east (Ruiz-Renteria, 1979). However, the scope and magnitude of such influence is yet to be determined. Nevertheless, the increase in Chl-*a* concentration supports this suggestion. Chl*-a* values decreased toward the adjacent Caribbean Sea with quantities from 0.01 to 0.07 mg  $\mathrm{m}^3$ that are the typical values reported by other authors for this region. This is in contrast to the coastal zone of the northern Yucatan Peninsula where the Chl-*a* contents are high (average monthly concentrations from 2.10 to 6.96 mg m<sup>-3</sup>, with the highest values  $>10$  mg m<sup>-3</sup>), largely due to enhanced nutrient inputs from groundwater (Morales et al., 2010).

The lack of nutrient data impeded a more refined analysis of phytoplankton growth during the surveys; however, considering data by other authors in the study region (El-Sayed et al., 1972; Furnas and Smayda, 1987; Merino, 1997), it is possible to deduce that the phytoplankton abundance (mainly diatoms) primarily reflects the nutrient concentration in the region, especially off Cape Catoche.

The region north of Cape Catoche has been characterized by upwelling phenomena whose maximum intensity occurs during spring and summer (Cochrane, 1969; Bessonov, 1971; Ruiz-Renteria, 1979; Merino, 1997). In this regard, our results fit well with those in the published literature because the highest Chl-*a* values were found there. These data place this region as one of the most productive on the Yucatan shelf, a fact previously mentioned based on high concentrations of dissolved oxygen, seston and plankton biomass (Cruz, 1968; Merino, 1992).

The Yucatan Current can generate a dynamic uplift of the thermocline at Cabo Catoche, inducing an important upwelling long known to enhance productivity in the Yucatan shelf. Recently obtained data have shown that this upwelling is active only during spring and summer. Occasionally, the waters upwelled in the Cabo Catoche region can travel across the entire northern Yucatan shelf, carried by the persistent westward currents influencing the southern Gulf of Mexico. Figure 7 shows the temperature contour map at 10 m depth showing evidence of cold waters (~23ºC) typical for the Cabo Catoche upwelling approaching the Bank of Campeche. In the southern Gulf of Mexico summer presents a typical stratified condition with most of the sites characterized by strong thermoclines with surface water temperatures from 25 to 29°C (Figure 8). In autumn a mixed water column induced by the effect of the northerlies produces a clear temperature decrease with values from 25 to 26ºC.

Figure 8. Section along longitude 93°W in the southern Gulf of Mexico, June 2011.

Intensive growth of the diatoms *Pseudo-nitzschia pungens* (Grunow ex Cleve) Hasle*, Skeletonema costatum* (Grev.) Cleve*, Chaetoceros affinis* Lauder*, Chaetoceros messanensis*  Castrac.*, Pseudosolenia calcar-avis* (Schultze) B. G. Sundström*, Guinardia striata* (Stolterf.) Hasle*, Hemiaulus membranaceus* Cleve and *H. hauckii* Grunow in Van Heurck was found along the Cape Catoche area (Licea et al., 2017). It has been suggested that for supporting such a high growth rate it is necessary to supply enough nutrients that must originate in the upwelled water. In contrast, several authors report oligotrophic conditions in some sites off the coast (El-Sayed et al., 1972; Merino, 1997), confirming that most of the Yucatan shelf is characterized by oligotrophic conditions. The presence of upwelling in the Cape Catoche area is also supported by SST and SeaWiFS images (Figure 5, left panels) in which both the low surface water temperature and high Chl-*a* concentrations are evident. However, in the coastal zone it is difficult to differentiate between Chl-*a* and CDOM (colored dissolved organic matter; also the so-called yellow substance) due to their identical spectral range of light absorbance; thus the results obtained may be misinterpreted.

The phytoplankton biomass data based on Chl-*a* in the present study may enable optimization of the commercial fisheries in the southern Gulf of Mexico by indicating the high productivity areas. Furthermore, these data present a long-term perspective for comparison between seasons, years and decades.

#### **ACKNOWLEDGMENTS**

We are indebted to many participants of the cruises, including the students and the crew of the R/V "Justo Sierra" who contributed to the collection of the data presented here. The ICMyL-UNAM is thanked for its logistic and financial support. Bernando Shirazago helped with hydrographic data. Ranulfo Rodríguez and Maria E. Zamudio-Resendiz assisted in graph production. We also thank Erik Marquez and Olivia Salmerón-García for technical assistance and Boris Okolodkov for editing figures. Gabriela Athié (ICIMAP, Universidad Veracruzana, Boca del Río, Veracruz, México) helped us with the literature. Marcia M. Gowing (University of California at Santa Cruz, California, USA) kindly improved the English style.

# **MOLECULAR IDENTIFICATION OF** *THUNNUS* **SPECIES**

## *Mei-Chen Tseng*

Department of Aquaculture, National Pingtung University of Science and Technology, Pingtung, Taiwan, ROC

#### **ABSTRACT**

The genus *Thunnus* includes eight economically important species. The ability to identify *Thunnus* species is critical in marketing and management because it determines the legitimacy of trading harvested fishes and can prevent incorrect food product labeling that could jeopardize the market value of these tunas. For the sustainable management of tuna, more-effective identification techniques to resolve these issues are essential. Advances in molecular techniques have made genetic identification much more reliable and feasible than traditional approaches. Therefore, several molecular methods which have been evaluated for species identification, phylogenetic analyses, and determining the population structure of *Thunnus* species are reviewed in this article. Those methods for species identification include sequencing, polymerase chain reaction - restriction fragment length polymorphism (PCR-RFLP), real-time PCR, and others. Some *Thunnus* phylogenetic studies have also been conducted using allozyme loci, mitochondrial (mt) genes (cytochrome *b*, ATPase, and the control region), and nuclear genes (*ITS1* and 5S ribosomal DNA) sequence analyses. Furthermore*,* to study population genetics of *Thunnus* species, allozyme loci, mt DNA PCR-RFLP, microsatellite loci, and singlenucleotide polymorphisms (SNPs) are often used as genetic markers to evaluate their population structure.

**Keywords**: species identification, phylogeny, population structure, sequencing, PCR-RFLP

#### **INTRODUCTION**

The genus *Thunnus* contains eight valid species, *Thunnus orientalis* (Temminck and Schlegel 1844), *T. maccoyii* (Castelnau 1872), *T. tonggle* (Bleeker 1851), *T. atlanticus* (Lesson 1831), *T. thynnus* (Linnaeus 1758), *T. albacares* (Bonnaterre 1788), *T. alalunga*

(Bonnaterre 1788), and *T. obesus* (Lowe 1839), with a fossil record extending back to the Middle Eocene, about 40 million years ago (Carrol 1988; Benton 1993).

The accurate determination of species is very important for understanding fishery species distributions, reproductive activities, and migration pathways. Some morphological characters have been systematically described for identifying tuna larvae and juveniles (Matsumoto 1957; Yabe et al. 1966; Ueyanagi 1966; Potthoff and Richards 1970; Matsumoto et al. 1972; Kohno et al. 1982). Nishikawa (1985) and Nishikawa and Ueyanagi (1991; 1992) described melanophore patterns in the larval stage that are the handiest morphological diagnostic characters for distinguishing *T. thynnus*, *T. maccoyii*, and *T. obesus*. However, the use of this character may be limited in other developmental stages. Compared to the larval stage, juveniles of tuna species are even more laborious to identify, because pigment patterns in juveniles become obscured by the gradual development of the general body pigmentation. In addition to pigment patterns, meristic characters in the juvenile stage are almost indistinguishable among *Thunnus* species (Nishikawa and Rimmer 1987).

Adult and young tuna species in fishery markets are commonly used for fillets and canned products. In the fishery industry, adults are customarily cut or fins are excised, which also renders species indistinguishable. However, identifying *Thunnus* species has become extremely important for detecting illegal fishing and trading, especially when external morphological characters are removed or when the fish are filleted or canned making them untraceable (Marko et al. 2004; Wong and Hanner 2008). Furthermore, tuna products have motivated economic deceit involving the mislabeling of fish species, with high-end market fish being replaced with lower-priced species (Hsieh et al. 1995; Rasmussen et al. 2009; Miller and Mariani 2010). Tuna misidentification can result into certain management problems and incorrect quota monitoring occurs. In addition, the conservation sustainability of overexploited tuna species has also been disregarded (Jacquet and Pauly 2008; Wong 2011).

It is extraordinarily difficult to accurately execute morphology-based identification when samples lack key morphological characteristics (Sotelo et al. 1992; Unlusayin et al. 2001; Smith et al. 2008). Although there are numerous protein electrophoretic analyses specifically developed for fish taxonomy (Ochiai et al. 2001; Tepedino et al. 2001), those methods are only available for raw fish samples. For example, Sharp and Pirages (1978) and Dotson and Graves (1984) compared the electrophoretic mobilities of more than ten enzymes from muscle and liver extracts of various tuna species. Their biochemical studies revealed close genetic relationships among species of *Thunnus.* Although allozyme electrophoretic patterns have proven very useful in identifying tuna species, this method requires fresh tissue to produce the best results. When dealing with tuna products, this technique usually becomes inapplicable because thermally labile proteins of fish are denatured by heat (Dooley et al. 2005). Furthermore, protein profiles of closely related fish species may be too similar to distinguish some electrophoretic patterns (Bartlett and Davidson 1991; Smith et al. 1996). In contrast, identifying genetic species using DNA-based techniques is highly reliable in all tissue conditions and life history stages. They should be convenient for fish species identification, phylogenetic assessments, and population genetic studies (Davidson 1998; Bossier 1999; Lockley and Bardsley 2000). Consequently, molecular genetic techniques developed for such studies include sequencing, polymerase chain reaction - restriction fragment length polymorphism (PCR-RFLP), real-time PCR, microsatellites, and enzymelinked immunosorbent assay (ELISA).
# **REVIEW OF THE MOLECULAR IDENTIFICATION HISTORY OF** *THUNNUS* **TUNAS SINCE THE 1990S**

Traditional identification techniques based on morphological features fall short in terms of the accuracy and resolution of identifying fishes in their early life stages or after having been processed into different forms. Misidentification of fish species often leads to a misinterpretation of their spatial distributions, life history, population dynamics, recruitment rates, survivorship, stock biomass, and the collapse or recovery of localized spawning sites (Vecchione et al. 2000; Ko et al. 2013). After the 1990s, DNA-based identification methods using mitochondrial (mt) and nuclear DNA markers were extensively applied in different research fields such as population genetics, molecular phylogenetics, and seafood authentication (Lockley and Bardsley 2000; Arif and Khan 2009). As for identifying *Thunnus* species, various molecular techniques were adopted including sequencing, RFLP (Cespedes et al. 1998; Hold et al. 2001; Sanjuan and Comesana 2002), microsatellites (Kawaka et al. 2007; Banhos et al. 2008), real-time PCR (Dalmasso et al. 2007; Chuang et al. 2012), and singlenucleotide polymorphisms (SNPs) (Liu et al. 2011; Sun et al. 2014).

## *THUNNUS* **SPECIES IDENTIFICATION**

## **Sequencing**

There are a number of studies applying nucleotide sequence variations of mt and nuclear DNA for *Thunnus* species identification. Bartlett and Davidson (1991) applied a direct mt cytochrome (Cyt) *b* sequence analysis to identify commercially important *Thunnus* species caught off the east coast of Canada. Portions of nucleotide sequences of the Cyt *b* gene (307 bp) were obtained from *T. thynnus, T. obesus, T. albacares*, and *T. alalunga*. Interspecific variations at this locus were found, *e.g*.*,* all *T. obesus* revealed a thymine (T) at position 35, but the other three species showed a guanine (G); *T. albacares* contained a cytosine (C) at position 62, while other species presented a T; *T. thynnus* had a C at position 240 where a T was observed in all other tuna; *T. alalunga* stood out among the four species at three sites (68, 89, and 227). More importantly, genetic markers can provide high reliability in identifying these four *Thunnus* species. Sequencing was also used for frozen and canned seafood; a genealogical analysis conducted by Terol et al. (2002) sequenced a 528-bp fragment of the Cyt *b* gene from frozen samples and a 171-bp fragment from canned samples of *T. albacares*, *T. obesus*, and *Katsuwonus pelamis*. The interspecific and intraspecific nucleotide variations with diagnostic usefulness as well as a high bootstrap value of the analysis were determined.

As detecting trickery and tracing seafood became important for trade controls to meet conservation requirements, identifying *Thunnus* species in trade was difficult due to the forms of various products. Several studies were evaluated to push the efficacy of molecular identification. Bottero et al. (2007) applied diagnostic sites of Cyt *b* with a multiplex primerextension assay to distinguish four *Thunnus* species (*T. alalunga*, *T. albacares*, *T. obesus*, and *T. thynnus*) and *K. pelamis* in raw and canned conditions. Viñas and Tudela (2009) validated the combination of two genetic markers (the mt control region, CR and the nuclear ribosomal DNA first internal transcribed spacer, *ITS1*) to fully distinguish eight *Thunnus* species using

any processed tissue. This methodology also considered the presence of introgression among *T. thynnus*, *T. orientalis,* and *T. alalunga*. A Cyt *c* oxidase subunit I (*COI*) character-based key was developed by Lowenstein et al. (2009; 2010) to identify all *Thunnus* species.

The three bluefin tunas (*T. orientalis*, *T. maccoyii*, and *T. thynnus*) are morphologically similar, which often causes problems for fisheries management and marketing. Tseng et al. (2011) examined intraspecific genetic diversity and interspecific genetic boundaries among these three species by analyzing the full Cyt *b* gene sequences. The phylogenetic tree showed distinct clades with high bootstrapping value support, and the high  $F_{ST}$  value indicated significant differentiation among these species, which could be individually distinguished from each other *Thunnus* tuna by the 132<sup>nd</sup>, 375<sup>th</sup>, and 1023<sup>rd</sup> sites of Cyt *b* sequences. A mtDNA sequence database including *T. alalunga*, *T. albacares*, and *T. obesus* was commercialized in South Africa (Cawthorn et al., 2011). The database demonstrated that nearly 98% of fish species examined could be differentiated by their barcode system, and additional CR sequencing was more useful for discriminating the three *Thunnus* species.

*Thunnus albacares* and *T. obesus* are two of the most economically important tuna species in the world. Their juveniles, especially at sizes of less than 40 cm, are extremely difficult to distinguish, often leading to misidentification and miscalculation of catch estimates. Pedrosa-Gerasmio et al. (2012) applied the mt CR as a marker along with liver morphological phenotypes to differentiate juveniles of yellowfin and bigeye tuna. More recently, Puncher et al. (2015) employed mt *COI* and nuclear *ITS1* to identify larvae of *T. thynnus*  $(n = 188)$  collected from three spawning areas in the Mediterranean Sea. Results revealed significantly different accuracies between morphology-based and molecular genetic methods of tuna identification.

### **PCR-RFLP**

The PCR-RFLP method allows very quick, uncomplicated, and low-priced detection of nucleotide mutations within sequences of PCR products. Mutations are discriminated by restriction endonuclease and are recognized by gel electrophoresis followed by staining with ethidium bromide (Ota et al. 2009). Chow and Inoue (1993) analyzed the flanking region between ATPase and Cyt oxidase subunit III genes (ATCO) of eight *Thunnus* species by PCR-RFLP. They found distinguishable interspecific differences among all eight species, except for one Pacific northern bluefin tuna which had the same haplotype as that of an Atlantic bluefin tuna in that study. Takayama et al. (2001) investigated the usefulness of the previous marker developed by Chow and Inoue (1993) on tuna specimens collected from different ocean basins. These markers performed properly in distinguishing all *Thunnus* species and different stocks of northern bluefin and bigeye tunas in spite of their various origins.

PCR-RFLP of the partial Cyt *b* fragment was used to identify six canned tuna species *T. alalunga*, *T. albacares*, *T. thynnus*, *T. obesus*, *Sarda sarda*, and *K. pelamis* collected from the Vigo (Spain) local market (Quinteiro et al. 1998). However, undetected intraspecific variability may exist in each species' gene pool. To confirm the effectiveness of the technique, more work in the future is needed to determine nucleotide substitutions at these target sites. Later, Pardo and Pérez-Villareal (2004) successfully applied a nested primer PCR-RFLP of partial Cyt *b* fragments to authenticate commercially canned tuna (*T. alalunga*,

*T. albacares*, *T. obesus*, *T. thynnus*, and *K. pelamis*) in oil, pickled, smoked, in brine, spiced, and in sauce. In the Far East, there are four *Thunnus* species: *T. thynnus*, *T. alalunga*, *T. albacares,* and *T. obesus*. Most customers cannot identify species of sliced tuna meat in the market. Therefore, Lin et al. (2005) developed a PCR-RFLP procedure with a portion of the Cyt *b* fragment that could accurately and quickly identify these *Thunnus* species. Lin and Hwang (2007) subsequently developed a PCR-RFLP technique based on a partial Cyt *b* gene to identify *T. thynnus*, *T*. *alalunga*, *T*. *obesus*, *T*. *albacares*, *K. pelamis*, *Euthynnus affinis*, *Auxis thazard*, and *S. orientalis* in canned products. Two sets of primers were designed to amplify the partial Cyt *b* gene followed by analysis of fragment patterns using five restriction enzymes. The method was successfully applied to verify species of commercially canned tuna.

Xu et al. (2016) amplified six mitochondrial genes (Cyt *b*, *COI*, CR, 12S rDNA, 16S rDNA, and ATPase) from *T. alalunga*, *T. albacares*, *T. obesus*, *T. maccoyii*, *T. tonggol*, and their relative species *K. pelamis*, *E*. *affinis*, *A. thazard*, *A. rochei,* and *S. orientalis*. Results of their PCR-RFLP patterns with two restriction enzymes indicated that ATPase and CR were suitable for sympatric species identification, and the *COI* and CR phylogenetic analyses fully discriminated all tested species in the study.

#### **Real-Time PCR**

The real-time PCR technique has gradually become more popular for fish species identification and examination of genetically modified organisms in recent years (Bertoja et al. 2009). It possesses advantages of high sensitivity, high specificity, excellent efficiency, reduced amplicon size, and no post-PCR steps to increase cross-contamination (Rodriguez-Lazaro et al. 2003), but is costly and requires specialized equipment. Lopez and Pardo (2005) developed two specific TaqMan systems using real-time PCR technology to identify *T. alalunga* and *T. albacares*. Terio et al. (2010) also developed a real-time PCR using three different minor groove binder (MGB) probes to rapidly and accurately identify canned *T. albacares*, *T. thynnus*, and *T. alalunga*. The method was advantageous for the quality control of canned tuna, *i.e.*, food traceability and consumer satisfaction. Four species-specific TaqMan probes were designed by Chuang et al. (2012) to identify *T. obesus*, *T. orientalis*, *T. maccoyii*, and *T. albacares*. The entire working time was reduced by half, which makes largescale examination more feasible.

Liu et al. (2015) developed a duplex real-time quantitative PCR for identifying five tuna species (*T. maccoyii*, *T. obesus*, *T. albacares*, *T. alalunga*, and *K. pelamis*) from processed products. Result showed that only four out of nine commercial specimens were correctly labeled. The 56% incorrectness of labels indicated serious food safety issues of commercial tuna products from China. Processed tuna products usually contain highly degraded DNA and/or PCR inhibitors from additives which often can interfere with the accuracy of molecular methods for tuna identification. Efforts were made to address this issue by Bojolly et al. (2017), who developed a routine TaqMan-based real-time PCR method to distinguish genetically closely related *T. obesus* and *T. albacares* in canned products*.* The unique character of this method is the design of a specific TaqMan probe for NADH dehydrogenase subunit 2 and Cyt *c* oxidase subunit II genes to identify these two species. In addition, two comparative quantitative methods were developed using the 12S rRNA gene to quantify the proportion of each species in mixed-tuna canned products.

#### **Other Techniques**

Pepe et al. (2010) examined the proteomics of *T. thynnus*, *T. albacares*, and *T. alalunga* for species identification. Proteins from muscle extracts were evaluated by both one- and twodimensional electrophoresis (2DE) and mass spectrometric techniques. Results of 2DE demonstrated noticeable interspecific differences from the assignment and distribution of electrophoretic spots. Analysis of the 2D gel revealed a protein of approximately 70 kDa in the *T. thynnus* 2DE pattern, which was absent from those of the other two species. Other proteins in the 2DE patterns of *T. albacares* and *T. alalunga* were species-specific.

On the other hand, Santaclara et al. (2015) developed a multiplex PCR-ELISA method for the genetic authentication of three *Thunnus* species and *K. pelamis* in food products of different forms. The remarkable advantage of this proposed method is that the analysis can reliably process high-throughput screening of all kinds of samples in just one working day. In the same year, Abdullah and Rehbein (2015) completed the identification of tunas from Indonesian waters (the Indo-West Pacific and Indian Ocean) using the partial Cyt *b* gene. In addition, the study also examined the differentiation of tuna and other scombrid fishes through amplification of parvalbumin gene introns by single-strand conformation polymorphism (SSCP) and RFLP analyses.

## **PHYLOGENETIC STUDIES**

#### **Allozyme Locus Analysis**

Collette (1978) classified tunas into two subgenera of temperate *Thunnus* (*T. alalunga*, *T. obesus*, *T. thynnus, T. orientalis*, and *T. maccoyii*) and tropical *Neothunnus* (*T. atlanticus*, *T. tonggol*, and *T. albacares*) by the presence or absence of a central heat exchanger. Although *T. obesus* shares some characters of each subgenus, it is classified as a member of the subgenus *Thunnus,* because its character shows adaptations for living in colder environments (Collette, 1978). Allozyme analysis using 35 loci was first carried out by Elliott and Ward (1995) to explore genetic relationships among eight species of tuna including *T*. *alalunga*, *T*. *obesus, T*. *orientalis, T*. *maccoyii, T*. *albacares, A. thazard, E. affiizii*, and *K. pelamis*. Regrettably, their phylogenetic analyses failed to resolve the branch order among *Thunnus* species.

#### **Gene Sequence Analysis**

Finnerty and Block (1995) collected five Atlantic tuna species and explored *Thunnus* systematics using a portion of the Cyt *b* gene. However, results were insufficient to draw conclusions about relationships within the genus *Thunnus*. Partial sequences of both the Cyt *b* (292 bp) and ATPase (400 bp) genes were first determined for all eight *Thunnus* species (Chow and Kishino, 1995). These molecular data indicated that mtDNA from *T. alalunga* has extensively displaced original mtDNA in the Pacific population of northern bluefin tuna which was later named *T. orientalis*. In the phylogenetic tree, two distinct clades are evident in the genus *Thunnus*: one consists of *T. alalunga* (ALB) and the dominant type of *T. t. orientalis* (PNB), and the other one consists of the rest *Thunnus* species including the rare type of PNB. Results also indicated that *T. alalunga* is highly divergent from all other *Thunnus* tunas, suggesting it was the earliest offshoot from the phylogenetic tree.

Alvarado-Bremer et al. (1997) constructed phylogenetic relationships among tunas from a portion of the mtDNA CR. A Neighbor-joining tree supported monophyletic origins for the temperate subgenus *Thunnus* and the tropical subgenus *Neothunnus,* except for *T. obesus* because it was difficult to place it in a clade in either subgenus. This result is consistent with allozyme data which suggested that *T. obesus* has a greater similarity to *T*. *albacares* and *T*. *atlanticus* than to temperate tunas (Sharp and Pirages 1978; Elliott and Ward 1995). Alvarado-Bermer et al. (1997), Ward (1995), and Chow and Kishino (1995) inferred that introgression of *T*. *alalunga* mtDNA into *T*. *orientalis* occurred a long time ago, and also suggested that mtDNAs of *T. alalunga* and *T. orientalis* share a common ancestry.

Chow et al. (2006) examined intra- and interspecific nucleotide sequence variations of rDNA *ITS1* among all *Thunnus* species. Their report supported introgression having occurred between species and contradicted the morphological subdivision of the genus into the two subgenera, *Neothunnus* and *Thunnus*. The cladogram constructed from *ITS1* indistinctly resolved phylogenetic relationships among three tropical tunas (*T. albacares*, *T. tonggol*, and *T. atlanticus*). The *ITS1* and mtDNA ATCO sequence data both supported the monophyletic status of the yellowfin tuna group and indicated that these tropical tunas were recently derived taxa; nevertheless, *T. thynnus* and *T. orientalis* shared almost identical *ITS1* sequences, while having distinct mtDNA. These molecular data suggested that intermittent speciation events occurred in species of the genus *Thunnus*. Consequently, relationships among closely related *Thunnus* taxa remain unresolved. Tseng et al. (2012) sequenced full Cyt *b* gene sequences from all eight *Thunnus* species to explore their phylogeny. The genealogical tree contained two explicit clades, the first group consisted of *T. maccoyii*, *T. thynnus*, *T. atlanticus*, *T. albacares*, *T. obesus*, and *T. tonggol,* and the second group included *T. alalunga* and *T. orientalis*, with extremely high bootstrapping (1000 replications) support. The genealogy suggested that both *T. orientalis* and *T. alalunga* are sister species and supported the monophyly of the tropical yellowfin group, but not of the temperate bluefin group. The phylogeny of *Thunnus* species does not fit into the two-subgenus *Thunnus* and *Neothunnus*  classification pattern.

Although *T. obesus* can adapt to cold water environments and is currently classified into the bluefin group (Collette 1978), it also shares external morphological features of both groups, and there is still debate as to whether bigeye tuna belongs to the bluefin or yellowfin group. Lee et al. (2018) further examined interspecific differences among *T. obesus*, *T. albacares*, *T. alalunga*, and *T. orientalis* by analyzing karyotypes, whole Cyt *b* genes, and 5S rDNA sequences; moreover, the systematic state of *T. obesus* was also discussed in their report. A phylogenetic analysis of *Thunnus* tunas with 100% bootstrap support showed that *T. orientalis* and *T. alalunga* are sister species. The result of the 5S rDNA analysis also suggested that two different duplicates occurred in *T. obesus*. The larger morphological and genetic polymorphisms of *T. obesus* may have been caused by a combination of environmental adaptations, introgressions, and a complicated process of speciation.

## **POPULATION GENETICS STUDIES**

#### *Thunnus albacares* **(Yellowfin Tuna)**

Yellowfin tuna are distributed in waters between 35°N and 35°S across the Pacific, Atlantic, and Indian Oceans. Most of them appear in waters near the equator and also move to deeper regions where water temperatures range 15~31°C (Collette and Nauen 1983). Different breeding peaks occur in different regions, *e.g.*, a breeding peak was observed in May to June in the Kuroshio Basin (Yabe and Ueyanagi 1962), while two peaks occurred in April and October in Philippine waters (Yamanaka 1990). Does the yellowfin tuna that is widely distributed throughout the world belong to one panmictic population or consist of different populations?

Scoles and Graves (1993) randomly sampled 20 yellowfin tuna from all specimens at each of five Pacific locations and one Atlantic location, and analyzed their mtDNA using 12 informative restriction endonucleases. The results demonstrated that no genetic differentiation occurred among samples. The null hypothesis that yellowfin tuna in the Pacific Ocean share a common gene pool could not be rejected in that study. Yellowfin tuna maintain sufficient gene flow among areas to prevent the accumulation of significant genetic differences. Ward et al. (1997) examined four polymorphic allozyme loci (*ADA*\*, *FH*\*, *GPI-A*\*, and *GPI-B*\*) and conducted an mt PCR-RFLP analysis of yellowfin tuna which were sampled from the Atlantic, Indian, and Pacific Oceans. *GPI-A*\* showed highly significant differentiation*.* MtDNA differentiation was more limited, but spatial heterogeneity supported the separation of Atlantic, Indian, and Pacific Ocean stocks. After that, the yellowfin tuna stock was found to have very limited heterogeneity in the Western Pacific Ocean using microsatellite markers (Appleyard et al., 2001) which was similar to earlier findings using allozyme and mtDNA markers.

Ely et al. (2005) investigated genetic variations of the partial mtDNA CR from 148 yellowfin tuna collected from the eastern Pacific Ocean, Indian Ocean, Gulf of Mexico, east coast of Florida (USA), and the Ivory Coast (west Africa). Much lower levels of genetic differentiation were discovered among subpopulations of yellowfin tuna. In addition, results of a PCR-RFLP analysis of the ATCO gene indicated low levels of genetic differentiation between yellowfin populations in the Atlantic and Pacific Oceans. Results suggested the occurrence of a very slow genetic drift due to the species' large population size. Similarly, yellowfin tuna populations in the Western Pacific and Western Indian Oceans revealed extensive gene flow between these ocean basins based on non-significant pairwise  $F_{ST}$  values (Wu et al. 2010). Since yellowfin tuna are oceanic and highly migratory, they are considered to be one population across the western and central Pacific region (Appleyard et al. 2001; Wu et al. 2010).

On the other hand, yellowfin tuna catch data of the 1990's in the western and central Pacific Ocean (WCPO) showed a slower growth rate along Philippine and Indonesian waters indicating probable population structuring (Langley et al. 2011). Aguila et al. (2015)

established the genetic stock structure of yellowfin tuna in the Philippines in comparison to the species in the Bismarck Sea, Papua New Guinea using nine DNA microsatellite markers. This study concluded that the yellowfin tuna population in the Philippines is independent of the Bismarck Sea population, suggesting there are at least two subpopulations of yellowfin tuna in the WCPO. In addition, Li et al. (2015) assessed polymorphisms of sequence variations in mtDNA *COI* genes and found genetic differentiation among 11 populations of yellowfin tuna sampled from the central Pacific Ocean. Recently Barth et al. (2017) sampled yellowfin tuna from most of its global distribution areas: Rhode Island, USA; Mindelo, Republic of Cabo Verde; Abidjan, Ivory Coast; Cape Town, South Africa; Barka, Oman; Denpasar, Indonesia; Sagami Bay and Okinawa, Japan; and central-eastern Pacific, El Salvador. Whole-genome sequencing was used in concert with a draft genome assembly to resolve the global population structure of yellowfin tuna, and investigate its population demographic history. The conclusions indicated significant differentiation between Atlantic and Indo-Pacific yellowfin tuna populations as well as the possibility of a third divergent yellowfin tuna group in the Arabian Sea. The study further observed evidence of past population expansion as well as asymmetric gene flow from the Indo-Pacific to the Atlantic Ocean.

#### *Thunnus alalunga* **(Albacore)**

The albacore is a highly migratory fish and is mainly distributed in tropical, subtropical, and temperate zones between 50°N and 40°S in the Atlantic Ocean including the Mediterranean Sea, Pacific Ocean, and Indian Ocean. It prefers water temperatures of 13.5~25.2 $\degree$ C, but also can tolerate a much-lower temperature of 9.5 $\degree$ C for a period of time (Collette and Nauen 1983). According to some fishery data, the hooking rates differ between the northern and southern populations, and the catch in the equatorial area is very low (Otsu and Uchida 1959; Beardsley 1969; Nakamura 1969; Suzuki et al. 1977; Murray 1994). Spawning was found to occur in the Indian Ocean between 10°S and 30°S, mainly to the east of Madagascar from October to January (Dhurmeea et al. 2016). Peak spawning of albacore in the Pacific Ocean is generally believed to occur in subtropical waters centered around 20°N and 20°S latitude. It is assumed that the albacore spawns from March through July on grounds located in the western and central Pacific Ocean. There appears to be a distinct spawning ground for albacore in the Mediterranean Sea (Collette and Nauen 1983), and growth rates of Mediterranean and Atlantic albacore are reported to differ (Megalofonou 2000). Furthermore, tag-recovery investigations in 1968 to 1999 also indicated restricted movement of albacore between these ocean basins (Arrizabalaga et al. 2002). According to these information, it is interesting that does the albacore have a significant population structure among different oceans and hemispheres?

Chow and Ushiama (1995) conducted a study using RFLP analysis of the mt ATPase gene of albacore. Highly significant heterogeneity was evident among Atlantic and Pacific samples, but no heterogeneity was observed among North and South Pacific samples, nor among North and South Atlantic samples. The result concluded that gene flow between the Atlantic and Pacific populations of albacore was restricted. Contrarily, Takagi et al. (2001) applied highly polymorphic nuclear microsatellites to detect genetic heterogeneity not only between Atlantic and Pacific samples but also between northern and southern samples within

each ocean. Several molecular analyses detected no or little genetic differentiation between Atlantic and Mediterranean albacore samples (Vinãs et al. 1999; Pujolar et al. 2003; Vinãs et al. 2004); nevertheless, Nakadate et al. (2005) proposed that gene flow between the Atlantic and Mediterranean albacore populations has been significantly restricted. The genetic population structure of albacore was investigated using fragment length variations of the glucose-6-phosphate dehydrogenase (G6PD) gene intron and restriction analysis of the mtDNA D-loop region (267~269 bp). Frequencies of two alleles (L and S) at the G6PD locus significantly differed between samples from the Atlantic and Mediterranean. Phylogenetic analysis using data of the D-loop showed that the emergence of the B type lineage from the ancestral A lineage in the Mediterranean Sea had not yet occurred in the Atlantic Ocean. Furthermore, NOAA (2014) reported that albacore may spawn multiple times in a year, and the spawning grounds appear to be discontinuous between the hemispheres with opposite seasonal peaks.

#### *Thunnus obesus* **(Bigeye)**

Bigeye tuna inhabit tropical and subtropical waters of the Atlantic, Indian and Pacific Oceans, where water temperatures range 13~29°C. They spawn in tropical waters year-round (Kailola et al. 1993). Alvarado-Bremer et al. (1998) used PCR-RFLP with a portion of the mtDNA CR on a total of 248 individuals for population analyses. Frequency distributions of haplotypes indicated that population of bigeye tuna in the Atlantic Ocean was genetically distinct from those in the Indian and Pacific Oceans. These results concluded that bigeye tuna does not have a single global population. Two mtDNA segments were analyzed by PCR-RFLP for a genetic stock study of bigeye tuna. Results clearly indicated that fish migration between the Atlantic and Indian Oceans was severely restricted, but the two populations do intermingle around South Africa (Chow et al. 2000).

#### *Thunnus orientalis* **(Pacific Bluefin Tuna)**

This species is primarily distributed in the North Pacific Ocean, from the Gulf of Alaska to southern California and Baja California and from Sakhalin Island in the southern Sea of Okhotsk to the northern Philippines; the tuna is also found in the South Pacific Ocean around Australia, the Galapagos Islands, the Gulf of Papua, and New Zealand (Collette and Smith 1981; Collette and Nauen 1983; Bayliff 1994; Ward et al. 1995; Smith et al. 2001). Pacific bluefin tuna spawn between Japan and the Philippines from April to June, south of Honshu Island in July, and in the Japan Sea in August (Chen et al. 2006; Tanaka et al. 2006; 2007; del Moral-Simanek and Vaca-Rodriguez 2009; Itoh 2009); larvae are transported northwards towards Japan by the Kuroshio Current, and juveniles are found in waters near Japan. Some young fish migrate east as far as the west coast of North America, and are presumed to return to the western Pacific to breed (Bayliff 1991; 2001). The Pacific bluefin tuna is believed to become sexually mature at about 5 years and to have a maximum lifespan of 25 years (Ueyanagi 1975; Bayliff 1994). Surprisingly little was known about the stock structure and population biology of Pacific bluefin tuna until Tseng et al. (2012) analyzed mtDNA CR and

microsatellite data and showed that Pacific bluefin tuna samples from Taiwanese and New Zealand waters lacked genetic differentiation.

#### *Thunnus thynnus* **(Atlantic North Bluefin Tuna)**

Alvarado-Bremer et al. (1999) sampled 140 individuals of north bluefin tuna from the Mediterranean and Western Atlantic Ocean, and analysis of their mt lineage distribution patterns allowed rejection of the null hypothesis of a global panmictic population. Antoniou et al. (2017) analyzed samples throughout the Mediterranean Sea as well as from the Moroccan coast in the Atlantic Ocean using polymorphic microsatellite loci and genome-wide SNPs which were obtained by a double-digestion restriction-associated DNA sequencing technique. Results showed weak evidence of the genetic structure which suggested the existence of a single panmictic unit. Spatial dynamics of mixed bluefin tuna in the Atlantic Ocean and Mediterranean Sea were examined using informative SNPs by Puncher et al. (2018). The results evidenced a persistent population structure across broad geographic areas, which means extensive mixing in the Atlantic Ocean, particularly in the mid-Atlantic Bight and Gulf of St. Lawrence.

#### *Thunnus maccoyii* **(Southern Bluefin Tuna)**

Southern bluefin tuna are widely distributed in southern hemisphere waters between 30° and 50°S but rarely found in the eastern Pacific. Adults spawn between August and March on a single spawning ground in the Indian Ocean, southeast of Java, Indonesia (Jenkins and Davis 1990; Caton 1991; Chambers et al. 2017). Samples of southern bluefin tuna collected off the coasts of South Africa, Western Australia, South Australia, and Tasmania from 1992 to 1994 were analyzed using six polymorphic allozyme loci (*ADA*\*, *GDA*\*, *GPI-A*\*, *MPI*\*, *PGDH*\*, and *PGM-1*\*,  $n = 595 \times 733$  per locus). In addition, mtDNA variants were constructed using three restriction enzymes to detect polymorphic restriction sites  $(n = 555)$ . Significant spatial heterogeneity was not detected, nor genetic evidence of heterogeneity found between groups sampled from disparate feeding grounds across the distribution of the species (Grewe et al. 1997). These results are consistent with the null hypothesis of a single stock of southern bluefin tuna within a single spawning area located to the south of Java and off the northwestern coast of Australia.

## **CONCLUSION**

The development of molecular identification techniques has dramatically improved the accuracy of tuna identification under different sample conditions, but none of these methods can yet be considered perfect. All methods reviewed in this article still have various shortcomings that need to be overcome. Sampling of previous studies usually only covers a portion of the known distribution areas of species, and small sample sizes are insufficient to reveal all possible intraspecific variations. Therefore, completeness of sampling is the initial requirement for all designated methods to have more reliable results. In terms of commercial applications of molecular identification methods, they should have quick turnover times, low costs, and be user friendly. Although most current molecular methods can provide more or less satisfactory accuracy for tuna identification, so far, none of the methods in this review can fulfill all of the above needs. Therefore, developing molecular techniques to meet the requirements of commercial applications in the future is an important goal. Regarding phylogenetic studies of *Thunnus*, *T. orientalis* and *T. alalunga* were confirmed to be sister species, while the evolutionary relationships of other tuna species are still not totally understood yet. In addition to phylogenetic studies, reports focusing on population structures and dynamics of *Thunnus* species remain quite limited. More studies of phylogenetic and population structural dynamics are definitely needed to elucidate these issues. In the future, more researchers need to be involved in examining population structures and dynamics of tunas to achieve the long-term goal of sustainable management.

# **MARINE BACTERIA WITH STRONG SURVIVABILITY TOWARD TRIBUTYLTIN**

# *Haruo Mimura\**

Graduate School of Maritime Sciences, Kobe University, Kobe, Japan

## **ABSTRACT**

Tributyltin (TBT) is a toxic compound with broad-spectrum activity toward diverse marine species. The amount of TBT used for preventing the biofouling of aquaculture fishing nets and ships' bottoms was drastically increased by the development of selfpolishing copolymer systems. As a result, morphological changes and a reduction in the population of bivalves occurred with exposure to TBT leached into marine environments from marine paints. Now, it has been determined that the compound acts as an endocrine disruptor. After 2008, the use of TBT in marine environments has been severely restricted by The International Convention on the Control of Harmful Anti-fouling Systems on Ships (adopted on October 5, 2001 and effective as of September 17, 2008). Tributyltin is difficult to degrade in seawater. Even after its use was banned in marine environments, the compound remains in the surface of sediments on the seafloor. Therefore, TBT's ecological threat to benthic invertebrates and microbial communities has continued. On the other hand, TBT-tolerant marine bacteria exist, and tolerance toward TBT is closely related to the adsorption capacity of cell walls, indicating that the sublethal damage to the microbial community in TBT-polluted sediment seems to be enhanced by the coexistence of TBT-tolerant marine bacteria accumulating TBT on their cell walls. In order to conserve the microbial ecosystem in sediments, removal of TBT from sediment surface is important. Tributyltin-degrading marine bacteria, such as nonpathogenic *Aeromonas molluscorum* Av27 isolated from an estuarine environment, seem to be useful for the efficient degradation of TBT to less toxic organotin compounds. Practical approaches of bioremediation using TBT-degradable marine bacteria are necessary to prevent human exposure to TBT through the food chain.

## **TRIBUTYLTIN IN A MARINE ENVIRONMENT**

Too much tributyltin (TBT) has been used mainly as an anti-fouling agent of marine paints and aquaculture fishing nets. The amount of TBT leaching from marine paints drastically increased with the development of self-polishing copolymer systems (Anti-fouling systems, IMO; Hoch 2001). As a result, morphological changes (Alzieu et al., 1986; Márquez et al., 2017) and a reduction in the population of marine gastropods (Bryan et al., 1986) occurred through exposure to TBT. Even in deep-sea organisms such as fish, crustaceans, and gastropods (Takahashi et al., 1997) and Antarctic marine sediment (Negri et al., 2004), TBT contamination has been confirmed. Near shore of the Antarctic, the efficient detachment of marine paint containing TBT might have occurred during ice breaking by an ice-breaking ship. In recent years, tributyltin has been recognized as an endocrine disruptor in humans (Santos-Silva et al., 2018).

The use of TBT in marine environments has been banned strictly since 2008 by the International Convention, adopted on October 5, 2001, and effective as of September 17, 2008 (International Convention on the Control of Harmful Anti-fouling Systems on Ships, IMO). On the other hand, from the viewpoint of conserving biodiversity, risks of invasion and the establishment of non-native fouling organisms seem to have increased in foreign ports after the enforcement of the International Convention. Balancing the risks from TBT and the invasion of non-indigenous marine fouling organisms is important (Lewis et al., 2004). As one solution for keeping hull surfaces clean for prolonged periods without using toxic chemicals, the application of irradiation-intensity blue LEDs for antifouling has been examined (Mimura and Hirono, 2018).

One property of tributyltin is that it adsorbs to cray-rich sediments in marine environments (pH 8, salinity 32‰) far more than a degrading product such as less toxic dibutyltin, which indicates that adsorption depends on the number of hydrophobic alkyl groups (Hoch, 2003). In such an alkaline pH, TBT seems to be neutralized by hydroxide. Because of the properties of TBT in the water phase, benthic ecosystems are continuously damaged by TBT.

## **BIODIVERSITY OF TBT-RESISTANT MARINE BACTERIA**

Tributyltin-resistant marine bacteria seem to be classified into two groups, although the resistance ability depends on the concentrations of TBT existing externally. In one group, each species has TBT tolerance but does not have degradation ability (Wuertz et al., 1991; Fukagawa et al., 1992; Jude et al., 2004; Mimura et al., 2008a; Mimura et al., 2008b; Mimura et al., 2017). Several marine bacteria became tolerant toward TBT during exposure to approximately 120  $\mu$ M TBTCl within 4 weeks (Suzuki et al., 1992). Such species adapted to a TBT-polluted environment might be able to be classified into the group "TBT tolerant but with no degradation ability." Marine bacteria possessing "TBT-degrading ability" belong to the other group (Cruz et al., 2007; Abubakar et al., 2015; Hassan, 2018).

Eight "TBT tolerant but with no degradation ability" isolates and three isolates with "TBT-degrading ability" are shown in Table 1. All isolates were to be Gram negative, indicating that the structure of cell wall plays an important role in coping with the inflow of

TBT into the cytoplasm. For example, the cell wall of tributyltin-tolerant *Pseudoalteromonas* sp. TBT1 (Mimura et al., 2008a and 2008b) and *Photobacterium* sp. TKY1 (Mimura, 2017) possessed high adsorption ability to TBT.

# **IMPORTANCE OF MARINE BACTERIAL CELL WALLS TO PROTECT AGAINST THE INFLOW OF TBT**

Bacterial cell walls play an important role in protecting against the inflow of toxic compounds with hydrophobic properties. In other words, marine bacterial tolerance toward TBT depends on the capacity of cell walls to adsorb TBT. Kubota et al., (2004) quantified the number of Sn elements originating in TBT associated with growing cells of *Pseudoalteromonas* sp. TBT1, which were isolated from a ship's ballast water, as having an atomic density of  $10^{19.5}$  cm<sup>-3</sup> with an accelerator when the cells were grown at an early stationary phase,  $10^{8.1}$  Colony-Forming Units (CFU) mL<sup>-1</sup>, in the presence of 150  $\mu$ M TBT for 3 days at 30°C in a nutrient medium. A typical particle-induced X-ray emission spectrum provided  $K_{\alpha}$  and  $K_{\beta}$  lines of Sn with energies of 25.3 and 28.6 keV, respectively, and the yield ratio, *Y* (K<sub>a</sub>)/*Y* (K<sub>B</sub>) = 9 ± 0.9, was consistent with the published value (Mayer and Rimini, 1977).

The number of cell-associated TBT molecules increased exponentially with an increase in the final concentration of TBT added externally up to 3 mM from 3  $\mu$ M, and the maximum number of TBT adsorbed was  $10^{7.6}$  molecules cell<sup>-1</sup> when resting cells,  $10^{9.5}$  CFU mL<sup>-1</sup>, were exposed to TBT (Mimura et al., 2008a). In the presence of more than 3 mM TBT, the value became saturated. The value was 10 times smaller than that obtained from calculation, i.e.,

the number of Sn originating in TBT adsorbed was  $10^{6.5}$  Sn cell<sup>-1</sup> in the presence of 150  $\mu$ M of TBT. On the other hand, the maximum value is estimated to be  $10^{7.5}$  Sn cell<sup>-1</sup> (( $150 \times 10^{-9}$ ) moles  $mL^{-1}$ )  $\times$  (6.0  $\times$  10<sup>23</sup> molecules moles<sup>-1</sup>)/(10<sup>9.5</sup> CFU mL<sup>-1</sup>)). The difference was observed for any concentration of TBT added externally. A possible explanation is that a certain number of TBT adsorbed by a single cell might be desorbed to reach a new equilibrium condition during the washing process.

The importance of the function of cell walls to adsorb TBT was confirmed by lysozymetreated cells (Mimura et al., 2008b). Lysozyme is an enzyme that preferentially hydrolyzes the β-1, 4 glucosidic linkages between *N*-acetylmuramic acid and *N*-acetyl-glucosamine in the mucopeptide cell wall. Resting cells treated with 1% lysozyme for 1 h at 30ºC retained their colony-forming ability. The amount of TBT adsorbed by the cells was reduced by approximately four-fifths as compared to that by native cells. Some kinds of Gram-negative marine bacteria seem to possess cell walls with a unique structure that can function to prevent TBT's interaction with the outer surface of the cell membrane. This function is very important for blocking the inflow of TBT into the cytoplasm.

As another function, the existence of an efflux pump has been reported in TBT-tolerant *Alteromonas* sp. M-1 (Fukagawa et al., 1992; Fukagawa et al., 1993) and *Pseudomonas stutzeri* (Jude et al., 2004). TbtABM in *P*. *stutzeri*, a multidrug efflux pump, showed the highest homology with the TtgDEF and SrpABC systems involved in aromatic compound tolerance in *P*. *putida*. It seems possible that highly hydrophobic TBT is pumped out by proteins associated with a hydrophobic membrane.

# **EXISTENCE OF ENVIRONMENTAL BACTERIA POSSESSING CONGENITAL TBT TOLERANCE**

Mimura et al. isolated three strains (Table 2) that could grow on a seawater-based nutrient agar plate containing 100 μM of TBTCl from sediment samples taken in busy Japanese ports (Figure 1), and the TBT tolerance of each isolate was compared with that of two kinds of strains that show high first and secondary similarities to the 16S rDNA sequences (Table 3 and Figure 2 (Mimura et al., 2017). In the experiment, the number of cellassociated TBT that could associate with a single cell could increase by the reduction of the number of resting cells in the mixture while the concentration of TBT was kept constant at 100 μM. As a result, *Photobacterium* sp. TKY1 isolated from Tokyo Bay showed very strong TBT tolerance. Even when the initial number of resting cells was reduced to  $10^{4.2}$  CFU mL<sup>-1</sup> from  $10^{9.4}$  CFU mL<sup>-1</sup>, cells of  $10^{3.8}$  CFU mL<sup>-1</sup> could survive, and the number of cellassociated TBT molecules increased by 5 orders of magnitude (Figure 2A), indicating that the isolate was highly resistant to TBT. The reduction of the number of surviving *P*. *ganghwense* JCM 12487<sup>T</sup> and *P*. *halotolerans* LMG 22194<sup>T</sup> cells was amplified with the reduction of resting cells initially added. Other isolates, *Halomonas* sp. TKY2 (Figure 2B) and *Photobacterium* sp. NGY1 (Figure 2C) showed sensitivity toward TBT when suspended in a mixture without nutrients, indicating that some kinds of amino acids might be essential for the survival of the isolates, e.g., those amino acids that might be used for the synthesis of stress proteins to cope with TBT toxicity. Type culture *H*. *alkaliphila* DSM 16354<sup>T</sup> showed strong tolerance to TBT. That strain was isolated from the water of a salt pool in Italy (Romano et al., 2006).

Sediments on the seafloor in busy ports, where overseas vessels with huge tonnage arrive with high frequency, have highly contaminated the waters with TBT eluted from their hull bottoms. Sublethal concentrations of TBT existing in the sediment might cause some continuous damage to the local community of marine bacteria. Therefore, it is possible that some marine bacteria species might acquire TBT tolerance by mutation during their prolonged exposure to sublethal concentrations of TBT. However, *H*. *alkaliphila* DSM 16354<sup>T</sup> isolated from a non-TBT-polluted salt pool showed strong tolerance toward TBT. Thus, it is possible to think that high resistance toward TBT is not caused by prolonged exposure to sublethal TBT concentrations but is possessed congenitally by a certain strain regardless of exposure to TBT.

Figure 1. Sampling sites of surface sediments. Samples of surface sediments were taken on board at anchorages of Tokyo Bay and Ise Bay, Japan.

Figure 2. Changes in the survivability of the isolate and the taxonomically similar type strains in relation to the given numbers of resting cells exposed to TBT. Surviving cells were counted by the colony-counting method after exposure to 100 μM of TBT for 1 h. The number of cell-associated TBT molecules varied with the number of resting cells exposed to TBT. Changes in the number of surviving cells of *Photobacterium* sp. TKY1 (closed circles), *P*. *ganghwense* JCM 12487<sup>T</sup> (open triangles), and *P*. *halotolerans* LMG 22194<sup>T</sup> (open triangles) are shown in relation to given numbers of resting cells (Figure 2A). The results obtained from *Halomonas* sp. TKY2 (closed circles), *H*. *venusta* DSM 4743<sup>T</sup> (open triangles), and *H*. *alkaliphila* DSM 16354<sup>T</sup> (open triangles) cells are shown in Figure 2B. For *Photobacterium* sp. NGY1 (closed circles), *P*. *rosenbergii* LMG 22228<sup>T</sup> (open triangles), and *P*. damsela ATCC 33539<sup>T</sup> (open triangles), the number of surviving cells is shown in Figure 2C. The dotted line in each figure means perfect survivability, regardless of the initial number of resting cells. The use of the figures is permitted by the Society for Antibacterial and Antifungal Agents, Japan.

# **ESTIMATION OF THE IMPACT OF TBT-RESISTANT MARINE BACTERIA IN TBT-POLLUTED SURFACE SEDIMENT**

Estimation of the impact of TBT-tolerant marine bacteria on an indigenous microbial population in surface sediment polluted with a sublethal TBT concentration has been carried out *in vitro* (Table 4). When resting cells of TBT-sensitive *Vibrio natriegens* ATCC 14048<sup>T</sup> were exposed for 1 h to 100 μM TBT, as a final concentration, the number of surviving cells was reduced to 106.2±0.3 CFU mL-1 . While resting cells of *V*. *natriegens* were mixed with those of TBT-resistant *Photobacterium* sp. TKY1, the number of surviving cells of *V*. *natriegens* was determined to be  $10^{4.4\pm0.4}$  CFU mL<sup>-1</sup>, the value of which decreased 2 orders of magnitude as compared with that when *V*. *natriegens* was examined alone.

**Table 3. List of two type strains with high similarities to the 16S rDNA sequences of each isolate**

Strain isolated	Type strains <sup>a</sup>	Origin	References
Photobacterium sp.	Photobacterium ganghwense JCM $12487T$	Seawater	Park et al. (2006)
TKY1	$(99.4\%)^b$		
	Photobacterium halotolerans LMG 22194 $T$	Saline lake	Rivas et al. (2006)
	$(94.2\%)$		
Halomonas sp.	Halomonas venusta DSM 4743 <sup>T</sup> (99.6%)	Seawater	Baumann et al. (1972)
TKY <sub>2</sub>	Halomonas alkaliphila DSM 16354 <sup>T</sup> (99.6%)	Salt pool	Romano et al. (2006)
Photobacterium sp.	Photobacterium rosenbergii LMG 22228 <sup>T</sup> (98.5%)	<b>Bleached</b>	Thompson et al.
NGY <sub>1</sub>		coral	(2005)
	Photobacterium damsela ATCC 33539 <sup>T</sup> (95.2%)	Damselfish	Smith et al. (1991)
		skin ulcers	

<sup>a</sup>We selected two kinds of type strains, which showed high first and secondary similarities to the 16S rDNA sequences of each isolate, based on the database of Apron DB-BA Version 4.0 (TechnoSuruga Laboratory Co., Ltd.).

<sup>b</sup>The homologous percentage between the isolate and each type strain is shown in parentheses. The type strain listed in the upper line made a cluster with the isolate on the phylogenetic tree.

## **Table 4. Changes in the survivability of TBT-sensitive Vibrio natriegens ATCC 14048<sup>T</sup> when** *Photobacterium* **sp. TKY1 possessing "TBT tolerant but with no degradation ability" coexist in the presence of TBTCl**

<sup>a</sup> Experiments were carried out three times independently, and the data are shown as the averaged value  $\pm$  standard deviation.

<sup>b</sup> No reduction of colony-forming *V. natriegens* 14048<sup>T</sup> cells was observed after being mixed with *Photobacterium* sp. TKY1 cells for 1 h in the absence of TBTCl.

The capacity of cell walls of TBT-tolerant marine bacteria is generally higher than that of TBT-sensitive marine bacteria. This means that the concentration of TBT increases locally with the presence of TBT-tolerant marine bacteria, and TBT toxicity is amplified when TBTtolerant species exist in the population in TBT-polluted sediment. In order to maintain the microbial ecosystem, TBT should be removed from surface sediment and degraded, especially TBT in the surface sediment of busy ports.

# **BIOREMEDIATION OF TBT-CONTAMINATED SEDIMENTS BY TBT-DEGRADABLE MARINE BACTERIA**

One of the possible uses of TBT-degradable marine bacteria is to apply the isolates to the bioremediation of TBT-polluted sediment. TBT-degradable *Aeromonas molluscorum* Av27 (Cruz et al., 2007) and *Stenotrophomonas chelatiphaga* HS2 (Hassan, 2018) are good candidates because they can degrade TBT to less toxic dibutyltin and monobutyltin, and they use one to two butyl groups of TBT as a carbon source during the growth. Cruz et al., (2007) compared the degradation ratio of TBT in the autoclaved sediment sample with that in the non-autoclaved sediment sample after inoculation with *A*. *molluscorum* Av27. The ratio obtained from the autoclaved sample was 2 to 3 times higher than that of the non-autoclaved sample during 150 days of degradation after freshly prepared cells were inoculated, indicating that the degradation activity was reduced by the isolate's competition for survival with the indigenous population. Similar results, showing the difficulties of survival for invasive species in non-indigenous population, have reported. Mimura and Miwa took seawater samples on board at busy ports and the quarantine anchorage in Tokyo Bay (Figure 3) and examined the survivability of non-indigenous *Vibrio* sp. cells (Figure 4). As a result, the survivability of marine *Vibrio* sp. cells was obviously reduced within two weeks under competition for survival with the indigenous population containing living  $10^{3.5}$  to  $10^{6.1}$  CFU  $mL^{-1}$  after the addition of freshly prepared resting cells to give an order of  $10^3$  to  $10^4$  CFU mL-1 (Mimura and Miwa, 2013). However, *Vibrio* sp. cells added to autoclaved samples could grow up to about  $10<sup>2</sup>$  times after two weeks. Bioremediation of TBT-contaminated sediments by TBT-degradable marine bacteria is better carried out in a bioreactor on land, rather than in situ degradation, after sediment samples polluted with TBT were taken and autoclaved.

Figure 3. Sampling sites of seawater in Tokyo Bay. Seawater was taken on board to estimate the survivability of a non-indigenous *Vibrio* sp. after invasion against seawater in busy ports.

Figure 4. Changes in the number of *Vibrio* sp. cells after their introduction into populations of native marine bacteria. Seawater was taken at Ariake Pier on June 14, 2009 (A), July 20, 2009 (B), and September 19, 2009 (C), Harumi Pier on January 17, 2010 (D), the quarantine anchorage on January 17, 2010 (E), and Yokohama Port on March 10, 2010 (F). Every sampling site is located in Tokyo Bay. Seawater at 5 m depth from the surface of the water body was taken for all the samples, except for sample F. The sediment sample (F) was taken at 10 m depth. Temperatures at the sampling sites were 22, 26, 23, 14, 11, and 12ºC for samples A, B, C, D, E, and F, respectively. *Vibrio* sp. cells freshly prepared were added to seawater in test tubes to give an order of  $10<sup>3</sup>$  (closed triangles) and  $10<sup>4</sup>$  (closed circles) CFU mL-1 . Surviving cells were counted using thiosulfate-citrate-bile salts-sucrose (TCBS) agar plates. The survivability of *Vibrio* sp. cells was also examined in the seawater autoclaved as a control (open triangles and open circles) in the left figure. Changes in the numbers of indigenous marine bacterial populations alone are shown in the figure on the right (open squares) using seawaterbased nutrient agar plates. In addition, changes in total populations including *Vibrio* sp. cells of an order of  $10^3$  (closed triangles) and  $10^4$  CFU mL<sup>-1</sup> (closed circles) are shown in the figure on the right. "TCBS" and "SW" in parentheses in the left and right figures mean TCBS agar plates and seawaterbased nutrient agar plates, respectively. The use of the figures is permitted by the Japan Institute of Marine Engineering.

# **THE STRAIT OF HORMUZ: CHARACTERISTICS, CHALLENGES AND OPPORTUNITIES IN THE NORTHERN COASTLINE**

# *Moslem Daliri , Morteza Salahi and Abolfazl Naji*

Fisheries Department, Faculty of Marine and Atmospheric Sciences and Technologies, University of Hormozgan, Bandar-Abbas, Iran

# **ABSTRACT**

The present study describes characteristics, challenges and opportunities in the Strait of Hormuz (Iranian waters) and reviews the present and future conditions of the marine environment in the region. Because of the diversity fauna, the Strait of Hormuz is known as an environmentally unique ecosystem. But, its health is seriously threatened by a number of anthropogenic stressors such as industrialization and urbanization, pollution, overfishing and climate change. We also discuss the potential ecotourism capacity of the Strait of Hormuz and the subsequent benefit to the economy of local communities. A comprehensive management plan is required to promote coastal ecotourism in the region, and unstable approaches would lead to rising anthropogenic pressures.

**Keywords:** The Strait of Hormuz, living marine resources, anthropogenic stressors, coastal ecotourism

# **1. GEOGRAPHY AND GEOMORPHOLOGY OF THE STRAIT OF HORMUZ**

The Strait of Hormuz, located in southwest Asia, lies between 26˚30́ N and 56˚30́ E, and connects the Persian Gulf to Gulf of Oman and the Indian Ocean (Figure 1). The mean width of the Strait of Hormuz is 56 kilometers (with the narrowest portion at 39 km). The length and maximum depth of the Strait are about 192 kilometers and 120 m. Iran (Islamic Republic of)

Corresponding Author's Emails: moslem.daliri@yahoo.com; daliri@hormozgan.ac.ir.

covers the northern shoreline and Oman and United Arab Emirates (UAE) border the southern portion of the Strait (Figure 1). The Strait of Hormuz is one of the most important petroleum transit channels in the world, with nearly 20% of global supply of oil passing through it (Cordesman 2007, Aghajanloo et al. 2013).

Figure 1. Location of the Strait of Hormuz.

There are numerous islands in the northern part of the Strait, namely Qeshm, Hormuz, Larak, Hengam, Greater Tunb, Lesser Tunb and Abu Musa, which are strategically important (Figure 2). Qeshm is the largest island with  $1491 \text{ km}^2$ ,  $115 \text{ km}$  length, and  $10\text{-}30 \text{ km}$  width, is separated from Iranian mainland by the Khoran estuary. Unlike Qeshm, which is mostly flat, Larak is covered by ditches and ridges in particularly in the south and southwestern areas. Hormuz Island is also a salt dome, which has an area of 42 km<sup>2</sup>, and is covered by sedimentary rock and layers of volcanic material on its surface. Qeshm Island has an area of

50 km<sup>2</sup> , shaped like a truncated cone and is generally calcareous. Abu Musa is close to the equator, and has warmer and more humid weather than other Iranian islands. Greater and Lesser Tunbs, with areas of 11 and  $2.5 \text{ km}^2$ , are 12 km and lie 20 km from the south of Qeshm. The two small islands are located in the deepest part of the Persian Gulf, as well as within the international marine transportation corridors, and has greater geopolitical and strategic importance (Ramazani 1979).

Previous geological studies indicate that there are two structural regions in the south-west Asia, including Arabian Peninsula and Iranian Plateau. The Strait of Hormuz is the narrowest waterway between these regions. The Iranian Plateau, which the Persian Gulf is a part of it, collided with the north-east portion of the Arabian Peninsula to create the convex-shape in the north of the Strait of Hormuz (Reynolds 1993, Roumina 2015).

Figure 3. Bathymetric map around the Strait of Hormuz.

Figure 4. Maritime boundaries around the Strait of Hormuz; Dashed line illustrates economic exclusive zone (EEZ).

Maritime boundaries (based on the United Nations Convention on the Law of the Sea (Albrecht 2014)), in the waters of Strait of Hormuz is shown in Figure 4. Iran's internal waters include the waters surrounding Qeshm, Hengam, Larak, and Hormuz islands, and the territorial waters within 3-12 km of the coastline of the waters surrounding Abu Musa and Greater and Lesser Tunbs, begins at the edges of these islands. Therefore, Iranian territorial waters are wider in this part of the Strait. In the narrowest place of the Strait of Hormuz (Larak and Qeshm islands), a controversial area, Iran and Oman have agreed upon a 12 mile territorial sea.

# **2. LIVING MARINE RESOURCES**

Because of wide variety fauna, the Strait of Hormuz has been known as an environmentally unique ecosystem. Sheppard (1993) argued that species richness in the Persian Gulf and the Strait of Hormuz is mostly related to the high nutrients of the water body. The purpose of this section is twofold. First, to introduce the major living groups and species that are prevalent in the northern part of the Strait of Hormuz, and second, to assess the status of these resources against the probably of future changes.

### **2.1. Coral Reefs**

Coral reefs are found in the Pacific Ocean, the Indian Ocean, the Caribbean Sea, the Red Sea, and the Persian Gulf, Florida and southern Japan. Globally, coral reefs cover an estimated 110,000 square miles (284,300 square kilometers). Coral reefs communities throughout the world are experiencing serious declines. Wilkinson (2004) showed that 30% of reefs are already severely damaged and close to 60% might be lost by 2030. Pandolfi et al. (2003) stated that overfishing and pollutions have been causing the decline of coral reefs communities directly and indirectly.

Because of extreme range of salinity and sea temperature and intense low tides in the Persian Gulf, coral reefs live in harsh environmental conditions (Sheppard et al. 2010). In the northern Persian Gulf, along the Iranian coastline, these unique habitats are mostly restricted to offshore islands. Wilson et al. (2002) mentioned that the best reefs in this area are around Khark and Kharku islands, and from the Lavan to Hormuz Islands. There are 27 species belonging to 20 genera and 9 families in the northern part of the Persian Gulf, with *Porites lutea* Milne-Edwards & haime, 1860; *Porites compressa* Dana, 1846 and *Acropora clathrata* (Brook, 1891) being the dominant species (Wilson et al. 2002). Sheppard and Salm (1988) argued that because the ecological conditions of the Persian Gulf are mostly close to the physiological tolerance limits of many species, the coral reefs have relatively low diversity compared to the Gulf of Oman (70 species).

Rezai et al. (2004) reviewed the status of coral reefs in the Persian Gulf, the Gulf of Oman and Arabian Sea during 100 last years. They concluded that reefs were almost certainly healthy at the beginning of the period, dominated by *Acropora* (staghorn) corals to about 4-5 m depth, then by massive corals (*Porites*, faviids) from 5 m to about 10 m. In 1994, substantial nearshore construction, landfilling, and oil and civil development changed coastal habitat, but corals were mostly affecting coral reef communities. In 2004, because of coral bleaching in 1996-98, many of the reefs declined and did not recover. They also predicted that future temperatures will be unfavorable for coral growth in the area, and the rising stress on nearshore reefs will lead to further destruction. Wilson et al. (2002) also argued that industry (power generation, sea water desalinization, petrochemicals and oil refining, aluminum and steel smelting), shipping and dredging and marine fisheries are the major human activities leading to coral decline in the Persian Gulf and the Gulf of Oman during the last decade. They also asserted petroleum extraction, processing and transport have also added to this decline, particularly in the Strait of Hormuz. Figure 5 shows the classification of coral reefs at different threat levels in the Persian Gulf and Oman Sea. It is obvious that coral reefs from the northern Persian Gulf (along the Iranian coastline), particularly in the Strait of Hormuz, are mostly classified as high or very highly threatened. The reviews above provide evidence to demonstrate that the poor condition of corals reefs in the Strait of Hormuz, and the ineffectiveness of ecosystem management plans at national or regional levels in this area.

Figure 5. Coral reefs condition in the Persian Gulf and Oman Sea.

#### **2.2. Mangrove Forests**

Mangroves are littoral woody plants which exist in tropical and sub-tropical sheltered coastlines. Globally, there are 54-75 species of true mangroves which found only in tidal zones (Saenger et al. 1983). They can grow in conditions of high salinity and temperature, extreme tides, strong winds, muddy and anaerobic soils (Kathiresan and Bingham 2001). Mangrove ecosystems not only reduce coastal erosion but provide also spawning and nursery grounds for aquatic organisms, breeding sites for birds, as well as ecotourism capability. Mangrove branches and leaves are also used to feed domestic animals by local communities. Iranian mangrove forests cover approximately 93  $km^2$  of the northern Persian Gulf and are one the most biodiverse marine ecosystems in the area, with more than 107 species of fishes, 100 species of sea and shoreline birds, 6 species of shrimp, and 10 species of crabs, 5 species of sea snake and 2 species of sea turtle (Zahed et al. 2010).

Alongi (2002) claimed that approximately one-third of the world's mangrove forests have been lost over the last half century. Walters et al. (2008) also concluded that increasing population in coastal areas and global climate change, particularly sea-level rise, are two important problems facing mangroves worldwide, and mangroves of the Persian Gulf and Oman Sea are no exception. Furthermore, short-term management decisions speed up the destruction of these valuable ecosystems in the region. For example, Azini lagoon a 15,000 ha mangrove area, located in the southwest of Bandar Sirik, is one of the four international lagoons of Hormozgan province. During the recent years, the lagoon's environment has been affected by destructive events such as oil spills. As is shown in Figure 6, the constructed petrol station in vicinity of the mangroves will make irreparable damage in future. Moreover, vessels and boats transition makes water turbulence which has negative impact on the mangrove roots. More description about mangrove forests of the Strait of Hormuz are given in section 5.1.

Figure 6. Location of petrol nearing the mangroves of Azini lagoon, Sirik region (satellite images date: September 9, 2016).

#### **2.3. Planktonic Assemblages**

Marine phytoplankton, including dinoflagellates; diatoms; blue-green algae; silicoflagellates and coccolithophores, contributes more than 90% of primary productivity in marine waters (Verlencar and Desai 2004). Sheppard et al. (1992) stated that primary productivity in the Persian Gulf is high compared to the Red Sea and Arabian Sea. However, information on planktonic communities in the northern coastal waters of the Persian Gulf is sparse. Research on plankton in Iranian waters of the Persian Gulf has been conducted by Fatemi et al. (2004), Fallahi et al. (2005) Namin et al. (2010), Alamzadeh (2011), Moradi and Kabiri (2012) and Fatemi et al. (2012a). With reference to these, diatoms, with 97 species, is dominant planktonic group in the northern waters of the Persian Gulf. Fatemi et al. (2004) also demonstrated temporal variation of diversity and concentration of diatoms. They observed the highest diversity in winter (with 63 species) and lowest in summer (with 18 species), while the highest and lowest concentrations were in autumn  $(627067 \text{ cell.m}^{-3})$  and summer (345139 cell.m<sup>-3</sup>), respectively. Fallahi et al. (2005) proved that planktonic density
has spatial variation in the area, and decreases from the west of the Persian Gulf to the Strait of Hormuz. They also identified 244 species of phytoplankton, of which 124 were diatoms (Bacillariophyceae), 113 Dinophyceae, 5 Cyanophyceae, 1 Chrysophyceae, and 1 Euglenophyta.

The input of excessive nitrogen and phosphorous into near-shore waters, through industrial and urban sewage, is also one of the important anthropogenic pressures on Iranian waters of the Persian Gulf ecosystem, in particularly the Strait of Hormuz, causing eutrophication and planktonic blooms. According to Behzadi et al. (2012) and Rahimi (2013), approximately 700 liters per second of urban and industrial sewage are released to near-shore waters of the Persian Gulf. Whereas, some studies have demonstrated that eutrophication and increasing respiration rates through the excess production of organic carbon in coastal waters, has led to increased acidification (Wallace et al. 2014, Gobler and Baumann 2016).

The marine ichthyotoxic dinoflagellate is mostly responsible for the harmful algal blooms (HABs), commonly referred to as "red tides," in waters of the Strait of Hormuz. Fatemi et al. (2012a) argued that *Noctiluca scintillans*, *Trichodesmium* sp. and *Nitzschia* sp. are the main species that are responsible for HABs in this area. They also noted that fish kills in August 2008 to May 2009 were related to blooms of the toxic dinoflagellate *Cochlodinium polykrikoides*. This event also caused massive damaged to coral reefs, restriction of fishing activities and forcing desalination plants (in Oman and the United Arab Emirates) to cease or modify operations due to clogging of intake filters or the fouling of reverse osmosis membranes (Richlen et al. 2010).

#### **2.4. Bony Fish and Elasmobranches**

Fish diversity in the Persian Gulf, considering the Strait of Hormuz and Iranian waters of the Gulf of Oman, includes 908 species belonging to 157 families. This includes 129 families of Teleostei (814 species), 18 families of sharks (60 species), 10 families of rays (34 species). The number of 62 families are mono-species family and 25 families have more than 10 species, such as *Gobiidae* (with 53 species), *Carangidae* (48 species), *Labridae* (41 species), *Blenniidae* (34 species), *Apogonidae* (32 species), *Lutjanidae* (31 species), *Carcarhinidae* (26 species) and *Dasyatidae* (12 species). Nevertheless, fish diversity of the Persian Gulf compared to tropic and subtropics areas in the Indo-Pacific region is most similar to the Red Sea and Bay of Bengal (Owfi 2015).

Fisheries is the most important natural resource, after petroleum, in the Persian Gulf and the Strait of Hormuz. Referring to IFO (2014), total fish landing in Iranian waters of the Persian Gulf and the Strait of Hormuz was 314,121 tons in 2014, with Hormozgan province landing the highest proportion (68%) (Figure 7). Target species in this region include mostly mackerel and various Perciforms such as families of *Carangidae*, *Haemulidae*, *Serranidae*, *Sparidae*, *Stromateidae*, *Lutjanidae*, *Scianidae*, *Mugilidae*, *Clupeidae* and *Trichiuridae*. Herein, a review of the fisheries and scientific research are presented.

Iran is the country with the largest fishery in the Persian Gulf area. Fishing in Iranian waters is both small-scale (using motorized dhows and sambuks, small wooden or fiberglass vessels, intertidal fixed stake net traps etc.) and large-scale (industrial-style trawlers). As shown above, Hormozgan Province which covers the northern part of the Strait of Hormuz, has the largest fishery of the region. There are now approximately 22,500 and 1,290 fishers employed respectively in the small-scale and large scale fisheries sector in Hormozgan (Daliri et al. 2016). The main types of fishing gear used are gillnets, wire traps (local name: gargoor), intertidal fixed stake net traps (local name: Moshta), hook and lines, beach seines, shrimp trawls, purse seines, Largehead hairtail trawls and some other traditional forms (FAO 2014). Gill-net fishery is the most common fishing method currently undertaken in the area, and drift gillnets are used for large pelagic fisheries such as tuna and tuna-like species. Fixed-gill nets are also used for catching demersal fish species such as *Pampus argenteus* (Euphrasen, 1788), *Pomadasys kaakan* (Cuvier, 1830), *Argyrosomus hololepidotus* (Lacepède, 1801), *Otolithes ruber* (Bloch & Schneider, 1801) and other species.

Some research on gillnet fishery have been conducted in Iranian waters of the Persian Gulf by Parsa (2011), Dastbaz (2011), Moein et al. (2012), Daliri et al. (2017), Hosseini and Kamali (2017) and Haghighatjo et al. (2018). They argued that the gillnets, due to high bycatch and harvesting of undersized target species, are mostly not selective and determining the standard mesh sizes is necessary.

Small-pelagic fish in the Persian Gulf waters are also harvested with purse seines and beach seines. Alaee et al. (2016) discussed that Hormozgan province, had the largest proportion (95%) of small-pelagic fish landing in Iranian waters of the Persian Gulf and Oman Sea. Salarpouri et al. (2008) also stated that waters of Qeshm Island, Bandar Lengeh and Bandar Jask are the main fishing grounds of small-pelagic fishes in Hormozgan, and sardines and anchovy are the most important species.

Figure 7. Total fish landing (tons) from Iranian waters of the Persian Gulf and Gulf of Oman. Hormozgan province covers the Strait of Hormuz waters, and Bushehr and Khuzestan provinces cover the central and western parts of Iranian waters of the Persian Gulf.

The intertidal stake traps, known as Moshta, are commonly used to capture littoral fish species in the Persian Gulf, particularly in Hormozgan (Al-Baz et al. 2007). Daliri (2016) reported that Moshta in the Strait of Hormuz waters captured a total of 81 species, including 65 teleost fish, 6 elasmobranchs, 6 crustaceans, 2 cephalopods, 1 sea turtle and 1 echinoderm species. The catch composition by weight also included 19.66% commercial catch, with a large percentage of the catch consisting of juveniles, and 80.33% discards.

Largehead hairtail trawls and Lanternfish trawls are also used as mid-water trawls in the area. Raeisi et al. (2012) estimated 1941.5 tons of the bycatch produced by the improved trawls (for Largehead hairtail fisheries) in Hormozgan, included 45 species from 31 families. They also reported that catch composition contained 67.75% largehead hairtail, and 32.25 % bycatch (17.81% incidental catch and 14.44% discards). Kiaalvandi et al. (2012) also examined bycatch of Lanternfish trawls in Hormozgan waters and reported that catch composition consisted of 29.64% target species and 70.36% bycatch.

In summary, the fish stocks of Iranian waters of the Persian Gulf are mostly fully exploited or overfished. The available catch data of this area indicates a 21% decrease in demersal fish landings during the recent years, whereas fishing effort has been increasing (Valinassab et al. 2006a, Hosseini et al. 2015).

#### **2.5. Macrobenthos**

Because of harsh environmental conditions, biodiversity of microbenthic communities of the Persian Gulf is high, but they have mostly low species richness (Sheppard et al. 2010, Sharifinia et al. 2019). In Iranian waters of the Strait of Hormuz, muddy subtidal habitats support many Macrobenthos species of shrimp and crab. Macrobenthic assemblages of the region have been investigated by some researchers such as Kamrani et al. (2010), Asgari et al. (2012), Fatemi et al. (2012b), Pourjomeh et al. (2014), Taherizadeh and Sharifinia (2015), Naderloo et al. (2015), Amini-Yekta et al. (2017) and Sharifinia (2017). These studies have mostly focused on identifying macrobenthic taxa and the effects of environmental change on their distribution in the region.

Figure 8. Location of shrimp fishing grounds in the Strait of Hormuz.

Shrimp is the most important commercial Macrobenthos in the northern waters of the Strait of Hormuz, and are captured by bottom trawls. Commercial shrimp species in the region include *Penaeus merguiensis* (De Man, 1888), *Metapenaeus affinis* (Milne-Edwards, 1837), *Penaeus semisulcatus* (de Haan, 1844). Fishing grounds for these species is shown in Figure 8. A high volume of bycatch is the main problem of the shrimp trawl fisheries in the Persian Gulf and the Strait of Hormuz (Valinassab et al. 2006b, Hosseini et al. 2015). Hosseini et al. (2015) reported that bycatch composition of shrimp trawlers in Hormozgan included 52 teleostei species, 23 invertebrates and 6 elasmobranchs. The bycatch-to-shrimp ratio was 6.8:1. They also stated that most of the incidental catches, such as *P. argenteus*, *Parastromateus niger* (Bloch, 1795), *Scomberomorus commerson* (Lacepède, 1800), *Carcharhinus dussumieri* (Müller & Henle, 1839) and *O. ruber*, were caught under the standard size.

# **3. CHANGING ENVIRONMENTAL CONDITIONS**

However, little research has been conducted on changing environmental conditions in the Persian Gulf and the Strait of Hormuz. For example, Jafari et al. (2016) demonstrated a significant rising of sea level between 1995 to 2010 (Figure 9). Data analyses of sea surface temperature (SST) also indicate a steady trend of warming (Figure 10). The change of mean sea level (MSL) as a function of SST in the Strait of Hormuz can be describe as follows (Jafari et al. 2016):

$$
MSL = 3.106 SST + 235 \tag{1}
$$

The coefficient of the model explains that changes in SST makes 3.106 times change in MSL. There is seasonal fluctuation of SST in the area, ranging between 20˚ to 34˚c. Interannual analysis of SST data also revealed that minimum and maximum temperature occurred in January and August with 19.4˚ and 34˚c (Figure 9).

Figure 9. Sea level rising in the Strait of Hormuz (from Jafari et al. (2016)).

Figure 10. Temporal fluctuation of SST in the Strait of Hormuz.

## **4. POLLUTION**

The Persian Gulf has the largest reserve of oil in the world, transported throughout worldwide through the Strait of Hormuz. Therefore, oil exploration, production, and transport are major contributors to pollution in the Persian Gulf (Khan et al. 2002, Abdul-Wahab et al. 2009). Some literature, such as Naji et al. (2017a), Naji et al. (2017b), Esmaili and Naji (2018) have examined the presence of plastic contamination in marine environment of the Persian Gulf, in particularly the Strait of Hormuz. The plastic pollution, which is steadily rising, is openly threatening marine biota at every level of the food web, from primary producers to higher trophic-level organisms (do Sul and Costa 2014). Naji et al. (2017b) examined microplastic (MPs: <5 mm) contamination in littoral sediments of the Strait of Hormuz and concluded that MPs were exist in 80% of the samples, and fiber particles were the most dominant (88%), followed by films (11.2%) and fragments (0.8%). The sediments with the highest numbers of MPs were from sites in the vicinity of highly populated centers and municipal effluent discharges.

Naji et al. (2017a) also explored abundance of plastic debris and microplastic contaminations in various stations along the beach of the Strait of Hormuz. This area exhibited different levels of industrialization and urbanization, and included a marine protected area (MPA). They found that polyethylene (PE), nylon, and PET (polyethylene terephthalate) were the commonly recovered polymers, and likely sources included beach debris, discarded fishing gear, and urban and industrial outflows. Moreover, trace metals are another type of contamination in the Persian Gulf. Due to the shallow depth and limited circulation the impact of the pollutants on the marine environment are significant (Pourang et al. 2005). Naji et al. (2015) assessed trace metal concentrations (Pb, Ni, Zn, and Fe) and potential ecological risk of them in intertidal surface sediments of a mangrove estuary in the Strait of Hormuz. The concentration of metals (all in  $\mu\alpha/g$ , except for Fe in %) were as follows: 2-9 Pb; 58.9-94.3 Ni; 111.9-185.6 Zn; 1.4- 2.2 Fe. They also found that Zn and Ni were mainly from anthropogenic discharge, while a significant portion of Pb and Fe were likely from natural inputs. Overall, frequent adverse effects were expected for Ni and occasional adverse biological effects were expected for Zn. Likewise, for Pb and Fe rare adverse biological effects were expected. Ghasemi et al. (2018) also investigated

accumulation of trace metals in the sediments of mangrove forests (Hara Protected Area and Azini estuary) in the Strait of Hormuz, and argued that the concentration of selected metals was  $Pb > Zn > Cu > Cd$  and in the HPA region and  $Zn > Cu > Pb > Cd$  in Azini estuary. Their results also revealed that the HPA region was in the range of moderate ecological risk and the Azini Bay region in the range of acceptable ecological risk. Potential human health risk of trace metals (Cd, Cu, Ni, Pb and Zn) via the consumption of marine fish in the Persian Gulf and the Strait of Hormuz was also assessed by Naji et al. (2016), who showed that metal concentrations were lower than legal limits. Cadmium target hazard quotient values suggested that the threshold to avoid the potential risk for children health is an exposure level lower than 3 meals per week. Hazard index values based on four metals (not including Pb) for the child age class were higher than those of the adult age class, suggesting that children may suffer from a higher health risk.

Figure 11. Example of macroplastic litter items as source of microplastic formation in the Strait of Hormuz (from Naji et al. (2017b)).

# **5. COASTAL ECOTOURISM POTENTIALS**

According to definition of The International Ecotourism Society, ecotourism means "*responsible travel or visitation to natural areas that conserves the environment and improves the well-being of local people*" (Bricker 2017). Ecotourism clearly includes a set of social, environmental and economic principles that contribute to sustainable development. Globally the tourism industry is constantly growing, so that the World Tourism Organization (WTO) statistics indicates an average increase of 10% per year from 1995-2005 (Figure 12). Rakhshani Nasab and Zarabi (2009) argued that the major proportion of this increase is due to ecotourism.

Figure 12. Average annual growth (%) of tourist arrivals during 1950 to 2005 (Vrujci 2005).

Iran (Islamic Republic of), in terms of tourism, ranked 5<sup>th</sup> among the Middle East countries (Table and Figure 13), whilst has known as the world's 5th largest country in terms of natural diversity (Rakhshani Nasab and Zarabi 2009). Today, all countries are mostly attempting to make maximum use of their tourist attractions, but Iran has not reached its maximum potential in this industry. Because of existence of mangrove forests, high biodiversity and numerous islands, the northern coastline of the Strait of Hormuz has a potential capacity for the development of Iran's tourism industry and the subsequent creation job opportunities for indigenous communities. Therefore, a comprehensive management plan is required to promote coastal ecotourism in this region. Some aspects of coastal ecotourism in Iran's coastline of the Strait of Hormuz are presented as below.

**Table 1. International tourist arrivals (million) in the Middle East countries in 2015 (UNWTO Library 2017)**

Rank	Country	International tourist	Change from
		Arrivals (million)	2014 to 2015 (%)
	Turkey	39.5	$-0.8$
2	Saudi Arabia	18.0	$-1.5$
3	<b>UAE</b>	14.2	$+7.6$
$\overline{4}$	Egypt	9.1	$-5.1$
5	Iran	5.2	$+5.4$
6	Jordan	3.8	$-5.7$
$\overline{7}$	Oatar	2.9	$+3.7$
8	Israel	2.8	$-4.4$
9	Oman	1.9	$+17.8$
10	Lebanon	1.5	$+12.1$

Figure 13. Average annual growth (%) of tourist arrivals in the Middle East countries during the last 55 years (Vrujci 2005).

#### **5.1. Mangrove Forests**

As stated above, mangrove forests are the only forests located at the intersection of land and sea in the world's subtropics and tropics (Alongi 2002). These have not only had a significant role in biological and biogeochemical cycles in coastal ecosystems, but also play an important role in regional and national economies. Because mangroves are known as an ecotone environment, they have wide variety of organisms making them a biologically rich habitat (Salam et al. 2000). Mangroves ecotourism throughout the world has been able to generate economic benefits for local communities and promote the countries' tourism industry (Murtini and Kurniawati 2018).

Figure 14. Location of mangroves forests in the northern coastline of the Strait of Hormuz (Zone I: Qeshm Island, called Harra Marine Protected Area; Zone II: Khamir estuaries and mouth of the Mehran River; Zone III: the east of the Bandar Abbas; Zone IV: Tiyab and the Kolahi regions; Zone V: Sirik region and Zone VI: Jask region).

The mangrove forests of coastline of the Strait of Hormuz, along the Iranian coastline (Hormozgan province) are distributed within six zones (Figure 14). Although there are more than 60 species of mangrove in the world, mangroves in this region includes only two species namely *Avicennia marina* (in Persian called Harra) and *Rhizophora macrunata* (in Persian called Chondal) (Danehkar 1996, Zahed et al. 2010). These evergreen forests are one of the most beautiful tourist destinations in the Persian Gulf and Oman Sea. As Zahed et al. (2010) stated, increasing industrialization, changing the environmental conditions as well as unstable political decisions are threatening the status of the mangroves in the region. Therefore, developing ecotourism in a non-destructive fashion could be a solution to mitigate the negative consequences on these unique ecosystems.

# **5.2. Marine Wildlife Watching**

Wildlife tourism has been known as a safe way to achieve sustainable economic benefits while supporting wildlife conservation and indigenous people (Higginbottom 2004). Globally marine wildlife watching is increasingly important for the tourism industry. The northern part of the Strait of Hormuz is no exception, and provide good opportunities to observe marine wildlife in their natural environment. Dolphin watching, during mid-autumn to mid-spring, in the coastal waters of Hengam Island is a popular activity for tourists.

Figure 18. Hawksbill in the coastline of Shibderaz village, Qeshm Island.

Nesting of Hawksbill turtle, *Eretmochelys imbricata* (Linnaeus, 1766), is another wonderful natural attraction to promote for ecotourism in the Strait of Hormuz (Figure 18). The Hawksbill turtle is a critically endangered (CR) species which has two Atlantic and Pacific subspecies (CITES 2016). The Pacific subspecies lives in the Persian Gulf and comes to its islands beaches, particularly to Qeshm Island, for spawning. The sandy coastline of

Shibderaz village, located in the central southern part of Qeshm Island, is a convenient site for nesting Hawksbill turtles to lay their eggs. Over the past few years, the reproductive behavior of this turtle species has attracted many enthusiasts to Qeshm Island. In addition to diving and water sports, watching the marine ornamental fishes by glass-bottom boat excursions is also one of the exciting recreational activities in this region. The rocky coasts of Qeshm, Hengam and Larak Islands provide natural aquariums, which people can visit and enjoy.

Nevertheless, Iran has not succeeded in utilizing its full potential for ecotourism. However, for developing countries, which mostly have a single-product economy and high unemployment rate, development of the tourism industry is an important key to progress. Coastal ecotourism development in the northern part of the Strait of Hormuz needs more collaboration between the Iranian government and private investors. The government should not only provide proper conditions for the private sector to improve infrastructure (transportation, hotel, restaurant and etc.), but to also develop the economies of local communities (Vahedpour and Jafari 2011).

# **MACROALGAL POLYPHENOLS: ISOLATION, CHARACTERIZATION AND BIOACTIVITY**

*Ana-Marija Cikoš<sup>1</sup> , Igor Jerković<sup>2</sup>and Stela Jokić1\**

<sup>1</sup>University of Josip Juraj Strossmayer in Osijek, Faculty of Food Technology Osijek, Osijek, Croatia <sup>2</sup>University of Split, Faculty of Chemistry and Technology, Split, Croatia

# **ABSTRACT**

Marine macroalgae, which are a part of the common diet in the Asian culture and which have beneficial properties for human health, have drawn attention because of the possibility for their application in various branches of industry, due to their bioactive compounds which have shown properties that can be beneficial for human health.

Macroalgae, aside from being a good source of essential amino acids, fatty acids, dietary fiber and minerals, represent an under-exploited source of phenolic compounds known for their high potential in therapeutic and industrial applications. The production of phenolic compounds in marine algae has been involved in protection against stress conditions, such as the production of antioxidant compounds. Polyphenolic compounds such as catechins and flavonols are the most dominant polyphenols in all classes of macroalgae: *Chlorophyta* (green algae), *Rhodophyta* (red algae) and *Phaeophyta* (brown algae). The latter contain a particular type of polyphenols called phlorotannins (polymers of 1,3,5-trihydroxybenzene) with various types of bioactivity. The concentration of polyphenols varies among the classes of macroalgae because of the different chemical composition, geographical occurrence of particular species, seasonal variations and the variation is also present within the different parts of thalli. The extraction of these compounds can be performed by conventional or alternative/modern methods. The modern methods have mostly been used in the last few decades because of their benefits in comparison to the conventional methods. It is necessary to find the most efficient method for obtaining the highest concentration of polyphenols in the extract. Aside from the antioxidant potential of macroalgal polyphenols, they also have anti-inflammatory, antibacterial and anti-allergic properties. They have a high potential for implementation in functional foods as naturally obtained compounds, as well as for replacing available synthetic compounds.

<sup>\*</sup> Corresponding Author's Email: stela.jokic@ptfos.hr.; Tel.: 00 385 31 224 300; Fax: 00385 31 207 115.

This chapter will highlight the application of the most active compounds present in marine macroalgae known as polyphenols, as well as their isolation using green extraction methods. Their bioactive properties will be reviewed and their potential for health improvement will be evaluated.

**Keywords**: marine macroalgae, polyphenols, extraction, bioactivity

## **1.INTRODUCTION**

Due to the fact that 70% of the Earth's surface is covered by oceans, the presence of diverse and complex marine organisms in oceans can potentially be considered as an abundant source of valuable compounds. Marine organisms are considered to be an unexplored source of valuable products, with particular interest devoted to algae, because of their high productivity and taxonomic and chemical diversity. The algal habitat is subjected to various extreme conditions which affect algal chemical composition and lead to the creation of novel and interesting compounds. Consequently, geographical conditions influence algal thalli structure and biochemical composition, which are responsible for the value of algae as a potential source of bioactive compounds (Stengel and Connan, 2015). According to their biochemical metabolic pathways and cellular composition, algae adapt better to external conditions, when compared to terrestrial plants (Mironiuk and Chojnacka, 2018). One of the defense mechanisms is the formation of antioxidant compounds or increased enzyme activity, which are used to deactivate the reactive oxygen species (ROS). The ROS accumulate in macroalgae as a result of environmental stresses (freezing, low temperatures, radiation, desiccation, salinity fluctuations) and can cause damage to the photosynthetic apparatus with the formation of singlet oxygen. The accumulation of antioxidant compounds in the algae contributes to the potential benefits for human health. The antioxidant activities and benefits of consuming terrestrial plants such as vegetables are known, but little information is given for the antioxidant potential of macroalgae. The bioavailability of antioxidant compounds and the intake of macroalgae must be taken into consideration due to a relatively small percentage of the world population consuming seaweed (Cornish and Garbary, 2010). Aside from the environmental variations, the following factors influence the chemical composition and diversity of secondary metabolites found in algae: the species of algae, geographical origin, area of cultivation and seasonal variations (Niemczyk et al., 2018). Compounds such as fatty acids, phenolic compounds, carotenoids, polysaccharides, terpenes and many others are natural metabolites of algae related processes and they represent the products of chemical transformations which occur inside the cells. Biological activity such as antioxidant, antiinflammatory, immunostimulating and many others types of activities have been examined for these compounds. Due to the presence of biologically active compounds, algae are considered as desirable ingredients in cosmetics, drugs, diet supplements and food (Leska et al., 2018).

Seaweeds have gathered attention among researchers due to their unique composition. Aside from being a good source of carbohydrates, dietary fiber, proteins, vitamins, minerals, fats and polyunsaturated fatty acids, they are a potential source of natural antioxidant compounds such as polyphenols (Gomez-Guzman et al., 2018). In this chapter, we will show the diversity of phenolic compounds which are present in algae, as well as their bioactivity, along with the potential for their technological implementation. The emphasis was on the extraction of phenolic compounds, using both conventional methods and the most commonly applied novel extraction techniques, such as Supercritical Fluid Extraction (SFE), Subcritical Water Extraction (SWE), Ultrasound-Assisted Extraction (UAE) and Microwave-Assisted Extraction (MAE). The summary of the techniques is followed by an analytical analysis of polyphenols. Various types of polyphenol bioactivity were also reviewed in this chapter.

#### **1.1. The Classes of Marine Algae and Their Bioactive Compounds**

Macroalgae are classified into three groups according to their pigment composition; which is related to their sea habitat. Accordingly, green algae (*Chlorophyceae*) mostly inhabit coastal water, where they can absorb large quantities of light, while brown (*Phaeophyceae*) and red (*Rhodophyceae*) algae are dominant in deeper water, where the sunlight is limited (Christaki et al., 2012). Green algae have no other pigments to mask the chlorophyll, while brown algae do contain other pigments that mask their chlorophyll, and one of these dominant pigments is fucoxanthin. Similar to brown algae, red algae also contain other pigments along with chlorophyll, such as phycocyanin and phycoerythrin. These differences correspond to their adaptation to the environment in the algal habitat (Haryatfrehni et al., 2015). The sizes, physical forms and behavior of certain groups of algae are highly diverse, for example, green algae range from microscopic single cells to large tubular, bushy plants; red algae have different physical forms, with both simple and branched filaments; while brown algae are solely multicellular, but they vary in their physical forms (Murugan et al., 2015).

The chemical composition of the mentioned algal groups is still under constant investigation due to the great diversity in terms of the number of different species of macroalgae, as well as the unique composition of their primary and secondary metabolites. They can be a rich source of bioactive compounds, including polyunsaturated fatty acids, polyphenols, polysaccharides and pigments (Michalak and Chojnacka, 2018). Considering that people today are aware of unprocessed healthy foods, without synthetic additives, algae exhibit a great potential for being a source of natural compounds which can be applied in food products and serve as food supplements. Studies showed that all of the mentioned compounds possess bioactivity, such as antioxidant (Matanjun et al., 2008), antimicrobial (Plaza et al., 2010), anti-inflammatory (Khan et al., 2008), antiaging (Fayad et al., 2017), antiproliferative (Gutierrez-Rodriguez et al., 2017) and many other types of bioactivity. Physiologically active compounds isolated from algae are divided into two groups according to their mechanisms: 1) non-absorbable high molecular compounds (dietary fibers) and 2) low molecular compounds, which affect the human homeostasis (Murata and Nakazoe, 2001; Pal et al., 2014). In addition, these valuable compounds can protect the human body and participate in processes against harmful effects within it. For example, algae produce antioxidant compounds used in the fight against free radicals that appear because of the stress conditions in the environment. Free radicals are responsible for many diseases, such as skin diseases, cancer, etc. (Korzeniowska et al., 2018). Antioxidant compounds from natural sources, like algae, can be a great replacement for synthetic antioxidants, being currently used, including butylated hydroxyanisole, butylated hydroxytoluene, *tert*-butylhydroxyquinone and propyl gallate. These synthetic antioxidants are strictly regulated in many countries because they can potentially cause harmful effects on human health (Cornish and Garbary, 2010). Thus, phenolic compounds are the main contributors to the antioxidant activity of algae, which makes them candidates for implementation in the food, cosmetic and therapeutic industries as natural antioxidants. They are a promising alternative with no harmful effects on the human body, produced with low cost and beneficial effects on our health (Niemczyk et al., 2018).

#### **1.2. The Diversity of Phenolic Compounds Derived from Macroalgae**

Polyphenols are the most highly distributed group of phytochemicals in plants. They are secondary metabolites synthesized from two pathways, the shikimate and the acetate (Ross and Kasum, 2002). The simplest polyphenol structure consists of an aromatic hydrocarbon group with a hydroxyl group bonded to it (Holdt and Kraan, 2011). However, these compounds show a wide diversity of structures due to the number of phenol rings that they contain and the types of bonded structural features (Manach et al., 2004). This large group of secondary metabolites is present in both terrestrial and marine environments. Plant polyphenols are derived from the ellagic acid and the gallic acid, while algal polyphenols are derived from polymerized 1,3,5-trihydroxybenzene (phloroglucinol) units (Holdt and Kraan, 2011). Due to their chemical diversity, they can be divided into several classes starting from simple molecules such as phenolic acids, followed by flavonoids, isoflavanoids, stilbenes and lignans, to highly polymerized phenolics such as tannins (Figure 1).

They are present in fruit and beverages (tea, coffee, wine), as well as in vegetables and legumes. Flavonoids account for two thirds of the total intake of polyphenols, while phenolic acids account for the remaining third. However, the bioavailability within polyphenols must also be taken into consideration because it differs significantly, along with their concentration in foods regarding the environmental, genetic and processing factors (Machu et al., 2015).

It is well known that plant polyphenols are essential for plant physiology because they provide resistance against pathogens and predators and they are involved in the process of growth and contribute to the morphology of the plant. These polyphenols are applied for various industrial purposes, such as the production of paper and paints, they serve as additives in the food industry and also as tanning agents in cosmetics. Additionally, they have some applications in the pharmaceutical industry, as antibiotics and anti-inflammatory agents, but they can also be used in the treatment of hypertension, allergies, hypercholesterolemia, etc. (Bravo, 1998). Consequently, their consumption can reduce the risk of different diseases, such as cancer and neurodegenerative and cardiovascular disorders (Gomez-Guzman et al., 2018). They can serve as therapeutic agents and they can be used for the protection of other bioactive compounds from harmful environmental effects (Korzeniowska et al., 2018).

Aside from polyphenolic compounds such as catechins and flavonols, macroalgae are also a rich source of a special type of polyphenols, called phlorotannins, found only in algae. Phlorotannins are a group of complex polymers of phloroglucinol and they represent dominant polyphenolic compounds in brown macroalgae. On the other hand, red and green macroalgae are abundant in bromophenols, phenolic acids and flavonoids (Gomez-Guzman et al., 2015). Generally, red and green algae contain a low content of polyphenols compared to brown algae. The phenol content varies from <1% to 14% of dry seaweed biomass among species, but the content is also dependent on the different parts of thalli and on seasonal variations (Holdt and Kraan, 2011). For example, Flodin et al. (1999) observed that the bromophenol content, in *Ulva lactuca*, changed as the seasons changed and there are high variations between the detected bromophenol compounds.

Figure 1. Classification of phenolic compounds (Niemczyk et al., 2018). Figure 1. Classification of phenolic compounds (Niemczyk et al., 2018).

Phlorotannins are the most interesting polyphenols found in macroalgae due to their composition and bioactivity, and because they represent integral structural components of the cell wall (Niemczyk et al., 2018). They are composed of polymerized phloroglucinol (1,3,5 trihydroxybenzene) monomer units (Figure 2) biosynthesized through the acetate-malonate pathway or the polyketide pathway. These are highly hydrophilic components and their molecular sizes range from 126 Da to 650 kDa (Murugan et al., 2015). They are synthesized in brown algae for protection in stressful situations, which they achieve by reducing the oxidative damage (Gomez-Guzman et al., 2018). Marine algae, especially brown algae, contain a wide variety of phloroglucinol-based polyphenols, which can be low, intermediate or high molecular weight phlorotannins, with both phenoxy and phenyl units. These units can be bonded with ether, phenyl, both ether and phenyl, and dibenzodioxin linkage. Based on the linkage, phlorotannins are classified into four groups: fuhalols and phlorethols, fucols, fucophlorethols and eckols (Figure 3) (Wijesekara et al., 2010). According to the presence of these unique compounds, it can be said that algae, specifically brown algae, are a valuable source of special ingredients which have a potential use in medicine and in the food industry (Korzeniowska et al., 2018). Their therapeutic properties are being intensively studied and it was shown that they possess antioxidative, anticancer, antibacterial, anti-allergic, antiaging, anti-inflammatory, and anti-HIV properties, which were reviewed by Thomas and Kim (2011). Lower molecular phlorotannins exhibit higher antioxidant activity, which decreases with higher molecular weight. Also, it was shown that they reduce the activity of DPPH and superoxide anion radicals better than antioxidant vitamins such as ascorbic acid and  $\alpha$ tocopherol. It was suggested that phenolic hydroxyl groups attached to the eckol skeleton have the most important role in the radical scavenging activities (Shibata et al., 2007; Gomez-Guzman et al., 2018). Aside from the antioxidant activity, the structure of phlorotannins also has an influence on the bactericidal effects, Nagayama et al. (2002) showed that it increased with the polymerization of phloroglucinol.

Figure 2. The chemical structure of phloroglucinol (Cikoš et al., 2018).

Regarding the available literature, polyphenols are antioxidants with a greatly diverse chemical composition, thereby making the activities of *in vitro* and *in vivo* systems difficult to correlate (Cornish and Garbary, 2010; Holdt and Kraan, 2011). Different algal species provide different total polyphenol content due to the geographical origin of the species, area of cultivation, environmental and seasonal variations. Polyphenols are synthesized when protection against biotic or abiotic factors is needed, and because of that, phenolic compounds are known as stress compounds (Niemczyk et al., 2018). One of these stress situations is oxidative stress, which occurs due to damage caused to important molecules and because of the production of free radicals. The imbalance between the production of free radicals and the

production of antioxidant compounds results in diseases and illnesses. Phenolic compounds stabilize these free radicals by binding with them or by inhibiting certain enzymes, and these are the main reasons why they are known as the most important group with antioxidant properties (Korzeniowska et al., 2018).

Figure 3. Different types of phlorotannins and their chemical structures: a) Tetrafuhalol A; b) Tetraphlorethol B; c) Diphlorethohydroxycarmalol (DPHC); d) 6,6'-Bieckol; e) Fucophlorethol A; f) Tetrafucol A (Cikoš et al., 2018).

# **2. THE ANALYSIS OF PHENOLIC COMPOUNDS**

The first step in the determination of phenolic compounds is the extraction of these phytochemicals from plant material, which plays a crucial role in the final result, so the extraction technique and the solvent need to be selected properly. The success of the extraction depends on the applied method and the selected process parameters, as well as on the nature of the desired compounds (Azmir et al., 2013). In recent years, there has been a huge interest in algal extracts due to the high demand for natural products, which all contributes to the improvement and the development of novel extraction techniques (Michalak and Chojnacka, 2014). Novel extraction techniques need to be able to provide an efficient isolation of biologically active compounds that can be used in food, cosmetic or pharmaceutical industry. The isolation of compounds depends on the solvent used for the extraction, also on the chemical composition and the type of algae. Solvent polarity is a crucial parameter in phenolic recovery. It is known that by increasing the polarity of the solvent, the amount of the extracted phenolic compounds is higher in the final extract (Azmir et al., 2013; Niemczyk et al., 2018). Aside from solvent polarity, other factors that influence the phenolic chemical profile of the obtained extract are: macroalgae species, season when they were collected and the applied extraction method (Tanniou et al., 2013).

Conventional methods, also known as traditional methods, include Soxhlet extraction, solid-liquid extraction (SLE) and liquid-liquid extraction (LLE). These techniques require the use of large amounts of inorganic and organic solvents, as well as long processing time, there is possible degradation of thermolabile compounds and they are very energy-consuming. Considering that large amounts of waste is released, especially chemicals, these methods represent an environmental issue (Michalak and Chojnacka, 2014; Wang and Weller, 2006). All of these disadvantages and limitations can be overcome and new extraction techniques with shorter time of the process, reduced amounts of organic solvents and performance at lower temperature can be introduced, and the formation of unwanted residue of chemicals can be avoided, which makes them environmentally friendly (Wang and Weller, 2006). The new extraction methods, used most frequently today for the isolation of bioactive compounds from marine macroalgae, include Supercritical Fluid Extraction (SFE), Subcritical Water Extraction (SWE), Ultrasound-Assisted Extraction (UAE) and Microwave-Assisted Extraction (MAE).

#### **2.1. The Extraction and Characterization of Polyphenols in Macroalgae**

#### *2.1.1. Conventional Polyphenol Extraction Methods*

The extraction of polyphenols from various species of macroalgae using conventional methods, including solid-liquid extraction (SLE) with different solvents, is shown in Table 1. Scientists isolated various types of polyphenols from various macroalgal species, including species from all algal classes: brown, red and green. Alcohols, such as ethanol and methanol and their aqueous solutions are mostly used as extracting solvents, but several other hazardous solvents such as chloroform, petroleum ether and hexane, are also used. The evaporation of solvent is needed for this kind of extraction, and the discharge of these hazardous solvents presents a problem for the environment, which means that this method is

not environmentally friendly. Aside from that, high temperature achieved during the conventional process can cause degradation of thermolabile compounds. Therefore, the novel extraction techniques are preferable.

#### **Table 1. The extraction of polyphenols from marine macroalgae using conventional extraction methods**

\* Hydrophilic interaction chromatography (HILIC) – the main retention mechanism is the liquid-liquid partitioning of the polar analytes through hydrophilic interactions (ion-exchange and hydrogen-bonding between the polar stationary phase and the non-polar mobile phase). In this method, retention depends on the composition of the mobile phase and the functional group of the stationary phase, as well as the structure of the analyte.

However, available literature demonstrates that SLE is an efficient method for the extraction of various types of polyphenols. For instance, Al-Saif et al. (2014) used four different solvents (ethanol, chloroform, petroleum ether and water) for the extraction of flavonoids: rutin, quercetin and kaempferol. Chloroform was demonstrated as the most effective solvent for the extraction of these polyphenols. Among the investigated species, the red algae *Gracillaria dendroides* had the highest amount of all three flavonoids. It is known that red seaweeds are rich in phenolic compounds such as catechol, catechin, epicatechin, hesperidin, rutin and others. Kazlowska et al. (2010) reported that catechol, rutin and hesperidin were present in the red algae *Porphyra dentata* and they suggested that these three phenolic compounds are primary bioactive compounds in the crude extract of this algae. Rodriguez-Bernaldo de Quiros et al. (2010) showed that catechin was present only in red algae, while epicatechin gallate was found only in brown algae. Rajauria (2017) detected a hydroxybenzoic acid derivative, hydroxycinnamic acid derivatives, flavonolos and one special type of polyphenol, phloroglucinol. The results for antioxidant activity showed that phloroglucinol contributes the most to the antioxidant capacity of *Himanthalia elongata*, but other identified phenolic compounds could have synergistic or antagonistic effects on the total activity. Lopez et al. (2011) used various solvents, but those that were less harmful for the environment. The obtained results showed that there is a significant difference in the total polyphenol content and the antioxidant activity according to the applied solvent. The solvent polarity affected the extraction of polyphenols and the antioxidant activity, and water was the best solvent for the extraction, while ethanol provided the lowest phenolic content in the extract. Consequently, HPLC chromatograms showed that the amounts of certain polyphenols changed depending on the used solvent and its polarity. Gallic acid was found to be the dominant phenolic compound in all of the extracts, except in the ethanolic extract, while the amount of protocatechuic acid increased as the polarity of the solvent decreased. The authors concluded that solvent polarity changes the phenolic profile, but it does not change the total amounts of phenolics.

Aside from the isolation of flavonoids and phenolic acids, several scientists reported the extraction of one special group of polyphenols, known as phlorotannins, which are present only in brown macroalgae. Three groups of authors, Heo et al. (2009), Kim et al. (2013) and Kim et al. (2016), based their research on the isolation of major phlorotannins, but they used different solvents for the extraction. Heo et al. (2009) used an aqueous methanol solution, Kim et al. (2013) and Kim et al. (2016) used ethanol and its aqueous solutions. Kim et al. (2013) successfully developed an HPLC method for the determination of dieckol which consists of six phloroglucinol units and functional hydroxyl groups, but it also includes other phlorotannins, such as eckol, phlorofucofuroeckol-A, 6,6'-bieckol and 8,8'-bieckol, which represented the most abundant phlorotannins, while Heo et al. (2009) showed the protective effects of these phlorotannins. It must be taken into consideration that the phlorotannins showed variations in their concentration throughout the year. It was demonstrated that the concentrations are high during the hot temperature season (June-September), while these concentrations started decreasing after September, and the lowest amount of phlorotannins was recorded in February (Kim et al., 2013). The geographical location also affected the degree of polymerization of phlorotannins. The specific feature of the *Fucus* species was that a higher degree of polymerization of phlorotannins was detected in the species located in the environment with higher temperatures and light exposure (Ferreres et al., 2012). Lopes et al. (2018) showed that there is a difference in the chemical composition of brown seaweed belonging to the *Fucus* genus, but phlorotannins of low molecular weight were characteristic for all the species of *Fucus*.

#### *2.1.2. Novel Extraction Methods for the Isolation of Polyphenols*

The most commonly applied novel extraction techniques for the isolation of bioactive compounds from marine macroalgae are Supercritical Fluid Extraction (SFE), Subcritical Water Extraction (SWE), Ultrasound-Assisted Extraction (UAE) and Microwave-Assisted Extraction (MAE). However, some of them are not suitable for the extraction of polyphenols because of the polarity of the solvent used. For example, pure  $CO<sub>2</sub>$  used for the extraction in supercritical conditions (SC) is not capable of extracting polyphenols due to its polarity. SC- $CO<sub>2</sub>$  can only extract non-polar constituents or compounds of low polarity because of its nonpolarity  $(CO<sub>2</sub>$  is a non-polar solvent). However, the extraction of polar compounds can be enhanced by adding a small amount of a polar co-solvent, such as ethanol or methanol, into the process. Therefore, the recommendation is to use other methods which are better for the isolation of phenolic compounds, such as SWE, UAE and MAE. The available data describing the application of the mentioned novel techniques is summarized in Table 2. It clearly shows that there is insufficient data available, about both the application of the novel techniques and about the analysis of the extracts, in order to provide enough information about the extracted polyphenols and about their composition in the extracts, as was previously described for SLE.

#### **Supercritical CO2Extraction (SC-CO2)**

Even though polyphenols are polar compounds, some authors used  $SC-CO<sub>2</sub>$  for the extraction of polyphenols.  $CO<sub>2</sub>$  is usually mixed with a polar co-solvent such as ethanol or water. For instance, Saravana et al. (2017) used sunflower, soybean and canola oil as cosolvents, along with water and ethanol. However, the results showed that these oils were neither suitable for the extraction of polyphenols nor for lipids and other non-polar compounds. Water was the best co-solvent for the extraction of polyphenols due to the highest phlorotannin content found in the extracts. The process parameters also influenced the amount of extracted polyphenols. Roh et al. (2008) noticed that the polyphenol content increased with the increase in pressure, which is due to the higher solvating power of the supercritical fluid. Also, the increased temperature caused the higher polyphenol content, which is explained with the dominance of polyphenol vapor pressure in solvating power. Similar observations were obtained by Saravana et al. (2017), who noticed the increase of phlorotannin content corresponding to the increase in pressure, temperature and the cosolvent flow rate. Two groups of authors, Tanniou et al. (2013) and Sivagnanam et al. (2015), compared the extraction efficiency of polyphenols between the conventional methods (usually SLE) and SFE. The obtained results were contradictory. While Sivagnanam et al. (2015) indicated that the SLE extracts exhibited a higher total polyphenol content (TPC), Tanniou et al.  $(2013)$  indicated the opposite, a lower TPC was observed when SC-CO<sub>2</sub> was used with ethanol as the co-solvent. These differences can be explained by using different macroalgal species and by applying different process parameters. The NMR extract profiles analyzed by Tanniou et al. (2013) showed significant differences among the extracts obtained using the other methods. That indicates that the extracted compounds are dependent on the applied extraction method and on the solvent used. SFE is a good method for obtaining extracts with

non-polar compounds from macroalgae, such as lipids and fatty acids, and also pigments like carotenoids (Cikoš et al., 2018).

#### **Ultrasound-Assisted Extraction (UAE)**

During UAE, many factors such as ultrasonic power, temperature, time, solid to solvent ratio influence the extraction of polyphenols. Dang et al. (2017) showed that the TPC was most affected by the extraction time, followed by temperature and power. The longer time combined with low ultrasonic power was found to be the most efficient method for the extraction of a higher amount of polyphenols. The temperature had an effect on the diffusivity and the mass transfer. When the temperature was higher, the solvent diffusion rate and the mass transfer increased due to the lower viscosity of the solvent and the surface tension, which caused better dissolution of polyphenols in the extraction medium. On the other hand, Topuz et al. (2016) showed that the solid to solvent ratio had the highest influence on the extraction of polyphenols from red seaweed. In this case, the biological variation of seaweed, as well as the solvent used, must be taken into consideration when explaining the different results. Lee et al. (2013) compared the TPC in the UAE extracts and the SLE extracts. The results showed that the SLE extracts exhibited higher TPC and antioxidant activity. On the other hand, Dang et al. (2017) showed that UAE was better for the extraction of polyphenols and that these extracts had higher antioxidant activity, and they concluded that UAE can serve as a good technique for the isolation and purification of phenolic compounds. However, both authors used different species of macroalgae and different solvents, so that can be the reason for the difference in the obtained results. The Q-TOF-MS analysis of the UAE extracts showed that the ultrasound had no effect on the degradation of phlorotannins in the algae *Ascophyllum nodosum* and that they were extracted in greater amounts compared to the control treatment (conventional extraction) (Kadam et al., 2015). According to the provided information it could be suggested that UAE is a compatible method for the isolation of polyphenols and that further purification can enable the application of phenolic compounds from macroalgae in the food and pharmaceutical industry.

#### **Subcritical Water Extraction (SWE)**

SWE operates at high temperatures (50–200°C) and high pressures (50-300 psi), with water in very small amounts as solvent. The high temperature and pressure keep the water below its boiling point, near the critical-region. Water is known as the greenest solvent, so this type of extraction is an environmentally friendly method (Duarte et al., 2014). Several authors tried to apply different enhancers for the extraction in order to obtain higher yield and a larger amount of extracted polyphenols. Sanchez-Camargo et al. (2016) applied enzymes with SWE for determining the possibility of a higher yield, a higher amount of polyphenols and phlorotannin recovery. The enzymes were used to disrupt cell wall polysaccharides which could influence the release of phlorotannins. However, the results showed that the recovery of polyphenols using combined enzyme-subcritical extraction is not better. Vo Dinh et al. (2017) used ionic liquids (IL) as catalysts in SWE+IL experiments. When IL were added, they increased the extraction ability of the subcritical solvent due to the high solvating property of IL in interactions with complex matrices. The antioxidant activity of SWE+IL extracts was higher than in the case of SWE, which is the consequence of the higher TPC in these extracts than in the SWE extracts. The IL exhibited a strong influence on the extraction of bioactive compounds. Also, the SWE+IL provided a higher quality and quantity of extracted phenolics

than in SWE and SLE. The comparison between SLE and SWE was carried out by Heffernan et al. (2014). They compared the conventional extraction (SLE) with SWE and the results showed that the extracts obtained with conventional method using water as solvent produced a higher extraction yield and a higher TPC, which indicates that the majority of soluble compounds in seaweed were of high polarity. Also, the brown algae *Fucus serratus* showed the highest content of polyphenols among all of the investigated species. This can be explained by the fact that phlorotannins are only present in brown algae. The lower concentration of phenolic compounds in SWE extracts can be explained by the loss of thermolabile compounds which occurred during the extraction. On the contrary, Tierney et al. (2012) showed that SWE extracts exhibited a higher yield than SLE extracts. This can be explained by improved diffusivity and enhanced penetration through the particles of the material, which leads to higher extraction capacity. The extraction of phenolics was higher in the extracts obtained using SLE. Even though the extraction yield was higher in the extracts obtained using SWE, the content of phenolics was higher in the extracts obtained using SLE. On the other hand, Vo Dinh et al. (2017) showed that SWE extracts have a higher TPC content than SLE extracts. Although, at a high temperature  $(250^{\circ}C)$  TPC was reduced, which can be explained by the degradation of phenolic compounds. This can be seen on the analyzed chromatograms, where the amount of certain phenolic compounds was reduced at higher temperatures. Aside from that, the solvent was for the extraction also influenced the extraction of polyphenols. Tierney et al. (2012) observed that the use of water as the solvent was the most suitable for the extraction of polyphenols, which reflects the hydrophilic nature of these compounds within macroalgae.

#### **Microwave-Assisted Extraction (MAE)**

MAE as one of the novel extraction techniques, also has several advantages, such as shorter extraction time and the reduced amount of solvents. Lou et al. (2010) compared the extraction efficiency of polyphenols by determining the TPC, and it was shown that MAE provided the highest TPC when compared to the other three methods (UAE, Soxhlet Extraction, Heat Reflux Extraction). Shorter time provided the preservation of labile compounds such as phlorotannins, which was shown in the research by Zhang et al. (2018.). They indicated that MAE extracts contained six major phlorotannin chemical groups, while only four groups were detected in SLE extracts. This can be explained by the higher degradation of the cell structure during MAE or the shorter time during the process, which prevented the oxidation of phlorotannins that occurred during SLE (48 hours). The conventional method SLE could not be used to obtain phlorotannins in any significant amount because the cell walls of the macroalgae could not be damaged through stirring. When MAE was applied, the degradation of the cell wall occurred, which enabled the extraction of phlorotannins. The degree of cell wall degradation was investigated using a scanning electron microscope, which showed that the highest distortion of cells walls occurred under MAE conditions. The obtained phlorotannins were analyzed using HPLC and it was shown that the major phlorotannins from *Carpophyllum flexuosum* belong to the fuhalol group. Magnusson et al. (2017) also used *Carpophyllum flexusoum* for the optimization of process parameters used during MAE for phlorotannins, but they also analyzed other macroalgal species commonly used for SLE. They confirmed that the extracts obtained using MAE contain twice the amount of polyphenols compared to the extracts obtained using SLE. Li et al. (2012) have been analyzing the MAE extracts using IR spectral analysis and RP-HPLC and they reported that the purification of the extracts using ethyl acetate and water enriched the phenolic compounds. Also, they determined the correlation between the TPC and antioxidant activity, and the HPLC analysis demonstrated that phenolic compounds with medium polarity were the major contributors to the antioxidant activity. The examined potential of phlorotannins as natural antioxidants confirms the fact that they are thermally stable and that they have high antioxidant activity. This was confirmed in the research by Zhang et al. (2018), where they showed that algal phlorotannins from *Carpophyllum flexuosum* have great potential for replacing ascorbic acid as natural antioxidants. MAE can be a superior method for the extraction of phenolic compounds from seaweed because the antioxidant activity of MAE extracts was higher compared to the activity of the extracts obtained using conventional methods (Yuan et al., 2018).

#### **2.2. The Analysis of Phenolic Compounds**

In the last two decades of the previous century, algae have become the center of attention for many scientists due to the bioactive compounds which can be isolated from them. In the 1950s, algae were used as food and in traditional and folk medicine, especially in China. Nowadays, studies have shown that algae are considered as a valuable source of compounds with many beneficial effects. The most popular algae used for the treatment of diseases such as hyperlipidemia, cancer, atherosclerosis and hypertension are the brown algae *Sargassum* with four main species: *S. fusiforme, S. pallidum, S. horneri* and *S. thunbergii*. Antioxidant activity is one of the most investigated properties of the compounds isolated from marine macroalgae. It is known that these compounds serve as protectors against various diseases, including skin diseases and cancer, by quenching free radicals (Korzeniowska et al., 2018).

As we already mentioned, polyphenols exhibit a broad spectrum of bioactivity. For instance, Holdt and Kraan (2011) reviewed the potential of macroalgal polyphenols for the application in various industries, but a special type of macroalgal-derived polyphenols is attracting special attention from scientists. Phlorotannins, as unique polyphenolic compounds, found only in brown macroalgae, exhibit varied beneficial biological activity. Several reviews that contain information about phlorotannins as agents against breast cancer (Padua et al., 2015), about their antidiabetic functions with no after-effects (Murugan et al., 2015), about the prevention of cardiovascular diseases caused by hypertension, and about the analysis of obesity and diabetes in both *in vivo* and *in vitro* mechanisms are available (Gomez-Guzman et al., 2018). Li et al. (2011) reviewed phlorotannins derived only from brown macroalgae with all the potential health benefits, such as antioxidant activity, enzyme inhibitory effect, bactericidal effect, anti-HIV, anticancer, radioprotective, anti-allergic and other biological activity. Also, they mentioned the bioavailability of marine-algal derived polyphenols, with the conclusion that further investigation with human subjects is needed because bioavailability was studied only on mouse model systems. Similarly, Thomas and Kim (2011) reviewed many potential pharmacological applications of phlorotannins isolated from brown algae. They suggested that it is important to screen phlorotannins from other brown algal species to provide more information on the interactions with human cellular systems.

Phlorotannins and their biological activity are presented in the following section due to the importance of these specific compounds and their potential benefits for human health.

Table 2. The extraction of polyphenols from marine macroalgae using novel extraction methods (supercritical CO2 extraction, **Table 2. The extraction of polyphenols from marine macroalgae using novel extraction methods (supercritical CO2 extraction,** 

# Table 2. (Continued) **Table 2. (Continued)**

Many scientists analyzed phlorotannins from various macroalgal species, but as demonstrated in Table 3, brown algae from the genus *Ecklonia* showed the highest potential for the isolation of biologically active phlorotannins with phloroglucinol, eckol and dieckol, as the most abundant phlorotannins in these macroalgal species. Ahn et al. (2007) purified these three phlorotannins from *Ecklonia cava* and tested them for both scavenging capacities on some radicals such as alkyl, DPPH, hydroxyl and the superoxide anion radical, as well as for their protective effect against  $H_2O_2$ -induced DNA damage. Eckol exhibited the highest potential for radical scavenging among the tested phlorotannins, but all three phlorotannins displayed strong antioxidant activity. The DNA damage inhibition activity of eckol was higher than that of phloroglucinol and dieckol, but these two phlorotannins also displayed significant inhibitory activity against  $H_2O_2$ -induced DNA damage. This study claims that all of the tested phlorotannins from *Ecklonia cava* have the potential for being used as effective antioxidants. Heo et al. (2009) showed the whitening ability of the three above mentioned phlorotannins through their inhibition of melanin synthesis, where dieckol showed the highest potential, but it was still lower than that of the commercial whitening agent retinol. However, it was higher than that of kojic acid. Also, they investigated the photo-protective effect against cell damage induced by UV-B radiation, where dieckol was the most active among the three investigated phlorotannins. Dieckol is a hexamer of phloroglucinol and due to more functional hydroxyl groups present in its structure, it can be applied in cosmeceutical and pharmaceutical industries as a natural compound for reducing UV-B radiation cell damage and for the inhibition of melanogenesis.

Cho et al. (2012) also studied *Ecklonia cava*, but they investigated the neurological activity of the phlorotannins found in this algae. According to the HPLC analysis, it was shown that the most abundant phlorotannins were phloroglucinol, eckol, eckostonol, triphlorethol-A and dieckol. They investigated the possible use of these phlorotannins for hypnotic effects and for inducing sleep through the binding affinity to the  $GABA_A-BZD$ receptors *in vivo* using animal models. Dieckol, the main phlorotannin found in *Ecklonia cava*, showed the highest binding affinity, followed by eckol. Their binding activities were similar to those of flavonoids from terrestrial plants. The phlorotannins from *Ecklonia cava* were also studied for potential anti-proliferative activity and anti-allergic activity. Firstly, their anti-proliferative activity was investigated by Kong et al. (2009). They isolated two phloroglucinol derivatives from *Ecklonia cava*; dioxinodehydroeckol and 1-(3',5' dihydroxyphenoxy)-7-(2",4",6- trihydroxyphenoxy)-2,4,9-trihydroxydibenzo-1,4-dioxin. Several tests were performed to show the inhibition of cell proliferation in human breast cancer cells, as well as the induction of apoptosis, which is known as a promising strategy for cancer prevention. The results showed that dioxinodehydroeckol can potentially have antiproliferative effects, as well as affect the induction of apoptosis, and it is more effective against MCF-7 human breast cancer cells. This phloroglucinol derivative has great potential for being used as an inhibitor of breast cancer. In addition, it is known that *Ecklonia cava* is used in Korea and Japan as a folk medicine against allergies. Consequently, Li et al. (2008) wanted to show which compounds contribute the most to this activity and they came up with the conclusion that phlorotannins are the main contributors to the anti-allergic effects of this alga. They isolated fucodiphloroethol G, phlorofuco-furoeckol A and eckol, and the first two phlorotannins exhibited strong inhibitory effects. Due to the different structure among phlorotannins, there were differences in inhibition, because of the linkages between phenol units and the number of hydroxyl groups. They suggested that fucodiphloroethol G and phlorofucofuroeckol A can be implemented in pharmaceuticals but further investigations must be carried out to determine the inhibition of mechanisms.

#### **Table 3. Bioactivity of different phlorotannins**

Aside from *Ecklonia cava, Ecklonia stolonifera* was also investigated due to its bioactive compounds. Iwai (2008) investigated the potential of macroalgal polyphenols in *Ecklonia stolonifera* for α-glucosidase inhibitory activity *in vitro*. According to the LC/MS analysis, it was assumed that phlorotannins (eckostonol, eckol, phlorofucofuroeckol A, dieckol and 8,8' bieckol) were responsible for the antioxidant activity and the  $\alpha$ -glucosidase inhibitory activity. It was concluded that *Ecklonia stolonifera* and its polyphenols can be used as antidiabetic pharmaceuticals. Kim et al. (2009) isolated three phlorotannins from *Ecklonia stolonifera:* phlorofucofuroeckol A, dieckol and dioxinodehydroeckol and they found out that they possess strong antioxidant activity against DPPH radicals, while phlorofucofuroeckol A and dieckol showed inhibitory activity against the production of intracellular ROS. They also tested isolated phlorotannins for anti-inflammatory activity and only phlorofucofuroeckol A exhibited this effect.

Food-borne bacteria and MRSA are still present and they represent a problem in the world due to the infections which they can cause. Plant extracts and tea catechins were used for the prevention of these infections, but Nagayama et al. (2002) showed that macroalgae exhibit great potential for use against these infections. They obtained five purified phlorotannins: phloroglucinol, eckol, phlorofucofuroeckol A, dieckol and 8,8-bieckol, from *Ecklonia kurome* and tested them for bactericidal effects on pathogenic bacteria. The results showed that all phlorotannins, except for phloroglucinol, exhibited antibactericidal activity against all the strains tested. Also, it was shown that these effects increased with the polymerization of phloroglucinol.

Lopes et al. (2018) showed that phlorotannins of the *Fucus* genus are of lower molecular weight, which leads to their possible application as natural antioxidants due to the fact that these phlorotannins exhibit higher antioxidant activity compared to higher molecular weight phlorotannins. Barbosa et al. (2017) determined that phlorotannins of the *Fucus* species have potential to be anti-inflammatory agents due to the effective inhibition of lipoxygenase. Continued investigations on *Fucus* species showed that phlorotannin extracts can reduce the degree of immune cell degranulation and counteract the enyzme systems (hyaluronidase, βhexosaminidase) which are correlated with allergic diseases (Barbosa et al., 2018). The authors suggested that phlorotannins are multi-target agents in the prevention and reduction of allergic symptoms. Ferreres et al. (2012) determined that *Fucus spiralis* contained a greater amount of higher molecular weight phlorotannins and, consequently, showed the strongest lipid peroxidation inhibitory activity, as well as hyaluronidase inhibition. *Cystoseira nodicaulis* showed the best superoxide scavenging capacity due to the presence of lower molecular weight phlorotannins.

#### **CONCLUSION**

This chapter has shown that macroalgae, aside from their use as food, can serve as functional ingredients in food products and that their bioactive compounds can be utilized in cosmeceutical and pharmaceutical products.

The main contributors to the antioxidant activity are phenolic compounds, which are produced in the algae under stress conditions. Nevertheless, the potential of phenolic compounds is beyond their antioxidant activity. Studies have shown that they can be great anti-inflammatory, anti-allergic and antiproliferative agents. These abilities were discovered in phlorotannins, a specific group of macroalgal phenolic compounds found only in brown macroalgae. Since brown algae and phlorotannins have great potential for technological use, scientists have been investigating a wide range of macroalgal species. But, in order to obtain the maximum amount of phlorotannins from macroalgal samples, it is very important to find

the appropriate extraction method. Due to the disadvantages of conventional methods (long time, large amounts of organic solvents, environmental pollution), the novel green extraction technologies are desirable for obtaining bioactive compounds without the traces of the toxic solvent used. Even though  $SC-CO<sub>2</sub>$  is mostly used for non-polar compounds, several authors showed that it can also be used for the extraction of phenols, but in a much smaller amount. UAE, SWE and MAE have been the appropriate methods for obtaining polar compounds such as phenols, but the solvents must be chosen wisely. There is little available literature on the topic of extraction of macroalgal polyphenols using modern extraction methods, especially UAE and SWE. MAE showed the most potential for implementation in the industrial isolation of macroalgal phenolic compounds.

## **ABSTRACT**

Burrows constructed by semi-terrestrial crabs affect the abiotic and biotic environmental functioning of the marine ecosystems. These burrows constructed in intertidal areas and protect amphibious crabs from predators, harsh environments and provide molting areas as well as reproductive sites. Understanding about burrow construction and burrowing behavior helps to understand the several aspects of marine ecological system. In turn, the bioturbation activities provide benefits to the surrounding environment by sediment turnover, grain size modification, nutrient recycling and penetration of oxygen into deep down that enhances the microbial activities in the deeper sedimentary layers.

Several environmental factors (temperature, salinity, organic matter, grain size, metal ion) effect density as well as distribution of burrowing crabs e.g., during extreme temperature (low or high) crab digs deep burrows and remain inactive in their burrow to protect them self from desiccation. These studies showed that substrate type, species diversity, stem and root density, predator, seasons, mate display activity affect the zonal and spatial distribution as well as the diameter of a burrow in semi-terrestrial crabs.

 $\overline{a}$ 

<sup>\*</sup> Corresponding Author's Email: noorusaher@yahoo.com.

Studies showed that the sediment texture (grain size) is an important factor in the distribution of different crab species. e.g., different species of *Uca* occupy sandy substrate while sentinel crabs (*M. depressus*) occupy muddy and sandy environment. Organic matter content in sediment is also a main contributor of crab distribution. Finer particle size retains more organic matter than coarse sand. Studies showed that within the sandy substrate, burrow density decreases with the increase of particle size as a coarse particle size retain less organic content; therefore the burrow construction and maintenance is also difficult. The study showed that the number of burrow density exceeds than the crab density; that increase the chance to escape from the predator. In addition, the diameter of the crabs burrow also helpful to determine the size of the resident crab as the study based on carapace length (CL) and burrow diameter (BD) showed a significant linear relationship. In general; studies on burrow morphology also showed the variation in shape, size as different species of *Uca* formed vertical burrows with single or branched shaft as well as single or multiple entrance. In sentinel crabs, M. *depressus,* the burrow cast shape were horizontally elongated with a single shaft. It was also observed that the species of *Uca* and *Ocypode* which occupies the high tide zone forms deeper burrows (to avoid extreme environmental condition) as compared to low to mid tide zone species. Ocypodoid crabs also construct a variety of earthen structure (e.g., chimney, barricades, shelter, pyramid, hoods, mud balls and mounds) by using mud or sand. The main purpose of these structures likely to convey the signals to other members of their population, protection from predators, conspecific competitor or to rear offspring as well as decrease the chance of intrusion by wandering crabs.

### **1.INTRODUCTION**

Burrow considered as the fundamental structure of semi terrestrial crab's life. Digging of burrows begins, when the megalopa start their lives as crab (Hyman, 1920; 1922; Herrnkind, 1968a, b). A variety of burrowing crabs dominated in coastal areas of the world and considered as an important component of the macrobenthic fauna. These crabs distributed in the wide range of substratum along the estuarine and marine environment and actively construct their burrows in the intertidal zone from coarse beach sand to fine clay-rich marshy mud at low tide as well as at high tide area. The principal burrowing behavior of these crabs has been described by various authors (Dembowski, 1926; Altevogt, 1955; Crane, 1975; Katz, 1980; Noman & Pennings, 1998; Saher, 2008) and these burrowing crabs mostly belong to the two super families Ocypodoidea and Grapsoidea.

The burrowing mangrove crabs are important grazers of bacteria and microalgae (Bouillon et al., 2002; Reinsel, 2004); sorted from sediments through specialized structures (maxilliped and setae) present in their mouth cavity and form small irregular balls (feeding pallets  $\leq$ 3 mm) of retained material (Penha-Lopes et al., 2009). The sub-surface sediment pallets (burrowing pallets) are used to form mounds (diameter ranges from 5 to 7 mm) near the burrow opening of fiddler crabs (Botto & Iribarne, 2000). These crabs stimulate the microbial metabolism, organic matter degradation and nutrient cycling by their bioturbation activities as well as they are also responsible for the floral productivity (Nielsen et al., 2003; McHenga & Tsuchiya, 2008).

The burrowing crabs of sandy coast construct deep and complex burrows may be as deep as 2m (George, 1982) which provide shelter against climatic extremes, predators and also serve as the sanctuary during molting and motherliness (Chan et al., 2006; Lucreziet al., 2009). Burrow construction is primarily an occupation of daylight hours; therefore, it is important to define the micro-environment of burrows as different types of organisms increase the rate of sedimentation. There is a mixture of different features of the environment, such as energy conditions under which the burrowers increase the rate of sedimentation and compactions of sediments that can be determined from a significant analysis of the burrow structural morphology (Richter, 1931; Charkarbarti,1981). Burrower crabs may also determine the concerns, includes the relationship between crab size and opening diameter as well as burrow depth, likewise the relationship between physical environment and crab behavior can be known (Reinech, 1967; Charkarbarti, 1981).

# **2. BIOTURBATION ROLE AND ECOLOGICAL SIGNIFICANCE OF BURROWS AND BURROWING**

In mangrove area, the benthic fauna are typically dominated by burrowing decapods and more than 80% of crabs belong to superfamily Ocypodoidea and Grapsoidea (Rosenberg, 2001; Saher, 2008; Saher et al., 2018). These crabs constitute a dense population on intertidal mudflats and in the mangrove canopy (Skov & Hartnoll 2001; Skov et al., 2002), In addition, they are important grazers of microalgae and bacteria (Reinsel, 2004). Burrowing crabs have been considered as ecosystem engineers due to their conspicuous role in the various processes of the mudflat ecosystem through biotic and abiotic activities (Jones et al., 1994; Kristensen, 2008; Saher & Qureshi, 2012; Saher et al., 2018). The crawling, foraging, burrow construction and maintenance activities of burrows results to increase sediment drainage, soil redox potential, translocation of sediment (organic matter and nutrients), change in sediment erosion threshold and increase the sediment area (Boto & Iribarne, 2000; Kristensen, 2008). In result, they are responsible for the stimulation of microbial metabolism, organic matter degradation, nutrient cycling and floral productivity (Kristensen & Alongi, 2006). These activities have an important effect on the sediment characteristics includes sediment chemistry (Katz, 1980; Montague, 1980; Bertness & Miller,1984; Bertness, 1985; Genoni, 1991; Noman & Pennings, 1998), burrows of crabs facilitate the general aeration of the sediments (Genoni, 1991; Noman & Pennings, 1998). These activities may be affected by anthropogenic eutrophication (McHenga & Tsuchiya, 2008).

The burrows have been attributed for the numerous functions (Figure 1) as are recognized to provide a microhabitat for a community of organisms (Bright & Hogue, 1972; Nielsen et al., 2003; Kristensen & Alongi, 2006) and also known to enhance the movement of tidal waters through sediments thus oxygenating and exchanging nutrients and metabolites that likely enhance the sediment stability (Hoffman et al., 1984; Bertness, 1985; Micheli et al., 1991) as well as increase the rate of the decomposition of plant debris within the sediments (Bell et al., 1978; Valiela et al., 1974; Howarth & Hobbie, 1982; Hoffman et al., 1984; Robertson, 1986; Lee, 1998; McHenga & Tsuchiya, 2008; Saher & Qureshi, 2012; Mokhtari et al., 2016). These burrows also act as an oxygen inlet tube and increase the depth to which oxygen can penetrate or enhance sediment oxygen level (Katz, 1980; Bertness, 1985).

Various authors (Katz, 1980; Montague, 1980; Bertness & Miller, 1984; Bertness, 1985; Genoni, 1991; Noman & Pennings, 1998) have previously studied the general effects of crab burrows on pore water chemistry. The burrows are also speculated to act as an outlet tube for toxins such as sulphide and as well as reducing the accumulation of metabolic products in the sediments (Katz, 1980; Bertness & Miller, 1984). They increase the amount of nutrients and decrease the sulfide concentration in the sediment and contribute to the secondary production like affect the mangrove productivity (Smith et al., 1991; Lee, 1997; Otani et al., 2016). As these factors are very important for the growth of micro- and meio-organisms and likely the overall turnover of organic matter; such faunal mediated disturbances of the physical, chemical and biological structure of sediment systems are known as 'bioturbation'. The bioturbation and fecal pellet production of crabs have been widely known and resulting is an increase in the growth of the cord grass, *Spartina alterniflora* in salt marshes (Montague, 1980; Bertness & Miller, 1984; Bertness, 1985).

Figure 1. Conceptual diagram of the function attributed to the burrow of crab.

The burrowing activity modifies the grain size in addition to altering the geochemical properties (Warren & Underwood, 1986; Katz, 1980; Wolfrath, 1992; Morrisey et al., 1999; Saher et al., 2016; Mokhtari et al., 2016). These activities enhance the carbon flow in the food chain that may later reach back to the crabs and may also serve other unidentified functions (Genoni, 1991; Otani et al., 2016). Burrows are important in the crab's life as attributes to a number of functions, mainly in order to avoid an excessive wave action, relief from both (hot and cold) ambient temperature and desiccation, provide a refuge from the aerial and terrestrial predators during exposed periods as well as aquatic and terrestrial predators during flooding and ebbing accordingly (Hyman, 1922; Wilkens & Fingerman, 1965; Smith & Miller, 1973; Crane, 1975; Power, 1975; Powers & Cole, 1976; Hyatt & Salmon, 1979; Katz, 1980; Christy, 1982; Thurman, 1984a; Bertness & Miller, 1984; Genoni, 1991; Lim & Diong, 2003; Lim, 2006). These biogenic structures also provide the neoichnological interpretations that support, associate and compare the traces produced by the fossil organisms (paleoichnology) with the current information (neoichnology) for a better understanding of the paleoclimatic conditions, limiting factors of paleoenvironment as well as paleoecology of benthic organisms from the coastal areas.

# **3. ENVIRONMENTAL FACTORS AFFECTING ON BURROW DENSITY AND DISTRIBUTION**

The environmental factors affect the physiological activities of crabs and determine their habitat selection as most of the species live in the diverse habitat of a collective dispersal coastal system that ultimately influenced by environmental inclines (Moore & Chapman, 1986) and ultimately effects on the density and distribution of crab burrows (Mouton & Felder, 1996; Takeda & Kurihara, 1987; Ashton et al., 2003; Saher et al., 2016; Saher et al., 2018). The distribution of Ocypodoid species along the coastal belt is solely dependent on sediment texture (burrow construction), which may be influenced by various physical and chemical factors, including temperature, salinity, vegetation, organics, metal ions and granular size and composition, etc. (Lighter, 1977; Barrass, 1963, Alberto & Fontoura, 1999; Turra et al., 2005; Chan et al., 2006; lucrezi et al., 2009; Saher & Qureshi, 2012). A number of studies have been conducted to determine the inter relationship of burrows, burrowing activity and previously described the physicochemical factors (Table 1).

### **Table 1. The previous studies conducted on the crab burrows and burrowing activity and their interaction with various physicochemical parameters**

Figure 2a. Monthly distributions of burrow density (m-2) at three levels (L1: low tidal level, L2: mid tidal level, L3: high tidal level) of Sandspit backwater mangrove area (S1 and S2) and Korangi creek.

Figure 2b. Distribution of burrows (m<sup>-2</sup>) at three levels (L1 = low tidal level, L2 = mid tidal level, L3 = high tidal level) at two stations of the Sandspit backwater mangrove area (S1 and S2) and Korangi Creek during March 2001 to February 2002 (Error bars indicate  $+$  1 SE).

The burrow openings of the sandy crabs are circular with accumulated sand mounds and are often surrounded by radiating feeding lines left by the crabs (Takahashi, 1932; Chakrabarti, 1981; Chan et al., 2006). There are clearly visible entrances of the sand crab on the surface of sandy beaches that maintained as territory (Vannini, 1976) by counting these holes, that can help to determine the densities of crab (Moss & McPhee, 2006; lucrezi, 2009). The inter-relationship based on the burrow structure, surrounding environment and correlation between them also helps to understand the different aspects of the burrows and physicochemical parameters. The study was conducted throughout the year from three coastal sites (two sites in Sandspit backwaters and one in Korangi creek) and once or twice visited sites (Bhambore, Dhabeji, Ketibunder, Sonmiani, Phitti creek, Manora, Sonari and Bhaira). The monthly burrows data (burrow density and burrow diameter) were collected by counting the total number of burrows present in each  $0.25$  m<sup>2</sup> quadrat at the three tidal level (from low tide mark to high tide mark in two transect (20 m apart) and the distance of levels (25 meters to 40 meters; depends on the exposed mudflat area during low tide period) at each station of all study sites. The sizes of the burrow opening (burrow diameter  $N = 10$ ) were measured randomly by Vernier calipers (correction 0.01 mm) within each quadrat.

The monthly variations were observed in the crab burrow density at three tidal levels during each month from the Sandspit (S1 and S2) areas as well as Korangi creek (Figure 2a). The number of the burrows was higher at KC ranged from 16 to 2376 burrows  $m<sup>-2</sup>$  and were in low density at Sandspit ranged from 12 to 376 burrows  $m<sup>2</sup>$  (Table 2). The density of crabs can be reduced by human disturbance and the burrow density of crabs has been proposed as an indicator of recreational impacts on sandy shores (Barros, 2001).

Tidal levels	Seasons	N	Sandspit (S1)	Sandspit (S2)	Korangi Creek
Low TL	<b>PRM</b>	6	$47.3 + 20.15$	$62.0 \pm 22.16$	$1235.3 + 138.2$

**Table 2. Seasonal and tidal distribution of burrow density(N m-2 ) from Sandspit backwater mangrove areas (S1 & S2) and Korangi creek mangrove area during study period** 

The highest number of crab burrows observed at low tidal level (L1) at all stations (Figure 2b) in comparison with mid and high tide level. The temperature patterns explain the several modifications in the activity patterns and temporal niche shifts of crabs (Hut et al., 2012). To regulate their body temperature, the crabs use three principal mechanisms (1) evaporation of water for cooling down the temperature; (2) remaining inactive inside their burrows during the extreme temperature conditions and (3) by an acclimatization process through metabolism either by increasing respiratory enzyme activity or by oxygen consumption (Vernberg & Vernberg, 1968; Berry 1976; Eshky et al., 1988; Weinstein et al., 1994; Strachan et al., 1999; Lucrezi & Schlacher, 2014). The seasonal variations were also observed in the burrow density as being highest during the Southwest monsoon season in Korangi creek and two stations of Sandspit. The lowest number of burrows were found in premonsoon season at S1 of Sandspit and in Northeast monsoon seasons at Korangi creek and S2 of Sandspit (Table 2). The CRD-ANOVA with the nested treatment showed that seasons nested within stations and levels nested between stations and seasons showed the significant differences at Sandspit (P < 0.00, F = 5.87; P > 0.00, F = 2.85, respectively). In Korangi creek level nested within seasons showed significant differences ( $F = 19.23$ ). The crabs can tolerate a wide range of temperature outside their burrows ranging from 12 to  $50^{\circ}$ C and the crabs become inactive as well as remain inside their burrows, if the temperature rise or decline (seasonal shifting) from the tolerant range (Lucrezi & Schlacher, 2014).

Recruitment (Strachan et al., 1999), winter dispersion (seasonal variation) and growth (Wolcott, 1978) may effect density of crab as well as their burrows. Beach type and exposure appear to impact density (Chan et al., 2006) as well as affect the zonal distribution (Jaramillo et al., 2000). Indeed, during storms the zonal distributions can shift landwards (Alberto & Fontoura, 1999; Hobbs et al., 2008).

There was a marked spatial variation ( $F = 5.76$ ,  $p < 0.001$ ) in density of crabs burrows m <sup>2</sup> were recorded from the coastal areas of Pakistan. The highest (722  $\pm$  706) mean burrows density m<sup>-2</sup> was observed at Sonmiani and the lowest (36.7  $\pm$  14.6) mean burrows m<sup>-2</sup> were at the Phitti creek (Table 3). Different sediment types and factors other than sediment particle size and organic content may play a significant role to determining the colonization of these burrowing crab species. These results clearly demonstrate the importance and interaction of substratum characteristics in controlling the distribution and abundance of crab and has interesting implication on the interspecific dynamics of the different species population at all sites. These crabs are known to adjust their burrowing activities to a variety of conditions, such as stem density, root mat density, substratum, water, ground temperature, tidal and diurnal rhythms, reproductive activity, the threat of potential predators, seasonal activities and mate display activities (Zucker, 1974; Ringold, 1979; Bertness, 1985; Genoni, 1991).

**Table 3. Summary of descriptive statistics of burrows density (m-2 ) from once visited collection sites during the study period**

<b>Sites</b>	N	Mean	<b>SD</b>	Minimum	Maximum
Bhaira	3	91.7	37.5	55.0	130.0
<b>Bhambore</b>	6	674.0	496.0	112.0	1592.0
Dhabeji	3	57.7	24.3	36.0	84.0
KetiBunder	3	267.0	174.0	66.0	376.0
Korangi Creek	3	855.0	646.0	176.0	1462.0
Phitti Creek	5	115.2	148.7	28.0	378.0
Sandspit	6	69.7	36.8	34.0	140.0
Sonari	5	259.2	83.6	190.0	402.0
Sonmiani Bay	6	648.0	673.0	101.0	1966.0

The seasonal variations and zonal distribution were also evident in crabs burrow opening diameters (mm). The burrow diameter (BD) ranged from 4 to 14.6 mm at Korangi creek and 4.7 to 21.1 mm at Sandspit. Spatial variations in the size of the burrow diameter (BD) were observed with small sized BD at low tide level  $(L1)$  and the largest at high tide level  $(L3)$  at all stations (Figure 3). The smallest mean BD  $(4.88 \pm 0.59 \text{ mm})$  was observed at Korangi creek during Northeast monsoon season and the largest mean BD ( $12.6 \pm 2.15$  mm) was during pre-monsoon season at Sandspit S1. There were also a significant difference in BD between all the once visited sites (Table 4;  $F = 9.21$ ). CRD-ANOVA with nested treatments showed a significant difference in the crab burrows diameter between stations ( $F = 25.48$ ), seasons nested in stations ( $F = 8.94$ ) and levels nested within stations and seasons ( $F = 2.23$ ) at Sandspit. The mean BD ranged between 7.6 mm at Sonmiani and 14.7 mm at Dhabeji (Table 4).

Figure 3. Distribution of average burrow diameter (mm) at Korangi creek and two station of Sandspit backwater mangrove area (Error bars indicate + 1 SE).

**Table 4. Summary of descriptive statistics of burrows diameter (mm) from once visited collection sites during the study period**

<b>Sites</b>	N	Mean	SD	<b>Minimum</b>	<b>Maximum</b>
<b>Bhaira</b>	3	10.20	1.567	8.57	11.70
<b>Bhambore</b>	6	8.35	2.72	5.05	11.40

Sonmiani Bay	6	8.04	1.80	6.10	10.67

Botto & Iribarne (2000) reported the higher moisture contents in sediments with the crabs as compared to the area devoid of crabs. According to Wang et al. (2009), the sediments of different micro habitat (such as slope, edge and bottom) have the different water holding capacity along the intertidal areas. Therefore, the burrow density of crabs decreases with the increase of water contents in sediments on the slope area. The flooding level also affect the sex ratio of *U. cordatus*, with a predominance of males in less-flooded mangroves, independently of the biological period and a gender balance in the more-flooded mangroves only during the breeding season. The results of previous studies suggested that the treespecies composition and tidal flooding level could have a significant effect on the habitat partitioning of sexes and sizes of the mangrove crab *U. cordatus* (Wunderlich & Pinheiro, 2013).

### **4. ROLE OF SUBSTRATUM IN MICROHABITAT SPECIFICATION**

Spatial variation in sediment properties and heterogeneous characteristics of mangrove sediment create different niches for different species of Ocypodoid and Grapsoid crabs to perform their living activities. Some species prefer fine-grained sediments, while others tend to occupy the coarse sandy substrates. The main example included the fiddler crab species that occupy sandy sediments possess higher numbers of spoon tipped setae on their second maxilliped and these setae are believed to hold sand grains during feeding activity and aid in the removal and sorting organic particles (e.g., bacteria) from the grains of sand (Crane, 1975; Mokhtari et al., 2015). The environmental heterogeneities within the tidal creek microhabitats (such as bottom, slope, edge and flat) play a substantial role in distribution of crab burrows (Wang et al., 2009), Figure 4 illustrated the different intertidal habitat along the coastal belt of Pakistan. Sediment properties varied among the microhabitats, therefore; the crab diversity and distributions also varied among the habitats, but usually crab selected relatively solid sediments to build their burrows.

The diversity of brachyuran crab considered as a potential indicator of the alterations of mangrove habitats. The age of the mangrove forest is also effected on the brachyuran crab diversity (Sen et al., 2014). The burrowing activities increase the substrate penetrability, for instance, *C. granulata* stabilizes the sediment by placing the fine and cohesive sediment on the surface; *A. uruguayensis* interrupts the surrounding sediments by pelletizing and increase their erodibility. The contrasting activities of these two species may also produce opposing and significant impacts on the structure of the benthic communities due to their impact on

sediment stability (Botto & Iribarne, 2000). As in temperate marshes, fiddler crabs can have significant ecological effects on mangrove communities, serving as ecological engineers by modulating the amount of resources available to marsh plants, and by altering the physical, chemical, and biological state of these soft sediment communities. The crab burrowing significantly increased the mangrove height by 27%, trunk diameter by 25% and leaf production by 15%, compared to mangroves in crab exclusion enclosures. Mangrove height, trunk diameter, and leaf production that variations in crab burrow density were positively associated with the number of crab burrows (Botto & Iribarne, 2000 Bezerra et al., 2006; Mokhtari et al., 2015).

#### **4.1. Organic Matter**

The presence of percent organic matter also accountable for the burrow density and crab distribution. The organic matter supply to the benthic environment and *in situ* the primary production is the fundamental determinants of deposit feeder production. The deposit feeder crab species extract their food in the form of organic content from the surface sediment and somewhat depend on the similar nutritional sources for their survival. They are important factor affecting the quantity and quality of the detrital food (Rice & Rhoads, 1989; Saher & Qureshi, 2012; Saher et al., 2018). Various studies showed the influence of organic matter on the presence of crabs along the coastal areas. For instance, organic matter seems higher in the crab dominance area as compared with nearby areas without crabs (Botto & Iribarne, 2000). However in another study, the movement of *Neohelice granulata* enhances the exchange of organic matter among habitats by faecal deposition between marsh and tidal flats with seasonal variations (Casariego et al., 2011).

#### **4.2. Grain Size Composition**

The sediment structure and composition determine the crab density. The current study also revealed the inter-relationship between the burrow properties with sedimentological properties (Figure 5a and b). In the current study, the burrow density and the total burrow opening area decreased with the increase in coarse sand (Saher et al., 2018) which suggested that the crabs do not construct burrows more efficiently in coarser sediment likely because this practice is energetically more expensive and time consuming (Grow, 1982). Alternatively, the burrow density increased as the increasing in mean grain size and fine sand (Saher et al., 2018). Finer sediments might provide a more stable substrate for the high burrow density and more complex burrow structure due to the cohesive nature of fine sediments (Takeda & Kurihara, 1987; Rudnick et al., 2005). Takeda & Kurihara (1987) also reported the depth of the water table and silt-clay content in the substratum largely determine the crab burrow distribution. The increase of soil surface area induced the crab burrows and significantly affects the biogeochemical processes by increasing the redox reactions and solute transport (Webb & Eyre, 2004; Wang et al., 2009). As discussed earlier, the burrows on the slope were smaller; however, the density was higher than that at the edge and on the flat. However, no crab burrows were found at the creek bottom. The density of small crab burrows (<10mm) was greater, but that of large burrows (>10mm) was lower in tidal creeks

than in non-creek habitats. Therefore, sediment properties showed a gradual transition from hydrophytic to terrestrial environments on the creek section that caused significant differences in burrow distribution among the microhabitats (Wang et al., 2009).

Figure 5a. Relationship of burrow properties with physicochemical properties from coastal environment of Pakistan.

Figure 5b. Factor analysis for Burrow properties (density and diameter) with sedimentological properties from coastal environment of Pakistan.

The factorial analysis showed that the sediment properties i.e., mean, median and sorting coefficient are also important factors that effect the burrow density and distribution. The particle size as well as sorting coefficient were significantly related to abundance of the crab (*Paratylodiplax blephariskios*) as best explained crab distributions from two estuaries (St. Lucia and the Mhlathuze) of southern Africa (Owen et al., 2000). *A. annulipes* was significantly associated with the sediments containing higher sand contents regardless of shore level, however, *T. vocans* was significantly associated with higher mud content sediments, and therefore, *A. annulipes* are generally found in sandier habitats than *T. vocans* (Lim et al., 2005). The Indus crab (*Austruca sindensis*) distribution primarily depends on sediment size and composition and this species preferred sandier type of sediments (Saher & Qureshi, 2012). The burrows of *H. crassa* were more abundant at muddy areas than the sandy areas (Morrisey et al., 1999). The distribution of fiddler crab (*Uca spinicarpa* and *U. longisignalis*) burrows in coastal marsh habitats described that *U. spinicarpa* preferred to burrow in substrates of higher percent clay (Mouton & Felder, 1996). Sediment characteristics, especially grain size, are usually considered the most important variables affect the crabs distribution (Checon  $\&$  Costa, 2017) and thus showed during the current study.

The substratum properties were of primary importance in the distribution of brachyuran crabs along the coast of Pakistan. In addition, it seems that the variable structure and composition of sediments facilitate the burrowing ability of different crab species as well as to inhibit and specify their respective habitat accordingly.

# **5. RELATIONSHIP BETWEEN DENSITY OF CRABS AND CRAB BURROWS**

It is notoriously difficult to study the densities of mangrove crabs therefore, the several techniques have been applied and tested for these burrowing mangrove crabs includes; use of pitfall traps, mark and recapture, burrow counts, visual or binocular counts and excavation of fiddler crabs (Nobbs & McGuinness, 1999; Skov & Hartnoll, 2001). Mark and recapture disturbs burrows and creates bias towards size and sex (Skov & Hartnoll, 2001) in the comparison to excavation of crabs is invasive as well as labour intensive and time consuming but gives reliable estimates of crab densities (Firth & Brunenmeister, 1980; Macintosh, 1984). The pitfall traps and binocular counts may underestimate or overestimate as usually depend on the degree of surface activity, but are quicker and non-invasive (Nobbs & McGuinness, 1999).

The number of crabs and the number of crab burrows varied considerably at each level of all three stations in each month (Figure 6). The numbers of burrows have been usually greater than the number of crabs collected from all levels at Korangi creek and both stations of the Sandspit, except a few instances at station 1 and station 2 in the months of March and May, respectively, when the number of crabs exceeded the number of crab burrows (Figure 6). Burrows have been also used to identify and estimate densities of crab population (Aspey, 1978; Krebs & Valiela, 1978; Warren, 1990; Steinke et al., 1993; Mouton & Felder, 1995; Skov & Hartnoll, 2001). At once visited sites, the numbers of burrows were also higher than the numbers of crabs  $(m<sup>-2</sup>)$  at each level, T-test was employed against the null hypothesis that expected burrow frequencies were equal to the number of crabs show the significant difference at Korangi creek, Sandspit S1, Bhaira, Bhambore, Dhabeji, Sonari and Sonmiani. The null hypothesis was rejected and concludes that the expected frequencies of crab burrows were significantly greater than the number of crabs collected at these sites (Table 7).

Figure 6. The monthly distribution of number of burrows  $(m<sup>2</sup>)$  and crabs  $(m<sup>2</sup>)$  at three levels of S1 and S2 collected from Sandspit back water mangrove area and S3 of Korangi Creek.

Site	DF	T-test	P-value
Korangi creek	79	7.81	0.000
Sandspit S1	105	4.78	0.000

**Table 5. T-test comparing the numbers of burrows (m-2 ) and the number of crabs (m-2 ) at all sites**

Similarly, burrow counts are related to surface activities related to biotic functions (feeding, availability of food, reproductive activities, agnostic behaviour, predation and recruitment) and abiotic features (substratum preference, harsh conditions, tidal periodicity, etc.) and can result in spatial and temporal variability and over estimates of crab densities (Skov & Hartnoll, 2001). The use of burrow densities as surrogate to crab densities have been established in literature (Aspey, 1978; Macintosh, 1984; Genoni, 1991; Mouton & Felder, 1995; Nobbs & McGuinness, 1999) and burrow densities have been correlated with the crab densities and have been predominantly used (Krebs & Valiela, 1978; Mouton & Felder, 1995). The present results showed that the ratio between number of burrows to number of crabs was greater than one, i.e., more burrow numbers were found compared to the number of crabs. Similar observations have been observed by Genoni (1991) in the salt marsh. The greater number of unoccupied versus occupied burrows in the study area appeared to be the usual characteristic of crab habitats and this has been observed by Crane (1975) and Firth  $\&$ Brunenmeister (1980). Burrow numbers in excess of crabs (supernumerary burrows) were common and were associated with the topographic heterogeneity of the substratum at higher levels on the shore and the composition of the sediment only accounted for a small fraction of this pattern (Mouton & Felder, 1996). Burrow counts tend to overestimate the population density because a number of burrows are unoccupied or have more than one opening (Frith & Frith, 1977). In many species of crabs, the burrowing depends on the cohesiveness of the substratum, its hardness, the presence of roots, grain-size, and moisture content (Warburg & Shuchman, 1979; Bertness & Miller, 1984; Takeda & Kurihara, 1987; Henmi, 1989; Kelaher et al., 1998; Morrisey et al., 1999).

Mouton & Felder (1995) concluded that the density of burrows despite seasonal variability can invariably be correlated to the crab densities to assess the population densities in intertidal marshes. Genoni (1991) in his study on *U. rapax* observed the high burrow turnover rates by the small sized crabs and concluded that crabs dig additional burrows despite the presence of pre-existing unoccupied burrows and that number of burrows may serve other needs like limited or low food availability to escape from predation and reproductive needs and suggested that early stages were more sensitive to food availability. Previous studies have also shown that megalopae were known to settle on a substratum with high organic content (Crane, 1975). Firth & Firth (1978) and Macintosh (1988) reached a similar conclusion in their studies of fiddler crabs from mangrove shores in Malaysia and Thailand. They also suggested that the higher number of burrows in relation to the real number of the crabs can be attributed to the crabs' need to improve the opportunity for escape from predators.

### **6. RELATIONSHIP OF CARAPACE LENGTH AND BURROW DIAMETER**

The size (carapace length) of resident crab species can be determined for each species by using linear equations relationship between carapace length (CL) and burrow diameter (BD). As the crab always enter its burrow sideways (Lim & Diong, 2003) therefore carapace lengths have been used to study the relationship between resident crabs and burrow diameters. A variable number of crabs approximately ( $n = 40$ ) for each species were randomly collected to analyze the burrow diameter and resident crab-length relationship. The burrow diameters were also measured with the Vernier caliper and the following parameters; sex, carapace width, carapace length (CL) of inhabitant crabs were recorded. The burrow diameter and crab length relationship was evaluated for the selected species of crabs by using the best fit regression line.

Carapace length  $(CL) = a + b$  (burrow diameter BD) Equation 1

Where, a, and b are coefficients to be estimated by the model. Data for male and females were pooled, as no difference between the sexes was observed during preliminary regression analysis. A data of male and female crabs were pooled as no significant differences were observed.

Figure 7. Linear relationships between the carapace length (CL) of crab and the burrow diameter (BD) of *Tubuca urvillei*, *Austruca sindensis*, *A. annulipes* and *A. iranica*.

The current study showed that the size of crabs was positively correlated to the burrow diameter, similar to the finding of  $\text{Lim}\ \& \text{Doing}(2003)$  who found large-sized crabs with large burrow diameters and length. Larger-sized crabs had a greater burrow diameter, larger burrow volume and bigger chamber diameter than small- and medium-sized crabs. This indicates that the larger-sized crabs generally excavate the larger entrances and reside in more spacious burrows. A good correspondence and significant positive linear relationships were observed in all species of Ocypodoid and Grapsoid crab (Figure 7 and 8).

Figure 8. Regression analysis values for the relationship between carapace length and burrow opening diameter in *O. ceratophthalmus* and *M. depressus.*

# **7.INTER AND INTRA-SPECIFIC VARIATIONS IN BURROW ARCHITECTURE**

The burrowing and other bioturbation activities in intertidal coastal areas may strongly affect the substrate topography and granulometry (Kristensen, 2008). The decomposition of the organic matter increased by the macro fauna, with the regular transport of the tidal water increased vertical and horizontal movement of sediment and detritus (Rhoads & Boyer, 1982, Meadows & Meadows, 1991), burrows increased the permeability of the sediment to water and air, stimulates microbial activity (Andersen & Kristensen, 1991) and the access of oxygenated water to areas. These changes in the sediment environment can, in turn influence the distribution and bioavailability of anthropogenic contaminants within the sediment.

The significant amount of information about the burrow structure is available for the larger burrowing species, but smaller burrowing species are highly ignored. Generally, crab species revealed the significant interspecific and intraspecific variations in their burrow morphology according to the biotic and abiotic factors of habitat. The various combinations of sediment, inundation levels as well as vegetation coverage influence the morphological features of crab burrows (Qureshi & Saher, 2012). Shapes of burrow casts generally consisted of at least one long tube varying in length and in the shape of the closed ends (forming L, J, U, and Y shapes) in vertical and complex branching morphologies.

Burrowing behaviour is commonly found in the invertebrate brachyuran crabs inhabiting marine soft sediments. The burrow morphology is species specific, but with the change in sediment characteristics, shore morphology, the species may modify their physical structures (Qureshi & Saher, 2012; Trivedi & Vachhrajani, 2016). Burrow morphology has been usually described by using plaster of Paris, rubber, or epoxy casts and general burrow morphology ranging from burrow diameter, burrow depth, burrow volume, angle of the burrow with respect to the shore and general burrow design has been studied in several species of crab (Table 6).

<b>Species</b>	Scientific name	Author

**Table 6. Literature review for burrow architecture of different crab species**

In the present study, the burrow architecture of some brachyuran crab studied with relation to variation in environmental factors like sediment structure and vegetation cover. Aqueous solution of plaster of Paris was poured in to the crab burrows with the help of a syringe until the burrow was completely filled and was allowed to dry for 30 to 60 minutes [\(Warburg](http://www.sciencedirect.com/science?_ob=ArticleURL&_udi=B6T8F-480CSGX-4&_user=3415223&_coverDate=05%2F13%2F2003&_rdoc=3&_fmt=full&_orig=browse&_srch=doc-info(%23toc%235085%232003%23997109997%23417548%23FLA%23display%23Volume)&_cdi=5085&_sort=d&_docanchor=&view=c&_ct=12&_acct=C000060484&_version=1&_urlVersion=0&_userid=3415223&md5=d291df91f9b80a672beb41a7fe081339#bbib45#bbib45) & Shuchman, 1979), after hardening these casts were carefully excavated by hand. Burrows casts were separately placed in pre-marked poly bags and brought back to the laboratory for further analyses. Different parameters measured for each burrow cast were: (1) burrow diameter (BD), total burrow length (TBL), total burrow depth (TBD), and burrow volume (BV). The volume of the burrow cast were determined by weighing the burrow cast  $(+0.1g)$  and dividing the weight of the burrow cast by the density (2.2 g cm<sup>-3</sup>) of plaster of Paris (Chan et al., 2006). Data for only complete burrow casts were used for analyses.

For each species, burrows openings with different diameters  $(N = 30$  at least) were randomly selected. Three species of genus *Austruca (Austruca annulipes, A. iranica* and *A. sindensis), two species of genus Ocypode (O. rotundata and O ceratophthalmus)* and single species of sentinel crabs (*Macrophthalmus (Mareotis) depressus*) are common and wider spread along intertidal shores of Pakistan, which were studied in order to investigate intra and interspecific variation of crab burrow architecture according to the habitat and tidal level (Figure 9). The burrow cast experiment for *A. iranica* was performed at three tidal heights as it was possible to identify the patches at three levels.

Fiddler crabs of genus *Austruca* (formerly called *Uca*) are common inhabitants of sandy shores, mudflats, mangroves and estuarine habitats of tropical and subtropical region. A red legged fiddler crab *(A. annulipes*) was mostly associated with fringing mangroves among pneumatophore from mid to low tidal areas. Morphology, size and structure of fiddler crab burrows were determined (Figure 9), however the general morphology of crab burrow is tube

like having straight shaft ended without chamber at the base with a single or double burrow opening (Figure 9). Total 5 different types of burrow shapes were recorded, including straight tube like with single burrow opening, straight tube like with bulb at the end, J shaped with single opening, Y shaped with two burrow opening and V shaped with two openings.

### **Table 7. Summary of descriptive statistics for difference in burrows morphological characters of three species of genus** *Austruca* **from Sandspit backwater mangrove area during the study period**

Fiddler crab (*A. iranica*) is the most frequently distributed from low to mid tide level of sandy and muddy areas. Indus fiddler crab (*A. sindensis*) inhabitant of high intertidal areas.

(C) Burrows cast of *Austrucaannulipes.*

Figure 9. Burrows cast in three species of fiddler crabs from Sandspit backwater mangrove areas of Pakistan.

The comparison of the size of burrow cast among three species of *Austruca* showed the mean TBL was 115.4 + 45.9 mm for *A. annulipes,* 118.0 + 34.2 mm for *A. iranica* and 220.2 + 71.0 mm for *A. sindensis* (Table 4.9). The mean BD was 13.7 + 3.0 mm (*A. annulipes*), 10.5  $\pm$  3.8 mm (*A. iranica*) and 12.8  $\pm$  1.9 mm (*A. sindensis*). The one way ANOVA showed significant differences in TBL, TBD, BD and BV among the three species studied. In *A. iranica*, the spatial variability was observed in morphological characters in burrow casts at three tidal levels. The mean TBL, TBD, BD, and BV at L1 was smaller than the L2 and L3 and one way ANOVA showed significant differences in all burrow cast morphological characters at the three tidal levels. The results also indicated the size specific zonal distribution of *A. iranica* in the intertidal area. The identification of burrow was an important issue to study burrow morphology of *Austruca* species with sympatric distribution and it was quite difficult to determine which burrow belongs to which crab species without identifying a pure distribution patch of each species. The number and size of burrows and size of crabs are related to reproductive cycle, recruitment and growth of these species.

Total burrow length, burrow depth and burrow volume were significantly varied among the different fiddler crab species. It was greater in *A. sindensis as* compared to the other two species (*A. sindensis*<*A. annulipes*≈*A. iranica*). The interspecific differences in burrowing behaviour between three species of *Austruca* demonstrated that these variations depend on variable combination of sediment composition and firmness (Qureshi & Saher, 2012).

The previous studies showed that the burrow depth increased with the distance from the water's edge (approximate mean sea level) increased along the marsh (Mouton & Felder, 1996). Likewise, the distance from the shore appeared to be the main determinant that is influencing the distribution and abundance of crab (Owen et al., 2000). The interspecific differences in burrowing behaviour between three species of *Austruca* (*A. annulipes, A. iranica* and *A. sindensis*) showed that these variations largely affected by the tidal height and distance from the shore (Qureshi & Saher, 2012). Mouton & Felder (1996) studied the influence of elevation and landward distance from the shoreline on burrow densities of two fiddler crab (*A. spinicarpa* and *A. longisignalis*).

Parameters	<b>Sites</b>	Mean	Min	Max
Total Burrow length (TBL) mm	Sandspit	$110.7 \pm 23.6$	70	158
	Korangi creek	$55.3 \pm 15.8$	40	85
Burrow diameter (BD) mm	Sandspit	$32+6.83$	18	48
	Korangi creek	$14.3 \pm 2.65$	10	19
Crab density/ $m^2$	Sandspit	$58.0 + 5.16$	52	64
	Korangi creek	$168 + 43.2$	140	232

**Table 8. Summary of descriptive statistics for burrow structure (mm) of**  *Macrophthalmusdepressus* **crab from two different sampling areas of Pakistan**

Sentinel crab (*M. depressus*) usually occupies mid to low tide area in sandy muddy intertidal shores. A total of 40 burrow cast were obtained from two backwaters mean density of crabs was  $58/m^2$  with CL 16.3 mm (Table 8). At Sandspit backwaters, the mean burrow length (TBL) 110.7± 24.6 was higher than crabs made in Korangi creek (55.3±16.4)*.* The density of *M. depressus* was higher in Korangi creek area  $(168/m^2)$  with mean CL = 6.7 mm, whereas in Sandspit BD) was 1.4±0.26 and 3.2 0.68 at Korangi creek and Sandspit

respectively. Crab built horizontal burrow with tube like shaft ended without chamber at the base having single burrow opening (Figure 10).

Figure 10. Burrow morphology of *M. depressus* from two different mangrove areas, (A) Korangi creek, and (B) Sandspit from coastal areas of Pakistan.

*For three species of fiddler crab,* burrows were nearly vertical, straight, and single or branched whereas in sentinel crab it was horizontally elongated with single shaft opening without any branch. Results in the present study showed that the species of crab occupy high zone form longer burrows than species which inhabitant from mid to low tide zones. Deeper burrows maintain lower burrow temperatures in areas that are exposed to sunlight for greater periods of time (Powers & Cole, 1976; Wolfrath, 1992; Lim & Diong, 2003). The ghost crab of genus *Ocypode* Weber, 1795 are nocturnal burrowing species distributed along sandy beaches of subtropical and tropical regions of the world. Two species (i.e., *O. rodondata* and *O. ceratopthalmas*) of ghost crabs frequently distributed along the coast of Pakistan and studied for burrow architecture (Figure 11). A total of 67 burrow casts for *O. rotundata,* with four different types of burrow architecture were obtained (Table 9), including straight tube like (694.1  $\pm$  278.2, 320–1400), J shaped (742.9  $\pm$  53.5, 700–800), L shaped (736.7  $\pm$  241.3, 410–900) and complex branched network (783.3 ± 57.7, 750–850). For 59 burrows of *O. ceratopthalmas,* four different types of burrow cast were obtained i.e., C shaped (493.7  $\pm$ 52.4, 405–550), J (465  $\pm$  9.1, 380–550) shaped, L shaped (650  $\pm$  77.5, 600–750) and Y shaped (640  $\pm$  69.6, 550–690) all with single opening (Table 9). The ghost crabs are the carnivore in a food chain of the dune and fore beach ecological environment and have been considered as an indicator of the dune and fore beach environment. Various species of Ocypodoid semi terrestrial group selectively burrow into inter tidal substrata, from coarse beach sand to fine clay-rich marshy mud (Teal, 1958). It appears that the changes in elevation, vegetation and sediment composition determine the dominancy of species in particular environment. As the tidal frequencies and magnitudes, along with temperature, appears to provide an important environmental regulator for feeding, burrowing and courtship (Crane, 1958; Power & Cole, 1976; Montague, 1980). The length of burrows varied depends on tidal levels and size of burrow diameters. The burrows with a greater angle could aid in the survival of the crabs, as more acutely bent burrows provide the better refuge from predators therefore, the open areas have a greater angle (Lim & Heng, 2007).

(B) Casts of burrows of *Ocypodeceratophthalmus*

#### **Table 9. Summary of descriptive statistics for difference in burrows morphology of two species of genus** *Ocypode* **from Sandspit area**

The pattern found for *A. sindensis* and *Ocypode* in the present study is consistent with that found for other crabs with deeper burrows in drier sediments (Takeda & Kurihara, 1987; Wolfrath, 1992; Lim & Diong, 2003). Species and even individuals can produce many different burrow architectures and different species can also produce the same architectures. Burrow morphology is generally influenced by organism morphology, behaviour and their response to variations in environmental stimuli, including biotic and abiotic factors (Bromley, 1996; Bowen & Hembree, 2014).

## **8. SEMATECTONIC COMMUNICATION THROUGH ALLIED LANDMARK AND STRUCTURES NEAR BURROWS**

Most of the crabs are inhabiting in intertidal mud flats and dig burrows to protect them from predation, environmental stresses and also creates unique habitats for infauna but in addition most of them also build earthen structures at their burrow entrance by using moist mud or sand (Crane, 1975; Christy, 1982). One of the basic function of burrow is to use for reproductive activities and through these landmark structures, the male shows up himself to females to attract them for copulation that usually occurs inside the burrows (Christy, 1987;

Netto et al. 2007). The male species of Ocypodoid and Grapsoid crabs construct various structures near their burrow, which are used for sematectonic communication (Wilson, 1975). These structures are named according to their appearance, such as the pillars, (Christy, 1988), chimneys, (Wada & Murata, 2000), mud balls, (Burford et al., 2001), pyramid (sand piles) fence (Crane, 1975; Christy, 1982; Wada et al., 1994), semidome or hoods, (Zucker, 1981; Clayton, 1998), shelters, (Zucker, 1974), and barricades, (Wada, 1994), built by 17 species of genus *Austruca* (formerly called *Uca*), (Burford et al., 2001) which resembles many of *Uca* sand structures, (Christy, 1988a, 1988b, 2001; Muramatsu, 2010; Saher & Qureshi) and the pyramids are used by ghost crabs female to attract them by not displaying themselves (Wilson, 2000). The other role of pyramid construction is to enforce the male territories and maintaining the neighbor distances like other species of family *Ocypodidae* (Oliveira et al, 1998; Mammatus, 2010).

The genus *Uca* is also well known for the behaviour to build the various earthen structures from mud excavated inside from their burrows. Christy (1988) suggested that the pillars of *A. beebei* may function as guide posts to allow the resident male to find his burrow entrance quickly when escaping a predator and/or to attract females to the males' burrows. In the fiddler crab (*A. beebei*) males build a small mud pillar next to their burrow which increases their attractiveness to the females.

Low semi-domes (hoods) *Cleistostoma kuwaitense* construct hood to ensure social spacing (Clayton 1988). *U. terpsichores* also constructed low massive semi-domes (i.e., hoods) on one edge of the burrow entrance as a territorial behaviour (Zucker, 1981). The semi-domes of some species may act as an object to provide wharf to the male, whilst engaged in forceful combat (Christy, 1982). However, in some species hoods play a part to attract females for courtship, for example, in *U. musica*, *U. terpsichores* and *U. beebei* occurrence of hoods reduces the frequency of combats between territorial males and their construction frequency is associated with high densities of male burrows (Zucker, 1981); similar observations were observed in the *A. iranica* along the Pakistan coast (Saher & Qureshi, 2017).

Chimneys are mud mounds walls that encircle the entrance to a crab burrow (Crane, 1975; Thurman, 1984). Different fiddler crab species build the chimneys but the proposed functions vary greatly among the species (Wada & Murata, 2000; Shih et al., 2005; Saher & Qureshi 2017). In some species (*Uca formosensis*) it is built only by males that have recently attracted a female into their burrow to mate while in others, assumed to hide male from rivals while he expands his burrow for the female (Shih et al., 2005; Saher & Qureshi 2017). By contrast, only large reproductive females build chimneys in *Uca urvillei, Uca coarctata* and *Uca forcipata* (Crane, 1975; Salmon, 1987). In *U. arcuata,* the chimney decreases the chance of intrusion by wandering crabs (Wada & Murata, 2000) and protect them during incubation. Thurman (1984) proposed that chimneys may help to regulate the environmental stresses (temperature or humidity) in *Uca subcylindrica*.

Sand piles (sand pyramids) made by male ghost crabs (*Ocypode saratan*, *O. ceratophthalmus* and *O. kuhlii*) near the burrow and these structures apparently function in male spacing and to attract female (Linsenmair, 1967). Mounds in *Ilyoplaxpingi* keep the neighbor crabs away from burrow (Wada et al., 1994). The barricade and fence built by *I. pusillus* a mud wall on the near side of a neighboring burrow (barricade) or apart from the burrow to defend the area around their burrows against intrusions by conspecific invasion (Kitaura et al., 1998).

### **9. ANTHROPOGENIC EFFECTS ON BURROW AND BURROWING**

The coastal developmental activities by human beings results in widespread modifications of the beach. Sandy beaches are the most important intentions for outdoor activities of human beings for their leisure time such as by driving off-road vehicles, walking on beaches or dunes, walking over the vegetation, inducing soil erosion and imposing the other drastic changes; however, these regions have various energetic and often sensitive ecosystems. The coastlines of the world are dominated by sandy beach ecosystems (McLachlan & Brown, 2006, Branco et al., 2010). By increasing coastal human population, the natural habitats of sandy beaches are being destroyed in the accelerating rate (Defoe et al., 2009). As the humans are shifting to coastal areas to utilize the habitats as their visiting places, they greatly exploit the natural resources of sandy beaches (Roberts & Hawkins, 1999). These variable types of anthropogenic activities are important and increasing the concern for coastal management (Beatley et al., 2002, Branco et al., 2010), and therefore, ghost crabs can be used for the assessment of human impact on the beach environment (Barros, 2001).

This is necessary to know the ecological responses to urban sewage by the fauna inhabited in the mangrove ecosystem. To understand the effect of sewage on crab directly or indirectly will help further knowledge about crab survival and bioturbation activities to comprehend the effects of organic discharge on the mangrove forests and develop sustainable mangrove wastewater wetlands. The waste water is a potential threat to mangrove forest ecosystem and recently these forests are recently expressed a potential as a natural wastewater treatment in China (Yang et al., 2008). These crabs have the potential to remove the nutrients and organic matter efficiently (Penha-Lopes et al., 2009). The mangrove forest productivity can be enhanced by applying the moderate sewage loadings (Mohamed et al., 2009) also responsible for the enhancement of benthic primary productivity and micro-heterotrophs (Meziane & Tsuchiya, 2002). The increased microalgal and bacterial growth in sewage contaminated mangrove forest ecosystem have no effect on Ocypodoid crabs biodiversity (Yu et al., 1997). Though, under poor hydrodynamic conditions the organic matter may increase above the ecosystem capacity and lead to eutrophication and hypoxic condition (Gray et al*.*, 2002). The crustaceans are considered as most sensitive species to hypoxia; consequently, faunal migration takes place because of lower activity of smaller burrow structures of marine benthic organisms and high mortality may be caused which may further lead to decrease in bioturbation activity (Diaz & Rosenberg, 1995).

On sandy beaches, the crabs construct their burrows generally in discrete zones on beaches. The studies suggest that burrows constructed by the crabs are generally above the high tide level (Grubb, 1971; Jones, 1972; Hartnoll, 1975; Burggren & McMahon, 1988) can be confirmed by the previous studies(Naidu, 1951; Barrass, 1963; Hughes, 1966; Jones, 1972; Vannini, 1980b; Burggren et al., 1988; Burggren & McMahon, 1988; Clayton, 2001; Tureli et al., 2009). Some species have adapted to construct their burrows on the supra littoral Zone (Magnus, 1960; Quijonet al., 2001; Clayton, 2005) whereas even other crabs show the burrow construction on inland of sandy soil (Borradaile, 1903; Pearse et al., 1942; Pearseet al., 1942; Macnae&Kalk, 1962; Jones, 1972; Hill & Hunter, 1973; Horch, 1975; Stoddart, 1984; Strachan et al., 1999; Strachan et al., 1999; Alberto &Fontoura, 1999; Clayton, 2005; Saher, 2008; Lucrezi et al., 2009; Saher & Qureshi, 2013; Lucrezi et al., 2014).

The previous studies recommend human disturbance from pedestrians and vehicles is a major factor affecting density of different sandy crab species (Hughes, 1966; Frey & Mayou, 1971; Chakrabati, 1981; Strachan et al., 1999; Barros, 2001; Blankesteyn, 2006; Maccarone& Matthews, 2007; Moss & Mcphee, 2006; Schlacher et al., 2007; Lucrezi et al., 2008; Hobbs et al., 2008; Brook et al., 2009; Magalhaes et al., 2009; Yong & Lim, 2009; Pombo & Turra, 2013; Hereward & Sluka, 2014; Sankar et al., 2013). Therefore, these previous studies suggest that *Ocypode* species as a good biological indicator, though densities may increase around the food waste, (Hill & Hunter, 1973; Steiner & Leatherman, 1981), while hot weather and short term human trampling can lead them to struggled temporarily and hide under burrows cause reduction in burrow counts (Lucrezi et al., 2009). Tide-dominated beaches also have too many confounding factors impacting density as they are particularly heterogeneous habitats (Turra et al., 2005).

# **ABSTRACT**

Temperature strongly affects the development of American lobster (*Homarus americanus* H. Milne Edwards, 1837) larvae. At temperatures below and above the species' lower  $(T_L)$  and upper  $(T_H)$  developmental thresholds, respectively, successful development should be prevented, while at temperatures between these warmer conditions should result in faster development, except as the upper threshold is approached. Likewise, the species should have an intrinsic optimum temperature for development  $(T_{\varphi})$ , at which its larval development rate is high while its other physiological characteristics are in good condition. These thermal parameters and the temperature-dependent development relationships they define mediate the effects of temperature on recruitment to lobster populations and fisheries, so it is important to know them. However, no previous study has defined all three thermal parameters for the development of American lobster larvae. In this chapter, a thermodynamic model, the Sharpe–Schoolfield–Ikemoto (SSI) model, was fit to development data for American lobster larvae through different stages and at different temperatures from eight previously published studies. Bootstrap 95% confidence intervals (C.I.s) were also generated for SSI thermal parameter ( $T_{\phi}$ ,  $T_{L}$ , and  $T_{H}$ ) estimates to allow them to be compared among larval stages and source studies. The estimates obtained varied widely and significantly among

 $\overline{a}$ 

<sup>\*</sup> Corresponding Author's Email: bk.quinn@unb.ca.

studies, with there being no consistent and few significant differences in thermal parameters among stages. Most *T<sup>Φ</sup>* estimates were biologically realistic, but the majority of  $T_L$  and  $T_H$  estimates were not. When all studies' datasets were combined in the same analyses, the  $T_{\phi}$ ,  $T_{L}$ , and  $T_{H}$  for American lobster larval development were estimated to be 16.534-17.326°C, 0.095-7.804°C, and 23.483-25.661°C, respectively. The *T<sup>Φ</sup>* of stage I was significantly lower than those of stages II and III, but all other differences in thermal parameters among stages were non-significant. Further, while all  $T_{\phi}$  and most  $T_L$ estimates were considered realistic, all  $T_H$  estimates were slightly too low. The SSI model was derived based on enzyme thermodynamics, and thus should provide useful information concerning lobster larval developmental optima and limits. The results found suggest that as ocean temperatures experienced by lobster larvae in nature more often exceed the  $T_{\phi}$  for their development due to climate change, larval development and survival may be impaired, which will have important impacts on lobster recruitment. However, none of the previous studies analyzed were conducted over a wide enough thermal range to allow a conclusive fit of their data to be done with the SSI model. Therefore, a future rearing study conducted over a wide thermal range, followed by analyses with the SSI model, is needed to better define the limiting and optimum temperatures for the development of this species' larvae.

# **1.INTRODUCTION**

Environmental temperatures have important and powerful impacts on the physiology and ecology of ectothermic animals (Bělehrádek 1935; Anger 2001; Angilletta Jr. 2006; Byrne 2011; Jost et al. 2012; Shi et al. 2011, 2012a, b, 2013, 2017), including lobsters (McLeese 1956; Boudreau et al. 2015; Quinn 2017a). Larval development is a particularly important temperature-sensitive process in the lifecycles of ectotherms, as it must be successfully completed for there to be recruitment to later life stages and for populations to be maintained (Schmalenbach and Franke 2010; Vaughn and Allen 2010; Byrne 2011; Pineda and Reyns 2018). At temperatures that are too low or too high, development cannot be completed; these limiting temperatures are termed the lower  $(T_L)$  and upper developmental thresholds  $(T_H)$ , respectively, and vary among species (Jost et al. 2012; Shi et al. 2017) and perhaps developmental stages of the same species (Campbell et al. 1974; Brière et al. 1999; Quinn 2017a). The rate at which larval development proceeds is also important, as a longer larval developmental period results in greater exposure of larvae to predation risks, environmental stress, possible dispersal away from juvenile habitat, and other sources of mortality, and thus decreases the probability of them surviving the larval period and recruiting to the adult population (Pechenik 1999; Vaughn and Allen 2010; O'Connor et al. 2007; Pineda and Reyns 2018; Gendron et al. in press). Over the majority of temperatures likely to be experienced by a species between its lower and upper thermal thresholds, higher temperatures result in faster development and thus shortened larval durations (Angilletta Jr. 2006; Campbell et al. 1974; Ikemoto and Takai 2000), and the relationship between temperature and development rate is usually linear across much of this range, although near extreme values it becomes nonlinear (Brière et al. 1999; Jost et al. 2012; Shi et al. 2011; 2012a,b; 2013; 2017). However, as

temperatures approach the upper threshold this beneficial effect of temperature breaks down and development speeds up less and less, and then eventually slows rapidly just before the threshold is reached (Schoolfield et al. 1981; Yamamoto et al. 2017). In light of ongoing and future climate change, there is much interest and importance in obtaining a better understanding of the effects of temperature changes on various organisms (Byrne 2011; Caputi et al. 2013; Pinsky et al. 2013). It is particularly important that the thermal thresholds and temperature-dependent development rates of ecologically and/or economically important species are quantified. However, for many species such information has not yet been sufficiently assessed due to the high costs and methodological challenges of needing to rear larvae over a wide range of temperatures to do so (e.g., Quinn 2017b; but see Yamamoto et al. 2017).

The American lobster, *Homarus americanus* H. Milne Edwards, 1837 (Crustacea: Decapoda: Astacidea: Nephropidae), is a large, clawed species of lobster than inhabits the coastal marine benthos of the Atlantic Shelf of eastern North America, from Cape Hatteras, NC, USA to Labrador, NL, Canada (Lawton and Lavalli 1995). This species is presumed to be an important heterotrophic component of many marine communities, and supports the most lucrative and socioeconomically important fishery in the region spanning Cape Cod, MA, USA to Newfoundland, Canada (Wahle et al. 2013). During the spring-summer months (ca. May-October), lobster larvae are released by benthic females, and then spend from 2-8 weeks or more (depending on water temperature) in the water column, living as planktonic and/or pelagic raptorial predators (Phillips and Sastry 1980; Ennis 1995). Lobster larvae develop through three zoea or mysis stages, termed larval stages I, II, and III, which are followed by a single decapodid stage, termed stage IV (and commonly called a 'postlarva') (Hadley 1906; MacKenzie 1988; Ennis 1995); stage IV lobsters are strong swimmers that settle to the benthos when they encounter suitable substrate, after which they moult into the first juvenile instar (stage V) (Lawton and Lavalli 1995). Some strong correlations have been found between the supply of potential settlers (i.e., larvae) to a given locality and its fisheries recruitment (e.g., Miller 1997; Wahle et al. 2004; Quinn et al. 2017; Gendron et al. in press), so it is likely that any factor that impacts larval survival and/or planktonic dispersal patterns (which affect the spatial distribution of settlers) could strongly impact lobster populations and the fisheries they support (Caputi et al. 2013; Boudreau et al. 2015; Jaini et al. 2018). Changing water temperature due to climate change is one such factor, as such change has the potential to expose lobster larvae to temperatures exceeding their developmental thresholds and/or to temperatures that lengthen larval duration (Quinn and Rochette 2015; Quinn 2017a). Therefore, it is clearly important that we know the thermal thresholds and temperaturedependent development rates of American lobster larvae to allow such changes and their potential impacts to be predicted.

A number of studies have investigated the impacts of temperatures on American lobster larval development times (e.g., Hadley 1906; Templeman 1936; Hughes and Matthiessen 1962; Ford et al. 1979; MacKenzie 1988; Hudon and Fradette 1988; Annis et al. 2007; Quinn et al. 2013; Waller et al. 2017; Harrington et al. 2019). Although studies have been done at rearing temperatures within the range of 6.7 to 26.3°C, no single study has been done over this full range, and none have yet investigated the larval development of this species across its full range of potentially biologically relevant temperatures (ca. 0-30°C or higher: Quinn and Rochette 2015). Thus, we do not yet have a detailed picture of its larval development curve, including the point at which rising temperatures cease to increase development rates (Quinn 2017a); although it should be noted that based on results of Templeman (1936) and Ford et al. (1979), development rates may plateau between 19.2 and  $23.8^{\circ}$ C and begin to decline slightly between 24.2 and 26.3°C. Further, although a handful of studies have attempted to estimate lethal temperature limits of lobster larvae (0°C and 28-35.5°C: Huntsman 1924; Sastry and Vargo 1977; Gruffydd et al. 1979), no comprehensive investigation of the thermal limits of larval development (i.e., using long-term exposures of large numbers of larvae to extreme temperatures) has yet been done (Quinn 2017a).

Until such studies are done, the only means available to assess potential developmental threshold temperatures for lobster larvae is the application of development functions that can estimate such thresholds to data from previous studies (Quinn 2017a, b). For example, Quinn (2017b) applied the linear sum (Winberg 1971), linear rate (Campbell et al. 1974), Bělehrádek (Bělehrádek 1935; McLaren 1963), modified Arrhenius (Guerrero et al. 1994), and Brière-2 (Brière et al. 1999) functions to data from MacKenzie (1988) and Quinn et al. (2013) to estimate  $T_L$  and/or  $T_H$  thresholds of lobster larvae of 0-8.8°C and 22.5-41.4°C, respectively (Quinn 2017a). However, many of these estimates were not considered biologically realistic and/or were made with limited power (see Quinn 2017b for discussion), and could further not be statistically compared among larval stages or data sources. These functions also did not allow the optimum temperature for larval development to be estimated (see below). There thus remains the potential for better estimates of developmental threshold temperatures to be made for this species.

A prominent and potentially very useful (but also extremely complex) development function that was not examined or applied to lobster data by Quinn (2017b) was the Sharpe– Schoolfield–Ikemoto (SSI) model (Schoolfield et al. 1981; Shi et al. 2011; Ikemoto et al. 2013). This model was derived from studies of enzyme thermodynamics, and equates the limiting temperatures for development  $(T_L$  and  $T_H$ ) to those at which a hypothetical enzyme (presumably one controlling and/or affecting development) has a 50% probability of being in either an active or temperature-inactivated state (Ikemoto et al. 2013). It thus has the potential to produce more realistic and meaningful estimates of thermal limits than many of the other models applied previously to lobsters. This model has been applied extensively in studies of insects and arachnids (e.g., Ikemoto 2005, 2008; Shi et al. 2011, 2012a, b, 2013, 2017; Jafari et al. 2012; Ikemoto and Egami 2013; Padmavathi et al. 2013; Sreedevi et al. 2013; Quinn 2017b), and has recently been applied to a few crustaceans (Yamamoto et al. 2017). The SSI model is represented by the equation:

$$
d(T) = \frac{\rho_{\Phi} \frac{T}{T_{\Phi}} \exp\left[\frac{\Delta H_A}{R} \left(\frac{1}{T_{\Phi}} - \frac{1}{T}\right)\right]}{1 + \exp\left[\frac{\Delta H_L}{R} \left(\frac{1}{T_L} - \frac{1}{T}\right)\right] + \exp\left[\frac{\Delta H_H}{R} \left(\frac{1}{T_H} - \frac{1}{T}\right)\right]}
$$
(1)

where  $d(T)$  is the development rate (1/development time, in  $1$ /day) at a given absolute temperature, *T* (in degrees Kelvin (K), such that  $0^{\circ}C = 273.15$  K), *R* is the gas constant (1.987) cal/deg/mol), *ΔH<sup>A</sup>* is the enthalpy (in cal/mol) of a reaction that is catalyzed by a hypothetical enzyme,  $T_L$  and  $T_H$  are the lower and upper threshold temperatures (in K) at which the enzyme is half active and either half low-temperature inactivated or half high-temperature inactivated, respectively,  $\Delta H_L$  and  $\Delta H_H$  are the changes in enthalpy (in cal/mol) associated with the low- or high-temperature inactivation of the enzyme, respectively,  $T_{\phi}$  is the intrinsic optimum temperature (in K) of the reaction at which the probability of the enzyme being in an

active state is maximized, and  $\rho_{\phi}$  is the development rate (in 1/day) at the  $T_{\phi}$  assuming no enzyme inactivation (Sharpe and DeMichele 1977; Schoolfield et al. 1981; Shi et al. 2011; Ikemoto et al. 2013).

The intrinsic optimum temperature,  $T_{\phi}$ , is related to the other parameters of the SSI model, and thus may be the most important and informative thermal parameter to estimate (Ikemoto et al. 2013). In previous work, the  $T_{\phi}$  was assumed to be equivalent to 25<sup>o</sup>C (in the SS model of Sharpe & DeMichele (1977)), but more recent studies using the SSI model have permitted the value of the  $T_{\phi}$  to vary as appropriate for the species and dataset under consideration (Shi et al. 2011, 2012a, 2013, 2019; Ikemoto et al. 2013). Traditionally, the 'optimum' temperature for the larval development of a species was considered to be the temperature at which its development rate was maximized (e.g., Amarasekare and Savage 2012). However, this is not really the case, as an increasing body of work has demonstrated that at temperatures causing the most rapid development possible a number of other physiological processes are impaired, causing reduced growth, survival, etc. (Ikemoto 2008; Martin and Huey 2008; Forster et al. 2011; Corkrey et al. 2012; Shi et al. 2012a, 2013, 2019); indeed, for lobsters this seems to be the case as well (Quinn 2017a; Harrington et al. 2019). Thus, the true intrinsic optimum temperature for the development of a species should be below the one at which development rate is maximized (Martin and Huey 2008; Shi et al. 2019), and algorithms used to estimate SSI model parameters should not constrain the value of  $T_{\phi}$  to be equal to either 25<sup>°</sup>C or the temperature at which the development rate is maximized.

There is obviously interest in determining the intrinsic optimum temperature for the development of a species under consideration. Many species of insects and crustaceans, for example, are reared in laboratory or hatchery settings for use as food for humans or livestock or to supplement natural stocks of their species (Van Olst et al. 1976; Carlberg and Van Olst 1977; Ford et al. 1979; Quinn 2017b), and to maximize their production and efficiency such efforts should be carried out at temperatures that maximize larval development rates while avoiding negative thermal effects on survivorship and other characteristics. It is also useful to know the optimum temperature for a species when making predictions about its dynamics in nature, as temperatures below and above the optimum can have important negative impacts on larval survival and supplies of recruits (Quinn and Rochette 2015; Quinn 2017a) and threshold temperatures may determine the boundaries of geographic distributions (Boudreau et al. 2015). There is a long history of studies of American lobster, which does suggest that the optimum temperature for larvae of this species is somewhere around  $18{\text -}20^{\circ}\text{C}$  (e.g., Van Olst et al. 1976; Carlberg and Van Olst 1977; Ford et al. 1979; Bartley et al. 1980; Quinn 2017a); however, such estimates vary among studies and have not been made while considering the thermodynamics of the enzymes controlling development. Therefore, it may be useful to estimate the intrinsic optimum temperatures for American lobster larval development using the SSI model.

Recently, techniques have also been developed that allow the thermal parameters  $T_{\phi}$ ,  $T_{L}$ , and  $T_H$  estimated by the SSI model to be compared among datasets based on analyses of bootstrap confidence intervals (Ikemoto et al. 2013). The possibility that such thermal characteristics differ among developmental stages within the same species has previously been raised (Anger 2001; Schmalenbach and Franke 2010; Jafari et al. 2012), and has implications to changes in the timing of events in nature under climate change; for example, if a certain stage is more sensitive to elevated temperatures than others, then it may represent a bottleneck for recruitment to all later life stages (Gruffydd et al. 1979; Caputi et al. 2013; Quinn 2019). Being able to compare limiting and optimum temperatures for the development of American lobster larvae among stages, and perhaps also among different source populations (e.g., to test for local adaptation; Quinn et al. 2013) would also be highly useful.

Therefore, in this chapter the SSI development model was fit to data for the development of American lobster larvae at different temperatures obtained from the literature using a series of statistical packages and techniques developed by Ikemoto et al. (2013). This was done to generate new and hopefully improved estimates of the lower and upper threshold temperatures for American lobster larval development compared to those produced in previous studies, and to compare these estimates statistically among larval stages and different source studies. During this procedure, estimates of the intrinsic optimum temperature for the larval development of this species were also produced and compared, which has not been done before. The results obtained were discussed in light of previous research on this species, as well as in relation to the species' larval ecology and potential impacts of climate change. The quality of the estimates obtained was also critically evaluated to make recommendations for future studies of this species' temperature-dependent larval development.

# **2. MATERIALS AND METHODS**

#### **2.1. Sources of Development Data**

Development times of American lobster larvae at different temperatures were obtained from 8 previously published studies (Table 1). These studies reported development times of American lobster larvae at three or more (up to 25) different temperatures, which were as low as 6.7°C, as high as 26.3°C, and covered a thermal range of 3.2 to 17.1°C (mean: 8.45°C) in total (Table 1). Many additional studies besides these 8 have also examined American lobster larval development times at different temperatures (e.g., Annis et al. 2007; Waller et al. 2017) but only compared two temperatures, meaning their data could not be fit with a complex curve like the SSI model; these other studies' data were thus not used herein.

The studies whose data were used were carried out in either a laboratory or hatchery setting (6/8 studies) or in the field (2 studies), and used larvae that originated from different locations across the species' range, as reviewed by Quinn et al. (2013) (Table 1). Larvae were reared individually (5 studies) or communally (2 studies), or sampled in field plankton tows (1 study) (Table 1). One field study (Hadley 1906) did not rely on plankton tows, but rather held groups of larvae in scrim bags moored in a harbor. Rearing temperatures were controlled and held ~constant in 4 studies, while in 3 other studies temperatures were allowed to undergo natural fluctuations, and 1 study tested both controlled and fluctuating temperatures (Table 1). All 8 studies reported total development times from hatch to the moult to stage IV (i.e., the combined duration of stages I, II, and III), and most (5/8 studies) also reported individual development times through each of stages I, II, and III (Table 1). However, development times for stage IV, and therefore total development times from hatch to the moult to stage V (i.e., the combined duration of stages I, II, III, and IV), were only reported by 3 of these studies (Table 1).

For each study, the mean development time (in days) spent in each stage (I, II, III, and IV) or combination of stages (I-III combined and I-IV combined) at each studied temperature was either taken directly from the published paper (if reported) or calculated from the data presented therein. These mean temperature-dependent development times were then used in all subsequent analyses.

# **2.2. Estimating SSI Model Parameters**

The mean development time data for each study and stage or combination of stages at different temperatures were fit with the SSI model using the *OptimSSI* package by Ikemoto et al. (2013) in R v.3.1.1 (R Core Team 2014). This package estimated the parameters  $T_{\phi}$ ,  $T_{L}$ , *T<sub>H</sub>*,  $ρ_Φ$ ,  $ΔH_A$ ,  $ΔH_L$ , and  $ΔH_H$  of the SSI model in equation (1) for each dataset, which were output as T-Phi, TL, TH, rho-Phi, HA, HL, and HH, respectively. It also produced  $\chi^2$  and  $R^2$ goodness-of-fit values for the fit of the model to each dataset, which were output as Chisquare and R-square, respectively. This package was used because the SSI model is extremely complex relative to other temperature-dependent development functions and is not always possible to fit to data using all statistical programs' nonlinear regression procedures (Quinn 2017b). Although earlier programs were made to estimate SSI model parameters (Ikemoto 2008; Shi et al. 2011), they tended to be too slow for practical purposes, whereas the package introduced by Ikemoto et al. (2013) is able to estimate parameters very quickly, which is particularly important for its use when calculating bootstrap confidence intervals for these estimates (see section 2.3).

The main inputs to the *OptimSSI* program are temperatures (in °C) and development times (in days); the package then converts the temperatures into degrees Kelvin (K) and the development times into development rates (1/day). The user must also specify what portion of the dataset represents the putative 'linear' portion of the temperature-development curve. Over the specified range, a linear fit is then made of the temperature-development rate relationship (Winberg 1971; Campbell et al. 1974; Ikemoto and Takai 2000), from which initial estimates of the parameters  $T_L$  and  $T_H$  are made (Ikemoto et al. 2013; Quinn 2017b). These initial estimates are then used as starting values for these parameters in the nonlinear fitting of the data to the SSI model.

For American lobster larvae, very few studies have examined development over a sufficiently broad range of temperatures to provide a good idea of where the 'linear' portion of their temperature-development relationship occurs (Quinn 2017a, b; Table 1). The lower boundary should occur where a decrease in temperature results in a decrease in the development rate that becomes greater in magnitude with each subsequent 1° decrease, while the upper boundary should occur at the point where an increase in temperature ceases to cause an increase in development rate, but rather begins to cause a decrease (Campbell et al. 1974; Jost et al. 2012). Several studies have identified 12°C as a potential lower 'threshold' affecting American lobster larvae, below which survival and settlement decrease markedly and development becomes very slow (MacKenzie 1988; Annis et al. 2013; Quinn 2017a). Meanwhile, the only study that observed slowing development of American lobster larvae with increasing temperature was Ford et al. (1979), who observed slower development at 26.3°C than that at 24.2°C, although Templeman (1936) reported that development time changed very little as the temperature increased from 19.2 to 23.8°C. Therefore, in this chapter the lower boundary of the linear portion of the development curve was set at 12°C and the upper boundary was set at 24.3°C. This was fixed for analyses of all studies and stages due to limited information on whether this should vary among stages or the region of larval origin.

In the calculation of parameter estimates, the *OptimSSI* package initially sets the values of *T<sup>L</sup>* and *T<sup>H</sup>* (in K) to those estimated from the linear fit, *T<sup>Φ</sup>* to 298.15 K (25°C), and *ΔHL* and *ΔHH* to −50,000 and 50,000 cal/mol, respectively; for other details of model initialization and parameter estimation algorithms, see Ikemoto et al. (2013). After performing all calculations, the program reports all parameter estimates for a given dataset as its final output. For ease of interpretation, all temperature parameter estimates, although reported in K by the program and used as such within the SSI function, were converted to °C for presentation in all tables and figures herein. Plots of the SSI curves for each stage and study dataset were made in R using the *SSIPlot* function of Ikemoto et al. (2013).

#### **2.3. Calculating Bootstrap Confidence Intervals of Parameter Estimates**

Because specialized algorithms are required to estimate parameters of the SSI model, it can be difficult to obtain reasonable estimates of the uncertainty around these parameter estimates, which also means that they cannot always be compared statistically (e.g., among larval stages, studies, populations of origin, etc.). Ikemoto et al. (2013) solved this issue by introducing the use of bootstrapping techniques to estimate 95% confidence intervals (95% C.I.s) of SSI model parameter estimates. Bootstrapping is a family of computerized techniques that perform random resamplings of a dataset or distribution with replacement to derive an estimate of the accuracy or repeatability of some sort of estimate made from a sample (DiCiccio and Efron 1992, 1996; Efron and Tibshirani 1994). Ikemoto et al. (2013) introduced two packages to estimate 95% C.I.s of SSI model parameter estimates using different bootstrap techniques in R. The first of these, *BCaSSI*, provides bootstrapped 95% C.I.s for all parameters estimated by the *OptimSSI* package using both the bootstrap percentile and the bias-corrected and accelerated bootstrap  $(BC_a)$  methods (Efron and Tibshirani 1994). The second, *mABCSSI*, provides bootstrapped 95% C.I.s for *T<sup>Φ</sup>* only using the approximate bootstrap confidence intervals (ABC) technique (DiCiccio and Efron 1992, 1996; Efron and Tibshirani 1994), which Ikemoto et al. (2013) identified as the most appropriate approach to use for making comparisons of *T<sup>Φ</sup>* values. Therefore, once *OptimSSI* had generated SSI parameter estimates for a given dataset, these algorithms were used to estimate 95% C.I.s of all parameter estimates in the present chapter's analyses.

#### **2.4. Comparisons of Estimates among Larval Stages and Studies**

Comparisons herein were focused on the parameters of the SSI model representing potential thermal thresholds for the development of lobster larvae (*T<sup>L</sup>* and *TH*), as well as the estimated intrinsic optimum temperature for larval development  $(T<sub>\phi</sub>)$ . As a first set of preliminary tests, one-way analyses of variance (ANOVAs) were performed in R to coarsely test whether estimated  $T_L$ ,  $T_H$ , and  $T_\phi$  values differed among American lobster larval stages, with different studies treated as replicates. Overall mean values of each parameter  $\pm$  95% C.I.s were also calculated for each stage or combination of stages across studies and plotted. Whether the results of these tests would lead to different conclusions than those of analyses based on bootstrapped 95% C.I.s (see below) was also considered.

Bootstrapped 95% C.I.s formed the primary basis of comparisons among SSI model parameters among American lobster larval stages and studies. Comparisons among the estimates for a given group (stage or study) were made using analysis of confidence intervals (Cummings et al. 2007). In this approach, if the 95% C.I.s of one group overlap with the mean value of another, then the two groups can be concluded to not be significantly different  $(p > 0.05)$ , whereas if both groups' 95% C.I.s do not overlap with one another's means (i.e., the 95% C.I. of the difference between the two groups does not overlap with zero; Lin et al. 2018; Shi et al. 2017, 2019) then they are significantly different  $(p < 0.05)$  (Cummings et al. 2007). SSI model parameter estimates were compared in place of mean values in the present chapter, and the 95% C.I.s were those produced by bootstrapping for each parameter.

Two series of comparisons were made. First, each of these estimates was compared among different larval stages (I, II, and III, and IV if data were available) for each study that provided data on multiple stages (Table 1). Second, each of these estimates was compared among different studies for each stage (I, III, III, and IV) and combination of stages (I-III and I-IV).  $T_L$  and  $T_H$  estimates were compared using the 95% C.I.s calculated for them based on both the bootstrap percentile and BC<sub>a</sub> methods.  $T<sub>\phi</sub>$  estimates were also compared using 95% C.I.s generated using these two techniques, in addition to using those generated with the ABC method; however, given the conclusions of Ikemoto et al. (2013) more weight was given to the results of comparison of  $T_{\phi}$  estimates based on ABC-derived 95% C.I.s.

Whether overall and per-study estimates of  $T_L$ ,  $T_H$ , and  $T_\phi$  values were biologically realistic was also considered. Since  $T_L$  and  $T_H$  are potential temperatures at which larval development could be impaired and prevented, estimates of these parameters that fell within the range of temperatures over which successful larval development has been observed in previous studies (6.7–26.3°C; Table 1; Quinn 2017a) were considered unrealistic. Estimates of  $T_L$ ,  $T_H$ , or  $T_\phi$  beyond the likely range of temperatures that are biologically relevant to American lobster larvae (e.g., those  $\lt 0^{\circ}C$  and  $\gt\gt 40^{\circ}C$ ; Quinn and Rochette 2015; Quinn 2017a, b) were also suspected of being unlikely to be true. If  $T_L > T_H$ ,  $T_L > T_\phi$ , or  $T_\phi > T_H$ , this was also obviously unrealistic. Previous studies have suggested (based on various criteria) that temperatures of ca.  $18{\text -}20^{\circ}\text{C}$  are 'optimal' for American lobster larval growth (Van Olst et al. 1976; Carlberg and Van Olst 1977; Ford et al. 1979; Bartley et al. 1980; Quinn 2017a), so  $T$ *φ* was expected to be near this range. A  $T$ *φ* estimate that was not excessively high, but high enough to be within the range over which higher temperatures begin to slow down development (i.e., beyond the upper bound of the 'linear' portion of the development curve, which was herein considered to be ca. 24.2-26.3°C (Ford et al. 1979)), was also suspected of being unrealistic.

#### **2.5. Combined Analyses Using All Studies' Data**

As only a relatively small sample size and limited range of temperatures was captured in most of the individual studies from which data were extracted herein (Table 1), a further set of analyses was done in which all 8 studies' data were combined into a single dataset. All of the procedures described above (sections 2.2-2.4) were then carried out on the combined dataset for each stage and combination of stages. Whether the use of the combined dataset resulted in different conclusions regarding the thermal parameters of lobster larval development than analyses of individual studies' datasets was then examined.

# **3. RESULTS**

#### **3.1. Overall Findings**

Estimates of the parameters of the SSI model when fit to development time data of American lobster larvae from different studies and their bootstrapped 95% C.I.s are presented in Tables 2-8. The corresponding temperature-dependent development rate curves based on the SSI model parameters estimated for each of these datasets are plotted in Figures 1-6.

For the majority of study and stage datasets to which the SSI model was fit, a reasonable fit with an  $\mathbb{R}^2 \geq 0.9$  was achieved (Tables 2-8), and a development curve of the appropriate shape corresponding to the SSI model over the range of biologically relevant temperatures for lobster larvae (ca. 0-40°C) was generated (Figures 1-6). Studies that considered a narrower range of test temperatures produced curves that were more narrow, whereas studies that tested a broader range of temperatures produced wider curves, as would be expected (Table 1; Figures 1-6).

Notes: LCI and UCI = lower and upper 95% C.I.s estimated with the bootstrap percentile (BP),  $BC_a$ , or ABC methods; ABC-derived 95% C.I.s were calculated for T-Phi only, and are presented in the same columns as BP-derived 95% C.I.s, but one row beneath them;  $aE\pm b = a \times 10^{-b}$ ;  $N/A =$  could not be estimated; NaN = non-numeric estimate; T-Phi, TL, and TH estimates are presented in units of °C; for the units and meanings of all SSI model parameters, see equation (1) in the Introduction, and for their abbreviations in this Table and in *OptimSSI* output, see section 2.2.

Figure 1. SSI model curves fit to development rates (y-axes, in 1/days) of American lobster larvae through different stages (different panels) at different temperatures (x-axes, in °C), using data obtained from Templeman (1936). Solid circles = observed data within the linear portion of the development curve; open circles = observed data outside the linear range; gray lines = the SSI development curve fit to all observed data; black lines = linear fit of data in the linear portion of the development curve; open squares = estimates of (from left to right)  $T_L$ ,  $T_\phi$ , and  $T_H$  based on the plotted data and curves. All plots made in R with the *SSIPlot* function of Ikemoto et al. (2013).

 $Chi-square$  1.541E-03 N/A N/A

However, there were several cases in which the development curve generated was highly abnormal and unlikely to be realistic. In 8 cases, the data to which the model were fitted ended up being treated as located very early in the linear portion of the temperaturedevelopment curve, with the temperature at which the maximum development rate occurs and above which the rate declines until the  $T_H$  is reached being extrapolated to extremely high temperatures. This problem occurred for data for stages IV and I-IV from Templeman (1936) (Figure 1), stages II and I-III from Hudon and Fradette (1988) (Figure 3), stages II, III, and I- III from Quinn et al. (2013) (Figure 4), and stage I from Harrington et al. (2019) (Figure 5). Further, in addition to suffering the aforementioned problem data for stage IV from Hudon and Fradette (1988) also produced an inverted linear fit (Figure 3) to produce starting values to estimate  $T_L$  and  $T_H$ , resulting in extremely high  $T_L$  and extremely low  $T_\phi$  and  $T_H$  estimates for this dataset (Table 4). Therefore, the estimates of  $T_{\phi}$ ,  $T_{L}$ , and  $T_{H}$  produced from such datasets are highly suspect and certainly incorrect. The structure of these datasets also in many cases did not permit bootstrap 95% C.I.s to be estimated, or if they were estimated they were often extremely wide and/or highly asymmetrical, limiting the ability for such estimates to be compared across studies or stages (Tables 4 and 5).

Figure 4. SSI model curves fit to development rates (y-axes, in 1/days) of American lobster larvae through different stages (different panels) at different temperatures (x-axes, in °C), using data obtained from Quinn et al. (2013). Solid circles = observed data within the linear portion of the development curve; open circles = observed data outside the linear range; gray lines = the SSI development curve fit to all observed data; black lines = linear fit of data in the linear portion of the development curve; open squares = estimates of (from left to right)  $T_L$ ,  $T_\phi$ , and  $T_H$  based on the plotted data and curves. All plots made in R with the *SSIPlot* function of Ikemoto et al. (2013).

The average estimated value of  $T_{\phi}$  for lobster larvae across all study datasets was 17.44°C (range: 14.72-20.99°C) for stage I, 17.72°C (range: 16.78-20.50°C) for stage II, 21.81°C (range: 16.70-41.17°C) for stage III, 1.44°C (range: -28.05-18.00°C) for stage IV, 18.46°C (range: 13.70-26.33°C) for stages I-III combined, and 15.08°C (range: 14.17- 16.373°C) for stages I-IV combined (Figure 8). The extremely low and unrealistic average estimated  $T_{\phi}$  for stage IV resulted from the highly abnormal development curve estimated for this stage from Hudon and Fradette's (1988) data (see above, and Figure 3). Three studies' datasets produced biologically unrealistic estimates of *TΦ*: -28.053°C for stage IV (Hudon and Fradette (1988): Table 4 and Figure 3), 26.333°C for stages I-III combined (Quinn et al. (2013): Table 5 and Figure 4), and  $41.172^{\circ}$ C for stage III (Quinn et al. (2013): Table 5 and Figure 4). Aside from these extremes, estimates of  $T_{\phi}$  for American lobster larvae generally fell within the more biologically realistic range of 13.703-20.503°C (Tables 2-8).

**Table 5. SSI parameter estimates for data from Quinn et al. (2013)**

Notes: LCI and UCI = lower and upper 95% C.I.s estimated with the bootstrap percentile (BP),  $BC_a$ , or ABC methods; ABC-derived 95% C.I.s were calculated for T-Phi only, and are presented in the same columns as BP-derived 95% C.I.s, but one row beneath them;  $aE\pm b = a \times 10^{\text{th}}$ ; N/A = could not be estimated; NaN = non-numeric estimate; T-Phi, TL, and TH estimates are presented in units of °C; for the units and meanings of all SSI model parameters, see equation (1) in the Introduction, and for their abbreviations in this Table and in *OptimSSI* output, see section 2.2.

The average estimated value of  $T_L$  for lobster larvae across all study datasets was  $-2.77^{\circ}$ C (range: -37.11-7.76°C) for stage I, -22.76°C (range: -132.72-8.10°C) for stage II, 4.57°C (range: -18.80-13.63°C) for stage III, 20.67°C (range: -1.25-54.01°C) for stage IV, 8.90°C (range:  $4.44$ -14.04 $^{\circ}$ C) for stages I-III combined, and  $9.05^{\circ}$ C (range: 6.30-11.78 $^{\circ}$ C) for stages I-IV combined (Figure 8). Clearly, most of these average estimates are biologically unrealistic, as they are subzero for stages I and II, above temperatures at which successful development has been reported for stages I-III and I-IV combined, and far too high and near the presumed optimum for stage IV. These results likely reflect the high variability in these estimates among study datasets, which was due to many datasets being unable to generate

reasonable estimates of  $T_L$ , or indeed to be fit with the SSI model at all (see above). Biologically realistic estimates of *T<sup>L</sup>* (i.e., between 0-6.7°C) were found for only 7 out of 29 (24.1%) cases (Tables 2-8).

The average estimated value of  $T_H$  for lobster larvae across all study datasets was 29.99°C (range: 20.39-53.55°C) for stage I, 39.79°C (range: 22.50-71.39°C) for stage II, 34.13°C (range: 17.60-71.27°C) for stage III, -3.48°C (range: -110.99-48.215°C) for stage IV, 41.74°C (range: 23.56-114.76°C) for stages I-III combined, and 42.44°C (range: 19.45- 73.78°C) for stages I-IV combined (Figure 8). While most of these averaged estimates are more reasonable, they are quite high, exceeding ca. 40°C for stages II, I-III, and I-IV, and are thus unlikely to be real; further, the average estimate for stage IV is far too low (subzero). As for  $T_L$  estimates, high variability and unreliable parameter estimations from many study datasets was likely responsible for these unrealistic estimates. Biologically realistic estimates of  $T_H$  (i.e., those > 26.3°C and not much more than 40°C) were only generated in 8 out of 29 (27.6%) cases (Tables 2-8).

Notes: LCI and UCI = lower and upper 95% C.I.s estimated with the bootstrap percentile (BP),  $BC_a$ , or  $ABC$  methods; ABC-derived 95% C.I.s were calculated for T-Phi only, and are presented in the same columns as BP-derived 95% C.I.s, but one row beneath them;  $aE\pm b = a \times 10^{\text{th}}$ ;  $N/A$  = could not be estimated; NaN = non-numeric estimate; T-Phi, TL, and TH estimates are presented in units of  $^{\circ}C$ ; for the units and meanings of all SSI model parameters, see equation (1) in the Introduction, and for their abbreviations in this Table and in *OptimSSI* output, see section 2.2.

Figure 5. SSI model curves fit to development rates (y-axes, in 1/days) of American lobster larvae through different stages (different panels) at different temperatures (x-axes, in °C), using data obtained from Harrington et al. (2019). Solid circles = observed data within the linear portion of the development curve; open circles = observed data outside the linear range; gray lines = the SSI development curve fit to all observed data; black lines = linear fit of data in the linear portion of the development curve; open squares = estimates of (from left to right)  $T_L$ ,  $T_{\phi}$ , and  $T_H$  based on the plotted data and curves. All plots made in R with the *SSIPlot* function of Ikemoto et al. (2013).

Notes: LCI and UCI = lower and upper 95% C.I.s estimated with the bootstrap percentile (BP), BC<sub>a</sub>, or ABC methods; ABCderived 95% C.I.s were calculated for T-Phi only, and are presented in the same columns as BP-derived 95% C.I.s, but one row beneath them;  $aE \pm b = a \times 10^{\pm b}$ ; N/A = could not be estimated; NaN = non-numeric estimate; T-Phi, TL, and TH estimates are presented in units of °C; for the units and meanings of all SSI model parameters, see equation (1) in the Introduction, and for their abbreviations in this Table and in *OptimSSI* output, see section 2.2.

Figure 6. SSI model curves fit to development rates (y-axes, in 1/days) of American lobster larvae through stages I-III combined at different temperatures (x-axes, in °C), using data from three different studies (different panels). Solid circles = observed data within the linear portion of the development curve; open circles = observed data outside the linear range; gray lines = the SSI development curve fit to all observed data; black lines = linear fit of data in the linear portion of the development curve; open squares = estimates of (from left to right)  $T_L$ ,  $T_\phi$ , and  $T_H$  based on the plotted data and curves. All plots made in R with the *SSIPlot* function of Ikemoto et al. (2013).

**Table 8. SSI parameter estimates for combined stages I-IV data from various studies**

Notes: LCI and UCI = lower and upper 95% C.I.s estimated with the bootstrap percentile (BP),  $BC_a$ , or  $ABC$  methods; ABC-derived 95% C.I.s were calculated for T-Phi only, and are presented in the same columns as BP-derived 95% C.I.s, but one row beneath them;  $aE \pm b = a \times 10^{-b}$ ;  $N/A =$  could not be estimated; NaN = non-numeric estimate; T-Phi, TL, and TH estimates are presented in units of °C; for the units and meanings of all SSI model parameters, see equation (1) in the Introduction, and for their abbreviations in this Table and in *OptimSSI* output, see section 2.2.

In preliminary analyses, when  $T_L$ ,  $T_H$ , or  $T_\phi$  estimates were averaged across studies, there were some apparent differences among stages (Figure 7). Specifically, the  $T_H$  and  $T_\phi$ estimates were lower and the *T<sup>L</sup>* estimates were higher for stage IV in comparison to those for all other larval stages; all estimates for stage IV also varied much more among studies than did those for other stages (Figure 7). Stage II also appeared to have a lower and more variable  $T_L$  than other stages (Figure 7). However, there were no statistically significant differences in these analyses among larval stages in their  $T_L$  (ANOVA: F  $_{3,14}$  = 0.943, p = 0.446),  $T_H$ (ANOVA: F<sub>3,14</sub> = 0.956, p = 0.437), or  $T_{\phi}$  (ANOVA: F<sub>3,14</sub> = 2.126, p = 0.143) estimates (Figure 7).

Figure 7. Estimates of the *T<sup>Φ</sup>* (T-Phi), *T<sup>L</sup>* (TL), and *T<sup>H</sup>* (TH) parameters of the SSI model averaged across all study datasets (y-axes, in °C) for each American lobster larval stage or combination of stages (x-axes). Error bars represent  $\pm$  95% C.I.s calculated for each mean across study datasets (n = 3-8, depending on stage). Preliminary analyses were done in which each parameter (different panels) was compared across stages with separate one-way ANOVAs, but no significant differences were found (see section 3.1 for details).

#### **3.2. Comparisons among Larval Stages for Each Study**

When data from Templeman (1936) were analyzed, the estimated intrinsic optimum temperature for larval development  $(T<sub>\phi</sub>)$  of stage II was significantly lower than those estimated for all other stages, but the  $T$ <sup> $\phi$ </sup> of all other stages (I, III, and IV) did not significantly differ from one another (Table 2; Figure 8). The  $T_{\phi}$  was significantly higher for stage II than that for stage I when data from MacKenzie (1988) were assessed and 95% C.I.s were bootstrapped using the ABC method, while that for stage III did not significantly differ from those for these stages (Table 3). The estimated  $T_{\phi}$  for stage IV based on MacKenzie's data was lower than those for stages I-III, but could not be compared to them because its 95% C.I.s could not be bootstrapped using the ABC method (Table 3; Figure 8). The  $T_{\phi}$  values estimated with data from Hudon and Fradette (1988) did not significantly differ among larval stages (Table 4; Figure 8). When data from Quinn et al. (2013) were assessed, *T<sup>Φ</sup>* values for all three larval stages significantly differed, with  $T_{\phi}$  values increasing with stage number (stage III > II > I) (Table 5; Figure 8). The  $T_{\phi}$  value estimated with data from Harrington et al. (2019) for stage I was significantly higher than that estimated for stage II; however, estimates for stages II and III did not significantly differ from one another, nor did those for stages I and III (Table 6; Figure 8).

When 95% C.I.s were bootstrapped using the bootstrap percentile or  $BC_a$  methods, the  $T_\phi$ values estimated for all datasets did not differ significantly among larval stages (Tables 2-6). Although the lower  $(T_L)$  and upper  $(T_H)$  threshold temperatures for larval development estimated for most study datasets both tended to increase with stage number, these did not significantly differ among larval stages based on comparisons using 95% C.I.s bootstrapped using the bootstrap percentile or  $BC_a$  methods (Tables 2-6).

#### **3.3. Comparisons among Studies for Each Larval Stage**

Comparisons of estimated values of the  $T_L$ ,  $T_H$ , and  $T_\phi$  parameters among study datasets for the same larval stage or combinations of stages did not result in consistent overall differences among studies. Often estimates based on data from Hudon and Fradette (1988) (Tables 4, 7, and 8) and Quinn et al. (2013) (Tables 5 and 7) were lower or higher than those based on most other studies' data, but with no consistent directionality or significance (Tables 2, 3, and 6-8). Differences among studies were more often significant for the *T<sup>Φ</sup>* than for the  $T_L$  and  $T_H$  parameters, especially when  $T_\phi$  estimates were compared based on 95% C.I.s bootstrapped using the ABC method (Tables 2-8; Figure 8).

Figure 8. Estimates of the intrinsic optimum temperature (*T<sup>Φ</sup>* or T-Phi) for the development of American lobster larvae estimated with the SSI model for each larval stage or combination of stages (x-axis) using data from different source studies (different symbol types; see Table 1). T-Phi estimates are presented in units of °C (y-axis). Error bars represent the lower and upper bootstrap 95% C.I.s calculated for each parameter estimate using the ABC method in R with the *mABCSSI* package of Ikemoto et al. (2013). For clarity, the y-axis in this figure is constrained to between 12-22°C; 95% C.I.s that extended beyond this range are not shown in their entirety, but the values of the three T-Phi estimates that were outside of this range are presented as numbers at the top or bottom of the graph. T-Phi estimates were compared among stages and studies based on whether their bootstrapped 95% C.I.s and estimates overlapped.

For analyses of *T<sup>Φ</sup>* estimates for data for the total combined development from hatch to stage IV, the estimates based on different studies' data were all significantly different from one another based on their ABC-derived 95% C.I.s (Table 7; Figure 8), with the *T<sup>Φ</sup>* estimated for Quinn et al. (2013) being significantly higher than that estimated for all other studies, and that for Harrington et al. (2019) being significantly higher than those for all other studies except for Quinn et al. (2013) (Table 7; Figure 8). For total development from hatch to stage V, the *T<sup>Φ</sup>* values estimated for data from MacKenzie (1988) and Hudon and Fradette (1988) did not significantly differ from each other according to their ABC-derived 95% C.I.s, but that estimated for data from Templeman (1936) was significantly higher than those for both of these studies (Table 8; Figure 8).

#### **3.4. Results for All Datasets Combined**

The SSI model parameter estimates and plots of the SSI development function produced from analyses of all studies' datasets combined are presented in Table 9 and Figure 9, respectively.

If data from all studies were combined, the data for all stages produced reasonable development curves (Figure 9). The *T<sup>Φ</sup>* value estimated for stage I based on data from all studies was significantly lower than those of stages II and III, but all other comparisons of  $T_{\phi}$ among stages were non-significant (Table 9). Comparisons of  $T_L$  and  $T_H$  estimates based on data from all studies combined among stages based on their bootstrap percentile- and BCaderived 95% C.I.s were all non-significant (Table 9), and *T<sup>Φ</sup>* estimates also did not significantly differ among stages when assessed based on these bootstrapped 95% C.I.s (Table 9). Aside from the significant difference between the *T<sup>Φ</sup>* of stage I and those of stages II and III, these comparisons of parameter estimates for all studies' data based on bootstrap 95% C.I.s generally agreed with the conclusions of preliminary analyses using ANOVAs (section 3.1 and Figure 7).

	Parameter	Estimate	LCI (BP/ABC)	UCI (BP/ABC)	LCI (BC <sub>a</sub> )	UCI (BC <sub>a</sub> )

**Table 9. SSI parameter estimates for data from all studies combined**

Notes: LCI and UCI = lower and upper 95% C.I.s estimated with the bootstrap percentile (BP),  $BC<sub>a</sub>$ , or ABC methods; ABC-derived 95% C.I.s were calculated for T-Phi only, and are presented in the same columns as BP-derived 95% C.I.s, but one row beneath them;  $aE \pm b = a \times 10^{\text{th}}$ ; N/A = could not be estimated; NaN = non-numeric estimate; T-Phi, TL, and TH estimates are presented in units of °C; for the units and meanings of all SSI model parameters, see equation (1) in the Introduction, and for their abbreviations in this Table and in *OptimSSI* output, see section 2.2.

Based on all studies' data,  $T_{\phi}$ ,  $T_L$ , and  $T_H$  estimates ranged from 16.534 to 17.326°C, 0.095 to 7.804°C, and 23.483 to 25.661°C, respectively (Table 9). All of these estimates of *TΦ*, most estimates of *T<sup>L</sup>* (except those for stages IV and I-IV, which were too high, 6.949 and 7.804 $\degree$ C, respectively), and none of the estimates of  $T_H$  (all were  $\lt$  26.3 $\degree$ C) were biologically realistic (Table 9; Figure 9). Compared with estimates based on individual studies' datasets (Tables 2-8), those based on all studies combined were more consistent among stages, were

more reliable in that they had smaller bootstrap 95% C.I.s, and tended to be more realistic (Table 9).

Figure 9. SSI model curves fit to development rates (y-axes, in 1/days) of American lobster larvae through different stages (different panels) at different temperatures (x-axes, in °C), using data from all studies combined (see Table 1). Solid circles = observed data within the linear portion of the development curve; open circles = observed data outside the linear range; gray lines = the SSI development curve fit to all observed data; black lines = linear fit of data in the linear portion of the development curve; open squares = estimates of (from left to right)  $T_L$ ,  $T_\phi$ , and  $T_H$  based on the plotted data and curves. All plots made in R with the *SSIPlot* function of Ikemoto et al. (2013).

# **4. DISCUSSION**

# **4.1. Variability and Issues among Estimates Based on Different Source Studies' Data**

This chapter represents the first published application of the SSI development function to American lobster larval development data, as well as the first time that such a thermodynamic

model has been used to estimate the intrinsic optimum temperature for the development of this species' larvae. When the estimated  $T_{\phi}$ ,  $T_L$ , and  $T_H$  values for a given larval stage produced for data from different individual studies were compared, however, they were found to vary markedly from one another, and in many cases the biological realism of these estimates and their reliability (inferred based on the width of their bootstrap 95% C.I.s) was very poor. Therefore, the discussion in the present section was restricted to explaining the sources of these variations and issues with individual studies' results, while comparisons of thermal parameter estimates to the published literature and discussion of their implications were saved for the discussion of estimates based on all studies' data combined in the following section (4.2).

The source data came from studies that used different larval source populations, and thus some differences could be expected among studies as a result of geographic differences in temperature-dependent development reflecting local thermal adaptation or acclimation (Quinn et al. 2013; 2017); indeed, the clear differences between the shapes of the development curves (and consequently thermal parameters) derived for data from Quinn et al. (2013) from those for all other studies, which were conducted in more southerly and relatively warm-water regions (Quinn and Rochette 2015), may support the conclusion that that study found evidence of thermal adaptation. However, the magnitudes of the differences found herein in thermal parameters, including among geographically close source locations, were far too great for this be a sufficient explanation by itself.

The data analyzed came from eight different studies spanning more than a century of research on lobster larvae (1906-2019), which obviously varied in a number of additional ways from one another in terms of the temperature range tested, setting (lab vs. field), holding conditions of larvae (individual vs. communal), temperature control (constant vs. variable) (Table 1), and many other ways (e.g., food, photoperiod, sample sizes, etc.; reviewed by MacKenzie (1988) and Quinn et al. (2013)). Such differences among studies were thus more likely reasons for the observed variability, and thus the limiting and optimum temperatures estimated based on any one specific study herein should likely not be considered representative of the entire species' developmental characteristics. The field sampling study of Hudon and Fradette (1988) produced particularly problematic estimates, which was likely due to the limited range of temperatures that can be captured by field sampling (see below), as well as possible errors resulting from not tracking the same larval individuals or cohorts across sampling dates (Annis et al. 2007; Quinn et al. 2013, 2017; Gendron et al. in press). In the future, then, estimation of SSI model parameters based on such indirect field sampling methods should probably be avoided. The small samples sizes included in the data from most of the individual studies examined (Table 1) were also likely too small to permit optimal fitting with the SSI model and the calculation of very precise 95% C.I.s for its parameter estimates (Ikemoto et al. 2013); this justified the analyses performed on combined data (see section 4.2).

The factor that likely had the greatest impact on the differences in the estimated thermal parameters among studies was the difference in the thermal ranges they used (Kontopoulos et al. 2018; Table 1). Although overall a thermal range from 6.7 to 26.3°C was investigated, which should extend into the nonlinear portions of the temperature-development curve and approach the actual  $T_L$  and  $T_H$  values for lobster larvae, no single study covered this entire range, and some covered very small ranges (e.g., 3.2-6.2°C: Hudon and Fradette 1988) and/or only extended towards very low (Templeman 1936) or high (Ford et al. 1979) temperatures,

but not both. The fitting of a complex nonlinear function like the SSI model to development data can only be accurate if the data cover both the lower and upper nonlinear portions of the development curve in addition to the intermediate linear portion (Schoolfield et al. 1981; Shi et al. 2011, 2017, 2019; Ikemoto et al. 2013). If one or more portions of this range are missing, then estimated thresholds will be placed either just outside of the observed data range (if there is some nonlinearity in the data) or very far beyond it (if the data are highly linear), which in either case results in unrealistic estimates (Jafari et al. 2012; Shi et al. 2012a, b, 2013; Quinn 2017b; Kontopoulos et al. 2018), and will also create quite wide and asymmetrical bootstrap 95% C.I.s. This can also result in a fit to data from one study estimating a threshold within the range of temperatures over which development was observed to be completed in another study; for example, the very high  $T_L$  estimate of 12.988°C for data from Ford et al. (1979), who only reared larvae at temperatures higher than 16.9°C, was well within the range of temperatures at which development was completed in most other studies considered (Table 1).

# **4.2. Interpretation and Implications of Estimates Based on All Studies' Data Combined**

To account for the above shortcomings, in this chapter SSI fits were also attempted using all studies' data combined. Although doing this masked much of the variability within the datasets (e.g., the strong differences in the development curves of Quinn et al. (2013) from all others; Figure 9) and was still not able to estimate biologically realistic  $T_H$  values > 26.3°C (Table 9), it did allow the widest thermal range possible to be investigated. Further, this approach resulted in much more reasonable and consistent parameter estimates than did analyses with individual study datasets. It also allowed a few patterns to be detected that were missed by preliminary analyses using conventional ANOVAs to make comparisons among stages. Using this approach, the  $T_{\phi}$ ,  $T_L$ , and  $T_H$  of American lobster larvae were estimated to be 16.534-17.326°C, 0.095-7.804°C, and 23.483-25.661°C, respectively (Table 9). Although these estimates did increase, to some extent, with stage number (i.e., thermal parameters of later stages tended to have higher values than those of earlier stages), none of these parameters differed significantly among stages except that the  $T<sub>\phi</sub>$  of stage I was less than that of stages II and III.

The range of  $T_L$  values found was mostly reasonable, although a few were too high, while all  $T_H$  estimates were likely too low, but perhaps close to (i.e., within  $\sim 2^{\circ}C$  of) being reasonable. The range of estimates of  $T_L$  and  $T_H$  produced agreed in general with previous experimental observations (Huntsman 1924; Sastry and Vargo 1977; Gruffydd et al. 1979; Quinn 2017a) and with those derived using other nonlinear development functions by Quinn (2017b) but with fewer  $T_L$  values of 0°C found, perhaps related to the inability for SSI parameter estimates to be constrained in the present analyses (see section 4.3 below). The lack of significant differences in *T<sup>L</sup>* and *T<sup>H</sup>* among stages may disagree with previous studies, in which thermal tolerance was suspected of increasing with stage number (e.g., Huntsman 1924; Gruffydd et al. 1979) or being lower in stage II (Sastry and Vargo 1977), although such results were overall inconclusive (Quinn 2017a). There is evidence from many arthropod taxa that developmental proportions, temperature effects, and thermal thresholds differ among stages (Quinn 2019). However, the rate isomorphy hypothesis developed in other studies of ectotherms, including arthropods like crustaceans (e.g., Jarošík et al. 2004), alternatively suggests that such thermal developmental threshold should not differ among stages within the same species, and that most apparent differences in these found among stages result from experimental errors. The lack of differences found herein therefore may agree with rate isomorphy, although due to the wide variability in the estimates obtained thus far this is uncertain.

Ultimately, if the thermal optima and limits for development differ among larval stages, this will have important implications to how larvae are affected by temperature changes in nature; for example, if the optima and tolerance limits of earlier stages are lower than those of later ones, then they could be impacted the soonest and most severely by climate warming (Sastry and Vargo 1977; Schmalenbach and Franke 2010; Caputi et al. 2013; Quinn 2019). Although the overall results found herein (as well as some of the results from analyses of individual study datasets) may suggest such stage-specific differences, the magnitudes and significances of the differences among the  $T_L$  and  $T_H$  estimates were too low and/or variable to conclude that such differences exist based on these data. However, The *T<sup>Φ</sup>* estimates produced through these analyses were much more consistent and realistic, and thus considering them may be more informative. According to Ikemoto et al. (2013), the *T<sup>Φ</sup>* parameter in the SSI model is related to the other thermal parameters (e.g.,  $T_L$  and  $T_H$ ) therein as follows:

$$
T_{\phi} = \frac{\Delta H_L - \Delta H_H}{R \ln \left( -\frac{\Delta H_L}{\Delta H_H} \right) + \left( \frac{\Delta H_L}{T_L} \right) - \left( \frac{\Delta H_H}{T_H} \right)}\tag{2}
$$

Therefore, comparisons of more reliable  $T<sub>\phi</sub>$  estimates may allow inferences to be drawn about the general differences in thermal tolerances, if there are any, among lobster larval stages, including differences in their presumed  $T_L$  and  $T_H$  parameters.

The overall values and consistency among stages of the *T<sup>Φ</sup>* estimates found herein were interesting. In previous research, the  $T<sub>Φ</sub>$  of terrestrial insects and arachnids was found to be mainly around 20°C (ca. 15-25°C) (Ikemoto 2005, 2008; Shi et al. 2011, 2012a, 2012b, 2013; Jafari et al. 2012; Ikemoto and Egami 2013; Padmavathi et al. 2013; Sreedevi et al. 2013), while those for decapod crustaceans varied among habitats, being approximately 7-9°C or 19- 27°C for species from cold- and warm-water habitats, respectively (Yamamoto et al. 2017) (Shi et al. 2019). The estimates found herein for American lobster are thus reasonable in light of the literature on arthropod developmental optima. Previous studies of American lobsters estimated (based on various criteria) that the optimal temperature for rearing their larvae was ca. 18-20°C (Van Olst et al. 1976; Carlberg and Van Olst 1977; Ford et al. 1979; Bartley et al. 1980; Quinn 2017a), which is close to (but slightly higher than) the intrinsic optimum temperatures estimated herein; these two sets of findings therefore lend some support to one another. The fact that, with one exception, the  $T<sub>\phi</sub>$  was mostly consistent across stages also agreed with the rate isomorphy hypothesis (Jarošík et al. 2004), but not with other studies that suggested differences in thermal optima among developmental stages (e.g., Sastry and Vargo 1977; Quinn 2019). However, the significantly lower *T<sup>Φ</sup>* of stage I than that of stages II and III does provide some evidence that thermal tolerances increase, if only slightly, among larval stages, which does agree somewhat with past studies (Huntsman 1924; Gruffydd et al. 1979) and make sense in light of the seasonal thermal trajectory from the time of larval release to

settlement across most of the species' range (Ennis 1995; Lawton and Lavalli 1995; Quinn and Rochette 2015).

The implications of lobster larvae developing optimally between 16.534 and 17.326°C are also of interest. Throughout most of this species' range, seawater temperatures  $\geq 18^{\circ}$ C were historically uncommon during the summer, when larvae are in the water (Quinn and Rochette 2015; Jaini et al. 2018), but recent climate change has resulted in waters being warmer during the summer (Guo et al. 2013; Quinn 2017a). In historically colder parts of the species' range, warming has been associated with increased abundances and fisheries landings of lobsters (Caputi et al. 2013; Jaini et al. 2018), which may be partly associated with lobster larvae more often experiencing temperatures close to or at their intrinsic developmental optimum, in addition to there being beneficial impacts of warming on other life stages (adults, juveniles, and eggs) and processes (e.g., predator-prey interactions: Boudreau et al. 2015). Conversely, in historically warmer parts of the species' range, temperatures exceeding 22°C now occur in the summer, and lobster abundances have declined (Guo et al. 2013; Boudreau et al. 2015); perhaps the fact that lobster larvae are exposed to supra-optimal temperatures in these regions, resulting in stress, physiological impairment, and perhaps some mortality, is related to these recent declines (Quinn 2017a). Throughout the species' range, summer water temperatures experienced by larvae are expected to increase into the future (Guo et al. 2013; Quinn 2017a), so it is possible that more lobster larvae will experience temperatures too far above their optima, perhaps even approaching their  $T_H$ , which may lead to further declines. The possibly lower optimum temperature found for stage I than those for later stages could also mean that this stage will be affected first and most strongly by rising water temperatures in the future.

#### **4.3. Findings Relevant to SSI Model Fitting Procedures**

In this chapter, comparisons of  $T_{\phi}$  estimates based on their 95% C.I.s bootstrapped using the ABC method detected statistically significant differences among stages and studies far more often than equivalent comparisons based on 95% C.I.s bootstrapped using the bootstrap percentile and  $BC_a$  methods. This confirms the conclusion of Ikemoto et al. (2013) that it is most appropriate to bootstrap and compare C.I.s of  $T<sub>Φ</sub>$  estimates using the ABC method. Congruently, all comparisons of  $T_L$  and  $T_H$  estimates, which were based on analyses of bootstrap percentile- or BCa-derived C.I.s only, were non-significant. It seems reasonable to expect, however, that if 95% C.I.s could be calculated for  $T_L$  and  $T_H$  estimates using the ABC method, then some significant differences might be detected that are lost in comparisons using bootstrap percentile- or  $BC_a$ -derived C.I.s because these tend to innately be too wide and variable, particularly for limited datasets such as those used in the present chapter. Although the  $T_L$  and  $T_H$  of a species are related to its  $T_\phi$  (Ikemoto et al. 2013; see equation (2) above), it is still important to know their precise values when making predictions of future changes. Therefore, in the future, a follow-up study to Ikemoto et al. (2013) should be done to develop a program like their *mABCSSI* package that would allow bootstrap C.I.s for *T<sup>L</sup>* and *T<sup>H</sup>* estimates to be calculated using the ABC method.

Many of the thermal parameter estimates derived from the SSI model in the present chapter were also concluded to be biologically unrealistic. This resulted partially because the *OptimSSI* package does not currently contain the means to constrain its parameter estimates.

When performing nonlinear regressions in many statistical packages, for example IBM SPSS Statistics, it is possible to define constraints on development function parameters that can 'force' them to be estimated within bounds defined by the user as 'realistic' (Guerrero et al. 1994); for example, this approach was used by Quinn (2017b) when fitting various complex nonlinear development functions including  $T_L$  and/or  $T_H$  parameters to arthropod larval development data. Typically this approach achieves a poorer fit than an unconstrained regression would, but avoids estimating unrealistic values for parameters that are defined as having biological meaning (Kontopoulos et al. 2018). Therefore, the addition of a means to constrain thermal parameter estimate values to the *OptimSSI* package (or more accurately a successor to it) should also be pursued.

The evaluation of the biological realism of *T<sup>L</sup>* and *T<sup>H</sup>* may also need to be revisited, or the implications of these parameters as defined in the SSI model to developmental observations considered more carefully. In the SSI model,  $T_L$  and  $T_H$  are the temperatures at which an enzyme involved in development is half active and half temperature-inactivated (Sharpe and DeMichele 1977; Schoolfield et al. 1981; Shi et al. 2011; Ikemoto et al. 2013), and thus at these temperatures not *all* copies of the enzyme are inactivated (Kontopoulos et al. 2018). Thus, while development would certainly be greatly impaired at or below these temperatures, it would not be entirely impossible. In laboratory studies, larval survival at near-extreme temperatures is often markedly reduced, but some individuals still manage to complete development (e.g., Templeman 1936; MacKenzie 1988). In this case, it is conceivable that they could be experiencing  $T_L$  or  $T_H$  conditions corresponding to the definitions in the SSI model, but development is still possible (Kontopoulos et al. 2018). This differs from the definition of equivalent lower and upper thermal thresholds in other development functions, at which development is supposed to be impossible (Quinn 2017b). Some of the estimated thermal limits produced in this chapter that were considered biologically unrealistic were only slightly within the range over which previous studies had observed some successful development, although with impaired larval survival (e.g., within 1-2°C of 6.7°C or 26.3°C (Templeman 1936; Ford et al. 1979)). Such estimates may thus in fact be realistic, but would need to be interpreted differently; this possibility should be investigated in a later study.

The definition of which portion of the datasets subjected to analyses with the *OptimSSI*  package was within the 'linear' portion of the temperature-development curve also impacted the shapes of the development curves and values of the thermal parameter estimates it produced (*sensu* Campbell et al. 1974; Ikemoto and Takai 2000; Ikemoto et al. 2013). This was because the linear fit produced at this point provided starting values for the values of *T<sup>L</sup>* (and thus indirectly of  $T_H$  and  $T_\phi$ , since these are interrelated (Ikemoto et al. 2013)) that were then fed into nonlinear regression procedures within this program, and such starting values can impact the final parameter estimates produced through such procedures (Campbell et al. 1974; Quinn 2017b). The data for stage IV analyzed from Hudon and Fradette (1988) herein provide an extreme example of this: due to the very narrow thermal range examined and the wide variability in development rates within it, the linear fit produced ended up having a *negative* slope (Figure 9), implying that development generally *slowed* as temperature increased, and resulting in the  $T_L$  produced being *greater* than the  $T_{\phi}$  and  $T_H$  (which were <  $0^{\circ}$ C!) (Table 4, Figure 8). In less extreme cases, the relatively shallow slope of the linear fit produced (e.g., data for Quinn et al. (2013)) and/or the lack or limited amount of data within the nonlinear portion of the development curve led to unnaturally extreme thermal parameter estimates and abnormal development curves (see sections 3.2 and 3.3).

In a series of side analyses (results not shown), for several of the datasets for which biologically unrealistic parameter estimates and/or abnormal development curves were produced using the definition of the linear portion set herein (temperatures  $> 12^{\circ}$ C and  $<$ 26.3°C; see section 2.2), changing the bounds of the linear portion produced more reasonable results. However, this procedure of 'optimizing' the linear portion's definition for each dataset was avoided in the main results presented in this chapter because it was considered potentially dubious. As all datasets examined herein were for the same species, it was unclear whether it was justifiable to redefine the shape of the development curve from study to study and/or stage to stage to this extent. It is entirely possible that the shape of the temperaturedevelopment curve, including the breath and bounds of its linear portion, could differ among the different populations of the same species examined in different source studies due to geographic variation (e.g., Quinn et al. 2013). However, given that no study has fully spanned the entire range of temperatures over which American lobster larval development is possible (see above and Table 1), we do not currently have sufficient information to conclude exactly where transitions in the development curve occur, much less whether their thermal location differs geographically. The potential sensitivity of the *OptimSSI* package to the definition of the linear portion of the development curve and its implications will bear further investigation, as will the better definition of the full development curve(s) of lobster larvae.

#### **4.4. Need for New Rearing Studies to be Analyzed with the SSI Model**

The present chapter produced a large database of SSI model parameters and their bootstrap C.I.s that may be useful for future studies of this species. However, based on the wide variability of the results among stages and source studies, this information cannot, unfortunately, be said to provide conclusive evidence of the exact optimum and limiting temperatures for the development of lobster larvae (although results produced based on all studies' data combined (Table 9) are potentially promising). The chief issue confounding the results is the fact that no one study of American lobster larval development has yet spanned the entire range of temperatures biologically relevant to the larvae of this species, i.e., those extending from its actual  $T_L$  to its actual  $T_H$ , which must be < 6.7°C (Templeman 1936) and > 26.3°C (Ford et al. 1979), respectively (Quinn 2017a). However, this shortcoming is by no means unique to the American lobster. For the vast majority of marine decapod crustaceans, studies of larval development have historically focused on rearing larvae at a few temperatures within a limited, but presumably most biologically relevant, range to assess their differential survival, growth, development times, etc. at different temperatures (Anger 2001; Quinn 2017b). Studies of crustacean development at thermal extremes and the identification of thermal thresholds have thus been less of interest, and rearing over a wide range of temperatures including extremes is often impractical and expensive for marine larvae, while conversely such studies are commonplace for terrestrial insects and arachnids (Quinn 2017b and references therein; see also: Campbell et al. 1974; Ikemoto 2005, 2008; Shi et al. 2011, 2012a, 2012b, 2013; Jafari et al. 2012; Ikemoto and Egami 2013; Padmavathi et al. 2013; Sreedevi et al. 2013).

However, this is beginning to change (e.g., Yamamoto et al. 2017), and given concerns about the effects of climate change on American lobster fisheries recruitment (Caputi et al. 2013; Boudreau et al. 2015; Jaini et al. 2018; Quinn 2017a) it is time for such an extensive
and thorough study to be done for this species' larvae. For example, a study rearing larvae in the laboratory at as many controlled temperatures as possible (optimally  $\geq 10$ ; Ikemoto et al. 2013) between ca. 0-5°C and ca. 27-30°C or higher should help to identify the lower and upper developmental thresholds and better define the shape of the development curve between them.

It should also be noted that most thermal parameter estimates produced for stage IV from a single study's dataset or with all studies' data combined in this chapter tended to be particularly variable and/or unrealistic. This was likely due in part to the low sample sizes available within individual studies for this stage, as well as the low number (3) of studies that provided data for its duration (Table 1). However, because stage IV is the settling stage of the American lobster's lifecycle, its duration can also be affected strongly by other factors besides temperature, especially the availability and type of bottom substrate. For example, in the absence of suitable substrate for settlement (cobble), this stage can be prolonged as a form of settlement delay, whereas if substrate is provided it can be greatly shortened (Phillips and Sastry 1980; Ennis 1995; Lawton and Lavalli 1995). Previous development studies done in the laboratory did not provide stage IV lobsters with substrate (Templeman 1936; MacKenzie 1988), which may have artificially prolonged this stage and also exacerbated developmental and behavioral differences among individuals. Therefore, a future study aiming to assess thermal parameters of stage IV development must also account for the impacts of substrate on its duration, for example by holding stage IV lobsters not only at different temperatures, but also with or without different types of substrate for settlement.

Once such a study has been done, analyzing its data using the SSI model, as done herein, should provide valuable information on the temperature-dependent development of this species' larvae, including their developmental thresholds and optimum temperature(s), which can then be used to predict the effects of future climate change on them. This chapter provides a framework to support the enactment of such a study. Further, the approaches taken herein could and likely should be applied to data for other species of lobsters and other decapod crustaceans, as these also support important fisheries that depend on larval supplies (e.g., Yao and Zhang, 2018) that are potentially impacted by changes in water temperature (Phillips and Sastry 1980; Caputi et al. 2013; see also other chapters in this volume).

## **CONCLUSION**

The estimates of the thermal parameters (*TΦ*, *TL*, and *TH*) of American lobster larval development obtained using the SSI model in this chapter varied widely among studies, but with no consistent and few significant differences in them among stages. Although most  $T_{\phi}$ estimates were biologically realistic, the majority of  $T_L$  and  $T_H$  estimates were not. When all studies' datasets were combined, the  $T_{\phi}$ ,  $T_{L}$ , and  $T_{H}$  for American lobster larval development were estimated to be 16.534-17.326°C, 0.095-7.804°C, and 23.483-25.661°C, respectively. The *T<sup>Φ</sup>* of stage I was significantly lower than those of stages II and III, but all other differences among stages were non-significant. However, none of the previous studies whose data were analyzed herein were conducted over a wide enough thermal range to allow for a conclusive fit of their data with the SSI model to be achieved. Therefore, a future rearing study conducted over a wide thermal range, followed by analyses with the SSI model, is

needed to better define the limiting and optimum temperatures for the development of this species' larvae for use in predicting the potential effects of climate change on its fisheries recruitment.

#### **ACKNOWLEDGMENTS**

The University of New Brunswick (UNB), Saint John Campus provided access to resources needed for this research. I thank Peijian Shi for introducing me to the SSI model and the *OptimSSI* package, and also providing helpful advice and guidance in its use. Erin Miller reviewed this chapter and provided helpful comments that improved it. I also thank M. Quinn for regular help and support, and Nadya S. Columbus and Nova Science Publishers, Inc. for inviting me to contribute to the present collection.

## **ABSTRACT**

A series of selected biological, ecological, and morphological traits of North Atlantic decapod crustaceans were used to discuss the possible biotope of juvenile European lobsters, *Homarus gammarus* (Linnaeus, 1758), and how to approach filling our knowledge gaps regarding the whereabouts of this life stage in nature. The information examined provided a review of what is known and what is anticipated regarding this species. This comparative and holistic ecological approach will provide useful information for future studies of the 'missing link' in this species' life history – small, juvenile European lobsters. Three hypotheses for the reasons these life stage have not been found are that they are: (1) located too deep to be found in shoreline-based field studies; (2) distributed too scarcely to be found; or (3) living deep inside shelters, which are unapproachable by competitors, predators, and humans. We compared the ecomorphology, life history, habitat, and behavior of *H. gammarus* to those of *Homarus americanus* H. Milne Edwards, 1837, as well as to those of other decapod species living within a similar geographical range to that of adult lobsters. The main differences found among the biotopes of the homarid lobsters were in the diversity of their predators and the number of competitive decapods present, which are both higher in European shallowwater cobble bottom areas. This should have strong impacts on the survival probabilities of settling lobsters. Larvae and adults of *H. gammarus* are found at much lower densities than those of *H. americanus*, although early-stage larvae of both species are regularly caught in light traps and plankton nets. Field and laboratory studies indicate limited dispersal of larvae in *H. gammarus*. In the laboratory, settling juveniles of both species show clear preferences for shelters by burrowing underneath or beside solid objects, which is symptomatic of a cryptic life habit. Juvenile *H. gammarus* show traits that are

 $\overline{a}$ 

<sup>\*</sup> Corresponding Author's Email: GroM@hi.no.

suggestive of adaptations to shallow habitats, even potentially to intertidal life. The higher biodiversity in European shallow waters may cause the young lobsters to stay sheltered deeper within the substrate in shallow places that competitors and predators cannot reach.

## **1.INTRODUCTION**

Traditionally, the acquisition of information on wild-living species used to be focused on assessing the presence and life habits of mature individuals. However, in the last century the importance of learning about the full life history to understand the ecology of an organism has become apparent, and is now known to be crucial to protecting and managing wild populations sustainably (Sadovy 2001; Denney et al. 2002). Lobsters, particularly the homarid species (*Homarus* spp.), are potentially vulnerable to overexploitation because they are long-lived and of low to medium fecundity (Agnalt et al. 1999; Wahle et al. 2013a). However, the whereabouts of the early life stages of the European lobster, *Homarus gammarus* (Linnaeus, 1758), are still an unsolved mystery (Mercer et al. 2001; van der Meeren 2005).

While little is known about the larger, commercially important decapod crustacean species of the Northern Atlantic Ocean, there are few species for which there are such limited field observations of critical life history stages as for *H. gammarus*. However, it is possible that more could be learned about these concealed life stages by comparing this lobster's living biotope, morphology, and behavior with those of other decapod crustaceans. Comparing behavioral traits is an established method in evolutionary science, which has been used to define phylogenetic relationships and evolutionary connections among taxa (Clutton-Brock and Harvey 1984; Harvey and Nee 1997). Ecomorphological adaptation has also been used as a tool to look at evolutionary habitat shifts in crabs (*Cancer* spp.) by analyzing such traits as size and habitat (Harrison and Crespi 1999). Life history traits include parental investment, which is closely connected to the ecological constraints placed on parents and offspring (Clutton-Brock and Godfray 1991). A comparison of such traits among a selection of North Atlantic decapod crustacean species was presented and discussed in this chapter. The reasoning behind this approach was that evolution and adaptation should have resulted in each species' body shape, pigmentation, environmental requirements, settlement and establishment choices, and behaviors in general being adapted to their optimal living biotope.

This chapter investigated and compared a selection of North Atlantic decapod crustacean species (Figure 1). This included: three nephropid lobsters, the European lobster *H. gammarus*, American lobster *Homarus americanus* (H. Milne Edwards, 1837), and Norway lobster *Nephrops norvegicus* (L., 1758), as well as the limnic noble crayfish *Astacus astacus* (L., 1758); brachyuran crabs, including the brown or edible crab *Cancer pagurus* (L., 1758) and green shore crab *Carcinus maenas* (L., 1758); the European spiny lobster *Palinurus elephas* (Fabricius, 1787); anomurans, such as the spiny squat lobster *Galathea strigosa* (L., 1761) and red king crab *Paralithodes camtschaticus* (Tilesius, 1815); and natantian species,

including the hooded shrimp *Athanas nitescens* (Leach, 1813) and northern deep-water shrimp *Pandalus borealis* Krøyer, 1838.

Figure 1. Selected decapod species with home ranges in the Northern Atlantic region of Europe, from upper-left to lower-right: *Homarus gammarus* (Linnaeus, 1758), *Homarus americanus*  H Milne Edwards, 1837, *Nephrops norvegicus* (Linnaeus, 1758), *Pandalus borealis* Krøyer, 1838, *Galathea strigosa*, (Linnaeus, 1761), *Athanas nitescens* (Leach, 1813), *Cancer pagurus* (Linnaeus, 1758), *Paralithodes camtschaticus* (Tilesius, 1815), *Carcinus maenas* (Linnaeus, 1758). Two nonnative species, *Homarus americanus* and *Paralithodes camtschaticus*, are present in northeastern Atlantic and Barents Sea waters. 'Lobster-shaped' species in upper section, 'crab-shaped' decapods in the lower section. Photographers: *P. borealis* by Ø. Paulsen/IMR, *A. nitescens* by Nils Aukan, the rest by AK Woll.

The above species are all temperate- to cold-water-adapted and occupy the same trophic level spectrum (2 to 3), but live at different depths, have different habitats and diurnal habits, and face different levels of competition and predation pressure (Williamson 1905; Pearson 1908; Herrick 1911; Crothers 1967, 1968; Christiansen 1969; Ansell and Robb 1977; Cooper and Uzmann 1980; Shumway et al. 1985; Factor 1995; Hunter 1999; Bergström 2000; Ulmestrand and Eggert 2001; Goñi and Latrouite 2005; Poore et al. 2011; Groeneveld et al. 2013; Stevens 2014; Sundet 2014; Füreder 2016). The little information found on *A. nitescens* was limited to the traits most of the other species have in common (Palomares and Pauly 2018), so this species was not included in the statistical comparisons performed. Even when information had been published on the traits of mature individuals of the rest of these species, information on the juvenile stages is lacking for several of them, not only *H. gammarus*. Some of the information that is available comes from laboratory studies, which may not extrapolate exactly to wild individuals. Nevertheless, our approach is an attempt that may possibly deduce the potential living areas and ecology of the hitherto cryptic life stages of young *H. gammarus*.

## **2. METHODS**

Interspecific similarities and differences in traits among species and their implications were assembled and analyzed for the following categories and types of traits:

- Morphology (Table 1): body shape; shape and relative strength of pereiopods, including chelae; spines in the larval stages; abdominal (tail) flexibility; carapace spines (adults and juveniles); length of second antennae relative to body length; and pigmentation.
- Life history (Table 2): Maximum age (lifespan); age of maturation; maximum size; fecundity; duration of larval period; and size at settling.
- Biotope (Table 3): use of shelter; habitat type; depth; competitors (other decapod species and groups); and predator diversity.
- Behavior (Table 4): Burrowing; tail flip escape response; nocturnal activity; level of aggression; social behavior; and diet.
- Other parameters (Table 5): Temperature range; and trophic level.

The above traits were analyzed and classified using cladistics and principal component analysis (PCA), inspired by the methods used for natural classification by Nelson and Platnick (1981) and Williams and Ebach (2004). Results of statistical analyses were discussed and related to the specific traits of each species, in both its mature and juvenile life stages. The significances of particular traits in relation to life history strategies were also discussed. The traits compared are shown in Tables 1-5.

For analyses, the phenotypic trait categories from Tables 1-5 were represented as numerical variables prior to performing clustering analyses (Tables 6 and 7). Clustering analyses were fitted by the 'Agnes' method (Kaufman and Rousseeuw 1990), implemented in the '*cluster*' package (Maechler et al. 2018) in R v.3.5.1 (R Core Team 2016).

The effects of ecologically important traits (predation pressure and competitive species richness) for the two *Homarus* species were analyzed to look at their possible impacts on survival strategies used in the juvenile phase of these two species.

The PCA conducted reduced *N* descriptive variables to *n* independent principal components (PCs). Retaining the PCs that explained the greatest proportions of the variance in the data reduced the dimensionality of the data to allow for greater ease of interpretation of the patterns present.

Table 1. #### **Table 5. Other traits (temperature range and trophic level) compared among adults and juveniles of the selected decapod species**

References: See Table 1.

In the PCA, the first three and six principal axes explained 59% and 84% of the total variance, respectively. Subsequent analyses were thus based on the first six out of 19 principal component axes.

The traits from all sections were included in the main analyses, but the significance of the different types of traits were discussed in separate sections when comparing species and life stages.

The trait information analyzed was collected from the trait databases at SeaLifeBase.org (Palomares and Pauly 2018) and MarLIN.uk.ac (MarLIN 2016), from scientific papers and books (cited in Tables 1-5), and, for some traits, the authors' personal observations and observations by experienced lobster professionals.

## **3. RESULTS**

## **3.1. Overall Comparisons among Decapods**

The results of the main clustering analysis are presented in Figure 2. On the dendrogram, the adult and juvenile stages of four species clustered together as each other's nearest neighbors (*A. astacus*, *P. borealis*, *N. norvegicus*, and *P. camtschaticus*). For the remaining species, the nearest neighbor of a group was usually the same life stage of another species. In such cases, the two species formed two clusters, where the first cluster consisted of the two adult stages and the second consisted of the two juvenile life stages; for example, this was found for *H. gammarus* and *H. americanus*. For these species, it can be inferred that the amount of dissimilarities between species at the same life stage was less than the amount of dissimilarities within the same species between different life stages.

However, for *H. gammarus*, the information on the life habit and biotope of juveniles (< 25 mm carapace length (CL)) included in the above analyses was based on laboratory studies. This was because these juveniles have never been seen in the field, except for a handful of single occasions in different habitats over a 40-year period. Anecdotal observations were made, but not published, of one *H. gammarus* juvenile in an empty mussel shell in shallow water in Sweden (observed by B. Dybern in the 1970s), one in a pearl net for oysters in Denmark (observed by C. Formsgaard Nielsen in 2015), and one in a crack between rocks in Norway (observed by A. K. Woll in 2015, see Figure 4). However, in the laboratory the two species behave very similarly (Wahle et al. 2013a), as is also reflected in the limited juvenile data available in Tables 1-5. The nephropid lobsters clustered together, and separated into one juvenile and one adult cluster (Figure 2), but the juvenile *H. gammarus* was more distinct from the juvenile *H. Americanus* than was expected from the similarities between the adult lobsters. Therefore, although information on wild juveniles is lacking, it seems that based on laboratory observations and inferred ecological traits there are several important differences between juvenile *H. gammarus* and *H. americanus*.

**All variables** 

dat Agglomerative Coefficient = 0.51

Figure 2. Clustering of the species, as adults and juveniles ('juv'), by the 'Agnes' method, based on data for all the traits listed in Tables 1-5. Agglomerative coefficient: 0.51. Statistics were performed by Francois Besnier, IMR.

#### **3.2. Morphology**

If bodily structure and function are closely connected to the ecological niche of a species (Dullemeijr 1974; Alexander 1988; Bock 1994), then it may be feasible to detect common ecological groups in decapods by comparing their morphological traits (e.g., body shape, sense organs, and the function of the tail, chelae, and pereiopods) by looking at their ecomorphology, as well as their functional morphology. The 'Agnes' analyses clustered shrimps, crayfish and lobsters, crabs, including *P camtschaticus* and galatheans, and *P.*   $elephas$  into three distinct clusters (agglomerate coefficient  $= 0.68$ ). For juveniles, the functionality of body shapes and appendages is closely related to their chances of survival. The crab-shaped decapods *C. pagurus*, *C. maenas*, and *P. camtschaticus*, with wide carapaces, also all seem to have relatively short antennae and an abdomen that is no more than a reduced flap tucked underneath the body. The long, slender *P. borealis*, *A. astacus*, *P. elephas*, *H. americanus*, and *H. gammarus* (and, to some extent, the prolonged, although still quite wide, *G. strigosa*) all have long to very long second antennae, and all have strong, flexible abdomens (see Figure 3).

Figure 3. Variation in morphological details between several species, with emphasis on chelae and claws and pereiopods, from upper-left to lower-right: *Homarus gammarus* (L., 1758*)*: chelae, and clawed pereiopods, *Nephrops norvegicus* (L., 1758) chelae and weak pereiopods, *Galathea strigosa* (L., 1761): chelae and hooked claws, *Cancer pagurus* (L., 1758) chelae (left) and straight claws on pereiopods (right), *Carcinus maenas* (L., 1758) chelae and claws, *Paralithodes camtschaticus* (Tilesius, 1815) chelae and claws. Photographer: AK Woll.

From these few morphological traits, it can be deduced that crab-like decapods could have different feeding and survival strategies from those of the more slender (shrimp- or lobster-like) species. The survival strategies of crab-like species appear to involve growing to a larger size (*P. camthschaticus* and *C. pagurus*) and having a more solid carapace with no vulnerable abdomen (*C. pagurus* and *C. maenas*). Conversely, the more slender species are better adapted for speed and making rapid escapes, although the longer, jointed tail they use for these purposes may be more vulnerable to attacks in open spaces.

Crabs and spiny lobsters, which live in the same region and partly in the same biotopes, are usually lighter in color, ranging from brown to spotted, some with starkly contrasting pigmentation providing color-camouflage in the surrounding habitat. They also tend to change pigmentation from lighter and spotted to more homogenous in the first years of life. All the deep-living species examined are reddish in color, from the brightly red *P. borealis* to the pale red *N. norvegicus* and light brownish red king crab. These species do not change their pigmentation as they grow. Red light does not penetrate very far into water, so red colors provide good camouflage in deeper waters. Pigmentation ranges from black through dark blue to dark brown or grayish brown in *H. gammarus* and *A. astacus*. *H. gammarus* tend to be all black in the northern part of their range, usually with some white markings near the mouth, while the coloration of *H. americanus* is more uniform throughout its range, with dark green and reddish brown undertones and less pronounced pale spots in the head region (Figure 3). Both lobster species seem to develop dark pigmentation at settlement, although this probably depends on food quality. Laboratory-reared juvenile lobsters tend to be paler than wild-caught juveniles if they are fed an astaxanthin-deficient diet (D'Agostino 1980; D'Abramo et al. 1983; Lim et al. 1997; Tlusty and Hyland 2005). Juvenile *H. gammarus* also respond with marked changes in pigmentation when their feed is changed by adding astaxanthin or by switching it from *Artemia* to mussels in the laboratory (Wickins and Lee 2002; Drengstig et al. 2003; Kristiansen et al. 2004). The dark pigmentation of lobsters may provide better camouflage in deep cracks and within caverns than the brown and green coloration of crabs. Lobsters are quite conspicuous on open ground, however, so their dark pigmentation can be seen as being linked to a cryptic lifestyle, in which they aim to stay hidden from predators on the sea bottom.

#### **3.3. Life History**

The 'Agnes' analyses of life history traits showed that the two *Homarus* species were closely clustered together, and seemed to have traits in common as both adults (agglomerate coefficient =  $0.58$ ) and juveniles (agglomerate coefficient =  $0.64$ ).

Internal mating, wherein the male deposit a sperm package in the spermathecae of the female, is a common feature of all decapods (Subramoniam 2016). However, besides this, the selection of North Atlantic species examined has a wide range of life history strategies, including very different cycles of reproduction and recruitment. Indeed, fecundity was very dissimilar among these species, ranging from low in *A. astacus* to high in *C. pagurus* (Pearson 1908; Herrick 1911; Cooper and Uzmann 1980; Shumway et al. 1985; Shields 1991; Ingle 1992; Factor 1995; Hunter 1999; Bergström 2000; Poore et al. 2011; Groeneveld et al. 2013; Stevens 2014; Füreder 2016; Bakke et al. 2018) (Figure 4).

Figure 4. Newly spawned egg clutches and early life stages, listed from upper-left corner to lower-right. Egg clutches: *Homarus gammarus* (L., 1758), *Nephrops norvegicus* (L., 1758), *Cancer pagurus* (L., 1758), *Carcinus maenas* (L., 1758), *Paralithodes camtschaticus* (Tilesius, 1815). Juveniles: *H. gammarus* (stage V, reared) and a small juvenile found in a crevice January, May and August 2016, *C. pagurus*, *C. maenas*, *P. camtschaticus*. Photographers: Egg clutch *H. Gammarus* by Finn Refsnes; Juvenile *H. gammarus* (reared) by GI van der Meeren/IMR and *C. maenas* by IMR, the rest by AK Woll.

Larval development is also widely different among these species, from the larval stages all being completed before hatching and extended parent care being provided to the newly molted juveniles in *A. astacus* to the prolonged larval stages of a year or more in duration in *P. elephas*. All the marine species examined release planktonic larvae at hatch, which then develop through several molts before they metamorphose into the settling stage that then molts into the bottom-dwelling juvenile stage. The fecundity of the different species reflects the results of trade-offs between the costs of parental care versus the survival of the brood (Sastry 1983; Clutton-Brock and Godfray 1991; Denney et al. 2002). The size of the eggs depends on how much energy is stored in each egg, and this ranged from the nearly microscopic eggs of the brachyuran crabs to the slightly larger eggs of *P. camtschaticus*, to the relatively large eggs, which hatch into larger larvae, in *P. borealis*, *G. strigosa*, *P. elephas*, and the three nephropid lobster species (Williamson 1983; Ingle 1992). The number of larval molts and time to maturation also vary. *Palinurus elephas* has an extremely long larval period, but homarid lobsters undergo only four larval molts, and may be ready to settle in less than three weeks if the temperature is optimal. Growth from the juvenile stages to maturity seems to be related more to the maximum body size of a species than to its clutch and egg sizes (Tables 2 and 3). Size at settling mostly reflects egg size, as for example newly settled *C. pagurus*, which have larger eggs, have carapace widths (CW) of 2-3 mm, while in *C. maenas*, which has smaller eggs, the carapace widths of new settlers are less than 0.5 mm. The first juvenile stage in both homarid species has a CL of almost 10 mm. However, the less fecund *H. gammarus*, with larger eggs, has slightly larger newly hatched larvae.

Age is difficult to determine in decapod crustaceans, as reviewed by Vogt (2012). The maximum age of a species seems to be connected with its general size, with larger species generally living longer, and homarid species continue to grow and produce new batches of recruits for over 50 years. However, *H. gammarus* differs from *H. americanus* in the rates of development during the larval stages. *H. gammarus* larvae are larger at hatch, and they start metamorphosis at stage III, becoming more developmentally advanced sooner than those of *H. americanus* and leading to less change between stages III and IV in *H. gammarus* (Rötzer and Haug 2015). After settling, however, juveniles of *H. americanus* grow faster than *H. gammarus*, and individuals of this species can thus reach larger sizes and weights over their lifetime than *H. gammarus* (Lawton and Lavalli 1995). For the other species examined, the lifespan is limited, and for *C. maenas*, which undergoes a terminal molt at an age of six to eight years, possibilities for further growth are terminated and reproduction is limited to one to two years more after the terminal molt (Crothers 1967, 1968).

The underlying causes for the evolution of dissimilarities in fecundity, larval and settling juvenile sizes, and growth potential between the two homarid species are so far not known, but may be discussed in relation to the different ecosystems wherein these species have evolved (see subsequent sections).

#### **3.4. Biotope**

In statistical analyses of the species in relation to their biotopes, a new clustering pattern emerged, which was mainly related to the species' habitat depth, substrate preference, predators, and competition (agglomerated coefficient  $= 0.59$ ). The habitat preferences of the selection of decapods examined range from deep, soft sea bottoms down to several hundred meters to shallow, intertidal cobble grounds (Williamson 1905; Pearson 1908; Herrick 1911; Crothers 1967; Christiansen 1969; Cooper and Uzmann 1980; Shumway et al. 1985; Factor 1995; Hunter 1999; Poore et al. 2011; Groeneveld et al. 2013; Stevens 2014; Füreder 2016). The habitats preferred by mature lobsters of *Homarus* spp. are rocky to mixed bottoms, in relatively shallow waters, particularly in the summer season, where they excavate shelters underneath protective rocks or other hard objects (Wahle et al. 2013b). Although *G. strigosa*, *P. elephas*, and *C. pagurus* are often found in similar habitats, *P. elephas* is mostly distributed in the southern part of the range of *H. gammarus*, while *C. pagurus* may be found in more exposed waters. *G. strigosa* prefers more sheltered and subtidal sites. *C. maenas* and *P. camtschaticus* can be found on both soft and rocky bottoms, while *P. camtschaticus*, *P. borealis*, and *N. norvegicus* are all found in deeper waters with soft or muddy bottoms, on open ground. High-density patches of *N. norvegicus* are usually found in cohesive mud, where they construct and occupy tunnel systems from which they periodically emerge nocturnally to forage (although females rarely emerge when carrying eggs). This is unlike the

fully epifaunistic *P. borealis* and *P. camtschaticus*, which congregate in large numbers as protection from predator attacks (Shumway et al. 1985; Hunter 1999; Stevens 2014).

Since the 1970s, there has been much speculation about the location of the settling and nursery habitats of commercially important species because of the risk of overexploitation and the need to develop conservation measures. Several laboratory studies have been conducted over the last 50 years examining the survival and growth of newly settled *H. gammarus* and *H. americanus*, but less is known from field studies, especially for *H. gammarus* but also for the deeper-living juveniles of *P. borealis* and *N. norvegicus* and the non-commercial *G. strigosa*.

The early life stages of *H. americanus* were equally unknown until the 1980s, when the newly settled juveniles were found in mixed and rocky cobble nursery grounds in shallow waters, from the lower intertidal zone to a few meters (rarely up to 80 m) down (Cobb 1971; Richards and Cobb 1986; Barshaw and Bryant-Rich 1988; Cobb and Wahle 1994; Lawton and Lavalli 1995; Cowan 1999). Settled juveniles are hardly ever seen until they are several years old, with a CL of more than 35 mm. In Europe, efforts in the early years to find *H. gammarus* juveniles failed (Howard and Bennett 1979; Howard and Nunny 1981), while later attempts to use suction sampling and settlement traps to track wild and released juveniles have not been successful at identifying where this species' juveniles live. During searches for the smallest *H. gammarus* in European cobble grounds by similar methods and in habitats preferred by *H. americanus*, none were found (Linnane et al. 1999, 2001; Mercer et al. 2001; Ringvold et al. 2015). The inability to capture early benthic stage lobsters in cobble was the case even in the vicinity of sites on known adult lobster grounds where large numbers of microtagged hatchery-reared lobsters were released, either directly onto the seabed by divers (Bannister and Addison 1998) or seeded from the surface in shallow waters (van der Meeren and Næss 1993); however, five to eight years later, these juveniles did apparently recruit in significant numbers to commercial lobster catchers at those same sites (Bannister and Addison 1998; Agnalt et al. 1999, 2004). The inference is that the hatchery-reared juveniles adopted the same cryptic behaviors as wild lobsters. During 30 years of lobster research, only three anecdotal observations of possible juvenile lobsters with reasonable certainty are known by the authors, with no patterns (see section 3.1).

The species richness of potential predators of lobsters (Figure 5) in Europe is very high (van der Meeren 2000; Robinson and Tully 2000; Mercer et al. 2001), and includes such highly efficient predatory fishes in the family Labridae as the ballan wrasse *Labrus bergylta* Ascanius, 1767, cuckoo wrasse *Labrus mixtus* L., 1758, goldsinny *Ctenolabrus rupestris* (L., 1758), and several other species of Labridae, as well as gadoid species, particularly the Atlantic cod *Gadus morhua* L., 1758, several species of sculpins, (Cottidae), and flatfishes (Pleuronectiformes) (Barshaw and Bryant-Rich 1988; Wahle et al. 2013b). In addition, octopuses are efficient predators of decapods, like the globally distributed *Octopus vulgaris* (Cuvier, 1797), and also cuttlefish (*Sepia* spp.), although this genus does not occur along the North America Atlantic coast (Young et al. 1998; Jereb et al. 2015). These visual predator species are present, often in high densities, over the entire range of *H. gammarus* (Froese and Pauly 2018), but are not present or are found at lower densities in American waters (Barshaw and Bryant-Rich 1988; Wahle et al. 2013b). Release trials have shown that all of these fishes would predate on newly released or tethered *H. gammarus* up to a size of 35 mm CL within the first day after release (van der Meeren, 2000; Ball et al. 2001; Mercer et al. 2001). MAFF divers saw that during lobster enhancement releases when the water was warm enough for

them to be active, hatchery-reared juveniles could only avoid predators by seeking shelter as quickly as possible (Howard 1983). Released lobsters were not seen in the gut contents of predators after the first 24 h from release, or seen by divers within the first year after release (van der Meeren and Næss 1993). However, recaptures have shown that sufficient numbers of juveniles can survive to boost local stocks if they are released after eight to 10 months in a hatchery and when predation pressure is at the lowest, such as in the early spring (van der Meeren 2001, 2005; Agnalt et al. 2004). Hardly any marine areas in the world have been better investigated than the European coasts, and yet intensive suction sampling and settlement trap deployments in selected, high-density adult lobster grounds with documented recruitment of emergent lobsters have still been unsuccessful in locating small juveniles. However, stage I and II larvae are easily captured, although in low numbers, in light traps and plankton net hauls during a few weeks in the late summer in the coastal waters of Sweden (Öresland and Ulmestrand 2013) and Norway (GI van der Meeren, pers. obs.). Laboratoryreared juveniles show clear selection for specific habitats in release trials, and should thus be even more concentrated after settling than during the planktonic larval stages, yet they have not been found. However, these attempts have revealed that areas with the pebble and cobble substrates in shallow waters that are preferred by the early post-settlement life stages of *H. americanus* are also settling grounds for many decapod species in Europe. This was exemplified by the West Norwegian sampling results from the Lobster Ecology and Recruitment (LEAR) project (Mercer et al. 2001), which is described more below (Figure 6).

Figure 5. Some of the common and efficient visual predators found in shallow European waters (from upper-left to lower-right): Atlantic cod *Gadus morhua* (L., 1758), ballan wrasse *Labrus bergylta* (Ascanius, 1767), goldsinny *Ctenolabrus rupestris* (L. 1758), plaice *Pleuronectes platessa* (L., 1758), curled octopus *Eledone cirrhosa* (Lamarck, 1798), shorthorn sculpin *Myoxocephalus scorpius*  (L., 1758). Photographer: AK Woll.

Figure 6. Overall benthic invertebrate diversity found through suction sampling on a mixed cobbleand sand-field (A) and in nine settlement traps with similar substrates (B) at the Vinnes location, Fusa, Hordaland, in western Norway in October 1999. The settlement traps were placed in the field at the beginning of the lobster hatching season in July and recovered after three months. The number of specimens found in each phylum and the percentage of all specimens represented by it is shown. The total sampled area and volume was  $1.08 \text{ m}^2$  and  $0.012 \text{ m}^3$ , respectively. Data are from the LEAR project (Mercer et al. 2001).

The decapods found among cobble during the LEAR project represented not only a high number of species, but also high numbers of individuals, in both suction sampling and settlement traps in natural and lobster fishing areas. Whereas *H. americanus* dominates cobble habitats in North America, a mix of shrimps and several galathean species in all life stages dominated similar habitats in European waters (Figure 7). Small settlement traps provided with cobble and mixed sand and cobble substrates attracted mostly shrimps and juvenile galatheans and brachyurans. Almost 200 small-sized shrimps and nearly 100 galathean juveniles were found per m<sup>2</sup>. Although too small to be predators of settling lobsters, both of these group could compete with them for space and food. There are also considerable gaps in our knowledge on the early life stages of galatheans and non-commercial brachyurans. Therefore, unpublished data and results from Norwegian experiments conducted

as parts of the LEAR project were used in the following sections to illuminate some of the similarities and differences in habitat and behavioral traits between laboratory- or hatcheryreared juvenile *H. gammarus* and selected species commonly found in European cobble grounds at 2-10 m depth.

Figure 7. Crustacean diversity in settlement traps recovered in Norway in October 1999. The number of species found in each taxon and the percentage of all specimens represented by it is presented. The total sampled area and volume was  $1.08 \text{ m}^2$  and  $0.012 \text{ m}^3$ , respectively. Data are from the LEAR project (Mercer et al. 2001).

Figure 8. Percentage of time observed out of shelter of newly settled *Homarus gammarus* (L., 1758) with or without different competitors, including *Liocarcinus navigator* (Herbst, 1794) [as *Liocarcinus arcuatus*] (swimming crabs) and/or *Galathea squamifera* Leach, 1814 (squat lobsters), that were either slightly smaller (small) or equal in size to or slightly larger (large) than the lobsters. All specimens used were in the same size range (total length/width: 35 to 50 mm) and were held under a 12/12 h day/night cycle while being observed and counted every 3 h over a 72-h period, in three replicate tanks. The number of lobsters used per tank was 15 individuals, with 15 individuals of each competitor species added per tank as treatments. Data are from the LEAR project (Mercer et al. 2001; Koponen 2003).

*A. nitescens*, the most common shrimp in the settlement traps and the species most closely resembling stage V of *H. gammarus*, was used to investigate whether and how potential competitors impacted stage V juveniles of *H. gammarus*. One hundred stage V lobsters were paired with 75 *A. nitescen*, sharing space and food in 100 meshed cages (length 135 mm, diameter 70 mm) left on the sea bottom for four months. The 75 lobsters sharing their cages had similar survival (32%) and growth (23.5% in controls and 24.6% overall) to control lobsters, while the weight gain was lower in the shared cages than in the controls (42.2 g in controls vs. 31.3 g overall) (data from the LEAR project: Mercer et al. 2001).

Figure 9. Typical use of biotope (from upper-left to lower-right): *Homarus gammarus* (L., 1758) alert when exposed (left) and in shelter (right), *Nephrops norvegicus* (L., 1758), *Galathea strigosa* (L., 1761), male *Cancer pagurus* (L., 1758) protecting mate, *Carcinus maenas* (L., 1758) partially burrowed in sand. Photographer: AK Woll.

When facing commonly found decapod species in shallow-water cobble grounds in Europe with relatively similar diurnal cycles and shelter preferences to them in the laboratory, naïve newly settled *H. gammarus* were quite effectively able to win and protect covered burrows from potential competitors (Figure 8). The burrowing behavior of *H. gammarus*  juveniles was previously described by Berrill (1974). Although lobsters were significantly less affected by their competitors than their competitors were by them (Mann-Whitney U-test:  $U = 16.5$ ,  $n_1$  and  $n_2 = 12$ ,  $p < 0.002$ ), lobsters were out of their shelter significantly more often during the daytime with competitors (e.g., when faced with small squat lobsters: 12.8  $\pm$ 3.14% more European lobsters were out of shelter vs. controls;  $\chi$ 2 = 5.99, df = 1, p = 0.014). Galatheans and brachyurans can find other shelter options that are unavailable to lobsters. The relatively wide- and flat-bodied crabs can dig into the substrate, while the galathean species can use their hooked claws to cling upside-down to the undersides of rocks and other hard objects (Figure 9). However, the presence of slightly larger competitors still led to more lobsters being out of their shelters, which in the field would expose them more to fish predators (Mercer et al. 2001; Koponen 2003) (Figure 8).

Both homarid species perform very similarly in laboratory settings, but to survive settlement and shelter competition in European waters, *H. gammarus* juveniles in the field may have developed antipredator and shelter selection choices that differ from those of *H. americanus* (Wahle and Steneck 1992; Lawton and Lavalli 1995). The competition for shelter and food in Norway, as in other European cobble-bottomed areas, must be very different from that in American waters (Mercer et al. 2001; Wahle et al. 2013a; Ringvold et al. 2015).

Statistical comparisons of the known and anticipated traits connected to the habitat of homarid species were made using the 'Agnes' clustering analysis and PCA on data for their habitat traits (Figure 10A). *H. gammarus* were placed in a separate branch from adult *H. americanus*, with juvenile *H. gammarus* clustered even more distantly from the juvenile *H. americanus* (Figure 10A). The PCA of descriptive functional traits showed that these species mainly differed along the PC axis that corresponded with the 'Predator diversity', 'Active burrower', 'Pigmentation', and 'Relative 2 antenna length' traits (Figure 10B). The similarities detected in the juvenile and adult *H. gammarus* may have been an artefact caused by the assumed juvenile biotope and optimal habitat being based on observations of juveniles reared in the laboratory and studied in semi-natural habitats (Figure 10C). Since the antennal length, pigmentation, and burrowing habits are known to be similar between homarid lobster species, at least in laboratory studies, the most significant differences in these analyses were thus caused by differences in predator diversity and decapod competitor diversity (Figure 10B) (van der Meeren 2000; Mercer et al. 2000). *H. gammarus* seems to have biotope traits more in line with those of *C. maenas* and *G. strigosa*, which live in shallow waters with high predation pressure and many decapod competitors, as these species were all clustered quite closely in Figure 10C; the adult *H. americanus* was also clustered within this type of habitat.

**Biotope** 

Figure 10. Analyses of similarities and differences among the preferred habitats of all the tested decapods through clustering by the 'Agnes' method (A, previous page) and principal component analyses (PCAs) of the descriptive variables (B) and species (C) along the principal component axes 3 (horizontal) and 5 (vertical). *Homarus gammarus* (L., 1758) are marked with gray stars and *H. americanus* H. Milne Edwards, 1837 are marked with black stars. Statistics were performed by Francois Besnier, IMR.

It is possible to interpret relative abundances of different species in different habitats and how this may impact juvenile lobster settlement and survival in two ways. From one point of view, one might conclude that European lobster juveniles are 'suppressed' by these 'ecological competitors'. On the other hand, the sparse lobster density and cryptic life cycle may be a low-density strategy that has evolved to reduce the prospects of them having to face predation and competition. The outcome is the same, but without careful experiments it is impossible to determine which one is the driver.

#### **3.5. Behavior**

The behaviors (Figure 11) of juvenile and adult *H. americanus* have been described in a number of studies (Cobb 1971; Stewart 1972; Barshaw and Bryant-Rich 1988; see also Atema and Voigt 1995, and references therein).

A behavioral trait that is clearly different among the selected species is seasonal migration. Some female *P. elephas* and *C. pagurus*, but not all, migrate as part of their recruitment strategy (Ansell and Robb 1977; Bennet and Brown 1983; Howard 1982; Follesa et al. 2009; Giacalone et al. 2015), and *P. camtshaticus* and some *H. americanus* migrate to deeper waters during the winter season (Stewart 1972; Sundet 2014). However, *H. gammarus*, *G. strigosa*, *N. norvegicus*, *C. maenas*, and *A. astacus* do not migrate seasonally, and are resident in the same areas throughout the year (Edwards, 1958; Klein Breteler 1976; Chapman 1980; Smith et al. 1998; Ulmestrand and Eggert 2003; Moland et al. 2011; Füreder 2016). Still, *H. gammarus* were found emigrating from artificial shelters over time, and the extents of the home ranges of large lobsters may have been previously underestimated (Jensen et al. 1993; Thorbjørnsen et al. 2018).

The homarid species avoid social interactions other than mating. They use body language and olfactory cues to signal dominance and mating and individual status (Atema and Voigt 1995; Skog 2009). Aggression seems to be negatively correlated to the body/chelae size, where female *H. gammarus* are more aggressive than male*s*, and male *H. gammarus* are more aggressive than male *H. americanus* (van der Meeren et al. 2008; Skog 2009). *H. gammarus* does not seem to respond with decreased aggression upon receiving submissive signals from a competitor: After fights between *H. americanus*, the winner will usually ignore a defeated lobster that tucks in its tail and lowers its chelae, but in *H. gammarus* the winner will continue to chase and attack the opponent as long as they are in the same tank (van der Meeren et al. 2008).

Like *H. americanus*, adult *H. gammarus* are nocturnal predators and scavengers (Smith et al. 1998) with very flexible bodies that can easily move both forwards and backwards. As nocturnal foragers, they shelter in caves and self-made burrows during daylight hours. Highdensity patches of *N. norvegicus* are usually found in cohesive mud, where they construct and occupy tunnel systems from which they periodically emerge nocturnally to forage, although females rarely emerge when carrying eggs. Naïve, hatchery-reared, one-year-old *H. gammarus* show responses to new environmental factors that are similar to those of wild, adult lobsters, which are active burrowers, nocturnal, shelter-seeking, solitary, and aggressive (van der Meeren 1993) (Figure 12). Whether this also applies to wild juveniles is not known. Homarid lobsters, even when reared in hatcheries, are observed to burrow when they have the opportunity, and are well-suited to life in modified interstitial spaces within rocky and complex bottoms, from which they remove sand and build up with rocks to make entrances that are easy to protect. Their antennae provide them with excellent olfactory and tactile senses for navigating their dark world (Cobb 1971; Atema and Voigt 1995).

Although *C. pagurus* and *C. maenas* are sometime seen buried in sand, only the three nephropid lobsters actually dig and shape shelters, such as by making tunnels underneath rocks or in compact sediments. These are all examples of these species' functional morphology and habitat ecology. The crabs are protected by their bulky carapace and may have less need for full body-covering shelters than the less armored homarid species. In laboratory experiments in which sand-covered tank bottoms are offered and used by crabs, *H.* 

*gammarus* juveniles usually prefer to dig underneath artificial shelters put in the tank, while galatheans will use natural crevices in the provided shelters (pers. obs. by the authors).

Figure 11. Interactive behaviors in (from top to bottom): male *Homarus gammarus* (L., 1758) (left) and *Homarus americanus* H. Milne Edwards, 1837 (right), fighting; *Paralithodes camtschaticus* (Tilesius, 1815) podding; *Galathea strigosa* (L., 1761) clinging (mating), *Cancer pagurus* L., 1758 (left) and *Carcinus maenas* (L., 1758) (right) foraging. Photographers: homarid lobsters by GI van der Meeren, the rest by AK Woll.

*P. borealis*, *P. camtschaticus*, *C. maneas*, and *C. pagurus* do not seek body-covering shelters, but also show other differences from shelter-making lobsters, including camouflage pigmentation and protective behavioral traits. *P. borealis* are good swimmers that live in dense shoals (Shumway et al. 1985). Crabs are often found on softer bottoms, near or in crevices in kelp and alga-covered substrates, environments where they can cover themselves with sand, cling to the surface, or wedge themselves inside crevices. Their pereiopods can fold underneath the body and provide a strong grip on the substrate. *P. camtschaticus* and *P. elephas* are both afforded protection from predators by forming social aggregations and possessing spiny carapaces and long appendages. *G. strigosa* are less social, but still not aggressive like *H. gammarus*. Due to their both flattened and elongated body shape, with a flexible tail tucked underneath the body, and the hooked claws present on all their pereiopods their grip on rocky surfaces and other objects is strong (Figure 9).

dat[, 13:19] Agglomerative Coefficient = 0.73

Figure 12. Analyses of similarities and differences between all the selected behavioral traits of the tested decapods ('Agnes' method). Statistics were performed by Francois Besnier, IMR.

Decapod species are found at different depths, from the upper intertidal zone (*C. maenas*), to the upper subtidal zone (*G. strigosa* and *A. astacus*), relatively shallow waters (*H. gammarus*, *C. pagurus*, and *P. elephas*), and deeper waters (*P. borealis* and *N. norvegicus*); some also occupy a wider depth range, from shallow waters down to more than 100 m depth (*P. camtschaticus* and *H. americanus*). Living in the littoral zone requires appropriate responses to the tide. The behavior of *C. maenas* is connected to the tidal cycle, and crabs will move into a shelter when the tide is going out (Crothers 1967, 1968). Typically, they hide under seaweed or rocks, staying humid and sheltered from direct sunlight. In the competition experiments done during the LEAR project, each test was finished by emptying the 0.9 m deep tanks with the experimental animals still in place. In this process, it was observed that the *H. gammarus* juveniles were all hiding underneath the cobble shelters, while the other species sampled from natural cobble grounds at 4 to 10 m depth all reacted by fleeing their shelters, moving out into full exposure on the open sand. The lobsters behaved exactly as the intertidal *C. maenas* would be expected to do (pers. obs. by the authors).

For the early life stages of *H. gammarus*, no previous attempts to document their natural living biotope has yet succeeded, and thus there are no published observations of the behavior of wild juveniles. After more than a century of studies of hatchery-reared lobsters and juvenile releases to the sea, our present knowledge of the juveniles of this species all comes from laboratory studies. Anecdotal information and observations of laboratory-hatched young-of-the-year juveniles in tanks exist, as described earlier in this chapter (section 3.1), which provide varying levels of detail for habitat reconstruction. Searches in nature for this life stage have been futile thus far. Even after releases of thousands of juveniles from one to 12 months old, very few are seen and none are recaptured in the next three to five years, after which they reappear in traps as adults, in the same location where released (Bannister and Addison 1998; van der Meeren 2003; Agnalt et al. 2004). Notably, a Swedish study suggested that lobster larvae may be retained in the area where they are hatched, which implies that they do seek shelters near to the adults' habitats (Öresland and Ulmestrand 2013). Releases and searches for wild juveniles have been based on knowledge of the habitat of larger lobsters more than 50 mm CL in size and biotopes known to attract *H. americanus* juveniles. However, the lack of actual knowledge of wild *H. gammarus* juveniles' habitat preferences and behavior in the rich biodiversity of European waters make proper monitoring of stock recruitment and conservation measures, including recruitment protection, difficult.

## **4. DISCUSSION: THE FULL PICTURE**

There has been substantial speculation regarding how the juveniles of *H. gammarus* manage to remain elusive. Are the juveniles suppressed by competitors and predators and therefore sparsely distributed, or is the low density of *H. gammarus* versus *H. americanus* a strategy to reduce the prospects of competition and predation? Three main hypothesis have been suggested, that they: (1) stay in deeper waters, (2) settle too sparsely to be detected, or (3) dig deep or hide deep in the substrate, in branched and long burrows or caverns (Mercer et al. 2001).

A bigger-picture perspective is needed to pinpoint how the young of *H. gammarus* differ from those of their closest relative. To evaluate the three hypotheses suggested above, a full ecological picture of this species and others, including their morphology, life history, habitat, and behavior, may be useful. In this chapter, the selection of Northern Atlantic decapod species examined all had several features in common with *H. gammarus*: they need protection when molting, are mainly nocturnal, more or less omnivorous, and live within the same temperature range. However, the species differ from each other in their preferences for habitat depth, bottom quality, and the temperature range they prefer. They also differ in how they avoid predators, the extent of parental care, the duration of the larval period, and in morphology. The most temperate species, *P. elephas*, and the polar *P. camtschaticus* represented the extremes of both temperature preferences and morphology considered, although both share part of their temperature tolerance zone with the homarid lobsters. *P. camtschaticu*s, *N. norvegicus*, and *P. borealis* are all commonly found below 100 m depth, well below *H. gammarus*, which is usually found above 70 m depth. These deep-living species have typically reddish pigmentation, less developed chelae, and weaker pereiopods that reflect their life in waters deeper than the sunlit intertidal zone, with reduced diversity of predators and competitors, and shelter from predators in self-made burrows in cohesive mud (*N. norvegicus*) or by gathering in large numbers (*P. camtschaticus* pods, *P. borealis* shoals). The pigmentation, behavior, and habitat of adult *H. gammarus* overlaps with the shallowliving marine species and even the limnic *A. astacus*. Adult lobsters stay in shallow waters even more in *H. americanus*, which are even more tolerant to low temperatures than *H. gammarus* in all life stages; they become inactive in waters colder than 7°C, and temperatures below 5°C inhibit larval molts (Templeman 1936; Nicosia and Lavalli 1999; Wickings and

Lee 2002). Still, hybridization of *H. americanus* females with *H. gammarus* males has been documented in European waters (Jørstad et al. 2011; Öresland et al. 2017). Without doubt, *H. gammarus* belongs to the group of shallow-dwelling species.

The natural living biotope of all animals is functionally reflected in their morphology, life history strategy, habitat selection, and behavior. In *H. americanus*, density-dependent population regulation is likely (Fogarty and Idoine 1986; Ennis and Fogarty 1997; Wahle et al. 2013b), while this is not expected in *H. gammarus* since it is rarely found in densities as high as *H. americanus* (Wahle et al. 2013a ). Still, habitat has impacts on the size composition of *H. gammarus* (Howard 1980), as well as conspecific chemical stimuli and interspecific interference competition (Wickins and Lee 2002). Wild-caught post-larval *C. maenas* respond to density-dependent cues that lead to slightly faster growth and the development of stronger chelae, increasing their competitive ability (Duarte et al. 2014).

As nocturnal foragers, adult *H. gammarus* are photophobic and darkly pigmented, fastmoving and highly mobile, and shelter during the daytime in caves and burrows that they usually modify and manipulate to provide better protection. In the northern part of their distribution, *H. gammarus* are black to nearly black in color. Their very dark colors are a good fit for living on rocky and complex bottoms, while their long antennae provide them with excellent senses of smell/taste and touch for navigating in their dark world, including when sitting inside deep caverns and tunnels. In many ways, *H. americanus* is similar in morphology to *H. gammarus*, although with slightly lighter pigmentation, which may indicate that their ecological niches are comparable but not exactly the same. In contrast, *P. elephas* adopts communal living in groups for protection, and is not found inside deep caves (Eggleston and Lipcius 1992; Diaz et al. 2001; Goñi and Latrouite 2005; Buscaino et al. 2011). The crayfish *A. astacus* is as dark as *H. gammarus*, but lives in lakes with no crustacean competitors and only fish and bird predators, where it shelters in natural crevices and protects the brood until the juveniles have completed the second post-hatch molt, making them large enough to be able to flee from visual fish predators (Stein and Magnusson 1976; Söderbäck 1994; Füreder 2016).

The ways in which morphology constrains how decapods can move are also telling. *P camtschaticus* move freely in open habitats, but cannot lift their own weight out of water, tailflip away from danger, or fold up to effectively cling to the substrate. However, they do not need to use these techniques because they instead obtain protection by moving in pods and outgrowing their predators (Dew 1990). Young ones, which are not protected by size, stay in social groups and are covered in pointed spines all over the carapace. *Pandalus borealis*, which is small in size and unable to grip anything, relies on tail-flip escape behaviors, camouflage pigmentation, and hiding in dense shoals above the seabed for protection. In shallower waters, wide-bodied crabs have relatively hard carapaces, no tail joints and strong chelae and pereiopods, making them increasingly difficult to break and swallow for predators as they grow. Young stages of crabs rely on digging shallow depressions in sandy bottoms, hiding in inaccessible crevices, and a strong grip achieved by folding the chelae and pereiopods around kelp stems or other objects to which they can cling, leading to them having a preference for sheltering in kelp forests or other places with algal cover or complex surfaces (Howard 1982; Fernandez et al. 1993). Both *G. strigosa* and *P. elephas* exhibit typically elongated 'lobster' shapes, with quite strong walking pereiopods, and use tail-flips for escape. (Robinson and Tully 2000; Linnane et al. 2001; Ringvold et al 2015). However, galatheans are more dorsoventrally compressed than the cylindrical homarid lobsters and *A. astacus*. Like brachyurans, galatheans can fold their pereiopods underneath the body and get a strong grip on the surface, as well as cling upside-down by the hooked claws on their strong legs and pointed claws. Lobsters cannot fold their legs underneath the body, but can fold them tightly up on each side of the body. They cannot cling to or grip the substrate or objects, but are shaped well for moving through narrow passages and pushing out sediments from burrows or tunnels. In emerging and adult homarid lobsters, this is the preferred habitat in laboratory studies (Linnane et al. 1999; Jørstad et al. 2001; Wahle et al. 2013a). Even if no *H. gammarus* juveniles have been found in cobble grounds, and extremely few have been found at all, the latter are found in habitats with empty shells or rocky reefs mixed with sandy spots, which can usually be improved by manipulating the entrance and shelter shape. Hatchery-reared *H. gammarus* juveniles released in laboratory tests will shelter faster when the water carries predator odors (Longva Nilsen 2007; Aspaas 2012) and show reduced aggression when a fish is present (van der Meeren 1993), showing how innate responses are still present in intensively cultivated juveniles.

Interestingly, a reaction to water drainage commonly found in intertidal species seems to also be a natural reaction in laboratory-reared *H. gammarus* juveniles. Water drainage induces them to move into drained, but humid and shaded, shelters, whereas galatheans, one of the most common benthic decapod groups in European shallow waters, flee their shelters in the absence of water. Thus, *H. gammarus* acts in the same way as the intertidal *C. maenas*. This could indicate that *H. gammarus* may have evolved to live in the upper littoral zone, perhaps even in the intertidal zone. The nursery grounds of *H. americanus* are shallow as well, but not usually intertidal (Cowan 1999, Wahle et al. 2013b). The innate reaction of *H. gammarus* to shelter in dark and moist places when left out of water indicates that the hypothesis that this species' juveniles have been hard to find because they avoid competition by growing up in deeper waters is not likely to be correct.

Looking at all traits together, the most similar species of those examined are the homarid lobsters (Figure 2 and Tables 1-5), even if they differ in terms of some characteristics of their microhabitats and ecology. In terms of habitat, the rich biodiversity of Europe most probably led to the differences found in juvenile, and to some extent adult, *H. gammarus* and *H. americanus* behavioral, morphological, and life history traits. In Late Medieval Scandinavian literature, before *H. gammarus* was fished commercially, Magnus (1556) and Pedersøn Friis (1599) claimed that foxes, ravens, otters, and men caught small lobsters at low tide by turning stones in the intertidal zone (as cited in Spanier et al. (2015)). No intertidal lobsters have been reported in later centuries. While the fiercest competitor any young lobster will meet is another lobster, the density and biodiversity of other species of competitors and predators is higher in European waters than that found along the North American east coast (and in the biotopes of *H. americanus*). These differences between regions could be the cause for some of the noticeable dissimilarities between *H. gammarus* and *H. americanus*. *H. gammarus* lobsters are more aggressive, showing no tolerance to other lobsters except during mating (van der Meeren et al. 2008; Skog 2009). In *H. gammarus*, each egg is larger and provided with more yolk, causing fewer eggs to be produced per clutch, while the newly hatched larvae are larger and start metamorphosis at larval stage III, leading to them becoming more developmentally advanced stage IV and post-larvae than those of *H. americanus* (Aiken and Waddy 1989; Agnalt 2008; Rötzer and Haug 2015). Larger larvae and juveniles are better prepared to fight for shelter and survival after settlement (Wahle and Steneck 1992).

Although *H. gammarus* is known to live in less dense populations, the catch-per-unit-trap in some locations of *H. gammarus* can be at the same level as that of *H. americanus* (Jørstad et al., unpublished data). The *H. gammarus* stock in the UK and Ireland has been stable and has supported a commercially healthy fishery since 1910 (CEFAS 2014). Stage I and II larvae are easily caught in plankton nets or light traps if these are deployed at hatching time and the following few weeks (Öresland and Ulmestrand 2013). Considering all of the fisheries and field research undertaken along the European coasts, as well as failures to recapture any of the newly released hatchery-reared lobsters that turn up years later in commercial catches (Bannister and Addison 1998; Agnalt et al. 2004), it is not likely that scarcity is the reason that juvenile European lobsters have not yet been found. The UK *H. gammarus* stock is stronger than ever, sustaining a healthy fishery, indicating that nursery ground availability is not limiting the stable recruitment of new lobsters to this stock, which probably has also benefitted from warmer summer ocean temperatures in recent years (CEFAS 2014; Selim et al. 2016). In Scandinavia, it is clear that although the warming seas should be beneficial for the lobsters in this northern portion of their distribution, overexploitation combined with low summer sea temperatures in the 1960s and 1970s resulted in stock collapse (Pettersen et al. 2009). The main cause for the still very low stock in areas outside of lobster marine protected areas, despite benign climate conditions, is still overexploitation (Kleiven et al. 2012; Moland et al. 2013; Thorbjørnsen et al. 2018). The overall picture discussed here indicates that a lack of nursery grounds for juveniles is not plausible, as their innate traits seem to keep them out of the microhabitats of their competitors and common predators.

The full picture points to *H. gammarus* juveniles, much like the adults, living in shallow waters, where they are well-dispersed but not necessarily rare. The cryptic life habit of *H. gammarus* for the first years of its life may have evolved in shallow, highly competitive, and predator-dense biotopes, as a strategy to reduce pressures from competitors and predators by occupying and manipulating their shelters and spaces to keep out predatory or competing species. Thus, the advanced larval metamorphosis, high level of aggression, solitary shelter occupation, and active digging and manipulation of the habitat of *H. gammarus* may all be traits that provide its juveniles access to unique shelters in shallow waters that are so successful they are also unapproachable by humans by all approaches utilized so far.

#### **ACKNOWLEDGMENTS**

This work is dedicated to John Mercer, for being an inspiring colleague, mentor, and friend. Thanks are given to Francois Besnier for doing the statistical analyses. The text and content has been greatly improved by additional information from the UK, general and specific inputs and critical comments by Colin Bannister, and suggestions from the editor and a reviewer. All these also assisted in needed language improvements. Without the assistance and collaboration of Hannu Kopponen, Haldis Ringvold, and Vidar Wennevik, we would have had even less information on the juvenile *H. gammarus*. The many and good discussions we had with Rick Wahle, Kari Lavalli, Stan Cobb, and many more lobster friends have been vital for the insights and shared knowledge presented in this chapter. We are also grateful for the exchange of knowledge with our Norwegian and Swedish lobster colleagues, Michaela Aschan (UiT) for shrimp literature, and financial support from the Institute of Marine

Research (IMR), Norway. Finally, without good dive buddies, the photos could not have been taken and made available for this chapter. In particular, we thank Nils Aukan, Finn Refsnes, and Øystein Paulsen, who provided additional photos.

# **BIOLOGIC AND SOCIOECONOMIC HARVESTING STRATEGIES FOR THE CARIBBEAN SPINY LOBSTER FISHERIES**

# *Ernesto A. Chávez\**

Centro Interdisciplinario de Ciencias Marinas, Instituto Politécnico Nacional, La Paz, B.C.S., México

## **ABSTRACT**

The spiny lobster fisheries exploited by 25 Caribbean countries are subject to heterogeneous harvesting practices, and some of them undergo recurrent socioeconomic crises. Therefore, in this chapter a meta-analysis was conducted with the purpose of providing general management recommendations by evaluating the performance of the five main Caribbean lobster fisheries (those in the Bahamas, Brazil, Cuba, Nicaragua, and the United States of America), as well as the total production of the region. The associated costs, benefits, and social values of a small fishery in southeastern Mexico, in the northwestern Caribbean, were used as reference values. The stocks were assessed by reconstructing the age structure of each population over a 15-year period, and then the catch, profit, direct provisioning of jobs, and profits per fisher were estimated for each fishery in simulations with different ages of first catch  $(t_c)$ . Based on these, the fisheries mortality (*F*) values needed to attain the maximum sustainable yield (*FMSY*) and the maximum economic yield (*FMEY*) were selected as the optimum harvesting options for different fisheries. The results showed that the yield increased with the *tc*, and in three cases the yields at the *FMSY* were higher than those at the *FMEY*. The profits were higher at higher  $t_c$  values in three fisheries, meaning that they were more profitable if harvested at their *FMEY* levels. One fishery (that in the Bahamas) was not profitable if harvested at the *FMSY* level at any age. The social value of most of the fisheries, calculated as the profits/fisher, was the highest at a *t<sup>c</sup>* of 3 years, and again was higher if the *FMEY* strategy was applied. However, in the Bahamas' fishery the social value at the *FMSY* was negative at any *tc*. Based on the widespread distribution of this species of spiny lobster across the coasts of the Caribbean and the heterogeneous exploitation practices applied to its fisheries, the creation of a multinational organization in charge of regulating and

managing the fishery in each country is recommended to achieve the sustainable exploitation of this resource within the framework of conservation.

**Keywords:** Caribbean, optimum yield, *Panulirus argus*, spiny lobster

# **1.INTRODUCTION**

Stock assessment has been a major focus of fisheries scientists' efforts for a long time, and the related exploitation of fished stocks to the level of their maximum sustainable yield has been one of the main goals of fisheries science and management (Beverton and Holt 1957; Cushing 1968; Gulland 1969, 1988; Ricker 1975; Hilborn and Walters 1992; Quinn II and Deriso 1999). This approach has the purpose of acting as a "holding action against the forces of resource depletion" (Walters 1986). In many fisheries, the objective of fisheries management is usually the achievement of the maximum sustainable yield, or *MSY* (Hilborn 2007). However, the maximum economic yield (*MEY*) is a more convenient option, although it is also more difficult to evaluate. Although the basis of studies of the population dynamics of fished species has remained essentially the same, in recent decades fisheries science has made enormous progress relative to traditional views and methods. This is because, since computers became accessible to scientists and fisheries managers for use in their everyday tasks, they have become able to handle enormous amounts of data, which has made it possible to test the outcomes of a wide variety of harvesting scenarios. Unfortunately, many fisheries remain unattended by management efforts or stock assessment studies, meaning that the use of their resources is under free access and they lack harvest controls, and they are thus often depleted (Beddington and Kirkwood 2005). The fisheries of the Caribbean spiny lobster (*Panulirus argus* (Latreille, 1804)) face such challenges, so this chapter focused on analyzing harvest strategies for this species' stocks.

The Caribbean spiny lobster, *Panulirus argus*, belongs to the group of about 20 species of tropical spiny lobsters that are of commercial interest (Holthuis 1991; Phillips et al. 2013). Most details on the life history and fisheries management of this lobster were summarized in the book edited by Phillips (2013). *P. argus* has nocturnal habits, and is associated with coral reef habitats, where it remains hidden in hollows during the day. It is distributed throughout the Caribbean, where it prefers shallow waters but can be found in waters up to 90 m deep or more (Holthuis 1991; Briones-Fourzán and Lozano-Álvarez 2013). It is a gregarious and migratory species. In this region, another species of the same genus (*P. gracilis* (Latreille, 1804)) also occurs, but it is smaller and less abundant than *P. argus* (Holthuis 1991; Briones-Fourzán and Lozano-Álvarez 2013). Lobsters are long-lived species that can live for more than 25 years and grow up to half a meter long, and may reach about 20 kg in weight (Phillips et al. 2013). This species' distribution mainly includes the waters of the Caribbean Sea and the Gulf of Mexico, although some individuals have been found as far north as Massachusetts, northeastern United States of America (USA) (Holthuis 1991; FAO 2019). Towards the south, it can be found until northeastern Brazil (Figure 1), being apparently absent in the waters of the Guianas, where the mouths of several large rivers impose an ecological barrier that may constrain its distribution. It has also been found on the tropical coast of West Africa (Holthuis 1991; FAO 2019).

There is some indirect evidence (Grober-Dunsmore and Keller 2008; Butler IV et al. 2010; Chávez and Chávez-Hidalgo 2012) suggesting that currents in the Caribbean and the long larval periods of spiny lobsters are factors that allow there to be high connectivity among the lobster populations of most islands and coastal zones of tropical America (Chávez and Chávez-Hidalgo 2012; Kough et al. 2013) (Figure 2). In the northern part of this species' range, larvae mainly occur in the water column from June to December (FAO 2019).

Figure 1. Spiny lobster (*Panulirus argus*) distribution; after the FAO (2019) Fisheries GLOBAL Information System (http://www.fao.org/fishery/species/3445/en).

Figure 2. Main pathways of connectivity among spiny lobster populations suggested for the Caribbean waters; after Chávez and Chávez-Hidalgo (2012).

These lobsters have a life cycle that includes larval stages that live in the plankton for about nine months (Kough et al. 2013; Phillips et al. 2013). This characteristic is one of the reasons for this species' wide distribution. At the end of the larval phase, after passing through a large number of planktonic stages (phyllosomas) and then undergoing metamorphosis, they transform into transparent swimming postlarvae (pueruli) with essentially the same shape as the adult (Briones-Fourzán and Lozano-Álvarez 2013; Phillips et al. 2013). These postlarvae then seek refuge in the reef benthos, where they hide in cavities and grow into juvenile lobsters (Briones-Fourzán and Lozano-Álvarez 2013). In this habitat, they reach sexual maturity after three years, at which point they start breeding (Phillips et al. 2013; FAO 2019).

Spiny lobsters have separate sexes, and although they can reproduce year-round, the main reproductive period takes place from March to September with two main peaks in May and September, corresponding with when water temperatures fall within the range of 23.7 to 28.0°C (Phillips et al. 2013). Females move to deeper water to spawn, and mass migrations occur in the autumn in which groups of animals (up to 50 individuals) move single-file in a certain direction in the daytime, with each animal having body contact with the next in line through the antennae (Phillips et al. 2013; FAO 2019). They lay 800 eggs per g of body weight, with a high fecundity of  $> 2 \times 10^6$  eggs per ripe female. Spawning takes place with a one-month lag, when the water temperature is generally above 24°C (Pollock 1997; Phillips et al. 2013). During fertilization, the male deposits a spermatophore on the belly of the female, which by its appearance is known as a 'tarspot', from which the eggs are fertilized after spawning (Phillips et al. 2013). After being extruded from the ovary and fertilized, the eggs are adhered to the filaments of the female's pleopods, where they are carried for about one month (Pollock 1997; FAO 2019). At the end of that process, hatching occurs in protected sites on the reef (Briones-Fourzán and Lozano-Álvarez 2013; FAO 2019). Length at settlement, takes place when postlarvae have a size of 6 mm carapace (Pollock, 1997).

Lobsters are predators that mainly feed upon mollusks and crustaceans (trophic level  $=$ 3.39 on a scale from 1 to 5, with 5 being top predators) (Phillips et al. 2013). Importantly, in the year 2000, a pathogenic virus was discovered in juvenile Caribbean spiny lobsters from the Florida Keys, USA. *Panulirus argus* is susceptible to infection by *Panulirus argus* virus 1 (PaV1), the only pathogenic virus known to naturally infect any lobster species, which profoundly affects its ecology and physiology. PaV1 is widespread in the Caribbean, with infections reported in Florida (USA), St. Croix, St. Kitts, and the Yucatan, Mexico (Butler IV et al. 2008; Behringer et al. 2012). The sharing of viral alleles among lobsters from distant locations supports the hypothesis of there being high genetic connectivity among lobsters within the Caribbean, and further supports the hypothesis that postlarvae infected with PaV1 may serve to disperse the virus over long distances (Moss et al. 2013). However, *P. argus* lobsters are able to mitigate PaV1 transmission risk by avoiding infected individuals (Behringer et al. 2012).

The Caribbean spiny lobster is a fisheries resource that is highly prized and exploited in all Caribbean countries and Brazil (Holthuis 1991; Phillips et al. 2013; FAO 2019). The most common commercial sizes harvested have a weight of half a kilogram (0.5 kg) and measure about 30 cm in length (Phillips et al. 2013; FAO 2019). In many Caribbean countries, there is open access to lobster harvesting, although some degree of management is applied in most others. For example, in Belize, the following management regulations are in effect: the minimum legal size is set at a carapace length of 3 inches or 7.6 cm or a minimum tail weight of 4 ounces or 113.4 g; there is a closed season from February 5 to June 14. Possession of diced lobster tail meat is prohibited; no commercial deep-water fishing is allowed, nor is lobster fishing with SCUBA gear; no lobster traps are allowed beyond the front reef, nor

within a distance of 300 m from any coral formation; and it is prohibited to capture 'berried' or egg-bearing lobsters, lobsters with a 'tarspot', or molting lobsters (FAO 2019). Most Caribbean countries apply management practices analogous to those described above for Belize (Phillips et al. 2013; FAO 2019), although with important differences in the specific rules and regulations applied and their degree of enforcement (Hilborn et al. 2005).

The heterogeneity in management practices among shared or connected lobster stocks (Chávez and Chávez-Hidalgo 2012; Kough et al. 2013; Phillips et al. 2013) and the fact that many are open access (Beddington and Kirkwood 2005) has led to uncertainty regarding the sustainability of and appropriate management approaches for Caribbean lobster fisheries (Pauly et al. 2002). For this reason, the present chapter examined the exploited stocks of the Caribbean spiny lobster (*P. argus*) by addressing some guidelines to improve the criteria of assessing the fisheries for this species in the countries within the Caribbean region in which it is exploited, to ensure that this is done sustainably.

## **2. MATERIALS AND METHODS**

#### **2.1. Data, Models, and Analyses**

Exploited Caribbean lobster stocks were assessed using catch data for the last fifteen years available at the Food and Agriculture Organization of the United Nations (FAO, 2011) website (http://www.fao.org/fishery/ fishfinder). The values of population parameters came from Ley-Cooper and Chávez (2010). Changes in abundance over time were determined based on changes in the catch data, which were examined in units of metric tons (mt) of fresh weight.

Trends in fishing mortality (*F*) and estimates of total stock biomass over time were examined. Different fishing scenarios among which the age of first catch (*tc*) differed were evaluated based on the *F* resulting if they were exploited at the level of their maximum sustainable yield (*FMSY*), as an extreme reference point. The other reference point examined was the *F* at the maximum economic yield (*FMEY*). These reference points were determined for each stock at each of the  $t_c$  values examined ( $1 \ge t_c \le 6$  years). Tests of  $t_c$  values higher than 6 years were deliberately omitted because consumers of this species demand lobsters of around 2 or 3 years old, and the relative value of larger lobsters thus decreases.

The maximum social value of a fishery in a given scenario was determined in two ways. First, the value was assessed in terms of the maximum level of employment or, in other words, the maximum number of fishers, potentially supported by the fishery. The second way in which social value was approached was in terms of the maximum profit per fisher. Economic and social values were assessed in terms of the value per kg landed, the number of fishers per boat, the number of boats, and the number of fishing days, all of which were obtained for the last fishing season in the dataset (FAO, 2011) and then later estimated based on overall trends throughout the 15 years of catch data considered. Costs were estimated by summing the cost/boat/day  $\times$  the total number of fishing days of the fleet over the fishing season. Profits were subtracted from the total value of the catch minus the total costs. Costs and values were linked to the catch in the semi-automated age-structured FISMO simulation model (Chávez 2005, 2014), which allowed all of the possible scenarios of exploitation to be tested.

The age of first capture was initialized at 3 years and was maintained at a constant value during the fitting process, but then for the simulations all of the  $F$  and  $t_c$  values feasible to apply to the data were tested to optimize harvest strategies and design exploitation policies for each stock. The age of first maturity of spiny lobsters occurs at the 3-year mark, after the larval and juvenile stages have been completed (Phillips et al. 2013).

Population parameter values were obtained from published sources (Chávez 2009; Ley-Cooper and Chávez 2010). Estimates of the age composition of the catch were made based on FAO (2011) records (http://www.fao.org/fishery/fishfinder). These estimates were made for each one of the main fisheries in the region (those in the Bahamas, Brazil, Cuba, Nicaragua, and the United States of America; Figure 3) over a time scale of 15 years each, and also from a global assessment of the catch data of all 25 spiny lobster fisheries in the Caribbean pooled together. Catch values per kg without value added were obtained as reference data from a small fishery in southeastern Mexico (Ley-Cooper and Chávez 2010), while assuming that their values were approximately the same as those for all other fisheries in the region.

In each case, total mortality  $(Z_t)$  was determined with the exponential decay model as follows:

$$
N_{a+1} = N_a \cdot e^{(-z_t)} \tag{1}
$$

where  $N_a$  is the number of spiny lobsters of age *a* and  $N_{a+1}$  is the number of spiny lobsters of age  $a+1$  in reconstructed age-groups. The time units used in this equation are years. The von Bertalanffy (1934) growth equation was used to determine the number of lobsters in each age group, as well as their corresponding sizes in terms of their lengths. These lengths were transformed into their respective weights by using the equation:

$$
W = 0.0404 \cdot L^3 \tag{2}
$$

where *W* is total weight (g) and *L* is total length (cm).

Figure 3. Catch (metric tons) and value (million USD) of the main Caribbean spiny lobster fisheries in the year 2010. Catch data were obtained from FAO (2011) records.

The age structures of each age group (in years) were estimated assuming a constant natural mortality rate. For setting the values of the variables in the initial state, the abundance per age class ( $N_{a,y}$ ) was set using the age-specific abundance,  $N_a/\sqrt{N_a}$ , obtained from equation (1). In subsequent years, the age structure was defined after the number of one-year-old recruits was estimated. These values were used to calculate the catch-at-age as proposed by Sparre and Venema (1992), and were integrated into the FISMO simulation model as follows:

$$
Y_{a,y} = N_{a,y} \cdot W_{a,y} \frac{F_t}{(F_t + M)} \left( 1 - e^{-(F_t + M)} \right)
$$
 (3)

where  $Y_{a,y}$  is the catch-at-age for age *a* in each year *y*,  $N_{a,y}$  is the number of spiny lobsters at age *a* in year *y*,  $W_{a,y}$  is the lobster weight equivalent of  $N_{a,y}$ ,  $F_t$  is the fishing mortality (as described earlier in this section), and *M* is the natural mortality coefficient. Given the initial conditions used, the values of  $Y_{a,y}$  were adjusted by varying the initial number of recruits, and then linked to equations (1-3) until the following condition was fulfilled:

$$
\sum_{a}^{1} Y_{a,y} = Y_{y(REC)} \tag{4}
$$

where  $Y_{\gamma(REC)}$  is the yield recorded during the year *y*,  $a = 3$  years, and  $t_{\lambda} = 3/K$  or the longevity of the species, where  $K$  is the growth constant of the von Bertalanffy (1934) growth equation. The value of  $t_\lambda$  was set to 13 years, a value found for this species by assuming that a reasonable life expectancy ( $L_{max}$ ) is that at which 95% of the population reaches 95% of  $L\infty$ , the asymptotic length. Thus, the longevity was found by making  $L_{max} = 0.95 \times L_{\infty}$  in the von Bertalanffy growth equation and finding the corresponding value of *t*. The catch equation was used for each year in the time-series analyzed. For the estimation of the natural mortality coefficient (*M*), the criterion proposed by Jensen (1996, 1997) was adopted, where  $M = 1.5K$  $= 0.1793$ ; the value of *K* used is further described below. Estimates of the stock biomass and the exploitation rate,  $E = [F/(M + F)]$ , were made for each age-class in every fishing year analyzed by the model. These values were compared to the  $E$  value at the  $F_{MSY}$  level. A special case is when *E* is equal to the *FMSY* level of fishing mortality, which corresponds to the maximum exploitation rate that a fishery should be able to attain before the stock is overexploited. A diagnosis of the years of the series in which the stock was under- or overexploited was also made, which provided an easy way to recommend either a further increase or decrease in the fishing intensity *F*.

The annual cohort abundance  $(N_{a,y})$  coming from ages older than the age-at-maturity  $(t_m =$ 3 years) was used to estimate the annual abundance of adults  $(S_y)$  over the years, whereas the abundance of the one-year-old group was used as the number of recruits  $(R_y)$ . The stockrecruitment relationship was evaluated by using a slightly modified version of the Beverton and Holt (1957) model of the form:

$$
R_{y+1} = \frac{a r s_o s_y}{s_y + b r s_o} \tag{5}
$$

where  $R_{y+1}$  is the number of one-year-old recruits in year  $y + 1$ ,  $S_y$  is the number of adults in year *y*, and *S<sup>o</sup>* is the maximum number of adults in the population. The parameters *a'* and *b*' are modified from the original model, such that *a′* is the maximum number of recruits and *b′* is the initial slope of the recruitment line, which was kept constant throughout the simulations done herein. The values of the parameters used as input to simulations are shown in Table 1.

Parameter	Value	Units	Model	Source

**Table 1. Population parameter values used for the evaluation of the main spiny lobster fisheries of the Caribbean**

Notes: *K*, *to*, *L∞*, and *W<sup>∞</sup>* are parameters of the von Bertalanffy (1934) growth model; *a* and *b* are obtained from the length-weight allometric equation (3);  $tc = age$  of first catch;  $M =$  natural mortality;  $t_m = age$  of maturity;  $t_\lambda =$ longevity;  $E_{max}$  = exploitation rate at the *MSY* level. To transform carapace length (*CL*) into total length ( $L_t$ ), the equation used was  $L_t = (CL/0.0275) + 3.2$ , which gave  $L_\infty = 56$  cm =  $L_t$ , which was the value used as an input in the model. The resulting  $W_\infty$  was obtained by using the length-weight equation (3):  $W = 0.0404 L^3$ .

Simulations described the main ecological processes underlying the stock dynamics of the spiny lobster fisheries examined. These allowed different exploitation scenarios, with different combinations of fishing intensities and age-at-first catch, to be simulated to see which scenarios maximized the biomass, profits, and social benefits of each fishery. For this purpose, analytical procedures adopting the principles and views of Chávez (1996, 2005) and Grafton et al. (2007) were used. The model used then estimated the simulated catch based on estimates of the stock biomass and fishing mortality for each year of the series for each of the fisheries examined.

The socioeconomics of a fishery were approached through the explicit consideration of the costs of fishing per boat per fishing day. Herein, these values were assessed based on the number of boats, number of fishers per boat, number of fishing days, and the costs of the 2009 fishing season of a small fishery in the southeastern Mexican part of the northwestern

Caribbean, while assuming that they were representative of all of the Caribbean fisheries examined. The value was set to the selling price at the dock of the spiny lobsters landed in the same fishery; the profit was the difference between the costs and the value. In these simulations, the costs of fishing and catch value per kg were assumed to be constant over time.

The socioeconomic information used allowed the economic trends within each of the fisheries analyzed to be reconstructed over the 15 years analyzed with the aid of the simulation model. This was done by using the estimated fishing mortality for each fishery over time as a reference value to estimate their corresponding value of each of the different economic variables.

Changes in each population's lobster biomass were estimated using the number of survivors in each cohort. The estimation of the potential yield in each case allowed the *MSY* and the *MEY* values for each  $t_c$  (where  $1 \le t_c \le 6$  years) to be found.

#### **2.2. The Simulations**

The estimated catch values showed that the level of exploitation at which the rate of change in the catch or profits of a fishery with respect to changes in its *F* was zero corresponded to the point at which the maximum values of these endpoints were attained, which was equivalent to the *MSY* of the catch and the *MEY* of the profits, respectively. A parallel trend in the *F* and *t<sup>c</sup>* values was required for the *MSY* and *MEY* to be found in most cases. The uncertainties of the estimates produced, after Hilborn and Liermann (1998), were expressed as coefficients of variation, estimated for each fishery, but for simplicity their values were deliberately ignored in the presentation of results, and instead the mean tendencies were presented. Parameter values were fixed at some 'best' estimated value herein rather than allowing for uncertainty in their values (Hilborn and Liermann 1998); simulations were done in this way to allow clear trends to be obtained and allow specific harvest recommendations to be addressed.

Figure 4. The response of a stock's yield (A) and value (B) to differing values of *F* and *tc*. Simulation outputs for the Florida spiny lobster fishery (in 2007) are presented. Potential yield (A) is presented in metric tons, and potential profits (B) are in USD.

Figure 5. Simulation outputs of potential yield (mt) (A) and potential profits (USD) (B) of the Florida spiny lobster fishery at different levels of *F* and a constant *t<sup>c</sup>* = 3 years. The *MSY* and *MEY* values are the peaks of the curves for catch and profit, respectively. The *MSY* value corresponds to the catch in the years 1997 and 1999.

#### **2.3. Theoretical Statement**

Results of previous stock assessments indicated that yield displays a dome-shaped response surface as a function of *F* and *tc*, as shown in Figure 4A and B. When a single set of outputs as a function of  $F$  was examined at a certain  $t_c$ , the yield and profits also displayed curves that peaked and attained their maximum values at the corresponding *MSY* and *MEY* (Figure 5A, B). In general, these peak values were found at the same *tc*, but the *MSY* was usually attained at a higher *F* than the *MEY* was. In highly valued fisheries like those of the spiny lobster, the *F* resulting in the *MEY* generally coincides with that of the *MSY*. Additionally, there should be a certain *F* value where the maximum yield is attained, declining at higher as well as lower *F* values, such as in the well-known figure of yield isopleths presented by Beverton and Holt (1957) that displayed the yield per recruit as a function of *F* and *tc*.

## **3. RESULTS**

#### **3.1. Optimum Yields**

As result of the examination of the long-term stock responses when attempting to maximize yields, it was found that this variable tended to increase with higher values of *tc*. In some cases, the yield at a  $t_c \leq 5$  was higher by 20% than that at the current  $t_c$  of 3 years, as shown in Figure 6A-C. In three of the fisheries examined (Nicaragua, the Bahamas, and Cuba), the *F* values required to reach the *MSY* were higher than those needed to reach the *MEY*. In the other fisheries, the *F* levels at the *MSY* and *MEY* overlapped.

Figure 6. Potential *MSY* and *MEY* of representative Caribbean spiny lobster fisheries as a function of *t<sup>c</sup>* (x-axes) and *F* (not displayed here). Results are presented for all 25 Caribbean fisheries and Cuba (A), for Brazil and the USA (B), and for Nicaragua and the Bahamas (C). In most cases, the yield at the *MSY* was higher than that at the *MEY*, and yields were higher with a higher *tc*.

#### **3.2. Optimum Economic Yields**

The profits of these fisheries were higher at the *F* values applied to reach the *MEY* than at those required for the *MSY*, as shown in Figure 7A-C. The *MEY* tended to increase as a function of the *t<sup>c</sup>* in the cases of Nicaragua and Brazil. In Cuba and the USA, this increasing trend was not very significant, and higher values were obtained when the *F* of the *MEY* was used rather than that of the *MSY*. These trends depended on the volume of spiny lobsters landed. The case of the Bahamas was remarkable, because the yields tended to decrease at all *t<sup>c</sup>* values examined, and the profits were negative when the *F* values required for the *MSY* were applied (Figure 7B). The case of the USA was not so critical because the line of profits was around the economic equilibrium level for this country, with profits being negative at only  $t_c = 4$  years (Figure 7C). Evidently, operating costs are sensitive to the size of the exploited stocks (Hannesson 2007).

Figure 7. Potential profits (in millions of USD) of representative Caribbean spiny lobster fisheries at the *MSY* and *MEY* as a function of *t<sup>c</sup>* and *F*. Results are shown for all 25 Caribbean fisheries combined and Cuba (A), for Brazil and the USA (B), and for Nicaragua and the Bahamas (C). In most cases, the yield at the *MEY* was higher than that at the *MSY*. In addition, profits were generally higher with a higher *tc*, except in the Bahamas, where the fishery was not profitable in any scenario when the *F* applied reached the *MSY*.

## **3.3. Social Benefits**

As described earlier (section 2.1), in the simulation model the economic and social values were linked to the costs and value of fishing activities, as well as to the number of fishers involved directly in this activity. Therefore, the model is sensitive to fishing effort and the resulting numbers of fishers, as shown in Figure 8A and B. The same increasing trend was observed for the number of fishers as was previously seen in the case of yield (Figure 7A-C), wherein a higher number of fishermen was required when *t<sup>c</sup>* values were higher as a consequence of the higher catches under these conditions. It was particularly remarkable to observe the case in which all of the fisheries were grouped together (Figure 8B), wherein nearly 30,000 fishers currently participate in all of the Caribbean lobster fisheries with a *t<sup>c</sup>* = 3 years, but this could be increased to nearly 50,000 if *t<sup>c</sup>* values were raised to 5 or 6 years. The Brazilian fishery displayed the steepest slope of this growing trend in relation to *t<sup>c</sup>* (Figure 8A). In a similar way as in some of the results already described, when the catch was set at the *MSY*, the number of direct jobs potentially supported by the fishery was the same or higher than that at the *MEY*.

Figure 8. Number of fishers involved in the main Caribbean lobster fisheries and in all of the fisheries combined in relation to *tc*. Increases were observed when higher *t<sup>c</sup>* values were used. The catch rate per fisher was maintained at a constant value, representing the mean value under current conditions. Results are shown for Brazil, Cuba, and Nicaragua (A) and for the USA, the Bahamas, and all 25 fisheries combined (B).

Figure 9. Social benefits, expressed as profits per fisher, of the five main Caribbean spiny lobster fisheries and all of the Caribbean fisheries combined. Results are shown for Brazil, Cuba, and the USA (A) and for the Bahamas, Nicaragua, and all 25 Caribbean fisheries combined (B). The social benefit mainly declined with increasing *tc*, and the social benefit was often much higher at the *MEY* than at the *MSY*.

The social benefit of a fishery was expressed herein as the profits obtained per fisher, which was simply calculated by dividing the profits by the number of fishers while assuming that they would have access to the same catch as in current conditions. In all cases except one, the social benefits of the fisheries declined when the stocks were exploited with higher  $t_c$ values (Figure 9A, B). The Bahamas fishery was not profitable when the *F* values required for the *MSY* were applied. In the USA, the social benefits were much higher under the *MEY* scenario.

## **4. DISCUSSION**

#### **4.1. The Model Output**

To begin, it must be remembered that the figure presented by Beverton and Holt (1957) displaying the relationship of the yield-per-recruit to  $F$  and  $t_c$  did not explicitly take recruitment into account. When a simulation is used as in the present case (Chavez 2005, 2014), a recruitment function must be explicitly defined, as this is a necessary condition to link the simulated cohorts over time. In earlier sections (2.1, 2.2, and 2.3), the simulations were described as being expected to provide the same kind of performance by estimating the stock biomass as the yield-per-recruit curve at high  $F$  and  $t_c$  values. However, this hypothesis has to be rejected. Therefore, it is easy to understand why yields and profits were found to increase when high *t<sup>c</sup>* values were considered because, in this case, the size of the breeding stock would be higher than that under current conditions, where there is a general tendency to catch smaller animals as a consequence of increasing competition among fishers. It must also be kept in mind that there should be a maximum number of adults and recruits that can occur within a stock, which is a limit imposed by the carrying capacity of the ecosystem. For example, in the case of adult biomass, the carrying capacity may be close to the virgin biomass of an unexploited stock, or, in other words, it could be twice the stock biomass at the *MSY* level.

In several instances, the approach presented herein was consistent with the methods used in the management strategy evaluation (MSE) approach, which relies on testing the whole management process through simulations using and specifying different performance measures with which to compare alternative management strategies (Sainsbury et al. 2000). In this chapter, 15-year time series of catch data were chosen to feed the model for two reasons: one was to minimize the effects of climate variability, which may induce significant changes in recruitment rates if longer time series are used; and the other was to be consistent with Jackson et al. (2001), who stated that "Retrospective data not only help to clarify underlying causes and rates of ecological change", but also help to "demonstrate achievable goals for restoration and management."

The estimation of potential yield is one of the goals to which any fishery's stock assessment should aspire, even if it is based on simple relations (Beddington and Kirkwood 2010). In the Introduction (section 1), it was mentioned that the *MEY* is a more convenient option for a target of fisheries assessment than the *MSY* because it is often achieved at lower levels of *F*, thus reducing the risks of overexploiting the stock. This may be a function of the discount rate (Grafton et al. 2007). In addition, in the method applied herein to assess stock biomass, Hilborn and Walters (1992) can be quoted in saying that "you cannot find the top of a [yield] curve without going beyond the top". The "top" they mention is the *MSY* level. In contrast, when the *MEY* is adopted as a target, when going beyond the top of the *MEY* curve the stock is still underexploited, or at least has not exceeded its reproductive potential. This was the case for about half of the Caribbean spiny lobster fisheries examined in this chapter.

#### **4.2. Management Options**

The Caribbean spiny lobster fisheries are a clear example of unsuccessful management systems, wherein access to the resource is open and there is poor ability to monitor its exploitation and implement regulations (Hilborn et al. 2005), and consequently these fisheries have rarely been sustainable (Pauly et al. 2002).

We are living in a world where the political incentive is to maintain the continuous exploitation of fished stocks, which has led to the generally depleted condition of fish stocks worldwide (Rosenberg 2003). Therefore, the purpose of the exercises done in this chapter was to provide some guidelines that could help achieve the sustainable management of Caribbean spiny lobster fisheries (Mora et al. 2009). The fisheries examined herein displayed great heterogeneity. For this reason, it was not possible to make a few general management recommendations that could be feasibly adopted for widespread application. However, based on the results, there are at least three reference points that can potentially be used to develop some planning guidelines, which are the *FMSY*, *FMEY*, and *tc*. Further, the yield, profits, and social benefit (herein referring to the profits per fisher) are the dependent variables that should be compared when assessing the performance of a fishery under different conditions. The combination of the *F* and the *t<sup>c</sup>* that produces the highest catch, profits, and social benefit is the feasible targets that should be sought for the management of these fisheries. In this approach, the economic and social aspects of the fisheries were incorporated, which agrees with modern trends in the definition of sustainability (Quinn II and Collie 2005), wherein the costs of management and the windfall profits of fisheries conservation should be shared (Hilborn et al. 2005).

As a final corollary, and after perceiving that the spiny lobster stocks are exploited under heterogeneous conditions and different fishing gears, it is apparent that recurrent socioeconomic crises in the exploitation of this resource can and do take place in some countries within the species' distribution. Therefore, it would be useful to create an international organization in charge of regulating and controlling regional access to this resource. This group would be in charge of carrying out stock assessments of the main stocks and assign catch quotas and minimum size limits every year, before the beginning of the next fishing season. In this way, the sustainable exploitation of this common property resource would be ensured. The adoption of these statements as general principles in stock assessment and management is therefore suggested, as well as those more specific principles recommended in a previous paper (Chávez 2007).

## **CONCLUSION**

As result of the analyses carried out in this chapter, the following conclusions were derived:

- 1. The *MSY* is attained at the same or higher *F* values as those required to reach the *MEY*. The highest values for these variables are obtained when  $t_c \geq 5$  years.
- 2. Likewise, the maximum profits are reached with the *F* values required to achieve the *MEY*. In some cases, when the *F* required for the *MSY* to be reached is applied, the fishery may become non-profitable.
- 3. The maximum social benefit, meaning the number of jobs directly supported by the fishery, is obtained at the *F* values required to reach the *MSY* and when  $t_c > 5$  years.
- 4. The maximum economic benefit per fisher is obtained when the *F* required to attain the *MEY* is applied, and when  $t_c < 3$  years.

## **ACKNOWLEDGMENTS**

Rene Buesa kindly provided catch data for the Florida spiny lobster fishery, read the manuscript, and made valuable suggestions. The author holds a research fellowship from COFAA and EDI, IPN.

 $\overline{a}$ 

# **MARINE DEBRIS: INTERAGENCY COMMITTEE MEMBERS ARE TAKING ACTION, BUT ADDITIONAL STEPS COULD ENHANCE THE FEDERAL RESPONSE**

# *United States Government Accountability Office*

# **WHY GAO DID THIS STUDY**

Marine debris—waste such as discarded plastic and abandoned fishing gear and vessels in the ocean—is a global problem that poses economic and environmental challenges. The Marine Debris Act, enacted in 2006, requires the committee to coordinate a program of marine debris research and activities among federal agencies. The act also requires the committee to submit biennial reports to Congress that include certain elements such as an analysis of the effectiveness of the committee's recommendations.

GAO was asked to review federal efforts to address marine debris. This report examines (1) how the committee coordinates among federal agencies and the process for determining membership, (2) the extent to which the committee's biennial reports contain required elements, and (3) experts' suggestions on actions the federal government could take to most effectively address marine debris. GAO examined the Marine Debris Act and committee reports, compared committee practices with leading collaboration practices, interviewed federal agency officials, and interviewed a nongeneralizable sample of 14 marine debris experts selected to reflect various sectors and experiences with different types of marine debris.

This is an edited, reformatted and augmented version of United States Government Accountability Office; Report to Congressional Requesters, Publication No. GAO-19-653, dated September 2019.

## **WHAT GAO RECOMMENDS**

GAO is making four recommendations, including that NOAA establish a time frame for documenting membership and the committee develop processes to analyze the effectiveness of its efforts and identify priority funding. The agency agreed with GAO's recommendations.

## **WHAT GAO FOUND**

The Marine Debris Research, Prevention, and Reduction Act, as amended, (Marine Debris Act) designated six agencies as members of the Interagency Marine Debris Coordinating Committee and specifies that members shall include senior officials from certain other agencies as the Secretary of Commerce determines appropriate. Within Commerce, the National Oceanic and Atmospheric Administration (NOAA) serves as the committee chair. The committee coordinates through sharing information about members' activities to address marine debris, but GAO found that NOAA has not established a process for determining committee membership for agencies not specifically designated in the act. As a result, such agencies may not be included in the biennial reports required by the act which discuss committee members' marine debris activities. NOAA officials said they plan to develop a membership process but have not established a time frame to do so. By establishing a time frame, the committee can more fully benefit from capturing all members' activities.

The committee's biennial reports provide information on members' activities such as education and cleanup, but they do not contain some information required by the Marine Debris Act. Specifically, the reports do not include (1) an analysis of the effectiveness of the committee's recommendations and strategies to address marine debris and (2) recommendations for priority funding needs. Our past work has shown that collaborative entities can better demonstrate progress if they develop a way to monitor and report the results of their collective efforts and identify and leverage resources. By doing so, the committee would be in a better position to know the extent to which it is effectively addressing marine debris and provide Congress with required information about priority funding needs.

Source: National Oceanic and Atmospheric Administration. | GAO-19-653.

Marine debris washed ashore on a beach.

Experts suggested a range of actions—from research to cleanup—the federal government could take to most effectively address marine debris. They stressed that there is not one solution to the growing problem (see figure). Committee officials noted factors to consider, such as cost, when evaluating these actions.

#### **ABBREVIATIONS**

September 25, 2019

 $\overline{a}$ 

Congressional Requesters

Marine debris—waste ranging from small, everyday items, such as cigarettes and discarded plastic bottles, to larger objects, such as abandoned fishing gear and vessels found in the ocean or Great Lakes environment—poses economic and environmental challenges and is an issue of growing local, national, and international concern.<sup>1</sup> Marine debris can harm coastal and marine species and habitats, obstruct navigational waterways, cause economic loss to fishing industries and coastal communities, and threaten human health and safety.<sup>2</sup> Debris can enter the aquatic environment directly from domestic or international water- based sources, such as when materials are intentionally dumped in the water or blown off fishing vessels. Debris can also enter the aquatic environment indirectly from land-based sources by washing into waterways that eventually flow to the ocean. Research has shown that a significant amount of marine debris stems from land-based sources, such as improperly managed plastic waste.<sup>3</sup>

<sup>&</sup>lt;sup>1</sup> For the purposes of this report, we use the term marine debris, but such waste is also referred to as "marine litter" or "marine trash." National Oceanic and Atmospheric Administration and U.S. Coast Guard regulations define marine debris as "any persistent solid material that is manufactured or processed and directly or indirectly, intentionally or unintentionally, disposed of or abandoned into the marine environment or the Great Lakes." 15 C.F.R. § 909.1(a), 33 C.F.R. § 151.3000(a). This definition is also found in the Marine Debris Act Amendments of 2012. Pub. L. No. 112-213, tit. VI, § 608(2), 126 Stat. 1540, 1578 (*codified at* 33 U.S.C. § 1956(3)).

<sup>2</sup> National Oceanic and Atmospheric Administration, *Report to Congress: 2016-2017 Interagency Marine Debris Coordinating Committee Biennial Report* (March 2019).

<sup>3</sup> Jambeck, J.R., et al., "Plastic waste inputs from land into the ocean," *Science*, 347 (2015): pp. 768-771. This study found that five Asian countries contributed the most waste by mass, but many other countries also contributed to the problem including the United States, which ranked 20th on this list. Countries were ranked by mass of mismanaged plastic waste in units of millions of metric tons per year. A metric ton is equal to 1,000 kilograms.

Numerous studies show that plastic is a particularly pervasive and persistent form of marine debris. <sup>4</sup> An estimated 8 million metric tons of mismanaged plastic waste entered the marine environment in 2010 according to one study,<sup>5</sup> and projections show that by 2025 this number could increase to 17.5 million metric tons each year.<sup>6</sup> According to a 2018 United Nations report, studies estimate that the total economic damage to the world's marine ecosystem caused by plastic amounts to at least \$13 billion each year.<sup>7</sup> Although chemicals in plastic provide valuable properties such as durability, there is growing concern that these chemicals may be toxic and harmful to marine species. <sup>8</sup> Over time, through exposure to sunlight and wave action, plastic breaks apart into increasingly smaller pieces, eventually becoming tiny particles called microplastics. Marine life may ingest these microplastics, raising concerns about potential health effects for such marine life and any organisms, including humans, which may eat them.<sup>9</sup>

Addressing marine debris is a complex, interdisciplinary issue involving many sectors and levels of government. Multiple federal agencies, often in coordination with state and local governments, Indian tribes, industry, international parties, and nongovernmental agencies, work to prevent, manage, remove, and raise awareness about marine debris. To help address marine debris, the Marine Debris Research, Prevention, and Reduction Act (Marine Debris Act) was enacted in 2006 and amended in 2012 and 2018.<sup>10</sup> The purpose of the Marine Debris Act is to address the adverse impacts of marine debris on the U.S. economy, the marine environment, and navigation safety through the identification, determination of sources, assessment, prevention, reduction, and removal of marine debris.<sup>11</sup>

Among other things, the Marine Debris Act reactivated the Interagency Marine Debris Coordinating Committee (interagency committee) to coordinate a comprehensive program of marine debris research and activities among federal agencies and in cooperation and coordination with nonfederal entities, such as nongovernmental organizations, industry,

<sup>9</sup> Early research has shown that microplastic-derived toxins may accumulate in organisms and potentially harm other marine life and humans when ingested, but additional research is needed. Environmental Protection Agency, *State of the Science White Paper* (December 2016).

<sup>10</sup> Marine Debris Research, Prevention, and Reduction Act, Pub. L. No. 109-449, 120 Stat. 3333 (2006), *as amended by* Marine Debris Act Amendments of 2012, Pub. L. No. 112- 213, tit. VI, 126 Stat. 1540, 1575-78 (2012); Save Our Seas Act of 2018, Pub. L. No. 115-265, tit. I, 132 Stat. 3742, 3742-3744 (2018) (*codified as amended at* 33 U.S.C. § 1951- 58). The Marine Debris Act Amendments of 2012 changed the name of the act from Marine Debris Research, Prevention, and Reduction Act to Marine Debris Act. Pub. L. No. 112-213, tit. VI, § 602(a), 126 Stat. 1540, 1575 (2012). In this report we use the term "Marine Debris Act" to refer to the act as amended through 2018.

universities and research institutions, states, Indian tribes, and other nations, as appropriate.<sup>12</sup> The act designates a senior official from the National Oceanic and Atmospheric Administration (NOAA), within the Department of Commerce, to serve as the chair of the interagency committee. Other federal agency members designated in the act are the Environmental Protection Agency (EPA), U.S. Coast Guard, U.S. Navy, Department of State, and Department of the Interior.<sup>13</sup> The act also specifies that the committee shall include senior officials from other federal agencies that have an interest in ocean issues or water pollution prevention and control as the Secretary of Commerce determines appropriate.

The Marine Debris Act requires the interagency committee to submit to Congress biennial reports that evaluate progress in meeting the purposes of the act.<sup>14</sup> The biennial reports are to include (1) the status of implementation of any recommendations and strategies of the committee and analysis of their effectiveness, and (2) estimated federal and nonfederal funding provided for marine debris and recommendations for priority funding needs.<sup>15</sup>

You asked us to review federal efforts to address marine debris under the Marine Debris Act. This report examines (1) how the interagency committee coordinates among federal agencies and the process for determining membership and agency representation, (2) the extent to which the interagency committee's biennial reports contain required elements, and (3) experts' suggestions on actions the federal government could take to most effectively address marine debris.

To examine how the interagency committee coordinates among federal agencies and the process for determining membership and agency representation, we reviewed the Marine Debris Act and interagency committee documents, including the committee's charter and the five biennial reports to Congress issued as of March 2019.<sup>16</sup> We also reviewed the most recently available minutes from quarterly committee meetings held from November 2012 through April 2019 to determine the types of topics and activities on which the committee has coordinated and the federal agencies that have participated. We attended five of the interagency committee's quarterly meetings (in May, September, and December of 2018, and April and July of 2019) to directly observe committee coordination among agencies during these meetings. We also reviewed documents from committee member agencies and interviewed and reviewed written responses from those agencies to obtain information on their coordination efforts. Agencies we included were those agencies designated as members in the Marine Debris Act as well as additional agencies identified as members in the

 $12$  The Coast Guard Authorization Act of 1996 required the Secretary of Commerce to establish a Marine Debris Coordinating Committee. Pub. L. No. 104-324, § 802(b),110 Stat. 3901, 3944-45 (1996). In 2006, the Marine Debris Act reactivated this committee and established it by statute. Officials from the National Oceanic and Atmospheric Administration said they do not have records of committee activities before 2006.

<sup>&</sup>lt;sup>13</sup> The Coast Guard Authorization Act of 1996 designated NOAA, EPA, the U.S. Coast Guard, and the U.S. Navy as members of the interagency committee. The Save Our Seas Act of 2018 designated the Departments of State and the Interior as members of the committee.

<sup>&</sup>lt;sup>14</sup> Biennial reports are required to be submitted to the Senate Committee on Commerce, Science, and Transportation, the House Committee on Transportation and Infrastructure, and the House Committee on Natural Resources.

<sup>&</sup>lt;sup>15</sup> The biennial reports are also to include other required elements listed in 33 U.S.C. § 1954(e). These other elements are about specific agency programs.

<sup>&</sup>lt;sup>16</sup> The five biennial reports were issued in March 2010, October 2012, September 2014, December 2016, and March 2019. Collectively, the reports include activities the interagency committee members reported conducting between June 2008 and December 2017.

committee's charter. <sup>17</sup> In addition, we compared these agencies' documents and written responses about the interagency committee's coordination with leading practices we identified in our past work on implementing interagency collaborative mechanisms.<sup>18</sup>

To examine the extent to which the interagency committee's biennial reports contain required elements, we compared information contained in the committee's five biennial reports (from 2010 to 2019) to the reporting requirements in the Marine Debris Act. Specifically, two analysts independently reviewed each of the five biennial reports to evaluate information the reports included about (1) the status of implementation of any recommendations and strategies of the committee, (2) analysis of the recommendations and strategies' effectiveness, (3) estimated federal and nonfederal funding provided for marine debris, and (4) recommendations for priority funding needs. The analysts then compared and summarized the results of their analyses. We also interviewed and reviewed written responses from NOAA officials (in the agency's capacity as chair of the interagency committee) and officials from other committee member agencies about steps to develop the biennial reports, including the reports' required elements. In addition, we compared information from the reports and information we obtained from agency officials to leading practices we identified in our past work on implementing interagency collaborative mechanisms.<sup>19</sup>

To obtain suggestions on actions the federal government could take to most effectively address marine debris, we conducted structured interviews with a nongeneralizable sample of 14 experts with expertise in marine debris-related issues. We selected these experts using factors such as the individuals' experience with different types of debris (e.g., abandoned fishing gear or consumer debris) or association with various sectors (e.g., academia or industry). The experts included: (1) academics with expertise in areas such as sources, prevalence, and transport of plastic marine debris; (2) officials representing the plastic manufacturing, food and beverage, and commercial fishing industries; (3) officials from nonprofit organizations with expertise in marine debris removal from coastal areas, litter prevention, and recycling management systems and strategies; and (4) state and local government officials from the District of Columbia, Florida, and Washington with expertise in local litter prevention efforts, derelict vessels, and lost and derelict fishing gear.<sup>20</sup>

We asked the 14 experts to suggest actions the federal government could take to most effectively address different types of marine debris. Specifically, we asked that experts identify up to 5 to 10 actions as well as advantages, disadvantages, and any challenges in potentially implementing these suggested actions. We then categorized the actions based on common themes. To do so, two analysts independently reviewed each expert's description of each action and identified an appropriate category using decision rules the team developed.

<sup>&</sup>lt;sup>17</sup> These agencies are: the Department of Commerce's NOAA; the Department of Defense's U.S. Army Corps of Engineers and U.S. Navy; the Department of Homeland Security's U.S. Coast Guard; the Department of the Interior's Bureau of Safety and Environmental Enforcement, National Park Service, and U.S. Fish and Wildlife Service; the Department of Justice; the Department of State; EPA; and the Marine Mammal Commission. In addition, we interviewed officials from the National Science Foundation, the U.S. Agency for International Development, and the Office of the U.S. Trade Representative based on suggestions from interagency committee officials and marine debris experts.

<sup>18</sup> GAO, *Managing for Results: Key Considerations for Implementing Interagency Collaborative Mechanisms*, GAO-12-1022 (Washington, D.C.: Sept. 27, 2012). We used leading practices that are relevant to the requirements for the interagency committee in the Marine Debris Act. These included practices related to participants, resources, outcomes and accountability, and written guidance and agreements.

<sup>19</sup> GAO-12-1022.

<sup>&</sup>lt;sup>20</sup> We selected these locations using factors such as geographic area and expertise in marine debris issues.
For reporting purposes, we selected several actions within each of the categories to provide illustrative examples of the types of actions experts suggested. Our selection was based on such factors as the number of experts that suggested similar types of actions, the detail provided by the experts, and the availability of supporting information, such as documentation of instances where an action had been taken by state or local governments. Actions suggested by the 14 experts cannot be generalized to actions that might be suggested by other experts, but provide examples of actions federal agencies could take to address marine debris.<sup>21</sup> We also interviewed and received written responses from officials from interagency committee agencies regarding issues that would be important to consider in potentially implementing any of the expert suggested actions. Appendix I presents a more detailed description of our objectives, scope, and methodology.

We conducted this performance audit from October 2017 to September 2019 in accordance with generally accepted government auditing standards. Those standards require that we plan and perform the audit to obtain sufficient, appropriate evidence to provide a reasonable basis for our findings and conclusions based on our audit objectives. We believe that the evidence obtained provides a reasonable basis for our findings and conclusions based on our audit objectives.

## **BACKGROUND**

Marine debris originates from multiple sources and types of materials, entering the marine environment in a variety of ways, as shown in figure 1.

Source: GAO. | GAO-19-653.

 $\overline{a}$ 

Figure 1. Overview of sources and types of marine debris.

<sup>&</sup>lt;sup>21</sup> We did not limit experts' suggestions to actions that agencies currently have authority to implement. We do not take a position on the merits of, the necessary legal authority for, or the most appropriate entity for the actions suggested by the 14 experts.

Prevalent types of marine debris and their effects include:

 **Plastics and microplastics**. Plastics, including items such as grocery bags, food wrappers, bottles, straws, and cigarette filters, are particularly ubiquitous, having been found in the deepest reaches of the ocean.<sup>22</sup> Microplastics—generally defined as plastic particles less than 5 millimeters in size—are especially pervasive. For instance, one study completed in 2018 found record concentrations of microplastics in Arctic sea ice.<sup>23</sup> Plastic marine debris can damage habitats, entangle wildlife, cause injury via ingestion, impair vessel engines, create navigation hazards, inflict economic loss, and transport non- native species, according to NOAA documents.

Most plastics do not biodegrade, that is, decay naturally and become absorbed by the environment. Instead, plastics slowly break down into smaller and smaller fragments, eventually becoming what are known as microplastics. Microplastics are very small pieces of plastic that are generally less than 5 millimeters in size (about the size of a sesame seed). The formation of microplastics occurs when plastic debris is exposed to sunlight and the plastic begins to weather and fragment.

Microplastics have been found in the stomachs of numerous aquatic organisms including insects, worms, fish, and clams, according to a 2018 study. A study from 2011 showed that once animals ingest microplastics, they can be stored in tissues and cells, providing a possible pathway for the accumulation of contaminants and potentially harming the animals.

Sources: GAO analysis of scientific studies; Sherri Mason/SUNY Fredonia (photo). | GAO-19- 653.

 **Derelict fishing gear**. Derelict fishing gear refers to nets, lines, crab pots, and other recreational or commercial fishing equipment that has been lost, neglected, or discarded in the marine environment. According to the Global Ghost Gear Initiative, at least 640,000 tons of derelict fishing gear enters the ocean each year, a weight

 $22$  According to research published in 2018, there have been multiple sightings of plastic deep in the ocean including a plastic bag found in the Pacific Ocean's Marianas Trench— the deepest part of the ocean and the deepest location on earth. Chiba, et al., "Human footprint in the abyss: 30 year records of deep-sea plastic debris," *Marine Policy* 96(2018) 204-212. Another study estimated that, globally, there are now more pieces of plastic in the ocean than there are stars in the Milky Way. Lavers, et al., "Significant plastic accumulation on the Cocos (Keeling) Islands, Australia." *Nature* 9:7102 (2019): pp. 1-9.

<sup>23</sup> Peeken, et al., "Arctic sea ice is an important temporal sink and means of transport for microplastic," *Nature Communications*, 9:1505 (2018): pp. 1-12.

equivalent to two Empire State Buildings.<sup>24</sup> Derelict fishing gear may entrap sea life, adversely affect marine habitats, present hazards to navigation, and cause other harmful effects (see Figure 2). For example, according to a 2015 NOAA report, derelict fishing gear threatens a variety of fish, turtles, seabirds, whales, and seals, and may be especially problematic for endangered and protected marine species.<sup>25</sup>

Source: National Oceanic and Atmospheric Administration. | GAO-19-653.

Figure 2. Marine life entangled in derelict fishing gear.

 $\overline{a}$ 

 **Abandoned and derelict vessels**. Abandoned and derelict vessels are vessels without identified ownership, in significant disrepair, or both.<sup>26</sup> There are thousands of such vessels in ports, waterways, and estuaries around the United States that have been left to deteriorate by the owner or operator or are the result of a catastrophic weather event, according to NOAA documents. Abandoned and derelict vessels can impede marine transportation by blocking navigable waterways, and, if not visible or well-marked, could pose collision risks to vessel operators. These vessels may also become sources of pollution since they may contain fuel oil or other hazardous materials that can leak into the water as the vessels deteriorate, impacting the local community, marine life, and nearby habitat.<sup>27</sup>

<sup>&</sup>lt;sup>24</sup> The Global Ghost Gear Initiative is a cross-sectoral alliance committed to finding solutions to the problem of lost, abandoned and otherwise discarded fishing gear (also known as "ghost gear") worldwide, according to its website. Participants in the alliance include the fishing industry, the private sector, academia, governments, and intergovernmental and nongovernmental organizations.

<sup>25</sup> National Oceanic and Atmospheric Administration, *Impact of "Ghost Fishing" via Derelict Fishing Gear*  (Charleston, SC, and Silver Spring, MD: March 2015).

<sup>26</sup> For additional information, see GAO, *Maritime Environment: Federal and State Actions, Expenditures, and Challenges to Addressing Abandoned and Derelict Vessels*, GAO-17-202 (Washington, D.C.: March 28, 2017).

<sup>&</sup>lt;sup>27</sup> According to U.S. Fish and Wildlife Service officials, abandoned and derelict vessels can also leach iron and other contaminants that result in the overgrowth of algae and invasive species that may physically damage coral reefs and other habitats.

Marine debris has garnered increasing interest from the international community. In September 2015, the United Nations General Assembly unanimously adopted an agenda with a set of global sustainable development goals through  $2030$ .<sup>28</sup> One of the goals (goal 14) calls for conservation and sustainable use of the oceans, seas, and marine resources, and includes a target for prevention and significant reduction of marine pollution of all kinds, including marine debris, by 2025. In June 2018, five members of the Group of Seven and the European Union endorsed the Group's Ocean Plastics Charter, which committed them to accelerating implementation of the Group of Seven Leaders' Action Plan to Combat Marine Litter, previously agreed to in 2015.<sup>29</sup> The United States and Japan were the two members of the Group of Seven that did not endorse the charter. Also, in May 2019, the parties to the Basel Convention on the Control of Transboundary Movements of Hazardous Waste and Their Disposal adopted a decision that would, beginning January 1, 2021, require parties to take appropriate measures to ensure that certain plastic waste is reduced to a minimum, taking into account social, technological and economic aspects, among other things.<sup>30</sup>

#### **Marine Debris Act**

 $\overline{a}$ 

The Marine Debris Act governs the activities of the interagency committee. For example, it required the interagency committee to issue a report to Congress that included recommendations to reduce marine debris domestically and internationally.<sup>31</sup> In 2008, the committee submitted an interagency recommendation report that contained 25 recommendations intended to guide the federal government's strategies for addressing marine debris (see appendix II for a list of the 25 recommendations). The recommendations were categorized by an overarching topic, such as education and outreach or cleanup. Within each category, the committee then identified specific recommendations. For example, within the education and outreach category, the committee specified three recommendations:

- Demonstrate leadership by distributing educational materials to personnel on the sources and impacts of marine debris as well as methods for prevention with the goal of reducing the federal contribution to marine debris.
- Support public awareness campaigns by providing technical expertise and educational materials and by encouraging private sector participation, when appropriate.

<sup>28</sup> United Nations, *Transforming Our World: The 2030 Agenda for Sustainable Development* (adopted Sept. 25, 2015). The agenda addressed five components of sustainable development (people, planet, prosperity, peace, and partnership), and included 17 goals with 169 associated targets.

<sup>&</sup>lt;sup>29</sup> The Group of Seven is an informal grouping of seven of the world's advanced economies—Canada, France, Germany, Italy, Japan, the United Kingdom, and the United States—that meets annually to discuss issues such as global economic governance, international security, and energy policy.

<sup>&</sup>lt;sup>30</sup> The United States is a signatory, but not a party, to the Convention. Parties to an international agreement are those countries that have consented to be bound by the agreement and for which the agreement is in force. Generally, countries express their consent to be bound by an agreement by ratifying, accepting, approving or acceding to it. Countries that have signed the agreement but not consented to be bound to it are obliged to refrain from acts that would defeat the object and purpose of the agreement until the country's intention not to become a party to the agreement is made clear.

<sup>&</sup>lt;sup>31</sup> Pub. L. No. 109-449, §  $5(c)(1)$ , 120 Stat. 3333, 3337 (2006). The report was due on December 22, 2007; the committee submitted the report to the congressional committees in August 2008. This requirement was repealed in 2012. *See* Pub. L. No. 112-213, § 606(a)(1), 126 Stat. 1540, 1577 (2012).

 Engage and partner with state, local, tribal and nongovernmental entities to support coordinated events, such as Earth Day, the International Coastal Cleanup, and other activities that have relevance to marine debris.

The act also requires the interagency committee to submit biennial reports to Congress that evaluate progress in meeting the purposes of the Marine Debris Act. Specifically, these biennial reports are to include:

- the status of implementation of any recommendations and strategies of the committee and analysis of their effectiveness, and
- estimated federal and nonfederal funding provided for marine debris and recommendations for priority funding needs.

Starting in 2010, the interagency committee has issued five biennial reports to Congress, issuing its most recent report in March 2019.<sup>32</sup>

The Marine Debris Act designates six federal agencies as interagency committee members. The six agencies are NOAA, EPA, U.S. Coast Guard, U.S. Navy, Department of State, and Department of the Interior.

The act also specifies that the committee shall include senior officials from other federal agencies that have an interest in ocean issues or water pollution prevention and control as the Secretary of Commerce determines appropriate. The act designates the senior official from NOAA to serve as the chair.

# **INTERAGENCY COMMITTEE COORDINATES THROUGH MEETINGS, BUT NOAA DOES NOT HAVE A PROCESS FOR DETERMINING COMMITTEE MEMBERSHIP AND AGENCY REPRESENTATION**

The interagency committee coordinates primarily through quarterly meetings where agencies share information about their individual activities related to addressing marine debris. Such activities range from education and outreach to research and technology development and are generally driven by the missions and authorities of the agencies. However, we found that NOAA has not established a process to determine the committee's membership. In addition, the Marine Debris Act requires the interagency committee to include a "senior official" from member agencies, but NOAA has not determined the level of official it would consider senior.

 $32$  In 2019, multiple versions of the Save Our Seas Act 2.0 were introduced in Congress. S. 1982, 116<sup>th</sup> Cong. (2019); S. 2260, 116th Cong. (2019); H.R. 3969, 116th Cong. (2019); S. 2364, 116th Cong. (2019); S. 2372, 116th Cong. (2019). If enacted into law, most of the bills would require the interagency committee to submit additional reports to Congress. For example, three of the bills would require the interagency committee to submit to Congress a report on innovative uses for plastic waste other than in infrastructure as well as a report on microfiber pollution that includes an assessment of the sources, prevalence, and causes of microfiber pollution.

# **Interagency Committee Holds Quarterly Meetings to Share Information about Individual Agency Activities Such as Education and Outreach**

The interagency committee coordinates primarily through quarterly meetings where federal agencies share information about their individual marine debris-related activities. According to its charter, which was last revised in 2014, the committee is responsible for sharing information, assessing and implementing best management practices, and coordinating interagency responses to marine debris. The charter states that the interagency committee will ensure the coordination of federal agency marine debris activities nationally and internationally as well as recommend research priorities, monitoring techniques, educational programs, and regulatory action. The charter also states that the interagency committee will work to consider the interests of nongovernmental organizations, industry, state governments, Indian tribes, and other nations, as appropriate.

NOAA officials said the main focus of the interagency committee has been to serve as an information-sharing body. The officials said they also seek opportunities to collaborate on individual projects, but the committee does not otherwise collaborate on activities, beyond compiling statutorily required biennial reports.<sup>33</sup> NOAA officials explained that individual agencies each have a unique set of authorities and missions that largely determine their role and involvement in marine debris-related issues. For example, under its Marine Debris Program, NOAA conducts a variety of education, outreach, research, and other activities to identify sources of and address marine debris. In recent years, congressional committee reports accompanying NOAA's annual appropriations have directed the agency to spend a certain amount of its appropriations on its marine debris program.<sup>34</sup> Specifically, these reports directed NOAA to spend \$7 million in fiscal year 2018 and \$7.5 million in fiscal year 2019 for its Marine Debris Program. The program is also authorized to award grants to, and enter into cooperative agreements and contracts with, eligible entities to identify the sources of, prevent, reduce, and remove marine debris.<sup>35</sup>

In contrast, officials from other agencies on the interagency committee said their agencies have not received such direction or specific appropriations to address marine debris. Rather, the activities these agencies have conducted generally tie to their authority or agency mission.

<sup>&</sup>lt;sup>33</sup> When the interagency committee was revising its charter, NOAA officials said they discussed expanding the role of the committee beyond information-sharing, but at the time participating agencies collectively agreed that the committee's primary role should be to regularly share information regarding individual agencies' activities and look for opportunities to collaborate, where possible.

<sup>&</sup>lt;sup>34</sup> 160 Cong. Rec. H475, H508 (daily ed. Jan. 15, 2014) (explanatory statement of the Consolidated Appropriations, 2014); S. Rep. No. 113-181, at 32 (2014) (Senate Report Accompanying the Departments of Commerce and Justice, and Science, and Related Agencies Appropriations Bill, 2015); S. Rep. No. 114-66 at 26 (2015) (Senate Report Accompanying the Departments of Commerce and Justice, and Science, and Related Agencies Appropriations Bill, 2016); 163 Cong. Rec. H3327, H3366 (daily ed. May 3, 2017) (explanatory statement of the Consolidated Appropriations Act, 2017); S. Rep. No. 115-139, at 27 (2017) (Senate Report Accompanying Departments of Commerce and Justice, Science, and Related Agencies Appropriations Bill, 2018); H.R. Rep. No. 116-9, at 614 (2019) (Conference Report Accompanying the Continuing Appropriations Act, 2019).

<sup>&</sup>lt;sup>35</sup> Grants and cooperative agreements are financial assistance instruments used to transfer a thing of value to a recipient to carry out a public purpose. The difference between the two instruments relates to the amount of involvement between the agency and the recipient during performance: when substantial involvement is not anticipated, agencies use grants; otherwise, they use cooperative agreements. For this report, we use the term "grants" to refer to both grants and cooperative agreements.

# **Table 1. Activities reported in the Interagency Marine Debris Coordinating Committee's 2016 and 2019 biennial reports**

Source: GAO analysis of Interagency Marine Debris Coordinating Committee reports. | GAO-19-653.

Note: This table reflects those activities reported by the interagency committee in its 2016 and 2019 biennial reports to Congress, which cover activities conducted in 2014-2015, and 2016-2017, respectively.

For example, EPA officials said they have relied on voluntary partnerships with states, industry, and other sources and leveraged existing funds from related programs, such as the agency's stormwater and water quality programs, to support its Trash Free Waters Program. This is a program that encourages collaborative actions by public and private stakeholders to prevent trash from entering water. EPA officials said they also support a number of other activities related to education, outreach, and research, and these activities are a high priority

for the agency, but EPA does not have a line item in its budget dedicated to marine debris activities.<sup>36</sup>

The interagency committee's biennial reports describe general types of activities individual agencies reported conducting—often in coordination with nonfederal partners such as nongovernmental organizations, industry, states, Indian tribes, and other nations—to address marine debris, which include activities in the following categories: (1) education and outreach; (2) legislation, regulation, and policy; (3) cleanup; (4) research and technology development; and (5) coordination (see table 1 for descriptions of types of activities in each category; see app. III for specific examples of activities carried out by agencies).

To help agencies share information, NOAA chairs quarterly meetings where agencies are invited to discuss their individual activities. In reviewing meeting minutes, we found that the meetings were generally well-attended by representatives from multiple agencies. During the meetings, officials discussed marine debris issues and some provided updates on their agencies' activities. For example, at the April 2019 meeting, officials discussed ways in which different agencies may be meeting the sense of Congress on international engagement in the Save our Seas Act of 2018.<sup>37</sup>

At the May 2018 meeting, officials from NOAA and U.S. Coast Guard gave presentations on their agencies' emergency response authorities and efforts. NOAA officials described their actions in response to Hurricanes Harvey, Irma, and Maria in 2017, which included coordinating debris removal activities across federal and state agencies, such as EPA and Florida State's Department of Environmental Protection. U.S. Coast Guard officials also presented information on their marine debris removal activities in response to Hurricanes Irma and Maria. These activities included coordinating with multiple federal, state, and local agencies and contractors to remove or mitigate potential environmental impacts from 2,366 damaged or derelict vessels in Florida and the Florida Keys after Hurricane Irma and 377 vessels in Puerto Rico and the Island of Vieques after Hurricane Maria, according to U.S. Coast Guard officials.

The interagency committee has also used its quarterly meetings to identify opportunities for collaboration among federal agencies and with nonfederal partners, according to NOAA officials. For example, during committee meetings in early 2018, NOAA, the National Park Service, and the Department of State identified an opportunity to collaborate with the German government to bring the Ocean Plastics Lab to the United States. This Lab is an international traveling exhibition that explains the role of science in helping to understand and address plastic pollution in the ocean. NOAA officials said that to collaborate on this effort, officials from three federal agencies served on a steering committee, leveraged volunteers, promoted the Ocean Plastics Lab through outreach efforts to the public and helped staff the exhibits while they were on display in Washington, D.C., during the summer of 2018.

<sup>&</sup>lt;sup>36</sup> In a March 2019 speech, the EPA Administrator cited marine debris as one of the three top global water priorities for the agency.

 $37$  Section 102 of the Save Our Seas Act of 2018 stated that it is the sense of Congress that the President should take five actions to respond to marine debris, including to work with representatives of foreign countries that discharge the largest amounts of solid waste from land-based sources into the marine environment, to develop mechanisms to reduce such discharges.

# **NOAA Has Not Established a Process for Determining Interagency Committee Membership and Agency Representation**

We found that NOAA has not established a process to determine interagency committee membership. The Marine Debris Act designates six federal agencies as members of the committee, and also specifies that committee members shall include senior officials from other federal agencies that have interests in ocean issues or water pollution prevention as the Secretary of Commerce determines appropriate.<sup>38</sup> The committee's 2014 charter lists five agencies as members in addition to the six identified in the act, for a total of 11 member agencies.<sup>39</sup> The charter also states that the committee consists of representatives from "any other federal agency that has an interest in ocean issues and water pollution prevention and control," but does not specify the process for documenting membership or how the Secretary of Commerce, or a delegate of the Secretary, will determine that such membership is appropriate, as required by the  $act<sup>40</sup>$ .

Various information sources, such as the committee's biennial reports and minutes from quarterly meetings, have provided differing lists of committee member agencies. For example, the committee's March 2019 biennial report and NOAA's website as of July 2019 listed the 11 agencies identified in its charter as members. But, various meeting minutes from meetings held in fiscal year 2019 listed up to 13 members. One agency, the U.S. Agency for International Development (USAID), has regularly attended the committee's quarterly meetings since early 2018 when USAID officials said they were invited to participate on the committee. USAID officials said that their understanding is that USAID is a member of the interagency committee and that this is especially important to recognize given their significant international development assistance related to marine debris over the last few years.<sup>41</sup> However, USAID is not listed as a member on NOAA's website and the agency's marine debris-related activities are not included in the committee's 2019 biennial report. As a result, some agencies may not be included in the required biennial reports on the committee members' marine debris activities.<sup>42</sup>

In April 2019, NOAA officials told us that USAID was a contributing member to the interagency committee.<sup>43</sup> The officials said that "official" member agencies are those six agencies designated by the Marine Debris Act and that they consider other participating

<sup>38</sup> 33 U.S.C. § 1954(b).

<sup>&</sup>lt;sup>39</sup> The interagency committee's charter identifies the following members, in addition to those listed in the Marine Debris Act: the Department of Defense's U.S. Army Corps of Engineers, the Department of the Interior's Bureau of Safety and Environmental Enforcement, National Park Service, and U.S. Fish and Wildlife Service, the Department of Justice, and the Marine Mammal Commission. The Marine Debris Act designates the Department of the Interior as a member of the interagency committee, whereas, the interagency committee's charter lists three agencies within Interior as members. For reporting purposes, we counted each of these agencies within Interior as separate member agencies.

<sup>&</sup>lt;sup>40</sup> The interagency committee first established its charter in 2006 and most recently revised it in 2014. The 2006 and 2014 versions of the charter list the same 11 agencies as members of the committee.

<sup>&</sup>lt;sup>41</sup> For example, officials from USAID said the agency assists developing countries in preventing and reducing landbased sources of marine debris through a variety of activities. Its activities include working with other countries or international cities to improve working conditions for waste collectors and piloting technology and equipment, such as bamboo trash traps in Vietnam. According to agency officials, USAID's activities in Asia—an area of the world that has been identified as a significant source of land-based marine debris—have resulted in 2.6 million people receiving or engaging in improved solid waste management services.

<sup>&</sup>lt;sup>42</sup> The biennial reports we reviewed were not consistent in capturing all members' activities.

<sup>&</sup>lt;sup>43</sup> In April 2019, NOAA officials said USAID and the White House Office of Science and Technology Policy, in addition to those agencies listed in its 2014 charter, were contributing members of the interagency committee.

agencies as "contributing" members.<sup>44</sup> They said it has been the practice of the interagency committee to enable participation and coordination with other agencies, including those who may not be designated as official members.

We found that NOAA does not have a documented process for determining membership on the interagency committee. NOAA officials were unable to locate records from 2006 or earlier documenting the addition of contributing agencies to the committee or the Secretary, or a delegate of the Secretary, making a determination of the appropriateness of such agencies being members. NOAA officials stated the need for the agency to establish a documented process to determine the appropriateness of federal agencies being committee members. The officials said they have started working with NOAA's General Counsel to formalize and document the committee's membership process, and that the process will include a step for the Secretary of Commerce, or a delegate of the Secretary to determine the appropriateness of additional agencies being members. However, NOAA officials did not have an estimated time frame for developing such a process.

Our past work on interagency collaboration has identified the importance of ensuring that relevant participants have been included in the collaborative effort.<sup>45</sup> By establishing a time frame for developing a documented membership process, NOAA and the interagency committee can benefit from capturing all members' activities, and ensuring it provides Congress a complete picture of marine debris efforts across the federal government.

In addition, the Marine Debris Act requires the interagency committee to include a "senior official" from member agencies, but NOAA has not determined the level of official it would consider senior.<sup>46</sup> The interagency committee's charter states that the committee will be composed of "federal agency managers and technical experts," but does not define what is meant by senior official. NOAA officials said that the level of engagement from agency officials has varied over time and often depends on the specific officials participating. The officials said they have had difficulty in the past getting some member agency officials to engage during quarterly meetings and often those that do participate are not decision makers. Specifically, for some agencies, participating officials may not represent the entire agency, but rather a program within the agency, and they may not have decision-making authority, according to NOAA officials. As a result, the officials may not be able to commit agency resources, or they may be uncertain what activities their agency may be able to commit to.

NOAA officials said that it may be helpful to specify the level of official needed to represent the agencies on the interagency committee. The officials said that they have been discussing potential revisions to the interagency committee's charter, and within that broader discussion they are looking into whether the charter should specify what level of official is needed. However, NOAA officials did not have an estimated time frame for revising its charter or determining what those revisions may entail. Our past work on interagency collaboration has identified the importance of ensuring that participants have full knowledge of the relevant resources in the agency, including the ability to commit resources for their agency.<sup>47</sup> By clarifying what is meant by "senior official" such as through revisions to its charter, NOAA would have greater assurance that it has the full engagement of member agency officials who can speak for their agency and commit to activities.

<sup>&</sup>lt;sup>44</sup> The interagency committee's charter does not distinguish between official or contributing members.

<sup>45</sup> GAO-12-1022.

<sup>46</sup> 33 U.S.C. § 1954(b).

<sup>47</sup> GAO-12-1022.

While the interagency committee's biennial reports provide information on marine debris-related activities of individual agencies, our review found that they do not contain certain required elements. As previously noted, the Marine Debris Act requires the biennial reports to include (1) the status of implementation of any recommendations and strategies of the committee and analysis of their effectiveness, and (2) estimated federal and nonfederal funding provided for marine debris and recommendations for priority funding needs. However, we found that the biennial reports did not include an analysis of the effectiveness of the recommendations implemented or recommendations for priority funding needs.

#### **Implementation of Recommendations and Analysis of Effectiveness**

The five biennial reports the interagency committee issued from 2010 to 2019 lay out the committee's 2008 recommendations along with a description of activities taken by individual member agencies related to those recommendations. Specifically, each biennial report references the 25 recommendations the committee first adopted in its 2008 interagency recommendation report, organized into categories (see app. II). The reports then provide a description of activities taken by individual member agencies that fell within the recommendation categories for each preceding 2-year period.<sup>48</sup>

However, we found that the five biennial reports do not include an analysis of the effectiveness of the implementation of the committee's recommendations and strategies as required by the Marine Debris Act. Some of the descriptions of agencies' activities include information on the number of people reached through education or outreach efforts or other quantitative information related to specific activities, but the reports do not include an analysis of the effectiveness of those activities.

NOAA and EPA officials confirmed that the interagency committee did not include an analysis of effectiveness in its biennial reports, stating that undertaking such an effort is beyond the scope of the information-sharing focus of the interagency committee. NOAA officials said that they have attempted to bring member agencies together to discuss how the committee could analyze the effectiveness of its collective efforts, but this has been a challenge because each member has its own priorities and legal authority related to addressing marine debris. Activities to implement the committee's 25 recommendations occur at each individual agency, rather than at the committee level, according to the officials. As such, NOAA officials said each member agency may evaluate the effectiveness of its individual activities and pointed to measures NOAA has in place to evaluate its Marine Debris Program. For example, NOAA estimates the amount of debris removed annually and the number of students it reaches through education and outreach efforts.

EPA officials said that determining a baseline and quantifying the results of specific marine debris efforts to determine effectiveness is challenging, as is the case for other broad, nonpoint sources of pollution. For example, trash enters water bodies through innumerable

l

<sup>&</sup>lt;sup>48</sup> The 2014, 2016, and 2019 biennial reports included activities organized by recommendation categories. The 2010 and 2012 biennial reports listed activities by agency, but not by recommendation category.

water and sewer system outfalls, so EPA may focus on strategies to change people's behavior to minimize trash from entering the systems (see Figure 3). But unlike measuring emissions from a smokestack, it is difficult to determine a baseline and then measure and demonstrate progress in terms of trash reduction exiting through the system outfalls. EPA officials said they recognize the need to measure the effectiveness of their efforts related to marine debris—especially as addressing marine debris has become a high priority for the agency but measuring progress has yet to be determined across all of its various offices and programs that carry out marine debris-related activities. Within the Trash Free Waters program specifically, EPA officials said they take steps to evaluate the effectiveness of the program through a variety of means, such as seeking feedback from stakeholders.

Our past work has shown that collaborative entities—including those addressing complex, cross-cutting issues—can better demonstrate progress and identify areas for improvement if they develop a means to monitor, evaluate, and report the results of their collective efforts.<sup>49</sup> Developing such a means would help the interagency committee ensure that its member agencies are using their authorities and aligning their priorities in the most effective manner possible. Moreover, developing and implementing a process to analyze the effectiveness of the interagency committee's recommendations and strategies, and reporting the results in its biennial reports as required by the Marine Debris Act would better position the committee to determine the extent to which its efforts are making a difference in addressing the complex facets of marine debris.

Source: Laura Stone, Mobile Baykeeper. | GAO-19-653.

Figure 3. Trash capture device to prevent debris from entering waterway.

 $\overline{a}$ <sup>49</sup> GAO-12-1022.

The five biennial reports include some estimates of funding for marine debris-related activities, but do not identify recommendations for priority funding needs as required by the Marine Debris Act. Specifically, we found that the reports included estimates for some member agencies' spending related to their marine debris-related activities and estimated nonfederal spending for certain activities.<sup>50</sup> The reports also state that several member agencies conduct activities within multiple programs, offices, and projects indirectly related to marine debris efforts. These agencies do not receive annual appropriations specifically for marine debris activities but instead receive appropriations to fulfill their missions or implement programs, making it difficult to estimate exact spending related to marine debris, according to the reports.

The 2019 biennial report states that the interagency committee's recommendations for priority funding needs are reflected in the President's budget request and operating plan for each member agency in any given fiscal year. NOAA officials said that it would be difficult to identify and communicate priority funding needs outside of these documents, particularly given the complications associated with estimating each agency's individual spending. For example, an EPA official said that EPA's efforts to address marine debris are decentralized and the agency does not receive an appropriation specifically for marine debris-related activities, making it difficult to determine how much the agency spends—or may need to spend—on marine debris. Moreover, NOAA and EPA officials said that because the interagency committee serves primarily as an information-sharing body and each member agency operates independently in identifying resource needs, the interagency committee has not needed to develop a process to identify recommendations for priority funding needs.

However, the Marine Debris Act requires the interagency committee to include recommendations for priority funding needs in its biennial reports, and without a process to identify such recommendations, the interagency committee cannot meet that requirement. Our past work on leading collaborative practices has shown the importance of identifying and leveraging resources, such as funding, in collaborative efforts.<sup>51</sup> By developing a process to identify recommendations for priority funding needs in its biennial reports, the interagency committee could provide Congress with required information about priority funding needs across the federal government to address marine debris.

<sup>50</sup> For example, in the interagency committee's 2019 biennial report, EPA estimated \$410,000 in fiscal year 2016 and \$320,000 in fiscal year 2017 for its Trash Free Waters Program. The Department of State estimated no funding for marine debris activities in fiscal year 2016 and \$1,000,000 in fiscal year 2017 for marine debrisrelated activities and grants. The interagency committee also stated in this report that it interpreted the reference to nonfederal funding in the act's biennial reporting requirement to mean the required nonfederal match associated with the grants program authorized under section 3 of the Marine Debris Act administered by NOAA's Marine Debris Program. NOAA estimated \$2,166,517 in nonfederal match for fiscal year 2016, and \$1,944,621 in fiscal year 2017.

# **EXPERTS SUGGESTED A RANGE OF ACTIONS THE FEDERAL GOVERNMENT COULD TAKE TO MOST EFFECTIVELY ADDRESS MARINE DEBRIS**

The 14 experts we interviewed with expertise in marine debris-related issues suggested a range of actions that the federal government could take to most effectively address various types of marine debris. Their suggestions included increasing or improving actions already being taken by some federal agencies as well as taking new actions. The experts stressed that there is not one solution to the growing, multi-dimensional problem of marine debris. Rather, they said that a multitude of actions involving federal agencies and nonfederal partners—such as international, state and local governments, Indian tribes, industry, and environmental groups—will need to be taken to address the issue.

Experts as well as agency officials we interviewed indicated that there would be a number of factors to consider in evaluating the suggested actions. Some of these factors are overarching, applying to most or all of the actions; others relate to specific actions. For example, several experts and agency officials said that competing priorities and limited resources would be important factors to consider related to all of the suggested actions. Several agency officials also said that their agencies may not have the authority to take some of the actions suggested by the experts, and therefore new legislation would need to be enacted before they could take those actions. Additionally, some actions could result in impacts or costs to particular industries, underserved communities, or consumer groups, and understanding and identifying ways to mitigate such impacts would be important. Moreover, several agency officials said some actions, such as those related to waste management, may be better suited for local or state governments and that those entities would be betterequipped to deal with particular aspects of marine debris.

The following are examples of actions the experts suggested that the federal government could take. We organized the actions into the following five categories, which generally correspond to the categories laid out in the interagency committee's reports: (1) education and outreach, (2) establishment of federal requirements or incentives, (3) cleanup, (4) research and technology development, and  $(5)$  coordination.<sup>52</sup>

# **Education and Outreach**

 $\overline{a}$ 

Seven of the 14 experts suggested actions to educate or conduct outreach to the public or specific consumer or industry groups or international governments about ways to prevent, reduce, mitigate, or clean up waste that can become marine debris. A few experts emphasized that education and outreach efforts should be focused on ways to prevent trash from entering the marine environment. Examples of education and outreach actions suggested include:

<sup>&</sup>lt;sup>52</sup> In our analysis, we categorized actions related to legislation, regulations, policies, or incentives as falling within the category of "establishment of federal requirements or incentives." In analyzing these actions, we did not determine whether laws would need to be enacted or regulations issued, or both, to implement such actions.

 **Domestic education and outreach**. Five experts suggested different types of education or outreach campaigns the federal government could undertake to target certain domestic groups, such as consumers. One expert suggested that the federal government develop a national campaign to educate the public about marine debris. Such a campaign would develop a single message that various entities, including federal agencies and nonfederal stakeholders, could include in advertisements, social media, and other public awareness efforts. The expert pointed to similar state-led campaigns, such as "Nobody Trashes Tennessee," a litter campaign developed by Tennessee's Department of Transportation. <sup>53</sup> This state campaign features celebrities, such as athletes and musicians, in advertisements and involves selling stickers, hats, and other items to help spread the message. However, the expert said that securing collaboration and agreement on a single message across federal agencies and nonfederal stakeholders could pose a challenge and that a national campaign would need a long-term commitment from all parties to be successful.

NOAA officials said that national campaigns can be expensive and demonstrating results from such efforts can be difficult, especially when they are broad in nature. As a result, these officials said that NOAA's Marine Debris Program targets its education and outreach efforts to a specific audience for a particular type of behavior change or type of debris, such as educating and training high school students to lead "Zero Litter Campaigns" in their schools and communities.

 **International outreach**. Two experts suggested actions the federal government could take to conduct outreach internationally to promote programs, policies, or technologies that can reduce marine debris. For example, one expert suggested the federal government conduct outreach to government officials in countries that have limited waste management infrastructure to demonstrate effective waste management technologies. The expert said that the federal government could partner with private sector companies to demonstrate waste-to-energy technologies, such as gasification and pyrolysis that can convert plastic waste to fuel.<sup>54</sup> According to the expert, demonstrating such technologies would provide information on its benefits, including reducing sources of waste and creating a source of energy to either use or sell.

Several agency officials we interviewed agreed that international outreach efforts are critical to successfully addressing marine debris and that emphasis should be placed on assisting countries with improving their waste management practices. However, these officials said there are many factors to consider with regard to wasteto-energy technologies. For instance, State Department officials said such technologies may not be supported by civil organizations because of environmental concerns. <sup>55</sup> Waste-to-energy technologies could also entail high upfront capital

<sup>53</sup> To learn more about the Tennessee Department of Transportation campaign, see https://nobody trashestennessee.com/.

<sup>54</sup> Waste-to-energy is a term used for technologies, such as gasification and pyrolysis that convert waste, including plastics, into fuels or chemicals. Gasification breaks down organic waste (e.g., plastics, wood chips, rice hulls) with heat and controlled amounts of oxygen to produce syngas. The syngas can then be burned as a fuel or can be used as a feedstock to produce other chemicals such as methane and methanol. Pyrolysis heats plastics with no oxygen to produce liquid fuel. According to the Energy Recovery Council's 2018 report, 75 waste-toenergy plants operate in 21 states in the United States.

<sup>&</sup>lt;sup>55</sup> In some cities in the United States, groups have raised concerns with the potential environmental and human health effects of waste-to-energy facilities on surrounding communities. For example, in February 2019, the

investments, and waste-to-energy facilities should adhere to strict environmental standards with monitoring and enforcement to help ensure the technology is not causing negative effects, according to agency officials. As a result, they said it may not be practical for some countries to adopt such technologies. In addition, USAID officials said that promoting waste-to-energy technology presupposes that waste is already being collected in sufficient quantity and quality to serve as a fuel for such technology, but that in some countries waste is openly dumped or burned and therefore sufficient waste may not be available. They cautioned that waste-to-energy technologies can be a part of a response to address marine debris abroad, but would not be sufficient alone.

#### **Establishment of Federal Requirements or Incentives**

Eleven experts suggested actions the federal government could take to establish requirements or incentives to address various types of marine debris. Examples included:

#### **Microfibers**

Microfibers are a widespread type of microplastic; they have been found on the shorelines of six continents and in oceans, rivers, soils, table salt, and public drinking water, according to scientific studies.

Microfibers enter the marine environment through various pathways. For example, microfibers are shed from synthetic clothing and other materials made of polyester and nylon. These microfibers pass through to waterways because washing machines and wastewater treatment plants typically do not have processes sufficiently refined to remove the fibers. Little is known about other potential sources of microfibers, such as carpet manufacturing; the rate of generation, such as how quickly materials break down and shed microfibers; and any health impacts to humans or wildlife.

Sources: GAO analysis of scientific studies and agency documents; Sherri Mason/State University of New York at Fredonia (photo). | GAO-19-653.

 **Design standards for products**. Five experts suggested establishing federal requirements for manufacturers to design certain products to minimize the chances of material becoming marine debris. For example, two experts suggested the federal government develop design standards for washing machine manufacturers to ensure filters are designed to prevent microfibers from entering wastewater systems and

city council of Baltimore, Maryland, passed an ordinance to place restrictions on two of the city's waste-toenergy facilities because of concerns that the facilities have contributed to asthma and other respiratory illnesses in surrounding communities.

then the marine environment. Three experts suggested the federal government develop design standards to require or incentivize manufacturers to use specific amounts of post-consumer material in developing certain products. For example, one expert recommended requiring the manufacturers of plastic beverage bottles to produce bottles using at least a minimum amount of recycled plastic. According to the expert, this would increase the demand for recycled plastic as a raw material, which in turn would reduce the likelihood that such plastic would end up as waste. The expert said that requiring the use of recycled plastic would likely impose increased costs on manufacturers because virgin plastic—the raw material typically used in producing plastic beverage bottles—is currently less expensive than recycled plastic. Such increases would likely be short term, however, because the increased demand would decrease the price after more of the recycled material is used, according to another expert. Some federal agency officials said that establishing such proposed federal design standards could be difficult due to limited existing statutory authorities.

- **Requirements for fishing gear**. Three experts suggested the federal government establish requirements to mitigate the impact of lost or derelict fishing gear in federal waters. <sup>56</sup> For example, one expert suggested requiring the use of modified fishing gear, such as crab traps with biodegradable escape mechanisms that allow entrapped marine life to escape if the trap is lost or abandoned (see Figure 4). Requiring the use of fishing gear with biodegradable escape mechanisms would likely impose increased costs to the fishing industry, according to the expert, but those costs could be minimized if the federal government offered a subsidy to help purchase required gear. NOAA officials said that it would be challenging to require the use of certain types of fishing gear in part because of the cost to the federal government in ensuring implementation of the requirement. On the other hand, NOAA officials said they promote innovation and voluntary use of certain types of fishing gear through various efforts such as their Fishing for Energy program.<sup>57</sup>
- **Restrictions on single-use plastics**. Four experts suggested that the federal government establish restrictions on the manufacturing or sale of certain single-use plastics. For example, the federal government could establish restrictions on the manufacturing and distribution of plastic bags in the form of thickness or material composition requirements, or production volume limits. Two of these experts also said that the federal government could review existing local, state, and international efforts to restrict single-use plastics to identify best practices so that these types of actions could potentially be scaled appropriately at the federal level. According to the United Nations Environmental Programme, 127 countries and two states have placed various types of restrictions on the retail distribution of plastic bags as of 2018.<sup>58</sup> One expert pointed to research that shows that plastic bags are one of the most abundant

<sup>&</sup>lt;sup>56</sup> Federal waters typically begin approximately 3 geographical miles from land and extend 200 nautical miles.

 $57$  Fishing for Energy is a partnership between NOAA, the fishing industry, and other stakeholders to prevent and reduce the impacts of derelict fishing gear in the marine environment by offering no-cost options for disposing of old or unwanted gear and converting gear into energy. For example, metal gear—such as crab pots—is recycled and nonmetal material is brought to a waste-to-energy facility where it is used in the production of electricity for local communities, according to NOAA documentation.

<sup>58</sup> In contrast, several states have enacted legislation prohibiting local governments from regulating the sale of plastic bags.

forms of marine debris and suggested that banning them would therefore significantly reduce the amount of debris entering the marine environment.<sup>59</sup>

Source: Virginia Institute of Marine Science. | GAO-19-653.

Figure 4. Crab trap with biodegradable escape mechanism.

NOAA officials agreed that restricting the sale of single-use plastic bags could help address the marine debris problem, but said that identifying an agency with sufficient legal authority to be responsible for implementing and enforcing any restriction would be important and could be a challenge at the federal level. NOAA and EPA officials said that it would be important to carefully determine and assess trade-offs or other potential impacts before considering these types of restrictions.

#### **Single-Use Plastics**

Single-use plastics are any plastic items— such as plastic soda or water bottles—that are intended for use only once before they are thrown away or recycled as defined by the United Nations Environment Programme.

Single-use plastics can have environmental impacts when they are left in the marine environment. For example, single-use plastics may be ingested by hundreds of species of marine wildlife, such as turtles and dolphins, who mistake them for food, potentially blocking their airways and stomachs, according to a 2018 report by the United Nations Environment Programme.

Sources: United Nations Environment Programme; National Oceanic and Atmospheric Administration (photo). | GAO-19-653.

<sup>&</sup>lt;sup>59</sup> For example, in 2018, the Ocean Conservancy's International Coastal Cleanup found that plastic bags were among the top five most common types of marine debris. *Building a Clean Swell: The International Coastal Cleanup's 2018 Report*, Ocean Conservancy, Washington, D.C.

 **Incentives for waste management**. Four experts suggested actions the federal government could take to provide incentives to local governments to help them improve their waste management and recycling programs. The experts said that waste and water management is typically the responsibility of local governments, but that given the scope and scale of the marine debris problem, the federal government could use its resources to provide incentives to help local governments make improvements. For example, the federal government could provide grants or subsidies to help local governments implement best management practices, such as using trash traps to help remove debris from waterways and prevent it from becoming marine debris. In addition, the experts said that the federal government could provide local governments with resources to help purchase bins with lids to help prevent inadvertent loss of waste or to pay for infrastructure such as trucks and recycling facilities to improve the collection and recycling of waste. According to one expert, transporting materials from consumers to the appropriate waste management or recycling facilities is a significant barrier to achieving better waste management.

EPA officials agreed with the importance of local waste management efforts. The officials emphasized that it is the agency's mission, in part, to address management of waste to prevent trash, and management of water that carries the trash to the marine environment. The officials said that this is particularly critical for addressing marine debris since an estimated 80 percent of aquatic trash originates from land-based sources. The officials said the agency has provided some funding to local governments to implement mechanisms to capture trash before it enters waterways or to remove trash from water. They added that there is no one size fits all approach, however, to working with local governments. Rather, different localities may have differing needs—such as for funding, information, or technical assistance—and EPA tries to create a climate where localities can identify and best address those needs, according to the officials.

#### **Cleanup**

Five of the 14 experts suggested the federal government support marine debris cleanup and removal activities by providing resources to organizations that coordinate cleanup projects (see Figure 5). Several agency officials said that preventing waste from entering the marine environment should be the primary focus of addressing marine debris, but cleaning up existing marine debris continues to be a critical part of the multi-faceted response to the problem, especially after severe weather events such as hurricanes. According to one expert, debris deposited into the marine environment around the Florida Keys after Hurricane Irma in 2017 included construction debris from demolished buildings, household items such as refrigerators and televisions, cars, and boats, among other types of debris. The expert suggested the federal government provide funding and technical assistance to state and local governments to help locate such debris. According to the expert, after a severe weather event, the distribution of debris can vary greatly with ocean and wind currents, and the debris can extend for miles into the ocean. As a result, the expert suggested that the federal government assist with conducting aerial flyovers to locate major concentrations of debris. The flyovers

would employ mapping technology, such as global positioning system equipment and cameras, to locate and map the debris for removal. NOAA officials agreed with the importance of cleanup activities, particularly after severe weather events. In 2018, NOAA provided \$18 million to states for the detection, removal, and disposal of debris after the 2017 hurricanes.

Source: National Part Service. | GAO 19-653.

Figure 5. Before and after beach cleanup at a national park.

#### **Research and Technology Development**

Ten of the 14 experts suggested actions related to research or technology development. A few experts commended federal research efforts related to marine debris to date but stressed that additional research is needed in multiple areas. Examples of research and technology development actions suggested by experts include:

- **Research on sources, pathways, and location of marine debris**. Five experts suggested the federal government support research on identifying and understanding the various sources, pathways, and location of marine debris. For example, one expert suggested that the federal government conduct a national study to identify where waste is generated, through which types of major pathways it enters the marine environment (such as rivers or stormwater), and where the waste ends up. This study could include a focus on specific pathways, such as where illegal dumping occurs, which has not been researched at the national level, according to the expert. The expert said that federal agencies and others could use the results of such a study to help target education for the public, policy makers, and law enforcement officials on how to prevent and properly dispose of the types of waste that most commonly end up as marine debris. NOAA officials said that illegal dumping tends to be localized, so it may be difficult to carry out research on a national scale, but agreed with the need to better understand sources and types of marine debris since many factors contribute to the problem.
- **Research on effects of marine debris**. Four experts suggested the federal government support research to determine the effects of debris on wildlife and the marine environment as well as on human health. For example, one expert suggested that the federal government conduct or fund research to determine the effects of

microplastics on human health to help the federal government and other stakeholders identify the most appropriate solutions. EPA officials said that this type of research is one among many competing areas related to marine debris research their agency has targeted.

 **Development of technology to address marine debris**. Five experts suggested actions that the federal government could take to develop new technology to help address marine debris. For example, one expert suggested that the federal government fund the development of new technology to recycle hard-to-recycle plastic materials so that these materials are less likely to end up as waste and become marine debris. The expert said that, in particular, plastic materials such as packaging used to preserve food products are not readily recyclable because the technology to recycle these types of plastics is not available or is not economically viable. EPA officials said that even when there is technology to recycle these types of plastics, food contamination is a problem that may prevent them from being recycled. In addition, an increased capacity for recycling may not result in a behavior change on the part of the consumer, which is another factor to consider in evaluating whether to pursue this type of action, according to the officials.

# **Coordination**

Nine experts suggested that the federal government coordinate with local, state, federal, and international governments and other nonfederal partners to address marine debris. Experts emphasized that because marine debris is a complex issue with domestic and international impacts, it requires contributions from and coordination across these many groups. Examples of coordination suggested by experts include:

 **Coordination with stakeholders on management of fishing gear**. Two experts suggested the federal government coordinate to identify ways to prevent fishing gear from becoming a source of marine debris and causing harm to fish and other marine species. One expert suggested the federal government coordinate with stakeholders to identify and implement best management practices for responsible management and use of fishing gear. Specifically, the expert suggested that the federal government coordinate with state agencies, gear designers and manufacturers, fishermen, and other stakeholders to adopt best practices in particular locations such as in the Chesapeake Bay or Puget Sound where there are extensive commercial or recreational fisheries. The expert said it would be important to work with industry stakeholders to avoid the best practices being perceived as unnecessary government intervention. In addition, one of the experts said that adoption of best practices could incur additional costs for activities such as replacing gear, which could be minimized through government subsidies or other incentives. NOAA officials said these types of coordination activities align with current efforts within their Marine Debris Program. For example, in 2016 NOAA partnered with California State University and other stakeholders to encourage the adoption of best practices to prevent the loss of gear used to catch spiny lobster in the Channel Islands in California.

 **Coordination with international governments**. Four experts suggested the federal government increase its coordination internationally such as through developing international agreements and participating in multinational forums. For example, one expert suggested that the United States and other countries enter into an international agreement to prevent further release of plastic into the ocean. Under such an agreement, each country would set a target to reduce the amount of plastic released into the ocean, develop strategies and approaches to meet that target, and measure and report on progress in meeting the target.<sup>60</sup> The expert said that taking actions to meet the target would incur costs and that securing commitments from countries could be difficult. However, the expert said that allowing countries the flexibility to develop their own strategies for meeting their targets could help overcome these difficulties.

State Department officials said that in addition to coordination with international governments, coordination is needed with other key stakeholders such as waste management and marine debris experts, local leaders, private-sector industry and retail entities, and nongovernmental organizations. This is in part because so much of the international marine debris problem stems from waste management issues at the local level. In some countries, as in the United States, the government may not have the authority to work on waste management at the local level and as a result, understanding this complexity is an important factor to consider in coordinating internationally, according to the officials. USAID officials agreed that coordination with international stakeholders beyond international governments is needed and said that given the local nature of waste management issues that contribute to the international marine debris problem, stakeholders such as local and municipal governments are also important and should be a major focus for coordination and capacity building.<sup>61</sup>

#### **CONCLUSION**

Marine debris is a global, multi-faceted problem and multiple federal agencies, along with nonfederal stakeholders such as nongovernmental organizations, industry, states, Indian tribes, and others, have important roles to play in addressing the problem. The interagency committee's sharing of information about its members' activities is a good first step to ensure the agencies are aware of their respective marine debris-related efforts. NOAA, as chair of the committee, has recognized the need to develop a documented membership process, but has not established a time frame for doing so. By establishing a time frame for developing a documented membership process, NOAA and the interagency committee can benefit from capturing all members' activities, and ensuring it provides Congress a complete picture of marine debris efforts across the federal government.

<sup>60</sup> See *Why We Need An International Agreement On Marine Plastic Pollution*, Stephanie B. Borrelle, Chelsea M. Rochman, Max Liboiron, Alexander L. Bond, Amy Lusher, Hillary Bradshaw, and Jennifer F. Provencher.

<sup>&</sup>lt;sup>61</sup> USAID officials further said that beyond coordination, many of the experts' suggestions to address marine debris— such as providing incentives for waste management, conducting research on sources, pathways and location of marine debris, and developing new technology to address marine debris—are also needed in developing countries.

*Marine Debris* 2591

NOAA also recognizes that it may be helpful to specify the level of the official needed to represent the agencies through revisions to its charter, but has not determined what those revisions may entail. By clarifying what is meant by "senior official" such as through revisions to its charter, NOAA would have greater assurance that it has the full engagement of member agency officials who can speak for their agency and commit to activities.

The interagency committee's biennial reports provide information on the committee's recommendations and individual agencies' activities to implement those recommendations, but the reports do not include an analysis of the effectiveness of the committee's recommendations and strategies as required by the Marine Debris Act. By developing and implementing a process to analyze the effectiveness of the interagency committee's recommendations and strategies, and reporting the results in its biennial reports as required, the interagency committee would be in a better position to determine the extent to which its efforts are making a difference in addressing the complex facets of marine debris.

Additionally, the interagency committee has not identified required recommendations for priority funding needs. By developing a process to identify recommendations for priority funding needs and including such recommendations in its biennial reports, the interagency committee could provide the Congress with required information about priority funding needs across the federal government to address marine debris.

# **RECOMMENDATIONS FOR EXECUTIVE ACTION**

We are making a total of four recommendations, including two recommendations to the NOAA Administrator and two recommendations to the chair of the interagency committee, specifically:

The NOAA Administrator, in coordination with interagency committee member agencies, should establish a time frame for documenting the committee's membership process. (Recommendation 1)

The NOAA Administrator, in coordination with interagency committee member agencies, should clarify what is meant by "senior official" in the Marine Debris Act, such as through revisions to its charter. (Recommendation 2)

The chair of the interagency committee, in coordination with member agencies, should develop and implement a process to analyze the effectiveness of the interagency committee's recommendations and strategies, and include the results in its biennial reports. (Recommendation 3)

The chair of the interagency committee, in coordination with member agencies, should develop a process to identify recommendations for priority funding needs to address marine debris, and include such recommendations in its biennial reports. (Recommendation 4)

#### **Agency Comments and Our Evaluation**

We provided the Departments of Commerce, Defense, Homeland Security, Interior, Justice, and State; EPA; the Marine Mammal Commission; and USAID a draft of this report for their review and comment. The Department of Commerce and USAID provided written

comments, which are reprinted in appendixes IV and V respectively, and discussed below. We also received technical comments from the Departments of Commerce, Homeland Security, the Interior, and State; EPA; the Marine Mammal Commission; and USAID, which we incorporated into the report as appropriate. The Departments of Defense and Justice indicated that they had no comments.

In written comments from the Department of Commerce, Commerce and NOAA agreed with our four recommendations. Regarding our first two recommendations, NOAA stated that its Administrator will establish a time frame for documenting the interagency committee's membership process and, in coordination with the interagency committee, will define the term "senior official" through revisions to its charter so that the term can be consistently applied across all federal agency structures. In forming its definition of "senior official," NOAA indicated that it would consider seniority requirements of similarly situated advisory committees, along with related factors such as the ability to make decisions on behalf of an agency.

Regarding our third recommendation on developing and implementing a process to analyze the effectiveness of the interagency committee's recommendations and strategies, NOAA stated that it agreed with this recommendation to the extent it can be implemented with available budgetary resources. It indicated that the interagency committee lacks the existing resources to require and routinely evaluate the effectiveness of agency activities. Instead, individual agencies are expected to work toward implementing the interagency committee's 2008 recommendations in accordance with each agency's legal and programmatic authorities, mission priorities, and resource limitations. Nevertheless, NOAA stated that to the extent possible it will work with interagency committee members to identify common or easily translatable metrics for evaluating the effectiveness of its 2008 recommendations and include these in the next biennial report to Congress.

Regarding our fourth recommendation, NOAA stated that it agreed with our recommendation, but noted that it does not have the authority to control the implementation of a process for identifying priority funding needs of other member agencies. It stated that the interagency committee's recommendations for priority funding needs are already reflected in the President's annual budget request and operating plan for each member agency. However, NOAA stated that to the extent possible, it will work with interagency committee members to develop a process for identifying priority areas, which can be reflected in each agency's respective budgeting process and shared in the committee's biennial reports. We agree that NOAA does not have the authority to control the implementation of a process for identifying priority funding needs of other member agencies. However, as chair of the committee, NOAA can coordinate with member agencies to develop a process that each individual member agency—under its individual authority and budgetary processes—can use to identify recommendations for priority funding needs to address marine debris. We believe that coordinating such information and providing it in the committee's biennial reports could provide Congress with required information about priority funding needs across the federal government to address marine debris.

In addition, in written comments from USAID, the agency said it is committed to addressing the challenge of marine debris through its programs and in collaboration with interagency committee partners. USAID stated that it has significant opportunities to play an important role in the international response to address marine debris and, as the lead federal agency on foreign assistance, has several programs that target mismanaged municipal waste

in the developing world. For example, USAID stated that the agency's Municipal-Waste Recycling Program has helped reduce land-based sources of ocean plastic waste in four of the top five contributing countries—Indonesia, the Philippines, Sri Lanka, and Vietnam—by providing small grants and technical assistance to a variety of local actors in towns and cities. USAID also stated that it greatly appreciates the work of its interagency committee partners in addressing marine debris and looks forward to continued collaboration with them.

Anne-Marie Fennell Director, Natural Resources and Environment

# **APPENDIX I: OBJECTIVES, SCOPE, AND METHODOLOGY**

This chapter examines (1) how the interagency committee coordinates among federal agencies and the process for determining membership and agency representation, (2) the extent to which the interagency committee's biennial reports contain required elements, and (3) experts' suggestions on actions the federal government could take to most effectively address marine debris.

To examine how the interagency committee has coordinated among federal agencies and the process for determining membership and agency representation, we reviewed the Marine Debris, Research, Prevention, and Reduction Act, as amended (Marine Debris Act), and interagency committee documents, including the committee's 2008 report with recommendations, charter,<sup>62</sup> and five biennial reports to Congress issued as of March 2019.<sup>63</sup> Specifically, we reviewed meeting minutes from the interagency committee's quarterly meetings from November 2012 through April 2019,<sup>64</sup> to understand the topics and activities the committee has coordinated on and the federal agencies that have participated. We attended five of the interagency committee's quarterly meetings (in May, September, and December of 2018, and April and July of 2019) to directly observe committee coordination among agencies during these meetings. We also reviewed documents from committee member agencies and interviewed and reviewed written responses from those agencies to obtain information on their coordination efforts.

Agencies we included were those agencies designated as members in the Marine Debris Act as well as additional agencies identified as members in the committee's charter (see table 2). In addition, we interviewed officials and reviewed documents from the National Science Foundation, Office of the U.S. Trade Representative, and the U.S. Agency for International Development, based on suggestions from interagency committee officials.<sup>65</sup>

 $62$  We reviewed the interagency committee's initial charter, developed in 2006, as well as its most recently revised 2014 charter.

<sup>&</sup>lt;sup>63</sup> The five biennial reports were issued in March 2010, October 2012, September 2014, December 2016, and March 2019. Collectively, the reports include activities the interagency committee member agencies reported conducting between June 2008 and December 2017.

<sup>&</sup>lt;sup>64</sup> Meeting minutes dating back to November 2012 were those minutes most readily available from the National Oceanic and Atmospheric Administration, the chair of the interagency committee.

<sup>&</sup>lt;sup>65</sup> We subsequently removed the National Science Foundation and the Office of the U.S. Trade Representative from our review because, unlike the U.S. Agency for International Development, those two agencies have not participated on the interagency committee.

#### **Table 2. Interagency Marine Debris Coordinating Committee member agencies, as identified in its 2014 charter**

Source: GAO analysis of Interagency Marine Debris Coordinating Committee documents. | GAO-19-653.

From the committee's 2008 report with recommendations, the five biennial reports, and other member agency documents, we summarized activities conducted by member agencies. For reporting purposes, we selected examples from the 2016 and 2019 biennial reports (those most recently available) of activities the agencies have taken to illustrate interagency committee member efforts to address marine debris, to reflect a range of activities across categories of activities and member agencies.<sup>66</sup> In addition, we compared information we received about the interagency committee's coordination to leading practices we identified in our past work on implementing interagency collaborative mechanisms.<sup>67</sup>

To examine the extent to which the interagency committee's biennial reports contain required elements, we compared information contained in the committee's five biennial reports to the statutory reporting requirements in the Marine Debris Act. Specifically, two analysts independently reviewed each of the five biennial reports to evaluate information the reports included about (1) the status of implementation of any recommendations and strategies of the committee, (2) analysis of the recommendations and strategies' effectiveness, (3) estimated federal and nonfederal funding provided for marine debris, and (4) recommendations for priority funding needs. The analysts then compared and summarized the results of their analyses. We also interviewed and reviewed written responses from National Oceanic and Atmospheric Administration (NOAA) officials (in the agency's capacity as chair of the interagency committee) and officials from other members of the committee about steps to develop the biennial reports, including the reports' required elements. In addition, we compared information from the reports and the information we received from the officials to leading practices we identified in our past work on implementing interagency collaborative mechanisms.<sup>68</sup>

<sup>&</sup>lt;sup>66</sup> The biennial progress reports identified eight categories of activities, but we consolidated activities reported under the "enforcement" and "incentive programs" categories into the "legislation, regulation, and policy" category because of similarities among the activities within these categories. Similarly, for presentation purposes, we consolidated activities reported under the "research" and "technology development" categories into one "research and technology development" category.

<sup>67</sup> GAO, *Managing for Results: Key Considerations for Implementing Interagency Collaborative Mechanisms*, GAO-12-1022 (Washington, D.C.: Sept. 27, 2012). We used leading practices that are relevant to the requirements for the interagency committee in the Marine Debris Act. These included practices related to participants, resources, outcomes and accountability, and written guidance and agreements.

<sup>68</sup> GAO-12-1022.

To obtain suggestions on actions the federal government could take to most effectively address marine debris, we conducted structured interviews with a nongeneralizable sample of 14 experts with expertise in marine debris-related issues. We selected the experts from a list of individuals we identified through interviews with agency officials and through a snowball approach, in which we reviewed relevant literature on marine debris, such as articles the experts authored, to identify other key experts and asked experts to identify other experts for including in this review. We also identified experts through our participation in key marine debris events, such as presenting at the Sixth International Marine Debris Conference.<sup>69</sup> We considered factors such as the individual's experience with different types of debris (e.g., abandoned fishing gear or consumer debris) or association with various sectors (e.g., academia or industry).

Experts selected included: (1) academics with expertise in areas such as sources, prevalence, and transport of plastic marine debris; (2) officials representing the plastic manufacturing, food and beverage, and commercial fishing industries; (3) officials from nonprofit organizations with expertise in marine debris removal from coastal areas, litter prevention, and recycling management systems and strategies; and (4) state and local government officials from the District of Columbia, Florida, and Washington with expertise in local litter prevention efforts, derelict vessels, and lost and derelict fishing gear.<sup>70</sup>

We asked the 14 experts to suggest up to 5 to 10 actions the federal government could take to most effectively address different types of marine debris. <sup>71</sup> We defined the term "actions" to mean any policy, program, effort, or intervention that could be taken by the federal government to prevent, remove, or dispose of marine debris. Actions could include new actions that the federal government may not have implemented or actions the federal government may already have taken. We did not limit experts' suggestions to actions that agencies currently have authority to implement. We do not take a position on the merits of, the necessary legal authority for, or the most appropriate entity for the actions suggested by the 14 experts.

Prior to the interview, we provided experts with background information about our review, the interview methodology, and definitions for key terms to ensure that terminology was used consistently throughout all the interviews. We also reviewed this information with each expert at the start of the interview. For each action, we asked that the expert identify:

**Name of action;**

- **Type(s) of debris:** (Select any or all of the following types of marine debris that may be affected by the action: consumer-based, abandoned fishing gear, derelict vessels, and/or miscellaneous. If miscellaneous is selected, please explain);
- **Describe this action:** (Briefly describe this action and how it will address (i.e., prevent, remove, or dispose) marine debris and if it is currently being implemented by the federal agencies);

<sup>69</sup> The Sixth International Marine Debris Conference was organized by NOAA and the United Nations Environment Programme. Over 700 participants from 54 countries attended the conference, including international governments and multinational bodies representatives; federal, state, and local government officials; coastal and ocean resource managers; waste management representatives; scientists; academics; and industry representatives.

 $70$  We selected these locations using factors such as geographic area and expertise in marine debris issues.

 $71$  One expert suggested 12 actions; we included each of the 12 expert's suggested actions in our analysis.

- **Federal agency(ies)** (Please briefly describe the federal agency(ies) that have implemented or could play a role in implementing the action);
- **Nonfederal partners:** (Please briefly describe the nonfederal partners the federal agencies may need to coordinate with when implementing the action (such as international, state and local governments, nonprofit groups, industry, and/or researchers);
- **Advantages:** (Briefly describe the advantages of the federal agencies implementing the action in terms of the ability of this action to address marine debris, the cost of the action, and the technical and administrative feasibility of implementing the action, or any other advantage that you believe may affect implementation);
- **• Disadvantages:** (Briefly describe the disadvantages of the federal agencies implementing the action in terms of the ability of this action to address marine debris, the cost of the action, and the technical and administrative feasibility of implementing the action, or any other disadvantage that you believe may affect implementation);<sup>72</sup>
- **Challenges:** (Describe any factors that may hinder this action from being successfully implemented by the federal agencies and how these factors may be overcome);
- **Examples:** (In instances where the federal agencies have previously implemented the action, please provide examples of how it helped address marine debris. If other entities that are not federal agencies have successfully implemented the action, please provide examples of how the action helped address marine debris);
- **Authorities:** (Briefly describe what legal authorities these actions would be implemented under. If new authorities are needed, please describe them); and
- **Support:** (Provide any studies, reports, or research you are basing your responses on).

We conducted the interviews via teleconference between July 2018 and November 2018. The experts suggested over 70 actions that we organized into five categories based on common themes. <sup>73</sup> Specifically, two analysts independently reviewed each expert's description for individual actions and identified an appropriate category using decision rules the team developed. The analysts then discussed and compared their decisions. For actions the analysts categorized differently, they reviewed the decision rules together and came to agreement on the best category for a particular action. For reporting purposes, we selected several actions within each of the broader categories to provide illustrative examples of the types of actions experts suggested. Our selection of actions was based on a variety of factors, including our analysis of the number experts that suggested similar types of actions, the detail

 $72$  We defined disadvantages of an action in terms of the ability of the action to address marine debris, the cost of the action, and the technical and administrative feasibility of implementing the action. We defined challenges as the factors that may hinder the action from being successfully implemented by the federal agencies. However, during many of the interviews the experts found it difficult to distinguish between the two terms. As a result, we use the term "challenge" in the report to indicate either a disadvantage or a challenge.

 $73$  The categories of actions generally correspond to the categories laid out in the interagency committee's biennial reports. However, we merged the categories "legislation, regulation, and policy," "incentive programs," and "enforcement" into the "establish federal requirements or incentives" category. We also merged the categories "technology development" and "research" to make the category "research and technology development."

provided by the experts, and the availability of supporting information, such as instances where an action had been taken by state or local governments. Actions suggested by the 14 experts cannot be generalized to actions that might be suggested by other experts but provide examples of actions federal agencies could take to address marine debris.

We also obtained written and oral responses to questions we asked of agency officials regarding factors their agencies would need to consider in potentially implementing any of the actions identified by the 14 experts. In addition, to corroborate statements from experts and agency officials and provide additional context on marine debris, we reviewed scientific studies and documents from international organizations, such as the United Nations; academic institutions and nonprofit organizations such as the Ocean Conservancy; and federal and state agencies to understand what is known about the types, sources, and effects of marine debris. We identified these studies and documents through various means, such as recommendations from experts and agency officials and authorship by experts. We also interviewed individuals from academia, environmental groups, and industry actively working on marine debris issues and attended the Sixth International Marine Debris Conference held in San Diego, California, in March 2018, to gain an understanding of areas of emphasis in the marine debris community.

We conducted this performance audit from October 2017 to September 2019 in accordance with generally accepted government auditing standards. Those standards require that we plan and perform the audit to obtain sufficient, appropriate evidence to provide a reasonable basis for our findings and conclusions based on our audit objectives. We believe that the evidence obtained provides a reasonable basis for our findings and conclusions based on our audit objectives.

# **APPENDIX II: RECOMMENDATIONS FROM THE INTERAGENCY MARINE DEBRIS COORDINATING COMMITTEE'S 2008 REPORT**

Table 3 lists the 25 recommendations contained in the Interagency Marine Debris Coordinating Committee's 2008 report entitled Interagency Report on Marine Debris Sources, Impacts, Strategies, and Recommendations.<sup>74</sup> According to this report, these recommendations are intended to guide the federal government's strategies with respect to addressing problems of persistent marine debris. Each of the five biennial reports the committee issued subsequent to its initial 2008 report reference the 25 recommendations; the committee has not revisited the recommendations to determine the extent to which any adjustments may be warranted.

<sup>&</sup>lt;sup>74</sup> The interagency committee submitted this report to relevant congressional committees in response to a requirement in the Marine Debris Research, Prevention, and Reduction Act. Pub. L. No. 109-449, § 5(c)(1), 120 Stat. 3333, 3337 (2006). The report was due by December 22, 2007; the committee submitted the report to the congressional committees in August 2008. This requirement was repealed in 2012. *See* Pub. L. No. 112- 213, § 606(a)(1), 126 Stat. 1540, 1577 (2012).

# **Table 3. Interagency Marine Debris Coordinating Committee 2008 recommendations**

Source: Interagency Report on Marine Debris Sources, Impacts, Strategies, and Recommendations, 2008. | GAO-19-653.

<sup>a</sup>Tackling Marine Debris in the 21st Century, Committee on the Effectiveness of International and National Measures to Prevent and Reduce Marine Debris and Its Impacts, National Research Council, National Academies Press (Washington, D.C.), 2009.

<sup>b</sup>Categorized as "incentive programs" in the committee's 2008 report. "Categorized as "enforcement" in the committee's 2008 report. <sup>d</sup>Categorized as "technology development" in the committee's 2008 report.

# **APPENDIX III: EXAMPLES OF INTERAGENCY MARINE DEBRIS COORDINATING COMMITTEE MEMBER AGENCIES' ACTIVITIES**

The following are examples of activities members of the Interagency Marine Debris Coordinating Committee (interagency committee) reported conducting—often in coordination with nonfederal partners such as nongovernmental organizations, industry, state governments, Indian tribes, and other nations—to address marine debris based on information from the committee's 2016 and 2019 biennial reports and agency documents and interviews.<sup>75</sup> These examples include activities from the categories outlined in the biennial reports: (1) education and outreach; (2) legislation, regulation, and policy; (3) cleanup; (4) research and technology development; and (5) coordination.<sup>76</sup> The examples discussed below do not represent all activities conducted by member agencies, but rather illustrate the nature and type of activities the agencies reported conducting. In addition, the examples include activities from agencies that were identified in the interagency committee's 2014 charter and were included in the committee's most recent biennial reports.<sup>77</sup>

#### **Education and Outreach**

Nine of the 11 member agencies reported conducting activities to support education and outreach related to addressing marine debris, such as developing and distributing educational materials, supporting public awareness campaigns, or partnering with or funding state, local, tribal, or nongovernmental education efforts. For example:

 **Online public education**. The Trash Free Waters Program—a program established in the spring of 2013 by the Environmental Protection Agency (EPA) to encourage collaborative actions by public and private stakeholders to prevent trash from entering water— provides information to the public, including online information about actions that can be taken to reduce trash from entering waterways. For example, in 2017, the program produced a series of eight webinars with experts on microplastics with the goal of promoting increased knowledge of the sources, distribution, and impacts of plastics and microplastics in the environment.<sup>78</sup> Additional topics included research on global waste management and

 $\overline{a}$ <sup>75</sup> The 2016 and 2019 biennial reports cover activities conducted in 2014-15, and 2016- 2017, respectively. We reviewed each of the five biennial reports issued by the interagency committee between 2010 and 2019, but selected examples of activities from the two most recent biennial reports to include in our report.

<sup>&</sup>lt;sup>76</sup> The biennial progress reports identified eight categories of activities, but we consolidated activities reported under the "enforcement" and "incentive programs" categories into the "legislation, regulation, and policy" category because of similarities among the activities within these categories. Similarly, for presentation purposes, we consolidated activities reported under the "research" and "technology development" categories into one "research and technology development" category.

<sup>77</sup> These agencies are: the Department of Commerce's NOAA; the Department of Defense's U.S. Army Corps of Engineers and U.S. Navy; the Department of Homeland Security's U.S. Coast Guard; the Department of the Interior's Bureau of Safety and Environmental Enforcement, National Park Service, and U.S. Fish and Wildlife Service; Department of Justice; Department of State; Environmental Protection Agency; and the Marine Mammal Commission.

<sup>78</sup> These webinars are available to the public at no cost, at: https://www.epa.gov/trash-free- waters/trash-free-waterswebinar-series.

mismanagement of plastics, potential replacements for plastic products, and ways to improve the design of materials and products to minimize their environmental impacts.

- **Grants for public awareness projects**. The National Oceanic and Atmospheric Administration's (NOAA) Marine Debris Program awards grants to eligible entities to, among other things, develop projects to educate the public about various aspects of preventing marine debris. For example, in 2014, NOAA awarded one grant to Virginia State's Department of Environmental Quality to develop and implement a social marketing approach to reduce balloon debris. Balloons can end up in streams, rivers, and the oceans where marine animals can ingest the balloons or become entangled by their attachments, causing injury or death. This project aimed to help educate the public about the importance of refraining from releasing balloons in parks or outside schools, churches, wedding venues, or other events where balloons may be common.
- **Sea Partners Program**. Through its Sea Partners Program established in 1994, the U.S. Coast Guard Auxiliary conducts education and outreach to waterway users such as boaters, fishermen, marina operators, marine industry, and the general public with information on protecting the marine environment. <sup>79</sup> For example, its Sayreville, New Jersey unit reaches an annual average audience of about 10,000 people, according to a program document, including youth groups, primary and secondary education science classes, senior citizen groups, and others. Topics presented include an introduction to marine pollution and oil spills and environmental pollution and recreational boating.

## **Legislation, Regulation, and Policy**

Nine member agencies reported conducting activities to identify noncompliance or help ensure compliance with laws and regulations and develop or encourage policies and programs to implement practices that address specific types of marine debris. For example:

 **Notice for offshore oil and gas operators**. In November 2018, the Bureau of Safety and Environmental Enforcement renewed a notice for offshore oil and gas lessees and operators in the Gulf of Mexico that clarifies and provides more detail about marine trash and debris awareness training. Specifically, the notice stated that all offshore employees and contractors active in offshore operations are to complete marine debris awareness training annually. The notice further specifies that lessees and operators are to provide the bureau with an annual report that describes their training process and certifies that the training process was followed.

 $79$  The U.S. Coast Guard Auxiliary was established pursuant to statute. Its mission is to promote and improve recreational boating safety; provide trained crews and facilities to augment the U.S. Coast Guard and enhance safety and security of our ports, waterways, and coastal regions; and support U.S. Coast Guard operational, administrative, and logistical requirements.

- **Criminal enforcement of environmental laws**. The Department of Justice prosecuted two shipping companies in 2017 for, among other things, falsifying records regarding disposal of garbage from a ship, in violation of the Act to Prevent Pollution from Ships.<sup>80</sup> Specifically, the ship's crew was instructed to throw plastic garbage bags filled with metal and incinerator ash overboard without recording the incidents in the ship's record book. The companies pled guilty and were, among other things, sentenced to pay a \$1.5 million fine and make a \$400,000 community service payment.<sup>81</sup>
- **Policies for financing waste management infrastructure in Asia**. The Department of State helped convene a meeting in Japan in 2016, under the Asia-Pacific Economic Cooperation framework, to discuss policy changes needed to overcome barriers to financing waste management infrastructure in the Asia-Pacific region to prevent and reduce debris from entering the marine environment.<sup>82</sup> The meeting brought together government officials from the economic cooperation, representatives from industry, international financial institutions, and experts. Ministers of the economic cooperation endorsed nine recommendations developed at the meeting. <sup>83</sup> State Department officials said they have continued to work with Asian governments, industry, and nongovernmental organizations to encourage policy changes and spur financial support for increasing waste management infrastructure and addressing land-based sources of plastic and in Asian countries. For example, at a 2017 meeting on waste management, State Department officials informed Asia-Pacific Economic Cooperation officials of the social and economic impacts of marine debris resulting from mismanaged waste in the region. Officials also said they used the meeting to connect economic cooperation officials with private sector stakeholders to encourage policy changes intended to enable private investment in waste management.

#### **Cleanup**

 $\overline{a}$ 

Eight of the 11 member agencies reported conducting a variety of activities to support the removal and disposal of marine debris, often in partnership with others, such as state governments. For example:

<sup>80</sup> *United States v. Thome Ship Management Pte, Ltd and Egyptian Tanker Company*, No. 17-cr-00075 (E.D. Tex.).

<sup>&</sup>lt;sup>81</sup> The community service payment was made to the National Fish and Wildlife Foundation, a nonprofit conservation organization that awards grants for the protection and restoration of the nation's fish, wildlife, plants and habitats from monies arising from legal and regulatory actions involving natural resources and the environment.

 $82$  The Asia-Pacific Economic Cooperation is a regional economic forum established in 1989 to leverage the growing interdependence of the Asia-Pacific region. Consisting of 21 member countries, its aim is to create greater prosperity for the people of the region by promoting balanced, inclusive, sustainable, innovative and secure growth and accelerate regional economic integration.

<sup>&</sup>lt;sup>83</sup> Meeting participants developed nine recommendations, including setting waste management targets at economywide and municipal levels as well as building waste management performance indicators and a methodology to track progress against economy-wide and municipal waste targets, maintain an economy-wide waste database, and encourage and acknowledge frontrunner cities for their overall waste and sanitation achievement through competitive award and certification.

- **Debris removal grants**. In 2016 and 2017, NOAA's Marine Debris Program awarded \$2.4 million in grants to 25 entities such as state and tribal governments in 17 coastal states and U.S. territories for projects including community cleanups, crab trap recovery, and derelict vessel removal. For example, in September 2017, the program awarded a grant to the Makah Indian Tribe to remove three sunken vessels from the Makah Marina within the Makah Tribe Indian Reservation on Washington's Olympic Peninsula.
- **National Park cleanup**. National Park Service staff conducted coastal cleanups across the various regions of the National Park System during 2016 and 2017. For example, in fiscal year 2017, park officials from Biscayne National Park, located off the coast of Southern Florida and comprised mostly of water, partnered with the Coastal Cleanup Corporation, a nonprofit organization, to organize 252 volunteers in removing 14,000 pounds of debris from the park.
- **Maintaining navigation channels**. The U.S. Army Corps of Engineers has authority to remove accumulated snags, obstructions, and other debris located in or adjacent to federally-maintained navigation channels. The Corps' operations and maintenance appropriation is available to pay for the removal of obstructions to navigation, and the Corps is sometimes directed to use this appropriation for drift removal. For instance, in fiscal year 2018, the explanatory statement accompanying the Corps' annual appropriation directed the Corps to use about \$9.9 million of its appropriation for drift removal in New York Harbor. Debris the Corps removes typically consists of lumber, trees and branches, large waste items like tires, and large plastic items, according to Corps' officials.

## **Research and Technology Development**

Five of the 11 member agencies reported coordinating activities to conduct or sponsor research to monitor, understand the sources of, prevent, mitigate, or reduce the effects of marine debris or to support developing new technologies such as using more sustainable or recyclable types of materials. For example:

 **Research grants**. Since 2006, NOAA's Marine Debris Program has supported at least two marine debris research projects that address questions such as monitoring marine debris, identifying fishing gear improvements and alternatives, or better understanding the environmental or economic impacts of marine debris. For example, in 2016, NOAA awarded a contract to a private research and consulting firm to conduct an economic study on how marine debris affects the economies of tourism-dependent coastal communities around the United States. The purpose of the project was to evaluate changes in tourism spending based on changes in the amount of marine debris to help prioritize areas of the United States where future prevention and removal efforts may be needed. NOAA officials said they expect the final report to be issued by the end of 2019.
- **Microplastics workshop**. In June 2017, EPA hosted a Microplastics Experts Workshop that convened experts from academia and other federal agencies, including NOAA, the U.S. Geological Survey, and the Food and Drug Administration, to identify microplastics research needs. The effort resulted in a 2018 report that identified four main areas where additional research is needed: (1) standardization of research methods, (2) debris sources and fate, (3) ecological risk assessment, and (4) human health risk assessment. EPA is using the report to consider how the agency can best address these high- priority microplastics research needs as it develops the agency's larger environmental research agenda, according to EPA officials.
- **Development of new fishing gear**. In 2016, the Marine Mammal Commission awarded a grant to the New England Aquarium to test a ropeless fishing gear prototype intended to prevent whale entanglements in fishing gear. According to a document from the Commission, entanglement in fishing gear is the number one direct cause of marine mammal injury and death, including the endangered Northern Atlantic right whale. <sup>84</sup> The Commission has used the results of this effort to emphasize the potential for ropeless gear to reduce and prevent entanglement in meetings with lobster and crab fishermen on the east and west coasts.

## **Coordination**

 $\overline{a}$ 

Seven of the 11 member agencies reported conducting a variety of activities to foster coordination among member agencies and with nonfederal partners, such as international, state, and local government agencies. For example:

 **Global Partnership on Marine Litter**. In 2012, the United Nations launched the Global Partnership on Marine Litter, a voluntary network of international governments, nongovernmental organizations, academia, private sector companies, and others with the goal of protecting human health and the global environment primarily by reducing and managing marine debris. <sup>85</sup> Interagency committee members, including NOAA and EPA, are partners to the global partnership. For example, from 2012 through 2017, the NOAA Marine Debris Program Director served as the Steering Committee chair of the global partnership. EPA has coordinated with the global partnership in Latin American and Caribbean countries to help develop a regional strategy for addressing marine debris in those regions and

<sup>&</sup>lt;sup>84</sup> Fishing gear entanglements cause the majority of right whale deaths and also contribute to declining calving rates through the prolonged health effects of nonlethal entanglements, according to a report from the Marine Mammal Commission.

<sup>&</sup>lt;sup>85</sup> Specifically, following recommendations made in the Manila Declaration on Furthering the Implementation of the Global Programme of Action for the Protection of the Marine Environment from Land-Based Activities issued in January 2012, the Global Partnership on Marine Litter was launched in June 2012 at the United Nations Conference on Sustainable Development (Rio + 20) in Brazil. Among others, objectives of the partnership include reducing the impacts of marine litter worldwide on economies, ecosystems, animal welfare and human health, and enhancing international cooperation and coordination through the promotion and implementation of the Honolulu Strategy, a global framework for the prevention and management of marine debris that was developed after the Fifth International Marine Debris Conference in 2011.

through in-person meetings and with other global partnership staff and NOAA colleagues through the steering committee.

- **Sister Cities initiative**. In 2015, the State Department announced the creation of a "Sister Cities" initiative with China to share best practices related to waste management and preventing marine debris. As part of the initiative, in November 2016, a Chinese delegation, comprised of central government officials and officials from Weihai and Xiamen, visited Chicago, New York City, and San Francisco to study U.S. practices in addressing marine debris. In November–December 2017, a U.S. delegation comprised of U.S. government officials and a New York City official, visited Xiamen, Weihai, and Beijing to learn about Chinese waste management practices. The partner city relationships were formalized with a memorandum of understanding between San Francisco and Xiamen in July 2016, and New York and Weihai in December 2017 to work together to address marine debris.
- **State emergency response guides and regional action plans**. NOAA's Marine Debris Program has coordinated with coastal managers, nongovernmental organizations, industry, academia, and other groups to develop state marine debris emergency response guides. For example, in 2016 and 2017, NOAA coordinated with Florida, Georgia, Mississippi, North Carolina, and South Carolina to develop individual guides for those states. According to NOAA officials, federal, state, and local officials used the Florida response guide during the 2017 and 2018 hurricane seasons to inform responding agencies which agency has jurisdiction and to better coordinate marine debris removal efforts after an event. In addition, NOAA coordinated efforts to develop, enhance, and implement regional action plans for the Great Lakes, the Gulf of Maine, the Gulf of Mexico, the Mid-Atlantic, the Southeast, California, Florida, Hawaii, Oregon, and Washington regions. The purpose of the action plans is to bring stakeholders together to prevent and reduce marine debris throughout the United States, according to NOAA documents. For example, NOAA officials said that under the Hawaii action plan, several federal agencies and nongovernmental organizations worked together to purchase and maintain bins to collect used fishing line for recycling.

## **APPENDIX IV: COMMENTS FROM THE DEPARTMENT OF COMMERCE**

UNITED STATES DEPARTMENT OF COMMERCE **The Secretary of Commerce** Washington, D.C. 20230

September 18, 2019

Ms. Anne-Marie Fennell Director Natural Resources and Environment U.S. Government Accountability Office 441 G Street, NW Washington, DC 20548

Dear Ms. Fennell:

Thank you for the opportunity to review and comment on the Government Accountability Office's (GAO) draft report entitled Marine Debris: Interagency Committee Members Are Taking Action, But Additional Steps Could Enhance the Federal Response (GAO-19-653).

The Department of Commerce agrees with GAO's four recommendations regarding the National Oceanic and Atmospheric Administration and the Chair of the Interagency Marine Debris Coordinating Committee. Enclosed is our response and recommended technical changes to the draft report.

Should you have any further questions, please contact MaryAnn Mausser, GAO Liaison, at (202) 482-8120 or MMausser@doc.gov.

Sincerely,

bur(box

Enclosure

#### **Department of Commerce** National Oceanic and Atmospheric Administration **Response to the GAO Draft Report Entitled** Marine Debris: Interagency Committee Members Are Taking Action, **But Additional Steps Could Enhance the Federal Response** (GAO-19-653, September 2019)

#### **General Comments**

The Department of Commerce's National Oceanic and Atmospheric Administration (NOAA) appreciates the opportunity to review the Government Accountability Office's (GAO) report on the Interagency Marine Debris Coordinating Committee (IMDCC) and Federal efforts to address marine debris. The report's analysis of IMDCC's current operations and the obligations of IMDCC and member agencies under the Marine Debris Act (33 U.S.C. § 1954) presents and analyzes the Federal Government's actions to fulfill this Congressional mandate.

#### **NOAA Response to GAO Recommendations**

The draft GAO report made four recommendations:

Recommendation 1: "The NOAA Administrator, in coordination with interagency committee member agencies, should establish a time frame for documenting the committee's membership process."

NOAA Response: NOAA agrees with this recommendation. The NOAA Administrator will establish a time frame for documenting the IMDCC's membership process that provides opportunities for both IMDCC and NOAA-based input. The Marine Debris Act, as amended by the Save Our Seas Act of 2018, requires six named agencies to participate in IMDCC. In addition to these agencies, IMDCC shall include such other Federal agency members that have an "...interest in ocean issues or water pollution prevention and control..." as the Secretary of Commerce determines appropriate. NOAA, in consultation with IMDCC, will determine objective criteria for evaluating Federal agency interest and identify other factors to consider as part of the membership process. NOAA is continuing to formalize and document the committee's membership process.

Recommendation 2: "The NOAA Administrator, in coordination with interagency committee member agencies, should clarify what is meant by "senior official" in the Marine Debris Act, such as through revisions to its charter."

NOAA Response: NOAA agrees with this recommendation. NOAA will work with IMDCC to revise the charter, which was last updated in 2014. As part of this process, NOAA, in coordination with IMDCC members, will define the term "senior official" so that the definition can be consistently applied across all Federal agency structures. In forming its definition, NOAA will consider seniority requirements of similarly situated advisory committees, along with related factors, such as the ability to make decisions on behalf of an agency and general awareness of an agency's available resources.

Recommendation 3: "The Chair of the interagency committee, in coordination with member agencies, should develop and implement a process to analyze the effectiveness of the interagency committee's recommendations and strategies, and include the results in its biennial reports."

NOAA Response: NOAA agrees with this recommendation to the extent it can be implemented using available budgetary resources. IMDCC is primarily a coordinating body focused on information sharing, and its biennial report highlights agency activities implementing the 2008 report recommendations (including 25 recommendations organized into eight overarching topics). However, IMDCC itself lacks the existing resources to require and routinely evaluate the effectiveness of these activities. Instead, individual agencies are expected to work toward implementing the 2008 report recommendations in accordance with each agency's legal and programmatic authorities, mission priorities, and resource limitations. To the extent possible, NOAA will work with IMDCC members to identify common or easily translatable metrics for evaluating the effectiveness of the 2008 recommendations and implement these in the next biennial report to Congress.

Recommendation 4: "The Chair of the interagency committee, in coordination with member agencies, should develop a process to identify recommendations for priority funding needs to address marine debris, and include such recommendations in its biennial reports."

NOAA Response: NOAA agrees with this recommendation, but notes that NOAA does not have the authority to control the implementation of a process for identifying priority funding needs of other member agencies. NOAA believes that IMDCC's recommendations for priority funding needs are already reflected in the President's annual budget request and operating plan for each member agency. To the extent possible, NOAA will work with IMDCC members to develop a process for identifying priority areas, which can be reflected in each agency's respective budgeting process and shared in IMDCC's biennial reports.

## **APPENDIX V: COMMENTS FROM THE U.S. AGENCY FOR INTERNATIONAL DEVELOPMENT**

Anne-Marie Fennell Director U.S. Government Accountability Office 441 G Street, N.W. Washington, D.C. 20226

Marine Debris: Interagency Committee Members Are Taking Action, but Additional Re: Steps Could Enhance the Federal Response (GAO-19-653)

Dear Ms. Fennell:

I am pleased to provide the formal response of the U.S. Agency for International Development (USAID) to the draft report produced by the U.S. Government Accountability Office (GAO) titled, Marine Debris: Interagency Committee Members Are Taking Action, but Additional Steps Could Enhance the Federal Response (GAO-19-653).

USAID remains committed to addressing the challenge of marine debris through our programs, in collaboration with interagency partners. Given the global nature of the problem, USAID has significant opportunities to play an important role in the international response, and is already doing so by providing technical assistance on the international titles of the draft "Save Our Seas 2.0" legislation. Through programs such as the Municipal-Waste Recycling Program, a partnership with Circulate Capital, and the new Clean Cities Blue Ocean initiative, USAID continues help developing countries manage these challenges.

I am transmitting this letter and the enclosed comments from USAID for inclusion in the GAO's final report. Thank you for the opportunity to respond to the draft report, and for the courtesies extended by your staff while conducting this engagement. We appreciate the opportunity to participate in the complete and thorough evaluation of our efforts to combat marine debris.

Sincerely,

Frederick Nutt Assistant Administrator Bureau for Management

Enclosure: a/s

#### COMMENTS BY THE U.S. AGENCY FOR INTERNATIONAL DEVELOPMENT ON THE DRAFT REPORT PRODUCED BY THE U.S. GOVERNMENT ACCOUNTABILITY OFFICE (GAO) TITLED, MARINE DEBRIS: Interagency Committee Members Are Taking Action, but Additional Steps Could Enhance the Federal **Response (GAO-19-653)**

The U.S. Agency for International Development (USAID) would like to thank the U.S. Government Accountability Office (GAO) for the opportunity to respond to this draft report. We appreciate the extensive work of the GAO's engagement team.

USAID appreciates the GAO's recognition of the challenge posed by marine debris and the incorporation of Agency's input on this important topic. In particular, USAID appreciates that the GAO's final report acknowledges the importance of municipal waste as a significant source of marine plastic pollution (p. 1), as well as recognizes USAID's participation in the Interagency Marine Debris Coordinating Committee.

As noted in the Science article cited in Footnote 3 on page one, the majority of plastic ocean debris comes from mismanaged municipal waste in the developing world, where waste-management systems, infrastructure, and governments struggle to keep pace with increasing amounts of trash from growing urban populations in riverine and coastal areas. As the lead Federal Agency on foreign assistance, USAID has several programs that target this aspect of the problem:

- · Municipal-Waste Recycling Program (2016-2021): Reduces land-based sources of ocean plastic waste in four of the top five contributing countries-Indonesia, The Philippines, Sri Lanka, and Vietnam-by providing small grants and technical assistance to a variety of local actors in towns and cities.
- · Partnership Circulate Capital Partnership: In June 2019, USAID's leadership launched a partnership, managed by Circulate Capital and funded by multinational companies, that leverages more than \$100 million to incentivize private investment in the recycling value-chain in South and Southeast Asia.
- Clean Cities, Blue Ocean: USAID recently awarded a new \$50 million contract to TetraTech to implement a program aimed at preventing land-based sources of ocean plastic pollution. The program will build capacity and commitment for the "3Rs"—reducing, reusing, recycling—and solid-waste management in urban and peri-urban settings, particularly in riverine and coastal areas.

USAID greatly appreciates the work of its interagency partners that are engaged in addressing marine debris, and looks forward to continued collaboration with them.

*Chapter 111*

l

# **THE EFFECTS OF MARINE DEBRIS ON BEACH RECREATION AND REGIONAL ECONOMIES IN FOUR COASTAL COMMUNITIES: A REGIONAL PILOT STUDY\***

## *National Oceanic and Atmospheric Administration Marine Debris Division*

## **EXECUTIVE SUMMARY**

Marine debris is a persistent problem in many coastal areas of the United States. There are a variety of potential economic losses associated with marine debris, including effects on commercial fisheries, effects on waterfront property values, costs incurred by local governments and volunteer organizations to remove and dispose of marine debris, and more general "existence" values reflecting the public's preference for a clean environment. This study evaluates two types of economic loss that result from the effects of marine debris on beach recreation: the loss of recreational value to beach visitors, and the regional economic impact from reduced spending on beach visits in a particular region.

The goal of this study was to better understand the economic effects of changes in the amount of debris on beaches. The results may help federal, state, and local agencies structure future debris abatement and mitigation projects to maximize social benefits provided by coastal resources. To address these goals, we collected data from four coastal areas in the United States: Gulf Coast beaches in Alabama, Atlantic Ocean beaches in Delaware and Maryland, Lake Erie beaches in Ohio, and Pacific Ocean beaches in Orange County, California.

<sup>\*</sup> This is an edited, reformatted and augmented version of National Oceanic and Atmospheric Administration Marine Debris Division, Abt Associates, 14553, dated July 2019.

#### **Recreational Value**

Recreational value is a monetary measure of the enjoyment people get from participating in beach recreation, or their "willingness to pay" for recreation and clean beaches.

We estimated the effect of marine debris using two different economic concepts: *the value of recreation and the economic impacts of recreation*. The value of recreation is a monetary measure of the enjoyment people get from participating in beach recreation. It can also be described as people's willingness to pay for recreational access to beaches, or for policies that improve beach recreation. The economic impact of recreation is a measure of the effect of beach recreation on spending by consumers and businesses in the region. It includes both direct spending on recreational activities and the effects of direct spending in stimulating the local economy. Because spending in some regions may increase as a result of a decrease in spending in other regions, amounts calculated for different regions should not be added together. Because they are interpreted in fundamentally different ways, economic impacts should also not be added together with estimates of recreation value.

#### **Economic Impacts of Recreation**

Economic impacts of recreation measure the effect of beach recreation on spending by consumers and businesses in the local economy.

We measured recreational value and economic impacts for two hypothetical scenarios involving marine debris on beaches: a *reduction in debris to almost none* (defined in the study as one piece of debris per 500 square feet of beach), and a *doubling of debris*.

#### **Study Design**

This study evaluated the relationship between marine debris and recreational beach use by recruiting participants at beaches in the four selected coastal areas. Those willing to participate in the study were sent a mail-in survey with questions about their beach recreation, their opinions about marine debris, and how their recreation would change if there were different amounts of debris on beaches.

The data from the surveys were used to estimate the total effect of changes in marine debris on the number of beach visits in each area. These estimates in turn were used in a nationwide recreation model originally developed during the natural resource damage assessment for the *Deepwater Horizon* oil spill (English et al., 2018) to estimate the change in recreational value from the hypothetical changes in debris. In addition, the estimates of changes in visits were incorporated into a regional input/output model to determine the regional economic impacts of marine debris (Figure ES-1).

Figure ES-1. Steps for estimating changes in recreational value and regional economic impacts associated with changes in marine debris on beaches.

#### **Survey Results**

l

The results of the mail survey indicate a potentially strong relationship between marine debris and beach recreation. The estimated effect of a reduction in debris to almost none is an increase in recreation days of between 2.2% and 9.5% for the three ocean coasts, and in increase of  $35.4\%$  in Ohio.<sup>1</sup> The increase in the number of beach visits ranged from  $369,000$ visitor days per year in Alabama to 2.9 million visitor days per year in Ohio (Figure ES-2). A doubling of debris would result in an estimated decrease in recreation days of between 16.3% and 26.5% for the three ocean coasts, and a decrease of 35.6% in Ohio. The decrease in the number of beach visits ranged from 1.2 million visitor days per year in Alabama to 5.7 million visitor days per year in Orange County.

<sup>&</sup>lt;sup>1</sup> Numbers in the text and tables of this report have been rounded for presentation. Calculations performed on these rounded numbers may not reproduce final results.

\* Ohio estimates account for multiple-day trips only.

Figure ES-2. Changes in the annual number of recreation days if the amount of marine debris is reduced to almost none, and if the amount of marine debris doubles.

### **Recreational Value**

The change in recreational value is calculated based on the change in the number of recreation days. For example, the nationwide recreation model from the *Deepwater Horizon* research estimates the annual number of recreation days at Alabama beaches is 4.55 million. Based on the results of our survey, if marine debris at those beaches were reduced to almost none, recreation days in Alabama would increase by 8.1%, for an estimated increase of approximately 369,000 recreation days. Based on the nationwide recreation model, recreators value each day of recreation at Alabama beaches at \$27.27. Thus if the a reduction in debris to almost none results in an additional 369,000 days of recreation, the resulting change in the value of recreation is estimated to be \$10.1 million (\$27.27 per day x 369,000 days). Estimates of recreation value for all four study areas are summarized in Table ES-1. For Alabama, Delaware/Maryland, and Orange County, California, the results account for trips of all lengths, including single-day and multiple-day trips. For Ohio, the national recreation model was able to provide results for multiple-day trips only.

Our results indicate that changes to recreation associated with marine debris provide substantial value to recreators. If marine debris were reduced to almost none, the estimated annual increase in recreation value is \$10.1 million in Alabama, \$19.8 million in Delaware/Maryland, \$88.0 million in Ohio (multiple-day trips only), and \$129.7 million in Orange County, California (Table ES-1). If the amount of marine debris on beaches were to double, the estimated annual decrease in recreational value is \$32.3 million in Alabama, \$140.9 million in Delaware/ Maryland, \$83.9 million in Ohio (multiple-day trips only), and \$275.1 million in Orange County, California.

a. For Ohio, estimates account only for multiple-day trips and exclude the value and quantity of single-day trips.

#### **Regional Economic Impacts**

As noted previously, changes in recreational beach visits because of changes in marine debris quantities would have cascading economic impacts on regional economics. We expressed the regional economic impacts using two key metrics:

- *Value added*: The value of gross output less intermediate inputs. The value of this metric is equal to the sum of compensation of employees, taxes on production and imports less subsidies, and gross operating surplus.
- *Employment*: Number of full- and part-time jobs (including proprietors' jobs).

We calculate that a reduction of debris to almost none would contribute an additional \$29 million in economic activity (measured as value added) in Alabama, \$27.8 million in Delaware and Maryland; \$206.0 million in Ohio, and \$137.8 million in Orange County, California (Table ES-2). This economic activity is estimated to provide between 464 and 3,703 jobs. Conversely, a doubling of debris is estimated to cost the local economies \$96.3 million in Alabama, \$203.2 million in Delaware and Maryland, \$207.3 million in Ohio, and \$304.5 million in Orange County, California; resulting in a loss of between 2,198 and 4,254 jobs (Table ES-2).

In summary, the results of this study indicate that the amount of marine debris on beaches have a substantial effect on recreational value and regional economies, outside of the costs municipalities incur to remove debris. Beachgoers surveyed indicated that they would increase their beach visits somewhat if marine debris were eliminated, and they would decrease beach visits substantially if the amount of marine debris on the beach were to double. These results can be used by policy and program evaluators to help understand how programs aimed at reducing marine debris levels can provide both significant value to recreators and contributions to the regional economy.

#### **Table ES-2. Regional economic impacts of changes to debris levels at the four study areas (2018 dollars)**

## **1.INTRODUCTION**

Marine debris is a persistent problem in many coastal areas of the United States. There are a variety of potential economic losses associated with marine debris, including effects on commercial fisheries, effects on waterfront property values, costs incurred by local governments and volunteer organizations to remove and dispose of marine debris, and more general "existence" values reflecting the public's preference for a clean environment. This study evaluates two types of economic loss that result from the effects of marine debris on beach recreation: the loss of recreational value to beach visitors, and the regional economic impact from reduced spending on beach visits in a particular region.

Research suggests that litter on beaches detracts from visitors' enjoyment and reduces the amount and value of recreation on coastal beaches (Ofiara and Brown, 1999; Brouwer et al., 2017; Krelling et al., 2017; Leggett et al., 2018). Marine debris may reduce the likelihood that people return to the same location, particularly among first-time visitors (Ballance et al., 2000; Schuhmann, 2012). Effects on beach recreation have implications for regional economies because tourism and spending by beach visitors is significant in many coastal communities (Kosaka and Steinback, 2018; Office for Coastal Management, 2019).

Visitors may perceive a decline in the natural beauty of an area if marine debris is present. Visitors may also perceive potential physical harm due to cuts or bacterial infections, which would have economic costs in terms of medical expenses and lost wages if such harm were to occur (Campbell et al., 2016). In contrast to debris or litter along the roadside or in parks, there is a high potential for dermal contact with marine debris on beaches as visitors frequently go barefoot, lie directly on the sand, and dig in the sand. The existence of numerous volunteer efforts to remove debris from beaches (Zielinski et al., 2019) and the fact

that many municipalities regularly rake beaches to remove debris are also indications that beach visitors prefer cleaner beaches.

#### **Recreational Value**

Recreational value is a monetary measure of the enjoyment people get from participating in beach recreation, or their "willingness to pay" for recreation and clean beaches.

This study was designed to determine how the quantity of marine debris on beaches affects the number of days that recreators will visit the beach, and how those changes in behavior translate to lost recreational value and regional economic impact. The goal of this study was to better understand the economic effects of changes in the amount of debris on beaches. The results may help federal, state, and local agencies structure future debris abatement and mitigation projects to maximize social benefits provided by coastal resources. To address these goals, we collected data from four coastal areas in the United States: Gulf Coast beaches in Alabama; Atlantic Ocean beaches in Delaware and Maryland; Lake Erie beaches in Ohio; and Pacific Ocean beaches in Orange County, California (Figure 1).

#### **Economic Impacts of Recreation**

 $\overline{a}$ 

Economic impacts of recreation measure the effect of beach recreation on spending by consumers and businesses in the local economy.

We estimated the effect of marine debris using two different economic concepts: the *value of recreation and the economic impacts of recreation*. The value of recreation is a monetary measure of the enjoyment people get from participating in beach recreation. It can also be described as people's willingness to pay for recreational access to beaches, or for policies that improve beach recreation. The economic impact of recreation is a measure of the effect of beach recreation on spending by consumers and businesses in the region. It includes both direct spending on recreational activities and the effects of direct spending in stimulating the local economy. Because spending in some regions may increase as a result of a decrease in spending in other regions, amounts calculated for different regions should not be added together. Because they are interpreted in fundamentally different ways, economic impacts should also not be added together with estimates of recreation value.<sup>22</sup> We measured these effects for two hypothetical scenarios of marine debris levels: a *reduction of debris to almost none* (defined in the study as one piece of debris per 500 square feet of beach), and a *doubling of debris*.

The first step in this study was an evaluation of the relationship between marine debris and recreational beach use using a survey. The data from the survey were used to estimate how changes in marine debris would influence the number of beach trips that recreators would take. These data in turn were used in a nationwide recreation model developed during the *Deepwater Horizon* oil spill (English et al., 2018) to estimate the value of recreation. In

<sup>&</sup>lt;sup>2</sup> For additional information, Stynes (2005) provides a review of concepts and methods for estimating the economic significance of recreational uses of public lands and provides a distinction between valuation and impact studies, aimed at non-economists, and Rosenberger et al. (2017) provides an overview of recreation valuation.

addition, the data on lost trips were incorporated into a regional input/output model to determine the regional economic impact of marine debris (Figure 2).

Figure 1. Study areas that define where beachgoers were interviewed and where regional economic impacts were evaluated.

As will be explained in subsequent sections, the scope of the recreational value study includes almost all beach recreation by residents from throughout the United States, occurring at beaches in each of the four study areas. For the assessment of regional economic impacts, the scope of the study includes the regional economies of the coastal counties where the beaches in each study area are located. Each study area was delineated to match a group of beaches that was aggregated into a single regional destination in data developed for the *Deepwater Horizon* oil spill assessment (English et al., 2018). The *Deepwater Horizon* dataset, collected from June 2012 to May 2013, is the basis for the nationwide recreation model.

The survey utilized stated preference techniques, an economic valuation method in which survey respondents are presented with hypothetical choice scenarios and asked what they would do in each scenario. When the choices involve changes in recreation behavior, the particular stated-preference technique is called "contingent behavior." In our study, respondents were asked how many more or fewer recreation trips they would take to beaches in a given study area if levels of marine debris decreased or increased. While statedpreference surveys have a long history of use in economics, it is worth noting the potential uncertainty in stated-preference methods because what people say they would do may not always reflect what they would actually do. Studies examining the accuracy of contingent behavior methods include Haener et al. (2001), Grijalva et al. (2002), and Morgan and Huth (2011).

Figure 2. Steps for estimating changes in recreational value and regional economic impacts associated with changes in marine debris on beaches.

For this study, estimating recreational value and regional economic impacts required benefit function transfer, a way of taking economic data and analysis developed for one purpose and revising it to be applied to a new research problem. We adapted recreation data and analyses developed for the *Deepwater Horizon* oil spill assessment (English et al., 2018) to evaluate recreation changes in our four study areas, including estimating the public's value for changes in marine debris in monetary terms. Finally, we analyzed regional economic impacts using the Regional Input-Output Modeling System (RIMS II) developed and maintained by the U.S. Bureau of Economic Analysis (U.S. BEA, 2018, 2019).

Below we describe the key steps of the study, grouped into the three major components: the marine debris survey, the model of recreation value, and the economic impact analysis.

## **1.1. Marine Debris Survey**

The marine debris survey (Section 2) was a mail survey where previously identified beachgoers were asked a series of questions about how marine debris affects their behavior. Specifically, the surveys involved the following steps:

- Interviews conducted onsite at beaches in each study area to collect information about the recreation trip the respondent was taking at the time of the interview, the respondent's demographic characteristics, and the respondent's address for use in a follow-up mail survey
- Implementation of a mail survey that asked respondents about their recreation activities at beaches in the study area during the previous year, the amount of debris they have seen on those beaches (ranking debris levels on a 1-to-5 scale, where 1 is almost no debris and 5 is a "high amount" of debris), and their response to hypothetical changes in the amount of debris on those beaches
- Development of onsite and mail-survey sampling weights that accounted for each respondent's likelihood of being selected into the sample, to help ensure that the opinions of sampled respondents accurately represent all beachgoers
- Analyses comparing respondents' demographic characteristics with their answers to the hypothetical debris scenarios to identify key characteristics that most influence preferences for marine debris
- Adjustment of mail-survey sampling weights such that mail survey respondents match the much larger sample of onsite respondents with respect to the key demographic characteristics, further improving the representativeness of mail survey respondents
- Calculation of the impact of potential changes in marine debris, including a reduction to almost no debris and a doubling of debris, on the number of recreations trips in each study area.

## **1.2. Nationwide Recreation Model**

The key result from the marine debris survey is the estimated percentage change in the number of trips to each study area resulting from the two debris scenarios (reduction to almost zero debris and doubling of debris). The percentage changes were incorporated into a nationwide model of recreation to estimate the resulting changes in total recreation trips and value. The primary steps in implementing the recreation model were:

- Adapting the nationwide model of recreation trips using data available from the *Deepwater Horizon* oil spill assessment (English et al., 2018) to apply to the four study areas using benefit function transfer
- Assessing the consistency of survey and model results with previous research, including a previous study in Orange County, California (Leggett et al., 2018) that used data on actual recreation choices (revealed preference) rather than hypothetical choices (stated preference) to value the effects of marine debris on recreation

 Adjusting model parameters to reproduce the percentage changes in trips from the marine debris survey, leading to final estimates of the total change in recreation trips and the total change in recreation value from the two study scenarios in the four study areas.

## **1.3. Regional Economic Impact Analysis**

The change in the number of recreation trips estimated using the national recreation model was also used to estimate regional economic impacts for the marine debris scenarios. A change in recreation trips results in a change in visitor spending, which we use to estimate the economic impacts of the two marine debris scenarios using input-output models. The primary steps in the economic impact analysis were as follows:

- Calculation of the proportion of trips in each study area coming from outside the local region, and the average number of recreation days per nonlocal trip, leading to an estimate of the increase or decrease in the number of nonlocal recreation days for each marine debris scenario
- Estimation of the average expenditures per recreation day in each study area using the National Economic Ocean Expenditure Survey (NORES) data on recreation expenditures (NOAA, 2012; Kosaka and Steinback, 2018)<sup>3</sup>
- Estimation of the regional economic impact of increased spending by visitor day in each study area by first mapping the NORES expenditure category to the appropriate RIMS II industry and then applying industry-specific RIMS II multipliers
- Calculation of estimates of the regional economic impacts from changes in beach recreation for each of the two marine debris scenarios (reduce debris to near zero and double the debris) in each of the four study areas.

The details of the study and the results are presented in subsequent sections. Section 2 presents information on the marine debris survey. Section 3 presents the model of recreational value, and Section 4 presents the regional economic impacts model. This is followed by the literature cited and appendices.

## **2. THE MARINE DEBRIS SURVEY**

The marine debris survey consisted of an onsite survey conducted at beaches in each study area, and a follow-up survey mailed to people who had been interviewed onsite and agreed to participate in the follow-up survey. The purpose of the onsite survey was to recruit people for the mail survey from the target population of beachgoers in each area, and to briefly collect minimal data on the respondents' trips, opinions, and characteristics. The purpose of the mail survey was to ask recreators about the effect of marine debris on their

l

<sup>&</sup>lt;sup>3</sup> Kosaka and Steinback (2018) recently published the NOAA (2012) NORES data. We were originally provided the data in 2017. For this report, we converted all dollar values to 2018 USD.

recreation choices, and to collect more extensive data on respondents' opinions and characteristics.

The main focus of the mail survey was to ask respondents the number of trips they took to the beach during the previous twelve months and how many more or fewer trips they would have taken under two contingent behavior scenarios: (1) if there had been almost no debris on beaches in the study area, and (2) if there had been twice as much debris on beaches in the study area. The term contingent behavior refers to survey questions that ask respondents how their recreation choices would change in response to changes in the quality of recreation sites. The mail survey also asked respondents to estimate the amount of debris on beaches in their area, and included other questions about their opinions and knowledge of debris on beaches.

Data collection occurred in 2018, with onsite interviews conducted from July 24 to September 3 and mail surveys sent out and received between October 5 and December 6. Response rates varied across the study areas and between the two stages of the study (onsite vs. mail). The overall response rate for the onsite survey was 76.7%. Accounting for recruitment into the mail survey and the mail-stage response rates, the final overall response rate for the mail survey was 19.0%. The number of responses provided to specific questions, as well as the number of missing responses to certain questions, was calculated and evaluated.

We weighted the sampling to help ensure that data from the survey was representative of the target population of people who used beaches in each study area. Sampling weights are critical in analyzing survey data whenever the sample design deviates from simple random sampling (Schaeffer et al., 2012). The weights include a base weight to control for differences among respondents in the probability of being selected into the sample, which was influenced by factors such as the amount of time a respondent spent at the beach. To further improve representativeness, the weights also include adjustments to make mail-survey respondents more similar to the much larger onsite sample with respect to key demographic characteristics, such as the proportion of people with a college degree.

Results of the marine debris survey included average ratings of the amount of debris on beaches and the total percentage change in the number of trips to beaches in each study area under the scenarios of a decrease or an increase in debris.

#### **2.1. Survey Design**

Below we first describe a pretest for the marine debris survey that was conducted in Orange County, California. A pretest is a common way to evaluate and refine a survey before final implementation. We then describe the final onsite and mail surveys and explain the reasons for each of the questions that were included. The surveys are provided in Appendix A.

#### *2.1.1. Onsite and Mail Survey Pretest*

During the survey pretest, we conducted onsite interviews at eight beaches in Orange County on Wednesday, September 27, 2017 and again on the following Saturday, September 30. The onsite interviewers asked several brief questions about each respondent's recreation and also elicited the respondent's address for completion of a follow-up mail survey. We intercepted 777 recreators and obtained onsite interviews with 504 of them. We obtained addresses for the follow-up mail survey from 345 onsite respondents.

On December 6, 2017, we mailed surveys to the 345 addresses and sent reminder postcards one week later. For any valid addresses from which we had not obtained a completed survey, we sent a follow-up survey on December 20 and a second reminder post card on January 18, 2018. By the end of January, we had received 49 completed surveys. The U.S. Postal Service returned a total of 64 surveys as undeliverable due to invalid addresses.

One issue identified in the pretest was a low response rate of only 17.4% in the mail stage of the study. We believed this was due to scheduling the first mailing before the December holidays and the second mailing after the holidays, an interruption necessitated by the timeline for completing the pretest. In fact, the final mail response rate in Orange County was 30.8% in the final study. Response rates for the full study are discussed in more detail below.

In the pretest, we also found that the item nonresponse rate was high for the contingent behavior questions. "Item nonresponse" refers to missing responses to particular questions in completed surveys, as opposed to nonresponse from those who did not return the survey. In the question about a reduction in debris, 3 out of 49 respondents (6.1%) did not provide a usable answer of either no change or a specified increase in trips. In the pretest question about a doubling of debris, 9 out of 49 respondents (18.3%) did not provide a usable answer of either no change or a specified decrease in trips. The formatting of the contingent behavior questions in the pretest required people to fill out a small table with the abbreviated question "How many more trips if there had been almost no garbage or manmade debris?" in the row heading and "day trips" and "overnight trips" as column headings.

To address this item nonresponse rate, we revised the original question to be two separate and complete questions about day trips and then overnight trips, with the belief that this might improve the clarity of the questions for some respondents. However, the rate of item nonresponse did not improve and as reported below it in fact increased to 7 out of 52 (13.4%) for a reduction in debris and 13 out of 52 (25.0%) for a doubling of debris in the final Orange County results. We do not believe the changes in formatting or wording had an effect on nonresponse or that other refinements could have induced more people to answer the question. High item nonresponse rates are typical for contingent behavior questions (Eisworth et al., 2000; Whitehead et al., 2010), possibly because such questions require an open-ended "fill in the blank" response. Some respondents may be unsure how their recreation would be affected in hypothetical situations and may find it difficult to make a quantitative estimate of the change in their annual total number of trips.

The pretest also included "probing" questions that asked respondents about the design of the survey, particularly the graphical representations. There is a page in the survey that shows a picture of a beach with an area outlined in red and defined as 500 square feet or "an area approximately equal to three parking spaces" (see Appendix A). Pictures are also included that show different amounts of debris that could potentially be found in a 500 square-foot area of a beach. In the pretest, probing questions asked about the pictures and descriptions. Regarding the area of beach defined as 500 square feet, 89.8% of respondents said the description was clear or somewhat clear. Regarding the pictures of debris, 83.7% of respondents said they were able to find a picture that accurately reflected the amount of debris on beaches in their area. These results were considered satisfactory and no changes were made to the description or pictures of marine debris.

One additional concern addressed in the pretest was the possibility that people associated debris on beaches with other types of pollution. A probing question in the pretest asked "When you answered the questions about your trips, were you thinking primarily about garbage or manmade debris, or were you also thinking about other types of pollution, such as runoff from factories or farms?" Of the 49 respondents in the pretest, 71.4% said they were thinking primarily about debris on beaches. This was viewed as acceptable and did not lead to any changes the survey.

#### *2.1.2. Onsite Survey – Regional Pilot*

Using an onsite survey to reach people on the beach and recruit respondents for the mail survey ensured that the sample included only respondents who visited beaches in each study location. Reaching an equivalent number of beachgoers using a random sample of addresses would have required considerably more effort and expense, especially given that some beachgoers may live hundreds of miles from the coast in areas where the participation rate for beach recreation is quite low.

The onsite sampling involved intercepting people at beaches in each study location. The beaches were selected to represent the various types of beach experiences available, including more- and less-developed beaches. Interviews were conducted on both weekdays and weekend days to reach people taking anything from short visits to longer vacations. Although we had obtained statistically robust estimates from just 49 observations in the pretest, the target number for completed mail surveys was 100 in each study area to allow for potential shortfalls in recruitment or response rates.

The onsite interviewers collected data to assist in developing sampling weights, including the size of the party from which each respondent was selected (we interviewed only one person in a given party); the number of hours they would spend at the beach on the day of the interview; and for those engaged in a multiple-day trip, the number of days during the trip when they would spend time at the beach. The onsite survey also included several demographic questions, such as age and education, and several attitudinal questions about beach characteristics such as the presence of marine debris. Finally, we asked the respondent's name and mailing address. Those who did not agree to participate in the mail survey were asked their zip code so that data collected onsite could be used in calculating the proportion of trips from outside the local area.

#### *2.1.3. Mail Survey – Regional Pilot*

Four versions of the mail survey were developed for the four study areas. Differences across versions included different maps showing the beaches specific to each study area. The wording used to refer to beaches also differed across survey versions, such as "ocean beaches in Delaware and Maryland" or "Lake Erie beaches in Ohio." All other aspects of the mail survey were identical for each of the study areas.

The first question in the mail survey asked respondents to review the map of beaches and indicate the beaches familiar to them. This served to familiarize respondents with the set of beaches they would be asked about in subsequent questions.

The next two questions asked respondents about the total number of their single-day and multiple-day trips during the previous year to all beaches in the study area. Respondents' total number of trips throughout the year were used as a baseline to which changes in trips, estimated in later questions, could be compared.

Question 4 of the mail survey asked about the importance to respondents of 13 beach attributes when they chose which beaches to visit. The attributes included things like water quality, the presence of natural debris on the beach, scenic beauty, how crowded a beach is, and presence of manmade debris. These questions allowed us to evaluate the importance of marine debris in a qualitative way. They may also have encouraged respondents to think carefully about how they respond to marine debris relative to other beach characteristics when answering the contingent behavior questions.

Question 5 asked respondents to report which beaches they visited over the last year and to rate the level of marine debris they encountered at each beach on a scale of 1-to-5 using the photographs of debris amounts provided. The debris ratings allowed us to characterize current debris levels, at least in relative terms. Current debris levels are the starting point for the contingent behavior questions, which ask about changes in debris that are proportionate to current levels.

To specify the size of the beach area respondents were asked to evaluate, the survey included a photograph that showed an area of beach outlined in red. The area was described as 500 square feet, or approximately the area of three parking spaces. Below the beach photo were pictures showing different amounts of debris that could be found in an area of the size shown. The debris photos included cigarette butts, plastic straws, and other common items found on beaches in the United States (NOAA, 2018).

Questions 6 and 7 asked whether respondents would have changed the number of trips they took over the past year to the beaches in a given study area under two hypothetical scenarios: (1) "If there had been almost no garbage or manmade debris at beaches," and (2) "If there had been twice as much garbage or manmade debris at beaches." These questions were to be used for estimating the total percentage change in trips in each scenario, the key input to the recreation model.

Questions 8 through 12 asked whether respondents were concerned about the presence of various types of garbage or manmade debris while visiting a beach, the types of debris they have actually seen on beaches, their understanding of the sources of debris found on beaches, and whether they had participated in beach cleanup efforts. These questions seek to provide helpful context for evaluating marine debris policies. This series of question also asked respondents whether they think marine debris is a problem on beaches in the study area. This question was used to adjust mail survey sampling weights to be consistent with onsite respondents, as described in Section 2.3.

Questions 13 through 19 asked respondents to report the number of adults and children in their household as well as their gender, age, ethnicity, race, education level, and income. These questions were used to investigate the relationship between the response to changes in marine debris levels and demographic characteristics and some of them were used to adjust the sampling weights in Section 2.3.

#### **2.2. Survey Implementation**

The survey schedule, the response rates for each stage of the survey, and the total number of completed surveys are reported below for each study area. The sampling procedures are also described, including the approach to selecting respondents during the onsite survey.

Sample statistics showing the final number of responses and missing responses for key questions in the final mail survey data are presented and discussed.

#### *2.2.1. Survey Schedule and Response Rates*

We conducted the survey in 2018, beginning with an initial onsite interview with respondents during the late summer, followed by a mail survey in the fall. Those who participated in the onsite interview were asked if they were willing to take part in the mail survey and if so, to provide their address. Although the mail survey asks about a full year of beach activity, we wished to reach visitors in the fall so that their activities during the peak summer beach season would be fresh in their minds. We scheduled our initial onsite interviews in the late summer to avoid an extended period between the initial onsite interviews and the final mail survey.

Table 1 shows the schedule of data collection in each study area. The number and timing of days spent interviewing onsite varied based on weather and the availability of interviewers. A minimum of eight person-days were spent interviewing onsite in all study areas, distributed approximately evenly between weekdays and weekend days. We avoided bad weather days to maximize the number of interviews. While such a practice underrepresents low-activity days and would be problematic in a survey designed to estimate total activity, in our study totals come from the nationwide recreation model. Even if visitors on bad weather days differ systematically with respect to their preferences about marine debris, the small number of people using the beach on bad weather days would mitigate the effects of any such difference when calculating the response to marine debris in the total population of beachgoers.

The field period for the mail survey was approximately two months. The initial mailing took place on October 5, 2018. Reminder postcards were sent October 15, though in Alabama the reminder was delayed one week to avoid contacting people during the immediate aftermath of Hurricane Michael. The second mailing of the mail survey took place November 5. In the three areas where the target of 100 completed surveys had not been met, an additional reminder postcard was sent on November 21.

In total there were 1,327 completed onsite surveys, with a response rate of 76.7% (Table 1). Of the 802 addresses provided for a follow-up survey, 61 were invalid. This left 741 valid addresses for the mail survey, a recruitment rate of 55.8%. The overall mail response rate was 44.4%, with a total of 329 completed mail surveys. The cumulative response rate was 19.0%. This is a typical response rate in survey research, and low levels of response are not necessarily indicative of bias (Groves and Peytcheva, 2008; Pew Research Center, 2012). As described in Section 2.3, the sampling weights for mail respondents in each study area were adjusted so that mail respondents were similar to onsite respondents with respect to key characteristics. This technique can improve representativeness by taking advantage of higher response rates in earlier stages of the study.

The number of onsite interviews, response rates and recruitment rates varied considerably among the four study areas. In Ohio, a low number of onsite interviews was partly offset by a high mail response rate. Onsite response, recruitment, and mail response were all high in Delaware/Maryland, leading to more than the targeted number of completes. Low onsite and mail response rates in Orange County were ultimately responsible for the low number of completed mail surveys in that area.

#### **Table 1. Survey implementation**

a. The cumulative response rate accounts for the onsite response rate, the recruitment rate, and the mail response rate. Mail survey responses were reweighted to be representative of respondents to the onsite survey in each study area.

#### *2.2.2. Onsite Sampling Procedures*

Onsite sampling procedures are important in ensuring representativeness and developing sampling weights. On the beach, interviewers approached a party of people and randomly selected one adult over 18 for an interview. Random selection ensures that interviewers do not oversample any particular type of person, which could lead to results that are not representative of all beachgoers. Interviewing only those over 18 is standard survey practice to avoid issues of parental consent. For random selection, interviewers picked the person farthest to the right-hand side of the party from wherever the interviewer was standing. Interviewers generally made a judgement about who was over 18 but if unsure, the interviewer would politely explain the situation and ask whether someone was over 18. When asking an address, the full name of the respondent was also elicited because questions in both the onsite and mail survey, including demographic characteristics and preference-based responses, were specific to an individual.

Interviewers walked from party to party along a beach. Interviewers proceeded in one direction from the main access point of a beach, and then returned to the main access point and proceeded in the other direction. The extent of the total sampling area was defined as the area easily accessible on foot from the main access point, determined by the interviewer's discretion. When interviewers had spent at least 1.5 hours at a beach, or had approached every party, they would proceed to the next beach in a prescribed order. The order was agreed upon by the research team in advance, based on the proximity of beaches and logistical efficiency in getting from one beach to the next. In some cases the list was broken into two groups of beaches that were geographically close to one another, with sequential sampling of beaches proceeding separately for each group.

When starting a new day of sampling, the interviewers began at the next beach on the list after the beach where they had last conducted interviews. The list included at least eight beaches located throughout each study area, which helped to ensure reasonable representation of the different types of beaches in the area. Including significantly more than eight beaches would have entailed excessive time requirements for interviewers to become familiar with the location and layout of beaches, find where public parking is available, check whether permission is required to sample at a beach, and other issues.

Maps of the beaches included in each study area are provided as part of the mail surveys provided in Appendix A. Below is a list of beaches where onsite surveys were administered:

## **Alabama**

- Cotton Bayou Beach
- Orange Beach
- Gulf State Park Pavilion
- Gulf Shores Public Beach
- Alabama Point/Florida Point
- Dauphin Island West End Beach
- Dauphin Island Public Beach
- Dauphin Island East End Beach.

## **Delaware/Maryland**

- Rehoboth Beach
- Dewey Beach
- Conquest Road Beach
- Bethany Beach
- Cape Henlopen Beach
- Assateague Island National Seashore
- Ocean City (Boardwalk)
- Assateague State Park.

## **Ohio**

- Euclid Beach Park
- Headlands Beach State Park
- Fairport Harbor Lakefront Park
- East Harbor State Park
- Cedar Point Beach
- Nickel Plate Beach
- Headlands Beach State Park
- Camp Perry Beach
- Edgewater Park Beach.

#### **Orange County, California**

- Balboa Beach
- Doheny State Beach
- Bolsa Chica
- Huntington City Beach
- Huntington State Beach
- Newport Beach
- Crystal Cove State Park Beach
- Laguna Beach.

Because of the high prevalence of single-day respondents on Ohio beaches, samplers skipped every other single-day respondent in an attempt to reach more multiple-day respondents. This feature of sampling was addressed in the sampling weights, described in Section 2.3.

#### *2.2.3. Sample Statistics*

We compiled descriptive statistics of the unweighted onsite and mail survey sample data prior to describing the development of sampling weights (Table 2). Section 2.3 discusses how we used these data to create sampling weights.

The number of single-day and multiple-day trips from the onsite sample is important for several reasons. Statistics on the origin of trips, as well as the number of recreation days in a multiple-day trip, were taken from the onsite data. These statistics determine the proportion of recreation days coming from outside the local area. A small sample of multiple-day trips could make these statistics, and the regional economic analysis in which they are used, less reliable. The proportion of trips that are single-day trips was also taken from the onsite data and this statistic was used to make final adjustments to the recreation model as part of the benefit function transfer, described in Section 3. Finally, the value of recreation is often expressed in terms of a value per recreation day, an approach we also take in our findings. This calculation again uses the number of recreation days per multiple-day trip from the onsite data.

The sample statistics also show that all beaches in each study area, as enumerated in the mail surveys, had been visited by least one respondent to the mail survey. Almost all beaches received a debris rating from at least one respondent. The total number of debris ratings provided for all beaches ranged from a low of 182 ratings for beaches in Ohio to a high of 281 ratings for Delaware/Maryland beaches (Table 2).

We aimed to have good representation of both single-day and multiple-day trips in the mail survey. It could be important in determining the total response to the debris scenarios if people view the importance of marine debris differently when planning these different types of trips. The number of people taking at least one multiple-day trip was lower in Ohio and Orange County, California. Multiple-day trips in both areas appear to be better represented in terms of the absolute number of trips.

## **Table 2. Selected descriptive statistics from samples collected via both the onsite and mail surveys**

Data from the contingent behavior questions are divided into three categories: those reporting a change in trips, those reporting no change in trips, and missing responses (Table 2). The number of people reporting a change in trips is somewhat low for the scenarios where debris is reduced, but this is not likely to present a problem for the final results. For example, only three people in Delaware/Maryland report an increase in trips in response to a reduction in debris. This fits with the evidence that debris levels are already perceived to be quite low and suggests that most people would not be significantly affected by a further reduction. Indeed, confidence intervals calculated in Section 2.4 indicate that results for all debris scenarios are statistically quite precise.

The number of missing responses is high and suggests that many people had trouble answering the contingent behavior questions. Overall, 9.1% of respondents did not provide an answer when asked about a reduction in debris and 27.7% did not provide an answer when asked about a doubling of debris. We do not believe this is due to the formatting or wording of the questions, which are relatively straightforward. It may be due in part to the fact that the scenarios involve a large area that includes many beaches, some of which may be unfamiliar to the respondent. Questions focusing on a single beach familiar to the respondent may have been preferred, but would not have been feasible given the need to match scenarios to the aggregate sites defined in the *Deepwater Horizon* data. A high rate of missing responses, often 25% or more, appears to be typical for contingent behavior questions (Eisworth et al., 2000; Whitehead et al., 2010). When performing analysis and computing results, respondents

who did not provide an answer to the questions about changing their trips in response to changes in debris were assumed to make no change in their trips. This approach is considered conservative and valid for stated-preference analysis (Carson et al., 2003).

There were a small number of missing responses for other mail-survey variables, such as age, education, and gender. The percentage of missing responses for all variables used in the analysis is shown as part of the summary statistics presented in Appendix B. The greatest number of missing responses for any variable was 6.7% for the question asking about household income, but this variable was not used in the analysis. Of the variables used in the analysis, the highest rate of missing responses was 4.0% for the question about level of education. In preparing the data for analysis, missing responses for all demographic variables were filled in using a random draw from all non-missing responses for the same variable (Andridge and Little, 2010).

#### **2.3. Development of Sampling Weights**

Sampling weights ensure that survey data is as representative as possible of the population of interest. A thorough description of sampling and weighting procedures can be found in Schaeffer et al. (2012). In this study, the population includes all people recreating at beaches in each study area. The first step in developing the sampling weights was calculating the base weights, which ensure that differences in the probability of being selected into the sample do not lead to over- or under-representation in the sample. For example, people who go to the beach frequently are more likely to be intercepted in the onsite surveys, so these respondents are given lower weights to ensure they are not overrepresented in the data. Even when accurately represented, the most active recreators are still likely to be more influential than other respondents in estimates of total recreation trips and value.

The second step in developing the sampling weights was adjusting the base weights so that mail-survey respondents represent as accurately as possible the much larger group of onsite-survey respondents. Reweighting to a larger sample with a higher response rate can make the data more representative of the target population. This adjustment to the weights involved first estimating a model that showed how certain key respondent characteristics and opinions were positively or negatively associated with respondents' response to the marine debris scenarios. We then adjusted the sampling weights so that the proportion of reweighted mail-survey respondents with each key characteristic matched the proportion for the analogous group of respondents in the onsite survey. While adjustments for some of the variables led to significant changes in the weights, we found that results were robust to the reweighting and there were only modest changes in the estimated total effect of the debris scenarios.

#### *2.3.1. Base Weights*

Base weights account for sample selection probabilities, which are determined by the sample design and by behavioral variables elicited in the onsite and mail surveys. Because data from the surveys are used to calculate proportions only and statistics are not expanded to the full population, selection probabilities and sampling weights can be expressed in relative rather than absolute terms (Piazzi, 2010).

There are four components used in calculating the base weights, reflecting four variables that determine the relative probability of selecting each respondent into the sample. The first variable is party size, or the number of people in the group from which an individual was selected during onsite sampling. The probability of selection for an individual is inversely related to party size, so the first factor for calculating relative selection probabilities is  $f_1 =$ 1/party size. The second variable is the number of hours the respondent spent at the beach during the day of the onsite interview. The probability of selection is directly proportional to time spent at the beach, so the second factor is  $f_2$  = number of hours at the beach. The third variable is the number of days the respondent went to the beach during the trip when he or she was interviewed. The probability of selection is directly proportional to the number of days in the trip, so  $f_3$  = number of days in the trip. The fourth variable is the number of trips the respondent took during the year. This is again directly proportional to the selection probability, so  $f_4$  = the number of trips the respondent took during the year.

The final base weights are inversely proportional to selection probabilities, so weights are calculated using the inverse of each of the above factors. Also, relative weights are scaled so that the sum of the weights equals the sample size, which is equal to the number of completed surveys shown in Table 1. Using *i* to represent individual respondents in the sample, *fi*1 through *fi*4 to represent the above factors for individual *i*, and *Nia* to represent the mailsurvey sample size for area *a* in which individual *i* was interviewed, the base weighs are calculated as

$$
w_{ib} = N_{ia} \frac{\binom{1_{f_{i1}}}{1_{f_{i2}}}\binom{1_{f_{i2}}}{1_{f_{i2}}}\binom{1_{f_{i3}}}\binom{1_{f_{i4}}}{1_{f_{i4}}}}{\sum_{i} \binom{1_{f_{i1}}}\binom{1_{f_{i2}}}\binom{1_{f_{i3}}}\binom{1_{f_{i4}}}}{\1_{f_{i4}}}}
$$
(1)

Although mail surveys were addressed to the specific individual who was interviewed onsite, in some instances the gender or age reported in a mail survey was different from what was recorded onsite, suggesting that someone else filled out the mail survey. We retained these surveys in the data and assumed that onsite variables needed for weighting procedures, such as party size and number of hours on the beach, could be applied to the mail respondent. In the 16 cases where mail survey respondents reported taking no trips during the previous year, we assumed they took a single trip. This assumption is required to calculate a sampling weight for these individuals. The same assumption was also used when calculating total baseline trips, which was the starting point for computing a percentage change in trips in the marine debris scenarios.

In certain instances, noted below, we used weights derived solely from the onsite survey. Weights for the onsite survey are calculated as

$$
w_{io} = N_{iao} \frac{\binom{1}{f_{i1}}\binom{1}{f_{i2}}\binom{1}{f_{i3}}}{\sum_{i}\binom{1}{f_{i1}}\binom{1}{f_{i2}}\binom{1}{f_{i3}}}
$$
(2)

*Niao* is the sample size for the onsite survey in area *a* where *i* was interviewed, equal to the number of completed onsite survey shown in Table 1. The final factor  $f_4$  is omitted because the number of trips respondents take during the year is obtained only in the mail survey.

#### *2.3.2. Reweighting Mail Respondents*

Respondents' characteristics and opinions are often related to their preferences. Using the mail-survey data, we developed a model to find which respondent characteristics and opinions, if any, helped predict how people would answer the contingent behavior questions about marine debris. The model estimated the relationship between respondents' stated change in trips for each scenario and eight explanatory variables, including the respondent's age, education, and gender; whether there were children in the respondent's household; whether the respondent felt that debris was a problem on local beaches; and the importance to the respondent of free or inexpensive parking, no crowds, and no debris. The model specification was a logit choice model, which is widely used is recreation applications (Train, 2003). Details of the model are described in Appendix C. In the model, three key variables were significant predictors of a response to debris: age, education, and whether the respondent felt marine debris was a problem on area beaches.

We then compared mail respondents to onsite respondents with respect to the three key variables. For any variable where mail respondents were significantly over- or underrepresented relative to onsite respondents, we reweighted the responses. For example, in the mail survey, 23% of respondents in Alabama were 45 years old or younger and 77% were older than 45. In the onsite survey, the percent frequencies were 52% for those 45 or younger and 48% for those older than 45. Therefore, we reduced the representation of older respondents in the mail survey could improve representativeness. A table showing detailed percent frequencies for all three key variables in the mail and onsite surveys is given in Appendix C.

Based on a review of the percent frequencies, we chose to reweight respondents in all four regions by all three variables, with one exception: for Ohio, the percentage of people who viewed marine debris as a problem was the same in the onsite survey and mail survey. Since it remained nearly the same after reweighting by age and education, reweighting by the two variables age and education was determined to be sufficient.

Table 3 shows the amount that representation of the key demographic groups changed before and after reweighting. The reweighing procedure changed the representation of all three key variables, in some cases by a factor as high as 2 or as low as 0.5. However, the results concerning the impact of marine debris changed only modestly, as shown in the last two rows of Table 3 for each study area. The largest absolute change was the estimated response to a decrease in debris in Alabama, which rose from 5.4% to 8.1%.

#### **2.4. Results of the Marine Debris Survey**

Below we describe the main results of the marine debris survey. For the complete set of weighted mail-survey statistics, see Appendix B. The main results include the proportion of trips that are single-day trips and the number of recreation days in a multiple-day trip. Both come from the onsite data and are used later in the modeling and analysis. We also report three of the importance ratings from Question 4 of the mail survey (q4 variables in Appendix B) that are helpful in providing context for people's response to marine debris. Finally, we report the percent change in trips for the two scenarios in each of the four study areas, the key inputs to the nationwide recreation model that calculates the number and value of trips.

## **Table 3. Representation of demographic categories and estimated response to debris scenarios before and after reweighting mail respondents**

a. In the mail weights for Ohio, observations were not adjusted to match the onsite data with respect to the proportion of people saying marine debris was a problem because the proportions were both 64% before adjustments. After adjusting for age and education the mail proportion saying debris was a problem dropped to 63%, but this small difference was viewed as acceptable.

#### *2.4.1. Population Statistics*

We calculated statistics from the onsite survey using the onsite weights described in Section 2.3.1 and statistics from the mail survey were calculated using the final mail sampling weights, including the demographic adjustments described in Section 2.3.3 (Table 4). To calculate standard deviations, we used the formula for weighted standard deviations. To calculate standard errors, we used a jackknife variance procedure (Tukey, 1958) in which any given statistic was calculated separately *Na* times, once with each of the *Na* observations removed, where *Na* refers to the number of respondents in a given study area.

Statistic	Alabama		Delaware and Maryland		Ohio		Orange County, California	
	Value	St. Dev. <b>or</b> St. Err.	Value	St. Dev. $\alpha$ St. Err.	Value	St. Dev. <sub>or</sub> St. Err.	Value	St. Dev. 0r St. Err.
Onsite survey statistics (with standard errors)								
Proportion of trips that are single-day trips	70.6%	2.5%	72.3%	2.4%	97.7%	0.7%	88.2%	2.2%
Average number of recreation days in a multiple-day trip	3.10	0.10	3.21	0.11	1.98	0.14	2.42	0.13
Proportion of recreation days from outside the local area	83.7%	1.7%	89.2%	1.8%	97.7%	1.2%	81.4%	3.9%

Average importance rating: manmade debris on the beach	4.75	0.55	4.42	1.20	4.77	0.48	4.40	0.77
Average importance rating: good water quality	4.76	0.59	4.58	0.86	4.76	0.55	4.30	0.71
Average importance rating: no natural debris on the beach	2.67	1.36	2.43	1.30	3.00	1.28	2.18	1.27
Mail survey statistics (with standard errors)								
Average debris rating	1.65	0.06	1.60	0.07	2.27	0.10	2.09	0.12
Change in the number of trips – "almost no" debris	8.1%	0.40%	2.2%	0.02%	35.4%	1.56%	9.5%	0.60%
Change in the number $trips - doubling of$ debris	$-26.5%$	0.58%	$-16.3%$	0.37%	$-35.6%$	0.84%	$-20.9%$	0.77%

**Table 4. Selected population statistics from the onsite and mail surveys by region**

a. Population statistics for demographic variables appear in Appendix B.

The proportion of trips that are single-day trips ranged from 70.6% in Alabama to 97.7% in Ohio. This reflects a variety of factors, including the appeal of beaches for those who wish to spend a few hours at the beach relative to those who wish to spend several days at the beach. It also reflects the number of people who live within a distance close enough to make single-day trips feasible, versus the number people who live at distances better suited to multiple-day trips. The average number of days in a multiple-day trip is determined by similar factors, and in our data it is generally inversely related to the proportion of single-day trips.

We also obtained estimates of the proportion of single-day trips from the mail survey data. Those numbers are 63.7% in Alabama, 61.0% in Delaware/Maryland, 94.5 % in Ohio, and 93.2% Orange County. We chose to use the onsite data in our calculations due to the larger number of observations available in the onsite data and the higher accuracy that is likely to result when people are reporting about the trip they are currently on rather than recalling trips over the course of the previous year.

Three importance ratings from Question 4 of the mail survey are useful in providing context for people's preferences about marine debris. The importance ratings were presented in the survey as a scale from 1 to 5, with 1 representing "not important," 3 representing "somewhat important," and 5 representing "very important." The first rating in Table 4 is for the importance of manmade debris. The average ratings were quite high, with a majority of respondents in all study areas giving this factor a rating of 5, or "very important." However, to the extent that there is variation, it is consistent with other results of the survey. For example, the average debris rating at beaches in Alabama is slightly higher but quite close to that of Delaware/Maryland. The difference in the estimated response to changes in debris may therefore be due to differences in preference more than differences in current conditions (recall that the scenarios describe changes in debris that are proportionate to current levels). Indeed the average importance rating for debris is higher in Alabama, supporting the idea that preferences are a factor in explaining the divergent results. Perceptions of current debris levels in Orange County are somewhat higher than those in Alabama, but the reported response to changes in debris are similar in the two areas. Orange County has the lowest importance rating for debris, which again suggests that differences in preference may be offsetting the difference in debris levels in determining the response to changes in debris levels.

Other important ratings shown in Table 4 include water quality and the presence of natural debris such as kelp or seaweed. Water quality is related to manmade debris in that both factors involve a disruption to the natural environment. The presence of natural debris is related to manmade debris in that both factors involve debris on the beach. All three factors show a similar pattern when comparing across regions, with the highest levels of importance in Ohio and the lowest levels of importance in Orange County. Since the importance ratings are not used in calculating final results, the precision of the average ratings is not important. Instead of standard errors, standard deviations are reported for these statistics to assist in understanding the variation in ratings across respondents.

The average debris ratings indicate that Ohio beaches have the highest levels of debris, while Alabama and Delaware/Maryland have comparatively low levels of debris. The average debris ratings were calculated as the weighted average of all ratings provided by respondents for all beaches in a given study area. The average ratings retained the same 1-to-5 scale used in data collection.

There are at least two alternative ways to aggregate the debris ratings. One alternative approach would involve averaging the ratings for each beach and then taking an average of the beach-specific ratings. Relative to the first method, this would place a greater emphasis on ratings for any beaches rated by only small number of people, since all beaches would get an equal weight in the average. Both measures lead to similar ratings for all study areas except Orange County, California, where the average rating increased to 2.43 using this alternative method. We think a single average grouping all ratings together is preferred because it

represents beaches in proportion to their familiarity to people who use the area, which is likely to better represent people's overall impression of debris in each study area.

A second method for calculating an average of debris ratings would involve first converting the ratings to actual estimated debris amount using information provided to survey respondents. For example, the rating of "1" would correspond to 1 piece of debris per 500 square feet, as shown in pictures provided in the mail survey. Likewise a rating of "5" would correspond to 16 pieces of debris per 500 square feet. We found that this alternative method generated ratings that varied dramatically across beaches. Importantly, there was a slight negative correlation between the debris averages for specific beaches calculated using this method and the onsite measurements of debris for those beaches. As described in Section 3.2, when the 1-to-5 debris ratings were averaged for the same beaches, the correlation with the onsite measurements was quite high. Although they can be interpreted in relative terms only, we retain the original 1-to-5 ratings when calculating summary measures of debris in the four study areas.

#### *2.4.2. Effects of Marine Debris on Recreation Trips*

The final estimates of the change in demand for trips that results from the two debris scenarios are shown in the last section of Table 4. For a reduction in debris to almost none, the percentage change in the number of trips is 8.1% in Alabama, 2.2% in Delaware/Maryland, 35.4% in Ohio, and 9.5% in Orange County, California. For a doubling of debris, the percentage change in the number of trips is -26.5% in Alabama, -16.3% in Delaware/Maryland, -35.6% in Ohio, and - 20.9% in Orange County, California. Standard errors are reported, and all estimates have high statistical precision. To evaluate the implications of these results for total trips, recreation value, and regional economic impacts, the percentage changes are used as an input to the nationwide recreation model, described below.

## **3. RECREATIONAL VALUE MODEL**

The key result from the marine debris survey was the percentage change in recreation trips from two potential debris scenarios in each study area: a decrease in debris to almost none and a doubling of current debris levels. In this section, we estimate the implication of these percentage changes on the total number and value of recreation trips using a nationwide model of people's recreation choices.

The basis for this analysis is the nationwide recreation model that was developed using data collected in 2012 and 2013 by experts working on behalf of state and federal agencies to assess recreation impacts from the *Deepwater Horizon* oil spill (English et al., 2018). The *Deepwater Horizon* data includes complete information on recreation trips for the Southeast United States, but only includes information about trips lasting two nights or more in other areas. We adapted these data to examine the recreational value in this study, a method known as benefit function transfer. Specifically, we used data from onsite surveys to adjust the model so that it would correctly estimate all trips in the three study areas outside the Southeast. However, we found that Lake Erie beaches in Ohio were too different from other areas to

effectively complete the benefit transfer, and only impacts to multiple-day trips were estimated for that study area.

We evaluated the reliability of our methods by comparing key results to external sources. We found that the estimated effects from changes in debris in our study were either comparable to or somewhat higher than the effects estimated in a previous study in Orange County (Leggett et al,, 2018), depending on the scenario examined. The results are not directly comparable because our model accounts for all trips and the previous model included single-day trips only. We found that respondents' ratings of the relative amounts of marine debris on beaches were highly correlated with previous onsite debris measurements, but that converting the ratings to absolute amounts of debris did not give reliable estimates. We also found some evidence that people using beaches at different times of the year may have a different response to marine debris, suggesting that additional efforts to contact recreators at beaches throughout the year could yield somewhat different results. The final estimates of changes in recreation trips and value for the two scenarios and the four regions are presented in Section 3.4.

## **3.1. Nationwide Recreation Model**

The nationwide recreation model developed for the marine debris study is a type of travel-cost model. It involves a system of demand functions where the price is the cost of traveling to recreation sites and the quantity is the number of trips people take to the sites. The model is based on data collected for the assessment of beach recreation losses following the *Deepwater Horizon* oil spill. An overview of data collection methods, procedures for cleaning the data, and calculation of model inputs are provided in a series of memoranda that are available in the *Deepwater Horizon* administrative record. <sup>4</sup> Specific memoranda are referenced below for details not provided in this report. An overview of the *Deepwater Horizon* beach recreation assessment can be found in English et al. (2018).

#### *3.1.1. Nationwide Coastal Recreation Data*

The *Deepwater Horizon* data were collected in a telephone survey of 41,708 respondents conducted over a 12-month period beginning June 2012. This was after the effects of the *Deepwater Horizon* spill had ended, according to onsite studies of recreation activity (Tourangeau et al., 2017). The sample for the survey was drawn from the full population of the contiguous 48 states. The data include information about all recreation trips to beaches in the Southeast United States. For other coastal areas the data include information only about trips lasting at least two nights away from home and originating from outside the Southeast. Specifically, respondents in eastern Texas, Louisiana, Mississippi, Alabama, Florida and southern Georgia were asked about all their beach trips to coastal areas from Texas to Georgia. These respondents were not asked about their trips to other areas of the country. Respondents from the remainder of the contiguous United States were asked about all their coastal trips to anywhere in the contiguous United States lasting at least two nights. Respondents from outside the Southeast were not asked about shorter trips because all of their

l

<sup>4</sup> The technical memoranda in the *Deepwater Horizon* administrative record are available at https://www.diver. orr.noaa.gov/deepwater-horizon-nrda-data#.
trips to the Gulf Coast from Louisiana to Florida, the focus of the *Deepwater Horizon* assessment, were at least two nights. On the other hand, these respondents were not asked to limit their answers to Gulf Coast destinations, because the additional information about overnight trips elsewhere in the country was viewed as potentially valuable in understanding the substitution of longer trips to areas outside the Gulf after the spill.

For this marine debris analysis, we simplified the *Deepwater Horizon* dataset in two ways. First, we eliminated trips with travel distances greater than 750 miles. This improved consistency of the data across regions. For example, while the full dataset includes trips from California to Alabama but omits trips from Alabama to California, we limited the geographic focus of the model in all regions. The 750-mile cutoff still retains 95.6% of all trips in the data to areas outside the Gulf, and a higher percentage of trips to areas within the Gulf where single-day and one-night trips are a large portion of total trips. Second, when reporting our results we avoid making a distinction between trips of two nights or more and multiple-day trips, a term which also includes trips with an overnight stay of just one night. Instead, we refer only to multiple-day trips as distinct from single-day trips.

For all estimates based on the *Deepwater Horizon* data, we made adjustments to convert trips of two nights or more into an estimate of all multiple-day trips, using the ratio of total multiple-day trips (including one-night stays) to trips of two nights or more. This ratio was estimated for each study area using data from the onsite marine debris survey, which asked respondents about the length of their trips and their overnight lodging.

In addition to information about recreation trips, the *Deepwater Horizon* data include information about respondents' demographic characteristics, such as age, income, education level, and gender. Sampling weights were developed for each respondent using sample selection probabilities as well as adjustments that matched key demographic groups in the sample to population statistics from the U.S. Census (English, 2015a, 2015b). All respondents were included in the recreation model regardless of whether they took coastal recreation trips or not.

The *Deepwater Horizon* data groups coastal beaches into 76 aggregate sites covering all coastal areas of the continental United States, including the Great Lakes. Travel costs from respondent origins to the 76 destinations were constructed using a weighted average of driving and flying costs (Leggett, 2015). The weights for a given respondent and site were equal to the proportion of people driving or flying for trips reported by respondents with similar incomes who traveled a similar distance. Driving costs were based on driving distances and travel times as calculated using PC\*Miler software. The cost per mile of driving, including gasoline and per-mile automobile depreciation, was estimated to be 25 cents per mile based on information from the American Automobile Association (2012). The cost per hour of travel time was set equal to one-third of the respondent's household income divided by 2,080. This procedure for estimating an individual's value of travel time is consistent with evidence in the literature (English et al., 2015). Flying costs were computed using the 30th percentile of fares for round-trip tickets as reported in the Airline Origin and Destination Survey, a 10% sample of all airline tickets collected each year by the U.S. Bureau of Transportation Statistics. Using the 30th percentile was intended to eliminate the effects of high fares related to business travel (Leggett, 2015).

#### *3.1.2. Model Structure*

The nationwide recreation model developed for the marine debris study uses a common mathematical structure called nested logit (Train, 2003). A nested logit model consists of a set of demand functions, one for each of the recreation sites in the model. It also allows sites that are similar to one another to be grouped together so that the greater amount of substitution between similar sites can be reflected in the model's behavior predictions.

The nesting structure in the nationwide recreation model first groups the 76 sites into distinct regions where sites may be more similar to each other than they are to sites outside each region. This allows the model to account for the possibility that if one site is affected by a decline in quality people are more likely to switch to other sites within a given region of the country rather than, say, switching between Lake Erie and the New Jersey shore. The regions were defined based on an exploration of the best model fit and were selected to be the Gulf Coast, the Atlantic Coast from Florida to Virginia, the Mid-Atlantic region from Maryland to New York, the Northeast from Connecticut to Maine, the Great Lakes, southern California from San Diego to Santa Barbara, and the remainder of the West Coast from San Luis Obispo, California to Washington State.

The nested-logit structure also includes a "participation" component, which is a separate nest describing substitution into and out of beach recreation. This allows for changes in the total number of trips to all sites in response to changes in beach amenities in addition to switching of trips between sites. Each site in the model is represented by an estimated constant that reflects the total effect of all site attributes, such as the size of each site and quality characteristics.

As noted earlier, single-day trips and one-night trips are not included in the data for sites outside of the Southeast United States. This would cause problems in model estimation because demand functions must be fit to data that shows an increase in trips as price decreases. In other words, the model expects complete data that would show people close to the beach taking more trips than people far from the beach. Since most trips from close to the beach are single-day trips, the exclusion of single-day and one-night trips means that low prices correspond to fewer trips rather than more trips in the *Deepwater Horizon* data.

To overcome this problem, we do not attempt to fit the model to trips originating less than 125 miles from a given site. Instead, we fit the model's prediction of total demand for all observations within 125 miles of a site to a constructed total number of trips that accounts for trips of all lengths. We chose the 125-mile threshold because in the data for Southeast sites, 88.3% of all one-night trips originated from within 125 miles of the trip destination. Adding in single-day trips, the 125-mile area accounted for 99.2% of all trips. This total was constructed using the average relationship between the number of longer and the number of shorter trips at sites in the Southeast, where complete data on trips is available. Specifically, we found that the total number of single-day and one-night trips to Southeast sites was six times greater than the total number of trips lasting two nights or longer. For a given site, we therefore multiplied the number of trips lasting two nights or more, as reported in the data, by a factor of six to estimate the number of single-day and one-night trips to the site. Finally, we added together the constructed total number of single-day and one-night trips to the total number of trips lasting two nights or more that also originated from within 125 miles of the site. In model estimation, this constructed total was matched to the sum of model predictions for all respondents living within 125 miles of the site.

We made one final adjustment to ensure accurate trip predictions for study area sites. The factor of six times as many short trips as long trips used above is an average. Therefore it is only an approximation for any given site. For the study area sites, we adjusted this factor until model predictions matched information from the onsite marine debris survey. For example, onsite data for Orange County, California indicates that 88.2% of trips are single-day trips. The number of single-day trips was calculated as the model's estimate of total trips minus the number of multiple-day trips reported in the data. Using the average factor of six times as many short trips as long trips, our initial model estimated that 79.1% of trips in Orange County were single-day trips. We adjusted the constructed total number of trips within the 125-mile threshold until the model predictions matched the onsite estimate of 88.2%. A similar adjustment was performed for the Delaware/Maryland site. No adjustment was needed for Alabama, since complete trip information was available for Gulf Coast sites.

For the Ohio study area we did not attempt to make an adjustment because the original model predicted almost no single-day trips. By contrast, the onsite data indicated that 98% of trips were single-day trips. We also found that the average distance people traveled to Ohio beaches for trips lasting at least two nights was considerably lower than the average distance in other regions of the country. We concluded that our model was not able to accurately estimate total trip demand for the Ohio study area. We therefore limited our results to multiple-day trips estimated directly from the *Deepwater Horizon* data and the onsite marine debris survey. The failure of the model to predict total trips for Ohio also indicates there is some uncertainty about using the model's estimate of value per day for multiple-day trips. However, with this caveat in mind we exclude only single-day trips and report both trip demand and value for multiple-day trips in the Ohio estimates.

## *3.1.3. Estimated Model Parameters*

The estimated coefficients and standard errors for the nationwide recreation model are shown in Table 5. The sample size 41,708, and the model was estimated using the maximum likelihood procedure in Aptech Gauss 12 software. The travel cost coefficient is negative and highly statistically significant (Table 5), indicating that people have a strong preference for sites that are closer and less expensive to access. The nesting structure of the model involves estimating scale parameters that characterize the effect of the nested groupings. The scale parameter for grouping the sites into the seven regions defined above is highly significant (Table 5), indicating that sites within regions are good substitutes for one another and that the selected nesting structure is preferred to a model without the regional nests. The scale parameter for participation is also highly significant (Table 5), indicating that this component of the nesting structure is also important to the model.

Most demographic variables are statistically significant determinants of the demand for recreation trips, and the coefficient on income is highly significant. The constants representing the attractiveness of each of the 76 sites to some extent represent variation in the quality but to a large extent represent variation in the size of the defined sites. Site constants cannot be interpreted in relation to zero but only in relation to each other, so the *p* values are omitted and the lowest constant for any site was normalized to zero. Most site constants are omitted from Table 5, but we report the estimated constants for the four study areas.

The last eight parameters in Table 5 show the adjustments needed to simulate the two debris scenarios in each of the four areas. For example, to simulate the 20.9% decrease in trips (see Table 5) from a doubling of debris in Orange County, California, a value of 0.338

must be subtracted from the site constant for Orange County. This causes the model's prediction of trips in Orange County to decline from 27.1 million to 21.5 million, a decline of 20.9%. No standard errors are reported for the debris-scenario parameters because they are not estimated as part of the model but are found by searching for the value that matches model predictions to the percentage changes from the marine debris survey.

### **Table 5. Parameter estimates from the recreation demand model using**  *Deepwater Horizon* **nationwide recreation data**

# **3.2. Comparisons to External Sources**

In this section we evaluate key results of the marine debris study using comparisons to external sources. To the extent that results from different sources are similar, the comparison provides some assurance that our estimates are accurate and robust. To the extent that results from different sources diverge, it is worth assessing the potential reasons and possible implications. The discussion in this section refers to results presented in Table 6.

a. These values are from a revealed-preference pilot study of marine debris impacts in Orange County, California, that was conducted by NOAA from July 2013 through January 2014 (IEc, 2014, Exhibit 29). Dollar values are in 2018 dollars, adjusted for inflation using the CPI (Federal Reserve Bank of St. Louis, 2019).

b. A pretest of the marine debris survey was conducted in Orange County, California, using methods that were similar to those of the final study. There were 49 completed mail interviews and 343 completed onsite interviews in the pretest.

- c. Pretest results could not be reweighted to match onsite data because attitudinal questions such as "Do you think marine debris is a problem" were not included in the onsite survey for the pretest. We therefore compare pretest results to full-study results that have not been adjusted to match the onsite sample. As shown in Table 4, the differences between adjusted and unadjusted full-study results are modest.
- d. The parameters for the Delaware/Maryland site and the Orange County, California, site were adjusted so that model predictions of single-day trips matched information obtained in the onsite surveys. No adjustment was made in Alabama because the *Deepwater Horizon* data includes complete information on trips of all lengths throughout the Southeastern United States. No adjustment was made in Ohio because the site was determined to be sufficiently different from other coastal sites that model predictions of single-day trips would not be reliable.

#### *3.2.1. Effects of Debris on Recreation*

Economic methods for valuing environmental quality fall broadly into two categories: revealed-preference methods and stated-preference methods. Revealed-preference involves inferring the value of environmental amenities based on choices people make about how to spend their time and money. For example, if people avoid nearby beaches with high levels of debris and instead travel further to get to clean beaches, we can infer they have a value for clean beaches. Stated-preference methods involve inferring value based on how people say they would spend their time and money in hypothetical circumstances. For example, people could be asked in a survey whether they would travel further to get to clean beaches. A comparison between revealed-preference and stated-preference results is one of the most common ways of evaluating the performance of studies using either method.

The first results in Table 6 compare our stated-preference estimates of the effect of debris on beach recreation to revealed-preference estimates from a previous study in Orange County, California (IEc, 2014; Leggett et al., 2018). The IEc (2014) study involved a survey of Orange County residents about their single-day trips to 31 local beaches in the summer of 2013. The study used a model of recreation choice to estimate the importance of marine debris to beach recreation based on which beaches people went to and the attributes of those beaches, including the amount of marine debris. Exhibit 29 of the IEc (2014) report shows model results for several debris scenarios. For comparison to our study, we selected two scenarios and two measures of the effects of marine debris for each scenario.

The first scenario we selected involves the elimination of debris at all 31 beaches in the IEc (2014) study. We compared this to our scenario of a reduction to almost no debris for beaches in Orange County. The scenarios are not directly comparable, because 13 of the 31 beaches in IEc (2014) were outside of Orange County, and the elimination of debris involves a greater change than a reduction in debris to almost none. The second scenario involves an increase in marine debris of 50% at all 31 beaches in IEc (2014). While still different from the scenario in our study with respect to the number of beaches, we were able to simulate the 50% increase by assuming a linear relationship between debris levels and the importance of debris to recreators. Specifically, we took the parameter of -0.338 for a doubling of debris and reduced it by half, to -0.169. This revised parameter was then entered into our recreation model to simulate the effects of a 50% increase in debris. A linear relationship between measured site attributes and their importance in a recreation model is an assumption used in many studies, including IEc (2014).

The first measure of effects we selected was the "benefit per baseline trip to impacted sites," as presented in Exhibit 29 of IEc (2014). This is the total change in recreation value resulting from the change in debris divided by the baseline number of recreation trips before the change. This measure is not directly comparable between the two studies, because in our study recreation trips includes both multiple-day trips and single-day trips, while IEc (2014) examined single-day trips only. However, it is preferable to normalize values to a per-trip amount since we expect that a total measure of value would be much higher in our study, given that our study includes trips by residents from throughout country rather than just residents of Orange County. The second measure of effects we selected was the percentage change in recreation trips resulting from a change in debris. There is no definitive reason why this percentage change should be higher or lower in either study, given a comparable scenario. However, the fact that the scope of the studies differ in both the types of trips

analyzed and extent of the population could also lead to a divergence in this measure of results.

For the scenario of a reduction in debris, our model estimated a value of \$5.58 per baseline trip for Orange County. This is quite close to the value of \$6.05 in IEc (2014). We adjusted all dollar values from IEc (2014) upward by a factor of 1.08 to account for inflation between 2013 and 2018 using the CPI (Federal Reserve Bank of St. Louis, 2019). The percentage increase in trips was 9.5% in our study, compared to 16.0% in IEc (2014). Due to the difference in scenarios, with a reduction in debris to almost none in our study rather than the complete elimination of debris, a smaller percentage change in our study is expected. The comparison of per-trip values is more ambiguous. A lower value per trip from a smaller change in debris in our study would be at least partially offset by the fact that the per-trip value for multiple-day trips (and therefore for all trips combined) is likely to be greater than the per-trip value for single-day trips only. Overall, we view the comparison for this scenario to be consistent with expectations. The lower effects in our study make sense given the smaller change in debris, but the difference in less pronounced with respect to value because of the inclusion of higher-value multiple-day trips.

For the scenario of a 50% increase in debris, our model estimated a value of -\$6.26 per baseline trip. This compares to a value of -\$2.31 in IEc (2014). The percent change in trips was -10.9% in our model, compared to -6.1% in IEc (2014). In this instance both measures of the change are definitively higher in our study. However, the divergence is sufficiently modest that it could be explained by differences in the scope of the two studies with respect to trips and population. One methodological difference that could also play a role is the assumption in IEc (2014) that the importance of debris to beachgoers is linear with respect to debris amounts over all ranges. In our study, we allow the effects of debris increases to be independent of the effect of debris reductions. If the response to a given change in debris is higher at higher levels of debris, the greater flexibility in debris response permitted in our model could help explain the greater divergence of results in the second scenario.

### *3.2.2. Seasonal Consistency*

Respondents to the marine debris mail survey reported their beach recreation trips, and the effects of changes in debris on their trips, for the period of an entire year. However, respondents were first contacted over a period of just several weeks in July, August, and September 2018. It is possible that preferences differ for those using beaches during late summer versus the full population of beachgoers that could be contacted with more extensive onsite sampling. The differences may be greater in areas where beach use continues throughout most or all of the year, such as Alabama and California.

To investigate this potential source of bias we compared results from the final survey in Orange County, California with earlier results obtained from the pretest phase of our study, also conducted in Orange County. Onsite recruitment for the full study in Orange County occurred in July 2018 and onsite recruitment for the pretest occurred in late September 2017. The pretest results for a reduction in debris showed a 4.9% increase in trips and the pretest results for a doubling of debris showed a 16.3% decrease in trips. In the pretest, our methods for reweighting mail survey respondents to match onsite respondents could not be applied because the pretest onsite survey did not ask whether debris was a problem at area beaches, one of the variables used in the reweighting. For a more consistent comparison, Table 6 therefore reports results from the final survey that are also calculated using the onsite base

weights only. These results show an 8.8% increase in trips and a 20.4% decrease in trips for the two scenarios.

The results from the pretest suggest a potentially lower response to debris by people contacted in fall rather than late summer. This comparison indicates that some bias may result from sampling people onsite over a period of a just a few weeks, and that a more extensive study that involves sampling onsite over the full year or full beach season could lead to different estimates.

### *3.2.3. Debris Ratings*

Respondents were asked to estimate the amount of marine debris on beaches in a given study area. It is important to understand the accuracy of respondents' estimates for at least two reasons. First, the debris estimates were used to characterize current conditions in the four study areas and provide context for other study results. For example, if it is true that current debris levels are higher on Lake Erie beaches relative to other study areas, then the high estimated response to the debris scenarios, which involve changes proportionate to current levels, would be expected. Second, if the debris ratings are consistent with external evidence then it suggests that respondents pay attention to debris on beaches and are aware of the relative amounts of debris on beaches. This indicates that respondents have some context for providing accurate responses to the hypothetical debris scenarios.

We compared the ratings of debris levels from survey respondents with estimates of debris from onsite measurements conducted by NOAA in the summer of 2016. The comparison accounts for all 13 beaches that were included in both studies: Ocean City, Maryland (Boardwalk area); Lewes Beach, Delaware; South Bethany Beach, Delaware; Fenwick Isle, Delaware; Bolsa Chica, California; Cedar Point Beach, Ohio; East Harbor State Park, Ohio; Nickel Plate Beach, Ohio; Port Clinton City Beach, Ohio; South Bass Island, Ohio; Fort Morgan, Alabama; Gulf State Park, Alabama; and Orange Beach, Alabama.

The correlation between respondent ratings and onsite measurements was 0.87. Consistent with the average rating calculated for a study area, the average rating for a given beach was calculated as the weighted average of all ratings provided for the beach. The high correlation with onsite measurements suggests that people have a high awareness of the relative levels of debris at beaches. However, as noted earlier, the consistency between respondent perceptions and onsite measurements applies only to the 1-to-5 debris ratings. If these ratings are converted into absolute measures of debris based on the debris levels associated with each numeric rating (1 item per 500 square feet for a rating of 1, up to 16 items per 500 square feet for a rating of 5), the resulting measure is not correlated with the onsite debris measurements. For this reason we used only the 1-to-5 numeric ratings in this study.

### *3.2.4. Benefit Function Transfer*

The *Deepwater Horizon* data has complete information about the number of trips to sites in the Southeast United States. In other coastal areas, the data only include longer trips with at least two overnight stays. As described earlier, for all model sites outside the Southeast United States we accounted for shorter trips using a constructed total number of trips for an area within 125 miles of each site. The constructed total was based on the ratio of longer trips to shorter trips for sites in the Southeast United States, and the result is what we call the "unadjusted" model in the last section of Table 6. In the final "adjusted" model, the

constructed totals in Delaware/Maryland and Orange County, California were further increased to ensure that the proportion of single-day trips predicted by the model exactly matched the proportion of single-day trips estimated from the onsite surveys. This type of adjustment falls under the classification of "benefit function transfer" in the economics literature (e.g., Wilson and Hoehn, 2006; Navrud and Ready, 2007).

The last section of Table 6 shows the original estimates from the unadjusted model, as well as the effect of the final adjustments. We include these results in Table 6 because they play a role in evaluating the reliability of the nationwide recreation model and the use of benefit function transfer in two ways. First, the unadjusted estimates of the percentage of single-day trips is lower in Delaware/Maryland (54.4%) than in Orange County, California (79.1%). A similar difference across regions is apparent in the adjusted percentages of 72.3% for Delaware/Maryland and 88.2% for Orange County, California. This suggests that the model is accurately accounting for important factors that differ across regions. For example, a large population density close to the coast in California would lead to predictions of a large number of single-day trips.

Second, the final adjustments illustrate how we are able to combine information from the *Deepwater Horizon* data with information from the marine debris survey to estimate the total number of trips as accurately as possible. The unadjusted model, while developed from reasonable assumptions, would likely be less reliable than the final adjusted model.

## **3.3. Caveats and Uncertainties**

There are a variety of caveats and uncertainties associated with the methods described above. We summarize them here and discuss their implications.

Stated preference methods have the advantage that they can directly examine a specific issue. If researchers wish to know the effect of a particular beach attribute on beach recreation, a hypothetical scenario can be developed in which only the attribute of interest changes. This differs from revealed-preference methods, in which two beaches that have different levels of one attribute will almost certainly differ with respect to other attributes as well. This makes stated-preference methods applicable to a wider variety of research problems than revealed-preference methods, and less likely to be biased due to the influence of confounding factors. The drawback of stated-preference data is that responses to hypothetical scenarios, and the resulting estimates of value, may differ from the values implied by people's actual choices.

The comparison of our results in Orange County, California to results from an earlier revealed-preference study in the same location provides some assurance that both studies are reliable. For a reduction in debris, the scenarios in the two studies were not exactly comparable and the more modest effects measured in our study could be attributable to the assumption of a smaller change in debris. For an increase in debris, our study measured a greater response than the previous study. The difference was within a modest range that could be explained by the more extensive scope of our study. While the previous study involved single-day trips by the local population, our study encompassed virtually all trips by people from throughout the county.

Another source of uncertainty was the high item nonresponse rate for the contingent behavior questions. Overall, 9.1% of respondents did not provide an answer when asked about a reduction in debris and 27.7% did not provide an answer when asked about a doubling of debris. It is not possible to know whether or how these respondents may differ from those who answered the contingent behavior questions. In our calculations we assumed these respondents made no change in their trips in response to changes in debris. This could be viewed as conservative. Other options would include filling in the missing responses using the average of the available responses, or analyzing the demographic characteristics of respondents who did not provide an answer and filling in missing responses using other similar respondents. These alternative options would have led to an increase in the size of the estimated change in trips and value from the debris scenarios.

We used onsite sampling to efficiently reach a target population of beachgoers. Some aspects of our onsite sampling procedures were randomized. For example, we selected randomly from each party of people on the beach and used party size to control for selection probabilities. Other aspects of our sampling procedures were nonrandom. For example, we divided beaches into more developed and less developed categories and ensured that both types of beach were included in our onsite surveys. This procedure was similar to stratified sampling. However, a fully random stratified sample would have involved drawing a random selection of days and times for conducting interviews at each type of beach, and then incorporating the sampling rates for each beach stratum into the sampling weights. Without these procedures, we cannot guarantee that our sample accurately represents beachgoers who use different types of beaches in the correct proportion. Likewise, the representation in our sample of times of day and weekdays versus weekend days is unlikely to match the correct proportions of a fully randomized sample. As discussed earlier, our sample does not represent the various seasons throughout the year.

Our comparison of results for different seasons, discussed above, suggested that preferences about marine debris may vary somewhat for people using the beach at different times of the year. It is also possible that a randomized selection of days, times, and beaches, resulting in a sample that better represents all beachgoers, would have led to changes in the estimated effect of debris on recreation. There is no reason to suspect a specific type of sample-selection bias, such as sampling onsite at beaches with high debris levels and therefore biasing the sample toward those who are tolerant of debris. However, there is no basis at this time for estimating the direction or magnitude of any effect of the nonrandom aspects of the onsite sampling.

Onsite sampling also omits from the study population those people who do not currently go to the beach in a given study area but would go if beaches had less debris. This means that some people who would benefit from a reduction in debris are excluded from the study and that the effects of a reduction in debris could be underestimated. This type of bias could be significant if current debris levels are high enough to significantly change not just the number of trips people take, but the number of people who take any trips in a given study area.

Our estimates of the total change in recreation trips and total change in recreation value for the two debris scenarios was based on a benefit-function transfer using the *Deepwater Horizon* data set. Benefit transfer is widely used in economic analysis because it allows researchers to evaluate policy or environmental changes without the potentially prohibitive expense of a full original study. The use of benefit transfer is supported by numerous precedents in the literature and guidance from government agencies (Wilson and Hoehn, 2006; Navrud and Ready, 2007; U.S. EPA, 2014). Benefit function transfer, which involves adapting an economic model to a new research problem, is considered preferable to simpler

forms of benefit transfer, such as applying values calculated in a previous study without the ability to revise the calculations.

The most significant assumption in the nationwide recreation model is that longer trips lasting at least two nights away from home provide sufficient information about the quality of beaches and the preferences of recreators to reliably estimate a recreation demand model. There are situations where this would not be the case. For example, two beaches may be equally attractive to area residents taking day trips, while only one of the beaches may be developed with hotels and beachfront resorts. The number of overnight trips to the less developed beach would not be a good predictor of the number of day trips. However, this type of issue may diminish as sites with divergent characteristics are aggregated together. Continuing the example of overnight accommodations, most of the 76 aggregate sites in our model are likely to be large enough that a lack of suitable hotels or campgrounds would not be a significant factor limiting overnight recreation trips.

The aggregation of beaches into larger areas would not diminish the effect of differences in beach attributes if beaches in one area are consistently different from beaches in another area. As noted earlier, this appears to be the case for Ohio beaches. For Delaware/Maryland and Orange County, California, where trips data from the nationwide model were incomplete, we believe the benefit function transfer is reliable. This is reflected in the fact that model parameters demonstrated consistency with a standard model specification, including a nesting structure that grouped sites into regions and that included a component for recreation participation, as shown in Table 5. Reliability of the benefit function transfer is also reflected in the fact that only modest adjustments were required to match model predictions in Maryland/Delaware and Orange County, California to information from the onsite data, as shown in Table 6.

# **3.4. Effects of Marine Debris on Recreation Value**

The recreational value model shows noteworthy effects of marine debris on beach recreation for the two scenarios and four study areas examined in the marine debris survey (Figure 3, Table 7). All amounts reflect annual total trips and value by residents living within 750 miles of the coast in the contiguous 48 states. As described previously, the two scenarios are a reduction in debris on beaches to almost none and a doubling of debris, and the four study areas are Gulf Coast beaches in Alabama, Atlantic beaches in Delaware and Maryland, Lake Erie beaches in Ohio, and Pacific beaches in Orange County, California. While confidence intervals were provided for earlier results derived directly from the marine debris survey, results in Table 7 rely on benefit function transfer and therefore do not include confidence intervals. The combination of multiple data sources and researcher judgments make confidence intervals difficult to estimate or justify in most benefit transfer contexts (McConnell, 1992).

The annual number of recreation days under "baseline conditions" ranges from 4.5 million in Alabama to over 27.1 million in Orange County (Table 7). Baseline conditions describes debris levels prior to the changes introduced in the hypothetical scenarios. The baseline number of recreation days was estimated using the nationwide recreation model, developed from data collected in 2012 and 2013 for the *Deepwater Horizon* oil spill assessment. Where possible the model was adjusted to match information collected as part of the marine debris survey. We assume that beach attributes and recreation activity at beaches in the four study areas have not changed significantly over the past several years and that the two sources combined in this study accurately summarize the starting point for the debris scenarios.

\* Ohio estimates account for multiple-day trips only.

Figure 3. Changes in annual number of recreation days if the amount of marine debris doubles, and if the amount of marine debris is reduced to almost none.

Scenario	Alabama	Delaware and Maryland	Ohio <sup>a</sup>	Orange County, California				
Annual number of recreation days	4,552,112	24,014,592	8,155,158	27, 143, 415				
Debris reduced to "almost none"								
Change in days	368,525	536,341	2,889,191	2,571,725				
Value per day	\$27.27	\$36.81	\$30.46	\$50.43				
Change in recreation value	\$10,051,517	\$19,741,209	\$88,006,606	\$129,689,616				
Doubling of marine debris								
Change in days	$-1,206,006$	$-3,915,792$	$-2,907,188$	$-5,682,362$				
Value per day	\$26.82	\$35.99	\$28.87	\$48.41				
Change in recreation value	$-$ \$32,347,029	$-$140.914.688$	$-$ \$83.935.614	$-$ \$275,077,340				

**Table 7. Recreation value from changes in debris on beaches (2018 dollars)**

a. For Ohio, estimates account only for multiple-day trips and exclude the value and quantity of single-day trips.

The estimated change in days is the percentage change in trips for each scenario, calculated from the marine debris survey and presented in Table 5, multiplied by the baseline number of days. The change in recreational value is derived using the nationwide recreation model. The value per day is the change in value divided by the change in days. The value per day is usually reported in economic studies of recreation as a common point of comparison across studies. Differences in the value per day across study areas reflect modeling assumptions, differences in recreation preferences by beachgoers in each study area, and differences in income, which is an input to travel cost for beachgoers in each area. The decision to limit recreation trips to a threshold of 750 miles, necessitated by limitations in the *Deepwater Horizon* data, is likely to reduce per-day values in areas with high demand from greater distances.

For a reduction to almost no debris, the estimated annual increase in recreation value is \$10.1 million in Alabama, \$19.8 million in Delaware/Maryland, \$88.0 in Ohio (multiple-day trips only), and \$129.7 million in Orange County, California. For a doubling of debris, the estimated annual decrease in value is \$32.3 in Alabama, \$140.9 in Delaware/Maryland, \$83.9 million in Ohio (multiple-day trips only), and \$275.1 million in Orange County, California.

# **4. REGIONAL ECONOMIC IMPACTS MODEL**

Coastal recreation is a significant component of the economies of coastal communities. A recent NOAA National Marine Fisheries Service study found that coastal recreation in the United States accounts for \$225 billion in gross domestic product (GDP; Kosaka and Steinback, 2018). The four study areas included in our analysis were selected because coastal recreation and tourism is an important part of the local economy in each area. Table 8 shows the total economic contribution of coastal recreation and tourism for the four study areas (Office for Coastal Management, 2019).

### **Table 8. Economic contribution of coastal recreation and tourism by study area (2018 dollars)**

Source: Office of Coastal Management, 2019.

a. Employment numbers are for 2015.

The total economic impact of recreation visits includes direct expenditures and subsequent flow-on impacts, which includes both indirect and induced expenditures. Direct expenditures include money that non-local residents spend while visiting and participating in recreation activities in coastal communities (e.g., park entrance fees, gas, equipment, retail purchases, lodging). Local businesses that benefit from direct spending then spend additional money on goods and services that they need to operate their businesses. These are termed indirect expenditures. Direct and indirect spending generates employment in the local region, creating additional income for households, which generates further spending known as induced expenditures.

To estimate the economic impact associated with marine debris, we multiplied the total change in recreation days for residents who live outside each study area by estimates of spending per recreation day. We include spending from only non-local residents because economic impact analysis assumes that residents who live in a given region and choose not to spend money on a particular good will spend the money on something else in the local economy. As noted earlier, for the economic impact assessment we define the scope of our analysis to be the coastal counties where the beaches in each study area are located.

Our analysis of economic impacts from marine debris can be summarized in the following three steps.

- 1. We began with the change in the number of nonlocal recreation days estimated in the previous steps for each of the four study areas and for each of the two scenarios in the marine debris survey.
- 2. We used the NORES dataset to estimate expenditures per recreation day in each of several categories and multiplied the expenditures per day by the change in recreation days. The result is an estimate of the change in direct expenditures in each study area.
- 3. We then multiplied direct expenditures in each category by the appropriate RIMS II multipliers (U.S. BEA, 2018, 2019). For each expenditure category there are several multipliers for several different types of indirect and induced economic impacts.

In the remainder of Section 4, we describe details of the estimated expenditures per day and the RIMS economic multipliers. In Section 4.1 we present the expenditures per recreation day associated with recreation activities impacted by marine debris. In Section 4.2, we estimate the economic impacts of a coastal-recreation day using the RIMS multipliers; and in Section 4.3, we present the economic impacts of our two marine debris scenarios  $-$  a reduction of debris to almost none and a doubling of debris – in the four tourism-dependent communities.

### **4.1. Trip Expenditures**

As our first step in conducting the economic impact analysis, we estimated the direct effects by determining the average spending per day by non-local visitors to the study areas. We included all expenditures that visitors make during their visits, not just those associated with recreational activities. This is based on the fact that the primary purpose of recreation trips in our data was to visit the beach, so a canceled trip to the beach is likely to be a canceled trip to the study area. The NORES data (NOAA, 2012) provide comprehensive expenditures for recreation trips, including spending on hotels, restaurants, transportation, entrance fees, etc.

The NORES data included estimates of trip expenditures for the Pacific, Northeast, Mid-Atlantic, South Atlantic, and Gulf of Mexico regions. There are also estimates of overall average expenditures for all regions. For each study area, we used the region that included that study area. Because the NORES study did not include estimates for the Great Lakes, we

applied the U.S. average expenditures to estimate the trip expenditures for the Lake Erie, Ohio region. 5

Although the NORES data included separate estimates for local and nonlocal recreation trips, we did not use this breakout. Their "local" regions are much larger than our coastal county areas. For example, the NORES Pacific region considers all recreators from California, Oregon, and Washington to be local, whereas our study defines recreators from outside of Orange County as "nonlocal." Thus, we used the average trip expenditures across all respondents to be more representative of our nonlocal respondents.

The NORES data provide average daily spending on trip-related items for trips involving a variety of recreational activities. Each trip is identified with a single activity based on the respondent's "most preferred" activity on the trip. NORES included eight types of coastal recreation activities. We used the four activities likely to involve trips to the beach:

- Viewing or photographing the ocean or coast
- Beachcombing, tidepooling, or collecting items
- Water contact sports

 $\overline{a}$ 

 Outdoor activities not involving water contact that occur near the ocean or coast because of the view or access to the water (e.g., sunbathing, walking, camping).

## **Table 9. Average visitor spending per day in the four regions examined in this study (2018 dollars)**

Spending by category varies by the type of activity.<sup>6</sup> We calculated the average visitor spending per day (Table 9) using the weighted average expenses and participation in the various marine debris-related beach activities.

To apply the RIMS II multipliers, we kept the average expenditures separate by category. For example, visiting recreators spend money on lodging, food, and transportation. These expenditure types have different impacts on the local economy and thus different multipliers. This is explained in more detail below. The detailed list of the average expenditures by category is included in Appendix D.

We next apply the changes in the number of recreation days estimated in Section 3 to the average expenditures per day for each of our four study areas and two debris scenarios. The results are described in the following section.<sup>7</sup>

<sup>5</sup> We checked the appropriateness of applying the U.S. average expenditures to the Ohio region using the Consumer Expenditure Survey (U.S. BLS, 2017). In the year the expenditure data were collected, 2012, average annual expenditures in the Midwest and Cleveland metropolitan area were 97% of the U.S. average.

<sup>6</sup> For example, the average auto fuel expense in the Pacific region is \$17.48 for "viewing or photographing the ocean" and \$22.10 for beachcombing participants.

<sup>7</sup> The aggregated changes in visitor spending are not used in the analysis. As described in the next section, in order to apply the RIMS II multipliers, we must keep visitor spending disaggregated by expenditure category. The expenditure categories are then mapped to the RIMS II industries, and the multipliers applied. These totals are presented here to illustrate the scale of money flowing into the economy.

# **4.2. Economic Impacts of Coastal Recreation**

The next step in estimating the potential impacts of a change in marine debris levels on beaches in our four study areas is to estimate the economic contribution of visitor expenditures on the local economy. Coastal recreation contributes to the local economy by bringing outside money into the economy in the form of visitor spending. Visiting recreators spend money on a number of goods and services, including hotel rooms, food, and retail, which affect several local industries, including restaurants, hotels, retail shops, and other tourist-related enterprises. These industries directly affect the economy by purchasing intermediate goods, such as restaurant supplies and wholesale goods, and by providing jobs. The industries that provide intermediate goods and services to the recreation and tourism industry purchase their own intermediate goods and services form other local industries, and the pattern repeats itself. Thus, the original money from visitor spending creates a multiplier effect on the local economy. At every stage, some portion of expenditures goes toward goods or services generated outside the local area. This is known as "leakage" and is incorporated in the calculations of multiplier effects (Bess and Ambargis, 2011).

Economists use input-output (I/O) analysis to estimate multiplier effects. I/O analysis entails calculating the extent to which direct activities – in our case, increased spending from tourists – stimulate further economic effects, spreading employment and income, thus accounting for linkages among industries (University of South Carolina, 2009). That is, I/O analysis accounts for the production linkages between different industries of the local economy, and in turn, calculates economic impacts using a multiplier effect. We used RIMS II multipliers developed by the Bureau of Economic Analysis (U.S. BEA, 2018, 2019).

We quantified the economic impacts of a visitor coastal recreation day using four metrics: output (sales), value added (GDP), earnings, and employment (full- and part-time jobs). These metrics are defined formally as follows (Bess and Ambargis, 2011):

- *Gross output*. Sum of the intermediate inputs and value added, where intermediate inputs are defined as goods and services that are used in the production process of other goods and services and are not sold in final-demand markets; also measured as the sum of the intermediate inputs and final use. Multipliers measure the total industry output per \$1 change in final demand.
- *Value added*. The value of gross output less intermediate inputs. The value of this metric is equal to the sum of compensation of employees, taxes on production and imports less subsidies, and gross operating surplus.
- *Earnings*. Sum of wages and salaries, proprietors' income, and employer contributions for health insurance excluding contributions for social insurance. Multipliers measure the total household earnings per \$1 change in final demand.
- *Employment*. Number of full- and part-time jobs (including proprietors' jobs). Multipliers measure the total number of jobs per \$1 change in final demand.<sup>8</sup>

Output is less preferred as a metric because it counts transactions at all stages of production without including the value of goods and services in previous stages. Value added is preferable because it eliminates this double counting, and is analogous to GDP for a local

 $\overline{a}$ 

<sup>8</sup> Employment multipliers are originally expressed as the change in jobs per \$1 million change in final demand.

region. Earnings is a subset of value added, representing the portion that ends up as wages and salaries rather than as a return on investment.

A fifth measure of economic impacts is government tax revenue. Calculating tax revenues can be quite complex because tax rates depend on the finances of numerous individual companies. We have not attempted to estimate government tax revenues in this study.

The multipliers are provided by industry type and are specific to each region. The multipliers estimate the economic impact of *outside money* coming into a region; thus, we estimate the economic impact of changes in coastal recreation associated with the marine debris scenarios for visiting recreators only.

As described above, the NOAA (2012) NORES dataset provides spending per coastal recreation day by study area and expenditure type. Different sectors of the economy such as lodging and food service contribute to the regional economy to different degrees. The RIMS II multipliers are provided for 64 aggregated industries. We mapped the expenditure categories provided in the NOAA (2012) NORES dataset to the appropriate RIMS II industry. That is, each industry has a unique multiplier, which we apply to the corresponding expenditure category. The total economic impact is the sum of the multipliers applied to the corresponding expenditure. We include the expenditure by category and RIMS II industry in Appendix D. We have included the multipliers in Appendix D, Table D-2.

To illustrate the regional economic impact of a change in spending, we provide the following example for increased spending on lodging in Alabama: From the NORES data, we estimated the average expenditure per day for lodging to be \$39.68 (see Appendix D, Table D-1). We then mapped the expenditure category "lodging" to the RIMS II industry "accommodation." The RIMS II final-demand multipliers (Appendix D, Table D-2) for the accommodation industry in Alabama (Baldwin and Mobile counties) are:

- Output: 1.6311
- $\bullet$  Earnings: 0.4604
- Jobs: 0.0000173756
- Value added: 1.0023.

First, we multiply the accommodation output multiplier, 1.6311, by the average daily expenditure for lodging of \$39.68. This yields output generated per recreation day from expenditures on lodging equal to \$64.72. This is \$25.39 more than the initial or direct expenditure of \$39.68. This additional increase of \$25.39 in output is the measure of the indirect and induced effects that result from the initial direct change in spending of \$39.33 on lodging. This is because the initial increase in spending stimulates additional changes in spending, such as by hotel employees. These additional changes in spending then cause further changes in production, income, and employment in the region.

Next we estimate the value-added portion of this output, which is the value of gross output less intermediate inputs. Multiplying our value-added multiplier, 1.0023, estimates the value added of lodging expenditures equal to \$39.77. The earnings portion of this valueadded is \$18.27 (0.4604 times \$39.77). To estimate the expected change in jobs, we would next apply the jobs multiplier of 0.0000173756, but we skip this final calculation in our perday example.

We conduct this step for each of the expenditure categories and industry combinations. The total economic impact is the sum of the product of each expenditure category/industry combination for each metric.

Finally, we conduct an additional step for retail industries in which we convert consumer value (i.e., the visitor expenditures) into producer value. This step is explained in Appendix D.

# **4.3. Regional Economic Impacts of Marine Debris**

The results of this regional economic impact analysis show that marine debris can have profound effects on regional economies. A reduction of debris to almost none is estimated to contribute an additional \$29 million in economic activity (measured as value-added) in Alabama; \$27.8 million in Delaware and Maryland; \$206.0 million in Ohio; and \$137.8 million in Orange County, California (Table 10). Conversely, a doubling of debris is estimated to cost the local economies \$96.3 million in Alabama; \$203.2 million in Delaware and Maryland; \$207.3 million in Ohio; and \$304.5 million in Orange County, California (Table 10).

	Alabama	Delaware and Maryland	Ohio	Orange County, California	
Recreation day expenditures	\$139	\$92	\$97	\$89	
Output generated per recreation day	\$169	\$102	\$130	\$116	
Earnings generated per recreation day	\$50	\$27	\$34	\$30	
Jobs generated per recreation day	0.0022	0.0010	0.0013	0.0009	
Value added generated per recreation day	\$95	\$58	\$73	\$66	
Debris change to almost none					
Change in visitor days	308,365	478,410	2,823,268	2,092,920	
Change in visitor spending	\$42,724,928	\$44,040,576	\$272,761,000	\$187,294,392	
Change in output	\$52,116,000	\$48,879,000	\$367,522,000	\$241,994,000	
Change in earnings	\$15,547,000	\$13,076,000	\$96,026,000	\$61,797,000	
Change in jobs	672	464	3,703	1,925	
Change in value added	\$29,423,000	\$27,834,000	\$205,977,000	\$137,830,000	
Doubling of debris					
Change in visitor days	$-1,009,130$	$-3,492,845$	$-2,840,854$	$-4,624,417$	
	$-$113,427,000$	$-$ \$254,086,000		$-$ \$413,837,000	
Change in visitor spending			\$274,460,000		
	$-$170,551,000$	$-$ \$356,865,000		$-$ \$534,698,000	
Change in output			\$369,811,000		
Change in earnings	$-$ \$50,877,000	$-$ \$95,467,000	$-$ \$96,624,000	$-$136,543,000$	
Change in jobs	$-2.198$	$-3,386$	$-3,726$	$-4,254$	
	$-$ \$96.288.000	$-$ \$203,211,000		$-$ \$304,542,000	
Change in value added			\$207,260,000		

**Table 10. Economic impacts of changes to debris levels at the four study areas (2018 dollars)**

# **4.4. Caveats and Uncertainties**

There are several areas of uncertainty in this calculation of regional economic impacts. First, the NOAA (2012) NORES dataset reports all expenditures per trip, which is not limited to expenditures made for individual respondents. For example, the NORES data include hotel expenditures for a family. To align these expenditures with the increased number of trips estimated in Section 3, we assume that the trips referred to in the NORES data and the trips referred to in our marine debris surveys have the same average number of people.

Second, as noted previously, the NOAA (2012) NORES data estimate trip expenditures that occur in a larger region than our study areas. Thus, some of the trip expenditures (e.g., gas, transportation) in the larger NORES regions may occur outside of our study area. For this analysis, we applied the trip expenditures to our smaller study region, noting that this may overstate transportation spending in the regions.

Finally, we note that RIMS II multipliers measure the impact of employment using a count of jobs that include both full-time and part-time workers (Bess and Ambargis, 2011). Since the tourism industry may have a large portion of part-time and seasonal workers, the employment impact may be an upper-bound.

# **5. SUMMARY OF RESULTS**

This study provides estimates of recreation value and regional economic impacts, including an evaluation of key features in the design of the study, the comparison of model output to external estimates, and potential implications for future research. Highlights of our study findings are described below.

- We adjusted mail-survey sampling weights to match key characteristics of respondents in the onsite survey, thereby taking advantage of the high response rate in the onsite survey (77%) and potentially improving representativeness of the mail survey data. The adjustments led to significant changes in the representation of certain demographic groups but only modest changes in the estimates of recreation value and economic impacts.
- We found a high correlation (0.87) between ratings of debris levels on beaches provided by survey respondents (where respondents rated debris levels on a 1-to-5 scale, with one referring to "almost no" debris and 5 referring to a "high amount" of debris) and actual debris amounts estimated from onsite measurements conducted by NOAA.
- The benefit function transfer based on the extensive *Deepwater Horizon* nationwide dataset resulted in a model that appeared to provide reliable estimates when applied to study areas in Alabama, Delaware/Maryland and Orange County, California. However, the model did not appear to fit well with Lake Erie beaches in Ohio, particularly for estimating changes in day use, and thus we only provide estimates of changes to multiple-day trips in Ohio.
- We compared our results in Orange County, California to recent estimates from a revealed-preference study in the same location (Leggett et al., 2018). Our estimates

of the impacts from debris on the value and number of trips were either comparable or somewhat higher than those of the previous study, depending on the scenario examined. However, an exact comparison was not possible because the Leggett et al. (2018) study focused exclusively on single-day trips, whereas our analysis included multiple-day trips.

 We used data from NORES that provides estimates of recreator expenditures during coastal recreation trips. We adjusted the expenditure values to account for differences with our study, which provided recently estimated expenditures for relevant recreation activities for each study area. The NORES data did not include the Great Lakes, however, so we used the national average for Lake Erie beaches in Ohio.

Table 11 provides a summary data table for all the results of this study. This section provides a summary of only selected data; additional information is included in subsequent sections and in the Executive Summary.

# **Table 11. Summary of study results**

a. Estimates for Lake Erie beaches in Ohio account for multiple-day trips only.

b. Value added is net combined value of all goods and services, analogous to GDP for the local area.

Although the data collection and analysis was based on changes in recreation trips, we have expressed the results in units of recreation days to reflect the relative importance of multiple-day trips in influencing economic value. Based on a benefits function transfer from the *Deepwater Horizon* dataset, the estimated annual number of recreation days is 4.5 million on beaches in Alabama, 24.0 million on beaches in Delaware and Maryland, and 27.1 million on beaches in Orange County, California (Table 11). We also estimate there are 8.2 million recreation days taken annually on Lake Erie beaches in Ohio, accounting for multiple-day trips only. As noted previously, estimates for Ohio account only for multiple-day trips because of limitations in how the nationwide recreation model could be applied to Lake Erie beaches.

All estimates include uncertainties that reflect not only statistical error, but also potential error from the combined use of data collected at different times between 2012 and 2018 and from a benefit-transfer analysis that relies on reasonable but imperfect assumptions about similarities in recreation behavior across different coastal locations.

Respondents' ratings of the amount of debris on beaches on a 1-to-5 scale ranged from 1.6 for Delaware/Maryland beaches to 2.3 for Lake Erie beaches in Ohio. The effect of changes in debris on recreation was lowest in Delaware/Maryland, where respondents said the beaches had less debris, and highest in Ohio, where respondents said that beaches have more debris. These results are consistent because the debris scenarios presented in the survey involved changes in debris that are proportionate to current debris levels. Estimates of the percentage increase in trips from reducing debris to "almost none" (defined in the survey as one piece of debris per 500 square feet) are 8.1% in Alabama; 2.2% in Delaware/Maryland; 35.4% in Ohio; and 9.5% in Orange County, California (Table 11).

The effect of a doubling of current debris levels is a decrease in trips and is a larger percentage change compared to debris reduction in all areas. The specific estimates of decreasing trips are 26.5% in Alabama, 16.3% in Delaware/Maryland, 35.6% in Ohio, and 20.9% in Orange County, California (Table 11).

Table 11 also shows changes in the value of recreation, reflecting the public's enjoyment of area beaches. If marine debris were reduced to almost none, the estimated annual increase in recreation value is \$10.1 million in Alabama, \$19.8 million in Delaware/Maryland, \$88.0 in Ohio (multiple-day trips only), and \$129.7 million in Orange County, California (Table 11). If the amount of marine debris on beaches were to double, the estimated annual decrease in recreational value is \$32.3 million in Alabama, \$140.9 million in Delaware/Maryland, \$83.9 million in Ohio (multiple-day trips only), and \$275.1 million in Orange County, California (Table 11).The differences in dollar amounts among study areas reflect differences in the baseline number and value of trips in each area in addition to the percentage changes in trips. All recreation values were adjusted for the 7.9% Consumer Price Index (CPI) inflation (Federal Reserve Bank of St. Louis, 2019) from 2013 (when the *Deepwater Horizon* data collection was completed) to 2018.

Reductions or increases in marine debris leads to changes in spending by non-local beach visitors that has a significant impact on the regional economies of beach communities. In all four of our study areas, the portion of recreation days that come from outside the local area is greater than 80% (Table 11). Based on NORES data (NOAA, 2012), spending by non-local visitors ranges from \$89 per day in Delaware/Maryland to \$139 per day in Alabama (Table 11).

Direct spending by visitors leads to "multiplier effects," which include additional spending for supplies by local business and additional spending by new employees hired by local businesses. Multiplier effects also account for the portion of visitor and additional spending that leaves the local economy, called "leakages" (Bess and Ambargis, 2011).

We expressed the regional economic impacts using two key metrics:

- *Value added*: The value of gross output less intermediate inputs. The value of this metric is equal to the sum of compensation of employees, taxes on production and imports less subsidies, and gross operating surplus. Value added is the net combined value of all goods and services and is analogous to GDP for the local area.
- *Employment*: Number of full- and part-time jobs (including proprietors' jobs).

For a reduction in debris to almost none, the increase in employment ranges from 464 additional jobs in the Delaware/Maryland study area to 3,703 additional jobs in Ohio (Table 11; as above, accounting only for multiple-day trips in Ohio). Under this scenario, value added ranges from an increase of \$27.8 million in the Delaware/Maryland study area to an increase of \$206.0 million in Ohio (Table 11).

For a doubling of debris, there is a decrease in employment ranging from 2,198 jobs in the Alabama study area to 4,254 jobs in Orange County, California (Table 1). Under this scenario, the decrease in value added ranges from \$96.3 million in the Alabama study area to \$304.5 million in Orange County, California (Table 11).

#### **Privacy Act Statement**

Authority: The collection of this information is authorized under 33 U.S.C. 1853 et seq, the Marine Debris Research, Prevention and Reduction Act, which, along with the Marine Debris Amendments of 2012, established the NOAA Marine Debris Program to "identify, determine sources of, assess, prevent, reduce, and remove marine debris and address the adverse impacts of marine debris on the economy of the United States, the marine environment, and navigation safety."

Purpose. The information will be used to estimate economic impacts associated with marine debris on beaches.

NOAA Routine Uses: The survey data will be combined with a national model of coastal recreation, which relies on data collected for the Deepwater Horizon oil spill assessment, to estimate the economic impacts of marine debris on tourism dependent communities. Disobsure of this information is permitted under the Phyacy Act of 1974 (5 U.S.C. Section 552a) to testaned among NOAA<br>staff for work-related purposes. Di Contact Information for Members of the Public Requesting or Providing Information Related to NOAA's Mission

Disclosure: Furnishing this information is voluntary; the only consequence of failure to provide accurate information is thatyour responses will not contribute to the successof this research

**Thank you for speaking with us a few weeks ago at the beach. This mail survey is the final step in our study. We appreciate your participation!**

Coastal beaches are vital to the area's economy and quality of life. Your answers to this survey will help inform decisions about improving and protecting coastal resources. We want to hear from everyone about things people want to experience when they visit the beach. Your response is important – please complete this *voluntary* survey.

Our questions are about ocean beaches in Alabama, shown in the map below.

1. In the list below, please circle the names of any beaches you went to between September 1, 2017 and August 31, 2018. If you don't know the name of a beach you went to or it is not on the list, please circle the name of a nearby beach.

- 1. Dauphin Island West End Beach 5. Bon Secour National Wildlife Refuge 8. Gulf State Park Pavilion
	-
- 3. Dauphin Island East End Beach 7. Gulf State Park Pier 10. Alabama Point/Florida Point
- 
- 2. Dauphin Island Public Beach 6. Gulf Shores Public Beach 9. Cotton Bayou/Orange Beach
- 4. Fort Morgan Public Beach

Now we would like to ask you about the number of day trips and overnight trips you took to ocean beaches in Alabama. A **day** trip is any time you went to the beach and returned home the same day. An overnight trip is when you spent at least one night away from home.

2. Between September 1, 2017 and August 31, 2018, did you take any *day* trips to ocean beaches in Alabama? Please check  $\boxtimes$  one box.

3. Between September 1, 2017 and August 31, 2018, did you take any *overnight* trips where the main purpose was visiting ocean beaches in Alabama? Please check  $\boxtimes$  one box.

The next question is about beach characteristics.

4. Please tell us how important the following characteristics are to you when you decide which beaches to visit. Please check  $\boxtimes$  one box in each row.

### *Garbage or Manmade Debris You May See on Beaches*

Different beaches can have different amounts of garbage or manmade debris. Garbage or manmade debris refers to items like bottles, wrappers, straws, plastic fragments, or cigarettes. It does not include twigs or seaweed.

The pictures below illustrate the amount of debris commonly found on United States beaches. Imagine you are picking up debris over an area of 500 square feet or approximately the area of three parking spaces, outlined in red below.

If you walked back and forth in this area and picked up all the debris, you might find different amounts ranging from "almost none" to a "high amount." As the pictures below show, different levels of debris on the beach can be given a score from 1 to 5. Higher scores mean more debris.

On the next page, we will ask you to use the above scale to estimate the amount of garbage or manmade debris you saw on ocean beaches you have been to in Alabama.

5. In the table below, please write the names of ocean beaches in Alabama that you went to between September 1, 2017 and August 31, 2018. You may want to refer back to the map at the beginning of this survey.

To the right of each beach you went to, use the debris scale from the previous page and write a number between 1 and 5, indicating the amount of garbage or manmade debris you saw on the beach. Writing a "1" indicates you saw almost none, while writing a "5" indicates you saw a high amount of garbage or manmade debris. For any beach where you don't recall the amount of debris, please write "don't recall" in place of a number.

6. Between September 1, 2017 and August 31, 2018, if there had been *almost no* garbage or manmade debris on ocean beaches in Alabama, would you have gone to the beach more often or the same number of times? Please check  $\boxtimes$  one box.

### **More often → Please answer the two questions below.**

7. Between September 1, 2017 and August 31, 2018, if there had been *twice as much* garbage or manmade debris on ocean beaches in Alabama, would you have gone to the beach less often or the same number of times? Please check  $\boxtimes$  one box.

### **Less often → Please answer the two questions below.**

Between September 1, 2017 and August 31, 2018, how many more overnight trips would you have taken if there were almost no garbage or manmade debris on ocean beaches in Alabama?

The same number of times

The next few questions ask about your experiences with debris on beaches.

8. How concerned would you be to see the following types of garbage or manmade debris while visiting a beach? Please check  $\boxtimes$  one box in each row.

9. Please look at the list below and check  $\boxtimes$  the box next to all the types of garbage or manmade debris that you have *actually seen* on ocean beaches in Alabama.

10. Do you think garbage or manmade debris is a problem on ocean beaches in Alabama? Please check  $\boxtimes$  one box.

11. To the best of your knowledge, what do you think is the largest source of garbage or manmade debris found on ocean beaches in Alabama? Please check  $\boxtimes$  one box.

Finally, we have just a few questions about you and your household. These questions are a way to make sure that we understand the values and opinions of all types of people visiting beaches in Alabama.

12. Have you participated in any beach cleanups within the last three years? Please check **x** one box.

- 13. How many adults and children live in your household? \_\_\_\_\_\_\_ Adults (18 and older) \_\_\_\_\_\_\_\_ Children (under 18)
- 14. What is your gender? Please check  $\boxtimes$  one box.

Female

- 15. In what year were you born? \_\_\_\_\_\_\_ Year
- 16. Are you of Hispanic, Latino, or Spanish origin? Please check  $\boxtimes$  one box.

 $N<sub>0</sub>$   $\qquad \qquad$  Yes

17. What is your race? Select all that apply.

18. What is the highest degree or level of school you have completed? Please check  $\boxtimes$ one box.

19. Which of the following income categories best describes your total household income last year, before taxes? Please check  $\boxtimes$  one box.

# **Thank you for participating!**

**Please return your survey in the enclosed Business Reply Mail envelope.**

# **Beach Recreation Survey – Delaware and Maryland**

#### vork Reduction Act Statement

The National Oceanic and Almospheric Administration (NOAA) is authorized by 33 U.S.C. 1951 et seq. to conduct this survey. The information collected will be used by NOAA to estimate economic impacts associated with marine debris on beache

Public reporting burden for this collection of information is estimated to average 10 minutes per response, including the time for reviewing instructions, searching existing data sources, gathering and maintaining the data needed, and completing and reviewing the collection of information. Send comments regarding this burden estimate or any other suggestions for reducing this burden to Arny V Uhrin, NOAA NOS, 1305 East-West Hwy, SSMC4, Room10240, Silver Spring, MD 20910.

The questionnaire has an identification number for mailing purposes only. Your name and address will be deleted after we receive your completed questionnaire. Notwithstanding any other provisions of the law, no person is required to respond to, nor shall any person be subjected to a penalty for failure to compty with, a collection of information subject to the requirements of the<br>Paperwork Reduction Act,

#### **Privacy Act Statement**

Authority: The collection of this information is authorized under 33 U.S.C. 1853 et seq, the Marine Debris Research, Prevention and Reduction Act, which, along with the Marine Debris Amendments<br>of 2012, established the NOA the economy of the United States, the marine environment, and navigation safety

Purpose: The information will be used to estimate economic impacts associated with marine debris on beaches.

NOAA Routine Uses: The survey data will be combined with a national model of coastal recreation, which relies on data collected for the Deepwater Horizon oil spill assessment, to estimate the economic impacts of marine debris on tourism-dependent communities. Disclosure of this information is permitted under the Privacy Act of 1974 (5 U.S.C. Section 552a) to be shared among N<br>staff for work-related purposes. Di **NOAA** Contact Information for Members of the Public Requesting or Providing Information Related to NOAA's Mission

Disclosure. Furnishing this information is voluntary, the only consequence of failure to provide accurate information is thatyour responses will not contribute to the successof this research

**Thank you for speaking with us a few weeks ago at the beach. This mail survey is the final step in our study. We appreciate your participation!**
Coastal beaches are vital to the area's economy and quality of life. Your answers to this survey will help inform decisions about improving and protecting coastal resources. We want to hear from everyone about things people want to experience when they visit the beach. Your response is important – please complete this **voluntary** survey.

Our questions are about ocean beaches in Delaware and Maryland, shown in the map below.

1. In the list below, please circle the names of any beaches you went to between September 1, 2017 and August 31, 2018. If you don't know the name of a beach you went to or it is not on the list, please circle the name of a nearby beach.

- 
- 
- 
- 7. Dewey Beach 8. Towers Beach
- 
- 11. South Indian River Inlet Beach 12. 3 R's Road Beach
- 
- 15. Fenwick Island State Park Beach 16. Town of Fenwick Island Beach
- 17. Ocean City (140th Street) 18. Ocean City (Boardwalk)
- 
- 1. Lewes Beach 2. Cape Henlopen Beach
- 3. Herring Point Beach 4. Gordon's Pond Beach
- 5. Deauville Beach 6. Rehoboth Beach
	-
- 9. Keybox Road Beach 10. Conquest Road Beach
	-
- 13. Bethany Beach 14. South Bethany Beach
	-
	-
- 19. Assateague State Park 20. Assateague Island National Seashore

Now we would like to ask you about the number of day trips and overnight trips you took to ocean beaches in Delaware and Maryland. A **day** trip is any time you went to the beach and returned home the same day. An **overnight** trip is when you spent at least one night away from home.

2. Between September 1, 2017 and August 31, 2018, did you take any day trips to ocean beaches in Delaware and Maryland? Please check **x** one box.

3. Between September 1, 2017 and August 31, 2018, did you take any *overnight* trips where the main purpose was visiting ocean beaches in Delaware and Maryland? Please check  $\boxtimes$  one box.

The next question is about beach characteristics.

4. Please tell us how important the following characteristics are to you when you decide which beaches to visit. Please check  $\boxtimes$  one box in each row.

#### *Garbage or Manmade Debris You May See on Beaches*

Different beaches can have different amounts of garbage or manmade debris. Garbage or manmade debris refers to items like bottles, wrappers, straws, plastic fragments, or cigarettes. It does not include twigs or seaweed.

The pictures below illustrate the amount of debris commonly found on United States beaches. Imagine you are picking up debris over an area of 500 square feet or approximately the area of three parking spaces, outlined in red below.

If you walked back and forth in this area and picked up all the debris, you might find different amounts ranging from "almost none" to a "high amount." As the pictures below show, different levels of debris on the beach can be given a score from 1 to 5. Higher scores mean more debris.

On the next page, we will ask you to use the above scale to estimate the amount of garbage or manmade debris you saw on ocean beaches you have been to in Delaware and Maryland.

5. In the table below, please write the names of ocean beaches in Delaware and Maryland that you went to between September 1, 2017 and August 31, 2018. You may want to refer back to the map at the beginning of this survey.

To the right of each beach you went to, use the debris scale from the previous page and write a number between 1 and 5, indicating the amount of garbage or manmade debris you saw on the beach. Writing a "1" indicates you saw almost none, while writing a "5" indicates you saw a high amount of garbage or manmade debris. For any beach where you don't recall the amount of debris, please write "don't recall" in place of a number.

6. Between September 1, 2017 and August 31, 2018, if there had been *almost no* garbage or manmade debris on ocean beaches in Delaware and Maryland, would you have gone to the beach more often or the same number of times? Please check  $\boxtimes$  one box.

#### More often → **Please answer the two questions below.**

7. Between September 1, 2017 and August 31, 2018, if there had been *twice as much* garbage or manmade debris on ocean beaches in Delaware and Maryland, would you have gone to the beach less often or the same number of times? Please check  $\boxtimes$  one box.

## Less often  $\rightarrow$  **Please answer the two questions below.**

Between September 1, 2017 and August 31, 2018, how many fewer day trips would you have taken if there had been twice as much garbage or manmade debris on ocean beaches in Delaware and Maryland?

Between September 1, 2017 and August 31, 2018, how many fewer overnight trips would you have taken if there had been twice as much garbage or manmade debris on ocean beaches in Delaware and Maryland?

The next few questions ask about your experiences with debris on beaches.

8. How concerned would you be to see the following types of garbage or manmade debris while visiting a beach? Please check  $\boxtimes$  one box in each row.

9. Please look at the list below and check  $\boxtimes$  the box next to all the types of garbage or manmade debris that you have *actually seen* on ocean beaches in Delaware and Maryland.

10. Do you think garbage or manmade debris is a problem on ocean beaches in Delaware and Maryland? Please check  $\boxtimes$  one box.

11. To the best of your knowledge, what do you think is the *largest* source of garbage or manmade debris found on ocean beaches in Delaware and Maryland? Please check **EX** one box.

Finally, we have just a few questions about you and your household. These questions are a way to make sure that we understand the values and opinions of all types of people visiting ocean beaches in Delaware and Maryland.

12. Have you participated in any beach cleanups within the last three years? Please check  $\mathbf{\times}$  one box.

13. How many adults and children live in your household?

Adults (18 and older) Children (under 18)

14. What is your gender? Please check  $\boxtimes$  one box.

Male **E** Female

- 15. In what year were you born? Year
- 16. Are you of Hispanic, Latino, or Spanish origin? Please check  $\boxtimes$  one box.

- 17. What is your race? Select all that apply.
	- American Indian or Alaskan Native
		- Asian
	- Black or African American
	- Native Hawaiian or other Pacific Islander
	- **White**
	- Other (please specify)
- 18. What is the highest degree or level of school you have completed? Please check  $\boxtimes$ one box.
	- Less than high school graduate Some college or Associate's degree High school graduate (includes GED)
		- Bachelor's degree

Graduate or professional degree, beyond a bachelor's degree

19. Which of the following income categories best describes your total household income last year, before taxes? Please check  $\boxtimes$  one box.

## **Thank you for participating!**

**Please return your survey in the enclosed Business Reply Mail envelope**.

## **Beach Recreation Survey – Lake Erie, Ohio**

#### **Paperwork Reduction Act Statement**

The National Oceanic and Atmospheric Administration (NOAA) is authorized by 33 U.S.C. 1951 et seq. to conduct this survey. The information collected will be used by NOAA to estimate economic impacts associated with marine debris on beaches

Public reporting burden for this collection of information is estimated to average 10 minutes per response, including the time for reviewing instructions, searching existing data sources, gathering and<br>maintaining the data Jhrin, NOAA NOS, 1305 East-West Hwy, SSMC4, Room10240, Silver Spring, MD 20910.

The questionnaire has an identification number for mailing purposes only. Your name and address will be deleted after we receive your completed questionnaire. Notwithstanding any other<br>provisions of the law, no person is r Paperwork Reduction Act, unless that collection of information displays a currently valid OMB Control Number OMB Control Number 0648-0756 I Current Expiration Date: 0831/2020

#### **Privacy Act Statement**

Authority: The collection of this information is authorized under 33 U.S.C. 1853 et seq. the Marine Debris Research, Prevention and Reduction Act, which, along with the Marne Debris Amendments<br>of 2012, established the NOAA the economy of the United States, the marine environment, and navigation safety.

Purpose. The information will be used to estimate economic impacts associated with marine debris on beaches.

NOAA Routine Uses: The survey data will be combined with a national model of coastal recreation, which relies on data collected for the Deepwater Horizon oil spill assessment, to estimate the<br>economic impacts of marine deb work-related purposes. ## **Thank you for participating!**

**Please return your survey in the enclosed Business Reply Mail envelope.**

# **APPENDIX B: MAIL SURVEY SUMMARY STATISTICS**

## **Table B-1. Variables in STATA survey data. The variables refer to the question numbers in the mail survey (Appendix A). Additional statistics for each question (variable) are provided in the subsequent tables in this appendix**

a. Denotes a dummy variable.

*Total 329 100*

## **APPENDIX C: METHODS FOR REWEIGHTING MAIL RESPONDENTS**

The first step in reweighting methods was to identify key variables that influence people's recreation response to marine debris on beaches. To estimate the relationship between explanatory variables and the effect of marine debris on an individual's recreation trips, we began with a logistic demand equation that is frequently used in recreation applications (Train, 2003). Individual *i*'s trips *y*<sup>i</sup> are given by:

$$
y_i = K \times 1/(1 + e^{\theta_i})
$$
 (C1)

*K* is a scalar that converts the logistic function that follows it from a number between zero and one into a demand function that can describe any quantity of trips less than *K*. The constant  $e$  generates the exponential function.  $\theta_i$  is the variable the determines the value of the logit expression and will later be defined in specific terms. We set *K* to equal 500 so that it was comfortably larger than the highest demand of 365 trips for any respondent in our data that further increases in  $K$  did not change the results. Since each respondent's baseline number of trips, *ti*, is known from the survey, we can rearrange the demand equation to show that under baseline beach conditions, with no change in debris:

$$
e^{\theta_i} = (K - t_i) / t_i \tag{C2}
$$

We can then represent an individual's demand after a change in beach quality as:

$$
y_{i\Delta} = K \times e^{\Delta_i} / (e^{\Delta_i} + (K - t_i) / t_i)
$$
 (C3)

Here  $e^{\theta_i}$  has been replaced with  $(K - t_i)/t_i$ , and  $\Delta_i$  has been introduced to represent the perceived quality change to individual *i* from a change in debris. We specify  $\Delta_I$  for a reduction in debris to almost none (*n*) as:

$$
\Delta_{in} = \beta_{a_in} + \beta_x x_i \tag{C4}
$$

The term  $\beta_{a_i n}$  is a constant representing the average effect on demand of a reduction to almost no debris, and is specific to the study area *a* where individual *i* was intercepted at the beach. The term  $\beta_{xx}$ <sup>*i*</sup> represents individual-specific deviations from the average, in which  $\beta_x$ are coefficients and *x<sup>i</sup>* are characteristics of individual *i*. We represent individual *i*'s perceived quality change for a doubling of debris (*d*) as:

$$
\Delta_{id} = \beta_{a_i d} - \beta_x x_i \tag{C5}
$$

These expressions allow us to interpret a positive *βan* as the average perceived increase in quality from a reduction of debris in area *a* and a negative *βad* as the average perceived decrease in quality from a doubling of debris in area *a*. Given the addition in the first expression and subtraction in the second expression, it is also possible to consistently interpret a positive coefficient  $\beta_x$  to mean that *x* is positively associated with a concern for marine debris. This is because in each case a positive coefficient augments the size of the estimated constant. For example, if the starting point for  $\Delta_{in}$  is a positive constant  $\beta_{an}$ , then  $\Delta_{in}$ becomes more positive when  $\beta_x$  is positive and  $x_i$  is increasing. Likewise, if the starting point for  $\Delta_{id}$  is a negative constant  $\beta_{ad}$ , then  $\Delta_{id}$  becomes more negative if  $\beta_x$  is positive and  $x_i$  is increasing.

The final demand equations used in estimation are:

$$
y_{in} = K \frac{e^{\beta a_{i}n + \beta_{x}x_{i}}}{e^{\beta a_{i}n + \beta_{x}x_{i}} + (K - t_{i})/t_{i}}
$$
(C6)

$$
y_{id} = K \frac{e^{\beta a_i d^{-\beta x x_i}}}{e^{\beta a_i d^{-\beta x x_i}} + (K - t_i)/t_i}
$$
(C7)

Using a Poisson estimator and defining  $t_{in}$  and  $t_{id}$  to be *i*'s trips with almost no debris and a doubling of debris, respectively, the likelihood function is:

$$
L(\beta; x, t) = \prod_{i} \left( \frac{e^{-y_{in}} y_{in} t_{in}}{t_{in}!} e^{-y_{id}} y_{id} t_{id} \right)^{W_{ib}}
$$
(C8)

The base weights  $w_{ib}$  are the mail-survey base weights derived in Section 2.3.1.

There were eight attitudinal or demographic variables included in *xi*. Since the goal was to detect the presence of an effect for each variable rather than a detailed characterization of the effect, all eight variables were expressed in a simple binary form for the purpose of model estimation. The eight variables were:

- Age  $= 1$  if the respondent was 50 years old or older
- $\bullet$  Education = 1 if the respondent had a bachelor's degree or higher
- Children in household  $= 1$  if there were children in the respondent's household
- Female  $= 1$  if the respondent was female
- Debris is a problem  $= 1$  if the respondent answered "yes" to the question whether debris was a problem on local beaches
- Parking  $= 1$  if the respondent gave a rating of "4" or "5" for the importance of free or inexpensive parking
- Not crowded  $= 1$  if the respondent gave a rating of "4" or "5" for the importance of beaches not being crowded
- $\bullet$  No debris = 1 if the respondent gave a rating of "5" for the importance of no debris on beaches.
Different break points were tested for each variable to find the binary specification with the greatest effect. The model was estimated using the maximum likelihood procedure in Aptech Gauss 12 software.

Table C-1 shows the results of the contingent behavior model. The sample includes all 329 completed mail surveys, with a breakout by region as presented in Table 1 of the report. The model coefficients have no intuitive interpretation apart from the way the sign and magnitude of the coefficients affect predicted demand. The constants representing the average effect of the two scenarios show the expected sign for all four study areas, with positive constants indicating an increase in trips when debris is reduced to almost none and negative constants indicating a decrease in trips when debris is doubled. The constants are larger for a doubling of debris than for a reduction in debris, consistent with the larger change in debris in the first scenario than in the second. Three of the four constants for a reduction in debris are not statistically significant at the 5% level, with *p* values greater than 0.05. However, we are not using the model to estimate the effects of the scenarios; the sampling-based estimates for the effect of the changes in debris reported in Table 4 of the report in fact have quite narrow confidence intervals.

Variable	Coefficient	Standard error	$p$ value
Debris reduced to almost none			
Constant – Alabama	0.174	0.104	0.094
Constant – Delaware/Maryland	0.174	0.110	0.113
Constant - Ohio	0.381	0.093	0.000
Constant – Orange County, California	0.156	0.098	0.110
Doubling of debris			
Constant - Alabama	$-0.465$	0.110	0.000
Constant – Delaware/Maryland	$-0.316$	0.113	0.005
$Constant - Ohio$	$-0.524$	0.100	0.000
Constant – Orange County, California	$-0.325$	0.102	0.001
Demographic and attitudinal variables <sup>a</sup>			
$Age \geq 50$	$-0.230$	0.046	0.000
Education $\geq$ bachelor's	0.101	0.039	0.010
Children in household	$-0.080$	0.049	0.104
Female	$-0.055$	0.041	0.183
Debris is a problem on local beaches	0.129	0.040	0.001
Importance of "parking is free or inexpensive"	$-0.017$	0.046	0.711
Importance of "not crowded"	$-0.008$	0.044	0.863
Importance of "no debris"	$-0.017$	0.046	0.713

**Table C-1. Results of the contingent behavior model**

a. Coefficients apply to both scenarios but with opposite signs, so that positive coefficients indicate a positive association with effects in both scenarios: a larger increase in trips for a reduction of debris to almost none, and a larger reduction in trips for a doubling of debris.

To help evaluate the performance of the contingent behavior model, we provide the total percentage change in trips implied by the model for each scenario in each study area, which are similar to the final estimates in Table 4. The model estimates for a decline in debris to almost none are 8.8% in Alabama, 6.6% in Delaware/Maryland, 38.8% in Ohio, and 8.2% in Orange County, California. The model estimates for a doubling of debris are -29.3% in Alabama; -17.1% in Delaware/Maryland; -36.5% in Ohio; and -19.6% in Orange County, California.

The purpose of the contingent behavior model is to identify the characteristics or attitudinal variables that most influence people's answers to the debris scenarios. Only three of the explanatory variables are statistically significant: age, education, and the response to the question of whether marine debris is a problem on beaches in a given study area. In the case of age, those at least 50 years old had a lower than average response to debris, reflected in the negative coefficient of -0.230. Those with a bachelor's degree or higher had a higher than average response to debris, reflected in the positive coefficient of 0.101. Those who answered "yes" to the question whether marine debris is a problem on local beaches had a higher than average response to debris, indicated by the positive coefficient of 0.129.

### **Adjusting Sampling Weights Using Key Variables**

The overall response rate for the onsite survey was 76.7%. Some onsite respondents did not provide their address, and some who provided their address did not return the mail survey that was sent to them. As a result, the overall response rate for the mail survey, which accounts for nonresponse at every stage of the study, was 19.0%. A common way to test and correct for potential nonresponse bias is to reweight the final mail-survey observations so that the proportions of reweighted mail-survey respondents with given key demographic characteristics match the proportions for the analogous groups of respondents in the onsite survey. This is a form of post-stratification described in Little (1993).

Table C-2 shows the onsite and mail survey percent frequencies for the four demographic variables that were included in both the onsite survey and the mail survey: age, education, whether there are children in the respondent's household, and the respondent's gender. Table C-2 also shows the percent frequencies for the question about whether debris is a problem on beaches in the area. Two attitudinal variables that were asked in both the onsite and mail surveys about the importance of crowding and free parking at beaches, are not shown in Table C-2 because they were not found to be associated with a response to marine debris.

In Table C-2, age is grouped into 6 categories, divided at age 25, 35, 45, 55, and 65. Education is divided into five categories, including those with less than a high school degree, those with a high school degree, those with some college but no bachelor's degree, those with a bachelor's degree, and those with a graduate degree. The categories for whether a household has children are "yes" and "no," and the categories for gender are "male" and "female." The categories for whether debris is a problem are "yes" and "no" for the onsite survey and "yes," "no," and "not sure" for the mail survey. Given the option of "not sure" included in the mail survey, we do not view the "no" response category as comparable in the two surveys. They are therefore separated into different columns in the table. The frequencies for the onsite survey and mail survey are both weighted using the onsite weights, so that measured differences between the two surveys reflect differences in representation of demographic groups rather than differences in sampling weights.

Cells shaded in light gray show under-representation in the mail survey relative to the onsite survey by at least five percentage points for the three key variables. This threshold was chosen as a reasonable way to highlight the most significant areas of divergence between the two surveys. Cells shaded in dark gray show over-representation by at least five percentage points.

#### **Table C-2. Onsite and mail survey percent frequencies showing mail survey over- and under-representation<sup>a</sup>**

#### **Table C-2. (Continued)**

a. Dark gray and light gray show, respectively, over-representation and under-representation by at least five percentage points in mail survey responses relative to onsite survey responses. Attitudinal variables involving crowded beaches and inexpensive parking are available from both the onsite and mail surveys but are excluded from the table because they are not related to marine debris and were not found to be associated with a response to marine debris in the contingent behavior model. For the demographic variables "children in household" and "gender," over- and underrepresentation are not highlighted because these variables were not found to be associated with a response to marine debris in the contingent behavior model.

b. The variable "debris a problem" refers to the question, "Do you think garbage or marine debris is a problem [on beaches in your local area]?" The mail survey elicited one of three responses: "yes," "no," or "not sure." The onsite survey elicited only a "yes" or "no" response.

To illustrate the selection of categories for reweighting, we use as examples age and education in Alabama. The first 3 age categories, including respondents aged less than or equal to 25, respondents aged 26 to 35, and respondents aged 36 to 45, are under-represented in the mail survey by at least five percentage points. The remaining three categories, including those aged 46 to 55, 56 to 65, and older than 65, are all over-represented by at least five percentage points. Representativeness could be improved by increasing the sampling weights for the first 3 groups and decreasing the sampling weights for the last three groups. For reweighting, we therefore combine the first 3 groups into a single category of those aged 45 or under and we combine the last 3 groups into a single category of those aged 46 or older. Aggregating into just two categories helps reduce variation in the size of the weighting adjustments and in the variance of the final weights.

In the case of education, Alabama respondents with a high school diploma or with some college but not a bachelor's degree are under-represented in the mail survey by at least five percentage points. Those with a bachelor's degree or a graduate degree are over-represented

by at least five percentage points. We therefore combine the first two groups and the second two groups, respectively. The remaining group, those without a high school degree, is quite small and is unlikely to significantly affect the adjusted weights or final weighted results. For simplicity, we combined it with the two other groups without a bachelor's degree to form two weighting categories: those with less than a bachelor's degree and those with a bachelor's degree or higher.

Based on a similar review of all variables in Table C-2, we chose to reweight by three variables (age, education, and debris is a problem) in all four regions, with one exception: for Ohio, the percentage of people who viewed marine debris as a problem was the same in the onsite survey and mail survey, and remained nearly the same after reweighting by age and education. Although the discrepancy in Alabama for the debris question was less than 5 percentage points (Table C-2), this diverged to more than 5 percentage points after reweighting by age and education, so all three variables were ultimately used in the adjustment.

The selection of variables for reweighting leads to the definition of "cells" used in the reweighting. Each variable was divided into two categories so that there were two cells for *n* variables. For example, if age were the only variable used, and respondents were divided into those age 45 or younger and those over 45, then there would be two cells. If the mail survey proportions for these two cells are 0.5 and 0.5 and the onsite survey proportions are 0.25 and 0.75, then the base weights for mail respondents in the first cell would each be reweighted by a factor of 0.25/0.5 and the base weights for mail respondents in the second cell would each be reweighted by 0.75/0.5. If the education variable were also used, with a division into those without a bachelor's degree and those with a bachelor's degree, there would now be four cells: "age  $\leq 45$ " and "education  $\leq$  bachelor's degree"; "age  $> 45$ " and "education  $\leq$ bachelor's degree"; "age  $\leq 45$ " and "education  $\geq$  bachelor's degree"; "age  $> 45$ " and "education ≥ bachelor's degree."

The final adjustments involved reweighting by eight cells in Alabama, Delaware/Maryland, and Orange County, California; and by four cells in Ohio as follows:

- In Alabama, every combination of "age  $\leq$  45" or "age  $>$  45," "education  $<$  bachelor's degree" or "education  $\geq$  bachelor's degree," and "problem = yes" or "problem  $\neq$  yes" formed one of eight cells.
- In Delaware/Maryland, every combination of "age  $\leq$  55" or "age  $>$  55," "education = either high school or graduate school" or "education  $\neq$  either high school or graduate school," and "problem = yes" or "problem  $\neq$  yes" formed one of eight cells.
- In Ohio, every combination of "age  $\leq 55$ " or "age  $> 55$ " and "education = some college" or "education  $\neq$  some college" formed one of four cells.
- In Orange County, California, every combination of "age  $\leq 55$ " or "age  $> 55$ " "education < graduate degree" or "education = graduate degree," and "problem = yes" or "problem  $\neq$  yes" formed one of eight cells.

Due to an oversight, the question asking whether marine debris was a problem at area beaches was not asked in exactly the same way in the onsite and mail surveys. The mail survey included the option to choose "not sure" while this option was not offered to onsite respondents. One might therefore expect that both the "yes" and "no" categories would be

overstated in the onsite survey relative to the mail survey, all else equal. This suggests that upward reweighting of "yes" responses in the mail survey to match "yes" responses in the onsite survey could lead to bias and would not be appropriate. In all cases described above, the proportion of respondents answering "yes" in the mail survey was weighted down to match the onsite survey. Although "yes" responses for the mail survey in Alabama initially appeared low, as shown in Table C-2, once the responses were reweighted by age and education, the reweighted frequency of "yes" responses was 45%, or five percentage points higher than the onsite frequency. This means that including the debris variable in the reweighting procedures for Alabama was appropriate, because it ultimately led to a downward reweighting of the variable relative to a procedure that only used age and education.

## **APPENDIX D: DETAILED METHODS OF ECONOMIC IMPACTS MODEL**

In this appendix, we present additional technical details of the economic impacts model.

#### **D.1. Converting Visitor Spending into Producer Value**

We used type II final demand multipliers from the U.S. Bureau of Economic Analysis's Regional Input-Output Modeling system (RIMS II). Type II multipliers are used to measure the economic impact of industry and household expenditures. These multipliers estimate the economic input using the *producer's value,* which excludes distribution costs such as transportation costs and wholesale and retail trade margins, but includes excise taxes collected and paid by producers (U.S. BEA, 2018). Producer values are calculated from expenditures using ratios from the RIMS II national distribution cost tables (Rebecca Bess, BEA, personal communication, August 20, 2009). Our analysis includes two expenditure categories that map to industries where we convert the consumer value (i.e., the visitor expenditures) into a producer value:

- Auto fuel costs are mapped into industry "petroleum and coal products manufacturing"
- Grocery and convenience stores are mapped into industry "food and beverage and tobacco product manufacturing."

Applying the ratios from the national accounts table, we assume 10.7% of the expenditures on auto fuel and 15.6% of expenditures on grocery and convenience stores flow into the local economy. These ratios are multiplied by the RIMS II multiplier for each of these industries.

## **D.2. Expenditure and Multiplier Tables**

In Table D-1, we present the expenditures by category included in our analysis as final demand changes. We report the expenses by category for marine-debris related activities, weighted by participation in each activity. Table D-2 presents final RIMS multipliers used in this study.

		Daily expenditures			
Expenditure category	RIMS II industry	Alabama	Delaware and Maryland	Ohio	Orange County, California
Auto fuel cost	24 Petroleum and coal products manufacturing	\$26.15	\$19.31	\$19.89	\$18.69
Auto rental cost	36 Transit and ground passenger transportation	\$3.77	\$0.55	\$2.48	\$3.00
Bus, taxi, etc.	36 Transit and ground passenger transportation	\$5.09	\$1.40	\$3.55	\$4.50
Parking, beach fees, etc.	63 Other services <sup>a</sup>	\$1.48	\$2.35	\$1.71	\$1.54
Lodging	61 Accommodation	\$39.33	\$27.77	\$27.07	\$24.86
Vacation package	$\frac{1}{2}$ accommodation – $\frac{1}{2}$ amusements	\$0.69	\$1.01	\$0.85	\$0.57
Restaurants, bars, etc.	62 Food services and drinking places	\$45.32	\$31.71	\$30.95	\$26.13
Grocery, convenience stores	19 Food and beverage and tobacco product manufacturing	\$16.54	\$7.87	\$9.69	\$8.71
Viewing whale, wildlife watching boat fees	38 Other transportation and support activities <sup>a</sup>	\$0.14	\$0.07	\$0.20	\$0.38
Viewing rental fees for sailboat, etc.	34 Water transportation	\$0.04	\$0.00	\$0.17	\$0.15
Water contact rented equipment, gear for snorkeling, etc.	60 Amusements, gambling, and recreation	\$0.00	\$0.00	\$0.00	\$0.33
Water contact rented equipment, gear for surfing, etc.	60 Amusements, gambling, and recreation	\$0.00	\$0.00	\$0.00	\$0.24
Water contact rented equipment, gear for kayaking, etc.	60 Amusements, gambling, and recreation	\$0.00	\$0.00	\$0.00	\$0.32
Outdoor rented equipment, gear for activities like biking, hiking, etc.	60 Amusements, gambling, and recreation	\$0.00	\$0.02	\$0.04	\$0.07
Outdoor rented equipment, gear for games like volleyball, frisbee, etc.	60 Amusements, gambling, and recreation	\$0.00	\$0.00	\$0.00	\$0.00
Outdoor horseback riding fees	60 Amusements, gambling, and recreation	\$0.00	\$0.00	\$0.00	\$0.00
<b>Total daily</b> expenditures		\$138.55	\$92.06	\$96.61	\$89.49

# **GREAT LAKES LAND-BASED MARINE DEBRIS ACTION PLAN ACCOMPLISHMENTS REPORT**

# *National Oceanic and Atmospheric Administration*

# **LIST OF ACRONYMS**

 This is an edited, reformatted and augmented version of a U.S. Department of Commerce on 2014-2019 Accomplishments Report, dated May 2014-May 2019.

## **INTRODUCTION**

The following document details accomplishments of the Great Lakes Land-based Marine Debris Action Plan. This Action Plan consisted of 53 actions, which were to be completed within five years (May 2014–May 2019). It is through the commitment, efforts, and care of the Action Plan's partners that there has been great progress made on the issue of marine debris in our community. Of the 53 actions in the Action Plan, contributors to the Great Lakes Land-based Marine Debris Action Plan successfully completed 34 actions, and are currently working on 17 actions. One action has not yet started, and another was removed during review.

The first workshop in the planning and development of the Action Plan brought the Great Lakes marine debris community together for the first time. Participants recognized the need and value of an action plan to promote collaboration, coordination, and raise awareness of each other's efforts. Through the process, multiple aspects of the marine debris issue were synthesized into shared goals that participants could work on together. Participants established diverse partnerships due to shared interests and networked across sectors. This collaborative approach has served as a model for other regional action plans around the United States.

Collectively, the group has helped to raise awareness of the marine debris issue in the Great Lakes through clear and consistent messaging. These developed partnerships amplified the voice and the role of freshwater in what has been largely considered an ocean problem. As a result, there has been increased attention and interest in research, policy, and management of marine debris within the Great Lakes.

The Great Lakes marine debris community made great strides to address the issue over the past five years. This includes completing research and publishing scientific articles, engaging with the policy and management community, educating the public and students, and removing debris from the environment. In total, 180,062 people were educated on the topic during 711 events and approximately 306,665 pounds of debris was removed by volunteers.

Semi-annual check-ins for the Action Plan were held via webinar in May and November of each year. During the webinars, participants heard and shared summaries of the progress of actions to date. Specifically, summary information was presented for each of the four goals in the Action Plan, completed actions were highlighted in presentations, and other high-level updates were given from action coordinators. The webinars ended with an open discussion of feedback on reporting, communications, and challenges. The majority of these webinars were recorded, and archived on the Great Lakes Marine Debris Collaborative Portal.

Action Plan participants reconvened in August 2019 to review these accomplishments, evaluate the Action Plan, discuss challenges, and plan for the future of marine debris efforts in the Great Lakes. While much progress has been made in addressing the issue, more work remains to see the Great Lakes free from the impacts of marine debris.

## **ACTION PLAN PURPOSE**

The overall purpose of the Great Lakes Land-based Marine Debris Action Plan is to establish a comprehensive framework for strategic action to ensure that the Great Lakes, its coasts, people, and wildlife are free from the impacts of marine debris.

## **ACTION PLAN STATUS**

The 2014-2019 Great Lakes Land-based Marine Debris Action Plan was completed in May 2019. Upon its completion, participants provided feedback on improvements to the Action Plan scope, structure, implementation, monitoring, and communication. Participants expressed an interest to build on successes and develop a new five-year Action Plan. The new 2020-2025 Great Lakes Land-based Marine Debris Action Plan will soon be publically available.

#### **MARINE DEBRIS GOALS, OBJECTIVES AND ACTIONS**

The Tables below are the core of the Action Plan. They list goals, objectives, and actions that contribute to achieving the Action Plan's goals.

## **GOALS**

• Goal 1: Research & Monitoring

Knowledge gaps are identified and filled through research and monitoring of land-based marine debris.

Goal 2: Science-based Approaches & Management

A science-based and strategic approach is used to guide land-based marine debris policy and management decisions in the Great Lakes.

Goal 3: Prevention & Education

Land-based marine debris is prevented and reduced through an educated and involved community.

• Goal 4: Removal & Tracking

The impacts of land-based marine debris are reduced through removal and tracking efforts.

#### **Objectives**

In the context of this Action Plan, the objectives define how each goal will be achieved. Typically, there are several objectives per goal.

### **Actions**

Actions are projects and activities supporting an objective, undertaken to achieve the associated goal.

In this Action Plan, Coordinators and Partners are entities that have volunteered to carry out a given action, pending the availability of resources (funding, staff, time, materials, etc.). Coordinators/Co-Coordinators were responsible for undertaking activities that fulfilled the action strategy and reported on the progress, challenges, and completion of the action. Partners were responsible for supporting and undertaking activities that fulfilled the action strategy and provided input on progress.

### **Vision**

The Great Lakes, its coasts, people, and wildlife are free from the impacts of marine debris.

#### **Mission**

The Great Lakes will be free from marine debris through an increased understanding of the problem, preventative actions, reductions in impacts, and collaborative efforts of diverse groups.

# **GOAL 1. RESEARCH AND MONITORING**

Knowledge gaps are identified and filled through research and monitoring of land-based marine debris.

## **Action Status**

- 7 Complete
- 6 In Progress
- 1 Removed.

# *Great Lakes Marine Debris Collaborative Portal (Objective 1.1)*

The NOAA Marine Debris Program, in cooperation with input from regional partners, developed a regional web-platform, the Great Lakes Marine Debris Collaborative Portal. Broader than a research platform, this tool provides the opportunity for all of those engaged in the regional marine debris community to share resources and ideas. Stakeholders submitted ideas on function and format for the platform, and provided input on the prioritization of features. The Collaborative Portal is also accessible to the public to serve as a tool for regional marine debris information. The site is available at https://greatlakes-mdc.diver.orr. noaa.gov/. This tool is currently being replicated in other regions around the country.

#### *Convened Researchers to Foster Collaboration (Objective 1.2)*

Marine debris researchers from around the region met at each of the last five annual conferences of the International Association of Great Lakes Research (IAGLR). Marine debris sessions at each of these conferences focused on microplastics in the Great Lakes environments and their sources, fates, and impacts. Each year, approximately 50 people attend the sessions, which generated discussions on the issue, as well as provided an opportunity for researchers to network and forge new collaborative opportunities.

#### *Completed a Research Summary and Gap Analysis (Objective 1.3)*

A synthesis paper, entitled "Plastic debris in the Laurentian Great Lakes: A review," was published in the March 2015 issue of the Journal of Great Lakes Research and authored by the research group at the University of Waterloo (doi:10.1016/j.jglr.2014.12.020). This work provided key information for attendees at an International Joint Commission (IJC) microplastics workshop in April 2016 and informed the identification of research gaps and recommendations to guide future research efforts. The IJC recommendations include:

- Communicate results of research to share information with the public of all ages and decision makers, through the development of Great Lakes focused educational materials.
- Encourage prevention of plastic marine debris through changing behavior by using education, outreach, policy, and market-based instruments.
- Assess the impacts of ecological and potential human health impacts using an ecological risk assessment framework (exposure/hazard).
- Compare and analyze existing programs and policies for the reduction and prevention of plastic marine debris and promote those that are good models for plastics management.
- Invest in solution-based research, including innovative product development and water infrastructure improvements.
- Conduct modelling to determine the sources and fate of microplastics in the Great Lakes.
- Enable the plastic industry, its clients and other Great Lakes stakeholders to enhance effective management and implementation of reduce, reuse, and recycle programs.
- Promote improved waste management and debris removal.
- Develop and strengthen binational Great Lakes linkages to support sharing of research, education and outreach programs, and best management practices.
- Develop and/or adopt standardized sampling and analytical methods for microplastics.

The IJC produced a final workshop report, which provided additional information on these recommendations. An updated research review is now in process from the University of Toronto.

#### *Management Community Connections (Objective 1.4)*

Conversations have begun to connect Great Lakes marine debris researchers with management agencies in an effort to foster collaborative research on relevant marine debris topics. This work is being done through the Plastic Working Group (PWG) in Cleveland, Ohio, as well as through science symposiums that were organized by ECCC.

### **Goal 1. Knowledge gaps are identified and filled through research and monitoring of land-based marine debris**

# **Goal 1. (Continued)**

## **GOAL 2. SCIENCE-BASED APPROACHES AND MANAGEMENT**

A science-based and strategic approach is used to guide land-based marine debris policy and management decisions in the Great Lakes.

### **Action Status**

- 5 Complete
- 5 In Progress
- 1 Not Started.

#### **Goal Accomplishments**

#### *Summary of Existing Marine Debris Policies (Objective 2.1)*

After reviewing policies from other regions, the Alliance for the Great Lakes and Keep America Beautiful created a list of categories and model examples of existing policies and best management practices. Based on this list, outreach began in 2017 across the Great Lakes basin to find relevant regional examples. The idea of a broad survey was eliminated due to logistical and practical concerns, and instead targeted outreach through the Great Lakes Landbased Marine Debris Action Plan list serve and other Great Lakes coalitions (such as the Healing Our Waters coalition) led to the creation of a list of communities that have implemented policies. Examples of these policies included bag bans/fees, bans on the use of single-use plastics in government facilities, public outreach campaigns, and social marketing campaigns. To date, few examples of local, county, or state level policies aimed at reducing marine debris appear to exist in the Great Lakes.

Based on the results of the outreach in 2017, it was determined that a toolkit for volunteer advocates would be the best way to encourage policies and best management practices in more communities. The toolkit, "Plastic-Free Great Lakes: An Advocacy Toolkit to Make a Difference in Your Community" was released by the Alliance for the Great Lakes on November 8, 2018 in conjunction with a public webinar. The toolkit features brief examples

of plastic pollution reduction policies and programs in the Great Lakes region and tools for volunteers to use in their advocacy to local and state policy makers.

## *Dissemination of Action Plan to Policy and Management Officials (Objective 2.2, Actions 2.2.1 and 2.2.2)*

Throughout the past five years, the Action Plan was presented 39 times, reaching approximately 1,796 policy and management representatives. Additionally, in 2014, the NOAA MDP, in partnership with state management programs (Coastal Zone Management Offices, Departments of Natural Resources or Environmental Quality), the Environmental Protection Agency, the Great Lakes Sea Grant Network, and the National Estuarine Research Reserves developed a contact list of relevant policy and management representatives from around the region. These contacts received the Great Lakes Land-based Marine Debris Action Plan via email on August 5, 2014.

#### **Goal 2. A science-based and strategic approach is used to guide land-based marine debris policy and management decisions in the Great Lakes**

#### **Goal 2. (Continued)**

# **GOAL 3. PREVENTION AND EDUCATION**

Land-based marine debris is prevented and reduced through an educated and involved community.

## **Action Status**

- 15 Complete
- $\bullet$  0 In Progress
- 0 Not Started.

#### **Goal Accomplishments**

All 15 of the actions outlined in Goal 3 were completed. Specific accomplishment highlights are below.

#### *Education Needs Assessment (Objective 3.1)*

In 2015, the Alliance for the Great Lakes interviewed Action Plan partners to identify a target audience for education efforts in the region. Based on feedback, it was determined that for this particular objective, the focus was on formal education, or education that takes place in a classroom setting. The Alliance for the Great Lakes compiled formal educational materials from partners around the region and attempted to review them for potential education gaps. However, they found it challenging to gather partners to analyze materials. Limited analysis has found many ocean-focused materials can simply be adapted for the Great Lakes region, but partners face time and document accessibility challenges, and difficulties adapting curricula that they do not own. Therefore, it was recommended that the adaptation of materials be the responsibility of owners.

#### *Awareness Campaign in Cleveland, OH (Objective 3.2)*

The City of Cleveland Mayor's Office of Sustainability, with the support of a NOAA Marine Debris Program Prevention Grant, identified barriers to the reduction of plastic marine debris and developed a community-based social marketing campaign to overcome these barriers. The goal of this project was to achieve lasting behavior change in Cleveland residents that would result in the reduction of littering, reduce the use of plastics, and increase proper disposal of plastics, which would ultimately reduce marine debris.

The pilot social marketing campaign, Don't Break the Lake, utilized various communication tools and methods, including signage at water refill stations and in grocery stores, an insert in mailed water bills, outreach through social media, and the purchase and giveaways of reusable bags and bottles. Preliminary grocery store results indicate that the number of reusable bags used in the store increased as a result of the campaign.

Number of informal education activities on land-based marine debris per lake, with the public:

Number of informal education activities on land-based marine debris per lake, with targeted audiences.

# **Outreach Highlights**

## **Goal 3. Land-based marine debris is prevented and reduced through an educated and involved community**

# **GOAL 4. REMOVAL AND TRACKING**

The impacts of land-based marine debris are reduced through removal and tracking efforts.

## **Action Status**

- 8 Complete
- 5 In Progress
- 0 Not Started.

## **Goal Accomplishments**

#### *Bi-Nationally Remove Marine Debris (Objective 4.1)*

The Alliance for the Great Lakes, the Great Canadian Shoreline Cleanup, the Ocean Conservancy, Partners for Clean Streams, and other volunteer cleanup organizations have annually reported the amount of debris removed from Great Lakes shorelines. Over the past five years approximately 306,665 pounds (153.3 tons) of land-based marine debris was removed from the environment by volunteers. This included collaborating with industry and manufacturers, such as Dow Chemical and Amcor, on volunteer employee cleanups. Additional cleanup opportunities are found on the Great Lakes Marine Debris Collaborative Portal.

*Best Management Practices for Removing and Preventing Debris (Objective 4.2)*

The Ohio Clean Marinas Program adapted marine debris removal best management practices (BMPs) for the marina and boating community and incorporated these BMPs into the Program's outreach materials. In spring 2018, a revised Clean Marina Program Tiered Checklist was completed, with the following required BMPs specifically addressing landbased marine debris removal:

- Cigarette disposal containers are available for patrons and staff.
- Collection bins for solid recyclables are available throughout the marina.
- Trash cans are emptied and litter pick-ups are conducted within the marina and along the shoreline daily.
- Derelict vessels are removed from the property.
- Shrink wrap is recycled or dry rack storage is available for winterization of boats.
- All storm drains are labelled to notify patrons of outfall points (i.e., "No Dumping, Drains to Lake").
- Boaters are required to sign an environmental commitment pledge.

In summer 2018, staff began certifying marinas using this revised checklist, and collaborated with Cuyahoga and Summit County Soil and Water Conservation Districts to provide Clean Boater BMPs as part of their outreach materials and social media posts.

Additionally, Old Woman Creek National Estuarine Research Reserve (OWC NERR) has begun to construct, paint, disseminate, and track monofilament fishing line recycling receptacles along Ohio's Lake Erie coastline. These recycling bins are placed at prominent fishing piers, marinas, beaches, and parks. Line is collected by volunteers and shipped to Berkley, Inc. to be recycled into other fishing products. OWC NERR has hosted workshops to educate adopters on the benefits of removing gear from the environment, and how to care for a bin.

## **Goal 4. The impacts of land-based marine debris are reduced through removal and tracking efforts**

# **Goal 4. (Continued)**

*Chapter 113*

 $\overline{a}$ 

# **STATEMENT OF ANNE KINSINGER, ASSOCIATE DIRECTOR FOR ECOSYSTEMS**

Chair McCollum, Ranking Member Joyce, and members of the Subcommittee, thank you for the opportunity to testify today regarding marine debris work conducted by the United States Geological Survey (USGS). The USGS conducts research and monitoring related to marine debris. Although we currently do not have an extensive program in this area, marine debris is becoming an increasingly important issue in the management of the Department of the Interior (DOI) trust lands and species, and we anticipate increased programmatic focus in future years.

My testimony today will focus on large debris and the breakdown products of that debris.

# **ROLE OF THE U.S. GEOLOGICAL SURVEY**

The USGS is the science agency of the DOI with a mission to provide unbiased scientific information to Federal and non-Federal resource managers and planners, emergency response officials, and the public. Debris, and the breakdown products of debris, are receiving increased attention due to possible impacts on fish and wildlife, particularly in the marine environment. The DOI has land management and administrative responsibilities for numerous coastal and estuarine units of the national park system, national wildlife refuges, public lands, Indian lands, U.S. territorial islands, and other insular areas that have documented or potential impact from marine debris. In addition, the DOI has management responsibilities for migratory birds, interjurisdictional fish, federally listed species, and marine mammals that may be impacted by marine debris outside DOI managed lands.

The Department of Commerce, through the National Oceanic and Atmospheric Administration's Marine Debris Program (MDP), leads national efforts to research, prevent, and reduce the impacts of marine debris. The MDP is authorized by Congress as the Federal lead to work on marine debris through the Marine Debris Act, and last October was reauthorized for an additional five years.

This is an edited, reformatted and augmented version of U.S. Geological Survey, Department of The Interior Before The Subcommittee on Interior, Environment, and Related Agencies House Committee on Appropriations on Marine Debris Publication, Dated September 19, 2019.

Over the past 10 years, the USGS has published marine debris research in the following three areas:

*Coastal Surveys:* This research comprised the design, conducting, or analysis of shoreline and benthic surveys for marine debris in Hawaii, Alaska, Caribbean, Gulf of Mexico, Mediterranean, and Pacific Islands, including Midway Atoll. These studies were designed to establish baseline conditions on specific lands important to the DOI; understand trends in marine debris accumulation over larger geographic areas; or characterize composition and transport of marine debris with potential to impact lands or species of concern. Many of these surveys involve the use of volunteers through citizen science programs.

*Species Impacts*: These studies focused on the incidence of ingested marine debris by sea turtles and seabirds, including black-footed albatross chicks. The purpose of these studies was to quantify the occurrence of marine debris in the digestive tract of species that utilize marine food sources in order to begin understanding if marine debris ingestion impacts survival of individuals or persistence of populations among species of concern.

*Contaminants*: This analysis examined the incidence of contaminants in ingested marine plastics, including those sorbed onto the plastics and those leached from the plastics. Endocrine disrupting compounds are one example. The purpose of these studies was to begin understanding if marine debris, particularly fragmented plastics, is a source of contaminants such as endocrine disruptors that can harm species directly or through decreased reproduction when ingested.

Although USGS and other science organizations have conducted research in these areas and other areas of marine debris, many unanswered questions remain related to the potential for marine debris to pose harm to lands or species managed by the DOI. This list is partially based on expert opinion of leading researchers from around the world that was published in  $2014<sup>1</sup>$  as well as a growing body of recent journal review articles identifying key knowledge gaps.

- 1. What are the impacts of marine debris on important coastal and marine habitats?
- 2. What are the impacts of marine debris on critical food webs?
- 3. Which species are most susceptible to marine debris impacts at the individual or population level?
- 4. What are the main sources of marine debris and what factors drive transport and deposition?
- 5. Does marine debris carry or concentrate contaminants of concern to wildlife when ingested?
- 6. What are standard approaches for the quantification of marine debris in coastal habitats?
- 7. How does marine debris contribute to the transport of invasive species and wildlife disease?
- 8. Are impacts of debris the same in freshwater systems and the Great Lakes as they are in marine environments?

l

<sup>1</sup> Vegter, et al. 2014. Global research priorities to mitigate plastic pollution impacts on marine wildlife. Endangered Species Research 25: 225-247.

## **USGS CAPABILITIES**

The USGS maintains extensive capability to conduct physical and biological research and monitoring in support of natural resource management by DOI bureaus and other Federal, State, and tribal partners. Capabilities available to help resolve questions related to marine debris include population assessments to determine changes in species numbers over time, trophic analysis for determining disruptions in food webs, physical assessments and remote sensing capabilities to determine habitat condition and changes due to environmental stressors, and contaminants research for determining the source, transport, fate, exposure pathways, and impact of compounds on species and their habitats. In addition, the USGS maintains specialized facilities in fish and wildlife disease diagnostics to determine the cause of animal fatalities and advanced genetics and genomics capability to detect and track new species and wildlife diseases using environmental DNA (eDNA). The USGS is a national leader in design and analysis of scientifically defensible surveys, including effective use of citizen science to engage the public in gathering scientific data. Finally, the USGS has invested significant resources in developing invasive species detection, tracking, and control technologies that may be important in understanding and managing secondary effects of marine transport in global ecosystems.

Thank you for this opportunity to testify today. I would be happy to answer any questions you may have.

*Chapter 114*

 $\overline{a}$ 

# **STATEMENT OF STEPHEN GUERTIN, DEPUTY DIRECTOR U.S. FISH AND WILDLIFE SERVICE, DEPARTMENT OF THE INTERIOR**

Good morning Chair McCollum, Ranking Member Joyce, and members of the Subcommittee. Thank you for the opportunity to discuss marine debris and its impact on wildlife. My testimony will focus on the U.S. Fish and Wildlife Service's (Service) role in addressing the threat of marine debris to our ocean and coastal areas.

## **MARINE DEBRIS OVERVIEW**

Marine debris is one of the most pervasive global threats to the health of the world's coastal areas, oceans, and waterways. It is an issue of local, regional, national, and international concern. Marine debris can injure or kill marine and coastal wildlife; damage and degrade habitats; interfere with navigational safety; cause economic loss to fishing and maritime industries; degrade the quality of life in coastal communities; and threaten human health and safety. The Service works collaboratively with Federal and non-Federal partners to address marine debris and its impacts on wildlife.

Marine debris is defined as "any persistent solid material that is manufactured or processed and directly or indirectly, intentionally or unintentionally, disposed of or abandoned into the marine environment or Great Lakes" (33 U.S.C. 1951 et seq., as amended by in 2012 by Title VI of Public Law 112-213 and 2018 by Public Law 115-265). Anything man-made – such as fishing gear, plastic bags, beverage bottles, balloons, food wrappers, and even vessels – can become marine debris through dumping, improper waste management, litter that is blown or washed out to sea through storm drains, and extreme natural events which can transport both small and large items into the ocean. Major marine debris events caused by natural disasters, such as the 2017 hurricanes Harvey, Irma and Maria and 2018

This is an edited, reformatted and augmented version of Statement Before the Subcommittee on Interior, Environment, and Related Agencies House Committee on Appropriations on Marine Debris , dated September 19, 2019.

typhoon Yutu, continue to bring national and international attention to the marine debris issue.

It is believed that at least 8 million tons of plastic end up in our oceans every year, and make up 80 percent of all marine debris from surface waters to deep-sea sediments. The National Oceanic and Atmospheric Administration (NOAA) estimates there are somewhere between 20 million and 1.8 billion pieces of plastic along the coastline of the United States, with the number likely at the upper end of this range. Marine debris can be found even in the deepest parts of our ocean.

For example, a plastic bag was documented in 2016 by the Okeanos Explorer submersible at Enigma Seamount in the Arc of Fire National Wildlife Refuge, part of the Marianas Trench Marine National Monument.

There are three main types of marine debris that impact wildlife: plastics, derelict fishing gear, and abandoned and derelict vessels. Each is discussed briefly below.

#### **Plastics and Microplastics**

Plastics are one of the most extensive types of marine debris. They are commonly used in many items, and as society has developed new uses for them the variety and quantity of plastic items found in the marine environment has increased dramatically. Plastics are now known to break down into smaller components, called microplastics. Microplastics and their associated toxic chemical components contribute to human and wildlife health risks as the toxic microplastics are ingested and move through the marine food web.

The impact of these plastics isn't limited to our oceans. Research in 2014 discovered that plastic particle counts reached one million plastic particle parts per square mile in Lake Erie, with higher counts found in Lake Ontario;<sup>1</sup> The Great Lakes have among the highest densities of microplastics recorded. Microfibers, a type of microplastic, are also pervasive in the marine environment, and while our knowledge of the impacts of microfibers is limited, they make up the majority of microplastics, and can even be found in the seafood we consume.

Plastics such as bottle caps, balloons, and lighters are mistaken for food or the debris item may have been attached and ingested accidentally with other food by wildlife such as sea turtles, seabirds, and marine mammals. Plastic ingestion leads to loss of nutrition, internal injury, intestinal blockage, starvation, and death in wildlife. Seabirds are especially vulnerable to plastic pollution; a recent study found plastic in 90 percent of seabirds.<sup>2</sup> In addition to plastic ingestion, other debris such as packing bands, balloon strings, rubber bands, six-pack rings, and mesh bags can lead to entanglement. Entanglement affects many different types of animals: 44 sea bird species, nine cetacean species, 11 pinniped species, 31 invertebrate species/taxa, and six sea turtle species reported entangled in marine debris in the United States.<sup>3</sup> Recovery Plans for Endangered Species Act listed loggerhead, leatherback,

 $\overline{a}$

<sup>2</sup> Wilcox, C., E. V. Sebille, and B. D. Hardesty. 2015. Plastic in seabirds is pervasive and increasing. Proceedings of the National Academy of Sciences 201502108; DOI: 10.1073/pnas.1502108112.

<sup>&</sup>lt;sup>3</sup> National Oceanic and Atmospheric Administration Marine Debris Program. 2014 Report on the Entanglement of Marine Species in Marine Debris with an Emphasis on Species in the United States. Silver Spring, MD. 28 pp.

green, and Kemp's Ridley sea turtles all list marine debris as one of the highest priority threats facing these protected species.

#### **Derelict Fishing Gear**

A second highly visible and impactful form of marine debris is derelict fishing gear (DFG). DFG has numerous impacts on the environment, including: damaging marine habitats, entangling marine species including seabirds and marine mammals, creating hazards to navigation, and ghost fishing of commercially important species resulting in lost catch opportunities and economic losses for fishermen. One of the most notable types of impacts from this type of marine debris is wildlife entanglement. Derelict nets, ropes, line, or other fishing gear can wrap around marine life. Entanglement has led to injury, illness, suffocation, starvation, and death.

Sea turtles are at great risk for entanglement in marine debris, and this has caused injuries and in many cases death for a variety of sea turtle species. One study found that between 1997–2009, over 1,000 sea turtles were found stranded in Florida due to entanglement in fishing gear.<sup>4</sup> Some of these entanglements resulted from netting and monofilament line that accumulated on both artificial and natural reefs. These areas are often heavily fished, resulting in snagging of hooks and discarding of lines. Turtles foraging and/or resting in these areas can become entangled and drown.

Bird species become entangled when swimming in bodies of water where line and netting is carelessly discarded, and sometimes use fishing line and netting fragments as nesting material, which can lead to entanglement of both the parents and chicks. Easy solutions for responsible fishers include proper disposal of monofilament line and awareness of safe procedures for de- hooking and disentangling entrapped birds.

#### **Abandoned and Derelict Vessels**

 $\overline{a}$ 

Abandoned and derelict vessels (ADVs) are a third highly visible type of marine debris with thousands littering our nation's coastal waters. ADVs threaten oceans, coasts, and waterways by obstructing navigational channels, causing harm to the environment, and diminishing commercial and recreational activities. ADVs may pose an immediate or future threat to wildlife and wildlife habitat from the release of hazardous substances to surrounding areas. ADVs may occur in large numbers, following a natural disaster such as a hurricane, or as a single vessel.

Following the 2017 hurricanes, the Service and its partners removed damaged vessels from Florida, Puerto Rico, U.S. Virgin Islands National Wildlife Refuges and adjacent communities.

ADVs occurring in remote locations are difficult to reach for cleanup and assessment of the impacts. Removal of such ADVs is very expensive and technical. As an example, in 1993

<sup>4</sup> Adimey, N.A, C.A. Hudak, J.R. Powell, K. Bassos-Hull, A. Foley, N.A. Farmer, L. White, and K. Minch. Fishery gear interactions from stranded bottlenose dolphins, Florida manatees and sea turtles in Florida, U.S.A. Marine Pollution Bulletin 81: 103-115.

Jin Shiang Fa wrecked at Rose Atoll National Wildlife Refuge in American Samoa. Although the sum of the wreck was removed initially by the responsible party, over 215 tons of debris were left behind on the perimeter of the reef and lagoon when funds ran out. Iron debris from the wreck caused an overgrowth of cyanobacteria, which the Service and partners continue to monitor. The Service has also removed nearly one million pounds of shipwrecks at Palmyra Atoll and Kingman Reef National Wildlife Refuges, which fueled outbreaks of algae and invasive corallimorphs.

# **EXAMPLES FROM ACROSS THE NATIONAL WILDLIFE REFUGE SYSTEM**

The National Wildlife Refuge System (Refuge System), managed by the Service, is the world's premier network of public lands devoted to conserving wildlife and habitat for the benefit of future generations. There are over 850 million acres of land and water in the Refuge System, which preserves a diverse array of terrestrial, wetland, and ocean ecosystems. The Refuge System plays an essential role in providing outdoor recreation opportunities to the American public and the associated economic benefits to local communities. The Refuge System includes more than 180 refuges and over 750 million acres that protect ocean, coastal or Great Lakes habitats. Spanning from above the Arctic Circle to south of the Equator, the Refuge System protects an incredible diversity of marine and coastal ecosystems, including salt marshes, rocky shorelines, tide pools, sandy beaches, kelp forests, mangroves, seagrass meadows, barrier islands, estuaries, lagoons, tidal creeks, tropical coral atolls, as well as open ocean. Marine debris is an issue that impacts coastal and island refuges across the country. Examples include:

#### **Northwestern Hawaiian Islands and Midway Atoll National Wildlife Refuges**

The Northwestern Hawaiian Islands are made up of dozens of tiny islands, atolls and shoals, spanning 1,200 nautical miles of the world's largest ocean. These remote islands and atolls are home to an ecosystem that hosts more than 7,000 species, including marine mammals, fishes, sea turtles, birds, and invertebrates. At least one quarter are endemic and found nowhere else on Earth. These remote islands are rarely visited, and often considered to be some of the most pristine places on earth. However, plastic from the "Great Pacific Garbage Patch," an enormous area where high concentrations of litter – the majority of which are microplastics – accumulates here.

Annual accumulation of marine debris within the Papahānaumokuākea Marine National Monument, which includes the Midway Atoll and Northwestern Hawaiian Islands National Wildlife Refuges, is estimated at 52 metric tons per year.<sup>5</sup> Much of this debris is comprised of derelict fishing gear: 848 metric tons (more than 900 tons or 1.9 million pounds) have been recovered since 1996. The Northwestern Hawaiian Islands are home to approximately 70 percent of the tropical, shallow-water coral reef habitat in the nation. Derelict fishing gear

l

<sup>5</sup> O. J. Damero, M. Parke, M. A. Albins, and R. Brainard. 2007. Marine debris accumulation in the Northwestern Hawaiian Islands: An examination of rates and processes. Marine Pollution Bulletin 54:4, p. 423-433.
threatens these reefs, as well as the threatened and endangered turtles, dolphins, seals, and other wildlife that inhabit them.

Tern Island is an important nesting site for Hawaiian green sea turtles, a monk seal pupping site, and home to many bird species. There, storms have eroded the islands' shores, exposing debris that entraps monk seals and sea turtles. Midway Atoll is home to nearly three million birds, including endangered Laysan ducks, the world's largest albatross colony, and 19 other seabird species. The oldest known wild bird continues to nest at Midway, a Laysan albatross named Wisdom that is at least 68 years old and currently raising another chick. Albatross scour thousands of ocean miles in search of food for their young. Along with fish, they scoop up plastic debris. The stomachs of nearly all dead albatross chicks contain plastic (e.g. cigarette lighters, parts of toys, and fishing gear) all fed to them by their parents. It is estimated that albatross carry over 5 tons of plastic to Midway each year to feed their chicks. Another 5-10 tons of marine debris washes up on Midway beaches each year. Recent studies indicate that there is a 20.4 percent chance of lifetime mortality for seabirds ingesting a single debris item, rising to 100 percent after consuming 93 items.<sup>6</sup>

The Service partners with NOAA and the U.S. Coast Guard to remove much of the marine debris on Midway and in the Northwestern Hawaiian Islands. The nets and plastics are brought back to Honolulu aboard the NOAA ship or charter vessel. A key partner in the recycling process, Schnitzer Steel (a metal recycling company) chops the fishing nets into small pieces. The net pieces are then transported to the City and County of Honolulu's H-Power Plant (a Covanta Energy Corporation facility), where they are safely incinerated to produce electricity for the island of Oahu.

#### **Maine Coastal Island National Wildlife Refuge Complex**

l

The Maine Coastal Islands National Wildlife Refuge Complex consists of five individual refuges that span the coast of Maine and support an incredible diversity of habitats, including coastal islands, forested headlands, estuaries, and freshwater wetlands. All totaled, the Refuge includes approximately 8,238 acres of diverse coastal Maine habitats, including forested and non-forested offshore islands, coastal salt marsh, open field, and upland mature spruce-fir forest. The majority of the islands within the refuge are considered nationally significant nesting islands and support endangered and threatened species, colonial nesting seabirds, wading birds, and waterfowl.

The islands and Refuge shoreline accumulate marine debris throughout the year, but especially during seasonal storms and high tides when debris, including derelict lobster traps, washes ashore. This derelict gear poses threats to the breeding birds that use the islands for nesting.

Cleanups held by the Refuge in past years have collected over 19,200 pounds of marine debris from a 0.66 mile section of shoreline. The Refuge continues to work with the community and partners, such as Maine Audubon, to support cleanups. Planning cleanup efforts on Refuge islands is logistically challenging as it requires calm seas, and volunteers and transportation to/from the cleanup site, as well as transfer of the debris to the mainland.

<sup>6</sup> L. Roman, B.D. Hardesty, M. A. Hindell, and C. Wilcox. 2019. A quantitative analysis linking seabird mortality and marine debris ingestion Scientific Reports v. 9, Article number: 3202.

### **Florida Keys National Wildlife Refuge Complex**

The Florida Keys National Wildlife Refuges Complex includes Key West National Wildlife Refuge, Great White Heron National Wildlife Refuge, and Crocodile Lake National Wildlife Refuge. Key West Refuge is among the first refuges established in the United States. President Roosevelt created the Refuge in 1908 as a preserve and breeding ground for colonial nesting birds and other wildlife. The Refuge encompasses 208,308 acres of land and water, only one percent of which (2,019 acres) is land. It contains vital feeding, breeding areas, and nesting beaches for both green and loggerhead sea turtles.

In 2017, Hurricane Irma delivered a significant blow to the communities and wildlife of the Florida Keys. The storm broke up fragile coral reefs, uprooted sponges, and blanketed the seafloor with sediment. Irma also left in its wake a significant amount of marine debris, which may float subsurface, making navigation challenging, or become submerged, causing damage to reef resources. An estimated 1,800 vessels sunk due to the hurricane, many of which were in the Keys, and Florida lobstermen estimated losing over 150,000 traps. Refuge beaches, important for nesting sea turtles and surrounded by seagrass habitats where turtles forage, were heavily impacted during the height of nesting season. The traps, ropes and buoys created dangerous obstacles for sea turtles and other wildlife. Following the hurricane, Refuge staff engaged in a complex exercise alongside Federal, State, and local partners to clean up Refuge lands and waters. Today, the Refuge continues to repair/restore infrastructure and habitats impacted by the storm, and to study impacts of resulting marine debris on wildlife resources.

#### **CONCLUSION**

The scope of marine debris and its impacts on wildlife is serious. The effects of marine debris can be observed at most of the Service's coastal and island refuges across the country. It also affects many species, including threatened and endangered plants and animals that the Service is working to recover. Preventing and cleaning up marine debris can be addressed by ensuring a comprehensive approach that is local in scale and global in scope, directed primarily at source prevention and education. Investing in prevention and education will reduce the threat of marine debris to wildlife and habitats, and future conservation efforts are likely to be less costly, more flexible, and more successful over time.

Addressing marine debris is a complex task that requires the engagement of multiple Federal agencies, State and local governments, Tribes, industry, and the international community. To that end, the Service participates in the Interagency Marine Debris Coordinating Committee (IMDCC), a multi-agency group tasked with ensuring that this comprehensive approach is implemented. The unanimous passage and 2018 signing of the Save our Seas Act, which extended NOAA's marine debris program for five years and focused efforts on addressing the waste stream at an international level, was also an important step towards addressing the problem of marine debris.

Marine debris is preventable through increased public awareness, changing individuals' behaviors, and movement towards an economy of reduced pollution and waste. The Service works to educate visitors to National Wildlife Refuges on the impacts of marine debris to humans and wildlife, and benefits from the commitment of hundreds of volunteers who participate in marine debris cleanups and citizen science on our National Wildlife Refuges. We are also working with Federal and non-Federal partners to better understand the causes and effects of marine debris, identify strategies to address this issue, and educate the public on ways they can be a part of the solution.

*Chapter 115*

 $\overline{a}$ 

# **TESTIMONY OF CHRISTY LEAVITT, CAMPAIGN DIRECTOR, OCEANA**

Good morning. Thank you, Chairwoman McCollum, Ranking Member Joyce and members of the committee for the opportunity to testify on marine debris and plastic pollution. My name is Christy Leavitt, and I am the plastics campaign director with Oceana. Oceana is the largest international advocacy organization dedicated solely to ocean conservation. We work in North America, South America, Europe and the Philippines to advocate for science-based policies that will restore the ocean's abundance and biodiversity. Oceana has protected more than 4.5 million square miles of ocean habitat and won 200 victories to stop overfishing, habitat destruction, pollution and killing of threatened species.

## **OCEANS ARE CRITICAL TO LIFE ON EARTH**

Oceans cover more than 70% of the Earth's surface and are critical to life on the planet. Over 50% of the Earth's oxygen comes from the oceans, supplying us with the air we breathe. More than 3 billion people worldwide depend on the ocean for their livelihoods. In the United States specifically, over half of the population lives in coastal communities, and the country derives \$280 billion a year from the ocean economy with three-quarters of U.S. trade being marine-based.

Oceans hold 97% of the world's water and also deliver some vital fresh water to land in the form of rain derived from ocean water evaporation. Oceans are home to a million species, according to Census of Marine Life, many of which have yet to be described. The powerful circulation of the atmosphere and the regulation of the climate are driven by the heat generated in equatorial seas, which is transported by currents to the Earth's poles. The climate crisis would be far worse if the oceans did not absorb and store 25% of the planet's carbon dioxide emissions.

This is an edited, reformatted and augmented version of Testimony before House Committee on Appropriations Subcommittee on Interior, Environment, and Related Agencies, dated September 19, 2019.

Despite the ocean's importance to life on Earth and the livelihoods of billions of people, humanity has altered or destroyed marine ecosystems and driven marine species to the brink of extinction. And now, as one scientist put it, the oceans are literally spitting plastic back at us with every wave. $<sup>1</sup>$ </sup>

## **PLASTIC POLLUTION IS A GROWING PROBLEM FOR OCEAN HEALTH**

Plastic pollution is a growing threat to the world's oceans, as well as our food, health and climate. Each year, an estimated 17.6 billion pounds of plastic enters the marine environment. This is roughly equivalent to a garbage truck full of plastic being dumped into the oceans every minute.<sup>2</sup> Freshwater lakes also suffer from plastic pollution. The Great Lakes, for example, are flooded with 22 million pounds of plastic annually.<sup>3</sup>

As of 2015, 8.3 billion metric tons of plastic have been produced, and 79% of that became waste, accumulating in landfills, on the ground or in the ocean.<sup>4</sup> None of that plastic in the environment ever goes away; it simply breaks up into smaller and smaller pieces.

More than 40% of all plastic produced is for packaging, most of which is used once and thrown away.<sup>5</sup> Single-use plastic is profoundly flawed by design. Bottles, grocery bags, utensils and other products are made from a material created to last forever even though these products are designed to be thrown away after one use.

Plastic pollution is everywhere. Scientists have found it around the globe, floating on the surface of the ocean, washing up on the world's most remote coastlines, melting in Arctic sea ice and even sitting at the deepest part of the ocean floor nearly 7 miles beneath the surface.<sup>6,7,8</sup> Plastic also has been found in rain in the Rocky Mountains and in the air above the secluded French Pyrenees mountains.<sup>9,10</sup>

As plastics continue to flood into the oceans, the list of marine species affected by plastic debris expands. A piece of plastic can look like food to a fish, turtle, marine mammal or bird.

We are seeing increasing reports of dead whales beached with bellies full of plastic debris.<sup>11</sup> Tens of thousands of individual marine organisms — almost 700 species — have been observed suffering from entanglement or ingestion of plastic permeating the marine environment. <sup>12</sup> Plastic ingestion and entanglements can lead to death by starvation or suffocation. Ingested plastic may also cause ulcers or punctures and impair feeding, growth, mobility, reproduction and behavior.<sup>13,14</sup> Scientists estimate that 90% of seabird species have ingested plastic, and a 2019 study investigating plastic in 102 sea turtles found plastic in every individual.<sup>15,16</sup> Even zooplankton, tiny marine organisms that form the base of the ocean food chain, are eating plastic, which can then accumulate in larger ocean predators like fish.

Ultimately plastic breaks up into microplastics, which are pieces of plastic smaller than 5 millimeters. Microplastics act as magnets for harmful chemical pollutants. <sup>17</sup> When eaten by fish and shellfish, some of those contaminants from microplastics may work their way into our food supply. <sup>18</sup> Everything from salt to water to beer has been found to contain microplastics.<sup>19</sup> Scientists are still studying how humans might be affected by the plastics that are making their way into our food,water and air.

While we begin to realize the extent of plastic pollution's effects on the oceans, plastic production is increasing at a rapid rate. The petrochemical industry is investing significantly in the future of plastic production. Global production of plastics has outpaced all other bulk materials — including steel, aluminum and cement — and has nearly doubled since the start of the millennium.<sup>20</sup> It's now projected to increase at least fourfold between 2014 and 2050.<sup>21</sup> As plastic production increases, so will the amount of plastic entering the ocean. Projections show a threefold increase of the amount of plastic in the ocean between 2015 and 2025.<sup>22</sup>

## **SOLUTION: REDUCE PLASTIC POLLUTION AT THE SOURCE**

Recycling is not enough to solve the plastic pollution crisis. Waste-management solutions have not adequately dealt with plastic pollution in the past and cannot realistically keep up with the rising rates of plastic production. Only 9% of all the plastic ever produced has been recycled.<sup>23</sup> Unless companies change course, more plastic will inevitably end up in the ocean.

The solution to the plastic pollution problem is clear: Reduce the amount of plastic produced.

Oceana is focused on stopping plastic pollution from entering the oceans by reducing the amount of single-use plastic being produced at the source. We're calling on companies to significantly reduce the amount of plastic they are putting on the market and offer consumers plastic-free choices for their products. Whether it's a hotel room, supermarket aisle or restaurant, the onus should be on the manufacturers and retailers responsible for creating and selling throwaway plastics – not the consumers. Oceana is also calling for policy change at the local, state and national levels that will require companies to reduce plastic production and use.

# **GOVERNMENTS PLAY A CRITICAL ROLE IN REDUCING PLASTIC POLLUTION**

While the responsibility to reverse the plastic pollution crisis should primarily fall on companies, governments play a critical role in moving society away from plastic, especially when companies are not motivated to change their ways. Policies governing the production and use of plastic can be effective in curbing the plastic pollution problem.

The United States has often been an international leader on environmental issues, but unfortunately it's falling behind other countries on addressing the plastics crisis on the national level. U.S. cities, towns, counties and states are not waiting for federal action and are instead leading the way in regulating single-use plastics. Around the world, other countries are announcing and implementing policies to reduce plastic pollution. The federal government should learn from these actions and implement national policies to stem the flow of plastic into our environment.

Local, state and national policies often focus on the plastic waste most commonly found on beaches, including plastic beverage bottles, grocery bags, straws, stirrers, lids, cups, foam and other containers. Policies like bans, fees, taxes, deposit return systems and extended producer responsibility can reduce plastic production, use and pollution.

U.S. cities, towns, counties and states that have taken action on plastics include:

- More than 450 cities and counties and seven states that have passed bans or put fees on plastic bags;
- *Washington, D.C*., which passed a 5-cent plastic- and paper-bag fee in 2009 that resulted in more than a 60% reduction in single-use carryout bag consumption and reduced plastic bag litter in D.C.'s Anacostia River;<sup>24</sup>

<sup>&</sup>lt;sup>23</sup> Geyer R, Jambeck JR and Law KL (2017) Production, use, and fate of all plastics ever made.

<sup>&</sup>lt;sup>24</sup> D.C. Department of Energy and Environment & Alice Ferguson Foundation (2013) D.C. Resident and Business Bag Use Surveys. Opinion Works. 18p.

- *Chicago, Illinois,* which passed a 7-cent tax on both paper and plastic single-use bags at all stores, effective February  $2017<sup>25</sup>$  The bag tax resulted in a 42% reduction in the number of single-use bags consumers used per trip to the store;  $26$
- More than 200 cities and counties that have passed polystyrene, or foam, bans;
- *Maine, Maryland and Vermont*, which passed statewide polystyrene bans in 2019;
- *St. Paul, Minnesota*, which passed a law in 2019 requiring restaurants and stores to use compostable or recyclable packaging for to-go and takeout containers. The law will go into effect in  $2021$ ;<sup>27</sup>
- Michigan, which implemented a bottle-deposit law in 1978, requiring a 10-cent deposit on certain containers under 1 gallon in size. <sup>28</sup> In 2017, Michigan's redemption rate was  $91.2\%$ ;<sup>29</sup> and
- Berkeley, California, which passed a comprehensive foodware ordinance in 2019 that ultimately will require food vendors to use only reusable foodware, with a few compostable exceptions.<sup>30</sup>

Other countries and regions have taken action to reduce single-use plastics, including:

- *The European Union*  In 2018, the European Union announced a phaseout of single- use plastics by 2021. The Single-Use Plastics Directive bans single-use plastic products, including plates, cutlery, polystyrene food and beverage containers, and other items that are estimated to represent 85% of single-use plastic found on beaches in the Union.<sup>31</sup>
- *Canada* In June 2019, Canada announced plans to develop a strategy to address and reduce priority single-use plastics by the end of 2021.<sup>32</sup>
- *Peru* In December 2018, Peru passed a law regulating throwaway plastics, which bans single-use plastics from sensitive areas like beaches and national parks; taxes plastics bags; and limits the manufacture and use of a broad swath of disposable plastics.<sup>33</sup>

The United States should join with the rest of the world and follow the lead of cities and states around the country to regulate the production and use of single-use plastic. Federal policies must enable states and localities to continue to lead the way and implement stronger regulations on plastics.

Thank you again for the opportunity to testify on the plastic pollution crisis threatening the future of our oceans.

# **WRITTEN TESTIMONY OF LINSEY E. HARAM, RESEARCH ECOLOGIST, SMITHSONIAN ENVIRONMENTAL RESEARCH CENTER**

# *Linsey E. Haram*

## **INTRODUCTION**

Thank you, Chair McCollum, Ranking Member Joyce, and members of the Subcommittee for the opportunity to come before you today to testify on behalf of the Smithsonian Institution. My name is Linsey Haram, and I am a marine ecologist from the Smithsonian Environmental Research Center, where I study how plastic marine debris alters the dispersal and distribution of marine organisms across oceans.

The Smithsonian Environmental Research Center, or SERC, is a world leader in environmental research, especially in coastal marine ecosystems. SERC scientists are based at core laboratories on the Chesapeake Bay and San Francisco Bay, and work with collaborators across a truly global network of sites. Primarily funded by grants and contracts through such agencies as the U.S. Coast Guard, the National Science Foundation, the National Oceanic and Atmospheric Administration, the Department of Defense, and many others; SERC research aims broadly to understand fundamental ecological processes and changes at the land-sea boundary.

One area of focus at our facility is the study of marine invasive species, which is my area of expertise. The Marine Invasions Research Lab at SERC is the largest research program in the nation on biological invasions in coastal marine waters. Biological invasions occur when species are transferred by human activities to new (unoccupied) areas, where they establish new populations and spread, sometimes resulting in unwanted economic and ecological

This is an edited, reformatted and augmented version of Written Testimony of Linsey E. Haram, Research Ecologist, Smithsonian Environmental Research Center Plastic Marine Debris Research, House Sub-Committee on Appropriations: Interior, Environment, and Related Agencies, U.S. House of Representatives Publication, dated September 19, 2019.

impacts. My colleagues have researched the causes, effects, and dispersal of invasive species within coastal ecosystems for over 3 decades. My research elucidates a missing link in our understanding of these processes - the emerging problem of plastic marine debris as a major source of invasive species spread across oceans.

## **PLASTIC MARINE DEBRIS**

Plastic production has rapidly increased since its industrialization in 1950, having grown from 2 million tons produced in 1950 to 380 million tons in 2015 – half of which was produced within the past 13 years.<sup>1</sup> From 1950 to 2015, a total of 7.8 billion tons has been produced, with 6.3 billion tons discarded; less than 10% of plastic waste in this same period was recycled.<sup>1</sup> A large portion of the waste produced annually occurs in coastal communities because human populations are concentrated on the coasts. In 2010 alone, over 35% of the 275 million tons of global plastic waste generation occurred in coastal communities.<sup>2</sup> In areas with mismanaged waste, plastic pollution can be directly delivered from the land to our oceans, with an estimated 8 million tons of debris entering the oceans from coastal communities each year.<sup>2</sup> Effluent from rivers<sup>3</sup> and fishing gear from offshore fisheries further contribute plastic waste to ocean ecosystems, though resolved estimates for these sources are needed.

We now know that plastic debris is widespread in our oceans and accumulates in high concentrations in gyres, which are areas of current convergence and low flow in the open ocean. <sup>4</sup> One of these areas is the North Pacific Subtropical Gyre (NPSG), commonly called the Great Pacific Garbage Patch, which has the greatest reported concentrations of plastics in the oceans.<sup>5</sup> While much of this plastic debris consists of small microplastics, larger meso- to megaplastics are also common and make up an estimated 75% of the total mass of plastics in the NPSG, $5$  including:

- Ghost nets (massive conglomerations of derelict fishing nets)
- Associated fishing gear (buoys, fish crates, eel trap cones)
- Bottles, buckets, and jugs
- Miscellaneous household goods
- Plastic fragments

 $\overline{a}$ 

Once at sea, plastics are often buoyant and do not biodegrade, allowing them to persist for long periods of time, accumulate in gyres, and be carried by currents over great distances. This is unlike wood and other natural materials that degrade much more rapidly. The emergence and persistence of large plastics has created a novel and growing *floating ocean ecosystem,* where large plastics are colonized by a wide diversity of organisms and

<sup>&</sup>lt;sup>5</sup> Lebreton et al. 2018. Evidence that the Great Pacific Garbage Patch is rapidly accumulating plastic. Scientific Reports, 8:4666.

transported across oceans. The magnitude and spatial scale of this species rafting on plastics is unprecedented in history, creating a new mechanism for invasive species introductions to coastal ecosystems of the United States and elsewhere.

## **FLOATING PLASTICS AS VECTORS FOR INVASIVE SPECIES**

Invasive species are animals, plants, and microbes that are introduced to a new ecosystem, usually through human activities, subsequently causing harm to their new ecosystems. When new predators, parasites, competitors, or pathogens are introduced, they can impact native biodiversity, fisheries, and water quality, impairing ecosystem services, local economies, and health.

Historically, the main drivers of invasive species introductions in coastal ecosystems are vessels, which deliver marine species from around the world in their ballast water and on their hulls.

Within the past decade, however, floating plastic debris has entered as a potential new source of coastal species introductions.

The scientific community became aware of the potential importance of plastics for invasion dynamics following the Eastern Japan Tsunami. On March 11, 2011, a devastating 9.0 magnitude earthquake struck off the coast of the Japan's Honshu region, causing a tsunami over 120 feet high in the hardest hit areas. As the wave receded, it carried millions of tons of debris with it into the Pacific Ocean. One year later, in the spring of 2012, Japanese tsunami debris began washing ashore along the coasts of western North America and Hawaii. In an international effort led by SERC and Williams College, scientists, natural resources managers, and volunteers collected 634 Japanese tsunami debris and surveyed them for the biology attached6. Over a 6- year period, 287 marine invertebrate species, 2 fish species, and 49 seaweed species from Japan arrived on North American beaches alive, and in some cases, reproductive; over 5,000 miles from their home shores of Japan.<sup>6,7</sup> This study, published in Science, marked the first time in history that scientists were able to observe the transport of non-native species to distant shores in real-time. The scale and duration of this event was unprecedented, due in part to the presence of highly durable man-made debris, particularly plastics and plastic-compound materials, which effectively acted as rafts for coastal species at sea.

### **CURRENT RESEARCH AND COLLABORATIONS**

Though the tsunami debris research provided essential information about the ability of hundreds of coastal species to raft across the open ocean and successfully land on new shores, many questions remain. In a NASA funded, multi-institutional research project, titled *Floating Ocean Ecosystems* (FloatEco), my colleagues and I build upon the results of the

<sup>6</sup> Carlton et al. 2017. Tsunami-driven rafting: transoceanic species dispersal and implications for marine biogeography. Science, 357: 1402-1406.

<sup>7</sup> Hansen et al. 2018. Genetic identification of macroalgal species on Japanese tsunami marine debris and genetic comparisons with their wild populations. Marine Pollution Bulletin, 132: 74-81.

Japanese tsunami debris effort with the purpose of better understanding the movement of large floating plastic marine debris in open ocean gyres and the ecological communities attached.

FloatEco combines expertise from marine ecologists from SERC, Fisheries and Oceans Canada, and Williams College and oceanographers and engineers from University of Hawaii, Scripps Institute of Oceanography and University of Washington – Applied Physics Laboratory. Our interdisciplinary team also includes the ocean health non-profit, Ocean Voyages Institute.

Our research, which takes place in the area of highest plastic accumulation in the NPSG, aims to elucidate the dynamics of this floating ocean ecosystem of marine debris and especially its role in dispersal and distribution of coastal species. We seek to answer the following questions:

- Are coastal species common on floating plastic debris in the open ocean, gyre ecosystems? How many coastal species utilize this new habitat?
- How does the distribution and movement of debris affect survival, reproduction, and fate of coastal organisms in the ocean?
- How does debris type influence community composition and origin of both coastal and open ocean species?
- How do different types of floating plastic debris drift through gyre environments? Can we predict their trajectories based on debris type, size, and oceanographic conditions?

These are large scale questions that can only be answered through the synthesis of effort by multiple stakeholders. Thus, the FloatEco team works closely with external collaborators to maximize our capacity for data collection. Below, we outline our research on floating ocean ecosystems in three primary efforts: *1) Ecological community surveys, 2) Large floating debris movement, and 3) Marine invertebrate colonization.*

#### **1. Ecological Community Surveys**

Through collaboration with non-profits and citizen scientists, we collect debris from our target study area in the NPSG. Oceanographers from the University of Hawaii model distributions of floating debris in the region and direct the collaborators to projected areas of highest plastic debris accumulation. During their journeys, our external collaborators either collect debris or they sample the marine invertebrates and seaweeds attached to the large floating debris in the field. All samples are sent to SERC and analyzed by FloatEco biologists.

Once in the lab, these samples are analyzed for the following characteristics:

- Species present (identified to lowest taxonomic level possible)
- Natural species distribution coastal vs. pelagic
- Signs of reproduction
- Size class structure

All species present are characterized as those with natural distributions in the open ocean or coastal ecosystems. To determine if populations are sustaining at sea, we also analyze the marine invertebrates for evidence of reproduction and presence of multiple generations through age structure.

During the past year, we collected over 150 floating plastic debris items with the help of five external collaborators.

### **2. Large Floating Debris Movement**

Though we know that plastic debris concentrates in gyres, there are gaps in the scientific knowledge regarding how large floating plastics respond to wind and oceanographic dynamics in these unique systems. Additionally, we do not know how differently floating debris responds based on type and size. To address these unknowns, we deploy Langrangian drifters, which measure ocean currents and conditions, and tag debris with GPS tracking buoys within the NPSG.

*Lagrangian Drifters.* FloatEco oceanographers from the Scripps Institute of Oceanography's Langrangian Drifter Lab and University of Hawaii, construct drifters of different shapes and depths within the water column to better determine how these factors affect the paths of floating debris.

*GPS-Tagged Debris.* Through our collaboration with Ocean Voyages Institute, we track large floating plastic debris in real-time within the NPSG. To do so, our external collaborators attach specially manufactured GPS tracking buoys to drifting derelict fishing nets (i.e. ghost nets). Once tagged, the locations of the ghost nets are tracked continuously via satellite GPS.

The trajectories of both the Langrangian drifters and the GPS-tracked ghost nets inform oceanographic models created to more accurately predict the seasonal distribution and movement of debris.

### **3. Marine Invertebrate Colonization of New Debris**

In addition to establishing the presence of coastal species on debris in the NPSG, we also need to know if coastal species can colonize new debris when it enters the open ocean. If coastal species do colonize new plastics, coastal species populations may be able to persist and spread within gyres, making these novel floating ecosystems a source of non-native species.

*Colonization Arrays.* To investigate the colonization of new debris by coastal species, we have adapted methods used by the SERC Marine Invasions Laboratory for monitoring invasive marine invertebrates along coastlines. In our current design, four PVC discs stacked 0.5 inches apart along a central axis create a complex structure meant to mimic plastic debris. The colonization arrays are attached to both drifters and GPS-tagged debris. After several months, the colonization arrays will be recovered, and we will analyze each PVC disc for community composition and abundance. As in our *Ecological Community Surveys*, we will also measure reproductive state and size class structure.

By combining what we learn from our above research efforts, we will better understand how floating plastic debris disperses coastal species and the extent to which it may contribute to the spread of marine invasive species.

### **4. Education and Outreach**

At SERC, as a complement to our research, we prioritize professional development of the next generation of scientists as well as effective science communication and education for the public.

The issue of plastic marine debris is truly global and one that requires buy-in from all stakeholders involved. Thus, in SERC's tradition, we prioritize outreach and education as a deliverable of our plastic marine debris research. Examples of our efforts include:

- A booth about floating plastic ecosystems at the World's Ocean Day event in the National Museum of Natural History.
- SERC Education department curriculum about plastic ingestion by albatrosses.
- Lectures and presentations at local community centers.
- Coverage in science journalism pieces and other media.
- Creation of a citizen science project for collection of plastic marine debris.
- Inclusion of young scientists in research activities.

From our participation in these activities, it is clear that more education about the societal and environmental context of our plastic pollution issue is needed; and in order to effectively communicate the issue to the public, we need to prioritize more cross-disciplinary research that identifies our current unknowns.

### **CONCLUSION**

The research presented above highlights an under-investigated aspect of plastic marine debris as a vector of future marine species invasions. Through this work, we aim to clarify the role of plastic marine debris in creating a novel open ocean ecosystem and in transporting species across oceans in historically unprecedented ways. Beyond this research, there are still many unknowns about plastic pollution's sources, sinks, impacts, and solutions. We are in the early stages of understanding the extent of our global plastic pollution issue. Given the scale of the plastic marine debris problem and the scope of the unknowns, greater prioritization and standardization of research is necessary to ensure the future health of our oceans.

# **WRITTEN TESTIMONY OF DR. CHELSEA ROCHMAN, HOUSE APPROPRIATIONS SUBCOMMITTEE ON INTERIOR, ENVIRONMENT AND RELATED AGENCIES HEARING ON ECOSYSTEM IMPACTS OF MARINE DEBRIS/OCEAN PLASTIC POLLUTION**

# *Chelsea Rochman*

Dear Chair McCollum and Ranking Member Joyce,

Thank you for holding this hearing on such an important topic. Plastic pollution presents a momentous challenge and it is heartening to see so much interest in finding solutions to tackle the issue on Capitol Hill. I'm thrilled to have the opportunity to share my expertise with you on this important issue and to help facilitate the use of science and evidence in informing policy.

I am Dr. Chelsea Rochman, an American citizen working abroad as a professor in Ecology at the University of Toronto. My expertise is in marine ecology, environmental chemistry and toxicology, I have been researching this issue for more than a decade. I currently run a research program where we investigate the sources, transport and effects of plastic pollution in our environment. I also serve as a Science Advisor to Ocean Conservancy, a nonprofit organization which works to create science-based solutions to the challenges facing our ocean. Ocean Conservancy is a leader in the global fight to address the proliferation of mismanaged plastic waste that has entered our oceans. In my capacity as a Science Advisor, I work with the organization to develop scientific research priorities and distill scientific findings into actionable information that can be used to provoke change, both here in the U.S. andabroad.

With more than a decade of experience researching plastic pollution, I have a vast knowledge base on this issue. I have published many papers about the topic and have advised

This is an edited, reformatted and augmented version of Written Testimony before the Department of Ecology and Evolutionary Biology, University of Toronto, dated September 19, 2019.

managers and policy-makers in several countries. For example, I presented at the 2016 Our Ocean Conference at the U.S. State Department and in front of the UN General Assembly in 2017. I have also traveled to Washington, D.C. for one-on-one discussions with the offices of several Members of Congress.

My work in this field began in the middle of the ocean, aboard the first scientific expedition to the Great Pacific Garbage Patch with the Scripps Institution of Oceanography in 2009. Every four hours we dropped our net in the water to quantify plastic at the surface and 24 hours a day we had observers on deck looking for large debris. Day after day, we were not seeing much in terms of an island of garbage in the middle of the Pacific. Then, on the fourth day, the observers called us all up for assistance. On the bow of the ship were two rulers being used by observers to count debris as it passed. Up to that point, they had counted a buoy, a drink tray, a fishing net here and there. But then, all of a sudden there were too many pieces of plastic to count and the two observers needed the eyes of many. Looking over the bow of the ship were thousands of little pieces of plastic smaller than a pencil eraser. This was not a garbage patch, this was a soup of microplastic (plastic particles < 5 mm in size). At that moment, I knew that this small plastic material could infiltrate every level of the food web. I also knew that this was not just an issue of cleanup – but also one of prevention.

Coming back to land, we analyzed the samples that were collected on the expedition. We found that there was plastic in every single one. This finding, that the majority of plastic pieces in the garbage patches were microplastics, demonstrated a need to shift the conversation in terms of the way we were thinking about mitigation by putting a stronger focus on preventing plastic from leaking into the environment in the first place. It also demonstrated a need for more science to better quantify the magnitude of the problem, including sources, transport, and impacts of microplastics in the marine environment.

Since this expedition, I have witnessed our scientific field grow globally and expand from oceans to freshwater to land. We've learned that microplastics are not just an ocean contaminant, but a global contaminant. We've learned that they are found in the stomachs of animals big and small and that this contamination extends beyond our environment - into seafood, salt and drinking water.

As a pioneer in this field, my research program is globally known for doing work on method development, contamination in the environment and effects to wildlife. We study microplastics across the United States, including in the San Francisco Bay, the Chesapeake Bay, the Great Lakes, and the Arctic. We also measure contamination in animals, exposure to humans via drinking water and seafood consumption, and the effects of plastic pollution to animals and ecosystems. The topic my lab focuses on the most is impacts to wildlife and their ecosystems.

Today, there is no doubt that anthropogenic debris of all shapes and sizes litters our oceans and freshwater ecosystems. This debris is found in hundreds of species of wildlife, including in the species we consider seafood. It is also found in our drinking water. We know that plastic pollution harms individual organisms, wildlife populations and communities. These impacts, combined with evidence for accelerating plastic production and leakage into the environment, suggest the international community should come together to limit future environmental leakage of anthropogenic litter now, before they transform ecosystems irreparably. Below, I will speak specifically to microplastics followed by plastic pollution in general.

### **MICROPLASTICS**

My research mainly focuses on microplastics (plastics 5mm in size or less) and demonstrates that microplastics are ubiquitous in the environment, including in seafood and waters extracted for drinking water. My research has also shown that microplastics are associated with a cocktail of toxins, including 78% of those we currently consider priority pollutants under the Clean Water Act. It also demonstrates that microplastics can be toxic to fish and invertebrates.

Although we often think of microbeads when we think of microplastics, the term microplastic incorporates a large diversity of plastic types, including those that were produced as microplastics (e.g., microbeads, pre-production pellets often referred to as "nurdles") and those that are literally degraded bits of larger plastic products (e.g., tire dust, microfibers and fragments of bottles, bags and film). The former is called primary microplastics and the latter is referred to as secondary microplastics. Secondary microplastics are the most common type of microplastic waste found at sea. Still, we must not forget the primary sources of microplastics as well as the sources that emit secondary microplastics into the oceans (e.g., microfibers). These particles, specifically microfibers, are some of the most common microplastic types found in global ecosystems.

Researchers estimate that there are between 15 and 51 trillion microplastic particles floating around in our oceans (van Sebille et al., 2015), reaching from the poles to the equator. Microplastic particles are found in large concentrations in Arctic sea ice (Obbard et al., 2014) and are also present in sediments (Browne et al., 2011) and wildlife from the deepest parts of the ocean (Woodall et al., 2014). Consequently, this widespread contamination has led to the contamination of hundreds of species of wildlife across all trophic levels (GESAMP, 2016). In our own work, for example, we find microplastics in several species of Great Lakes fish, including white sucker, brown bullhead, lake trout, shiners and minnow – and sometimes at concentrations of more than 100 pieces per fish sampled.

For microplastics, there have been many studies testing the effects on organisms. Although the results are variable, there is irrefutable evidence that microplastics can impact organisms. In laboratory studies, microplastics have been shown to cause a variety of biological effects including: changes in gene expression (e.g., Paul-Pont et al., 2016), inflammation (e.g., von Moos, Burkhardt-Holm, & Köhler, 2012), disruption of feeding behaviour (e.g., Cole, Lindeque, Fileman, Halsband, & Galloway, 2015), decreases in growth (e.g. Au, Bruce, Bridges, & Klaine, 2015), decreases in reproductive success (e.g., Au et al., 2015; Sussarellu et al., 2016), changes in larval development (e.g., Nobre et al., 2015), reduced filtration and respiration rates (e.g., Paul-Pont et al., 2016), and decreased survival (e.g., Au et al., 2015; Cui, Kim, & An, 2017). In my own work, we have seen deformities in larval fish (Figure 2) and tumor promotion in the liver of adult fish (Figure 3; Rochman et al., 2013) from exposure to microplastic debris. Although we do not yet understand how they affect human health, we know we are exposed via sea salt, seafood and drinking water – and thus relevant research is necessary.

Although policies that mitigate large plastic debris also reduce microplastic debris, we need to make sure we consider microplastics when we consider all of the policy options for plastic pollution. Policies specific to microplastics may include, but are not limited to, leakage

standards for microplastics (e.g., from washing machine effluent, wastewater, stormwater, etc. …), filters on washing machines to trap microfibers, bioretention cells (or rain gardens) on stormdrains, increasing industry participation in the voluntary initiative to reduce pellet loss (Operation Clean Sweep) and extend this model to textiles, material innovation, and banning microbeads.

The above mitigation strategies are simple solutions to combat some sources of microplastics. Still, when it comes to plastic pollution, we know the least about sources, fate and effects of microplastics. As such, while we begin implementing policies now related to known sources of microplastics, we must continue to put resources into research that helps us better understand what some other sources of microplastics are and which may be prioritized for policy based on contamination and risk.

By weight, large plastic debris such as fishing nets, make up the largest percentage of plastic floating in our oceans. However, as discussed above, microplastics are ubiquitous and infiltrate every level of the food web. As we develop policies aimed at plastic pollution, we must be mindful that sources of plastic pollution are diverse, and the policies to address them must therefore include unique considerations for microplastics and macroplastics. We cannot make the mistake of assuming that one policy intervention will fix all aspects of the problem.

Figure 1. Microplastics picked from surface water samples in the San Francisco Bay, California, USA.

Figure 2. Livers of fish taken under a microscope after exposure to different treatments in a laboratory experiment. The liver on the left is from a fish exposed to a no-plastic control and is healthy, the liver in the middle is from a fish exposed to virgin polyethylene and has an abnormal proliferation of cells, and the liver on the right is from a fish exposed to polyethylene that was soaking in the San Diego Bay, California for a 3-month period. The image of the liver on the right is zoomed out to highlight a tumor comprising 25% of the liver. (Rochman et al., 2013)

Figure 3. Larval fish with deformities taken under a microscope after exposure to microplastic debris collected from the shorelines of Lake Ontario. (Bucci et al., unpublished work).

## **MACROPLASTICS**

When it comes to large plastic debris, there is no doubt that plastic pollution can have an impact on wildlife, and there is compelling evidence suggesting macroplastics are already impacting marine populations, species, and ecosystems. Studies have reported contamination via entanglement or ingestion in hundreds of species of wildlife. This contamination can lead to laceration of the tissues, mortality of an individual organism, declines in population size, and/or changes in the assemblages of species. A recent study published in *Science* found that plastic debris was correlated with disease in coral reefs (Lamb et al., 2018). In a recent systematic review, we found reports of adverse effects in 23 species of marine mammals, 4 species of turtles, 11 species of birds, 4 species of fish, many species of invertebrates, and one species of algae. The weight of evidence for how microplastic debris impacts wildlife suggests that the time to act is now.

Researchers estimate that about eight million metric tons of plastic enters the oceans annually from land (Jambeck et al., 2015). If we continue business as usual, this number is expected to increase by an order of magnitude by 2050.

I hope my words have expressed to you that the issue is large - and urgent. This issue is complex. The sources of plastics into the environment are diverse. The types of plastics we produce, sell and find in nature are diverse. The ecosystems and organisms this pollution contaminates are diverse. As a consequence, the solutions need to be diverse. As you know, there is no one size fits all solution. Instead, we need a toolbox of solutions that include plastic reduction, the building of a circular economy, improved waste management systems, innovation of new materials and technologies for prevention, cleanup, outreach and education. We also need everyone working together, including the plastics industry, waste managers, communities, scientists and all levels of government.

In the U.S., I think we have an opportunity to lead in this space. The U.S. can and should be a large part of the solution, and show other countries that reducing leakage of plastic is possible. I envision diverse policies that work in tandem to reduce our plastic leakage. For

example, we may adopt container deposit schemes to improve recycling rates, implement standards that increase the use of recycled content in new products, eliminate the use of some single-use plastic items that are unnecessary and/or replaceable (e.g., microbeads, straws), improve waste collection and recycling infrastructure, and agree to market only plastics that are recyclable and/or reusable in their region. We should also consider providing aid to build new infrastructure for waste collection and recycling in emerging economies abroad and also here at home. I welcome the chance to sit down with any of you and discuss the state of the science and how it might inform policy around this important issue both nationally and internationally.

Thank you for this opportunity to speak with you and I'd be very happy to answer any questions today or in the future.

Many thanks for your time. Sincerely, Chelsea M. Rochman Assistant Professor *Chapter 118*

# **MUSSELS AS SENTINEL ORGANISMS IN METAL AND METALLOID CONTAMINATION SCENARIOS: ENVIRONMENTAL AND PUBLIC HEALTH RISK BIOINDICATORS**

# *Rachel Ann Hauser-Davis1,\* , PhD and Raquel Teixeira Lavradas<sup>2</sup> , PhD*

# **ABSTRACT**

Among environmental pollutants, metals and metalloids are of particular concern due to their potential toxic effects and the ability to bioaccumulate throughout the aquatic trophic web. However, the simple measurement of chemicals levels present in the environment is often not enough to reveal the actual adverse effects of the contamination, making it necessary to also assess the biological effects of contamination on living organisms, applying bioindicators and biomarker measurements. Mussels have been recognized as one of the best sentinel organisms regarding aquatic environments and have been increasingly used in many worldwide environmental monitoring programs. This chapter will discuss the role of several mussel species in environmental monitoring programs, with emphasis on metal contamination, including metal bioaccumulation and biomarker investigations. In addition, the fact that these organisms may be an important contaminant transfer link to the human population and pose important public health risks will also be discussed.

**Keywords:** mussels, sentinel organism, metal contamination, biomarkers, oxidative stress, public health risks.

### **1.INTRODUCTION**

One of the major damaging effects in aquatic environments due to anthropic activities is contamination by chemical pollutants. These contaminants continuously enter the aquatic environment through inadequate waste disposal, incomplete removal by sewage treatment plants, and sewage dumped into water bodies without adequate collection and treatment. Among the many different environmental contaminants present in these ecosystems, those of greatest concern present environmental persistence, bioavailability, a tendency to bioaccumulate in the food chain and the ability to cause toxic effects, such as persistent organic pollutants (Jones and de Voogt, 1999), polycyclic aromatic hydrocarbons (Abdel-Shafy and Mansour, 2016), metals (Singh et al., 2011) and, more recently, emerging contaminants originating from substances used by the human population in daily life, such as pharmaceutical formulations and personal products (Burkhardt-Holm, 2010).

Among environmental pollutants, metals and metalloids are of particular concern due to their potential toxic effects and the ability to bioaccumulate throughout the aquatic trophic web (Censi et al., 2006; MacFarlane and Burchett, 2000; Miller et al., 2002), thus being the subject of many biomonitoring efforts.

Metal and metalloids enter aquatic systems through both natural and man-made processes. The natural processes that most contribute to their presence in aquatic environments are rock weathering and the erosion of soils rich in metals and metalloids, while the main anthropic sources are industrial and mining activities, domestic effluents, surface water runoff from areas cultivated in the presence of chemical fertilizers and agricultural pesticides, and atmospheric precipitation of ash or small particles from fires (Esteves, 1988; Jordão et al., 1999; Mortatti and Probst, 1998; Nriagu and Pacyna, 1988; Ramalho et al., 2000; Yabe and Oliveira, 1998).

In the aquatic environment, metals and metalloids are distributed in both the aqueous (water column and interstitial water) and the solid (suspended and sedimented) phase, as well as in aquatic organisms, with a dynamic exchange between these phases, varying from one ecosystem to another (Conceição, 2004). Aquatic organisms assimilate metals and metalloids from both the aqueous and solid phases, namely water and sediments and, especially, food. These elements may then accumulate in tissues in several orders of magnitude above concentrations found in the water column. Therefore, aquatic organisms are responsible for much of the dynamics of these pollutants in the aquatic environment. It is important to note that the effects of these pollutants can be toxic and/or lethal to all components of the biota, such as phytoplankton, benthos, fish, birds, and, finally, humans that feed on contaminated organisms (Canli and Atli, 2003; Fowler, 1982; Junior et al., 2002; Pfeiffer et al., 1985), through bioaccumulation and bio magnification processes.

## **2. METAL AND METALLOID TOXICITY**

Metals and metalloids can be classified as essential, non-essential and toxic elements. Essential elements, when present in low concentrations, play an important role in organism metabolism. Non-essential elements and toxic elements, however, do not play any known biological functions. Increasing essential element concentrations, up to a certain range, lead to improvements in organism development and metabolism. Above this range, these elements become toxic and, beyond a certain limit, lethal. Non-essential elements, on the other hand, are tolerated by the body to a certain extent and, if present above certain concentration limits, follow the same behavior described above, becoming toxic and then lethal to the organism. These differences are displayed in Figure 1.

Figure 1. Graphical representation of the relationship between essential and non-essential concentrations and their effects on organisms. Adapted from Galvão (2003).

Element toxicity also depends on the chemical form present, i.e., the bioavailable fraction. Some metals and metalloids, such as Cd, Pb, Hg and As, for example, are non-toxic in the forms of free condensed elements, while, when present in their cation forms and when bonded to short carbon atom chains, become toxic. The amount absorbed by the organism also influences element toxicity, since even essential elements can be toxic when absorbed above limits tolerable for normal organism metabolism, as stated previously (Baird, 2002; Melo, 2003).

Different metal and metalloid toxicity mechanisms have been described, including (i) enzymatic inactivation due to the high reactivity of divalent transition metals with the amino and sulfhydryl groups of proteins; (ii) metal competition with essential elements and their replacement in the enzymatic metabolism - Pb, for example, can replace Zn in several proteins that function as transcription regulators - and (iii) the "cocktail effect," in which the excess of one element can cause the deficiency of another(s), such as the case of excess of Pb, that interferes in the absorption of Ca, Fe, Cu and Zn, for example (Förstner, 1989; Melo, 2003; Moreira and Moreira, 2004).

Thus, although the determination of metals and metalloids in tissues and organs of different aquatic organisms is an important method to evaluate metal contamination in aquatic ecosystems (Farkas et al., 2001), the simple measurement of metal levels present in the environment is often not enough to reveal the actual adverse effects of the contamination, making it necessary to also assess the biological effects of contamination on living organisms. This is performed through the use of bioindicators, also termed sentinel species, and biomarker measurements.

## **3. MUSSELS AS BIOINDICATORS CONCERNING ENVIRONMENTAL METAL AND METALLOID CONTAMINATION**

Mussels are widely used as bioindicators for a number of aquatic contaminants, due to their sessile nature, which facilitates their sampling, their worldwide distribution, reasonable size, known biology and ecology, and filtering feeding habits, leading to the absorbance and retention of solid particles and, consequently, any contaminant adsorbed therein (Lamparelli, 1987; Rainbow, 1995; Resgalla Jr. et al., 2008; Wallner-Kersanach and Bianchini, 2008).

These organisms are able to concentrate contaminants in their tissues and survive, and even, thrive, in contaminated environments and are, therefore responsible for part of pollutant dynamics in the aquatic environment. In addition, they concentrate environmental contaminants proportionally to external (water) concentrations, thus reflecting the contamination history of the environment and, because they settle on shallow water substrates, they are exposed to environmental factors on a local scale, allowing for the comparison of environmental contamination between different locations (Chase et al., 2001; Chou et al., 2004; Dame, 1996; Rainbow, 1995; Storelli et al., 2000; Sun et al., 2004).

Because of these characteristics, mussels have been recognized as one of the best sentinel organisms regarding aquatic environments and have been increasingly used in national and international environmental monitoring programs (Bellotto et al., 2005) for both freshwater and marine ecosystems. For example, the United States National Oceanic and Atmospheric Administration Mussel Watch Program, the nation's longest running continuous coastal contaminant monitoring program, has applied several *Mytilus* species, such as *Mytilus edulis*, *Mytilus californianus*, *Mytilus galloprovincialis* and *Mytilus trossulusto*, to evaluate the contamination status of US coasts (Binelli et al., 2015), while many other species have been applied as bioindicators for metal and metalloid contamination scenarios worldwide.

Several biomarkers have been routinely investigated in these contamination scenarios, in order to evaluate the potentially deleterious effects of metal and metalloids, which shall be discussed further ahead in this chapter. First, however, it is important to understand the subcellular and molecular effects of metal and metalloid exposure in living organisms.

# **4. SUBCELLULAR AND MOLECULAR EFFECTS OF METAL AND METALLOID EXPOSURE: REACTIVE OXYGEN SPECIES AND OXIDATIVE STRESS**

One of the main deleterious effects of metals and metalloids are alterations in cellular redox regulation or oxidative reaction cycles, producing reactive oxygen species (ROS) and certain non-radicals derived from oxygen capable of generating free radicals, such as hydrogen peroxide and hypochlorous acid, which, in turn, may lead to oxidative stress (Buonocore and Groenendaal, 2007; Halliwell and Gutteridge, 2007).

Free radicals, like ROS, are small molecules with a short half-life that possess one or more unpaired electrons, characterized by high reactivity, sequestering electrons from neighboring molecules in order to become stable (Buonocore and Groenendaal, 2007; Halliwell and Gutteridge, 2007). The main ROS species are usually formed by the main oxygen metabolism route in the body, which is completely reduced to water, integrating four

electrons at the end of the electron transport chain inside the mitochondria. The main ROS, superoxide anion, hydrogen peroxide and hydroxyl radical, are produced when the oxygen molecule is reduced, along with a smaller number of electrons along the respiratory chain.

The body, however, possesses natural ROS elimination systems, known as intracellular antioxidant defenses, which are substances that prevent, delay or remove oxidative damage from a target molecule (Cogo et al., 2009; Halliwell and Gutteridge, 2007). When these antioxidant substances are present in amounts equivalent to ROS concentrations, the metabolism and cellular functioning of living organisms remain unchanged. However, situations where excessive ROS are being produced, and/or cases of failure of antioxidant defenses may lead to oxidative stress, caused by the imbalance between the formation rate of oxidant molecules and antioxidants in the body (Halliwell and Gutteridge, 2007). Oxidative stress may then lead to protein carbonylation, a process by which proteins can undergo reversible and irreversible oxidation and covalent modifications in their amino acids, modifying them into aldehyde or ketone groups, which are harmful to proteins, causing their aggregation, inactivation and degradation, and the produced ROS may interact with lipids, proteins or nucleic acids, resulting in various biochemical or genetic damages (Costa et al., 2002; Ghezzi and Bonetto, 2003; Levine et al., 1990).

The presence of metals and metalloid in biological systems in an uncomplexed form, not as protein co-factor or any other type of protective metal complex, can significantly increase oxidative stress levels (Dalle-Donne et al., 2006). In this context, certain redox-active metals, that undergo redox-cycling reactions, such as Cr, V, Co and Cr, are known to induce oxidative stress, causing damage to mitochondrial respiration (He et al., 2008; He et al., 2007; Valko et al., 2005), while other metals, such as Fe and Cu, are known to produce ROS by the Haber-Weiss (Equation 1) and Fenton (Equation 2) reactions (Barreiros et al., 2006).

$$
O_2 + H_2O_2 \rightarrow \cdot OH + OH^+ + O_2 \tag{1}
$$

$$
Fe^{2+}/Cu^{+} + H_{2}O_{2} \rightarrow Fe^{2+}/Cu^{2+} + \cdot OH^{+} + OH^{-}
$$
 (2)

The Fenton reaction occurs in the presence of metal ions and hydrogen peroxide, forming the hydroxyl radical, hydroxyl anion and leading to metal oxidation. In the Haber-Weiss reaction, metals can react with the superoxide anion through its reduction, generating molecular oxygen, and the reduced metal the reacts react with the hydrogen peroxide, generating the hydroxyl radical in the Fenton reaction (Leonard et al., 2004).

The generation of these radicals may lead to negative effects if organism defenses are overwhelmed. In this context, biomarker responses, meaning measurable alterations of any physiological, biochemical or behavioral steady state induced by an environmental change, against metal- and metalloid-induced oxidative stress are applied as early warning signs of the possible deleterious effects of these contaminants.

## **5. MUSSEL BIOMARKER RESPONSES AGAINST METAL - AND METALLOID-INDUCED OXIDATIVE STRESS**

Mussel gills, digestive gland and haemolymph are regarded as excellent candidates for assessing toxic impacts of metal and metalloid exposure, due to their direct contact with the environment (water medium) and the fact that they are the center of metabolic regulations and metal transfer pathways to detoxifying tissues (Chandurvelan et al., 2013). Thus, biomarkers against metal- and metalloid-induced oxidative stress in these tissues are investigated in order to detect early negative effects and allow for decision-making processes regarding these environmental contaminants.

In this regard, one of the main biomarkers established by monitoring programs developed and implemented in the European community to investigate contamination by metals and metalloids is the metalloprotein metallothionein (MT) (Bebianno et al., 1993; Garrigues et al., 2002; Sarkars et al., 2006).

Metallothioneins are a group of low molecular weight (6 to 7 KDa) metalloproteins (proteins that bind to metals), rich in cysteines and presenting heat stability. They display a high affinity for metal ions and play an important role in several biological functions, such as essential metal homeostasis and detoxification of both non-essential elements and essential elements present in excess in the organism (Freire et al., 2008; Monserrat et al., 2007; Motta, 2012; Sarkars et al., 2006; Viarengo et al., 2007). Their synthesis is induced through the presence of metal and metalloid cations in the body, and the thiol group (-SH) present in this metalloprotein's structure allows binding with these elements, restricting their bioavailability (Freire et al., 2008; Linde et al., 1999; Monserrat et al., 2007; Nicholson and Lam, 2005; Viarengo et al., 2007).

Usually, these proteins bind to 7 equivalents of divalent metal ions, through the formation of metal-sulfhydryl clusters (Figure 2) (Melendez et al., 2012; Motta, 2012), in which the order of affinity is usually Cd>Pb>Cu>Hg>Zn>Ag>Ni>Co (Waalkes et al., 1984), although this may vary according to the bioavailability of the metals in the cell.

Figure 2. Metal binding sites present in one metallothionein molecule. "M" indicates metal ion binding sites. Adapted from UVED (2015).

Several metals have been shown to induce MT synthesis in mussels. For example, Mourgaud et al. (2002) observed that As, Cd, Cr, Cu, Hg, Ni, Pb and Zn concentrations were significantly correlated to MT in the mussel species *Mytilus galloprovincialis* mussels, while Purina et al. (2013) observed the same for Cd, Pb, Hg, Cu and Zn and MT in the freshwater mussel *Anodonta* spp. In another study, an increase in MTs in *Dreissena polymorpha* was shown to occur at relatively low aqueous Pd concentrations indicating that there is the need for Pd detoxification in these mussel, with significant correlations between MT and Pd associated with adverse effects on the mussels (Frank et al., 2008), while significant correlations were determined between MT induction and metal contamination in the greenlipped mussel, *Perna canaliculus*, indicating that different sampling sites were clearly distinguishable based on the metal contamination profiles and this biomarker response (Chandurvelan et al., 2015).

Tissue-specific responses have been reported for this biomarker, such as in the study conducted by Lavradas and collaborators with *Perna perna* mussels sampled from 3 contaminated areas in an extremely contaminated bay and compared to a reference site in southeastern Brazil, where the digestive gland was shown to be a better bioindicator for metal and metalloid contamination compared to muscle tissue (Lavradas et al., 2016). This was also observed in a study that investigated investigated Cd and MT distribution different tissues of the freshwater mussel *Anodonta woodiana* following Cd exposure. In this case, the authors reports that Cd was distributed in all tissues in the concentration order of gills>mantle>foot>visceral mass>digestive gland, and that the highest Cd accumulation was found in the digestive gland, while MT levels in the gills and mantle increased significantly and were positively correlated to Cd accumulation in the different tissues (Li et al., 2015).

However, it is important to note that variations in MT isoforms may be present, in which one or more may contribute to metal detoxification, while others may not display a function in this regard, or may even be inhibited following metal or metalloid exposure. For example, in one study, *Mytilus edulis* specimens were exposed to Cd and Hg for 21 days and the gills, mantle and digestive gland were evaluated regarding MT isoforms. Size exclusion chromatography showed the presence of an MT monomer and a dimer in gills, of respective apparent molecular weight of about 12 kDa and 20 kDa, which were then resolved into five components by anion exchange chromatography in the gills of control or Hg-treated mussels, whereas a sixth isoform was isolated in the gills of Cd-exposed mussels. In the mantle of mussels, exposed or not, five isoforms were separated, and in the digestive gland of mussels exposed or not, six isoforms were separated (Geret and Cosson, 2002). In another study, different MT isoforms were observed in the digestive gland of control and experimentally Cdexposed mussels in *Mytilus edulis* (200 μg  $L^{-1}$  Cd<sup>2+</sup> and 400 μg  $L^{-1}$  Cd<sup>2+</sup>; 20 days), where an induction of the dimeric form MT20 II was detected in the 400  $\mu$ g L<sup>-1</sup> exposed mussels and an inhibition of the monomeric form MT10 IV was verified (Ciocan and Rotchell, 2004).

It is thus, important to investigate MT expressions in mussels through analytical techniques that allow for isoform differentiation, since different MT isoforms may contribute to different metal and metalloid detoxification mechanisms.

The glutathione metabolism is also extremely important in conferring protection against metal and metalloid toxicity.

Glutathione (γ-L-glutamyl-L-cysteinylglycine) (Figure 3). is a tripeptide with strong antioxidant capacity, determined by the reactive grouping of its cysteine, the thiol group (- SH).

Figure 3. γ-L-glutamyl-L-cysteinylglycine.

This tripeptide acts directly or indirectly in many biological processes, such as in metabolic and transport processes, acting against the production of free radicals, in thiol homeostasis, maintenance of the redox balance of the cell, defense against xenobiotics and playing a central role in the biotransformation and elimination of electrophilic agents and protecting cells against the toxic effects of a variety of compounds. GSH is used as a substrate in conjugation reactions, catalyzed by glutathione S-transferase enzymes, but is also capable of participating in nonenzymatic conjugations with many xenobiotics (Aquilano et al., 2014).

Several studies demonstrate the induction of metal-GSH complexes in different organisms after exposure to these compounds, through the sulfhydryl group, such as  $Cu^{2+}$  and Fe<sup>3+</sup>, that readily catalyze GSH oxidation, producing several free radical species (Rabestein et al., 1985; Stohs and Bagchi, 1995), and the  $Cu^{2+}$  reduction by GSH, that produces a stable  $Cu<sup>1+</sup>-SG$  complex that impedes further redox cycling and leads to the generation of free radicals (Corazza et al., 1996). Thus, it has been proposed that GSH is able to complex with metals and detoxify organisms soon after the entry of these elements into the cell, representing a first line of defense against metal cytotoxicity (Canesi et al., 1999).

The glutathione metabolism also includes several glutathione-based enzymes, such as glutathione S-transferase (GST), glutathione peroxidase (GPx) and glutathione reductase (GR), which have also been implicated in metal and metalloid biomarker responses.

In this regard, research has investigated glutathione metabolism proteins and enzymes in mussels and their responses after metal and metalloid exposure. For example, several studies indicate impairment of the antioxidant system and decreases in GR activity and GSH levels when *Perna perna* mussels were exposed to zinc (Franco et al., 2006; Trevisan et al., 2014). Exposure to sublethal copper concentrations in *Mytilus galloproincialis* also led to alterations (decreases) in total GSH content in both gills and the digestive gland, while sublethal mercury concentrations in the same species decreased tissue glutathione content when exposure was conducted with the organic mercury form (methylmercury), but did not significantly affect GSH content and metabolism when present in the inorganic form (Canesi et al., 1999), thus indicating that the chemical form of the contaminant is also of importance when evaluating metal and metalloid effects in these organisms. Other studies conducted with environmentally exposed mussels, such as the freshwater *Lasmigona costata* inhabiting a metal gradient, indicate that several biomarkers involving the SH metabolism, namely GSH, SH protein, total SH, GR and GST, were significantly correlated to gill metal concentrations (Machado et al., 2014), while alterations in GR and GPx were detected in the brown mussel *Perna perna* after exposure to 30 and 100  $\mu$ mol L<sup>-1</sup> zinc (Franco et al., 2006).

Thus, it is a consensus that the glutathione metabolism plays an essential role in metaland metalloid-induced responses in these organisms.

Several other enzymes are important in this regard, since they participate in the biotransformation process of xenobiotics, which occurs in two stages, Phase I and Phase II.

Phase I reactions are responsible for exposing or introducing functional chemical groups into xenobiotic molecules leading to an increase in their polarity, which can lead to the loss of toxic potential and their excretion, resulting in detoxification. At this stage reduction reactions catalyzed by the cytochrome P450 enzymes occur, as well as hydrolysis reactions, catalyzed by esterases and amylases, and oxidation reactions. Metabolites resulting from the metabolism of this first phase may subsequently undergo detoxifying during biotransformation in Phase II. During this second phase, conjugation reactions catalyzed by sulfotransferases, glucuronosyltransferases and GST occur, promoting the conjugation of a variety of toxic molecules with endogenous molecules. The conjugates, mostly soluble and often inactive, are then excreted.

However, the mechanism by which metals and metalloids alter the activity of these enzymes is still unknown. Thus, some hypotheses that attempt to explain this phenomenon have been postulated, as follows: (i) Metals and metalloids cause protein denaturation because they alter the ionic interactions existing between the amino acid side chains, causing changes in enzyme conformation, leading to loss of catalytic activity; (ii) Metals and metalloids may bind to an amino acid residue, for example, cysteines, containing the sulfhydryl group and displaying affinity for various metals and metalloids, close to the active site of the enzyme, making it impossible for the substrate to fit into the enzyme for the enzymatic catalysis process (Bainy et al., 2006; Goncalves et al., 2010; Romani et al., 2003; Sant'anna et al., 2011). It is important to emphasize that studies on the effect of metals and metalloids on enzyme activities are discrepant since certain parameters, such as exposure time and test concentrations, can stimulate, diminish or even alter the activity of this group of enzymes in exposed organisms (Bainy et al., 2006; Barata et al., 2004; Najimi et al., 1997; Richetti et al., 2011; Vioque-Fernández et al., 2007).

Several of these enzymatic biomarkers have been evaluated in mussels regarding metal exposure scenarios. In one study, the mussel species *Mytilus galloprovincialis* from the Saronikos Gulf of Greece was applied to monitor metal pollution in three contaminated sites and the results were compared to unpolluted site. Seasonal variations in superoxide dismutase (SOD) and catalase (CAT) activities were observed over three years in relation to concentrations of trace metals mussel gills and mantle, with SOD activity increasing at least 2-fold at the polluted sites, while CAT activity increased 2-3 times at the polluted sites, both compared to the control site (Vlahogianni et al., 2007). Another study investigated the toxic effects of zinc on antioxidant status and stress proteins in the gills of the brown mussel *Perna perna*, and indicated significant induction of CAT activities (Franco et al., 2006).

However, discrepant results in the literature are frequent regarding metal-induced alterations in these organisms. For example, in a study that conducted both a transplantation experiment of these organisms to a contaminated site and laboratory-exposure study to copper with *Mytilus galloprovincialis* polluted organisms (native, transplanted and Cu-exposed) showed significantly lower levels of glutathione and higher activities of glyoxalases (which detoxify reactive α-ketoaldehydes formed in cellular oxidative processes). However, native mussels from both the polluted and control populations exhibited similar GR, GPx, catalase, SOD and alkaline phosphatase activities, whereas, in both transplanted and Cu-exposed mussels, these enzymes showed significant variations. The authors postulate that these findings could suggest the occurrence of an adaptation or compensatory mechanism in

chronically polluted organisms. In addition, they state that no clear results were obtained regarding GST, and that other esterases (arylesterases and cholinesterases) appeared not to be affected by metal pollution (Regoli and Principato, 1995).

### **6. MUSSEL RESPONSES TO NANOPARTICLE EXPOSURE**

Nanotechnology applications have significantly expanded in the last decades, leading to the inevitable release of nanoparticles, mainly metal nanoparticles, into aquatic systems, resulting in growing environmental and human health concerns (Rocha et al., 2015b). Although very small, nanoparticles exhibit a high surface/volume ratio, providing them with a high reactivity potential and unique physical and chemical properties that differ from conventional forms (Oberdörster et al., 2005).

In this context, research regarding these metal contaminants has increased in the last decades. Most studies expose mussels to both a metal nanoparticle and the dissolved form of the metal, in order to compare mechanisms of action and ecotoxicological effects. For example, *Mytilus galloprovincialis* specimens were exposed to 10 μg L−<sup>1</sup> of Ag nanoparticles (Ag NPs) and ionic silver (Ag<sup>+</sup>) for 15 days. Results indicate that both Ag forms, the NPs and ionic form, accumulated in both gills and digestive glands of the organisms. Regarding antioxidant enzymes, activities of superoxide dismutase, catalase and glutathione peroxidase were activated by both Ag NPs and Ag<sup>+</sup>, and displayed different antioxidant patterns in both gills and digestive glands. Moreover, metallothionein was inducted in gills, directly related to Ag accumulation, while in the digestive glands only a small fraction of Ag seems to be associated with this protein. Thus, the authors indicate that Ag NPs and  $Ag<sup>+</sup>$  cause oxidative stress with distinct modes of action and it is not clear if for Ag NPs the observed effects are due to the free Ag<sup>+</sup> ions associated with the nanoparticle effect (Gomes et al., 2014).

In another study conducted with the same species, *Mytilus galloprovincialis* specimens were exposed to 10 µg Cu $\cdot$ L<sup>-1</sup> copper nanoparticles (CuO NPs) and Cu<sup>2+</sup> in gills for 15 days. Results indicate that mussels accumulated copper in gills and responded differently to both copper forms, suggesting distinct modes of action. The CuO NPs induced oxidative stress by overwhelming the antioxidant defense system in gills, while  $Cu^{2+}$  exposure led to either unchanged or increased enzymatic activities. MT induction was also observed during both types of exposure, while neurotoxic effects reflected as AChE inhibition were only detected at the end of the exposure period for both copper forms (Gomes et al., 2011).

Tissue-specific responses related to alterations in the antioxidant defense system induced by CdTe quantum dots, in comparison with its dissolved counterpart, using the marine mussel *Mytilus galloprovincialis* have also been conducted. Results indicate that both Cd forms altered mussel antioxidant responses with distinct modes of action, tissue- and timedependent differences in the biochemical responses to each Cd form, wherein QDs were more pro-oxidant when compared to dissolved Cd. Regarding tissue, the gills were observed as being the main tissue affected by QDs, with effects related to the increase of SOD, GST and GP*x* activities, while dissolved Cd was associated to increases in CAT activity, Cd accumulation and exposure time. The authors report that the digestive gland was the main tissue for accumulation of both Cd forms, but changes in antioxidant enzyme activities were noted as being lower than in gills. The authors conducted a multivariate analysis, that revealed that the observed antioxidant patterns are tissue dependent, indicating nano-specific effects possibly associated to oxidative stress and changes in redox homeostasis (Rocha et al., 2015a).

Another study on *Mytilus galloprovincialis* evaluated short-term effects on antioxidant enzyme activities and long-term genotoxic and carcinogenic potential of CuO NPs (NPs) in comparison to bulk CuO and ionic copper after 21 days exposure to 10 μg Cu L−<sup>1</sup> . After exposure, mussels were kept for up to 122 days in clean water. Results indicate that Cu accumulation depended on the form of the metal and on the exposure time, and that the three Cu forms produced different effects on antioxidant enzyme activities in digestive glands, overall increasing antioxidant activities. In addition, the authors report that CuO NPs significantly induced both catalase and superoxide dismutase activities, with fewer effects observed in gills (Ruiz et al., 2015).

However, nanoparticle studies have mostly been conducted on seawater species, with *Mytilus* genus as the main investigated taxa used as a model system (Rocha et al., 2015b). Thus, scarce literature is available on other species, indicating the need for further research in this regard in order to increase knowledge on the ecotoxicological effects of these emerging contaminants.

Some of the few examples found in the literature conducted with other species include a recent study on the toxicological perturbations resulting from zinc oxide nanoparticle exposure in the *Coelatura aegyptiaca* mussel, where the organisms were exposed to ZnO NPs  $(2, 10 \text{ and } 50 \text{ mg } L^{-1})$  for 6 consecutive days. Exposure at 10 and 50 mg  $L^{-1}$  induced a significant increase in malondialdehyde, superoxide dismutase and nitric oxide, with a concomitant decrease in reduced glutathione, glutathione-S-transferase and catalase levels in the haemolymph, digestive glands and gills of the treated mussels, indicating significant oxidative stress mechanisms of action (Fahmy and Sayed, 2017).

Sublethal effects of nanoparticle exposure in the freshwater mussel *Elliptio complanata* have also been evaluated. On study investigated the effects of CdTe quantum (1.6–8 mg L<sup>-1</sup>) dot exposure in this species, while another, by the same research group, investigated the effects of increasing concentrations of 20-nm and 80-nm silver nanoparticles, as well as dissolved Ag<sup>+</sup> , for 48 h at 15°C. The former observed significant effects on hemocyte immuno competence (phagocytic activity, viability and cell lysis potential), as well as oxidative stress in gills and digestive glands, while a significant decrease in the number of DNA strand breaks was also observed at 4 and 8 mg  $L^{-1}$ , indicating inhibition of the DNA repair activity (Gagné et al., 2008). The latter observed that the response pattern of 80 nm nAg was more closely related to ionic Ag<sup>+</sup> than 20 nm Ag, suggesting higher release of dissolved Ag from the 80 nm nAg. The authors, however, also report that all forms of Ag increased MT and LPO levels, suggesting that the presence of ionic  $Ag<sup>+</sup>$  leads to oxidative stress. The nanoparticles also induced alterations in other proteins, such as ubiquitin, actinomyosin-ATPase, MT, and DNA strand breaks in the digestive gland in a manner different from Ag<sup>+</sup>, while LPO was closely associated with DNA strand breaks in the digestive gland and was not entirely explained by induction of MT, suggesting another type of toxic interaction. It was concluded that the presence of nAg not only increases the toxic loadings of released Ag ions but also generates other and perhaps cumulative effects of nanoparticle-induced toxicity related to size and surface properties (Gagné et al., 2013).

Overall, mussels display significant oxidative stress effects after nanoparticle exposure, and it seems that metals in the nanoparticle form show different mechanisms of action than those in free form, thus creating increased concerns regarding the effects of these emerging contaminants in the aquatic environment.

# **7. NECESSARY CONSIDERATIONS WHEN APPLYING MUSSELS AS BIOINDICATORS FOR METAL AND METALLOID EXPOSURE IN AQUATIC ECOSYSTEMS**

Seasonal metal accumulation variations may be due to several abiotic factors. For example, increased precipitation in the summer may be responsible for pollutant dilution of pollutants and decreased metal concentrations in the water and, consequently, in mussels, while differences in water temperature between summer and winter, which may affect mussel physiology and cause changes in metal concentrations in certain tissues (Szefer et al., 2004). In this regard, several factors have been postulated as the cause of the seasonal variations observed for biomarkers in mussels (Petes et al., 2008), including hyperthermia, hyposmotic stress, temperature and dissolved oxygen (Gourgou et al., 2010; Hamer et al., 2008; Jarque et al., 2014), as well as reproductive events, food availability and water temperature, among other factors (Amiard and Berthet, 1996; Mubiana et al., 2005; Wang and Dei, 1999).

In this context, significant seasonal variations have been reported for several antioxidant enzymes in mussel species, and conflicting results have ensued. For example, a study on the green-lipped mussel *Perna viridis* from Goa indicated that, although the oxidative stress status of gills and digestive gland of *P. viridis* expressed in terms of LPX and H<sub>2</sub>O<sub>2</sub> were lowest in February, their levels were maximal in gills and digestive gland during May and November, respectively. On the other hand, SOD and GPX activities were low in August, and CAT and GR activities were low in February. GST activity in gills although remained high in February, while elevated values in the digestive gland were recorded in August and November (Verlecar et al., 2008). in another study, *Mytilus galloprovincialis* from the Gulf of Greece displayed seasonal variations in superoxide dismutase (SOD) and catalase (CAT) activities, as well as lipid peroxidation (LP). SOD activity displayed higher activity in spring, whereas CAT activity was highest activity in winter and spring. LP concentration was twice higher at the polluted sites, following the same seasonal pattern. However, trace metal showed only moderate variations along the months, with a winter maximum followed by a summer pre-spawning minimum (Vlahogianni et al., 2007).

Reproductive efforts, in particular, are known to lead to increases in metabolic activity, ROS and, consequently oxidative stress, as a result of reduced energy available for antioxidant defenses (Petes et al., 2008). Therefore, sampling should be avoided during the reproductive period, which is well documented for several commercial species (Mourgaud et al., 2002).

In addition, mussel development stage may also be a confounding factor. For example, when comparing adult and juvenile *Mytilus edulis* after cadmium exposure for 20 days, juveniles expressed increased GSTpi expression compared to the adults, revealing variations in the expression of this GST isoform among control and  $Cd^{2+}$ -exposed mussels of different ages (Ciocan and Rotchell, 2004).

In view of these factors, environmental monitoring studies should take care to conduct sampling efforts under standardized conditions (as much as possible), in order to avoid misinterpretation of biomarker results.

## **8. MUSSELS AND PUBLIC HEALTH**

Bivalve shellfish culture and production for commercial purposes has been noted as a substantial contribution to the economic development of many countries (Santos et al., 2017).

However, the quality of mussels as food is closely related to the sanitary conditions of the marine environment where these bivalves are found (Oliveira et al., 2016), and public health risks associated with metal concentrations in these organisms have been increasingly reported for several species and geographical areas (Jović and Stanković, 2014). For example, in a study conducted with *Mytilus galloprovincialis* mussels sampled along the marine coast of Boka Kotorska Bay, Montenegro, in the Adriatic sea, Cd, Co and Pb levels were recognized as limiting factors for mussel consumption by humans for some Adriatic areas in relation to the provisional tolerable weekly intake prescribed by the Joint FAO/WHO Expert Committee on Food Additives (JECFA), and the target hazard quotient (*THQ*) for average and high level mussels consumers in order to evaluate possible alert regarding adverse health effects that may be caused by trace metals individually (Jović and Stanković, 2014). A study conducted on *Perna perna* mussels in southern Brazil compared metal concentrations from 3 contaminated areas from the contaminated Guanabara Bay to a reference site, Ilha Grande Bay, and concluded that mussels from all sampling sites were improper for human consumption due to metal contamination (As, Se, Zn, Pb) according to both Brazilian and international standards, including Ilha Grande Bay, which was previously considered a reference site (Lavradas et al., 2016). Another study indicated that the invasive Indo-Pacific green mussel, *Perna viridis* (Linnaeus, 1758) in Jamaica accumulates significantly high levels of Cr and Cd, and that risks to public health through consumption of these mussels from Kingston Harbour are significant, exceeding the European Standards and Guidelines for Trace Metals in fish and shellfish. The authors suggest that depuration of the mussels prior to consumption should be carried out (Buddo et al., 2012).

The presence of metals in seafood depends on several factors including geographic location, species, size, feeding patterns and metal concentrations in the environment, which, in turn, are affected by many abiotic factors, such as solubility, temperature, salinity, dissolved oxygen and pH, among others (Stankovic and Jovic, 2012). Thus, it is clear that biomonitoring applying mussels as bioindicatores is vital and directly linked to risk assessments regarding human population health, since these animals are a staple diet for many coastal populations, and, in recent years, have become commercially important seafood species worldwide (Stankovic and Jovic, 2012).

It is very important to note that many reports in the literature indicate no risk to human consumers due to low metal and metalloid levels in the digestive gland or gills of certain mussel species. However, these organisms are almost always ingested whole, so levels in this tissue only cannot be used to indicate public health risks, since total levels would be those present in muscle tissue, digestive gland and gills, summed. Thus, care should be taken in this regard when calculating possible public health risks.

### **CONCLUSION**

Mussels are one of the most important bioindicator species applied to date to investigate the effects of metals and metalloids in the environment. Biomarker responses, such as protein and enzymatic alterations, to metal and metalloid exposure are routinely evaluated in several marine and freshwater species, although research on emerging contaminants, such as metal nanoparticles, is still recent. Public health risks associated with metal concentrations in these organisms have been increasingly reported for several species and geographical areas, since metal contamination in aquatic ecosystems has increased in the last decades, and thus, environmental monitoring efforts applying these organisms is paramount to attempt public decision-making processes regarding environmental metal and metalloid contamination.

# **MUSSEL SHELLS'THERMAL VALORISATION AND ODOUR EMISSIONS**

# *Pastora M. Bello Bugallo\* , Adriana García Rellán, Carmen Barros Frieiro and Laura Cristóbal Andrade*

Department of Chemical Engineering, Universidade de Santiago de Compostela Santiago de Compostela, Spain

# **ABSTRACT**

Seafood processing industries in the NW coast of Spain generate significant amounts of shell waste. Recent regulations and strategies on waste open up new opportunities to sustainable development through the management and the treatment of aquaculture materials, previously considered as waste. They encourage the recovery of waste and their use as raw materials in such a way that the consumption of resources is reduced and the sources of pollution can be minimised. This paper presents a plant dealing with mussel shell waste as input in its valorisation process, which is considered *a priori* an eco-friendly solution to the disposal of these products. It is a clear procedure to turn waste into a high value-added product like lime, a secondary but sustainable raw material with a market potential to be used in different applications. However, as a result of the thermal treatment of the shell waste, odour emissions to the atmosphere become a serious problem. The pollution caused by these odours produces an environmental and social conflict between the industry and the population of the surrounding area. Accordingly, our work aims at identifying the sources of pollution to seek solutions for the odorous emissions from the installation.

# **1.INTRODUCTION**

In 2015, Spanish aquaculture generated 293,000 tons of marine products, including 277,000 tons from the cultivation of marine species (94.5% of the total production), and the rest from continental aquaculture (5.5% of the total production). The highest production of Spanish aquaculture corresponds to mussel farming (mainly *Mytilus galloprovincialis*), which in 2015 represented 77% of the total national production with 225,000 tons (FAO, 2017).

Spanish aquaculture stands out in Europe and worldwide for the breeding of bivalve molluscs. In 2015, the production of molluscs in the world was 16,473,112 of tons, which 3.8% corresponded to the European Union (APROMAR, 2017). Galicia, in the north-western coast of Spain, is the world leader in the cultivation of mussels for human consumption, producing more than 212,000 tons in 2010 (Bello Bugallo et al. 2012).

Mussels farmed in floating nurseries are hence the most important product of the sector, requiring neither input of nutrients nor control over its reproduction cycle thanks to the special conditions of the warm water temperatures and high primary production of the estuaries.

Therefore, agro-food industries encompass a group of industrial activities aimed at transforming, manufacturing, preserving and canning foodstuffs, generally from raw vegetal or animal-natured materials. These industrial activities, as any other productive processes, show several features that have a great bearing on the environmental impacts they cause, as follows (Álvarez-Campana et al. 2004):

- The exploitation of raw materials never achieves the 100%.
- The necessary auxiliary materials in the manufacturing process, which are not incorporated in the final product, turn them into waste when they do not gather the essential specifications for their usage.
- The specific operations of a productive process generate emissions.

This is the case of the marine aquaculture and seafood-processing industries that fulfil the above conditions by generating a huge amount of shell waste that could be environmentally sound recovered.

Since the mid-1970s, the EU's environmental policy has been articulated around action programs that establish priority objectives for a period of several years. The current program, which is the seventh of its kind, was approved by the European Parliament and the Council of the European Union in November 2013 and covers the period up to 2020 (EC, 2013). The Program has helped to move towards a policy based on sustainable consumption and production. This highlights the importance of the Thematic Strategies on the Sustainable Use of Natural Resources and on the Prevention and Recycling of Residues (EC, 2013), regulated through the Directive 2008/98/EC (EC, 2008) on waste that includes specific obligations in this matter. Thus, the Member States would develop waste prevention programs with the ultimate objective of decoupling the waste generation from the economic growth. So, the kingdom of Spain has the obligation to have a Waste Prevention Program. On his behalf, Law 22/2011, of July 28, on waste and contaminated soils (Spanish Government, 2011), establishes in article 15 that public administrations, in their respective areas of competence, will approve waste prevention programs, in which the objectives of prevention and reduction

of the amount of generated waste will be established (MAPAMA, 2017). These regulations and strategies on waste point to new opportunities to sustainable development, since they promote the application of environmental technologies and the recovery of waste in such a way they could be exploited as resources (COM, 2005). However, this valorisation process is a source of odours owing to its inherent features. On the other hand, dimensions of nuisance odour provide a commonly accepted basis for the development of jurisdictional criteria of environmental odours (Brancher et al. 2017). Odours emitted by food and waste valorisation industries are even more worrying the nearer the installations are to the residential areas. Nuisance odours are the result of an industrial process where the biological or chemical reactions give rise to odorous VOC (Volatile Organic Compounds) and are frequently accelerated by thermal treatments such as drying or calcination. Generally, the odour threshold in the surrounding area and the sensations it causes are very subjective.

The Integrated Pollution Prevention and Control regulation, the so-called IPPC Directive (EC, 2010) that was updated in 2010 and transposed to the Spanish legal framework by the law 5/2013 on 11 of June (Spanish Government, 2013), has established a framework for assessing and regulating the most polluting industrial activities. The priority of this Directive is to achieve a high level of protection of the environment taken as a whole, especially by the prevention or, where not practicable, the reduction of pollutants, and thus, avoiding the transference from one medium to another (air, water and land). Specific processes that fall under the IPPC scope, like those carried out in plants for treating animal by-products, are required to determine their impact on several criteria, including odour impact. The industrial sectors involved are encouraged to define 'Best Available Techniques' (BAT) and 'Emission Limit Values' (ELV) at European level to achieve a greater efficiency in the environmental management and the performance of these facilities.

This work presents a plant dealing with mussel shell waste as input in its valorisation process, which is considered *a priori* an eco-friendly solution to the problem of disposal of this product. In fact, it is a clear procedure to turn waste into a high value-added product like lime, a secondary but sustainable raw material with a market potential to be used in different applications. However, as a result of the thermal treatment of the shell waste, odour emissions to the atmosphere become a serious problem. The pollution caused by these odours is creating an environmental and social conflict between the industry and the population of the surrounding area. Accordingly, this work aims to identify the sources of pollution to seek solutions and options for the prevention and control of odorous emissions from the installation. This is a new step in the greening process of the existing industrial activity.

#### **1.1. Odour Management**

The waste incineration activity in the EU is regulated by Directive 2010/75/UE (EC, 2010). It was transposed to the Spanish legal system by Royal Decree 815/2013 (Spanish Government, 2013), which establishes the design, equipment, building and exploitation conditions for the incineration installations. However, materials as specific as the by-products derived from the mussel industry (mainly mussel shells) are not included into the scope of these regulations. The whole animal carcasses and parts thereof can be considered as unprocessed animal by-products and must be incinerated or co-incinerated in accordance with Regulation (EC) nº 1069/2009 (EC, 2009). This law sets the health rules concerning animal

by-products not intended for human consumption. Should this waste be destined for incineration it will be regulated by law 22/2011 on waste, of July 28 (EC, 2013).

The shell, as part of an animal or product of animal origin not intended for human consumption, is considered a by-product, a category 3 material, as far as section j or section k (i) of article 10 is concerned according to Animal By-products Regulation (EC, 2009). It defines shells as the animal by-products of aquatic animals of establishments or plants that manufacture products for human consumption in section j or as a material of animal that does not present any sign of a disease transmissible to humans or he animals through said material, like mollusc shells stripped of soft tissue or meat. Consequently, their treatment has to comply with the specific provisions imposed by this law for this kind of material. Despite the extensive regulations regarding animal by-products processing, the already mentioned legislation does not include any measure concerning atmospheric emissions control, although waste treatment processes are known to produce both chemical and biological emissions that can be perceived as odour (Aatamila et al. 2011).

Odours have been ranked as the major generators of public complaints to regulatory agencies in North American and European communities (Leonardos, 1995), and it has even been reported that in some European countries between 13% and 20% of the population is bothered by environmental odours (Hudon et al. 2000). These complaints are mainly consequence of the negative effects that prolonged exposure to foul odours can generate on people, causing reactions that range from emotional stress to physical symptoms (National Research Council Committee on Odors, 1979). In these situations, in which an odour is proved to have substantial negative impacts on the quality of life of a community, the odour emissions are considered to be a nuisance (Duffee, 1995).

Currently, there is no specific legislation on odours either in the EU or in Spain. However, efforts towards regulations addressing odour control are being made. One example is the "Horizontal Guidance for Odour" (UKEPA, 2002) from the UK Environment Agency. This is used as a reference for environmental permits in Europe, and also establishes some reference limit values for odorous emissions. Another European example is the "Netherlands Emission Guidelines for Air" (*Nederlandse emissierichtlijn lucht*) (Netherlands Agency, 2004), which proposes the application of emission-abating measures by implementing Best Available Control Technology for reducing air pollution with regard to the ALARA principle (As Low As Reasonably Achievable).

Spain has no specific instruments to legislate on odours at federal level. Generally, odours are treated subjectively in federal environmental laws. The Spanish regulation is still incipient in this regard, and is based on municipal ordinances or activity licences (Brancher et al. 2017). For this, air quality is ruled by Law 34/2007 (Spanish Government, 2007) that in spite of not including any specific regulation about odours, it establishes the bases for preventing, monitoring and reducing atmospheric pollution in order to avoid, and when not possible lessen the damage they could cause to people and environment. The government of the Autonomous Community of Catalonia has been the first Spanish region to develop a draft (Generalitat de Catalunya, 2010) for a future law concerning odorous pollution. It started in 2005 and it is still being updated, as the latest draft version is from 2010. Although this does not fix any ELV, it establishes odour immission objectives for those areas requiring special protection, such as residential areas. These objective limits range between 3 and 7  $ou_{E}$ (European odour units) calculated as 98th percentile. Areas exceeding these values are considered to be odorously polluted, whereas immission values over 10 ou<sub>E</sub> cause nuisances

to people. The draft also proposes reducing odours by implementing techniques candidate to be BAT, as well as good practices over the individual focus.

Against this lack of regulation on odours, some authors develop strategies to control and mitigate them. That is the case of Nicell (2009), who has proposed a framework for the regulation of odours that states that facilities that are identified as sources of potentially offensive odours shall ensure odours concentrations below 1 ou 99,55% of the reference time, which is considered to be 10 minutes. Other authors carried out studies to analyse the origin of odours in order to reduce them. For instance Kim et al. (2008), measured emission concentrations of several compounds from various facilities located in a large industrial complex. They analyse their effect over odour pollution according to two major criteria, namely the industrial type and the source process unit. Another example is Cheng et al. (2009), who performed several odour sampling campaigns after implementing different odour control measures to reduce dimethyl sulphide emissions.

# **2. CASE STUDY**

The shell is produced as a rejected material in different marine aquaculture activities and seafood processing industries such as production companies, mollusc purification plants and boiling facilities and canneries. For the particular case of the mussel, the shell roughly represents between 31-33% of the total weight for this kind of molluscs used in the canning and processing installations aforementioned (Conservas Isabel Galicia S. L., 2006; Barros et al. 2009a). The shell is a composite biomaterial, for which the mineral phase, calcium carbonate, accounts for 95 to 99% per weight, whilst the remaining 1-5% represents organic matter (Barros et al. 2007). This abundance of calcium carbonate in the shells can be exploited to be used for a wide range of applications.

The installation under study was a shell valorisation plant extracting calcium carbonate from mussel shells or other seashells by a thermal treatment to obtain commercial valueadded products to be used in diverse applications. The plant, whose theoretical capacity was around 80,000 tons per year, was strategically located in Galicia, near the estuary of Arousa, in the north-western coast of Spain, to absorb the significant amounts of shell waste generated by the production centres located in the coastal areas of the region (Figure 1). It was placed in an industrial park taking up an area of  $21,450$  m<sup>2</sup>. The built-up surface accounts for  $5,120$  m<sup>2</sup>, where the production plant has  $4,150 \text{ m}^2$  and eleven-meter high.

Since the beginning, the installation faced some general difficulties related to its environmental behaviour, but also specific problems related to odours, as the process uses as raw material an organic by-product, mussel shells, whose degradation results in odorous compounds among other pollutants. Aiming to improve the performance of the plant, the whole process was qualitatively analysed stage by stage, so that the potential Improvable Flows (IF) were identified and characterised. According to the results of this analysis, some techniques and good practices were proposed and implemented through a first five-year period aiming to "green the process." After this first period, as odour problems persisted, it was suggested a deeper study whose main objective was to qualitative and quantitatively identify and define the potential odour sources in order to select the most appropriate techniques to avoid odour emissions.

Figure 1. Geographical location of the installation under study and the shell production centres in Galicia.

# **3. METHODOLOGY**

The method used in this work includes three main steps as indicated below.

- *1. Greening the process*. The whole plant was subjected to a greening process due to several facts: a) as a response to the first environmental problems detected in the plant, b) the growing awareness on the impact of emissions over the surrounding areas and, c) supported by the implementation of more restrictive regulations. It implied a deep qualitative analysis of the process following the methodology described by Barros et al (2009b). It continued with the proposal and implementation of several techniques and good practices addressed to improve the environmental performance of the installation. Key improvements were carried out during five years (first period) to reduce the polluting emissions and improve the working conditions in the plant. These results are explained in detail by Barros et al. (2009a).
- *2. Olfactometric analysis. This technique was proposed and implemented in 2007 owing to the persistence of the odour pollution in the plant. It includes three substages:*
- a) Qualitative analysis. Identification and justification of the potential odour sources of the plant, according to the process description included in the previous stage (Barros et al. 2009a).
- b) Quantitative analysis. Sampling in the identified sources and analysis of the samples according to the European Standard EN 13725 (UNE, 2011). Odour and odorous compounds emissions, namely as VOC (Volatile Organic Compounds), NH3, H2S and R-SH, were quantified.
- c) Immission analysis. Passive sampling in selected locations (inside the plant and in its surrounding area) to determine the immission concentrations of VOC and NH3.
- *3. Results. Evaluation and discussion of the results of the olfactometric analysis. It includes two sub-stages.*
	- a) Detection of improvable flows. According to the results obtained from the quantification of emissions, the most likely flows to be improved are identified and ranked according to their contribution to the total odour emissions of the plant.
	- b) Identification of solutions. Techniques and good practices aiming to avoid, or at least reduce, odour emissions are proposed to each of the identified improvable flows.

## **3.1. Greening the Process**

Greening the shell valorisation process solved several major problems that the plant was facing at that time (Barros et al. 2009a). During a first five-year period, 18 techniques and good practices aiming to improve the environmental performance of the plant were proposed and applied with quite satisfactory results since emissions of some pollutants (mainly dust, CO and VOC) were greatly reduced. Amongst the measures implemented during these years, five of them specifically referred to odour emissions:

- Use of fresh mussel shells as raw material, to reduce the grade of decomposition and minimise VOC releases.
- Hoppers with automatic doors permanently closed, except for loading and unloading. The material should be processed in the same day of its reception.
- Periodic water-cooling of the washed shells stored in the silos to avoid fermentation and VOC releases. Three days will be the maximum storage time in silos.
- Substituting the existing wet scrubber with a more efficient abatement technique. When inherently malodorous substances are produced during the calcination of the shell, the low intensity/high volume gases should go through some abatement equipment, such as a biofilter or an oxidiser, to clean the gas stream where odour prevention is not reasonably practicable. There are several devices to treat VOC emissions that should be considered to collect the waste gas stream by an extraction system prior to the end of pipe treatment. They are divided into recovery techniques, such as membrane separation, condensation, adsorption and wet scrubbers for gas removal and, abatement techniques such as biofiltration, bioscrubbing, biotrickling,

thermal or catalytic oxidation and flaring (EC, 2016). The technique chosen for the plant was a regenerative oxidiser (Figure 2), given the nature of the waste gas stream from the kiln. Besides its content in organic substances (carbon monoxide, VOC and others), the existence of ashes made necessary a bag filter prior to the abatement equipment to firstly scrub the exhaust gases. Thus, both equipments assure not only the removal of particulate matter from the gaseous stream (less than  $10 \text{ mg}/\text{Nm}^3$ ), but also the destruction of any existing VOC at temperatures of 800-1000ºC inside the combustion chamber (efficiency higher than 95%).

Figure 2. Bag filter and regenerative thermal oxidiser.

 Monitor all sources of fugitive emissions. Despite the olfactory aggressiveness of some odorous emissions, their concentrations are usually below the detection level of conventional chemical analyses. This measure is deeply developed in the next stage of the methodology.

#### **3.2. Olfactometric Analysis**

Determining the odourous compounds is a complex process, as the odour potential of a compound depends on objective aspects such as volatility and solubility, and subjective ones such as physiological and psychological characteristics of the receptor (Bruno et al. 2007). Olfactometry is a technique for sampling and analysing odours, coupled with dispersion modelling, which allows evaluating the nuisance caused by odours and determining their origin. Olfactometric studies are a useful tool to control and reduce odours emitted by different types of sources as they do not only determine the degree of nuisance created in the environment, but also identify odour sources. This permits the adoption of effective elimination or reduction measures.

The olfactometric analysis performed at the installation includes three stages that will be discussed below, namely qualitative, quantitative and immission analysis.

#### *3.2.1. Qualitative Analysis*

A general flow sheet of the valorisation process is shown in Figure 3 as part of the mussel shell life cycle from de reception of de mussel shell to the exit of the  $CaCO<sub>3</sub>$ . The valorisation process carried out in the plant can be divided in three main stages, such as preliminary operations, processing and auxiliary operations. Preliminary operations consists in the reception and unloading of the raw materials, in addition to those operations involving the elimination of salt and mud contained in the shells and the storage prior to their processing. Processing involves the thermal treatment of the shells and the subsequent cooling of the burnt material and, finally, auxiliary operations, which are additional operations such as milling and sorting, that prepare the final product for marketing. Other operations are the final product storage and its packing and shipment.

Figure 3. Flow sheet for the mussel shell valorisation process. S1 to S6 indicate the sampling points for quantitative olfactometric analysis in Table 2.

Considering the analysis of the process developed in a previous work (Barros et al. 2009a), the potential odour sources have been qualitatively identified. They mainly correspond to the storage of raw material prior to its processing and to thermal treatments, where VOC derived from the destruction of the organic fraction are released. The selected points, as well as their effect over the odorous emissions released by the plant, are described below:

 Reception and storage. Raw mussel shells are unloaded in two ground-level reception hoppers where they remain until they are processed (the same day they are received). The transport of raw materials from the production centres to the valorisation plant strongly influences the emission of odours. A key parameter to consider is the shell lifetime at the time of collecting, as it has a remarkable importance in the degradation state of the waste. The flesh attached to the shell is highly perishable and generally requires either rapid storage and containment or quick processing to avoid decomposition and, consequently, odour emission and dispersal of pathogens. Other parameters to take into account are the climatic conditions (sunny and hot weather

favours faster reactions), as well as the cleaning of the vehicles and the storage time of the shell in the production centres.

- Washing and dripping. This step consists in cleaning the shell with freshwater to reduce the salt content of the final product, avoid the wear of the equipment by corrosion and obtain a more concentrated product of  $CaCO<sub>3</sub>$ . Therefore, it is very demanding on water and accounts for 80-90% of the total water consumption inside the installation. This activity is carried out in two rotary washing machines operating counter currently to increase the performance of the salt extraction. Afterwards, there is a shaker draining rack to remove the water dragged by the product. Then, wastewaters and mud waste go to the on-site wastewater treatment plant (WWTP) where they undergo a physicochemical treatment.
- Storage. After washing, clean mussel shells are stored while they complete their dripping in stainless steel silos that are loaded by gravity and unloaded by a vibrating system to favour the thermal treatment. The washed shells stay here at most for three days. The leachates generated here are channelled to the WWTP for its treatment. Odours released in this stage are mostly related to the dripping of the washed shells, which generates leachates containing some remains of the dirt and organic matter that embedded the raw mussel shells received in the plant.
- Calcination. Mussel shells are burnt in a counter-current rotary kiln that integrates two processes, drying and calcining, in a single piece of equipment. The kiln, whose production capacity is 18 tons per hour, is 17 meters long and 2.5/3.0 meters diameter, and it is divided in three sections (Figure 4). The residence time of the material depends on the spin velocity of the kiln, but it ranges between 20-30 minutes. Four thermocouples (T1-T4) register and monitor the temperature in different sections inside the kiln.

Figure 4. Rotary kiln. The four thermocouples indicate the following temperatures: T1 (125-250ºC), T2 (225-250ºC), T3 (300-325ºC) and T4 (475-500ºC).

Calcination is an important source of odours since its operating temperature ranges between 125-500ºC. This is not enough to destroy odorous compounds, as incineration processes with temperatures below 850ºC can result in odour emissions (EC, 2006). The gases emitted by the kiln during the analysed mussel shell valorisation process show the following features:

- Volume of flow:  $14,000 \text{ Nm}^3/\text{h}$
- Temperature: 130-150°C
- Moisture: 17% (vol.)
- VOC (as TOC) concentration:  $650 \text{ mg}/\text{Nm}^3$

In spite of being hardly detectable concentrations of organic substances, the released gases are aggressive olfactory emissions of an intense and unpleasant smell and with high temperatures. As a result of the "greening the process" stage, an abatement technique for odorous compounds was implemented. This technique combines a bag filter, which assures the removal of particulate matter from the gas stream  $\left(\frac{10 \text{ mg}}{Nm^3}\right)$ , with a regenerative oxidiser that destroys more than 95% of the VOC operating at temperatures that range between 800-1000ºC.

• Cooling. The burnt material is cooled down from 500-600°C to 60°C through a twostep process. It begins with the injection of thinly dispersed water to reduce temperature from 500-600ºC to 170-190ºC, and finishes with air refrigeration, that completes the reduction of the temperature from 170-190ºC to 60ºC.

Both the leachates from water injection and the refrigeration air could drag some organic compounds still stuck to the burnt shells that may result in odour emissions.

 Milling. Milling is aimed at crushing the shell to obtain products with purity levels of 90-95% in CaCO3 and different sizes of particle that will determine its industrial application. This stage includes diverse operations to obtain different particulate sizes (Table 1), namely grinding, screening and micronizing.

This process mainly generates dust and particulate matter emissions that are conducted to the dust abatement equipment that recovers dust and reincorporates it to the process. Besides dust, VOC can also be released during milling processes. Mostly because of some remains of organic compounds that were not totally destroyed during the thermal processes.

 Storage. After sorting the milled shells according to their particulate size, the sorted fractions of the final products are stored in three adjustable hoppers with regard to its grain size. From them, the products can be stored either in two enclosed warehouses or in silos depending on the final use of the product or the packaging format in which it is marketed.

Despite the high quality of the final product (90-95% of CaCO<sub>3</sub>), some VOC can still be released during storage.

• Packing and shipment. The final products are packaged in bulk (tanks or containers) or big bags of 35 kg and 1 tons, and shipped off for sale.

#### **Table 1. Particle size related to milling operations**

#### *3.2.2. Quantitative Analysis*

The quantitative olfactometric analysis was done according to the procedure described by the European Standard EN 1372:2004 ERRATIUM:2011, Air quality – Determination of odour concentration by dynamic olfactometry (UNE, 2011), which provides a reference method for sampling and assessing odours, whose concentrations are calculated and expressed in European odour units ( $ouE/m<sup>3</sup>$ ).

The sampling points (S1 to S6) shown in Figure 3 correspond to the qualitatively identified potential odour sources (Table 2).

The samples taken from the identified sources were analysed by dynamic olfactometry, procedure PE-OLF/007 (UNE-EN 13.725), which resulted in odour concentrations for each sample in ou $E/m^3$  (Table 3). From these results, the punctual odour emissions (ou $E/h$ ) were calculated using data about the gas flows and the exposed area in each focus. Furthermore, for all the odour sources, sulphide, ammonia and mercaptan concentrations were assessed with Dräger colorimetric tubes. Ammonia results were confirmed by measurement with a specific electrochemical detector, Gas Alert Micro 5Pid (BW Technologies, Calgary, Canada).

Sample		Process stage
S <sub>0</sub>		Reception and storage
S <sub>2</sub>		Storage (in a silo)
<b>S.3</b>	S.3.1	Calcination (exhaust gases from the thermal oxidiser)
	S.3.2	
<b>S.4</b>		Cooling
S.5		Milling (shed)
S.6		Storage (shed)

**Table 2. Process stage points sampled for the quantitative olfactometric analysis**

#### **Table 3. Odour emissions and odorous compounds emissions in the sampled points**

For sample 3 (S.3.1/2), considering the odour concentrations obtained for each sample, an average odour concentration value is calculated, resulting  $93,015$  ou $E/m<sup>3</sup>$ . The airflow is calculated considering the gases output velocity and the section area in the sampling point. The gases output temperature was 174.2ºC and 180.3ºC respectively, and the pressure 1,013 mbar. The average odour emission calculated using the data obtained for both samples is  $1.488 \text{ ouE/h}.$ 

The characteristics of the mussel shell drying/calcining gases depend on the nature of the VOC they contain. Thus the odours they release can be different in type and intensity. The gas stream resulting from the drying/calcination stage has been analysed to identify the most abundant and odorous VOC present in the gases released during the thermal treatments. The analysis focuses on the most odorous compounds shown in Table 4, where two different samples are compared:

- Sample A, taken and analysed in 2004, before implementing the abatement equipment for the gas stream of the kiln (bag filter – regenerative oxidiser). The sample corresponds to the gas stream emitted by the calcination kiln.
- Sample B (duplicated), as part of the present sampling, taken after implementing and operating the bag filter and the thermal oxidiser. The samples correspond to the gas stream emitted by the thermal oxidiser.

### **Table 4. VOC concentration in samples taken before and after implementing the thermal oxidizer**

\* Semi-quantitatively analysed with respect to the areas corresponding to a pattern of benzene and chloroform (125  $\mu$ g/m<sup>3</sup>).

The gas output from the drying/calcination process in the case study is composed by a big amount of substances (mainly VOC) characterised by their odorous intensity, and with really low odour thresholds. The analysis results show quite high concentrations of some VOC, such as benzene, acetone, toluene and  $C_4H_6$ . For most of the compounds, the concentrations were found to be  $\langle 0.10 \text{ mg/Nm}^3$ , although for some other compounds the concentrations were quite higher (Table 4).

As it can be seen in Table 4, the observed differences in the results of VOC emissions in 2004 and 2007samples indicate malfunctions, not adequate techniques or abnormal operating conditions, among others.

#### *3.2.3. Immission Analysis*

Passive sampling was used to determine the immission concentrations of VOC and ammonia in different locations. The procedure used for sampling was UNE-EN 13528-1/2, ambient air quality: diffusive samplers for the determination of concentrations of gases and vapours (UNE, 2011). Twelve sampling points were selected from the plant and its perimeter to evaluate the effect of odorous compounds over the environment. The sampled points were:

P1: Truck unloading area P2: Perimeter fence (close to entrance) P3: Outer road P4: Perimeter fence (close to fuel tank) P5: Outflow of the air conditioner of the offices P6: Reception P7: Silos ship (6 m high) P8: Silos ship (12 m high) P9: Calcination ship P11: Final product storage ship P12: Sewage

Ammonia was determined by water sensor extraction according to the Radiello protocol followed by indophenols colorimetric analysis (Spectrophotometer Shimadzu UV-1603). On the other hand, VOC samples are taken with a graphitized carbon cartridge, which thermally desorbs using a thermo-desorption system directly coupled to a gas chromatography (Agilent 6890N) mass spectrometry detector (Agilent 5973).

The immission results (Table 5) show quite high  $NH<sub>3</sub>$  concentrations, especially in those sampling points where process equipment is located. The same applies to VOC emissions, although sampling point P4 shows quite big immission concentrations of certain VOC, owing to the fact that fuel is stored in that area. These results show that although VOC and NH3 concentrations may be quite high in the areas where the proper process takes place, they are reduced with the distance.

\* Problems in the chromatograph injector made it impossible to analyse the sample. \* Problems in the chromatograph injector made it impossible to analyse the sample.

## **3.3. Results**

#### *3.3.1. Detection of Improvable Flows*

According to the results obtained from the olfactometric analysis (Table 3), the most important odour sources are the thermal treatments, as calcination has been pointed out the most odorous process by far. The storing areas are the next most odorous sources, being the storage of the raw materials more odorous than the storage of the final products. Finally, the analysed stage generating less odour emissions is milling. This ranking is supported by the results obtained from the analyses of  $NH_3$ ,  $H_2S$  and R-SH concentrations, as calcination showed by far the highest concentration for all the compounds, whereas the rest of the sampled processes presented concentrations below the range in most of the cases. Consequently, calcination is the most important improvable flow detected in this process, as the odour concentration of its gas stream is more than fifty times bigger than the next most polluting source, namely cooling. However, in spite of these great differences between the sampled points, none of them are negligible when compared with the "relative offensiveness of odours" proposed in the Horizontal Guidance for Odour (UKEPA, 2002). Here it is suggested that offensive odours, such as the ones derived from activities involving putrescible waste or from processes involving animal of fish remains, can cause annoyances if they exceed 1.5  $\text{ou}_\text{E}/\text{m}^3$  98th percentile (hourly average concentration for odour measured at the nearest odour sensitive receptor beyond the facilities boundary), which is by far exceeded by all the analysed samples.

The stages likely to generate some leachates have been found to be quite odorous, as storage after washing (where the raw materials drips water), reception and storage of raw materials and cooling. According to this conclusion, the wastewater treatment plant should have been included as an out of process sampling point, as it may be a potential odour source. But its odour emissions have not been included into the scope of this paper because it is only focused on the mussel shell valorisation process itself. However, some techniques and good practices will be proposed to mitigate odour emissions from the wastewater treatment plant.

## *3.3.2. Identification of Solutions*

Although diverse technologies to control odour nuisances have been developed or improved (EC, 2005), the best method to manage this type of emissions is the elimination of the odorous components before their formation, thus avoiding a further treatment of the waste gas stream. Nonetheless, most of the waste valorisation installations cannot have an exhaustive control over all the VOC emitted during their processes.

Considering the improvable flows detected after evaluating the results of the olfactometric analysis, some measures and alternatives aiming to prevent and/or limit the odours in the installation have been selected and proposed for their implementation in the plant. They are classified according to the process stage where they should be applied.

#### **3.3.2.1. Reception and Storage of Raw Materials**

 Collect the shells as soon as possible after their production. This measure can be easily implemented due to the strategic position of the objective plant with regard to the production centres (Figure 1), so the shell arrives to the plant within 48 hours after its rejection.

- Raw materials should be transported in hermetically sealed containers to prevent the emission of liquid effluents. Waste should be saved dry whenever possible to avoid increasing odour problems.
- Containers, packaging and vehicles used for transporting unprocessed material must be cleaned in a specifically designed area.
- The floor in the storage facilities should be waterproof and extraction systems should be installed to collect residual gases for further treatment.
- Installations and equipment must be regularly cleaned and disinfected.
- Preventing anaerobic conditions by aeration, turning of waste and short timescales (UKEPA, 2002).
- Reduce temperature during storage by avoiding direct sunlight or otherwise reducing the water evaporation rate and the release of dissolved odorous chemicals (UKEPA, 2002)
- Minimise airflow over the surface of odour-releasing materials, which also reduces the rate of evaporation (UKEPA, 2002).
- The shells must be processed immediately after their arrival to the plant, otherwise stored properly until processed in enclosed buildings with sealed hoppers to avoid the emissions outside the facilities. In the plant, the maximum storage time in the hoppers is the same day they are received to avoid the decomposition of the remaining flesh attached to the shells.
- The shells are stored in silos up to three days after washing to avoid fermentation processes and the release of odours. But if fermentation occurred, the shells should be washed to control the achievable temperatures (up to 70ºC).

# **3.3.2.2. Thermal Treatment**

- The shell must be placed straight in the kiln without any direct handling in order to prevent kiln opening during loading operations that favours the release of residual gases. The input of shell to the kiln is done and regulated by a dosing machine.
- Adjust the main parameters of the process, such as temperature, duration, pressure or venting, to reduce formation and/or release of odorous compounds (UKEPA, 2002).
- Contain odorous air within process machinery to avoid contaminating larger volumes of ventilation air within buildings, which can consequently reduce the cost of air treating (UKEPA, 2002).
- Enclosing odorous waste all the way to the thermal treatments stage (UKEPA, 2002).
- Drawing air from odorous areas at a rate that will ensure that odour is captured and feeding, as far as possible, odorous air into the combustion process (UKEPA, 2002).
- Control the temperature up to 850ºC ensuring that is maintained at all times during operation and as long as unburned material is inside.
- The gas resulting from the process is heated, in controlled conditions, to a temperature of 850ºC for two seconds. As previously explained, the temperatures inside the combustion chamber achieved this figure.

#### **3.3.2.3. Final Product Management**

- Avoid odours emissions by keeping windows and doors shut in process building, by implementing remotely operated roller doors that reduce the time that doors are open or by maintaining negative pressure within the process plant (UKEPA, 2002).
- Good housekeeping to avoid the appearance of malodorous materials and wastes except in designated (and appropriately managed) areas (UKEPA, 2002).
- Suitable and sufficient staff training with regard to odour control. Staff should also be aware of relevant licence conditions and emission limits in its work (UKEPA, 2002).
- Buffer zones in areas where odour is emitted at low level (UKEPA, 2002).

#### **3.3.2.4. Waste Water Treatment Plant (WWTP)**

- Prevent wastewater stagnation by laying the pipelines related to the WWTP with a certain inclination.
- Subject the leachates and the effluents to a biological treatment process, aerobic or anaerobic. At present, the treatment carried out in the plant consists on a physicochemical treatment including solid screening, homogenization and dissolved air flotation, where the flocculation-coagulation processes take place. Once the flocculates are separated, they are transferred to a sludge pit and then they are thickened and dewatered in a centrifuge. However these processes are not enough to comply with the emission values set by the Competent Authorities due to the high organic load in the wastewaters. For this reason, a biological stage of nitrificationdenitrification is planned to be included in the WWTP for further treatment of the wastewaters. This stage is currently starting up and no data is available, but it is expected to meet the allowable discharge limits. Furthermore, water consumption in the most water-demanding step, the washing of shells, is minimised as cleaned water is fed back to this operation.

# **CONCLUSION**

The case study of this work is a pioneering industrial activity on thermal valorisation of mussel shells reutilizing wastes as resources. This makes every unexpected technical fault is faced up to without any previous background. Therefore, the organisation is a source of new experiences regarding technological development.

Getting the environmental permit required to operate according to the provisions of the IPPC is a driving force to audit and monitor odour emissions, reduce their generation to the surrounding area by means of the aforementioned measures and best environmental practices and upgrade the operating conditions of the equipment and the facilities. Nevertheless, despite the efforts carried out over the years in order to improve the productive process, hard work is still going to be addressed to prevent and/or control the environmental impacts derived from shell valorisation.

In spite of the variety of prevention and abatement alternatives proposed, odour problems are better dealt with at source, by means of process design or modification, or even managing the activity differently (UKEPA, 2002). Therefore the best odour management program for the process analysed, mussel shell valorisation, should include a complete re-design of the process, taking into account the conclusions extracted from this work, which has pointed out thermal treatments as the most odorous processes, followed by raw materials storage. Operating procedures should also be updated to eliminate those practices that can affect the total odours emissions released by the plant.

# **DETERMINATION OF EMERGING METAL POLLUTANTS AND TOXIC METALS IN MUSSELS AND BIVALVE MOLLUSKS, VERY IMPORTANT FOOD AND ENVIRONMENTAL BIO-MONITORING SPECIES**

# *Clinio Locatelli , Dora Melucci, Francesco de Laurentiis and Alessandro Zappi*

Department of Chemistry "Giacomo Ciamician," University of Bologna, Italy

# **ABSTRACT**

A quick and widespread diffusion of heavy metals as contaminants in all the environmental systems has called the attention to their determination. Indeed, heavy metals, together with pesticides, are very dangerous pollutants owing to their bioaccumulation and toxicity. It is, therefore, necessary to determine these metals at trace and ultra-trace level especially in aquatic ecosystems to establish reasonable water quality criteria.

Certain marine species, in particular mussels, clams, but also oysters accumulate toxic metals, being filtering organisms. It was verified that an adult organism is able to filter several liters per hours (also up to  $4-5$  L h<sup>-1</sup>), depending on its weight.

This prerogative involves two important facts and consequences:

- 1. The ability to accumulate all harmful substances for humans, toxic metals, in particular, requires particular attention and inspections before being sold on the market.
- 2. In addition to this important and fundamental aspect of public health, the determination of toxic metals in mussels, clams and also oysters, that are not only filtering organisms but also sessile species, can be usefully employed for biomonitoring campaigns, that evaluate the long-term trend of the pollution load of an aquatic ecosystem, information that evidently cannot be provided by punctual

 $\overline{a}$ 

Corresponding Author's Email: clinio.locatelli@unibo.it.

determinations. For completely mapping environmental pollution, the sampling duration and cadence are very important. However, it should be emphasized that the use of bio-monitors, just proposed by several authors, but certainly not scientifically supported, is possible only in the case of a long sampling plan.

In any case, the metal determination in mussels and bivalve mollusks evidently must be accurate, reproducible and especially it must show very low limits of detection.

The present work reports and discusses the different analytical methodologies for the determination of emerging metals pollutants, together with all toxic metals, in mussels, clams, and oysters.

**Keywords**: mussels, bivalve mollusks, toxic metals, instrumental determination.

# **INTRODUCTION**

Metals are an integral part of the food chain, and everything is ingested by humans contains metals. Metals (that can have natural or artificial origins, the latter including also criminal acts) may become very dangerous in several cases, sometimes with effects irreversible for human life. Therefore, it is important to characterize and quantify these species also at trace and ultra-trace concentration levels, that is often enough for several metals to give high risks of toxicity to humans [1-3].

Moreover, toxic metals enter in the food chain by accumulation in certain marine species. In particular mussels, clams, and oysters, but also shrimps, algae and fishes, were found to sequestrate and concentrate metals from the aqueous environment. It is clear that these species, being part of the food chain, may be dangerous for human health. In particular mussels, clams and oysters are filtering organisms – an adult organism can filter up to  $5 L h^{-1}$ , depending on weight, size, and water temperature −, thus they require special attention and surveys before placing them on the market.

Furthermore, it should be emphasized another aspect: mussels, clams, and oysters, which are also sessile species, may be employed as interesting bio-monitors of metal pollution in limited ecosystems [4-13]. Up today, it has not been described a rigorous correlation between pollution of the aquatic ecosystem and toxic metal content in bio-monitor species. Anyway, it is at least very close to the truth the statement "*high concentration of toxic metals in biomonitor species most likely implies a strong pollution of their aquatic ecosystem.*" The use of bio-monitors is probably the only possibility to obtain a long period environmental information and to evaluate the pollution trend of an aquatic ecosystem in the long-term; clearly, such information cannot be provided by punctual determinations: single samplings at different times to quantify metal contents in water can give only punctual information, without any information on the concentrations trend in the considered ecosystem. Instead, the pollutants determination in organisms living for a long period in a certain ecosystem, give more reliable information about the previous history of that ecosystem. In any case, it should be highlighted that, to obtain a complete environmental pollution information from biomonitoring samplings, the sampling duration and cadence are extremely important.

The use of bio-monitors (mussels, clams, and oysters in the present case), proposed by many authors, is probably possible only with a long sampling plan. Obviously, this is a disadvantage, but perhaps it is also the only way to get long period environmental information.

The determination of toxic metals in mussels, clams, and oysters, both to establish a food quality and to be employed for bio-monitoring, must certainly be accurate, with very low detection limits.

This review provides the results of a research line followed for several years in our laboratories, i.e., the determination of toxic metals in environmental matrices involved in the food chain including mussels, clams, and oysters.

For each metal or group of metals, all instrumental techniques used for their determination in filtering organisms are also reported.

Together with this purely instrumental part, the possibilities to test and monitor the pollution load from toxic metals of an aquatic ecosystem using these species as bio-monitor organisms will also be highlighted.

Finally, last but not least, the use of these species in bio-remediation processes of aquatic ecosystems will be underlined and discussed.

Moreover, a new section has been inserted. It regards the thallium, a polluting metal of new generation, poorly considered for a long time, but recently subject of great interest from many researchers, owing to its increasing diffusion in the environment and very high toxicity.

Of this metal will be reported the most significant works relevant to its determination in filtering organisms, and will be described in detail also the analytical procedure developed by our research group for its voltammetric and spectroscopic determination in mussels, clams, and oysters.

Our Proposals concerning voltammetric and spectroscopic determination of toxic metals in bivalve mollusks is the following.

From about two decades, our research group is interested in the development of analytical methods for voltammetric and spectroscopic determination of toxic metals in matrices involved in the food chain. Among these, certainly mussels, clams, and oysters are particularly important. For these matrices, and in an extremely concise way, the experimental conditions proposed by us and the results obtained [1, 14-29] are summarized in the following.

## **EXPERIMENTAL**

## **Reagents, Reference Solutions, and Standard Reference Materials**

All acids and chemicals were supra-pure grade (Merck, Germany). Acidic stock solutions of all the elements  $(1000 \text{ mg } L^{-1}$ , Sigma-Aldrich, Germany) and Osmium tetroxide solution (4 wt% in water, Sigma-Aldrich, Germany) were employed in the preparation of reference solutions at varying concentrations, using for diluting water demineralized through a Milli-Q system.

Mussel Tissue BCR-CRM 278 (from Institute for Reference Materials and Measurements, European Commission, Joint Research Centre, Geel, Belgium) and Oyster Tissue NIST-SRM 1566a (from National Institute of Standards and Technology, Gaithersburg, MD, USA) were employed as Standard Reference Materials (SRMs).

#### **Sampling Area and Sampling Sites**

Mussels, clams, and oysters were sampled in the Goro Bay (Province of Ferrara, Italy; salinity: 2.7%; average temperature from June to September:  $23-27^{\circ}$ C). This is a very important area devoted to the fishing and breeding of mussels and clams for food, but with considerable pollution problems due to its location in proximity of the Po River mouth, which is the carrier towards the sea of a large amount of industrial and domestic wastewater.

Moreover, the waterways are also strongly influenced by atmospheric pollution load and then, they result to be also carriers of air pollutants, especially including those related to vehicular traffic as in particular the platinum group metals (PGMs).

In the Goro Bay flow three branches of the Po river delta mouth, i.e., Po of Volano, Canal Bianco and Po of Goro.

Samplings of bivalve mollusks were carried out in front of the points where such branches flow into the bay and in the central area of the bay itself, while an additional sampling, for eventual comparisons, was chosen at open sea.

All samplings were performed using a rubber boat without a motor to avoid any kind of pollution.

#### **Sample Preparation before the Instrumental Determination**

About *7-8 kg of Mytilus galloprovincialis* and of *Tapes philippinarum*, and 5-6 kg of *Crassostrea gigas* were collected in five sites (see section 2.1.2 "Sampling Area and Sampling Sites"), four within the mouth of the Po river (Goro Bay, Italy) and the fifth at open Adriatic Sea, taken to the laboratory and prepared for analyses.

They were opened with a plastic appliance and the organisms were carefully extracted and placed in polyethylene containers, previously treated with supra-pure HNO<sub>3</sub> diluted in 1:1 proportion with water and followed by repeated rinsing for 48 h with Milli-Q water in order to avoid any contamination. The samples were frozen and then lyophilized for 30 h. After that treatment, the samples were homogenized thoroughly in an agate mortar.

For all three kinds of real samples (mussels, clams, and oysters), the same sample mineralization procedure was carried out.

The sample preparation of Mussel Tissue BCR-CRM 278, Oyster Tissue NIST-SRM 1566a and of real samples of mussels, clams and oysters was the following: approximately 1.0 g, accurately weighed, was placed in a platinum crucible and dissolved in 5 mL 69%  $_{\text{w/w}}$  $HNO<sub>3</sub> + 4 mL 37%<sub>w/w</sub> HCl + 6 mL 98%<sub>w/w</sub> H<sub>2</sub>SO<sub>4</sub> at 130-150°C. The mixture was evaporated$ to dryness and, after cooling, soluble salts were dissolved in 25 mL of the electrolyte employed in the determination of the different metals.

## **Voltammetric Procedure**

All voltammetric curves were recorded by an Amel Model 433 multipolarograph, employing a conventional three-electrode cell. As for the working electrode, a hanging mercury drop electrode (HMDE) was employed for the determination of Cu(II), Pb(II), Cd(II) and  $Zn(II)$  [14-16, 20-22, 24-27], Sn(II) and Sb(III) [15, 16], As(III) and Se(IV) [16, 24, 26], Pt(II), Pd(II), Rh(III) [16], Os(VIII) and Ru(III) [16, 17, 19], a gold electrode (GE) (surface area: 0.785 mm<sup>2</sup>, AMEL, Milan) was employed for the determination of Hg(II) [14-16,20-22], and a glassy carbon electrode (GCE) (surface area: 7.065 mm<sup>2</sup>, AMEL, Milan) was employed for the determination of Ir(III) [16, 18]. An Ag  $|AgCl|Cl$ -satd. electrode and platinum wire were chosen as reference and auxiliary electrode, respectively.

The Teflon voltammetric cell was rinsed every day with supra-pure concentrated nitric acid, diluted 1:1, in order to prevent any contamination. Standard additions were made by disposable plastic tips.

Keeping the temperature at  $20.0 \pm 0.5^{\circ}$ C, the solutions were deaerated by water-saturated pure nitrogen for 5 min prior to measurements, while a nitrogen blanket was maintained above the solution during the analysis. The solutions were deaerated after each standard addition for 1 min. In the electrolysis step, the solutions were stirred using a magnetic stirrer.

## **Spectroscopic Procedure**

Atomic absorption spectrometric measurements were performed using a Perkin-Elmer Mod. A-Analyst 400 Atomic Absorption Spectrometer, equipped with a deuterium background corrector, Autosampler AS-72 and with HGA 800 graphite furnace. Singleelement Lumina (Perkin-Elmer) hollow-cathode lamps were used. All measurements were carried out after studying the relevant ashing and atomization curves for each element [30], at the instrumental conditions suggested by manufacturer.

Except Hg(II), As(III), Se(IV) and Sb(III), which were determined by Cold Vapour Atomic Absorption Spectrometry (CV-AAS), all the elements were determined by electrothermal atomic absorption spectrometry (ET-AAS), employing argon flow at 300 mL min<sup>-1</sup> in all steps except during atomization (60 mL min<sup>-1</sup>).

### **Limits of Detection**

In the aqueous reference solution, in the solutions obtained by digestion of the standard reference material and of mussels, clams, and oysters sampled in the Goro Bay, the limits of detection (LODs) for both techniques (voltammetry and spectroscopy) were obtained by the equation LOD =  $K s_{y/x} / b$  [31], where  $s_{y/x}$  and *b* are the estimated standard deviation and the slope of the analytical calibration function of each element, respectively, with a 99.7% ( $K =$ 3) confidence level [32].

In the case of voltammetric technique, since the analytical calibration functions were determined by standard addition method, it was possible to obtain the LODs directly also in the real matrix.

### **Metals of Interest**

The present work will concern and discuss the most significant elements that are present in mussels, clams, and oysters mainly for environmental and anthropic causes, and the different analytical methodologies for their voltammetric and spectroscopic determination.

For each metal or group of metals, a brief introduction is reported. This to emphasize the most recent, but also the most significant and interesting works relevant to the various analytical procedures and techniques for determining the same metals in mussels, clams, and oysters.

#### *Copper, Lead, Cadmium and Zinc*

 $Cu(II)$ ,  $Pb(II)$ ,  $Cd(II)$  and  $Zn(II)$  are surely the most studied metals, and many works reported in the literature are devoted both to analytical procedures for the determination of these metals in bivalve mollusks and to the employment of such organisms as bio-monitors.

Among these elements,  $Pb(II)$  and  $Cd(II)$  are the most toxic and hazardous to human health.

The main sources of both Pb(II) and Cd(II) are vehicular traffic and industries. In gasoline, lead-tetraethyl has been added for a long time as anti-knock. Factories (paints, tires) and solid-waste management are the main sources of cadmium, while their emissions are correlated with the lead content in the air.

Cu(II) and Zn(II) are semi-essential metals: they are necessary for human beings and become toxic only at high concentrations. Their pollution is due to human activities as industries for the production of cosmetics, fungicides, and paints. Even if Cu (II) and Zn (II) are widespread in the environment (mostly in food), they become highly dangerous only in the presence of already existing physiological problems (altered regulatory mechanisms). On the contrary, poisoning due to  $Cd(II)$  and  $Pb(II)$  is not frequent but might appear also in healthy subjects.

For  $Cu(II)$ ,  $Pb(II)$ ,  $Cd(II)$  and  $Zn(II)$  determinations, the most widely used techniques are all the different types of spectroscopy [23, 28, 29, 33-39]. Other techniques as Neutron Activation Analysis (NAA) [40, 41] or Voltammetry [14-16, 21, 25-27, 29, 42-45] are seldom employed. Moreover, some authors proposed the use of Total Reflection X-Ray Fluorescence (TRXRF) [46, 47] for the determination of these four elements in mussels, clams, and oysters.

Finally, it is very interesting the work by Wu and coworkers [48], which proposes an "artificial mussel" for monitoring heavy metals in marine environments. In the field of artificial mussels, it is also interesting the work of Degger and coworkers [49], which takes into consideration Cu, Pb, Cd, Zn, and Cr. It is observed a significant spatial and temporal correlation for the majority of the analyzed elements. In any case, there is still much experimentation to be done for a definitive set-up.

For the study of these metals, mussels, clams, and oysters have also the advantage to be extremely versatile bio-monitors, because they can be used in all surface waters, like seas, rivers, lakes, and lacustrine areas.

In this context, the work of George and coworkers [50] should be highlighted, because it describes the use of mollusks to analyze the pollution of backwaters during the monsoon, post-monsoon and pre-monsoon periods. Bivalve mollusks are also used to bio-monitor intertidal areas [51-53], to identify sources of contamination in rivers [54, 55], coastal waters or sea [56-65].

#### *Mercury*

Every year, human activities, mainly industries, release in the ecosystem a large amount of mercury. This element has the ability to enter in the alimentary chain and to accumulate into organism tissues in progressively larger quantities. Thus, the dangerousness for human
health of this form of contamination comes mainly from food, especially in the case of marine filtering organisms like mussels, clams, and oysters.

Mercury can be introduced into the human body also by contact with the skin of eyes or inhalation. Although the percent of absorption is low, toxicity is severe. Hence the chemical risk is high. Particularly dangerous is the metal as it is, because it is liquid at atmospheric conditions, and its vapors are intensively absorbed [66]. Also, mercury compounds are very hazardous because they can be easily accumulated through food; its organic compounds are particularly dangerous.

Once absorbed, mercury can have harmful effects on nervous system and brain (it reduces the capacity of learning and memorizing, but causes also imbalances in personality, tremors, headache, diseases in viewing and hearing), chromosomes, and reproductive system, besides possible allergy onsets. The effect of intoxication depends on the assumed quantity.

For the mercury determination spectroscopic techniques [22, 23, 25, 27-29, 36, 39, 67- 77] are mostly employed, sometimes also voltammetric techniques [22, 44, 78, 79]. There are also interesting works that quantify the inorganic mercury in mussel samples by Atomic Fluorescence Spectrometry (AFS) [80] and by NAA [81].

Until now, bio-monitoring of this element in environmental matrices seems not to be regularly used. In any case, some works concerning fresh- and sea-water, suggests mainly the use of *Mytilus galloprovincialis* as an important bio-monitoring organism [82]. Special attention was paid to coastal waters with nearby industries, that have released large amounts of mercury [83, 84].

## *Arsenic and Selenium*

Arsenic and selenium are commonly present in coal. Therefore, the main sources of arsenic and selenium pollution are foundries and coal power plants. Furthermore, the coal is used also in cement plants, so these two elements can be commonly found in the air and in the areas around these implants, causing pollution of all the environmental matrices around them.

Toxicity of arsenic is mainly due to its compounds. Organic compounds have a relatively low toxicity because they are absorbed with water, but their water solubility is low. Moreover, they are easily eliminated by feces and urine [66].

On the contrary, inorganic arsenic compounds are very dangerous because they are very easily absorbed by the human organism and can be transported in all its parts, with irreversible consequences (up to death) for various systems: nervous, circulatory, hematopoietic, gastric. Moreover, inorganic arsenic easily passes placenta, causing malformations and fetal pathologies and it is carcinogenic to liver, kidneys, breast, skin, lungs, bladder [66].

Arsenic is naturally present in the environment, mostly in soils and rocks, that contain small quantities. However, human activities are the main source of pollution from this element. In particular, industries release arsenic as wastes and emissions, contaminating soil, water, and airborne particulate matter. There are also some fertilizers, herbicides, and pesticides that illegally contain arsenic, contributing to the diffusion of this pollutant.

Recently, a new excellent semiconductor, gallium arsenide (GaAs), has become particularly important. Therefore, it is massively used in integrated circuits, especially in photovoltaic panels, determining a certain environmental pollution due to incorrect disposal of them.

Unlike arsenic, which is highly toxic, selenium is a semi-essential element, since it is essential to the development of animal and vegetal life, but very toxic beyond certain levels.

Human organism needs a daily dose of selenium of about 60 µg, which is easily achieved through the normal diet (mostly from meat and seafood). Selenium produces selenoderivatives of some amino acids (like cysteine and methionine) that are involved in many enzymes. Its main function is in muscles functionality, in the production of the thyroid hormone, and to prevent inflammation, cardiovascular pathologies, and arteriosclerosis. Moreover, seleno-enzymes are useful to prevent the Keshan cardiomyopathy, a disorder widely diffused in the Keshan region of China but also in Finland and in New Zealand, where the soil is very poor in selenium.

The main sources of selenium pollution are electronic industries, because this element has excellent photovoltaic and photoconductive properties, and is used to produce photocells and photovoltaic cells.

The determination of  $As(III)$  and  $Se(IV)$  in mussels, clams and oysters, is prevalently reported in the literature with spectroscopy [39, 54, 57, 85-94]. NAA [41, 56, 95] and voltammetry [24, 44] are less frequently employed, while interesting are the works using EDXRF [96, 97] and AFS [98, 99].

Arsenic is an element particularly investigated by bio-monitors.

Also for this element, the water component was monitored by mussels [63, 100-102] and clams [103].

Even if selenium is not considered to be toxic, it is generally investigated in biomonitoring studies. In the case of water, the literature reports an interesting work by Gay and Maher [104], who propose mollusks to bio-monitor selenium together copper, zinc, and cadmium.

#### *Tin and Antimony*

The mainly employing of tin is for the production of cans for the preservation of food. Antimony, instead, is used for the production of ceramics, rubbers, paint and glazes (as pigment), fungicides, and in the military industries. These industries are therefore the primary pollution source for these two metals. With regard to the toxicity, tin is a semi-essential element generally present in traces, but, in excessive amounts, it can interfere with the absorption of calcium and zinc. Antimony, on the contrary, is extremely toxic to human health.

Moreover, as in the case of mercury, these two elements to bio-accumulate in marine organisms. The determination at trace and ultra-trace level becomes, thus, very important to control the pollution due to these metals, especially in matrices that enter in the food chain, such as mussels, clams, and oysters.

Toxicity of tin is increased when it is involved in organic compounds, especially with two or three substituents, which are very dangerous for the immunologic system also at low concentration. Antimony compounds, on the other hand, may cause severe diseases to the human heart, respiratory system, stomach, intestine, and skin.

The environmental concentration of these two metals is generally low, but it varies considerably in space and time.

Most of the works on the Sn (II) and Sb (III) determination in mussels, clams, and oysters regard the investigation of the organic tin compounds, and in any case, they are not numerous. Spectroscopic [105-108], NAA [109], voltammetric [110] and AFS [111] techniques are the

most used, while Ferrarello and coworkers [112] employed size-exclusion chromatography and double focusing ICP-MS allowing the resolution of several spectral interferences that cannot be resolved by quadrupole ICP-MS.

#### *Nickel and Cobalt*

Nickel and cobalt are essential elements because they are used by some enzymes. For instance, cobalamin (Vitamin B12) contains Co and it is involved in iron metabolism and nucleic acid synthesis. Moreover, cobalt is also involved in the endocrine system (stimulating thyroid, pancreas, and adrenal) and in red-blood cells production (a long-time deficiency, although rare, may generate anemia and slowness in body development). However, high concentrations of nickel and cobalt cause some diseases: asthma, bronchitis, pulmonary embolism in the case of nickel, cardiac and vascular pathologies, migraine attacks, digestive diseases for cobalt.

The main sources of pollution from Ni (II) and Co (II) are the industries that use them: manufacture of alloy steels (they make alloys highly resistant to corrosion), rechargeable catalyst batteries, paint and pigment industry.

The determination of cobalt and nickel in bivalve organisms was performed mainly by spectroscopic techniques: electrothermal furnace (ET-AAS) or flame (FAAS) atomic absorption spectrometry [113-116], inductively coupled plasma-optical emission spectroscopy (ICP-OES) [117-119] and inductively coupled plasma-atomic emission spectroscopy (ICP-AES) [37, 120, 121].

Voltammetric techniques [43, 122] and neutron activation analysis [41,123] are less frequently used.

Concerning the determination of these two elements, some extremely interesting works should be reported. Three of these illustrate specific sample preparation methods: the dispersive liquid-liquid microextraction (DLLME) and subsequent determination of nickel and cobalt in mussels by ICP-OES [117], the ultrasonic bath-induced acid leaching [124] and rapid micro-assisted digestion and subsequent determination of nickel via ET-AAS [125].

Finally, two more works are of utmost interest.

The former concerns the comparison and development of two instrumental methods, the laser ablation-inductively coupled plasma-mass spectrometry (LA-ICP-MS) and the microdrill sampling and solution [126].

The latter illustrates a sensitive and low-cost flow injection method that combines acid extraction, pre-concentration and FAAS determination of nickel in mussels and clams [114].

Ni and Co were intensively monitored by biological species in all environmental components. In this context, as regards the water component, sea- and fresh-water, the most commonly used species are bivalve organisms: mussels in prevalence [127-130], but also clams and oysters [131-133].

#### **Chromium**

Chromium has two principal degrees of oxidation:  $Cr(III)$  and  $Cr(VI)$ .  $Cr(III)$  is an essential element in low concentration (about 50-200 µg/day). Even if some studies gave contradictory results about its toxicity, its compounds are water soluble, hence they are not much dangerous for human health.

On the contrary, Cr(VI) is very dangerous: its toxicity and carcinogenicity have been demonstrated since a long time. Most of all, Cr(VI) affect respiratory system (asthma, bronchitis, and laryngitis), gastrointestinal tract, kidney, liver, and eyes. A recent research correlated this metal also with autism [134].

Moreover, Cr(VI) is produced by many urban and industrial activities, like the metallurgical field, production of enamels and paints, and industrial manufacturing of catalysts determining a huge release of this pollutant in all the environmental matrices.

Also in the case of chromium, for its determination in the filtering organisms, the literature reports works that employ prevalently as instrumental techniques all the spectroscopic methods: ET-AAS [135-138], ICP-OES [139, 140], and ICP-AES [37, 141].

The INAA is often used in biomonitoring studies [56, 63].

Finally, two very interesting works are reported. The former illustrates the comparison of three techniques for the determination of Cr, together with other elements in raw clams and commercial clam meat, i.e., ET-AAS, ICP-OES, and wavelength dispersive X-ray fluorescence (WD-XRF) [142].

The latter one proposes the flame atomic absorption spectroscopic determination of total chromium in mussel samples using a continuous ultrasound-assisted extraction system connected to an on-line flow injection manifold [143].

Precisely because of its high toxicity, chromium has always been considered in all environmental pollution studies, both by samplings and punctual determinations and by biomonitoring.

As usual, mussels, clams, and oysters are the species predominantly used in the case of water. Indeed, they are the species perhaps considered indispensable in studies concerning the pollutant load from Cr and other elements in the lagoon ecosystems [102, 144-148], but also in the sea- [101, 149] and fresh-water [150, 151].

#### **Bismuth**

Bismuth is toxic only at high concentrations, while it is not dangerous at low levels. Damages to human health due to a long-time exposure to bismuth have been demonstrated Fowler and coworkers [152], which can affect the intestine, kidneys, and skin. Recent studies [152] indicate that bismuth is not much absorbed by the skin, however, no reliable quantitative results are yet available. For this reason, cosmetic products should be accurately checked for the bismuth content.

The main sources of pollution are industries using this metal. For example, it is used to prepare low melting alloys used in fuses, but also as a catalyst in the production of acrylic fibers. Moreover, bismuth has been recently used to produce low-temperature superconductors to be employed in medical diagnostic machinery, like Magnetic Resonance Tomography (MRT).

As for the determination of the bismuth in filtering organisms, of extreme interest is the work of Das and coworkers [153]. It illustrates all the techniques for its accurate and highly sensitive detection in solid environmental samples at extremely low concentration levels, discussing all steps of sample preparation prior to instrumental measurements such as pretreatment, separation, and pre-concentration.

Although at least in our knowledge, the literature does not report specific works about the bio-monitoring of Bi in superficial waters employing filtering organisms, Das and coworkers [153] suggest the possibility of using mussels as biomonitors.

Really, aquatic plants rather than filtering organisms are used in the biomonitoring of aquatic ecosystems.

Indeed, bio-monitoring of bismuth together also with tin and antimony in surface waters is carried out by aquatic plants, as reported in the very interesting work by Luy and coworkers [154], who use *Posidonia oceanica (L.)* as biomonitor.

#### **Vanadium**

Vanadium is an essential element at low concentration, so it is required to assume it with diet. However, high amounts of vanadium may cause cardiovascular pathologies and stomach and intestines diseases, besides allergenic dermatitis.

Vanadium is widely used in metal alloys and as a catalyst for various industrial processes. Industries involved in this kind of processes are easily identifiable as the main sources of pollution.

Electrothermal atomic absorption spectroscopy is largely used in the determination of vanadium in bivalve organisms [87, 155-157], but also instrumental neutron activation analysis is often used by several authors [123, 158].

Finally, some interesting works have to be reported.

The first by Santos and Lemos [159] relates to a new method for pre-concentration and spectrophotometric determination of vanadium using dispersive liquid-liquid microextraction (DLLME) and optical sensors using 4-(5bromo-2pyridylazo)-5-(diethylamino)-phenol (Br-PADAP) as a complexing agent.

Lastly, three works in which vanadium is determined in mussels and clams by highperformance liquid chromatography [160-162].

Even if it is considered a semi-essential element, vanadium is often studied and taken into account in environmental bio-monitoring studies of water systems.

Concerning aquatic ecosystems, interesting are two works that use mussels [163] and oysters [131] as bio-monitor species.

Finally, the work by Tarique and coworkers [164] should be highlighted. It describes the use of the *Amiantis umborella* clams in monitoring metal contamination in coastal sediments, vanadium included.

#### **Platinum Group Metals (PGMs)**

Platinum group metals (PGMs) pollution is undoubtedly due mainly to vehicle emissions. The concentration of PGMs is constantly increasing in all the environmental matrices [165, 166] with great risk for human health [167, 168]. Indeed, PGMs have been massively used in the latest year for the production of autocatalytic converters. This resulted in a decrease of pollutants like carbon monoxide, nitrogen oxides, unburned hydrocarbons and also lead (present in exhaust gases of motor vehicles), but, at the same time, is increasing the concentration of fine particulate and dust at a high concentration of PGMs. This is mainly originated from deterioration or abrasion of the bulk catalysts due to the incorrect "stop and go" use of the vehicles

In order to try to solve this problem, instead of a massive use of platinum, palladium, and rhodium for autocatalytic converters, there has been a gradual reduction of these PGMs and a growing use of osmium, ruthenium and iridium.

Indeed, in recent years, alloys of these elements together with PGMs have been employed more and more frequently for the production of autocatalytic converters. These alloys have the advantage to better withstand high temperatures and high wear, increasing the lifetime of the same converters.

#### *Determination of PGMs, Part I: Pt(II), Pd(II) and Rh(III)*

In the case of  $Pf(I)$ ,  $Pd(I)$  and  $Rh(III)$ , spectroscopy is the technique most widely employed [169-173], while very interesting is the paper by Essumang and coworkers [174] who proposes NAA as instrumental technique.

As regards the voltammetric techniques, the literature reports prevalently the works of two research team: the former (Zimmermann and coworkers [175-180]) that develops the research on the use of mussels as biomonitors for  $Pt(II)$ ,  $Pd(II)$  and  $Rh(III)$ , the latter (Locatelli and coworkers [181-194]) that proposes analytic voltammetric methods for the determination either of Pt(II), Pd(II), Rh(III) or of Os(VIII), Ru(III), Ir(III).

Indeed, in our laboratories since some years it is underway an important line of research on the development of analytical methods for the voltammetric determination of PGMs in all the environmental matrices, starting with those most investigated (platinum, palladium, rhodium) [181-187] to finish those generally considered, at least until a few years ago, less important from the environmental pollution point of view (osmium, ruthenium and iridium) [188-194].

#### *Determination of PGMs, Part II: Os(VIII), Ru(III) and Ir(III)*

As regards the determination of Os(VIII), Ru(III) and Ir(III) in mussels, clams, and oysters, the literature reports interesting reviews by Locatelli and Melucci [16-19, and therein references].

As regards the bio-monitoring aspect, only recently all the PGMs have attracted great attention and an increasing number of authors have begun to investigate the possibility to employ biological species to monitor the mentioned metals [16, and therein references].

In any case for such metals, the bio-monitoring path is only at the beginning. Certainly, in the near future, there will be important and interesting developments.

## **Thallium**

Thallium salts are very toxic [195, 196] and must, therefore, be handled with extreme care. Thallium has the ability to replace the positive ions of the alkaline metals present in the body, mainly sodium and potassium. This replacement alters many of the normal cellular processes. Thallium is also a suspected carcinogen. The first symptoms of poisoning are nausea, vomiting, tachycardia, fever, diarrhea, abdominal pain. Over time, ataxia (loss of muscle coordination), alopecia (loss of hair and hair) appear, until death. Poisoning can occur through ingestion and inhalation (maximum permissible concentration of long-term exposure to thallium salts should not exceed  $0.1$  mg m<sup>-3</sup>). Contact with the skin is also extremely dangerous.

Precisely because of its toxicity, the use of thallium salts as a rat poison has been banned in many countries. For example, since 1972 this use has been prohibited in the United States.

Much of thallium production is used in the electronics industry.

It is also used in the pharmaceutical industry, in glass production, and in the construction of infrared light detectors. Thallium-201 radioisotope is used in small amounts as a non-toxic

radiotracer in biomedical imaging examinations in nuclear medicine, particularly in myocardial scintigraphy.

According to International Organizations, in addition to the industries above mentioned, among anthropogenic sources of thallium environmental pollution, there are also gaseous emissions from cement factories, coal-fired power plants and metal sewers (underground ducts to drain water or waste material).

Also in the case of thallium, its determination in the filtering organisms is carried out prevalently by spectroscopic methods [197-199].

Electroanalytical methods [200] are less frequently used.

Finally, very interesting is the paper by Michalski and coworkers [201] that shows how the hyphenated techniques, in which separation method is coupled with multidimensional detectors, have become useful alternative in speciation analysis of thallium, together with arsenic and antimony, in environmental and food matrices

#### *Analytical Procedure for the Voltammetric Determination of Tl(I)*

0.5 mol  $L^{-1}$  ammonium citrate buffer pH 6.5 + 6.9 x 10<sup>-3</sup> mol  $L^{-1}$  EDTA-Na<sub>2</sub> was employed as supporting electrolyte, which was the aqueous reference solution.

As regards the composition of the supporting electrolyte, it should be emphasized that the presence of EDTA-Na<sup>2</sup> is necessary to obtain better resolution for the Tl(I) in presence of Pb(II), Sn(II) and Sb(III).

Indeed, in the marine ecosystems Pb(II), Sn(II) and Sb(III) are always and inevitably present. Unfortunately, it shows to have a peak potential very close to those of Tl(I).

In the supporting electrolyte without the presence of EDTA-Na<sub>2</sub> the peak potentials E<sub>p</sub> (V/ Ag | AgCl | Cl<sup>-</sup>satd.) are:  $E_p$  <sub>Tl(I)</sub> = -0.509  $\pm$  0.010  $E_p$  Pb(II) = -0.569  $\pm$  0.015,  $E_p$  Sn(II) = -0.677  $\pm$  0.015 and  $E_p$  Sb(III) = -0.783  $\pm$  0.010.

The problem is decidedly important, considering that the same problem is also present in the standard reference material and in the real samples collected in the sampling sites. Also, in this case, our methodological procedure proposes the possibility to shift the interferent peaks towards more cathodic potential values by adding EDTA-Na2. Indeed, the presence of EDTA-Na<sub>2</sub> shifts towards more cathodic potential the values of all the four elements:  $T1(I)$ : - $0.523 \pm 0.010$ ; Pb(II):  $-0.657 \pm 0.010$ ; Sn(II):  $-0.796 \pm 0.015$  and Sb(III):  $-0.949 \pm 0.015$  V *vs.* Ag $|AgCl|Cl<sub>satd</sub>$ . Evidently, the new peak position of the elements allows their resolution and then also their quantitative determination.

Evidently, the proposed analytical procedure, with the addition of EDTA-Na2, allows determining beyond Tl(I) also Pb(II), Sn(II) and Sb(III).

10 mL sample aliquots of supporting electrolyte or of solutions obtained in the mineralization step of the standard reference material and of real samples (see section 2.1.3. "Sample Preparation before the Instrumental Determination") were pipetted into the voltammetric cell and deaerated for 5 min by bubbling water-saturated pure nitrogen. Square wave anodic stripping voltammetry was employed as voltammetric technique, using hanging mercury drop electrode (HMDE) as working electrode.

The voltammetric experimental conditions are the following.

Deposition potential E<sub>d</sub> (V/Ag, AgCl, Cl<sup>-</sup>satd.): -1.150; initial potential E<sub>i</sub> (V/Ag, AgCl, Cl<sup>-</sup> satd.): -1.150; final potential  $E_f$  (V/Ag, AgCl, Cl<sup>-</sup>satd.): -0300; electrodeposition time  $t_d$  (s): 420; delay time before the potential sweep  $t_r$  (s): 10; potential scan rate dE/dt (mV/s): 100;

superposed potential amplitude  $\Delta E$  (mV): 50; sampling time τ (s): 0.010; wave period v (s): 0.100; wave increment  $\eta$  (mV): 10; stirring rate u (r.p.m.): 600.

The experimental peak potentials  $E_p$  (V/ Ag | AgCl | Cl<sup>-</sup>satd.) of Tl(I) are reported in Table 1.

## **Table 1. Peak potentials**  $(E_p, V/Ag \nvert AgCl \nvert KCl_{sat})$  **in the reference solutions and in solutions obtained by digestion of mussels, clams, and oysters sampled in the Goro Bay. The determined values are the mean of 5 independent determinations. Confidence level: 95%**

[a] In the case of Oyster samplings in site E, the absence of element concentration data is due to lack of sample present in the same sampling site.

The spectroscopic experimental conditions are the following: Wave-length (nm): 276.8; Slit (nm): 0.7; Drying Temperature (°C): 105; Charring Temperature (°C): 750; Atomization Temperature (°C): 1850; Matrix Modifiers: 0.015 mg Pd + 0.01 mg  $Mg(NO<sub>3</sub>)<sub>2</sub>$ .

## **RESULTS AND DISCUSSION**

In this section, in a synthetic way, the fundamental parameters that characterize a correct analytical procedure — limits of detection, linear range, trueness, and precision — are reported.

## **Limits of Detection and Linear Range**

In the aqueous reference solution, in the solutions obtained by digestion of the standard reference materials and of real samples, the LOD<sup>s</sup> (Table 2) for both techniques were calculated as described in section "Limits of Detection."

At the experimental conditions employed, the linear range for all the elements in the aqueous reference solutions is  $\langle$  LOD – 15.0 µg L<sup>-1</sup>.

#### **Quality Control and Quality Assessment**

The method set up in aqueous reference solutions was applied to Mussel Tissue BCR-CRM 278 and Oyster Tissue NIST-SRM 1566a standard reference materials in order to confirm and verify the applicability of the analytical procedure (see section 8.2.2).

Trueness and precision for the voltammetric and spectroscopic measurements were determined and reported in Table 3.

#### **Practical Application**

Once the procedure for the Tl(I) determination was set up, the method was applied to mussels, clams, and oysters sampled in the Goro Bay (see section 2.1.2. "Sampling Area and Sampling Sites").

The experimental results relevant to both techniques are reported in Table 4.

Table 2. LOD<sub>s</sub><sup>[a]</sup> of Tl(I) determined in the supporting electrolyte (µg L<sup>-1</sup>), **in the solutions obtained by digestion of Mussel Tissue BCR-CRM 278 and Oyster Tissue NIST-SRM 1566a standard reference materials, and in the solutions obtained by digestion of real samples (calculated in µg L-1 and expressed in µg kg-1 ). The determined values are the mean of 5 independent determinations; confidence level: 95%**

<sup>[a]</sup> In the case of spectroscopic measurements, the Tl(I) LOD in the aqueous reference solution is 0.69 µg  $L<sup>-1</sup>$ . Considering a sample weight exactly equal to 1.0 g (see section 2.1.3. "Sample Preparation before the Instrumental Determination"), the same limit of detection is  $26.9 \,\mu g$  kg<sup>-1</sup>.

<sup>[b]</sup> In the case of Oyster samplings in site E, the absence of element concentration data is due to lack of sample present in the same sampling site.

## **Table 3. Accuracy of the analytical procedure for the determination of Tl(I). The determined values are the mean of 5 independent determinations. Confidence level: 95%. Concentrations in µg kg-1**

## **Table 4. Mean values of Tl(I) (µg kg-1 ) relevant to oysters, mussels, and clams sampled in the Goro Bay. The determined values are the mean of 5 independent determinations. Confidence level: 95 %**

[a] In the case of Oyster samplings in site E, the absence of element concentration data is due to lack of sample present in the same sampling site.

## **Bio-Remediation**

This very short paragraph highlights another aspect of the use of biological organisms in the environmental field. This aspect concerns bio-remediation, i.e., the possibility of reducing the pollutant load of an ecosystem by the use of bio-accumulative organisms. These are biological organisms that can survive in the presence of pollutants accumulating in their tissues. Evidently, bio-remediation can be carried out in quite narrow ecosystems showing a few inbound and outbound paths.

In the case of limited polluted aquatic ecosystems, the organisms most often used in this type of procedure are predominantly vascular plants [202, 203]. However, it is a conviction of the authors that also mussels and clams, organisms that require the water for their nourishment, can be successfully used in bioremediation processes.

It should be emphasized that for this procedure, the studies and subsequent feasibility checks are still in progress. In any case, the possibility of cleaning up, or at least limiting the pollution of an ecosystem with biological organisms, shows a very interesting path, to be developed and increased more and more in the future.

## **CONFLICT OF INTEREST**

The authors declare no conflicts of interest.

## **ABSTRACT**

Bivalve mollusks exposed to a wide variety of natural and anthropogenic environmental changes are widely used as sentinels. These factors can cause an imbalance between the generation and elimination of reactive oxygen species (ROS) and reactive nitrogen species (RNS), leading to an oxidative stress that is manifested by alterations of the antioxidant defense system and/or oxidative damage. The hemocytes constitute the immune system in bivalves, and cell death processes have been recently described as part of the mechanism of defense against various pathogens and contaminants. Previous studies showed a higher content of trace metals Fe and Cd in the gills and digestive gland of the *Aulacomya atra atra* from Folías Wreck (impacted area) than from Punta Cuevas (control area). In order to compare oxidative stress conditions in bivalves obtained from both sites, we evaluated the production of ROS and oxidative stress biomarkers in hemocytes from the *A. atra atra* during the month of September of 2015. The results obtained by flow cytometry, using MitoSox as probe, showed that superoxide anion was 58% higher in bivalve's hemocytes from Folías Wreck than in

 $\overline{a}$

those from the reference place Punta Cuevas. The oxidation of the dye 2´7´dichlorofluorescein diacetate (DCFH-DA), as a general indicator of oxidative stress, showed a 14% increase in bivalve's hemocytes from Folías Wreck, as compared to hemocytes from Punta Cuevas. Thiobarbituric acid reactive substances (TBARS) content showed no differences between hemocytes from animals isolated from both locations. In addition, the content of lipid radical measured by Electron Spin Resonance increased 2.1 fold in the hemocytes from Folías Wreck samples as compared to the level obtained in hemocytes from bivalves collected from Punta Cuevas. The oxidized/depleted cardiolipin was 16% higher in samples obtained from Folías Wreck than in Punta Cuevas. Based on these results, it can be concluded that hemocytes from the ribbed mussel *A. atra atra* could be used as a model to evaluate oxidative stress induced by pollutants or other environmental stressors.

**Keywords**: bivalves, reactive oxygen species, hemocytes, superoxide anion, cardiolipin

## **INTRODUCTION**

Marine invertebrates represent 95% of animal species, which ecological role is determinant in the evaluation of potential routes of exposure to the toxicity of metals. Bivalves have been employed as sentinel organisms in worldwide routine biomonitoring programs based on their wide geographic distribution, their straightforward availability in the field and through aquaculture, and their suitability for caging experiments along coast lines (Viarengo et al., 2007). The ribbed mussel *Aulacomya atra atra* (Molina 1782) is a filter feeder organism with the ability to accumulate a wide range of contaminants and a typical species of the rocky shores along the Patagonian coast of Argentina forming extensive beds (Zaixso, 1999). It is an important habitat-forming species for numerous species of algae and animals and it is also a food source for gastropods, asteroids and sea birds as well as for humans (Zaixso, 2003). It has been used as biomonitor to evaluate the recovery of normal cytogenetic records through micronucleus test after cessation of urban discharges in Puerto Madryn (Nuevo Gulf) (Machado-Schiaffino et al., 2009). In ribbed mussels from the same area, several biomarkers of oxidative stress have been measured for environment quality assessment (Giarratano et al., 2013; 2014).

The physico-chemical characteristics of seawater were within the range of the previously informed data (Gil, 2001; Solís, 1998; Giarratano et al., 2013; 2014). Previous studies have shown that the presence of a high concentration of metals such as Fe Al, Cu and Cd, from Folías Wreck seemed to be caused by the ship's metal corrosion (Giarratano et al., 2013; 2014).

Metabolic homeostasis in bivalves is performed at least partially upon cells circulating in hemolymph described as hemocytes, which are routinely used to understand the impact of pollutants with accurate precision (Ladhar-Chaabouni and Hamza-Chaffai, 2016). These cells are involved in different and numerous physiological functions as well as shell and tissue repair (Sparks and Morado, 1988; Mount et al., 2004). Hemocytes also mediate cellular internal defense mechanism through accumulation and detoxification of toxicants, phagocytosis and encapsulation of different biological toxins and inorganic material (Matozzo et al., 2001).

Reactive oxygen species (ROS) are molecules produced by hemocytes of different bivalve's species including oysters, mussels, scallops and clams (Donaghy et al., 2012). In order to protect themselves against the effect of toxic substances, marine organisms developed a variety of detoxification pathways including an important battery of antioxidant mechanisms against ROS, as observed in mammals. The presence of oxidative stress is quite common in marine organisms due to a wide variety of natural and anthropogenic environmental changes. Induction of the antioxidant system can be considered as an adaptation of the organisms to overcome an unsafe environment and to prevent toxicity. The use of biomarkers has been proposed as a sensitive tool for biological effects monitoring, playing an important role in the risk assessment of complex ecosystems (Monserrat et al., 2007). Since several pollutants can directly or indirectly modify the balance between the concentration of pro-oxidants and antioxidants, the determination of oxidative stress and/or antioxidant responses in aquatic species is commonly and successfully employed as a nonspecific biomarker (Bainy et al., 1996).

## **OBJECTIVE**

The production of ROS and oxidative stress biomarkers were evaluated in hemocytes of ribbed mussel *A. atra atra* obtained from two sites within Nuevo Gulf.

## **MATERIALS AND METHODS**

## **Zones Selected**

*A. atra atra* is present along the Pacific Ocean from El Callao, Peru, to the Strait of Magellan in Chile, extending along the Atlantic Ocean from the south of Argentina to the south of Brazil (Caza et al., 2016). Two sites within Nuevo Gulf were selected in order to obtain the ribbed mussel samples (Figure 1). Folías Wreck is a ship of 60 m in length located at 300 m of the shore of Paraná Beach, used for scuba diving activities. Punta Cuevas is a dive site that hosts fishes, crabs, sea stars, among other, and is located at the south end of the city. The last one was considered the reference place.

## **Animal Collection**

In September 2015, 30 individuals of *A. atra atra* were collected by scuba diving at each sampling site. Following collection, mussels were placed in isolated plastic containers previously filled with water from the sampling site and transported to the laboratory within 2 hours of collection. After hemolymph collection from the posterior adductor muscle sinus with sterile hypodermic needles, the hemocytes were filtered and maintained on ice. Each experiment was performed after pooling hemolymph from 3-5 ribbed mussels to obtain enough volume and to minimize the individual variability.

Figure 1. Map of the studied area.

## **Flow Cytometry Studies**

Flow cytometry assays were performed in a FACS calibur (Becton-Dickinson, US) equipped with a 488 nm argon laser and a 615 nm red diode laser. The studied hemocytes population with high FSC (Forward Scatter) and high SSC (SideScatter) characteristics was chosen as the gate (R1) according to the typical cellular hemocyte size, calibrated for all the cytometric studies.

#### **Superoxide Anion Production**

Superoxide anion  $(O_2)$  production was determined in unstimulated isolated hemocytes. Cells suspended in 1ml PBS and incubated at  $25^{\circ}$ C for 20 min in the presence of 12.5 $\mu$ M MitoSox, a potentiometric probe that is used for direct measurement of mitochondrial superoxide by flow cytometry. Samples were protected from light until acquired by the cytometer FACS calibur (Becton-Dickinson, US (Bustamante et al., 2004)). After autofluorescence evaluation, MitoSox fluorescence was analyzed using the median value of the fluorescence events distribution from each treatment. Differences in MitoSox fluorescence histograms were evaluated in the gated R1 population from three independent experiments as the number of events that drop under a common marker. The results were expressed as the

percentage of control MitoSox fluorescence from hemocytes obtained from animals located in Punta Cuevas (reference place), which was considered as 100%.

## **DCFH-DA Oxidation Rate**

The membrane-permeable non-fluorescent DCFH-DA oxidation has been used for detecting several ROS in biological media (McDowell et al., 2013). DCFH-DA was initially thought to be useful as a specific indicator for hydroperoxides. It was already demonstrated that DCFH is oxidized by different reactive molecules, including superoxide anion  $(O_2)$ , hydroxyl radical, peroxyl, alkoxyl, hydroperoxyl and peroxynitrite which are products of normal metabolism (Halliwell and Gutteridge, 2007). DCFH-DA is a fluorogenic probe that passes through cell membranes and is cleaved by cellular esterases. During incubation, DCFH-DA is hydrolyzed by intracellular hydrolytic deacetylation to DCFH, which is trapped inside the cell due to its polarity. This substance is then rapidly oxidized to the highly fluorescent compound, DCF that allows the evaluation of oxidant cellular levels. Hemocytes were incubated *in vivo* in the dark for 30 min in 2 ml of 40 mM Tris-HCl buffer (pH 7.0) in the presence of 5 µM DCFH-DA at 27°C (Bass et al., 1983; Malanga et al., 2001). Fluorescence was measured with  $\lambda_{ex} = 498$  nm and  $\lambda_{em} = 525$  nm.

### **Content of Thiobarbituric Acid Reactive Substances (TBARS)**

The hemocytes were homogenized in relation 1:3 of 0.1 M Tris buffer pH 7.8. The homogenates were treated with 30% (w/v) trichloroacetic acid and 50 mM potassium phosphate buffer (pH 7.0). After centrifugation, the content of TBARS was determined in the supernatant spectrophotometrically at  $\lambda = 535$  nm, using the acid hydrolysis of 1, 1, 3, 3 tetraethoxy propane as standard, according to Malanga et al., (2004).

## **Quantification of Lipid Radicals by Electron Paramagnetic Resonance (EPR)-Spin Trapping**

Lipid radical (LR<sup>•</sup>) content in hemocytes was detected by a spin trapping technique using  $N$ -t-butil- $\alpha$ -phenyl nitrone (PBN). A 40 mM PBN stock solution was prepared in DMSO immediately prior to use. The homogenates were prepared in DMSO-PBN (stock solution). EPR spectra were obtained at room temperature using a Bruker spectrometer ECS 106, operating at 9.81 GHz with 50 kHz modulation frequency. EPR instrument settings for the spin trapping experiments were: microwave power, 20 mW; modulation amplitude, 1.194 G; time constant, 81.92 ms; scans number, 5; center fields, 3480 G; modulation frequency, 50 kHz; and receiver gain, 2 104 (Lai et al., 1986). Quantification was performed according to Kotake et al., (1996).

### **Cardiolipin Content**

Acridine orange 10-nonyl bromide (nonyl acridine orange, NAO,  $\lambda_{em} = 525$  nm) binds specifically to cardiolipin providing a direct and reliable method for evaluating the cardiolipin content in mitochondria (McMillin and Dowhan, 2002; Petit et al., 1992; Wright et al., 2004). Nomura et al., (2000) reported that NAO is associated selectively with monolayer of cardiolipin. Also, they described that the binding of NAO to cardiolipin decreased by oxidation/depletion of cardiolipin; NAO is notable to bind to peroxidated cardiolipin (CL-OOH) producing a decreased NAO fluorescence. Previous observations indicate that low NAO fluorescence would be due to oxidation/depletion of cardiolipin (Nomura et al., 2000; Paradies et al., 2000; 2001). This can explained by the fact that free radicals-induced cardiolipin damage leads to decreased cardiolipin accessibility to NAO. After suspension of hemocytes in PBS, samples were loaded with 100 nM NAO during 20 min at 25<sup>o</sup>C in a dark room and data acquired by the cytometer as previously described. NAO relative fluorescence intensity (r.f.i.) of hemocytes evaluated in three independent experiments as the number of events, which drop under a common and specific marker were evaluated in the presence or absence of antimycin (0.5 μM). Quantification is shown by cardiolipin oxidation/depletion for each hemocyte sample. Hemocytes autofluorescence without probe was also evaluated.

#### **Statistical Analyses**

Data in the text and tables were expressed as mean  $\pm$  S.E.M. of three independent experiments, with two replicates in each experiment. Significant differences were tested by factorial analysis of variance ANOVA ( $P < 0.05$ ).

## **RESULTS**

Ribbed mussels *A. atra atra* from Punta Cuevas and Folías Wreck (Nuevo Gulf) were analyzed by flow cytometry using the probe MitoSox to measure their ability to produce  $O_2$ . Unstimulated hemocytes loaded with MitoSox were used for the flow cytometry assays. Typical histograms of FL-1MitoSox fluorescence for both samples are presented in Figure 2 a. Histograms under the respective markers showed two different  $O_2$  producing hemocytes populations with: low r.f.i (population 1) and high r.f.i. (population 2). Quantification of three different experiments was shown in the bar graph of Figure 2 b indicating a significant 58% increase ( $P < 0.05$ ) in  $O_2$  level in Folías Wreck hemocytes as compared to Punta Cuevas hemocytes from population (2).

In addition, ROS were also determined using DCFH-DA. The results obtained by this procedure showed a high rate of DFC oxidation by hemocyte loading. As shown in Table 1, hemocytes from Folías Wreck samples showed a 14% increase as compared to hemocytes from Punta Cuevas in agreement with the results obtained by flow cytometry using MitoSox as a probe.

\* Significant different as compared to values obtained in hemocytes of ribbed mussel collected at Punta Cuevas ( $P < 0.05$ ).

**Fig.2b Malanga et al.** Punta Cuevas and Folías Wreck. a. Overlay of MitoSox fluorescence histograms from both hemocytes Figure 2. Determination of superoxide anion levels in hemocytes of ribbed mussel *A. atra atra* from populations. b. Quantification of MitoSox fluorescence as a bars graph representing the mean  $\pm$  SEM of 3 different experiments.

## **Table 1. DCF-DA oxidation rate, TBARS content and LR content in hemocytes isolated from ribbed mussels from Punta Cuevas and Folías Wreck**

Values represent the mean  $\pm$  S.E.M. of 3 different experiments.

\*Significant different as compared to values obtained in hemocytes of ribbed mussel collected at Punta Cuevas values (P < 0.05).

The TBARS content showed in Table 1 was similar in hemocytes from Folías Wreck as compared to the values obtained in samples collected from Punta Cuevas.

Oxidative damage to lipid in the hemocytes of *A. atra atra* was also estimated in the present study, as the content of LR● assessed by EPR. LR● content in hemocytes combined with the spin trap PBN resulted in adducts that gave a characteristic EPR spectrum with hyperfine coupling constants of  $a_N = 15.8$  G and  $a_H = 2.6$  G, in concordance with computer spectral simulated signals obtained using the overall mentioned parameters (Figure 3). A solution of PBN and DMSO itself was examined and no PBN spin adduct was observed (Figure 3d). LR● content showed significant differences between the zones (Table 1), being 70.6% higher in Folías Wreck samples than in hemocytes isolated from ribbed mussel collected in Punta Cuevas ( $P < 0.05$ ).

Figure 3. LR<sup>•</sup> detection by EPR in hemocytes of the ribbed mussel *A. atra atra.* Spectra from: a. computer-simulated EPR spectra exhibiting hyperfine splittings that are characteristic of PBN/LR<sup>.</sup>,  $a_N = 15.8$  G and  $a_H = 2.6$  G, b. hemocytes from Folías Wreck, c. hemocytes from Punta Cuevas and d. EPR spectra of PBN itself, are shown.

Immediately after hemocytes isolation, they were stained with NAO to detect mitochondrial cardiolipin oxidation/depletion by flow cytometry as shown in Figure 4 a. We can observe in the overlay histograms that Folías Wreck samples presented higher amount of events with lower NAO-fluorescence indicating a higher rmitochondrial cardiolipin oxidation/depletion as compared with the samples collected in Punta Cuevas samples. In Figure 4 b the quantification of the cardiolipin histograms showed a significant increase ( $P \lt$ 0.05) of 16% in cardiolipin oxidation/depletion from Folías Wreck hemocytes as compared to hemocytes of ribbed mussel from Punta Cuevas. When hemocytes from both zones were stimulated with antimycin, the levels of mitochondrial cardiolipin oxidation/depletion were decreased in both samples.

Cuevas ( $P < 0.05$ ). \*Significant different as compared to values obtained in hemocytes of ribbed mussel collected at Punta

Figure 4. Determination of the cardiolipin content in hemocytes of the ribbed mussel *A. atra atra* from Punta Cuevas and Folías Wreck. a. Overlay of NAO fluorescence histograms. b. Quantification of the level of cardiolipin oxidation/depletion present in both hemocytes samples with and without antimycin. The bars represent the mean  $\pm$  SEM of 3 different experiments.

## **DISCUSSION**

Effective  $O_2$  detection has been performed using flow cytometry with a variety of different probes such as dihydroethidium (Ding et al., 2007) and MitoSox (Velez-Pardo et al., 2010; Bustamante et al., 2014). These fluorophores are readily oxidized by  $O_2$  but not by other ROS and specifically bind to the mitochondria, which is an important place of  $O_2$ generation. In this work, two different hemocytes populations were observed in agreement with previous studies where hemocytes after characterization by flow cytometry and morphological studies presented also two different groups of cells (Soares da Silva et al., 2002). Both hemocytes populations observed in our study presented different ability to

produce  $O_2$ . The results obtained showed that hemocytes from Folías Wreck (population 2) showed higher levels of FL-1 fluorescence as compared to the population 2 from Punta Cuevas. Interesting to note was the fact that hemocytes from the reference place Punta Cuevas presented the highest population (1) with low  $O_2$  production. Different types of radicals can mediate DCFH oxidation (Curtin et al., 2002; Rao et al., 1992); by reacting with different types of hydroperoxides after intracellular de-esterification and oxidation. Hemocytes from Folías Wreck showed a higher level of DCFH fluorescence than hemocytes isolated from samples collected in Punta Cuevas. These results indicated an enhanced hydroperoxide metabolism in *A atra atra*, potentially due to a higher exposure to metals such as Fe and Cd (Giarratano et al., 2013). Toxicological studies at cellular level have shown that metals such as Fe and Cd can affect mitochondrial metabolism and induce ROS production (Wang et al., 2004; Taze et al., 2016).

Although the measurement of TBARS is rather an unspecific test, it was used with other method to unequivocally characterize the lipid peroxidation process (Rice-Evans et al., 1991). Since endogenous lipid radicals show short half-lives and are present in low concentrations, detection is a difficult task. Spin trapping-EPR analysis overcomes the limit of sensitivity of endogenous radical content in biological systems, being the best method available to detect short-lived reactive free radicals generated in low concentrations in biological systems (Luo et al., 2006). Even though EPR detection of lipid radicals could be considered a fingerprint of radical presence, spin trapping studies cannot really distinguish among peroxyl, alcohoxyl and alkyl adducts owing to the similarity of the corresponding coupling constants (Jurkiewicz and Buettner, 1994). Coincidently with TBARS results, the EPR analysis showed higher LR content in hemocytes from Folías Wreck than in those from Punta Cuevas. This fact could be in agreement with observations of Giarratano et al., (2013, 2014), in which gills and digestive glands of bivalves presented higher  $LR^{\bullet}$  by EPR procedure.

The high efficiency of the mitochondrial electron transport is mainly due to the presence of the phospholipid cardiolipin at the inner mitochondrial membrane, which is required for the proper structure and activity of mitochondrial respiratory chain complexes. NAO is a mitochondrial probe that binds specifically to cardiolipin. Cardiolipin content has been used as a parameter of mitochondrial function in marine bivalves (Barmo et al., 2013; Ciacci et al., 2012). This fluorescent dye binds tightly to the acidic phospholipid cardiolipin, which is found exclusively in inner mitochondrial and bacterial membranes (Petit et al., 1994). In this work the level of cardiolipin oxidation/depletion measured as low NAO fluorescence, was higher in Folías Wreck hemocytes than in Punta Cuevas organisms. Contrary to mammalian cells, incubation of ribbed mussel's hemocytes from Punta Cuevas and Folías Wreck with antimycin (complex III inhibitor) resulted in a decrease ROS production, coincident with the results reported for the Pacific oyster *Crassostrea gigas* (Donaghy et al., 2012). Antimycin effect in mitochondrial mammalians induces an increase in ROS, mediated by its ability to inhibit the respiratory chain at complex III between cytochrome b and cytochrome c1 (Alexandre and Lehninger, 1984; Maguire et al., 1992). The decrease in ROS production observed in bivalves could be due to the fact that in invertebrates the electron transport chain is branched with the presence of additional terminal oxidases (Buchner et al., 2001; Tschischka et al., 2000). The occurrence of these terminal oxidases and its genetic basis could indicate an alternative pathway for the electron transport, accepting electron directly from ubiquinol and reducing  $O_2$  to  $H_2O$  (Hoffman and Brookes, 2009).
Monitoring of mixed beds containing *A. atra atra* has been proposed as an important opportunity to study the effect of climate change and pollution on the marine ecosystems in this area (Caza et al., 2016). In this sense, we can conclude that Folías Wreck bivalves seem to be exposed to higher stressing factors than those from Punta Cuevas, such as the high metal content that would induce an oxidative pressure. This fact could have a deleterious effect against organisms itself but could lead to important ecological alterations. Thus, we could conclude that hemocytes represent a sensitive model for the rapid screening of the cellular effects of different contaminants and pathogens. Furthermore, they could be useful to generate valuable tools for pollution monitoring and for establishing preventive measures that tend to protect the environment. Finally, we can state that this is the first work that indicates that two populations of *A. atra atra* hemocytes show different level of  $O_2$  content. It is interesting to note that the source of production is not already known and, requires future deeper studies.

## **ACKNOWLEDGMENTS**

This study was supported by grants from the University of Buenos Aires (UBA), National Agency for Scientific and Technological Promotion (ANPCyT), National Council for Science and Technology (CONICET) and Centro de Altos Estudios en Ciencias Humanas y de la Salud (CAECIHS, PS1/CAE 2017), Universidad Abierta Interamericana. G. M., E. G., S. L. A. and S. P. are career researchers from CONICET.

## *BIOGRAPHICAL SKETCHES*

## *Gabriela Malanga*

**Affiliation:** Universidad de Buenos Aires, Facultad de Farmacia y Bioquímica, Fisicoquímica. Buenos Aires, Argentina. CONICET-Universidad de Buenos Aires. Instituto de Bioquímica y Medicina Molecular (IBIMOL). Buenos Aires, Argentina

## **Education:** Pharmacist and Doctor in Biochemistry, University of Buenos Aires

## **Business Address**: Junín 956 (C1113AAD), Buenos Aires. Argentina

**Research and Professional Experience**: Dr. Gabriela Malanga is a career investigator at the National Council of Science and Technology (CONICET) and teacher from the University of Buenos Aires, School of Pharmacy and Biochemistry, Argentina, in the subject Physical Chemistry and in post graduate courses. Her specialty is oxidative stress in fish, invertebrates and algae. Malanga has been working in Antarctic (Instituto Antártico Argentino). She has published forty-two papers in peer review journals, and sixteen book chapters. She has participated and published in more than one hundred national and international meetings. She has also been a reviewer of several international journals. She had directed doctoral students and obtained research supports.

## **Professional Appointments**: Doctor

## *Erica Giarratano*

**Affiliation:** Centro para el Estudio de Sistemas Marinos (CESIMAR-CONICET), CCT CONICET-CENPAT

**Education:** Bachelor of Biological Sciences from National University of Patagonia "San Juan Bosco" and Doctor in Biology from National University of Comahue

**Business Address**: Boulevard Brown 2915, U9120ACF, Puerto Madryn, Chubut, Argentina

**Research and Professional Experience**: Dr. Erica Giarratano is a researcher at the National Council of Science and Technology (CONICET). Her specialty is focused on geochemistry of metals and metalloids, ecotoxicology, environmental monitoring and risk assessment studies and remediation. She has published fourteen papers in international peer-reviewed journals plus one book chapter, being in addition reviewer for twenty-seven international journals. She has participated and published in about forty national and international meetings. She had codirected two bachelor students and is now codirecting two doctoral students. She has been granted with scholarships to work abroad with colleagues from Norway, Italy, Brasil, Canada and Mexico.

#### **Professional Appointments**: Doctor

## *Silvia Lores-Arnaiz*

**Affiliation:** Universidad de Buenos Aires, Facultad de Farmacia y Bioquímica, Fisicoquímica. Buenos Aires, Argentina. CONICET-Universidad de Buenos Aires. Instituto de Bioquímica y Medicina Molecular (IBIMOL). Buenos Aires, Argentina

**Education:** Biochemist, Pharmacist and Doctor in Biochemistry, University of Buenos Aires

**Business Address**: Junín 956 (C1113AAD), Buenos Aires. Argentina

**Research and Professional Experience**: Dr. Silvia Lores-Arnaiz is a career investigator at the National Council of Science and Technology (CONICET) and teacher from the University of Buenos Aires, School of Pharmacy and Biochemistry, Argentina, in the subject Physical Chemistry and in post graduate courses. Her area of expertise is focused on mitochondrial physiology and free radical generation in central nervous system. She has directed doctoral students and obtained research supports. She has published forty-six papers in international peer review journals, and eight book chapters, as well as participated in more than one hundred national and international meetings. She acted as member of the Local and Scientific Organizing Committee of three international meetings related to the area of free radical research. She has been a Member of the Editorial Board of the journal Neurochemical Research and acted as reviewer for many other international journals.

## *Susana Puntarulo*

**Affiliation**: Universidad de Buenos Aires, Facultad de Farmacia y Bioquímica, Fisicoquímica. Buenos Aires, Argentina. CONICET-Universidad de Buenos Aires. Instituto de Bioquímica y Medicina Molecular (IBIMOL). Buenos Aires, Argentina

**Education**: Doctor in Biochemistry, University of Buenos Aires

**Business Address**: Junín 956 (C1113AAD), Buenos Aires. Argentina

**Research and Professional Experience**: Dr. Susana Puntarulo is a Professor of Physical Chemistry, at the School of Pharmacy and Biochemistry, University of Buenos Aires, and a Senior Researcher at the National Council of Science and Technology (CONICET), Argentina. She is studying the role of free radicals in biological systems, mainly focused on the participation of iron in the generation and metabolism of active oxygen and nitrogen species. She was director of 11 PhD thesis, and mentor of magister dissertations. Up to now, she is author of over 155 scientific papers, 32 book chapters, and participated in web publications, and national and international meetings.

## **ABSTRACT**

The evaluation of oxidative stress in relation to the impact of global climate change on bivalves through the study of the organism's responses to mitigate the damage and control the generation of reactive oxygen species is analyzed in this chapter. Biomarkers are biological components that complement physico-chemical factors analysis in aquatic organisms by providing first biological signals of environmental situations. Since integration of individual biomarker responses into a set of tools and indices capable of detecting and monitoring the degradation in health of a particular organism is an actual challenge, we propose to evaluate the information on oxidative and physiological biomarkers triggered in bivalves in relation to the exposure to different environmental changes to obtain the best approach to it particular variation. We analyzed bivalves facing "natural stress conditions" (acidification, seasonality, temperature, oxygen partial pressure, salinity, biotoxins). From the revised researches, we found that some of the biomarkers seemed to respond in a better way than others depending on the environmental conditions faced by the bivalves. This chapter expands our understanding of multifactorial effects on the marine ecosystem, providing insight into the acclimation, adaptive and stress response processes of bivalves. Finally, such ecological and biogeochemical changes in the oceans could have profound consequences for marine biodiversity and seafood quality with deep implications for fishery industries in the upcoming decades.

## **INTRODUCTION**

Over the last decades, global warming has increased having substantial effects on acidification, salinity, temperature, dissolved oxygen  $(O_2)$ , light penetration, nutrient conditions, biotoxins presence and metal inputs due to higher sediment run-off specially impacting on coastal and benthic ecosystems, between others (Dierssen et al., 2002; Quartino et al., 2013; Gutt et al., 2015; Sahade et al., 2015).

O<sup>2</sup> consumption is required by animals for the oxidation of food and the generation of energy. This partial reduction of  $O_2$  results in the formation of reactive oxygen species (ROS), including superoxide anion radical  $(O_2^-)$ , hydroxyl radical and hydrogen peroxide (H<sub>2</sub>O<sub>2</sub>). A basal amount of ROS is formed continuously in all aerobic cells, and the steady state concentration of ROS in each cell depends on the formation rate of these molecules, their reactivity and the concentration of available reaction partners. Then, when ROS formation exceeds antioxidant defense capability or disrupt redox signaling, affecting cell functionality, oxidative stress occurs (Jones, 2006). Regulated production of ROS and maintenance of "redox homeostasis" are essential for the physiological health of organisms (Ames et al.,1993). Antioxidant defenses include antioxidant molecules and enzymes which protect organisms from oxidative stress episodes. Essentially, pro- and anti-oxidant processes are the same in marine invertebrates and in mammalian systems (Livingstone et al., 1990; Livingstone, 1991; Winston & Di Giulio, 1991). However, the specific conditions for ROS formation are different and highly variable among invertebrate aquatic species (Lesser, 2006) where metabolic rates are much lower than in mammals (Abele & Puntarulo, 2004). Despite the presence of antioxidant defense systems, increased levels of oxidative damage generated by ROS to protein, lipid and DNA occurs in bivalves studied in laboratory and field (Livingstone, 2003).

Biomarkers are biological components that complement physico-chemical factors analysis in aquatic organisms by providing first biological signals of environmental situations. These components may be related to oxidative stress or to biochemical factors. Oxidative biomarkers, such as enzymatic antioxidants activities, non-enzymatic molecules, redox balances, oxidative indexes, and damage to lipid, protein and DNA can be considered. Also, other enzymes and biochemical components are involved in several metabolic pathways (Figure 1). Therefore, all of them can be taken as potentially indicators of the ecosystem fitness (Martinez-Haro et al., 2015). The balance between the mechanisms of damage and defense has ecological relevance since it keeps the ecosystem productivity and contributes to the regulation of potential climate change (Hernando et al., 2016). Even more, bivalves are considered key biomarkers organisms for environmental monitoring based on their economic importance, wide geographical distribution, abundance, sedentarism, tolerance to environmental alterations, their ability to concentrate pollutants, their levels of metabolizing enzyme activities of organic contaminants, the nature of the populations, the life span, the body size, and the potential to survive in laboratory and field studies in cages.

Figure 1. Diagram showing biomarkers commonly used to detect alterations related to natural factors modified by climate change on bivalves.

Actually, there is growing interest in the evaluation of oxidative stress in relation to the impact of global climate change on natural ecosystems in different trophic levels, through the study of the organism's responses to mitigate the damage and control the generation of ROS (Hernando et al., 2016). Since integration of individual biomarker responses into a set of tools and indices capable of detecting and monitoring the degradation in health of a particular organism is an actual challenge, we propose to evaluate the information on oxidative and physiological biomarkers triggered in bivalves in relation to the exposure to different environmental changes to obtain the best approach to it particular variation. We analyzed bivalves facing "natural stress conditions" (acidification, seasonality, temperature, O<sub>2</sub> partial pressure  $(pO_2)$ , salinity and biotoxins).

## **ACIDIFICATION**

Ocean acidification, a complex phenomenon that lowers seawater pH, is the net outcome of several contributions. They include the dissolution of increasing atmospheric carbon dioxide  $(CO<sub>2</sub>)$  in addition with dissolved inorganic carbon generated upon mineralization of primary producers and dissolved organic matter (Mostofa et al., 2016). Marine organisms at low and high latitudes do not respond uniformly to ocean acidification (Hendriks et al., 2010; Toseland et al., 2013), and the expected effects can thus be stimulative, inhibitory, or neutral (Anthony et al., 2008; Gao et al., 2012; Hutchins et al., 2013). Facing ocean acidification marine organisms would express detrimental impacts which may derive from several processes that are closely interlinked: (i) acidification, (ii) synergistic effects of acidification and oxidative stress in surface seawater, (iii) low dissolved  $O<sub>2</sub>$  (hypoxia) and acidification in subsurface/deep seawater, and (iv) stress by algal or biotoxins and pathogens (Mostofa et al., 2016). Species that might be resilient to elevated  $CO_2$  partial pressure ( $pCO_2$ ) have been predicted to be metabolically active to compensate acid–base disturbances (Fabry et al., 2008; Widdicombe & Spicer, 2008). The capacity to compensate the reduction of the pH is related to the excretion of acid equivalents (e.g.,  $H^+$ ) or the increase in the intracellular buffering capacity via the import of  $HCO<sub>3</sub><sup>-</sup>$  to compensate the intracellular acidosis.

Hemocytes of *Mytilus edulis* were analyzed under the effects of  $CO<sub>2</sub>$  or HCl-induced seawater acidification (pH 7.7 or 7.1 and control: pH 8.1) (Sun et al., 2017). It was observed that ROS production was significantly induced in both  $CO<sub>2</sub>$  and HCl treatments, and four antioxidant components, glutathione (GSH), glutsthione-S-transferase (GST), glutathione reductase (GR) and glutathione peroxidase (GPx), had active responses to the acidification stress. Comparatively,  $CO<sub>2</sub>$  had more severe destructive effects on hemocytes than HCl at the same pH level, indicating that  $CO<sub>2</sub>$  stressed cells in other ways beyond the increasing  $H<sup>+</sup>$ concentration. One possible explanation was that seawater acidification induced ROS overproduction, which damaged the ultrastructure of hemocytes and decreased phagocytosis.

In gills and digestive glands of the mussel *Mytilus coruscus* three pH levels were studied (8.1, 7.7 and 7.3). It was detected that mussels exposed to pH 7.3 showed significantly higher activities for superoxide dismutase (SOD), catalase (CAT), GPx, alkaline phosphatase and glutamic-pyruvic transaminase, but a decrease in the acid phosphatase activity was observed when compared to those under higher pH condition (Hu et al., 2015). Tomanek et al. (2011) also showed that a decreased pH (pH 7.5) resulted in SOD upregulation in the mantle tissue of *Crassostrea virginica*. In that study, other proteins involved in antioxidant defence, such as peroxiredoxins, also showed upregulations, suggesting prooxidant conditions and potential oxidative stress.

Results obtained from Freitas et al. (2017) in *Mytilus galloprovincialis* showed that mussels exposed to seawater acidification, pH 7.3, presented decreased metabolic capacity that may have induced lower energy expenditure (observed in higher glycogen, protein and lipids content at this condition) compared to the control pH 7.8. Low pH condition induced the increase of carbonic anhydrase activity that was related to acid-base balance, while no significant activation of CAT and SOD activities were observed resulting in higher lipoperoxidation (LPO).

The clam *Scrobicularia plana* was able to develop mechanisms to prevent oxidative damage when was exposed to low pH 7.1 for 28 days compared to control pH 7.8. Freitas et al. (2016) findings further demonstrated that the antioxidant enzymes were maintained (SOD activity) or significantly decreased (CAT activity); however, GST activity was increased when exposed to low pH. These results may be related to the higher LPO levels obtained, when *S. plana* was exposed to low pH compared to control. The results obtained revealed that after 28 days of exposure clams seem to have acquired the ability to adapt to pH 7.1 since mortality was recorded only up to 96 h of exposure. This is in concordance with the findings of Lindinger et al. (1984) which showed that decreases in intracellular pH appear to be almost fully compensated for after 24-48 h exposure in a wide range of marine invertebrates.

Priya et al. (2016) reported the investigation of the sublethal impacts of ocean acidification inducing hypercapnia (pH 7.5 and 7.0) and leakage of benthic  $CO<sub>2</sub>$  storage sites (pH 6.5-5.5) on the marine clam *Donax cuneatus*. The increase in LPO and CAT activities suggested that hypercapnia induced oxidative alterations. The decreasing pH also increased the activity of GSH and GST which act as detoxifying enzymes for hypercapnia induced toxicity. However, the hypercapnic conditions inhibited the levels of acetylcholine esterase, which indicates that the polluted environment induced high rate of mortality at low pH levels.

Bamber (1990) reported that the critical acid tolerances of marine bivalves, after 30 days exposure, could range from pH 6.6 in *M. edulis* to pH 6.0 in the oyster *Crassostrea gigas*. The impact of elevated  $pCO<sub>2</sub>$  in an organism will reflect the magnitude and duration of exposure and the physiological capacity of that organism to regulate tissue  $pCO<sub>2</sub>$  (Stumpp et al., 2012; Thomsen et al., 2013). Actually, whilst exposure to elevated  $pCO<sub>2</sub>$  has been reported to cause negative impacts in key marine invertebrates (Pörtner, 2008), other studies have shown that some species can succeed in the field in unfavorable pH environments (Thomsen et al., 2013). Maintenance of intracellular pH is essential for countless cellular functions and regulations (Putnam & Roos, 1997) and, in general, intracellular pH is regulated at 0.5–0.8 pH units below extracellular pH (Pörtner et al., 2004). Recent studies also confirmed that calcifying organisms can biologically control the environment of carbonate deposition by controlling the pH in extracellular fluid, or by controlling deposition in a regulated intracellular environment (Hendriks et al., 2015).

## **SEASONALITY**

Abiotic and biotic environmental features such as temperature,  $O_2$  consumption, availability of food, endogenous rhythms and algal blooms, may fluctuate according to the annual seasons. These factors might be potential stressors for aquatic organisms via induction of disbalance between the generation and elimination of ROS that would lead to damage to macromolecules (Abele & Puntarulo, 2004). Seasonal changes in oxidative metabolism have frequently been reported in marine ectotherms, including various bivalve species (Viarengo et al., 1991; Solé et al., 1995; Wilhelm Filho et al., 2001).

A decrease in the activity of antioxidant defenses in the digestive gland of *M. edulis* has been observed in winter with respect to summer, accompanied by an increase in the LPO (Viarengo et al., 1991); and also, the lipid content of these organisms changed significantly due to seasonal and metabolic factors (Okumuş & Stirling, 1998). Wilhelm Filho et al. (2001) reported in the brown mussels *Perna perna* an increase in  $O<sub>2</sub>$  consumption, endogenous antioxidants and lipid damage in summer compared to winter measurements. Lesser  $\&$  Kruse

(2004) showed no seasonal-dependent changes in either SOD activity or protein levels in the subtidal horse mussels *Modiolus modiolus*, although respiration rates were high during summer with respect to winter. However, seasonal variability of antioxidant parameters evaluated in the digestive gland of the ribbed mussel *Aulacomya atra atra* showed that the antioxidant activities of both GST and CAT were induced in summer compared to winter, meanwhile SOD activity and ascorbyl radical content were parameters seasonallyindependent (Giarratano et al., 2013). Giarratano et al. (2011) reported in the mussels *Mytilus edulis chilensis* a significant effect of seasonal-dependent variation on biological responses, in metal bioaccumulation and antioxidant enzymes activity. SOD activity was higher in winter than in summer organisms; meanwhile, CAT activity was not altered in *M. edulis chilensis*.

From these studies, it is notice that significant changes of antioxidant parameters in bivalves are closely correlated with the seasonal variations of temperature, dissolved  $O<sub>2</sub>$ , chlorophyll a and many other changing factors. Seasonal variations arise from a complex interaction between exogenous and endogenous factors; consequently, it is difficult to draw unambiguous conclusions from such variations. However, these reports show the importance to include such variables in biomonitoring programs when analyzing data obtained from different periods of the year. Moreover, seasonal data may be useful to indicate the periods of the year more suitable for the marketing and consumption of commercial species. When the organisms have a best antioxidant protection during the year, it could be a contributing factor to prevent lipid damage, that is essential to improve organoleptic characteristics and to control stress during the processes of conservation and commercialization.

## **TEMPERATURE**

Increases in surface seawater temperatures  $(2-4.5 \degree C)$  are probable to occur during the next decades (IPCC, 2007). Most physiological processes are temperature-dependent on various organisms; then, the increase of environmental temperature may lead to metabolic activation, which combined with an increase in  $O<sub>2</sub>$  consumption, initiates oxidative stress (Allakhverdiev et al., 2008; Halliwell & Gutteridge, 1989).

Matozzo et al. (2013) studied the effects of temperature changes (22 and  $28^{\circ}$ C), at 34 psu and 8.1 pH, in gills and digestive glands of *Chamelea gallina* and *M. galloprovincialis*. In the clams, only the thiobarbituric acid reactive substances in gills, and the CAT in the digestive gland, were affected. However, no modifications were observed in these parameters evaluated in the tissues of the mussel. In *M. galloprovincialis* respiratory tissues*,* hyperthermia (30°C) induced a p38 mitogen-activated protein kinase (p38-MAPK) activation in a rapid (maximum at 30 min), sustained (over 120 min) and considerable way; whereas the effect of hypothermia was not so intense (Kefaloyianni et al., 2005). The moderate response of p38-MAPK to hypothermia could be attributed to the fact that these organisms are routinely subjected to hypothermic stress and have consequently developed multiple adaptive responses in order to preserve their function under analogous conditions (Sheehan & Power, 1999; Lesser & Kruse, 2004).

An & Choi (2010) also evaluated physiological alterations at 10, 20 and 30 $\degree$ C in the ark clam *Scapharca broughtonii*. Water temperature changes significantly increased antioxidant SOD and CAT mRNA expression and activity in the digestive glands and gills in a timedependent manner at  $30^{\circ}$ C compared to the other temperatures. H<sub>2</sub>O<sub>2</sub> concentrations, LPO, aspartate aminotransferase and alanine aminotransferase levels also increased significantly in a time-dependent manner in the high-temperature treatments, while lysozyme activity decreased. Therefore, in an early-stage exposure to high temperatures, oxidative stress was regulated by antioxidant enzymes, but continued thermal stress resulted in an increase the oxidative stress and damage due to the diminished protection.

Green-lipped mussels *Perna viridis* were observed to increased activities of antioxidants such as SOD, CAT, GPX, GR and GST both in gills and digestive glands under long-term exposures to 32 compared to 26°C, suggesting the activation of physiological mechanism to scavenge the ROS produced during heat stress. Also decreased values of GSH on long exposures to temperature stress indicate utilization of this antioxidant, either to scavenge ROS or to act in combination with other enzymes (Verlecar et al., 2007).

The results on different bivalves exposed to temperature variations suggested that they alter the oxidative metabolism by modulating antioxidant enzyme activities. Even more, as the frequency of extreme thermal events increases, intertidal animals may activate their cellular defense and repair mechanisms; otherwise, they may accumulate higher concentrations of cellular damage due to heat stress (Jimenez et al., 2016).

## **SALINITY**

Salinity is a major controlling factor in coastal systems whose fast change, often associated to tidal oscillations, causes drastic alterations on aquatic communities by promoting a physiologically stressful environment. Hyposaline conditions may be produced by dilution factors such as rainy periods and fresh water inputs by rivers, snow or glacial melting. Meanwhile, hypersaline situations are due to salts concentration events such as marine water evaporation. Salinity is one of the main controlling factors of growth, causing great constrains on species productivity and diversity, and a variety of physiological responses (Regalla et al., 2007; Kirrolia et al., 2011; Verdelhos et al., 2015). Osmotic stress exerts considerable oxidative stress, associated with enhanced ROS generation, in organism living in the intertidal zone. Bivalve species are able to tolerate large salinity changes, even though they do not show osmo-regulatory abilities (Evans, 2009).

Freitas et al. (2017) exposed *M. galloprovincialis* to high (35 psu) and low (14 psu) salinities. Mussels presented lower metabolic activity (also related to lower energetic expenditure) at high salinity compared to low salinity organisms. This lower metabolic activity, probably related to valves closure, helped to mitigate the increase of lipid damage in this condition. At low salinity, despite the rise of CAT and SOD activities, lipid damage increased, probably as a result of ROS overproduction from higher electron transport system activity. Carbonic anhydrase slightly augmented at stressful salinity conditions, a mechanism of homeostasis maintenance. Matozzo et al. (2013) also studied the effects of salinity changes in gills and digestive glands of *M. galloprovincialis* and *C. gallina*. They observed that 28, 34 and 40 psu conditions significantly influenced the oxidative parameters (CAT, SOD, GST, thiobarbituric acid reactive substances) of the bivalves; although the variation pattern varied depending on the species and tissues analyzed. Even more, Hamer et al. (2008) previously investigated the exposure to reduced seawater salinities and its effect on DNA integrity, p38MAPK activation, metallothionein induction and  $O_2$  consumption rate on the gills of the mussel *M. galloprovincialis*. O<sub>2</sub> consumption rate was dependent to salt concentrations and increased considerably to about 51 and 65% in 28 and 18 psu, respectively, compared to control mussels (37 psu). DNA integrity was negatively impacted by hyposalinity. Reduced salinities (18.5 and 11 psu) resulted in significantly higher p38-MAPK phosphorylation, whereas at 28 psu it was significantly decreased compared to control. The concentration of metallothioneins in mussels' gills was reduced at 28 and 18.5 psu, while it was significantly higher at 11 psu.

In two estuarine commercial clam species *Cerastoderma edule* and *S. plana*, biomarker responses on the foot around their optimal salinity value of 20 psu (from 10 to 35 psu) were studied (Gonςalves et al., 2017). They found a decrease on SOD enzymatic activities in both species, but the GST was reduced in *S. plana* and increased in *C. edule*. Similarly, Tankoua et al. (2011) also demonstrated the influence of salinity in some classes of biomarkers (GST, acetylcholynsterase, lactate dehy-drogenase and digestive enzymes) determined in *S. plana*. When unsaturated fatty acids were analyzed in these two bivalve species, their diversity and quantity presented the highest values at the extreme salinity treatments compared to control organisms.

In the ark shell *S. broughtonii* the response to hyposalinity and hypersalinity was studied in digestive glands, gills and hemolymph (An & Choi, 2010). The authors hypothesized that salinity changes increase oxidative stresses and SOD and CAT provided the antioxidant defense and protection. SOD was the first-line of defense against  $O_2^-$ , since SOD mRNA expression and activity increased when  $H_2O_2$  concentrations in the hemolymph were high. As a second-line of defense, CAT mRNA expression and activity increased to reduce  $H_2O_2$ concentrations. They also found that the lysozyme activity decreased in the hemolymph throughout the experiment, suggesting that salinity changes negatively affected immunity and reduced lysozyme activity. The observed increases in aspartate aminotransferase and alanine aminotransferase levels indicated that tissue damage also occurred facing the salinity changes.

The present findings demonstrated that bivalve's oxidative status and metabolic capacity were negatively affected by salinity changes, with alterations that may lead to physiological impairments namely on mussels reproductive output, growth performance and resistance to disease, with ecological and economic implications (Freitas el al., 2017).

## **OXYGEN PARTIAL PRESSURE (PO2)**

Marine coastal environments can become hypoxic or anoxic, changing completely the geochemistry of the areas. The rocky intertidal zone is a highly variable environment that ranges from fully aquatic to fully terrestrial conditions over the tidal cycle (Jimenez et al., 2016). Even more, low  $pQ_2$  is a frequently condition of many estuaries, swamps, and tidal flats, which receive high amounts of organic matter from coastal runoff (Abele et al., 2017). Conditions may worsen during warm summers when benthic biological and chemical  $O<sub>2</sub>$ demands increase. Gills of bivalve filter feeders serve as a particle filter and as gas exchanger at the same time; meanwhile the mantle is also involved in gas and ionic exchange (Henry and Saintsing, 1983). They might therefore be prone to suffer both elevated ROS levels and oxidative damage related to continuous contact between these tissues and modifications in the

pO2. To cope with these situations, the bivalve shell enables its occupant to behaviorally adjust the internal environment with respect to dissolved gases, nutrients and the composition of bacterial communities in the surroundings of the soft tissues (Abele & Philipp, 2012).

Rivera-Ingraham et al. (2013) studied the effect of hypoxia and anoxia exposures in gills of *M. edulis*. Exposure to declining  $pO<sub>2</sub>$  caused an increase of gill metabolic rate between 21 and 10 kPa, a  $pO<sub>2</sub>$  range in which whole animal respiration is reported to be oxyregulating. Exposure of the animals to severe anoxia caused an onset of anaerobiosis (succinate accumulation). Concentrations of ROS decreased strongly during anoxic exposure of the mussels and increased upon reoxygenation. This ROS burst induced LPO in the mantle, but neither was protein carbonyl levels increased, nor did the tissue SOD and CAT activities and GSH concentration change. Further, analysis of apoptosis markers (activity of caspases 3/7) indicated no induction of cell death in the gills. The authors conclude that these hypoxia tolerant intertidal mussels did not suffer major oxidative stress in gill under these experimental conditions. *M. edulis* from high shore (naturally experienced 6 h air exposure, twice a day) and low shore (naturally experienced 2-2.5 h air exposure, few days a month) was also studied in gills and digestive glands collected after 2 h of air exposure. The authors found that the antioxidant enzymatic activities (CAT, SOD, GST, GPX, GR) were higher in mussels living in the upper intertidal zone, suggesting an ability to adjust their antioxidant defenses in response to the stressful situation induced by living in this part of the habitat (Letendre et al., 2009).

Mussels *P. perna* were exposed to air for 24 h showing a clear increase in the levels of LPO in the digestive gland and gills, while oxidative DNA damage increased only in the gills. In mussels re-submersed for a period of 3 h after the 24 h of air exposure these values returned to pre-aerial exposure levels. On the other hand, in a group of mussels exposed to air for 18 h and then to 1 h of re-submersion, SOD, CAT, GPX, GR, glucose-6-phosphate dehydrogenase, and total GSH were not modified. Only a 52% increase in the GST activity was observed in the digestive gland, which remained elevated after 1 h of re-submersion (Almeida et al., 2005).

Several studies have demonstrated that bivalves from tidal shores maintain respiratory independence against variable and diminishing ambient  $pO<sub>2</sub>$  by inducing ventilation and circulation of mantle-cavity water in order to maintain a sufficiently oxygenated state of their tissues (Bayne, 1971; Taylor & Brand, 1975; Brand & Morris, 1984; Strahl et al., 2011; Abele & Philipp, 2012; Rivera-Ingraham et al., 2013). However, physiological normal conditions, in the absence of water, require a complex and finely tuned set of mechanisms working in close coordination (França et al., 2007). In this context, enzymatic antioxidant defences suggest having the ability to acclimate during the hypoxic state (Chandel et al., 1998; Chandel & Schumacker, 2000) or following a hypoxic episode (Boveris & Chance, 1973; Loschen et al., 1973; Duranteau et al., 1998), where ROS are released from ubisemiquinone during tissue reoxygenation. Therefore, the location of organisms on the shore should be taken into account in sampling for ecotoxicological studies.

## **BIOTOXINS**

Temperature changes and nutrient pollution in coastal areas contributes to the advance and maintenance of harmful planktonic toxins; however, physical, biological, and other chemical factors may promote harmful responses (Sellner et al., 2003). An enhancement of human activity in coastal areas has increased eutrophication processes which resulted augmentation in frequency, intensity and geographical distribution of harmful algal blooms (HAB) during the last several decades (Derwent et al., 1998; Ibelings et al., 2007; Aguiar et al., 2011). These blooms can produce an extensive range of phycotoxins from a variety of microalgal species (Glibert et al., 2005). Aquatic animal species, such as bivalves, can accumulate bloom forming algae and their toxins by filtering water containing them, while less amounts are directly absorbed in a dissolved manner (Burmester et al., 2011). Responses of some mussel species to algal toxins have been previously described (Pflugmacher et al., 1998; Contardo-Jara et al., 2008; Burmester et al., 2011; Vareli et al., 2012; Kwok et al., 2012). The capacity to bioaccumulate and respond to toxins differs in a species-specific manner among bivalves and the harmful microalgae on which they may feed (Cembella et al., 1993; Nagai et al., 1996; Smolowitz & Shumway, 1997; Shumway, 2006; Hégaret et al., 2007 a,b). These relationships suggest that bivalves are more than simple transference vectors of phycotoxins to humans or other feeders at higher trophic levels. In fact, it has been reported that some types of marine toxins can reduce growth and reproduction rates of bivalves and could be lethal for some species (Shumway et al., 2006; Samson et al., 2008).

Digestive glands from *M. edulis platensis* were isolated from specimens collected in the Argentinean Sea during summer, winter and spring (in the presence of harmful planktonic toxins) (González & Puntarulo, 2016). It was shown that SOD and GST activities decreased in winter and spring, compared to samples collected in summer. During the spring season, the bivalves were facing oxidative stress, as indicated by the increases measured on hydrophilic (ascorbyl radical/ascorbate) and lipophilic (lipid radical/α-tocopherol) cellular media indexes of redox balance and on 2′,7′ dichlorofluorescein diacetate oxidation rate. Meanwhile, under physiological conditions, these biomarkers seem to be adequately controlled to keep steady state concentrations of damaging reactive species far from dangerous levels.

Qiu et al. (2013) studied the effect of a paralytic shellfish toxin (PST)-producing dinoflagellate, *Alexandrium tamarense*, on the muscle and digestive glands of the scallops *Patinopecten yessoensis* and the mussels *M. galloprovincialis*. Their results showed that ROS was quickly generated and then disappeared in the tissues of scallop and mussel in the PSTaccumulating and depurating periods, and that a different response of antioxidant enzymes to ROS occurred in the two different bivalves. Only GPx enzyme was induced to remove ROS in the scallop, but SOD, CAT, and GPx enzymes were stimulated to avoid oxidative damage in the mussel. *M. galloprovincialis* was also sampled to study the possible impairments of physiological parameters under naturally exposed to algal yessotoxins (YTX) levels (Buratti et al., 2011). Clear correlations were established between the increase of homo-YTX (and concomitant decrease of YTX) and the increase of cAMP levels, thus providing further insights into the mechanisms of action of these compounds. Similarly, direct correlations were established between the increase of homo-YTX, cAMP levels and multixenobiotic resistance gene products expression at submaximal algal concentrations. On the contrary, at the maximum levels of algal accumulation, multixenobiotic resistance gene expressions were greatly reduced. A significant reduction of lysosome membrane stability was also observed in paralytic shellfish poisoning- or lipophilic toxin-positive mouse bioassay mussels, reinforcing the hypothesis that lysosomes are relevant targets of YTXs. Considering the significance of this biomarker as predictive of detrimental effects at the organism level (Viarengo et al., 2007; Moore et al., 2008), this result suggests the development of a stress syndrome in

mussels due to algal toxin accumulation. This apparent reduction of health status was concomitant with the inhibition of the multixenobiotic resistance-related gene expression in the mussels, therefore with a possible reduction in their defense system. These results corroborate previous reports indicating alterations of mussel physiological functions after exposure to algal toxins and suggest some molecular targets.

Hemolymph of the bivalve *Mytilus chilensis* was analyzed after the injection of an extract of the marine microalgae *Alexandrium catenella* which produces saxitoxin (STX) (Núñez-Acuña et al., 2013). The authors evaluated the expression of 13 candidate genes associated with cellular stress and immune response. Analysis by qPCR showed higher gene transcription levels in *M. chilensis* injected with STX than in control mussels. High levels of differential gene expression were observed for SOD, CAT, ferritin and heat-shock protein genes. To a lesser extent, ependymin, fibrinogen-like, galectin and mytilin B genes were also significantly more expressed in hemocytes of mussels injected with STX that in control mussels. These results provided insights into how marine toxins could modulate the innate immune system of marine invertebrates.

Besides deep investigations regarding contaminated seafood toxicity to humans with an association to economic losses, many studies were also undertaken to examine the influence of algal toxins on bivalves themselves since they lead to significant ecological damage (Geraci et al., 1989; Shumway, 1990; Bourdelais et al., 2002). Biotoxins may affect mussel physiological pathways, including hemocyte functionality, lysosome membrane stability, antioxidant enzymes activities, gene expression and cell signaling.

## **CONCLUSION**

The revision on the biomarkers responses in bivalves affected by environmental stressors associated to the global climate change undertaken in this chapter indicates a high modulation capability of biochemical responses of the organisms. In this fluctuating global context, organisms will be chronically exposed to elevated temperature, a decreased pH, changes in salinity, modifications during seasons,  $pQ_2$  and biotoxins presence. The energy costs associated with the found stress responses in this chapter may alter organism energy budget and translate it into negative effects on fitness. We verified biomarkers related to the commented environmental stressful changes in ten mussel species (*M. coruscus, M. galloprovincialis, M. chilensis, M. edulis chilensis, M. edulis, M. edulis platensis, A. atra atra, P. viridis, P. perna, M. mondiolus*), five species of clams (*S. plana, D. cuneatus, C. gallina, S. broughtonii, C. edule*), one scallop (*P. yessoensis*) and two oysters (*C. virginica*, *C. gigas*). The variations in environmental factors caused by climate change generate a situation of oxidative damage and biochemical changes in bivalves as a direct or indirect consequence.

According to the data tested and the biomarkers evaluated form all the mentioned authors we found that some of them seemed to respond in a better way than others depending on the environmental conditions faced by the bivalves (Figure 2). When analyzing the acidification factor, it was revealed that GSH related enzymes and lipid damage were augmented. The antioxidant enzymes studied over different seasons showed a high variability effect according to the species and their habitat latitude, so they do not seem the best indicator of stress. Other

biomarkers should be tested instead, like hydrophilic and lipophilic indexes (González & Puntarulo, 2016). However, when these molluscs were exposed to increments in temperature, many antioxidant enzymes were activated. Salinity changes generated DNA and lipid damage with antioxidant enzymes modifications. Even more, various signal transduction pathways are involved in the regulation of the environmental stress response, apoptosis and facilitation of the repairmen of damaged proteins and other cellular components (Woessmann et al., 1999). In particular, p38-MAPK has been characterized as the principal stress-kinase responsive to fluctuations in ambient osmolality and temperature (Zhang & Cohen, 1996; Kultz & Burg, 1998; Gon et al., 1998). The effect of the diminished  $pO<sub>2</sub>$  also evidenced an increase in the DNA and lipid damage even though the increment observed in the activity of the antioxidant enzymes. Good biomarkers associated to biotoxins were ROS tests and oxidative stress indexes. Genes codifying for antioxidants enzymes and their activities were also affected but in different ways according to the studied toxin and bivalve species.

Figure 2. Biomarkers used to evaluate the effect and consequences of climate change on bivalves over the last few years.

Even more, nitric oxide (NO) has been shown to act as intracellular or transcellular signal and as cytotoxic host defense compound (Moncada et al., 1991; Knowles & Moncada, 1994; Moncada & Higgs, 1995). ROS and reactive nitrogen species cellular pathways are related through the reaction of  $O_2^-$  with NO to generate peroxynitrite (ONOO<sup>-</sup>). ONOO<sup>-</sup> is a nitrating agent and a potent oxidant able to modify proteins, lipids and nucleic acids (Lu et al., 2014). González & Puntarulo (2016) compared NO content in digestive glands from *M. edulis platensis* isolated during three seasons. Spring samples showed a 2.7-fold NO increased compared to summer; however, this enhancement was significantly lower than the

value reached during winter. Thus, seasonality seems to be one factor responsible for altering NO content in this species. Tomanek et al. (2011) hypothesized that oysters exposed to elevated  $pCO<sub>2</sub>$  can cause oxidative and nitrosative stress by the ROS production reacting with ONOO– . Future studies may include NO measurements as a possible biomarker for climate change stressors (Figure 2).

This chapter expands our understanding of multifactorial effects on the marine ecosystem in the specificity of investigated biomarkers and biotests, providing insight into the acclimation, adaptive and stress response processes of bivalves. Finally, such ecological and biogeochemical changes in the oceans could have profound consequences for marine biodiversity and seafood quality with deep implications for fishery industries in the upcoming decades (Figure 2) (Doney et al., 2009; Mora et al., 2013; Jin et al., 2015).

#### **ACKNOWLEDGMENTS**

The research was supported by grants from the University of Buenos Aires (20020130100383BA), National Agency of Science and Scientific Promotion (ANPCYT PICT 00845), National Council for Science and Technology (CONICET PIP 0697 and PIP 0635) and Federal Council of Science and Technology (PFIF Project TDF 004, COFECYT 095, MINCYT 1622/07). The authors G.M. and P.M.G. are career investigators from CONICET and J.C. is a fellow from CONICET.

## *BIOGRAPHICAL SKETCHES*

## *Paula Mariela González*

- **Affiliation:** Universidad de Buenos Aires, Facultad de Farmacia y Bioquímica, Fisicoquímica. Buenos Aires, Argentina. CONICET-Universidad de Buenos Aires. Instituto de Bioquímica y Medicina Molecular (IBIMOL). Buenos Aires, Argentina.
- **Education:** Licenciate in Biological Sciences and Doctor of the University of Buenos Aires in Biophysics
- **Business Address**: Junín 956 (C1113AAD), Buenos Aires. Argentina.
- **Research and Professional Experience:** Dr. Paula Mariela González is a career investigator at the National Council of Science and Technology (CONICET) and teacher from the University of Buenos Aires, School of Pharmacy and Biochemistry, Argentina, in the subject Physical Chemistry and in post graduate courses. Her specialty is oxidative stress in molluscs and algae. González has been working in Antarctic and Germany institutions (Instituto Antártico Argentino and Alfred Wegener Institute, respectively). She has published eighteen papers in peer review journals, and eight book chapters. She has participated and published in more than thirty national and international meetings. She has also been a reviewer of several international journals.

## **ABSTRACT**

The peculiarity of membrane lipids with high polyunsaturated fatty acids content in mollusks, suggests a special pattern for the development of lipid oxidation, decreased organoleptic characteristics and loss of product value for sale. In the Puerto Almanza area, Tierra del Fuego, mussel extraction is carried out for fresh commercialization in local cities. The antioxidants application in different marine resources at any stage of processing has been effective for the oxidative control. Our objective was to evaluate the level of lipid oxidation (tiobarbituric acid reactive species content, TBARS) and nonenzymatic antioxidants content in mussel (*Mytilus edulis chilensis*) for commercialization, after the treatment with ascorbic acid (AH- ). Mussels extracted from offshore batch culture, were exposed to different treatments: T1: dry control, T2: control in seawater without antioxidant, T3: exposed to AH- (10 mM) and T4: exposed to AH- (5 mM). Subsamples of each treatment were taken at 0, 6 and 24h, for analysis. A TBARS increase of 36% and ascorbyl radical content  $(A<sup>o</sup>)$  were observed during the first 24h on T1. The AH-incorporated by the mussels showed an antioxidant activity avoiding lipids oxidation during the first stage of processing (24h of exposure) comparing T1 and T4. These results showed the generation of oxidative stress in mussels during dry condition.

 $\overline{a}$ 

Corresponding Author's Email: gmalanga@ffyb.uba.ar.

The AH<sup>-</sup> content in frozen mussels decreased significantly after 24h of exposure to the antioxidant in T1 and T4, probably due to consumption. In addition, both A● as the A● /AH-index, increased significantly comparing T1, T3 and T4 treatments. This indicates that the manipulation conditions, transfer and cold storage generated an oxidative stress situation.

Overall, our results indicated that the maintenance in water for 24h and that the addition of AH- (5 mM) after the mussel extraction, are beneficial during the transfer period and avoid the stress generated by manipulation of *M. edulis chilensis*. Higher concentrations of the AH-could produce an effect contrary (pro-oxidant) in 24h. Further, cold storage (-20 ºC) for 5 days, regardless of the addition of antioxidants, does not prevent the oxidative lipid damage nor improve product quality.

**Keywords:** antioxidant, ascorbic acid, *Mytilus edulis chilensis*, oxidative stress

## **INTRODUCTION**

Placed at the southern extreme of South America (54°52'50,01" S, 67°45'21,82" W), the Beagle Channel is a drowned glacial valley that connects the Pacific and Atlantic oceans trough the islands of Tierra del Fuego. Due to its particular location, it is considered a key environment for the study of interactions between the sub-Antarctic and the Antarctic regions (Pérez-Barros et al., 2004). Navarino and Isla Grande de Tierra del Fuego act as barriers to give this part of the Beagle channel the character of a semi-enclosed water body. Low surface salinity (2.5-2.7 PSU) from intense local inputs of great amounts of glacial meltwater (Klöser, 1996) can produce a strong stratification, which will remain as long as intense winds are absent (Villafañe et al., 2001). Ushuaia city, the biggest settlement on the channel with about 70000 inhabitants, exerts an increasing anthropic pressure by the way of discharges of urban and industrial effluents to its waters (Torres et al., 2009).

ROS generate damage to macromolecules through the reaction of these species with proteins, DNA and lipids constituting the biological systems (Elstner, 1982; Halliwell and Gutteridge, 1984). Proteins and peptides are composed of amino acids that are the object of attack both free radicals and other reactive molecules (Dalle-Donne et al., 2003). Studies on oxidative damage to amino acids have provided sufficient information about changes in the macrostructure of proteins. Lipid oxidation is the oxidative deterioration suffered by polyunsaturated fatty acids (PUFA) (Girotti, 1985). This process occurs through a mechanism that involves free radicals and causes cytotoxic effects that include membrane structural alterations, decreased fluidity, increased permeability of cellular components, and inactivation of enzymes and membrane transporters (Girotti, 1985; Halliwell, 1999).

The non-enzymatic antioxidant defenses are low molecular weight biomolecules that exert their activity through different mechanisms. These antioxidants can be liposoluble, so they are related to the protection of membranes (tocopherols, carotenoids, ubiquinols), as well as water-soluble (glutathione, ascorbic acid), phenolic compounds (flavonoids) and complex molecules. Ascorbate (AH- ) is located in all subcellular compartments (Smirnoff, 2000), being able to intervene in spontaneous reactions with free radicals generated in a biological system (Buettner and Jurkiewicz, 1993). It´s an excellent antioxidant and participates in both enzymatic and non-enzymatic reactions. Direct reactions not catalyzed enzymatically include the role of AH<sup>-</sup> as a trap for hydroxyl,  ${}^{1}O_{2}$  and  $O_{2}$ <sup>-</sup> (Foyer et al., 1994). Additionally, it can
protect biological membranes through the regeneration of oxidized α-Tocopherol ( $α$ -T), being probably it´s most important function (Packer et al., 1979; Buettner and Jurkiewicz, 1996). However, the AH<sup>-</sup> in high concentrations and in presence of transition metals, can act as a pro-oxidant agent. The A<sup>•</sup>/AH<sup>-</sup> ratio can be used as an indicator of the balance between damage caused by free radicals and antioxidant protection (Galleanoet al., 2002).

Considering the Beagle Channel characteristics explained above, an incipient mussel aquaculture (*Mytilus edulis chilensis*) has developed in the area in the last years, representing an important commercial resource for local populations. Shelf-life extension can be achieved by various preservation methods, i.e., refrigeration, freezing, salting, brining (wet salting), icing, smoking, glazing, drying, frying, modified atmosphere packaging, supplementation with antioxidant (Gandotra et al., 2012). Mussels are an excellent source of long-chain polyunsaturated acids. The particularity of the membrane lipids of marine organisms, with a high content of polyunsaturated fatty acids (PUFA), suggests a special pattern for the lipid oxidation and consequent reduction of energy as a source for human consumption. This oxidation causes rancid flavors and odors, which make it unacceptable from the consumer's point of view. The development of lipid oxidation can occur during the stage of collection, processing and cold storage for subsequent sale and consumption, depending on variables such as: period and temperature of storage, natural antioxidants, presence of physical or chemical treatments and packaging (Fernández-Reiriz et al., 1995). For this reason, in some of the production stages of this sea food, the food industry incorporates natural or synthetic antioxidants (Cuppett, 2001; Pokorný, 2007). The supplementation with antioxidant is a food preservation method used to extend the shelf life and to retain the quality of various foods.

The main goal of the present study, was to evaluate the levels of lipid peroxidation and content of non-enzymatic antioxidants in *Mytilus edulis chilensis*. The research was developed with organisms extracted from commercial cultivation, being developed in Almanza, Tierra del Fuego. The determinations were made in the different stages of the usual processing of the organisms destined for commercialization, after treatment with ascorbic acid.

### **MATERIALS AND METHODS**

#### **Experimental Design**

To determine the effects of oxidative damage and antioxidants responses in mussels, 420 individuals of commercial size were harvested from mussel farmers in Bahía Brown, Almanza, Tierra del Fuego. The mussels were obtained manually from the floating rafts, and were immediately transported to the processing plant, where the animals were submitted to different treatments. The organisms were divided into 4 groups of 100 individuals each and were conditioned in tanks with filtered sea water and controlled temperature and salinity during 24h. The following treatments were then applied: T1: dry control, T2: control in seawater without antioxidant, T3: exposed to AH (10 mM) and T4: exposed to AH (5 mM). Sub-samples of 10 mussels were taken at 0, 6 and 24h in order to determine lipid damage and antioxidant content for each treatment. Additionally, sub-samples were taken and preserved in -20°C for 5 days. The mussels were processed until biochemical's determinations. For

determination on mussel's tissue, 10 g of sample was homogenized in 20 ml of distillated water and pH was measured using a pH probe (Woyewodaet al., 1986).

#### *Physico-Chemical Determination in the Sampling Area*

The parameters were evaluated at 1m depth in the water column. The following were measured: pH, temperature, dissolved oxygen, and salinity, using a Horiba U-10 multiparameter probe. The accuracies of the readings were 0.01 for the pH and 0.1 for the temperature, dissolved oxygen and salinity. With the same probe used for *in situ* measurements, it was determined the temperature and pH in the containers corresponding to each experimental treatment.

#### *TBARS Content*

The homogenates were treated with  $30\%$  (w/v) trichloroacetic acid and 50 mM potassium phosphate buffer (pH 7.0). After centrifugation, the content of TBARS was determined in the supernatant spectrophotometrically at  $\lambda = 535$  nm, using TBARS standards that were created by the acid hydrolysis of 1, 1, 3, 3 tetraethoxypropane, according to Malanga *et al*., (2004).

#### *Lipid Soluble Antioxidants Content*

The  $\alpha$ -T content mussels was quantified by reverse-phase HPLC with electrochemical detection using a Bioanalytical Systems LC-4C amperometric detector with a glassy carbon working electrode at an applied oxidation potential of 0.6V (Desai, 1984). Samples were extracted with 1 mL of ethanol and 4 mL of hexane. After centrifugation at  $600 \times g$  for 10 min, the hexane phase was removed and evaporated to dryness under  $N_2$ . Extracts were dissolved in methanol/ethanol (1:1) and injected for HPLC analysis (Desai, 1984). D,L-αtocopherol (Sigma) was used as standards.

#### *Ascorbyl Radical Content (A•)*

A Bruker ECS 106 spectrometer was used for A• measurements. Homogenates from mussels were prepared in pure dimethylsulfoxide (DMSO) (1:3) and the spectra were scanned at room temperature under the following conditions: 50 kHz field modulation, microwave power 20 mW, modulation amplitude 1 G, time constant 655 ms, receiver gain 1 105, microwave frequency 9.81GHz, and scan rate 0.18G/s (Giulivi and Cadenas, 1993). Quantification was performed according to Kotake et al., (1996). The amount of spin adduct was calibrated using an aqueous solution of TEMPO, introduced into the same cell used for spin trapping. EPR spectra of spin adduct solution and TEMPO solution were recorded at the same spectrometer settings and the first-derivative EPR spectra were double integrated by a computer attached to the EPR spectrometer to obtain the area intensity, and then the concentration of spin adduct was calculated using the ratio of these areas.

#### *Ascorbate Content (AH-)*

The content of AH- was measured by reverse-phase HPLC. The samples were homogenized in metaphosphoric acid  $(10\%, w/v)$  according to Kutnink et al.,  $(1987)$ . The content of ascorbate in the cell homogenates was quantified by reverse-phase HPLC with electrochemical detection using a LC-4C amperometric detector with a carbon working electrode at an applied oxidation potential of 0.6 V. A Supelcosil LC-18 column was stabilized with metaphosphoric acid (0.8%, w/v) and a freshly prepared solution of ascorbic acid in metaphosphoric acid (10%, w/v) (1 µg/ml) was used as standard.

Considering that a AH- concentration was variable between the different treatments, the A● /AH-ratio was calculated in order to show more precisely the non-generation of an oxidative stress situation after supplementation with ascorbic acid.

#### *Statistical Analyses*

Data in the text and tables are expressed as mean  $\pm$ S.E.M. of five independent experiments, with two replicates in each experiment. Statistical tests (Mann-Whitney) were carried out using GraphPadInStat, version 3.01.version 5.0 (Abacus Concepts, Inc., Berkeley).

### **RESULTS**

The physico-chemical parameters measured on the Beagle Channel (Almanza) in the sampling area can be seen in Table 1. They are within the average values for the area during the time of year in which the sampling was done (Hernando et al., 2007).

The seawater pH value in the treatment containers were close to neutrality and no significant variations were observed over time in the treatment without addition of antioxidants. However, in the containers supplemented with ascorbic acid, significant decreased values were observed after 6h independently of concentrations (P< 0.05, Table 2). Regarding to seawater temperature, the values in the treatment containers were close to the Beagle Channel values (Table 1) and no significant variations were observed over time or treatments ( $P > 0.05$ , Table 2).

pH	$8.36 \pm 0.05$
Conductivity $(mS/cm)$	$43.3 \pm 0.9$
Dissolved oxygen $(mg/l)$	$12.0 \pm 0.8$
Temperature $(^{\circ}C)$	$9.5 + 0.4$
Salinity (PSU)	$27.2 + 3.2$

**Table 1. Physico-chemical parameters in the Beagle Channel for sampling area**

### **Table 2. Seawater pH and temperature for different treatments with**  *Mitylus edulis chilensis*

T1: dry control, T2: control in seawater without antioxidant, T3: exposed to AH- (10 mM) and T4: exposed to AH- (5 mM).

**\*** Significantly different from the value of T2 at any experimental time in the same maintenance conditions  $(P < 0.05)$ .

The AH- content in seawater before to the incorporation of the mussels in the different treatments were:  $0.071 \pm 0.005 \mu M$  for T2 (control in seawater without antioxidants); 446  $\pm$ 65  $\mu$ M in T3 (seawater with 10 mM ascorbic acid) and 154  $\pm$  38  $\mu$ M in the T4 (seawater with 5 mM ascorbic acid), but decreased significantly ( $P < 0.05$ ) in the containers that were supplemented with ascorbic acid after 6 and 24h (Figure 1).

Time exposition (h)

\* Significantly different from the ascorbate value at time 0 under the same culture conditions  $(P < 0.05)$ .

Figur 1. Ascorbic acid content in seawater for different treatments.  $(\Box)$  T3: high AH concentration (10 mM); (■) T4: low AH-concentration (5mM).

After exposing the mussels to ascorbic acid for 24h at  $T = 10.2$ °C, no significant differences were observed in the internal pH, except an increase of 5.5 to 6.2 from 0 to 6h of exposure, in mussels from T3. Non-significant differences were observed in the pH values of all the mussels treated during 5 days of cold storage (5.8  $\pm$  0.3). The TBARS content for the mussels during the first stage of processing, exposed or not to ascorbic acid during 6h, did not show significant differences comparing with time 0 ( $P > 0.05$ ). However, after 24h, a significant decrease  $(P < 0.05)$  was observed in mussels exposed to seawater supplemented with the highest concentration of ascorbic acid (10 mM). On the other hand, there was a significant increase ( $P < 0.05$ ) of the TBARS content in mussels kept dry for 24 h compared to the value at time 0, immediately after being collected (Table 3).

The AH<sup>-</sup> content increased significantly  $(P< 0.05)$  in the mussels from the containers supplemented with ascorbic acid, independently of the concentration for 6 and 24h (Table 3). A typical EPR spectrum for the  $A^{\bullet}$  in the presence or absence of mussel tissue is shown in Figure 2. No significant differences were observed on it for any of the treatments ( $P > 0.05$ , Table 3). The A<sup>•</sup> content and the ratio A<sup>•</sup>/AH<sup>-</sup> were determined in order to evaluate if the supplementation with ascorbic acid generated an oxidative stress situation "per se". A nonsignificant increase ( $P > 0.05$ ) was observed in the ratio  $A^{\bullet}/AH^-$  at 6h in T1. However, for the same exposure time, a significant decrease was observed after supplementation with 10 mM of ascorbate (Table 3).

### **Table 3. Ascorbate content, ascorbyl radical, ratio A● /AH- , TBARS and α-T for**  *Mytilus edulis chilensis* **samples exposed to different treatments during the first stage of processing**

T1: dry control, T2: control in seawater without antioxidant, T3: exposed to AH- (10 mM) and T4: exposed to AH- (5 mM).

\* Significantly different from the ascorbate value at time 0 under the same culture conditions ( $P < 0.05$ ).

\*\*Significantly different from the ascorbate value at 6 and 24 h in samples without seawater exposure  $(P< 0,05)$ .

\*Significantly different from the  $A^{\bullet}/AH$  values at time 0 under the same culture conditions (P< 0,05).

\*Significantly different from  $\alpha$ -T values at time 0 under the same culture conditions (P< 0,05).

Figure 2. Characteristic spectrum of  $A^{\bullet}$  by EPR. (a) simulated spectrum using the following parameters:  $g = 2.00518$  and  $a_H = 1.8$  G, corresponding to  $A^{\bullet}$  (Jurkiewicz and Buettner, 1994). (b) Spectrum of the reaction medium (DMSO) in the absence of the mussel homogenate. (c) Spectrum of  $A^{\bullet}$  in the presence of the mussel homogenate.

In the second stage of processing, after 5 days of storage at  $-20^{\circ}$ C, the TBARS mussels content in presence or absence of ascorbic acid, showed no statistically significant differences (P> 0.05, Table 4). However, after 5 days of storage, the TBARS values obtained for all the treatments were significantly higher (100 times high) than those obtained in the first stage of processing (Table 3). The AH<sup>-</sup> content decreased significantly  $(46.7\%, P < 0.05)$ , in mussels coming from the different groups in relation to the initial content (Table 4). Only a significant decrease in ascorbate content was observed after 24h of exposure to ascorbic acid for T1 and T4. Both the A<sup>•</sup> content and the A<sup>•</sup>/AH<sup>-</sup> ratio (oxidative stress indices) increased significantly between T1 and T4. The  $\alpha$ -T content showed a significant decrease after 6h of treatment for T2 and T3 ( $P < 0.05$ , Table 4).

T1: dry control, T2: control in seawater without antioxidant, T3: exposed to AH- (10 mM) and T4: exposed to AH- (5 mM).

\* Significantly different from the ascorbate value at time 0 under the same culture conditions ( $P < 0.05$ ).

\*\*Significantly different from  $\alpha$ -T values in samples without seawater exposure during 6h (P< 0,05). nd: no determined.

### **DISCUSSION**

Molluscs removed from their natural marine habitat are under constant stress due to changes in the environment, such as temperature and anaerobiosis. Various methods and techniques are used to measure stress in live mussels (Khan et al., 2006). The mussel species that inhabits naturally the Beagle Channel is used in the mussel farming, being *Mitylus edulis chilensis* very abundant in the area (Calvoet al.,1998). This species has been previously characterized from physiological and biochemical analyses (Giarratano, 2010). The antioxidants concentrations values in mussels of T1 (controls at time 0) match those observed by Giarratano and Amin (2010); Duarte et al., (2011); Giarratanoet al., (2010), in mussels transplanted for ecotoxicology studies. The organisms that are in better physiological responses conditions will respond better to the stress generated by the activities of handling, processing and storage (Gonzalézet al., 2017).

The adverse effects on mollusks due to oxidative stress should be minimized to reach commercialization standards. Many studies have shown an increase in the mortality rate and loss of product quality due to damage to the internal tissues of mollusks (Harding et al., 2004). All fresh foods of marine origin (fish, mollusks) are susceptible to deterioration caused by both microbial activity and chemical reactions. Lipid damage occurs easily and limits the organoleptic properties during the storage of such products (Chaijan et al., 2006). This deterioration produces free fatty acids that under oxidation conditions produce low molecular weight compounds responsible for rancidity, loss of aroma and flavor. The mechanisms of lipid oxidation reactions can be characterized by three steps: initiation, propagation and termination reactions. This phenomenon can be modified by intrinsic and extrinsic factors, such as: fatty acid composition, concentration of pro-oxidants-antioxidants, metals, enzymes, pH, temperature, ionic strength and oxygen consumption. Lipid oxidation can be initiated and accelerated by several mechanisms, including ROS. The lipid oxidation products can interact with thiobarbituric acid and develop a pink colored compound (TBARS), establishing a method to measure lipid oxidation and is commonly used in mollusks to measure it´s quality (Jardine *e*t al., 2002, Khan et al., 2006). Several studies had shown that the values of TBARS increase during the cooking and storage of different products: turkey, chicken, mackerel, sardines, steaks, pork (Cuppett, 2001, Khan et al., 2006). According with these previous studies, our results showed a 36% increase in TBARS content during the first 24h of processing in T1 (control).

The balance between pro and endogenous antioxidants as well as exposure to different environmental variables, determine the susceptibility to oxidative damage in marine organisms (Gonzaléz *et* al., 2015). In this study we shift the balance (damage/protection) to antioxidants, through physical treatment with different concentrations of ascorbic acid. This technique has been used efficiently to control lipid oxidation during cold storage of fish for 6 months (Erickson 1997). In other studies, the opposite effect has been seen, which would indicate that many variables such as concentration, application technique, storage period, among others, play an important role in the efficiency of the use of ascorbic acid as an antioxidant in sea products. In our study, the ascorbic acid incorporated by *Mytilus edulis chilensis* showed an antioxidant activity to control lipid oxidation during the first stage of processing (24h exposure) between the T1 and those exposed to ascorbic acid (5 mM) (T3). However, the ascorbic acid is highly susceptible to oxidation at high pH levels (Jacobsen *et al*., 2001). This could explain partially the considerable decrease in antioxidant activity after 5 days of storage. On the other hand, this decrease in activity could eventually indicate a prooxidant action of ascorbic acid on the lipids of mussels during storage.

The  $A<sup>*</sup>$  content can be considered as a final product of radical transformations in biological systems of antioxidant defense and alsoused as an early and global indicator of oxidative stress. Some fundamental aspects that allow the use of A• as an index of oxidative stress, are the following: (a)  $A^*$  has a relatively low reduction potential that allows ascorbic acid to react as an antioxidant with virtually any radical that is generated in a biological system (Buettner and Jurkiewicz 1993); (b) A<sup>•</sup> is produced in very early stages of oxidative stress, while the concentration of ascorbic acid only decreases if regeneration is not enough.

Previous research has shown that when variables such as pH, concentration of catalytic metals and ascorbic acid levels are controlled, the use of A<sup>•</sup> is useful as an index of oxidative stress (Malanga et al., 2012). However, since the generation of  $A<sup>*</sup>$  depends on the oxidation of AH, and the reaction of AH<sup>-</sup> with free radicals, the use of the concentration of  $A^*$  by itself, as an index of oxidative stress, would not be adequate in systems where the content of ascorbic acid varies in relation to the oxidative condition. For this reason, it is more adequate to use the index A /AH- , as a possible tool to evaluate a situation of oxidative stress in different biological systems (Stegmann and Schuler, 1993; Kozak et al., 1997; Galleano et al., 2002; Gonzalez et al., 2008; Lattuca et al., 2009; Malanga et al., 2004; 2012;2016). In our study we determined only a non significant increase in mussels exposed to 6h in dry conditions (T1) in coincidence with an increased A● . These results could indicate the generation of a minor oxidative stress in the mussels extracted in Almanza, which are kept dry during their transfer to the Processing Plant located at 700 kilometers. However, this situation was not observed in those organisms that were kept in seawater or incubated with ascorbic acid during the same period.

A decrease in the α-T content was also observed coincident with that observed in other studies in fish and mussels (Brannan and Ericsson 1996; Tseng et al., 2005; Khan et al., 2006). In addition, such decrease was also observed in other non-enzymatic antioxidants, such as glutathione (data not shown) and could be related to the presence of free Fe or other metals that after a prolonged storage time, lead to cell death with changes in lipid oxidation. Previous work has shown that re-immersion for 12, 24 and 48h prior to the processing activities, reduces the stress response increasing the quality of the product and prolonging it´s commercial life (Harding et al., 2004). The data obtained in this work show that the maintenance in water for 24h is beneficial for the transfer of the mussels and that not only the use of the antioxidant aggregate would be beneficial in the prevention of the stress generated by the manipulation of the mussel *Mytilus edulis chilensis*.

The TBARS content in mussels during the second stage of processing, in the presence or absence of ascorbic acid, did not show significant differences ( $P > 0.05$ ). However, after 5 days of storage, the values observed for all treatments were significantly higher than those obtained in the first stage of processing, probably as a consequence of freezing. These results would indicate that the different forms of ascorbic acid could eventually have a pro-oxidant action on the lipids of mussels during storage. Similar results were observed by Khan et al., (2006) for *Mytilus edulis* in crops. On the other hand, the content of ascorbic acid in mussels decreased significantly after 24h of exposure to ascorbic acid in dry exposure (T1) and for the lowest concentration used (T4), probably due to consumption by organisms. Ascorbic acid can react with peroxyl radicals to give hydroperoxides and A<sup>•</sup>, which can be evaluated. This has been observed in *in vivo* and *in vitro* studies (Zhang and Omaye 2000). In the conditions of this work, it was observed that both the content of A● and the ratio A● /AH-increased significantly when the mussels were maintained in the absence of seawater or when were exposed to the ascorbic acids in both concentrations, indicating the generation of minor oxidative stress.

As was previously shown, there were a decrease in  $\alpha$ -T in mussels exposed to seawater without ascorbic aggregate and in those exposed to 10 mM of the antioxidant after 6h of treatment and 5 days of cold storage. For *in vitro* studies, Yamamoto (2007) observed that vitamin E is oxidized under prolonged storage conditions. These results allow us to ensure

that cold storage (-20 $^{\circ}$ C) for 5 days, regardless of the treatment, does not improve the quality of the product.

Overall, the results of this study, as well as previous data in other aquatic organisms (Perez 2009, Vicetti et al., 2005), have shown that not always the increase in the concentration of a single antioxidant is the best option for the improvement of the product quality. Currently, the combined use of antioxidants with a synergistic effect is recommended. On the other hand, these results are not enough to accept or reject this type of treatment and must be completed with other studies such as: the evaluation of oxidative damage to proteins; the evaluation of other enzymatic and non-enzymatic antioxidants, as well as the quantification and identification of lipids present in mussels at different seasonal moments.

# **A SEA OF PROBLEMS: IMPACTS OF PLASTIC POLLUTION ON OCEANS AND WILDLIFE**

Tuesday, October 29, 2019 U.S. House of Representatives Subcommittee on Water, Oceans, and Wildlife Committee on Natural Resources, Washington, DC

The Subcommittee met, pursuant to notice, at 2:27 p.m., in room 1324, Longworth House Office Building, Hon. Alan S. Lowenthal [Member of the Subcommittee] presiding.

Present: Representatives Lowenthal, Sablan, Van Drew, Case, Cox, Neguse, Cunningham; McClintock, Lamborn, and Graves.

Also present: Representative Haaland.

Dr. LOWENTHAL. The Subcommittee on Water, Oceans and Wildlife will come to order.

I may look like Congressman Huffman, but I am not. [Laughter.]

Dr. LOWENTHAL. I know it is a shock. I am Congressman Lowenthal. Congressman Huffman is back in Sonoma, dealing with the wildfires that are there, and never was able to get back here to Washington. We are all hoping that the fires subside, that many people are safe, and that Mr. Huffman returns soon.

With that, the Subcommittee on Water, Oceans, and Wildlife will come to order.

The Subcommittee is meeting today to hear testimony on "A Sea of Problems: the Impacts of Plastic Pollution on Oceans and Wildlife."

Under Committee Rule 4(f), any oral opening statements at hearings are limited to the Chairman, the Ranking Minority Member, the Vice Chair, and the Vice Ranking Member. This will allow us to hear from our witnesses sooner, and help Members keep to their schedules.

This is an edited, reformatted and augmented version of Oversight Hearing, before the Subcommittee on Water, Oceans, and Wildlife, of the Committee on Natural Resources, U.S. House of Representatives, One Hundred Sixteenth Congress, First Session, Serial No. 116–27, dated October 29, 2019.

Therefore, I ask unanimous consent that all other Members' opening statements be made part of the hearing record if they are submitted to the Subcommittee Clerk by 5 p.m. today, or the close of the hearing, whichever comes first.

Hearing no objections, so ordered.

# **STATEMENT OF THE HON. S. ALAN LOWENTHAL, REPRESENTATIVE IN CONGRESS FROM THE STATE OF CALIFORNIA**

Dr. LOWENTHAL. I am going to open up now, and I want to welcome all the witnesses. We are here today to discuss a pressing environmental issue, and that is plastic pollution.

Certainly, single-use plastics have made life easier, but these materials come at a much higher cost than many would like to admit. Plastics last for centuries in the natural environment, and are found nearly everywhere on our planet.

Last year, I witnessed the impact of plastic pollution on wildlife in Antarctica, one of the few places on earth that has been relatively untouched by human activity, but certainly not untouched by the scourge of plastics.

Personally, I have been involved in trying to tackle the growing plastic crisis for over 20 years, working with my constituent and friend, Captain Charles Moore, who created the scientific research organization Algalita, and who did some of the early research on the plastic garbage gyre.

There is an estimated 8 million metric tons of plastic that enter the oceans each year at a rate of about one garbage truck per minute, threatening biodiversity and accumulating in the seafood that we eat and in the water that we drink. Plastics have even been found in water samples right here in the Capitol Visitors Center.

Plastics are also making climate change worse. The global life cycle emissions from one year's plastic production throughout the United States are about the same as 462 coal-fired power plants per year, and that number is rising.

Plastic production is an environmental justice issue, also. Petrochemical factories and incineration facilities are often located in low-income communities, where local health impacts and air quality impacts are quite significant, but frequently are ignored.

Finally, in this Subcommittee, we need to look at solutions to deal with, for example, ghost fishing gear, fishing gear that has been lost at sea but continues to catch fish, marine mammals, turtles, birds, and corals.

It is clear that we need to reduce plastic pollution. Higher recycling commitments, and bans and taxes on single-use plastic items can be part of the solution, but we must expand our tools to address this growing environmental and public health problem.

In this Committee, we switched to reusable pitchers and glasses for water, rather than the disposable plastic water bottles we see so often around the Capitol. But not every switch is as easy, and not everyone has the option.

The financial burden of cleaning up pollution should not be solely on the taxpayers. It is imperative that the companies that manufacture and sell these products take ownership of their environmental impacts. Congress needs to step up, too.

It is for this reason that I have been working on comprehensive legislation with Senator Udall. Our legislation seeks to create a more circular approach by putting in place an extended producer responsibility program, implementing recycling content standards, as well as phasing out certain single-use-only items that have more sustainable alternatives.

I am excited to announce that we should have a discussion draft of this legislation quite soon, which we will disseminate publicly, and I encourage all of you to let me know your thoughts and comments after its release.

Some Federal agencies are also doing their part. NOAA's Marine Debris Program recently funded 14 new projects addressing aspects of this problem. However, the \$2.7 million provided to these projects doesn't even come close to addressing the scale of the ocean plastic problem.

The bottom line is this: We need to do more, we need to look at a broader range of solutions that are going to prevent wildlife from being strangled, and to keep microplastics from ending up on our plate.

With that, I look forward to hearing more from our witnesses about their ideas.

[The prepared statement of Dr. Lowenthal follows:]

# **PREPARED STATEMENT OF THE HON. ALAN S. LOWENTHAL, REPRESENTATIVE IN CONGRESS FROM THE STATE OF CALIFORNIA**

Today we're here to discuss a pressing environmental issue: plastic pollution.

Certainly, single-use plastics have made life easier. But these materials come at a much higher cost than many would like to admit. Plastics last for centuries in the natural environment and are found nearly everywhere on our planet. Last year I witnessed the impacts of plastic pollution on wildlife in Antarctica, one of the few places on earth that has been relatively untouched by human activity.

Personally, I have been involved in trying to tackle the growing plastic crisis for over 20 years, working with my constituent and friend, Captain Charles Moore, who created the scientific research organization Algalita and who did the early research on the pacific garbage gyre.

An estimated 8 million metric tons of plastic enter the oceans each year at a rate of about one garbage truck per minute, threatening biodiversity and accumulating in the seafood that we eat and in the water that we drink. Plastic has even been found in water samples from the Capitol Visitors Center!

Plastics are also making climate change worse. The global lifecycle emissions from one year's plastic production are about the same as 462 coal fired power plants per year – and that number is rising.

Plastic production is an environmental justice issue too. Petrochemical factories and incineration facilities are often located in low-income communities, where local health impacts and air quality impacts are significant but often ignored.

Finally, in this subcommittee, we need to look at solutions to deal with ghost fishing gear—fishing gear that's been lost at sea but continues to catch fish, marine mammals, turtles, birds, and corals.

It's clear that we need to reduce plastic pollution. Higher recycling commitments and bans and taxes on single-use plastic items can be part of the solution, but we must expand our tools to address this growing environmental and public health problem.

In this Committee we switched to reusable pitchers and glasses for water, rather than the disposable plastic water bottles we see so often around the Capitol. But not every switch is as easy, and not everyone has the option.

The financial burden of cleaning up pollution should not just be on the taxpayers. It's imperative that the companies that manufacture and sell these products take ownership of their environmental impacts.

Congress needs to step up, too. It is for this reason that I have been working on comprehensive legislation with Senator Udall. Our legislation seeks to create a more circular approach by putting in place an extended producer responsibility program, implementing recycling content standards, as well as phasing out certain single-use only items that have more sustainable alternatives available.

I am excited to announce that we should have a discussion draft of the legislation very soon, which we will disseminate publicly, and I encourage all of you to let me know your thoughts and comments after it is released.

Some federal agencies are also doing their part - NOAA's Marine Debris Program recently funded 14 new projects addressing aspects of this problem. However, the \$2.7 million provided to these projects doesn't even come close to addressing the scale of the ocean plastic problem.

The bottom line is this: we need to do more and we need to look at a broader range of solutions to prevent wildlife from being strangled and to keep microplastics from ending up on our plate.

With that, I look forward to hearing more from our witnesses about their ideas, and I will now invite the Ranking Member to share his remarks.

\* \* \*

Dr. LOWENTHAL. I will now invite the Ranking Member to share his remarks.

# **STATEMENT OF THE HON. TOM MCCLINTOCK, REPRESENTATIVE IN CONGRESS FROM THE STATE OF CALIFORNIA**

Mr. MCCLINTOCK. Thank you, Mr. Chairman. The Subcommittee meets today to hear testimony on plastics and their impact on our oceans.

From the tenor of the written testimony, it appears the Majority is blaming American consumers for the plastic waste that reaches our oceans, and is proposing to place restrictions on them that will dramatically reduce the convenience and higher quality of life that plastics have contributed to our modern society, while increasing costs dramatically.

Blaming America first seems to be a recurring theme, but the facts paint a very different picture. A 2017 study published in the *Environmental Science & Technology* magazine found that between 88–95 percent of all the plastic debris that enters our oceans comes from 10 rivers, none of which is anywhere close to the United States—8 of those rivers are in Asia, and 2 are in Africa.

According to a 2015 study, the top 20 marine plastic polluters produced as much as 10.76 million metric tons of waterborne plastic debris. The United States generated just 0.11 million

metric tons, barely 1 percent. Indeed, the entire United States contributed less waterborne plastic pollution than North Korea.

So, who does the Majority blame for this? American consumers. But, as Jeane Kirkpatrick once observed, they always blame America first.

According to the EPA, Americans have increased plastic recycling from 20,000 tons in 1980 to 3.1 million tons in 2015. That is a 155-fold increase. American consumers go to great lengths to responsibly dispose of plastic waste, and the numbers show that. American consumers are heroes, not villains, in this fight against plastic pollution of our oceans. We should be celebrating them, not punishing them.

Yet, that is just what draconian restrictions on plastic use would do, starting with the 1.7 million families who depend on plastics manufacturing to put food on the table, roofs over their heads, and taxes into our government coffers. The single largest state employing them remains my home state of California, where 80,000 Californians are directly employed in the plastics industry.

The misplaced object of the left's ire appears to be single-use plastic containers, the toothpaste tube, the shampoo bottle, the plastic bag. They criticize them as wasteful, since the plastic is used once and discarded, and yet takes between 50 and 1,000 years to decay. Well, if they are properly disposed of—and Americans do—I have to ask, what exactly is that problem?

The most common single-use packaging of the ancient world, once we had progressed from animal skins and gourds, was the amphora, usually a ceramic. A massive hill called Mount Testaccio in Rome is composed of discarded amphora, which have not degraded in nearly 2,000 years. Yet, the world is not worse for it, and the Romans were infinitely better off for it. Which begs the question: If we are going to ban single-use plastic containers, exactly what will replace them?

How about your toothpaste? Before plastics, toothpaste came in collapsible metal tubes. Do the opponents of plastics find this a more environmentally-friendly container? The toothpaste tube was invented to protect consumers from the unhygienic practice of getting toothpaste in glass jars and dipping your toothbrush into them. Shall we return to glass jars? Before that, toothpaste came in powdered form in cardboard boxes and wax paper, which required mixing a batch every time you wanted to brush your teeth.

Plastics have largely replaced aluminum as the best container to protect food against food spoilage. Before aluminum, it was tin. It takes 4 pounds of bauxite, usually by strip mining, and 71⁄2 kilowatts of electricity to make 1 pound of aluminum. Do the plastic critics really think an environmentally-friendly alternative is to return to the era of metal containers?

Before metal containers, glass was commonly used. Glass takes roughly 1 million years to decompose, 1,000 times longer than the longest estimate for plastic decomposition. I suppose we could go back to cardboard and paper, but I remember the campaign a decade ago to ban paper bags as wasteful and environmentally offensive, so we dutifully replaced them with plastic bags, which have now attracted the ire of the environmental left.

Single-use plastics, properly disposed of, mean greater convenience and lower prices for American consumers, and a much smaller environmental footprint than all of the different packaging materials that they have replaced.

So, I am very interested in hearing today why Americans, who have an exemplary record of responsible plastic disposal and recycling, are to blame for the excesses of other people in

other countries, and why those same Americans should now be punished with higher prices, less convenience, and a lower standard of living.

And, finally, I would like to know what are the plastics critics proposing as an alternative to plastic containers that they haven't already rejected over the years.

I yield back.

[The prepared statement of Mr. McClintock follows:]

# **PREPARED STATEMENT OF THE HON. TOM MCCLINTOCK, RANKING MEMBER, SUBCOMMITTEE ON WATER, OCEANS, AND WILDLIFE**

The sub-committee meets today to hear testimony on plastics and their impact on our oceans. From the tenor of the written testimony, it appears that the majority is blaming American consumers for the plastic waste that reaches our oceans and is proposing to place restrictions on them that will dramatically reduce the convenience and higher quality of life that plastics have contributed to our modern society.

Blaming America first seems to be a recurring theme, but the facts paint a very different picture. A 2017 study published in the Environmental Science and Technology Magazine found that between 88-95 percent of all the plastic debris that enters our oceans comes from ten rivers – none of which is anywhere close to the United States: eight of those rivers are in Asia and the other two are in Africa.

According to a [2015 study,](https://www.earthday.org/2018/04/06/top-20-countries-ranked-by-mass-of-mismanaged-plastic-waste/) the top 20 marine plastic polluters produced as much as 10.76 million metric tons of waterborne plastic debris. The United States generated just 0.11 million metric tons – or barely one percent. Indeed, the entire United States contributed less waterborne plastic pollution than North Korea.

Who does the majority blame for this? American consumers. But as Jeanne Kirkpatrick once observed, they always blame America first.

According to [the EPA,](https://www.earthday.org/2018/04/06/top-20-countries-ranked-by-mass-of-mismanaged-plastic-waste/) Americans have increased plastic recycling from 20,000 tons in 1980 to 3.1 million tons in 2015. American consumers go to great lengths to responsibly dispose of plastic waste – and the numbers show that.

American consumers are heroes – not villains – in the fight against plastics pollution of our oceans. We should be celebrating them and not punishing them!

Yet that is just what Draconian restrictions on plastic use would do, starting with the [1.7](https://www.plasticsindustry.org/sites/default/files/SizeImpact2019_Summary_Final.pdf)  [million families w](https://www.plasticsindustry.org/sites/default/files/SizeImpact2019_Summary_Final.pdf)ho depend on plastics manufacturing to put food on the table, roofs over their heads and taxes into our coffers. The single largest state employing them remains my home state of [California,](https://www.plasticsindustry.org/factsheet/california) where 80,000 Californians are directly employed in the plastics industry.

The misplaced object of the left's ire appears to be single-use plastic containers: the toothpaste tube, the shampoo bottle, the plastic bag. They criticize them as wasteful, since the plastic is used once and discarded and yet take between 50 and 1,000 years to decay.

If they are properly disposed of – and Americans do that better than just about any other people on this planet – I have to ask, what exactly is the problem? The most common singleuse packaging of the ancient world – once we had progressed from animal skins and gourds – was the amphora, usually a ceramic. A massive hill called [Mt. Testaccio i](https://www.atlasobscura.com/places/monte-testaccio)n Rome is

composed of discarded amphorae, which have not degraded in nearly 2,000 years. Yet the world isn't the worse for it – and the Romans were infinitely better off for it.

Which begs the question, if we are going to ban single use plastic containers, exactly what will replace them? How about your toothpaste? Before plastics, toothpaste came in collapsible metal tubes. Do the opponents of plastics find this a more environmentally friendly container? The toothpaste tube was invented to protect consumers from the unhygienic practice of getting toothpaste in glass jars and dipping your toothbrush into them. Shall we return to glass jars? Before that, toothpaste came in powder form in cardboard boxes and wax paper, which required mixing a batch every time you brushed your teeth.

Plastics have largely replaced aluminum as the best container to protect against food spoilage. Before aluminum, it was tin. It takes [four pounds of](http://www.madehow.com/Volume-5/Aluminum.html) [bauxite u](http://www.madehow.com/Volume-5/Aluminum.html)sually by strip mining and 7 kilowatts of electricity to make one pound of aluminum. Do the plastic critics really think an environmentally friendly alternative is to return to the era of metal containers? Before metal containers, glass was commonly used. Glass takes roughly one million years to decompose – one thousand times longer than the longest estimate for plastic decomposition. I suppose we could go back to cardboard and paper, but I remember the campaign a decade ago to ban paper bags as wasteful and environmentally offensive. So we dutifully replaced them with plastic bags, which have now attracted the ire of the environmental left.

Single use plastics – properly disposed of – mean greater convenience and lower prices for American consumers, and a much smaller environmental footprint than all the different packaging materials that they replaced.

So I'm very interested in hearing why Americans – with an exemplary record of responsible plastic disposal and recycling – are to blame for the excesses of other people in other countries; and why those same Americans should now be punished with higher prices, less convenience and a lower standard of living. And finally, I would like to know what the plastics critics are proposing as an alternative to plastic containers, that they haven't already rejected over the years.

\* \* \*

Dr. LOWENTHAL. I am going to ask unanimous consent that the gentleperson from New Mexico, Representative Haaland, be allowed to sit on the dais and participate in today's proceedings.

Without objection, that is ordered.

Now I am going to introduce our witnesses.

Our first witness is Mr. Ted Danson. You may know him better as Michael on "The Good Place," or Sam on "Cheers." But Mr. Danson is also the Vice Chair of the Board of Directors at Oceana, where he has been closely involved since its inception.

Our next witness will be Mr. Juan Parras, who is the Founder and Executive Director at the Texas Environmental Justice Advocacy Service, or TEJAS.

Following him we will hear from Dr. Jenna Jambeck, Professor of Environmental Engineering at the University of Georgia, and the lead author of a groundbreaking study on plastic.

And, finally, our last witness will be Tony Radoszewski, who is the President and CEO of the Plastics Industry Association.

Let me remind all the witnesses that, under our Committee Rules, they must limit their oral statements to 5 minutes, but that their entire statement will appear in the hearing record.

When you begin, the lights on the witness table will turn green. After 4 minutes, the yellow light will come on. Your time will have expired when the red light comes on, and I will ask you to please complete your statement.

I will also allow the entire panel to testify before questioning witnesses.

The Chair now recognizes Mr. Danson to testify.

Welcome to our Committee.

### **STATEMENT OF TED DANSON, ACTOR, ADVOCATE, AND BOARD MEMBER, OCEANA, LOS ANGELES, CALIFORNIA**

Mr. DANSON. I would like to thank the Chair and Ranking Member, and members of the Committee for the opportunity to testify on plastic pollution.

I am the Vice Chair of Oceana's Board of Directors. Oceana is the largest international advocacy organization dedicated solely to ocean conservation. I have been working on ocean issues for more than 30 years. In the late 1980s, I co-founded the American Oceans Campaign, which then joined with Oceana in 2002. I am here to testify today about the growing problem of plastic pollution that is threatening our oceans.

Almost from the moment we wake up, to the time we go to bed, we are faced with throwaway plastic. We face it when we brush our teeth with a toothbrush made of plastic, and squeeze toothpaste out of a plastic tube, and when we wash our hair with shampoo and conditioner from plastic bottles. The rest of our daily routines might include one or several coffees in cups with plastic lids, lunch in plastic take-out containers with plastic utensils, and grocery shopping, where single-use plastic is unavoidable. There isn't a place on earth untouched by the pollution from all this plastic.

The list of marine animals affected by plastic pollution grows. Plastic has been consumed by an estimated 90 percent of seabird species, and eaten by every species of sea turtle. Even our corals are threatened.

In addition to polluting the marine environment, plastic poses a risk to human health. We are now seeing plastic in our water, our food, soil, air, and bodies. Plastic particles have been found in everything from honey and beer to salt and tea.

Plastic is also affecting our climate. If plastic was a country, it would be the planet's fifth largest emitter of greenhouse gases. With plastic production rates anticipated to increase, so will plastic's effects on the climate and oceans.

The most important thing to remember about plastic is that it lasts for centuries. This is what makes single-use plastics so profoundly flawed. They are created from a material made to last forever, but are designed to be used once and thrown away.

Simply improving recycling rates will not solve the plastic crisis. Of all the plastic waste ever generated, only 9 percent has been recycled. That means the vast majority was sent to a landfill, incinerated, or ended up polluting our natural environment, including our oceans. Recycling is like trying to mop up water from an overflowing bathtub, while the faucet is still running. We need to turn off the faucet and reduce the production of plastic.

Companies need to significantly reduce the amount of single-use plastic they are putting onto the market, and offer consumers plastic-free choices for their products. Unfortunately, companies aren't doing enough, and that is why we need your help.

Policies governing the production and use of single-use plastic are effective, and these policies are becoming more common around the world and across this country. The European Union, Peru, Chile, and Canada have all announced or are implementing policies to reduce plastic pollution. U.S. cities, counties, and states have taken the initiative, passing policies to reduce single-use plastics. But ultimately, comprehensive U.S. Federal action is needed.

This Committee should use its authority to tackle the problem. I applaud you for stopping the use of plastic water bottles in Committee hearings.

The National Park Service had a policy to encourage national parks to stop selling water in plastic bottles. Unfortunately, the policy has been reversed. The Committee should make our national parks, wildlife refuges, marine sanctuaries, and other Federal lands and waters into single-use plastic-free zones.

I urge Congress to pass Federal legislation that stops plastic pollution at the source, that significantly reduces the production of this everlasting pollutant, that holds corporations responsible for this global crisis, and enables states and cities to continue to lead the way on solutions.

Don't fall for the false promise of recycling. And please don't stoop to incineration. We must stop the runaway increase in plastic production and reduce the amount of plastic that companies are making and foisting on us, because it will last for centuries. We have no more time to waste. Thank you.

[The prepared statement of Mr. Danson follows:]

# **PREPARED STATEMENT OF TED DANSON, VICE CHAIR, OCEANA BOARD OF DIRECTORS, LOS ANGELES, CALIFORNIA**

Good afternoon. Thank you, Chairman Huffman, Ranking Member McClintock and members of the committee, for the opportunity to testify today on plastic pollution's effects on our oceans. My name is Ted Danson, and I am the vice chair of Oceana's board of directors. Oceana is the largest international advocacy organization dedicated solely to ocean conservation. We work in North, South and Central America, Asia and Europe to advocate for science-based policies that will restore the ocean's abundance and biodiversity.

I've been working on ocean issues for more than 30 years. My interest in the oceans started when one day, I decided to take my daughters — who were 4 and 8 years old at the time — to go swimming at the beach in Southern California. We were ready to go and running toward the water, but were stopped by a sign that said, "no swimming, ocean polluted."

My girls couldn't believe it, and neither could I. The ocean was closed. They asked me, "Why, why can't we go swimming — in this beautiful ocean?" So, in the late 1980s, I cofounded the American Oceans Campaign to clean up beaches and the ocean. And for 15 years, we worked to protect the oceans from oil drilling and other threats.

To expand the capacity of the American Oceans Campaign, we decided to join with Oceana in 2002. Oceana has protected more than 4.5 million square miles of ocean and won

over 200 victories to stop overfishing, habitat destruction, pollution and the killing of threatened species. I am here today to testify about the growing problem of plastic pollution that is threatening our oceans.

Almost from the moment we wake up to the time we go to bed, we are faced with throwaway plastic. We face it when we brush our teeth with a toothbrush made of plastic and squeeze toothpaste out of a plastic tube, and when we wash our hair with shampoo and conditioner from plastic bottles. The rest of our daily routines might include one or several coffees in cups with plastic lids, lunch in plastic takeout containers with plastic utensils, and grocery shopping, where single-use plastic is unavoidable.

If you tried to avoid the plastic typically encounter in a day, you'd hit countless obstacles. There was an article in *The New York Times* earlier this year about people who managed to maintain generally plastic-free lifestyles — their days involved using homemade shampoo, toothpaste and more. This effort is extraordinarily admirable, but not many could manage it.<sup>1</sup> Millions of consumers should not have to restructure their daily routines to avoid plastic when the country's leading producers of food, personal care products and other everyday staples could start using sustainable alternatives to single-use plastic, stopping the problem at the source.

Plastic hasn't been around for as long as you might imagine, considering the level of plastic pollution we're seeing in the environment. It wasn't being used for consumer goods like beverage bottles until the 1940s. By the 1950s, we had entered the era of "throwaway living" — meaning our current culture of relying on single-use, disposable materials to make our lives more efficient and convenient. Plastic was convenient for producers too — it was a cheap, durable and lightweight material. This trend's environmental impact was evident within just a few years. Disposable items were suddenly cluttering roadsides around the country.

Fast forward to today, and we're seeing plastic floating on the surface of the sea, washing up on the world's most remote coastlines, melting out of Arctic sea ice and sitting at the deepest point of the ocean floor. <sup>2</sup> There isn't a place on earth untouched by plastic pollution. In fact, it's now cemented in our fossil record. For the first time, researchers have documented plastic building up exponentially in the sediments off the coast of Santa Barbara, California, that precisely mirrors the massive expansion in global plastic production from 1945 to the present decade.<sup>3</sup>

We are leaving behind a permanent legacy of plastic pollution for future generations.

The list of marine animals affected by plastic pollution is continually growing. Plastic has been consumed by an estimated 90% of seabird species and eaten by every species of sea turtle.<sup>4</sup> Some organisms, such as corals, appear even more attracted to plastic than food.<sup>5</sup>

What's worse, studies have shown when corals come into direct contact with plastic debris, their likelihood of disease increases from 4% to a staggering 89%.<sup>6</sup> At least 17% of the species observed to be affected by marine debris are listed as threatened or near threatened with extinction by the International Union for the Conservation of Nature, indicating that marine plastic debris may be contributing to the possibility of these species' extinction.<sup>7</sup>

One study estimated that up to 51 trillion microplastic particles were present in the ocean in 2014. This number is only expected to increase as plastic continues to pour into our oceans and breaks up into smaller pieces.<sup>8</sup>

In addition to polluting the marine environment, plastic poses a risk to human health. We're now seeing plastic in our water, our food, our soil, our air and our bodies.<sup>9</sup> Plastic particles have been found in everything from our water and beer to honey, salt and tea.<sup>10</sup> The particles also make their way into the seafood we eat.<sup>11</sup> Scientists are still studying the potential impacts the plastic particles themselves are having on our health.

Plastic is also affecting our climate. If plastic was a country, it would be the planet's fifth-largest emitter of greenhouse gases.<sup>12</sup> Studies have shown that plastic contributes to climate change by using fossil fuels and emitting greenhouse gases throughout its life cycle, from production and transportation to waste management. Plastic at the ocean's surface and on land continually releases methane and other greenhouse gases throughout its existence, and these emissions increase as plastic breaks apart in sunlight.<sup>13</sup> With plastic production rates anticipated to increase, so will plastic's effects on our climate.

<sup>&</sup>lt;sup>13</sup> -- (2019) Plastic and Climate: The Hidden Costs of a Plastic Planet. Center for International Environmental Law.

Perhaps the single most important thing to remember about plastic is that it lasts for centuries.<sup>14</sup> Most of the plastic you've used in your lifetime still exists on the planet in some form or another. This is what makes single-use plastics so profoundly flawed. Single-use plastics are created from a material made to last forever, but are designed to be used once and thrown away. Sometimes single-use plastics are only used for a few moments before polluting the earth for years to come.

Half of all the plastic ever made in our planet's history was produced in the past 15 years.<sup>15</sup> Plastic production is expected to quadruple between 2014 and 2050, rising 40% in just the next decade.<sup>16</sup> Waste-management options don't have a chance at keeping up. Take recycling, for instance. Now that companies are seeing their names on the bottles floating in the ocean and polluting our beaches, plastic producers frequently tout their commitments to improving recycling rates and their investments in waste-management systems. They proclaim recycling as the panacea to our plastic problem.

But of all the plastic waste ever generated as of 2015, only 9% has been recycled. That means the vast majority, 91%, either was sent to a landfill, was incinerated or ended up polluting our natural environment — including our oceans. <sup>17</sup> Simply improving recycling rates will not solve this crisis.

In fact, not everything that goes into the recycling bin actually gets recycled. Some is disposed of in landfills or lost in the recycling process. Some is turned into lower-value products, known as "downcycling." And some is exported to developing nations with less robust waste management systems. This means the plastic we thought was being recycled often ends up in a landfill or in the ocean on the other side of the globe.<sup>18</sup> The United States is no exception. In 2015, plastic recycling rates in the U.S. were only 9%.<sup>19</sup> The U.S. and other developed countries have been adding to the problem by shipping some of our plastic waste to countries in Asia because it's cheaper than dealing with it at home.<sup>20</sup>

The truth is, recycling can't solve the ever-growing plastic crisis. Recycling is like trying to mop up water from an overflowing bathtub while the faucet is still running. We need to turn off the faucet and reduce the production of single-use plastic. Companies that have created this problem need to change the way they do business. They must do more than recycle. We need them to significantly reduce the amount of single-use plastic they are putting onto the market and offer consumers plastic-free choices for their products.

Unfortunately, those companies aren't doing enough, and that's why we need your help. It's up to our national, state and local governments to require companies to reduce single-use plastic. Policies governing the production and use of single-use plastic are the most effective way to stem the flow of it into our oceans, and these policies are becoming more common around the world. $21$ 

The European Union, Peru, Chile and Canada have all announced or are implementing policies to reduce plastic pollution. The United States should create a national policy that comprehensively addresses the plastics crisis threatening our future. U.S. cities, towns, counties and states have recognized the urgency of the issue and taken the initiative on their own, passing policies to reduce single-use plastics. Effective policies include bans, taxes, deposit return systems and extended producer responsibility.

Here are a few examples:

In 2018, the European Union announced a phaseout of single-use plastics by 2021. The Single-Use Plastics Directive bans single-use plastic products, including plates, cutlery, polystyrene food and beverage containers, and other items that are estimated to represent 85% of single-use plastic found on beaches in the EU.<sup>22</sup>

Earlier this year, Santa Monica, California prohibited food and beverage sellers from offering disposable food ware, including plates, cups, bowls, trays and utensils, made predominantly with plastic. The city has already banned expanded polystyrene products.<sup>23</sup>

In 2019, Vermont passed a law that includes a ban on single-use plastic bags, a ban on expanded polystyrene food service products, a minimum 10-cent tax on recyclable paper bags, a ban on single-use plastic stirrers, and a policy making straws available by request-only in food service establishments.<sup>24</sup>

On the federal level, this committee should use its authority to tackle the plastic pollution problem. I applaud you for stopping the use of plastic water bottles in committee hearings and votes, the rest of Congress should take this same step. There's no need to wait. In 2011, the National Park Service implemented a policy to encourage national parks to stop selling water in plastic bottles.

Unfortunately, the policy has been reversed. The committee should make our national parks, national wildlife refuges, marine sanctuaries and other federal lands and waters into single-use plastic free zones, stopping the sale of single-use plastics including plastic beverage bottles throughout the Department of Interior system.

Local and state policies move us in the right direction, and ultimately comprehensive U.S. federal action is needed — and soon. I urge you, our policy-makers tasked with protecting our country's natural resources, to pass federal legislation that stops plastic pollution at the source, significantly reduces the production of this everlasting pollutant, holds corporations responsible for this global crisis and enables states and cities to continue to lead the way on solutions. Don't fall for the false promise of recycling and don't stoop to incineration. We must stop the runaway increase in plastic production and reduce the amount

# **QUESTIONS SUBMITTED FOR THE RECORD BY REP. VELÁZQUEZ TO TED DANSON**

Question from Rep. Nydia M. Velázquez:

*In my district, the Brooklyn Bridge Park Conservancy reported that over 75% of the waste discovered in their cleanup project was single-use plastics — particularly straws and plastic bottles. As you mentioned in your testimony, recycling alone will not address the worsening plastic crisis. We need timely action from both consumers and producers. Throughout your time working on this front, what corporations or industries have been the most unresponsive to advocates' request to start using sustainable alternatives to single-use plastic?*

Answer: Solving the plastic pollution crisis will require efforts from all companies and industries producing unnecessary single-use plastic, but some industries have played a larger role in the problem than others. The 2018 International Coastal Cleanup found that the most commonly collected plastic items included plastic grocery bags, plastic straws, plastic stirrers, plastic lids, plastic takeout containers, foam takeout containers, plastic beverage bottles and plastic bottle caps. Plastic bottles were among the top three most common plastic items found in Break Free from Plastic's global cleanup this past September.

The responsibility for curbing the amount of plastic beverage bottles and plastic bottle caps ending up in our waterways should fall on the companies producing these products, but unfortunately, we're not seeing significant progress. If you go to your average supermarket or lunch counter wanting a beverage or a salad, you'll often find your only choices have a plastic package. Four decades of the industry knowing about the plastic pollution problem hasn't changed that. Beverage companies continue to tout their recycling commitments as a solution to the problem rather than switching to more sustainable packaging. Some of these companies even make vague promises to reduce their use of virgin plastic that lack quantifiable goals, making it impossible for us to hold them accountable.

Similarly, it is no surprise that plastic bags, straws, stirrers, lids and takeout containers are ending up in our oceans when they're so readily available at retailers and restaurants. These are single-use items that these companies could choose to avoid, but we haven't seen enough take the initiative to stop using these items or swap them out for less harmful alternatives. Policies like plastic bag, straw and polystyrene bans that have passed in cities, counties and states around the country are effective in driving widespread change around these items.

Companies have the power to greatly reduce the amount of plastic flowing into our oceans by quitting their reliance on plastic packaging and giving consumers plastic-free choices. We need to demand that change now and implement policies that support it.

\* \* \*

Dr. LOWENTHAL. Thank you, Mr. Danson.

The Chair now recognizes Mr. Parras to testify for 5 minutes. Welcome to the Committee.

# **STATEMENT OF JUAN PARRAS, FOUNDER, EXECUTIVE DIRECTOR, TEXAS ENVIRONMENTAL JUSTICE ADVOCACY SERVICES (TEJAS), HOUSTON, TEXAS**

Mr. PARRAS. I, too, thank you, Chairman Lowenthal and Ranking Member McClintock. I am Juan Parras with Texas Environmental Justice Advocacy Services (TEJAS). TEJAS has been working on environmental justice issues along the Houston Ship Channel for over 16 years. We work at the intersection of human rights and social justice issues.

We call Houston home and share that home with the largest petrochemical complex in the Nation, the second-largest in the world. It is also the largest city with no zoning, meaning that refineries and petrochemical plants, storage tanks, and other industries and infrastructures can be built on the fence line of communities bordering them.

Ninety-nine percent of plastic is derived from fossil fuels. Of those plastics produced, they are derived from either fracked gas or oil. The explosion of natural gas products has led to an ever increasing demand for natural gas liquid, rich in the chemicals that serve as the building block of plastic production.

Naphtha is a product of oil refining. It is another key element of plastic production. Only five companies account for over half of global naphtha sales: British BP, Chevron, ExxonMobil, Shell, and China National Petroleum Corporation. Four of the five have refining capacities along our coast within an hour of our front-door communities.

We are already exposed to a dangerous mix of toxic pollutants, both authorized and unauthorized, released by many different industrial sources located along the Houston Ship Channel. Over the last several years, that petrochemical complex has been expanding. Post-Hurricane Harvey, we began tracking the emissions and realized that the expansions seen in our communities were related to a rapidly, ever-growing market in plastic. Ethane crackers, terminals, and logistics plants all centered around one thing, the production of plastics.

We understood that these expansions were focused on ethylene crackers and LNG facilities. However, we now understand the major economic pivot oil and gas is undergoing, shifting from traditional production into new forms of petroleum utilization.

However, as they expanded, so too did the instability of these petrochemical plants, and we have seen an increase of chemical disasters in the Houston Ship Channel. In the most recent fire, 37 people were injured, some with first-degree burns. Workers were initially evacuated, but later required to re-enter the plant as the fire was still burning.

To compound the problems, the Commission's Baytown air quality monitors had malfunctioned during the event, and thus deprived community members of invaluable air quality data to protect their health.

While those fires blazed, community members were wholly unaware of the fire or proper shelter-in-place. ExxonMobil has a 10-year investment of \$20 billion in their expansion projects for the Gulf of Texas.

Recent disasters: the ExxonMobil fire on March 16, 2019; the ITC Fire on March 17, 2019, where over 8 cities were held hostage under a chemical plume 47 miles long and 17 miles wide; the ExxonMobil Olefins fire on July 31, 2019, where 37 workers were injured; and on September 20, 2019, where nine chemical barges collided after Tropical Storm Imelda damaged evacuation routes.

A recent report for the Center for International Environmental Law found that if trends in the oil consumption continue as expected, the consumption of oil by the entire plastic sector will account for 20 percent of the total consumption by 2050. A recent study uncovered twothirds of the 90 plastic-related facilities in the Houston region violated air pollution control laws over the last 5 years, and were subject to environmental enforcements. But many more exceeded their permits and were not penalized.

State records show these compounding emissions result in cumulative impacts on neighboring communities, including an increased risk for developing cancer and other health conditions. Plastic poses a distinct risk to public health, from wellhead to waste. From our dinner table to the depths of our oceans, every part of the chain that creates plastic harms us.

Plastic is being produced near vulnerable communities, predominantly people of color, poor people, indigenous, and immigrant people who have to pay the price in shortening the life span of our children and elderlies.

And I see that I am out of time, but I will submit the entire document. Thank you.

[The prepared statement of Mr. Parras follows:]

# **PREPARED STATEMENT OF JUAN PARRAS, EXECUTIVE DIRECTOR, TEXAS ENVIRONMENTAL JUSTICE ADVOCACY SERVICES (T.E.J.A.S.)**

T.E.J.A.S has been working on environmental justice issues along the Houston Ship Channel for over 16 years, we work at the intersection of human rights and social justice issues. We call Houston home and share that home with the largest petrochemical complex in the nation, second-largest in the world. It is also the largest city with no zoning. This means you can put parks, homes, and preschools next petrochemical facilities, refineries, storage tanks and other industry infrastructure, in fact you can find living examples in our community of Manchester and throughout the Gulf Coast. 99% of plastic is derived from fossil fuels. Of those plastics produced they will derive from either fracked gas or oil. The explosion of natural gas production has led to ever increasing demand for natural gas liquid, rich in the chemicals that serve as the building blocks of plastic production. Naphtha, a product of oil refining is another key of production. Only five companies account for over half of global naphtha sales: BP, Chevron, ExxonMobil, Shell and China National Petroleum Corporation. Four of five have refining capacity along our coast within an hour of our front door.<sup>25</sup>

We are already exposed to a dangerous mix of toxic pollutants, both authorized and unauthorized, released by many different industrial sources located along the Houston Ship Channel. Over the last several years that petrochemical complex has been expanding. Post hurricane Harvey we began tracking emissions and came to understand that the expansions hitting our communities were related to a rapidly, and ever-growing, market in plastic. Ethane crackers, terminals, and logistics plants all centered around one thing: the production of plastic. We understood that these expansions focused on ethylene crackers and LNG but now we began to understand the major economic pivot oil and gas is undergoing, shifting from traditional production into new forms of petroleum utilization. However, as they grew, so too did the instability of these petrochemical plants and with it has come an increase in chemical disasters.

In the most recent fire, 37 people were injured, some with first-degree burns. Workers were initially evacuated but later required to reenter the plant as the fire was still burning. To compound the problem, the Commission's Baytown air quality monitors malfunctioned during the event and thus deprived community members of invaluable air quality data to protect their health. While those fires blazed community members were wholly unaware of the fire or proper shelter-in-place procedures. ExxonMobil has a 10 year investment of \$20 billion in their Grow the Gulf Project.

Recently Disasters:

 $\overline{a}$ 

- ExxonMobil Fire March 16, 2019.
- The ITC fire, March 17, 2019 over 8 cities held hostage under a chemical plume 47 miles long 17 miles wide.<sup>26</sup>
- ExxonMobil Olefins Fire, July 31, 2019, 37 workers were injured.<sup>27</sup>
- September 20, 2019, 9 chemical barges collide after Tropical Storm Imelda damaging evacuation routes.<sup>28</sup>

In a recent report the Center for International Environmental Law found that, "If trends in oil consumption continue as expected, the consumption of oil by the entire plastics sector will account for 20% of the total consumption by 2050."

A recent study by uncovered "two-thirds of the 90 plastics-related facilities in the Houston region violated air pollution control laws over the last five years and were subject to enforcement actions. But many more exceeded their permits and were not penalized, state

<sup>25</sup> Center for International Environmental Law, *Fueling Plastics: Fossils, Plastic & Petrochemical Feedstocks*  (September, 2019), available electronically https://www.ciel.org/wp-content/uploads/2017/09/Fueling-Plastics-Fossils-Plastics-Petrochemical-Feedstocks.pdf.

<sup>&</sup>lt;sup>26</sup> https://www.click2houston.com/news/how-it-happened-a-timeline-of-the-deer-park-chemical-fire.

<sup>27</sup> https://www.houstonchronicle.com/news/houston-texas/houston/article/ExxonMobil-s-Baytown-fire-the-latest-ina-14270558.php#photo-18007536.

<sup>28</sup> https://www.khou.com/article/traffic/i-10-east-freeway-shut-down-after-barges-break-loose-hit-bridge/285 d522e91e-1a54-4b2d-9269- fe44d75f6c81.

records show."<sup>29</sup> These compounding emissions result in cumulative impacts for neighboring communities, including an increased risk for developing cancer and other health conditions.

The production of plastic releases toxics like 1,3, butadiene, benzene, ethane, styrene, toluene. In the short term they look like: headaches, fatigue, weakness, memory loss, nausea, nose bleeds, unconsciousness. In the long term: asthma, anemia, central nervous system damage, childhood leukemia and other cancers, kidney and liver damage, sterility, and even death.<sup>30</sup> The effect is even more severe on children, seniors and the already sick.

Plastic poses a distinct risk to public health from wellhead to waste. From our dinner table to the depths of our oceans. Every part of the chain that creates plastic harms us. Plastic had to be produced near vulnerable communities that used fossil fuel that were extracted next to PEOPLE. BLACK, BROWN, POOR, INDIGENOUS, IMMIGRANT and so many others had to pay the price in shortening the lives of our children's health. The devastating extraction of from our land that shakes our earth. The production of plastic treats us as disposable, as a byproduct that can be ignored. OUR LIVES CANNOT AND WILL NOT BE SACRFICED FOR CONVIENCE.

The American Chemistry Council predicts industry will invest in \$204 billion by 2030 on 334 new and expanded facilities in the US alone.<sup>31</sup>

We know our community is not alone in this struggle. The Gulf Coast is known for housing some of the most sophisticated refining capacity in the world. This should not come at the detriment of use at the fenceline.

For us on the fenceline, this is not an exercise in paper pushing or number crunching: not addressing this issue with the necessary enforcement disproportionately harms people of color. There is no amount of money that can make up health impacts from additional emissions and also fugitive emissions associated with additional units or points of emission.

It is vital that community voices be heard at the decision-making table, these are the daily decisions that can drastically alter the outcomes for generations to come. Legislation and policies that safeguard our already overburdened is necessary for our survival. You don't have to lose a child, mother or friend to understand our fight for life.

Juan Parras, Executive Director Texas Environmental Justice Advocacy Services.

# **QUESTIONS SUBMITTED FOR THE RECORD TO MR. JUAN PARRAS**

Mr. Parras did not submit responses to the Committee by the appropriate deadline for inclusion in the printed record.

#### **Question Submitted by Rep. Lowenthal**

*Question 1. Mr. Parras, the environmental justice component and how frontline communities are affected by the health impacts of plastic refining and production facilities are too often overlooked. Can you please describe for the Committee the relationship between the plastic life cycle and environmental justice?*

*1a. The industry is looking to increase production over the next decade, if the projections for increasing plastic production come true, what will the impacts of new facilities be on communities of color and other overburdened communities?*

*1b. How can Congress better support EJ communities in their fight against the plastic industry?*

*1c. Given the relationship between greenhouse gas emissions and plastic production, how much of an impact would phasing out single-use plastics have on curbing greenhouse gas emissions?*

#### **Question Submitted by Rep. Velázquez**

*Question 1. Can you describe the relationship between the plastic life cycle and environmental justice? What institutional systems are in place that have allowed these impacts to occur?*

#### **Question Submitted by Rep. Cox**

*Question 1. Mr. Parras, while the research is still out on microplastics' human health impacts, it sounds like the communities that TEJAS works with have some experience with that question. Recently, I introduced a bill to help prevent asthma in rural communities. Is asthma a potential concern with plastic production and incineration?*

\* \* \*

Dr. LOWENTHAL. Thank you, Mr. Parras.

The Chair now recognizes Dr. Jambeck to testify for 5 minutes. Welcome to the Committee, Dr. Jambeck.

# **STATEMENT OF DR. JENNA JAMBECK, PROFESSOR OF ENVIRONMENTAL ENGINEERING, UNIVERSITY OF GEORGIA, ATHENS, GEORGIA**

Dr. JAMBECK. Thank you, Chairman Lowenthal, Ranking Member McClintock, and the rest of the Subcommittee. I am honored to be here to testify at this hearing.

My name is Jenna Jambeck, I am a professor of Environmental Engineering at the University of Georgia and a National Geographic Fellow. I have been conducting research on solid waste for over 23 years, with related projects on marine debris itself for 18, especially projects regarding location and spatial analysis, quantification and characterization, and global plastic waste management.

I have also witnessed and sampled plastic in the ocean, sailing across the Atlantic in 2014. I have co-developed the Mobile Litter Logging App—Marine Debris Tracker, which was funded by the NOAA Marine Debris Program in 2011, where over 2 million items have been logged by people all over the world.

I have previously testified to the Senate on this issue, to the Subcommittee on Fisheries, Water, and Wildlife.

I am also a participant in the International Informational Speakers Program with the U.S. State Department. This has brought me to 13 different countries and economies around the world to engage with governments, academics, NGOs, and citizens on this issue.

I have submitted a longer written document, but my testimony today is my opinion based upon my background and experience conducting research on marine debris plastic and waste.

When I testified previously to Congress in 2016, I spoke to educate and raise awareness of this issue based upon my research. But we now know we have a major problem with plastic ending up in our environment and in the ocean. The science on this issue has increased rapidly just in the past 4 years.

We now know we have produced 8.3 billion metric tons of plastic as of 2017. And since about 40 percent of this is used for packaging and single-use items, it means that 6.3 billion of that had become waste by 2015.

So, what have we done with that waste? How did we manage it? We have recycled about 9 percent of that cumulatively, those vary locally. But, on average, globally recycled only about 9 percent. Another 12 percent had been incinerated. That means 79 percent has ended up either in a landfill or in the open environment.

As a result of weathering and exposure to sunlight, plastic that is in the environment doesn't biodegrade. It simply fragments into smaller and smaller pieces, and with an unknown fate, I would say, of the smallest particles that we can't even measure yet.

You heard the number in our *Science* paper in 2015. We estimated the global quantity of plastic entering the oceans at 8 million metric tons in 2010, and that is equal to about a dump truck of plastic entering every minute. So, although there have been actions taken globally to stop the business-as-usual projection of this input doubling by 2025, plastic production use and population growth are all driving factors that have resulted in an increase of plastic used and in our waste streams.

We can all agree we want to keep plastic out of the ocean in the first place. There is a tremendous opportunity for continued bipartisan support and action on this issue. In the intervention framework I developed in 2016, we start all the way upstream with reducing waste generation, especially in places with high per-person waste generation rates, like here in the USA. Our waste generation rate is two to six times that of many countries around the world, especially still economically developing countries. And this reduction can be obtained through a combination of individual choice, policies, and industry-led changes.

For when we do need packaging, there needs to be a more distinct connection between design, material choice, and end-of-life management of materials. Currently, the waste management system has to deal with whatever comes their way. This is one contributing factor to the historical practice of exporting nearly 50 percent of our plastic recycling to other countries, primarily those of lower income, which contributes to the environmental pollution in their country, as well.

Engagement of all stakeholders across all points of this issue, from production, to use, to management, is critical to make sure all voices are heard. So, one reminder I always have to give: there are people behind all the numbers I gave you. We need to collectively come up with creative, socially and culturally appropriate solutions, because we are all here today presenting to you. I am optimistic we can do that, and I will continue to work hard on science to inform policy. But everyone has an important role to play.

In my last points, I want to encourage you to try two experiments.

First, for the next 24 hours, take note of everything that you touch that is plastic. From this you will see how widely used and useful the material is, but it also makes you reflect upon where and when are the right times and places to use this material.

Second, go outside on a scavenger hunt for litter—you won't likely have to go far—and look at each item you find as a message for you, the figurative or sometimes literal message in a bottle. Ask yourself three questions: one, what is it; two, how did it get here; and three, what are we going to do about it?

Community-based data collection and citizen science within a framework and structure can contribute to critical data needed to inform circular materials management in communities. And I believe questions like these can empower citizens, NGOs, corporations, and policy makers like you to take the most relevant, impactful action for their country, state, or community.

Thank you.

[The prepared statement of Dr. Jambeck follows:]

# **PREPARED STATEMENT OF JENNA R. JAMBECK, PHD, PROFESSOR OF ENVIRONMENTAL ENGINEERING, COLLEGE OF ENGINEERING, UNIVERSITY OF GEORGIA, ATHENS, GEORGIA; NATIONAL GEOGRAPHIC FELLOW**

### **Key Points**

Based upon my testimony, the top five recommendations for how Congress can best support research, cleanup, or prevention efforts to combat marine debris are:

- 1) Funding the current agencies and initiatives, as well as new research through other agencies to provide science to further determine human health impacts (e.g., micro and nanoplastics) and mitigate this issue through the entire value chain of plastic (e.g., fate and transport of plastic in the environment, new materials and product design), which can provide economic innovation and growth, and also inform policy. Community-based data collection and citizen science with proper frameworks and structure can contribute to critical data needed to inform circular materials management in communities on the front lines of waste management.
- 2) To support prevention domestically, Congress could support legislation to reduce waste generation to reduce leakage of especially plastic packaging (and those items found in typical beach cleanups), like deposit-return schemes which show a 40% reduction in beverage containers where in place in the USA, as well as, for example, product stewardship/extended responsibility initiatives to increase the collection and value of waste.
- 3) To support prevention internationally, we can continue to provide funding through USAID and other bilateral initiatives, which I have seen give NGOs the opportunity to catalyze action, improve infrastructure and the economy, in countries like Vietnam, Philippines and Indonesia. We also need to make sure our exports are not negatively impacting other countries and support development in other countries so they may participate in trade using standards such as the OECD. We can also determine if our trade-agreements can influence other countries improvement of environmental standards, including solid waste management.
- 4) Show support for global initiatives to assist with the reduction of plastic entering the ocean and improvement of waste management infrastructure development around the world (e.g., with world development banks, NGOs and industry), along with technology and knowledge transfer to other countries on solid waste management

through, for example, the U.S. State Department, US EPA and NOAA. The newest USAID CCBO funding is one aspect of this process.

5) Derelict fishing gear is one of the most dangerous types of debris in the environment. Supporting the development of a program (through an agency) for fisherman to drop off gear that is broken or that they find could help this program (providing collection and disposal in areas where DFG has an impact). NOAA Marine Debris Program "Fishing for Energy" or similar could continue and/or expand.

### **Introduction**

I would like to thank Chairman Huffman, and the rest of the Water, Oceans and Wildlife Subcommittee for the opportunity to testify at this hearing to examine plastic's impact on the ocean. It is an honor and privilege to be with you today. My name is Jenna Jambeck and I am a Professor of Environmental Engineering at the University of Georgia and a National Geographic Fellow. I have been conducting research on solid waste issues for 23 years with related projects on marine debris since 2001, especially projects regarding location and spatial analysis of debris, debris quantification and characterization, global plastic waste mismanagement and technology/mobile device usage (mapping, etc.). I have also sampled open ocean plastic sailing across the Atlantic and co-developed the mobile app, Marine Debris Tracker, funded by the NOAA Marine Debris Program. I have presented at three Capitol Hill staffer briefings, a Global Ocean Commission meeting, the 2015 Our Ocean Conference, a 2015 G7 workshop, and at the White House Office of Science Technology and Policy (OSTP). I also serve as the U.S. representative on an Advisory Panel for the United Nations Environment Program Global Partnership on Marine Litter. I testified on May 17, 2016 to the Senate Subcommittee on Fisheries, Water and Wildlife on this topic. I have been in the International Informational Speakers Program with the US State Department since 2017 and have been to thirteen different countries/economies working on the issue of marine debris and plastic waste in public environmental diplomacy (Chile, Philippines, Indonesia, Japan, South Africa, Vietnam, Jordan, Israel, South Korea, India, Bulgaria, Taiwan, and China). My testimony today is my opinion, based upon my background and experience in studying marine debris and plastic pollution.

#### **Context**

I think it is important to provide context and introduction similar to when I gave testimony to the US Senate in 2016, the US regulatory history is always relevant. I grew up in the 1970s outside a small town (fewer than 3,000 people) in Minnesota. Like many people at the time, we managed our trash by taking it to the landfill and putting it in ourselves. I always found it fascinating to see what people throw away – and I have seen bowling balls to bologna in landfills. In graduate school, my fascination turned into a passion for studying solid waste management as an environmental engineer. Environmental engineers can also design urban drinking water and wastewater facilities, but to me, solid waste management felt like it most closely involved people. Unlike the small effort required to turn off a faucet or flush a toilet (even a sensor can do this with no human effort), we all have to decide daily

what to consume, what materials to use, what *is and is not* "solid waste" in our own home, and then whether to give away, discard, compost or recycle unwanted materials. The human component of solid waste management, and the direct interaction with people, is an aspect of my work that continues to be essential to my work.

In 1976 Congress passed the Resource Conservation and Recovery Act (RCRA) that required the U.S. EPA (typically through the states) to regulate solid and hazardous waste.<sup>32</sup> "Open dumping" was prohibited and replaced by engineered and regulated landfills, composting and recovery systems.[33](#page-4154-0) RCRA also specifically called for research to inform solutions, including demonstrations and special studies on measures to reduce the generation of waste, waste collection practices, and economic incentives to promote recycling and waste reduction (among other things).[34](#page-4154-1) Because of RCRA, we had outstanding progress in solid waste management, just in my lifetime. When I heard about our trash ending up in the ocean in 2001, I knew we must be contributing to it from the land, and started down the path of my current research. In this testimony, I am going to illustrate the direct connection between the solid waste (trash) we produce on land and the plastic found in our ocean, recalling that the human component goes hand in hand with local, state, regional, national and international initiatives to address this problem.

### **Introduction**

 $\overline{a}$ 

Marine debris has been recognized as a contamination issue for more than 50 years<sup>[35](#page-3026-0)</sup> but the laser-focus on plastic has occurred just in the past 5-7 years. Plastic completely changed our world after it's expanded use in World War II, and global annual plastic production has increased from 1.7 million metric tons/yr in 1950 to 360 million metric tons/yr (not including polyester fibers) in 2019. [36](#page-2589-0) Along with a steep increase in production, we have seen a resulting increase in plastic in the waste stream from 0.4% in 1960 to 12.7% in 2012 (by mass) in the U.S. All traditional plastics do not biodegrade, but only fragment into smaller, ultimately microscopic or nanoscopic, pieces. A cumulative 8.3 billion metric tons of plastic has been produced since 1950.<sup>37</sup> Since approximately 40% of plastic is used for packaging and single use items, this means that 6.4 billion metric tons has become waste by 2015 (Figure 1). Globally, on average, we have recycled only about 9% of plastic, with 12% recycled and 79% ending up in our landfills or in the environment. With cumulative quantities projected to reach 34 billion metric tons of production and 12 billion metric tons of waste, the management of plastic in the waste stream is only continuing to grow.

Figure 1. Global materials flow of plastic.

Polymers that make up the plastics that we commonly encounter are listed in Table 1. But plastics also contain additives to alter color, texture, shape, form, antimicrobial surfaces, make it flame retardant, and for other properties.<sup>[38](#page-4215-0)</sup> The wide variety of available additives results in thousands of different plastic material compounds for particular purposes, creating a diverse array of plastic materials that end up in our trash, which can make recovery and recycling challenging. In the USA, the per person waste generation rate ranges from 4.48 to 6 lbs/person/day (2 to 2.7 kg/person/day), depending on the reference examined.<sup>39</sup> This is 2-6 times the waste generation rates of many countries around the world. <sup>40</sup> The recycling percentage for all plastic in the USA is the same as the global average, with only about 9% of plastic recycled, although rates for individual polymers vary (Table 1). $41$

## 2930 *A Sea of Problems*

Since plastic "degrades" through fragmentation, the result is microplastic (smaller than 5 mm in size) in the environment. Secondary microplastics are formed by the fragmentation of larger items. Primary microplastics are manufactured in these small sizes. Some sources of primary microplastic are resin pellets and microbeads. Resin pellet loss has been addressed by the industry though their Operation CleanSweep program, $42$  and recent federal legislation banned microbeads in personal care products as of 2018.[43](#page-3031-0) Secondary microplastics are found on our coastlines, in our sediments, and floating in the ocean aggregating in the five oceanic gyres. Using the largest available ocean microplastics dataset, a recent study estimated that 15 to 51 trillion particles, with a mass of 93 to 236 thousand metric tons, are floating on the sea surface globally; this is equivalent to only about 1% of the estimated input of plastic waste to the ocean from land in a single year.<sup>[44](#page-3029-0)</sup> Where the remaining plastic debris is in the ocean remains a major unanswered question. The majority of field sampling to date captures only particles larger than approximately one-third of a millimeter in size, but increasing numbers of reports of synthetic fibers (from clothing and woven ropes, for example) in freshwater and marine environments, and even in air, make microfibers now a major concern.<sup>[45](#page-3030-0)</sup> And, while many people think of marine debris as being only in the ocean environment, the Great Lakes are governed by NOAA's Marine Debris Program, and are known to be contaminated with plastic (REF) and not to be overlooked are inland riverine inputs of which there are two global estimates for, but could make up 5% to 50% (likely around 25%) of the global inputs of plastic into the ocean.<sup>46</sup>

In the last decade, scientific research into marine debris, and especially plastic, has increased. In 2011, a scientific working group was convened at the National Center for Ecological Analysis and Synthesis (NCEAS). I was honored to be a part of this working group that spent three and a half years synthesizing data to describe the scale and impact of trash in ocean ecosystems. At least nine scientific articles have been produced from this group describing information to date, $47$  advancing the science. The NCEAS work, along with other recent scientific work, has brought attention to the issue of plastic in the oceans further validating action at the global scale by the G7, G20, United Nations, and multinational global funding entities like the World Bank, the Global Environment Fund (GEF). In 2018, the Save Our Seas Act was passed with unanimous bipartisan support. And Save Our Seas 2.0 is in the legislative process now.

Similar to RCRA in the 1970's, sound science should be used when determining policies and solutions. Today, we have sufficient evidence to guide action to reduce inputs of plastic into the ocean. In parallel, new scientific information should be created to help us better understand the sources, sinks and impacts of plastic in our oceans.

## **Impacts from Plastic Marine Debris**

 $\overline{a}$ 

I will cover impacts briefly here, with further detail able to be obtained in my previous testimony to the Senate.<sup>48</sup> In 1966, two U.S. Fish and Wildlife Service employees, Karl W. Kenyon and Eugene Kridler, were among the first scientists to document plastic and wildlife interactions when they discovered plastic was consumed by seabird (Albatross) chicks that had died in the Hawaiian Islands National Wildlife Refuge. [49](#page-3031-1) Since that time, many individuals of a multitude of different species of wildlife have been found to be impacted by plastic. Like in the Albatross chicks in 1966, ingestion of and entanglement are the most commonly reported interactions. A comprehensive critical review of the literature on marine debris impacts was led by Dr. Chelsea Rochman in the NCEAS group. Of the 296 perceived threats of debris to wildlife that were tested, 83% were demonstrated (proven), and 82% of those were from plastic. There is evidence of impacts to individual animals and to assemblages of organisms suggesting decision-makers should take action in order to avoid risk of "irreversible harm."<sup>50</sup>

Lost fishing equipment (e.g., nets and traps) can "ghost fish," or drift while continuing to catch fish and kill wildlife. This can have an impact on the fishing and shellfish industry. One study in Puget Sound alone analyzed 870 recovered "lost" gillnets and found 31,278 invertebrates (76 species), 1036 fishes (22 species), 514 birds (16 species), and 23 mammals (4 species); 56% of invertebrates, 93% of fish, and 100% of birds and mammals were dead when recovered.<sup>51</sup> When experts were asked which marine debris item poses the greatest risk to marine life, fishing-related gear ranked first, followed by balloons and plastic bags.<sup>52</sup>

Marine debris can present physical hazards to shipping, boating, fishing and industrial systems by blocking navigation, fouling boat propellers, clogging water intakes or blocking pumping systems. Coastal tourism is also affected by marine debris and other litter. In the 1980s, when medical waste was found on some beaches, communities lost millions of dollars from a decline in tourism and increased costs for beach cleanup maintenance.<sup>[53](#page-4225-0)</sup> A 2014 study by the NOAA Marine Debris Program in Orange County, CA found that 1) residents are concerned about marine debris, and it significantly influences their decisions to go to the

<sup>53</sup> NRC (National Research Council) Committee on Shipborne Wastes, Clean Ships, Clean Ports, Clean Oceans, National Academy Press, Washington D.C., 1995.

beach, 2) No marine debris on the beach and good water quality are the two most important beach characteristics to them, and 3) Avoiding littered beaches costs Orange County residents millions of dollars each year. If the debris were reduced by just 25%, it would save residents roughly \$32 million dollars in reduced travel to other beaches.<sup>54</sup> UNEP estimates the financial damage of plastics to marine ecosystems globally is \$13 billion each year.<sup>[55](#page-2592-0)</sup> A recent study outlined that there are negative impacts to almost all marine ecosystem services, negative impacts to human wellbeing (fisheries, heritage and recreation) at a cost of \$3300 to \$33,000 per metric ton of marine plastic per year, equaling \$264 billion per year at the mid-input estimate.<sup>56</sup>

Plastic also hosts an entire microbial community termed the "plastisphere."[57](#page-4190-0) Plastic can transport non-native species and provide habitat for microbes that might not otherwise thrive, but we don't yet know the full extent of this microbiome on ocean microbiology or the broader ocean ecosystem. Plastics in the ocean are associated with chemicals. This includes organic compounds like flame retardants, pesticides, and polychlorinated biphenyls (PCBs) that accumulate on the plastic from surrounding water. It also includes the additive ingredients of the plastic that can leach into the surrounding environment. Thus, plastic can transport these compounds around the world and be another potential source of contaminants to wildlife.<sup>[58](#page-4228-0)</sup> Some of the additives to plastic have come under question for toxicity,<sup>59</sup> but we don't yet know the full impact they have on aquatic systems. [60](#page-3035-0) Still, there has been evidence of the transfer of chemicals from plastic to fish in the lab, causing liver toxicity and impacting functions of the endocrine system and to other organisms in the field.<sup>[61](#page-2594-0)</sup> Plastic particles and fibers have also been found in the stomachs of fish, and in shellfish sold for human consumption. 62

## **Input into the Ocean from Mismanaged Plastic Waste**

In the NCEAS group, as we started compiling information about sources and inputs of plastic into the ocean, we quickly concluded that mismanaged solid waste (trash) made up a large portion of the input. Other inputs include, but are not limited to, commercial fishing gear, shipping, recreational boating and fishing, and catastrophic events. Our first objective was to quantify mismanaged waste from land. To make the estimate of plastics entering the ocean from waste management, we developed a comprehensive framework (Figure 1).

Our methods for this estimate were to look at per person waste generation rates in 2010 from 192 countries with a coastline in the world. Because people's activities nearest the coast are responsible for most of the plastic going into the water, we limited our analysis to a 50km strip of the coastline. From there, we looked at what percent of that waste is plastic, and what percentage of that is mismanaged waste (which means litter or when waste is not captured and dumped on the land). From there we had three scenarios of input into the ocean: low, mid and high.

The results were that in 2010, we estimate that 275 million metric tons (MMT) of plastic waste was generated in 192 countries. Of that, 99.5 MMT of this waste was generated within 50km of the coastline, and 31.9 MMT was mismanaged. We then estimated that between 4.8 and 12.7 MMT (a mid-scenario of 8 MMT) reached the oceans<sup>63</sup> (Figure 2). This annual input of plastic is equal to 5 grocery-size bags filled with plastic going into the ocean along every foot of coastline in the world.

Figure 2. Plastic waste inputs from land into the ocean in 2010.

l

<sup>63</sup> Jambeck, J. R., Andrady, A., Geyer, R., Narayan, R., Perryman, M., Siegler, T., Wilcox, C., Lavender Law, K., (2015). Plastic waste inputs from land into the ocean, Science, 347, p. 768-771.

The U.S. is one high income country on the list, and while our waste management systems are well-designed and very effective, and the only mismanaged waste is from litter, we have a large coastal population and a large waste generation rate. If we look to the future, and assume a business as usual projection with growing populations, increasing plastic consumption and increased waste generation, but no increase in capture of waste, by 2025, the 8 million metric tons doubles – with a cumulative input by 2025 of 155 million metric tons.

#### **Import-Export of Plastic Waste**

While recycling and the circular economy have been touted as potential solutions to this issue, one can see from the recycling percentages given in the introduction, we have a long way to go for recycling to be significant. Approximately half of the plastic waste intended for recycling has been exported to hundreds of countries around the world (Figure 3).

Figure 3. Trade of plastic waste in mass and trade value (UN Comtrade data).

Before their import restrictions (resulting really in a ban) in 2017, China had imported a cumulative  $45\%$  of plastic waste since  $1992.64$  Compiled commodity trade data by Amy Brooks in my research group illustrated that higher-income countries in the Organization for Economic Cooperation (OECD) have been exporting plastic waste (70% in 2016) to lowerincome countries in the East Asia and Pacific for decades. An estimated 111 million metric tons of plastic waste is displaced with the new Chinese policy by 2030 begging the question of where this plastic goes now and will continue to  $g_0$  – and causing one of the biggest

l

<sup>64</sup> Brooks, A., Wang, S. Jambeck, J. (2018). The Chinese import ban and its impact on global plastic waste trade, Science Advances, 20 Jun 2018: Vol. 4, no. 6, DOI: 10.1126/sciadv.aat0131.

economic disruptions to recycling ever to happen in the USA. With 89% of historical exports consist of polymer groups often used in single-use plastic food packaging (polyethylene, polypropylene, and polyethylene terephthalate), bold global ideas and actions for reducing quantities of nonrecyclable materials, redesigning products, and funding domestic plastic waste management are needed. The USA and others who have exported to countries that lack waste management systems are responsible for some of this mismanagement. In China alone, this added another 11% of plastic mass to their waste stream to manage in 2015. Rethinking trade agreements and the balance of resources to be able to participate in trade for countries (like small island sates) that need to, is important. This is also a large global economic system that involves the livelihood of millions of people around the world. Improving their conditions and protecting the environment should be paramount. New amendments to the Basel Convention have put requirements on exporting countries to at least notify and get consent for shipments. <sup>65</sup> The USA could help lead efforts to both improve and develop domestic infrastructure while participating in responsible global trade of recycled materials.

## **It's a Global Issue**

 $\overline{a}$ 

Once plastic is in our oceans, it becomes a global issue and poses great logistical and economic challenges to get it out. In addition, the plastic is not always visible (although we find it everywhere we look, we have only quantified a fraction in our ocean compared with what is going in), so understanding potential risk to our ecosystems requires two things: 1) understanding the impact and 2) understanding the exposure. Our recent estimate of plastic entering the oceans informs the second part – exposure, just how much plastic is going into the ocean? But it also makes us ask – where is all the plastic going? While we know action will help "turn off the faucet" of plastic input (see potential interventions, below), there are still gaps in the sources, distribution, fate and impacts of plastics in the ocean that need more research if we want to continue to move forward in addressing this issue based upon science.<sup>66</sup>

## **Interventions and Mitigation Strategies**

I developed the framework below for my 2016 testimony<sup>67</sup> and would like to submit it again with some ideas, further explanation and answers to some of the questions posed by the senators in this hearing. This framework provides intervention points (1 through 5) and then a list of potential (but not all encompassing) interventions that may occur at the various points. In general, this represents a hierarchy of interventions. However, the most "bang for your buck" interventions will depend on the needs of the specific geography addressing the issue, however, in many cases, all geographies have points along the entire framework that will help

<sup>65</sup> http://www.basel.int/Implementation/Plasticwastes/Overview/tabid/6068/Default.aspx.

<sup>66</sup> A good recent review of why it is important to move forward with science –based solutions is provided in Rochman, C. (2016). Strategies for reducing ocean plastic debris should be diverse and guided by science, *Environmental Research Letters*, 11 014006.

<sup>67</sup> https://www.epw.senate.gov/public/\_cache/files/8/0/8074ded1-5986-4a9b-b033-2eb69e66993f/B775115948AB 5A3C80BDDB5B0287E8B3.jambeck-testimony.pdf.

## 2936 *A Sea of Problems*

reduce debris and plastic going into the ocean. Some interventions can be immediate and some will take more time. The framework starts on the left with the most "upstream" interventions and ends with a last chance to capture the material before it enters the ocean. In many cases the interventions offer the opportunity for economic innovation and growth. The USA could be a leader in several of these categories of interventions.

Figure 4. Intervention and Mitigation Strategies along some Points in the Plastic Value Chain I'll now discuss some potential intervention points identified in Figure 2 in a bit more detail.

## *1. Reducing Plastic Production*

Plastic production is one of the "book ends" of the plastic value chain. Other than a few of the past 65 years, global plastic production has increased annually, and is anticipated to continue to do so into the near future. Although it comes from fossil fuels for the most part, and is produced from monomers that come from the processing of oil and natural gas, these monomers (e.g., ethylene and propylene) are used to make many different compounds, not just polymers. As long as other common chemicals are made, it is likely that polymers will continue to be made as well. And, as economies around the world continue to develop, packaged goods become more prevalent. Unless the industry changes its own course, this stage is mostly influenced if levers in other stages are pushed (e.g., demand is decreased for other reasons along the value chain). Reduction in demand comes primarily from the points given below.

- 1. Consumers demanding less packaging or no packaging (some markets)
	- Not everyone has access to clean water, for example, so can't always make the choice of a reusable bottle, but these choices taken collectively where possible do make a difference
- 2. Local initiatives (e.g., bans, taxes)
	- a. These are often very local-specific, but are also becoming more common
	- b. Mass of items removed may be relatively small, but numbers of items are also important – there is more than one way to measure debris (e.g., mass, count, etc.)
- 3. Voluntary industry actions
	- a. Industry has become more engaged on this issue I wonder if they will volunteer some changes to help in the future as well?
	- b. The reality is that all signs point to further growth in waste generation, as well as plastic use, especially where economic development is occurring or predicted to occur in the future.

## *2. Innovative Materials and Product Design*

<span id="page-2960-0"></span>New materials development and product design take time to advance, so these activities need to be happening now – and they are, but even more time and resource investment is needed. Overall, I think Green Engineering principles, <sup>[68](#page-2960-0)</sup> if followed during material development and product design, would help to avoid many of the externalities of plastic that we are dealing with currently. In addition, circular economy concepts, emerging all over the world now, will be important to also apply to plastic materials. Both of these guiding principles promote non-toxic materials, ultimately with the capability of biodegrading and/or being recycled. Materials and products made with more homogenous compounds would make recycling more efficient and effective. Materials and products can be designed to retain their value, for collection, recovery and recycling. Several of these concepts are outlined in Ellen MacArthur Foundation's report on the "The New Plastic Economy: Rethinking the future of plastics," which focuses specifically on packaging.[69](#page-2596-0) The University of Georgia has combed environmental engineering and polymer chemistry in a successful and rapidly expanding New Materials Institute with centers on biodegradable polymers and circular materials management to develop and test materials to reduce the flow of plastic into the ocean. NMI has become part of a National Science Foundation (NSF) Industry–University Cooperative Research Centers (IUCRC) that has over 30 corporate partners interested in more sustainable and biodegradable polymer products. These industry-research groups participate in precompetitive research and development as new materials need to scale to be economical for all to use. There is no doubt that developing alternative materials without the unintended consequences of traditional plastics will spark innovation and economic growth in the USA where truly biodegradable polymer production facilities (e.g., Polyhydroxyalkanoates (PHA)), like the ones in Georgia owned by Danimer Scientific and RWDC are creating jobs. There are many current corporate commitments to change materials, use more recycled materials, and be more circular with materials – many of these commitments have been made at the Our Ocean meeting that just occurred for the sixth time in Oslo Oct 23-24. \$652 million was committed by governments, corporations and NGOs to reduce ocean pollution, including plastics. Commitments to move to redesign were made by Unilever and PepsiCo, for example, moving to reduction in virgin plastic use and increases in recycled content.<sup>70</sup> Specific points are given for redesign and material substitution below:

- 1. Sustainable packaging associations (pre-competitive collaborations)
	- a. E.g., UGA's New Materials Institute IUCRC, Sustainable packaging coalition, Green-Blue: These pre-competitive environments could help develop alternatives, standardize packaging and help packaging retain value so that it is easier to recycle and less leakage will occur if it has value.
- 2. Truly biodegradable alternatives (e.g., PHA)

 $\overline{a}$ 

a. PHA is expanding in the market in the USA and is creating economic value (new facility opening in Kentucky – several open in Georgia already). While it may biodegrade if littered in the environment, it should still be managed in the solid

<sup>68</sup> http://www.acs.org/content/acs/en/greenchemistry/what-is-green-chemistry/principles/12-principles-of-greenengineering.html.

<sup>69</sup> https://www.ellenmacarthurfoundation.org/publications/the-new-plastics-economy-rethinking-the-future-ofplastics.

<sup>70</sup> https://ourocean2019.no/wp-content/uploads/2019/10/20191025-Commitments-1616.pdf.

waste system, and be thoughtful about where used (in currently non-recyclable items, for example). But it has the possibility of being home-composted as well. The USA is currently a leader in the development of this material.

- b. An important distinction should be made with polylactic acid (PLA), a popular corn-based polymer is bio-based and industrial compostable (avoids using fossil fuels as feedstock), but it will not biodegrade in home composting or in the ocean. It will not biodegrade if littered on land. It has to reach a high temperature (reached in industrial composting) to be able to biodegrade.
- 3. Packaging with more value (e.g., single, homogenous materials, design for recycling/end-of-life)
	- a. This can be helped by collaborations between industry, brands and waste managers/experts
- 4. Design out problematic items/materials (e.g., caps/lids)
	- a. Similar to how aluminum can "pop-top" opening was changed to a tab that stayed on (so the pull tabs did not get littered), we can innovate design for items that leak into the environment (if data is collected – see intervention point 5, last chance capture).

## *3. Reduce Waste Generation*

In places like the U.S., where we already have high per person waste generation rates, we can examine methods of waste reduction. For example, some of us have the luxury of being able to make choices about single use items we use daily. The majority of us have access to clean drinking water infrastructure so we can use a reusable water bottle, reusable coffee mug, bring a reusable bag to the grocery store, and say "no" to straws (or get reusable ones). These seem like small and mundane things, but what our research on plastic input showed is that since population density is such a big driver of these inputs, just one small choice, taken collectively, can make a big difference. There is a bit of a "chicken and egg" scenario here though, consumers can make choices, but they also need availability and access to those choices. For example, it might be hard to not buy bottled water if you don't have access to a drinking fountain or water filling station. But this is also where policies regarding specific items of concern can provide motivation. Waste reduction can also occur from participation in new collaborative and sharing economies. These new paradigms are emerging and technology and social media are helping to move them forward. People are choosing to own less and "share" more. It started with car and bike shares, but has expanded to tools, and even clothing. As people become more aware of the issue of plastic in our environment, they are demanding companies reduce waste themselves, and help provide the right choices and infrastructure for people to reduce their own waste generation.

Specific points on waste reduction below – and asking the question, *can we decouple waste generation from economic growth?* I get very excited to see what my students and young innovators will create in this category daily.

- 1) Using reusable items (e.g., bottles, mugs, bags, etc.) and if this is challenging for citizens, I ask them to think about why and what change is needed so it is possible at the government or corporate level? Then advocate for that change.
- 2) Sharing, Collaborative Economy concepts
- a. Bike shares, car shares, tool shares, clothing rental, etc. these all reduce the need to purchase and create waste (facilitated by technology), but still meet people's needs and can still create revenue for the companies providing the services.
- b. How can these concepts be related to packaging? (see 2.b)
- 3) Decouple waste generation with economic growth (facilitated by technology)
	- a. Reuse programs (using mobile phones, which many people have globally, especially where rapid economic growth is occurring)
	- b. RFID, mobile phones, smart-labels, etc. (e.g., RFID water refill stations exist for both Coca-Cola and PepsiCo products, but are not yet widely distributed yet)

#### *4. Improve Waste Management Globally*

l

Improving waste management globally could go a long way to keeping a large mass of plastic out of the ocean (realizing mass is not the only meaningful metric for plastic – volume, count, shape, or impact to wildlife are other metrics). For example, in our *Science* paper the top 20 countries' mismanaged plastic waste encompassed 83% of the total input in 2010. But with a combined strategy, in which total waste management is achieved in the 10 top-ranked countries and plastic waste generation is capped, a 77% reduction could be realized by 2025. That sounds simple. We know how to design waste management systems, but in light of the context I gave at the beginning, waste management is much more than just a design challenge, it also has deep social and cultural dimensions. So we need to work together at a combination of local and global initiatives, and we need global participation from various stakeholders along the entire value chain of plastic (see following section on Circularity Assessment Protocol). Per person waste generation is coupled with economic development and, in many cases, the waste stream has fairly quickly changed characteristics to include more plastic. There are still many people in both the U.S. and globally that are unaware of the consequences of plastic in our aquatic environment.

Globally, innovation and creativity is needed in this space and people are heeding the call. Large, global NGOs are partnering with local groups in areas of concern to try to implement culturally appropriate mitigation strategies. Infrastructure is being integrated into existing informal waste management sectors in the hopes of continuing and improving people's livelihoods. U.S.-based groups can help in efforts for this global problem by connecting with groups who are trying to address these issues in their own countries, and there is a lot of work to be done. Some concepts that can be drivers in this area: zero waste (reduce disposal or destruction of waste to as close to zero as possible) and product stewardship/extended producer responsibility (waste management responsibility is shared or is the entire responsibility of product manufacturers). Plastic reuse and recycling can grow if the right economic structure is in place to motivate the collection of plastic waste and its reprocessing. Many local groups in global communities need some added support to elevate and expand what they are already doing to bring it to scale. Policies like deposit-return schemes reduce the quantity of plastic that reaches the environment. In US states that have these schemes, a 40% reduction of beverage containers is observed.<sup>71</sup>

Solid waste collection can be a hyper-local activity and can look different in each country, city and even neighborhood. Plastic has made it a more complicated and created a

<sup>71</sup> Schuyler, Q., Hardesty, B.D., Lawson, TJ., Opie, K., Wilcox, C., Economic incentives reduce plastic inputs to the ocean, Marine Policy, Volume 96, 2018, Pages 250-255.

rapid change in the waste stream that we were ill prepared for. It creates a waste stream that is more varied and dynamic than we have ever experienced before. It has proved to be quite a challenge for waste operators and municipalities to manage. I have developed a "Five C" approach for this intervention point.

- 1) Collect: May be traditional, on-demand, or decentralized waste collection a. Collection innovation is needed – revers logistics may play a role
- 2) Capture: Material Recovery Facilities, waste depots, waste banks, community centers (e.g., "punto limpio" in Chile)
- 3) Contain: Recycling or engineered disposal
- 4) Context and 5. Culture these can "make or break" the success of a potential intervention. The local community and stakeholders absolutely need to be engaged and involved from the start through the end of any project and not just led through it, but their local and indigenous knowledge is critical.

## *5. Litter Capture*

 $\overline{a}$ 

Litter capture and collection is the last point to keep materials from entering the ocean. It is reserved for mostly the litter that occurs from inadvertent littering, lack of awareness and behavior issues. After outreach and education to prevent litter in the first place, there are street sweeping, municipal litter clean-up programs and stormwater catchment systems, all which will only be conducted in their respective jurisdictions. An innovative example of a final catchment device is the Baltimore Water Wheel.<sup>72</sup> Operated off of mechanical and solar energy in Baltimore Harbor, "Mr. Trash Wheel" has booms that skim the surface of the harbor and direct the floating trash to the conveyer system that removes it from the water and places it into a dumpster to be managed properly.

Non-governmental organization and volunteer cleanups to remove litter have been occurring for years. These events certainly help to keep litter from entering the ocean, and they are also a source of data. The Ocean Conservancy's International Coastal Cleanup is now in its 33rd year and it not only helped to remove 0ver 10,500 metric tons of debris from beaches in 2018, but it has spread awareness and education as well. For the first time in 2017 and also in 2018, the top ten items found on beaches for the ICC were all plastic. In 2011, my colleague Dr. Kyle Johnsen and I co-developed a mobile app called Marine Debris Tracker at the University of Georgia funded by the NOAA Marine Debris Program. The Marine Debris Tracker mobile app and citizen science program allow for the collection of global standardized data at a scale, speed, and efficiency that wasn't previously possible.<sup>73</sup> It also spreads awareness and education about this issue wherever it is used. Individuals all over the world have helped to clean-up or document over 2 million items – by simply hitting a few buttons on their mobile phone to tell us what they found. User metrics provide a ranking and our largest group user is the Georgia Sea Turtle Center protecting and caring for Sea Turtles on Jekyll Island, GA and one of our largest individual user is in Omaha, NE (not far from the Missouri River) where he has collected over 87,000 pieces of litter alone, over the past 7.5 years. We, along with our app users, have fostered an online community through social

<sup>72</sup> http://baltimorewaterfront.com/healthy-harbor/water-wheel/.

<sup>73</sup> Jambeck, J.R., Johnsen, K. (2015). Marine Debris Tracker: Citizen-based Litter and Marine Debris Data Collection and Mapping, *Computing in Science and Engineering,* 17(4), 20-26; http://www.marinedebris.engr. uga.edu/.

*A Sea of Problems* 2941

networks – everyone is supportive of each other's efforts and individuals know that they are a part of a large global effort. There is now enough (opportunistic) data in the database to start to examine characteristics and trends based upon the spatial and temporal data provided by our extremely dedicated users. Data is critical to informing upstream solutions and can really empower communities and decision-makers to be able to take actions driven by data. Lastchance cleanup points are summarized below.

- 1. Engineered, mechanical systems
	- Mr. Trash Wheel or other engineered devices
- 2. Manual (by hand)
	- a. Cleanups (e.g., ICC by Ocean Conservancy)
	- b. Use of ocean-bound plastic can catalyze the development of infrastructure since the material now has value – often a much higher value than it did previously (e.g., Parley, Dell, NextWave plastics)
- 3. Data to feed back to Interventions 1 through 4 in the Framework
	- a. E.g., Marine Debris Tracker developed by UGA (or other apps) to collect data
	- b. Could make upstream choices/changes based upon what is leaking into the environment

## **Community-Based Data Collection and Assessment**

Communities are the at the front lines of this issue. They are where solid waste is managed and many decisions and development of waste management systems are made. They also experience the direct impacts of plastic pollution in their local environment. It is important we work with communities in the decision-making process to be able to come together on realistic and viable solutions. After I began traveling for the US State Department for the International Informational Speakers Program in 2017 (that has now brought me to 13 countries), I often find myself in the same situation over and over again. Speaking with governments and communities about this issue, they would say to me, "Well now that we know more about this issue, what can we do?" and I would pause (since I had not often been there very long typically), and tell them that they have the local and indigenous knowledge for solutions to this issue – they know their own context and culture. But I could also look around and take note of what I saw to contribute data for them to use… from what stores and cafes were selling in packing, from waste and recycle bins I saw, to litter on the ground. I also thought more about the concept of the circular economy – being touted as a solution to this issue, what does it really mean at the community level? How does a community move closer, or even see where they are at, related to the circular economy? In addition the community systems are an inherently complex, sociotechnical system, which is difficult to define with traditional metrics. There was a need for a methodology and a framework that provides a baseline understanding, illustrates the impacts of changes in the system, and facilitates useful knowledge exchange between cities, while allowing for flexible adaptation to local knowledge and expertise.

Figure 5. The Hub and Spoke model of the Circularity Assessment Protocol (CAP).

This is the context for how our Circularity Assessment Protocol (CAP) was developed in our Center for Circular Materials Management (the only center of its kind in the USA), in our New Materials Institute at the University of Georgia. Conducted in collaboration with a community and eventually by the community itself, the CAP characterizes seven community components: 1) inputs, 2) consumers, 3) product design, 4) use, 5) collection, 6) end-of-cycle management (e.g., waste management), and 7) plastic leakage into the environment. Various influencing factors drive this system including governance, economics, policy and legislation (e.g., bans, taxes, extended producer responsibility). Furthermore, multiple stakeholders exist at every level of the CAP influencing the complex system and these include citizens, government, industry, NGOs and academia. While the hub and spoke model illustrates the CAP (Figure 4), it is a complex system with components inherently interconnected to each other and to life-cycle impacts beyond each component.

While the CAP is a framework approach to addressing marine litter originating from land-based sources, it can also include data collection for marine or water-based sources through parallel research questions, and the quantity of leakage from this sector can be characterized during litter assessments (e.g., if fishing gear is an issue, it is typically evident on litter surveys on land as well). The framework supports points of intervention and actions, including guidance on effective impact (in terms of environmental and economic) to improve circularity. The CAP can help to inform a community by giving them a baseline assessment to work from and direct potential actions to take to improve the areas that most need it, and to answer specific questions they have about their own community. The CAP can inform and support the government to define policies and good practices related to solid waste management and infrastructure, including facilitating an understanding of solid waste and plastic management through a social lens. This can provide an understanding of people's actions (both local and transient) which will inform policy and interventions.

The CAP is being used for projects funded by the World Bank, National Geographic, the Asia-Pacific Economic Cooperation (APEC) through the Ocean Conservancy, and USAID. Projects are completed or active in the Seychelles, Philippines (metro Manila), Chile, India, Bangladesh and at least two places in the USA, one small island community and a large metropolitan coastal city. A scaled-down version of CAP is being conducted in 30 small island and coastal community stopovers around the world with eXXpedition, and further development of the CAP for communities to conduct the process themselves within the framework is underway.

## **The U.S. Can Be a Global Leader in Addressing This Issue**

Once plastic enters the ocean, it quickly becomes a global problem. The United Nations Environment Program has been addressing this issue through the Global Partnership for Marine Litter, with resolutions anticipated out of a meeting later this month. There is also the discussion of a global agreement with the potential for flexibility of countries to be able to reach reduction goals as they see fit. But the U.S. should be a leader in addressing this global issue, and it has in some ways. The U.S. Department of State has worked on this issue through the G7, G20 and Our Oceans conference. The NOAA Marine Debris Program started in 2006 with the Marine Debris Reduction Act (reauthorized in the Save Our Seas Act) and is one of the few agencies to provide grant assistance to community groups and research. The U.S. EPA has a Trash Free Waters Program that has expanded recently in bringing in partners and pilot sites around the U.S. NOAA and the U.S. EPA (chair and vice chair, respectively) lead the Interagency Marine Debris Coordinating Committee (IMDCC), a multi-agency body responsible for streamlining the federal government's efforts to address marine debris. Representatives meet to coordinate a comprehensive program of marine debris activities and make recommendations for research priorities, monitoring techniques, educational programs, and regulatory action. The IMDCC participants are the U.S. Army Corps of Engineers, U.S. Navy, U.S. Coast Guard, U.S. Fish and Wildlife Service, Bureau of Safety and Environmental Enforcement, Department of Justice, Environmental and Natural Resources Division, Department of State, Office of Marine Conservation, and the Marine Mammal Commission. Another group that has worked on U.S.-based marine debris issues is the National Fish and Wildlife Foundation. While U.S. scientists, universities, and research groups are at the forefront of the science of marine debris, there have only been a few research grants funded through the National Science Foundation and NOAA. Even while a multitude of domestic agencies and research groups have been working on this issue, resources are limited for addressing this issue and meeting our goals in being global leaders. Multi-agency cooperative programs could further advance the science of plastic contamination and pollution while also providing future economic benefits through startup companies and whole new industries. Community-based and citizen science programs to collect badly needed data, like our CAP using the Marine Debris Tracker mobile app can be used in the USA, as well as around the world.

## **Summary**

Based upon my testimony, the top five recommendations for how Congress can best support research, cleanup, or prevention efforts to combat marine debris are:

- 1) Funding the current agencies and initiatives, as well as new research through other agencies to provide science to further determine human health impacts (e.g., micro and nanoplastics) and mitigate this issue through the entire value chain of plastic (e.g., fate and transport of plastic in the environment, new materials and product design), which can provide economic innovation and growth, and also inform policy. Community-based data collection and citizen science with proper frameworks and structure can contribute to critical data needed to inform circular materials management in communities on the front lines of waste management.
- 2) To support prevention domestically, Congress could support legislation to reduce waste generation to reduce leakage of especially plastic packaging (and those items found in typical beach cleanups), like deposit-return schemes which show a 40% reduction in beverage containers where in place in the USA, as well as, for example, product stewardship/extended responsibility initiatives to increase the collection and value of waste.
- 3) To support prevention internationally, we can continue to provide funding through USAID and other bilateral initiatives, which I have seen give NGOs the opportunity to catalyze action, improve infrastructure and the economy, in countries like Vietnam, Philippines and Indonesia. We also need to make sure our exports are not negatively impacting other countries and support development in other countries so they may participate in trade using standards such as the OECD. We can also determine if our trade-agreements can influence other countries improvement of environmental standards, including solid waste management.
- 4) Show support for global initiatives to assist with the reduction of plastic entering the ocean and improvement of waste management infrastructure development around the world (e.g., with world development banks, NGOs and industry), along with technology and knowledge transfer to other countries on solid waste management through, for example, the U.S. State Department, US EPA and NOAA. The newest USAID CCBO funding is one aspect of this process.
- 5) Derelict fishing gear is one of the most dangerous types of debris in the environment. Supporting the development of a program (through an agency) for fisherman to drop off gear that is broken or that they find could help this program (providing collection and disposal in areas where DFG has an impact). NOAA Marine Debris Program "Fishing for Energy" or similar could continue and/or expand.

As environmental engineers, we manage all solid waste that comes our way. But by connecting our activities on land with what ends up in our oceans, and through that awareness, realizing that we should be thinking about end-of-life in materials development and product design stages, we can shift the paradigm of "waste" to materials management. Also, the worldwide interest on this topic has put the spotlight on global solid waste management infrastructure needs, and so we need to collectively come up with creative, socially and culturally-appropriate mitigation strategies. Collectively, we hold the key to this problem. By changing the way we think about waste, reducing at source, designing products for their end-of-life management, valuing secondary materials, collecting, capturing and containing our waste, we can open up new jobs and opportunities for economic innovation, and in addition, improve the living conditions and health for millions of people around the world while protecting our oceans.

#### *1. What are some of the most promising innovations?*

In my opinion some of the most interesting and promising innovations are the ones that decouple waste generation from economic growth. How can we meet people's needs and increase livelihood without creating more waste to manage? Sharing and collaborative economy concepts, RFID cups, using technology to connect people and facilitate sharing and reuse programs all lead to potential interventions. Reduce waste generation in the first place. See page X, above.

#### *2. What is role of PLA and other bio-based plastics?*

I think there is a role for material and product innovation and bio-based and biodegradable (truly) polymers will be a part of the solution. However, these materials are being produced at relatively low quantities right now, so they are not going to be a big market share for some time. And thought needs to go into what they replace as well as life-cycle tradeoffs. And an understanding of situational biodegradability is critical. See page X, above.

## *3. Fisherman incentives*

I think incentives for fisherman to collect or bring back gear would be a way to get some of the most deadly gear out of the ocean and marine environment. I think also supplying a place for fisherman to put used gear is important (e.g., dumpster or recycle bin at the port). Tracking and transparency of nets – and really all plastic (as much as feasible) could help keep the material out of the ocean because we would have a better inventory of it.

#### *4. What are some of the root causes?*

Responsibility – while not particularly popular in the USA, product stewardship is an important concept to discuss here. From an engineering standpoint, when a company wants to build a development/civil engineering project, there often is a partnership with the community. One example, I live near an above ground storage tank farm, and trucks come and go from it regularly. There were likely road improvements needed to be able to build the tank farm and the company who constructed it may have contributed to that infrastructure since they were building at this site. In some ways, this can be analogous to selling products in a country or location that does not have infrastructure to manage the waste created from those products. I don't think companies knew the issues this would bring. And I think they want to help based upon new awareness, but we are certainly playing "catchup" with the issue now. Besides policies in other countries, some companies are doing this individually, but many still don't know how to help with infrastructure. I think that facilitating this in some way could be significant – maybe it will all be individual public-private partnerships, but some thought could go into how to facilitate companies engaging in shared responsibility. Ultimately it will take shared actions by industry, municipalities, and citizens to make significant positive change on this issue.

As often said, there is no one solution to this issue, but an integrated approach is needed to reduce and eliminate plastic entering and impacting our ocean.

# **QUESTIONS SUBMITTED FOR THE RECORD TO JENNA R. JAMBECK, PHD PROFESSOR OF ENVIRONMENTAL ENGINEERING, COLLEGE OF ENGINEERING, UNIVERSITY OF GEORGIA**

## **Questions from Rep. Alan Lowenthal**

1. Why is it important to work with local communities to identify their sources of plastic pollution and possible solutions?

It is important to work with local communities because plastic inputs and waste are created and managed at the community level, i.e., our communities are on the front lines. So understanding their needs, context and situation is important. Even if a federal policy is enacted, the communities will be impacted. Disposal and recycling are commonly different from community to community. Community engagement, including co-creation, or at least buy-in, on potential solutions is critical to implementation and participation. While local solutions can scale to make them larger and more impactful, exploring what communities need can inform federal legislation.

As referenced in my written testimony, one example is the Circularity Assessment Protocol (CAP), developed in the Center for Circular Materials Management (the only center of its kind in the USA), in the New Materials Institute at the University of Georgia. Conducted in collaboration with a community and eventually by the community itself, the CAP characterizes seven community components: 1) inputs, 2) consumers, 3) product design, 4) use, 5) collection, 6) end-of-cycle management (e.g., waste management), and 7) plastic leakage into the environment. Various influencing factors drive this system including governance, economics, policy and legislation. Furthermore, multiple stakeholders exist at every level of the CAP influencing the complex system and these include citizens, government, industry, NGOs and academia. While a simple hub and spoke model illustrates the CAP, and data collection is rapid and easy to collect through a collaborative effort by the community members and researchers, it is a complex system with components inherently interconnected to each other.

One of the largest benefits to CAP is that it can help to inform and empower a community by giving them a starting assessment to work from and direct potential actions to take to improve the areas that most need it, and to answer specific questions they have about their own community. The CAP can inform and support the government to define policies and good practices related to solid waste management and infrastructure, including facilitating an understanding of solid waste and plastic management through both and technical *and* social lens. This can provide an understanding of people's actions (both local and transient) which will inform policy and interventions.

Other community-based work that I have participated in is the National Geographic Sea to Source Expedition along the Ganges River in India. This expedition focuses on plastic pollution in three key areas: land, water and people. On land, we collect data about the input and use of plastic in communities, how waste is collected and managed, and characterize the movement and type of plastic in the environment. The water team studies plastic pollution in the air, water, sediment and species in and around the river. The socioeconomic team surveys local communities along the expedition route to better understand awareness and perceptions

of plastic pollution, household plastic waste management and local solutions for addressing this issue. During the expeditions, we engage the local community, and work with stakeholders to empower then to find context-sensitive solutions that can help drive a longterm positive change. This kind of interdisciplinary and community-based work, incorporating easy-to follow citizen science methods and cutting-edge technology can be a spark for continued change on this issue. Similar kind of work could be conducted in major river waterways in the USA as well. Previous data on the USA is only an estimated model based upon reported solid waste infrastructure. And, as one of the largest waste generators in the world, we really don't know (except for a few exceptions where collection takes place, like Mr. Trash Wheel<sup>74</sup>) what plastic leaks into and from our waterways in our own backyard.

2. There was a lot of discussion on the societal relevance of plastic as it is. What innovations and alternatives are available or coming very soon?

I think the USA was sold short by the hearing discussion that there was no alternatives and no other material to use besides traditional plastic. E.g., we have solved the "what to do without plastic to hold toothpaste problem" and there are solid toothpaste "chews" in several different brands available packaged without plastic, including one very successful womenowned and operated US-based company called Bite.<sup>75</sup> The USA in many ways is, and can continue to expand, in leading the world on innovative materials and alternatives to traditional plastic. Already polylactic acid (PLA) exists and a large amount of R&D has been conducted in the USA on it. While it does not avoid all unintended consequences of traditional plastic, it does avoid using fossil fuels as a feedstock and serves as an example to the economic growth and development of a new material that serves the needs of traditional plastics but is different from it in some ways. As stated in the testimony though, an important distinction should be made with PLA, as it will not biodegrade in home composting or in the ocean. It will not biodegrade if littered on land. It has to reach a high temperature (reached in industrial composting) to be able to biodegrade.

Also included in my testimony is an entire section on Innovation summarized here:

Overall, I think Green Engineering principles,<sup>76</sup> if followed during material development and product design, would help to avoid many of the externalities of plastic that we are dealing with currently. In addition, circular economy concepts, emerging all over the world now, will be important to also apply to plastic materials. Both of these guiding principles promote non-toxic materials, ultimately with the capability of biodegrading and/or being recycled. Materials and products made with more homogenous compounds would make recycling more efficient and effective. Materials and products can be designed to retain their value, for collection, recovery and recycling. The University of Georgia has combined environmental engineering and polymer chemistry in a successful and rapidly expanding New Materials Institute with centers on biodegradable polymers and circular materials management to develop and test materials to reduce the flow of plastic into the ocean. NMI has become part of a National Science Foundation (NSF) Industry–University Cooperative Research Centers (IUCRC) that has over 30 corporate partners interested in more sustainable

<sup>74</sup> https://www.mrtrashwheel.com/.

<sup>75</sup> https://bitetoothpastebits.com/.

<sup>76</sup> http://www.acs.org/content/acs/en/greenchemistry/what-is-green-chemistry/principles/12-principles-of-greenengineering.html.

and biodegradable polymer products. These industry-research groups participate in precompetitive research and development as new materials need to scale to be economical for all to use. There is no doubt that developing alternative materials without the unintended consequences of traditional plastics will spark innovation and economic growth in the USA where truly biodegradable polymer production facilities (e.g., Polyhydroxyalkanoates (PHA)), like the ones in Georgia owned by Danimer Scientific and RWDC are creating jobs (see more in the answer below to question 3). Specific points for redesign and material substitution are:

- A. Sustainable packaging associations (pre-competitive collaborations)
	- E.g., UGA's New Materials Institute IUCRC, Sustainable packaging coalition, Green-Blue: These pre-competitive environments could help develop alternatives, standardize packaging and help packaging retain value so that it is easier to recycle and less leakage will occur if it has value.
- B. Truly biodegradable alternatives (e.g., PHA)
	- a. PHA is expanding in the market in the USA and is creating economic value (new facility opening in Kentucky – several open in Georgia already). While it may biodegrade if littered in the environment, it should still be managed in the solid waste system and be thoughtful about where used (in currently non-recyclable items, for example). But it has the possibility of being home-composted as well. The USA is currently a leader in the development of this material.
	- b. Danimer Scientific in collaboration with Frito-Lay is working on PHA packaging as well, so a major brand is making this shift too, scaling this to more USA-based economic growth.
- C. Packaging with more value (e.g., single, homogenous materials, design for recycling/end-of-life)
	- a. This can be helped by collaborations between industry, brands and waste managers/experts
- D. Design out problematic items/materials (e.g., caps/lids)
	- a. Similar to how aluminum can "pop-top" opening was changed to a tab that stayed on (so the pull tabs did not get littered), we can innovate design for items that leak into the environment (if data is collected at last chance capture).
- 3. Is there a positive economic impact from the development of alternatives to traditional plastic?

Yes, while there is an economic component to traditional plastics to the economy and jobs, the alternatives can create similar output and work opportunities (see some in the answer to question 2, above). And the USA can be at the forefront of this change.

One specific example is a company called RWDC that works closely with the New Materials Institute at the University of Georgia. RWDC has just purchased a property in Athens, GA for their first production facility. They have already hired approximately 40 people and will bring 100 jobs to Athens-Clarke County, Georgia (one of Georgia's 91 persistently poor counties) in the next year, and an estimated 210 jobs after 5 years. There is another site in Monroe, GA, where another 86 jobs will be created within the next two years. And this is just one company growing as quickly as it can in the USA.

4. What are some of the benefits and trade-offs from switching away from traditional plastics?

There is no doubt that plastic has changed our society and culture. It has brought us many things we rely on every day – this was the point of my 24-hour experiment. But, do we really need it for all those things? Some things yes, medicine, electronics, many what we call "durable goods" – but the single-use plastic, the packaging, and what ends up in the environment (the second and other critical part to the experiment I presented!) – how much of that needs to be plastic? We are not going to get rid of all plastic, but I think we need to be more thoughtful about where, when, and how we use it.

Here are some examples of trade-offs that we might consider while thinking about plastic. Certainly plastic has brought light-weight benefits to food packaging, transport and allows food to be stored in sanitary ways, protecting the embodied energy that went into that food. Many times the carbon footprint of that food is large. Something to ponder, where do we draw the lines in these analyses? Why does our food have such a high carbon footprint/embodied energy? Should all food be distributed through the current model if it requires plastic packaging? I encourage people to think "out of the packaging container" and outline all the ways we can change the delivery of products and design of packaging. But, the best thing, environmentally-speaking, is to not produce any waste in the first place, so that lends itself to reusable items. However, for when packaging is needed, what then, should it be made out of? Life-cycle assessments (LCA) were referred to in the hearing and I have conducted LCAs on various waste management scenarios myself.<sup>77</sup> More upstream, product LCAs can inform packaging choices, so we can compare carbon footprint, energy use, water consumption, etc. of two products, for example a plastic v. a reusable bag. While the energy input or carbon footprint for production, for example, may be more for the reusable bag, the fact that you do not have to manage waste after it's end-of-life is an energy and carbon offset. While the plastic bag is light, it will have to be transported to a recycling or disposal facility and then managed there. In a carbon balance scenario, plastic does not release carbon at end of life, because as far as we know it does not practically degrade, so while it is not a benefit that it remains forever in a landfill, it does not release carbon while there. In addition, plastic bags have been known to jam up recycling systems at material recovery facilities (MRFs) and blow from landfills, making containment a challenge (and requiring human effort and machines to manage at landfills). These two situations do not fit into an LCA in a straight-forward way. And a last major limitation of this kind of LCA is that there is no way to include a littered plastic bag ending up in the ocean and a turtle eating it and dying. Animals killed from plastic litter does not fit into any LCA. So there are trade-offs that are a challenge to compare, and we need a better way to look at the systems holistically, even beyond our typical LCA. At a minimum, we need to be able to acknowledge, and talk through some of these tradeoffs, in a systematic way.

## **Questions from Rep. Nydia M. Velazquez**

1. In your testimony you highlight corporate commitments made at the Our Ocean meeting in Oslo, can you describe what steps exactly are in motion to help reduce plastic pollution in the environment? Is it enough?

The Our Ocean Commitments are available here: [https://ourocean2019.no/wp-content/](https://ourocean2019.no/wp-content/uploads/2019/10/20191025-Commitments-1616.pdf)  [uploads/2019/10/20191025-Commitments-1616.pdf.](https://ourocean2019.no/wp-content/uploads/2019/10/20191025-Commitments-1616.pdf)

For the first time that I can recall a company, Unilever, committed to an absolute reduction of plastic use. They are finding alternative ways of delivering products, as PepsiCo announced purchasing Soda Stream an alternative delivery mechanism for carbonated beverages as well. Other companies and governments made commitments too (and my mentioning those two companies by no means is an endorsement in any way). But no, these commitments are still not enough for a couple reasons. First, the corporations have the capacity to go further with these commitments and make them more impactful, but the commitments continue to get stronger each year, so they do indicate movement in the right direction. Another reason it is not enough is that I think multiple entities need to be involved to create a larger positive impact. No one "group" (e.g., industry, government, NGO) can do this alone. For example, corporations designing and using packaging need to speak with the waste management companies and these two systems, the input and the management, should be better integrated. I still see a lot of issues related to design and management that could be addressed by these two end-of-the-spectrum entities working together. For example if product stewardship or extended producer responsibility is considered, the impacts to the waste management companies – and their input – needs to be considered and heard. For all groups working on, and involved in, this issue  $-$  if each group makes some compromises, the shift each entity needs to make can be smaller in order to meet in the middle, yet still creating a truly impactful way forward. I recommend a US-based summit where the relevant stakeholders can gather together to actively negotiate how new federal policies could be endorsed in order to better protect the environment for all.

## **Questions Submitted by Rep. Cox**

 $\overline{a}$ 

*Question 1. A recent study found 16 microplastic fibers in a single half-liter sample of water taken from the Capitol Visitor's Center. How did the microplastics get into the Capitol Visitor's Center drinking water or anybody's drinking water for that matter?*

Answer. I would have to see this study's methods to be able to comment on this specific result, but microfibers and microplastics have been found in freshwater, tap drinking water, groundwater and wastewater in published studies.<sup>78</sup> This same research was a review of these published studies, and they found that methods are still widely conducted and not standardized, and in order to really find out the risk to human health from exposure, these methods need to be standardized to high levels. So to properly answer your question, there

<sup>78</sup> Albert A. Koelmans, Nur Hazimah Mohamed Nor, Enya Hermsen, et al. Microplastics in freshwaters and drinking water: Critical review and assessment of data quality, Water Research, Volume 155, 2019, Pages 410–422.

needs to be more research conducted based upon common research methods and standards. This would be a good role for the U.S. EPA to play in the USA, to direct the methods and standards for comparative purposes.

At this point without more data, we can only guess at the sources of the fibers and particles. We know fibers are generated from washing clothes and unless otherwise captured,  $79$  these go out with our wastewater to either septic or treatment plants (when treated). In cases where not treated, they would be directly discharged to the environment. Although we know that typically over 90 percent of the fibers can be removed from the wastewater treatment facility,<sup>80</sup> it means they end up in the sludge that settles out and then is either managed at a landfill or in some cases, applied to the land where run-off could reintroduce them to the environment again. We also know that fibers are transported by air, so atmospheric deposition (mostly regional, near-range likely) could be a transport into our freshwaters.<sup>81</sup> So, it can end up in our source water from point source (wastewater), run-off and from the air. And, although drinking water is treated and many particles are removed, it is possible that some could remain. There has not been an investigation into the drinking water distribution system and its contribution, if any, to microplastic in water, but it is doubtful for microfibers as far as I am aware. If water is stored in an open glass in a room, microfibers will very likely fall into it—they are in the air all around us. Identifying them as a polymer with FTIR or Raman, for example, is very important so that we correctly identify if they are plastic or not.

## *Question 2. What do we know about the human health impacts of ingesting microplastics?*

Answer. We really don't know at this point—there are likely studies underway on this topic, but the potential impacts are not easy to study and if some of the plastics are at the nanoscale level, they are not able to be analyzed or identified at this point with current analytical capability. We know we are exposed through beverages we consume (including water) and some of the food we eat (e.g., salt), but we don't yet know the impact to humans. I also recommend referring to Dr. Chelsea Rochman's recent testimony to the House on this  $i$ ssue. $82$ 

*Question 3. Oftentimes we turn to alternatives to address environmental challenges like plastic pollution. In the case of climate change, we might use renewable power instead of coal. In the transportation sector, we see people switching to electric vehicles. However, there are always bumps in the road when we make these transitions, and it's our job here in Congress to smooth those out. Take the idea of adopting alternatives to plastic as an example. Explain to the Committee why we have not seen a more rapid transition to biodegradable plastics or plastic alternatives.*

<sup>79</sup> Hayley K. McIlwraith, Jack Lin, Lisa M. Erdle, et al. Capturing microfibers—marketed technologies reduce microfiber emissions from washing machines, Marine Pollution Bulletin, Volume 139, 2019, Pages 40–45.

 $82$  https:// docs.house.gov / meetings / AP / AP06 / 20190919 / 109934 / HHRG-116-AP06-WState- RochmanC-20190919.pdf.

## 2952 *A Sea of Problems*

Answer. I think the biggest reason here is cost. Traditional plastics are so inexpensive. There are alternatives developed and companies are working hard to scale them (see my answer to Rep. Lowenthal's Question 2, above). But the cost makes it challenging until they are able to scale. The development and manufacturing of alternative materials will have economic growth and provide job opportunities in the USA (also see my answers in Rep. Lowenthal's Question 3, above), so like your other examples for climate change, we can see transitions to different businesses and job growth, while making some of these changes. Policies that level the playing field for other materials and products would be helpful.

## *Question 4. What are some of the actions that Congress could take to allow for increased adoption of more recyclable and environmentally friendly alternatives to plastic?*

Answer. As mentioned above, policies to level the playing field in the cost of materials for use can help here. These could include a tax or fee on certain kids of traditional resins, bans, and required design and procurement standards. Again, I think that these kinds of actions should take into account the impact on all relevant stakeholders to be able to move forward with a balance in terms of compromise. In some cases, end-of-life policies have an upstream impact, e.g., depending on how a product stewardship policy is written, it can impact design of products and materials chosen as well. The example from Norway that I often talk about it is the Extended Producer Responsibility (EPR) law in Norway influenced upstream design and recyclability of products. By requiring a certain percent of PET to be recycled, a company formed to help make this happen and in order to reach the needed recycling rates in the most efficient way, the design of PET bottles were changed so that they could be recycled bottle-to-bottle by Infinitum.<sup>83</sup>

\* \* \*

Dr. LOWENTHAL. Thank you, Dr. Jambeck. The Chair now recognizes Tony Radoszewski to testify. Welcome to the Committee, Mr. Radoszewski.

## **STATEMENT OF TONY RADOSZEWSKI, PRESIDENT AND CEO, PLASTICS INDUSTRY ASSOCIATION, WASHINGTON, DC**

Mr. RADOSZEWSKI. Good afternoon, Chairman Lowenthal, Ranking Member McClintock, and members of the Subcommittee. Thank you for having me here today. My name is Tony Radoszewski, and I am the President and CEO of the Plastics Industry Association. We call ourselves PLASTICS for short, and we use that term proudly.

Plastics were first developed by John Wesley Hyatt in the 19th century as a synthetic replacement for billiard balls. Yes, that is right, billiard balls. Ivory was expensive, and the process of collecting it was gruesome and inhumane. So, Hyatt tinkered around in his lab and developed the material that could behave like ivory, but at a fraction of the cost, and at a fraction of the environmental impact. That has been the story of plastics from their genesis to

<sup>83</sup> https://infinitum.no/english/about-us.

today. It is a material that meets or exceeds the performance of other materials, and does so at a fraction of the cost, and with lower environmental impact.

Since they were first developed, plastics have grown to make hospitals safer, surgeries less invasive, patient care more sterile, safer, effective, and affordable. In a century-and-a-half since they were invented, plastics have also made cars, trucks, and planes more efficient, more affordable, more environmentally friendly, and, ultimately, safer.

Plastic pipe brings fresh water to people and takes wastewater away for treatment in the most economical and environmentally sustainable way. Plastics have also made food last longer, improving health and safety to millions across the world.

The plastics industry employs 993,000 people in the United States. The state with the largest number of plastics employees is California, where 79,700 men and women are directly employed by our industry. I can say with confidence that none of them got into this business in order to pollute our oceans and waterways. I can also say with confidence that many of them entered the industry with a passion to improve the safety and quality of a lot of people. That our products end up where they shouldn't upsets me. And I am sure every one of those nearly 1 million people who work in this industry feel the same way. But it is a fact. It is also a fact that a staggering 8 million tons of plastic ends up in the world's oceans each year, 90 percent of which originates from 10 rivers in Southeast Asia and Africa. The remaining 10 percent comes from elsewhere around the world. That is a great deal of value being wasted when these products end up in lakes, rivers, and, ultimately, oceans.

Our industry agrees with everyone in this room that there is a plastic waste problem. The urgency of the situation cries out for a solution more thoughtful than simply saying "no" to a material that lowers greenhouse gas emissions, is more efficient to produce than other materials like metal, paper, and glass, and has delivered numerous benefits to society as a whole.

Study after study, including one conducted recently by the California Water Board, has shown that banning of plastic products simply drives consumers to other less sustainable materials. Bans have a very minor impact on litter, if they have any impact at all.

Plastics are used in such a diverse array of applications because they are the best option when all considerations are evaluated. In a free market society, consumers decide which products provide the best value and performance. In so many applications the chief characteristics of plastics—that is, their lower weight, durability, flexibility, and versatility constantly make them superior to other competing materials.

Plastic bags became popular due to concerns about how many trees were being cut down to make paper bags. Plastic bottles are lighter and don't break as easily as glass ones, reducing product loss and shipping costs. When they are disposed of properly, these plastic products have a smaller environmental footprint than identical products made of other materials.

Rather than trying to deny the value of plastics, we need to head in the opposite direction, and aim to preserve and enhance their value so that they are worth too much to waste. This can happen by investing in recycling and waste management infrastructure.

We continue to support legislation that would provide grants to the Environmental Protection Agency, to state and local entities to improve recycling infrastructure, which is what we need to close the loop on these issues.

We have also supported the Save Our Seas 2.0 Act, which aims to improve efforts to combat marine debris, and is currently seeing action in various Senate committees, with companion legislation having been introduced here in the House.

The industry itself has stepped up to this challenge by innovating, like it always has, developing new chemistries, investing in new recycling and collection technologies, developing ways to convert plastic waste into energy, and creating the supply to meet the demand for recycled plastic content. Still, we need the support of Federal, state, and local authorities to ensure that no American has to wonder if the bottle they toss into the blue bin will end up being recycled, or if it will end up as landfill fodder.

Perhaps I should sum up our industry's position with a recent quote from Japan's Prime Minister, Shinzo Abe: "We shouldn't treat plastic as an enemy, nor ostracize those who use it. What is needed is appropriate management of trash, and to search for solutions through innovation."

On a personal note, I love this industry. I have worked for it for nearly 40 years. I sincerely believe that plastics are among humankind's greatest innovations, and that they have delivered an enormous benefit to public health and commerce all over the world. We need to learn how to live with these materials, because I can assure you we would never want to have to live without them.

Thank you, and I look forward to your questions.

[The prepared statement of Mr. Radoszewski follows:]

# **PREPARED STATEMENT OF TONY RADOSZEWSKI, PRESIDENT AND CEO, PLASTICS INDUSTRY ASSOCIATION**

Good afternoon Mr. Chairman, the ranking member and members of the subcommittee. Thank you for having me here to speak today.

My name is Tony Radoszewski and I am the president and CEO of the Plastics Industry Association. We call ourselves PLASTICS for short, and we use that term proudly.

Founded in 1937, we're the only association that supports the entire plastics supply chain, and we have a track record of fostering collaboration between each segment of the industry.

We believe in working to make [our members a](https://www.plasticsindustry.org/membership/why-join/join-us)nd the industry more globally competitive. We believe in advancing sustainability and being a good steward of resources. We believe in promoting plastics manufacturing as a viable career option.

We provide education to the industry and to the public about plastics. We support technology-driven innovation to solve problems. We work to change the public's perceptions about plastics and show how they impact our lives for the better. We understand what's important to our members' business and we advocate on their behalf to enact sustainable policies and create sustainable business growth for the industry.

Our councils, committees and [events s](https://www.plasticsindustry.org/events)uch as our signature global tradeshow [NPE®,](http://npe.org/) bring the boldest and brightest innovators, influencers and new technologies together to create connections, expand business growth and showcase our industry.

We're dedicated to helping our members shape the future and make a positive impact every day.

Plastics themselves were first developed by John Wesley Hyatt in the 19th century as a synthetic replacement for ivory in billiard balls.

Ivory was expensive and the process of collecting it was gruesome and inhumane. So, Hyatt tinkered around in his lab and developed a material that could behave like ivory but at a fraction of the cost and a fraction of the environmental impact.

That's the been the story of plastics from their genesis to today; it's a material that does what other materials can't and does so at a fraction of the cost and a fraction of the environmental impact of other materials.

Since they were first developed, plastics have grown to make hospitals safer, surgeries less invasive, patient care more sterile and effective and affordable— they do things in the medical realm that could scarcely have been dreamt of by the original innovators and creators of this material: stents, prostheses, bandages, replacement hips, shoulder sockets, knees, antimicrobial surfaces, dissolvable sutures, syringes, pill bottles, contact lenses and on and on and on.

In the century and a half since they were invented, plastics have also made cars, trucks and planes more efficient, more affordable, more environmentally friendly and safer.

In the United States and around the world, plastic pipe brings fresh water to people and takes wastewater away for treatment in the most economical and environmentally sustainable way. In developing countries, this one aspect has significantly improved the health and viability of millions of people.

And a similar story takes place in food packaging. Plastics make food last longer and enabled it to travel farther to help feed those most desperately in need of assistance. Again, peoples' quality of life, especially in developing countries, is dramatically improved due to the use of plastics.

Why would anyone want to ban such a material?

The plastics industry employs 993,000 people in the U.S. The state with the largest number of plastics employees is California, where 79,700 men and women are directly employed by our industry. I can say with confidence that none of them got into this business in order to pollute our oceans and waterways.

That our products end up where they shouldn't upsets me and every one of those nearly one million people who not only rely on this industry to make a living, but innovate with passion.

But it is a fact. It is a fact that a [staggering eight million tons of plastics](https://www.unenvironment.org/interactive/beat-plastic-pollution/) ends up in [the](https://www.unenvironment.org/interactive/beat-plastic-pollution/)  [world's oceans](https://www.unenvironment.org/interactive/beat-plastic-pollution/) each year—90% of which originates from 10 rivers in southeast Asia and Africa. The remaining 10% comes from elsewhere around the world. There's a great deal of value being flushed down the drain when these products end up in lakes, rivers and ultimately oceans.

Our industry agrees that there is a plastic waste problem. But the urgency of the situation cries out for a solution more thoughtful than simply saying no to a material that lowers greenhouse gas emissions, is more efficient to produce than other materials like metal, paper and glass, and has delivered numerous benefits to society as a whole.

Study after study—including one conducted recently by the California water board—has shown that banning a plastic product simply drives consumers to other less sustainable materials. Bans have a very minor impact on litter, if they have any impact at all.

Take plastic bags, for instance.

## 2956 *A Sea of Problems*

Plastic bags make up extremely small percentages of the waste and litter streams, which is why banning them doesn't have much of an impact. According to the EPA, they make up 0.3% of municipal solid waste and they typically make up less than 1% of litter (branded plastic retail bags made up 0.8% of litter in New Jersey, for example).

Alternatives to plastic bags are also often worse for the environment. Paper, woven polypropylene, and cotton/canvas bags all have a higher carbon footprint than traditional plastic bags. The [UK,](https://assets.publishing.service.gov.uk/government/uploads/system/uploads/attachment_data/file/291023/scho0711buan-e-e.pdf) [Denmark,](https://www2.mst.dk/udgiv/publications/2018/02/978-87-93614-73-4.pdf) and [Quebec g](https://monsacintelligent.ca/wp-content/uploads/2018/03/ENGLISH_FINAL-Quebec-LCA-Full-Report.pdf)overnments all did studies on this and came to a similar conclusion—plastic bags are the best environmental option at the checkout counter.

California's plastic bag ban led to an increase in carbon emissions due to increased paper bag usage as well as skyrocketing trash bag sales, which use more plastic (see [NPR article](https://www.npr.org/sections/money/2019/04/09/711181385/are-plastic-bag-bans-garbage)  and the [study\)](https://www.sciencedirect.com/science/article/pii/S0095069618305291?utm_source=npr_newsletter&utm_medium=email&utm_content=20190408&utm_campaign=money&utm_term=nprnews). Overall, if you ban plastic bags, you will see fewer of them around. But consumers will switch to options that have a much higher carbon footprint, and litter and waste won't be meaningfully changed for the better.

This is true for bags but also for product bans in general. As an example, McDonalds in the United Kingdom and Ireland banned plastics straws and replaced them with paper ones. The company recently was forced to admit that the new paper straws weren't recyclable. Many consumers also don't like paper straws either. As mentioned before, banning a product drives consumers to use other less sustainable and less functional options while having a negative economic impact on the industry and its workers.

Plastics and plastic products exist for a reason.

They're used in such a diverse array of applications because they are the best option when all considerations are evaluated. In a free market society like we enjoy here in the U.S., the marketplace is driven by consumer demand, which determines which products provide the best value and performance. In so many applications, the chief characteristics of plastics that is, their lower weight, durability, flexibility and versatility—constantly make them superior to other competing materials.

Even products that we encounter here in the U.S. in our day-to-day lives solve problems. Plastic bags became popular due to concerns about how many trees we were cutting down to make paper bags. Plastic bottles are lighter and don't break as easily as glass ones, reducing product loss and shipping costs. When they're disposed of properly, these plastic products have a smaller environmental footprint than identical products made of other materials.

Rather than trying to deny the value of plastics, we need to head in the opposite direction and aim to preserve and enhance their value so that they're worth too much to waste. This can happen by investing in recycling and waste management infrastructure.

We continue to support legislation that would provide grants through the Environmental Protection Agency to state and local entities to improve recycling infrastructure—which is what we need to close the loop on these issues.

This could be as simple as an education program on recycling in a particular community to the provision of new optical sorting equipment within existing Materials Recovery Facilities (MRFs). Simply put, we need to improve the collection of materials as one way of keeping it from becoming waste in a landfill, or litter in the ocean or along the side of the road. We believe having a reliable, steady supply of recovered material will encourage companies to use more recycled content.

Making it easier for consumers to recycle is a major factor in keeping our products out of the water and other environments where they do not belong. We would certainly support efforts to raise awareness on the impact of littering and better waste management practices.

But this should not be the only tool deployed to address this challenge. The industry supports voluntary, industry-led or public-private initiatives designed to increase the recovery of plastic materials that meet the standards of Sustainable Materials Management (SMM) analysis. Such initiatives could include programs aimed at increasing the use of postconsumer recycled material or bioplastics, as long as the industry has been involved in the creation of such initiatives, and they can be supported by economic analysis, adequate supply and transition time and remain consistent with other regulatory requirements pertaining to the manufacture and use of the product, such as food packaging safety rules.

Additionally, any potential language that imposes a fee on containers or packaging should apply to all materials—not just plastic—as all materials are found in the waste stream.

PLASTICS advocates for the use of SMM as a guiding policy principle—one that considers the entire ecosystem of the product and prioritizes the use of materials and processes that consider total energy and resource inputs throughout the entire lifecycle of a product and minimizes associated waste. SMM's holistic approach achieves this goal by using metrics like greenhouse gas emissions, water usage and transportation efficiencies for different materials, and comparing their advantages while meeting economic, social and environmental requirements. With that in mind we would caution against any product ban that does not consider the implications of what would replace that product. In many cases, what is broadly considered a "single-use" plastic product is the more environmentally sound choice when considering the manufacturing process, shipping and recyclability over the life of the product. Shortsighted bans would only create more problems without proper, detailed analysis.

We've also supported the Save Our Seas 2.0 Act which aims to improve efforts to combat marine debris and is currently seeing action in various Senate committees with companion legislation having been introduced here in the House.

Save Our Seas 2.0 is an important, bipartisan step forward to address the critical issue of marine waste and its impact on the environment. The legislation will build upon the progress the industry is making to address marine debris across the world. New proposals like the Marine Debris Response Trust Fund, as well as more research to understand the root causes of this global issue and federal support for improving water and waste management infrastructure are all critical to any effort to comprehensively address the threat marine debris poses to our oceans and waterways.

The industry itself has stepped up to the plastic waste challenge by innovating like it always has—developing new chemistries, investing in new recycling and collection technologies, developing ways to convert plastic waste into energy and creating the supply to meet the demand for recycled plastic content.

In addition to finding new ways to increase the effectiveness of traditional recycling typically a curbside pickup program or local drop off—the industry has explored advanced recycling through the use of new additives like compatibilizers that help incompatible resins chemically bond, and property enhancers that improve the strength, quality and ultimately value of recycled materials.

The industry is also building on processes like chemical recycling, pyrolysis and gasification. Each of these processes are used to turn plastic polymers back into individual monomers—allowing materials to be reused in a variety of ways. In these processes, the chemical building blocks that make up the recycled plastic are recovered. The fundamental building blocks can in some cases be repolymerized endlessly, giving them the qualities of brand-new, or virgin, resin.

The transformation can occur through a variety of processes, all of which avoid combustion, or burning, of plastics.

*Chemical recycling* is any process by which a polymer is chemically reduced to its original monomer form so that it can eventually be processed (re-polymerized) and remade into new plastic materials that go on to be new plastic products.

Chemical recycling helps us overcome the limits of [traditional recycling.](https://www.thisisplastics.com/environment/recycling-101-recycle-matters/) It also helps manufacturers continue to push the boundaries of how, and where, recycled plastics can be used. Chemical recycling has long been used for nylons, and the industry is working to make it possible for other resin types.

*Pyrolysis*, sometimes called "plastics to fuel," turns non-recycled plastics from municipal solid waste (garbage) into a synthetic crude oil that can be refined into diesel fuel, gasoline, heating oil or waxes. Using pyrolysis to convert non-recycled plastics into ultra-low sulfur diesel (ULSD) fuel reduces greenhouse gas emissions by 14% and water consumption by 58%, and it saves up to 96% in traditional energy use as opposed to ULSD from conventional crude oil.

*Gasification* turns non-recycled materials from municipal solid waste (garbage) into a synthesis gas, or "syngas," which can be used for electric power generation or converted into fuel or chemical feedstocks, such as ethanol and methanol, some of which can also be used to make new plastics that go into consumer products.

Numerous companies are already engaged in these processes across the country.

*[Agilyx](http://www.agilyx.com/polystyrene-to-styrene-monomer-technology.html)*, an alternative energy company, recycles polystyrene (which most people know as Styrofoam™) into high-value petrochemicals. Agilyx's polystyrene recycling process creates like-new materials while generating fewer greenhouse gases than manufacturing does.

*[Shaw Industries Group](https://shawinc.com/Newsroom/Press-Releases/Shaw-Carpet-Recycling-Facility-Successfully-Proces/)* uses chemical recycling for nylon and polyester fiber in carpets. The company has invested more than \$20 million to convert products that were once seen as waste into valuable resources. They reclaimed and recycled more than 800 million pounds of carpet from 2006 to 2015.

*[Resinate Materials Group](http://www.recyclingtoday.com/article/petg-medical-packaging-recycling/)* collects chemicals from plastic materials and works to promote the practical and economical value of chemically recycled plastics. The company has found several high-value applications for the chemicals harvested from recycled medical plastics. It uses certain types of recycled packaging to create coatings, adhesives and sealants.

*[Patagonia](https://www.patagonia.com/blog/2009/03/closing-the-loop-a-report-on-patagonias-common-threads-garment-recycling-program/)*, an outdoor clothing brand, chemically recycles non-wearable Capilene® polyester and fleece products. Today, the brand features a collection of products made completely from recycled materials. Patagonia's chemical recycling process uses 76% less energy than the process used to make new polyester.

Beyond that, the industry continues to expand its energy recovery capacity, which enables companies to convert post-use, non-recyclable plastics into a range of useful products such as fuels and electricity. Unfortunately, there are still some items that we can't recycle at this time and these items are typically sent to landfills.

Energy recovery technologies are changing that. They complement recycling to add a new dimension to the solid waste management toolkit.

It all starts with waste. Municipal solid waste is an underutilized resource of energy that can boost energy security, reduce landfill waste and lower greenhouse gas emissions. Energy recovery is a powerful process that has the potential to change the way we fuel the world. If

all the non-recycled plastics in municipal solid waste were converted to oil instead of landfilled, these plastics could power up t[o nine million cars per year.](https://www.thisisplastics.com/environment/recycling-101-energy-recovery-technologies/)

When it comes to traditional recycling, companies are making big investments and commitments to collect more material and find new uses for it.

For instance, here are a few recent examples of companies investing in expanding recycling:

- GDB International is making "sizeable investments" in New Jersey and Ohio to pelletize plastics that were previously being sent to China.
- PureCycle Technologies is building \$120 million polypropylene recycling facility in Ohio.
- East Terra built a new facility in Indiana.
- Merlin Plastics in British Columbia and Peninsula Plastics in California have made significant investments in mixed plastics recycling for the west coast.
- Azek invested in 100-million-pounds per year processing line for PE films in Illinois.
- Green Tech Solution plans to invest \$75 million in a new plastics and metals recycling facility in Blacksburg, South Carolina.
- The Carton Council invested in artificial intelligence and robotics to help MRFs sort recycled materials more efficiently in Colorado, Minnesota and Florida.

That's just an example list. Additionally, we are seeing major shifts in the behaviors of plastics material suppliers who are forming strategic relationships with recyclers and brands. Again, some examples:

- Indorama entered a joint venture with Loop Industries for PET monomers from chemical recycling.
- Americas Styrenics has an off-take agreement with Agilyx for styrene monomer from chemical recycling. This joint venture is now call Regenyx and is moving quickly to commercial scale operations.
- LyondellBasell entered an agreement with Suez to jointly own QCP. This joint venture leverages the two partners' strengths and provides a platform for growth.
- Pepsi signed a multi-year supply agreement with Loop Industries.
- BP has an off-take agreement for oil produced by RES Polyflow from their pyrolysis system.
- A partnership was announced between the ReVital Polymers startup Pyrowave, and global plastics producer INEOS Styrolution to recycled polystyrene packaging.

The plastics industry is changing the ecology of how plastics are made and the supply chains that create them.

Brand Owners are also making unprecedented commitments to using recycled content. Those growing commitments are being tracked in the Sustainable Packaging Coalition's Goals database.

There is not currently sufficient quantity and quality of material in the market today to meet the 2025 goals that have been set by big name companies. New investments will help meet that demand, but we must find a way to grow the supply of material available to feed the growing domestic recycling market— namely by implementing legislation that helps accomplish this goal.

The U.S. plastics recycling industry is undoubtedly in a period of transition, but it is certainly not dead. As a result of some of the challenges facing this sector, the U.S. domestic processing capability and capacity are growing more and more robust and able to handle more. The industry believes we must focus on how to improve our collection and recovery systems to expand recovery opportunities for more plastic products—while also creating new supplies of recycled plastics to feed domestic investments.

As an organization, PLASTICS has taken a leading role in promoting the aforementioned investments, commitments and technologies and exploring other ways to combat marine debris and deliver solutions to the end-users of our products.

PLASTICS leads the Pacific Northwest Secondary Sorting Demonstration project—a 60 day recycling demonstration that involves installing a portable secondary sorting system where selected materials from four regional MRFs will be further sorted. This innovation will help create six additional streams of recyclables which will reduce waste going to landfills or adversely affecting our environment.

Our Transportation and Industrial Plastics (TIP) Committee participates in the End-of-Life Vehicle (ELV) Recycling Project. Launched in 2015, the ELV project aims to demonstrate the viability of collection and recycling of auto plastics from ELVs and build a basic recovery model, beginning with thermoplastic polyolefin (TPO), which can be eventually expanded upon to include a broader range of resins and parts. To date, a variety of testing has been conducted on TPO recovered from bumpers and initial evaluation suggests there could be strong demand for the recycled TPO if the right end markets are identified. Through collaboration with various other association and member companies, PLASTICS works to prove out those end markets, creating new opportunity for auto recyclers to generate revenue.

PLASTICS' Flexible Film and Bag Division launched the New End Market Opportunities (NEMO) for Film Project in 2017, which aims to develop a reliable source of materials for companies that can use recycled plastic bags, wraps and films in their products.

We're also a part of the Materials Recovery for the Future (MRFF) project which aims to make it easier for MRFs around the country to empower their communities with the ability to recycle flexible packaging—again, bags and wraps but also punches and other packages—in their normal recycling stream and curbside.

PLASTICS also offers a number of tools and resources to companies in the industry that they can use to make their own operations more sustainable:

We help educate companies on how they can turn their waste into valuable resources, or eliminate waste altogether using the tools offered through PLASTICS' Zero Net Waste program. Through this program manufacturers learn how to maximize diversion—achieving in some cases 90% recycling rates and even 100% recovery rates—engage employees in environmental efforts and avoid landfill costs and generate revenue by recycling.

Since the 1980s, PLASTICS and the American Chemistry Council (ACC) have jointly operated Operation Clean Sweep (OCS), an international stewardship program designed to prevent resin pellet, flake and powder loss and help keep this material out of the marine environment.

More recently we've hosted a series of presentations for the industry focused on advancing sustainability, specifically on subjects like energy reduction through the Better

Plants Program, zero net waste, sustainability 101 for new professionals, water reduction, benchmarking, transportation efficiency and calculating economic impacts.

Despite all these efforts, we still need the support of federal, state and local authorities and new legislative solutions to ensure that no American has to wonder if the water bottle they toss in the blue bin will end up being recycled or if it will end up as landfill fodder.

Perhaps I could sum up our industry's position with a recent quote from Japan's Prime Minister Shinzo Abe: "We shouldn't treat plastic as an enemy, nor ostracize those who use it. What's needed is appropriate management of trash and to search for solutions through innovation."

Plastics are among humankind's greatest innovations and they've delivered an enormous benefit to public health and commerce all over the world. We need to learn how to live with these materials, because I can assure you, we would never want to have to live without them.

Thank you.

# **QUESTIONS SUBMITTED FOR THE RECORD BY REP. MCCLINTOCK TO MR. TONY RADOSZEWSKI, PLASTICS INDUSTRY ASSOCIATION**

*Question 1. During the hearing the topic of green house gas emission, as it relates to plastic products, was brought up on several occasions. Can plastics play a role in reducing green house gas emissions?*

Answer. Thank you for the follow-up question regarding plastics' impact on greenhouse gas emissions. To put it simply, plastics reduce greenhouse gasses when compared to currently available alternative materials. As I mentioned the day of the hearing, plastics would be replaced with less sustainable options if bans on plastics were implemented. Life cycle analyses continuously show how plastics is the better choice to reduce greenhouse gas. Whether that is by light-weighting vehicles which increases fuel mileage and decreases emissions, or the fact that paper, woven polypropylene and cotton/canvas bags all have a higher carbon footprint than traditional plastic bags. I could go on, but I will let the science speak for itself. I've included several studies that illustrate what I am referencing. It cannot be overstated: plastic as a material improves the overall picture as it relates to greenhouse gasses when looking at the full life cycle of a product.

Plastics' lighter weight minimizes their environmental footprint by decreasing production of waste, energy use and carbon emissions through the full life cycle of the product. Beyond energy savings and water conservation, plastics help preserve the shelf-life of food, thereby preventing food waste, a huge problem worldwide. According to the EPA, most uneaten food decays in landfills, where it accounts for 34 percent of U.S. methane emissions (methane is a powerful greenhouse gas that is 21 times more harmful to the environment than CO2.<sup>84</sup>)

Many people think glass bottles are "greener" than plastic. But glass bottles require 46 percent more greenhouse gases and 55 percent more energy to produce than plastic bottles do.<sup>85</sup>

The American Chemistry Council (ACC) released several studies showing the positive impact plastics can have versus alternatives. In particular, a Franklin Associates studies, "Life

l

<sup>84</sup> https://www.scientificamerican.com/article/earth-talk-waste-land/.

<sup>&</sup>lt;sup>85</sup> https://posterng.netkey.at/esr/viewing/index.php?module=viewing□poster&doi=10.1594/ ecr2015/C-2599.

Cycle Impacts of Plastic Packaging Compared to Substitutes in the United States and Canada" from April 2018<sup>86</sup> and "Life Cycle Inventory of Packaging Options for Shipment of Retail Mail-Order Soft Goods" from April 2004, pgs. ES15–17.<sup>87</sup>

Additionally, a study by Trucost estimates that substitution of plastic components with alternative materials in passenger vehicles sold in North America in 2015 would lead to an increase in lifetime fuel demand for those vehicles of over 336 million liters (89 million gallons) of gasoline and diesel, and at an environmental cost of \$2.3 billion. This equates to an environmental cost increase of \$169 per gasoline or diesel passenger car sold in North America in 2015. As another example, improved skin-type plastic packaging for sirloin steak can cut food waste by almost half compared to conventional plastic packaging (34 percent waste to 18 percent waste) with environmental savings of \$606 per metric ton of beef sirloin sold. This equates to environmental savings of over \$2.2 million for every additional 1 percent of sirloin steak sold in improved packaging in the USA. This case study illustrates the significant environmental net benefits that plastic food packaging can deliver where it helps to avoid the waste of resource intensive food products.<sup>88</sup>

On a national level, to substitute the 14.4 million metric tonnes of plastic packaging in the six packaging categories analyzed in one study, more than 64 million metric tonnes of other types of packaging would be required. The substitute packaging would require 80 percent more cumulative energy demand and result in 130 percent more global warming potential impacts, expressed as CO2 equivalents, compared to the equivalent plastic packaging.<sup>89</sup>

A study by Denkstatt which looked at the impact of plastic packaging on life cycle energy consumption and greenhouse gas emissions in Europe showed that substituting plastic packaging with other materials would on average increase the respective packaging mass by a factor 3.6. The study also showed life cycle energy demand would increase by a factor 2.2 or by 1,240 million GJ per year, which is equivalent of 27 Mt of crude oil in 106 VLCC tankers or comparable to 20 million heated homes.

Additionally, greenhouse gas emissions would increase by a factor 2.7 or by 61 million tonnes of CO2-equivalents per year, comparable to 21 million cars on the road or equivalent to the CO2-emissions of Denmark.<sup>90</sup>

It is our conclusion that plastic is the best overall material to use for a variety of reasons and these studies show over and over again sustainability is a success story of our material.

Thank you again for the opportunity to testify and for your follow-up question.

\* \* \*

Dr. LOWENTHAL. Thank you for your testimony, Mr. Radoszewski.

I am going to remind the members of the Committee that Rule 3(d) imposes a 5-minute limit on questions. And now, the Chairman is going to recognize Members for any questions they may wish to ask members of the panel or the witnesses.

<sup>86</sup> https://plastics.americanchemistry.com/Reports-and-Publications/LCA-of-Plastic-Packaging- Compared-to-Substitutes.pdf.

<sup>87</sup> https://www.oregon.gov/deq/FilterDocs/LifeCycleInventory.pdf.

<sup>88</sup> https://plastics.americanchemistry.com/Plastics-and-Sustainability.pdf.

<sup>89</sup> https://plastics.americanchemistry.com/Education-Resources/Publications/Impact-of-Plastics- Packaging.pdf.

<sup>90</sup> https://denkstatt.eu/download/1994/.

I am going to recognize myself for 5 minutes of questions. My first question goes to Dr. Jambeck.

I want to follow up on something you have said, but also something that the Ranking Member spoke about in his introduction, where he said there is no real problem here in the United States, the real amount of plastics in the ocean really come from other countries, Asian countries and African countries.

So, Dr. Jambeck, in your work, how much of the waste is entering the oceans from China, Vietnam, and other southeastern Asia countries. Can you tell us, is this the real picture of the origins of the waste?

Can you tell us more about the full impact of the United States' role in contributing to oceans debris and plastic waste?

And has that been partially hidden by our reliance on exporting our waste primarily to Asia?

Can you respond to that? That is really how it was framed.

Dr. JAMBECK. Yes. That is a big question.

But, certainly, when we first did those calculations of the global impact of plastic into the ocean, we couldn't take into account that import-export aspect. So, what we did see were these influencing factors—really rapidly developing economies, where infrastructure to manage the waste that comes with the increased waste generation, that comes with economic growth, that infrastructure was lagging behind.

The areas that have been referred to here, so many of those rapidly developing economies, is where we saw the most leakage. But as I mentioned in my testimony, our perperson waste generation rate is two to six times that within the United States. And if we look at leakage as a percentage of what we generate, the reason the United States is the only highincome country within the top 20 countries within that original paper is because of our waste generation rates.

So, in terms of a contribution to the global plastic quantity of waste, the 6.4 million that I mentioned—or billion, excuse me—we are a major contributor.

So, what has become an issue that started in the 1990s, in terms of our single stream recycling, to make it easier we can put everything in one bin. That meant our commodities, as well as the WTO encouraging global trade, and China needing material for manufacturing, becoming the manufacturing hub of the world, that set up this rapid increase in exporting of our recycled materials. And for me, we looked at recycled plastic. Over half of that had been going to China until they stopped that in the end of 2017, which caused a cascade impact on our recycle industry within the United States itself. So, that has been a major problem, because we were relying on lower-income countries to manage that material, in many cases with China having trouble managing their own, and then us exporting on top of that. That contributes to pollution in those countries, as well.

So, it is very interconnected and complex, but I hope that clarifies some.

Dr. LOWENTHAL. Thank you. I want to talk a little, raise some questions about—we know about the waste and plastics, and how much going into the ocean. But the question is how does this impact species?

The first question is, we have just seen the IPBES—I hope that I pronounced it right report that was released earlier this year that included plastic pollution as a threat to marine biodiversity. So, it is seen as a threat.

My first question is, Mr. Danson, do you know if plastic is affecting species that are in danger of extinction?

We are trying to understand not only how it gets into the ocean, but what some of the impacts are.

Mr. DANSON. Some of the impacts. Turtles, every species of turtle, is either on the endangered species list or close to it. And every species of turtle has ingested plastic. Plastic doesn't go away completely. It just breaks down into smaller and smaller pieces, so a turtle or a sea mammal or another fish may ingest that plastic. They think that they are full, because their stomachs are full of plastic, so they stop eating and they starve to death.

Albatross end up dipping into what they think is some sort of something they like to eat in the water, but it is plastic. Then they feed it to their child, their little bird, and the bird dies for the same reason; they starve to death.

So, yes, it is having an impact on whales, on many species.

Dr. LOWENTHAL. Thank you. I think my time has been up, so I am going to yield. I will now call upon Representative Graves, who looked very good sitting on the Democratic side there for a while, and we welcome him back.

[Laughter.]

Mr. GRAVES. Thank you, Mr. Chairman. I have recruited a number of your Members to come to our side.

Dr. LOWENTHAL. Are you coming to my district this weekend? Mr. GRAVES. I look forward to it. And I want to make note—Mr.

Lowenthal and I, I was arguing with him awhile back and I said, you need to come see the people that I represent, the communities that I represent, so you understand why I say the things that I do, and why I vote the way that I do. And to his credit, he came down and spent 3 days in Louisiana. And I put him on a boat, an airboat. We put you on an airplane or a helicopter, maybe, took him all over the place, made him eat crawfish, all sorts of things plastic-free crawfish.

So, I do want to thank you, and I am looking forward to going over to your part of the country-

Dr. LOWENTHAL. It is going to be great.

Mr. GRAVES [continuing]. To see if we can talk some wisdom into those people.

[Laughter.]

Dr. LOWENTHAL. But now you have to ask questions. Now you have 5 minutes. Thank you.

Mr. GRAVES. No, seriously, thank you very much. Dr. LOWENTHAL. Thank you.

Mr. GRAVES. I appreciate the friendship and I am looking forward to the opportunity to meet with some of your constituents. Thank you all very much for being here. And I want to be clear that I very much appreciate all of your efforts to remove plastic from the waste stream, a goal that I very much share. I represent part of the coast of Louisiana, and one of the top commercial and recreational fishing destinations and producers in the United States. And not just fishing for fun, but for subsistence, and a really important part of our culture, community economy in south Louisiana.

Look, we can talk end game for a minute, but I am curious. There is a huge part of the waste stream that exists right now. You have plastic in the oceans. You have plastic that is somewhere in the recycle chain, as we know, with what China has done.
What do we do right now, just putting the long-term aside, looking at the incredible waste streams that are in the ocean—and I am well aware and supportive of some of the legislation that we have pushed out of the House to deal with that. But what do we do with the current waste stream of plastic?

The current waste stream that is supposed to be recycled, but with a China ban has created some problems with where it goes, what do we do with the plastic that is in the ocean?

If you were king for the day, could make any decision, what would you do?

Mr. Danson, I would like to ask all of your opinions.

Mr. DANSON. I would reduce single-use plastic. It is designed to live forever, and yet you use it once and throw it away. You take the easy things like that, that aren't really necessary——

Mr. GRAVES. Can I just clarify my question, though?

My point, though, is you have plastic that has already been singularly used, and so it is already somewhere in the waste stream. Whether it is in our oceans, it is somewhere in the shipping or somewhere, where it is going to be recycled, but it is somewhere in the waste stream already. How do we handle that waste stream? Mr. DANSON. I am not sure. If it is in the ocean, I am not sure you can. It is like oil. Once it is in the water column, you are not going to get it out. You may be able to scoop some of the obvious bigger pieces out. You can do beach cleanup, and all of that. But really, compared to the amount of plastic that is about to be produced in the next 20, 30 years, it is going to be scaled up. You just can't compete with the amount of plastic production by recycling and picking up on the beaches.

Mr. GRAVES. Thank you. Mr. Parras?

Mr. PARRAS. What I see in our neighborhoods and communities all over the country is that plastic, it is actually made to be disposable, it seems like. It is affordable because it is plastic, so what happens is that people just don't consider it as trash, or as valuable, so they get rid of it. And until we start actually either charging more for the production of plastic so that we can have major cleanups, that may help.

Mr. GRAVES. Thank you. Dr. Jambeck—and I just want to reemphasize I am talking about the existing load that is there. I am interested to hear—our last witness talked a little bit about some of the technologies moving forward, but please.

Dr. JAMBECK. Sure, so quickly, what is already in existence, probably the easiest thing to grab are nets, something that your area is well familiar with, and they are one of the materials, typically nylon, very valuable, and could be recycled.

The problem with what already exists is the diversity of plastic that is there, the challenges with recycling that. Most of it is getting landfilled here in the United States, so that is not the best thing. We wish that more of it could be recycled.

Mr. GRAVES. Thank you.

Mr. RADOSZEWSKI. Thank you. Today, our industry, the four value components of our value chain, from the resin manufacturers, the machinery manufacturers, processors, and end users are all actively engaged in recycling and re-use of these products, ranging from sorting to the plastics that are most predominately used in recycling, PET and high-density polyethylene, and then also developing technologies that can sort out the other materials and develop enough of a waste stream so that they can be used in applications.

The other technologies that are being used right now are chemical recycling, in which we can take the products back to their basic form, re-polymerize it, and use it again in food contact packaging, where before, if it is recycled, we can't use it in food packaging. So, these are technologies that we are actively involved in right now.

Mr. GRAVES. Thank you. I yield back.

Dr. LOWENTHAL. Thank you. I now recognize Representative Case for 5 minutes.

Mr. CASE. Thank you, Chair. The Ranking Member asked two, I think, good questions.

The first is that he asked what exactly is the problem, and the second question that he asked was why should Americans take the blame for the excesses of the rest of the world. Those are two good questions in this debate.

As to the first question, I will give a couple of examples from my perspective. In the state of Hawaii, we have the largest marine monument in our country, Papaha¯ naumokua¯ kea National Marine Monument. And there we get somewhere around 52 metric tons of marine debris, almost all ghost fishing gear, every year. Every year.

Now, why is that a problem? Well, it wrecks coral reefs, which are endangered around the world, and it degrades into smaller parcels, which then are ingested by our marine life. We have 1,400 Hawaiian monk seals left in the entire world, and declining. They get entrapped in this debris and die. That species is highly endangered. We have invasive species from elsewhere in the world hitching a ride on ghost fishing gear to Hawaii, the endangered species capital of the world, where we cannot take that kind of external impact.

We have in Hawaii—I went, on the first World Reef Day on June 1 of this year, to the north shore of Oahu to a beach in Kahuku, where I tried to clean up a coastline with Sustainable Coastlines Hawaii, one of many grassroots organizations across our country trying to do something about it on a micro level. A beach that I used to walk on that was pretty white is now all different colors: green, yellow, red. Very small particles of plastics not degraded, but down into the level of ingestion at the very lowest levels of marine life. Now, that is what the problem is.

As to the Ranking Member's second question, why should we take the hit when the rest of the world isn't doing anything about it. I think that is a really legitimate question, because it reminds me greatly of the debate over climate change, where, essentially, the same question is posed: Why should we reduce our emissions when the rest of the world is not doing that?

And that leads us to international agreements, as what I can see as being one of the only ways to get at this problem from an international perspective.

So, Mr. Danson, does Oceana partner with international organizations toward an international solution to plastics in the ocean, given that it does put us at a disadvantage for us to unilaterally curb our plastics use from several perspectives, and yet we need to do it. Cities and counties and states throughout the country are doing that. The City of Honolulu is doing it right now. Are you partnering with the rest of the world to try to find those international agreements?

Mr. DANSON. Yes, I believe we are. I think there are literally thousands, or at least 1,000 groups around the world working on plastics. This is a united effort. I can get you more specifics when I talk to the staff of Oceana.

I mean, we haven't talked about climate change and greenhouse gases, but plastic is such a huge part of that story. I don't see how we cannot address our plastic, our greenhouse gas emissions—and if we don't do that, how we expect the rest of the world to follow along.

So, yes, sorry, that is my-

Mr. CASE. OK. Thank you very much.

Mr. Radoszewski, you stated in your testimony that you and your industry are supportive of Save Our Seas 2.0, which is a bipartisan, bicameral bill introduced in both the House and the Senate, and that calls for much greater studies, some incentives at the Federal level, but it also calls for pursuing international agreements that would curb plastic use, especially singleuse plastic use around the world.

And your testimony sounded to be inconsistent with that position, that part of Save Our Seas 2.0. Are you supportive of pursuing international agreements whereby the entire world would agree to a reduction in plastic use and a reduction of dumping of plastics into the oceans?

Mr. RADOSZEWSKI. I would say we are involved and eagerly working with international organizations to find solutions to the problems that exist today. We are engaged with—whether it is the British Plastics Union, the Canadian Plastics Industry Association, the New Zealand Plastic Association, working in consortium with them to define those abilities to minimize the waste in the ocean, and in the land, as well.

Mr. CASE. OK. That doesn't sound like what I am talking about. It sounds like you are working with the rest of the plastics industry around the world to manage it going into the oceans, but not necessarily reducing it.

Mr. RADOSZEWSKI. Reducing or reusing or recycling, there are a lot of different options that we are looking at. And in the Save Our Seas 2.0, there are many parts of it that we do like and other parts that we would still like to negotiate with.

Mr. CASE. OK, thank you.

Dr. LOWENTHAL. Thank you. I now recognize the Ranking Member for 5 minutes of questions.

Mr. McClintock.

Mr. MCCLINTOCK. Thank you, Mr. Chairman.

First, I don't think Mr. Case was listening very carefully to what I said. I was referring specifically to properly-disposed-of plastics, plastics put in landfills, incinerated or recycled, none of which gets into the ocean.

And we know that America accounts for less than 1 percent of plastic marine pollution.

So, even if we went to the extreme of banning all plastics in the United States, in addition to having a devastating effect on the economy, it would at best affect just 1 percent of plastic pollution in our oceans.

But Mr. Radoszewski, Dr. Jambeck asked a very intriguing question. Think about how much plastic you touch every day. Isn't that an indication of how useful plastic has become in our daily lives?

Mr. RADOSZEWSKI. Absolutely. If you look at what plastics have replaced in the past, whether it is glass, paper, steel, aluminum, the reason why there is so much plastic is it is the best choice in terms of many of the packaging applications that it finds itself-

Mr. MCCLINTOCK. Isn't her question also a warning of how our quality of life would decline if the left is successful in restricting or banning it?

Mr. RADOSZEWSKI. Well, I would think a lot of things that we have taken for granted today would be gone, and the accessibility to those foodstuffs that give us a higher quality of life, not only to Americans on the East and West Coast, but in the middle of the country, and poorer areas, as well. The availability to get foods to different parts of the world because of lower transportation costs, and the food stays safer and healthier and fresher are all reasons why the quality of life, not only in the United States but across world, has increased.

Mr. MCCLINTOCK. I think Dr. Jambeck's question also begs a correlated question. Let's think about everything that we touch every single day. Everything is either mined or it is grown, is it not?

Mr. RADOSZEWSKI. I would think that would be right.

Mr. MCCLINTOCK. I don't know of a single exception to that. And that then opens a new question, and that is, what is the alternative to plastics? I used the example of a toothpaste tube. What would be the alternative to that?

Mr. RADOSZEWSKI. Well, I think, even in your original testimony, you mentioned what it used to be. And, as far as we know, the only thing we could do is go back to what it was. And that would mean glass bottles. That would mean lead, I think, was what was once used in toothpaste tubes, because of the softness of it.

So, if you go backward, you are talking about materials that have a higher carbon footprint, take more energy to produce, usually weigh more. The transportation costs also increase, so you have that aspect, as well.

Mr. MCCLINTOCK. So, at this juncture in our technology and science and advancement of our civilization, plastics are the most environmentally friendly alternative that we have, if we are to engage in the commerce that makes our civilization possible, is it not?

Mr. RADOSZEWSKI. I think that is very right. In fact, again, I go back to the point of let's look at food packaging. The ability to get a bratwurst at any place in the country at any time because it is wrapped in plastic and has a foam board packet, which is made of styrene, makes it accessible to everybody. Your meat stuffs, your sausage containers for your breakfast patties, all those are packaged in plastics because they get product to the shelf economically, safely, and fresh.

Mr. MCCLINTOCK. I am curious, Mr. Danson. How are we going to get our toothpaste, for example? How do you propose that we package our toothpaste in the future? You want to ban plastic containers? You want to go back to metal tubes or glass jars?

Mr. DANSON. You know, I don't really know the answer to that.

Mr. MCCLINTOCK. Well, that is the problem, isn't it? I have not heard a single alternative offered by the critics of plastics. And I think it has become very clear that plastics we have found to be a far better solution, economically and environmentally, to the materials that we have used in the past.

Mr. Radoszewski, tell me how a ban on single-use plastics would impact the overall economy.

Mr. RADOSZEWSKI. I think it would be detrimental to it. It could have an effect of putting people out of work. I don't think there is a quick response to supply the demand that the marketplace has created for these products. So, you would have a shortage of goods. You would have an economic decline because of lack of innovation of materials that we are seeing in the plastics industry. There is a whole host of things that would be affected immediately with some of these immediate bans-

Mr. MCCLINTOCK. And what would happen to consumer prices?

Mr. RADOSZEWSKI. They would go up. I mean it is a simple example of supply and demand. If the demand is not satisfied by the supply, the price goes up.

Mr. MCCLINTOCK. Well, our automobiles, for example, instead of using plastic materials, would go back to using metal materials. I mean, I am just looking at these nameplates right here. They are plastic. In a previous day, they were brass, much more expensive and much harder on the environment to mine. Is that correct?

Mr. RADOSZEWSKI. It is. And, in fact, if you look at the CAFE standards, one of the reasons the automobile industry has been able to meet those standards over the last couple of decades is because of the incorporation of higher-performing plastics that do the same performance as metal——

Mr. MCCLINTOCK. So, once again, it is blame America first, let's harm the American consumer, even though the American consumer is responsibly disposing plastic products, and without any alternative. That, to me, sounds almost childlike.

I yield back.

Dr. LOWENTHAL. Thank you, Ranking Member. I now call upon Representative Cunningham for 5 minutes of questions.

Mr. CUNNINGHAM. Thank you, Mr. Chairman. And thank you for holding this hearing today on an issue that is near and dear to my heart, and also our constituents in the 1st District of South Carolina, which stretches from Charleston all the way down to Hilton Head.

This issue is certainly on the minds of South Carolinians, many of whom dedicate their free time to support local beach cleanups in an effort to preserve our beautiful, God-given natural resources. And I am proud to represent so many of these conservation leaders. The local Surfrider Foundation chapter in my Congressional District hosts beach cleanups almost every single weekend.

And we also have Andrew Wunderley of the Charleston Waterkeeper, who has made it his livelihood to protect and restore the quality of Charleston's waterways, while fighting for the right to swimmable, drinkable, fishable water.

And, today, I actually came up here from Charleston with some of the plastic treasures that were recently found on our shoreline over the weekend from the Goose Creek Reservoir, which is the source of the Goose Creek water supply. So, let's see what we have here today and this was just found this weekend.

It looks like we have a used piece of Styrofoam here. We have a plastic water bottle; a single-use straw; a single-use plastic bag, and this actually looks like it has been kind of shredded or nibbled on, more than likely ingested by some type of marine life, this is what is left of it right now; some other straw, a shredded straw— we have all seen the pictures of sea turtles ingesting these and the damage that causes; a glass jar; and it looks like a potato chip bag, plastic.

And this isn't abnormal, unfortunately. This has become kind of the norm of what washes up on our shore lines or into our water-ways every single weekend, and a lot of people in this room are aware of it.

In fact, earlier this year NOAA published a report on the economic impacts of marine debris. And without objection, I would like to enter this report for the record.

Not surprisingly, this report found that getting rid of debris from our beaches can have a significant positive impact on the tourism economy. That is kind of a no-brainer.

Mr. Danson, every year the Ocean Conservancy's International Coastal Cleanup Report shows the most frequently found items on the beach. In 2017, data showed, for the first time, that the top 10 most commonly found items were all made of plastic. And that trend continued in 2018.

So, Mr. Danson, is what you saw here today, is this typical of the items typically found in beach cleanups, in your experience?

And how do these discoveries help shape policy?

Mr. DANSON. Well, they are all single-use plastics, which is something we would like to reduce. They are all very convenient and easy for us to use in our everyday life, but create incredible problems, everything from greenhouse gases to sea animals dying from ingesting it. That is our disposable lifestyle, of which I am part of. It is very hard to deal with that every day.

But people are coming up with solutions. There is a toothpaste called Bite that now comes in a little jar that is a powder, and you add water. That creates jobs and money and taxes. So, there are alternatives that we need to find.

It has been incredibly useful, and now it has become incredibly dangerous. And I think that is the argument, not that the left or the right has any monopoly on being smart about things. It is this is a problem for all of us, and we all need to find ways to do it. And I do believe we are capable of that.

Mr. CUNNINGHAM. I appreciate it, Mr. Danson, and I appreciate you all being here today.

Unfortunately, my time is coming to a close. I know there has been some discussion here today as far as where the United States is, as far as the polluting and cleanup and everything. But I think we should all agree that the United States of America is a leader, and we should lead on this issue. And no matter where we fall in the list of polluters, we should be leading by example and being more responsible, being more of like a Sam, instead of the Norm, if you will.

[Laughter.]

Mr. CUNNINGHAM. But just being out in the front on this, and recognizing that this is not sustainable, and we have to do every single thing in our power to make that come to an end.

So, I appreciate the work you all are doing, I appreciate the time here today. And, with that, I would yield back.

Dr. LOWENTHAL. Thank you, Mr. Cunningham. And I now recognize Congressman Sablan for 5 minutes of questions.

Mr. SABLAN. Thank you very much, Mr. Chairman, for holding today's hearing.

In my first few months here in Congress, in my first year, I had this naïve thought. If there was a possibility for some committee members to get on an airplane and fly over this garbage patch that is in the Pacific—now it has a new name, actually—it is the Great Pacific Garbage Patch, and it is located just a little north of Hawaii, and right next to a place called Micronesia.

I come from the Northern Marianas, which is a part of Micronesia—called Micronesia because it is a lot of small islands together. And you take all of those islands together, all of them, and put them together, it is hardly a large part of this garbage patch.

We have in the Northern Marianas, islands that are conservation islands—and unless you are a scientist with a permit, you can't get on these islands. But there have been scientists who have gotten permits and gotten on and found, to their dismay, that they had to collect bags and bags and bags of garbage, plastic garbage.

I don't mean any disrespect to all of you, thank you.

Mr. Danson, sir, thank you very much for so many wonderful hours of great entertainment. I enjoyed your show, "Cheers."

I also noticed, among the four witnesses on the table, sir—Mr. Rado——

Mr. RADOSZEWSKI. It is OK. Call me Tony. How about that?

Mr. SABLAN. OK, Tony. Among all the four witnesses, you are the only one with a plastic bottle of water.

Mr. RADOSZEWSKI. Right.

Mr. SABLAN. Yes. I mean you really are for your product. [Laughter.]

Mr. RADOSZEWSKI. Sir, if you would like me to comment on that, I—

Mr. SABLAN. No, I am not asking you for a comment, it was just an observation, sir. You didn't have to bring that, because there are glasses of water in front of you.

But, you see, these Micronesian Islands, yes, we probably contributed to some of this debris. But we are not responsible for that debris, and that thing is floating and growing. And it is one day going to cover Micronesia. Micronesia is—the area is the size of the 48 contiguous states.

So, what do we do about that?

Dr. Jambeck, how much effort and resource would you think it would take to clean up this garbage patch?

Dr. JAMBECK. What is floating out there is only about 3 percent of what we think is going in every year. So, it is not a large amount. But you are absolutely right in that what is floating often ends up on islands like yours that sort of interrupt those currents. To be honest, the best way to sort of get that out is if it is ending up on land, and then cleaning that land, like they do in Hawaii. There are folks who are trying to design systems to collect out in the Great Pacific Garbage Patch. But there are a lot of resources that go into that, and that is similar to the analogy of mopping up your bathroom floor while the tap is on.

Mr. SABLAN. OK. Just imagine what it would be like for Hawaii if that garbage gets any closer and just keeps going on land, because tourism is their major industry.

I don't have an answer to the problem. I really don't. I do have a serious concern, because I eat a lot of fish, reef-caught fish, and tuna caught by trawling, and everything.

I agree that these things get into the fish, so it gets into what I eat, probably, most likelihood. But I don't know. I don't have an answer. I am not as smart as the four of you sitting at the witness table, but we do need to act on, get something going, and try to find a way to resolve this, and maybe find an alternative to plastic that is not going to hurt people's jobs, you know?

There has to be something. We are a much better Nation than we think we are, than we give ourselves credit for.

My time is up. Thank you, Mr. Chairman.

Dr. LOWENTHAL. Thank you, Mr. Sablan. Next, the Chair recognizes Mr. Neguse for 5 minutes of questions.

Mr. NEGUSE. Thank you, Mr. Chair, and thank you for hosting this important hearing.

The topic of plastic in our waters and oceans cannot be more pressing. A study conducted by the U.S. Department of the Interior and the U.S. Geological Survey, aptly and alarmingly called "It's Raining Plastic," was published in May, and found that plastic was found in 90 percent of rainfall samples in Denver and in Boulder, Colorado, which happens to be— Boulder, in particular—the area that I represent in Congress, amongst many others.

An earlier study found that people are swallowing an average of 5 grams of plastic every week, about the weight of a credit card. For my constituents, who are suffering from this reality every day, ultimately, for the people across this Nation and the world who are doing the same, it is imperative that we address this issue. It just so happens, Mr. Chair, quite fittingly—literally, 1 week ago, or a week-and-a-half ago, on October 16, 2019, a constituent

of mine—her name is Annie, she is a sophomore at Fort Collins Polaris Expeditionary Learning School in my district—wrote to me about this very issue, about the issue of microplastics in our world's oceans and water systems at large.

And in her letter she said, "I am such a small part of this world, but I want to do everything I can to fix this problem." I am certainly inspired by her commitment to fixing this problem, and am heartened by the Chairman's decision to host this important hearing, and my fellow Committee members in their attempt to address this issue collectively, and, of course, to the witnesses who have joined us, and to their testimony.

I will confess I had a number of competing scheduling commitments, from both a hearing perspective as well as meetings, but I was watching the testimony and some of the exchanges on the television in our office. And there was one exchange in particular that was a bit interesting to me, and I had noticed that Mr. Danson, you didn't have an opportunity to really respond to the question that was being posed by the gentleman from California, Mr. McClintock.

So, I would like to go back to the point that he made about toothpaste. In 1984, how old were you, Mr. Danson?

[Laughter.]

Mr. NEGUSE. I mean, if you are comfortable sharing it, of course. I don't want to—

Mr. DANSON. Tough question. I was born in 1947. Would you do the math for me? [Laughter.]

Mr. NEGUSE. I am a lawyer, not a mathematician, unfortunately. But I believe that that would put you at, what 34——

Mr. DANSON. Sounds right.

Mr. NEGUSE. Forty-three. I think that is right.

Dr. LOWENTHAL. No, 47.

Mr. NEGUSE. In 1984, when you were 43, what kind of—

Mr. DANSON. Thirty-three.

Dr. LOWENTHAL. Thirty-three.

Mr. DANSON. Go ahead. I am old. Go on. [Laughter.]

Mr. NEGUSE. That is all right. I don't want to get stuck on your age, Mr. Danson. What kind of car were you driving back in the 1980s?

Mr. DANSON. The 1980s? Mr. NEGUSE. Yes.

Mr. DANSON. A Ford Explorer for a while.

Mr. NEGUSE. A Ford. And I take it it probably wasn't an electric car, right?

Mr. DANSON. No. But I did have the first EV–1.

Mr. NEGUSE. All right. And I suspect you might have been renting back then, or you owned a home. Did your home have solar panels back then?

Mr. DANSON. No, it did not.

Mr. NEGUSE. No. And my point is this, the reason why I ask. I was born in 1984. I am 35 today. I have a daughter who is 14 months old. And I think a lot about the world that she will inherit. And much of the work that we do here in this Committee and in this Congress is about fighting to make sure that the world she inherits is a better one than we did.

The transformative changes that have happened just in the last 35 years since I was born have been dramatic, right? And you have chosen, amongst many other citizens in our country—and, of course, several of the panelists here—to try to make a difference, to adopt strategies in your own life and the way in which you conduct yourself to be environmentally

conscious and, of course, taking advantage of the technological capabilities that have also changed.

So, this notion that we can't adapt, that removing microplastics—suddenly we all will be amiss—with the realities of trying to replace the plastic tube that carries toothpaste, to me is a false choice. Fundamentally, we all collectively are going to have to adopt strategies that enable us to move into a future in which microplastics are not polluting our planet and in the communities that we are all so lucky to call home. That, to me, is what this hearing should collectively be about.

So, to the extent, Mr. Danson, that you would care to respond further, I know you did talk a little bit about some of the alternatives to toothpaste containers, and toothpaste brushes that are non-plastic options, but if you care to also illuminate further, or expound further on that—

Mr. DANSON. Just briefly, I do know that people will invent new things, and create more jobs, and not create stuff that is worse for the climate.

But just in general, if you are talking about your children, then you are talking about climate change. You just are. And you are talking about greenhouse gases. And if you are talking about greenhouse gases, and we are in the middle of a Committee about ocean plastic, you have to acknowledge that the plastic is coming from petroleum and chemicals, and that life span, from the time of production to it lying on a beach, is the equivalent, all of the plastic, as the fifth-largest emitter of greenhouse gases.

So, if you want to take care of your children, you have to start addressing these incredibly inconvenient things that we have all gotten used to, and enjoy. But they are no longer good for us, and they are going to land on our children and our grandchildren in a huge way.

Mr. NEGUSE. Thank you. I yield the balance of my time, and apologize to Mr. Danson for revealing his age.

[Laughter.]

—

Mr. NEGUSE. And with that, I yield back.

Dr. LOWENTHAL. The gentleman yields back. How old are you?

Mr. NEGUSE. Thirty-five.

Dr. LOWENTHAL. All right. [Laughter.]

Dr. LOWENTHAL. Thank you. I would like to thank the witnesses for their valuable testimony and the Members for their questions. I found this very interesting.

The members of the Committee may wish to have some additional questions for the witnesses, and we are going to ask you to respond to these in writing.

Under Committee Rule 3(o), members of the Committee must submit witness questions within 3 business days following the hearing, and the hearing record will be held open for 10 business days for their responses.

Just before I end, I want to introduce into the record a journal article from Volume 9 of the journal *Nature Climate Change* of 2019, which was a study that showed that the global life cycle greenhouse gas emissions from conventional plastics which were produced in 2015 were 1.8 billion metric tons of carbon dioxide equivalent. This is approximately the annual emissions, as I pointed out in my introduction, of 462 coal-fired power plants. That is what we are just talking about in terms of CO2 emissions. I want to get that formally into the record.

Mr. MCCLINTOCK. A point of order, Mr. Chairman. Dr. LOWENTHAL. Yes?

Mr. MCCLINTOCK. I am wondering whose time are you speaking on? Because we are out of questions. If we are, I am prepared to engage—

Dr. LOWENTHAL. No, I am just introducing something into the record.

Mr. MCCLINTOCK. And there is no objection.

Dr. LOWENTHAL. Thank you.

If there is no further business, without objection, this Committee stands adjourned. [Whereupon, at 3:43 p.m., the Subcommittee was adjourned.]

November 12, 2019

Chairman Jared Huffman United States Congress 1527 Longworth House Office Building Washington, DC 20515 Ranking Member Tom McClintock United States Congress 2312 Rayburn House Office Building Washington, DC 20515

RE: Written Testimony for October 29, 2019 Hearing from Kathleen Pitre, Chief Sustainability Officer at Ball Corporation

Chairman Huffman, Ranking Member McClintock, and members of the Committee:

I write on behalf of Ball Corporation, the world's largest aluminum beverage and aerosol can maker, to provide testimony for your October 29, 2019 hearing, "*A Sea of Problems: Impacts of Plastic Pollution on Oceans and Wildlife."*

Founded in 1880, Ball Corporation is the leading manufacturer of innovative sustainable packaging solutions to customers around the globe. In addition to our packaging solutions business, Ball also provides sensors and satellites to the federal government through our subsidiary Ball Aerospace. We employ 18,300 people in 90 manufacturing locations with operations in North and Central America, South America, Europe, Asia, the Middle East and Africa.

Sustainability is one of our top priorities at Ball and is supported by global policies, quantitative targets, and tools for performance monitoring. We strive to put the right people, processes and partners in place to help us create long-term shared value for our company and our stakeholders.

Ball is very concerned about the increasing amount of plastic that pollutes our waterways and oceans and believe fundamental change is required. If we want to mitigate, and even reverse, the plastic pollution crisis, government as well as business need to take action.

#### **Sustainable Packaging**

Packaging is critical to delivering consumer products safely, conveniently and in good condition, and it preserves and protects beverage, aerosol, and other products as they move through supply chains.

Relative to glass, plastic and other substrates, aluminum cans exemplify a circular economy. They are infinitely recyclable, easily collected and sorted, and are by far the package with the highest economic value in the recycling stream. Currently, the US recycles 50% of its aluminum cans, Europe recycles 75% and Brazil recycles 97%, given the right policy, aluminum is capable of getting close to a 100% recycling rate in the U.S, too.

By contrast, plastic is the least recycled substrate with only an estimated 5% of plastics being effectively recycled around the world, while 40% are deposited in landfills and another third end up in ecosystems such as our world's oceans and rivers. It is estimated that 8 million tons of plastic leaks into the ocean every year. This is the equivalent of dumping the contents of one garbage truck into the ocean every minute, and it's only getting worse. If nothing changes, the rate of pollution is expected to increase at the equivalent of two garbage truck's worth per minute by 2030 and four per minute by 2050. By then, there could be more plastic in the ocean than fish. 91

#### **Government Response**

The "take, make, waste" paradigm has created products that are extremely cheap to produce yet very expensive to be recycled. For many products, technical capabilities are insufficient to fully close the material loop and significant losses persist in material quality and quantity from established recycling processes. Simply put, these materials cannot be kept in the material loop; they are hard to recycle adequately and will eventually become trash. It is just cheaper to continue using the primary materials instead of recycled ones.

Since these products do not reflect the true cost of the environmental degradation they cause, both consumers and manufacturers have no incentive to change their habits, further exacerbating the plastic crisis. Communities everywhere are struggling to take in the sheer amount of plastic waste that enters the waste stream, and now that countries like China no longer accept our trash, this waste is increasingly landfilled or, worse yet, finds its way into our oceans and waterways. We need proactive government leaders to step in and instigate change.

In the absence of federal legislation, states across the nation have taken the initiative and begun to introduce measures to mitigate the growing environmental and human health crisis. These bills offer a range of solutions to plastic pollution, including recycling content minimums, extended producer responsibility programs, taxes, and even outright bans. While some of these might not be politically feasible at the federal level now, Congress has the responsibility to, at the very least, provide these states with the guidance, expertise and resources necessary to inform sensible policy.

 $\overline{a}$ 

<sup>&</sup>lt;sup>91</sup> Ball Sustainability Report, p. 5.

#### **Possible Solutions**

A circular economy strives to create favorable conditions for economically viable recycling, rather than developing lowest cost products that are not recycled and require expensive recycling technologies to be recovered. Instead of trying to develop end-of-the-pipe solutions, businesses must invest in creating truly circular products with the end goal of preventing waste in the first place.

While there are a variety of policy tools Congress could use catalyze change, we believe there are three areas where legislators can start:

- *Define Recyclability*: Currently, there is no single yardstick for measuring "recycling" and, as a result, businesses have inappropriately twisted this word to give the façade that their products are recyclable. Recyclability claims suggest that it is a great achievement when a product is recyclable. The truth is that recyclability is only an achievement when a product can be consistently and infinitely recycled, and the material can be kept in the loop without loss in material quality. Congress should clearly define "recycling" so that it reflects the goals of circularity rather than another marketing ploy.
- *Promote Smart Packaging Design*: Many products today are made of multiple materials and consist of different pieces that vastly complicate sorting and processing. Congress should incentivize industry and business to use homogenous products - those made of only one material or designed for easy disassembly - that do not require complex processing in order to be reused or recycled.
- *Offer Technical Assistance*: As states like California, Massachusetts, Washington and many others begin considering legislation regarding plastic, the federal government and its agencies, at the very least, should act as a resource for technical assistance. Many of these bills propose sweeping changes to the states' waste management industries specifically, and to the economy more broadly. The federal government should be a resource for every state, no matter their policy preferences.

Establishing the right policy is a key component to achieve a truly circular economy. Opening an honest discussion about how we design and recycle packaging materials is the place to start. We cannot recycle our way out of this problem. Rather, we need to develop packaging solutions with circularity in mind from the beginning. This is the only way we will begin to stem the tide of plastic in our oceans.

We commend you for scheduling this hearing and thank you for your work on this important national matter.

### **SUBMISSION FOR THE RECORD BY REP. LOWENTHAL**

GOVERNMENT OF THE DISTRICT OF COLUMBIA Department of Energy and Environment

#### **NOV 13 2019**

l

Representative Jared Huffman Chairman Subcommittee on Water, Oceans, and Wildlife Natural Resources Committee 1324 Longworth House Office Building Washington, DC 20515

Representative Tom McClintock Ranking Member Subcommittee on Water, Oceans, and Wildlife Natural Resources Committee 1329 Longworth House Office Building Washington, DC 20515

Subject: Written Testimony for recent U.S. House of Representatives hearing entitled *A Sea of Problems: Impacts of Plastic Pollution* on *Oceans and Wildlife*

Dear Rep. Huffman and Rep. McClintock:

Thank you for your interest in addressing the impacts of plastic pollution on the world's oceans. Plastic pollution is one of the great environmental challenges of our time and will not be solved without robust participation from federal, state, and local governments. We welcome this opportunity to provide written testimony and stand ready to work with you on further efforts to address this issue.

The District has been a leader in the nation for over a decade on addressing trash, particularly plastic materials, in our local waterways. According to a 2015 article published in the journal, *Science,* researchers estimate over 8 million metric tons of trash enter the oceans annually from land-based sources.<sup>92</sup> In a heavily urbanized area like the District, a large portion of that trash comes from litter being conveyed via storm sewer and combined sewer systems to estuaries like the Potomac and Anacostia Rivers. In response to this problem, the District, in collaboration with U.S. Environmental Protection Agency (EPA) and upstream jurisdictions, established a total maximum daily load (TMDL) for trash in the Anacostia River. As a result, the District is compelled by EPA and our own priorities to reduce trash in the Anacostia River as part of our efforts to make the Anacostia fishable and swimmable once more. We believe addressing trash, including plastic pollution, starts upstream in our streams, rivers, and estuaries. Trash, especially plastic, affects our local waterways as much as it does the oceans.

We are very proud of our accomplishments over the past decade and would like to share details of some of our efforts in hopes that this work can, and will be, emulated elsewhere throughout the nation. Three important components have helped us to effectively manage

<sup>92</sup> Jambeck, J.R., R. Geyer, C. Wilcox, T.R. Siegler, M. Perryman, A. Andrady, R. Narayan, & K.L. Law. 2015. Plastic waste inputs from land into the ocean. Science 347: 768-771.

trash in our waterways: regional partnerships, using sound science to inform policy, and taking multi pronged, innovative approaches.

#### **Regional Partners/Zips**

The issue of trash impacting the Potomac River watershed began over a decade ago thanks to a regional collaboration facilitated primarily by the Alice Ferguson Foundation of Accoceek, MD. Since 2005, the Alice Ferguson Foundation has held an annual Potomac Watershed Trash Summit in the DC metropolitan area. This summit brings federal, state, and local government agencies, elected officials, and non-governmental organizations together to discuss efforts to reduce trash in the watershed. This would not be possible without grant funding from the NOAA Marine Debris Program, which has been an invaluable partner in regional efforts to address this issue.

Example of trash condition s in Watts Branch, a tributary lo the upper Anacostia River in Washington, DC.

Over the years, participants have implemented key efforts discussed at this summit including a regional anti-littering campaign, innovative local policies for reducing trash, and regional collaborations to establish the TMDL for trash for the Anacostia, one of the most urbanized tributaries to the Potomac River. The summit brought together leaders from the District, the state of Maryland, local Maryland counties, EPA, and local advocates to reach common ground on establishing the TMDL. Without this regional partnership it is very unlikely this effort would have been successful. As we will highlight more specifically, several new innovative approaches for trash reduction have been implemented since that time.

In 2016, the District, Montgomery County, and Prince George's County reaffirmed their commitment to making the Potomac and Anacostia River free of trash by signing the Anacostia River Accord. The Accord was signed by the District's Mayor Muriel Bowser, as well as Montgomery County Executive Isiah Leggett, and Prince George's County Executive Rushern Baker. In addition, the Anacostia Watershed Restoration Partnership, housed at the Metropolitan Washington Council of Governments, has convened a trash working group to develop consistent methods for tracking and reporting trash reductions across all three jurisdictions. This is further evidence of the importance of regional partnerships at combatting the issue of trash in our waterways.

#### **Using Sound Science to Inform Policy**

One of the first things the District did to address the problem of trash in the Anacostia River was conduct a two-year comprehensive study of trash conditions. The District Department of Energy and Environment (DOEE) funded the Anacostia Watershed Society of Bladensburg, MD to conduct surveys of litter along the river and its many tributaries, and monitor trash loads from storm sewer outfalls. The study provided two important pieces of information: (1) data on the most common types of trash in the Anacostia River and its watershed and (2) data on total weight of trash entering the Anacostia River on an annual basis. The first dataset informed District policies targeted to address specific types of trash most common in our waterways such as single-use plastic bags and expanded polystyrene foam products. The graph below shows the most common types of trash found out of 44 different categories sampled along DC shorelines in the Anacostia River, its tributaries, Kingman Lake (a semi-enclosed lake in the Anacostia River), and land in the Anacostia River watershed. The District utilized the second dataset on trash loads to develop the trash TMDL and identify and strategically address hotspots in the watershed which are conveying above average amounts of trash to the river.

Graph displaying most common types or trash found by count in 2008 in the Anacostia River, its tributaries, Kingman Lake, and land in the Anacostia watershed.

Since 2016, DOEE has been working with the Metropolitan Washington Council of Governments to sample trash along rivers and streams throughout the District. We provide this data annually to U.S. EPA Region III. This work builds upon a larger monitoring dataset the Council of Governments has been collecting in the Maryland portion of the Anacostia River watershed since the early part of this decade, making it one of the most robust datasets for trash for a waterway anywhere in the nation. Having this data is imperative to making future strategic decisions for implementation and informing development of new policies.

Our local partners have also been monitoring for microplastics in local waterways. Water samples collected in the Anacostia River by Anacostia Riverkeeper in 2019 contained microplastic concentrations as high as 696 microplastic particles per liter. To provide some perspective, samples taken in another highly urbanized river, the River Thames in London, England, revealed concentrations as high as  $84.1$  microplastic particles per liter.<sup>93</sup> A recent report from the Chesapeake Bay Program Scientific and Technical Advisory Committee revealed that microplastics are ubiquitous throughout the Chesapeake Bay and its watershed (which includes the District); however more research needs to be done on the potential ecological effects of microplastics. The report recommends conducting an ecological risk assessment looking at the effects on multiple species of importance to the bay and its watershed. A copy of the report can be found at: https:// pub-data.diver.orr.noaa.2ov/marinedebris/midatlantic/FINAL.STAC%20Re port Microplastics.pdf.

#### **Multi-Pronged, Innovative Approaches**

As with most environmental challenges, there is no "silver bullet" for eliminating the harm trash poses to our waterways and wildlife. The District has devised a plan that utilizes innovative policies, trash capture technologies, education, and outreach.

As mentioned previously, our monitoring efforts helped us to determine the most common types of trash found in our waterbodies. The District utilized monitoring data described previously to justify the need to reduce three of the most common types of trash found during sampling: single-use plastic bags, expanded polystyrene foam products (commonly referred to as StyrofoamTM), and other food service ware.

In 2009, the District enacted the Anacostia River Clean Up and Protection Act (also known as the Bag Law) to create a five-cent fee on single-use plastic bags. Starting January 1, 2010, consumers in the District pay the fee at the time of purchase in a restaurant, grocery, liquor, or convenience store. DOEE employs an inspection team to ensure businesses are in compliance with the law. Revenue, fines, and other contributions generated by the law goes into the Anacostia River Clean Up and Protection Fund to pay for projects like trash capture devices, stream restoration, stormwater management projects, education, outreach, and administrative costs. In Fiscal Year 2019, the Department found that 77% of businesses inspected were in compliance with the law. More information on the District's Bag Law, including annual revenue and expenditure reports, are available at https;://doee.dc.gov/bugs.

 $\overline{a}$ 

<sup>93</sup> For more information, please go to the Anacoslia Riverkeeper story map, *Single-Use River: Microplastics in the Anacostia River,* at https://www.arcgis.com/apps/Cascade/index.html?appid=0ff0d351069a477c915570513 f01d082.

In 2014, the District enacted the Sustainable DC Omnibus Amendment Act, which includes restrictions on food service ware packaged and intended for consumption without further preparation. Specifically, a ban on food service ware made of Styrofoam<sup>TM</sup> (foam) took effect January 1, 2016, and the law requires food service ware to be made of recyclable or compostable materials starting January 1, 2017. Plastic straws were banned as part of the recyclable and compostable requirements in October of 2018. As with the Bag Law, DOEE inspects businesses to make sure they are in full compliance with the law. In fiscal year 2019, DOEE found that 97% of District businesses inspected were no longer using foam, and compliance rates with the new plastic straw and stirrer ban were rapidly increasing. Further information on the District's food service ware requirements is available at https://doee.dc. gov/foodseryiceware.

The District has also implemented innovative structural controls for capturing trash. Since 2009, the District has installed nine trash traps in the Anacostia River watershed. These traps have varied from proprietary products to custom devices designed by local non-profits. The pictures below display examples of the devices. These devices have primarily been funded by the Anacostia River Clean Up and Protection Fund and other local funding sources through grants to local nonprofits to design. install, and maintain these devices. The nonprofits also collect data on trash collected in the traps to further inform policy and management. Since installation of the first device in 2009, these devices together have helped capture and remove over 60,000 lbs of trash and debris from the Anacostia River and its tributaries.

Photo of a Bandalong<sup>TM</sup> liner trap designed and installed by Stormwater Systems of Cleveland, GA, along a tributary to the Anacostia River. The District has funded the installation and maintenance of nine structural controls like this one from funding sources such as the Anacostia River Clean Up and Protection Fund generated from the five cent fee on single -use plastic retail bags.

Lastly, the District has led many education and outreach activities over the years to change behavior. In 2010, DOEE funded the Alice Ferguson Foundation (AFF) to conduct a study of littering behavior that guided the development of an anti-littering campaign throughout the District. The campaign's central message, *"Your Litter Hits Close to Home,"*  was based on AFF's social marketing research that found people were most impacted by the effects litter has on their personal space, health, and well-being. Below is an example graphic from the anti littering campaign. Other local governments in the Potomac River watershed have adopted these campaign materials.

Example poster from the DOEE and Alice Ferguson Foundation Anti-Littering Campaign.

In closing, I want to again thank you and the Subcommittee on Water, Oceans, and Wildlife for your interest in this important subject. As the nation's capital, the District has an important role to play in restoring urban waterways. We have set the stage for reducing trash in our rivers and streams using multi-faceted, innovative approaches, but we are not done. We are truly alarmed by the potential impact of microplastics on our local waterways. Additional research is needed looking at the broader ecological effects of microplastics, including effects on living resources important to recreation and commerce.

I would encourage the subcommittee to peruse reports on our monitoring efforts. If you are interested in receiving copies, or have any other questions regarding our efforts to reduce trash in our waterways, please contact Matt Robinson of the DOEE Watershed Protection Division at matthew.robinson@dc.gov or (202) 442-3204.

Sincerely, Tommy Wells **Director** 

### **SUBMISSION FOR THE RECORD BY REP. LOWENTHAL, STRATEGIES TO REDUCE THE GLOBAL CARBON FOOTPRINT OF PLASTICS**

### *Jiajia Zheng and Sangwon Suh*

Over the past four decades, global plastics production has quadrupled [1]. If this trend were to continue, the GHG emissions from plastics would reach 15% of the global carbon budget by 2050 [2]. Strategies to mitigate the life-cycle GHG emissions of plastics, however, have not been evaluated on a global scale. Here, we compile a dataset covering ten conventional and five bio-based plastics and their life-cycle GHG emissions under various mitigation strategies. Our results show that the global life-cycle GHG emissions of conventional plastics were 1.7 Gt of CO2-equivalent (CO2e) in 2015, which would grow to 6.5 GtCO2e by 2050 under the current trajectory. However, aggressive application of renewable energy, recycling and demand-management strategies, in concert, has the potential to keep 2050 emissions comparable to 2015 levels. In addition, replacing fossil fuel feedstock with biomass can further reduce emissions and achieve an absolute reduction from the current level. Our study demonstrates the need for integrating energy, materials, recycling and demand-management strategies to curb growing life-cycle GHG emissions from plastics.

Global production of plastics grew from 2 Mt to 380 Mt between 1950 and 2015, at a compound annual growth rate of 8.4% (ref. [1]). Globally, 58% of plastic waste was discarded or landfilled, and only 18% was recycled in 2015 [1]. It is estimated that 4.8–12.7 Mt of plastic waste generated by coastal countries entered the ocean in 20103. Growing alongside the volume of global production and consumption of plastics are the diverse concerns on their impacts on the ecosystem and human health [4–7]. However, relatively little attention has been paid to their contributions to climate change. Although the chemical industry as a whole is responsible for about 15% of global anthropogenic GHG emissions [8], the magnitude of global life-cycle GHG emissions from plastics has yet to be quantified.

Various strategies to reduce GHG emissions from plastics have been discussed in the literature, such as replacing fossil fuel-based plastics with bio-based plastics [9–11]. Biobased plastics generally show lower life-cycle GHG emissions than their fossil fuel-based counterparts12. It is estimated that substituting 65.8% of the world's conventional plastics with bio-based plastics would avoid 241–316 MtCO2-equivalent (CO2e) yr–1 (ref. [13]). Both biodegradable and non-biodegradable forms of bio-based plastics are available on the market [14]. Bio-based non-biodegradable polymers such as bio-polyethylene (bio-PE) and bio-polyethylene terephthalate (bio-PET), also referred to as 'drop-in' polymers, offer virtually identical properties to their fossil fuel-based counterparts. However, bio-based biodegradable polymers, such as polylactic acid (PLA), polyhydroxyalkanoates (PHAs) and thermoplastic starch (TPS), display different mechanical and chemical properties [12]. Strategies to promote bio-based plastics have been initiated by the European Commission and countries such as Japan, Korea and Thailand [15, 16]. In 2017, the total global production of bio-based plastics reached 2.05 Mt, and is projected to grow by 20% over the next five years [17].

 $\overline{a}$

Low-carbon energy is another strategy to reduce the life-cycle GHG emissions of plastics. Under a 100%-renewable-energy scenario, the GHG emissions from US plastics production could be reduced by 50–75% (ref. [18]). Another strategy to reduce the GHG emissions from plastics is recycling, which reduces, in part, carbonintensive virgin polymer production [19] while preventing GHG emissions from some end-of-life (EoL) processes such as incineration [20].

However, the literature so far has focused on a subset of plastic types, mitigation options or geographical locations in isolation [18, 21]. Here, we develop a dataset that covers GHG emissions from resin production, conversion and EoL processes for ten fossil fuel-based and five bio-based plastics. We then integrate the dataset with projections of global plastics demand and GHG mitigation strategies. We evaluate the following mitigation strategies and their combinations:

- 1) Bio-based plastics. Fossil fuel-based plastics are gradually substituted by bio-based plastics until they are completely phased out by 2050. Although bio-based plastics can be derived from a variety of feedstocks, here we model corn and sugarcane given their dominance in the current market [11].
- 2) Renewable energy. The energy mix of the plastics supply chain is gradually decarbonized and reaches 100% renewables (that is, wind power and biogas) by 2050. Emissions under the current energy mix are modelled for comparison.
- 3) Recycling. Recycling rates of EoL plastics gradually increase and reach 100% by 2050. For comparison, we also model the emissions under a projected EoL management mix scenario and a 100% incineration/composting scenario.
- 4) Reducing growth in demand. The current annual growth rate of global plastics demand (4%) is reduced to 2%.

We examine these strategies as illustrative scenarios, rather than as realistic projections of future trajectories, with the purpose of envisioning their potentials for GHG mitigation. We acknowledge that achieving 100% recycling or renewable energy may be neither practical nor economically feasible in reality. Details on these scenarios can be found in Supplementary Table 1.

Our analysis shows that conventional (fossil fuel-based) plastics produced in 2015 emitted 1.8 GtCO2e over their life cycle, excluding any carbon credits from recycling (Figure 1). The amount corresponds to 3.8% of the 47 GtCO2e emitted globally that year [22]. The resin-production stage generated the majority of emissions (61%), followed by the conversion stage (30%). Of all plastic types, polyester, polyamide and acrylic (PP&A) fibres had the highest GHG emissions in both stages. The polyolefin family (polypropylene, PP; lowdensity/linear low-density polyethylene, L/LLDPE; and high-density polyethylene, HDPE), which accounts for nearly 50% of the world's plastics consumption, was also a significant contributor. GHG emissions from bio-based plastics are not considered for 2015 given their negligible market share (<1%).

The EoL stage accounted for 9% of total life-cycle emissions, excluding the carbon credits from recycling. Incineration was the dominant source of GHG emissions among EoL processes. Landfill generated the least GHG emissions, although the process handles the largest share of plastic waste (58%). The recycling process itself generated 49 MtCO2e. However, if the displacement of carbon-intensive virgin polymer production by recyclates is

considered, the GHG emissions of recycling would go down to negative 67 MtCO2e, and the total emissions from the EoL stage would be reduced from 161 MtCO2e to 45 MtCO2e. In this case, the total global life-cycle GHG emissions of plastics become 1.7 GtCO2e, or 3.5% of the global annual GHG emissions in 2015.

Figure 1. Global life-cycle GHG emissions of conventional plastics in 2015 by life-cycle stage and plastic type. Carbon credits generated by recycling are not included. Blue, orange and green represent the resin-production, conversion and EoL-management stages, respectively. The emissions from each stage are broken down by plastic type or EoL-treatment method, indicated with different shades of the corresponding colour. PUR, polyurethane.

Under the current trajectory, the global life-cycle GHG emissions from plastics are poised to grow rapidly (Figure 2a). The global economy produced 407 Mt of plastics in 2015, with an average annual growth rate of 4% between 2010 and 2015 [1]. Following this trend, annual plastics production is expected to grow to 1,606 Mt by 2050, and the life-cycle GHG emissions are expected to grow from 1.7 GtCO2e in 2015 to 6.5 GtCO2e in 2050, using the projected EoL-management mix change1, and maintaining the current energy mix (the baseline is the blue solid line in Figure 2a). If all plastic waste is incinerated by 2050, total annual emissions will reach 8.0 GtCO2e (a 22% increase from the baseline). Recycling all plastic waste, however, would reduce the emissions to 4.9 GtCO2e by 2050 (a 25% reduction from the baseline).

Figure 2. Global life-cycle GHG emissions of plastics under scenarios of different feedstock sources, energy mixes, EoL management strategies and growth in plastics demand for 2015–2050. a, Plastics demand grows at 4% yr−1 under the current energy mix. b, Plastics demand grows at 4% yr−1, and the energy mix decarbonizes by 2050. c, Plastics demand grows at 2% yr−1 under the current energy mix. d, Plastics demand grows at 2% yr−1, and the energy mix decarbonizes by 2050. Solid lines represent the projected EoL-management mix (Supplementary Table 10); whereas shaded areas represent ranges due to EoL options. The bars on the right side of each panel represent ranges due to different EoL options in 2050.

With a plastics demand growth rate of 4% yr−1, it has been estimated that a complete replacement of fossil fuel-based plastics with corn-based plastics would reduce global lifecycle GHG emissions of plastics to 5.6 GtCO2e by 2050 under the current energy mix and the projected EoL mix, which is 1.0 GtCO2e (or 15%) less than the baseline (Figure 2a). If all EoL drop-in plastics are incinerated and all EoL biodegradable plastics are composted, global life-cycle GHG emissions of corn-based plastics would increase to 6.7 GtCO2e. Recycling all EoL bio-based plastics, however, would reduce the emissions to 4.4 GtCO2e. Sugarcanebased plastics can further reduce global life-cycle GHG emissions of plastics to 4.9 GtCO2e, which is 1.7 GtCO2e (or 25%) less than the baseline, with a range between 5.8 GtCO2e (100% incineration/composting) and 4.0 GtCO2e (100% recycling). A 100% recycling scenario for fossil fuel-based plastics in our model results in similar, or even lower, emissions compared to bio-based plastics with the projected EoL mix (Figure 2a,b, sidebars). This implies that the recycling of conventional plastics may be as beneficial as using renewable feedstock.

An energy decarbonization scenario shows substantial potential to reduce GHG emissions (Figure 2b,d). On average, switching to 100% renewable energy would reduce life-cycle GHG emissions from plastics by 62% in 2050, assuming 4% yr−1 growth in demand. Even if fossil fuel sources (petroleum, natural gas and coal) serve as the sole feedstock for future plastics production, using 100% renewable energy can achieve 51% reduction (projected EoL mix) compared to the baseline, although the absolute total emissions would double the 2015 level by 2050. However, recycling all EoL plastics under 100% renewable energy allows 77%, 84% and 86% reductions in life-cycle GHG emissions from fossil fuel-, corn- and sugarcane-based plastics, respectively. This result shows that absolute reduction of emissions can only be achieved by combining aggressive deployment of renewable energy and extensive recycling of plastics.

Reducing plastics demand growth rate from 4% to 2% yr−1 reduces emissions by 56% (under the current energy mix) to 81% (under low-carbon energy) relative to the baseline in 2050 (Figure 2c,d). Using 100% renewable energy keeps the emissions virtually constant at the 2015 level for fossil fuel-based plastics with projected EoL mix, and replacing them with bio-based ones brings the emission levels down further. Among all the scenarios tested, the global life-cycle GHG emissions of plastics were the lowest under the 100% sugarcane-based plastics with 100% renewable energy combined with 100% recycling and reduced demand growth, which achieved 0.5 GtCO2e yr–1, or 93% reduction from the baseline. This demonstrates that a drastic reduction in global life-cycle GHG emissions of plastics would be possible in a technical sense, but it would require implementing all of the four strategies examined at an unprecedented scale and pace.

Figure 3 shows the breakdown of GHG emissions by life-cycle stage, for each kilogram of plastics derived from different feedstock types. The total life cycle GHG emissions for fossil fuel-based, corn-based and sugarcane-based plastics are on average 4.1, 3.5 and 3.0 kgCO2e per kg plastic in 2050, respectively, under the current energy mix (Figure 3a). Under a 100%-renewable-energy scenario, however, the average life-cycle emissions will be reduced to 2.0, 1.4 and 1.3 kgCO2e per kg plastic, respectively (Figure 3b). Plastics derived from renewable feedstock (assuming projected EoL mix) generate lower GHG emissions over the whole life cycle compared to their fossil fuel-based counterparts regardless of the energy system used.

The resin-production and conversion stages are major contributors to the life-cycle GHG emissions of all feedstock types under the current energy mix (Figure 3a). However, under the 100% renewable-energy scenario, incineration becomes the largest contributor to the total emissions for bio-based plastics (Figure 3b). Under the 100%-renewable-energy scenario, recycling generates fewer carbon credits, as the low GHG emissions of renewable energy undercut the carbon benefits of avoiding virgin polymer production.

In summary, our results show that none of the four strategies— namely bio-based plastics, renewable energy, recycling and demand management—can achieve sufficient GHG mitigation for absolute reduction below the current level on their own; only when implemented in concert can these strategies achieve the much-needed absolute reduction. Among them, decarbonization of the energy system—which is an economically more favourable option for GHG mitigation compared to the use of bio-based plastics [18]—shows the greatest potential. Even if fossil fuel feedstock is used as the sole source for plastics

production, a 100%-renewable-energy scenario will reduce the average life-cycle GHG emissions by half from the baseline emissions. If combined with extensive recycling or demand management, decarbonization of energy can maintain the current level of GHG emissions until 2050. Reducing GHG emissions even further to achieve absolute reduction from the current level requires large-scale adoption of bio-based plastics in addition to implementing all of the other three strategies examined.

Figure 3. GHG-emissions breakdown by life-cycle stage of plastics derived from different feedstock types under two energy-mix scenarios in 2050. a, GHG emissions under the current energy-mix scenario in 2050. b, GHG emissions under a 100%-renewable-energy scenario in 2050. Emissions results are based on the scenario with a 4% yr–1 growth rate for plastics demand and the projected EoLmanagement mix (Supplementary Table 10). Carbon credits generated by recycling are considered.

Going forward, we see both opportunities and challenges in reducing the life-cycle GHG emissions of plastics. The current global average plastics recycling rate of 18% (ref. 1) certainly presents substantial room for further improvement. The low price of fossil fuelbased plastics, however, is a key barrier to dramatically increasing recycling rates. Together with technological innovations in plastics recycling, fiscal policies, such as carbon pricing and incentivising recycling infrastructure expansion, should be considered to overcome such barriers [23, 24].

Replacing fossil fuel-based plastics with bio-based plastics is shown to play an important role in GHG mitigation. Nevertheless, our results show that the emissions of bio-based plastics are highly dependent on the EoL-management method chosen. Composting or incinerating bio-based plastic waste, for example, showed similar or even higher GHG emissions than the scenario in which 100% fossil fuel-based plastics were used under the projected EoL mix in 2050. Moreover, EoL management of bio-based—especially biodegradable—plastics requires systematic changes such as separate collection and recycling infrastructure, since inclusion of biodegradable plastics in the mix of conventional plastic waste can affect the quality of the recyclates [25]. Furthermore, composting of biodegradable plastics in home composting conditions or natural environments is much less effective than in industrial composting facilities [14]. Finally, the land-use implications of a large-scale shift to bio-based plastics require further research. In 2017, land use for bioplastics was reported to be 0.82 million hectares (or 0.016% of global land area), which would increase to 0.021% in 2022 under the projected market growth [17]. A complete shift of the plastics production of approximately 250 million tonnes to bio-based plastics would require as much as 5% of all arable land [26], which, depending on where they take place, may undermine the carbon benefits of bio-based plastics. The use of lignocellulosic or waste biomass as feedstock, and growing material crops in fallow lands, would alleviate the pressure of cropland expansion and associated GHG emissions from land-use change.

Our study shows that an aggressive implementation of multi-layered strategies would be needed in order to curb the GHG emissions from plastics. GHG-mitigation strategies are often implemented within energy, materials, waste-reduction and management policies in isolation. Our results indicate that absolute reduction in life-cycle GHG emissions of plastics requires a combination of the decarbonization of energy infrastructure, improvement of recycling capability, adoption of bio-based plastics and demand management.

 $\overline{a}$ 

# **CLEANING UP THE OCEANS: HOW TO REDUCE THE IMPACT OF MAN-MADE TRASH ON THE ENVIRONMENT, WILDLIFE, AND HUMAN HEALTH**

THURSDAY, SEPTEMBER 26, 2018 U.S. SENATE, COMMITTEE ON ENVIRONMENT AND PUBLIC WORKS, *Washington, DC.*

The committee met, pursuant to notice, at 10:05 a.m. in room 406, Dirksen Senate Office Building, Hon. John Barrasso (chairman of the committee) presiding.

Present: Senators Barrasso, Carper, Inhofe, Boozman, Wicker, Fischer, Rounds, Ernst, Sullivan, Cardin, Whitehouse, Gillibrand, Booker, and Van Hollen.

# **OPENING STATEMENT OF HON. JOHN BARRASSO, U.S. SENATOR FROM THE STATE OF WYOMING**

Senator BARRASSO. I call this hearing to order.

Today the Committee will examine the issues of man-made trash that is polluting the oceans, also known as marine debris.

While marine debris can range from metals, glass, rubber, paper, and textiles, the vast majority of marine debris is plastic.

Plastic plays an incredibly important role in our lives. As a doctor, I have seen firsthand how plastic can be indispensable in the field of medicine and healthcare. Similarly, plastic is crucial in virtually every aspect of modern society and economy, including the field of environmental protection. This doesn't mean, of course, that plastics should end up in our rivers, in our lakes, in our streams, and in our oceans.

This is an edited, reformatted and augmented version of Hearing before the Committee on Environment and Public Works, United States Senate, One Hundred Fifteenth Congress, Second Session, Publication No. S. HRG. 115–385, dated September 26, 2018.

It is estimated that around 8 million metric tons of plastic waste ends up in the world's oceans each year. While some of this plastic is dumped directly into the ocean, like discarded fishing nets, most of the plastic flows from rivers.

Experts believe that about 90 percent of all plastic pollution flows into the oceans from just ten rivers, eight of which are in Asia. It is estimated that Asia contributes to about 80 percent of all ocean plastic. Specifically, China, Indonesia, the Philippines, Thailand, and Vietnam are responsible for more plastic pollution than the rest of the world combined.

By now, many Americans have heard of the Great Pacific Garbage Patch. This is an area in the Pacific Ocean where currents have concentrated plastic and other man-made trash. It now stands as the world's largest concentration of marine debris.

Similar debris concentrations exist elsewhere throughout the world. In fact, plastic has been found in almost all corners of the ocean.

Plastic takes at least 450 years to degrade completely; sometimes much longer than that. In the meantime, the debris will continue to entangle and kill marine wildlife, as well as threaten human health. If little is done to stem the accumulation of plastic in the ocean, experts believe that by 2050 there will be more plastic in the ocean than fish, as measured by weight.

Earlier this summer, National Geographic dedicated its June issue to this problem. It is a remarkable cover where it looks like it is an iceberg, but actually it is an upside-down plastic bag. And I don't know is responsible for this, but Senator Whitehouse and I both had this on our desks in our offices and pointed to this as he and I were talking about another issue.

I think it is a remarkable effort by National Geographic to display in picture form something that we know is a major problem affecting——

Senator WHITEHOUSE.

[Comment made off microphone.]

[Laughter.]

Senator BARRASSO. I defer to my colleague from Rhode Island.

Senator WHITEHOUSE. Isn't this bipartisanship?

[Laughter.]

Senator WHITEHOUSE. Here is a visual demonstration.

Senator BARRASSO. Well, it says, "Some people see ocean plastic as a looming catastrophe worth mentioning in the same breath as climate change." I have it from the plastic standpoint. I am glad, Jonathan, that you, Dr. Baillie, National Geographic's Executive Vice President and Chief Scientist, are able to join us here today.

Environmentalists aren't alone in recognizing this problem. Plastic manufacturers also acknowledge we need to address this problem.

Earlier this summer, another one of our witnesses today, Cal Dooley, announced that he would extend his tenure atop the American Chemistry Council, as he said, to "fight the spread of mismanaged plastic waste and help lay the foundation for a sustained global industry effort to address it." Thank you.

Likewise, Coca-Cola, which is also represented here today and one of the world's biggest producers of plastic bottles, has taken steps to confront the problem. In January this year, Coca-Cola announced that it would "help collect and recycle a bottle or can for everyone it sells by 2030."

Today the Committee will want to hear what more can be and should be done. Specifically, we want to know what private industry, what local and State governments, what the Federal Government, and what international institutions should help do to address the crisis.

I would like to point out that today's hearing follows one that Senator Sullivan held as Chairman of the Subcommittee on Fisheries, Water, and Wildlife in May 2016. It also follows the efforts, as well, as those of Senator Whitehouse to pass the Save Our Seas Act, which I understand is under consideration as we speak.

I want to thank them for their leadership on this issue.

I am going to give each of you an opportunity to say what you would like, a few words, about that after I turn to Ranking Member Carper. This issue is very important to the Ranking Member, to whom I now turn for his opening comments.

### **OPENING STATEMENT OF HON. THOMAS R. CARPER, U.S. SENATOR FROM THE STATE OF DELAWARE**

Senator CARPER. Thanks so much, Mr. Chairman. Thank you very much for holding this hearing.

I really want to say to Sheldon and to Dan, thank you for your wonderful leadership. Thank you for demonstrating how we can work across the aisle on really important issues. I think we are going to make some real progress, including today. So, thank you both.

This is actually a timely issue for us in Delaware. Every year for 31 years we have done something called the Annual Delaware Coastal Cleanup. We start just north of Ocean City, Maryland all the way up to Pennsylvania, about 100 miles, and we pick up trash, all kinds of trash. This is a photograph that was taken at Fox Point State Park, not too far from actually Martha and I live in Wilmington.

We had a lot of kids who showed up. There were scouts and there were people who were just there for a good time and, frankly, for a good cause, and we netted about four tons of trash going up and down the Delaware coast on Saturday.

You might not believe the types of items we cleanup. No, you probably would believe it. From tennis balls, plastic water caps, lip balm containers, a metal baseball bat, and a whole lot more. Four tons is a massive amount of marine debris, and that is just from one cleanup weekend along Delaware's 100-mile coast.

Those numbers pale in comparison to the amount of trash in our oceans. As the Chairman has already mentioned, the infamous Great Pacific Garbage Patch, the largest mass of marine debris floating in the ocean, is over 300 times the size of Delaware and nearly the size of Alaska.

If you were able to lift Alaska up off the face of the earth and put one end of it on the U.S.-Canadian border, the other end would stretch all the way to Mexico. Imagine that. There is a massive marine debris floating in the ocean that is that big.

As we all know, all this debris has serious impacts on our water quality, on our wildlife, on our food chain, and while the extent of its impacts are not fully known, we know that hundreds of species interact with plastics. Plastic consumption can harm wildlife and all states of life. Recent research suggests it can also decrease reproduction rates. We also know that tiny plastic particles called microplastics may be present in our drinking water and in the food that all of us consume.

Cleanup efforts like the Delaware Coastal Cleanup provide hands-on opportunities for citizens of all ages to learn about this global problem and to contribute to the solution. Not just talk about it, not just worry about it, but to do something about it. However, most environmental experts agree that stopping debris from ending up in our waters in the first place is more of an urgent priority.

We thank all of our witnesses for coming today. We are going to hear about potential solutions from our esteemed panel this morning.

As Co-Chair and Co-Founder of the Bipartisan Senate Recycling Caucus, along with my Republican partner, Senator John Boozman, I want to mention recycling is one such solution.

Delaware is a little State. It doesn't have a whole lot of space for landfills, so we had to get serious not too long ago about recycling. As Governor, I signed two executive orders to improve and promote recycling. The first established a citizens' workgroup on recycling to evaluate recycling in our State. The second established a goal of a 30 percent diversion rate for recyclables from Delaware's solid waste stream.

Delaware's recycling activities continue to grow with the implementation of the universal recycling law in 2010, which eventually led to curbside recycling collection for all singlefamily households and commercial businesses. These practices work for both our environment and for our economy.

I am proud of our State's work, but while Delaware has made some strides, good strides, other States struggle. I will just say it is a mixed bag. I think we were late to the game. Other States were a little bit ahead of us. But we are making great strides now. Some other States and communities, frankly, aren't doing their share; they are not doing enough. Maybe we can inspire them.

In many places it is cheaper to dispose of recyclable materials in landfills. These items can then make their way into our waters, unfortunately. This problem worsened when China announced earlier this year that it would no longer accept plastic waste from other countries to convert into new plastic-containing products.

Why is that a big deal? Because China was previously taking 30 percent of U.S. plastic waste for recycling. We, as a Nation, will need to invest in better waste management and recycling infrastructure to address challenges like this. We also need to find creative ways to finance these investments. Further, we may want to consider proposals to incentivize the use of recyclable plastics for manufacturing purposes.

All that said, the Federal Government cannot undertake this effort alone. In the last several years, corporations and industry partners have stepped up and really led the way. Good for you.

To our witnesses today testifying on behalf of these partners, we are truly grateful for your work and for the commitments that you have already made to recycling and help prevent debris from entering our oceans.

Agreeing on solutions and figuring out how to implement them will not be easy, but I am encouraged by the strong bipartisan support and leadership of our two colleagues from Alaska and from Rhode Island. With their continued resolve and with the help of the rest of us, I believe we can put our heads together, put our hands together and make a real difference on this issue, and I look forward to doing so.

Thank you one and all.

Senator BARRASSO. Thank you, Senator Carper. Senator Sullivan, anything you would like to say?

## **OPENING STATEMENT OF HON. DAN SULLIVAN, U.S. SENATOR FROM THE STATE OF ALASKA**

Senator SULLIVAN. Thank you, Mr. Chairman and Ranking Member Carper, for holding this very important hearing today. This is important for the Country, for the world, for Rhode Island, for New Jersey. It is certainly important for my State, Alaska, which has more coastline than the rest of the lower 48 States combined.

The prevalence of marine debris on our shores is a chronic issue. As noted, this marine debris results from a number of man-made sources, including derelict fishing gear, poor solid waste management practices, major storm events, and everyday litter.

But, as the Chairman mentioned, this is a preventable issue. Of the plastics that enter the oceans from land, more than half comes from just five developing countries. In Asia, ten river systems, eight in Asia and two in Africa, contribute almost 90 percent of land-based ocean plastics. To me, this presents a huge opportunity to curb this issue at its source globally.

I want to emphasize what has already been stated, but for the media covering this hearing, hold your breath. This is a fiercely bipartisan issue.

[Laughter.]

Senator SULLIVAN. It does happen here. Matter of fact, it happens quite a lot. Senator Whitehouse, I am going to talk about all the great work he has done. Senator Booker also has been a huge champion of this.

To just give you a little sense of the work that has been done, this past year, Senator Whitehouse and I have engaged early and often with the EPA, the Commerce Department, the U.S. Trade Representative's Office, the State Department, the American Delegation to the G7, other countries in the G7, countries in the G20; and what has resulted is a growing strong commitment to pursue marine debris prevention goals through future international trade agreements and development aid agreements.

This is an important step forward, actionable step to impact curbing this man-made plight on our oceans that we all agree is a big problem.

Last Congress, Senator Whitehouse and I, in this Committee, as Chair and Ranking Member of the Wildlife Subcommittee, held a hearing on the issue of marine debris. Much of which came out of that hearing is now in our Save Our Seas Act, the SOS Act, which I am happy to report we think is going to be hot-lined and passed today, we hope, in the Senate.

It has already passed once. The House liked it so much they added a bunch of other elements to it, and we are going to try to repass it again here in the Senate today.

This bill would serve to strengthen the Federal response capabilities to marine debris disasters, combat land-based marine debris resources, and encourage interagency coordination in stemming the tide of ocean plastics and, importantly, encourage the Trump Administration to pursue international agreements with regard to this challenge. And I think, talking to the senior members of the Administration, they are already there, so we are hopeful this is going to become law soon.

Senator Whitehouse and I are also talking about an SOS 2.0 bill, and I know Senator Booker is interested in that as well. It is my hope that this hearing will help provide ideas and momentum for the goals on what we think would be a good followup bill.

Finally, again in the spirit of bipartisanship, last night I had the honor of presenting the International Conservation Caucus Foundation, the ICCF, Teddy Roosevelt International Conservation Award to Senator Whitehouse at an annual gala event. Although to make sure it stays a little partisan, I was glad to note that this was an award named after one of America's great Republican presidents.

Thank you again, Mr. Chairman, for holding his hearing and giving me an opportunity to speak on this issue. We look forward to a very good, robust discussion today.

Senator BARRASSO. Thank you, Senator Sullivan. Congratulations, Senator Whitehouse. The floor is yours.

### **OPENING STATEMENT OF HON. SHELDON WHITEHOUSE, U.S. SENATOR FROM THE STATE OF RHODE ISLAND**

Senator WHITEHOUSE. Thank you, Chairman Barrasso. I will note that Senator Sullivan, my friend and colleague, was quite restrained last night in his comparisons of the relative size of his State and mine, which I thought was a kindness certainly appreciated by the Senator from Rhode Island.

Let me first thank you, Chairman, for holding this hearing. You and the Ranking Member have been very great to work with. I appreciate your focus on this. It is, I think, a really productive opportunity for us and I am grateful to you.

I want to also thank you and the former Chairman, Senator Inhofe, sitting beside you, because both of you have been able to overcome the disability of living in landlocked States in order to take a very positive interest in the marine debris problem.

I want to particularly thank Senator Inhofe, who became an original co-sponsor of the SOS bill that Dan and I worked on. I appreciate his support and leadership for it. Senator Inhofe is a powerful legislator, and when he puts his shoulder behind something, it tends to happen, so I give him a lot of credit for his support for our Save Our Seas bill.

Senator Sullivan has been an incredible partner in all of this, and I want to pay a lot of respect to him for his work. We wouldn't have even had the original hearing had Senator Sullivan not been able to successfully negotiate with the Commerce Committee, particularly the Fisheries Subcommittee of the Commerce Committee, to allow this to go forward, because there are turf issues involved.

Fortunately, the chairman of the Fisheries Subcommittee of the Commerce Committee is also Dan Sullivan, so he was able to have that conversation with himself and reach an agreement to go forward in the Environment and Public Works Committee and have that hearing. It is from that hearing that the interest of Senator Inhofe and others was provoked, and from that hearing that the SOS bill went forward.

We do expect that it will pass the Senate by unanimous consent again today, with some of the additions that our friends who see a bill moving want to take an opportunity to add things to. That has been what has slowed it down. It has not been a lack of enthusiasm for the underlying bill; it has been other people saying, wow, something good is happening, let's see if I can get my thing on it.

So it has been a very, very positive experience and Dan's leadership has been phenomenal not only legislatively, but also with pushing really hard on the Administration to make this a policy priority in the Administration. He has been harassing the trade representative, the White House, the Department of Commerce. He has been very, very energized, and I appreciate that very much.

I also want to express my appreciation to our former colleague in Congress, Cal Dooley, who is here for the American Chemistry Council, and I would like to put into the record the press release that the American Chemistry Council put out when it announced the extension of Mr. Dooley's tenure.

The reason I want to put it into the record is that in one small page it has four separate mentions of how important the American Chemistry Council thinks solving the marine debris problem is and very strong personal statements of commitment and determination by Mr. Dooley, so I think that puts us in a very good opening position.

Senator BARRASSO. Without objection, submitted. [The referenced information follows:]

### **DOOLEY TO REMAIN AT ACC THROUGH THE END OF 2019**

WASHINGTON (June 11, 2018) – The American Chemistry Council (ACC) today announced that [Cal Dooley](https://www.americanchemistry.com/Dooley) has agreed to delay his retirement and extend his tenure as President and CEO through 2019. In April, Dooley announced his intention to retire at the end of 2018. The decision to delay retirement comes after ACC's Annual Meeting which took place June 4th through June 6th in Colorado Springs, CO, where the board of directors agreed that the chemicals and plastics industry must take a global leadership role to reduce and ultimately eliminate plastic waste.

"Cal's leadership at ACC has been essential to the industry's success in recent years. As [ACC members](https://www.americanchemistry.com/Members) embark on an effort to [reduce and eliminate plastic](https://www.americanchemistry.com/Media/PressReleasesTranscripts/ACC-news-releases/US-Plastics-Producers-Set-Circular-Economy-Goals-to-Recycle-or-Recover-100-Percent-of-Plastic-Packaging-by-2040.html) waste in the years to come, the ACC officers felt strongly that Cal's experience and leadership were essential to aligning the global industry around a coordinated strategy," said [Bob Patel,](https://www.lyondellbasell.com/en/about-us/leadership/bob-patel/) ACC Chairman and Chief Executive Officer of Lyondell Basell. "With a little arm twisting and agreement from his gracious wife Linda, we were able to convince Cal to stay on to lead the development of this critical effort."

"The global chemicals and plastics industry has an imperative to fight the spread of mismanaged plastic waste that is increasingly littering our rivers, oceans and landscapes. While plastic products provide countless health, safety, lifestyle and sustainability benefits, those benefits cannot be fully realized unless we take swift and aggressive actions to make the most of all resources and leverage technology to dramatically increase rates of reuse, recycling and recovery of all plastic products," said Dooley. "Ending plastic waste is an issue of personal, as well as professional interest, and I am excited to help lay the foundation for a sustained, global industry effort to address it."

Korn Ferry International was retained to conduct the search for Dooley's replacement when his retirement was announced in April 2018. With Dooley's announcement today, Korn Ferry's efforts have been suspended, but they will resume their search in mid-2019.

\* \* \*

Senator WHITEHOUSE. We clearly need to do things to clean up our oceans and to clean up the rivers; there are a few of them that are flowing this into our oceans. We have a map here of some of the places around the world which are the top 10 sources, as you will see. They focus on the Pacific, which is one of the reasons that Senator Sullivan has been so strong on this and Senator Murkowski has pledged to work on this through our Oceans Caucus as well.

Senator Carper showed the beach cleanup in Delaware. We do beach cleanups in Rhode Island as well. We do our beach cleanups with trash bags. Senator Sullivan and Senator Murkowski have beach cleanups in Alaska where they have to use front-end loaders, dumpsters, barges because they are on a very, very burdened Pacific coast.

So, it is a few countries and it is a few rivers that are the main sources, and we can do a lot to try to clean that up through trade policy treaties and simple public shaming and friendly persuasion.

We also need to work, and this is where the American Chemistry Council will come in so strongly, on trying to find ways to actually have plastic biodegrade in the oceans. It breaks down into smaller and smaller bits, but it doesn't actually biodegrade into natural elements. It can do that often in a landfill because the composting heat will help it break down, but in the ocean that doesn't happen; and we need to do research in order to find products that will allow that to happen without undercutting the fundamental value of plastic, which is that it lasts a bit.

We need to worry about entanglements and try to help our fishermen cleanup the oceans as they are out there. We see too much marine life dying from ghost fishing gear that still sweeps the ocean and kills, but with no gain to anyone because nobody ever recovers it.

Finally, I think we need to understand the consequences for human health of plastic at the micro level beginning to get into the human diet in a way that the human species has never experienced before through our long history. We have eaten a lot of things through our long history, but it has all been stuff that fundamentally came back to certain natural elements. To have microscopic plastic now in our diet is something new that we need to undertake health research into.

So, I appreciate this going forward and I thank very much my friend, Senator Sullivan, for what a superb leader and partner he has been on this, and I look forward to working with him productively on SOS 2.0, along with all who are present here today. Thank you.

Senator BARRASSO. Thank you very much, Senator Whitehouse, for your leadership. Thank you, Senator Sullivan.

We now will hear from our witnesses. Today we are joined by four: Dr. Jonathan Baillie, Executive Vice President and Chief Scientist of the National Geographic Society; Hon. Cal Dooley, President and Chief Executive Officer of the American Chemistry Council; Mr. Bruce Karas, who is Vice President of Environment & Sustainability at Coca-Cola North America; and Dr. Kara Lavender Law, who is Research Professor of Oceanography at the Sea Education Association.

I want to remind the witnesses your full written testimony will be made part of the official hearing record today. Please keep your statements to 5 minutes so we will have plenty of time for questions.

I look forward to hearing the testimony and I would like to begin with Dr. Baillie.
## **STATEMENT OF JONATHAN BAILLIE, EXECUTIVE VICE PRESIDENT AND CHIEF SCIENTIST, NATIONAL GEOGRAPHIC SOCIETY**

Mr. BAILLIE. Good morning. Thank you, Chairman Barrasso, Ranking Member Carper, and the distinguished members of the Committee. I would like to thank you for holding this timely hearing on cleaning up the world's oceans. I would also like to congratulate Senator Whitehouse on his award last night. Congratulations.

The Committee's leadership on this global crisis is critical, and I am grateful to have the opportunity to share my expertise as a representative of National Geographic.

I am going to talk about the scale of the crisis; then I am going to discuss the implications for wildlife, for people, and for the economy; and then I am going to close discussing what National Geographic is doing and what we can do better as a Nation.

The use of plastics is rapidly increasing throughout the world and is now a major threat to the environment, to marine species, human health, and the economy. As you can see on this map, over here and over here, the problem of plastics is global, is visible, and it is harmful. But it is also solvable.

Today there are 9.2 billion tons of plastics in this world, and annually we are producing about 500 million tons of plastics, 40 percent of which is just used once and then discarded. There is estimated to be about 150 million tons of plastics just floating around our oceans and our marine environment, and no one knows really how long it takes for these plastics to biodegrade. Of course, it depends on the particular plastics, but estimates range between 450 years to never.

This leaves our world with an ever-increasing amount of plastic waste. It is a problem we can no longer ignore.

Research indicates that hundreds of marine species consume plastic or become entangled in it. The animals confuse plastic bags or small plastic fragments for food, and it is absolutely devastating to see a sea bird fly in and feed it chick plastic waste unknowingly.

Species face entanglement in plastic packaging such as six-pack rings, as well as ghost nets, fishing nets that have been cut loose or are simply lost.

And we know that plastics have already entered the food chain. Microplastics have been found in 114 aquatic species, more than half of which we actually consume. Organic pollutions also fasten on to these plastic particles. And then there are nanoplastics.

Now, this is concerning, as the full implications are unknown. We, however, do know that plastics are linked to everything from weight gain to brain development impairment in humans.

Now, ocean plastic waste is also a threat to our economy. The ocean supports over 28 million American jobs. One in six U.S. jobs is marine-related. And coastal areas account for 85 percent of the U.S. tourism revenue.

I could give you many more statistics, but it is clear that unchecked plastic pollution poses a major threat to this important component of the U.S. economy.

Now, National Geographic is stepping up. We are using our combined power of our cutting-edge science and exploration and our storytelling to draw attention to this critical issue and to help people understand all over the world what they can do.

In May 2018, we launched Planet or Plastic?, which has already been referred to. This is a multiyear initiative that is focusing on the plastic crisis and how we can stop single-use plastics entering the oceans. We also give out many awards to explorers around the world, many of which are working on this particular issue, explorers like Heather Koldewey, who is working in the Philippines to help remove these ghost nets from the oceans and have them turned into carpet tiles. It is innovations such as this that we find very encouraging.

Can we please play the film? [Video played.]

Mr. BAILLIE. That is just one of our amazing explorers. Heather said there is hope, but not without major change, and that change has to start right here, right now, in the United States.

We are one of the most developed Nations in the world, and we have to ask ourselves why are we sending over half our plastic recyclables overseas instead of developing our own robust recycling capability? Why do we continue to use multilayer plastics like disposable coffee cups that can't be recycled? And why are we creating recycling standards that reduce confusion and address the fact that 91 percent of recyclable plastic is not being recycled?

Now, while federalism and regulations make addressing this issue challenging, we must shift how our Nation manages plastic design and recapture, a task that only the U.S. Federal Government is able to take on. To support this, National Geographic would like to offer to convene a summit in Washington, DC. To bring together policymakers, to bring together industry leaders, and to bring together other stakeholders to have a critical discussion about how the U.S. can take a leadership position in this space.

Now, imagine a future where we don't address this solvable issue. Imagine a future with billions of tons of plastics floating around the oceans, the impacts on species, the impacts on people and the economy. This is unthinkable. It is time for us to address this head-on. It is time for bold decisions and bold action. And it is time for the United States to take a leadership position to demonstrate best practice and to continue to drive innovation.

Thank you.

[The prepared statement of Mr. Baillie follows:]

# **WRITTEN TESTIMONY OF DR. JONATHAN BAILLIE, EXECUTIVE VICE PRESIDENT AND CHIEF SCIENTIST NATIONAL GEOGRAPHIC SOCIETY, BEFORE THE UNITED STATES SENATE COMMITTEE ON ENVIRONMENT AND PUBLIC WORKS "CLEANING UP THE OCEANS: HOW TO REDUCE THE IMPACT OF MAN-MADE TRASH ON THE ENVIRONMENT, WILDLIFE, AND HUMAN HEALTH?," 26 SEPTEMBER 2018**

Chairman Barrasso, Ranking Member Carper, and distinguished members of the Committee, I would like to thank you for holding this timely hearing about cleaning up our world's oceans. The Committee's leadership on this global crisis is critical, and I am grateful for the opportunity to share my expertise on behalf of National Geographic and to assist with your mission.

As my testimony will further demonstrate, understanding and addressing how man-made trash reaches and impacts our oceans is a top priority for National Geographic. Our world's oceans are deeply impacted by human activities, including overfishing, man-made pollutants, and beyond.

Due to its widespread and consistently increasing use, plastic is one of the top threats to the environment, marine wildlife, human health, and the economy. Whether it takes the form of abandoned fishing nets or litter making its way into our oceans, and whether the pieces are large or small, the world's unchecked use of plastics has sparked a global crisis.

### **Plastics: A Global Crisis**

There are about 9.2 billion tons of plastic in the world today. And nearly 500 million tons of plastic continue to be produced annually.

About 40 percent — or roughly 180 million tons — of this annual total is only used once before being discarded. This leaves more than 6.9 billion tons, or over 75 percent of the plastic existing globally, as plastic waste.

Unlike most other consumer materials, no one knows how long it takes plastic to biodegrade completely, with estimates ranging from 450 years to never. This leaves our world with an ever increasing amount of plastic waste.<sup>1</sup>

An estimated 150 million tons of plastic are currently circulating in our marine environments.<sup>2</sup> And a 2015 study found that between 5.3 and 14 million additional tons of plastic enter the ocean each year.<sup>3</sup>

Due to plastic's relatively recent introduction, more research into its impact on our oceans is needed. However, some alarming consequences have already been identified.

#### *Impact of Plastic Debris on Marine Wildlife<sup>4</sup>*

 $\overline{a}$ 

There is a large body of evidence demonstrating that plastic debris is often deadly to marine wildlife. Unfortunately, the durability of plastic ensures that its presence in marine ecosystems is persistent at all levels, ranging from large marine mammals to the smallest  $k$ rill. $5$ 

Research indicates that at least 700 marine animal species have consumed or become entangled in plastics. They face entanglement in plastics such as "ghost nets" — fishing nets that have been left or lost in the ocean by fishermen — or six pack rings. The animals confuse plastic bags or smaller plastic fragments with food. Plastics of all sizes are tied to everything from digestive track blockages to immediate death. 6

<sup>6</sup> Elizabeth Royte, "A Threat to Us?" *National Geographic*, June 2018, 84-87.

Photo by Brian Skerry, National Geographic.

Plastic debris not only exists in forms that we can see, such as bottles and plastic bags, but is also broken down into much smaller pieces by light exposure, ocean drift, and marine organism digestion. These microplastics — or pieces smaller than one-fifth of an inch linger for centuries.<sup>7</sup> Scientists have already found microplastics in 114 aquatic species, more than half of which are consumed by humans.<sup>8</sup>

In addition, microplastics cause physiological issues in marine species. Pollutants that wash off the land and into the sea adhere to microplastics, causing problems ranging from organ damage to reproductive abnormalities in the marine organisms that consume them.<sup>9</sup>

We do not yet understand the full implications of plastic debris on marine wildlife. However, National Geographic and scientists around the world are working every day to better understand this issue.

#### *Impact of Plastic Debris on Humans*

Research has demonstrated that many of the fish and shellfish humans eat are consuming microplastics. It has also tied plastics to issues ranging from weight gain to brain development impairment.

We do not yet know at what quantity human consumption of microplastics will have adverse effects and how other factors such as food preparation affect microplastic toxicity.<sup>10</sup> However, we do know that microplastics have entered our food chain.

Scientists are expressing additional concern about the potential impact of nanoplastics on human health. Nanoplastics are less than 100 billionths of a meter in size and are created as microplastics continue to degrade. Their miniscule size makes them impossible for scientists to trace in the seafood humans consume. However, scientists worry that these tiny nanoplastics, which can penetrate cells and move into tissues and organs, pose a risk to humans.

Photo by Randy Olson, National Geographic.

Despite the scientific questions that remain at the micro- and nanoscales, the impact of marine plastic is evident at the macroscale. Oceans and coastal ecosystems provide an irreplaceable benefit to the U.S. economy. Our oceans support over 28 million American jobs. In fact, between the fishing, boating, tourism, recreation, and ocean transport industries combined, one in six U.S. jobs is marine-related. Additionally, U.S. consumers alone spend over \$55 billion on fishery products, and coastal areas account for 85 percent of U.S. tourism revenue.<sup>11</sup>

Scientists are still in the early phase of studying how extensively the global plastic crisis has impacted and will continue to impact our world. However, they have already demonstrated that plastic pollution poses a tremendous threat to our oceans, the marine wildlife that inhabits them, and the U.S. economy.

#### *My Background on the Issue*

 $\overline{a}$ 

Prior to joining National Geographic in 2016, I spent 20 years at the Zoological Society of London (ZSL) working on projects focused on threatened species and their habitats in over 50 countries.

While at ZSL, I helped develop the Living Planet Index, Sampled Red List Index, and Wildlife Picture Index. I also worked with a network of 8,000 scientists to produce the first International Union for the Conservation of Nature (IUCN) Red List of Threatened Species using quantitative criteria to assess extinction risk. I then partnered with IUCN to produce the first list of the 100 most threatened animals, plants, and fungi and co-chaired the IUCN Regional Red List working group and the IUCN Special Survival Commission Pangolin Specialist Group.

I led the ZSL team that founded the EDGE of Existence program, which focuses on Evolutionarily Distinct and Globally Endangered (EDGE) species and supporting young scientists around the world working to protect animals facing extinction. While at ZSL, I also founded the Conservation Technology Unit and the Business and Biodiversity Programme.

<sup>&</sup>lt;sup>11</sup> U.S. Department of Commerce, National Oceanic and Atmospheric Administration, National Ocean Service. "What does the ocean have to do with human health?" https://oceanservice.noaa.gov/facts/ocean-humanhealth.html.

I helped initiate United for Wildlife, a collaboration of seven of the most influential conservation organizations working to address illegal wildlife trade at scale. Under this collaboration, I led the development of the award-winning digital conservation leadership training platform, the Rhino Impact Investment, and the development of technology for nature.

It was also during this time that I co-led the first large-scale retail activism project to focus on ocean conservation: Project Ocean. The partnership between ZSL and Selfridges, a chain of high-end department stores in the United Kingdom, highlighted the unthinkable prospect of the world's major fisheries collapsing by 2050.

The retail platform provided the opportunity for conservationists from ZSL to reach a wider audience and have a global impact. Twenty-two non-governmental organizations (NGOs) dedicated to environmental and sustainable issues embraced the initiative, leading to public discussions between political figures at Selfridges on World Oceans Day 2011. Project Ocean culminated with a long-term joint project between Selfridges and ZSL: a 50-hectare, or 124-acre, marine protected area in the Philippines, aiming to safeguard fish species and their coral reef ecosystem.

The success of this initiative demonstrated the effect that public awareness initiatives can have on major global problems. Now, as National Geographic's Executive Vice President and Chief Scientist, I have access to an unparalleled media megaphone to address the issues facing our oceans today.

#### *Planet or Plastic?*

 $\overline{a}$ 

For 130 years, National Geographic has pushed the boundaries of exploration to further our understanding of the planet and empower us all to create a healthy and sustainable future for generations to come. We do this by investing in bold people and transformative ideas and sharing what we learn with audiences around the globe. Our ultimate goal is to achieve a planet in balance, one that provides for humanity and the untold millions of other species with which we live.

Today, our brand reaches millions of people of all ages in 172 countries every month. National Geographic publishes in 37 languages, our broadcast channels air in 43 languages, and our social media channels reach 436 million.

Through the power of our scientific research and storytelling, the integrity of our brand, and the reach of our global media platforms, we are uniquely positioned to engage with the public, to educate and raise awareness, and to build consciousness and help drive change.

In May of 2018, National Geographic launched *Planet or Plastic?*, a multiyear initiative aimed at raising awareness about the global plastic waste crisis and reducing the amount of single-use plastic that enters the world's oceans. The initiative was showcased in the June 2018 "Planet or Plastic?" issue of National Geographic magazine and across our digital platforms to educate our audiences about the crisis and to show them how to take accountability for this global emergency.

We're encouraging our audiences to pledge to take small, attainable steps, such as using reusable shopping bags, skipping straws, carrying a reusable bottle, and properly disposing of trash. We are demonstrating that when we work together, we can reduce single-use plastics and make a lasting impact on the global plastic crisis.<sup>12</sup>

<sup>12</sup> National Geographic. "Planet or Plastic?" https://www.nationalgeographic.com/environment/plasticpledge/.

June 2018 issue of National Geographic Magazine.

As of last month, our *Planet or Plastic?* education initiative had already generated over 938 million content views across our digital platforms. And our worldwide reach has prompted 47,000 people to take the pledge to reduce single-use plastics.

## **Investing in Change**

 $\overline{a}$ 

National Geographic's commitment to addressing this issue goes beyond storytelling. It also includes grants to support hundreds of National Geographic Explorers. Through the power of our grants program, these bold individuals are changing the world by furthering the collective understanding of our planet and empowering the global community to generate solutions for a healthier and more sustainable future.

## *Stopping Plastic Pollution at Its Source<sup>13</sup>*

Inland plastic can travel many miles to enter our world's oceans. A combination of direct dumping of waste into rivers and litter flowing from land to local waterways during

<sup>13</sup> National Geographic. "Plastics: Source to Sea." https://www.nationalgeographic.org/projects/ocean-plastics/.

rainstorms creates an unintentional plastic waste conveyor system. The waste from local waterways feeds into larger tributaries and rivers that ultimately transport the inland waste into our oceans. Via this mechanism, polluted rivers deliver a significant portion of the millions of tons of plastic that enter oceans annually.<sup>14</sup>

Through our grants program, we are partnering with scientists and innovators who are working diligently to find ways to keep plastics from ever reaching the ocean. To better understand how plastic waste flows to the ocean in the first place and to prevent it from ending up there, National Geographic Explorers will be journeying from the source of the plastic in the rivers to the ocean. Their goal: to understand the types and pathways of plastic in a river system and to provide science-based information that will engage citizens and help policymakers, businesses, and NGOs implement solutions to this growing crisis.

## *Improving Plastics Waste Management<sup>15</sup>*

Approximately 80 percent of marine debris comes from land-based sources.<sup>16</sup> Improved solid waste management reduces the amount of plastics entering the oceans annually.

Award-winning National Geographic Explorer and environmental engineer Jenna Jambeck has researched marine debris since 2001 and has raised awareness via her research on plastic waste leakage into water systems. In her 2016 testimony before the Senate Committee on Environment and Public Works Subcommittee on Fisheries, Water, and Wildlife, Jambeck pointed to plastic pollution's economic and environmental impact as well as the ability to combat widespread plastic pollution via well-researched and culturally appropriate strategies. 17

Today, Jambeck advances her work on finding scientifically supported and culturally relevant solutions with funding from National Geographic's grants program. She works in Vietnam — a country with an often-informal solid waste management system — to better understand and improve waste management, and to ultimately reduce the quantity of plastics entering water systems via local partnerships and education.

## *Cleaning Up Plastic Fishing Gear Pollution<sup>18</sup>*

National Geographic Explorer Heather Koldewey works with ZSL to help communities clean up ocean plastic as part of the National Geographic Ocean Plastics Initiative. Through interdisciplinary research and conservation action at the interface between communities and the environment, Koldewey drives real change in the communities she touches.

Today, Koldewey works in the Philippines and beyond to combat ocean plastics, starting with ghost nets. Abandoned fishing gear comprises around 10 percent of all plastic trash in the oceans. More than 705,000 tons of fishing nets are lost yearly, according to the United

 $\overline{a}$ 

<sup>14</sup> Laura Parker et al, "What Happens to the Plastic We Throw Out," *National Geographic*. https://www.national geographic.com/magazine/2018/06/the-journey-of-plastic-around-the-globe/.

<sup>&</sup>lt;sup>15</sup> National Geographic. "Grants Across the Globe: Working With The Independent Waste Collector Community In Vietnam To Reduce Leakage Of Plastic To The Ocean." https://www.nationalgeographic.org/grants/wherewe-work/A1228097?filter=activity\_status:All&q=Jenna%20Romness%20Jambeck.

<sup>16</sup> Oceans Caucus Foundation. "Marine Debris."

<sup>17</sup> *Marine Debris and Wildlife: Impacts, Sources and Solutions: Hearing before the U.S. Senate Committee on Environment and Public Works*, 114th Cong. (2016) (written testimony of Jenna R. Jambeck, Ph.D., Associate Professor of Environmental Engineering, College of Engineering, University of Georgia).

<sup>18</sup> Laura Parker, "These Communities Turn Discarded Fishing Nets Into Carpets," *National Geographic*, Published June 13, 2018. https://news.nationalgeographic.com/2018/06/heather-koldeway-explorer-nets-plasticphilippines- ocean-culture/?beta=true.

Nations,<sup>19</sup> and nearly half the weight of the Great Pacific Garbage Patch's surface debris is fishing gear.

Abandoned fishing gear is directly connected with a disproportionately large number of marine wildlife fatalities. World Animal Protection estimates that more than 100,000 large whales, sea lions, and seals are killed every year by fishing gear, in addition to an "inestimable" number of sea birds, turtles, and fish.

Koldewey saw this critical issue as an opportunity for partnership. By developing Net-Works, a collaboration between global carpet tile manufacturer Interface, Inc. and ZSL, she developed a successful community-based supply chain for retrieving and discarding fishing nets. Net-Works partners with coastal communities to collect discarded fishing nets, convert them into nylon yarn, and sell them to Interface to create carpet tiles. So far, the initiative has collected and recycled 208 tons of discarded fishing nets, removing these dangerous threats to marine wildlife from our oceans and empowering local communities with economic opportunity.<sup>20</sup>

## *Partnership for Change<sup>21</sup>*

 $\overline{a}$ 

National Geographic is also partnering with Sky Ocean Ventures to create the largest global media campaign to reduce plastic litter in the ocean. We've committed \$10 million to bring our scientific expertise, grants, and media reach to the partnership.

The partnership will make grants available to proposals that will measurably reduce plastic pollution before it reaches the ocean, including improved recycling, waste management, stakeholder engagement, and more. It will also convene a series of Innovation Challenges, uniting the best international minds around technologies designed to reduce plastic waste and its impact on oceans. Additionally, the partnership will create an event series engaging industry leaders, corporations, institutions and foundations around the issue of marine plastic pollution.

## **An Opportunity for U.S. Leadership**

Our planet is at a crossroads. World plastic production is increasing exponentially. In 1950, 2.3 million tons were produced. In 1993, 162 million tons were produced. And in 2015, 448 million tons were produced.<sup>22</sup> As plastic production grows, so does the threat plastic waste poses to our oceans and the wildlife and economies that depend upon them.

However, as Laura Parker wrote in the June National Geographic magazine cover story, plastics have been a boon to humanity. They helped the Allies win World War II, "eased travel into space, and revolutionized medicine … In airbags, incubators, helmets, or simply

<sup>19</sup> Eric Gilman et al, Food and Agriculture Organization of the United Nations, *Abandoned, lost or otherwise discarded gillnets and trammel nets: Methods to estimate ghost fishing mortality, and the status of regional monitoring and management*, 2016, FAO Fisheries and Aquaculture Technical Paper No. 600, Rome, Italy.

<sup>20</sup> Zoological Society of London. "Asia: Net-Works." https://www.zsl.org/conservation/regions/asia/net-works.

<sup>&</sup>lt;sup>21</sup> National Geographic 2018. "Sky and National Geographic Work Together to Fight Ocean Plastic." http://press.nationalgeographic.com/2018/04/16/sky-and-national-geographic-work-together-to-fight-oceanplastic/.

<sup>22</sup> National Geographic. "10 Shocking Facts About Plastic." https://www.nationalgeographic.com/environment/ plastic-facts/.

by delivering clean drinking water to poor people in those now demonized disposable bottles, plastics save lives daily."<sup>23</sup>

Now, it's a matter of learning to balance the potential provided by plastic with the threat plastic waste poses to our world. We know that the ocean's currents ensure that marine plastic pollution will never be just one nation's problem. Any plastic waste that is introduced to the system will impact wildlife and economies around the globe.

This is why National Geographic launched the *Planet or Plastic?* initiative and why we are dedicated to encouraging consumers to end their reliance on the single-use plastics.

National Geographic is committed to continuing to raise international awareness through our media and education arms and to better understanding and addressing the issue through research and community partnership. We are working with corporations, NGOs, and other institutions around the world to eliminate single-use plastic and promote recyclability.

However, addressing this issue will require true global partnership. In this process, it's important to remember that our work must start with evaluating our own practices.

With *Planet or Plastic?*, we hope to do nothing less than transform consumer behavior and we're starting at home. To kick off this multiyear initiative, National Geographic is conducting an internal audit of our headquarters in Washington, D.C., to assess how our own operations and supply chain use plastic. From the plastic wrappers in which our magazines were formerly distributed to the materials we use in our cafeteria, we're identifying and eliminating single-use plastics.

Now, it's time for the United States to do the same. The United States is one of the most developed nations in the world. So why aren't we addressing this issue head-on? Why are we relying on sending our plastic recyclables overseas instead of developing a robust recycling capability of our own? And why do we continue to use plastics that can't be recycled at all?

#### *U.S. Plastic Waste*

 $\overline{a}$ 

Today, an estimated 94 percent of Americans have access to recycling. However, our nation lacks standardization on which materials are considered recyclable and what community collection practices look like.<sup>24</sup> This contributes to this shocking metric: In the United States, 91 percent of recyclable plastic is not actually recycled.<sup>25</sup>

Additionally, more than half of plastic waste that is recycled in the United States has been exported to hundreds of countries around the world because our own recycling sector is under resourced. Historically, China has been responsible for recycling 45 percent the world's plastic and paper products.

However, this year, China stopped accepting recycling from abroad. This is related to the fact that many countries, including the United States, transitioned to single-stream recycling. Single-stream recycling was designed to streamline recycling and reduce consumer burden by allowing all recyclables — from paper to plastic to glass — to go into the same bin. However, this streamlining process means that much of the waste reaching China is too contaminated with non-recyclables to provide China with the profit margin needed to continue processing

<sup>23</sup> Susan Goldberg, "The Plastic Apocalypse," *National Geographic*, June 2018, 6.

<sup>24</sup> Drew Desilver, "Perceptions and realities of recycling vary widely from place to place," *Pew Research Center*, Published October 7, 2016. http://www.pewresearch.org/fact-tank/2016/10/07/perceptions-and-realities-ofrecycling- vary-widely-from-place-to-place/.

<sup>25</sup> Faye Flam, "The Recycling Game Is Rigged Against You," *Bloomberg*, Published June 27, 2018. https://www.bloomberg.com/view/articles/2018-06-27/plastic-recycling-is-a-problem-consumers-can-t-solve.

the world's recyclables. As a result, estimates predict that 122 tons of potentially recyclable plastic will be diverted from Chinese recycling facilities, likely ending up in landfills. <sup>26</sup> However, the global shortage in recycling capabilities is only one piece of the issue.

Some plastics are too difficult to recycle in the first place. Due to their prevalence in our daily lives, multilayer plastics, which are used in products ranging from disposable coffee cups to snack packaging, are particularly problematic. Multilayer plastics incorporate materials such as paper or aluminum, tightly stacking thin layers of the materials alongside plastic and making the separation and processing of these materials nearly impossible. While material production advancements make these multilayer plastics cheap, readily available, and utilitarian, the non-recyclable nature of these single-use materials is a major contributor to the global plastic crisis.<sup>27</sup>

Unfortunately, this means that our nation's plastic waste footprint is an issue that consumers and individual organizations cannot solve alone. It requires a shift in how our nation as a whole manages plastic design and recapture, a task that only the U.S. federal government is able to take on.

#### *Model Nation and Innovation*

 $\overline{a}$ 

I understand that federalism and regulation concerns make addressing this issue challenging. However, we cannot stymie the global plastic crisis without U.S. federal government involvement.

The U.S. government can play a stronger role in addressing the global plastic crisis by convening conversations with industry leaders and encouraging them to present solutions and commit to targets. The United States is a global leader in innovation. Our government continuously invests in American ingenuity. Now, it must invest in solutions to the global plastic crisis through private sector and entrepreneurial innovation around better material design and recapture.

Only the federal government is positioned to implement the solutions developed by private sector leaders at a nationwide scale. But as part of our *Planet or Plastic?* initiative, National Geographic would like to offer our support to U.S. policymakers as they address this issue.

On behalf of National Geographic, I would like to offer to convene a summit in Washington, D.C., to bring together policymakers, industry leaders, and other essential stakeholders for a critical discussion about how the United States can lead in this space. The *Planet or Plastic?* Summit will ensure that the right voices are in the room as we look at the current state of plastic waste in the United States and, in turn, how to advance the American recycling industry, move away from non-recyclable and single-use plastics, and find better alternatives to plastic where possible. And equally importantly, National Geographic wants to bring our powerful storytelling to bear to amplify the results of this conversation and to raise awareness of what the United States is doing to address the global plastic crisis.

While the plastic crisis has no boundaries, the U.S. government must first take its own steps to protect the oceans and marine wildlife upon which one in six American jobs

<sup>&</sup>lt;sup>26</sup> Amy Brooks, Shunli Wang, and Jenna Jambeck, "The Chinese import ban and its impact on global plastic waste trade," *Science Advances* Vol. 4, no. 6 (2018). http://advances.sciencemag.org/content/4/6/eaat0131.

<sup>27</sup> Lilly Sedaghat, "7 Things You Didn't Know About Plastic (and Recycling)," *National Geographic*, Published April 4, 2018. https://blog.nationalgeographic.org/2018/04/04/7-things-you-didnt-know-about-plastic-andrecycling/.

depend. <sup>28</sup> Perhaps the time has come to examine the feasibility of a federal regulatory approach that would provide minimum standards on plastic use and recycling. The approach could provide incentives and mandates — carrots and sticks — for states to adopt the right recycling protocols and provide national standards for plastic import, manufacturing, and use.

It's a bold solution, but this crisis requires one. It's time to stop the plastic pollution that got us into this mess in the first place — and to step up and be a true global leader on this issue.

# **SENATE COMMITTEE ON ENVIRONMENT AND PUBLIC WORKS, HEARING ENTITLED, "CLEANING UP THE OCEANS: HOW TO REDUCE THE IMPACT OF MAN-MADE TRASH ON THE ENVIRONMENT, WILDLIFE, AND HUMAN HEALTH?", SEPTEMBER 26, 2018**

Questions for the Record for Dr. Jonathan Baillie Executive Vice President and Chief Scientist National Geographic Society

## **Chairman Barrasso**

 $\overline{a}$ 

1. Experts seem to agree that stopping the flow of debris into the ocean is a bigger priority than cleaning up the debris already in the ocean. Is this an assessment that you agree with? If not, why not?

Yes, l agree. Studies have found that approximately 80 percent of marine debris comes from land-based sources. While stopping the flow of plastic debris from land into waterways and cleaning up the debris that already pollutes the world's oceans are important from an

<sup>28</sup> U.S. Department of Commerce, National Oceanic and Atmospheric Administration, National Ocean Service. "What does the ocean have to do with human health?" https://oceanservice.noaa.gov/facts/ocean-humanhealth.html.

environmental and economic standpoint, addressing the origins of plastic pollution would provide a major boost to combating this issue.

2. We know that five countries in Asia bear much of the responsibility for the increase in ocean plastic. That does not mean that we in the United States do not have a critical role to play. What additional steps can local and state governments as well as the federal government take to address this problem?

The U.S. government can play a stronger role in addressing the global plastic crisis by convening conversations with industry leaders and encouraging them to present solutions and commit to targets. The federal government has an advantage in that it maintains the capability to implement solutions developed by the private sector on a nationwide scale. I suggest that the federal government explore a federal regulatory approach that would provide minimum standards on plastic use and recycling. Local and state governments can also examine and address their waste management practices to stymie the paths by which plastics flow from land in their jurisdiction into waterways.

3. On January 24, 2018, the *Financial Times* published an article, by Clive Cookson, entitled, "The problem with plastic." It explained that:

"While the personal-care industry is phasing out microbeads, concern is growing about another ubiquitous micropollutant: plastic fibres. Analysis shows these to be present in streams, rivers, lakes, and seas worldwide, as well as household drinking water. Their main source seems to be clothing and textiles made from synthetic fibres, which become detached in washing machines and are not filtered out by water-treatments plants."

Do you agree with this assessment? If so, how do we begin to address this issue?

We know that microplastics such as plastic fibers have already entered our food chain and that pollutants adhering to these microplastics can cause issues like organ damage and reproductive abnormalities in the marine organisms that consume them. We also know that as microplastics degrade, they become nanoplastics, which have the ability to penetrate cells and move into tissues and organs. Per GESAMP, potential avenues of addressing the fiber issue could specifically involve enhanced washing machine filters or other new technologies that would limit the release of these microplastics during washing, such as laundry detergent additives and textile finishing treatments.<sup>29</sup>

In addition, there are companies that are looking into design-based solutions. For example, some fleece manufacturers are working to design materials that shed fewer fibers.

4. What regions of the world are the least studied when it comes to plastic pollution?

Plastic use and the problem of plastic waste have grown exponentially in a very short period of time. While there are regions of the world that may be less studied, the National

l

<sup>&</sup>lt;sup>29</sup> http://ec.europa.eu/environment/marine/good-cnvironmcntal-status/descriptor-l0/pdf/GESAMP\_microplastics% 20full%20study.pdf.

Geographic Society is focusing initially on areas where plastic use is high and where high levels of plastic waste are seeping into the environment.

In fact, National Geographic is already taking steps to study plastic pollution in several of these areas by investing in the work of our scientists and explorers. Through our grants program, we partner with scientists and innovators who are working diligently to find ways to keep plastics from ever reaching the ocean.

For example, National Geographic Explorer Jenna Jam beck works in Vietnam, which has an often-informal solid waste management system, to better understand and improve waste management. Explorer Heather Koldewey works in the Philippines to help communities clean up ocean plastic as part of the National Geographic Ocean Plastics Initiative.

We have found that even highly remote areas like the uninhabited Henderson Island in the Pacific can play host to what is estimated to be the highest concentration of debris anywhere in the world. Further research could and should be conducted around the world on the plastic crisis. This is a global issue that affects the world's connected waterways and oceans.

## **Ranking Member Carper**

5. Stopping the flow of marine debris into the ocean and mitigating its impacts are not problems that can be solved overnight. Long-term, thoughtful, and collaborative solutions are necessary in order to address the full scope of the issue. Solutions that have been discussed included: improving recycling; incentivizing the use of recycled materials in the global supply chain; developing more biodegradable alternatives; and changing manufacturing protocols. What steps can this Committee and the Congress take now to advance these potential solutions here in the United States?

The federal government should explore a federal regulatory approach that would provide minimum standards on recycling and the recyclability of plastic products. The approach could provide incentives and mandates-carrots and sticks for states to adopt the right recycling protocols and provide national standards for plastic import, manufacturing, and use. Only the federal government is able to implement change now on a nationwide scale.

6. Now that China has implemented its "Green Fence Policy," a ban on importing plastic waste, our market for these materials in the United States is flooded. China previously accepted 30 percent of our plastic waste. Local municipalities are now having even more trouble breaking even when collecting and recycling this waste. In your opinion, what are the best ways for the United States to address this new challenge?

Many countries, including the United States, use single-stream recycling. Single-stream recycling was designed to streamline recycling and reduce consumer burden by allowing all recyclables-from paper to plastic to glass-to go into the same bin. However. This streamlining process means that much of the waste reaching China is too contaminated with nonrecyclables to provide China with the profit margin needed to continue processing the world's recyclables. Many of the recycling facilities in the United States are facing the same issue now.

Our nation lacks standardization on which materials are considered recyclable and what community collection practices look like. This contributes to this shocking metric: In the United States, 91 percent of recyclable plastic is not actually recycled.

This can be addressed via a three-pronged approach:

- 1) *The United States must streamline its recycling standards and practices to reduce contamination***.** I understand that federalism and regulation concerns make addressing this issue challenging. However, an effort on this scale is something that only the federal government-with the help of participatory stakeholders can manage. Our nation must explore a federal regulatory approach that would provide minimum standards on plastic use and recycling. The approach could provide incentives and mandates-carrots and sticks tor states to adopt the right recycling protocols and provide national standards tor plastic import, manufacturing, and use.
- 2) *We must move away from non-recyclable plastics that have no value to the recycling industry***.** The U.S. government can play a stronger role in addressing the global plastic crisis by convening conversations with industry leaders and encouraging them to present solutions and commit to targets. The United States is a global leader in innovation. Our government continuously invests in American ingenuity. Now, it must invest in solutions to the global plastic crisis through private- sector and entrepreneurial innovation around better material design and recapture.
- 3) *We must educate consumers about what is recyclable and how it should be recycled***.** Once recycling practices are standardized, the United States will need to engage in a nationwide education campaign to raise awareness, highlight recycling myths versus facts, and ensure consistency in our nation's consumer recycling practices. National Geographic is committed to using our media reach to aid in this education process.

## **Senator Markey**

7. For the past 25 years, China has imported 45 percent of the world's plastic waste, over l00 million tons every year. From the United States, about 3,700 shipping containers of recycling went to China on a daily basis. That changed this past January, when China closed its borders to 24 categories of solid waste, leaving the United States and Europe without a market for much of our plastic trash. Municipal waste managers in the United States may now have to put recyclable plastic in landfills as falling prices and lack of demand for recyclables could also lead to recycling centers closing.

a. Does the closing of China's borders to many kinds of plastic waste force a fundamental shift in the U.S.'s recycling economy?

Yes, China's decision to stop accepting plastic recyclables from abroad requires a major shift in our nation's recycling economy. In addition to the three essential steps l outlined in question 6, we need to improve the design of plastics in the United States to ensure that they are recyclable in the first place.

One way to do this is by reducing our reliance on multilayer plastics, used in products ranging from disposable coffee cups to snack packaging, as they are particularly problematic. Multilayer plastics incorporate materials such as paper or aluminum, tightly stacking thin layers of the materials alongside plastic and making the separation and processing of these materials nearly impossible. While material production advancements make these multilayer plastics cheap, readily available, and utilitarian, the non-recyclable nature of these single-use materials is a major contributor to the global plastic crisis. We must find recyclable alternatives to multilayer plastics as well as better substitutes for single-use plastics wherever possible.

b. Will this increase the risk of more U.S. plastic ending up in the oceans in addition to landfills?

Yes, a global analysis of all plastics ever made showed that only 9 percent were recycled. The vast majority (79 percent) accumulated either in the environment or in landfills. Estimates predict that 122 tons of potentially recyclable plastic will be diverted from Chinese recycling facilities.<sup>30</sup> In all likelihood, this break in the global recycling system will lead to an additional influx of marine plastic pollution in our oceans.

### **Senator Merkley**

 $\overline{a}$ 

8. In your testimony, you spoke about the need for U.S. leadership on marine debris. What are the most important policy steps the United States should be taking to address marine debris on an international scale?

Much of my background on this issue comes from my decades of experience as a scientist and from leading advocacy projects that convened a variety of business, conservation, and non-governmental organization (NGO) stakeholders in order to enact meaningful change on a large scale. Through this lens, and as I've outlined above, I believe the United States should explore methods for advancing the American recycling industry, moving away from single-use plastics, looking for plastic alternatives, where possible, and providing incentives and mandates for states to adopt the right recycling protocols and provide national standards for plastic import, manufacturing, and use.

<sup>30</sup> https://news.nationalgeographic.com/2017/07/piastic-produced-recycling-waste-ocean-trash-debris-environment/.

## **Senator Whitehouse**

9. During your testimony, you offered to convene a summit of essential stakeholders in Washington, D.C., to discuss U.S. leadership in this area. Do you see a role for the federal government in this discussion? What other sectors and stakeholders will be involved?

The federal government has a vital role to play in this process as a convener of conversations with industry leaders in order to encourage them to present solutions and commit to targets to address the crisis. Members and senators, as well as their staff, on and beyond the committees of jurisdiction are important participants in the ongoing dialogue to resolve this issue. Industry leaders, NGOs, and other organizations are also key components of this process.

10. National Geographic magazine's recent marine debris issue punctuated the crisis with poignant photos and articles. What role do these stories and images play in encouraging change and support for marine debris solutions?

At National Geographic, we take our role in addressing this issue very seriously, whether through scientific research or storytelling. Our global reach across numerous media channels allows us to engage and educate audiences on issues affecting a planet we all share. By raising public consciousness and consumer awareness, National Geographic helps shine a light on global issues like plastic pollution. Increased public awareness leads to individuals making changes in their own lives and expanding those choices among their family, friends, and communities. Poignant storytelling and striking images are effective tools in illustrating issues that may otherwise go overlooked, and the global plastic crisis is a perfect example of that.

11. What misconceptions remain among the general public about marine debris?

A common misconception among the general public is that the biggest issue we face is the type of marine debris that we can see, such as bottles and plastic bags. Awareness is often low about the risk imposed by plastics breaking down into much smaller pieces by light exposure, ocean drift, and marine organism digestion. These microplastics-or pieces smaller than one-fifth of an inch-linger for centuries. Scientists have already found microplastics in 114 aquatic species, more than half of which are consumed by humans. In addition, microplastics cause physiological issues in marine species. Pollutants that wash off the land and into the sea adhere to microplastics, causing problems ranging from organ damage to reproductive abnormalities in the marine organisms that consume them.

Research has demonstrated that many of the fish and shellfish humans eat are consuming microplastics. It has also tied plastics to issues ranging from weight gain to brain development impairment. We do not yet know at what quantity human consumption of microplastics will have adverse effects and how other factors such as food preparation affect microplastic toxicity. However, we do know that microplastics have entered our food chain.

Scientists are expressing additional concern about the potential impact of nanoplastics on human health. Nanoplastics are less than 100 billionths of a meter in size and are created as microplastics continue to degrade. Their miniscule size makes them impossible for scientists

to trace in the seafood humans consume. However, scientists worry that these tiny nanoplastics, which can penetrate cells and move into tissues and organs, pose a risk to humans.

12. National Geographic launched its *Planet or Plastic?* campaign this summer. The initiative asks people to pledge to reduce their use of single-use plastics.

a. How many people have taken the pledge so far?

As of November I, 2018, our *Planet or Plastic?* education initiative had already generated more than 972 million content views across our digital platforms. And our worldwide reach has prompted more than 91,000 people to take the pledge to reduce singleuse plastics.

b. How will Nat Geo track the effect of this campaign on plastics reduction? National Geographic is sharing metrics on its *Planet or Plastic?* pledge campaign online at [www.nationalgeographic.com/environmentlplasticpledge.](http://www.nationalgeographic.com/environmentlplasticpledge.) 

Our goal is to prevent 1 billion items from reaching the ocean by 2020, and we are using our global media platform to provide updates on the campaign, share resources, and help inspire others to reduce their use of single-use plastics.

In addition, we will be advancing education initiatives, citizen science efforts, and innovation challenges. We will also be developing a global framework to enable better selection and siting of interventions. Finally, we will be hosting convenings and will continue to shine a light on plastic pollution through our unparalleled storytelling and global media platforms.

c. What role can these voluntary campaigns play in changing consumer and producer or retailer behavior?

These campaigns can play a large role in changing consumer, producer, and retailer behavior. For more than 130 years, National Geographic has sought to further our understanding of the planet and empower us all to create a healthy and sustainable future for generations to come.

By leveraging our brand, we are able to reach millions of people in 172 countries and educate them on this issue. We are also able to share tips for consumers to take actionable steps in order to reduce plastic waste.

13. How do voluntary actions by corporations and individuals support marine debris reduction?

About 40 percent of the nearly 500 million tons of plastic produced annually is only used once before being discarded. Voluntary actions by corporations and individuals can play a major role in reducing this number.

This is why to kick off our multiyear *Planet or Plastic?* initiative. National Geographic is conducting an internal audit of our headquarters in Washington, D.C., to assess how our own operations and supply chain use plastic. From the plastic wrappers in which our magazines were formerly distributed to the materials we use in our cafeteria, we're working to identify and eliminate single-use plastics. Actions such as these are an essential first step toward the broader nationwide and international reform needed to combat the global plastic crisis.

14. As we work on the next iteration of the Save Our Seas Act, do you have any additional recommendations or comments you would like to share to inform our development of this bill?

The Save Our Seas Act is a powerful piece of legislation. I am glad to see that Congress is taking bipartisan steps to address the global plastic crisis and understands the need to improve international waste management practices to reduce the influx of plastics into our world's oceans.

I recommend a companion piece of legislation that would focus not only on reforming international plastic waste management, but also on addressing what the United States can do within our nation's borders. This legislation could further study the impacts of plastics-at both the micro and macro scales-on our waterways; invest in private-sector and entrepreneurial innovation around better material design and recapture in the United States; and provide incentives and mandates-carrots and sticks tor states to adopt the right recycling protocols and provide national standards tor plastic import, manufacturing, and use.

\* \* \*

Senator BARRASSO. Thank you so much for your testimony and your leadership on this.

Mr. DOOLEY.

## **STATEMENT OF HON. CAL DOOLEY, PRESIDENT AND CEO, AMERICAN CHEMISTRY COUNCIL**

Mr. DOOLEY. Thank you, Mr. Chairman and members of the Committee. I am delighted to be joining you all.

ACC represents a diverse set of companies engaged in the U.S. business of chemistry, and the chemical industry is at the forefront of developing the innovations, the technologies, and the products that are essential to advancing global environmental sustainability.

If you look at the increased fuel efficiency in our vehicles, they are really a function of the plastics and the composites that are contributing their light-weighting.

When we look at the enhanced energy efficiency of our built environment, our homes, our offices, and our factories, it is the products of chemistry that are increasing their energy efficiency and reducing greenhouse gas emissions. Even when we look at the plastic packaging that is reducing the weight of consumer products, that is reducing emissions.

So, there is a lot of really positive contributions that the products of chemistry are making to enhance sustainability. Unfortunately, we have too many plastics that are entering into the environment where they clearly do not belong.

As many of you already noted, the first step to ending plastic waste in the environment starts with understanding the sources. Twenty countries account for 83 percent of plastic waste entering into the ocean. The largest sources are rapidly developing economies, mainly in Asia, where basic plastic waste management infrastructure has not kept pace with the rise in demand for consumer goods.

Studies by The World Bank and McKinsey have identified that the most cost-effective investments to reduce plastic waste in the environment are the implementation of waste collection infrastructure and improved processing of collected waste in source countries.

ACC applauds the efforts of Senator Sullivan and Senator Whitehouse for leading efforts to secure the passage of the Save Our Seas Act. It is a good first step.

But ACC and our value chain partners are excited about the opportunity to provide private sector support that would complement a bigger, bolder, and more effective Save Our Seas Act 2.0.

There is a unique opportunity to build bipartisan congressional and Administration support for increasing the U.S. global leadership in advancing policies that will significantly reduce man-made waste from entering into the environment.

We would encourage your consideration of policies that would include encouraging The World Bank and international development banks and USAID to prioritize waste collection and management. According to the International Solid Waste Association, waste management accounts for only .3 percent of development aid assistance.

We also would encourage promotion of public-private partnerships and business-led efforts to fund waste management in the developing world. We encourage the Department of Defense and other agencies to fund waste management pilot projects at their facilities, particularly in the Asia Pacific region, to transform plastic waste into fuels, feedstocks, and infrastructure materials.

In addition to policies designed to reduce waste in the developing world, there are domestic policies that can enhance waste management systems in the U.S. and also contribute to the development and implementation of new technologies that can capture the value in plastic waste. Plastic waste has more captured energy than coal, and many of ACC's companies are investing in developing technologies that can unlock the captured energy, transforming non-recycled plastics into alternative fuels and feedstock materials for new manufacturing. But current regulations do not specifically recognize these emerging technologies as recycling, which is an impediment to capturing the value of plastic waste.

Some specific opportunities to address this issue include: providing guidance to States recognizing pyrolysis and gasification facilities which take waste plastics and convert them back to chemicals or fuels as manufacturing and not hazardous waste facilities; revise EPA's guidelines for the assessment of environmental performance standards and equal labels for Federal procurement to prefer products and services that utilize recovered plastics as recycled content; partner with the Department of Energy and Department of Transportation and other appropriate agencies to research opportunities that utilize plastic waste and innovative construction materials in transportation and water infrastructure projects nationwide; and, finally, designating fuel derived from plastic waste as a renewable fuel.

We have a great opportunity to create a global public-private initiative to eliminate manmade waste in the environment. ACC and our partners in the plastic value chain are committed to working with you and environmental organizations to identify the policies and the most cost-effective investments of public and private resources that will eliminate manmade waste from entering into the environment.

Thank you.

[The prepared statement of Mr. Dooley follows:]

# **AMERICAN CHEMISTRY COUNCIL, STATEMENT FOR THE RECORD, SENATE COMMITTEE ON ENVIRONMENT AND PUBLIC WORKS, "CLEANING UP THE OCEANS: HOW TO REDUCE THE IMPACT OF MAN-MADE TRASH ON THE ENVIRONMENT, WILDLIFE, AND HUMAN HEALTH," SEPTEMBER 26, 2018**

The American Chemistry Council (ACC) is pleased to submit this Written Testimony to the Senate Committee on Environment and Public Works regarding the September 26, 2018 hearing, "Cleaning Up the Oceans: How to Reduce the Impact of Man-Made Trash on the Environment, Wildlife, and Human Health."

While marine debris is a huge problem, it is also a solvable one. ACC, together with America's Plastics Makers®, are committed to ending plastic waste in the environment. We are proud to have partnered with governments, NGOs, and the private sector to deliver sustainable solutions to marine debris. Hundreds of projects are underway or already completed, but we know that there is much more to be done.

ACC represents a diverse set of companies engaged in the U.S. business of chemistry, a \$768 billion enterprise that is helping to solve the biggest challenges facing our country and the world. Chemistry touches 96 percent of all manufactured goods, and the use of plastics in modern automotive, building and construction, and food packaging industries is helping to create a more sustainable society.

- *Automotive*: Today's plastics make up 50 percent of the volume of new cars but only 10 percent of the weight. Lighter cars are more fuel efficient, and as a result, emit fewer CO2 emissions.
- *Building and Construction*: Architects and designers rely on plastics to help maximize energy efficiency, durability and performance of our homes, offices, and schools.
- *Food Packaging*: Plastics help keep our food fresh and clean with less packaging while reducing food waste. Reducing food waste is important because EPA estimates that more food reaches landfills and incinerators than any other single material in our everyday trash, constituting 22 percent of discarded municipal solid waste.

Although plastics provide important benefits to society, plastics and other trash don't belong in our waterways or the environment. That's why ACC and our members are actively engaged in concrete, well-researched, and sustainable actions to reduce litter and prevent marine debris.

The first step to ending plastic waste in the environment starts with understanding the sources. A number of scientific studies have concluded that plastic litter in the ocean is the result of poor or insufficient waste management and lack of sufficient collection, recycling and recovery facilities infrastructure in rapidly developing countries.

Twenty countries account for 83 percent of the mismanaged plastic waste available to enter the ocean.<sup>31</sup> The largest sources are rapidly developing economies, mainly in Asia, where basic waste management infrastructure has not kept pace with the rise in demand for consumer goods. Over half of land-based plastic waste leaks from just five countries: China, Indonesia, the Philippines, Thailand, and Vietnam.

A recent World Bank study confirms that root cause. Human trash in Indonesian rivers includes 53 percent organic waste, 13 percent diapers, 29 percent plastic and the remainder other debris.<sup>32</sup> Although consumer plastics are a large fraction of the waste stream, holistic solutions are needed to keep plastics out of our oceans and waterways.

The World Bank finding is also consistent with McKinsey's analysis for Ocean Conservancy's Trash Free Seas Alliance® which identified the need to immediately accelerate implementation of waste collection infrastructure, plug post collection leakage, and improve processing of collected waste in source countries.<sup>33</sup>

S. 756, "The Save our Seas Act," first passed in the Senate in 2017 and later by the House in 2018, is a well-designed and thoughtful piece of bipartisan, bicameral legislation. ACC and our members have long supported S. 756 for three important reasons:

- first, it emphasizes greater engagement with the key source countries;
- second, the bill would help ensure that precious waste management resources, technologies and investments are allocated to where they are needed most; and

 $\overline{a}$ 

<sup>31</sup> J. R. Jambeck, R. Geyer, C. Wilcox, T. R. Siegler, M. Perryman, A. Andrady, R. Narayan, and K. L. Law, "Plastic waste inputs from land into the ocean," Science, 2015, Volume 347, Number 6223.

<sup>&</sup>lt;sup>32</sup> The World Bank Group, Indonesia Marine Debris Hotspot Rapid Assessment Synthesis Report, April 2018.

<sup>33</sup> Ocean Conservancy, McKinsey Center for Business and Environment, "Stemming the Tide: Land-based strategies for a plastic-free ocean," Oct. 2015.

 third, it reauthorizes the Marine Debris Act, which provides provisions to further study land-based waste management solutions and causes of marine debris, as well as increase investment and technical assistance to help expand waste management systems and best-practices in rapidly industrializing nations.

We are pleased that Senate passage of S. 756, with House amendments, is imminent and will allow for expeditious passage in the House before being sent to the President for his signature.

Legislation is one part of the answer. ACC and our members are working with governments, NGOs, and our industry peers to deliver sustainable solutions to marine debris. In 2011, ACC helped lead the development of the Declaration of the Global Plastics Associations for Solutions on Marine Litter.<sup>34</sup> The Global Declaration obliges signatories to commit to action in six areas: education, research, public policy, best practices, recycling/recovery, and product stewardship.

Attached to this Testimony are two documents which highlight work both completed and underway on several marine debris projects across each of the six focus areas:

- "America's Plastics Makers Contribute to Solutions on Marine Litter" (*See Appendix A*);
- "The Declaration of the Global Plastics Associations for Solutions on Marine Litter, 4th Progress Report – Executive Summary" (*See Appendix B*).

75 plastics associations in 40 countries have signed the Declaration since its launch. More than 355 marine litter projects are planned, underway, or have been completed around the globe. Each of them helps to forge cooperation and continuous progress to prevent, reduce, and improve understanding of marine litter.

One of those projects involves a unique partnership between ACC and Circulate Capital, an investment management firm dedicated to financing innovation, companies, and infrastructure that prevent the flow of plastic waste into the world's oceans. Starting initially with Southeast Asia, Circulate Capital will provide capital investments to improve collection, sorting and recycling markets, particularly across the plastic value chain. This emphasis on international cooperation on waste management in the largest source countries is critical to reducing trash in our oceans.

ACC and America's Plastics Makers® are also taking important steps in the United States. In May, ACC's Plastics Division announced three ambitious goals that crystalize U.S. plastics resin producers' commitment to recycle or recover all plastic packaging used in the United States by 2040 and to further enhance plastic pellet stewardship by 2022.

Specifically, members of ACC's Plastics Division have set the following goals for capturing, recycling, and recovering plastics:

- 100 percent of plastics packaging is re-used, recycled or recovered by 2040.
- 100 percent of plastics packaging is recyclable or recoverable by 2030.

 $\overline{a}$ 

<sup>34</sup> www.marinelittersolutions.com.

Circularity at its core is about reducing waste, promoting reuse, increasing recycling rates and developing new recovery technologies. Achieving a more "circular economy" for plastics will enable society to continue to harness plastics' essential benefits, like enhancing the safety and sanitary packaging of food and personal care products, while helping to protect and restore the environment for future generations.

It's important to note that achieving a circular economy does not mean eliminating plastics, since plastics serve an essential role in helping to accomplish ambitious goals in sustainability across all three pillars – social, environmental, and economic. Many proposals to restrict or eliminate certain plastics fail to consider how they can help reduce environmental costs.

For example, a July 2016 study by Trucost found that replacing plastics in consumer products and packaging with a mix of alternative materials with the same function would increase environmental costs from \$139 billion to \$533 billion annually. <sup>35</sup> The higher environmental cost of alternatives to plastic is a function of the increased quantity of materials needed to fulfill plastic functions. Every material has a cost, including plastics, but the Trucost study tell us that using alternatives to plastic has costs that are almost four times higher.

Another important feature of plastics that is not commonly known is that their "captured energy" is greater than wood, paper or even coal. Today, an emerging set of technologies has begun to unlock that captured energy, transforming non-recycled plastics into alternative fuels and feedstock materials for new manufacturing. In fact, established energy recovery facilities can reduce by 80 percent the volume of waste that goes to landfill.

Plastics that go on to become fuel and other forms of energy are plastics that do not end up in our oceans. Some of the most widely used and rapidly emerging technologies include plastics-to-fuels, pyrolysis, gasification, solid recovery fuels, and waste-to-energy. With the rise of these new technologies comes new jobs and economic growth.

Together with the Trucost findings, the increased recycling and the potential shift toward greater recovery of plastics serves as another example for why product-specific restrictions do not advance social, environmental, or economic goals. Contrary to popular opinion, product bans are not sustainable solutions. Legislation like the "Save Our Seas Act" recognizes this important fact.

Innovations in plastics have helped improve the lives of billions of people around the globe. At the same time, the problem of marine debris is one that businesses, environmental groups, policymakers, and citizens around the globe have become all too familiar with.

ACC believes that awareness, deep appreciation and understanding of the marine debris problem now serves as the necessary prologue to embark on a journey toward creating and implementing sustainable solutions.

We thank you for the opportunity to testify today and look forward to our continued partnership in protecting and restoring the environment for future generations.

The American Chemistry Council (ACC) represents the leading companies engaged in the business of chemistry. ACC members apply the science of chemistry to make innovative products and services that make people's lives better, healthier and safer. ACC is committed to improved environmental, health and safety performance through Responsible Care®;

l

<sup>&</sup>lt;sup>35</sup> Trucost, "Plastics and Sustainability: A Valuation of Environmental Benefits, Costs and Opportunities for Continuous Improvement," July 2016.

common sense advocacy designed to address major public policy issues; and health and environmental research and product testing. The business of chemistry is a \$768 billion enterprise and a key element of the nation's economy. It is among the largest exporters in the nation, accounting for fourteen percent of all U.S. goods exports. Chemistry companies are among the largest investors in research and development. Safety and security have always been primary concerns of ACC members, and they have intensified their efforts, working closely with government agencies to improve security and to defend against any threat to the nation's critical infrastructure.

# **SENATE COMMITTEE ON ENVIRONMENT AND PUBLIC WORKS, HEARING ENTITLED,** *"CLEANING UP THE OCEANS: HOW TO REDUCE THE IMPACT OF MAN-MADE TRASH ON THE ENVIRONMENT, WILDLIFE, AND HUMAN HEALTH?",* **SEPTEMBER 26, 2018, QUESTIONS FOR THE RECORD FOR THE HONORABLE CAL DOOLEY**

## **Chairman Barrasso**

 $\overline{a}$ 

l. Experts seem to agree that stopping the flow of debris into the ocean is a bigger priority than cleaning up the debris already in the ocean. Is this an assessment that you agree with? If not, why not?

Yes, we agree that priority should be given to stopping the flow of debris into the ocean. While there is a need to clean up debris that is presently in the ocean, the highest priority is to stop leakage of additional plastic into the ocean.

A broad coalition of non-governmental organizations, academics, and private sector stakeholders brought together by the Ocean Conservancy, supported the development of *Stemming the Tide<sup>36</sup>*, and *The Next Wave.*<sup>37</sup> The reports looked closely at all options to reduce marine debris and concluded that waste management is the critical measure, while finding that bans on plastic products would not solve the problem.

The reports identify solutions for reducing plastic inputs to the ocean and recommend a program for global action to solve the problem. Here are some of the major recommendations from *Stemming the Tide:*

- Close leakage points within local collection systems by optimizing transport systems to eliminate illegal dumping
- Close or improve dump sites located near waterways, and increase waste collection rates by offering expanded services
- Keep leakage points closed by increasing the value of waste, and manually sort waste in rural areas to extract high value plastic waste for recycling

<sup>36</sup> Ocean Conservancy, 2015. http://www.oceanconservancy.org/our-work/marine-debris/mckinsey-report-files/fullreport-stemming-the.pdf.

<sup>37</sup> http://www.oceanconservancy.org/wp-content/uploads/2017/05/the-next-wave.pdf.

2. Five countries in Asia China, Indonesia, the Philippines, Thailand, and Vietnam bear much of the responsibility for the increase in ocean plastic. What steps is the private sector taking to reduce plastic waste coming from these countries?

The private sector is engaged in various efforts across the Asia-Pacific region to address leakage of waste into the ocean. Some of these efforts include supporting Circulate Capital, developing of a new global effort to eliminate plastic waste, and engaging in the Asia Pacific Economic Cooperation Forum.

### *Circulate Capital*

In 2017, ACC and the World Plastics Council joined a coalition of partners to support Closed Loop Ocean (CLO), a \$150 million fund to support waste management in key source countries. The objective is to absorb some of the risk associated with waste management infrastructure projects in developing countries. The fund also serves as catalytic capital to attract other investors such as multi-national development banks, sovereign wealth funds, and private investors.

In 2018, CLO became Circulate Capital, a separate entity to manage investments in waste management infrastructure in developing countries. Initially, Circulate Capital will focus on waste infrastructure solutions in Southeast Asia. Circulate Capital investments will be provided to improve collection, sorting and recycling markets, particularly across the plastic value chain.

Circulate Capital recently announced the creation of an Incubator Network in partnership with Second Muse to rapidly scale the number of innovators in the sector in South and Southeast Asia, building out their capacity, and providing acceleration support for those innovations.

#### *Asia Pacific Economic Cooperation (APEC)*

ACC has been engaged in the APEC for over 20 years and specifically on marine debris issues since 2015. Our work has focused on prioritizing investment in waste management. In 2016, ACC helped to organize a high-level APEC workshop with the Government of Japan on de-risking investment in waste management infrastructure. From the workshop, we helped develop policy and practice recommendations for overcoming barriers to financing waste management systems and reducing marine litter. Since 2016, we have continued to work through various APEC working groups to support investment in waste management, as well as support the development of projects to address marine debris.

3. We know that five countries in Asia bear much of the responsibility for the increase in ocean plastic. That does not mean that we in the United States do not have a critical role to play. What additional steps can local and state government, as well as the federal government, take to address this problem?

The United States has an important role to play in addressing sources of marine debris. The Save Our Seas Act is an excellent step and positions the United States to lead in the global effort to address marine debris. There are many domestic companies with technology solutions that can be deployed to help address the lack of waste management infrastructure and especially waste treatment infrastructure.

Focusing on domestic efforts, the Congress can encourage investment in technologies that repurpose used plastics into a wide range of raw materials, chemical and plastic feedstocks, and lower carbon fuels. The U.S. EPA can communicate a more circular vision of plastics materials management via the use of new technologies and strategies for converting plastics to raw materials, feedstocks, and fuels. If Congress reauthorizes the alternative fuel tax credit and alternative fuels mixture credit, it can make promote fairness by including fuels derived from post-use plastics. If Congress decides to reauthorize the Renewable Fuels Standard, it should also look at the role alternative fuels derived from plastics play in conserving energy and water and reducing greenhouse gas emissions and reducing waste to landfill or litter. Local and state governments can support programs to address littering behavior, improve recycling access and infrastructure, and optimize public services such as collection and street sweeping to reduce littering.

Local governments can also work with groups such as The Recycling Partnership<sup>38</sup> to take advantage of funding to move communities into lidded recycling carts. The program reduces littering, while increasing the volume of recycled material collected.

Plastics recycling and recovery is not only good for the environment but also creates manufacturing jobs. A critical missing piece of the puzzle is our lack of good infrastructure. As part of any infrastructure discussion, Congress should consider how it can incentivize investment in collection (especially in more rural areas) as well as investment in newer and more technologically proficient sortation and processing of post-use materials including plastics.

4. In an answer to one of my questions, you said that:

"'there are some simple things that Congress could do that would not treat plastic waste and the recovery of it as a 'hazardous waste' because that is stemming the flow of investment dollars in the development of new technologies that could advance the value of that waste stream and recapture some of the value..."

Are there specific provisions in statute or specific regulatory provisions that Congress should re-examine and consider addressing? If so, please identify those provisions.

At the federal level, we could ensure that regulations do not impede innovative, readily available alternative uses to non-recycled plastics. We already know that plastics can be reused in a wide variety of ways, from use as fuel to reinforcing roadways and making decking and fencing. One simple change would be to classify plastics used as fuel to make cement as categorical non-hazardous secondary materials (NHSM), which would ease regulatory burden and cost for these facilities. To make this simple change, Congress could direct EPA to add plastics to an existing regulatory list of authorized alternative fuels.

In the past year alone, states such as Florida, Wisconsin, and Georgia overwhelmingly approved legislation to treat post-use plastics as valuable feedstocks for manufacturing and ensured that newer technologies such as pyrolysis and gasification would be regulated as manufacturing and not waste disposal. Congress should work to understand what these states have done and sec if there is equivalent legislation at the federal level. Led by Senators Wyden and Cassidy, S. 1460 Energy and Natural Resources Act of 2017, included a provision

 $\overline{a}$ 

<sup>38</sup> https://recyclingpartnership.org/.

for the Department of Energy to study how to utilize post-use plastics as a valuable source of domestic energy and raw materials for remanufacturing.

5. On January 24, 2018, the *Financial Times* published an article, by Clive Cookson, that was entitled, "The problem with plastic." It explained that:

"While the personal-care industry is phasing out microbeads, concern is growing about another ubiquitous micro pollutant: plastic fibers. Analysis shows these to be present in streams, rivers, lakes and seas worldwide, as well as household drinking water. Their main source seems to be clothing and textiles made from synthetic fibers, which become detached in washing machines and are not filtered out by water-treatments plants."

Do you agree with this assessment? lf so, how do we begin to address this issue?

Effective filtration- and then treatment- of wastewater is important. New technologies are now being developed to help washing machines more effectively remove microfibers from home laundry wastewater, and that's a great start. In the meantime, we need to continue work to better understand potential sources of microfibers; how to detect them with accuracy; and to evaluate whether they pose a risk in drinking water or to humans from seafood.

With respect to foods, Congress could ask the Federal Food and Drug Agency and U.S. Department of Agriculture experts in understanding whether water or food are safe- to confirm that seafood's arc currently safe for human consumption while undertaking targeted studies. Congress could also direct USDA to increase its inspection of shellfish and to specifically document any incidence of microfibers. With respect to drinking water, Congress could direct EPA to review the state of technology for dirt and particle removal from drinking water, and provide additional funding if needed to improve technologies for coagulation and f1occulation (removes dirt and other particles through the addition of alum (or other metal salts) to form coagulated masses called f1oc that attract other particles); sedimentation (sifts coagulated, heavy particles through gravity to the bottom of a basin) and filtration (channels water after sedimentation through sand, gravel. coal, activated carbon, or membranes to remove smaller solid particles not already removed).

## **Ranking Member Carper**

6. Stopping the f1ow of marine debris into the ocean and mitigating its impacts- are not problems that can be solved overnight. Long-term. thoughtful, and collaborative solutions are necessary in order to address the full scope of the issue. Solutions that have been discussed included: improving recycling, incentivizing the use of recycled materials in the global supply chain, developing more biodegradable alternatives, and changing manufacturing protocols are potential solutions to help address this issue. What steps can this Committee and the Congress take now to advance these potential solutions here in the United States?

We agree that improving recycling is important. Congress could encourage investment in recycling and modernizing materials recovery facilities to capture more recyclable materials. Congress could also incentivize innovative technologies that convert plastics to monomers or fuels through including fuels made from otherwise unrecycled plastics in the renewable fuel tax credit.

Congress can signal that technologies that convert plastics to raw materials, chemical and plastic feedstocks and lower carbon fuels are part of the circular economy. As noted in response to question 4, Congress could work with EPA to classify plastics used as fuel to make cement as categorical non-hazardous secondary materials (NHSM), which would ease regulatory burden and cost for these facilities. This would be done through the addition of plastics to an existing regulatory list of authorized alternative fuels.

Congress could also work to understand state legislation to treat post-use plastics as valuable feedstocks for manufacturing and see if there is equivalent legislation at the federal level to ensure that newer technologies such as pyrolysis and gasification would be regulated as manufacturing and not waste disposal.

7. Now that China has implemented its "Green Fence Policy," a ban on importing plastic waste, our market for these materials in the United States is flooded. China previously accepted 30% of our plastic waste. Local municipalities are now having even more trouble breaking even when collecting and recycling this waste. In your opinion, what are the best ways for the United States to address this new challenge?

#### *Education of Consumers*

There is a need to better education consumers regarding how to properly recycle used plastics to reduce contamination and increase value. A good example is the How to Recycle® label placed on many packages. which provides easy-to-follow directions on proper recycling and disposal of used packaging. Other programs such as ACC's Wrap Recycling Action Program<sup>39</sup> (WRAP) educate consumers on how to properly recycling used bags and films by taking them back to over 18,000 locations across the United States.

#### *Investment in Technology and Infrastructure*

Investing in the domestic recycling industry will help to create new market opportunities for material previously sent to China for recycling. By upgrading sortation equipment at material recovery facilities, we will reduce contamination and increase value of used plastics. Chemical recycling and recovery of used plastics through pyrolysis, gasification, and other technologies will create additional markets for used plastics. Increased consumer and brand demand for recycled content in plastic packaging will help to drive investment in needed technologies.

 $\overline{a}$ 

<sup>39</sup> https://www.plasticfilmrecycling.org.

## **Senator Whitehouse**

8. ACC has been a leading voice among the plastics industry in support of both domestic and international marine debris efforts. What are some of the initiatives ACC is leading or supporting that aim to reduce the flow of plastic from land into the oceans?

h ACC appreciates the compliment and takes great pride in helping to address the sources of marine debris. The following fact sheet. America's Plastic Makers Contribute to Solutions on Marine Litter<sup>40</sup>, and the 41 Progress Report for The Declaration of the Global Plastics Associations for Solutions on Marine Litter <sup>41</sup> provide additional information on ACC's domestic and international efforts to address marine debris. Below are some examples of projects.

#### *Save the Bay Narragansett Bay, Rhode Island*

America's Plastics Makers® are partnering with Save the Bay® on the City of Warwick Shoreline Trash Reduction & Prevention project. This initiative aims to reduce littering behavior with a combination of cleanups, community engagement and education. The project is utilizing lessons learned from other efforts to reduce litter and marine debris.

## *Keep It Beachy Clean (Virginia Beach)*

Keep it Beachy Clean is an education and outreach program aimed at reducing beach litter. Clean Virginia Waterways developed the program, which provides Virginia Beach's resort community with anti-litter messaging. Following a successful first year, the program is expanding to capture a wider segment of the Virginia Beach resort community.

#### *Circulate Capital*

In 2017, ACC and the World Plastics Council (WPC) joined a coalition of partners to support Closed Loop Ocean (CLO). In 2017 WPC and CLO announced the creation of a \$150 million fund to support waste management in key source countries. In 2018, CLO became Circulate Capital, a separate entity to manage investments in waste management infrastructure in developing countries. Initially, Circulate Capital will focus on waste infrastructure solutions in Southeast Asia. Research indicates that the majority of plastic debris originates from five fast growing economics in Asia-Indonesia, the Philippines, Vietnam, Thailand and China. Circulate Capital investments will be provided to improve collection, sorting and recycling markets, particularly across the plastic value chain.

9. Is there a role for materials innovation in reducing the risks plastics pose to wildlife and ecosystems if they enter the oceans?

Material innovation may play a role in reducing the impact of marine debris on wildlife. For example, a marine degradable part was developed for a crab trap to cause a pot to stop catching crabs if it is lost for a significant period of time. Innovations like this arc important

 $40^{\circ}$ <sup>40</sup> http://plastics.americanchemistry.com/fact-sheets-and-infographics/Americas-Plastics-Markets-Contribute-to-Solutions-on-Marine-Litter.pdf.

<sup>41</sup> https://www.marinelittersolutions.com//wp-content/uploads/2018/04/Marine-Litter-Report-2018.pdf.

but arc challenging and must still meet the original function of the product. Plastics makers continue to look for new materials as well as improvements to existing materials in an effort to balance material use, performance, and recyclability.

10. Is there a role for materials innovation in increasing the value of plastics to ensure they are collected for reuse and recycling?

We are already seeing great potential for increasing the value of used plastics through the development of compatibilizers. This family of technologies improves performance of recycled resins; enables recycling of multi-material, multi-layer pouches; and allows for higher incorporation rates of post-consumer recycled resin into new products.

11. Is ACC investing in any cleanup solutions, including improving wastewater management to better collect microplastics and microfibers from water supplies?

, ACC staff participate in annual International Coastal Clean-up events. although our investments related to address marine debris are focused on infrastructure and education. For example, we have provided funding for trash and recycling bins; consumer education regarding proper recycling of plastics wrap, bags, and film; and anti-litter and litter reduction programs; among other projects. As noted above, the following fact sheet, America's Plastic Makers Contribute to Solutions on Marine Litter  $42$  and the  $4''$  Progress Report for The Declaration of the Global Plastics Associations for Solutions on Marine Litter<sup>43</sup> provide additional information on ACCs domestic and international efforts to address marine debris.

microfibers such as the Cora Ball<sup>44</sup> and Guppy Friend<sup>45</sup> That said, industry efforts to improve ACC has not invested into projects to better collect microplastics and microfibers from wastewater management systems. We are aware of several efforts to address the issue of the technology to filter microfibers at the source-in wastewater from washing machines-is well-documented.

12. As we work on the next iteration of the Save Our Seas Act, do you have any additional recommendations or comments you would like to share to inform our development of this bill?

We welcome the opportunity to work with you and your staff as the next iteration of the Save Our Seas Act is developed. The Save our Seas Act of 2018 included new language to coordinate with developing countries which are the largest sources of marine debris. This assistance will be the highest priority to solve this problem for the foreseeable future. Unfortunately only a very small fraction of development finance goes to improve waste management (0.3%). There may be a way for the US to encourage development financing agencies to prioritize waste management.

\* \* \*

Senator BARRASSO. Thank you so much for your testimony, Mr. Dooley. Mr. KARAS.

## **STATEMENT OF BRUCE KARAS, PRESIDENT OF ENVIRONMENT AND SUSTAINABILITY, COCA-COLA NORTH AMERICA**

Mr. KARAS. Chairman Barrasso, Ranking Member Carper, and members of the Committee, thank you for the opportunity for inviting me before you to discuss the very issue of marine debris.

Our world has a waste problem. According to the Ocean Conservancy, scientists estimate that more than 8 million metric tons of plastic is entering our ocean every year. From our perspective, it is unacceptable that packaging ends up in the wrong place, in our oceans and waterways or littering the communities where we work and live.

As a total beverage company, we bring people drinks that make life's everyday moments more enjoying, create a shared opportunity for people and communities we call home. While growth is important, we cannot grow at any cost. We believe in doing business the right way, not just the easy way. For us, that means continuously working to reduce our environmental impact by collecting and recycling our packaging footprint, providing access to clean drinking water, supporting women's economic empowerment, and strengthening local communities.

We are a global company operating in more than 200 countries and territories, but through our bottling partners we also have deep, local connections and relationships that offer a unique ability to make a meaningful difference. The key areas where we strive to lead are clean, sustainable water for communities and women's economic empowerment.

A third area we launched just this year is our new packaging vision, World Without Waste. The goal is to rethink how bottles and cans are designed and made, as well as how they are recycled and repurposed. The centerpiece is a bold, ambitious goal to help collect and recycle the equivalent of every bottle or can we sell globally by 2030. The Coca-Cola system intends to back World Without Waste with a multiyear investment that augments ongoing work to make our packaging 100 percent recyclable by 2025.

When it comes to PET, we believe that every package has value and a life beyond its initial use, and should be collected and recycled into either a new package or another beneficial use. We aim to be part of collaborative solutions that prevent waste from getting to the ocean in the first place.

Regardless of where it comes from, we want our packages to have more than one life. To date, all 17 of our geographic business units have developed local plans to address our three strategic pillars: design, collect, and partner.

Design means we aspire to create packaging that is at least 50 percent recycled material by 2030; continue working to make all consumer packaging 100 percent recyclable by 2025.

Collect means to collect and recycle the equivalent of 100 percent of the primary packaging we sell by 2030. Partner means we will work together to support a healthy debrisfree environment at both the land and the sea.

In the context of design, our research and development team is working with chemical recycling technologies toward future piloting or partnerships. Additionally, our procurement team is working with our suppliers to advance progress on and increase availability of recycled PET, known as rPET.

In Mexico, our bottled water brand seal is now available in 100 percent rPET bottle as a result of strong collection and conversion infrastructure that our system has partnered in over the past decade. We are also looking at 100 percent rPET bottle in the Hong Kong market later this year. We will pilot the use of rPET in several other Asia Pacific markets in 2019. The increased use of rPET is crucial to accelerate a transition to a true circular economy for plastics.

In the innovation space, we have expanded our package-less delivery model for beverages with both our freestyle touchscreen operated dispenser and our innovative Dasani pure fill.

In the context of collect, marine plastic is driven in larger part by limited collection and waste management infrastructure in many emerging markets. That is why our second strategic pillar centers on improving packaging collection.

We are working around the world to have an up-to-date understanding of collection recycling data and approaches. Where systems do not exist is where we are focusing. Cities with a very active informal sector, like unofficial, small-scale businesses, have high rates of collection. There are correspondingly lower rates of collection for recycling in more developed cities where there is less incentive for small-scale collectors.

We will use the data we collect to partner with government, industry, civil society, and local communities to tailor, co-create, and roll out the type of collection recycling models that have been successful in developing markets in other parts of the world and scalable models that will improve collection rates.

Last is partner. We recognize that although we are part of a problem, we cannot solve the packaging waste problem alone. It is for that reason we have established, joined, and expanded cross-sectoral partnerships around the world. We intend to do all of this not just in a cross-sector way, but in a scalable way that drives systemic change.

We are working with groups from the international level to the very local level, from the Ocean Conservancy Trash for Seas Alliance, the Ellen MacArthur Foundation, to the Closed Loop Fund and local chambers of commerce.

Thank you for your time. I look forward to answering your questions.

[The prepared statement of Mr. Karas follows:]

# **TESTIMONY OF BRUCE KARAS, VICE PRESIDENT OF ENVIRONMENT AND SUSTAINABILITY, THE COCA-COLA COMPANY NORTH AMERICA, BEFORE THE UNITED STATES SENATE, ENVIRONMENT AND PUBLIC WORKS COMMITTEE, HEARING ON MARINE DEBRIS, SEPTEMBER 26, 2018**

Good Morning Senators. Thank you for inviting me before you today to discuss the very real issue and concern of Marine Debris. Our world has a waste problem. According to the Ocean Conservancy, scientists estimate that more than 8 million metric tons of plastic is entering our ocean every year. From our perspective, it is unacceptable that packaging ends up in the wrong place, in our oceans and waterways or littering the communities where we work and live.

As a total beverage company, we bring people drinks that make life's everyday moments more enjoyable, to create shared opportunity for the people and communities we call home. While growth is important, we cannot grow at any cost. We believe in doing business the right way, not just the easy way. For us, that means continuously working to reduce our environmental impact by collecting and recycling our packaging footprint, providing access to clean drinking water, supporting women's economic empowerment, and strengthening local communities.

We may be a global company operating in more than 200 countries and territories, but through our bottling partners we also have deep, local connections and relationships that offer a unique ability to make a meaningful difference. The key areas where we strive to lead are clean, sustainable water for communities, women's economic empowerment, and to working to create a world without waste by collecting and recycling the equivalent of our bottles and cans in the marketplace.

In 2010, The Coca-Cola Company made a commitment to be water neutral by 2020- a goal we achieved in 2015. Through projects implemented by the end of 2017, The Coca-Cola Company is replenishing an estimated 248 billion liters per year through community and watershed projects globally. We are also working to improve our water-use ration 25% over 2010 levels. To date we have made a 15% improvement and continuing to do more.

At the same time, our commitment to strengthening communities by empowering women has never been stronger. Our 5by20 initiative, also launched in 2010 to enable economic empowerment to 5 million women by 2020 has to date enabled more than 2.4 million women entrepreneurs across 75 countries.

This year, to help tackle the world's packaging problem, we launched our new packaging vision, World Without Waste. It involves rethinking how bottles and cans are designed and made, as well as how they're recycled and repurposed within our system around the world. The centerpiece of this vision is a bold, ambitious goal to help collect and recycle the equivalent of every bottle or can we sell globally by 2030. The Coca-Cola system intends to back World Without Waste with a multi-year investment that includes ongoing work to make our packaging 100 percent recyclable by 2025.

When it comes to PET, we believe every package has value and life beyond its initial use and should be collected and recycled into either a new package or another beneficial use. We aim to be part of collaborative solutions that prevent waste from getting to the ocean in the first place.

Regardless of where it comes from (i.e., whether the package is made by Coca-Cola or one of our competitors), we want it to have more than one life. To date, all 17 of our geographic business units have developed local plans to address our (3) strategic pillars - Design, Collect and Partner:

- Design Aspire to create packaging that is at least 50% recycled material by 2030; continue working to make all consumer packaging 100% recyclable by 2025
- Collect Collect and recycle the equivalent of 100% of the primary packaging we sell by 2030
- Partner Work together to support a healthy, debris-free environment (land & sea)

## **Design**

Our Research and Development team is working with chemical recycling technologies towards future partnerships or piloting. Additionally, our Procurement team is working with our suppliers to forward progress on and increase availability of rPET.

In Mexico, our bottled water brand, Ciel, is now available in a 100% rPET bottle, which builds on the extremely strong collection and conversion infrastructure that our system has financed over the past decade. In Australia, our Mount Franklin water brand is also now available in 100% rPET, and we are launching our water brand in Hong Kong in 100% rPET later this year. We will pilot the use of rPET in a number of ASEAN markets beginning in 2019 and we believe this is going to be very important to accelerate a transition to a true circular economy for plastics.

In the innovation space, we have expanded our "package-less" delivery model for beverages, our innovative Freestyle technology to more than 50,000 machines serving 14 million drinks daily, with continued expansion in North American and moving to Europe and Latin America. Freestyle is a touchscreen-operated dispenser that uses "micro-dosing" technology to deliver nearly 200 beverage options - including 117 low/no-calorie beverages and more than 100 varieties, with only a cup.

### **Collect**

We are keenly aware from research conducted by the Ocean Conservancy and others that marine plastic is primarily a land-based issue, driven in large part by limited collection and waste management infrastructure in many emerging markets. That's why our second strategic pillar centers on improving packaging collection. We are working around the world to have an, up-to-date understanding of existing collection and recycling data and approaches, as you would expect some parts of the world have much stronger systems in place than others. Where the systems do not exist is where we are focusing our efforts.

Data on solid waste management collection and recycling is a significant challenge in ASEAN (governments and civil society don't have this kind of date on PET collection rates) and so we've commissioned a Singapore- based circular economy advisory and action company to conduct baseline research for us in six markets across Southeast Asia. What we've seen from the research is high rates of collection for recycling for PET in cities like Myanmar (estimated 82% collection for recycling rate for PET in Mandalay, 74% in Yangon) or Jakarta (estimated 69% collection for recycling rate for PET) with a very active informal sector (i.e., unofficial small-scale businesses such as street scavengers, recycling pickers and junk shops) and correspondingly lower rates of collection for recycling in more developed cities like Kuala Lumpur (estimated 23% collection for recycling rate for PET) where there's less incentive for waste collectors and recycling pickers with higher incomes to collect recyclables.

As ASEAN develops, driving source segregation will be the only way to capture recyclables. This will require government conviction that segregation is necessary and government commitment to implement and enforce source segregation initiatives. We will be using the data to tailor, co-create and roll-out with government, industry, civil society and local communities the type of collection and recycling models that have been very successful in developing markets in other parts of the world (e.g., Mexico) and scalable models that improve collection rates by empowering and strengthening the informal collection sector. We see extensive opportunity to do this starting in major cities and tourist destinations in the ASEAN region and we already have a number of industry alliances set up in ASEAN. A few examples are:

- *Indonesia* is the second largest global contributor to issue of ocean plastic, with plastic waste a serious threat to the economy (particularly industries like tourism and fishery) as well as the environment. In 2017, the government launched a *National Plan of Action Against Marine Debris,* developed by a task force led by the Coordinating Ministry for Maritime Affairs. Ahead of National Waste Awareness Day in February, and as part of industry efforts to step up and contribute to solutions, six companies, including Coca-Cola Indonesia, jointly announced the formation of the Packaging and Recycling Alliance for Indonesia Sustainable Environment (PRAISE). The vision of PRAISE is to establish best practices that support sustainable and integrated packaging waste management solutions in Indonesia. This approach to waste management aligns with the government's move towards a circular economy and PRAISE has engaged on a regular basis with the Ministry of Environment and Forestry and the Coordinating Ministry for Maritime Affairs. By contributing to research, education, collaboration and engaging stakeholders in government and civil society, PRAISE is an important industry platform to help advocate for a circular economy and drive industry efforts to reduce impacts of packaging waste on the environment. PRAISE was represented last year at the World Ocean Summit in Indonesia, the first-ever ASEAN Conference on Reducing Marine Debris held in Thailand, the APEC High-Level Meeting on Accelerating Waste Management Solutions to Reduce Marine Litter in Bali and the Responsible Business Forum on Sustainable Development in Singapore. This year, as part of an agreement with the Coordinating Minister of Maritime Affairs, PRAISE commissioned a study in Bali to look at the value chain of Plastic Waste in order to obtain better data on plastic waste and subsequently to implement a pilot project on Sustainable Plastic Waste Management using the data collected. In parallel, this year PRAISE is also starting to implement a Drop Box program in Jakarta, through which 100 drop boxes are being distributed in public as well as retail spaces.
- *Philippines* Coca-Cola Philippines is a member and active supporter of The Philippine Alliance for Recycling and Materials Sustainability (PARMS) a non-profit industry organization incorporated in 2015 to bring together stakeholders in the recycling value chain, including manufacturers, industry groups, retail groups, waste consolidators and haulers, recyclers and non-government and government entities. The objective of PARMS is to develop and implement holistic and comprehensive programs to increase waste recovery and reduce landfill dependence towards zero waste through strategic partnerships. PARMS recently entered into a Memorandum of Understanding with the Local Government Unit of Paranaque (a fully urbanized city in Metro Manila) to build a plastics recycling facility towards the implementation of a Full Waste-Recovery Program within this year. Once fully operational, this facility will be able to process approximately 365 tons of waste per annum - waste diverted from landfills, from water streams, and the like. During the
Earth Day celebration in April 2018, PARMS formally turned over the proposed recycling facility design to the chief executive of Paranaque City. The project is supported by 8 leading fast-moving consumer goods companies including Coca-Cola and many of our competitors and leading local industry organizations.

 *Vietnam* - we are now advancing a partnership with Unilever, Dow and the Vietnam Chamber of Commerce and Industry to implement a circular economy approach in Ho Chi Minh City. The partnership is still in its infancy, but we will be working together to strengthen recycling infrastructure. We are also getting ready to launch a new community-focused program focused on the iconic tourist area of Ha Long City, working with a local NGO called Green Hub to empower 250 women waste pickers and raise awareness across stakeholder groups and decision-makers about the importance of tackling plastic waste.

## **Partner**

We recognize that although we are a part of the problem, we cannot solve the packaging waste problem alone. It is for that reason we have created, established, joined and expanded cross-sectoral partnerships around the world. We intend to do all of this not just in a crosssector way but in a scalable way that drives systemic change - to do so will take catalytic funding. Some of our other partners in driving this change are:

- The European Union Beverage Industry: Beverage packaging is already the most collected packaging in the European Union, but the beverage industry just announced a new set of EU-wide ambitions:
	- By 2025 100% of soft drinks primary plastic packaging will be recyclable;
	- By 2025 soft drinks PET bottles will contain a minimum of 25% recycled material on average;
	- Collection rates of soft drinks primary plastic packaging for recycling will be further increased and optimized in all EU markets in collaboration with other packaging recovery actors;
	- Soft drinks primary plastic packaging will be reused including refillable bottles - where it makes environmental and economic sense.
- The Ocean Conservancy/Trash Free Seas Alliance: A partner since 1995, our partnership activities range from participation in the annual International Coastal Cleanup to supporting recycling infrastructure. Together with the Ocean Conservancy and others, we launched the Trash Free Seas Alliance in 2011 to advance the scientific understanding of marine debris globally, including research to determine the regions contributing the most waste to the oceans.
- Closed Loop Fund: We have worked with the Closed Loop Fund since its inception, predominantly through Coca-Cola North America (as most of its first efforts were focused in the U.S.). More recently, we joined a new initiative of Closed Loop Partners called Closed Loop Ocean that will target innovative approaches on funding waste management and recycling solutions in Southeast Asia.
- Circulate Capital we are an early-stage supporter of the just-announced Circulate Capital initiative established to advance the circular economy- it builds on our long partnership in North America with the Closed Loop Fund. Circulate Capital is focused on catalyzing investments in ocean plastic solutions in Southeast Asia and India. Priority markets are Indonesia and India. Secondary markets are the Philippines, Vietnam and Thailand.
- *Ellen MacArthur Foundation (EMF)* New Plastics Economy initiative: The Company is a founding partner of the New Plastics Economy initiative, which includes leading consumer goods companies and other plastics users and producers. The Company continues to work closely with EMF on the development of our packaging strategy and metrics. EMF is a leading voice supporting the circular economy and pushing for private sector led innovations and solutions to the addressing plastic waste.
- *World Economic Forum Platform for Accelerating the Circular Economy (PACE) initiative* is a public-private multi-stakeholder platform focused on shaping global policy and accelerating targeted action towards the circular economy. Plastics is a core focus area with specific project work underway in ASEAN. We are actively engaged in shaping the agenda at both the strategic and tactical levels. Our CEO James Quincey serves on the PACE Leadership Board.

## **SENATE COMMITTEE ON ENVIRONMENT AND PUBLIC WORKS, HEARING ENTITLED,** *"CLEANING UP THE OCEANS: HOW TO REDUCE THE IMPACT OF MAN-MADE TRASH ON THE ENVIRONMENT, WILDLIFE, AND HUMAN HEALTH?",* **SEPTEMBER 26, 2018, QUESTIONS FOR THE RECORD FOR MR. BRUCE KARAS**

## **Chairman Barrasso**

l. Experts seem to agree that stopping the flow of debris into the ocean is a bigger priority than cleaning up the debris already in the ocean. Is this an assessment that you agree with? If not, why not?

Agree as The Coca-Cola Company, we believe that the most effective way to impact change is to address the problem of waste before it reaches waterways and ultimately, oceans. That is where our efforts are focused.

2. Five countries in Asia- China, Indonesia, the Philippines, Thailand, and Vietnam- bear much of the responsibility for the increase in ocean plastic. What steps is the private sector taking to reduce plastic waste coming from these five countries?

The Coca-Cola Company is one example of one private sector organization, and our efforts are focused around our World Without Waste vision. We've set an ambitious goal to help collect and recycle the equivalent of a bottle or can for everyone we sell by 2030 and to make all of our packaging I 00% recyclable by 2025.

We are working to accomplish this industry-first, ambitious goal through 3 main pillars:

- Design Aspire to create packaging that is at least 50% recycled material by 2030; continue working to make all consumer packaging 100% recyclable by 2025
- Collect- Collect and recycle the equivalent of 100% of the primary packaging we sell by 2030
- Partner-Work together to support a healthy, debris-free environment (land  $\&$  sea)

Our goal is not only a worldwide goal, but also a local goal. We have strategies, partnerships and engagements in each of the five countries listed above that are tailored to the not just the country, but the needs of the cities within each of those countries as the needs vary depending on locality. Across the Asia-Pacific region our local teams are focused on addressing PET collection systems, raising public awareness, creating and promoting publicprivate partnerships and establishing recycling infrastructure. We won't reach solutions overnight or by ourselves, but they must come, and we aim to play an important role in achieving progress.

### *China*

Using cutting-edge facial recognition technologies and a voice interactive system, the new VenCycling machine both dispenses beverages and collects used packaging for recycling. In exchange for returning used cans or plastic bottles into the machine, consumers receive credits, primarily via mobile devices, for products made from recycled plastics.

These innovative vending machines are helping to build a circular pathway for our packaging while educating and incentivizing recycling behaviors. We have also partnered with the One Foundation in China to work on public education around recycling.

#### *Indonesia*

We are an early-stage supporter of the just-announced Circulate Capital initiative that is focused on catalyzing investments in ocean plastic solutions in Southeast Asia and India. It is an initiative to advance the circular economy and builds on our contribution to and work with the Closed Loop Fund over the last few years in the United States.

In 2007, Coca-Cola Amatil lndonesia and Quiksilver Indonesia initiated the Bali Beach Clean Up (BBCU), a daily clean-up program in five main beaches of Bali. Ten years later, the Bali Beach Clean Up teams have removed more than 34 million kg of rubbish from 9.7 kilometers of shoreline in Bali. The program is powered by 150 new bins per year, 4 beach tractors, 2 barber surf rakes, 3 garbage trucks, and 78 crews from local communities surrounding the beaches. BBCU crews also act as ambassadors to promote the importance of taking care of the environment. Complementing the daily BBCU program, Bali's Big Eco Weekend is an annual festival to drive more support from everyone to keep Bali beaches clean and green.

The Coca-Cola Company is contributing our marketing and communications expertise to public campaigns that bring awareness to the importance of recycling and circular economy solutions. For example, in Jakarta, Coca-Cola Indonesia has launched a program called "Plastic Reborn: Give your Plastic Bottle A Second Life" targeted at millennials and showing that "Recycling can be cool". Plastic Reborn is increasing awareness about responsible waste

management and the importance of a circular economy. The program has deployed I 00 bins in 77 schools/universities/public places in Jakarta and already collected 1.8 tons of post-consumer PET bottles. These bottles are then shredded into PET flakes and then the process of upcycling turns the flakes into fashionable multi-function bags. 5000 bags already produced through this program.

### *Philippines*

Coca-Cola Philippines is a member and active supporter of The Philippine Alliance for Recycling and Materials Sustainability (PARMS), a non-profit industry organization incorporated in 2015 to bring together stakeholders in the recycling value chain, including manufacturers, industry groups, retail groups, waste consolidators and haulers, recyclers and non-government and government entities. The objective of PARMS is to develop and implement holistic and comprehensive programs to increase waste resource recovery and reduce landfill dependence towards zero waste through strategic partnerships. PARMS recently entered into a Memorandum of Understanding with the Local Government Unit of Paranaque (a fully urbanized city in Metro Manila) to build a materials recovery facility towards the implementation of a Full Waste-Recovery Program within this year.

Once fully operational, this facility will be able to process approximately 365 tons of waste per annum-waste diverted from landfills, from water streams, and the like. During the Earth Day celebration in April 2018, PARMS formally turned over the proposed recycling facility design to the chief executive of Paranaque City. The project is supported by leading fast-moving consumer goods companies including Coca-Cola, Liwayway Marketing Corporation, Monde Nissin, Nestle Philippines, Pepsi-Cola Products Philippines, Procter & Gamble Philippines, Unilever Philippines, and Universal Robina Corporation. Other alliance members are Philippine Chamber of Commerce and Industry. Philippines Business for the Environment, the Zero Waste Recycling Movement. Department of Trade and Industry, Department of Science and Technology, Department of Environment, Philippine Plastics Industries Association, Philippine League of Environment and Natural Resource Officers.

#### *Thailand*

Coca-Cola supported the first-ever ASEAN Conference on Reducing Marine Debris hosted by the government of Thailand, the ASEAN Secretariat and UN Environment with participation from ASEAN member governments, civil society and private sector. The theme of partnership was pervasive throughout the conference-. "The Time Is Now" with an emphasis on partnerships across the plastic value chain.

#### *Vietnam*

We are now advancing a partnership with Unilever. Dow and the Vietnam Chamber of Commerce and Industry to implement a circular economy approach in Ho Chi Minh City. The partnership is still in its infancy. We are also getting ready to launch a new communityfocused program focused on the iconic tourist area of Ha Long City, working with a local NGO called Green Hub to empower 250 women waste pickers and raise awareness across stakeholder groups and decision-makers about the importance of tackling plastic waste.

3. We know that five countries in Asia bear much of the responsibility for the increase in ocean plastic. That does not mean that we in the United States do not have a critical role to play. What additional steps can local and state governments as well as the federal government take to address this problem?

The Coca-Cola Company has long championed public-private partnerships, or what we call the Golden Triangle consisting of private companies, non-profits and government working together to solve a problem. Recycling systems and infrastructure need to be improved throughout the US which is the best way to impact national recycling rates. We believe that working with the broader waste management sector in transitioning from a land filling approach for all waste to a more refined system that builds an infrastructure that increases recycling is key to the success of recycling. Additionally, education on proper waste management, and innovation when it comes to our packaging are areas where we as a Company will continue to focus our efforts.

4. In an answer to one of my questions, you mentioned "waste infrastructure 2.0." How would you (Coca-Cola) design "waste infrastructure 2.0" to ensure that we in the United States collect materials that are not currently recycled?

Waste infrastructure 2.0 is a transition to an infrastructure that reflects more of a circular economy that captures commodities that do have intrinsic value and can be re-used. It is a closed loop. The 2.0 system will have an increased capability to identify, select, sort and bale commodities that can be re-used in a meaningful way. In today's system we are essentially retiring the carbon consumed in making materials in the ground, when recycling and reuse can significantly reduce our carbon emissions. In the beverage sector, glass PET and aluminum arc highly recyclable commodities that represent future supply in a circular economy. If we have an updated system, a steady supply of used PET and high demand for recycled PET is achievable.

#### **Ranking Member Carper**

5. Stopping the flow of marine debris into the ocean- and mitigating its impacts- are not problems that can be solved overnight. Long-term, thoughtful, and collaborative solutions are necessary in order to address the full scope of the issue. Solutions that have been discussed included: improving recycling, incentivizing the use of recycled materials in the global supply chain, developing more biodegradable alternatives, and changing manufacturing protocols are potential solutions to help address this issue. What steps can this Committee and the Congress take now to advance these potential solutions here in the United States?

The Coca-Cola Company believes that we need to focus on designing better packaging, collecting the packaging that we sell and partnering in order to achieve both of those goals. Improving recycling infrastructure both in the US and globally is an immediate first step toward improving recycling rates which will ultimately reduce the flow of marine debris into the ocean. It is absolutely critical that in considering the necessary infrastructure thought is given to the economic incentive of creating fully functional end markets that convert the recycled commodities into future products. These end markets represent green jobs and incentivize the infrastructure as it is a viable business.

Now that China has implemented its "Green Fence Policy," a ban on importing plastic waste, our market for these materials in the United States is flooded. China previously accepted 30% of our plastic waste. Local municipalities are now having even more trouble breaking even when collecting and recycling this waste. In your opinion, what are the best ways for the United States to address this new challenge?

Recycled PET (rPET) has a value on the market. One reason The Coca-Cola Company has set the target of making our bottles out of 50% rPET by 2030 is that will further drive the rPET market. The challenge in the US is that our recycling stream has high levels of contamination that impacts the productivity of the recovery facilities (MRFs). When we improve and update MRFs, we will have a rPET product for which there is a market, one that is in fact growing and becoming more competitive. This is one example of the importance of a viable end market that has a demand for the recycled material.

6. In your testimony, you mentioned Coca-Cola's three strategic pillars for recycling as part of the "World Without Waste" campaign: one of them is "collect." I agree that improving our nation's recycling practices is vitally important. However, many local communities and states do not have sufficient waste management and recycling infrastructure. From your perspective, what can local and state governments do to build this capacity? How might this Committee and the federal government support them?

Business must collaborate with governments, communities, the private sector and NGO's to establish or further develop recycling programs. One example of such is our partnership with the Closed Loop Fund. We are working to advance recycling technologies and partnering with local communities to improve their recycling infrastructure. Aluminum and PET are the two highest value commodities in the waste stream today. There is an opportunity to created viable businesses and green jobs that harvest recyclables. Our work with the Closed Loop Fund has shown that often the ROI for investments in the local infrastructure is positive. We welcome the opportunity to participate in more such partnerships.

#### **Senator Markey**

7. The Ocean Plastics Charter was agreed to in June 2018 by five of the G7 countries to encourage a more sustainable approach to the management of plastics. The United States and Japan did not join. But on September 20, Coca-Cola and several other large corporations pledged to help reduce plastic pollution in support of the Ocean Plastics Charter.

a. How important is it for the United States and the private sector to get on board with reducing plastic waste if we are truly going to address the marine debris crisis on a global scale?

As a company headquartered in the United States, we know that our actions, commitments and progress impact movement on a global scale. For our part, as a global business operating in 200 countries and territories, we will continue to work to address our contributions on a global scale. Our World Without Waste commitment is a global commitment because marine debris is a global issue. We believe it is of vital importance that this continue to be an area of international focus.

#### **Senator Merkley**

8. To achieve your goal of recycling all your bottles, you have commented that you will need help collecting them. What challenges has Coca-Cola faced in increasing collection rates abroad?

Today, in some countries, our packaging and collection rates are high while in others, there is still a lot of work to be done. It's a huge challenge and there are a lot of moving targets. We operate in 200 countries and territories, and each of them has its own government, regulatory system, and collection and recycling infrastructure challenges. Measurement and data that pertain to recycling is also lacking in many parts of the world. Certain parts of the world have no infrastructure for collecting and recycling packaging, and others have minimal infrastructure. In these cases, sometimes the market for recycled material doesn't exist. Creating a valuable "end market" component is key. To achieve our goals, we will need the support of many cross-sector partners.

9. Will Coca-Cola support bottle deposit arrangements in the United States, to work in conjunction with curbside recycling?

For many years, we have favored a holistic recycling approach.

We are open to further looking at deposit programs that are non-discriminatory and fair, on a case-by-case basis, to determine whether they may be the most effective and sustainable option for some communities.

Despite our belief that deposit programs are not suitable for every society or economy, and are not always the most efficient solution, we have organized some fair and efficient deposit programs in some of our markets. The rate of recycling has not increased which is why it is time to try new solutions, deposit programs are one of multiple way to do this.

## **Senator Whitehouse**

10. What lessons has Coca-Cola learned through its other sustainability and resource management work within its supply chain and distribution network that can be applied to plastics?

From our water stewardship work, we know that business must collaborate with governments, local communities, the private sector and NGO's to establish or further effective programs. It takes many partners to be successful. We are also acutely aware that when we harness our entire supply chain we have the ability to affect real change with compounded results. That is our goal with World Without Waste.

11. This year, Coca-Cola launched its "World Without Waste" initiative which sets the goal of collecting and recycling every bottle and can Coca-Cola sells by 2030. It also aims to make all Coca-Cola products recyclable by 2025.

a. What types of initiatives are Coca-Cola programs already undertaking or likely to undertake to implement the World Without Waste goals?

The Coca-Cola Company is building partnerships, creating initiatives and joining collaborations for localized programs around the world. Two good examples of collaboratives are Closed Loop Partners ("CLP") and The Recycling Partnership ("TRP"). CLP includes the Closed Loop Fund, a \$100 million fund delivering solutions that remove recycling bottleneck with technology. TRP is a collaboration of over 40 companies and enterprises that is working on increasing curbside collection in the U.S. There is no one solution or silver bullet to improving recycling, which is why we are working within cities, towns and counties to find the solution that best tits, but also sharing best practices around the globe.

b. What investments is Coca-Cola making in improving collection and recycling infrastructure in the over 200 countries and territories it operates in?

The Coca-Cola Company has become and is becoming financial partners with organizations that are focused on recycling: from Keep America Beautiful, The Recycling Partnership and Ocean Conservancy, to the Closed Loop Fund and Circulate Capital, a venture loan fund established to address plastics in the Asia-Pacific oceans. Every country in which Coca-Cola operates will make investments to support World Without Waste.

c. What is the role of the private sector, especially in developing countries, in improving waste infrastructure?

The role of the private sector is to work with the local governments. Because we are a global company, The Coca-Cola Company can bring expertise and best practices to contribute to the expansion (or creation) of recycling infrastructure.

d. As part of this initiative, does Coca-Cola plan to redesign its packaging to reduce plastic composition?

By 2030, we will have no single use primary packaging, as we will collect 100%, incorporate at least 50% recycled content in each package, and ensure the balance is recycled in other ways. We will also continue to innovate to lightweight the plastic that is used to further reduce the amount of virgin plastic in our bottles.

12. What other areas of materials innovation or packaging design is Coca-Cola investigating to minimize its waste production?

Our focus is on our packaging materials, primarily PET plastic. We are innovating new packaging that will include 50% recycled PET (rPET) by 2030. We have pledged that our packaging will be I 00% recyclable by 2025. Additionally, we are looking at future process innovations such as chemical recycling and package-less delivery of beverages. We will continue to design and innovate new packaging that meets our goals.

13. Does China's new prohibition on imported waste alter Coca-Cola's ambitions at all?

No, our World Without Waste goals exist independent of governmental action. In order to meet our World Without Waste goals, we need to collect and reuse PET. Having a strong local supply of pure rPET is an asset to our business in the U.S. and throughout the world.

14. As a user of plastic materials, what pressure can Coca-Cola exert on plastic producers and prod net developers to innovate and minimize the harm these materials can cause if they end up in the oceans?

We are working with Global Procurement and our mainstream suppliers to phase in rPET content globally. As a leader in the industry, our goal is by creating this demand developers will further innovate, and it will encourage greater waste collection to grow the supply of rPET.

15. What role has consumer demand played in encouraging Coca-Cola to be an active participant in marine debris work?

We are always working to listen to consumer points of view, particularly where our business intersects with an opportunity to do good in the communities that we serve- we are a part of them too.

We are committed to marine debris work because we, like others, have a responsibility to help solve the world's packaging problem. We know it's time for us to help lead the way and do more- and we are, through our World Without Waste initiative.

Our work is not reactionary. We have supported recycling and packaging recovery programs throughout the world for decades. We have partnered with the Ocean Conservancy since 1995 on research and action to cleanup marine litter, including being a lead sponsor of the International Coastal Cleanup. Together with the Ocean Conservancy and others, we launched the Trash Free Seas Alliance® in 20 I I to advance the scientific understanding of marine debris globally.

16. As we work on the next iteration of the Save Our Seas Act, do you have any additional recommendations or comments you would like to share to inform our development of this bill?

We look forward to working with the Senate in the creation of the next iteration of Save Our Seas Act.

\* \* \*

Senator BARRASSO. Thank you very much, Mr. Karas. Dr. LAW.

## **STATEMENT OF KARA LAVENDER LAW, RESEARCH PROFESSOR OF OCEANOGRAPHY, SEA EDUCATION ASSOCIATION**

Ms. LAW. Good morning. Thank you, Chairman Barrasso, Ranking Member Carper, and members of the Committee for the invitation to testify at this important hearing on man-made debris in the marine environment. My name is Dr. Kara Lavender Law, and I am a Research Professor of Oceanography at Sea Education Association, or SEA.

Since 1971, SEA has taken undergraduate students to sea on tall sailing ships to study the open ocean firsthand as navigators, sailors, shipmates, and scientists. More than 8,000 SEA semester students, some of whom are in the room today, have contributed to our 30-plus year data set on floating plastics in the ocean, assembled by towing plankton nets from our sailing research ships twice a day, every day, and hand-counting their contents.

Trained in ocean physics, I first learned about ocean plastics in 2003, when I joined SEA, where the distribution of floating plastic debris was common knowledge based upon decades of student research. In contracts to misconceptions about immense floating islands of recognizable items of plastic trash, often referred to as garbage patches, SEA scientists knew that the most numerous type of plastic debris are microplastics, particles smaller than your pinky fingernail that are not readily visible even from the deck of a ship. I have a sample here.

Since 2010, I have carried out scientific research on ocean plastics to better understand their sources, abundance, distribution, and transformation in the marine environment not only to advance scientific understanding, but also to inform solutions to this global problem.

Of all the man-made debris in the marine environment, we focus on plastics because of their ubiquity, persistence, and the risks they pose to wildlife and, potentially, human health. To date, wide-spread encounters of more than 800 species of marine wildlife with plastic debris have been well documented, and scientific evidence clearly demonstrates physical harm that can lead to death of individuals from entanglement or ingestion of large debris.

Laboratory studies have also provided evidence of harm from animal uptake of microplastics and their associated chemicals. However, because experiments are carefully controlled to test single outcomes, it is impossible to generalize results across species of debris types, or from the laboratory to populations in nature. Further research into the ecological impacts of contamination by microplastics is sorely needed.

However, we must not wait for all scientific questions to be comprehensively and definitively answered before taking action to eliminate plastic debris from our oceans. In the short-term, the most important action is to stop uncontained plastic waste from entering the ocean from land.

It is estimated that of the 5 to 13 million metric tons of plastic trash entering the ocean annually, nearly half originates from four countries in Southeast Asia, where inadequate infrastructure cannot keep pace with the rapidly increasing waste generation.

However, here in the United States, the amount of plastic waste generated per capita outranks that in each of those four Southeast Asian countries, and the amount of plastic waste generated each day in the coastal United States is the highest of any country in the world.

In the U.S. we are fortunate to also have a robust waste management system. But even the relatively small amount of waste that is accidentally lost or intentionally littered adds up to a large amount available to enter the ocean. Global investment in waste management, especially where no formal system currently exists, but even where it does, is the first line of defense in keeping trash out of the ocean.

Cleaning up litter on land, especially in rivers and on coastlines, will continue to be an important "last chance" strategy to capture waste before it enters the ocean. Cleaning up debris in the sea itself is more challenging and resource-intensive, but can be effective when targeting large items in nearshore areas or collecting floating trash before it can move offshore and break apart into millions of microplastics.

Waste collection and cleanups are imperative in the short-term, but long-term sustainable solutions to ocean plastics pollution must address the increasing amounts of plastics in use. We must act to eliminate unnecessary usage and waste; increase demand for recovering and recycling, perhaps through product design that ensures material value at the end of product life; and identify suitable material alternatives where possible.

In summary, to reduce the impact of man-made trash on the oceans, wildlife, and human health, it is imperative that we prevent debris, especially that made of plastics, from entering the ocean. There is an immediate and critical need to assist countries that have inadequate waste management systems and there is much more to do in our own communities here in the U.S. as well.

No matter where in the world we choose to work, a necessary first step is to clearly identify and measure the local sources of ocean debris, as well as the drivers behind each source, which could be a lack of infrastructure, a consequence of product design or use, or factors influencing human behavior. With this information in hand, we can best focus our time, attention, and resources to design appropriate interventions that will reduce input from each source. These actions should always be appropriate to place. There is no silver bullet or one-size-fits-all solution.

Ocean plastics pollution is an environmental problem that is global in scope, in impact, and in responsibility. We all have a stake in a clean and healthy ocean. Whether in towns, cities, or States in the United States, or through international partnerships, we must work together toward short-term and long-term solutions.

Thank you for the opportunity to testify. I look forward to the day when our oceans are clean because of the work we have accomplished together.

[The prepared statement of Ms. Law follows:]

# **WRITTEN TESTIMONY OF: KARA LAVENDER LAW, PHD, RESEARCH PROFESSOR OF OCEANOGRAPHY, SEA EDUCATION ASSOCIATION, WOODS HOLE, MASSACHUSETTS, BEFORE THE U.S. SENATE COMMITTEE ON ENVIRONMENT AND PUBLIC WORKS, HEARING: "CLEANING UP THE OCEANS: HOW TO REDUCE THE IMPACT OF MAN-MADE TRASH ON THE ENVIRONMENT, WILDLIFE, AND HUMAN HEALTH?", SEPTEMBER 26, 2018**

## **Introduction**

Good morning. Thank you Chairman Barrasso, Ranking Member Carper, and members of the Committee, for the invitation to testify at this important hearing on man-made debris in the marine environment. My name is Dr. Kara Lavender Law, and I am a Research Professor of Oceanography at Sea Education Association (SEA), a non-profit educational organization based in Woods Hole, MA. Since 1971, SEA has taken undergraduate students to sea on tall sailing ships to study the open ocean, first-hand, as navigators, sailors, shipmates and scientists. More than 8,000 SEA Semester students have contributed to our 30+-year data set on floating plastics in the ocean, assembled by towing plankton nets from our sailing research ships twice a day, every day, and hand-counting their contents. In 2016, for our work in, "fostering scientific discovery and stewardship of the world's oceans," the National Science Board awarded SEA its Public Service Award.

As an oceanographer trained in ocean physics, I knew little about marine debris before joining the faculty at SEA 15 years ago. More seasoned faculty quickly taught me that the "plastics project" was a popular independent research topic for our students who were concerned about ocean pollution, and also one of the most reliable because, unlike projects focused on particular marine organisms, one could guarantee that along certain cruise tracks small bits of plastic debris would be found floating at the sea surface. It wasn't until 2007 when I first heard the term "garbage patch," a term rife with misconceptions about immense floating islands of recognizable plastic trash. In fact, the most numerous type of plastic debris in the ocean, and what we typically collect in our plankton nets, are "microplastics," particles smaller than your pinky fingernail that are composed of a variety of synthetic polymers (Figure 1). These microplastics are not readily visible from the deck of a ship, let alone from an aircraft or satellite. At SEA, we recognized the need to shift the focus away from mythical floating islands of trash and towards a scientifically informed description of ocean plastics pollution. To this end, in 2010 we published an analysis of our unprecedented data set, which now consists of more than 10,000 measurements of the concentration of floating plastic particles in the Atlantic and Pacific Oceans. For the past 10 years, I have carried out scientific research on ocean plastics to better understand their sources, abundance, distribution and transformation in the marine environment, not only to advance scientific understanding, but also to inform solutions to this global problem.

It is important to remember than not all marine debris is plastic, and not all is found floating at the sea surface. Trash on beaches and shorelines is marine debris (Figure 2). Litter on the seabed is marine debris, whether close to land (Figure 3) or in deep and remote places (Figure 4). Debris can be tens of meters long, such as lost fishing nets (Figure 5) or derelict vessels, or it can be microscopic in size. Man-made debris is composed of paper, glass, aluminum or other metals, as well as plastics. Yet the debris of greatest concern and focus, both by scientists and citizens, is that made of plastics.

### **Plastics: Ubiquitous, Long-Lived and Harmful to Wildlife**

We focus on plastics in the marine environment because of their ubiquity, and the risks they pose to wildlife and potentially human health. In a 2017 study<sup>46</sup> led by Roland Geyer of University of California, Santa Barbara, we estimated that since the start of mass production, 8.3 billion metric tons of plastics have been produced, more than most other man-made

l

<sup>46</sup> Geyer, R., J. R. Jambeck and K. L. Law, 2017. Production, use, and fate of all plastics ever made. *Sci. Adv.* 3, e1700782.

materials, with the exceptions of steel and cement. Further, we estimated that 90% of these plastics still exist on the planet, with only a small fraction of plastic waste having been incinerated, and the majority of waste either residing in landfills or in the environment. Plastics are designed for strength and durability and do not biodegrade; thus, once in the environment, plastics persist for years to decades or longer. Other man-made materials such as glass and metals are also persistent in the environment; however, unlike glass and metals, the light weight of plastics makes them easily transportable. As plastics are carried by wind or water in the environment, they are weakened by sunlight and fragment to smaller and smaller pieces. Their chemical composition changes as well, as additives leach out and contaminants already present in seawater transfer to plastics. Thus, as plastic debris moves around in the oceans, its size, shape, and chemical makeup change. As these debris characteristics evolve, so too do the potential impacts on wildlife that encounter these plastics.

More than 800 marine species have been affected by man-made debris  $47$  through interactions such as ingestion, entanglement (including ghost fishing), and displacement of species that drift with, or upon, floating debris. Further, plastic debris accounts for 92% of reported encounters with individual organisms.<sup>48</sup> Large whales have ingested items as large as flower pots and meters-long lengths of rope and plastic sheeting; $49$  bottle caps and cigarette lighters have been found in the guts of dead albatross chicks; <sup>50</sup> and small microplastics particles contaminate a multitude of species, including fish and shellfish we consume as seafood.<sup>51</sup> Plastics ingestion has now been documented for more than 200 marine species, including all species of sea turtles, 59% of whale species, and 59% of seabird species.<sup>52,53</sup> Further, for particular populations, such as the northern fulmar seabird population in the North Sea, as many as 95% of individuals studied have ingested plastics. <sup>54</sup> The direct consequences to wildlife of ingesting relatively large plastic debris can include physical injury and gut obstruction, ultimately leading to death, whereas the consequences of ingesting microplastics remain less well understood. An area of intense scientific inquiry asks whether or not chemicals associated with ingested microplastics transfer into animal tissue and cause physiological damage. Some laboratory studies have demonstrated that for particular animalplastic-chemical combinations, physiological harm does occur,55,56 yet more work remains to determine whether or not these impacts are occurring in nature and, if so, at what scale.

Although recent scientific research has largely focused on impacts of microplastics ingestion, evidence clearly demonstrates impacts of debris on marine wildlife through entanglement and species transport. Entanglements, now reported for 344 marine species, most commonly involve components of derelict fishing gear, such as plastic rope and netting, as well as looped packing or strapping bands, which may cause severe injury and death.<sup>3,7</sup> In 29 years of surveying the critically endangered North Atlantic right whale, 83% of individuals showed evidence of entanglement.<sup>57</sup> The most recent demonstration of species transport on floating debris was the delivery of 289 living marine species from the coast of Japan across the Pacific Ocean to North America for six years following the 2011 Tohoku earthquake and tsunami.<sup>58</sup> Although we don't yet know whether these species will become established and threaten native species, the six-year duration of the invasion is unprecedented, and is likely due to the persistence of plastics in the ocean.

To date, widespread encounters of marine wildlife with plastic debris have been well documented, and scientific evidence clearly demonstrates harm from interactions with large debris. Laboratory studies have also provided evidence of harm from animal uptake of microplastics. However, because experiments are carefully controlled to test single outcomes, it is impossible to generalize results across species or debris types, or from the laboratory to populations in nature. Further research into the ecological impacts of contamination by microplastics is sorely needed.

## **Identifying the Sources**

 $\overline{a}$ 

The most effective way to reduce the impacts of plastic debris on wildlife and the marine environment is to prevent plastics from becoming ocean debris in the first place. This can only be accomplished by first understanding the origins of the debris, and the pathways by which it enters the ocean. Plastics can enter the environment at any point in their life cycle, starting from losses of industrial resin pellets (the material feedstock for plastic products), to accidental loss during product use, such as with fishing and aquaculture gear, to accidental or deliberate discard of plastic waste into the environment. A 2015 study<sup>59</sup> led by Jenna Jambeck of University of Georgia estimated that between 5 and 13 million metric tons of plastic trash generated in coastal regions worldwide enters the ocean in a single year because the waste is not properly captured and contained. We estimated that nearly half of this mismanaged plastic waste originates from four countries in southeast Asia (China, Indonesia, Philippines and Vietnam), countries that have experienced rapid economic growth accompanied by an increase in the amount of plastic waste produced by large coastal populations. When waste generation rates outpace the capacity of existing waste management systems, uncaptured plastic waste can flow into the oceans from rivers and waterways, or wash out to sea during storms or with the tides.

The United States also has a large coastal population, and the amount of plastic waste generated per capita outranks that in each of the four southeast Asian countries. According to

<sup>57</sup> Knowlton, A. R. *et al.*, 2012. Monitoring North Atlantic right whale *Eubalaena glacialis* entanglement rates: a 30 yr retrospective. *Mar. Ecol. Prog. Ser.* 466, 293-302.

<sup>58</sup> Carlton, J. T. *et al.*, 2017. Tsunami-driven rafting: Transoceanic species dispersal and implications for marine biogeography. *Science* 357, 1402-1406.

<sup>59</sup> Jambeck, J. *et al.*, 2015. Plastic waste inputs from land into the ocean. *Science* 347, 768-771.

our analysis, the amount of plastic waste generated each day in the coastal United States is the highest of any country in the world. We are fortunate to also have a robust waste management system – garbage and recycling collection, material sorting, and treatment either in sanitary landfills or by incineration. However, because of the sheer amount of plastic waste we create, even the small amount that is accidentally lost, or intentionally littered, adds up to a large amount available to enter the ocean.

Not all plastic debris in the marine environment originates from improperly managed waste on land. Abandoned, lost or otherwise discarded fishing gear is also a very large source of plastic debris, although no estimate of the global input yet exists. Natural disasters, such as hurricanes, floods and tsunamis, can inject a tremendous amount of debris of all materials into the ocean in a single, short-term event. And microplastics from a variety of sources – including microbeads in cosmetics, dust from tire wear, fragments of agricultural films, and fibers from synthetic clothing – can enter the ocean by pathways such as runoff into waterways, and stormwater and wastewater outflows.

#### **From Sources to Solutions**

Ocean plastics pollution is a global problem that has grown in size and scale since the 1950s as an unintended consequence of rapidly increasing production and use of these innovative and, in many cases, indispensible materials. Plastics were never intended to contaminate our oceans, rivers, lakes and soils, posing risks to wildlife and potentially even human health. Yet we are faced with ever increasing applications and use of these materials, without a clear strategy for management at the end of their useful life. Preventing plastics from becoming marine debris requires a suite of actions from local to global scales, carried out by individual consumers as well as material and product manufacturers; by municipal, state and national governments as well as international bodies. These actions should always be appropriate to place – there is no silver bullet, or one-size-fits-all solution.

#### *Contain the Waste*

The most pressing short-term need to prevent marine debris is to ensure that no waste is left uncontained in the natural environment, whether terrestrial, freshwater or marine. This requires global investment in waste management systems, especially where no formal waste management currently exists. In the 2015 Jambeck study, we estimated that if plastic waste generation were capped and total waste management achieved in the top ten emitting countries by 2025, then the annual input into the oceans would be reduced by 77%.

Even in countries like the United States, where we have established collection and processing of waste, we must ensure that trash cans are lidded and emptied before they overflow, and that the stray candy wrapper is caught before it blows away in the wind. We must invest in infrastructure that streamlines collection and processing of recyclable materials. The design of waste management systems anywhere in the world must be tailored for the needs of a particular community, understanding how, where and what kind of waste is generated, as well as existing social and cultural practices, to ensure community buy-in and long-term success in managing waste.

#### *Clean Up Uncontained Waste*

Cleaning up litter on land, especially in rivers and on coastlines, will continue to be an important strategy to prevent waste from entering the ocean. Seemingly simple interventions can be extremely effective, such as Baltimore's Mr. Trash Wheel, a solar- and hydro-powered river trash collection device with a personality, which has prevented 1.7 million pounds of debris from flowing into the Chesapeake Bay. Cleanups are also effective ways to engage and educate citizens as volunteers, as demonstrated by the nearly 250 million pounds of trash collected by nearly 13 million volunteers around the world since 1985 in Ocean Conservancy's International Coastal Cleanup.

Cleaning up debris in the sea itself is more challenging and resource intensive, but can be effective when targeting large items in nearshore areas, or collecting floating trash before it can move offshore and break apart into millions of microplastics. Fishing for Litter programs engage those in the fishing industry to remove litter from the sea in the course of normal fishing activity, at the same time raising awareness of the importance of keeping trash and derelict fishing gear out of the ocean in the first place. Project AWARE's Dive Against Debris program engages scuba diving enthusiasts to participate in underwater debris cleanups to not only report and remove trash on the seafloor, but also to serve as citizen scientists, collecting data on types and amounts of debris in order to inform prevention efforts.

#### *Sustainable Solutions*

Improved waste collection and cleanup of uncaptured waste are imperative in the short term, but long-term, sustainable solutions to ocean plastics pollution must address the increasing amounts of plastics in use by employing a variety of strategies to: eliminate unnecessary waste; increase demand for recovery and recycling; and identify suitable alternatives where possible. In some instances, where plastics are unnecessary for function (or are known to be particularly harmful), a mandated ban may be appropriate. The Microbead-Free Waters Act passed by the U.S. Congress in 2015, banning plastic microbeads in rinse-off cosmetics, is an example of this type of action. In other cases, a reduction in use can be incentivized by government policies (municipal, state, or national), such as mandated fees for single-use retail bags. A complimentary positive incentive to reduce single-use bags is provided by individual businesses that give a discount to customers who bring their own bags. Municipalities and institutions can promote waste reduction not only by offering separate recycling and food waste collection, but also by making improvements to infrastructure, such as installing water bottle refill stations to facilitate use of reusable, rather than single-serve, water bottles, thereby reducing plastic waste. Finally, campaigns by individuals or organizations can influence changes in behavior that will reduce waste. For example, the plastic drinking straw movement has recently grown from a simple "Skip the Straw" pledge to refuse an unneeded drinking straw, to an all-out social media blitz promoted by conservation organizations and celebrities alike, driving strong responses from major consumer goods companies down to stand-alone restaurants and individuals. As consumers, we all make innumerable decisions every day about products that we buy, use and throw away. Although we bear ultimate responsibility for our own decisions, good choices can be made easier by employing a variety of strategies to encourage waste reduction.

Perhaps with an ultimate long-term goal of zero waste, steps should be taken to bring value to products and materials at the end of their useful life. This will ultimately increase demand for reuse, recovery and recycling over disposal. Manufacturers engaged in product stewardship agree to share responsibility for their end-of-life product, such as through takeback and recycling programs, for example. A successful example of cross-brand product recovery and recycling is demonstrated in communities with container deposit schemes for beverage containers including plastic bottles, glass bottles and aluminum cans. Because of the uniformity in materials used across brands, and efficient recovery incentivized by the deposit, recycling of these materials is more cost effective and the waste material more valuable. With attention at the product design stage to ensure material value at the end of life, market incentives can reduce the number of one-way trips most items eventually take to the landfill or incinerator, or the environment.

Finally, continued scientific research to inform evidence-based decision-making is essential to addressing the problem of ocean plastics pollution, so that limited resources can be efficiently and effectively deployed to the greatest benefit. This does not mean that we must wait for all scientific questions to be definitively answered before taking action. Rather, prevention efforts will be most successful when research is first undertaken to understand the local sources and driving factors behind them. For example, Virginia Coastal Zone Management Program and Clean Virginia Waterways used data to identify balloon litter as items of concern, with nearly 9,000 balloons collected on Virginia beaches during 9 years of International Coastal Cleanups<sup>60</sup>. In response, they conducted public surveying and interviews to understand the who, where, when and why behind mass balloon releases in Virginia and, with this knowledge, designed a community-based social marketing campaign to discourage balloon releases and provide context-specific alternatives, a more targeted and informed strategy than a simple information-sharing education campaign alone.

## **Concluding Remarks**

 $\overline{a}$ 

In summary, to reduce the impact of man-made trash on the oceans, wildlife and human health, it is imperative that we prevent debris, especially that made of plastics, from entering the ocean. There is an immediate and critical need to assist countries that have inadequate waste management systems, and there is much more we need to do in our own communities as well.

No matter where in the world we choose to work, a necessary first step is to clearly identify and measure the local sources of ocean debris, including item types and locations, as well as the pathways the debris follows from the source to the sea. Second, we must determine the drivers behind each source, which could be a lack of infrastructure, a consequence of product design or use, or factors influencing human behavior. With this information in hand, we can best focus our time, attention and resources to design appropriate interventions that will reduce input from the source. Interventions may be relatively simple and inexpensive, such as installing and servicing lidded trash cans. Interventions may be engineered, such as debris traps in waterways or storm drains. Interventions may involve technological design innovations to ensure effective recovery and recyclability, and they may aim to influence human behavior away from a "disposable" mentality to reduce unnecessary

<sup>60</sup> Witmer, V., K. Register and L. McKay, 2017. *Balloon Release Research in Virginia and Reducing Balloon Debris through Community-Based Social Marketing.* Virginia Coastal Zone Management Program (Virginia Department of Environmental Quality), 117 pp.

usage and waste. Interventions may be legislated to mandate or incentivize actions by plastics producers, product manufacturers and consumers that will ultimately reduce the input of plastics to the ocean. Finally, we must continue to increase waste literacy and raise public awareness of this problem in order to drive action by consumers, producers, and governments alike, to both reduce unnecessary consumption and revolutionize our management of waste.

Ocean plastics pollution is an environmental problem that is global in scope, in impact, and in responsibility. We all have a stake in a clean and healthy ocean. Whether in towns, cities or states in the United States, or through international partnerships, we must work together towards short-term and long-term solutions as citizens, scientists, businesses, governments and people. Thank you for the opportunity to testify. I look forward to the day when our oceans are clean because of the work we have accomplished together.

Figure 1. Microplastics collected from surface seawater in the North Pacific Ocean by towing a plankton net. Microplastics are typically defined as particles smaller than 5 mm in size, and are composed of a variety of plastics. Microplastics may be manufactured at this size, such as the industrial resin pellet indicated by the orange arrow, but most are generated when larger plastic items break apart upon exposure to sunlight. # **SENATE COMMITTEE ON ENVIRONMENT AND PUBLIC WORKS, HEARING ENTITLED,** *"CLEANING UP THE OCEANS: HOW TO REDUCE THE IMPACT OF MAN-MADE TRASH ON THE ENVIRONMENT, WILDLIFE, AND HUMAN HEALTH?",* **SEPTEMBER 26, 2018, QUESTIONS FOR THE RECORD FOR DR. KARA LAVENDER LAW**

#### **Chairman Barrasso**

1. Experts seem to agree that stopping the flow of debris into the ocean is a bigger priority than cleaning up the debris already in the ocean. Is this an assessment that you agree with? If not, why not?

Yes, I agree. Cleaning up debris already in the ocean treats the symptom of the problem and not the cause. Even if it were possible to clean up all the debris in the ocean at one moment in time, more and more continues to flow in every day the task would never be complete. Further, scientists still do not know where the vast majority of trash entering the oceans from land is located in the ocean, making efficient and effective removal a virtualy impossible task. Targeted, local cleanups are worthwhile, especially if they take place on coastlines, beaches or in nearshore waters, but cleanups alone cannot solve this pollution problem. Stopping debris from entering the oceans is the top priority.

2. We know that five countries in Asia bear much of the responsibility for the increase in ocean plastic. That does not mean that we in the United States do not have a critical role to play. What additional steps can local and state governments as well as the federal government take to address this problem?

Yes, the United States population also contributes large amounts of debris to the ocean through leakage of waste from land, as well as through other sources (such as lost recreational and commercial fishing gear; losses due to natural disasters; losses of microplastics in wastewater and stormwater/runoff). Governments at all levels can take steps to help mitigate the problem. At the federal level, incentives (or disincentives) to reduce unnecessary plastics usage could serve to reduce the amount of plastic waste generated that needs to be managed. The Microbead Free Waters Act of 2016 is a good example of this kind of action. Further, the federal government could stimulate growth in the industries that collect and process materials for recycling. State governments could evaluate and improve waste management services, especially by streamlining recycling collection and processing for efficiency and consistency across municipalities. In particular, container deposit policies have demonstrated success in improving capture and recycling rates. Municipal governments can take steps to identify; specific "leakage" points of waste to the environment, and action directly mitigate those potential sources of waste to the ocean. For example, they could ensure the presence of public waste and recycling receptacles that are regularly serviced and designed to prevent/asses in heavy weather (e.g., wind). At all levels, funding will be necessary for research and implementation of mitigation actions.

3. On January 24, 2018, the *Financial Times* published an article, by Clive Cookson, entitled, "The problem with plastic." It explained that:

"While the personal-care industry is phasing out microbeads, concern is growing about another ubiquitous micropollutant: plastic fibres. Analysis shows these to be present in streams, rivers, lakes and seas worldwide, as well as household drinking water. Their main source seems to be clothing and textiles made from synthetic fibres, which become detached in washing machines and are not filtered out by water-treatments plants."

Do you agree with this assessment? If so, how do we begin to address this issue?

Synthetic fibers have been detected in a variety of water bodies, as well as in marine organisms, food and drinking water, and as airborne particles. They appear to be the most ubiquitous of the "microplastics." It is reasonable to assume that many of these fibers originate from clothing and textiles, but there may be other sources, such as synthetic ropes used in marine applications. Fibers shed from synthetic clothing during laundering have been identified as a source f pollution in wastewater that, if not captured, could enter the environment in effluent from wastewater treatment plants.

There is no easy solution to the shedding of micro fibers- they cannot simply be phased out like cosmetic microbeads because of a much greater reliance on synthetic textiles. Individuals can reduce the frequency of clothes laundering and install filters on washing machines to trap these particles before they enter wastewater, and perhaps wastewater treatment plans could develop additional methods to filter out: synthetic fibers. Further up the chain, textile manufacturers could work to engineer fabrics that are less susceptible to shedding. Most importantly, we must better understand the impacts of exposure to these microfibers to both wildlife and humans, especially through ingestion and inhalation, to evaluate the risks posed by microfibers. Only then can we properly evaluate the overall benefits and risks of synthetic textiles.

4. What regions of the world are the least studied when it comes to plastic pollution?

On a global scale, we have barely scratched the surface in our scientific understanding of plastics pollution. There are perhaps a handful of regions of the ocean in which plastic debris has been measured extensively and over long periods of time, but this is only the case for plastics in a specific size range floating at the sea surface. In other regions, a single study to document the presence of plastic debris may have been carried out, and, in most 4the world's oceans, plastic debris has not been studied at all. We have only a relatively coarse assessment of the size and distribution of one major source of plastic debris to the oceans (waste generated on land), whereas there exist very few direct measurements of the movement of trash or debris from land into the sea to inform targeted mitigation efforts.

#### **Ranking Member Carper**

5. Stopping the flow of marine debris into the ocean- and mitigating its impacts are not problems that can be solved overnight. Long-term, thoughtful, and collaborative solutions are necessary in order to address the full scope of the issue. Solutions that have been discussed included: improving recycling, incentivizing the use of recycled materials in the global supply chain, developing more biodegradable alternatives, and changing manufacturing protocols are potential solutions to help address this issue. What steps can this Committee and the Congress take now to advance these potential solutions here in the United States?

The most pressing short-term need to solve the problem of plastics pollution is to stop the flow of debris into the environment. The science to date suggests that the biggest source of debris to the ocean is likely waste entering from land, including from the coastal United States, where more plastic waste is produced per day than in any other country in the world. The Committee and Congress could commission a study into the state of waste generation, collection and processing (including recycling) in the United States, as well as research to determine the dominant pathways by which lost waste enters the oceans (e.g., via rivers and waterways, from beaches, transported by wind, stormwater/runoff) to gain a baseline understanding of both waste generation and waste leakage to the environment. Using this informed baseline, which will reveal "hotspots" of extremely high waste production, waste leakage, and flows of leaked waste into the ocean, direct intervention strategies can then be designed and implemented at multiple levels (federal, state, local).

6. Now that China has implemented its "Green Fence Policy," a ban on importing plastic waste, our market for these materials in the United States is flooded. China previously accepted 30% of our plastic waste. Local municipalities are now having even more trouble breaking even when collecting and recycling this waste. In your opinion, what are the best ways for the United States to address this new challenge?

I am an ocean scientist by training, and as such cannot comment with any expertise on how to reinvent or reimagine the domestic recycling industry. However, as a citizen and producer of' waste (including recyclables), I can attest to the many challenges at the household and municipal/eve/ in managing individual items. The "Do/Do Not Recycle" list often varies from municipality to municipality, making it extremely challenging for a consumer to know whether any particular item (especially those made of plastics) belongs in the trash or recycling collection. It is my understanding that contamination of recycling collection by items that do not belong (e.g., plastic bags) causes major problems for materials recovery facilities (MRF), which do not have the technical or human power (as China did for so long) to remove every such item. We must revolutionize current systems, starting from the redesign of products and packaging to facilitate recovery of disposed items. Container deposit schemes (e.g., for glass, plastic and aluminum beverage containers) are one example of a successful design and recovery strategy, in which uniform material use across brands, together with recovery incentivized by the deposit, allow recycling of these materials to be more cost effective, and the collected waste material more valuable.

7. Dr. Law, in your testimony, you mentioned that the United States produces more waste - per person, per year- than the Asian countries responsible for most of our world's marine debris. So while the United States may not be contributing as much to the problem as other countries, we can clearly do better. If we are going to do better, we need to fully understand how this waste from the U.S. makes its way into our oceans. What do we already know about this? If we have successfully identified sources, what can we do at each source to better prevent more waste from entering the ocean?

Yes, according to our research, the coastal population of the United States produces more plastic waste per year than any country in the world. In no country has the actual amount of waste entering the oceans from land, or the pathways it takes (e.g., rivers and waterways; storm water/runoff; wind transport; dumping) been directly measured. Before we can design effective interventions, we must better identify the "hotspots" of waste generation, waste leakage (i.e., that escaping the waste management system), and flows of waste from land into the ocean. Ultimately, we need direct measurements of leakage resulting from litter, improper handling, or accidental loss  $\cdot$ - on a local scale.

## **Senator Markey**

8. There is clear consensus that the number one way to reduce the impact of marine debris-from tiny microplastics to piles of plastic water bottles-is to prevent plastic from getting into the ocean in the first place.

a. Can you speak to the importance of grassroots movements that begin at the local or small-business scale when it comes to bringing attention to the marine debris issue and cutting off marine debris at the source? Can you provide some examples?

As a scientist studying ocean plastics pollution, I think that grassroots movements and the concerns of individual citizens have propelled this issue into the spotlight not only for the public and policymakers, but also for scientists themselves. The level of public concern and willingness of individuals and small businesses to take action to solve this pollution problem are absolutely critical. An excellent example is the recent attention to reducing the use of single-use plastic straws. In 2011, a 9-year old in Vermont (Milo Cress) started a local campaign to "Be Straw-Free." encouraging restaurants to provide straws only upon request, and to educate the public about the impacts of plastic waste on the environment. Since then, momentum on the straw/single-use plastics reduction movement has steadily grown through other grassroots campaigns (e.g., StrawFree.org, The Last Plastic Straw, One Less Straw, ReThink Disposable), eventually drawing the attention of celebrities (e.g., Lonely Whale-For a Strawless Ocean), and most recently reaching policymakers who have proposed and/or implemented bans and/or reduction policies at municipal levels (e.g., Seattle, WA; Davis, San Luis Obispo and Malibu, CA), national levels (e.g., France, Scotland, Taiwan, UK) and international levels (e.g., European Commission, G7 Ocean Plastics Charter (without the U.S. and Japan)). Ocean plastics pollution is a problem that/he public cares about, and grassroots movements have propelled not only the science forward, but also the demand for and action on solutions.

### **Senator Merley**

9. In 2010, a total of 270 million metric tons of plastic was produced globally, an estimated 4.8 to 12.7 million metric tons of which escaped into the oceans. How can we scale recycling systems to keep up with the expanding production of plastics?

Plastics are innovative and, in many cases, indispensible materials that were never intended to contaminate our environment or to pose risks to wildlife and potentially even human health. Yet, our development, production and use of these materials continue to grow without a clear strategy for management at the end of their useful life. While scaling and revolutionizing recycling systems must be part of the actions to address accelerating plastics use and waste production, recycling merely delays (through a limited number of additional uses) the ultimate need for disposal. Manufacturers must play a role, starting at the design phase, in planning for recovery, recycling, and eventual disposal of the materials and products they produce. Ultimately, all plastics must be prevented from entering the ocean it doesn't matter to marine wildlife whether the plastic debris they encounter is made from recycled or virgin feedstock.

10. What tools and/or technologies arc available to help remove the marine debris that is already in the ocean? What can the federal government do to support the development of these technologies or scale up technologies that already exist?

Although the top priority is the prevention of debris from entering the oceans, removal of debris from coastlines and nearshore areas is important to not only clean up those areas, but to prevent debris from moving offshore where efficient cleanup is essentially impossible, not least because scientists do not yet know where most of the plastic waste is located in the open oceans.

Current innovations for coastal cleanups include Baltimore's "Mr. Trash Wheel," a river trash collection device that prevents debris from flowing into the Chesapeake Bay. Other trash collectors in development include "Seabin" and "Trash Shark," which gather floating debris in harbors. In my opinion, before investing in cleanup technology, the federal government should first invest in research to clearly identify and measure the largest sources of debris, including the item types and locations and the pathways the debris follows from land to the sea. Armed with this information, the government can then invest in the infrastructure, incentives and/or policies that directly address these sources.

11. As Oregon's experience with the aftern1ath of the tragic 2011 tsunami in Japan shows, natural disasters can introduce a tremendous amount of debris of all materials into the ocean in a single, short-term event. What can we be doing to minimize the introduction of debris into the ocean from such events?

Indeed, natural disasters such as tsunamis, floods and hurricanes can deposit a tremendous amount of debris of all material types into the ocean in a single event. Aside from disincentivizing or banning coastal development, the best approach to minimize losses (human, material and debris alike) due to such catastrophic events may be to build structures designed to withstand extreme winds and flooding events. A very recent example is the "Sand Palace" home in Mexico Beach, FL (http[s://www.nytimes.com/20](http://www.nytimes.com/20181I0114/us/hurricane-michae/-jlorida-mexico-beach)18[1I0114/us/hurricane-](http://www.nytimes.com/20181I0114/us/hurricane-michae/-jlorida-mexico-beach) [michael-florida-mexico-beach-h](http://www.nytimes.com/20181I0114/us/hurricane-michae/-jlorida-mexico-beach)ouse.html), which was constructed to withstand 250 mph winds far exceeding local building code requirements, and which was one of very few homes left standing after Hurricane Michael. Not only was the home still standing, but because the roof, doors, and essentially all windows remained intact, it appears nothing, from inside the house was lost to the sea as debris.

## **Senator Whitehouse**

12. What are some of the risks plastics in the ocean pose to wildlife? To humans?

Scientific evidence clearly demonstrates physical harm to marine wildlife, including severe injury and death, due to entanglement in looping materials such as plastic rope or netting, and plastic strapping bands. There is also clear evidence of internal injury and death due to ingestion of plastic debris, especially large debris. The consequences and harm due to ingestion of microplastics (particles smaller than 5 mm in size) by marine wildlife remain less well understood, although there is laboratory evidence of risks associated with physical impacts of ingested debris, as well as with potential transfer of chemicals associated with plastics into animal tissues. We do no/yet know if these impacts are occurring in nature, or if there are measurable risks to humans from eating seafood that may be contaminated with plastics and the chemicals associated with them.

13. What are the current gaps in understanding, or emerging areas of research, we must invest in to better understand and combat the marine debris crisis?

Some of the most basic questions about marine debris remain the largest gaps in our scientific understanding. We have a coarse estimate of only one source of debris to the oceans (plastic waste leakage from land), with very limited direct measurements of the flow of debris from land to the sea (e.g., in rivers. Stormwater/runoff; carried by wind or waves/tides, etc.). In order to design effective interventions, we must first identify and measure inputs at a local scale.

Second, we do not know where in the ocean most of the debris is located. We can only account for -1-3% of the plastic waste estimated to enter the ocean in a single year from our (fairly rudimentary) measurements of floating microplastics. We do not yet know whether most of the debris is residing on coastlines, on the seafloor or in marine wildlife.

We must invest in robust new technologies to efficiently detect and quantify debris of all sizes (nanoscale to large debris) in all marine reservoirs.

Third, we do not know how plastics are transformed and transported within the marine environment, including pathways between the major reservoirs. We have a very limited understanding of the chemical degradation and physical fragmentation of plastics from large items to microplastics and nanoplastics, including the time scales of these processes, and we do not yet know the ultimate fate of plastics (and their chemical additives) in the oceans.

Finally, we cannot fully evaluate the risk of marine debris to wildlife because of the gaps described above. For any particular species or cohort, we cannot yet quantify; the exposure to marine debris because we have little understanding of where the debris is located and the form (size, shape, chemical composition) it takes. For microplastics (and potentially

nanoplastics) in particular, there is some laboratory evidence of harm due to ingestion or uptake into marine animals, butji1rther research into the ecological impacts of contamination by plastics occurring in nature is sorely needed.

14. What marine species are particularly vulnerable to ham1ful marine debris interactions, either from ingestion or entanglement?

Scientific evidence of encounters and/or contamination by marine debris is steadily increasing, with documentation of debris interaction existing for more than 800 species. However, contamination may not always result in harm to an individual, and harm to an individual can only be determined if the animal was encountered, recovered and examined. Thus far, there is clear evidence of harm due to entanglement for animals including marine mammals, sea turtles, seals and sea lions, seabirds, fish and some invertebrates. Many entanglement reports are cases of "ghost fishing" by derelict fishing nets. For ingestion of plastics, clear evidence of harm has been documented for marine mammals, sea turtles, seabirds, fish, shellfish, some invertebrates and even zooplankton, although it should be noted that some of this evidence of harm due to microplastics ingestion comes from controlled laboratory studies. The current scientific understanding of risk due to marine debris is limited to those marine species that have either been encountered or targeted for study, and current understanding of harm occurring in nature due to encounters with microplastics is severely limited.

#### 15. How widespread are micro plastics in the environment?

The abundance of microplastics in the environment (marine, freshwater, soils, air) appears to inversely scale with particle size. That is, the smaller the particle, the more widespread the occurrence seems to be. For example, microfibers (such as those shed from synthetic textiles) seem to be ubiquitous in the environment, including in our homes, workplaces and in scientific laboratories. This makes careful control against procedural contamination by airborne particles in the field and/or laboratory absolutely essential for scientific study of these particles. More generally, because research into environmental contamination by microplastics is still in very early stages, and is severely limited by a lack of robust, efficient and consistent identification and measurement techniques, we cannot yet make broad generalizations about their abundance and distribution in the environment.

16. As we work on the next iteration of the Save Our Seas Act, do you have any additional recommendations or comments you would like to share to infom1 our development of this bill?

Thank you for your dedication to and hard work on this legislation, and congratulations on the successful passage of the Save Our Seas Act of 2018 into law. The reauthorization of the Marine Debris Program (MDP) within the National Oceanic and Atmospheric Administration is instrumental to continuing critical scientific research that informs the design of solutions including, most importantly, the prevention of marine debris. An increase in the MDP budget has been sorely needed, especially as this is the only federal agency substantially investing in scientific research in this field. I think the program will continue to

experience strong and growing competition even for these expanded resources, given the increase in scientific inquiry in this field.

I strongly support the Act's promotion of international engagement and action, especially related to expansion of waste management systems, as this is a critical need to stop the flow of debris to the oceans. I would also like to see attention to waste generation and management in the United States, to better quantify challenges and weaknesses in the current waste and recycling systems that result in leakage to the environment. The coastal United States is the largest producer of plastic waste of any country in the world, thus even proportionally small losses can add up to large inputs of waste into the oceans. In particular, we need to invest in research to identify and measure local sources of ocean debris so that we can design appropriate local interventions. Finally, we need to focus ji1rther upstream to avoid unnecessary use of plastics through reduction and/or redesign, and to ensure a safe and sustainable end-of-life plan for these manufactured materials.

\* \* \*

Senator BARRASSO. Well, thank you all for your testimony. Very thoughtful, very insightful.

We are going to start with some questioning. I am going to ask each of you, and maybe we want to start with Dr. Law and then work down the panel. You talked about training in ocean physics, undergraduate degree in math. Obviously, very thoughtful on these topics.

There are a couple of articles that were in The Economist that ran 2 weeks ago on this specific topic, in the science and technology section. One was entitled "On the Plastic Highway." Road makers are using waste to create harder wearing surfaces, the idea of using some of the recyclables not just for some of the things that you mentioned, Dr. Baillie, but actually for hardened surfaces on the roads.

The second title, which made me think to start with you, was a teenager in California. This article is called "Sweeping the Ocean: A Teenager's Plan to Troll for Plastic in the North Pacific Becomes Reality," and you are familiar with what he is doing out there.

I would like each of you to describe what you think are some of the most promising areas of innovation that are taking place right now. And if it is OK, we can start with you, Dr. Law.

Ms. LAW. Sure. Thank you for the question. I actually think that some of the most promising innovations and interventions are actually quite simple. So, thinking about communities in the United States, in Portland, Maine, where I live, there has been an initiative to replace open garbage cans with lidded garbage cans. So, this is a way that we simply prevent waste from blowing out on a windy day.

In Baltimore there is a river trash catching device called Mr. Trash Wheel that captures litter that is floating down the river before it can enter the ocean.

These are relatively simple interventions. Mr. Trash Wheel runs on solar and hydropower, and actually has a great personality if you follow his Twitter feed. So, raising awareness, as well.

Senator BARRASSO. You are paying close attention to the personality.

Senator WHITEHOUSE. Mr. Trash Wheel. OK. Senator BARRASSO. Let the record reflect.

Ms. LAW. So, I think these innovations are critical because those are acting to trap the trash before it enters the environment and ultimately the ocean.

I think it is laudable that we are thinking big about trying to clean up the open ocean, but I have some concerns about trying to go out in the middle of the ocean to collect particles, most of which are as small as those found in this little vial. So, I do applaud all kinds of innovation and hope people will continue thinking big about how to solve this problem.

Senator BARRASSO. Mr. Karas?

Mr. KARAS. It is a great question. I think in the area of innovation, one of the things to consider is really thinking about innovation in process, how we do things. At least where we sit, as a company that makes beverages, it is very challenging for us to even get PET plastic back into our packages. So, we have partnered with groups like the Closed Loop Fund, which is focused on innovative solutions and they have done some great things in different geographies, basically applying technology to enhance the collection and recycling of materials.

I think we have looked at things like the water wheel. We have looked at partnering with aquariums on different innovations like that. The key is how can you get close to the source of generation, and the innovation would be how do you recycle better.

We can do carts in the street, and we work with the Recycling Partnership. We have a coastal communities grant that we had with the Recycling Partnership, exactly as you talked about in Portland. So, we are learning, as a company, what are some of those next steps that we can take that would be innovations that would improve collection, recycling.

But I would say what we see where we sit today is the recycling infrastructure is very challenging for us to negotiate even in the U.S. It is a combination of privately owned companies, small municipalities, and each one is a little bit separated. What we would like to see longer term is really thinking through what is the waste infrastructure 2.0. What does it need to be to properly collect materials? And then you enable end markets to really function properly.

#### Senator BARRASSO. Mr. Dooley?

Mr. DOOLEY. Thank you, Mr. Chairman. What I guess I would start off is that there is not one silver bullet that will solve this issue. But one of the things I think is very, very important is how do you establish policies that will result in adding value to the waste stream. And by that I mean how can you see an incentive for the investment in technologies that can ensure that waste plastic is more easily recyclable or the captured energy is more recoverable.

How do you ensure, too, that there could be added value by finding new uses and applications of that plastic waste stream, as you mentioned, in terms of enhancing the infrastructure, the asphalt, and adding, even actually enhancing performance attributes there.

That is where I think there are some simple things that Congress could do that would not treat the plastic waste and the recovery of it as a hazardous waste, because that is stemming the flow of investment dollars and the development of new technologies that could advance the value of that waste stream and recapture some of the value.

A lot of our companies are making investments in pyrolysis. Actually, one company is about ready to launch, where they can take a mixed plastic waste stream that they can break down, run it through pyrolysis, basically, and break it down into a new feedstock that can be recycled into the plastic manufacturing and conversion stream.

Senator BARRASSO. I will get to you in a second, Mr. Baillie, to answer that same question.

I think, Mr. Dooley, in your comments you earlier talked about a public-private partnership. There has to be a profit motive for this, and some of these new advances may lead right to that, it sounds like.

Mr. DOOLEY. Absolutely. If you increase the value of it, you are going to have individuals be more willing to play a role in recovering, picking it up. You could have more incentives for the investment in water wheels in the developing world if there was a greater value to it. National Geographic is doing a lot of work looking at these scalable technologies as well, which we are very supportive of the work they are doing there.

Senator BARRASSO. Well, then, to National Geographic. Mr. Baillie.

Mr. BAILLIE. Thank you. We have been thinking a lot about innovation and we have actually developed an impact investing fund with Sky. We have also developed a number of global challenges which we will be launching to promote innovation.

In our community, we have some interesting projects which are being developed. The one I highlighted there with Heather Koldewey is very interesting, where you take nets from the ocean, which are basically floating around and capturing and killing a broad range of species. The local community benefits, but then we also get a recycled product in the end, so it is an interesting win-win-win scenario.

We also have other explorers that are working on technology to take plastics locally and then convert that into building materials that people can actually use.

In addition to that, we have another woman we are working with who is taking plastics that can't be recycled and looking at how that can be converted into fuel.

So, there are lots of exciting things on the horizon, but I would agree with my colleagues that the greatest innovation is more about process and it is more about incentives. Here in Washington, DC, the five-cent charge on bags made a world of difference, so why don't we have that across the entire United States? Norway has 90 percent of its bottles being recycled with a simple incentive program around that.

We are behind, actually, China and Europe in recycling, so let's look to the others. We are about 9 percent of our plastics being recycled. Let's look to the others and see these basic measures that we can put in place first, and then make sure that that innovation catches up with us as we move forward.

Senator BARRASSO. Thank you. Senator Van Hollen.

Senator Van Hollen. Thank you, Mr. Chairman, for holding this hearing.

It is great to see all of you.

I want to commend my colleagues, Senators Sullivan and Whitehouse, for the SOS Act. I heard you, Mr. Chairman, say we might pass that by unanimous consent today. I am proud to be a co-sponsor.

Great to see Cal Dooley. We served together in the House.

So, as I see it and listening to the testimony, we have to do a couple things. No. 1, we try and reduce upfront the amount of plastic packaging; No. 2, we need to significantly increase our recycling and improve our waste management, and not just here at home, but as has been discussed, you have major sources overseas.

Dr. Law, thank you for giving a shout out to Mr. Trash Wheel. Baltimore is home to the National Aquarium, and the Aquarium works hard to try to educate people throughout the Country and around the world about the importance of protecting our environment and ocean environment.

I should say that since we gave a shout out to Mr. Trash Wheel in the Baltimore Harbor, Canton, Maryland has Professor Trash Wheel. These are actually really important innovations to try and prevent trash that does get into our waterways and rivers from going out into the Chesapeake Bay and, of course, ultimately into the ocean. So, we want to prevent it from getting into rivers in the first place, but, when they get there, it is easier to catch it there than when it disburses.

My question really relates to some of the testimony we have heard this morning on how plastics, as it breaks down, can get into the food chain.

There was a story in Science Alert that just came out a few days ago, September 22d, saying that plastic pollution is now spreading from ocean food chains to land mammals via mosquitos. I don't know if you saw that article.

Dr. Baillie, you say in your written testimony here, "Research has demonstrated that many of the fish and shellfish humans eat are consuming microplastics. It has also tied plastics to issues ranging from weight gain to brain development impairment."

So, if our two doctors here today could comment on the issue of plastics breaking down into microplastics and getting into the food chain, the animal food chain, and then what risk is there currently to the human food chain?

Ms. LAW. Thank you for the question. So, scientific studies have indeed found contamination by microplastics in a wide variety of species who have ingested them, and when you look at the size of these particles, you can see how we can be entering the bottom of the food chain.

When we look at the percentage of individual animals that have microplastics when they are captured, the percentage may be around 20 or 30 percent, but this can add up if we eat a lot of seafood. Of course, it depends on the animal. We eat invertebrates whole, so if there is plastic in the invertebrate, we will be eating that. If it is a fish, likely, the plastics are in the gut, and we don't typically eat the guts of those animals.

I think there is reason to be concerned, of course, because the amount of plastics that we are producing that are leaking into the ocean are going up over time, so the amounts we may ingest can go up over time as well. But there is so much remaining to be learned about what actually happens when an animal eats plastic or when a human eats plastic, including how long is it spending in the body. Are chemicals transferring from those particles to the organism? Do those chemicals bioaccumulate? And we simply don't have those answers yet.

One thing to consider, there was one study looking at plastics ingestion in invertebrates, I believe, mussels or shellfish, and, as a side part of the study, they put out a Petri dish at a typical dinner table, and the number of plastic particles that landed in that Petri dish, sort of equivalent to on your dinner place, was much higher than what was in the seafood itself.

So, I think we need to think beyond just seafood. Think about our drinking water, our bottled water, sea salt, all these other studies that are finding microplastics far beyond just the fish and shellfish.

Mr. BAILLIE. I would agree with all of that. With the number of plastics increasing in the oceans, we are going to see more and more of this. There is plastics breaking down into their tiny fragments, but then there are nanoplastics as well; and the science is at a very early stage in terms of understanding the implications, but we do know with these plastics that the organic pollutants do bind with them in the ocean, which will probably make things even worse.

But even if it turned out that there wasn't major implications for our health, which I don't think will be the case, I don't think future generations will be grateful for having plastics as a large part of their diet.

Senator Van Hollen. I agree. I just wanted to get the most recent State of the science on this, as I said.

Mr. Chairman, if I could ask unanimous consent to put in the record the article that appeared recently, because my understanding is, as you said, in fish, plastics seem to concentrate in the gut. But if you have mosquitos, then passing this on to land mammals, then there are questions about the food chain there. But there are all sorts of reasons to try and want to reduce this huge volume of trash. Obviously, this is one of them.

Thank you.

Senator BARRASSO. Without objection, it is entered into the record.

## **G7 INNOVATION CHALLENGE TO ADDRESS MARINE PLASTIC LITTER**

Plastics are one of the most revolutionary inventions of the past century and play an important role in our economy and daily lives. They are used in almost everything from cars, appliances and construction to packaging and food services, because they are low cost, durable and versatile, This Challenge provides an opportunity to spur innovation while promoting both environmental well-being and economic prosperity. The Challenge will also help retain the significant value, resources and energy lost in plastic waste, as well as minimize threats to the environment.

All countries face difficulties in addressing marine plastic pollution. G7 members are well positioned to share their expertise and promote innovations that can be used elsewhere, including among countries that are large sources of marine plastic litter. This G7 challenge is designed to stimulate innovations, raise awareness of how to address marine plastic liner or facilitate much needed improvements to the management of plastic, especially plastic waste, in developing countries. Scalable solutions are needed to foster a more sustainable use of plastic products and reduce plastic waste and marine plastic pollution including technological and social innovations in plastics design and production, use, reuse, as well as management of plastic waste.

G7 members are part of a larger global community committed to addressing marine plastic pollution. We acknowledge the essential role that the private sector, innovators and entrepreneurs play in developing innovative alternatives and solutions for increasing resource efficiency and circular economy in the use of plastics and plastic products by using their expertise, knowledge, and relationships.

'Innovation challenges' are a recognized and effective mechanism by which solutions can be developed and implemented in an economically viable way, as well be responsive to countries' needs and target recipients.

While respecting each participating member's expertise and reflecting national priorities. G7 members commit to undertake international and/or domestic initiatives, individually or jointly, in support of a common objective to promote innovation in addressing marine plastic pollution by managing plastics more sustainably throughout the whole life cycle. G7 plastic initiatives will respond to varied individual country needs accordingly. For example, domestic initiatives could focus on plastic design or recycling questions in accordance with national needs, while international efforts could respond to the need for support in improving waste management systems or creation of secondary markets. G7 members commit to sharing information their activities in support of this Challenge through the G7 Alliance on Resource Efficiency.

In implementing the Challenge, G7 initiatives will aim to:

- Leverage, build on, and complement existing initiatives throughout the plastics lifecycle,
- Leverage the strength of a diversity of expertise, including entrepreneurs, innovators, small to medium enterprises, researchers, not for profit organizations, and/or large multi-national companies.
- Support gender equality, women's empowerment and women's leadership.
- Encourage innovative solutions that are sustainable, feasible, lasting, economically viable, and scalable (scaling up of an existing initiative; or developing new initiatives that can be scaled up *through* mechanisms such as blended finance) as well as reflect local and regional circumstances and gender dimensions.
- Develop and maximize *effective* relationships *by leveraging* implementation mechanisms including international financial institutions such as the World Bank, Inter-American Development Bank, and Asian Development Bank.as well as pursuing alternative approaches including philanthropic foundations.

The overall objective of the Challenge is to incentivize the development of innovative social or technological solutions for a more sustainable management of plastics throughout their lifecycle in order to increase resource efficiency and to reduce marine plastic pollution including by finding innovative ways to enhance waste management of plastics that may become marine litter. More specific objectives to encourage innovation could include:

- Product Design and Waste Prevention:
	- Developing new product designs and management processes to increase resource efficiency and the durability, reusability and recyclability of plastic products, in particular those that are not currently recycled.
	- Supporting technologies for repair, refurbishment and remanufacturing of plastic products.
	- Developing processes to incorporate recycled content in local manufacturing processes and products to create markets for collected and recycled materials.
	- Developing and using more sustainable plastics and environmentally sound alternatives within a context of science-based and lifecycle decision-making and in consideration of environment, social and economic factors. For those G7 Members that choose to do so, single-use plastics may be an area of focus.
	- Developing solutions that reduce microplastics in products and reduce by design, to the extent possible, unintentional release of microplastics by wear and tear of products during their use.
- Improving production *processes* to minimize loss of plastic materials, including pellets and maximize resource efficiency in the use of the materials.
- Waste and Wastewater Management and Clean-up:
	- Supporting major source countries to manage waste (e.g., collection, sorting, treatment recovery, refurbishment and recycling, disposal, infrastructure, legal frameworks) in a manner that is cost-effective and transferable in order to prevent plastics from entering the environment.
	- Developing new cost-effective technologies and infrastructure to collect, recycle and *treat plastic* waste, including mobile and small scale technologies.
	- Promoting technologies to improve collection and facilitate recycling or recovery of single-use plastics.
	- Using technology to *make it easier for* remote *and* small island developing states to prevent and manage plastic waste.
	- Developing new and utilizing existing technologies and processes to prevent plastic litter and microplastics entering water bodies through improved storm water and waste water management, effectively cleaning-up marine plastic litter from waterways and shorelines in an environmentally sound manner.
	- Strengthening measures to prevent plastics entering the sea from fishing (including ghost gear) and shipping, and to ensure adequate reception facilities in to collect and manage the waste from ships and facility users (including fished waste old/derelict fishing gear).
	- Creating new technologies and processes or improving existing technology to recycle mixed plastic wastes.
	- Developing cost-effective processes to reduce contamination during the collection and recycling process.
- Markets, education and awareness:
	- Developing business models and approaches to establishing new markets and value for used and recycled to achieve environmental, social and economic benefits, including supporting local entrepreneurs in major marine sm1rce countries.
	- Supporting the development of markets for recycled plastics through greater use of secondary plastics into finished products.
	- Creating innovative partnerships along the plastic value-chain to reduce plastic waste and plastic pellets losses.
	- Supporting community-based approaches to changing behaviours towards reducing, reusing plastics, or recycling plastic wastes.
	- Supporting plastic waste mitigation approaches through socially innovative solutions (e.g., education, innovative alliances, connectors, enabling conditions. etc.).
	- Supporting: local and indigenous solutions and initiatives of women and youth, that can be leveraged to support plastic waste mitigation approaches.
	- Forging public-private partnerships to improve plastic waste management in major marine plastics source countries.

 Developing, harmonizing, and sharing methodologies for monitoring and assessing marine litter and microplastics, including their amount and distribution, as well as related environmental and human health impacts.

#### **Examples of Implementation Mechanisms**

- Public private partnerships (domestic and international).
- Domestic mechanisms within each G7 member.
- Multilateral organizations efforts such as World Bank Problue: new umbrella multidonor trust fund in support of the Bank's Global Blue Economy Strategy through consultations with their governing bodies.
- Third party organizations external private organizations who leads leveraged, incentivized prize competitions with ambitious goals, that target market failures, that can be won by small groups and ultimately that is achievable.

\* \* \*

Senator BARRASSO. Senator Ernst.

Senator ERNST. Thank you, Mr. Chair. I appreciate the discussion today. I think a number of us are in and out, but it does tend to be a very bipartisan issue, so I want to thank you all very much for being here.

Mr. Dooley, a lot of the testimony that we have heard today has been about how to better manage the plastic waste that ends up in our oceans. However, I also think it is important to touch on the work being done to make plastic more eco-friendly. I think a number of us have discussed this before.

The Iowa Corn Promotion Board was one of the first groups to fund research on polylactic acid, PLA, which is compostable and made from corn; and PLA is the most widely used bioplastic and is used to make straws, cups, plates, cutlery, and other items. After composting, PLA doesn't contain any hazardous byproducts that we see from other plastics and doesn't release toxic chemicals into the environment.

Though advancements will need to be made for PLA to become more widely used, do you see that PLA or other bio-based plastics could be part of the solution to the problem that we are facing right now?

Mr. DOOLEY. Yes. Thank you. Like I said before, there is not going to be one silver bullet, and what you have identified is where there is going to be an opportunity, and our companies are investing a lot of money in research and development of some of the biodegradable plastic alternatives that are out there.

We have to, though, be also concerned in terms of making sure that we do a comprehensive evaluation in terms of how that can be managed through the waste stream as well, because some of these compostable plastics can also contaminate the recycling, the more traditional and other plastic waste streams as well. So it has a role in the marketplace and it is where we see a lot of investment going into.

There is also an increasing demand, as Bruce said in terms of Coca-Cola, with an increased demand that they are making a commitment to 50 percent recycled content. That, again, is going to add value to that plastic waste stream. The industry, the resin producers and the plastic producers, have to do a better job in investing the technology that facilitates the recovery of this material so that it can go more easily into that recycled content. So that is also going to be a component.

But we have to be careful that we don't go down a path that goes all to biodegradable that then when a consumer or a homeowner mixes it into the recycling bin and then it creates another sorting opportunity and, if not sorted appropriately, then it contaminates the recycled material that some of the consumer product companies need.

Senator ERNST. And we obviously know that there is a multipronged approach to really wrangling with this issue, so certainly I think that composting type products should be part of that discussion.

But then would you all agree maybe then that we need to be looking at additional research and development opportunities for all of these? I think opportunities really is there. With Iowa and the resources that we have, many of our other States as well, through the various commodities that we have, we can produce a number of those types of materials, and that might be one part of the solution, and I do hope that we will take an opportunity to look at that.

Any other comments on those biodegradables?

Mr. BAILLIE. I would just add, and maybe to build on what Cal had mentioned, is I think as we design things for use and they are plastic, you have to design with the end in mind. I think one of the reasons why we are where we are today is many plastics are designed to—a bag is designed to carry materials, but the thought isn't given to the end market, and I think that is a key piece of development in the process, is understanding what we are building and does it actually have value later.

If it has value, it is going to come back and create that circular economy that we want. But if it is very difficult to recycle, we don't have technologies, as Cal mentioned, to actually solve for, then that is when we run into problems. So really focusing on making sure we design with the end use in mind when we make things.

Senator ERNEST. Absolutely. I think that is very smart. So looking at, perhaps, straws, there is the big debate about plastic straws right now, how many plastic straws are actually recycled. I don't know that many of those are, so that could be a potential stream or opportunity for something that is biodegradable and something that would be composted in a landfill, perhaps. So I think that is a very smart approach, is understanding what is recoverable later on and what is actually put into our landfill system.

Did you have a comment as well, Dr. Lavender Law?

Ms. LAW. Yes. Thank you for bringing up straws, because I think that is a really good example of if we don't need a straw, not creating the waste in the first place is actually a higher level strategy so that we don't even have to worry about managing it.

But from the perspective of the oceans, I just wanted to comment on the biodegradable plastics as well. Specifically, the PLA is designed to biodegrade in an industrial composting facility.

Senator ERNST. Composting, correct.

Ms. LAW. So, if you are in a municipality that doesn't have access to one of those facilities, your PLA is trash, and the ocean doesn't really care if it is PLA or polyethylene or polypropylene. So that is something just to keep in mind when we talk. We talk broadly about

these materials, but really we need to think carefully about which specific material we are talking about.

Senator ERNST. Right. Exactly. I will make another plug for it, though. With the PLAs, we still do have to look at other research and development, and understanding where perhaps this particular stream of PLA may not be appropriate for oceans, but certainly if there is additional research that can be done that does support another biodegradable product that is ocean-friendly, we certainly should be looking at all those opportunities.

So, thank you. Oh, excuse me, yes, Dr. Baillie.

Mr. BAILLIE. Just on the straws, Americans are using 500 million straws every day, and there are alternatives. You can use a straw like this and keep it with you at all times. But with a lot of these plastic items that we simply don't need, there is an opportunity to take leadership and just say we are going to ban certain items. You have the French, which have made a commitment to banning plastic cups and plates by 2020. You have many countries that have banned the use of plastic bags. We have about a trillion plastic bags per year being produced. While I gave my testimony, I think about 10 million plastic bags were used, with an average lifespan of about 15 minutes.

So, there are many kinds of interventions that we can make immediately if we are truly serious about addressing the small waste issues like straws.

Senator ERNST. Well, I appreciate it.

Thank you very much, Mr. Chair.

Senator BARRASSO. Thank you, Senator Ernst.

Senator WHITEHOUSE.

Senator WHITEHOUSE. Thank you, Chairman, and thank you again to you for this hearing and to the witnesses for appearing here.

In my opening comments I mentioned a couple of topic areas. One is cleaning up in the oceans, and particularly cleaning up in the rivers that feed the oceans, where much of this plastic comes downriver; trying to find ways to pick the plastic out of the flow points before it hits the ocean. Once it is out there floating around in the great Pacific Garbage Patch, it is really hard, really inefficient, really expensive to deal with it. To try to get it upstream is more significant.

I think to prevent that we need to have a strong focus on requiring countries with whom we have trade relationships to meet elementary standards of upland waste disposal responsibility. We have never been very good at enforcing pollution control standards overseas as a part of trying to balance our trade, so there has been a lot of cheating, where an American company has to keep its junk out of the river and the competitor doesn't, so the price of the competitor's product can go down, but we all pay the price when it ends up in the ocean.

And I think there are technical ways to go about doing that. Even in Newport Harbor we have a little basically a sunk dumpster with a solar pump that keeps pumping the water out so that there is constant inflow and there is enough inflow the plastic flows in, it gets trapped in the dumpster and you can clear it out.

Rivers have similar catchment technologies. But until there is a revenue basis for doing that, it is hard to get it done, so that is something I think that we can work on.

Biodegradability we have talked about, so I don't need to add to that.

Again, on entanglement, if a fisherman loses a long-line rig, for instance, first of all, it may be hard to find, but it is not really hard to put pingers on things these days. Supporting
people in trying to make fishing gear more traceable once it is lost could be a good strategy. Having a bounty so that if you are out fishing and you come across somebody's gear, you take the trouble to bring it in and bring it home and take it out of the ocean.

Fisherman work incredibly hard and it is a very uncertain world out there. It is even more uncertain with oceans warming and populations of fish moving around, so to expect fishermen to stop what they are doing and become the people who are responsible for cleaning the oceans themselves I don't think is really fair unless all of us have found a way to help make that a productive use of their time.

And then I think the human health research is the other point. We really, I think, need to know pretty quickly what risks this poses so we can know with what degree of urgency and alacrity we need to take on the problem.

So, I would just like to ask each of you to comment on those four topic areas for our 2.0, and if there is anything further you think I have completely missed, please throw it in.

We will start with Dr. Baillie. This will be my only question, so if we could just run it out, that would be fine.

Mr. BAILLIE. Sure. So, on the initial map that I showed, it showed the major river systems where plastic pollutants are getting into the oceans and, of course, you commented on the top 20 being in Asia and being a significant problem.

At National Geographic we are committed to doing an exploration looking at some of the major rivers around the world and understanding where the plastics are actually coming from and looking at the social issues and the political issues, but also looking at innovation that we can help promote so that that process can be addressed.

When it comes to fishing gear, you saw the short video in terms of using the nets. It would be wonderful if we could look at creating more of a market for those nets, as many of them are made of nylon, which is actually quite a valuable material that can be reused for things like the carpet tile right here. So, I think it is about exploring some of those innovative approaches, but also putting more pressure on the fishermen to actually keep track of those nets when they are out there.

I very much like your idea of the tracking device. Again, at National Geographic, we are developing a whole bunch of sensor systems, so this is just the type of thing we could explore, sensors to try and keep greater tracking.

Mr. DOOLEY. Thank you. You know, I think that what we are interested in and we are trying again to really establish a private sector initiative that would represent constituents throughout the value chain. Part of our interest is how do we do a better job of identifying those initiatives and those investments that are going to be the most cost-effective in making a meaningful impact on reducing plastic waste in the environment.

We think the public agencies, the U.S. Government, has an opportunity to help and facilitate that as well.

I think when we look at, again, the Asia region, which is the primary source for certainly the Pacific driver, we have the opportunity to focus on cities. Ocean Conservancy has just launched an initiative called Cities, and cities on rivers, because, as you said, the rivers are the source that enters into the ocean. If we focus on developing a comprehensive waste management assistance program for cities on rivers in the Asia region, I think you would be able to see significant private sector resources that would complement public sector investments as well.

You can even get that a little more granular because you also, in order to have a sustainable waste management system, you have to add more value to that waste stream; and that is where I think the U.S. Government also has an opportunity to make investments in pilot programs in that region. We have a number of military bases there that could make an investment in a pilot program that could be able to demonstrate and capture the value in the waste stream not only from their own operations, but perhaps even extend it to the communities.

You can even see it with fishing nets. If you had a pyrolysis unit that could develop syn fuel or diesel fuel from a plastic waste stream, as well as fishing nets, it could be a source of income for the local community that was playing a major role in trying to be a collection center or providing the collection of unused fishing nets.

So we think that there is just a wonderful opportunity for the U.S. to show leadership that would complement and encourage private sector involvement in meaningful initiatives that really focus on making waste management more effective.

Senator WHITEHOUSE. My time has long expired, so I should probably invite the other two witnesses to make their responses for the record, if you would do that.

It is up to the discretion of the Chair, but I think we probably need to be thinking about bounties, as well, because I doubt there is enough of a resource there to make it selfsustaining without some help.

Senator BARRASSO. Senator Inhofe.

Senator INHOFE. Thank you, Mr. Chairman.

Senator Whitehouse, you opened your great comments about the fact that we don't have the control over some of the foreign countries that we would otherwise have. I want to give another side to that because in some of these countries they actually have ideas that we haven't gotten. One of my close friends on the continent of Africa is Paul Kagame, who is head of Rwanda. He made a decision to really cleanup his country. And I have to tell you guys that of all 54 countries, and I have been to all of them, in Africa, you go in there, that is the clean, pristine country, Rwanda.

Don't get me wrong on this, I am not suggesting this, Mr. Karas, but the first thing he did was outlaw plastic bags. Then he went on. Now when you go from the airport to the headquarters, you just see a pristine country. I think we ought to really sit down and look and see some of the things that he has done successfully and emulate those.

I am kind of surprised not many people talked about the meeting that took place just last week. Maybe it is because it is so soon afterwards, but it was in Nova Scotia, where the G7 people, and our participant there, of course, was Andrew Wheeler, who worked for me for 14 years, who was very active on this Committee. He attended that. It was a meeting where they discussed the very thing that we are discussing here.

The objective, and I am going to read this and then I am going to be asking to put the outline in the record, is to "incentive the development of innovative social and technological solutions for a more sustainable management of plastics throughout their life cycle in order to increase resource efficiency and to reduce marine plastic pollution, including by finding innovative ways to enhance waste management of plastics that may become marine litter."

They have excellent suggestions, and I ask, at this point in the record, you include this. With no objection. Thank you.

Re: Further comments on the hearing titled, "Cleaning Up the Oceans: How to Reduce the Impact of Man-Made Trash on the Environment, Wildlife, and Human Health?"

Thank you for the opportunity to provide comment on the hearing titled, "Cleaning Up the Oceans: How to Reduce the Impact of Man-Made Trash on the Environment, Wildlife, and Human Health?" I am environmental engineering professor at the University of Georgia and have been working in solid waste management for 22 years and on marine debris since 2001. I testified on May 17, 2016 to the subcommittee on this topic. I am also now currently in the International Informational Speakers Program with the US State Department and have been to nine different countries since 2017 working on the issue of marine debris in public environmental diplomacy (Philippines, Indonesia, Japan, South Africa, Vietnam, Jordan, Israel, and India).

As all the witnesses testified to, there is no *one* solution to this issue, but an integrated approach is needed to make headway on reducing plastic entering the ocean. I developed the framework below for my 2016 testimony and would like to submit it again with some ideas, further explanation and answers to some of the questions posed by the senators in this hearing. This framework provides intervention points (1through 5) and then a list of potential (but not all encompassing) interventions that may occur at the various points. In general, this represents a hierarchy of interventions. However, the most "bang for your buck" interventions will depend on the needs of the specific geography addressing the issue, however, in many cases, all geographies have points along the entire framework that will help reduce debris and plastic going into the ocean. Some interventions can be immediate and some will take more time. The framework starts on the left with the most "upstream" interventions and ends with a last chance to capture the material before it enters the ocean. In many cases the interventions offer the opportunity for economic innovation and growth. The USA could be a leader in several of these categories of interventions.

(1) Reduction in demand

a. Consumers demanding less packaging or no packaging (some markets)

i. Not everyone has access to clean water, for example, so can't always make the choice of a reusable bottle, but these choices taken collectively where possible do make a difference

b. Local initiatives (e.g., bans, taxes)

i. These are often very local-specific, but are also becoming more common

ii. Mass of items removed may be relatively small, but numbers of items are also important- there is more than one way to measure debris (e.g., mass, count, etc.)

c. Voluntary industry actions

i. Industry has become more engaged on this issue I wonder if they will volunteer some changes to help in the future as well?

d. The reality is that all signs point to further growth in waste generation, as well as plastic use, especially where economic development is occurring or predicted to occur in the future

(2) Innovative materials and product design

a. Sustainable packaging associations (pre-competitive collaborations)

i. E.g., Sustainable packaging coalition, Green-Blue: These pre-competitive environments could help to standardize packaging and help packaging retain value so that it is easier to recycle and less leakage will occur if it has value.

b. Truly biodegradable alternatives (e.g., PHA)

i. PLA was mentioned in the hearing and while it is bio-based and industrial compostable, it will not biodegrade in the ocean. It will not biodegrade if littered on land. It has to reach a high temperature (reached in industrial composting) to be able to biodegrade.

ii. One polymer that may biodegrade in the ocean is PHA. This polymer is expanding in the market in the USA and will be creating economic value in the future (new facility opening in Kentucky- one open in Georgia already). While it may biodegrade if littered in the environment, it should still be managed in the solid waste system, and be thoughtful about where used (in currently non-recyclable items, for example). But it has the possibility of being home-composted as well. The USA is currently a leader in the development of this material and other bio-based and biodegradable materials.

c. Packaging with more value (e.g., single, homogenous materials, design for recycling/end-of-life)

i. This can be helped by collaborations between industry, brands and waste managers/experts

d. Design out problematic items/materials (e.g., caps/lids)

i. Similar to how aluminum can opening was changed to a tab that stayed on (so the pull tabs did not get littered), we can innovate design for items that leak into the environment (if data is collected on them- see point S.c.).

(3) Reduce waste generation- *how can we decouple waste generation from economic growth?*

I believe we can through creativity and innovation- and I get very excited to see what my students will create in this category one day.

a. Sharing, Collaborative Economy concepts

i. Bike shares, car shares, tool shares, clothing rental, etc. these all reduce the need to purchase and create waste (facilitated by technology), but still meet people's needs and can still create revenue for the companies providing the services.

ii. How can these concepts be related to packaging? (see b.ii.)

b. Decouple waste generation with economic growth (facilitated by technology) Reuse programs (using mobile phones, which many people have globally, especially where rapid economic growth is occurring)

ii. RFID, mobile phones, smart-labels, etc. (e.g., RFID water refill stations exist for both Coca-Cola and PepsiCo products, but are not yet widely distributed yet)

(4) Improve global solid waste management

This has some basic similar concepts, but solid waste collection can be a hyper-local activity and can look different in each country, city and even neighborhood. Global resources are needed to further develop the infrastructure needed. Waste needs to be managed globally no matter what the materials it is composed of. Plastic has made it a more complicated and created a rapid change in the waste stream that we were ill prepared for. It creates a waste stream that is more varied and dynamic than we have ever experienced before. It has proved to be quite a challenge for waste operators and municipalities to manage. Improving infrastructure is especially needed in rapidly developing economies with high population growth.

a. Collect: May be traditional, on-demand, or decentralized waste collection

i. Collection innovation is needed- revers logistics may play a role

b. Capture: Material Recovery Facilities, waste depots, waste banks, community centers (e.g., "punto limpio" in Chile)

c. Contain: Recycling or engineered disposal

d. Important to keep in mind: *Context and Culture- these can "make or break" the success of a potential intervention. The local community and stakeholders need to be engaged and involved from the start through the end of any project.*

(5) last-chance cleanup

a. Engineered, mechanical systems

i. Mr. Trash Wheel or other engineered devices

b. Manual (by hand)

i. Cleanups (e.g., ICC by Ocean Conservancy)

ii. Use of ocean-bound plastic can catalyze the development of infrastructure since the material now has value- often a much higher value than it did previously (e.g., Parley, Dell, NextWave plastics)

c. Data to feed back to Interventions 1through 4

i. E.g., Marine Debris Tracker developed by NOAA and UGA (or other apps) to collect data

ii. Could make upstream choices/changes based upon what is leaking into the environment

Specific questions asked:

1. What are some of the most promising innovations?

In my opinion some of the most interesting and promising innovations are the ones that decouple waste generation from economic growth. How can we meet people's needs and increase livelihood without creating more waste to manage? Sharing and collaborative economy concepts, RFID cups, using technology to connect people and facilitate sharing and reuse programs all lead to potential interventions. Reduce waste generation in the first place.

2. What is role of PLA and other bio-based plastics?

I think there is a role for material and product innovation and bio-based and biodegradable (truly) polymers will be a part of the solution. However, these materials are being produced at relatively low quantities right now, so they are not going to be a big market for some time- if ever (also see 2.b., above).

3. Fisherman incentives

I think incentives for fisherman to collect or bring back gear would be a way to get some of the most deadly gear out of the ocean and marine environment. I think also supplying a place for fisherman to put used gear is important (e.g., dumpster or recycle bin at the port). Tracking and transparency of nets- and really all plastic (as much as feasible) could help keep the material out of the ocean because we would have a better inventory of it.

4. Root causes

Responsibility- while not particularly popular in the USA, product stewardship is an important concept to discuss here. From an engineering standpoint, when a company wants to build a development/civil engineering project, there often is a partnership with the community. One example, I live near an above ground storage tank farm, and trucks come and go from it regularly. There were likely road improvements needed to be able to build the tank farm and the company who constructed it may have contributed to that infrastructure since they were building at this site. In some ways, this can be analogous to selling products in a country or location that does not have infrastructure to manage the waste created from those products. I don't think companies knew the issues this would bring. And I think they want to help based upon new awareness, but we are certainly playing "catchup" with the issue now. I have seen some good examples of shared responsibility in South Africa and Norway. And some companies are doing this individually, but many still don't know how to help with infrastructure. I think that facilitating this in some way could be significant- maybe it will all be individual public-private partnerships, but some thought could go into how to facilitate companies engaging in shared responsibility. Ultimately it will take shared actions by industry, municipalities, and citizens to make significant positive change on this issue.

Thank you again for your attention to this issue and for the opportunity to offer my thoughts.

\* \* \*

Senator INHOFE. I would ask you, Mr. Dooley, I think you are familiar with this. Nothing much has been said about this, but I would like to know what thoughts you have about the recommendations that have come from the G7 talks that took place. Actually, that meeting took place in Nova Scotia right up until last Saturday, I think they concluded it, so your thoughts about what has happened there and how that coordinates with the recommendations that we are making with this excellent panel that we have.

Mr. DOOLEY. Well, ACC was very pleased that Administrator Wheeler attended that meeting and also committed, along with the balance of the environmental ministers there, to really support moving forward on how could they collectively create greater incentives for the development of innovations that would contribute to the elimination of plastic waste.

It really was building upon one of the commitments that Trudeau made at the G7 principals meeting, where he committed to doing \$100 million innovation grant that was really trying to provide public sector investment that would be matched oftentimes by private sector commitments that was focused on trying to eliminate plastic waste in the environment. That was further developed under the challenge program that was talked about at the Halifax meeting of the G7.

We think those are opportunities to really leverage the private sector funding and to ensure, again, that we have a collaborative effort to identify what are going to be the most cost-effective investments of both taxpayers' dollars, as well as private sector funds. We are very supportive.

Senator INHOFE. That is good. I think we need to become more familiar with that. A lot of heavyweights were involved in those decisions and that discussion in Nova Scotia.

Mr. Karas, I think we may share one philosophy that I kind of picked out of your opening statement, and that is it has been my experience over the years—and I have been on this Committee since, I don't know, a lot of years—that some of the solutions to problems are best handled by the private sector.

I can remember when we had a lot of the Superfund problems. I was actually chairing this Committee at that time. What happened, and I won't mention the oil company, it was an oil company, though, that was working at that time in Louisiana, and they did have a spill, and it was a pretty serious one. So they went in and evaluated what it would take to clean that up and what it would cost to clean that up.

I am going from memory now, but I think it was something like it would take 13 months if this oil company were allowed to do it at the cost of \$7 million. EPA rejected it at that time. We were kicking and screaming about that, but they did. They took this on and it ended up taking not 13 months, but 4 years; and not \$7 million, but \$15 million.

I guess what I would ask you, your thoughts on the things that can be done through private sectors that cannot be done through the public and what your experience has been.

Mr. KARAS. Thank you, Senator. I think the way I would answer that question would be in really looking at this space. We are good at making beverages and marketing beverages and selling; that is our core business, we make beverages. And what we find when we get into a space like waste is we have to rely, in my comments I talked about the critical importance of partnerships, we have to rely on others.

What we have learned in the course of we had a water stewardship goal to replenish the volume of water that we put in our products by 2020. We met that early. We met that because one of the reasons was public-private partnerships. We have a public-private partnership with USDA, U.S. Forest Service. For us, it gives us resources that we thought we would never have, knowledge and information that we wouldn't have access to, and, really, we learned a lot and advanced quickly.

So I think our learning in these spaces has been it is absolutely mandatory for us to really reach out and engage with trade groups like ACC, with technical people that are knowledgeable, to really come to a great solution collectively. I think that is what ultimately wins the day.

Even when we do partnerships through our foundation, we have something called a Golden Triangle partnership, and what we learned when we link business, civil society, and the government together to look at a problem, we usually get to a really good place, a place that we wouldn't have gotten to by ourselves.

Senator INHOFE. Thank you very much.

Thank you, Mr. Chairman.

Senator BARRASSO. Senator Carper.

Senator CARPER. I am told by my colleagues and our staff that you all are doing a good job. As you know, we serve on a bunch of different committees and, unfortunately, all my committees are meeting right now, so I am trying to be three or four places at once. I am not doing really well at it, but now I am with you and look forward to asking a couple questions.

First, I want to ask unanimous consent, Mr. Chairman, to enter a letter from MERR and supplemental materials be entered into the record from the Marine Education, Research & Rehabilitation Institute in Delaware, as well as some other supplemental materials.

Senator BARRASSO. Without objection.

[The referenced information follows:]

\* \* \*

The Honorable Thomas R. Carper Ranking Member Committee on Environmental and Public Works United States Senate Washington, D.C.

Dear Senator Carper,

The Marine Education, Research & Rehabilitation Institute, Inc. (MERR) has been providing stranding response for marine mammals and sea turtles in the state of Delaware for over 18 years. As Delaware's leading authority on marine animal health and welfare, we have observed first hand the negative impacts of marine debris on the marine environment, and on the creatures that reside there.

MERR responds to approximately 300 stranded animals per year. the majority of which have stranded due to some type of human impact These impacts include fisheries, dredging, underwater noise pollution, oil spills, marine debris, and more. Marine debris with all of its various components causes constricting entanglements, and is ingested when it is mistaken for prey. Marine animals become entangled in the copious amount of material that we have introduced into their habitat, such as ribbons from balloons, discarded six pack rings, fishing line, fisheries gear, packing straps, etc. The effect of this type of debris on marine animals is slow and painful debilitation as the constricting debris cuts into the animals tissues, leading to infection, strangulation, osteomyelitis, and ultimately death.

The components of marine debris are far too many to list, but plastics pose an especial threat to the quality of ocean habitat. In their intact form, they can appear to be food sources, as in the case of plastic bags, which are accidentally ingested by marine animals, leading ultimately to starvation. Plastic bags and balloons resemble jellyfish in the water, a favored food source by the endangered leatherback sea turtle, and the loggerhead sea turtle. Pieces of plastic large and small have the capacity to photo-degrade, causing smaller and smaller particles to emit into the ocean, ultimately to be consumed by fish. Micro-plastics are consumed by the smaller organisms, which leach into their tissues. The smaller organisms are ultimately consumed by the macro-organisms, such as dolphins, whales, seals, and humans. The prey source for these endangered species is contaminated, as is the water in which they live, due to the inundation of micro-plastics in the ocean and the inland waterways that ultimately lead to the ocean.

Our stranding response team has witnessed the excruciatingly painful suffering of beautiful and majestic whales, dolphins, seals and sea turtles as a result of human based trash and debris in their habitat. A loggerhead sea turtle on the Delaware Bay that had over 65 different types of plastic in its stomach, whales and dolphins maimed and ultimately drowned by Jishing gear, a young pilot whale that had mistaken shredded packaging from beef ramen noodle soup as squid, a helpless one month old seal pup barely able to breath because of constricting fishing net, ribbons and plastic bags, and a bungee cord wrapped around its throat-these are just some of the heart breaking examples of how these animals suffer due to the impacts of marine debris. Our organization invests thousands of hours in an attempt to inform and educate students and the public about the harm caused by marine debris, in hopes that this information will lead to consumer choices that minimize the amount of trash in the ocean.

We know of the astounding statistics surrounding the Pacific Garbage Patch, now believed to be twice as large as the state of Texas on the surface, with depths surpassing that size. The Marianna trench, the deepest known area of the ocean, has been identified as 50 times more toxic than the most polluted rivers of China, due to the cumulative and concentrating effects of plastic in the marine environment. Phytoplankton, which makes up the basis of the food web for all other organisms, is being impacted as algae accumulates on both large and micro sized particles of plastic, interfering with sunlight penetration to stimulate photosynthesis. Plankton is the foundation species for all life forms in the ocean, without which the entire ecosystem is destined to collapse.

Reducing the quantities of marine debris and its toxicity in the oceans is imperative to the health of the marine ecosystem. Our organization strongly supports any initiatives to reduce

the presence of marine debris in the ocean environment. We greatly appreciate any efforts that are put forth to accomplish this important goal.

Sincerely,

Suzanne Thurman Executive Director

\* \* \*

Senator CARPER. Thanks very much.

Dr. Law, if I could just aim my first question at you. I am told by my staff that you spent a lot of time at sea. They said more than probably anybody in the room. I was in the Navy for 23 years, mostly in airplanes; some time on seas, but I would be happy to give that honor to you today.

They tell me you spend a lot of time at sea observing firsthand the impact of marine debris on the environment, but also especially on wildlife. Do you want to share with us some specific examples of some things you have seen with respect to marine debris' harm to wildlife, including marine mammals, sea turtles and birds?

In addition to minimizing the amount of debris that ends up in our oceans, what else should we be doing to mitigate these impacts?

First some examples.

Ms. LAW. Sorry.

Senator CARPER. First some examples.

Ms. LAW. Some examples, yes.

Senator CARPER. And then some ideas on what we ought to be doing to mitigate these impacts.

Ms. LAW. Sure. So, most of my sailing experience has been in the open ocean, much of it in what are called the subtropical gyres, which are areas of the "garbage patches." These are areas of the ocean that are actually quite nutrient poor and not——

Senator CARPER. Most people probably try to avoid those.

Ms. LAW. Sorry?

Senator CARPER. Most people try to avoid those.

Ms. LAW. Most people try to avoid those, that is right; there are not a lot of wind. They are not places many people spend a lot of time, but we do spend time doing our science there.

I think the most important observation I have had is that many of the descriptions we hear about this problem are not what you observe out at sea on the boat. I don't see very large objects going by, but when you do it is very surprising to see a shoe or a bucket or a teapot or a toothbrush drifting by thousands of miles from land.

When you look over the side, you see these little bits of plastic. And in terms of interaction with wildlife, what I have observe personally is sea birds who are feeding at the sea surface where these little bits of plastic are floating. So while you can't actually see it hanging out of their mouths, you know that the birds are eating these plastics.

Similarly, we have captured in our nets, at one point we captured a five-gallon bucket that did have a fish swimming under it. That fish, we brought aboard and it had 42 pieces of microplastic in its gut. We also tow a fishing line. We brought a mahi-mahi on-board and it had a piece of plastic——

Senator CARPER. Was the fish dead or alive?

Ms. LAW. Just a line with a hook.

Senator CARPER. OK.

Ms. LAW. We brought a mahi-mahi on board for dinner and it had a piece of plastic this big in its stomach. So we were faced right then, do we want to eat this fish or not? We did. It was delicious.

Senator CARPER. Did you? OK.

Ms. LAW. But I have not seen marine mammals entangled myself, so I don't have that personal experience.

I really think I come back to we have to keep this out of the ocean to solve it. The rescue efforts, when people spend lots of time and resources to help these animals when they are entangled are critical, and when we have access that is very important, but we just have to stop it from entering.

Senator CARPER. All right.

I like to focus on root causes. I just came from a Homeland Security business meeting; we are marking up about 20 different bills.

One of the things we focus on in Homeland Security is border security, including border security with the border with Mexico. We spend a lot of time, effort, and energy trying to keep people from getting into our country from places like Honduras, Guatemala, El Salvador. The root cause of all that, though, is the lives that they live in those three countries are miserable; and we are complicit in their misery given our dependency and addition to all kinds of drugs, narcotics.

But part of the root cause in solving that problem, all these people trying to get into our Country from our southern borders, is to help make sure that their lives are less miserable in those three countries; they have some hope of opportunity. That is the root cause.

Is there a root cause in this case? Is there a similar root cause we ought to be focused on, rather than just focusing on the symptoms of the problem? I have a great photograph of Coast Day in Delaware this last weekend, but we are addressing the symptoms of problems. There is always trash that washes up on the east coast, including in Delaware, so we focus on the symptom of the problem.

If we looked for the root cause, where should we be looking? Because we are really good at spending a lot of time and energy and resources on symptoms of problems, not always on the root cause.

Mr. DOOLEY. Senator, the way that I would respond to that, if you look at where the major source of the problem, it is in the developing economies; and in those developing economies they have a host of public needs. Some of it is nutrition, some of it is education, some of it is healthcare, and some of it also is waste management systems. When they prioritize them, oftentimes the waste management investments come down very low on the list, and that is why, oftentimes, they lag behind in developing the waste management systems. As their economy develops, it becomes the source of a lot of the waste plastic and other waste that is getting into the environment.

That is where I think we have an opportunity in the industrialized world in the private sector to allocate resources to help prioritize waste management, and part of that help in prioritizing investments in waste management is providing public and private sector support.

We think if you do that in the developing world, we can make a tangible difference in reducing the amount of plastic waste in the environment.

Senator CARPER. Good. Thank you.

Mr. Karas, please.

Mr. KARAS. Just an add-in. I think we maybe touched on it around the fringes in the conversation here, but infrastructure is absolutely important. But the layer over that, and we have learned this as we have done projects, it is the level of I guess you would call public education and awareness. How do people value that material? Obviously, if it is all in the ocean, it is a throwaway, and we are not thinking about it. Even in the developed world it takes time to change sort of the hearts and minds, and that has to accompany all the work that we are doing. So, it maybe starts with PSAs, but maybe ingraining into younger generations what should you do with materials when they are in your hand.

I would suspect that if you asked most of the public about recycling, recycling is the act of putting something in a specific container, and not thinking about the circular economy and where it needs to go in the long-run. So, I think some of that cultural piece is important to mix in with that.

Senator CARPER. All right, thanks.

Senator BARRASSO. Senator Whitehouse, now that Senator Inhofe has completed, did you want to get a continuation of the line of questioning?

Senator WHITEHOUSE. Sure, if Mr. Karas and Dr. Law. I don't know if you recall the question; it had to do with the various recommendations about trying to stem the flow into the seas, particularly in the big rivers; about trying to invest in biodegradability; about trying to make it a better revenue proposition for fishermen to keep and recover lost fishing gear; and the last one was research on the human health effects of ingesting microplastics. Are those areas we should be working on and are there other areas you would recommend? That was the question.

Mr. KARAS. Senator, I think those are all good areas that you highlighted there. I think what we have learned in the Asia Pacific region as our business units work is we are having to form some of these cooperative partnerships. We are doing it in Indonesia and the Philippines, starting some of that in Vietnam to really start to look at where do you start. I think that is sometimes the challenge. Here we can look at our infrastructure that exists. Maybe it is not well connected, but it is like where do you start, what is ground zero, and we have to do that collaboratively.

So, what we are seeing is brands are engaging with different NGO's and governments to say, OK, how do we move the needle in that. I think those will help in the long-run, but it takes time to build those out.

Senator WHITEHOUSE. And in this case it takes incentives.

Mr. KARAS. Correct. Correct. But I would add that in terms of incentives, and maybe it is something that Cal has already touched upon, I think we have to really think closely about the end markets and the value of the materials.

What often is lacking, you could sort out polypropylene, but there may not be a market there; and if that doesn't happen, if the economics aren't there, it just isn't going to work. But if we can work to build the proper end markets, it really starts to close the loop. To me, when a business has an incentive to get that material and put it into something else, that is going to be a powerful driver in that space.

Senator WHITEHOUSE. You will agree that there is a discrepancy between the recovered value of waste plastic and the value to humanity of not having an ocean in which there is more plastic than fish.

Mr. KARAS. I would agree. I would agree.

I guess in terms of waterways, one of the interesting experiences we have had here, I talked about partnerships earlier, a group called Living Lands and Waters works our own Mississippi River system. Actually, six barges collecting materials, anything from cars, tires, drums, and plastic.

We have had the opportunity to be able to really create a circular economy with those kinds of activities, actually bring material out of the Mississippi. We had an example, last year sorted 9,000 pounds of PET hand-sorted by our own bottler there, and it was turned into bottles for a product 30 days later. That is a circular economy, but we had to force it.

So, ultimately, I think it is how do we really have a vertically integrated waste management system that really allows it to pull through where there is economic viability to that activity. If you have to prop it up because it doesn't have economic viability, it is going to collapse sooner or later, or you are always going to be feeding it funding. So, to get the 2.0 system it really requires some thinking and thoughtful examination of where we want to go.

Senator WHITEHOUSE. Dr. Law.

Ms. LAW. Thank you. I do agree with all of your priorities, especially the impacts on human health, and I think we need to expand that conversation more broadly into impacts of plastics and fresh-water and soils and agriculture, and things like that.

Other opportunities, though, that I would like to raise are the idea that we can try to make less waste; and this is falling on the previous question as well, starting to think about a cultural shift away from disposable, away from I use it, I put it in the garbage can, and it goes somewhere that is no longer my problem. So, encouraging reuse programs.

One really simple intervention we can all do is put in refillable water stations into our public spaces to encourage people to carry a reusable bottle, as opposed to using something a single time. So I would just like to point out not just information campaigns, sort of your traditional education campaigns, but thinking about targeted interventions in spaces that are locally defined about quite simple interventions that will cause us to just simply make less trash that we then have to deal with.

Senator WHITEHOUSE. Mr. Chairman, shall I tell a brief sailor story that Dr. Law's testimony called to my recollection?

Senator BARRASSO. Please.

Senator WHITEHOUSE. Newport, Rhode Island is probably the sailing capital of the world; we claim that, anyway. Delaware may have a disagreement, but I am sure we have Wyoming beat.

[Laughter.]

Senator WHITEHOUSE. A lot of sailboat racing goes through Newport, including what is now called the Volvo Ocean Race, which is perhaps the most dangerous and demanding sporting event on the planet; and it is around the world, very fast race, very high-tech boats going very fast. Racing boats have, for generations, had to learn a man overboard drill.

You don't go offshore racing without having drilled and drilled on the man overboard situation; who is the spotter, how quickly do you turn the boat. You know, the whole routine is just drilled until you can, as soon as somebody yells overboard, everybody knows exactly what they are supposed to do.

For the first time these racing boats have to have a new and different drill, and that is a keel clearing drill. They sail through the South Atlantic on their course and they sail near the place that is farthest from land anywhere on the surface of the earth; and even out there they are still doing these keel clearing drills. When the boats came into Newport from Brazil on their leg that ended with us, you could see the boats in Newport Harbor as they came in within sight of each other.

They had sailed all the way from Brazil and these races are still so close that they end up within minutes of each other, within sight of each other as they finish, so you really, really need to make sure that your vessel is operating at peak performance. And they have enough computers to know when it is off performance, so they then have to deploy—they know what is wrong, the keep clearing drill; and somebody has to go over the side real quick, with goggles and a knife and whatever else they need, to get the junk, the plastic junk, usually, that the keel has swept like a single comb tooth out of the ocean and get their boat operating back at speed again.

So, it is an interesting physical comparison to the longstanding, ancient, well established man overboard drill. It is only now, only in the last few years that ocean racers now have to come up with a whole new drill that they have to practice, keel clearing, even in the farthest corners of the South Atlantic.

Senator BARRASSO. Thank you, Senator Whitehouse.

Senator CARPER.

Senator CARPER. Mr. Karas, I don't know a whole lot about Coca-Cola's World Without Waste campaign, but I am told that the goals are ambitious. I am told that it will really make a difference to improving international recycling practices and reduce waste in our oceans, and that is encouraging. What are the biggest challenges that your company faces in implementing these goals domestically and what can Congress do to support your efforts in this Country?

Mr. KARAS. I think domestically the biggest challenge that we are trying to work through now, and I mentioned this in some of my earlier comments, at times I am dealing with sort of the waste infrastructure 1.0. I may have five different entities, public and/or private. One might be hauling, one might be operating the material recovery facility or the MRF. My end market might be somewhere off in the distance, and it is very disconnected.

So, for us to be able to deliver 50 percent recycled content, I have to do it in a way that I have an adequate supply, adequate a good quality material, so I think the challenge is I am looking to see what the next 2.0 waste management system will be in the long-term.

We have a combination of different efforts that we are doing to really work on vertically integrating that system, so, from a business perspective, if you are one and the same entity, I just toured a MRF, material recovery facility, earlier this week. They are integrated with making cardboard boxes, so they pull the cardboard out of the materials coming into this site, drive across the parking lot and they are making brand new cardboard boxes. When they do it that way, it works; it has value. I think that is sort of the area that we are seeing as the biggest challenge, is how do we really get that system to work.

I think the second piece is we have probably, it is something I mentioned earlier, about the culture right here in this Country. I really believe that people don't understand the concept of the circular economy and we have very much a culture that is throwaway, so we are working on that space as well.

Senator CARPER. Any question you have not been asked that you would like to be asked?

Mr. BAILLIE. I just wanted an opportunity to respond to the systemic question that you asked.

Senator CARPER. Oh, good.

Mr. BAILLIE. I think there is nothing inherently bad about plastics, but in 1950 we were producing 2.3 million tons.

Senator CARPER. How much?

Mr. BAILLIE. Two point three.

Senator CARPER. In what year?

Mr. BAILLIE. In 1950. And now it is 500 million tons. So that is a massive increase. And we haven't moved to that closed loop economy, so we are producing these plastics without a full cycle of what will happen to them going forward, and there is just too much of it.

But when you talk about the source, it is really working with the industries and saying how can we produce plastics that can definitely be recycled. When you have multiple plastics, say, in a tooth-brush—there are three types of plastics, often—it makes it much more difficult to recycle. So how can we create conditions where it is easy to recycle things? And things like coffee cups, we have plastics being mixed and layered with wood and with aluminum. Again, it makes it extremely difficult to recycle that. How do we simplify that process?

If we can do that and then we develop more standardized approach across the United States in terms of recycling, we can bring recycling to scale. The things you do in D.C. are different than you might do in States across America. We have to standardize this process so we can work at scale and we can innovate at scale.

Then we talked about innovation. I mentioned the Impact Investment Fund we are promoting, but there are much larger funds out there, and I think there is a real opportunity for Government to work with the private sector to develop these large funds to actually drive innovation.

Then, finally, incentives. We talked about the five cents on a plastic bag, which makes a world of difference, or the five cents to collect a bottle, which makes a world of difference. We have to explore and deliver on these standards.

Then, I think that the United States can then play a much stronger global role. We are now only recycling 9 percent of our plastics. Some of these other countries that we are talking about that are putting more waste into the world are actually recycling more than we are. So, we should set a target of going from at least our 9 percent to what Europe is doing, which is around 30 percent, to ensure that we can then move into a leadership position in this space and lead with our innovation as well.

Senator CARPER. Congressman Dooley.

Mr. DOOLEY. If I may respond. I would say that the fact that we have seen an increased use of plastics, that has been a significant contributor to enhancing global sustainability. A few years ago, UNEP, the United States Environmental Program, at the request of one of their members, did a study in terms of trying to identify the environmental costs of plastics. They hired a firm called True Cost that went out and did this study, and they came back and they said, OK, it is about \$90 billion a year.

From a policymaker's perspective, I said, what would you respond to a study that said that? You could be led down to say, well, then we ought to eliminate the use of plastics. What we did at ACC, we said, you know, you need to do a more comprehensive assessment.

We went back to True Cost, we said, not only should you do an assessment of the environmental cost of plastics, but what would be the environmental costs of the alternatives. They did that and they came back to us and they said, it is a good news, bad news story. It is not 90 billion, it is 139 billion for the environmental cost of plastics. But the good news is, from a plastic manufacturer, is that the environmental cost of using alternatives to plastics was four times as large.

So I think we have to be careful here when we are trying to develop policies that are going to ultimately enhance global sustainability, that we should do so in a manner that is really based on doing comprehensive assessments of the life cycle impact of the various materials. When you take that approach based on the more comprehensive study, it sends a signal to us as manufacturers that we have to do a better job of ensuring that the plastics that are increasingly being used are more easily recycled, that their energy and their chemicals can be more easily recoverable so that we can minimize their impact in terms of the environment, but still capitalizing on the positive environmental benefits from their use.

Senator CARPER. Fair enough. Thank you. Thank you, Cal.

Could I have one more question, Mr. Chairman?

I am trying to remember the name of the new program they have over in China. I think it is called the Green Fence policy. It is a ban on importing plastic waste. As you know, China was our market for these materials and for a long time they previously accepted about 30 percent maybe a third of our plastic waste. In our Country, local municipalities are having more trouble now breaking even when collecting and recycling this waste.

Anybody have an idea what are some of the best ways for the U.S. to address this new challenge? Any thoughts?

Mr. DOOLEY. Again, I think that there are some real opportunities to use this as an inflection point where we could see opportunities to increase the value of this accumulating plastic waste. In my opening remarks, we identified some policies that we currently have in place in the United States that are impeding the flow of investment capital in developing the innovations that can transform that mixed waste or plastic waste stream accumulated into energy as well as into going through a pyrolysis where you can turn it into feedstocks.

Now, if you want to try to get a permit for a pyrolysis unit to do waste plastic, sometimes it is subject to being permitted as a hazardous waste facility versus what could be a recycling center. If you make that small change, you could, again, create a greater incentive for the flow of that investment capital to develop those new innovations.

The same thing, if you could develop diesel or a syn fuel from a plastic waste stream, it doesn't qualify for the alternative fuels treatment or renewable fuels. Making simple changes like that are going to encourage a lot of investment from a lot of startup companies, as well as a lot of large companies, to make investments that can add value and capture the energy and the value in that plastic waste stream.

Senator CARPER. Were you this smart when you were a Congressman? [Laughter.] Mr. DOOLEY. I was smart enough to leave. [Laughter.]

Senator CARPER. I will say in closing, for myself, this is a really important issue and I again want to thank Senator Whitehouse and Senator Sullivan for their great leadership on this, and our Chairman for holding this hearing and for Senator Inhofe's strong interest in this issue as well. This is one I care about enormously. I am sorry there is so much other stuff going on that hasn't allowed me to be here.

One of my favorite witnesses, the guy who is the controller general of the Country, the head of GAO, General Accountability Office. His name is Gene Dodaro. I don't know if you have ever met him, but he comes and testified fairly regularly on different committees. Sometimes he will be sitting right where you are, Mr. Karas, and he speaks opening statement, no notes. Answers every question, no notes. Finally, I noticed 1 day that when he would speak there was a woman sitting right behind him and her lips were moving when he spoke.

I have been watching you and your responses, and there is a lady in a red dress right behind you, and I noticed that her lips were moving when you speak. She looks very familiar and I just want to say to Missy, welcome to our hearing; it is great to see you. You have another career ahead of you if you can take this show on the road.

Thank you very much.

Senator BARRASSO. Thank you, Senator Carper.

Thank you all. This was very productive.

Senator Whitehouse, thank you for your leadership. Thank Senator Sullivan as well.

If there are no more questions today from the panel, members might submit written questions for up to 2 weeks, so the record will stay open for that period of time.

But I really do want to thank all of you for being here, as well as what you are doing on this vital, vital issue. Thank you to National Geographic for your leadership and for putting visually something that I think really caught the attention of the Country and the world.

With that, this hearing is adjourned.

[Whereupon, at 11:52 a.m. the committee was adjourned.]

[Additional material submitted for the record follows.]

# **PLASTIC POLLUTION IS NOW SPREADING FROM OCEAN FOOD CHAINS INTO LAND ANIMALS, THANKS TO THIS INSECT**

#### **Just when you thought it couldn't get worse.**

#### DAVID NIELD

SEP 201

We know that plastic pollution is a major problem for the world's oceans, but scientists just discovered a new way that discarded microplastics are making their way out of the water and into other food chains through mosquitoes.

What's happening is mosquito larvae are ingesting microplastics as water- dwelling larvae, and those plastic particles are sticking around as they transition into flying mosquitoes.

Those adult insects provide tasty snacks for birds and bats in the air above, which means microplastics are now ending up in the stomachs of land animals, not just marine creatures.

This process is technically known as ontogenic transference, meaning it happens as the organism matures and moves habitats.

Once the plastic-carrying mosquitoes have been eaten by birds and bats, the pollution can then make it further into other food chains and ecosystems, according to the researchers from the University of Reading in the UK.

"This is eye-opening research, which has shown us for the first time that microplastics are able to navigate several life stages in flying insects, allowing them to contaminate all kinds of living creatures who would not normally be exposed to them," says one of the researchers, biological scientist Amanda Callaghan.

"It is a shocking reality that plastic is contaminating almost every corner of the environment and its ecosystems."

Callaghan and her colleagues fed fluorescent plastic microbeads to mosquito larvae in lab conditions then monitored their growth through a microscope.

The plastic remained in place through the non-feeding pupal stage and into the adult insect, via the Malpighian tubules (structures equivalent to the human kidneys).

Microplastics like these can take hundreds of years to be broken down in the environment, and the study showed that the smaller the plastic beads were, the more likely they were to stick around in the bodies of the mosquitoes.

We already know that plastics polluting our oceans and waterways can have a damaging effect on wildlife and make progress through the food chain.

Now we know these harmful, microscopic fragments stick around as mosquitoes change form and make their way out of the water too.

Fluorescent microplastic in a mosquito abdomen. (University of Reading).

Friends of the Earth plastics campaigner Emma Priestland, who wasn't involved in the research, said the findings were "disturbing" "Knowing that plastic can be transferred from the larval stage to the adult mosquito, which then serves as food to a multitude of larger animals, highlights the urgency with which we need to drastically reduce our use of plastic," Priestland told the BBC.

As well as mosquitoes, insects like mayflies, dragonflies and midges start life in ponds and puddles before making their way into the outside world, where they're often eaten by bigger creatures - so the problem could go way beyond the boundaries of this study.

We know that as plastic seeps into the natural world it can get passed further and further between animals and ultimately have serious consequences for natural ecosystems.

Let's hope this new study helps underline the potential scale of the problem and spurs efforts to cut back on plastic use.

"Much recent attention has been given to the plastics polluting our oceans, but this research reveals it is also in our skies," says Callaghan.

The research has been published in *Biology Letters.*

# **STATEMENT FOR THE RECORD, OF THE SEPTEMBER 26, 2018, SENATE COMMITTEE ON ENVIRONMENT AND PUBLIC WORKS PUBLIC, PUBLIC HEARING, ON THE SUBJECT: "CLEANING UP THE OCEANS: HOW TO REDUCE THE IMPACT OF MAN-MADE TRASH ON THE ENVIRONMENT, WILDLIFE, AND HUMAN HEALTH"**

[http:/!www.epw.scnatc.gov/public/index.cfm/2018/9/clcaning-up-the-oceans-how-to](http://www.epw.scnatc.gov/public/index.cfm/2018/9/clcaning-up-the-oceans-how-to-reduce-the-impact-ot)[reduce-the-impact-ot](http://www.epw.scnatc.gov/public/index.cfm/2018/9/clcaning-up-the-oceans-how-to-reduce-the-impact-ot) man-made-trash-on-the-em·ironment-wildlife-and-human-health

*"Food waste is a multi-billion dollar problem"* or *"opportunity"* according to Rethink Food Waste through Economics and Data (ReFED) www.refed.com/-ReFED and others are working diligently and successfully to reduce food waste.

However, when a consumer discards food, the packaging that accompanies the food is also discarded. The Animal Digestible Food Packaging Initiative (ADFPI www.adfpi.org) is an effort to *encourage/convince/inspire representatives of grocery stores, quick service restaurants, food manufacturers and food packaging manufacturers to establish a publicprivate partnership (PPP) with the objective of funding research necessary to identify new food packaging materials that not only meet food safety, integrity and quality requirements but that are also digestible by animals so that grocery and quick service restaurant waste may be sent to a renderer for manufacture into anima/feed instead of being sent to a landfill.*

Because food packaging that meets food safety, integrity and quality requirements and that is digestible by animals either does not exist or is not readily available, and because the United States does not have an economically robust recycling industry, food waste along with its accompanying packaging generated by quick service restaurants and grocers, that is not beneficially used, is sent to a landfill for disposal.

But if grocery stores and quick service restaurants were to utilize food packaging that meets food safety, integrity and quality requirements and that is also digestible by animals, food waste along with its accompanying packaging could be sent to a renderer for manufacture into animal feed [http://www.nationalrcndcrers.org/publications/prcss-kit/nra](http://www.nationalrcndcrers.org/publications/prcss-kit/nra-releases-industrv-vidcorcndering-the-sustainablc)[releases-industrv-vidcorcndering-the-sustainablc-s](http://www.nationalrcndcrers.org/publications/prcss-kit/nra-releases-industrv-vidcorcndering-the-sustainablc)olutionl-Recovered would be all the energy and natural resources that went into producing and manufacturing the wasted food and its inherent packaging, including its inherent animal nutrition value and its economic value as a feed source.

No one industry, be it food or package manufacturers, quick service restaurants or grocers, is willing or financially able to assume the responsibility to fund millions of dollars of research necessary for the identification of new food packaging materials that would meet food safety, integrity and quality requirements and also be digestible by animals.

If such food packaging is to be found, a food industry cooperative research effort will be required through creation of a public-private partnership (PPP) comprised of key stakeholders (including food and package manufactures, grocers and foodservice companies, renderers, pet food manufacturers, their trade associations, government agencies, foundations, think tanks and universities).

Funding for such a PPP can be found through the Foundation for Food and Agriculture Research (FFAR)

https://toundationfar.org/ and the National Science Foundation (NSF) *"Innovations at the Nexus of Food, Energy and Water Systems"* program [https://www.grants.gov/web/grants/view](https://www.grants.gov/web/grants/view-opportunitv.html)  [-opportunitv.html'?oppld=JO1132.](https://www.grants.gov/web/grants/view-opportunitv.html)

- FFAR and/or NSF funding would *unleash the genius of students and professors at tbe Nation's land grant universities and other research organizations***-** Let us put them to work on the challenge to discover animal digestible food packaging that meets necessary safety, integrity and quality requirements!

- FFAR" ... *builds unique partnerships to support innovative and actionable science addressing today's food and agriculture challenges. The Foundation was established by the Farm Bill passed* in *2014 and charged with complementing and furthering the important work of the U.S. Department of Agriculture. Leveraging public and private resources, FFAR will increase the scientific and technological research, innovation, and partnerships critical to enhancing sustainable production of nutritious food for a growing global population."*

- The NSF grant program " ... *seeks to support research that conceptualizes FEW systems broadly and inclusively, incorporating social and behavioral processes (such as decision making and governance), physical processes (such as built infrastructure and new technologies for more efficient resource utilization), natural processes (such as biogeochemical and hydrologic cycles), biological processes (such as agroecosystem structure and productivity), and cyber-components (such as sensing, networking, computation and visualization for decision-making and assessment)* ..."

This public hearing is one example of the public's demand that manufacturers take responsibility for the after- life environmental effects of single use packaging as exemplified by the Earth Day site, titled *"Initiatives to Ban or Reduce Consumption o(Single-Use Plastics"* at [https://www.earthdav.org/plasticban/](http://www.earthdav.org/plasticban/) and the Linkedin posts of Jack Cooper, ADFPI Executive Director, at https://wVIw.linkcdin.com/in/juck-coopcr-21474b14/detail/ rccent-activitv/sharcs/.

- Further, "... *increased consumer and regulatory concern toward single-use plastic and other packaging materials* is *a critical investment theme, especially for asset managers with an Environmental, Social and Governance (ESG) mandate ..."* according to an extensive August 2018 Citi Global Perspectives and Solutions (GPS) Report, titled *"Rethinking Single-Use Plastics: Responding to a Sea Change in Consumer Behavior"* at https://ir.citi .com/ *II* A 9tF7xva3Sl J 5qL6ghGCV oXt4Wi3eDYs3Nd/tXPY7srxTM21 ihP4orVMVpvfvOW.

Another reason to support such a PPP is presented in a September 2018 University of Cambridge Institute tor Sustainability Leadership report: "... *The significant challenges presented by plastic packaging waste can only be solved through collaborative actions from* 

*business, government and society* ... *We do not know if it will even ever be achievable to totally eliminate plastic packaging waste. However, there* is *a need to act now, before all of these unknowns can be addressed, and to set a high level of ambition, even if* it *seems hard to achieve in the current context ..."-* The report is available here: hllQs://www.cis/cam.ac.uk/ resources/circular-cconom\'/towards-sustainable-packaging-a-plan-to-eliminatc-plusticpackaging-waste-from-uk-bottlcd-watcr-and-sort-drinks.

- As well, according to a June 28, 2018 Sustainable Brands http://www. sustainablebrands.com/ report, when individual food companies and their trade associations take a stand on issues the public cares about, like the after-life environmental effects of single use plastic packaging, consumers are "... *ready to reward brands that take stands* ... *Consumers want brands to stand up for issues* in *their areas of expertise* ... *{Consumer;] believe companies should provide ongoing support for issues that align with the types of products or services they offer companies {should] look to their primary business first to refine their purpose and prioritize relevant social issues* ... *It is clear that brands have much to gain from taking stances that fit with their organization's purpose and product ... The key is effectively communicating those stances* ..." - The SB report is here: https://www.sustainable brans.com.com/ncws\_and\_views/marketing comms/sustainablebrands/consumers\_ready\_ reward\_brands\_take\_stands/utm\_source=newsletter&utm\_medium=brandsweekly&utm\_cam naign=jun28.

- Also, according to an August 20, 2018 Boston Consulting Group report, titled *"Tackling the 1.6-Billion-Ton Food Loss and Waste Crisis""... no one group, government, or company can* ... *[solve the food waste crisis on its own but]* ... *Companies that play a role in the food value chain stand to reap tangible business benefits* ...

[*and*] can burnish their brand ..." by addressing the issue: [https://www.bcg.com/en](http://www.bcg.com/en-)us/publications/2018/tackling-1.6-billion-ton-food-loss-and-waste-crisis.aspx

Finally, plastic waste recycling is not projected to be effective and efficient in the United States and the EU for a decade or two:

- The U.S. Plastics Resin Producers have set the following goals: I 00% of plastics packaging to be re-used, recycled or recovered by 2040 with 100% of plastics packaging to be recyclable or recoverable by 2030, according to a May 9, 2018 The American Chemistry Council's (ACC) news release at [httos://www.americanchemistry.com/Media/Press](http://www.arnericanchemistrv.com/Media!PressReleasesTranscripts/ACC-news-releases/US-Plastics) [ReleasesTranscripts/ACC-news-releases/US-Plastics-P](http://www.arnericanchemistrv.com/Media!PressReleasesTranscripts/ACC-news-releases/US-Plastics)roducers-Set-Circular-Economy-Goals-to-Recycle-or-Recover-100-Percent-of-Plastic-Packaging-by-2040.html.

- The European Union proposed EU plastics strategy calls for"... *all plastic packaging ... [to be] recyclable by 2030* ..." according to a January 16, 2018 European Commission News Release a[t http://europa.eu/rapid/press-release](http://europa.eu/rapid/press-release) IP-18-5 en.htm.

- Many cities are abandoning recycling programs because of soaring costs in the wake of new waste acceptance policies adopted by China, according a September 14, 2018 Bloomberg Environment story at [https://www.bna.com/curbside-recycling-threat-n730l4482530/.](http://www.bna.com/curbside-recycling-threat-n730l4482530/)

- *"More Recycling Won't Solve Plastic Pollution"* is the title of an August 6, 2018 Scientific American "Observations" which argues that "... *It's a lie that wasteful consumers cause the problem and that changing our individual habits can fix it ... The real problem is that single-use plastic* ... *is an incredibly reckless abuse of technology ... At face value* ... *{Keep America Beautiful and other] efforts seem benevolent, but they ... shift the onus of* *environmental responsibility onto the public* ... *A better alternative is the circular economy model, where waste is minimized by planning in advance how materials can be reused and recycled at a product's end of life rather than trying to figure that out after the fact* ..."

https://blogs.scientificarnerican.corn/observations/more-recycling-wont-solve-plasticpollution/.

- Whether or not food and other packages become "recyclable," are actually recovered and "recycled" (that is, actually manufactured into new products), the plastics industry will continue to be robust according to this story: *"Plastics Industry Flourishes in Response to Market Demand'* is the title of an article in the Third Quarter 2018 issue of the Area Development Magazine which notes that"... *It's a good time to be in the plastics manufacturing business. Plastics manufacturers in the US, are continuing to enjoy increased demand for their products* ... *along with decreasing production costs* ... *Packaging* ... *is showing especially strong growth ..."-* The article is here: [http://www.areadevelopment.](http://www.areadevelopment.com/Plastics/03-2018/nlastics-industry) [com/Plastics/03-2018/nlastics-industry-](http://www.areadevelopment.com/Plastics/03-2018/nlastics-industry) flourishes-in-response-to-market-demand.shtml.

RE: Hearing: Cleaning Up the Oceans: How to reduce the impacts of man-made trash to the environment, wildlife, and human health?"

Dear Chairman Barrasso and Ranking Member Senator Carper,

Thank you for providing me with the opportunity to submit testimony. I also want to thank you for giving time to this important issue.

I am Dr. Chelsea Rochman, a professor in Marine and Freshwater Ecology at the University of Toronto, have been researching the issue of plastic pollution for more than a decade. During this time, I have watched the state of the evidence grow tremendously. Today, there is no doubt that anthropogenic debris of all shapes and sizes litters our oceans and freshwater ecosystems. This debris is found in hundreds of species of wildlife, including in the species we consider seafood. We know that plastic pollution harms individual organisms, wildlife populations and communities. These impacts, combined with evidence for accelerating plastic production and emissions into the environment, suggest the international community should come together to limit future environmental emissions of anthropogenic litter now, before they transform ecosystems irreparably. Below, I will speak specifically to microplastics followed by marine debris in general.

## **Microplastics**

My research mainly focuses on microplastics (plastics 5mm in size) and demonstrates that microplastics are ubiquitous in the environment, including in seafood. My research has also shown that microplastics are associated with a cocktail of toxicants, including 78% of those we currently consider priority pollutants under the US EPA. It also demonstrates that microplastics can be toxic to fish and invertebrates.

By weight, large plastic debris such as fishing nets, make up the largest percentage of plastic floating in our oceans. However, by count, microplastics by far exceed the number of plastic in our environment. Thus, as we design policies aimed at plastic pollution, we must be mindful to include policies specific to rnicroplastics. Because some sources of microplastics arc unique (e.g., microfibers, tire dust, pre-production pellets), policies will also be unique to larger items of plastic waste. As such, it is important that we invest time thinking about creative and effective solutions for mitigating microplastics.

Although we often think of microbeads when we think of microplastics, the term microplastic incorporates a large diversity of plastic types, including those that were produced as microplastics (e.g., microbeads, pre-production pellets often referred to as "nurdles") and those that are literally degraded bits of larger plastic products (e.g., tire dust, microfibers and fragments of bottles, bags and film). The former is called primary microplastics and the latter is referred to as secondary microplastics. Secondary microplastics are the most common type of microplastic waste found at sea. Still, we must not forget the primary sources of microplastics as well as the sources that emit secondary microplastics into the oceans (e.g., microfibers). These particles, specifically microfibers, are some of the most common microplastic types found in global ecosystems.

Researchers estimate that there are between 15 and 51 trillion microplastic particles floating around in our oceans, reaching from the poles to the equator. Microplastic particles are found in large concentrations in Arctic sea ice and are also present in sediments and wildlife from the deepest parts of the ocean. Consequently, this widespread contamination has led to the contamination of 100s of species of wildlife across all trophic levels. Laboratory studies demonstrate that microplastics can lead to mortality, reduced growth, and decreased reproductive output in marine animals. Although we do not yet understand how they may affect human health, they are also found in sea salt, seafood and drinking water.

Although policies that mitigate large plastic debris also reduce microplastic debris, we need to make sure we consider microplastics when we consider all of the policy options for plastic pollution. Policies specific to microplastics may include, but are not limited to, emissions standards for microplastics (e.g., from washing machine effluent, wastewater, storm water, etc...), filters on washing machines to trap microfibers, increasing participation for operation clean sweep and extend this model to textiles, material innovation, and banning microbeads.

The above mitigation strategies are simple solutions to combat some sources of microplastics. Still, when it comes to plastic pollution, we know the least about sources, fate and effects of microplastics. As such, while we begin implementing policies now related to

known sources of microplastics, we must continue to put resources into research that helps us better understand what some other sources of microplastics are and which may be prioritized for policy based on quantities and risk.

#### **Marine Debris in General**

Today's estimates suggest that about eight million metric tons of plastic enters the oceans annually from land. If we continue business as usual, this number is expected to increase by an order of magnitude by 2050. In the US, I think we have at1 opportunity to lead in this space. The US can and should be a large part of the solution, and show other countries that reducing emissions of plastic is possible.

Last year, I co-Jed a paper in the journal *Proceedings of the National Academy of Sciences* titled, "Why we need an international agreement on marine plastic pollution." Like many other contaminants, plastic is not constrained by borders. It migrates via air and water currents in and out of parts of the oceans that are beyond national jurisdiction. Because plastic pollution does not observe borders, neither should policy. At this time, there are no international agreements for plastic pollution. I recognize that the Clean Seas Initiative is a great first step, but I think it is time to move to something similar to the Paris Agreement and at a faster pace than in took to get to the Paris Agreement. To measurably reduce emissions of plastic pollution, we need defined reduction targets, signatories, methods of reporting progress and a global fund.

I envision an agreement where countries sign on as signatories with a defined reduction target. For example, in the US we might agree to reduce 25% of our emissions by 2025. To meet reduction targets, each conn try needs to come up with strategies to do it. Because there is no one-size-fits-all solution, each country may take on its own set of unique solutions to reach its target. For example, countries may adopt container deposit schemes to improve recycling rates, eliminate the use of some single-use plastic items that are unnecessary (e.g., microbeads, straws), improve waste collection and management infrastructure, and agree to market only plastics that are recyclable and/or reusable in their region. For some countries, particularly in the developing world, aid is necessary to build new infrastructure for waste. These countries need access to a global fund, similar to the UNFCCC's climate fund. To build this fund, an extended producer responsibility program can be implemented. If the fund pulled in one penny for every pound of plastic produced, the fund would build by over \$6.8 billion per year. Finally, each year countries would report on their success measuring the reduction of plastic emissions globally over time and ensuring signatories reached their goal.

With more than a decade of experience researching plastic pollution, I have a vast knowledge base on this issue, I have published many papers about the topic and have advised managers and policy-makers in several countries. For example, I presented at the Our Ocean Conference at the US State Department and in front of the UN General Assembly in New York City. I have also had one-on-one discussion with the offices of several congressmen and women in the United States. I would be more than happy to sit down with you and discuss the state of the science and how it might inform policy around this important issue both nationally and internationally. Please feel free to connect with me anytime.

Many thanks for your time. Sincerely,

Chelsea M. Rochman Assistant Professor

GOVERNMENT OF THE DISTRICT OF COLUMBIA Deportment of Energy and Environment

October 10, 2018

Senator John Barrasso Chairman Committee on Environment and Public Works 410 Dirksen Senate Office Building Washington, DC 205IO

Senator Tom Carper Ranking Member Committee on Environment and Public Works 456 Dirksen Senate Office Building Washington, DC 20510

Subject: Written Testimony for recent U.S. Senate hearing entitled *Cleaning up the Oceans: How to reduce the impact of man made trash on the environment, wildlife, and human health*

Dear Sen. Barrasso and Sen. Carper:

l

Thank you for your leadership to reduce the impacts of trash on our nation's waterways. Trash is one of the great environmental challenges of our time and will not be solved without robust participation from federal, state, and local governments. We welcome this opportunity to provide written testimony and stand ready to work with you on further efforts to address this issue.

The District has been a leader in the nation for over a decade on addressing trash in our local waterways. According to a 2015 article published in the journal, *Science,* researchers estimate over 8 million metric tons of trash enter the oceans, annually from land-based sources.<sup>61</sup> In a heavily urbanized area like the District, a large portion of that trash comes from litter being conveyed via storm sewer and combined sewer systems to waterways like the Potomac and Anacostia Rivers. In response to this problem, the District, in collaboration with U.S. Environmental Protection Agency (EPA) and upstream jurisdictions, established a

<sup>61</sup> Jambeck, J.R., R. Geyer, C. Wilcox, T.R. Siegler, M. Perryman. A. Andrady, R Narayan, & K.L Law. 20L"L Plaslic waste inputs from land into the ocean. Science 347: 768-771.

total maximum daily load (TMDL) for trash in the Anacostia River. As a result, the District is compelled by EPA and our own priorities to reduce trash in the Anacostia River as part of our efforts to make the Anacostia fishable and swimmable once more. Given that the District has declared 2018 the Year of the Anacostia River, it is very timely for us to provide the Senate with a summary of our experiences. We are proud of all of our accomplishments and would like to share details of some of our efforts in hopes that this work can, and will be, emulated elsewhere throughout the nation.

Three important components have helped us to effectively manage trash in our waterways: regional partnerships, using sound science to inform policy, and taking multipronged, innovative approaches.

# **Regional Partnerships**

The issue of trash impacting the Potomac River watershed began over a decade ago thanks to a regional collaboration facilitated primarily by the Alice Ferguson Foundation of Accoceek, MD. Since 2005, the Alice Ferguson Foundation has held an annual Potomac Watershed Trash Summit in the DC metropolitan area. This summit brings federal, state, and local government agencies, elected officials, and non-governmental organizations together to discuss efforts to reduce trash in the watershed. This would not be possible without grant funding from the NOAA Marine Debris Program, which has been an invaluable partner in regional efforts to address this issue.

Example of trash conditions in Watts Branch, a tributary to the upper Anacostia River in Washington, DC.

Over the years, participants have implemented key efforts discussed at this summit including a regional anti-littering campaign, innovative local policies for reducing trash, and regional collaborations to establish the TMDL for trash for the Anacostia, one of the most

urbanized tributaries to the Potomac River. The summit brought together leaders from the District, the state of Maryland, local Maryland counties, EPA, and local advocates to reach common ground on establishing the TMDL. Without this regional partnership it is very unlikely this effort would have been successful. As we will highlight more specifically, several new innovative approaches for trash reduction have been implemented since that time.

In 2016, the District, Montgomery County, and Prince George's County reaffirmed their commitment to making the Potomac and Anacostia River free of trash by signing the Anacostia River Accord. The accord was signed by the District's Mayor Muriel Bowser, as well as Montgomery County Executive Isiah Leggett, and Prince George's County Executive Rushern Baker. In addition, the Anacostia Watershed Restoration Partnership, housed at the Metropolitan Washington Council of Governments, has convened a trash working group to develop consistent methods for tracking and reporting trash reductions across all three jurisdictions. This is further evidence of the importance of regional partnerships at combatting the issue of trash in our waterways.

The next Potomac Watershed Trash Summit to discuss what the District, other jurisdictions businesses, and non-governmental organizations are doing to address trash in the Potomac River will he held on October 16'h, 2018 at George Mason University in Arlington, VA.

### **Using Sound Science to Inform Policy**

One of the first things the District did to address the problem of trash in the Anacostia River was conduct a two-year comprehensive study of trash conditions. The District Department of Energy and Environment (DOEE) funded the Anacostia Watershed Society of Bladensburg, MD to conduct surveys of litter along the river and its many tributaries and monitor trash loads from storm sewer outfalls. The study provided two important pieces of information: (I) data on the most common types of trash in the Anacostia River and its watershed and (2) data on total weight of trash entering the Anacostia River on an annual basis. The first dataset informed District policies targeted to address specific types of trash most common in our waterways such as single-use plastic bags and expanded polystyrene foam products. The graph below shows the most common types of trash found out of 44 different categories sampled along DC shorelines in the Anacostia River, its tributaries, Kingman Lake (a semi-enclosed lake in the Anacostia River), and land in the Anacostia River watershed. The District utilized the second dataset to develop the trash TMDL and identify and strategically address hotspots in the watershed which are conveying above average amounts of trash to the river.
