$ , where  $r_e = \frac{1}{2}D_e = 0.1 \text{ m}$ . Thus,  $r_{o,\text{final}} = \left[ \frac{1}{2}(r_e^2 + r_i^2) \right]^{1/2} = 0.0715 \text{ m}$ . The above differential equation is most easily solved numerically. It has been solved using IHT to generate the following graph.

Continued...

### PROBLEM 9.106 (Cont.)

The final radius criterion,  $r_o = 0.0715$  m, is satisfied at  $t = 2.88$  h.

<

**COMMENTS:** (1) The solid-liquid interface moves slowly, traveling around 70 mm in 2.88 h. It is likely that the free convection motion can adjust to the instantaneous conditions relatively quickly compared with the rate at which the interface is moving. That is, the quasi-steady approximation is probably accurate. (2) The sensible energy associated with the portion of PCM above its melting temperature was neglected. The temperature of the molten PCM varies from the melting temperature to the heater temperature. We can estimate the average PCM temperature as  $(27.4+50)^\circ\text{C}/2 = 38.7^\circ\text{C}$ . The ratio of the sensible energy to the latent energy is  $mc_p(T - T_m)/mh_{sf} = c_p(T - T_m)/h_{sf}$ . This ratio is a dimensionless parameter known as the Stefan number,  $Ste$ . Here  $Ste = 0.10$ . Thus, the error associated with neglecting the sensible energy is on the order of 10%.

### PROBLEM 9.107

**KNOWN:** Diameters and temperatures of concentric spheres.

**FIND:** Rate at which stored nitrogen is vented.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible radiation.

**PROPERTIES:** Liquid nitrogen (given):  $h_{fg} = 2 \times 10^5 \text{ J/kg}$ ; Table A-4, Helium ( $\bar{T} = (T_i + T_o)/2 = 180\text{K}$ , 1 atm):  $\nu = 51.3 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.107 \text{ W/m}\cdot\text{K}$ ,  $\alpha = 76.2 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.673$ ,  $\beta = 0.00556 \text{ K}^{-1}$ .

**ANALYSIS:** Performing an energy balance for a control surface about the liquid nitrogen, it follows that

$$q = q_{\text{conv}} = \dot{m} h_{fg}$$

From the Raithby and Hollands expressions for free convection between concentric spheres,

$$q_{\text{conv}} = \frac{4\pi k_{\text{eff}} (T_i - T_o)}{(1/r_i) - (1/r_o)}$$

$$k_{\text{eff}} = 0.74k \left[ \text{Pr} / (0.861 + \text{Pr}) \right]^{1/4} \left( \text{Ra}_s \right)^{1/4}$$

where  $L_s = \frac{(1/r_i - 1/r_o)^{4/3}}{2^{1/3} (r_i^{-7/5} + r_o^{-7/5})^{5/3}} = 5.69 \times 10^{-3} \text{ m}$

$$\text{Ra}_s = \frac{g\beta(T_o - T_i)L_s^3}{\nu\alpha} = \frac{9.8 \text{ m/s}^2 (0.00556 \text{ K}^{-1})(206 \text{ K})(5.69 \times 10^{-3} \text{ m})^3}{(51.3 \times 10^{-6} \text{ m}^2/\text{s})(76.2 \times 10^{-6} \text{ m}^2/\text{s})} = 528$$

$$k_{\text{eff}} = 0.74(0.107 \text{ W/m}\cdot\text{K}) \left[ 0.673 / (0.861 + 0.673) \right]^{1/4} (528)^{1/4} = 0.309 \text{ W/m}\cdot\text{K}$$

Hence,  $q_{\text{conv}} = \frac{(0.309 \text{ W/m}\cdot\text{K}) \times 4\pi (206 \text{ K})}{(1/0.5 \text{ m}) - (1/0.55 \text{ m})} = 4399 \text{ W}$

The rate at which nitrogen is lost from the system is therefore

$$\dot{m} = q_{\text{conv}} / h_{fg} = 4399 \text{ W} / 2 \times 10^5 \text{ J/kg} = 0.022 \text{ kg/s}$$

<

**COMMENTS:** The heat gain and mass loss are large. Helium should be replaced by a noncondensing gas of smaller  $k$ , or the cavity should be evacuated.

## PROBLEM 9.108

**KNOWN:** Dimensions of enclosure, surface temperatures, and properties of aqueous humor.

**FIND:** The ratio of the effective to the bulk thermal conductivity of the aqueous humor.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Constant properties, (2) Steady-state conditions, (3) Person is standing or sitting vertically.

**PROPERTIES:** Given, see schematic.

**ANALYSIS:** The kinematic viscosity is  $\nu = \mu/\rho = 7.1 \times 10^{-4} \text{ N}\cdot\text{s}/\text{m}^2/990 \text{ kg}/\text{m}^3 = 7.17 \times 10^{-9} \text{ m}^2/\text{s}$ . The thermal diffusivity is  $\alpha = k/\rho c_p = 0.58 \text{ W}/\text{m}\cdot\text{K}/(990 \text{ kg}/\text{m}^3 \times 4.2 \times 10^3 \text{ J}/\text{kg}\cdot\text{K}) = 139.5 \times 10^{-4} \text{ m}^2/\text{s}$ , while the Prandtl number is  $\text{Pr} = \nu/\alpha = (7.17 \times 10^{-9} \text{ m}^2/\text{s})/(139.5 \times 10^{-4} \text{ m}^2/\text{s}) = 5.14$ . The characteristic length for use in Equation 9.61 is

$$L_s = \frac{\left(\frac{1}{r_i} - \frac{1}{r_o}\right)^{4/3}}{2^{1/3} \left(r_i^{-7/5} + r_o^{-7/5}\right)^{5/3}} = \frac{\left(\frac{1}{7 \times 10^{-3} \text{ m}} - \frac{1}{10 \times 10^{-3} \text{ m}}\right)^{4/3}}{2^{1/3} \left((7 \times 10^{-3} \text{ m})^{-7/5} + (10 \times 10^{-3} \text{ m})^{-7/5}\right)^{5/3}} = 506 \times 10^{-6} \text{ m}$$

The Rayleigh number is

$$\text{Ra}_s = \frac{g\beta(T_s - T_o)L_s^3}{\nu \cdot \alpha} = \frac{9.8 \text{ m}/\text{s}^2 \times 3.2 \times 10^{-4} \text{ K}^{-1} \times (37 - 34)^\circ\text{C} \times (506 \times 10^{-6} \text{ m})^3}{7.17 \times 10^{-9} \text{ m}^2/\text{s} \times 139.5 \times 10^{-4} \text{ m}^2/\text{s}} = 12.2$$

The ratio of the effective thermal conductivity to bulk thermal conductivity is

$$\frac{k_{\text{eff}}}{k} = 0.74 \left(\frac{\text{Pr}}{0.861 + \text{Pr}}\right)^{1/4} \text{Ra}_s^{1/4} = 0.74 \times \left(\frac{5.14}{0.861 + 5.14}\right)^{1/4} \times (12.2)^{1/4} = 1.33 <$$

Since  $k_{\text{eff}}/k > 1$ , we conclude that free convection does occur in the aqueous humor.

**Comments:** (1). The velocity of the aqueous humor could be estimated by performing a detailed simulation using a CFD (computational fluid dynamics) tool. (2) Fluid motion is upward near the iris and downward adjacent to the cornea when the person is standing or sitting vertically.

### PROBLEM 9.109

**KNOWN:** Diameter and temperature of cylinder. Velocity and temperature of fluid in cross flow. Four different fluids.

**FIND:** Whether heat transfer by free convection is significant.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady state, (2) Constant properties, (3) Air can be modeled as an ideal gas.

**PROPERTIES:** Air (300K, 1 atm):  $\beta = 1/T_f = 3.333 \times 10^{-3} \text{ K}^{-1}$ ; Table A-6, Water ( $T_f = (T_\infty + T_s)/2 = 300\text{K}$ ):  $\beta = 276.1 \times 10^{-6} \text{ K}^{-1}$ ; Table A-5, Engine oil ( $T_f = (T_\infty + T_s)/2 = 300\text{K}$ ):  $\beta = 0.7 \times 10^{-3} \text{ K}^{-1}$ ; Table A-5, Mercury ( $T_f = (T_\infty + T_s)/2 = 300\text{K}$ ):  $\beta = 0.181 \times 10^{-3} \text{ K}^{-1}$ .

**ANALYSIS:** Following the discussion of Section 9.9, the general criterion for delineating the relative significance of free and forced convection depends upon the value of  $Gr/Re^2$ . Free convection is insignificant if  $Gr/Re^2 \ll 1$ , where  $Gr = g\beta(T_s - T_\infty)D^3/\nu^2$  and  $Re = VD/\nu$ . Thus,

$$Gr / Re^2 = g\beta(T_s - T_\infty)D / V^2$$

The only material property that impacts the determination of the significance of free convection is the thermal expansion coefficient,  $\beta$ . Furthermore with all other parameters held fixed, it is useful to express  $Gr/Re^2 = G\beta$ , where

$$G = g(T_s - T_\infty)D/V^2 = 9.8 \text{ m/s}^2 \times (35 - 20)^\circ\text{C} \times 0.025 \text{ m}/(0.05 \text{ m/s})^2 = 1470 \text{ K}$$

Thus, for air,

$$Gr/Re^2 = G\beta = 1470 \text{ K} \times 3.333 \times 10^{-3} \text{ K}^{-1} = 4.90$$

Since  $Gr/Re^2 > 1$ , free convection is significant. <

For water,

$$Gr/Re^2 = G\beta = 1470 \text{ K} \times 276.1 \times 10^{-6} \text{ K}^{-1} = 0.406$$

Since  $Gr/Re^2$  is not small compared to 1, free convection is likely to be important. <

Continued...

### PROBLEM 9.109 (Cont.)

For engine oil,

$$Gr/Re^2 = G\beta = 1470 \text{ K} \times 0.7 \times 10^{-3} \text{ K}^{-1} = 1.03$$

Since  $Gr/Re^2$  is of order 1, free and forced convection are likely to be equally important. <

For mercury,

$$Gr/Re^2 = G\beta = 1470 \text{ K} \times 0.181 \times 10^{-3} \text{ K}^{-1} = 0.266$$

Since  $Gr/Re^2$  is somewhat small compared to 1, free convection might be negligible, depending on the desired accuracy of the solution. <

**COMMENTS:** (1) None of the situations considered here correspond to conditions where heat transfer is clearly dominated by either natural or forced convection. In such situations, it may be necessary to determine the convection heat transfer rates experimentally, or by solving the three-dimensional, unsteady forms of the convection transfer equations computationally. (2)  $Gr/Re^2$  is sometimes referred to as the Richardson number,  $Ri$ .

### PROBLEM 9.110

**KNOWN:** Parallel air flow over a uniform temperature, heated vertical plate; the effect of free convection on the heat transfer coefficient will be 5% when  $Gr_L / Re_L^2 = 0.08$ .

**FIND:** Minimum vertical velocity required of air flow such that free convection effects will be less than 5% of the heat rate.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Criterion for combined free-forced convection determined from experimental results.

**PROPERTIES:** Table A-4, Air ( $T_f = (T_s + T_\infty)/2 = 315\text{K}$ , 1 atm):  $\nu = 17.40 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\beta = 1/T_f$ .

**ANALYSIS:** To delineate flow regimes, according to Section 9.9, the general criterion for predominately forced convection is that

$$Gr_L / Re_L^2 \ll 1. \quad (1)$$

From experimental results, when  $Gr_L / Re_L^2 \approx 0.08$ , free convection will be equal to 5% of the total heat rate.

For the vertical plate using Eq. 9.12,

$$Gr_L = \frac{g \beta (T_1 - T_2) L^3}{\nu^2} = \frac{9.8 \text{ m/s}^2 \times 1/315\text{K} \times (60 - 25)\text{K} \times (0.3\text{m})^3}{(17.40 \times 10^{-6} \text{ m}^2/\text{s})^2} = 9.711 \times 10^7. \quad (2)$$

For the vertical plate with forced convection,

$$Re_L = \frac{u_\infty L}{\nu} = \frac{u_\infty (0.3\text{m})}{17.4 \times 10^{-6} \text{ m}^2/\text{s}} = 1.724 \times 10^4 u_\infty. \quad (3)$$

By combining Eqs. (2) and (3),

$$\frac{Gr_L}{Re_L^2} = \frac{9.711 \times 10^7}{[1.724 \times 10^4 u_\infty]^2} = 0.08$$

find that

$$u_\infty = 2.02 \text{ m/s}. \quad <$$

That is, when  $u_\infty \geq 2.02 \text{ m/s}$ , free convection effects will not exceed 5% of the total heat rate.

### PROBLEM 9.111

**KNOWN:** Vertical array of circuit boards 0.15m high with maximum allowable uniform surface temperature for prescribed ambient air temperature.

**FIND:** Allowable electrical power dissipation per board,  $q'$  [W/m], for these cooling arrangements:

(a) Free convection only, (b) Air flow downward at 0.6 m/s, (c) Air flow upward at 0.3 m/s, and (d) Air flow upward or downward at 5 m/s.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Uniform surface temperature, (2) Board horizontal spacing sufficient that boundary layers don't interfere, (3) Ambient air behaves as quiescent medium, (4) Perfect gas behavior.

**PROPERTIES:** Table A-4, Air ( $T_f = (T_s + T_\infty)/2 \approx 315\text{K}$ , 1 atm):  $\nu = 17.40 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0274 \text{ W/m}\cdot\text{K}$ ,  $\alpha = 24.7 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.705$ ,  $\beta = 1/T_f$ .

**ANALYSIS:** (a) For *free convection* only, the allowable electrical power dissipation rate is

$$q' = \bar{h}_L (2L)(T_s - T_\infty) \quad (1)$$

where  $\bar{h}_L$  is estimated using the appropriate correlation for free convection from a vertical plate. Find the Rayleigh number,

$$\text{Ra}_L = \frac{g \beta \Delta T L^3}{\nu \alpha} = \frac{9.8 \text{ m/s}^2 (1/315\text{K})(60 - 25)\text{K} (0.150\text{m})^3}{17.4 \times 10^{-6} \text{ m}^2/\text{s} \times 24.7 \times 10^{-6} \text{ m}^2/\text{s}} = 8.551 \times 10^6. \quad (2)$$

Since  $\text{Ra}_L < 10^9$ , the flow is laminar. With Eq. 9.27 find

$$\bar{\text{Nu}}_L = \frac{\bar{h}_L}{k} = 0.68 + \frac{0.670 \text{ Ra}_L^{1/4}}{\left[1 + (0.492/\text{Pr})^{9/16}\right]^{4/9}} = 0.68 + \frac{\left(0.670 \left[8.551 \times 10^6\right]^{1/4}\right)}{\left[1 + (0.492/0.705)^{9/16}\right]^{4/9}} = 28.47 \quad (3)$$

$$\bar{h}_L = (0.0274 \text{ W/m}\cdot\text{K} / 0.150\text{m}) \times 28.47 = 5.20 \text{ W/m}^2 \cdot \text{K}.$$

Hence, the allowable electrical power dissipation rate is,

$$q' = 5.20 \text{ W/m}^2 \cdot \text{K} (2 \times 0.150\text{m})(60 - 25)^\circ\text{C} = 54.6 \text{ W/m}. \quad \leftarrow$$

(b) With *downward velocity*  $V = 0.6 \text{ m/s}$ , the possibility of mixed forced-free convection must be considered. With  $\text{Re}_L = VL/\nu$ , find

$$\left(\text{Gr}_L / \text{Re}_L^2\right) = \left(\frac{\text{Ra}_L}{\text{Pr}} / \text{Re}_L^2\right) \quad (4)$$

$$\left(\text{Gr}_L / \text{Re}_L^2\right) = \left(8.551 \times 10^6 / 0.705\right) / \left(0.6 \text{ m/s} \times 0.150\text{m} / 17.40 \times 10^{-6} \text{ m}^2/\text{s}\right)^2 = 0.453.$$

Continued ...

**PROBLEM 9.111 (Cont.)**

Since  $(Gr_L / Re_L^2) \sim 1$ , flow is mixed and the average heat transfer coefficient may be found from a correlating equation of the form

$$\overline{Nu}^n = Nu_F^n \pm Nu_N^n \quad (5)$$

where  $n = 3$  for the vertical plate geometry and the minus sign is appropriate since the natural convection (N) flow opposes the forced convection (F) flow. For the forced convection flow,  $Re_L = 5172$  and the flow is laminar; using Eq. 7.30,

$$\overline{Nu}_F = 0.664 Re_L^{1/2} Pr^{1/3} = 0.664(5172)^{1/2} (0.705)^{1/3} = 42.50. \quad (6)$$

Using  $\overline{Nu}_N = 28.47$  from Eq. (3), Eq. (5) now becomes

$$\overline{Nu}^3 = \left( \frac{\overline{h}L}{k} \right)^3 = (42.50)^3 - (28.47)^3 \quad \overline{Nu} = 37.72$$

$$\overline{h} = \left( \frac{0.0274 \text{ W/m} \cdot \text{K}}{0.150 \text{ m}} \right) \times 37.72 = 6.89 \text{ W/m}^2 \cdot \text{K}.$$

Substituting for  $\overline{h}$  into the rate equation, Eq. (1), the allowable power dissipation with a downward velocity of 0.6 m/s is

$$q' = 6.89 \text{ W/m}^2 \cdot \text{K} (2 \times 0.150 \text{ m}) (60 - 25)^\circ\text{C} = 72.3 \text{ W/m}. \quad <$$

(c) With an *upward velocity*  $V = 0.3$  m/s, the positive sign of Eq. (5) applies since the N-flow is assisting the F-flow. For forced convection, find

$$Re_L = VL/\nu = 0.3 \text{ m/s} \times 0.150 \text{ m} / (17.40 \times 10^{-6} \text{ m}^2/\text{s}) = 2586.$$

The flow is again laminar, hence Eq. (6) is appropriate.

$$\overline{Nu}_F = 0.664(2586)^{1/2} (0.705)^{1/3} = 30.05.$$

From Eq. (5), with the positive sign, and  $\overline{Nu}_N$  from Eq. (4),

$$\overline{Nu}^3 = (30.05)^3 + (28.47)^3 \quad \text{or} \quad \overline{Nu} = 36.88 \quad \text{and} \quad \overline{h} = 6.74 \text{ W/m}^2 \cdot \text{K}.$$

From Eq. (1), the allowable power dissipation with an upward velocity of 0.3 m/s is

$$q' = 6.74 \text{ W/m}^2 \cdot \text{K} (2 \times 0.150 \text{ m}) (60 - 25)^\circ\text{C} = 70.7 \text{ W/m}. \quad <$$

(d) With a *forced convection* velocity  $V = 5$  m/s, very likely forced convection will dominate. Check by evaluating whether  $(Gr_L / Re_L^2) \ll 1$  where  $Re_L = VL/\nu = 5 \text{ m/s} \times 0.150 \text{ m} / (17.40 \times 10^{-6} \text{ m}^2/\text{s}) = 43,103$ . Hence,

$$\left( Gr_L / Re_L^2 \right) = \left( \frac{Ra_L}{Pr} / Re_L^2 \right) = (8.551 \times 10^6 / 0.705) / 43,103^2 = 0.007.$$

The flow is not mixed, but pure forced convection. Using Eq. (6), find

$$\overline{h} = (0.0274 \text{ W/m} \cdot \text{K} / 0.150 \text{ m}) 0.664(43,103)^{1/2} (0.705)^{1/3} = 22.4 \text{ W/m}^2 \cdot \text{K}$$

and the allowable dissipation rate is

$$q' = 22.4 \text{ W/m}^2 \cdot \text{K} (2 \times 0.150 \text{ m}) (60 - 25)^\circ\text{C} = 235 \text{ W/m}. \quad <$$

**COMMENTS:** Be sure to compare dissipation rates to see relative importance of mixed flow conditions.

## PROBLEM 9.112

**KNOWN:** Dimensions of horizontal tube in wind tunnel. Air velocity and temperature, surroundings temperature, emissivity of tube surface, power dissipation.

**FIND:** (a) Tube surface temperature for  $T_\infty = 25^\circ\text{C}$ ,  $V = 0.1 \text{ m/s}$ , (b) Plot of the tube surface temperature versus the cross flow velocity for  $0.05 \text{ m/s} \leq V \leq 1 \text{ m/s}$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Constant properties, (2) Large surroundings, (3) Steady-state conditions, (4) Ideal gas.

**PROPERTIES:** Table A.4, air ( $T_f \approx 300 \text{ K}$ ):  $\nu = 15.89 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0263 \text{ W/m}\cdot\text{K}$ ,  $\alpha = 22.5 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $Pr = 0.707$ ,  $\beta = 1/T_f = 0.0033 \text{ K}^{-1}$ .

**ANALYSIS:** (a) An energy balance on the cylinder yields

$$\begin{aligned}
 P = 1.5 \text{ W} &= q_{\text{conv}} + q_{\text{rad}} = \pi DL \left[ \bar{h}(T_s - T_\infty) + \varepsilon \sigma (T_s^4 - T_{\text{sur}}^4) \right] \\
 &= \pi 0.008 \text{ m} \times 0.10 \text{ m} \left[ \bar{h}(T_s - (25 + 273) \text{ K}) + 0.95 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (T_s^4 - (25 + 273 \text{ K})^4) \right]
 \end{aligned} \tag{1}$$

From Equation 9.64 for mixed convection from a cylinder in transverse flows,

$$\overline{Nu}_D^4 = \overline{Nu}_{D,F}^4 + \overline{Nu}_{D,N}^4 \tag{2}$$

where the forced convection Nusselt number,  $\overline{Nu}_{D,F}$ , is provided by the Churchill and Bernstein correlation of Chapter 7, and  $Re_D = VD/\nu = (0.1 \text{ m/s} \times 0.008 \text{ m})/15.89 \times 10^{-6} \text{ m}^2/\text{s} = 50.35$ .

$$\begin{aligned}
 \overline{Nu}_{D,F} &= 0.3 + \frac{0.62 Re_D^{1/2} Pr^{1/3}}{\left[ 1 + (0.4/Pr)^{2/3} \right]^{1/4}} \left[ 1 + \left( \frac{Re_D}{282,000} \right)^{5/8} \right]^{4/5} \\
 &= 0.3 + \frac{0.62 \times 50.35^{1/2} \times 0.707^{1/3}}{\left[ 1 + (0.4/0.707)^{2/3} \right]^{1/4}} \left[ 1 + \left( \frac{50.35}{282,000} \right)^{5/8} \right]^{4/5} = 3.75
 \end{aligned} \tag{3}$$

The natural (free) convection Nusselt number,  $\overline{Nu}_{D,N}$ , is found from the Churchill and Chu correlation,

Continued...

**PROBLEM 9.112 (Cont.)**

$$\overline{Nu}_{D,N} = \left\{ 0.60 + \frac{0.387 Ra_D^{1/6}}{\left[ 1 + (0.559 / Pr)^{9/16} \right]^{8/27}} \right\}^2 \quad (4a)$$

where the Rayleigh number is,

$$Ra_D = \frac{g\beta(T_s - T_\infty)D^3}{\nu\alpha} = \frac{9.8 \text{ m/s}^2 \times (0.0033 \text{ K}^{-1}) \times (T_s - (25 + 273) \text{ K}) \times (0.008 \text{ m})^3}{15.89 \text{ m}^2/\text{s} \times 22.5 \times 10^{-12} \text{ m}^2/\text{s}} \quad (4b)$$

Finally,  $\bar{h} = \overline{Nu}_D k / D$  (5)

Simultaneous solution of Equations (1) through (5) yields  $T_s = 328.1 \text{ K} = 55.1^\circ\text{C}$  <

(b) The dependence of the surface temperature on the air velocity is shown below.

**COMMENTS:** (1) In part (a), the convective and radiative heat rates are  $q_{\text{conv}} = 1 \text{ W}$  and  $q_{\text{rad}} = 0.5 \text{ W}$ , respectively. Therefore, it is important to include radiative losses in the analysis, (2) If free convection is ignored in part (a), the predicted surface temperature is  $T_s = 329.4 \text{ K}$ . Alternatively, if the forced convection component is ignored,  $T_s = 334.3 \text{ K}$ , (3) The surface temperature is strongly dependent on the air velocity, as evident in the solution to part (b). Using modern infrared detectors, the resolution of the surface temperature measurement could be as small as  $\Delta T = 0.05 \text{ K}$ . Hence, the measured surface temperature could be used to determine the air velocity.

### PROBLEM 9.113

**KNOWN:** Horizontal pipe passing hot oil used to heat water.

**FIND:** Effect of water flow direction on the heat rate.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Uniform pipe surface temperature, (2) Constant properties.

**PROPERTIES:** Table A-6, Water ( $T_f = (T_s + T_\infty)/2 \approx 335\text{K}$ ):  $\nu = \mu_f \nu_f = 4.625 \times 10^{-7} \text{ m}^2/\text{s}$ ,  $k = 0.656 \text{ W/m}\cdot\text{K}$ ,  $\alpha = k \nu_f / c_p = 1.595 \times 10^{-7} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 2.88$ ,  $\beta = 535.5 \times 10^{-6} \text{ K}^{-1}$ ; Table A-6, Water ( $T_\infty = 310\text{K}$ ):  $\nu = \mu_f \nu_f = 6.999 \times 10^{-7} \text{ m}^2/\text{s}$ ,  $k = 0.028 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 4.62$ ; Table A-6, Water ( $T_s = 358\text{K}$ ):  $\text{Pr} = 2.07$

**ANALYSIS:** The rate equation for the flow situations is of the form

$$q' = \bar{h} (\pi D) (T_s - T_\infty).$$

To determine whether mixed flow conditions are present, evaluate  $(\text{Gr}_D / \text{Re}_D^2)$ .

$$\text{Gr}_D = \frac{g \beta \Delta T D^3}{\nu^2} = \frac{9.8 \text{ m/s}^2 \times 535.5 \times 10^{-6} \text{ K}^{-1} (85 - 37) \text{ K} (0.100 \text{ m})^3}{(4.625 \times 10^{-7} \text{ m}^2/\text{s})^2} = 1.178 \times 10^9$$

$$\text{Re}_D = VD / \nu = 0.5 \text{ m/s} \times 0.100 \text{ m} / 6.999 \times 10^{-7} \text{ m}^2/\text{s} = 7.144 \times 10^4.$$

It follows that  $(\text{Gr}_D / \text{Re}_D^2) = 0.231$ ; since this ratio is of order unity, the flow condition is mixed. Using

Eq. 9.64,  $\overline{\text{Nu}}^n = \overline{\text{Nu}}_F^n \pm \overline{\text{Nu}}_N^n$  and for the three flow arrangements,

(a) Transverse flow:	(b) Opposing flow:	(c) Assisting flow:
$\overline{\text{Nu}}^4 = \overline{\text{Nu}}_F^4 + \overline{\text{Nu}}_N^4$	$\overline{\text{Nu}}^3 = \overline{\text{Nu}}_F^3 - \overline{\text{Nu}}_N^3$	$\overline{\text{Nu}}^3 = \overline{\text{Nu}}_F^3 + \overline{\text{Nu}}_N^3$

For *natural convection* from the cylinder, use Eq. 9.34 with  $\text{Ra} = \text{Gr} \cdot \text{Pr}$ .

$$\overline{\text{Nu}}_N = \left\{ 0.60 + \frac{0.387 \text{ Ra}_D^{1/6}}{\left[ 1 + (0.559 / \text{Pr})^{9/16} \right]^{8/27}} \right\}^2 = \left\{ 0.60 + \frac{0.387 \left( 1.178 \times 10^9 \times 2.88 \right)^{1/6}}{\left[ 1 + (0.559 / 2.88)^{9/16} \right]^{8/27}} \right\}^2 = 201.2$$

For *forced convection* in cross flow over the cylinder, from Table 7-4 use

$$\overline{\text{Nu}}_F = C \text{ Re}_D^m \text{ Pr}^n (\text{Pr} / \text{Pr}_s)^{1/4}$$

$$\overline{\text{Nu}}_F = 0.26 \left( 7.144 \times 10^4 \right)^{0.6} (4.62)^{0.37} (4.62 / 2.07)^{1/4} = 457.5$$

Continued ...

**PROBLEM 9.113 (Cont.)**

where  $n = 0.37$  since  $Pr \leq 10$ . The results of the calculations are tabulated.

Flow	$\overline{Nu}$	$\overline{h} \left( W / m^2 \cdot K \right)$	$q' \times 10^{-4} \left( W / m \right)$
(a) Transverse	461.7	3029	4.57
(b) Opposing	444.1	2913	4.39
(c) Assisting	470.1	3083	4.65

**COMMENTS:** Note that the flow direction has a minor effect (<6%) for these conditions.

## PROBLEM 9.114

**KNOWN:** Plate dimensions and initial temperature. Velocity and temperature of air in parallel flow over plates.

**FIND:** Initial rate of heat transfer from plate. Initial rate of change of plate temperature. Graph of the free, forced and mixed convection heat transfer coefficients over the range  $2 \leq u_\infty \leq 10$  m/s.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible radiation, (2) Negligible effect of conveyor velocity on boundary layer development, (3) Lumped capacitance behavior, (4) Negligible heat transfer from sides of plate.

**PROPERTIES:** Table A.1, AISI 1010 steel ( $T = 573$  K):  $k_p = 49.2$  W/m·K,  $c = 549$  J/kg·K,  $\rho = 7832$  kg/m<sup>3</sup>. Table A.4, air: ( $p = 1$  atm,  $T_f = 433$  K):  $k = 0.0361$  W/m·K,  $\nu = 30.4 \times 10^{-6}$  m<sup>2</sup>/s,  $\alpha = 4.417 \times 10^{-5}$  m<sup>2</sup>/s,  $\text{Pr} = 0.688$ .

**ANALYSIS:** The initial rate of heat transfer from the plate is

$$q_i = 2\bar{h}A_s(T_i - T_\infty) = 2\bar{h}L(T_i - T_\infty)$$

With  $\text{Re}_L = u_\infty L / \nu = 10 \text{ m/s} \times 1 \text{ m} / 30.4 \times 10^{-6} \text{ m}^2/\text{s} = 3.29 \times 10^5$ , the forced convection is laminar. Therefore,  $\bar{\text{Nu}}_L = \text{Nu}_F = 0.664 \text{Re}_L^{1/2} \text{Pr}^{1/3} = 0.664 \times (3.29 \times 10^5)^{1/2} \times (0.688)^{1/3} = 336$ . With  $\text{Ra}_L = g\beta(T_i - T_\infty)L^3 / \nu\alpha = 9.8 \text{ m/s}^2 \times (1/433 \text{ K}) \times (300 - 20)^\circ\text{C} \times (1 \text{ m})^3 / (30.4 \times 10^{-6} \text{ m}^2/\text{s} \times 4.417 \times 10^{-5} \text{ m}^2/\text{s}) = 4.72 \times 10^9$ , The Churchill and Chu correlation yields

$$\bar{\text{Nu}}_L = \text{Nu}_N = \left\{ 0.825 + \frac{0.387\text{Ra}^{1/6}}{\left[1 + (0.492/\text{Pr})^{9/16}\right]^{8/27}} \right\}^2 = \left\{ 0.825 + \frac{0.387(4.72 \times 10^9)^{1/6}}{\left[1 + (0.492/0.688)^{9/16}\right]^{8/27}} \right\}^2 = 198$$

Continued...

### PROBLEM 9.114 (Cont.)

Since the forced and free convection induced flows are transverse,  $Nu = (Nu_F^3 + Nu_N^3)^{1/3} = (336^3 + 198^3) = 357$ . Hence,  $\bar{h} = Nu k/L = 357 \times 0.0361 \text{ W/m} \cdot \text{K} / 1\text{m} = 12.9 \text{ W/m}^2 \cdot \text{K}$  and

$$q_i = 2 \times 12.9 \text{ W/m}^2 \cdot \text{K} \times (1\text{m})^2 \times (300 - 20)^\circ\text{C} = 7224 \text{ W} \quad <$$

Performing an energy balance at an instant in time for the plate,  $-\dot{E}_{\text{out}} = \dot{E}_{\text{st}}$ , we obtain

$$\rho \delta L^2 c \left. \frac{dT}{dt} \right|_i = -\bar{h} 2L^2 (T_i - T_\infty)$$

or

$$\left. \frac{dT}{dt} \right|_i = \frac{2 \times 12.9 \text{ W/m}^2 \cdot \text{K} \times (300 - 20)^\circ\text{C}}{7832 \text{ kg/m}^3 \times 0.006 \text{ m} \times 549 \text{ J/kg} \cdot \text{K}} = -0.28^\circ\text{C/s} \quad <$$

The heat transfer coefficient may be evaluated over the velocity range  $2 \leq u_\infty \leq 10$  /ms, yielding

**COMMENTS:** (1) The Grashof number is  $Gr_L = Ra_L/Pr = 4.72 \times 10^9/0.688 = 6.86 \times 10^9$ . For the  $u_\infty = 10$  m/s case,  $Gr_L/Re_L^2 = 6.86 \times 10^9/(3.29 \times 10^5)^2 = 0.063 \ll 1$ . We therefore expect free convection effects to be minor. (2) At  $u_\infty \approx 3.5$  m/s the value of the free convection coefficient exceeds that of the forced convection coefficient. Free convection effects dominate at lower air forced velocities. (3) The Reynolds number,  $Re_L$ , is smaller than the transition Reynolds number ( $Re_{x,c} = 5 \times 10^5$ ) while the Rayleigh number,  $Ra_L$ , exceeds the value associated with transition to turbulent flow ( $Ra_{x,c} \approx 10^9$ ). This implies that flow conditions are very complex and the estimates of heat transfer rates are, at best, approximate. (4) At very low air forced velocities the plate motion will likely affect the boundary layer development. (5) The Biot number is  $Bi = \bar{h} \delta/k_p = 12.9 \text{ W/m}^2 \cdot \text{K} \times 0.006 \text{ m} / 49.2 \text{ W/m} \cdot \text{K} = 0.0016$  and the lumped capacitance approximation is valid.

## PROBLEM 9.115

**KNOWN:** Very small sphere.

**FIND:** Minimum value of the convection heat transfer coefficient expressed in terms of the sphere diameter and the thermal conductivity of air.

**SCHEMATIC:**

**ASSUMPTIONS:** Steady-state conditions.

**ANALYSIS:** According to Eq. 9.64, the Nusselt number for opposing flow is given by

$$Nu^n = Nu_F^n - Nu_N^n$$

The Nusselt number for pure forced convection past a sphere is given by Eq. 7.56. In the limit as  $D \rightarrow 0$ ,  $Re_D \rightarrow 0$ , and

$$Nu_F = 2$$

For pure free convection past a sphere, the Nusselt number is given by Eq. 9.35, and in the limit as  $D \rightarrow 0$ ,  $Ra_D \rightarrow 0$ , and

$$Nu_N = 2$$

Therefore, according to Eq. 9.64,

$$Nu^n = Nu_F^n - Nu_N^n = 0, \quad Nu = 0$$

Thus, Eq. 9.64 *implies* that convection heat losses could be entirely eliminated by incorporating the assistant's suggestion. However, this conclusion is flawed. The limiting values of Nusselt numbers for *both* the pure forced and pure free convection cases correspond to the conduction limit, that is, the limit of zero velocity everywhere. The best one could possibly achieve by superimposing a forced flow in opposition to free convection would be to eliminate the fluid motion. This condition would then correspond to heat loss from the sphere by pure conduction, yielding

$$Nu = 2 \text{ and } h = Nu(k/D) = 2k/D \quad <$$

**COMMENTS:** (1) It is not possible to completely eliminate heat losses, since heat transfer by conduction cannot be eliminated (except in a vacuum). (2) This exercise illustrates the approximate nature of Eq. 9.64, which is not correct in the limit of pure conduction. (3) In reality, it is not possible to completely eliminate motion at all points in the flow by superimposing a uniform downward flow on free convection.

### PROBLEM 9.116

**KNOWN:** Horizontal square panel removed from an oven and cooled in quiescent or moving air.

**FIND:** Initial convection heat rates for both methods of cooling.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Quasi-steady state conditions, (2) Backside of plates insulated, (3) Air flow is in the length-wise (not diagonal) direction, (4) Constant properties, (5) Radiative exchange negligible.

**PROPERTIES:** Table A-4, Air ( $T_f = (T_\infty + T_s)/2 = 350\text{K}$ , 1 atm):  $\nu = 20.92 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.030 \text{ W/m}\cdot\text{K}$ ,  $\alpha = 29.9 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 0.700$ ,  $\beta = 1/T_f$ .

**ANALYSIS:** The initial heat transfer rate from the plates by convection is given by the rate equation  $q = \bar{h} A_s (T_s - T_\infty)$ . Test for the existence of combined free-forced convection by calculation of the ratio  $\text{Gr}_L / \text{Re}_L^2$ . Use the same characteristic length in both parameters,  $L = 250\text{mm}$ , the side length.

$$\text{Gr}_L = \frac{g \beta \Delta T L^3}{\nu^2} = \frac{9.8 \text{ m/s}^2 (1/350\text{K})(125 - 29) \text{ K} (0.250\text{m})^3}{(20.92 \times 10^{-6} \text{ m}^2/\text{s})^2} = 9.597 \times 10^7$$

$$\text{Re}_L = u_\infty L / \nu = 0.5 \text{ m/s} \times 0.250 \text{ m} / (20.92 \times 10^{-6} \text{ m}^2/\text{s}) = 5.975 \times 10^3.$$

Since  $\text{Gr}_L / \text{Re}_L^2 = 2.69$  flow is mixed. For the *stationary plate*,  $\text{Ra}_L = \text{Gr}_L \cdot \text{Pr} = 6.718 \times 10^7$  and Eq. 9.31 is the appropriate correlation,

$$\overline{\text{Nu}}_N = \frac{\bar{h}L}{k} = 0.15 \text{ Ra}_L^{1/3} = 0.15 (6.718 \times 10^7)^{1/3} = 60.9$$

$$\bar{h} = (0.030 \text{ W/m}\cdot\text{K} / 0.250\text{m}) \times 60.9 = 7.31 \text{ W/m}^2 \cdot \text{K}.$$

$$q = 7.31 \text{ W/m}^2 \cdot \text{K} \times (0.250\text{m})^2 (125 - 29) \text{ K} = 43.9 \text{ W}. \quad <$$

For the *plate with moving air*,  $\text{Re}_L = 5.975 \times 10^3$  and the flow is laminar.

$$\overline{\text{Nu}}_F = 0.664 \text{ Re}_L^{1/2} \text{ Pr}^{1/3} = 0.664 (5.975 \times 10^3)^{1/2} (0.700)^{1/3} = 45.6.$$

For combined free-forced convection, use the correlating equation with  $n = 7/2$ .

$$\overline{\text{Nu}}^{7/2} = \overline{\text{Nu}}_F^{7/2} + \overline{\text{Nu}}_N^{7/2} = (45.6)^{7/2} + (60.9)^{7/2} \quad \overline{\text{Nu}} = 66.5.$$

$$\bar{h} = \overline{\text{Nu}} k / L = 66.5 (0.030 \text{ W/m}\cdot\text{K} / 0.25\text{m}) = 7.99 \text{ W/m}^2 \cdot \text{K}$$

$$q = 7.99 \text{ W/m}^2 \cdot \text{K} (0.250\text{m})^2 (125 - 29) \text{ K} = 47.9 \text{ W}. \quad <$$

**COMMENTS:** (1) The conveyor method provides only slight enhancement of heat transfer.

### PROBLEM 9.117

**KNOWN:** Wet garment at 25°C hanging in a room with still, dry air at 40°C.

**FIND:** Drying rate per unit width of garment.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Analogy between heat and mass transfer applies, (2) Water vapor at garment surface is saturated at  $T_s$ , (3) Perfect gas behavior of vapor and air.

**PROPERTIES:** Table A-4, Air ( $T_f \approx (T_s + T_\infty)/2 = 305\text{K}$ , 1 atm):  $\nu = 16.39 \times 10^{-6} \text{ m}^2/\text{s}$ ; Table A-6, Water vapor ( $T_s = 298\text{K}$ , 1 atm):  $p_{A,s} = 0.0317 \text{ bar}$ ,  $\rho_{A,s} = 1/\nu_f = 0.02660 \text{ kg/m}^3$ ; Table A-8, Air-water vapor (305 K):  $D_{AB} = 0.27 \times 10^{-4} \text{ m}^2/\text{s}$ ,  $Sc = \nu/D_{AB} = 0.607$ .

**ANALYSIS:** The drying rate per unit width of the garment is

$$\dot{m}'_A = \bar{h}_m \cdot L (\rho_{A,s} - \rho_{A,\infty})$$

where  $\bar{h}_m$  is the mass transfer coefficient associated with a vertical surface that models the garment. From the heat and mass transfer analogy, Eq. 9.24 with  $C$  and  $n$  from Section 9.6.1 yields

$$\bar{Sh}_L = 0.59 (\text{Gr}_L \text{Sc})^{1/4}$$

where  $\text{Gr}_L = g\Delta\rho L^3/\rho\nu^2$  and  $\Delta\rho = \rho_s - \rho_\infty$ . Since the still air is dry,  $\rho_\infty = \rho_{B,\infty} = p_{B,\infty}/R_B T_\infty$ , where  $R_B = \mathcal{R}/\mathcal{M}_B = 8.314 \times 10^{-2} \text{ m}^3 \cdot \text{bar}/\text{kg} \cdot \text{K}/29 \text{ kg}/\text{kmol} = 0.00287 \text{ m}^3 \cdot \text{bar}/\text{kg} \cdot \text{K}$ . With  $p_{B,\infty} = 1 \text{ atm} = 1.0133 \text{ bar}$ ,

$$\rho_\infty = \frac{1.0133 \text{ bar}}{0.00287 \text{ m}^3 \cdot \text{bar}/\text{kg} \cdot \text{K} \times 313 \text{ K}} = 1.1280 \text{ kg/m}^3$$

The density of the air/vapor mixture at the surface is  $\rho_s = \rho_{A,s} + \rho_{B,s}$ . With  $p_{B,s} = 1 \text{ atm} - p_{A,s} = 1.0133 \text{ bar} - 0.0317 \text{ bar} = 0.9816 \text{ bar}$ ,

$$\rho_{B,s} = \frac{p_{B,s}}{R_B T_s} = \frac{0.9816 \text{ bar}}{0.00287 (\text{m}^3 \cdot \text{bar}/\text{kg} \cdot \text{K}) \times 298 \text{ K}} = 1.1477 \text{ kg/m}^3$$

Hence,  $\rho_s = (0.0266 + 1.1477) \text{ kg/m}^3 = 1.1743 \text{ kg/m}^3$  and  $\rho = (\rho_s + \rho_\infty)/2 = 1.1512 \text{ kg/m}^3$ . The Grashof number is then

$$\text{Gr}_L = \frac{9.8 \text{ m/s}^2 \times (1.1743 - 1.1280) \text{ kg/m}^3 (1 \text{ m})^3}{1.1512 \text{ kg/m}^3 \times (16.39 \times 10^{-6} \text{ m}^2/\text{s})^2} = 1.467 \times 10^9$$

and  $(\text{Gr}_L \text{Sc}) = 8.905 \times 10^8$ . The convection coefficient is then

$$\bar{h}_m = \frac{D_{AB}}{L} \bar{Sh}_L = \frac{0.27 \times 10^{-4} \text{ m}^2/\text{s}}{1 \text{ m}} \times 0.59 (8.905 \times 10^8)^{1/4} = 0.00275 \text{ m/s}$$

The drying rate is then

$$\dot{m}'_A = 2.750 \times 10^{-3} \text{ m/s} \times 1.0 \text{ m} (0.0226 - 0) \text{ kg/m}^3 = 6.21 \times 10^{-5} \text{ kg/s} \cdot \text{m} \quad <$$

**COMMENTS:** Since  $\rho_s > \rho_\infty$ , the buoyancy driven flow *descends* along the garment.

## PROBLEM 9.118

**KNOWN:** A water bath maintained at a uniform temperature of 37°C with top surface exposed to draft-free air and uniform temperature walls in a laboratory.

**FIND:** (a) The heat loss from the surface of the bath by radiation exchange with the surroundings; (b) Calculate the Grashof number using Eq. 9.65 with a characteristic length  $L$  that is appropriate for the exposed surface of the water bath; (c) Estimate the free convection heat transfer coefficient using the result for  $Gr_L$  obtained in part (b); (d) Invoke the heat-mass analogy and use an appropriate correlation to estimate the mass transfer coefficient using  $Gr_L$ ; calculate the water evaporation rate on a daily basis and the heat loss by evaporation; and (e) Calculate the total heat loss from the surface and compare relative contributions of the sensible, latent and radiative effects. Review assumptions made in your analysis, especially those relating to the heat-mass analogy.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Laboratory air is quiescent, (3) Laboratory walls are isothermal and large compared to water bath exposed surface, (4) Emissivity of the water surface is 0.96, (5) Heat-mass analogy is applicable, and (6) Constant properties.

**PROPERTIES:** Table A-6, Water vapor ( $T_\infty = 293$  K):  $\rho_{A,\infty,\text{sat}} = 0.01693$  kg/m<sup>3</sup>; ( $T_s = 310$  K):  $\rho_{A,s} = 0.04361$  kg/m<sup>3</sup>,  $h_{fg} = 2.414 \times 10^6$  J/kg; Table A-4, Air ( $T_\infty = 293$  K, 1 atm):  $\rho_{B,\infty} = 1.194$  kg/m<sup>3</sup>; ( $T_s = 310$  K, 1 atm):  $\rho_{B,s} = 1.128$  kg/m<sup>3</sup>; ( $T_f = (T_s + T_\infty)/2 = 302$  K, 1 atm):  $\nu_B = 1.604 \times 10^{-5}$  m<sup>2</sup>/s,  $k = 0.0270$  W/m·K,  $Pr = 0.706$ ; Table A-8, Water vapor-air ( $T_f = 302$  K, 1 atm):  $D_{AB} = 0.24 \times 10^{-4}$  m<sup>2</sup>/s  $(302/298)^{3/2} = 2.45 \times 10^{-5}$  m<sup>2</sup>/s.

**ANALYSIS:** (a) Using the linearized form of the radiation exchange rate equation, the heat rate and radiation coefficient can be estimated.

$$h_{\text{rad}} = \varepsilon\sigma(T_s + T_{\text{sur}})(T_s^2 + T_{\text{sur}}^2) \quad (1)$$

$$h_{\text{rad}} = 0.96\sigma(310 + 298)(310^2 + 298^2) \text{ K}^3 = 6.12 \text{ W/m}^2 \cdot \text{K} \quad <$$

$$q_{\text{rad}} = h_{\text{rad}}A_s(T_s - T_{\text{sur}}) \quad (2)$$

$$q_{\text{rad}} = 6.12 \text{ W/m}^2 \cdot \text{K} \times (0.25 \times 0.50) \text{ m}^2 \times (37 - 25) \text{ K} = 9.18 \text{ W}$$

(b) The general form of the Grashof number, Eq. 9.65, applied to natural convection flows driven by concentration gradients

$$Gr_L = g(\rho_\infty - \rho_s)L^3 / \rho\nu^2 \quad (3)$$

where  $L$  is the characteristic length defined in Eq. 9.29 as  $L = A_s/P$ , where  $A_s$  and  $P$  are the exposed surface area and perimeter, respectively;  $\rho_s$  and  $\rho_\infty$  are the density of the mixture at the surface and in the quiescent fluid, respectively; and,  $\rho$  is the mean boundary layer density,  $(\rho_\infty + \rho_s)/2$ , and  $\nu$  is the kinematic viscosity of fluid B, evaluated at the film temperature  $T_f = (T_s + T_\infty)/2$ . Using the property values from above,

Continued ...

**PROBLEM 9.118 (Cont.)**

$$\rho_s = \rho_{A,s} + \rho_{B,s} = (0.04361 + 1.128) \text{ kg/m}^3 = 1.1716 \text{ kg/m}^3$$

$$\rho_\infty = \rho_{A,\infty} + \rho_{B,\infty} = \phi_\infty \rho_{A,\infty,\text{sat}} + \rho_{B,\infty}$$

$$\rho_\infty = (0.6 \times 0.01693 + 1.194) \text{ kg/m}^3 = 1.2042 \text{ kg/m}^3$$

$$\rho = (\rho_s + \rho_\infty) / 2 = 1.188 \text{ kg/m}^3$$

Substituting numerical values in Eq. (3), find the Grashof number.

$$\text{Gr}_L = \frac{9.8 \text{ m/s}^2 (1.2042 - 1.1716) \text{ kg/m}^3 \times (0.0833 \text{ m})^3}{1.188 \text{ kg/m}^3 (1.604 \times 10^{-5} \text{ m}^2/\text{s})^2}$$

$$\text{Gr}_L = 6.040 \times 10^5$$

&lt;

where the characteristic length is defined by Eq. 9.29,

$$L = A_s / P = (0.25 \times 0.5) \text{ m}^2 / 2(0.25 + 0.50) \text{ m} = 0.0833 \text{ m}$$

(c) The free convection heat transfer coefficient for the horizontal surface, Eq. 9.30, for *upper surface of heated plate*, is estimated as follows:

$$\text{Ra}_L = \text{Gr}_L \text{Pr}_L = 6.040 \times 10^5 \times 0.706 = 4.264 \times 10^5$$

$$\overline{\text{Nu}}_L = \frac{\bar{h}L}{k} = 0.54 \text{ Ra}_L^{1/4} = 13.80$$

$$\bar{h} = 13.80 \times 0.0270 \text{ W/m} \cdot \text{K} / 0.0833 \text{ m} = 4.47 \text{ W/m}^2 \cdot \text{K}$$

&lt;

(d) Invoking the heat-mass analogy, the mass transfer coefficient is estimated as follows,

$$\text{Ra}_{L,m} = \text{Gr}_L \text{Sc} = 6.040 \times 10^5 \times 0.655 = 3.954 \times 10^5$$

where the Schmidt number is given as

$$\text{Sc} = \nu / D_{AB} = 1.604 \times 10^{-5} \text{ m}^2/\text{s} / 2.45 \times 10^{-5} \text{ m}^2/\text{s} = 0.655$$

The correlation has the form

$$\overline{\text{Sh}}_L = \frac{\bar{h}_m L}{D_{AB}} = 0.54 \text{ Ra}_{L,m}^{1/4} = 13.54$$

$$\bar{h}_m = 13.54 \times 2.45 \times 10^{-5} \text{ m}^2/\text{s} / 0.0833 \text{ m} = 0.00398 \text{ m/s}$$

&lt;

The water evaporation rate on a daily basis is

$$n_A = \bar{h}_m A_s (\rho_{A,\text{sat}} - \rho_{A,\infty})$$

$$n_A = 0.00398 \text{ m/s} (0.25 \times 0.50) \text{ m}^2 (0.04361 - 0.6 \times 0.01693) \text{ kg/m}^3$$

Continued ...

**PROBLEM 9.118 (Cont.)**

$$n_A = 1.66 \times 10^{-5} \text{ kg/s} = 1.44 \text{ kg/day} \quad <$$

and the *heat loss by evaporation* is

$$q_{\text{evap}} = n_A h_{\text{fg}} = 1.66 \times 10^{-5} \text{ kg/s} \times 2.414 \times 10^6 \text{ J/kg} = 40.2 \text{ W} \quad <$$

(e) The *convective heat loss* is that of free convection,

$$q_{\text{cv}} = \bar{h} A_s (T_s - T_\infty)$$

$$q_{\text{cv}} = 4.47 \text{ W/m}^2 \times (0.25 \times 0.50) \text{ m}^2 (37 - 20) \text{ K} = 9.50 \text{ W} \quad <$$

In summary, the *total heat loss* from the surface of the bath, which must be supplied as electrical power to the bath heaters, is

$$q_{\text{tot}} = q_{\text{rad}} + q_{\text{cv}} + q_{\text{evap}}$$

$$q_{\text{tot}} = (9.18 + 9.50 + 40.2) \text{ W} = 59 \text{ W} \quad <$$

The *sensible heat losses* are by convection ( $q_{\text{rad}} + q_{\text{cv}}$ ), which represent 31% of the total; the balance is the *latent loss* by evaporation, 68%.

## PROBLEM 9.119

**KNOWN:** Diameter and surface temperature of lake. Temperature and relative humidity of air. Surroundings temperature.

**FIND:** Heat loss from lake by radiation, free convection, and evaporation. Justify use of heat transfer correlation outside of  $Ra_L$  range.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions. (2) Negligible breeze. (3) Heat-mass transfer analogy is applicable. (4) Heat transfer correlation can be used outside of  $Ra_L$  range.

**PROPERTIES:** Table A-6, Water vapor ( $T_{\infty} = 296 \text{ K}$ ):  $\rho_{A,\infty,sat} = 0.02025 \text{ kg/m}^3$ ; ( $T_s = 303 \text{ K}$ ):  $\rho_{A,s} = 0.02985 \text{ kg/m}^3$ ,  $h_{fg} = 2.431 \times 10^6 \text{ J/kg}$ ; Table A-4, Air ( $T_{\infty} = 296 \text{ K}$ , 1 atm):  $\rho_{B,\infty} = 1.180 \text{ kg/m}^3$ ; ( $T_s = 303 \text{ K}$ , 1 atm):  $\rho_{B,s} = 1.151 \text{ kg/m}^3$ ; ( $T_f = (T_s + T_{\infty})/2 \approx 300 \text{ K}$ , 1 atm):  $\nu_B = 1.589 \times 10^{-5} \text{ m}^2/\text{s}$ ,  $k = 0.0263 \text{ W/m}\cdot\text{K}$ ,  $Pr = 0.707$ ; Table A-8, Water vapor-air ( $T_f \approx 300 \text{ K}$ , 1 atm):  $D_{AB} = 0.26 \times 10^{-4} \text{ m}^2/\text{s}$  ( $300/298$ )<sup>3/2</sup> =  $2.63 \times 10^{-5} \text{ m}^2/\text{s}$ ; Table A-11, Water ( $T_s \approx 300 \text{ K}$ ):  $\varepsilon = 0.96$ .

**ANALYSIS:** The radiation heat transfer can be calculated from

$$q_{rad} = \varepsilon \sigma A_s (T_s^4 - T_{sur}^4) \quad (1)$$

$$= 0.96 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times \frac{\pi(4000 \text{ m})^2}{4} \times (303^4 - 285^4) \text{ K}^4 = 1253 \text{ MW} <$$

The natural convection above the lake surface is driven by the combination of temperature and concentration gradient. The general form of the Grashof number, Equation 9.65, is

$$Gr_L = g(\rho_{\infty} - \rho_s)L^3 / \rho \nu^2 \quad (2)$$

where  $L$  is the characteristic length defined in Eq. 9.29 as  $L = A_s/P$ , where  $A_s$  and  $P$  are the exposed surface area and perimeter, respectively;  $\rho_s$  and  $\rho_{\infty}$  are the density of the mixture at the surface and in the quiescent fluid, respectively;  $\rho$  is the mean boundary layer density,  $(\rho_{\infty} + \rho_s)/2$ ; and  $\nu$  is the kinematic viscosity of the mixture (approximated here as the value for pure air), evaluated at the film temperature  $T_f = (T_s + T_{\infty})/2$ . Using the property values from above,

$$\rho_s = \rho_{A,s} + \rho_{B,s} = (0.02985 + 1.151) \text{ kg/m}^3 = 1.181 \text{ kg/m}^3$$

$$\rho_{\infty} = \rho_{A,\infty} + \rho_{B,\infty} = \phi_{\infty} \rho_{A,\infty,sat} + \rho_{B,\infty}$$

$$\rho_{\infty} = (0.8 \times 0.02025 + 1.180) \text{ kg/m}^3 = 1.196 \text{ kg/m}^3$$

$$\rho = (\rho_s + \rho_{\infty})/2 = 1.189 \text{ kg/m}^3$$

$$L = A_s / P = \left( \frac{\pi(4000)^2}{4} \right) \text{ m}^2 / \pi(4000) \text{ m} = 1000 \text{ m}$$

Substituting numerical values in Equation (2) for the Grashof number,

Continued...

**PROBLEM 9.119 (Cont.)**

$$\text{Gr}_L = \frac{9.8 \text{ m/s}^2 (1.196 - 1.181) \text{ kg/m}^3 \times (1000 \text{ m})^3}{1.189 \text{ kg/m}^3 \left(1.589 \times 10^{-5} \text{ m}^2/\text{s}\right)^2} = 5.01 \times 10^{17}$$

Then  $\text{Ra}_L = \text{Gr}_L \text{Pr} = 5.01 \times 10^{17} \times 0.707 = 3.54 \times 10^{17}$  <

The free convection heat transfer coefficient for the upper surface of a hot plate is given by Equation 9.31, but the Rayleigh number is larger than the upper limit specified for this correlation. However, since  $\text{Ra}_L$  is raised to the 1/3 power, this correlation yields a heat transfer coefficient which is independent of  $L$ . Therefore it is reasonable to expect that the heat transfer coefficient calculated by this correlation is valid even though  $\text{Ra}_L$  is outside the range. Proceeding,

$$\overline{\text{Nu}}_L = \frac{\overline{h}L}{k} = 0.15 \text{ Ra}_L^{1/3} = 1.06 \times 10^5$$

$$\overline{h} = 1.06 \times 10^5 \times 0.0263 \text{ W/m} \cdot \text{K} / 1000 \text{ m} = 2.79 \text{ W/m}^2 \cdot \text{K}$$

$$q_{\text{cv}} = \overline{h}A_s (T_s - T_\infty)$$

$$q_{\text{cv}} = 2.79 \text{ W/m}^2 \times \left( \frac{\pi(4000)^2}{4} \right) \text{m}^2 (30 - 23) \text{ K} = 246 \text{ MW}$$
 <

Invoking the heat-mass analogy, the mass transfer coefficient is estimated as follows,

$$\text{Ra}_{L,m} = \text{Gr}_L \text{Sc} = 5.01 \times 10^{17} \times 0.604 = 3.03 \times 10^{17}$$

where the Schmidt number is given as

$$\text{Sc} = \nu / D_{\text{AB}} = 1.589 \times 10^{-5} \text{ m}^2/\text{s} / 2.63 \times 10^{-5} \text{ m}^2/\text{s} = 0.604$$

The correlation has the form

$$\overline{\text{Sh}}_L = \frac{\overline{h}_m L}{D_{\text{AB}}} = 0.15 \text{ Ra}_{L,m}^{1/3} = 1.01 \times 10^5$$

$$\overline{h}_m = 1.01 \times 10^5 \times 2.63 \times 10^{-5} \text{ m}^2/\text{s} / 1000 \text{ m} = 2.65 \times 10^{-3} \text{ m/s}$$

The water evaporation rate on a daily basis is

$$n_A = \overline{h}_m A_s (\rho_{\text{A,sat}} - \rho_{\text{A},\infty})$$

$$n_A = 2.65 \times 10^{-3} \text{ m/s} \times \pi(4000^2/4) \text{m}^2 (0.02985 - 0.8 \times 0.02025) \text{ kg/m}^3$$

$$n_A = 4.54 \times 10^2 \text{ kg/s} = 3.93 \times 10^7 \text{ kg/day}$$

and the *heat loss by evaporation* is

$$q_{\text{evap}} = n_A h_{\text{fg}} = 4.54 \times 10^2 \text{ kg/s} \times 2.431 \times 10^6 \text{ J/kg} = 1105 \text{ MW}$$
 <

In summary, the *total heat loss* from the surface of the lake, which determines the rate at which the lake can be used to cool the condenser, is

$$q_{\text{tot}} = q_{\text{rad}} + q_{\text{cv}} + q_{\text{evap}} = 1253 \text{ MW} + 246 \text{ MW} + 1105 \text{ MW} = 2604 \text{ MW}$$
 <

**COMMENTS:** The *sensible heat losses* are by convection ( $q_{\text{rad}} + q_{\text{cv}}$ ), which represent 58% of the total; the balance is the *latent loss* by evaporation, 42%.

## PROBLEM 9.120

**KNOWN:** Fuel cell cathode dimensions, oxygen mass fraction in the ambient and adjacent to the cathode, orientation of cathode, relationship between oxygen transfer rate and electrical current.

**FIND:** Maximum possible electrical current produced by the fuel cell.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Ideal gas behavior, (2) Isothermal conditions, (3) Thermophysical properties of species B are those of air, except for the mass density.

**PROPERTIES:** Table A.4, air: ( $p = 1 \text{ atm}$ ,  $T_f = 298 \text{ K}$ ):  $\nu = 1.571 \times 10^{-5} \text{ m}^2/\text{s}$ , Table A.8, oxygen in air:  $D_{AB} = 0.21 \times 10^{-4} \text{ m}^2/\text{s}$ .

**ANALYSIS:** The molecular weights of oxygen (A) and nitrogen (B) are  $\mathcal{M}_A = 32 \text{ kg/kmol}$  and  $\mathcal{M}_B = 28 \text{ kg/kmol}$ , respectively. The mole fraction of A in the ambient is  $x_{A,\infty} = (m_{A,\infty}/\mathcal{M}_A)/[m_{A,\infty}/\mathcal{M}_A + (1 - m_{A,\infty})/\mathcal{M}_B] = (0.233/32 \text{ kg/kmol})/[0.233/32 \text{ kg/kmol} + (1 - 0.233)/28 \text{ kg/kmol}] = 0.210$ . Therefore,  $x_{B,\infty} = 1 - 0.210 = 0.790$ . The molecular weight of the ambient gas is  $\mathcal{M}_\infty = x_{A,\infty}\mathcal{M}_A + (1 - x_{A,\infty})\mathcal{M}_B = 0.210 \times 32 \text{ kg/kmol} + (1 - 0.210) \times 28 \text{ kg/kmol} = 28.84 \text{ kg/mol}$ . The gas constant of the ambient is  $R_\infty = \mathcal{R}/\mathcal{M}_\infty = 8.315 \text{ kJ/kmol}\cdot\text{K}/28.84 \text{ kg/kmol} = 288.3 \times 10^{-3} \text{ kJ/kg}\cdot\text{K}$ .

The mole fraction of A at the surface is  $x_{A,s} = (m_{A,s}/\mathcal{M}_A)/[m_{A,s}/\mathcal{M}_A + (1 - m_{A,s})/\mathcal{M}_B] = (0.10/32 \text{ kg/kmol})/[0.1/32 \text{ kg/kmol} + (1-0.1)/28\text{kg/kmol}] = 0.089$ . Therefore,  $x_{B,s} = 1 - 0.089 = 0.911$ . The molecular weight of the gas at the surface is  $\mathcal{M}_s = x_{A,s}\mathcal{M}_A + (1 - x_{A,s})\mathcal{M}_B = 0.089 \times 32 \text{ kg/kmol} + (1 - 0.089) \times 28 \text{ kg/kmol} = 28.36 \text{ kg/kmol}$ . The gas constant of the fluid at the surface is  $R_s = \mathcal{R}/\mathcal{M}_s = 8.315 \text{ kJ/kmol}\cdot\text{K}/28.36 \text{ kg/kmol} = 293.2 \times 10^{-3} \text{ kJ/kg}\cdot\text{K}$ .

The ambient gas density is

$$\rho_\infty = \frac{p}{R_\infty T} = \frac{1.0133 \times 10^5 \text{ N/m}^2}{288.3 \times 10^{-3} \text{ kJ/kg}\cdot\text{K} \times (25 + 273) \text{ K}} \times 0.001 \text{ kJ/J} = 1.1794 \text{ kg/m}^3$$

The surface gas density is

Continued...

**PROBLEM 9.120 (Cont.)**

$$\rho_s = \frac{p}{R_s T} = \frac{1.0133 \times 10^5 \text{ N/m}^2}{293.2 \times 10^{-3} \text{ kJ/kg} \cdot \text{K} \times (25 + 273) \text{ K}} \times 0.001 \text{ kJ/J} = 1.1597 \text{ kg/m}^3$$

The average gas density is  $\rho = (1.1794 \text{ kg/m}^3 + 1.1597 \text{ kg/m}^3)/2 = 1.1696 \text{ kg/m}^3$ .

Case a: Vertical Cathode. The Rayleigh number is

$$\begin{aligned} \text{Ra}_L &= \text{Gr}_L \text{Sc} = \left[ g(\rho_s - \rho_\infty) L^3 / \rho v^2 \right] \times [v / D_{AB}] \\ &= \frac{9.8 \text{ m/s}^2 \times (1.1597 - 1.1794) \text{ kg/m}^3 \times (0.12 \text{ m})^3}{1.1696 \text{ kg/m}^3 \times 1.571 \times 10^{-5} \text{ m}^2/\text{s} \times 0.21 \times 10^{-4} \text{ m}^2/\text{s}} = 865 \times 10^3 \end{aligned}$$

and the Schmidt number is  $\text{Sc} = v/D_{AB} = 1.571 \times 10^{-5} \text{ m}^2/\text{s} / 0.21 \times 10^{-4} \text{ m}^2/\text{s} = 0.748$ . The heat and mass transfer analogy may be applied to the Churchill and Chu correlation to yield

$$\begin{aligned} \bar{h}_{m,L} &= \frac{D_{AB}}{L} \left\{ 0.825 + \frac{0.387 \text{Ra}_L^{1/6}}{\left[ 1 + (0.492/\text{Sc})^{9/16} \right]^{8/27}} \right\}^2 \\ &= \frac{0.21 \times 10^{-4} \text{ m}^2/\text{s}}{0.12 \text{ m}} \times \left\{ 0.825 + \frac{0.387 \times (865 \times 10^3)^{1/6}}{\left[ 1 + (0.492/0.748)^{9/16} \right]^{8/27}} \right\}^2 = 0.0028 \text{ m/s} \end{aligned}$$

The mass transfer rate is

$$\begin{aligned} n_A &= \bar{h}_{m,L} A_s (\rho_{A,s} - \rho_{A,\infty}) = 0.0028 \text{ m/s} \times (0.12 \text{ m})^2 \times (1.1597 \text{ kg/m}^3 \times 0.1 - 1.1794 \text{ kg/m}^3 \times 0.233) \\ &= -6.4 \times 10^{-6} \text{ kg/s} \end{aligned}$$

The negative sign implies oxygen transfer to the cathode. The electric current is

$$I = 4n_A F / \mathcal{M}_A = \frac{4 \times 6.4 \times 10^{-6} \text{ kg/s} \times 96489 \text{ coulombs/mol} \times 1000 \text{ mol/kmol}}{32 \text{ kg/kmol}} = 77 \text{ A} <$$

Case b: Horizontal, Upward Facing Cathode. Since  $\rho_s < \rho_\infty$ , the analogous situation is the upper surface of a hot plate. The characteristic length is  $L = A_s/P = L^2/4L = L/4 = 0.12 \text{ m}/4 = 0.03 \text{ m}$ . The Rayleigh number is

$$\text{Ra}_L = \frac{9.8 \text{ m/s}^2 \times (1.1597 - 1.1794) \text{ kg/m}^3 \times (0.03 \text{ m})^3}{1.1696 \text{ kg/m}^3 \times 1.571 \times 10^{-5} \text{ m}^2/\text{s} \times 0.21 \times 10^{-4} \text{ m}^2/\text{s}} = 13500$$

Continued...

### PROBLEM 9.120 (Cont.)

From Equation 9.30,

$$\overline{Sh}_L = 0.54 \times (13500)^{1/4} = 5.82 \quad \text{and} \quad \overline{h}_L = \overline{Sh}_L D_{AB} / L = 5.82 \times 0.21 \times 10^{-4} \text{ m}^2 / \text{s} / 0.03 \text{ m} = 0.0041 \text{ m/s}$$

Hence, the mass transfer rate is

$$n_A = 0.0041 \text{ m/s} \times (0.12 \text{ m})^2 \times (1.1597 \text{ kg/m}^3 \times 0.1 - 1.1794 \text{ kg/m}^3 \times 0.233) = -9.38 \times 10^{-6} \text{ kg/s}$$

and the electric current is

$$I = \frac{4 \times 9.38 \times 10^{-6} \text{ kg/s} \times 96489 \text{ coulombs/mol} \times 1000 \text{ mol/kmol}}{32 \text{ kg/kmol}} = 102 \text{ A} \quad <$$

**COMMENTS:** Although the analysis is approximate because of the assumption of isothermal conditions, the fuel cell performance is clearly dependent upon its orientation.

## PROBLEM 10.1

**KNOWN:** Water at 1 atm with  $T_s - T_{\text{sat}} = 10^\circ\text{C}$ .

**FIND:** Show that the Jakob number is much less than unity; what is the physical significance of the result; does result apply to other fluids?

**ASSUMPTIONS:** (1) Boiling situation,  $T_s > T_{\text{sat}}$ .

**PROPERTIES:** *Table A-5 and Table A-6, (1 atm):*

	$h_{\text{fg}}$ (kJ/kg)	$c_{p,\ell}$ (J/kg·K)	$T_{\text{sat}}$ (K)
Water	2257	4217	373
Ethylene glycol	812	2742*	470
Mercury	301	135.5*	630
R-134a	217	1281	247

\* Estimated based upon value at highest temperature cited in Table A-5.

**ANALYSIS:** The Jakob number is the ratio of the maximum sensible energy absorbed by the vapor or liquid to the latent energy absorbed during boiling or condensation. That is,

$$\text{Ja} = c_p \Delta T / h_{\text{fg}}$$

The Jakob number can be based on the liquid or vapor specific heat depending on the circumstances. Since they are the same order of magnitude and we have liquid specific heats available for all the fluids listed above, we will use  $c_{p,\ell}$ .

For *water* with an excess temperature  $\Delta T_s = T_e - T_\infty = 10^\circ\text{C}$ , find

$$\text{Ja} = (4217 \text{ J/kg} \cdot \text{K} \times 10\text{K}) / 2257 \times 10^3 \text{ J/kg}$$

$$\text{Ja} = 0.019.$$

Since  $\text{Ja} \ll 1$ , the implication is that the sensible energy absorbed by the vapor is much less than the latent energy absorbed during the boiling phase change. Using the appropriate thermophysical properties for three other fluids, the Jakob numbers are:

$$\text{Ethylene glycol:} \quad \text{Ja} = (2742 \text{ J/kg} \cdot \text{K} \times 10\text{K}) / 812 \times 10^3 \text{ J/kg} = 0.0338 \quad <$$

$$\text{Mercury:} \quad \text{Ja} = (135.5 \text{ J/kg} \cdot \text{K} \times 10\text{K}) / 301 \times 10^3 \text{ J/kg} = 0.0045 \quad <$$

$$\text{Refrigerant, R-12:} \quad \text{Ja} = (1281 \text{ J/kg} \cdot \text{K} \times 10\text{K}) / 217 \times 10^3 \text{ J/kg} = 0.059 \quad <$$

For ethylene glycol and R-12, the Jakob number is larger than the value for water, but still much less than unity. Based upon these example fluids, we conclude that generally we'd expect Ja to be much less than unity.

**COMMENTS:** We would expect the same low value of Ja for the condensation process since  $c_{p,g}$  and  $c_{p,f}$  are of the same order of magnitude.

## PROBLEM 10.2

**KNOWN:** Diameter and temperature of horizontal cylinder or wire.

**FIND:** Heat flux due to natural convection and comparison with values shown in Figure 10.4

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Constant properties, (2) No bubble nucleation.

**PROPERTIES:** Table A-6, Water (Saturated liquid,  $T_f = (T_{\text{sat}} + T_s)/2 = 102.5^\circ\text{C} = 375.5 \text{ K}$ ):  $k = 0.681 \text{ W/m}\cdot\text{K}$ ,  $\nu = 2.85 \times 10^{-7} \text{ m}^2/\text{s}$ ,  $\rho = 956.6 \text{ kg/m}^3$ ,  $c_p = 4221 \text{ J/kg}\cdot\text{K}$ ,  $Pr = 1.69$ ,  $\beta = 765 \times 10^{-6} \text{ K}^{-1}$ .

**ANALYSIS:** The thermal diffusivity is  $\alpha = k/\rho c_p = 0.681 \text{ W/m}\cdot\text{K}/(956.6 \text{ kg/m}^3 \times 4221 \text{ J/kg}\cdot\text{K}) = 1.68 \times 10^{-7} \text{ m}^2/\text{s}$ . For the  $D = 7 \text{ mm}$  cylinder, the Rayleigh number is

$$Ra_D = \frac{g\beta\Delta T_e D^3}{\nu\alpha} = \frac{9.81 \text{ m/s}^2 \times 765 \times 10^{-6} \text{ K}^{-1} \times 5 \text{ K} \times (7/1000 \text{ m})^3}{2.85 \times 10^{-7} \text{ m}^2/\text{s} \times 1.68 \times 10^{-7} \text{ m}^2/\text{s}} = 2.77 \times 10^5$$

Using the Churchill-Chu correlation,

$$\overline{Nu}_D = \frac{\bar{h}D}{k} = \left\{ 0.60 + \frac{0.387 Ra_D^{1/6}}{\left[ 1 + (0.559/Pr)^{9/16} \right]^{8/27}} \right\}^2 = \left\{ 0.60 + \frac{0.387 \times (2.77 \times 10^5)^{1/6}}{\left[ 1 + (0.559/1.69)^{9/16} \right]^{8/27}} \right\}^2 = 11.12$$

from which  $\bar{h} = \overline{Nu}_D k / D = 11.12 \times 0.681 \text{ W/m}\cdot\text{K} / (7/1000 \text{ m}) = 1083 \text{ W/m}^2 \cdot \text{K}$ .

Hence,  $q'' = h(\Delta T_e) = 1083 \text{ W/m}^2 \cdot \text{K} \times 5 \text{ K} = 5413 \text{ W/m}^2$ . <

The preceding calculations may be repeated for the  $D = 7 \mu\text{m}$  wire, yielding

$$Ra_D = 0.00027, \overline{Nu}_D = 0.471, \bar{h} = 4.586 \times 10^4 \text{ W/m}^2 \cdot \text{K}, q'' = 2.29 \times 10^5 \text{ W/m}^2. <$$

From Figure 10.4, the heat flux corresponding to  $\Delta T_e = 5^\circ\text{C}$  is approximately  $8,000 \text{ W/m}^2$ . The heat flux for the  $D = 7 \text{ mm}$  diameter cylinder is approximately 67% of this value. However, for the  $D = 7 \mu\text{m}$  wire, the heat flux is nearly 29 times greater than shown in Figure 10.4 and corresponds to values associated with vigorous nucleate boiling. Hence, Figure 10.4 is *not* generally applicable to all situations involving boiling of water at 1 atmosphere pressure and should be used, with caution, only in the absence of more detailed information. <

**Comments.** (1) Use of Equation 9.33 to calculate the heat flux for the wire yields

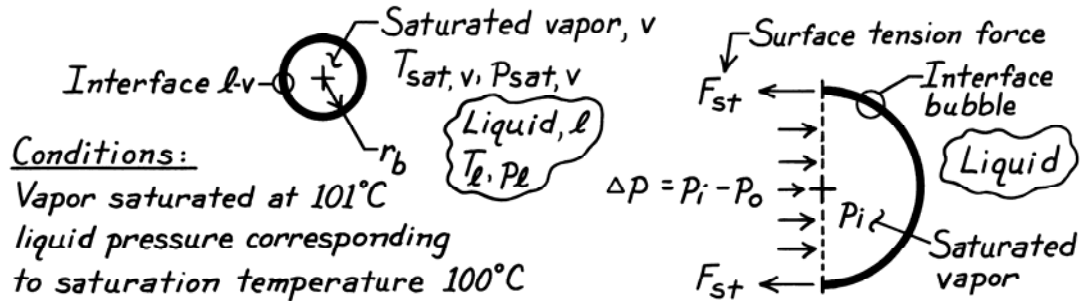

$\bar{h} = (0.681 \text{ W/m}\cdot\text{K} / 7 \times 10^{-6} \text{ m}) \times 0.675 \times 0.00027^{0.058} = 4.076 \times 10^4 \text{ W/m}^2 \cdot \text{K}$  and  $q'' = 2.04 \times 10^5 \text{ W/m}^2$ . This is in good agreement with the value calculated from the Churchill-Chu relation. (2) We would expect the boiling heat flux from the small wire to far exceed the values shown in Figure 10.4.

### PROBLEM 10.3

**KNOWN:** Spherical bubble of pure saturated vapor in mechanical and thermal equilibrium with its liquid.

**FIND:** (a) Expression for the bubble radius, (b) Bubble vapor and liquid states on a p-v diagram; how changes in these conditions cause bubble to collapse or grow, and (c) Bubble size for specified conditions.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Liquid-vapor medium, (2) Thermal and mechanical equilibrium.

**PROPERTIES:** Table A-6, Water ( $T_{\text{sat}} = 101^\circ\text{C} = 374.15\text{K}$ ):  $p_{\text{sat}} = 1.0502\text{ bar}$ ; ( $T_{\text{sat}} = 100^\circ\text{C} = 373.15\text{K}$ ):  $p_{\text{sat}} = 1.0133\text{ bar}$ ,  $\sigma = 58.9 \times 10^{-3}\text{ N/m}$ .

**ANALYSIS:** (a) For mechanical equilibrium, the difference in pressure between the vapor inside the bubble and the liquid outside the bubble will be offset by the surface tension of the liquid-vapor interface. The force balance follows from the free-body diagram shown above (right),

$$F_{\text{St}} = (\pi r_b^2) \Delta p = (p_i - p_o) (\pi r_b^2)$$

$$(2\pi r_b) \sigma = (\pi r_b^2) (p_i - p_o)$$

$$r_b = 2\sigma / (p_i - p_o) \quad (1)$$

Thermal equilibrium requires that the temperatures of the vapor and liquid be equal. Since the vapor inside the bubble is saturated,  $p_i = p_{\text{sat},v}(T)$ . Since  $p_o < p_i$ , it follows that the liquid outside the bubble must be superheated; hence,  $p_o = p_\ell(T)$ , the pressure of superheated liquid at  $T$ . Hence, we can write,

$$r_b = 2\sigma / (p_{\text{sat},v} - p_\ell) \quad (2) <$$

(b) The vapor [1] and liquid [2] states are represented on the following p-v diagram. Thermal equilibrium requires both the vapor and liquid to be at the same temperature [3]. But mechanical equilibrium requires that the outside liquid pressure be less than the inside vapor pressure [4]. Hence the liquid must be in a superheated state. That is, its saturation temperature,  $T_{\text{sat}}(p_o)$  [5] is less than  $T_{\text{sat}}(p_i)$ ;  $T_\ell = T_{\text{sat}}(p_o)$  and  $p_o = p_\ell$ .

Continued ...

PROBLEM 10.3 (Cont.)

The equilibrium condition for the bubble is unstable. Consider situations for which the pressure of the surrounding liquid is greater or less than the equilibrium value. These situations are presented on portions of the p-v diagram

When  $p'_0 < p_0$ ,  $T'_\ell < T_{sat,v}$  and heat must be transferred out of the bubble and vapor condenses. Hence, the bubble collapses.

A similar argument for the condition  $p'_0 > p_0$  leads to  $T'_\ell > T_{sat,v}$  and heat is transferred into the bubble causing evaporation with the formation of vapor. Hence, the bubble begins to grow.

(c) Consider the specific conditions

$$T_{sat,v} = 101^\circ\text{C} \quad \text{and} \quad T_\ell = T_{sat}(p_0) = 100^\circ\text{C}$$

and calculate the radius of the bubble using the appropriate properties in Eq. (2).

$$r_b = 2 \times 58.9 \times 10^{-3} \frac{\text{N}}{\text{m}} / (1.0502 - 1.0133) \text{ bar} \times \left( 10^5 \frac{\text{N}}{\text{m}^2} / \text{bar} \right)$$

$$r_b = 0.032 \text{ mm.}$$

Note the small bubble size. This implies that nucleation sites of the same magnitude formed by pits and crevices are important in promoting the boiling process.

## PROBLEM 10.4

**KNOWN:** Boiling curve of Figure 10.4.

**FIND:** Heat transfer coefficient associated with Points A, B, C, D, and E. Which points are associated with the largest and smallest values of  $h$ . Thickness of vapor blanket at the Leidenfrost point.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Neglect radiation during film boiling, (2) Surface is flat, (3) Vapor thermal conductivity can be evaluated at the film temperature.

**PROPERTIES:** Table A-6, Water vapor ( $T = 433 \text{ K}$ ) =  $0.0308 \text{ W/m} \cdot \text{K}$ .

**ANALYSIS:** Since  $h = q_s'' / \Delta T_e$ , the values of  $h$  can be found by reading  $q_s''$  and  $\Delta T_e$  from the graph.

Point	$q_s''$ ( $\text{W/m}^2$ )	$\Delta T_e$ ( $^\circ\text{C}$ )	$h$ ( $\text{W/m}^2 \cdot \text{K}$ )
A	6700	5	1300
B	$10^5$	10	10,000
C	$1.4 \times 10^6$	30	47,000
D	$2.5 \times 10^4$	120	210
E	$1.4 \times 10^6$	1200	1200

Among these points, the largest heat transfer coefficient occurs at point C, corresponding to the critical heat flux. The smallest heat transfer coefficient occurs at point D, the Leidenfrost point. <

Continued...

### PROBLEM 10.4 (Cont.)

At the Leidenfrost point, if radiation is neglected, heat transfer is due solely to conduction through the vapor film. The surface temperature is  $T_s = \Delta T_e + T_{\text{sat}} = 120^\circ\text{C} + 100^\circ\text{C} = 220^\circ\text{C}$ , so the film temperature is  $T_f = (220 + 100)^\circ\text{C}/2 = 160^\circ\text{C} = 433\text{ K}$ . Evaluating the vapor thermal conductivity at the film temperature, the film thickness is given by

$$\ell = k_v \Delta T_e / q'' = 0.0308\text{ W/m}\cdot\text{K} \times 120^\circ\text{C} / 2.5 \times 10^4\text{ W/m}^2 = 1.5 \times 10^{-4}\text{ m} = 0.15\text{ mm} \quad \leftarrow$$

**COMMENTS:** (1) Section 10.4.4 describes how to account for radiation heat transfer in film boiling. From Eq. 10.11, assuming  $\varepsilon = 1$  to maximize the effect of radiation, and using  $T_s = 220^\circ\text{C}$  corresponding to the Leidenfrost point, we find  $\bar{h}_{\text{rad}} = 19\text{ W/m}^2 \cdot \text{K}$ . This is considerably smaller than the overall heat transfer coefficient of  $h = 210\text{ W/m}^2 \cdot \text{K}$ . Figure 10.4 is based on experimental data, and therefore includes the effect of radiation, which becomes more significant as  $\Delta T_e$  increases. (2) Leidenfrost boiling can be observed by sprinkling water drops on a very hot flat pan surface. The vapor blanket beneath the droplets provides a means for the droplets to meander about the surface, and the droplets remain suspended for a relatively long time, indicative of relatively low heat transfer rates.

## PROBLEM 10.5

**KNOWN:** Long wire, 1 mm diameter, reaches a surface temperature of 126°C in water at 1 atm while dissipating 3150 W/m.

**FIND:** (a) Boiling heat transfer coefficient and (b) Correlation coefficient,  $C_{s,f}$ , if nucleate boiling occurs.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Nucleate boiling.

**PROPERTIES:** Table A-6, Water (saturated, 1 atm):  $T_s = 100^\circ\text{C}$ ,  $\rho_\ell = 1/v_f = 957.9 \text{ kg/m}^3$ ,  $\rho_v = 1/v_g = 0.5955 \text{ kg/m}^3$ ,  $c_{p,\ell} = 4217 \text{ J/kg}\cdot\text{K}$ ,  $\mu_\ell = 279 \times 10^{-6} \text{ N}\cdot\text{s/m}^2$ ,  $\text{Pr}_\ell = 1.76$ ,  $h_{fg} = 2257 \text{ kJ/kg}$ ,  $\sigma = 58.9 \times 10^{-3} \text{ N/m}$ .

**ANALYSIS:** (a) For the boiling process, the rate equation can be rewritten as

$$\bar{h} = q_s'' / (T_s - T_{\text{sat}}) = \frac{q_s'}{\pi D} / (T_s - T_{\text{sat}})$$

$$\bar{h} = \frac{3150 \text{ W/m}}{\pi \times 0.001 \text{ m}} / (126 - 100)^\circ\text{C} = 1.00 \times 10^6 \frac{\text{W}}{\text{m}^2} / 26^\circ\text{C} = 38,600 \text{ W/m}^2 \cdot \text{K} \quad <$$

Note the heat flux is very close to  $q''_{\text{max}}$ , and nucleate boiling does exist.

(b) For nucleate boiling, the Rohsenow correlation may be solved for  $C_{s,f}$  to give

$$C_{s,f} = \left\{ \frac{\mu_\ell h_{fg}}{q_s''} \right\}^{1/3} \left[ \frac{g(\rho_\ell - \rho_v)}{\sigma} \right]^{1/6} \left( \frac{c_{p,\ell} \Delta T_e}{h_{fg} \text{Pr}_\ell^n} \right).$$

Assuming the liquid-surface combination is such that  $n = 1$  and substituting numerical values with  $\Delta T_e = T_s - T_{\text{sat}}$ , find

$$C_{s,f} = \left\{ \frac{279 \times 10^{-6} \text{ N}\cdot\text{s/m}^2 \times 2257 \times 10^3 \text{ J/kg}}{1.00 \times 10^6 \text{ W/m}^2} \right\}^{1/3} \left[ \frac{9.8 \frac{\text{m}}{\text{s}^2} (957.9 - 0.5955) \frac{\text{kg}}{\text{m}^3}}{58.9 \times 10^{-3} \text{ N/m}} \right]^{1/6} \times \left( \frac{4217 \text{ J/kg}\cdot\text{K} \times 26 \text{ K}}{2257 \times 10^3 \text{ J/kg} \times 1.76} \right)$$

$$C_{s,f} = 0.017. \quad <$$

**COMMENTS:** By comparison with the values of  $C_{s,f}$  for other water-surface combinations of Table 10.1, the  $C_{s,f}$  value for the wire is large, suggesting that its surface must be highly polished. Note that the value of the boiling heat transfer coefficient is much larger than values common to single-phase convection.

## PROBLEM 10.6

**KNOWN:** Nucleate pool boiling on a 10 mm-diameter tube maintained at  $\Delta T_e = 10^\circ\text{C}$  in water at 1 atm; tube is platinum-plated.

**FIND:** Heat transfer coefficient.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Nucleate pool boiling.

**PROPERTIES:** Table A-6, Water (saturated, 1 atm):  $T_s = 100^\circ\text{C}$ ,  $\rho_\ell = 1/v_f = 957.9 \text{ kg/m}^3$ ,  $\rho_v = 1/v_g = 0.5955 \text{ kg/m}^3$ ,  $c_{p,\ell} = 4217 \text{ J/kg}\cdot\text{K}$ ,  $\mu_\ell = 279 \times 10^{-6} \text{ N}\cdot\text{s/m}^2$ ,  $\text{Pr}_\ell = 1.76$ ,  $h_{fg} = 2257 \text{ kJ/kg}$ ,  $\sigma = 58.9 \times 10^{-3} \text{ N/m}$ .

**ANALYSIS:** The heat transfer coefficient can be estimated using the Rohsenow nucleate-boiling correlation and the rate equation

$$h = \frac{q_s''}{\Delta T_e} = \frac{\mu_\ell h_{fg}}{\Delta T_e} \left[ \frac{g(\rho_\ell - \rho_v)}{\sigma} \right]^{1/2} \left( \frac{c_{p,\ell} \Delta T_e}{C_{s,f} h_{fg} \text{Pr}_\ell^n} \right)^3.$$

From Table 10.1, find  $C_{s,f} = 0.013$  and  $n = 1$  for the water-platinum surface combination. Substituting numerical values,

$$h = \frac{279 \times 10^{-6} \text{ N}\cdot\text{s/m}^2 \times 2257 \times 10^3 \text{ J/kg}}{10 \text{ K}} \left[ \frac{9.8 \text{ m/s}^2 (957.9 - 0.5955) \text{ kg/m}^3}{58.9 \times 10^{-3} \text{ N/m}} \right]^{1/2} \times \left( \frac{4217 \text{ J/kg}\cdot\text{K} \times 10 \text{ K}}{0.013 \times 2257 \times 10^3 \text{ J/kg} \times 1.76} \right)^3$$

$$h = 13,690 \text{ W/m}^2 \cdot \text{K}.$$

<

**COMMENTS:** For this liquid-surface combination,  $q_s'' = 0.137 \text{ MW/m}^2$ , which is in general agreement with the *typical* boiling curve of Fig. 10.4. To a first approximation, the effect of the tube diameter is negligible.

## PROBLEM 10.7

**KNOWN:** Saturated water at 1 atm boiling on large, horizontal, polished copper plate.

**FIND:** Nucleate boiling heat flux over excess temperature range  $5^\circ\text{C} \leq \Delta T_e \leq 30^\circ\text{C}$ . Compare with Figure 10.4. Find excess temperature corresponding to critical heat flux.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions. (2) Nucleate pool boiling.

**PROPERTIES:** Table A-6, Saturated water (1 atm):  $T_{\text{sat}} = 100^\circ\text{C}$ ,  $\rho_\ell = 957.9 \text{ kg/m}^3$ ,  $\rho_v = 0.596 \text{ kg/m}^3$ ,  $c_{p,\ell} = 4217 \text{ J/kg}\cdot\text{K}$ ,  $\mu_\ell = 279 \times 10^{-6} \text{ N}\cdot\text{s/m}^2$ ,  $\text{Pr}_\ell = 1.76$ ,  $\sigma = 58.9 \times 10^{-3} \text{ N/m}$ ,  $h_{fg} = 2257 \text{ kJ/kg}$ .

**ANALYSIS:** The nucleate pool boiling heat flux can be estimated using the Rohsenow correlation.

$$q_s'' = \mu_\ell h_{fg} \left[ \frac{g(\rho_\ell - \rho_v)}{\sigma} \right]^{1/2} \left( \frac{c_{p,\ell} \Delta T_e}{C_{s,f} h_{fg} \text{Pr}_\ell^n} \right)^3$$

From Table 10.1, find for this liquid-surface combination,  $C_{s,f} = 0.0128$  and  $n = 1$ , and substituting numerical values,

$$q_s'' = 279 \times 10^{-6} \text{ N}\cdot\text{s/m}^2 \times 2257 \times 10^3 \text{ J/kg} \left[ \frac{9.8 \text{ m/s}^2 (957.9 - 0.596) \text{ kg/m}^3}{58.9 \times 10^{-3} \text{ N/m}} \right]^{1/2} \times \left( \frac{4217 \text{ J/kg}\cdot\text{K} \times \Delta T_e}{0.0128 \times 2257 \times 10^3 \text{ J/kg} \times 1.76} \right)^3$$

$$q_s'' = 143(\Delta T_e)^3 \text{ W/m}^2. \quad \leftarrow$$

This is plotted below.

Continued...

### PROBLEM 10.7 (Cont.)

Compared with Figure 10.4, we see that this curve is a straight line on a log-log plot. The heat flux is higher than in Figure 10.4, especially for the higher values of excess temperature.

To find the excess temperature corresponding to the critical heat flux, we equate Eqs. (10.5) and (10.6) and solve for  $\Delta T_e$ .

$$\mu_\ell h_{fg} \left[ \frac{g(\rho_\ell - \rho_v)}{\sigma} \right]^{1/2} \left( \frac{c_{p,\ell} \Delta T_e}{C_{s,f} h_{fg} Pr_\ell^n} \right)^3 = Ch_{fg} \rho_v \left[ \frac{\sigma g(\rho_\ell - \rho_v)}{\rho_v^2} \right]^{1/4}$$

$$\Delta T_e = \frac{C_{s,f} h_{fg} Pr_\ell^n}{c_{p,\ell}} \left\{ Ch_{fg} \rho_v \left[ \frac{\sigma g(\rho_\ell - \rho_v)}{\rho_v^2} \right]^{1/4} \middle/ \left( \mu_\ell h_{fg} \left[ \frac{g(\rho_\ell - \rho_v)}{\sigma} \right]^{1/2} \right) \right\}^{1/3}$$

where  $C = 0.149$  for a large horizontal plate. Substituting numbers we find

$$\Delta T_e = 20.6^\circ\text{C}$$

<

**COMMENTS:** (1) The correlation and Figure 10.4 do not agree extremely well. The error is worst near ONB (70% error at  $\Delta T_e = 5^\circ\text{C}$ ) and CHF (170% error at  $\Delta T_e = 30^\circ\text{C}$ ). Since the correlation is a straight line on a log-log plot, it doesn't reproduce the curvature at the two ends of the curve. Since the correlation isn't accurate near CHF, it does not do an excellent job of predicting  $\Delta T_e$ , which appears to be around  $30^\circ\text{C}$  from Figure 10.4. (2) Figure 10.4 is a *typical* boiling curve. The boiling curve will shift as different boiling surfaces and geometries (and, in turn, different values of  $C_{s,f}$ ) are considered.

## PROBLEM 10.8

**KNOWN:** Simple expression to account for the effect of pressure on the nucleate boiling convection coefficient in water.

**FIND:** Compare predictions of this expression with the Rohsenow correlation for specified  $\Delta T_e$  and pressures (2 and 5 bar) applied to a horizontal plate.

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Nucleate pool boiling, (3)  $C_{s,f} = 0.013$ ,  $n = 1$ .

**PROPERTIES:** Table A-6, Saturated water (2 bar):  $\rho_\ell = 942.7 \text{ kg/m}^3$ ,  $c_{p,\ell} = 4244.3 \text{ J/kg}\cdot\text{K}$ ,  $\mu_\ell = 230.7 \times 10^{-6} \text{ N}\cdot\text{s/m}^2$ ,  $\text{Pr}_\ell = 1.43$ ,  $h_{fg} = 2203 \text{ kJ/kg}$ ,  $\sigma = 54.97 \times 10^{-3} \text{ N/m}$ ,  $\rho_v = 1.1082 \text{ kg/m}^3$ ;  
Saturated water (5 bar):  $\rho_\ell = 914.7 \text{ kg/m}^3$ ,  $c_{p,\ell} = 4316 \text{ J/kg}\cdot\text{K}$ ,  $\mu_\ell = 179 \times 10^{-6} \text{ N}\cdot\text{s/m}^2$ ,  $\text{Pr}_\ell = 1.13$ ,  $h_{fg} = 2107.8 \text{ kJ/kg}$ ,  $\sigma = 48.4 \times 10^{-3} \text{ N/m}$ ,  $\rho_v = 2.629 \text{ kg/m}^3$ .

**ANALYSIS:** The simple expression by Jakob accounting for pressure effects is

$$h = C(\Delta T_e)^n (p/p_a)^{0.4} \quad (1)$$

where  $p$  and  $p_a$  are the system and standard atmospheric pressures. For a horizontal plate,  $C = 5.56$  and  $n = 3$  for the range  $15 < q_s'' < 235 \text{ kW/m}^2$ . For  $\Delta T_e = 10^\circ\text{C}$ ,

$$p = 2 \text{ bar} \quad h = 5.56(10)^3 (2 \text{ bar}/1.0133 \text{ bar})^{0.4} = 7,298 \text{ W/m}^2 \cdot \text{K}, \quad q_s'' = 73 \text{ kW/m}^2 <$$

$$p = 5 \text{ bar} \quad h = 5.56(10)^3 (5 \text{ bar}/1.0133 \text{ bar})^{0.4} = 10,529 \text{ W/m}^2 \cdot \text{K}, \quad q_s'' = 105 \text{ kW/m}^2 <$$

where  $q_s'' = h\Delta T_e$ . The Rohsenow correlation, Eq. 10.5, with  $C_{s,f} = 0.013$  and  $n = 1$ , is of the form

$$q_s'' = \mu_\ell h_{fg} \left[ \frac{g(\rho_\ell - \rho_v)}{\sigma} \right]^{1/2} \left[ \frac{c_{p,\ell} \Delta T_e}{C_{s,f} h_{fg} \text{Pr}_\ell^n} \right]^3 \quad (2)$$

$$p = 2 \text{ bar}: \quad q_s'' = 230.7 \times 10^{-6} \frac{\text{N}\cdot\text{s}}{\text{m}^2} \times 2203 \times 10^3 \frac{\text{J}}{\text{kg}} \left[ \frac{9.8 \frac{\text{m}}{\text{s}^2} (942.7 - 1.1082) \frac{\text{kg}}{\text{m}^3}}{54.97 \times 10^{-3} \text{ N/m}} \right]^{1/2} \times \left[ \frac{4244.3 \text{ J/kg}\cdot\text{K} \times 10 \text{ K}}{0.013 \times 2203 \times 10^3 \frac{\text{J}}{\text{kg}} \times 1.43^1} \right]^3$$

$$q_s'' = 232 \text{ kW/m}^2 <$$

$$p = 5 \text{ bar}: \quad q_s'' = 439 \text{ kW/m}^2 <$$

**COMMENTS:** For ease of comparison, the results with  $p_a = 1.0133 \text{ bar}$  are:

	$q_s'' \left( \text{kW/m}^2 \right)$		
Correlation/p (bar)	1	2	4
Simple	56	73	105
Rohsenow	135	232	439

Note that the range of  $q_s''$  is within the limits of the Simple correlation. The comparison is poor and therefore the correlation is not to be recommended. By manipulation of the Rohsenow results, find that the  $(p/p_o)^m$  dependence provides  $m \approx 0.75$ , compared to the exponent of 0.4 in the Simple correlation.

## PROBLEM 10.9

**KNOWN:** Diameter of copper pan. Initial temperature of water and saturation temperature of boiling water. Range of heat rates ( $1 \leq q \leq 100 \text{ kW}$ ).

**FIND:** (a) Variation of pan temperature with heat rate for boiling water, (b) Pan temperature shortly after start of heating with  $q = 8 \text{ kW}$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Conditions of part (a) correspond to steady nucleate boiling, (2) Surface of pan corresponds to polished copper, (3) Conditions of part (b) correspond to natural convection from a heated plate to an infinite quiescent medium, (4) Negligible heat loss to surroundings.

**PROPERTIES:** Table A-6, saturated water ( $T_{\text{sat}} = 100^\circ\text{C}$ ):  $\rho_\ell = 957.9 \text{ kg/m}^3$ ,  $\rho_v = 0.60 \text{ kg/m}^3$ ,

$c_{p,\ell} = 4217 \text{ J/kg}\cdot\text{K}$ ,  $\mu_\ell = 279 \times 10^{-6} \text{ N}\cdot\text{s/m}^2$ ,  $\text{Pr}_\ell = 1.76$ ,  $h_{fg} = 2.257 \times 10^6 \text{ J/kg}$ ,  $\sigma = 0.0589 \text{ N/M}$ .

Table A-6, saturated water (assume  $T_s = 100^\circ\text{C}$ ,  $T_f = 60^\circ\text{C} = 333 \text{ K}$ ):  $\rho = 983 \text{ kg/m}^3$ ,  $\mu = 467 \times 10^{-6} \text{ N}\cdot\text{s/m}^2$ ,  $k = 0.654 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 2.99$ ,  $\beta = 523 \times 10^{-6} \text{ K}^{-1}$ . Hence,  $\nu = 0.475 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\alpha = 0.159 \times 10^{-6} \text{ m}^2/\text{s}$ .

**ANALYSIS:** (a) From Eq. (10.5),

$$\Delta T_e = T_s - T_{\text{sat}} = \frac{C_{s,f} h_{fg} \text{Pr}_\ell^n}{c_{p,\ell}} \times \left\{ \frac{q_s / \mu_\ell h_{fg} A_s}{[g(\rho_\ell - \rho_v) / \sigma]^{1/2}} \right\}^{1/3}$$

For  $n = 1.0$ ,  $C_{s,f} = 0.0128$  and  $A_s = \pi D^2/4 = 0.0707 \text{ m}^2$ , the following variation of  $T_s$  with  $q_s$  is obtained.

As indicated by the correlation, the surface temperature increases as the cube root of the heat rate, permitting large increases in  $q$  for modest changes in  $T_s$ . For  $q = 1 \text{ kW}$ ,  $T_s = 104.7^\circ\text{C}$ , which is barely sufficient to sustain boiling.

(b) Assuming  $10^7 < \text{Ra}_L < 10^{11}$ , the convection coefficient may be obtained from Eq. (9.31). Hence, with  $L = A_s/P = D/4 = 0.075 \text{ m}$ ,

Continued ...

**PROBLEM 10.9 (Cont.)**

$$\begin{aligned}\bar{h} &= \left(\frac{k}{L}\right) 0.15 \text{Ra}_L^{1/3} = \left(\frac{0.654 \text{ W/m}\cdot\text{K}}{0.075 \text{ m}}\right) 0.15 \left[ \frac{9.8 \text{ m/s}^2 \times 523 \times 10^{-6} \text{ K}^{-1} (T_s - T_i) (0.075 \text{ m})^3}{0.475 \times 0.159 \times 10^{-12} \text{ m}^4/\text{s}^2} \right]^{1/3} \\ &= 1.308 \left(2.86 \times 10^7\right)^{1/3} (T_s - T_i)^{1/3} = 400 (T_s - T_i)^{1/3}\end{aligned}$$

With  $A_s = \pi D^2/4 = 0.0707 \text{ m}^2$ , the heat rate is then

$$q = \bar{h} A_s (T_s - T_i) = \left(400 \text{ W/m}^2 \cdot \text{K}^{4/3}\right) 0.0707 \text{ m}^2 (T_s - T_i)^{4/3}$$

With  $q = 8000 \text{ W}$ ,

$$T_s = T_i + 69^\circ\text{C} = 89^\circ\text{C}$$

<

**COMMENTS:** (1) With  $(T_s - T_i) = 69^\circ\text{C}$ ,  $\text{Ra}_L = 1.97 \times 10^9$ , which is within the assumed Rayleigh number range. (2) The surface temperature increases as the temperature of the water increases, and bubbles may nucleate when it exceeds  $100^\circ\text{C}$ . However, while the water temperature remains below the saturation temperature, the bubbles will collapse in the subcooled liquid.

## PROBLEM 10.10

**KNOWN:** Fluids at 1 atm: mercury, ethanol, R-134a.

**FIND:** Critical heat flux; compare with value for water also at 1 atm.

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Nucleate pool boiling.

**PROPERTIES:** Table A-5 and Table A-6 at 1 atm,

	$h_{fg}$ (kJ/kg)	$\rho_v$ (kg/m <sup>3</sup> )	$\rho_l$ (kg/m <sup>3</sup> )	$\sigma \times 10^3$ (N/m)	$T_{sat}$ (K)
Mercury	301	3.90	12,740	417	630
Ethanol	846	1.44	757	17.7	351
R-134a	217	5.26	1,377	15.4	247
Water	2257	0.596	957.9	58.9	373

**ANALYSIS:** The critical heat flux can be estimated by Eq. 10.6 with  $C = 0.149$ ,

$$q''_{max} = 0.149 h_{fg} \rho_v \left[ \frac{\sigma g (\rho_l - \rho_v)}{\rho_v^2} \right]^{1/4}.$$

To illustrate the calculation procedure, consider numerical values for *mercury*.

$$q''_{max} = 0.149 \times 301 \times 10^3 \text{ J/kg} \times 3.90 \text{ kg/m}^3 \times \left[ \frac{417 \times 10^{-3} \text{ N/m} \times 9.8 \text{ m/s}^2 (12,740 - 3.90) \text{ kg/m}^3}{(3.90 \text{ kg/m}^3)^2} \right]^{1/4}$$

$$q''_{max} = 1.34 \text{ MW/m}^2.$$

For the other fluids, the results are tabulated along with the ratio of the critical heat fluxes to that for water.

Fluid	$q''_{max}$ (MW/m <sup>2</sup> )	$q''_{max} / q''_{max, water}$
Mercury	1.34	1.06
Ethanol	0.512	0.41
R-134a	0.281	0.22
Water	1.26	1.00

**COMMENTS:** Note that, despite the large difference between mercury and water properties, their critical heat fluxes are similar.

## PROBLEM 10.11

**KNOWN:** Water at atmospheric pressure boiling on horizontal copper tube. Heat flux is 90% of critical value.

**FIND:** Tube surface temperature under scored conditions and conditions similar to a polished surface.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, (2) Uniform tube wall temperature, (3) Nucleate boiling at outer surface of tube, (4) Constant properties.

**PROPERTIES:** Table A-6, Water ( $T = 373 \text{ K}$ ):  $\rho_l = 957.9 \text{ kg/m}^3$ ,  $\rho_v = 0.596 \text{ kg/m}^3$ ,  $h_{fg} = 2257 \text{ kJ/kg}$ ,  $c_{p,l} = 4.217 \text{ kJ/kg}\cdot\text{K}$ ,  $\mu_l = 279 \times 10^{-6} \text{ N}\cdot\text{s/m}^2$ ,  $k_l = 0.680 \text{ W/m}\cdot\text{K}$ ,  $Pr_l = 1.76$ ,  $\sigma = 58.9 \times 10^{-3} \text{ N/m}$ .

**ANALYSIS:** The heat flux is 90% of the critical heat flux given by Eq. 10.6, thus with  $C = 0.131$  for a large horizontal tube,

$$\begin{aligned}
 q_s'' &= 0.9 C h_{fg} \rho_v \left[ \frac{\sigma g (\rho_l - \rho_v)}{\rho_v^2} \right]^{1/4} = 0.9 \times 0.131 \times 2257 \times 10^3 \text{ J/kg} \times 0.596 \text{ kg/m}^3 \\
 &\times \left[ \frac{58.9 \times 10^{-3} \text{ N/m} \times 9.8 \text{ m/s}^2 \times (957.9 \text{ kg/m}^3 - 0.596 \text{ kg/m}^3)}{(0.596 \text{ kg/m}^3)^2} \right]^{1/4} \\
 &= 9.96 \times 10^5 \text{ W/m}^2
 \end{aligned}$$

The nucleate boiling heat flux is given by Eq. 10.5, with  $C_{s,f} = 0.0068$ ,  $n = 1.0$  for a scored copper surface. Solving for the excess temperature,

$$\begin{aligned}
 \Delta T_e &= \frac{C_{s,f} h_{fg} Pr_l^n}{c_{p,l}} \left\{ \frac{q_s''}{\mu_l h_{fg}} \left[ \frac{\sigma}{g (\rho_l - \rho_v)} \right]^{1/2} \right\}^{1/3} = \frac{0.0068 \times 2257 \times 10^3 \text{ J/kg} \times 1.76}{4217 \text{ J/kg}\cdot\text{K}} \\
 &\times \left\{ \frac{9.96 \times 10^5 \text{ W/m}^2}{279 \times 10^{-6} \text{ N}\cdot\text{s/m}^2 \times 2257 \times 10^3 \text{ J/kg}} \left[ \frac{58.9 \times 10^{-3} \text{ N/m}}{9.8 \text{ m/s}^2 (957.9 - 0.596) \text{ kg/m}^3} \right]^{1/2} \right\}^{1/3} \\
 &= 10.1^\circ\text{C}
 \end{aligned}$$

Thus, for the scored surface

$$T_s = \Delta T_e + T_{\text{sat}} = 10.1^\circ\text{C} + 100^\circ\text{C} = 110.1^\circ\text{C}$$

<

Continued...

### PROBLEM 10.11 (Cont.)

After the surface degrades to conditions similar to a polished surface, the value of  $C_{s,f}$  becomes 0.0128. Recognizing that  $\Delta T_e$  is proportional to  $C_{s,f}$ ,  $\Delta T_e = 10.1^\circ\text{C}(0.0128/0.0068) = 19.1^\circ\text{C}$ . Hence, after prolonged service,

$$T_s = \Delta T_e + T_{\text{sat}} = 19.1^\circ\text{C} + 100^\circ\text{C} = 119.1^\circ\text{C}$$

&lt;

**COMMENTS:** (1) A scored surface provides nucleation sites that enhance nucleate boiling, resulting in a smaller excess temperature relative to a smooth surface, for the same heat flux.

## PROBLEM 10.12

**KNOWN:** Copper pan, 150 mm diameter and filled with water at 1 atm, is maintained at 115°C.

**FIND:** Power required to boil water and the evaporation rate; ratio of heat flux to critical heat flux; pan temperature required to achieve critical heat flux.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Nucleate pool boiling, (2) Copper pan is polished surface.

**PROPERTIES:** Table A-6, Water (1 atm):  $T_{\text{sat}} = 100^\circ\text{C}$ ,  $\rho_\ell = 957.9\text{ kg/m}^3$ ,  $\rho_v = 0.5955\text{ kg/m}^3$ ,  $c_{p,\ell} = 4217\text{ J/kg}\cdot\text{K}$ ,  $\mu_\ell = 279 \times 10^{-6}\text{ N}\cdot\text{s/m}^2$ ,  $\text{Pr}_\ell = 1.76$ ,  $h_{\text{fg}} = 2257\text{ kJ/kg}$ ,  $\sigma = 58.9 \times 10^{-3}\text{ N/m}$ .

**ANALYSIS:** The power requirement for boiling and the evaporation rate can be expressed as follows,

$$q_{\text{boil}} = q_s'' \cdot A_s \quad \dot{m} = q_{\text{boil}} / h_{\text{fg}}$$

The heat flux for nucleate pool boiling can be estimated using the Rohsenow correlation.

$$q_s'' = \mu_\ell h_{\text{fg}} \left[ \frac{g(\rho_\ell - \rho_v)}{\sigma} \right]^{1/2} \left( \frac{c_{p,\ell} \Delta T_e}{C_{s,f} h_{\text{fg}} \text{Pr}_\ell^n} \right)^3$$

Selecting  $C_{s,f} = 0.0128$  and  $n = 1$  from Table 10.1 for the polished copper finish, find

$$q_s'' = 279 \times 10^{-6} \frac{\text{N}\cdot\text{s}}{\text{m}^2} \times 2257 \times 10^3 \frac{\text{J}}{\text{kg}} \left[ \frac{9.8 \frac{\text{m}}{\text{s}^2} (957.9 - 0.5955) \frac{\text{kg}}{\text{m}^3}}{58.9 \times 10^{-3} \text{ N/m}} \right]^{1/2} \left( \frac{4217 \frac{\text{J}}{\text{kg}\cdot\text{K}} \times 15^\circ\text{C}}{0.0128 \times 2257 \times 10^3 \frac{\text{J}}{\text{kg}} \times 1.76} \right)^3$$

$$q_s'' = 4.839 \times 10^5 \text{ W/m}^2$$

The power and evaporation rate are

$$q_{\text{boil}} = 4.839 \times 10^5 \text{ W/m}^2 \times \frac{\pi}{4} (0.150\text{ m})^2 = 8.55 \text{ kW} \quad <$$

$$\dot{m}_{\text{boil}} = 8.55 \text{ kW} / 2257 \times 10^3 \text{ J/kg} = 3.79 \times 10^{-3} \text{ kg/s} = 14 \text{ kg/h} \quad <$$

The maximum or critical heat flux was found in Example 10.1 as

$$q_{\text{max}}'' = 1.26 \text{ MW/m}^2$$

Hence, the ratio of the operating to maximum heat flux is

$$\frac{q_s''}{q_{\text{max}}''} = 4.619 \times 10^5 \text{ W/m}^2 / 1.26 \text{ MW/m}^2 = 0.384 \quad <$$

From the boiling curve, Fig. 10.4,  $\Delta T_e \approx 30^\circ\text{C}$  will provide the maximum heat flux. <

### PROBLEM 10.13

**KNOWN:** Nickel-coated heater element exposed to saturated water at atmospheric pressure; thermocouple attached to the insulated, backside surface indicates a temperature  $T_o = 266.4^\circ\text{C}$  when the electrical power dissipation in the heater element is  $6.950 \times 10^7 \text{ W/m}^3$ .

**FIND:** (a) From the foregoing data, calculate the surface temperature,  $T_s$ , and the heat flux at the exposed surface, and (b) Using an appropriate boiling correlation, estimate the surface temperature based upon the surface heat flux determined in part (a).

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Water exposed to standard atmospheric pressure and uniform temperature,  $T_{\text{sat}}$ , and (3) Nucleate pool boiling occurs on exposed surface, (4) Uniform volumetric generation in element, and (5) Backside of heater is perfectly insulated.

**PROPERTIES:** Table A-6, Saturated water, liquid ( $100^\circ\text{C}$ ):  $\rho_\ell = 1/v_f = 957.9 \text{ kg/m}^3$ ,  $c_{p,\ell} = c_{p,f} = 4.217 \text{ kJ/kg}\cdot\text{K}$ ,  $\mu_\ell = \mu_f = 279 \times 10^{-6} \text{ N}\cdot\text{s/m}^2$ ,  $\text{Pr}_\ell = \text{Pr}_f = 1.76$ ,  $h_{fg} = 2257 \text{ kJ/kg}$ ,  $\sigma = 58.9 \times 10^{-3} \text{ N/m}$ ; Saturated water, vapor ( $100^\circ\text{C}$ ):  $\rho_v = 1/v_g = 0.5955 \text{ kg/m}^3$ .

**ANALYSIS:** (a) From Eq. 3.58, the temperature at the exposed surface,  $T_s$ , is

$$T_s = T_o - \frac{\dot{q}L^2}{2k} = 266.4^\circ\text{C} - \frac{6.95 \times 10^7 \text{ W/m}^3 (0.015 \text{ m})^2}{2 \times 50 \text{ W/m}\cdot\text{K}}$$

$$T_s = 110.0^\circ\text{C} \quad <$$

The heat flux at the exposed surface is

$$q_s'' = \dot{q}L = 6.95 \times 10^7 \text{ W/m}^3 \times 0.015 \text{ m} = 1.043 \times 10^6 \text{ W/m}^2 \quad <$$

(b) Since  $\Delta T_e = T_s - T_{\text{sat}} = (110 - 100)^\circ\text{C} = 10^\circ\text{C}$ , nucleate pool boiling occurs and the Rohsenow correlation, Eq. 10.5, with  $q_s''$  from part (a) can be used to estimate the surface temperature,  $T_{s,c}$ ,

$$q_s'' = \mu_\ell h_{fg} \left[ \frac{g(\rho_\ell - \rho_v)}{\sigma} \right]^{1/2} \left( \frac{c_{p,\ell} \Delta T_{e,c}}{C_{s,f} h_{fg} \text{Pr}_\ell^n} \right)^3$$

From Table 10.1, for the water-nickel surface-fluid combination,  $C_{s,f} = 0.006$  and  $n = 1.0$ .

Substituting numerical values, find  $\Delta T_{e,c}$  and  $T_{s,c}$ .

Continued ...

**PROBLEM 10.13 (Cont.)**

$$1.043 \times 10^6 \text{ W/m}^2 = 279 \times 10^{-6} \text{ N} \cdot \text{s/m}^2 \times 2257 \times 10^3 \text{ J/kg}$$

$$\times \left[ \frac{9.8 \text{ m/s}^2 (957.9 - 0.5955) \text{ kg/m}^3}{58.9 \times 10^{-3} \text{ N/m}} \right]^{1/2}$$

$$\times \left( \frac{4.217 \times 10^3 \text{ J/kg} \cdot \text{K} \times \Delta T_{e,c}}{0.006 \times 2257 \times 10^3 \text{ J/kg} \times 1.76} \right)^3$$

$$\Delta T_{e,c} = T_{s,c} - T_{\text{sat}} = 9.1^\circ\text{C}$$

$$T_{s,c} = 109.1^\circ\text{C}$$

<

**COMMENTS:** From the experimental data, part (a), the surface temperature is determined from the conduction analysis as  $T_s = 110.0^\circ\text{C}$ . Using the traditional nucleate boiling correlation with the experimental value for the heat flux, the surface temperature is estimated as  $T_{s,c} = 109.1^\circ\text{C}$ . The two approaches provide excess temperatures that are 10.0 vs. 9.1°C, which amounts to nearly a 10% difference.

## PROBLEM 10.14

**KNOWN:** Chips on a ceramic substrate operating at power levels corresponding to 50% of the critical heat flux.

**FIND:** (a) Chip power level and temperature rise of the chip surface, and (b) Compute and plot the chip temperature  $T_s$  as a function of heat flux for the range  $0.25 \leq q_s''/q_{s,\text{max}}'' \leq 0.90$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Nucleate boiling, (2) Fluid-surface with  $C_{s,f} = 0.004$ ,  $n = 1.7$  for Rohsenow correlation, (3) Backside of substrate insulated.

**PROPERTIES:** Table A-5, Refrigerant R-134a (1 atm):  $T_{\text{sat}} = 247 \text{ K} = -26^\circ\text{C}$ ,  $\rho_\ell = 1377 \text{ kg/m}^3$ ,  $\rho_v = 5.26 \text{ kg/m}^3$ ,  $h_{fg} = 217 \text{ kJ/kg}$ ,  $\sigma = 15.4 \times 10^{-3} \text{ N/m}$ ; R-134a, sat. liquid (given, 247 K):  $c_{p,\ell} = 1551 \text{ J/kg}\cdot\text{K}$ ,  $\mu_\ell = 1.46 \times 10^{-4} \text{ N}\cdot\text{s/m}^2$ ,  $\text{Pr}_\ell = 3.2$ .

**ANALYSIS:** (a) The operating power level (flux) is  $0.50 q_{s,\text{max}}''$ , where the critical heat flux is estimated from Eq. 10.6 with  $C=0.149$  for nucleate pool boiling,

$$q_{s,\text{max}}'' = 0.149 h_{fg} \rho_v \left[ \frac{\sigma g (\rho_\ell - \rho_v)}{\rho_v^2} \right]^{1/4}$$

$$q_{s,\text{max}}'' = 0.149 \times 217 \times 10^3 \frac{\text{J}}{\text{kg}} \times 5.26 \frac{\text{kg}}{\text{m}^3} \left[ \frac{15.4 \times 10^{-3} \frac{\text{N}}{\text{m}} \times 9.8 \frac{\text{m}}{\text{s}^2} (1377 - 5.26) \frac{\text{kg}}{\text{m}^3}}{\left( 5.26 \frac{\text{kg}}{\text{m}^3} \right)^2} \right]^{1/4}$$

$$q_{s,\text{max}}'' = 281 \text{ kW/m}^2.$$

Hence, the heat flux on a chip is  $0.5 \times 281 \text{ kW/m}^2 = 141 \text{ kW/m}^2$  and the power level is

$$q_{\text{chip}} = q_s'' \times A_s = 141 \times 10^3 \text{ W/m}^2 \times 25 \text{ mm}^2 \left( 10^{-3} \text{ m/mm} \right)^2 = 3.5 \text{ W}. \quad <$$

To determine the chip surface temperature for this condition, use the Rohsenow equation to find  $\Delta T_e = T_s - T_{\text{sat}}$  with  $q_s'' = 141 \times 10^3 \text{ W/m}^2$ . The correlation, Eq. 10.5, solved for  $\Delta T_e$  is

$$\Delta T_e = \frac{C_{s,f} h_{fg} \text{Pr}_\ell^n}{c_{p,\ell}} \left( \frac{q_s''}{\mu_\ell h_{fg}} \right)^{1/3} \left[ \frac{\sigma}{g (\rho_\ell - \rho_v)} \right]^{1/6} = \frac{0.004 \times 217 \times 10^3 \text{ J/kg} (3.2)^{1.7}}{1551 \text{ J/kg}\cdot\text{K}} \times$$

$$\left( \frac{141 \times 10^3 \text{ W/m}^2}{1.46 \times 10^{-4} \frac{\text{N}\cdot\text{s}}{\text{m}^2} \times 217 \times 10^3 \frac{\text{J}}{\text{kg}}} \right)^{1/3} \left[ \frac{15.4 \times 10^{-3} \text{ N/m}}{9.8 \frac{\text{m}}{\text{s}^2} (1377 - 5.26) \frac{\text{kg}}{\text{m}^3}} \right]^{1/6} = 6.8^\circ\text{C}.$$

Hence, the chip surface temperature is

Continued...

### PROBLEM 10.14 (Cont.)

$$T_s = T_{\text{sat}} + \Delta T_e = -26^\circ\text{C} + 6.8^\circ\text{C} \approx -19^\circ\text{C}$$

<

(b) Using the *IHT Correlations Tools, Boiling, Nucleate Pool Boiling -- Heat flux and Maximum heat flux*, the chip surface temperature,  $T_s$ , was calculated as a function of the ratio  $q''_s/q''_{\text{max}}$ . The required thermophysical properties as provided in the problem statement were entered directly into the IHT workspace. The results are plotted below.

**COMMENTS:** (1) A copy of the *IHT Workspace* model used to generate the above plot is shown below.

```

// Correlations Tool – Boiling, Nucleate pool boiling, Critical heat flux
q''max = qmax_dprime_NPB(C,rhol,rhov,hfg,sigma,g) // Eq 10.6
g = 9.8 // Gravitational constant, m/s^2
// Evaluate liquid(l) and vapor(v) properties at Tsat.
// C = 0.131 for large horizontal cylinders and spheres
// C = 0.149 for large horizontal plates
C = 0.149
/* Correlation description: Critical (maximum) heat flux for nucleate pool boiling (NPB). Eq 10.6,
C=0.131 or 0.149 depending on geometry. See boiling curve, Fig 10.4 . */
// Correlations Tool – Boiling, Nucleate pool boiling, Heat flux
q''s = qs_dprime_NPB(Csf,n,rhol,rhov,hfg,cpl,mul,Prl,sigma,deltaTe,g) // Eq 10.5
//g = 9.8 // gravitational constant, m/s^2
deltaTe = Ts - Tsat // excess temperature, K
Tsat = 247 // saturation temperature, K
/* Evaluate liquid(l) and vapor(v) properties at Tsat. From Table 10.1 (Fill in as required), */
// fluid-surface combination:
Csf = 0.004 // Given
n = 1.7 // Given
/* Correlation description: Heat flux for nucleate pool boiling (NPB), water-surface combination
(Cf,n), Eq 10.5, Table 10.1 . See boiling curve, Fig 10.4 . */
// Heat rates:
qsqm = q''s / q''max // Ratio, heat flux over critical heat flux
qsqm = 0.5
// Thermophysical properties (given):
rhol = 1377 // Density, liquid, kg/m^3
rhov = 5.26 // Density, vapor, kg/m^3
hfg = 217000 // Heat of vaporization, J/kg
sigma = 15.4e-3 // Surface tension, N/m
cpl = 1551 // Specific heat, saturated liquid, J/kg.K
mul = 1.46e-4 // Viscosity, saturated liquid, N.s/m^2
Prl = 3.2 // Prandtl number, saturated liquid

```

### PROBLEM 10.15

**KNOWN:** Saturated ethylene glycol at 1 atm heated by a chromium-plated heater of 200 mm diameter and maintained at 480K.

**FIND:** Heater power, rate of evaporation, and ratio of required power to maximum power for critical heat flux.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Nucleate pool boiling, (2) Fluid-surface,  $C_{s,f} = 0.010$  and  $n = 1$ .

**PROPERTIES:** Table A-5, Saturated ethylene glycol (1 atm):  $T_{sat} = 470\text{K}$ ,  $h_{fg} = 812\text{ kJ/kg}$ ,  $\rho_f = 1111\text{ kg/m}^3$ ,  $\sigma = 32.7 \times 10^{-3}\text{ N/m}$ ; Saturated ethylene glycol (given, 470K):  $\rho_v = 1.66\text{ kg/m}^3$ ,  $\mu_\ell = 0.38 \times 10^{-3}\text{ N}\cdot\text{s/m}^2$ ,  $c_{p,\ell} = 3280\text{ J/kg}\cdot\text{K}$ ,  $Pr_\ell = 8.7$ .

**ANALYSIS:** The power requirement for boiling and the evaporation rate are  $q_{boil} = q_s'' \cdot A_s$  and  $\dot{m} = q_{boil} / h_{fg}$ . Using the Rohsenow correlation,

$$q_s'' = \mu_\ell h_{fg} \left[ \frac{g(\rho_\ell - \rho_v)}{\sigma} \right]^{1/2} \left( \frac{c_{p,\ell} \Delta T_e}{C_{s,f} h_{fg} Pr_\ell^n} \right)^3$$

$$q_s'' = 0.38 \times 10^{-3} \frac{\text{N}\cdot\text{s}}{\text{m}^2} \times 812 \times 10^3 \frac{\text{J}}{\text{kg}} \left[ \frac{9.8\text{ m/s}^2 (1111 - 1.66)\text{ kg/m}^3}{32.7 \times 10^{-3}\text{ N/m}} \right]^{1/2} \left( \frac{3280\text{ J/kg}\cdot\text{K} (480 - 470)\text{ K}}{0.01 \times 812 \times 10^3 \frac{\text{J}}{\text{kg}} (8.7)^1} \right)^3$$

$$q_s'' = 1.78 \times 10^4\text{ W/m}^2 \quad q_{boil} = 1.78 \times 10^4\text{ W/m}^2 \times \pi/4 (0.200\text{ m})^2 = 559\text{ W} \quad <$$

$$\dot{m} = 559\text{ W} / 812 \times 10^3\text{ J/kg} = 6.89 \times 10^{-4}\text{ kg/s.} \quad <$$

For this fluid, the critical heat flux is estimated from Eq. 10.6 with  $C=0.149$ ,

$$q_{max}'' = 0.149 h_{fg} \rho_v \left[ \sigma g (\rho_\ell - \rho_v) / \rho_v^2 \right]^{1/4}$$

$$q_{max}'' = 0.149 \times 812 \times 10^3 \frac{\text{J}}{\text{kg}} \times 1.66 \frac{\text{kg}}{\text{m}^3} \left[ \frac{32.7 \times 10^{-3}\text{ N/m} \times 9.8\text{ m/s}^2 (1111 - 1.66)\text{ kg/m}^3}{(1.66\text{ kg/m}^3)^2} \right]^{1/4}$$

$$q_{max}'' = 6.77 \times 10^5\text{ W/m}^2.$$

Hence, the ratio of the operating heat flux to the critical heat flux is,

$$\frac{q_s''}{q_{max}''} = \frac{1.78 \times 10^4\text{ W/m}^2}{6.77 \times 10^5\text{ W/m}^2} \approx 0.026 \quad \text{or} \quad 2.6\%. \quad <$$

**COMMENTS:** Recognize that the results are crude approximations since the values for  $C_{s,f}$  and  $n$  are just estimates. This fluid is not normally used for boiling processes since it decomposes at higher temperatures.

## PROBLEM 10.16

**KNOWN:** Copper tubes, 25 mm diameter  $\times$  0.75 m long, used to boil saturated water at 1 atm operating at 75% of the critical heat flux.

**FIND:** (a) Number of tubes,  $N$ , required to evaporate at a rate of 750 kg/h; tube surface temperature,  $T_s$ , for these conditions, and (b) Compute and plot  $T_s$  and  $N$  required to provide the prescribed vapor production as a function of the heat flux ratio,  $0.25 \leq q_s''/q_{s,\max}'' \leq 0.90$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Nucleate pool boiling, (2) Polished copper tube surfaces.

**PROPERTIES:** Table A-6, Saturated water (100°C):  $\rho_\ell = 957.9 \text{ kg/m}^3$ ,  $c_{p,\ell} = 4217 \text{ J/kg}\cdot\text{K}$ ,  $\mu_\ell = 279 \times 10^{-6} \text{ N}\cdot\text{s/m}^2$ ,  $\text{Pr}_\ell = 1.76$ ,  $h_{fg} = 2257 \text{ kJ/kg}$ ,  $\sigma = 58.9 \times 10^{-3} \text{ N/m}$ ,  $\rho_v = 0.5955 \text{ kg/m}^3$ .

**ANALYSIS:** (a) The total number of tubes,  $N$ , can be evaluated from the rate equations

$$q = q_s'' A_s = q_s'' N \pi D L \quad q = \dot{m} h_{fg} \quad N = \dot{m} h_{fg} / q_s'' \pi D L \quad (1,2,3)$$

The tubes are operated at 75% of the critical flux. From Eq. 10.6, the heat flux is

$$q_{s,\max}'' = 0.75 \times C h_{fg} \rho_v \left[ \frac{\sigma g (\rho_\ell - \rho_v)}{\rho_v^2} \right]^{1/4} = 0.75 \times 0.131 \times 2257 \times 10^3 \text{ J/kg} \times 0.5955 \text{ kg/m}^3 \times$$

$$\left[ \frac{58.9 \times 10^{-3} \text{ N/m} \times 9.8 \text{ m/s}^2 (957.9 - 0.5955) \text{ kg/m}^3}{(0.5955 \text{ kg/m}^3)^2} \right]^{1/4} = 8.30 \times 10^5 \text{ W/m}^2$$

Substituting numerical values into Eq. (3), find

$$N = \frac{750 \text{ kg/h}}{3600 \text{ s/h}} \times 2257 \times 10^3 \text{ J/kg} / \left( 8.30 \times 10^5 \text{ W/m}^2 \times \pi \times 0.025 \text{ m} \times 0.75 \text{ m} \right) = 9.6 \approx 10. \blacktriangleleft$$

To determine the tube surface temperature, use the Rohsenow correlation,

$$\Delta T_e = \frac{C_{s,f} h_{fg} \text{Pr}_\ell^n}{c_{p,\ell}} \left( \frac{q_s''}{\mu_\ell h_{fg}} \right)^{1/3} \left[ \frac{\sigma}{g (\rho_\ell - \rho_v)} \right]^{1/6}$$

From Table 10.1 for the polished copper-water combination,  $C_{s,f} = 0.0128$  and  $n = 1.0$ .

Continued...

**PROBLEM 10.16 (Cont.)**

$$\Delta T_e = \frac{0.0128 \times 2257 \times 10^3 \text{ J/kg} (1.76)^1}{4217 \text{ J/kg} \cdot \text{K}} \left( \frac{8.30 \times 10^5 \text{ W/m}^2}{279 \times 10^{-6} \text{ N} \cdot \text{s/m}^2 \times 2257 \times 10^3 \text{ J/kg}} \right)^{1/3} \times \left[ \frac{58.9 \times 10^{-3} \text{ N/m}}{9.8 \text{ m/s}^2 (957.9 - 0.5955) \text{ kg/m}^3} \right]^{1/6} = 18.0^\circ \text{C}.$$

Hence,

$$T_s = T_{\text{sat}} + \Delta T_e = (100 + 18.0)^\circ \text{C} = 118^\circ \text{C}.$$

<

(b) Using the *IHT Correlations Tool, Boiling, Nucleate Pool Boiling, Heat flux* and the *Properties Tool for Water*, combined with Eqs. (1,2,3) above, the surface temperature  $T_s$  and  $N$  can be computed as a function of  $q_s''/q_{\text{max}}''$ . The results are plotted below.

Note that the tube surface temperature increases only slightly (112 to 119°C) as the ratio  $q_s''/q_{\text{max}}''$  increases. The number of tubes required to provide the prescribed evaporation rate decreases markedly as  $q_s''/q_{\text{max}}''$  increases.

**COMMENTS:** The critical heat flux for pool boiling on a flat plate is calculated in Example 10.1 to be  $q_{\text{max}}'' = 1.26 \text{ MW/m}^2$ . For a horizontal cylinder, the critical heat flux is smaller by a factor of  $0.131/0.149 = 0.88$ . Hence, surface curvature effects can impact boiling phenomena.

## PROBLEM 10.17

**KNOWN:** Diameter and length of tube submerged in pressurized water. Water pressure. Flowrate and inlet temperature of gas flow through the tube.

**FIND:** Tube wall and gas outlet temperatures for (a) new, scored tube surfaces and (b) aged conditions with smooth tube walls.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, (2) Uniform tube wall temperature, (3) Nucleate boiling at outer surface of tube, (4) Fully developed flow in tube, (5) Combustion gas is ideal with negligible viscous dissipation and pressure work, (6) Constant properties, (7) Thin tube wall.

**PROPERTIES:** Table A-6, saturated water ( $p_{\text{sat}} = 4.37$  bars):  $T_{\text{sat}} = 420$  K,  $h_{\text{fg}} = 2.123 \times 10^6$  J/kg,  $\rho_{\ell} = 919$  kg/m<sup>3</sup>,  $\rho_{\nu} = 2.4$  kg/m<sup>3</sup>,  $\mu_{\ell} = 185 \times 10^{-6}$  N·s/m<sup>2</sup>,  $c_{p,\ell} = 4302$  J/kg·K,  $\text{Pr}_{\ell} = 1.16$ ,  $\sigma = 0.0494$  N/m. Table A-4, air ( $p = 1$  atm,  $\bar{T}_m \approx 700$  K):  $c_p = 1075$  J/kg·K,  $\mu = 339 \times 10^{-7}$  N·s/m<sup>2</sup>,  $k = 0.0524$  W/m·K,  $\text{Pr} = 0.695$ .

**ANALYSIS:** (a) From an energy balance performed for a control surface that bounds the tube, we know that the rate of heat transfer by convection from the gas to the inner surface must equal the rate of heat transfer due to boiling at the outer surface. Hence, from Eqs. 8.34 and 10.5, the energy balance for a single tube is of the form

$$\dot{m}c_p(T_{m,i} - T_{m,o}) = A_s \mu_{\ell} h_{\text{fg}} \left[ \frac{g(\rho_{\ell} - \rho_{\nu})}{\sigma} \right]^{1/2} \left( \frac{c_{p,\ell} \Delta T_e}{C_{s,f} h_{\text{fg}} \text{Pr}_{\ell}^n} \right)^3 \quad (1)$$

where  $C_{s,f} = 0.0068$  and  $n = 1.0$  from Table 10.1. The corresponding unknowns are the wall temperature  $T_s$  and gas outlet temperature,  $T_{m,o}$ , which are also related through Eq. 8.41b.

$$\frac{T_s - T_{m,o}}{T_s - T_{m,i}} = \exp\left(-\frac{\pi DL \bar{h}}{\dot{m} c_p}\right) \quad (2)$$

For  $\text{Re}_D = 4\dot{m}/\pi D\mu = 119,600$ , the flow is turbulent, and with  $n = 0.3$ , Eq. 8.60 yields,

$$\bar{h} = h_{\text{fd}} = \left(\frac{k}{D}\right) 0.023 \text{Re}_D^{4/5} \text{Pr}^{0.3} = \left(\frac{0.0524 \text{ W/m}\cdot\text{K}}{0.025 \text{ m}}\right) 0.023 (119,600)^{4/5} (0.695)^{0.3} = 502 \text{ W/m}^2 \cdot \text{K}$$

Continued...

### PROBLEM 10.17 (Cont.)

Solving Eqs. (1) and (2), we obtain

$$T_s = 150^\circ\text{C}, \quad T_{m,o} = 164^\circ\text{C} \quad <$$

(b) When the surface degrades to become similar to a polished surface, the value of  $C_{s,f}$  changes to 0.00128. Repeating the calculations yields

$$T_s = 152.6^\circ\text{C}, \quad T_{m,o} = 166.7^\circ\text{C} \quad <$$

**COMMENTS:** (1) The heat rate per tube in part (a) is  $q = \dot{m} c_p (T_{m,i} - T_{m,o}) = 46,100 \text{ W}$ , and the total heat rate is  $Nq = 230,500 \text{ W}$ , in which case the rate of steam production is  $\dot{m}_{\text{steam}} = q / h_{fg} = 0.109 \text{ kg/s}$ . (2) The boiling heat transfer coefficient,  $h_{\text{boil}} = q_s'' / (T_s - T_{\text{sat}})$ , is  $2.5 \times 10^4$  and  $1.3 \times 10^4 \text{ W/m}^2 \cdot \text{K}$  in parts (a) and (b), respectively. This large change has only a small effect on the surface and outlet temperatures because the dominant resistance is the internal forced convection gas resistance. (3) It would not be possible to maintain isothermal tube walls without a large wall thickness, and  $T_s$ , as well as the intensity of boiling, would decrease with increasing distance from the tube entrance. However the foregoing analysis suffices as a first approximation.

## PROBLEM 10.18

**KNOWN:** Nickel wire passing current while submerged in water at atmospheric pressure.

**FIND:** Current at which wire burns out.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Pool boiling.

**ANALYSIS:** The burnout condition will occur when electrical power dissipation creates a surface heat flux exceeding the critical heat flux,  $q''_{max}$ . This burn out condition is illustrated on the boiling curve to the right and in Figure 10.3.

The criterion for burnout can be expressed as

$$q''_{max} \cdot \pi D = q'_{elec} \quad q'_{elec} = I^2 R'_e \quad (1,2)$$

That is,

$$I = [q''_{max} \pi D / R'_e]^{1/2} \quad (3)$$

For pool boiling of water at 1 atm, we found in Example 10.1 that

$$q''_{max} = 1.26 \text{ MW} / \text{m}^2.$$

Substituting numerical values into Eq. (3), find

$$I = \left[ 1.26 \times 10^6 \text{ W} / \text{m}^2 (\pi \times 0.001 \text{ m}) / 0.129 \Omega / \text{m} \right]^{1/2} = 175 \text{ A.} \quad <$$

**COMMENTS:** The magnitude of the current required to burn out the 1 mm diameter wire is very large. What current would burn out the wire in air?

## PROBLEM 10.19

**KNOWN:** Saturated water boiling on a brass plate maintained at  $\Delta T_e = 15^\circ\text{C}$ .

**FIND:** Power required ( $\text{W/m}^2$ ) for pressures of 1 and 10 atm; fraction of critical heat flux at which plate is operating.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Nucleate pool boiling, (2)  $\Delta T_e = 15^\circ\text{C}$  for both pressure levels.

**PROPERTIES:** Table A-6, Saturated water, liquid (1 atm,  $T_{\text{sat}} = 100^\circ\text{C}$ ):  $\rho_\ell = 957.9 \text{ kg/m}^3$ ,  $c_{p,\ell} = 4217 \text{ J/kg}\cdot\text{K}$ ,  $\mu_\ell = 279 \times 10^{-6} \text{ N}\cdot\text{s/m}^2$ ,  $\text{Pr}_\ell = 1.76$ ,  $h_{\text{fg}} = 2257 \text{ kJ/kg}$ ,  $\sigma = 58.9 \times 10^{-3} \text{ N/m}$ ; Table A-6, Saturated water, vapor (1 atm):  $\rho_v = 0.596 \text{ kg/m}^3$ ; Table A-6, Saturated water, liquid (10 atm = 10.133 bar,  $T_{\text{sat}} = 453.4 \text{ K} = 180.4^\circ\text{C}$ ):  $\rho_\ell = 886.7 \text{ kg/m}^3$ ,  $c_{p,\ell} = 4410 \text{ J/kg}\cdot\text{K}$ ,  $\mu_\ell = 149 \times 10^{-6} \text{ N}\cdot\text{s/m}^2$ ,  $\text{Pr}_\ell = 0.98$ ,  $h_{\text{fg}} = 2012 \text{ kJ/kg}$ ,  $\sigma = 42.2 \times 10^{-3} \text{ N/m}$ ; Table A-6, Water, vapor (10.133 bar):  $\rho_v = 5.155 \text{ kg/m}^3$ .

**ANALYSIS:** With  $\Delta T_e = 15^\circ\text{C}$ , we expect nucleate pool boiling. The Rohsenow correlation with  $C_{s,f} = 0.006$  and  $n = 1.0$  for the brass-water combination gives

$$q_s'' = \mu_\ell h_{\text{fg}} \left[ \frac{g(\rho_\ell - \rho_v)}{\sigma} \right]^{1/2} \left( \frac{c_{p,\ell} \Delta T_e}{C_{s,f} h_{\text{fg}} \text{Pr}_\ell^n} \right)^3$$

$$1 \text{ atm: } q_s'' = 279 \times 10^{-6} \text{ N}\cdot\text{s/m}^2 \times 2257 \times 10^3 \text{ J/kg} \left[ \frac{9.8 \text{ m/s}^2 (957.9 - 0.596) \text{ kg/m}^3}{58.9 \times 10^{-3} \text{ N/m}} \right]^{1/2} \times \left( \frac{4217 \text{ J/kg}\cdot\text{K} \times 15 \text{ K}}{0.006 \times 2257 \times 10^3 \text{ J/kg} \times 1.76^1} \right)^3 = 4.70 \text{ MW/m}^2$$

$$10 \text{ atm: } q_s'' = 23.8 \text{ MW/m}^2$$

From Example 10.1,  $q_{\text{max}}'' (1 \text{ atm}) = 1.26 \text{ MW/m}^2$ . To find the critical heat flux at 10 atm, use the correlation of Eq. 10.6 with  $C = 0.149$ ,

$$q_{\text{max}}'' = 0.149 h_{\text{fg}} \rho_v \left[ \sigma g(\rho_\ell - \rho_v) / \rho_v^2 \right]^{1/4}$$

$$q_{\text{max}}'' (10 \text{ atm}) = 0.149 \times 2012 \times 10^3 \text{ J/kg} \times 5.155 \text{ kg/m}^3 \times$$

$$\left[ \frac{42.2 \times 10^{-3} \text{ N/m} \times 9.8 \text{ m/s}^2 (886.7 - 5.16) \text{ kg/m}^3}{(5.155 \text{ kg/m}^3)^2} \right]^{1/4} = 2.97 \text{ MW/m}^2$$

For both conditions, the Rohsenow correlation predicts a heat flux that exceeds the maximum heat flux,  $q_{\text{max}}''$ . We conclude that the boiling condition with  $\Delta T_e = 15^\circ\text{C}$  for the brass-water combination is beyond the inflection point (P, see Fig. 10.4) where the boiling heat flux is no longer proportional to  $\Delta T_e^3$ .

$$q_s'' \approx q_{\text{max}}'' (1 \text{ atm}) \leq 1.26 \text{ MW/m}^2 \quad q_s'' \approx q_{\text{max}}'' (10 \text{ atm}) \leq 2.97 \text{ MW/m}^2. \quad <$$

## PROBLEM 10.20

**KNOWN:** Properties of dielectric fluid boiling at 1 atm on a horizontal platinum wire of 0.5 mm diameter. Nucleate boiling constants. Correction factor for small horizontal cylinders.

**FIND:** Temperature of wire when heated at 50% of critical heat flux.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions. (2) Nucleate pool boiling.

**PROPERTIES:** Dielectric fluid, given:  $T_{\text{sat}} = 34^\circ\text{C}$ ,  $\rho_\ell = 1400 \text{ kg/m}^3$ ,  $\rho_v = 7.2 \text{ kg/m}^3$ ,  $c_{p,\ell} = 1300 \text{ J/kg}\cdot\text{K}$ ,  $k_\ell = 0.075 \text{ W/m}\cdot\text{K}$ ,  $\nu_\ell = 0.32 \times 10^{-6} \text{ N}\cdot\text{s/m}^2$ ,  $\sigma = 12.4 \times 10^{-3} \text{ N/m}$ ,  $h_{fg} = 142 \text{ kJ/kg}$ .

**ANALYSIS:** The critical heat flux for a large horizontal cylinder can be estimated using Eq. 10.6, with  $C = 0.131$ .

$$\begin{aligned} q''_{\max,\text{large}} &= Ch_{fg}\rho_v \left[ \frac{\sigma g (\rho_\ell - \rho_v)}{\rho_v^2} \right]^{1/4} \\ &= 0.131 \times 142 \times 10^3 \text{ J/kg} \times 7.2 \text{ kg/m}^3 \\ &\quad \times \left[ \frac{12.4 \times 10^{-3} \text{ N/m} \times 9.8 \text{ m/s}^2 \times (1400 - 7.2) \text{ kg/m}^3}{(7.2 \text{ kg/m}^3)^2} \right]^{1/4} \\ &= 180 \text{ kW/m}^2 \end{aligned}$$

The Confinement number is given by  $Co = \sqrt{\sigma/[g(\rho_\ell - \rho_v)]}/R = 3.81$ , which is in the range of applicability of the expression for the correction factor,  $F$ ,

$$F = 0.89 + 2.27 \exp(-3.44Co^{-1/2}) = 0.89 + 2.27 \exp[-3.44(3.81)^{-1/2}] = 1.28$$

The wire is operated at 50% of the critical heat flux or,

$$q''_s = 0.5Fq''_{\max,\text{large}} = 0.5 \times 1.28 \times 180 \text{ kW/m}^2 = 115 \text{ kW/m}^2$$

The excess temperature can then be found from Eq. 10.5, the Rohsenow correlation,

$$q''_s = \mu_\ell h_{fg} \left[ \frac{g(\rho_\ell - \rho_v)}{\sigma} \right]^{1/2} \left( \frac{c_{p,\ell} \Delta T_e}{C_{s,f} h_{fg} Pr_\ell^n} \right)^3 = 115 \text{ kW/m}^2$$

Continued...

### PROBLEM 10.20 (Cont.)

Substituting numerical values, with  $\mu_\ell = \nu_\ell \rho_\ell = 4.48 \times 10^{-4} \text{ m/s}^2$  and  $\text{Pr}_\ell = \mu_\ell c_{p,\ell} / k_\ell = 7.77$ ,

$$4.48 \times 10^{-4} \text{ N} \cdot \text{s/m}^2 \times 142 \times 10^3 \text{ J/kg} \left[ \frac{9.8 \text{ m/s}^2 (1400 - 7.2) \text{ kg/m}^3}{12.4 \times 10^{-3} \text{ N/m}} \right]^{1/2} \times \\ \left( \frac{1300 \text{ J/kg} \cdot \text{K} \times \Delta T_e}{0.005 \times 142 \times 10^3 \text{ J/kg} \times 7.77^{1.7}} \right)^3 = 115 \times 10^3 \text{ W/m}^2$$

$$\Delta T_e = 21.4^\circ\text{C}$$

Thus

$$T_s = 34^\circ\text{C} + 21.4^\circ\text{C} = 55.4^\circ\text{C}$$

<

**COMMENTS:** The critical heat flux on the small wire is 28% higher than on a large cylinder.

## PROBLEM 10.21

**KNOWN:** Zuber-Kutateladze correlation for critical heat flux,  $q''_{\max}$ .

**FIND:** Pressure dependence of  $q''_{\max}$  for water; demonstrate maximum value occurs at approximately  $1/3 p_{\text{crit}}$ ; suggest coordinates for a universal curve to represent other fluids.

**ASSUMPTIONS:** Nucleate pool boiling conditions.

**PROPERTIES:** Table A-6, Water, saturated at various pressures; see below.

**ANALYSIS:** The Z-K correlation for estimating the critical heat flux, has the form

$$q''_{\max} = 0.149 \rho_v h_{fg} \left[ \frac{g \sigma (\rho_\ell - \rho_v)}{\rho_v^2} \right]^{1/4}$$

where the properties for saturation conditions are a function of pressure. The properties (Table A-6) and the values for  $q''_{\max}$  are as follows:

p (bar)	p/p <sub>c</sub>	$\rho_\ell$ (kg/m <sup>3</sup> )	$\rho_v$	$h_{fg}$ (kJ/kg)	$\sigma \times 10^3$ (N/m)	$q''_{\max}$ (MW/m <sup>2</sup> )
1.01	0.0045	957.9	0.59552257	58.9	1.258	
11.71	0.053	879.5	5.988	1989	40.7	3.138
26.40	0.120	831.3	13.05	1825	31.6	3.935
44.58	0.202	788.1	22.47	1679	24.5	4.398
61.19	0.277	755.9	31.55	1564	19.7	4.549
82.16	0.372	718.4	43.86	1429	15.0	4.520
123.5	0.557	648.9	72.99	1176	8.4	4.047
169.1	0.765	562.4	117.6	858	3.5	2.905
221.2	1.000	315.5	315.5	0	0	0

The  $q''_{\max}$  values are plotted as a function of  $p/p_c$ , where  $p_c$  is the critical pressure. Note the rapid decrease of  $h_{fg}$  and  $\sigma$  with increasing pressure. The universal curve coordinates would be  $q''_{\max} / q''_{\max}(1/3 p_{\text{crit}})$  vs.  $p/p_c$ .

<

## PROBLEM 10.22

**KNOWN:** Kutateladze's dimensional analysis and the bubble diameter parameter.

**FIND:** Verify the dimensional consistency of the critical heat flux expression.

**ASSUMPTIONS:** Nucleate pool boiling.

**ANALYSIS:** Kutateladze postulated that the critical flux was dependent upon four parameters,

$$q''_{\max} = q''_{\max}(h_{fg}, \rho_v, \sigma, D_b)$$

where  $D_b$  is the bubble diameter parameter having the form

$$D_b = [\sigma / g(\rho_\ell - \rho_v)]^{1/2}. \quad (1)$$

The form of the critical heat flux expression was presumed to be

$$q''_{\max} = C h_{fg} \rho_v^{1/2} D_b^{-1/2} \sigma^{1/2} \quad (2)$$

where  $C$  is a constant. It is not possible to derive this equation from a dimensional (Pi) analysis. We can only determine that the equation is dimensionally consistent. Using SI units, check Eq. (1) for  $D_b$ ,

$$D_b \Rightarrow \left[ (\text{Nm}^{-1}) (\text{m}^{-1}\text{s}^2) (\text{kg}^{-1}\text{m}^3) \right]^{1/2} \Rightarrow \left[ \text{N} \left( \frac{\text{s}^2}{\text{kg} \cdot \text{m}} \right) \text{m}^2 \right]^{1/2} \Rightarrow [\text{m}]$$

and in Eq. (2) for  $q''_{\max}$ ,

$$q''_{\max} \Rightarrow \left[ (\text{J kg}^{-1}) (\text{kg}^{1/2} \text{m}^{-3/2}) (\text{m}^{-1/2}) (\text{N}^{1/2} \text{m}^{-1/2}) \right] \Rightarrow \left[ \frac{\text{J}}{\text{s}} \cdot \left( \frac{\text{N} \cdot \text{s}^2}{\text{kg} \cdot \text{m}} \right)^{1/2} \text{m}^{-2} \right] \Rightarrow \left[ \frac{\text{W}}{\text{m}^2} \right].$$

Hence, the equations are dimensionally consistent.

**COMMENTS:** Dimensional (Pi) analysis yields the following result:  $q''_{\max} / \rho_v h_{fg}^{2/3} = f(\sigma / \rho_v h_{fg} D_b)$ .

If  $f(\sigma / \rho_v h_{fg} D_b) = C(\sigma / \rho_v h_{fg} D_b)^{1/2}$ , we recover Eq.(2).

### PROBLEM 10.23

**KNOWN:** Thickness and thermal conductivity of a silicon chip. Properties of saturated fluorocarbon liquid.

**FIND:** (a) Temperature at bottom surface of chip for a prescribed heat flux and 90% of CHF, (b) Effect of heat flux on chip surface temperatures; maximum allowable heat flux.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Uniform heat flux and adiabatic sides, hence one-dimensional conduction in chip, (3) Constant properties, (4) Nucleate boiling in liquid.

**PROPERTIES:** Saturated fluorocarbon (given):  $c_{p,l} = 1100 \text{ J/kg}\cdot\text{K}$ ,  $h_{fg} = 84,400 \text{ J/kg}$ ,  $\rho_l = 1619.2 \text{ kg/m}^3$ ,  $\rho_v = 13.4 \text{ kg/m}^3$ ,  $\sigma = 8.1 \times 10^{-3} \text{ kg/s}^2$ ,  $\mu_l = 440 \times 10^{-6} \text{ kg/m}\cdot\text{s}$ ,  $\text{Pr}_l = 9.01$ .

**ANALYSIS:** (a) Energy balances at the top and bottom surfaces yield  $q_o'' = q''_{cond} = k_s (T_o - T_s)/L = q_s''$ ; where  $T_s$  and  $q_s''$  are related by the Rohsenow correlation,

$$T_s - T_{sat} = \frac{C_{s,f} h_{fg} \text{Pr}_l^n}{c_{p,l}} \left( \frac{q_s''}{\mu_l h_{fg}} \right)^{1/3} \left[ \frac{\sigma}{g(\rho_l - \rho_v)} \right]^{1/6}$$

Hence, for  $q_s'' = 5 \times 10^4 \text{ W/m}^2$ ,

$$T_s - T_{sat} = \frac{0.005(84,400 \text{ J/kg})9.01^{1.7}}{1100 \text{ J/kg}\cdot\text{K}} \left( \frac{5 \times 10^4 \text{ W/m}^2}{440 \times 10^{-6} \text{ kg/m}\cdot\text{s} \times 84,400 \text{ J/kg}} \right)^{1/3} \times \left[ \frac{8.1 \times 10^{-3} \text{ kg/s}^2}{9.8 \text{ m/s}^2 (1619.2 - 13.4) \text{ kg/m}^3} \right]^{1/6} = 15.9^\circ \text{C}$$

$$T_s = (15.9 + 57)^\circ \text{C} = 72.9^\circ \text{C}.$$

From Fourier's law,

$$T_o = T_s + \frac{q_o'' L}{k_s} = 72.9^\circ \text{C} + \frac{5 \times 10^4 \text{ W/m}^2 \times 0.0025 \text{ m}}{135 \text{ W/m}\cdot\text{K}} = 73.8^\circ \text{C} \quad <$$

For a heat flux which is 90% of the critical heat flux ( $C_1 = 0.9$ ), it follows that

$$q_o'' = 0.9 q_{max}'' = 0.9 \times 0.149 h_{fg} \rho_v \left[ \frac{\sigma g (\rho_l - \rho_v)}{\rho_v^2} \right]^{1/4} = 0.9 \times 0.149 \times 84,400 \text{ J/kg} \times 13.4 \text{ kg/m}^3$$

Continued...

**PROBLEM 10.23 (Cont.)**

$$\times \left[ \frac{8.1 \times 10^{-3} \text{ kg/s}^2 \times 9.8 \text{ m/s}^2 (1619.2 - 13.4) \text{ kg/m}^3}{(13.4 \text{ kg/m}^3)^2} \right]^{1/4}$$

$$q''_o = 0.9 \times 15.5 \times 10^4 \text{ W/m}^2 = 13.9 \times 10^4 \text{ W/m}^2$$

From the results of the previous calculation and the Rohsenow correlation, it follows that

$$\Delta T_e = 15.9^\circ \text{C} \left( q''_o / 5 \times 10^4 \text{ W/m}^2 \right)^{1/3} = 15.9^\circ \text{C} (13.9/5)^{1/3} = 22.4^\circ \text{C}$$

Hence,  $T_s = 79.4^\circ \text{C}$  and

$$T_o = 79.4^\circ \text{C} + \frac{13.9 \times 10^4 \text{ W/m}^2 \times 0.0025 \text{ m}}{135 \text{ W/m} \cdot \text{K}} = 82^\circ \text{C}$$

<

(b) Using the energy balance equations with the *Correlations* Toolpad of IHT to perform the parametric calculations for  $0.2 \leq C_1 \leq 0.9$ , the following results are obtained.

The chip surface temperatures, as well as the difference between temperatures, increase with increasing heat flux. The maximum chip temperature is associated with the bottom surface, and  $T_o = 80^\circ \text{C}$  corresponds to

$$q''_{o,\max} = 11.3 \times 10^4 \text{ W/m}^2$$

<

which is 73% of CHF ( $q''_{\max} = 15.5 \times 10^4 \text{ W/m}^2$ ).

**COMMENTS:** Many of today's VLSI chip designs involve heat fluxes well in excess of  $15 \text{ W/cm}^2$ , in which case pool boiling in a fluorocarbon would not be an appropriate means of heat dissipation.

### PROBLEM 10.24

**KNOWN:** Boiling water at 1 atm pressure on moon where the gravitational field is 1/6 that of the earth.

**FIND:** Critical heat flux.

**ASSUMPTIONS:** Nucleate pool boiling conditions.

**PROPERTIES:** Table A-6, Water (1 atm):  $T_{\text{sat}} = 100^\circ\text{C}$ ,  $\rho_\ell = 957.9 \text{ kg/m}^3$ ,  $\rho_v = 0.5955 \text{ kg/m}^3$ ,  $h_{\text{fg}} = 2257 \text{ kJ/kg}$ ,  $\sigma = 58.9 \times 10^{-3} \text{ N/m}$ .

**ANALYSIS:** The critical heat flux is given by Eq. 10.6 with  $C=0.149$ .

$$q''_{\text{max}} = 0.149 \rho_v^{1/2} h_{\text{fg}} [\sigma g (\rho_\ell - \rho_v)]^{1/4}.$$

The relation predicts the critical flux dependency on the gravitational acceleration as

$$q''_{\text{max}} \sim g^{1/4}.$$

It follows that if  $g_{\text{moon}} = (1/6) g_{\text{earth}}$  and recognizing  $q''_{\text{max,e}} = 1.26 \text{ MW/m}^2$  for earth acceleration (see Example 10.1),

$$q''_{\text{max,moon}} = q''_{\text{max,earth}} (g_{\text{moon}} / g_{\text{earth}})^{1/4}$$

$$q''_{\text{max,moon}} = 1.26 \frac{\text{MW}}{\text{m}^2} \left(\frac{1}{6}\right)^{1/4} = 0.81 \text{ MW/m}^2. \quad <$$

**COMMENTS:** Note from the discussion in Section 10.4.5 that the  $g^{1/4}$  dependence on the critical heat flux has been experimentally confirmed. In the nucleate pool boiling regime, the heat flux is nearly independent of the gravitational field.

## PROBLEM 10.25

**KNOWN:** Concentric stainless steel tubes packed with dense boron nitride powder. Inner tube has heat generation while outer tube surface is exposed to boiling heat flux,  $q_s'' = C(T_s - T_{sat})^3$ . Saturation temperature of boiling liquid and temperature of the outer tube surface.

**FIND:** Expressions for the maximum temperature in the stainless steel (ss) tubes and in the boron nitride (bn).

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) One-dimensional (cylindrical) steady-state heat transfer in tubes and boron nitride.

**ANALYSIS:** Construct the thermal circuit shown above where  $R'_{23}$  and  $R'_{34}$  represent the resistances due to the boron nitride between  $r_2$  and  $r_3$  and to the outer stainless steel tube, respectively. From an overall energy balance,

$$q'_{gen} = q'_{boil}$$

$$\dot{q}\pi(r_2^2 - r_1^2) = (2\pi r_4)C(T_s - T_{sat})^3.$$

With prescribed values for  $T_{sat}$ ,  $T_s$  and  $C$ , the required volumetric heating of the inner stainless steel tube is

$$\dot{q} = \frac{2r_4}{(r_2^2 - r_1^2)} C(T_s - T_{sat})^3.$$

Using the thermal circuit, we can write expressions for the *maximum* temperature of the stainless steel (ss) and boron nitride (bn).

*Stainless steel:*  $T_{ss,max}$  occurs at  $r_1$ . Using the results of Section 3.5.2, the temperature distribution in a radial tube of inner and outer radii  $r_1$  and  $r_2$  is

$$T(r) = -\frac{\dot{q}}{4k_{ss}}r^2 + C_1 \ln r + C_2$$

for which the boundary conditions are

$$\text{BC\#1:} \quad r = r_1 \quad \frac{dT}{dr} = 0 \quad 0 = -\frac{\dot{q}}{4k_{ss}}2r_1 + \frac{C_1}{r_1} + 0 \rightarrow C_1 = +\frac{\dot{q}r_1^2}{2k_{ss}}$$

Continued ...

**PROBLEM 10.25 (Cont.)**

$$\text{BC \#2:} \quad r = r_2 \quad T(r_2) = T_2 \quad T_2 = -\frac{\dot{q}}{4k_{ss}}r_2^2 + \frac{\dot{q}r_1^2}{2k_{ss}}\ln r_2 + C_2$$

$$C_2 = T_2 + \frac{\dot{q}}{4k_{ss}}r_2^2 - \frac{\dot{q}r_1^2}{2k_{ss}}\ln r_2$$

Hence,

$$T(r) = -\frac{\dot{q}}{4k_{ss}}(r^2 - r_2^2) + \frac{\dot{q}r_1^2}{2k_{ss}}\ln(r/r_2) + T_2.$$

Using the thermal circuit, find  $T_2$  in terms of known parameters  $T_s$ ,  $T_{\text{sat}}$  and  $C$ .

$$\frac{T_2 - T_s}{R'_{23} + R'_{34}} = (2\pi r_4)C(T_s - T_{\text{sat}})^3.$$

Hence, the maximum temperature in the inner stainless steel tube ( $r = r_1$ ) is

$$T_{\text{ss,max}} = T(r_1) = -\frac{\dot{q}}{4k_{ss}}(r_1^2 - r_2^2) + \frac{\dot{q}r_1^2}{2k_{ss}}\ln(r_1/r_2) + T_s$$

$$+ (R'_{23} + R'_{34})(2\pi r_4)C(T_s - T_{\text{sat}})^3 \quad <$$

where from Eq. 3.33

$$R'_{23} = \frac{\ln(r_3/r_2)}{2\pi k_{\text{bn}}} \quad R'_{34} = \frac{\ln(r_4/r_3)}{2\pi k_{\text{ss}}}.$$

*Boron nitride:*  $T_{\text{bn,max}}$  occurs at  $r_1$ . Hence

$$T_{\text{bn,max}} = T(r_1) \quad <$$

as derived above for the inner stainless steel tube.

## PROBLEM 10.26

**KNOWN:** Operating conditions of apparatus used to determine surface boiling characteristics.

**FIND:** (a) Nucleate boiling coefficient for special coating, (b) Surface temperature as a function of heat flux; apparatus temperatures for a prescribed heat flux; applicability of nucleate boiling correlation for a specified heat flux.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) One-dimensional, steady-state conduction in the bar, (2) Water is saturated at 1 atm, (3) Applicability of Rohsenow correlation with  $n = 1$ .

**PROPERTIES:** Table A.6, saturated water (100°C):  $\rho_\ell = 957.9 \text{ kg/m}^3$ ,  $c_{p,\ell} = 4217 \text{ J/kg}\cdot\text{K}$ ,  $\mu_\ell = 279 \times 10^{-6} \text{ N}\cdot\text{s/m}^2$ ,  $\text{Pr}_\ell = 1.76$ ,  $h_{fg} = 2.257 \times 10^6 \text{ J/kg}$ ,  $\sigma = 0.0589 \text{ N/m}$ ,  $\rho_v = 0.5955 \text{ kg/m}^3$ .

**ANALYSIS:** (a) The coefficient  $C_{s,f}$  associated with Eq. 10.5 may be determined if  $q_s''$  and  $T_s$  are known. Applying Fourier's law between  $x_1$  and  $x_2$ ,

$$q_s'' = q_{\text{cond}}'' = k \frac{T_2 - T_1}{x_2 - x_1} = 400 \text{ W/m}\cdot\text{K} \times \frac{(158.6 - 133.7)^\circ\text{C}}{0.015 \text{ m}} = 6.64 \times 10^5 \text{ W/m}^2$$

Since the temperature distribution in the bar is linear,  $T_s = T_1 - (dT/dx)x_1 = T_1 - [(T_2 - T_1)/(x_2 - x_1)]x_1$ . Hence,

$$T_s = 133.7^\circ\text{C} - \left[ 24.9^\circ\text{C}/0.015 \text{ m} \right] 0.01 \text{ m} = 117.1^\circ\text{C}$$

From Eq. 10.5, with  $n = 1$ ,

$$C_{s,f} = \frac{c_{p,\ell} \Delta T_e}{h_{fg} \text{Pr}_\ell} \left( \frac{\mu_\ell h_{fg}}{q_s''} \right)^{1/3} \left[ \frac{g(\rho_\ell - \rho_v)}{\sigma} \right]^{1/6}$$

$$C_{s,f} = \frac{4217 \text{ J/kg}\cdot\text{K} (17.1^\circ\text{C})}{2.257 \times 10^6 \text{ J/kg} (1.76)} \left( \frac{279 \times 10^{-6} \text{ kg/s}\cdot\text{m} \times 2.257 \times 10^6 \text{ J/kg}}{6.64 \times 10^5 \text{ W/m}^2} \right)^{1/3} \left[ \frac{9.8 \text{ m/s}^2 \times 957.3 \text{ kg/m}^3}{0.0589 \text{ kg/s}^2} \right]^{1/6}$$

$$C_{s,f} = 0.0131 \quad \leftarrow$$

(b) Using the appropriate IHT *Correlations and Properties* Toolpads, the following portion of the nucleate boiling regime was computed.

Continued...

### PROBLEM 10.26 (Cont.)

For  $q_s'' = 10^6 \text{ W/m}^2 = q_{\text{cond}}''$ ,  $T_s = 119.6^\circ\text{C}$  and

$$T_1 = 144.6^\circ\text{C} \quad \text{and} \quad T_2 = 182.1^\circ\text{C}$$

With the critical heat flux given by Eq. 10.6 with  $C=0.149$ ,

$$q_{\text{max}}'' = 0.149 h_{\text{fg}} \rho_v \left[ \frac{\sigma g (\rho_\ell - \rho_v)}{\rho_v^2} \right]^{1/4}$$

$$q_{\text{max}}'' = 0.149 \left( 2.257 \times 10^6 \text{ J/kg} \right) 0.5955 \text{ kg/m}^3 \left[ \frac{0.0589 \text{ kg/s}^2 \times 9.8 \text{ m/s}^2 \times 957.3 \text{ kg/m}^3}{(0.5955 \text{ kg/m}^3)^2} \right]^{1/4}$$

$$q_{\text{max}}'' = 1.25 \times 10^6 \text{ W/m}^2$$

Since  $q_s'' = 1.5 \times 10^6 \text{ W/m}^2 > q_{\text{max}}''$ , the heat flux exceeds that associated with nucleate boiling and the foregoing results can not be used.

**COMMENTS:** For  $q_s'' > q_{\text{max}}''$ , conditions correspond to film boiling, for which  $T_s$  may exceed acceptable operating conditions.

## PROBLEM 10.27

**KNOWN:** Small copper sphere, initially at a uniform temperature,  $T_i$ , greater than that corresponding to the Leidenfrost point,  $T_D$ , suddenly immersed in a large fluid bath maintained at  $T_{sat}$ .

**FIND:** (a) Sketch the temperature-time history,  $T(t)$ , during the quenching process; indicate temperature corresponding to  $T_i$ ,  $T_D$ , and  $T_{sat}$ , identify regimes of film, transition and nucleate boiling and the single-phase convection regime; identify key features; and (b) Identify times(s) in this quenching process when you expect the surface temperature of the sphere to deviate most from its center temperature.

**SCHEMATIC:**

**ANALYSIS:** (a) In the right-hand schematic above, the quench process is shown on the “boiling curve” similar to Figure 10.4. Beginning at an initial temperature,  $T_i > T_D$ , the process proceeds as indicated by the arrows: film regime from  $i$  to  $D$ , transition regime from  $D$  to  $C$ , nucleate regime from  $C$  to  $A$ , and single-phase (free convection) from  $A$  to the condition when  $\Delta T_e = T_s - T_{sat} = 0$ . The quench process is shown on the temperature-time plot below and the boiling regimes and key temperatures are labeled..

The highest temperature-time change should occur in the nucleate pool boiling regime, especially near the critical flux condition,  $T_c$ . The lowest temperature-time change will occur in the single-phase, free convection regime.

(b) The difference between the center and surface temperatures will be greatest when the Biot number is largest, which occurs in regimes with the highest convection coefficients. The convection coefficient is maximum at point  $P$  on the boiling curve of Fig. 10.4, which falls between points  $C$  and  $A$  on the above plots.

## PROBLEM 10.28

**KNOWN:** A sphere (aluminum alloy 2024) with a uniform temperature of 500°C and emissivity of 0.25 is suddenly immersed in a saturated water bath maintained at atmospheric pressure.

**FIND:** (a) The total heat transfer coefficient for the initial condition; fraction of the total coefficient contributed by radiation; and (b) Estimate the temperature of the sphere 30 s after it has been immersed in the bath.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Water exposed to standard atmospheric pressure and uniform temperature,  $T_{\text{sat}}$ , and (2) Lumped capacitance method is valid.

**PROPERTIES:** See Comment 2; properties obtained with *IHT* code.

**ANALYSIS:** (a) For the initial condition with  $T_s = 500^\circ\text{C}$ , *film boiling* will occur and the coefficients due to convection and radiation are estimated using Eqs. 10.8 and 10.11, respectively,

$$\overline{\text{Nu}}_D = \frac{\bar{h}_{\text{conv}} D}{k_v} = C \left[ \frac{g(\rho_\ell - \rho_v) h'_{\text{fg}} D^3}{\nu_v k_v (T_s - T_{\text{sat}})} \right]^{1/4} \quad (1)$$

$$\bar{h}_{\text{rad}} = \frac{\varepsilon \sigma (T_s^4 - T_{\text{sat}}^4)}{T_s - T_{\text{sat}}} \quad (2)$$

where  $C = 0.67$  for spheres and  $\sigma = 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4$ . The corrected latent heat is

$$h'_{\text{fg}} = h_{\text{fg}} + 0.8 c_{p,v} (T_s - T_{\text{sat}}) \quad (3)$$

The total heat transfer coefficient is given by Eq. 10.9 as

$$\bar{h}^{4/3} = \bar{h}_{\text{conv}}^{4/3} + \bar{h}_{\text{rad}} \cdot \bar{h}^{1/3} \quad (4)$$

The vapor properties are evaluated at the film temperature,

$$T_f = (T_s + T_{\text{sat}}) / 2 \quad (5)$$

while the liquid properties are evaluated at the saturation temperature. Using the foregoing relations in *IHT* (see Comments), the following results are obtained.

$\overline{\text{Nu}}_D$	$\bar{h}_{\text{cnv}} \left( \text{W/m}^2 \cdot \text{K} \right)$	$\bar{h}_{\text{rad}} \left( \text{W/m}^2 \cdot \text{K} \right)$	$\bar{h} \left( \text{W/m}^2 \cdot \text{K} \right)$	
85.5	171	12.0	180	<

The radiation process contribution is 6.7% that of the total heat rate.

(b) For the lumped-capacitance method, from Section 5.3, the energy balance is

$$-\bar{h} A_s (T_s - T_{\text{sat}}) = \rho_s V c_s \frac{dT_s}{dt} \quad (6)$$

where  $\rho_s$  and  $c_s$  are properties of the sphere. To determine  $T_s(t)$ , it is necessary to evaluate  $\bar{h}$  as a function of  $T_s$ . Using the foregoing relations in *IHT* (see Comments), the sphere temperature after 30s is

$$T_s(30\text{s}) = 300^\circ\text{C}. \quad <$$

Continued ...

## PROBLEM 10.28 (Cont.)

**COMMENTS:** (1) The Biot number associated with the aluminum alloy sphere cooling process for the initial condition is  $Bi = 0.019$ . Hence, the lumped-capacitance method is valid.

(2) The *IHT* code to solve this application uses the film-boiling correlation, the water properties functions, and the lumped capacitance energy balance, Eq. (6). The results for part (a), including the properties required of the correlation, are shown at the outset of the code.

## PROBLEM 10.29

**KNOWN:** Initial temperature of hot rotor, temperature of water quenching bath, rotor orientation.

**FIND:** (a) Sketch of the rotor temperature versus time for Orientation A, (b) Relative cooling rate of the rotor for Orientation B.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Lumped capacitance behavior, (2) Constant properties.

**ANALYSIS:** Assuming lumped capacitance behavior for the rotor, the time rate of change of the rotor temperature is proportional to the instantaneous heat flux from the rotor surface. In either orientation, the quenching process begins at an initial rotor temperature associated with film boiling (see Fig. 10.4 and the RHS schematic).

(a) For Orientation A, the rotor temperature versus time is shown in the sketch below. In the film boiling regime, the slope of the  $T(t)$  curve continually decreases as the boiling heat flux decreases until the Leidenfrost point (Point D) is reached. Between Points D and C, transition boiling occurs and the heat flux increases as the rotor temperature decreases until the critical heat flux value (Point C) is reached. Point C corresponds to a local maximum rotor cooling rate. As the rotor continues to cool, the heat flux continues to decrease throughout the nucleate boiling regime until Point A is reached, corresponding to the curtailment of boiling, the onset of free convection cooling, and very slow decreases in the rotor temperature with time.

(b) For Orientation A, vapor rises unimpeded from the vicinity of the rotor. For Orientation B, however, the rotor obstructs the movement of vapor away from the bottom surface of the rotor. Hence, even in the nucleate boiling regime, an insulating vapor blanket would tend to form on the bottom surface, resulting in slower cooling relative to Orientation A.

### PROBLEM 10.30

**KNOWN:** Steel bar upon removal from a furnace immersed in water bath.

**FIND:** Initial heat transfer rate from bar.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Uniform bar surface temperature, (2) Film pool boiling conditions.

**PROPERTIES:** Table A-6, Water, liquid (1 atm,  $T_{\text{sat}} = 100^\circ\text{C}$ ):  $\rho_\ell = 957.9 \text{ kg/m}^3$ ,  $h_{\text{fg}} = 2257 \text{ kJ/kg}$ ; Table A-4, Water, vapor ( $T_f = (T_s + T_{\text{sat}})/2 = 550\text{K}$ ):  $\rho_v = 0.4005 \text{ kg/m}^3$ ,  $c_{p,v} = 1997 \text{ J/kg}\cdot\text{K}$ ,  $\nu_v = 47.04 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k_v = 0.0379 \text{ W/m}\cdot\text{K}$ .

**ANALYSIS:** The total heat transfer rate from the bar at the instant of time it is removed from the furnace and immersed in the water is

$$q_s = \bar{h} A_s (T_s - T_{\text{sat}}) = \bar{h} A_s \Delta T_e \quad (1)$$

where  $\Delta T_e = 455 - 100 = 355\text{K}$ . According to the boiling curve of Figure 10.4, with such a high  $\Delta T_e$ , film pool boiling will occur. From Eq. 10.9 or 10.10,

$$\bar{h}^{4/3} = \bar{h}_{\text{conv}}^{4/3} + \bar{h}_{\text{rad}} \cdot \bar{h}^{1/3} \quad \text{or} \quad \bar{h} = \bar{h}_{\text{conv}} + \frac{3}{4} \bar{h}_{\text{rad}} \quad (\text{if } h_{\text{conv}} > h_{\text{rad}}). \quad (2)$$

To estimate the convection coefficient, use Eq. 10.8,

$$\overline{\text{Nu}}_D = \frac{\bar{h}_{\text{conv}} D}{k_v} = C \left[ \frac{g(\rho_\ell - \rho_v) h'_{\text{fg}} D^3}{\nu_v k_v \Delta T_e} \right]^{1/4} \quad (3)$$

where  $C = 0.62$  for the horizontal cylinder and  $h'_{\text{fg}} = h_{\text{fg}} + 0.8 c_{p,v} (T_s - T_{\text{sat}})$ . Find

$$\bar{h}_{\text{conv}} = \frac{0.0379 \text{ W/m}\cdot\text{K}}{0.020 \text{ m}} \cdot 0.62 \left[ \frac{9.8 \text{ m/s}^2 (957.9 - 0.4005) \text{ kg/m}^3 \left[ 2257 \times 10^3 + 0.8 \times 1997 \times 355 \right] \text{ J/kg} (0.020 \text{ m})^3}{(47.04 \times 10^{-6}) \text{ m}^2/\text{s} \times 0.0379 \text{ W/m}\cdot\text{K} \times 355 \text{ K}} \right]^{1/4}$$

$$\bar{h}_{\text{conv}} = 159 \text{ W/m}^2 \cdot \text{K}.$$

To estimate the radiation coefficient, use Eq. 10.11,

$$\bar{h}_{\text{rad}} = \frac{\varepsilon \sigma (T_s^4 - T_{\text{sat}}^4)}{T_s - T_{\text{sat}}} = \frac{0.9 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (728^4 - 373^4) \text{ K}^4}{355 \text{ K}} = 37.6 \text{ W/m}^2 \cdot \text{K}.$$

Substituting numerical values into the simpler form of Eq. (2), find

$$\bar{h} = (159 + (3/4)37.6) \text{ W/m}^2 \cdot \text{K} = 187 \text{ W/m}^2 \cdot \text{K}.$$

Using Eq. (1), the heat rate, with  $A_s = \pi D L$ , is

$$q_s = 187 \text{ W/m}^2 \cdot \text{K} (\pi \times 0.020 \text{ m} \times 0.200 \text{ m}) \times 355 \text{ K} = 835 \text{ W}. \quad <$$

**COMMENTS:** For these conditions, the combined radiation and convection heat transfer coefficient is 18% larger than the convection coefficient alone.

### PROBLEM 10.31

**KNOWN:** Electrical conductor with prescribed surface temperature immersed in water.

**FIND:** (a) Power dissipation per unit length,  $q'_s$  and (b) Compute and plot  $q'_s$  as a function of surface temperature  $250 \leq T_s \leq 650^\circ\text{C}$  for conductor diameters of 1.5, 2.0, and 2.5 mm; separately plot the percentage contribution of radiation as a function of  $T_s$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Water saturated at 1 atm, (3) Film pool boiling.

**PROPERTIES:** Table A-6, Water, liquid (1 atm,  $T_{\text{sat}} = 100^\circ\text{C}$ ):  $\rho_\ell = 957.9 \text{ kg/m}^3$ ,  $h_{\text{fg}} = 2257 \text{ kJ/kg}$ ; Table A-4, Water, vapor ( $T_f = (T_s + T_{\text{sat}}) / 2 = 600 \text{ K}$ ):  $\rho_v = 0.3652 \text{ kg/m}^3$ ,  $c_{p,v} = 2026 \text{ J/kg}\cdot\text{K}$ ,  $\nu_v = 56.60 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k_v = 0.0422 \text{ W/m}\cdot\text{K}$ .

**ANALYSIS:** (a) The heat rate per unit length due to electrical power dissipation is

$$q'_s = \frac{q_s}{\ell} = \bar{h} \frac{A_s}{\ell} (T_s - T_{\text{sat}}) = \bar{h} \pi D \Delta T_e$$

where  $\Delta T_e = (555 - 100)^\circ\text{C} = 455^\circ\text{C}$ . According to the boiling curve of Figure 10.4, with such a high  $\Delta T_e$ , film pool boiling will occur. From Eq 10.9 or 10.10,

$$\bar{h}^{4/3} = \bar{h}_{\text{conv}}^{4/3} + \bar{h}_{\text{rad}} \cdot \bar{h}^{1/3} \quad \text{or} \quad \bar{h} = \bar{h}_{\text{conv}} + \frac{3}{4} \bar{h}_{\text{rad}} \quad (\text{if } \bar{h}_{\text{conv}} > \bar{h}_{\text{rad}}).$$

To estimate the convection coefficient, use Eq. 10.8,

$$\overline{\text{Nu}}_D = \frac{\bar{h}_{\text{conv}} D}{k_v} = C \left[ \frac{g(\rho_\ell - \rho_v) h'_{\text{fg}} D^3}{\nu_v k_v \Delta T_e} \right]^{1/4}$$

where  $C = 0.62$  for the horizontal cylinder and  $h'_{\text{fg}} = h_{\text{fg}} + 0.8c_{p,v} (T_s - T_{\text{sat}})$ . Find

$$\bar{h}_{\text{conv}} = \frac{0.0422 \text{ W/m}\cdot\text{K}}{0.002 \text{ m}} \times 0.62 \left[ \frac{9.8 \text{ m/s}^2 (957.9 - 0.3652) \text{ kg/m}^3 \left[ 2257 \times 10^3 + 0.8 \times 2026 \times 455 \right] \text{ J/kg} (0.002 \text{ m})^3}{(56.60 \times 10^{-6}) \text{ m}^2/\text{s} \times 0.0422 \text{ W/m}\cdot\text{K} \times 455 \text{ K}} \right]^{1/4}$$

$$\bar{h}_{\text{conv}} = 279 \text{ W/m}^2 \cdot \text{K}.$$

To estimate the radiation coefficient, use Eq. 10.11.

$$\bar{h}_{\text{rad}} = \frac{\varepsilon \sigma (T_s^4 - T_{\text{sat}}^4)}{T_s - T_{\text{sat}}} = \frac{0.5 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (828^4 - 373^4) \text{ K}^4}{455 \text{ K}} = 28 \text{ W/m}^2 \cdot \text{K}.$$

Since  $\bar{h}_{\text{conv}} > \bar{h}_{\text{rad}}$ , the simpler form of Eq. 10.10 is appropriate. Find,

$$\bar{h} = (279 + (3/4) \times 28) \text{ W/m}^2 \cdot \text{K} = 300 \text{ W/m}^2 \cdot \text{K}$$

Continued...

### PROBLEM 10.31 (Cont.)

The heat rate is

$$q' = 300 \text{ W/m}^2 \cdot \text{K} \times \pi(0.002\text{m}) \times 455 \text{ K} = 858 \text{ kW/m.}$$

<

(b) Using the *IHT Correlation Tool, Boiling, Film Pool Boiling*, combined with the *Properties Tool for Water Vapor*, the heat rate,  $q'$ , was calculated as a function of the surface temperature,  $T_s$ , for conductor diameters of 1.5, 2.0, and 2.5 mm. Also plotted below is the ratio (%) of  $q'_{\text{rad}}/q'$  as a function of surface temperature.

From the  $q'$  vs.  $T_s$  plot, note that the heat rate increases with increasing surface temperature, and as expected, the heat rate increases with increasing diameter. From the  $q'_{\text{rad}}/q'$  vs.  $T_s$  plot, the maximum contribution by radiation is 14%, and occurs at the maximum surface temperature.

### PROBLEM 10.32

**KNOWN:** Diameter and emissivity of heated platinum wire in saturated water at atmospheric pressure. Water vapor properties at film temperature.

**FIND:** Heat flux from wire when it is at its melting temperature and corresponding centerline temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Film pool boiling occurs.

**PROPERTIES:** Table A.1, Platinum:  $T_{\text{melt}} = 2045 \text{ K}$ ,  $k_p = 99.4 \text{ W/m}\cdot\text{K}$ . Table A.6, Saturated water, liquid ( $T_{\text{sat}} = 100^\circ\text{C}$ , 1 atm):  $\rho_\ell = 957.9 \text{ kg/m}^3$ ,  $h_{fg} = 2257 \text{ kJ/kg}$ ; Water vapor at film temperature ( $T_f = 1209 \text{ K}$ , 1 atm), given:  $\rho_v = 0.189 \text{ kg/m}^3$ ,  $c_{p,v} = 2404 \text{ J/kg}\cdot\text{K}$ ,  $\nu_v = 231 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k_v = 0.113 \text{ W/m}\cdot\text{K}$ .

**ANALYSIS:** The heat flux is

$$q_s'' = \bar{h}(T_s - T_{\text{sat}}) = \bar{h}\Delta T_e \quad (1)$$

where  $\Delta T_e = (2045 - 373)\text{K} = 1672$  is indicative of film boiling. From Eq. 10.9,

$$\bar{h}^{4/3} = \bar{h}_{\text{conv}}^{4/3} + \bar{h}_{\text{rad}}\bar{h}^{1/3}$$

For  $\bar{h}_{\text{conv}}$  use Eq. 10.8 with  $C = 0.62$  for a horizontal cylinder,

$$\text{Nu}_D = \frac{\bar{h}_{\text{conv}}D}{k_v} = C \left[ \frac{g(\rho_\ell - \rho_v)h'_{fg}D^3}{\nu_v k_v (T_s - T_{\text{sat}})} \right]^{1/4}$$

$$\frac{\bar{h}_{\text{conv}} \times 0.001 \text{ m}}{0.113 \text{ W/m}\cdot\text{K}} = 0.62 \left[ \frac{9.8 \text{ m/s}^2 (957.9 - 0.189) \text{ kg/m}^3 \times 5473 \times 10^3 \text{ J/kg} (0.001 \text{ m})^3}{231 \times 10^{-6} \text{ m}^2/\text{s} \times 0.113 \text{ W/m}\cdot\text{K} (2045 - 373) \text{ K}} \right]^{1/4}$$

$$\bar{h}_{\text{conv}} = 410 \text{ W/m}^2 \cdot \text{K}$$

where

$h'_{fg} = h_{fg} + 0.8c_{p,v}(T_s - T_{\text{sat}}) = 2257 \text{ kJ/kg} + 0.8 \times 2.404 \text{ kJ/kg}\cdot\text{K} (2045 - 373) \text{ K} = 5473 \text{ kJ/kg}$ . To estimate the radiation coefficient, use Eq. 10.11,

$$\bar{h}_{\text{rad}} = \frac{\varepsilon\sigma(T_s^4 - T_{\text{sat}}^4)}{T_s - T_{\text{sat}}} = \frac{0.80 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (2045^4 - 373^4) \text{ K}^4}{(2045 - 373) \text{ K}} = 474 \text{ W/m}^2 \cdot \text{K}.$$

Continued...

### PROBLEM 10.32 (Cont.)

Then Eq. 10.9 becomes

$$\bar{h}^{4/3} = \left(410 \text{ W/m}^2 \cdot \text{K}\right)^{4/3} + \left(474 \text{ W/m}^2 \cdot \text{K}\right) \bar{h}^{1/3}$$

Solving iteratively, find  $\bar{h} = 802 \text{ W/m}^2 \cdot \text{K}$ . Then, using Eq. (1), find

$$q_s'' = 802 \text{ W/m}^2 \cdot \text{K} (2045 - 373) \text{ K} = 1.34 \text{ MW/m}^2. \quad <$$

The volumetric heat generation rate due to the electrical current can be found from the energy balance,

$$q_s'' \pi D = \dot{q} \pi D^2 / 4 \quad \dot{q} = 4q_s'' / D = 4 \times 1.34 \text{ MW/m}^2 / 0.001 \text{ m} = 5.36 \times 10^9 \text{ W/m}^3$$

From Eq. 3.59,

$$T_c = T(r=0) = \frac{\dot{q} r_0^2}{4k} + T_s$$

$$= \frac{5.36 \times 10^9 \text{ W/m}^2 \times (0.0005 \text{ m})^2}{4 \times 99.4 \text{ W/m} \cdot \text{K}} + 2045 \text{ K} = 2048 \text{ K} \quad <$$

**COMMENTS:** (1) The film boiling heat flux which causes the platinum wire to melt is not much greater than the critical heat flux. A system which was operating near the critical heat flux and underwent a small, unintentional increase in electrical power could cause destruction of the wire. (2) Radiation accounts for 60% of the heat flux from the wire at burnout. (3) Radial temperature differences in the wire are small because of the small radius and large thermal conductivity.

### PROBLEM 10.33

**KNOWN:** Heater element of 5-mm diameter maintained at a surface temperature of 350°C when immersed in water under atmospheric pressure; element sheath is stainless steel with a mechanically polished finish having an emissivity of 0.25.

**FIND:** (a) The electrical power dissipation and the rate of evaporation per unit length; (b) If the heater element were operated at the same power dissipation rate in the nucleate boiling regime, what temperature would the surface achieve? Calculate the rate of evaporation per unit length for this operating condition; and (c) Make a sketch of the boiling curve and represent the two operating conditions of parts (a) and (b). Compare the results of your analysis. If the heater element is operated in the power-controlled mode, explain how you would achieve these two operating conditions beginning with a cold element.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, and (2) Water exposed to standard atmospheric pressure and uniform temperature,  $T_{\text{sat}}$ .

**PROPERTIES:** Table A-6, Saturated water, liquid (100°C):  $\rho_\ell = 957.9 \text{ kg/m}^3$ ,  $c_{p,\ell} = 4217 \text{ J/kg}\cdot\text{K}$ ,  $\mu_\ell = 279 \times 10^{-6} \text{ N}\cdot\text{s/m}^2$ ,  $\text{Pr}_\ell = 1.76$ ,  $h_{\text{fg}} = 2257 \text{ kJ/kg}$ ,  $h'_{\text{fg}} = h_{\text{fg}} + 0.80 c_{p,v} (T_s - T_{\text{sat}}) = 2654 \text{ kJ/kg}$ ,  $\sigma = 58.9 \times 10^{-3} \text{ N/m}$ ; Saturated water, vapor (100°C):  $\rho_v = 0.5955 \text{ kg/m}^3$ ; Table A-4, Water vapor ( $T_f \approx 500 \text{ K}$ ):  $\rho_v = 0.4405 \text{ kg/m}^3$ ,  $c_{p,v} = 1985 \text{ J/kg}\cdot\text{K}$ ,  $k_v = 0.0339 \text{ W/m}\cdot\text{K}$ ,  $\nu_v = 38.68 \times 10^{-6} \text{ m}^2/\text{s}$ .

**ANALYSIS:** (a) Since  $\Delta T_e > 120^\circ\text{C}$ , the element is operating in the *film-boiling* (FB) regime. The electrical power dissipation per unit length is

$$q'_s = \bar{h}(\pi D)(T_s - T_{\text{sat}}) \quad (1)$$

where the total heat transfer coefficient is

$$\bar{h}^{4/3} = \bar{h}_{\text{conv}}^{4/3} + \bar{h}_{\text{rad}} \bar{h}^{1/3} \quad (2)$$

The convection coefficient is given by the correlation, Eq. 10.8, with  $C = 0.62$ ,

$$\frac{\bar{h}_{\text{conv}} D}{k_v} = C \left[ \frac{g(\rho_\ell - \rho_v) h'_{\text{fg}} D^3}{\nu_v k_v (T_s - T_{\text{sat}})} \right]^{1/4} \quad (3)$$

$$\bar{h}_{\text{conv}} = \frac{0.339 \text{ W/m}\cdot\text{K}}{0.005 \text{ m}} (0.62) \left[ \frac{9.8 \text{ m/s}^2 (833.9 - 0.4405) \text{ kg/m}^3 \times 2.654 \times 10^6 \text{ J/kg}\cdot\text{K} (0.005 \text{ m})^3}{38.68 \times 10^{-6} \text{ m}^2/\text{s} \times 0.0339 \text{ W/m}\cdot\text{K} (350 - 100) \text{ K}} \right]^{1/4}$$

$$\bar{h}_{\text{conv}} = 225 \text{ W/m}^2\cdot\text{K}$$

The radiation coefficient, Eq. (10.11), with  $\sigma = 5.67 \times 10^{-8} \text{ W/m}^2\cdot\text{K}^4$ , is

Continued ...

**PROBLEM 10.33 (Cont.)**

$$\bar{h}_{\text{rad}} = \frac{\varepsilon\sigma(T_s^4 - T_{\text{sat}}^4)}{(T_s - T_{\text{sat}})}$$

$$\bar{h}_{\text{rad}} = \frac{0.25\sigma(623^4 - 373^4)\text{K}^4}{(350 - 100)\text{K}} = 7.4 \text{ W/m}^2 \cdot \text{K}$$

Substituting numerical values into Eq. (2) for  $\bar{h}$ , and into Eq. (1) for  $q'_s$ , find

$$\bar{h} = 231 \text{ W/m}^2 \cdot \text{K}$$

$$q'_s = 231 \text{ W/m}^2 \cdot \text{K} (\pi \times 0.005 \text{ m})(350 - 100)\text{K} = 907 \text{ W/m} \quad <$$

$$q''_s = q'_s / \pi D = 57.8 \text{ kW/m}^2$$

The evaporation rate per unit length is

$$\dot{m}'_b = q'_s / h_{\text{fg}} = 1.4 \text{ kg/h} \cdot \text{m} \quad <$$

(b) For the same heat flux,  $q''_s = 57.8 \text{ kW/m}^2$ , using the Rohsenow correlation for the *nucleate boiling* (NB) regime, find  $\Delta T_e$ , and hence  $T_s$ .

$$q''_s = \mu_\ell h_{\text{fg}} \left[ \frac{g(\rho_\ell - \rho_v)}{\sigma} \right]^{1/2} \left( \frac{c_{p,\ell} \Delta T_e}{C_{s,f} h_{\text{fg}} \text{Pr}_\ell^n} \right)^3$$

where, from Table 10.1, for stainless steel mechanically polished finish with water,  $C_{s,f} = 0.0132$  and  $n = 1.0$ .

$$\begin{aligned} 57.8 \times 10^3 \text{ W/m}^2 &= 279 \times 10^{-6} \text{ N} \cdot \text{s/m}^2 \times 2.257 \times 10^6 \text{ J/kg} \\ &\times \left[ \frac{9.8 \text{ m/s}^2 (957.9 - 0.5955) \text{ kg/m}^3}{58.9 \times 10^{-3} \text{ N/m}} \right]^{1/2} \\ &\times \left( \frac{4217 \text{ J/kg} \cdot \text{K} \times \Delta T_e}{0.0132 \times 2.257 \times 10^6 \text{ J/kg} \times 1.76} \right)^3 \end{aligned}$$

$$\Delta T_e = T_s - T_{\text{sat}} = 7.6 \text{ K}$$

$$T_s = 107.6^\circ\text{C} \quad <$$

The evaporation rate per unit length is

$$\dot{m}'_b = q''_s (\pi D) h_{\text{fg}} = 1.4 \text{ kg/h} \cdot \text{m} \quad <$$

Continued ...

### PROBLEM 10.33 (Cont.)

(c) The two operating conditions are shown on the boiling curve, which is fashioned after Figure 10.4. For FB the surface temperature is  $T_s = 350^\circ\text{C}$  ( $\Delta T_e = 250^\circ\text{C}$ ). The element can be operated at NB with the same heat flux,  $q_s'' = 57.8 \text{ kW/m}^2$ , with a surface temperature of  $T_s = 108^\circ\text{C}$  ( $\Delta T_e = 8^\circ\text{C}$ ). Since the heat fluxes are the same for both conditions, the evaporation rates are the same.

If the element is cold, and operated in a power-controlled mode, the element would be brought to the NB condition following the arrow shown next to the boiling curve near  $\Delta T_e = 0$ . If the power is increased beyond that for the NB point, the element will approach the critical heat flux (CHF) condition. If  $q_s''$  is increased beyond  $q_{s''\text{max}}$ , the temperature of the element will increase abruptly, and the burnout condition will likely occur. If burnout does not occur, reducing the heat flux would allow the element to reach the FB point.

### PROBLEM 10.34

**KNOWN:** Thickness and thermal conductivity of silicon chip. Properties of saturated fluorocarbon boiling on top of chip. Nucleate boiling constants. Surge in heat flux causes film boiling, then returns to 30% of critical heat flux.

**FIND:** (a) Boiling regime when heat flux returns to original value. (b) How much clock speed must be reduced to return to nucleate boiling regime.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Uniform heat flux and adiabatic sides, hence one-dimensional conduction in chip, (3) Constant properties.

**PROPERTIES:** Saturated fluorocarbon (given):  $c_{p,\ell} = 1100 \text{ J/kg}\cdot\text{K}$ ,  $h_{fg} = 84,400 \text{ J/kg}$ ,  $\rho_\ell = 1619.2 \text{ kg/m}^3$ ,  $\rho_v = 13.4 \text{ kg/m}^3$ ,  $\sigma = 8.1 \times 10^{-3} \text{ kg/s}^2$ ,  $\mu_\ell = 440 \times 10^{-6} \text{ kg/m}\cdot\text{s}$ ,  $\text{Pr}_\ell = 9.01$ .

**ANALYSIS:** (a) We begin by calculating the critical heat flux from Eq. 10.6 with  $C = 0.149$  for a large horizontal plate.

$$\begin{aligned}
 q''_{\max} &= 0.149 h_{fg} \rho_v \left[ \frac{\sigma g (\rho_\ell - \rho_v)}{\rho_v^2} \right]^{1/4} \\
 &= 0.149 \times 84,400 \text{ J/kg} \times 13.4 \text{ kg/m}^3 \times \left[ \frac{8.1 \times 10^{-3} \text{ kg/s}^2 \times 9.8 \text{ m/s}^2 (1619.2 - 13.4) \text{ kg/m}^3}{(13.4 \text{ kg/m}^3)^2} \right]^{1/4} \\
 &= 1.55 \times 10^5 \text{ W/m}^2
 \end{aligned}$$

Thus the design heat flux is  $q''_{\text{des}} = 0.3q''_{\max} = 4.64 \times 10^4 \text{ W/m}^2$ . When a power surge causes film boiling and then the heat flux returns to this value, the regime will still be film boiling if this value exceeds the minimum heat flux. However, if it drops below the minimum heat flux it will return to nucleate boiling. The minimum heat flux can be calculated from Eq. 10.7,

$$q''_{\min} = 0.09 h_{fg} \rho_v \left[ \frac{\sigma g (\rho_\ell - \rho_v)}{(\rho_\ell + \rho_v)^2} \right]^{1/4}$$

Continued...

**PROBLEM 10.34 (Cont.)**

$$q''_{\min} = 0.09 \times 84,400 \text{ J/kg} \times 13.4 \text{ kg/m}^3 \times \left[ \frac{8.1 \times 10^{-3} \text{ kg/s}^2 \times 9.8 \text{ m/s}^2 (1619.2 - 13.4) \text{ kg/m}^3}{(1619.2 + 13.4 \text{ kg/m}^3)^2} \right]^{1/4}$$
$$= 8.46 \times 10^3 \text{ W/m}^2$$

Thus  $q''_{\text{des}} > q''_{\min}$  and the chip will operate in the film boiling regime after the heat flux returns to the design value. <

(b) The heat flux must be reduced below  $q''_{\min} = 8.46 \times 10^3 \text{ W/m}^2$  in order to return to the nucleate boiling regime. That is, it must be reduced to 18% of the design value, or a reduction of 82%. <

**COMMENTS:** In addition to having limited capability to cool VLSI chips (see Solution to Problem 10.23), boiling limits their reliability since, for all practical purposes, the chip must cease functioning in order to return to a safe operating condition.

### PROBLEM 10.35

**KNOWN:** Cylinder of 120 mm diameter at 1000K quenched in saturated water at 1 atm

**FIND:** Describe the quenching process and estimate the maximum heat removal rate per unit length during cooling.

**SCHEMATIC:**

**ASSUMPTIONS:** Water exposed to 1 atm pressure,  $T_{\text{sat}} = 100^\circ\text{C}$ .

**ANALYSIS:** At the start of the quenching process, the surface temperature is  $T_s(0) = 1000\text{K}$ . Hence,  $\Delta T_e = T_s - T_{\text{sat}} = 1000\text{K} - 373\text{K} = 627\text{K}$ , and from the typical boiling curve of Figure 10.4, film boiling occurs, with  $q'' < q''_{\text{max}}$ .

As the cylinder temperature decreases,  $\Delta T_e$  decreases, and the cooling process follows the boiling curve sketched above. The cylinder boiling process passes through the Leidenfrost point D, into the transition or unstable boiling regime ( $D \rightarrow C$ ).

At point C, the boiling heat flux has reached a maximum,  $q''_{\text{max}} = 1.26\text{ MW/m}^2$  (see Example 10.1). Hence, the heat rate per unit length of the cylinder is

$$q'_s = q'_{\text{max}} = q''_{\text{max}} (\pi D) = 1.26\text{ MW/m}^2 [\pi (0.120\text{m})] = 0.475\text{ MW/m}. \quad <$$

As the cylinder cools further, nucleate boiling occurs ( $C \rightarrow A$ ) and the heat rate drops rapidly. Finally, at point A, boiling no longer is present and the cylinder is cooled by free convection.

**COMMENTS:** Why doesn't the quenching process follow the cooling curve of Figure 10.3?

### PROBLEM 10.36

**KNOWN:** Horizontal platinum wire of diameter of 1 mm, emissivity of 0.25, and surface temperature of 800 K in saturated water at 1 atm pressure.

**FIND:** (a) Surface heat flux,  $q_s''$ , when the surface temperature is  $T_s = 800$  K and (b) Compute and plot on log-log coordinates the heat flux as a function of the excess temperature,  $\Delta T_e = T_s - T_{sat}$ , for the range  $150 \leq \Delta T_e \leq 550$  K for emissivities of 0.1, 0.25, and 0.95; separately plot the percentage contribution of radiation as a function of  $\Delta T_e$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Film pool boiling.

**PROPERTIES:** Table A.6, Saturated water, liquid ( $T_{sat} = 100^\circ\text{C}$ , 1 atm):  $\rho_\ell = 957.9$  kg/m<sup>3</sup>,  $h_{fg} = 2257$  kJ/kg; Table A.4, Water, vapor ( $T_f = (T_s + T_{sat})/2 = (800 + 373)\text{K}/2 = 587$  K):  $\rho_v = 0.3744$  kg/m<sup>3</sup>,  $c_{p,v} = 2018$  J/kg·K,  $\nu_v = 54.11 \times 10^{-6}$  m<sup>2</sup>/s,  $k_v = 41.1 \times 10^{-3}$  W/m·K.

**ANALYSIS:** (a) The heat flux is

$$q_s'' = \bar{h}(T_s - T_{sat}) = \bar{h}\Delta T_e$$

where  $\Delta T_e = (800 - 373)\text{K} = 427$  is indicative of film boiling. From Eq. 10.9 or 10.10,

$$\bar{h}^{4/3} = \bar{h}_{conv}^{4/3} + \bar{h}_{rad}\bar{h}^{-1/3} \quad \text{or} \quad \bar{h} = \bar{h}_{conv} + (3/4)\bar{h}_{rad}$$

if  $\bar{h}_{rad} < \bar{h}_{conv}$ . Use Eq. 10.8 with  $C = 0.62$  for a horizontal cylinder,

$$\overline{\text{Nu}}_D = \frac{\bar{h}_{conv}D}{k_v} = C \left[ \frac{g(\rho_\ell - \rho_v)h'_{fg}D^3}{\nu_v k_v (T_s - T_{sat})} \right]^{1/4}$$

$$\frac{\bar{h}_{conv} \times 0.001 \text{ m}}{41.1 \times 10^{-3} \text{ W/m}\cdot\text{K}} = 0.62 \left[ \frac{9.8 \text{ m/s}^2 (957.9 - 0.3744) \text{ kg/m}^3 \times 2946 \text{ kJ/kg} (0.001 \text{ m})^3}{(54.11 \times 10^{-6} \text{ m}^2/\text{s}) \times 0.0411 \text{ W/m}\cdot\text{K} (800 - 373) \text{ K}} \right]^{1/4}$$

$$\bar{h}_{conv} = 333 \text{ W/m}^2 \cdot \text{K}$$

where  $h'_{fg} = h_{fg} + 0.8c_{p,v}(T_s - T_{sat}) = 2257 \text{ kJ/kg} + 0.8 \times 2018 \text{ J/kg}\cdot\text{K} (800 - 373) \text{ K} = 2946 \text{ kJ/kg}$ . To estimate the radiation coefficient, use Eq. 10.11,

$$\bar{h}_{rad} = \frac{\epsilon\sigma(T_s^4 - T_{sat}^4)}{T_s - T_{sat}} = \frac{0.25\sigma(800^4 - 373^4) \text{ K}^4}{(800 - 373) \text{ K}} = 13.0 \text{ W/m}^2 \cdot \text{K}.$$

Since  $\bar{h}_{rad} < \bar{h}_{conv}$ , use the simpler expression,

$$\bar{h} = 333 \text{ W/m}^2 \cdot \text{K} + (3/4)13.0 \text{ W/m}^2 \cdot \text{K} = 343 \text{ W/m}^2 \cdot \text{K}.$$

Using the rate equation, find

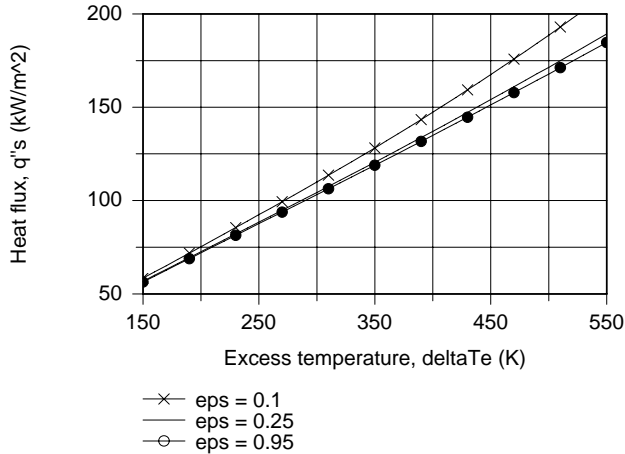

Continued...

**PROBLEM 10.36 (Cont.)**

$$q_s'' = 343 \text{ W/m}^2 \cdot \text{K} (800 - 373) \text{ K} = 146 \text{ kW/m}^2.$$

<

b) Using the *IHT Correlation Tool, Boiling, Film Pool Boiling*, combined with the *Properties Tool for Water Vapor*, the heat flux,  $q_s''$ , was calculated as a function of the surface temperature,  $\Delta T_e$ , for emissivities of 0.1, 0.25, and 0.95. Also plotted below is the ratio (%) of  $q_{\text{rad}}''/q_s''$  as a function of  $\Delta T_e$ .

From the  $q_s''$  vs.  $\Delta T_e$  plot, note that the heat flux increases with increasing excess temperature and increasing emissivity. The heat flux falls between the minimum heat flux (Liedenfrost point) of  $18.9 \text{ kW/m}^2$  and the critical heat flux,  $1.26 \text{ MW/m}^2$  (see Example 10.1 for these values), however for sufficiently large excess temperature, the film boiling heat flux will exceed the critical heat flux. From the  $q_{\text{rad}}''/q_s''$  vs.  $\Delta T_e$  plot, the maximum contribution by radiation is around 16%, and occurs at the maximum surface temperature.

**COMMENTS:** Since  $q_s'' < q_{\text{max}}'' = 1.26 \text{ MW/m}^2$ , the prescribed condition can only be achieved in power-controlled heating by first exceeding  $q_{\text{max}}''$  and then decreasing the flux to  $146 \text{ kW/m}^2$ .

### PROBLEM 10.37

**KNOWN:** Surface temperature and emissivity of strip steel.

**FIND:** Heat flux across vapor blanket.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Vapor/jet interface is at  $T_{\text{sat}}$  for  $p = 1$  atm, (3) Negligible effect of jet and strip motion.

**PROPERTIES:** Table A-6, Saturated water ( $100^\circ\text{C}$ ):  $\rho_\ell = 957.9$  kg/m<sup>3</sup>,  $h_{fg} = 2257$  kJ/kg; Table A-4, Water vapor ( $T_f = 640\text{K}$ ):  $\rho_v = 0.3434$  kg/m<sup>3</sup>,  $c_{p,v} = 2050$  J/kg·K,  $\nu_v = 64.50 \times 10^{-6}$  m<sup>2</sup>/s,  $k = 0.0456$  W/m·K.

**ANALYSIS:** The heat flux is  $q_s'' = \bar{h}\Delta T_e$

where  $\Delta T_e = 907\text{ K} - 373\text{ K} = 534\text{ K}$

and  $\bar{h}^{4/3} = \bar{h}_{\text{conv}}^{4/3} + \bar{h}_{\text{rad}}\bar{h}^{1/3}$  or  $\bar{h} = \bar{h}_{\text{conv}} + (3/4)\bar{h}_{\text{rad}}$ . (1,2)

With  $h'_{fg} = h_{fg} + 0.80c_{p,v}(T_s - T_{\text{sat}}) = 3.13 \times 10^6$  J/kg

Equation 10.9 yields

$$\overline{\text{Nu}}_D = 0.62 \left[ \frac{9.8\text{ m/s}^2 (957.9 - 0.3434)\text{ kg/m}^3 (3.13 \times 10^6\text{ J/kg})(1\text{ m})^3}{64.50 \times 10^{-6}\text{ m}^2/\text{s} (0.0456\text{ W/m}\cdot\text{K})(907 - 373)\text{ K}} \right]^{1/4} = 1290.$$

Hence,

$$\bar{h}_{\text{conv}} = \overline{\text{Nu}}_D k_v / D = 1290\text{ W/m}^2 \cdot \text{K} (0.0456\text{ W/m}\cdot\text{K} / 1\text{ m}) = 58.8\text{ W/m}^2 \cdot \text{K}$$

$$\bar{h}_{\text{rad}} = \frac{\varepsilon \sigma (T_s^4 - T_{\text{sat}}^4)}{T_s - T_{\text{sat}}} = \frac{0.35 \times 5.67 \times 10^{-8}\text{ W/m}^2 \cdot \text{K}^4 (907^4 - 373^4)\text{ K}^4}{(907 - 373)\text{ K}}$$

$$\bar{h}_{\text{rad}} = 24\text{ W/m}^2 \cdot \text{K}$$

Hence,  $\bar{h} = 58.8\text{ W/m}^2 \cdot \text{K} + (3/4)(24\text{ W/m}^2 \cdot \text{K}) = 77.1\text{ W/m}^2 \cdot \text{K}$

Since  $h_{\text{conv}}$  and  $h_{\text{rad}}$  are the same order of magnitude, greater accuracy can be found by iterating on Eq.(1), which yields  $\bar{h} = 78.0\text{ W/m}^2 \cdot \text{K}$ . Then,

$$q_s'' = 78.0\text{ W/m}^2 \cdot \text{K} (907 - 373)\text{ K} = 4.16 \times 10^4\text{ W/m}^2. \quad \leftarrow$$

**COMMENTS:** The foregoing analysis is a very rough approximation to a complex problem. A more rigorous treatment is provided by Zumbrennen et al. in ASME Paper 87-WA/HT-5.

### PROBLEM 10.38

**KNOWN:** Copper sphere, 10 mm diameter, initially at a prescribed elevated temperature is quenched in a saturated (1 atm) water bath.

**FIND:** The time for the sphere to cool (a) from  $T_i = 130$  to  $110^\circ\text{C}$  and (b) from  $T_i = 550^\circ\text{C}$  to  $220^\circ\text{C}$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Sphere approximates lumped capacitance, (2) Water saturated at 1 atm, (3) Negligible radiation during film boiling process due to low emissivity of polished copper, (4) Average sphere temperature can be used in evaluating properties.

**PROPERTIES:** Table A-1, Copper:  $\rho = 8933 \text{ kg/m}^3$ , ( $T = (130 + 120)^\circ\text{C}/2 = 110^\circ\text{C} = 383 \text{ K}$ )  $c_p = 392 \text{ J/kg} \cdot \text{K}$ ; ( $T = (550 + 220)^\circ\text{C}/2 = 385^\circ\text{C} = 658 \text{ K}$ ,  $c_p = 422 \text{ J/kg} \cdot \text{K}$ . Table A.11, Copper (polished) :  $\varepsilon = 0.04$ , typical value; Table A.6, Water ( $T = 373 \text{ K}$ ),  $\rho_l = 1/v_f = 958 \text{ kg/m}^3$ ,  $\rho_v = 1/v_g = 0.596 \text{ kg/m}^3$ ,  $h_{fg} = 2257 \text{ kJ/kg}$ ,  $c_{p,l} = 4.217 \text{ kJ/kg} \cdot \text{K}$ ,  $\mu_l = 279 \times 10^{-6} \text{ N} \cdot \text{s/m}^2$ ,  $\sigma = 58.9 \times 10^{-3} \text{ N/m}$ ,  $Pr_l = 1.76$ ; Table A.4, Water ( $T_f = (T_s + T_{\text{sat}})/2 \approx 515 \text{ K}$ ),  $\rho_v = 1/v_g = 0.428 \text{ kg/m}^3$ ,  $c_{p,v} = 1.989 \text{ kJ/kg} \cdot \text{K}$ ,  $\nu_v = 4.13 \times 10^{-5} \text{ m}^2/\text{s}$ ,  $k_v = 0.0351 \text{ W/m} \cdot \text{K}$ .

**ANALYSIS:** For a heat transfer coefficient of the form given by Eq. 5.26, namely  $h = C(T - T_\infty)^n$ , the temperature distribution is given by Eq. 5.28. For boiling,  $T_\infty$  is replaced with  $T_{\text{sat}}$  in the expression for  $h$ . Making use of this substitution in Eq. 5.28 yields

$$\frac{\theta}{\theta_i} = \frac{T - T_{\text{sat}}}{T_i - T_{\text{sat}}} = \left[ \frac{nCA_{s,c}(T_i - T_{\text{sat}})^n}{\rho Vc} t + 1 \right]^{-1/n} \quad (1)$$

Solving for  $t$ ,

$$t = \frac{\rho Vc}{nCA_{s,c}(T_i - T_{\text{sat}})^n} \left[ \left( \frac{T - T_{\text{sat}}}{T_i - T_{\text{sat}}} \right)^{-n} - 1 \right] \quad (2)$$

(a) For cooling from  $T_i = 130^\circ$  to  $110^\circ\text{C}$ , with  $T_{\text{sat}} = 100^\circ\text{C}$ ,  $\Delta T_e = 30^\circ$  to  $10^\circ\text{C}$ . From Figure 10.4 the regime is nucleate pool boiling. From the Rohsenow correlation, Eq. 10.5,  $h = q''_s / \Delta T_e = C(\Delta T_e)^2$ , where

$$C = \mu_l h_{fg} \left[ \frac{g(\rho_l - \rho_v)}{\sigma} \right]^{1/2} \left( \frac{c_{p,l}}{C_{s,f} h_{fg} Pr_l^m} \right)^3$$

Note that exponent  $m$  has been used instead of  $n$ , to distinguish from the  $n$  exponent in Eqs. (1) and (2). From Table 10.1,  $C_{s,f} = 0.0128$ ,  $m = 1.0$ , thus

Continued...

**PROBLEM 10.38 (Cont.)**

$$C = 279 \times 10^{-6} \text{ N} \cdot \text{s/m}^2 \times 2257 \times 10^3 \text{ J/kg} \times \left[ \frac{9.81 \text{ m/s}^2 (958 \text{ kg/m}^3 - 0.596 \text{ kg/m}^3)}{58.9 \times 10^{-3} \text{ N/m}} \right]^{1/2} \\ \times \left( \frac{4217 \text{ J/kg} \cdot \text{K}}{0.0128 \times 2257 \times 10^3 \text{ J/kg} \times 1.76^{1.0}} \right)^3 = 143 \text{ W/m}^2 \cdot \text{K}^3$$

Thus, from Eq. (2), with  $n = 2$

$$t = \frac{8933 \text{ kg/m}^3 \times 395 \text{ J/kg} \cdot \text{K} \times 0.010 \text{ m/6}}{2 \times 143 \text{ W/m}^2 \cdot \text{K}^3 \times (130^\circ\text{C} - 100^\circ\text{C})^2} \left[ \left( \frac{110^\circ\text{C} - 100^\circ\text{C}}{130^\circ\text{C} - 100^\circ\text{C}} \right)^{-2} - 1 \right] = 0.18 \text{ s} <$$

(b) For cooling from  $T_i = 550^\circ$  to  $220^\circ\text{C}$ , with  $T_{\text{sat}} = 100^\circ\text{C}$ ,  $\Delta T_e = 450^\circ$  to  $120^\circ\text{C}$ . From Figure 10.4 the regime is film pool boiling. From Eq. 10.8 with  $C = 0.67$  for a sphere,  $h = C(\Delta T_e)^{-1/4}$ , where

$$C = 0.67 \frac{k_v}{D} \left[ \frac{g(\rho_l - \rho_v)h'_{fg}D^3}{\nu_v k_v} \right]^{-1/4}$$

In this expression,  $h'_{fg}$  is a function of temperature,  $h'_{fg} = h_{fg} + 0.80c_{p,v}(T - T_{\text{sat}})$ . However, since Eqs. (1) and (2) are only valid for  $C = \text{const.}$ , we evaluate  $h'_{fg}$  at the average temperature,  $T = (550 + 220)^\circ\text{C}/2 = 385^\circ\text{C}$ . This is a reasonable approximation since the temperature-dependent second term is substantially smaller than  $h_{fg}$ . Thus,

$$h'_{fg} = h_{fg} + 0.80c_{p,v}(T - T_{\text{sat}}) = 2257 \text{ kJ/kg} + 0.80 \times 1.989 \text{ kJ/kg} \cdot \text{K} \times (385 - 100)^\circ\text{C} = 2710 \text{ kJ/kg}$$

and

$$C = 0.67 \frac{0.0351 \text{ W/m} \cdot \text{K}}{0.010 \text{ m}} \left[ \frac{9.81 \text{ m/s}^2 (958 \text{ kg/m}^3 - 0.428 \text{ kg/m}^3) \times 2710 \times 10^3 \text{ J/kg} \times (0.010 \text{ m})^3}{4.13 \times 10^{-5} \text{ m}^2/\text{s} \times 0.0351 \text{ W/m} \cdot \text{K}} \right]^{1/4} \\ = 856 \text{ W/m}^2 \cdot \text{K}^{3/4}$$

Thus, from Eq. (2), with  $n = -1/4$ ,

$$t = \frac{8933 \text{ kg/m}^3 \times 422 \text{ J/kg} \cdot \text{K} \times 0.010 \text{ m/6}}{-(1/4) \times 856 \text{ W/m}^2 \cdot \text{K}^{3/4} \times (550^\circ\text{C} - 100^\circ\text{C})^{-1/4}} \left[ \left( \frac{220^\circ\text{C} - 100^\circ\text{C}}{550^\circ\text{C} - 100^\circ\text{C}} \right)^{1/4} - 1 \right] = 38.0 \text{ s} <$$

**COMMENTS:** Comparing the elapsed times for the two processes, the nucleate pool boiling process cools  $20^\circ\text{C}$  in 0.18s ( $110^\circ\text{C/s}$ ) vs.  $330^\circ\text{C}$  in 38.0s ( $8.7^\circ\text{C/s}$ ) for the film pool boiling process.

### PROBLEM 10.39

**KNOWN:** Saturated water at 1 atm is heated in cross flow with velocities 0 – 2 m/s over a 2 mm-diameter tube.

**FIND:** Plot the critical heat flux as a function of water velocity; identify the pool boiling and transition regions between the low and high velocity ranges.

**SCHEMATIC:**

**ASSUMPTIONS:** Nucleate boiling in the presence of external forced convection.

**PROPERTIES:** Table A-6, Water (1 atm):  $T_{sat} = 100^\circ\text{C}$ ,  $\rho_\ell = 957.9 \text{ kg/m}^3$ ,  $\rho_v = 0.5955 \text{ kg/m}^3$ ,  $h_{fg} = 2257 \text{ kJ/kg}$ ,  $\sigma = 58.9 \times 10^{-3} \text{ N/m}$ .

**ANALYSIS:** The Lienhard-Eichhorn correlations for forced convection boiling with cross flow over a cylinder are appropriate for estimating  $q''_{max}$ , Eqs. 10.12 and 10.13.

*Low Velocity*

$$q''_{max} = \frac{\rho_v h_{fg}}{\pi} \left[ 1 + \left( \frac{4\sigma}{\rho_v V^2 D} \right)^{1/3} \right] V$$

$$q''_{max} = \frac{1}{\pi} 0.5955 \frac{\text{kg}}{\text{m}^3} \times 2257 \times 10^3 \frac{\text{J}}{\text{kg}} \left[ 1 + \left( \frac{4 \times 58.9 \times 10^{-3} \text{ N/m}}{0.5955 \text{ kg/m}^3 V^2 0.002 \text{ m}} \right)^{1/3} \right] V$$

$$q''_{max} = 4.2782 \times 10^5 V + 2.493 \times 10^6 V^{1/3}$$

*High Velocity*

$$q''_{max} = \frac{\rho_v h_{fg}}{\pi} \left[ \frac{1}{169} \left( \frac{\rho_\ell}{\rho_v} \right)^{3/4} + \frac{1}{19.2} \left( \frac{\rho_\ell}{\rho_v} \right)^{1/2} \left( \frac{\sigma}{\rho_v V^2 D} \right)^{1/3} \right] V$$

$$q''_{max} = \frac{1}{\pi} 0.5955 \frac{\text{kg}}{\text{m}^3} \times 2257 \times 10^3 \frac{\text{J}}{\text{kg}} \left[ \frac{1}{169} \left( \frac{957.9}{0.5955} \right)^{3/4} + \frac{1}{19.2} \left( \frac{957.9}{0.5955} \right)^{1/2} \left( \frac{58.9 \times 10^{-3} \text{ N/m}}{0.5955 \text{ kg/m}^3 V^2 0.002 \text{ m}} \right)^{1/3} \right] V$$

$$q''_{max} = 6.4299 \times 10^5 V + 3.280 \times 10^6 V^{1/3}$$

Continued ...

### PROBLEM 10.39 (Cont.)

The *transition* between the low and high velocity regions occurs when

$$q''_{\max} = \rho_v h_{fg} V \left[ \frac{0.275 \left( \frac{\rho_\ell}{\rho_v} \right)^{1/2}}{\pi} + 1 \right]$$

$$q''_{\max} = 0.5955 \frac{\text{kg}}{\text{m}^3} \times 2257 \times 10^3 \frac{\text{J}}{\text{kg}} V \left[ \frac{0.275 \left( \frac{957.9}{0.5955} \right)^{1/2}}{\pi} + 1 \right] = 6.0627 \times 10^6 V. \quad (3)$$

For pool boiling conditions when the velocity is zero, the critical heat flux must be estimated according to the correlation for the small horizontal cylinder as introduced in Problem 10.20. If the cylinder were “large,” the critical heat flux would be  $1.26 \text{ MW/m}^2$  as given by Eq. 10.6 with  $C=0.149$ . The Confinement number and correction factor are

$$Co = \frac{\sqrt{\sigma/g(\rho_\ell - \rho_v)}}{r} = \frac{\sqrt{58.9 \times 10^{-3} \text{ N/m}/9.8 \text{ m/s}^2 (957.9 - 0.5955) \text{ kg/m}^3}}{0.001 \text{ m}} = 2.51$$

$$F = 0.89 + 2.27 \exp(-3.44 Co^{-1/2}) = 1.15$$

and the critical heat flux for the “small” 2 mm cylinder is

$$q''_{\max} \Big|_{\text{pool}} = 1.15 \times 1.26 \text{ MW/m}^2 = 1.45 \text{ MW/m}^2.$$

The graph below identifies four regions: pool boiling where  $q''_{\max} = 1.45 \text{ MW/m}^2$  from  $V = 0$  to  $0.17 \text{ m/s}$  and the low velocity, transition and high velocity regimes.

### PROBLEM 10.40

**KNOWN:** Saturated water at 1 atm and velocity 2 m/s in cross flow over a heater element of 5 mm diameter.

**FIND:** Maximum heating rate,  $q'$  [W/m].

**SCHEMATIC:**

**ASSUMPTIONS:** Nucleate boiling in the presence of external forced convection.

**PROPERTIES:** Table A-6, Water (1 atm):  $T_{sat} = 100^\circ\text{C}$ ,  $\rho_\ell = 957.9 \text{ kg/m}^3$ ,  $\rho_v = 0.5955 \text{ kg/m}^3$ ,  $h_{fg} = 2257 \text{ kJ/kg}$ ,  $\sigma = 58.9 \times 10^{-3} \text{ N/m}$ .

**ANALYSIS:** The Lienhard-Eichhorn correlation for forced convection with cross flow over a cylinder is appropriate for estimating  $q''_{max}$ . Assuming high-velocity region flow, Eq. 10.13 with Eq. 10.14 can be written as

$$q''_{max} = \frac{\rho_v h_{fg} V}{\pi} \left[ \frac{1}{169} \left( \frac{\rho_\ell}{\rho_v} \right)^{3/4} + \frac{1}{19.2} \left( \frac{\rho_\ell}{\rho_v} \right)^{1/2} \left( \frac{\sigma}{\rho_v V^2 D} \right)^{1/3} \right].$$

Substituting numerical values, find

$$q''_{max} = \frac{1}{\pi} 0.5955 \text{ kg/m}^3 \times 2257 \times 10^3 \text{ J/kg} \times 2 \text{ m/s} \left[ \frac{1}{169} \left( \frac{957.9}{0.5955} \right)^{3/4} + \frac{1}{19.2} \left( \frac{957.9}{0.5955} \right)^{1/2} \left( \frac{58.9 \times 10^{-3} \text{ N/m}}{0.5955 \text{ kg/m}^3 (2 \text{ m/s})^2 0.005 \text{ m}} \right)^{1/3} \right]$$

$$q''_{max} = 4.331 \text{ MW/m}^2.$$

The high-velocity region assumption is satisfied if

$$\frac{q''_{max}}{\rho_v h_{fg} V} \stackrel{?}{<} \frac{0.275}{\pi} \left( \frac{\rho_\ell}{\rho_v} \right)^{1/2} + 1$$

$$\frac{4.331 \times 10^6 \text{ W/m}^2}{0.5955 \text{ kg/m}^3 \times 2257 \times 10^3 \text{ J/kg} \times 2 \text{ m/s}} = 1.61 \stackrel{?}{<} \frac{0.275}{\pi} \left( \frac{957.9}{0.5955} \right)^{1/2} + 1 = 4.51.$$

The inequality is satisfied. Using the  $q''_{max}$  estimate, the maximum heating rate is

$$q'_{max} = q''_{max} \cdot \pi D = 4.331 \text{ MW/m}^2 \times \pi (0.005 \text{ m}) = 68.0 \text{ kW/m}. \quad <$$

**COMMENTS:** Note that the effect of the forced convection is to increase the critical heat flux by  $4.33/1.26 = 3.4$  over the pool boiling case.

### PROBLEM 10.41

**KNOWN:** Diameter and wall heat flux for vertical steel tube. Velocity and pressure of saturated liquid water entering at bottom end.

**FIND:** (a) Tube wall temperature and water quality at  $x = 15$  m. (b) Tube wall temperature at location where single-phase vapor flow exists at mean temperature  $T_{\text{sat}}$ . (c) Plot tube wall temperature for  $-5 \text{ m} \leq x \leq 30 \text{ m}$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Constant properties. (3)  $G_{\text{sf}} = 1$ .

**PROPERTIES:** Table A.6, Saturated water, liquid (10 bars):  $T_{\text{sat}} = 452.8 \text{ K}$ ,  $\rho_{\ell} = 887.3 \text{ kg/m}^3$ ,  $h_{\text{fg}} = 2014 \text{ kJ/kg}$ ,  $\mu_{\ell} = 149.4 \times 10^{-6} \text{ N}\cdot\text{s/m}^2$ ,  $\nu_{\ell} = \mu_{\ell} / \rho_{\ell} = 1.684 \times 10^{-7} \text{ m}^2/\text{s}$ ,  $k_{\ell} = 0.6766 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr}_{\ell} = 0.979$ . Table A.4, water vapor ( $T = 452.8 \text{ K}$ ):  $\rho_{\text{v}} = 5.094 \text{ kg/m}^3$ ,  $\mu_{\text{v}} = 14.95 \times 10^{-6} \text{ N}\cdot\text{s/m}^2$ ,  $k_{\text{v}} = 0.03353 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr}_{\text{v}} = 1.149$ .

**ANALYSIS:** (a) The mass flow rate is

$$\dot{m} = \rho_{\ell} u_m A_c = 887.3 \text{ kg/m}^3 \times 0.05 \text{ m/s} \times \pi(0.1 \text{ m})^2 / 4 = 0.348 \text{ kg/s}$$

Then from Eq. 10.16,

$$\bar{X}(x = 15 \text{ m}) = \frac{q''_s \pi D x}{\dot{m} h_{\text{fg}}} = \frac{100,000 \text{ W/m}^2 \times \pi \times 0.1 \text{ m} \times 15 \text{ m}}{0.348 \text{ kg/s} \times 2.014 \times 10^6 \text{ J/kg}} = 0.672 \quad (1) \quad <$$

To find the wall temperature, we must first find the convection coefficient from Eq. 10.15. The Reynolds number is

$$\text{Re}_D = u_m D / \nu_{\ell} = 0.05 \text{ m/s} \times 0.1 \text{ m} / 1.684 \times 10^{-7} \text{ m}^2/\text{s} = 2.97 \times 10^4$$

Thus the flow is turbulent and the single phase convection coefficient can be calculated from Eq. 8.62,

$$\text{Nu}_D = \frac{(f/8) (\text{Re}_D - 1000) \text{Pr}_{\ell}}{1 + 12.7 (f/8)^{1/2} (\text{Pr}_{\ell}^{2/3} - 1)} = \frac{(0.0237/8) (2.97 \times 10^4 - 1000) 0.979}{1 + 12.7 (0.0237/8)^{1/2} (0.979^{2/3} - 1)} = 84.0$$

where from Equation 8.21,

$$f = (0.790 \ln \text{Re}_D - 1.64)^{-2} = (0.790 \ln (2.97 \times 10^4) - 1.64)^{-2} = 0.0237$$

Thus

$$h_{\text{sp}} = \text{Nu}_D k_{\ell} / D = 84.0 \times 0.6766 \text{ W/m}\cdot\text{K} / 0.1 \text{ m} = 568 \text{ W/m}^2 \cdot \text{K}$$

Continued...

### PROBLEM 10.41 (Cont.)

We must evaluate  $h$  from both Eqs. 10.15a and 10.15b and take the larger value. From Eq. 10.15b (which yields the larger value),

$$\begin{aligned} \frac{h}{h_{sp}} &= 1.136 \left( \frac{\rho_\ell}{\rho_v} \right)^{0.45} \bar{X}^{0.72} (1 - \bar{X})^{0.08} f(\text{Fr}) + 667.2 \left( \frac{q_s''}{\dot{m}'' h_{fg}} \right)^{0.7} (1 - \bar{X})^{0.8} G_{sf} \quad (2) \\ &= 1.136 \left( \frac{887.3}{5.094} \right)^{0.45} 0.672^{0.72} (1 - 0.672)^{0.08} \times 1 + 667.2 \left( \frac{10^5 \text{ W/m}^2}{44.4 \text{ kg/m}^2 \cdot \text{s} \times 2.014 \times 10^6 \text{ J/kg}} \right)^{0.7} (1 - 0.672)^{0.8} \times 1 \\ &= 10.3 \end{aligned}$$

where  $\dot{m}'' = \rho_\ell u_m = 44.4 \text{ kg/m}^2 \cdot \text{K}$ ,  $f(\text{Fr}) = 1$  for a vertical tube, and  $G_{sf} = 1$ . Thus  $h = 10.3(568 \text{ W/m}^2 \cdot \text{K}) = 5860 \text{ W/m}^2 \cdot \text{K}$  and from Eq. 10.3,

$$T_s = T_{\text{sat}} + q''/h = 452.8 \text{ K} + 10^5 \text{ W/m}^2 / 5860 \text{ W/m}^2 \cdot \text{K} = 470 \text{ K} = 197^\circ\text{C} \quad (3) \quad \leftarrow$$

(b) The mass flow rate is unchanged, but the viscosity is now that of the vapor, therefore,

$$\text{Re}_D = 4\dot{m} / \pi D \mu_v = 4 \times 0.348 \text{ kg/s} / \pi \times 0.1 \text{ m} \times 14.95 \times 10^{-6} \text{ N} \cdot \text{s/m}^2 = 2.97 \times 10^5$$

And once again from Eqs. 8.62 and 8.21,

$$\text{Nu}_D = \frac{(f/8)(\text{Re}_D - 1000) \text{Pr}_v}{1 + 12.7(f/8)^{1/2}(\text{Pr}_v^{2/3} - 1)} = \frac{(0.0145/8)(2.97 \times 10^5 - 1000) 1.149}{1 + 12.7(0.0145/8)^{1/2}(1.149^{2/3} - 1)} = 584$$

where

$$f = (0.790 \ln \text{Re}_D - 1.64)^{-2} = (0.790 \ln(2.97 \times 10^5) - 1.64)^{-2} = 0.0145$$

Thus

$$h = \text{Nu}_D k_v / D = 584 \times 0.03353 \text{ W/m} \cdot \text{K} / 0.1 \text{ m} = 196 \text{ W/m}^2 \cdot \text{K}$$

and

$$T_s = T_{\text{sat}} + q''/h = 452.8 \text{ K} + 10^5 \text{ W/m}^2 / 196 \text{ W/m}^2 \cdot \text{K} = 964 \text{ K} = 691^\circ\text{C} \quad \leftarrow$$

(c) For  $x < 0$ , the liquid is at its saturation temperature and the heat transfer coefficient is the single-phase value calculated in part (a). Thus the surface temperature is  $T_s = T_{\text{sat}} + q''/h_{sp} = 356^\circ\text{C}$ . For  $x > 0$  (until the fluid becomes fully vapor) Eqs. (1), (2), and (3) were entered into the *IHT* workspace along with the property values, previously calculated values of  $\dot{m}$ ,  $\dot{m}''$ , and  $h_{sp}$ , and other inputs. For locations where pure single-phase vapor exists,  $T_s = 691^\circ\text{C}$  as calculated in part (b). The results are shown below.

Continued....

### PROBLEM 10.41 (Cont.)

**COMMENTS:** (1) During pool boiling, we are concerned about approaching the critical heat flux. During forced convection boiling, an analogous situation exists whereby, once the liquid phase is entirely consumed, surface temperatures rise very rapidly, potentially melting the tube material. In applications where production of superheated steam is desired, such as in a Rankine power cycle, precautions must be made to ensure the tube material will survive the high temperatures in regions associated with pure vapor conditions. (2) Surface temperatures at negative  $x$  values will be slightly less than shown for the pure liquid flow. This is because the fluid quality is averaged across the tube radius and, for  $x < 0$ , fluid near the centerline of the tube will consist of subcooled liquid while superheated vapor exists near the tube wall. This situation can yield values of  $\bar{X}$  equal to zero, even though two-phase flow exists in the fluid, increasing the convection coefficient. Similarly, the average quality reaches a value of unity at  $x = 22.3$  m. Just beyond this location, the flow consists mainly of vapor, but a subcooled liquid mist can exist near the core of the flow, suppressing tube surface temperatures relative to those indicated just beyond  $x = 22.3$  m. (3) The quality reaches a value of 0.8 at  $x = 17.8$  m and Equation 10.15 is no longer applicable. The surface temperatures reported in the range  $17.8 \text{ m} \leq x \leq 22.3 \text{ m}$  will be less accurate than for those further upstream. (4) The pressure will decrease with increasing  $x$  due to friction losses. Prediction of pressure drops in flow boiling is difficult.

## PROBLEM 10.42

**KNOWN:** Diameter and wall thickness of horizontal tube. Saturation temperature and flow rate of R-134a. Wall heat flux.

**FIND:** Maximum wall temperature at  $x = 0.4$  m for (a) copper tube, (b) stainless steel tube.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Constant properties, (2) Steady-state conditions, (3) The heat flux value of  $10^5 \text{ W/m}^2$  is based on the inner wall surface area.

**PROPERTIES:** *Table A.5*, Saturated liquid R-134a: ( $T_{\text{sat}} = 288 \text{ K}$ ):  $k_\ell = 0.0855 \text{ W/m}\cdot\text{K}$ ,  $c_{p,\ell} = 1387 \text{ J/kg}\cdot\text{K}$ ,  $\mu_\ell = 2.213 \times 10^{-4} \text{ N}\cdot\text{s/m}^2$ ,  $\text{Pr}_\ell = 3.54$ ,  $\rho_\ell = 1243.8 \text{ kg/m}^3$ ,  $h_{\text{fg}} = 186.6 \text{ kJ/kg}$ . Saturated vapor R-134a (given):  $\rho_v = 23.75 \text{ kg/m}^3$ . *Table A.1*, Pure copper ( $T \approx 300 \text{ K}$ ):  $k_w = 401 \text{ W/m}\cdot\text{K}$ . *Table A.1*, AISI 316 SS ( $T \approx 300 \text{ K}$ ):  $k_w = 13.4 \text{ W/m}\cdot\text{K}$ .

**ANALYSIS:** (a) From Eq. 10.16,

$$\bar{X}(x = 0.4 \text{ m}) = \frac{q''_s \pi D x}{\dot{m} h_{\text{fg}}} = \frac{10^5 \text{ W/m}^2 \times \pi \times 0.01 \text{ m} \times 0.4 \text{ m}}{0.01 \text{ kg/s} \times 186.6 \times 10^3 \text{ J/kg}} = 0.673$$

To find the wall temperature, we must first find the convection coefficient from Eq. 10.15. The Reynolds number is

$$\text{Re}_D = 4\dot{m} / \pi D \mu_\ell = 4 \times 0.01 \text{ kg/s} / \pi \times 0.01 \text{ m} \times 2.213 \times 10^{-4} \text{ N}\cdot\text{s/m}^2 = 5753$$

Thus the flow is turbulent and the single phase convection coefficient can be calculated from Eq. 8.62,

$$\text{Nu}_D = \frac{(f/8) (\text{Re}_D - 1000) \text{Pr}_\ell}{1 + 12.7 (f/8)^{1/2} (\text{Pr}_\ell^{2/3} - 1)} = \frac{(0.0370/8) (5753 - 1000) 3.54}{1 + 12.7 (0.0370/8)^{1/2} (3.54^{2/3} - 1)} = 36.3$$

where from Equation 8.21,

$$f = (0.790 \ln \text{Re}_D - 1.64)^{-2} = (0.790 \ln (5753) - 1.64)^{-2} = 0.0370$$

Thus

$$h_{\text{sp}} = \text{Nu}_D k_\ell / D = 36.3 \times 0.0855 \text{ W/m}\cdot\text{K} / 0.01 \text{ m} = 311 \text{ W/m}^2 \cdot \text{K}$$

Continued...

### PROBLEM 10.42 (Cont.)

We must evaluate  $h$  from both Eqs. 10.15a and 10.15b and take the larger value. We first calculate  $\dot{m}'' = \dot{m} / A_c = 127 \text{ kg/m}^2 \cdot \text{s}$ ,  $Fr = (\dot{m}'' / \rho_\ell)^2 / gD = 0.1069$ ,  $f(Fr) = 2.63Fr^{0.3} = 1.34$ , and note that  $G_{sf} = 1.63$  from Table 10.2. Then, from Eq. 10.15a (which yields the larger value),

$$\begin{aligned} \frac{h}{h_{sp}} &= 0.6683 \left( \frac{\rho_\ell}{\rho_v} \right)^{0.1} \bar{X}^{0.16} (1 - \bar{X})^{0.64} f(Fr) + 1058 \left( \frac{q_s''}{\dot{m}'' h_{fg}} \right)^{0.7} (1 - \bar{X})^{0.8} G_{sf} \\ &= 0.6683 \left( \frac{1243.8}{23.75} \right)^{0.1} 0.673^{0.16} (1 - 0.673)^{0.64} \times 1.34 + 1058 \left( \frac{10^5 \text{ W/m}^2}{127 \text{ kg/m}^2 \cdot \text{s} \times 186.6 \times 10^3 \text{ J/kg}} \right)^{0.7} (1 - 0.673)^{0.8} \times 1.63 \\ &= 15.9 \end{aligned}$$

Thus  $h = 15.9(311 \text{ W/m}^2 \cdot \text{K}) = 4942 \text{ W/m}^2 \cdot \text{K}$  and from Eq. 10.3,

$$T_s = T_{sat} + q'' / h = 15^\circ\text{C} + 10^5 \text{ W/m}^2 / 4942 \text{ W/m}^2 \cdot \text{K} = 35.2^\circ\text{C}$$

This is the inner wall temperature. The maximum wall temperature is the outer wall temperature, given by

$$T_{s,o} = T_s + q'' r_i \ln(r_o / r_i) / k_w = 35.2^\circ\text{C} + 10^5 \text{ W/m}^2 \times 0.005 \text{ m} \ln(0.007 / 0.005) / 401 \text{ W/m} \cdot \text{K}$$

$$T_{s,o} = 35.6^\circ\text{C} \quad \leftarrow$$

(b) For stainless steel, the value of  $G_{sf}$  changes,  $G_{sf} = 1$ , and the wall thermal conductivity is lower. Repeating the calculations (with Eq. 10.15b now yielding the larger value of  $h$ ) we find  $h = 3776 \text{ W/m}^2 \cdot \text{K}$ ,  $T_s = 41.5^\circ\text{C}$ , and

$$T_{s,o} = 54.0^\circ\text{C} \quad \leftarrow$$

**COMMENTS:** (1) The confinement number is  $Co = 0.089$  which is less than  $1/2$ , therefore Eq. 10.15 may be used. (2) For vertical tubes, the corresponding maximum wall temperatures are  $T_{max} = 35.9^\circ\text{C}$  and  $58.1^\circ\text{C}$ , respectively.

### PROBLEM 10.43

**KNOWN:** Various fluids at atmospheric pressure boiling in a tube.

**FIND:** Tube diameter associated with a Confinement number of 0.5.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Constant properties.

**PROPERTIES:** *Table A.5*, Saturated ethanol ( $p = 1$  atm):  $\rho_\ell = 757$  kg/m<sup>3</sup>,  $\rho_v = 1.44$  kg/m<sup>3</sup>,  $\sigma = 17.7 \times 10^{-3}$  N/m. Saturated mercury ( $p = 1$  atm):  $\rho_\ell = 12,740$  kg/m<sup>3</sup>,  $\rho_v = 3.90$  kg/m<sup>3</sup>,  $\sigma = 417 \times 10^{-3}$  N/m. Saturated R-134a ( $p = 1$  atm):  $\rho_\ell = 1377$  kg/m<sup>3</sup>,  $\rho_v = 5.26$  kg/m<sup>3</sup>,  $\sigma = 15.4 \times 10^{-3}$  N/m. Saturated dielectric fluid, given in Problem 10.23 ( $p = 1$  atm):  $\rho_\ell = 1619.2$  kg/m<sup>3</sup>,  $\rho_v = 13.4$  kg/m<sup>3</sup>,  $\sigma = 8.1 \times 10^{-3}$  N/m. *Table A.6*, Saturated water ( $p = 1$  atm):  $\rho_\ell = 989$  kg/m<sup>3</sup>,  $\rho_v = 0.595$  kg/m<sup>3</sup>,  $\sigma = 58.9 \times 10^{-3}$  N/m.

**ANALYSIS:** The Confinement number is defined as,

$$Co = \sqrt{\sigma/[g(\rho_\ell - \rho_v)]} / D$$

Thus for a critical Confinement number of 0.5,

$$D = 2\sqrt{\sigma/[g(\rho_\ell - \rho_v)]}$$

The results are tabulated below for all five fluids.

Fluid	Critical diameter (mm)
Ethanol	3.03
Mercury	3.65
Water	4.93
R-134a	2.14
Dielectric fluid	1.43

**COMMENTS:** Despite the wide range of individual property values, the critical tube diameter below which the bubble occupies a significant fraction of the tube volume is confined to a relatively narrow range.

<

### PROBLEM 10.44

**KNOWN:** Saturated steam condensing on the outside of a brass tube and water flowing on the inside of the tube; convection coefficients are prescribed.

**FIND:** Steam condensation rate per unit length of the tube.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions.

**PROPERTIES:** Table A-6, Water, vapor (0.1 bar):  $T_{\text{sat}} \approx 320\text{K}$ ,  $h_{\text{fg}} = 2390 \times 10^3 \text{ J/kg}$ ; Table A-1, Brass ( $\bar{T} = (T_m + T_{\text{sat}})/2 \approx 300\text{K}$ ):  $k = 110 \text{ W/m} \cdot \text{K}$

**ANALYSIS:** The condensation rate per unit length follows from Eq. 10.34 written as

$$\dot{m}' = q' / h'_{\text{fg}} \quad (1)$$

where the heat rate follows from Eq. 10.33 using an overall heat transfer coefficient

$$q' = U_o \cdot \pi D_o (T_{\text{sat}} - T_m) \quad (2)$$

and from Eq. 3.36,

$$U_o = \left[ \frac{1}{h_o} + \frac{D_o/2}{k} \ln \frac{D_o}{D_i} + \frac{D_o}{D_i} \frac{1}{h_i} \right]^{-1} \quad (3)$$

$$U_o = \left[ \frac{1}{6800 \text{ W/m}^2 \cdot \text{K}} + \frac{0.0095 \text{ m}}{110 \text{ W/m} \cdot \text{K}} \ln \frac{19}{16.5} + \frac{19}{16.5} \frac{1}{5200 \text{ W/m}^2 \cdot \text{K}} \right]^{-1}$$

$$U_o = \left[ 147.1 \times 10^{-6} + 12.18 \times 10^{-6} + 192.3 \times 10^{-6} \right]^{-1} \text{ W/m}^2 \cdot \text{K} = 2627 \text{ W/m}^2 \cdot \text{K}$$

Combining Eqs. (1) and (2) and substituting numerical values (see below for  $h'_{\text{fg}}$ ), find

$$\dot{m}' = U_o \pi D_o (T_{\text{sat}} - T_m) / h'_{\text{fg}}$$

$$\dot{m}' = 2627 \text{ W/m}^2 \cdot \text{K} \pi (0.019 \text{ m}) (320 - 303) \text{ K} / 2410 \times 10^3 \text{ J/kg} = 1.11 \times 10^{-3} \text{ kg/s. } <$$

**COMMENTS:** (1) Note from evaluation of Eq. (3) that the thermal resistance of the brass tube is not negligible. (2) From Eq. 10.27, with  $\text{Ja} = c_{p,\ell} (T_{\text{sat}} - T_s) / h_{\text{fg}}$ ,  $h'_{\text{fg}} = h_{\text{fg}} [1 + 0.68 \text{ Ja}]$ . Note from expression for  $U_o$ , that the internal resistance is the largest. Hence, estimate  $T_{s,o} \approx T_o - (R_o / \Sigma R) (T_o - T_m) \approx 313\text{K}$ . Hence,

$$h'_{\text{fg}} \approx 2390 \times 10^3 \text{ J/kg} \left[ 1 + 0.68 \times 4179 \text{ J/kg} \cdot \text{K} (320 - 313) \text{ K} / 2390 \times 10^3 \text{ J/kg} \right]$$

$$h'_{\text{fg}} = 2410 \text{ kJ/kg}$$

where  $c_{p,\ell}$  for water (liquid) is evaluated at  $T_f = (T_{s,o} + T_o) / 2 \approx 317\text{K}$ .

### PROBLEM 10.45

**KNOWN:** Insulated container having cold bottom surface and exposed to saturated vapor.

**FIND:** Expression for growth rate of liquid layer,  $\delta(t)$ ; thickness formed for prescribed conditions; compare with vertical plate condensate for same conditions.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Side wall effects are negligible and, (2) Vapor-liquid interface is at  $T_{\text{sat}}$ , (3) Temperature distribution in liquid is linear, (4) Constant properties.

**PROPERTIES:** Table A-6, Saturated vapor ( $p = 1.0133 \text{ bar}$ ):  $T_{\text{sat}} = 100^\circ\text{C}$ ,  $\rho_v = 0.596 \text{ kg/m}^3$ ,  $h_{\text{fg}} = 2257 \text{ kJ/kg}$ ; Table A-6, Saturated liquid ( $T_f = 90^\circ\text{C} = 363\text{K}$ ):  $\rho_\ell = 965 \text{ kg/m}^3$ ,  $\mu_\ell = 313 \times 10^{-6} \text{ N}\cdot\text{s/m}^2$ ,  $k_\ell = 0.676 \text{ W/m}\cdot\text{K}$ ,  $c_{p,\ell} = 4207 \text{ J/kg}\cdot\text{K}$ ,  $\nu_\ell = \mu_\ell / \rho_\ell = 3.24 \times 10^{-7} \text{ m}^2/\text{s}$ .

**ANALYSIS:** Perform a surface energy balance on the interface (see above) recognizing that  $\dot{m}_\ell / A = \rho_\ell d\delta / dt$  from an overall mass rate balance on the liquid to obtain

$$\dot{E}_{\text{in}}'' - \dot{E}_{\text{out}}'' = q_{\text{conds}}'' - q_{\text{cond}}'' = \frac{\dot{m}}{A} h_{\text{fg}} - k_\ell \frac{T_{\text{sat}} - T_s}{\delta} = \rho_\ell \frac{d\delta}{dt} h_{\text{fg}} - k_\ell \frac{T_{\text{sat}} - T_s}{\delta} = 0 \quad (1)$$

where  $q_{\text{conds}}''$  is the condensation heat flux and  $q_{\text{cond}}''$  is the conduction heat flux into the liquid layer of thickness  $\delta$  with linear temperature distribution. Eq. (1) can be rewritten as

$$\rho_\ell h_{\text{fg}} \frac{d\delta}{dt} = k_\ell \frac{T_{\text{sat}} - T_s}{\delta}.$$

Separate variables and integrate with limits shown to obtain the liquid layer growth rate,

$$\int_0^\delta \delta d\delta = \int_0^t \frac{k_\ell (T_{\text{sat}} - T_s)}{\rho_\ell h_{\text{fg}}} dt \quad \text{or} \quad \delta = \left[ \frac{2k_\ell (T_{\text{sat}} - T_s)}{\rho_\ell h_{\text{fg}}} t \right]^{1/2}. \quad (2) \quad <$$

For the prescribed conditions, the liquid layer thickness and condensate formed in one hour are

$$\delta(1\text{h}) = \left[ 2 \times 0.676 \frac{\text{W}}{\text{m}\cdot\text{K}} (100 - 80)^\circ\text{C} \times 3600\text{s} / 965 \frac{\text{kg}}{\text{m}^3} \times 2257 \times 10^3 \frac{\text{J}}{\text{kg}} \right]^{1/2} = 6.69 \text{ mm} \quad <$$

$$M(1\text{h}) = \rho_\ell A \delta = 965 \text{ kg/m}^3 \times 200 \times 10^{-6} \text{ m}^2 \times 6.69 \times 10^{-3} \text{ m} = 1.29 \times 10^{-3} \text{ kg}. \quad <$$

Continued ...

**PROBLEM 10.45 (Cont.)**

The condensate formed on a vertical plate of length  $L = \sqrt{200 \text{ mm}^2} = 0.0141 \text{ m}$  with the same conditions follows from Eq. 10.34,

$$M_{vp} = \dot{m} \cdot t = \bar{h}_L A (T_{sat} - T_s) \cdot t / h'_{fg}$$

where  $h'_{fg}$  and  $\bar{h}_L$  follow from Eqs. 10.27 and one of Eqs. 10.43 - 10.45, respectively, with P given by Eq. 10.42.

$$h'_{fg} = h_{fg} (1 + 0.68 \text{Ja}) = h_{fg} \left( 1 + 0.68 c_{p,\ell} \Delta T / h_{fg} \right)$$

$$h'_{fg} = 2257 \times 10^3 \text{ J/kg} \left( 1 + 0.68 \times 4207 \frac{\text{J}}{\text{kg} \cdot \text{K}} (100 - 80)^\circ\text{C} / 2257 \times 10^3 \text{ J/kg} \right) = 2314 \text{ kJ/kg}$$

From Eq. 10.42,

$$P = \frac{k_\ell L (T_{sat} - T_s)}{\mu_\ell h'_{fg} (v_\ell^2 / g)^{1/3}}$$

$$= \frac{0.676 \text{ W/m} \cdot \text{K} \times 0.0141 \text{ m} (100 - 80)^\circ\text{C}}{313 \times 10^{-6} \text{ N} \cdot \text{s/m}^2 \times 2314 \times 10^3 \text{ J/kg} \times \left[ (3.24 \times 10^{-7} \text{ m}^2/\text{s})^2 / 9.8 \text{ m/s}^2 \right]^{1/3}} = 11.9$$

Since  $P < 15.8$ , Eq. 10.43 gives

$$\bar{h}_L = \frac{k_\ell}{(v_\ell^2 / g)^{1/3}} 0.943 P^{-1/4} = \frac{0.676 \text{ W/m} \cdot \text{K}}{\left[ (3.24 \times 10^{-7} \text{ m}^2/\text{s})^2 / 9.8 \text{ m/s}^2 \right]^{1/3}} 0.943 \times 11.9^{-1/4} = 15,560 \text{ W/m}^2 \cdot \text{K}$$

Hence,

$$M_{vp} = 15,560 \text{ W/m}^2 \cdot \text{K} \times 200 \times 10^{-6} \text{ m}^2 (100 - 80)^\circ\text{C} \times 3600 \text{ s} / 2314 \times 10^3 \text{ J/kg}$$

$$M_{vp} = 9.7 \times 10^{-2} \text{ kg.} \quad <$$

**COMMENTS:** Note that the condensate formed by the vertical plate is almost two orders of magnitude larger. For the vertical plate the rate of condensate formation is constant. For the container bottom surface, the rate decreases with increasing time since the conduction resistance increases as the liquid layer thickness increases.

### PROBLEM 10.46

**KNOWN:** Vertical tube experiencing condensation of steam on its outer surface.

**FIND:** Heat transfer and condensation rates.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Film condensation, (2) Negligible non-condensibles, (3)  $D/2 \gg \delta$ , vertical plate behavior.

**PROPERTIES:** Table A-6, Water, vapor (1.0133 bar):  $T_{\text{sat}} = 100^\circ\text{C}$ ,  $\rho_v = 0.596 \text{ kg/m}^3$ ,  $h_{\text{fg}} = 2257 \text{ kJ/kg}$ ; Table A-6, Water, liquid ( $T_f = 97^\circ\text{C}$ ):  $\rho_\ell = 960.6 \text{ kg/m}^3$ ,  $\mu_\ell = 289 \times 10^{-6} \text{ N}\cdot\text{s/m}^2$ ,  $c_{p,\ell} = 4214 \text{ J/kg}\cdot\text{K}$ ,  $k_\ell = 0.679 \text{ W/m}\cdot\text{K}$ ,  $\nu_\ell = \mu_\ell / \rho_\ell = 3.01 \times 10^{-7} \text{ m}^2/\text{s}$ .

**ANALYSIS:** The heat transfer and condensation rates are

$$q = \bar{h}_L (\pi DL) (T_{\text{sat}} - T_s) \quad \dot{m} = q / h'_{\text{fg}}$$

where  $h'_{\text{fg}} = h_{\text{fg}} (1 + 0.68 \text{Ja})$  and  $\text{Ja} = c_{p,\ell} (T_{\text{sat}} - T_s) / h_{\text{fg}}$ . Hence  $\text{Ja} = 4214 \text{ J/kg}\cdot\text{K} (100 - 94)\text{K} / 2257 \times 10^3 \text{ J/kg} = 0.0112$  and  $h'_{\text{fg}} = 2274 \text{ kJ/kg}$ .

Eq. 10.42 yields,

$$P = \frac{k_\ell L (T_{\text{sat}} - T_s)}{\mu_\ell h'_{\text{fg}} (\nu_\ell^2 / g)^{1/3}} = \frac{0.679 \text{ W/m}\cdot\text{K} \times 1 \text{ m} \times (100 - 94)^\circ\text{C}}{289 \times 10^{-6} \text{ N}\cdot\text{s/m}^2 \times 2274 \times 10^3 \text{ J/kg} \times \left[ (3.01 \times 10^{-7} \text{ m}^2/\text{s})^2 / 9.8 \text{ m/s}^2 \right]^{1/3}} = 295$$

Since  $15.8 < P < 2530$ , Eq. 10.44 yields

$$\begin{aligned} \bar{h}_L &= \frac{k_\ell}{(\nu_\ell^2 / g)^{1/3}} \frac{1}{P} (0.68P + 0.89)^{0.82} \\ &= \frac{0.679 \text{ W/m}\cdot\text{K}}{\left[ (3.01 \times 10^{-7} \text{ m}^2/\text{s})^2 / 9.8 \text{ m/s}^2 \right]^{1/3}} \frac{1}{295} (0.68 \times 295 + 0.89)^{0.82} = 8500 \text{ W/m}^2 \cdot \text{K} \end{aligned}$$

Then from Eqs. 10.33 and 10.34,

$$\begin{aligned} q &= \bar{h}_L A (T_{\text{sat}} - T_s) = 8500 \text{ W/m}^2 \cdot \text{K} \times \pi \times 0.1 \text{ m} \times 1 \text{ m} \times (100 - 94)^\circ\text{C} = 16.0 \text{ kW} &< \\ \dot{m} &= q / h'_{\text{fg}} = (16.0 \times 10^3 \text{ W}) / (2.274 \times 10^6 \text{ J/kg}) = 7.1 \times 10^{-3} \text{ kg/s} &< \end{aligned}$$

**COMMENTS:** To determine whether the assumption  $D/2 \gg \delta$  is satisfied, use Eq. 10.26 to estimate  $\delta(L) \approx 0.12 \text{ mm}$ . Despite the laminar film assumption, clearly the assumption is justified and the vertical plate correlation is applicable.

### PROBLEM 10.47

**KNOWN:** Vertical tube experiencing condensation of steam on its outer surface.

**FIND:** Heat transfer and condensation rates.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Film condensation, (2) Negligible condensibles in steam, (3)  $D/2 \gg \delta$ , vertical plate behavior.

**PROPERTIES:** Table A-6, Water, vapor (1.5 bar):  $T_{\text{sat}} \approx 385\text{ K}$ ,  $\rho_v = 0.876\text{ kg/m}^3$ ,  $h_{\text{fg}} = 2225\text{ kJ/kg}$ ;  
 Table A-6, Water, (liquid  $T_f = 376\text{ K}$ ):  $\rho_\ell = 956.2\text{ kg/m}^3$ ,  $c_{p,\ell} = 4220\text{ J/kg}\cdot\text{K}$ ,  $\mu_\ell = 271 \times 10^{-6}\text{ N}\cdot\text{s/m}^2$ ,  $k_\ell = 0.681\text{ W/m}\cdot\text{K}$ ,  $\nu_\ell = \mu_\ell / \rho_\ell = 2.83 \times 10^{-7}\text{ m}^2/\text{s}$ .

**ANALYSIS:** The heat transfer and condensation rates are

$$q = \bar{h}_L (\pi D L) (T_{\text{sat}} - T_s) \quad \dot{m} = q / h'_{\text{fg}}$$

where  $h'_{\text{fg}} = h_{\text{fg}} (1 + 0.68 \text{ Ja})$  and  $\text{Ja} = c_{p,\ell} (T_{\text{sat}} - T_s) / h_{\text{fg}}$ . Hence,  $\text{Ja} = 4220\text{ J/kg}\cdot\text{K} (385 - 367)\text{ K} / 2225 \times 10^3\text{ J/kg} = 0.0171$  and  $h'_{\text{fg}} = 2277\text{ kJ/kg}$ .

Eq. 10.42 yields,

$$P = \frac{k_\ell L (T_{\text{sat}} - T_s)}{\mu_\ell h'_{\text{fg}} (\nu_\ell^2 / g)^{1/3}} = \frac{0.681\text{ W/m}\cdot\text{K} \times 1\text{ m} \times (385 - 367)\text{ K}}{271 \times 10^{-6}\text{ N}\cdot\text{s/m}^2 \times 2277 \times 10^3\text{ J/kg} \times \left[ (2.83 \times 10^{-7}\text{ m}^2/\text{s})^2 / 9.8\text{ m/s}^2 \right]^{1/3}} = 986$$

Since  $15.8 < P < 2530$ , Eq. 10.44 yields

$$\begin{aligned} \bar{h}_L &= \frac{k_\ell}{(\nu_\ell^2 / g)^{1/3}} \frac{1}{P} (0.68P + 0.89)^{0.82} \\ &= \frac{0.681\text{ W/m}\cdot\text{K}}{\left[ (2.83 \times 10^{-7}\text{ m}^2/\text{s})^2 / 9.8\text{ m/s}^2 \right]^{1/3}} \frac{1}{986} (0.68 \times 986 + 0.89)^{0.82} = 7130\text{ W/m}^2 \cdot \text{K} \end{aligned}$$

$$\text{Hence, } q = 7130\text{ W/m}^2 \cdot \text{K} (\pi \times 0.1\text{ m} \times 1\text{ m}) (385 - 367)\text{ K} = 40.3\text{ kW} \quad <$$

$$\dot{m} = 40.3 \times 10^3\text{ W} / 2277 \times 10^3\text{ J/kg} = 0.0177\text{ kg/s.} \quad <$$

**COMMENTS:** By comparing these results with those of Problem 10.46, the effect of increased pressure on condensation can be seen.

p (bar)	$T_{\text{sat}}$ (K)	$T_{\text{sat}} - T_s$ (K)	$\bar{h}_L$ (W/m <sup>2</sup> ·K)	q (kW)	$\dot{m} \cdot 10^3$ (kg/s)
1.01	373	6	8500	16.0	7.1
1.5	385	18	7130	40.3	17.7

The effect of increasing the pressure from 1.01 to 1.5 bar is to increase the excess temperature three-fold, to decrease  $\bar{h}_L$  by 16%, and to increase the rates by a factor of 2.5.

## PROBLEM 10.48

**KNOWN:** Length of isothermal vertical plate,  $L$ , experiencing wave-free laminar condensation.

**FIND:** Expression for the average heat transfer coefficients for  $N$  plates each of length  $L_N = L/N$  to the average coefficient for the single plate.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Constant properties.

**ANALYSIS:** Equation 10.42 gives

$$P = \frac{k_\ell L (T_{\text{sat}} - T_s)}{\mu_\ell h'_{fg} (v_\ell^2 / g)^{1/3}}$$

For wave free laminar condensation, Eq. 10.43 reveals that

$$\bar{h}_{L,1} \propto P^{-1/4} \propto L^{-1/4}$$

For multiple plates, each of length  $L_N = L/N$ ,

$$\bar{h}_{L,N} \propto L_N^{-1/4} \propto \left(\frac{L}{N}\right)^{-1/4}$$

Therefore,  $\bar{h}_{L,N} / \bar{h}_{L,1} = N^{1/4}$

<

**COMMENTS:** By breaking the single plate into shorter segments, the average liquid film thickness is reduced, resulting in a modest increase in the average heat transfer coefficient, resulting in heat transfer *enhancement*.

### PROBLEM 10.49

**KNOWN:** Cooled vertical plate 500-mm high and 200-mm wide condensing saturated steam at 1 atm.

**FIND:** (a) Surface temperature,  $T_s$ , required to achieve a condensation rate of  $\dot{m} = 25 \text{ kg/h}$ , (b) Compute and plot  $T_s$  as a function of the condensation rate for the range  $15 \leq \dot{m} \leq 50 \text{ kg/h}$ , and (c) Compute and plot  $T_s$  for the same range of  $\dot{m}$ , but if the plate is 200 mm high and 500 mm wide (vs. 500 mm high and 200 mm wide for parts (a) and (b)).

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Film condensation, (2) Negligible non-condensables in steam.

**PROPERTIES:** Table A-6, Water, vapor (1.0133 bar):  $T_{\text{sat}} = 100^\circ\text{C}$ ,  $h_{\text{fg}} = 2257 \text{ kJ/kg}$ ; Table A-6, Water, liquid ( $T_f \approx (74 + 100)^\circ\text{C}/2 \approx 360 \text{ K}$ ):  $\rho_\ell = 967.1 \text{ kg/m}^3$ ,  $c_{p,\ell} = 4203 \text{ J/kg}\cdot\text{K}$ ,  $\mu_\ell = 324 \times 10^{-6} \text{ N}\cdot\text{s/m}^2$ ,  $k_\ell = 0.674 \text{ W/m}\cdot\text{K}$ ,  $\nu_\ell = \mu_\ell / \rho_\ell = 3.35 \times 10^{-7} \text{ m}^2/\text{s}$ .

**ANALYSIS:** (a) With knowledge of  $\dot{m} = 25 \text{ kg/h} = 6.94 \times 10^{-4} \text{ kg/s}$ ,  $\text{Re}_\delta$  can be calculated from Eq. 10.36,

$$\text{Re}_\delta = \frac{4\dot{m}}{\mu_\ell b} = \left(4 \times 6.94 \times 10^{-4} \text{ kg/s}\right) / \left(324 \times 10^{-6} \text{ N}\cdot\text{s/m}^2 \times 0.2 \text{ m}\right) = 429$$

Thus the flow is wavy laminar and Eq. 10.39 applies, from which

$$\begin{aligned} \bar{h}_L &= \frac{k_\ell}{(\nu_\ell^2/g)^{1/3}} \frac{\text{Re}_\delta}{1.08 \text{Re}_\delta^{1.22} - 5.2} \\ &= \frac{0.674 \text{ W/m}\cdot\text{K}}{\left[(3.35 \times 10^{-7} \text{ m}^2/\text{s})^2/9.8 \text{ m/s}^2\right]^{1/3}} \frac{429}{1.08 \times 429^{1.22} - 5.2} = 7320 \text{ W/m}^2 \cdot \text{K} \end{aligned}$$

Equation 10.34 can then be solved for  $T_{\text{sat}} - T_s$ , making use of Eq. 10.27, to give

$$T_{\text{sat}} - T_s = \frac{\dot{m} h_{\text{fg}}}{\bar{h}_L A - 0.68 \dot{m} c_{p,\ell}} = \frac{6.94 \times 10^{-4} \text{ kg/s} \times 2257 \times 10^3 \text{ J/kg}\cdot\text{K}}{7320 \text{ W/m}^2 \cdot \text{K} \times 0.1 \text{ m}^2 - 0.68 \times 6.94 \times 10^{-4} \text{ kg/s} \times 4203 \text{ J/kg}\cdot\text{K}} = 22.0^\circ\text{C}$$

Thus

$$T_s = 78^\circ\text{C} \quad \leftarrow$$

This value is to be compared to the assumed value of  $74^\circ\text{C}$  used for evaluating properties. See comment 1.

(b,c) Using the *IHT Correlations Tool, Film Condensation, Vertical Plate* for laminar, wavy-laminar and turbulent regions, combined with the *Properties Tool* for Water, the surface temperature  $T_s$  was calculated as a function of the condensation rate,  $\dot{m}$ , considering the two plate configurations as indicated in the plot below.

Continued...

## PROBLEM 10.49 (Cont.)

As expected the condensation rate increases with decreasing surface temperature. The plate with the shorter height ( $L = 200$  mm vs  $500$  mm) will have the thinner boundary layer and, hence, the higher average convection coefficient. Since both plate configurations have the same total surface area, the  $200$ -mm height plate will have the larger heat transfer and condensation rates. For the range of conditions examined, the condensate flow is in the wavy-laminar region.

**COMMENTS:** (1) With the IHT model developed for parts (b) and (c), the result for the part (a) conditions with  $\dot{m} = 25$  kg/h is  $T_s = 77.9^\circ\text{C}$  ( $Re_\delta = 438$  and  $\bar{h}_L = 7400$  W/m<sup>2</sup> · K). Hence, the assumed value ( $T_s = 74^\circ\text{C}$ ) required to initiate the analysis was a good one.

(2) A copy of the IHT Workspace model used to generate the above plot is shown below.

```

/* Correlations Tool
- Film Condensation, Vertical Plate, Laminar, wavy-laminar and turbulent regions: */
NuLbar = NuL_bar_FCO_VP(Re_delta,Pr) // Eq 10.38, 39, 40
NuLbar = hLbar * (nu^2 / g)^(1/3) / kl
g = 9.8 // Gravitational constant, m/s^2
Ts = Ts_C + 273 // Surface temperature, K
Ts_C = 78 // Initial guess value used to solve the model
Tsat = 100 + 273 // Saturation temperature, K
// The liquid properties are evaluated at the film temperature, Tf,
Tf = Tfluid_avg(Ts,Tsat)
// The condensation and heat rates are
q = hLbar * As * (Tsat - Ts) // Eq 10.33
As = L * b // Surface Area, m^2
mdot = q / h'fg // Eq 10.34
h'fg = hfg + 0.68 * cpl * (Tsat - Ts) // Eq 10.27
// The Reynolds number based upon film thickness is
Re_delta = 4 * mdot / (mu * b) // Eq 10.36
// Assigned Variables:
L = 0.5 // Vertical height, m
b = 0.2 // Width, m
mdot_h = mdot * 3600 // Condensation rate, kg/h
//mdot_h = 25 // Design value, part (a)
// Properties Tool - Water:
// Water property functions :T dependence, From Table A.6
// Units: T(K), p(bars);
xl = 0 // Quality (0=sat liquid or 1=sat vapor)
rho_l = rho_Tx("Water",Tf,xl) // Density, kg/m^3
hfg = hfg_T("Water",Tsat) // Heat of vaporization, J/kg
cpl = cp_Tx("Water",Tf,xl) // Specific heat, J/kg-K
mu_l = mu_Tx("Water",Tf,xl) // Viscosity, N-s/m^2
nu_l = nu_Tx("Water",Tf,xl) // Kinematic viscosity, m^2/s
kl = k_Tx("Water",Tf,xl) // Thermal conductivity, W/m-K
Pr_l = Pr_Tx("Water",Tf,xl) // Prandtl number

```

### PROBLEM 10.50

**KNOWN:** Plate dimensions, temperature and inclination. Pressure of saturated steam.

**FIND:** (a) Heat transfer and condensation rates for vertical plate, (b) Heat transfer and condensation rates for inclined plate.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Constant properties.

**PROPERTIES:** Table A-6, saturated vapor ( $p=1.0133$  bars):  $T_{\text{sat}} = 100^\circ\text{C}$ ,  $h_{\text{fg}} = 2257$  kJ/kg. Table A-6, saturated liquid ( $T_f = 75^\circ\text{C}$ ):  $\rho_\ell = 975$  kg/m<sup>3</sup>,  $\mu_\ell = 375 \times 10^{-6}$  N·s/m<sup>2</sup>,  $k_\ell = 0.668$  W/m·K,  $c_{p,\ell} = 4193$  J/kg·K,  $\nu_\ell = \mu_\ell / \rho_\ell = 3.85 \times 10^{-7}$  m<sup>2</sup>/s,  $\text{Pr}_\ell = 2.35$ .

**ANALYSIS:** (a) Equation 10.27 gives  $h'_{\text{fg}} = h_{\text{fg}} + 0.68c_{p,\ell}(T_{\text{sat}} - T_s) = 2400$  kJ/kg. Then, from Eq. 10.42,

$$P = \frac{k_\ell L (T_{\text{sat}} - T_s)}{\mu_\ell h'_{\text{fg}} (\nu_\ell^2 / g)^{1/3}} = \frac{0.668 \text{ W/m} \cdot \text{K} \times 2 \text{ m} \times (100 - 50)^\circ\text{C}}{375 \times 10^{-6} \text{ N} \cdot \text{s/m}^2 \times 2400 \times 10^3 \text{ J/kg} \times \left[ (3.85 \times 10^{-7} \text{ m}^2/\text{s})^2 / 9.8 \text{ m/s}^2 \right]^{1/3}} = 3000$$

Therefore, Eq. 10.45 applies, and

$$\bar{h}_L = \frac{k_\ell}{(\nu_\ell^2 / g)^{1/3}} \frac{1}{P} \left[ (0.024P - 53) \text{Pr}_\ell^{1/2} + 89 \right]^{4/3} = \frac{0.668 \text{ W/m} \cdot \text{K}}{\left[ (3.85 \times 10^{-7} \text{ m}^2/\text{s})^2 / 9.8 \text{ m/s}^2 \right]^{1/3}} \frac{1}{3000} \left[ (0.024 \times 3000 - 53) \times 2.35^{1/2} + 89 \right]^{4/3} = 5220 \text{ W/m}^2 \cdot \text{K}$$

From Eqs. (10.33) and (10.34) the heat and condensation rates are then

$$q = \bar{h}_L A (T_{\text{sat}} - T_s) = 5220 \text{ W/m}^2 \cdot \text{K} \times 2 \text{ m} \times 2 \text{ m} \times (100 - 50)^\circ\text{C} = 1.04 \times 10^6 \text{ W} \quad <$$

$$\dot{m} = q/h'_{\text{fg}} = (1.04 \times 10^6 \text{ W}) / (2400 \times 10^3 \text{ J/kg}) = 0.435 \text{ kg/s} \quad <$$

(b) With  $\bar{h}_{L(\text{incl})} \approx (\cos \theta)^{1/4} \bar{h}_L$ , we obtain  $\bar{h}_{L(\text{incl})} \approx 0.917 \times 5220 \text{ W/m}^2 \cdot \text{K} = 4820 \text{ W/m}^2 \cdot \text{K}$ . If the inclination reduces  $\bar{h}_L$  by 8.4%, the heat and condensation rates are reduced by equivalent amounts. Hence,

$$q = 0.964 \times 10^6 \text{ W}, \quad \dot{m} = 0.402 \text{ kg/s} \quad <$$

### PROBLEM 10.51

**KNOWN:** Saturated ethylene glycol (1 atm) condensing on a vertical plate at 420 K.

**FIND:** Heat transfer rate to the plate and condensation rate.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Film condensation, (2) Negligible non-condensable gases in vapor.

**PROPERTIES:** Table A-5, Ethylene glycol vapor (1 atm):  $T_{sat} = 470\text{ K}$ ,  $\rho_v \approx 0\text{ kg/m}^3$ ,  $h_{fg} = 812\text{ kJ/kg}$ ;  
Table A-5, Ethylene glycol, liquid ( $T_f = (T_s + T_{sat})/2 \approx 445\text{ K}$ ; use properties at upper limit of table 373K):  $\rho_\ell = 1058.5\text{ kg/m}^3$ ,  $c_{p,\ell} = 2742\text{ J/kg}\cdot\text{K}$ ,  $\mu_\ell = 0.215 \times 10^{-2}\text{ N}\cdot\text{s/m}^2$ ,  $k_\ell = 0.263\text{ W/m}\cdot\text{K}$ ,  $\nu_\ell = 2.03 \times 10^{-6}\text{ m}^2/\text{s}$ .

**ANALYSIS:** Equation 10.27 gives  $h'_{fg} = h_{fg} + 0.68c_{p,\ell}(T_{sat} - T_s) = 905\text{ kJ/kg}$ . Then Eq. 10.42 yields,

$$P = \frac{k_\ell L (T_{sat} - T_s)}{\mu_\ell h'_{fg} (\nu_\ell^2 / g)^{1/3}} = \frac{0.263\text{ W/m}\cdot\text{K} \times 0.3\text{ m} \times (470 - 420)\text{ K}}{0.215 \times 10^{-2}\text{ N}\cdot\text{s/m}^2 \times 905 \times 10^3\text{ J/kg} \times \left[ (2.03 \times 10^{-6}\text{ m}^2/\text{s})^2 / 9.8\text{ m/s}^2 \right]^{1/3}} = 27.1$$

Since  $15.8 < P < 2530$ , Eq. 10.44 yields

$$\begin{aligned} \bar{h}_L &= \frac{k_\ell}{(\nu_\ell^2 / g)^{1/3}} \frac{1}{P} (0.68P + 0.89)^{0.82} \\ &= \frac{0.263\text{ W/m}\cdot\text{K}}{\left[ (2.03 \times 10^{-6}\text{ m}^2/\text{s})^2 / 9.8\text{ m/s}^2 \right]^{1/3}} \frac{1}{27.1} (0.68 \times 27.1 + 0.89)^{0.82} = 1470\text{ W/m}^2\cdot\text{K} \end{aligned}$$

Then from Eqs. 10.33 and 10.34,

$$q = \bar{h}_L A (T_{sat} - T_s) = 1470\text{ W/m}^2\cdot\text{K} \times 0.3\text{ m} \times 0.1\text{ m} \times (470 - 420)\text{ K} = 2200\text{ W} \quad <$$

$$\dot{m} = q / h'_{fg} = (2200\text{ W}) / (905 \times 10^3\text{ J/kg}) = 2.43 \times 10^{-3}\text{ kg/s} \quad <$$

**COMMENTS:** Laminar condensation would yield results for the heat and mass rates within 1.2% of the wavy laminar values.

## PROBLEM 10.52

**KNOWN:** Vertical plate 2.5 m high at a surface temperature  $T_s = 54^\circ\text{C}$  exposed to steam at atmospheric pressure.

**FIND:** (a) Condensation and heat transfer rates per unit width, (b) Whether flow regime would stay the same or change if the height were halved, and (c) Compute and plot the condensation rates for the two plate heights (2.5 m and 1.25 m) as a function of surface temperature for the range,  $54 \leq T_s \leq 90^\circ\text{C}$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Film condensation, (2) Negligible non-condensables in steam.

**PROPERTIES:** Table A-6, Water, vapor (1 atm):  $T_{\text{sat}} = 100^\circ\text{C}$ ,  $h_{\text{fg}} = 2257 \text{ kJ/kg}$ ; Table A-6, Water, liquid ( $T_f = (100 + 54)^\circ\text{C}/2 = 350 \text{ K}$ ):  $\rho_\ell = 973.7 \text{ kg/m}^3$ ,  $k_\ell = 0.668 \text{ W/m}\cdot\text{K}$ ,  $\mu_\ell = 365 \times 10^{-6} \text{ N}\cdot\text{s/m}^2$ ,  $c_{p,\ell} = 4195 \text{ J/kg}\cdot\text{K}$ ,  $\text{Pr}_\ell = 2.29$ ,  $\nu_\ell = \mu_\ell / \rho_\ell = 3.75 \times 10^{-7} \text{ m}^2/\text{s}$ .

**ANALYSIS:** (a) From Equation 10.27,  $h'_{\text{fg}} = h_{\text{fg}} + 0.68c_{p,\ell}(T_{\text{sat}} - T_s) = 2388 \text{ kJ/kg}$ . Then Eq. 10.42 yields,

$$P = \frac{k_\ell L (T_{\text{sat}} - T_s)}{\mu_\ell h'_{\text{fg}} (\nu_\ell^2 / g)^{1/3}} = \frac{0.668 \text{ W/m}\cdot\text{K} \times 2.5 \text{ m} \times (100 - 54)^\circ\text{C}}{365 \times 10^{-6} \text{ N}\cdot\text{s/m}^2 \times 2388 \times 10^3 \text{ J/kg} \times [(3.75 \times 10^{-7} \text{ m}^2/\text{s})^2 / 9.8 \text{ m/s}^2]^{1/3}} = 3630$$

Since  $P > 2530$ , the regime is turbulent and Eq. 10.45 yields

$$\begin{aligned} \bar{h}_L &= \frac{k_\ell}{(\nu_\ell^2 / g)^{1/3}} \frac{1}{P} \left[ (0.024P - 53) \text{Pr}_\ell^{1/2} + 89 \right]^{4/3} \\ &= \frac{0.668 \text{ W/m}\cdot\text{K}}{[(3.75 \times 10^{-7} \text{ m}^2/\text{s})^2 / 9.8 \text{ m/s}^2]^{1/3}} \frac{1}{3630} \left[ (0.024 \times 3630 - 53) \times 2.29^{1/2} + 89 \right]^{4/3} = 5540 \text{ W/m}^2 \cdot \text{K} \end{aligned}$$

Then from Eqs. 10.33 and 10.34,

$$q' = \bar{h}_L L (T_{\text{sat}} - T_s) = 5540 \text{ W/m}^2 \cdot \text{K} \times 2.5 \text{ m} \times (100 - 54)^\circ\text{C} = 637 \text{ kW/m} \quad <$$

$$\dot{m}' = q' / h'_{\text{fg}} = 637 \times 10^3 \text{ W/m} / 2388 \times 10^3 \text{ J/kg} = 0.267 \text{ kg/m}\cdot\text{s} \quad <$$

(b) If the length is halved,  $L = 1.25 \text{ m}$ , then  $P$  will be halved,  $P = 1810$ .

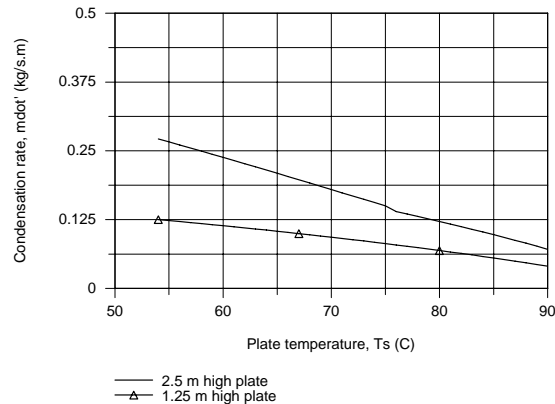

Since  $15.8 < P < 2530$ , the flow regime changes to wavy laminar flow. <

Continued...

### PROBLEM 10.52 (Cont.)

Eq. 10.44 then yields  $\bar{h}_L = 5190 \text{ W/m}^2 \cdot \text{K}$  and we find  $q' = \bar{h}_L L (T_{\text{sat}} - T_s) = 299 \text{ kW/m}$  and  $\dot{m}' = q'/h'_{fg} = 0.125 \text{ kg/m} \cdot \text{s}$ . Note that the height was decreased by a factor of 2 while the rates decreased by a factor of 2.13. Would you have expected this result?

(c) Using the *IHT Correlation Tool, Film Condensation, Vertical Plate* for laminar, wavy-laminar, and turbulent regions, combined with the *Properties Tool for Water*, the condensation rates were calculated as a function of the surface temperature considering the two plate heights indicated.

The condensation rate decreases nearly linearly with increasing surface temperature. The inflection in the upper curve ( $L = 2.5 \text{ m}$ ) corresponds to the flow transition at  $P = 2530$  between wavy-laminar and turbulent. For surface temperature lower than  $76^\circ\text{C}$ , the flow is turbulent over the  $2.5 \text{ m}$  plate. The flow over the  $1.25 \text{ m}$  plate is always in the wavy-laminar region. The fact that the  $2.5 \text{ m}$  plate experiences turbulent flow explains the height-rate relationship mentioned in the closing sentences of part (b).

**COMMENTS:** A copy of the IHT model used to generate the above plot is shown below.

```

/* Correlations Tool
- Film Condensation, Vertical Plate, Laminar, wavy-laminar and turbulent regions: */
NuLbar = NuL_bar_FCO_VP(Redelta,Pr) // Eq 10.38, 39, 40
NuLbar = hLbar * (nuL^2 / g)^(1/3) / kl
g = 9.8 // Gravitational constant, m/s^2
Ts = Ts_C + 273 // Surface temperature, K
Ts_C = 54 // Part (a) design condition
Tsat = 100 + 273 // Saturation temperature, K
// The liquid properties are evaluated at the film temperature, Tf
Tf = Tfluid_avg(Ts,Tsat)
// The condensation and heat rates are
q = hLbar * As * (Tsat - Ts) // Eq 10.33
As = L * b // Surface Area, m^2
mdot = q / h'fg // Eq 10.34
h'fg = hfg + 0.68 * cpl * (Tsat - Ts) // Eq 10.27
// The Reynolds number based upon film thickness is
Redelta = 4 * mdot / (muL * b) // Eq 10.36

// Assigned Variables:
L = 1.25 // Height, m
b = 1 // Width, m

// Properties Tool - Water:
// Water property functions :T dependence, From Table A.6
// Units: T(K), p(bars);
xl = 0 // Quality (0=sat liquid or 1=sat vapor)
rhoL = rho_Tx("Water",Tf,xl) // Density, kg/m^3
hfg = hfg_T("Water",Tsat) // Heat of vaporization, J/kg
cpl = cp_Tx("Water",Tf,xl) // Specific heat, J/kg-K
muL = mu_Tx("Water",Tf,xl) // Viscosity, N-s/m^2
nuL = nu_Tx("Water",Tf,xl) // Kinematic viscosity, m^2/s
kl = k_Tx("Water",Tf,xl) // Thermal conductivity, W/m-K
PrL = Pr_Tx("Water",Tf,xl) // Prandtl number

```

### PROBLEM 10.53

**KNOWN:** Two vertical plate configurations maintained at  $90^\circ\text{C}$  for condensing saturated steam at 1 atm: single plate  $L \times w$  and two plates each  $L/2 \times w$  where  $L$  and  $w$  are the vertical and horizontal dimensions, respectively.

**FIND:** Which case will provide the larger heat transfer or condensation rate.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible concentration of non-condensable gases in the steam.

**PROPERTIES:** Table A-6, Saturated water vapor (1 atm):  $T_{\text{sat}} = 100^\circ\text{C}$ ,  $h_{\text{fg}} = 2257 \text{ kJ/kg}$ ; Saturated water ( $T_f = (T_s + T_{\text{sat}})/2 = (90 + 100)^\circ\text{C}/2 = 95^\circ\text{C} = 368\text{K}$ ):  $\rho_\ell = (1/v_f) = 962 \text{ kg/m}^3$ ,  $\mu_\ell = 296 \times 10^{-6} \text{ N}\cdot\text{s/m}^2$ ,  $k_\ell = 0.678 \text{ W/m}\cdot\text{K}$ ,  $c_{p,\ell} = 4212 \text{ J/kg}\cdot\text{K}$ ,  $\nu_\ell = \mu_\ell / \rho_\ell = 3.08 \times 10^{-7} \text{ m}^2/\text{s}$ .

**ANALYSIS:** The heat transfer and condensation rates are

$$q = \bar{h}_L A_s (T_{\text{sat}} - T_s) \quad \dot{m} = q / h'_{\text{fg}}$$

where the total area,  $A_s$ , is the same for the two cases. Hence,

$$\frac{q_1}{q_2} = \frac{\dot{m}_1}{\dot{m}_2} = \frac{\bar{h}_{L,1}}{\bar{h}_{L,2}}$$

where the average convection coefficients  $\bar{h}_{L,1}$  and  $\bar{h}_{L,2}$  are evaluated for plate lengths of  $L$  and  $L/2$ , respectively. For *laminar film* condensation on both plates, using the correlation of Eq. 10.31, with  $\bar{h}_L \propto L^{-1/4}$ ,

$$q_1 / q_2 = (L / [L/2])^{-1/4} = 0.84.$$

Hence, case 2 is preferred and provides 19% more heat transfer ( $q_2 / q_1 = 1/0.84 = 1.19$ ). <

The laminar solution is valid provided that  $P < 15.8$ , therefore from Eq. 10.42 we require

Continued ...

### PROBLEM 10.53 (Cont.)

$$L < 15.8 \frac{\mu_\ell h'_{fg} (v_\ell^2/g)^{1/3}}{k_\ell (T_{\text{sat}} - T_s)} = 15.8 \times \frac{296 \times 10^{-6} \text{ N} \cdot \text{s}/\text{m}^2 \times 2286 \times 10^3 \text{ J}/\text{kg} \times \left[ (3.08 \times 10^{-7} \text{ m}^2/\text{s})^2 / 9.8 \text{ m}/\text{s}^2 \right]^{1/3}}{0.678 \text{ W}/\text{m} \cdot \text{K} \times (100 - 90)^\circ\text{C}}$$
$$= 0.035 \text{ m} = 35 \text{ mm}$$

where from Eq. 10.27,

$$h'_{fg} = h_{fg} + 0.68 c_{p,\ell} (T_{\text{sat}} - T_s)$$

$$h'_{fg} = 2257 \text{ kJ}/\text{kg} + 0.68 \times 4212 \text{ J}/\text{kg} \cdot \text{K} (100 - 90) \text{ K} = 2286 \text{ kJ}/\text{kg}.$$

We can anticipate for other, larger values of  $L$  that the comparison of  $\bar{h}_L$  values cannot be so easily made. However, according to Figure 10.13, we expect the same behavior of  $\bar{h}_L$  in the *wavy* region since  $\bar{h}_L$  decreases with increasing  $\text{Re}_\delta$  (corresponding to increasing  $L$ ), and anticipate that indeed case 2 will provide the greater condensation rate. Note that in the turbulent region with the increase in  $\bar{h}_L$  with  $\text{Re}_\delta$ , we cannot conclude with certainty which case is preferred.

**COMMENTS:** In dealing with single-phase, forced or free convection, we associate thin thermal boundary layers with higher heat transfer rates. For vertical plates, we would expect the shorter plate to have the higher convection heat transfer coefficient. The results of this problem suggest the same is true for condensation on the vertical plate.

## PROBLEM 10.54

**KNOWN:** Number, diameter and wall temperature of condenser tubes in a square array. Pressure of saturated steam around tubes.

**FIND:** Rates of heat transfer and condensation per unit length of the array.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Spatially uniform cylinder temperature, (2) Negligible concentration of noncondensable gases in steam, (3) Average heat transfer coefficient varies with tube row as  $n = -1/6$  in Eq. 10.49.

**PROPERTIES:** Table A-6, saturated vapor ( $p_{\text{sat}} = 0.105 \text{ bar}$ ):  $T_{\text{sat}} = 320 \text{ K} = 47^\circ\text{C}$ ,  $\rho_v = 0.0713 \text{ kg/m}^3$ ,  $h_{\text{fg}} = 2390 \text{ kJ/kg}$ . Table A-6, saturated liquid ( $T_f = 32^\circ\text{C} = 305 \text{ K}$ ):  $\rho_\ell = 995 \text{ kg/m}^3$ ,  $\mu_\ell = 769 \times 10^{-6} \text{ N}\cdot\text{s/m}^2$ ,  $k_\ell = 0.620 \text{ W/m}\cdot\text{K}$ ,  $c_{p,\ell} = 4178 \text{ J/kg}\cdot\text{K}$ .

**ANALYSIS:** Equation 10.46 may be used to find the convection coefficient for the top, unfinned tube. With  $\text{Ja} = c_{p,\ell} (T_{\text{sat}} - T_s) / h_{\text{fg}} = 0.052$  and  $h'_{\text{fg}} = h_{\text{fg}} (1 + 0.68 \text{Ja}) = 1.04 (2.390 \times 10^6 \text{ J/kg}) = 2.51 \times 10^6 \text{ J/kg}$ ,

$$\bar{h}_D = 0.729 \left[ \frac{g \rho_\ell (\rho_\ell - \rho_v) k_\ell^3 h'_{\text{fg}}}{\mu_\ell (T_{\text{sat}} - T_s) D} \right]^{1/4}$$

$$\bar{h}_D = 0.729 \left[ \frac{9.8 \text{ m/s}^2 \times 995 \text{ kg/m}^3 (995 - 0.0713) \text{ kg/m}^3 (0.62 \text{ W/m}\cdot\text{K})^3 2.51 \times 10^6 \text{ J/kg}}{769 \times 10^{-6} \text{ N}\cdot\text{s/m}^2 (30^\circ\text{C}) 0.025 \text{ m}} \right]^{1/4} = 7308 \text{ W/m}^2 \cdot \text{K}$$

From Eq. 10.49 the array-averaged convection coefficient is

$$\bar{h}_{D,N} = \bar{h}_D N^n = 7308 \text{ W/m}^2 \cdot \text{K} \times 25^{-1/6} = 4274 \text{ W/m}^2 \cdot \text{K}.$$

The heat rate per unit length of the array is

$$q' = N^2 \bar{h}_{D,N} (\pi D) (T_{\text{sat}} - T_s) = 625 \times 4274 \text{ W/m}^2 \cdot \text{K} (\pi \times 0.025 \text{ m}) 30^\circ\text{C} = 6.29 \times 10^6 \text{ W/m} \quad <$$

The corresponding condensation rate is

$$\dot{m}' = \frac{q'}{h'_{\text{fg}}} = \frac{6.29 \times 10^6 \text{ W/m}}{2.51 \times 10^6 \text{ J/kg}} = 2.51 \text{ kg/s}\cdot\text{m} \quad <$$

**COMMENTS:** The heat transfer rate could be increased by adding fins to the tubes.

## PROBLEM 10.55

**KNOWN:** Tube wall diameters and thermal conductivity. Mean temperature and flow rate of water flow through tube. Pressure of saturated steam around tube.

**FIND:** (a) Rates of heat transfer and condensation per unit length, (b) Effect of flow rate on heat transfer.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible concentration of noncondensable gases in the steam, (2) Uniform tube surface temperatures, (3) Laminar film condensation, (4) Fully-developed internal flow, (5) Constant properties.

**PROPERTIES:** Table A-6, water ( $T_m = 290$  K):  $\mu = 0.00108$  N·s/m<sup>2</sup>,  $k = 0.598$  W/m·K,  $Pr = 7.56$ .

Table A-6, saturated vapor ( $p = 0.135$  bar):  $T_{sat} = 325$  K = 52°C,  $\rho_v = 0.0904$  kg/m<sup>3</sup>,  $h_{fg} = 2378$

kJ/kg. Table A-6, saturated liquid ( $T_f \approx T_{sat}$ ):  $\rho_\ell = 987$  kg/m<sup>3</sup>,  $c_{p,\ell} = 4182$  J/kg·K,

$\mu_\ell = 528 \times 10^{-6}$  N·s/m<sup>2</sup>,  $k_\ell = 0.645$  W/m·K.

**ANALYSIS:** (a) From the thermal circuit, the heat rate may be expressed as

$$q' = \frac{T_{sat} - T_m}{R'_{fc} + R'_{cond} + R'_{conv}} \quad (1)$$

where,  $R'_{cond} = \ln(D_o / D_i) / 2\pi k_s = 0.00152$  m·K/W

The convection resistance is  $R'_{conv} = (\pi D_i h_i)^{-1}$ . With  $Re_D = 4\dot{m} / \pi D_i \mu = 11,336$ , the flow is turbulent and the Dittus-Boelter correlation yields

$$h_i = \left( \frac{k}{D_i} \right) 0.023 Re_D^{4/5} Pr^{0.4} = \left( \frac{0.598 \text{ W/m}\cdot\text{K}}{0.026 \text{ m}} \right) 0.023 (11,336)^{4/5} (7.56)^{0.4} = 2082 \text{ W/m}^2 \cdot \text{K}$$

The convection resistance is then

$$R'_{conv} = (\pi D_i h_i)^{-1} = \left( \pi \times 0.026 \text{ m} \times 2082 \text{ W/m}^2 \cdot \text{K} \right)^{-1} = 0.00588 \text{ m}\cdot\text{K/W}$$

The resistance associated with the condensate film is  $R'_{fc} = (\pi D_o \bar{h}_o)^{-1}$ , where  $\bar{h}_o$  is given by Eq. 10.46. With  $C = 0.729$ ,

$$\bar{h}_o = C \left[ \frac{g \rho_\ell (\rho_\ell - \rho_v) k_\ell^3 h'_{fg}}{\mu_\ell (T_{sat} - T_{s,o}) D_o} \right]^{1/4} = 0.729 \left[ \frac{9.8 \text{ m/s}^2 \times 987 (987 - 0.09) \text{ kg}^2/\text{m}^6 (0.645 \text{ W/m}\cdot\text{K})^3 h'_{fg}}{528 \times 10^{-6} \text{ N}\cdot\text{s/m}^2 (325 - T_{s,o}) \times 0.030 \text{ m}} \right]^{1/4}$$

$$\bar{h}_o = 462 \left( \frac{\text{W}^3 \cdot \text{kg}}{\text{m}^8 \cdot \text{K}^3 \cdot \text{s}} \right)^{1/4} \left( \frac{h'_{fg}}{325 - T_{s,o}} \right)^{1/4}$$

where  $h'_{fg} = h_{fg} + 0.68 c_{p,\ell} (T_{sat} - T_{s,o}) = 2.38 \times 10^6$  J/kg + 2844 J/kg·K (325 -  $T_{s,o}$ )

The unknown surface temperature may be determined from an additional rate equation, such as

Continued ...

**PROBLEM 10.55 (Cont.)**

$$q' = \frac{T_{s,o} - T_m}{R'_{\text{cond}} + R'_{\text{conv}}} \quad (2)$$

Substituting the thermal resistances into Eqs. (1) and (2), an iterative solution yields

$$T_{s,o} = 321.6 \text{ K} = 48.6^\circ\text{C} \quad q' = 4270 \text{ W/m} \quad <$$

The condensation rate is then

$$\dot{m}'_{\text{cond}} = \frac{q'}{h'_{\text{fg}}} = \frac{4270 \text{ W/m}}{2.39 \times 10^6 \text{ J/kg}} = 0.00179 \text{ kg/s} \cdot \text{m} \quad <$$

The corresponding values of the condensate convection coefficient and resistance are

$$\bar{h}_o = 13,380 \text{ W/m}^2 \cdot \text{K}$$

and  $R'_{\text{fc}} = 0.000793 \text{ m} \cdot \text{K/W}$

Because  $R'_{\text{conv}}$  is much larger than  $R'_{\text{cond}}$  and  $R'_{\text{fc}}$ , attention should be paid to reducing the convection resistance in order to increase the heat rate. The resistance to heat flow by convection is the *limiting factor*.

(b) The effects of varying the flow rate are shown below

The effect of increasing  $\dot{m}$  on  $q'$  is significant and is accompanied by a reduction in  $T_{s,o}$ .

**COMMENTS:** (1) Use of the IHT convection and condensation correlations, as well as its temperature-dependent properties of water facilitated the numerical solution. (2) Evaluation of the film properties at  $T_{\text{sat}}$  is reasonable for part (a), since  $T_f = (T_{s,o} + T_{\text{sat}})/2 = 50.3^\circ\text{C} \approx T_{\text{sat}}$ . However, with increasing  $\dot{m}$  and hence decreasing  $T_{s,o}$ , the approximation would become inappropriate.

### PROBLEM 10.56

**KNOWN:** Inner surface of a vertical thin-walled container of length  $L$  and diameter  $D$  experiences condensation of a saturated vapor. Container wall maintained at a uniform surface temperature by flowing cold water across its outer surface.

**FIND:** Expression for the time,  $t_f$ , required to fill the container with condensate assuming the condensate film is laminar. Express your result in terms of  $D$ ,  $L$ ,  $(T_{sat} - T_s)$ ,  $g$ , and appropriate fluid properties.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Laminar film condensation on a vertical surface, (2) Uniform temperature container wall surface, and (3) Mass of liquid condensate in the laminar film negligible compared to liquid mass on bottom of container.

**ANALYSIS:** From an instantaneous mass balance on the container,

$$\dot{m}(t) = \frac{dM}{dt} \quad (1)$$

Where  $\dot{m}(t)$  is the condensate rate and the liquid mass in the container,  $M$ , is

$$M = \rho_\ell \left( \pi D^2 / 4 \right) (L - x) \quad (2)$$

The condensate rate from Eq. 10.34 can be expressed as

$$\dot{m}(t) = \frac{q}{h'_{fg}} = \frac{\bar{h}_s A_s (T_{sat} - T_s)}{h'_{fg}} \quad (3)$$

where the average film coefficient over the height 0 to  $x$  from Eq. 10.31 is,

$$\bar{h}_s = 0.943 \left[ \frac{g \rho_\ell (\rho_\ell - \rho_v) k_\ell^3 h'_{fg}}{\mu_\ell (T_{sat} - T_s) x} \right]^{1/4} \quad (4)$$

and the surface area over which condensation occurs is

$$A_s = \pi D x \quad (5)$$

Continued...

**PROBLEM 10.56 (Cont.)**

Substituting Eqs (2-5) into Eq. (1),

$$0.943 \left[ \frac{g \rho_\ell (\rho_\ell - \rho_v) k_\ell^3 h'_{fg}}{\mu_\ell (T_{sat} - T_s) L} \right]^{1/4} \frac{L^{1/4}}{x^{1/4}} (\pi D x) (T_{sat} - T_s) / h'_{fg} = -\rho_\ell \left( \pi D^2 / 4 \right) \frac{dx}{dt} \quad (6)$$

Separate variables and identify the limits of integration,

$$\left\{ 0.943 \left[ \frac{g \rho_\ell (\rho_\ell - \rho_v) k_\ell^3 h'_{fg}}{\mu_\ell (T_{sat} - T_s) L} \right]^{1/4} L^{1/4} (\pi D) (T_{sat} - T_s) / \left[ h'_{fg} \rho_\ell \left( \pi D^2 / 4 \right) \right] \right\} \int_0^{t_f} dt = - \int_{x=L}^0 x^{-3/4} dx \quad (7)$$

The RHS integrates to

$$- \left[ x^{1/4} / (1/4) \right]_L^0 = 4L^{1/4} \quad (8)$$

and solving for  $t_f$ ,

$$t_f = 4 \left[ \frac{\rho_\ell \left( \pi D^2 / 4 \right) L h'_{fg}}{0.943 \left[ \frac{g \rho_\ell (\rho_\ell - \rho_v) k_\ell^3 h'_{fg}}{\mu_\ell (T_{sat} - T_s) L} \right]^{1/4} (\pi D L) (T_{sat} - T_s)} \right] <$$

**COMMENTS:** The numerator and denominator in the bracketed expression are of special significance. The numerator is the product of the mass in the filled container and the latent heat of vaporization; that is, the total energy removed by the cold water. What is the physical significance of the denominator? Can you interpret the time-to-fill,  $t_f$ , expression in light of these terms?

## PROBLEM 10.57

Determine the total condensation rate and heat transfer rate for the process of Problem 10.46 when the pipe is oriented at angles of  $\theta = 0, 30, 45$  and  $60^\circ$  from the horizontal.

**KNOWN:** Dimensions and surface temperature of tube exposed to steam. Non-vertical orientation angles.

**FIND:** Heat transfer and condensation rates.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Laminar film condensation, (2) Negligible end effects, (3) Negligible concentration of non-condensable gases in steam.

**PROPERTIES:** Table A-6, Water Vapor (1 atm):  $T_{\text{sat}} = 100^\circ\text{C}$ ,  $\rho_v = 0.596\text{ kg/m}^3$ ,  $h_{fg} = 2257\text{ kJ/kg}$ ; Table A-6, Liquid Water ( $T_f = (T_s + T_{\text{sat}})/2 = 370\text{K}$ ):  $\rho_l = 960.6\text{ kg/m}^3$ ,  $c_{p,l} = 4214\text{ J/kg}\cdot\text{K}$ ,  $\mu_l = 289 \times 10^{-6}\text{ N}\cdot\text{s/m}^2$ ,  $k_l = 0.679\text{ W/m}\cdot\text{K}$ .

**ANALYSIS:** The tube's length to diameter ratio,  $L/D = 10$ , must exceed  $B = 1.8 \tan \theta$  in order to use Equation 10.46. The value of  $B$  is 0, 1.039, 1.8, and 3.118 for  $\theta = 0, 30, 45$  and  $60^\circ$ , respectively. Therefore, Equation 10.46 may be used by replacing  $g$  with  $g \cos \theta$  where the modified latent heat is found from Equation 10.27

$$\begin{aligned} h'_{fg} &= h_{fg} (1 + 0.68Ja) = h_{fg} + 0.68c_{p,l} (T_{\text{sat}} - T_s) \\ &= 2257\text{ kJ/kg} + 0.68 \times 4.214\text{ kJ/kg}\cdot\text{K} (100 - 94)^\circ\text{C} = 2274\text{ kJ/kg} \end{aligned}$$

Hence,

$$\begin{aligned} \bar{h}_D &= 0.729 \left[ \frac{g \cos \theta \rho_l (\rho_l - \rho_v) k_l^3 h'_{fg}}{\mu_l (T_{\text{sat}} - T_s) D} \right]^{1/4} \\ &= 0.729 \left[ \frac{9.81\text{ m/s}^2 \times \cos \theta \times 960.6\text{ kg/m}^3 (960.6 - 0.596)\text{ kg/m}^3 \times (0.679\text{ W/m}\cdot\text{K})^3 \times 2274 \times 10^3\text{ J/kg}\cdot\text{K}}{289 \times 10^{-6}\text{ N}\cdot\text{s/m}^2 (100 - 94)^\circ\text{C} \times 0.1\text{ m}} \right]^{1/4} \\ &= 10,120\text{ W/m}^2 \cdot \text{K} (\cos \theta)^{1/4} \end{aligned}$$

and the values of  $\bar{h}_D$  are 10,120, 9760, 9280 and 8510  $\text{W/m}^2 \cdot \text{K}$  for  $\theta = 0, 30, 45$  and  $60^\circ$ , respectively.

For  $\theta = 0^\circ$ , the heat transfer rate is

$$q = \bar{h}_D (\pi DL) (T_{\text{sat}} - T_s) = 10,120\text{ W/m}^2 \cdot \text{K} (\pi \times 0.1\text{ m} \times 1\text{ m}) (100 - 94)^\circ\text{C} = 19,076\text{ W} \quad <$$

$$\text{and the condensation rate is } \dot{m} = q / h'_{fg} = 19076\text{ W} / 2274 \times 10^3\text{ J/kg} = 8.39 \times 10^{-3}\text{ kg/s} \quad <$$

Similarly,  $q = 18,400, 17,500$  and  $16,000\text{ W}$  and  $\dot{m} = 8.09 \times 10^{-3}, 7.69 \times 10^{-3}$  and  $7.05 \times 10^{-3}\text{ kg/s}$ , for  $\theta = 30, 45$  and  $60^\circ$ , respectively. <

**COMMENTS:** The condensation rates decrease with increasing  $\theta$ . Why?

### PROBLEM 10.58

**KNOWN:** Horizontal tube, 50mm diameter, with surface temperature of 34°C is exposed to steam at 0.2 bar.

**FIND:** Estimate the heat transfer and condensation rates per unit length of the tube.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Laminar film condensation, (2) Negligible non-condensibles in steam.

**PROPERTIES:** Table A-6, Saturated steam (0.2 bar):  $T_{\text{sat}} = 333\text{K}$ ,  $\rho_v = 0.129\text{ kg/m}^3$ ,  $h_{\text{fg}} = 2358\text{ kJ/kg}$ ; Table A-6, Water, liquid ( $T_f = (T_s + T_{\text{sat}})/2 = 320\text{K}$ ):  $\rho_\ell = 989.1\text{ kg/m}^3$ ,  $c_{p,\ell} = 4180\text{ J/kg}\cdot\text{K}$ ,  $\mu_\ell = 577 \times 10^{-6}\text{ N}\cdot\text{s/m}^2$ ,  $k_\ell = 0.640\text{ W/m}\cdot\text{K}$ .

**ANALYSIS:** From Eqs. 10.33 and 10.34, the heat transfer and condensate rates per unit length of the tube are

$$q' = \bar{h}_D (\pi D) (T_{\text{sat}} - T_s) \quad \dot{m}' = q' / h'_{\text{fg}}$$

where from Eq. 10.27 with  $\text{Ja} = c_{p,\ell} (T_{\text{sat}} - T_s) / h_{\text{fg}}$ ,

$$h'_{\text{fg}} = h_{\text{fg}} [1 + 0.68 \text{Ja}] = 2358 \frac{\text{kJ}}{\text{kg}} \left[ 1 + 0.68 \times 4180 \text{ J/kg}\cdot\text{K} (333 - 307) \text{ K} / 2358 \times 10^3 \text{ J/kg} \right]$$

$$h'_{\text{fg}} = 2432 \text{ kJ/kg.}$$

For laminar film condensation, Eq. 10.45 is appropriate for estimating  $\bar{h}_D$  with  $C = 0.729$ ,

$$\bar{h}_D = 0.729 \left[ \frac{g \rho_\ell (\rho_\ell - \rho_v) k_\ell^3 h'_{\text{fg}}}{\mu_\ell (T_{\text{sat}} - T_s) D} \right]^{1/4}$$

$$\bar{h}_D = 0.729 \left[ \frac{9.8 \text{ m/s}^2 \times 989.1 \text{ kg/m}^3 (989.1 - 0.129) \text{ kg/m}^3 (0.640 \text{ W/m}\cdot\text{K})^3 \times 2432 \times 10^3 \text{ J/kg}}{577 \times 10^{-6} \text{ N}\cdot\text{s/m}^2 (333 - 307) \text{ K} \times 0.050 \text{ m}} \right]^{1/4}$$

$$\bar{h}_D = 6926 \text{ W/m}^2 \cdot \text{K.}$$

Hence, the heat transfer and condensation rates are

$$q' = 6926 \text{ W/m}^2 \cdot \text{K} (\pi \times 0.050 \text{ m}) (333 - 307) \text{ K} = 28.3 \text{ kW/m} \quad <$$

$$\dot{m}' = 28.3 \times 10^3 \text{ W/m} / 2432 \times 10^3 \text{ J/kg} = 1.16 \times 10^{-2} \text{ kg/s}\cdot\text{m.} \quad <$$

## PROBLEM 10.59

**KNOWN:** Dimensions and surface temperature of grooved horizontal tube exposed to steam at 0.2 bar.

**FIND:** Minimum condensation and heat transfer rates per unit length of the tube.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Laminar film condensation, (2) Negligible non-condensable gas in steam.

**PROPERTIES:** Table A-6, Saturated steam (0.2 bar):  $T_{\text{sat}} = 333 \text{ K}$ ,  $\rho_v = 0.129 \text{ kg/m}^3$ ,  $h_{fg} = 2358 \text{ kJ/kg}$ ,  $\sigma = 66.1 \times 10^{-3} \text{ N/m}$ ; Table A-6, Water, liquid ( $T_f = (T_s + T_{\text{sat}})/2 = 320 \text{ K}$ ):  $\rho_\ell = 989.1 \text{ kg/m}^3$ ,  $c_{p,\ell} = 4180 \text{ J/kg}\cdot\text{K}$ ,  $\mu_\ell = 577 \times 10^{-6} \text{ N}\cdot\text{s/m}^2$ ,  $k_\ell = 0.640 \text{ W/m}\cdot\text{K}$ .

**ANALYSIS:** The heat transfer rate of Problem 10.58 is based upon an unmilled tube of diameter  $D_2 = 50 \text{ mm}$ . From Eqs. 10.33 and 10.34, the heat transfer and condensation rates per unit length for this tube are

$$q'_2 = \bar{h}_D (\pi D_2) (T_{\text{sat}} - T_s) \quad \dot{m}' = q' / h'_{fg} \quad (1a,b)$$

where from Eq. 10.27 with  $Ja = c_{p,\ell} (T_{\text{sat}} - T_s) / h_{fg}$ ,

$$h'_{fg} = h_{fg} [1 + 0.68 Ja] = 2358 \text{ kJ/kg} [1 + 0.68 \times 4180 \text{ J/kg}\cdot\text{K} (333 - 307) \text{ K} / 2358 \times 10^3 \text{ J/kg}]$$

$$h'_{fg} = 2432 \text{ kJ/kg.}$$

For laminar film condensation, Eq. 10.46 is appropriate for estimating  $\bar{h}_D$  with  $C = 0.729$ ,

$$\bar{h}_D = C \frac{k_\ell}{D_2} \left[ \frac{\rho_l g (\rho_l - \rho_v) h'_{fg} D_2^3}{\mu_\ell k_\ell (T_{\text{sat}} - T_s)} \right]^{1/4} \quad (2)$$

Continued...

**PROBLEM 10.59 (Cont.)**

$$\begin{aligned}\bar{h}_D &= 0.729 \frac{0.640 \text{ W/m} \cdot \text{K}}{0.05 \text{ m}} \left[ \frac{989.1 \text{ kg/m}^3 \times 9.8 \text{ m/s}^2 (989.1 - 0.129) \text{ kg/m}^3 \times 2432 \times 10^3 \text{ J/kg} \times (0.05 \text{ m})^3}{577 \times 10^{-6} \text{ N} \cdot \text{s/m}^2 \times 0.640 \text{ W/m} \cdot \text{K} \times (333 - 307) \text{ K}} \right]^{1/4} \\ &= 6926 \text{ W/m}^2 \cdot \text{K}.\end{aligned}$$

Hence, the heat transfer and condensation rates for the smooth large tube are

$$\begin{aligned}q'_2 &= 6926 \text{ W/m}^2 \cdot \text{K} (\pi \times 0.05 \text{ m}) (333 - 307) \text{ K} = 28.3 \text{ kW/m} \\ \dot{m}'_{\text{cond},2} &= q'_2 / h'_{fg} = 28.3 \text{ kW/m} / 2432 \text{ kJ/kg} = 0.0116 \text{ kg/s} \cdot \text{m}\end{aligned}$$

The portions of the larger tube that are not milled away serve as fins. Therefore, the heat transfer rate from the grooved large tube is related to the heat transfer rate from a corresponding smooth tube of smaller diameter  $D_1 = 46 \text{ mm}$ , modified by the enhancement ratio, Eq. 10.48. We must first determine the heat transfer rate  $q'_{\text{uft},1}$  from a smooth tube of diameter  $D_1$ . From Eqs. (2) and (1a) above, with  $D_2$  replaced by  $D_1$ , and the same value for  $h'_{fg}$  :

$$q'_{\text{uft},1} = 26.6 \text{ kW/m}$$

The enhancement factor is given by Eq. 10.48.

$$\begin{aligned}\varepsilon_{\text{ft},\text{min}} &= \frac{q_{\text{ft},\text{min}}}{q_{\text{uft}}} = \frac{tr_2}{Sr_1} \left[ \frac{r_1}{r_2} + 1.02 \frac{\sigma r_1}{(\rho_l - \rho_v) g t^3} \right]^{1/4} \\ &= \frac{2 \text{ mm} \times 25 \text{ mm}}{4 \text{ mm} \times 23 \text{ mm}} \left[ \frac{23 \text{ mm}}{25 \text{ mm}} + 1.02 \frac{66.1 \times 10^{-3} \text{ N/m} \times 0.023 \text{ m}}{(989.1 - 0.129) 9.8 \text{ m/s}^2 (0.002 \text{ m})^3} \right]^{1/4} \\ &= 1.16\end{aligned}$$

Thus the minimum heat transfer rate for the grooved tube is

$$q'_{\text{ft},\text{min},1} = \varepsilon_{\text{ft},\text{min}} q'_{\text{uft},1} = 1.16 \times 26.6 \text{ kW/m} = 30.9 \text{ kW/m} \quad <$$

The corresponding condensation rate is

$$\dot{m}' = 30.9 \times 10^3 \text{ W/m} / 2432 \times 10^3 \text{ J/kg} = 1.27 \times 10^{-2} \text{ kg/s} \cdot \text{m} \quad <$$

The enhancement due to milling the larger diameter tube, for either heat transfer or condensation rate, is therefore

$$\text{Enhancement ratio} = q'_{\text{ft},\text{min},1} / q'_2 = 30.9 \text{ kW/m} / 28.3 \text{ kW/m} = 1.09 \quad <$$

**COMMENTS:** For a given fluid and operating conditions would an optimum groove geometry exist?

### PROBLEM 10.60

**KNOWN:** Horizontal tube 1m long with surface temperature of 70°C used to condense steam at 1 bar.

**FIND:** Diameter required for condensation rate of 125 kg/h.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Laminar film condensation, (2) Negligible non-condensibles in steam.

**PROPERTIES:** Table A-6, Water, vapor (1 atm):  $T_{\text{sat}} = 100^\circ\text{C}$ ,  $\rho_v = 0.596 \text{ kg/m}^3$ ,  $h_{\text{fg}} = 2257 \text{ kJ/kg}$ ; Table A-6, Water, liquid ( $T_f = (T_s + T_{\text{sat}})/2 = 358\text{K}$ ):  $\rho_\ell = 968.6 \text{ kg/m}^3$ ,  $c_{p,\ell} = 4201 \text{ J/kg}\cdot\text{K}$ ,  $\mu_\ell = 332 \times 10^{-6} \text{ N}\cdot\text{s/m}^2$ ,  $k_\ell = 0.673 \text{ W/m}\cdot\text{K}$ .

**ANALYSIS:** From the rate equation, Eq. 10.34, with  $A = \pi D L$ , the required diameter is

$$D = \dot{m} h'_{\text{fg}} / \pi L \bar{h}_D (T_{\text{sat}} - T_s) \quad (1)$$

where from Eq. 10.27 with  $\text{Ja} = c_{p,\ell} (T_{\text{sat}} - T_s) / h_{\text{fg}}$ ,

$$h'_{\text{fg}} = h_{\text{fg}} (1 + 0.68 \text{Ja}) = 2257 \frac{\text{kJ}}{\text{kg}} \left( 1 + 0.68 \frac{4201 \text{ J/kg}\cdot\text{K} \times (100 - 70) \text{K}}{2257 \times 10^3 \text{ J/kg}} \right) = 2343 \text{ kJ/kg}. \quad (2)$$

Substituting numerical values, Eq. (1) becomes

$$D = \frac{125 \text{ kg}}{3600 \text{ s}} \times 2343 \times 10^3 \frac{\text{J}}{\text{kg}} / \pi \times 1 \text{m} \times \bar{h}_D (100 - 70) \text{K} = 863.2 \bar{h}_D^{-1}. \quad (3)$$

The appropriate correlation for  $\bar{h}_D$  is Eq. 10.46 with  $C = 0.729$ ,

$$\bar{h}_D = 0.729 \left[ \frac{g \rho_\ell (\rho_\ell - \rho_v) k_\ell^3 h'_{\text{fg}}}{\mu_\ell (T_{\text{sat}} - T_s) D} \right]^{1/4}. \quad (4)$$

Substitute Eq. (4) for  $\bar{h}_D$  into Eq. (3) and use numerical values,

$$863.2 D^{-1} = 0.729 \times$$

$$\left[ \frac{9.8 \text{ m/s}^2 \times 968.6 \text{ kg/m}^3 (968.6 - 0.596) \text{ kg/m}^3 (0.673 \text{ W/m}\cdot\text{K})^3 \times 2343 \times 10^3 \text{ J/kg}}{332 \times 10^{-6} \text{ N}\cdot\text{s/m}^2 (100 - 70) \text{K} \times D} \right]^{1/4}$$

$$863.2 D^{-1} = 3693.4 D^{-1/4}$$

$$D = 0.144 \text{m} = 144 \text{mm}. \quad <$$

**COMMENTS:** Note for this situation  $\text{Ja} = 0.06$ .

## PROBLEM 10.61

**KNOWN:** Array of condenser tubes exposed to saturated steam at 0.1 bar.

**FIND:** (a) Condensation rate per unit length of square array, (b) Options for increasing the condensation rate.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Spatially uniform cylinder temperature. (2) Average heat transfer coefficient varies with tube row with  $n = -1/6$  in Eq. 10.49. (3) Negligible concentration of noncondensable gases in the steam.

**PROPERTIES:** Table A.6, Saturated water vapor (0.1 bar):  $T_{\text{sat}} \approx 319 \text{ K}$ ,  $\rho_v = 0.067 \text{ kg/m}^3$ ,  $h_{\text{fg}} = 2393 \text{ kJ/kg}$ ; Table A.6, Water, liquid ( $T_f = (T_s + T_{\text{sat}})/2 = 309 \text{ K}$ ):  $\rho_\ell = 993 \text{ kg/m}^3$ ,  $c_{p,\ell} = 4178 \text{ J/kg}\cdot\text{K}$ ,  $\mu_\ell = 703 \times 10^{-6} \text{ N}\cdot\text{s/m}^2$ ,  $k_\ell = 0.627 \text{ W/m}\cdot\text{K}$ .

**ANALYSIS:** (a) With  $\text{Ja} = c_{p,\ell} \Delta T / h_{\text{fg}} = 4178 \text{ J/kg}\cdot\text{K} \times (319 - 300) \text{ K} / 2393 \times 10^3 \text{ J/kg} = 0.033$ ,  $h'_{\text{fg}} = h_{\text{fg}}(1 + 0.68 \text{ Ja}) = 2393 \text{ kJ/kg}(1 + 0.68 \times 0.033) = 2470 \text{ kJ/kg}$ .

Equation 10.46 may be written for the top tube,

$$\bar{h}_D = 0.729 \left[ \frac{g \rho_\ell (\rho_\ell - \rho_v) k_\ell^3 h'_{\text{fg}}}{\mu_\ell (T_{\text{sat}} - T_s) D} \right]^{1/4}$$

$$\bar{h}_D = 0.729 \left[ \frac{9.8 \text{ m/s}^2 \times 993 \text{ kg/m}^3 (993 - 0.067) \text{ kg/m}^3 (0.627 \text{ W/m}\cdot\text{K})^3 \times 2470 \times 10^3 \text{ J/kg}}{703 \times 10^{-6} \text{ N}\cdot\text{s/m}^2 (319 - 300) \text{ K} \times 0.008 \text{ m}} \right]^{1/4}$$

$$\bar{h}_D = 11,190 \text{ W/m}^2 \cdot \text{K}$$

From Eq. 10.49 the array-averaged convection coefficient is

$$\bar{h}_{D,N} = \bar{h}_D N^n = 11,190 \text{ W/m}^2 \cdot \text{K} \times 10^{-1/6} = 7622 \text{ W/m}^2 \cdot \text{K}$$

Hence, the condensation rate for the entire array per unit tube length is

$$\dot{m}' = 7622 \text{ W/m}^2 \cdot \text{K} (100) \pi \times 0.008 \text{ m} (319 - 300) \text{ K} / 2470 \times 10^3 \text{ J/kg}$$

$$\dot{m}' = 0.147 \text{ kg/s} \cdot \text{m} = 530 \text{ kg/h} \cdot \text{m} \quad \leftarrow$$

(b) Options for increasing the condensation rate include reducing the surface temperature and/or the number of tubes in a vertical tier. The following results were obtained using IHT.

Continued...

### PROBLEM 10.61 (Cont.)

Condensation rate versus tube temperature (10 vertical tubes).

Condensation rate versus number of vertical tubes ( $T_s = 300\text{K}$ ).

**COMMENTS:** Note the sensitivity of the condensation rate to the manner in which the tubes are positioned within the array.

## PROBLEM 10.62

**KNOWN:** Thin-walled concentric tube arrangement for heating deionized water by condensation of steam.

**FIND:** Estimates for convection coefficients on both sides of the inner tube. Inner tube wall outlet temperature. Whether condensation provides fairly uniform inner tube wall temperature approximately equal to the steam saturation temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible thermal resistance of inner tube wall, (2) Internal flow is fully developed.

**PROPERTIES:** Deionized water (given):  $\rho = 982.3 \text{ kg/m}^3$ ,  $c_p = 4181 \text{ J/kg}\cdot\text{K}$ ,  $k = 0.643 \text{ W/m}\cdot\text{K}$ ,  $\mu = 548 \times 10^{-6} \text{ N}\cdot\text{s/m}^2$ ,  $Pr = 3.56$ ; *Table A-6*, Saturated vapor (1 atm):  $T_{\text{sat}} = 100^\circ\text{C}$ ,  $\rho_v = (1/v_g) = 0.596 \text{ kg/m}^3$ ,  $h'_{fg} = 2257 \text{ kJ/kg}$ ; *Table A-6*, Saturated water (assume  $T_s \approx 75^\circ\text{C}$ ,  $T_f = (75 + 100)^\circ\text{C}/2 = 360\text{K}$ ):  $\rho_\ell = (1/v_f) = 967 \text{ kg/m}^3$ ,  $\mu_\ell = 324 \times 10^{-6} \text{ N}\cdot\text{s/m}^2$ ,  $k_\ell = 0.674 \text{ W/m}\cdot\text{K}$ ,  $c_{p,\ell} = 4203 \text{ J/kg}\cdot\text{K}$ .

**ANALYSIS:** From an energy balance on the inner tube at the outlet assuming a constant wall temperature,

$$\bar{h}_c (T_{\text{sat}} - T_s) = h_i (T_s - T_{m,o})$$

where  $\bar{h}_c$  and  $h_i$  are, respectively, the heat transfer coefficients for condensation (c) on a horizontal cylinder and internal (i) flow in a tube.

*Condensation.* From Eq. 10.46, for the horizontal tube,

$$\bar{h}_c = 0.729 \left[ \frac{g \rho_\ell (\rho_\ell - \rho_v) k_\ell^3 h'_{fg}}{\mu_\ell (T_{\text{sat}} - T_s) D} \right]^{1/4}$$

where  $h'_{fg} = h_{fg} \left\{ 1 + 0.68 c_{p,\ell} (T_{\text{sat}} - T_s) / h_{fg} \right\}$

$$h'_{fg} = 2257 \text{ kJ/kg} \left\{ 1 + 0.68 \times 4203 \text{ J/kg}\cdot\text{K} (100 - T_s) / 2257 \times 10^3 \text{ J/kg} \right\}$$

$$h'_{fg} = 2257 \text{ kJ/kg} \left\{ 1 + 1.266 \times 10^{-3} (100 - T_s) \right\}$$

$$\bar{h}_c = 0.729 \left[ 9.8 \text{ m/s}^2 \times 967 \text{ kg/m}^3 (967 - 0.596) \text{ kg/m}^3 (0.674 \text{ W/m}\cdot\text{K})^3 \times \right.$$

$$\left. 2257 \left\{ 1 + 1.266 \times 10^{-3} (100 - T_s) \right\} \text{ kJ/kg} / 324 \times 10^{-6} \text{ N}\cdot\text{s/m}^2 (100 - T_s) 0.030 \text{ m} \right]^{1/4}$$

Continued ...

**PROBLEM 10.62 (Cont.)**

$$\bar{h}_c = 2.071 \times 10^4 \left[ \frac{1 + 1.266 \times 10^{-3} (100 - T_s)}{100 - T_s} \right]^{1/4}.$$

*Internal flow.* From Eq. 8.6, evaluating properties at  $\bar{T}_m$ , find

$$\text{Re}_D = \frac{4\dot{m}}{\pi\mu D} = \frac{4 \times 5 \text{ kg/s}}{\pi \times 548 \times 10^{-6} \text{ N}\cdot\text{s/m}^2 \times 0.030 \text{ m}} = 3.872 \times 10^5$$

and for turbulent flow use the Dittus Boelter equation,

$$\text{Nu}_D = \frac{h_i D}{k} = 0.023 \text{Re}_D^{0.8} \text{Pr}^{0.4}$$

$$h_i = \frac{0.023 \times 0.643 \text{ W/m}\cdot\text{K}}{0.03 \text{ m}} \left( 3.872 \times 10^5 \right)^{0.8} (3.56)^{1/3} = 2.42 \times 10^4 \text{ W/m}^2 \cdot \text{K}. <$$

Substituting numerical values into the energy balance relation,

$$\begin{aligned} 2.071 \times 10^4 \left[ \frac{1 + 1.266 \times 10^{-3} (100 - T_s)}{100 - T_{s,o}} \right]^{1/4} (100 - T_s) \text{ K} \\ = 2.42 \times 10^4 \text{ W/m}^2 \cdot \text{K} (T_s - 60) \text{ K} \end{aligned}$$

and by trial-and-error, find

$$T_s \approx 70.8^\circ\text{C}.$$

With this value of  $T_s$ , find that

$$\bar{h}_c = 8990 \text{ W/m}^2 \cdot \text{K} <$$

which is approximately half that for the internal flow. Hence, the tube wall cannot be at a uniform temperature. This could only be achieved if  $\bar{h}_c \approx h_i$ .

### PROBLEM 10.63

**KNOWN:** Heat dissipation from multichip module to saturated liquid of prescribed temperature and properties. Diameter and inlet and outlet water temperatures for a condenser coil.

**FIND:** (a) Condensation and water flow rates. (b) Tube surface inlet and outlet temperatures. (c) Coil length.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions since rate of heat transfer from the module is balanced by rate of heat transfer to coil, (2) Fully developed flow in tube, (3) Water is incompressible liquid with negligible viscous dissipation.

**PROPERTIES:** Saturated fluorocarbon ( $T_{\text{sat}} = 57^\circ\text{C}$ , given):  $k_\ell = 0.0537 \text{ W/m}\cdot\text{K}$ ,  $c_{p,\ell} = 1100 \text{ J/kg}\cdot\text{K}$ ,  $h'_{\text{fg}} \approx h_{\text{fg}} = 84,400 \text{ J/kg}$ .  $\rho_\ell = 1619.2 \text{ kg/m}^3$ ,  $\rho_v = 13.4 \text{ kg/m}^3$ ,  $\sigma = 8.1 \times 10^{-3} \text{ kg/s}^2$ ,  $\mu_\ell = 440 \times 10^{-6} \text{ kg/m}\cdot\text{s}$ ,  $\text{Pr}_\ell = 9$ ; Table A-6, Water, sat. liquid ( $\bar{T}_m = 300\text{K}$ ):  $\rho = 997 \text{ kg/m}^3$ ,  $c_p = 4179 \text{ J/kg}\cdot\text{K}$ ,  $\mu = 855 \times 10^{-6} \text{ N}\cdot\text{s/m}^2$ ,  $k = 0.613 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 5.83$ .

**ANALYSIS:** (a) With

$$q = (q'' \times A)_{\text{module}} = 10^5 \text{ W/m}^2 (0.1 \text{ m})^2 = 10^3 \text{ W}$$

the condensation rate is

$$\dot{m}_{\text{con}} = \frac{q}{h'_{\text{fg}}} = \frac{10^3 \text{ W}}{84,400 \text{ J/kg}} = 0.0118 \text{ kg/s} \quad <$$

and the required water flow rate is

$$\dot{m} = \frac{q}{c_p (T_{m,o} - T_{m,i})} = \frac{1000 \text{ W}}{4179 \text{ J/kg}\cdot\text{K} (30 \text{ K})} = 7.98 \times 10^{-3} \text{ kg/s} \quad <$$

(b) The Reynolds number for flow through the tube is

$$\text{Re}_D = \frac{4 \dot{m}}{\pi D \mu} = \frac{4 \times 7.98 \times 10^{-3} \text{ kg/s}}{\pi (0.01 \text{ m}) 855 \times 10^{-6} \text{ N}\cdot\text{s/m}^2} = 1188.$$

Hence, the flow is laminar. Assuming a uniform wall temperature,

$$h_i = \text{Nu}_D k / D = 3.66 (0.613 \text{ W/m}\cdot\text{K} / 0.01 \text{ m}) = 224 \text{ W/m}^2 \cdot \text{K}.$$

Continued ...

**PROBLEM 10.63 (Cont.)**

For film condensation on the outer surface, Eq. 10.46 yields

$$h_o = 0.729 \left[ \frac{9.8 \text{ m/s}^2 \left( 1619.2 \text{ kg/m}^3 \right) \left( 1605.8 \text{ kg/m}^3 \right) \left( 0.0537 \text{ W/m}\cdot\text{K} \right)^3 84,400 \text{ J/kg}}{440 \times 10^{-6} \text{ kg/m}\cdot\text{s} \times 0.01 \text{ m} (T_{\text{sat}} - T_s)} \right]^{1/4}$$

$$h_o = 2150(57 - T_s)^{-1/4}.$$

From an energy balance on a portion of the tube surface,

$$h_o (T_{\text{sat}} - T_s) = h_i (T_s - T_m)$$

or

$$2150(57 - T_s)^{3/4} = 224(T_s - T_m)$$

At the entrance where  $(T_{m,i} = 285\text{K})$ , trial-and-error yields:

$$T_{s,i} = 50.6^\circ\text{C} \quad <$$

and at the exit where  $(T_{m,o} = 315\text{K})$ ,

$$T_{s,o} = 55.4^\circ\text{C} \quad <$$

We use an average value of  $T_s \approx 53^\circ\text{C}$  in the following.

(c) From Eqs. 8.43 and 8.44,

$$L = \frac{q}{h_i \pi D \Delta T_{\ell m}}$$

where

$$\Delta T_{\ell m} = \frac{(T_s - T_{m,i}) - (T_s - T_{m,o})}{\ln \left[ (T_s - T_{m,i}) / (T_s - T_{m,o}) \right]} = \frac{41 - 11}{\ln(41/11)} = 22.8^\circ\text{C}$$

$$L = \frac{1000 \text{ W}}{(224 \text{ W/m}^2 \cdot \text{K}) \pi (0.01 \text{ m}) 22.8^\circ\text{C}} = 6.23 \text{ m.} \quad <$$

**COMMENTS:** Some control over system performance may be exercised by adjusting the water flow rate. By increasing  $\dot{m}$ ,  $(T_{m,o} - T_{m,i})$  is reduced for a prescribed  $q$ . The value of  $h_i$  is increased substantially if the internal flow is turbulent.

### PROBLEM 10.64

**KNOWN:** Saturated ethylene glycol vapor at 1 atm condensing on a sphere of 100 mm diameter having surface temperature of 150°C.

**FIND:** Condensation rate.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Laminar film condensation, (2) Negligible non-condensibles in vapor.

**PROPERTIES:** Table A-5, Saturated ethylene glycol, vapor (1 atm):  $T_{\text{sat}} = 470\text{ K}$ ,  $\rho_v \approx 0\text{ kg/m}^3$ ,  $h_{\text{fg}} = 812\text{ kJ/kg}$ ; Table A-5, Ethylene glycol, liquid ( $T_f = 423\text{ K}$ , but use values at 373 K, limit of data in table):  $\rho_\ell = 1058.5\text{ kg/m}^3$ ,  $c_{p,\ell} = 2742\text{ J/kg}\cdot\text{K}$ ,  $\mu_\ell = 0.215 \times 10^{-2}\text{ N}\cdot\text{s/m}^2$ ,  $k_\ell = 0.263\text{ W/m}\cdot\text{K}$ .

**ANALYSIS:** The condensation rate is given by Eq. 10.34 as

$$\dot{m} = \frac{q}{h'_{\text{fg}}} = \frac{\bar{h}_L (\pi D^2) (T_{\text{sat}} - T_s)}{h'_{\text{fg}}}$$

where  $A = \pi D^2$  for the sphere and  $h'_{\text{fg}}$ , with  $\text{Ja} = c_{p,\ell} \Delta T / h_{\text{fg}}$ , is given by Eq. 10.27 as

$$h'_{\text{fg}} = h_{\text{fg}} (1 + 0.68 \text{Ja}) = 812 \frac{\text{kJ}}{\text{kg}} \left( 1 + 0.68 \times 2742 \frac{\text{J}}{\text{kg}\cdot\text{K}} (470 - 423)\text{ K} / 812 \times 10^3 \text{ J/kg} \right) = 900 \text{ kJ/kg}.$$

The average heat transfer coefficient for the sphere follows from Eq. 10.46 with  $C = 0.826$ ,

$$\bar{h}_D = 0.826 \left[ \frac{g \rho_\ell (\rho_\ell - \rho_v) k_\ell^3 h'_{\text{fg}}}{\mu_\ell (T_{\text{sat}} - T_s) D} \right]^{1/4}$$

$$\bar{h}_D = 0.826 \left[ \frac{9.8 \text{ m/s}^2 \times 1058.5 \text{ kg/m}^3 (1058.5 - 0) \text{ kg/m}^3 (0.263 \text{ W/m}\cdot\text{K})^3 \times 900 \times 10^3 \text{ J/kg}}{0.215 \times 10^{-2} \text{ N}\cdot\text{s/m}^2 (470 - 423) \text{ K} \times 0.100 \text{ m}} \right]^{1/4}$$

$$\bar{h}_D = 1696 \text{ W/m}^2 \cdot \text{K}.$$

Hence, the condensation rate is

$$\dot{m} = 1696 \text{ W/m}^2 \cdot \text{K} \times \pi (0.100 \text{ m})^2 (470 - 423) \text{ K} / 900 \times 10^3 \text{ J/kg}$$

$$\dot{m} = 2.78 \times 10^{-3} \text{ kg/s}.$$

<

**COMMENTS:** Recognize this estimate is likely to be a poor one since properties were not evaluated at the proper  $T_f$  which was beyond the limit of the table.

### PROBLEM 10.65

**KNOWN:** Copper sphere of 10 mm diameter, initially at 50°C, is placed in a large container filled with saturated steam at 1 atm.

**FIND:** Time required for sphere to reach equilibrium and the condensate formed during this period.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Laminar film condensation, (2) Negligible non-condensables in vapor, (3) Sphere is spacewise isothermal, (4) Sphere experiences heat gain by condensation only.

**PROPERTIES:** Table A-6, Saturated water vapor (1 atm):  $T_{\text{sat}} = 100^\circ\text{C}$ ,  $\rho_v = 0.596 \text{ kg/m}^3$ ,  $h_{\text{fg}} = 2257 \text{ kJ/kg}$ ; Table A-6, Water, liquid ( $T_f \approx (75 + 100)^\circ\text{C}/2 = 360\text{K}$ ):  $\rho_\ell = 967.1 \text{ kg/m}^3$ ,  $c_{p,\ell} = 4203 \text{ J/kg}\cdot\text{K}$ ,  $\mu_\ell = 324 \times 10^{-6} \text{ N}\cdot\text{s/m}^2$ ,  $k_\ell = 0.674 \text{ W/m}\cdot\text{K}$ ; Table A-1, Copper, pure ( $\bar{T} = 75^\circ\text{C}$ ):  $\rho_{\text{sp}} = 8933 \text{ kg/m}^3$ ,  $c_{p,\text{sp}} = 389 \text{ J/kg}\cdot\text{K}$ .

**ANALYSIS:** Using the lumped capacitance approach, an energy balance on the sphere provides,

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \dot{E}_{\text{st}}$$

$$\dot{m} h'_{\text{fg}} = \bar{h}_D A_s (T_{\text{sat}} - T_s) = \rho_{\text{sp}} c_{p,\text{sp}} V_s \frac{dT_s}{dt}. \quad (1)$$

Properties of the sphere,  $\rho_{\text{sp}}$  and  $c_{p,\text{sp}}$ , will be evaluated at  $\bar{T}_s = (50 + 100)^\circ\text{C}/2 = 75^\circ\text{C}$ , while water (liquid) properties will be evaluated at  $\bar{T}_f = (\bar{T}_s + T_{\text{sat}})/2 = 87.5^\circ\text{C} \approx 360\text{K}$ . From Eq. 10.27 with  $\text{Ja} = c_{p,\ell} \Delta T / h_{\text{fg}}$  where  $\Delta T = T_{\text{sat}} - \bar{T}_s$ , find

$$h'_{\text{fg}} = h_{\text{fg}} (1 + 0.68 \text{Ja}) = 2257 \frac{\text{kJ}}{\text{kg}} \left( 1 + 0.68 \left[ 4203 \frac{\text{J}}{\text{kg}\cdot\text{K}} \times (100 - 75) \text{K} / 2257 \times 10^3 \text{J/kg} \right] \right) = 2328 \frac{\text{kJ}}{\text{kg}}. \quad (2)$$

To estimate the time required to reach equilibrium, we need to integrate Eq. (1) with appropriate limits. However, to perform the integration, an appropriate relation for the temperature dependence of  $\bar{h}_D$  needs to be found, as discussed in Chapter 5. Using Eq. 10.46 with  $C = 0.826$ ,

$$\bar{h}_D = 0.826 \left[ \frac{g \rho_\ell (\rho_\ell - \rho_v) k_\ell^3 h'_{\text{fg}}}{\mu_\ell (T_{\text{sat}} - T_s) D} \right]^{1/4}.$$

Substitute numerical values and find,

$$\bar{h}_D = 0.826 \left[ \frac{9.8 \text{ m/s}^2 \times 967.1 \text{ kg/m}^3 (967.1 - 0.596) \text{ kg/m}^3 (0.674 \text{ W/m}\cdot\text{K})^3 \times 2328 \times 10^3 \text{ J/kg}}{324 \times 10^{-6} \text{ N}\cdot\text{s/m}^2 (T_{\text{sat}} - T_s) \times 0.010 \text{ m}} \right]^{1/4}$$

$$\bar{h}_D = B (T_{\text{sat}} - T_s)^{-1/4} \quad \text{where} \quad B = 31,120 \text{ W/m}^2 \cdot (\text{K})^{3/4}. \quad (3)$$

Continued ...

**PROBLEM 10.65 (Cont.)**

Substitute Eq. (3) into Eq. (1) for  $\bar{h}_D$  and recognize  $V_s / A_s = \frac{1}{6} \pi D^3 / \pi D^2 = D/6$ ,

$$B(T_{\text{sat}} - T_s)^{-1/4} (T_{\text{sat}} - T_s) = \rho_{\text{sp}} c_{p,\text{sp}} (D/6) \frac{dT_s}{dt}. \quad (4)$$

Note that  $d(T_s) = -d(T_{\text{sat}} - T_s)$ ; letting  $\Delta T \equiv T_{\text{sat}} - T_s$  and separating variables, the energy balance relation has the form

$$\int_0^t dt = -\frac{\rho_{\text{sp}} c_{p,\text{sp}} (D/6)}{B} \int_{\Delta T_o}^{\Delta T} \frac{d(\Delta T)}{\Delta T^{3/4}} \quad (5)$$

where the limits of integration have been identified, with  $\Delta T_o = T_{\text{sat}} - T_i$  and  $T_i = T_s(0)$ . Performing the integration, find

$$t = -\frac{\rho_{\text{sp}} c_{p,\text{sp}} (D/6)}{B} \cdot \frac{1}{1-3/4} \left[ \Delta T^{1/4} - \Delta T_o^{1/4} \right].$$

Substituting numerical values with the limits,  $\Delta T = 0$  and  $\Delta T_o = 100 - 50 = 50^\circ\text{C}$ ,

$$t = -\frac{8933 \text{ kg/m}^3 \times 389 \text{ J/kg} \cdot \text{K} (0.010 \text{ m}/6)}{31,120 \text{ W/m}^2 \cdot \text{K}^{3/4}} \times 4 \left[ 0^{1/4} - 50^{1/4} \right] \text{K}^{1/4}$$

$$t = 2.0 \text{ s.} \quad <$$

To determine the total amount of condensate formed during this period, perform an energy balance on a time interval basis,

$$E_{\text{in}} - E_{\text{out}} = \Delta E = E_{\text{final}} - E_{\text{initial}}$$

$$E_{\text{in}} = \rho_{\text{sp}} c_{p,\text{sp}} V (T_{\text{final}} - T_{\text{initial}}) \quad (6)$$

where  $T_{\text{final}} = T_{\text{sat}}$  and  $T_{\text{initial}} = T_i = T_s(0)$ . Recognize that

$$E_{\text{in}} = M h'_{\text{fg}} \quad (7)$$

where  $M$  is the total mass of vapor that condenses. Combining Eqs. (6) and (7),

$$M = \frac{\rho_{\text{sp}} c_{p,\text{sp}} V}{h'_{\text{fg}}} [T_{\text{sat}} - T_i]$$

$$M = \frac{8933 \text{ kg/m}^3 \times 389 \text{ J/kg} \cdot \text{K} (\pi/6) (0.010 \text{ m})^3}{2328 \times 10^3 \text{ J/kg}} [100 - 50] \text{K}$$

$$M = 3.91 \times 10^{-5} \text{ kg.} \quad <$$

**COMMENTS:** The total amount of condensate could have been evaluated from the integral,

$$M = \int_0^t \dot{m} dt = \int_0^t \frac{q}{h'_{\text{fg}}} dt = \int_0^t \frac{\bar{h}_D A_s (T_{\text{sat}} - T_s) dt}{h'_{\text{fg}}}$$

giving the same result, but with more effort.

### PROBLEM 10.66

**KNOWN:** Saturation temperature and inlet flow rate of refrigerant. Diameter, length, and temperature of tube.

**FIND:** Rate of condensation and outlet flow rate.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible concentration of noncondensable gases in vapor.

**PROPERTIES:** Given, R-12, saturated vapor ( $T_{\text{sat}} = 310 \text{ K}$ ):  $\rho_v = 50.1 \text{ kg/m}^3$ ,  $h_{\text{fg}} = 160 \text{ kJ/kg}$ ,  $\mu_v = 150 \times 10^{-7} \text{ N}\cdot\text{s/m}^2$ . Saturated liquid ( $T_f = 300 \text{ K}$ ):  $\rho_\ell = 1306 \text{ kg/m}^3$ ,  $c_{p,\ell} = 978 \text{ J/kg}\cdot\text{K}$ ,  $\mu_\ell = 0.0254 \times 10^{-2} \text{ N}\cdot\text{s/m}^2$ ,  $k_\ell = 0.072 \text{ W/m}\cdot\text{K}$ . R-134a, saturated vapor ( $T_{\text{sat}} = 310 \text{ K}$ ):  $\rho_v = 46.1 \text{ kg/m}^3$ ,  $h_{\text{fg}} = 166 \text{ kJ/kg}$ ,  $\mu_v = 136 \times 10^{-7} \text{ N}\cdot\text{s/m}^2$ . *Table A.5:* R-134a, Saturated liquid ( $T_f = 300 \text{ K}$ ):  $\rho_\ell = 1199.7 \text{ kg/m}^3$ ,  $c_{p,\ell} = 1432 \text{ J/kg}\cdot\text{K}$ ,  $\mu_\ell = 0.01905 \times 10^{-2} \text{ N}\cdot\text{s/m}^2$ ,  $k_\ell = 0.0803 \text{ W/m}\cdot\text{K}$ .

**ANALYSIS: For R-12:** The Reynolds number associated with the inlet vapor flow is

$Re_{v,i} = 4 \dot{m}_{v,i} / \pi D \mu_v = 0.04 \text{ kg/s} / \pi \times 0.03 \text{ m} \times 150 \times 10^{-7} \text{ N}\cdot\text{s/m}^2 = 28,290 < 35,000$ . Hence, the average convection coefficient may be obtained from Eq. 10.46 with  $C = 0.555$ , where  $h'_{\text{fg}} = h_{\text{fg}} + 0.375 c_{p,\ell} (T_{\text{sat}} - T_s) = (1.6 \times 10^5 + 0.375 \times 978 \times 20) \text{ J/kg} = 1.67 \times 10^5 \text{ J/kg}$ .

$$\bar{h}_D = 0.555 \left[ \frac{g \rho_\ell (\rho_\ell - \rho_v) k_\ell^3 h'_{\text{fg}}}{\mu_\ell (T_{\text{sat}} - T_s) D} \right]^{1/4} = 0.555 \left[ \frac{9.8 \text{ m/s}^2 \times 1306 \text{ kg/m}^3 (1306 - 50.1) \text{ kg/m}^3 (0.072 \text{ W/m}\cdot\text{K})^3 1.67 \times 10^5 \text{ J/kg}}{0.0254 \times 10^{-2} \text{ N}\cdot\text{s/m}^2 \times 20 \text{ K} \times 0.03 \text{ m}} \right]^{1/4}$$

$$\bar{h}_D = 889 \text{ W/m}^2 \cdot \text{K}$$

The heat rate is then

$$q = \pi D L \bar{h}_D (T_{\text{sat}} - T_s) = \pi \times 0.03 \text{ m} \times 0.8 \text{ m} \times 889 \text{ W/m}^2 \cdot \text{K} \times 20 \text{ K} = 1340 \text{ W}$$

and the condensation rate is

$$\dot{m}_{\text{cond}} = \frac{q}{h'_{\text{fg}}} = \frac{1340 \text{ W}}{1.67 \times 10^5} = 0.0080 \text{ kg/s} \quad <$$

The flow rate of vapor leaving the tube is then

$$\dot{m}_{v,o} = \dot{m}_{v,i} - \dot{m}_{\text{cond}} = (0.0100 - 0.0080) \text{ kg/s} = 0.0020 \text{ kg/s} \quad <$$

Continued...

**PROBLEM 10.66 (Cont.)**

Repeating the analysis for R-134a, we find that  $\bar{h}_D = 1007 \text{ W/m}^2 \cdot \text{K}$ ,  $q = 1520 \text{ W}$ ,

$\dot{m}_{\text{cond}} = 0.0086 \text{ kg/s}$ , and  $\dot{m}_{\text{v,o}} = 0.0014 \text{ kg/s}$ .

<

**COMMENTS:** The behavior of the two refrigerants is comparable since the properties are similar, and R-134a could replace R-12 in many applications. The R-134a provides somewhat higher heat transfer and condensation rates in this application.

### PROBLEM 10.67

**KNOWN:** Saturated steam condensing on the inside of a horizontal pipe.

**FIND:** Heat transfer coefficient and the condensation rate per unit length of the pipe.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Film condensation with low vapor velocities.

**PROPERTIES:** Table A-6, Saturated water vapor (1.5 bar):  $T_{\text{sat}} \approx 385 \text{ K}$ ,  $\rho_v = 0.88 \text{ kg/m}^3$ ,  $h_{\text{fg}} = 2225 \text{ kJ/kg}$ ; Table A-6, Saturated water ( $T_f = (T_{\text{sat}} + T_s)/2 \approx 380 \text{ K}$ ):  $\rho_\ell = 953.3 \text{ kg/m}^3$ ,  $c_{p,\ell} = 4226 \text{ J/kg}\cdot\text{K}$ ,  $\mu_\ell = 260 \times 10^{-6} \text{ N}\cdot\text{s/m}^2$ ,  $k_\ell = 0.683 \text{ W/m}\cdot\text{K}$ .

**ANALYSIS:** The condensation rate per unit length follows from Eq. 10.34 with  $A = \pi D L$  and has the form

$$\dot{m}' = \frac{\dot{m}}{L} = \bar{h}_D (\pi D) (T_{\text{sat}} - T_s) / h'_{\text{fg}}$$

where  $\bar{h}_D$  is estimated from the correlation of Eq. 10.46 with the expression for  $h'_{\text{fg}}$  following the discussion after Eq. 10.50,

$$\bar{h}_D = 0.555 \left[ \frac{g \rho_\ell (\rho_\ell - \rho_v) k_\ell^3 h'_{\text{fg}}}{\mu_\ell (T_{\text{sat}} - T_s) D} \right]^{1/4}$$

where

$$h'_{\text{fg}} = h_{\text{fg}} + \frac{3}{8} c_{p,\ell} (T_{\text{sat}} - T_s) = 2225 \times 10^3 \frac{\text{J}}{\text{kg}} + \frac{3}{8} \times 4226 \frac{\text{J}}{\text{kg}\cdot\text{K}} (385 - 373) \text{ K}$$

$$h'_{\text{fg}} = 2244 \text{ kJ/kg.}$$

Hence,

$$\bar{h}_D = 0.555 \left[ \frac{9.8 \text{ m/s}^2 \times 953.3 \frac{\text{kg}}{\text{m}^3} (953.3 - 0.88) \frac{\text{kg}}{\text{m}^3} (0.683 \text{ W/m}\cdot\text{K})^3 2244 \times 10^3 \text{ J/kg}}{260 \times 10^{-6} \text{ N}\cdot\text{s/m}^2 (385 - 373) \text{ K} \times 0.075 \text{ m}} \right]^{1/4}$$

$$\bar{h}_D = 7127 \text{ W/m}^2 \cdot \text{K.}$$

It follows that the condensate rate per unit length of the tube is

$$\dot{m}' = 7127 \text{ W/m}^2 \cdot \text{K} (\pi \times 0.075 \text{ m}) (385 - 373) \text{ K} / 2244 \times 10^3 \text{ J/kg} = 9.0 \times 10^{-3} \text{ kg/s}\cdot\text{m.} \quad <$$

### PROBLEM 10.68

**KNOWN:** Pressure of saturated steam condensing on the inside of a horizontal pipe. Diameter and surface temperature of pipe. Mass flow rate.

**FIND:** (a) Heat transfer coefficient and condensation rate per unit length of the pipe for  $X = 0.2$ . (b) Plot heat transfer coefficient and condensation rate for  $0.1 \leq X \leq 0.3$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Film condensation with high vapor velocities, annular flow.

**PROPERTIES:** Table A-6, Saturated water (1.5 bar):  $T_{\text{sat}} \approx 385 \text{ K}$ ,  $\rho_l = 949.7 \text{ kg/m}^3$ ,  $\rho_v = 0.88 \text{ kg/m}^3$ ,  $h_{fg} = 2225 \text{ kJ/kg}$ ,  $c_{p,l} = 4.232 \text{ kJ/kg}$ ,  $\mu_l = 248 \times 10^{-6} \text{ N} \cdot \text{s/m}^2$ ,  $\mu_v = 12.49 \times 10^{-6} \text{ N} \cdot \text{s/m}^2$ ,  $k_l = 0.685 \text{ W/m} \cdot \text{K}$ ,  $Pr_l = 1.53$ .

**ANALYSIS:** The mass flow rate per unit cross sectional tube area is

$$\frac{\dot{m}}{A_c} = \frac{2.5 \text{ kg/s}}{\pi(0.075 \text{ m})^2 / 4} = 566 \text{ kg/s} \cdot \text{m}^2$$

Since this exceeds  $500 \text{ kg/s} \cdot \text{m}^2$ , the Dobson and Chato correlation, Eq. 10.51a can be used. The Reynolds number is

$$Re_{D,l} = 4\dot{m}(1 - X) / (\pi D \mu_l) = 4 \times 2.5 \text{ kg/s} \times (1 - 0.2) / (\pi \times 0.075 \text{ m} \times 248 \times 10^{-6} \text{ N} \cdot \text{s/m}^2) = 1.37 \times 10^5$$

and the Martinelli parameter is

$$X_u = \left( \frac{1 - X}{X} \right)^{0.9} \left( \frac{\rho_v}{\rho_l} \right)^{0.5} \left( \frac{\mu_l}{\mu_v} \right)^{0.1} = \left( \frac{1 - 0.2}{0.2} \right)^{0.9} \left( \frac{0.88}{949.7} \right)^{0.5} \left( \frac{248}{12.49} \right)^{0.1} = 0.143$$

Then,

$$Nu_D = \frac{hD}{k_l} = 0.023 Re_{D,l}^{0.8} Pr_l^{0.4} \left[ 1 + \frac{2.22}{X_u^{0.89}} \right] = 0.023 \times (1.37 \times 10^5)^{0.8} \times 1.53^{0.4} \left[ 1 + \frac{2.22}{0.143^{0.89}} \right] = 4750$$

The heat transfer coefficient is

$$h = Nu_D k_l / D = 4750 \times 0.685 \text{ W/m} \cdot \text{K} / 0.075 \text{ m} = 43,300 \text{ W/m}^2 \cdot \text{K}$$

<

### PROBLEM 10.68 (Cont.)

The condensation rate per unit length follows from Eq. 10.34 with  $A = \pi DL$  and

$$h'_{fg} = h_{fg} + 0.375c_{p,l}(T_{\text{sat}} - T_s) = 2225 \text{ kJ/kg} + 0.375 \times 4.232 \text{ kJ/kg} \cdot \text{K} \times (385 - 373) \text{ K} = 2244 \text{ kJ/kg}.$$

Thus,

$$\dot{m}'_{\text{cond}} = \frac{\dot{m}_{\text{cond}}}{L} = h(\pi D)(T_{\text{sat}} - T_s) / h'_{fg}$$

$$= 43,400 \text{ W/m}^2 \cdot \text{K} \times \pi \times 0.075 \text{ m} \times (385 - 373) \text{ K} / 2244 \times 10^3 \text{ J/kg} = 0.0546 \text{ kg/s} \cdot \text{m} \quad \leftarrow$$

(b) Solving the same equations for  $0.1 \leq X \leq 0.3$  yields the plots below.

**COMMENTS:** (1) The value of  $X$  strongly impacts the heat transfer coefficient and condensation rate. (2) The condensation rate corresponding to the low vapor velocity case of Problem 10.67 is  $9.0 \times 10^{-3} \text{ kg/s} \cdot \text{m}$ . The higher vapor velocity yields a six-fold increase in heat transfer coefficient and condensation rate. (3) If the fluid were all vapor at the inlet,  $X = 1$ , the vapor velocity would be  $u_v = \dot{m} / (\rho_v A_c) = 2.5 / (0.88 \text{ kg/m}^3 \times \pi (0.075 \text{ m})^2 / 4) = 643 \text{ m/s}$ . The inlet Reynolds number would then be  $3.4 \times 10^6$ , and the criterion for the low vapor velocity solution, Eq. 10.50 would not be satisfied. (4) Treating water vapor as an ideal gas, the speed of sound at 385 K would be 479 m/s as determined in Comment 5. The mass flow rate specified in the problem could not be achieved in a tube of constant cross-sectional area with  $X = 1$ . (5) For water at  $T = 385 \text{ K}$  and  $p = 1.5 \text{ bar}$ ,  $R \equiv \mathcal{R}/M = 8315 \text{ J/kmol} \cdot \text{K} / 18 \text{ kg/kmol} = 462 \text{ J/kg}$ . The specific heat at constant volume is  $c_v \equiv c_p - R = 2080 \text{ J/kg} \cdot \text{K} - 462 \text{ J/kg} \cdot \text{K} = 1618 \text{ J/kg} \cdot \text{K}$ . Therefore the specific heat ratio is  $\gamma = c_p/c_v = 2080 \text{ J/kg} \cdot \text{K} / 1618 \text{ J/kg} \cdot \text{K} = 1.29$  and the speed of sound is  $a = \sqrt{1.29 \times 462 \text{ J/kg} \cdot \text{K} \times 385 \text{ K}} = 479 \text{ m/s}$ .

### PROBLEM 10.69

**KNOWN:** Mass flow rate and quality of R-22 condensing in tube. Tube diameter. Wall and saturation temperatures. Refrigerant properties.

**FIND:** Heat transfer coefficient, heat transfer rate, and condensation rate for (a)  $X = 0.5$ , (b)  $0.2 < X < 0.8$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Film condensation with high vapor velocities, annular flow. (2) Heat of vaporization not strong function of temperature.

**PROPERTIES:** Refrigerant R-22 ( $T_{\text{sat}} = 318 \text{ K}$ ): Given  $\rho_v = 77 \text{ kg/m}^3$ ,  $\mu_v = 15 \times 10^{-6} \text{ N}\cdot\text{s/m}^2$ ; Table A-5,  $\rho_l = 1106 \text{ kg/m}^3$ ,  $\mu_l = 131 \times 10^{-6} \text{ N}\cdot\text{s/m}^2$ ,  $c_{p,l} = 1377 \text{ J/kg}\cdot\text{K}$ ,  $k_l = 0.0741 \text{ W/m}\cdot\text{K}$ ,  $Pr_l = 2.4$ ,  $h_{fg} = 234 \text{ kJ/kg}$ .

**ANALYSIS:** The mass flow rate per unit cross sectional tube area is

$$\frac{\dot{m}}{A_c} = \frac{8.75 \times 10^{-3} \text{ kg/s}}{\pi(0.007 \text{ m})^2 / 4} = 227 \text{ kg/s}\cdot\text{m}^2$$

Although this is below the recommended threshold of  $500 \text{ kg/s}\cdot\text{m}^2$ , since annular flow was observed, the Dobson and Chato correlation, Eq. 10.51a can be used. The Reynolds number is

$Re_{D,l} = 4\dot{m}(1-X) / (\pi D \mu_l) = 4 \times 8.75 \times 10^{-3} \text{ kg/s} \times (1-0.5) / (\pi \times 0.007 \text{ m} \times 131 \times 10^{-6} \text{ N}\cdot\text{s/m}^2) = 6070$   
and the Martinelli parameter is

$$X_{tt} = \left( \frac{1-X}{X} \right)^{0.9} \left( \frac{\rho_v}{\rho_l} \right)^{0.5} \left( \frac{\mu_l}{\mu_v} \right)^{0.1} = \left( \frac{1-0.5}{0.5} \right)^{0.9} \left( \frac{77}{1106} \right)^{0.5} \left( \frac{131}{15} \right)^{0.1} = 0.328$$

Then,

$$Nu_D = \frac{hD}{k_l} = 0.023 Re_{D,l}^{0.8} Pr_l^{0.4} \left[ 1 + \frac{2.22}{X_{tt}^{0.89}} \right] = 0.023 \times (6070)^{0.8} \times 2.4^{0.4} \left[ 1 + \frac{2.22}{0.328^{0.89}} \right] = 243$$

The heat transfer coefficient and heat transfer rate per unit length are

$$h = Nu_D k_l / D = 243 \times 0.0741 \text{ W/m}\cdot\text{K} / 0.007 \text{ m} = 2570 \text{ W/m}^2\cdot\text{K} \quad <$$

$$q'_s = h\pi D(T_{\text{sat}} - T_s) = 2570 \text{ W/m}^2\cdot\text{K} \times \pi \times 0.007 \text{ m} \times (45 - 40)^\circ\text{C} = 283 \text{ W/m}^2 \quad <$$

Continued...

### PROBLEM 10.69 (Cont.)

The condensation rate per unit length follows from Eq. 10.34 with  $A = \pi DL$  and

$$h'_{fg} = h_{fg} + 0.375c_{p,l}(T_{\text{sat}} - T_s) = 234 \text{ kJ/kg} + 0.375 \times 1.377 \text{ kJ/kg} \cdot \text{K} \times (45 - 40)^\circ\text{C} = 237 \text{ kJ/kg} . \text{ Thus,}$$

$$\dot{m}'_{\text{cond}} = q'_s / h'_{fg} = 283 \text{ W/m}^2 / 237 \times 10^3 \text{ J/kg} = 1.19 \times 10^{-3} \text{ kg/s} \cdot \text{m} \quad \leftarrow$$

(b) Solving the same equations for  $0.2 < X < 0.8$  yields the condensation rate plot below.

**COMMENTS:** (1) The value of  $X$  strongly impacts the heat transfer coefficient, heat transfer rate, and condensation rate. (2) This problem corresponds to one of the experimental conditions on which the Dobson and Chato correlation is based. Annular flow was observed for this and many, but not all, of the other cases for which the mass flow rate per unit area was less than  $500 \text{ kg/s} \cdot \text{m}^2$ . Annular flow was always observed for values greater than  $500 \text{ kg/s} \cdot \text{m}^2$ . Hence the recommended threshold value of  $\dot{m} / A_c = 500 \text{ kg/s} \cdot \text{m}^2$  is conservative. <

### PROBLEM 10.70

**KNOWN:** Inner and outer diameter of brass tube. Thickness of Teflon coating. Saturated steam at 1 bar outside tube. Convection coefficient and mean temperature of water flowing inside tube.

**FIND:** Condensation convection coefficient. Steam condensation rate per unit length. Comparison with condensation rate for uncoated brass tube.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Dropwise condensation, (2) Correlations for a copper surface can be applied to Teflon, and (3) Negligible effect of noncondensable vapors.

**PROPERTIES:** Table A.6, Water, vapor (0.1 bar):  $T_{\text{sat}} = 318.9 \text{ K}$ ,  $h_{\text{fg}} = 2393 \times 10^3 \text{ J/kg}$ ; Table A.1, Brass ( $\bar{T} = (T_m + T_{\text{sat}})/2 \approx 300\text{K}$ ):  $k_b = 110 \text{ W/m} \cdot \text{K}$ ; Table A.3, Teflon ( $T \approx 300 \text{ K}$ ):  $k_t = 0.35 \text{ W/m} \cdot \text{K}$ .

**ANALYSIS:** The condensation rate per unit length follows from Eq. 10.34 written as

$$\dot{m}' = q' / h'_{\text{fg}} \quad (1)$$

where the heat rate per unit length follows from Eq. 10.33 using an overall heat transfer coefficient

$$q' = UP(T_{\text{sat}} - T_m) \quad (2)$$

where P is the perimeter. From Eq. 3.36, with resistances for the brass tube and Teflon coating,

$$UP = \left[ \frac{1}{h_o \pi (D_o + 2L)} + \frac{\ln[(D_o + 2L)/D_o]}{2\pi k_t} + \frac{\ln(D_o/D_i)}{2\pi k_b} + \frac{1}{h_i \pi D_i} \right]^{-1}$$

The outer heat transfer coefficient,  $h_o = \bar{h}_{\text{dc}}$ , can be calculated from Eq. 10.52,

$$\bar{h}_{\text{dc}} = 51,104 + 2044T_{\text{sat}}(^{\circ}\text{C}) = 51,104 + 2044(319.9 - 273) = 144,900 \text{ W/m}^2 \cdot \text{K}$$

Thus

$$UP = \left[ \frac{1}{144,900 \text{ W/m}^2 \cdot \text{K} \times \pi (19.2 \times 10^{-3} \text{ m})} + \frac{\ln(19.2/19)}{2\pi \times 0.35 \text{ W/m} \cdot \text{K}} \right. \\ \left. + \frac{\ln(19/16.5)}{2\pi \times 110 \text{ W/m} \cdot \text{K}} + \frac{1}{5200 \text{ W/m}^2 \cdot \text{K} \times \pi (16.5 \times 10^{-3} \text{ m})} \right]^{-1}$$

Continued...

**PROBLEM 10.70 (Cont.)**

$$UP = \left[ 1.14 \times 10^{-4} + 4.76 \times 10^{-3} + 2.04 \times 10^{-4} + 3.71 \times 10^{-3} \right]^{-1} \text{ W/m} \cdot \text{K} = 114 \text{ W/m} \cdot \text{K}.$$

Combining Eqs. (1) and (2) and substituting numerical values (see below for  $h'_{fg}$ ), find

$$\dot{m}' = UP(T_{\text{sat}} - T_m) / h'_{fg} = 114 \text{ W/m} \cdot \text{K} (318.9 - 303) \text{ K} / 2393 \times 10^3 \text{ J/kg}$$

$$\dot{m}' = 7.56 \times 10^{-4} \text{ kg/s.} \quad <$$

**COMMENTS:** (1) Since the outer convection resistance is small relative to the sum of the remaining resistances,  $T_{s,o} \approx T_{\text{sat}}$  and from Eq. 10.27,  $h'_{fg} \approx h_{fg}$ . (2) The Teflon coating induces a 21-fold increase in the condensation convection coefficient. However, the condensation rate decreases by 25 percent. This is because of the significant conduction resistance posed by the thin Teflon coating. (3) In addition to the conduction resistance, a contact resistance would exist at the Teflon-brass interface as well as constriction resistances at the droplet-Teflon interfaces, further reducing the condensation rate.

## PROBLEM 10.71

**KNOWN:** Conditions of saturated steam. Surface temperature of aluminum and stainless steel plates of known dimension.

**FIND:** (a) Temperature of the cold surface of the aluminum plate, (b) Temperature of the cold surface of the stainless steel plate.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Dropwise condensation on stainless steel described by Equation 10.52, (2) Filmwise condensation on aluminum, (3) Constant properties, (4) Steady state.

**PROPERTIES:** Table A.6, Water vapor ( $T_\infty = 100^\circ\text{C} = 373 \text{ K}$ ):  $p_{\text{A,sat}} = 1.008 \text{ bar}$ ,  $h_{fg} = 2.257 \times 10^6 \text{ J/kg}$ ; Table A.6, Water, liquid ( $T_f = (T_s + T_{\text{sat}})/2 = 95^\circ\text{C} = 368 \text{ K}$ ):  $c_{p,l} = 4212 \text{ J/kg}\cdot\text{K}$ ,  $\mu_l = 0.0002958 \text{ N}\cdot\text{s/m}^2$ ,  $k_l = 0.6782 \text{ W/m}\cdot\text{K}$ ,  $\nu_l = 3.076 \times 10^{-7} \text{ m}^2/\text{s}$ ; Table A.1, Aluminum 2024-T6 ( $T = 300 \text{ K}$ ):  $k_{\text{Al}} = 177 \text{ W/m}\cdot\text{K}$ ; Table A.1 A302 Stainless Steel ( $T = 300 \text{ K}$ ):  $k_{\text{SS}} = 15.1 \text{ W/m}\cdot\text{K}$ .

**ANALYSIS:** An energy balance for the control surface at  $T_s$  yields

$$q = \bar{h}bL(T_{\text{sat}} - T_s) = \frac{k_m bL}{t}(T_s - T_c) \quad (1)$$

where  $k_m$  is the thermal conductivity of the metal plate. Equation (1) may be rearranged to yield

$$T_c = T_s - \frac{t\bar{h}}{k_m}(T_{\text{sat}} - T_s) \quad (2)$$

(a) For filmwise condensation on the aluminum plate,  $Ja = c_{p,l}(T_{\text{sat}} - T_s)/h_{fg} = 4212 \text{ J/kg}\cdot\text{K}(100 - 90)\text{K}/2.257 \times 10^6 \text{ J/kg} = 0.0187$ . The modified latent heat is  $h'_{fg} = h_{fg}(1 + 0.68Ja) = 2.257 \times 10^6 \text{ J/kg} \times (1 + 0.68 \times 0.0187) = 2.286 \times 10^6 \text{ J/kg}$ . Evaluation of Equation 10.42 yields

$$P = \frac{k_l L (T_{\text{sat}} - T_s)}{\mu_l h'_{fg} (\nu_l^2 / g)^{1/3}} = \frac{0.6782 \text{ W/m}\cdot\text{K} \times 0.25 \text{ m} \times (100 - 90)\text{K}}{0.0002958 \text{ N}\cdot\text{s/m}^2 \times 2.286 \times 10^6 \text{ J/kg} \times \left[ (3.076 \times 10^{-7} \text{ m}^2/\text{s})^2 / 9.8 \text{ m/s}^2 \right]^{1/3}} = 118$$

which is in the range of application of Equation 10.44. Therefore,

Continued...

### PROBLEM 10.71 (Cont.)

$$\begin{aligned}\bar{h}_L &= \frac{k_l}{(v_l^2/g)^{1/3}} \frac{1}{P} (0.68P + 0.89)^{0.82} \\ &= \frac{0.6782 \text{ W/m} \cdot \text{K}}{\left[ (3.076 \times 10^{-7} \text{ m}^2/\text{s})^2 / 9.8 \text{ m}^2/\text{s} \right]^{1/3}} \frac{1}{118} (0.68 \times 118 + 0.89)^{0.82} = 9930 \text{ W/m}^2 \cdot \text{K}\end{aligned}$$

From Equation (2), the cold surface temperature is

$$T_{c,AL} = 90^\circ\text{C} - \frac{0.001 \text{ m} \times 9930 \text{ W/m}^2 \cdot \text{K}}{177 \text{ W/m} \cdot \text{K}} (100 - 90) \text{ K} = 89.4^\circ\text{C} \quad <$$

(b) For dropwise condensation on the stainless steel plate, Equation 10.52 yields

$$\bar{h} = 51,104 + 2044 \times 100^\circ\text{C} = 255,500 \text{ W/m}^2 \cdot \text{K}$$

From Equation (2), the cold surface temperature is

$$T_{c,SS} = 90^\circ\text{C} - \frac{0.001 \text{ m} \times 255,500 \text{ W/m}^2 \cdot \text{K}}{15.1 \text{ W/m} \cdot \text{K}} (100 - 90) \text{ K} = -79^\circ\text{C} \quad <$$

**COMMENTS:** (1) The required cold surface temperature associated with the stainless steel is very low, compared to the corresponding value associated with the aluminum. (2) The heat transfer rate associated with the aluminum is

$$q_{AL} = \bar{h}bL(T_{\text{sat}} - T_s) = 9930 \text{ W/m}^2 \cdot \text{K} \times 0.1 \text{ m} \times 0.25 \text{ m} \times (100 - 90) \text{ K} = 2,480 \text{ W}$$

while heat transfer rate associated with the stainless steel is

$$q_{SS} = \bar{h}bL(T_{\text{sat}} - T_s) = 255,500 \text{ W/m}^2 \cdot \text{K} \times 0.1 \text{ m} \times 0.25 \text{ m} \times (100 - 90) \text{ K} = 63,900 \text{ W}.$$

(3) For the aluminum with film condensation, the thermal resistances associated with conduction and condensation are  $R_{t,\text{cond}} = t/kA = 0.001 \text{ m} / (177 \text{ W/m} \cdot \text{K} \times 0.25 \text{ m} \times 0.1 \text{ m}) = 225 \times 10^{-6} \text{ K/W}$  and

$$R_{t,\text{conv}} = 1/\bar{h}bL = 1/\left[ 9930 \text{ W/m}^2 \cdot \text{K} \times 0.25 \text{ m} \times 0.1 \text{ m} \right] = 4030 \times 10^{-6} \text{ K/W} \text{ respectively. Hence, if}$$

dropwise condensation could be promoted on the aluminum plate, the overall thermal resistance would decrease and the heat transfer rate would increase. (4) For the stainless steel with dropwise condensation, the thermal resistances associated with conduction and condensation are

$$R_{t,\text{cond}} = t/kA = 0.001 \text{ m} / (15.1 \text{ W/m} \cdot \text{K} \times 0.25 \text{ m} \times 0.1 \text{ m}) = 2650 \times 10^{-6} \text{ K/W} \text{ and}$$

$$R_{t,\text{conv}} = 1/\bar{h}bL = 1/\left[ 255,500 \text{ W/m}^2 \cdot \text{K} \times 0.25 \text{ m} \times 0.1 \text{ m} \right] = 157 \times 10^{-6} \text{ K/W} \text{ respectively. Hence, the}$$

primary resistance is associated with conduction within the metal. Further increases in the heat transfer coefficient associated with the condensation would not significantly increase the heat transfer rate. (5) Further information on the ion implantation effect on condensation is available in the following two references.

M.H. Rausch, A.P. Fröba, A. Leipertz, "Dropwise condensation heat transfer on ion implanted aluminum surfaces," *International Journal of Heat and Mass Transfer*, Vol. 51, pp. 1061 – 1070, 2008.

A. Bani Kananeh, M.H. Rausch, A.P. Fröba, A. Leipertz, "Experimental study of dropwise condensation on plasma-ion implanted stainless steel tubes," *International Journal of Heat and Mass Transfer*, Vol. 49, pp. 5018-5026, 2006.

## PROBLEM 10.72

**KNOWN:** Surface temperature and area of integrated circuits submerged in a dielectric fluid of prescribed properties. Height and temperature of condenser plates.

**FIND:** (a) Heat dissipation by an integrated circuit, (b) Condenser surface area needed to balance heat load.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Nucleate pool boiling in liquid, (2) Laminar film condensation of vapor, (3) Negligible heat loss to surroundings.

**PROPERTIES:** Dielectric fluid (given,  $T_{\text{sat}} = 50^\circ\text{C}$ ):  $\rho_\ell = 1700\text{kg/m}^3$ ,  $c_{p,\ell} = 1005\text{J/kg}\cdot\text{K}$ ,  $\mu_\ell = 6.80 \times 10^{-4}\text{kg/s}\cdot\text{m}$ ,  $k_\ell = 0.062\text{W/m}\cdot\text{K}$ ,  $\text{Pr}_\ell = 11$ ,  $\sigma = 0.013\text{kg/s}^2$ ,  $h_{\text{fg}} = 1.05 \times 10^5\text{J/kg}$ ,  $C_{s,f} = 0.004$ ,  $n = 1.7$ ,  $\nu_\ell = \mu_\ell / \rho_\ell = 4.0 \times 10^{-7}\text{m}^2/\text{s}$ .

**ANALYSIS:** (a) For nucleate pool boiling,

$$q_s'' = \mu_\ell h_{\text{fg}} \left[ \frac{g(\rho_\ell - \rho_v)}{\sigma} \right]^{1/2} \left( \frac{c_{p,\ell} \Delta T_e}{C_{s,f} h_{\text{fg}} \text{Pr}_\ell^n} \right)^3 \approx 6.8 \times 10^{-4}\text{kg/s}\cdot\text{m} \left( 1.05 \times 10^5\text{J/kg} \right)$$

$$\times \left[ \frac{9.8\text{m/s}^2 \times 1700\text{kg/m}^3}{0.013\text{kg/s}^2} \right]^{1/2} \left( \frac{1005\text{J/kg}\cdot\text{K} \times 25\text{K}}{0.004 \times 1.05 \times 10^5\text{J/kg} \times 11^{1.7}} \right)^3 = 84,530\text{W/m}^2$$

$$q_s = A_s q_s'' = 84,530\text{W/m}^2 \times 25 \times 10^{-6}\text{m}^2 = 2.11\text{W} \quad <$$

(b) From Eq. 10.42,

$$P = \frac{k_\ell L (T_{\text{sat}} - T_s)}{\mu_\ell h'_{\text{fg}} (\nu_\ell^2 / g)^{1/3}}$$

$$= \frac{0.062\text{W/m}\cdot\text{K} \times 0.05\text{m} (50 - 15)\text{K}}{6.80 \times 10^{-4}\text{kg/s}\cdot\text{m} \times 1.29 \times 10^5\text{J/kg} \times \left[ (4.0 \times 10^{-7}\text{m}^2/\text{s})^2 / 9.8\text{m/s}^2 \right]^{1/3}} = 48.8$$

where  $h'_{\text{fg}} = h_{\text{fg}} + 0.68c_{p,\ell}(T_{\text{sat}} - T_s) = 1.29 \times 10^5\text{J/kg}$ . With  $15.8 < P < 2530$ , the flow is wavy laminar and Eq. 10.44 gives

$$\bar{h}_L = \frac{k_\ell}{(\nu_\ell^2 / g)^{1/3}} \frac{1}{P} (0.68P + 0.89)^{0.82}$$

$$= \frac{0.062\text{W/m}\cdot\text{K}}{\left[ (4.0 \times 10^{-7}\text{m}^2/\text{s})^2 / 9.8\text{m}^2/\text{s} \right]^{1/3}} \frac{1}{48.8} (0.68 \times 48.8 + 0.89)^{0.82} = 904\text{W/m}^2 \cdot \text{K}$$

To balance the heat load,  $q_c = Nq_s$ , thus from Eq. 10.33,

$$\bar{h}_L A_c (T_{\text{sat}} - T_c) = Nq_s = 500 \times 2.11\text{W} = 1055\text{W}$$

$$A_c = \frac{1055\text{W}}{904\text{W/m}^2 \cdot \text{K} \times (50 - 15)^\circ\text{C}} = 0.033\text{m}^2 \quad <$$

### PROBLEM 10.73

**KNOWN:** Thin-walled thermosyphon. Absorbs heat by boiling saturated water at atmospheric pressure on boiling section  $L_b$ . Rejects heat by condensing vapor into a thick film which falls length of condensation section  $L_c$  back into boiling section.

**FIND:** (a) Mean surface temperature,  $T_{s,b}$ , of the boiling surface if nucleate boiling flux is 30% critical flux, (b) Mean surface temperature,  $T_{s,c}$  of condensation section, and total condensation flow rate,  $\dot{m}$ , in thermosyphon.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Film condensation occurs in condensation section which approximates a vertical plate, (2) Boiling and condensing section are separated by insulated length  $L_i$ , (3) Top surface of condensation section is insulated, (4) For condensation, liquid properties evaluated at  $T_f = 90^\circ\text{C}$ .

**PROPERTIES:** Table A-6, Saturated water ( $100^\circ\text{C}$ ):  $\rho_\ell = 1/v_f = 957.9 \text{ kg/m}^3$ ,  $c_{p,\ell} = 4217 \text{ J/kg}\cdot\text{K}$ ,  $\mu_\ell = 279 \times 10^{-6} \text{ N}\cdot\text{s/m}^2$ ,  $\text{Pr}_\ell = 1.76$ ,  $h_{fg} = 2257 \text{ kJ/kg}$ ,  $\sigma = 58.9 \times 10^{-3} \text{ N/m}$ ; Saturated vapor ( $100^\circ\text{C}$ ):  $\rho_v = 1/v_g = 0.5955 \text{ kg/m}^3$ ; Saturated water ( $90^\circ\text{C}$ ):  $\rho_\ell = 1/v_f = 964.9 \text{ kg/m}^3$ ,  $c_{p,\ell} = 4207 \text{ J/kg}\cdot\text{K}$ ,  $\mu_\ell = 313 \times 10^{-6} \text{ N}\cdot\text{s/m}^2$ ,  $k_\ell = 0.676 \text{ W/m}\cdot\text{K}$ ,  $\nu_\ell = \mu_\ell/\rho_\ell = 3.24 \times 10^{-7} \text{ m}^2/\text{s}$ .

**ANALYSIS:** (a) The heat flux for the boiling section is 30% of the critical heat flux which at atmospheric pressure is

$$q''_{s,b} = 0.30q''_{\max} = 0.30 \times 1.26 \times 10^6 \text{ W/m}^2 = 3.78 \times 10^5 \text{ W/m}^2.$$

Using the Rohsenow correlation for nucleate boiling with  $T_{\text{sat}} = 100^\circ\text{C}$  and typical values for the surface of  $C_{s,f} = 0.0130$  and  $n = 1.0$ , find

$$q''_{s,b} = \mu_\ell h_{fg} \left[ \frac{g(\rho_\ell - \rho_v)}{\sigma} \right]^{1/2} \left( \frac{c_{p,\ell} (T_{s,b} - T_{\text{sat}})}{C_{s,f} h_{fg} \text{Pr}_\ell^n} \right)^3$$

$$3.78 \times 10^5 \text{ W/m}^2 = 279 \times 10^{-6} \text{ N}\cdot\text{s/m}^2 \times 2257 \times 10^3 \text{ J/kg} \times$$

$$\left[ \frac{9.8 \text{ m/s}^2 (957.9 - 0.5955) \text{ kg/m}^3}{58.9 \times 10^{-3} \text{ N/m}} \right]^{1/2} \left( \frac{4217 \text{ J/kg}\cdot\text{K} (T_{s,b} - 100)}{0.013 \times 2257 \times 10^3 \text{ J/kg} \cdot 1.76^{1.0}} \right)^3$$

Continued ...

**PROBLEM 10.73 (Cont.)**

$$T_{s,b} = 114.0^\circ\text{C} \quad <$$

(b) The heat transferred into the boiling section must be rejected by film condensation,

$$q_c = q_b = q''_{s,b} \left[ \pi D^2 / 4 + \pi DL_b \right]$$

$$q_c = 3.78 \times 10^5 \text{ W/m}^2 \left[ \pi (0.020 \text{ m})^2 / 4 + \pi (0.020 \text{ m}) \times 0.020 \text{ m} \right] = 594 \text{ W}.$$

Thus from Eq. 10.34,  $\dot{m} = q_c / h'_{fg}$  and from Eq. 10.36,  $Re_\delta = 4\dot{m} / \mu_\ell b = 4q_c / h'_{fg} \mu_\ell \pi D$ , where  $h'_{fg} = h_{fg} + 0.68c_{p,\ell}(T_{sat} - T_{s,c})$ . We approximate  $h'_{fg} = h_{fg}$  and find  $Re_\delta \approx 53.5$ . Thus the flow is wavy laminar. From Eq. 10.39 we have

$$\begin{aligned} \bar{h}_L &= \frac{k_\ell}{(v_\ell^2/g)^{1/3}} \frac{Re_\delta}{1.08Re_\delta^{1.22} - 5.2} = \\ &= \frac{0.676 \text{ W/m} \cdot \text{K}}{\left[ (3.24 \times 10^{-7} \text{ m}^2/\text{s})^2 / 9.8 \text{ m}^2/\text{s} \right]^{1/3}} \frac{53.5}{1.08 \times 53.5^{1.22} - 5.2} = 12,290 \text{ W/m}^2 \cdot \text{K} \end{aligned} \quad (1)$$

From Eq. 10.33 we can solve for  $T_{sat} - T_{s,c}$ , as

$$T_{sat} - T_{s,c} = q_c / \bar{h}_L \pi DL = 594 \text{ W} / (12,290 \text{ W/m}^2 \cdot \text{K} \times \pi \times 0.02 \text{ m} \times 0.04 \text{ m}) = 19.2^\circ\text{C} \quad (2)$$

This solution can now be iterated by recalculating  $h'_{fg}$  and  $Re_\delta$  and re-solving Eqs. (1) and (2). The iterations converge to  $T_{sat} - T_{s,c} = 19.1^\circ\text{C}$ . Thus

$$T_{s,c} = 80.9^\circ\text{C} \quad <$$

Finally, with  $h'_{fg} = 2.31 \times 10^6 \text{ J/kg}$ ,

$$\dot{m} = q_c / h'_{fg} = 594 \text{ W} / 2.31 \times 10^6 \text{ J/kg} = 2.6 \times 10^{-4} \text{ kg/s} \quad <$$

## PROBLEM 10.74

**KNOWN:** Thermosyphon configuration for cooling a computer chip of prescribed size.

**FIND:** (a) Chip temperature and total power dissipation when chip operates at 90% of critical heat flux, (b) Required condenser length.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, (2) Saturated liquid/vapor conditions, (3) Negligible heat transfer from bottom of chip.

**PROPERTIES:** Fluorocarbon (prescribed):  $T_{sat} = 57^\circ\text{C}$ ,  $c_{p,l} = 1100 \text{ J/kg}\cdot\text{K}$ ,  $h_{fg} = 84,400 \text{ J/kg}$ ,  $\rho_l = 1619.2 \text{ kg/m}^3$ ,  $\rho_v = 13.4 \text{ kg/m}^3$ ,  $\sigma = 8.1 \times 10^{-3} \text{ kg/s}^2$ ,  $\mu_l = 440 \times 10^{-6} \text{ kg/m}\cdot\text{s}$ ,  $\text{Pr}_l = 9.01$ ,  $k_l = 0.054 \text{ W/m}\cdot\text{K}$ ,  $\nu_l = \mu_l / \rho_l = 0.272 \times 10^{-6} \text{ m}^2/\text{s}$ .

**ANALYSIS:** (a) With  $q'' = 0.9 q''_{max}$  and the critical heat flux given by Eq. 10.6 with  $C=0.149$ , the chip power dissipation is

$$q = 0.9 L_c^2 \times 0.149 h_{fg} \rho_v \left[ \frac{\sigma g (\rho_l - \rho_v)}{\rho_v^2} \right]^{1/4}$$

$$q = 0.9 (0.02 \text{ m})^2 \times 0.149 (84,400 \text{ J/kg}) 13.4 \text{ kg/m}^3 \left[ \frac{0.0081 \text{ kg/s}^2 (9.8 \text{ m/s}^2) (1605.8 \text{ kg/m}^3)}{(13.4 \text{ kg/m}^3)^2} \right]^{1/4}$$

$$q_c = 0.9 (4 \times 10^{-4} \text{ m}^2) 1.55 \times 10^5 \text{ W/m}^2 = 55.7 \text{ W} \quad <$$

With operation at  $q'' = 1.40 \times 10^5 \text{ W/m}^2$  in the nucleate boiling region, Eq. 10.5 yields

$$T = T_{sat} + \frac{C_{s,f} h_{fg} \text{Pr}_l^n}{c_{p,l}} \left( \frac{q''}{\mu_l h_{fg}} \right)^{1/3} \left[ \frac{\sigma}{g (\rho_l - \rho_v)} \right]^{1/6}$$

$$T = 57^\circ\text{C} + \frac{0.005 (84,400 \text{ J/kg}) (9.01)^{1.7}}{1100 \text{ J/kg}\cdot\text{K}} \left( \frac{1.40 \times 10^5 \text{ W/m}^2}{4.4 \times 10^{-4} \text{ kg/m}\cdot\text{s} \times 84,400 \text{ J/kg}} \right)^{1/3} \left[ \frac{0.0081 \text{ kg/s}^2}{9.8 \text{ m/s}^2 (1605.8 \text{ kg/m}^3)} \right]^{1/6}$$

Continued...

**PROBLEM 10.74 (Cont.)**

$$T = 57^\circ\text{C} + 22.4^\circ\text{C} = 79.4^\circ\text{C}$$

&lt;

(b) The power dissipated by the chip must be balanced by the rate of heat transfer from the condensing section. We combine Eqs. 10.34 and 10.36 to obtain  $\text{Re}_\delta = 4q/\mu_\ell b h'_{fg}$ , where  $b = \pi D = 0.0942\text{ m}$  and  $h'_{fg} = h_{fg} + 0.68c_{p,1}(T_{\text{sat}} - T_s) = 84,400\text{ J/kg} + 0.68(1100\text{ J/kg}\cdot\text{K})32^\circ\text{C} = 108,300\text{ J/kg}$ . Hence,  $\text{Re}_\delta = 4(55.7\text{ W})/4.4 \times 10^{-4}\text{ kg/m}\cdot\text{s}(0.0942\text{ m})108,300\text{ J/kg} = 49.6$  and the condensate film is in the laminar-wavy region. Hence, from Eq. 10.39

$$\begin{aligned} \bar{h}_L &= \frac{k_\ell}{(v_\ell^2/g)^{1/3}} \frac{\text{Re}_\delta}{1.08\text{Re}_\delta^{1.22} - 5.2} = \\ &= \frac{0.054\text{ W/m}\cdot\text{K}}{\left[(0.272 \times 10^{-6}\text{ m}^2/\text{s})^2 / 9.8\text{ m}^2/\text{s}\right]^{1/3}} \frac{49.6}{1.08 \times 49.6^{1.22} - 5.2} = 1130\text{ W/m}^2 \cdot \text{K} \end{aligned}$$

and from Eq. 10.33,

$$L = \frac{q_c}{\bar{h}_L \pi D (T_{\text{sat}} - T_s)} = \frac{55.7\text{ W}}{1130\text{ W/m}^2 \cdot \text{K} \times 0.0942\text{ m} \times 32^\circ\text{C}} = 16.4\text{ mm}$$

&lt;

**COMMENTS:** The chip operating temperature ( $T = 79.4^\circ\text{C}$ ) is not excessive, and the proposed scheme provides a compact means of cooling high performance chips.

## PROBLEM 10.75

**KNOWN:** Copper plate,  $2\text{ m} \times 2\text{ m}$ , in a condenser-boiler section maintained at  $T_s = 100^\circ\text{C}$  separates condensing saturated steam and nucleate-pool boiling of saturated liquid X.

**FIND:** (a) Rates of evaporation and condensation (kg/s) for the two fluids and (b) Saturation temperature  $T_{\text{sat}}$  and pressure  $p$  for the steam, assuming that film condensation occurs.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Isothermal copper plate.

**PROPERTIES:** *Fluid-X* (Given, 1 atm):  $T_{\text{sat}} = 80^\circ\text{C}$ ,  $h_{\text{fg}} = 700\text{ kJ/kg}$ , portion of boiling curve shown above for operating condition,  $\Delta T_e = T_s - T_{\text{sat}} = (100 - 80)^\circ\text{C} = 20^\circ\text{C}$ ,  $q_s'' = 5 \times 10^4\text{ W/m}^2$ ; *Table A.6*, Water (saturated,  $T_f \approx 100^\circ\text{C}$ ):  $\rho_\ell = 957.9\text{ kg/m}^3$ ,  $h_{\text{fg}} = 2257\text{ kJ/kg}$ ,  $c_{p,\ell} = 4217\text{ J/kg}$ ,  $\mu_\ell = 279 \times 10^{-6}\text{ N}\cdot\text{s/m}^2$ ,  $k_\ell = 0.680\text{ W/m}\cdot\text{K}$ ,  $\text{Pr}_\ell = 1.76$ ,  $\nu_\ell = \mu_\ell / \rho_\ell = 2.91 \times 10^{-7}\text{ m}^2/\text{s}$ .

**ANALYSIS:** (a) For fluid-X, with  $\Delta T_e = T_s - T_{\text{sat}} = (100 - 80)^\circ\text{C} = 20\text{ K}$ , the heat flux from the boiling curve is

$$q_s'' = 50,000\text{ W/m}^2$$

and the heat rate from the copper plate section into liquid-X is

$$q_s = q_s'' \times A_s = 50,000\text{ W/m}^2 \times (2 \times 2)\text{ m}^2 = 200,000\text{ W}$$

From an energy balance around liquid-X, the evaporation rate for fluid-X is

$$\dot{m}_X = q_s / h_{\text{fg},X} = 200,000\text{ W} / 700,000\text{ J/kg} = 0.286\text{ kg/s} \quad <$$

The heat rate into the copper plate section from the steam is  $q_s = 200,000\text{ W}$ , and from an energy balance around the condensate film, the condensation rate for steam (w)

$$\dot{m}_w = q_s / h'_{\text{fg},w} = 200,000\text{ W} / 2.257 \times 10^6\text{ J/kg} = 0.0886\text{ kg/s}$$

where we are assuming that  $T_{\text{sat},w}$  is only a few degrees above  $T_s$  so that  $h'_{\text{fg}} \approx h_{\text{fg}}$ .

(b) With  $T_{\text{sat}}$  unknown, we begin by evaluating the liquid water properties at  $100^\circ\text{C}$  as given above. Then from Eq. 10.36,

$$\text{Re}_\delta = 4\dot{m}_w / \mu_\ell b = 4 \times 0.0886\text{ kg/s} / 279 \times 10^{-6}\text{ N}\cdot\text{s/m}^2 \times 2\text{ m} = 635$$

Continued...

### PROBLEM 10.75 (Cont.)

Thus the flow is wavy laminar. From Eq. 10.39 we have

$$\begin{aligned}\bar{h}_L &= \frac{k_\ell}{(v_\ell^2/g)^{1/3}} \frac{\text{Re}_\delta}{1.08\text{Re}_\delta^{1.22} - 5.2} = \\ &= \frac{0.680 \text{ W/m}\cdot\text{K}}{\left[ (2.91 \times 10^{-7} \text{ m}^2/\text{s})^2 / 9.8 \text{ m}^2/\text{s} \right]^{1/3}} \frac{635}{1.08 \times 635^{1.22} - 5.2} = 7430 \text{ W/m}^2 \cdot \text{K}\end{aligned}$$

From Eq. 10.33 we can solve for  $T_{\text{sat}} - T_{\text{s,c}}$ , as

$$T_{\text{sat}} - T_{\text{s,c}} = q_c / \bar{h}_L A = 200,000 \text{ W} / (7430 \text{ W/m}^2 \cdot \text{K} \times 4 \text{ m}^2) = 6.7^\circ\text{C}$$

Thus

$$T_{\text{sat}} = 106.7^\circ\text{C} = 379.7 \text{ K} \quad <$$

$$\text{From Table A.6, } p = p_{\text{sat}}(379.7 \text{ K}) = 1.27 \text{ bars} \quad <$$

**COMMENTS:** The calculation could be repeated with properties evaluated at  $T_f = 103^\circ\text{C}$  and with  $h'_{fg} \neq h_{fg}$ , but the results would not change much.

### PROBLEM 10.76

**KNOWN:** Thin-walled container filled with a low boiling point liquid (A) at  $T_{\text{sat},A}$ . Outer surface of container experiences laminar-film condensation with the vapor of a high-boiling point fluid (B). Laminar film extends from the location of the liquid-A free surface. The heat flux for nucleate pool boiling in liquid-A along the container wall is given as  $q''_{\text{npb}} = C(T_s - T_{\text{sat}})^3$ , where  $C$  is a known empirical constant.

**FIND:** (a) Expression for the average temperature of the container wall,  $T_s$ ; assume that the properties of fluids A and B are known; (b) Heat rate supplied to liquid-A, and (c) Time required to evaporate all the liquid-A in the container, assuming that initially the container is filled,  $y = L$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Nucleate pool boiling occurs on the inner surface of the container with liquid-A, (2) Laminar film condensation occurs on the outer surface of the container with fluid-B over the liquid-A free surface,  $y$ , and (3) Negligible wall thermal resistance.

**ANALYSIS:** (a) Perform an energy balance on the control surface about the container wall along locations experiencing boiling (A) and condensation (B) as shown in the schematic above.

$$\dot{E}''_{\text{in}} - \dot{E}''_{\text{out}} = 0 \quad (1)$$

$$q''_{\text{cond}} - q''_{\text{npb}} = 0 \quad (2)$$

$$\bar{h}_y (\pi D y) (T_{\text{sat},B} - T_s) - (\pi D y) C (T_s^3 - T_{\text{sat},A}^3) = 0$$

$$\bar{h}_y (T_{\text{sat},B} - T_s) = C (T_s - T_{\text{sat},A})^3 \quad (3) <$$

where  $\bar{h}_y$  is the average convection coefficient for laminar film condensation over the surface length 0 to  $y$ . From Eqs. 10.31 and 10.27,

Continued...

**PROBLEM 10.76 (Cont.)**

$$\bar{h}_y = 0.943 \left[ \frac{g \rho_\ell (\rho_\ell - \rho_v) k_\ell^3 h'_{fg}}{\mu_\ell (T_{sat} - T_s) y} \right]_B^{1/4} \quad (3)$$

$$h'_{fg} = h_{fg,B} + 0.68 c_{p,B} (T_{sat,B} - T_s) \quad (4)$$

where the properties are for fluid-B.

(b) The heat flux supplied to liquid-A is, from Eq. (2),  $q''_{cond} = q''_{npb}$ . Since  $\bar{h}_y$  is a function of  $y$ ,  $T_s$  and, hence, the heat fluxes will be functions of  $y$ , the height of liquid A in the container.

(c) To determine the dry-out time,  $t_f$ , begin with an energy balance on the inside of the container (fluid-A). The heat transfer supplied to liquid-A results in an evaporation rate of liquid-A,

$$q''_{npb} (\pi D y) - \frac{dM}{dt} h_{fg} = 0 \quad (4)$$

where  $M$  is the mass of liquid-A in the container,

$$M = \rho_{\ell,A} \left( \pi D^2 / 4 \right) y \quad (5)$$

Substituting Eq. (5) into (4), separating variables and identifying integration limits, find

$$C (T_s - T_{sat,A})^3 (\pi D y) = \frac{d}{dt} \left[ \rho_{\ell,A} \left( \pi D^2 / 4 \right) y \right] h_{fg}$$

$$\int_0^{t_f} dt = t_f = \frac{\rho_{\ell,A} \left( \pi D^2 / 4 \right) h_{fg}}{C \pi D} \int_L^0 \frac{dy}{(T_s - T_{sat,A})^3 y} \quad (6)$$

The definite integral could be numerically evaluated using values for  $T_s(y)$  obtained by solving Eq. (3).

### PROBLEM 10.77

**KNOWN:** Dimensions of ten thin-walled thermosyphons with boiling, insulated, and condensing sections of known lengths. Working fluid is saturated water at 0.047 bars.

**FIND:** (a) Heating rate delivered by thermosyphons if nucleate boiling heat flux is 25% of CHF and mean temperatures of boiling and condensing sections, (b) Heat loss from hot water tank to cool attic.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Bottom of thermosyphon can be treated as a large horizontal surface, (2) Nucleate boiling constants are typical values of  $C_{s,f} = 0.0130$  and  $n = 1.0$ , (3) Boiling and condensing section are separated by insulated length  $L_i$ , (4) Laminar film condensation occurs in condensation section which approximates a vertical plate, (5) Top surface of condensation section is insulated, (6) For condensation, liquid properties evaluated at  $T_f = 300$  K.

**PROPERTIES:** Table A-6, Saturated water ( $p = 0.047$  bars):  $T_{\text{sat}} = 305$  K,  $\rho_\ell = 1/v_f = 995$  kg/m<sup>3</sup>,  $c_{p,\ell} = 4178$  J/kg·K,  $\mu_\ell = 769 \times 10^{-6}$  N·s/m<sup>2</sup>,  $\text{Pr}_\ell = 5.20$ ,  $h_{fg} = 2426$  kJ/kg,  $\sigma = 70.9 \times 10^{-3}$  N/m; Saturated vapor ( $p = 0.047$  bars):  $\rho_v = 1/v_g = 0.0336$  kg/m<sup>3</sup>; Saturated water (300 K):  $\rho_\ell = 1/v_f = 997$  kg/m<sup>3</sup>,  $c_{p,\ell} = 4179$  J/kg·K,  $\mu_\ell = 855 \times 10^{-6}$  N·s/m<sup>2</sup>,  $\nu_\ell = \mu_\ell / \rho_\ell = 8.58 \times 10^{-7}$  m<sup>2</sup>/s,  $k_\ell = 0.613$  W/m·K.

**ANALYSIS:** (a) The heat flux for the boiling section is 25% of the critical heat flux, which is given by Eq. 10.6 with  $C = 0.149$  for a large horizontal surface,

$$q''_{s,b} = 0.25q''_{\text{max}} = (0.25)0.149h_{fg}\rho_v \left[ \frac{\sigma g(\rho_\ell - \rho_v)}{\rho_v^2} \right]^{1/4}$$

Continued ...

**PROBLEM 10.77 (Cont.)**

$$\begin{aligned}
 &= (0.25)0.149 \times 2426 \times 10^3 \text{ J/kg} \times 0.0336 \text{ kg/m}^3 \\
 &\quad \times \left[ \frac{70.9 \times 10^{-3} \text{ N/m} \times 9.8 \text{ m/s}^2 (995 - 0.0336) \text{ kg/m}^3}{(0.0336 \text{ kg/m}^3)^2} \right]^{1/4} \\
 &= 84,900 \text{ W/m}^2
 \end{aligned}$$

Using the Rohsenow correlation for nucleate boiling, find

$$\begin{aligned}
 q''_{s,b} &= \mu_\ell h_{fg} \left[ \frac{g(\rho_\ell - \rho_v)}{\sigma} \right]^{1/2} \left( \frac{c_{p,\ell} (T_{s,b} - T_{sat})}{C_{s,f} h_{fg} Pr_\ell^n} \right)^3 \\
 84,900 \text{ W/m}^2 &= 769 \times 10^{-6} \text{ N} \cdot \text{s/m}^2 \times 2426 \times 10^3 \text{ J/kg} \times
 \end{aligned}$$

$$\begin{aligned}
 &\left[ \frac{9.8 \text{ m/s}^2 (995 - 0.0336) \text{ kg/m}^3}{70.9 \times 10^{-3} \text{ N/m}} \right]^{1/2} \left( \frac{4178 \text{ J/kg} \cdot \text{K} (T_{s,b} - 305)}{0.013 \times 2426 \times 10^3 \text{ J/kg} \times 5.20^{1.0}} \right)^3 \\
 T_{s,b} &= 325 \text{ K.} &<
 \end{aligned}$$

The heat transferred into the boiling section must be rejected by film condensation,

$$\begin{aligned}
 q_c &= q_b = q''_{s,b} \left[ \pi D^2 / 4 + \pi D L_b \right] \\
 q_c &= 84,900 \text{ W/m}^2 \left[ \pi (0.020 \text{ m})^2 / 4 + \pi (0.020 \text{ m}) \times 0.030 \text{ m} \right] = 187 \text{ W.}
 \end{aligned}$$

For all ten thermosyphons, the heating rate is therefore

$$q_{tot} = 1870 \text{ W} \quad <$$

Thus from Eq. 10.34,  $\dot{m} = q_c / h'_{fg}$  and from Eq. 10.36,  $Re_\delta = 4\dot{m} / \mu_\ell b = 4q_c / h'_{fg} \mu_\ell \pi D$ , where  $h'_{fg} = h_{fg} + 0.68c_{p,\ell}(T_{sat} - T_{s,c})$ . We approximate  $h'_{fg} = h_{fg}$  and find  $Re_\delta \approx 5.7$ . Thus the flow is laminar as assumed. From Eq. 10.38 we have

$$\begin{aligned}
 \bar{h}_L &= \frac{k_\ell}{(v_\ell^2/g)^{1/3}} 1.47 Re_\delta^{-1/3} = \\
 &= \frac{0.613 \text{ W/m} \cdot \text{K}}{\left[ (8.58 \times 10^{-7} \text{ m}^2/\text{s})^2 / 9.8 \text{ m}^2/\text{s} \right]^{1/3}} 1.47 \times 5.7^{-1/3} = 11,930 \text{ W/m}^2 \cdot \text{K} \quad (1)
 \end{aligned}$$

Continued ...

### PROBLEM 10.77 (Cont.)

From Eq. 10.33 we can solve for  $T_{\text{sat}} - T_{\text{s,c}}$ , as

$$T_{\text{sat}} - T_{\text{s,c}} = q_c / \bar{h}_L \pi D L_c = 187 \text{ W} / (11,930 \text{ W/m}^2 \cdot \text{K} \times \pi \times 0.02 \text{ m} \times 0.05 \text{ m}) = 5.0^\circ\text{C} \quad (2)$$

This solution can now be iterated by recalculating  $h'_{fg}$  and  $Re_\delta$  and re-solving Eqs. (1) and (2). Subsequent iterations do not change the value of  $T_{\text{sat}} - T_{\text{s,c}}$ . Thus

$$T_{\text{s,c}} = T_{\text{sat}} - 5.0 \text{ K} = 300 \text{ K} \quad <$$

Note that  $T_f = 302.5 \text{ K}$ , which is not far from the assumed value of  $300 \text{ K}$ .

(b) There would be heat conduction through thermally-stratified water vapor in the thermosyphon tubes (neglecting tube wall conduction) which would yield a very small heat transfer rate. Hence the heat loss is approximately zero. <

**COMMENTS:** (1) The thermosyphon is a unique device in that it acts like a *thermal diode*, promoting high heat transfer rates in one direction, while serving as an effective insulator in the opposite direction. (2) The convective resistance between the boiling section and the attic air will be extremely large for an un-finned thermosyphon. Hence, it would be necessary to significantly reduce this resistance by, for example, attaching annular fins to each boiling section and using a fan to heat the fins with forced convection. (3) The operating temperatures in the boiling and condensation sections of the thermosyphon may not be optimal values. Adjustment of these temperatures can be accomplished by changing the pressure within the thermosyphon, or by using a working fluid other than water.

### PROBLEM 11.1

**KNOWN:** Initial overall heat transfer coefficient of a fire-tube boiler. Fouling factors following one year's application.

**FIND:** Whether cleaning should be scheduled.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible tube wall conduction resistance, (2) Negligible changes in  $h_c$  and  $h_h$ .

**ANALYSIS:** From Equation 11.1b, the overall heat transfer coefficient after one year is

$$\frac{1}{U} = \frac{1}{h_i} + \frac{1}{h_o} + R''_{f,i} + R''_{f,o}.$$

Since the first two terms on the right-hand side correspond to the reciprocal of the initial overall coefficient,

$$\frac{1}{U} = \frac{1}{400 \text{ W}/\text{m}^2 \cdot \text{K}} + (0.0015 + 0.0005) \text{ m}^2 \cdot \text{K}/\text{W} = 0.0045 \text{ m}^2 \cdot \text{K}/\text{W}$$

$$U = 222 \text{ W}/\text{m}^2 \cdot \text{K}.$$

**COMMENTS:** Periodic cleaning of the tube inner surfaces is essential to maintaining efficient fire-tube boiler operations.

## PROBLEM 11.2

**KNOWN:** Type-302 stainless tube with prescribed inner and outer diameters used in a cross-flow heat exchanger. Prescribed fouling factors and internal water flow conditions.

**FIND:** (a) Overall coefficient based upon the outer surface,  $U_o$ , with air at  $T_o = 15^\circ\text{C}$  and velocity  $V_o = 20$  m/s in cross-flow; compare thermal resistances due to convection, tube wall conduction and fouling; (b) Overall coefficient,  $U_o$ , with water (rather than air) at  $T_o = 15^\circ\text{C}$  and velocity  $V_o = 1$  m/s in cross-flow; compare thermal resistances due to convection, tube wall conduction and fouling; (c) For the water-air conditions of part (a), compute and plot  $U_o$  as a function of the air cross-flow velocity for  $5 \leq V_o \leq 30$  m/s for water mean velocities of  $u_{m,i} = 0.2, 0.5$  and  $1.0$  m/s; and (d) For the water-water conditions of part (b), compute and plot  $U_o$  as a function of the water mean velocity for  $0.5 \leq u_{m,i} \leq 2.5$  m/s for air cross-flow velocities of  $V_o = 1, 3$  and  $8$  m/s.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Fully developed internal flow,

**PROPERTIES:** *Table A.1*, Stainless steel, AISI 302 (300 K):  $k_w = 15.1$  W/m·K; *Table A.6*, Water ( $\bar{T}_{m,i} = 348$  K):  $\rho_i = 974.8$  kg/m<sup>3</sup>,  $\mu_i = 3.746 \times 10^{-4}$  N·s/m<sup>2</sup>,  $k_i = 0.668$  W/m·K,  $Pr_i = 2.354$ ; *Table A.4*, Air (assume  $\bar{T}_{f,o} = 315$  K, 1 atm):  $k_o = 0.02737$  W/m·K,  $\nu_o = 17.35 \times 10^{-6}$  m<sup>2</sup>/s,  $Pr_o = 0.705$ .

**ANALYSIS:** (a) For the water-air condition, the overall coefficient, Eq. 11.1, based upon the outer area can be expressed as the sum of the thermal resistances due to convection (cv), tube wall conduction (w) and fouling (f):

$$1/U_o A_o = R_{\text{tot}} = R_{\text{cv},i} + R_{\text{f},i} + R_w + R_{\text{f},o} + R_{\text{cv},o}$$

$$R_{\text{cv},i} = 1/\bar{h}_i A_i \quad R_{\text{cv},o} = 1/\bar{h}_o A_o$$

$$R_{\text{f},i} = R''_{\text{f},i}/A_i \quad R_{\text{f},o} = R''_{\text{f},o}/A_o$$

and from Eq. 3.33,

$$R_w = \ln(D_o/D_i)/(2\pi L k_w)$$

The convection coefficients can be estimated from appropriate correlations.

Continued...

### PROBLEM 11.2 (Cont.)

*Estimating  $\bar{h}_i$* : For internal flow, characterize the flow evaluating thermophysical properties at  $T_{m,i}$  with

$$\text{Re}_{D,i} = \frac{u_{m,i} D_i}{\nu_i} = \frac{0.5 \text{ m/s} \times 0.022 \text{ m}}{3.746 \times 10^{-4} \text{ N} \cdot \text{s/m}^2 / 974.8 \text{ kg/m}^3} = 28,625$$

For the turbulent flow, use the Dittus-Boelter correlation, Eq. 8.60,

$$\text{Nu}_{D,i} = 0.023 \text{Re}_{D,i}^{0.8} \text{Pr}_i^{0.3}$$

$$\text{Nu}_{D,i} = 0.023(28,625)^{0.8} (2.354)^{0.3} = 109.3$$

$$\bar{h}_i = \text{Nu}_{D,i} k_i / D_i = 109.3 \times 0.668 \text{ W/m}^2 \cdot \text{K} / 0.022 \text{ m} = 3313 \text{ W/m}^2 \cdot \text{K}$$

*Estimating  $\bar{h}_o$* : For external flow, characterize the flow with

$$\text{Re}_{D,o} = \frac{V_o D_o}{\nu_o} = \frac{20 \text{ m/s} \times 0.027 \text{ m}}{17.35 \times 10^{-6} \text{ m}^2/\text{s}} = 31,124$$

evaluating thermophysical properties at  $T_{f,o} = (T_{s,o} + T_o)/2$  when the surface temperature is determined from the thermal circuit analysis result,

$$(T_{m,i} - T_o) / R_{\text{tot}} = (T_{s,o} - T_o) / R_{\text{cv},o}$$

Assume  $T_{f,o} = 315 \text{ K}$ , and check later. Using the Churchill-Bernstein correlation, Eq. 7.54, find

$$\bar{\text{Nu}}_{D,o} = 0.3 + \frac{0.62 \text{Re}_{D,o}^{1/2} \text{Pr}_o^{1/3}}{\left[1 + (0.4/\text{Pr}_o)^{2/3}\right]^{1/4}} \left[1 + \left(\frac{\text{Re}_{D,o}}{282,000}\right)^{5/8}\right]^{4/5}$$

$$\bar{\text{Nu}}_{D,o} = 0.3 + \frac{0.62(31,124)^{1/2} (0.705)^{1/3}}{\left[1 + (0.4/0.705)^{2/3}\right]^{1/4}} \left[1 + \left(\frac{31,124}{282,000}\right)^{5/8}\right]^{4/5}$$

$$\bar{\text{Nu}}_{D,o} = 102.6$$

$$\bar{h}_o = \bar{\text{Nu}}_{D,o} k_o / D_o = 102.6 \times 0.02737 \text{ W/m} \cdot \text{K} / 0.027 \text{ m} = 104.0 \text{ W/m} \cdot \text{K}$$

Using the above values for  $\bar{h}_i$ , and  $\bar{h}_o$ , and other prescribed values, the thermal resistances and overall coefficient can be evaluated and are tabulated below.

$R_{\text{cv},i}$	$R_{f,i}$	$R_w$	$R_{f,o}$	$R_{\text{cv},o}$	$U_o$	$R_{\text{tot}}$
(K/W)	(K/W)	(K/W)	(K/W)	(K/W)	(W/m <sup>2</sup> ·K)	(K/W)
0.00436	0.00578	0.00216	0.00236	0.1134	92.1	0.128

The major thermal resistance is due to outside (air) convection, accounting for 89% of the total resistance. The other thermal resistances are of similar magnitude, nearly 50 times smaller than  $R_{\text{cv},o}$ .

(b) For the water-water condition, the method of analysis follows that of part (a). For the internal flow, the estimated convection coefficient is the same as part (a). For an assumed outer film coefficient,  $\bar{T}_{f,o} = 292 \text{ K}$ , the convection correlation for the outer water flow condition  $V_o = 1 \text{ m/s}$  and  $T_o = 15^\circ\text{C}$ ,

Continued...

### PROBLEM 11.2 (Cont.)

find

$$Re_{D,o} = 26,260 \quad Nu_{D,o} = 220.6 \quad \bar{h}_o = 4914 \text{ W/m}^2 \cdot \text{K}$$

The thermal resistances and overall coefficient are tabulated below.

$R_{cv,i}$	$R_{f,i}$	$R_w$	$R_{f,o}$	$R_{cv,o}$	$R_{tot}$	$U_o$
(K/W)	(K/W)	(K/W)	(K/W)	(K/W)	(K/W)	(W/m <sup>2</sup> ·K)
0.00436	0.00579	0.00216	0.00236	0.00240	0.0171	691

Note that the thermal resistances are of similar magnitude. In contrast with the results for the water-air condition of part (a), the thermal resistance of the outside convection process,  $R_{cv,o}$ , is nearly 50 times smaller. The overall coefficient for the water-water condition is 7.5 times greater than that for the water-air condition.

(c) For the water-air condition, using the IHT workspace with the analysis of part (a),  $U_o$  was calculated as a function of the air cross-flow velocity for selected mean water velocities.

The effect of increasing the cross-flow air velocity is to increase  $U_o$  since the  $R_{cv,o}$  is the dominant thermal resistance for the system. While increasing the water mean velocity will increase  $\bar{h}_i$ , because  $R_{cv,i} \ll R_{cv,o}$ , this increase has only a small effect on  $U_o$ .

(d) For the water-water condition, using the IHT workplace with the analysis of part (b),  $U_o$  was calculated as a function of the mean water velocity for selected air cross-flow velocities.

Because the thermal resistances for the convection processes,  $R_{cv,i}$  and  $R_{cv,o}$ , are of similar magnitude according to the results of part (b), we expect to see  $U_o$  significantly increase with increasing water mean velocity and air cross-flow velocity.

### PROBLEM 11.3

**KNOWN:** Inner and outer diameters of tubes in shell-and-tube heat exchanger. Inner and outer heat transfer coefficients. Properties of plastic and metal candidate wall materials.

**FIND:** (a) Ratio of surface areas for the two materials for the same heat transfer rate, (b) Ratio of masses for the two materials, (c) Which tube material would be lower cost.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Negligible fouling.

**ANALYSIS:** (a) From Eq. 11.14, the heat transfer rates will be the same for the two wall materials when  $UA$  is the same for both. From Eq. 11.1, with no fouling or fins, and with the wall resistance given by Eq. 3.33,

$$\frac{1}{UA} = \left( \frac{1}{h_i \pi D_i} + \frac{\ln(D_o/D_i)}{2\pi k_w} + \frac{1}{h_o \pi D_o} \right) \frac{1}{L} = (R'_{\text{conv},i} + R'_w + R'_{\text{conv},o}) \frac{1}{L} \quad (1)$$

where

$$R'_{\text{conv},i} = \frac{1}{h_i \pi D_i} = \frac{1}{1500 \text{ W/m}^2 \cdot \text{K} \times \pi \times 0.01 \text{ m}} = 0.0212 \text{ m} \cdot \text{K/W}$$

$$R'_{\text{conv},o} = \frac{1}{h_o \pi D_o} = \frac{1}{200 \text{ W/m}^2 \cdot \text{K} \times \pi \times 0.011 \text{ m}} = 0.1447 \text{ m} \cdot \text{K/W}$$

and

$$R'_w = \frac{\ln(D_o/D_i)}{2\pi k_w} = \begin{cases} \frac{\ln(11/10)}{2\pi \times 8 \text{ W/m} \cdot \text{K}} = 0.0019 \text{ W/m} \cdot \text{K} & \text{metal alloy} \\ \frac{\ln(11/10)}{2\pi \times 0.17 \text{ W/m} \cdot \text{K}} = 0.0892 \text{ W/m} \cdot \text{K} & \text{plastic} \end{cases}$$

Thus, from Eq. (1),  $(UA)_m = (UA)_p$  implies the following ratio of areas,

Continued...

### PROBLEM 11.3 (Cont.)

$$\frac{A_p}{A_m} = \frac{L_p}{L_m} = \frac{R_{\text{conv},i} + R_{w,p} + R_{\text{conv},o}}{R_{\text{conv},i} + R_{w,m} + R_{\text{conv},o}}$$
$$= \frac{0.0212 \text{ m} \cdot \text{K/W} + 0.0892 \text{ m} \cdot \text{K/W} + 0.1447 \text{ m} \cdot \text{K/W}}{0.0212 \text{ m} \cdot \text{K/W} + 0.0019 \text{ m} \cdot \text{K/W} + 0.1447 \text{ m} \cdot \text{K/W}}$$

$$\frac{A_p}{A_m} = 1.52 \quad <$$

(b) The mass ratio is found as follows,

$$\frac{m_p}{m_m} = \frac{\rho_p A_p}{\rho_m A_m} = \frac{1780 \text{ kg/m}^3}{8900 \text{ kg/m}^3} 1.52 = 0.304 \quad <$$

(c) The cost ratio is

$$\frac{C_p}{C_m} = \frac{m_p}{3m_m} = \frac{1}{3} 0.304 = 0.10$$

The plastic should be specified on the basis of cost. <

**COMMENTS:** (1) Because of its lower thermal conductivity, the plastic heat exchanger wall requires 50% more surface area than the metal wall. Nonetheless, it is 70% lighter and 90% less expensive. (2) Plastic heat exchanger components must operate at temperatures below their glass transition point, which for PVDF is approximately 160°C. If the plastic heat exchanger is operated above the glass transition temperature, it will soften and lose all structural rigidity. (3) The cost-based selection of the material will change depending on the values of the inside and outside heat transfer coefficients. For example, as the inside and outside heat transfer coefficients approach infinity, the metal core should be selected on the basis of cost. For applications involving condensation or boiling, the heat transfer coefficients will depend strongly on the tube material, as discussed in Chapter 10.

## PROBLEM 11.4

**KNOWN:** Dimensions of heat exchanger tube with or without fins. Cold and hot side convection coefficients.

**FIND:** Cold side overall heat transfer coefficient without and with fins.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible fouling, (2) Negligible contact resistance between fins and tube wall, (3)  $h_h$  is not affected by fins, (4) One-dimensional conduction in fins, (5) Adiabatic fin tip.

**ANALYSIS:** From Eq. 11.1,

$$\frac{1}{U_c} = \frac{1}{(\eta_o h)_c} + \frac{D_i \ln(D_o/D_i)}{2k} + \frac{A_c}{(\eta_o h A)_h}$$

Without fins:  $\eta_{o,c} = \eta_{o,h} = 1$

$$\frac{1}{U_c} = \frac{1}{8000 \text{ W/m}^2 \cdot \text{K}} + \frac{(0.02 \text{ m}) \ln(26/20)}{100 \text{ W/m} \cdot \text{K}} + \frac{1}{200 \text{ W/m}^2 \cdot \text{K}} \frac{20}{26}$$

$$1/U_c = (1.25 \times 10^{-4} + 5.25 \times 10^{-5} + 3.85 \times 10^{-3}) \text{ m}^2 \cdot \text{K/W} = 4.02 \times 10^{-3} \text{ m}^2 \cdot \text{K/W}$$

$$U_c = 249 \text{ W/m}^2 \cdot \text{K}. \quad <$$

With fins:  $\eta_{o,c} = 1$ ,  $\eta_{o,h} = 1 - (A_f/A)(1 - \eta_f)$  Per unit length along the tube axis,

$$A_f = N(2L_f + t) = 16(30 + 2) \text{ mm} = 512 \text{ mm}$$

$$A_h = A_f + (\pi D_o - 16t) = (512 + 81.7 - 32) \text{ mm} = 561.7 \text{ mm}$$

$$\text{With } m = (2h/kt)^{1/2} = (400 \text{ W/m}^2 \cdot \text{K} / 50 \text{ W/m} \cdot \text{K} \times 0.002 \text{ m})^{1/2} = 63.3 \text{ m}^{-1}$$

$$mL_f = (63.3 \text{ m}^{-1})(0.015 \text{ m}) = 0.95$$

and Eq. 11.4 yields

$$\eta_f = \tanh(mL_f) / mL_f = 0.739 / 0.95 = 0.778.$$

The overall surface efficiency is then

$$\eta_o = 1 - (A_f/A_h)(1 - \eta_f) = 1 - (512/561.7)(1 - 0.778) = 0.798.$$

$$\text{Hence } \frac{1}{U_c} = \left( 1.25 \times 10^{-4} + 5.25 \times 10^{-5} + \frac{\pi(20)}{0.798(200)561.7} \right) \text{ m}^2 \cdot \text{K/W} = 8.78 \times 10^{-4} \text{ m}^2 \cdot \text{K/W}$$

$$U_c = 1138 \text{ W/m}^2 \cdot \text{K}. \quad <$$

## PROBLEM 11.5

**KNOWN:** Geometry of finned, annular heat exchanger. Gas-side temperature and convection coefficient. Water-side flowrate and temperature.

**FIND:** Heat rate per unit length.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Constant properties, (3) One-dimensional conduction in strut, (4) Adiabatic outer surface conditions, (5) Negligible gas-side radiation, (6) Fully-developed internal flow, (7) Negligible fouling.

**PROPERTIES:** Table A-6, Water (300 K):  $k = 0.613 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 5.83$ ,  $\mu = 855 \times 10^{-6} \text{ N}\cdot\text{s/m}^2$ .

**ANALYSIS:** The heat rate is

$$q = (UA)_c (T_{m,h} - T_{m,c})$$

where

$$1/(UA)_c = 1/(hA)_c + R_w + 1/(\eta_o hA)_h$$

$$R_w = \frac{\ln(D_{i,2}/D_{i,1})}{2\pi kL} = \frac{\ln(30/24)}{2\pi(50 \text{ W/m}\cdot\text{K})\text{lm}} = 7.10 \times 10^{-4} \text{ K/W}.$$

With

$$\text{Re}_D = \frac{4\dot{m}}{\pi D_{i,1}\mu} = \frac{4 \times 0.161 \text{ kg/s}}{\pi(0.024\text{m})855 \times 10^{-6} \text{ N}\cdot\text{s/m}^2} = 9990$$

internal flow is turbulent and the Dittus-Boelter correlation gives

$$h_c = (k/D_{i,1})0.023 \text{Re}_D^{4/5} \text{Pr}^{0.4} = \left(\frac{0.613 \text{ W/m}\cdot\text{K}}{0.024\text{m}}\right)0.023(9990)^{4/5} (5.83)^{0.4} = 1883 \text{ W/m}^2 \cdot \text{K}$$

$$(hA)_c^{-1} = (1883 \text{ W/m}^2 \cdot \text{K} \times \pi \times 0.024\text{m})^{-1} = 7.043 \times 10^{-3} \text{ K/W}.$$

Find the fin efficiency as

$$\eta_o = 1 - (A_f/A)(1 - \eta_f)$$

$$A_f = 8 \times 2(L \cdot w) = 8 \times 2(0.015\text{m} \times 1\text{m}) = 0.24\text{m}^2$$

$$A = A_f + (\pi D_{i,2} - 8t)w = 0.24\text{m}^2 + (\pi \times 0.03\text{m} - 8 \times 0.003\text{m}) = 0.31\text{m}^2.$$

Continued...

### PROBLEM 11.5 (Cont.)

From Eq. 11.4,

$$\eta_f = \frac{\tanh(mL)}{mL}$$

where

$$m = [2h/kt]^{1/2} = [2 \times 100 \text{ W/m}^2 \cdot \text{K} / 50 \text{ W/m} \cdot \text{K} (0.003\text{m})]^{1/2} = 36.5 \text{ m}^{-1}$$

$$mL = (2h/kt)^{1/2} L = 36.5 \text{ m}^{-1} \times 0.015\text{m} = 0.55$$

$$\tanh\left[(2h/kt)^{1/2} L\right] = 0.499.$$

Hence

$$\eta_f = 0.499 / 0.55 = 0.911$$

$$\eta_o = 1 - (A_f / A)(1 - \eta_f) = 1 - (0.24 / 0.31)(1 - 0.911) = 0.931$$

$$(\eta_o h A)_h^{-1} = (0.931 \times 100 \text{ W/m}^2 \cdot \text{K} \times 0.31\text{m}^2)^{-1} = 0.0347 \text{ K/W}.$$

Hence

$$(UA)_c^{-1} = (7.043 \times 10^{-3} + 7.1 \times 10^{-4} + 0.0347) \text{ K/W}$$

$$(UA)_c = 23.6 \text{ W/K}$$

and

$$q = 23.6 \text{ W/K} (800 - 300) \text{ K} = 11,800 \text{ W} \quad <$$

for a 1m long section.

**COMMENTS:** (1) The gas-side resistance is substantially decreased by using the fins ( $A_f \gg \pi D_{i,2}$ ) and  $q$  is increased.

(2) Heat transfer enhancement by the fins could be increased further by using a material of larger  $k$ , but material selection would be limited by the large  $T_{m,h}$ .

## PROBLEM 11.6

**KNOWN:** Condenser arrangement of tube with six longitudinal fins ( $k = 200 \text{ W/m}\cdot\text{K}$ ). Condensing refrigerant at temperature  $45^\circ\text{C}$  flows axially through inner tube while water flows at  $0.012 \text{ kg/s}$  and  $15^\circ\text{C}$  through the six channels formed by the splines.

**FIND:** Heat removal rate per unit length of the exchanger.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) No heat loss/gain to the surroundings, (2) Water is incompressible liquid with negligible viscous dissipation, (3) Negligible thermal resistance on condensing refrigerant side,  $h_i \rightarrow \infty$ , (4) Water flow is fully developed, (5) Negligible thermal contact between splines and inner tube, (6) Heat transfer from outer tube negligible.

**PROPERTIES:** Table A-6, Water ( $\bar{T}_c = 15^\circ\text{C} = 288 \text{ K}$ ):  $\rho = 1000 \text{ kg/m}^3$ ,  $k = 0.595 \text{ W/m}\cdot\text{K}$ ,  $\nu = \mu/\rho = 1138 \times 10^{-6} \text{ N}\cdot\text{s/m}^2/1000 \text{ kg/m}^3 = 1.138 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\text{Pr} = 8.06$ ; Tube fins (given):  $k = 200 \text{ W/m}\cdot\text{K}$ .

**ANALYSIS:** Following the discussion of Section 11.2,

$$q' = UA'(T_h - T_c)$$

$$\frac{1}{UA'} = R'_h + R'_w + R'_c = R'_w + \frac{1}{(\eta_o h A')_c}$$

where  $R'_h = 0$ , due to the negligible thermal resistance on the refrigerant side ( $h$ ), and

$$R'_w = \frac{\ln(D_2/D_1)}{2\pi k} = \frac{\ln(14/10)}{2\pi(200 \text{ W/m}\cdot\text{K})} = 2.678 \times 10^{-4} \text{ m}\cdot\text{K/W}$$

To estimate the thermal resistance on the water side ( $c$ ), first evaluate the convection coefficient. The hydraulic diameter for a passage, where  $A_c$  is the cross-sectional area of the passage is

$$D_{h,c} = \frac{4A_c}{P} = \frac{4 \left[ \pi(D_3^2 - D_2^2)/4 - 6(D_3 - D_2)t/2 \right] / 6}{(\pi D_2 - 6t)/6 + (\pi D_3 - 6t)/6 + 2(D_3 - D_2)/2}$$

$$D_{h,c} = \frac{4 \left[ \pi(50^2 - 14^2)/4 - 6(50 - 14) \right] \times 10^{-6} \text{ m}^2 / 6}{\left[ (14\pi - 6 \times 2)/6 + (50\pi - 6 \times 2)/6 + (50 - 14) \right] \times 10^{-3} \text{ m}}$$

$$D_{h,c} = \frac{4 \times 2.656 \times 10^{-4} \text{ m}^2}{6.551 \times 10^{-2} \text{ m}} = 0.01622 \text{ m}$$

Hence the Reynolds number is

Continued ...

**PROBLEM 11.6 (Cont.)**

$$\text{Re}_{D,c} = \frac{\left[ (0.012 \text{ kg/s} / 6) / \left( 1000 \text{ kg/m}^3 \times 2.656 \times 10^{-4} \text{ m}^2 \right) \right] \times 0.01622 \text{ m}}{1.138 \times 10^{-6} \text{ m}^2/\text{s}} = 107$$

and assuming the flow is fully developed,

$$\text{Nu}_{D,c} = \frac{h_c D_{h,c}}{k} = 3.66$$

$$h_c = 3.66 \times 0.595 \text{ W/m} \cdot \text{K} / 0.01622 = 134 \text{ W/m}^2 \cdot \text{K}.$$

The temperature effectiveness of the splines (fins) on the cold side is

$$\eta_o = 1 - \frac{A_{f,c}}{A_c} (1 - \eta_f)$$

where  $A_{f,c}$  and  $A_c$  are, respectively, the finned and total (fin plus prime) surface areas, while

$$\eta_f = \frac{\tanh(mL)}{mL}$$

$$m = (2h_c / kt)^{1/2} = \left[ (2 \times 134 \text{ W/m}^2 \cdot \text{K}) / (200 \text{ W/m} \cdot \text{K} \times 0.002 \text{ m}) \right]^{1/2} = 25.88 \text{ m}^{-1}$$

$$\eta_f = \frac{\tanh(25.88 \text{ m}^{-1} \times 0.018 \text{ m})}{25.88 \text{ m}^{-1} \times 0.018 \text{ m}} = \frac{0.4348}{0.4658} = 0.934.$$

Hence

$$\eta_o = 1 - \frac{6(D_3 - D_2)}{6(D_3 - D_2) + (\pi D_2 - 6t)} [1 - \eta_f]$$

$$\eta_o = 1 - \frac{6(50 - 14)}{6(50 - 14) + (14\pi - 6 \times 2)} (1 - 0.934) = 0.943$$

$$\frac{1}{\eta_o h A'_c} = \frac{1}{0.943 \times 134 \text{ W/m}^2 \cdot \text{K} [6(50 - 14) + (14\pi - 6 \times 2)] \times 10^{-3} \text{ m}} = 3.22 \times 10^{-2} \text{ m} \cdot \text{K} / \text{W}$$

and the heat rate is

$$q' = \frac{T_h - T_c}{R'_w + 1/(\eta_o h A'_c)}$$

$$q' = \frac{(45 - 15) \text{ K}}{2.678 \times 10^{-4} \text{ m} \cdot \text{K} / \text{W} + 3.22 \times 10^{-2} \text{ m} \cdot \text{K} / \text{W}} = 924 \text{ W/m.} \quad <$$

**COMMENTS:** (1) The effective length of the fin representing the splines was conservatively estimated. The heat transfer by conduction through the splines to the outer tube and then by convection to the water was ignored.

(2) Without the splines, find  $D_h = (D_3 - D_2) = 36 \text{ mm}$  so that  $h_c = 60.5 \text{ W/m}^2 \cdot \text{K}$ . The heat rate with  $A'_c = \pi D_2$  is

$$q' = (h A'_c)(T_h - T_c) = 60.5 \text{ W/m}^2 \cdot \text{K} (0.014\pi \text{ m}) (45 - 15) \text{ K} = 79 \text{ W/m.}$$

The splines enhance the heat transfer rate by a factor of  $924/79 = 11.7$ .

## PROBLEM 11.7

**KNOWN:** Number, inner and outer diameters, and thermal conductivity of condenser tubes. Convection coefficient at outer surface. Overall flow rate, inlet temperature and properties of water flow through the tubes. Flow rate and pressure of condensing steam. Fouling factor for inner surface.

**FIND:** (a) Overall coefficient based on outer surface area,  $U_o$ , without fouling, (b) Overall coefficient with fouling, (c) Temperature of water leaving the condenser.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Water is incompressible with negligible viscous dissipation, (2) Fully-developed flow in tubes, (3) Negligible effect of fouling on  $D_i$ .

**PROPERTIES:** Water (Given):  $c_p = 4180 \text{ J/kg}\cdot\text{K}$ ,  $\mu = 9.6 \times 10^{-4} \text{ N}\cdot\text{s/m}^2$ ,  $k = 0.60 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 6.6$ .  
Table A-6, Water, saturated vapor ( $p = 0.0622 \text{ bars}$ ):  $T_{\text{sat}} = 310 \text{ K}$ ,  $h_{\text{fg}} = 2.414 \times 10^6 \text{ J/kg}$ .

**ANALYSIS:** (a) Without fouling, Eq. 11.5 yields

$$\frac{1}{U_o} = \frac{1}{h_i} \left( \frac{D_o}{D_i} \right) + \frac{D_o \ln(D_o/D_i)}{2k_t} + \frac{1}{h_o}$$

With  $\text{Re}_{D_i} = 4 \dot{m}_1 / \pi D_i \mu = 1.60 \text{ kg/s} / (\pi \times 0.025 \text{ m} \times 9.6 \times 10^{-4} \text{ N}\cdot\text{s/m}^2) = 21,220$ , flow in the tubes is turbulent, and from Eq. 8.60

$$h_i = \left( \frac{k}{D_i} \right) 0.023 \text{Re}_{D_i}^{4/5} \text{Pr}^{0.4} = \left( \frac{0.60 \text{ W/m}\cdot\text{K}}{0.025 \text{ m}} \right) 0.023 (21,200)^{4/5} (6.6)^{0.4} = 3400 \text{ W/m}^2\cdot\text{K}$$

$$U_o = \left[ \frac{1}{3400} \left( \frac{28}{25} \right) + \frac{0.028 \ln(28/25)}{2 \times 110} + \frac{1}{10,000} \right]^{-1} \text{ W/m}^2\cdot\text{K} =$$

$$\left( 3.29 \times 10^{-4} + 1.44 \times 10^{-5} + 10^{-4} \right)^{-1} \text{ W/m}^2\cdot\text{K} = 2255 \text{ W/m}^2\cdot\text{K} \quad <$$

(b) With fouling, Eq. 11.5 yields

$$U_o = \left[ 4.43 \times 10^{-4} + (D_o/D_i) R_{f,i}'' \right]^{-1} = \left( 5.55 \times 10^{-4} \right)^{-1} = 1800 \text{ W/m}^2\cdot\text{K} \quad <$$

(c) The rate at which energy is extracted from the steam equals the rate of heat transfer to the water,  $\dot{m}_h h_{\text{fg}} = \dot{m}_c c_p (T_{m,o} - T_{m,i})$ , in which case

$$T_{m,o} = T_{m,i} + \frac{\dot{m}_h h_{\text{fg}}}{\dot{m}_c c_p} = 15^\circ\text{C} + \frac{10 \text{ kg/s} \times 2.414 \times 10^6 \text{ J/kg}}{400 \text{ kg/s} \times 4180 \text{ J/kg}\cdot\text{K}} = 29.4^\circ\text{C} \quad <$$

**COMMENTS:** (1) The largest contribution to the thermal resistance is due to convection at the interior of the tube. To increase  $U_o$ ,  $h_i$  could be increased by increasing  $\dot{m}_1$ , either by increasing  $\dot{m}_c$  or decreasing  $N$ . (2) Note that  $T_{m,o} = 302.4 \text{ K} < T_{\text{sat}} = 310 \text{ K}$ , as must be the case.

## PROBLEM 11.8

**KNOWN:** Diameter and inner and outer convection coefficients of a condenser tube. Thickness, outer diameter, and pitch of aluminum fins.

**FIND:** (a) Overall heat transfer coefficient without fins, (b) Effect of fin thickness and pitch on overall heat transfer coefficient with fins.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible tube wall conduction resistance, (2) Negligible fouling and fin contact resistance, (3) One-dimensional conduction in fin.

**PROPERTIES:** Table A.1, Aluminum ( $T = 300$  K):  $k = 237$  W/m·K.

**ANALYSIS:** (a) With no fins, Eq. 11.1 yields

$$U = \left( h_i^{-1} + h_o^{-1} \right)^{-1} = \left( 2 \times 10^{-4} + 0.01 \right)^{-1} \text{ W/m}^2 \cdot \text{K} = 98.0 \text{ W/m}^2 \cdot \text{K} \quad <$$

(b) With fins and a unit tube length, Eqs. 11.1 and 11.3 yield

$$\frac{1}{U_i \pi D_i} = \frac{1}{h_i \pi D_i} + \frac{1}{\eta_o h_o A'_o}$$

and  $\eta_o = 1 - (A'_f/A'_o)(1 - \eta_f)$ . The total fin surface area per unit length is  $A'_f = N' 2\pi (r_{oc}^2 - r_i^2)$ , where the number of fins per unit length is  $N' = 1m/S(m)$ . The total outside surface area per unit length is  $A'_o = A'_f + (1 - N't)\pi D_i$ , and the fin efficiency is given by Eq. 3.96 or Fig. 3.20.

For  $t = 0.0015$  m and  $S = 0.0035$  m,  $r_{oc} = (D_o/2) + (t/2) = 0.01075$  m,  $N' \approx 286$ ,  $A'_f = 0.163$  m<sup>2</sup>/m, and  $A'_o = (0.163 + 0.018)$  m<sup>2</sup>/m = 0.181 m<sup>2</sup>/m. With  $r_{oc}/r_i = 2.15$ ,  $L_c = 0.00575$  m,  $A_p = 8.625 \times 10^{-6}$  m<sup>2</sup>, and  $L_c^{3/2} (h_o/kA_p)^{1/2} = 0.0964$ , Fig. 3.20 yields  $\eta_f \approx 0.99$ . Hence,  $\eta_o \approx 1 - (0.163/0.181)(0.01) = 0.99$  and

$$U_i = \left[ (1/h_i) + (\pi D_i / \eta_o h_o A'_o) \right]^{-1}$$

$$U_i = \left[ 2 \times 10^{-4} \text{ m}^2 \cdot \text{K/W} + \pi \times 0.01 \text{ m} / 0.99 \times 100 \text{ W/m}^2 \cdot \text{K} \times 0.181 \text{ m}^2/\text{m} \right]^{-1} = 512 \text{ W/m}^2 \cdot \text{K} <$$

We may use the IHT *Extended Surface Model (Performance Calculations for a Circular Rectangular Fin Array)* to consider the effect of varying  $t$  and  $S$ . To maximize  $N'$ , the minimum allowable value of

Continued...

### PROBLEM 11.8 (Cont.)

$S - t = 1.5$  mm should be selected. It is then a matter of choosing between a large number of thin fins or a smaller number of thicker fins. Calculations were performed for the following options.

$t$ (mm)	$S$ (mm)	$N'$	$U_i$ (W/m <sup>2</sup> ·K)
1	2.5	400	640
2	3.5	286	512
3	4.5	222	460
4	5.5	182	420

Since heat transfer increases with  $U_i$ , the best configuration corresponds to  $t = 1$  mm and  $S = 2.5$  mm, which provides the largest airside surface area.

**COMMENTS:** The best performance is always associated with a large number of closely spaced fins, so long as the flow between adjoining fins is sufficient to maintain the convection coefficient.

## PROBLEM 11.9

**KNOWN:** Operating conditions and surface area of a finned-tube, cross-flow exchanger.

**FIND:** Overall heat transfer coefficient.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat loss to surroundings, (2) Constant properties, (3) Exhaust gas properties are those of air.

**PROPERTIES:** Table A-6, Water ( $\bar{T}_m = 87^\circ\text{C}$ ):  $\bar{c}_p = 4203 \text{ J/kg}\cdot\text{K}$ ; Table A-4, Air ( $T_m \approx 275^\circ\text{C}$ ):  $\bar{c}_p = 1040 \text{ J/kg}\cdot\text{K}$ .

**ANALYSIS:** Since this is a cross-flow heat exchanger, we will use the  $\epsilon - \text{NTU}$  method, for which

$$C_c = \dot{m}_c c_{p,c} = 0.5 \text{ kg/s} \times 4203 \text{ J/kg}\cdot\text{K} = 2102 \text{ W/K}$$

$$C_h = \dot{m}_h c_{p,h} = 2 \text{ kg/s} \times 1040 \text{ J/kg}\cdot\text{K} = 2080 \text{ W/K}$$

$$C_r = C_{\min} / C_{\max} = 0.990$$

$$q_{\max} = C_{\min} (T_{h,i} - T_{c,i}) = 2080 \text{ W/K} (325 - 25)^\circ\text{C} = 6.24 \times 10^5 \text{ W}$$

$$q = C_c (T_{c,o} - T_{c,i}) = 2102 \text{ W/K} (150 - 25)^\circ\text{C} = 2.63 \times 10^5 \text{ W}$$

Thus

$$\epsilon = q/q_{\max} = 0.421$$

and from Figure 11.14 or solving Eq. 11.32 iteratively for NTU,

$$\text{NTU} = 0.81$$

and

$$U = C_{\min} \text{NTU} / A = 2080 \text{ W/K} \times 0.81 / 10 \text{ m}^2 = 168 \text{ W/m}^2\cdot\text{K}$$

<

**COMMENTS:** The hot outlet temperature is found from  $q = C_h (T_{h,i} - T_{h,o})$  to be  $199^\circ\text{C}$ , thus properties of the hot fluid should be evaluated at around  $262^\circ\text{C}$ . This will have little effect since  $c_p$  is not a strong function of temperature for water.

### PROBLEM 11.10

**KNOWN:** Heat exchanger with two shell passes and eight tube passes having an area  $925\text{m}^2$ ;  $45,500\text{ kg/h}$  water is heated from  $80^\circ\text{C}$  to  $150^\circ\text{C}$ ; hot exhaust gases enter at  $350^\circ\text{C}$  and exit at  $175^\circ\text{C}$ .

**FIND:** Overall heat transfer coefficient.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible losses to surroundings, (2) Constant properties, (3) Exhaust gas properties are approximated as those of atmospheric air.

**PROPERTIES:** Table A-6, Water ( $\bar{T}_c = (80 + 150)^\circ\text{C} / 2 = 388\text{K}$ ):  $c_c = c_{p,f} = 4236\text{ J/kg}\cdot\text{K}$ .

**ANALYSIS:** Since this is a shell-and-tube heat exchanger, we will use the  $\epsilon$  - NTU method, for which

$$C_c = \dot{m}_c c_c = \frac{45,500\text{ kg/h}}{3600\text{ s/h}} \times 4236\text{ J/kg}\cdot\text{K} = 5.35 \times 10^4\text{ W/K}$$

$$q = C_c(T_{c,o} - T_{c,i}) = 5.35 \times 10^4\text{ W/K} (150 - 80)^\circ\text{C} = 3.75 \times 10^6\text{ W}$$

Then we can find  $C_h$  from an energy balance on the hot stream,

$$C_h = q / (T_{h,i} - T_{h,o}) = 3.75 \times 10^6\text{ W} / (350 - 175)^\circ\text{C} = 2.14 \times 10^4\text{ W/K}$$

Thus

$$C_r = C_{\min} / C_{\max} = 0.40$$

$$\epsilon = q / C_{\min} (T_{h,i} - T_{c,i}) = 3.75 \times 10^6\text{ W} / 2.14 \times 10^4\text{ W/K} (350 - 80)^\circ\text{C} = 0.648$$

From Eqs. 11.31b and c, with  $n = 2$ ,

$$F = \left( \frac{\epsilon C_r - 1}{\epsilon - 1} \right)^{1/n} = 1.45, \quad \epsilon_1 = \frac{F - 1}{F - C_r} = 0.429$$

From Eqs. 11.30c and 11.30b,

$$E = \frac{2/\epsilon_1 - (1 + C_r)}{(1 + C_r^2)^{1/2}} = 3.0$$

$$(\text{NTU})_1 = -(1 + C_r^2)^{-1/2} \ln \left[ \frac{E - 1}{E + 1} \right] = 0.637$$

and from Eq. 11.31d,

$$\text{NTU} = n(\text{NTU})_1 = 1.27$$

Therefore,

$$U = \text{NTU} \times C_{\min} / A = 1.27 \times 2.14 \times 10^4\text{ W/K} / (925\text{ m}^2) = 29.5\text{ W/m}^2\cdot\text{K}$$

<

**COMMENTS:** Compare the above result with representative values for air-water exchangers, as given in Table 11.2.

## PROBLEM 11.11

**KNOWN:** Geometry of heat exchanger made from extruded polypropylene sheets. Thermal conductivity of polypropylene. Temperature, pressure, and velocity, of air and carbon dioxide flowing in channels.

**FIND:** Product of overall heat transfer coefficient and surface area,  $UA$ , for 200 cool and 200 warm channels.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Constant properties and steady-state conditions, (2) Density of air and  $\text{CO}_2$  is proportional to pressure, (3) Wall temperature is approximately uniform along channels, (4) Thermal resistance at welded interface is negligible, (5) Channel walls can be treated as fins.

**PROPERTIES:** Table A.5, Air: ( $T_{m,h} = 303 \text{ K}$ ,  $p = 2 \text{ atm}$ ):  $k_h = 0.0265 \text{ W/m}\cdot\text{K}$ ,  $c_{p,h} = 1007 \text{ J/kg}\cdot\text{K}$ ,  $\mu_h = 186 \times 10^{-7} \text{ N}\cdot\text{s/m}^2$ ,  $\text{Pr}_h = 0.707$ ,  $\rho_h = 2.303 \text{ kg/m}^3$ ;  $\text{CO}_2$  ( $T_{m,c} = 283 \text{ K}$ ):  $k_c = 0.0154 \text{ W/m}\cdot\text{K}$ ,  $c_{p,c} = 833 \text{ J/kg}\cdot\text{K}$ ,  $\mu_c = 141 \times 10^{-7} \text{ N}\cdot\text{s/m}^2$ ,  $\text{Pr}_c = 0.765$ ,  $\rho_c = 3.76 \text{ kg/m}^3$ . Polypropylene (given):  $k_p = 0.17 \text{ W/m}\cdot\text{K}$ .

**ANALYSIS:** We begin by finding the heat transfer coefficients for air and  $\text{CO}_2$ . In both cases, the hydraulic diameter is  $D_h = 4A_c/P = 4 \times 11 \times 4 / (2(11+4)) \text{ mm} = 5.87 \text{ mm}$ . The Reynolds number for air is

$$\text{Re}_{D,h} = \frac{\rho_h u_{m,h} D_h}{\mu_h} = \frac{2.303 \text{ kg/m}^3 \times 0.2 \text{ m/s} \times 0.00587 \text{ m}}{186 \times 10^{-7} \text{ N}\cdot\text{s/m}^2} = 145$$

A similar calculation for  $\text{CO}_2$  gives  $\text{Re}_{D,c} = 156$ , thus both flows are laminar. From Table 8.1, assuming uniform wall temperature and interpolating for an aspect ratio of  $(d-c)/a = 2.75$ , we find  $\text{Nu}_D = 3.82$ . Then for air,

Continued...

### PROBLEM 11.11 (Cont.)

$$h_h = \text{Nu}_{D,h} k_h / D_h = 3.82 \times 0.0265 \text{ W/m} \cdot \text{K} / 0.00587 \text{ m} = 17.2 \text{ W/m}^2 \cdot \text{K}$$

And a similar calculation for CO<sub>2</sub> yields  $h_c = 10.0 \text{ W/m}^2 \cdot \text{K}$ .

Focusing on one vertical wall of thickness  $c$  in the schematic above, we see that it has fins extending to the right and left into the two fluids. By symmetry, the midpoint of those fins is an adiabat, and we can treat the fins as having length  $L = (d-c)/2 = 5.5 \text{ mm}$ , with an insulated tip. We will use Eq. 11.1 for  $UA$ , with Eqs. 11.3 and 11.4 for the fin efficiency. Note that for channels of length  $w$ ,  $P/A_c = 2(w+b)/wb \approx 2/b$ . For air,

$$m_h = \sqrt{\frac{h_h P}{k_p A_c}} = \sqrt{\frac{2h_h}{k_p b}} = \sqrt{\frac{2 \times 17.2 \text{ W/m}^2 \cdot \text{K}}{0.17 \text{ W/m} \cdot \text{K} \times 0.004 \text{ m}}} = 225 \text{ m}^{-1}$$

$$m_h L = 225 \text{ m}^{-1} \times 0.0055 \text{ m} = 1.24$$

$$\eta_{f,h} = \tanh(m_h L) / m_h L = \tanh(1.24) / 1.24 = 0.682$$

Then  $A_f/A = 2L/(2L + a) = 0.733$  and

$$\eta_{o,h} = 1 - \frac{A_f}{A} (1 - \eta_{f,h}) = 1 - 0.733(1 - 0.682) = 0.767$$

A similar calculation for CO<sub>2</sub> yields  $\eta_{o,c} = 0.839$ . Finally, we use Eq. 11.1 to calculate  $UA$ .

Note that for  $N = 200$  channels (and  $N$  fins) of depth  $w$ ,  $A = 2LwN + awN = 3w \text{ m}^2$  and  $A_w = (a+b)wN = 1.6w \text{ m}^2$ . Thus, for a unit length of the heat exchanger ( $w = 1 \text{ m}$ ),

$$\begin{aligned} \frac{1}{UA} &= \frac{1}{(\eta_o h A)_c} + \frac{c}{k_p A_w} + \frac{1}{(\eta_o h A)_c} \\ &= \frac{1}{0.839 \times 10.0 \text{ W/m}^2 \cdot \text{K} \times 3 \text{ m}^2} + \frac{0.004 \text{ m}}{0.17 \text{ W/m} \cdot \text{K} \times 1.6 \text{ m}^2} + \frac{1}{0.767 \times 17.2 \text{ W/m}^2 \cdot \text{K} \times 3 \text{ m}^2} \end{aligned}$$

$$UA = 12.6 \text{ W/m}^2 \cdot \text{K}$$

<

**COMMENTS:** (1) The product of the overall heat transfer coefficient and the heat transfer area is not large, but the design enables production of a compact heat exchanger that is not prone to corrosion and can be constructed at low cost. (2) The low thermal conductivity of the “fins” may result in significant temperature variation across their thickness, rendering the assumption of one-dimensional heat transfer in these extended surfaces invalid. (3) The contact resistance at the welded interfaces may not be negligible. In this case the system is not symmetric about the channel centerlines. (4) A numerical solution could account for two-dimensional conduction and address the considerations of Comments 2 and 3. (5) The thermal boundary condition at the channel boundaries is neither constant temperature nor constant heat flux. (6) Polypropylene is a semitransparent material (see Chapter 12) and radiation transfer may occur between the two gases. Since the temperatures are relatively low and the convective heat transfer coefficient is relatively high, radiation heat transfer will not be significant.

### PROBLEM 11.12

**KNOWN:** Properties and flow rates for the hot and cold fluid of a heat exchanger.

**FIND:** Which fluid limits the heat transfer rate of the exchanger?

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Constant properties, and (3) Negligible losses to the surroundings.

**ANALYSIS:** The properties and flow rates for the hot and cold fluid of the heat exchanger are tabulated below.

	<i>Cold fluid</i>	<i>Hot fluid</i>
Density, kg/m <sup>3</sup>	997	1247
Specific heat, J/kg·K	4179	2564
Thermal conductivity, W/m·K	0.613	0.287
Viscosity, N·s/m <sup>2</sup>	$8.55 \times 10^{-4}$	$1.68 \times 10^{-4}$
Flow rate, m <sup>3</sup> /h	14	16

The fluid which limits the heat transfer rate of the exchanger is the minimum fluid,

$C_{\min} = (\dot{m} \cdot c)_{\min}$ . For the hot and cold fluids, find

$$C_h = \dot{m}_h c_h = 16 \text{ m}^3 / \text{h} \times 1247 \text{ kg} / \text{m}^3 \times 2564 \text{ J} / \text{kg} \cdot \text{K} \times (1\text{h} / 3600\text{s}) = 14.21 \text{ kW} / \text{K}$$

$$C_c = \dot{m}_c c_c = 14 \text{ m}^3 / \text{h} \times 997 \text{ kg} / \text{m}^3 \times 4179 \text{ J} / \text{kg} \cdot \text{K} \times (1\text{h} / 3600\text{s}) = 16.20 \text{ kW} / \text{K}$$

Hence, the hot fluid is the minimum fluid,

$$C_{\min} = C_h \quad <$$

For any exchanger, the heat rate is  $q = \varepsilon q_{\max}$ , where  $\varepsilon$  depends upon the exchanger type. The maximum heat rate is  $q_{\max} = C_{\min} (T_{h,i} - T_{c,i})$ . Hence, it is the conditions for the minimum fluid that limit the performance of the exchanger.

### PROBLEM 11.13

**KNOWN:** Process (hot) fluid having a specific heat of 3500 J/kg·K and flowing at 2 kg/s is to be cooled from 80°C to 50°C with chilled-water (cold fluid) supplied at 2.5 kg/s and 15°C assuming an overall heat transfer coefficient of 2000 W/m<sup>2</sup>·K.

**FIND:** The required heat transfer areas for the following heat exchanger configurations; (a) Concentric tube (CT) - parallel flow, (b) CT - counterflow, (c) Shell and tube, one-shell pass and 2 tube passes; (d) Cross flow, single pass, both fluids unmixed. Use the *IHT Tools | Heat Exchanger* models as your solution tool.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Negligible losses to the surroundings, (3) Overall heat transfer coefficient remains constant with different configurations, and (4) Constant properties.

**ANALYSIS:** The *IHT Tools | Heat Exchanger* models are based upon the effectiveness-NTU method and suited for design-type problems. The table below summarizes the results of our analysis using the IHT models including model equations, figures, and the required heat transfer area. The cold fluid outlet temperature for all configurations is  $T_{c,o} = 35.1^\circ\text{C}$ . The IHT code for the concentric tube, parallel flow heat exchanger is provided in the Comments.

Heat exchanger type	Eqs.	Figs	$A(\text{m}^2)$
(a) CT -Parallel flow	11.28b	11.10	3.09
(b) CT -Counterflow	11.29b	11.11	2.64
(c) Shell and tube (1 - sp, 2 - tp)	11.30b	11.12	2.83
(d) Crossflow (1 - p, unmixed)	11.32	11.14	2.84

**COMMENTS:** (1) Referring to the tabulated results, note that for the concentric tube exchangers, the area required for parallel flow is 17% larger than for counterflow. Under what circumstances would you choose to use the PF arrangement if the area has to be significantly larger?

(2) The shell-tube and crossflow exchangers require nearly the same heat transfer area. What are other factors that might influence your decision to select one type over the other for an application?

(3) Based upon area considerations only, the CF arrangement requires the smallest heat transfer area. What practical issues need to be considered in making a CF heat exchanger with a 2.6 m<sup>2</sup> area?

```

### PROBLEM 11.14

**KNOWN:** A shell and tube Hxer (two shells, four tube passes) heats 10,000 kg/h of pressurized water from 35°C to 120°C with 5,000 kg/h water entering at 300°C.

**FIND:** Required heat transfer area,  $A_s$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat loss to surroundings, (2) Constant properties.

**PROPERTIES:** Table A-6, Water ( $\bar{T}_c = 350$  K):  $c_p = 4195$  J/kg·K; Table A-6, Water (Assume  $T_{h,o} \approx 150^\circ\text{C}$ ,  $\bar{T}_h \approx 500$  K):  $c_p = 4660$  J/kg·K.

**ANALYSIS:** For a shell and tube heat exchanger, we use the  $\epsilon$  – NTU method. An energy balance on the cold fluid yields

$$q = \dot{m}_c c_{p,c} (T_{c,o} - T_{c,i}) = \frac{10,000 \text{ kg/h}}{3600 \text{ s/h}} \times 4195 \frac{\text{J}}{\text{kg} \cdot \text{K}} (120 - 35) \text{ K} = 9.905 \times 10^5 \text{ W}.$$

An energy balance on the hot fluid yields

$$T_{h,o} = T_{h,i} - q / \dot{m}_h c_{p,h} = 300^\circ\text{C} - 9.905 \times 10^5 \text{ W} / \frac{5000 \text{ kg}}{3600 \text{ s}} \times 4660 \frac{\text{J}}{\text{kg} \cdot \text{K}} = 147^\circ\text{C}.$$

Thus  $\bar{T}_h = (300 + 147)^\circ\text{C}/2 = 497$  K is the proper temperature for evaluating properties of the hot fluid. Then

$$C_c = \dot{m}_c c_{p,c} = \frac{10,000 \text{ kg/h}}{3,600 \text{ s/h}} \times 4195 \text{ J/kg} \cdot \text{K} = 11,650 \text{ W/K}$$

$$C_h = \dot{m}_h c_{p,h} = \frac{5,000 \text{ kg/h}}{3,600 \text{ s/h}} \times 4660 \text{ J/kg} \cdot \text{K} = 6470 \text{ W/K}$$

$$C_r = C_{\min} / C_{\max} = 6470 / 11,650 = 0.555$$

$$q_{\max} = C_{\min} (T_{h,i} - T_{c,i}) = 6470 \text{ W/K} (300 - 35)^\circ\text{C} = 1.75 \times 10^6 \text{ W}$$

$$\epsilon = q / q_{\max} = 9.905 \times 10^5 \text{ W} / 1.72 \times 10^6 \text{ W} = 0.577$$

From Eqs. 11.31c, 11.31b, and 11.30c, with  $n=2$ ,

$$F = \left( \frac{\epsilon C_r - 1}{\epsilon - 1} \right)^{1/n} = 1.27, \quad \epsilon_1 = \frac{F - 1}{F - C_r} = 0.376$$

$$E = \frac{2/\epsilon_1 - (1 + C_r)}{(1 + C_r^2)^{1/2}} = 3.29$$

then from Eqs. 11.30b and 11.31d,

$$\text{NTU} = n (\text{NTU})_1 = -n (1 + C_r^2)^{-1/2} \ln \left[ \frac{E - 1}{E + 1} \right] = 1.10$$

Finally,

$$A = \text{NTU} \times C_{\min} / U = (1.10 \times 6470 \text{ W/K}) / (1500 \text{ W/m}^2 \cdot \text{K}) = 4.75 \text{ m}^2$$

<

### PROBLEM 11.15

**KNOWN:** The shell and tube Hxer (two shells, four tube passes) of Problem 11.14, known to have an area  $4.75\text{m}^2$ , provides  $95^\circ\text{C}$  water at the cold outlet (rather than  $120^\circ\text{C}$ ) after several years of operation. Flow rates and inlet temperatures of the fluids remain the same.

**FIND:** The fouling factor,  $R_f$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat loss to surroundings, (2) Constant properties, (3) Thermal resistance for the clean condition is  $R_t'' = (1500 \text{ W/m}^2 \cdot \text{K})^{-1}$ .

**PROPERTIES:** Table A-6, Water ( $\bar{T}_c \approx 338 \text{ K}$ ):  $c_p = 4187 \text{ J/kg} \cdot \text{K}$ ; Table A-6, Water (Assume  $T_{h,o} \approx 190^\circ\text{C}$ ,  $\bar{T}_h \approx 520 \text{ K}$ ):  $c_p = 4840 \text{ J/kg} \cdot \text{K}$ .

**ANALYSIS:** The overall heat transfer coefficient can be expressed as

$$U = 1/(R_t'' + R_f'') \quad \text{or} \quad R_f'' = 1/U - R_t'' \quad (1)$$

where  $R_t''$  is the thermal resistance for the clean condition and  $R_f''$ , the fouling factor, represents the additional resistance due to fouling of the surface. We use the  $\epsilon - \text{NTU}$  method as follows,

$$C_c = \dot{m}_c c_{p,c} = \frac{10,000 \text{ kg/h}}{3,600 \text{ s/h}} \times 4187 \text{ J/kg} \cdot \text{K} = 1.16 \times 10^4 \text{ W/K}$$

$$C_h = \dot{m}_h c_{p,h} = \frac{5,000 \text{ kg/h}}{3,600 \text{ s/h}} \times 4840 \text{ J/kg} \cdot \text{K} = 6.72 \times 10^3 \text{ W/K}$$

$$C_r = C_{\min} / C_{\max} = 0.578$$

$$q_{\max} = C_{\min} (T_{h,i} - T_{c,i}) = 6.72 \times 10^3 \text{ W/K} (300 - 35)^\circ\text{C} = 1.78 \times 10^6 \text{ W}$$

$$q = C_c (T_{c,o} - T_{c,i}) = 1.16 \times 10^4 \text{ W/K} (95 - 35)^\circ\text{C} = 6.98 \times 10^5 \text{ W}$$

$$\epsilon = q/q_{\max} = 0.392$$

Note, that  $T_{h,o} = T_{h,i} - q/C_h = 196^\circ\text{C}$ , so properties should be evaluated at

$\bar{T}_h = (T_{h,i} + T_{h,o})/2 = 248^\circ\text{C} = 521 \text{ K}$ , very close to the assumed value. From Eqs. 11.31 and 11.30, with  $n = 2$ ,

$$F = \left( \frac{\epsilon C_r - 1}{\epsilon - 1} \right)^{1/n} = 1.13, \quad \epsilon_1 = \frac{F - 1}{F - C_r} = 0.232,$$

$$E = \frac{2/\epsilon_1 - (1 + C_r)}{(1 + C_r^2)^{1/2}} = 6.09$$

$$\text{NTU} = -n (1 + C_r^2)^{-1/2} \ln \left[ \frac{E - 1}{E + 1} \right] = 0.574$$

Continued...

### PROBLEM 11.15 (Cont.)

Thus,

$$U = NTU \times C_{\min}/A = (0.574 \times 6.72 \times 10^3 \text{ W/K})/(4.75 \text{ m}^2) = 813 \text{ W/m}^2 \cdot \text{K}$$

From Eq. (1), the fouling factor is

$$R_f'' = \frac{1}{813 \text{ W/m}^2 \cdot \text{K}} - \frac{1}{1500 \text{ W/m}^2 \cdot \text{K}} = 5.64 \times 10^{-4} \text{ m}^2 \cdot \text{K/W}. \quad <$$

**COMMENTS:** Note that the effect of fouling is to nearly double ( $U_{\text{clean}}/U_{\text{fouled}} = 1500/813 \approx 1.9$ ) the resistance to heat transfer. Note also the assumption for  $T_{h,o}$  used for property evaluation is satisfactory.

## PROBLEM 11.16

**KNOWN:** Inlet and outlet temperatures of hot and cold fluid streams in a concentric tube heat exchanger.

**FIND:** Whether the heat exchanger is operated in counter- or parallel flow, heat exchanger effectiveness, heat exchanger NTU.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat transfer between the heat exchanger and the surroundings, (2) Constant properties.

**ANALYSIS:** The heat exchanger must be operating in a counterflow configuration because  $T_{h,o} < T_{c,o}$ . <

From energy balances on each fluid,  $q = C_h(T_{h,i} - T_{h,o}) = C_c(T_{c,o} - T_{c,i})$ , from which

$$C_h/C_c = C_{\min}/C_{\max} = (T_{c,o} - T_{c,i})/(T_{h,i} - T_{h,o}) = 25/90 = 0.278 \text{ and } C_{\min} = C_h.$$

From the definition of the effectiveness,  $q = \varepsilon C_{\min}(T_{h,i} - T_{c,i}) = \varepsilon C_h(T_{h,i} - T_{c,i}) = C_h(T_{h,o} - T_{h,i})$  from which

$$\varepsilon = (T_{h,o} - T_{h,i})/(T_{h,i} - T_{c,i}) = 90/100 = 0.90 \quad <$$

From Fig. 11.11,  $NTU \approx 2.8$  <

**COMMENTS:** The NTU may also be found from Eq. 11.28b, yielding  $NTU = 2.79$ .

## PROBLEM 11.17

**KNOWN:** Inlet temperatures of pharmaceutical product and water in a concentric tube heat exchanger. Tube diameters and fluid velocities.

**FIND:** (a) Value of the overall heat transfer coefficient,  $U$ , (b) Mean outlet temperature of the pharmaceutical product for counterflow operation, (c) Mean outlet temperature of the pharmaceutical product for parallel-flow operation.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat transfer between the heat exchanger and the surroundings, (2) Constant properties, (3) Negligible conduction resistance posed by the thin-walled inner tube, (4) Smooth tube surfaces.

**PROPERTIES:** Pharmaceutical product (given):  $\nu = 10 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.25 \text{ W/m}\cdot\text{K}$ ,  $\rho = 1100 \text{ kg/m}^3$  and  $c_p = 2460 \text{ J/kg}\cdot\text{K}$ . Table A.6, water ( $\bar{T}_h = 50^\circ\text{C}$ ):  $\nu = 5.54 \times 10^{-7} \text{ m}^2/\text{s}$ ,  $k = 0.643 \text{ W/m}\cdot\text{K}$ ,  $\rho = 987.9 \text{ kg/m}^3$ ,  $Pr = 3.56$  and  $c_p = 4181 \text{ J/kg}\cdot\text{K}$ .

**ANALYSIS:** (a) The Prandtl number of the pharmaceutical product is  $Pr_c = \rho c_p \nu / k = (1100 \text{ kg/m}^3 \times 2460 \text{ J/kg}\cdot\text{K} \times 10 \times 10^{-6} \text{ m}^2/\text{s}) / 0.25 \text{ W/m}\cdot\text{K} = 108$ . The overall heat transfer coefficient is  $U = (1/h_i + 1/h_o)^{-1}$ . For the flow in the inner tube,  $Re_{D_i} = u_{m,c} D_i / \nu = (0.1 \text{ m/s} \times 0.01 \text{ m}) / 10 \times 10^{-6} \text{ m}^2/\text{s} = 100$ . The thermal entrance length is  $x_{fd,t} = 0.05 Re_{D_i} Pr D_i = 0.05 Re_{D_i} (\rho c_p \nu / k) D_i = 0.05 \times 100 \times (1100 \text{ kg/m}^3 \times 2460 \text{ J/kg}\cdot\text{K} \times 10 \times 10^{-6} \text{ m}^2/\text{s} / 0.25 \text{ W/m}\cdot\text{K}) \times 0.01 \text{ m} = 5.41 \text{ m}$ . Therefore, entrance effects are important. The Hausen correlation is appropriate for determining the average Nusselt number associated with the inner tube flow.

$$\overline{Nu}_{D_i} = 3.66 + \frac{0.0668(D/L)Re_{D_i}Pr}{1 + 0.04[(D/L)Re_{D_i}Pr]^{2/3}} = 3.66 + \frac{0.0668 \times (0.01/2) \times 100 \times 108}{1 + 0.04[(0.01/2) \times 100 \times 108]^{2/3}} = 5.96$$

Therefore,

$$h_i = \frac{\overline{Nu}_{D_i} k}{D_i} = \frac{5.96 \times 0.25 \text{ W/m}\cdot\text{K}}{0.01 \text{ m}} = 149 \text{ W/m}^2 \cdot \text{K}$$

Continued...

### Problem 11.17 (Cont.)

For the annular flow,  $Re_{Dh} = u_{m,h}(D_o - D_i)/\nu = 0.2 \text{ m/s} \times 0.01 \text{ m}/5.54 \times 10^{-7} \text{ m}^2/\text{s} = 3610$ . Hence, the Gnielinski correlation is appropriate for use. The friction factor for the annular region is obtained from Eq. 8.21 and is

$$f = (0.790 \ln Re_{Dh} - 1.64)^{-2} = (0.790 \ln(3610) - 1.64)^{-2} = 0.0428$$

Therefore,

$$\overline{Nu}_{Dh} = \frac{(f/8)(Re_{Dh} - 1000)Pr}{1 + 12.7(f/8)^{1/2}(Pr^{2/3} - 1)} = \frac{(0.0428/8)(3610 - 1000)3.56}{1 + 12.7(0.0428/8)^{1/2}(3.56^{2/3} - 1)} = 22.22$$

and

$$h_o = \frac{\overline{Nu}_{Dh}k}{D_o - D_i} = \frac{22.22 \times 0.643 \text{ W/m} \cdot \text{K}}{0.01 \text{ m}} = 1430 \text{ W/m}^2 \cdot \text{K}$$

The overall heat transfer coefficient is

$$U = (1/h_i + 1/h_o)^{-1} = [1/(149 \text{ W/m}^2 \cdot \text{K}) + 1/(1430 \text{ W/m}^2 \cdot \text{K})]^{-1} = 135 \text{ W/m}^2 \cdot \text{K} \quad <$$

(b) The heat capacity rate of the cold (pharmaceutical product) stream is

$$C_c = \dot{m}_c c_p = \left[ u_{m,c} \rho \pi D_i^2 / 4 \right] c_p = \left[ \frac{0.1 \text{ m/s} \times 1100 \text{ kg/m}^3 \times \pi \times (0.01 \text{ m})^2}{4} \right] \times 2460 \text{ J/kg} \cdot \text{K} = 21.3 \text{ W/K}$$

The heat capacity rate of the hot (water) stream is

$$C_c = \dot{m}_c c_p = \left[ u_{m,c} \rho \pi (D_o^2 - D_i^2) / 4 \right] c_p \\ = \left[ \frac{0.2 \text{ m/s} \times 987.9 \text{ kg/m}^3 \times \pi \times [(0.02 \text{ m})^2 - (0.01 \text{ m})^2]}{4} \right] \times 4181 \text{ J/kg} \cdot \text{K} = 195 \text{ W/K}$$

Therefore,  $C_r = C_{\min}/C_{\max} = (21.3 \text{ W/K})/(195 \text{ W/K}) = 0.11$  and the number of transfer units is  $NTU = UA/C_{\min} = U\pi D_i L/C_{\min} = (135 \text{ W/m}^2 \cdot \text{K} \times \pi \times 0.01 \text{ m} \times 2 \text{ m})/21.3 \text{ W/K} = 0.398$ . The effectiveness of the counterflow heat exchanger is obtained from Eq. 11.29a and is

$$\varepsilon = \frac{1 - \exp[-NTU(1 - C_r)]}{1 - C_r \exp[-NTU(1 - C_r)]} = \frac{1 - \exp[-0.398(1 - 0.11)]}{1 - 0.11 \exp[-0.398(1 - 0.11)]} = 0.323$$

Continued...

### Problem 11.17 (Cont.)

The heat transfer rate is

$$q = \dot{m}_c c_p (T_{c,o} - T_{c,i}) = \varepsilon C_{\min} (T_{h,i} - T_{c,i}) \quad \text{from which}$$

$$T_{c,o} = T_{c,i} + \frac{\varepsilon C_{\min} (T_{h,i} - T_{c,i})}{\rho u_{m,c} (\pi D_i^2 / 4) c_p} = 20^\circ\text{C} + \frac{0.323 \times 21.3 \text{ W/K} \times (60^\circ\text{C} - 20^\circ\text{C})}{1100 \text{ kg/m}^3 \times 0.1 \text{ m/s} \times (\pi (0.01 \text{ m})^2 / 4) 2460 \text{ J/kg} \cdot \text{K}} = 33.0^\circ\text{C} <$$

(c) For parallel-flow operation,

$$\varepsilon = \frac{1 - \exp[-NTU(1 + C_r)]}{1 + C_r} = \frac{1 - \exp[-0.398(1 + 0.11)]}{1 + 0.11} = 0.322$$

Therefore, the cold stream outlet temperature is

$$T_{c,o} = T_{c,i} + \frac{\varepsilon C_{\min} (T_{h,i} - T_{c,i})}{\rho u_{m,c} (\pi D_i^2 / 4) c_p} = 20^\circ\text{C} + \frac{0.322 \times 21.3 \text{ W/K} \times (60^\circ\text{C} - 20^\circ\text{C})}{1100 \text{ kg/m}^3 \times 0.1 \text{ m/s} \times (\pi (0.01 \text{ m})^2 / 4) 2460 \text{ J/kg} \cdot \text{K}} = 31.2^\circ\text{C} <$$

**COMMENTS:** There is little difference in the outlet temperature of the pharmaceutical product. However, if the outlet temperature of the pharmaceutical product cannot exceed some critical value, the heat exchanger should be operated in parallel-flow since the ultimate outlet temperature associated with a very long concentric tube apparatus would be determined by the conservation of energy principle.

## PROBLEM 11.18

**KNOWN:** Inner tube diameter ( $D = 0.02 \text{ m}$ ) and fluid inlet and outlet temperatures corresponding to design conditions for a counterflow, concentric tube heat exchanger. Overall heat transfer coefficient ( $U = 500 \text{ W/m}^2\cdot\text{K}$ ) and desired heat rate ( $q = 3000 \text{ W}$ ). Cold fluid outlet temperature after three years of operation.

**FIND:** (a) Required heat exchanger length, (b) Heat rate, hot fluid outlet temperature, overall heat transfer coefficient, and fouling factor after three years.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat loss to the surroundings, (2) Negligible tube wall conduction resistance, (3) Constant properties.

**ANALYSIS:** (a) The tube length needed to achieve the prescribed conditions may be obtained from Eqs. 11.14 and 11.15 where  $\Delta T_1 = T_{h,i} - T_{c,o} = 80^\circ\text{C}$  and  $\Delta T_2 = T_{h,o} - T_{c,i} = 120^\circ\text{C}$ . Hence,  $\Delta T_{1m} = (120 - 80)^\circ\text{C}/\ln(120/80) = 98.7^\circ\text{C}$  and

$$L = \frac{q}{(\pi D)U\Delta T_{1m}} = \frac{3000 \text{ W}}{(\pi \times 0.02 \text{ m})500 \text{ W/m}^2 \cdot \text{K} \times 98.7^\circ\text{C}} = 0.968 \text{ m} \quad <$$

(b) With  $q = C_c(T_{c,o} - T_{c,i})$ , the following ratio may be formed in terms of the design and 3 year conditions.

$$\frac{q}{q_3} = \frac{C_c(T_{c,o} - T_{c,i})}{C_c(T_{c,o} - T_{c,i})_3} = \frac{60^\circ\text{C}}{45^\circ\text{C}} = 1.333$$

Hence,

$$q_3 = q/1.33 = 3000 \text{ W}/1.333 = 2250 \text{ W} \quad <$$

Having determined the ratio of heat rates, it follows that

$$\frac{q}{q_3} = \frac{C_h(T_{h,i} - T_{h,o})}{C_h(T_{h,i} - T_{h,o})_3} = \frac{20^\circ\text{C}}{160^\circ\text{C} - T_{h,o(3)}} = 1.333$$

Hence,

$$T_{h,o(3)} = 160^\circ\text{C} - 20^\circ\text{C}/1.333 = 145^\circ\text{C} \quad <$$

With  $\Delta T_{1m,3} = (125 - 95)/\ln(125/95) = 109.3^\circ\text{C}$ ,

$$U_3 = \frac{q_3}{(\pi DL)\Delta T_{1m,3}} = \frac{2250 \text{ W}}{\pi(0.02 \text{ m})0.968 \text{ m}(109.3^\circ\text{C})} = 338 \text{ W/m}^2 \cdot \text{K} \quad <$$

Continued...

**PROBLEM 11.18 (Cont.)**

With  $U = [(1/h_i) + (1/h_o)]^{-1}$  and  $U_3 = [(1/h_i) + (1/h_o) + R_{f,c}'' ]^{-1}$ ,

$$R_{f,c}'' = \frac{1}{U_3} - \frac{1}{U} = \left( \frac{1}{338} - \frac{1}{500} \right) \text{m}^2 \cdot \text{K/W} = 9.59 \times 10^{-4} \text{m}^2 \cdot \text{K/W}$$

<

**COMMENTS:** Over time fouling will always contribute to a degradation of heat exchanger performance. In practice it is desirable to remove fluid contaminants and to implement a regular maintenance (cleaning) procedure.

## PROBLEM 11.19

**KNOWN:** Counterflow, concentric tube heat exchanger of Example 11.1; maintaining the outlet oil temperature of 60°C, but with variable rate of cooling water, all other conditions remaining the same.

**FIND:** (a) Calculate and plot the required exchanger tube length  $L$  and water outlet temperature  $T_{c,o}$  for the cooling water flow rate in the range 0.15 to 0.3 kg/s, and (b) Calculate  $U$  as a function of the water flow rate assuming the water properties are independent of temperature; justify using a constant value of  $U$  for the part (a) calculations.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Negligible losses to the surroundings, (3) Overall heat transfer coefficient independent of water flow rate for this range, and (4) Constant properties.

**PROPERTIES:** Table A-6, Water ( $\bar{T}_c = 35^\circ\text{C} = 308\text{K}$ ):  $c_p = 4178\text{ J/kg}\cdot\text{K}$ ,  $\mu = 725 \times 10^{-6}\text{ N}\cdot\text{s/m}^2$ ,  $k = 0.625\text{ W/m}\cdot\text{K}$ ,  $Pr = 4.85$ , Table A-4, Unused engine oil ( $\bar{T}_h = 353\text{K}$ ):  $c_p = 2131\text{ J/kg}\cdot\text{K}$ .

**ANALYSIS:** (a) The NTU- $\varepsilon$  method will be used to calculate the tube length  $L$  and water outlet temperature  $T_{c,o}$  using this system of equations in the *IHT* workspace:

*NTU relation, CF hxer, Eq. 11.29b*

$$NTU = \frac{1}{C_r - 1} \ln \frac{(\varepsilon - 1)}{(\varepsilon C_r - 1)} \quad C_r = C_{\max} / C_{\min} \quad (1, 2)$$

$$NTU = U \cdot A / C_{\min} \quad (3)$$

$$A = \pi D_i \cdot L \quad (4)$$

*Capacity rates, find minimum fluid*

$$C_h = \dot{m}_h c_h = 0.1\text{ kg/s} \times 2131\text{ J/kg}\cdot\text{K} = 213.1\text{ W/K}$$

$$C_c = \dot{m}_c c_c = (0.15\text{ to }0.30)\text{ kg/s} \times 4178\text{ J/kg}\cdot\text{K} = 626.7 - 1253\text{ W/K} \quad (5)$$

$$C_{\min} = C_h \quad (6)$$

*Effectiveness and maximum heat rate, Eqs. 11.18 and 11.19*

$$\varepsilon = q / q_{\max} \quad (7)$$

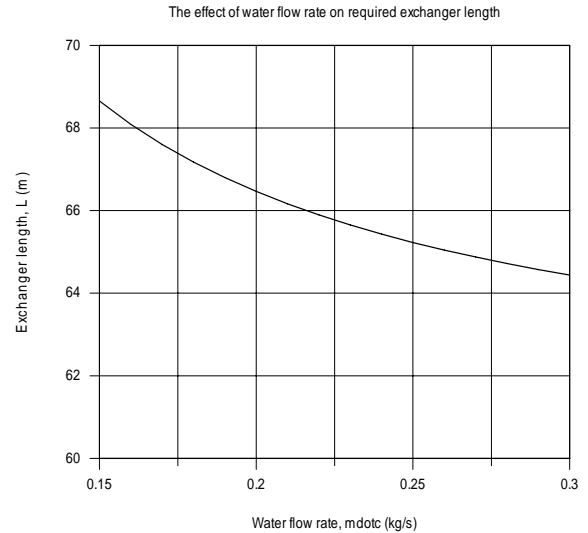

$$q_{\max} = C_{\min} (T_{h,i} - T_{c,i}) = C_c (T_{h,i} - T_{c,i}) \quad (8)$$

Continued ...

### PROBLEM 11.19 (Cont.)

$$q = C_h(T_{h,i} - T_{h,o}) \quad (9)$$

With the foregoing equations and the parameters specified in the schematic, the results are plotted in the graphs below.

(b) The overall coefficient can be written in terms of the inner (cold) and outer (hot) side convection coefficients,

$$U = 1 / (1 / h_i + 1 / h_o) \quad (10)$$

From Example 11.1,  $h_o = 38.8 \text{ W/m}^2 \cdot \text{K}$ , and  $h_i$  will vary with the flow rate from Eq. 8.60 as

$$h_i = h_{i,b} (\dot{m}_i / \dot{m}_{i,b})^{0.8} \quad (11)$$

where the subscript  $b$  denotes the base case when  $\dot{m}_i = 0.2 \text{ kg/s}$ . From these equations, the results are tabulated.

$\dot{m}_c$ (kg/s)	$h_i$ ( $\text{W/m}^2 \cdot \text{K}$ )	$h_o$ ( $\text{W/m}^2 \cdot \text{K}$ )	$U$ ( $\text{W/m}^2 \cdot \text{K}$ )
0.15	1787	38.8	38.0
0.20	2250	38.8	38.1
0.25	2690	38.8	38.2
0.30	3112	38.8	38.3

Note that while  $h_i$  varies nearly 50%, there is a negligible effect on the value of  $U$ .

**COMMENTS:** Note from the graphical results, that by doubling the flow rate (from 0.15 to 0.30 kg/s), the required length of the exchanger can be decreased by approximately 6%. Increasing the flow rate is not a good strategy for reducing the length of the exchanger. However, any increase in the hot-side (oil) convection coefficient would provide a proportional decrease in the length.

## PROBLEM 11.20

**KNOWN:** Concentric tube heat exchanger with area of  $50 \text{ m}^2$  with operating conditions as shown on the schematic.

**FIND:** (a) Outlet temperature of the hot fluid; (b) Whether the exchanger is operating in counterflow or parallel flow; or can't tell from information provided; (c) Overall heat transfer coefficient; (d) Effectiveness of the exchanger; and (e) Effectiveness of the exchanger if its length is made very long

**SCHEMATIC:**

Operating conditions Concentric tube HXer, $A = 50 \text{ m}^2$		
	Hot fluid (h)	Cold fluid (c)
Capacity rate, kW/K	6	3
Inlet temperature, °C	60	30
Outlet temperature, °C	--	54

**ASSUMPTIONS:** (1) Negligible heat loss to surroundings, (2) Constant properties.

**ANALYSIS:** From overall energy balances on the hot and cold fluids, find the hot fluid outlet temperature

$$q = C_c (T_{c,o} - T_{c,i}) = C_h (T_{h,i} - T_{h,o}) \quad (1)$$

$$3000 \text{ W/K} (54 - 30) \text{ K} = 6000 (60 - T_{h,o}) \quad T_{h,o} = 48^\circ\text{C} \quad <$$

(b) HXer must be operating in counterflow (CF) since  $T_{h,o} < T_{c,o}$ . See schematic for temperature distribution.

(c) From the rate equation with  $A = 50 \text{ m}^2$ , with Eq. (1) for  $q$ ,

$$q = C_c (T_{c,o} - T_{c,i}) = UA \Delta T_{lm} \quad (2)$$

$$\Delta T_{lm} = \frac{\Delta T_1 - \Delta T_2}{\ln(\Delta T_1 / \Delta T_2)} = \frac{(60 - 54) \text{ K} - (48 - 30) \text{ K}}{\ln(6/18)} = 10.9^\circ\text{C} \quad (3)$$

$$3000 \text{ W/K} (54 - 30) \text{ K} = U \times 50 \text{ m}^2 \times 10.9 \text{ K}$$

$$U = 132 \text{ W/m}^2 \cdot \text{K} \quad <$$

(d) The effectiveness, from Eq. 11.19, with the cold fluid as the minimum fluid,  $C_c = C_{min}$ ,

$$\varepsilon = \frac{q}{q_{max}} = \frac{C_c (T_{c,o} - T_{c,i})}{C_{min} (T_{h,i} - T_{c,i})} = \frac{(54 - 30) \text{ K}}{(60 - 30) \text{ K}} = 0.8 \quad <$$

(e) For a very long CF HXer, the outlet of the minimum fluid,  $C_{min} = C_c$ , will approach  $T_{h,i}$ . That is,

$$q \rightarrow C_{min} (T_{c,o} - T_{c,i}) \rightarrow q_{max} \quad \varepsilon = 1 \quad <$$

## PROBLEM 11.21

**KNOWN:** Specifications for a water-to-water heat exchanger as shown in the schematic including the flow rate, and inlet and outlet temperatures.

**FIND:** (a) Design a heat exchanger to meet the specifications; that is, size the heat exchanger, and (b) Evaluate your design by identifying what features and configurations could be explored with your customer in order to develop more complete, detailed specifications.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat loss to surroundings, (2) Tube walls have negligible thermal resistance, (3) Flow is fully developed, and (4) Constant properties.

**ANALYSIS:** (a) Referring to the schematic above and using the rate equation, we can determine the value of the  $UA$  product required to satisfy the design requirements. Sizing the heat exchanger involves determining the heat transfer area,  $A$  (tube diameter, length and number), and the associated overall convection coefficient,  $U$ , such that  $U \times A$  satisfies the required  $UA$  product. Our approach has five steps: (1) *Calculate the UA product:* Select a configuration and calculate the required  $UA$  product; (2) *Estimate the area, A:* Assume a range for the overall coefficient, calculate the area and consider suitable tube diameter(s); (3) *Estimate the overall coefficient, U:* For selected tube diameter(s), use correlations to estimate hot- and cold-side convection coefficients and the overall coefficient; (4) *Evaluate first-pass design:* Check whether the  $A$  and  $U$  values ( $U \times A$ ) from Steps 2 and 3 satisfy the required  $UA$  product; if not, then (5) *Repeat the analysis:* Iterate on different values for area parameters until a satisfactory match is made,  $(U \times A) = UA$ .

To perform the analysis, *IHT* models and tools will be used for the effectiveness-NTU method relations, internal flow convection correlations, and thermophysical properties. See the Comments section for details.

*Step 1 Calculate the required UA.* For the initial design, select a concentric tube, counterflow heat exchanger. Calculate  $UA$  using the following set of equations, Eqs. 11.29a,

$$\varepsilon = \frac{1 - \exp[-NTU(1 - C_r)]}{1 - C_r \exp[-NTU(1 - C_r)]} \quad (1)$$

$$NTU = UA / C_{\min} \quad C_r = C_{\min} / C_{\max} \quad (2,3)$$

$$\varepsilon = q / q_{\max} \quad q_{\max} = C_{\min} (T_{h,i} - T_{c,i}) \quad (4,5)$$

where  $C = \dot{m} c_p$ , and  $c_p$  is evaluated at the average mean temperature of the fluid,  $\bar{T}_m = (T_{m,i} + T_{m,o})/2$ . Substituting numerical values, find

$$\varepsilon = 0.464 \quad NTU = 0.8523 \quad q = 2.934 \times 10^6 \text{ W} \quad T_{h,o} = 65.0^\circ\text{C}$$

Continued ...

**PROBLEM 11.21 (Cont.)**

$$UA = 9.62 \times 10^4 \text{ W/K} \quad <$$

*Step 2 Estimate the area, A.* From Table 11.2, the typical range of U for water-to-water exchangers is 850 – 1700 W/m<sup>2</sup>·K. With  $UA = 9.619 \times 10^4 \text{ W/K}$ , the range for A is 57 – 113 m<sup>2</sup>, where

$$A = \pi D_i LN \quad (6)$$

where L and N are the length and number of tubes, respectively. Consider these values of D<sub>i</sub> with L = 10 m to describe the exchanger:

Case	D <sub>i</sub> (mm)	L (m)	N	A (m <sup>2</sup> )
1	25	10	73-146	57-113
2	50	10	36-72	57-113
3	75	10	24-48	57-113

*Step 3 Estimate the overall coefficient, U.* With the inner (hot) and outer (cold) fluids in the concentric tube arrangement, the overall coefficient is

$$1/U = 1/\bar{h}_i + 1/\bar{h}_o \quad (7)$$

and the  $\bar{h}$  are estimated using the Dittus-Boelter correlation assuming fully developed turbulent flow.

*Coefficient, hot side,  $\bar{h}_i$ .* For flow in the inner tube,

$$\text{Re}_{D_i} = \frac{4 \dot{m}_{h,i}}{\pi D_i \mu_h} \quad \dot{m}_h = \dot{m}_{hi} \cdot N \quad (8,9)$$

and the correlation, Eq. 8.60 with n = 0.3, is

$$\frac{\bar{h}_i}{k} = \frac{\bar{h}_i D_i}{k} = 0.037 \text{Re}_{D_i}^{4/5} \text{Pr}^{0.3} \quad (10)$$

where properties are evaluated at the average mean temperature,  $\bar{T}_h = (T_{hi} + T_{ho})/2$ .

*Coefficient, cold side,  $\bar{h}_o$ .* For flow in the annular space,  $D_o - D_i$ , the above relations apply where the characteristic dimension is the hydraulic diameter,

$$D_{h,o} = 4 A_{c,o} / P_o \quad A_{c,o} = \pi (D_o^2 - D_i^2) / 4 \quad P_o = \pi (D_o + D_i) \quad (11-13)$$

To determine the outer diameter D<sub>o</sub>, require that the inner and outer fluid flow areas are the same, that is,

$$A_{c,i} = A_{c,o} \quad \pi D_i^2 / 4 = \pi (D_o^2 - D_i^2) / 4 \quad (14,15)$$

*Summary of the convection coefficient calculations.* The results of the analysis with L = 10 m are summarized below.

Continued ...

### PROBLEM 11.21 (Cont.)

Case	$D_i$ (mm)	N	A ( $m^2$ )	$\bar{h}_i$ ( $W/m^2 \cdot K$ )	$\bar{h}_o$ ( $W/m^2 \cdot K$ )	U ( $W/m^2 \cdot K$ )	$U \times A$ W/K
1a	25	73	57	4795	4877	2418	$1.39 \times 10^5$
2a	50	36	57	2424	2465	1222	$6.91 \times 10^4$
3a	75	24	57	1616	1644	814	$4.61 \times 10^4$

For all these cases, the Reynolds numbers are above 10,000 and turbulent flow occurs.

*Step 4 Evaluate first-pass design.* The required UA product value determined in step 1 is  $UA = 9.62 \times 10^4$  W/K. By comparison with the results in the above table, note that the  $U \times A$  values for cases 1a and 2a are, respectively, larger and smaller than that required. In this first-pass design trial we have identified the range of  $D_i$  and N (with  $L = 10$  m) that could satisfy the exchanger specifications. A strategy can now be developed in *Step 5* to iterate the analysis on values for  $D_i$  and N, as well as with different L, to identify a combination that will meet specifications.

(b) What information could have been provided by the customer to simplify the analysis for design of the exchanger? Looking back at the analysis, recognize that we had to assume the exchanger configuration (type) and overall length. Will knowledge of the customer's installation provide any insight? While no consideration was given in our analysis to pumping power limitations, that would affect the flow velocities, and hence selection of tube diameter.

**COMMENTS:** The *IHT* workspace with the relations for step 3 analysis is shown below, including summary of key correlation parameters. The set of equations is quite stiff so that good initial guesses are required to make the initial solve.

```

## PROBLEM 11.22

**KNOWN:** Inlet and outlet temperatures for a shell-and-tube heat exchanger with 10 tubes making eight passes. Heat transfer coefficient for oil flowing in shell. Mass flow rate of water in tubes. Tube diameter.

**FIND:** Oil flow rate required to achieve specified outlet temperature. Tube length required to achieve specified water heating.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat loss to the surroundings, (2) Constant properties, (3) Negligible tube wall thermal resistance and fouling effects, (4) Fully developed water flow in tubes.

**PROPERTIES:** Table A.5, unused engine oil: ( $\bar{T}_h = 130^\circ\text{C}$ ):  $c_p = 2350 \text{ J/kg}\cdot\text{K}$ . Table A.6, water ( $\bar{T}_c = 50^\circ\text{C}$ ):  $c_p = 4181 \text{ J/kg}\cdot\text{K}$ ,  $\mu = 548 \times 10^{-6} \text{ N}\cdot\text{s/m}^2$ ,  $k = 0.643 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 3.56$ .

**ANALYSIS:** From the overall energy balance, Eq. 11.7b, the heat transfer required of the exchanger is

$$q = \dot{m}_c c_{p,c} (T_{c,o} - T_{c,i}) = 2.5 \text{ kg/s} \times 4181 \text{ J/kg}\cdot\text{K} (85 - 15)^\circ\text{C} = 7.317 \times 10^5 \text{ W}$$

Hence from Eq. 11.6b,

$$\dot{m}_h = \frac{q}{c_{p,h} (T_{h,i} - T_{h,o})} = \frac{7.317 \times 10^5 \text{ W}}{2350 \text{ J/kg}\cdot\text{K} (160 - 100)^\circ\text{C}} = 5.19 \text{ kg/s} \quad <$$

The required tube length may be obtained using the  $\epsilon$ -NTU method. We first calculate the heat capacity rates,  $C_h = \dot{m}_h c_{p,h} = 12,195 \text{ W/K}$ ,  $C_c = \dot{m}_c c_{p,c} = 10,453 \text{ W/K}$ . Thus,  $C_{\min} = C_c$ , and  $C_r = C_{\min}/C_{\max} = 0.857$ . Then from Eq. 11.21,

$$\epsilon = \frac{T_{c,o} - T_{c,i}}{T_{h,i} - T_{c,i}} = \frac{(85 - 15)^\circ\text{C}}{(160 - 15)^\circ\text{C}} = 0.483$$

Using Eqs. 11.30b,c for one shell pass and an even number of tube passes, we find

Continued...

**PROBLEM 11.22 (Cont.)**

$$E = \frac{2/\varepsilon - (1 + C_r)}{(1 + C_r^2)^{1/2}} = \frac{2/0.483 - (1 + 0.857)}{(1 + 0.857^2)^{1/2}} = 1.74$$

$$\text{NTU} = -(1 + C_r^2)^{-1/2} \ln\left(\frac{E - 1}{E + 1}\right) = -(1 + 0.857^2)^{-1/2} \ln\left(\frac{1.74 - 1}{1.74 + 1}\right) = 0.997$$

Thus  $UA = \text{NTU} \times C_{\min} = 10,420 \text{ W/K}$ . To find the required tube length, we must know the heat transfer coefficients for the water flow. We calculate the Reynolds number, with  $\dot{m}_1 = \dot{m}_c / N = 0.25 \text{ kg/s}$  defined as the water flow rate per tube, Eq. 8.6 yields

$$\text{Re}_D = \frac{4\dot{m}_1}{\pi D \mu_c} = \frac{4 \times 0.25 \text{ kg/s}}{\pi (0.025 \text{ m}) 548 \times 10^{-6} \text{ N} \cdot \text{s/m}^2} = 23,234$$

Hence the flow is turbulent, and from Eq. 8.60,

$$\text{Nu}_D = 0.023 \text{Re}_D^{4/5} \text{Pr}^{0.4} = 0.023(23,234)^{4/5} (3.56)^{0.4} = 119$$

and

$$h_c = \frac{k_c}{D} \text{Nu}_D = \frac{0.643 \text{ W/m} \cdot \text{K}}{0.025 \text{ m}} 119 = 3060 \text{ W/m}^2 \cdot \text{K}$$

Hence  $U = [1/h_c + 1/h_h]^{-1} = 354 \text{ W/m}^2 \cdot \text{K}$  and we can find the required tube length from

$$L = \frac{UA}{UN\pi D} = \frac{10,420 \text{ W/K}}{354 \text{ W/m}^2 \cdot \text{K} \times 10 \times \pi \times 0.025 \text{ m}} = 37.5 \text{ m} \quad <$$

**COMMENTS:** (1) With  $L/D = 1516$ , the assumption of fully developed conditions throughout the tube is justified. (2) With eight passes, the shell length is approximately  $L/8 = 4.7 \text{ m}$ .

### PROBLEM 11.23

**KNOWN:** Counterflow concentric tube heat exchanger.

**FIND:** (a) Total heat transfer rate and outlet temperature of the water and (b) Required length.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat loss to surroundings, (2) Negligible thermal resistance due to tube wall thickness.

**PROPERTIES:** (given):

	$\rho$ (kg/m <sup>3</sup> )	$c_p$ (J/kg·K)	$\nu$ (m <sup>2</sup> /s)	$k$ (W/m·K)	Pr
Water	1000	4200	$7 \times 10^{-7}$	0.64	4.7
Oil	800	1900	$1 \times 10^{-5}$	0.134	140

**ANALYSIS:** (a) With the outlet temperature,  $T_{c,o} = 60^\circ\text{C}$ , from an overall energy balance on the hot (oil) fluid, find

$$q = \dot{m}_h c_h (T_{h,i} - T_{h,o}) = 0.1 \text{ kg/s} \times 1900 \text{ J/kg} \cdot \text{K} (100 - 60)^\circ\text{C} = 7600 \text{ W.} \quad <$$

From an energy balance on the cold (water) fluid, find

$$T_{c,o} = T_{c,i} + q / \dot{m}_c c_c = 30^\circ\text{C} + 7600 \text{ W} / 0.1 \text{ kg/s} \times 4200 \text{ J/kg} \cdot \text{K} = 48.1^\circ\text{C.} \quad <$$

(b) Using the LMTD method, the length of the CF heat exchanger follows from

$$q = UA\Delta T_{\text{lm,CF}} = U(\pi DL)\Delta T_{\text{lm,CF}} \quad L = q / U(\pi D)\Delta T_{\text{lm,CF}}$$

where

$$\Delta T_{\text{lm,CF}} = \frac{\Delta T_1 - \Delta T_2}{\ln(\Delta T_1 / \Delta T_2)} = \frac{(60 - 30)^\circ\text{C} - (100 - 48.1)^\circ\text{C}}{\ln(30 / 51.9)} = 40.0^\circ\text{C}$$

$$L = 7600 \text{ W} / 60 \text{ W/m}^2 \cdot \text{K} (\pi \times 0.025 \text{ m}) \times 40.0^\circ\text{C} = 40.3 \text{ m.} \quad <$$

**COMMENTS:** Using the  $\epsilon$ -NTU method, find  $C_{\min} = C_h = 190 \text{ W/K}$  and  $C_{\max} = C_c = 420 \text{ W/K}$ . Hence

$$q_{\max} = C_{\min} (T_{h,i} - T_{c,i}) = 190 \text{ W/K} (100 - 30) \text{ K} = 13,300 \text{ W}$$

and  $\epsilon = q/q_{\max} = 0.571$ . With  $C_r = C_{\min}/C_{\max} = 0.452$  and using Eq. 11.29b,

$$\text{NTU} = \frac{UA}{C_{\min}} = \frac{1}{C_r - 1} \ln\left(\frac{\epsilon - 1}{\epsilon C_r - 1}\right) = \frac{1}{0.452 - 1} \ln\left(\frac{0.571 - 1}{0.571 \times 0.452 - 1}\right) = 1.00$$

so that with  $A = \pi DL$ , find  $L = 40.3 \text{ m}$ .

### PROBLEM 11.24

**KNOWN:** Counterflow, concentric tube heat exchanger undergoing test after service for an extended period of time; surface area of  $5 \text{ m}^2$  and design value for the overall heat transfer coefficient of  $U_d = 38 \text{ W/m}^2 \cdot \text{K}$ .

**FIND:** Fouling factor, if any, based upon the test results of engine oil flowing at  $0.1 \text{ kg/s}$  cooled from  $110^\circ\text{C}$  to  $66^\circ\text{C}$  by water supplied at  $25^\circ\text{C}$  and a flow rate of  $0.2 \text{ kg/s}$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Negligible losses to the surroundings, (3) Constant properties.

**PROPERTIES:** Table A-5, Engine oil ( $\bar{T}_h = 361 \text{ K}$ ):  $c = 2166 \text{ J/kg}\cdot\text{K}$ ; Table A-6, Water ( $\bar{T}_c = 304 \text{ K}$ , assuming  $T_{c,o} = 36^\circ\text{C}$ ):  $c = 4178 \text{ J/kg}\cdot\text{K}$ .

**ANALYSIS:** For the CF conditions shown in the Schematic, find the heat rate,  $q$ , from an energy balance on the hot fluid (oil); the cold fluid outlet temperature,  $T_{c,o}$ , from an energy balance on the cold fluid (water); the overall coefficient  $U$  from the rate equation; and a fouling factor,  $R$ , by comparison with the design value,  $U_d$ .

*Energy balance on hot fluid*

$$q = \dot{m}_h c_h (T_{h,i} - T_{h,o}) = 0.1 \text{ kg/s} \times 2166 \text{ J/kg}\cdot\text{K} (110 - 66) \text{ K} = 9530 \text{ W}$$

*Energy balance on the cold fluid*

$$q = \dot{m}_c c_c (T_{c,o} - T_{c,i}), \quad \text{find } T_{c,o} = 36.4^\circ\text{C}$$

*Rate equation*

$$q = UA \Delta T_{\ln,CF}$$

$$\Delta T_{\ln,CF} = \frac{(T_{h,i} - T_{c,o}) - (T_{h,o} - T_{c,i})}{\ln\left[\frac{(T_{h,i} - T_{c,o})}{(T_{h,o} - T_{c,i})}\right]} = \frac{(110 - 36.4)^\circ\text{C} - (66 - 25)^\circ\text{C}}{\ln[73.6/41.0]} = 55.7^\circ\text{C}$$

$$9530 \text{ W} = U \times 5 \text{ m}^2 \times 55.7^\circ\text{C}$$

$$U = 34.2 \text{ W/m}^2 \cdot \text{K}$$

*Overall resistance including fouling factor*

$$U = 1/[1/U_d + R_f']$$

$$34.2 \text{ W/m}^2 \cdot \text{K} = 1/[1/38 \text{ W/m}^2 \cdot \text{K} + R_f']$$

$$R_f' = 0.0029 \text{ m}^2 \cdot \text{K/W}$$

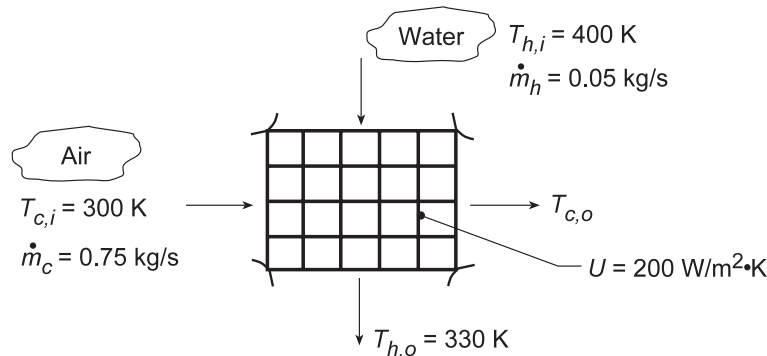

<

### PROBLEM 11.25

**KNOWN:** Flow rates and inlet temperatures for automobile radiator configured as a cross-flow heat exchanger with both fluids unmixed. Overall heat transfer coefficient.

**FIND:** (a) Area required to achieve hot fluid (water) outlet temperature,  $T_{h,o} = 330$  K, and (b) Outlet temperatures,  $T_{h,o}$  and  $T_{c,o}$ , as a function of the overall coefficient for the range,  $200 \leq U \leq 400$  W/m<sup>2</sup>·K with the surface area  $A$  found in part (a) with all other heat transfer conditions remaining the same as for part (a).

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat loss to surroundings, (2) Constant properties.

**PROPERTIES:** Table A.6, Water ( $\bar{T}_h = 365$  K):  $c_{p,h} = 4209$  J/kg·K; Table A.4, Air ( $\bar{T}_c \approx 310$  K):  $c_{p,c} = 1007$  J/kg·K.

**ANALYSIS:** (a) The required heat transfer rate is

$$q = \dot{m}_h c_{p,h} (T_{h,i} - T_{h,o}) = 0.05 \text{ kg/s} (4209 \text{ J/kg} \cdot \text{K}) 70 \text{ K} = 14,732 \text{ W} .$$

Using the  $\varepsilon$ -NTU method,

$$C_{\min} = C_h = 210.45 \text{ W/K} \quad C_{\max} = C_c = 755.25 \text{ W/K} .$$

Hence,  $C_{\min}/C_{\max} = 0.279$  and

$$q_{\max} = C_{\min} (T_{h,i} - T_{c,i}) = 210.45 \text{ W/K} (100 \text{ K}) = 21,045 \text{ W}$$

$$\varepsilon = q/q_{\max} = 14,732 \text{ W}/21,045 \text{ W} = 0.700 .$$

Figure 11.14 yields  $NTU \approx 1.5$ , hence,

$$A = NTU (C_{\min}/U) = 1.5 \times 210.45 \text{ W/K} / (200 \text{ W/m}^2 \cdot \text{K}) = 1.58 \text{ m}^2 . \quad <$$

(b) Using the *IHT Heat Exchanger Tool* for *Cross-flow with both fluids unmixed* arrangement and the *Properties Tool* for *Air* and *Water*, a model was generated to solve part (a) evaluating the efficiency using Eq. 11.32. The following results were obtained:

$$A = 1.516 \text{ m}^2 \quad NTU = 1.441 \quad T_{c,o} = 319.5 \text{ K}$$

Using the model but assigning  $A = 1.516$  m<sup>2</sup>, the outlet temperature  $T_{h,o}$  and  $T_{c,o}$  were calculated as a function of  $U$  and the results plotted below.

Continued...

## PROBLEM 11.25 (Cont.)

With a higher  $U$ , the outlet temperature of the hot fluid (water) decreases. A benefit is enhanced heat removal from the engine block and a cooler operating temperature. If it is desired to cool the engine with water at 330 K, the heat exchanger surface area and, hence its volume in the engine component could be reduced.

**COMMENTS:** (1) For the results of part (a), the air outlet temperature is

$$T_{c,o} = T_{c,i} + q/C_c = 300 \text{ K} + (14,732 \text{ W}/755.25 \text{ W/K}) = 319.5 \text{ K} .$$

(2) The IHT workspace with the model to generate the above plot is shown below. Note that it is necessary to enter the overall energy balances on the fluids from the keyboard.

```

// Heat Exchanger Tool - Cross-flow with both fluids unmixed:
// For the cross-flow, single-pass heat exchanger with both fluids unmixed,
eps = 1 - exp((1 / Cr) * (NTU^0.22) * (exp(-Cr * NTU^0.78) - 1)) // Eq 11.32
// where the heat-capacity ratio is
Cr = Cmin / Cmax
// and the number of transfer units, NTU, is
NTU = U * A / Cmin // Eq 11.24
// The effectiveness is defined as
eps = q / qmax
qmax = Cmin * (Thi - Tci) // Eq 11.18, 11.19
// See Tables 11.3 and 11.4 and Fig 11.14
// Overall Energy Balances on Fluids:
q = mdoth * cph * (Thi - Tho)
q = mdotc * cpc * (Tco - Tci)
// Assigned Variables:
Cmin = Ch // Capacity rate, minimum fluid, W/K
Ch = mdoth * cph // Capacity rate, hot fluid, W/K
mdoth = 0.05 // Flow rate, hot fluid, kg/s
Thi = 400 // Inlet temperature, hot fluid, K
Tho = 330 // Outlet temperature, hot fluid, K; specified for part (a)
Cmax = Cc // Capacity rate, maximum fluid, W/K
Cc = mdotc * cpc // Capacity rate, cold fluid, W/K
mdotc = 0.75 // Flow rate, cold fluid, kg/s
Tci = 300 // Inlet temperature, cold fluid, K
U = 200 // Overall coefficient, W/m^2.K
// Properties Tool - Water (h)
// Water property functions :T dependence, From Table A.6
// Units: T(K), p(bars);
xh = 0 // Quality (0=sat liquid or 1=sat vapor)
rho_h = rho_Tx("Water",Tmh,xh) // Density, kg/m^3
cph = cp_Tx("Water",Tmh,xh) // Specific heat, J/kg.K
Tmh = Tfluid_avg(Thi,Tho)
// Properties Tool - Air(c)
// Air property functions : From Table A.4
// Units: T(K); 1 atm pressure
rho_c = rho_T("Air",Tmc) // Density, kg/m^3
cpc = cp_T("Air",Tmc) // Specific heat, J/kg.K
Tmc = Tfluid_avg(Tci,Tco)

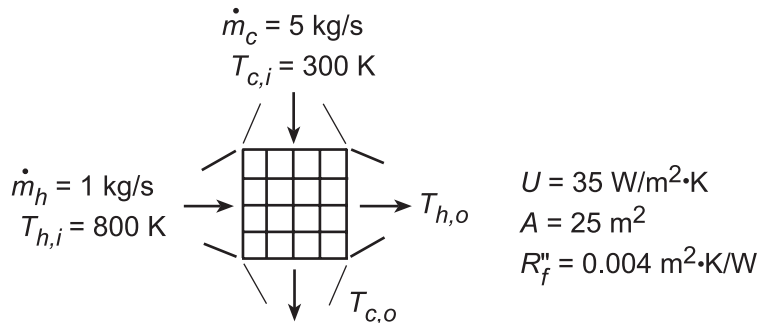

```

## PROBLEM 11.26

**KNOWN:** Flowrates and inlet temperatures of a cross-flow heat exchanger with both fluids unmixed. Total surface area and overall heat transfer coefficient for clean surfaces. Fouling resistance associated with extended operation.

**FIND:** (a) Fluid outlet temperatures, (b) Effect of fouling, (c) Effect of UA on air outlet temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat loss to surroundings, (2) Constant properties, (3) Negligible tube wall resistance.

**PROPERTIES:** Air and gas (given):  $c_p = 1040 \text{ J/kg}\cdot\text{K}$ .

**ANALYSIS:** (a) With  $C_{\min} = C_h = 1 \text{ kg/s} \times 1040 \text{ J/kg}\cdot\text{K} = 1040 \text{ W/K}$  and  $C_{\max} = C_c = 5 \text{ kg/s} \times 1040 \text{ J/kg}\cdot\text{K} = 5200 \text{ W/K}$ ,  $C_{\min}/C_{\max} = 0.2$ . Hence,  $\text{NTU} = UA/C_{\min} = 35 \text{ W/m}^2\cdot\text{K}(25 \text{ m}^2)/1040 \text{ W/K} = 0.841$  and Fig. 11.14 yields  $\varepsilon \approx 0.57$ . With  $C_{\min}(T_{h,i} - T_{c,i}) = 1040 \text{ W/K}(500 \text{ K}) = 520,000 \text{ W} = q_{\max}$ , Eqs. (11.20) and (11.21) yield

$$T_{h,o} = T_{h,i} - \varepsilon q_{\max} / C_h = 800 \text{ K} - 0.57(520,000 \text{ W}) / 1040 \text{ W/K} = 515 \text{ K} \quad <$$

$$T_{c,o} = T_{c,i} + \varepsilon q_{\max} / C_c = 300 \text{ K} + 0.57(520,000 \text{ W}) / 5200 \text{ W/K} = 357 \text{ K} \quad <$$

(b) With fouling, the overall heat transfer coefficient is reduced to

$$U_f = \left( U^{-1} + R_f'' \right)^{-1} = \left[ (0.029 + 0.004) \text{ m}^2 \cdot \text{K/W} \right]^{-1} = 30.7 \text{ W/m}^2 \cdot \text{K}$$

This 12% reduction in performance is large enough to justify cleaning of the tubes. <

(c) Using the *Heat Exchangers* option from the IHT Toolpad to explore the effect of UA, we obtain the following result.

The heat rate, and hence the air outlet temperature, increases with increasing UA, with  $T_{c,o}$  approaching a maximum outlet temperature of 400 K as  $UA \rightarrow \infty$  and  $\varepsilon \rightarrow 1$ .

**COMMENTS:** Note that, for conditions of part (a), Eq. 11.32 yields a value of  $\varepsilon = 0.538$ , which reveals the level of approximation associated with reading  $\varepsilon$  from Fig. 11.14.

## PROBLEM 11.27

**KNOWN:** Cooling milk from a dairy operation to a safe-to-store temperature,  $T_{h,o} \leq 13^\circ\text{C}$ , using ground water in a counterflow concentric tube heat exchanger with a 50-mm diameter inner pipe and overall heat transfer coefficient of  $1000 \text{ W/m}^2 \cdot \text{K}$ .

**FIND:** (a) The UA product required for the chilling process and the length  $L$  of the exchanger, (b) The outlet temperature of the ground water, and (c) the milk outlet temperatures for the cases when the water flow rate is halved and doubled, using the UA product found in part (a)

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Negligible heat loss to surroundings, and (3) Constant properties.

**PROPERTIES:** Table A-6, Water ( $\bar{T}_c = 287 \text{ K}$ , assume  $T_{c,o} = 18^\circ\text{C}$ ):  $\rho = 1000 \text{ kg/m}^3$ ,

$c_p = 4187 \text{ J/kg} \cdot \text{K}$ ; Milk (given):  $\rho = 1030 \text{ kg/m}^3$ ,  $c_p = 3860 \text{ J/kg} \cdot \text{K}$ .

**ANALYSIS:** (a) Using the effectiveness-NTU method, determine the capacity rates and the minimum fluid.

*Hot fluid, milk:*

$$\dot{m}_h = \rho_h \dot{V}_h = 1030 \text{ kg/m}^3 \times 250 \text{ liter/h} \times 10^{-3} \text{ m}^3/\text{liter} \times 1 \text{ h}/3600 \text{ s} = 0.0715 \text{ kg/s}$$

$$C_h = \dot{m}_h c_h = 0.0715 \text{ kg/s} \times 3860 \text{ J/kg} \cdot \text{K} = 276 \text{ W/K}$$

*Cold fluid, water:*

$$C_c = \dot{m}_c c_c = 1000 \text{ kg/m}^3 \times (0.72/3600 \text{ m}^3/\text{s}) \times 4187 \text{ J/kg} \cdot \text{K} = 837 \text{ W/K}$$

It follows that  $C_{\min} = C_h$ . The effectiveness of the exchanger from Eq. 11.20 is

$$\varepsilon = \frac{q}{q_{\max}} = \frac{C_h (T_{h,i} - T_{h,o})}{C_{\min} (T_{h,i} - T_{c,i})} = \frac{(38.6 - 13)\text{K}}{(38.6 - 10)\text{K}} = 0.895 \quad (1)$$

The NTU can be calculated from Eq. 11.29b, where  $C_r = C_{\min}/C_{\max} = 0.330$ ,

$$\text{NTU} = \frac{1}{C_r - 1} \ln \left( \frac{\varepsilon - 1}{\varepsilon C_r - 1} \right) \quad (2)$$

$$\text{NTU} = \frac{1}{0.330 - 1} \ln \left( \frac{0.895 - 1}{0.895 \times 0.330 - 1} \right) = 2.842$$

Continued ...

### PROBLEM 11.27 (Cont.)

From Eq. 11.24, find UA

$$[UA] = NTU \cdot C_{\min} = 2.842 \times 276 \text{ W/K} = 785 \text{ W/K} \quad <$$

and the exchanger tube length with  $A = \pi DL$  is

$$L = [UA] / \pi DU = 785 \text{ W/K} / \pi 0.050 \text{ m} \times 1000 \text{ W/m}^2 \cdot \text{K} = 5.0 \text{ m} \quad <$$

(b) The water outlet temperature,  $T_{c,o}$ , can be calculated from the heat rates,

$$C_h (T_{h,i} - T_{h,o}) = C_c (T_{c,o} - T_{c,i}) \quad (3)$$

$$276 \text{ W/K} (38.6 - 13) \text{K} = 837 \text{ W/K} (T_{c,o} - 10) \text{K}$$

$$T_{c,o} = 18.4^\circ \text{C} \quad <$$

(c) Using the foregoing Eqs. (1 - 3) in the *IHT* workspace, the hot fluid (milk) outlet temperatures are evaluated with  $UA = 785 \text{ W/K}$  for different water flow rates. The results, including the hot fluid outlet temperatures, are compared to the base case, part (a).

Case	$C_c$ (W/K)	$T_{c,o}$ ( $^\circ\text{C}$ )	$T_{h,o}$ ( $^\circ\text{C}$ )
1, halved flow rate	419	14.9	25.6
Base, part (a)	837	13	18.4
2, doubled flow rate	1675	12.3	14.3

**COMMENTS:** (1) From the results table in part (c), note that if the water flow rate is halved, the milk will not be properly chilled, since  $T_{c,o} = 14.9^\circ\text{C} > 13^\circ\text{C}$ . Doubling the water flow rate reduces the outlet milk temperature by less than  $1^\circ\text{C}$ .

(2) From the results table, note that the water outlet temperature changes are substantially larger than those of the milk with changes in the water flow rate. Why is this so? What operational advantage is achieved using the heat exchanger under the present conditions?

(3) The water thermophysical properties were evaluated at the average cold fluid temperature,  $\bar{T}_c = (T_{c,i} + T_{c,o})/2$ . We assumed an outlet temperature of  $18^\circ\text{C}$ , which as the results show, was a good choice. Because the water properties are not highly temperature dependent, it was acceptable to use the same values for the calculations of part (c). You could, of course, use the properties function in *IHT* that will automatically use the appropriate values.

(4) The value of the overall heat transfer coefficient,  $U$ , will change as the mass flow rate is varied. The answer to part (c) would be different if this variation is accounted for.

## PROBLEM 11.28

**KNOWN:** Flow rate, inlet temperatures and overall heat transfer coefficient for a regenerator. Desired regenerator effectiveness. Cost of natural gas.

**FIND:** (a) Heat transfer area required for regenerator and corresponding heat recovery rate and outlet temperatures, (b) Annual energy and fuel cost savings.

**SCHEMATIC:**

**ASSUMPTIONS:** (a) Negligible heat loss to surroundings, (b) Constant properties.

**PROPERTIES:** Problem 11.27, milk:  $c_p = 3860 \text{ J/kg}\cdot\text{K}$ .

**ANALYSIS:** (a) With  $C_r = 1$  and  $\varepsilon = 0.50$  for one shell and two tube passes, Eq. 11.30c yields  $E = 1.414$ . With  $C_{\min} = 5 \text{ kg/s} \times 3860 \text{ J/kg}\cdot\text{K} = 19,300 \text{ W/K}$ , Eq. 11.30b then yields

$$A = -\frac{C_{\min}}{U} \frac{\ln[(E-1)/(E+1)]}{(1+C_r^2)^{1/2}} = -\frac{19,300 \text{ W/K}}{2000 \text{ W/m}^2 \cdot \text{K}} \frac{\ln(0.171)}{1.414} = 12.03 \text{ m}^2 \quad <$$

With  $\varepsilon = 0.50$ , the heat recovery rate is then

$$q = \varepsilon C_{\min} (T_{h,i} - T_{c,i}) = 627,000 \text{ W} \quad <$$

and the outlet temperatures are

$$T_{c,o} = T_{c,i} + \frac{q}{C_c} = 5^\circ\text{C} + \frac{627,000 \text{ W}}{19,300 \text{ W/K}} = 37.5^\circ\text{C} \quad <$$

$$T_{h,o} = T_{h,i} - \frac{q}{C_h} = 70^\circ\text{C} - \frac{627,000 \text{ W}}{19,300 \text{ W/K}} = 37.5^\circ\text{C} \quad <$$

(b) The amount of energy recovered for continuous operation over 365 days is

$$\Delta E = 627,000 \text{ W} \times 365 \text{ d/yr} \times 24 \text{ h/d} \times 3600 \text{ s/h} = 1.98 \times 10^{13} \text{ J/yr}$$

The annual fuel savings  $S_A$  is then

$$S_A = \frac{\Delta E \times C_{\text{ng}}}{\eta} = \frac{1.98 \times 10^7 \text{ MJ/yr} \times \$0.02/\text{MJ}}{0.9} = \$440,000/\text{yr} \quad <$$

**COMMENTS:** (1) With  $C_c = C_h$ , the temperature changes are the same for the two fluids, (2) A larger effectiveness and hence a smaller value of  $A$  can be achieved with a counterflow exchanger (compare Figs. 11.11 and 11.12 for  $C_r = 1$ ), (c) The savings are significant and well worth the cost of the heat exchanger. An additional benefit is that, with  $T_{h,o}$  reduced from 70 to 37.5°C, less energy is consumed by the refrigeration system used to restore the milk temperature to 5°C.

## PROBLEM 11.29

**KNOWN:** Twin-tube counterflow heat exchanger with balanced flow rates,  $\dot{m}_h = 0.003 \text{ kg/s}$ . Cold airstream enters at 280 K and must be heated to 340 K. Maximum allowable pressure drop of cold airstream is 10 kPa.

**FIND:** (a) Tube diameter  $D$  and length  $L$  which satisfies the heat transfer and pressure drop requirements, and (b) Compute and plot the cold stream outlet temperature  $T_{c,o}$ , the heat rate  $q$ , and pressure drop  $\Delta p$  as a function of the balanced flow rate from 0.002 to 0.004 kg/s.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Negligible heat loss to surroundings, (3) Average pressure of the airstreams is 1 atm, (4) Tube walls act as fins with 100% efficiency, (4) Fully developed flow.

**PROPERTIES:** Table A.4, Air ( $\bar{T}_m = 310 \text{ K}$ , 1 atm):  $\rho = 1.128 \text{ kg/m}^3$ ,  $c_p = 1007 \text{ J/kg}\cdot\text{K}$ ,  $\mu = 18.93 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $k = 0.0270 \text{ W/m}\cdot\text{K}$ ,  $Pr = 0.7056$ .

**ANALYSIS:** (a) The heat exchanger diameter  $D$  and length  $L$  can be specified through two analyses: (1) heat transfer based upon the effectiveness-NTU method to meet the cold air heating requirement and (2) pressure drop calculation to meet the requirement of 10 kPa. The *heat transfer analysis* begins by determining the effectiveness from Eq. 11.21, since  $C_{\min} = C_{\max}$  and  $C_r = 1$ ,

$$\varepsilon = \frac{q}{q_{\max}} = \frac{C(T_{c,o} - T_{c,i})}{C(T_{h,i} - T_{c,i})} = \frac{(340 - 280) \text{ K}}{(360 - 280) \text{ K}} = 0.750 \quad (1)$$

From Table 11.4, Eq. 11.29b for  $C_r = 1$ ,

$$NTU = \frac{\varepsilon}{1 - \varepsilon} = \frac{0.750}{1 - 0.750} = 3 \quad (2)$$

where NTU, following its definition, Eq. 11.24, is

$$NTU = \frac{\bar{U}A}{C_{\min}} \quad (3)$$

with

$$C_{\min} = \dot{m}c_p = 0.003 \text{ kg/s} \times 1007 \text{ J/kg}\cdot\text{K} = 3.021 \text{ K/W} \quad (4)$$

Continued...

**PROBLEM 11.29 (Cont.)**

and  $1/\bar{U}A$  represents the thermal resistance between the two fluids at  $T_{m,h}$  and  $T_{m,c}$  as illustrated in the above-right schematic. Since the tube walls are isothermal, it follows that

$$1/UA = 1/\bar{h}_c A + 1/\bar{h}_h A \quad (5)$$

and since the flow conditions are nearly identical  $\bar{h}_c = \bar{h}_h$  so that

$$U = 0.5\bar{h} \quad (6)$$

where the heat transfer area is

$$A = \pi DL \quad (7)$$

This is a consequence of the assumption that the walls act as fins with 100% efficiency. Hence, Eq. (3) can now be expressed as

$$3 = \frac{0.5\bar{h}(\pi DL)}{3.021 \text{ K/W}}$$

$$\bar{h}DL = 5.7697 \quad (8)$$

Assuming an average mean temperature  $\bar{T}_{m,c} = 310 \text{ K}$ , characterize the flow with

$$\text{Re}_D = \frac{4\dot{m}}{\pi D \mu} = \frac{4 \times 0.003 \text{ kg/s}}{\pi \times D \times 18.93 \times 10^{-6} \text{ m}^2/\text{s}} = \frac{201.78}{D} \quad (9)$$

and assuming the flow is both turbulent and fully developed using the Dittus-Boelter, Eq. 8.60,

$$\frac{\bar{h}D}{k} = 0.023 \text{Re}_D^{0.8} \text{Pr}^{0.4}$$

$$\bar{h}D = 0.023 \times 0.0270 \text{ W/m} \cdot \text{K} (201.78/D)^{0.8} (0.7056)^{0.4}$$

$$\bar{h}D^{1.8} = 0.0377 \quad (10)$$

Note that the heating condition has been selected ( $n = 0.4$ ) for both streams, as an estimate.

The *pressure drop* for fully developed flow, Eq. 8.22a, is

$$\Delta p = f \frac{\rho u_m^2 L}{2D} \quad (11)$$

where the mean velocity is  $u_m = \dot{m}/(\rho\pi D^2/4)$  so that

$$\Delta p = f \frac{\rho \left(4\dot{m}/\rho\pi D^2\right)^2 L}{2D} = \frac{8}{\pi^2} f \frac{\dot{m}^2 L}{\rho D^5}$$

$$\Delta p = \frac{8}{\pi^2} f \frac{(0.003 \text{ kg/s})^2 L}{(1.128 \text{ kg/m}^3) D^5} = 6.467 \times 10^{-6} f L D^{-5} \quad (12)$$

Recall that the pressure drop requirement is  $\Delta p = 10 \text{ kPa} = 10^4 \text{ N/m}^2$ , so that Eq. (12) can be rewritten as

$$f L D^{-5} = 1.546 \times 10^9 \quad (13)$$

Continued...

### PROBLEM 11.29 (Cont.)

For the Reynolds number range,  $3000 \leq \text{Re}_D \leq 5 \times 10^6$ , Eq. 8.21 provides an estimate for the friction factor,

$$f = \left[ (0.790 \ln(\text{Re}_D) - 1.64) \right]^{-2}$$

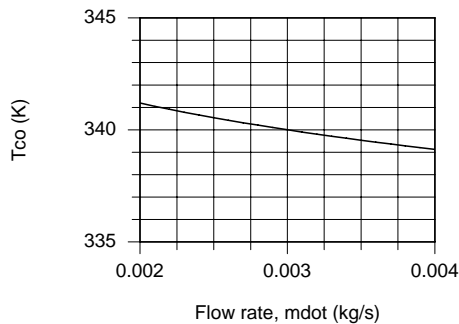

$$f = \left[ (0.790 \ln(201.78/D) - 1.64) \right]^{-2} \quad (14)$$

In the foregoing analysis, there are 4 unknowns ( $D$ ,  $L$ ,  $f$ ,  $\bar{h}$ ) and 4 equations (8, 10, 13, 14). Using the IHT workspace, find

$$D = 9.0 \text{ mm} \quad L = 3.5 \text{ m} \quad f = 0.0254 \quad \bar{h} = 183 \text{ W/m}^2 \cdot \text{K}$$

For this configuration,  $\text{Re}_D = 22,500$  so the flow is turbulent and since  $L/D = 3.5/0.0090 = 390 \gg 10$ , the fully developed assumption is reasonable.

(b) The foregoing analysis entered into the IHT workspace was used to determine  $T_{c,o}$ ,  $q$  and  $\Delta p$  as a function of the balanced flow rate,  $\dot{m}$ .

The outlet temperature of the cold air,  $T_{c,o}$ , is nearly insensitive to the flow rate. It follows that the heat rate,  $q$ , must be nearly proportional to the flow rate as can be seen in the  $q$  vs.  $\dot{m}$  plot above. The pressure drop varies with the mean velocity squared.

### PROBLEM 11.30

**KNOWN:** Dimensions and thermal conductivity of twin-tube, counterflow heat exchanger. Contact resistance between tubes. Air inlet conditions for one tube and pressure of saturated steam in other tube.

**FIND:** Air outlet temperature and condensation rate.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat exchange with surroundings, (2) Fully developed air flow, (3) Negligible fouling, (4) Constant properties.

**PROPERTIES:** Table A-4, air ( $\bar{T}_c \approx 325 \text{ K}$ ,  $p = 5 \text{ atm}$ ):  $c_p = 1008 \text{ J/kg}\cdot\text{K}$ ,  $\mu = 196.4 \times 10^{-7}$

$\text{N}\cdot\text{s/m}^2$ ,  $k = 0.0281 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.703$ . Table A-6, sat. steam ( $p = 2.455 \text{ bar}$ ):  $T_{h,i} = T_{h,o} = 400 \text{ K}$ ,  $h_{fg} = 2183 \text{ kJ/kg}$ .

**ANALYSIS:** With  $C_{\max} \rightarrow \infty$ ,  $C_r = 0$  and Eqs. 11.21 and 11.35a yield

$$\varepsilon = \frac{T_{c,o} - T_{c,i}}{T_{h,i} - T_{c,i}} = 1 - \exp(-\text{NTU}) \quad (1)$$

From Eq. 11.1,

$$\frac{1}{UA} = \frac{1}{(\eta_o hA)_c} + \frac{R'_t}{L} + \frac{1}{(\eta_o hA)_h} \quad (2)$$

With  $\text{Re}_D = 4\dot{m}/\pi D_i \mu = 0.12 \text{ kg/s}/\pi(0.05\text{m})196.4 \times 10^{-7} \text{ N}\cdot\text{s/m}^2 = 38,900$ , the air flow is turbulent and the Dittus-Boelter correlation yields

$$h_c \approx h_{fD} = \left(\frac{k}{D_i}\right) 0.023 \text{Re}_D^{4/5} \text{Pr}^{0.4} = \left(\frac{0.0281 \text{ W/m}\cdot\text{K}}{0.05\text{m}}\right) 0.023(38,900)^{4/5} (0.703)^{0.4} = 52.7 \text{ W/m}^2 \cdot \text{K}$$

As shown on the inset, each tube wall may be modelled as two fins, each of length  $L_f \approx \pi D_i/2 = 0.0785\text{m}$ . The total surface area for heat transfer is  $A_t = \pi D_i L = 0.785 \text{ m}^2 = A_c$ , which is equivalent to the surface area of the fins. With  $NA_f = A_t$  from Eq. 3.102,  $\eta_o = \eta_f$ . Because the outer surface of the tube is insulated, a wall thickness of  $2t$  must be used in evaluating  $\eta_f$ . With  $m = (2h/k \times 2t)^{1/2} = (h/kt)^{1/2} = [52.7 \text{ W/m}^2 \cdot \text{K}/(60 \text{ W/m}\cdot\text{K} \times 0.004\text{m})]^{1/2} = 14.8 \text{ m}^{-1}$ ,  $L_c = L_f$  for an adiabatic tip, and  $mL_f = 1.163$ , Eq. 3.92 yields

$$\eta_f = \frac{\tanh mL_f}{mL_f} = \frac{0.821}{1.163} = 0.706 = \eta_{o,c}$$

Continued ...

### PROBLEM 11.30 (Cont.)

Similarly, for the steam tube,  $m = (h/kt)^{1/2} = [5,000 \text{ W/m}^2 \cdot \text{K}/(60 \text{ W/m} \cdot \text{K} \times 0.004\text{m})]^{1/2} = 144.3 \text{ m}^{-1}$  and  $mL_f = 11.33$ . Hence,

$$\eta_f = \frac{\tanh mL_f}{mL_f} = \frac{1.00}{11.33} = 0.088 = \eta_{o,h}$$

Substituting into Eq. (2),

$$UA = \left[ \frac{1}{0.706 \times 52.7 \times 0.785} + \frac{0.01}{5} + \frac{1}{0.088 \times 5000 \times 0.785} \right]^{-1} \frac{\text{W}}{\text{K}} = 25.6 \frac{\text{W}}{\text{K}}$$

Hence, with  $C_{\min} = (\dot{m} c_p)_c = 0.03 \text{ kg/s} \times 1008 \text{ J/kg} \cdot \text{K} = 30.2 \text{ W/K}$ ,  $NTU = UA/C_{\min} = 0.847$  and  $\varepsilon = 1 - \exp(-NTU) = 0.571$ . From Eq. (1), the air outlet temperature is then

$$T_{c,o} = T_{c,i} + \varepsilon(T_{h,i} - T_{c,i}) = 17^\circ\text{C} + 0.571(127 - 17)^\circ\text{C} = 79.8^\circ\text{C} \quad <$$

The rate of heat transfer to the air is

$$q = \dot{m} c_p (T_{c,o} - T_{c,i}) = 0.03 \text{ kg/s} \times 1008 \text{ J/kg} \cdot \text{K} \times 62.8^\circ\text{C} = 1900 \text{ W}$$

and the rate of condensation is

$$\dot{m}_{\text{cond}} = \frac{q}{h_{fg}} = \frac{1900 \text{ W}}{2.183 \times 10^6 \text{ J/kg}} = 8.70 \times 10^{-4} \text{ kg/s} \quad <$$

**COMMENTS:** (1) With  $\bar{T}_c = 321.4 \text{ K}$ , the initial estimate of  $325 \text{ K}$  is reasonable and iteration on the property values is not necessary, (2) The major contribution to the total thermal resistance is due to air-side convection, (3) The foregoing results are independent of air pressure.

### PROBLEM 11.31

**KNOWN:** Tube inner and outer diameters and longitudinal and transverse pitches for a cross-flow heat exchanger. Number of tubes in transverse plane. Water and gas flow rates and inlet temperatures. Water outlet temperature.

**FIND:** (a) Gas outlet temperature and number of longitudinal tube rows, (b) Effect of gas flowrate and inlet temperature on fluid outlet temperatures.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat loss to surroundings, (2) Constant properties, (3) Negligible fouling.

**PROPERTIES:** Table A.6, Water ( $\bar{T}_c = 320$  K):  $c_p = 4180$  J/kg·K,  $\mu = 577 \times 10^{-6}$  N·s/m<sup>2</sup>,  $k_f = 0.640$  W/m·K,  $Pr = 3.77$ ; Table A.4, Air ( $\bar{T}_h \approx 550$  K):  $c_p = 1040$  J/kg·K,  $\mu = 288.4 \times 10^{-7}$  N·s/m<sup>2</sup>,  $k = 0.0439$  W/m·K,  $Pr = 0.683$ ,  $\rho = 0.633$  kg/m<sup>3</sup>.

**ANALYSIS:** (a) The required heat transfer rate is

$$q = \dot{m}_c c_{p,c} (T_{c,o} - T_{c,i}) = 50 \text{ kg/s} (4180 \text{ J/kg} \cdot \text{K}) 60 \text{ K} = 1.254 \times 10^7 \text{ W}.$$

Hence, with  $T_{h,o} = T_{h,i} - q/\dot{m}_h c_{p,h}$ ,

$$T_{h,o} = 700 \text{ K} - 1.254 \times 10^7 \text{ W} / (40 \text{ kg/s} \times 1040 \text{ J/kg} \cdot \text{K}) = 398.6 \text{ K} \quad <$$

Use the  $\epsilon$ -NTU method to compute the hot side HX surface area,  $A_H$ . To calculate  $U_h$ , we must find  $h_h$ .

For the tube bank,  $S_D = 44.7 \text{ mm} > (S_T + D)/2 = 30 \text{ mm}$ . Hence, with  $\rho V_{\max} = [S_T / (S_T - D_o)] \rho V = [S_T / (S_T - D_o)] (\dot{m}_h / WH)$ ,

$$\rho V_{\max} = (40/20) \left[ 40 \text{ kg/s} / (2 \times 1.2) \text{ m}^2 \right] = 33.3 \text{ kg/s} \cdot \text{m}^2$$

$$Re_{D,\max} = (\rho V_{\max} D_o) / \mu = \left[ 33.3 \text{ kg/s} \cdot \text{m}^2 (0.02 \text{ m}) \right] / 288.4 \times 10^{-7} \text{ N} \cdot \text{s/m}^2 = 23,116.$$

From the Zukauskas correlation, with  $(Pr/Pr_s) \approx 1$ , and Table 7.5,

$$\overline{Nu}_D = 0.35 Re_D^{0.6} Pr^{0.36} = 0.35 (23,116)^{0.6} (0.683)^{0.36} = 127$$

where it is assumed that  $N_L > 20$ . Hence,

$$h_h = \overline{Nu}_D (k/D_o) = 127 (0.0439 \text{ W/m} \cdot \text{K} / 0.02 \text{ m}) = 279 \text{ W/m}^2 \cdot \text{K}.$$

From Eq. 11.1,

Continued...

**PROBLEM 11.31 (Cont.)**

$$\frac{1}{U_h} = \frac{1}{h_c} \frac{D_o}{D_i} + \frac{D_o \ln(D_o/D_i)}{2k} + \frac{1}{h_h} = \frac{1}{3000 \text{ W/m}^2 \cdot \text{K}} \frac{20}{15} + \frac{0.02 \text{ m} \ln(20/15)}{60 \text{ W/m} \cdot \text{K}} + \frac{1}{279 \text{ W/m}^2 \cdot \text{K}}$$

$$\frac{1}{U_h} = \left( 4.44 \times 10^{-4} + 9.59 \times 10^{-5} + 3.58 \times 10^{-3} \right) \text{ m}^2 \cdot \text{K/W} = 4.12 \times 10^{-3} \text{ m}^2 \cdot \text{K/W}$$

$$U_h = 243 \text{ W/m}^2 \cdot \text{K}.$$

With  $C_h = C_{\min} = 4.160 \times 10^4 \text{ W/K}$  and  $C_c = C_{\max} = 2.09 \times 10^5 \text{ W/K}$ ,  $C_{\min}/C_{\max} = 0.199$  and  $q_{\max} = C_{\min}(T_{h,i} - T_{c,i}) = 4.16 \times 10^4 \text{ W/K}(410 \text{ K}) = 1.71 \times 10^7 \text{ W}$ . Hence,  $\epsilon = (q/q_{\max}) = (1.254 \times 10^7 \text{ W}/1.71 \times 10^7 \text{ W}) = 0.735$ . With  $C_{\min}$  mixed and  $C_{\max}$  unmixed, Eq. 11.34b gives  $\text{NTU} = 1.54$  and

$$A_h = \text{NTU}(C_{\min}/U_h) = 1.54 \left( 4.160 \times 10^4 \text{ W/K} / 243 \text{ W/m}^2 \cdot \text{K} \right) = 264 \text{ m}^2.$$

$$\text{Hence, } N_L = \frac{A_h}{(\pi D_o W) N_T} = \frac{264 \text{ m}^2}{\pi (0.02) 2(30) \text{ m}^2} = 70$$

(b) Using the IHT *Correlations, Heat Exchangers* and *Properties* Toolpads to perform the parametric calculations, we obtain the following results for  $N_L = 90$ .

Since  $h_h$ , and hence  $U_h$ , increases with  $\dot{m}_h$ ,  $q$ , and hence,  $T_{c,o}$ , increases with increasing  $\dot{m}_h$ , as well as with increasing  $T_{h,i}$ . Although  $q$  increases with  $\dot{m}_h$ , the proportionality is not linear ( $q \propto \dot{m}_h^a$ , where  $a < 1$ ) and  $(T_{h,i} - T_{h,o})$  must decrease with increasing  $\dot{m}_h$ , in which case  $T_{h,o}$  must increase. From the above results, it is clear that operation is restricted to  $\dot{m}_h \geq 40 \text{ kg/s}$  and  $T_{h,i} \geq 700 \text{ K}$ , if corrosion of the heat exchanger surfaces is to be avoided.

**COMMENTS:** To check the presumed value of  $h_c = 3000 \text{ W/m}^2 \cdot \text{K}$ , compute

$$\text{Re}_D = \frac{4(\dot{m}_c/N)}{\pi D_i \mu} = \frac{4(50 \text{ kg/s})/70 \times 30}{\pi (0.015 \text{ m}) 577 \times 10^{-6} \text{ N} \cdot \text{s/m}^2} = 3500.$$

$$\text{Hence, } \text{Nu}_D = 0.023 \text{Re}_D^{4/5} \text{Pr}^{0.4} = 0.023(3500)^{4/5} (3.77)^{0.4} = 26.8$$

$$h_c = (k/D) \text{Nu}_D = (0.640 \text{ W/m} \cdot \text{K} / 0.015 \text{ m}) 26.8 = 1142 \text{ W/m}^2 \cdot \text{K}.$$

Hence, the cold side convection coefficient has been overestimated and the calculations should be repeated using a value of  $h_c$  calculated from the Gnielinski correlation, which applies in this Reynolds number range.

### PROBLEM 11.32

**KNOWN:** Single pass, cross-flow heat exchanger with hot exhaust gases (mixed) to heat water (unmixed)

**FIND:** Required surface area.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat loss to surroundings, (2) Exhaust gas properties assumed to be those of air.

**PROPERTIES:** Table A-6, Water ( $\bar{T}_c = (80 + 30)^\circ\text{C}/2 = 328\text{ K}$ ):  $c_p = 4184\text{ J/kg}\cdot\text{K}$ ; Table A-4, Air (1 atm,  $\bar{T}_h = (100 + 225)^\circ\text{C}/2 = 436\text{ K}$ ):  $c_p = 1019\text{ J/kg}\cdot\text{K}$ .

**ANALYSIS:** Using the  $\epsilon$ -NTU method,

$$C_c = \dot{m}_c c_c = 3\text{ kg/s} \times 4184\text{ J/kg}\cdot\text{K} = 12,552\text{ W/K}$$

$$q = C_c (T_{c,o} - T_{c,i}) = 12,552\text{ W/K} (80 - 30)^\circ\text{C} = 627,600\text{ W}$$

From an energy balance on the hot fluid,

$$C_h = q / (T_{h,i} - T_{h,o}) = 627,600\text{ W} / (225 - 100)^\circ\text{C} = 5,021\text{ W/K}$$

Thus,  $C_r = C_{\min} / C_{\max} = 0.40$  and  $\epsilon = q / C_{\min} (T_{h,i} - T_{c,i}) = 0.641$ . With  $C_{\min}$  mixed and  $C_{\max}$  unmixed, Eq. 11.34b yields

$$\text{NTU} = -\frac{1}{C_r} \ln [C_r \ln(1 - \epsilon) + 1] = -\frac{1}{0.4} \ln [0.4 \ln(1 - 0.641) + 1] = 1.32$$

Thus,

$$A = \text{NTU} \times C_{\min} / U = 1.32 \times 5021\text{ W/K} / 200\text{ W/m}^2\cdot\text{K} = 33.1\text{ m}^2$$

<

### PROBLEM 11.33

**KNOWN:** Concentric tube heat exchanger operating in parallel flow (PF) conditions with a thin-walled separator tube of 100-mm diameter; fluid conditions as specified.

**FIND:** (a) Required length for the exchanger; (b) Convection coefficient for water flow, assumed to be fully developed; (c) Compute and plot the heat transfer rate,  $q$ , and fluid inlet temperatures,  $T_{h,o}$  and  $T_{c,o}$ , as a function of the tube length for  $60 \leq L \leq 400$  m with the PF arrangement and overall coefficient ( $U = 200 \text{ W/m}^2 \cdot \text{K}$ ), inlet temperatures ( $T_{h,i} = 225^\circ\text{C}$  and  $T_{c,i} = 30^\circ\text{C}$ ), and fluid flow rates from Problem 11.32; (d) Reduction in required length relative to the value found in part (a) if the exchanger were operated in the counterflow (CF) arrangement; and (e) Compute and plot the effectiveness and fluid outlet temperatures as a function of tube length for  $60 \leq L \leq 400$  m for the CF arrangement of part (c).

**SCHEMATIC:**

**ASSUMPTIONS:** (1) No losses to surroundings, (2) Separation tube has negligible thermal resistance, (3) Water flow is fully developed, (4) Constant properties, (5) Exhaust gas properties are those of atmospheric air.

**PROPERTIES:** Table A-4, Hot fluid, Air (1 atm,  $\bar{T} = (225 + 100)^\circ\text{C} / 2 = 436 \text{ K}$ ):  $c_p = 1019 \text{ J/kg}\cdot\text{K}$ ; Table A-6, Cold fluid, Water  $\bar{T} = (30 + 80)^\circ\text{C} / 2 \approx 328 \text{ K}$ :  $\rho = 1/v_f = 985.4 \text{ kg/m}^3$ ,  $c_p = 4183 \text{ J/kg}\cdot\text{K}$ ,  $k = 0.648 \text{ W/m}\cdot\text{K}$ ,  $\mu = 505 \times 10^{-6} \text{ N}\cdot\text{s/m}^2$ ,  $\text{Pr} = 3.58$ .

**ANALYSIS:** (a) From the rate equation, Eq. 11.14, with  $A = \pi DL$ , the length of the exchanger is

$$L = q / U \cdot \pi D \cdot \Delta T_{\ell m, \text{PF}} \quad (1)$$

The heat rate follows from an energy balance on the cold fluid, using Eq. 11.7, find

$$q = \dot{m}_c c_c (T_{c,o} - T_{c,i}) = 3 \text{ kg/s} \times 4183 \text{ J/kg}\cdot\text{K} (80 - 30) \text{ K} = 627.5 \times 10^3 \text{ W}.$$

Using an energy balance on the hot fluid, find  $\dot{m}_h$  for later use.

$$\dot{m}_h = q / c_h (T_{h,i} - T_{h,o}) = 627.5 \times 10^3 \text{ W} / 1019 \text{ J/kg}\cdot\text{K} (225 - 100) \text{ K} = 4.93 \text{ kg/s} \quad (2)$$

For parallel flow, Eqs. 11.15 and 11.16,

$$\Delta T_{\ell m, \text{PF}} = \frac{\Delta T_1 - \Delta T_2}{\ln \Delta T_1 / \Delta T_2} = \frac{(225 - 30)^\circ\text{C} - (100 - 80)^\circ\text{C}}{\ln(225 - 30) / (100 - 80)} = 76.8^\circ\text{C}.$$

Substituting numerical values into Eq. (1), find

$$L = 627.5 \times 10^3 \text{ W} / 200 \text{ W/m}^2 \cdot \text{K} (\pi \times 0.1 \text{ m}) 76.8 \text{ K} = 130 \text{ m}.$$

<

Continued...

### PROBLEM 11.33 (Cont.)

(b) Considering the water flow within the separator tube, from Eq. 8.6,

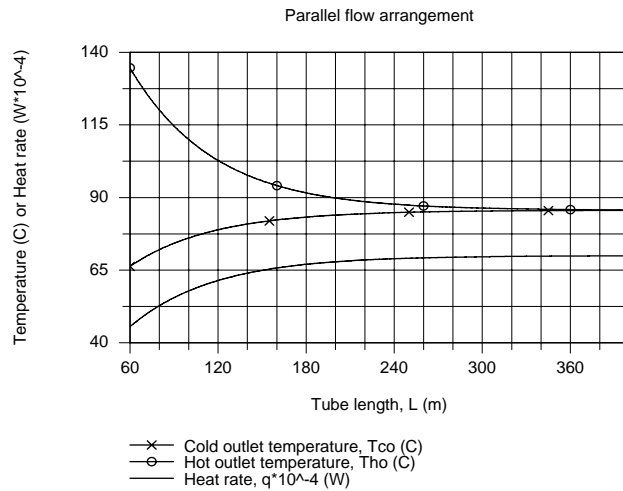

$$Re_D = 4\dot{m}/\pi D\mu = 4 \times 3 \text{ kg/s} / \left( \pi \times 0.1 \text{ m} \times 505 \times 10^{-6} \text{ N/s} \cdot \text{m}^2 \right) = 75,638.$$

Since  $Re_D > 2300$ , the flow is turbulent and since flow is assumed to be fully developed, use the Dittus-Boelter correlation with  $n = 0.4$  for heating,

$$Nu_D = 0.023 Re_D^{0.8} Pr^{0.4} = 0.023 (75,638)^{0.8} (3.58)^{0.4} = 306.4$$

$$h = Nu_D \frac{k}{D} = 306.4 \times 0.648 \text{ W/m} \cdot \text{K} / (0.1 \text{ m}) = 1985 \text{ W/m}^2 \cdot \text{K}.$$

(c) Using the *IHT Heat Exchanger Tool, Concentric Tube, Parallel Flow, Effectiveness relation*, and the *Properties Tool for Water and Air*, a model was developed for the PF arrangement. With  $U = 200 \text{ W/m}^2 \cdot \text{K}$  and prescribed inlet temperatures,  $T_{h,i} = 225^\circ\text{C}$  and  $T_{c,i} = 30^\circ\text{C}$ , the outlet temperatures,  $T_{h,o}$  and  $T_{c,o}$  and heat rate,  $q$ , were computed as a function of tube length  $L$ .

As the tube length increases, the outlet temperatures approach one another and eventually reach  $T_{h,o} = T_{c,o} = 85.6^\circ\text{C}$ .

(d) If the exchanger as for part (a) is operated in counterflow (rather than parallel flow), the log mean temperature difference is

$$\Delta T_{\ell m, CF} = \frac{\Delta T_1 - \Delta T_2}{\ln \Delta T_1 / \Delta T_2}$$

$$\Delta T_{\ell m, CF} = \frac{(225 - 80) - (100 - 30)}{\ln(225 - 80) / (100 - 30)} = 103.0^\circ\text{C}.$$

Using Eq. (1), the required length is

$$L = 627.5 \times 10^3 \text{ W} / 200 \text{ W/m}^2 \cdot \text{K} \times \pi \times 0.1 \text{ m} \times 103.0 \text{ K} = 97 \text{ m}.$$

The reduction in required length of CF relative to PF operation is

Continued...

### PROBLEM 11.33 (Cont.)

$$\Delta L = (L_{PF} - L_{CF}) / L_{PF} = (103 - 97) / 103 = 5.8\%$$

<

(e) Using the *IHT Heat Exchanger Tool, Concentric Tube, Counterflow, Effectiveness relation*, and the *Properties Tool for Water and Air*, a model was developed for the CF arrangement. For the same conditions as part (c), but CF rather than PF, the effectiveness and fluid outlet temperatures were computed as a function of tube length  $L$ .

Note that as the length increases, the effectiveness tends toward unity, and the hot fluid outlet temperature tends toward  $T_{c,i} = 30^\circ\text{C}$ . Remember the heat rate for an infinitely long CF heat exchanger is  $q_{\max}$  and the minimum fluid (hot in our case) experiences the temperature change,  $T_{h,i} - T_{c,i}$ .

**COMMENTS:** (1) As anticipated, the required length for CF operations was less than for PF operation.

(2) Note that  $U$  is substantially less than  $h_i$  implying that the gas-side coefficient must be the controlling thermal resistance.

### PROBLEM 11.34

**KNOWN:** Heat exchanger in car operating between warm radiator fluid and cooler outside air. Effectiveness of heater is  $\varepsilon \sim \dot{m}_{\text{air}}^{-0.2}$  since water flow rate is large compared to that of the air. For low-speed fan condition, heater warms outdoor air from  $0^\circ\text{C}$  to  $30^\circ\text{C}$ .

**FIND:** (a) Increase in heat added to car for high-speed fan condition causing  $\dot{m}_{\text{air}}$  to be doubled while inlet temperatures remain the same, and (b) Air outlet temperature for medium-speed fan condition where air flow rate increases 50% and heat transfer increases 20%.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat losses from heat exchanger to surroundings, (2)  $T_{h,i}$  and  $T_{c,i}$  remain fixed for all fan-speed conditions, (3) Water flow rate is much larger than that of air.

**ANALYSIS:** (a) Assuming the flow rate of the water is much larger than that of air,

$$C_{\min} = C_c = \dot{m}_{\text{air}} c_{p,c}$$

Hence, the heat rate can be written as

$$q = \varepsilon q_{\max} = \varepsilon C_{\min} (T_{h,i} - T_{c,i}) = \varepsilon \cdot \dot{m}_{\text{air}} c_{p,\text{air}} (T_{h,i} - T_{c,i})$$

Taking the ratio of the heat rates for the high and low speed fan conditions, find

$$\frac{q_{\text{hi}}}{q_{\text{lo}}} = \frac{(\varepsilon \dot{m}_{\text{air}})_{\text{hi}}}{(\varepsilon \dot{m}_{\text{air}})_{\text{lo}}} = \frac{(\dot{m}_{\text{air}}^{0.8})_{\text{hi}}}{(\dot{m}_{\text{air}}^{0.8})_{\text{lo}}} = 2^{0.8} = 1.74 \quad <$$

where we have used  $\varepsilon \sim \dot{m}_{\text{air}}^{-0.2}$  and recognized that for the high speed fan condition, the air flow rate is doubled. Hence the heat rate is increased by 74%.

(b) Considering the medium and low speed conditions, it was observed that,

$$\frac{q_{\text{med}}}{q_{\text{lo}}} = 1.2 \quad \frac{(\dot{m}_{\text{air}})_{\text{med}}}{(\dot{m}_{\text{air}})_{\text{lo}}} = 1.5$$

To find the outlet air temperature for the medium speed condition,

$$\frac{q_{\text{med}}}{q_{\text{lo}}} = \frac{[\dot{m}_{\text{air}} c_{p,c} (T_{c,o} - T_{c,i})]_{\text{med}}}{[\dot{m}_{\text{air}} c_{p,c} (T_{c,o} - T_{c,i})]_{\text{lo}}}$$

$$1.2 = \frac{1.5 (T_{c,o} - 0^\circ\text{C})}{(30 - 0^\circ\text{C})} \quad T_{c,o} = 24^\circ\text{C} \quad <$$

### PROBLEM 11.35

**KNOWN:** Counterflow heat exchanger formed by two brazed tubes with prescribed hot and cold fluid inlet temperatures and flow rates.

**FIND:** Outlet temperature of the air.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible loss/gain from tubes to surroundings, (2) Flow in tubes is fully developed since  $L/D_h = 40 \text{ m}/0.030 \text{ m} = 1333$ .

**PROPERTIES:** Table A-6, Water ( $\bar{T}_h = 335 \text{ K}$ ):  $c_h = c_{p,h} = 4186 \text{ J/kg}\cdot\text{K}$ ,  $\mu = 453 \times 10^{-6} \text{ N}\cdot\text{s/m}^2$ ,  $k = 0.656 \text{ W/m}\cdot\text{K}$ ,  $Pr = 2.88$ ; Table A-4, Air (300 K):  $c_c = c_{p,c} = 1007 \text{ J/kg}\cdot\text{K}$ ,  $\mu = 184.6 \times 10^{-7} \text{ N}\cdot\text{s/m}^2$ ,  $k = 0.0263 \text{ W/m}\cdot\text{K}$ ,  $Pr = 0.707$ ; Table A-1, Nickel ( $\bar{T} = (23 + 85)^\circ\text{C}/2 = 327 \text{ K}$ ):  $k = 88 \text{ W/m}\cdot\text{K}$ .

**ANALYSIS:** Using the NTU -  $\epsilon$  method, from Eq. 11.28a,

$$\epsilon = \frac{1 - \exp[-NTU(1 - C_r)]}{1 - C_r \exp[-NTU(1 - C_r)]} \quad NTU = UA / C_{\min} \quad C_r = C_{\min} / C_{\max} \quad (1,2,3)$$

Estimate UA from a model of the tubes and flows, and determine the outlet temperature from the expression

$$\epsilon = C_c (T_{c,o} - T_{c,i}) / C_{\min} (T_{h,i} - T_{c,i}) \quad (4)$$

$$\text{Water-side:} \quad Re_D = \frac{4\dot{m}_h}{\pi D \mu} = \frac{4 \times 0.04 \text{ kg/s}}{\pi \times 0.010 \text{ m} \times 453 \times 10^{-6} \text{ N}\cdot\text{s/m}^2} = 11,243.$$

The flow is turbulent and since fully developed, use the Dittus-Boelter correlation,

$$\overline{Nu}_h = \bar{h}_h D / k = 0.023 Re_D^{0.8} Pr^{0.3} = 0.023 (11,243)^{0.8} (2.88)^{0.3} = 54.99$$

$$\bar{h}_h = 54.99 \times 0.656 \text{ W/m}\cdot\text{K} / 0.01 \text{ m} = 3,607 \text{ W/m}^2 \cdot \text{K}.$$

$$\text{Air-side:} \quad Re_D = \frac{4\dot{m}_c}{\pi D \mu} = \frac{4 \times 0.120 \text{ kg/s}}{\pi \times 0.030 \text{ m} \times 184.6 \times 10^{-7} \text{ N}\cdot\text{s/m}^2} = 275,890.$$

The flow is turbulent and since fully developed, again use the correlation

$$\overline{Nu}_c = \bar{h}_c D / k = 0.023 Re_D^{0.8} Pr^{0.4} = 0.023 (275,890)^{0.8} (0.707)^{0.4} = 450.9$$

$$\bar{h}_c = 450.9 \times 0.0263 \text{ W/m}\cdot\text{K} / 0.030 \text{ m} = 395.3 \text{ W/m}^2 \cdot \text{K}.$$

**Overall coefficient:** From Eq. 11.1, considering the temperature effectiveness of the tube walls and the thermal conductance across the brazed region,

Continued ...

**PROBLEM 11.35 (Cont.)**

$$\frac{1}{UA} = \frac{1}{(\eta_o hA)_h} + \frac{1}{K'_t L} + \frac{1}{(\eta_o hA)_c} \quad (5)$$

where  $\eta_o$  needs to be evaluated for each of the tubes. Note that each tube can be viewed as two fins of length  $\pi D/2$ . However, since the fins exchange heat on only one side, they can be combined into a single fin of length  $\pi D/2$  and thickness  $2t$ , exchanging heat on both sides.

*Water-side temperature effectiveness:*  $A_h = \pi D_h L = \pi (0.010\text{m}) 40\text{m} = 1.257\text{m}^2$

$$\eta_{o,h} = \eta_{f,h} = \tanh(mL_h) / mL_h \quad m = (\bar{h}_h P / kA)^{1/2} = (h_h / kt)^{1/2}$$

$$m = \left( 3607 \text{ W/m}^2 \cdot \text{K} / 88 \text{ W/m} \cdot \text{K} \times 0.002\text{m} \right)^{1/2} = 143.2 \text{ m}^{-1}$$

and with  $L_h = 0.5 \pi D_h$ ,  $\eta_{o,h} = \tanh(143.2 \text{ m}^{-1} \times 0.5 \pi \times 0.010\text{m}) / 143.2 \text{ m}^{-1} \times 0.5 \pi \times 0.010 \text{m} = 0.435$ .

*Air-side temperature effectiveness:*  $A_c = \pi D_c L = \pi (0.030\text{m}) 40\text{m} = 3.770\text{m}^2$

$$\eta_{o,c} = \eta_{f,c} = \tanh(mL_c) / mL_c \quad m = \left( 395.3 \text{ W/m}^2 \cdot \text{K} / 88 \text{ W/m} \cdot \text{K} \times 0.002\text{m} \right)^{1/2} = 47.39 \text{ m}^{-1}$$

and with  $L_c = 0.5 \pi D_c$ ,  $\eta_{o,c} = \tanh(47.39 \text{ m}^{-1} \times 0.5 \pi \times 0.030\text{m}) / 47.39 \text{ m}^{-1} \times 0.5 \pi \times 0.030\text{m} = 0.438$ .

Hence, the overall heat transfer coefficient using Eq. (5) is

$$\frac{1}{UA} = \frac{1}{0.435 \times 3607 \text{ W/m}^2 \cdot \text{K} \times 1.257\text{m}^2} + \frac{1}{100 \text{ W/m} \cdot \text{K} (40\text{m})} + \frac{1}{0.438 \times 395.3 \text{ W/m}^2 \cdot \text{K} \times 3.770\text{m}^2}$$

$$UA = \left[ 5.070 \times 10^{-4} + 2.50 \times 10^{-4} + 1.533 \times 10^{-3} \right]^{-1} \text{ W/K} = 437 \text{ W/K}.$$

Evaluating now the *heat exchanger effectiveness* from Eq. (1) with

$$\left. \begin{aligned} C_h = \dot{m}_h c_h = 0.040 \text{ kg/s} \times 4186 \text{ J/kg} \cdot \text{K} = 167.4 \text{ W/K} \leftarrow C_{\max} \\ C_c = \dot{m}_c c_c = 0.120 \text{ kg/s} \times 1007 \text{ J/kg} \cdot \text{K} = 120.8 \text{ W/K} \leftarrow C_{\min} \end{aligned} \right\} C_r = C_{\min} / C_{\max} = 0.722$$

$$NTU = \frac{UA}{C_{\min}} = \frac{437 \text{ W/K}}{120.8 \text{ W/K}} = 3.62 \quad \varepsilon = \frac{1 - \exp[-3.62(1 - 0.722)]}{1 - 0.722 \exp[-3.62(1 - 0.722)]} = 0.862$$

and finally from Eq. (4) with  $C_{\min} = C_c$ ,

$$0.862 = \frac{C_c (T_{c,o} - 23^\circ\text{C})}{C_c (85 - 23)^\circ\text{C}} \quad T_{c,o} = 76.4^\circ\text{C} \quad <$$

**COMMENTS:** (1) Using overall energy balances, the water outlet temperature is

$$T_{h,o} = T_{h,i} + (C_c / C_h)(T_{c,o} - T_{c,i}) = 85^\circ\text{C} - 0.722(76.4 - 23)^\circ\text{C} = 46.4^\circ\text{C}.$$

(2) To initially evaluate the properties, we assumed that  $\bar{T}_h \approx 335 \text{ K}$  and  $\bar{T}_c \approx 300 \text{ K}$ . From the calculated values of  $T_{h,o}$  and  $T_{c,o}$ , more appropriate estimates of  $\bar{T}_h$  and  $\bar{T}_c$  are  $338 \text{ K}$  and  $322 \text{ K}$ , respectively. We conclude that proper thermophysical properties were used for water but that the estimates could be improved for air.

## PROBLEM 11.36

**KNOWN:** Air and ammonia flow rates and inlet temperatures. Relationship of  $UA$  product to water flow rate. Water mass flow rates in tubes. Heat exchanger type.

**FIND:** (a) Air and ammonia outlet temperatures and heat transfer rate. (b) Air and ammonia outlet temperatures for water flow rates in the range  $0 \text{ kg/s} \leq \dot{m}_{c,A} = \dot{m}_{h,B} \leq 2 \text{ kg/s}$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat transfer between heat exchangers and surroundings, negligible heat transfer between two heat exchangers, (2) Constant properties, (3) Negligible energy added to the system by the pump.

**PROPERTIES:** Table A.6 (water) ( $\bar{T} = 400 \text{ K}$ ):  $c_p = 4256 \text{ J/kg}\cdot\text{K}$ . Table A.4 (air) ( $\bar{T} = 500 \text{ K}$ ):  $c_p = 1030 \text{ J/kg}\cdot\text{K}$ . Table A.4 (ammonia) ( $\bar{T} = 300 \text{ K}$ ):  $c_p = 2158 \text{ J/kg}\cdot\text{K}$ .

**ANALYSIS:** (a) For heat exchanger A,  $C_{h,A} = 10 \text{ kg/s} \times 1030 \text{ J/kg}\cdot\text{K} = 10,300 \text{ W/K}$ . For heat exchanger B,  $C_{c,B} = 5 \text{ kg/s} \times 2158 \text{ J/kg}\cdot\text{K} = 10790 \text{ W/K}$ . For the water,  $C_{c,A} = C_{h,B} = 1 \text{ kg/s} \times 4256 \text{ J/kg}\cdot\text{K} = 4256 \text{ W/K}$ . Therefore,  $C_{\min,A} = C_{\min,B} = 4256 \text{ W/K}$ . For heat exchanger A,  $UA_A = 6000 \text{ W/K} + 100 \text{ J/kg}\cdot\text{K} \times 1 \text{ kg/s} = 6100 \text{ W/K}$  while for heat exchanger B,  $UA_B = 1.2UA_A = 7320 \text{ W/K}$ . The relative heat rates are  $C_{r,A} = 4256/10,300 = 0.4132$  and  $C_{r,B} = 4256/10,790 = 0.3944$ . The number of transfer units for heat exchanger A is  $NTU_A = 6100/4256 = 1.433$ , while for heat exchanger B  $NTU_B = 7320/4256 = 1.720$ . The effectiveness may be evaluated using Eq. 11.30a resulting in  $\varepsilon_A = 0.6468$ ,  $\varepsilon_B = 0.6966$ .

For heat exchangers A and B, the following equations may be written, making special note that the water temperature is the same between the inlet and outlet of the shell-side of each heat exchanger.

$$q_A = \varepsilon_A C_{\min,A} (T_{h,i,A} - T_{c,i,A}) = 0.6468 \times 4256 \text{ W/K} \times (520 \text{ K} - T_{c,i,A}) \quad (1)$$

$$q_B = \varepsilon_B C_{\min,B} (T_{h,i,B} - T_{c,i,B}) = 0.6966 \times 4256 \text{ W/K} \times (T_{h,i,B} - 280 \text{ K}) \quad (2)$$

$$T_{h,o,A} = T_{h,i,A} - q_A / C_{\max,A} = 520 \text{ K} - q_A / 10300 \text{ W/K} \quad (3)$$

$$T_{c,o,B} = T_{c,i,B} + q_B / C_{\max,B} = 280 \text{ K} + q_B / 10790 \text{ W/K} \quad (4)$$

$$T_{h,i,B} = T_{c,o,A} \quad (5)$$

$$T_{h,o,B} = T_{c,i,A} \quad (6)$$

Equations (1) through (6) may be solved simultaneously to yield

$$q_A = q_B = 5.17 \times 10^5 \text{ W}, T_{h,o,A} = 469.8 \text{ K}, T_{c,o,B} = 327.9 \text{ K}$$

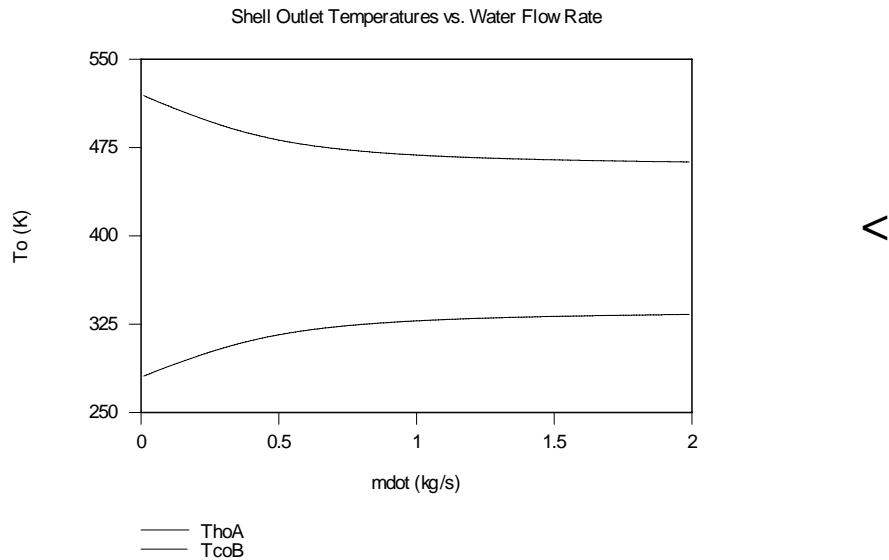

<  
Continued...

### PROBLEM 11.36 (Cont.)

In addition, we note that

$$T_{h,i,B} = T_{c,o,A} = 454.5\text{K} \qquad T_{h,o,B} = T_{c,i,A} = 332.9\text{K}$$

(b) *IHT* was used to solve the preceding equations simultaneously, and to plot the following results.

**COMMENTS:** (1) The *IHT* code used in part (b) is listed below. (2) As evident in part (b), fine-tuning is feasible, but to a limited degree for the conditions of this problem. The capability to fine-tune the device is dependent upon the *UA* values associated with each heat exchanger. Neglecting the dependence of *UA* on the water mass flow rate, the calculations were repeated and the outlet temperatures of the air in heat exchanger A are shown in the plot below.

## PROBLEM 11.37

**KNOWN:** Air and ammonia flow rates and inlet temperatures. Relationship of  $UA$  product to water flow rate. Mass flow rate of water in tubes.

**FIND:** (a) Air and ammonia outlet temperatures and heat transfer rate. (b) Air and ammonia outlet temperatures for water flow rates in the range  $5 \text{ kg/s} \leq \dot{m}_{c,A} = \dot{m}_{h,B} \leq 50 \text{ kg/s}$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat transfer between heat exchangers and surroundings, negligible heat transfer between two heat exchangers, (2) Constant properties.

**PROPERTIES:** Table A.6 (water) ( $\bar{T} = 400 \text{ K}$ ):  $c_p = 4256 \text{ J/kg}\cdot\text{K}$ . Table A.4 (air) ( $\bar{T} = 500 \text{ K}$ ):  $c_p = 1030 \text{ J/kg}\cdot\text{K}$ . Table A.4 (ammonia) ( $\bar{T} = 300 \text{ K}$ ):  $c_p = 2158 \text{ J/kg}\cdot\text{K}$ .

**ANALYSIS:** (a) For heat exchanger A,  $C_{h,A} = 10 \text{ kg/s} \times 1030 \text{ J/kg}\cdot\text{K} = 10,300 \text{ W/K}$ . For heat exchanger B,  $C_{c,B} = 5 \text{ kg/s} \times 2158 \text{ J/kg}\cdot\text{K} = 10,790 \text{ W/K}$ . For the water,  $C_{c,A} = C_{h,B} = 10 \text{ kg/s} \times 4256 \text{ J/kg}\cdot\text{K} = 42,560 \text{ W/K}$ . Therefore,  $C_{\min,A} = 10,300 \text{ W/K}$  and  $C_{\min,B} = 10,790 \text{ W/K}$ . For heat exchanger A,  $UA_A = 6000 \text{ W/K} + 100 \text{ J/kg}\cdot\text{K} \times 10 \text{ kg/s} = 7000 \text{ W/K}$  while for heat exchanger B,  $UA_B = 1.2UA_A = 8400 \text{ W/K}$ . The relative heat rates are  $C_{r,A} = 10,300/42,560 = 0.2420$  and  $C_{r,B} = 10,790/42,560 = 0.2535$ . The number of transfer units for heat exchanger A is  $NTU_A = 7000/10,300 = 0.6796$ , while for heat exchanger B  $NTU_B = 8400/10,790 = 0.779$ . The effectiveness may be evaluated using Eq. 11.30a resulting in  $\varepsilon_A = 0.4647$ ,  $\varepsilon_B = 0.5052$ .

For heat exchangers A and B, we may write the following, making special note that the water temperature is the same between the inlet and outlet of the shell-side of each heat exchanger.

$$q_A = \varepsilon_A C_{\min,A} (T_{h,i,A} - T_{c,i,A}) = 0.4647 \times 10300 \text{ W/K} \times (520 \text{ K} - T_{c,i,A}) \quad (1)$$

$$q_B = \varepsilon_B C_{\min,B} (T_{h,i,B} - T_{c,i,B}) = 0.5052 \times 10790 \text{ W/K} \times (T_{h,i,B} - 280 \text{ K}) \quad (2)$$

$$T_{h,o,A} = T_{h,i,A} - q_A / C_{\max,A} = 520 \text{ K} - q_A / 10300 \text{ W/K} \quad (3)$$

$$T_{c,o,B} = T_{c,i,B} + q_B / C_{\max,B} = 280 \text{ K} + q_B / 10790 \text{ W/K} \quad (4)$$

$$T_{h,i,B} = T_{c,o,A} \quad (5)$$

$$T_{h,o,B} = T_{c,i,A} \quad (6)$$

Equations (1) through (6) may be solved simultaneously to yield

$$q_A = q_B = 6.51 \times 10^5 \text{ W}, T_{h,o,A} = 456.8 \text{ K}, T_{c,o,B} = 340.3 \text{ K}$$

<

## PROBLEM 11.37 (Cont.)

In addition, we note that

$$T_{h,i,B} = T_{c,o,A} = 399.4\text{K} \qquad T_{h,o,B} = T_{c,i,A} = 384.1\text{K}$$

(b) *IHT* was used to solve the preceding equations simultaneously, and to plot the following results.

**COMMENTS:** (1) The *IHT* code used in part (b) is listed below. (2) As evident in part (b), fine-tuning is feasible.

```
//IHT code for Cmin associated with the shell-side flows
/* For the shell-and tube heat exchanger with one shell and any multiple of two tube passes (2, 4, ...),
*/
epsA = 2 * (1 + CrA + (1 + CrA^2)^0.5 * (1 + exp(-NTUA * (1 + CrA^2)^0.5)) / (1 - exp(-NTUA * (1 +
CrA^2)^0.5)))^(-1) /
// where the heat-capacity ratio is
CrA = CminA / CmaxA
// and the number of transfer units, NTUA, is
NTUA = UAA / CminA
// The effectiveness is defined as
epsA = qA / qmaxA
qmaxA = CminA * (ThiA - TciA)
// See Tables 11.3 and 11.4 and Fig 11.12

/* For the shell-and tube heat exchanger with one shell and any multiple of two tube passes (2, 4, ...),
*/
epsB = 2 * (1 + CrB + (1 + CrB^2)^0.5 * (1 + exp(-NTUB * (1 + CrB^2)^0.5)) / (1 - exp(-NTUB * (1 +
CrB^2)^0.5)))^(-1)
// where the heat-capacity ratio is
CrB = CminB / CmaxB
// and the number of transfer units, NTUB, is
NTUB = UAB / CminB
// The effectiveness is defined as
epsB = qB / qmaxB
qmaxB = CminB * (ThiB - TciB)
// See Tables 11.3 and 11.4 and Fig 11.16
```

## PROBLEM 11.37 (Cont.)

$$\dot{m} = 10$$

$$c_{pw} = 4256$$

$$U_{AA} = 6000 + 100\dot{m}$$

$$U_{AB} = 1.2U_{AA}$$

$$C_{minA} = 10300$$

$$C_{maxA} = \dot{m}c_{pw}$$

$$C_{maxB} = \dot{m}c_{pw}$$

$$C_{minB} = 10790$$

$$T_{hiA} = 520$$

$$T_{ciB} = 280$$

$$q_A = \dot{m}c_{pw}(T_{coA} - T_{ciA})$$

$$q_B = \dot{m}c_{pw}(T_{hiB} - T_{hoB})$$

$$T_{hiB} = T_{coA}$$

$$T_{hoB} = T_{ciA}$$

//Equations to determine outlet temperatures on shell side

$$T_{hoA} = T_{hiA} - q_A/10300$$

$$T_{coB} = T_{ciB} + q_B/10790$$

## PROBLEM 11.38

**KNOWN:** Air flow rate, cold outside temperature, warm indoor temperature, dew point temperature,  $UA$  product.

**FIND:** (a) Required water flow rate.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat transfer between heat exchangers and surroundings, negligible heat transfer between two heat exchangers, (2) Constant properties, (3) Negligible energy added to the system by the pump, (4)  $C_{\max}$  is associated with the air, (5) Properties of water with anti-freeze agent are the same as properties of water.

**PROPERTIES:** Table A.6 (water) ( $\bar{T} = 9^\circ\text{C} = 283\text{ K}$ ):  $c_p = 4194\text{ J/kg}\cdot\text{K}$ . Table A.4 (air) ( $\bar{T} = 9^\circ\text{C} = 283\text{ K}$ ):  $c_p = 1007\text{ J/kg}\cdot\text{K}$ .

**ANALYSIS:** (a) Note that  $C_{\max} = C_{\text{air}} = \dot{m}c_p = 1.50\text{ kg/s} \times 1007\text{ J/kg}\cdot\text{K} = 1510\text{ W/K}$ . The heat transfer rate is  $q = q_A = q_B = C_{\max} \times (T_{h,i,B} - T_{h,o,B}) = 1510\text{ W/K} \times (23 - 13)^\circ\text{C} = 15,100\text{ W}$ . The following equations describe the behavior of the system.

$$\begin{aligned} NTU &= UA/C_{\min} = (2500\text{ W/K})/C_{\min} \\ q &= \varepsilon C_{\min} (T_{h,i,A} - T_{c,i,A}) = 15,100\text{ W} = \varepsilon C_{\min} (T_{h,i,A} - (-4^\circ\text{C})) \\ q &= \varepsilon C_{\min} (T_{h,i,B} - T_{c,i,B}) = 15,100\text{ W} = \varepsilon C_{\min} (23^\circ\text{C} - T_{c,i,B}) \\ q &= C_{\min} (T_{c,o,B} - T_{c,i,B}) = 15,100\text{ W} = C_{\min} (T_{c,o,B} - T_{c,i,B}) \\ C_r &= C_{\min}/C_{\max} \\ T_{c,o,B} &= T_{h,i,A} \\ T_{h,o,A} &= T_{c,i,B} \\ \varepsilon &= 1 - \exp\left[\left(\frac{1}{C_r}\right)(NTU)^{0.22} \left\{\exp[-C_r(NTU)^{0.78}] - 1\right\}\right] \end{aligned}$$

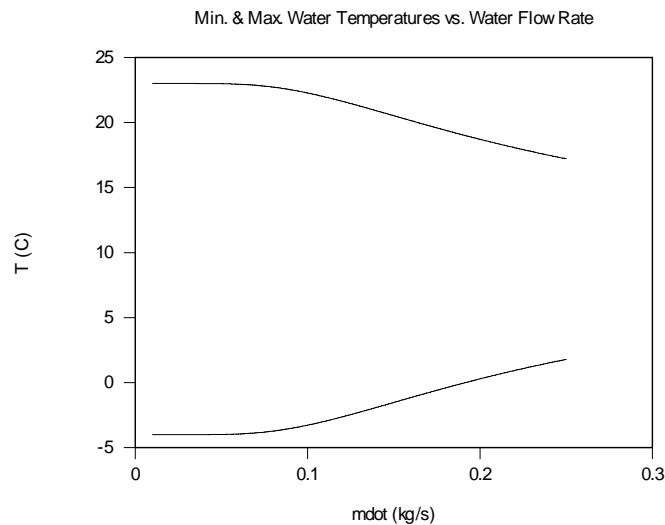

A trial-and-error solution yields  $\dot{m}_w = C_{\min}/c_{p,w} = (776\text{ K/W})/4194\text{ J/kg}\cdot\text{K} = 0.185\text{ kg/s}$

<

Continued...

### PROBLEM 11.38 (Cont.)

**COMMENTS:** (1) Note that the maximum allowable water flow rate to justify the assumption that  $C_{\max}$  is associated with the air flow is  $\dot{m}_{\max} = C_{\max}/c_{p,w} = 1510 \text{ W/K}/4194 \text{ J/kg}\cdot\text{K} = 0.36 \text{ kg/s}$ . The assumption is valid. (2) The maximum heat transfer rate is associated with an infinite water flow rate. For this case, the water temperature is constant at an average value of  $\bar{T} = 9^\circ\text{C} = 283 \text{ K}$  and  $C_{\min}$  is associated with the air flow and is equal to  $1510 \text{ K/W}$ . Assuming a constant value of  $UA$ , the effectiveness for an infinite  $C_{\max}$  is given by Eq. 11.35a and is  $\varepsilon = 1 - \exp(-NTU) = 1 - \exp(-2500/1510) = 0.81$ . Hence, for an infinite water flow rate,  $q = 0.81 \times 1510 \text{ W/K} \times (23 - 9.5)^\circ\text{C} = 16,500 \text{ W}$ . (3) The heat transfer rate, as well as the maximum and minimum water temperatures as a function of the water flow rate, are shown in the plots below (letting the cool stale air temperature be unknown). Note that at water mass flow rates of approximately  $0.25 \text{ kg/s}$ , the heat transfer rate asymptotically approaches that of an infinite water flow rate calculated in Comment 2.

### PROBLEM 11.39

**KNOWN:** Cross-flow heat exchanger (both fluids unmixed) cools blood to induce body hypothermia using ice-water as the coolant.

**FIND:** (a) Heat transfer rate from the blood, (b) Water flow rate,  $\dot{V}_c$  (liter/min), (c) Surface area of the exchanger, and (d) Calculate and plot the blood and water outlet temperatures as a function of the water flow rate for the range,  $2 \leq \dot{V} \leq 4$  liter/min, assuming all other parameters remain unchanged.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Negligible losses to the surroundings, (3) Overall heat transfer coefficient remains constant with water flow rate changes, and (4) Constant properties.

**PROPERTIES:** Table A-6, Water ( $\bar{T}_c = 280\text{K}$ ),  $\rho = 1000 \text{ kg/m}^3$ ,  $c = 4198 \text{ J/kg}\cdot\text{K}$ . Blood (given):  $\rho = 1050 \text{ kg/m}^3$ ,  $c = 3740 \text{ J/kg}\cdot\text{K}$ .

**ANALYSIS:** (a) The heat transfer rate from the blood is calculated from an energy balance on the hot fluid,

$$\dot{m}_h = \rho_h \dot{V}_h = 1050 \text{ kg/m}^3 \times (5 \text{ liter/min} \times 1 \text{ min/60 s}) \times 10^{-3} \text{ m}^3/\text{liter} = 0.0875 \text{ kg/s}$$

$$q = \dot{m}_h c_h (T_{h,i} - T_{h,o}) = 0.0875 \text{ kg/s} \times 3740 \text{ J/kg}\cdot\text{K} (37 - 25)\text{K} = 3927 \text{ W} \quad (1)$$

(b) From an energy balance on the cold fluid, find the coolant water flow rate,

$$q = \dot{m}_c c_c (T_{c,o} - T_{c,i}) \quad (2)$$

$$3927 \text{ W} = \dot{m}_c \times 4198 \text{ J/kg}\cdot\text{K} (15 - 0)\text{K} \quad \dot{m}_c = 0.0624 \text{ kg/s}$$

$$\dot{V}_c = \dot{m}_c / \rho_c = 0.0624 \text{ kg/s} / 1000 \text{ kg/m}^3 \times 10^3 \text{ liter/m}^3 \times 60 \text{ s/min} = 3.74 \text{ liter/min} \quad (3)$$

(c) The surface area can be determined using the effectiveness-NTU method. The capacity rates for the exchanger are

$$C_h = \dot{m}_h c_h = 327 \text{ W/K} \quad C_c = \dot{m}_c c_c = 262 \text{ W/K} \quad C_{\min} = C_c \quad (3, 4, 5)$$

From Eq. 11.18 and 11.19, the maximum heat rate and effectiveness are

Continued .....

**PROBLEM 11.39 (Cont.)**

$$q_{\max} = C_{\min}(T_{h,i} - T_{c,i}) = 262 \text{ W / K } (37 - 0)\text{K} = 9694 \text{ W} \quad (6)$$

$$\varepsilon = q / q_{\max} = 3927 / 9694 = 0.405 \quad (7)$$

For the cross flow exchanger, with both fluids unmixed, substitute numerical values into Eq. 11.32 to find the number of transfer units, NTU, where  $C_r = C_{\min} / C_{\max}$ .

$$\varepsilon = 1 - \exp\left[\left(1/C_r\right)NTU^{0.22}\left\{\exp\left[-C_rNTU^{0.78}\right] - 1\right\}\right] \quad (8)$$

$$NTU = 0.691$$

From Eq. 11.24, find the surface area, A.

$$NTU = UA / C_{\min}$$

$$A = 0.691 \times 262 \text{ W / K } / 750 \text{ W / m}^2 \cdot \text{K} = 0.241 \text{ m}^2 \quad <$$

(d) Using the foregoing equations in the *IHT* workspace, the blood and water outlet temperatures,  $T_{h,o}$  and  $T_{c,o}$ , respectively, are calculated and plotted as a function of the water flow rate, all other parameters remaining unchanged.

From the graph, note that with increasing water flow rate, both the blood and water outlet temperatures decrease. However, the effect of the water flow rate is greater on the water outlet temperature. This is an advantage for this application, since it is desirable to have the blood outlet temperature relatively insensitive to changes in the water flow rate. That is, if there are pressure changes on the water supply line or a slight mis-setting of the water flow rate controller, the outlet blood temperature will not change markedly.

## PROBLEM 11.40

**KNOWN:** Steam at 0.14 bar condensing in a shell and tube HXer (one shell, two tube passes consisting of 130 brass tubes of length 2 m,  $D_i = 13.4$  mm,  $D_o = 15.9$  mm). Cooling water enters at 20°C with a mean velocity 1.25 m/s. Heat transfer convection coefficient for condensation on outer tube surface is  $h_o = 13,500$  W/m<sup>2</sup>·K.

**FIND:** (a) Overall heat transfer coefficient,  $U$ , for the HXer, outlet temperature of cooling water,  $T_{c,o}$ , and condensation rate of the steam  $\dot{m}_h$ ; and (b) Compute and plot  $T_{c,o}$  and  $\dot{m}_h$  as a function of the water flow rate  $10 \leq \dot{m}_c \leq 30$  kg/s with all other conditions remaining the same, but accounting for changes in  $U$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat loss to surroundings, (2) Constant properties, (3) Fully developed water flow in tubes.

**PROPERTIES:** Table A-6, Steam (0.14 bar):  $T_{\text{sat}} = T_h = 327$  K,  $h_{fg} = 2373$  kJ/kg,  $c_p = 1898$  J/kg·K; Table A-6, Water (Assume  $T_{c,o} \approx 44^\circ\text{C}$  or  $\bar{T}_C \approx 305$  K):  $\nu_f = 1.005 \times 10^{-3}$  m<sup>3</sup>/kg,  $c_p = 4178$  J/kg·K,  $\mu_f = 769 \times 10^{-6}$  N·s/m<sup>2</sup>,  $k_f = 0.620$  W/m·K,  $\text{Pr}_f = 5.2$ ; Table A-1, Brass - 70/30 (Evaluate at  $\bar{T} = (T_h + \bar{T}_C)/2 = 316$  K):  $k = 114$  W/m·K.

**ANALYSIS:** (a) The overall heat transfer coefficient based upon the outside tube area follows from Eq. 11.5,

$$U_o = \left[ \frac{1}{h_o} + \frac{r_o}{k} \ln \frac{r_o}{r_i} + \left( \frac{r_o}{r_i} \right) \frac{1}{h_i} \right]^{-1} \quad (1)$$

The value for  $h_i$  can be estimated from an appropriate internal flow correlation. First determine the nature of the flow within the tubes. From Eq. 8.1,

$$\text{Re}_{D_i} = \rho u_m \frac{D_i}{\mu} = \frac{(1.005 \times 10^{-3} \text{ m}^3/\text{kg})^{-1} \times 1.25 \text{ m/s} \times 13.4 \times 10^{-3} \text{ m}}{769 \times 10^{-6} \text{ N}\cdot\text{s}/\text{m}^2} = 21,673.$$

The water flow is turbulent and fully developed ( $L/D_i = 2 \text{ m} / 13.4 \times 10^{-3} \text{ m} = 150 > 10$ ). The Dittus-Boelter correlation with  $n = 0.4$  is appropriate,

$$\text{Nu}_D = h_i D_i / k_f = 0.023 \text{Re}_D^{0.8} \text{Pr}_f^{0.4} = 0.023 \times (21,673)^{0.8} (5.2)^{0.4} = 130.9$$

Continued...

**PROBLEM 11.40 (Cont.)**

$$h_i = \frac{k_f}{D_i} \text{Nu}_D = \frac{0.620 \text{ W/m} \cdot \text{K}}{13.4 \times 10^{-3} \text{ m}} \times 130.9 = 6057 \text{ W/m}^2 \cdot \text{K}.$$

Substituting numerical values into Eq. (1), the overall heat transfer coefficient is

$$U_o = \left[ \frac{1}{13,500 \text{ W/m}^2 \cdot \text{K}} + \frac{(15.9 \times 10^{-3} \text{ m})/2}{114 \text{ W/m} \cdot \text{K}} \ln \frac{15.9}{13.4} + \frac{15.9}{13.4} \times \frac{1}{6057 \text{ W/m}^2 \cdot \text{K}} \right]^{-1}$$

$$U_o = \left[ 7.407 \times 10^{-5} + 1.193 \times 10^{-5} + 19.590 \times 10^{-5} \right]^{-1} \text{ W/m}^2 \cdot \text{K} = 3549 \text{ W/m}^2 \cdot \text{K}. \quad <$$

To find the outlet temperature of the water, we'll employ the  $\epsilon - \text{NTU}$  method. From an energy balance on the cold fluid,

$$T_{c,o} = T_{c,i} + q/C_c \quad (3)$$

where the heat rate can be expressed as

$$q = \epsilon q_{\max} \quad q_{\max} = C_{\min} (T_{h,i} - T_{h,o}). \quad (4,5)$$

The minimum capacity rate is that of the cold water since  $C_h \rightarrow \infty$ . Evaluating, find

$$C_{\min} = C_c = (\dot{m} c_p)_c = 22.8 \text{ kg/s} \times 4178 \text{ J/kg} \cdot \text{K} = 95,270 \text{ W/K}.$$

where

$$\dot{m}_c = (\rho A u_m) N = 995.0 \text{ kg/m}^3 \times \pi/4 (0.0134 \text{ m})^2 \times 1.25 \text{ m/s} \times 130 = 22.8 \text{ kg/s}$$

To determine  $\epsilon$ , use Fig. 11.12 (one shell and any multiple of tube passes) with  $C_r = 0$  and

$$\text{NTU} = \frac{U_o A_o}{C_{\min}} = \frac{3549 \text{ W/m}^2 \cdot \text{K} (\pi 0.0159 \text{ m} \times 2 \text{ m} \times 130 \times 2)}{95,270 \text{ W/K}} = 0.968$$

where 130 and 2 represent the number of tubes and passes, respectively, to find  $\epsilon \approx 0.62$ . Combining Eqs. (4) and (5) into Eq. (3), find

$$T_{c,o} = T_{c,i} + \epsilon C_{\min} (T_{h,i} - T_{c,i}) / C_c = 20^\circ \text{C} + 0.62 (327 - 293) \text{K} = 41.1^\circ \text{C}. \quad <$$

The condensation rate of the steam is given by

$$\dot{m}_h = q/h_{fg} \quad (6)$$

where the heat rate can be determined from Eq. (3) with  $T_{c,o}$ ,

$$\dot{m}_h = C_c (T_{c,o} - T_{c,i}) / h_{fg} = 95,270 \text{ W/K} (41.1 - 20.0) \text{K} / 2373 \times 10^3 \text{ J/kg} \cdot \text{K} = 0.85 \text{ kg/s}. \quad <$$

(b) Using the *IHT Heat Exchanger Tool, All Exchangers*,  $C_r = 0$ , and the *Properties Tool for Water*, a model was developed and the cold outlet temperature and condensation rate were computed and plotted.

Continued...

### PROBLEM 11.40 (Cont.)

With increasing cold flow rate, the cold outlet temperature decreases as expected. The condensation rate increases with increasing cold flow rate. Note that  $T_{c,o}$  and  $\dot{m}_h$  are nearly linear with the cold flow rate.

**COMMENTS:** For part (a) analysis, note that the assumption  $T_{c,o} \approx 44^\circ\text{C}$  used for evaluation of the cold fluid properties was reasonable. Using the IHT model of part (b), we found  $T_{c,o} = 40.2^\circ\text{C}$  and  $\dot{m}_h = 0.812 \text{ kg /s}$ .

## PROBLEM 11.41

**KNOWN:** Shell-and-tube (one shell, two tube passes) heat exchanger design. Water flow rate and inlet temperature. Steam pressure and convection coefficient.

**FIND:** (a) Water outlet temperature,  $T_{c,o}$ ; (b)  $T_{c,o}$  as a function of flow rate,  $\dot{m}_c$ , for the range,  $5 \leq \dot{m}_c \leq 20$  kg/s, with all other conditions remaining the same, but accounting for changes in the overall coefficient,  $U$ ; and (c) Plot  $T_{c,o}$  on the same graph considering fouling factors of  $R_f'' = 0.0002$  and  $0.0005$  m<sup>2</sup>·K/W

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat loss to surroundings, (2) Negligible wall conduction and fouling resistances, (3) Constant properties.

**PROPERTIES:** Table A-6, Sat. water ( $p = 1.0133$  bar):  $T_{\text{sat}} = T = 373.1$  K; ( $\bar{T}_C \approx 320$  K):  $c_p = 4180$  J/kg·K,  $\mu = 577 \times 10^{-6}$  N·s/m<sup>2</sup>,  $k = 0.640$  W/m·K,  $Pr = 3.77$ .

**ANALYSIS:** Using the NTU-effectiveness method, calculate  $U$  by finding  $h_i$ . With

$$Re_D = 4\dot{m}/\pi D\mu = [4(10 \text{ kg/s})/100] / [\pi(0.02 \text{ m})(577 \times 10^{-6} \text{ N}\cdot\text{s}/\text{m}^2)] = 11,033 \quad (1)$$

and using the Dittus-Boelter correlation,

$$Nu_D = 0.023 Re_D^{4/5} Pr^{0.4} = 0.023(11,033)^{4/5} (3.77)^{0.4} = 67.05 \quad (2)$$

$$h_i = (k/D) Nu_D = (0.640 \text{ W}/\text{m}\cdot\text{K}/0.02 \text{ m}) 67.05 = 2146 \text{ W}/\text{m}^2\cdot\text{K}.$$

From Eq. 11.5

$$1/U = 1/h_i + 1/h_o = [(1/10,000) + (1/2146)] \text{ m}^2\cdot\text{K}/\text{W} = 5.66 \times 10^{-4} \text{ m}^2\cdot\text{K}/\text{W} \quad (3)$$

$$U = 1766 \text{ W}/\text{m}^2\cdot\text{K}.$$

The heat transfer surface area, capacity rates and NTU are

$$A = N(\pi D) 2L = 100(\pi 0.02 \text{ m}) 2 \times 2 \text{ m} = 25.1 \text{ m}^2$$

$$C_{\min} = C_c = 10 \text{ kg/s}(4180 \text{ J}/\text{kg}\cdot\text{K}) = 41,800 \text{ W}/\text{K}$$

$$NTU = UA/C_{\min} = 1766 \text{ W}/\text{m}^2\cdot\text{K} \times 25.1 \text{ m}^2 / 41,800 \text{ W}/\text{K} = 1.06$$

From Eq. 11.35a

Continued...

### PROBLEM 11.41 (Cont.)

$$\varepsilon = 1 - \exp(-NTU) = 1 - \exp(-1.06) = 0.654. \quad (4)$$

With

$$q_{\max} = C_{\min} (T_{h,i} - T_{c,i}) = 41,800 \text{ W/K} (373.15 - 290) \text{ K} = 3.48 \times 10^6 \text{ W} \quad (5)$$

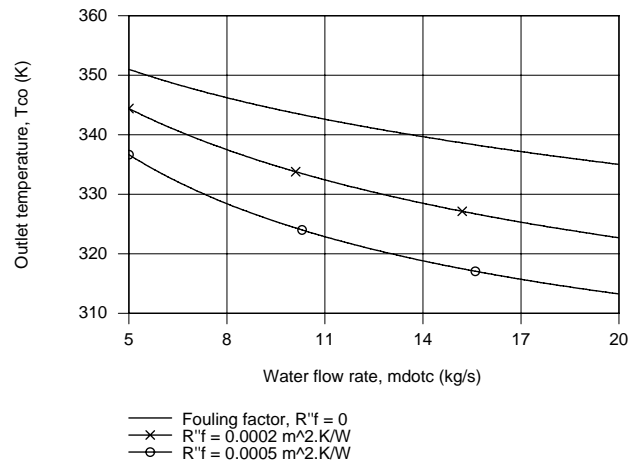

$$q = \varepsilon q_{\max} = 0.654 (3.48 \times 10^6 \text{ W}) = 2.27 \times 10^6 \text{ W}$$

find

$$T_{c,o} = T_{c,i} + (q/C_c) = 290 \text{ K} + (2.27 \times 10^6 \text{ W} / 41,800 \text{ W/K}) = 344.4 \text{ K}. \quad (6) <$$

(b,c) Using the *IHT Heat Exchanger Tool, All Exchangers*,  $C_r = 0$ , the *Properties Tool* for Water and the *Correlation Tool, Forced Convection, Internal Flow*, for Turbulent, fully developed conditions, a model was developed following the foregoing analysis to compute and plot the outlet temperature  $T_{c,o}$  as a function of the cold fluid flow rate,  $\dot{m}_c$ . The expression for the overall coefficient, Eq.(1), was modified to include the fouling factor,

$$1/U = 1/h_i + R_f'' + 1/h_o.$$

The effect of increasing the cold flow rate is to decrease the outlet temperature. The effect of the fouling resistance is to decrease the outlet temperature as well.

**COMMENTS:** (1) For the part (a) analysis,  $\bar{T}_c = 317 \text{ K}$  and the initial guess of 320 K was reasonably good.

(2) In the analysis of parts (b,c),  $Re_{D,c}$  is as low as 4880, below the turbulent range (10,000) and above the laminar range (2300). We chose to treat the flow as turbulent.

## PROBLEM 11.42

**KNOWN:** Saturated steam at 110°C condensing in a shell and tube heat exchanger (one shell pass, 2, 4, tube passes) with a UA value of 2.5 kW/K; cooling water enters at 40°C.

**FIND:** Cooling water flow rate required to maintain a heat rate of 150 kW; and (b) Calculate and plot the water flow rate required to provide heat rates over the range 130 to 160 kW, assuming that UA is independent of flow rate. Comment on the validity of the assumption.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat loss to surroundings, (2) UA independent of flow rate, and (3) Constant properties.

**PROPERTIES:** Table A-6, Water ( $T_{m,c} = (T_{c,i} + T_{c,o})/2 = 49.5^\circ\text{C} = 322.5\text{ K}$ ):  $c_{p,c} = 4181\text{ J/kg}\cdot\text{K}$ .

**ANALYSIS:** (a) For the shell-tube heat exchanger with any multiple of two-tube passes, from Eq. 11.35a with  $C_r = 0$ , using Eqs. 11.19 and 11.22,

$$\varepsilon = 1 - \exp(-NTU) \quad NTU = UA / C_{\min} \quad (1,2)$$

$$\varepsilon = q / q_{\max} \quad q_{\max} = C_c (T_{h,i} - T_{c,i}) \quad (3,4)$$

By combining the equations with  $C_{\min} = C_c = \dot{m}_c c_{p,c}$ ,

$$\frac{q}{\dot{m}_c c_{p,c} (T_{h,i} - T_{c,i})} = 1 - \exp\left(-\frac{UA}{\dot{m}_c c_{p,c}}\right) \quad (5)$$

Substituting numerical values, and solving using *IHT* find

$$\dot{m}_c = 1.89\text{ kg/s} \quad <$$

The specific heat of the cold fluid,  $c_{p,c}$ , is evaluated at the average of the mean inlet and outlet temperatures,  $T_{m,c} = (T_{c,i} + T_{c,o})/2$ , with  $T_{c,o}$  determined from the energy balance equation,

$$q = \dot{m}_c c_{p,c} (T_{c,o} - T_{c,i}). \quad (6)$$

(b) Solving the above system of equations in the *IHT* workspace, the graph below illustrates the water flow rate required to provide a range of heat rates.

Continued ...

### PROBLEM 11.42 (Cont.)

**COMMENTS:** (1) The assumption that  $UA$  is constant with flow rate is a poor one. Because the heat transfer coefficient for condensation is so high, the overall coefficient is controlled by the water-side coefficient. Presuming the flow is turbulent, from the Dittus-Boelter correlation, we'd expect  $U \propto \dot{m}_c^{0.8}$ . Over the range of the graph above,  $U$  will vary by approximately a factor of  $(3.5/1)^{0.8} = 2.7$ .

(2) If we considered  $UA$  to vary with the cold water flow rate as just described, make a sketch of  $\dot{m}_c$  vs.  $q$  and compare it to the graph above.

### PROBLEM 11.43

**KNOWN:** Temperature, convection coefficient and condensation rate of saturated steam. Tube diameter for shell-and-tube heat exchanger with one shell pass and two tube passes. Velocity and inlet and maximum allowable exit temperatures of cooling water.

**FIND:** (a) Minimum number of tubes and tube length per pass, (b) Effect of tube-side heat transfer enhancement on tube length.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat exchange with surroundings, (2) Negligible tube wall conduction and fouling resistance, (3) Constant properties, (4) Fully developed internal flow throughout.

**PROPERTIES:** Table A-6, Sat. water (340 K):  $h_{fg} = 2.342 \times 10^6$  J/kg; Sat. water ( $\bar{T}_c = 22.5^\circ\text{C} \approx 295$  K):  $\rho = 998$  kg/m<sup>3</sup>,  $c_p = 4181$  J/kg·K,  $\mu = 959 \times 10^{-6}$  N·s/m<sup>2</sup>,  $k = 0.606$  W/m·K, Pr = 6.62.

**ANALYSIS:** (a) The required heat rate and the maximum allowable temperature rise of the water determine the minimum allowable flow rate. That is, with

$$q = q_{\text{cond}} = \dot{m}_{\text{cond}} h_{fg} = 2.73 \text{ kg/s} \times 2.342 \times 10^6 \text{ J/kg} = 6.39 \times 10^6 \text{ W}$$

$$\dot{m}_{c,\text{min}} = \frac{q}{c_{p,c} (T_{c,o} - T_{c,i})} = \frac{6.39 \times 10^6 \text{ W}}{4181 \text{ J/kg} \cdot \text{K} (15^\circ\text{C})} = 101.9 \text{ kg/s}$$

With a specified flow rate per tube of  $\dot{m}_{c,1} = \rho u_m \pi D^2/4 = 998 \text{ kg/m}^3 \times 0.5 \text{ m/s} \times \pi (0.019 \text{ m})^2/4 = 0.141 \text{ kg/s}$ , the minimum number of tubes is

$$N_{\text{min}} = \frac{\dot{m}_{c,\text{min}}}{\dot{m}_{c,1}} = \frac{101.9 \text{ kg/s}}{0.141 \text{ kg/s}} = 720 \quad \leftarrow$$

To determine the corresponding tube length, we must first find the required heat transfer surface area. With  $Re_D = \rho u_m D / \mu = 998 \text{ kg/m}^3 (0.5 \text{ m/s}) 0.019 \text{ m} / 959 \times 10^{-6} \text{ N} \cdot \text{s/m}^2 = 9,886$ , the Dittus-Boelter equation yields

$$\bar{h}_i = (k/D) 0.023 Re_D^{4/5} Pr^{0.4} = (0.606 \text{ W/m} \cdot \text{K} / 0.019 \text{ m}) 0.023 (9886)^{4/5} (6.62)^{0.4} = 2454 \text{ W/m}^2 \cdot \text{K}$$

Continued ...

**PROBLEM 11.43 (Cont.)**

$$\text{Hence, } U = \left[ \bar{h}_i^{-1} + h_o^{-1} \right]^{-1} = 1970 \text{ W/m}^2 \cdot \text{K}$$

With  $C_r = 0$ ,  $C_{\min} = \dot{m}_c c_{p,c} = 101.9 \text{ kg/s} \times 4181 \text{ J/kg} \cdot \text{K} = 4.26 \times 10^5 \text{ W/K}$ ,  $q_{\max} = C_{\min} (T_{h,i} - T_{c,i}) = 4.26 \times 10^5 \text{ W/K} (340 - 288) \text{ K} = 2.215 \times 10^7 \text{ W}$  and  $\varepsilon = q/q_{\max} = 0.289$ , Eq. 11.35b yields  $\text{NTU} = -\ln(1 - \varepsilon) = -\ln(1 - 0.289) = 0.341$ . Hence the tube length per pass is

$$L = \frac{A}{2N\pi D} = \frac{\text{NTU} \times C_{\min}}{2N\pi DU} = \frac{0.341 \times 4.26 \times 10^5 \text{ W/K}}{2 \times 720 \times \pi (0.019\text{m}) 1970 \text{ W/m}^2 \cdot \text{K}} = 0.858\text{m} \quad <$$

(b) If the tube-side convection coefficient is doubled,  $\bar{h}_i = 4908 \text{ W/m}^2 \cdot \text{K}$  and  $U = 3292 \text{ W/m}^2 \cdot \text{K}$ . Since  $q$ ,  $C_r$ ,  $C_{\min}$ ,  $q_{\max}$  and hence  $\varepsilon$  are unchanged, the number of transfer units is still  $\text{NTU} = 0.341$ . Hence, the tube length per pass is now

$$L = \frac{\text{NTU} \times C_{\min}}{2N\pi DU} = \frac{0.341 \times 4.26 \times 10^5 \text{ W/K}}{2 \times 720 \times \pi (0.019\text{m}) 3292 \text{ W/m}^2 \cdot \text{K}} = 0.513\text{m} \quad <$$

**COMMENTS:** Heat transfer enhancement for the flow with the smallest convection coefficient significantly reduces the size of the heat exchanger.

### PROBLEM 11.44

**KNOWN:** Pressure and initial flow rate of water vapor. Water inlet and outlet temperatures. Initial and final overall heat transfer coefficients.

**FIND:** (a) Surface area for initial U and water flow rate, (b) Vapor flow rate for final U.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat loss to surroundings, (2) Negligible wall conduction resistance.

**PROPERTIES:** Table A-6, Sat. water ( $\bar{T}_c = 310$  K):  $c_{p,c} = 4178$  J/kg·K; ( $p = 0.51$  bars):  $T_{\text{sat}} = 355$  K,  $h_{fg} = 2304$  kJ/kg.

**ANALYSIS:** (a) The required heat transfer rate is

$$q = \dot{m}_h h_{fg} = 1.5 \text{ kg/s} \left( 2.304 \times 10^6 \text{ J/kg} \right) = 3.46 \times 10^6 \text{ W}$$

and the corresponding heat capacity rate for the water is

$$C_c = C_{\min} = q / (T_{c,o} - T_{c,i}) = 3.46 \times 10^6 \text{ W} / 40 \text{ K} = 86,400 \text{ W/K}.$$

$$\text{Hence, } \varepsilon = q / (C_{\min} [T_{h,i} - T_{c,i}]) = 3.46 \times 10^6 \text{ W} / 86,400 \text{ W/K} (65 \text{ K}) = 0.62.$$

Since  $C_{\min}/C_{\max} = 0$ , Eq. 11.35b yields

$$NTU = -\ln(1 - \varepsilon) = -\ln(1 - 0.62) = 0.97$$

$$\text{and } A = NTU (C_{\min} / U) = 0.97 \left( 86,400 \text{ W/K} / 2000 \text{ W/m}^2 \cdot \text{K} \right) = 41.9 \text{ m}^2 \quad <$$

$$\dot{m}_c = C_c / c_{p,c} = 86,400 \text{ W/K} / 4178 \text{ J/kg} \cdot \text{K} = 20.7 \text{ kg/s.} \quad <$$

(b) Using the final overall heat transfer coefficient, find

$$NTU = UA / C_{\min} = 1000 \text{ W/m}^2 \cdot \text{K} \left( 41.9 \text{ m}^2 \right) / 86,400 \text{ W/K} = 0.485.$$

Since  $C_{\min}/C_{\max} = 0$ , Eq. 11.35a yields

$$\varepsilon = 1 - \exp(-NTU) = 1 - \exp(-0.485) = 0.384.$$

$$\text{Hence, } q = \varepsilon C_{\min} (T_{h,i} - T_{c,i}) = 0.384 (86,400 \text{ W/K}) 65 \text{ K} = 2.16 \times 10^6 \text{ W}$$

$$\dot{m}_h = q / h_{fg} = 2.16 \times 10^6 \text{ W} / 2.304 \times 10^6 \text{ J/kg} = 0.936 \text{ kg/s.} \quad <$$

**COMMENTS:** The significant reduction (38%) in  $\dot{m}_h$  represents a significant loss in turbine power. Periodic cleaning of condenser surfaces should be employed to minimize the adverse effects of fouling.

### PROBLEM 11.45

**KNOWN:** Two-fluid heat exchanger with prescribed inlet and outlet temperatures of the two fluids.

**FIND:** (a) Whether exchanger is operating in parallel or counter flow, (b) Effectiveness of the exchanger when  $C_c = C_{\min}$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat loss to the surroundings.

**ANALYSIS:** (a) To determine whether operation is PF or CF, consider the temperature distributions. From the distributions we note that PF or CF operation is possible.

(b) The effectiveness of the exchanger follows from Eq. 11.19,

$$\varepsilon = q / q_{\max} \quad (1)$$

where from Eq. 11.18,

$$q_{\max} = C_{\min} (T_{h,i} - T_{c,i}). \quad (2)$$

Since the hot fluid undergoes a larger temperature change than the cold fluid,  $C_{\min} = C_h$  and performing an energy balance on the cold fluid, Eq. (1) with Eq. (2) becomes

$$\varepsilon = C_h (T_{h,i} - T_{h,o}) / C_{\min} (T_{h,i} - T_{c,i}) = (T_{h,i} - T_{h,o}) / (T_{h,i} - T_{c,i})$$

$$\varepsilon = (65 - 40)^\circ\text{C} / (65 - 15)^\circ\text{C} = 0.50. \quad <$$

**COMMENTS:** If  $T_{c,o}$  were greater than  $T_{h,o}$ , parallel-flow operation would not be possible.

## PROBLEM 11.46

**KNOWN:** Length and diameters of vein and artery running from chest to base of skull. Separation distance. Inlet temperatures and mass flow rates of blood flowing in opposite directions in vein and artery. Thermal conductivity of surrounding tissue.

**FIND:** Outlet temperature of arterial blood. How much higher the arterial blood inlet temperature can be if blood flow rate is halved and exit temperature must still be below 37°C.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Constant properties and steady-state conditions, (2) Blood properties are those of water, (3) All heat leaving artery enters vein, (4) Vessel walls have negligible thermal resistance. (4) Properties of both flows can be evaluated at 305 K, (5) Uniform wall temperature correlation is appropriate, (5) Flows are hydrodynamically and thermally fully developed.

**PROPERTIES:** Table A.6, water: ( $T = 305 \text{ K}$ ):  $c_p = 4178 \text{ J/kg}\cdot\text{K}$ ,  $\mu = 769 \times 10^{-6} \text{ N}\cdot\text{s/m}^2$ ,  $k = 0.620 \text{ W/m}\cdot\text{K}$ . Tissue (given):  $k_t = 0.5 \text{ W/m}\cdot\text{K}$ .

**ANALYSIS:** The pair of vessels can be seen as a counterflow heat exchanger. We begin by evaluating the heat transfer coefficients, which will be the same in both vessels. From Eq. 8.6,

$$\text{Re}_D = \frac{4\dot{m}}{\pi D \mu} = \frac{4 \times 0.003 \text{ kg/s}}{\pi(0.005 \text{ m})769 \times 10^{-6} \text{ N}\cdot\text{s/m}^2} = 993$$

Hence the flow is laminar and  $\text{Nu}_D = 3.66$ . Therefore,

$$h_c = \frac{k}{D} \text{Nu}_D = \frac{0.620 \text{ W/m}\cdot\text{K}}{0.005 \text{ m}} 3.66 = 454 \text{ W/m}^2 \cdot \text{K}$$

With the assumption that all the heat that leaves the artery enters the vein, conduction between the two cylinders can be represented by the shape factor in Table 4.1, case 4. Then

$$R_{\text{cond}} = \frac{1}{S k_t} = \frac{\cosh^{-1} \left( \frac{4w^2 - 2D^2}{2D^2} \right)}{2\pi L k_t} = \frac{\cosh^{-1} \left( \frac{4(0.007 \text{ m})^2 - 2(0.005 \text{ m})^2}{2(0.005 \text{ m})^2} \right)}{2\pi \times 0.250 \text{ m} \times 0.5 \text{ W/m}\cdot\text{K}} = 2.208 \text{ K/W}$$

Then we can find  $UA$  for heat transfer between the two blood flows.

Continued...

**PROBLEM 11.46 (Cont.)**

$$\begin{aligned}
 UA^{-1} &= \frac{1}{h\pi DL} + R_{\text{cond}} + \frac{1}{h\pi DL} \\
 &= 2 \frac{1}{454 \text{ W/m}^2 \cdot \text{K} \times \pi \times 0.005 \text{ m} \times 0.25 \text{ m}} + 2.208 \text{ K/W} = 3.33 \text{ K/W}
 \end{aligned}$$

$$UA = 0.300 \text{ W/K}$$

Now using the  $\epsilon$ -NTU method, with equal heat capacity rates for the two flows,

$$NTU = \frac{UA}{\dot{m}c_p} = \frac{0.300 \text{ W/K}}{0.003 \text{ kg/s} \times 4178 \text{ J/kg} \cdot \text{K}} = 0.0240, \quad C_r = 1$$

From Eq. 11.29b, with  $C_r = 1$  and using Eq. 11.20

$$\epsilon = \frac{NTU}{NTU + 1} = \frac{0.024}{0.024 + 1} = 0.0234 = \frac{T_{h,i} - T_{h,o}}{T_{h,i} - T_{c,i}}$$

Thus

$$T_{h,o} = T_{h,i} - \epsilon(T_{h,i} - T_{c,i}) = 37^\circ\text{C} - 0.0234(37^\circ\text{C} - 27^\circ\text{C})$$

$$T_{h,o} = 36.8^\circ\text{C} \quad <$$

If the mass flow rate is halved, the flows remain laminar and the heat transfer coefficients are unchanged, as is  $UA$ . Thus,  $NTU$  doubles, i.e.  $NTU = 0.0480$ , and  $\epsilon = 0.048/1.048 = 0.0458$ .

Thus

$$\epsilon = \frac{T_{h,i} - T_{h,o}}{T_{h,i} - T_{c,i}}, \quad T_{h,i} = \frac{T_{h,o} - \epsilon T_{c,i}}{1 - \epsilon} = \frac{37^\circ\text{C} - 0.0458 \times 27^\circ\text{C}}{1 - 0.0458} = 37.5^\circ\text{C} \quad <$$

**COMMENTS:** (1) The assumed mean temperature is not accurate, but this is not worth correcting since the properties of blood are not those of water. (2) With  $x_{fd,h} = 0.05\text{Re}_D\text{Pr}_D = 1.3$  m, the flow is not fully developed thermally. The actual heat transfer coefficients would be greater and there would be a larger temperature change between inlet and outlet. (3) Heat transfer from the artery to the cooler neck surface can have a comparable or somewhat larger effect on cooling the arterial blood.

### PROBLEM 11.47

**KNOWN:** A very long, concentric tube heat exchanger having hot and cold water inlet temperatures, 85°C and 15°C, respectively; flow rate of hot water is twice that of the cold water.

**FIND:** Outlet temperatures for counterflow and parallel flow operation.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Equivalent hot and cold water specific heats, (2) No heat loss to surroundings.

**ANALYSIS:** The heat rate for a concentric tube heat exchanger with very large surface area operating in the counterflow mode is

$$q = q_{\max} = C_{\min} (T_{h,i} - T_{c,i})$$

where  $C_{\min} = C_c$ . From an energy balance on the hot fluid,

$$q = C_h (T_{h,i} - T_{h,o}).$$

Combining the above relations and rearranging, find

$$T_{h,o} = -\frac{C_{\min}}{C_h} (T_{h,i} - T_{c,i}) + T_{h,i} = -\frac{C_c}{C_h} (T_{h,i} - T_{c,i}) + T_{h,i}.$$

Substituting numerical values,

$$T_{h,o} = -\frac{1}{2} (85 - 15)^\circ\text{C} + 85^\circ\text{C} = 50^\circ\text{C}.$$

For parallel flow operation, the hot and cold outlet temperatures will be equal; that is,  $T_{c,o} = T_{h,o}$ . Hence,

$$C_c (T_{c,o} - T_{c,i}) = C_h (T_{h,i} - T_{h,o}).$$

Setting  $T_{c,o} = T_{h,o}$  and rearranging,

$$T_{h,o} = \left( T_{h,i} + \frac{C_c}{C_h} T_{c,i} \right) / \left( 1 + \frac{C_c}{C_h} \right)$$

$$T_{h,o} = \left( 85 + \frac{1}{2} \times 15 \right)^\circ\text{C} / \left( 1 + \frac{1}{2} \right) = 61.7^\circ\text{C}.$$

**COMMENTS:** Note that while  $\varepsilon = 1$  for CF operation, for PF operation find  $\varepsilon = q/q_{\max} = 0.67$ .

## PROBLEM 11.48

**KNOWN:** Saturation temperature and condensation rate of refrigerant. Frontal area of condenser and dependence of overall coefficient on inlet velocity. Operational range of the air inlet temperature.

**FIND:** (a) Required heat exchanger area and air outlet temperature for prescribed air inlet velocity and temperature, (b) Variation in air velocity needed to achieve prescribed condensation rate.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat loss to surroundings, (2) Constant properties.

**PROPERTIES:** Given (Refrigerant):  $h_{fg} = 1.35 \times 10^5 \text{ J/kg}$ . Table A-4, air ( $T_{c,i} = 303 \text{ K}$ ):  $\rho_c = 1.17 \text{ kg/m}^3$ ,  $c_{p,c} = 1007 \text{ J/kg}\cdot\text{K}$ .

**ANALYSIS:** (a) With  $\dot{m}_c = \rho_c V A_{fr} = 1.17 \text{ kg/m}^3 \times 2 \text{ m/s} \times 0.25 \text{ m}^2 = 0.585 \text{ kg/s}$ ,

$C_{\min} = \dot{m}_c c_{p,c} = 589 \text{ W/K}$ . Hence, from Eq. 11.18, with  $T_{h,i} = T_{\text{sat}}$ ,

$$q_{\max} = C_{\min} (T_{h,i} - T_{c,i}) = 589 \text{ W/K} (45 - 30) \text{ K} = 8,836 \text{ W}$$

and with  $q = \dot{m}_h h_{fg} = 0.015 \text{ kg/s} \times 1.35 \times 10^5 \text{ J/kg} = 2025 \text{ W}$

$$\varepsilon = \frac{q}{q_{\max}} = \frac{2025}{8836} = 0.229$$

From Eq. 11.35b we then obtain (for  $C_r = 0$ ),

$$A = \frac{C_{\min}}{U} \text{NTU} = -\frac{C_{\min}}{U} \ln(1 - \varepsilon) = -\frac{589 \text{ W/K}}{50 \text{ W/m}^2 \cdot \text{K}} \ln(0.771) = 3.067 \text{ m}^2 \quad <$$

With  $q = C_{\min} (T_{c,o} - T_{c,i})$ , the outlet temperature is

$$T_{c,o} = T_{c,i} + \frac{q}{C_{\min}} = 30^\circ\text{C} + \frac{2025 \text{ W}}{589 \text{ W/K}} = 33.4^\circ\text{C} \quad <$$

(b) With  $q = 2025 \text{ W}$ ,  $A = 3.06 \text{ m}^2$  and  $U = 50 \text{ W/m}^2 \cdot \text{K} (V/2)^{0.7}$ , the foregoing equations may be solved to obtain  $V$  as a function of  $T_{c,i}$ .

Continued...

### PROBLEM 11.48 (Cont.)

With increasing  $T_{c,i}$ , the driving potential for heat transfer,  $T_{h,i} - T_{c,i}$ , decreases and a larger value of  $U$ , and hence  $V$ , is needed to maintain the required heat rate. For  $27 \leq T_{c,i} \leq 38^\circ\text{C}$ ,  $1.56 \leq V \leq 5.66$  m/s and  $42.1 \leq U \leq 103.6 \text{ W/m}^2 \cdot \text{K}$ .

**COMMENTS:** The variation of  $V$  with  $T_{c,i}$  is nonlinear, and, in principle,  $V \rightarrow \infty$  as  $T_{c,i} \rightarrow T_{\text{sat}}$ .

## PROBLEM 11.49

**KNOWN:** Conditions of oil and water for heat exchanger, one shell with 4 tube passes.

**FIND:** Length of exchanger tubes per pass,  $L$ ; and (b) Compute and plot the effectiveness,  $\epsilon$ , fluid outlet temperatures,  $T_{h,o}$  and  $T_{c,o}$ , and water-side convection coefficient,  $h_c$ , as a function of the water flow rate for  $5000 \leq \dot{m}_c \leq 15,000$  kg/h for the tube length found in part (a) with all other conditions remaining the same.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat loss to surroundings, (2) Constant properties, (3) Fully-developed flow in tubes.

**PROPERTIES:** Table A-1, Brass (400 K):  $k = 137$  W/m·K; Table A-5, Water (323 K):  $\rho = 998.1$  kg/m<sup>3</sup>,  $k = 0.643$  W/m·K,  $c_p = 4182$  J/kg·K,  $\mu = 548 \times 10^{-6}$  N·s/m<sup>2</sup>,  $Pr = 3.56$ .

**ANALYSIS:** (a) Using the  $\epsilon$ -NTU method,

$$C_c = \dot{m}_c c_c = \frac{10,000 \text{ kg/h}}{3600 \text{ s/h}} \times 4182 \text{ J/kg} \cdot \text{K} = 11,620 \text{ W/K}$$

From an energy balance on the water,  $q = C_c(T_{c,o} - T_{c,i}) = 11,620 \text{ W/K}(84 - 16)^\circ\text{C} = 789,900 \text{ W}$

From an energy balance on the oil,  $C_h = q/(T_{h,i} - T_{h,o}) = 789,900 \text{ W}/(160 - 94)^\circ\text{C} = 11,970 \text{ W/K}$

Thus,  $C_r = C_{\min}/C_{\max} = 0.971$ ,  $q_{\max} = C_{\min}(T_{h,i} - T_{c,i}) = 11,620 \text{ W/K}(160 - 16)^\circ\text{C} = 1.673 \times 10^6 \text{ W}$ , and  $\epsilon = q/q_{\max} = 0.472$ . From Eqs. 11.30c and 11.30b,

$$E = \frac{2/\epsilon - (1 + C_r)}{(1 + C_r^2)^{1/2}} = \frac{2/0.472 - (1 + 0.971)}{(1 + 0.971^2)^{1/2}} = 1.625$$

$$NTU = -(1 + C_r^2)^{-1/2} \ln\left(\frac{E-1}{E+1}\right) = -(1 + 0.971^2)^{-1/2} \ln\left(\frac{1.625-1}{1.625+1}\right) = 1.03 \quad (1)$$

and since  $NTU = UA/C_{\min}$ ,  $A_o = NTU \times C_{\min}/U_o$  (2)

Thus we can determine  $L$  if we know  $U_o$ . From Eq. 11.5,

$$U_o = \left[ \frac{1}{h_o} + \frac{r_o}{k} \ln \frac{r_o}{r_i} + \frac{r_o}{r_i} \frac{1}{h_i} \right]^{-1}$$

where  $h_i$  must be estimated from the appropriate correlation. With  $N = 11$ , the number of tubes,

Continued...

**PROBLEM 11.49 (Cont.)**

$$Re_D = \frac{4\dot{m}/N}{\pi D \mu} = \frac{4 \times (10,000/3600) \text{ kg/s} / (11)}{\pi \times 22.9 \times 10^{-3} \text{ m} \times 548 \times 10^{-6} \text{ N}\cdot\text{s}/\text{m}^2} = 25,621.$$

For fully developed turbulent flow, the Dittus-Boelter correlation with  $n = 0.4$  yields

$$Nu_D = h_i D/k = 0.023 Re_D^{0.8} Pr^{0.4} = 0.023 (25,621)^{0.8} (3.56)^{0.4} = 128.6$$

$$h_i = Nu_D (k/D) = 128.6 \times 0.643 \text{ W/m}\cdot\text{K} / (22.9 \times 10^{-3} \text{ m}) = 3610 \text{ W/m}^2 \cdot \text{K}.$$

$$U_o = \left[ \frac{1}{400 \text{ W/m}^2 \cdot \text{K}} + \frac{25.4 \times 10^{-3} \text{ m}}{2 \times 137 \text{ W/m}\cdot\text{K}} \ln \frac{25.4}{22.9} + \frac{25.4}{22.9} \times \frac{1}{3610 \text{ W/m}^2 \cdot \text{K}} \right]^{-1} = 355 \text{ W/m}^2 \cdot \text{K}.$$

Returning now to Eq. (2), find  $A_o$ , then the length,

$$A_o = \pi D_o L \times \text{No. of Passes} \times \text{No. of Tubes} = \pi \times 25.4 \times 10^{-3} \text{ m} \times 4 \times 11 L = 3.511 L$$

$$L = NTU \times C_{\min} / 3.511 U_o = 1.03 \times 11,620 \text{ W/K} / 3.511 \text{ m} \times 355 \text{ W/m}^2 \cdot \text{K} = 9.6 \text{ m} \quad <$$

(b) Using the *IHT Heat Exchanger Tool, Shell and Tube, One-shell pass and N tube passes*, the *Correlation Tool, Forced Convection, Internal Flow for Turbulent, fully developed condition*, and the *Properties Tool for Water*, a model was developed using the effectiveness - NTU method to compute and plot  $T_{c,o}$ ,  $T_{h,o}$ ,  $\epsilon$ , and  $h_i$  as a function of  $\dot{m}_c$ .

In order to avoid a boiling condition in the cold fluid, the cold flow rate should not be less than 8000 kg/h. As expected,  $T_{c,o}$  and  $T_{h,o}$  decrease and the internal convection coefficient increases nearly linearly with increasing flow rate. The effectiveness increases with increasing flow rate since the overall convection coefficient is increasing.

**COMMENT:** The thermal resistance of the brass tubes is negligible. Since  $L/D_i = 400$ , fully-developed conditions are reasonable.

## PROBLEM 11.50

**KNOWN:** Properties and flow rate of computer coolant. Diameter and number of heat exchanger tubes. Heat exchanger transfer rate and inlet temperature of computer coolant. Flow rate, specific heat, inlet temperature, and average convection coefficient of water.

**FIND:** (a) Tube flow convection coefficient,  $\bar{h}_i$ , (b) Tube length/pass required to achieve prescribed fluid outlet temperature, (c) Compute and plot the dielectric fluid outlet temperature,  $T_{f,o}$ , as a function of its flow rate  $\dot{m}_f$  for the range  $4 \leq \dot{m}_f \leq 6$  kg/s based upon the length/pass found in part (c), (d) the effect of  $\pm 10\%$  change in the water flow rate,  $\dot{m}_w$ , on  $T_{f,o}$  and (e) the effect of  $\pm 3^\circ\text{C}$  change in inlet water temperature,  $T_{w,i}$ , on  $T_{f,o}$ . For parts (c, d, e), account for any changes in the overall convection coefficient, while all other conditions remain the same.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat loss to surroundings, fouling and tube wall resistance; (2) Constant properties; (3) Fully developed flow, (4) Convection coefficient on shell side,  $\bar{h}_o$ , remains constant for all operating conditions.

**PROPERTIES:** Coolant (given):  $c_p = 1040$  J/kg·K,  $\mu = 7.65 \times 10^{-4}$  kg/s·m,  $k = 0.058$  W/m·K,  $Pr = 14$ ; Water (given):  $c_p = 4200$  J/kg·K.

**ANALYSIS:** (a) For flow through a single tube,

$$Re_D = \frac{4\dot{m}_{f,t}}{\pi D \mu} = \frac{4(4.81 \text{ kg/s})/72}{\pi(0.01 \text{ m})7.65 \times 10^{-4} \text{ kg/s} \cdot \text{m}} = 11,120$$

and using the Dittus-Boelter correlation, find

$$h_i = (k/D)0.023 Re_D^{4/5} Pr^{0.3} = 0.023 \frac{0.058 \text{ W/m} \cdot \text{K}}{0.01 \text{ m}} (11,120)^{4/5} (14)^{0.3} = 508 \text{ W/m}^2 \cdot \text{K} <$$

(b) Find the capacity ratio

$$C_f = \dot{m}_f c_{p,f} = 4.81 \text{ kg/s} (1040 \text{ J/kg} \cdot \text{K}) = 5002 \text{ W/K} = C_{\min}$$

$$C_w = \dot{m}_w c_{p,w} = 2.5 \text{ kg/s} (4200 \text{ J/kg} \cdot \text{K}) = 10,500 \text{ W/K} = C_{\max}$$

hence,  $C_r = C_{\min}/C_{\max} = 0.476$  and

$$\varepsilon = \frac{q}{q_{\max}} = \frac{C_f (T_{f,i} - T_{f,o})}{C_f (T_{f,i} - T_{w,i})} = \frac{(25 - 15)^\circ \text{C}}{(25 - 5)^\circ \text{C}} = 0.500.$$

Using Fig. 11.12 with  $NTU = (UA/C_{\min}) = (UN\pi D^2 L/C_{\min}) \approx 0.85$ ,

Continued...

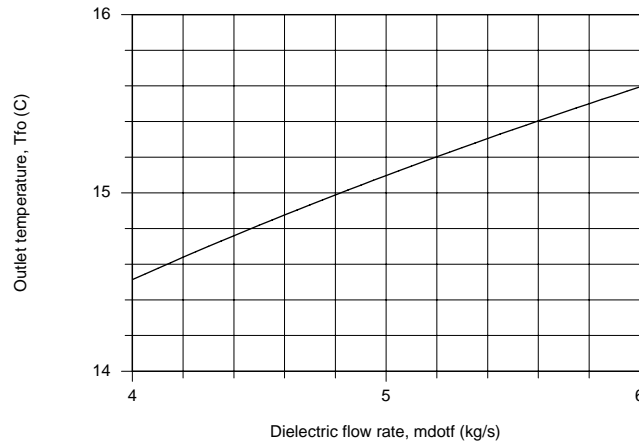

**PROBLEM 11.50 (Cont.)**

$$U = (h_i^{-1} + h_o^{-1})^{-1} = \left[ (508)^{-1} + (10^4)^{-1} \right]^{-1} \text{ W/m}^2 \cdot \text{K} = 483 \text{ W/m}^2 \cdot \text{K}$$

$$L = 0.85(5002 \text{ W/K}) / 144\pi (483 \text{ W/m}^2 \cdot \text{K}) 0.01 \text{ m} = 1.95 \text{ m} .$$

<

(c) Using the *IHT Heat Exchanger Tool, Shell and Tube, One-shell pass and N-tube passes*, and the *Correlation Tool, Forced Convection, Internal Flow for Turbulent, fully developed conditions*, a model was developed using the effectiveness-NTU method employed above to compute and plot  $T_{f,o}$  as a function of  $\dot{m}_f$ .

A change in the dielectric fluid flow rate of  $\pm 1$  kg/s causes approximately  $\pm 0.5^\circ\text{C}$  change in its outlet temperature.

(d) Using the above IHT model with the base conditions for part (c), the effect of a  $\pm 10\%$  change in the water flow rate from its design value,  $\dot{m}_w = 2.5$  kg/s ( $2.25 \leq \dot{m}_w \leq 2.75$  kg/s) causes the dielectric fluid outlet temperature to change as

$$T_{f,o} = 15 \pm 0.14^\circ\text{C}$$

<

(e) Using the IHT model of part (c) with the base case conditions for part (c), the effect of a  $\pm 3^\circ\text{C}$  in the water inlet temperature from its design value,  $T_{c,i} = 5^\circ\text{C}$  ( $2 \leq T_{c,i} \leq 8^\circ\text{C}$ ) cause the dielectric fluid outlet temperature to change as

$$T_{f,o} = 15 \pm 1.5^\circ\text{C}$$

<

**COMMENTS:** (1) For the analyses of part (a), Eq. 11.30b,c yields  $\text{NTU} = 0.85$  and  $q = 50$  kW and  $T_{w,o} = 9.76^\circ\text{C}$ .

(2) The results of the analyses provide operating performance information on the effect of changes due to dielectric fluid flow rate ( $\pm 1$  kg/s of  $\dot{m}_f$ ), water fluid flow rate ( $\leq 10\%$  of  $\dot{m}_w$ ) and water inlet temperature ( $\pm 3^\circ\text{C}$  of  $T_{w,i}$ ) on the dielectric fluid outlet temperature,  $T_{f,o}$ , supplied to the computer. The greatest effect on  $T_{f,o}$ , is that by the input water temperature.

## PROBLEM 11.51

**KNOWN:** Inlet temperatures of brine and working fluid in a geothermal power plant heat exchanger. Brine outlet temperature. Electric power generation and thermal efficiency of the geothermal plant. Overall heat transfer coefficients under clean and fouled conditions.

**FIND:** (a) Brine flow rate, heat exchanger effectiveness, required heat transfer surface area for clean conditions. (b) Electric power generated under fouled conditions.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat transfer between heat exchanger and surroundings, (2) Constant properties.

**PROPERTIES:** Table A.6 brine (water),  $\bar{T} = 140^\circ\text{C}$ :  $c_p = 4285 \text{ J/kg}\cdot\text{K}$ .

**ANALYSIS:** (a) The heat input to the working fluid of the Rankine cycle is supplied from the heat exchanger and is  $q = P/\eta = 25 \times 10^6 \text{ W}/0.20 = 125 \times 10^6 \text{ W}$ . Therefore, the required brine flow rate is

$$\dot{m} = q/[c_p(T_{h,i} - T_{h,o})] = 125 \times 10^6 \text{ W}/[4285 \text{ J/kg}\cdot\text{K} \times (200^\circ\text{C} - 80^\circ\text{C})] = 243 \text{ kg/s} \quad <$$

and  $C_{\min} = \dot{m}c_p = 243 \text{ kg/s} \times 4285 \text{ J/kg}\cdot\text{K} = 1.04 \times 10^6 \text{ W/K}$ . The required effectiveness is

$$\varepsilon = q/[C_{\min}(T_{h,i} - T_{c,i})] = 125 \times 10^6 \text{ W}/[1.04 \times 10^6 \text{ W/K}(200^\circ\text{C} - 45^\circ\text{C})] = 0.775 \quad <$$

From Fig. 11.12, the NTU is 1.5 and  $A = \text{NTU} \cdot C_{\min}/U = (1.5 \times 1.04 \times 10^6 \text{ W/K})/4000 \text{ W/m}^2\cdot\text{K} = 390 \text{ m}^2$ . <

(b) Under fouled conditions,  $\text{NTU} = UA/C_{\min} = 2000 \text{ W/m}^2\cdot\text{K} \times 390 \text{ m}^2/(1.04 \times 10^6 \text{ W/m}^2\cdot\text{K}) = 0.75$ . From Fig. 11.12, the effectiveness is  $\varepsilon = 0.55$ . Hence,  $q = \varepsilon C_{\min}(T_{h,i} - T_{c,i}) = 0.55 \times 1.04 \times 10^6 \text{ W/K} \times (200^\circ - 45^\circ\text{C}) = 88.7 \times 10^6 \text{ W}$  and the electric power generated is  $P = \eta q = 0.20 \times 88.7 \times 10^6 \text{ W} = 17.7 \times 10^6 \text{ W} = 17.7 \text{ MW}$  (electric). <

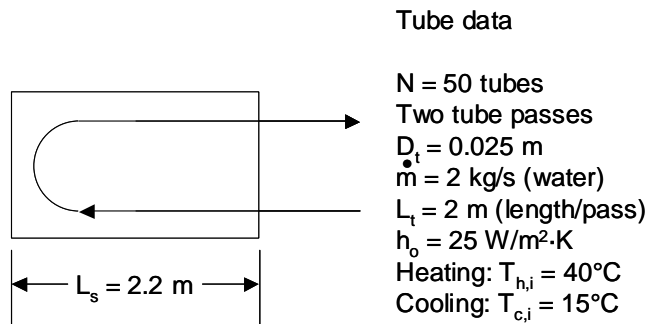

**COMMENTS:** (1) With this analysis, the electric power output is reduced by  $[(25 - 17.7)/25] \times 100 = 29\%$  due to fouling. (2) The outlet brine temperature as well as the inlet Rankine fluid temperature would also change as a result of fouling. A more accurate estimate of the effect of fouling would require coupling the heat transfer analysis with an analysis of the Rankine cycle and its components. (3) Use of Eq. 11.35b yields  $\text{NTU} = 1.49$  in part (a) and  $\varepsilon = 0.525$  and  $P = 17.0 \text{ MW}$  in part (b). (4) See Tester et al., "Impact of Enhanced Geothermal Systems on U.S. Energy Supply in the Twenty-First Century," *Philosophical Transactions of the Royal Society A*, Vol. 365, pp. 1057 – 1094, 2007 for a discussion of the geothermal energy potential in the United States.

## PROBLEM 11.52

**KNOWN:** Warm water flow rate and temperature. Cold water flow rate and temperature. Configuration of a shell-and-tube heat exchanger including number of tube passes, number of tubes, and tube length and tube diameter. Outside heat transfer coefficient during melting of the phase change material. Duration of melting.

**FIND:** (a) Volume of phase change material melted over a 12-hour period. Diameter of shell. (b) Heat transfer rate during solidification of phase change material relative to heat transfer rate in part (a).

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat transfer between heat exchanger and surroundings, (2) Negligible fouling effects, (3) Negligible wall resistance, (4) Negligible convective resistance on inside of tubing, (5) Negligible sensible energy change in phase change material, (6) Constant properties.

**PROPERTIES:** *n*-octadecane (Problem 8.47):  $T_f = 27.4^\circ\text{C}$ ,  $h_{sf} = 244$  kJ/kg,  $\rho = 770$  kg/m<sup>3</sup>. Table A.6 (water) ( $\bar{T} = 27^\circ\text{C} = 300$  K):  $c_p = 4179$  J/kg·K.

**ANALYSIS:** (a) With no change in the *n*-octadecane temperature, the minimum heat rate is associated with the water and is  $C_{\min} = C_h = \dot{m}c_p = 2\text{ kg/s} \times 4179$  J/kg·K = 8358 W/K. The heat transfer area is  $A = 2N(\pi D_t L_t) = 2 \times 50 \times (\pi \times 0.025$  m  $\times 2\text{ m}) = 15.7$  m<sup>2</sup>. For negligible convective and tube wall resistances and negligible fouling effects,  $U = h_o = 25$  W/m<sup>2</sup>·K. Therefore,  $\text{NTU} = UA/C_{\min} = (25$  W/m<sup>2</sup>·K  $\times 15.7$  m<sup>2</sup>)/8358 W/K = 0.047. The effectiveness is

$$\varepsilon = 1 - \exp(-\text{NTU}) = 1 - \exp(-0.047) = 0.0458.$$

and the heat transfer rate is

$$q = \varepsilon C_{\min} (T_{h,i} - T_f) = 0.0458 \times 8358 \text{ W/K} \times (40 - 27.4)^\circ\text{C} = 4823 \text{ W}$$

Over a 12-hour period, the volume of phase change material that is melted is

$$V_{pcm} = qt / (\rho h_{s,f}) = (4823 \text{ W} \times 12 \text{ h} \times 60 \text{ min/h} \times 60 \text{ s/min}) / (770 \text{ kg/m}^3 \times 244 \times 10^3 \text{ J/kg}) = 1.11 \text{ m}^3 <$$

so the total volume of phase change material in the shell is  $V_{\text{tot}} = 1.5 \times 1.11 \text{ m}^3 = 1.66 \text{ m}^3$ .

Continued...

### PROBLEM 11.52 (Cont.)

The total shell volume is occupied by (i) phase change material and (ii) tubing. The tubing volume is

$$V_{tub} = 2NL_t(\pi D_t^2 / 4) = 2 \times 50 \times 2\text{m} \times (\pi [0.025\text{m}]^2 / 4) = 0.098\text{m}^3$$

Therefore, the shell diameter is

$$D_s = \sqrt{\frac{4(V_{tub} + V_{pcm})}{\pi L_s}} = \sqrt{\frac{4(0.098\text{m}^3 + 1.66\text{m}^3)}{\pi \times 2.2\text{m}}} = 1.0\text{ m} \quad <$$

(b) The difference between the water temperature and the melting temperature of the phase change material is approximately 12.5 degrees Celsius for both heating and cooling modes. However, during solidification of the phase change material, the solid phase will form adjacent to the cold tube wall. Since the thermal conductivity of the phase change material is small ( $k = 0.653\text{ W/m}\cdot\text{K}$ ; Problem 8.47) we expect the conduction resistance posed by the solid material to be very large and will increase as the solidification ensues. Hence, the overall heat transfer coefficient,  $U$ , will be much smaller during solidification and the overall heat transfer rate will be much smaller relative to that of part (a).

<

**COMMENTS:** (1) Evaluating water properties at  $40^\circ\text{C}$  and for  $N = 50$  tubes,  $Re_D = 4\dot{m}/(N\pi D\mu) = 3100$ ,  $Nu_D = 22.2$  and  $h_i = 560\text{ W/m}^2\cdot\text{K}$  using the Dittus-Boelter relationship of Chapter 8. Since  $h_i \gg h_o$ , the assumption of negligible convection resistance on the inside of the tube is reasonable. (2) The outlet temperature of the warm water is

$$T_{h,o} = T_{h,i} - q/C_{\min} = 40^\circ\text{C} - 4823\text{W}/8358\text{K/W} = 39.4^\circ\text{C}$$

(3) During melting, the value of the overall heat transfer coefficient will vary with time as the distance between the warm tube wall and the solid-liquid interface increases. (4) A detailed analysis would be necessary to determine the time-variation of the overall heat transfer coefficient, particularly when operating in the solidification mode.

### PROBLEM 11.53

**KNOWN:** Shell and tube heat exchanger with 135 tubes (one shell, double pass) of inner diameter 12.5 mm and surface area 47.5 m<sup>2</sup>.

**FIND:** (a) Exchanger gas and water outlet temperatures, (b) Tube heat transfer coefficient,  $\bar{h}_i$ , assuming fully developed flow, (c) Compute and plot the effectiveness and fluid outlet temperatures,  $T_{c,o}$  and  $T_{h,o}$  for the water flow rate range  $6 \leq \dot{m}_c \leq 12$  kg/s with all other conditions remaining the same, and (d) Hot gas inlet temperature,  $T_{h,i}$ , required to supply 10 kg/s of hot water with an outlet temperature of 42°C with all other conditions the same; determine also the effectiveness.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat lost to surroundings, (2) Fully-developed conditions for internal flow of water in tubes, (3) Exhaust gas properties are those of air, and (4) The overall coefficient remains unchanged for the operating conditions examined.

**PROPERTIES:** Table A-6, Water ( $\bar{T}_c \approx 300$  K):  $\rho = 997$  kg/m<sup>3</sup>,  $c = 4179$  J/kg·K,  $k = 0.613$  W/m·K,  $\mu = 855 \times 10^{-6}$  N·s/m<sup>2</sup>,  $Pr = 5.83$ ; Table A-4, Air (1 atm,  $\bar{T}_h \approx 400$  K):  $\rho = 0.8711$  kg/m<sup>3</sup>,  $c = 1014$  J/kg·K.

**ANALYSIS:** (a) Using the  $\epsilon$ -NTU method, first find the capacity rates,  $C = \dot{m}c$ ,

$$C_c = 6.5 \text{ kg/s} \times 4179 \text{ J/kg} \cdot \text{K} = 27,164 \text{ W/K} \quad C_h = 5.0 \text{ kg/s} \times 1014 \text{ J/kg} \cdot \text{K} = 5,070 \text{ W/K}.$$

Recognize that  $C_h = C_{\min}$  and determine

$$\frac{C_{\min}}{C_{\max}} = \frac{C_h}{C_c} = \frac{5,070}{27,164} = 0.19 \quad NTU = \frac{AU}{C_{\min}} = \frac{47.5 \text{ m}^2 \times 200 \text{ W/m}^2 \cdot \text{K}}{5,070 \text{ W/K}} = 1.87.$$

From Fig. 11.12 for the shell and tube exchanger, find with  $NTU = 1.87$  and  $C_{\min}/C_{\max} = 0.19$  that  $\epsilon \approx 0.78$ . From the definition of effectiveness,

$$\epsilon = \frac{q}{q_{\max}} = \frac{C_h (T_{h,i} - T_{h,o})}{C_{\min} (T_{h,i} - T_{c,i})} = \frac{200 - T_{h,o}}{200 - 15} = 0.78 \quad \text{or} \quad T_{h,o} = 55.7^\circ \text{C}. \quad <$$

From energy balances on the two fluids,  $C_h (T_{h,i} - T_{h,o}) = C_c (T_{c,o} - T_{c,i})$ , find

$$T_{c,o} = T_{c,i} + (C_h/C_c)(T_{h,i} - T_{h,o}) = 15^\circ \text{C} + 0.19(200 - 55.7)^\circ \text{C} = 41.9^\circ \text{C}. \quad <$$

(b) To estimate  $\bar{h}_i$  for the water, find first the Reynolds number. From Eq. 8.6,

Continued...

**PROBLEM 11.53 (Cont.)**

$$\text{Re}_{D_i} = \frac{4\dot{m}}{\pi D_i \mu} = \frac{4\dot{m}_C / N}{\pi D_i \mu} = \frac{4 \times 6.5 \text{ kg/s} / 135}{\pi 12.5 \times 10^{-3} \text{ m} \times 855 \times 10^{-6} \text{ N/s} \cdot \text{m}^2} = 5736$$

While the flow is fully developed and turbulent,  $\text{Re}_D = 10,000$  such that Dittus-Boelter correlation is not strictly applicable. However, its use allows a first estimate.

$$\overline{\text{Nu}}_{D_i} = \bar{h} D_i / k = 0.023 \text{Re}_D^{4/5} \text{Pr}^{0.4} = 0.023 (5736)^{4/5} (5.83)^{0.4} = 47.3$$

$$\bar{h}_i = \overline{\text{Nu}}_D k / D_i = 47.3 \times 0.613 \text{ W/m}^2 \cdot \text{K} / 12.5 \times 10^{-3} \text{ m} = 2320 \text{ W/m}^2 \cdot \text{K} .$$

<

(c) Using the *IHT Heat Exchanger Tool, Shell and Tube, One-shell pass and N-tube passes*, and the prescribed properties, a model was developed following the analysis of part (a) to compute and plot  $\epsilon$ ,  $T_{c,o}$ , and  $T_{h,o}$  for a function of  $\dot{m}_C$ .

The outlet temperatures decrease nearly linearly with increasing cold fluid flow rate; the decrease in the cold outlet temperature is nearly twice that of the hot fluid. The change in the effectiveness with increasing flow rate is only slightly increased.

(d) Using the above IHT model, the hot inlet temperature  $T_{h,i}$ , required to provide  $\dot{m}_C = 10 \text{ kg/s}$  with  $T_{c,o} = 42^\circ\text{C}$  and the effectiveness for this operating condition are

$$T_{h,i} = 74.4^\circ\text{C} \quad \epsilon = 0.55$$

<

**COMMENTS:** (1) Check that assumptions for  $\bar{T}_h$  and  $\bar{T}_c$  used in part (a) for evaluation of the fluid properties are satisfactory as  $\bar{T}_h = 400.7 \text{ K}$  and  $\bar{T}_c = 301.5 \text{ K}$ .

(2) From part (b), with  $\bar{h}_i = 2320 \text{ W/m}^2 \cdot \text{K}$  and  $U = 200 \text{ W/m}^2 \cdot \text{K}$ , the shell-side convection coefficient is  $\bar{h}_o = 219 \text{ W/m}^2 \cdot \text{K}$ . As such,  $U$  is controlled by shell-side conditions. Assuming  $U$  as a constant in part (c) with changes in  $\dot{m}_C$  is therefore reasonable. However, for part (d) with  $\dot{m}_h$  doubling, we should expect  $U$  to increase.

### PROBLEM 11.54

**KNOWN:** Power output and efficiency of an ocean energy conversion system. Temperatures and overall heat transfer coefficient of shell-and-tube evaporator.

**FIND:** (a) Evaporator area, (b) Water flow rate.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat loss to surroundings, (2) Constant properties.

**PROPERTIES:** Table A-6, Water ( $\bar{T}_m = 296 \text{ K}$ ):  $c_p = 4181 \text{ J/kg}\cdot\text{K}$ .

**ANALYSIS:** (a) The efficiency is

$$\eta = \frac{\dot{W}}{q} = \frac{2 \text{ MW}}{q} = 0.03.$$

Hence the required heat transfer rate is  $q = \frac{2 \text{ MW}}{0.03} = 66.7 \text{ MW}$ .

From the  $\varepsilon$ -NTU method,  $C_c \rightarrow \infty$ , and  $C_h = C_{\min}$  can be found from an energy balance on the hot fluid,

$$C_h = q / (T_{h,i} - T_{h,o}) = 66.7 \times 10^6 \text{ W} / (300 - 292) \text{ K} = 8.33 \times 10^6 \text{ W/K}$$

Thus  $q_{\max} = C_{\min}(T_{h,i} - T_{c,i}) = 8.33 \times 10^7 \text{ W}$  and  $\varepsilon = q/q_{\max} = 0.80$ . Then, from Eqs. 11.30 b and c,

$$E = \frac{2/\varepsilon - (1 + C_r)}{(1 + C_r^2)^{1/2}} = \frac{2/0.8 - (1 + 0)}{1} = 1.50$$

$$\text{NTU} = -\left(1 + C_r^2\right)^{-1/2} \ln\left(\frac{E-1}{E+1}\right) = -\ln\left(\frac{1.5-1}{1.5+1}\right) = 1.61$$

Then,  $A = \text{NTU} \times C_{\min}/U = 1.61 \times 8.33 \times 10^6 \text{ W/K} / 1200 \text{ W/m}^2\cdot\text{K} = 11,200 \text{ m}^2$  <

(b) The water flow rate through the evaporator is

$$\dot{m}_h = \frac{q}{c_{p,h}(T_{h,i} - T_{h,o})} = \frac{6.67 \times 10^7 \text{ W}}{4181 \text{ J/kg}\cdot\text{K}(300 - 292)}$$

$$\dot{m}_h = 1994 \text{ kg/s.} <$$

**COMMENT:** (1) The required heat exchanger size is enormous due to the small temperature differences involved.

## PROBLEM 11.55

**KNOWN:** Single-pass cross-flow heat exchanger with both fluids unmixed. Flow rate and inlet and outlet temperatures of cold water. Inlet temperature of hot exhaust gases. Value of UA.

**FIND:** Required mass flow rate of exhaust gases.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Constant properties and steady-state conditions, (2) Negligible heat loss to surroundings, (3) U independent of mass flow rates.

**PROPERTIES:** Water (given):  $c_{p,c} = 4200 \text{ J/kg}\cdot\text{K}$ . Oil (given):  $c_{p,h} = 1200 \text{ J/kg}\cdot\text{K}$ .

**ANALYSIS:** We use the  $\varepsilon$ -NTU method, but without knowing the hot mass flow rate or the hot outlet temperature we don't know which fluid is the minimum fluid. We begin by assuming the cold fluid is the minimum fluid: if this leads to a solution for which the cold heat capacity rate is indeed lower than for the hot fluid, this is the correct solution. If it does not lead to a consistent solution, our assumption is incorrect. Thus, we assume

$$C_{\min} = \dot{m}_c c_{p,c} = 2 \text{ kg/s} \times 4200 \text{ J/kg}\cdot\text{K} = 8400 \text{ W/K}$$

Thus,  $\text{NTU} = UA/C_{\min} = 4700/8400 = 0.560$ ,  $q = C_c(T_{c,o} - T_{c,i}) = 6.72 \times 10^5 \text{ W}$  and from Eqs. 11.18 and 11.19,

$$\varepsilon = \frac{q}{C_{\min}(T_{h,i} - T_{c,i})} = \frac{6.72 \times 10^5 \text{ W}}{8400 \text{ W/K} (320 - 20)^\circ\text{C}} = 0.267$$

Referring to Figure 11.14, we see that there is no solution for  $\text{NTU} = 0.560$ ,  $\varepsilon = 0.267$ , therefore our initial assumption was incorrect and the hot fluid is the minimum fluid. We have the following four equations relating the four unknowns  $\varepsilon$ ,  $C_{\min}$ , NTU, and  $C_r$ ,

$$\varepsilon = \frac{q}{C_{\min}(T_{h,i} - T_{c,i})} = \frac{6.72 \times 10^5 \text{ W}}{C_{\min}(320 - 20)^\circ\text{C}} = \frac{2240 \text{ W/K}}{C_{\min}} \quad (1)$$

$$\text{NTU} = \frac{UA}{C_{\min}} = \frac{4700 \text{ W/K}}{C_{\min}}, \quad C_r = \frac{C_{\min}}{C_{\max}} = \frac{C_{\min}}{8400 \text{ W/K}} \quad (2,3)$$

and from Eq. 11.32,

Continued...

**PROBLEM 11.55 (Cont.)**

$$\varepsilon = 1 - \exp \left[ \left( \frac{1}{C_r} \right) (\text{NTU})^{0.22} \left\{ \exp \left[ -C_r (\text{NTU})^{0.78} \right] - 1 \right\} \right] \quad (4)$$

These equations can be solved simultaneously using *IHT*, or by hand. One approach to solving the equations by hand is as follows. Substituting Eqs. (1), (2), and (3) into Eq. (4) yields (where the units have been omitted),

$$\frac{2240}{C_{\min}} = 1 - \exp \left[ \frac{8400}{C_{\min}} \left( \frac{4700}{C_{\min}} \right)^{0.22} \left\{ \exp \left[ -\frac{C_{\min}}{8400} \left( \frac{4700}{C_{\min}} \right)^{0.78} \right] - 1 \right\} \right]$$

Beginning with an assumed value of  $C_{\min}$  and substituting it into the right hand side, we solve for  $C_{\min}$  on the left hand side, and repeat the process until it converges. Beginning with  $C_{\min} = 5000$ , the sequence of  $C_{\min}$  values is 5000, 4375, 3984, 3745, 3601, 3515, 3463, 3434, 3416, 3406, 3400, 3396, 3394, 3393, 3392, 3392. Thus

$$\dot{m}_h = C_{\min} / c_{p,h} = 3392 \text{ W/K} / 1200 \text{ J/kg} \cdot \text{K} = 2.83 \text{ kg/s} \quad <$$

**COMMENTS:** It is easier to solve the system of simultaneous equations using *IHT* or other non-linear equation solver.

## PROBLEM 11.56

**KNOWN:** Shell(1)-and-tube (two passes,  $p = 2$ ) heat exchanger for condensing saturated steam at 1 atm. Inlet cooling water temperature and mean velocity. Thin-walled tube diameter and length prescribed, as well as, convective heat transfer coefficient on outer tube surface,  $h_o$ .

**FIND:** (a) Number of tubes/pass,  $N$ , required to condense 2.3 kg/s of steam, (b) Outlet water temperature,  $T_{c,o}$ , (c) Maximum condensation rate possible for same water flowrate and inlet temperature, and (d) Compute and plot  $T_{c,o}$  and the condensation rate,  $\dot{m}_h$ , for water mean velocity,  $u_m$ , in the range  $1 \leq u_m \leq 5$  m/s, using the heat transfer surface area found in part (a) assuming the shell-side convection coefficient remains unchanged.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat loss to surroundings, (2) Negligible thermal resistance due to the tube walls.

**PROPERTIES:** Table A.6, Saturated steam (1 atm):  $T_{\text{sat}} = 100^\circ\text{C}$ ,  $h_{\text{fg}} = 2257$  kJ/kg; Water (assume  $T_{c,o} \approx 25^\circ\text{C}$ ,  $\bar{T}_m = (T_h + T_c)/2 \approx 295$  K):  $\rho = 1/v_f = 998$  kg/m<sup>3</sup>,  $c_c = c_{p,f} = 4181$  J/kg·K,  $\mu = \mu_f = 959 \times 10^{-6}$  N·s/m<sup>2</sup>,  $k = k_f = 0.606$  W/m·K,  $\text{Pr} = \text{Pr}_f = 6.62$ .

**ANALYSIS:** (a) The heat transfer rate for the heat exchanger is

$$q = \dot{m}_h h_{\text{fg}} = 2.3 \text{ kg/s} \times 2257 \times 10^3 \text{ J/kg} = 5.191 \times 10^6 \text{ W} \quad (1)$$

Using the  $\varepsilon$ -NTU method, evaluate the following parameters:

Water-side heat transfer coefficient:

$$\text{Re}_D = \frac{u_m D}{\mu / \rho} = \frac{3.5 \text{ m/s} \times 0.014 \text{ m}}{959 \times 10^{-6} \text{ N} \cdot \text{s} / \text{m}^2 / 998 \text{ kg} / \text{m}^3} = 50,993 \quad (2)$$

$$h_i = \frac{k}{D} \text{Nu}_D = \frac{k}{D} 0.023 \text{Re}_D^{0.8} \text{Pr}^{0.4} = \frac{0.606 \text{ W/m} \cdot \text{K}}{0.014 \text{ m}} \times 0.023 (50,993)^{0.8} (6.62)^{0.4} = 12,400 \text{ W/m}^2 \cdot \text{K} \quad (3)$$

using the Dittus-Boelter equation for fully developed turbulent conditions.

Overall coefficient:

$$\bar{U} = (1/h_i + 1/h_o)^{-1} = (1/12,400 + 1/21,800)^{-1} = 7900 \text{ W/m}^2 \cdot \text{K} \quad (4)$$

Effectiveness relations: With  $C_{\text{min}} = C_c$  and  $\dot{m}_c = \rho(\pi D^2/4)u_m N$ ,

$$q = \varepsilon q_{\text{max}} = \varepsilon C_{\text{min}} (T_{h,i} - T_{c,i}) \quad (5)$$

$$C_{\text{min}} = \dot{m}_c c_c = 998 \text{ kg/m}^3 \left( \pi \times 0.014^2 \text{ m}^2 / 4 \right) \times 3.5 \text{ m/s} \times N \times 4181 \text{ J/kg} \cdot \text{K} = 2248 N \quad (6)$$

Continued...

### PROBLEM 11.56 (Cont.)

$$5.191 \times 10^6 \text{ W} = \varepsilon \times 2248 \text{ N} (100 - 15) \text{ K}$$

$$\varepsilon \text{ N} = 27.17 \tag{7}$$

From Eq. 11.35a with  $C_r = 0$ , the effectiveness is

$$\varepsilon = 1 - \exp(-\text{NTU}) = 1 - \exp(-0.155) = 0.144 \tag{8}$$

where, using  $A_s = \pi \text{DLNP}$ , NTU is evaluated as,

$$\text{NTU} = \frac{\bar{U} A_s}{C_{\min}} = \frac{7900 \text{ W/m}^2 \cdot \text{K} (\pi \times 0.014 \text{ m} \times 0.5 \text{ m}) \text{ N} \times 2}{2248 \text{ N}} = 0.155$$

Hence, using Eq. (7), the required number of tubes is

$$N = 27.17 / \varepsilon = 205.8 \approx 189 \tag{9}$$

and the total surface area is

$$A_s = \pi \text{DLNP} = \pi \times 0.014 \text{ m} \times 0.5 \text{ m} \times 189 \times 2 = 8.31 \text{ m}^2.$$

(b) The water outlet temperature with  $C_{\min} = 2248 \text{ N} = 424,900 \text{ W/K}$ ,

$$T_{c,o} = T_{c,i} + q / C_{\min} = 15^\circ \text{C} + 5.191 \times 10^6 \text{ W} / 424,900 \text{ W/K} = 27.2^\circ \text{C} \tag{10}$$

(c) The maximum condensation rate will occur when  $q = q_{\max}$ . Hence

$$\dot{m}_{h,\max} = \frac{q_{\max}}{h_{fg}} = \frac{C_{\min} (T_{h,i} - T_{c,i})}{h_{fg}} = \frac{424,900 \text{ W/K} (100 - 15) \text{ K}}{2257 \times 10^3 \text{ J/kg}} = 16.0 \text{ kg/s}. \tag{11}$$

(d) Using the *IHT Heat Exchanger Tool, All Exchangers*,  $C_r = 0$ , along with the *Properties Tool* for *Water*, the foregoing analysis was performed to obtain  $T_{h,o}$  and  $\dot{m}_h$  using the heat transfer surface area  $A_s = 8.31 \text{ m}^2$  (part a) as a function of  $u_m$ .

Note that the condensation rate increases nearly linearly with the water mean velocity. The cold water outlet temperature decreases nearly linearly with  $u_m$ . We should expect this behavior from energy balance considerations. Since  $h_h$  is nearly two times greater than  $h_c$ ,  $\bar{U}$  is controlled by the water side coefficient. Hence  $\bar{U}$  will increase with increasing  $u_m$ .

**COMMENTS:** Note that the assumed value for  $\bar{T}_m$  to evaluate water properties in part (a) was a good choice.

## PROBLEM 11.57

**KNOWN:** Dimensions of counterflow, concentric tube heat exchanger for recovering heat from shower drains. Inlet temperatures of hot and cold water streams. Heat transfer coefficient of inner (hot) flow. Mass flow rate of outer (cold) flow.

**FIND:** (a) Heat transfer rate and outlet temperature of cold flow, (b) Heat transfer rate and outlet temperature of cold flow when helical spring provides specified outer heat transfer coefficient, (c) Daily savings if 15,000 students each take a 10-minute shower per day and cost of heating water is \$0.07/kW·h.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Constant properties and steady-state conditions, (2) Negligible heat transfer to surroundings, (3) Fully developed flow in the annular gap, (4) Uniform surface temperature correlation is appropriate, (5) Inner tube wall thermal resistance is negligible.

**PROPERTIES:** Table A.6, water ( $T \approx 285$  K):  $k = 0.591$  W/m·K,  $c_p = 4189$  J/kg·K,  $\mu = 1225 \times 10^{-6}$  N·s/m<sup>2</sup>,  $Pr = 8.81$ .

**ANALYSIS:** (a) We begin by finding the heat transfer coefficient for the flow in the annular gap. The Reynolds number is

$$Re_D = \frac{\rho u_m D_h}{\mu} = \frac{\dot{m} D_h}{\mu A_c} = \frac{4\dot{m}}{\mu P} = \frac{4 \times 10 \text{ kg/min} / 60 \text{ min/s}}{1225 \times 10^{-6} \text{ N} \cdot \text{s/m}^2 \times \pi(0.05 \text{ m} + 0.07 \text{ m})} = 1444$$

Thus the flow is laminar, and from Table 8.2 with  $D_i/D_o = 0.71$ ,  $Nu_i = 5.36$ . Hence,

$$h_c = \frac{Nu_i k}{D_h} = \frac{5.36 \times 0.591 \text{ W/m} \cdot \text{K}}{0.02 \text{ m}} = 158 \text{ W/m}^2 \cdot \text{K}$$

Continued...

### PROBLEM 11.57 (Cont.)

Then the overall heat transfer coefficient is

$$U = [1/h_c + 1/h_h]^{-1} = [1/158 \text{ W/m}^2 \cdot \text{K} + 1/10,000 \text{ W/m}^2 \cdot \text{K}]^{-1} = 156 \text{ W/m}^2 \cdot \text{K}$$

and using the  $\varepsilon$ -NTU method, with  $C_{\min} = C_{\max} = \dot{m}c_p = 698 \text{ W/K}$ ,  $C_r = 1$ , we have

$$\text{NTU} = UA/C_{\min} = U\pi D_i L/C_{\min} = 156 \text{ W/m}^2 \cdot \text{K} \times \pi \times 0.05 \text{ m} \times 1 \text{ m}/698 \text{ W/K} = 0.035$$

And from Eq. 11.29a,  $\varepsilon = \text{NTU}/(1 + \text{NTU}) = 0.034$ . Thus from Eqs. 11.18 and 11.19,

$$q = \varepsilon C_{\min}(T_{h,i} - T_{c,i}) = 0.034 \times 698 \text{ W/K} (38 - 10)^\circ\text{C} = 661 \text{ W} \quad <$$

and from Eq. 11.7b,

$$T_{c,o} = T_{c,i} + q/C_c = 10^\circ\text{C} + 661 \text{ W}/698 \text{ W/K} = 11.0^\circ\text{C} \quad <$$

(b) The value of  $U$  changes to  $U = [1/9050 \text{ W/m}^2 \cdot \text{K} + 1/10,000 \text{ W/m}^2 \cdot \text{K}]^{-1} = 4751 \text{ W/K}$ . Then  $\text{NTU} = 1.07$ ,  $\varepsilon = 0.517$ , and

$$q = \varepsilon C_{\min}(T_{h,i} - T_{c,i}) = 0.517 \times 697 \text{ W/K} (38 - 10)^\circ\text{C} = 10,100 \text{ W} \quad <$$

$$T_{c,o} = T_{c,i} + q/C_c = 10^\circ\text{C} + 10,100 \text{ W}/698 \text{ W/K} = 24.5^\circ\text{C} \quad <$$

(c) The savings is the cost of the energy transferred from the wastewater to the cold water,

$$\text{Savings} = 10.1 \text{ kW} \times 600 \text{ s} \times 15,000/3600 \text{ s/h} \times \$0.07/\text{kW}\cdot\text{h} = \$1767 \quad <$$

**COMMENTS:** (1) Commercially-available devices that are used in high density buildings such as dormitories are typically installed on larger drains that collect shower water from multiple showers, rather than on individual showers. The devices use heat transfer enhancement techniques to ensure large values of the cold side heat transfer coefficient. (2) With  $x_{fd,t} = 0.05\text{Re}_D\text{Pr}_h = 13 \text{ m}$ , the flow in the annular gap is not fully developed, and the actual heat transfer coefficient would be higher than predicted in part (a). (3) In part (a), the mean temperature of the cold stream is 283.5 K. Evaluation of properties at 285 K is appropriate.

### PROBLEM 11.58

**KNOWN:** Shell-and-tube heat exchanger with one shell pass and 20 tube passes.

**FIND:** Average convection coefficient for the outer tube surface.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat loss to surroundings, (2) Constant properties, (3) Type of oil not specified, (4) Thermal resistance of tubes negligible; no fouling.

**PROPERTIES:** Table A-6, Water, liquid ( $\bar{T}_h = 330 \text{ K}$ ):  $c_p = 4184 \text{ J/kg}\cdot\text{K}$ ,  $k = 0.650 \text{ W/m}\cdot\text{K}$ ,  $\mu = 489 \times 10^{-6} \text{ N}\cdot\text{s/m}^2$ ,  $\text{Pr} = 3.15$ .

**ANALYSIS:** To find the average coefficient for the outer tube surface,  $h_o$ , we need to evaluate  $h_i$  for the internal tube flow and  $U$ , the overall coefficient. From Eq. 11.5,

$$\frac{1}{UA} = \frac{1}{h_i A_i} + \frac{1}{h_o A_o} = \frac{1}{N_t \pi L} \left[ \frac{1}{h_i D_i} + \frac{1}{h_o D_o} \right]$$

where  $N_t$  is the total number of tubes. Solving for  $h_o$ ,

$$h_o = D_o^{-1} \left[ (UA)^{-1} N_t \pi L - 1/h_i D_i \right]^{-1}. \quad (1)$$

Evaluate  $h_i$  from an appropriate correlation; begin by calculating the Reynolds number.

$$\text{Re}_{D,i} = \frac{4 \dot{m}_h}{\pi D_i \mu} = \frac{4 \times 0.2 \text{ kg/s}}{\pi (0.020 \text{ m}) 489 \times 10^{-6} \text{ N}\cdot\text{s/m}^2} = 26,038.$$

Hence, flow is turbulent and since  $L \gg D_i$ , the flow is likely to be fully developed. Use the Dittus-Boelter correlation with  $n = 0.3$  since  $T_s < T_m$ ,  $\text{Nu}_D = 0.023 \text{ Re}_D^{4/5} \text{ Pr}^{0.3}$

$$h_i = \frac{k}{D} \text{Nu}_D = \frac{0.650 \text{ W/m}\cdot\text{K}}{0.020 \text{ m}} \times 0.023 (26,038)^{4/5} (3.15)^{0.3} = 3594 \text{ W/m}^2 \cdot \text{K}. \quad (2)$$

To evaluate  $UA$ , we use the  $\epsilon$ -NTU method.

$$C_h = \dot{m}_h c_{p,h} = 0.2 \text{ kg/s} \times 4184 \text{ J/kg}\cdot\text{K} = 836.8 \text{ W/K}$$

$$q = C_h (T_{h,i} - T_{h,o}) = 836.8 \text{ W/K} (87 - 27)^\circ\text{C} = 50,208 \text{ W}$$

Then from an energy balance on the cold fluid,

$$C_c = q/(T_{c,o} - T_{c,i}) = 50,208 \text{ W}/(37 - 7)^\circ\text{C} = 1674 \text{ W/K}$$

Thus  $C_r = C_{\min}/C_{\max} = 0.50$ ,  $q_{\max} = C_{\min}(T_{h,i} - T_{c,i}) = 66,944 \text{ W}$ , and  $\epsilon = q/q_{\max} = 0.75$ . From Eqs. 11.30b,c,

Continued...

**PROBLEM 11.58 (Cont.)**

$$E = \frac{2/\varepsilon - (1 + C_r)}{(1 + C_r^2)^{1/2}} = \frac{2/0.75 - (1 + 0.5)}{(1 + 0.5^2)^{1/2}} = 1.04$$

$$NTU = -(1 + C_r^2) \ln\left(\frac{E - 1}{E + 1}\right) = 3.44$$

Therefore,

$$UA = NTU \times C_{\min} = 3.44 \times 836.8 \text{ W/K} = 2881 \text{ W/K} \quad (3)$$

and

$$h_o = (0.024\text{m})^{-1} \left[ (2881 \text{ W/K})^{-1} \times 20 \times \pi \times 3\text{m} - 1/3594 \text{ W/m}^2 \cdot \text{K} \times 0.020\text{m} \right]^{-1}$$
$$= 808 \text{ W/m}^2 \cdot \text{K} \quad <$$

### PROBLEM 11.59

**KNOWN:** Engine oil cooled by air in a cross-flow heat exchanger with both fluids unmixed.

**FIND:** (a) Heat transfer coefficient on oil side of exchanger assuming fully-developed conditions and constant wall heat flux, (b) Effectiveness, and (c) Outlet temperature of the oil.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat loss to surroundings, (2) Constant properties, (3) Oil flow and thermal conditions are fully developed, (4) Oil cooling process approximates constant wall flux conditions.

**PROPERTIES:** Table A-5, Engine oil (assume  $T_{h,o} \approx 45^\circ\text{C}$ ,  $\bar{T}_h = (45 + 75)^\circ\text{C}/2 = 333\text{ K}$ ):  $c_h = 2047\text{ J/kg}\cdot\text{K}$ ,  $\mu = 7.45 \times 10^{-2}\text{ N}\cdot\text{s/m}^2$ ,  $k = 0.140\text{ W/m}\cdot\text{K}$ ; Table A-4, Air (assume  $T_{c,o} \approx 40^\circ\text{C}$ ,  $\bar{T}_c = (30 + 40)^\circ\text{C}/2 = 308\text{ K}$ , 1 atm):  $c_c = 1007\text{ J/kg}\cdot\text{K}$ .

**ANALYSIS:** (a) For the oil side, using Eq. 8.6, find,

$$\text{Re}_D = 4 \dot{m} / \pi D \mu = 4(0.026\text{ kg/s}) / (\pi(0.01\text{m})7.45 \times 10^{-2}\text{ N}\cdot\text{s/m}^2) = 44.4$$

Since  $\text{Re}_D < 2000$  the flow is laminar. For the fully-developed conditions with constant wall flux,

$$\text{Nu}_D = \frac{h_i D}{k} = 4.36, \quad h_i = 4.36 \frac{k}{D} = 4.36 \frac{0.140\text{ W/m}\cdot\text{K}}{0.01\text{m}} = 61.0\text{ W/m}^2\cdot\text{K}. \quad <$$

(b) The effectiveness can be determined by the  $\epsilon$ -NTU method.

$$C_h = \dot{m}_h c_h = 0.026\text{ kg/s} \times 2047\text{ J/kg}\cdot\text{K} = 53.22\text{ W/K} \quad C_{\min} = C_h$$

$$C_c = \dot{m}_c c_c = 0.53\text{ kg/s} \times 1007\text{ J/kg}\cdot\text{K} = 533.7\text{ W/K} \quad C_{\min}/C_{\max} = 0.10$$

$$\text{NTU} = UA/C_{\min} = 53\text{ W/m}^2\cdot\text{K} \times 1\text{m}^2 / 53.22\text{ W/K} = 1.00.$$

Using Fig. 11.14, with  $C_{\min}/C_{\max} = 0.1$  and  $\text{NTU} = 1$ , find  $\epsilon \approx 0.64$ . <

(c) From Eqs. 11.19 and 11.18,

$$\epsilon = \frac{q}{q_{\max}} = \frac{C_h (T_{h,i} - T_{h,o})}{C_{\min} (T_{h,i} - T_{c,i})} = \frac{T_{h,i} - T_{h,o}}{T_{h,i} - T_{c,i}}.$$

Solving for  $T_{h,o}$  and substituting numerical values, find

$$T_{h,o} = T_{h,i} - \epsilon (T_{h,i} - T_{c,i}) = 75^\circ\text{C} - 0.64(75 - 30)^\circ\text{C} = 46.2^\circ\text{C}. \quad <$$

**COMMENTS:** Note that the  $\bar{T}_h$  value at which the oil properties were evaluated is reasonable.

## PROBLEM 11.60

**KNOWN:** Dimensions, configuration and material of a single-pass, cross-flow heat exchanger. Inlet conditions of inner and outer flow. Fouling factor of inner surface.

**FIND:** (a) Percent fuel savings for prescribed conditions, (b) Effect of UA on air outlet temperature and fuel savings.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat loss to surroundings, (2) Air properties are those of atmospheric air at 300 K, (3) Gas properties are those of atmospheric air at 1400 K, (4) Tube wall temperature may be approximated as 800 K for treating variable property effects.

**PROPERTIES:** Table A.4, Air (1 atm, T = 300 K):  $\nu = 15.89 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $c_p = 1007 \text{ J/kg}\cdot\text{K}$ ,  $k = 0.0263 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.707$ ; (T = 1400 K):  $\mu = 530 \times 10^{-7} \text{ kg/s}\cdot\text{m}$ ,  $c_p = 1207 \text{ J/kg}\cdot\text{K}$ ,  $k = 0.091 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.703$ ; (T = 800 K):  $\text{Pr} = 0.709$ .

**ANALYSIS:** (a) With capacity rates of  $C_c = \dot{m}_c c_{p,c} = 1 \text{ kg/s} \times 1007 \text{ J/kg}\cdot\text{K} = 1007 \text{ W/K} = C_{\min}$  and  $C_h = \dot{m}_h c_{p,h} = 1.05 \text{ kg/s} \times 1207 \text{ J/kg}\cdot\text{K} = 1267 \text{ W/K} = C_{\max}$ ,  $C_{\min}/C_{\max} = 0.795$ . The overall coefficient is

$$\frac{1}{UA} = \frac{1}{h_i A_i} + \frac{R''_{f,i}}{A_i} + \frac{\ln(D_o/D_i)}{(2\pi kL)N} + \frac{1}{h_o A_o}$$

For flow through a single tube,

$$\text{Re}_D = \frac{4\dot{m}_h}{N\pi D_i \mu} = \frac{4 \times 1.05 \text{ kg/s}}{80\pi (0.055 \text{ m}) 530 \times 10^{-7} \text{ kg/s}\cdot\text{m}} = 5733$$

Assuming fully developed turbulent flow throughout and using the Gnielinski correlation,

$$\text{Nu}_D = \frac{(f/8)(\text{Re}_D - 1000)\text{Pr}}{1 + 12.7(f/8)^{1/2}(\text{Pr}^{2/3} - 1)} = 18.8$$

where  $f = (0.79 \ln \text{Re}_D - 1.64)^{-2} = 0.0370$

$$h_i = \text{Nu}_D k / D_i = 18.8 (0.091 \text{ W/m}\cdot\text{K}) / 0.055 \text{ m} = 31.1 \text{ W/m}^2\cdot\text{K}$$

For flow over the tube bank,

$$V_{\max} = [S_T / (S_T - D_o)] V = [0.12 \text{ m} / (0.12 - 0.08) \text{ m}] 1 \text{ m/s} = 3 \text{ m/s}$$

$$\text{Re}_{D,\max} = \frac{V_{\max} D_o}{\nu} = \frac{3 \text{ m/s} (0.08 \text{ m})}{15.89 \times 10^{-6} \text{ m}^2/\text{s}} = 15,100$$

From the Zukauskas correlation for a tube bank,

$$\overline{\text{Nu}}_D = 0.27 (15,100)^{0.63} (0.707)^{0.36} (0.707/0.709)^{1/4} = 102.3$$

$$\overline{h}_o = \overline{\text{Nu}}_D (k/D_o) = 102.3 (0.0263 \text{ W/m}\cdot\text{K}) / 0.08 \text{ m} = 33.6 \text{ W/m}^2\cdot\text{K}$$

Hence, based on the inner surface, the overall coefficient is

Continued...

**PROBLEM 11.60 (Cont.)**

$$\frac{1}{U_i} = \frac{1}{h_i} + R_{f,i}'' + \frac{D_i \ln(D_o/D_i)}{2k} + \frac{D_i}{D_o h_o}$$

$$\frac{1}{U_i} = \left( 0.0322 + 0.0002 + \frac{0.055 \ln(0.08/0.055)}{20} + \frac{0.055}{0.08 \times 33.6} \right) \text{m}^2 \cdot \text{K/W}$$

$$U_i = \left[ 0.0322 + 0.0002 + 0.001 + 0.0205 \text{m}^2 \cdot \text{K/W} \right]^{-1} = 18.6 \text{ W/m}^2 \cdot \text{K}$$

Hence,  $(UA)_i = U_i N \pi D_i L = 18.6 \text{ W/m}^2 \cdot \text{K} \times 80 \pi (0.055 \text{ m}) 1.4 \text{ m} = 360 \text{ W/K}$ . The number of transfer units is then  $NTU = UA/C_{\min} = 360 \text{ W/K}/1007 \text{ W/K} = 0.357$ , and with  $C_{\text{mixed}}/C_{\text{unmixed}} = C_c/C_h = C_{\min}/C_{\max} = 0.795$ , Fig. 11.15 yields  $\varepsilon \approx 0.29$  or, from Eq. 11.34 a,

$$\varepsilon = 1 - \exp\left(-C_r^{-1} \{1 - \exp[-C_r \cdot NTU]\}\right) = 0.267.$$

Hence, with

$$q_{\max} = C_{\min} (T_{h,i} - T_{c,i}) = 1007 \text{ W/K} (1100 \text{ K}) = 1.11 \times 10^6 \text{ W}$$

$$q = \varepsilon q_{\max} = 0.267 \times 1.11 \times 10^6 \text{ W} = 295,800 \text{ W}$$

$$T_{c,o} = T_{c,i} + q/C_{\min} = 300 \text{ K} + (295,800 \text{ W}/1007 \text{ W/K}) = 594 \text{ K}.$$

Hence,

$$\% \text{ fuel savings} \equiv FS = (\Delta T_c / 10 \text{ K}) \times 1\% = (294 \text{ K}/10 \text{ K}) \times 1\% = 29.4\%$$

(b) Using the Heat Exchangers Toolpad of IHT to perform the parametric calculations, the following results are obtained.

Significant benefits are derived by increasing UA, with values of  $T_{c,o} = 716 \text{ K}$  and  $FS = 41.6\%$  obtained for  $UA = 600 \text{ W/K}$ . The major contributions to the total resistance are made by the inner and outer convection resistances. These contributions could be reduced by using extended surfaces on both the inner and outer surfaces.

**COMMENTS:** For part (a), properties of the flue gas should be evaluated at  $(T_{h,i} + T_{h,o})/2$  and the calculations repeated.

## PROBLEM 11.61

**KNOWN:** Rate of thermal energy production in combustor and transfer to load in furnace. Cold air and flue gas flowrates and specific heats in recuperator. Recuperator cold air inlet temperature.

**FIND:** Recuperator hot gas inlet and outlet temperatures and air outlet temperature for a recuperator effectiveness of  $\varepsilon = 0.3$ . Value of  $\varepsilon$  needed to achieve a recuperator outlet temperature of 800 K.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Constant properties, (2) Negligible effect of fuel addition on flow rate.

**PROPERTIES:** Air and gas:  $c_{p,c} = c_{p,h} = 1200 \text{ J/kg}\cdot\text{K}$ .

**ANALYSIS:** With  $C_c = C_h = C_{\min}$ , the effectiveness of the recuperator,  $\varepsilon = q/q_{\max}$ , may be expressed as

$$\varepsilon = \frac{C_c (T_{c,o} - T_{c,i})}{C_{\min} (T_{h,i} - T_{c,i})} = \frac{T_{c,o} - 300 \text{ K}}{T_{h,i} - 300 \text{ K}} = 0.3$$

The unknown temperatures,  $T_{c,o}$  and  $T_{h,i}$ , are also related through an energy balance performed on the air entering the combustor and leaving the furnace. Specifically,

$$C(T_{h,i} - T_{c,o}) = q_{\text{comb}} - q_{\text{load}} = 0.6 \times 10^6 \text{ W}$$

where  $C = 1 \text{ kg/s} \times 1200 \text{ J/kg}\cdot\text{K} = 1200 \text{ W/K}$ . Solving the foregoing equations, we obtain

$$T_{h,i} = 1014 \text{ K} \quad T_{c,o} = 514 \text{ K} \quad \leftarrow$$

Expressing the effectiveness as

$$\varepsilon = \frac{C_h (T_{h,i} - T_{h,o})}{C_{\min} (T_{h,i} - T_{c,i})} = \frac{1014 \text{ K} - T_{h,o}}{714 \text{ K}}$$

we also obtain  $T_{h,o} = 800 \text{ K}$ . ←

For a combustor air inlet temperature of  $T_{c,o} = 800 \text{ K}$  and  $T_{h,i} = 1014 \text{ K}$ , the required effectiveness is

$$\varepsilon = \frac{T_{c,o} - T_{c,i}}{T_{h,i} - T_{c,i}} = \frac{(800 - 300) \text{ K}}{(1014 - 300) \text{ K}} = 0.70 \quad \leftarrow$$

**COMMENTS:** The effectiveness of the recuperator may be increased by increasing NTU and hence UA, as, for example, by increasing the number of tubes.

## PROBLEM 11.62

**KNOWN:** Shell-tube heat exchanger with one shell and single tube pass; Tube side: exhaust gas with specified flow rate and temperature change; Shell side: supply of saturated water at 11.7 bar; Tube dimensions and thermal conductivity, and fouling resistance on gas side,  $R''_{f,h}$ , specified.

**FIND:** Number of tubes and their length if the gas velocity is not to exceed  $u_{m,i} = 25$  m/s.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Negligible losses to the surroundings, (3) Negligible water-side thermal resistance, (4) Exhaust gas properties are those of atmospheric air, (5) Gas-side flow is fully developed, and (6) Constant properties.

**PROPERTIES:** Table A-4, Air ( $\bar{T}_h = 581$  K):  $\rho = 0.600$  kg/m<sup>3</sup>,  $c = 1047$  J/kg·K,  $\nu = 4.991 \times 10^{-5}$  m<sup>2</sup>/s,  $k = 0.0457$  W/m·K,  $Pr = 0.684$ . Table A-6, Water (11.7 bar, saturated):  $T_{c,i} = 460$  K = 187°C.

**ANALYSIS:** We'll employ the NTU- $\epsilon$  method to design the exchanger. Since  $C_r = 0$ , use Eq. 11.35b.

$$NTU = -\ln(1 - \epsilon)$$

where the effectiveness can be evaluated from Eqs. 11.18 and 11.19.

$$C_{\min} = C_h = \dot{m}_h c_h = 2 \text{ kg/s} \times 1047 \text{ J/kg} \cdot \text{K} = 2094 \text{ W/K}$$

$$\epsilon = \frac{C_h (T_{h,i} - T_{h,o})}{C_{\min} (T_{h,i} - T_{c,i})} = \frac{(400 - 215)^\circ\text{C}}{(400 - 187)^\circ\text{C}} = 0.868$$

$$NTU = -\ln(1 - 0.868) = 2.029$$

From Eq. 11.24,

$$UA = C_{\min} \cdot NTU = 2094 \text{ W/K} \times 2.029 = 4249 \text{ W/K} \quad (1)$$

Considering the gas-side flow rate and velocity criteria, find the number of tubes required as

$$\dot{m}_h = N \cdot \rho_h \cdot A_c \cdot u_{m,i} = N \cdot \rho_h \left( \pi D_1^2 / 4 \right) u_{m,i}$$

Continued ...

### PROBLEM 11.62 (Cont.)

$$2 \text{ kg/s} = N \times 0.600 \text{ kg/m}^3 \times \pi (0.050 \text{ m})^2 / 4 \times 25 \text{ m/s}$$

$$N = 67.9 \text{ tubes, specify 68}$$

&lt;

The overall coefficient, considering the convection process, fouling resistance and the tube thermal resistance, is evaluated as

$$U_i = 1 / [R_{f,i}'' + R_{cv,i}'' + R_{cd,t}''] = 56.4 \text{ W/m}^2 \cdot \text{K}$$

$$R_{f,i}'' = 0.0015 \text{ m}^2 \cdot \text{K/W}$$

$$R_{cv,i}'' = 1/h_i = 1/62 \text{ W/m}^2 \cdot \text{K} = 0.0161 \text{ m}^2 \cdot \text{K/W}$$

$$R_{cd,t}'' = \frac{D_i \ln(D_o/D_i)}{2k} = \frac{0.050 \text{ m} \ln(58/50)}{2 \times 40 \text{ W/m} \cdot \text{K}} = 9.28 \times 10^{-5} \text{ m}^2 \cdot \text{K/W}$$

where the gas-side convection coefficient estimate is explained in the Comments section. Substituting numerical values, determine the required tube length

$$[UA] = U_i \cdot A_i = U_i (N \pi D_i L)$$

$$4249 \text{ W/K} = 56.4 \text{ W/m}^2 \cdot \text{K} \times 68 \times \pi \times 0.050 \text{ m} \times L$$

$$L = 7.1 \text{ m}$$

&lt;

**COMMENTS:** (1) Is the assumption of negligible water-side thermal resistance reasonable? Explain why.

(2) Knowing the tube gas-side velocity, the usual convection correlation calculation methodology is followed. The flow is turbulent,  $Re_{D_i} = 2.5 \times 10^4$ , and assuming fully developed flow, use the Dittius-Boelter correlation, Eq. 8.60, to find  $Nu_{D_i} = 67.8$  and  $h_i = 62.0 \text{ W/m}^2 \cdot \text{K}$ .

### PROBLEM 11.63

**KNOWN:** Hot and cold gas flow rates and inlet temperatures of a recuperator. Overall heat transfer coefficient. Desired cold gas outlet temperature.

**FIND:** (a) Required surface area, (b) Effect of surface area on cold-gas outlet temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat loss to surroundings, (2) Constant properties.

**PROPERTIES:** Given:  $c_{p,c} = c_{p,h} = 1040 \text{ W/m}\cdot\text{K}$ .

**ANALYSIS:** (a) With  $C_{\min} = C_c = 6.2 \text{ kg/s} \times 1040 \text{ J/kg}\cdot\text{K} = 6,448 \text{ W/K}$ ,  $C_{\max} = C_h = 6.5 \text{ kg/s} \times 1040 \text{ J/kg}\cdot\text{K} = 6,760 \text{ W/K}$ ,  $C_r = C_{\min}/C_{\max} = 0.954$ ,  $q = C_c (T_{c,o} - T_{c,i}) = 6,448 \text{ W/K} (200 \text{ K}) = 1.29 \times 10^6 \text{ W}$ ,  $q_{\max} = C_{\min} (T_{h,i} - T_{c,i}) = 6,448 \text{ W/K} (400 \text{ K}) = 2.58 \times 10^6 \text{ W}$ , and  $\epsilon = q/q_{\max} = 0.50$ , Fig. 11.14 yields  $\text{NTU} \approx 1.10$ . Hence

$$A = \frac{\text{NTU} \times C_{\min}}{U} = \frac{1.10 \times 6,448 \text{ W/K}}{100 \text{ W/m}^2 \cdot \text{K}} = 70.9 \text{ m}^2 \quad <$$

(b) Using the Heat Exchanger option of *IHT*, the following result was obtained

The air outlet temperature increases, of course, with increasing heat exchanger area, but the approach to the maximum possible outlet temperature,  $T_{h,i}$ , is slow and the heat exchanger size needed to achieve a large outlet temperature may be prohibitively expensive.

### PROBLEM 11.64

**KNOWN:** Inlet temperature and flow rates for a concentric tube heat exchanger. Hot fluid outlet temperature.

**FIND:** (a) Maximum possible heat transfer rate and effectiveness, (b) Preferred mode of operation.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state operation, (2) Negligible heat loss to surroundings, (3) Fixed overall heat transfer coefficient.

**PROPERTIES:** Table A-5, Ethylene glycol ( $\bar{T}_m = 80^\circ\text{C}$ ):  $c_p = 2650 \text{ J/kg}\cdot\text{K}$ ; Table A-6, Water ( $\bar{T}_m \approx 30^\circ\text{C}$ ):  $c_p = 4178 \text{ J/kg}\cdot\text{K}$ .

**ANALYSIS:** (a) Using the  $\epsilon$ -NTU method, find

$$C_{\min} = C_h = \dot{m}_h c_{p,h} = (0.5 \text{ kg/s})(2650 \text{ J/kg}\cdot\text{K}) = 1325 \text{ W/K}.$$

Hence from Eqs. 11.18 and 11.6,

$$q_{\max} = C_{\min} (T_{h,i} - T_{c,i}) = (1325 \text{ W/K})(100 - 15)^\circ\text{C} = 1.13 \times 10^5 \text{ W}.$$

$$q = \dot{m}_h c_{p,h} (T_{h,i} - T_{h,o}) = 0.5 \text{ kg/s} (2650 \text{ J/kg}\cdot\text{K})(100 - 60)^\circ\text{C} = 0.53 \times 10^5 \text{ W}. <$$

Hence from Eq. 11.19,

$$\epsilon = q/q_{\max} = 0.53 \times 10^5 / 1.13 \times 10^5 = 0.47. <$$

(b) From Eq. 11.7,

$$T_{c,o} = T_{c,i} + \frac{q}{\dot{m}_c c_{p,c}} = 15^\circ\text{C} + \frac{0.53 \times 10^5}{0.5 \text{ kg/s} \times 4178 \text{ J/kg}\cdot\text{K}} = 40.4^\circ\text{C}.$$

Since  $T_{c,o} < T_{h,o}$ , a *parallel flow* mode of operation is possible. However, with  $(C_{\min}/C_{\max}) = (\dot{m}_h c_{p,h}/\dot{m}_c c_{p,c}) = 0.63$ ,

$$\text{Fig. 11.10} \rightarrow (\text{NTU})_{\text{PF}} \approx 0.95$$

$$\text{Fig. 11.11} \rightarrow (\text{NTU})_{\text{CF}} \approx 0.75.$$

Hence from Eq. 11.24

$$(A_{\text{CF}}/A_{\text{PF}}) = (\text{NTU})_{\text{CF}}/(\text{NTU})_{\text{PF}} \approx (0.75/0.95) = 0.79.$$

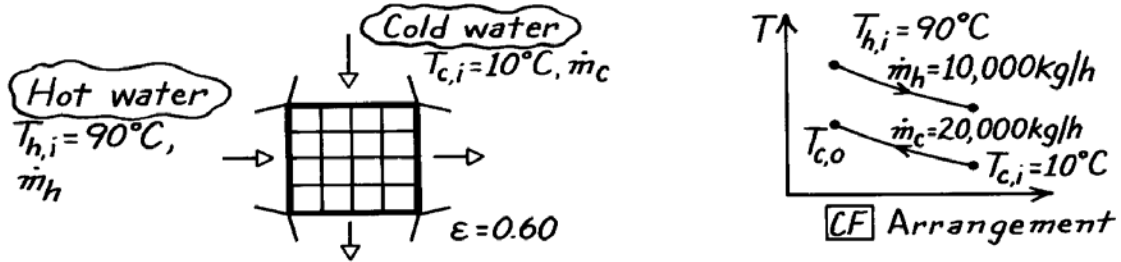

Because of the reduced size requirement, and hence capital investment, the *counterflow* mode of operation is preferred.

### PROBLEM 11.65

**KNOWN:** Single-pass, cross-flow heat exchanger with both fluids (water) unmixed; hot water enters at  $90^\circ\text{C}$  and at  $10,000\text{ kg/h}$  while cold water enters at  $10^\circ\text{C}$  and at  $20,000\text{ kg/h}$ ; effectiveness is  $60\%$ .

**FIND:** Cold water exit temperature,  $T_{c,o}$ .

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat loss to surroundings, (2) Constant properties.

**PROPERTIES:** Table A-6, Water ( $\bar{T}_c \approx (10 + 40)^\circ\text{C}/2 \approx 300\text{ K}$ ):  $c_c = 4179\text{ J/kg}\cdot\text{K}$ ; Table A-6, Water ( $\bar{T}_h \approx (90 + 60)^\circ\text{C}/2 \approx 350\text{ K}$ ):  $c_h = 4195\text{ J/kg}\cdot\text{K}$ .

**ANALYSIS:** From an energy balance on the cold fluid, Eq. 11.7, the outlet temperature can be expressed as

$$T_{c,o} = T_{c,i} + q / \dot{m}_c C_c.$$

The heat rate can be written in terms of the effectiveness and  $q_{\max}$ . Using Eqs. 11.19 and 11.18,

$$q = \varepsilon q_{\max} = \varepsilon C_{\min} (T_{h,i} - T_{c,i}).$$

By inspection, it can be noted that the hot fluid is the minimum capacity fluid. Substituting numerical values,

$$q = \varepsilon (\dot{m}_h c_h) (T_{h,i} - T_{c,i})$$

$$q = 0.60(10,000\text{ kg/h} / 3600\text{ s/h}) 4195\text{ J/kg}\cdot\text{K} (90 - 10)^\circ\text{C} = 559.3 \times 10^3\text{ W}.$$

The exit temperature of the cold water is then

$$T_{c,o} = 10^\circ\text{C} + 559.3 \times 10^3\text{ W} / \frac{20,000}{3600}\text{ kg/s} \times 4179\text{ J/kg}\cdot\text{K} = 34.1^\circ\text{C}. \quad <$$

**COMMENTS:** (1) The properties of the cold fluid should be evaluated at  $\bar{T} = (T_{c,o} + T_{c,i})/2 = (34.1 + 10)^\circ\text{C}/2 = 295\text{ K}$ . Note the analysis assumed  $\bar{T}_c \approx 300\text{ K}$ , hence little error is incurred. For best precision, one should check  $\bar{T}_h$  and  $C_h$ .

(2) From Fig. 11.14, the value of NTU could be determined. First evaluate the term

$$C_{\min} / C_{\max} = \dot{m}_h C_h / \dot{m}_c C_c = \frac{10,000 \times 4195}{20,000 \times 4179} = 0.50$$

and with  $\varepsilon = 0.60$ , find  $\text{NTU} \approx 1.2$ .

### PROBLEM 11.66

**KNOWN:** Hxer consisting of 32 tubes in 0.6m square duct. Hot water enters tubes at 150°C with mean velocity 0.5 m/s. Atmospheric air at 10°C enters exchanger with volumetric flow rate of 1 m<sup>3</sup>/s. Heat transfer coefficient on tube outer surfaces is 400 W/m<sup>2</sup>·K.

**FIND:** Outlet temperatures of the fluids, T<sub>c,o</sub> and T<sub>h,o</sub>.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat loss to surroundings, (2) Constant properties, (3) Hxer is a single-pass, cross-flow type with one fluid mixed (air) and the other unmixed (water), (4) Tube water flow is fully developed, (5) Negligible thermal resistance due to tube wall.

**PROPERTIES:** Table A-4, Air (T<sub>c,i</sub> = 10°C = 283 K, 1 atm): ρ = 1.2407 kg/m<sup>3</sup>; Table A-4, Air (assume T<sub>c,o</sub> ≈ 40°C, T̄<sub>c</sub> = (10 + 40)°C/2 = 298 K, 1 atm): c<sub>p</sub> = 1007 J/kg·K; Table A-6, Water (assume T<sub>h,o</sub> ≈ 140°C, T̄<sub>h</sub> = (140 + 150)°C/2 = 418 K): ρ = 1/v<sub>f</sub> = 1/1.0850 × 10<sup>-3</sup> m<sup>3</sup>/kg, c<sub>p</sub> = 4297 J/kg·K, μ<sub>f</sub> = 188 × 10<sup>-6</sup> N·s/m<sup>2</sup>, k<sub>f</sub> = 0.688 W/m·K, Pr<sub>f</sub> = 1.18.

**ANALYSIS:** Using the ε-NTU method, first find the capacity rates.

$$C_h = \dot{m}_h c_{p,h} = (\rho A_c u_m)_h N \cdot c_{p,h}$$

$$C_h = \frac{1}{1.0850 \times 10^{-3} \text{ m}^3/\text{kg}} \times \frac{\pi}{4} \left(10.2 \times 10^{-3} \text{ m}\right)^2 \times 0.5 \frac{\text{m}}{\text{s}} \times 32 \times 4297 \frac{\text{J}}{\text{kg} \cdot \text{K}} = 5178 \frac{\text{W}}{\text{K}}$$

$$C_c = \dot{m}_c c_{p,c} = (\rho V)_c c_{p,c} = 1.2407 \frac{\text{kg}}{\text{m}^3} \times 1 \text{ m}^3/\text{s} \times 1007 \text{ J/kg} \cdot \text{K} = 1249 \frac{\text{W}}{\text{K}}. \quad (1,2)$$

Note that the cold fluid is the minimum fluid, C<sub>c</sub> = C<sub>min</sub>. The overall heat transfer coefficient follows from Eq. 11.5,

$$U_o A_o = \left[ \frac{1}{h_i A_i} + \frac{1}{h_o A_o} \right]^{-1} \quad (3)$$

where h<sub>i</sub> must be estimated from an appropriate internal flow correlation. The Reynolds number for water flow is

$$\text{Re}_D = \frac{\rho u_m D_i}{\mu} = \frac{\left(1/1.0850 \times 10^{-3} \text{ m}^3/\text{kg}\right) \times 0.5 \text{ m/s} \times \left(10.2 \times 10^{-3} \text{ m}\right)}{188 \times 10^{-6} \text{ N} \cdot \text{s}/\text{m}^2} = 25,002. \quad (4)$$

Continued ...

### PROBLEM 11.66 (Cont.)

The flow is turbulent and since  $L/D_i = 0.6\text{m}/10.2 \times 10^{-3}\text{m} = 59$ , fully developed conditions may be assumed. The Dittus-Boelter correlation with  $n = 0.3$  is appropriate.

$$\text{Nu}_D = \frac{h_i D_i}{k} = 0.023 \text{Re}_D^{0.8} \text{Pr}^{0.3} = 0.023(25,002)^{0.8} (1.18)^{0.3} = 79.7$$

$$h_i = \frac{k}{D_i} \text{Nu}_D = \frac{0.688 \text{W/m}\cdot\text{K}}{10.2 \times 10^{-3}\text{m}} \times 79.7 = 5376 \text{W/m}^2 \cdot \text{K}.$$

Substituting numerical values into Eq. (3), find

$$U_o = \left[ \left( \frac{12.5\text{mm}}{10.2\text{mm}} \right) \frac{1}{5376 \text{W/m}^2 \cdot \text{K}} + \frac{1}{400 \text{W/m}^2 \cdot \text{K}} \right]^{-1} = 366.6 \text{W/m}^2 \cdot \text{K}.$$

It follows from Eq. 11.24, with  $A_o = N(\pi D_o L)$ , that

$$\text{NTU} = \frac{U_o A_o}{C_{\min}} = 366.6 \frac{\text{W}}{\text{m}^2 \cdot \text{K}} \times \left( 32 \times \pi \times 12.5 \times 10^{-3}\text{m} \times 0.6\text{m} \right) / 1249 \frac{\text{W}}{\text{K}} = 0.22.$$

From Fig. 11.15, noting that  $C_{\min} = C_c$  is the mixed fluid (solid curves),

$$\frac{C_{\text{mixed}}}{C_{\text{unmixed}}} = \frac{C_{\min}}{C_{\max}} = \frac{C_c}{C_h} = \frac{1249 \text{W/K}}{5178 \text{W/K}} = 0.24$$

and with  $\text{NTU} = 0.22$  find  $\varepsilon \approx 0.19$ . From the definition of effectiveness, Eq. 11.19,

$$\varepsilon = \frac{q}{q_{\max}} = \frac{C_c (T_{c,o} - T_{c,i})}{C_{\min} (T_{h,i} - T_{c,i})}$$

$$T_{c,o} = T_{c,i} + \varepsilon (T_{h,i} - T_{c,i}) = 10^\circ\text{C} + 0.19(150 - 10)^\circ\text{C} = 36.6^\circ\text{C}. \quad <$$

Equating the energy balances on both fluids,

$$C_c (T_{c,o} - T_{c,i}) = C_h (T_{h,i} - T_{h,o})$$

or

$$T_{h,o} = T_{h,i} - \frac{C_c}{C_h} (T_{c,o} - T_{c,i})$$

$$T_{h,o} = 150^\circ\text{C} - \frac{1249 \text{W/K}}{5178 \text{W/K}} (36.6 - 10)^\circ\text{C} = 143.5^\circ\text{C}. \quad <$$

**COMMENTS:** (1) Note that the assumptions of  $T_{h,o}$  and  $T_{c,o}$  used in evaluating properties are reasonable.

(2) Note that to calculate  $\dot{m}_c$  from  $V$ , the density at  $10^\circ\text{C}$  is more appropriate than at  $\bar{T}_c$ .

### PROBLEM 11.67

**KNOWN:** Flow rates and inlet temperatures of exhaust gases and combustion air used in a cross-flow (one fluid mixed) heat exchanger. Overall heat transfer coefficient. Desired air outlet temperature.

**FIND:** Required heat exchanger surface area.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Negligible heat loss to surroundings, (3) Constant properties, (4) Gas properties are those of air.

**PROPERTIES:** Table A-4, Air ( $\bar{T}_m \approx 700\text{ K}$ , 1 atm):  $c_p = 1075\text{ J/kg}\cdot\text{K}$ .

**ANALYSIS:** Using the  $\epsilon - \text{NTU}$  method,

$$C_c = \dot{m}_c c_{p,c} = 10\text{ kg/s} \times 1075\text{ J/kg}\cdot\text{K} = 10,750\text{ W/K}$$

$$C_h = \dot{m}_h c_{p,h} = 15\text{ kg/s} \times 1075\text{ J/kg}\cdot\text{K} = 16,125\text{ W/K}$$

$$\text{Thus } C_r = C_{\min}/C_{\max} = 0.667, \quad \epsilon = q/q_{\max} = (T_{c,o} - T_{c,i})/(T_{h,i} - T_{c,i}) = 0.688$$

From Eq. 11.34b,

$$\text{NTU} = -\frac{1}{C_r} \ln[C_r \ln(1 - \epsilon) + 1] = -\frac{1}{0.667} \ln[0.667 \ln(1 - 0.688) + 1] = 2.24$$

Therefore,

$$A = \text{NTU} \times C_{\min}/U = (2.24 \times 10,750\text{ W/K}) / (100\text{ W/m}^2\cdot\text{K}) = 241\text{ m}^2$$

<

## PROBLEM 11.68

**KNOWN:** Heat exchanger with  $C_r = 0$ .

**FIND:** Derivation of Equation 11.35a.

**ASSUMPTIONS:** (1) Negligible heat transfer between heat exchangers and surroundings, negligible heat transfer between two heat exchangers, (2) Constant properties.

**ANALYSIS:** For  $C_r = 0$ ,  $C_{\max} \rightarrow \infty$ . If the hot stream is associated with  $C_{\max}$ , then  $T_{h,i} = T_{h,o}$ . From Eq. 8.45 with  $T_{\infty} = T_{h,i}$  and  $T_{m,o} = T_{c,o}$ ,  $T_{m,i} = T_{c,i}$ ,

$$\frac{T_{h,i} - T_{c,o}}{T_{h,i} - T_{c,i}} = \exp\left(-\frac{UA}{\dot{m}c_p}\right) = \exp(-NTU) \quad (1)$$

where  $\dot{m}c_p = C_c = C_{\min}$  or

$$T_{c,o} = T_{h,i} - (T_{h,i} - T_{c,i})\exp(-NTU) \quad (2)$$

and

$$q = \dot{m}c_p (T_{m,o} - T_{m,i}) = C_{\min} (T_{c,o} - T_{c,i}) = C_{\min} [T_{h,i} - (T_{h,i} - T_{c,i})\exp(-NTU) - T_{c,i}] \quad (3)$$

From Eq. 11.22,

$$q = \varepsilon C_{\min} (T_{h,i} - T_{c,i}) \quad (4)$$

Equating Eqs. (3) and (4) yields

$$\varepsilon C_{\min} (T_{h,i} - T_{c,i}) = C_{\min} [T_{h,i} - (T_{h,i} - T_{c,i})\exp(-NTU) - T_{c,i}]$$

or

$$\varepsilon = 1 - \exp(-NTU) \quad <$$
