# **DIARRHETIC SHELLFISH POISONING**

# *Toshiyuki Suzuki\**

National Research Institute of Fisheries Science, Fukuura, Kanazawa, Yokohama, Kanagawa, Japan

#### **ABSTRACT**

Okadaic acid (OA) and dinophysistoxins (DTXs) are the causative toxins of diarrhetic shellfish poisoning (DSP). OA/DTX analogues are produced by dinoflagellates that belong to the genera *Dinophysis* and *Prorocentrum*. In the present chapter, chemical nature, bioactivities, accumulation and metabolisms of toxins in bivalves, analytical methods of OA/DTX analogues are described.

**Keywords**: okadaic acid (OA), *Dinophysis*, dinophysistoxins (DTXs), diarrhetic shellfish poisoning (DSP), Liquid chromatography-mass spectrometry (LC/MS), metabolism

# **INTRODUCTION**

Diarrhetic shellfish poisoning (DSP) in humans caused by consumptions of bivalves was first reported in Japan in 1978 [1]. DSP human symptoms are diarrhoea, nausea, vomiting and abdominal pain starting 30 min to a few hours after ingestion and complete recovery occurs within 3 days [1]. Okadaic acid (OA) [2] and its analogues dinophysistoxins (DTXs) are the causative toxins of diarrhetic shellfish poisoning (DSP) [3, 4]. OA/DTX analogues are produced by dinoflagellates that belong to the genera *Dinophysis* [5, 6]. Bivalves become contaminated with OA/DTX analogues by feeding on toxic *Dinophysis* species. Although the dinoflagellate *Prorocentrum* is found to be a producer of OA/DTX analogues, involvement of bivalve contamination is unknown. Some predators of bivalves such as crabs and lobsters are also contaminated with OA/DTX analogues by feeding toxic bivalves.

DSP has been reported from almost all over the world including North and South America, Europe, East Asian countries, and New Zealand etc. Table 1 shows some DSP cases reported with epidemiological investigations which succeeded in estimating the amount of bivlave molluscs and the toxins consumed by affected people [1, 7-12]. It is estimated that consumption of 48  $\mu$ g of OA or 38  $\mu$ g of DTX-1 per person results in diarrhea [13]. The regulation of OA/DTX analogues recommended by Codex Alimentarius (CODEX STAN 292-2008) is 0.16 mg OA equivalent/kg in the edible tissues of bivalves. This regulatory level is widely accepted in the world.

#### **CHEMISTRY AND BIOACTIVITIES**

OA was originally isolated from the two sponges, *Halichondria okadai* Kodata in Japan and *H. melanodocia* in the Florida Keys and the structure was elucidated by single crystal Xray diffraction techniques for *o*-bromobenzyl ester of OA, nuclear magnetic resonance (NMR) spectroscopy, and mass spectrometry (MS) [2]. The chemical structures of OA/DTX analogues are shown in Figure 1. In 1982, DTX-1 was isolated from the mussel *Mytilus edulis* involved in the DSP in Japan and the structure elucidated by NMR and MS spectrometry was reported as 35(*S*)-methyl OA [3]. This was the first report identifying that OA analogues are the causative agent in DSP. The stereochemistry at the C-35 was later corrected as 35(*R*) methyl [14, 15]. DTX-3 was first isolated from Japanese scallops, *Patinopecten yessoensis*, and the structure was elucidated as 7-*O*-acyl-DTX-1 in 1985 [4]. Detailed fatty acid profiles of the DTX-3 in bivalves had later been elucidated by LC/MS and LC/MS/MS techniques [16-21]. OA diol esters were found from the benthic dinoflagellate *Prorocentrum lima* in 1987 [22] and several diol esters had later been found from *Prorocentrum lima*, *P*. *concavum*, *P. maculosum, P. belizeanum* [23-31] and *Dinophysis acuta* [32-35]. In 1992, DTX-2 was isolated from Irish mussel and the structure was elucidated as 35(*S*)-methyl 31-demethyl OA by NMR [36]. A new OA analogue, 19-*epi*-OA, was isolated from *P. belizenaum* and the structure was elucidated as the 19-epimer of OA by NMR [37]. In 2008, two forms of hybrid diol esters esterified with fatty acids were found from blue mussels, *Mytilus edulis*: one with the fatty acid conjugated to the 7-OH of the OA moiety and the other with the fatty acid conjugated to the OH group in the diol moiety [38]. These new esters were tentatively identified by iontrap LC/MS<sup>n</sup> technique.

OA is a lipophilic polyether compound of a  $C_{38}$  fatty acid. OA/DTX analogues are soluble in organic solvents such as acetone, methanol and chloroform (Figure 1). It shows no absorption maximum in UV region. The IR bands at  $3450$ ,  $1740$ ,  $1080$ ,  $880$  cm<sup>-1</sup> are observed due to absorption by the hydroxyl and a carboxyl moiety [2]. There are 17 chiral centers and 3 spiroketal moieties within the molecule of OA. The absolute stereochemistry of OA was assigned as 2*R*, 4*S*, 7*R*, 8*R*, 12*S*, 13*R*, 16*R*, 19*S*, 22*R*, 23*S*, 24*R*, 26*S*, 27*S*, 29*S*, 30*S*, 31*R*, 34*S* [2]. X-ray crystallographic studies of OA have shown that OA has a pseudomacrocyclic structure due to hydrogen bond between the C-1 carboxyl terminus and the C-24 hydroxyl group [2]. The pseudo-macrocyclic structure of OA in not necessarily the case in 19-epimer of OA [37], therefore 19-*epi*-OA is more polar than OA, as demonstrated by the fact that it is soluble in methanol but not in chloroform.

OA/DTX analogues are known as an inhibitor of serine/threonine protein phosphatases (PPs) [39]. OA methyl ester does not inhibit PPs due to the loss of the acidic nature of the carboxyl group. It is reported that the carboxyl group as well as the four hydroxyl groups at C-2, C-7, C-24 and C-27 of OA are important for PPs inhibition activity [40]. The reduced activity of PPs has been implicated in the brain of carboxyl group (AD) patients and it is suggested that OA induced neurotoxicity may be a novel tool to study Alzheimer's disease pathology for development of new therapeutic approach [41].

19-*epi*-OA potently inhibited protein phosphatase 2A(PP2A) equally to OA, whereas the inhibitory activity of 19-*epi*-OA for protein phosphatase 1 (PP1) was far lower than OA. 19*epi*-OA selectivity for PP2A versus PP1 surpasses that shown by okadaic acid 10-fold, making it one of the most selective inhibitors of this class [37]. DTX-1 and DTX-2 have a stereochemistry opposite at the C-35. DTX-1 and DTX-2 are 35(*R*)-methyl OA [14, 15] and 35(*S*)-methyl 31-demethyl OA [36, 42], respectively. DTX-2 is about half as toxic in the mouse bioassay and has about half the affinity for PP2A as OA [43]. Molecular modeling studies indicated that 35(*S*)-methyl of DTX-2 had an unfavorable interaction in the PP2A binding site and this has been proposed as the reason for the reduced toxicity of DTX-2 [42, 44].

The C-1 carboxyl terminus and the C-7 hydroxyl group are both commonly modified by esterification. One group is the so-called "OA diol-esters" in which the carboxyl group of OA is conjugated to several different unsaturated diols to form allylic diol-esters. Several OA diol-esters have been found in toxic algae [22-35]. Esterification at the C-1 positions of OA, DTX-1 and DTX-2 markedly decrease the binding of the toxins to PP2A [23, 24]. The other group is a complex mixture of 7-*O*-acyl ester derivatives of OA, DTX-1 and DTX-2. This group is also known as the "DTX-3" complex although DTX-3 was originally named for 7-*O*acyl-DTX-1 [4]. They can be formed as metabolites of free OA, DTX-1 and DTX-2 in bivalves that have consumed toxic dinoflagellates. The activities of OA were generally decreased by acylation of the C-7 hydroxyl group [45]. The decrease was most significant in the mouse lethality, moderate in cytotoxicity, and only slight in the fluid accumulating potency in mouse intestinal loops. Diarrheagenicity measured by suckling mouse assays was affected little by the acylation. Potency of 7-*O*-acyl ester derivatives generally increased in parallel with the unsaturation in the acyls [45]. Esterified OA, DTX-1 and DTX-2 can be converted to their free parent toxin at strong basic conditions [4]. This also indicates that OA analogues are chemically stable at the strong basic conditions. This alkaline hydrolysis is widely applied to quantify both free toxins and esterified toxins by chemical and biochemical methods [46].

The ratios between the toxicity of the analogues and that of a reference compound within the same toxin group are termed "Toxicity Equivalency Factors" (TEFs). TEFs of marine toxins associated with shellfish were recently summarized [47]. The TEFs recommended by the FAO/WHO expert group for OA/DTX analogues are: OA=1, DTX-1=1, DTX-2=0.5. Recently the oral TEF values on mice was reported [48]. Results confirmed that DTX-1 is more toxic than OA by oral route while DTX-2 is less toxic. The oral TEF values are: OA=1,  $DTX-1=1.5$  and  $DTX-2=0.3$ .

# **TOXIN CONTENTS AND PROFILES IN** *DINOPHYSIS* **SPP.**

OA, DTX-1 and DTX-2, as well as the other lipophilic toxin group pectenotoxins (PTXs) are produced by the genus of *Dinophysis*. Bivalves become contaminated with these toxins by feeding on toxic *Dinophysis* species. Analysis of individually picked cells was historically the only unambiguous way to ascribe a toxin profile and content information to a *Dinophysis* species, until 2006, when cultures of *D. acuminata* became available [49]. The cellular toxin content and profiles of *Dinophysis* species of pooled picked cells reported in previous studies are shown in Table 2 [50–67]. These data would be still useful to predict bivalve contamination with OA/DTX analogues in each monitoring area.

# **Table 2. Reported toxin content and profiles in** *Dinophysis* **field specimens**

# **ACCUMULATION AND METABOLISM OF TOXINS IN SHELLFISH**

Free OA, DTX-1, DTX-2 and these esters at the C-1 carboxyl terminus in bivalves is absorbed from algae and metabolized. Esters at the C-7 position of OA, DTX-1 and DTX-2 had widely been observed in several bivalve species. Rapid conversion of DTX-1 to 7-*O*acyl-DTX-1 was observed in scallops, *P. yessoensis*, fed DTX-1-producing *D. fortii* for 5 days [46]. This conversion from DTX-1 to 7-*O*-acyl-DTX-1 in mussels, *Mytilus galloprovincialis* and *M. coruscus*, was relatively slow in comparison with scallops, *P. yessoensis* [21, 68, 69]. In general, *Mytilus* spp. (blue mussels) tended to have the lowest proportion of esterified toxin of any shellfish species and it is rare to find more than half the OA group toxin content of blue mussels esterified [70]. The conversion of free toxins to their 7-*O*-acyl derivatives markedly reduces the intraperitoneal toxicity in mice [45]. Therefore, the bioconversion of toxins may be a kind of a defense mechanism of bivalves. The most dominant fatty acids esterified to the C-7 position of OA, DTX-1 and DTX-2 are 16:0, 14:0, and 16:1 in several reports [16-21]. It has been suggested that bacteria present in the bivalve gut could contribute substantially to the acylation of the toxins, however treating mussels with antibiotics did not have any significant effect on the acylation of the supplied OA, suggesting that bacteria do not play any significant role in this process [71]. When a purified OA diol ester was incubated with a crude extract from green-lipped mussels, rapid hydrolysis to free OA was observed [72]. In contrast to the rapid hydrolysis of OA diol esters in the green-lipped mussels, two forms of hybrid diol esters esterified with fatty acids were the most abundant toxins in blue mussels, *Mytilus edulis* [38], suggesting slow hydrolysis of OA diol esters in the blue mussels.

The absorption efficiency for DTX-1 and DTX-1 esters combined was estimated to be less than 3% in scallop, *P. yessoensis*, fed DTX-1-producing *D. fortii* for 5 days [46]. Similar absorption efficiency of OA analogues was obtained in Canadian Bay scallop, *Argopecten irradians* (<5%) [73], and mussel, *Mytilus galloprovincialis* (9%) [74]. When Japanese scallops, *Patinopecten yessoensis*, were fed with sufficient cells of cultured *D. fortii* producing DTX-1, the absorption efficiency for DTX-1 and DTX-1 esters combined was 7- 23% [75]. Toxins were almost exclusively accumulated in the digestive gland with only low levels being detected in the gills, mantles, gonads, and adductor muscles (Figure 2). When a DTX-1-producing microalgae, *Prorocentrum foraminosum* was fed to Gray's mussels, *Crenomytilus grayanus*, for 12 days, the digestive gland accumulated 91–100% of DTX-1 and DTX-1 esters; and kidneys and gills accumulated up to 8.5% and 4.3%, respectively [76]. Contents of OA/DTX in mussels, *Mytilus edulis,* increased linearly with incubation time exposed to cultured *D. acuta* producing OA and DTX-1b, which is a putative DTX-1 isomer, for a week, and the net toxin accumulation was 66% and 71% for OA and DTX-1b, respectively [77].

Several field studies have suggested marked species-specific differences in diarrhetic shellfish toxin (DST) accumulation among commercial bivalves. Oysters hardly accumulate OA/DTX analogues even when co-occurring mussels accumulate toxins. This trend was demonstrated by a laboratory experiment using oysters (*Crassostrea gigas* and *C. brasiliana*) and mussels (*Perna perna*) exposed to a plankton suspension containing *D. acuminata* [78].

When mussels (*Mytilus galloprovincialis*) were exposed to different concentrations of purified OA and DTX-1 in filtered (0.45 um) seawater for 96 h, mussels accumulated toxins if suspended particulate matter is added in filtered seawater, suggesting a new understanding of the mechanisms of DST accumulation by bivalves in marine aquaculture environments [79].

The residual ratios for OA and DTX-1 analogues in scallops, *P. yessoensis*, administered these toxins via syringe were 2-7% and 5-12%, respectively [80].

Figure 2. PTXs and DTXs contents in scallops #1-3 and control tissues (A) mantle; (B) gonad; (C) adductor muscle; (D) others; (E) gill; (F) digestive gland. Toxins indicated with and asterisk were obtained for post-hydrolysis extracts. DTX3; 16:0-O-DTX1. (Figure 4 from Toxins 2015, 7, 5141-5154).

#### **INSTRUMENTAL ANALYTICAL METHODS**

#### **Liquid Chromatography (LC)/ Mass Spectrometric (MS) Detection**

Since the very early ESI LC/MS investigation for OA and DTX-1 was reported in 1990 [81], several studies on the development and application of LC/MS for OA/DTX-1 analogues and other lipophilic toxins had been reported as summarized in previous reviews [82, 83]. Determination of these toxins by LC/MS is usually carried out using a reversed phase chromatography on a C8- or C18-silica column and isocratic or gradient elution with acetonitrile/water or methanol/water mobile phases containing volatile modifiers such as acetic acid, formic acid, ammonium formate or ammonium acetate. The mobile phase that is most useful for LC/MS of the OA/DTX analogues and other lipophilic toxins is one composed of aqueous acetonitrile with 50 mM formic acid and 2 mM ammonium formate. The acidic conditions (pH 2.3) facilitate good chromatography of acidic toxins including OA/DTX analogues by suppressing ionization of the carboxyl groups and preventing deleterious ion exchange interactions with residual silanol groups in the stationary phase. It is reported that a change of a mobile phase pH to alkaline conditions results in better sensitivity of acidic toxins OA/DTX analogues in negative ionization mode by using the new type of cross-linked silica based C18 column materials which are stable up to pH 12 [84]. Approximately two times higher sensitivity for OA was obtained with alkaline mobile phase when compared with acidic mobile phase. Multiple reaction monitoring (MRM) LC/MS/MS chromatogram of OA/DTX-1 analogues and other lipophilic toxins analyzed with an acidic mobile phase obtained from scallop extract is shown in Figure 3. The most common MRM ion channel to detect acidic free OA/DTX-1is recorded for the [M-H]- precursor ion to the characteristic ion at *m/z* 255 in the negative mode (Figure 4).

Figure 3. MRM LC/MS/MS chromatogram of OA/DTX analogues and other lipophilic toxins obtained from scallops (Figure 3 from *Toxins* 7 (2015) 5141-5154).

The qTOF MS/MS fragmentation spectra of OA and DTX-1 obtained on the negative and positive modes are shown in Figures 4 and 5, respectively. The qTOF MS/MS spectra obtained on the positive mode give more structural information than those obtained on the negative mode. The spectrum showed a series of ions resulting from the loss of first ammonium and then water molecules from  $[M+NH_4]^+$ , as well as several characteristic fragment ions of OA, such as  $m/z$  429, 305, 223 and 169 [32, 85]. The corresponding ions were also obtained from DTX1. The MS/MS fragmentation diagram supported by accurate mass measurements on the fragment ions using a qTOF MS/MS and previous study [32, 85, 86, 87] is also shown in Figures 4 and 5. Assignment of *m/z* 111(OA), 125 (DTX1) on the positive mode was carried out by our recent qTOF MS/MS experiment. Elucidation of the mass fragmentation pathways of  $[M+Na]^+$  of OA, DTX1 and DTX2 by a hybrid linear ion trap (LTQ) Orbitrap MS was reported [87].

Figure 4. qTOF MS/MS product ion spectra obtained for [M-H]- of OA and DTX1.

The 7-*O*-acyl derivatives of OA and DTXs are well-suited for negative ion MS/MS as they form intense [M-H] – ions and the collision-induced fragmentation of ions provides good structural information. Figure 6 shows an example of the negative ion MRM LC/MS/MS chromatogram of several 7-*O*-acyl DTX1 obtained from Japanese scallops [21]. The MRM ion channel was recorded for the [M-H]<sup>-</sup> precursor ion to [M-H]<sup>-</sup> of the fatty acids.

Figure 6. Multiple reaction monitoring (MRM) LC-MS/MS chromatogram of several 7-*O*-acyl-DTX1 analogues detected in scallops. (Figure 6 from *Fish. Sci*. 75 (2009) 1039-1048).

#### **Liquid Chromatography (LC)/ Fluorometric (FL) Detection**

Pre-column fluorescence analysis of free OA/DTX by isocratic LC/FL after derivatization with 9-anthryldiazomethane (ADAM) was reported in 1987 [88]. This method had widely been used for plankton and shellfish analyses. The derivatisation of toxins with ADAM has also been used for confirmation of the presence of a carboxyl group in structural studies [89]. Other fluorescence reagents, 1-bromoacetylpyrene (BAP) [90], 3-bromomethyl-6,7-dimethoxy-1-methyl-2(1H)-quinoxalinone (BrDMEQ) [91], and 9-chloromethylanthracene (CA) [91] can be applicable for analyses of toxins with carboxyl groups. Separation of fluorescent toxin derivatives by LC is usually carried out using C18 reversed phase chromatography with acetonitrile/water mobile phases.

Although clean-up of ADAM derivative of OA/DTX analogues by Sep Pak silica cartridge [88] is useful, this cleanup method of 9-anthrylmethyl esters using a cartridge column is unsuitable for the automated handling of large numbers of samples in routine monitoring. Recently a convenient LC/FL for determining OA/DTX analogues as 9 anthrylmethyl esters was developed with the addition of column switching to simplify and automate cleanup [92]. Figure 7 shows the schematic diagram of the LC/FL with column switching valve. The peak of OA or DTX-1 ADAM derivative eluted from a cleanup column was introduced to an analytical column by switching the valve from A to B. The LC chromatograms obtained from scallops fortified with OA are shown in Figure 8. A clear peak of OA ADAM derivative was obtained from the scallop extracts in the range between 0.08 and 0.8  $\mu$ g/g. The recoveries of OA and DTX-1 at all fortification levels obtained for bivalve extracts ranged from 90 and 113%, with relative standard deviation (RSD) values of 0.9-9.9% [92].

Figure 8. Chromatograms of ADAM derivatives of toxins obtained from scallops fortified with OA on the automatic column switching cleanup LC/FD.

#### **Quantitative Nuclear Magnetic Resonance Spectroscopy (qNMR)**

NMR spectroscopy is a powerful analytical technique for structure elucidation of natural and synthetic organic compounds. Recently <sup>1</sup>H-NMR has also been applied as a quantitative analytical technique as the NMR signal intensity is proportional to the number of nuclei under specific controlled conditions. Quantitative NMR (qNMR) gives accurate and precise quantitative results for analytes when internal or external standards are used since the concentration of analytes is directly determined via the integral value ratio. Figure 9 shows <sup>1</sup>H-NMR spectrum of OA dissolved in CD<sub>3</sub>OD. OA and DTX1 were accurately quantified by qNMR with the well-separated proton signals at 5.78, 5.52, 5.36, 5.30 and 5.06 ppm corresponding to H-14, H-15, H-41, H-9 and H-41 of OA [93]. Similar result using other well-separated signals was reported from another laboratory [94].

Figure 9. Chemical structure and <sup>1</sup>H-NMR spectrum of okadaic acid dissolved in CD 3OD (800 MHz).

Signal choice could depend on very slight amounts of contaminants in analytes (OA/DTX) purified from algae or bivalves. This technique is intrinsically useful to prepare certified reference materials (CRMs) of OA/DTX analogues for instrumental analysis such as LC/MS.

## **ABSTRACT**

The marine thecate dinoflagellate *Pyrodinium bahamense* inhabits the tropical to subtropical waters of the Indo-Pacific, Arabian coasts, eastern Pacific and Atlantic-Caribbean. The species produces the neurotoxins saxitoxins (STXs), a collective compounds that caused paralytic shellfish poisoning (PSP) in human since the 1970s. This review highlights recent findings and information after the previous reviews, focusing on the species classification, and the biological and ecological significances. The varietal identities of *P*. *bahamense* (var. *compressum* and var. *bahamense*) have been reviewed. Blooms of *P*. *bahamense* is believed to exhibit a seasonal signature, however, factors that drive the variability in bloom magnitude, frequency and toxin production remain elusive. Some knowledge gaps are identified in this review to advance research of this important toxigenic dinoflagellate species.

**Keywords:** bioluminescence, human illness, paralytic shellfish poisoning, saxitoxins

### **INTRODUCTION**

*Pyrodinium bahamense* Plate (1906) is a marine thecate dinoflagellate. This neritic species is widely distributed in the tropical waters of the Indo-Pacific, Arabian coasts, eastern Pacific and Atlantic-Caribbean (Usup et al. 2012). The species, together with *Gymnodinium* 

Corresponding Author's Emails: cpleaw@um.edu.my; chuipinleaw@gmail.com.

*catenatum* and some species in the genus *Alexandrium*, have gained considerable attention when they were found to cause numerous human illnesses and even fatalities in the Southeast Asian countries after consuming contaminated shellfish (e.g., Maclean 1989; Holmes & Teo 2002; Lim et al. 2007, 2012; Yñiguez et al. 2020), a phenomenon termed paralytic shellfish poisoning (PSP). While *Pyrodinium bahamense* has been categorized as harmful in the Pacific region, its blooms are considered positive in the Atlantic, mainly the Caribbean, as the bioluminescence produced during the blooms in the bays and lagoons is an important tourist attraction (Sastre et al. 2013).

While previous publications have provided comprehensive reviews on the taxonomy, biology, and ecology of this harmful dinoflagellate (Hallegraeff and Maclean 1989; Azanza and Taylor 2001; Usup et al. 2012; Morquecho 2019), this chapter highlights recent findings after the review of Usup et al. (2012), focusing on the classification, biological and ecological significances of the species. Significant scientific gaps are identified to advance research of this important toxigenic species.

#### **TAXONOMY AND BIOLOGY**

The species *Pyrodinium bahamense* was first described by Plate (1906) from New Providence Island, Bahama, Atlantic Ocean, and later Böhm (1931) described an anterioposteriorly compressed form of the species from Persian Gulf, Indian Ocean. The genus *Pyrodinium* is monotypic, with a single species *P*. *bahamense* described. Steidinger et al. (1980) recognized morphological variations between the Atlantic and Pacific populations, gave these the infraspecific status of variety. They related *P*. *bahamense* var. *bahamense* to the Atlantic population, while *P*. *bahamense* var. *compressum* to the Pacific.

The history of its taxonomic classification was detailed in Taylor and Fukuyo (1989) and Usup et al. (2012). Likewise, phylogenetic placement of the species has been implied in several studies (Fensome et al. 1993; Leaw et al. 2005; Mertens et al. 2015). The genus is classified in the family Ostreopsidaceae, subfamily Pyrodinioideae by Fensome et al. (1993) based on the fossilizable dinosporin cysts and the motile stage of cells. The molecular phylogenetic position of *P*. *bahamense* inferred from the nuclear encoded ribosomal RNA genes (Usup et al. 2002; Ellegaard et al. 2003; Leaw et al. 2005; Zhang et al. 2005) and the mitochondrial gene of cytochrome b (Zhang et al. 2005) both placed this species in the order Gonyaulacales.

#### **Thecal Morphology**

Morphological characteristics of the thecal plates, like many thecate dinoflagellates, are commonly used for species delineation and classification (Figure 1). This morphological feature has been well studied and documented (e.g., Matenauer 1933, Schiller 1937, Osorio Tafall 1942, Taylor 1976, Wall and Dale, 1969, Steidinger et al. 1980, Balech 1985; Morquecho 2008; Usup et al. 2012; Mertens et al. 2015).

Motile cells of *Pyrodinium bahamense* are readily distinguished from other thecate dinoflagellate species by its heavily armoured thecal surface and the ornamented apical projections (Figure 1). The thecal plate tabulation, after the taxonomic revision of Mertens et al. (2015), is shown as [Po, Pi, 4ˊ, 0a, 6ˊˊ, 6c, 9s, 5ˊˊˊ, 1p, 1ˊˊˊˊ] (Figure 2). Detailed descriptions of the thecal morphology have been provided in Mertens et al. (2015).

Figure 1. Scanning electron micrographs of *Pyrodinium bahamense*. Culture specimens from Sabah, Malaysia. (A) Ventral view of vegetative cell. (B) Gamete-like cell (arrow). (C) Apical view. (D) Antapical view.

Figure 2. Schematic drawing of *Pyrodinium bahamense* thecal plate tabulation according to the Kofoidian model (after Mertens et al. 2015) (A) as compared to the Taylor-Evitt scheme (B). Po, apical pore plate; Pi, closing or cover plate; att. p., attachement pore.

*Pyrodinium bahamense* has always been considered as a sister taxon of *Alexandrium*, on the basis of similar plate tabulation and structural homology (Steidinger et al. 1980; Balech 1985). They were distinguished at the generic level based on the strongly developed theca with apical and antapical spines in *P. bahamense* as compared to the thinly thecate *Alexandrium* species (Balech 1985), variation in the sulcal tabulation (Balech 1985) and distinct cyst morphology (Balech 1985; Mertens et al. 2015); this was later supported by the molecular phylogenetic analysis inferred from the ribosomal RNA cistron (Leaw et al. 2005; Mertens et al. 2015; Cusick et al. 2016). Morphologically *P. bahamense* shares the same features of long and twisted posterior sulcal plate (S.p. in Kofoidian or Z in Taylor-Evitt homology, see Figure 2) and the trapezoid, metasert first apical plate with some *Alexandrium* species (e.g., *A*. *pseudogonyaulax* and *A*. *taylori*).

#### **Varietal Status of** *Pyrodinium bahamense*

The species was widely accepted to consist of two morphological varieties: *P. bahamense* var. *bahamense* and var. *compressum* (Steidinger et al. 1980) that corresponded to the broadly recognised non-toxic Atlantic and toxic Pacific populations. The former is reported with more developed apical spines and can occur in pairs but never in long chains; the latter is anterioposteriorly compressed and forms long chains of up to tens of cells. Morphological comparative studies between the two varieties depicted contrasting opinions on the varietal separation of *P. bahamense* (Steidinger et al. 1980; Balech 1985; Badylak et al. 2004; Mertens et al. 2015). While Baldylak et al. (2004), who observed Atlantic populations from Indian River Lagoon, Florida, supported separate varieties, Mertens et al. (2015), agreeing with Balech (1985) and others (reveiwed in Mertens et al. 2015), showed no consistent morphological criterion to unequivocally separate both varieties. Nonetheless, the authors suggested that the field-observed variations represent different life-stage forms. The presence of both varieties in the Pacific Ocean off Central America and Mexico further supported the conclusion of no varietal separation (Martínez-López et al. 2007; Morquecho 2008; Gárate-Lizárraga and González-Armas 2011). The phylogenetic analysis by Mertens et al. (2015) based on LSU rDNA sequences, however, revealed two distinct LSU ribotypes within the *Pyrodinium* clade, depicting Indo-Pacific and Atlantic-Caribbean populations, respectively.

# **Reproduction**

The species *Pyrodinium bahamense*, like most dinoflagellate species, produces resting cysts as part of the sexual life cycle in their life history. The fossilized cysts have the paleontological name *Polysphaeridium zoharyi* (Rossignol) Bujak, Downie, Eaton and Williams. It was first described as *Hystrichosphaeridium zoharyi* by Rossignol (1962) from the Israelian Wuaternary coastal sediment dated in late Paleocene to early Eocene (McLean 1976; Williams et al. 1993), and from Pleistocene sediments in the Western Pacific (Matsuoka 1976; Mao and Harland 1993).Wall and Dale (1969) related the motile stage of *P*. *bahamense* to *Hystrichosphaeridium zoharyi*, and they transferred the species to a new genus *Hemistocystodinium*. It was later transferred to *Polysphaeridum* by Bujak et al. (1980). Matsuoka (1989) related *P. bahamense* var. *compressum* to *P. zoharyi*. Detailed cyst
morphology of *P*. *bahamense* are documented in numerous studies (Matsuoka et al. 1989; Mertens et al. 2015). Mertens et al. (2015) noted significant intergradation in the cyst morphologies of both varieties.

The life cycle of *P*. *bahamense* plays an important role in the ecology and bloom dynamics. The species undergoes a haplontic life cycle with sexual and asexual reproduction. Detailed description of the life cycle has been documented (reviewed by Usup and Azanza 1998). The asexual reproduction involved binary fission of the haploidic cells (Usup 1995) or ecdysis from the pellicle cyst stage (Onda et al. 2014). Pellicle cyst formation has been observed *in vitro* by Onda et al. (2014) and found that the pellicle cysts were developed at sub-optimum culture conditions.

The sexual life cycle of *P*. *bahamense* is similar to most dinoflagellates that form resting cysts (hypnozygotes). The cycle begins with fusion of gametes of the same size (isogamous); this was observed in laboratory cultures (Corrales et al. 1995) but not from natural populations. Gametes are small (Azanza and Larsen 1997; see also Figure 1B) while planozygotes are larger than the vegetative cells; chromatophores were observed in the hypnozygotes (Corrales et al. 1995). The resting cysts produced from laboratory cultures undergo a mandatory dormancy period of 2.5-3 months prior to excystment (Corrales et al. 1995; Usup, per. comm.). While life-cycle transition of dinoflagellate cells in natural bloom condition have been considered to play an important role in bloom dynamics, in particular the toxic *Alexandrium* species (Figueroa et al. 2011; Lau et al. 2017), the environmental drivers for the sexual processes of natural *Pyrodinium* populations are not known.

## **Bioluminescence**

The species is capable of producing and emitting light, also termed bioluminescence, by a chemical reaction involving a substrate luciferin and the enzyme luciferase (Biggley et al. 1969). Cusick et al. (2016) revealed the diversity of the luciferase gene (*lcf*) in *P*. *bahamense*, and demonstrated that *lcf* sequences formed distinct geographical-defined clusters of the Western Atlantic (Indian River Lagoon and Mosquito Bay, Puerto Rico) and the Indo-Pacific. Evolutionally, *P*. *bahamense lcf* is closer to *Pyrocystis lcf* than its sister taxon *Alexandrium* (Cusick et al. 2016). While it has been suggested that bioluminescence system in dinoflagellates may act as defense again predation pressure (Esaias and Curl 1972; White 1979; Marcinko et al. 2013; Valiadi and Iglesias-Rodriquez 2013) and oxidative stress (Wilson and Hastings 2013), the ecological function as well as the physiological role of bioluminescence in this species has yet to be determined.

Coastal embayments with natural bioluminescence are unique and are considered popular tourist attractions. In the Caribbean, bioluminescent bays and lagoons are attributed to the persistent blooms of *P*. *bahamense*, however, the blooms have been reported to be declining over the years (Sastre et al. 2013). Efforts have been made to conserve the continuous *P*. *bahamense* populations and its bioluminescence in Laguna Grande, Puerto Rico, by maintaining the water quality and to preserve mangrove communities within the basin and adjacent areas (Sastre et al. 2013).

## **Saxitoxin Production**

The species *Pyrodinium bahamense* produces a group of neurotoxins, saxitoxins (STXs), and is often associated with PSP in the Indo-Pacific and Pacific coasts of Central America (Usup et al. 2012). PSP was recorded for the first time in Papua New Guinea in 1972 (Maclean 1973). Reports of PSP associated with *P*. *bahamense* have been reviewed by Azanza and Taylor (2001), Usup et al. (2012), and Morquecho (2019). Only *P*. *bahamense* in the Pacific (broadly recognized as var. *compressum*) was assumed to be toxic until a toxic Atlantic population was reported, for the first time, by Landsberg et al. (2002), but no shellfish poisoning incident was implicated, but puffer fish poisoning was believed to be due to the occurrence of *P*. *bahamense* (Landsberg et al. 2006).

With regards to the cellular toxin quota (toxin content in a cell), *P*. *bahamense* is one of the most toxic paralytic shellfish toxins (PSTs)-producing species, with the toxicity up to 1600 fmol cell<sup>-1</sup> reported thus far (Montojo et al. 2006; Table 2). Toxin profile of *P*. *bahamense* was stable in both culture strains and natural bloom populations examined (Table 2; references herein), composed mainly of STX, dcSTX and B1 (GTX5), with traces of neoSTX and B2 (GTX6) (Table 2). The toxin compositions, however, varied among culture strains and natural populations. A summary of the levels and composition of saxitoxins from culture and natural populations of *P*. *bahamense* is given in Table 2. There is a significant intraspecific variation in *P*. *bahamense* toxin productions in both culture and natural populations (Table 2). Likewise, very limited field studies have indicated the dynamics of toxin production in the natural populations, making it difficult to draw conclusion on the mechanisms that affect toxin production in this species.

The saxitoxins biosynthesis pathway in the toxigenic marine dinoflagellates has been partly discovered and the related genes have been elucidated (Stuken et al. 2011; Murray et al. 2015; Tsuchiya et al. 2016, 2017; Cho et al. 2019), but the complete route, including of those in *P. bahamense*, remain to be resolved.

## **Sterol Production**

Production of sterols, an array of membrance-reinforming lipids in *P*. *bahamense* has been elucidated by Usup et al. (2008) and Houle et al. (2018). These macromolecules were used to study chemotaxonomic relationship among eukaryotes, including dinoflagellates (Leblond et al. 2010). The isolates of *P*. *bahamense* from Florida produced three sterols (cholesterol, dinosterol, and  $4\alpha$ -methylgorgostanol, similar to other cholesterol- and dinosterol-producing thecate dinoflagellate species (Houle et al. 2018).

# **ECOLOGICAL SIGNIFICANCE**

#### **Ecological Niches**

While the modern cysts have been found in tropical to subtropical regions with wider distribution, *Pyrodinium bahamense* motile cells in general are confined to tropical coastal waters (reviewed in Usup et al. 2012). Both the motile cells and cysts were recorded from the biogeographical regions of Indo-Pacific, Arabian coasts (Persian Gulf and Red Sea), eastern Pacific coasts of central America, and the Atlantic-Carribean, which spans a narrow latitudinal extent of 30°N and 10°S with seawater temperatures above 20℃. *Pyrodinium* cysts in the Gulf of Tehuantepec, the Pacific coast of Mexico revealed that *Pyrodinium* cysts were present since the 1860s to present (Sanchez-Cabeza et al. 2012). In the eastern Atlantic Ocean, *P*. *bahamense* cyst type was first recorded by Amorim and Dale (1998).

New reports of *P*. *bahamense* motile cell and cyst occurrences since the review of Usup et al. (2012) are: San José, Yavaros, El Colorado Lagoon, Gulf of California (Morquecho et al. 2012); Laguna Grande, Puerto Rico (Sastre et al. 2013); Yemeni coastal waters, Red Sea (Alkawri et al. 2016); King Abdullah Economic City, Red Sea (Banguera-Hinestroza et al. 2016); Gulf of Gemlik, Marmara Sea, Turkey (cyst; Balkis et al. 2016); St. Croix, US Virgin Islands (cyst; Reidhaar et al. 2016).

### **Saxitoxins in the Food Web**

Human intoxication is primarily caused by the ingestion of saxitoxin-contaminated shellfish (Table 2). Minimal variation in the toxin profiles was observed between the contaminated shellfishes from Malaysia and the Philippines, and the dinoflagellate (Montojo et al. 2006; Usup et al. 2006). However, different types of shellfish contaminated by *P. bahamense* toxins exhibit a degree of variability in the toxin accumulation (Montojo et al. 2010; 2012). On the other hand, Rañada et al. (2016) demonstrated that smaller *Perna viridis* mussels, an indicator species used in the Philippines saxitoxin monitoring program, are more toxic than larger mussels when exposed to low density of *P*. *bahamense*. Studies on toxin bioaccumulation in shellfish and other types of vectors by *P*. *bahamense* are scarce and require further investigation.

In 2013, the species has been implicated, for the first time, as the cause of massive sea turtle mortality in El Salvador, with *G*. *catenatum* and *P*. *bahamense* recorded in the water (Amaya et al. 2018).

Paralytic Shellfish Poisoning (PSP) is of great concern due to the potency of PSTs that can cause severe human illness and death. PSP has also expanded globally (Hallegraeff 1993) although of course part of this is due to increased awareness. Most of these PSP cases due to *Pyrodinium* comes from the Southeast Asian region with the Philippines and Malaysia as the two most affected countries (Azanza and Taylor, 2001; Usup et al. 2012; Yñiguez et al. 2020). For example, in the Philippines, there have been more than 2200 PSP cases from 1983 to 2013 with more than 123 fatalities (Bajarias et al. 2006; Arcamo et al. 2014). Fortunately, the illnesses have been declining through time (Arcamo et al. 2014) even though many areas are still affected by *Pyrodinium* blooms. In Malaysia, there have been at least 200 PSP cases and 20 deaths reported (Jipanin et al. 2019; Yñiguez et al. 2020). This decline in PSP cases, especially in the Philippines, is attributed to the active monitoring and warning program spearheaded by the relevant government agencies.

#### **Bloom Dynamics**

Blooms of *Pyrodinium bahamense* across geographic areas from the Atlantic (Phlips et al. 2006, 2015; Soler-Figueroa and Otero 2015; Morquecho 2019), eastern Pacific (Moquecho et al. 2012; Morquecho 2019), to the Red Sea (Alkawri et al. 2016; Banguera-Hinestroza et al. 2016) and the Indo-Pacific (Maclean 1989; Usup et al. 1989; Azanza et al. 1998; Montojo et al. 2006; Villanoy et al. 2006; Adam et al. 2011; Mohammad-Noor et al. 2014; Yñiguez et al. 2018), distinctly occurred at sites characterized by warm (tropical to subtropical), relatively shallow (from one to a few tens of meters), semi-enclosed or protected areas with long water residence times, and usually with relatively variable salinity.

A consistent pattern in the initiation of *P. bahamense* blooms is the important role of the germination of cysts from cyst beds (Anderson 1989; Usup et al. 2012; Azanza et al. 2018). These cyst beds are also key in the recurrence of blooms within the same site. Cysts most likely need to be resuspended before they can germinate (Azanza et al. 2018), after which appropriate conditions for higher population growth rates need to be present for a bloom to develop (Yñiguez et al. 2018). Conditions for the increase in cell numbers appear to be pulses of sufficiently high nutrients (though what this threshold is, if there is one, is not clear) and low flushing rates. These conditions, together with the capacity of *P. bahamense* to withstand a large range of salinities, and possibly decrease grazing through its toxin, can be the key factors leading to its blooms (Phlips et al. 2006; Usup et al. 2012). These bloom patches can then be transported to other areas beyond the sites where blooms are initiated.

One primary factor associated with these blooms is either a dry period followed by rainfall (Usup et al. 1989; Azanza 2013; Yñiguez et al. 2018) or rainfall per se (Morquecho et al. 2012; Phlips et al. 2006, 2015). This rainfall is believed to lead to increased run-off that introduces nutrients into coastal waters and satisfies the nutrient requirements of *P. bahamense*. Bloom conditions are also observed to be related to periods of calmer and stratified conditions that potentially comes after wind-induced mixing (Usup et al. 1989; Villanoy et al. 2006; Usup et al. 2012; Yñiguez et al. 2018). There is evidence that blooms can have a seasonal signature, particularly occurring during seasons when rainfall increases and/or the transition periods from drier to rainy conditions. For example, in subtropical Florida, *P. bahamense* blooms during the rainy summer period (Phlips et al. 2006, 2015). In Southeast Asia, which experiences a monsoon system, blooms are typically during the rainy monsoon period: e.g., southwest monsoon in the Philippines (Azanza et al. 2004; Montojo et al. 2006; Adam et al. 2011; Azanza 2013; Yñiguez et al. 2018) and northwest monsoon in Papua New Guinea (Maclean 1989). These blooms have been linked to El Niño Southern Oscillation (ENSO) patterns. Azanza and Taylor (2001) related the occurrence of red tide events of *P. bahamense* with El Niño in Southeast Asia. This relationship is still not fully understood due to the rarity of long-term data on *Pyrodinium* blooms. Phlips et al. (2015) found that in the 16-years of data from Florida lagoons, El Niño conditions (rainy in this area) was correlated to *Pyrodinium* blooms. Sanchez-Cabeza et al. (2012), on the other hand, observed increased flux of *P. baha*mense cysts into the sediments presumably from blooms in the water column during transitions from dry La Niña conditions in Mexico to higher rainfall.

*Pyrodinium bahamense* blooms can last from weeks to months. What leads to their decline is less understood compared to how they are initiated. One hypothesis is that when *P. bahamense* encounters certain, possibly stressful conditions (e.g., nutrient limitation or high cell densities), they encyst into hypnozygotes, which serve to decrease cells in the water

column (Azanza et al. 2018). Other potential factors contributing to the decline is the shift in hydrographic conditions, i.e., more mixing or turbulent conditions, and top-down control through grazing (Usup et al. 2012; Azanza et al. 2018; Yñiguez et al. 2018).

## **Bacteria Interaction**

Knowledge on the interaction between *P*. *bahamense* and bacteria is still lacking. Bacterial community compositions associated with *P*. *bahamense* have been investigated in several studies based on the *P*. *bahamense* cultures established from the Philippines (Azanza et al. 2006; Onda et al. 2015). Azanza et al. (2006) found STX and neoSTX at levels <73 ng STXs/10<sup>7</sup> cells in the bacterial strains of *Moraxella*, *Erythrobacter* and *Bacillus*, suggesting possible contribution of bacterial endosymbionts in the toxin production of *P. bahamense*.

# **CONCLUSION: KNOWLEDGE GAPS AND SUGGESTIONS FOR FUTURE RESEARCH**

- Is there a sign of geographical expansion in *P*. *bahamense*? The information on distinct ribotypes of *P. bahamense* has provided a framework for further investigation of the genetic diversity of *P*. *bahamense* across biogeographical regions.
- What causes the diminishing of *Pyrodinium* blooms in areas that used to have persistent blooms? Does eutrophication at the coastal embayment drive the shift of plankton assemblages?
- Sexual transition and reproduction of paralytic shellfish toxins-producing dinoflagellates have been demonstrated to play an important role in bloom development (Anderson, 1998) but field evidence for *P*. *bahamense* is still limited. Investigating the life-cycle transitions of *P*. *bahamense* during bloom periods would provide more insights into the bloom dynamics, and possibly enable prediction of the duration and timing of bloom.
- Environmental drivers such as salinity, temperature and nutrient availability are among the triggering factors in the sexuality of *Alexandrium* species (e.g., Garcés et al. 2004; Figueroa et al. 2011). How do these factors affect the *Pyrodinium* life cycle?
- Considering the distinct toxin profile of *P*. *bahamense* as compared to the sister group *Alexandrium*, and the total absence of hydroxysulfate toxins (GTX1-4, C1-4), it would be crucial to understand how the evolution of the STX biosynthetic genes and its pathway occurred in this dinoflagellate.
- The genetic basis of saxitoxin production in this species and how the environmental stressors affect the toxigenesis of this species are worth further investigation.

### **ACKNOWLEDGMENTS**

We gratefully acknowledge funding supports from the Highest Institution Centre of Excellence Grant from the Minstry of Education, Malaysia [IOES-2014C]; and partial support from the National Key Research & Development Program of China [2016YFE0202100]. We wish to thank the three reviewers for their critical constructive comments and suggestions.

# **ABSTRACT**

The cosmopolitan bloom forming dinoflagellate *Noctiluca scintillans* exists in two forms, the heterotrophic red *Noctiluca* and the mixotrophic green form which harbors a photosynthetic symbiont *Protoeuglena noctilucae* while also having a phagotrophic mode of nutrition. The combining facets of being a primary producer and a consumer appears to underpin green *Noctiluca*'s recent expansion in the Arabian Sea, where it now appears annually as large-scale blooms outcompeting the well-known winter diatom blooms and posing a threat to regional fisheries and the long-term health of an ecosystem that supports a coastal population of nearly 120 million people. Although more ubiquitous than green *Noctiluca* which until now has been confined to the tropics, blooms of the more cosmopolitan, heterotrophic red *Noctiluca* are also occurring more often, lasting longer and have expanded even into the Southern Ocean. In this review, we discuss the ecology of these two disparate varieties of *Noctiluca*, and synthesize a growing body of evidence that ascribes their recent expansion to anthropogenic activities. We also address some of the ecological and socio-economic impacts of these blooms especially those related to the food web, and summarize recent efforts to provide their spatial and temporal estimates using satellite ocean color remote sensing.

**Keywords**: green *Noctiluca,* red *Noctiluca*, mixotrophy, hypoxia, climate change

# **1.INTRODUCTION**

The heterotrophic dinoflagellate *Noctiluca scintillans* Macartney 1810 (Kofoid and Swezy 1921) is one of the most prominent 'red tide' organisms as well as one of the most extensively studied (Elbrachter and Qi 1998, Hallegraeff et al. 2008, Harrison et al. 2011; and references within). It is commonly known as 'Sea Sparkle' because it appears as brightly bioluminescent blooms globally. There exists only one species in the genus *Noctiluca* and the synonym *Noctiluca miliaris* Lamarck (Suriray 1836) which was used in the past has been discontinued. Thus, only the genus name *Noctiluca* will be used throughout this paper. *Noctiluca* is large  $(200 - 1000 \mu m)$  in diameter), bulbous and occurs in two forms: red *Noctiluca* which is heterotrophic, and when present, constitutes one of the major microzooplankton grazers in the food web (Elbrachter and Qi 1998, Fonda-Umani et al. 2004, Kiorboe and Titelman 1998, Kirchner et al. 1996, Nakamura 1998) exerting significant feeding pressure on phytoplankton especially diatoms but also feeding on an extensive variety of food items including bacteria, microzooplankton, copepod and fish eggs, protozoans and even detritus (Zhang et al. 2015). Red *Noctiluca* (Figure 1) appears as large reddish streaks and patches in surface waters of coastal and shoreline areas worldwide, because of the presence of small droplets of carotenoids that are thought to be derived from the plankton that it feeds on (Balch and Haxo 1984), although the coloration still remains poorly understood. Green *Noctiluca* (Figure 2a), on the other hand, is a mixotroph that harbors thousands of freeswimming photosynthetic symbionts (Figure 2b), but it can also be phagotrophic when food is available (Hansen et al. 2004, Sweeney 1978, Harrison et al. 2011, Gomes et al. 2008). Green *Noctiluca* blooms form large green slicks that turn yellowish brown as the bloom decays (Furuya et al. 2006a, Gomes et al. 2008, 2009) (Figure 3a-b). Unlike some other 'red tide' organisms (Anderson et al. 2002) both red and green *Noctiluca* are essentially non-toxic but repercussions for the food web from their indiscriminate feeding and from gelatinous zooplankton being their top predators, as well as their accumulation of ammonia, have raised concerns for fisheries, tourism, offshore oil refineries and desalination plants (Suvapepun 1989, Goes and Gomes 2016, Goes et al. 2018).

This review attempts to feature some of the more recent findings related to red *Noctiluca* and the lesser studied green *Noctiluca*, especially its ecophysiology and complex mixotrophic behavior and its appearance and expansion as anthropogenic activities continue to change the planet. Although this review is more focused on the mixotrophic green *Noctiluca*, comparisons are drawn to red *Noctiluca* to elucidate their similarities and dissimilarities. As noted by Harrison et al. (2011), previous reports did not clearly differentiate between the two, creating confusion that still persists even in more recent reports.

We start (Section 2) by comparing the distribution of green *Noctiluca* which is restricted to tropical waters *vis a vis* the more ubiquitous red *Noctiluca*. Following this, Section 3 describes the characteristics of the heterotrophic red and the mixotrophic green *Noctiluca* and describes the endosymbionts of the latter. Section 4 addresses the consequences of *Noctiluca*'s proliferation for the food web, and how phototrophy combined with phagotrophy provide a more flexible strategy in nutrient acquisition, growth, and production for the mixotrophic green *Noctiluca*. Section 5 describes the recent efforts by the oceanographic community to develop methods to identify and discriminate green *Noctiluca* from other phytoplankton based on the optical signature of its photosynthetic endosymbionts, and studies

that use daily, synoptic images from various remote ocean color instruments to provide insights into the dynamics of *Noctiluca* blooms that cannot be achieved by conventional *in situ* sampling alone. Section 6 traces the expansion of *Noctiluca* blooms, especially the mixotrophic green variety from localized and sporadic blooms to widespread annually recurring events like those seen in the Arabian Sea. Finally, Section 7 summarizes various reports on the adverse effects of *Noctiluca*. Albeit nontoxic, outbreaks of thick and widespread blooms of *Noctiluca* seen in the northern Indian Ocean, the Gulf of Thailand and the Sea of Oman can cause severe damage to fisheries, tourism and other marine related industries. It also addresses the potential repercussions of these blooms for the food web.

Figure 1. Cells of the red *Noctiluca scintillans* from a surface slick from Sullivans Cove, Tasmania, Australia. Photo kindly provided by Dr. Gustaaf Hallegraeff, Institute for Marine and Antarctic Studies, University of Tasmania, Australia.

Figure 2. a) A single cell of the green *Noctiluca scintillans* with free-swimming endosymbionts *Protoeuglena noctilucae*. Tentacle used to capture food is seen in the center b) A cluster of cells of the green *Noctiluca scintillans* with healthy endosymbionts floating outside the cells. Both images were produced with an AmScope 40X-900X phase tissue culture inverted microscope with a  $10\times$  and  $4\times$  objective.

# **2. DISTRIBUTION**

*Noctiluca*'s ubiquitous distribution world-wide has been very well documented in an excellent review by Harrison et al. (2011) which provides the first map of the global distribution of both red and green *Noctiluca* as well as lists of all reported occurrences with locations, coordinates and dates. Figure 4 is a redrawn and updated map of Harrison et al. (2011) with two new reports of green *Noctiluca* from the coasts of Tanzania and Seychelles.

Figure 3. a) Thick surface bloom of *Noctiluca* in the Sea of Oman observed on 7<sup>th</sup> February 2018 b) *Noctiluca scintillans* cells from the bloom in a beaker showing the density of the bloom.

Figure 4. Updated map of the global distribution of red (red dots) and green (green dots) *Noctiluca scintillans* redrawn from Harrison et al. (2011) to include recent reports of green *Noctiluca* off the Tanzanian coast (Lugomela, 2007) and off Seychelles (David Rowat, Marine Conservation Society, Seychelles, pers. comm.). Dots are proportional to the concentration of cells recorded in Tables 1 and 2 of Harrison et al. (2011).

Red *Noctiluca* occurs widely in temperate to sub-tropical coastal regions of the world in a temperature range of about  $10{\text -}25^{\circ}\text{C}$  (Harrison et al. 2011) although reports by Qi et al. (2019) for the East China Sea and by Baliarsingh et al. (2016) and Mohanty et al. (2007) for the Bay of Bengal, indicate that it can grow beyond this temperature range (Figure 4). It generally, seems to prefer higher salinities because it has not been observed in estuaries (Harrison et al. 2011). It is particularly abundant in high productivity areas such as upwelling or eutrophic areas where diatoms dominate since they are its preferred food source (Figure 4; Harrison et al. 2011).

Some of the more well studied regions where red *Noctiluca* occurs recurrently, include the German Bight (Uhlig and Sahling 1990, Fock and Greve 2002); the North Sea (Hauke et al. 1998); Northern and Southern Black Sea (Kideys and Romanova 2001, Kideys et al. 2000) and the northern Adriatic Sea (Degobbis et al. 1995, Fonda-Umani et al. 2004). In Asia, red *Noctiluca* appears repeatedly in the Seto Inland Sea, Japan (Pithakpol et al. 2000, Tada et al. 2004); Sagami Bay, Japan (Miyaguchi et al. 2006); Southern Korea in the Jinhae Bay (Baek and Kim 2011), Bohai Sea, China (Zou et al. 1985); East China Sea (Yan et al. 2002); and Tolo Harbor, Hong Kong (Tang et al. 2006, Zhang et al. 2017b). Further south, red *Noctiluca* has been observed in the Gulf of Thailand (Suvapepun 1989, Cheevaporn and Menasveta 2003); Jakarta Bay, Indonesia (Adnan 1989) and off the west coast of India (Sahayak et al. 2005), in the Gulf of Mannar (Edward et al. 2009) and the Bay of Bengal (Mohanty et al. 2007). Red *Noctiluca* has also been reported from the Gulf of Mexico (Gomez-Aguirre 1998), the Chesapeake Bay, USA (Marshall et al. 2006); NSW, Australia (Tong et al. 1998, Dela-Cruz et al. 2002; 2008, Oke and Middleton 2001) and SE, Australia (Dela-Cruz et al. 2003); the Australian coastal waters (Hallegraeff et al. 2008) and off Tasmanian waters (Thompson et al. 2008). For a more detailed survey of the various locations globally where red *Noctiluca* has been found, the reader is directed to Table 1 in Harrison et al. (2011).

In contrast, green *Noctiluca*, because of its pre-disposition to warmer waters (24-30 °C) is restricted to coastal and open tropical waters (Figure 4) with the first report of green *Noctiluca* in association with endosymbionts originating from the Dutch Indies (Weber and Bosse 1890). Since then, large green blooms have been observed in the Arabian Sea annually during the winter monsoon (Gomes et al. 2008, Parab et al. 2006, Prasad 1953, Prasad 1958, Subrahmanyan 1954), but, until now, not in the Bay Bengal probably because of the low salinities caused by excessive precipitation and river runoff (Gomes et al. 2016).

Sporadic blooms of the green *Noctiluca* have also been observed in the tropical waters of Southeast Asia including the Gulf of Manila (Furuya et al. 2006a), Gulf of Thailand (Lirdwitayaprasit et al. 2006, Sriwoon et al. 2008) and Jakarta Bay (Praseno and Wiadnyana 1996) and the coastal waters of Vietnam (Lam and Hai 1996). In the Sea of Oman (Gulf of Oman) red *Noctiluca* was documented since 1988, but green *Noctiluca* was seen for the first time in 1999 (Thangaraja et al. 2007), and since then appears annually almost throughout the year (Figure 3a-b) (Gomes et al. 2008, 2009; Al-Hashmi et al. 2015, Al-Azri et al. 2007). There are also recent reports of green *Noctiluca* from the coastal waters of Tanzania (Lugomela 2007).

Figure 5. *Noctiluca scintillans* cells grown in media of salinity a) 32 b) 33 c) 34 d) 36. Endosymbionts *P. noctilucae* were much denser at the highest salinity of 36. Images were collected using a confocal microscope.

There are no reports of the co-existence of red and green *Noctiluca* and our research also confirms that while green *Noctiluca* proliferates during the winter monsoon in the northern Arabian Sea (Parab et al. 2006, Gomes et al. 2008, 2009), red *Noctiluca* is seen mostly in summer, restricted to the coastal waters of western India especially in association with cold, hypoxic waters that upwell off the shelf (Padmakumar et al. 2009, 2016; Joseph et al. 2008, Vijayalakshmy et al. 2018, Shaju et al. 2018). Our preliminary studies with a laboratory culture of green *Noctiluca* indicates that both *Noctiluca* and the endosymbionts grow and proliferate only in a very narrow salinity range of 32-26 with the largest population of endosymbionts at the highest salinity of 36 (Figure 5a-d). In the Gulf of Thailand, (Sriwoon et al. 2008) found green *Noctiluca* in a wide salinity range of 14-35 but blooms only formed in a narrower salinity range of 25-30.

## **3. DESCRIPTION**

Both the red and the green varieties of *Noctiluca* are large cells (often up to 1000 µm) (Figure 1, & 2a-b) with an oral pouch which is an invagination of the more or less spherical cell (Elbrachter and Qi 1998). Within this pouch is located a tentacle and a flagellum (Lucas 1982), a permanent cytostome, a rod organelle and a projecting tooth (Elbrachter and Qi 1998, Takayama 1983). Unlike the flagellum, the tentacle is highly visible, beating slowly and repeatedly to capture food (Figure 2a-b). Neither the flagellum nor the tentacle aid in vertical movement, which is mostly controlled by active ionic regulation of the specific gravity (Elbrachter and Qi 1998). In addition, large amounts of ammonia and lipids are concentrated within its cells (Gomes et al. 2018) which may aid in its buoyancy but accumulation of ammonia can also make *Noctiluca*, ichthyotoxic (Okaichi and Nishio 1976).

In contrast to the exclusively heterotrophic red *Noctiluca*, the green variety presents a highly interesting and specialized case of mixotrophy amongst the large and varied groups of mixotrophic protists recently classified by Mitra et al. (2016) and (Stoecker 2017) based on their mechanisms for energy and nutrient acquisition. The free-swimming green endosymbionts were first described by Subrahmanyan (1954) as *Protoeuglena noctilucae* because of their similarity to euglenoids in flagellar structure and the absence of a cellulose wall (Elbrachter and Qi 1998). Sweeney (1976) however reclassified it as a new species, *Pedinomonas noctilucae* based on its starch storage, dissimilarities in color, flagellum orientation and subcellular structures (Elbrachter and Qi 1998). More recently, Wang et al. (2016) used phylogenetics and ecological characteristics to reinstate it to the genus *Protoeuglena* and reclassify the endosymbiont as *Protoeuglena noctilucae*.

Vegetative cell division is by binary fission as is the case in most dinoflagellates, but, in addition to binary fission, *Noctiluca* also produces zoospores with one or more flagella (Elbrachter and Qi 1998). In the North Sea, red *Noctiluca* zoospore formation is common in spring and early summer, which Uhlig and Sahling (1990) ascribed to the cell maximal populations seen from March-June, but rare during population decline suggesting that it cannot be responsible for the decline of the bloom (Elbrachter and Qi 1998). Sexual reproduction has also been observed in the red *Noctiluca* (Schnepf and Drebes 1993, Fukuda and Endoh 2006). One of the first reports of both vegetative cell division and sexual reproduction in the mixotrophic green *Noctiluca* is by Furuya et al. (2006b) in cultures

isolated from the Gulf of Thailand and Manila Bay. They found that non-feeding strains of green *Noctiluca* that grow autotrophically for generations, (i.e., without an external food supply), form gametocytes only when food is supplied. A later field study by these authors in the Gulf of Thailand (Sriwoon et al. 2008) supported this interesting finding; gametocytes of green *Noctiluca* were frequently observed during the dense summer monsoonal blooms as well during the transition into the winter monsoon when food was still available, but not in winter when blooms are sparse, indicating that sexual reproduction occurred only under favorable food conditions.

Bioluminescence another distinctive feature of *Noctiluca* cells, originates from thousands of scintillons, which are organelles distributed throughout the peripheral cytoplasm. They contain luciferin and luciferase and are capable of emitting light flashes when triggered by mechanical stimulation of the cell. In both green and red *Noctiluca,* bioluminescence is a defense behavior against predators. It usually prevents the cells from being grazed upon, because the flash responses serve to startle predators that contact the cell as well as act as a light alarm to attract secondary predators of *Noctiluca*'s predators (Valiadi et al. 2019). Although most varieties of *Noctiluca* are bioluminescent, intriguingly the ones found on the west coast of USA are not, which Valiadi et al. (2019) have ascribed to a mutated gene and lack of luciferase.

# **4. GROWTH AND GRAZING**

Red *Noctiluca* is known to be a voracious feeder, ingesting all particles, even those with no dietary value, all of which are engulfed using the tentacle that aids in both food uptake and the elimination of faeces (Elbrachter and Qi 1998). However, more focused studies now show that *Noctiluca* may have some food preferences that promote its growth over others (Buskey 1995), with a more recent study (Zhang et al. 2016) suggesting that while growth and feeding showed no significant relationship with cell size or swimming motility of the prey, over longer incubation times of approximately 2 days red *Noctiluca* preferred food mixtures that were nutritionally superior even if less abundant. In the natural environment, *Noctiluca* exerts significant pressure on phytoplankton, especially diatoms (Fonda-Umani et al. 2004, Baek and Kim 2011, Huang and Qi 1997), copepod eggs (Cabal et al. 2008, Quevedo et al. 1999), and even toxigenic *Dinophysis* and *Pseudo-nitzschia* suggesting that if consumed, *Noctiluca* could act as a vector for transfer of phycotoxins to higher trophic levels (Harrison et al. 2011)*.* Escalera et al. (2007) found toxigenic microalgae of the genera *Dinophysis* and *Pseudonitzschia* in red *Noctiluca* food vacuoles from the Galician Rías Baixas (NW Spain). Although this was the first report of ingestion of toxigenic microalgae of these 2 genera by *Noctiluca*, no information is available on its role as a transvector of toxins to higher levels of the food web. However, Frangópulos et al. (2011), showed that although red *Noctiluca* actively fed on the toxic dinoflagellate *Alexandrium mintum*, the fed cells showed no detectable amounts of toxin, suggesting that the toxin was either bioconverted or excreted by *Noctiluca.* In the case of green *Noctiluca*, a study by Azanza et al. (2010) also oberved bioconveration/excretion of toxin of *Pyrodinium sp.* by *Noctiluca* as well as a preference for less toxic species of food.

Being mixotrophic, the green *Noctiluca*, can survive even without an external food supply, because it can sustain itself either by feeding on its endosymbionts (Figure 2b) or their photosynthetic products although mechanisms for both are currently unclear. External food, however significantly enhances growth and there is some evidence of food preferences. This has been shown in our recent study (Gomes et al. 2018) with a strain of the green *Noctiluca* isolated from the Arabian Sea, which showed its distinct preference for the dinoflagellate *Kryptoperidinium foliaceum* and the pennate diatom *Phaeodactylum tricornutum*, but not the chlorophyte *Pyramimonas* sp., nor the chain forming diatom *Thalassiosira weissflogii*. Growth rates of *K. foliaceum* fed green *Noctiluca* were double of those for unfed *Noctiluca*. However, irrespective of the food provided, adequate light was required for green *Noctiluca* to grow as evidenced by its maximum growth rates of 0.3 day−1 when fed the preferred dinoflagellate *K. foliaceum* and exposed to optimal irradiance of 250  $\mu$ E m<sup>-2</sup> s<sup>-1</sup> versus growth rates of 0.13 day<sup>-1</sup> with the same food but at a low irradiance of 10  $\mu$ E m<sup>-2</sup> s<sup>-1</sup>. Similar growth rates were obtained by Hansen et al. (2004) for a strain isolated from Manila Bay where the preferred algae were two dinoflagellates, *Pyrodinium bahamense* and *Akashiwo sanguinea* growing at similar light intensities. The laboratory results of Gomes et al. (2018) are in agreement with those obtained for feeding experiments conducted during a winter *Noctiluca* bloom in the Arabian Sea to elucidate the interplay between the dependence of *Noctiluca* on its autotrophic endosymbionts and its facultative phagotrophy (Gomes et al. 2014). Growth rates were much lower in the dark even with addition of food as compared to the rates for cells grown in the light indicating the importance of autotrophic endosymbionts for growth. Even more interesting was the fact that growth rates in samples where light and nutrients were provided were comparable to those where light and food (but not nutrients) were provided. Growth rates did not increase when nutrients were added to flasks containing food and exposed to light, suggesting that when food is available, *Noctiluca* is capable of meeting a large fraction of its metabolic requirements via phagotrophy. Similar observations were made by (Sriwoon et al. 2008) who during four green *Noctiluca* bloom events in the Gulf of Thailand found a better correlation between the abundance of *Noctiluca* and the  $\langle 20 \mu m$  fraction of phytoplankton (food) than with nutrient concentrations.

One reason why green *Noctiluca* may not require extraneous nutrients is because it is known to accumulate ammonium and phosphate in its cells which the endosymbionts can utilize (Okaichi et al. 1991). Montani et al. (1998) found the intracellular concentrations of ammonium and phosphate in red *Noctiluca* to be  $26-67 \times 10^3$  and  $8.5-28 \times 10^3$  times higher respectively, than those in the extracellular environment while Okaichi et al. (1991) found lower concentrations of the same in green *Noctiluca*, which they attributed to uptake by the endosymbionts. Our measurements of the intracellular concentrations of  $NH<sub>4</sub>$ <sup>+</sup> show similar results with increases and then decreases over the course of the experiment due to uptake by endosymbionts when light levels were conducive for photosynthesis and growth (Gomes et al. 2018). In contrast, intracellular NH<sub>4</sub><sup>+</sup> concentrations for low light exposed cells were almost an order higher than those exposed to optimal light levels indicating that nutrient uptake by endosymbionts was lower when photosynthesis was light limited.

Another interesting result from our laboratory study using the Arabian Sea isolated strain of *Noctiluca* is that parameters of the Photosynthesis-Light (P-E) curves derived using variable fluorescence measurements against a gradient of light (Gorbunov and Falkowski 2004) did not show any statistically significant differences between fed and unfed cells (Gomes et al. 2018). These parameters and variable fluorescence in general are sensitive to

changes in nutrient and trace metal concentrations (Falkowski and Kolber 1995, Behrenfeld and Kolber 1999) and their invariance indicates that endosymbionts did not experience nutrient variations whether they were fed or not. Similar results were obtained by Saito et al. (2006) who performed P-E curves using oxygen as a measure of photosynthesis. The fact that our culture of *Noctiluca* can survive for several months without food or replenishment of nutrients reinforces the idea of tight nutrient recycling by green *Noctiluca*, that allows its endosymbionts to grow while also supporting its own growth. This is also well demonstrated in the study by Zhang et al. (2017b) which shows that the heterotrophic red *Noctiluca* strictly regulates its stoichiometry to allow it to survive when resources are scarce. Total cellular elemental ratios of this red *Noctiluca* strain were nearly homeostatic, although its intracellular pools of NH<sup>4</sup> <sup>+</sup>and PO<sup>4</sup> were weakly regulated. Similar studies are required for green *Noctiluca* because like some other mixotrophs it appears to have the potential to mitigate variable or skewed inorganic nutrient levels that autotrophs face by using phagotrophy and internal nutrient cycling (Flynn et al. 2018).

In addition to being a significant predator that can influence carbon flow in marine food webs, red *Noctiluca* is also an important agent of nutrients to the environment it lives in, regenerating and excreting large amounts of dissolved inorganic nutrients (i.e., NH<sub>4</sub>+ and PO<sub>4</sub><sup>3−</sup>) (Ara et al. 2013, Montani et al. 1998, Okaichi and Nishio 1976) and more complex organic substances (Zhang et al. 2017b). However, the study of Zhang et al. (2017) shows that both the internal dissolved pools and excretion rates of NH<sub>4</sub><sup>+</sup> and PO<sub>4</sub><sup>-</sup> of red *Noctiluca* depend on its nutritional status and growth rate. Thus, the algal prey type of *Noctiluca* should have important consequences for marine ecosystems that are impacted by its blooms (Zhang et al. 2017b). Similar nutrient enhancement from excretion by *Noctiluca* has not been observed by us during the large-scale blooms of green *Noctiluca* that we sampled for several years in the Arabian Sea (Gomes et al. 2008, Parab et al. 2006) and no clear information is available for coastal waters and enclosed systems (Al-Azri et al. 2007, Sriwoon et al. 2008).

# **5. REMOTE SENSING OF** *NOCTILUCA*

Recognizing that no other observational strategy can provide synoptic views of *Noctiluca* blooms with the spatial and temporal resolution required to better understand bloom dynamics and their expansion and proliferation, researchers have turned to satellite-based remote sensing. These methods involve the exploitation of optical properties of phytoplankton, such as absorption, scattering, and fluorescence excitation and emission spectra, to broadly separate *Noctiluca* from phytoplankton. One of the earliest attempts was by Balch and Haxo (1984) who compared the absorption spectra of the heterotrophic red *Noctiluca* from a bloom off the Scripps Pier in California with autotrophic dinoflagellates that served as its food. Although, the study showed that *Noctiluca* had a spectrum distinct from other dinoflagellates it was mostly from carotenoids from the *Lingulodinium* (*Gonyaulax) polyedrum* that it had ingested. Similar results were obtained by Astoreca et al. (2005) who found variable spectra related mostly to gut content and food availability. Using airborne hyperspectral images as well as *in situ* measured reflectance spectra and laboratory measurements of absorbance and reflectance from a thick and distinct *Noctiluca* bloom off the coast of Oostende, Belgium, Van Mol et al. (2007) were able to obtain spectra for *Noctiluca* distinct from phytoplankton

and non-algal particles. These spectra, which are highly reflective in the red and NIR wavelengths and have strong absorption in the blue-green wavelengths were exploited by Qi et al. (2019) who provided a proof-of-concept of the detection of red *Noctiluca* blooms using medium resolution MODIS and hyperspectral HICO data. Albeit with limitations cited in the paper, this optical signature allowed them to do a retrospective analysis of MODIS data from 2000-2017 over the East China Sea to reveal seasonal patterns and interannual changes as well as show an increase in red *Noctiluca* blooms possibly because of changes in nutrient stoichiometry caused by the construction of the Three Gorges Dam. Increased reflectance in the red and NIR wavelengths from dense blooms of *Noctiluca* was also exploited by Baliarsingh et al. (2017) guided by reports of *Noctiluca* blooms that had occurred in the Bay of Bengal (Baliarsingh et al. 2016, Mohanty et al. 2007, Gopakumar et al. 2009) and off the southwestern coast of India (Padmakumar et al. 2009, Sahayak et al. 2005).

Attempts have also been made to characterize green *Noctiluca* by taking advantage of the optical signature of the pigments of its endosymbiont *P. noctilucae.* One of the first attempts was by Thibodeau et al. (2014) who sampled the green *Noctiluca* bloom of 2011 in the northeastern Arabian Sea using a multichannel excitation chlorophyll *a* fluorescence (excitation at 440, 470 and 532nm and emission at 695nm) that was validated with microscopy, pigment composition, and spectral absorption. This effort provided them with a bio-optical proxy for the green *Noctiluca* based on the excitation and emission characteristics associated with pigment fluorescence. The fluorescence ratio proxy  $F_{532}$ : $F_{440}$  could distinguish *Noctiluca* from diatoms when the numerical dominance of the former was above 10% of the total population. This was confirmed by both cell counts and pigment analysis. This study, which uses optical proxies to discern phytoplankton groups, offers great promise for identifying and monitoring green *Noctiluca* cheaply and rapidly by placing fluorescence probes on remote platforms such as moorings, floats and gliders and is ideally suited for countries like Oman, Thailand, Vietnam and India, which experience repeated *Noctiluca* bloom outbreaks.

The first study to show the temporal progression and spatial breadth of the distribution of *Noctiluca* in the Arabian Sea from space was that of Werdell et al. (2014) wherein they parameterized an ocean reflectance inversion model (ORM) to identify green *Noctiluca* in a mixed phytoplankton community using satellite ocean color data records that were collected in the northern Arabian Sea. Simply put, an ORM provides a common method for inverting the "color" of the water observed by a satellite into the spectral absorption and scattering characteristics of ocean water and its dissolved and particulate constituents all of which are known as marine inherent optical properties (IOPs). The ORM used by Werdell et al. (2014) discriminated between *Noctiluca* and other phytoplankton by producing estimates of spectral absorption for these two algal groups which were validated using measurements of spectral reflectance and spectral absorption coefficients during the field campaign described in Thibodeau et al. (2014). The ORM robustly detected whether or not *Noctiluca* appeared in the simulated water column but the authors advised caution when interpreting the absolute magnitudes of the retrievals. Incorporating reflectance data at additional wavelengths improved the quality of the ORM retrievals, underscoring the benefit of forthcoming satellite missions such as NASA's hyperspectral 'Pre-Aerosol Cloud and Ocean Ecosystem (PACE) which has a spectroradiometer that spans the ultraviolet to shortwave infrared region at 5 nm resolution. Other commendable efforts include that of Dwivedi et al. (2015) who used *in situ* reflectance spectra from a hyperspectral radiometer for the bloom and non-bloom waters in

several field campaigns in the northeastern Arabian Sea from 2001 to 2012. Shapes of the reflectance spectra for *Noctiluca* dominated waters, diatom dominated waters and non-bloom oceanic and non-bloom coastal waters were distinctly different. This classification based on the reflectance spectra was then applied to MODIS-derived remote sensing reflectance images for several wavebands as input images and a color-coded classified output image was generated. The latter was successfully validated with microscopically derived *Noctiluca* and diatom counts. However, an application of this method in Lotliker et al. (2018), showed that green *Noctiluca* could only be reliably detected at abundances  $> 1.5 \times 10^3$ cells/L or approx. more than 50% of the total cells.

# **6. EMERGENCE AND EXPANSION OF** *NOCTILUCA* **BLOOMS**

While the earliest documentation of green *Noctiluca* in the coastal waters of the Arabian Sea dates back to the 1950s (Subrahmanyan 1954)*,* this early report showed it to be confined to episodic blooms in coastal waters and enclosed systems (Devassy and Sreekumaran Nair 1987, Eashwar et al. 2001). In the last decade and a half however, the northern Arabian Sea has witnessed a radical shift in the composition of winter phytoplankton blooms, with green *Noctiluca* emerging as the dominant bloom-forming organism every February through March with unprecedented regularity. Winter convective mixing; the primary mechanism for fertilizing the euphotic column of the northern Arabian Sea (Banse and English 2000) has been known to give rise to rich phytoplankton blooms that are dominated by diatoms. This was established by the British ARABESQUE study in 1994 (Tarran et al. 1999), the US JGOFS study from 1994 to 1996 (Garrison et al. 1998, Latasa and Bidigare 1998) and the Indian JGOFS effort (Sawant and Madhupratap 1996). None of these studies reported the presence of *Noctiluca* blooms either during the winter or summer monsoon. The study of Tarran et al. (1999) which forms part of the extensive JGOFS field campaigns in the Arabian Sea from 1990 to 1997 cites only diatoms as the dominant group of phytoplankton blooms fueled by nutrient inputs from winter convective mixing.

A large-scale, ongoing study conducted by the National Institute of Oceanography, India, from 2003 onward in support of India's ocean color program first documented the appearance of extensive blooms of green *Noctiluca* in late winter and early spring for several consecutive years (Gomes et al. 2008, 2009, Gomes et al. 2014, Goes et al. 2018, Goes and Gomes 2016, Dwivedi et al. 2012, 2015, Parab et al. 2006, Prakash et al. 2008, Madhu et al. 2012).

As mentioned in Section 2, a similar expansion of red *Noctiluca* has not been observed for the Arabian Sea and observations of its appearance suggest that it is confined to the coastal waters of western India especially in association with cold, hypoxic waters that upwell off the shelf (Joseph et al. 2008, Padmakumar et al. 2009, 2016, Shaju et al. 2018, Vijayalakshmy et al. 2018). Since its first appearance in in the Sea of Oman in 1999 (Thangaraja et al. 2007), dedicated sampling at two stations from 2005 onwards has shown the rapid increase in blooms of green *Noctiluca* both in the Sea of Oman (Figure 3a-b) and along the Arabian Sea coast of Oman, not only in early winter (November onwards) but in summer (July onward) as well, suggesting a likely temporal range expansion of these blooms (Al-Azri et al. 2007, 2012, Al-Hashmi et al. 2015, Gomes et al. 2008, 2009). Summer monsoonal *Noctiluca* blooms are however; largely confined to sheltered coastal embayments where the water column is relatively stable compared to offshore, indicating that stable a water column is essential for *Noctiluca*'s growth. In the Arabian Sea too, green *Noctiluca* blooms are seen in Feb-March advantaged by both the stable water column and mixed diatom blooms that arises in early January (Gomes et al. 2008, 2009) and on which this mixotroph can feed.

In our quest towards understanding why *Noctiluca* blooms recur and proliferate annually we have conducted detailed studies using the available information on the environmental conditions prior to, and during the onset of blooms. During the winter monsoons of 2003 and 2004, green *Noctiluca* blooms were seen north of 17<sup>o</sup>N in the eastern Arabian Sea, in waters that were under-saturated with respect to oxygen, nutrient rich, and cooler  $(<25^{\circ}C$ ) (Gomes et al. 2008, 2014). This was also the case in the Gulf of Oman, during the winter monsoonal seasons from 2004 to 2006 when *Noctiluca* were also observed in association with cooler, nutrient rich, oxygen poor waters. Episodic coastal *Noctiluca* blooms seen off the west coast of India in earlier studies have also been in a water column of low oxygen content and cooler water temperatures, although generally in the summer monsoon when upwelling conditions prevail along this coast (Devassy and Sreekumaran Nair 1987, Naqvi et al. 1998, Nayar et al. 2001, Sahayak et al. 2005, Shetye et al. 1990). Onboard experiments (Gomes et al. 2014) conducted by us while sampling the *Noctiluca* blooms of 2010 and 2011 in the northern Arabian Sea provided us the first evidence that green *Noctiluca* is predisposed to hypoxic waters and is able to fix  $CO_2$  more efficiently under hypoxic (~3.5 ml L<sup>-1</sup>) rather than in norm-oxic (~6.5 ml L<sup>-1</sup>) seawater (Gomes et al. 2014). In almost all the shipboard experiments, CO<sup>2</sup> fixation rates of the mixotrophic *Noctiluca* cells were consistently higher over ambient  $O_2$  controls. In contrast, diatoms and other phytoplankton showed a  $>50\%$ decrease in CO<sup>2</sup> fixation rates under low O2. While it appears that green *Noctiluca* is predisposed to hypoxic waters, we do not know whether *Noctiluca* is capable of modulating its intracellular environment in order to maximize photosynthetic rates by its endosymbionts.

In Gomes et al. (2014), we posited that the advent of green *Noctiluca* blooms may be tied to a recent decrease in dissolved  $O_2$  content of the upper water column of the Arabian Sea. Oxygen deficiency in the northeastern Arabian Sea is a unique mid-depth (>120–1,500 m) feature formed by the combined influences of monsoon-driven high surface productivity of the semi-annual phytoplankton blooms, sub- thermocline source waters that have naturally low dissolved  $O_2$  content flowing from the Southern Ocean and poor ventilation of subsurface waters in the landlocked north (Morrison et al. 1999). While there are no known physical mechanisms to explain the appearance of  $O<sub>2</sub>$  deficient waters above 40m in the offshore region in winter, there is the possibility that the Arabian Sea's permanent oxygen minimum zone (OMZ) is expanding horizontally and vertically because of increased organic matter delivery to deeper depths (Gomes et al. 2014). Two possible sources of enhanced organic matter could be: 1) enhanced phytoplankton blooms in summer due to enhanced the land–sea pressure gradient, a consequence of the warming of the Eurasian continent and the systematic decrease in spring snow persistence over large parts of southwest Asia and the Himalayan– Tibetan Plateau region. This in turn has strengthened southwest monsoonal winds resulting in intensified wind-driven coastal upwelling favoring more intense phytoplankton blooms and greater export of carbon to depths (Goes et al. 2005)*;* 2) Domestic and industrial outfall from megacities bordering the Arabian Sea where waste water treatment plants have not kept pace with rapid population growth and urbanization of coastal cities (Al-Said et al. 2018, Gomes et al. 2014, Chaghtai and Saifullah 2006, Dhage et al. 2006). It is probable that *Noctiluca* not only proliferates in low-oxygen waters but also exacerbates low oxygen conditions further by creating particulate and dissolved organic matter that decomposes through bacterial activity and utilizes oxygen in the process.

A more recent study (Lotliker et al. 2018) refutes the premise that *Noctiluca* blooms are tied to the vertical expansion of the OMZ, driven by cultural eutrophication from major coastal cities in western India. Their conclusions are however not backed up by experimental data of the type conducted in Gomes et al. (2014). They also cite data from oxygen sensors on BGC-ARGO from Feb 2013 to April 2016 to show that, regardless of the presence of a *Noctiluca* bloom, the dissolved oxygen in the photic zone was always >70% saturated, with an average oxygen saturation >90%. However, close inspection of the data shows that the ARGO floats were located south of the locations where Gomes et al. (2014) undertook their studies. Sensor calibration is also a contentious issue and Lotliker et al. (2018) provided only six calibration points for a dataset that spanned from Feb 2013 to April 2016. Additionally, they also provided dissolved oxygen concentrations for five cruises conducted in Feb.-Mar of 2009 and 2009 and measured by Winkler's titrimetric method, two of which were coincident with those in Gomes et al. (2014). These data too did not show the percentage saturation of oxygen approaching hypoxia observed by Gomes et al. (2014). Dissolved oxygen values in the latter study, however, were measured using Winkler method and the high-precision amperometric end-point of Langdon (2010) as opposed to titration employed in (Lotliker et al. 2018). Focused studies with data from sensors that have been accurately and repeatedly calibrated on ARGO floats in the northern Arabian Sea should provide more clarity on the disparate conclusions in the two studies. Another hypothesis for the sudden emergence of green *Noctluca* blooms is from Sarma et al. (2019) who attribute it to the deepening of the oxygen minimum zone (OMZ) and associated silicate limitation in the Arabian Sea during the winter monsoon. Shifts from diatoms to non-siliceous phytoplankton have been observed in several estuarine and coastal regions especially (Ittekkot et al. 2000), but there are no reports the appearance of *Noctiluca* when silicate is limiting. Additionally, the Sea of Oman (Emara 2010, Al-Azri et al. 2010), the coastal and open Gulf of Thailand (Sriwoon et al. 2008) and the coastal waters of Vietnam (Rochelle-Newall et al. 2011) where *Noctiluca* blooms have become common, are not silicate limited.

A comparison of the rise in green *Noctiluca* blooms in the Arabian Sea and the Gulf of Thailand by Goes et al. (2018) suggests some similarities although the latter is much smaller and very shallow. Both are monsoonal driven systems, with *Noctiluca* blooms seen in the upper Gulf of Thailand during the summer upwelling season and in the western half of the Gulf, where there is upward shoaling of nutrient rich, subsurface hypoxic nutrient-rich waters. However, because of the prevailing direction of flow of the currents, which is clockwise along the northern coastline, *Noctiluca* blooms accumulate downstream in the eastern half of the Gulf of Thailand where they are advantaged from a huge influx of nitrogenous nutrients from land runoff during the rainy season and the associated phytoplankton that serves as food. During the winter monsoon, currents reverse their direction and *Noctiluca* begins to accumulate in the western half of the upper Gulf of Thailand. Although winter *Noctiluca* blooms are smaller and sparser at this time of the year, they are still sustained by excess nutrients and consequently the plentiful prey phytoplankton throughout the water column (Goes et al. 2018). Increased frequency of intense *Noctiluca* blooms witnessed in recent years in the Gulf of Thailand, has been ascribed to excessive N-nutrient influxes from agricultural lands, urban waste water treatment plants, as well as shrimp farms located along the coast

(Cheevaporn and Menasveta 2003). However, Oman, which presently experiences the worst outbreaks of *Noctiluca* blooms (Figure 3a-b), has no long history of nitrogenous fertilizer use, and blooms are most intense and extensive during winter, a period when land runoff is low. In this case, the most likely N-nutrient-rich source could be from deeper depths, when cyclonic eddies that typically begin to populate the coast of Oman around the beginning of the winter monsoon season bring subsurface low-oxygen, nutrient-rich waters into the euphotic zone (Goes et al. 2018). This is based on earlier studies (Gomes et al. 2009, Harrison et al. 2017) using satellite altimetry data which suggested a strong coupling between green *Noctiluca* blooms and mesoscale cold-core eddies in this region. We are uncertain as to whether enhanced N nutrients promote growth simply through uptake and/or provide a large population of phytoplankton prey. A preliminary experiment with our Arabian Sea green *Noctiluca* isolate, with no supply of prey but optimal light conditions compared its growth rates in the presence of  $NO_3$ ,  $NH_4$ <sup>+</sup>, and urea (Goes et al. 2018). The results revealed that urea, a common ingredient in commercially available fertilizers, is the most preferred N source with cells grown in urea exhibiting the largest size  $(>1000 \mu m)$ , the largest population of endosymbionts (measured as the concentration of pigment chlorophyll *a*) and highest photosynthetic competency (see Figure 17.3 in Goes et al. 2018).

Similar uncertainties also arise in ascribing a single causative factor to the emergence of red *Noctiluca.* In their review of the geographic distribution of red and green *Noctiluca,* (Harrison et al. 2011) also attempt to include some of the environmental features that lead to *Noctiluca* blooms. This included the recurring blooms of red *Noctiluca* covering much of the Adriatic from 1980 (Fonda-Umani et al. 2004) which decreased sharply when phosphorus in detergents was banned in 1988. This caused a shift to a mucilaginous phenomenon with low *Noctiluca* abundance (Degobbis et al. 1995) but since 1997, *Noctiluca* blooms have reappeared with highest abundances in areas near the Po River where plankton productivity and stratification are high (Fonda-Umani et al. 2004). Severe eutrophication has been linked to explosive development of *Noctiluca* in western Black Sea (Porumb 1992), while outbreaks in the Seto Inland Sea of Japan (Tada et al. 2004) and the Sagami Bay, near Tokyo (Baek et al. 2009) are more complex and depend on the water column stability, wind direction and rainfall.

Increasing incidents of the expansion of *Noctiluca* are now being reported elsewhere across the global oceans. Australia has seen the expansion of red *Noctiluca* along its entire coast from a rare bloom former in the 1980s, to one of the most prominent red-tide organisms in Sydney coastal waters, starting in 1993 (Hallegraeff et al. 2008) when 3 deep water ocean sewage outfalls were commissioned. This was followed by its appearance in March, 1994, in Tasmania when it was carried by the East Australian Current and it has persisted ever since by establishing permanent overwintering populations that thrive even in the winter months in colder Tasmanian waters of 10-12°C. Hallegraeff et al. (2008) speculate that the gradual warming of East Coast Tasmanian waters (up  $1.6^{\circ}$ C in the past 50 years and thrice the global average warming), associated with a greater influence of the East Australian Current (Ridgway and Dunn 2007), has paved the way for the apparent range extension of this warmwater dinoflagellate into Tasmanian waters. Of concern now is the recent report of its expansion into the Southern Ocean with a warm-core eddy moving southwards from Tasmania as the potential vector for its transport (McLeod et al. 2012).

# **7. SOCIOECONOMIC EFFECTS FROM BLOOMS OF** *NOCTILUCA*

Although *Noctiluca* blooms are not known to be toxic, adverse effects on fisheries, aquaculture, human health and the coastal environment have been reported globally. In countries like Oman, where *Noctiluca* blooms are being seen throughout the year, effects are felt far beyond fisheries, and extend to tourism and recreation; aquaculture, oil refineries, ship repair, and a host of other coastal industries, including desalination plants threatening the supply of freshwater to major cities of Oman. The report by the Ministry of Fisheries, Oman (Thangaraja et al. 2007) cites several cases of fish mortality due to *Noctiluca* blooms starting from 1988. Toxicity appears to be primarily from the large amount of ammonia that it accumulates in its cells (Okaichi and Nishio 1976). Six incidences of fish mortality were reported from 1976-2001. Dissolved oxygen was depleted which increased the severity of fish kills, and in 1988 bacterial infection caused 'fin and tail rot' disease. Thangaraja et al. (2007) also noted that planktonic fish eggs collected from red *Noctiluca* bloom locations off the coast of Oman were also infected killing growing embryos before they hatched and possibly affecting forthcoming recruitments. There are reports (Chen et al. 2014) of red tides of *Noctiluca* causing heavy mortality of cultured prawn in the Northern China Sea in 1989-1990 and more recently in the summer of 2019 in the South China Sea with estimated losses win excess of US\$ 100 million. The authors also found that the intensity and distribution range of *Noctiluca* have expanded from year to year, with a ten times increase from 1959 to 1993. A large bloom in March 2002 posed a significant threat to the salmonid aquaculture industry in Nubeena on the Tasman Peninsula (Hallegraeff et al. 2008). Instances of fish kill associated with the appearance of red *Noctiluca*, off the west coast of India and in association with summer monsoonal upwelling have been reported with a strong stench of ammonia, possibly causing the death of fish (Naqvi et al. 1998, Padmakumar et al. 2009). In this region, Padmakumar et al. (2009) observed that *Noctiluca* competes for food with the oil sardine (*Sardinella longiceps*) as both feed on diatoms like *Coscinodiscus*, *Nitzschia, Fragilaria* and *Thalassiosira* etc and this is now reflecting in the decreased oil sardine catch from this area. Although *Noctiluca* are nontoxic, thick blooms in the upper Gulf of Thailand often exacerbate oxygen loss and also cause the massive accumulation of NH4<sup>+</sup> in water column, both of which have been blamed for massive fish kills that follow (Wattayakorn 2006).

With their polyphagous feeding behavior, both red and green *Noctiluca* could severely affect and impair the food chain by competing with other grazers, such as copepods that are reliant on the same food source. It can replace copepods as primary grazers of phytoplankton. In the Bay of Biscay, blooms of the red *Noctiluca* have shown to exert heavy predation pressure on eggs of the copepod *Acartia clausi* (Cabal et al. 2008, Quevedo et al. 1999) while in the Sea of Marmara which connects the Mediterranean and the Black Sea, it plays an important role in the top-down control of the zooplankton community (Harrison et al., 2011). While some work suggests that *Noctiluca* can serve as a "biocontrol" by grazing on toxic algal blooms such as *Gymnodinium catenatum* (Rodrıguez et al. 2006) or the cysts of the genus *Alexandrium* (Drits et al. 2013)*,* other work suggests that it might act as a vector of phycotoxins to higher trophic levels or transport it to natural shellfish beds (Escalera et al. 2007) as described earlier.

Although *Noctiluca*'s large size, its bioluminescence and intracellular ammonia concentrations preclude it from being grazed by large zooplankton (Yılmaz et al. 2005), it appears that jellyfish and salps find *Noctiluca* highly palatable. These gelatinous, tubular zooplankton, distributed widely in the world ocean, are known to be highly efficient filter feeders exploiting particles over a wide size range, from bacteria to large diatoms and microzooplankton. This coupled with their rapid growth in suboxic waters, and unusual life history with alternation of asexual and sexual reproduction, enable them to form extensive swarms with hundreds of specimens per cubic meter (Batistić et al. 2018, Stone and Steinberg 2016). We have observed large jellyfish and salp populations associated with *Noctiluca* blooms during our field campaigns and we have conducted preliminary grazing experiments on board which estimated clearance rates of 200 to 800 ml per hour for the salp *Pegea confoederata*, suggesting that high concentrations of salps (up to hundreds of zooids per m*<sup>2</sup>* ) could rapidly consume dense aggregations of *Noctiluca*. Using pigments as a measure of food consumed in the first 3 h, we observed that a single salp can remove on average 71% of chl *a* and 78% of chl *b* from seawater that is dominated by *Noctiluca* with the deposition of large pellets (Gomes et al. 2014). A more recent study (Thomas et al. in press) shows the appearance of gelatinous zooplankton swarms during and after *Noctiluca* bloom events along eastern Arabian Sea with increased frequency of both events during the period from 2010 to 2017. Their feeding experiments with jellyfish and salps also showed rapid ingestion of *Noctiluca* although ingestion rates are not provided.

Although *Noctiluca* may not appear to contribute significantly to particulate organic carbon export, judging from the absence of any cells in shallow water sediment traps deployed during our cruises (Gomes et al. 2014), their contribution to carbon flux could be significant though the export of large, fast sinking salp pellets (Smith et al. 2014)*,* found in floating particle intereceptor traps deployed by us during our Arabian Sea cruise of 2009 and 2010. Salps have also been found in association with high abundance of *Noctiluca* in the Adriatic Sea (Batistić et al. 2018) and in the coastal waters of Dubai (Murugesan et al. 2017). Although, not much is known of other predators of *Noctiluca* because its fragile nature does not allow it to persist in gut contents, its vegetative cells are grazed by large copepods (Petipa 1960), crab larvae (Lehto et al. 1998) and progametes are consumed by ciliates (Zhang et al. 2017a).

## **CONCLUSION**

Findings from recent research synthesized in this review, provide an overview of the apparent expansion of both red and green *Noctiluca* and how anthropogenic activities may be contributing towards their recurrence and expansion. In a bid to gain a better understanding of the anthropogenic and climate-driven factors that have caused drastic changes in the biodiversity of winter blooms of the Arabian Sea and to circumvent the problems of piracy which hinders large, long-term multidisciplinary shipboard studies, our recent study (Yan et al. 2019) uses machine learning to investigate the onset and patterns of the *Noctiluca* blooms. In this study, a robust learning algorithm was developed, that uses sequences of ocean color remotely sensed data and drifter array data to understand the local-scale impact of the physico-chemical and physical oceanographic factors that contribute to green *Noctiluca* blooms that form in the Sea of Oman and along the Arabian Sea coast of Oman and their dispersal eastwards into the central and eastern Arabian Sea. It is suggested that the

mixotrophic green *Noctiluca* may be advantaged in a warming world where the upper layers of the ocean are experiencing diminishing nutrients from increased stratification and a weakened convective mixing (Gomes et al. 2014), a process that fertilizes the euphotic column during the winter monsoon of the Arabian Sea. We now seek to unravel the green *Noctiluca*'s flexible nutrient acquisition using a range of tools including implanting novel optical microchips inside the cells, to better understand how the mixotrophic mode of nutrition may play a significant role in *Noctiluca*'s ability to grow and establish itself as the dominant bloom forming organism even when the mixed layer stratifies and nutrients are limiting. In order to more rigorously test our earlier findings (Gomes et al. 2014) that the green *Noctiluca* can thrive under low O<sub>2</sub> conditions we plan to conduct studies that assess the transcriptome level response of the endosymbiont to hypoxic conditions. In other words, in order to ascertain whether the photosynthetic response of *Noctiluca* cells to different  $O<sub>2</sub>$ concentrations occurs at the genetic level we plan to identify the significantly expressed genes associated with photosynthesis and tolerance to hypoxia in *Noctiluca* bearing endosymbionts and exposed to different  $O_2$  concentrations.

Another line of research that we are initiating is the identification of sterols and alkenones of green *Noctiluca* that are known to preserve well in sediment samples, and their use as paleo biomarkers (Sonja Schulte et al., 1999) of past *Noctiluca* blooms which may have coincided with wholesale fluctuations in productivity and expansion of mid-water oxygen depletion (from fully aerobic to anoxic) in the Arabian Sea as observed by Reichart et al. (1998); Schulz et al. (1998). In the case of red *Noctiluca*, researchers at the Guangdong Ocean University, China (Xie et al. 2015) recently launched three-dimensional observations from the air, onboard and from land to understand the horizontal and vertical distribution as well as environmental conditions that led to a large red *Noctiluca* bloom along the Guangdong coast and to possibly use the information in future modelling efforts.

### **PUTTING IT ALL TOGETHER: THE ARABIAN GULF DINOFLAGELLATES**

*D. V. Subba Rao\* and Ravi V. Durvasula*

Department of Medicine, Loyola University Medical Center, Maywood, Chicago, Illinois, US

### **ABSTRACT**

The Persian Gulf, a small hyper-saline semi-arid almost enclosed sea, is unique. The Gulf is subtropical, approximately 1000 km long, 200-300km wide; with a mean depth of 35 m. Indian Ocean Surface Water (IOSW) and water from the Gulf of Oman enter the Gulf via the Hormuz Strait during spring. Natural environmental stresses include the input of eolian dust, and the discharge from Tigris, Euphrates and Karun rivers. About 20,000 ships visit the Gulf annually for oil transportation also contribute pollutants. The Strait of Hormuz acts as a chokepoint for introduction of biota into the Gulf. Historical data showed an increase in the dinoflagellate xenobiodiversity with 509 species attributed to the incursion of the Central Indian Ocean Water (IOSW) and discharge of ballast water from ships' traffic. Dinoflagellate diversity is rich in the Hormuz-Oman waters and decreased towards the north, which coincides with the decreasing volume and dilution of Hormuz-Oman waters. Anthropogenic activities such as the discharge of effluents from slaughter houses, dairy plants, and brine from over 50 desalination plants, sewage wastewater, mariculture operations result in eutrophication of the Gulf. The prevailing high temperatures and high salinities probably limit the establishment and survival of many exotic dinoflagellates. There are 28 potentially bloom forming harmful species in the Gulf. Implementation of a long-term regional ecosystem-based "de-eutrophication strategy" is recommended to prevent further decline of this unique environment.

**Keywords:** semi arid waters, hypersaline, xenbobiodiversity, desalination plants, pollutants, de-eutrophication

#### **INTRODUCTION**

The Persian Gulf (hereafter called the Gulf), is a small, nearly enclosed hyper-saline semi-arid sea. The Gulf is subtropical and measures approximately 1000 km long, 200-300km wide, with a mean depth of 35 m. About 20,000 ships visit the Gulf annually for oil transportation. Absence of seasons, lack of monsoons and classical upwelling characterize this body of water. The Gulf is referred to as the Regional Organization for Protection of the Marine Environment (ROPME). Based on the circulation pattern ROPME comprises of 4 regions: 1. The Northern Gulf (NAG) 2. Central region (Qatar to United Arab Emirates) 3. Iran 4. Strait of Hormuz –Gulf of Oman. From the northern part of Hormuz Strait, 0.23 Sv (Sverdrup =  $0.001 \text{km}^3 \text{ s}^{-1}$ ) of Indian Ocean Surface Water (IOSW) enters the Gulf during spring (Swift and Bower 2003) and skirts partly along the eastern Gulf (Iranian Coast) and forms an anticlockwise circulation front (Figure 1, Reynolds 1993) with 3 branches (Johns et al. 2003). In the central part, one of its branches (off Qatar) feeds a 0.21 Sv outflow through the southern part of the strait (Johns et al. 2003). The NAG region remains relatively stagnant.

With a total volume of approximately  $8,600 \text{ km}^3$ , the Gulf experiences several natural environmental stresses, including little precipitation  $(<100$  mm  $y<sup>-1</sup>$ ), discharge from Tigris, Euphrates and Karun rivers (35-133 km<sup>3</sup> y<sup>-1</sup>), 62.4 x 10<sup>6</sup> tons sediment y<sup>-1</sup>, and input of 60- $200 \times 10^6$  tons y<sup>-1</sup> eolian dust (Sheppard et al. 2010). Satellite observations have shown that eolian dust fertilizes the Gulf waters (Nezlin et al. 2010); in outdoor enrichment experiments conducted during summer, enrichment of trace elements via eolian dust sustained bloom levels (527 μg chlorophyll a l<sup>-1</sup>) of phytoplankton (Subba Rao et al. 1999). The Iranian region experienced 156 dust storms since 2001, with a maximum of 9.36 mg  $m<sup>3</sup>$  (Rbbaniha et al. 2013). Also, anthropogenic activities contribute  $160 \times 10^6$  t y<sup>-1</sup> of oil The Strait of Hormuz acts as a chokepoint for introduction of dinoflagellates into the Gulf. spillage, effluents from slaughter houses and dairy plants,  $0.023 \times 10^6$  km<sup>3</sup> d<sup>-1</sup> wastewater and  $0.003 \times 10^6$  km<sup>3</sup> d<sup>-1</sup> sanitary waste water. Mariculture operations result in eutrophication of the environment. The present total seawater desalination in the Gulf is  $5000 \times 10^6$  m<sup>3</sup> and to augment future needs is expected to increase by about  $9000 \times 10^6$  m<sup>3</sup> in 2013 (Dawoud and Al Mulla 2012).

Light and nutrient levels do not seem to limit microalgal growth in the Gulf. Nutrient levels (μM) in the Gulf are on the increase; values for 1985-1998 are from Subba Rao and Al-Yamani (2000) and for 2000-2012 from Al-Said et al. 2017). In the offshore waters of Kuwait, nitrate levels ranged from 0.00-1.54 (1985-1993), 0.00-8.40 (1994-1998) and traces-32.79 (2000-2012). Corresponding phosphate vales were 0.00-0.30 (1985-1993), 0.00-2.1 (1994-1998) and traces -5.91 (2000-2012). Silicates were 0.11-11.60 (1985-1993), 0.84-17.77 (1994-1998) and 0.05-33.0 (2000-2012). Dissolved trace metals (nM) that sustain microalgal growth are also high: Fe 0.67-3.08, Cu 10.58-23.25, Ni 15.63-23.35, Co 0.53-1.03, Zn 6.32- 25.33 (Al-Said et al. 2017b). A scaled critical depth model for Kuwait Bay based on the incident radiation, depth of mixed layer and scaled mixed layer showed availability of 83-275 W m<sup>-2</sup> light near the bottom which is sufficient for microalgal growth (Subba Rao and Al-Yamani (1999).

Coupled with a severe decline in the freshwater runoff from the North, discharges of brine from over 50 desalination plants resulted in an increase in salinity (Al-Said et al., 2017) leading to shifts in functional groups of the plankton community.

Figure 1. Conceptual circulation in the Arabian Gulf based on Reynolds (1993) and Johns et al. 2003). Inflow from IOSW is indicated in dark and the outflow from the Gulf in dashed line.

In the Gulf, long-term institutionalized phytoplankton studies are absent. Phytoplankton studies in the Gulf are reviewed (Subba Rao and Al-Faiza 1998, and Dorgham 2013). Dorgham (2013) listed 74 publications on phytoplankton studies mostly derived from onetime collections using 30-55 μm plankton nets. Thus, serious gaps exist due to sampling bias such as inadequacy in the spatial and temporal coverage of sampling sites and loss of biota. However, *massive* algal blooms  $(2906.75 - 4525.47 \text{ µg Chl } a l^{-1})$ , dominated by diatoms and dinoflagellates were reported off Kuwait (Subba Rao et al. 2003).

Data gathered from various publications showed an increase in the abundance of dinoflagellate species in the Gulf (Subba Rao and Al-Yamani, 2000). Red tide episodes off Kuwait are frequent, ephemeral, massive (Subba Rao et al. 1999) and potentially harmful (Heil et al. 2001, Glibert et al. 2002, Al-Yamani et al. 2012). This review assembles the scattered observations on dinoflagellates in the Gulf from various journals. Shortcomings in the data suggest the need for research for a better understanding of the toxigenic harmful dinoflagellate blooms in the Gulf. Recommendations are made to better understand the structure and physiology of dinoflagellates thriving under unique conditions of high temperature and high salinity prevailing in the Gulf.

#### **DINOFLAGELLATE DISTRIBUTION**

A south to north gradient in the distribution of phytoplankton exists in the Gulf (Subba Rao and Al-Yamani, 1998). A maximum diversity of 509 dinoflagellate species exists in the Gulf of Oman and Straits of Hormuz (Dorgham and Moftah 1989). Diversity decreased to 148 species off Kuwait (Subba Rao and Faiza, 1998) and further to 116 species in the Shatt Al-Arab (Hadi et al. 1984).

Table 1. Occurrence (P) of dinoflagellate species in the Arabian Gulf **Table 1. Occurrence (P) of dinoflagellate species in the Arabian Gulf**

Historical analyses of dinoflagellate populations in the Gulf are limited and based on net collections; thus they underestimate breadth of species. Net collections from the Iranian coast (Bohm 1931) and Al-Harbi (2005) from the ROPME area yielded 45 species in each area. Net samples (55 μm net) from Iranian –Oman Sea contained 100 species (Saraji et al. 2014) and 108 species from the Hormuz Strait (Darki and Karkmahmalnyi 2017). However, water samples off Qatar contained 143 species (Dorgham and Moftah 1986), 106 species off Oman (Dorgham and Moftah 1989) and 102 dinoflagellate species off Kuwait, (Al-Kandari et al. 2009). When the analyses were extended to water samples collected from 2004 to 2017, 203 species were reported off Kuwait (Al-Yamani and Saburova 2019), underscoring the need for extended observations. In the Gulf, a high diversity of dinoflagellates- 509 species- exists (Table 1) and this could increase with enhanced sampling from sub-surface depths, throughout the year and over several years.

The waters between Hormuz and Oman represent a staging area for a mix of Gulf water with the incoming Indian Ocean Surface Water (IOSW) from the Gulf of Oman through the Straits of Hormuz, and an admixture of deeper water flow from Oman (Figure 1). Hormuz and Oman waters contain 198 dinoflagellate species (92 species off Hormuz and 106 off Oman) (Dorgham and Moftah 1989, Table 1). Compared to the total Gulf volume (~8,600 km<sup>3</sup>), exchange of waters from the Western Indian Ocean (WIO) is high (7253 km<sup>3</sup> y-1) via the northern part of Hormuz Strait that flow into the Gulf (Johns et al. 2003 ). It is reasonable to assume that the Hormuz-Oman region serves as an exchange point for a number of dinoflagellates in the Gulf.

Utilizing 198 species of Hormuz-Oman area as a base, their contribution to Oman was 53%, Qatar 41%, UAE 38%, Kuwait 32%, Saudi Arabia 17% and Iran 8%. This pattern of distribution i.e., decreases of number of species from south to north is consistent with the decreasing volume and dilution of Hormuz-Oman waters as they flow into the Gulf. Observations of Thorrington-Smith (1971) corroborate this conclusion; components of the Western Indian Ocean (WIO) decreased from south to north. The number of such WIO dinoflagellate species in the Gulf of Oman was 61 (Dorghan and Moftah 1989), 17 in the Gulf in general, 12 off Qatar and 7 in Kuwait waters. North of Bushehr, Iran, probably due to lesser exchange with the open ocean, the number of species common to their southern waters is further reduced (Hulburt et al. 1981).

Based on samples collected during September 1986, Dorgham and Moftah (1989) recognized 6 patterns in the distribution of dinoflagellates: group 1. represents species common to the Gulf and the Gulf of Oman, 2. Species mainly found in the Gulf but extended to the straits of Hormuz and even to the Gulf of Oman, 3. Species restricted to the Gulf, 4. Species limited to Straits of Hormuz, 5. Species observed in the Gulf of Oman and in the Straits of Hormuz, and 6. Species restricted to the Gulf of Oman. Notably, sampling methods differed across the seasons. Analyses of Al-Kandari et al. (2009) off Kuwait (Table 1) are annual and based on whole water samples while those of Al-Harbi (2005) in ROPME area, and Darki and Karkmahmalnyi (2017) in Hormuz are net samples (35-55  $\mu$ m). Thus, the spatial and temporal coverage of data do not permit a true comparison.

#### **DISTRIBUTION LIMITATIONS**

There were 55 dinoflagellate species present in the Gulf with no limitation to any region: *Ceratium arietinum, C. biceps, C. breve, C. breve* var *parallelum, C. deflexum, C. dens, C. falctum, C. furca, C. furca eugrammum, C. fusus, C. fusus var seta, C. humile, C. lineatum, C. macroceros, C. masseliense, C. masseliense* var *armatum, C. massliense* var *protruberans, C. minutum, C. trichoceros, C. tripos, C. tripos* var *atlanticum, D. caudata, D. miles, Exuviella compressa, Gonyaulax danicum, G. diegensis, G. digitale, G. minuta, G. monocantha, G. polyedra, G. polygramma, Histioneis vouckii, Ornithocercus thurnii, P. rotundatum P. palmipes, Pronoctiluca pelagica, P. micans, Protoperdinium conicum, P. crassipes, P. depressum, P. diabolus, P. divergens, P. globule, P. grande, P. granii, P. oceanicum, P. ovum,, P. ovatum, P. pellucidum, P. pentagomum, Pyrophacus horologicum, P. stenii, P. fusiformis, P. obtusa, Triadinium sphaericum,* and *T. polyedricum.*

As data on the Gulf dinoflagellates are scanty, many detailed studies will have to be carried out, which may necessitate revision of the present interpretation of the pattern of spatial and temporal distribution. The number of species exclusively present in Oman, Qatar, Saudi Arabia, UAE, Kuwait and Iran correspond to 24, 1, 1, 0, 119 and 11, respectively (Table 2). Analyses of more samples collected in Kuwait region during 2004 to 2017 emphasized the need for extended studies; they also account for the larger number of species (119 species) in Kuwait waters compared to other regions of the Gulf with limited sampling. Of interest is the dominance of Gymnodinians, *Peridinium* and *Protoperidinium* species in Kuwait waters. Parasitic dinoflagellate *Euduboscquella* sp. is recorded from the lorica of the tintinnid *Eutintinnus* sp. (Al-Yamani and Suburova, 2019).

### **XENOBIODIVERSITY AND PLAUSIBLE BALLAST WATER INTRODUCTIONS**

Ecosystems of young enclosed brackish water seas such as the Caspian and Aral Sea have lower biological diversity, but major changes in structure and functioning do occur due to increased "foreign" or xenobiodiversity biological diversity (Leppäkoski and Olenin, 2000). A young Sea - the Arabian Gulf (Sheppard et al. 2010) - fits into this category. In this shallow Gulf, the diversity is ever changing due to increased anthropogenic stresses such as discharge of ballast waters from 20,000 ships that visit annually, dumping of sewage in the coastal waters and discharge of brine from the desalination plants that act synergistically; this is exacerbated by the Gulf's small size and slow circulation. The inadvertent introduction of alien biota via ballast water is sizeable. The Strait of Hormuz serves as a chokepoint for oil tankers that transport, in an opposite direction more than 17 million barrels of water from different regions of the world to the ROPME area every day. Introduction of non-indigenous species to the inner ROPME area and UAE and the Iranian waters is known (Hamza 2006, Jalili et al. 2008, Al-Yamani et al. 2015). The warm ROPME Sea Area receives a greater volume of ballast water discharges from crude oil tankers than any other area in the world, and is characterized as a high-risk area (Al-Yamani et al. 2015). The warm well-illuminated waters with high levels of nitrates and phosphates are conducive for the growth of *Gymnodinium* sp*.* (Heil et al. 2001), *Gymnodinium catenatum*, *Gyrodinium impudicum*, and *Pyrodinium bahamense* var. *compressum* (Glibert et al. 2002).

### **Table 2. Species restricted in distribution**

<b>Species</b>	Occurrence in the Gulf	Earlier records outside the Gulf	Reference	
Achradina pulchra	Frequent	Atlantic, Pacific, Black Sea	<b>Nival 1969</b> Konovalova 1998	
Akashiwo sanguinea	Rare	Japan, New Zealand, Atlantic, Pacific	Hallegraeff 1991 Keifer and - Lasker 1975 Bockstahler and Coats 1993, Voltolina 1993	
Corythodinium tesselatum	Rare	Atlantic	Wood 1968, Dodge 1985, Balech 1988	
Gymnodinium catenatum	Freq	N. American waters, European, Australian and Japanese waters	Morey-Gaines 1982, Mee et al. 1986, Hallegraeff et al. 1995, Estrada et al. 1984	
Peridinium quinquecorne	very rare	Japan, Malaysia, Philippines, S. Africa, Australia, Belige	Horiguchi and Pienaar 1991, Faust et al. 2005, Mohammad-Noor et al.2007	
Pyrodinium bahamense var. compressa	Rare	Tropical Atlantic, Indian Ocean. Red Sea, Brunei, Philippines, New Guinea, Oman, Hormuz	Dodge 1985 Hallegraeff et al. 1995	
Sinophysis ebriolum	very rare	North German, Japan, Russia	Selina and Hoppenrath 2004, Hoppenrath 2000	

**Table 3. Exotic species possibly introduced into the Arabian Gulf and the Sea of Oman**

Data (1987 to 2019) based on analyses of water samples show an increase in the dinoflagellate populations off Kuwait from 39 species (Dorgham et al. 1987) to 108 (Al-Kandari et al. (2009) to 203 (Al-Yamani and Suburova 2019). This increase in the dinoflagellate diversity (119 to 203) in Kuwait waters (Table 2) suggests their possible introduction by ships visiting Kuwait from various geographic regions. It is possible that every species that could have been introduced has been introduced into the Gulf, evident from new records. Earlier it was suggested that the Strait of Hormuz acts as a chokepoint for ~20,000 ships that visit the Gulf annually. Occurrence of *Achradiona pulchr, Akashiwo sanguine, Corythodinium tesselatum, Gymnodinium catenatum, Peridinium quinquecorne, Pyrodinium bahamense var compressa* and *Sinophysis ebriolum* for the first time from the Gulf suggests their possible introduction from Malaysia, Brunei, Philippines, New Guinea, Japanese waters, Australia, Belige, Russia, and S. African seas by shipping traffic, similar to the occurrence of Indo-Pacific dinoflagellates in the Mediterranean (Gómez 2006). It is possible that the prevailing high temperatures and salinities in the Gulf may restrain the growth of potentially harmful and bloom forming species or the establishment of species introduced via shipping.

According to the "window of introduction theory" (Gollasch 1999), several physical and biological constraints determine the successful establishment of an exotic dinoflagellate. These include survival during the voyage, ballasting and deballasting cycle, predation and competition by native species. Also, of the invading species, only 10% have a significant impact (Williamson and Fitter 1996). It is to be noted that the species dominant in the blooms during different years differed (Table 4). Of interest is the change in the constituent dinoflagellate species from time to time (Table 4, Subba Rao D.V. et al. 2003) and the same

species did not recur which suggests that species newly introduced may have found the medium conducive for temporary growth. Usually recurrence of the same species is common as was the case with *Prorocentrum donghaiense* in the East China Sea (Zhou et al.2003, Zhou and Zhu 2006), *Karenia brevis* blooms off Florida (Vargo 2009) and *Alexandrium* blooms in the Gulf of Maine region in the U.S. [\(McGillicuddy](file:///C:/Users/Ramana/Desktop/HABs%20in%20a%20changing%20world_.html%23R46) et al. 2005). Our time series analysis of dinoflagellates from Kuwait Bay corroborates this; there were 103 species in 2000-2007 with a decrease to 58 species by 2012 – 2013. However in the offshore waters there were 48 species of dinoflagellates during 2005-2006 which increased to 67 by 2012-2013 (Al-Said et al. 2017).

A report on the winter phytoplankton distribution during a research cruise from February to March 2006 (Al-Yamani et al. (2008 and 2012) in the ROPME Sea Area (RSA) is of interest. These data are based on water samples collected from 2 and 4 meters, mid depth samples from 5 to 50m, and bottom samples (from 10 to 100m) from 101 stations spread over 23 transects. These stations were grouped into the Northeast Gulf (38 stations), 34 (South east) and the rest in the Gulf of Oman and Hormuz Strait which receives water from the Indian Ocean and the Arabian Sea which decrease from south to north. A total of 170 dinoflagellates were present and are categorized into ubiquitous, common, frequent, occasional, rare, and very rare. For survival and establishment of exotic species in a harsh environment, more cells than in the categories occasional, rare, and very rare will be required which can be possible only with a larger inoculum. Blanco (Ch.19, 2.1 this volume) discussed the role of resting cysts of recurrent species in initiating a dinoflagellate bloom. This is comparable to the observations of Bohutskyi et al. (2016) who reported increased effluent (inoculum) increased nutrient levels that supported higher growth rates , productivities and robustness in the micro algae *Chlorella* and *Scenedesmus.* There were marked differences in the dinoflagellate distribution between the Northeast Gulf, South east waters and the Hormuz Strait and Gulf of Oman. Although these data are based on one –time collections, suffice to say that dinoflagellate diversity is high in the RSA; of these a few were ubiquitous (*Gyrodinium fusiforme, Oxytoxum variable*, and *Torodinium robustum*); 16 species limited to Northwest area and 18 to the Southeast area.

However, of particular interest is the occurrence of 65 Species, common to the Central Indian Ocean (IOSW) and the Arabian Gulf; these include *Amphisolenia bidentata, Amphisolenia globifera, Balechina coerulea, Ceratium breve, Ceratium candelabrum, Ceratium dens, Ceratium extensum, Ceratium falcatum,, Ceratium furca, Ceratium fusus, Ceratium gibberum*, *Ceratium hexacanthum, Ceratium horridum, Ceratium lunula, Ceratium macroceros, Ceratium massiliense, Ceratium massiliense var. armata, Ceratium, Ceratium ranipes, Ceratium vultur v. sumatranum, Ceratocorys armata, Cochlodinium* sp*., Dicroerisma psilonereiella, Dinophysis caudata*, *Dinophysis miles, Dinophysis mitra, Diplopelta bomba, Diplopsalis lenticula, Goniodoma polyedricum, Gonyaulax fragilis, Gonyaulax hyalinum, Gonyaulax polygramma, Gonyaulax spinifera, Gyrodinium spirale), Histoneis costata, Noctiluca scintillans, Ornithocercus magnificus, Ornithocercus quadrates, Oxytoxum curvatum, Oxytoxum scolapax, Podalampas bipes, Polykrikos schwarzii, Pronoctiluca pelagic, Pronoctiluca spinifera, Prorocentrum compressum, Prorocentrum gracile, Prorocentrum micans, Prorocentrum minimum, Protoperedinium curtipes, Protoperidinium curvipes*, *Protoperidinium depressum*, *Protoperidinium divergens*, *Protoperidinium globules, Protoperidinium ovatum, Protoperidinium murrayi, Protoperidinium oceanicum, Protoperidinium steinii*, *Protoperidinium subinerme, Pyrocystis* 

*fusiformis*, *Pyrocystis noctiluca, Pyrodinium bahamense, Pyrophacus horologicum, Spiraulax jolliffei*, *Triposolenia bicornis* and *Warnowia violesces.* Compared to the distribution of dinoflagellates in the Strait of Hormuz and the Gulf of Oman (groups iv, v and vi, Dorgham and Moftah 1989), the RAS had a different assemblage of 60 dinoflagellates; only *Ceratium vulture, Gonyaulax hyalinum, Oxytoxum scolapax, Podalampas bipes and Pyrocystis fusiformis* were common. More annual data based on systematic frequent sampling are needed to establish to what extent these differences are dependent on the incursion and the volume of Central Indian Ocean (IOSW) which decreases from south to north. The number of such IOSW dinoflagellate species in the Gulf of Oman was 61 (Dorgham and Moftah 1989), 17 in the Gulf in general, 12 off Qatar and 7 in Kuwait waters. North of Bushehr, Iran, probably due to lesser exchange with the open ocean, the number of species common to their southern waters is further reduced (Hulburt et al. 1981).

### **HARMFUL ALGAL BLOOMS IN THE GULF**

During September to October 1999 the first fish kill in the Gulf, largely mullet *Liza macrolepis,* was reported (Heil et al. 2001). This was associated with *Gymnodinium* sp. that grew to  $>6 \times 10^6$  cells l<sup>-1</sup> when the inorganic nitrogen increased by more than 20 fold and phosphate levels rose. Other dinoflagellates present were *Amphidinium carterae*, *Ceratium symmetriam, Ceratium fusus, Dinophysis caudata, Dinophysis miles, Gymnodinium galantum, Gymnodinium simplex, Gymnodinium* sp., *Gyrodinium fusiformis, Gyrodinium spirale, Gyrodinium* spp., *Polykrikos* sp, *Prorocentrum concavum, Prorocentrum emarginatum, Prorocentrum lima, Prorocentrum micans, Prorocentrum minimum, Protoperidinium minutum, Protoperidinium* spp., *Pyrophacus steinii and Scrippsiella troichiodea.* There was a massive kill of greater than 2500 metric tons of wild mullet (*Liza klunzingeri*), preceded by a small fish kill (100–1000 dead fish per day) of gilthead sea bream (*Sparus auratus*) in aquaculture net pens in August-September 2001 (Glibert et al. 2002)*.*  Causative harmful dinoflagellates included a set of dinoflagellates different from those of 1999 i.e., blooms of *Ceratium furca* and  $\langle 10^6 \text{ cells } l^{-1} \text{ of } Gymnodinium catenatum,$ *Gyrodinium impudicum,* and *Pyrodinium bahamense var. compressum*. PSP and brevitoxin levels were below the detection limits and the fish kills were attributed to unusually warm temperatures (up to 35 ◦C) and growth of the bacterium *Streptococcus agalactiae*.

The ciguatera-related dinoflagellate *Gambierdiscus yasumotoi* is reported for the first time from two sampling sites on the southern Kuwait coast (Saburova et al. 2013).

Mortalities of marine biota associated with dinoflagellates from various regions in the Gulf (Table 3) show that *Prorocentrum micans* was common between 1999-2001 episodes in Kuwait, and in Oman in 2005 (Al-Busaidi et al. 2008). *Cochlodinium polykrikoides* was the causative dinoflagellate in the UAE (Richlen et al. 2010) and Iran (Saeedi et al. 2011) and seems to be persistent and spreading. Following the regular blooms of *Noctiluca scintillans*, massive blooms of *G. polykrikoides*  $(4.6 \times 10^3 \text{ to } 9 \times 10^6 \text{ cells L}^{-1}$  and chlorophyll *a* 78.0 µg  $L^{-1}$ ) sustained over 8 months are associated with NH<sub>4</sub><sup>+</sup>, urea, PO<sub>4</sub><sup>3-</sup>, and organic nitrogen and phosphorus, many fold higher than observed earlier (Al-Azri et al 2014). The high nutrient levels are attributed to stronger than normal upwelling along the Iranian and northern Omani coasts.

Taxa	Region	Period	Mortality if any	Reference
Noctiluca scintillans	Oman	Oct 2005	Fish	Al Gheilani 2011
Cochlodinium polykrikoides		Oct 2008-Apr 2009	Fish and Shellfish	
Prorocentrum minimum, P. arabianum		Oct 2005

**Table 4. Harmful dinoflagellate blooms in the Gulf**

Dinoflagellate species in the Gulf are on the increase; for example in Kuwait they numbered 39 in 1987 (Dorham et al. 1987), 102 in 2009 (Al-Kandari et al. 2009) and 203 in 2019 (Al-Yamani and Saburova 2019). Of these, only *Dinophysis caudata, Ceratium furca*  and *C. fusus* are potentially harmful species (Al-Yamani et al. 2012) present during November 1984 (Dorgham et al. 1987). By 2009, 12 harmful species occurred and included *Alexandrium leei, A. minutum, Pyrodinium bahamense var. compressum, Dinophysis acuminata, D. acuta, D. miles, D. norvegica, D. tripos, Phalacroma mitra, Lingulodinium polyedrum, Protoceratium reticulatum, Noctiluca scintillans* (Al-Kandari et al. 2009). Harmful species *Alexandrium pseudogonyaulax, A. tamarense A. tamiyavanichiia, Alexandrium catenella, Karenia papilionacea, K. selliformis, Karenia mikimotoi, Scrippsiella trochoidea, Gonyaulax polygramma* and *Peridinium quinquecorne* were found in 2019 (Al-Yamani and Saburova 2019). It remains to be investigated whether these dinoflagellates were accidentally introduced and whether they have found a niche in this harsh environment to sustain bloom levels.

There have been several studies on the dinoflagellate cysts buried in the sediments of the Atlantic Ocean, Mediterranean Sea and adjacent basins (Marret and Zonneveld (2003), Zonneveld (1997), Zonneveld et al. (2013) and serve as cyst reservoirs. These cysts can remain viable in the sediment even for 100 years (Ribeiro et al. 2010) and when transported

to the warmer upper water column, excyst and play an important role in seeding recurrent annual blooms (Anderson and Wall 1978; Walsh et al. 2011a). However, in the Arabian Sea (northwestern Indian Ocean) occurrence of dinoflagellate cysts is affected by the SW and NE monsoons (Zonneveld 1997). In the Gulf of Aqaba qualitative and quantitative distribution of cysts varied between the sediments, the Gulf and the Red Sea. Phototrophic dinoflagellates *Brigantedinium* spp., *Votadinium calvum*, *Echinidinium* spp., *Lingulodinium machaerophorum*, *Spiniferites* spp., *Spiniferites bentorii*, *Spiniferites membranaceus* and *Spiniferites mirabilis* dominate the sediment while cysts of the heterotrophic dinoflagellates of *Impagidinium aculeatum*, *Impagidinium sphaericum*, *Operculodinium israelianum*, *Operculodinium longispinigerum*, *Operculodinium centrocarpum*, cysts of *Pentapharsodinium dalei*, and *Selenopemphix nephroides* are in the Gulf of Aqaba and the Red Sea (Elshanawany and Zonneveld (2016). Such comparative studies from the Arabian Gulf are absent. Availability of nutrients, light, suitable temperature and absence of predators dictate how well a species survives and finds it own niche. This may lead to expansion and their range of distribution. A case in point is the emergence and spread of *Cochlodinium polykrikoides* over 8 months in the Gulf and Gulf of Oman (Richelin et al. 2010) that coincides with an apparent global expansion of this taxon. Cultures of this organism were established in *f*/2 –Si medium and DNA analysis confirmed the *C. polykrikoides* isolates from the Gulf were identical to isolates from the northeastern USA, Puerto Rico, Mexico, and Malaysia, known as the ''American/Malaysian'' ribotype (Richelin et al 2010). The frequent dust storms during 2001 and 2012 in the Persian Gulf and Oman Sea coincided with 36 red tides and included the dinoflagellate *Cochlodinium polykrikoides* besides *Nitzschia, Noctiluca, Trichodesmium* and *Oscillatoria* (Rbbaniha et al. 2013).

#### **CONCLUSION**

The Gulf functions as a reverse estuary and receives waters from the Western Indian Ocean over the Hormuz Strait. The Gulf experiences several anthropogenic stressors and the hypereutrophic high-saline warm waters of the Gulf have a high xenobiodiversity, with 509 dinoflagellates. The number of dinoflagellate species, including potentially harmful species, has been on the increase. Of the 39 dinoflagellate species originally reported in 1987 (Dorgham et al. 1987), only *Ceratium tripos, Protoperidinium divergens* and *Pyrodinium bahamense* were present in 2009 (Al-Kandari et al. 2009); probably the rest have been replaced due to increased salinity, and taken over by those introduced via ballast waters. Dinoflagellate blooms in the Gulf are elusive; unique species neither recurred nor contributed to bloom formation in a defined region.

There are 28 potentially harmful dinoflagellate species from Kuwait waters *Alexandrium leei, A. minutum, A. pseudogonyaulax, A. tamarense, A. tamiyavanichii, Pyrodinium bahamense* var*. compressum* implicated elsewhere in Paralytic Shellish Poisoning, *Dinophysis acuminate, D. acuta, D. caudata, D. miles, D. norvegica, D. tripos, Phalacroma mitra, P. rapa, P. rotundatum, Prorocentrum lima* in Diarrhetic Shellfish Poisoning, *Karenia papilionacea, K. selliformis* in Neurotoxic Shellfish Poisoning, *Karenia mikimotoi, Scrippsiella trochoidea* in icthyotoxicity and *Lingulodinium polyedrum* in Yessotoxin*. Akashiwo sanguine, Alexandrium catenella, Ceratium furca, C. fusus, Gonyaulax* 

*polygramma, Noctiluca scintillans* and *Peridinium quinquecorne* also occurred. So far these suspect species did not evolve into bloom proportions needed to deliver toxins but studies on their physiological ecology are required to elucidate their functioning in this unique environment.

#### **RECOMMENDATIONS**

The Gulf is the main water body for Gulf countries and is heavily used for oil transportation, desalination, recreation and mariculture. The Gulf receives enormous quantities of nutrients, such as inorganic nitrogen, phosphorous compounds and trace elements from many sources, such as urban wastewater, sewage treatment plant discharges, erosion of soil containing nutrients and eolian dust storms. Inorganic nitrogen, phosphorous compounds and carbon are involved in the eutrophication and human activities can accelerate their enrichment rate and impact ecosystems. Reduction of phosphorus loading - a means of 'de-eutrophication'- resulted in a decrease in dinoflagellate abundance in Thau Lagoon, France (Gowen et al. 2015). It is to be recognized that eutrophication in the Gulf countries is uninterrupted while blooming of most dinoflagellates is short lived with an exception of *Cochlodinium polykrikoides* that bloomed for 8 month in Oman waters. So, any models attempting to relate these and to explain their cause and effect should be based on comparable short –term spatial and temporal resolutions of the physical, meteorological nutritional and biological data.

Implementation of a regional ecosystem-based nutrient management strategy plan, the HELCOM Baltic Sea Action Plan, suggests long-term reduction of nutrient inputs to improve eutrophication status in the Baltic Marine environment (OSPAR, 2017; Murray et al. 2019). Environmentally, this young Arabian Gulf is on the decline (Sheppard et al. 2010), which should be prevented through mass environmental education at all levels and across multiple disciplines and policy makers. A central organization involving all Gulf nations should be set up to achieve a broader understanding of the problem.

Discharge of pollutants and brine from desalination plants should be abated, probably by pumping them to the desert. Ballast water discharge should be regulated adhering to the IMO mandate (2004). In recent years there has been an increase in the incidence of harmful algal blooms with impacts on human health, tourism and recreation and fishery. This problem has to be addressed. To mitigate these socio-economic impacts, a good monitoring program and strategies to reduce HAB episodes are to be planned. It is highly desirable to have an institutionalized phytoplankton program between the Gulf countries and to conduct synoptic spatio-temporal surveys on the origin, growth and progression of blooms. Also, aerial drone based sampling and underwater robots with autonomous capabilities are being developed to investigate the eelgrass beds in 36 different sites from San Diego to Juneau, Alaska and for water quality research in coastal and inland waters (Washburn et al. 2018). These can be utilized to map and track algal blooms in the Gulf.

Representative keystone dinoflagellate species from the Gulf should be brought into laboratory culture and utilized as analogues of natural blooms to obtain data on their growth response and production of toxins to multifactorial physical and nutrient conditions. Such data would enhance our understanding of the structure and functioning of the harmful algal
blooms. Microbial communities associated with HABS and "biomarkers" can be determined using metagenomics, with which progression of blooms can be predicted (Galuzzi et al. 2004 and Penna, and Galluzzi, 2013).

#### **ACKNOWLEDGMENT**

We thank Dr. B. Charan Kumar, Chennai for help with drafting the Gulf circulation figure.

# **DINOFLAGELLATES AND GLOBAL ENVIRONMENTAL CHANGE**

# *Gustaaf Hallegraeff\**

Institute for Marine and Antarctic Studies, University of Tasmania, Hobart, Tasmania, Australia

### **ABSTRACT**

The scarcity of sustained  $(>30 \text{ yrs})$  biological time series represents a major bottle neck in progressing our understanding of global plankton trends. Ecosystem responses to natural climate variability in the past can provide a glimpse into assessing the impact of anthropogenic stressors such as eutrophication or novel species introductions as well as climate-induced changes in the future. We can learn important lessons from the dinoflagellate cyst fossil record and from the few long-term data sets available such as Continuous Plankton Records (CPR) of morphologically distinctive dinoflagellate taxa. We can also learn from dinoflagellate responses to unusual climate events such as El Niño. Many aquaculture areas have accumulated long-term dinoflagellate plankton and seafood biotoxin time series which are now available to be carefully analysed for trends. eDNA approaches of environmental samples as well as ancient sediments offer considerable promise to define the environmental indicator value of keystone dinoflagellate taxa. Selected examples are explored and the increased use of metadata analyses is emphasized.

**Keywords**: eutrophication, introduced species, climate change, dinoflagellate cyst record, eDNA

### **1.INTRODUCTION**

Dinoflagellates, being an ancient group of protists dating back to 330-400M years ago, exhibit a perplexing morphological, physiological and genetic diversity, which allowed them

 $\overline{a}$ 

<sup>\*</sup> Corresponding Author's Email: Hallegraeff@utas.edu.au.

to explore a broad range of nutritional strategies (photosynthetic, mixotrophic, phagotrophic, symbiotic, parasitic) and thrive in a wide range of planktonic and benthic marine and freshwater habitats. Reliable taxonomic monographs on planktonic (Taylor 1976; Steidinger & Tangen 1996) and benthic dinoflagellates (Hoppenrath et al. 2014) and their fossil cyst stages (Fensome et al. 1993; Zonneveld and Pospelova 2015) are now available. Solid data bases have been generated on extant dinoflagellates (Ocean Biogeographic Information System OBIS; http://www. iobis.org) and harmful dinoflagellates (Harmful Algae Event Database HAEDAT; *http://haedat.iode. org*) as well as fossil dinoflagellate cysts (Zonneveld et al. 2013).

Coupled with human society's increasing interest in monitoring for harmful dinoflagellate blooms and seafood toxins, and the fact that a range of species produce fossilisable cysts, dinoflagellates have been widely explored as environmental indicators. Selected examples are explored from the dinoflagellate cyst record, of continuous plankton records, and preliminary time series of key HAB species. Examples are provided of dinoflagellates that track eutrophication trends, which reflect ocean currents, or point to recent ballast water introductions or climate driven range expansions. In many cases multiple environmental drivers may be at play, such as eutrophication or climate disturbed habitats are more prone to new species introductions, and high biomass blooms triggered by eutrophication have a better chance of expanding their range via changing ocean currents. Only with increased build-up of environmental data bases such as OBIS or HAEDAT can we start to resolve the precise mechanisms underpinning ever changing dinoflagellate species distributions.

# **2. CASE STUDIES FROM THE OSLOFJORD AND SKAGERRAK FOSSIL RECORD**

Some 80 out of 2000 extant dinoflagellate taxa produce fossilisable sporopollenin cysts which have been extensively explored as stratigraphic biomarkers in oil exploration, to reconstruct the impact of past climate on plankton communities, but also in assessing the suitability of new aquaculture sites with respect to toxic dinoflagellate blooms. Dale et al. (2009) used the dinoflagellate cyst record from the Oslofjord in the last 100 years to assess the role of local eutrophication. While spring phytoplankton in the Oslofjord has access to unlimited nutrients, late summer species operate in a nutrient limited system. Eutrophication thus benefitted summer species such as *Lingulodinium* whereas spring species such as *Pentapharsodinium* were relatively unaffected. Smaller punctuated peaks of increased *Lingulodinium* may reflect local oceanography such as the North Atlantic Oscillation, but the main signal was of increased amounts of cysts of mostly *Lingulodinium* tracking eutrophication (Figure 1).

Dale (2009) subsequently identified a second eutrophication signal in other sites in the Skagerrak coastal system marked by an increase in heterotrophic cyst species, and differentiated this from the Oslofjord signal.

In the Skagerrak, Thorsen et al. (1995), working with a much longer (860cm) sediment core, documented the immigration into the region 6000 Before Present (B.P.) of *Gymnodinium nolleri* (microreticulate cyst initially reported as *Gymnodinium catenatum*).

Figure 1. Dinoflagellate cyst data for the Oslofjord demonstrating increased total cyst abundance (left) towards the early 1900s, as well as (right) a shift from *Operculodinium* (2) and *Pentaspharsodinium* (3) towards the summer species *Lingulodinium* (redrawn after Dale et al. 2009).

Figure 2A. Distribution of *Gymnodinium nolleri* cysts and total dinoflagellate cysts (cysts per gram dry sediment) in a 860cm long sediment core from the southern Kattegat (redrawn after Thorsen et al. 1995) demonstrating this species influx associated with a warming period 500 to 2000 years Before Present; 2B. Quantitative abundance of *Gymnodinium catenatum* cysts (as a percentage of total dinoflagellate cysts in 215cm and 80cm cores from Tasmania, Australia (after McMinn et al. 1997) demonstrating the new appearance of a putative ballast water introduction around 1972.

This species achieved bloom proportions from 2000 to 500 B.P. during a warming period, followed by a near extinction during the cooling period that commenced in 300 B.P. (Figure 2A). It is important to note that both cyst production and sediment input contribute to the amounts of cysts/g dry sediment, and therefore cysts may have also been produced in lower amounts but over a longer period of time rather than as a short-lived bloom.

The selectivity of the dinoflagellate cyst record complicates interpretation of microfossil sediment records. Promising novel approaches using ancient DNA technologies (Shaw et al. 2019) are now newly giving us access to fossil records also of non fossilisable cyst producing taxa such as *Alexandrium, Karlodinium, Noctiluca, Pfiesteria*. In the Bay of Brest (Brittany, France), the toxic dinoflagellate *Alexandrium minutum* had been detected since 1990 by the routine plankton monitoring network REPHY (Reseau de surveillance et d'observation du Phytoplankton et des Phycotoxines) but its abundance was low until 2012.

Figure 3. ITS1 rDNA copies g−1 sediment for *Alexandrium minutum* (purple) estimated by real-time PCR in a Bay of Brest sediment core. Colored shadows indicate the layers for which reliable rDNA quantifications were obtained. Stars indicate the layers where the presence of the species was detected but quantitative data were below detection limit of real-time PCR. The dashed lines indicate the limit layer of respective species germination (adapted from Klouch et al. 2016. *FEMS Microbiology Ecology*).

Working on a 60 cm sediment core from the Bay of Brest, France, Klouch et al. (2016) detected the first genetic traces of *Alexandrium minutum* dating back to 1873 (Figure 3), while quantitative real-time PCR approaches showed evidence for increasing abundance over time, corroborating observations from three decades of local plankton data.

# **3. CASE STUDIES OF POSSIBLE ANTHROPOGENIC TRANSPORT OF DINOFLAGELLATE SPECIES VIA SHIP'S BALLAST WATER OR TRANSLOCATION OF SHELLFISH PRODUCTS**

Whether new species occurrences represent new introductions, or the emergence of previously hidden flora remains an open debate in many dinoflagellate surveys. The potential for transport of non-indigenous marine microalgae via ship's ballast water (estimated to move 3 Billion tons per year) has been amply demonstrated. Nearly all known harmful dinoflagellate species have been documented in viable form from ship's ballast water, including *Alexandrium catenella, A. minutum*, *A. tamarense, Dinophysis* spp., *Gymnodinium catenatum, Karlodinium veneficum, Pfiesteria piscicida,* and *Pyrodinium bahamense* (Hallegraeff 2015). Ballast water uptake needs to be strongly discouraged during harmful algal bloom events. The adoption of the International Maritime Organisation's Ballast Water Management Convention (IMO) has served as an important catalyst for shipping industries to invest in significant research and development of treatment technologies to reduce this risk. This Convention came into force on 8 September 2017 after member states representing > 35% of shipping tonnage had signed off. The Convention requires ships to exchange ballast water at sea to a minimum of 95% volumetric exchange (Regulation D-1); or the discharge of ballast water so that the number of valuable organisms does not exceed specified limits (Regulation D-2). Available ballast water treatment technologies to achieve this have been reviewed by Murray and Hallegraeff (2018).

To prove that a dinoflagellate species has been introduced is complex. With *Gymnodinium catenatum* in South-Eastern Australia evidence focused on molecular markers to identify the suspected source population, combined with cyst studies in dated sediment depth cores that showed absence in historic times and appearance around 1972 coinciding with the start up of a woodchip mill attracting ships from known overseas source population (McMinn et al. 1997; Bolch and de Salas 2007; Figure 2B). *Alexandrium* do not tend to produce fossilisable cysts and the most convincing evidence for anthropogenic translocation has been the molecular detection in the Mediterranean ports of Sete and Barcelona of *Alexandrium pacificum* (as *A. catenella*) with a temperate Asian ribotype not found anywhere else in Europe (Lilly et al. 2002). Just like ballast water, the potential for transport of microalgae via the translocation of shellfish products has been well demonstrated (Shumway et al. 2004). The fine-scale genetic structure of *Alexandrium* populations in Japanese coastal waters thus strongly suggests a role for human-assisted dispersal associated with expansion of the aquaculture industry and translocation of shellfish stocks (Nagai et al. 2007).

In the past two decades, massive benthic *Ostreopsis* blooms, mostly *O.* cf. *ovata* , have newly occurred during summer along Mediterranean coasts associated with noxious aerosol effects on human health and mass mortalities of benthic marine invertebrates and/or macroalgae. Mortalities have been circumstantially attributed to the production of palytoxinlike compounds. The first record of *Ostreopsis* bloom in this sea dates back to 1972, when *O. siamensis* (likely *O. ovata*) was reported within a mucilaginous matrix covering macroalgae in Villefranche-sur-Mer Bay (F.J.R. Taylor, pers. comm.). While this apparent bloom expansion (Figure 4) has often been attributed to tropicalisation of the Mediterranean, molecular studies revealed genetic homogeneity ("founder effect") of Mediterranean *Ostreopsis* contrasting with high genetic diversity of *Ostreopsis* along the West Pacific coast (Sato et al. 2011). This points to the fact that *Ostreopsis* may have been introduced into the Mediterranean from Japan for example with oyster spat.

# **4. DINOFLAGELLATES AS INDICATORS OF OCEAN CURRENTS AND BIOREGIONS**

Marine dinoflagellates around the globe display the occurrence of the same morphospecies within broad latitudinal limits, the boundaries of which approximate to sea surface isotherms (Figure 6), a concept which Taylor (1976) referred to as latitudinal cosmopolitanism. The use of plankton communities to demarkate water masses dates back to Cleve (1900) and Schütt (1893). Dinoflagellates belonging to what used to be referred to as the genus *Ceratium*, now *Tripos*, are widespread in most marine plankton samples. The genus exhibits an amazing morphologically diversity, with over 77 species and numerous varieties and forms documented globally, and with numerous regional taxonomic monographs devoted to this dinoflagellate genus. All these studies hint at the potential of using *Tripos* species as water mass indicators, which has been quantitatively explored for the North Atlantic (Dodge and Marshall 1994) or to detect environmental change in the Mediterranean (Tunin-Ley et al. 2009). *Tripos* is best collected by phytoplankton or zooplankton nets, and Tunin-Ley et al. (2009) in the Mediterranean determined that a minimum sample volume of 70L was needed for a good estimate of *Tripos* species richness. The majority of *Tripos* species exhibit very broad temperate to subtropical to tropical temperature preferences from 10 to 25  $(30)$ <sup>o</sup>C (Dodge and Marshall 1994).

Figure 4. Expansion of the benthic dinoflagellate *Ostreopsis* in Mediterranean (map courtesy A. Zingone).

It is also noted that some species which are used as warm water indicators in the North Atlantic, e.g. *T. hexacanthus* (Figure 5 A; 7-30<sup>o</sup>C, but "prefers higher temperature") are not necessarily diagnostic for warm-waters of the Australian region.

Figure 5A. Occurrence of the coldwater *Tripos longipes* and warm-water *T. hexacanthus* in North Atlantic Continuous Plankton Recorder data 1958-1999 (from Barnard et al. 2004 *Marine Ecology Progress Series*); 5B. Australia wide distribution of the warm-water marine dinoflagellate species *Tripos cephalotus, T. praelongus*, and *T. gravidus*. Southward transport of these taxa reflects the Leeuwin Current (in winter) or East Australian Current (in summer).

Similarly, Tunin-Ley et al. (2009) observed some strictly warm-water species such as *T. digitatus* in winter in the Mediterranean. Using a strict definition of stenothermal tropical species, in Australian waters we identified a narrow group of warm-water species including *T*. *belone, T*. *cephalotus, T*. *dens, T*. *digitatus, T*. *gravidus, T*. *incisus, T*. *paradoxides,* and *T*. *praelongus* which should receive careful attention in monitoring for future range expansions or upwelling/incursion of deep tropical waters (Hallegraeff et al. 2020). The power of this approach is well demonstrated by the early plankton studies by Wood (1954) who produced the first conclusive biological evidence for what is now called the Leeuwin Current occasionally transporting Indian Ocean dinoflagellates all the way to the west coast of Tasmania (Figure 5B), many decades before satellite images confirmed its existence (Cresswell and Domingues 2009).

#### **5. DINOFLAGELLATES AND CLIMATE CHANGE**

The dinoflagellate *Pyrodinium bahamense* is presently confined to tropical, mangrovefringed coastal waters of the Atlantic and Indo-West Pacific. A survey of cyst fossils (named *Polysphaeridium zoharyii*) going back to the warmer Eocene 50M years ago indicates a much wider range of distribution in the past (Figure 6). For example, in the Australasian region at present, the alga is not found farther south than Papua New Guinea but, some 100 000 years ago in the Pleistocene, the species ranged as far south as Sydney Harbour. In the Philippines alone, *Pyrodinium* has been responsible in the period 1980 to 2010 for more than 2000 human illnesses and 100 deaths resulting from the consumption of contaminated shellfish as well as sardines and anchovies. There is concern that, with increased greenhouse warming of the oceans, this paralytic shellfish toxin-producing species may one day return to Australian waters. Comparable examples of spreading of dinoflagellate cyst species distributions with increasing temperatures, and shrinkage of biogeographical zones with decreasing temperatures, are known. The fossil dinocyst *Dapsilidinium pastielsii* became extinct in the Atlantic during cooling in the early Pleistocene, but a warm-water refuge for this taxon was recently discovered in the Indo-Pacific Warm Pool (Japan, Indonesia, Vietnam, Palau, Philippines) (Mertens et al. 2014).

Figure 6. Global distribution of *Pyrodinium bahamense* in recent plankton (A) and much wider distribution in the fossil cyst record (C) (after Usup et al. 2012. *Harmful Algae*). Micrographs of *Pyrodinium* vegetative cells (B) from Bahia Phosphorescente (Puerto Rico) and hemispherical cyst with sulcal notch from Port Moresby, Papua New Guinea (D).

Azanza and Taylor (2001) presented strong evidence for a coincidence between *Pyrodinium bahamense* blooms and El Niño-Southern Oscillation (ENSO) climatic events in the tropical Indo-West Pacific. El Niño is caused by an imbalance in atmospheric pressure and sea temperature between the eastern and western parts of the tropical Pacific Ocean and results in a shoaling of the thermocline. The first *Pyrodinium* blooms became evident in 1972

in Papua New Guinea and coincided with the fatal food poisoning of three children. Since then *Pyrodinium* blooms have apparently spread to Brunei and Sabah (1976), the central (1983) and northern Philippines (1987) and Indonesia (North Mollucas). The pattern of initial *P. bahamense* blooms in Southeast Asia in the late 1970s to mid-1980s suggested that the cells or cysts were transported from place to place (reviewed by Usup et al. 2012). In the case of Manila Bay, *P. bahamense* might have inhabited the Bay since the 1950s and were present in Malampaya Sound, Palawan since the 1970s and Manila Bay since the 1920s, while in Indonesia, cysts were probably present in Hurun Bay since the 1860s and Ambon Bay since the 1850s. In Sabah, Malaysia the oldest occurrence of cysts was probably around 1966, about 10 years earlier than the first recorded bloom.

These results suggested that the expansion of *P. bahamense* blooms in Southeast Asia in the early 1980s might have been more the result of significant environmental changes in the region rather than the result the species being newly introduced to the area. Interestingly *Pyrodinium* blooms have declined in the Phillipines after 2000, and were replaced by less harmful blooms of green *Noctiluca*.

Ciguatera caused by benthic *Gambierdiscus* dinoflagellate species is a tropical seafood poisoning syndrome well-known in coral reef areas in the Caribbean, Australia, and especially French Polynesia. Whereas, in a strict sense, this is a completely natural phenomenon, from being a rare disease two centuries ago, ciguatera has now reached epidemic proportions in French Polynesia and the Caribbean. More than 500,000 Pacific Islanders suffer ciguatera during their life time, which means approximately 1 in every 4 persons in the Oceania region, which is about 2-fold higher than reported from the Caribbean. Evidence is accumulating that reef disturbance by hurricanes, military and tourist developments, as well as coral bleaching (linked to global warming) and perhaps in future increasing coral damage and changing macrophyte cover due to ocean acidification are increasing the risk of ciguatera. A recent game changer has been the elucidation via molecular tools that what was once thought to be a single causative dinoflagellate, is now considered to be a species complex of 19+ different morphospecies (Litaker et al. 2010). At least 4 *Gambierdiscus* species (*G. belizeanus*, *G. caribaeus*, *G. carolinianus* and *G. carpenteri*), are distributed globally, with the other 7 found only in the Pacific (*G. australes*, *G. pacificus*, *G. polynesiensis*, *G. toxicus*, *G. yasumotoi*), Indian (*G.toxicus*) or the Atlantic Oceans (*G. ruetzleri*, *G. excentricus*)*.* This finding sheds new light on the previously recognised *>*100 fold variation in toxicity, but also suggests a much broader range of environmental tolerances. An apparent range expansion of human ciguatera poisonings has been claimed for the Mediterranean and the Canary Islands, the Caribbean and West Indies, and the East Coast of Australia (Farrell et al. 2016; Kohli et al. 2014; Litaker et al. 2010; Rodriguez et al. 2017) which needs to be rigorously monitored (Figure 7). It is not yet clear whether this is caused by range expansions of *Gambierdiscus* dinoflagellates, or migration of ciguatoxic fish, or both.

Several dinoflagellate species can exhibit invasive behavior that can disrupt ecosystems via strong phagotrophic feeding (red *Noctiluca*), mixotrophy (green *Noctiluca*, *Cochlodinium*), the killing of zooplankton or fish (*Karlodinium*), or the inability of being grazed. These phenomena have been referred to as Ecosystem Disturbing Algal Blooms (Sunda et al. 2006).

Figure 7. Left: Current global distribution of ciguatera food poisoning from fish, indicating ciguatera endemic areas, countries where cases have resulted from imported fish, and areas where ciguatera is considered to currently expand, either by expansion of the causative dinoflagellate and/or migration of fish (courtesy Louis Marde Institute, French Polynesia); Right: The causative benthic dinoflagellate *Gambierdiscus* from the Australian Great Barrier Reef (Map courtesy Ciguatera-Online@ ciguateraonline).

Figure 8. Expansion of global distribution of the fish-killer *Cochlodinium polykrikoides.* Redrawn after Iwataki et al. 2008. *Harmful Algae.,*

*Noctiluca* is an example of a HAB species that appears to have been increasing globally in the past two decades (Harrison et al. 2011, Gomes et al., this volume). Although in some regions this may be, at least in part, a function of increasing observations and awareness, in other regions such as southeast Asia this appears to reflect a real change in plankton dynamics associated with eutrophication and climate change. *Noctiluca* has sometimes been interpreted as a coastal or offshore manifestation of eutrophication, since an increase in nutrients provides an increase in phytoplankton, its main food supply as a grazer. Red *Noctiluca* has

dramatically increased along the east coast of Australia. While in the period 1860 - 1950 it was only known from Sydney where it has been responsible for tourist beach closures, from 1980-1993 it expanded along the New South Wales coast in response to eutrophication, during 1994 - 2005 the changing East Australian Current drove a range extension down to Tasmania (34°S) where it impacted on salmon farms, and in 2008 - 2013 it expanded against prevailing current systems also implying a role for domestic ballast water dispersal (McLeod et al. 2012, Hallegraeff et al. 2019). Green *Noctiluca* has expanded in the last decade into the northern Arabian Sea where winter phytoplankton blooms were previously comprised mainly of diatoms, but now have been replaced by green *Noctiluca.* This organism combines carbon fixation from its green endosymbiont with ingestion of prey to the detriment of regional fisheries and the long-term health of an ecosystem supporting a coastal population of 120 million people (Gomes et al. 2014).

The fish-killing dinoflagellate *Cochlodinium polykrikoides* long known from Japan and Korean waters (\$95M aquaculture kill in 1995) but also Mexico, California and British Columbia , exhibited apparent recent range expansions in 2004 into the Malaysian region and in 2008-2009 caused a major bloom in the Arabian Gulf region where it led to fish kills and even the closure of desalination plants (Figure 8). The latter was caused by the American/Malaysian ribotype, which is distinct from the East Asian and Philippines ribotypes (Iwataki et al. 2008).

We cannot yet resolve whether this Gulf bloom represents a ballast water introduction, a climate driven range expansion, or a response of a previously cryptic species to anthropogenic nutrient enrichment.

Figure 9. Time series of OBIS location records of the HAB genera *Dinophysis and Alexandrium* between 1900 and 2019, associated with the seafood poisoning syndromes DSP and PSP. Records are biased towards Europe (Adopted from Hallegraeff et al. 2017).

Dinoflagellate species responsible for shellfish toxicity syndromes such as *Alexandrium* (causative organism of Paralytic Shellfish Poisoning, PSP) and *Dinophysis* (causative organism of Diarrhetic Shellfish Poisoning, DSP) have been extensively monitored in many regions for >30 years (Figure 9).

PSP is the dominant seafood toxin syndrome in North America, and DSP in Europe. Ocean Biogeographic Information System (OBIS) Time series data for location records of the key target genera *Alexandrium* and *Dinophysis* exhibit an increase in frequency over the past 30 years, undoubtedly reflective of increased awareness and monitoring effort. Climate change is adding a new level of uncertainty to seafood safety and HAB monitoring programs**.**  While we made considerable progress in understanding the physics of climate change, understanding of the impacts on biological communities is in its infancy. There will be winners and losers from climate change, but predicting how individual species will respond poses a formidable challenge.

Key environmental factors driving changes in HABs include: increased temperature, enhanced surface stratification (affecting nutrient and light availability), elevated  $CO<sub>2</sub>$ (stimulating photosynthesis and driving 'ocean acidification' biogeochemistry), and increased extreme precipitation and storm events. International Panel Climate Change (IPCC) physicochemical models predict uneven geographic changes in temperature, ocean acidification and nutrient depletion hotspots (Bopp et al. 2013). Potentially emerging HAB climate responses include: range expansion of warm-water (e.g. *Gambierdiscus*) at the expense of cold-water species; changes in abundance and seasonal bloom window; and increased cellular toxin content of key HABs (*Alexandrium, Karlodinium*). Developing predictive capability on how HABs may respond has been frustrated by: contradictory species and especially strainspecific responses, lack of insights into evolutionary adaptation; and into how HABs interact with the broader phytoplankton and zooplankton grazer communities (Hallegraeff 2010; Wells et al. 2015). Indirect climate effects also need to be taken into account such as demise of coral reefs due to bleaching, which can increase macroalgal-dominated sea-beds and the risk of harmful benthic epiphyte blooms such as *Ostreopsis* and *Gambierdiscus*. Not all trophic levels are responding to the same extent, and where zooplankton or fish grazers are differentially impacted by ocean warming, this may have cascading impacts on the structure of marine food webs. Addressing these challenges calls for significant departures from traditional HAB experiments, such as studying multiple strains, with multifactorial experiments the norm, agreeing on best practices techniques, and making global extrapolations via modelling approaches. The analysis of long-term dinoflagellate data series, whether they be fossil cyst records, continuous plankton records, or seafood toxicity syndromes such as ciguatera, PSP and DSP, play an important role in improving our predictive capability of the impacts of global environmental change on ocean biology.

# **EVOLUTION OF DINOFLAGELLATE GENOMICS AND GENE EXPRESSION OF TOXINS**

## *Adinarayana Kunamneni, D. V. Subba Rao and Ravi V. Durvasula\**

Department of Medicine, Loyola University Medical Center, Chicago, Illinois, US

### **ABSTRACT**

Dinoflagellates are key species in marine environments but remain poorly understood due to their large, complex genomes, unique molecular biology, and unresolved in-group relationships. They are the source of "red tides" that cause fish killings and shellfish poisoning. Depending on the species, their toxins can trigger paralytic shellfish poisoning (PSP), neurotoxic shellfish poisoning (NSP), diarrhetic shellfish poisoning (DSP) and Ciguatera poisoning (CP). Dinoflagellate toxins and bioactive compounds are of increasing interest because of their commercial impact, influence on safety of seafood and potential medical applications. Our understanding of the genes involved in toxin biosynthesis in dinoflagellates is currently limited due to the complex genomic features of these organisms. In evolutionary history, dinoflagellate genomes not only have undergone vertical evolution but have also been impacted by active horizontal gene transfer from their plastids, endosymbionts, as well as other organisms. The recent sequencing of various dinoflagellate transcriptomes has provided us with new valuable insights into the biosynthesis of paralytic shellfish toxins (PSTs) in dinoflagellate species. This chapter summarizes the genomics, biosynthesis and biotechnological applications of toxins and other bioactive molecules from dinoflagellates.

**Keywords:** dinoflagellates, genomics, transcriptomics, toxins, biosynthesis, bioactive applications

#### **1. DINOFLAGELLATES**

Dinoflagellates are unicellular algae. Of the 2377 extant dinoflagellates, 116 are constitutive mixotrophs and 109 are non-constitutive mixotrophs (See chapter 7: Hansen and Tillman), ingesting other algae or dissolved organic matter [1], some of which can enslave ingested algal chloroplasts and perform photosynthesis (e.g., [2, 3]). These heterotrophic taxa are potentially important micrograzers in the microbial food web [4]. More than 60 taxa of dinoflagellates are known to form red tides, over 20 of which produce toxins that have profound impacts on fisheries, recreational values of coastal zones and public health [5].

Dinoflagellates possess a number of unusual features, e.g., unique plastids acquired from red algae via endosymbiosis [6-9], mitochondrial genomes encoding three proteins for the electron transport chain, and fragmented genes for rRNA [8, 9]. The nuclei of dinoflagellates referred to as dinokaryon [10] have unique features such as condensed chromosomes during interphase and lack of nucleosomes, thus the dinokaryons are distinctly different from typical eukaryotic nuclei (Figure 1) [11, 12]. In the dinokaryon the chromosomes exist in a condensed, liquid crystal state throughout the cell cycle. Instead of packaging DNA in nucleosomes, dinoflagellates appear to have replaced the bulk histone function with two noneukaryotic proteins, the dino-viral like protein (DVNP) and a histone like protein (HLP) [13- 16]. The chromosome interior is densely packed with DNA, with very low levels of protein, some RNA, and a large number of  $Mg^{2+}$  and  $Ca^{2+}$  ions [12]. The chromosomes appear to be too dense for transcription to occur on the interior; instead genes located on the extrachromosomal loops associated with HLPs are probably transcriptionally active (Figure 2) [17-19].

In addition to these structural anomalies of the nucleus, dinoflagellates further distinguish themselves from other alveolates (an ancient group of eukaryotes that occupy a diverse array of ecological niches, both free-living and parasitic) with high DNA content. Core dinoflagellates have a large number of chromosomes, with haploid DNA content ranging from 1.5 pg of DNA per cell in the coral symbiont *Symbiodinium* to 189 pg in the bioluminescent species *Lingulodinium polyedrum* [12, 20]. Due to a DNA content often orders of magnitude larger than the human genome (3 pg of DNA per haploid cell), full genome sequencing is very difficult. To date only draft genomes of *Symbiodinium* and the syndinean *Hematodinium* have been published [21-23]. Most sequencing work was focused on transcriptomes which, with recent advances in sequencing technologies linked to lower costs, could facilitate sequencing of more dinoflagellates.

These atypical features continue down to the most basic unit of information, DNA. In dinoflagellates up to 70% of thymine bases are replaced with 5 hydroxymethyl uracil, more commonly found in bacteria and bacteriophage and found in eukaryotic cells only under oxidative stress conditions [11, 24-26]. At the transcript level, a 22 nucleotide spliced leader (SL) sequence is added to the 5' end of all messenger RNA (mRNA) transcripts in dinoflagellates (Figure 2) [26-28]. This feature confirms that transcripts are complete and that they originate from dinoflagellate DNA rather than from contaminants or bacteria that may reside in the intracellular space or attached to the cell surface. Some highly expressed dinoflagellate genes are encoded in large tandem arrays with short intergenic spacers and are trans-spliced while moderately expressed genes tend to be intron rich and are encoded by a single gene [29, 30].

Figure 1. Model of evolutionary characteristics of dinoflagellates. Figure denotes character states for dinoflagellates mapped onto a phylogeny. Some of the key features seen in the core dinoflagellates are spliced leader trans-splicing of mRNA, loss of nucleosomes, presence of histone like proteins (HLP), liquid crystalline chromosomes, and the presence of 4-methyl sterols and dinosterol. Representative morphotypes are pictured in the upper right. Figure from Janouskovec et al. [31].

### **2. DINOFLAGELLATE GENOMICS**

Genomes of dinoflagellates have undergone vertical evolution and were significantly impacted by horizontal gene transfer. Some dinoflagellates represent a photosynthetic organism with the most reduced plastid genome. The characteristic peridinin-containing lineages have plastid genomes broken into single-gene minicircles that encode only 16 of the typically 130-200 plastid proteins [32]. Transfer of the rest of the plastid genes to the nucleus has dramatically reconfigured the nuclear genome in dinoflagellates [33]. In addition, plant Rubisco (Ribulose-1,5-bisphosphate carboxylase/oxygenase) has been replaced by that of proteobacterial origin (form II) likely through lateral gene transfer [34, 35]. Dinoflagellates lack histone proteins with few exceptions (e.g., *Amoebophrya*) [36], but a histone H3-like protein [37] and a histone H2A.X [38] were reported recently in addition to findings of basic

and acidic nuclear proteins [38, 39]. Also, typical dinoflagellate cells divide with closed mitosis and extranuclear spindles and chromosomes remain permanently condensed. Other uncommon features for an eukaryote include the rarity of mRNA splicing and deviation from the universal GT/AG rule [40, 41], the extensive and novel mRNA editing in mitochondrial genes [42, 43] and widespread spliced leader RNA *trans*-splicing [44].

Figure 2. Distinct features of dinoflagellate nuclear, plastid, and mitochondrial genomes. Model showing the liquid crystalline chromosome structure and peripheral loops on which transcription occurs. B) Model showing trans-splicing of mRNA messages as well as tandem gene arrays, and polyadenylation which completes the mature mRNA transcript. C) Model showing fragmented mitochondrial genome. D) Plastid minicircles found in dinoflagellate plastids and the genes associated with them. Figure from Wisecaver and Hackett [11].

In the past half century, the genome sizes of more than 30 dinoflagellates have been measured, ranging between 3 and 278 pg DNA per genome or cell [20, 45-47], which is about 1-80 times larger than that of the human haploid genome. Although smaller genomes may occur in some yet unrecognized dinoflagellates [48], dinoflagellate genomes are still huge considering their relatively small cell size and being "simple" organisms, another case of Cvalue enigma [49]. Equally striking is the wide range of genome size, which cannot be explained by differences in function or cell size. These peculiarities raise questions about the functions of the dinoflagellate genome in protein coding and other activities. Early work on biochemical properties has shown that a large fraction of the nuclear DNA in the dinoflagellate *Crypthecodinium cohnii* and *Prorocentrum cassubicum* is composed of repeated and interspersed DNA sequences [46, 50-52]. Hence, it has been suggested that significant portions of the dinoflagellate genomes are nonfunctional [53]. Recently, Lin [48] has detected potential binding targets of microRNA in dinoflagellate mRNA, suggesting existence of functional noncoding elements in dinoflagellate genomes.

The regulation of gene expression in these enigmatic organisms is currently being explored using a genomics approach. Several Expressed Sequence Tag (EST) projects have been conducted in recent years. For instance, Okamoto and Hastings [37] utilized microarrays and found that circadian clock-related genes in dinoflagellates were regulated at the transcriptional level. Erdner and Anderson [54] used Massively Parallel Signature Sequencing and found that only about one-fourth of the expressed gene pool was regulated transcriptionally while the remaining genes did not exhibit transcriptional regulation. Similarly, a microarray analysis on *Karenia brevis* revealed little transcriptional regulation of its genome [55]. Furthermore, several other studies using EST analyzed the evolution of plastid genomes in dinoflagellates [6, 38, 56, 57]. Taken together, these studies concluded that: 1) transcriptional regulation of dinoflagellate genes is rare and 2) most dinoflagellate plastid genes were transferred to the nuclear genome. It is still poorly understood what the dinoflagellate genomes consist of and which genes are commonly expressed under natural conditions ("Dino core genes") versus specific conditions. Lin et al. [58] have launched an EST project to investigate profiles of expressed genes in three trophically contrasting taxa: *Prorocentrum minimum* (photoautotrophic), *Karlodinium micrum* (mixotrophic), and *Pfiesteria piscicida* (heterotrophic). They observed distinct (largely undescribed) gene signatures expressed among the three species as well as changes in the profile of expressed genes in *Pfiesteria* from fed to starved conditions. Notably, the majority of these dinoflagellate genes produce no significant hits in the GenBank database. The traditional ESTs often do not provide sufficient information for prediction of the functions of these "novel" genes. To overcome this shortcoming, Lin et al. [58] took advantage of the recently discovered spliced leader at the 5' end of dinoflagellate nuclear-encoded mRNA and constructed cDNA libraries (e-cDNAs) from one marine and two freshwater plankton assemblages to sequence full-length cDNA. Small-scale sequencing of the e-cDNAs revealed functionally diverse transcriptomes proven to be of dinoflagellate origin. A set of dinoflagellate common genes and transcripts of dominant dinoflagellate species were identified. Further analyses of the dataset prompted them to delve into the existing, largely unannotated dinoflagellate EST (DinoEST) datasets. Consequently, all four nucleosome core histones, two histone modification proteins, and a nucleosome assembly protein were detected, clearly indicating the presence of nucleosome-like machinery long thought not to exist in dinoflagellates. The isolation of rhodopsin from taxonomically and ecotypically

diverse dinoflagellates and its structural similarity and phylogenetic affinity to xanthorhodopsin suggest a common genetic potential in dinoflagellates to use solar energy non-photosynthetically. Additionally, they found 55 cytoplasmic ribosomal proteins (RPs) from the e-cDNAs and 24 more from DinoEST, showing that the dinoflagellate phylum possesses all 79 eukaryotic RPs. Their results suggest that a sophisticated eukaryotic molecular machine operates in dinoflagellates that likely encodes many more unsuspected physiological capabilities and, meanwhile, demonstrate that unique spliced leaders are useful for profiling lineage-specific microbial transcriptomes *in situ*.

At present, very little is known about gene expression regulation in dinoflagellates. No canonical TATA box has been found in dinoflagellate genes, but TBP-like protein 2 (TBP-2), intermediate between TATA box binding proteins (TBPs) and TBP-like factors (TLFs), were found in *C. cohnii* [59]. In mammalian cells, TBP-2 has functions distinct from classical TBP that may be related to non-condensed chromatin conformation [60]. Homologs of TBP-2 and related proteins have been identified in recent dinoflagellate transcriptomes, such as the cDNA dataset in Lin et al., [58] and Toulza et al., [61]. Transcriptional regulation is quite limited in dinoflagellates. A microarray analysis on *Karenia brevis* revealed that only about 10% of genes were transcriptionally regulated [62]. Massively parallel signature sequencing studies of two *Alexandrium* species showed that 10%-27% of the detected cDNA pools exhibit transcriptional regulation [54, 63]. A metatranscriptomic analysis without normalization showed strikingly even levels of transcript abundance for the majority of the cDNAs detected, for all three (one marine and two freshwater) samples, with only a small number of genes showing markedly higher transcript levels [58]. The scarcity of transcriptional regulation is consistent with the lower abundance of histones in dinoflagellates given that histones play a key role in regulation of gene transcription in eukaryotes. Thus, the majority of genes in dinoflagellates are most likely regulated translationally or posttranslationally. Post-translational modification of proteins, including phosphorylation, methylation, and sumoylation (by a small ubiquitin-like modifier), are widely recognized as important modification processes regulating protein activity in eukaryotes, yet their potential roles in dinoflagellate gene regulation remain largely unexplored.

Of the small proportion of genes that are transcriptionally regulated, those highly expressed are of particular interest but have not been given much attention. A small number of genes are highly represented in the EST datasets reported recently, e.g., *K. brevis* [62] and *Alexandrium catenella* [64]. In the latter case, the cDNA library was dominated by 17 genes, of which luciferin binding protein accounted for 15.6%, S-adenosyl-L-homocysteine hydrolase 4.9%, glyceraldehyde-3-phosphate dehydrogenase isoform 2 (GPDH) 3.7%, and Sadenosylmethionine (SAM) synthetase 3%.

Lin et al. [58] compared the sequenced cDNA libraries derived from two freshwater and one marine natural plankton assemblages along with the existing DinoEST dataset to identify commonly expressed genes. Five genes coding for major basic nuclear proteins, ubiquitin, centrin/caltractin, calmodulin and 14-3-3, were found to be commonly and highly expressed in both the cultured and wild dinoflagellate assemblages.

A literature survey shows that some of these and other genes are highly expressed, such as SAM synthetase, S-adenosyl-L-homocysteine hydrolase (¼S-adenosylhomocysteinase), glyceraldehyde-3-phosphate dehydrogenase, peridinin-chlorophyll-binding protein, heat shock proteins 90, 70, and 40, elongation factor 1a and calmodulin. These genes are important in methylation of DNA and toxin precursors, carbohydrate metabolism, light harvesting,

stress response, translation as well as signal transduction. In addition, the analysis of the environmental cDNA and DinoEST datasets yields a set of 79 ribosomal proteins that commonly occur in eukaryotes [58]. Some of these genes are highly represented in DinoEST. DinoESTs serve as markers for genes expressed under specific conditions and can be used as probes in the recovery of full-length cDNA or genomic sequences, recognition of exon and intron boundaries, delineation of protein families, and for the development of probes for genome wide expression profiling [38, 57, 62, 65]. Furthermore, transcriptomic surveys, in particular by way of next-generation sequencing (NGS) RNA-Seq, have illuminated our understanding of the unique biology, metabolism, and ecology of dinoflagellates [66-68].

### **3. DINOFLAGELLATE TOXINS**

Dinoflagellates are the greatest contributors to harmful algal blooms and biotoxins in the ocean. Several types of toxins produced by dinoflagellates (reviewed by Wang, [69]) are responsible for all but one of the classical seafood poisoning syndromes, including paralytic shellfish poisoning (PSP), diarrhetic shellfish poisoning (DSP), neurotoxic shellfish poisoning (NSP), *ciguatera* fish poisoning (CFP)**,** amnesic shellfish poisoning (ASP) and azaspiracid shellfish poisoning (AZP) [70]. The only exception is amnesic shellfish poisoning (ASP), which is caused by the diatom *Pseudonitzschia* spp. Of these syndromes, PSP and DSP are most harmful to humans [71].

#### **3.1. Paralytic Shellfish Poisoning (PSP) Toxin**

Paralytic shellfish poisoning toxins (PSTs) are a group of naturally occurring small heterocyclic guanidinium alkaloids. The most common dinoflagellate toxin is saxitoxin (STX), a neurotoxin 100,000 times more potent than cyanide [72]. It has been found in North American shellfish from Alaska to Mexico, and from Newfoundland to Florida. The most notorious producers of saxitoxin are *Protogonyaulax catenella* on the west coast and *Gessnerium monilatum* on the east coast of North America. Both have been known to cause paralytic shellfish poisoning (PSP). The worst cases of PSP result in respiratory failure and death within 12 hours in humans. STX (Table 1) is the most common of at least 21 analogues of toxic cyclic guanidines that are known in shellfish. STXs exert their effects by directly binding to voltage-gated sodium channels in nerve and muscle cells blocking the influx of sodium and the generation of action potentials, leading to paralysis [73]. STX-producing Dinoflagellates belong to the three genera *Alexandrium*, *Gymnodinium* and *Pyrodinium*.

#### **3.2. Neurotoxic Shellfish Poisoning (NSP) Toxin**

Another toxin that accumulates in shellfish is brevetoxin (BTX), produced by the dinoflagellate *Karenia brevis* (Table 1). BTX is unique in that it becomes aerosolized when the aquatic dinoflagellates are transported to the surf zone from where it is blown onto the beach causing respiratory irritation in humans. Beachgoers on the Gulf coast of Florida who notice asthma-like breathing symptoms, may be experiencing toxicity from an offshore *Karenia* bloom. A review on how BTX and its analogues can also affect finfish, aquatic mammals and birds has been published recently [74]. The symptoms of NSP include gastroenteritis and neurological problems [75]. The mode of action of BTXs is binding to sodium channels in nerve, muscle and cardiac tissue, arresting them in the "open" position thus enhancing sodium entry into the cell. This leads to incessant activation, which causes paralysis and fatigue of these excitatory cells [76]. Animal illnesses are also common during *Karenia* blooms with recorded deaths of bottlenose dolphins and manatees due to brevetoxin ingestion of contaminated organisms [74].

#### **3.3. Diarrhetic Shellfish Poisoning (DSP) Toxin**

Toxins produced by the dinoflagellate *Dinophysis* and *Prorocentrum* spp. cause diarrhetic shellfish poisoning (DSP), which results in digestive upset although it is not fatal. DSP toxins were originally divided into three different structural classes, (a) okadaic acid (OA) and its analogues, the dinophysistoxins (DTXs), (b) pectenotoxins (PTXs), and (c) yessotoxins (YTXs) (Table 1) [77]. However, YTXs have now been excluded from the DSP classification since they are not orally toxic and do not induce diarrhea [78, 79]. The mechanism of action of the OA group toxins is exerted via inhibition of the serine-threonine protein phosphatase 2A (PP2A) [80], which plays important roles in many regulatory processes within the cell. OA most likely causes diarrhea by stimulating phosphorylation of proteins that control sodium secretion in intestinal cells [81]. The production profiles of DSP toxins by dinoflagellates can vary within a single species [82, 83].

#### **3.4. Ciguatera Fish Poisoning (CFP) Toxin**

Ciguatera is another form of dinoflagellate toxicity in tropical areas caused by eating fish contaminated by toxins of *Gambierdiscus toxicus*. These toxins can accumulate in the food chain to larger carnivorous fish such as barracuda, snapper, and amberjacks to levels high enough to cause human illness [84]. Ciguatoxins are polycyclic polyether compounds that activate human voltage-gated sodium channels (VGSC), which leads to gastrointestinal, neurological, and cardiovascular disturbances [85-87]. Due to bioaccumulation in humans, ciguatera symptoms can persist from days to months depending on the amount of toxin ingested [84]. The number of congeners produced by dinoflagellates of not only ciguatoxin, but most dinoflagellate toxins, are difficult to quantify as new congeners are constantly being discovered with slightly different structures and varying potencies [88, 89]. For example, Pacific ciguatoxin PCTX-1 can cause illness at levels of 0.1 µg/kg in the flesh of fish while Caribbean ciguatoxin C-CTX-1 is 10 fold less toxic as it is more polar and therefore easier to detoxify [90]. In areas where ciguatoxins are prevalent, monitoring programs are in place to prevent contaminated fish from reaching markets for consumption [89, 90].

Table 1. Suite of toxins identified from marine dinoflagellate species. Table generated using information<br>from Cembella [100] and Shimizu [101] **Table 1. Suite of toxins identified from marine dinoflagellate species. Table generated using information from Cembella [100] and Shimizu [101]**

#### **3.5. Azaspiracid Poisoning (AZP) Toxin**

AZP is the most recently discovered toxic syndrome from shellfish consumption and several analogues belonging to this new class of toxins have been identified in contaminated mussels [91-93]. More than 20 analogues of azaspiracid AZA1 have been described in shellfish [92-95], which complicates the regulatory control of these compounds as most have not yet been toxicologically evaluated. Cytotoxicity studies using neuroblastoma cells showed that AZA1 disrupts cytoskeletal structure, inducing a time- and dose-dependent decrease in Factin pools. A link between F-actin changes and diarrhea has been suggested, which may explain the severe gastrointestinal disturbances during AZP outbreaks. AZPs have been identified in two dinoflagellates, *Protoperidinium crassipes* [94] and a new species, *Azadinium spinosum* [96].

Traditionally, the biosynthetic pathways for these complex compounds are elucidated by isotope labelled studies on cultured microorganisms [97, 98]. While these studies have not been able to comprehensively elucidate all involved biosynthetic pathways, they have provided great insights into the structural complexity of these compounds [98, 99].

### **4. DINOFLAGELLATE TOXIN SYNTHESIS**

Toxin-producing taxa do not seem to show a phylogenetic trend [102], which suggests multiple independent evolutionary origins for this capability, such as horizontal gene transfer or multiple losses of the capacity in descendants of a toxin-producing ancestor.

Paralytic shellfish poisoning toxins (PSTs) are a group of naturally occurring small heterocyclic guanidinium alkaloids. Saxitoxin (STX), as the basic form, is the most researched PST to date, and since its discovery in 1957 58 other analogues have been described [103] [104]. The STX synthesis pathway in dinoflagellates is elusive. It is hypothesized that PSTs are synthesized via a pathway involving arginine, SAM and acetate, and that the methyl group of SAM is incorporated into the final PST molecule (reviewed by Shimizu [105]). Therefore, SAM synthetase is likely to play a key role in STX biosynthesis. The expression of SAM synthase in the heterotrophic dinoflagellate *Crypthecodinium cohnii* is slightly upregulated in the G1 phase of the cell cycle [106]. Interestingly, this coincidence with higher saxitoxin production in this phase in *Alexandrium fundyense* [107]. Using degenerate primer sets in PCRs, homologs of SAM synthetase gene were identified in 11 dinoflagellate species [108], not all of which are PST producers. Studies by John et al. [109] and Wang et al. [110] identified all three genes involved in the initiation-step of STX biosynthesis, sxtA, sxtG and sxtB, in *Alexandrium fundyense* and *Alexandrium pacificum*, which are phylogenetically close to the cyanobacteria (Table 2). Additional genes involved in STX biosynthesis were identified in an *A. pacifi*cum transcriptome study, including sxtD, sxtS, sxtU, sxtH/T, sxt I, sxtL, sxtN, sxtX, sxtF/M and sxtP (Table 2). In the PST-producing cyanobacterium *Cylindrospermopsis raciborskii*, the STX biosynthetic pathway is encoded by more than 35 kb, which contains 30 catalytic functions in 26 proteins [sxtA(sxtZ)] (Table 2) (Figure 3). STX biosynthesis is initiated with arginine, SAM and acetate by a new type of polyketide synthase, followed by three heterocyclizations and various tailoring reactions to yield the numerous isoforms of STX [111]. A comparative phylogenomic analysis for toxic

and non-toxic strains of *Anabaena circinalis* and *Cylindrospermopsis raciborskii* revealed that nine of the 26 putative STX genes (Table 2) were horizontally transferred from noncyanobacterial sources. One key gene, sxtA, originated in STX þ cyanobacteria via two independent horizontal transfers followed by fusion [63]. Other evidence is provided through phylogenetic analysis, where the second key gene, sxtG, in dinoflagellates seems be similar to its ancestral gene in bacteria, actinobacteria and cyanobacteria [112]. Previous findings showed that the initial three genes, sxtA, sxtG and sxtB, have originated from proteobacteria before being transferred to cyanobacteria and further to dinoflagellates via HGT events [105, 113-115]. However, the toxin genes were modified significantly during this evolutionary process, resulting in higher GC content, conversion into monocistronic structure, generation of multiple copies, introduction of typical dinoflagellate spliced-leader sequences and eukaryotic poly (A) tails [112, 116].

Other dinoflagellate toxins are derivatives of polyketide. Essentially a polyether ring ladder (Table 1), the synthesis of polyketide requires sequential extension of the C backbone, which is catalyzed by a polyketide synthase (PKS) system. There are three types of PKSs (for review see Snyder et al. [117]; Monroe and Van Dolah [118]). Type I PKSs are large multifunctional enzymes in which several catalytic domains are located on a single protein (Fig. 4A). These functional domains may be used iteratively (fungal PKSs) or they can be arranged into modules with each module directing one round of chain extension (b-ketoacyl synthase [KS] domain) and post-condensation modifications (b-ketoacyl reductase [KR], dehydratase [DH], and enoyl reductase [ER]). Type II PKSs are multiprotein complexes of several individual enzymes, and are found only in bacteria that synthesize aromatic polyketides. Individual enzymes in type II PKSs are used repetitively for each cycle of chain extension. Type III PKSs are smaller PKSs (40-47 kDa) and are involved in flavonoid biosynthesis in plants and melanin in bacteria. Sequences of genes in several species of dinoflagellates that are similar to type I PKSs were first identified using PCR [117], for example *K. brevis*, the major producer of brevetoxin [119] and *Amphidinium* sp., which produces amphidinolides, a group of cytotoxins [120]. Subsequent screening of cDNA libraries revealed that while PKS sequences in *K. brevis* are similar to modular type I PKSs the organization of the genes resembles Type II PKSs, i.e., each functional 'domain' is present but is expressed as a separate protein [118] (Figure 4B). Using antibodies against peptides generated from deduced PKS amino acid sequences in *K. brevis*, Monroe *et al*. [121] found that protein abundance in the non-toxic substrain was 50-75% lower than in the toxic substrain although transcript abundance was similar between the two substrains. Furthermore, the authors found that the PKS proteins were localized to chloroplasts. This intracellular distribution is consistent with that of another polyketide toxin, okadaic acid (OA), in *Prorocentrum lima* and *Prorocentrum maculosum* [122]. This is particularly interesting, since the *Prorocentrum* spp. possesses peridinin plastids, whereas *K. brevis* possesses a haptophyte-type plastid. PKS genes from *P. lima* should be coded in the nuclear genome because the peridinin plastid only contains about 16 plastid genes, all related to photosynthesis. Presumably, PKS genes in *K. brevis* are also nuclear-encoded because their transcripts are SL trans-spliced [118]. These results will help determine the next directions to take to determine not only how brevetoxin is synthesized, but also its function within the cell.

Figure 3. Structural organization of the sxt gene cluster from *Cylindrospermopsis raciborskii* T3. Abbreviations used are as follows: SXT, saxitoxin gene; IS4, insertion sequence 4; ompR, transcriptional regulator of ompR family; hisA, two-component histidine kinase; orf24, ORF 4. The scale indicates gene cluster lengths in base pairs. From Kellmann et al. [111] and Lin [57].

Figure 4. Model of PKS transcripts in *Karenia brevis*. A) Typical modular type I PKS transcript encoding multiple catalytic domains on a single transcript that form modules. B) K. brevis PKS transcripts with the SL sequence at the 50 end and 1e2 catalytic domains per transcript. KS: ketosynthase, AT: acyl transferase, DH: dehydratase, ER: enoyl reductase, KR: ketoreductase, ACP: acyl carrier protein. (BeC) are from Monroe and Van Dolah [118] and Lin [57].

# **5. APPLICATIONS FOR DETECTION AND QUANTIFICATION OF TOXIC DINOFLAGELLATE**

The monitoring of toxic dinoflagellates is required by many countries to ensure the safety of fish and seafood intended for human consumption [130]. Microscopic identification and enumeration of dinoflagellate species are, however, very tedious and time-consuming. PSTproducing *Alexandrium* spp. can be particularly difficult in this respect, due to the morphological similarities to cryptic species that occur in the same habitat [109, 131]. To meet these challenges, numerous molecular tools are under development. These are mainly aimed to detect species with toxin-specific nucleic acids, using qualitative and quantitative PCR, and DNA-hybridization-based methods. Comparisons between methods for the determination of *Alexandrium* cell density indicated that these molecular methods facilitate the required sensitivity to monitor and discriminate between species in the field [132].

Several studies have shown that rRNA gene copy numbers can be highly variable [133- 136], which may lead to over- or underestimation of cell densities [132, 137]. Characterization of SXT genes facilitated the development of qPCR assays that identify PSTproducing strains [138-141]. Studies have shown that the copy numbers of SXT genes in genomes vary less when compared to rRNA genes, allowing for more accurate cell density estimates [128, 132, 140]. These assays have been successfully tested on toxic dinoflagellate strains in seawater [139-143], as well as in commercially harvested oysters [143].

The design of toxin-specific molecular assays for dinoflagellates was made possible by the identification of the first SXT genes utilizing EST data, and subsequent direct sequencing of the candidate genes [116, 124]. Qualitative screening for the presence of *sxtA1*, *sxtA4*, and *sxtG* genes in cultured dinoflagellate strains has revealed that they differ in the specificity of PST production. The results indicate that of these three target genes, *sxtA4* is the best predictor of toxin production [109, 116, 123, 125, 138]. Currently, there are five primer pairs available for qPCR and qRT-PCR assays as well as one locked nucleic acid (LNA)-based hydrolysis probe targeted for the dinoflagellate genes *sxtA1*, *sxtA4*, and *sxtG* in *Alexandrium* spp. and *G. catenatum*, respectively (Table 3). While the *sxtG* qPCR assay was 100% specific, a longer *sxtG* amplification product was obtained from four non-PST producing *Alexandrium* strains [144]. In the expression study by Perini *et al.* [145], only four *A. minutum* strains were analyzed, and assay specificity was not extensively addressed. The sensitivities of the different SXT assays cannot be directly compared, as they depend on the targeted nucleic acid, and the method of standard curve construction (Table 3).

The detection of toxic strains by sxt gene-based qPCR assays at low dinoflagellate concentrations in seawater, provides a means for early warning systems designed to identify developing harmful blooms. In the future, combining qPCR with other analysis methods such as meta-transcriptomics could provide even more information on the active metabolic processes related to toxin production throughout bloom events [146].

## **6. DINOFLAGELLATE BIOACTIVES: POTENTIAL APPLICATIONS**

Dinoflagellates are able to produce bioactive compounds with distinctive chemical structures, with a wide range of functional groups possessing various toxicological and biological features; macrolides, cyclic polyethers, spirolides and purine alkaloids are a few examples of such categories [98, 149]. Due to their variable structures, these biocompounds form a heterogeneous group that has the potential to strongly affect a variety of biological receptors and metabolic processes [150]. Hence, their potential pharmacological activities hold the promise of beneficial applications in human or veterinary medicine, i.e., in analgesic, antitumor, anticholesterol, cytotoxic, anti-infective, immuno-suppressive and/or neurological disease therapeutics [151].

#### **Table 3. qPCR and qRT-PCR assays targeted at dinoflagellate** *sxt* **genes**

Since STX blocks at site 1 of the sodium ion channel, saxitoxin has therapeutic potential as a potent blocker of nerve conduction that can produce prolonged anesthesia without myoand neurotoxic effects [152]. Diluted concentrations of the toxin produce a temporary paralytic state, which aids in the treatment of anal fissures and chronic tension headaches, which otherwise require longer durations of anesthesia. Studies have also concluded the synergistic potential of STX with other anesthetics. The synthesis of STX as a pharmaceutical could be lucrative, yet its potential systemic toxicity prevents the compound from passing clinical trials. BTX, a neuroagonist, increases the plasticity of neurons, revealing its potential for disease treatment such as apoplexy, neurodegeneration, and mucociliary dysfunction [153]. OA has inhibitory activities against serine/threonine protein phosphatase and can regulate intracellular signaling pathways, which opens up possible uses against Alzheimer's disease and other neurodegenerative disorders that are associated with memory impairment [154-156]. In addition, OA is a potent inhibitor of tumorigenesis, causing cell growth inhibition and apoptosis of lung and colon cancer cells, and may thus be an important candidate for anticancer drug screening [157, 158]. PTXs have demonstrated significant antitumor activities against human lung, colon, and breast cancer cells, and are considered potential chemotherapeutic molecules against p53-mutant type tumors [159-161].

#### **Table 4. Selected patents related to biotoxins produced by dinoflagellates and potential therapeutic uses. Table adapted from Assunção et al. [149, 164]**

Other interesting dinoflagellate-derived compounds, such as pigments (e.g., peridinin), fatty acids (e.g., PUFAs) and polysaccharides, may exhibit health benefits such as nutraceuticals, prevention of anti-proliferation and development of tumors, as well as antiinflammatory and antiviral activities [162, 163].

Due to their biological potential, and despite several difficulties in obtaining the minimum amounts of biotoxins for testing, several studies and patents encompassing applications of dinoflagellates, directly associated with biotoxins, have been published or filed (Table 4).

## **CONCLUSION**

Dinoflagellates are a diverse group of microalgae with numerous peculiar genetic features [165] that provide novel insights into their cellular processes [166]. Due to their immense sizes, no complete dinoflagellate genomes have yet been sequenced. Information on genomic structure mainly derives from analyses of the genomic sequences of individual genes. Coding sequences were largely obtained from cDNA and EST analyses. With the rapid advances in sequencing technology, the volume of dinoflagellate EST (transcriptomic) data has grown rapidly and can now span genome-wide, with affordable cost. Wholedinoflagellate genome sequencing is also on the horizon. However, the challenge lies in the bioinformatical assembly of sequenced bits into genes or chromosomes. As secondgeneration sequencing platforms are improving their read lengths (e.g., 454 GSFLX titanium promising 1 kb read length) and third-generation sequencing technology (e.g., single molecule sequencing promising  $>10$  kb read length) is emerging, these challenges may soon subside to some extent. In addition, advances in bioinformatics are continuously improving algorithms for genome assembly. The elucidation of genes involved in the biosynthesis of PSP toxin in dinoflagellates will provide new knowledge and a deeper understanding of the evolution and the origins of toxin-related genes in dinoflagellates. New insights on the genetic regulation of sxt gene expression will provide fundamental information about the STX biosynthesis pathway in dinoflagellates and cyanobacteria. In addition, the understanding of different environmental conditions that influence toxin production in dinoflagellates will also provide further insights into the ecophysiological aspects of the toxins. The development of targeted approaches, combined with advances in chemical identification of these toxic compounds, will allow us to address these issues and advance the discovery of the genetic basis and regulation of dinoflagellate toxins into the future. Dinoflagellate toxins and bioactives are potentially useful in many applications.

# **IMPACTS AND MANAGEMENT OF DINOFLAGELLATE HARMFUL BLOOMS**

## *Elisa Berdalet\**

Institute of Marine Sciences (ICM, CSIC), Barcelona, Catalonia, Spain

## **ABSTRACT**

This chapter summarizes the impacts caused by harmful blooms of some dinoflagellates that produce phycotoxins. Phycotoxins can contaminate seafood products causing poisonings in humans that consume them. To prevent human health diseases, harvesting and commercialization of the sea products is forbidden by law, resulting in important economic losses. Other species produce toxins that cause health problems due to direct contact with the water or inhalation of the aerosolized toxins. Wild and cultured fish and marine fauna may also be severely affected by some harmful blooms with subsequent economic problems. When blooms decay, bacterial degradation consumes oxygen and releases compounds, degrading water quality. Many blooms are natural processes; they cannot be completely avoided. However, some tools are available for the prevention, management and mitigation of the harmful blooms impacts. These include monitoring of the causative organisms and their toxins, sustainable use of the natural resources, and fundamental multidisciplinary research to predict occurrence of blooms. Information of the economic cost of impacts, prevention and mitigation strategies is a key element for the appropriate management of HABs. However, estimations of such economic studies are scarce and very difficult to obtain. In this document, economic data have been provided when available. A recent initiative to improve the understanding of the economic costs of harmful dinoflagellate blooms that could help to advance the comprehension of their costs and to mitigate their impacts is also presented.

## **1.INTRODUCTION**

Harmful Algal Blooms (HABs) caused by dinoflagellates can occur in freshwater, estuarine and marine waters. Dinoflagellate blooms are a natural phenomenon known from ancient times in all cultures. The eminent ecologist Professor Ramon Margalef in a plenary session at the VIII International Conference on Harmful Algae (ICHA) in Vigo, Spain in 1997 (Margalef 1998), observed:

"Alvar Núñez Cabeza de Vaca (1490?-1564), in his *Naufragios* (Ship-wrecks, Ferrando, 1984) composed between 1537 and 1549, referred to a place along the north coast of the Gulf of Mexico, probably not far from the present Apalachee Bay. He wrote that the indigenous people there did not know how to relate the passage of time to the movements of the Sun and the Moon, and used neither months nor years, but *they understand and know about the different periods in nature by observing when the fruits mature and when the fish die.* That is, native populations took as witness of the passage of time the return of the seasons marked by the death of fish, a mortality that could have been caused, then as nowadays, by the action of *Gymnodinium breve (=Karenia brevis)*."

Because the ICHA meeting was hosted by the Ría de Vigo (NW Iberian Peninsula), Professor Margalef referred to dinoflagellate blooms in this area that he had deeply studied in the 1950's (e.g., Margalef 1955; 1958):

"To people making a living around the Galician Rías, red-tides ("purgas de mar") are familiar events, traditionally compared with menstruation, through which process the local waters would be cleansed from time to time, most notoriously in autumn. It was general knowledge that it is not safe to eat shellfish gathered when the water has the reddish-brownish hue. I suppose that when mass cultivation of mussels in the Galician Rías came to be in the hands of relatively inexperienced developers, regrettable events of dispersal of mussels became more frequent, with one particular instance of autumn of 1976.

If red tides are compared with events of "acute illness," ciguatera may be described more appropriately as a "chronic situation," due to the persistence of benthic populations of active and toxic cells on well illuminated solid substrates, so long as nutrients are sufficient, under relatively steady conditions which prevail in warm seas. Species of *Gambierdiscus*, *Prorocentrum*, *Exuviella*, and *Ostreopsis*, occuring in such scenarios, are highly toxic. The fish contaminated by ingesting toxic algae are dangerous to humans who consume them. Serious consequences are perhaps less frequent than it could be feared. A considerable degree of familiarity with Caribbean fishermen convinced me that by observing subtle changes in aspect and behaviour they could recognize the individual fishes that had developed the condition of *ciguatos*, and discard them. Different fishermen did not always agreed exactly in the description and the relative importance assigned to the relevant criteria, but they tended to agree more about the list of fish species to which ciguatera appears locally to be restricted or, at least, most common. One is led to suspect that ichthyophagous species are also sensitive in some way to the condition of *ciguatos* in their potential prey."

Fukuyo et al. (2002) explained that

"In Japan, one of the old historical books entitled "The History of Great Japan" (Dai Nippon Shi), edited more than 300 years ago, described 16 cases of red tide, seven in freshwater and the rest in the marine environment. The oldest was an occurrence in 731 AD. A case that occurred in 1234 AD was reported to cause fish mass mortality and human fatalities after eating fishes.

In some fishing villages in northern Japan, warning about possible toxin contamination might be passed on from ancestors and known among elderly local fishermen. There are several traditional folk tales such as "Do not eat shellfish during snow water runoff into the sea," i.e., it warns that shellfish may become inedible in early spring. After modern aquaculture developed, fishermen tried to sell their products year round but closure of marketing happens often in the spring. Thus we notice the wisdom from the experience that led to the folk tale. Perhaps this indicates that toxin contamination of shellfish has repeatedly occurred almost every year over a long time, leading to many tragedies among the local people. (The Canadian fishermen's warning "not to eat shellfish harvested in the month with no R May to August)."

This illustrates examples of harmful dinoflagellate (and other microalgal) blooms with multiple human health, economic and ecological impacts. In fact, the problems associated to dinoflagellate blooms vary with the species and depend on the combination of i) the biomass level reached during the bloom, ii) the production of toxins directly affecting human health through different vectors (food-borne, water-borne, air-borne), iii) the effects on other aquatic organisms and iv) the duration and spatial dimension of the bloom. Thus, a priori, evaluating the human health, social, economic and ecological cost of dinoflagellate blooms will have species-specific and site-specific components. In this book, paradigmatic dinoflagellates causing blooms are described in detail and provide the necessary information to point out their negative effects (illustrated in Figure 1), namely:

1. *Karenia brevis* synthesises brevetoxin and analogues, and produces high biomass toxic blooms particularly in the Gulf of Mexico, East China Sea, and New Zealand waters. *K. brevis* blooms have a negative impact on:

- Human health, primarily via the consumption of shellfish contaminated with toxins causing neurotoxin shellfish poisoning (NSP), and also respiratory irritation by inhalation of aerosolized toxins;
- Macrofauna, due to brevetoxin bioaccumulation and transfer through the food webs causing massive mortalities of fish, marine mammals, birds, macroinvertebrates, etc.;
- Water quality through discoloration due to high *K. brevis* biomass, which limits light availability to aquatic photosynthetic organisms and thus alters  $O_2$  and  $CO_2$  levels with cascading impacts in the food webs;
- The overall ecosystem when the bloom decays, due to  $O<sub>2</sub>$  depletion (hypoxia) associated to the bacterial degradation;
- Economy, due to i) closures of shellfish extraction and losses on professional and recreational fishing activities or aquaculture, ii) tourism disturbance in the bloom affected areas due to unpleasant odour during and after the bloom decay, iii) overall damage in the environment.

## 4028 *Elisa Berdalet*

2. *Dinophysis* spp. producing low biomass toxic blooms in general (Campbell et al. 2010, Alves and Mafra 2019), synthesize okadaic acid and analogues and pectenotoxins. *Dinophysis*  spp. blooms occur worldwide and impact:

- Human health, via the consumption of contaminated shellfish causing diarrheic shellfish poisoning (DSP);
- Shellfish industry, due to closures of shellfish extraction.

Figure 1. Multiple impacts on the environment and human health caused by dinoflagellate blooms. A. Massive fish kills by ichthyotoxic species, decrease in water quality (light availability, oxygen levels), respiratory problems by aerosolized toxins, contamination of food products by toxins produced by plankton and benthic species. B. Biotoxins bioaccumulation and transfer through the food webs causing seafood borne poisonings in humans. DSP, PSP and ASP occur due to consumption of contaminated shellfish, while different fish species are involved on CFP and palytoxicosis.

3. *Pyrodinium bahamense* var. *compressum* a tropical organism that synthesises saxitoxin and analogues and produces high biomass toxic blooms with impacts on:

- Human health, via the consumption of contaminated shellfish (also some crustaceans and fish) causing paralytic shellfish poisoning (PSP);
- Economy, due to closures of shellfish extraction.
- Macrofauna, by cuasing mortalities on marine mammals, sea turtles, etc.

4. *Gambierdiscus* spp. tropical benthic dinoflagellates (grown attached to live and dead corals, macroalgae, sand, rocks) producing ciguatoxins, whose blooms do not always reach high cell numbers, having impacts on:

- Human health, via the consumption of coral reef fish and some shellfish, contaminated with ciguatoxins causing ciguatera fish poisoning (CFP);
- Economic impacts on personal incomes due to chronic neurologic symptoms that persist for months, impairing working activities;
- Social disruption of fish eating habits to avoid local fish consumption, including loss of traditional fish related jobs.

5. *Noctiluca* spp. this non-toxic heterotrophic dinoflagellate (feeds on microorganisms) causes high biomass blooms resulting in:

- Decrease in water quality due to i) discolorations that limit light availability to aquatic photosynthetic organisms and thus alter  $O_2$  and  $CO_2$  concentrations with cascading impacts in the food webs, and ii) to subsequent reduction of  $O_2$  by bacterial degradation of the organic matter (BOD) when the bloom decays;
- Economic losses for the tourist industry that avoids low beach water quality (affected also by bad odours during the senescent phase of the blooms), although *Noctiluca* natural bioluminescence may also constitute a touristic attraction in some places.

Following a description of the various impacts of harmful dinoflagellate blooms, key tools available for prevention of occurrence of HABs and for management and mitigating their impacts, including their cost when possible, are discussed. The chapter details information on the economic cost of impacts, prevention and mitigation, which are the key elements for the appropriate management of HABs. However, these data are scarce and difficult to obtain. A final section briefly presents a recent initiative to improve the understanding of the economic costs of harmful dinoflagellate blooms that could help to advance the comprehension of their costs and mitigate their impacts.

## **2.IMPACTS OF HARMFUL DINOFLAGELLATE BLOOMS**

This section summarizes the main impacts caused by harmful dinoflagellate blooms and, when possible, information on their economic costs. Note that the monetary numbers are copied from the original citations, without any conversion to the current year.

#### **2.1. Direct Impacts on Human Health**

Toxic dinoflagellate blooms can impact human health mainly through:

- I. Consumption of seafood contaminated with toxins that have bioaccumulated through the food webs (Figure 1). For example, *Dinophysis*, *Alexandrium*, *Gymnodinium catenatum* or *Karenia* are ingested by cultured or naturally growing filter feeders (mainly shellfish) that bioaccumulate the phycotoxins, causing diarrheic- (DSP), paralytic- (PSP) or neurotoxic (NSP) shellfish poisonings in humans (Table 1). *Gambierdiscus* and *Ostreopsis* grow attached to corals or macroalgae (mainly in the tropics), that are grazed by small fish which, in turn, are consumed by other carnivorous fish; by eating different fish species considered to be within the (not well understood) food webs, humans can suffer ciguatera fish poisoning (CFP) or palytoxicosis (intestinal injuries) (Table 1).
- II. inhaling aerosolized biotoxins produced by *Karenia* and *Ostreopsis* (Figure 1, Table 1).

## **Table 1. Main poisoning syndromes, toxins involved, dinoflagellates toxin producing taxa, main vector and a few selected references that contain more detailed and specific information**

Humans exposed to dinoflagellate-produced phycotoxins can experience different clinical syndromes characterized by non-specific acute symptomatic modes (Table 1). In developed countries, health infrastructures are ready to effectively assist the most common HAB-related poisonings, i.e., PSP, DSP, NSP, Azaspiracid Shellfish Poisoning (AZP) and Amnesic Shellfish Poisoning (produced by some species of the diatom genus *Pseudo-nitzschia*). Given the efficient monitoring of toxins and toxic organisms implemented there, the real incidence of poisoning is relatively low, although unexpected intoxications from new and emergent toxins can occur. From 1970 to 2010, these four shellfish poisonings accounted for about 4000 cases reported worldwide (Visciano et al*.* 2016). These data are still to be updated. This is partly due to the non-specificity of the symptoms related to phycotoxin poisonings, which can be misdiagnosed with viral or bacterial food poisonings, and thus underreported except during exceptional outbreaks and when testing specifically for okadaic acid or dinophysistoxin (e.g., Taylor et al. 2013). Detailed and updated information on dinoflagellate toxins and the associated human poisonings can be found for instance in Vilariño et al. 2018. This overview also indicates potential, but still poorly known, threats due to chronic exposure to phycotoxins. It also highlights the variety of toxin analogues lacking standards and the current limitations of existing data to improve consumer´s protection from a toxicological point of view.

*K. brevis* blooms along the Florida coast of the Gulf of Mexico are one of the best studied cases concerning their associated health costs. A review of the intensive and costly interdisciplinary and inter-agency research conducted over 10 years in the US to understand the ecology, toxicology, early warning detection, modelling, impacts on public health, economic cost, etc. of *K. brevis* blooms can be found in Fleming et al. 2011. Direct medical care costs associated with the respiratory and digestive illnesses ranged from 0.1 to 0.7 million USD annually (Hoagland et al*.* 2009; 2014) and up to 1.0 million USD per year for large, long-lasting blooms (such as one occurred during 2005-2006).

CFP is a threat to public health in most tropical areas, and it is the most widespread and best-described (non-bacterial nor viral) seafood poisoning in the Pacific and the Caribbean (e.g., Friedman et al*.* 2017, and references therein). During 1973-83, in the 17 Pacific Island Countries and Territories, the Health and Fisheries Authorities (Skinner et al*.* 2011) estimated a mean annual incidence of 104 cases per 100,000 people across the region. In Moorea, the second most populated island in French Polynesia, with a high number of regular fishermen, the mean incidence rate was 8 cases per 10,000 inhabitants on 2007–2013 with a 54% average of underreporting rate (Morin et al*.* 2016). Taking into account hospitalization and medication fees, and loss of productive days, the health-related costs due to CFP were estimated to be USD \$1613 and \$749 for each reported and unreported case, respectively, with an overall cost of USD \$241,847 for the study period.

Indeed, the real extent of CFP is also unknown due to under-reporting and misdiagnosis (Radke et al*.* 2015). The most important challenge to cope with CFP is developing a reliable, cost-efficient and easy to use method to detect ciguatoxins in seafood products to be applied by the local people in the tropical areas, because CFP has associated economic and social impact, and because the monitoring of benthic dinoflagellates and their toxins is complex (see the Monitoring 3.1. section). Furthermore, in recent years, CFP is becoming an emerging issue in non-tropical, non-endemic areas, given the increase in trade and tourism (Epelboin et al*.* 2014; Mattei et al*.* 2014). For instance in Canada, CFP cost was estimated at about 2,470 CAD per case, with about 1,000 cases per year related to tourism and food imports in 1990 (Todd, 1995; Fleming et al*.* 2002). More recently, CFP cases have been reported in subtropical zones, such as the Canary Islands (Pérez-Arellano et al. 2005), where this illness had not been previously documented. The presence of *Gambierdiscus* species seems to be

spreading to temperate waters, including the Mediterranean, likely due to global warming (Bravo et al*.* 2019; Fernández-Zabala et al*.* 2019; Tudó et al*.* 2018).

#### **2.2. Losses in Shellfish and Finfish Aquaculture**

The contamination of seafood products by dinoflagellate toxins results in closures of commercial and recreational harvesting or growing areas in order to prevent risks to human health. In many countries, law establishes bans on harvesting the toxic species and/or when their biotoxins are detected above species-specific alert levels in the production areas. Closures have negative impacts on the producers as well as related industries (processing, distribution, product shipping, and selling) (e.g., see details in Guillotreau et al. 2017; Adams et al*.* 2018), at least over a short term. For instance, in Japan, temporary workers employed to ship bivalves, such as scallops, actually lose their jobs during the period of quarantine (Imai et al. 2014). Fish killing algae (FKA) including dinoflagellates (*Cochlodinium*, *Karenia*, *Heterocapsa, Alexandrium catenella*, *Karlodinium veneficum*, *K. australe*) and other microalgal taxa (*Pseudochattonella verruculosa, Chattonella marina, Prymnesium / Chrysochromulina*, *Pseudochattonella / Vicicitus, Heterosigma*) can massively affect natural and cultured fish causing important negative impacts. Economic loss is also due to reluctance by consumers to buy seafood products during the HAB events.

Although estimating the economic cost of HABs is difficult, in part for confidentiality reasons, scientific collaboration with aquaculture and fishing companies is facilitating a better understanding of the problem. As an example, the Workshop on Economic Costs of Harmful Algal Blooms on Fisheries and Aquaculture, hold during the North Pacific Marine Science Association (PICES) 2013 Annual Meeting in Nanaimo, Canada (Yoshida and Trainer 2014), detailed the information about the economic and social impacts of HABs in the eastern and western Pacific by PICES and UN-NOWPAP (Northwest Pacific Action Plan) researchers. A summary of the main reports of economic cost of harmful dinoflagellates is included next (Table 2), but the readers are invited to download the Report freely available from the PICES website https://meetings.pices.int/publications/scientific-reports). Detailed information is given on potential impacts in the Russian east coasts (Orlova et al. 2014) and impacts on shellfish closures due to *Pseudo-nitzschia* blooms in the Pacific coast of the US, Washington State (Huppert and Trainer 2014).

Haigh and Esenkulova (2014) discussed that in 1999 the first recorded bloom of *Cochlodinium* sp. caused fish mortalities with approximately \$2 million CAD in losses in British Columbia, Canada (Whyte et al. 2001). Microalgal cells produce direct physical damage or irritation of gill tissue or are ichthyotoxic, and the massive blooms result in oxygen limitation (Rensel and Whyte 2003). However, finfish flesh does not become toxic to humans. The impacts on farmed fish constitute an indicator of how HABs could also affect the health of wild fish, much more difficult to monitor, and the environmental conditions.

In Japan, PSP and DSP events caused the complete closure of shellfish harvesting in the 1980s, resulting in dramatic economic impacts (more than 100 milion JPY) (Fukuyo et al*.* 2002). Concerning fish kills (Itakura and Imai 2014), the most severe events from 1972 to 2012 were due to *Chattonella* (*C. antiqua/marina/ovata* complex) blooms, with economic impacts of 7.1 billion JPY (approximately 73 million USD that year). Also, intense fish kills were caused by dinoflagellates such as *Karenia mikimotoi* in 1984 (4.6 billion JPY), 1991

(1.5 billion JPY) and 2012 (1.3 billion JPY), *Herocapsa circularisquama* in 1992 (3.0 billion JPY) and *Cochlodinium polykrikoides* in 2000 (4.0 billion JPY).

## **Table 2. Some of the most negative impacts of dinoflagellate blooms mentioned in this document, documented in detail in Trainer, and Yoshida (2014). Note that, for comparison and given their magnitude, non-dinoflagellate HAB events have been included**

In China, more than 330 HAB events were reported over approximately  $52,777 \text{ km}^2$ annually from 2008 to 2012, with a total direct economic loss of nearly 2.23 billion CNY (364 million USD) (Guo et al. 2014). The dinoflagellates involved in harmful events include *Karenia mikimotoi* and *Cochlodinium geminatum*, *Noctiluca scintillans* (non toxic, high biomass, NH<sup>4</sup> production impacting in the ecosystem), and *Prorocentrum donghaiense* (non toxic, high biomass, fish kills). Since 2006, *Cochlodinium* blooms are increasingly affecting the coast of China with high impacts on aquaculture fish up to 3.2 million CNY (0.52 million USD). In 2012, *K. mikimotoi* caused massive abalone kills with a direct economic cost of more than 2 billion CNY (330 million USD).

In Korea (Lee et al*.* 2014, and references there in), HABs have become more frequent since the 1990s. Fish kills have been caused by blooms of *Karenia mikimotoi* (1981) and *Gyrodinium* sp. (1992) with fisheries losses of 1.7 and 5 million USD, respectively. *Cochlodinium polykrikoides* recurrent and annual blooms caused fish kills with fisheries losses of 7 million USD in 1993 and 60 million USD in 1995 (the largest fish kill). Through the 2000s and 2010s, *C. polykrikoides* was the single most important fish killing species causing damage to aquaculture farms in Korea.

In the highly productive Galician (NW Iberian Peninsula) ecosystem, shellfish production accounting for about 0.2-0.3 million tonnes of mussels (*Mytilus galloprovincialis*) per year is mainly threatened by DSP, and to a lesser extent by PSP producing dinoflagellates and domoic acid produced by diatoms (*Pseudo-nitzschia* spp.). *Dinophysis* blooms may result in harvesting bans up to nine months in hot spot areas, whenever DSP biotoxin levels exceed European Union regulatory thresholds. Similar situations occur in western Ireland, western Scotland and Atlantic coast of France (see e.g., Blanco et al*.* 2005; 2013).

In Southern Chile, the worst reported bloom of *Alexandrium catenella* in terms of geographical extension and affected species, occurred in the late summer of 2016 (Guzmán et al. 2016, Álvarez et al. 2019). The event spread along the Pacific Ocean coastal zone from the southernmost of the Chiloé Archipelago (43º50' S) to Mehuín, Los Ríos Region (39º25' S). The bloom, occurred in the late summer, caused human intoxications (12 people were affected) and dramatic socioeconomic impacts for more than a thousand fishermen in the affected area because of the banning of shellfish harvesting from the involved natural beds. The bloom massively affected marine fauna (see section 2.5).

#### **2.3. Societal Losses: Tourism and Culture**

Coastal tourism may be specially affected by high biomass algal blooms, either toxigenic or innocuous. Beaches can be unpleasant to tourists due to high accumulations of foam (consisting on microalgal cells and excreted carbohydrates and proteins) at the surface, water colour changes due to the microalgal pigments (red, brown, green), noxious odors from compounds released by the microalgae (in particular Dimethylsulfoniopropionate - DMSP) or from bacterial decomposition when the bloom decays. Exploitation of coastal resources includes recreational shellfish (oysters, scallops, clams, mussels, crabs, or marine snails) collection and fishing, which can be forbidden when microalgal toxic blooms or massive fish kills occur. In the tropical and subtropical areas, expansion of CFP may constitute a problem for touristic activities in the future.

However, nowadays data on the economic costs of HABs on tourism, most of them just rough approximations, are rare so that conclusions cannot be drawn yet. A brief discussion of the challenges to conduct these studies can be found in Berdalet et al*.* (2015) and more technical details in Adams et al*.* (2018). Here, as an example, the research conducted on *Karenia brevis* blooms impacts in Florida (Morgan et al*.* 2010) is summarized. The authors studied how and why participation in marine-based activities (beach-going, fishing, and coastal restaurant patronage) could be affected during a red tide. Using a sample of residents in Southwest Florida, participant choice models for each activity were estimated to determine the likelihood of alternate behavioral decisions during a red tide event. Factors influenced by extension activities appeared to have a larger impact than socioeconomic factors commonly hypothesized to affect individual response behavior. Overall, the survey suggested that while some local activities may have direct negative impacts, change in behaviour of the tourists and residents may benefit others.

Furthermore, Morgan et al*.* (2009) estimated monetary losses that some businesses may have suffered due to *K. brevis* blooms. From three beachfront restaurants, daily proprietary data along 7 years were combined with environmental data from nearby weather stations. Using statistical models, the study revealed that reductions in daily sales ranged from \$868 to \$3734 (13.7%–15.3% on average) during bloom conditions, which were similar to losses due to other environmental events. The economic incidences occurred when *K. brevis* cell concentrations were ca.  $181x10^3$  cells/liter within 6 miles near the restaurants. The authors concluded that this value could constitute a threshold cell count for future localized economic losses projections.

Socio-cultural changes can also occur due to HABs. A paradigmatic case is CFP. To avoid CFP, Pacific islanders have been reducing traditional fishing and consumption of coral reef fish (Dewailly et al*.* 2008) and increased eating imported, canned fish or red meat. In Rarotonga (Cook Islands), with the highest CFP incidence the per-capita fresh fish consumption decreased from 149 g/day in 1989 to 75 g/day in 2006, concurrent to the increase in obtention of alternative proteins, particularly imported meat. The direct loss in value of marketable goods from commercial fisheries amounted to 0.8 million NZD (about 0.5 million USD) per year, and the approximate costs associated with dietary shifts to 1.0 million NZD (about 0.7 million USD) per year. After a decline in cases of CFP cases in recent years, fresh fish has returned to Rarotonga diet, and per-capita fresh fish consumption increased to 104 g/day in 2011.

#### **2.4. Losses on Desalination Plants**

In 2008 and 2009, a dense bloom of the ichthyotoxic dinoflagellate *Cochlodinium polykrikoides* in the Arabian Gulf and Gulf of Oman that lasted for more than eight months forced the halt of operation of at least five seawater desalination plants in the United Arab Emirates (UAE) (Richlen et al*.* 2010; Anderson and McCarthy 2012). Algal biomass clogged the filtration systems and reverse membranes in the desalinization process. In this case, the high biomass bloom resulted in the disruption of water production and significant economic losses.

An additional risk is posed by the removal of small (300 - 900 Da) HAB biotoxins (saxitoxins, brevetoxins and domoic acid). Laboratory tests and a 5-year monitoring of an operational plant in California (Seubert et al*.* 2012) confirmed that the osmosis membranes can efficiently remove these small toxins, provided they had no micro-fissures such as those produced by high pressures when they are clogged.

The increase in drinking water supply from desalination systems worldwide requires to carefully studying the potential risks posed by HABs and at least, conduct preventive monitoring around the plants.

#### **2.5. Impacts on Marine Organisms**

Section 2.2 considered only the economic impacts of fish mortalities and shellfish extraction bans. The direct effects of HABs on fish and shellfish and marine fauna with noncommercial value are briefly presented in this section.

Fish killing algae (FKA) produce lytic compounds that damage fish gill tissues causing death from suffocation (e.g., Deeds et al. 2002, Lim et al. 2014). However, the particular impairment mechanisms are still poorly understood. For instance, *Cochlodinium polykrikoides* ichthyotoxicity depends on viability of cells and direct physical contact between fish and cells is not required to cause mortality (Tang and Gobler 2008). Shin et al. (2019) found significantly elevated levels of DNA damage in gill tissue exposed to 1,000 and 3,000 *C. polykrikoides* cells/mL. The study suggested that one of the major mechanisms mediating *C. polykrikoides* induced devastation in aquaculture and fisheries would consist on increases in the activity of the antioxidant defense system and DNA damage. Still, more work should be done using the latest technologies available to understand key questions on FKA blooms. With the aim to progress in the subject, an Advanced International Colloquium and Technical Workshop was held in Puerto Varas, Chile, 8 – 11 October, 2019, under the auspices of IOC-IPHAB and GlobalHAB (http://www.globalhab.info/activities/globalhabactivities), with the support of the government of Chile through CORFO and collaboration of CREAN-IFOP. Participants reviewed the state-of-knowledge, main gaps and challenges to develop strategies for technological and scientific approaches to mitigate impacts. Publication of the main conclusions and a road map for research in the coming years will be available soon.

Marine organisms and ecosystems may experience lethal or harmful effects when exposed to certain HABs as well. Massive mortalities associated to blooms of FKA are the most known events, because they often affect commercial aquaculture sites. However, effects on wild fauna and ecosystems are more difficult to be detected, especially at low trophic levels and plankton food webs (e.g., Li et al. 2017). When visible, these impacts are perceived as a degradation of ecosystem services potentially leading to passive value losses.

In the natural ecosystems, high biomass and toxic microalgal blooms could be involved in about 50% of the mass mortalities of wild fauna (turtles, dolphins, manatees, whales, birds (e.g., Scholin et al*.* 2000), according to the US National Oceanic and Atmospheric Administration (NOAA). For instance, mortalities of sand eels (*Ammodytes* spp.) and an estimated 80% of the breeding population of shag (*Phalacrocorax aristotelis*) in 1968 coincided with a bloom of *Alexandrium tamarense* off the northeast coast of the United Kingdom (Adams et al*.* 1968; Coulson et al*.* 1968). Saxitoxins (White 1984, references in Amaya et al. 2018) were associated to four cases of fish kills, deaths of 19 humpback whales and likely to the deaths of pygmy, dwarf sperm, and North Atlantic right whales off Cape Cod (USA), as well as Southern right whale mortalities in Peninsula Valdés (Argentina). In the coast of El Salvador, PSP events are recurrent and have been associated to the death of turtles reported since 2005 (Amaya et al. 2018), based on combined analysis of paralytic shellfish toxins (PST) in the animals and phytoplankton monitoring *in situ* and by MODIS-Aqua satellite. Extensive marine bird mortality by hypothermia in the Pacific Northwest (Monterey Bay, California, USA) in winter 2007 was caused by a bloom of the non-toxic dinoflagellate *Akashiwo sanguinea* that produced high amount of foam containing surfactant-like proteins

accumulated at water surface and destroying the waterproofing and insulative characteristics of the bird feathers (Jessup et al*.* 2009).

In Southern Chile, the exceptional bloom of *Alexandrium catenella* occurred in 2016 caused the mortality of vertebrates, including sea lions (*Otaria flavescens*), seagulls (*Larus dominicanus*) and dogs. The toxic episode resulted in the largest invertebrate massive mortalities ever recorded in Chile (Álvarez et al. 2019). Organisms mostly affected were crustaceans (*Austromegabalanus psittacus* and *Romaleon polyodon*) and mollusks (*Mesodesma donacium* and *Gari solida*). High and variable levels of PST were found in different tissues of *M. donacium* that also exhibited different degree of histopathologies. It was hypothesized that the mortality of the surf clam was an indirect effect of PST-induced paralysis hampering clams to burrow and thus leading to death by desiccation. In this case, massive and sudden mortality suggested that clams had not been previously in contact with PST, so that toxin resistance mechanisms had not been developed. Monitoring records indicating that previous and recurrent PST events had not occurred in the area supported this hypothesis.

Studies in molecular technology are rapidly shedding light on the mechanisms of detoxification, resistance and biotransformation of exogenous compounds activated in bivalves after being exposed to HAB toxins (e.g., Rolton et al. 2016). As an example, Prego-Faraldo et al. (2019) recently described the transcriptome and gene expression profiles of the mussel *Mytilus galloprovincialis* digestive gland and gills exposed to *Prorocentrum lima* (okadaic acid -OA- producer) cell concentrations corresponding to the early stages of the blooms. The first and fast responses of the mussel tissues involved defense, immunity and metabolism genes. The expressed genes were to some extent unspecific, which can indicate the rapid protective response of the mussels to OA. Similarly, Chi et al. (2019) presented the inmune- and detoxification-associated genes involved on the resistance to OA exposure by bay scallop. These studies can explain lack of lethal or acutely toxic effects of *A. catenella* to Northern scallops (Hégaret et al. 2012). However, combined to other stressors, relatively low *A. catenella* cell density could modify the susceptibility of scallops, to both parasites and predators. In turn, impacts on scallops could have effects in the benthic communities, as scallops are a preferred food source for sea stars and crabs.

Since the end of the 20<sup>th</sup> century, blooms of the benthic dinoflagellate *Ostreopsis* have been linked to damage to marine fauna (i.e., mussel mortalities, loss of spines and death of sea urchins, loss of one or more arms in sea stars, and coral bleaching) and subsequent alterations of the coastal ecosystems (e.g., in the Mediterranean, Brazilian -Rio de Janeiro -, and New Zealand - norteastern shallow reefs- coasts) (Simoni et al*.* 2003; Shears and Ross 2009) in temperate waters. Oxygen depletion seems to be the most likely cause of the observed effects given that rusty-brown coloured mucilaginous films containing high *Ostreopsis* cell densities covered the benthos. The fact that palytoxin analogues (i.e., ostreocin and ovatoxin) produced by *Ostreopsis* have been isolated from certain macrofauna in certain Mediterranean sites, suggests a plausible direct toxicity to the fauna and potentially to humans (Aligizaki et al*.* 2008; 2011; Amzil et al*.* 2011; Biré et al*.* 2013).

## **3. PREVENTION, MANAGEMENT AND MITIGATION**

#### **3.1. Prevention: Monitoring and Scientific Research**

As already mentioned, monitoring programmes on harmful species and their toxins in seafood and in the production areas have been successful in protecting human health (e.g., Davidson and Bresnan 2009) and reducing economic costs by e.g., limiting any shellfish harvesting closures to the minimum time needed. As an example, in the Pacific coast of the Washington State, US, phytoplankton monitoring provided by programs such as ORHAB and SoundToxins helped reduce the number of beach closures to shellfish harvesting (Huppert and Trainer 2014). The economic balance of less closures exceeded the 150 thousand USD cost of monitoring HABs. Also, the study revealed that razor clam diggers were willing to pay 625 thousand USD to avoid frequent closures of the recreational fishery. Thus, the established monitoring systems should be maintained, reinforced and improved with new technologies. In developing countries and in transition economies, monitoring is very rudimentary, or even absent concerning goods consumed by the local population, but monitoring efforts focus on exportation to other countries.

Monitoring tools include:

- Light microscopy. It is the most widespread monitoring tool for harmful algal species. Although it is time consuming and requires specialized training and expertise, it is relatively cheap and effective as an early warning of the likely occurrence of a harmful event. Thus, training of microscopists in the identification and quantification of biotoxin-producing species should be maintained and supported worldwide.
- Quantitative biomolecular tools can facilitate monitoring, and progress have been achieved in the last years in order to track and enumerate the long and diverse list of harmful microalgae. Still, molecular tools are incipient and expensive for most monitoring agencies.
- Biotoxins monitoring in seafood or in the environment is necessary because the presence of harmful microalgal species in the water is not always linked to toxicity in seafood. For example, toxic and non-toxic species can occur simultaneously (e.g., Touzet et al*.* 2010), or some toxic organisms are not always efficiently detected by microscopy due to their fragility when preserved or their small size (as in the case of *Azadinium* species e.g., Tillmann et al*.* 2009). Also, their patchy distribution difficults their sampling (Escalera et al. 2012). However, toxin analysis is limited in itself, partly because some biotoxins may be present in complex mixtures and matrices (animal tissues), associated to unexpected vectors, below detection levels for common analytical instruments, or difficult to get quantified due to the lack of pure toxin standards. This is especially problematic in the case of ciguatoxins or of some emergent toxins, such as tetrodotoxin, fast acting cyclic amines (gymnodimine, spirolides, pinnatoxins) (FAT toxins), and ß-N-methylamino-L-alanine (BMAA). For these technical reasons, mouse bioassays have been a fast tool for years and the standard method to detect the presence of toxins in potentially contaminated seafood, although the method has other technical and ethical issues (Hess et al*.* 2006). New

approaches are nowadays being explored and implemented including non-animal alternatives, i.e., cell tissue cultures (Van Dolah et al*.* 2012), biosensor systems (Campbell et al*.* 2014, and references therein; Dechraoui-Bottein and Clausing 2017), and passive capture of biotoxins by resins (MacKenzie et al*.* 2004). As discussed in Berdalet et al*.* 2015 "*The large number of compounds that need to be detected and an inability to validate new tools for detection mean that many monitoring agencies will need to continue to rely on either insensitive (and ethically questionable) mouse bioassays or on comparatively complex and expensive LC-MS/MS detection methods, neither of which can be implemented in situ.*"

- Automatic devices developed to facilitate frequent sampling of microalgae and biotoxins. Two successfully tested instruments are the Environmental Sample Processor (ESP) (Scholin et al*.* 2009) and the Imaging Flow Cytobot (IFCB) (Olson and Sosik 2007). The ESP collects and processes water samples *in situ*, using sensitive and specific molecular assays to detect target HAB cells and toxins, and transmitting the data to the laboratory in near real time. The IFCB is an imaging flow cytometer that captures the high-resolution images and fluorescence characteristics of all plankton cells (in the  $5-150 \mu m$  size range) at a high frequency (3 samples per hour); the data can also be sent to a laboratory in near real time (e.g., Campbell et al*.* 2010). Nowadays, these instruments are improving the scientific understanding of HABs dynamics, but are still too expensive to be widely used in monitoring programs.
- Artificial substrates for a low cost, efficient and standardized sampling method for benthic harmful species (e.g., *Gambierdiscus, Ostreopsis, Prorocentrum lima*) are under development and being tested by different researchers (Fernández-Zabala et al*.* 2019; Jauzein et al*.* 2016; Tester et al*.* 2014), which will help to detect CFP causing organisms.
- In addition to monitoring for microalgae and their toxins, it is necessary to sample physical (temperature, salinity) and chemical (nutrients, oxygen) variables to better understand the dynamics of the harmful blooms and develop site-specific forecast models. This knowledge constitutes an added value of monitoring as early warning systems and helps in the adaptation of each particular monitoring to detect natural and antropogenic changes in the aquatic environment, including those attributed to climate change. A successful example constitutes the ASIMUTH (Applied Simulations and Integrated Modelling for the Understanding of Toxic and Harmful algal blooms) project (e.g., Maguire et al. 2016) aimed to develop short-term HAB alert systems for Atlantic Europe. ASIMUTH used information on the most current marine conditions (weather, water characteristics, toxicity, harmful algal presence etc.) combined with high-resolution local numerical predictions (Aleynik et al. 2016). As noted by Maguire et al. 2016, on one side, "*the integrated, multidisciplinary, trans-boundary approach to the study of HABs developed during ASIMUTH led to a better understanding of the physical, chemical and ecological factors controlling these blooms, as well as their impact on human activities.*" Multidisciplinary data combined with modelling allowed the development of an alert system that it is, nowadays, facilitating an effective management of areas usually associated with HAB events and diminish their negative impact on human activities.

#### 4040 *Elisa Berdalet*

Nowadays, weekly prediction maps on the occurrence of HABs enables aquaculture professionals to adapt their working practices in time to prevent mortalities in finfish farms and/or manage their shellfish harvest more effectively.

The costs of monitoring should be evaluated in each area. Bernard et al*.* (2014) estimated the total cost of monitoring worldwide on the order of 1 billion USD annually. This value would correspond to 10% of the overall costs of HABs, estimated to be at 10 billion USD annually for marine and freshwaters. Satellites, which are used to detect and track high biomass blooms such as those of *Karenia brevis*, could also help monitoring in other areas. International cooperation in the collection, interpretation, and sharing of Earth observation information, as conceived by the Global Earth Observation System of Systems (GEOSS) (Fritz et al*.* 2008) is necessary. As an example, efforts are undertaken nowadays to integrate the HABs monitoring to the wide Ocean Observing Systems (Anderson et al*.* 2019).

### **3.2. Management and Mitigation**

Because HABs are natural phenomena, they cannot be completely avoided. However, a good understanding of their dynamics can help to predict their occurrence and thus prevent or mitigate their impacts. This understanding, coordinated with efficient monitoring of the harmful organisms and their toxins is, so far, the most proven tool to manage the risks posed by HABs occurrence. In addition, certain anthropogenic forcings on coastal ecosystems (eutrophication, harbour and artificial beach construction, fishing intensity) and global warning are also contributing to the observed increased trend of some HAB events intensity and frequency (Wells et al. 2019). An efficient management is essential to decrease the risk of HAB occurrences and minimize their impacts. See Anderson et al*.* (2012) for a review.

Management strategies or programmes should:

- i. Address the control of factors that increase the risk of HAB occurrence, such as coastal eutrophication (Glibert and Burford 2017); excessive use of the coastal zone that destroy the natural habitat (e.g., Airoldi and Beck 2007); ballast water discharges in harbors and coastal areas that contribute to dispersion of harmful organisms among areas (Hallegraeff and Bolch 1999), etc. These initiatives will have a cost to be compared with the potential benefits in each area, i.e., monitoring systems should be cost-effective.
- ii. Implement microalgal monitoring to detect harmful organisms as discussed in the previous section.
- iii. Implement biotoxin monitoring programmes, such as those carried out in Europe by Food Hygiene Regulations (EC) No 853/2004 and (EC) No 854/2004, which require Member States to monitor both for biotoxin concentrations in shellfish tissues and the presence of marine biotoxin-producing phytoplankton in coastal waters.
- iv. Limit shellfish harvesting closures to the minimum possible by varying the timing of shellfish or finfish harvesting to reduce the impacts of HABs, although these actions will also have associated costs in terms of product marketability at least in a short term. However, mandatory seafood inspection programs can effectively restore the consumer's confidence and expand the demand (Wessels et al*.* 1995).
- v. Develop closure strategies in shellfish production areas that can be beneficial over the long term, because the organisms and stocks can recuperate from exploitation, as it has been proven in Japan (Imai et al*.* 2014).
- vi. Develop efficient strategies for fishermen in tropical waters affected by CFP by avoiding their access to areas where finfish may have bioaccumulated ciguatoxin, which could diseminate CFP.
- vii. In aquaculture sites, protect finfish cages from HABs by moving the fish cages to unaffected zones, using barrier curtains, pumping of deep water into cages or water oxygenation/aeration. Cost of maintaining equipment and fuel is estimated to be about \$1 to 2 million CAD annually per company in British Columbia (Haigh and Esenkulova 2014).
- viii. Explore and improve strategies to stop HABs, for example by means of modified clay flocculation (Louzao et al*.* 2015; Seger et al*.* 2017) of algal biomass and/or mopping up of ichthyotoxins.
	- ix. Offer aquaculture insurance (mutual aid system), as it is done in Japan by the Fishery Damage Indemnification System, to mitigate the economic losses due to HABs. The System is both a mutual aid system and an important part of the national government's fishery damage assistance policy (Imai et al*.* 2014). However, risk perception varies with countries, professional activities and cultured seaproducts and requires detailed studies as well (e.g., Le Bihan et al. 2013).
	- x. Increase the knowledge of medical professionals to detect symptoms in patients exposed to marine biotoxins. In general, there is a need to improve coordination between marine biotoxin monitoring and public health surveillance and epidemiology activities. This will facilitate both the correct diagnosis and reporting. Examples of successful initiatives are the Harmful Algal Bloom-related Illness Surveillance System (HABISS) (http://www.cdc.gov/hab/surveillance.htm in the USA, the Antipoison Centers in France, and the Accord RAMOGE (www.ramoge.org) at Mediterranean region level (mainly on the coasts of Italy, Monaco, France and Spain).
- xi. Develop diagnostic tools for biotoxins, such as those that have been achieved for the detection of saxitoxins in human urine (Johnson et al*.* 2009).
- xii. Coordinate monitoring with operational oceanography and modelling, to provide forecasts and early warnings and ultimately predictions of HAB events (e.g., GEOHAB, 2011; Aleynik et al*.* 2016).
- xiii. Sustain fundamental research, needed for gaining a better understanding of HAB dynamics, to inform and improve monitoring programmes, and to design methods to mitigate the impacts of HABs on human health and well-being.

# **4. HOW TO PROGRESS ON THE ESTIMATION OF THE ECONOMIC COSTS OF HARMFUL DINOFLAGELLATE BLOOMS?**

Estimating the economic losses and impacts of HABs and dinoflagellate blooms is challenging. The cost of the impacts described in earlier sections vary markedly, depending on the kind of biotoxin and produced illness on humans, the duration, extension and frequency of the toxic bloom, the affected geographic region, the kind of contaminated or lost seafood products, etc. Consistent data on market sectors are lacking and there are very different methods to determine the economic costs of HABs. Recently, a Workshop "GlobalHAB: Evaluating, Reducing and Mitigating the Cost of Harmful Algal Blooms: A Compendium of Case Studies" was held in Victoria, BC, Canada within the PICES Annual Meeting (https://meetings.pices.int/meetings/annual/2019/PICES/Program).

The Workshop brought together expertise in the science of HABs and economics to review and analyze case studies to better estimate the economic impacts of HABs on fisheries and aquaculture. The Workshop was structured in three parts:

- 1) Overview of Economics Analysis of HABs impacts. The discussion was focused on types of economic assessment that guided the discussions of case studies on workshop day 2.
- 2) Case studies: examples of HAB impacts to wild fisheries, recreational fisheries and aquaculture worldwide. The discussions focused on what economic studies can be done in the future and identifying gaps in the data.
- 3) Mitigation strategies, Value of Information. The discussions focused on the value of HAB forecasts; wrap up and writing assignments were taken.

The output of this workshop will be a compendium of examples describing economic approaches used to estimate the costs of HABs and their mitigation, focusing on establishing connections between HAB scientists and economists. A shorter version of the compendium may be prepared for submission to a journal. In addition, the workshop will (1) propose priorities for research and effective management in the future, (2) develop partnerships between economists and HAB researchers to develop transdisciplinary projects, and (3) attract resources to the field. Outcome of the Workshop will improve the understanding of the impacts of HABs and manage and mitigate them. When entering the UN Decade of the Sustainable Development Goals, this activity should provide tools to implement them.

#### **ACKNOWLEDGMENTS**

This document contributes to the implementation of the project CoCliME an ERA4CS Network (ERA-NET) initiated by JPI Climate, and funded by EPA (IE), ANR (FR), BMBF (DE), UEFISCDI (RO), RCN (NO) and FORMAS (SE), with co-funding by the European Union (Grant agreement No. 690462). It is also aimed to foster interdisciplinary and internationally coordinated research studies on the Economic Impacts of HABs, which constitutes a topic of the SCOR and IOC/UNESCO GlobalHAB Program (www.globalhab.info).

# **MITIGATION OF THE EFFECTS OF HARMFUL ALGAL BLOOMS ORIGINATED BY DINOFLAGELLATES**

# *Juan Blanco*

Centro de Investigacións Mariñas, Consellería do Mar, Xunta de Galicia, Vilanova de Arousa, Spain

## **ABSTRACT**

Harmful algal blooms (HABs) originated by dinoflagellates can produce multiple damages to aquaculture of shellfisheries. A number of methods have been devised to mitigate their effects some of which are in use and others are promising alternatives to be used in the future. In this work, possible ways of mitigation and the methods that can be used in each way are reviewed.

**Keywords**: mitigation, clay, algicidal, bacteria, virus, flocculation, chemicals

# **1.INTRODUCTION**

Phytoplankton is the basis for the biological production of aquatic ecosystems and dinoflagellates are an important part of it, especially in marine environments. Blooms of most of the species constitute a valuable food source for filter-feeding organisms, as some bivalves, which can be used in aquaculture or whose natural populations can be exploited. In some cases, notwithstanding, blooms can be harmful to the organisms or for humans that consume them, acting through several ways: a) by modifying the characteristics of seawater; b) by producing substances that affect the cultured or exploited population; or c) by producing toxins that affect humans and that, consequently, render the cultured of fished product useless as food. Additionally to public health, several human activities can be affected by the blooms,

 $\overline{a}$

mainly, aquaculture, fisheries, tourism, and water desalination, having large social and economic impact.

Very dense blooms can modify the characteristics of the seawater making it unsuitable for the life of different organisms, including some which are important for aquaculture as bivalves or fishes. Massive blooms of photosynthetic species can produce hyperoxia during the day –due to the production of oxygen in photosynthesis– and hypoxia or even anoxia at night, when photosynthesis does not take place and respiration can deplete the oxygen dissolved in the seawater. Hyperoxia, especially when bubbles are formed, can produce different alterations but anoxia (or hypoxia) is a frequent cause of mortality in aquaculture facilities and even in relatively confined areas [1-4]. The effects of low oxygen concentration can be amplified by the production of polymers [5] that increase water viscosity, thus reducing the oxygen exchange with an environment that is already poor in it [6].

Figure 1. Sampling a HAB of *Alexandrium minutum* in the ría de Vigo (Spain) (courtesy of María García Portela) (A), time course of dissolved oxygen concentration (B) and resultant squid mortality in Bahía Tongoy, Chile (courtesy of Gonzalo Álvarez, project FONDEF IT17F10002) (C).

Some dinoflagellate species produce or release noxious compounds for commercially important marine organisms, being or not also toxic for humans. Large mortalities have been caused by (or associated with) intense blooms of several dinoflagellate species. *Karenia brevis*, which produces brevetoxins, *K. mikimotoi* and other species of the genus produced, in different oceans, large kills of both, fish [7-21] and bivalves [7, 8, 22, 23] or their larvae [23, 24, 17, 25, 20, 26]. The genus *Karlodinium* also includes some species whose blooms are known to produce fish and shellfish kills, as *K. veneficum* [23, 27], *K. armiger* [28, 29], *K. micrum* [30] and *K. australe* [31]. Some species of the genus *Alexandrium* have also been involved in marine fauna mortalities [32-39] and, as recently reviewed by Costa [40], they can also have a number of effects on fish, mainly due to the presence of the PSP (Paralytic shellfish poisoning) toxins they produce, but also by the combination of reactive oxygen species (ROS) and fatty acids [41-43], and by the action of other biologically active compounds [44-46]. Some yessotoxin producers, as *Protoceratium reticulatum* (*Gonyaulax grindley*), *Gonyaulax spinifera* and *Lingulodinium polyedrum*, have been associated with mortalities of abalone and other marine organism in South Africa [47, 48]. *Heterocapsa circularisquama* produces mass mortalities of bivalves in Japan [49-55] and China (Hong Kong) [56]. *Cochlodinium polykrikoides* can also produce problems in bivalves but it mostly

affects fishes in different areas of Japan [57], Korea [58-60], Malaysia [61], Philippines [62], and several other countries [63-68]. Other dinoflagellate species can also be involved in damages to populations of marine organisms, but, in general, with less importance.

Additionally to these direct effects, noxious substances can produce alterations in the organisms, as changes in their optimal commercial aspect or their organoleptic characteristics, with a consequent total or partial loss of value [69, 70].

When the algae produce toxins that affect humans, the situation becomes more complex. First, because it is necessary to regulate the allowable levels of the compounds in the products used as food. Second, because systems to monitor the toxin levels in the organisms should be designed, implemented and ran. Third, because the marketing of the products must be stopped while their toxin content is above the regulated allowable levels.

To minimize the effects of the harmful algal blooms, several strategies have been followed and different methods are under development. In this chapter, the most important are reviewed. Basically, it is possible to act at four points of the problem: 1) directly on the phytoplankton populations, 2) on the alterations they produce in the environment, 3) on the accumulation of toxic or noxious substances in fish and shellfish, and 4) on the regulation and monitoring of toxic substances.

# **2. ACTIONS ON PHYTOPLANKTON POPULATIONS**

### **2.1. Inoculum Reduction**

The development of phytoplankton populations in any area requires an inoculum. Some cells are required to start a bloom. The characteristics of the inoculum vary with the species involved and the area. Some dinoflagellate species have a life cycle that includes resting cysts, that can be in the sediment until they are exposed to favourable environmental conditions and germinate releasing vegetative cells that start planktonic populations. Other species do not produce those cysts and the blooms have to be started by vegetative cells or temporary cysts. In enclosed or semi-enclosed area, advection of vegetative cells from other areas can be very limited and, in such cases, the start of the blooms can depend on resting cysts. In those areas, in which blooms of resting cyst-producing species are usually recurring, reducing the number of cysts by dredging [71] or by any treatment that kills them, for example, hydrogen peroxide [72], can be useful to reduce the number or intensity of HABs. An additional possibility would be to add new sediment to bury the viable cysts and reduce its germination capability (complete suppression of germination would be impossible in natural conditions because bioturbation and sediment reworking should affect cyst resuspension). When the areas are not enclosed, then, advection would be important, whether or not the initial populations are originated by cyst germination, and this kind of measure would very likely be ineffective.

Especially for the dinoflagellates that form resting cysts (but also for other dinoflagellates) the inoculum can come from very distant areas through human activities. Viable cysts or cells can be present in ship ballast water, which is released to the sea supplying and inoculum, even of species that were not previously present in an area [73-75]. This can be also the case with shellfish transplantation [76]. Managing and reducing these

possible sources of cells can contribute to reduce the expansion of HABs, but it is not an easy task. Several methods have been devised and developed [77-80, 75], but some adverse effects of the needed treatments have been identified [81], and the maritime traffic and the behaviour of the individual vessels are very difficult to control.

Figure 2. Some dinoflagellate cysts. *Alexandrium tamarense* (A), *A. minutum* (B), *Gymnodinium catenatum* (C), *Polykrikos kofoidi* (D), *P.swartzii* (E) and *Gonyaulax scrippsae* (F).

### **2.2. Flocculation/Sedimentation of Algae from the Water Column**

Once the populations start their development, different strategies can be used. Currently, the most common one is the use of flocculant clays. When some clays are dispersed in the water, they form aggregates with the dinoflagellate cells of the bloom, increasing their sedimentation thus removing them from the water column. This method, obviously, can be used to protect relatively small areas, usually surrounding aquaculture facilities, as fish cages or shellfish rafts, but has noticeable problems to be used in large extensions. The first attempts to control HABs with flocculant clays were made in Japan by Shirota [82-84] and in Korea by Kim [85] with good results. Currently, yellow clay (mostly composed by montmorillonite and kaolinite [86]) is used in Korea to protect fish aquaculture cages from several species but mainly from *Cochlodinium polykrikoides* [84]. Numerous studies have also been carried out using other clays unmodified or chemically modified, to increase the removal capability of cells but also of dissolved toxins [87-98].

The removal efficiency of this technique is, in general, high, attaining 90% or even more (depending on the size of the clay particles and other characteristics) and the cost of the clay is low. Notwithstanding, the operating costs are much higher and protecting an area of approximately 1.5 km<sup>2</sup> can reach 70,000 USD per day, without including labour costs [84], which makes this kind of methodology useless for species that do not have a high economic value.

In addition to the above, using clays as a way to remove cells from the water has some problems. One is that large amounts of clay have to be dispersed, which complicates the operational procedures. To minimize this problem, a number of physical or chemical modifications of diverse clays have been tried, in several cases attaining a noticeable increase of the removal efficiency [89, 92, 94, 95, 99, 84, 96, 97, 100, 98]. A second problem is the impact of the formed aggregates on marine fauna, especially on filter-feeding organisms. In this sense, Shumway et al. [101] demonstrated the adverse effects of yellow clay on several molluscs and hydroids and [102] found that they can produce important damages to the benthic community. The same kind of clay (montmorillonite yellow clay) was shown to reduce drastically the growth of the clam *Mercenaria mercenaria* when it is suspended, as it happens in high energy environments, but not when it quickly sediments (low energy environments) [103]. The recovery of the settled dinoflagellate populations can represent a problem when dealing with some species. Sun and Choi [90] found that *Alexandrium* and *Cochlodinium* cells were nearly completely destroyed after being settled with clays, but that, when *Scripssiella* was treated, cells were less affected and additionally a large amount of resting cysts were formed in the settled clay, reaching 87,000 cysts per gram of clay. Obviously, this can contribute to the persistence of the species in the area where the clay is dispersed. Another problem is the release by the clay of different substances that can be toxic. Finally, the concentration of cells in the water has to be high for the treatment to be effective. Sengco [104], for example, found reduced removal efficiencies (70%) for blooms of *Karenia brevis* below 1000 cells/mL, and also for other dinoflagellate species.

### **2.3. Chemical Methods to Kill Algae**

Several chemical treatments have been tried to eliminate or reduce toxic algae blooms, with some success in very precise situations. Copper sulphate was used to eliminate the HABs that usually take place in Florida (*Karenia brevis*), but was found to be too expensive and to have toxic effects on the marine biota [106]. Posteriorly, diverse surfactants were tried with little success also on *K. brevis* [107]. The same group found aponin, a compound produced by the bluegreen algae *Gomphosphaeria aponina*, to kill *K. brevis* [108, 109] and tried to apply both, the algae and the compound, to control the populations of *K. brevis* [110] finding that cellular lysis can increase the ichtyotoxicity. Sophorolipids, other surfactants, have been shown to have some effect on *Cochlodinium polykrikoides* and have been used in Korea to increase the effectivity of the yellow loess, but requires concentrations of  $5 \text{ g/L}$ [111, 112, 92]. Oxidizing agents have also been applied. Sodium hypochlorite, electrolytically obtained from seawater, has been used in Korea [113, 114] and more recently, in a channel in The Netherlands, hydrogen peroxide was utilized to terminate a bloom of *A. ostenfeldii* [115]. Ozone has been shown to be useful in eliminating *K. brevis* toxins [116-119]. Some other compounds (mostly of biological origin) have also found to affect the growth of some dinoflagellate species but have not been used to mitigate blooms (reviewed in Sellner and Rensel [120]).

Except for some special cases of very noxious events in restricted areas, the effectivity of chemical methods to reduce dinoflagellate populations seems to have limited applicability because mainly of their cost and the side effects on the local biota. Some compounds, with selective effect on harmful algae are being studied [121].

### **2.4. Biological Methods**

Predation, parasitism, and allelopathy can, theoretically, be used to reduce or eliminate populations of harmful dinoflagellates and other algae (reviewed in Salomon and Imai [122]).

### *2.4.1. Predation*

Adding predators, as tintinids or copepods, for example, can be expected to contribute to bloom termination or impede the bloom initiation [123-132]. The practical use of this process, notwithstanding, is very difficult because massive cultures of the predators are expensive and difficult to synchronize with the blooms.

### *2.4.2. Parasitism*

Many parasites of dinoflagellates probably exist and have some potential for mitigation [133-137]. Some bacteria have been shown to be algicidal [138-141], but it is sometimes difficult to discriminate if they are parasitic of if they produce algicidal substances.

Figure 4. Sporozoites of *Parvilucifera* emerging from an infected cell of *Dinophysis caudata* (left) (courtesy of Isabel Bravo), and cycle of the infection of *Alexandrium fundyense* by *Amoebophrya* (right) (green color indicates the presence of the parasite) (reprinted from [142]).

Among protozoans, the dinoflagellate genus *Amoebophrya* [143-148, 134, 149-152, 135, 153, 154, 136, 155, 27, 142, 156-158] and the Perkinsidae genus *Parvilucifera* [159-171], have been shown to affect, to a different degree, the development of the proliferation of several species. Even when these parasites can contribute substantially to bloom termination, that does not happen in all cases (e.g., Velo-Suárez et al. [172]) and their use presents the same problems than the predators, mainly the difficulty of producing cultures to add a significant amount of parasites to the blooms and additionally, the risk that other dinoflagellate or phytoplanktonic species can be affected, producing damages to the ecosystem. The use of *Parvilucifera infectans* as a way to mitigate harmful algal blooms is, nevertheless, the object of a currently active patent [173].

# **3. ACTIONS ON THE ENVIRONMENT**

The most important environmental effect of HABs is decreasing the concentration of dissolved oxygen to hypoxia or anoxia levels. This mainly occurs because the oxygen consumption by microalgae or bacteria is not balanced by the photosynthesis. This can happen mainly during the night when HABs are very intense or during the decay phase of the blooms, due to the respiration by the bacteria that are consuming the organic matter released by cell breakdown of the phytoplanktonic populations. The two obvious ways to mitigate this problem are: a) restoring the balance between photosynthesis and respiration; and b) supplying oxygen to the water. The first way is quite difficult to implement because it would require lighting the area during the night, which would be very expensive and relatively ineffective if light transmission is reduced because of the high plankton biomass. The second way is more feasible [120] and some methods trying to implementing it exist, as aeration with porous stones or use of airlifts, for example. Some of them are already in use in fish farms to minimize the problems associated with high fish densities (which also deplete oxygen) and can be easily used to mitigate HAB-induced anoxia or hyperoxia. Some of the possible approaches can be simultaneously used, as hydrodynamic barriers (e.g. air curtains at the walls of the cages) or to replace surface water –usually rich in HAB organisms– by bottom water, with smaller concentrations (as airlifts) [120].

# **4. ACTIONS ON THE ACCUMULATION OF TOXIC OR NOXIOUS SUBSTANCES IN FISH AND SHELLFISH**

### **4.1. Actions on the Accessibility of the Harmful Algae to the Cultured Organisms**

There are three possibilities of action: a) moving the cultured organisms or the culture facilities; b) isolate the cultured organisms; and c) reduce the rate at which the harmful cells reach the affected organisms.

Spatially segregating the HABs and the exploited organisms, by means of moving the culture facilities or the organisms themselves, is a useful action (1) when the blooms are not extensive (leaving some areas unaffected), (2) when the culture facilities or the organisms can be easily transported, and (3) when the price of the product is high enough to balance the costs of the required operations with its loss of value due to the effect of the HAB. Relocating fish cages or even farms to areas with little or no exposition to a bloom has been suggested by several authors [174-178, 84] and used to avoid the fish mortalities produced by HABs in many places as, for example, New Zealand [179], Canada [180], USA [181] and Norway [182]. This approach can be used also with shellfish, but, in general, the technical difficulties involved are much higher. Long lines, for example, are very difficult to relocate and, in all culture devices in which bivalves are attached to a vertical rope (as usual in mussel culture in rafts and long lines), detachment, with the consequent loss of product, can be easily produced by movements during relocation. In some countries, moreover, as in Chile, for example, moving mollusc culture facilities is not allowed and this strategy cannot be used.

Changing the depth at which the fish cages or shellfish culture systems are placed can help to avoid blooms that develop at the sea surface. However, fishes can suffer several problems depending on the species. Some of them, that tend to swim to the surface, can become stressed, and some others can undergo problems to regulate the contents of the gas bladders they use to attain neutral buoyancy. Theoretically, shellfish should have fewer problems with this method, but their cultures are usually located in areas of high plankton concentration, which usually are relatively shallow, and consequently, there is no room to deepen the culture devices. Additionally, the food reduction at depth can originate substantial weight losses, with two main consequences: reduction of the amount of product, and–in the case that some toxins had already been accumulated– an increase of their concentration (as toxins are usually not lost with biomass). Notwithstanding, this method has been successfully used in mussel cultures in Canada [183], Italy [184] and Venezuela [185].

Isolating the cultured organisms is also a possibility to avoid their contact with blooms and, therefore, minimize the effects of HABs in terms of damages to the organisms or toxin accumulation. *In situ* isolation methods are possible (plastic envelopes, for example) but are difficult to deploy and require equipment to maintain oxygen levels and to avoid high concentrations of toxic excretions. Using recirculating aquaculture systems (RAS) [186], are probably the most effective solution, but they are expensive and have to be optimized and equilibrated previously. When the organisms are already being cultured in RAS, the typical water renewal rates of the system can be reduced, or even temporally suppressed, when blooms are detected in the area. In other cases, using this kind of systems can be much more difficult or ineffective, because increasing suddenly the charge of the system will, very likely, led to the impossibility to regulate the water quality.

Reducing the rate at which the harmful cells reach the affected organisms can also be employed to mitigate the consequences of HABs, especially when the impact derives from the ingestion of cells and not from the exposure to dissolved toxins. These methods, consequently, are expected to be more effective in suspension feeders, like bivalves, than in fishes. Blanco, Martín, and Mariño [187], during a *Dinophysis* bloom (okadaic acid producer) used an envelope made of fishing net (a net cylinder) to limit the water flow to the mussel ropes in a raft, managing to reduce the toxin concentration to a half and obtained a similar result by grouping ropes, thus reducing the amount of toxic cells that reach the inner part of the groups. The method can be fine-tuned by choosing the net mesh but also presents some drawbacks. The first one is that, in some occasions (if the phytoplankton concentration is low or the flow reduction too high), shellfish can receive less food than the maintenance ration, therefore losing biomass and concentrating the toxin that has accumulated. The second is that,

when the phytoplankton concentration is higher than the optimum for ingestion, a reduction can place it near the optimum level producing, consequently, an increase in the ingestion of toxic cells [188, 189].

Figure 5. Expected effect of hydrodynamic barriers (A and B left panel) and rope clustering (A and B right panel) on the water flow to mussel ropes in a raft and its effect on okadaic acid concentration during a *Dinophysis* bloom. From Blanco, Martín, and Mariño [187] (with permission (Elsevier)).

Selecting individuals which ingest low amounts of toxic cells can also be a feasible approach, especially for cultures. Bricelj et al. [36], for example, found strong differences in PSP toxin uptake between *Mya arenaria* strains, and Pino-Querido et al. [190] found that the accumulation of DSP toxins by the mussel *Mytilus galloprovincialis* is a trait with a high heritability (>33%), both during the toxin incorporation and elimination phases. In some cases, as in the one of *M. arenaria*, notwithstanding, the reduction of toxin uptake can be due to the toxicity of the algae, more than to an active rejection, and consequently, that selection can pose a noticeable risk for the survival of the selected populations.

#### **4.2. Actions on Toxin Accumulation**

Toxin accumulation results from the balance between absorption and elimination. As, in most toxins, nearly no breakdown has been observed, from a practical point of view, elimination is equivalent to the efflux of the toxins from the body tissues. Absorption is, in general, made from ingested toxic particles or toxin-producing organisms – as it happens with bivalves and other filter feeders – or from other organisms that have accumulated the toxins through the food web, which is the case of some fishes – for example, barracuda in the Caribbean [191, 192] or amberjack in West Africa [193, 194] – that can accumulate ciguatoxins, primarily produced by the benthic dinoflagellate genus *Gambierdiscus*. Typical planktonic HABs affect mainly to filter feeders, even when other animals that consume them can also be affected, as crabs or lobsters [195, 196, 197 and references therein].

No method has been devised to reduce the accumulation in fishes, but some possibilities exist for filter feeders.

Absorption efficiency of organic matter (including toxins) is mainly regulated by the time that the ingested materials remain in the digestive system (GPT, gut passage time), which, in turn, depends on the volume of those materials. It is, therefore, dependent on the ratio between the toxic compound and the volume of the ingested materials (Moroño et al. [198] and reviewed in Blanco [189]). Sampayo et al. [199] showed that mussels accumulate less DSP toxins when the populations of the causative species (*Dinophysis* spp.) co-occurred with other non-toxic populations. Using this knowledge to reduce accumulation in cultured or natural population of bivalves is, notwithstanding, very difficult because large amounts of microalgae –that are expensive to produce and dispense– should be supplied to large areas.

Several approaches have been used to try to accelerate the depuration of the accumulated toxins from bivalves, in general, with little or no success [200]. Changes in temperature, salinity, pH, as well as chlorination, ozonation, electric discharges, emersion, and other treatments have been tested [201-204, 177 and references therein], but none of them is currently in use. Supplying non-toxic food has been shown to accelerate the reduction of toxicity in some bivalves [200] but this is probably due to an increase of body weight more than to a decrease of toxin content, and consequently, this method cannot be expected to increase substantially the depuration rate. Moreover, the cost of supplying that additional food can be substantial, therefore limiting the possible use to very high-valued bivalve species. Some attempts to reduce toxin accumulation have been also made by adding N-acetylcysteine [205], emulsifiers [206], activated charcoal [207], synthetic resins [189], a sucrose polyester [189], or chitosan [208] in some cases with apparent success, but additional studies about their economic viability and about the combination of toxins, species and phases of toxin accumulation in which these compound can be used are still needed. Toxin accumulation has three main components that have different importance during the time-course of the intoxication-depuration process. During the early steps, toxins are mainly accumulated in the lumen of the digestive system and start to be accumulated inside the cells of the digestive gland. During the subsequent steps, the toxin is, first, mainly accumulated into the digestive gland cells and finally accumulated in other organs or tissues [189]. In the first phase, compounds that bind the toxins and that make them less efficiently absorbed, or compounds that accelerate the digestive system evacuation, can be effective but might have no effect on the toxin accumulation during other phases (probiotic bacteria, for example, can be used at this step [209]). During the second accumulation step, compounds that favour the efflux of the toxins by facilitating the activity of the involved membrane transporters or by activating the vesicular transport (with the formation or excretion spherules [210]) can be used, but those compounds or materials should be absorbed by the digestive cells and not digested by them (as probably is the case with the resin Diaion HP20 and Olestra (Procter & Gamble), a polyester of sucrose that have been shown to be effective in reducing okadaic acid accumulation [189]). In the third phase, probably, compounds with the capability to mobilize resources between organs or that increase the transfer from other organs to the two main excretory organs of bivalves (digestive gland and kidney) should be used.

As already commented in the previous section, the selection of strains with low rates of accumulation can be possible, at least for DSP toxins in mussels, as the heritability of this trait is higher than 33%.

### **4.3. Actions on the Final Product**

#### *4.3.1. Selection of Individuals*

Once the organisms have been extracted from the sea a number of actions can be taken in order to avoid risk for consumers while minimizing economic losses.

When the organisms are large and high-valued, individual selection is possible. This method is being used, for example, for ciguatoxin-contaminated fishes in Canary Islands

(Spain). There, the current regulation establishes that fishes of certain species which exceed a species-dependent weight, have to be analysed for their ciguatoxin concentration and they are allowed to be commercialized only when the toxins do not exceed the established level [211].

Source: http://www.gobiernodecanarias.org/cmsgobcan/export/sites/agricultura/pesca/galerias/doc/primera\_ venta/Cartel-protocolo-ciguatera\_2018.pdf.

Figure 6. Poster describing the procedure used in Canary Islands to select fishes to be analysed to determine their contents in ciguatoxins.

#### *4.3.2. Selective Evisceration*

Removing the most toxic organs or tissues from bivalves or fishes is another possibility to reduce the impact of toxins. For some fishes contaminated with ciguatoxins, removing viscera is, in some regulations, mandatory. The king scallop *Pecten maximus* which accumulates domoic acid (ASP toxin) for a long time, mostly (more than 90%) in the digestive gland can only be marketed, in Europe, after selectively removing that organ (and checking the levels in the remaining tissues) [212]. The possibility of effectively use this method strongly depends on the anatomical distribution of the toxin and the commercial value of the bivalves, as the processing step and the mandatory post-process analysis introduce a noticeable cost to the final product.

#### *4.3.3. Industrial Processing*

If the organisms are to be industrially transformed, some steps with the capability of reducing the concentration of some toxins can be included. PSP toxins in *Acanthocardia tuberculatum* are completely or nearly completely destroyed by some canning procedures [213] and this has led the European Union to implement an exception to the general regulation to allow the collection of this species, contaminated with PSP toxins, to be processed in that way [214]. Other cooking methods, especially in alkaline conditions, have been found experimentally to be effective with this group of toxins in other species [215]. Some bacteria can degrade PSP toxins but they have not been used in industrial processing [216, 217].

Thermal processes, like those used in cooking and canning, do not have relevant effects on toxins of the okadaic acid group [215, 218, 219]. Although some degradation of those toxins takes place at high temperatures it is compensated by the increase of toxicity due to dehydration [218, 219].

The toxins in this group can be extracted from bivalves using supercritical fluid extraction [220] but the organisms should be dehydrated, which limits the possible use of the procedure, and the economic aspects have not been evaluated.

## **5. REGULATION AND MONITORING**

When human health is at risk because the blooming organism produces toxins, the allowable levels of these compounds in the products that are going to be consumed, have to be regulated, and how such products have to be monitored should be defined and implemented.

Establishing the allowable limits for the toxins is a difficult task for several reasons. When a toxin first appears, producing a human intoxication, it is necessary to identify and quantify the toxin in the food which caused the intoxication. Frequently, the precise product consumed is not available and the same organisms gathered from the same or nearby areas, at the same time or sometime later (usually days), should be used, thus adding uncertainty to the estimations. Additionally, nor optimized methods for the determination of the toxins neither reference materials are usually available. These drawbacks make the estimates of the LOAEL (lowest observed adverse effect level), and other parameters needed to establish a safe level, very imprecise. Reasonably, Health Authorities lower the allowable levels to include this

uncertainty (and others, as body weight, sensitivity or impairment of some metabolic functions) in order to protect the consumers. For producers, notwithstanding, this means that the periods in which marketing of their products is closed can be longer than necessary. When analogues of the known toxins or other products which are shown to be toxic in the usual assays, have to be regulated, the situation is even more complex because no data about their actual effect on humans exist (but they are expected to have one) and consequently, their toxicity has to be indirectly estimated.

The effects of differences in regulated levels can be important because, in most cases, toxin depuration takes place following an exponential decay. A reduction from 800  $\mu$ g/kg of PSP toxins to approximately 400, for example, would extend the closure period in some mussel cultures of Galicia, for even more than 200% [221].

Figure 7. Extension of the banning period if the limit of quantification of bioassay, instead of the current regulatory limit, was taking as allowable level, during a *Gymnodinium catenatum* bloom in 2005 in Galicia. The numbers above the bars are the percentage of extension. The production areas are coded as Ría-Zone-Subzone (ARO= Arousa, BAI= Baiona, PO= Pontevedra, VIG= Vigo). [Modified from 221].

Detailed studies of the actual toxicity and the strictly required allowable toxin levels are, therefore, a tool to mitigate the impact of toxic blooms.

To ensure that the products which reach the market do not surpass the levels established in the regulation, different methods are used. In Europe (and in all countries that sell their products in Europe) several control steps have been regulated, which can be grouped into two categories [222]: pre-harvest and post-harvest. The first one is in charge of the competent authorities (CA), and the second one is in charge of each intermediary between the sea and the final consumer ("from sea to fork"). If the product at any step is shown to surpass the allowed levels, it should be destroyed or re-installed in the aquaculture facilities or the production areas.

The pre-harvest controls (used in Europe and some countries outside Europe) require the implementation of monitoring systems, which frequently (always in Europe) include periodic (usually weekly) determinations of the concentration of dangerous phytoplankton in water and of toxins in bivalves (or fishes, in some cases) from the harvested areas. The costs of

these monitoring systems are not low and frequently lay between 3 and 5% of the product's first-sale value and their structure is usually defined by the cost/benefit ratio. Developing and using cost-effective methodologies to determine phytoplankton and toxin concentration in the organisms can considerably reduce the cost of running the monitoring. Optimizing the sampling design and strategies, mainly by means of risk analysis and predictive modelling, can reduce the number of samples to be processed, reducing the cost, or allow to subdivide the monitored areas, maintaining the cost but increasing the benefit for the producers, and therefore, in both cases, reducing the cost/benefit ratio and contributing in that way to mitigate the consequences of toxic blooms.

# **U.S. OFFSHORE AQUACULTURE REGULATION AND DEVELOPMENT**

## *Harold F. Upton*

## **ABSTRACT**

Regulatory uncertainty has been identified as one of the main barriers to offshore aquaculture development in the United States. Many industry observers have emphasized that congressional action may be necessary to provide statutory authority to develop aquaculture in offshore areas. Offshore aquaculture is generally defined as the rearing of marine organisms in ocean waters beyond significant coastal influence, primarily in the federal waters of the exclusive economic zone (EEZ). Establishing an offshore aquaculture operation is contingent on obtaining several federal permits and fulfilling a number of additional consultation and review requirements from different federal agencies responsible for various general authorities that apply to aquaculture. However, there is no explicit statutory authority for permitting and developing aquaculture in federal waters. The aquaculture permit and consultation process in federal waters has been described as complex, time consuming, and difficult to navigate.

Supporters of aquaculture have asserted that development of the industry, especially in offshore areas, has significant potential to increase U.S. seafood production and provide economic opportunities for coastal communities. Currently, marine aquaculture facilities are located in nearshore state waters. Although there are some research-focused and proposed commercial offshore facilities, no commercial facilities are currently operating in U.S. federal waters. Aquaculture supporters note that the extensive U.S. coastline and adjacent U.S. ocean waters provide potential sites for offshore aquaculture development. They reason that by moving offshore, aquaculturalists can avoid many user conflicts they have encountered in inshore areas. Offshore areas also are considered to be less prone to pollution and fish diseases.

Environmental organizations and fishermen generally have opposed development of offshore aquaculture. They assert that poorly regulated aquaculture development in inshore areas has degraded the environment and harmed wild fish populations and ecosystems. Those who oppose aquaculture development generally advocate for new

This is an edited, reformatted and augmented version of Congressional Research Service, Publication No. R45952, dated October 10, 2019.

authorities to regulate offshore aquaculture and to safeguard the environment and other uses of offshore waters. Some segments of the commercial fishing industry also have expressed concerns with potential development of aquaculture on fishing grounds and competition between cultured and wild products in domestic markets.

Proponents of aquaculture counter that in many parts of the world a combination of farming experiences, technological advances, proper siting, and industry regulation has decreased environmental impacts and improved efficiency of marine aquaculture. They argue that many who oppose marine aquaculture lack an understanding of the benefits and risks of aquaculture and that opposition persists despite research that contradicts the extent or existence of these risks.

Generally, the outcomes associated with aquaculture development depend on a variety of factors, such as the characteristics of aquaculture sites, species, technology, and facility management. Regardless of potential environmental harm, it remains to be seen whether moving to offshore areas would be profitable and if offshore aquaculture could compete with inshore aquaculture development and lower costs in other countries.

Comprehensive offshore aquaculture bills were introduced in the  $109<sup>th</sup>$ ,  $110<sup>th</sup>$ ,  $111<sup>th</sup>$ ,  $112<sup>th</sup>$ , and  $115<sup>th</sup>$  Congresses, but none were enacted. In the  $115<sup>th</sup>$  Congress, the Advancing the Quality and Understanding of American Aquaculture Act (AQUAA; S. 3138 and H.R. 6966) was introduced; AQUAA would have established a regulatory framework for aquaculture development in federal waters. It also would have provided National Oceanic and Atmospheric Administration (NOAA) Fisheries with the authority to issue aquaculture permits and coordinate with other federal agencies that have permitting and consultative responsibilities. Conversely, since the 109<sup>th</sup> Congress, bills have been introduced that would constrain or prohibit the permitting of aquaculture in the EEZ. The Keep Finfish Free Act of 2019 (H.R. 2467), introduced in the  $116<sup>th</sup>$  Congress, would prohibit the issuance of permits to conduct finfish aquaculture in the EEZ until a law is enacted that allows such action. It remains an open question whether legislation could be crafted that would provide the regulatory framework desired by potential commercial developers of offshore aquaculture and avoid or minimize risks of environmental harm to the satisfaction of those currently opposed to offshore aquaculture development.

## **INTRODUCTION**

Offshore aquaculture is generally defined as the rearing of marine organisms in ocean waters beyond significant coastal influence, primarily in the federal waters of the exclusive economic zone (EEZ).<sup>1</sup> Currently, marine aquaculture facilities are located in nearshore state waters, but no commercial facilities operate in U.S. federal waters. Some aquaculture advocates contend that developing such offshore aquaculture facilities could increase U.S. seafood production and provide economic opportunities for coastal communities; opponents counter that doing so could harm the environment and have negative impacts on other coastal activities, such as fishing.

Offshore aquaculture development will likely depend on several interrelated legal and institutional requisites, such as establishing a regulatory framework, minimizing environmental harm, and developing the capacity to manage and support the industry. Regulatory uncertainty has been identified as one of the main barriers to developing offshore

<sup>1</sup> Proclamation 5030, "Exclusive Economic Zone of the United States of America," March 10, 1983.

aquaculture in federal waters of the United States.<sup>2</sup> According to the U.S. Commission on Ocean Policy, "aquaculture operations in offshore waters lack a clear regulatory regime, and questions about exclusive access have created an environment of uncertainty that is detrimental to investment in the industry."<sup>3</sup> Some observers have concluded that "offshore aquaculture will not fully develop unless governments create a supportive political climate and resulting regulatory conditions." <sup>4</sup> A framework also may be needed to assure environmentalists, fishermen, and other stakeholders that coastal and fisheries managers would have the authority to address potential threats to the environment and other impacts.

According to most observers, congressional action may be necessary to develop a comprehensive regulatory framework for offshore aquaculture. Comprehensive legislation has been introduced a number of times since the 109<sup>th</sup> Congress, but none of the bills have been enacted. Controversy has stemmed from different perspectives of aquaculturalists, environmentalists, fishermen, and others. Some environmental organizations and fishermen have asserted that poorly regulated aquaculture development has degraded the environment and harmed wild fish populations and ecosystems. <sup>5</sup> Some segments of the commercial fishing industry are opposed to marine aquaculture because of potential development on fishing grounds, environmental effects on fish populations, and competition of cultured products with wild products in domestic markets. Offshore aquaculture advocates counter that a combination of farming experiences, technological advances, proper siting, and industry regulation has decreased environmental impacts and improved the efficiency of marine aquaculture. It appears that renewed efforts have emerged in the  $116<sup>th</sup>$  Congress to meet current challenges by attempting to improve regulatory efficiency, minimize environmental degradation, and avoid impacts on existing ocean uses.

Additional related factors, such as technical advances, economic feasibility, and the level of government support, also are likely to affect future growth of the U.S. aquaculture industry. Although a regulatory framework appears to be necessary for establishing offshore aquaculture in federal waters, it may not be sufficient for significant development of the industry. Sometimes overlooked are the services that may be needed to establish a new industry, such as program administration, research, and other services (e.g., disaster assistance, insurance). Technical uncertainties related to harsher offshore environmental conditions and higher costs of operating farther from shore may slow extensive offshore development, especially in the immediate future.

This report examines issues and challenges related to the development of offshore aquaculture in federal waters.<sup>6</sup> It introduces the topic with background information that

<sup>2</sup> U.S. Congress, Senate Committee on Commerce, Science, and Transportation, Ocean Policy Study, *Statement of William T. Hogarth, Assistance Administrator, National Marine Fisheries Service*, Hearing on Offshore Aquaculture, 109th Cong., 2nd sess., April 6, 2006.

<sup>&</sup>lt;sup>5</sup> Center for Food Safety, Fishing and Public Interest Groups File Challenge to Fed's Unprecedented Decision to Establish Aquaculture in Offshore U.S. Waters, February 16, 2016, at https://www.centerforfoodsafety.org/ press-releases/4229/fishing-and-public-interest-groups-file-challenge-to-feds-unprecedented-decision-toestablish-aquaculture-in-offshore-us-waters.

<sup>6</sup> Comparisons and references are made to inshore and land-based aquaculture, but the focus of this report is offshore aquaculture.

covers aquaculture production and methods, federal agencies involved in aquaculture, and potential congressional interest in the topic. It then focuses on three of the main challenges faced by the industry, including the current regulatory framework, environmental concerns, and economic viability. The report concludes with issues related to regulatory and institutional development that have been identified by researchers and stakeholders, potential issues for Congress, and a summary of legislation that has been introduced in recent Congresses.

## **BACKGROUND**

## **Seafood Production**

Global aquaculture production is nearly equal to the volume of seafood produced for human consumption by wild fisheries.<sup>7</sup> From 1997 to 2016, world seafood production from wild sources (capture fisheries) leveled off at a range of 89 million metric tons (mmt) to 96 mmt. <sup>8</sup> According to the United Nations Food and Agriculture Organization, further growth of global wild fisheries production is unlikely, because approximately 93% of marine stocks are now either fished unsustainably or fished at maximum sustainable levels.<sup>9</sup> During the same period, world aquaculture production increased from 28.3 mmt to 80.0 mmt; it now makes up 47% of global fish production.<sup>10</sup> It is likely that aquaculture production will continue to expand with advances in aquaculture technologies and the need to satisfy the demand of the world's growing population.<sup>11</sup> Figure 1 illustrates the growth in global aquaculture production and relatively constant wild fisheries production. Nearly all of global marine aquaculture production is from inshore areas, such as estuaries and coastal areas, not from offshore areas.

Wild fisheries in the United States are limited by the productive capacity of U.S. waters. Most U.S. stocks are now fished at their maximum sustainable levels. However, unlike worldwide trends, U.S. aquaculture production has generally stagnated and makes up a relatively small portion of total U.S. seafood production. In 2016, the United States ranked fifth in global seafood production at 5.36 mmt; 0.44 mmt (8.2%) of this total was produced by aquaculture.<sup>12</sup> Figure 2 illustrates the relatively constant domestic production of aquaculture and wild fisheries. Most U.S. aquaculture production consists of freshwater species, such as catfish, trout, and crawfish. Growth in U.S. seafood consumption has depended on imports, which provide approximately 80% to 90% of the seafood consumed in the United States.<sup>13</sup>

<sup>7</sup> Global aquaculture totals include both freshwater and marine aquaculture.

<sup>8</sup> Food and Agriculture Organization (FAO), *The State of World Fisheries and Aquaculture 2018*: *Meeting the Sustainable Development Goals*, 2018. Hereinafter cited as FAO, *State of World Fisheries*. The total includes all fresh and marine landings, which was 90.9 mmt in 2016.

<sup>9</sup> FAO, *State of World Fisheries*, p. 40.

<sup>10</sup> Aquaculture represents 47% of all fish landings, including fish used for purposes other than direct human consumption such as fish meal and fish oil for animal feeds, and 53% of fish landed for direct human consumption. The term *fish* includes harvest of invertebrates such as crustaceans, mollusks, and echinoderms.

<sup>11</sup> FAO, *State of World Fisheries*, p. 182.

 $12$  U.S. total and aquaculture production reported to FAO includes shell weight of oysters and clams. The National Marine Fisheries Service (NMFS) reported U.S. aquaculture production in meat weight without shells. Thus, the NMFS reported figure was 0.29 million metric tons (mmt).

<sup>13</sup> NMFS, Office of Science and Technology, *Fisheries of the United States, 2017 Report*, Current Fishery Statistics No. 2017, September 2018, p. 114. Hereinafter cited as NMFS, *Fisheries of the United States*. A portion of

Approximately 50% of seafood imports, such as shrimp from Southeast Asia and salmon from Norway or Chile, are produced by aquaculture in ponds and nearshore areas. According to some observers, U.S. reliance on seafood imports will continue to increase without changes to current policies and regulatory obstacles that currently impede expansion of aquaculture.<sup>14</sup>

## **Aquaculture Overview**

 $\overline{a}$ 

Aquaculture is broadly defined as the propagation and rearing of aquatic species in controlled or selected environments.<sup>15</sup> Aquaculture is difficult to characterize because of the

imports include domestic catch that was exported for further processing and returned to the United States as an import in processed form.

<sup>&</sup>lt;sup>14</sup> Hauke L. Kite-Powell, Michael C. Rubino, and Bruce Morehead, "The Future of U.S. Seafood Supply," *Aquaculture Economics & Management*, vol. 17, no. 3 (August 2013), p. 229.

<sup>&</sup>lt;sup>15</sup> This definition of aquaculture is from the Aquaculture Act of 1980 (16 U.S.C. §1802(1)).

diverse nature of facilities, methods, technologies, and species that are cultured. Organisms are cultured in freshwater environments, land-based closed systems, coastal and estuarine areas, and offshore areas.<sup>16</sup> Often, hatcheries are used to spawn fish and shellfish to produce eggs that are hatched and grown to specific stages; these organisms are then transferred to facilities where they are grown to marketable size.

Aquaculture operations range from systems where there is only minimal control over the organism's environment to intensive operations where there is complete control at each stage of the organism's life history. For example, an intensive system would include freshwater species such as catfish that are often raised in shallow earthen ponds; production relies on control of inputs. Water, feed, and disease treatment are controlled to maximize growth while minimizing costs. Farming of finfish, such as salmon, also requires stocking at high densities and relies on extensive feeding. Commercial salmon aquaculture facilities often employ net pens (Figure 3), which are moored to the bottom and located in protected inshore marine areas, such as bays and fjords.<sup>17</sup>

Bivalves such as oysters and clams are grown in estuaries and inshore areas, feeding on a diet of plankton and detritus that they filter from seawater. Bivalve aquaculture may employ varying degrees of control. In some cases, they are suspended on lines, in wire cages, and on rafts. Oyster larvae are grown in hatcheries and transferred to these structures as oyster spat or seed and grown to market size. Some oyster production is less intensive and depends on enhancement of the benthic (ocean bottom) environment by placing oyster shells on the bottom to facilitate attachment of wild oyster larvae.<sup>18</sup>

In Alaska, hatcheries are used to enhance the production of salmon fry, which are released to the wild to feed and grow until they are caught by fishermen as adults. These programs are run as nonprofit cooperatives overseen by Alaska fishermen.<sup>19</sup> Most states and the U.S. Fish and Wildlife Service run public stocking programs, which often address a variety of objectives such as enhancing recreational fisheries and restoring depleted populations. Each strategy requires different inputs and interacts with the environment to differing degrees. Nevertheless, a common factor is to control some aspect(s) of the organism's life to enhance survival and growth.

Over the last decade, catfish aquaculture has accounted for most food fish production by volume and revenue in the United States (Table 1). However, catfish production has declined by nearly 44% over this period due to a variety of factors, including competition from Asian imports. For freshwater species, only crawfish production (78.0%) and revenue (66.2%) increased significantly. During the same period, production of salmon and oysters increased in both volume and revenue. Cultured oysters exhibited the largest increases in production (66.0%) and revenue (86.5%), which is likely related to greater demand for high quality raw

<sup>&</sup>lt;sup>16</sup> Most production is from freshwater and coastal areas, whereas offshore and closed systems account for only a small portion of global and domestic production.

 $17$  Most commercial salmon aquaculture facilities use net pens, floating enclosures that are anchored to the ocean bottom. The enclosures are separated from the environment by netting which allows for the free exchange of water and fish wastes between the enclosure and the environment. Salmon aquaculture also can be conducted in land-based tanks and raceways.

<sup>&</sup>lt;sup>18</sup> In other cases, small oysters (spat) may already be attached to the shell when it is placed on the bottom of the estuary.

<sup>&</sup>lt;sup>19</sup> Alaska Department of Fish and Game, Hatcheries at https://www.adfg.alaska.gov/index.cfm? adfg=fishing Hatcheries.main.

oysters.<sup>20</sup> However, except for cultured oysters, production of most domestic marine seafood products is from wild marine fisheries.<sup>21</sup>

Species	Production (thousands of pounds)		Production (metric tons)		Revenue (\$ in thousands)	
	2006a	2016	2006	2016	2006b	2016

#### **Offshore Aquaculture**

As stated above, offshore aquaculture is the rearing of marine organisms in ocean waters beyond significant coastal influence, primarily in the federal waters of the EEZ. Aquaculturalists, the Department of Commerce, several task force and commission reports, and some academics have identified offshore aquaculture as a potential alternative to some land-based and nearshore aquaculture. Supporters of aquaculture have asserted that development of the industry, especially in offshore areas, has significant potential to increase U.S. seafood production and provide economic opportunities for coastal communities. The potential of offshore aquaculture in the United States is likely to differ by species, region, and technology. $^{22}$ 

Despite plans for several offshore operations, no commercial offshore aquaculture facilities are currently operating in the U.S. EEZ. Some marine aquaculture facilities are located in nearshore state waters, however. In the future, inshore marine production is likely to be constrained by the availability of suitable sites, poor water quality, high coastal land values, and competition with other ocean uses.<sup>23</sup> Potential aquaculture development in offshore areas has received increasing attention because of these limitations.

The cost of working offshore may be greater than the costs of working in inshore and land-based areas, in part because offshore aquaculture in the EEZ would be subject to relatively high-energy offshore environments caused by high and variable winds and storms.<sup>24</sup> However, research and technical advances have demonstrated that operating in these environments is feasible. Expansion of offshore aquaculture into clean, well-flushed waters appears to have nearly unlimited potential, although major technological and operational challenges remain.<sup>25</sup> For example, further development will require structures and materials that will contain stocks under harsh oceanic conditions and keep costs low enough to remain profitable.<sup>26</sup>

It is likely that offshore aquaculture, at least initially, would employ species with established markets and production systems that are similar to those used in inshore areas.<sup>27</sup> Examples of marine species that are candidates for offshore areas may include Atlantic salmon (*Salmo salar*), white sea bass (*Atractoscion nobils*), cobia (*Rachycentron canadum*),

<sup>22</sup> Gunnar Knapp, "Economic Potential for U.S. Offshore Aquaculture: An Analytical Approach," in *Offshore Aquaculture in the United States: Economic Considerations, Implications, and Opportunities,* NOAA, NOAA Technical Memorandum NMFS F/SPO-103, July 2008, pp. 15-50. Hereinafter cited as Knapp, "Economic Potential."

<sup>23</sup> B. Cicin-Sain et al., *An Operational Framework for Offshore Marine Aquaculture in Federal Waters*, Center for Marine Policy, University of Delaware, 2005.

<sup>24</sup> This report uses the terms *open ocean* and *offshore* interchangeably to refer to aquaculture in federal waters in the exclusive economic zone (EEZ). *Federal waters* and *EEZ* are also used interchangeably to refer to water ranging from 3 nautical miles (nm) to 200 nm from shore.

<sup>25</sup> Peter Edwards, "Aquaculture Environment Interactions: Past, Present and Likely Future Trends," *Aquaculture*, vol. 447 (2015), pp. 2-14. Hereinafter cited as Edwards, "Aquaculture Environment Interactions."

and blue mussel (*Mytilus edulis*).<sup>28</sup> Currently, salmon net pen facilities operate in protected inshore waters of Maine and Washington. Several other net pen aquaculture facilities have operated in exposed state waters of Hawaii and Puerto Rico that have characteristics similar to those of offshore areas.<sup>29</sup> Over the last two decades, permits have been issued to conduct research and limited commercial aquaculture in the  $EEZ$ <sup>30</sup> Recently, three mussel farms received permits from the U.S. Army Corps of Engineers (USACE) to operate in offshore waters. Several other ventures have been proposed;  $31$  including proposals to operate commercial facilities in several regions.

Researchers are developing systems to adapt facilities used in inshore areas to the unique needs of offshore aquaculture. Offshore systems (e.g., submersible cages, net pens, longline arrays) may be free-floating, secured to a structure, moored to the ocean bottom, or towed by a vessel. Systems have been developed to overcome problems associated with harsh open ocean conditions, including submersible cage designs that do not deform under strong currents and waves, and single-point moorings. Cage-mounted autonomous feeding systems have been developed that can operate both at the surface and submerged. Other components under development include mechanized and remote systems that can be controlled from landbased facilities; for example, universities and private-sector research interests are developing automated buoys that can monitor the condition of stock and feed fish on a regular basis for weeks at a time. $32$ 

## **FEDERAL GOVERNMENT INVOLVEMENT IN AQUACULTURE**

Federal aquaculture, regulation, research, and support are conducted by a number of federal agencies. Their roles vary widely depending on the agency's statutory responsibilities, which may be related directly or indirectly to aquaculture. Congress enacted the National Aquaculture Act of 1980 to encourage development of the aquaculture industry and coordinate federal activities.<sup>33</sup> The act established the Subcommittee on Aquaculture (SCA) to provide opportunities to exchange information and enhance cooperation among federal agencies.<sup>34</sup> SCA's main functions include the following:

<sup>&</sup>lt;sup>28</sup> There are many potential candidates, and this list includes only selected species commonly considered in the press or aquaculture trade literature.

 $29$  It appears that only one of these facilities is currently operating in the United States. See State of Hawaii, Animal Industry Division, "Open Ocean Fish Farming," at http://hdoa.hawaii.gov/ai/aquaculture-and-livestocksupportservices-branch/open-ocean-fish-farming/.

<sup>&</sup>lt;sup>30</sup> No commercial production statistics are available for these cases, and production has not been significant. Examples include blue mussel and scallop culture off New England. In the Southeast, permits have been issued for live rock aquaculture that provides material for use in aquaria.

<sup>&</sup>lt;sup>31</sup> NMFS, "NOAA Expands Opportunities for U.S. Aquaculture," press release, January 11, 2016, https://www.fisheries.noaa.gov/media-release/noaa-expands-opportunities-us-aquaculture. Proposals have included mussel and seaweed aquaculture off California and striped bass net pen culture off Long Island, NY. According to the National Oceanic and Atmospheric Administration's (NOAA's) aquaculture website, as of January 2016 there were no commercial aquaculture facilities operating in the EEZ.

<sup>32</sup> Forster, *Emerging Technologies*.

<sup>33</sup> 16 U.S.C. §§2801 et seq.

<sup>&</sup>lt;sup>34</sup> The Subcommittee on Aquaculture was known previously as the Interagency Working Group on Aquaculture and initially as the Joint Subcommittee on Aquaculture.

- reviewing national needs for aquaculture research, technology transfer, and technology assistance programs;
- supporting coordination and communication among federal agencies engaged in the science, engineering, and technology of aquaculture;
- collecting and disseminating information on aquaculture;
- encouraging joint programs among federal agencies in areas of mutual interest relating to aquaculture; and
- recommending specific actions on issues, problems, plans, and programs in aquaculture. 35

SCA operates under the Committee on Environment of the National Science and Technology Council in the Executive Office of the President. SCA is chaired by the Secretary of Agriculture, in consultation with the Secretaries of Commerce and the Interior. In addition to the three main departments, SCA includes nine additional departments and agencies with an interest in aquaculture.<sup>36</sup> SCA meets quarterly and has provided information on topics such as fish disease, aquaculture regulation, and other areas of interest.

Most federal aquaculture activities and programs that are specific to aquaculture are carried out by the Department of the Interior (DOI), Department of Commerce (DOC), and the Department of Agriculture (USDA). Other federal agencies have roles that are indirectly related to aquaculture, such as regulatory programs that apply to a variety of aquatic or marine activities, including aquaculture. Examples include USACE for activities in navigable waters, the Environmental Protection Agency (EPA) for protection of environmental quality, and the Food and Drug Administration for regulation of drugs used to treat fish diseases.

## **U.S. Department of Agriculture**

 $\overline{a}$ 

USDA plays a lead role in support of freshwater aquaculture for species such as catfish that are raised on private property in fishponds. USDA is authorized to conduct cooperative research and extension: it funds five aquaculture regional research centers. Work at aquaculture centers complements other USDA research and education programs undertaken at state land-grant universities. The USDA National Agricultural Statistics Service periodically conducts the national aquaculture census and collects and publishes other related statistical information. The Animal and Plant Inspection Service provides animal health certifications for exports of live species and products; assistance for producers experiencing losses from predators; and veterinary biologics for preventing and treating animal diseases, including those affecting aquatic species. The Farm Service Agency administers farm lending programs, including ownership, operating, and emergency disaster loans. Under certain circumstances, aquaculture operations may be eligible for disaster assistance under the Noninsured Crop Disaster Assistance Program and the Emergency Assistance for Livestock,

<sup>35</sup> National Institute of Food and Agriculture, USDA, "Notice of Public Meeting for the IWGA of the Committee on Science of the National Science and Technology Council," 82 *Federal Register* 4026-4027, January 29, 2018.

Honeybees, and Farm-Raised Fish Program.<sup>37</sup> It appears that some of USDA's programs and experiences that focus on land-based agriculture, such as finance, research, disaster assistance, marketing, and extension, may be adapted and applied to marine aquaculture development.

#### **Department of the Interior**

DOI's U.S. Fish and Wildlife Service (FWS) focuses on support of public efforts, such as stocking programs, that benefit recreational fishing of freshwater and anadromous species. FWS operates the National Fish Hatchery System, which consists of more than 60 facilities used to enhance fish stocks, restore fish populations, and mitigate fish losses. The system includes fish production and distribution facilities, fish health centers, fish passage facilities, and technology centers. FWS research programs indirectly benefit the private sector through research and applications that control fish disease and regulation of potentially invasive species. FWS and NMFS are responsible for regulating potential interactions between aquaculture activities and endangered species and marine mammals under the Endangered Species Act (ESA) and the Marine Mammal Protection Act (MMPA).<sup>38</sup>

#### **Department of Commerce**

The NMFS Office of Aquaculture in DOC focuses on regulatory, technical, and scientific services related to marine aquaculture. NOAA headquarters provides general direction for the program and coordinates with other NOAA offices, federal agencies, and the general public. The program includes five regional aquaculture coordinators, who coordinate regulatory and permitting activities, serve as liaisons with the state and local government and stockholders, and assist with grant management. Aquaculture in federal waters is regulated as a regional fishery under the Magnuson Stevens Fishery Conservation and Management Act (MSA).<sup>39</sup> NOAA's efforts to regulate offshore aquaculture are discussed in the following section concerning federal agency regulatory responsibilities (see Current Regulatory Framework).

In October 2015, NOAA released its five-year strategic plan (2016-2020) for marine aquaculture.<sup>40</sup> NOAA's vision is a "robust U.S. marine aquaculture sector that creates jobs, provides sustainable seafood, and supports a healthy ocean." The plan provides a blueprint of NOAA's involvement in marine aquaculture, including program impact, goals and strategies, deliverables, and crosscutting strategies. To increase aquaculture production, the program's four main goals are to

 develop coordinated, consistent, and efficient regulatory processes for the marine aquaculture sector;

<sup>37</sup> For further discussion, see CRS Report RS21212, *Agricultural Disaster Assistance*, by Megan Stubbs.

<sup>38</sup> 16 U.S.C. §§1531 et seq. (ESA) and 16 U.S.C. §§1361 et seq. (MMPA).

<sup>39</sup> 16 U.S.C. §§1801 et seq.

<sup>40</sup> Office of Aquaculture, *Marine Aquaculture Strategic Plan FY2016-2020*, NMFS, February 2015, https://www.fisheries.noaa.gov/aquaculture-library.

- encourage environmentally responsible marine aquaculture using the best available science;
- develop technologies and provide extension services for the aquaculture sector; and
- improve public understanding of marine aquaculture.

The plan also includes four crosscutting strategies to achieve these goals and objectives:

- strengthen government, academic, industry, and other partnerships;
- improve communications within NOAA;
- build agency infrastructure within NOAA; and
- develop sound and consistent management within NOAA.

Various NOAA programs may support aquaculture both directly and indirectly. The National Sea Grant Marine Aquaculture Grant Program is the only U.S. government grant program that funds marine aquaculture exclusively. <sup>41</sup> These grants focus on industry challenges, such as improving aquaculture feeds, enhancing seafood safety and quality, refining culture methods, and diversifying aquaculture species.<sup>42</sup> Other NOAA offices or programs that may contribute to or become involved in aquaculture development include inspections provided by the NOAA Seafood Inspection Program, research conducted at NOAA regional fisheries science centers, and awards funded by the Saltonstall-Kennedy Grant Program.<sup>43</sup>

## **OFFSHORE AQUACULTURE CHALLENGES**

A broad array of challenges is associated with offshore aquaculture development and expansion. These challenges pertain to evolving production technology, uncertain economic costs and benefits, and potential environmental and social impacts. Generalizations about how to address these challenges are difficult to make because of the variety of candidate species, different technologies, and potential scales of operation.

Major categories of concerns related to offshore aquaculture development include (1) the legal and regulatory environment; (2) potential environmental harm; (3) economic, trade, and stakeholder concerns related to development of a new industry; and (4) business and institutional support.<sup>44</sup>

<sup>&</sup>lt;sup>41</sup> The general mission of the Sea Grant College Program is to enhance the practical use and conservation of coastal, marine, and Great Lakes resources to provide for a sustainable economy and environment.

<sup>42</sup> NOAA Sea Grant, "Sea Grant in Aquaculture," at https://seagrant.noaa.gov/Our-Work/ Aquaculture.

<sup>43</sup> NMFS, "Saltonstall-Kennedy Grant Program," at https://www.fisheries.noaa.gov/grant/ saltonstall-kennedygrantprogram.

<sup>44</sup> Detailed discussions of many of the issues discussed in this section are available in *Development of a Policy Framework for Offshore Marine Aquaculture in the 3-200 Mile U.S. Ocean Zone* (2001) by the University of Delaware's Center for the Study of Marine Policy, at http://darc.cms.udel.edu/sgeez/sgeez1final.pdf; and *Recommendations for an Operational Framework for Offshore Aquaculture in U.S. Federal Waters* (October 2005) by the University of Delaware's Gerard J. Mangone Center for Marine Policy, at http://darc.cms.udel. edu/sgeez/ sgeez2final.pdf.

## **Current Regulatory Framework<sup>45</sup>**

One of the main issues associated with marine offshore aquaculture is the concept of ownership and individuals' rights to use the marine environment for economic gain (in contrast to, for example, the catfish industry, where fishponds are constructed and operated on private land). Some envision development and management as a partnership, where the government's role is one of both enabler and steward.<sup>46</sup> This partnership could provide for property rights and regulatory clarity, certainty, and stability. For example, the government already provides specific rights to businesses that extract or use resources of the continental shelf, such as oil and gas and wind energy development.

Aquaculture regulation depends primarily on the geographic location and characteristics of aquaculture facilities. In state waters, in accordance with the federal Submerged Lands Act of 1953, coastal states exercise jurisdiction over an area extending 3 nautical miles (nm) from their officially recognized coast (or *baseline*).<sup>47</sup> States also have jurisdiction over internal waters, areas inside the baseline in bays and estuaries, such as the Chesapeake Bay or Puget Sound. States may impose restrictions or requirements as they see fit, subject to any applicable federal laws. If located in federal waters, in waters from 3 nm to 200 nm from the baseline, aquaculture facilities are regulated primarily by federal agencies under a number of federal statutes and regulatory requirements (Figure 4). Some federal laws apply to marine aquaculture and waters of the United States generally and include facilities located in both state and federal marine waters.

#### **Marine Jurisdictional Zones**

Federal management of marine fisheries generally extends from 3 nautical miles (nm) to 200 nm from shore (baseline). State waters are measured from the baseline to 3 nm offshore. Exceptions include the west coast of Florida, Texas, and the Commonwealth of Puerto Rico, where state and commonwealth waters extend out to 9 nm. Under international law, internal waters include those areas landward of the baseline, territorial waters include those waters from 0 nm to 12 nm seaward of the baseline, and the exclusive economic zone (EEZ) includes waters from 12 nm to 200 nm from the baseline. In the United States, fisheries in the territorial sea beyond state waters and in the EEZ are managed by the federal government under the MSA.

**Internal Waters** – waters landward of the baseline from which the territorial sea is measured. States manage internal waters.

**Baseline** – generally measured as the low-water line along the coast; also accounts for features such as bays, river mouths, and fringing reefs.

**Territorial Sea** – the coastal state (nation) may claim sovereignty over the territorial sea, the airspace above it, and the seabed and subsoil below it from 0 nm to 12 nm seaward of the baseline. In 1988, the United States claimed a territorial sea (Presidential Proclamation 5928), which includes both state waters (generally 0 nm to 3 nm and federal waters (generally from 3 nm to 12 nm).

**Exclusive Economic Zone** – the coastal state (nation) may claim sovereign rights for the purpose of exploring, exploiting, conserving, and managing natural resources, either living or nonliving, in the EEZ.

<sup>45</sup> Adam Vann of the CRS American Law Division contributed to this section.

<sup>46</sup> John Forster, "Broader Issues in the Offshore Fish Farming Debate," in *Offshore Aquaculture in the United States: Economic Considerations, Implications, and Opportunities*, NOAA, NOAA Technical Memorandum NMFS F/SPO103, July 2008, pp. 245-263. Hereinafter cited as Forster, "Broader Issues."

Notes:  $EEZ =$  exclusive economic zone; MHW = mean high water; MLLW = mean lower low water. The tidal datum is a standard elevation defined by a certain phase of the tide.

Figure 4. U.S. Maritime zones.

Currently, no single federal agency is authorized to approve or permit offshore aquaculture facilities in federal waters, generally the EEZ. USACE, NMFS (NOAA Fisheries), and EPA are separately authorized to regulate certain activities that are required to establish and operate aquaculture facilities.<sup>48</sup> Federal agencies that issue permits are required to consult with other regulatory agencies concerning the potential effects of each application. The permitting process also involves consultation and other requirements that are incorporated into the review of these applications. The following sections summarize the required federal permits, consultation, and review requirements.

*Federal Permits to Conduct Aquaculture in the Federal Waters* 

#### **Section 10 Permits**

Section 10 of the Rivers and Harbors Act of 1899 (hereinafter referred to as Section 10) prohibits the unauthorized obstruction or alteration of any navigable water of the United States.<sup>49</sup> Authorization by the Secretary of the Army, through USACE, must be provided before construction is initiated. Construction may include any structure or work in or affecting the course, condition, or capacity of navigable waters, excavation or fill, including aquaculture facilities, in or over any navigable waters of the United States within 3 nm from

<sup>48</sup> Stephanie S. Otts and Terra Bowling, *Offshore Mussel Culture Operations: Current Legal Framework and Regulatory Authority*, National Sea Grant Law Center, April 2012.

<sup>49</sup> 33 U.S.C. §403.

shore. Because aquaculture facilities may be located in and may affect navigable waters, the developer of the facility may be required to obtain authorization from USACE under Section 10. USACE's role is to regulate the use of the navigable water (not to regulate aquaculture per se).

The Outer Continental Shelf Lands Act extends USACE authority over all artificial islands and all installations and other devices permanently or temporarily attached to the seabed, which may be erected for the purpose of exploring for, developing, or producing resources.<sup>50</sup> Therefore, a Section 10 permit is also required prior to construction or placement of installations—such as aquaculture facilities—in federal waters from the seaward limit of state waters to the seaward limit of the outer continental shelf.<sup>51</sup> The decision to issue a permit is based on the effects on navigation and the proposed activity's probable impacts on the public interest. The public interest is assessed by comparing the benefits that may be expected to accrue from the proposed activity and the reasonably foreseeable harm that reflects the national concern for the protection and use of important resources.<sup>52</sup> Offshore aquaculture permits would be required for structures such as cages, net pens, or lines that are anchored or attached to the sea floor.

Section 10 permit requirements for aquaculture development beyond 3 nm may differ from those within 3 nm, because installations or other devices that are not temporarily or permanently attached to the seabed do not appear to be included. Examples of facilities beyond 3 nm that may not require Section 10 permits include bottom shellfish culture or unmoored floating aquaculture facilities if they do not impede navigation.

## **National Pollutant Discharge Elimination System Permit**

EPA protects water quality by regulating the discharges of pollutants into U.S. waters under the Clean Water Act (CWA).<sup>53</sup> Under the CWA, a National Pollutant Discharge Elimination System (NPDES) permit is required to discharge pollutants from point sources into federal ocean waters.<sup>54</sup> A *point source* is defined as "any discernable, confined and discrete conveyance, including but not limited to any pipe, ditch, channel, tunnel, conduit, well, discrete fissure, container, rolling stock, concentrated animal feeding operation, or vessel or other floating craft, from which pollutants are or may be discharged."<sup>55</sup>

Aquaculture facilities may discharge materials such as fecal matter; excess feed; antifoulants; and therapeutic agents, such as antibiotics. EPA currently regulates aquaculture facilities as a point source if the activity qualifies as a Concentrated Aquatic Animal Production (CAAP) facility;<sup>56</sup> CAAPs are defined according to discharge frequency and production level or as designated by EPA on a case-by-case basis if they are significant contributors of pollution. <sup>57</sup> Commercial scale aquaculture operations in federal waters would be likely to trigger the CAAPs threshold and require a NPDES permit.<sup>58</sup>

<sup>50</sup> 43 U.S.C. §1333(a)(1).

<sup>51</sup> 33 C.F.R. §320.2(b).

 $52$  33 C.F.R. §320.4(a)(1). The processing of the permits is addressed in 33 C.F.R. §325.

<sup>53</sup> 33 U.S.C. §§1251 et seq.

<sup>54</sup> 33 U.S.C. §1342.

<sup>55</sup> 33 U.S.C. §1362(14).

<sup>56</sup> 40 C.F.R. §122.24(a).

<sup>57</sup> 40 C.F.R. §122.24(a), 40 C.F.R. 122 Appendix C. Concentrated Aquatic Animal Production facilities include cold-water facilities that discharge at least 30 days per year, produce more than 20,000 pounds of fish per year,

#### **Fishing (Aquaculture) Permit**

NMFS is the only federal agency that claims explicit management authority over offshore aquaculture. Currently, NMFS manages federal fisheries under authority of the MSA. The MSA regulates fishing in the EEZ through development and implementation of federal fishery management plans (FMPs). The MSA "does not expressly address whether aquaculture falls within the purview of the act."<sup>59</sup> The MSA defines a *fishery* as "one or more stocks of fish ... and any fishing for such stocks" and *fishing* as the "catching, taking, or harvesting of fish."<sup>60</sup>

The Magnuson-Stevens Act does not expressly address whether aquaculture falls within the purview of the Act. However, the Magnuson-Stevens Act's assertion of exclusive fishery management authority over all fish within the EEZ, its direction to fishery management councils to prepare fishery management plans for any "fishery" needing conservation and management, together with the statutory definitions of "fishery" and "fishing," provide a sound basis for interpreting the Act as providing authority to regulate aquaculture in the EEZ.<sup>61</sup>

Under the MSA's authority, several regional fishery management councils and NMFS have exercised regulatory oversight over offshore aquaculture.<sup>62</sup> In some cases, NMFS authorized offshore aquaculture in federal waters for research and experimental purposes under an exempted fishing permit.<sup>63</sup> These permits are of limited duration and not intended to apply to development of permanent commercial operations.

The Gulf of Mexico Fishery Management Council (GMFMC) has been particularly active on aquaculture issues. $64$  In 2009, an aquaculture FMP was approved by the GMFMC; NMFS issued its final rule to implement that  $FMP$  in 2016.<sup>65</sup> The aquaculture plan establishes a regional permitting process for regulating aquaculture in the Gulf of Mexico EEZ. The regulations authorize permits for up to 20 facilities that are limited to combined total production of 64 million pounds annually of species that are native to the Gulf of Mexico. Applicants are required to acquire other federal permits before NMFS can issue a Gulf aquaculture permit. NMFS also has developed a memorandum of understanding to coordinate federal agency actions and outline the permitting responsibilities of each agency in the Gulf.<sup>66</sup>

and use 5,000 pounds or more of feed per month and warm-water facilities that discharge at least 30 days per year and produce at least 100,000 pounds of fish per year.

<sup>58</sup> Section 404 of the Clean Water Act regulates discharges of dredged or fill material into the waters of the United States, which does not include federal waters beyond 3 nm. This permit is often required for shellfish aquaculture in state waters.

<sup>59</sup> Memorandum from Constance Sathre, Office of the General Counsel, to Lois Schiffer, NOAA General Counsel, June 9, 2011. Hereinafter cited as Sathre, 2011.

<sup>60</sup> Sathre, 2011.

<sup>61</sup> Sathre, 2011.

 $62$  Regional fishery management councils were established by Congress under the Fishery Conservation and Management Act (P.L. 94-265).

<sup>63</sup> 50 C.F.R. §600.745(b).

<sup>64</sup> Eight Regional Fishery Management Councils were established under the Magnuson Stevens Fishery Conservation and Management Act (16 U.S.C. §§1801 et seq.) to develop fishery management plans for fisheries in each of the eight regions.

<sup>65</sup> NMFS, "Fisheries of the Caribbean, Gulf, and South Atlantic; Aquaculture," 81 *Federal Register* 1762-1800, January 13, 2016.

<sup>66</sup> NOAA, *Memorandum of Understanding for Permitting Offshore Aquaculture Activities in Federal Waters of the Gulf of Mexico*, 2016, at http://sero.nmfs.noaa.gov/sustainable\_ fisheries/gulf\_fisheries/aquaculture/ documents/pdfs/final\_offshore\_aquaculture\_mou\_020617.pdf.

However, a recent legal decision has cast doubt on NMFS's authority to regulate aquaculture under the MSA. In *Gulf Fisherman's Association v. National Marine Fisheries*  Service,<sup>67</sup> the U.S. District Court for the Eastern District of Louisiana held that NMFS exceeded its authority under the MSA when it adopted a regulatory scheme for aquaculture operations in the Gulf of Mexico. The court found that the MSA's grant of authority to regulate "fishing" and "harvesting" did not include aquaculture, noting that "[h]ad Congress intended to give [NMFS] the authority to create an entirely new regulatory permitting scheme for aquaculture operations, it would have said more than 'harvesting.' The MSA is a conservation statute, aimed at the conservation and management of natural resources. Fish farmed in aquaculture are neither 'found' off the coasts of the United States nor are they 'natural resources<sup>"68</sup>

Some are concerned that regional management of offshore aquaculture under the MSA may add another additional administrative requirements, especially if several regional fishery management councils develop their own, possibly contradictory, open ocean aquaculture management policies.<sup>69</sup> Currently, commercial aquaculture is less likely to occur in federal waters under the jurisdiction of other regional fishery management councils because they have not prepared aquaculture FMPs or generic aquaculture amendments to the appropriate FMPs for species that could be cultured. In addition, it is unclear what regulatory authority NMFS and the regional councils might have over species, such as mussels, that are not managed under a federal FMP.

#### *Federal Consultation and Review Requirements*

Consultation and review requirements are often triggered by federal permitting programs. Some crosscutting environmental requirements are entirely procedural, because they require that the federal agency implement certain procedures to ensure the agency identifies and analyzes potential impacts the proposal would have on certain resources before deciding whether to issue the permit. Other environmental requirements may prohibit the agency from permitting the action, as proposed, unless the level of adverse impacts can be minimized or mitigated.

#### **Coastal Zone Management Act**

Under Section 306 of the Coastal Zone Management Act (CZMA),<sup>70</sup> states may develop and implement a coastal management program (CMP) pursuant to federal guidance. State CMPs "describe the uses subject to the management program, the authorities and enforceable policies of the management program, the boundaries of the state's coastal zone, the organization of the management program, and related state coastal management concerns."<sup>71</sup>

Arguably the main feature of the CZMA is federal consistency.<sup>72</sup> Federal agency activities that have reasonably foreseeable effects on a state's coastal zone resources and uses

 $\overline{a}$ 

<sup>72</sup> 16 U.S.C. §§1451 et seq.

<sup>67</sup> No. 16-1271, 2018 U.S. Dist. LEXIS 163685 (E.D. La. Sept. 25, 2018).

<sup>68</sup> No. 16-1271, 2018 U.S. Dist. LEXIS 163685 (E.D. La. Sept. 25, 2018).

<sup>69</sup> Gulf of Mexico Fishery Management Council, *Fishery Management Plan for Regulating Aquaculture in the Gulf of Mexico* (Tampa, FL: January 2009).

 $70$  16 U.S.C. §1455.

<sup>71</sup> NOAA, *CZMA Federal Consistency Overview*, February 20, 2009 (revised January 4, 2016), p. 3.

should be consistent with the enforceable policies of the state's coastal management plan.<sup>73</sup> Section 307 of the CZMA requires

any applicant for a required Federal license or permit to conduct an activity, in or outside of the coastal zone, affecting any land or water use or natural resource of the coastal zone of that state" to "provide in the application to the licensing or permitting agency a certification that the proposed activity complies with the enforceable policies of the state's approved program and that such activity will be conducted in a manner consistent with the program.<sup>74</sup>

Enforceable policies are legally binding state policies, such as constitutional provisions, laws, regulations, land use plans, or judicial or administrative decisions.<sup>75</sup>

Federal licensing and permitting (such as aquaculture permit requirements) is one of four general categories of federal activities that may be reviewed for consistency.<sup>76</sup> The state lists federal licenses and permits that affect coastal uses and resources in its federally approved CMP. For listed activities, the applicant submits related data and information and a consistency certification that the proposed activity will be conducted in a manner consistent with the state's approved management program.<sup>77</sup> For a listed activity outside the coastal zone (such as in federal waters), the state also must describe the geographic location or area in its  $CMP.<sup>78</sup>$ 

If a license, permit, or geographic location in federal waters is not listed in the state's CMP, the activity is treated as unlisted. To review an unlisted activity, the state notifies the applicant, federal agency, and NOAA Office of Coastal Management (OCM) that it intends to review the activity. OCM decides whether to approve the request, generally based on whether the activity will have reasonably foreseeable effects on the state's coastal zone. If approved, the consistency review proceeds as in the case of a listed activity.

The state may object to the applicant's consistency certification and stop the federal agency from authorizing the activity or issue a conditional concurrence to the applicant. The permit is issued for the activity if  $(1)$  the state concurs with the consistency determination;  $(2)$ the state fails to act, resulting in a presumption of consistency; or (3) the Secretary of Commerce overrules the state on appeal and concludes that the activity is consistent with CZMA objectives or is otherwise necessary for national security.<sup>79</sup> In the vast majority of federal actions, states concur with the applicant's self-certification, often resolving any disputes collaboratively.

## **National Environmental Policy Act**

The National Environmental Policy Act (NEPA) requires federal agencies to consider the potential environmental consequences of proposed federal actions but does not compel

<sup>73</sup> NOAA, *CZMA Federal Consistency Overview*, February 20, 2009 (revised January 4, 2016).

<sup>74</sup> 16 U.S.C. §1456(c)(3)(A).

<sup>75</sup> NOAA, *CZMA Federal Consistency Overview*, February 20, 2009 (revised January 4, 2016).

<sup>&</sup>lt;sup>76</sup> Other activities that may be subject to review include direct federal agency activities; outer continental shelf exploration, development, and production plans; and federal assistance to state and local governments.

<sup>77</sup> 30 C.F.R. §930.50.

agencies to choose a particular course of action.<sup>80</sup> If an agency anticipates that an action would significantly affect the quality of the human environment, the agency must document its consideration of those impacts in an environmental impact statement (EIS). <sup>81</sup> If the impacts are uncertain, an agency may prepare an environmental assessment (EA) to determine whether a finding of no significant impact could be made or whether an EIS is necessary. <sup>82</sup> NEPA creates procedural requirements but does not mandate specific outcomes.<sup>83</sup>

#### **Endangered Species Act and Marine Mammal Protection Act**

NMFS and FWS have responsibilities under the ESA and the MMPA to review project proposals that may affect marine mammals or threatened and endangered species. <sup>84</sup> If issuance of a federal permit may adversely affect a species listed under the ESA, consultation may be required under Section 7 of the ESA.<sup>85</sup> Through consultation with either FWS or NMFS, federal agencies must ensure that their actions are not likely to jeopardize the continued existence of any endangered or threatened species or adversely modify critical habitat. If the appropriate Secretary judges that the proposed activity jeopardizes the listed species or adversely modifies critical habitat, then the Secretary must suggest reasonable and prudent alternatives that would avoid harm to the species. <sup>86</sup> If reasonable and prudent measures are adopted, the federal action is allowed to go forward.

The MMPA prohibits the harassment, hunting, capturing, killing (or *taking*) of marine mammals without a permit from the Secretary of the Interior or the Secretary of Commerce.<sup>87</sup> If marine mammals are likely to interact with aquaculture facilities and this interaction is likely to result in the taking of marine mammals, a marine mammal exemption would be required.<sup>88</sup> To be eligible for an exemption, the aquaculture facility would need to obtain a Marine Mammal Authorization Program certificate from NMFS.<sup>89</sup>

<sup>80</sup> See 42 U.S.C. §4332.

<sup>81</sup> 40 C.F.R. §1502.

<sup>82</sup> 40 C.F.R. §1508.9.

<sup>83</sup> CRS Report RL33152, *The National Environmental Policy Act (NEPA): Background and Implementation*, by Linda Luther.

<sup>84</sup> Endangered Species Act (ESA; 16 U.S.C. §§1531 et seq.) and Marine Mammal Protection Act (MMPA; 16 U.S.C. §§1361 et seq.).

<sup>85</sup> For further information on the ESA, see CRS Report RL31654, *The Endangered Species Act: A Primer*, by Pervaze A. Sheikh.

<sup>&</sup>lt;sup>86</sup> The Secretary of Commerce is generally responsible for listing and ESA-related activities for marine species, and the Secretary of the Interior is responsible for all other species.

<sup>87</sup> Under the MMPA, the Secretary of Commerce, acting through NMFS is responsible for the conservation and management of whales, dolphins, and porpoises (cetaceans), as well as seals and sea lions (pinnipeds). The Secretary of the Interior, acting through the Fish and Wildlife Service, is responsible for walruses, sea and marine otters, polar bears, manatees, and dugongs. This division of authority derives from agency responsibilities as they existed when the MMPA was enacted.

<sup>88</sup> A Marine Mammal Authorization Program certificate is issued when marine mammals may be taken incidentally in marine fisheries. If aquaculture is not defined as fishing, an incidental take authorization may be required, as in the case of nonfishing activities that take marine mammals such as construction projects and oil and gas development. See NMFS, "Incidental Take Authorizations Under the Marine Mammal Protection Act," at https://www.fisheries.noaa.gov/node/23111.

<sup>89</sup> NMFS, *A Guide to the Application Process for Offshore Aquaculture in U.S. Federal Waters of the Gulf of Mexico*, Southeast Regional Office, August 2017, at http://sero.nmfs. noaa.gov/sustainable\_fisheries/ gulf\_fisheries/aquaculture/documents/pdfs/permit\_applicant\_guide\_updated\_aug2017.pdf.

#### **MSA Essential Fish Habitat**

The MSA also requires the federal permitting agency (e.g., USACE) for any aquaculture facility to consult with NMFS if the activity has the potential to harm essential fish habitat (EFH). EFH is designated for all marine species for which there is an FMP and may include habitat in both state and federal waters.<sup>90</sup>

#### **National Marine Sanctuary Act**

NOAA manages national marine sanctuaries established under the National Marine Sanctuary Act  $(NMSA)$ <sup>91</sup> Federal agencies are required to consult with the Secretary of Commerce when federal actions within or outside a national marine sanctuary, including activities that are authorized by licenses, leases, and permits, are likely to harm sanctuary resources.<sup>92</sup> If the Secretary finds that the activity is likely to injure a sanctuary resource, the Secretary recommends reasonable and prudent measures that the federal agency can take to avoid harm to the sanctuary resource. If the measures are not followed and sanctuary resources are destroyed or injured, the NMSA requires the federal agency that issued the permit to restore or replace the damaged resources.

#### **National Historic Preservation Act**

The National Historic Preservation Act (NHPA) is another procedural statute.<sup>93</sup> Under Section 106 of NHPA,<sup>94</sup> federal agencies must determine whether actions they may permit or license will have adverse effects on properties listed or eligible for listing in the National Register of Historic Places. Such sites could include shipwrecks, prehistoric sites, or other cultural resources. Federal agencies must determine whether such resources may be affected in consultation with state and/or tribal historic preservation officers.<sup>95</sup>

## **Fish and Wildlife Coordination Act**

The Fish and Wildlife Coordination Act requires federal agencies to consult with FWS, NMFS, and state wildlife agencies when activities that are authorized, permitted, or funded by the federal government affect, control, or modify waters of any stream or bodies of water.<sup>96</sup> Consultation generally is incorporated into the process of complying with other federal permit requirements, such as the NEPA and CWA.

#### *Other Authorizations and Approvals*

The Coast Guard has authority to control private aids to navigation in U.S. waters.<sup>97</sup> Regulations require structures such as aquaculture facilities be marked with lights and signals for protection of maritime navigation.<sup>98</sup> To establish a private aid to navigation, the applicant would need formal authorization from the appropriate U.S. Coast Guard district.

<sup>90</sup> 16 U.S.C. §1855(b).

<sup>&</sup>lt;sup>91</sup> 16 U.S.C. §§1431 et seq.

<sup>92</sup> 16 U.S.C. §1434(d).

<sup>93 16</sup> U.S.C. 470 et seq.

<sup>94 54</sup> U.S.C. §306108.

<sup>95</sup> CRS Report R45800, *The Federal Role in Historic Preservation: An Overview*, by Mark K. DeSantis.

<sup>97</sup> 14 U.S.C. §83.

<sup>98</sup> 33 C.F.R. §§66.01 and 64.21.

The Bureau of Safety and Environmental Enforcement (BSEE) has regulatory responsibility for the offshore energy industry on the outer continental shelf.<sup>99</sup> BSEE would review aquaculture applications and provide comments regarding potential conflicts, interactions, or effects on mineral exploration, development, and production operations. The Bureau of Ocean Energy Management (BOEM) manages development of the outer continental shelf energy and mineral resources. BOEM would require a right-of-use easement for any offshore aquaculture operations that uses or tethers to an existing oil and gas facility.<sup>100</sup>

## **Environmental Concerns**

One of the main features of many previous aquaculture bills has been consideration of environmental protection and monitoring of offshore aquaculture facilities. Critics of offshore aquaculture have expressed concern with potential environmental degradation and conflicts with existing uses of marine areas. They cite historic problems in inshore areas—such as escapes of cultured organisms, the introduction of disease and invasive species, pollution in areas adjacent to net pens, and habitat loss—which have created a negative perception of aquaculture.<sup>101</sup>

Aquaculture supporters assert that those who oppose marine aquaculture lack an understanding of aquaculture's benefits and risks and that "these perceptions persist despite significant scientific literature that contradicts the extent or existence of risk to the values that these groups want to protect."<sup>102</sup> Supporters contend that, in many parts of the world, a combination of farming experiences, technological advances, proper siting, and industry regulation has decreased environmental impacts and improved efficiency of marine aquaculture. Some researchers suggest that by moving operations offshore and selecting appropriate sites, the remaining impacts can be further reduced.<sup>103</sup> Others add that offshore waters would be less prone to environmental impacts than inshore waters because fish wastes and other pollutants would dissipate more rapidly in the deeper and better-flushed offshore areas.

A present lack of knowledge—owing to limited experience and few studies focusing specifically on offshore aquaculture—limits understanding of potential harm to the environment from offshore aquaculture. Most information has been collected from inshore areas, where salmon net pens and other types of aquaculture farms have been established. Some characteristics of inshore operations are similar to those that would be established offshore (e.g., both are open to the surrounding environment); however, other characteristics of offshore operations, such as offshore currents, wind and waves, water quality, and depth, are likely to differ from inshore areas. Generally, the outcomes associated with offshore

<sup>99</sup> 43 U.S.C. §§1331 et seq*.*

<sup>103</sup> Rebecca R. Gentry et al., "Mapping the Global Potential for Marine Aquaculture," *Nature Ecology & Evolution*, vol. 1 (September 2017), pp. 1317-1324.

aquaculture development depend on characteristics of aquaculture sites and how technology is employed and managed.

Over the years, researchers have identified several issues related to marine aquaculture and the use of net pens in inshore areas. These issues include water pollution from uneaten feed and waste products (including drugs, chemicals, and other inputs); habitat degradation, such as alteration of benthic habitat from settling wastes; sustainability of fish used in aquaculture feeds; use of antibiotics and other animal drugs; introduction of invasive species; escape of cultured organisms; and the spread of waterborne disease from cultured to wild fish. During the last two decades, technical advances and farming practices have reduced these impacts in nearshore areas. <sup>104</sup> Existing laws and regulations also have established performance standards and addressed many of the potential adverse environmental effects of net pen aquaculture.<sup>105</sup>

#### *Fish Waste*

 $\overline{a}$ 

Fish feed is the main source of waste from aquaculture and contributes to most environmental impacts associated with aquaculture.<sup>106</sup> The discharge of wastes, such as unused feed, and metabolic fish wastes, such as nitrogen (ammonia and urea), has been an ongoing concern because of potential effects on water quality and degradation of the seafloor environment under net pens. Treatment of effluent is not feasible because wastes are discharged directly into the ocean through net enclosures. Impacts on the environment depend on a variety of factors, such as feed quality, digestion and metabolism, feeding rate, biomass of fish, and species. Site characteristics such as cage design, depth, currents, existing water quality or nutrient levels, and benthic features also influence nutrient dispersion and impacts.

Impacts on water quality in the water column adjacent to net pens are often related to a combination of increases in nitrogen, phosphorus, lipids, and turbidity and depletion of oxygen.<sup>107</sup> Eutrophication may occur when net pens are placed at high densities and flushing of semi-enclosed water bodies is poor.<sup>108</sup> According to studies, aquaculture's contribution to nitrogen in areas adjacent to net pens ranged broadly from none to significant levels depending on a variety of factors, including environmental characteristics and species.<sup>109</sup> In some cases, it appears that nutrients are flushed away from the immediate cage area to the surrounding water body. Management practices such as choosing sites with adequate current and depth are likely to improve circulation and dissipation of waste products.<sup>110</sup>

<sup>&</sup>lt;sup>107</sup> Lipids are a large group of organic compounds composed of fats and fatty compounds that are insoluble in water. They are a source of stored energy and a component of cell membranes.

<sup>108</sup> Eutrophication is the process by which a water body or coastal area is overly enriched with nutrients that stimulate excessive growth of algae. When algae die, they are decomposed by bacteria that use and deplete oxygen.

<sup>109</sup> Carol Seals Price and James A. Morris Jr., *Marine Cage Culture and the Environment*, NOAA, NOAA Technical Memorandum NOS NCCOS 164, December 2013. Hereinafter cited as Price and Morris, *Marine Cage Culture*.

<sup>110</sup> Rust et al., "Environmental Performance," p. 513.

Solid feed and fish waste descend through the water column and may accumulate on the bottom below and around aquaculture facilities. In some cases, wastes accumulate at rates greater than the assimilative capacity of the environment, and the increase of respiration from microbial decomposition decreases oxygen levels (hypoxia) and changes sediment chemistry. This may cause hypoxia in sediments and the water overlying the bottom, which may in turn affect the abundance and diversity of marine organisms in the area. Reviews have identified changes to sediment chemistry as one of the primary impacts of marine aquaculture in the United States.<sup>111</sup>

Over the last several decades, harmful environmental impacts have been reduced because of advances in technology, improved facility siting, better feed management, and stricter regulatory requirements.<sup>112</sup> Feed formulations have been modified to improve digestibility without losses in growth. When feed is more fully digested, the amount of waste (nutrient) outputs per unit of fish produced is reduced and fewer solid wastes and nutrients are released to the environment. Modifying feeding practices also has reduced the loss of uneaten food.<sup>113</sup> Some facilities now use underwater devices to monitor feeding to avoid overfeeding and waste. Environmental monitoring also informs farmers and regulators of the need to leave a site fallow or to adjust feeding.

Some researchers and aquaculturalists have proposed the use of multi-tropic aquaculture by adding other organisms such as invertebrates and seaweeds to the aquaculture system. The system would mimic natural tropic relationships, where wastes from cultured organisms are food for other organisms, such as shellfish, and supply nutrients for seaweed. <sup>114</sup> These additions could lessen environmental impacts from nutrients and increase the efficiency of feed utilization<sup>115</sup>

Proponents suggest that offshore aquaculture may produce fewer and less severe environmental impacts than those caused in nearshore areas. They hold that open ocean waters are normally nutrient deficient, and nutrients released from offshore aquaculture operations would likely dissipate. Critics question whether experiences with experimental facilities are relevant to future commercial operations, which may need to operate at larger scales to be profitable. Generally, environmental impacts are likely to vary depending on management and culture techniques, location, size and scale, and species.

### *Fish Diseases*

 $\overline{a}$ 

Fish diseases are caused by bacteria, viruses, and parasites that commonly occur in wild populations. Aquaculture production is vulnerable to mortality associated with fish diseases, and serious losses have occurred.<sup>116</sup> Disease outbreaks cost the global aquaculture industry an

<sup>111</sup> Price and Morris, *Marine Cage Culture*, p. 22.

<sup>112</sup> Rust et al., "Environmental Performance," p. 519.

<sup>113</sup> Rust et al., "Environmental Performance," p. 512.

<sup>&</sup>lt;sup>115</sup> In nature, different tropic levels generally refer to plants (algae and seaweed), herbivores (organisms that graze on plants), and carnivores (predators of herbivores).

<sup>116</sup> Frank Asche et al., "The Salmon Disease Crisis in Chile," *Marine Resource Economics*, vol. 24, no. 4 (2009), pp. 405-411. Hereinafter cited as Asche et al., "Salmon Disease Crisis."

estimated \$6 billion per year.<sup>117</sup> Starting in 2007, the Chilean aquaculture industry suffered the worst disease outbreak ever observed in salmon aquaculture.<sup>118</sup> The outbreak of infectious salmon anemia virus cost the industry  $350,000-400,000$  mt of production and \$2 billion.<sup>119</sup>

Net pens are open to the marine environment, so pathogens may pass freely as water moves through net pen enclosures. Cultured organisms are often more susceptible to diseases because fish are kept at higher densities, which increases the rate of contact among fish and may induce stress. Research suggests that fish pathogens may be transferred from farmed to wild fish and that nonnative pathogens may be introduced when fish are moved from different areas.<sup>120</sup> Some fish farmers counter that more disease problems originate in wild populations, where reservoirs of disease naturally exist and are subsequently transferred to cultured organisms.

For example, some researchers have identified sea lice as a serious problem for Atlantic salmon farming because of lost production and the costs of disease management.<sup>121</sup> Studies demonstrate that high host densities in net pens promote transmission and growth of the parasite.<sup>122</sup> It has been hypothesized that sea lice may be spread from salmon in net pens to wild counterparts that are passing in adjacent waters. Some assert that sea lice have harmed wild salmon populations migrating near infested salmon farms. Studies have shown that transmission is initiated from wild to cultured fish, and then the lice are transmitted back to wild salmon hosts.<sup>123</sup> The extent of the impact on wild salmon is a matter of debate, because many different factors affect salmon population abundance. However, a recent study concluded that "Atlantic salmon populations are already under pressure from reductions in marine survival and the addition of significant lice-related mortality during the coastal stage of smolt out-migration could be critical."<sup>124</sup> Sea lice control and prevention strategies have included the use of approved therapeutants (aquaculture drugs) and fallowing of sites between production cycles.

## *Drugs and Other Chemicals*

 $\overline{a}$ 

Various drugs have been used to treat and prevent the occurrence of disease, including disinfectants, such as hydrogen peroxide and malachite green; antibiotics, such as sulfonamides and tetracyclines; and anthelmintic agents, such as pyrethroid insecticides and avermectins. <sup>125</sup> Antibiotics are used to control bacterial diseases and are sometimes introduced to cultured fish in their feed. Drugs also are used to aid in spawning, to treat

Anthelmintics are a type of medicine that kills helminths, worm-like parasites such as flukes, roundworms, and tapeworms. The medicine is selectively toxic to the parasite and not the host, in this case salmon.

infections, to remove parasites, and to sedate fish for transport or handling. Viral diseases are managed by monitoring and focusing on management practices, such as lowering stress, selecting organisms with greater resistance, and providing feed with proper nutrients. However, in some cases it is necessary to depopulate farms to stop the spread of the disease.

The Food and Drug Administration (FDA) is responsible for approving drugs used in aquaculture. The drug must be shown to be safe and effective for a specific use in a specific species.<sup>126</sup> Only drugs approved by the FDA Center for Veterinary Medicine may be administered to aquatic animals. Drug withdrawal periods and testing are required to prevent the sale of fish that contain drug residues. The USDA Animal and Plant Health Inspection Service is responsible for controlling the spread of infectious diseases and requires an import permit and health certificate for certain fish species.<sup>127</sup> Many states also have animal health regulations to prevent disease introductions and manage disease outbreaks.

Aquaculture drugs such as antibiotics that are used to treat marine finfish may be transferred to open water environments when unconsumed feed or fish wastes pass through net pen enclosures. Extensive use of these agents may result in the development and spread of bacteria that are resistant to antibiotics.<sup>128</sup> The use of many of these drugs reportedly is declining, as vaccines eliminate the need to treat bacterial diseases with antibiotics and other drugs.<sup>129</sup> Examples include salmon farming in Norway, where antibiotic use has decreased by 95%, and in Maine, where antibiotics are now rarely used. <sup>130</sup> Proponents of offshore aquaculture suggest that, because of the more pristine and better oxygenated water conditions offshore as compared to many inshore areas, the occurrence of fish diseases could be lower for offshore aquaculture.

#### *Escapes, Genetic Concerns, and Invasive Species*

The escape of organisms from aquaculture facilities, especially nonnative species, is another environmental concern related to aquaculture. This issue might arise if genetically selected or nonnative fish escape and persist in the wild. Historically, nonnative species have been used in aquaculture, sometimes resulting in long-term environmental harm. For example, Asian carp such as silver, bighead, and grass carp were introduced to the United States from Asia to improve water quality of freshwater aquaculture ponds and waste treatment ponds. These species are now found in most of the Mississippi drainage area, and they have affected the basin's aquatic ecology and harmed species such as freshwater mussels and native fish.<sup>131</sup>

Genetic diversity could be affected if hatchery-raised fish spawn with wild conspecifics (wild fish of the same species). Interbreeding could result in the loss of fitness in the

<sup>&</sup>lt;sup>126</sup> Letter from FDA, Center for Veterinary Medicine to Aquaculture Professionals, October 2015, at https://www.fda.gov/animal-veterinary/product-safety-information/letter-aquaculture-professionals.

<sup>131</sup> U.S. Geological Survey, *Nonindigenous Aquatic Species*, Data Queries and Species Lists, at https://nas.er.usgs.gov/ taxgroup/fish/default.aspx.

population due in part to the loss of genetic diversity. Genetic risks would depend on the number of escapes relative to the number of wild fish, the genetic differences between wild and escaped fish, and the ability of escaped fish to successfully spawn in the wild.<sup>132</sup> There are also concerns that nonnative fish could become established in the wild and compete with wild fish for food, habitat, mates, and other resources.

Experiences with farmed Atlantic salmon may provide some insight regarding escape of farmed fish both within and outside their native ranges.<sup>133</sup> Atlantic salmon have escaped from farms in the Pacific Northwest (outside their native range) and have been recaptured in Alaskan commercial fisheries. In 2017, over 100,000 Atlantic salmon escaped from facilities owned by Cook Aquaculture off Cypress Island, WA.<sup>134</sup> Many of the escaped fish were recovered, and fishery managers assumed the remaining fish were unable to make the transition to a natural diet. In British Columbia, escaped Atlantic salmon have spawned and produced wild-spawned juvenile Atlantic salmon, but it is uncertain whether they have established self-reproducing breeding populations.<sup>135</sup>

Within the range of Atlantic salmon, farmed salmon have been found on spawning grounds during the period when wild Atlantic salmon spawning occurs. Domestication of farmed salmon has changed their genetic composition and reduced genetic variation. These changes have occurred because limited numbers of brood fish are used for spawning farmed fish and farmers select for specific traits.<sup>136</sup> Much present-day farm production of Atlantic salmon is based on five Norwegian strains. Farmed and wild hybrids and backcrossing of hybrids in subsequent generations may change genetic variability and the frequency and type of alleles present in wild populations.<sup>137</sup> The extent and nature of these changes to genetic variability may affect survival (fitness) of these populations. <sup>138</sup> Changes in the genetic profiles of wild populations have been found in several rivers in Norway and Ireland, where interbreeding of wild and farmed fish is common.<sup>139</sup> Large-scale experiments in Norway and Ireland show highly reduced survival and lifetime success rates of farmed and hybrid salmon compared to wild salmon.<sup>140</sup> Some researchers have concluded that further measures are needed to reduce the escape of salmon from aquaculture farms and their spawning with wild populations.<sup>141</sup>

Researchers and managers have made several recommendations to decrease the risk of invasive species introductions and the loss of genetic diversity. There appears to be common agreement, as in the case of the Gulf of Mexico FMP, that only native species should be

<sup>132</sup> Price et al., *Protected Species*.

farmed. To decrease genetic risks associated with escapes, farmers might be required to use wild broodstock with a genetic makeup that is similar to local wild populations. However, by using this approach, farmers may forgo benefits of selective breeding. Another approach might involve the use of sterile fish created through techniques such as hybridization, chemical sterilization, polyploidy, and others.  $142$  However, these methods are not always 100% effective and the approach may increase costs of production. 143

#### *Interactions with Other Species*

Interactions between aquaculture operations and marine wildlife may occur when predators in search of food are attracted to aquaculture facilities or if aquaculture sites overlap with the ranges or migration of marine species. These interactions are common in Chile, British Columbia, and Norway, where marine mammals and birds often are attracted to salmon farms.<sup>144</sup> Most interactions are seasonal and involve sea lions, seals, and otters, as well as seabirds such as sea gulls and cormorants. Predation can result in loss of fish, damage to equipment, and stress to fish. Deterrence measures seek to address these concerns; for example, predator nets may be placed outside the main net to stop marine mammals directly accessing the net pen. Some farms also install bird nets over net pens to protect fish from bird predation. When nonlethal measures fail, sea mammals are sometime culled.

Offshore facilities could affect some endangered species as they migrate or alter essential habitat for feeding, breeding, and nursing. Information on incidental entanglement and mortality is limited, because of the small number of facilities working in offshore areas. NOAA recently investigated longline aquaculture gear that might be used for mussel culture and found that interactions are rare.<sup>145</sup> However, researchers questioned whether the small number of interactions indicates that this type of aquaculture is benign or is due to the failure to detect and report interactions. Minimizing impacts on protected species may require monitoring and research into natural interactions between predators and prey. Management strategies might involve preventive measures, such as spatial planning and aquaculture gear modifications.

Wild fish also are sometimes attracted to net pens to consume feed that has fallen through net pen enclosures.<sup>146</sup> The attraction of wild fish may provide a benefit, because their consumption of feed may lessen environmental impacts such as the release of nutrients or deposits of feed near net pens. At the same time, it could have negative impacts, such as the transfer of diseases from farmed to wild fish or from wild to farmed fish. Impacts related to changes in wild fish physiology from the ingestion of feed and changes in the distribution of wild fish are unknown.

#### *Aquaculture Feeds and Related Issues*

Fish feed is a critical input, because it must provide all of the essential nutrients and energy needed to meet the cultured organism's physiological requirements. The supply and use of aquaculture feed are directly related to the economic viability of aquaculture

<sup>&</sup>lt;sup>142</sup> Polypliody occurs in organisms with cells containing more than two paired sets of chromosomes.

operations, fish growth and health, environmental quality, ecological concerns, and human nutritional benefits from aquaculture products.<sup>147</sup> Fish meal and oil are used to produce feed for carnivorous species such as salmon, because these ingredients provide nutritional requirements that are similar to those found in the wild. Aquaculture feeds must have a composition that maintains growth and fish health while balancing the costs of feed components against the value of outputs associated with fish growth. Researchers note that future aquaculture production is likely to be constrained if feeds are limited to sources of fish meal and oil, which require wild fish production and fish processing wastes. Research efforts have focused on the use of fish meal and oil substitutes that are derived from terrestrial plants.<sup>148</sup> Plant meal and oils now supply the bulk of feed ingredients, but they are not a perfect substitute and, in many cases, fish meal and oil are still an important component of most fish feeds.

#### **Feed Production and Use**

Nutritional requirements and feed composition vary according to species, the life stage of the organism (e.g., larvae, fry, fingerlings, adults), and management objectives.<sup>149</sup> Fish feeds are formulated to provide a mixture of ingredients, such as proteins, lipids, carbohydrates, vitamins, and minerals, which provide the greatest growth at the lowest cost. Historically, fish meal and oil have been principal ingredients of many aquaculture feeds, because these ingredients have been a cost-effective means of providing the nutritional requirements of many cultured species. Fish meal and oil are obtained from reduction fisheries that target small pelagic species such as anchovies, capelin, herring, and menhaden and from fish processing wastes of wild and aquaculture products.<sup>150</sup> Reduction fisheries target species that are generally less valuable than those used for human consumption.<sup>151</sup> The fish are heated and pressed to obtain fish oil and milled and dried to produce fish meal. Since 2006, the annual world supply of fish meal has ranged from 4.49 mmt to 5.86 mmt and the supply of fish oil has ranged from  $0.86$  mmt to  $1.08$  mmt.<sup>152</sup> In 2016, the United States produced 253,600 metric tons (mt) of fish meal and 80,500 mt of fish oil, approximately 5% and 8% of global production, respectively.<sup>153</sup>

Reduction fisheries supply approximately 70% of fish meal and fish oil, with the remainder obtained from fish processing wastes.<sup>154</sup> In the last 20 years, global production of fish meal and oil has declined in part because of increasing use of fish from reduction fisheries for direct human consumption and tighter quotas and controls on unregulated

<sup>&</sup>lt;sup>147</sup> Hixson, "Fish Nutrition," p. 1.

<sup>148</sup> Michael B. Rust, *The Future of Aquafeeds*, NOAA and USDA, December 2011.

<sup>&</sup>lt;sup>149</sup> Production of food fish is one of many potential objectives of aquaculture. Other examples of aquaculture objectives may involve enhancement of recreational fishing or restoration of aquatic populations.

<sup>&</sup>lt;sup>150</sup> A reduction fishery uses fish to produce fish oil and fish meal for animal feeds, including those used for aquaculture.

<sup>&</sup>lt;sup>151</sup> Many oppose the use of these species for animal feeds, because they assert that the protein should be available for direct human consumption. In many cases, such as U.S. menhaden fisheries, fish are not marketed as food items because of the taste and texture of their flesh. However, in some parts of the world, direct human consumption of other forage fisrubionh (often small pelagic species) is increasing.

fishing.<sup>155</sup> The global decrease in total fish meal production has occurred despite increasing production of meal and oil from fish processing wastes.

#### **Conversion of Aquaculture Feed to Fish Flesh**

Researchers have found that fish meal (protein) and fish oil (lipids) are important ingredients for fish growth. <sup>156</sup> Most feeds are formulated to increase efficiency by using highenergy lipid to allow for greater conversion of dietary protein into fish muscle. In addition to fish protein and oil, fish feeds may include plant proteins, terrestrial animal protein, carbohydrates, moisture, ash, vitamins, and minerals. In comparison to other animals, fish are relatively efficient in converting fish feed to flesh.<sup>157</sup> For example, feed conversion ratios for Atlantic salmon are approximately 1.15 (approximately 1.15 kilograms [kg] of dry feed are used to produce 1.0 kg of salmon flesh [wet]). <sup>158</sup> In 2013, salmon fish feed used on Norwegian farms consisted of approximately 18% fish meal and 11% fish oil.

The amount of marine fish protein and oil needed to produce a unit measure of seafood such as salmon has been decreasing with the use of plant-based substitutes. The "fish in fish out" ratio is the amount of wild fish needed to produce the fish meal and fish oil required to produce one kilogram of farmed fish. The ratio of "fish in to fish out" varies according to the nutritional requirements of different species, with higher ratios for carnivorous fish such as eels (1.75) that are fed higher fish protein and fish oil diets and lower ratios for omnivorous fish such as tilapia  $(0.18)$ .<sup>159</sup> When aggregated across species, worldwide aquaculture is a net producer of fish protein, with estimates ranging from 0.22 kg to 0.5 kg of wild marine fish used to produce a kilogram of farmed seafood.<sup>160</sup>

#### **Substitutes for Fish Meal and Oil**

Over the last two decades, research on fish dietary requirements has contributed to progress in developing substitutes for fish meal and oil from terrestrial plant ingredients and other potential sources, such as marine algae. <sup>161</sup> This has led to reductions in the use of fish meal and oil as ingredients in fish food. Terrestrial plant meal and oils now supply the bulk of feed ingredients for most fish species.<sup>162</sup> The focus of research has been on plant protein and oil sources such as soy, canola, sunflower, cottonseed, and others. For example, the Norwegian salmon industry has reduced the content of fish meal and oil in fish feed from over  $60\%$  to less than 25% by using plant proteins and oils.<sup>163</sup>

<sup>&</sup>lt;sup>161</sup> Fish oils are produced by marine algae, and in nature algae are consumed by fish that feed at relatively low tropic levels.

<sup>162</sup> Michael B. Rust, *The Future of Aquafeeds*, NOAA and USDA, December 2011.

<sup>&</sup>lt;sup>163</sup> Rust et al., "Environmental Performance," p. 512.

In spite of decreasing global production of fish oil and meal, use of plant-based substitutes has allowed production of feeds for all aquaculture to expand at 6% to 8% per year.<sup>164</sup> Increasing demand and a limited supply of fish meal and oil have caused prices to triple for these ingredients in recent years.<sup>165</sup> These price increases are likely to continue, because production is generally limited to supplies from wild sources. <sup>166</sup> The cost of aquaculture feeds accounts for approximately 50% of net pen aquaculture operating costs. Limited wild supplies and rising feed costs have encouraged researchers and aquaculturalists to improve feeding techniques to reduce waste, modify feed formulations, use alternatives such as waste from fish-processing plants, and investigate new sources. Substitution has become more attractive, as the prices of fish meal and oil have risen faster than the prices of plant proteins and oils. Fish can be cultured with substitutes for fish meal and oil, but the commercial use of substitutes depend on whether the lower costs of the substitute can offset losses associated with lower growth rates, less disease resistance, and inferior nutritional value of aquaculture products.<sup>167</sup>

Although significant progress has been made in using plant protein and oil substitutes for fish feeds, there are still limitations to their use. In the near future, some fish meal and oil will still be needed in feed formulations. Plant meals are deficient in certain essential amino acids and contain fiber, carbohydrates, and certain antinutritional factors, which can adversely affect absorption, digestion, and growth.<sup>168</sup> Nutritional quality of plant proteins can be improved through chemical and mechanical processing, which can reduce certain antinutrients and concentrate protein. Plant oils are an excellent source of energy, but they do not contain omega-3 fatty acids (eicosapentaenoic acid [EPA] and docosahexaenoic acid [DHA]). These fish oils have been found to improve immune responses and fish health generally.<sup>169</sup> Fish species have differing tolerances to diets without certain fatty acids, which appear to be related to their natural diet. The use and substitution of plant protein and oils is likely to increase with further research into alternatives and as prices of fish meal and oil increase.

#### **Fish Health**

 $\overline{a}$ 

Proper feed formulations also are essential to promote fish health and prevent disease outbreaks. When fish are farmed at high densities, good nutrition tends to reduce stress, decrease the incidence of disease, and boost immune systems. A deficiency in any required nutrient may impair health by affecting the organism's metabolism and increasing susceptibility to disease. Research has shown that the use of plant oils and the ratio of different fatty acids can affect the immune response in fish. Dietary additives of immunostimulants, probiotics, and prebiotics have been found to increase immunity, feed efficiency, and growth.<sup>170</sup> An ongoing challenge is to improve knowledge and commercial application of feed formulations, especially for nutrimental requirements of newly domesticated species.

<sup>&</sup>lt;sup>169</sup> Hixson, "Fish Nutrition," p. 5.

<sup>&</sup>lt;sup>170</sup> Hixson, "Fish Nutrition," p. 5.

#### **Human Health and Preferences**

The human health benefits of seafood are widely recognized because fish species contain high-quality protein, oils, minerals, and vitamins. Some research has found that diets that include omega-3 fatty acids enhance early brain and eye development and reduce heart disease and cognitive decline later in life. Feeds with plant-based substitutes can affect the quality of seafood products because these alternatives lack the fatty acids that are beneficial to human health. Farmed fish products that have been fed plant substitutes for fish oil may have lower concentrations of beneficial fish oils in their flesh. Two potential ways to reduce the use of fish oils in feed while maintaining high levels of omega-3 fatty acids in fish are (1) to develop genetically modified plants, fungi, or microbes to produce DHA and EPA for use in fish feeds or (2) to grow fish on low fish oil diets in the beginning of the production cycle and boost the omega-3 fatty acids in fish diets to raise their levels at the end of the production cycle.

There also are growing public health concerns about persistent organic pollutants, such as polychlorinated biphenyls (PCBs), and inorganic contaminants, such as heavy metals, in farmed fish. The accumulation of contaminants varies by location and associated sources of pollutants. It can occur in both wild and farmed fish.<sup>171</sup> Fish fed with fish meal and oils may accumulate contaminants from marine sources. Several studies have reported elevated levels of contaminants in feeds and farmed Atlantic salmon flesh. An advantage of using plant protein and oil is the potentially lower contaminant levels than those found in some wild seafood products. Several studies have found that replacing fish protein and oil with plantderived material lowered the level of contaminants significantly.<sup>172</sup>

Consumer perceptions of changes in the quality of fish raised with substitute feeds also may affect acceptance of aquaculture products. There are widely held beliefs regarding the composition and health benefits of farmed and wild fish. Studies have shown that there are differences in taste and texture of fish farmed with alternative proteins and oils, but consumer preference studies have yielded mixed results.<sup>173</sup> Public perceptions of aquaculture products also include concerns with the use of therapeutants such as antibiotics and the crowding and industrial nature of fish farming.

#### **Sustainability Concerns**

Some stakeholders have described the use of fish meal and oils for aquaculture feeds as an issue related to the sustainability of forage species and marine ecosystems. More than 30% of global fish production and a large portion of fish meal and oil used for aquaculture feeds (75%) is derived from the harvest of forage species, such as herring, anchovies, capelin, and menhaden. Fatty acids are produced by marine algae (phytoplankton), consumed and concentrated in fish that consume algae, and transferred to organisms higher in the food chain that consume forage species. As stated earlier, forage species have a relatively low economic value, and most are not marketed for direct human consumption. However, their biomass is relatively large because they feed at somewhat low tropic levels, and they can be caught fairly

<sup>171</sup> Hixson, "Fish Nutrition," p. 7.

<sup>&</sup>lt;sup>172</sup> Hixson, "Fish Nutrition," p. 8.

<sup>&</sup>lt;sup>173</sup> Hixson, "Fish Nutrition," p. 7.

easily in large volumes because they are schooling species.<sup>174</sup> Forage species serve as prey for higher tropic level fish species such as tuna, cod, and striped bass, marine mammals, and marine birds.<sup>175</sup>

Aquatic ecologists question whether aquaculture demand and increasing prices may encourage higher levels of fishing pressure and cause or continue overfishing of forage fish populations. Management of wild fish stocks is improving in many parts of the world, and many stocks are now considered to be well managed. However, some researchers have concluded that fishing for forage species should be limited to relatively low levels, because forage species are needed to support production of other marine species.<sup>176</sup> Research using ecosystem models suggests that forage fish should be fished at lower rates to benefit the ecosystem rather than at rates that would provide long-term maximum yield.<sup>177</sup> One report recommended that catch rates should be reduced by half and biomass of forage fish should be doubled.<sup>178</sup> However, other researchers have questioned whether there is a strong connection between forage fish abundance and the abundance of their predators; $1^{79}$  they conclude that harvest policies for forage species need to be guided by a variety of factors that recognize the complexities of fisheries and ecosystems.

## **Economics, International Conditions, and Stakeholder Concerns**

Increasing demand for seafood, advances in aquaculture methods, and increases in global aquaculture production have led many observers to take an optimistic view of potential offshore aquaculture development in the United States. Nevertheless, the future of offshore development is uncertain because of the paucity of experiences in establishing and managing U.S. offshore aquaculture facilities. Greater regulatory certainty may encourage U.S. offshore development, but economic viability will determine whether the industry expands and produces significant quantities of seafood.

The viability of offshore aquaculture in the United States is likely to depend on future developments, such as further technical advances, economic conditions, and social and political acceptance. Another economic consideration for policymakers is how to integrate policies that recognize the potential costs (externalities) of environmental harm that may be caused by offshore aquaculture and are not captured by markets.<sup>180</sup> In addition to economics, user conflicts and related political factors are likely to play a role in the potential development of an offshore industry.

<sup>174</sup> *Tropic levels* generally refer to organisms in an ecosystem that occupy a similar level in the food chain. Prey items, such as sardines, occupy a lower tropic level with relatively higher levels of biomass than predators at higher tropic levels and lower biomass, such as tuna.

<sup>&</sup>lt;sup>180</sup> Externalities are defined as spillover costs or benefits, which are unintended consequences or side effects associated with an economic activity.

### *Factors Related to the Economic Viability of Offshore Aquaculture*

The economic potential of offshore aquaculture will depend on the prices of seafood products and the cost to produce them. The following discussion identifies some of the factors that will determine whether offshore aquaculture may be profitable.

#### **Demand**

The quantity demanded for an aquaculture product is a function of price—each point along the demand curve is the quantity that consumers are willing to buy at a specific price. Consumers are generally willing to buy less product at higher prices and more product for lower prices. A change in demand, a shift of the demand curve, depends on a variety of factors, such as changes in income, prices of substitutes (domestic wild fish) and complements, and consumer tastes and preferences.<sup>181</sup>

Offshore aquaculture production will compete with a variety of other protein products, such as imported seafood; domestically produced wild fish; and agriculture sources such as chicken, pork, and beef. Generally, demand for seafood products is rising both globally and domestically because of increasing population levels and incomes. The health benefits of seafood are also influencing changes in consumer preferences, with general movement away from traditional protein sources such as beef. Other types of domestic marine aquaculture production, such as land-based and inshore aquaculture, may compete with offshore aquaculture, but currently these activities provide a relatively small portion of the seafood consumed in the United States.<sup>182</sup> Domestic sources of seafood may increase marginally as some overfished stocks recover, but most domestic fisheries are already at or near their natural limits.

Some have reported that offshore aquaculture could produce a higher-quality product because of the constant flow of clean water through net pens. If it can be shown that offshore products contain fewer toxin residues or if offshore products can be raised without aquaculture drugs, these products may become more attractive to health-conscious consumers. The FDA Seafood Safety Program and the NOAA Seafood Inspection Program also may reassure U.S. consumers of the safety and quality of domestic seafood, including seafood produced by offshore aquaculture.<sup>183</sup> These factors may allow offshore producers to differentiate their products and receive higher prices relative to imports or other domestic seafood, especially in niche markets.

### **Supply**

 $\overline{a}$ 

The amount of seafood that aquaculturalists will be willing to produce at a given price depends on production costs. Economic conditions determine the costs of labor, hatchery supplies for stocking, feed, maintenance, and other inputs. For most aquaculture operations, the bulk of costs are for feed and stocking of early life stages, such as finfish fingerlings or

<sup>&</sup>lt;sup>181</sup> A change in demand results in a shift of the demand curve rather than a change in quantity demanded, movement along the demand curve.

<sup>&</sup>lt;sup>182</sup> Advances in more intensive land-based culture techniques, such as recirculating systems, are another means to increase production with minimal environmental impacts, but the viability of these operations is still uncertain.

<sup>183</sup> The FDA program also inspects imports and may be found at https://www.fda. gov/food/resources-you-food/ seafood. The Department of Commerce program can be found at https://www.fisheries.noaa.gov/insight/ noaas-seafoodinspection-program.

oyster seed. <sup>184</sup> Fixed costs include equipment depreciation, insurance, taxes, and lease payments. Shifts in supply result from changes in input prices, which also may be affected by technology, weather conditions, and other influences. At the level of individual farms or facilities, most costs are not set and often depend on short-run and long-run choices of the aquaculturalist. For example, in the short run, the producer may change feed quality and quantity, harvest intervals, or stocking rates, while in the longer term she may change species, location, technology, and scale.<sup>185</sup>

Costs to produce seafood in offshore aquaculture facilities are likely to be higher than costs in inshore areas, because of the need for more resilient cage materials and construction, shore-side infrastructure, specialized vessels, and automation of facility systems. The location of offshore aquaculture facilities also is likely to increase costs for fuel, monitoring, harvest, and security. <sup>186</sup> According to the Food and Agriculture Organization, offshore facilities operating at distances of greater than 25 nm from shore are unlikely to be profitable, because costs increase with distance from shore.<sup>187</sup>

Some have speculated that offshore facilities will need to take advantage of economies of scale because of the relatively high costs of transporting materials between inshore and offshore facilities. Operating large-scale operations will require new coastal facilities and networks to supply and transport feed, construction materials, fingerlings, and harvested fish. Logistics networks to supply these inputs would need to be developed in coastal areas, where "working waterfronts" are already threatened due to competing uses and the relatively high cost of coastal real estate. These startup costs may exclude smaller producers who may not have access to the capital and resources needed to establish large-scale operations.

Financial risk, generally the probability of losing money, is another factor that is related to potential viability of offshore aquaculture and may affect the availability of capital and insurance. *Risk* is defined as uncertain consequences, usually unfavorable outcomes, due to imperfect knowledge.<sup>188</sup> Assessing risk for offshore aquaculture is complicated by different species, technologies, site characteristics, and the lack of experience working in offshore areas. Risks may be greater in offshore than inshore areas because of the threat of severe weather conditions and exposed offshore environments. Attracting investment may be difficult because offshore aquaculture is a new industry with limited experiences for investors to evaluate. As risk and uncertainty increase, generally, a greater revenue stream is required to justify the same level of investment.<sup>189</sup> Known risks can be reduced by decreasing the probability of adverse outcomes, such as by using stronger materials to build more resilient structures. The cost of reducing risks must be weighed against the probability and magnitude of potential losses.

<sup>&</sup>lt;sup>184</sup> Early stages of marine organisms are often raised in hatcheries and subsequently transferred to larger enclosures to be grown to adult size.

Another approach to reducing risk is through insurance. Insurance transfers risk from the producer to the insurance underwriter through payments of insurance premiums. The cost of insurance premiums may be higher for offshore than inshore areas because of greater uncertainty and potentially higher risks of losses for offshore facilities.

#### *Private Benefits and Externalities*

The previous discussion of supply and demand considers private costs of production that are borne by the producer. Policymakers are concerned with a broader definition of costs that may affect individuals who are not involved in the aquaculture business—often referred to as *externalities*. Externalities are defined as spillover costs or benefits, which are unintended consequences or side effects associated with an economic activity.  $190$  For example, commercial fishermen may be harmed by habitat degradation caused by pollution from aquaculture because of associated declines of wild populations. When externalities are not considered, markets become inefficient because more of a good or service is produced than when the externality is fully considered.

The recognition of externalities is another way in which policymakers can examine the tradeoffs related to the private benefits from aquaculture production and the environmental harm caused by the activity. In the case of offshore aquaculture, external costs may be associated with environmental harm from pollution, escaped organisms, disease transmission, and other effects. The existence of externalities means that policymakers may need to consider whether and to what degree the government should intervene to account for these costs. Intervention may involve regulatory measures that minimize externalities while maximizing benefits associated with the industry (e.g., fish production). Decisions related to site selection, technology, and facility operations are likely to be some of the main factors that determine the level of offshore aquaculture externalities.

#### *International Factors and Domestic Experiences*

#### **Trade**

 $\overline{a}$ 

DOC has expressed concern with increasing U.S. imports of seafood products. According to NMFS, 80%-90% of the seafood consumed in the United States is imported. <sup>191</sup> International trade in seafood has grown over the last several decades. The value of seafood trade is now more than twice the trade of meat and poultry combined.<sup>192</sup> Relatively highvalue seafood from wild fisheries and aquaculture dominates imports. In 2017, the United States imported approximately 2.7 mmt of edible seafood valued at \$21.5 billion.<sup>193</sup> After accounting for exports valued at \$5.7 billion, the value of imports was \$15.8 billion greater than exports of edible seafood products. Approximately half of seafood imports are cultured.

<sup>&</sup>lt;sup>190</sup> Externalities may be related to costs or harm related to pollution or benefits, such as the utility gained from observing flowers planted in roadside areas.

<sup>&</sup>lt;sup>191</sup> NMFS, 2018. A portion of imports include domestic catch that was exported for further processing and returned to the United States as an import in processed form.

<sup>192</sup> James L. Anderson and Gina Shamshak, "Future Markets for Aquaculture Products," in *Offshore Aquaculture in the United States: Economic Considerations, Implications, and Opportunities,* NOAA, NOAA Technical Memorandum NMFS F/SPO-103, July 2008, pp. 231-244.

<sup>193</sup> NMFS, *Imports and Exports of Fishery Products Annual Summary, 2016*, Current Fishery Statistics No. 2016-2, Silver Spring, MD, July 19, 2017, at https://www.st.nmfs.noaa.gov/ Assets/commercial/trade/Trade2016.pdf.

The two main imported products are farmed shrimp and salmon. In 2017, shrimp accounted for \$6.5 billion and salmon accounted for \$3.5 billion of U.S. seafood imports.<sup>194</sup>

Supporters of offshore aquaculture assert that development of offshore areas and associated increases in seafood production could reduce the U.S. deficit in seafood trade. The Department of Commerce Strategic Plan states that, "a strong U.S. marine aquaculture industry will serve a key role in U.S. food security and improve our trade balance with other nations."<sup>195</sup>

Some may counter that the seafood trade deficit is not a good reason to support development of the aquaculture industry. Cultured salmon and shrimp imports have lowered prices and, therefore, the profits of domestic wild fisheries and aquaculture producers, but U.S. consumers have benefited from lower salmon and shrimp prices. According to economic theory, countries gain from trade when they specialize in products that they are best at producing. If other countries have an absolute or comparative advantage in aquaculture, the United States would likely benefit from supporting other industries. <sup>196</sup> Advocates of aquaculture note that the United States has advantages compared to other countries because of its extensive coastline and EEZ, skilled labor, technology, domestic feed production, stable government and economy, and large seafood market.<sup>197</sup> Others counter that U.S. federal waters are exposed to high winds and wave action for large parts of the year, whereas other parts of the world have readily available inshore areas and calmer offshore waters that could be developed, as well as lower labor costs.<sup>198</sup>

Overall operating costs and environmental standards for aquaculture in other countries are often lower than in the United States. Some have speculated that costs of inputs such as labor and less strict regulations provide producers outside the United States with an insurmountable competitive advantage. Other observers stress that costs may be lower in other countries, but if prices are high enough, U.S. producers may still be able to operate profitably.<sup>199</sup> Domestic producers also have some advantages, such as a large and relatively wealthy market and lower shipping costs than those for imports.

The government sometimes provides government-sponsored trade protections such as tariffs or import quotas to new industries. Protection may be rationalized by an infant industry that claims it requires time to overcome short-term cost disadvantages.<sup>200</sup> Cost disadvantages may be related to the need to become more efficient by constructing new facilities, training workers, and installing new equipment. In these cases, tariffs would act as a subsidy that increases the domestic price of the good. When the industry becomes more efficient, the tariff

<sup>&</sup>lt;sup>194</sup> An unknown portion of seafood imports, including salmon, was harvested in U.S. wild fisheries and exported to other countries for processing. Some of these products are then exported back into the United States.

<sup>195</sup> U.S. Department of Commerce, *U.S. Department of Commerce Strategic Plan 2018-2022*: *Helping the American Economy Grow*, 2018, p. 9, at https://www.commerce.gov/about/ strategic-plan.

<sup>&</sup>lt;sup>196</sup> A country has an absolute advantage if its production costs for a good are lower than those of other countries at prevailing prices and exchange rates. According to the concept of comparative advantage, a country should import goods when the international price is less than the domestic opportunity cost (the potential benefit foregone) of producing an additional unit domestically. The opportunity cost is the cost of producing additional units of the product in terms of the reduction in the output of another product.

would expire. However, as the industry becomes larger and more politically powerful, it may become difficult to remove the tariff<sup> $201$ </sup>

#### **U.S. Experiences**

U.S. aquaculture production from inshore marine areas and freshwater ponds and raceways is small relative to global production levels. The bulk of U.S. aquaculture production is from freshwater catfish, crayfish, and trout. Catfish production increased from 62,256 mt in 1983 to its peak of 300,056 mt in 2003. Factors that have supported the industry's development include research and development, marketing efforts, industry leadership, and vertical integration.<sup>202</sup> However, production decreased from 215,888 mt in 2009 to 145,230 mt in 2016. An increase of pangasius (an Asian catfish) and tilapia imports has contributed to lower prices, which have contributed to decisions by less profitable catfish farms to take acreage out of production.<sup>203</sup>

Salmon is the only marine finfish with significant U.S. marine aquaculture production, but it has struggled to compete with relatively inexpensive imports from Norway, Chile, and Canada.<sup>204</sup> These countries are endowed with protected coastal areas such as fjords or bays where net pens may be deployed. Although environmental regulations and limitations on inshore leases may have affected U.S. salmon aquaculture production, stagnant prices and competitive imports also appear to have played a role. There is room for expansion of inshore net pen salmon aquaculture in areas of Maine, Washington, and Alaska.<sup>205</sup> However, many residents in these areas do not support establishing or expanding net pen aquaculture because of environmental concerns and potential impacts on existing fishing industries. The ban on finfish aquaculture in Alaska and regulatory constraints in other states reflect these concerns.<sup>206</sup>

#### **Offshore Development in Other Countries**

Currently, nearly all worldwide marine aquaculture production is from relatively wellprotected inshore waters. Countries in the forefront of efforts to move offshore have experience with inshore aquaculture and with aquaculture industries that are characterized by relatively large investments in vertically integrated firms.<sup>207</sup> Norway and China are the two largest investors in offshore aquaculture development, but neither country has facilities that are operating commercially. Their efforts have focused on developing structures that can withstand harsh offshore conditions and operate at scales that may offset the higher costs of offshore areas as compared to inshore areas.<sup>208</sup>

<sup>201</sup> Houck, *Elements of Agricultural Trade,* p. 21.

<sup>202</sup> James L. Anderson and Gina Shamshak, "Lessons from the Development of the U.S. Broiler and Catfish Industries: Implications for Offshore Aquaculture in the United States," in *Offshore Aquaculture in the United States: Economic Considerations, Implications, and Opportunities,* NOAA, NOAA Technical Memorandum NMFS F/SPO-103, July 2008, pp. 97-116. Hereinafter cited as Anderson and Shamshak, "Lessons."

<sup>&</sup>lt;sup>203</sup> The increase in fish feed prices is another factor that has affected U.S. catfish businesses.

<sup>&</sup>lt;sup>204</sup> Shrimp are the largest seafood import by value and volume, but shrimp are not considered to be a viable candidate for offshore aquaculture because they are raised in topical coastal ponds and do not appear to be suited for offshore aquaculture.

<sup>&</sup>lt;sup>205</sup> Atlantic salmon net pen aquaculture is not currently allowed in Alaska. Washington and Maine allow net pen salmon aquaculture but have limited its expansion because of environmental concerns.

<sup>206</sup> Knapp, "Economic Potential," p. 183.

<sup>207</sup> CEA, *Offshore Finfish Aquaculture*, p. 5.

<sup>208</sup> CEA, *Offshore Finfish Aquaculture*, p. 4.

Norway's industry already has extensive experience with inshore salmon aquaculture industry and is a leader in developing technology needed to move farther offshore.<sup>209</sup> Norway has granted development licenses in offshore waters, and Norwegian companies are experimenting with different offshore concepts. Although there has been significant investment in offshore aquaculture in Norway, it is unclear whether these concepts will be profitable. It appears that long-term business strategies are still focused on inshore waters.<sup>210</sup> Offshore aquaculture facilities are also under development in other countries, including Mexico, Panama, and Turkey. 211

The characteristics of specific regions also may offer advantages, as some believe future development will occur in the calm water tropical belt between  $10^{\circ}$ N and  $10^{\circ}$ S.<sup>212</sup> One former offshore aquaculture farmer believes future investment will focus on new species in tropical and subtropical regions.<sup>213</sup> It appears that growth of marine aquaculture may take different approaches in different parts of the world, with further increases in production from proven nearshore areas and research and development of potential land-based and offshore areas. Generally, movement offshore is likely to occur if seafood demand continues to increase and suitable nearshore areas are occupied or constrained by other factors.<sup>214</sup>

#### *Stakeholder Concerns and Aquaculture Development*

Some stakeholders have expressed concerns about offshore aquaculture that include environmental degradation, competition for ocean space, and market interactions between wild fishery and aquaculture products. Historically, user conflicts associated with aquaculture have occurred in inshore areas where oceans activity and use are more intensive. For example, some fishermen oppose aquaculture and perceive it as competition that lowers prices and fishing revenues. Most interactions are characterized as conflicts, but in some cases synergistic relationships may emerge.<sup>215</sup>

Environmental concerns have been among the most controversial elements of the aquaculture debate, including expansion of aquaculture into offshore waters. Generally, environmental and commercial fishing interests have been opposed to plans for offshore aquaculture development because of potential harm to marine resources. They have asserted that poorly regulated inshore aquaculture development has degraded the environment and harmed wild fish populations and ecosystems.<sup>216</sup> Concerns identified by these stakeholders

<sup>&</sup>lt;sup>209</sup> The Alaska shoreline may include suitable areas for salmon net pens, but the state does not allow net pen aquaculture and many salmon fishermen believe this activity is not compatible with wild salmon fisheries.

<sup>210</sup> CEA, *Offshore Finfish Aquaculture*, p. 21.

<sup>&</sup>lt;sup>211</sup> The definition of offshore aquaculture varies across countries. For example, offshore aquaculture facilities in Turkey are reported have characteristics that more closely resemble inshore aquaculture. CEA, *Offshore Finfish Aquaculture*.

<sup>&</sup>lt;sup>216</sup> Center for Food Safety, "Fishing and Public Interest Groups File Challenge to Fed's Unprecedented Decision to Establish Aquaculture in Offshore U.S. Waters," press release, February 16, 2016, at https://www.center forfoodsafety.org/press-releases/4229/fishing-and-public-interest-groups-file-challenge-to-fedsunprecedenteddecision-to-establish-aquaculture-in-offshore-us-waters. Hereinafter cited as Center for Food Safety, "Fishing and Public Interest Groups."

include pollution, the use of wild species for fishmeal, fish escapement, threat of disease and parasites, harm to marine wildlife, and general impacts on marine ecosystems.  $217$  Most commercial fishing and environmental interests advocate a precautionary approach.

Industry supporters and aquaculturalists respond that research, innovation, and management practices have reduced or eliminated environmental risks. <sup>218</sup> Generally, aquaculturalists assert that many previous environmental concerns have been addressed and that long-term aquaculture production relies on maintaining a clean and productive environment, an objective that environmental and fishing industry advocates also hold. Some also view offshore aquaculture as an additional means to support the domestic seafood industry, which has decreasing levels of employment in many regions. Some have noted that synergistic effects might support infrastructure and services such as docks, cold storage, and processing facilities that benefit both wild fishing and aquaculture.

Seafood imports from aquaculture production have affected seafood markets and coastal communities, such as salmon fishermen in Alaska and shrimp fishermen in the Gulf of Mexico.<sup>219</sup> Prices fell during the 1990s, as global salmon and shrimp aquaculture production and associated imports increased. This shift caused significant economic difficulties for Alaska salmon fishermen, processors, and communities. <sup>220</sup> Wild salmon prices have recovered to some extent, likely due to growing consumer differentiation between wild and cultured products. Some have responded that competition will occur with or without domestic growth in aquaculture because imports of farmed products are likely to continue and grow.<sup>221</sup> Other changes that have been attributed to aquaculture include accelerated globalization of the seafood industry, increased industry concentration and vertical integration, and introduction of new product forms.<sup>222</sup>

Marine aquaculture, especially the offshore aquaculture industry, is a small and new industry with few committed supporters and relatively little money and political influence.<sup>223</sup> One observer noted that, "marine aquaculture will become politically stronger as it grows but it is difficult to grow without becoming politically stronger."<sup>224</sup> The industry also faces opposition from environmental and commercial fishing interests. Several developments will need to take place if offshore aquaculture can be expected to become established and grow into a viable commercial industry; these developments are discussed in the next section.

# **INSTITUTIONAL NEEDS AND INDUSTRY SUPPORT**

## **Regulatory Framework for Offshore Aquaculture**

Most stakeholders agree that a regulatory framework likely needs to be developed before establishing offshore aquaculture in U.S. federal waters. A potential framework would need to fulfill the government's public trust responsibilities while remaining flexible enough to take advantage of evolving technology and markets.<sup>225</sup> Many of the basic elements of the framework would depend on legislation providing statutory authority and requirements for leasing offshore areas, agency leadership and interagency coordination, and environmental protection. A regulatory framework could provide the industry with clear and understandable requirements for aquaculture facilities while minimizing potential environmental harm. Supporters of offshore aquaculture have advocated for a permitting and consultation process that is more timely, efficient, and orderly than the existing process. Most also agree that the regulatory process should be transparent and support public involvement.

#### *Lead Agency*

NMFS has been the lead federal agency for marine aquaculture in inshore areas and for the potential development of offshore aquaculture.<sup>226</sup> According to a 2008 U.S. Government Accountability Office (GAO) study, "there is no lead federal agency for regulating offshore aquaculture, and no comprehensive law that directly addresses how it should be administered, regulated, and monitored."<sup>227</sup> Stakeholders also have supported NOAA's role in managing federal aquaculture research, including research and development of offshore aquaculture technologies.<sup>228</sup>

Since publication of the GAO report, NMFS has attempted to regulate offshore aquaculture under the MSA. A recent court decision, however, cast doubt on whether NOAA has the authority under MSA to regulate offshore aquaculture. Several studies have recommended that NOAA should be granted clear authority to regulate offshore aquaculture.<sup>229</sup> They point out that NOAA already has authority to evaluate proposed marine activities and projects to ensure the protection of marine mammals, endangered species, and marine sanctuaries. Furthermore, NOAA is responsible for federal management of marine fisheries and essential fish habitat.

#### *Permits and Leases*

 $\overline{a}$ 

One of the needs for offshore aquaculture development is permitting or leasing of discrete ocean areas.<sup>230</sup> Within the EEZ, the United States has sovereign rights for the purpose

<sup>225</sup> Oceans Commission, *Ocean Blueprint*, p. 332.

<sup>&</sup>lt;sup>226</sup> NOAA has played a supportive role in state waters but does not have jurisdiction to lease or regulate aquaculture in state waters.

<sup>227</sup> U.S. Government Accountability Office (GAO), *Offshore Marine Aquaculture*, GAO—08-594, May 2008. p. 2. Hereinafter cited as GAO, *Offshore Marine Aquaculture*.

<sup>228</sup> GAO, *Offshore Marine Aquaculture*.

<sup>229</sup> B. Cicin-Sain et al., *An Operational Framework for Offshore Marine Aquaculture in Federal Waters*, Center for Marnie Policy, University of Delaware, 2005; Oceans Commission, *Ocean Blueprint*.

<sup>230</sup> The terms *permits* and *leases* are used interchangeably in this report. The rights to discrete areas associated with permits or leases define their general meaning. Whether considered a lease or permit, the most important concerns are related to the rights and responsibilities granted to the offshore aquaculture developer.

of exploring, exploiting, conserving, and managing natural resources, whether living and nonliving, of the seabed and subsoil and superjacent waters. The federal government grants rights to develop specific areas for specific activities in the EEZ are granted. Currently, no permitting or leasing program is specific to offshore aquaculture and leases depend on permits and consultation requirements under different laws and agencies that apply to marine activities generally.

Observers generally agree that aquaculture developers will need assurances that they will have exclusive rights via leases or permits to use specific ocean areas for agreed-upon periods.<sup>231</sup> A leasing system could provide aquaculturalists with clearly defined rights to ocean space including the water surface, water column, and ocean bottom. Other characteristics of a leasing system might include transferability of the lease or permit, which would allow the aquaculturalist to transfer the permit or lease and benefit from its sale or use. Stakeholders told GAO that clear rights to use specific ocean areas would be needed to obtain loans.<sup>232</sup> Proponents of offshore aquaculture development stress that, without some form of long-term (at least 25 years) permitting or leasing, offshore aquaculture will have problems securing capital from traditional funding sources and obtaining suitable insurance on the capital investment and stock.<sup>233</sup>

The Gulf of Mexico Aquaculture Fishery Management Plan (Gulf FMP) provides a 10 year site permit and 5-year permit renewals.<sup>234</sup> Aquaculture industry representatives have expressed concern that these intervals are too short because of the time it will take their businesses to become profitable. Environmentalists would prefer "shorter timeframes to ensure more frequent reviews and closer scrutiny of environmental impacts during the lease or permit renewal process."<sup>235</sup> In state waters, Maine grants 10-year leases for salmon net pen aquaculture. Hawaii grants 20-year leases for permits in its waters.

The public's primary concerns are likely to include minimizing harmful effects on environmental quality and conflicts among ocean uses. Most recognize that a leasing framework will require review of potential environmental impacts of offshore aquaculture. This review likely would require the preparation of a programmatic environmental impact statement (PEIS) with a follow-up site-specific environmental review before a facility might be established. <sup>236</sup> A PEIS could review potential environmental impacts of offshore aquaculture over broad areas of the ocean. Aquaculturalists generally agree that this approach would be useful if it reduced the need for facility-specific reviews.<sup>237</sup>

Some have suggested that permits should be issued on a case-by-case basis by determining whether a specific site is appropriate for the proposed aquaculture facility. Others oppose this approach, because it could lead to an approval process that is less consistent and it

<sup>231</sup> Anderson and Shamshak, "Lessons."

<sup>232</sup> GAO, *Offshore Marine Aquaculture*, p. 5.

<sup>&</sup>lt;sup>233</sup> Some nations (e.g., Canada) lease nearshore areas with implied automatic renewal of tenure as long as the lessee meets current licensing requirements.

<sup>235</sup> GAO, *Offshore Marine Aquaculture*, p. 5.

<sup>236</sup> Bureau of Reclamation, *What is the Difference Between a Programmatic and a Project-Level Environmental Impact Statement?*, Yakima River Basin Integrated Water Resource Management Plan, November 2013, at https://www.usbr.gov/pn/programs/eis/kkc/ scoping/progsite.pdf. A programmatic environmental impact statement evaluates the effects of broad proposals for planning-level decisions that may include a wide variety of individual projects.

<sup>237</sup> GAO, *Offshore Marine Aquaculture*.

could make it more difficult for regulators to assess cumulative impacts of different facilities within a region.

Still others have suggested that ocean planning should identify both appropriate and prohibited areas for aquaculture. Regulators could assess potential sites for permitting aquaculture before and independently of individual permit applications. Some believe that this would make permitting more predictable and consistent. For example, the likelihood of harm to marine mammals might be decreased by limiting permits for aquaculture facilities to areas with a low risk of interactions. <sup>238</sup> However, some aquaculturalists question whether regulators will choose the most viable sites for aquaculture.

## *Conditions of Use*

A regulatory framework is likely to require specific conditions on the use of a site. These requirements likely will vary depending on the species and technology employed. Nevertheless, some basic requirements related to environmental quality, inspections, and other public concerns are likely to be common to many offshore aquaculture operations. The Gulf FMP includes specific requirements that could be applicable to managing offshore aquaculture in other regions. A partial list of operational requirements under the Gulf FMP includes the following:

- placing at least 25% of the facility in the water at the site within two years of issuance of the permit;
- marking each system placed in the water with an electronic locating device;
- obtaining juveniles for stocking from certified hatcheries within the United States;
- providing a health certificate prior to stocking fish at the aquaculture facility;
- complying with all FDA requirements when using drugs or other chemicals;
- monitoring and reporting environmental survey parameters consistent with NMFS guidelines,
- inspecting for interactions or entanglements of protected species; and
- allowing access to facilities to conduct inspections.

Some have recommended requirements for aquaculture facility plans to address potential contingencies, such as fish escapes from aquaculture facilities. Some representatives of fishery management councils supported marking or tagging hatchery fish as a potential means of tracking escaped organisms. However, some have questioned whether the added costs of marking fish are warranted and contend that tagging requirements should depend on the level of associated risk to natural resources.

Monitoring could also be required to track interactions with marine life and other changes to the environment. State regulators in Maine and Washington have developed monitoring requirements for net pen salmon aquaculture, such as monitoring the benthic community under net pens. Both states also require notification of disease outbreaks and can require specific mitigation measures depending on the severity of the outbreak. Federal monitoring requirements could be informed by state experiences and modified as better information becomes available. The Gulf FMP includes reporting requirements for stocking, major

<sup>238</sup> GAO, *Offshore Marine Aquaculture*, p. 24.

escapement, pathogen episodes (disease), harvest, change of hatchery, marine mammal and sea bird entanglement, and other activities or events.

Aquaculture facilities in offshore areas would occupy areas that may be used for other ocean uses, such as oil and gas development, wind and tidal energy, maritime transportation, and commercial and recreational fisheries. Some have recommended that "development of a national aquaculture management framework must be considered within the context of overall ocean policy development, taking into account other traditional, existing, and proposed uses of the nation's ocean resources."<sup>239</sup> If conflicts develop over access to particular areas, a process would need to be developed to identify suitable areas in federal waters for aquaculture development and/or to mediate disputes. For example, commercial and recreational fishermen may have concerns regarding access to areas they have fished historically and potential interactions of cultured and wild fish. Some ocean managers have suggested that overlaying maps of different jurisdictions, ocean uses, and conditions favorable to aquaculture would be useful in avoiding user conflicts. $240$ 

#### *Other Management Entities*

As a regulatory framework for offshore aquaculture is developed, it could be enhanced by improving coordination and cooperation among federal, state, territorial, and tribal entities. Existing groups, such as the Subcommittee on Aquaculture, have provided a means for communication among federal agencies that might be used to enhance federal coordination of offshore aquaculture development and management.

The fishery management councils established under the MSA likely would have a role in offshore aquaculture development. Each of the eight regional councils develops FMPs for wild marine fisheries within its particular region. These plans are then sent to NMFS for approval and implementation. Historically, fishery management councils have had a role in considering whether to support offshore aquaculture in federal waters. In addition to the Gulf of Mexico FMP for aquaculture, several exempted fishing permits were issued for limited periods to investigate potential aquaculture development in federal waters off New England. Potential interactions with wild fisheries and harm to essential fish habitat and wild fish populations are likely to be fishery management councils' main concerns.

In addition to consultation requirements under the Coastal Zone Management Act, the state role in developing a regulatory framework for offshore aquaculture may deserve additional consideration. Some stakeholders support an opt-out provision allowing states to refuse development in federal waters adjacent to state waters. Others suggest that the opt-out provision should apply only within a certain distance of shore (such as  $12 \text{ nm}$ ).<sup>241</sup> In response to earlier proposed legislation, NOAA supported a 12 nm distance to provide states with a buffer zone and simplify the difficulties of projecting state boundaries out to 200 nm.<sup>242</sup> Harmonizing aquaculture regulations with adjacent states could provide an advantage to future development, because states would be in a position to limit or promote offshore aquaculture development.

<sup>239</sup> Oceans Commission, *Ocean Blueprint*, p. 333.

<sup>240</sup> Carol S. Price and Jessica Beck-Stimpert, *Best Management Practices for Marine Cage Culture Operations in the U.S. Caribbean*, NOAA, GCFI Special Publication Series Number 4, 2014.

<sup>241</sup> GAO, *Offshore Marine Aquaculture*.

<sup>&</sup>lt;sup>242</sup> Projecting state zones in the northeastern United States could be problematic because of the number and geography of coastal states in the region.

#### *Federal Support for Offshore Aquaculture*

Some assert that federal government assistance would be needed to promote the initial development of a U.S. offshore aquaculture industry. Assistance could range from general support of research to direct support of industry needs, such as finance. One argument in support of government assistance is that, in comparison to relatively well-known agriculture sectors such as animal husbandry, there are more uncertainties associated with offshore aquaculture.<sup>243</sup> With the exception of Atlantic salmon, culture of most marine finfish is still at a relatively early stage of development. Development of offshore aquaculture is likely to require new culture techniques for rearing species not presently cultured. For this reason, the U.S. Oceans Commission recommended more assistance for aquaculture generally and an active government role to foster industry development.

Stakeholders identified federal research needs in four areas:<sup>244</sup>

- developing fish feeds that do not rely on harvesting wild fish;
- developing best management practices;
- exploring how escaped offshore aquaculture-raised fish might impact wild fish populations; and
- developing strategies to breed and raise fish while effectively managing disease.

In addition to improving culture techniques, further research of interactions between aquaculture and the environment and potential harm to specific species and ecosystems could inform decisions related to site selection and monitoring needs.

A remaining question is which agency or agencies will provide the support needed for offshore aquaculture development. Some may question whether NOAA has adequate institutional experience with aquaculture or whether additional resources are needed to provide adequate program management and services. Some NOAA programs support the fishing industry, but none focus specifically on offshore aquaculture. Similarly, USDA administers a number of programs that support agriculture in areas such as finance, research, extension, market development, and disaster assistance, but none are specifically focused on offshore aquaculture. Legislation in the  $116<sup>th</sup>$  Congress to support offshore aquaculture may address whether and how NOAA and/or USDA programs could be adapted to the needs of offshore aquaculture, which is the appropriate agency to manage specific programs, and what level of federal support is appropriate.

# **POTENTIAL ISSUES FOR CONGRESS**

Currently, development of offshore aquaculture appears unlikely because of regulatory, technical, and economic uncertainties. One of the main issues for Congress is whether legislation can be developed that could provide the industry with greater regulatory certainty while assuring other stakeholders that environmental quality can be maintained and other potential conflicts minimized. Research and development of inshore facilities have shown that

<sup>244</sup> GAO, *Offshore Marine Aquaculture*.

<sup>&</sup>lt;sup>243</sup> Some would argue that this is also true for most inshore and freshwater species. Only freshwater finfish, such as catfish, salmon, and trout, and oysters in estuarine waters have been cultured extensively in the United States.

offshore aquaculture is technically feasible but have not shown whether moving facilities to offshore areas would be profitable. It is likely that the investment required for commercial development of offshore aquaculture facilities will depend to some degree on greater regulatory certainty. For example, one business that was developing offshore aquaculture in Puerto Rico has moved its operations to Panama; according to the owner, U.S. regulations made expansion impossible.<sup>245</sup>

Aquaculturalists and investors are likely to require secure property or leasing rights and clear regulatory requirements before investing in large-scale operations. Stakeholders with concerns that aquaculture will degrade the environment also may need assurances that adequate regulation, inspections, and enforcement will be required features of a regulatory program. These concerns have been reflected in several aquaculture bills that would prohibit offshore development until comprehensive legislation is enacted.

Previous congressional actions, such as hearings and bills, have concentrated on several areas, which include

- providing institutional support for aquaculture, such as planning, research, and technology transfer;
- identifying a lead agency to administer and coordinate aquaculture development and regulation;
- establishing and streamlining permit and consultation requirements to improve the efficiency of the permitting process;
- developing processes to consult and communicate with other stakeholders to reduce user conflicts; and
- minimizing environmental harm and addressing environmental concerns through planning and monitoring.

If aquaculture is developed in the EEZ, most stakeholders likely would agree that there is a need for better coordination, clear regulation, and focused agency leadership. Some assert that congressional action will be necessary to support both commercial development and environmental protection.

# **CONGRESSIONAL ACTIONS**

Congress has made several attempts to pass offshore aquaculture legislation, including bills in the  $109<sup>th</sup>$ ,  $110<sup>th</sup>$ ,  $111<sup>th</sup>$ ,  $112<sup>th</sup>$ , and  $115<sup>th</sup>$  Congresses, but none of these bills were enacted. Bills also were introduced that would have prevented aquaculture development in federal waters until statutory authority for offshore aquaculture development is enacted. While many stakeholders continue to call for federal legislation, it has been difficult to find a common vision among them for future development of an offshore aquaculture industry.

<sup>245</sup> Eva Tallaksen, "Deep-Sea Cobia Producer Gears up for Full-Scale Launch," *Under Current News*, March 22, 2013, at https://www.undercurrentnews.com/2013/03/22/deep-sea-cobia-producer-gears-up-for-full-scalelaunch/.

## **116th Congress**

In the  $116<sup>th</sup>$  Congress, no comprehensive offshore aquaculture legislation has been introduced, but several bills have been introduced that are related to offshore aquaculture and aquaculture generally. The Keep Finfish Free Act of 2019 (H.R. 2467) would prohibit the issuance of permits to conduct finfish aquaculture in the EEZ until a law is enacted that allows such action. The Commercial Fishing and Aquaculture Protection Act of 2019 (S. 2209) would amend the MSA to provide assistance to eligible commercial fishermen and aquaculture producers.<sup>246</sup> Assistance could be provided when an eligible loss occurs due to an algal bloom, freshwater intrusion, adverse weather, bird depredation, disease, or another condition determined by the Secretary of Commerce. Other bills include the Prevention of Escapement of Genetically Altered Salmon to the United States Act (H.R. 1105) and the Shellfish Aquaculture Improvement Act of 2019 (H.R. 2425).

## **115th Congress**

 $\overline{a}$ 

In the  $115<sup>th</sup>$  Congress, the Advancing the Quality and Understanding of American Aquaculture Act (AQUAA Act; S. 3138 and H.R. 6966) would have established a regulatory framework for aquaculture development in federal waters.<sup>247</sup> The bills would have provided NMFS with the authority to issue aquaculture permits and to coordinate with other federal agencies that have permitting and consultative responsibilities. They also would have identified NOAA as the lead federal agency for providing information on federal permitting requirements in federal waters.

S. 3138 and H.R. 6966 would have required the Secretary of Commerce to develop programmatic environmental impact statements for areas determined to be favorable for marine aquaculture and compatible with other ocean uses. Section 9 of the bills stated that it would not supersede the requirements of the National Environmental Policy Act of 1969 (NEPA) and that individual projects may require additional review pursuant to NEPA.<sup>248</sup> The bills would have required the Secretary of Commerce to consult with other federal agencies, coastal states, and fishery management councils to identify the environmental and management requirements and standards that apply to offshore aquaculture under existing federal and state laws. The bills also identified 10 standards that should be considered for offshore aquaculture and applied when issuing permits conducting programmatic environmental impact statements. These standards included other ocean uses, conservation and management of fisheries under the MSA, and minimizing adverse impacts on the marine environment, among others.

S. 3138 and H.R. 6966 would have provided institutional support of offshore aquaculture by establishing the Office of Marine Aquaculture within NOAA. The Office of Marine Aquaculture would have been responsible for coordinating NOAA activities related to

<sup>246</sup> An eligible commercial fisherman and farm-raised fish producer generally are described as an individual or entity that assumes production and market risks associated with harvesting fish (fisherman) or production of fish in a controlled environment (farm-raised fish producer) for commerce. The term *fish* would include shellfish, finfish, and other aquatic organisms harvested with the intent of entering commerce.

 $247$  H.R. 6966 is nearly identical to S. 3138 and was introduced in the House near the end of the 115<sup>th</sup> Congress. <sup>248</sup> 42 U.S.C. §§4321 et seq.

regulation, scientific research, outreach, and international issues. The Office of Marine Aquaculture would have replaced the current Office of Aquaculture, which conducts activities that are similar to those proposed by the bills.<sup>249</sup> The bills also would have made NOAA the lead agency for establishing and coordinating a research and development aquaculture grant program.

A bill was also introduced (H.R. 223) that would have prohibited the issuance of permits to conduct finfish aquaculture in the EEZ except in accordance with a law authorizing such action. Similar bills also were introduced in earlier Congresses to stop offshore aquaculture development in the EEZ.

# **Congressional Actions Prior to the 115th Congress**

Offshore aquaculture bills also were introduced in the  $109<sup>th</sup>$ ,  $110<sup>th</sup>$ ,  $111<sup>th</sup>$ , and  $112<sup>th</sup>$ Congresses. <sup>250</sup> Generally, these bills focused on establishing a regulatory framework to develop offshore aquaculture in federal waters of the EEZ. The bills varied to some degree on the balance between the potential rights and responsibilities of aquaculturalists, especially between aquaculture development and environmental protection. For example, S. 1195 (109<sup>th</sup>) Congress), and H.R. 2010 and S. 1609 (110<sup>th</sup> Congress) would have supported production of food, encouraged development, established a permitting process, and promoted research and development of offshore aquaculture. In contrast, H.R. 4363 (111<sup>th</sup> Congress) and H.R. 2373  $(112<sup>th</sup> Congress)$  would have focused to a greater degree on potential impacts of offshore aquaculture. These bills stressed elements such as determining appropriate locations, issuing regulations to prevent impacts on marine ecosystems and fisheries, and supporting research to guide precautionary development of offshore aquaculture.

Other bills that would have constrained offshore aquaculture development were introduced in the  $108<sup>th</sup>$ ,  $109<sup>th</sup>$ ,  $110<sup>th</sup>$ ,  $112<sup>th</sup>$ ,  $113<sup>th</sup>$ , and  $114<sup>th</sup>$  Congresses. Most of these bills would have prohibited the issuance of permits for marine aquaculture facilities in the EEZ until requirements for issuing aquaculture permits are enacted into law.<sup>251</sup>

## **CONCLUSION**

The United States is the largest importer of seafood products in the world, and nearly half of domestic seafood imports are produced by aquaculture. Aquaculture development and production in the United States have lagged behind other countries due to a variety of factors, such as relatively inexpensive imports, regulatory policies, user conflicts, and higher costs of production. Some have speculated that marine aquaculture facilities could be developed farther offshore in federal waters, where they would be subject to fewer user conflicts and have space to operate in relatively clean ocean waters. However, movement to offshore areas also would involve several significant challenges, such as establishing a regulatory

<sup>&</sup>lt;sup>249</sup> NMFS, NOAA Office of Aquaculture, at https://www.fisheries.noaa.gov/about/office-aquaculture.

<sup>&</sup>lt;sup>250</sup> Bills included S. 1195 (109<sup>th</sup> Congress), S. 1609 and H.R. 2010 (110<sup>th</sup> Congress), H.R. 4363 (111<sup>th</sup> Congress), and H.R. 2373 (112<sup>th</sup> Congress).

<sup>&</sup>lt;sup>251</sup> Examples include S. 2859 (108<sup>th</sup> Congress), S. 796 (109<sup>th</sup> Congress), S. 533 and H.R. 7109 (110<sup>th</sup> Congress), H.R. 574 (112<sup>th</sup> Congress), H.R. 753 (113<sup>th</sup> Congress), and H.R. 331 (114<sup>th</sup> Congress).

framework, developing new technologies, and competing with other existing sources of seafood.

According to many stakeholders and researchers, the lack of a governance system for regulating offshore aquaculture hinders the industry's development in the United States. Development of marine offshore aquaculture would likely require a new regulatory framework for establishing offshore aquaculture in federal waters.<sup>252</sup> A regulatory framework potentially could provide the industry with clear requirements for its development while minimizing potential environmental harm. It remains an open question whether legislation could be crafted to achieve a balance between providing the certainty sought by potential commercial developers of aquaculture and satisfying environmental and other concerns of stakeholders such as environmentalists and fishermen.

While a new regulatory framework potentially could provide greater certainty to offshore aquaculture developers, other challenges would remain. For example, offshore aquaculture may involve higher costs and greater risk of losses associated as compared to inshore operations. Lack of experience operating in offshore areas and limited knowledge of culture techniques for many candidate marine species contribute to the financial risk of offshore aquaculture. Some observers expect that offshore aquaculture may occur incrementally as inshore areas are developed and culture techniques are refined. Federal support may be needed for finance, research, extension, market development, and disaster assistance, similar to USDA support of agriculture.

# **AN APPROACH TO DETERMINING ECONOMIC IMPACTS OF U.S. AQUACULTURE**

# *Doug Lipton, Matt Parker, John DuBerg and Michael Rubino*

## **ABSTRACT**

*Fisheries Economics of the United States* is produced annually by the National Marine Fisheries Service and provides national and state level estimates of the total economic impacts of U.S. seafood landings and imported seafood on the U.S. economy. However, it does not contain an estimate of the impact of U.S. aquaculturally produced seafood. As a demonstration of the potential for incorporating this information into *Fisheries Economics of the United States*, we took estimates of production and value for four aquaculture species: crawfish, salmon, oysters and clams. Using published production cost data and the same input/output model used for *Fisheries Economics of the United States*, we produced estimates of economic impacts. We make recommendations for improving the annual production and value estimates that are used for the input/output model, and for developing standardized industry surveys on production costs so that reliable impact estimates can be developed on an annual basis and included as part of *Fisheries Economics of the United States*.

# **EXECUTIVE SUMMARY**

This report describes initial efforts to develop an estimate of the economic impacts of all U.S. aquaculture (marine and freshwater) that could be integrated into *Fisheries Economics of the United States*, an annual report published by the National Marine Fisheries Service. Our approach was to gather production budgets for several aquaculture species from published reports along with the annual production and value estimates obtained on an annual basis

This is an edited, reformatted and augmented version of U.S. Department of Commerce, National Oceanic and Atmospheric Administration, National Marine Fisheries Service, NOAA Technical Memorandum NMFS-F/SPO-197, dated September 2019.

through various sources, and using these numbers, calculate the direct, indirect, and induced economic impacts using an input-output model of the U.S. seafood economy.

The U.S. fishing and seafood industries are important components of the U.S. economy. According to *Fisheries Economics of the U.S. 2015*, the seafood industry supported 1.2 million full-and part-time jobs and generated \$144.2 billion in sales, \$39.7 billion in income, and \$60.6 billion in value-added impacts nationwide. These estimates include the impacts from domestic wild harvest products and imports of wild-harvested and foreign aquaculture products, but not the impacts of domestic aquaculture. The omission of domestic aquaculture production from the estimates will become more problematic as domestic aquaculture expands and becomes a greater share of the U.S. seafood market. Domestic aquaculture already represents one fifth of U.S. seafood production by value.

Due to a lack of current, sufficiently detailed and standardized production budgets for major aquaculture species, it is not currently possible to produce a comprehensive estimate of the national economic impact from aquaculture production for all major species. NOAA and USDA in partnership with industry associations and university researchers could work with aquaculture companies to develop representative and updated aquaculture production budgets to be used in the development of annual estimates of aquaculture impacts.

To explore how this could be accomplished, we developed estimates of the economic impacts of four major species: crawfish, salmon, clams and oysters. Crawfish are a freshwater species and have the most reliable production and cost estimates compared to the other three marine species. Oysters, clams and salmon represented 95% of the first sale value of marine aquaculture production in 2015. From *Fisheries of the U.S. 2016*, marine aquaculture production in 2015 had total first sales (farm gate) of about \$394 million. By assuming that the 5% of production we have not calculated impacts for create impacts in the same proportion as those we have calculated, then the total impact for marine aquaculture production on the U.S. economy is estimated to be about \$5.1 billion, and results in over 53,000 jobs.

We envision what the economic impact would be if a goal of increasing U.S. aquaculture production to times its current level in ten years is met. Depending on assumptions about the species composition of the increase, we estimate the total economic impact would range from \$10.7 - \$12.8 billion and the number of jobs from 109,500 - 133,400.

The above estimates should be used cautiously given the lack of reliability in the statistics about the current level of aquaculture production, and the production budgets on which the estimates are based. We make several findings and recommendations as to actions needed to produce reliable annual economic impact estimates that are summarized here:

- 1) *Fisheries Economics of the United States* currently provides useful information to stakeholders and the general public about the economic impact of the fishing and seafood industries, and should include domestic aquaculture impact estimates, particularly as domestic aquaculture increases in importance as a component of U.S. seafood supply.
- 2) There is insufficient extant cost information and only greatly outdated information on production costs for several major species to develop a reasonable national estimate of economic impacts.
- 3) A systematic way of collecting annual aquaculture production data from states, industry associations, or directly from producers is essential to ensuring the quality of the estimates that rely on these numbers.
	- a) A clear definition of what constitutes aquaculture production, particularly for shellfish, is necessary and will help avoid some double counting in commercial landings that occurs now.
	- b) Since there is interest in reporting on marine versus freshwater aquaculture production, classification of what constitutes each will have to be agreed upon.
	- c) Protecting confidentiality of firm level data will be an issue when there are a small number of firms constituting the production for a particular species.
- 4) Systematic collection of production costs via standardized industry surveys will provide the most reliable information for economic impact analysis. The relevant Federal agencies (i.e., USDA and NOAA), in conjunction with state agencies and aquaculture industry organizations, should come together and plan a survey methodology and a way to administer maintain and update it on a regular basis.
	- a) Updating industry cost data every five years would allow National Income and Product Accounts data to be updated at the same frequency.
	- b) Short of a census, any type of survey sample would have to be designed to capture the heterogeneity of the industry, even for production of the same species.
- 5) A comprehensive study on the seafood market chain would allow us to more accurately model product flows and increase reliability of the impact analysis.
	- a) Interstate product flows need to be quantified

l

- b) Upstream (i.e., hatchery and nursery) production costs need to be better quantified, particularly for emerging industries.
- 6) Aquaculture production for other than just seafood markets (e.g., bait fish, pond stocking, etc.) will require additional analysis.

## **1.INTRODUCTION**

Estimating the economic impact contributed by the aquaculture sector is essential information used to inform Federal, state and local policies. An economic impact analysis denotes the relative importance of the sector to the overall economy as well as quantifies the dependencies among different economic sectors on a regional and national level. Each year, the National Marine Fisheries Service (NMFS) publishes *Fisheries Economics of the United States*  $(FEUS)^{1}$ , providing national and state-by-state economic impact estimates. These estimates include commercial fisheries landings impacts on a state- by-state level, as well as state-level and national impacts from imported seafood as it moves through the value chain to the final consumer. NMFS also has developed regional economic impact models which aid in determining impacts for fisheries management regulations on a more detailed level than the

<sup>1</sup> National Marine Fisheries Service (2017a) Available at: http://www.st.nmfs.noaa.gov/economics/publications/ feus/fisheries\_economics\_2015/index.

national model. NMFS's analysis to date has not included domestic or imported aquaculture products, except some domestic product that may be included in domestic wild catch<sup>2</sup>.

It is estimated that as much as 90% by value of U.S. seafood consumed by Americans is imported, with about 50% of that produced via aquaculture<sup>3</sup>. Because *FEUS* includes imports, the contribution of imported aquaculture products to the U.S. economy is accounted for in the *FEUS* analysis. Missing from these reports, however, are the economic impacts of domestic aquaculture production. While still a small percentage of domestic fisheries production in pounds (6.5%), U.S. aquaculture production in 2015 was 21% of the first sale value (*Fisheries of the U.S. 2016*). As domestic aquaculture grows in importance, ignoring its role in economic impact estimates will become more problematic in terms of correctly quantifying the impact of fish and seafood production on the U.S. economy. Additionally, a greater understanding of the economic linkages of domestic aquaculture production in the economy will help in predicting and planning for the potential future contribution of aquaculture as it expands to play an even more significant role in the seafood economy.

Without an annual national survey for all aquaculture, NMFS relies on a variety of sources to estimate U.S. aquaculture production and value on an annual basis, and publishes this with an additional year lag in *Fisheries of the United States* (Table 1)<sup>4</sup> . Sources include the USDA Census of Agriculture and the periodic Census of Aquaculture<sup>[5](#page-2589-0)</sup> along with state and industry association supplied data. As in wild harvest production, an accurate estimate of annual production and value is essential to producing meaningful economic impact estimates because these numbers form the basis of all subsequent calculations of impacts, as will be discussed below.

## **1.1. Purpose and Organization of the Study**

The original purpose of this study was to demonstrate that we could produce aquaculture economic impact estimates for most species from existing data that could be incorporated on a regular basis into *Fisheries Economics of the U.S.* By attempting to calculate the economic impact of four aquaculture species with currently available cost data and production estimates, we uncover what changes and additional research are necessary to produce future estimates that are equivalent in rigor to those currently published in *Fisheries Economics of the U.S.* for domestic wild caught fish production.

The work was conducted by a team of University of Maryland and NMFS staff. The research team received design guidance from an Advisory Committee of university and private sector economists along with staff at the U.S. Department of Agriculture (USDA). Difficulties gathering reliable production data for several species and advice from our Advisory Committee led us to narrow the study from all U.S. aquaculture to one focused on four species and one that would provide guidance in terms of data collection and analysis for

<sup>&</sup>lt;sup>2</sup> Some aquaculture production statistics, particularly those for shellfish, may be mixed in with commercial landings data at the individual state level. For example, oyster aquaculture on public bottom may be counted as part of wild harvest landings.

<sup>3</sup> https://www.fisheries.noaa.gov/national/aquaculture/us-aquaculture.

<sup>4</sup> Fisheries of the United States, 2016 (National Marine Fisheries Service, 2017b) is released in 2017, but the aquaculture production estimates that are included are from 2015.

<sup>5</sup> https://www.agcensus.usda.gov/Publications/Census\_of\_Aquaculture/.

developing future estimates of the economic impact of all of U.S. domestic aquaculture production. The four species are oysters, clams, salmon, and crawfish.

The paper is organized as follows. First we provide a description of the *FEUS* calculation framework and then demonstrate how domestic aquaculture production can enter into the framework. Case studies for several species, where current data was of acceptable quality, are developed to demonstrate the approach. We discuss shortcomings of the existing data for the case study species, and the necessary steps to include all the major aquaculture species in the analysis. We conclude with recommendations for steps necessary to achieve the goal of producing an annual estimate of the economic impact of U.S. aquaculture production.

# **2.INTEGRATING DOMESTIC AQUACULTURE PRODUCTION IMPACTS INTO FISHERIES ECONOMICS OF THE U.S.**

Since our goal is to develop a method to integrate domestic aquaculture production into the calculations made for *FEUS*, we briefly describe the current methodology for the calculations for wild harvest and imports. Fish harvesting and seafood production is a major industry and data collected by the Economic Census, Bureau of Labor Statistics, and other sources are used by the Bureau of Economic Analysis as part of the development of national income accounts used to calculate the gross domestic product of the United States. The North American Industry Classification System (NAICS) describes industry code 114111 Finfish Fishing as:

"This U.S. industry comprises establishments primarily engaged in the commercial catching or taking of finfish (e.g., bluefish, salmon, trout, tuna) from their natural habitat"

Code 114112 is Shellfish Fishing. With only one code for finfish harvesting and one for shellfish, this is a highly aggregated accounting of a diverse industry that is of limited use for decision-making impacting a particular species or region. [6](#page-3030-0) Additionally, the underlying source of data used by BEA<sup>[7](#page-4220-0)</sup> does not capture the great variability of scale and input use in commercial fisheries harvest in the United States. For these reasons, NMFS had developed its own national economic impact model and also has developed regional models with even greater specificity to support the economic analyses required by law for fisheries management plans.

#### **2.1. Wild Domestic Harvest in Fisheries Economics of the U.S.**

Kirkley (2009) describes the process used by the National Marine Fisheries Service for developing economic impact estimates for the domestic fishing and seafood industry. The approach is a modification and customization of a basic input/output model of the U.S. economy using IMPLAN<sup>8</sup> software and data. The model is designed to provide a national estimate of impacts and state level estimates for 23 coastal states. Figure 1 demonstrates the linkages. Starting with domestic landings, to develop estimates of the upstream impacts, it is necessary to determine fishing production costs by category. The downstream impacts require knowledge of the percentage of product that flows to each of the downstream sectors, and then the value added by expenditure category by each of those downstream sectors.

Downstream

Figure 1. Schematic of the seafood market underlying calculations of economic impacts for Fisheries Economics of the U.S.

<sup>6</sup> There is some greater species specificity in the underlying data that helps to generate the input-output tables in the national accounts. The categories are: Alaska pollock, tuna, salmon, sardines, ground fish (cod, cusk, haddock, hake, Atlantic ocean perch, Atlantic pollock and whiting), flounder, other finfish, shrimp, crabs, oysters, clams, other shellfish, surimi and frozen fish blocks.

<sup>7</sup> See NIPA Handbook: Concepts and Methods of the U.S. National Income and Product Accounts, https://www.bea.gov/methodologies/index.htm.

<sup>&</sup>lt;sup>8</sup> IMPLAN is a commercial software product commonly used for the calculation of economic impacts of industry sectors, nationally and regionally (www.implan.com).

## **Table 2. Typical fishing expenditure categories for inclusion in Fisheries Economics of the U.S. calculations (from Kirkley, 2009)**

Table 2 shows the typical expenditure categories for which data is obtained for domestic fish landings. One decision made early on in developing the process was that it would not be feasible to develop separate expenditure estimates for every species in the landings database. Landings were aggregated into 16 major groupings as shown in Table 3. This aggregation ameliorates the complication that many fisheries are mixed, in that they catch multiple species on the same trip, and it would be difficult to allocate both trip and durable expenditures by category to individual species. Cost data corresponding to the categories shown in Table 2 were obtained from a variety of existing surveys and publications and assigned to each of the harvest groupings. Cost data is periodically updated when new studies and surveys become available. Adjustments are also made on an annual basis for price changes for some volatile sectors such as energy. As can be seen in Table 4, downstream product flows are even more highly aggregated than fish harvesting with only seven harvester categories, three processors and two wholesale/distributor categories. These percentages are updated periodically as new data becomes available.

Once the product flows and expenditures are estimated for the 16 categories of seafood, these are then mapped into North American Industrial Classification System (NAICS) codes, and the direct, indirect and induced impacts can be calculated using an input-output model such as IMPLAN.

**Table 4. Downstream product flow for fishing & seafood industries related to domestic harvest (from Kirkley, 2009)**

## **2.2. Aquaculture Integration**

 $\overline{a}$ 

Similar to wild caught fisheries, the National Accounts include highly aggregated NAICS codes for finfish (112511), shellfish (112512) and other (112519) aquaculture production and hatcheries. The [d](#page-2939-0)efinitions from the 2017 NAICS publication<sup>9</sup> demonstrate the lack of specificity for these industries. For finfish farming and fish hatcheries, the description is *"This U.S. industry comprises establishments primarily engaged in (1) farm raising finfish (e.g., catfish, trout, goldfish, tropical fish, minnows) and/or (2) hatching fish of any kind."*  For shellfish farming and hatcheries, the description is, *"This U.S. industry comprises* 

<sup>9</sup> https://www.census.gov/eos/www/naics/2017NAICS/2017\_NAICS\_Manual.pdf (pp. 95-96).

*establishments primarily engaged in farm raising shellfish (e.g., crayfish, shrimp, oysters, clams, mollusks)."* Finally, for other, the description is, *"This U.S. industry comprises establishments primarily engaged in (1) farm raising of aquatic animals (except finfish and shellfish) and/or (2) farm raising of aquatic plants. Alligator, algae, frog, seaweed, or turtle production is included in this industry."*

Figure 2 depicts, in general, how a more detailed economic impact analysis can be conducted for domestic aquaculture production. As shown, domestic aquaculture production is assumed to enter the market in a parallel manner to wild caught seafood, and thus can be handled exactly the same for estimating downstream impacts. In the analysis that follows, the aquaculture product is matched with the species groupings in Table 3 and then enters the marketing channels as shown in Table 4. In contrast, for upstream impacts – the upper ovals in Figure  $2 -$  the economics of the production of aquacultured species is treated as fundamentally different from wild-caught fish production. For wild caught fish, all production costs are only associated with harvest. For aquaculture, most of the costs incurred are prior to harvest, with harvesting cost playing a lesser role in the overall cost of production depending on the species and grow-out method. As a result, even if the farm-gate price for an aquacultured species is the same as or similar to the ex-vessel price for a wild caught species, the upstream impacts by expenditure category may be quite different; although the aggregate effect on the economy may be similar. Therefore, it is necessary to develop production expenditure estimates by species and production method for aquaculture production in a manner similar to what was done for wild caught species. A comprehensive literature review revealed a number of studies of aquaculture budgets for different species and production methods that form the basis of the analysis in the ensuing "Case Studies" section of this report.

Downstream

Figure 2. Schematic of the domestic aquaculture seafood market for estimating economic impacts.

## **3. CASE STUDIES**

In this section, we develop case study production budgets for four aquaculture species: crawfish, salmon, clams, and oysters. Although crawfish is not a marine species, we include it here because it has the most complete data. A brief discussion of the data used for each species and its potential shortcomings are discussed, and then we present a table of the calculated economic impact estimates using the NMFS national economic impact model.

## **3.1. Crawfish Aquaculture**

#### *3.1.1. Crawfish Production Data*

Production cost and returns data on crawfish was derived from Boucher and Gillespie (2014) which provides estimates for three types of crawfish operations: a single crop crawfish operation and two types of rice-crawfish double crop operations. The report provides significant detail on costs and the volume of production, but we had to reach out to the authors for explanation of some of the costs to properly classify them for the IMPLAN modeling. For example, a significant portion of costs were attributed in the text to "irrig single" and "pond&eq single." These costs were later determined to be associated with the cost of running the pond pump to irrigate in single crop crawfish operations, and the pond and equipment costs, respectively. Another challenge was how to convert detailed data on labor hours required to produce crawfish to a jobs impact in IMPLAN, due to the likelihood of parttime or seasonal employment in crawfish production. For our purposes we assumed that on average, a job in crawfish production is equivalent to 1,200 labor hours per year. Another uncertainty was determining how much of the three different production operations for which costs were obtained contributed to aggregate production. In the absence of additional information, we assumed that the models each represented one-third of aggregate production, and thus were assigned equal weights.

## *3.1.2. Crawfish Economic Impacts*

Given the above qualifications, the estimated national impacts of aquaculture crawfish are presented in Table 5. Estimates of employment impacts (a mix of full-time and part-time jobs), income (both employee compensation and proprietor income), and output are provided for the aquaculture operations (i.e., harvesters) and the other segments in the value-added chain as well as a summary for all industry segments. Estimates include direct effects (the segment itself), indirect effects (those associated with the segment's supply chain), and induced effects (those created by the consumer spending of the directly and indirectly affected workers).

Reading horizontally across Table 5, one can see the impact on the national economy in terms of output, income, and jobs of just the farm level sales. Growers sell \$199 million worth of crawfish which leads to a total economic impact of \$590 million, due to the indirect and induced effects. Looking at the table vertically at the direct impacts, the farm level sales of \$199 million lead to sales to final consumers (grocery and restaurant sales) of \$877 million, which is the sum of farm level sales and the value-added for each of the downstream market sectors (i.e., processors, wholesalers, grocers, and restaurants) of \$678 million.

Finally, the total economic impact of crawfish aquaculture in 2015 was over \$2.6 billion, the summing up of direct, indirect, and induced effects from all segments of the market. Note that the largest contributor to the impact are induced impacts related to restaurant sales (\$528 million). We want to emphasize the large contribution that the restaurant final demand sector makes, accounting for 46% of the output impacts and 55% of the jobs.

<b>Industry Sector</b>	Direct	Indirect	Induced	Total

## **3.2. Oyster Aquaculture**

#### *3.2.1. Oyster Production Data*

Unlike crawfish aquaculture production, which is concentrated in Louisiana, significant aquaculture production of oysters occurs in many coastal states, including Massachusetts, Maryland, Virginia, North Carolina, Washington, Oregon, and California. The state of Washington, however, dominates production, accounting for nearly half of the total value of production. Production cost data were available for each of these states and were weighted by value of production per state to determine a "national" production cost for aquaculture oyster production.<sup>10</sup>

 $\overline{a}$ <sup>10</sup> Data on production costs in Maryland, Virginia, and North Carolina were collected by the authors in consultation with industry experts. Data on Massachusetts were taken from "Massachusetts Shellfish Aquaculture Economic Impact Study," Winter 2015, a report from the University of Massachusetts, Dartmouth. Data for West Coast states was derived from surveys conducted for "The Economic Impact of Shellfish Aquaculture in

Among the significant uncertainties associated with these production costs are the facts that oyster production is often mingled with other shellfish and the wide variation in size of shellfish operations. Reports on production costs in Massachusetts (Augusto and Homes, 2013) and the West Coast states (Northern Economics, 2013) have detailed data on costs, but the data typically address operations that produce two or more shellfish species. Because of this mixing of data on species, it was necessary to dig deeper into the data in order to use it for a national estimate of oyster production costs. For the estimates below, survey data from Washington and California were reviewed, and only those operations that exclusively produced oysters were used to estimate production costs. These "oyster-only" producers were a minority of all operations, accounting for a small fraction of production value, therefore production costs from the West Coast states may be lower in reality than those included in this study since the dominant and potentially lower cost producers grow multiple species of shellfish. Alternatively, a report on Massachusetts shellfish production determined that oyster production accounted for roughly 90 percent of total shellfish production value.

The wide variation in size of operation is also likely to affect estimates of unit costs of production. For example, West Coast production is dominated by two large shellfish companies, which raise multiple species. On the East Coast, where there are about 1,000 shellfish aquaculture companies, three companies in Virginia represent a large share of the production.

As with crawfish, estimating job impacts involved assumptions that introduce uncertainty into the overall estimates. For Maryland, Virginia, and North Carolina, detailed information on either labor hours or labor costs was available. These data made clear that employment involves a mix of full-time and part-time or seasonal work. Accordingly, an average of 1,200 hours per job was assumed in generating an estimate of the number of jobs associated with these operations. Data on employment in Massachusetts, Washington, and California were defined in terms of employees (i.e., jobs) and could be used with less uncertainty to estimate the relationship between value of production and employment.

Other uncertainties include unspecified costs, which made up a significant share of the production data for West Coast states. Guidance from the lead author of that report (Northern Economics, 2013) was used to allocate the unspecified costs to memberships, travel, and marketing. As with other production operations, it was not always clear how costs (e.g., capital or oyster seed/spat) should be modeled. For capital, it was general assumed that trucks or boats were the primary capital cost for small and mid- sized oyster-only operations. Large scale operations also have high capital costs associated with their own hatchery and nursery operations. Seed or spat costs were allocated to an IMPLAN sector that includes fish hatcheries, but may not accurately reflect the economic characteristics of oyster seed production operations.

## *3.2.2. Oyster Economic Impacts*

l

The preliminary estimates of impacts of aquaculture oysters are presented in Table 6. The 2015 first sale oyster production value was estimated to be \$173 million, \$26 million less (13%) than crawfish value. Interestingly, the indirect effect of this oyster production was significantly less (60%) than the impact from crawfish, while the induced effect is higher by 23% for oysters. This is due to the fact that labor costs make up a much higher percentage of oyster production compared to crawfish production. The greater labor reliance in oyster production can be seen in the direct employment estimates which equate to 23 jobs per \$1 million of production compared to less than 7 jobs per \$1 million for crawfish.

**Table 6. Summary of all impacts for aquaculture: Oysters**

## **3.3. Clam Aquaculture**

## *3.3.1. Clam Production Data*

Washington State is the largest producer of aquaculture clams with 45% of U.S. value. While there are good data on shellfish aquaculture operations in Washington State, most operations produce more than one type of shellfish. Consequently, extracting data on individual species was not practical for this effort.

Data for costs of production and income are from operations in Florida and Virginia as reported by the University of Florida Institute of Food and Agricultural Sciences Shellfish Aquaculture Extension Program and the Virginia Institute of Marine Science, Virginia Sea Grant Extension Program. Data represent statewide conditions and are assumed to be reasonable reflections of the average aquaculture operation in each state. Florida and Virginia are major sources of hard clams, representing 15% and 17% of 2014 value of production, respectively. Connecticut is another significant producer of hard clams with 15% of U.S. production value, but no cost data from Connecticut were available for this analysis.

#### *3.3.2. Clam Economic Impacts*

Table 7 provides the summary economic impacts for clam aquaculture. One thing that stands out immediately is that as currently practiced, clam aquaculture is nowhere near as labor intensive as oyster aquaculture; it is more similar in labor utilization to crawfish production. As a result, the induced impacts at the first sale level are more in line with crawfish production.

**Table 7. Summary of all impacts for aquaculture: Clams**

## **3.4. Salmon Aquaculture**

## *3.4.1. Salmon Production Data*

Obtaining detailed farm production budgets for salmon aquaculture in the U.S. is difficult because of the limited number of operations. Even when data is available, protecting confidentiality to prevent disclosure of sensitive company financial data is an issue. Atlantic salmon farming in net pens in Maine and Washington State is now almost all owned by one company, Cooke Aquaculture. Pacific Aquaculture has several steelhead net pen farms on the Columbia River with operational features and costs similar to Atlantic salmon. Several small operations growing Atlantic salmon are using land-based recirculating aquaculture facilities and at least four larger land-based Atlantic salmon facilities are in construction or design phases in the U.S. Given these limitations, we examined more readily available production cost data from Canada and Norway to provide cost estimates for this study.

Through discussion with industry experts, we estimate that currently, nearly 100% of U.S. aquaculture salmon production is from open water net pens. We developed an enterprise budget based on Boulet et al. (2010) to determine the percentage cost of production for each input. Due to the geographic proximity and the fact that there is a significant percentage of U.S. net pen salmon operation with Canadian ownership, we determined that these British Columbia-based net pen production estimates were better estimates of U.S. production cost and returns than a set of Norwegian production estimates available in Liu et al. (2016). Cost data in Boulet et al. (2010) was inflated from 2010 U.S. dollars to 2015 U.S. dollars based on the producer price index from the Bureau of Labor Statistics<sup>11</sup>.

Once the direct impacts of aquaculture salmon were calculated, the output from growers was treated as the equivalent of commercially harvested wild salmon in the downstream sectors. That is, it was distributed among processors, wholesalers, and retailers as if it were commercially harvested salmon, as calculated in Table 4. However, it is clear from Boulet et al. (2010) that the enterprise budgets represented operations that produced head-on, gutted salmon as the initial product entering the marketing chain. This level of vertical integration is different from the product of commercial fishing and undermines the assumption about how farmed salmon moves through the value-added chain. Compared to commercially harvested salmon, it would seem reasonable to assume large producers process their own product and that a smaller share of aquaculture salmon flows to secondary processors and a larger share to other value-added segments.

**Table 8. Summary of all impacts for aquaculture: Salmon**

 $\overline{a}$ <sup>11</sup> https://www.bls.gov/ppi/.

#### *3.4.2. Salmon Economic Impacts*

Table 8 provides estimates of the 2015 production by U.S. salmon aquaculture operations. Basic input is the *Fisheries of the United States* estimate of the value of this production in 2015:\$87.7 million. The direct impacts of salmon aquaculture are based on revenue and expense data for net-pen operations from a feasibility study of British Columbia closed containment aquaculture (Boulet et al. 2010).

# **4. AGGREGATE SUMMARY AND ANALYSIS**

## **4.1. Overview**

The four species for which we provide impact estimates only comprise 41% of the total first sales value of U.S. aquaculture production. Catfish, which we did not include due to a lack of readily available recent cost and returns data, comprises 25% of the total value of production. However, from the marine production perspective, the three marine species analyzed, oysters, clams, and salmon, represent 95% of the first sale value of marine aquaculture production in 2015. Total aquaculture first sale value was \$1.3 billion in 2014 and \$1.4 billion in 2015. For aquaculture production as a whole, it would be misleading to extrapolate from our measured values in this study to the full impact of U.S. aquaculture, but for marine aquaculture production it is reasonable to extrapolate our estimates from the 95% of production value included in the analysis to an estimate of the full impacts of marine aquaculture production.

From *Fisheries of the U.S. 2016*, marine aquaculture production in 2015 had total first sales of about \$394 million. By assuming that the 5% of production we have not calculated impacts for creates impacts in the same proportion as those we have calculated, then the total impacts for marine aquaculture production are estimated in Table 9.

The \$394 million in first sales of U.S. marine aquaculture production, through processing and distribution, ended up with final sales to consumers of over \$1.7 billion. The indirect and induced effects added \$1.3 billion and \$2.0 billion, respectively, for a total impact on the U.S. economy of \$5.1 billion. There were 33,429 jobs directly related to the production, processing, distribution, and final sales of marine aquaculture products. The indirect and induced effects added an additional 19,926 jobs for a total impact of 53,355 jobs.

## **4.2. Demonstration - Using Analysis for Future Impacts**

The NMFS Office of Aquaculture, in consultation with industry leaders, suggests a reasonable target is for there to be a 2.5 times increase in U.S. marine aquaculture production in the next ten years. We adopt that target to demonstrate how the preceding analysis can be used to provide an estimate of the economic impacts from achieving that goal. Even though a 2.5 times increase in marine aquaculture is larger than the recent growth as indicated in *Fisheries of the U.S.*, an even larger expansion is possible. This will depend on changes in U.S. policy (e.g., opening up federal waters to aquaculture), providing access to sites in state waters by overcoming reluctance of coastal landowners to support aquaculture in some states, and via a reduction in production costs in recirculating aquaculture systems (see Knapp and Rubino, 2016).

## *4.2.1. Estimating Increase in First Sales Value*

To estimate the economic impact of an increase in U.S. marine aquaculture production, it is necessary to project what the composition of the increased production will be. Scenario 1 uses a simple and perhaps naïve assumption that production will maintain its current composition of species, prices will not change, and thus result in a simple 2.5 times increase in first sale value to \$985 million. It is rather straightforward, then, to estimate the increase in impacts, since the underlying impact model structure is linear, and all the values increase by the same 2.5 times.

Alternatively, for Scenario 2, the Office of Aquaculture, based on interviews with market experts, estimates that a larger percentage, say 75%, of the production volume increase will result from an expansion in finfish production, and this will require a different weighting. We will use salmon value and production costs for this weighting, but it is believed that other species for which we do not yet have reliable production budgets or price projections such as red drum, striped bass, yellowtail, sablefish, and cobia are likely to contribute to this increase. For the assumption of a greater increase in finfish production, we take the same absolute increase in sales volume, but assign 75% of the volume to a price associated with finfish (i.e., salmon) production. This yields a projected first sale value for marine finfish of \$288 million, compared with Scenario 1 finfish value of \$219 million. The remaining 25% of the increase in volume is split between oysters and clams in proportion to their 2015 production volume.

The total first sale value produced in Scenario 2 is \$821 million. The weighting towards more finfish lowers the overall first sales value because current production is more heavily weighted towards high unit value oysters and clams.

#### *4.2.2. Estimating Total Impact and Jobs of First Sales Value*

The process of estimating total economic impacts, once the first sale production number is set, proceeds as in the previous examples. Impact estimates are provided in Tables 10 and 11 for Scenarios 1 and 2, respectively. At the producer/grower level, total impacts are \$2.7 billion (Scenario 1) or \$2.3 billion (Scenario 2). Direct employment associated with production is 13,343 jobs (Scenario 1) or 9,503 jobs (Scenario 2). The difference in scenarios is driven by the fact that the budget we used for salmon production is much less labor intensive than for either shellfish species. Total employment associated with production is estimated at 22,805 jobs (Scenario 1) or 17,468 jobs (Scenario 2). That represents an increase in employment of 13,683 jobs (Scenario 1) or 8,346 jobs (Scenario 2). The increase in jobs associated with production are of particular note, because they potentially represent the difference between producing the increased seafood in the U.S. and importing product produced in overseas aquaculture. The downstream impacts discussed in the next section are generated regardless of where the seafood product is initially grown.

### *4.2.3. Including Downstream Impacts*

The downstream impacts calculated in Tables 10 and 11 are based not only on the assumption that aquaculture products will follow the same distribution and consumption patterns of wild caught domestic products, but also that this pattern will continue into the future. If those assumptions hold, then 2.5 times growth will result in 133,386 jobs (Scenario 1) or 109,515 jobs (Scenario 2) associated with production and final sale of U.S. aquaculture products. This is an increase over the year 2015 associated jobs of 80,031 (Scenario 1) or 56,160 (Scenario 2). The total impact on the U.S. economy will be \$12.8 billion (Scenario 1) or \$10.7 billion (Scenario 2).

# **CONCLUSION AND RECOMMENDATIONS**

*Fisheries Economics of the United States* currently provides useful information to stakeholders and the general public about the importance of the fishing and seafood industries, and demonstrates year over year changes and trends in economic impacts. Adding domestic aquaculture production estimates will increase the utility of this information and provide a greater understanding of the entire seafood industry, particularly as domestic aquaculture increases in importance as a component of U.S. supply.

When we started on this study, the original intent was to develop an estimate of the total economic impact from U.S. aquaculture production for most major species as a demonstration

of how this could be incorporated into *FEUS*. We discovered that there is insufficient extant cost information and only greatly outdated information on production for several major species to develop a reasonable national estimate of economic impacts. Many of the published budgets were out of date, missing key pieces of information, did not include newer production methods, or were only relevant to a single production method in a specific geographic area so that it might not be representative of the industry as a whole. As a result, the project morphed into a data and methodological gap analysis focused on four species as an initial trial analysis of economic impact.

We began the impact analysis with an estimate of annual aquaculture production value by major species as published in *Fisheries of the U.S.* These figures are based on a combination of state reports, industry reports and estimates, USDA's Census of Agriculture and Census of Aquaculture (a survey done once every five years), USDA's regular collection of catfish and trout production data, information from selected companies, and NMFS and USDA staff estimates based on professional knowledge about the industry. Production numbers from some states are not available on an annual basis. Some states gather production data as part of lease or permit requirements but are unwilling to make the data available to a federal agency. A systematic way of collecting this data from states, industry associations or directly from producers is essential to ensuring the quality of the estimates that rely on these numbers.

There are other issues that arise when developing annual aquaculture production estimates. A clear definition of what constitutes aquaculture production, particularly for  $shellfish<sup>12</sup>$ , is necessary and will help avoid some double counting in commercial landings that occurs now. Close coordination with reporting states is essential for determining this data. Responsibility for aquaculture production figures may be housed in different state agencies or different parts of the same agency than that with which NMFS typically coordinates in reporting fish landings. Since there is interest in reporting on marine versus freshwater aquaculture production, classification of what constitutes each will have to be agreed upon. For example, land-based recirculating aquaculture systems produce both freshwater and marine species. Is a marine species grown in a land-based system considered marine aquaculture production? The annual industry survey-based report produced by the Virginia Sea Grant Marine Extension Program (Hudson, 2018) is an excellent example of the type and quality of production data needed for all aquaculture species. Another challenge in reporting production by species will be the requirement of protecting confidentiality of firm level data, which may be raised as an issue when there are a small number of firms constituting the production for a particular species. Atlantic salmon farming in net pens in Maine and Washington State is currently all owned by one company and shellfish farming is dominated by two companies on the West Coast and three in Virginia.

Once we determined production levels and farm gate values, our next step was to allocate production value to different cost categories. Even when there were recent comprehensive studies of aquaculture production costs for a species, it was sometimes difficult to place costs in an appropriate category. Multiple studies may classify costs differently. As a result, relying on one-off production cost studies that appear in the literature from time to time is an unreliable way of developing representative industry budgets. Systematic collection of

<sup>&</sup>lt;sup>12</sup> There is a long history of state-supported preparation of shellfish bottom, planting shell and placing wild or hatchery produced seed oysters subsequently harvested by a limited access fishery and reported as part of total fish landings. Essentially, the same production methods are used in privately held leased bottom, which may be reported separately.

production costs via standardized industry surveys will provide the most reliable information. The relevant Federal agencies (i.e., USDA and NOAA), in conjunction with state agencies and aquaculture industry organizations, should come together and plan a survey methodology and a way to administer, maintain, and update it on a regular basis.

Two of the major items to be determined in planning an aquaculture industry production cost survey are the survey frequency and the target sample size. The Bureau of Economic Analysis, in producing National Income Accounts, opens up their underlying model to major revisions every five years, so it would make sense for the same level of updating for an aquaculture survey. The need for a particular industry sample size will depend on the ultimate use of the survey data and will be higher when there is a need for stratification when the industry is diverse in its production technologies. As mentioned above, some of the published cost data from specialized surveys were not representative of the industry. An industry census would ameliorate the concern about representativeness, but short of a census, any type of survey sample would have to be designed with this concern in mind. The aggregate species groupings for commercial landings (Table 3) demonstrates the tradeoffs necessary in developing representative cost estimates.

Our analysis used a very simple assumption about downstream impacts of aquaculture fish. We used the same product flows as shown in Table 4. We are aware that even for currently produced aquaculture species like Atlantic salmon, these product flows may be inaccurate. Emerging aquaculture production may also follow very different routes through the marketing chain. A comprehensive study on the seafood market chain would allow us to relax this assumption and provide insight on how inaccurate or not the impact estimates are as a result. Some publicly available data (e.g., What We Eat in America<sup>13</sup>) and private industry data should be researched to get a better understanding of the geographic distribution of final purchase of seafood. This will be particularly important to eventually produce state level economic impact estimates.

We also need to be concerned about measuring upstream impacts from aquaculture production. Budgets should be developed for finfish and shellfish hatcheries and nurseries for the key aquaculture species as an improvement over the current NAICS data.

Not all aquaculture production is for seafood. Some freshwater aquaculture is for pond stocking for recreational fishing, and there is a substantial market for aquacultured baitfish (Senten and Engle, 2017). Marine algae production will likely be used for both direct consumption and as additives to foods and other products. These other markets will have to be examined and quantified as they develop.

# **SALTONSTALL-KENNEDY ACT: BACKGROUND AND ISSUES**

# *Harold F. Upton*

## **ABSTRACT**

The Saltonstall-Kennedy (S-K) Act of 1954 (15 U.S.C. §713c-3) established a program to provide financial support for research and development of commercial fisheries. The S-K Act created a fund (known as the S-K fund) that is financed by a permanent appropriation of a portion of import duties on marine products. S-K funds are distributed by the Secretary of Commerce as grants and cooperative agreements to address needs of the U.S. fishing industry, including but not limited to harvesting, processing, marketing, and associated infrastructure. However, Congress allocates most funding to the National Marine Fisheries Service (NMFS) to fund agency activities related to marine fisheries research and management. Some have questioned whether the allocation of S-K funds reflects the original intent of the S-K Act and whether the S-K Grant Program addresses the needs and priorities of the fishing industry.

Since its creation, the S-K fund's authorizing language and priorities have evolved with changes to the fishing industry, new or amended federal laws governing fisheries management, and changing federal agency responsibilities. In 1980, the American Fisheries Promotion Act (AFPA) amended the S-K Act to authorize a competitive grant program, known as the Saltonstall-Kennedy Grant Program(S-K Grant Program) and the National Program to support fishing industry research and development projects. Both programs are administered by NMFS, part of the National Oceanic and Atmospheric Administration (NOAA). In the 1980s, the S-K Grant Program focused on fisheries development, but in subsequent years, as U.S. fisheries became fully or overexploited, priorities generally shifted to resource conservation and management. The S-K Grant Program has supported a variety of different projects, such as gear technology research, seafood marketing, aquaculture, andothers.

The S-K Grant Program is funded by a permanent appropriation of 30% of the previous calendar year's customs receipts from imports of fish and fish products. These funds are transferred into NOAA's Promote and Develop American Fisheries Products and

This is an edited, reformatted and augmented version of Congressional Research Service Publication No. R46335, dated July 14, 2020.

Research Pertaining to American Fisheries Fund (P&D account). Transfers of revenue into the P&D account have grown steadily from\$26.7 million in 1980 to \$182.8 million in 2020. Congress subsequently transfers most funds into the Operations, Research, and Facilities (ORF) account within NOAA. Congress has directed NMFS to use funds allocated to the ORF account for specific activities including stock assessments, fishing information networks, survey and monitoring projects, cooperative research, and interjurisdictional fisheries. The remaining funds are available forsupporting the annual competitive S-K Grant Program and in some cases the National Program.

Since the early 1980s, Congress has transferred most P&D account funds into the ORF discretionary account, sometimes leaving little or no funding for the specified purposes of the S-K Act. Some critics have questioned whether fundsfrom the P&D account could be used more effectively by targeting fishing industry needs, as Congress originally intended. For example, in the  $112^{\text{th}}$ ,  $113^{\text{th}}$ , and  $114^{\text{th}}$  Congresses, bills were introduced that would have used most S-K funds to establish a regional fisheries grant program. By contrast, some have expressed concerns that if significant funding is shifted away from NMFS fisheries management programs, additional funds would need to be appropriated or activities such as data collection and fish population assessments could be compromised. These NMFS activities provide informationandanalyses used to manage and conserve fish populations.

Some also have questioned whether the S-K Grant Program could be modified to provide the fishing industry with more direct input into the S-K grant process. Currently, NMFS, in consultation with the fishing industry, identifies S-KGrant Program priorities and selects the recipients of S-K grants. Over the last several Congresses, bills have been introduced that would change the procedure for screening, evaluating, and awarding S-K grants. In the  $116<sup>th</sup>$  Congress, the American Fisheries Advisory Committee Act (H.R. 1218) and S. 494) would establish an industry advisory committee to identify the needs of the fishing industry, develop requests for proposals, review grant applications, and select grant applications for approval. S. 494 was reported on August 16, 2019, by the Senate Committee on Commerce, Science, and Transportation; on June 6, 2020, H.R. 1218 was reportedby the House Committee on Natural Resources.

## **INTRODUCTION**

The Saltonstall-Kennedy (S-K) Act of 1954 (15 U.S.C. §713c-3) established a fund (known as the S-K fund) to support U.S. fisheries development and research. Funding originates from a transfer by the Secretary of Agriculture into the Promote and Develop American Fisheries Products and Research Pertaining to American Fisheries Fund (P&D account). The P&D account is administered by the National Marine Fisheries Service (NMFS) of the National Oceanic and Atmospheric Administration (NOAA) in the Department of Commerce.<sup>1</sup> Transfers of revenue into the P&D account have grown steadily from \$26.7 million in 1980 to \$182.8 million in2020.

Currently, the bulk of P&D account revenue is transferred into the Operations, Research, and Faculties (ORF) account, which supports fisheries science and management administered by NMFS.<sup>2</sup> The remaining funds support the Saltonstall-Kennedy Grant Program (S-K Grant

<sup>&</sup>lt;sup>1</sup> NMFS is also known as National Oceanic and Atmospheric Administration (NOAA) Fisheries.

<sup>2</sup> he ORF account, NOAA's largest, funds a portion of all of NOAA's line office budgets, including the National Weather Service; National Ocean Service; Oceanic and At mospheric Research; NMFS; National Environmental Satellite, Data, and Information Service; and the Office of Marine and Aviation Operations.

Program) and sometimes the National Program, which focus on fishing industry research and development projects.

Figure 1. Flow and use of Saltonstall-Kennedy Act (S-K) Funds.

 $\overline{a}$ 

Historically, the use of the S-K fund has evolved with changing fisheries management institutions and changing needs of U.S. fisheries.<sup>3</sup> Congress is continuing to consider whether current funding from the P&D account meets the needs of U.S. fisheries and the U.S. fishing industry. Some have questioned whether the U.S. commercial fishing industry receives sufficient opportunities to provide input into the S-K competitive grant process.<sup>4</sup> Due in part to what they perceive as a lack of industry input, some critics assert that NMFS has not distributed funding in accordance with the primary purposes of the S-KAct, such as supporting projects related to the marketing of fish.<sup>5</sup> Another concern is the allocation of funds, and specifically whether there is a need for more financial support of S-K competitive grants than for funding NMFS fisheries science and management activities in the ORF

<sup>3</sup> The Magnuson-Stevens Fishery Conservation and Management Act ( P.L. 94-265) defines fishery as "(A) one or more stocks of fish which can be treated as a unit for purposes of conservation and management and which are identified on the basis of geographical, scientific, technical, recreational, and economic characteristics; and (B) any fishing for such stocks."

<sup>4</sup> Senator Dan Sullivan, "Senators Pass Bill Out of Committee to Give Fishermen Voice in Grant Process, Boost U.S. Seafood," press release, June 29, 2016.

account.<sup>6</sup> However, if funding were reallocated to provide greater support of the S-K Grant Program, Congress may need to consider implications of the likely decrease in funds that would be transferred to ORF from the P&D account to support NMFS fishery research and management activities. *[Figure 1](#page-4154-0)* summarizes the flow of funding from the P&D account into NOAAand the S-K program.

## **THE SALTONSTALL-KENNEDY ACT**

#### **Current Provisions**

The S-K Act requires the Secretary of Agriculture to transfer 30% of duties on marine products collected under the so-called Section 32 Program to the Secretary of Commerce.<sup>7</sup> These funds are transferred into the P&D account and made available to NMFS. Currently, the uses of S-K funds as specified in 15 U.S.C. 713c-3 include the following:<sup>8</sup>

- providing grants in support of fisheries research and development projects under subsection (c),
- implementing a national fisheries research and development program under subsection (d),
- implementing the Northwest Atlantic Ocean Fisheries Reinvestment Program, and
- funding the federal share of a fisheries capacity reduction fund.

The S-K Act requires the Secretary of Commerce to use no less than 60% of funds to make direct industry-assistance grants pursuant to subsection (c). Subsection (c) refers to topics that may be addressed by research and development grants, including but not limited to harvesting, processing, marketing, and associated infrastructures. Subsection (c) also identifies the terms and conditions of grant awards.

The S-K Act requires the balance of S-K funds to be allocated to finance NMFS activities that support development of U.S. fisheries pursuant to subsection (d). Subsection (d) refers to a national fisheries research and development program (including but not limited to harvesting, processing, marketing, and associated infrastructures), if not adequately covered by projects assisted under subsection (c) of this section or as the Secretary deems appropriate.

#### **History of the Saltonstall-Kennedy Act**

In 1935, Congress passed legislation to provide financial support for domestic agricultural commodity markets. Section 32 of the Act of August 24, 1935, provided a permanent

<sup>6</sup> "Senators Kerry and Snowe Will Introduce Bill to Restore Intent of Saltonstall-Kennedy Act," Saving Seafood, March 9, 2012.

<sup>&</sup>lt;sup>7</sup> The program's name is from the section that established the program, Section 32 of the Act of August 24, 1935, Chapter 641, §32; 7 U.S.C. §612c.

<sup>8</sup> 15 U.S.C. §713c-3(c) and (d).

appropriation equal to 30% of gross receipts from all duties collected under customs laws.<sup>9</sup> The act authorized the Secretary of Agriculture to use these funds to support exports and domestic consumption of agricultural commodities. The Act of August 11, 1939, authorized the Secretary of Agriculture to transfer up to \$1.5 million from funds collected under Section 32 to support the fishing industry. Funds were transferred to the Federal Surplus Commodities Corporation to purchase and distribute surplus fishery products and to the Secretary of the Interior to promote markets for fishery products of domestic origin. <sup>10</sup> *[Table 1](#page-4214-0)* provides a history of legislative changes to the S-KAct.

In 1954, the S-KAct amended the Act of August 11, 1939, to provide additional funding from Section 32 funds to support the U.S. fishing industry.<sup>11</sup> The S-KAct authorized the transfer from the Secretary of Agriculture to the Secretary of the Interior, from the larger Section 32 account's funding, an amount equal to 30% of gross receipts from duties collected on fishery products.<sup>12</sup> These funds were maintained in a separate account for use by the Secretary of the Interior to support the flow of fishery products in commerce, develop and increase markets for fishery products, and conduct research. Annual expenditures from the fund were limited to \$3 million, and the balance of the fund was not allowed to exceed \$5 million at the end of any year. In 1956, the S-K Act was amended to remove the limit on annual expenditures from the fund. The S-KAct also authorized the Secretary of the Interior to appoint a fishing industry advisory committee to provide guidance on the formulation of policy, rules, and regulations pertaining to requests for assistance, and other matters.<sup>13</sup>

In 1976, the Fishery Conservation and Management Act (FCMA; P.L. 94-265) established a 200- nautical mile fishery conservation zone (FCZ) and brought marine fisheries within the FCZ under domestic control.<sup>14</sup> Foreign fishing was allowed to continue in the FCZ, but the domestic fishing industry was granted priority fishing rights under the FCMA. <sup>15</sup> In the following years, U.S. policy emphasized development of domestic fisheries and replacement of foreign fishing with domestic fishing in the FCZ. <sup>16</sup> According to the Government Accountability Office, until 1979, NMFS used nearly all S-K funds to support fisheries management and development activities; it granted only small amounts to the fishing industry for development projects.<sup>17</sup> In 1979, likely because of growing industry support of domestic fisheries development, NMFS made available approximately \$5.3 million of S-K funds to

<sup>9</sup> The Act of August 24, 1935, Chapter 641, §32; 7 U.S.C. §612c. See CRS Report RL34081, *Farm and Food Support Under USDA's Section 32 Program* , coordinated by Jim Monke.

<sup>10</sup> Act of August 11, 1939, Chapter 696; 15 U.S.C. §713c-2. The Act of 1939 authorized the Secretary of Agriculture to transfer these funds to the Federal Surplus Commodities Corporation under the Section 32 program.

<sup>&</sup>lt;sup>11</sup> Act of July 1, 1954, Chapter 447; 15 U.S.C. §713c-3.

<sup>&</sup>lt;sup>12</sup> Products included fish, shellfish, mollusks, crustaceans, aquatic plants and animals, and any products thereof, including processed and manufactured products.

<sup>13</sup> Act of July 1, 1954, Chapter 447, §2(c).

<sup>&</sup>lt;sup>14</sup> On March 10, 1983, President Reagan issued Proclamation 5030, which established the 200-nautical mile exclusive economic zone (EEZ). The EEZ provided sovereign rights over the natural resources in the zone, including fisheries, and replaced the fishery conservation zone established by the Fishery Conservation and Management Act (P.L. 94-265) in 1976.

<sup>&</sup>lt;sup>15</sup> Foreign fishing was allocated the surplus after U.S. domestic fishing needs were met. Allocations to foreign operations were terminated when the surplus was completely utilized by U.S. domestic fishing.

<sup>&</sup>lt;sup>16</sup> The capacity of U.S. domestic fishing fleets increased during the 1980s; by 1990, domestic fleets had replaced nearly all foreign fishing fleets operating in the U.S. EEZ.

regional fisheries development foundations, universities, private industry, and state and local governments.<sup>18</sup>

Year	Act	<b>Brief Description</b>
1935	Act of August 24, 1935, Chapter 641, Section 32	Established a permanent appropriation $(\S32)$ to set aside 30% of annual customs receipts; supported the farm sector by purchasing surplus commodities and funding a variety of other activities.
1939	Act of August 11, 1939 (P.L. 76-392), Chapter 696, Section 1	Authorized the purchase and distribution of surplus fishery products with funding of up to \$1.5 million per year.
1954	Act of July 1, 1954 (Saltonstall- Kennedy Act), Chapter 447	Required U.S. Department of Agriculture to transfer to the Department of Commerce 30% of duties on marine products to fund U.S. fisheries and limited expenditures to no more than \$3 million per year.
1956	Fish and Wildlife Act of 1956, Act of August 8, 1956, Chapter 1036, Section 12(b)	Removed limitation on annual expenditures.
1980	American Fisheries Act (P.L. 96- 561), Title II, Section 210	Authorized competitive grants and national fisheries research and development programs; directed that at least 50% of funds be used for competitive grant program, with the balance for the National Program.
1983	Highway Improvement Act of 1982 (P.L. 97-424), Title IV, Section 423(a)	Increased competitive grant share to at least 60% of funds; stipulated that S-K funds were to be used exclusively for promoting U.S. fisheries.
1986	Fish and Seafood Promotion Act of 1986 (P.L. 99-659), Title II, Section 209(e)	Expanded authorized uses of S-K funds to include the Fisheries Promotion Fund for several years.
1992	National Oceanic and Atmospheric Administration Authorization Act of 1992 (P.L. 102-567), Title IX, Section 902(c)	Expanded authorized uses of S-K funds to include implementation of the Northwest Atlantic Ocean Fisheries Reinvestment Program.
1996	Sustainable Fisheries Act (P.L. 104- 297), Title I, Section 116(c)	Expanded authorized uses of S-K funds to include the federal share of a fishing capacity reduction program.
2013	Consolidated and Further Continuing Appropriations Act, 2013 (P.L. 113- $6$ ), Title I	Restricted the use of the Promote and Develop Fisheries Products funds transferred to the Operations, Research, and Facilities account to cooperative research, annual stock assessments, data collection, interjurisdictional fisheries grants, and fisheries information networks. Subsequent appropriations acts have adopted similar language.

**Table 1. History of legislation related to the Saltonstall-Kennedy Act**

Source: CRS.

In 1980, Congress formally authorized the current competitive S-K Grant Program in Section 210 of the American Fisheries Promotion Act (AFPA; P.L. 96-561). The AFPA directed the Secretary of Commerce to use at least 50% of S-K funds for the S-K Grant Program and the balance of funds for a National Program. Both programs supported research and development efforts to address areas such as harvesting, processing, marketing, and related infrastructures. By 1980, the transfer from the U.S. Department of Agriculture (USDA) had grown to \$26.7 million (*[Table A-](#page-2939-0) [1](#page-2939-0)*). The AFPA also formally transferred responsibility for administering the fund from the Secretary of the Interior to the Secretary of Commerce. The House committee report accompanying the AFPA noted that the definition of *fishery* includes

recreational fishing and that recreational projects would be eligible for grants.<sup>19</sup> The AFPA also removed a section that established the S-K fishing industry advisory committee; the advisory committee had been previously terminated pursuant to the Federal Advisory Committee Act  $(P.L. 92-463).^{20}$ 

In subsequent years, Congress made additional changes to the allocation and use of the S-K fund (*[Table 1](#page-4214-0)*). The Highway Improvement Act of 1982 (P.L. 97-424) increased the share of funds used for the competitive grant program from 50% to 60%. In the following years, potential uses of the fund were broadened to include the Fisheries Promotion Fund (P.L. 99- 659), the Northwest Atlantic Ocean Fisheries Reinvestment Fund (P.L. 102-567), and the federal share of a fishing capacity reduction program (P.L. 104-297). Congress established the Fisheries Promotion Fund to support domestic and international markets for domestically produced seafood. A portion of S-K funds was transferred to the fund from FY1987 to FY1991 for this purpose (*[Table](#page-2939-0) A-1*).<sup>21</sup>

#### **Revenue**

 $\overline{a}$ 

The revenues that are transferred into the P&D account from USDA are derived from duties on fishery products, "including fish, shellfish, mollusks, crustaceans, aquatic plants and animals, and any products thereof, including processed and manufactured products."<sup>22</sup> The P&D account is a mandatory fund that requires no periodic reauthorization or appropriation.<sup>23</sup> Transfers from USDA to NOAA's P&D account have steadily increased from \$26.7 million in 1980 to \$182.8 million in 2020 (*[Figure 2](#page-4215-0)*).<sup>24</sup> In CY2017, approximately 77% of revenues were from duties collected on imports of nonedible marine products, including jewelry, ink, various chemicals, and skins.<sup>25</sup> The remaining 23% of revenues were from duties on imports of edible seafood products. Tariffs on edible fish products have been reduced or eliminated for many seafood products, and most remaining duties are collected on canned products such as tuna or processed products such as fish sticks. In CY2017, most duties were collected on imports from India (\$89.9 million), China (\$86.2 million), Thailand (\$79.8 million), Italy (\$53.2 million), and France (\$36.2 million).<sup>26</sup>

<sup>19</sup> U.S. Congress, House Committee on Merchant Marine and Fisheries, *American Fisheries Promotion Act*, to accompany H.R. 7039, 96<sup>th</sup> Cong., 2<sup>nd</sup> sess., June 26, 1980, H. Rept. 96-1138, p. 39.

<sup>20</sup> 5 U.S.C. App., Section 14 of Federal Advisory Committee Act (P.L. 92 -463) terminated advisory committees within two years of the law's enactment (January 5, 1973) unless the committee was renewed within that two-year period or, in the case of a committee established by Congress, its duration is otherwise provided by law.

<sup>&</sup>lt;sup>21</sup> Funding levels included \$750,000 in FY1987, \$2.6 million in FY1988, \$3 million in FY1989, \$2 million in FY1990, and \$2 million in FY1991.

<sup>&</sup>lt;sup>22</sup> Duties are collected by calendar year but not appropriated for use until the subsequent fiscal year (i.e., collect ions from CY2012 would be appropriated in FY2014).

<sup>&</sup>lt;sup>23</sup> When funds from the P&D account are used to offset ORF funding, the funding is considered to be discretionary because the ORF is a discretionary account. However, P&D funds used for the S-K Grant Program or the National Program are identified in law and used by NOAA as mandatory funding.

<sup>&</sup>lt;sup>24</sup> According to NOAA's FY2021budget request, a legislative proposal is being developed to appropriate mandatory funding to the Department of Commerce directly rather than as a transfer from USDA. This change would be part of a broader reform of the USDA Section 32 program.

Notes: USDA = U.S. Department of Agriculture. For a detailed account of funding, see [Table A-1.](#page-2939-0)

Figure 2. Total Funds Transferred From USDA and Funds Transferred to Operations, Research, and Facilities (ORF). (FY1979 to FY2019)

#### **Use of Funds**

l

#### **Operations, Research, and Facilities Account**

Congress has allocated a growing portion of revenue in the P&D account to the ORF account rather than funding the S-K Grant Program as prescribed by the S-KAct. The transfer to the ORF account has ranged from \$5 million, or 29% of the P&D account in 1979, to over \$130 million in the five most recent years (FY2016-FY2020), which is more than 90% of the annual transfer into the P&D account (*[Table 2](#page-3029-0)*). ORF funds are used "to support fisheries research and management activities including the analysis and decision-making that supports ecosystem approaches to management."<sup>27</sup> Often the allocation of most funds to the OFR account limits the funding that is available for the specified purposes of the S-KAct.

In the last three fiscal years (FY2018-FY2020), the NOAA budget request proposed that all P&D account funding be transferred to the ORF account in support of NMFS activities. However, the Consolidated and Further Continuing Appropriations Act, 2013 (P.L. 113-6), restricted the use of P&D funds that are transferred into the ORF account. It limited this funding to fisheries activities related to cooperative research, annual stock assessments, survey and monitoring projects, interjurisdictional fisheries grants, and fish information networks. In subsequent years, agency budget requests have reflected this intent by identifying similar areas,

<sup>&</sup>lt;sup>27</sup> NOAA, NMFS, The Saltonstall-Kennedy Grant Program: Fisheries Research and Development Report, 2011.

and Congress has continued to include similar language in appropriations laws and accompanying Senate committee reports.<sup>28</sup>

#### *Remaining Funding*

In most years, the majority of the funds that remain in the P&D account after the transfer into the ORF account have been used for the competitive S-K Grant Program as described in subsection of the S-KAct and the National Program as described in subsection (d) [\(Table 2\)](#page-3029-0).<sup>29</sup> The amount of remaining funding for the S-K Grant Program has varied considerably from year to year, ranging from no funding in FY2011 and FY2012, when Congress did not leave any remaining funding for S-K program, to its highest level of \$29.5 million in FY2009 (*[Table](#page-3029-0)  [2](#page-3029-0)*). The S-K Act directs the Secretary of Commerce to use no less than 60% of funds for fisheries research and development grants pursuant to subsection (c). The Secretary also is required to use the remaining funds to finance NMFS activities directly related to U.S. fisheries development, as outlined in subsection (d). Since 1982, S-K grant funding has been less than 30% of total transfers from USDA, and it has been significantly lower in most years. In many years, Congress did not fund the National Program or provided a small portion of the remaining funds for that purpose.

Historically, financial support also was provided for the Fisheries Promotion Fund, which was funded between \$750,000 and \$3 million from FY1987 to FY1990. (*[Table A-1](#page-2939-0)*). No funding has been provided for the Fisheries Promotion Fund since 1991. From FY2003 to FY2006, most funding remaining after the ORF transfer was used for congressionally directed projects that supported several regional seafood marketing initiatives (*[Table A-1](#page-2939-0)*).<sup>30</sup> Annual S-K reports and other sources indicate that S-K funds have not been used for either the Northwest Atlantic Ocean Fisheries Reinvestment fund or the fishing capacity reduction program.

#### *Saltonstall-Kennedy Grant Program*

 $\overline{a}$ 

According to NMFS, the S-K program's general goals are to fund projects that address the needs of fishing communities, optimize economic benefits by building and maintaining sustainable fisheries, and increase other opportunities to keep working waterfronts viable. Historically, examples of areas funded by the S-K Grant Program have included enhancing markets for fishery products, examining fishery management options, and developing more efficient and selective fishing gear. Projects often have focused on both state and federal marine commercial fisheries, but other sectors—such as aquaculture and recreational fishing—also have been eligible for and received support.

NMFS solicits proposals as a federal funding opportunity on the federal grants website, which includes funding priorities, application requirements, and proposal evaluation criteria. Funding priorities are developed in coordination with regional fishery management councils, interstate fishery commissions, NMFS science centers, and NMFS regional offices. For

<sup>28</sup> P.L. 113-76, P.L. 113-235, P.L. 114-113, and P.L. 115-31 added the S-K Grant Program to the list of fishery-related activities that should be funded from the P&D account. Fishery-related activities identified in P.L. 115-141, P.L. 116-6, and P.L. 116-93 included the S-K Grant Program, fishery data collection, surveys and assessments, and interjurisdictional fisheries.

 $29$  15 U.S.C. §713c-3(c) and (d). A portion of the remainder also has been used to administer the use of S-K funds for the S-K Grant Program and the National Program.

 $30$  S-K funds also have supported congressionally directed projects focused generally on regional marketing initiatives, including \$10 million in FY2003, \$17.5 million in FY2004, \$12 million in FY2005, and \$12 million in FY2006.

example in 2020, S-K program priorities are seafood promotion, development, and marketing, and science or technology that promotes sustainable U.S. seafood production and harvesting.<sup>31</sup>

The review process includes (1) pre-proposal review, (2) technical review and ranking, (3) panel review and ranking, and (4) grant selection. Pre-proposals undergo an administrative review by NOAA staff, a review by subject matter experts, and S-K program evaluation. Full review includes administrative screening; technical review by federal, public, and private sector experts; and funding recommendations by program and NMFS leadership. NMFS also may solicit comments and evaluation from a constituent review panel composed of three or more representatives chosen by the NMFS assistant administrator of fisheries.<sup>32</sup>

**Table 2. Requested and Enacted ORF Transfers and S-K Grant Funding (funding in thousands of dollars)**

Sources: NOAA, Budget Office, Email, January 20, 2020; NOAA, Budget Office, Email, December 2, 2019.

<sup>a</sup> Includes the S-K Grant Program, National Program, and NMFS administrative costs.

Funding of proposals is recommended by the S-K program manager; constituent panel ranking (if applicable); and input from NMFS regional directors, science center directors, and office directors. The agency selecting official, the NMFS assistant administrator, determines which proposals will be funded. The decision is based on the order of the proposals' ranking and other considerations, such as availability of funding, balance and distribution of funds, and duplication.<sup>33</sup> Recently, NMFS has been considering whether the program and fishing industry would benefit from placing greater emphasis on monitoring approved projects and disseminating results. During 2019, feedback sessions were arranged with regional fishery

management councils to solicit constituents' views on how to improve the dissemination and use of results from funded projects.<sup>34</sup>

# **ISSUES FOR CONGRESS**

Some fishing industry representatives have questioned whether the U.S. commercial fishing industry and fishing communities could benefit from greater direct support from S-K funding. Two of the main concerns have been whether the competitive grant process should include greater fishing industry input and whether a greater portion of P&D funds should be allocated to the annual S-K Grant Program. Some assert that NMFS decides by its own criteria which programs receive grants and that in some cases the fishing industry's priorities do not match those of NMFS.<sup>35</sup> They contend that broader, more direct fishing industry participation is needed to inform the process of identifying the needs and priorities of grant funding.

Another concern has been whether a greater portion of P&D funding should be allocated to the S- K Grant Program.<sup>36</sup> Some contend that Congress, as reflected in statute, intended to provide at least 60% of funds to the S-K Grant Program and remaining funding to the National Program for fishing industry research and development.<sup>37</sup> However, shifting significant funding from current NMFS activities may prompt questions about whether additional discretionary funding would be forthcoming to support other NMFS functions, such as data collection and fish population assessments.

#### **Congressional Actions**

#### *Funding Allocation*

 $\overline{a}$ 

Several bills were introduced during the  $112<sup>th</sup>$ ,  $113<sup>th</sup>$ , and  $114<sup>th</sup>$  Congresses that would have significantly changed the allocation of P&D funding. Similar versions of the Fisheries Investment and Regulatory Relief Act in each of these Congresses would have allocated funding to fisheries management regions and would have established a regional fisheries grant program. <sup>38</sup> Under these bills, each regional fishery management council would have established a fishery investment committee, which would focus resources on strengthening regional fisheries management.<sup>39</sup> Each fishery investment committee would have

<sup>34</sup> Mid-Atlantic Fishery Management Council, "Saltonstall-Kennedy Grant Program - Public Feedback Webinar," press release, June 14, 2019, at http://www.mafmc.org/council-events/2019/saltonstallkennedy-grant-program-public- feedback-webinar.

<sup>&</sup>lt;sup>35</sup> Senator Dan Sullivan, "Sullivan Applauds Senate Passage of American Fisheries Advisory Committee Act," press release, July 28, 2018.

<sup>36</sup> Leslie Taylor, "Opinion: Don't Be Fooled by NOAA Grants Increase," October 24, 2014.

<sup>37</sup> Senator Kerry, "Introduction of S. 2184," *Congressional Record*, daily edition, March 12, 2012, p. S1579.

<sup>&</sup>lt;sup>38</sup> The Fisheries Investment and Regulatory Relief Act of 2012 (H.R. 4208 and S. 2184) was introduced during the 112<sup>th</sup> Congress; the Fisheries Disaster Relief and Research Investment Act ( H.R. 799) was introduced during the 113<sup>th</sup> Congress; and the Fisheries Investment and Regulatory Relief Act of 2015 ( H.R. 2106) was introduced in the 114th Congress. No further action was taken following introduction of any of these bills.

 $39$  Regional fishery management councils were established under the Fishery Conservation and Management Act (currently known as the Magnuson-Stevens Act) to develop fishery management plans that conserve and manage fisheries in federal waters.

- developed a regional fishery investment plan;
- reviewed grant applications and projects to implement regional fishery investment plans; and
- made recommendations on grant applications.

The regional fishery investment plans would have identified research, conservation, and management needs, as well as corresponding actions to rebuild and maintain fish populations and associated fisheries. Each regional investment plan would have been required to include topics related to

- supporting stock surveys, stock assessments, and cooperative fishery research;
- improving the collection and accuracy of recreational and commercialdata;
- analyzing social and economic impacts of fishery management decisions;
- providing financial assistance and investment for fishermen and fishing communities;
- developing methods or technologies to improve the quality and value of landings;
- researching and developing conservation engineering technologies; and
- restoring and protecting fishhabitat.<sup>40</sup>

Investment plans would have been reviewed by the Secretary of Commerce to ensure consistency with the Magnuson-Stevens Fishery Conservation and Management Act (16 U.S.C. §§1801 et seq.). Limited funding also would have been provided for administrative costs of the grant program and for the development and implementation of investment plans.

Under these versions of the Fisheries Investment and Regulatory Relief Act, the Secretary of Commerce also would have established a regional fisheries grant program to provide funds to advance the regional priorities identified in the regional fishery investment plans. The Secretary would have awarded grants only to projects that would implement regional fishery investment plans and to projects recommended by respective regional fishery investment committees and approved by each regional fishery management council. The Secretary would have been required to allocate 70% of funds from the P&D account to the eight council regions. Half of this funding would have been allocated equally among the councils, and half would have been distributed according to the combined economic impact of recreational and commercial fisheries in each region.

The Secretary also would have been required to allocate 20% of funds for a national fisheries investment program that would support rebuilding and maintaining fish populations and promote sustainable fisheries. Funding would have been divided equally among five general areas: (1) regional fisheries commissions; (2) seafood promotion; (3) fisheries management; (4) fisheries disasters; and (5) other needs, including highly migratory species and international fisheries. Each of the bills would have limited the transfer of ORF funding from the P&D account to 10% of receipts. The legislation also included a provision to provide funding to review regulations and procedures used to implement management under the Magnuson-Stevens Fishery Conservation and Management Act and to make recommendations to streamline regulations and incorporate new information into the management process.

l

<sup>40</sup> Research priority plans are developed by regional fishery management councils according to 16 U.S.C. §1852(h)(7).

#### *Stopping the Transfer to the Operations, Research, and Facilities Account*

In the 113th Congress, a section of the Magnuson-Stevens Fishery Conservation and Management Reauthorization Act of 2014 (S. 2991) would have attempted to stop the transfer of P&D funds to the ORF account. According to Section 205 of S. 2991, it would not be in order in the Senate or in the House of Representatives to consider any bill, resolution, amendment, or conference report that would reduce any amount in the fund ( $P&D$  account).<sup>41</sup> This change in the Senate and House rules would have allowed any Senator or Representative to stop the transfer of P&D funds to the ORF discretionary account by making a point of order that a rule is being violated. No further action was taken following the introduction of S.2991.

#### **American Fisheries Advisory Committee Act**

In the 116th Congress, identical versions of the American Fisheries Advisory Committee Act (S. 494 and H.R. 1218) were reported from the committees of jurisdiction in the Senate and the House.<sup>42</sup> The bills would establish an American fisheries advisory committee and would change the process for awarding S-K competitive grants. The committee would

- identify the needs of the seafood industry;
- develop requests for proposals;
- review grant applications; and

 $\overline{a}$ 

select grant applications for approval.

Currently, NMFS is responsible for these functions, and NMFS considers industry input during the selection process. Both bills also would expand the specified purposes of fisheries research and development projects by explicitly including projects that focus on fisheries science and recreational fishing.<sup>43</sup>

The committee would be composed of representatives from six geographic regions of the United States.<sup>44</sup> The Secretary of Commerce would appoint three members from each region, including (1) an individual with experience as a seafood harvester or processor, (2) an individual with experience in recreational or commercial fishing or growing seafood, and (3) an individual who represents the fisheries science community or the relevant regional fishery

<sup>&</sup>lt;sup>41</sup> A point of order is a claim from the floor made by a Senator or Representative that a rule of the House of Representatives or Senate is being violated. If the chair sustains the point of order, the action in violation of the rule is not permitted.

<sup>&</sup>lt;sup>42</sup> S. 494 was reported by the Senate Committee on Commerce, Science, and Transportation on August 16, 2019, and H.R. 1218 was reported by the House Committee on Natural Resources on June 4, 2020. Similar versions also were introduced in previous Congresses, including S. 3087, reported in the 114<sup>th</sup> Congress; S. 1322, passed the Senate in the  $115<sup>th</sup>$  Congress; and H.R. 5775, introduced in the  $114<sup>th</sup>$ Congress; and H.R. 214, introduced in the 115<sup>th</sup> Congress.

<sup>&</sup>lt;sup>43</sup> Projects related to recreational fisheries and science historically have been included, but these projects are not explicitly considered in the statute.

<sup>44</sup> Region 1 would include Alaska and the Western Pacific, including Hawaii, the Commonwealth of the Northern Mariana Islands, and the territories of Guam and American Samoa. Region 2 would include Connecticut, Rhode Island, Massachusetts, New Hampshire, and Maine. Region 3 would include Texas, Louisiana, Mississippi, Alabama, Florida, Arkansas, Puerto Rico, and the Territory of the U.S. Virgin Islands. Region 4 would include California, Oregon, Washington, and Idaho. Region 5 would include New York, New Jersey, Delaware, Maryland, Virginia, North Carolina, South Carolina, and Georgia. Region 6 would include Michigan, Minnesota, Wisconsin, Illinois, Indiana, Ohio, and Pennsylvania.

management council. The Secretary also would appoint four at-large members, including (1) an individual who has experience in food distribution, marketing, retail, or service; (2) an individual with experience in the recreational fishing industry supply chain; (3) an individual with experience in the commercial fishing industry supply chain; and (4) an individual who is an employee of NMFS with expertise in fisheries research. <sup>45</sup> The committee members would meet twice annually, and meetings would rotate among the sixregions.

The Secretary of Commerce would identify three or more experts to undertake technical review of grant applications, which would occur prior to committee review. The Secretary also would be required to develop guidance related to technical review, including criteria for elimination of applications that fail to meet a minimum level of technical merit. A grant would not be approved unless the Secretary was satisfied with the applicant's technical and financial capability. Based on the committee's recommendations, the Secretary would evaluate the proposed project according to listed criteria and other criteria the Secretary may require. If the Secretary fails to provide funds to a grant selected by the committee, the Secretary would be required to send a written document to the committee justifying the decision.

*Chapter 158*

 $\overline{a}$ 

# **AMERICAN FISHERIES ADVISORY COMMITTEE ACT**

The Committee on Natural Resources, to whom was referred the bill (H.R. 1218) to establish the American Fisheries Advisory Committee to assist in the awarding of fisheries research and development grants, and for other purposes, having considered the same, reports favorably thereon with an amendment and recommends that the bill as amended do pass.

The amendment is as follows:

Strike all after the enacting clause and insert the following:

# **SECTION 1. SHORT TITLE**

This Act may be cited as the "American Fisheries Advisory Committee Act."

# **SECTION 2. AMERICAN FISHERIES ADVISORY COMMITTEE**

(a) ESTABLISHMENT.—Section 2 of the Act of August 11, 1939 (15 U.S.C. 713c–3), is amended—

(1) by redesignating subsection (e) as subsection (f); and

(2) by inserting after subsection (d) the following:

"(e) AMERICAN FISHERIES ADVISORY COMMITTEE.—

"(1) DEFINITIONS.—In this subsection:

"(A) COMMITTEE.—The term 'Committee' means the American Fisheries Advisory Committee established under paragraph (2).

"(B) FISHING COMMUNITY.—The term 'fishing community' means harvesters, marketers, growers, processors, recreational fishermen, charter fishermen, and persons providing them with goods and services.

"(C) MARKETING AND PROMOTION.—The term 'marketing and promotion' means an activity aimed at encouraging the consumption of seafood or expanding or maintaining commercial markets for seafood.

This is an edited, reformatted and augmented version of House of Representatives Report , Publication No. 116– 428, dated June 4, 2020.

"(D) PROCESSOR.—The term 'processor' means any person in the business of preparing or packaging seafood (including seafood of the processor's own harvesting) for sale.

"(E) SEAFOOD.—The term 'seafood' means farm-raised and wildcaught fish, shellfish, or marine algae harvested in the United States or by a United States flagged vessel for human consumption.

"(2) ESTABLISHMENT.—Not later than 90 days after the date of the enactment of the American Fisheries Advisory Committee Act, the Secretary shall establish 6 regions within the American Fisheries Advisory Committee as follows:

"(A) Region 1 shall consist of Alaska, Hawaii, the Commonwealth of the Northern Mariana Islands, and the Territories of Guam and American Samoa.

"(B) Region 2 shall consist of Maine, New Hampshire, Massachusetts, Rhode Island, and Connecticut.

"(C) Region 3 shall consist of Texas, Alabama, Louisiana, Mississippi, Florida, Arkansas, Puerto Rico, and the Territory of the Virgin Islands of the United States.

"(D) Region 4 shall consist of California, Washington, Oregon, and Idaho.

"(E) Region 5 shall consist of New Jersey, New York, Delaware, Maryland, Virginia, North Carolina, South Carolina, and Georgia.

"(F) Region 6 shall consist of Michigan, Minnesota, Wisconsin, Illinois, Indiana, Ohio, and Pennsylvania.

"(3) MEMBERSHIP.—The Committee shall be composed of the following members:

"(A) REGIONAL REPRESENTATION.—Each of the regions listed in subparagraphs (A) through (F) of paragraph (2) shall be represented on the Committee by 3 members—

"(i) who are appointed by the Secretary;

"(ii) who reside in a State or territory in the region that the member will represent;

"(iii) of which—

" (I) one shall have experience as a seafood harvester or processor;

"(II) one shall have experience as recreational or commercial fisher or have experience growing seafood; and

"(III) one shall be an individual who represents the fisheries science community or the relevant Regional Fishery Management Council; and

"(iv) that are selected so that the members of the Committee have experience or expertise with as many seafood species as practicable.

"(B) AT-LARGE MEMBERS.—The Secretary shall appoint to the Committee at-large members as follows:

"(i) One individual with experience in food distribution, marketing, retail, or food service.

"(ii) One individual with experience in the recreational fishing industry supply chain, such as fishermen, manufacturers, retailers, and distributors.

"(iii) One individual with experience in the commercial fishing industry supply chain, such as fishermen, manufacturers, retailers, and distributors.

"(iv) One individual who is an employee of the National Marine Fisheries Service with expertise in fisheries research.

"(C) BALANCED REPRESENTATION.—In selecting the members described in subparagraphs (A) and (B), the Secretary shall seek to maximize on the Committee, to the

extent practicable, a balanced representation of expertise in United States fisheries, seafood production, and science.

"(4) MEMBER TERMS.—The term for a member of the Committee shall be 3 years, except that the Secretary shall designate staggered terms for the members initially appointed to the Committee.

"(5) RESPONSIBILITIES.—The Committee shall be responsible for—

"(A) identifying needs of the fishing community that may be addressed by a project funded with a grant under subsection (c);

"(B) developing the request for proposals for such grants;

"(C) reviewing applications for such grants; and

"(D) selecting applications for approval under subsection  $(c)(2)(B)$ .

"(6) CHAIR.—The Committee shall elect a chair by a majority of those voting, if a quorum is present.

"(7) QUORUM.—A simple majority of members of the Committee shall constitute a quorum, but a lesser number may hold hearings.

"(8) MEETINGS.—

"(A) FREQUENCY.—The Committee shall meet not more than 2 times each year.

"(B) LOCATION.—The meetings of the Committee shall rotate between the geographic regions described under paragraph (2).

"(C) MINIMIZING COSTS.—The Committee shall seek to minimize the operational costs associated with meetings, hearings, or other business of the Committee, including through the use of video or teleconference.

"(9) DESIGNATION OF STAFF MEMBER.—The Secretary shall designate a staff member to coordinate the activities of the Committee and to assist with administrative and other functions as requested by the Committee.

"(10) PER DIEM AND EXPENSES AND FUNDING.—

"(A) IN GENERAL.—A member of the Committee shall serve without compensation, but shall be reimbursed in accordance with section 5703 of title 5, United States Code, for reasonable travel costs and expenses incurred in performing duties as a member of the Committee.

"(B) FUNDING.—The costs of reimbursements under subparagraph (A) and the other costs associated with the Committee shall be paid from funds made available to carry out this section (which may include funds described in subsection  $(f)(1)(B)$ ), except that no funds allocated for grants under sub-section  $(f)(1)(A)$  shall be expended for any purpose under this subsection.

"(11) CONFLICT OF INTEREST.—The conflict of interest and recusal provisions set out in section 302(j) of the Magnuson-Stevens Fishery Conservation and Management Act (16 U.S.C. 1852(j)) shall apply to any decision by the Committee and to all members of the Committee as if each member of the Committee is an affected individual within the meaning of such section 302(j), except that in addition to the disclosure requirements of section  $302(i)(2)(C)$  of such Act (16 U.S.C. 1852(j)(2)(C)), each member of the Committee shall disclose any financial interest or relationship in an organization or with an individual that is applying for a grant under subsection (c) held by the member of the Committee, including an interest as an officer, director, trustee, partner, employee, contractor, agent, or other representative.

#### "(12) TECHNICAL REVIEW OF APPLICATIONS.—

"(A) IN GENERAL.—Prior to review of an application for a grant under subsection (c) by the Committee, the Secretary shall obtain an independent written technical evaluation from 3 or more appropriate Federal, private, or public sector experts (such as industry, academia, or governmental experts) who—

"(i) have subject matter expertise to determine the technical merit of the proposal in the application;

"(ii) shall independently evaluate each such proposal; and

"(iii) shall certify that the expert does not have a conflict of interest concerning the application that the expert is reviewing.

"(B) GUIDANCE.—Not later than 180 days after the date of enactment of the American Fisheries Advisory Committee Act, the Secretary shall issue guidance related to carrying out the technical evaluations under subparagraph (A). Such guidance shall include criteria for the elimination by the National Oceanic and Atmospheric Administration of applications that fail to meet a minimum level of technical merit as determined by the review described in subparagraph (A)."

(b) ROLE IN APPROVAL OF GRANTS.—Section 2(c)(3) of the Act of August 11, 1939 (15 U.S.C. 713c–3(c)(3)), is amended to read as follows:

 $\mathcal{L}(3)(A)$  No application for a grant under this subsection may be approved unless the Secretary—

"(i) is satisfied that the applicant has the requisite technical and financial capability to carry out the project; and

"(ii) based on the recommendations of the American Fisheries Advisory Committee established in subsection (e), evaluates the proposed project as to—

"(I) soundness of design;

"(II) the possibilities of securing productive results;

"(III) minimization of duplication with other fisheries research and development projects;

"(IV) the organization and management of the project;

"(V) methods proposed for monitoring and evaluating the success or failure of the project; and

"(VI) such other criteria as the Secretary may require.

"(B) If the Secretary fails to provide funds to a grant selected by the American Fisheries Advisory Committee, the Secretary shall provide a written document to the Committee justifying the decision.".

# **SECTION 3. EXPANSION OF SPECIFIED PURPOSES OF FISHERIES RESEARCH AND DEVELOPMENT PROJECTS GRANTS PROGRAM TO INCLUDE FISHERIES RESEARCH AND DEVELOPMENT PROJECTS**

Section  $2(c)(1)$  of the Act of August 11, 1939 (15 U.S.C. 713c–3(c)(1)) is amended by inserting "fisheries science, recreational fishing," before "harvesting".

### **SECTION 4. PUBLIC AVAILABILITY OF GRANTS PROPOSALS**

Section 2(c) of the Act of August 11, 1939 (15 U.S.C. 713c–3(c)), is amended by adding at the end the following:

"(6) Any person awarded a grant under this subsection shall make publicly available a title and abstract of the project to be carried out by the grant funds that serves as the public justification for funding the project that includes a statement describing how the project serves to enhance United States fisheries, including harvesting, processing, marketing, and associated infrastructures, if applicable."

## **PURPOSE OF THE BILL**

The purpose of H.R. 1218 is to establish the American Fisheries Advisory Committee to assist in the awarding of fisheries research and development grants, and for other purposes.

## **BACKGROUND AND NEED FOR LEGISLATION**

The Saltonstall-Kennedy Grant Program (S–K Grant Program), established by the 1939 Saltonstall-Kennedy Act<sup>1</sup> (S-K Act), provides a mechanism to fund research and development projects involving seafood harvesting, processing, marketing, associated infrastructure, and more,<sup>2</sup> funded through tariffs paid to the Department of Agriculture on imported seafood products and other fisheries products.<sup>3</sup> This fund was originally overseen by an advisory committee, which was eliminated under the 1972 Federal Advisory Committee Act.<sup>4</sup> The National Marine Fisheries Service (NMFS) has since managed the grant program to "address the needs of fishing communities, optimize economic benefits by building and maintaining sustainable fisheries, and increase other opportunities to keep working waterfronts viable."<sup>5</sup>

Lawmakers and stakeholders have raised concerns over the years that NMFS does not administer the program fairly and in accordance with statute. For example, NMFS has arguably underfunded seafood marketing projects in favor of internal priorities.<sup>6</sup> Indeed, much of the statutorily dedicated tariff revenue has been diverted from the grant program to fund NOAA operations over the years,<sup>7</sup> although in some cases at Congress's direction.<sup>8</sup> For Fiscal Year 2019, NMFS recommended awarding five projects using S–K funds for almost

<sup>&</sup>lt;sup>1</sup> Act of Aug. 11, 1939, 53 Stat. 1411.

<sup>2</sup> 15 U.S.C. § 713c–3(c).

<sup>7</sup> Richard Gaines, Feds Ignore Law on Fishing Fund, GLOUCESTER TIMES, Mar. 28, 2011, https://www. gloucestertimes.com/news/localnews/feds-ignore-law-on-fishing-fund/article062b6ce8-2551-5536-ad29-af879 a2f73bf.html.

<sup>8</sup> Eugene H. Buck, Cong. Research Serv., RS21799, SALTONSTALL-KENNEDY ACT 3–5, 6, 7, 3 n.12 (2012).

\$1.3 million: three projects for marine aquaculture; one for promotion, development, and marketing; and one in support of science that maximizes fishing opportunities, revenue, and jobs in U.S. fisheries.<sup>9</sup>

The purpose of this bill is to create an advisory committee comprised of representatives from the seafood industry to develop grant proposal requests and to review and select grant applications.

## **COMMITTEE ACTION**

H.R. 1218 was introduced on February 13, 2019, by Representative Don Young (R–AK). The bill was referred solely to the Committee on Natural Resources, and within the Committee to the Subcommittee on Water, Oceans, and Wildlife. On May 8, 2019, the Subcommittee held a hearing on the bill. On September 18, 2019, the Natural Resources Committee met to consider the bill. The Subcommittee was discharged by unanimous consent. Chair Rau´ l Grijalva (D–AZ) filed an amendment in the nature of a substitute. By unanimous consent, the sponsor of the amendment in the nature of a substitute was changed from Chair Grijalva to Representative Joe Cunningham (D–SC) and Representative Garret Graves (R–LA). The amendment in the nature of a substitute was agreed to by unanimous consent. The bill, as amended, was adopted and ordered favorably reported to the House of Representatives by unanimous consent.

### **HEARINGS**

For the purposes of section 103(i) of H. Res. 6 of the 116th Congress—the following hearing was used to develop or consider H.R. 1218: legislative hearing by the Subcommittee on Water, Oceans, and Wildlife held on May 8, 2019.

# **SECTION-BY-SECTION ANALYSIS**

## **Section 1. Short Title**

l

This section provides the short title of the bill, the "American Fisheries Advisory Committee Act."

#### **Section 2. American Fisheries Advisory Committee**

This section establishes the American Fisheries Advisory Committee, which manages the administration of grant proposal requests and provides recommendations to the Secretary of

<sup>9</sup> FY19 Successful Saltonstall-Kennedy Grant Applicants, NOAA FISHERIES, https:// www.fisheries.noaa.gov/ content/fy19-successful-saltonstall-kennedy-grant-applicants (last up- dated Sept. 18, 2019).

Commerce for fisheries research and development grants that fund projects meeting the needs of the fishing community. This committee consists of representatives from six geographic regions who are from the seafood harvesting and processing industries; the fishing or seafood-growing communities; and the fisheries science community or the relevant Regional Fishery Management Council. In addition, the committee consists of at-large members with experience in seafood distribution, marketing, retail, or food service; the recreational fishing industry supply chain; the commercial fishing industry supply chain; and an employee of NMFS.

## **Section 3. Expansion of Specified Purposes of Fisheries Research and Development Projects Grants Program to Include Fisheries Research and Development Projects**

This section includes fisheries science and recreational fishing projects among the research and development project grants eligible for funding by the Secretary of Commerce.

#### **Section 4. Public Availability of Grants Proposals**

This section requires grantees to make publicly available a title and abstract of each project as public justification for funding, including a description of how the project enhances U.S. fisheries.

## **COMMITTEE OVERSIGHT FINDINGS AND RECOMMENDATIONS**

Regarding clause  $2(b)(1)$  of rule X and clause  $3(c)(1)$  of rule XIII of the Rules of the House of Representatives, the Committee on Natural Resources' oversight findings and recommendations are reflected in the body of this report.

# **COMPLIANCE WITH HOUSE RULE XIII AND CONGRESSIONAL BUDGET ACT**

*(1) Cost of Legislation and the Congressional Budget Act.* With respect to the requirements of clause  $3(c)(2)$  and (3) of rule XIII of the Rules of the House of Representatives and sections 308(a) and 402 of the Congressional Budget Act of 1974, the Committee has received the following estimate for the bill from the Director of the Congressional Budget Office:

H.R. 1218 would establish the American Fisheries Advisory Committee within the Department of Commerce (DOC). The committee would consist of representatives from each of six geographic regions and at-large members with experience in the seafood and fisheries industries, as selected by DOC. Under the bill, the committee would be responsible for identifying the needs of fishing communities, developing requests for proposals for research and development grants to meet those needs, reviewing grant applications, and selecting applicants to receive funding.

The National Oceanic and Atmospheric Administration currently administers the fishery research and development grant program described above. That program's funding is derived from DOC's permanent statutory authority to spend 30 percent of customs receipts collected from imported fishery products. In 2018 the agency spent \$16 million for those purposes. H.R. 1218 would shift the authority to administer that grant program to the newly established committee. The bill also would expand eligibility for grant applicants to include projects related to fisheries science and recreational fishing.

H.R. 1218 would not change the total amount of authorized spending of custom receipts (although the composition of that spending might change). Thus, CBO estimates that enacting H.R. 1218 would not affect the federal budget.

On April 18, 2019, CBO transmitted a cost estimate for S. 494, the American Fisheries Advisory Committee Act, as ordered reported by the Senate Committee on Commerce, Science, and Transportation on April 3, 2019. H.R. 1218 is similar to S. 494 and CBO's estimates of the budgetary effects are the same for both pieces of legislation.

The CBO staff contact for this estimate is David Hughes. The estimate was reviewed by H. Samuel Papenfuss, Deputy Assistant Director for Budget Analysis.

*1. General Performance Goals and Objectives.* As required by clause 3(c)(4) of rule XIII, the general performance goals and objectives of this bill are to establish the American Fisheries Advisory Committee to assist in the awarding of fisheries research and development grants.

## **EARMARK STATEMENT**

This bill does not contain any Congressional earmarks, limited tax benefits, or limited tariff benefits as defined under clause  $9(e)$ ,  $9(f)$ , and  $9(g)$  of rule XXI of the Rules of the House of Representatives.

## **UNFUNDED MANDATES REFORM ACT STATEMENT**

This bill contains no unfunded mandates.

## **FEDERAL ADVISORY COMMITTEE ACT STATEMENT**

The functions of the American Fisheries Advisory Committee required to be established by this bill are currently being performed, in part, by the Secretary of Commerce acting through the National Marine Fisheries Service and previously by an advisory committee eliminated by the Federal Advisory Committee Act. In reporting the bill favorably to the House of Representatives, the Committee on Natural Resources finds that these functions would be better performed by the proposed advisory committee than by one or more agencies or another existing advisory committee.

## **EXISTING PROGRAMS**

This bill does not establish or reauthorize a program of the federal government known to be duplicative of another program. Such program was not included in any report from the Government Accountability Office to Congress pursuant to section 21 of Public Law 111– 139. The Fisheries Development and Utilization Research and Development Grants and Cooperative Agreements Program (CFDA No. 11.427) expanded by this bill is related and complementary to, but not duplicative of, the following programs identified in the most recent Catalog of Federal Domestic Assistance published pursuant to 31 U.S.C. § 6104: Interjurisdictional Fisheries Act of 1986 (CFDA No. 11.407) and Sea Grant Support (CFDA No. 11.417).

## **APPLICABILITY TO LEGISLATIVE BRANCH**

The Committee finds that the legislation does not relate to the terms and conditions of employment or access to public services or accommodations within the meaning of section 102(b)(3) of the Congressional Accountability Act.

## **PREEMPTION OF STATE, LOCAL, OR TRIBAL LAW**

Any preemptive effect of this bill over state, local, or tribal law is intended to be consistent with the bill's purposes and text and the Supremacy Clause of Article VI of the U.S. Constitution.

## **CHANGES IN EXISTING LAW MADE BY THE BILL, AS REPORTED**

In compliance with clause 3(e) of rule XIII of the Rules of the House of Representatives, changes in existing law made by the bill, as reported, are shown as follows (existing law proposed to be omitted is enclosed in black brackets, new matter is printed in italics, and existing law in which no change is proposed is shown in roman):

## **ACT OF AUGUST 11, 1939**

AN ACT To authorize the Federal Surplus Commodities Corporation to purchase and distribute surplus products of the fishing industry.

SEC. 2. (a) DEFINITIONS.—As used in this section—

(2) The term "person" means—

(A) any individual who is a citizen or national of the United States or a citizen of the Northern Mariana Islands;

(B) any fishery development foundation or other private nonprofit corporation in Alaska; and

(C) any corporation, partnership, association, or other entity (including, but not limited to, any fishery development foundation or other private nonprofit corporation not located in Alaska), nonprofit or otherwise, if such entity is a citizen of the United States within the meaning of section 2 of the Shipping Act, 1916 (46 U.S.C. 802) and for purposes of applying such section 2 with respect to this section—

(i) the term "State" as used therein includes any State referred to in paragraph (3),

(ii) citizens of the United States must own not less than 75 percent of the interest in the entity or, in the case of a nonprofit entity, exercise control in the entity that is determined by the Secretary to be the equivalent of such ownership, and

(iii) nationals of the United States and citizens of the Northern Mariana Islands shall be treated as citizens of the United States in meeting the ownership and control requirements referred to in clause (ii).

(2) The term "Secretary" means the Secretary of Commerce.

(3) The term "State" means any State, the District of Columbia, the Commonwealth of Puerto Rico, American Samoa, the Virgin Islands of the United States, Guam, the Northern Mariana Islands, and any other Commonwealth, territory, or possession of the United States.

(4) The term "United States fishery" means any fishery, including any tuna fishery, that is, or may be, engaged in by citizens or nationals of the United States or citizens of the Northern Mariana Islands.

(5) The term "citizen of the Northern Mariana Islands" means—

(A) an individual who qualifies as such under section 8 of the Schedule on Transitional Matters attached to the Constitution of the Northern Mariana Islands; or

(B) a corporation, partnership, association, or other entity organized or existing under the laws of the Northern Mariana Islands, not less than 75 percent of the interest in which is owned by individuals referred to in subparagraph (A) or citizens or nationals of the United States, in cases in which "owned" is used in the same sense as in section 2 of the Shipping Act, 1916 (46 U.S.C. 802).

(b) FUND.—(1) The Secretary of Agriculture shall transfer to the Secretary each fiscal year, beginning with the fiscal year commencing July 1, 1954, and ending on June 30, 1957, from moneys made available to carry out the provisions of section 32 of such Act of August 24, 1935, an amount equal to 30 per centum of the gross receipts from duties collected under the customs laws on fishery products (including fish, shellfish, mollusks, crustacea, aquatic plants and animals, and any products thereof, including processed and manufactured products), which shall be maintained in a separate fund only for—

(A) use by the Secretary—

(i) to provide financial assistance for the purpose of carrying out fisheries research and development projects approved under subsection (c);

(ii) to implement the national fisheries research and development program provided for under subsection (d);

(iii) to implement the Northwest Atlantic Ocean Fisheries Reinvestment Program established under section 314 of the Magnuson Fishery Conservation and Management Act; and

(iv) to fund the Federal share of a fishing capacity reduction program established under section 312 of the Magnuson Fishery Conservation and Management Act; and

(B) the provision of moneys, subject to paragraph (2), to carry out the purposes of the Fisheries Promotion Fund established under section 208(a) of the Fish and Seafood Promotion Act of 1986.

(2) There are transferred from the fund established under paragraph (1) to the Fisheries Promotion Fund referred to in paragraph (1)(B) \$750,000 in fiscal year 1987, \$3,000,000 in each of fiscal years 1988 and 1989, and \$2,000,000 in each of fiscal years 1990 and 1991.

(c) FISHERIES RESEARCH AND DEVELOPMENT PROJECTS.—(1) The Secretary shall make grants from the fund established under sub- section (b) to assist persons in carrying out research and development projects addressed to any aspect of United States fisheries, including, but not limited to, *fisheries science, recreational fishing,* harvesting, processing, marketing, and associated infrastructures.

(2) The Secretary shall—

(A) at least once each fiscal year, receive, during a 60-day period specified by him, applications for grants under this subsection;

(B) prescribe the form and manner in which applications for grants under this subsection must be made, including, but not limited to, the specification of the information which must accompany applications to ensure that the proposed projects comply with Federal law and can be evaluated in accordance with paragraph (3)(B); and

(C) approve or disapprove each such application before the close of the 120th day after the last day of the 60-day period (specified under subparagraph (A)) in which the application was received.

 $\varphi(3)$  No application for a grant under this subsection may be approved unless the Secretary—

 $\phi(A)$  is satisfied that the applicant has the requisite technical and financial capability to carry out the project; and

 $\phi$ (B) evaluates the proposed project as to-

 $\varphi$ (i) soundness of design,

 $\phi$ (ii) the possibilities of securing productive results,

 $\varphi$ (iii) minimization of duplication with other fisheries research and development projects,

 $\phi(iv)$  the organization and management of the project,

 $\phi$ (v) methods proposed for monitoring and evaluating the success or failure of the project, and

 $\phi$ (vi) such other criteria as the Secretary may require.

*(3)(A) No application for a grant under this subsection may be approved unless the Secretary—*

*(i)is satisfied that the applicant has the requisite technical and financial capability to carry out the project; and*

*(ii) based on the recommendations of the American Fisheries Advisory Committee established in subsection (e), evaluates the proposed project as to—*

*(I) soundness of design;*

*(II) the possibilities of securing productive results;*

*(III) minimization of duplication with other fisheries research and development projects;*

*(IV) the organization and management of the project;*

*(V) methods proposed for monitoring and evaluating the success or failure of the project; and*

*(VI) such other criteria as the Secretary may require.*

*(B) If the Secretary fails to provide funds to a grant selected by the American Fisheries Advisory Committee, the Secretary shall provide a written document to the Committee justifying the decision.*

(4) Each grant made under this subsection shall be subject to such terms and conditions as the Secretary may require to protect the interests of the United States, including, but not limited to, the following:

(A) The recipient of the grant must keep such records as the Secretary shall require as being necessary or appropriate for disclosing the use made of grant funds and shall allow the Secretary and the Comptroller General of the United States, or any of their authorized representatives, access to such records for purposes of audit and examination.

(B) The amount of a grant may not be less than 50 percent of the estimated cost of the project.

(C) The recipient of the grant must submit to the Secretary periodic project status reports.

(5)(A) If the cost of a project will be shared by the grant recipient, the Secretary shall accept, as a part of all of that share, the value of inkind contributions made by the recipient, or made available to, and applied by, the recipient, with respect to the project.

(B) For purposes of subparagraph (A), inkind contributions may be in the form of, but are not limited to, personal services rendered in carrying out functions related to, and permission to use real or personal property owned by others (for which consideration is not required) in carrying out the project. The Secretary shall establish

(i) the training, experience, and other qualifications which shall be required in order for services to be considered as inkind contributions; and (ii) the standards under which the Secretary will determine the value of inkind contributions for purposes of subparagraph (A).

(C) Any valuation determination made by the Secretary for purposes of this paragraph shall be conclusive.

*(6) Any person awarded a grant under this subsection shall make publicly available a title and abstract of the project to be carried out by the grant funds that serves as the public justification for funding the project that includes a statement describing how the project*  *serves to enhance United States fisheries, including harvesting, processing, marketing, and associated infrastructures, if applicable.*

(d) NATIONAL FISHERIES RESEARCH AND DEVELOPMENT PROGRAM.—(1) The Secretary shall carry out a national program of research and development addressed to such aspects of United States fisheries (including, but not limited to, harvesting, processing, marketing, and associated infrastructures), if not adequately covered by projects assisted under subsection (c), as the Secretary deems appropriate.

(2) The Secretary shall, after consultation with appropriate representatives of the fishing industry, submit to the Committee on Commerce, Science, and Transportation of the Senate and the Committee on Merchant Marine and Fisheries of the House of Representatives, an annual report, that must be submitted not later than 60 days before the close of each fiscal year, containing—

(A) the fisheries development goals and funding priorities under paragraph (1) for the next fiscal year;

(B) a description of all pending projects assisted under subsection (c) or carried out under paragraph (1), in addition to—

(i) a list of those applications approved and those disapproved under subsection (c), and the total amount of grants made, for the current fiscal year, and

(ii) a statement of the extent to which available funds were not obligated or expended by the Secretary for grants under subsection (c) during the current fiscal year; and

(C) an assessment of each project assisted under subsection

(c) or carried out under paragraph (1) that was completed in the preceding fiscal year regarding the extent to which (i) the objectives of the project were attained, and (ii) the project contributed to fishery development.

*(e) AMERICAN FISHERIES ADVISORY COMMITTEE.—*

*(1) DEFINITIONS.—In this subsection:*

*(A) COMMITTEE.—The term "Committee" means the American Fisheries Advisory Committee established under paragraph (2).*

*(B) FISHING COMMUNITY.—The term "fishing community" means harvesters, marketers, growers, processors, recreational fishermen, charter fishermen, and persons providing them with goods and services.*

*(C) MARKETING AND PROMOTION.—The term "marketing and promotion" means an activity aimed at encouraging the consumption of seafood or expanding or maintaining commercial markets for seafood.*

*(D) PROCESSOR.—The term "processor" means any person in the business of preparing or packaging seafood (including seafood of the processor's own harvesting) for sale.*

*(E) SEAFOOD.—The term "seafood" means farm-raised and wild-caught fish, shellfish, or marine algae harvested in the United States or by a United States flagged vessel for human consumption.*

*(2) ESTABLISHMENT.—Not later than 90 days after the date of the enactment of the American Fisheries Advisory Committee Act, the Secretary shall establish 6 regions within the American Fisheries Advisory Committee as follows:*

*(A) Region 1 shall consist of Alaska, Hawaii, the Commonwealth of the Northern Mariana Islands, and the Territories of Guam and American Samoa.*

*(B) Region 2 shall consist of Maine, New Hampshire, Massachusetts, Rhode Island, and Connecticut.*

*(C) Region 3 shall consist of Texas, Alabama, Louisiana, Mississippi, Florida, Arkansas, Puerto Rico, and the Territory of the Virgin Islands of the United States.*

*(D) Region 4 shall consist of California, Washington, Oregon, and Idaho.*

*(E) Region 5 shall consist of New Jersey, New York, Delaware, Maryland, Virginia, North Carolina, South Carolina, and Georgia.*

*(F) Region 6 shall consist of Michigan, Minnesota, Wisconsin, Illinois, Indiana, Ohio, and Pennsylvania.*

*(3) MEMBERSHIP.—The Committee shall be composed of the following members:*

*(A) REGIONAL REPRESENTATION.—Each of the regions listed in subparagraphs (A) through (F) of paragraph (2) shall be represented on the Committee by 3 members—*

*(i) who are appointed by the Secretary;*

*(ii) who reside in a State or territory in the region that the member will represent; (iii) of which—*

*(I) one shall have experience as a seafood harvester or processor;*

*(II) one shall have experience as recreational or commercial fisher or have experience growing seafood; and*

*(III) one shall be an individual who represents the fisheries science community or the relevant Regional Fishery Management Council; and*

*(iv) that are selected so that the members of the Committee have experience or expertise with as many seafood species as practicable.*

*(B) AT-LARGE MEMBERS.—The Secretary shall appoint to the Committee at-large members as follows:*

*(i) One individual with experience in food distribution, marketing, retail, or food service.*

*(ii) One individual with experience in the recreational fishing industry supply chain, such as fishermen, manufacturers, retailers, and distributors.*

*(iii) One individual with experience in the commercial fishing industry supply chain, such as fishermen, manufacturers, retailers, and distributors.*

*(iv) One individual who is an employee of the National Marine Fisheries Service with expertise in fisheries research.*

*(C) BALANCED REPRESENTATION.—In selecting the members described in subparagraphs (A) and (B), the Secretary shall seek to maximize on the Committee, to the extent practicable, a balanced representation of expertise in United States fisheries, seafood production, and science.*

*(4) MEMBER TERMS.—The term for a member of the Committee shall be 3 years, except that the Secretary shall designate staggered terms for the members initially appointed to the Committee.*

*(5) RESPONSIBILITIES.—The Committee shall be responsible for—*

*(A) identifying needs of the fishing community that may be addressed by a project funded with a grant under subsection (c);*

*(B) developing the request for proposals for such grants;*

*(C) reviewing applications for such grants; and*

*(D) selecting applications for approval under subsection (c)(2)(B).*

*(6) CHAIR.—The Committee shall elect a chair by a majority of those voting, if a quorum is present.*

*(7) QUORUM.—A simple majority of members of the Committee shall constitute a quorum, but a lesser number may hold hearings.*

*(8) MEETINGS.—(A) FREQUENCY.—The Committee shall meet not more than 2 times each year.*

*(B) LOCATION.—The meetings of the Committee shall rotate between the geographic regions described under paragraph (2).*

*(C) MINIMIZING COSTS.—The Committee shall seek to minimize the operational costs associated with meetings, hearings, or other business of the Committee, including through the use of video or teleconference.*

*(9) DESIGNATION OF STAFF MEMBER.—The Secretary shall designate a staff member to coordinate the activities of the Committee and to assist with administrative and other functions as requested by the Committee.*

*(10) PER DIEM AND EXPENSES AND FUNDING.—*

*(A) IN GENERAL.—A member of the Committee shall serve without compensation, but shall be reimbursed in accordance with section 5703 of title 5, United States Code, for reasonable travel costs and expenses incurred in performing duties as a member of the Committee.*

*(B) FUNDING.—The costs of reimbursements under sub-paragraph (A) and the other costs associated with the Committee shall be paid from funds made available to carry out this section (which may include funds described in subsection (f)(1)(B)), except that no funds allocated for grants under subsection (f)(1)(A) shall be expended for any purpose under this subsection.*

*(11) CONFLICT OF INTEREST.—The conflict of interest and recusal provisions set out in section 302(j) of the Magnuson-Stevens Fishery Conservation and Management Act (16 U.S.C. 1852(j)) shall apply to any decision by the Committee and to all members of the Committee as if each member of the Committee is an affected individual within the meaning of such section 302(j), except that in addition to the disclosure requirements of section 302(j)(2)(C) of such Act (16 U.S.C. 1852(j)(2)(C)), each member of the Committee shall disclose any financial interest or relationship in an organization or with an individual that is applying for a grant under subsection (c) held by the member of the Committee, including an interest as an officer, director, trustee, partner, employee, contractor, agent, or other representative.*

*(12) TECHNICAL REVIEW OF APPLICATIONS.—*

*(A) IN GENERAL.—Prior to review of an application for a grant under subsection (c) by the Committee, the Secretary shall obtain an independent written technical evaluation from 3 or more appropriate Federal, private, or public sector experts (such as industry, academia, or governmental experts) who—*

*(i) have subject matter expertise to determine the technical merit of the proposal in the application;*

*(ii) shall independently evaluate each such proposal; and*

*(iii) shall certify that the expert does not have a conflict of interest concerning the application that the expert is reviewing.*

*(B) GUIDANCE.—Not later than 180 days after the date of enactment of the American Fisheries Advisory Committee Act, the Secretary shall issue guidance related to carrying out the technical evaluations under subparagraph (A). Such guidance shall include criteria for the elimination by the National Oceanic and Atmospheric Administration of applications that* 

*fail to meet a minimum level of technical merit as determined by the review described in subparagraph (A).*

ø(e)¿ *(f)* ALLOCATION OF FUND MONEYS.—(1) Notwithstanding any other provisions of law, all moneys in the fund shall be used exclusively for the purpose of promoting United States fisheries in accordance with the provisions of this section, and no such moneys shall be transferred from the fund for any other purpose. With respect to any fiscal year, all moneys in the fund, including the sum of all unexpended moneys carried over into that fiscal year and all moneys transferred to the fund under subsection (b) or any other provision of law with respect to that fiscal year, shall be allocated as follows:

(A) the Secretary shall use no less than 60 per centum of such moneys to make direct industry assistance grants to develop the United States fisheries and to expand domestic and foreign markets for United States fishery products pursuant to subsection (c) of this section; and

(B) the Secretary shall use the balance of the moneys in the fund to finance those activities of the National Marine Fisheries Service which are directly related to development of the United States fisheries pursuant to subsection (d) of this section.

(2) The Secretary shall, consistent with the number of meritorious applications received with respect to any fiscal year, obligate or expend all of the moneys in the fund described in paragraph (1). Any such moneys which are not expended in a given fiscal year shall remain available for expenditure in accordance with this section without fiscal year limitation, except that the Secretary shall not obligate such moneys at a rate less than that necessary to prevent the balance of moneys in the fund from exceeding \$3,000,000 at the end of any fiscal year.

 $\overline{a}$ 

# **FISHERY DISASTER ASSISTANCE (UPDATED)**

# *Harold F. Upton*

### **ABSTRACT**

The Secretary of Commerce is authorized to provide disaster assistance to the fishing industry when fish populations decline or other disruptions cause economic losses. The criteria for determining whether a commercial fishery failure or fishery resource disaster has occurred are provided in Section 308(b) and Section 308(d) of the Interjurisdictional Fisheries Act (IFA; 16 U.S.C. §4107), and in Sections 312(a) and 315 of the Magnuson-Stevens Fishery Conservation and Management Act (MSA; 16 U.S.C. §1861(a) and §1864).

The governor of a state, the Secretary of Commerce, or a representative of a fishing community may initiate a request for assistance. The National Marine Fisheries Service (NMFS), state agencies, and fishing communities compile information needed to make a determination. When all necessary information has been obtained and reviewed, the Secretary of Commerce determines whether a fishery failure or fishery disaster has occurred. In most cases, Congress has appropriated funds to support the fishing industry following the Secretary's determination. NMFS, states, regional commissions, and industry representatives often work together to plan how assistance will be distributed to the fishing industry and allocated among potential projects.

Oceanic conditions, climate, and weather events can affect fishery resources and commercial infrastructure, such as boats, shoreside processing, and ports. Since 1990, the Secretary of Commerce has made 72 fishery disaster determinations and Congress has appropriated nearly \$1.15 billion for fishery disaster relief. Recent fishery disaster determinations have been made for salmon fisheries in the Pacific Northwest and Alaska, Dungeness crab fisheries in the Pacific Northwest, the West Coast sardine fishery, and fisheries affected by several hurricanes.

Direct federal financial assistance has been provided to fishermen and fishing communities in the form of grants, job retraining, and low-interest loans. Assistance also supported efforts to prevent or lessen the effects of future disruptions to fisheries. These efforts included fishery data collection, habitat restoration, research, and fishing capacity reduction programs. Whereas some observers support efforts to provide assistance, others

This is an edited, reformatted and augmented version of Congressional Research Service, Publication No. RL34209, dated April 7, 2020.

contend that disaster assistance programs sometimes fall short of expectations when funds are not disbursed in a timely manner, relief is not integrated with long-term fishery management objectives, and funds do not reach the people who may be in the greatest need of assistance.

In the 116th Congress, similar versions of the Fishery Failures: Urgently Needed Disaster Declarations Act (S. 2346 and H.R. 5548) have been introduced that would make extensive changes to the current law. Both bills would amend Section 312 of the MSA, repeal Section 315 of the MSA, and repeal Section 308 of the IFA. Generally, the legislation would consolidate and clarify fishery disaster provisions in the MSA and the IFA and incorporate some parts of the NMFS agency directive on fishery disasters. Both bills would define terms frequently used when making fishery disaster determinations, clarify procedures and criteria for making fishery disaster determinations, provide guidance for allocating and disbursing funds, and place additional conditions on assistance for fishing capacity reduction programs. On November 13, 2019, S. 2346 was marked up by the Committee on Commerce, Science, and Transportation, and on January 14, 2020, the House Natural Resources Subcommittee on Water, Oceans, and Wildlife held a hearing that included testimony related to H.R. 5548.

Several additional bills related to fishery disaster assistance have been introduced. The Strengthening Fishing Communities and Increasing Flexibility in Fisheries Management Act (H.R. 3697) includes a section that would require the Secretary of Commerce to make a fishery disaster determination within 90 days of receiving an estimate of the economic impact of the disaster from the entity making the request. H.R. 3697 also would require the Secretary to publish the estimated cost of recovery from a fishery resource disaster within 30 days of making a determination. Two identical bills (H.R. 3514 and S. 1984) would add the effects of certain duties on seafood markets as a potential cause of a commercial fishery failure under the MSA. The Commercial Fishing and Aquaculture Protection Act of 2019 (S. 2209) would provide assistance to eligible commercial fishermen and aquaculture producers who suffer losses in revenue. No further actions have been taken on any of these bills.

## **INTRODUCTION**

The productivity and profitability of marine fisheries may vary significantly due to natural and anthropogenic causes, such as oceanic conditions, climate, pollution, and weather events. These factors can cause fishery resource declines and fishery closures and can damage commercial infrastructure such as boats, shoreside processing, and ports. Fishery disasters occur when fishermen endure economic hardships resulting from fish population declines or other disruptions to the fishery. The federal government may provide disaster relief to assist the fishing industry when it has been harmed by a fishery disaster.

A governor of a state, the Secretary of Commerce (Secretary), or a representative of a fishing community initiates a request for assistance. The National Marine Fisheries Service (NMFS) at the National Oceanic and Atmospheric Administration (NOAA), state agencies, and fishing communities compile information needed to make a determination. When all necessary information has been obtained, the Secretary makes a determination of whether a fishery disaster or failure has occurred. In most cases, Congress appropriates funds to support the fishing industry following the Secretary's disaster determination. Congress generally appropriates funding in supplemental or annual appropriations as needs arise rather than in anticipation of future needs.

#### **Statutory Authorities and Different Types of Fishery Disasters<sup>1</sup>**

The Secretary of Commerce (Secretary) is authorized to determine that a fishery disaster has occurred under the Magnuson-Stevens Fishery Conservation and Management Act (MSA; 16 U.S.C. §1861(a) and 16 U.S.C. §1864) and the Interjurisdictional Fisheries Act (IFA; 16 U.S.C. §4107). Secretarial determinations are similar but vary according to the underlying cause of the disruption to a fishery.<sup>2</sup> *Commercial Fishery Failure*—A commercial fishery failure occurs when revenues from commerce in the fishery decrease due to a fishery resource disaster, such that the decrease causes fishermen to suffer economic hardship.

*Fishery Resource Disaster*—A fishery resource disaster is a sudden, unexpected, large decrease in fish stock biomass or other change that results in significant loss of access to the fishery resource. Section 312(a) of the MSA authorizes the Secretary to determine whether a *commercial fishery failure*  has occurred due to a *fishery resource disaster*.

- Section 315 of the MSA authorizes the Secretary to determine whether a catastrophic regional disaster has occurred. The cause of the catastrophic regional disaster may be a *commercial fishery failure* under Section 312(a) of the MSA or a *fishery resource disaster* under Section 308(d) of the IFA.
- Section 308(b) of the IFA authorizes the Secretary to provide assistance when a fishery has been affected by a *commercial fishery failure* or serious disruption to future production due to a *fishery resource disaster* arising from natural or undetermined causes.
- Section 308(d) of the IFA authorizes the Secretary to initiate projects to alleviate harm determined by the Secretary to have been incurred as a direct result of a *fishery resource disaster* arising from a hurricane or other natural disaster.

NMFS, states, regional commissions, and industry representatives often work together to distribute assistance to the fishing industry and to allocate funding among potential projects.

The federal government and its partners have allocated fishing disaster funds to fisheries of the North Pacific, Western Pacific, Pacific Northwest, Gulf of Mexico, Southeast, and the Northeast regions. Fisheries with multiple commercial fishery failure determinations include the West Coast salmon troll fishery, Fraser River sockeye salmon fishery, the Northeast multispecies fishery, Gulf fisheries following hurricanes, New England shellfish fisheries, Alaska salmon fisheries, and the Bering Sea snow crab fishery.

Under the fishing disaster authorities, the federal government has provided direct financial assistance to fishermen and fishing communities in the form of grants, job retraining, and low- interest loans. The federal government has also provided indirect assistance that has included fishery data collection, resource restoration, research, and fishing capacity reduction programs to prevent or lessen the effects of future disruptions to fisheries. Whereas most observers recognize that disaster assistance has provided much-needed assistance to the fishing industry, others contend that disaster assistance programs sometimes fall short of expectations because funds may not be appropriated or disbursed in a timely manner, relief may not be integrated with long-term fishery management objectives, economic estimates of fishery disasters are inconsistent, and funds may not reach the people in the greatest need of assistance.

<sup>1</sup> National Marine Fisheries Service (NMFS), *Policy on Disaster Assistance under the Magnuson-Stevens Act 312(a) and 315 and Interjurisdictional Fisheries Act 308(b) and 308(d)*, National Marine Fisheries Service Policy 01-122, June 16, 2011. Hereinafter cited as NMFS, *Policy*.

<sup>2</sup> The term *fishery disaster* is used in parts of this report to make general references to commercial fishery failures and fishery resource disasters.

## **DISASTER REQUIREMENTS AND PROCEDURES**

The Department of Commerce provides fishery disaster assistance under the Magnuson-Stevens Fishery Conservation and Management Act (MSA; 16 U.S.C. §1861(a) and 16 U.S.C. §1864) and the Interjurisdictional Fisheries Act (IFA; 16 U.S.C. §4107) [\(Table 1\)](#page-3026-0). Assistance may be provided to fisheries managed by states, such as blue crab, and to fisheries under federal management, such as the Northeast multispecies fishery.<sup>3</sup> Differences exist under each law with regard to the allowable causes of a commercial fishery failure or fishery resource disaster and the use of funds. Often fishery disasters have been declared under both laws, which may provide managers with greater latitude when matching relief with different needs of the fishery and its participants.

#### **Table 1. Fishery disaster causes, types of assistance, and use of funds**

Source: National Marine Fisheries Service (NMFS), Policy on Disaster Assistance under the Magnuson-Stevens Act 312(a) and 315 and Interjurisdictional Fisheries Act 308(b) and 308(d), National Marine Fisheries Service Policy 01-122, June 16, 2011.

Notes: MSA = Magnuson-Stevens Fishery Conservation and Management Act (16 U.S.C. §1861(a) and 16 U.S.C. §1864). IFA = Interjurisdictional Fisheries Act (16 U.S.C. §4107).

<sup>3</sup> Fisheries under state jurisdiction generally occur in state waters that include internal waters such as Chesapeake Bay or from 0-3 nautical miles (nm) from shore. State jurisdiction off the west coast of Florida and Texas extend to 9 nm from shore. Fisheries under federal jurisdiction generally occur from 3 to 200 nm from shore.
#### **Magnuson-Stevens Fishery Conservation and Management Act**

In 1996, Section 312(a) was added to the MSA to provide fishery disaster relief when a commercial fishery failure occurs as the result of a fishery resource disaster. <sup>4</sup> A *fishery resource disaster* is "a sudden unexpected, large decrease in fish stock biomass or other change that results in a significant loss of access to the fishery resource."<sup>5</sup>

In 2007, NMFS developed a policy directive to provide guidance for the disaster relief process.<sup>6</sup> The process begins at the discretion of the Secretary of Commerce, following the request of the governor of an affected state or at the request of a fishing community representative.<sup>7</sup> The Secretary determines whether a commercial fishery failure has occurred, depending on three factors.

First, there must be a fishery resource disaster resulting from a decrease in fish population biomass or the loss of access to the fishery resource.<sup>8</sup> Second, under the MSA, the cause of the fishery resource disaster must be one of the following:

- natural causes:
- man-made causes beyond the control of fishery managers to mitigate through conservation and management measures, including regulatory restrictions imposed to protect human health or the marine environment; or
- undetermined causes.

Finally, there must be an economic harm resulting from the commercial fishery disaster.

Requests for a commercial fishery failure determination usually contain information describing how the fishery and its users were harmed. The Secretary typically directs the appropriate Regional Administrator for NMFS to collect and analyze information such as landings, stock assessments, number of participants, and revenues. These data are used to determine the magnitude of the disaster and the relationship between underlying causes and the alleged fishery disaster. The magnitude of the disaster may be measured by the percentage decline in landings and revenues, the number of fishermen affected, loss of habitat, and lost or restricted fishing time. Depending on the circumstances, the analysis usually is conducted in consultation with the state(s) and typically includes information and data that the state(s) provide. According to NMFS, a reasonably predictable, foreseeable, and recurrent fishery resource cycle of variations in species distribution or stock abundance does not constitute a fishery resource disaster.<sup>9</sup>

Once it is concluded that a fishery resource disaster has occurred and its cause(s) is covered under the MSA, economic data are reviewed to determine whether a commercial fishery failure exists. The final decision depends on whether a significant number of people engaged in the fishery have suffered economic hardship as a result of the fishery resource disaster. NMFS has developed policy guidance to clarify and interpret the fishery disaster

<sup>4</sup> Section 312(a) was added by the Sustainable Fisheries Act of 1996 (P.L. 104-297).

<sup>5</sup> NMFS, *Policy.*

<sup>6</sup> NMFS, *Policy.*

<sup>7</sup> According to NMFS, a fishing community representative may include a tribal representative, city manager, or county executive.

<sup>&</sup>lt;sup>8</sup> Loss of access to the resource may result from damages to fishing vessels, gear and related infrastructure or fishery closures because of oil spills or toxic algal blooms.

<sup>9</sup> NMFS, *Policy.*

assistance provisions of the MSA and the IFA.<sup>10</sup> The guidance specifies the following thresholds based on the loss of annual revenue compared to average annual revenue over the most recent five-year period:

- Revenue losses greater than 80% will result in the determination of a commercial fishery failure.
- Revenue losses between 35% and 80% will be further evaluated to determine the severity of losses.
- Revenue losses less than 35% will not be eligible for determination of a commercial fishery failure, except where the Secretary determines there are special and unique circumstances that may justify considering and using a lower threshold in making the  $d$ etermination.<sup>11</sup>

Once it is determined that a commercial fishery failure exists, Congress may use the authorization in the MSA to appropriate funds for financial assistance to harvesters and other affected parties.

After funds are appropriated, the affected state, community, or group must develop a spending plan that is evaluated by NMFS regional offices. Funding under the MSA may be used to address a broad variety of needs, including an assessment of the social and economic effects of the failure, assistance to the community, and projects to restore the fishery or prevent reoccurrence of a similar failure. Before releasing funds, the Secretary must also determine that activities would not expand the size and scope of the failure in that fishery or other fisheries, or affect fisheries in other geographic regions. The federal share of assistance carried out under Section 312(a) of the MSA cannot be greater than 75% of the cost of relief activities, while the other 25% is usually provided by the state or other local entity. In some cases, regional fishery commissions administer claims and disburse funds to fishing communities.<sup>12</sup>

#### **MSA Regional Coastal Disaster Assistance**

In 2006, the MSA was amended by adding Section 315—the Regional Coastal Disaster Assistance, Transition, and Recovery Program. A *catastrophic regional fishery disaster* is defined as a natural disaster, such as a hurricane or tsunami, or a regulatory closure to protect human health or the marine environment. A catastrophic regional fishery disaster is an event that

- results in economic losses to the coastal or fishing communities;
- affects more than one state or a major fishery managed by a council or interstate fishery commission;<sup>13</sup> and

<sup>10</sup> NMFS, *Policy.*

<sup>11</sup> NMFS, *Policy.*

 $12$  For example, the Pacific States Marine Fisheries Commission disbursed funds to fishermen following the Pacific Salmon commercial fishery failure in 2009-2011.

<sup>&</sup>lt;sup>13</sup> Eight regional Fishery Management Councils are created by the MSA. Council members are appointed by the Secretary of Commerce from lists of candidates knowledgeable of fishery resources, provided by state

 is determined by the Secretary to be a commercial fishery failure under Section 312(a) of MSA or a fishery resource disaster under Section 308(d) of IFA of 1986.

Within two months after a catastrophic regional fishery disaster, the Secretary is required to provide the governor of each participating state with a comprehensive economic and socioeconomic evaluation of the region's fisheries. The evaluation assesses the current and future economic viability of affected fisheries, including the economic impact of foreign fish imports and direct, indirect, or environmental impacts of the disaster on the fishery and coastal communities. Subject to the availability of appropriations, the program may provide funds for infrastructure needs, job training assistance, fishing capacity reduction, and other activities authorized under either MSA or IFA. Various fishing groups in the region may be eligible for disaster assistance, including fishermen, charter fishing operators, U.S. fish processors, and owners of related fishery infrastructure. <sup>14</sup> Under the Regional Coastal Disaster Assistance, Transition, and Recovery Program, the Secretary may waive the matching requirements if no reasonable means are available for meeting the match and the probable benefit of 100% federal financing outweighs the public interest in imposing the match. Since it was added to the MSA, determinations under Section 315 have been made only for Hurricane Sandy in 2012; Hurricanes Irma and Maria in 2017; and Gulf of Mexico freshwater flooding in Louisiana, Mississippi, and Alabama in 2019.

#### **Interjurisdictional Fisheries Act**

The IFA was enacted in 1986 to provide federal support to states for developing interstate fishery research programs. Under IFA, funds are authorized to provide assistance for a commercial fishery failure (§308(b)) or for a fishery resource disaster (§308(d)). Under Section 308(b), a *commercial fishery failure* is a serious disruption to future production due to a fishery resource disaster arising from natural or undetermined causes. The process of collecting information and determining whether a commercial fishery failure has occurred under Section 308(b) of the IFA is similar to requirements of Section 312(a) of the MSA.

In Section 308(d), *fishery resource disasters* are referred to as natural disasters. Instead of assessing the occurrence of a commercial fishery failure, Section 308(d) of the IFA requires demonstration of harm. *Harm* is defined as uninsured damage to fishing vessels, fishing gear, processing facilities, marketability, habitat, or infrastructure. The same thresholds used for MSA fishery failure determinations are used for IFA determinations.<sup>15</sup>

IFA funding under Section 308(b) may be used by states alone or by the Secretary in cooperation with the states. Funding may be provided for any purpose the Secretary

governors. The councils prepare fishery management plans for those fisheries that occur primarily within the federal waters of the Exclusive Economic Zone (3-200 nautical miles from shore). Links to Council websites are at http://www.nmfs.noaa.gov/ole/fishery\_mgmt.html.

The three interstate fisheries commissions include the Atlantic States Marine Fisheries Commission, http://www.asmfc.org/; the Gulf States Marine Fisheries Commission, http://www.gsmfc.org/#:links@1; and the Pacific States Marine Fisheries Commission, http://www.psmfc.org/.

<sup>&</sup>lt;sup>14</sup> Businesses supported by recreational fisheries may be eligible of fishery disaster assistance under Section  $312(a)$ of the MSA if they are part of the affected fishing community. Recreational charter fishing businesses are mentioned explicitly in Section 315 of the MSA.

<sup>15</sup> NMFS, *Policy*.

determines appropriate to restore a fishery affected by a commercial fishery failure or to prevent a future fishery failure.

Under Section 308(b), funds may not be used to charter fishing vessels, and the federal share of funding is limited to 75% of costs. Funding under Section 308(d) of IFA may be used to provide direct assistance to fishermen or to provide assistance indirectly through state agencies, local government, and nonprofit organizations. In contrast to the MSA and Section 308(b) of IFA, there is no limit on the federal share of costs under Section 308(d). Section 308(d) also outlines the conditions under which funding may be used for other activities such as fishing capacity reduction programs. These programs include fishing vessel buybacks, gear reduction, or fishing permit retirement.

#### *Other Potential Sources of Assistance*

When businesses suffer economic injuries from a disaster, the Small Business Administration (SBA) may also determine whether a disaster declaration is warranted.<sup>16</sup> For example, when red tide required closure of the Maine shellfish fishery in 2005, SBA evaluated the impact on small businesses and determined a disaster declaration was justified. The declaration makes affected businesses eligible for Economic Injury Disaster Loans.<sup>17</sup> The purpose of the loan program is to provide working capital at low interest rates to assist recovery of businesses harmed by a disaster.

The Economic Development Administration (EDA) provides community grants and revolving loan funds to help distressed communities.<sup>18</sup> EDA has assisted fishing communities through its Public Works Program by funding port and harbor improvements. EDA's Economic Adjustment Program helps communities adjust to economic disruptions through support of business development, planning, and market research. Industries that have been adversely affected by increased imports of similar or competitive goods can seek technical assistance under EDA's Trade Adjustment Assistance Program.

#### **SECRETARIAL DISASTER DETERMINATIONS**

Since 1990, the Secretary of Commerce has made 72 different fishery disaster determinations, of which 58 were original determinations and 14 were extensions to existing determinations.<sup>19</sup> In 27 cases, the determination of a fishery failure or a fishery disaster was made under both the MSA and the IFA. During this period, Congress has appropriated nearly \$1.15 billion for fishery disaster relief. Funds for disaster assistance have been used for a wide variety of purposes and may include direct assistance to fishermen, such as

<sup>&</sup>lt;sup>16</sup> For Small Business Administration purposes, disasters also may be declared by the President, state governor, Secretary of Agriculture, or Secretary of Commerce.

<sup>17</sup> CRS Report RL33243, *Small Business Administration: A Primer on Programs and Funding*, by Robert Jay Dilger and Sean Lowry.

<sup>18</sup> For information on Economic Development Administration programs, see https://www.eda.gov/about/.

<sup>19</sup> National Oceanic and Atmospheric Administration (NOAA) Fisheries, Funding, and Financial Services, *Fishery Disaster Determinations*, at https://www.fisheries.noaa.gov/national/funding-and-financial-services/fisherydisaster- determinations.

- compensation;
- community grants;
- training;
- loans and debt refinancing; and
- employment on fishery related projects.

Other forms of indirect fishery-related assistance have included fishing capacity reduction (vessel, permit, and gear buybacks), formation of a fisheries research trust, economic planning grants, and research grants.

Fishery failures are diverse with respect to their causes and scope. Most declarations have resulted from natural events such as hurricanes, floods, changes in ocean conditions, or algal blooms such as red tide. In coastal areas hurricanes may damage fishing industry infrastructure such as vessels, docks, fish houses, and related businesses. Even if the resource remains abundant, harvesting, processing, and transport to markets may not be possible until repairs are undertaken and basic services are restored. In addition to the costs of repairs and the replacement of equipment and gear, lost fishing time also can be costly. Hurricanes also may damage natural resources such as oyster beds by depositing silt and debris. Algal blooms such as red tide are another type of natural event that can render seafood toxic and result in fishery closures. Under these conditions, fishermen may be completely shut down for months until toxin levels in shellfish decline to acceptable levels.

Declines in fishery resource abundance are often caused by several factors, such as natural environmental variations, human effects on the environment (e.g., pollution), and overfishing. For example, salmon fisheries are sensitive to natural changes in oceanic conditions. However, salmon abundance has also been affected where dams, irrigation, grazing, mining, and forestry practices have degraded salmon habitat in the Pacific Northwest. Overfishing by itself may not be used to qualify for a fishery failure determination, because it is usually within the control of fishery managers.<sup>20</sup> However, a fishery failure caused by natural or undetermined causes, criteria that may be considered by the Secretary of Commerce, may be exacerbated by overfishing. In these cases assistance may include efforts to rationalize (decrease) fishing capacity. For example, overfishing contributed to fish population declines in several resource disaster cases, such as the New England multispecies fishery and the Pacific groundfish fishery. In these cases, fish abundance decreased significantly and stock rebuilding has required substantial decreases in harvest. However, it was determined that other factors beyond the control of fishery managers played a role in the fishery failure.<sup>21</sup>

#### **State Role**

States are frequently active partners throughout the fishery disaster process, from requesting the Secretary to declare a fishery failure and providing related data to disbursing relief to fishermen and related businesses. The disaster request typically includes a spending

<sup>20</sup> NMFS, *Policy.*

<sup>&</sup>lt;sup>21</sup> Letter from Rebecca M. Blank, Acting Secretary of Commerce, to Honorable Deval L. Patrick, Governor of Massachusetts, September 13, 2012.

plan that addresses the causes of the disaster. Relief funding is often provided directly to states or through regional commissions, such as the Pacific States Marine Fisheries Commission. For example, in 2007, distribution of Oregon salmon troll fishery relief was planned and coordinated by the state's department of agriculture in cooperation with related agencies and nonprofit organizations such as the Oregon Salmon Commission. In addition to matching funds, state governments may also provide funding when federal funds are not available, although historically such funding has been limited.

#### **Fishing Capacity Reduction Programs**

Historically, many U.S. fisheries have been overcapitalized—investments in fishing capacity became greater than that needed to harvest the fishery resource on a sustainable basis. Fishing capacity reduction, often referred to as buyback programs, has been a prominent feature of several disaster relief programs.<sup>22</sup> Capacity reduction is usually accomplished through the direct purchase and permanent retirement of fishing vessels, gear, and/or fishing permits. Programs may be funded by the federal government, by fishermen who remain in the fishery, or by a combination of both. The general objectives of buyback programs are to provide immediate relief to fishermen, decrease the level of fishing effort to improve the profitability of the remaining fishing fleet, and conserve the resource.

The effectiveness of buyback programs in reducing fishing capacity depends on whether the remaining fishermen have the incentive to continue investing in boats and gear. Often there is also "latent" fishing effort—boats and gear with permits to fish that are inactive or only marginally utilized in the fishery. The exit of some vessels may encourage this latent fishing effort (vessels) to reenter the fishery, resulting in little or no net reduction in fishing capacity. Furthermore, the first to accept buybacks may be the least efficient vessels in the fleet. This results in fleet reductions that are relatively modest yet expensive, because only the oldest and least efficient units are taken out of production.

Although capacity reduction programs attempt to provide long-term benefits to those who decide to remain in the fishery, poorly crafted programs may result in little or no benefit at the expense of taxpayers. Although capacity reduction can be a means to ease financial hardship caused by a fishing disaster, lasting benefits may depend on better recognition of the motivations of vessel owners and fishermen.

#### **Selected Fishery Failure Cases**

 $\overline{a}$ 

#### *West Coast Salmon Ocean Troll Fishery (Sacramento)*

On April 10, 2008, the Pacific Fishery Management Council adopted a complete closure of commercial and sport fisheries off California and most of Oregon in response to the collapse of the Sacramento River fall Chinook salmon run. The minimum conservation goal for Sacramento fall Chinook is  $122,000$  to  $180,000$  spawning salmon,<sup>23</sup> while as recently as 2002, 769,868 adults returned to spawn.<sup>24</sup> Even with ocean fishery closures, the 2008 returns

<sup>&</sup>lt;sup>22</sup> Capacity reduction is referred to in Section 312(b) of the MSA and Section 308(d) of the IFA.

<sup>&</sup>lt;sup>23</sup> The number of salmon needed to return to the river to sustain this salmon population.

<sup>24</sup> For Pacific salmon fishery management information, see http://www.pcouncil.org/.

of Sacramento fall Chinook were projected to be 59,000 fish and actual returns totaled 65,364 fish.<sup>25</sup> In March 2009, NMFS released a report on the causes of the decline of Sacramento fall Chinook. The report identified unfavorable ocean conditions as the primary factor that led to poor survival of juvenile salmon when they entered the ocean in 2005 and 2006. It also found that the stock was more susceptible to poor ocean conditions because of habitat degradation in the freshwater portion of its range.

On May 1, 2008, in response to requests by the governors of California, Oregon, and Washington, the Secretary of Commerce declared a commercial fishery failure for the West Coast salmon troll fishery. Congress provided \$170 million in disaster funds in the Food, Conservation, and Energy Act of 2008 (P.L. 110-246) for commercial and recreational members of fishing communities who were affected by the fishery failure. In September 2008, \$100 million was released to the Pacific States Marine Fishery Commission for distribution to commercial fishermen, processors, charter boat operators, recreational guides, and other businesses dependent on fishing. The declaration also allowed the SBA to make economic injury loans available to businesses affected by the fishery failure. On April 30, 2009, the Secretary of Commerce notified the governors of California and Oregon that the fishery failure would continue in 2009. Returns of Sacramento fall Chinook salmon remained below levels required for a fishery and the 2009 commercial salmon troll fishery was closed for most of Oregon and all of California. The ocean recreational fisheries were also limited in both states, especially California. The extension of the disaster declaration ensured release of the remaining unspent funds from the original \$170 million.

In 2010, revenue from commercial salmon landings in California remained significantly lower than the 2003-2005 average. On September 2, 2010, the Secretary of Commerce continued the fishery failure for California and Oregon commercial salmon fisheries under Section 308(d) of the IFA and 312(a) of the MSA. The availability of SBA economic injury loans was continued, but additional disaster relief was not appropriated by Congress. In 2012, PFMC reported that a total of nearly 286,000 fall Chinook salmon returned to the Sacramento River. This was the first year since 2007 that commercial and recreational ocean landings returned to historical levels off California.

#### *New England Red Tide*

 $\overline{a}$ 

Red tide has been a reoccurring problem for shellfish fisheries in northern New England. Blooms of the algae *Alexandrium fundyense*, commonly referred to as red tide, produce a toxin that is ingested and concentrated by shellfish such as clams, mussels, and oysters. When the concentration of the algae is high, shellfish beds must be closed because shellfish may cause paralytic shellfish poisoning, which can be toxic to humans. <sup>26</sup> In 2005, shellfish beds were closed from Canada to Martha's Vineyard, Massachusetts. On June 23, 2005, NOAA announced a commercial fishery failure determination for the region's shellfish fishery. In 2006, \$5 million was appropriated in the Emergency Supplemental Appropriations Act for Defense, the Global War on Terror, and Hurricane Recovery, 2006 (P.L. 109-234), to assist fishermen who were affected by the red tide bloom.

<sup>25</sup> Pacific Fishery Management Council, *Stock Assessment and Fishery Evaluation (SAFE) Documents: Review of the 2016 Ocean Salmon Fisheries*, February 2017, p. 203, at http://www.pcouncil.org/salmon/stockassessment-and-fishery-evaluation-safe-documents/review-of-2016-ocean-salmon-fisheries/.

<sup>26</sup> In extreme cases, paralytic shellfish poisoning (PSP) can be fatal to humans. PSP also has been implicated in the mortality of certain species of marine mammals.

During 2008, red tide was also widespread in ocean waters off New England. On November 14, 2008, the Secretary of Commerce determined a commercial fishery failure had occurred because the bloom triggered closures of shellfish fisheries. The Consolidated Security, Disaster Assistance, and Continuing Appropriations Act, 2009 (P.L. 110-329), provided up to \$5 million to assist the fishing industry and for research and monitoring related to red tide events. On December 22, 2010, the Secretary of Commerce determined that red tide caused another fishery failure in the Maine shellfish fishery during the 2009 season, but Congress did not appropriate funding for this event.

#### *Gulf of Mexico Fisheries (Hurricanes Katrina and Rita)*

In the wake of Hurricanes Katrina and Rita, Gulf of Mexico harvesting and shoreside fishery infrastructure were damaged or in some cases destroyed. On September 9, 2005, the Secretary determined that a fishery failure in the Gulf of Mexico had occurred. On October 4, 2005, the Secretary announced a formal determination of an additional fishery failure in Louisiana and Texas due to the effects of Hurricane Rita.

The immediate effects of the fishery failure were difficult to discern because of the broad geographic area affected by the hurricanes and the substantial damage to infrastructure such as ports, processing, and general access to markets. In 2004, Gulf of Mexico annual landings of major fisheries, including shrimp, finfish, and oysters, totaled 1.476 billion pounds with a dockside value of \$669 million.<sup>27</sup> In the areas initially affected by Katrina there were 15 major fishing ports, 177 seafood processing facilities, 1,816 federally permitted fishing vessels, and more than 13,000 state-permitted fishing vessels. Private recreational fishing boats, charter boats, and related infrastructure were also extensively damaged.

In July 2007, NMFS released its *Report to Congress on the Impacts of Hurricanes Katrina, Rita, and Wilma on Alabama, Louisiana, Florida, Mississippi, and Texas Fisheries*. This report described fishery conditions before and after the 2005 hurricane season and also described other factors that affect the fishing industry, such as rising costs and seafood imports. A second report, *Economic Damages to Infrastructure Incurred by Louisiana Fishing Industries Due to Hurricanes Katrina and Rita in 2005*, was also released in July 2007. This report estimated losses to the fishing industry of \$582 million in Louisiana and \$988 million for the entire Gulf of Mexico.<sup>28</sup> Both reports stressed that estimates should be conditioned on data and methods used in each state, factors influencing fisheries, and uncertainties related to the rate of recovery from storm damage.

On June 15, 2006, the Emergency Supplemental Appropriations Act for Defense, the Global War on Terror, and Hurricane Recovery, 2006 (P.L. 109-234), was enacted. It allocated \$128 million to the National Oceanic and Atmospheric Administration (NOAA) "Operations, Research, and Facilities" account for expenses related to Hurricane Katrina.<sup>29</sup> On May 25, 2007, the U.S. Troop Readiness, Veterans' Care, Katrina Recovery, and Iraq Accountability Appropriations Act, 2007 (P.L. 110-28), was enacted. Additional funding was allocated to the NOAA "Operations, Research, and Facilities" account totaling \$110 million

<sup>27</sup> U.S. Department of Commerce, National Marine Fisheries Service, *Fisheries of the United States, 2005*, Current Fishery Statistics No. 2005 (Washington, DC: February 2007), p. 6.

<sup>28</sup> R. H. Caffey et al., *Economic Damages to Infrastructure Incurred by Louisiana Fishing Industries Due to Hurricanes Katrina and Rita in 2005*, Report to the U.S. Department of Commerce National Oceanic and Atmospheric Administration, July 2007, pp. 86-88.

<sup>&</sup>lt;sup>29</sup> The measure included \$90 million plus a \$38 million transfer from the U.S. Department of Agriculture that was to be used for improving oyster grounds.

for impacts of Hurricanes Katrina and Rita on the shrimp and fishing industries. The Gulf States Marine Fisheries Commission, through a cooperative agreement with NOAA, administered and coordinated funding of recovery programs through grant agreements with each of the Gulf states. Funds appropriated in 2006 were used to restore damaged oyster beds, remove debris, restore fishery habitat, and support cooperative research.<sup>30</sup> Funds appropriated in 2007 were used to assist individual commercial fishermen, other fishing industry businesses, and seafood promotion of Gulf fishery products.<sup>31</sup>

#### *California Dungeness and Rock Crab Fishery*

In early November 2015, the California Dungeness crab and rock crab fisheries were closed due to a harmful algal bloom along the California coast. The California Office of Environmental Health Hazard Assessment and California Department of Health determined that there were unsafe levels of domoic acid in crab tissue. Domoic acid is a neurotoxin, and when ingested by people it can cause nausea, diarrhea, vomiting, memory loss, seizures, and sometimes death. In response, the California Department of Fish and Game closed commercial and recreational crab fisheries in the affected areas. The closure occurred during the peak months of the fishery from December through January and was persistent, as many areas remained closed through May.

The initial estimate of economic impact based on average commercial landings over the previous five years was \$48.3 million for Dungeness crab and \$376,000 for rock crab.<sup>32</sup> On February 9, 2016, the California governor requested a commercial fishery failure determination under Section 312(a) of the MSA and a fishery resource disaster under Section 308(d) of the IFA. <sup>33</sup> On January 18, 2017, the Secretary of Commerce found that the Dungeness crab and rock crab fisheries met requirements for a determination under both laws.

In the  $114<sup>th</sup>$  and  $115<sup>th</sup>$  Congresses, several bills were introduced in the House and Senate to fund the Dungeness and rock crab fishery failures but no bills were enacted. On February 9, 2018, Congress included \$200 million in the Bipartisan Budget Act of 2018 (P.L. 115-123) for fishery resource disasters declared by the Secretary in 2017. Of the total, \$25.8 million was allocated to provide assistance to the California Dungeness crab and rock crab fisheries. In August 2018, the draft crab disaster relief spending plan was finalized, dividing total funding among mitigation of future disasters (10%), direct payments (89%), and administration (1%).<sup>34</sup> On May 22, 2019, the Pacific States Marine Fisheries Commission announced that it had received funds to be disbursed to crab fishermen.

#### **POTENTIAL ISSUES FOR CONGRESS**

Commercial fisheries are strongly influenced by environmental conditions that affect the abundance and distribution of fishery resources and fishing infrastructure. These changes often take place suddenly with little or no warning, as in the cases of hurricanes, oil spills, and harmful algal blooms. Disaster relief programs may help businesses that have been harmed by these events and can address these disruptions to fisheries by providing assistance until conditions return to "normal." As Congress continues to debate and respond to fishery disasters, several issues have emerged related to the nature of commercial fisheries and disaster relief programs, including (1) timing relief to meet crucial needs, (2) relating disaster relief to long-term fisheries management, (3) defining a fishery failure, (4) determining who benefits from relief, and (5) considering other related sectors.

#### **Timing of Relief**

 $\overline{a}$ 

The delivery of disaster relief depends on the determination by the Secretary that a fishery failure has occurred and on the appropriation of relief funding by Congress. Historically, approximately half of fishery failure determinations have been made within six months of the initial request and over two-thirds have been made within one year.<sup>35</sup> Information related to the scope of the disaster usually needs to be compiled by the fishing industry, state and local governments, and NMFS. Difficulties in concluding this task can be compounded by the lack of data and readily available economic studies. In cases such as Hurricane Katrina (2005), it was immediately clear that a disaster had occurred and the Secretary made a determination within two weeks of when the hurricane made landfall.<sup>36</sup> In other cases, such as the Long Island, NY, hard shell clam fishery (2009), Northern Mariana Islands fisheries following a super typhoon (2003), and the Florida shark fishery (2008), it took two to three years before the Secretary made a determination (in these cases a determination to deny the requests).

After a fishery failure is declared, funding is dependent on appropriations by Congress. In most cases, Congress has provided funding for declared fishery failures, but the timing of appropriations has varied considerably. For some approved determinations, such as the Dungeness crab and rock crab fisheries, pink salmon in Alaska, Fraser River Sockeye salmon, and Washington coastal salmon, Congress appropriated funds over two years after the time of the Secretary's fishery failure determination.<sup>37</sup> Hurricanes Katrina and Rita fishery disaster funding was appropriated in June 2006, more than nine months after the Gulf fishery failure

<sup>35</sup> NOAA Fisheries, *Fisheries Disaster Determinations*, at https://www.fisheries.noaa.gov/national/funding-andfinancial-services/fishery-disaster-determinations.

<sup>&</sup>lt;sup>36</sup> The Secretary of Commerce made the fishery failure determination before the actual request for a fishery failure was made later in 2006.

 $37$  Fraser River sockeye salmon fishery failure requests were made by several different tribes in 1999-2000, 2007, 2009, 2013, and 2015 and approved by the Secretary of Commerce. Congress did not appropriate funds for the first determination in 2002. A request for a continuation of the fishery failure in 2007 and 2008 was approved and funded in 2008. A request for a continuation of a fishery failure was made in 2009 and approved in 2011 but not funded. A new fishery failure request in 2013 was approved in 2014 and funded in 2018. An additional fishery failure request in 2015 was approved in 2017 and funded in 2018. Another request was made in 2019, but as of March 2020 the Secretary had not made a fishery failure determination.

was declared in September 2005. Many in the industry believed the greatest need occurred immediately after the hurricanes, when fishermen lost fishing opportunities because of damaged infrastructure, vessels, and gear and disrupted markets. <sup>38</sup> Although the full dimensions of the disaster and the level and scope of resource needs remained uncertain, some fishermen thought some basic aid should have been provided to members of the fishing industry immediately after the disaster.

For immediate needs following a fishery failure, some have advocated establishing a disaster fund with annual appropriations that could provide assistance on short notice.<sup>39</sup> For example, the Robert T. Stafford Disaster Relief and Emergency Assistance Act (P.L. 93-288) provides disaster assistance to state and local governments. The funds are provided by the Federal Emergency Management Agency in various forms through its Disaster Relief Fund (DRF). The DRF is funded through regular appropriations acts using a formula that includes several factors, including historical disaster costs. Fishery disaster assistance is sometimes included in NOAA's annual appropriations, such as the FY2018 and FY2019 Consolidated Appropriations Acts, but in most years disaster assistance is not included in the agency's appropriations requests or annual appropriations acts passed by Congress.

Others have considered the use of existing agriculture programs to supplement existing fishery disaster assistance. For example, during the  $112<sup>th</sup>$  Congress, the Senate approved an amendment to S. 3240, the Agriculture Reform, Food, and Jobs Act of 2012 (the 2012 farm bill), which would have made commercial fishermen eligible for emergency loans that are currently available to farmers. Emergency loans assist farmers who have suffered physical or production losses in disaster areas that are declared by the President. <sup>40</sup> However, the amendment was not included in the Agricultural Act of 2014 (P.L. 113-79) when it was passed by Congress.

#### **Long-Term Management Approaches**

 $\overline{a}$ 

Often, direct or indirect assistance to the fishing industry is part of a relief program. Some have criticized federal assistance because it can delay the readjustment that may be needed for fisheries with excess harvesting capacity. These critics argue that climatic and/or environmental conditions are often blamed for fish population declines caused by overfishing.

Features of several programs, such as buybacks and training for fishermen in other vocations, focus on concerns related to the need to decrease fishing fleet size. Yet, when relief is provided, even when it includes a buyback program, greater numbers of fishermen and effort may often remain in the fishery than might be sustainable in the long run.<sup>41</sup> Many fisheries managers agree that relief such as vessel buybacks needs to be more closely

integrated with ongoing fisheries management objectives.<sup>42</sup> Some have proposed that longterm measures and disaster planning should occur before disasters occur. In this way, more deliberate approaches to build resiliency may be considered and potentially enacted instead of emergency measures that fill short-run needs. Other types of assistance that may provide long-term fishery benefits include habitat restoration and enhancement, marketing and promotion programs, and cooperative research.

#### **Defining Fishery Failures**

The general causes of fishery resource disasters that result in determination of a commercial fishery failure are defined by the MSA and IFA. However, specific characteristics of a fishery resource disaster, such as scale, timing, and extent, are not defined in statute. Since Congress did not fully define a fishery failure or fishery resource disaster, the Secretary of Commerce has a large degree of discretion when determining whether a fishery failure has occurred.

The NOAA policy guidance provides specific revenue thresholds for determining whether a commercial fishery failure has occurred.<sup>43</sup> However, unless the revenue decline is greater than 80%, the request for a commercial fishery failure would still be evaluated on a case-by-case basis. Most fish populations vary over time, and frequently it is difficult to determine the relative importance of the factors that cause these variations. Thus, the factors that are responsible for the decline may include causes that are allowable, such as environmental changes, and not allowable, such as overfishing. It might be questioned whether additional criteria can be developed to make fishery failure determinations more consistent.

#### **Who Benefits?**

Who benefits from disaster funding is a recurring point of contention.<sup>44</sup> Participants such as fishermen and fish processors may be difficult to identify and directly associate with a fishery failure. Although it is often possible to contact vessel and processing plant owners, industry- related labor such as crew members and fish processing employees may be difficult to track. In some fisheries, crew members are temporary laborers that follow fishing opportunities. Because of the transient nature of employment in the fishing industry and seasonal movement of fishing vessels among regions, labor statistics regarding the employment of fishermen are either difficult to obtain or may not exist. Similar problems may occur in related fishery processing and distribution sectors.

Economic effects of fishery disasters on the local community and region are also difficult to quantify. Services directly related to fishing, such as boat repairs, dock services, and

<sup>&</sup>lt;sup>42</sup> Eric Thunberg, Andrew Kitts, and John Walden, "A Case Study of New England Groundfish Fishing Capacity Reduction," in *Fisheries Buybacks*, ed. Rita Curtis and Dale Squires (La Jolla, CA: Blackwell Publishing, 2004), pp. 239-249.

<sup>43</sup> NMFS, *Policy.*

<sup>44</sup> Tom Dempsey, *Dempsey Commentary on Federal Disaster Aid*, Cape Cod Commercial Fishermen's Alliance, June 9, 2014, at http://www.capecodfishermen.org/item/commentary-dempsey-federal-aid.

fishing equipment suppliers, as well as other businesses indirectly related to fishing, are likely to be harmed by losses in the fish harvesting and processing sectors. Although general regional impacts can be estimated using economic models, it is often difficult to identify the level of impacts on these businesses because of their dispersed nature and their indirect relationship to fishing. A broader understanding of these community impacts depends on more deliberate and long-term data collection and planning to link community concerns with marine fisheries management. An open question is whether NOAA's efforts to integrate management with social concerns might be applied to increasing fishing community resilience to fishery failures and to improving assistance programs when disasters occur.<sup>45</sup>

#### **Aquaculture, Subsistence, and Recreational Fisheries**

Fishery disasters affect other resource users, such as recreational fishermen, subsistence users, and aquaculture facilities, but there is ambiguity regarding the eligibility of these groups for disaster relief. These groups are not considered explicitly in disaster relief sections of either the MSA or the IFA.

Charter boat operators who take paying customers for fishing trips have been included in previous determinations and have benefited from assistance. However, it is unclear whether and how assistance would be provided to businesses that support recreational fishing, such as bait and tackle shops. Some observers could contend that these businesses should be included because they are dependent on fisheries and a part of the coastal community. Congress also might consider questions related to whether a disaster could be determined for the decline of a species only sought after by recreational fisherman, such as red drum, and how the losses to these businesses would be quantified.

Subsistence users are affected by resource declines and associated losses to household benefits. These impacts are difficult to assess in economic terms; consequently, it may be difficult to determine the form that relief might take. Furthermore, the term *subsistence*, as it relates to fisheries, is not defined in either the MSA or the IFA.<sup>46</sup> Some observers might contend that different approaches may be needed for cases of subsistence disaster relief.

*Aquaculture* is broadly defined as the propagation and rearing of aquatic species in controlled or selected environments. Aquaculture operations range from extensive farming where there is only minimal control over the organism's environment to intensive systems where complete control is taken at each stage of the organism's life history.<sup>47</sup> Aquaculture is not addressed or defined in the MSA, but according to NMFS, the act's management authority over all fish within the exclusive economic zone (EEZ) and statutory definitions of *fishery* and *fishing* provide a sound basis for regulating aquaculture in the EEZ.<sup>48</sup> NMFS has included marine aquaculture operations in disaster assistance determinations. For red tide

<sup>45</sup> National Marine Fisheries Service, *Human Dimensions*, Office of Science and Technology, at http://www.st. nmfs.noaa.gov/humandimensions/index.

<sup>46</sup> For example, *subsistence* is defined by the state of Alaska as customary and traditional uses of fish and wildlife, and the definition highlights the unique importance of wild resources and the continuing role of subsistence activities in sustaining the way of life in Alaska.

<sup>&</sup>lt;sup>47</sup> For example, oyster farming may resemble a fishery where the habitat is enhanced by adding substrate (shells) for spat (small oyster) attachment. In other cases, greater control is taken and oysters are raised in cages or trays.

<sup>48</sup> Memorandum from Constance Sathre, Office of the General Counsel, to Lois Schiffer, NOAA General Counsel, June 9, 2011.

fishery failures, oyster farms were included in the request for assistance with wild shellfish fisheries. However, questions remain regarding the eligibility of losses that are specific to aquaculture, such as salmon cage culture or events that affect only aquaculture and not wild fisheries. Further, a recent court decision cast doubt on whether NMFS has authority to regulate aquaculture under the MSA.<sup>49</sup>

#### **Recent Congressional Actions**

#### *Fishery Failures: Urgently Needed Disaster Declarations Act*

In the 116<sup>th</sup> Congress, similar versions of the Fishery Failures: Urgently Needed Disaster Declarations Act (S. 2346 and H.R. 5548) have been introduced that would make extensive changes to current law.<sup>50</sup> Both bills would amend Section 312 of the MSA, repeal Section 315 of the MSA, and repeal Section 308 of the IFA. Generally, the legislation would consolidate and clarify many of the fishery disaster provisions in the MSA and the IFA and incorporate parts of the NMFS agency directive on fishery disasters.

The bills cover the main elements of the current fishery disaster program, including

- definitions of terms, including fishery disaster;
- initiation of a fishery resource disaster review;
- the review process, including information required for the review;
- evaluation of requests and criteria for disaster determinations;
- allocation and disbursement of appropriated fishery resource disaster assistance; and
- eligible uses of disaster funds.

The bills also include requirements for the timing of determinations and the disbursement of funds. The marked-up versions of S. 2346 and H.R. 5548 also include subsistence, charter, and recreational users as eligible entities but make no specific references to assistance for aquaculture producers.<sup>51</sup>

Both bills also include sections on the following related topics:

- additional conditions on assistance for fishing capacity reduction programs;
- a report from the Comptroller General on efforts to prepare and adapt U.S. fishery management for the impacts of climate change; and
- reporting and certification under the High Seas Driftnet Fishing Moratorium Protection Act (16 U.S.C. §§1826f and 1826h).

<sup>49</sup> In Gulf Fisherman's Association v. National Marine Fisheries Service, the U.S. District Court for the Eastern District of Louisiana held that NOAA Fisheries exceeded its authority under the MSA when it adopted a regulatory scheme for aquaculture operations in the Gulf of Mexico. The court found that the MSA's grant of authority to regulate "fishing" and "harvesting" did not include aquaculture.

 $50$  Most sections of the marked up version of S. 2346 and the version of H.R. 5548 that was introduced in the House of Representatives are either identical or similar.

<sup>&</sup>lt;sup>51</sup> The introduced version of S. 2346 included aquaculture producers.

On November 13, 2019, S. 2346 was marked up by the Committee on Commerce, Science, and Transportation, and on January 14, 2020, a hearing was held by the House Natural Resources Subcommittee on Water, Oceans, and Wildlife that included testimony related to H.R. 5548.

#### *Other Bills Introduced in the 116th Congress*

Several additional bills related to fishery disaster assistance have been introduced during the  $116<sup>th</sup>$  Congress, but no action has been taken on any of them since their introduction. A bill that would reauthorize the MSA, Strengthening Fishing Communities and Increasing Flexibility in Fisheries Management Act (H.R. 3697), would make several changes to fishery disaster provisions of the act.<sup>52</sup> Section 401 of the bill would require the Secretary of Commerce to publish the estimated cost of recovery from a fishery resource disaster no later than 30 days after the Secretary makes the fishery disaster determination. For requests from a state governor, Section 402 would require the Secretary to make a fishery failure determination within 90 days of receiving an estimate of the economic impact from the entity requesting the relief.

The Commercial Fishing and Aquaculture Protection Act of 2019 (S. 2209) would amend the MSA to provide supplemental revenue assistance to eligible commercial fishermen and aquaculture producers.<sup>53</sup> Assistance could be provided when an eligible loss occurs due to an algal bloom, freshwater intrusion, adverse weather, bird depredation, disease, or another condition determined by the Secretary of Commerce. Eligible losses would be calculated as the difference between gross revenue in the calendar year in which losses occurred and 85% of the average gross revenue for the three previous years.<sup>54</sup> The assistance could be provided by the Secretary whether or not a fishery resource disaster determination was made.

Two identical bills (H.R. 3514 and S. 1984) were introduced in response to duties imposed on U.S. seafood products. The bills would add certain duties to the list of potential causes of a commercial fishery failure listed in Section 312 of the MSA. Fishery disaster assistance could be provided if duties are placed by other countries on U.S. seafood products as retaliation for increases in duties imposed by the United States.<sup>55</sup>

#### *Recent Disaster Determinations and Appropriations*

 $\overline{a}$ 

Funding of fisheries disaster assistance depends on congressional action, because there is no permanent fund to provide relief after the Secretary of Commerce makes determinations. Usually, funding is appropriated for a number of disasters and allocated among specific fishery disasters by NOAA. For example, P.L. 115-123 funded 10 disasters and P.L. 115-141 funded 7 disasters. In the 116<sup>th</sup> Congress, fishery disasters have been funded by the Consolidated Appropriations Act, 2019 (P.L. 116-6), and the Additional Supplemental Appropriations for Disaster Relief Act, 2019 (P.L. 116-20). [Table 2 p](#page-4190-0)rovides a list of fishery

 $52$  H.R. 200, which was introduced in the 115<sup>th</sup> Congress and passed the House, proposed identical amendments to MSA fishery disaster assistance provisions.

 $53$  An eligible commercial fisherman and farm-raised fish producer are generally described as an individual or entity that assumes production and market risks associated with harvesting fish (fisherman) or production of fish in a controlled environment (farm-raised fish producer) for commerce. The term *fish* would include shellfish, finfish, and other aquatic organisms harvested with the intent of entering commerce.

<sup>&</sup>lt;sup>54</sup> Payment could not exceed 85% of the average gross revenue received during the three previous calendar years.

<sup>&</sup>lt;sup>55</sup> The bill refers to increases in duties imposed by the United States pursuant to Section 232 of the Trade Expansion Act of 1962 (19 U.S.C. §1862) or Section 301 of the Trade Act of 1974 (19 U.S.C. §2411).

disasters that have that been approved or are under consideration for a determination by the Secretary of Commerce during the 116<sup>th</sup> Congress. [Table 3 p](#page-4228-0)rovides a list of disasters that were approved and funded during the 115<sup>th</sup> Congress.

*Chapter 160*

 $\overline{a}$ 

#### **MIXED-USE FISHERIES: SOUTH ATLANTIC AND GULF OF MEXICO COUNCILS WOULD BENEFIT FROM DOCUMENTED PROCESSES FOR ALLOCATION REVIEWS**

#### *United States Government Accountability Office*

#### **WHY GAO DID THIS STUDY**

Commercial and recreational marine fisheries—including those in the South Atlantic and Gulf of Mexico—are critical to the nation's economy, contributing approximately \$99.5 billion to the U.S. gross domestic product in 2016, according to the Department of Commerce. NMFS and the councils may allocate fishing privileges for mixed-use fisheries in federal waters, but establishing and revising such allocations can be complex, in part because of concerns about equity.

The Modernizing Recreational Fisheries Management Act of 2018 includes a provision for GAO to review mixed-use fisheries allocations in the South Atlantic and Gulf of Mexico. For these regions, this report examines (1) the extent to which the councils established or revised mixed-use fisheries allocations, (2) key sources of information that may be available for reviewing allocations, and (3) the extent to which the councils have developed processes to help guide such reviews. GAO reviewed NMFS and council policies and other council documents; analyzed information on allocations established and revised; compared council processes to agency guidance and internal control standards; and interviewed NMFS officials, council members and staff, and 46 stakeholders that reflected various interests. Views from these stakeholders are not generalizable.

This is an edited, reformatted and augmented version of United States Government Accountability Office; Report to Congressional Committees, Publication No. GAO-20-216, dated March 2020.

#### **WHAT GAO RECOMMENDS**

GAO is making two recommendations, including that NMFS work with the councils to develop documented processes for conducting allocation reviews. The agency agreed with GAO's recommendations.

#### **WHAT GAO FOUND**

The South Atlantic and Gulf of Mexico regional fishery management councils, with approval from Department of Commerce's National Marine Fisheries Service (NMFS), established and revised allocations to varying degrees for mixed-use fish stocks—fisheries with a combination of commercial and recreational fishing. Regional councils were created by statute to help manage fisheries in federal waters, including allocating—or distributing fishing privileges, when warranted. Starting in 1985, the South Atlantic council established allocations, generally a percentage of allowable harvest, for 50 of its 51 mixed-use fish stocks and revised most of those at least once. The Gulf of Mexico council established allocations for nine of its 23 mixed-use fish stocks, revising three of those once. Historically, allocations have been largely based on estimates of the commercial and recreational fishing sectors' past use of the resource, according to NMFS.

Key sources of information that may be available to help NMFS and the councils review allocations include trends in catch and landings (the amount of fish caught or brought to shore); fish stock assessments; and economic analyses. Each source presents some challenges in supporting allocation decisions, however. For example, NMFS works with states to estimate recreational catch, which provides information about demand, but faces difficulties generating reliable estimates. This is in part because of attributes of the recreational fishing sector, including the greater number of recreational anglers compared with commercial fishing participants. NMFS issued guidance in 2019 to promote consistency in estimating recreational catch data to help improve the quality of the information.

Source: National Marine Fisheries Service (images). | GAO-20-216.

Examples of Fish Stocks with Allocation Reviews Underway as of December 2019.

The South Atlantic and Gulf of Mexico councils developed processes for when to initiate fish stock allocation reviews, but not for how to conduct those reviews. A 2012 report for NMFS found that reviews had been done inconsistently, and stakeholders were dissatisfied with allocation decision-making. In response, NMFS developed guidance calling for structured and transparent allocation review processes. Both councils established criteria for initiating reviews, such as time-based triggers, and as of December 2019 they had several *Mixed-Use Fisheries* 4209

reviews underway (see figure). In April 2019, the Gulf of Mexico council began convening a workgroup to propose a draft allocation review process, but has not indicated what actions it will take, if any, in response to a proposal. The South Atlantic council postponed any discussions until March 2020. As of December 2019, neither council had a documented process. Documented processes for conducting allocation reviews would provide NMFS with better assurance that the councils carry out upcoming reviews in a structured and transparent manner.

#### **ABBREVIATIONS**

March 31, 2020

 $\overline{a}$ 

The Honorable Roger Wicker Chairman The Honorable Maria Cantwell Ranking Member Committee on Commerce, Science, and Transportation United States Senate

The Honorable Raúl M. Grijalva Chairman The Honorable Rob Bishop Ranking Member Committee on Natural Resources House of Representatives

Commercial and recreational marine fisheries are critical to the nation's economy, contributing approximately \$99.5 billion to the U.S. gross domestic product and supporting approximately 1.7 million jobs in 2016, according to the Department of Commerce's National Oceanic and Atmospheric Administration (NOAA).<sup>1</sup> The South Atlantic and Gulf of Mexico regions are each home to multiple fisheries with a combination of commercial and

<sup>&</sup>lt;sup>1</sup> U.S. Department of Commerce, National Oceanic and Atmospheric Administration, National Marine Fisheries Service, *Fisheries Economics of the United States, 2016*, Technical Memorandum NMFS-F/SPO-187a (Silver Spring, MD: December 2018). Information on gross domestic product and jobs includes data on commercial seafood harvesters, processors, dealers, wholesalers, distributors, importers, and retailers, as well as recreational fishing trips and fishing equipment. Data for 2016 were the most recent available at the time of our review.

recreational fishing,<sup>2</sup> known as mixed-use fisheries.<sup>3</sup> Commercial fishing in these regions landed nearly 2 billion pounds of seafood in 2016, valued at more than \$1 billion dollars.<sup>4</sup> These regions also have the greatest recreational fishing activity in federal waters, according to NOAA, which estimates that recreational anglers in these regions made more than 127 million fishing trips in  $2016<sup>5</sup>$ 

The lead federal agency responsible for managing commercial and recreational marine fisheries is NOAA's National Marine Fisheries Service (NMFS). Under the Fishery Conservation and Management Act of 1976, often referred to as the Magnuson-Stevens Act, as amended,<sup>6</sup> NMFS and eight regional fishery management councils (councils) created by the act are responsible for fisheries management and conservation in federal waters.<sup>7</sup> In particular, NMFS and the councils, including the South Atlantic and Gulf of Mexico councils, are responsible for allocating—or distributing—privileges for catching fish between the commercial and recreational fishing sectors in these two regions when such allocations may be warranted.<sup>8</sup> Allocations are generally a percentage of the fisheries' allowable harvest. Historically, mixed-use fisheries allocations have been predominantly based on estimates of each fishing sector's past use of the resource, according to NOAA.<sup>9</sup>

Allocations between the commercial and recreational fishing sectors can be complex and difficult, in part due to perceptions of fairness that arise in making allocation decisions. Allocation decisions establish the proportional access each sector has to a fishery, which in turn may result in economic and social impacts for participants in the sectors. There may be differences in the economic and social values that participants in each fishing sector place on fishery resources, leading to divergent views on what the allocations should be.

Differences in the management of the commercial and recreational fishing sectors have also led to questions about the equity of allocations. For instance, participants from the commercial fishing sector have raised concerns that fishery management disparities between the two sectors could result in unfair allocations. Specifically, commercial participation in

<sup>2</sup> The recreational fishing sector comprises anglers accessing fisheries from private boats and for-hire sector business entities, which include charter boats and head boats. A charter boat is usually hired by a group of anglers for a period of time. Head boats are typically large capacity multi-passenger vessels that charge a per angler fee for a fishing trip.

<sup>&</sup>lt;sup>3</sup> A fishery refers to one or more fish stocks that can be treated as a unit for conservation and management purposes and that are identified on the basis of geographical, scientific, technical, recreational, and economic characteristics. A fish stock refers to a species, subspecies, geographical grouping, or other category of fish capable of management as a unit. A fish stock may be one species or a complex of comparable species.

<sup>4</sup> National Marine Fisheries Service, *Fisheries Economics, 2016*.

<sup>5</sup> U.S. Department of Commerce, National Oceanic and Atmospheric Administration, National Marine Fisheries Service, *Fisheries of the United States, 2017*, NOAA Current Fishery Statistics No. 2017 (Silver Spring, MD: September 2018). Federal waters of the United States are generally located 3 to 200 nautical miles offshore. However, federal waters in some areas and for the management of some fish begin at 9 nautical miles.

<sup>6</sup> The Fishery Conservation and Management Act of 1976, as amended, among other things, sets forth national standards for federal fisheries conservation and management. Pub. L. No. 94-265, § 301(a), 90 Stat. 331, 346 (1976) (codified as amended at 16 U.S.C. § 1851(a)).

<sup>7</sup> The councils are supported by federal funds and generally comprise NMFS regional administrators, the principal state official with responsibility for marine fishery management in each state within the council's region, and members of the fishing industry and conservation groups appointed by the Secretary of Commerce as voting members. The councils also include nonvoting members, such as officials from other federal agencies.

<sup>8</sup> NMFS defines an allocation of fishing privileges as a direct and deliberate distribution of the opportunity to participate in a fishery among identifiable, discrete user groups or individuals. 50 C.F.R. § 600.325(c)(1).

<sup>9</sup> Morrison, W.E., and T.L. Scott, *Review of Laws, Guidance, Technical Memorandums and Case Studies Related to Fisheries Allocation Decisions,* U.S. Department of Commerce, National Oceanic and Atmospheric Administration Technical Memorandum NMFS-F/SPO-148 (Silver Spring, MD: 2014).

fisheries is generally limited through federal permits, but recreational anglers do not have similar limits, according to commercial sector participants. They also noted that the recreational sector has at times exceeded its allocations for certain fisheries, and that the two sectors are not always held accountable for adhering to their allocations in the same way. In contrast, recreational participants have expressed concerns that recreational interests have been historically underrepresented in allocations. These participants indicated that as coastal populations have increased and fishing technologies such as navigational systems have improved, recreational fishing has become more popular, generating significant economic activity in related sales and jobs, including in the South Atlantic and Gulf of Mexico. They indicated that some allocations may be outdated and called for NMFS and the councils to review those allocations.

In 2016, NMFS issued a policy and guidance to the councils on establishing and reviewing fisheries allocations, which are intended to help the councils and NMFS review and update allocations under the Magnuson-Stevens  $Act<sup>10</sup>$  In particular, the NMFS guidance calls for the councils to identify criteria for triggering allocation reviews and outlines various factors the councils should consider in conducting their allocation reviews and when making allocation decisions. The NMFS guidance calls for the councils to develop a structured and transparent process by which allocation reviews are to be conducted.

The Modernizing Recreational Fisheries Management Act of 2018 includes a provision for us to review mixed-use fisheries allocations in the South Atlantic and Gulf of Mexico regions.<sup>11</sup> This report examines, for the South Atlantic and Gulf of Mexico regions, (1) the extent to which the councils have established or revised mixed-use fisheries allocations, (2) key sources of information that may be available to help NMFS and the councils conduct allocation reviews, and (3) the extent to which the councils have developed processes to help guide their allocation reviews.

To conduct our work, we focused on mixed-use fisheries allocations between the commercial and recreational fishing sectors in the South Atlantic and Gulf of Mexico regions.<sup>12</sup> We reviewed the Magnuson- Stevens Act and policies and guidance related to allocations from NMFS and the councils. We interviewed officials from NMFS, the two relevant councils, and the related interstate fisheries commissions. Specifically, we interviewed the following:

 NMFS officials from the agency's Southeast Regional Office and Southeast Fisheries Science Center;

<sup>10</sup> U.S. Department of Commerce, National Oceanic and Atmospheric Administration, National Marine Fisheries Service, *Fisheries Allocation Review Policy*, NMFS Policy 01- 119 (effective July 27, 2016 and renewed September 27, 2018); *Criteria for Initiating Fisheries Allocation Reviews Council Coordinating Committee Allocation Workgroup Guidance Document,* NMFS Procedure 01-119-01 (effective July 27, 2016 and renewed October 3, 2018); and *Recommended Practices and Factors to Consider When Reviewing and Making Allocation Decisions*, NMFS Procedure 01-119-02 (effective July 27, 2016 and renewed October 3, 2018).

<sup>&</sup>lt;sup>11</sup> Pub. L. No. 115-405,  $\S$  101, 132 Stat. 5355, 5356 (2018). The act defines a mixed-use fishery as a federal fishery in which two or more of the following occur: (a) recreational fishing, (b) charter fishing, or (c) commercial fishing. *Id.* § 3(4). In our report, we consider for-hire fishing (both charter fishing and head boats) to be part of the recreational fishing sector because the South Atlantic and Gulf of Mexico councils generally manage forhire fishing as part of the recreational sector, according to council staff.

 $12$  NMFS and the councils may also establish other types of allocations for the fisheries they manage, such as for the use of different fishing gear types.

- South Atlantic and Gulf of Mexico council members, including members from state fisheries agencies in Alabama, Florida, Georgia, Louisiana, Mississippi, North Carolina, South Carolina, and Texas;
- South Atlantic and Gulf of Mexico council staff, including the two councils' executive directors, economists, and social scientists;
- members of the two councils' socioeconomic panels, which report to the councils' scientific and statistical committees;<sup>13</sup> and
- the executive directors of the Atlantic and Gulf States Marine Fisheries Commissions.<sup>14</sup>

In addition, to inform our work, we interviewed 46 stakeholders from the commercial and recreational fishing sectors, related industries, and conservation organizations to gather their perspectives, as well as any associated information, on allocations. We included a diversity of stakeholders across the council regions. For example, these stakeholders included fishing associations and individual fishing participants from the commercial and recreational sectors (including charter fishing), seafood dealers or retailers, food and lodging industry representatives, and conservation organizations. We met with many of these stakeholders in person when we attended the June 2019 meetings of the South Atlantic and Gulf of Mexico councils in Florida. In advance of the meetings, each council publicized our attendance at the meeting and provided our contact information so that interested stakeholders could contact us to set up a meeting. We interviewed stakeholders that (1) contacted us before or after the meetings, and (2) contacted us on a first-come, first-served basis at the council meetings.<sup>15</sup> During our interviews, we discussed, among other things, how allocation decisions may affect stakeholders and the councils' processes for reviewing allocations. The results of our interviews with NMFS officials; council members, staff, and socioeconomic panels; and stakeholders cannot be generalized to other regions or stakeholders, but provide a range of examples of perspectives on allocations within the South Atlantic and Gulf of Mexico regions.

To determine the extent to which the councils have established or revised mixed-use fisheries allocations, we asked the councils' staff to identify (1) any allocations established or revised for each of the mixed-use fish stocks they manage and what those allocation percentages comprised, and (2) when the councils established or revised those allocations (from 1976, when the Magnuson-Stevens Act was enacted and the councils were established, through December 2019). We analyzed the information to summarize and describe the number of allocations established for mixed-use fish stocks in the two council regions and the

<sup>&</sup>lt;sup>13</sup> Socioeconomic panels comprise economists and social scientists who provide the councils' scientific and statistical committees with information on potential economic and social implications of fishery management plans. Scientific and statistical committees— which may comprise federal or state officials, academics, or independent experts— evaluate technical aspects of fisheries and advise councils on the scientific adequacy of statistical, biological, economic, and social information as it pertains to fishery management plans.

<sup>&</sup>lt;sup>14</sup> The Atlantic and Gulf States Marine Fisheries Commissions are interstate compacts that seek to promote better utilization of fisheries, the promotion and protection of such fisheries, and the prevention of physical waste of the fisheries for the Atlantic seaboard and Gulf of Mexico. The Atlantic States Marine Fisheries Commission was formed in 1942 and develops plans to sustain the shared coastal fishery resources of Atlantic coast states from Maine to Florida. The Gulf States Marine Fisheries Commission was established in 1949 and recommends management measures to the governors and legislatures of the five Gulf States (Alabama, Florida, Louisiana, Mississippi, and Texas).

<sup>&</sup>lt;sup>15</sup> In addition, nine other stakeholders submitted their perspectives on allocations to us in writing.

extent to which those allocations have been revised. To verify the information provided by the councils, we reviewed related documents, including fishery management plans and plan amendments the councils submitted to NMFS that established or revised allocations for specific fish stocks.<sup>16</sup> To clarify any potential discrepancies in their documents on allocations, we also interviewed council staff or reviewed their written responses to our questions. Based on our review of the documents and information from council staff, we determined that the information on allocations the councils provided is sufficiently reliable for describing the allocations for mixed-use fisheries in the South Atlantic and Gulf of Mexico.

To identify key sources of information that may be available to help NMFS and the councils conduct allocation reviews, we reviewed NMFS' 2016 policy and guidance on establishing and reviewing fisheries allocations and interviewed or received written comments from NMFS officials and staff from the two councils. We reviewed documents on key sources of economic, social, ecological, and other information identified by NMFS officials and council staff, including NMFS and other documents on recreational fishing data collection, stock assessments, economic analyses, social indicators, and ecosystem or other ecological models.<sup>17</sup> The information sources we include are key sources identified by NMFS and the councils; other sources of information may also be available to NMFS and the councils that are not reflected in our report. In addition, we interviewed or received written comments from NMFS officials and staff and members from the two councils to obtain their perspectives on any challenges related to such information, and to identify steps NMFS or the councils are taking related to the information or challenges. We also reviewed available documents on those steps.

To determine the extent to which the councils have developed processes to help guide their allocation reviews, we obtained documents on the councils' plans for future reviews of mixed-use fisheries allocations. These documents include their council policies for specific criteria that will trigger reviews and available documents on their plans for when and how they plan to conduct those reviews. We compared this information with criteria in NMFS' allocations policy and guidance, the agency's operational guidelines for processes under the Magnuson-Stevens Act and associated regional operating agreements,<sup>18</sup> and the framework for internal controls established by the Committee of Sponsoring Organizations of the

<sup>&</sup>lt;sup>16</sup> According to NMFS' website, the councils develop fishery management plans or plan amendments to, among other things, prevent overfishing, allocate fishing quotas to different fishing groups, implement gear restrictions, and protect sensitive habitats. To help ensure transparency and incorporate stakeholder feedback, proposed decisions included in plans or plan amendments are subject to review and comment by scientists, stakeholders, and the public. In this report, we present the dates the councils established or revised allocations based on the dates the councils submitted fishery management plans or plan amendments to NMFS for review and approval.

<sup>&</sup>lt;sup>17</sup> For example, we reviewed NMFS technical memorandums on economic efficiency analyses the agency had conducted for fisheries in the Gulf of Mexico or South Atlantic regions. These analyses examined the economic efficiency of allocations for red snapper and gag, red, and black grouper in the Gulf of Mexico.

<sup>&</sup>lt;sup>18</sup> U.S. Department of Commerce, National Oceanic and Atmospheric Administration, National Marine Fisheries Service, *Operational Guidelines for the Magnuson-Stevens Fishery Conservation and Management Act Fishery Management Process*, NMFS Procedure 01-101-03 (effective October 25, 2017); South Atlantic Fishery Management Council, *Operating Agreement Between the South Atlantic Fishery Management Council, NOAA Fisheries Service Southeast Regional Office, and NOAA Fisheries Service Southeast Fisheries Science Center* (January 2014); and Gulf of Mexico Fishery Management Council, *Regional Operating Agreement Between the Gulf of Mexico Fishery Management Council, NOAA National Marine Fisheries Service Southeast Regional Office, NOAA National Marine Fisheries Service Southeast Fisheries Science Center, and NOAA General Counsel, Southeast Section* (August 2016)*.*

Treadway Commission.<sup>19</sup> This framework is recognized as a leading model for designing, implementing, and conducting internal control and assessing the effectiveness of internal control. In addition, we interviewed or received written comments from NMFS officials and council staff and members to obtain information on how the planned allocation reviews may affect their workloads and priorities.

We conducted this performance audit from April 2019 to March 2020 in accordance with generally accepted government auditing standards. Those standards require that we plan and perform the audit to obtain sufficient, appropriate evidence to provide a reasonable basis for our findings and conclusions based on our audit objectives. We believe that the evidence obtained provides a reasonable basis for our findings and conclusions based on our audit objectives.

#### **BACKGROUND**

NMFS and the eight regional fishery management councils are responsible for managing approximately 460 fish stocks in federal waters, as shown in Figure  $1<sup>20</sup>$ 

NMFS has overall responsibility for collecting data on fish stocks and ocean conditions and for generating scientific information for the conservation, management, and use of marine resources.<sup>21</sup> NMFS carries out this responsibility primarily through its five regional offices and six regional fisheries science centers, which are responsible for collecting and analyzing data to conduct stock assessments. Stock assessments consider information about the past and current status of a managed fish stock, including information on fish biology, abundance, and distribution that can be used to inform management decisions.<sup>22</sup> To the extent possible, stock assessments also predict future trends of stock abundance. NMFS provides the results of its stock assessments and other analyses, as appropriate, to the councils for use in implementing their respective fisheries management responsibilities. In the South Atlantic and Gulf of Mexico regions, NMFS provides support to the councils' management efforts through its Southeast Regional Office and the Southeast Fisheries Science Center.

Under the Magnuson-Stevens Act, the councils are responsible for managing the fisheries in their region. This includes developing fishery management plans, subject to NMFS approval, based on the best scientific information available and through collaboration with a range of stakeholders. The councils convene committees and advisory panels to assist them in developing research priorities and selecting fishery management options, in addition to

<sup>19</sup> Committee of Sponsoring Organizations of the Treadway Commission, *Internal Control- Integrated Framework*  (2013). This framework is a common internal control model against which companies and organizations can evaluate their control systems and provides a means to apply internal control to any type of entity. The framework comprises principles related to the five components of internal control, and the *Standards for Internal Control in the Federal Government*—adapted for a government environment—uses the same components and similar language. See GAO, *Standards for Internal Control in the Federal Government*, GAO-14-704G (Washington, D.C.: September 2014).

<sup>&</sup>lt;sup>20</sup> The number of fish stocks NMFS manages can vary from year to year, according to NMFS officials. For more information, see https://www.fisheries.noaa.gov/national/population-assessments/fishery-stock-status- updates.

<sup>&</sup>lt;sup>21</sup> In addition to NMFS<sup>5</sup> fisheries management responsibilities, the agency is also responsible for, among other things, managing marine species protected under the Endangered Species Act.

<sup>22</sup> We previously reviewed NMFS' fish stock assessment prioritization process. See GAO, *Fish Stock Assessments: Prioritization and Funding*, GAO-14-794R (Washington, D.C.: Sept. 19, 2014).

conducting public meetings. The councils are to comprise members from federal and state agencies, as well as the commercial and recreational fishing sectors (see Figure 2).

- Sources: National Marine Fisheries Service officials and *Fisheries of the United States, 2014* (data); Map Resources (map). | GAO-20-216.
- Note: Coastal states are generally responsible for managing fisheries in waters that extend approximately 3 nautical miles from their coastlines, and the National Marine Fisheries Service and the councils manage fisheries in federal waters, which generally extend from 3 to 200 nautical miles off the coast of the United States. However, federal waters in some areas and for the management of some fish begin at 9 nautical miles. The Western Pacific council includes the Mariana Islands archipelago, American Samoa, and a range of remote island areas in the central and western Pacific Ocean that are not depicted on this map.

Figure 1. Boundaries of the eight Regional Fishery Management Councils.

l

The councils—supported by council staff such as biologists, economists, and social scientists—are responsible for preparing proposed fishery management plans or plan amendments for NMFS review. These plans or amendments are to identify, among other things, conservation and management measures to be used to manage a fishery, including determining the maximum size of a fish stock's allowable harvest. This is generally done by developing annual catch limits for each fish stock, that is, the amount of fish that can be harvested in the year.<sup>23</sup> Fishery management plans or amendments also include establishing

<sup>&</sup>lt;sup>23</sup> The annual catch limit cannot exceed the recommended acceptable biological catch level set by the council's scientific and statistical committee.

or revising any allocations between the commercial and recreational sectors for mixed-use fish stocks where the councils determine it may be warranted.<sup>24</sup> For example, councils may allocate a percentage of a fish stock's annual catch limit between the recreational and commercial fishing sectors. See Figure 3 for an overview of the federal fisheries management process.

Council staff facilitate the fisheries management process by organizing council meetings, preparing and providing analyses for those meetings, and facilitating input from stakeholders and the public on fisheries management issues, among other things.<sup>25</sup> Stakeholders include participants in the commercial and recreational fishing sectors and related industries, such as fishing associations, seafood dealers and processors, food and travel industry representatives, and conservation groups. Once the councils complete proposed fishery management plans or plan amendments, they are to provide them to NMFS for review. NMFS is responsible for determining if the plans or amendments are consistent with the Magnuson-Stevens Act and other applicable laws, and for issuing and enforcing final regulations to implement approved plans.

Source: 16 U.S.C. § 1852; GAO analysis. | GAO-20-216.

<sup>a</sup>For members appointed by the Secretary of Commerce, the governors of the states in the council's region submit to the Secretary a list of nominees who are knowledgeable regarding fisheries conservation and management, or the commercial or recreational harvest of fishery resources in the region. When selecting members, the Secretary is required to ensure, to the extent practicable, a balance of participants from the commercial and recreational sectors. In addition, 16 U.S.C. §  $1852(b)(2)(D)$  directed the governors submitting names for appointment to the Gulf of Mexico Regional Fishery Management Council to include: (1) at least one nominee each from the commercial, recreational, and charter fishing sectors, and (2) at least one other individual who is knowledgeable regarding the conservation and management of fisheries resources in the jurisdiction of the council. That requirement expired at the end of fiscal year 2012.

Figure 2. Membership of the Regional Fishery Management Councils.

<sup>&</sup>lt;sup>24</sup> Fishery management plans also identify other management measures that will be used to manage a fishery, such as fishing equipment restrictions, permitting policies, and restrictions on the timing or location of permissible fishing.

<sup>&</sup>lt;sup>25</sup> In addition, the councils maintain scientific and statistical committees and socioeconomic panels to receive specialized input to the councils on fishery management plans or amendments.

## Data collection

ocean conditions on an ongoing basis to support scientific analyses and to help evaluate the results of management actions. Types of The National Marine Fisheries Service (NMFS) and a number of academia) conduct research and collect data on fish stocks and stakeholders (such as the fishing industry, state agencies, and data collected can include:

- Catch data the amount of fish removed from a stock by fishing.
- Abundance data the number or weight of fish in a stock
- Biological data information on fish size, age, growth, mortality, reproductive rates, and other biological information.
- (such as predator-prey relationships), physical ocean parameters Ecosystem data - information on habitats, species interactions
	- Economic and social data information on fishing costs, (such as ocean temperature), and other environmental information.
- expenditures, and revenues; demographic information for fishing communities; and other socio-economic information.

# Management actions

assessments and other analyses to help inform management actions NMFS and the councils use the scientific information from stock related to harvesting federally managed fish stocks, including:

- Setting annual catch limits (the amount of fish that can be harvested in a year).
- Amending fishery management plans, which, among other things, identify management measures (such as fishing season closures or restrictions on the number of fish that individuals can catch) to prevent catch from exceeding the annual catch limit.
- annual catch limit between the commercial and recreational Establishing, reviewing, and revising allocations for fish stocks when warranted (such as dividing a fish stock's fishing sectors).

### Analysis

NMFS and the regional fishery management councils (councils) analyze data on fish stocks and ocean conditions to develop scientific information for use in fisheries management. Such analyses are often performed as part of stock assessments. Analyses that NMFS and the councils develop produce key information such as:

- Estimates of fish stock abundance, mortality, and reproduction
	- Information on the geographic distribution of species.
- Determinations of stock status, such as whether it is overfished (its population size is too low) or has experienced overfishing<br>(its harvest rate is too high).
	- Information on the economic and social impacts of management actions.

#### **Table 1. Mixed-use fish stocks managed by the South Atlantic fishery management council**

Source: GAO analysis of documents from the South Atlantic Fishery Management Council and information from council staff. | GAO-20-216.

- Note: Fish stocks listed by complex are managed together as a group. For this report, we count a complex as a single fish stock if the allocation is for the complex, rather than for the individual stock within the complex. If the fish stocks within a complex have their own allocations, as they do in the South Atlantic, we count them as separate stocks for reporting purposes. In addition, the South Atlantic Fishery Management Council manages golden crab and shrimp, which are exclusively fished by the commercial sector, and sailor's choice, tomtate, and scup, which are exclusively fished by the recreational sector, according to council staff. The staff said the council also manages over 130 species of corals but has delegated management of the harvest—which is primarily commercial but not allowed for most species—to the state of Florida.
- <sup>a</sup>The South Atlantic and Gulf of Mexico Fishery Management Councils jointly manage cobia, king mackerel, and Spanish mackerel through a single fishery management plan for coastal migratory pelagic resources.
- <sup>b</sup>In 2016, the South Atlantic Fishery Management Council split the South Atlantic hogfish stock into two: Georgia-North Carolina hogfish and Florida Keys/East Coast of Florida hogfish.
- <sup>c</sup>Harvest is not allowed for speckled hind and warsaw grouper as of December 2019.
- <sup>d</sup>The South Atlantic and Gulf of Mexico Fishery Management Councils jointly manage spiny lobster through a single fishery management plan for spiny lobster.
- <sup>e</sup>Saucereye porgy in the South Atlantic is, in practice, a recreational fish stock, according to South Atlantic Fishery Management Council staff. Council staff indicated that because the total annual catch limit for the fish stock is low, there is no commercial fishing in practice for the stock.

Tables 1 and 2 highlight the mixed-use fish stocks the South Atlantic and Gulf of Mexico councils manage, respectively.<sup>1</sup>

#### **Table 2. Mixed-use fish stocks managed by the Gulf of Mexico fishery management council**

Source: GAO analysis of documents from the Gulf of Mexico Fishery Management Council and information from council staff. | GAO-20-216.

- Note: Fish stocks listed by complex are managed together as a group. For this report, we count a complex as a single fish stock if the allocation is for the complex, rather than for the individual stock within the complex. If the fish stocks within a complex have their own allocations, we count them as separate fish stocks for reporting purposes. In addition, the Gulf of Mexico Fishery Management Council manages commercial fishing for several types of shrimp. The council also manages recreational fishing for red drum; however, harvest of red drum is not allowed as of December 2019, according to National Marine Fisheries Service officials.
- <sup>a</sup>The South Atlantic and Gulf of Mexico Fishery Management Councils jointly manage cobia, king mackerel, and Spanish mackerel through a single fishery management plan for coastal migratory pelagic resources.

<sup>b</sup>Harvest is not allowed for goliath grouper as of December 2019.

- c In 2019, the Gulf of Mexico Fishery Management Council began taking steps to delegate responsibility for the management of certain recreational fishing for red snapper in federal waters to the coastal states in the Gulf of Mexico. Specifically, following a pilot program in 2018 and 2019, the council completed an amendment to the fishery management plan for reef fish in May 2019 that would, among other things, allow a Gulf of Mexico state with an approved management program to manage private angling for red snapper in federal waters. The Secretary of Commerce approved the amendment on November 5, 2019 and the final rule implementing the amendment was under development as of December 2019, according to National Marine Fisheries Service officials.
- <sup>d</sup>The South Atlantic and Gulf of Mexico Fishery Management Councils jointly manage spiny lobster through a single fishery management plan for spiny lobster.
- <sup>e</sup>Harvest of stony corals, sea fans (soft corals), and wild live rock is generally prohibited in federal waters of the Gulf of Mexico as of December 2019.

<sup>1</sup> For some fish stocks, the councils manage groups of comparable species as complexes of fish. For this report, we count a complex as a single fish stock if the allocation is for the stock complex, rather than for the individual stock within the complex. If the fish stocks within a complex each have their own allocations, we count them as separate fish stocks for reporting purposes. In addition, the councils manage several fish stocks that are exclusively fished by the commercial or recreational sectors, according to council staff. In the South Atlantic, the staff said that the council manages commercial fishing for golden crab and shrimp, as well as recreational fishing for sailor's choice and tomtate (both part of the grunts complex) and scup (part of the porgy complex). The Gulf of Mexico council manages commercial fishing for several types of shrimp. The council also manages recreational fishing for red drum. However, harvest of red drum is not allowed as of December 2019, according to NMFS officials.

#### **Fisheries Allocations**

Under the Magnuson-Stevens Act's national standards for fishery management plans, allocations are to be fair and equitable to all U.S. fishermen; reasonably calculated to promote conservation; and carried out in such manner that no particular individual, corporation, or other entity acquires an excessive share.<sup>2</sup> NMFS guidelines for the national standards further indicate that in making allocations, councils should consider certain factors relevant to the fishery management plan's objectives. These factors include economic and social consequences of the allocations, food production, consumer interest, dependence on the fishery by present participants and coastal communities, efficiency of various types of gear used in the fishery, transferability of effort to and impact on other fisheries, opportunity for new participants to enter the fishery, and enhancement of opportunities for recreational fishing. In reviewing and approving fishery management plans and amendments, NMFS is responsible for ensuring that the councils' allocation decisions comply with the Magnuson-Stevens Act's national standards. In this report, the terms "established" and "revised" allocations refer to allocations established or revised by the councils and subsequently approved by NMFS, unless otherwise stated.

Historically, mixed-use fisheries allocations have been based predominantly on data estimating each fishing sector's past use of the resource, according to NOAA. To collect commercial and recreational data, NMFS works with partners such as coastal states and interstate marine fisheries commissions. In particular, for the commercial fishing sector, NMFS collects data on landings, which include the weight and value of fish stocks sold to seafood dealers using a network of cooperative agreements with states.<sup>3</sup> For recreational fishing, NMFS uses data from its Marine Recreational Information Program, which the agency began implementing in 2008 in place of the Marine Recreational Fisheries Statistics Survey. The Marine Recreational Information Program collects data on private anglers' fishing effort and catch rates and uses these to estimate total recreational fishing catch.<sup>4</sup> NMFS officials said that the program also collects information to estimate recreational landings. The program collects these data through such methods as mail surveys and shoreside interviews of anglers at public access fishing sites.<sup>5</sup>

Recognizing the difficulty in making allocation decisions—in part because allocations may be perceived as unfair by some stakeholders—NMFS commissioned a nationwide study in 2012 to examine allocation issues and gain stakeholders' perspectives from commercial and recreational fishing sectors.<sup>6</sup> The results of the study showed widespread dissatisfaction with how past allocation decisions were made. The study found little consensus on how to

<sup>&</sup>lt;sup>2</sup> Pub. L. No. 94-265, § 301(a)(4), 90 Stat. 331, 346 (1976) (codified as amended at 16 U.S.C. § 1851(a)(4)). The national standards are statutory principles that must be followed in any fishery management plan.

<sup>&</sup>lt;sup>3</sup> Landings are defined as the number or poundage of fish unloaded by commercial fishermen and sold to seafood dealers or brought to shore by private anglers for personal use.

<sup>4</sup> Effort measures the number of angler trips, and catch rates measure the average number and size of fish per trip by species—that are brought to shore, caught and used as bait, or discarded (i.e., caught but then released alive or dead).

<sup>5</sup> For more information on the Marine Recreational Information Program, see https://www.fisheries. noaa.gov/topic/recreational-fishing-data. We previously reported on recreational fisheries data. See GAO, *Recreational Fisheries Management: The National Marine Fisheries Service Should Develop a Comprehensive Strategy to Guide Its Data Collection Efforts*, GAO-16-131 (Washington, D.C.: Dec. 8, 2015).

<sup>6</sup> Lapointe, George, *Marine Fishery Allocation Issues: Findings, Discussion, and Options* (George Lapointe Consulting LLC, December 2012).

address concerns with allocations. For example, some stakeholders said that some allocations were outdated and that changes over time in human population, seafood demand, and recreational fishing warranted a comprehensive examination of allocations. Other stakeholders expressed concern that a uniform approach to allocation policy could harm fishing sectors, while others noted that it is important for the councils to have the flexibility to make regionally-focused decisions. The study concluded that many stakeholders may continue to view allocations as unbalanced or unfair unless the outcomes align with the positions they seek. The study recommended that NMFS take a number of steps to address allocation issues, including increasing stakeholder engagement in allocation decisions, periodically reviewing allocations, and creating a list of factors to guide allocation decisions.

In response to the 2012 study, NMFS issued a fisheries allocation review policy in 2016 and two guidance documents to the councils, $<sup>7</sup>$  intended to help the councils and NMFS review</sup> and update allocations.<sup>8</sup> The objective of the NMFS policy was to describe the fisheries allocation review process, which called for using an adaptive management approach.<sup>9</sup> NMFS policy defined fisheries allocation review as the evaluation that leads to the decision of whether or not the development and evaluation of allocation options is warranted, but the allocation review is not, in and of itself, an implicit trigger to consider alternative allocations.

Through its policy, NMFS established a multi-step process for reviewing and potentially revising fisheries allocations. Specifically, once an allocation review trigger has been met (as described below), the councils are to complete an allocation review. For this review, NMFS policy does not call for in-depth analyses but calls for a clear articulation of how objectives are or are not being met and a clear rationale and documentation on relevant factors considered. Based on the allocation review, the councils may decide to maintain existing allocations, or proceed to evaluate allocation options for a fishery management plan amendment. When proceeding with this next step, the councils are to undertake formal analyses and follow the fishery management plan amendment process to ultimately recommend that an existing allocation either be retained or revised.

To supplement its fisheries allocation review policy, NMFS also issued two guidance documents, as follows:

<sup>7</sup> NMFS developed the policy and guidance in coordination with the Council Coordination Committee. The reauthorization of the Magnuson-Stevens Act in 2007 permitted the councils to establish a Council Coordination Committee, which consists of the chairs, vice chairs, and executive directors from each council, or other council members or staff, as appropriate. Pub. L. No. 109-479, §103(g), 120 Stat. 3575, 3581 (2007) (codified at 16 U.S.C. § 1852(*l*)). The committee meets twice each year to discuss issues relevant to all councils, including issues related to the implementation of the Magnuson-StevensAct.

<sup>8</sup> National Marine Fisheries Service, *Fisheries Allocation Review Policy, Criteria for Initiating Fisheries Allocation Reviews,* and *Recommended Practices and Factors to Consider When Reviewing and Making Allocation Decisions*. In addition, a 2018 NMFS technical memorandum recommended that councils develop and document a process for making allocation decisions when fish stocks change their distributions. See Karp, M. A., J. Peterson, P. D. Lynch, and R. Griffis (editors), *Accounting for Shifting Distributions and Changing Productivity in the Fishery Management Process: From Detection to Management Action*, U.S. Department of Commerce, National Oceanic and Atmospheric Administration Technical Memorandum NMFS-F/SPO-188 (Silver Spring, MD: 2018).

<sup>9</sup> NMFS policy defined adaptive management as the ongoing process of evaluating if management objectives have been met and adjusting management strategies in response. It stated the process includes periodic re-evaluation and updating of the management goals and objectives to ensure they are relevant to current conditions and needs.

- **Criteria for initiating fisheries allocation reviews. <sup>10</sup>** NMFS guidance recommended that the councils establish criteria for initiating allocation reviews—or allocation review triggers—within 3 years, or as soon as practicable, for all fisheries that have allocations between sectors. The guidance identified three types of potential criteria for allocation review triggers: (1) time-based, which include provisions for periodic allocation reviews at specific time intervals on a regular basis; (2) public interest-based, which provide an opportunity for the public to express interest in allocation reviews; and (3) indicator-based, such as triggers based upon economic or other metrics.
- **Factors to consider when reviewing and making allocation decisions**. <sup>11</sup> NMFS guidance outlined four categories of factors for the councils to consider when making allocation decisions, and noted that there may also be other appropriate factors to consider. These factors are not intended to prescribe particular outcomes with respect to allocations, but rather are intended to provide a framework for analysis, according to the guidance. The four categories of factors include:
	- **Fishery performance and change factors**, to assess the current conditions of a fishery and any changes in those conditions that may indicate a need for updated allocations. Such factors could include historical or current trends in catch or landings, the status of the fish stock (for example, whether it is subject to overfishing, is overfished, or is rebuilding<sup>12</sup>), or changes in the distribution of species within the fishery.
	- **Economic factors**, to consider the monetary consequences of an allocation, such as by analyzing (1) whether the existing or recommended allocation is the most economically efficient, and (2) the economic impacts of the allocation.<sup>13</sup>
	- **Social factors**, to assess the consequences of an allocation on individuals and communities, such as whether an allocation may have disproportionate adverse effects on low income or minority groups or could lead to fishing despite unsafe conditions if access to the fishery is restricted to a limited number of days.
	- **Ecological factors**, to consider the potential ecological impacts of allocations, such as impacts on the habitat or predator-prey dynamics of the fishery or of other fisheries within the ecosystem.

<sup>10</sup> National Marine Fisheries Service, *Criteria for Initiating Fisheries Allocation Reviews*.

<sup>11</sup> National Marine Fisheries Service, *Recommended Practices and Factors to Consider When Reviewing and Making Allocation Decisions.*

 $12$  A fish stock that is subject to overfishing has a fishing mortality (harvest) rate that is too high to meet long-term sustainable catch level targets under current conditions. Under the Magnuson-Stevens Act, overfished means a rate or level of fishing mortality that jeopardizes the capacity of a fishery to produce the maximum sustainable yield on a continuing basis. 16 U.S.C. § 1802(34). Rebuilding a stock involves taking actions to allow it to grow back to a predefined target level.

<sup>&</sup>lt;sup>13</sup> According to the guidance, analyses that estimate the monetary value individuals or sectors place on their share of the harvest—their willingness to pay—can inform how allocation changes could improve economic efficiency. Economic impacts may be analyzed using models that include, for example, changes to sales, income, and employment levels.

#### **SOUTH ATLANTIC AND GULF OF MEXICO COUNCILS HAVE ESTABLISHED AND REVISED ALLOCATIONS TO VARYING DEGREES**

Since the Magnuson-Stevens Act was passed in 1976, the South Atlantic and Gulf of Mexico councils have established and revised allocations to varying degrees for the mixeduse fish stocks they manage in their regions. The South Atlantic council has established allocations for almost all of its mixed-use fish stocks and the Gulf of Mexico council has done so for certain stocks.

#### **South Atlantic Council Has Established Allocations for Almost All Mixed-Use Fish Stocks and Revised Most of Those Allocations in 2012**

Based on documents from the South Atlantic council, we found that the council has established allocations for 50 of the region's 51 mixed-use fish stocks.<sup>14</sup> The council first established an allocation for one fish stock—king mackerel—in 1985. From 1987 through 2010, the council set allocations for eight fish stocks. The council then established most allocations, encompassing 40 of its mixed-use fish stocks, in 2011, with allocations generally based on estimates of each fishing sector's historical landings.<sup>15</sup> The council's most recently established allocation—for a cobia stock—was in 2014, according to council documents. Appendix I provides additional information on the allocations for the mixed-use fisheries in the South Atlantic council region and the years in which the council established and revised allocations.

According to South Atlantic council staff, the council's approach to revising allocations has been to rely on stakeholder input to inform them of allocations that may need revision but to otherwise leave established allocations in place. For example, council staff noted that the allocation for king mackerel—which distributes a percentage of the annual catch limit to each fishing sector—has not changed since 1985 because it is still effective for both the commercial and recreational fishing sectors. Council staff explained that because neither sector has typically caught the amount of king mackerel they have been allocated, the council has not needed to revise the allocation.

<sup>&</sup>lt;sup>14</sup> The South Atlantic council has not established an allocation for spiny lobster. Council staff said this is because spiny lobster fishing primarily occurs in the waters off Florida, where the state takes the lead in regulating this fishery through a protocol developed with NMFS and the South Atlantic and Gulf of Mexico councils. Outside of these Florida state- managed waters, spiny lobster fishing is subject to a two lobsters-per-person, per-trip catch limit, according to a council document.

<sup>&</sup>lt;sup>15</sup> For example, the council based allocations for many snapper and grouper stocks on the following formula: 50 percent of each fishing sector's average landings for the period 1986 to 2008, plus 50 percent of each sector's average landings for the period 2006 to 2008, according to a council document.

#### **Table 3. Mixed-use fish stocks with commercial and recreational allocations and subsequent revisions in the South Atlantic Fishery Management Council Region, as of December 2019**

Source: GAO analysis of documents from the South Atlantic Fishery Management Council. | GAO-20-216.

Note: Years shown represent the year that the council completed its fishery management plan amendment and sent it to the National Marine Fisheries Service for review and approval. For allocations that have not been revised, the dates shown are the years the councils established the allocations. For allocations that have been revised, the years shown are the years the councils revised them. The fish stocks listed as part of complexes are managed together as groups. In the South Atlantic region, the fish stocks within these complexes have their own allocations.

a In 2016, the South Atlantic Fishery Management Council split the South Atlantic hogfish stock into two and established allocations for Georgia-North Carolina hogfish and Florida Keys/East Coast of Florida hogfish.

<sup>b</sup>Harvest is not allowed for speckled hind and warsaw grouper as of December 2019.

<sup>c</sup>Saucereye porgy in the South Atlantic is, in practice, a recreational fish stock, according to South Atlantic Fishery Management Council staff. The staff said because the total annual catch limit for the stock is low, there is no commercial fishing in practice for the stock.
As of December 2019, the South Atlantic council had revised allocations for most of their mixed-use fish stocks once, according to council documents, as shown in Table 3. The council revised allocations for 30 fish stocks in  $2012<sup>16</sup>$  based on changes to the source of recreational catch data the council was using in its formulas for calculating allocation percentages.<sup>17</sup>

Source: GAO analysis of documents from the National Marine Fisheries Service and South Atlantic Fishery Management Council. | GAO-29-216.

Note: Years shown represent the year that the South Atlantic Fishery Management Council sent a fishery management plan amendment to the National Marine Fisheries Service for its review and approval. The allocation represents each sector's percentage of the annual catch limit for dolphin, as measured in pounds of whole fish. The council has set allocation percentages to two decimal places, as indicated in the figure.

Figure 4. History of the Commercial and Recreational Allocation for Dolphin in the South Atlantic, as of December 2019.

The South Atlantic council has revised few allocations more than once. Specifically, they revised allocations for two fish stocks twice and for one, dolphin, three times.<sup>18</sup> For example, the council first established an allocation for dolphin (also known as mahimahi, dolphinfish, and dorado) in 2003. It established the allocation to maintain the fishery as predominantly

<sup>&</sup>lt;sup>16</sup> The 30 fish stocks with allocations revised in 2012 include hogfish, which the council revised in 2012, and then again in 2016.

<sup>&</sup>lt;sup>17</sup> In 2012, the South Atlantic council changed from using Marine Recreational Fisheries Statistics Survey data to data calculated from NMFS' Marine Recreational Information Program. Specifically, the council adjusted allocation amounts using data from the Marine Recreational Information Program for recreational catch estimates for the years 2004- 2008. The council also based allocation amounts on updated recreational catch estimates for 1986-2003. For these estimates, the council used data developed by a regional working group that developed a regional calibration method to recalculate previous recreational fishing estimates for these years.

<sup>&</sup>lt;sup>18</sup> In addition, the council began work in March 2016 on a draft fishery management plan amendment that considers alternatives for revising dolphin and wahoo allocations by increasing the recreational sector's allocation. The allocation alternatives under consideration were based on catch and landings data. At the council's December 2019 meeting, the council postponed discussion of the amendment until its June 2020 meeting.

recreational and based the allocation on historical landings, according to the council's fishery management plan (see Figure 4). According to council documents, the council then revised the dolphin allocation three times:

- in 2011, when initially setting annual catch limits for dolphin,
- in 2013, based on changes to the source of recreational catch data used to calculate allocation percentages, and
- in 2015, because the recreational sector had not been catching the amount of fish it was allocated, and the council was concerned that the commercial sector could exceed its allocation in the future.

The extent to which the South Atlantic council may have considered other revisions to allocations is unclear. For example, South Atlantic council staff said that their council had deliberated on revising allocations for some fish stocks at council meetings, but they do not have records of the deliberations because the council decided not to make revisions and did not initiate related fishery management plan amendments. South Atlantic council staff explained that they document all allocation revisions through fishery management plan amendments, but they have not otherwise formally documented reviews that did not result in revisions.<sup>19</sup> Council staff said they recognize the need to better document such reviews in the future; however, the council did not identify how it plans to do so, as discussed later in this report.

# **Gulf of Mexico Council Has Established Allocations for Certain Mixed-Use Fish Stocks and Revised Three of Those Allocations in 2008**

The Gulf of Mexico council established commercial and recreational allocations for nine of the region's 23 mixed-use fish stocks, according to documents from the council (see app. I for allocations for the mixed-use fisheries in the Gulf of Mexico council region). Council staff said most of the council's allocations were made based on estimates of each sector's historical landings. The council has not established allocations for most mixed-use fish stocks in the region because allocations for these stocks have not been warranted, according to council staff. <sup>20</sup> Council staff said the council generally considers establishing allocations when stakeholders identify issues, or if new information such as a stock assessment becomes available and indicates that allocations may be needed to help manage a fish stock. In the absence of such information, the Gulf of Mexico council manages the fish stocks with other methods— for example, with seasonal closures or trip or bag limits, which establish the number of fish that can be legally taken in a specified period.

 $19$  South Atlantic council staff said that in 2019 the council began to convert its historical meeting minutes and final documents into a searchable format that will improve the council's ability to track past discussions of allocations. They said that this project will take several years to complete.

<sup>&</sup>lt;sup>20</sup> Specifically, the council has not established allocations for the following mixed-use fish stocks: (1) cobia; (2) corals; (3) cubera, (4) gray, (5) lane, (6) mutton, (7) vermillion, and (8) yellowtail snapper; (9) goliath grouper; (10) hogfish; (11) Spanish mackerel; (12) spiny lobster; (13) the Jacks complex (almaco jack, banded rudderfish, and lesser amberjack); and (14) the mid-water snapper complex (blackfin snapper, queen snapper, silk snapper, and wenchman).

As of December 2019, the Gulf of Mexico council had revised allocations for three mixed-use fish stocks, as shown in Table 4. For example, the council revised the allocation for red grouper in 2008 to increase the recreational sector's allocation after a stock assessment indicated the fishery had recovered from overfishing, according to a council document. In 2008, the council also revised the gag grouper allocation to increase the commercial sector's allocation. In addition, the Gulf of Mexico council completed a fishery management plan amendment in 2015 that revised the red snapper allocation by increasing the recreational sector's percentage. However, after the Secretary of Commerce approved the amendment in 2016, a U.S. District Court vacated the amendment in 2017, and the council returned to the initial allocation established for red snapper. $21$ 

# **Table 4. Mixed-use fish stocks with commercial and recreational allocations and subsequent revisions in the Gulf of Mexico Fishery Management Council Region, as of December 2019**

Source: GAO analysis of documents from the Gulf of Mexico Fishery Management Council. | GAO-20-216.

- Note: Years shown represent the year that the council completed its fishery management plan amendment and sent it to the National Marine Fisheries Service (NMFS) for review and approval. For allocations that have not been revised, the dates shown are the years the councils established the allocations. For allocations that have been revised, the years shown are the years the councils revised them. The fish stocks listed as part of complexes are managed together as groups. In the Gulf of Mexico region, the fish stocks within these complexes do not have their own allocations.
- a In 2015, the Gulf of Mexico Fishery Management Council completed a fishery management plan amendment that revised the red snapper allocation. However, after the Secretary of Commerce approved the amendment in 2016, a U.S. District Court vacated the amendment in 2017 and the council returned to the initial allocation established for red snapper. *See Guindon v. Pritzker*, 240 F. Supp. 3d 181 (D.D.C. 2017).
- <sup>b</sup>According to NMFS officials, the Gulf of Mexico Fishery Management Council established allocation percentages for each complex as a whole, based on quotas for commercial fishing established for these complexes. Recreational allocation percentages for the complexes represent the remainder of allowable harvest, after factoring in quota amounts.
- <sup>c</sup>For greater amberjack, the council did not revise the allocation directly; instead, the council indirectly revised the commercial and recreational allocations by establishing harvest reductions that were applied unequally to these fishing sectors, according to a 2008 fishery management plan amendment.

<sup>21</sup> *Guindon v. Pritzker*, 240 F. Supp. 3d 181 (D.D.C. 2017). The court held that the revised allocation was not fair and equitable and therefore violated National Standard 4. The council also began work in January 2018 on a separate fishery management plan amendment to consider revising red snapper allocations. As of August 2019, the council decided to postpone further work on the amendment until 2020, to review our report and further progress in calibrating estimates of recreational fishing for red snapper through the Marine Recreational Information Program, according to council documents.

Gulf of Mexico council staff said the council has not identified a need to revise allocations for the other mixed-use fish stocks in the region with allocations. For instance, for the deep water grouper and tilefish complexes, council staff said there has been limited competition between the recreational and commercial fishing sectors and the council has not needed to revise the allocations initially established for those fish stocks in 2011.

When the Gulf of Mexico council has considered revising allocations, it has done so through fishery management plan amendments, according to council staff. For example, in a 2016 fishery management plan amendment, the council considered revising the allocation for king mackerel because estimates indicated that the recreational sector had not been landing the amount of fish it was allocated. However, the council decided not to revise the allocation, citing the potential for increased recreational fishing for king mackerel in the future.<sup>22</sup>

# **VARIOUS SOURCES OF INFORMATION MAY BE AVAILABLE TO HELP NMFS AND THE COUNCILS CONDUCT ALLOCATION REVIEWS**

Through our review of agency documents and interviews with NMFS and South Atlantic and Gulf of Mexico council staff, we found that various sources of information may be available to help NMFS and the councils review allocations, but each source presents some challenges to councils for supporting allocation decisions. Councils can use these sources of information to consider the factors NMFS' 2016 guidance calls for— including fishery performance and change, economic, social, and ecological factors—when reviewing allocations.<sup>23</sup> Five key sources of information that NMFS and the councils identified are trends in catch and landings, stock assessments, economic analyses, social indicators, and ecosystem models. NMFS officials said that the councils would like to incorporate these key sources into their allocation reviews, and use such information in supporting future allocation decisions. However, they said the availability, specificity, or quality of information can present challenges to using some of the information. In particular, they noted that available information other than landings is often sparse and uncertain for many fish stocks. As a result, the officials said it may be difficult for the councils to use such information as the basis for allocation decisions. NMFS is taking some steps to improve the information available, as discussed below.

### **Trends in Catch and Landings**

 $\overline{a}$ 

NMFS' 2016 guidance states that changes in the performance or conditions of a fishery may indicate the need for updated allocations. Fishery performance and change factors include trends in catch or landings. Data on historical and current catch and landings can

 $22$  For example, the amendment noted that an increase in the recreational bag limit and recent short recreational seasons for other popular fish could result in more fishing effort shifting to king mackerel. However, the amendment also noted it seemed unlikely that recreational fishing for king mackerel would increase substantially in the near future, even with an increase in the bag limit.

<sup>&</sup>lt;sup>23</sup> The guidance states that the factors are intended to provide a framework for analyses, but that the priority and weight afforded each factor may vary depending on such things as the fishery, the objectives of the fishery management plan or the allocation, and overarching council goals.

provide the councils with important information about demand, according to NMFS guidance, including whether a fishing sector may be catching above or below its allocation. Generally, NMFS collects landings data for commercial fisheries from state fisheries agencies, who obtain landings data from monthly reports submitted by seafood dealers on the weight and value of fish sold at the dock. NMFS collects data to estimate recreational catch and landings through survey and interview methods through its Marine Recreational Information Program.

However, recreational catch estimates present some limitations. A 2017 National Academies study noted that obtaining reliable data on recreational catch can be challenging because of several attributes of the recreational fishing sector.<sup>24</sup> For example, the greater number of recreational anglers compared with the number of participants in the commercial fishing sector, and the greater number of access and landing points available to recreational anglers, make it difficult to obtain reliable data on the extent of recreational fishing, according to the study.

In 2018, the Marine Recreational Information Program updated how NMFS estimates recreational catch based on a change in the survey methodology used to collect data from anglers on the Atlantic and Gulf of Mexico coasts.<sup>25</sup> According to NMFS documents, updated recreational catch estimates for many fish stocks are several times higher than previous estimates because of the change in methodology.<sup>26</sup> However, any implications these updated estimates may have for allocations in the South Atlantic and Gulf of Mexico may not be fully understood until NMFS incorporates the estimates into stock assessments, which were scheduled for completion between 2019 and 2021, according to NMFS documents.

Further, in the Gulf of Mexico, states collect recreational catch data through their own programs, which supplement NMFS' Marine Recreational Information Program data. The states' programs use different methodologies, however, which Gulf of Mexico council staff said make it difficult to reconcile the states' recreational fisheries data with NMFS' data on catch estimates. According to an NMFS document, some of the different methodologies the states use to design surveys have produced different estimates in years when two or more surveys were conducted side by side, making it difficult to determine the best estimates of recreational catch in the Gulf of Mexico.<sup>27</sup>

NMFS is taking steps to improve its recreational catch estimates. For instance, in September 2019 NMFS issued procedural guidance to help ensure that survey estimates from the Marine Recreational Information Program are based upon the best scientific information available and to promote nationwide consistency in collecting data and estimating

<sup>24</sup> National Academies of Sciences, Engineering, and Medicine, *Review of the Marine Recreational Information Program* (Washington, D.C.: The National Academies Press, 2017). We also reported on this topic in 2015. See GAO-16-131.

<sup>&</sup>lt;sup>25</sup> In 2018, the Marine Recreational Information Program completed its transition from using its Coastal Household Telephone Survey to its mail-based Fishing Effort Survey for shore and private boat fishing in the Atlantic and Gulf of Mexico. Because these surveys used two different methodologies to collect data, and because fishery managers need consistent data that can be compared over time, NMFS has been working to calibrate data from the telephone survey to the mail survey. From 2015 to 2018, NMFS worked to calibrate the data using a model it developed to adjust historic estimates so that those estimates can be compared with new estimates. In July 2018, the program released revised estimates of recreational catch and effort for 1981 through 2017.

<sup>&</sup>lt;sup>26</sup> According to an agency document, NMFS determined that the higher estimates resulted from improved methods for estimating fishing activity and not a sudden rise in fishing.

<sup>&</sup>lt;sup>27</sup> U.S. Department of Commerce, National Oceanic and Atmospheric Administration, National Marine Fisheries Service, *Recommended Use of the Current Gulf of Mexico Surveys of Marine Recreational Fishing in Stock Assessments* (July 2019).

recreational catch.<sup>28</sup> NMFS is also working with Gulf of Mexico states to evaluate the critical assumptions made by each state's data collection program and to help ensure that the states' recreational catch estimates are comparable across years and with other states. As part of this effort, NMFS is calibrating recreational catch estimates from Gulf of Mexico states with data from the Marine Recreational Information Program. According to an agency official, NMFS anticipates completing this effort in May 2020.

#### **Stock Assessments**

Stock assessments are a key source of information the councils can use to review allocations given the information they provide on the status of fish stocks, according to NMFS documents. Stock assessments can range in complexity from a simple description of historical trends in catch and landings to complex assessment models that incorporate spatial and seasonal analyses in addition to ecosystem or multispecies considerations. <sup>29</sup> Stock assessments are not available for all fish stocks with allocations, however. In the South Atlantic, 32 of the 50 mixed-use fish stocks with allocations do not have stock assessments, according to council staff.<sup>30</sup> Of these fish stocks, NMFS plans to complete stock assessments for three—gray triggerfish, scamp, and white grunt—by 2024, according to South Atlantic council staff. In the Gulf of Mexico, stock assessments are available for the mixed-use fish stocks with allocations, with the exception of the shallow and deep water grouper aggregate complexes.<sup>31</sup>

Stock assessments can provide maps of the spatial distributions of fish stocks and may show changes in those distributions over time, according to NMFS officials. Changes in a fish stock's distribution may lead to allocation disputes, and basing allocations on historical catch may not be appropriate in such situations, according to an NMFS document. NMFS' 2016 guidance states that the councils may need to update allocations if the distributions of fish stocks change over time for reasons such as climate change or natural fluctuations in abundance. <sup>32</sup> However, NMFS officials noted that few stock assessments incorporate spatial

<sup>&</sup>lt;sup>28</sup> U.S. Department of Commerce, National Oceanic and Atmospheric Administration, National Marine Fisheries Service, *Implementing Recreational Fishery Catch and Effort Survey Design Changes: Guidance and Procedures for the MRIP Certification Process,* NMFS Procedure 04-114-02 (Sept. 4, 2019).

<sup>&</sup>lt;sup>29</sup> According to an NMFS report, the level of complexity of a stock assessment has a large impact on the amount of data and effort needed to complete the assessment, as well as on the extensiveness of review needed of assessment results. Some fish stocks necessitate frequent and complex assessments because they have high importance to the fishery, play an important ecosystem role, or are vulnerable to overexploitation. However, other stocks do not need such comprehensive monitoring, according to the NMFSreport.

<sup>&</sup>lt;sup>30</sup> South Atlantic council staff cited the following as reasons why stock assessments may not be conducted: existing data are insufficient for the analyses needed; NMFS staff or funding are not available to perform the analyses; and some species are encountered infrequently during fishing. For fish stocks that do not have stock assessments, the council's scientific and statistical committee has formulated rules for determining acceptable biological catch using proxy measures of landings and the council sets annual catch limits based on these, according to council staff.

 $31$  A stock assessment is available for black grouper, which is within the shallow water grouper aggregate complex.

 $32$  A 2018 NMFS technical memorandum recommended that councils develop and document a process for making allocation decisions when fish stocks change their distributions. See Karp, M. A., J. Peterson, P. D. Lynch, and R. Griffis (editors), *Accounting for Shifting Distributions and Changing Productivity in the Fishery Management Process: From Detection to Management Action*, U.S. Department of Commerce, National Oceanic and Atmospheric Administration Technical Memorandum NMFS-F/SPO-188 (Silver Spring, MD: 2018).

models that would allow forecasts of future spatial distributions. <sup>33</sup> To help improve the availability of such information, NMFS is conducting evaluations that will, among other things, assess changes in the distribution of fish stocks in the Gulf of Mexico and South Atlantic in response to regional climate change impacts. NMFS officials said they anticipate completion of these evaluations in 2020, which will help them forecast future spatial distributions for some fish stocks going forward.

In addition, stock assessments are one source of information that the councils can use to assess each fishing sector's expected ecological impacts, according to NMFS officials. For example, NMFS officials said that stock assessments commonly provide information on each sector's discards—fish intentionally thrown back. Discards may be caught as bycatch—that is, incidentally to the harvest of the primary fish stock targeted. NMFS' 2016 guidance states that councils can consider the expected impacts of each fishing sector's allocation on bycatch and bycatch mortality. <sup>34</sup> However, the availability and certainty of bycatch and discard information can vary, according to NMFS officials.

NMFS is taking steps to improve information on bycatch and discards. For instance, beginning in 2020, the for-hire component of the recreational fishing sector is to use an electronic system to report its bycatch and discards in the South Atlantic and Gulf of Mexico, according to NMFS officials. The officials said that the commercial fishing sector will begin using this system by 2023. NMFS officials said that the agency is also developing a model that will, among other things, estimate the number of released fish caught by the recreational fishing sector in the South Atlantic and Gulf of Mexico. <sup>35</sup> The officials said that the first version of the model is focused on gag grouper in the Gulf of Mexico, but that the model could be customized to any fish stock with the necessary data available. As of December 2019, NMFS officials anticipated completion of the model by late 2020 and estimated that the model would be ready to incorporate into stock assessments in fiscal year 2021 or later.

#### **Economic Analyses**

 $\overline{a}$ 

Economic analyses can provide information on the economic consequences of allocations, according to NMFS documents. NMFS' 2016 guidance notes that councils should consider if the current or preferred allocation results in the most economically efficient use of the fishery resource.<sup>36</sup> According to the guidance and NMFS officials, economic efficiency

<sup>&</sup>lt;sup>33</sup> In addition, in 2016, we found that NMFS and the councils have limited stock-specific information about the magnitude and timing of climate change effects—such as changes in distribution—for federally managed fish stocks. See GAO, *Federal Fisheries Management: Additional Actions Could Advance Efforts to Incorporate Climate Information into Management Decisions*, GAO-16-827 (Washington, D.C.: Sept. 28, 2016).

<sup>34</sup> According to a 2019 Gulf of Mexico council report, mortality from discards in the recreational fishing sector is a problem in the region. Fish may be discarded because they are under a minimum size limit or out of season, anglers have already retained their bag limit, or they may be voluntarily discarded because anglers prefer to catch and release, according to the report. In October 2019, the Gulf of Mexico council hosted a discard mortality symposium with the goal of reducing discard mortality from recreational fishing efforts. See Gulf of Mexico Fishery Management Council, *Release Mortality Symposium Summary Report* (October 2019).

<sup>&</sup>lt;sup>35</sup> According to NMFS officials, this model is based on work originally done for groundfish in the Northeast. See Lee, Min-Yang, Scott Steinback, and Kristy Wallmo, *Applying a Bioeconomic Model to Recreational Fisheries Management: Groundfish in the Northeast United States,* Marine Resource Economics, volume 32, number 2 (Chicago, IL: Feb. 3, 2017).

<sup>36</sup> Under the Magnuson-Stevens Act, National Standard 5 provides that fishery management plan measures shall, where practicable, consider efficiency in the utilization of fishery resources; except that no such measure shall

refers to how well scarce resources are used in production and consumption, and is achieved when all resources are allocated to their most valuable productive use. In principle, an allocation is most economically efficient when the net economic benefits to the commercial and recreational fishing sectors in total are maximized.<sup>37</sup> If net economic benefits are not maximized, then modifying the allocation may increase economic efficiency and economic benefits to the nation. NMFS officials said the agency focuses on conducting economic efficiency analyses to help guide allocation reviews.<sup>38</sup> Economic efficiency analyses can help NMFS and the councils analyze whether a proposed change in an allocation would generate greater net economic benefits for society (that is, improve economic efficiency), compared with the current allocation, according to NMFS officials.

We found the councils face challenges in using economic efficiency analyses in allocation decisions. According to NMFS officials and the agency's published research, reliable data for estimating economic values associated with recreational fishing may not be readily available. This is because no market prices for fish caught by private anglers are available and thus, non-market valuation techniques must be used to estimate the marginal value of fish to recreational anglers.<sup>39</sup> For example, a 2014 NMFS study on the economic efficiency of allocations for gag, red, and black grouper found that there are insufficient data on the recreational harvest by grouper species to generate statistically reliable estimates of economic value for each fish stock.<sup>40</sup>

In addition, it is difficult to estimate the economic value associated with one fish stock because recreational anglers may be willing to catch other species of fish if fishery managers limit anglers' access to a particular stock, according to members of both councils' socioeconomic panels. This transfer of effort from one fish stock to another makes it difficult to determine which fish stock drives the economic value that anglers associate with fishing. Further, a 2014 NMFS study on the economic efficiency of red snapper allocations indicated that a relevant market price that could be used as a benchmark for the recreational estimates is unavailable. The study found that in prior work the agency attempted to use charter fishing trip prices to address this concern, but no current data on charter prices existed to update that

have economic allocation as its sole purpose. 16 U.S.C. § 1851(a)(5). National Standard 5 Guidelines state that this standard prohibits only those measures that distribute fishery resources on the basis of economic factors alone and that have economic allocation as their only purpose. 50 C.F.R. § 600.330(e). The guidelines also explain that given a set of objectives for the fishery, a fishery management plan should contain management measures that result in as efficient a fishery as is practicable or desirable. 50 C.F.R. § 600.330(b)(1).

<sup>&</sup>lt;sup>37</sup> More specifically, net economic benefits are maximized at the allocation where the marginal values are equalized across the commercial and recreational sectors. In principle, net benefits are measured in terms of changes in consumer and producer surplus. Consumer surplus is the difference between the amounts consumers are willing to pay for goods and services, and the amounts they actually pay. Producer surplus is the difference between the amounts producers actually receive for providing goods and services, and the economic cost producers incur in doing so.

<sup>&</sup>lt;sup>38</sup> According to NMFS' 2016 guidance, the councils should only use certain data points as measured by economic impact analyses to understand the potential short-term distributive effects of allocation decisions on the affected communities. For example, a change in an allocation may increase seafood sales and business income in one community but decrease them in another. However, NMFS officials said they discourage using economic impact analyses when considering allocations because economic impact analyses do not measure changes in economic welfare.

<sup>39</sup> Agar, Juan J. and David W. Carter, *Is the 2012 Allocation of Red Snapper in the Gulf of Mexico Economically Efficient?,* National Oceanic and Atmospheric Administration Technical Memorandum NMFS-SEFSC-659 (Miami, FL: June 2014).

<sup>40</sup> Agar, Juan J. and David W. Carter, *Are the 2012 Allocations of Gag, Red, and Black Grouper in the Gulf of Mexico Economically Efficient?,* National Oceanic and Atmospheric Administration Technical Memorandum NMFS-SEFSC-660 (Miami, FL: June 2014).

analysis.<sup>41</sup> As a result, the study cautioned against comparing estimates of recreational value to that in the commercial sector, which is a key aspect of determining an economically efficient allocation.

Moreover, two 2014 NMFS studies found that there are also methodological and data challenges related to obtaining economic information from the commercial fishing sector.<sup>42</sup> For example, the studies raised questions about the quality of some of the price data that were used in developing estimates of economic values for the commercial sector.<sup>43</sup> In addition, the studies' estimates of the economic value of commercial fishing did not include the potential net value derived from other components of the commercial seafood supply chain, such as the processing, distribution, and sale of the fish to the end consumers, according to the NMFS studies and agency officials (see Figure 5). <sup>44</sup> These NMFS studies noted that data for estimating the values from these other components are not readily available. Council staff and members, socioeconomic panel members, and fishery stakeholders we interviewed noted the importance of including the value of fish to the end consumers when considering the economic value of commercial fishing. To estimate the values of these other components of the commercial seafood supply chain, NMFS would need information about the consumer demand for fish as a function of domestic and international production, as well as information on changes in the price of the fish as they move from the dockside to retail markets, according to a separate NMFS study.<sup>45</sup>

NMFS officials said they are taking some steps related to improving economic analyses that the councils could consider in allocation reviews. For example, the agency is developing a manual of best practices for NMFS and council staff responsible for conducting economic analyses. NMFS officials said that they anticipate completing the manual by the end of fiscal year 2020. According to NMFS officials, the manual is intended to help (1) achieve consistency in analyses across the councils and regions, (2) establish an understanding of why economic analyses of allocations are important to fisheries management decisions, as well as their role in complying with various legal requirements and NMFS' policy, and (3) establish an understanding of the basic concepts and tools used in these analyses and how they are expected to be applied in practice. In addition, NMFS conducted a study on the economics of the for-hire fishing sector in federal waters of the South Atlantic and Gulf of Mexico and completed a report on the study at the end of 2019.<sup>46</sup> Among other things, agency officials said the study provides data sufficient to estimate producer surplus for the for-hire sector. This information could help inform future allocation decisions, according to NMFS officials.

<sup>41</sup> Agar and Carter, *Is the 2012 Allocation of Red Snapper in the Gulf of Mexico Economically Efficient?*.

<sup>42</sup> Agar and Carter, *Is the 2012 Allocation of Red Snapper in the Gulf of Mexico Economically Efficient?* and *Are the 2012 Allocations of Gag, Red, and Black Grouper in the Gulf of Mexico Economically Efficient?*.

<sup>&</sup>lt;sup>43</sup> Specifically, the 2014 NMFS studies used lease prices for commercial fishing quotas and other information to derive willingness to pay estimates for the commercial sector. However, the studies stated that many of the lease prices were low and that it is vital to ensure that correct prices are reported if the data are to be used in an economic analysis.

<sup>44</sup> Specifically, NMFS' 2014 studies indicated that the estimates of the economic value of commercial fishing did not include consumer surplus—the difference between the price that consumers pay and the price they are willing to pay for a service or product.

<sup>45</sup> Carter, David W., Juan J. Agar, and James R. Waters, *Economic Framework for Fishery Allocation Decisions with an Application to Gulf of Mexico Red Grouper*, National Oceanic and Atmospheric Administration Technical Memorandum NMFS-SEFSC-576 (Miami, FL: 2008).

Source: GAO. | GAO-20-216.

## **Social Indicators**

 $\overline{a}$ 

NMFS has developed social indicators to characterize community well- being for coastal communities engaged in fishing activities, which the councils could consider in reviewing allocations, according to NMFS officials. NMFS' 2016 guidance states that the councils could consider individual, local, and regional fishing dependence and engagement, and that such analyses should include potential impacts on commercial, for- hire, private angler, and subsistence fishing, as well as fishing-related industries if data are available. NMFS' social indicators are numerical measures that describe the well-being of fishing communities in coastal counties across the United States and their level of dependence on commercial and recreational fishing.  $47$  For example, one indicator describes the vulnerability of fishing communities to disruptive events, such as a change to a fishing sector's access to a fishery. Communities that are dependent on commercial fishing can be more socially vulnerable than other communities to changes, according to an NMFS document.

<sup>47</sup> For more information on NMFS' social indicators, see https://www.st.nmfs.noaa.gov/humandimensions/socialindicators/. See also Jepson, Michael and Lisa L. Colburn, *Development of Social Indicators of Fishing Community Vulnerability and Resilience in the U.S. Southeast and Northeast Regions,* U.S. Department of Commerce, National Oceanic and Atmospheric Administration Technical Memorandum NMFS-F/SPO-129 (St. Petersburg, FL: 2013).

However, NMFS' social indicators on communities' reliance on and engagement in commercial and recreational fishing are not specific to particular fish stocks. NMFS officials said this makes it challenging for councils to incorporate the information into their allocation reviews for specific fish stocks. The officials said that given current resource limitations and limited data available, it would be difficult to generate social indicators that are specific to fish stocks. In some instances, NMFS has some stock-specific information at the community level for the commercial fishing sector. <sup>48</sup> But NMFS officials said that comparable information is not available for the recreational sector at the community level, making it difficult to develop fish stock-specific social indicators.

NMFS officials said that the agency continues to work to update and improve social indicators relevant to recreational and commercial fisheries and is exploring other sources to provide better social data for fisheries management decisions. However, NMFS officials did not identify specific steps they plan to take to improve social indicators—such as developing information specific to particular fish stocks—so that the councils could more easily incorporate such information into their allocation reviews.

#### **Ecosystem Models**

 $\overline{a}$ 

NMFS' 2016 guidance calls for the councils to consider the potential ecological impacts of allocation alternatives in determining the allocation between different sectors or groups. However, NMFS officials said there are few ecosystem models that incorporate ecological information that could be considered in reviewing allocations, in part because limited quantifiable ecological information is available. They said that it will be difficult to use ecosystem models in allocation decisions until such models are more fully developed.

NMFS officials said they are taking some steps to enhance the use of ecological and ecosystem-based information. For instance, they noted that in 2016, NMFS released a policy to, among other things, establish a framework of guiding principles to enhance and accelerate the implementation of ecosystem-based fisheries management. <sup>49</sup> Ecosystem- based fisheries management is a systematic approach to fisheries management in a geographically specified area that: contributes to the resilience and sustainability of the ecosystem; recognizes the physical, biological, economic, and social interactions among the affected fishery- related components of the ecosystem, including humans; and seeks to optimize benefits among a diverse set of societal goals, according to the policy. Among other things, this approach can help communicate the potential consequences of management decisions—including allocations—across fish stocks and improve the understanding of the potential benefits and effectiveness of management decisions, according to the policy. In 2019, NMFS issued plans for implementing ecosystem- based fisheries management in the South Atlantic and Gulf of Mexico.<sup>50</sup>

<sup>48</sup> For example, NMFS has indicators of communities' engagement in and reliance on commercial fishing for certain fish stocks.

<sup>49</sup> U.S. Department of Commerce, National Oceanic and Atmospheric Administration, National Marine Fisheries Service, *Ecosystem-Based Fisheries Management Policy,* NMFS Policy 01-120 (effective May 23, 2016 and renewed September 27, 2018).

<sup>50</sup> U.S. Department of Commerce, National Oceanic and Atmospheric Administration, National Marine Fisheries Service, *Ecosystem Based Fisheries Management Implementation Plan for the South Atlantic* (May 2019) and *2019 Gulf of Mexico Ecosystem Based Fisheries Management Implementation Plan* (2019).

# **SOUTH ATLANTIC AND GULF OF MEXICO COUNCILS DEVELOPED CRITERIA FOR INITIATING ALLOCATION REVIEWS, BUT NOT PROCESSES FOR CONDUCTING OR DOCUMENTING THEM**

The South Atlantic and Gulf of Mexico councils each established criteria for initiating allocation reviews in response to NMFS' 2016 guidance, but neither council has developed processes to guide how they will conduct or document their allocation reviews. The Gulf of Mexico council has taken initial steps to develop a process for how it will review allocations, and staff from both councils said they are waiting for our report to inform their next steps on developing processes for conducting allocation reviews in the future.

# **Both Councils Established Criteria for Initiating Allocation Reviews**

The South Atlantic and Gulf of Mexico councils each developed policies that established criteria for initiating allocation reviews. The South Atlantic council's July 2019 policy established certain conditions as the primary criteria for triggering allocation reviews. Specifically, the policy states that the council is to initiate an allocation review for a particular fish stock if any of the following conditions are met: $51$ 

- the commercial or recreational fishing sector exceeds its annual catch limit or closes prior to the end of its fishing year in 3 out of 5 consecutive years;
- the commercial or recreational fishing sector under harvests its annual catch limit or optimum yield by at least 50 percent in 3 out of 5 consecutive years;<sup>52</sup>
- the council's scientific and statistical committee approves a stock assessment and presents it to the council; or
- $\bullet$  the council reviews a fishery performance report.<sup>53</sup>

The South Atlantic council's policy also established time-based triggers as secondary criteria for initiating allocation reviews. <sup>54</sup> Its policy states that the council will review

<sup>&</sup>lt;sup>51</sup> The South Atlantic council's policy also states that the council's allowance of harvest of speckled hind or warsaw grouper, which have annual catch limits of zero, would trigger an allocation review for those fish stocks.

 $52$  The Magnuson-Stevens Act defines optimum, with respect to the yield from a fishery, as the amount of fish that (1) will provide the greatest overall benefit to the nation, particularly with respect to food production and recreational opportunities and taking into account the protection of marine ecosystems; (2) is prescribed on the basis of the maximum sustainable yield from the fishery, as reduced by any relevant social, economic, or ecological factor; and (3) in the case of an overfished fishery, provides for rebuilding to a level consistent with producing the maximum sustainable yield in such fishery. 16 U.S.C. § 1802(33).

<sup>53</sup> South Atlantic council staff said they began in 2017 to develop fishery performance reports using information provided by the council's advisory panels—panels that include representatives from the recreational and commercial fishing sectors and conservation groups that may provide information about trends in fisheries, environmental concerns, and the impacts of any allocation changes. Each fishery performance report is to focus on a specific species and provide insights into regional differences, catch, and regulatory concerns, among other things, according to the council's website.

<sup>54</sup> The 2016 NMFS guidance also identified, as a third option, the potential for public interest-based triggers, to provide an opportunity for the public to express interest in allocation reviews. The South Atlantic council did not select public interest as an allocation review trigger because, according to the council's policy, the council provides sufficient opportunity for public input on allocations and receives substantial and regular comments from the public through scoping and public hearing sessions, general public comment periods held at every

allocations not less than every 7 years if one of the conditions identified in the policy has not already triggered a review. The policy also states that once a review occurs, the next one will be automatically scheduled for 7 years later.

#### **Regional Fishery Management Councils That Have Established Allocation Review Criteria**

Of the eight regional fishery management councils (councils), six developed policies by August 2019 establishing specific criteria for initiating allocation reviews. In addition to the South Atlantic and Gulf of Mexico councils, the other four councils' plans include the following:

- The New England council plans to review certain allocations 8 to 10 years after initial implementation.
- The Mid-Atlantic council plans to review Atlantic mackerel allocations at least every 3 years, spiny dogfish allocations at least every 5 years, and certain other allocations every 10 years.
- The North Pacific council plans to review allocations every 10 years.
- The Pacific council plans to review certain allocations every 1 to 2 years.

The four councils also identified public input as a potential allocation review trigger, but they did not specify what threshold of public interest would trigger a review.

The remaining two councils—the Western Pacific and Caribbean—do not have allocations subject to National Marine Fisheries Service (NMFS) policy requiring councils to establish allocation review criteria, according to NMFS officials.

#### Source: GAO analysis of council documents and information from NMFS officials. | GAO-20-216.

In contrast, the Gulf of Mexico council's April 2019 policy established time-based triggers as its primary criteria for initiating allocation reviews. Specifically, its policy indicates time intervals of 4 to 7 years for reviewing allocations, depending on the particular fish stock, and identifies the planned month and year for beginning each review. The council's policy also identified public interest as a secondary allocation review trigger but did not specify thresholds for the level or type of public input that would trigger an allocation review. According to the policy, the council is to consider relevant social, economic, and ecological conditions as an intermediate step before determining whether public interest will trigger a review.

According to NMFS' 2016 guidance, periodic review of allocations on a set schedule is in several respects the most simple and straightforward criterion for such a review—it is unambiguous and less vulnerable to political and council dynamics. The guidance also states that time-based triggers for initiating allocation reviews might be most suitable for fisheries where the conflict among sectors or stakeholder groups makes the decision to simply initiate a review so contentious that use of alternative criteria is infeasible. In such a situation, a fixed schedule ensures that periodic reviews occur regardless of political dynamics or specific fishery outcomes, according to the guidance. However, the guidance also indicates that, compared with alternative approaches, adherence to a fixed schedule may be less sensitive to other council priorities and the availability of time and resources to conduct such reviews, which could potentially lead to significant expenditures. Therefore, given the inflexible nature

l

council meeting, the public comment form on the council's website, and through other more informal channels.

of time-based triggers, the guidance recommends that they be used only in those situations where the benefit of certainty outweighs the costs of inflexibility.

The South Atlantic and Gulf of Mexico councils' policies laid out planned schedules for their respective allocation reviews, which both councils adjusted after issuing their policies. Table 5 shows both councils' plans for allocation reviews as of December 2019. For example, the Gulf of Mexico council's policy states that it plans to review the red grouper allocation in 2026. However, in response to the completion of an updated stock assessment for red grouper in July 2019, the council directed its staff in October 2019 to begin work on a fishery management plan amendment to update the red grouper allocation, according to a council document. <sup>55</sup> The stock assessment for red grouper included the Marine Recreational Information Program's updated estimates for recreational landings. The updated estimates approximately doubled previous estimates of recreational landings, according to a council newsletter. Council staff said that applying these updated estimates to the time series the council had used to establish the red grouper allocation could result in a percentage shift of the allocation to the recreational fishing sector.<sup>56</sup> As a result, the council decided to begin review of the red grouper allocation sooner than the policy's scheduled 2026 time frame, according to the staff.

In addition, we found that the councils' planned allocation review schedules may affect their workload and other priorities, but it is not clear to what extent. NMFS' 2016 allocation guidance states that the councils' allocation review processes should include consideration of current council priorities, other actions under deliberation, and available resources. NMFS officials and council staff expressed concern that the councils' planned schedules—as identified in their April and July 2019 policies—may negatively affect the workloads and other priorities of NMFS' social scientists, economists, and data analysts and council staff. For instance, staff from both councils said the planned allocation review schedules will increase their workloads and, depending on the nature and substance of how those reviews are conducted, could take resources away from other council activities and lead them to reprioritize or delay those activities. One council's staff also noted that the council members have a difficult time keeping up with existing workloads.

Further, NMFS officials stated the councils' accelerated schedules as of December 2019, as shown in Table 5, will exacerbate the concerns. These schedules include starting reviews for 50 allocations in the South Atlantic between 2019 and 2026, assuming no conditions trigger earlier reviews, and reviews for 10 allocations in the Gulf of Mexico between 2019 and 2026.<sup>57</sup> One NMFS official said that any additional workload for economists and social scientists in the Southeast Fisheries Science Center is difficult to anticipate because it will depend on the type of information the councils would like to use for the reviews and whether additional studies may be needed or data collected. Another NMFS official stated that the regional office will shift priorities from less important tasks and gain efficiencies where possible to accommodate the planned allocation reviews.

<sup>55</sup> The proposed amendment 53 to the fishery management plan for reef fish in the Gulf of Mexico addressed options for red grouper allocations.

<sup>&</sup>lt;sup>56</sup> According to NMFS and council documents, if the council used the same allocation formula that it used in establishing the allocation for red grouper, but applied the updated Marine Recreational Information Program's estimates from July 2019, then the allocation for the recreational fishing sector would shift from 24 percent to 41 percent, and the allocation for the commercial sector would shift from 76 percent to 59 percent.

<sup>57</sup> In addition, the Gulf of Mexico council plans to review some allocations between gear types, zones, states, or councils, according to the council's policy.

Note: The years shown represent the years in which the councils plan to begin—not necessarily complete—their allocation reviews. This table only includes reviews of allocations between the commercial and recreational fishing sectors or within the recreational sector. The Gulf of Mexico Fishery Management Council also plans to review red snapper allocations among the Gulf of Mexico states in 2024; allocations of king mackerel between zones and between gear types in 2025; and allocations between the Gulf of Mexico and South Atlantic Fishery Management Councils for black grouper, mutton snapper, and yellowtail snapper in 2026. According to South Atlantic Fishery Management Council staff, the council plans to use a single fishery management plan amendment in 2020 to review allocations for Atlantic spadefish; bar jack; black grouper; blackfin snapper; gray triggerfish; hogfish (Georgia-North Carolina stock); scamp; and the deepwater, grunts, jacks, porgy, shallow-water groupers, and snappers complexes.

#### **NMFS' and the Councils' Costs of Establishing, Reviewing, or Revising Allocations**

Establishing, reviewing, or revising allocations may involve a variety of costs, according to National Marine Fisheries Service (NMFS) officials and South Atlantic and Gulf of Mexico Regional Fishery Management Council (council) staff, such as:

- NMFS and council staff time for collecting data, conducting analyses, and developing recommendations and proposed revisions;
- council staff time for conducting scoping meetings, public workshops, and hearings; and
- travel, document preparation and review, and information dissemination.

NMFS officials and council staff said that factors that may affect these types of costs include the complexity of the analyses, the number of NMFS or council staff involved in the process, and the degree of public interest. Fishery management plan amendments that establish or revise allocations can be controversial, and will likely have more public hearings and opportunity for public comment than other types of amendments, according to NMFS officials and council staff.

NMFS officials and South Atlantic and Gulf of Mexico council staff said they have not tracked costs of establishing, reviewing, or revising allocations. The councils often make allocation decisions concurrently with other management actions, making it difficult to isolate costs.

Source: GAO analysis of information from NMFS officials and staff from the South Atlantic and Gulf of Mexico councils. | GAO-20-216.

# **Neither Council Has Developed a Process for How to Conduct or Document Allocation Reviews, Although the Gulf of Mexico Council Began Taking Steps to Develop One**

The South Atlantic and Gulf of Mexico councils have not developed processes for how they will conduct or document their allocation reviews to implement NMFS' 2016 policy and related guidance, although the Gulf of Mexico council has begun taking steps to do so. As noted, NMFS policy calls for a multi-step process for reviewing and potentially revising fisheries allocations. Specifically, once an allocation review trigger has been met, NMFS policy calls for an allocation review, after which the councils may maintain existing allocations or evaluate allocation options through a fishery management plan amendment. NMFS guidance states that the councils should develop a structured and transparent process for conducting allocation reviews, including consideration of current council priorities, other actions under deliberation, and available resources.

In April 2019, the Gulf of Mexico council began taking steps to develop an allocation review process, according to council documents. Specifically, the Gulf of Mexico council convened an allocation review workgroup consisting of staff from the council and from NMFS' Southeast Regional Office and Southeast Fisheries Science Center. The council expects the workgroup to propose draft allocation review procedures, including identifying data sources that would be needed to conduct allocation reviews, according to a council document. The workgroup met in June and July 2019 and discussed these topics and other potential proposals, such as establishing a tiered system for allocation reviews that would involve different levels of analysis for different tiers of reviews, according to council

documents. Council staff said the workgroup plans to next meet after the issuance of our report to finalize a proposal for developing an allocation review process for the council to consider. However, the council has not indicated what actions it will take, if any, regarding the workgroup's proposal; instead, the council will determine its course of action after reviewing this report, according to council staff.

The South Atlantic council postponed discussion of defining or documenting its allocation review process until March 2020, according to council staff and members, to review our report before deciding any next steps. At the council's June 2019 meeting, the council chair questioned the need for developing an allocation review process through policy. For instance, the chair cited concerns that the council may be continuously developing exceptions to such a policy to accommodate fishery-specific issues or other unique circumstances. The chair also stated that aside from establishing criteria for initiating allocation reviews, NMFS' guidance does not require the councils to take other actions related to developing allocation review processes.

NMFS officials said that the agency's 2016 guidance recommending that the councils develop a structured and transparent process was not intended to require the councils to develop a separate policy or documented process for conducting allocation reviews. NMFS officials said that the agency's operational guidelines for processes under the Magnuson-Stevens Act and associated regional operating agreements with the councils lay out the key requirements and processes guiding development, review, and implementation of fishery management plans and plan amendments, which would include actions related to allocations.<sup>58</sup> The officials further explained that in developing the 2016 allocation policy, they intended that allocation reviews be conducted through the processes identified in the agency's operational guidelines and regional operating agreements with the councils, which allow the councils flexibility to factor in their own needs.

However, the operational guidelines and regional operating agreements for the South Atlantic and Gulf of Mexico councils apply to the fishery management plan and amendment process overall, and they do not specifically address allocations. The goals of the operational guidelines include promoting a timely, effective, and transparent public process for development and implementation of fishery management measures, and the guidelines note that the regional operating agreements are meant to make council procedures and processes transparent. The guidelines and agreements, however, do not lay out processes the councils are to follow in reviewing allocations apart from developing fishery management plans or plan amendments. As noted in NMFS' 2016 policy and guidance, the councils may conduct allocation reviews separate from the fishery management plan amendment process. Moreover, the regional operating agreements are not intended to limit or prevent the councils' use of additional processes in response to specific management needs, according to these documents and the operational guidelines, and the Gulf of Mexico council has taken initial steps in developing an allocation review process as previously described.

Based on the framework for internal controls established by the Committee of Sponsoring Organizations of the Treadway Commission, documented policies and processes can be more difficult to circumvent, less costly to an organization if there is turnover in personnel, and

l

<sup>58</sup> National Marine Fisheries Service, *Operational Guidelines*; South Atlantic Fishery Management Council, *Operating Agreement*; and Gulf of Mexico Fishery Management Council, *Regional Operating Agreement.*

increase accountability. <sup>59</sup> The framework also states that when subject to external party review, policies and processes would be expected to be formally documented. Among other things, documented processes— according to the framework—promote consistency; assist in communicating the who, what, when, where, and why of internal control execution; enable proper monitoring; and provide a means to retain organizational knowledge and mitigate the risk of having the knowledge within the minds of a limited number of individuals.

The 2012 report commissioned by NMFS to review fisheries allocation issues found that allocation reviews had not been done in a regular, consistent manner and stated that this makes it harder for stakeholders to understand the reviews as well as the process for conducting them.<sup>60</sup> Similarly, stakeholders we interviewed indicated that a clear process for conducting allocation reviews is needed and would increase their confidence in or understanding of the councils' decisions, regardless of specific outcomes. <sup>61</sup> Other stakeholders stressed the need for predictability and certainty to be able to plan critical business decisions, such as securing loans from local banks or other lenders. Such uncertainty may cause participants in the commercial sector to leave the fishery because they cannot secure loans or meet other business requirements, according to one stakeholder, or it may create instability that could affect the market price of fish, according to another stakeholder. By working with the councils to develop documented allocation review processes, NMFS would have better assurance that the councils carry out their upcoming allocation reviews in a structured and transparent manner, consistent with the agency's 2016 guidance.

Further, it is unclear whether or how the councils plan to document each allocation review, such as the basis for their allocation decisions, whether fishery management plan objectives are being met, and what factors were considered in each review. <sup>62</sup> NMFS' operational guidelines state that fishery management decisions must be supported by a record providing the basis for the decision. In addition, NMFS' 2016 policy and guidance call for the councils to clearly articulate in their allocation reviews how fishery management plan objectives are or are not being met, as well as to document their rationale for determining whether any factors are unimportant or not applicable in making an allocation decision.

NMFS officials and council staff said that any allocation revisions would be documented through fishery management plan amendments. However, the councils may conduct allocation reviews separate from the fishery management plan amendment process, and it is not clear whether or how the councils will document those reviews. For example, as previously noted, in the past the South Atlantic council has not formally documented the results of allocation reviews that did not lead to fishery management plan amendments that

<sup>59</sup> Committee of Sponsoring Organizations of the Treadway Commission, *Internal Control- Integrated Framework*.

<sup>60</sup> Lapointe, *Marine Fishery Allocation Issues*.

<sup>&</sup>lt;sup>61</sup> These stakeholder views are consistent with our past work on effective stakeholder participation in fisheries management, in which we found that using a clearly defined decision-making process helps provide transparency and gives stakeholders clear expectations about how decisions will be made, enhancing understanding and trust in the organization's decisions. See GAO, *Fisheries Management: Core Principles and a Strategic Approach Would Enhance Stakeholder Participation in Developing Quota-Based Programs*, GAO-06-289 (Washington, D.C.: Feb. 23, 2006).

 $62$  According to South Atlantic council staff, the council has begun using a spreadsheet to track allocation discussions and plans to develop an electronic tracking system. The spreadsheet tracks allocation percentages and dates of associated fishery management plan amendments, and it will capture future discussions of potential allocation revisions, according to council staff. However, the spreadsheet does not contain information on the basis for the council's decisions, whether fishery management plan objectives are being met, and what factors were considered in reviewing the allocations.

revised the allocations. By working with the councils to specify how they plan to document their allocation reviews, NMFS could help ensure that the councils provide a clear record of the basis for their decisions, whether fishery management plan objectives are being met, and applicable factors considered. Clear records could also help increase transparency and stakeholder understanding of the councils' decisions, particularly in those instances when reviews are separate from the fishery management plan amendment process.

## **CONCLUSION**

Making allocation decisions between the commercial and recreational fishing sectors can be complex and difficult, and the outcomes of those decisions may have important economic and social implications for stakeholders in each of the sectors. The South Atlantic and Gulf of Mexico councils have taken an important step in developing policies outlining criteria for initiating allocation reviews, in accordance with NMFS guidance. The Gulf of Mexico council has also taken initial steps to define how it will conduct its allocation reviews. However, neither council has developed a process for how they will conduct such reviews. By working with the councils to develop documented allocation review processes, NMFS would have better assurance that the councils carry out their upcoming allocation reviews in a structured and transparent manner, consistent with the agency's 2016 guidance. Moreover, by working with the councils to also specify how they plan to document their allocation reviews, NMFS could help ensure that the councils provide a clear record of the basis for their decisions, whether fishery management plan objectives are being met, and applicable factors considered.

# **RECOMMENDATIONS FOR EXECUTIVE ACTION**

We are making the following two recommendations to the NMFS Assistant Administrator for Fisheries:

The NMFS Assistant Administrator for Fisheries should work with the South Atlantic and Gulf of Mexico councils, and other councils as appropriate, to develop documented processes for conducting allocation reviews. (Recommendation 1)

The NMFS Assistant Administrator for Fisheries should work with the South Atlantic and Gulf of Mexico councils, and other councils as appropriate, to specify how the councils will document their allocation reviews, including the basis for their allocation decisions, whether fishery management plan objectives are being met, and what factors were considered in the reviews. (Recommendation 2)

# **AGENCY COMMENTS AND OUR EVALUATION**

We provided a draft of this report to the Department of Commerce for review and comment. In written comments (reproduced in app. II), Commerce and NOAA agreed with our recommendations and stated that NOAA's NMFS will work to implement them to the extent possible. NOAA stated that the report accurately describes the extent to which the councils established and revised allocations for mixed-use fisheries, the key sources of information that may be available for reviewing allocations, and the extent to which the councils have developed processes to help guide such reviews. NOAA also highlighted the delicate balance that councils seek to achieve in deciding what fishery management approaches to implement to comply with the Magnuson-Stevens Act and its 10 national standards.

In addition, Commerce and NOAA stated that NMFS does not have the legal authority to direct the councils to take the actions included in our two recommendations, stating that such actions are outside of legal requirements that guide council fishery management actions. In response, we revised the wording of our two recommendations to state that the NMFS Assistant Administrator for Fisheries should "work with," rather than "direct," the councils to take the recommended actions.

In response to our first recommendation, NOAA stated that it would build on the recommendations in its allocation policy by working with the South Atlantic and Gulf of Mexico councils, and other councils as appropriate, to develop documented processes for conducting allocation reviews. In response to our second recommendation on specifying how the councils will document their allocation reviews, NOAA stated that it will work with the councils on consistent documentation of allocation reviews. NOAA noted that transparency in the allocation process improves with a documented process for conducting allocation reviews, and that consistent documentation of those reviews will create further transparency in the allocation process and could improve stakeholders' understanding of the councils' decisions. NOAA also provided technical comments, which we incorporated as appropriate.

Anne-Marie Fennell Director, Natural Resources and Environment

# **APPENDIX I: MIXED-USE FISHERIES ALLOCATIONS IN THE SOUTH ATLANTIC AND GULF OF MEXICO FISHERY MANAGEMENT COUNCIL REGIONS**

Tables 6 and 7 provide information on mixed-use fisheries allocations— privileges for catching fish between the commercial and recreational fishing sectors—in the South Atlantic and Gulf of Mexico Fishery Management Council (council) regions, respectively.<sup>63</sup> Not all mixed-use fish stocks in these regions have allocations. In the South Atlantic council region,

<sup>&</sup>lt;sup>63</sup> The National Marine Fisheries Service (NMFS) defines an allocation of fishing privileges as a direct and deliberate distribution of the opportunity to participate in a fishery among identifiable, discrete user groups or individuals. 50 C.F.R. § 600.325(c)(1). In our report, we consider for-hire fishing (both charter fishing and head boats) to be part of the recreational fishing sector because the South Atlantic and Gulf of Mexico councils generally manage for-hire fishing as part of the recreational sector, according to council staff. A fishery refers to one or more fish stocks that can be treated as a unit for conservation and management purposes and that are identified on the basis of geographical, scientific, technical, recreational, and economic characteristics. A fish stock refers to a species, subspecies, geographical grouping, or other category of fish capable of management as a unit. A fish stock may be one species or a complex of comparable species.

spiny lobster does not have an allocation.<sup>64</sup> In the Gulf of Mexico council region, 14 of 23 mixed-use fish stocks do not have allocations.<sup>65</sup>

# **Table 6. Mixed-use fish stock allocations in the South Atlantic Fishery Management Council Region, as of December 2019**

<sup>64</sup> South Atlantic council staff said spiny lobster does not have an allocation because fishing primarily occurs in the waters off Florida, where the state takes the lead in regulating this fishery through a protocol developed with NMFS and the South Atlantic and Gulf of Mexico councils. Outside of these Florida state-managed waters, spiny lobster fishing is subject to a two lobsters-per-person, per-trip catch limit, according to a council document.

<sup>65</sup> Specifically, the Gulf of Mexico council has not established allocations for the following mixed-use fish stocks:  $(1)$  cobia; (2) corals; (3) cubera, (4) gray, (5) lane, (6) mutton, (7) vermillion, and (8) yellowtail snapper; (9) goliath grouper; (10) hogfish; (11) Spanish mackerel; (12) spiny lobster; (13) the Jacks complex (almaco jack, banded rudderfish, and lesser amberjack); and (14) the mid-water snapper complex (blackfin snapper, queen snapper, silk snapper, and wenchman).

#### **Table 6. (Continued)**

Legend:  $\_\ =$  not applicable.

Source: GAO analysis of South Atlantic Fishery Management Council documents and information from council staff. | GAO-20-216.

- Note: This table includes fish stocks that have allocations between the commercial and recreational fishing sectors. Fish stocks listed by complex are managed together as a group. For this report, we count a complex as a single fish stock if the allocation is for the stock complex, rather than for the individual stock within the complex. If the fish stocks within a complex each have their own allocations, we count them as separate fish stocks for reporting purposes. The years shown represent the year the council completed a fishery management plan amendment and sent it to the National Marine Fisheries Service (NMFS) for review and approval. The South Atlantic Fishery Management Council has set allocation percentages to two decimal places, as indicated in this table.
- <sup>a</sup>Prior to the initial allocations shown in this table, NMFS and the South Atlantic Fishery Management Council managed black grouper, red grouper, and gag grouper as a complex, including establishing one combined allocation for the three fish stocks.
- <sup>b</sup>In 2016, the South Atlantic Fishery Management Council split the South Atlantic hogfish fish stock into two and established allocations for Georgia-North Carolina hogfish and Florida Keys/East Coast of Florida hogfish.

<sup>c</sup>Allocation shown is for the Georgia-North Carolina hogfish stock.

<sup>d</sup>Allocation shown is for the Florida Keys/East Coast of Florida hogfish stock.

<sup>e</sup>Harvest is not allowed for speckled hind and warsaw grouper as of December 2019.

<sup>f</sup>Saucereye porgy in the South Atlantic is, in practice, a recreational fish stock, according to South Atlantic Fishery Management Council staff. Council staff indicated that because the total annual catch limit for the fish stock is low, there is no commercial fishing in practice for the stock.

# **Table 7. Mixed-use fish stock allocations in the Gulf of Mexico Fishery Management Council Region, as of December 2019**

 $Legend: — = not applicable.$ 

Source: GAO analysis of Gulf of Mexico Fishery Management Council documents and information from council staff and National Marine Fisheries Service (NMFS) officials. | GAO-20-216.

- Note: This table includes fish stocks that have allocations between the commercial and recreational fishing sectors. Fish stocks listed by complex are managed together as a group. For this report, we count a complex as a single fish stock if the allocation is for the stock complex, rather than for the individual stock within the complex. If the fish stocks within a complex each have their own allocations, we count them as separate fish stocks for reporting purposes. The years shown represent the year the council completed a fishery management plan amendment and sent it to the National Marine Fisheries Service for review and approval.
- <sup>a</sup>For greater amberjack, the council did not revise the allocation directly; instead, the council indirectly revised the commercial and recreational allocations by establishing harvest reductions that were applied unequally to these fishing sectors, according to a 2008 fishery management plan amendment.
- <sup>b</sup>In addition, in 2014 the Gulf of Mexico Fishery Management Council finalized a fishery management plan amendment that established an allocation between the private angling and for-hire components of the recreational allocation for red snapper. This resulted in a private angling allocation of 57.7 percent of the recreational allocation and a for-hire fishing allocation of 42.3 percent of the recreational allocation.
- c In 2015, the Gulf of Mexico Fishery Management Council completed a fishery management plan amendment that revised the red snapper allocation to 48.5 percent commercial and 51.5 percent recreational. However, after the Secretary of Commerce approved the amendment in 2016, a U.S. District Court vacated the amendment in 2017 and the council returned to the initial allocation established for red snapper. *See Guindon v. Pritzker*, 240 F. Supp. 3d 181 (D.D.C. 2017).
- <sup>d</sup>Fish stocks managed as part of a complex in the Gulf of Mexico do not have individual allocation percentages for each fish stock. Instead, the Gulf of Mexico Fishery Management Council established allocation percentages for each complex as a whole, based on quotas for commercial fishing established for these complexes. Recreational allocation percentages for the complexes represent the remainder of allowable harvest, after factoring in quota amounts, according to NMFS officials. Allocation percentages for these complexes are presented to one decimal point to reflect percentages provided by the Gulf of Mexico Fishery Management Council.

# **APPENDIX II: COMMENTS FROM THE DEPARTMENT OF COMMERCE**

UNITED STATES DEPARTMENT OF COMMERCE The Secretary of Commerce<br>Washington, D.C. 20230

March 17, 2020

Ms. Anne-Marie Fennell Director Natural Resources and Environment U.S. Government Accountability Office 441 G Street, NW Washington, DC 20548

Dear Ms. Fennell:

Thank you for the opportunity to review and comment on the Government Accountability Office's (GAO) draft report Mixed-Use Fisheries: South Atlantic and Gulf of Mexico Councils Would Benefit from Documented Processes for Allocation Reviews (GAO-20-216).

The Department of Commerce agrees with GAO's two recommendations regarding the National Oceanic and Atmospheric Administration (NOAA) and will work to implement them to the extent possible. Specifically, NOAA's National Marine Fisheries Service (NMFS) will work with the fishery management councils on these recommendations; however, neither the Department nor NMFS has the authority to direct councils to take action. Enclosed is our response and recommended technical changes to the draft report.

If you have any further questions, please contact MaryAnn Mausser, GAO Liaison, at (202) 482-8120 or mmausser@doc.gov.

Sincerely.

Enclosure

**Department of Commerce** National Oceanic and Atmospheric Administration **Response to the GAO Draft Report Entitled** Mixed-Use Fisheries: South Atlantic and Gulf of Mexico Councils **Would Benefit from Documented Processes for Allocation Reviews** (GAO-20-216, March 2020)

#### **General Comments**

The Department of Commerce's National Oceanic and Atmospheric Administration (NOAA) appreciates the opportunity to review the Government Accountability Office's (GAO) report. GAO does a thorough job in reviewing allocations for mixed-use fisheries in the South Atlantic and Gulf of Mexico. The report accurately describes the extent to which the fishery management councils (councils) established and revised allocations to mixed-use fisheries, the key sources of information that may be available for reviewing allocations, and the extent to which the councils have developed processes to help guide such reviews.

We appreciate the report's acknowledgment of the National Marine Fisheries Service's (NMFS) 2016 Allocation Policy, which required councils to identify allocation triggers for all fisheries with an allocation, including allocations to mixed-use fisheries. The recommendations from this report (see below) reiterate the importance of this policy and request documentation of the process and results consistent with the policy. We also appreciate the report's discussion of the various data challenges, in particular for economic analyses, as well as acknowledgment of NMFS efforts to address these challenges such as our upcoming best practices manual on conducting economic analyses for use in allocation decisions.

We would like to highlight the delicate balance that councils seek to achieve in deciding what fishery management approaches to implement so that there is compliance with all ten national standards and other Magnuson-Stevens Fishery Conservation and Management Act (MSA) requirements. When considering the different means by which the conservation goals of the MSA can be achieved, the councils can consider the potential trade-offs between the national standards. For example, maintaining employment may be in conflict with improving economic efficiency. Similarly, long-term goals related to rebuilding stocks may also be in conflict with short-term goals of minimizing impacts on fishery-dependent communities. Updated and measurable objectives help clarify decisions about these trade-offs within and between fishery management plans (FMP).

#### **NOAA Response to GAO Recommendations**

The draft GAO report made two recommendations:

Recommendation 1: "The NMFS Assistant Administrator for Fisheries should direct the South Atlantic and Gulf of Mexico councils, and other councils as appropriate, to develop documented processes for conducting allocation reviews."

NOAA Response: Building on recommendations in the Allocation Policy, we will work with the South Atlantic and Gulf of Mexico Councils, and other councils as appropriate, to develop

documented processes for conducting allocation reviews. However, NOAA lacks authority to "direct" the council to take such action as it is outside of legal requirements that guide council fishery management actions. We suggest that GAO reword the recommendation to say, "The NMFS Assistant Administrator for Fisheries should work with..." instead of "should direct."

Note that a fishery allocation review is the initial evaluation that leads to the decision of whether or not to maintain current allocations or develop alternative allocation options, as described in the Allocation Policy. It does not require in-depth data and analyses and is not, in and of itself, an implicit trigger to consider alternative allocations. Because they may or may not lead to a fishery management action, these initial reviews are not currently documented in a consistent way and could benefit from established or documented processes. If following an initial allocation review, a council proceeds with a formal analysis to consider alternative allocations, this would occur through the fishery management plan process. These processes are well established and documented through the agency's Operational Guidelines and associated Regional Operating Agreements.

Transparency in the allocation process improves with a documented process for conducting allocation reviews. NOAA looks forward to working with the councils in implementing these recommendations.

Recommendation 2: "The NMFS Assistant Administrator for Fisheries should direct the South Atlantic and Gulf of Mexico councils, and other councils as appropriate, to specify how the councils will document their allocation reviews, including the basis for their allocation decisions, whether fishery management plan objectives are being met, and what factors were considered in the reviews."

NOAA Response: We will work with the South Atlantic and Gulf of Mexico Councils, and other councils as appropriate, on consistent documentation of allocation reviews. However, NOAA lacks authority to "direct" the council to take such action as it is outside of legal requirements that guide council fishery management actions. We suggest that GAO reword the recommendation to say, "The NMFS Assistant Administrator for Fisheries should work with..." instead of "should direct."

Consistent documentation of allocation reviews, including timing, factors considered, summaries of how the fishery is or is not meeting its objectives, and the basis of final decisions to keep status quo or proceed to the FMP amendment process will create further transparency in the allocation process. Clear records could also improve stakeholder understanding of the councils' decisions, particularly in those instances when reviews do not result in pursuit of alternative allocations through the FMP amendment process. NOAA looks forward to working with the councils in implementing these recommendations.

biopolymers, 1326, 1954, 1957, 1960, 2042, 2990

- bioprocesses, 1289, 1414, 1435
- bioproducts, 1351, 1375, 1377, 1413, 1414, 1415, 1429, 1432, 1435, 1726, 1942, 1944, 1979, 2028, 2050
- bioreactor, 1336, 1380, 1394, 1952, 2378, 3517
- bioreductant, 1981, 1982
- biorefinery, xi, xiii, 1293, 1298, 1299, 1347, 1350, 1351, 1354, 1361, 1365, 1367, 1371, 1373, 1374, 1375, 1382, 1413, 1414, 1415, 1419, 1420, 1422, 1423, 1424, 1425, 1426, 1431, 1432, 1435, 1436, 1437, 1439, 1440, 1441, 1719, 1726, 1813, 1814, 1818, 1825, 1827, 1828, 1837, 1925, 1926, 1932, 1933, 1935, 1936, 1937, 1938, 1939, 1941, 1942, 1943, 1944, 1945, 1946, 1947, 1948, 1949, 2003, 2071, 2081, 2082
- bioremediation, xiii, 1369, 1422, 1433, 1730, 1736, 1741, 1746, 1818, 1851, 1858, 1928, 2055, 2056, 2057, 2058, 2061, 2063, 2064, 2065, 2066, 2069, 2371, 2378, 2380, 2831, 3253, 3321, 3340, 3387, 3388
- bioscrubbing, 2799
- biosorbent, 1435, 1935, 1939, 1981, 1982, 1983, 1993, 1998, 2000, 2001, 2002, 2004, 2005, 2007, 2060, 2061, 2067

biosorption, 1936, 1937, 1938, 1940, 1941, 1942, 1981, 1985, 1986, 1987, 1988, 1989, 1998, 2002, 2004, 2005, 2007, 2008, 2009, 2059, 2061, 2065, 2066, 2067, 2068, 2069, 2070, 3406

- biostimulants, 1956, 1963, 2019
- biosynthesis, 30, 258, 754, 760, 763, 1304, 1321, 1322, 1386, 1394, 1395, 1396, 1397, 1398, 1400, 1405, 1406, 1408, 1430, 1434, 1437, 1626, 1701, 1899, 1999, 2000, 2002, 2003, 2006, 2024, 2114, 2787, 3189, 3476, 3688, 3790, 3845, 3846, 3847, 3848, 3868, 3903, 3911, 3997, 4007, 4008, 4014, 4018, 4019, 4020, 4021, 4022
- biotic factors, 380, 574, 684, 2216, 2248, 3148, 3481, 3482, 3483, 3484, 3488, 3824
- biotrickling, 2799
- bioturbation, xv, 641, 642, 647, 649, 650, 652, 1748, 1876, 1914, 1921, 2190, 2198, 2207, 2220, 2222, 2223, 2229, 2431, 2432, 2433, 2434, 2447, 2454, 2459, 3228, 4055
- bivalve mollusks, 497, 906, 1657, 1659, 1748, 2816, 2817, 2818, 2820, 2847, 2887, 3245
- blindness, 2302
- blue whiting, 975, 976, 977, 978, 979, 980, 981, 982, 983, 984, 985, 1711
- bluefin group, 2357
- body length, 213, 955, 1359, 1485, 1497, 1594, 1613, 1640, 1651, 1655, 1661, 1663, 1664, 2186,

2210, 2221, 2274, 2506, 2507, 2511, 2512, 3109, 3318 *Bohadschia* sp., 260, 267 bootstrap confidence intervals, 2464, 2467, 2470, 2471, 2499 *Bosmina* spp., 2212 bothriocephalosis, 2224, 2284, 2306 *Bothriocephalus*, 2219, 2306, 2316, 2317, 2319, 2320, 2321 bottlenose dolphin, 619, 620, 623, 624, 625, 626, 627, 630, 633, 634, 635, 636, 637, 638, 639, 913, 931, 932, 950, 952, 958, 960, 963, 966, 972, 973, 2747, 3131, 3132, 3133, 3689, 3710, 4004 bottom dwellers, 2141, 2144 bottom-up processes, 2191, 2222 botulism, 2185, 2198 bovine lactoferricin, 1394, 1402 *Brachybacterium*, 1889 brachycladiidae, 912, 914, 916, 946, 947, 949, 955 brain, 5, 27, 29, 32, 104, 299, 300, 301, 302, 303, 304, 305, 306, 307, 309, 310, 312, 313, 314, 315, 318, 319, 320, 322, 323, 325, 326, 327, 328, 329, 330, 331, 341, 359, 374, 664, 713, 745, 876, 877, 912, 1646, 1649, 1675, 1685, 1686, 1832, 1862, 2026, 2047, 2108, 2109, 2235, 2238, 2239, 2240, 2241, 2245, 2252, 2277, 2278, 2293, 2299, 2457, 2789, 2821, 2858, 2860, 2862, 2863, 2864, 2865, 2866, 2867, 3001, 3004, 3017, 3066, 3142, 3161, 3230, 3378, 3379, 3380, 3878, 4113 branchial sieve, 2187 branchyomycosis, 2284, 2286 brauninidae, 912, 914, 916, 950 Brazilian Rookeries, 134, 136, 139, 140, 141, 142, 143, 144, 145, 148, 160, 867 BrdU, 305, 322, 368, 663 breeding, xiv, 122, 126, 162, 175, 179, 343, 345, 621, 623, 624, 625, 628, 671, 772, 786, 790, 792, 825, 834, 838, 840, 842, 843, 846, 847, 848, 849, 859, 860, 861, 868, 869, 1209, 1213, 1408, 1476, 1563, 1741, 1744, 2073, 2093, 2094, 2098, 2099, 2107, 2143, 2153,2157, 2158, 2159, 2161, 2162, 2163, 2164, 2165, 2166, 2167, 2168, 2169, 2170, 2171, 2175, 2176, 2177, 2178, 2180, 2181, 2198, 2256, 2262, 2265, 2274, 2358, 2366, 2387, 2439, 2457, 2546, 2556, 2749, 2750, 2794, 2818, 3109, 3324, 3342, 4036, 4108, 4109 breeding line(s), 2161, 2162, 2163, 2164, 2165, 2166, 2167, 2168, 2169, 2170, 2171, 2175, 2176, 2177, 2179, 2180, 2181 brevetoxin, 710, 711, 718, 720, 722, 905, 1710, 3682, 3689, 3690, 3707, 3708, 3709, 3710, 3716, 3718, 3719, 3736, 3737, 3741, 3838, 3866, 3868, 4003, 4008, 4013, 4021, 4027, 4050

broad genomic and transcriptional analysis reveals a highly derived genome in dinoflagellate mitochondria, 4015 bromex, 2301

bromodeoxyuridine, 322

broodstock, 182, 183, 184, 197, 209, 210, 211, 213,

- 214, 215, 272, 1211, 1217, 1222, 1734, 4109
- brown ghost *Apteronotus leptorhynchus*, 320
- bullfrog, 320, 1045

buoyancy, 106, 1599, 1626, 2073, 3289, 3920, 4060

- burrow, xv, 649, 651, 661, 1066, 2431, 2432, 2433, 2434, 2435, 2436, 2437, 2438, 2439, 2441, 2442, 2443, 2445, 2446, 2447, 2448, 2449, 2450, 2451, 2452, 2453, 2454, 2455, 2456, 2458, 2459, 2460, 2461, 2511, 2512, 2525, 4037
- b–value, 2142, 2148
- by-product(s), 36, 1334, 1353, 1431, 1925, 1926, 1928, 1929, 1930, 1931, 1932, 1933, 1934, 1935, 1936, 1937, 1938, 1939, 1940, 1941, 1945, 1951, 1959, 1960, 1982, 2028, 2055, 2056, 2057, 2058, 2059, 2060, 2061, 2062, 2064, 2068, 2072, 2795, 2796, 2797, 2812, 3220, 3396

- volatile organic compounds (VOC), 2795, 2799, 2801, 2803, 2805, 2806, 2807, 2808

#### **W**

warepan stage, 1119, 1120, 1121, 1123, 1128, 1130 waste management, 1426, 2577, 2582, 2583, 2587, 2590, 2596, 2601, 2603, 2606, 2726, 2745, 2769, 2793, 2820, 2915, 2916, 2924, 2925, 2926, 2927, 2928, 2933, 2934, 2935, 2939, 2941, 2942, 2944, 2946, 2947, 2949, 2950, 2953, 2956, 2957, 2958, 2976, 2990, 2996, 2997, 3008, 3009, 3013, 3014, 3019, 3020, 3022, 3023, 3025, 3026, 3030, 3031, 3033, 3035, 3036, 3037, 3040, 3041, 3042, 3046, 3047, 3050, 3051, 3053, 3056, 3059, 3063, 3065, 3068, 3069, 3073, 3074, 3075, 3077, 3083, 3085, 3086 waste recycling, 1731, 1736, 1741, 3093 wastes, 276, 481, 483, 508, 595, 1413, 1422, 1746, 1821, 1827, 1836, 1837, 1925, 1926, 1928, 1929, 1930, 1931, 1932, 1934, 1935, 1936, 1938, 1939,

1940, 1941, 1943, 1944, 1959, 1960, 1965, 2073, 2079, 2085, 2221, 2810, 2821, 2837, 2928, 2931, 3069, 3287, 3342, 3394, 4088, 4103, 4104, 4105, 4107, 4110, 4112

wastewater treatment plants, 1426, 2584, 3057, 3189, 3281, 3296, 3298, 3300

- wastewaters, 1370, 1439, 1516, 1986, 1995, 1999, 2005, 2006, 2055, 2068, 2230, 2802, 2810, 3293, 3395
- water bodies, 335, 906, 1044, 1045, 1084, 1494, 1618, 1734, 1767, 1910, 1918, 2208, 2222, 2247,

2579, 2772, 3057, 3069, 3157, 3230, 3261, 3279, 3281, 3290, 3305, 3394, 3705, 4104

- water column, 54, 383, 395, 397, 401, 403, 405, 406, 442, 484, 511, 797, 898, 906, 1154, 1240, 1249, 1250, 1251, 1252, 1266, 1267, 1269, 1270, 1450, 1457, 1480, 1487, 1488, 1499, 1500, 1504, 1518, 1532, 1548, 1599, 1644, 1653, 1659, 1664, 1676, 1703, 1735, 1736, 1740,1851, 2089, 2090, 2154, 2187, 2214, 2220, 2302, 2324, 2325, 2336, 2337, 2342, 2344, 2345, 2465, 2545, 2763, 2772, 2894, 2965, 3228, 3233, 3262, 3266, 3267, 3273, 3312, 3483, 3488, 3489, 3531, 3692, 3693, 3702, 3703, 3705, 3711, 3719, 3806, 3808, 3809, 3905, 3906, 3924, 3926, 3927, 3928, 3929, 3938, 3940, 3971, 3979, 4056, 4078, 4104, 4105, 4106, 4123
- water pollution, 295, 483, 1147, 1171, 1426, 2058, 2059, 2095, 2096, 2097, 2221, 2567, 2573, 2577, 3147, 3157, 3163, 3390, 3872, 3933, 4104
- water quality, 450, 510, 545, 628, 1044, 1081, 1091, 1094, 1278, 1355, 1378, 1533, 1538, 1544, 1560, 1703, 1731, 1736, 1740, 1767, 1851, 1860, 2057, 2068, 2092, 2093, 2094, 2098, 2158, 2195, 2197, 2199, 2200, 2201, 2202, 2203, 2204, 2208, 2216, 2220, 2221, 2223, 2232, 2252, 2284, 2285, 2288, 2289, 2290, 2294, 2298, 2300, 2315, 2330, 2575, 2627, 2637, 2638, 2670, 2678, 2686, 2694, 2736, 2761, 2815, 2832, 2833, 2932, 2995, 3146, 3167, 3170, 3300, 3312, 3343, 3349, 3350, 3375, 3382, 3708, 3745, 3805, 3817, 3820, 3901, 3933, 3937, 3972, 3979, 4025, 4027, 4028, 4029, 4060, 4090, 4097, 4103, 4104, 4107
- water temperature, 57, 296, 352, 353, 357, 463, 464, 466, 525, 680, 717, 796, 806, 1180, 1209, 1212, 1469, 1501, 1504, 1518, 1532, 1568, 1570, 1571, 1574, 1575, 1577, 1578, 1579, 1580, 1583, 1585, 1664, 1666, 1696, 1716, 1733, 2089, 2092, 2093, 2095, 2151, 2152, 2153, 2188, 2194, 2211, 2216, 2236, 2287, 2289, 2290, 2291, 2293, 2294, 2295, 2296, 2297, 2298, 2300, 2302, 2306, 2310, 2311, 2325, 2336, 2337, 2341, 2345, 2346, 2358, 2359, 2360, 2465, 2494, 2497, 2501, 2546, 2782, 2794, 2816, 2874, 3107, 3170, 3173, 3177, 3179, 3181, 3553, 3600, 3610, 3638, 3705, 3826, 3831, 3926, 3933
- water transparency, 464, 1641, 1810, 2209, 2217, 2221
- water turbidity, 1518, 2142, 2289

water-cooling, 2799

- weight loss, 1723, 1817, 1984, 1987, 2300, 2303, 2311, 4060
- western coast of Portugal, 1536, 1560, 1588, 1766, 1767

vulnerable taxa, 2207, 2216

wet deposition, 3259, 3262, 3263, 3264, 3267, 3268, 3273, 3274, 3276, 3287 wet scrubber, 2799 wetlands, 476, 619, 623, 630, 633, 638, 827, 828, 1066, 1083, 1087, 2153, 2156, 2231, 2454, 2458, 2460, 2749, 2845, 3219, 3243, 3302, 3306, 3354 wild animal toxicity, 3231 wind speed, 467, 3170, 3263, 3264, 3265, 3266, 3268, 3288, 3690 winter convective mixing, 3925 worms, 196, 346, 647, 659, 664, 728, 945, 959, 1657, 1736, 1741, 1749, 2149, 2308, 2322, 2536, 2570,

3249, 3358, 4137

#### **X**

xanthophyll, 1390, 1398, 1400, 1405, 2052 xenbobiodiversity, 3943

## **Y**

- yeast, 767, 1309, 1313, 1316, 1326, 1327, 1332, 1340, 1346, 1353, 1357, 1817, 1818, 1820, 1825, 1826, 1827, 1830, 1882, 1883, 1885, 1886, 1978, 2033, 2069, 2074, 2081, 2083, 2085, 2202, 2262, 2267, 3511
- yellowfin group, 2357, 4218, 4219, 4224, 4227, 4239, 4246, 4247
- yellowfin porgy growth hormone (YPGH), 1394, 1395, 1402
- yellowfin tuna, 1028, 1234, 2357, 2358, 2362, 2363, 2365, 2368, 2369, 2370, 3455
- yessotoxin, 710, 711, 718, 719, 720, 722, 723, 1154, 1167, 1168, 1169, 1170, 1172, 1175, 1254, 1258, 1259, 1272, 1273, 1274, 1277, 1278, 1279, 1280, 3476, 3517, 3542, 3836, 3890, 3895, 3896, 3971, 4013, 4018, 4054, 4069
- yolk sac, 775, 2210

#### **Z**

Zash-1a, 307

- Zash-1b, 307
- zeaxanthin, 1350, 1355, 1362, 1368, 1382, 1386, 1398, 1400, 1429, 1430, 1720, 3461, 3775
- zebrafish, 23, 300, 301, 302, 303, 305, 306, 307, 308, 309, 310, 311, 312, 313, 314, 315, 318, 320, 322, 327, 328, 329, 330, 370, 372, 375, 376, 377, 378, 675, 1410, 1411, 1938, 2115, 2789, 2790, 2834, 4023
- zebrafish *Danio rerio*, 320
- Zeocin, 1391, 1393, 1402
- Zic1, 322
- Zic3, 322
- ZO1, 322
- zoobenthos, 2094, 2183, 2184, 2185, 2188, 2190, 2191, 2194, 2210, 2221, 2266
- zoobenthos assemblages, 2190
- zoonotic diseases, 965
- zooplankters, 1678, 2213, 2221
- zooplankton abundance, 1197, 1456, 1476, 1482, 1483, 1487, 1490, 1517, 1551, 1552, 1557, 1561, 1580, 2194, 2216, 2221, 3491
- zooplankton community, 1447, 1479, 1480, 1498, 1504, 1510, 1512, 1540, 1542, 1543, 1545, 1553, 1557, 1558, 1568, 1583, 1589, 1596, 1618, 1621, 1627, 1642, 1671, 1672, 2191, 2200, 2202, 2207, 2209, 2211, 2213, 2214, 2216, 2217, 2221, 2222, 2223, 3720, 3929, 3941
- zooplankton inoculation, 2217
- zooplankton populations, 1541, 1542, 2208, 2216, 2218
- zooplankton size, 2217
- zooplankton taxa, 578, 1472, 2207, 2212, 2221
- zygote, 3796, 3798, 3816
